(2) We say that a given simplicial structure $(K, \Theta \colon |K| \to M)$ is smooth if for each k-simplex s the corresponding characteristic map $\Theta \circ \Phi_s \colon \Delta^k \to M$ is a smooth embedding.

Remark. At first glance there are different definitions of "smooth simplicial structure" in the literature. For example our definition of a "smooth simplicial structure" is at first glance different from the one given in [**Mun1966a**, p. 81]. But [**Mun1966a**, Theorem 8.4] shows that our definition is in fact equivalent to the definition used in Munkres' book. Also, it is not difficult to see that our definition is equivalent to the one used in Whitney's book [**Why1957**].

Example. In the figure below we show smooth simplicial structures for the closed disk, the annulus, the 2-dimensional sphere and for the torus minus an open disk.

The following lemma contains two basic statements about (smooth) simplicial structures of smooth manifolds.

Lemma 96.1. Let M be a smooth manifold which is equipped with a smooth simplicial structure. If M is n-dimensional, then the dimension of each simplex is at most n.

Remark. In the Manifold-Simplex Proposition 98.1 we will prove several other statements regarding simplicial structures on smooth manifolds. In particular we will give an alternative proof of Lemma 96.1. Furthermore we will show that any (smooth) simplicial structure on a manifold M restricts to a (smooth) simplicial structure on the smooth manifold ∂M.

Proof. Let s be a k-simplex of the given smooth simplicial structure. Combining the characteristic map of the simplex with a chart we obtain a map from an open non-empty subset of $\mathbb{R}^k$ to $\mathbb{R}^n$. If the simplicial structure is smooth this map is in fact an embedding. It follows almost immediately from the Smooth Invariance of Domain Theorem 19.13 that $k \leq n$. ■

Now we can formulate the following theorem.

Theorem 96.2. (Smooth Manifold-Simplicial Structure Theorem)

(1) Every smooth manifold admits a countable smooth simplicial structure.
(2) If M is a smooth manifold with boundary ∂M, then any smooth simplicial structure for ∂M can be *extended* to a smooth simplicial structure for M.
(3) If M is a smooth manifold and if N is a proper submanifold of M, then there exists a smooth simplicial structure for M that *restricts* to a smooth simplicial structure on N.
(4) If $M = A \cup B$ is a decomposition into two n-dimensional submanifolds such that $A \cap B$ is a union of boundary components of A and a union of boundary components of B, then we can find a smooth simplicial structure on M such that A and B are subcomplexes.

Remark.

(1) Note that the conclusion of the Smooth Manifold-Simplicial Structure Theorem 96.2 (3) is somewhat weaker than the conclusion of the Smooth Manifold-Simplicial Structure Theorem 96.2 (2), it does not say that we can extend a given smooth simplicial structure on N to a smooth simplicial structure on M.
(2) By [**Bin1983**, Theorem XVIII.3.C] any PL-structure on the boundary of a 3-dimensional topological manifold can be extended to a PL-structure on the 3-dimensional topological manifold.
(3) Many more subtle results on finding smooth simplicial structures on smooth manifolds can be found in [**Vero1984**, Chapter 7].

Proof. We start out with giving precise references for the three statements.

(1) This statement is contained in [**Mun1966a**, Theorem 10.6]. For smooth manifolds without boundary the statement is also shown in [**Why1957**, Chapter IV.12]. For closed smooth manifolds, with a slightly weaker conclusion, the statement was first proved by Whitehead [**WhdJ1940**, Theorem 7] in 1940, building on earlier work of Cairns [**Cai1934**]. Other proofs for (some types of) smooth manifolds are given in [**Cai1961, Freu1939**] and [**Muk2015**, Theorem 9.5.1]. A sketch of an argument is also given in [**Thu1997**, Theorem 3.10.2].

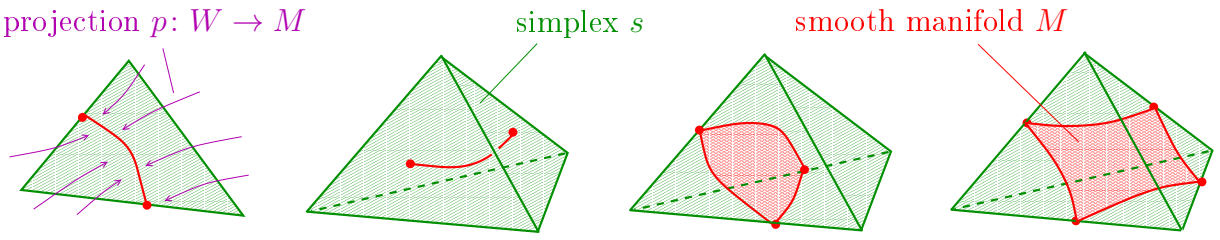
(2) This statement is also contained in [**Mun1966a**, Theorem 10.6], alternatively see the discussion on [**WhdJ1940**, p. 822f].
(3) If N is a closed submanifold of M, then this statement can be proved by solving [**Mun1966a**, Problem 10.14]. The general case can be deduced from [**Vero1984**, Theorem 7.8], once one has unraveled the statement [**Vero1984**, Theorem 7.8].
(4) First we apply (1) to equip the smooth manifold $A \cap B$ with a simplicial structure. Next we use (2) to extend the smooth simplicial structure to A and B. It is fairly straightforward to verify that putting these two smooth simplicial structures together we obtain a smooth simplicial structure for $M = A \cup B$.

To give the reader a sense of how one can possibly construct smooth simplicial structures on smooth manifolds we provide a sketch for the proof of Statement (1). The sketch is partially inspired by the argument given by Whitney [**Why1957**, Chapter IV.12].

For simplicity let M be a closed n-dimensional smooth manifold. Recall that by the Euclidean Embedding Theorem 27.1 and the Smooth Embedding Theorem 24.10 we can view M as a submanifold of $\mathbb{R}^m$ for some $m \geq n$. By the General Tubular Neighborhood Theorem **??** we can pick a tubular neighborhood $p\colon W \to M$. (For the purpose of this sketchy proof we might as well assume that the tubular neighborhood is given by $W = \overline{B}^{m-n} \times M$ and that $p\colon \overline{B}^{m-n} \times M \to M$ is the obvious projection.) We equip $\mathbb{R}^m$ with the canonical simplicial structure defined in Lemma 93.17.

We make the following, ever so slightly vague observation.

Observation. Using a suitable generalization of the Transversality Theorem 42.4 and using the definition of a smooth map and a smooth submanifold ("locally everything is close to being linear") we can shrink the cubes to a suitably small size and we can find an isotopy of M such that the resulting simplicial structure (V, S) for $\mathbb{R}^m$ satisfies the following two conditions:[1184]



(a) For every simplex $s \in S$ the intersection of s with M is "close" to the transverse[1185] intersection of an n-dimensional affine space with s.
(b) Every simplex s with $s \cap M \neq \varnothing$ is contained in the tubular neighborhood W and the restriction of the projection $p\colon W \to M$ to s is "close" to being an affine linear map.

We refer to the figure below for an illustration.

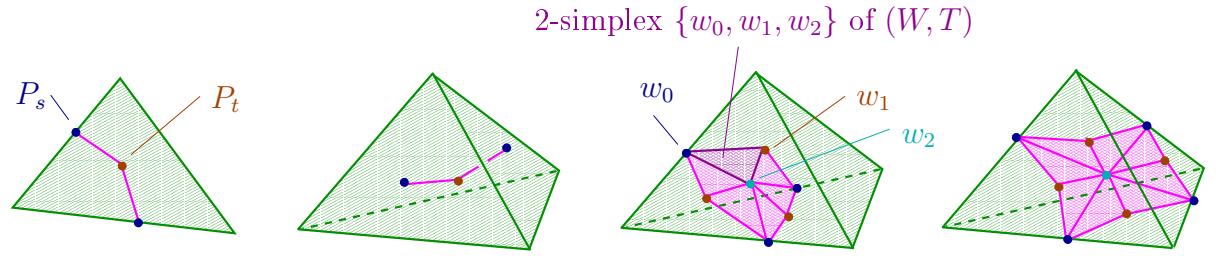
We set $k := m - n$. In the following we spell out two consequences of (a).

(1) No simplex of dimension less than k intersects M.
(2) If a k-simplex s intersects M, then it does so in a unique point $P = P_s$, which we know by (1) lies necessarily in the interior of s.

[1184] In our notation we blur the difference between the abstract simplices of the simplicial structure and the corresponding simplices in $\mathbb{R}^n$.
[1185] Here by "transverse" we mean the following: if s is an l-dimensional simplex, then it is contained in an l-dimensional affine subspace. The transverse intersection of an n-dimensional affine space with an l-dimensional affine space in $\mathbb{R}^m$ is of dimension $m + l - n$, where negative dimension is understood to be the empty set.

$n = 1$ and $m = 2$ $n = 1$ and $m = 3$ $n = 2$ and $m = 3$ $n = 2$ and $m = 3$

Next we make the following constructions.



(3) For each l-simplex t with $l > k$ which has the property that the corresponding open simplex $\langle t \rangle$ intersects M we pick a point P_t that lies in the intersection of M with the interior of t.

(4) We consider the abstract simplicial complex

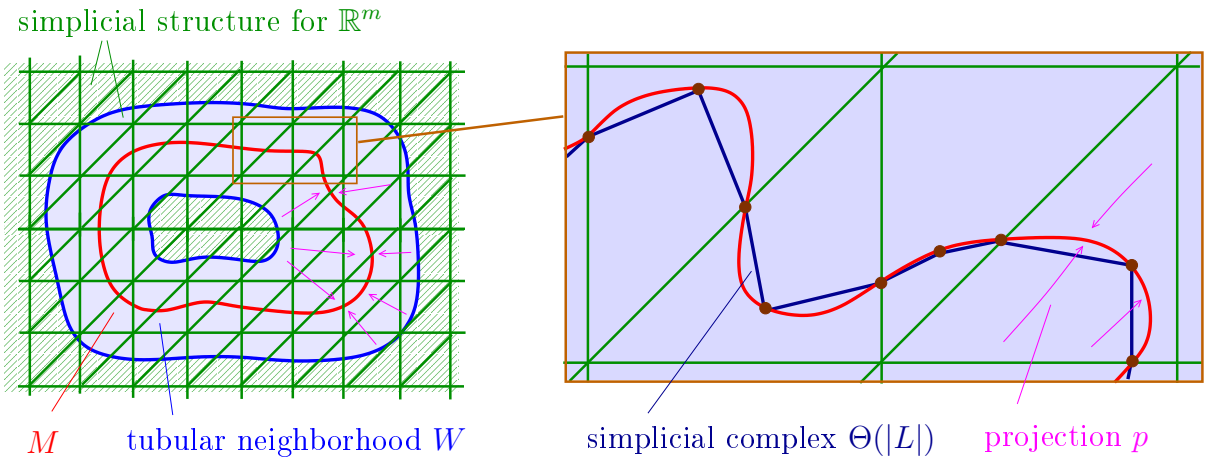
$$L := (W, T) \qquad \text{where } W := \{s \in S \,|\, \langle s \rangle \cap M \neq \varnothing\} \text{ and}$$
$$T := \{(w_0, \ldots, w_l) \,|\, w_0, \ldots, w_l \in S \text{ and } w_0 \subsetneq \ldots \subsetneq w_l\}.$$

(5) Let $\Theta\colon |L| \to \mathbb{R}^m$ be the unique map with $\Theta(w) = P_w$ for $w \in W$ and which is affine linear on each simplex $|t|$.

Some of these definitions are illustrated in the figure below. We continue with the following

$n = 1$ and $m = 2$ $n = 1$ and $m = 3$ $n = 2$ and $m = 3$ $n = 2$ and $m = 3$

observations:



(6) It follows from (a) and (b) that the map $p\colon W \to M$ restricts to a homeomorphism $\Theta(|L|) \to M$. Furthermore, for each simplex $t \in T$ the map $p\colon \Theta(|t|) \to M$ is a submersion, i.e. at each point the differential has full rank.

(7) By (6) we now know that $(L = (W, T), p \circ \Theta\colon |L| \to M)$ is a smooth simplicial structure for M.

We refer to the figure below for a more "global" illustration of the above argument. Evidently this outline has several serious issues. For example we never made it clear what we mean by "close". Nonetheless we feel that with enough effort one can turn the above sketch of an argument into a proper proof.

We refer to [**Why1957**, Chapter IV.12] for a very detailed discussion how a variation on the above approach can be made to work. ■

Just for fun we mention that in our sketch of a proof of the Smooth Manifold-Simplicial Structure Theorem 96.2 we basically proved the following proposition which says that any

submanifold of $\mathbb{R}^m$ can be "arbitrarily" approximated by a linear simplicial subcomplex of $\mathbb{R}^m$. We will not make use of this proposition, hence we have no qualms about the rather sketchy proof.

Proposition 96.3. Let M be a closed smooth submanifold of $\mathbb{R}^m$. Given any $\epsilon > 0$ there exists a linear simplicial complex $(L = (W, T), \Theta\colon |L| \to X)$ with $X \subset \mathbb{R}^m$ and an isotopy $F\colon X \times [0,1] \to \mathbb{R}^m$ with the following properties:

(1) We have $F_0 = \mathrm{id}$.
(2) The map F_1 is a homeomorphism $F_1\colon X \to M$ and it has the property that $F_1 \circ \Theta$ defines a smooth simplicial structure for M.
(3) For every $x \in X$ the map $[0,1] \to \mathbb{R}^m$ given by $t \mapsto F(x,t)$ is affine linear.
(4) For every $x \in X$ we have $\|x - F_1(x)\| < \epsilon$.

Example. Proposition 96.3 says in particular that we can approximate any knot M in $\mathbb{R}^3$ by a "simplicial knot" X. We refer to the figure below for an illustration.

Sketch of proof. We continue with the notation and results in the proof of the Smooth Manifold-Simplicial Structure Theorem 96.2. The $\epsilon > 0$ corresponds to a suitable interpretation of "close" in the formulation of (a) and (b). We set $X := \Theta(|L|)$. The isotopy F is the map which interpolates the identity id_X and the projection $p\colon X \to M$. ■

In Theorem 95.20 we saw that there exist compact spaces which admit two "inequivalent" simplicial structures, in other words, in Theorem 95.20 we saw that the Hauptvermutung 95.19 is false in general. Interestingly, the "smooth" analogue of the Hauptvermutung 95.19 is actually correct. More precisely, the following theorem holds.

Theorem 96.4. Let M and N be smooth manifolds and suppose we are given two smooth simplicial structures $(K, \Theta\colon |K| \to M)$ and $(L, \Omega\colon |L| \to N)$. If M and N are diffeomorphic, then there are subdivisions of K and L which are simplicially isomorphic.

Proof. This statement is shown in [**WhdJ1940**, Theorem 8] and alternatively in [**Mun1966a**, Theorem 10.5] (see also [**Mun1975**, Theorem 10.13]). It is perhaps worth pointing out that we do not need to assume that M is compact. ■

Theorem 96.4 will come in handy at a later stage. But for the foreseeable future it is of no real interest to us.

We conclude this section with picking up some low-hanging fruit that we obtain almost for free from the Smooth Manifold-Simplicial Structure Theorem 96.2. First we have the following theorem.

Theorem 96.5. (Smooth Manifold-CW Structure Theorem) Every (compact) n-dimensional smooth manifold M admits a (finite) CW-structure with the following properties:

(1) every cell has dimension at most n,
(2) the boundary ∂M is a subcomplex.

Furthermore, if $M = A \cup B$ is a decomposition into two n-dimensional submanifolds such that $A \cap B$ is a union of boundary components of A and a union of boundary components of B, then we can find a CW-structure on M which has all the above properties and such that A and B are subcomplexes.

Remark.

(1) Theorems 96.2 and 96.5 can be viewed as a significant strengthening of Corollary 95.37. Later on, in the Topological Manifold-Simplicial Complex Retract Theorem 104.13 together with the CW-Complex Domination Proposition 162.8, and in the Morse Functions-Cells Proposition 138.6 and in the Smooth Manifold-CW-Homotopy Type Proposition 139.8 we will get to know two more methods for equipping a smooth manifold with CW-structure, at least up to a homotopy equivalence.
(2) Note that the Smooth Manifold-CW Structure Theorem 96.5 is stated for smooth manifolds and *not* for topological manifolds. The situation for topological manifolds is in fact much more complicated and we will deal with it later on in Section 104.6.

Proof. The theorem follows immediately from the Smooth Manifold-Simplicial Structure Theorem 96.2 together with Lemma 96.1 and the Simplicial-Implies-CW Lemma 93.24. ■

Almost for free we now obtain the following proposition which gives us some control over the "size" of invariants of smooth manifolds.

Proposition 96.6. (Smooth Manifolds-Invariants Proposition) Let M be an n-dimensional 0-connected smooth manifold.

(1) For every $k > n$ and for every abelian group G we have $\mathrm{H}_k(M; G) = 0$.
(2) The higher homotopy groups of M are countable.

If M is compact then the following further statements hold:

(3) The fundamental group of M is finitely presented.
(4) All homology groups of M are finitely generated abelian groups. Furthermore, given any field $\mathbb{F}$ the homology groups $\mathrm{H}_k(M; \mathbb{F})$ are finite-dimensional.

Remark.

(1) Note that in Exercise 86.9 we saw that there exists a closed smooth manifold M such that $\pi_2(M)$ is infinitely generated as an abelian group. In other words, the Smooth Manifolds-Invariants Proposition 96.6 (2) is in a sense optimal.
(2) On page 2997 we will give an alternative proof for some of the Statements (1), (3) and (4) of the Topological Manifolds-Invariants Proposition 104.14 using "handle decompositions". An alternative approach to proving these three statements is also given by using the Smoothly Good Cover Theorem **??**. We will carry out this idea in Exercise 96.8.
(3) In Chapter 98 we will see that the existence of smooth simplicial structures on smooth manifolds can be used to extract even more information on homology groups of compact smooth manifolds.
(4) In the Topological Manifolds-Invariants Proposition 104.14 we will extend the Smooth Manifolds-Invariants Proposition 96.6 to compact *topological* manifolds.

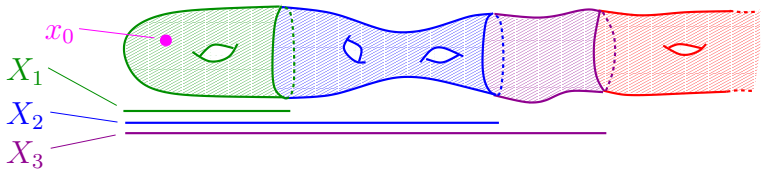
Proof.

(1) This statement follows from the Smooth Manifold-CW Structure Theorem 96.5 together with the Homology-of-CW-Complex Proposition 80.6 (1) and the discussion on page 1915.
(2) This statement follows from the Smooth Manifold-Simplicial Structure Theorem 96.2 together with Proposition 94.9.
(3) This statement follows from the Smooth Manifold-CW Structure Theorem 96.5 together with the CW-Skeleton-π_1-Proposition 69.13 (3).
(4) It follows from the Smooth Manifold-CW Structure Theorem 96.5 together with the Homology-of-CW-Complex Proposition 80.6 (2) that all homology groups are finitely generated. Furthermore it follows from the discussion on page 1915 that each $\mathrm{H}_k(M;\mathbb{F})$ is finite-dimensional. ■

We can even use our results to say something meaningful about fundamental groups and homology groups for non-compact smooth manifolds.

Proposition 96.7. Let M be a 0-connected smooth manifold.
(3′) The fundamental group of M is countable.
(4′) All homology groups $\mathrm{H}_k(M)$ are countable abelian groups. Furthermore, given any field $\mathbb{F}$ the dimension of each homology groups $\mathrm{H}_k(M;\mathbb{F})$ is countable.[1186]

Remark.



(1) In the Countable Fundamental Group Proposition 49.1 we already showed that fundamental groups of (possibly non-compact) topological manifolds are countable. But it seems difficult to adapt the approach of the Countable Fundamental Group Proposition 49.1 to deal with homology groups.
(2) In Proposition 104.15 we will extend Proposition 96.7 to *topological* manifolds.

Proof. Let M be a 0-connected smooth manifold. By the Push-Away-from-Boundary Corollary 28.5 we know that M is homotopy equivalent to $M \setminus \partial M$. It follows from this

[1186]Note that in contrast we will see on page 2476 that the "cohomology groups" of a non-compact smooth manifold can be uncountable.

fact, together with the Homotopy-π_1-Proposition 50.3 and the Homotopy Equivalence-H_*-Corollary 73.9, that we might as well assume that M has no boundary. Since M has no boundary we know by the Compact Submanifold Exhaustion Proposition 31.2 that there exists a sequence $X_1, X_2, \ldots$ of n-dimensional smooth submanifolds of M with the following three properties:

(1) For each $i \in \mathbb{N}$ we have $X_i \subset \overset{\circ}{X}_{i+1}$.
(2) Each M_i is compact and 0-connected.
(3) We have $\bigcup_{i\in\mathbb{N}} \overset{\circ}{X}_i = M$.

We pick a base point $x_0 \in X_1$. Given $i \leq j$ we denote by $\varphi_{ij}\colon X_i \to X_j$ the inclusion map. We then see that

$$\pi_1(M,x_0) \underset{\uparrow}{\cong} \varinjlim \pi_1(X_i) \underset{\uparrow}{\cong} \Big(\underset{i\in I}{*}\pi_1(X_i,x_0)\Big)/\langle\langle\{\varphi_{ij*}(g)\cdot g^{-1} \mid i\leq j \text{ and } g\in\pi_1(X_i,x_0)\}\rangle\rangle.$$

Direct Limit Proposition 56.7 — proof of the Direct Limit Existence Proposition 56.1 (2)

By the Smooth Manifolds-Invariants Proposition 96.6 we know that each $\pi_1(X_i, x_0)$ is finitely presented, in particular countable. It follows from the above discussion that $\pi_1(M, x_0)$ is countable.

Similarly we see that given any $k \in \mathbb{N}_0$ we have the following isomorphisms:

$$\mathrm{H}_k(M) \underset{\uparrow}{\cong} \varinjlim \mathrm{H}_k(X_i) \underset{\uparrow}{\cong} \Big(\bigoplus_{i\in I}\mathrm{H}_k(X_i)\Big)/\{\varphi_{ij*}(g) - g \mid \ i\leq j \text{ and } g\in \mathrm{H}_k(X_i)\}.$$

Homology-via-Exhaustions Proposition 79.4 — proof of the Direct Limit Existence Proposition 56.1 (3)

It is now clear that $\mathrm{H}_k(M)$ is countable. A very similar argument also works if we work with coefficients in a field $\mathbb{F}$. ■

On several occasions we will also study relative homology groups of a compact smooth manifold M, for example we will be interested in the relative homology groups $\mathrm{H}_k(M, \partial M)$. The following lemma, together with the Smooth Manifolds-Invariants Proposition 96.6 (4), gives us some control over these invariants.

Lemma 96.8. Let X be a topological space, let $A \subset X$ be a subset and let $k \in \mathbb{N}_0$.

(1) If the homology groups $\mathrm{H}_k(X)$ and $\mathrm{H}_{k-1}(A)$ are finitely generated, then so is the relative homology group $\mathrm{H}_k(X, A)$.
(2) Let $\mathbb{F}$ be a field. If the homology groups $\mathrm{H}_k(X;\mathbb{F})$ and $\mathrm{H}_{k-1}(A;\mathbb{F})$ are finite-dimensional, then so is the relative homology group $\mathrm{H}_k(X, A;\mathbb{F})$.

Proof. The first statement follows from the long exact sequence of the pair (X, A) together with the Rank Additivity Lemma 51.7. The second statement is proved in a similar fashion. ■

96.2. **PL-manifolds.** Throughout these notes we have so far only encountered two flavors of manifolds, namely topological manifolds and smooth manifolds. In this section we will introduce a new variety of manifolds, namely we will introduce the concept of PL-manifolds. In a nutshell a PL-manifold is a topological manifold together with a well-behaved simplicial structure.

For the reader's convenience we recall the following definition from page 2048.

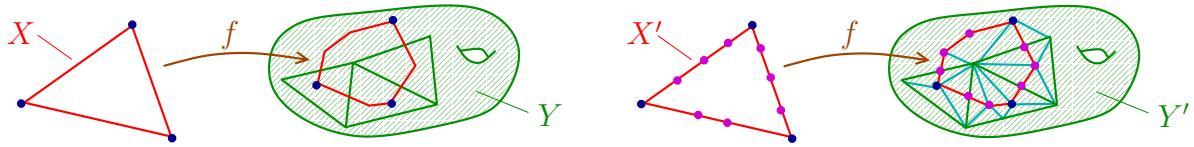
Definition. We say that a simplicial complex Y is a subdivision of some simplicial complex X if the following three conditions are satisfied:

(1) the underlying topological spaces are the same,
(2) every simplex of Y is contained in some simplex of X,
(3) for every l-simplex t of Y and every k-simplex s of X which contains t the map $\Phi_s^{-1} \circ \Phi_t \colon \Delta^l \to \Delta^k$ is affine linear.

Remark. Let X be a simplicial complex and let Y be a subdivision. In Exercise 96.3 we will see that every k-simplex of X is the union of finitely many simplices of Y of dimension $\leq k$. This shows that our definition of a subdivision agrees with the definition given in [**Mun1966a**, p. 83]. It also shows that if we use the Simplicial-Implies-CW Lemma 93.24 to view X and Y as CW-complexes, then the identity map $X \to Y$ is cellular.

We continue with the following definition.

Definition. Let X and Y be simplicial complexes. We say a map $f \colon X \to Y$ is piecewise linear, if there exist subdivisions X' and Y' such that $f \colon X' \to Y'$ is simplicial.[1187]



Remark. The definition of a piecewise linear map is the one given in [**Zee1963b**, p. 6] and [**Gla1970**, p. 13]. It follows from [**RS1972**, Theorem 2.14] and [**RS1972**, Example 1.5(4)] that the definition of a piecewise linear map on [**RS1972**, p. 5] is equivalent to the above definition. Furthermore, by [**Zee1963b**, Lemma I.7] the definition of a piecewise linear map on [**Hud1969**, p. 2] is also equivalent to the above definition.

Warning. Many of our favorite reference, e.g. [**Zee1963b**], mostly deals with finite simplicial complexes. Thus on several occasions we will also restrict to the case of finite simplicial complex. We leave it to the undaunted reader to figure out to what degree the results of this section also generalize to infinite simplicial complexes.

We start out with some examples of piecewise linear maps.

Examples.

(1) In the figure below we show a map $f \colon X \to Y$ between two finite linear simplicial complexes which is not simplicial, but which is piecewise linear.

(2) Let $f \colon X \to Y$ be a map between linear simplicial complexes. If X is a finite linear simplicial complex, then it follows from the Simplicial Approximation Theorem 94.8 that f is homotopic to a piecewise linear map.

[1187] Colloquially one usually says "PL" instead of "piecewise linear".

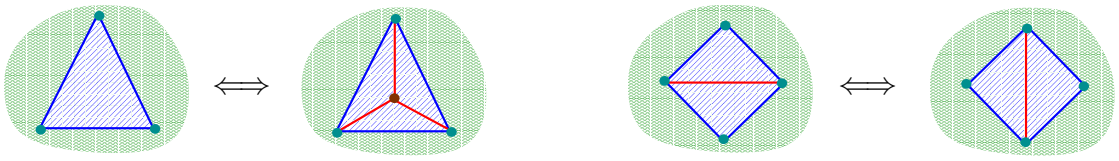
From the definitions it is not entirely clear that the composition of two piecewise linear maps is again piecewise linear. Fortunately, with some effort one can show that this is indeed the case.

Proposition 96.9. The composition of two piecewise linear maps between *finite* simplicial complexes is again piecewise linear.

Proof. The proposition is proved in [**Zee1963b**, Lemma I.2] and [**Gla1970**, Theorem I.6]. ■

Remark. As we hinted at above, both references for the proof of Proposition 96.9 do indeed assume that the simplicial complexes involved are finite. It is not clear to me whether the statement holds for maps between arbitrary simplicial complexes.

We move on to the following basically self-explanatory definition.



Definition. Let X and Y be two simplicial complexes.

(1) A map $f\colon X \to Y$ is called a PL-homeomorphism if f is piecewise linear, if f is a bijection and if f^{-1} is also piecewise linear.[1188]
(2) We say X and Y are PL-homeomorphic if there exists a PL-homeomorphism $X \to Y$.

We continue with two examples of PL-homeomorphisms.

Examples.

(1) If X' is a subdivision of a simplicial complex X, then it follows immediately from the definition that the map $X' \to X$ is a PL-homeomorphism.
(2) If $f\colon X \to Y$ is a map such that there exists subdivision X' of X and Y' of Y such that the map $f\colon X' \to Y'$ is a simplicial isomorphism, then f is evidently a PL-homeomorphism.
(3) (a) In the figure below we show to the left 2-dimensional linear simplicial complexes X_1 and Y_1 which are related by adding a vertex to a 2-dimensional simplex. It follows from (1) that X_1 and Y_1 are PL-homeomorphic.
    (b) In the figure below we show to the right 2-dimensional simplicial complexes X_2 and Y_2. If we subdivide X_2 and Y_2 by adding the intersection point of the two diagonals, then the resulting two linear simplicial complexes are simplicially isomorphic. By (2) this shows that X_2 and Y_2 are PL-homeomorphic.

$|X_1|$ $|Y_1|$ $|X_2|$ $|Y_2|$

(4) Let $n \in \mathbb{N}$. We consider the two linear simplicial complexes $\mathrm{Cone}(\partial\Delta^n)$ and Δ^n. It follows from the discussion on page 2049 that Δ^n admits a subdivision, given by adding a single vertex, which is simplicially isomorphic to $\mathrm{Cone}(\partial\Delta^n)$. By (1) this shows that $\mathrm{Cone}(\partial\Delta^n)$ and Δ^n are PL-homeomorphic.

[1188] For the record we state that it follows from Proposition 93.7 that every piecewise linear map is continuous.

(5) By Proposition 95.17 (1) we know that any two finite linear simplicial complexes X and Y with $|X| = |Y|$ are PL-homeomorphic.

Later on we will need the following elementary lemma.

Lemma 96.10. If $f_1 \colon X_1 \to Y_1$ and $f_2 \colon X_2 \to Y_2$ are two PL-homeomorphisms between two finite simplicial complexes, then the map

$$f_1 * f_2 \colon X_1 * X_2 \;\to\; Y_1 * Y_2$$

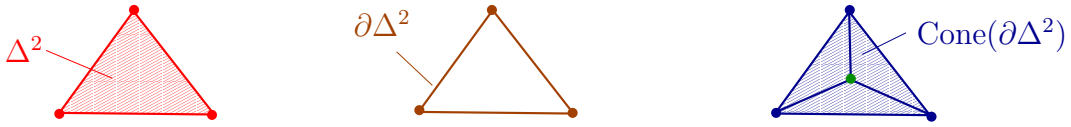
is also a PL-homeomorphism.

Proof. We leave it to the reader to provide the proof. ■

Before we give the definition of a PL-manifold let us introduce the following convention.

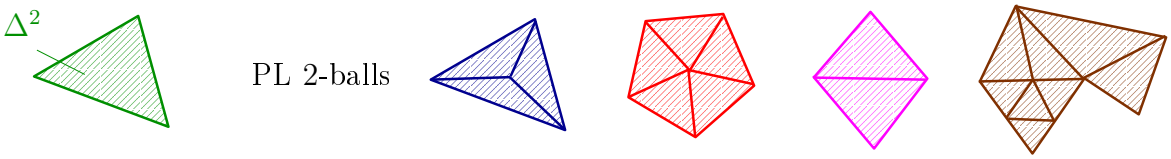
Convention. Let $n \in \mathbb{N}_0$. On page 1978 we introduced the abstract simplicial complexes

(1) $D_n := (V, S)$ with $V = \{0, \ldots, n\}$ and $S = \mathcal{P}(V) \setminus \{\varnothing\}$, and
(2) $S_{n-1} := (V, T)$ with $V = \{0, \ldots, n\}$ and $T = \mathcal{P}(V) \setminus \{\varnothing, V\}$.



On page 1989 we saw that there exists a canonical homeomorphism $f \colon |D_n| \to \Delta^n$ which restricts to a homeomorphism $|S_{n-1}| \to \partial\Delta^n$. Unless we say explicitly something else we will always use these homeomorphisms to view Δ^n and $\partial\Delta^n$ as simplicial complexes.

The above convention leads us to our next definition.

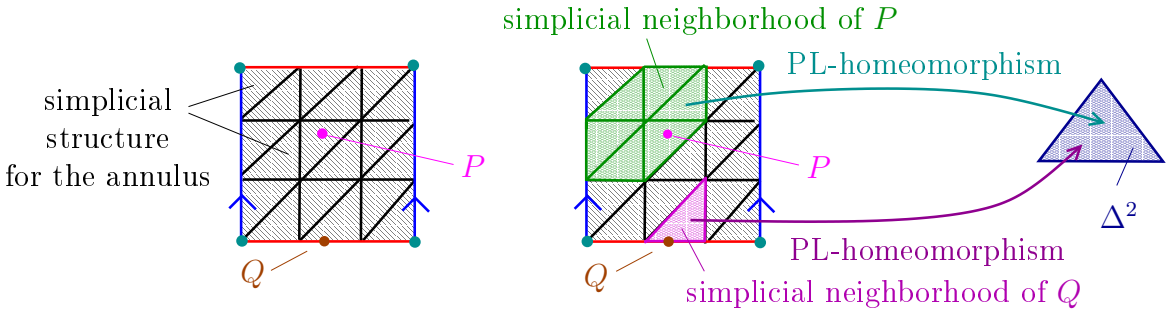


Definition. Let $n \in \mathbb{N}$.

(1) A PL n-ball is defined as a simplicial complex that is PL-homeomorphic to the simplicial complex Δ^n.
(2) A PL n-sphere is defined as a simplicial complex that is PL-homeomorphic to the simplicial complex $\partial\Delta^{n+1}$.

Example. Let $n \in \mathbb{N}_0$. In Exercise 96.2 we will show that $\mathrm{Cone}(\partial\Delta^n)$ is a PL n-ball.

Remark. In practice it can be a little tricky to show that a given simplicial complex is in fact a PL n-ball or a PL n-sphere. But in most cases one can verify, with enough patience and dexterity, that if a simplicial complex "looks" like an n-ball or an n-sphere, then it is in fact a PL n-ball respectively a PL n-sphere. For example it is entertaining to show that all the simplicial complexes shown in the figure below are in fact PL 2-balls. Shortly we will get to know a more systematic way for finding PL-homeomorphisms.



Now we can provide the definition of a PL-manifold. The definition is modelled on the definition of a topological manifold that we gave on page 511. The key difference is that we replace the words "neighborhood", "ball" and "homeomorphic" by "simplicial neighborhood", "PL-ball" and "PL-homeomorphic".

Definition.

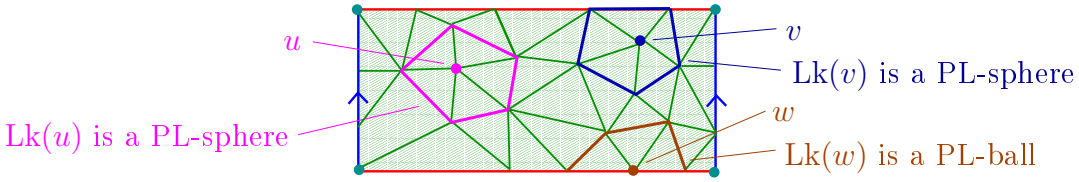
(1) Let X be a simplicial complex and $P \in X$. A simplicial neighborhood is a subcomplex of X that is a neighborhood of P in the usual sense as defined on page 113.
(2) An n-dimensional PL-structure on a topological space X is defined as a simplicial structure $(K = (V, S), \Theta\colon |K| \to X)$ such that every point $P \in X$ admits a simplicial neighborhood that is a PL n-ball.
(3) An n-dimensional PL-manifold is a pair (X, Θ) where X is a topological space and Θ is an n-dimensional PL-structure with countably many simplices.

Examples.

(1) In the figure below we see to the left a simplicial structure for the annulus $S^1 \times [0, 1]$. The illustrations to the right of the figure should convince the reader that the simplicial structure for the annulus is a PL-structure.

(2) Let $n \in \mathbb{N}_0$. The canonical simplicial structure on Δ^n is basically by definition a PL-structure. Recall that in the Standard Simplex Homeomorphism Lemma 72.1 we gave an explicit homeomorphism $\Phi\colon \overline{B}^n \to \Delta^n$. Thus $(D_n, \Phi^{-1}\colon \Delta_n = |D_n| \to \overline{B}^n)$ is a PL-structure for $\overline{B}^n$. Similar to the discussion on page 1997 we will refer to it as the *canonical* PL-*structure* of $\overline{B}^n$.
(3) Let $n \in \mathbb{N}_0$. We consider $\partial\Delta^{n+1}$ with the usual simplicial structure defined on page 2092. Given any vertex v the star $\mathrm{St}(\partial\Delta^n, v)$ is, basically by definition, simplicially isomorphic to $\mathrm{Cone}(\partial\Delta^n)$. It follows from the example on page 2092 that $\mathrm{St}(\partial\Delta^n, v)$ is a PL n-ball. This shows that $\partial\Delta^n$ is an n-dimensional PL-manifold. Recall that in the Standard Simplex Homeomorphism Lemma 72.1 we gave an explicit homeomorphism $\Phi\colon S^n \to \partial\Delta^{n+1}$. This shows that $(S_n, \Phi^{-1}\colon \partial\Delta_{n+1} = |S_n| \to S^n)$ defines a PL-structure on S^n. We refer to it as the *canonical* PL-*structure* on S^n.

Proposition 96.11. Let X and Y be two simplicial complexes. If X is an n-dimensional PL-manifold and if X and Y are PL-homeomorphic, then Y is also an n-dimensional PL-manifold.



Example. It follows from Proposition 96.11 that any PL n-ball and any PL n-sphere is indeed an n-dimensional PL-manifold.

Proof. This proposition is less trivial than it might appear initially. Fortunately a proof is given in [**Gla1970**, Theorem II.2]. ■

The following proposition gives an alternative characterization of PL-manifolds.

Proposition 96.12. (PL-Manifold Characterization Proposition) We consider a simplicial complex $(K = (V, S), \Theta\colon |K| \to X)$. The following statements are equivalent:

(1) (X, Θ) is an n-dimensional PL-manifold.
(2) For every vertex $v \in V$ the link $\mathrm{Lk}(K, v)$ is a PL $(n-1)$-sphere or a PL $(n-1)$-ball.
(3) For every vertex $v \in V$ the star $\mathrm{St}(K, v)$ is a PL n-ball.
(4) For every k-simplex $s \in S$ the link $\mathrm{Lk}(K, s)$ is a PL $(n-k-1)$-sphere or a PL $(n-k-1)$-ball.
(5) For every k-simplex $s \in S$ the star $\mathrm{St}(K, s)$ is a PL $(n-k)$-ball.

Proof.

(1)⇒(2) This implication is shown in [**Hud1969**, p. 26] (alternatively see also [**Zee1963b**, p. III.2]).

(2)⇒(3) Let $v \in V$. First we consider the case that the link $\mathrm{Lk}(v)$ is a PL $(n-1)$-sphere. In this case we have the following PL-homeomorphisms:

$$\mathrm{St}(v) \underset{\uparrow}{\cong} \{v\} * \mathrm{Lk}(v) \underset{\uparrow}{\cong} \{v\} * \text{PL } (n-1)\text{-sphere} \underset{\uparrow}{\cong} \{v\} * \partial\Delta^n \underset{\uparrow}{\cong} \Delta^n.$$

Link Star Lemma 94.5 (1c) — since (2) holds — Lemma 96.10 — see page 2091

The case that the link $\mathrm{Lk}(v)$ is a PL $(n-1)$-ball is dealt with the same way, except that this time we use the basically trivial fact, first pointed out on page 2003 that $\{v\} * \Delta^{n-1}$ is in fact simplicially isomorphic to Δ^n. We have thus shown that (2) implies (3).

(3)⇒(1) This implication follows immediately from the Link Star Lemma 94.5 (1).

(2)⇒(4) We prove the statement by induction on k. Note that the case $k = 0$ is precisely Statement (2). Now suppose that the statement holds for some $k-1$. Let $K = (V, S)$ be an abstract simplicial complex and let $t = \{v_0, \ldots, v_k\}$ be a k-simplex. We consider the $(k-1)$-simplex $s = \{v_0, \ldots, v_{k-1}\}$. By induction hypothesis we know that $\mathrm{Lk}(K, s)$ is a PL $(n-k)$-sphere or a PL $(n-k)$-ball. As we pointed out on page 2093, it follows from Proposition 96.11 that $\mathrm{Lk}(K, s)$ is in fact an $(n-k)$-dimensional PL-manifold. Now we see that

$$\mathrm{Lk}(K, t) \underset{\uparrow}{=} \mathrm{Lk}(\mathrm{Lk}(K, s), v_k) \underset{\uparrow}{=} \mathrm{Lk}\left(\begin{matrix}(n-k)\text{-dimensl.}\\ \text{PL-manifold}\end{matrix}, v_k\right) \underset{\uparrow}{=} \begin{matrix}\text{PL } (n-k-1)\text{-sphere}\\ \text{or a PL } (n-k-1)\text{-ball.}\end{matrix}$$

follows easily from definitions — by induction hypothesis — by (1)⇒(2)

(4)⇒(5) The proof of this statement is basically identical to the proof of (2)⇒(3).

(5)⇒(3) This implication holds for the trivial reason that every vertex is in particular a 0-simplex. ■

Remark.

(1) The notion of a PL-manifold gets defined differently by different authors. There is the usual question whether or not one wants a manifold to be second-countable or not which in our case translates into the question whether or not one wants the simplicial complex to be countable. But if we ignore this rather technical issue, then we see the following:
   (a) The above definition above is basically the one given in [**Hud1969**, p. 20] and [**Zee1963b**, p. II.10].
   (b) It follows from the PL-Manifold Characterization Proposition 96.12 (1)⇔(2) that our definition is equivalent to the definition provided in [**Bry2002**, p. 223] and [**Stal1967**, Definition 4.4.9].
   (c) It follows from the PL-Manifold Characterization Proposition 96.12 (1)⇔(5) that our definition is equivalent to the definition given in [**Geo2008**, p. 134].
   (d) It is a consequence of [**RS1972**, Theorem 2.2] that our definition is equivalent to the one given in [**RS1972**, p. 7].
   (e) In the literature an n-dimensional PL-manifold is sometimes defined as a pair $(X, \{\Phi_i \colon U_i \to V_i\})$ where X is an n-dimensional topological manifold and where $\{\Phi_i \colon U_i \to V_i\}$ is an atlas for X such that given any $i, j \in I$ the corresponding transition map $\Phi_j \circ \Phi_i^{-1} \colon V_i \cap \Phi_i(U_j) \to V_j \cap \Phi_j(U_j)$ is "piecewise linear". Here, in this context we say that a map $f \colon U \to V$ between open subsets of $\mathbb{R}^n$ is *piecewise linear* if any point $P \in U$ there exists a linear simplicial complex $X \subset U$ which is a neighborhood of P such that the restriction of f to each simplex of X is linear. This definition is for example used in [**GoS1999**, p. 7], [**Rudy2016**, p. 16] and [**HiM1974**, p. 8]. It seems to me that the discussions on [**Hud1969**, p. 82] and [**Ded1962**, p. 370] show that these two concepts of PL-manifolds basically agree. It would be nice though to have a more direct reference for this statement.
(2) A PL-structure for a topological space is sometimes called a *piecewise linear triangulation*, or shorter, a PL-*triangulation*.

the PL-Manifold Characterization Proposition 96.12, and drawing enough pictures, shows that the following definition captures the right intuition.

Definition. We say a PL-manifold is closed if X is compact and for every vertex the link $\mathrm{Lk}(v)$ is a PL-sphere.

We have no intention of going deep into the theory of PL-manifolds. Instead we refer the interested reader to [**Hud1969, Zee1963b, Gla1970, RS1972**] for a much more detailed introduction to PL-manifolds. For example these references contain the definition of the boundary a PL-manifold and a discussion of PL-submanifolds and the existence of "regular neighborhoods" (see also the next section) of subcomplexes.
As an aside we mention only one result, namely suppose that M is a PL-manifold. Similar to the statements of the Smooth Manifold-Simplicial Structure Theorem 96.2 (2) and (3), one can extend a given PL-structure on the boundary to a PL-structure on M and one can extend a given PL-structure on a proper submanifold to a PL-structure of M. We refer to [**Arm1967**] for the precise statements and proofs.

96.3. **Regular Neighborhoods.** In this short section we introduce the notion of a regular neighborhood of a subcomplex of a simplicial complex. This is an object that gets used

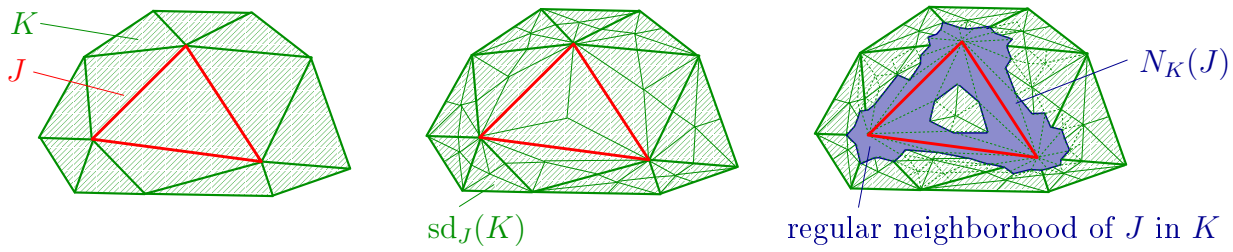
commonly in topology and thus we want to give a definition and we want state to some of the main properties of regular neighborhoods. Otherwise we will barely make use of this concept.
First we give a slight generalization of the concept of the barycentric subdivision of an abstract simplicial complex.

Definition. Let $K = (V, S)$ be an abstract simplicial complex and let $J = (U, R)$ be a finite subcomplex. We define the barycentric subdivision $\mathrm{sd}_J(K)$ of K away from J by barycentric subdividing every simplex that is not contained in J. More formally, and much less readably, $\mathrm{sd}_J(K)$ is defined as follows:

$$\begin{aligned} \text{vertices of } \mathrm{sd}_J(K) &:= U \cup \{\underline{s}\}_{s \in S \setminus R} \\ \text{simplices of } \mathrm{sd}_J(K) &:= \left\{ r \cup \{\underline{s_0}, \ldots, \underline{s_k}\} \;\middle|\; \begin{array}{c} \text{where } r \in R \cup \{\varnothing\} \text{ and } s_0, \ldots, s_k \in S \\ \text{such that } r \subsetneq s_0 \subsetneq \cdots \subsetneq s_k \end{array} \right\}. \end{aligned}$$

It follows immediately from the definitions that $\mathrm{sd}_J(K)$ is an abstract simplicial complex and that for $J = \varnothing$ we obtain the usual barycentric subdivision $\mathrm{sd}(K)$.

The obvious generalization of the SD-Lemma 94.3 holds in the above context. But there is certainly no need for formulating the generalizations. Let us move on to the definition of regular neighborhoods.



Definition. Let $(K = (V, S), \Theta\colon |K| \to X)$ be a simplicial complex and let $J = (U, R)$ be a subcomplex. We set

$$S_K(J) := \{s \in \mathrm{sd}_J(\mathrm{sd}_J(K)) \,|\, \text{there exists an } r \in R \text{ with } r \subset s\}.$$

Now we define

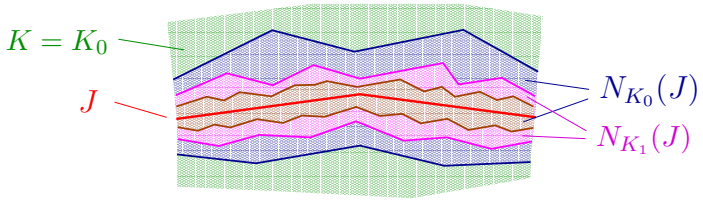
$$N_K(J) := \bigcup_{s \in S_K(J)} \Theta(|s|) \quad \text{and} \quad \mathring{N}_K(J) := \bigcup_{s \in S_K(J)} \Theta(\langle s \rangle).$$

We refer to $N_K(J)$ as the regular neighborhood of J in K.

Remark. The notion of a regular neighborhood gets defined differently by different authors. Our definition of *the* regular neighborhood of J in K is an example of *a* regular neighborhood as introduced in [**RS1972**, p. 33] or alternatively in [**Gla1970**, Theorem II.15n].

The following proposition states a few key properties of regular neighborhoods of subcomplexes of PL-manifolds.

Proposition 96.13. (Simplicial Regular Neighborhood Proposition) Let $(K = (V,S), \Theta\colon |K| \to M)$ be a compact PL-manifold and let $J = (U,R)$ be a subcomplex with $\Theta(|J|) \subset M \setminus \partial M$.



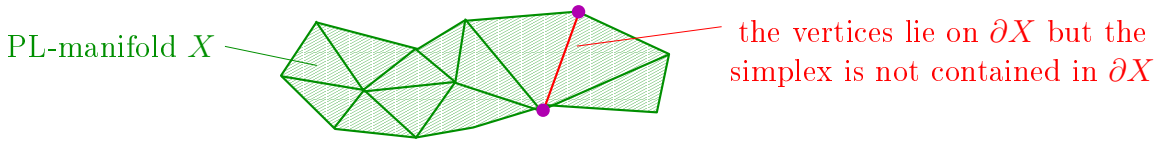
(1) $N_K(J)$ is a compact PL-manifold and it is a submanifold of the topological manifold M.
(2) (a) $\mathring{N}_K(J)$ is an open subset of M.
    (b) The boundary of $N_K(J)$ as a subset of M equals $N_K(J) \setminus \mathring{N}_K(J)$.
    (c) $N_K(J)$ and $\mathring{N}_K(J)$ are both neighborhoods of $\Theta(|J|)$.
(3) $\Theta(|J|)$ is a deformation retract of $N_K(J)$.
(4) $\partial N_K(J)$ is a deformation retract of $N_K(J) \setminus \Theta(|J|)$.

Sketch of proof. Evidently we can just assume that $M = |K|$ and that $\Theta = \mathrm{id}$. As mentioned above, our definition of the regular neighborhood is an example of a regular neighborhood as defined in [**RS1972**, p. 33]. Thus we can use the results from [**RS1972**].

(1) This statement is explicitly and implicitly proved in [**RS1972**, Propostion 3.10].
(2) We leave the fairly routine verification of these statements to the reader.
(3) This statement is proved in [**RS1972**, Corollary 3.30 (ii)], see also [**Gla1970**, p. 77].
(4) We only provide an outline of a proof. First we define a sequence of abstract simplicial complexes via setting $K_0 := K$ and iteratively via setting $K_{n+1} := \mathrm{sd}_J(K_n)$ for $n \in \mathbb{N}$. Similarly to the SD-Lemma 94.3 (3) we see that these abstract simplicial complexes define again naturally simplicial structures for M. Using a suitable variation on Lemma 94.7 one can show that $\bigcap_{n\in\mathbb{N}_0} N_{K_n}(J) = |J|$. The key input at this point is [**RS1972**, Corollary 3.18] which implies that for every $n \in \mathbb{N}_0$ there exists a homeomorphism $F_n\colon N_{K_n}(J) \times [0,1] \to N_{K_n}(J) \setminus \mathring{N}_{K_{n+1}}(J)$ such that for every $P \in N_{K_n}(J)$ we have $F_n(P,0) = P$ and $F_n(P,1) \in \partial N_{K_{n+1}}(J)$. Next we want to combine all these maps F_n to obtain a homeomorphism $\partial N_K(J) \times [0,1] \to N_K(J) \setminus |J|$. To do so we set $s_0 = 0$, $s_1 = \frac{1}{2}$, $s_2 = \frac{3}{4}$, $s_3 = \frac{7}{8}$ and so on. Furthermore, given $n \in \mathbb{N}_0$ we define $\Xi_n\colon \partial N_K(J) \to \partial N_{K_n}(J)$ via $\Xi_n(P) = F_{n-1}(\ldots(F_1(F_0(P,1),1),\ldots,1)$. Finally we consider the map

$$\begin{array}{rcl} \partial N_K(J)\times[0,1) & \to & N_K(J)\setminus|J| \\ (P,t) & \mapsto & F_n(\Xi_n(P), 2^{n+1}\cdot(t-s_n)), \quad \text{if } t\in[s_n,s_{n+1}) \text{ for some } n\in\mathbb{N}_0. \end{array}$$

Some thought shows that this map is actually a homeomorphism. The desired statement follows from the observation that $\partial N_K(J) = \partial N_K(J) \times \{0\}$ is a deformation retract of $N_K(J) \times [0,1)$. The more carefully one looks at this outline, the more little exercises one detects which need to be carried out to turn this argument into a proper proof. ■



This concludes our discussion of regular neighborhoods. This concept is discussed in much greater detail in [**WhdJ1939**], [**RS1972**, Chapter 3], [**Gla1970**, Chapter III.B], [**Hud1969**, Chapter 2] and [**Zee1963b**, Chapter 3]. Some properties are also discussed in [**Hem1976**, p. 7f]. In particular we refer to [**RS1972**, Theorems 3.8 and 3.24] and [**Gla1970**, Theorem II.16n] for some uniqueness theorems which explain to what degree the regular neighborhood depends on the choice of simplicial structures on a given PL-manifold. Unfortunately it is not always immediately apparent that the various definitions in the above literature are mutually compatible.

96.4. **The interplay between topological, smooth and PL-manifolds.** Now that the PL-manifolds joined the playground, let us see how they interact with our old friends, the topological and smooth manifolds. Since morally speaking topological manifolds have the least amount of structure it is not surprising that PL-manifolds are indeed topological manifolds:

Proposition 96.14. Let X be an *n-dimensional* PL-*manifold*. The following statements hold:

(1) X is an n-dimensional topological manifold.
(2) A vertex v of the PL-structure lies on the boundary of the topological manifold X if and only if the link $\mathrm{Lk}(v)$ is a PL-ball.

Remark. Let X be a PL-manifold and let s be a simplex such that all vertices lie on the boundary ∂X of X, viewed as a topological manifold. As we see in the figure below, this piece of information does not imply that s is actually contained in ∂X.

Proof. Let $(K = (V, S), \Theta\colon |K| \to X)$ be an *n-dimensional* PL-*manifold*. Without loss of generality we can assume that $\Theta = \mathrm{id}$, in particular we can assume that $|K| = X$.

(1) In the following we will show that X is an n-dimensional topological manifold.
  (a) By the Simplex-Embedding Lemma 93.5 we know that X is Hausdorff.
  (b) By definition of a PL-manifold we know that S is countable, in particular V is countable. Furthermore note that the PL-Manifold Characterization Proposition 96.12 says that for each $v \in V$ the open star $\mathring{\mathrm{St}}(v)$ is homeomorphic to a subset of $\mathbb{R}^n$. From the Second Countability Lemma 9.1 (1) and (2) we obtain that each open star is second-countable. Thus it follows from the Link Star Lemma 94.5 (2) that X is the countable union of countably many second-countable open subsets. Hence we obtain from the Second Countability Lemma 9.1 (4) that X itself is second-countable.
  (c) By definition of a PL-manifold we know that for each $P \in X$ there exists in particular a neighborhood U of P and a homeomorphism $\Phi\colon U \to \overline{B}^n$. On page 513 we showed that $\overline{B}^n$ itself is an n-dimensional topological manifold. It it now elementary to see that there exists a chart, in the sense of the definition on page 511, for X at P.

We have thus verified that X is indeed an n-dimensional topological manifold.

(2) Let $v \in V$ be a vertex. We calculate that

$$\begin{array}{ccccc} \mathrm{H}_n(X, X\setminus\{v\}) & \underset{\uparrow}{\cong} & \mathrm{H}_n(\mathrm{St}(v), \mathrm{St}(v)\setminus\{v\}) & \underset{\uparrow}{\cong} & \mathrm{H}_n(\mathrm{St}(v), \mathrm{Lk}(v)) \\ & \text{by the Excision Theorem 74.18 which we can apply by the Link Star Lemma 94.5 (1d)} & & \text{Link Star Lemma 94.5 (1f) and Corollary 74.16 (2a)} & \end{array}$$

$$\begin{array}{ccc} \underset{\uparrow}{\cong}\ \widetilde{\mathrm{H}}_{n-1}(\mathrm{Lk}(v)) & \cong & \begin{cases} \mathbb{Z}, & \text{if } \mathrm{Lk}(v) \text{ is a PL } (n-1)\text{-sphere,} \\ 0, & \text{if } \mathrm{Lk}(v) \text{ is a PL } (n-1)\text{-ball.} \end{cases} \\ \text{by the long exact sequence in reduced homology of the pair } (\mathrm{St}(v), \mathrm{Lk}(v)) & & \\ \text{together with the Link Star Lemma 94.5 (1g)} & & \end{array}$$

It follows from the Manifold-Local Homology Lemma 75.1 that $v \in \partial X$ if and only if $\mathrm{Lk}(v)$ is a PL $(n-1)$-ball. ■

Next we turn to the relationship between smooth manifolds and PL-manifolds. The following theorem says that any smooth manifold admits an essentially natural PL-structure.

Theorem 96.15.

(1) Every smooth simplicial structure on an n-dimensional smooth manifold is an n-dimensional PL-structure.
(2) If M is a closed smooth manifold, then for every smooth simplicial structure the corresponding PL-manifold is also closed.
(3) Every smooth manifold admits the structure of a PL-manifold.
(4) Any two smooth simplicial structures on a smooth manifold are PL-homeomorphic.

Proof.

(1) It follows from [**WhdJ1940**, Theorem 5] (see also the argument of [**Mun1966a**, p. 82]) together with the PL-Manifold Characterization Proposition 96.12 that every smooth simplicial structure on a smooth manifold is a PL-structure in the above sense.
(2) This statement follows immediately from Proposition 96.14, together with fact, proved in the Topological Manifold Boundary Proposition 75.2 (2), that a smooth manifold is closed as a smooth manifold if and only if it is closed as a topological manifold.
(3) This statement follows from (1) together with the Smooth Manifold-Simplicial Structure Theorem 96.2 where we showed that every smooth manifold admits a countable *smooth* simplicial structure.
(4) This statement follows immediately from Theorem 96.4. ■

Theorem 96.15 says in particular that given any $n \in \mathbb{N}_0$ the map

$$\begin{array}{rccc} \mathfrak{w}_n\colon & \left\{\begin{array}{c}\text{diffeomorphism classes of closed}\\ n\text{-dimensional smooth manifolds}\end{array}\right\} & \to & \left\{\begin{array}{c}\text{PL-homeomorphism classes of closed}\\ n\text{-dimensional PL-manifolds.}\end{array}\right\} \\ & [M] & \mapsto & [(M, \text{smooth simplicial structure})] \end{array}$$

is well-defined. It is natural to ask whether $\mathfrak{w}_n$ is a bijection. It turns out that the answer is complicated. More precisely, we have the following theorem.

Theorem 96.16.

(1) For $n = 1, \ldots, 6$ the map $\mathfrak{w}_n$ is a bijection.

(2) For $n = 7$ (and many other dimensions) the map $\mathfrak{w}_n$ is not a monomorphism.
(3) For $n = 10$ (and many other dimensions) the map $\mathfrak{w}_n$ is not an epimorphism. In fact there exists a closed 10-dimensional PL-manifold that does not admit a single smooth structure.

Proof. The theorem is a combination of several major results in topology. Later in Section **??** we will discuss this theorem in much greater detail and we will give all the necessary references. In particular we will restate (1) as the PL-Smoothing Theorem **??**. ■

We turn our focus back to the relationship between topological and PL-manifolds. In light of Proposition 96.14 it is perhaps tempting to think that a PL-manifold is the same as a topological manifold together with some simplicial structure. But it turns out that the situation is more delicate.

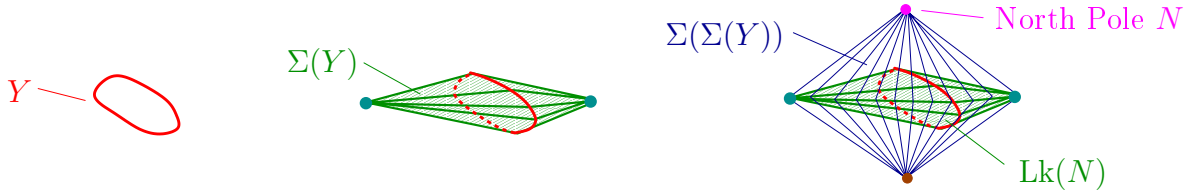
Theorem 96.17. There exists a simplicial structure on S^5 that is not a PL-structure.

The key to proving Theorem 96.17 is the following very subtle and very difficult theorem which was proved independently by Jim Cannon [**Cann1979**] and Richard Edwards [**Edw1980, Edw2006**] in the late 1970s. We also refer to [**Dav1986**, Corollary VII.2.C] and [**Lat1979**] for alternative accounts of the proof. It is also worth reading Jim Cannon's reminiscences [**Cann1994**].

Theorem 96.18. (Double Suspension Theorem) Let Y be an n-dimensional PL-manifold. If Y is a homology sphere, i.e. if $\mathrm{H}_k(Y;\mathbb{Z}) \cong \mathrm{H}_k(S^n;\mathbb{Z})$ for all k, then the *double* suspension $\Sigma(\Sigma(Y))$ is homeomorphic to S^{n+2}.

The proof of Theorem 96.17 also requires the following lemma.

Lemma 96.19. Let $n \in \mathbb{N}_{\geq 2}$ and let M be a closed 0-connected n-dimensional topological manifold. If $\pi_1(M)$ is non-trivial, then the suspension $\Sigma(M)$ is not an $(n+1)$-dimensional topological manifold.



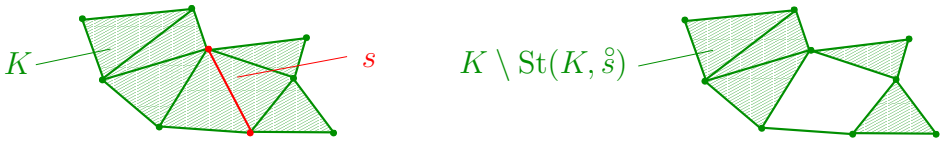
Proof. We outsource the proof to the very amusing Exercise 76.9. ■

With these preparations it is now quite easy to provide a proof of Theorem 96.17.

Proof of Theorem 96.17.

(1) By Proposition 98.11 we know that there exists a closed orientable 3-dimensional smooth manifold Y that is a homology 3-sphere, but such that $\pi_1(Y)$ is a non-trivial group.
(2) By Theorem 96.15 we can equip Y with a PL-structure.
(3) It follows from (2) and the Double Suspension Theorem 96.18 that $\Sigma(\Sigma(Y))$ is homeomorphic to S^5.
(4) By (2) we know that Y is equipped with a simplicial structure. We equip the double suspension $\Sigma(\Sigma(Y))$ with the simplicial structure given by "the double suspension" of the simplicial structure. More precisely, we equip $\Sigma(\Sigma(Y))$ with the simplicial structure given by applying the Simplicial Cone-Suspension Corollary 93.21 twice.
(5) Let N be the "North Pole" of the second suspension. It follows from the discussion on page 2018 that $\mathrm{Lk}(\Sigma(\Sigma(Y)), N) = \Sigma(Y)$.
(6) Since $\pi_1(Y)$ is non-trivial we obtain from Lemma 96.19 that $\Sigma(Y)$ is not even a 4-dimensional topological manifold. Therefore we obtain from Proposition 96.14 that $\mathrm{Lk}(\Sigma(\Sigma(Y)), N) = \Sigma(Y)$ is not a 4-dimensional PL-manifold, let alone a PL 4-sphere.

(7) We obtain from the above, together with the PL-Manifold Characterization Proposition 96.12, that $\Sigma(\Sigma(Y))$ admits a simplicial structure that is not a PL-structure.
(8) In (3) we saw that $\Sigma(\Sigma(Y))$ is homeomorphic to S^5. It follows from (7) that S^5 admits a simplicial structure that is not a PL-structure. ■



Towards the end of these notes, in Section **??**, we will study the relationship between topological manifolds, smooth manifolds and PL-manifolds in greater detail.

96.5. **Stellar subdivisions and the Alexander-Newman Theorem.** The notion of a PL-homeomorphism, and thus also the notion of a PL-manifold, relies on the notion of a subdivision which, as discussed on page 2048, is not combinatorial. In the final two sections of this chapter we will discuss how one can turn the theory of PL-homeomorphisms and PL-manifolds into a purely combinatorial theory.
First, given an abstract simplicial complex we introduce, inspired by the definition on page 2018 and by the Link Star Lemma 94.5 (1b), the combinatorial notion of the star and the link of a simplex.

Definition. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$ be a simplex. We introduce the following three subcomplexes[1189] of K:

$$\begin{aligned}
\mathrm{St}(K,s) &:= \Big(\bigcup_{t\in S \text{ with } s\subset t} t,\ \{t \in S \,|\, s\cup t \in S\}\Big)\\
\mathrm{Lk}(K,s) &:= \Big(\bigcup_{t\in S \text{ with } s\subset t} t \setminus s, \{t \in S \,|\, s\cup t \in S \text{ and } s\cap t = \varnothing\}\Big)\\
K\setminus \mathrm{St}(K,\mathring{s}) &:= \begin{cases} (V\setminus\{v\}, \{t\in S \,|\, s\not\subset t\}), & \text{if } s=\{v\} \text{ is a 0-simplex,}\\ (V, \{t\in S \,|\, s\not\subset t\}), & \text{otherwise.}\end{cases}
\end{aligned}$$

We refer to the figure below for an illustration of the definition of $K \setminus \mathrm{St}(K, \mathring{s})$.

Remark. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$.

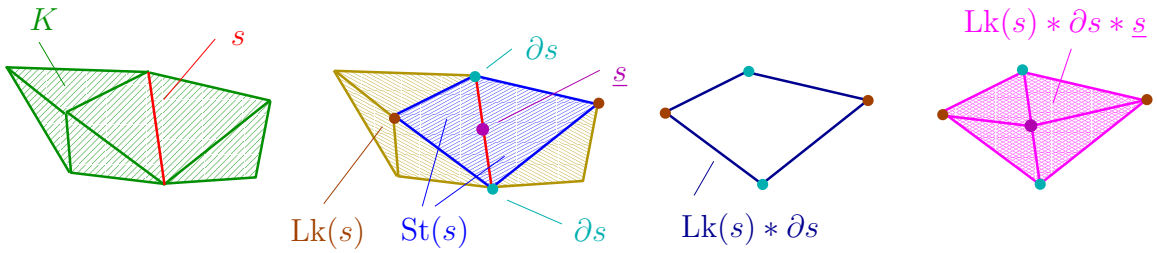
(1) The vigilant reader will have noticed that we defined $\mathrm{St}(K, s)$ and $\mathrm{Lk}(K, s)$ twice, namely on page 2018 as suitable subsets of $|K|$ and now as abstract subcomplexes. The vigilant reader surely will have no troubles in figuring out which of the two definitions we are working with at any given moment.
(2) The notation "$K \setminus \mathrm{St}(K, \mathring{s})$" is meant to be suggestive, but note that on its own $\mathring{s}$ makes no sense.

Next we recall the following definitions from page 1980 and page 2014.

[1189] One can easily verify that all three are indeed subcomplexes.

Definition. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$ be a simplex.

(1) (a) If s is a 0-simplex, then we define $\partial s = (\varnothing, \varnothing)$.
(b) If s is not a 0-simplex, then we define ∂s to be the abstract simplicial complex $(s, \mathcal{P}(s) \setminus \{\varnothing, s\})$.



(2) We denote by $\underline{s} := \sum_{v \in s} \frac{1}{\dim(s)+1} \cdot v \in |K|$ the barycenter.[1190]

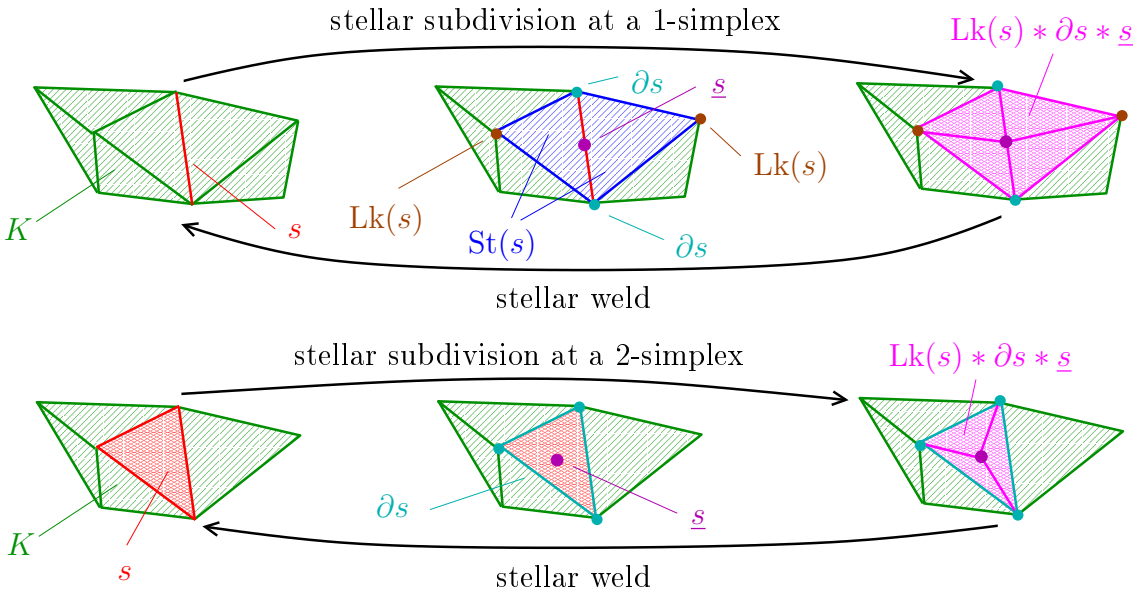
The following lemma summarizes several basic relations between the objects we just introduced.

Lemma 96.20. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$. The following statements hold:

(1) $\mathrm{St}(K, s) = \mathrm{Lk}(K, s) * s$.
(2) The union of the subcomplexes $K \setminus \mathrm{St}(K, \mathring{s})$ and $\mathrm{St}(K, s) = \mathrm{Lk}(K, s) * s$ equals K and the intersection equals $\mathrm{Lk}(K, s) * \partial s$.
(3) The intersection of the abstract simplicial complexes $K \setminus \mathrm{St}(K, \mathring{s})$ and $\mathrm{Lk}(K, s) * \partial s * \underline{s}$ also equals $\mathrm{Lk}(K, s) * \partial s$.

Proof. We leave it to the reader to verify that all the statement follow indeed immediately from the definitions. ∎

Now we define the notion of a "stellar subdivision at a simplex s". The basic idea is to add a vertex in the interior of s and subdivide all the simplices that contain s accordingly. Slightly more precisely, the "stellar subdivision at a simplex s" is defined as replacing the subcomplex $\mathrm{St}(K, s) = \mathrm{Lk}(K, s) * s$ by the abstract simplicial complex $\mathrm{Lk}(K, s) * \partial s * \underline{s}$. Even more precisely, it is defined as follows.



Definition.

(1) Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$. We define the stellar subdivision of K at s to be the abstract simplicial complex[1191]

$$\sigma_s(K) \ := \ (K \setminus \mathrm{St}(K, \mathring{s})) \cup \mathrm{Lk}(K, s) * \partial s * \underline{s}.$$

(2) Let K be an abstract simplicial complex. If K' is a stellar subdivision of K, then we say that K is a stellar weld of K'.
(3) We say two abstract simplicial complexes K and L are stellar equivalent if there exists a finite sequence $K = K_0, K_1, \ldots, K_m = L$ of abstract simplicial complexes such that each K_{i+1} is simplicially isomorphic to either a stellar subdivision or a stellar weld of K_i.

[1190] The meticulous reader will notice that in this section, on several occasions, we will use the Barycenter Lemma 94.1.

Remark.

(1) We follow the naming conventions used in **[Lic1999]** which differ slightly from the ones used in say **[Hud1969, Zee1963b, RS1972]**. More precisely, what we call a *stellar subdivision* is called an *elementary stellar subdivision* in **[Hud1969, Zee1963b, RS1972]**.

(2) It follows easily from the definitions and the Barycenter Lemma 94.1 (3) that the stellar subdivision at a 0-simplex is the identity.

Lemma 96.21. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$. If $\mathrm{Lk}(K, s)$ is finite, then there exists a natural PL-homeomorphism $|K| \to |\sigma_s(K)|$.

Remark. The proof of Lemma 96.21 shows that $|\sigma_s(K)|$ is essentially a subdivision of $|K|$. This shows that the name "stellar *subdivision*" is justified.

Proof. Let $K = (V, S)$ be a finite abstract simplicial complex and let $s \in S$. Recall that on page 2091 we saw that there exists a natural PL-homeomorphism $\varphi\colon |s| \to |\partial s * \underline{s}|$ which is the identity on the common subset $|\partial s|$. It follows from Lemmas 93.20 and 96.10, together with our hypothesis that $\mathrm{Lk}(K, s)$ is finite, that the map $\mathrm{id}_{\mathrm{Lk}(K,s)}$ and φ give rise to a natural PL-homeomorphism $f\colon |\mathrm{Lk}(K, s) * s| \to |\mathrm{Lk}(K, s) * \partial s * \underline{s}|$ which has the following property:

(∗) The map f is the identity on the common subset $|\mathrm{Lk}(K, s) * \partial s|$.

Next we consider the two maps

$$\Phi\colon |K| \to |\sigma_s(K)| \qquad P \mapsto \begin{cases} P, & \text{if } P \in |K \setminus \mathrm{St}(K, \overset{\circ}{s})|, \\ f(P), & \text{if } P \in |\mathrm{St}(K, s)| \end{cases}$$

$$\Psi\colon |\sigma_s(K)| \to |K| \qquad P \mapsto \begin{cases} P, & \text{if } P \in |K \setminus \mathrm{St}(K, \overset{\circ}{s})|, \\ f^{-1}(P), & \text{if } P \in |\mathrm{Lk}(K, s) * \partial s * \underline{s}|. \end{cases}$$

[1191] It follows from Lemma 93.2 (1) that $\sigma_s(K)$ is indeed an abstract simplicial complex.

We make the following observations:

(1) It follows from Lemma 96.20 (2) and (3) together with (∗) that both maps are well-defined.
(2) By Lemma 93.8 together with Pasting Proposition 2.6 we know that both maps are continuous.
(3) Basically by construction the maps are inverses of one another.

In summary we have shown that both maps are homeomorphisms. It remains to show that $\Phi\colon |K| \to |\sigma_s(K)|$ is in fact a PL-homeomorphism. To do so, note that it follows easily from the definition of the map Φ that the simplicial complex $(\sigma_s(K), \Phi^{-1}\colon |\sigma_s(K)| \to |K|)$ is a subdivision of $|K|$. With respect to this subdivision the map Φ is evidently a simplicial isomorphism. Thus we see that Φ is in fact a PL-homeomorphism. ■

The following rather amazing theorem is one of the key bridges between topology and combinatorics.

Theorem 96.22. (Alexander-Newman Theorem) Let K and L be two finite abstract simplicial complexes. The following two statements are equivalent:

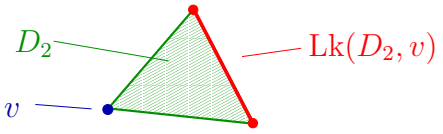
(1) The abstract simplicial complexes K and L are stellar equivalent.
(2) The simplicial complexes $|K|$ and $|L|$ are PL-homeomorphic.

Proof. The "(1)⇒(2)"-direction is just the combination of Lemma 96.21 and Proposition 96.9. The much harder "(2)⇒(1)"-direction was first proved by James Alexander [**Al1930**, Theorem 15:1] in 1930, building on work of Max Newman [**New1926**]. More modern expositions of the proof are given in [**Gla1970**, Theorem II.17] and in [**Lic1999**, Theorem 4.5]. ■

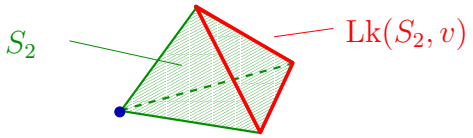
According to [**Lic1999**, p. 311] and [**Mel2018**, p. 1] the following question, posed in particular in [**Hud1969**, p. 14] and [**Pac1991**, Problem 3.3], is still open. An affirmative answer for 2-dimensional abstract simplicial complexes was given by Jürgen Ewald [**Ewa1986**] in 1986.

Question 96.23. Let K and L be two finite abstract simplicial complexes such that the simplicial complexes $|K|$ and $|L|$ are PL-homeomorphic. Do there exist iterated stellar subdivisions of K and L which are simplicially isomorphic?

96.6. **Combinatorial manifolds and Pachner's Theorem.** The Alexander-Newman Theorem 96.22 and Propositions 96.12 and 96.14 (2) motivate the following definitions.



Definition.



(1) We say that two finite abstract simplicial complexes K and L are combinatorially homeomorphic if K and L are stellar equivalent.
(2) Let $n \in \mathbb{N}_0$. We say that a finite abstract simplicial complex is a combinatorial n-ball if it is combinatorially homeomorphic to D_n and we say it is a combinatorial n-sphere if it is combinatorially homeomorphic to S_n.[1192]
(3) Let K be a finite abstract simplicial complex. We say K is an n-dimensional combinatorial manifold if for every vertex v the link $\mathrm{Lk}(K, v)$ is a combinatorial $(n-1)$-sphere or a combinatorial $(n-1)$-ball.
(4) We say an n-dimensional combinatorial manifold K is closed if for every vertex v the link $\mathrm{Lk}(K, v)$ is a combinatorial $(n-1)$-sphere.

.

Examples. Let $n \in \mathbb{N}$. We consider the abstract simplicial complexes D_n and S_n.

(1) For every vertex v of D_n we have, basically by definition, that $\mathrm{Lk}(D_n, v)$ is simplicially isomorphic to D_{n-1}. Thus we see that D_n is an n-dimensional combinatorial manifold.
(2) Similarly, for every vertex v of S_n we have, again basically by definition, that $\mathrm{Lk}(S_n, v)$ is simplicially isomorphic to S_{n-1}. Thus we obtain that S_n is a closed n-dimensional combinatorial manifold.

Remark.

(1) From what I can see, there is no combinatorial analogue of the notion that a map between two finite abstract simplicial complexes is piecewise linear.
(2) In the literature, see e.g. [**Hud1969**, p. 26] and [**Gla1970**, p. 18], a *combinatorial manifold* is often defined as a PL-manifold. Even though the concept of a "wrong definition" does not exist, it seems to me that it is more appropriate to define a combinatorial manifold as above, namely to define it immediately as a purely combinatorial object.

The statement of the following proposition, which can be viewed as an analogue of Proposition 96.11, does not come as a surprise.

Proposition 96.24. Let K and L be two finite abstract simplicial complexes. If K is a (closed) n-dimensional combinatorial manifold and if L is combinatorially homeomorphic to K, then L is a (closed) n-dimensional combinatorial manifold.

Example. It follows from Proposition 96.24 and the previous examples that every combinatorial n-ball is indeed an n-dimensional combinatorial manifold and that every combinatorial n-sphere is indeed a closed n-dimensional combinatorial manifold.

Proof. A short moment's thought shows that this statement does indeed need a proof, it does not follow immediately from the definitions. In fact the proposition is a consequence of [**Gla1970**, Lemma on p. 19]. ■

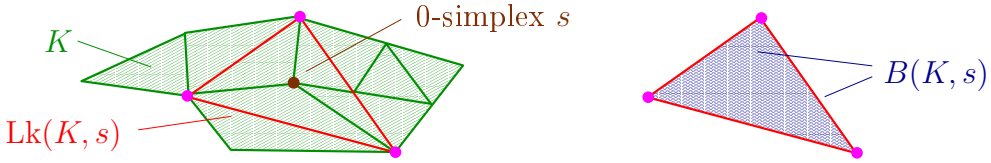
By definition the link of any 0-simplex in a closed combinatorial manifold is a combinatorial sphere. The following lemma, which is an analogue of the PL-Manifold Characterization Proposition 96.12 (2)⇒(4), generalizes this statement to higher dimensional simplices.

Lemma 96.25. Let K be a closed n-dimensional combinatorial manifold. If s is a k-simplex, then the link $\mathrm{Lk}(K, s)$ is a combinatorial $(n-k-1)$-sphere.

Proof. The proof of this lemma is almost the same as the proof of the PL-Manifold Characterization Proposition 96.12 (2)⇒(4). The only slight difference is that now we need to use the fact, mentioned above, that every combinatorial k-sphere is a closed k-dimensional combinatorial manifold. ■

[1192]We refer to page 1978 for the definition of the abstract simplicial complexes S_n and D_n

By definition two combinatorially homeomorphic combinatorial manifolds are related by a sequence of stellar subdivisions and stellar welds. In the following we will see that they are also related by the more elegant "bistellar moves".



To introduce the notion of a bistellar move we need the following basic definition.

Definition. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$ be a simplex.

(1) Let $m \in \mathbb{N}_0$. We say that $\mathrm{Lk}(K, s) =: (U, R)$ is a non-trivial m-sphere in K if the following two conditions are satisfied:
   (a) we have $\#U = m + 2$ and $R = \mathcal{P}(U) \setminus \{\varnothing, U\}$,[1193]
   (b) the vertex set U is not a simplex of K.
   In this case we denote by $B(K, s)$ the abstract simplicial complex $(U, \mathcal{P}(U) \setminus \{\varnothing\})$. We illustrate the definition in the figure below.

(2) We say that $\mathrm{Lk}(K, s)$ is a non-trivial (-1)-sphere in K if it is the empty subcomplex. In this case we define $B(K, s)$ to be abstract simplicial complex consisting of the single vertex $\underline{s}$.

As usual, if K is understood then we write $B(s)$ instead of $B(K, s)$.

We move on to the next lemma which can be viewed as the fourth part of Lemma 96.20.

Lemma 96.26. Let $K = (V, S)$ be a closed n-dimensional combinatorial manifold and let $s \in S$ be a k-simplex. We suppose that the link $\mathrm{Lk}(K, s)$ is a non-trivial $(n - k - 1)$-sphere in K. Then the intersection of the abstract simplicial complexes $K \setminus \mathrm{St}(K, \mathring{s})$ and $\partial s * B(K, s)$ equals $\mathrm{Lk}(K, s) * \partial s$.

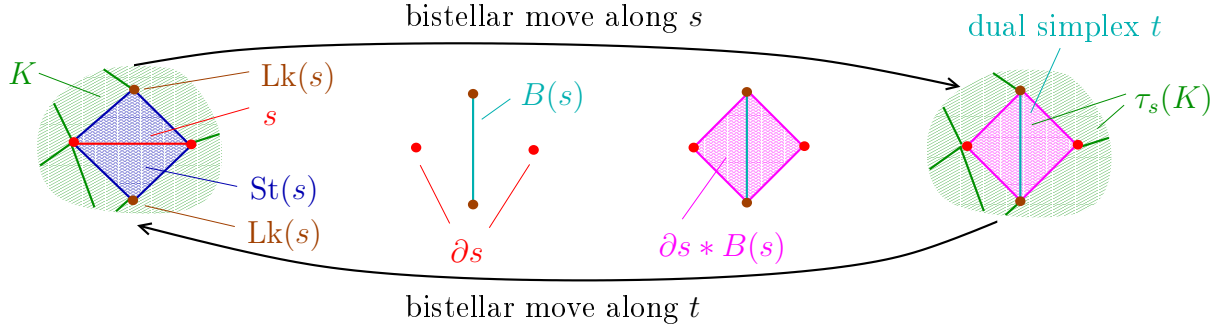
Proof. Again we leave the task of verifying the lemma to the reader. ■

Suppose we are in the setting of Lemma 96.26. Loosely speaking the *bistellar move along* s is defined as the result of replacing the subcomplex

$$\mathrm{St}(K, s) \;=\; \underset{\cong D_k}{s} \;*\; \underset{\cong S_{n-k-1}}{\mathrm{Lk}(K, s)} \quad \text{by the abstract simplicial complex} \quad \underset{\cong S_{k-1}}{\partial s} \;*\; \underset{\cong D_{n-k}}{B(K, s)}.$$

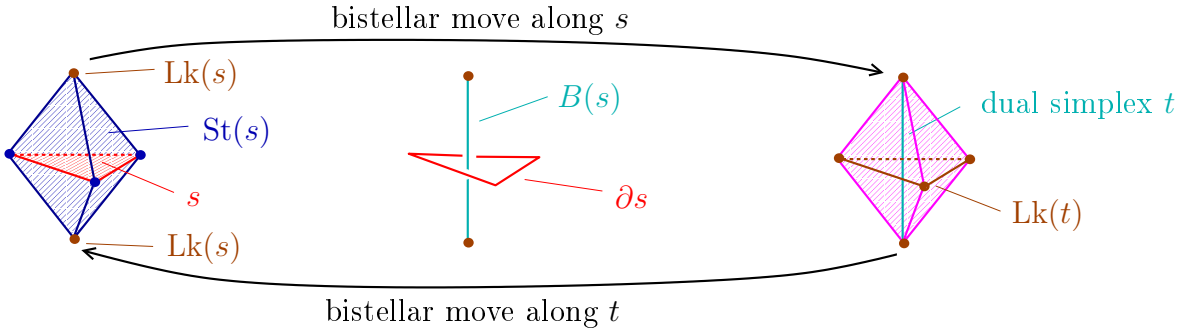
More precisely, we have the following definition.

Definition. Let $K = (V, S)$ be a closed n-dimensional combinatorial manifold and let $s \in S$ be a k-simplex such that $\mathrm{Lk}(K, s)$ is a non-trivial $(n-k-1)$-sphere in K. We define



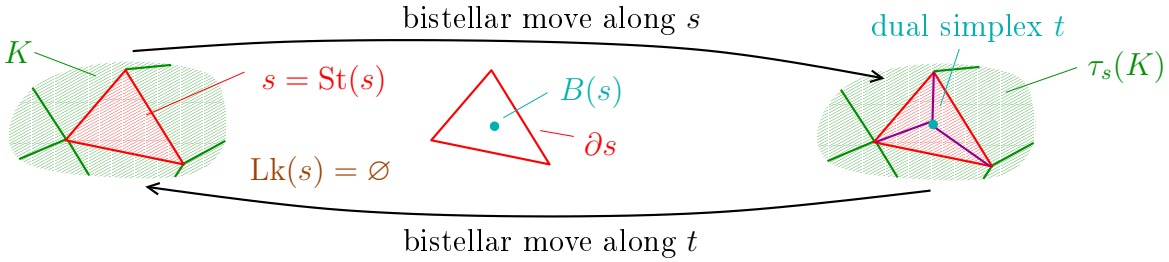
$$\tau_s(K) \;:=\; (K \setminus \mathrm{St}(K, \mathring{s})) \cup \partial s * B(K, s).$$

We refer to the unique $(n - k)$-simplex in $B(K, s)$ as the dual simplex. We say $\tau_s(K)$ is obtained from K by a bistellar move along s.



[1193] This just means that $\mathrm{Lk}(K, s)$ is simplicially isomorphic to the abstract simplicial complex S_m. It is worth recalling that Lemma 96.25 says that the link of a k-simplex in a closed n-dimensional combinatorial manifold is combinatorially homeomorphic to S_{n-k-1}, which is a much weaker condition than demanding that the link is simplicially isomorphic to S_{n-k-1}.

Examples.



(1) In the figure below we show a bistellar move along a 1-simplex s in a 2-dimensional combinatorial manifold.

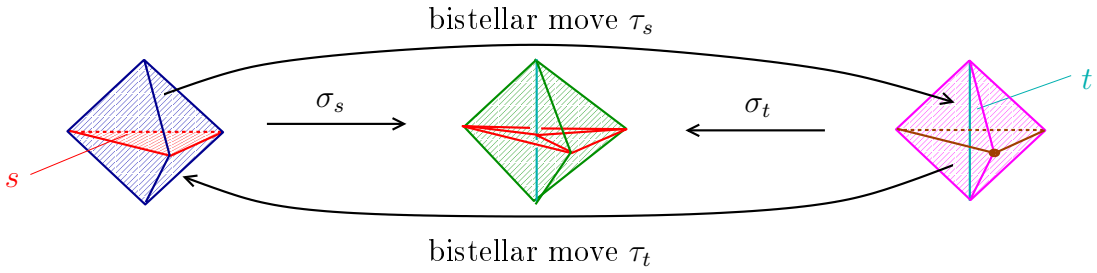
(2) In the figure below we show a bistellar move along a 2-simplex s in a 3-dimensional combinatorial manifold.

(3) In the figure below we show a bistellar move along a 2-simplex s in a 2-dimensional combinatorial manifold. In this case $\mathrm{Lk}(s) = \varnothing$, which by the above convention, is a non-trivial (-1)-sphere.

Note that in each example we see that the bistellar move along the dual simplex actually gets us back to the original abstract simplicial complex. In the next lemma we will see that this is not a coincidence.

The following lemma summarizes a few key properties of bistellar moves.

Lemma 96.27. (Bistellar Lemma) Let $K = (V, S)$ be a closed n-dimensional combinatorial manifold and let $s \in S$ be a k-simplex such that $\mathrm{Lk}(K, s)$ is a non-trivial $(n-k-1)$-sphere in K. We denote by t the dual simplex. The following statements hold:



(1) The dual simplex t is an $(n-k)$-simplex in $\tau_s(K)$ with the following properties:
  (a) $\partial t = \mathrm{Lk}(K, s)$,
  (b) $\mathrm{Lk}(\tau_s(K), t) = \partial s$,
  (c) (i) if $s = \{v\}$ is a 0-simplex, then $B(\tau_s(K), t) = (\{\underline{t}\}, \{\underline{t}\})$,
    (ii) if s is not a 0-simplex, then $B(\tau_s(K), t) = s$,[1194]
  (d) $\tau_s(K) \setminus \mathrm{St}(\tau_s(K), \mathring{t}) = K \setminus \mathrm{St}(K, \mathring{s})$.

  Furthermore ∂s is a non-trivial $(k-1)$-sphere in $\tau_s(K)$.

(2) $\sigma_s(K)$ is naturally simplicially isomorphic to $\sigma_t(\tau_s(K))$.

(3) $\tau_s(K)$ is a closed n-dimensional combinatorial manifold which is naturally combinatorially homeomorphic to K.

(4) $\tau_t(\tau_s(K))$[1195] is naturally simplicially isomorphic to K.

Remark. The Bistellar Lemma 96.27 shows that in particular that if two closed n-dimensional combinatorial manifold are bistellar equivalent, then they are also stellar equivalent. Furthermore the Bistellar Lemma 96.27 gives us also the justification for the name "bistellar move".

Proof.

(1) We leave the elementary verification of these statements to the reader. Note that the slightly awkward fact that we need to deal with 0-simplices separately is due to the fact that already in the definitions on page 2106 and page 2101 we were forced to treat 0-simplices slightly differently.

(2) This statement follows easily from (1). Indeed, we see that

$$\sigma_t(\tau_s(K)) \underset{\text{by definition}}{=} \overbrace{(\tau_s(K) \setminus \mathrm{St}(\tau_s(K), \mathring{t}))}^{= K \setminus \mathrm{St}(K, \mathring{s}) \text{ by (1)}} \cup \overbrace{\mathrm{Lk}(\tau_s(K), t) * \partial t * \underline{t}}^{= \partial s * \mathrm{Lk}(K,s) * \underline{t} \text{ by (1)}} \underset{\text{by Lemma 96.20 the map } \underline{s} \mapsto \underline{t} \text{ defines a simplicial isomorphism}}{\overset{\cong}{\to}} \sigma_s(K).$$

(3) It follows from (2) that $\tau_s(K)$ is naturally stellar equivalent to K. In other words, $\tau_s(K)$ is naturally combinatorially homeomorphic to K. It follows from Proposition 96.24 that $\tau_s(K)$ is also a closed n-dimensional combinatorial manifold.

[1194] Here we view the simplex s as an abstract simplicial complex in its own right.

[1195] It follows from (1) that we can form $\tau_t(\tau_s(K))$.

(4) First assume that s is not a 0-simplex. In this case we see that

$$\tau_t(\tau_s(K)) \underset{\text{by definition}}{=} \overbrace{(\tau_s(K) \setminus \mathrm{St}(\tau_s(K), \overset{\circ}{t}))}^{= K \setminus \mathrm{St}(K, \overset{\circ}{s}) \text{ by (1)}} \cup \overbrace{\partial t * B(\tau_s(K), t)}^{=\mathrm{Lk}(K,s)*s \text{ by (1)}} \underset{\text{Lemma 96.20}}{=} K.$$

Finally we deal with the case that $s = \{v\}$ is a 0-simplex. Note that in this case the vertex set of $\tau_t(\tau_s(K))$ equals $(V \setminus \{v\}) \cup \{\underline{t}\}$. The obvious bijection between the vertex sets of $\tau_t(\tau_s(K))$ and of K, i.e. the map given by $\underline{t} \mapsto v$, induces, by the same argument as above, a simplicial isomorphism $\tau_t(\tau_s(K)) \to K$. ■

Note that the Bistellar Lemma 96.27 (4) implies in particular that "being related by a sequence of bistellar moves" is an equivalence relation. This observation motivates the following definition.

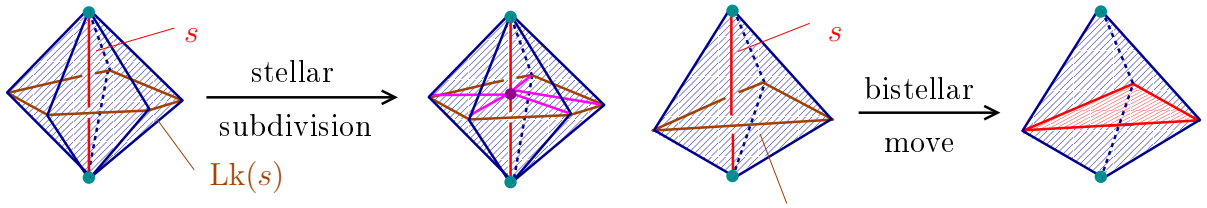
Definition. We say that two closed n-dimensional combinatorial manifold are bistellar equivalent if one can be obtained from the other via a finite sequence of bistellar moves and simplicial isomorphisms.

The following theorem can be viewed as a refinement of the Alexander-Newman Theorem 96.22 for closed combinatorial manifolds. The theorem was proved in 1991 by Udo Pachner [**Pac1991**].

Theorem 96.28. (Pachner's Theorem) Let K and L be two closed combinatorial manifolds. The following two statements are equivalent:

(1) The abstract simplicial complexes K and L are bistellar equivalent.
(2) The abstract simplicial complexes K and L are combinatorially homeomorphic (i.e. they are stellar equivalent).

Remark.



(1) Pachner's Theorem 96.28 is the reason why bistellar moves are often called *Pachner moves*.
(2) An analogue of Pachner's Theorem 96.28 for combinatorial manifolds that are not closed is given in [**Pac1991**, Theorem 6.3] and [**Lic1997b**, Theorem 5.10].
(3) The Alexander-Newman Theorem 96.22 and Pachner's Theorem 96.28 can be viewed as an analogue of the Reidemeister Moves Theorem 59.21 which says that any two knot diagrams for a given knot are related by a finite sequence of Reidemeister moves.

Proof. The "(1)⇒(2)"-direction is an immediate consequence of the Bistellar Lemma 96.27. The much more interesting "(2)⇒(1)"-direction is proved in [**Pac1991**, Theorem 5.5]. An exposition of the proof is also given in [**Lic1999**, Theorem 5.9]. For combinatorial manifolds of dimension ≤ 3 a more elementary proof is given in [**BW1996**, Theorem 4.11] and implicitly in [**TV1992**]. Furthermore for combinatorial manifolds of dimension ≤ 4 a proof is also given in [**Pac1978**]. ■

Let us quickly compare the statements and roles of the Alexander-Newman Theorem 96.22 and Pachner's Theorem 96.28.

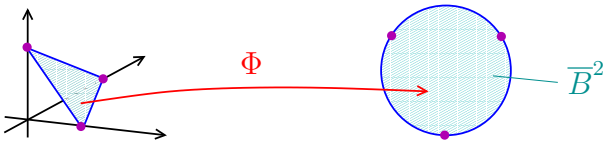
(1) The Alexander-Newman Theorem 96.22 is more general in so far as it applies to any two finite simplicial complexes whereas Pachner's Theorem 96.28 only deals with closed combinatorial manifolds.

(2) Now we restrict ourselves to the class of closed n-dimensional combinatorial manifolds.
   (a) A stellar subdivision consists in replacing $\mathrm{Lk}(K,s) * s$ by $\mathrm{Lk}(K,s) * \partial s * \underline{s}$. As should become clear from considering the figure below, for $n \geq 3$ there are infinitely many simplicial isomorphism types of links of simplices that can appear. Thus we see that even for closed n-dimensional combinatorial manifolds there are infinitely many[1196] "combinatorially distinct" stellar subdivisions.
   (b) On the other hand a Pachner move can only be applied if the link $\mathrm{Lk}(K,s)$ is in fact simplicially isomorphic to some S_k, $k = 0, \ldots, n$. Recall that if a Pachner move is possible, then it replaces $\mathrm{Lk}(K,s) * s$ by $\partial s * B(K,s)$. Thus we see that there are only $n+1$ "combinatorially distinct" moves.

stellar subdivision is always possible

$\mathrm{Lk}(s)$ needs to be some S_k

Now, at the end the end of this chapter we have obtained the following sequence of maps:

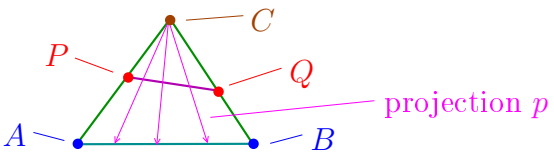


$$\begin{array}{c}
\{\text{diffeomorphism classes of closed } n\text{-dimensional smooth manifolds}\} \\
\Big\downarrow \boldsymbol{w}_n \quad \text{by Theorem 96.16 a bijection for } n \leq 6 \\
\{\text{PL-homeomorphism classes of closed } n\text{-dimensional PL-manifolds}\} \\
\Big\uparrow |K| \\
\Big\updownarrow K \quad \text{a bijection by the Alexander-Newman Theorem 96.22} \\
\left\{ \begin{array}{c} \text{combinatorial homeomorphism classes of} \\ \text{closed } n\text{-dimensional combinatorial manifolds} \end{array} \right\} \\
\Big\uparrow \quad \text{identity by Pachner's Theorem 96.28} \\
\{\text{bistellar equivalence classes of closed } n\text{-dimensional combinatorial manifolds}\}
\end{array}$$

This shows in particular that for dimensions ≤ 6 the classification of closed smooth manifolds boils down to (very difficult!) combinatorics.
In particular the sequence of maps gives us an approach to defining invariants of closed n-dimensional PL-manifolds (or equivalently smooth manifolds for $n \leq 6$): we "just" need to define an invariant for closed n-dimensional combinatorial manifolds that is invariant under the $n+1$ bistellar moves. This approach to defining invariants has been used by Vladimir Turaev and Oleg Viro [**TV1992**] and John Barrett and Bruce Westbury [**BW1996**] in the 3-dimensional setting and by Christopher Douglas and David Reutter [**DR2018**] in the 4-dimensional setting.
Finally we mention that the significance of Pachner's Theorem 96.28 in mathematics and theoretical physics ("loop quantum gravity theory") is nicely explained in [**Lic1997b, Lic1999**] and [**Kle2018**].

[1196] We leave it to the reader to fill the expression "combinatorially distinct" with meaning.

Exercises for Chapter 96.



Exercise 96.1. We equip the smooth manifold $\overline{B}^2$ with the canonical simplicial structure $\Phi\colon \Delta^2 \to \overline{B}^2$ introduced on page 1997. Is this a smooth simplicial structure for the smooth manifold $\overline{B}^2$?

Exercise 96.2. Let $n \in \mathbb{N}_0$. Show that $\mathrm{Cone}(\partial\Delta^n)$ is PL-homeomorphic to Δ^n. We refer to the figure on page 2092 for an illustration.

Exercise 96.3. Let X be a simplicial complex and let Y be a subdivision. Show that every k-simplex of X is the union of finitely many simplices of Y of dimension $\leq k$.

Exercise 96.4. We consider the triangle Δ_{ABC} shown in the figure below. Let $P \in \overline{AC}$ and $Q \in \overline{BC}$ be two points such that the segment $\overline{PQ}$ is not parallel to the segment $\overline{AB}$. Let p be the radial projection from C of the segment $\overline{PQ}$ to the base $\overline{AB}$ of the triangle. We equip $\overline{PQ}$ and $\overline{AB}$ with the obvious simplicial structures. Show that the map p is not piecewise linear.
Remark. The fact that the radial projection p is not piecewise linear is called the "standard mistake" in [**Zee1963b**, p. I.6] and [**RS1972**, p. 6].

Exercise 96.5. We consider the two abstract simplicial complexes K and L shown in the figure below.

(a) Show that L is not a stellar subdivision of K.
(b) Show "by hand" that K and L are stellar equivalent.

Exercise 96.6. Use the Alexander-Newman Theorem 96.22 to prove Pachner's Theorem 96.28 in the 2-dimensional case.

Exercise 96.7. Let K be an abstract simplicial complex. Show that if K is a closed n-dimensional combinatorial manifold, then the maximal dimension of a simplex of K is precisely n.
Hint. You could do an induction on n.

Exercise 96.8. Let M be an n-dimensional smooth manifold. In the Smoothly Good Cover Theorem **??** we showed that M admits a smoothly good finite open cover. In plain English this means that there exists an open cover $U_1, \ldots, U_k$ of M such that the intersection of any selection of these sets is diffeomorphic to $\mathbb{R}^n$. Use this result to give an alternative proof of Statements (1), (2) and (4) of the Smooth Manifolds-Invariants Proposition 96.6 for M. More precisely, prove the following statements:

(1) For every $k > n$ and for every abelian group G we have $\mathrm{H}_k(M; G) = 0$.
(3) The fundamental group of M is finitely presented.
(4) All homology groups of M are finitely generated abelian groups. Furthermore, given any field $\mathbb{F}$ the homology groups $\mathrm{H}_k(M; \mathbb{F})$ are finite-dimensional.

Remark. You should make use of the calculations of the invariants for $\mathbb{R}^n$, the Mayer–Vietoris Theorem 78.5, the Seifert-van Kampen Theorem 54.1 and the HNN-Seifert-van Kampen Theorem 57.3.

97. The Lefschetz Fixed Point Theorem

In this chapter we will state and prove the Lefschetz Fixed Point Theorem which gives a criterion for a self-map to have a fixed point. This theorem can be viewed as a far reaching generalization of the Brouwer Fixed Point Theorem 31.4.

97.1. **The trace of an endomorphism.** In the formulation of the Lefschetz Fixed Point Theorem we need the notion of the trace of suitable endomorphisms. Even though this notion is surely well-known to the reader we recall the definition and a few properties of the trace of an endomorphism. This short section will facilitate the discussion below. Nonetheless, the author will not hold it against the reader if the reader decides to skip this section.

Definition. Let R be a ring. Given an $(n \times n)$-matrix $A = (a_{ij})$ over R we define its trace to be

$$\operatorname{tr}(A) \;:=\; \sum_{i=1}^{n} a_{ii}.$$

Lemma 97.1. Let R be a ring and let A and B be two $(n \times n)$-matrices over R. If R is commutative, then we have

$$\operatorname{tr}(A \cdot B) \;=\; \operatorname{tr}(B \cdot A).$$

Proof. We perform the following simple calculation:

$$\operatorname{tr}(A\cdot B) = \operatorname{tr}\Big(\text{matrix with } (i,j)\text{-entry } \sum_{k=1}^{n} a_{ik}\cdot b_{kj}\Big) = \sum_{i=1}^{n}\sum_{k=1}^{n} a_{ik}\cdot b_{ki} \underset{\text{since } R \text{ is commutative}}{\overset{\uparrow}{=}} \sum_{i=1}^{n}\sum_{k=1}^{n} b_{ki}\cdot a_{ik} \underset{\text{same calculation backwards}}{\overset{\downarrow}{=}} \operatorname{tr}(B\cdot A).$$

∎

Lemma 97.2. Let R be a commutative domain, let V be a free R-module of rank n and let $\varphi\colon V \to V$ be an endomorphism. We pick a basis for V. Then

$$\operatorname{tr}(\varphi) \;:=\; \text{trace of the matrix representing } \varphi \text{ with the respect to the given basis}$$

does not depend on the choice of the basis. We refer to $\operatorname{tr}(\varphi)$ as the trace of the endomorphism.

Notation. Given a commutative domain R, a free R-module V of finite rank and an endomorphism $\varphi\colon V \to V$, depending on the amount of space we have, we use one of the following three notations:

$$\operatorname{tr}(\varphi) \;=\; \operatorname{tr}(\varphi\colon V \to V) \;=\; \operatorname{tr}(\varphi \circlearrowleft V).$$

Example. Let R be a commutative domain and let V be a free R-module of finite rank. It follows immediately from the definitions that $\operatorname{tr}(\mathrm{id}_V) = \operatorname{rank}(V)$.

Proof. Let R be a commutative domain. Let $\{v_1, \ldots, v_m\}$ and $\{w_1, \ldots, w_n\}$ be two bases for V. Since R is a commutative domain the rank of V is well-defined, see page 99. Thus we see that $m = n$. Now let $P = (p_{ij})$ be the transition matrix, i.e. $P = (p_{ij})$ is the matrix that is uniquely determined by the condition that given any $i \in \{1, \ldots, n\}$ we have $v_i = \sum_{j=1}^{n} p_{ji} \cdot w_j$. The "opposite" transition matrix is evidently an inverse to P, in particular

we see that P is invertible. We denote by A and B the matrices representing φ with respect to the two bases. We see that

$$\operatorname{tr}(B) \underset{\substack{\uparrow\\ \text{an elementary calculation}\\ \text{shows that } B\cdot P = P\cdot A}}{=} \operatorname{tr}(P\cdot A\cdot P^{-1}) \underset{\substack{\uparrow\\ \text{by Lemma 97.1 since } R \text{ is commutative and since all}\\ \text{matrices are square matrices of the same size}}}{=} \operatorname{tr}(P^{-1}\cdot P\cdot A) = \operatorname{tr}(A).$$

■

In many of the applications below we will consider the case that R is a field. But on several occasions the case $R = \mathbb{Z}$ is also of interest.

Lemma 97.3. Let $\varphi\colon V \to V$ be an endomorphism of a finitely generated free abelian group and let R be a commutative domain. Let $\gamma\colon \mathbb{Z} \to R$ be the natural ring homomorphism with $\gamma(1_{\mathbb{Z}}) = 1_R$ from page 205. Then

$$\gamma\big(\operatorname{tr}\big(\underbrace{\varphi\colon V\to V}_{\substack{\text{homomorphism of}\\ \text{free } \mathbb{Z}\text{-modules}}}\big)\big) = \operatorname{tr}\big(\underbrace{\varphi\otimes \mathrm{id}_R\colon V\otimes R\to V\otimes R}_{\substack{\text{homomorphism of free } R\text{-modules}\\ \text{by the Tensor-with-Ring Lemma 89.5}}}\big) \in R.$$

Proof. Let $\{v_1,\dots,v_n\}$ be a basis for the free abelian group V and let A be the $(n\times n)$-matrix that represents φ with respect to this basis. It is straightforward to verify that $v_1\otimes 1,\dots,v_n\otimes 1$ is a basis for the R-module $V\otimes R$ and that $\gamma(A)$ is the matrix that represents the endomorphism $\varphi\otimes\mathrm{id}$. Since the trace commutes with ring homomorphisms we obtain the desired equality $\gamma(\operatorname{tr}(A)) = \operatorname{tr}(\gamma(A))$. ■

Sometimes it is also convenient to consider the trace of an endomorphism of a finitely generated abelian group. This leads us to the following definition.

Definition.

(1) Given a finitely generated abelian group H we refer to

$$\mathrm{F}H := H/\operatorname{Tor}(H) \quad \text{where } \operatorname{Tor}(H) \text{ denotes the torsion subgroup of } H$$

as the maximal torsion-free quotient of H.

(2) Given a homomorphism $\alpha\colon A\to B$ between two finitely generated abelian groups we denote the obvious induced map $\mathrm{F}A\to \mathrm{F}B$ by α as well.

Lemma 97.4. Given a finitely generated abelian group H the maximal torsion-free quotient $\mathrm{F}H = H/\operatorname{Tor}(H)$ of H is a free abelian group.

Proof. A very elementary exercise shows that $\mathrm{F}H = H/\operatorname{Tor}(H)$ is a torsion-free abelian group. Since H is finitely generated we obtain from the Finitely Generated Abelian Group Classification Theorem 51.4 that $\mathrm{F}H$ is in fact a free abelian group. ■

Remark.

(1) It follows easily from the definition that the map $H\to \mathrm{F}H$ defines a functor from the category of finitely generated abelian groups to the category of free abelian groups.

(2) It might sound silly to mention the Finitely Generated Abelian Group Classification Theorem 51.4 explicitly in the proof of Lemma 97.4, but it is worth noting that for commutative rings R which are not PIDs there is usually no meaningful functor from the category of finitely generated R-modules to the category of free R-modules.

(3) The hypothesis that H is finitely generated is of course necessary, for example the maximal torsion-free quotient of the abelian group $(\mathbb{Q},+)$ is again $(\mathbb{Q},+)$, which is certainly not a free abelian group.

Definition. Given an endomorphism $\varphi\colon H\to H$ of a finitely generated abelian group we define

$$\operatorname{tr}(\varphi) \;=\; \operatorname{tr}\begin{pmatrix} \mathrm{F}H & \to & \mathrm{F}H \\ [h] & \mapsto & [\varphi(h)] \end{pmatrix}.$$

We conclude this elementary section with the following basic lemma which is a variation on Lemma 97.3.

Lemma 97.5. Let H be a finitely generated abelian group and let $\varphi\colon H\to H$ be an endomorphism. Then the following equality holds:

$$\operatorname{tr}(\varphi\colon H\to H) \;=\; \operatorname{tr}(\varphi\otimes\mathrm{id}\colon H\otimes\mathbb{Q}\to H\otimes\mathbb{Q}) \;\in\; \mathbb{Q}.$$

Proof. By the Finitely Generated Abelian Group Classification Theorem 51.4 we can write $H=F\oplus T$ where F is a free abelian group and T is a torsion group. We denote by ψ the map $F\xrightarrow{f\mapsto f\oplus 0}F\oplus T\xrightarrow{\varphi}F\oplus T\xrightarrow{f\oplus t\mapsto f}F$. Then we see that

$$\operatorname{tr}(\varphi\colon H\to H)\underset{\text{follows easily from the definitions}}{\uparrow=}\operatorname{tr}(\psi\colon F\to F)\underset{\text{by Lemma 97.3}}{\uparrow=}\operatorname{tr}(\psi\otimes\mathrm{id}\colon F\otimes\mathbb{Q}\to F\otimes\mathbb{Q})\underset{\text{by the Tensor Lemma 89.3}}{\uparrow=}\operatorname{tr}(\varphi\otimes\mathrm{id}\colon H\otimes\mathbb{Q}\to H\otimes\mathbb{Q}).$$

∎

97.2. The Lefschetz number.

In this section we return to topology.

Definition. Let $\mathbb{F}$ be a field.

(1) Let X be a topological space. We say the homology of X is $\mathbb{F}$-finite if all homology groups $\mathrm{H}_i(X;\mathbb{F})$ with $\mathbb{F}$-coefficients are finite-dimensional vector spaces and if all but finitely many homology groups $\mathrm{H}_i(X;\mathbb{F})$ are zero.

(2) Let X be a topological space such that the homology is $\mathbb{F}$-finite. Let $\varphi\colon X\to X$ be a map. We define the $\mathbb{F}$-Lefschetz number of φ to be[1197]

$$\Lambda(\varphi,\mathbb{F}) \;:=\; \sum_{n\in\mathbb{N}_0}(-1)^n\cdot\operatorname{tr}(\varphi_*\colon \mathrm{H}_n(X;\mathbb{F})\to\mathrm{H}_n(X;\mathbb{F})).$$

Remark. In Exercise 97.1 we will see that the $\mathbb{F}$-Lefschetz number depends only rather mildly on the choice of the field $\mathbb{F}$.

In general it can be tricky to determine (the trace of) an induced map on homology. The following lemma gives us some basic (partial) calculations of Lefschetz numbers.

Lemma 97.6.

(1) If X is a finite CW-complex, then for any field $\mathbb{F}$ we have $\Lambda(\mathrm{id}_X,\mathbb{F})=\chi(X)$.

(2) Let X be a 0-connected space and let $\varphi\colon X\to X$ be a map. For every field $\mathbb{F}$ we have $\operatorname{tr}(\varphi_*\colon \mathrm{H}_0(X;\mathbb{F})\to\mathrm{H}_0(X;\mathbb{F}))=1$.

(3) Let $\mathbb{F}$ be a field and let X be a 0-connected space with $\mathbb{F}$-finite homology. If $\varphi\colon X\to X$ is a constant map, then $\Lambda(\varphi,\mathbb{F})=1$.

[1197] Recall that on page 1914 we pointed out that the induced map $\varphi_*\colon \mathrm{H}_n(X;\mathbb{F})\to\mathrm{H}_n(X;\mathbb{F})$ is an endomorphism of an $\mathbb{F}$-vector space. Since the vector space $\mathrm{H}_n(X;\mathbb{F})$ is by hypothesis finite-dimensional we see that the trace is in fact defined.

Proof.

(1) We calculate that

$$\Lambda(\mathrm{id}_X, \mathbb{F}) \underset{\text{by definition}}{\uparrow} \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \mathrm{tr}(\mathrm{id}_* \circlearrowleft \mathrm{H}_n(X;\mathbb{F})) \underset{\text{see example on page 2113}}{\uparrow} \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \dim_{\mathbb{F}}(\mathrm{H}_n(X;\mathbb{F})) \underset{\text{see page 1915}}{\uparrow} \chi(X).$$

(2) This statement follows immediately from the obvious generalizations of the H_0-Proposition 72.5 and the discussion on page 1594 to homology with $\mathbb{F}$-coefficients.

(3) This statement follows immediately from (2). ■

The following lemma is an immediate and quite useful consequence of the Homotopic Maps-and-Homology Proposition 73.6 and the discussion on page 1914.

Lemma 97.7. Let $\mathbb{F}$ be a field and let X be a topological space such that the homology is $\mathbb{F}$-finite. Let $\varphi, \psi\colon X \to X$ be two maps. If φ and ψ are homotopic, then the Lefschetz numbers agree, i.e. $\Lambda(\varphi, \mathbb{F}) = \Lambda(\psi, \mathbb{F})$.

At times it is more efficient to work with the "usual" homology groups, i.e. the homology groups with $\mathbb{Z}$-coefficients. This leads to the following unexciting definition.

Definition.

(1) Let X be a topological space. We say the homology of X is $\mathbb{Z}$-finite if all homology groups $\mathrm{H}_i(X)$ are finitely generated abelian groups and if all but finitely many homology groups $\mathrm{H}_i(X)$ are zero.

(2) Let X be a topological space such that the homology is $\mathbb{Z}$-finite. Let $\varphi\colon X \to X$ be a map. We define the Lefschetz number of φ to be

$$\Lambda(\varphi) \;:=\; \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \mathrm{tr}(\varphi_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(X)).$$

The following lemma relates the above Lefschetz number $\Lambda(\varphi)$ to the Lefschetz number $\Lambda(\varphi, \mathbb{Q})$.

Lemma 97.8. Let X be a topological space and let $\varphi\colon X \to X$ be a map.

(1) Let $k \in \mathbb{N}_0$. We have $\mathrm{rank}(\mathrm{H}_k(X)) = \dim(\mathrm{H}_k(X;\mathbb{Q}))$. Furthermore, if $\mathrm{H}_k(X)$ is finitely generated, then we have

$$\mathrm{tr}(\varphi_*\colon \mathrm{H}_k(X) \to \mathrm{H}_k(X)) \;=\; \mathrm{tr}(\varphi_*\colon \mathrm{H}_k(X;\mathbb{Q}) \to \mathrm{H}_k(X;\mathbb{Q})).$$

(2) If the homology of X is $\mathbb{Z}$-finite, then the homology of X is also $\mathbb{Q}$-finite and we have the equality $\Lambda(\varphi) = \Lambda(\varphi, \mathbb{Q})$.

Proof. Statement (2) is an immediate consequence of Statement (1). Thus let us prove the first statement. Let $k \in \mathbb{N}_0$. The equality $\mathrm{rank}(\mathrm{H}_k(X)) = \dim(\mathrm{H}_k(X;\mathbb{Q}))$ was shown in Corollary 89.19 (2). Now assume that $\mathrm{H}_k(X)$ is finitely generated. We have the following equalities:

$$\mathrm{tr}\left(\mathrm{H}_k(X) \xrightarrow{\varphi_*} \mathrm{H}_k(X)\right) \underset{\text{by Lemma 97.5}}{=} \mathrm{tr}\left(\mathrm{H}_k(X)\otimes\mathbb{Q} \xrightarrow{\varphi_*\otimes\mathrm{id}} \mathrm{H}_k(X)\otimes\mathbb{Q}\right) \underset{\substack{\text{by the naturality of the short exact sequence of the Universal Coefficient Theorem 89.17 and the observation that by Lemma 89.15 (4) the Tor-groups with } \mathbb{Q}\text{-coefficients vanish}}}{=} \mathrm{tr}\left(\mathrm{H}_k(X;\mathbb{Q}) \xrightarrow{\varphi_*} \mathrm{H}_k(X;\mathbb{Q})\right).$$

■

97.3. **The formulation of the Lefschetz Fixed Point Theorems.** Now we can finally formulate the long promised Lefschetz Fixed Point Theorem. This theorem, with somewhat different language, was first proved in 1926 by Solomon Lefschetz [**Lef1926**, p. 48].[1198]

Theorem 97.9. (Lefschetz Fixed Point Theorem I) Let X be a finite simplicial complex and let $\varphi\colon X \to X$ be a map. If there exists a field $\mathbb{F}$ such that the $\mathbb{F}$-Lefschetz number $\Lambda(\varphi, \mathbb{F})$ is non-zero, then φ has a fixed point.

We will prove the Lefschetz Fixed Point Theorem 97.9 in the next section. First we will see that one of our earlier great successes, namely the Sphere-Degree Fixed Point Theorem Theorem 38.11, is just a special case of the Lefschetz Fixed Point Theorem 97.9.

Theorem 38.11. (Sphere-Degree Fixed Point Theorem) Let $n \in \mathbb{N}$ and let $\varphi\colon S^n \to S^n$ be a map. If $\deg(\varphi) \neq (-1)^{n+1}$, then φ has a fixed point.

Proof. We consider the topological space S^n. By the discussion on page 1997 we know that S^n admits the structure of a finite simplicial complex. Let $\varphi\colon S^n \to S^n$ be a map. We calculate that

$$\Lambda(\varphi, \mathbb{Q}) \overset{\text{by Lemmas 97.8 we have } \Lambda(\varphi,\mathbb{Q}) = \Lambda(\varphi)}{\downarrow} = \underbrace{\operatorname{tr}\left(\mathrm{H}_0(S^n) \xrightarrow{\varphi_*} \mathrm{H}_0(S^n)\right)}_{=1 \text{ by Lemma 97.6 (2)}} + (-1)^n \cdot \underbrace{\operatorname{tr}\left(\mathrm{H}_n(S^n) \xrightarrow{\varphi_*} \mathrm{H}_n(S^n)\right)}_{=\deg(\varphi) \text{ by definition of the degree}} = 1 + (-1)^n \cdot \deg(\varphi).$$

The Lefschetz Fixed Point Theorem 97.9 thus says that if $1 + (-1)^n \cdot \deg(\varphi) \neq 0$, then φ has a fixed point. But that is exactly what we wanted to show. ■

For many applications the following variation on the Lefschetz Fixed Point Theorem 97.9 is particularly useful.

Theorem 97.10. (Lefschetz Fixed Point Theorem II) Let M be a compact smooth manifold and let $\varphi\colon M \to M$ be a map. If there exists a field $\mathbb{F}$ such that the $\mathbb{F}$-Lefschetz number $\Lambda(\varphi, \mathbb{F})$ is non-zero, then φ has a fixed point.

Remark.

(1) Later on in Theorem 104.12 we will prove the Lefschetz Fixed Point Theorem also for finite CW-complexes and compact topological manifolds. In fact not only is the statement of Theorem 104.12 more general than the statement of Theorem 97.10, the proof of Theorem 104.12 will also be self-contained, since we will not make use of the Smooth Manifold-Simplicial Structure Theorem 96.2 for which we provided only a sketch of a proof.
(2) Reading (1) one might be tempted to think that the conclusion of the Lefschetz Fixed Point Theorem holds for every compact space. But in Exercise 97.5 we will see that this is certainly *not* the case.
(3) We will prove a generalization of the Lefschetz Fixed Point Theorem 97.10 in the Lefschetz-Hopf Theorem 128.5.

Proof. Let M be a compact smooth manifold. By the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a finite simplicial structure. Thus we can apply the Lefschetz Fixed Point Theorem 97.9 and we are done. ■

[1198] Solomon Lefschetz (1884-1972) was an American mathematician.

Corollary 97.11. Let M be a compact connected smooth manifold such that $\mathrm{H}_n(M)$ is torsion for all $n \geq 1$. Then every map $\varphi\colon M \to M$ has a fixed point.

Proof. Let M be a compact connected smooth manifold such that $\mathrm{H}_n(M)$ is torsion for all $n \geq 1$. We calculate that

$$\Lambda(\varphi, \mathbb{Q}) \overset{\text{by Lemma 97.8}}{=} \underbrace{\mathrm{tr}(\varphi_*\colon \mathrm{H}_0(M) \to \mathrm{H}_0(M))}_{=1 \text{ by Lemma 97.6 (2)}} + \sum_{n\in\mathbb{N}} (-1)^n \cdot \underbrace{\mathrm{tr}(\varphi_*\colon \mathrm{H}_n(M) \to \mathrm{H}_n(M))}_{=0, \text{ since } \mathrm{H}_n(M) \text{ is torsion}} = 1.$$

It follows from the Lefschetz Fixed Point Theorem 97.10 that φ has a fixed point. ■

Examples.

(1) If we apply Corollary 97.11 to the compact connected smooth manifold $M = \overline{B}^n$, then we recover the Brouwer Fixed Point Theorem 31.4, which we had already proved on page 784 and on page 1618.

(2) In Proposition 80.11 we computed the homology groups of the real projective spaces $\mathbb{R}\mathrm{P}^n$. These calculations show in particular that the hypotheses of Corollary 97.11 are satisfied for *even*-dimensional real projective spaces $\mathbb{R}\mathrm{P}^{2n}$. Thus we see that every self-map $f\colon \mathbb{R}\mathrm{P}^{2n} \to \mathbb{R}\mathrm{P}^{2n}$ has a fixed point. (This gives an alternative solution of Exercise 76.12.) We will consider the case of *odd*-dimensional real projective spaces in Exercise 97.3.

In the next section we will provide a proof of the Lefschetz Fixed Point Theorem 97.9 and afterwards we will consider two more elaborate applications of the Lefschetz Fixed Point Theorem 97.9. There are many other pretty consequences of the Lefschetz Fixed Point Theorem 97.9 which we cannot mention in these modest notes. In fact the book by Brown [**BrownR1971**] is completely dedicated to the proof of the Lefschetz Fixed Point Theorem 97.9 and its numerous applications and generalizations.

97.4. **Proof of the Lefschetz Fixed Point Theorem 97.9.** One of the keys to proving the Lefschetz Fixed Point Theorem 97.9 is the following result in linear algebra which is a not-so-distant relative to Lemma 87.3.

Theorem 97.12. (Hopf Trace Formula)

(1) Let $\mathbb{F}$ be a field. If

$$C_* := 0 \to \mathrm{C}_k \xrightarrow{\partial_k} \mathrm{C}_{k-1} \xrightarrow{\partial_{k-1}} \dots \xrightarrow{\partial_2} \mathrm{C}_1 \xrightarrow{\partial_1} \mathrm{C}_0 \to 0$$

is a chain complex of finite-dimensional $\mathbb{F}$-vector spaces, then given any chain map $\varphi_*\colon C_* \to \mathrm{C}_*$ we have

$$\sum_{i=0}^{k} (-1)^i \cdot \mathrm{tr}(\varphi_i\colon \mathrm{C}_i \to \mathrm{C}_i) = \sum_{i=0}^{k} (-1)^i \cdot \mathrm{tr}(\varphi_*\colon \mathrm{H}_i(C_*) \to \mathrm{H}_i(C_*)).$$

(2) The analogue of (1) also holds if we start out with a chain complex of finitely generated free abelian groups.

The key to proving the Hopf Trace Formula 97.12 is the following lemma.

Lemma 97.13. Let $\mathbb{F}$ be a field. Suppose we are given a commutative diagram of homomorphisms of finite-dimensional $\mathbb{F}$-vector spaces of the following type:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A & \xrightarrow{i} & B & \xrightarrow{p} & C & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\gamma} & & \\ 0 & \longrightarrow & A & \xrightarrow{i} & B & \xrightarrow{p} & C & \longrightarrow & 0. \end{array}$$

If the horizontal sequences are exact, then

$$\operatorname{tr}(\beta\colon B \to B) \;=\; \operatorname{tr}(\alpha\colon A \to A) + \operatorname{tr}(\gamma\colon C \to C).$$

Proof. Let $a_1, \ldots, a_m$ be a basis for A and let $c_1, \ldots, c_n$ be a basis for C. For $i = 1, \ldots, n$ we pick a $\overline{c}_i \in B$ with $p(\overline{c}_i) = c_i$. It follows easily from our hypothesis that the horizontal sequences are exact that $i(a_1), \ldots, i(a_m), \overline{c}_1, \ldots, \overline{c}_n$ form a basis for B. Furthermore it is elementary to show, using the hypothesis that the diagram commutes, that the matrix of β with respect to this basis is of the following form:

$$\begin{pmatrix} \text{matrix that} & * \;\; * \\ \text{represents } \alpha & * \;\; * \\ 0 \;\; 0 & \text{matrix that} \\ 0 \;\; 0 & \text{represents } \gamma \end{pmatrix}$$

where each "$*$" indicates some element in $\mathbb{F}$.

It is now clear that $\operatorname{tr}(\beta) = \operatorname{tr}(\alpha) + \operatorname{tr}(\gamma)$. ∎

Now that Lemma 97.13 is in our toolbox the proof of the Hopf Trace Formula 97.12 is almost embarrassingly similar to the proof of Lemma 87.3.

Proof of Hopf Trace Formula 97.12. First we note that Statement (2) follows almost immediately from Statement (1) applied to $\mathbb{F} = \mathbb{Q}$, together with Lemma 97.5 and the Universal Coefficient Theorem 89.16. We leave it to the reader to fill in the details.

Thus it remains to prove Statement (1). For the given chain complex $(\mathrm{C}_*, \partial_*)$ over some field $\mathbb{F}$ we write for each $n \in \mathbb{N}_0$

$$Z_n := \ker(\partial_n), \quad B_n := \operatorname{im}(\partial_{n+1}) \quad \text{and} \quad H_n = Z_n/B_n.$$

We write $\varphi_{B_n} := \varphi_n|_{B_n}$ and $\varphi_{Z_n} := \varphi_n|_{Z_n}$. For symmetry reasons we also write $\varphi_{\mathrm{C}_n} := \varphi_n$ and $\varphi_{H_n} := \varphi_*\colon H_n \to H_n$. These $\mathbb{F}$-vector spaces and homomorphisms form the following two types of commutative diagrams of short exact sequences

(a)
$$\begin{array}{ccccccccc} 0 & \longrightarrow & Z_n & \longrightarrow & \mathrm{C}_n & \xrightarrow{\partial_n} & B_{n-1} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle\varphi_{Z_n}} & & \downarrow{\scriptstyle\varphi_{\mathrm{C}_n}} & & \downarrow{\scriptstyle\varphi_{B_{n-1}}} & & \\ 0 & \longrightarrow & Z_n & \longrightarrow & \mathrm{C}_n & \xrightarrow{\partial_n} & B_{n-1} & \longrightarrow & 0 \end{array}$$

and

(b)
$$\begin{array}{ccccccccc} 0 & \longrightarrow & B_n & \longrightarrow & Z_n & \longrightarrow & H_n & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle\varphi_{B_n}} & & \downarrow{\scriptstyle\varphi_{Z_n}} & & \downarrow{\scriptstyle\varphi_{H_n}} & & \\ 0 & \longrightarrow & B_n & \longrightarrow & Z_n & \xrightarrow{\partial_n} & H_n & \longrightarrow & 0. \end{array}$$

Now we see that

$$\begin{aligned}
\sum_{n=0}^{k}(-1)^n\cdot\operatorname{tr}(\varphi_{\mathrm{C}_n}) &\overset{\text{by (a) and Lemma 97.13 we know that } \operatorname{tr}(\varphi_{\mathrm{C}_n})=\operatorname{tr}(\varphi_{Z_n})+\operatorname{tr}(\varphi_{B_{n-1}})}{\downarrow} \\
&= \sum_{n=0}^{k}(-1)^n\cdot(\operatorname{tr}(\varphi_{Z_n})+\operatorname{tr}(\varphi_{B_{n-1}})) \\
&= \sum_{n=0}^{k}(-1)^n\cdot(\operatorname{tr}(\varphi_{B_n})+\operatorname{tr}(\varphi_{H_n})+\operatorname{tr}(\varphi_{B_{n-1}})) \\
&\overset{\text{by (b) and Lemma 97.13 we know that } \operatorname{tr}(\varphi_{Z_n})=\operatorname{tr}(\varphi_{B_n})+\operatorname{tr}(\varphi_{H_n})}{\uparrow} \\
&= \sum_{n=0}^{k}(-1)^n\cdot\operatorname{tr}(\varphi_{H_n}) + \sum_{n=0}^{k}(-1)^n\cdot\operatorname{tr}(\varphi_{B_n}) + \sum_{n=0}^{k}(-1)^n\operatorname{tr}(\varphi_{B_{n-1}}) \\
&= \sum_{n=0}^{k}(-1)^n\cdot\operatorname{tr}(\varphi_{H_n}) + \sum_{n=0}^{k-1}(-1)^n\cdot\operatorname{tr}(\varphi_{B_n}) - \sum_{m=0}^{k-1}(-1)^m\cdot\operatorname{tr}(\varphi_{B_m}) \\
&\overset{\text{we do the substitution } m=n-1 \text{ and we use that } B_k=0 \text{ and } B_{-1}=0}{\uparrow} \\
&= \sum_{n=0}^{k}(-1)^n\cdot\operatorname{tr}(\varphi_{H_n}).
\end{aligned}$$

■

Now we are fully prepared for tackling the proof of the Lefschetz Fixed Point Theorem 97.

Proof of the Lefschetz Fixed Point Theorem 97.9. Let X be a finite simplicial complex and let $\varphi\colon X\to X$ be a map *without* a fixed point. Furthermore let $\mathbb{F}$ be a field. We need to show that

$$\Lambda(\varphi,\mathbb{F}) \;:=\; \sum_{n\in\mathbb{N}_0}(-1)^n\cdot\operatorname{tr}(\varphi_*\colon \mathrm{H}_n(X;\mathbb{F})\to\mathrm{H}_n(X;\mathbb{F})) \;=\; 0.$$

The basic idea for the proof is quite simple:

> We need to upgrade the fact that $\varphi(x)\neq x$ for every $x\in X$ to the statement that for a suitable chain complex C_* that calculates $\mathrm{H}_*(X)$ we also have $\varphi(\sigma)\neq\sigma$ for every element σ of a suitable basis. This implies that the trace on the chain group level is zero, hence we get the desired statement from the Hopf Trace Formula 97.12 (1).

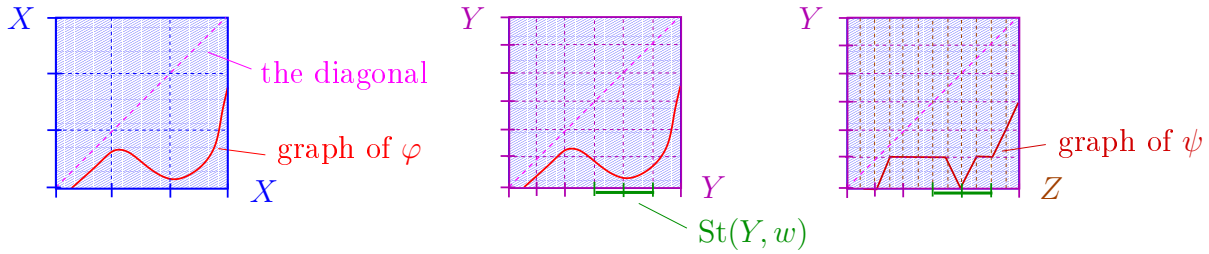
For better or worse turning the idea into a proper proof requires a substantial effort. First of all we note that since X is a finite simplicial complex we can use Lemma 93.9 to view X as a subspace of some $\mathbb{R}^n$. In particular we can and will equip X with the usual Euclidean metric $d(x,y):=\|x-y\|_{\mathbb{R}^n}$.

Claim 1. There exists an iterated barycentric subdivision Y of X such that for every vertex w of Y we have $\varphi(\mathrm{St}(Y,w))\cap\mathrm{St}(Y,w)=\varnothing$.

Proof. The claim is proved in several easy steps:

(1) Since X is a finite simplicial complex we know by Lemma 93.9 that X is compact.
(2) From the compactness of X together with our hypothesis that for every $x\in X$ we have $\varphi(x)\neq x$ we obtain through some elementary arguments, as provided in Exercise 6.3, that there exists an $\epsilon>0$ such that for every $x\in X$ we have $d(\varphi(x),x)\geq\epsilon$
(3) By Lemma 94.7 there exists a $j\in\mathbb{N}_0$ such that for every vertex v of the iterated barycentric subdivision $\mathrm{sd}^j(X)$ we have $\operatorname{diam}(\mathrm{St}(\mathrm{sd}^j(X),v))<\frac{\epsilon}{2}$.
(4) It follows from (2) and (3) that $\varphi(\mathrm{St}(\mathrm{sd}^j(X),w))\cap\mathrm{St}(\mathrm{sd}^j(X),w)=\varnothing$. Indeed, let $x,y\in\mathrm{St}(\mathrm{sd}^j(X),w)$. We calculate that

$$d(\varphi(x),y) \underset{\text{triangle inequality}}{\overset{\uparrow}{\geq}} d(\varphi(x),x)-d(x,y) \underset{\text{by (2) and (3)}}{\overset{\uparrow}{\geq}} \epsilon-\tfrac{\epsilon}{2} \geq \tfrac{\epsilon}{2} > 0.$$



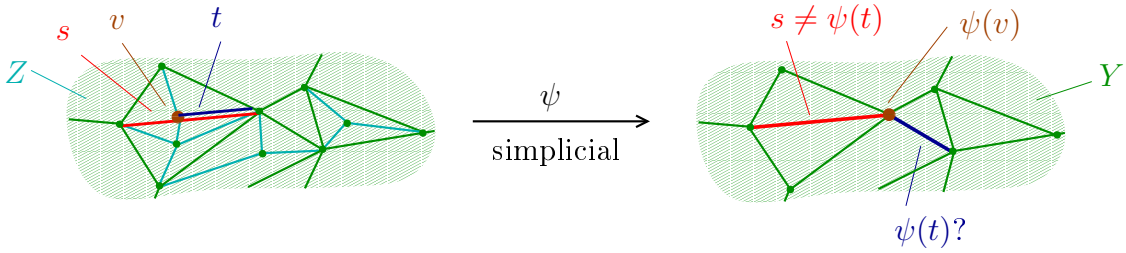
This implies that $\varphi(\mathrm{St}(\mathrm{sd}^j(X), w)) \cap \mathrm{St}(\mathrm{sd}^j(X), w) = \varnothing$.

Thus the iterated barycentric subdivision $Y := \mathrm{sd}^j(K)$ has the desired property. ⊞

Next we apply the Simplicial Approximation Theorem 94.8 to the map $\varphi\colon Y \to Y$. We obtain an $i \in \mathbb{N}_{\geq 0}$ and a simplicial map $\psi\colon Z := \mathrm{sd}^i(Y) \to Y$ with the following properties:

(A) The map ψ is homotopic to φ as a map $Y \to Y$.
(B) For every vertex w of $Z = \mathrm{sd}^i(Y)$ we have $\varphi(\mathrm{St}(\underbrace{\mathrm{sd}^i(Y)}_{=Z}, w)) \subset \mathrm{St}(Y, \psi(w))$.

It follows from (A) and Lemma 97.7 that the Lefschetz numbers of φ and ψ agree.



The map $\psi\colon Z \to Y$ is a simplicial map between two different simplicial complexes. The following claim gets as close as possible to saying that ψ does not fix a simplex.

Claim 2. For every simplex s of Y and every simplex t of Z with $t \subset s$ we have $\psi(t) \neq s$.

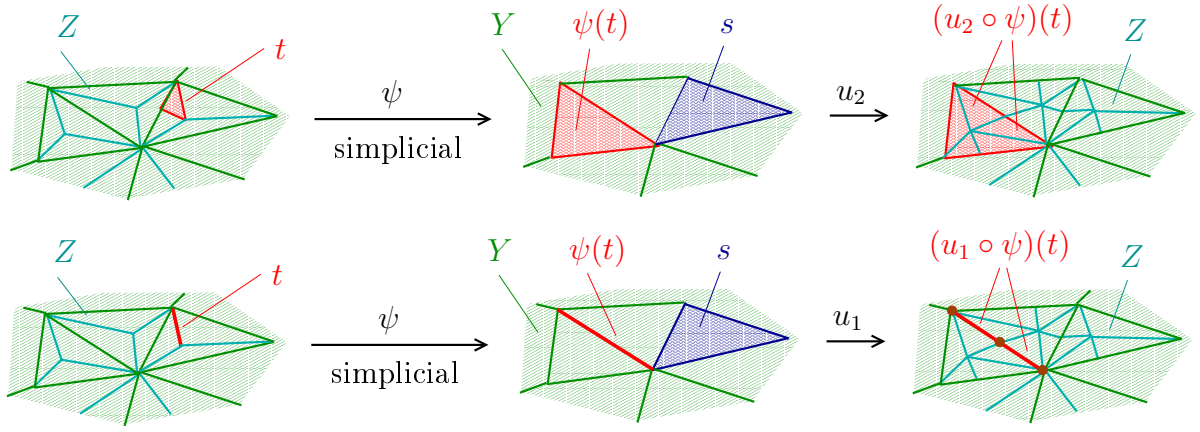
Proof. Let s be a simplex of Y and let t be a simplex of Z with $t \subset s$. Let v be a vertex of t. (It might be helpful to consider the figure below.) We make the following deductions:

v a vertex of the simplex t of Z
$\implies t \subset \mathrm{St}(Z, v) \implies \varphi(t) \subset \varphi(\mathrm{St}(Z, v)) \implies \varphi(t) \subset \mathrm{St}(Y, \psi(v))$
by the definition of $\mathrm{St}(Z, v)$, see page 2018 — by (B)
$\implies \varphi(t) \cap \varphi(\mathrm{St}(Y, \psi(v))) = \varnothing \implies t \cap \mathrm{St}(Y, \psi(v)) = \varnothing$
by Claim 1 — Image-Preimage Lemma 0.2 (4)
$\implies t \cap \mathrm{St}(Y, \psi(t)) = \varnothing \implies \psi(t) \neq s.$
since $\psi(v)$ is a vertex of $\psi(t)$ we have $\mathrm{St}(Y, \psi(t)) \subset \mathrm{St}(Y, \psi(v))$ — we have $t \subset \mathrm{St}(Y, s)$, indeed this follows from $t \subset s$ and from $s \subset \mathrm{St}(Y, s)$, which in turn holds by definition of $\mathrm{St}(Y, s)$

⊞

Next, given $n \in \mathbb{N}_0$ let

$$u_n\colon \mathrm{C}_n^{\mathrm{simp}}(Y) \to \mathrm{C}_n^{\mathrm{simp}}(\underbrace{\mathrm{sd}^i(Y)}_{=Z})$$



be the i-fold iterated simplicial subdivision map that we introduced in the Chain Subdivision Lemma 95.41.

Claim 3. For each $n \in \mathbb{N}_0$ the map $u_n \circ \psi_* \colon \mathrm{C}_n^{\mathrm{simp}}(Z) \to \mathrm{C}_n^{\mathrm{simp}}(Z)$ has trace zero.

Proof. Let T_n be the set of n-simplices of Z. It follows from Lemma 95.5 that T_n, with some choice of ordering for each $t \in T_n$, is a basis of $\mathrm{C}_n^{\mathrm{simp}}(Z)$. Now let $t \in T_n$. If $\psi(t)$ is not an n-simplex of Y, then by definition we have $\psi_*(t) = 0$. Now suppose that $\psi(t)$ is an n-simplex of Y. Then we see that

$$\begin{aligned}
(u_n \circ \psi_*)(t) &\overset{\text{by definition of the simplicial subdivision map}}{=} \text{linear combination of } n\text{-simplices of } Z \text{ contained in } \psi(t) \\
&= \text{linear combination of } n\text{-simplices of } Z \text{ not equal to } t. \\
&\quad \text{here we need to distinguish two cases:}[1199] \\
&\quad (1)\ \text{If } t \text{ is contained in some } n\text{-simplex } s \text{ of } Y, \text{ then the conclusion follows from Claim 2.} \\
&\quad (2)\ \text{If } t \text{ is not contained in any } n\text{-simplex of } Y, \text{ then it is in particular} \\
&\qquad \text{not contained in the } n\text{-simplex } \psi(t) \text{ of } Y \\
&= \text{linear combination of elements in } T_n \setminus \{t\}.
\end{aligned}$$

This calculation shows that, with respect to the basis T_n, each diagonal entry of the map $u_n \circ \psi_*$ is zero. In particular the trace of the map $u_n \circ \psi_* \colon \mathrm{C}_n^{\mathrm{simp}}(Z) \to \mathrm{C}_n^{\mathrm{simp}}(Z)$ is zero. ⊞

In the following we will use simplicial homology with $\mathbb{F}$-coefficients. The definition should be clear to the reader and it should be clear that some of the statements which we cite below, which were formulated for homology without coefficients, also have obvious generalizations to homology with $\mathbb{F}$-coefficients.

Claim 4. The following diagram commutes:

$$\begin{array}{ccccc}
\mathrm{H}_n^{\mathrm{simp}}(Z;\mathbb{F}) & \xrightarrow{\psi_*} & \mathrm{H}_n^{\mathrm{simp}}(Y;\mathbb{F}) & \xrightarrow{u_n} & \mathrm{H}_n^{\mathrm{simp}}(Z;\mathbb{F}) \\
\downarrow & & \downarrow & & \downarrow \\
\mathrm{H}_n(Z;\mathbb{F}) & \xrightarrow{\psi_*} & \mathrm{H}_n(Z;\mathbb{F}) & \xrightarrow{u_n} & \mathrm{H}_n(Z;\mathbb{F})
\end{array}$$

here the vertical maps are the natural isomorphism defined on page 2058.

Proof. It turns out that there is not much to say. The rectangle to the left commutes by the naturality of the vertical maps and the rectangle to the right commutes by Proposition 95.45. ⊞

[1199] The two cases are illustrated in the figure below.

Now we can quickly conclude the proof of the Lefschetz Fixed Point Theorem 97.9. Indeed, we see that

$$\begin{array}{lll}
\Lambda(\varphi,\mathbb{F}) \overset{\text{Lemma 97.7}}{=} \Lambda(\psi,\mathbb{F}) = \sum_{i\in\mathbb{N}_0}(-1)^i\cdot\operatorname{tr}(\psi_*\circlearrowleft \mathrm{H}_i(Z;\mathbb{F})) & \overset{\text{by Lemma 74.27 the singular subdivision maps } u_* \text{ are chain homotopic to the identity, thus the induced map on homology is the identity}}{=} & \sum_{i\in\mathbb{N}_0}(-1)^i\cdot\operatorname{tr}(u_*\circ\psi_*\circlearrowleft \mathrm{H}_i(Z;\mathbb{F})) \\
= \sum_{i\in\mathbb{N}_0}(-1)^i\cdot\operatorname{tr}(u_*\circ\psi_*\circlearrowleft \mathrm{H}_i^{\mathrm{simp}}(Z;\mathbb{F})) & & = \sum_{i\in\mathbb{N}_0}(-1)^i\cdot\operatorname{tr}(u_*\circ\psi_*\circlearrowleft \mathrm{C}_i^{\mathrm{simp}}(Z;\mathbb{F})) \\
\uparrow \text{ by Claim 4} & & \uparrow \text{ by the Hopf Trace Formula 97.12 (1)} \\
= \sum_{i\in\mathbb{N}_0}(-1)^i\cdot\operatorname{tr}(u_*\circ\psi_*\circlearrowleft \mathrm{C}_i^{\mathrm{simp}}(Z)) & & = 0. \\
\uparrow \text{ by Lemma 97.3 and since by definition } \mathrm{C}_i^{\mathrm{simp}}(Z;\mathbb{F}) = \mathrm{C}_i^{\mathrm{simp}}(Z)\otimes\mathbb{F} & & \uparrow \text{ by Claim 3}
\end{array}$$

We have thus proved that if φ has no fixed points, then $\Lambda(\varphi,\mathbb{F}) = 0$. ∎

97.5. **Vector fields on smooth manifolds.** In this section we will apply the Lefschetz Fixed Point Theorem 97.9 to the study of the (non-)existence of certain vector fields on smooth manifolds.

For the reader's convenience we recall the following definition from page 639.

Definition. Let M be an n-dimensional smooth manifold.

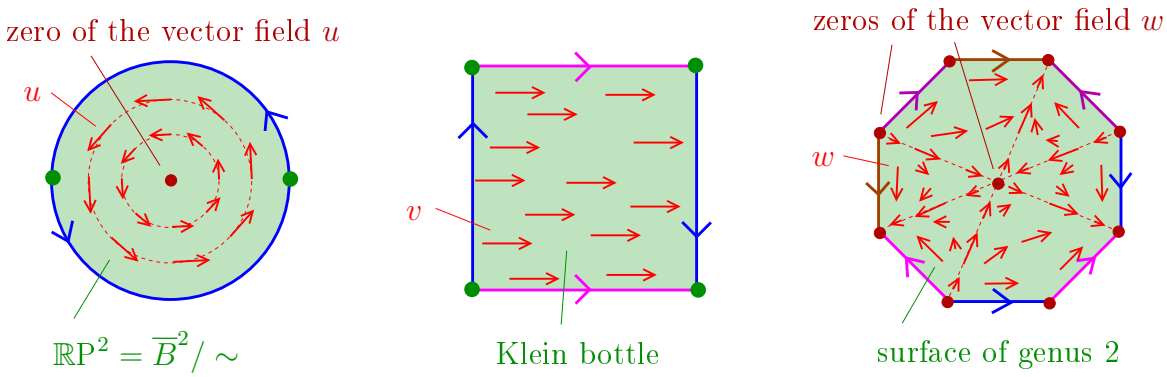
(1) A vector field on M is a map v which assigns to each $P \in M$ a vector $v(P) \in \mathrm{T}_P M$ such that the following condition is satisfied: For every chart[1200] $\Phi\colon U \to V$ from an open set U of M to an open set V of $\mathbb{R}^n$ the map

$$\begin{array}{ccccc}
V & \to & \mathbb{R}^n & & \\
P & \mapsto & \mathrm{D}\Phi_{\Phi^{-1}(P)}\big(\underbrace{v(\Phi^{-1}(P))}_{\in \mathrm{T}_{\Phi^{-1}(P)}M}\big) & \subset & \mathrm{T}_P V \underset{\uparrow}{=} \mathbb{R}^n \\
 & & & & \text{identification from Proposition 23.9}
\end{array}$$

is continuous. We say that the vector field v is smooth if for every chart the above map is smooth.

(2) Given a vector field v on M we say that $x \in M$ is a zero of v if $v(x) = 0$.

One of the goals of this section is to address the following time-honored question.



Question 23.19 Which closed connected 2-dimensional smooth manifolds admit a nowhere-vanishing vector field?

Example. In the figure below we show vector fields on the projective plane $\mathbb{R}\mathrm{P}^2$, on the Klein bottle and the surface of genus 2. The vector field on the Klein bottle is nowhere-vanishing, whereas the vector field on $\mathbb{R}\mathrm{P}^2$ and the surface of genus 2 both have zeros.

The attentive reader will not have failed to notice that it is the right moment to recall one of the highlights from one of the earlier chapters:

Theorem 38.12. (Hairy Ball Theorem) Every vector field on an even-dimensional sphere vanishes on at least one point.

[1200] Recall that for a smooth manifold we mean by a "chart" a chart from the given smooth structure.

Sketch of proof. Let v be a nowhere-vanishing vector field on a sphere S^n. By "traveling along the great circle defined by v" we can find a homotopy $F\colon S^n \times [0,1] \to S^n$ from the identity to the antipodal map $\rho\colon S^n \to S^n$ given by $\rho(x) = -x$. In particular we see that $(-1)^{n+1} = \deg(\rho) = \deg(\mathrm{id}) = 1$. Thus we see that n is odd. ■

Remark. Regarding Question 23.19 the Hairy Ball Theorem 38.12 says in particular that S^2 does not admit a nowhere-vanishing vector field.

To address Question 23.19 it is also helpful to add a few ways to construct new vector fields to our toolbox.

Lemma 97.14.

(1) Let $f\colon M \to N$ be a map between smooth manifolds which is a local diffeomorphism. Let v be a vector field on N. The map

$$P \mapsto (\mathrm{D}f_P)^{-1}\big(\underbrace{v(f(P))}_{\in \mathrm{T}_{f(P)}(N)}\big)$$

is a vector field on M that we denote by f^*v. A point $P \in M$ is a zero of f^*v if and only if $f(P)$ is a zero of v.

(2) Let M be a smooth manifold and let v be a vector field on M. Suppose $p\colon \widetilde{M} \to M$ is a covering. Then p^*v is a vector field on $\widetilde{M}$.

(3) Let M be a smooth manifold and let v be a vector field on M. Suppose we are given a group G that acts freely, properly and smoothly on M such that for every $g \in G$ we have $(g\cdot\colon M \to M)^*(v) = v$. Then there exists a unique vector field u on M/G such that $v = p^*u$ where $p\colon M \to M/G$ is the projection .[1201]

Proof.

(1) The mature reader will have no troubles with providing a proof for this statement.
(2) This statement follows from (1) and the Manifold Covering Proposition 49.2 (2a).
(3) The proof of this statement is very similar to the proof of (1) and it is also left to the reader. ■

Lemma 97.14 allows us to answer Question 23.19 in some special cases:

[1201] Recall that by the Manifold Quotient-by-Group Action Proposition 19.32 we know that M/G is a smooth manifold and that the projection $p\colon M \to M/G$ is a local diffeomorphism.

Examples.

(1) If v is a vector field on $\mathbb{R}\mathrm{P}^2$ with n zeros, then it follows from Lemma 97.14, applied to the 2-fold covering $p\colon S^2 \to \mathbb{R}\mathrm{P}^2 = S^2/x \sim -x$ that S^2 admits a vector field with $2n$ zeros. By the Hairy Ball Theorem 38.12 we know that $2n > 0$. In other words, we have just shown that every vector field on $\mathbb{R}\mathrm{P}^2$ has at least one zero.

(2) On the smooth manifold $\mathbb{R}^2$ we now consider the constant "horizontal" vector field $v(x,y) = (1,0) \in T_{(x,y)}\mathbb{R}^2 = \mathbb{R}^2$. As discussed in Lemma 5.25 and on page 1075 we can view the torus and the Klein bottle as quotients of $\mathbb{R}^2$ by a group G that acts freely, properly and smoothly. Furthermore, in both cases one can easily verify that the given G-action preserves the vector field v. This shows that the nowhere-vanishing vector field v descends to a nowhere-vanishing vector field on the torus and the Klein bottle. For the Klein bottle we obtain precisely the vector field shown in the figure on page 2124.

The following theorem is the main result of this section.

Theorem 97.15. (Euler Characteristic-Vector Field Theorem) Let M be a closed smooth manifold. If M admits a nowhere-vanishing vector field, then $\chi(M) = 0$.

Remark.

(1) On page 1879 we saw that for even n the Euler characteristic $\chi(S^n)$ equals 2. Thus we see that the Euler Characteristic-Vector Field Theorem 97.15 is a generalization of the Hairy Ball Theorem 38.12.

(2) In Smooth Euler Characteristic-Vector Field Theorem 45.22 we proved the same statement for closed orientable smooth manifolds.

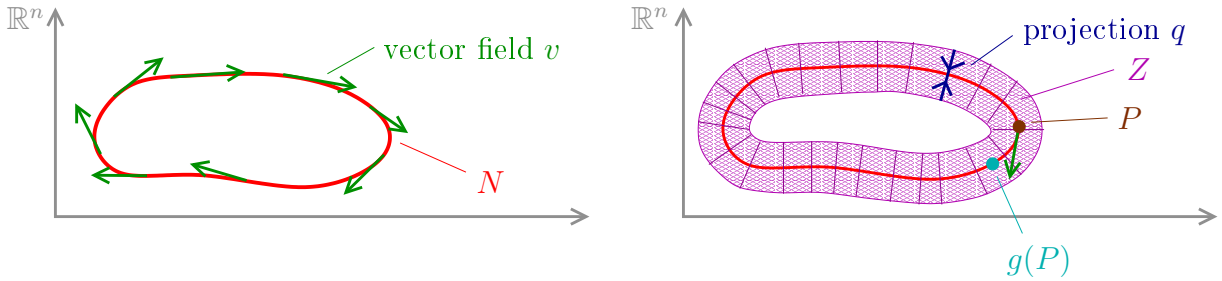
(3) For 2-dimensional smooth manifolds a low-tech proof of the Euler Characteristic-Vector Field Theorem 97.15 involving "negative, neutral and positive charges" is given in [**Thu1997**, Proposition 1.3.3].

(4) Let M be a closed connected 2-dimensional smooth manifold that is not diffeomorphic to the torus or the Klein bottle. It follows from the calculations on pages 1879 and 1885 that $\chi(M) \neq 0$. Thus we obtain from the Euler Characteristic-Vector Field Theorem 97.15 that M does not admit a nowhere-vanishing vector field. Together with the above discussion we now have a complete answer to Question 23.19.

(5) In the Nowhere Vanishing Vector Field Existence Theorem 129.6 we will see that the converse to the Euler Characteristic-Vector Field Theorem 97.15 holds. Namely we will see that if M is a closed connected smooth manifold with $\chi(M)$, then M admits a nowhere-vanishing vector field.

(6) In Corollary 129.8 we will prove a suitable extension of the Euler Characteristic-Vector Field Theorem 97.15 to the setting of smooth manifolds with non-empty boundary.

The key idea behind the proof of the Euler Characteristic-Vector Field Theorem 97.15 is similar to the proof of the Hairy Ball Theorem 38.12, namely we want to use the nowhere-vanishing vector field v on M to construct an interesting self-map of M. This is done in the following proposition.



Proposition 97.16. Let M be a closed smooth manifold. If there exists a nowhere-vanishing vector field, then there exists a map $g\colon M \to M$ that is homotopic to the identity and which has no fixed points.

Proof. The proposition follows immediately from the combination of the Replace-by-Smooth Vector Field Proposition 29.6, the Flow Theorem 35.1 and the Flow Fixed Point Theorem 35.4.

Recall that our proof of the Flow Theorem 35.1 was built on the Fundamental Theorem 35.7 for Autonomous ODEs which we did not prove. Therefore, for the reader's peace of mind we will sketch in the following a self-contained proof of the proposition. By the Euclidean Embedding Theorem 27.1 (1) together with the Smooth Embedding Theorem 24.10 we can and will view M as a submanifold of some $\mathbb{R}^n$. It follows from Theorem **??** that there exists an $\epsilon > 0$ such that the following two conditions are satisfied:

(a) The subset $Z := \{P + w \,|\, P \in M \text{ and } w \in (\widetilde{\mathrm{T}}_P M)^\perp \text{ with } \|w\| \leq \epsilon\}$ of $\mathbb{R}^n$ is a neighborhood of M.

(b) The map
$$\begin{array}{rcl} q\colon Z & \to & M \\ P + w & \mapsto & P \end{array} \quad \text{where } P \in M \text{ and } w \in (\widetilde{\mathrm{T}}_P M)^\perp \text{ with } \|w\| \leq \epsilon$$
is well-defined and continuous.

Next we consider the map
$$\begin{array}{rcl} F\colon M \times \mathbb{R}_{\geq 0} & \to & \mathbb{R}^n \\ (P, t) & \mapsto & P + t \cdot v(P). \end{array}$$

We make the following observations:

(1) As in the Convex Homotopy Lemma 14.1 we see that F is, unsurprisingly, continuous.

(2) It follows from (a), together with the fact that M is in particular compact and together with some elementary point-set theoretic arguments along the lines of Exercise 5.9, that there exists a $\mu > 0$ such that $F(M \times [0, \mu]) \subset Z$.

(3) We set $g := q \circ F_\mu\colon M \to M$.

(4) By (1) we know that $q \circ F\colon M \times [0, \mu] \to M$ defines a homotopy between the identity and g.

(5) It remains to show that g has no fixed points. Thus let $P \in M$. By (b) we can write $F_\mu(P) = P + \mu \cdot v(P) =: Q + w$ with $Q \in M$ and $w \in (\widetilde{\mathrm{T}}_Q M)^\perp$ with $\|w\| \leq \epsilon$. Since $\widetilde{\mathrm{T}}_P M \cap \widetilde{\mathrm{T}}_P M^\perp = \{0\}$ and since $v(P)$ is a non-zero vector in $\widetilde{\mathrm{T}}_P M$ we see that $P \neq Q$. By definition we have $g(P) = Q$. Thus we have shown that $g(P) \neq P$.

This concludes the second proof of the proposition. ∎

Now it is straightforward to provide the proof of the Euler Characteristic-Vector Field Theorem 97.15.

Proof of the Euler Characteristic-Vector Field Theorem 97.15. Let M be a closed smooth manifold. Suppose there exists a nowhere-vanishing vector field v on M. By Proposition 97.16 there exists a map $g\colon M \to M$ that is homotopic to the identity and which has no fixed points. Now we calculate that

$$\chi(M) \overset{\text{Lemma 97.6 (1)}}{\overset{\downarrow}{=}} \Lambda(\mathrm{id}\colon M \to M) \overset{\text{by Lemma 97.7 since } f \text{ and id are homotopic}}{\overset{\uparrow}{=}} \Lambda(f\colon M \to M) \overset{\text{Lemma 97.8 (2)}}{\overset{\uparrow}{=}} \Lambda(f\colon M \to M, \mathbb{Q}) \overset{\text{by the claim and the Lefschetz Fixed Point Theorem II 97.10}}{\overset{\downarrow}{=}} 0.$$

■

As a teaser we state the following theorem which we will prove later on. This proposition is basically the converse to the Euler Characteristic-Vector Field Theorem 97.15.

Theorem 129.6.(Nowhere Vanishing Vector Field Existence Theorem) Let M be a closed connected smooth manifold. If $\chi(M) = 0$, then M admits a nowhere-vanishing smooth vector field.

In Chapter 129 we will not only provide a proof of the Nowhere Vanishing Vector Field Existence Theorem 129.6 but we will also formulate and prove a significant generalization of the Euler Characteristic-Vector Field Theorem 97.15, namely the Poincaré-Hopf Theorem 129.7 which, given a vector field, relates the type of zeros which occur to the Euler characteristic of the smooth manifold.

97.6. **The Borsuk-Ulam Theorem II ❀.** In this section we will see how to use the Lefschetz Fixed Point Theorem 97.9 to give an alternative proof of the Borsuk-Ulam Theorem 39.8. First we remind the reader of the statement of the Borsuk-Ulam Theorem 39.8.

Theorem 39.8. (Borsuk-Ulam Theorem) Let $n \in \mathbb{N}_0$. For every map $g\colon S^n \to \mathbb{R}^n$ there exists a pair of antipodal points x and $-x$ on S^n with $g(x) = g(-x)$.

Remark. Let us remind the reader that the Borsuk-Ulam Theorem 39.8 has many beautiful applications, in particular the Lusternik-Schnirelmann Theorem 40.1, the Ham-Sandwich Theorem 40.2, Pfister's Level Theorem 40.9 and the Necklace Theorem 40.11.

The key to our second proof of the Borsuk-Ulam Theorem 39.8 is the following proposition.

Proposition 97.17. Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a map. If $f(-x) = -f(x)$ for all $x \in S^n$, then the Lefschetz number $\Lambda(f)$ is even.

Examples.

(1) Let $A \in \mathrm{O}(n+1)$. We consider the map $f\colon S^n \to S^n$ that is given by $f(x) := A \cdot x$. Evidently we have $f(-x) = -f(x)$ for all $x \in S^n$. Furthermore it follows from the Sphere Degree Lemma 76.11 (6) together with Lemma 97.6 (2) that $\Lambda(f) = 1 + (-1)^n \cdot \det(A)$.

(2) In Exercise 97.13 we will see that given any $n \in \mathbb{N}$ and given any *even* $m \in \mathbb{Z}$ there exists a map $f\colon S^n \to S^n$ with $\Lambda(f) = m$ and such that $f(-x) = -f(x)$ for all $x \in S^n$.

Remark. The proof of Proposition 97.17 is an expanded write-up of the arguments in [**Deo2018**, Theorem 4.9.17] and [**Arm1983**, Chapter 9.3].

The following gives us a criterion for showing that a trace is even.

Lemma 97.18. Let V be a finitely generated free $\mathbb{Z}$-module and let $\rho\colon V \to V$ be an isomorphism with the following two properties:

(i) There exists a subset T of V such that $T \cap \rho(T) = \varnothing$ and such that $T \cup \rho(T)$ is a basis for V.

(ii) We have $\rho \circ \rho = \mathrm{id}_V$.

Let $\varphi\colon V \to V$ be a homomorphism. If φ commutes with ρ, then $\mathrm{tr}(\varphi\colon V \to V)$ is even.

Proof. We equip V with the basis $T \sqcup \rho(T)$. It follows immediately from (ii) that

$$\text{matrix representing } \rho \text{ with respect to the basis } T \sqcup \rho(T) \;=\; \begin{matrix} \\ T \\ \rho(T) \end{matrix} \begin{matrix} \begin{matrix} T & \rho(T) \end{matrix} \\ \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix} \end{matrix}.$$

Now let $\varphi\colon V \to V$ be a homomorphism that commutes with ρ. We write

$$\text{matrix representing } \varphi \text{ with respect to the basis } T \sqcup \rho(T) \;=:\; \begin{matrix} \\ T \\ \rho(T) \end{matrix} \begin{matrix} \begin{matrix} T & \rho(T) \end{matrix} \\ \begin{pmatrix} A & B \\ C & D \end{pmatrix} \end{matrix}.$$

Since φ commutes with g we see that

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} \cdot \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix} = \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix} \cdot \begin{pmatrix} A & B \\ C & D \end{pmatrix}.$$

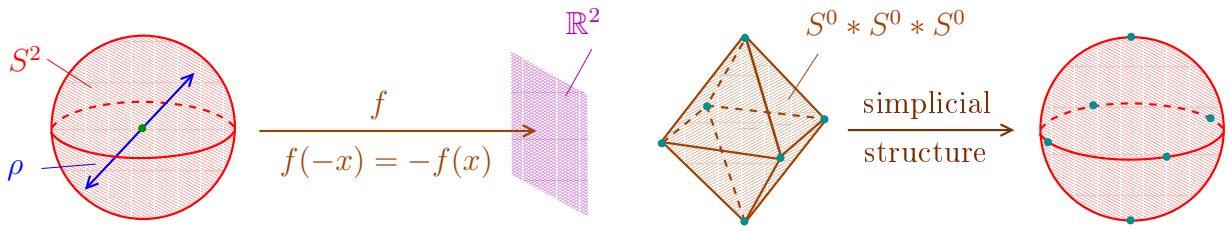
Multiplying out both sides we see in particular that $A = D$. But this implies evidently that the trace of the above matrix representing φ is even. Thus we have shown that $\mathrm{tr}(\varphi)$ is even. ∎

Proof of Proposition 97.17. Let $f\colon S^n \to S^n$ be a map which has the property that $f(-x) = -f(x)$ for all $x \in S^n$. We denote by $\rho\colon S^n \to S^n$ the map that is given by $\rho(x) = -x$. Note that our hypothesis on f is equivalent to the statement that f commutes with ρ. We need to show that $\Lambda(f)$ is even. Similar to the proof of the Lefschetz Fixed Point Theorem 97.9 on page 2120 we intend to proceed as follows:

> We want to upgrade the hypothesis that $f \circ \rho = \rho \circ f$ to a statement about an induced map on a suitable simplicial chain complex C_* such that we can conclude from Lemma 97.18 and the Hopf Trace Formula 97.12 (2) that $\Lambda(f)$ is even.

To carry out this program we do the following: We equip S^n with the simplicial structure given by the homeomorphisms

$$\begin{array}{ccccc} & & & & \text{here } S_0 \text{ is the abstract simplicial complex with vertex set } \{0,1\} \\ & & & & \downarrow \\ S^n & \xleftarrow[\uparrow]{\cong} & S^0 * \cdots * S^0 & = & |S_0| * \cdots * |S_0| \quad \xrightarrow[\uparrow]{\cong} \quad |S_0 * \cdots * S_0|. \\ & & \text{homeomorphism given by the Join-Simplex Lemma 93.19 (1)} & & \text{homeomorphism given by the Join Lemma 93.20} \end{array}$$



We introduce the following notation:

(1) We write $K := S_0 * \cdots * S_0$ and we denote by $\Psi\colon |K| \to S^n$ the above homeomorphism.

(2) Given any $k \in \mathbb{N}_0$ we denote by $\mathfrak{V}\colon |\mathrm{sd}^k(K)| \to |K|$ the natural homeomorphism given by the SD-Lemma 94.3 (3).

(3) By a slight abuse of notation we denote by $\rho\colon K \to K$ the map that is induced by the reflection on the simplices of all the copies of S_0.

(4) Note that by the SD-Lemma 94.3 (5) the simplicial map $\rho\colon K \to K$ induces a simplicial map $\mathrm{sd}^k(K) \to \mathrm{sd}^k(K)$ which we also denote by ρ.

Claim 1. There exists a $k \in \mathbb{N}_0$ and a *simplicial* map $\varphi\colon \mathrm{sd}^k(K) \to K$ with the following properties:

(1) the map $\Psi \circ |\varphi| \circ \mathfrak{V}^{-1} \circ \Psi^{-1}\colon S^n \to S^n$ is homotopic to f,
(2) the map φ commutes with the maps ρ, more precisely, the following diagram commutes

$$\begin{array}{ccc} \mathrm{sd}^k(K) & \xrightarrow{\varphi} & K \\ {\scriptstyle\rho}\downarrow & & \downarrow{\scriptstyle\rho} \\ \mathrm{sd}^k(K) & \xrightarrow{\varphi} & K. \end{array}$$

Proof. As we will see, the proof of Claim 1 follows from a careful reading of the proof of the Simplicial Approximation Theorem 94.8.

(a) First note that Claim 1 of the proof of the Simplicial Approximation Theorem 94.8 shows that there exists a $k \in \mathbb{N}_0$ such that for every vertex v of $\mathrm{sd}^k(K)$ there exists a vertex w of K with $f((\Psi \circ \mathfrak{V})(\mathrm{St}(|\mathrm{sd}^k(K)|, v))) \subset \Psi(\mathring{\mathrm{St}}(|K|, w))$. We denote by V the vertex set of $\mathrm{sd}^k(K)$ and we denote by W the vertex set of K. By the above there exists a map $\varphi\colon V \to W$ with the following property:
($*$) For every vertex $v \in V$ we have $f((\Psi \circ \mathfrak{V})(\mathrm{St}(|\mathrm{sd}^k(K)|, v))) \subset \Psi(\mathring{\mathrm{St}}(|K|, \varphi(v)))$.
(b) In the proof of the Simplicial Approximation Theorem 94.8 we have shown that every map $\varphi\colon V \to W$ that satisfies ($*$) is a simplicial map and that it has the property that $\Psi \circ |\varphi| \circ \mathfrak{V}^{-1} \circ \Psi^{-1}$ is homotopic to f.
(c) It follows immediately from the definition of Ψ and the naturality of $\mathfrak{V}$ that the following two diagrams commute:

$$\begin{array}{ccc} |K| & \xrightarrow{\rho} & |K| \\ {\scriptstyle\Psi}\downarrow & & \downarrow{\scriptstyle\Psi} \\ S^n & \xrightarrow{\rho} & S^n \end{array} \qquad \text{and} \qquad \begin{array}{ccc} |\mathrm{sd}^k(K)| & \xrightarrow{\rho} & |\mathrm{sd}^k(K)| \\ {\scriptstyle\mathfrak{v}}\downarrow & & \downarrow{\scriptstyle\mathfrak{v}} \\ |K| & \xrightarrow{\rho} & |K|. \end{array}$$

(d) Since all maps called ρ satisfy the condition that $\rho \circ \rho = \mathrm{id}$ we obtain easily from (a) and (c) that we can pick a map $\varphi\colon V \to W$ which satisfies ($*$) and such that $\varphi \circ \rho = \rho \circ \varphi$.
(e) By (b) we know that φ satisfies (1). Furthermore, by (d) we know that the simplicial map φ also satisfies (2). ⊞

Before we move on to the next claim we introduce and recall some notation:

(1) Now we write $g := \Psi \circ |\varphi| \circ \mathfrak{V}^{-1} \circ \Psi^{-1}$.

(2) We denote by $u_*\colon \mathrm{C}_*^{\mathrm{simp}}(K) \to \mathrm{C}_*^{\mathrm{simp}}(\mathrm{sd}^k(K))$ the k-fold iterated simplicial subdivision map that we introduced in the Chain Subdivision Lemma 95.41.

Claim 2. For every $j \in \mathbb{N}_0$ there exists an isomorphism $\mu\colon \mathrm{H}_j^{\mathrm{simp}}(\mathrm{sd}^k(K)) \to \mathrm{H}_j(S^n)$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_j^{\mathrm{simp}}(\mathrm{sd}^k(K)) & \xrightarrow{u_j \circ \varphi_*} & \mathrm{H}_j^{\mathrm{simp}}(\mathrm{sd}^k(K)) \\ \mu \downarrow \cong & & \cong \downarrow \mu \\ \mathrm{H}_j(S^n) & \xrightarrow[(\Psi \circ |\varphi| \circ \mho^{-1} \circ \Psi^{-1})_*]{g_*} & \mathrm{H}_j(S^n). \end{array}$$

Proof. We consider the following much more elaborate diagram:

$$\begin{array}{ccccc} \mathrm{H}_j^{\mathrm{simp}}(\mathrm{sd}^k(K)) & \xrightarrow{\varphi_*} & \mathrm{H}_j^{\mathrm{simp}}(K) & \xrightarrow{u_j} & \mathrm{H}_j^{\mathrm{simp}}(\mathrm{sd}^k(K)) \\ \downarrow{\scriptstyle \Theta_{\mathrm{sd}^k(K)}} & & \downarrow{\scriptstyle \Theta_K} & & \downarrow{\scriptstyle \Theta_{\mathrm{sd}^k(K)}} \\ \mathrm{H}_j(|\mathrm{sd}^k(K)|) & \xrightarrow{|\varphi|_*} & \mathrm{H}_j(|K|) & \xrightarrow{u_j} & \mathrm{H}_j(|K|) \\ \downarrow{\scriptstyle (\Psi \circ \mho)_*} & & & \searrow^{\Psi_*} & \downarrow{\scriptstyle \Psi_*} \\ \mathrm{H}_j(S^n) & & \xrightarrow[(\Psi \circ |\varphi| \circ \mho^{-1} \circ \Psi^{-1})_*]{g_*} & & \mathrm{H}_j(S^n). \end{array}$$

We make the following observations and clarifications:

(1) The maps Θ are the natural isomorphisms introduced on page 2058.
(2) We denote by $u_*\colon \mathrm{C}_*(|K|) \to \mathrm{C}_*(|K|)$ the k-fold iterated singular subdivision map that we introduced on page 1640.
(3) It follows from Proposition 95.45, applied iteratively k times, that the rectangle to the top right commutes.
(4) The quadrilateral at the bottom commutes by definition.
(5) The triangle at the bottom right commutes by Lemma 74.27.
(6) The square to the top left commutes by the naturality of Θ.

It follows from the above that the isomorphism $\mu := \Psi_* \circ \mho_* \circ \Theta_{\mathrm{sd}^k(K)}$ has the desired property. ⊞

To shorten the notation a little bit we now write $L := \mathrm{sd}^k(K)$. We calculate that

$$\begin{aligned} \Lambda(f) \overset{\text{by Lemma 97.7 and Claim 1 (1)}}{\downarrow =} \Lambda(g) &= \sum_{j \in \mathbb{N}_0} (-1)^j \cdot \mathrm{tr}\left(g_* \circlearrowleft \mathrm{H}_i(S^n)\right) \overset{\text{by Claim 2}}{\downarrow =} \sum_{j \in \mathbb{N}_0} (-1)^j \cdot \mathrm{tr}\left((u_j \circ \varphi_*) \circlearrowleft \mathrm{H}_i^{\mathrm{simp}}(L)\right) \\ &= \sum_{j \in \mathbb{N}_0} (-1)^j \cdot \mathrm{tr}\left((u_j \circ \varphi_*) \circlearrowleft \mathrm{C}_i^{\mathrm{simp}}(L)\right). \\ &\quad \uparrow \text{by the Hopf Trace Formula 97.12 (2)} \end{aligned}$$

At this point we see that it suffices to prove the following claim.

Claim 3. For each $j \in \mathbb{N}_0$ the trace $\mathrm{tr}\left((u_j \circ \varphi_*) \circlearrowleft \mathrm{C}_j^{\mathrm{simp}}(L)\right)$ is even.

Proof. Evidently the plan is to apply Lemma 97.18. We make a few more preparations:

(1) We consider the following diagram:

$$\begin{array}{ccccc} \mathrm{C}_j^{\mathrm{simp}}(L) & \xrightarrow{g_*} & \mathrm{C}_j^{\mathrm{simp}}(K) & \xrightarrow{u_j} & \mathrm{C}_j^{\mathrm{simp}}(L) \\ \downarrow{\scriptstyle \rho_*} & & \downarrow{\scriptstyle \rho_*} & & \downarrow{\scriptstyle \rho_*} \\ \mathrm{C}_j^{\mathrm{simp}}(L) & \xrightarrow{g_*} & \mathrm{C}_j^{\mathrm{simp}}(K) & \xrightarrow{u_j} & \mathrm{C}_j^{\mathrm{simp}}(L). \end{array}$$

It follows from Claim 1 (2) that the square to the left commutes. It follows from the naturality of the simplicial subdivision maps that the square to the right commutes.

(2) Note that it follows immediately from the definition of the map $\rho\colon K \to K$ that $\rho\colon K \to K$ does not fix a single simplex of K and that $\rho \circ \rho = \mathrm{id}_K$. Since the map $K \mapsto L = \mathrm{sd}^k(K) = L$ is functorial we see that $\rho\colon L \to L$ has the same properties, i.e. $\rho\colon L \to L$ does not fix a single simplex of L and it satisfies $\rho \circ \rho = \mathrm{id}_L$.

(3) We denote by S_j the set of j-simplices of L. It follows immediately from (2) that there exists a subset T_j of S_j with the following properties:

$$\text{(i)} \qquad T_j \cap \rho(T_j) \;=\; \varnothing \qquad\qquad \text{and} \qquad\qquad \text{(ii)} \qquad T_j \cup \rho(T_j) \;=\; S_j.$$

We equip each $t \in T_j$ with some order and we use these orders to view T_j as a subset of $\mathrm{C}_j^{\mathrm{simp}}(L)$. It follows from (ii) and Lemma 95.5 that $T_j \cup \rho(T_j)$ is a basis of $\mathrm{C}_j^{\mathrm{simp}}(L)$.

Now we apply Lemma 97.18 to $V = \mathrm{C}_j^{\mathrm{simp}}(L)$, $T = T_j$, $\rho = \rho_*$ and $\varphi = \varphi$. It follows from (1), (2) and (3) that all the hypotheses of Lemma 97.18 are satisfied. Thus we obtain that the trace of $u_j \circ \varphi_*$ is indeed even. ∎

The argument for deducing the Borsuk-Ulam Theorem 39.8 from Proposition 97.17 is almost identical to the argument on page 1957 for deducing the Borsuk-Ulam Theorem 39.8 from the Odd Degree Proposition 91.3.

Proof of the Borsuk-Ulam Theorem 39.8. Let $g\colon S^n \to \mathbb{R}^n$ be a map. Suppose there exists no pair of antipodal points x and $-x$ in S^n with $g(x) = g(-x)$. Put differently, suppose that for any $x \in S^n$ we have $g(x) \neq g(-x)$. We consider the composition of the following two maps

$$\begin{array}{rccccl} \Phi\colon S^{n-1} \times [0,1] & \to & & S^n_{\geq 0} & \to & S^{n-1}. \\ (y,t) & \mapsto & (y \cdot \sqrt{1-t^2}, t) & & & \\ & & & x & \mapsto & \underbrace{\frac{g(x)-g(-x)}{\|g(x)-g(-x)\|}}_{\text{defined since } g(x) \neq g(-x)} \end{array}$$

Now we see that

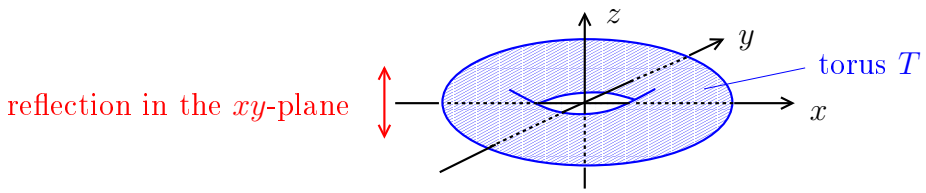
$$\begin{array}{ccccccc} \text{even number} & \overset{\downarrow}{=} & \Lambda(\Phi_0) & = & \Lambda(\Phi_1) & = & \Lambda(\text{constant map}) \;=\; 1. \\ & & \text{by Lemma 97.7 since } \Phi_0 \text{ and } \Phi_1 \text{ are homotopic} & & \text{by definition of } \Phi_1 & & \text{Lemma 97.6 (3)} \end{array}$$

by definition we have $\Phi(-x,0) = -\Phi(x,0)$, thus it follows from Proposition 97.17 that $\Lambda(\Phi_0)$ is even

We have thus obtained a contradiction. ∎

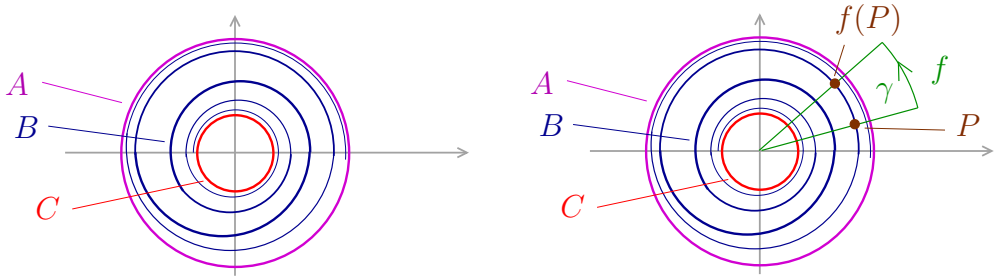
Exercises for Chapter 97.

Exercise 97.1. Let X be a finite simplicial complex, let $\varphi\colon X \to X$ be a map and let $\mathbb{F}$ be a field. We denote by $\gamma\colon \mathbb{Z} \to \mathbb{F}$ the ring homomorphism that is given by $\gamma(n) = n \cdot 1_{\mathbb{F}}$. Show that



$$\Lambda(X, \mathbb{F}) \;=\; \gamma(\Lambda(X)).$$

Hint. Use Exercise 89.3.



Exercise 97.2. Let $n \in \mathbb{N}$. Show that there exists a compact smooth manifold M and a map $\varphi\colon M \to M$ with Lefschetz number $\Lambda(\varphi) = n$ such that φ has precisely one fixed point.

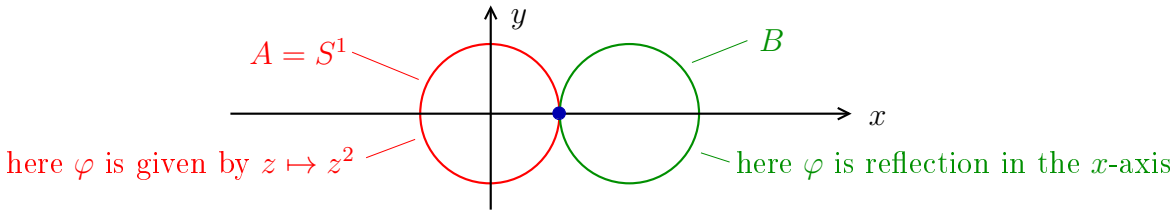
Exercise 97.3. Let $n \in \mathbb{N}$. Does the real projective space $\mathbb{R}\mathrm{P}^{2n+1}$ admit a self-map without fixed points?

Exercise 97.4. We consider the torus $T := S^1 \times S^1$ embedded in $\mathbb{R}^3$ as shown in the figure below. Let $f\colon T \to T$ be the map that is given by reflection in the xy-plane. Is f homotopic to a map without fixed points?

Exercise 97.5. We consider the topological space $X = A \cup B \cup C$ that is shown in the figure below. Here A is a circle of radius 3, C is a circle of radius 1 around the origin and B is the image of an embedding $\mathbb{R} \to \mathbb{R}^2$ which spirals towards A and C.

(a) Give a rigorous description of X.
(b) Show that X is compact.
(c) Compute the homology groups of X.

Fix some "angle" $\gamma \in (0, \pi)$. Let $f\colon X \to X$ be the map that is given by rotation by the angle γ on A and C and which is given by sending a point $s \cdot \exp(\mathrm{i}\varphi)$ on B to the "next" point on B of the form $t \cdot \exp(\mathrm{i}(\varphi + \gamma))$ with $s > t$.



(d) Show that f is continuous.
(e) Show that f has no fixed points.
(f) Show that the Lefschetz number $\Lambda(f) \neq 0$.

This long but fun exercise shows that in the formulation of the Lefschetz Fixed Point Theorems it does not suffice to work with compact spaces that are say $\mathbb{Q}$-homology finite. We need the topological space to be "sufficiently nice".

Exercise 97.6. We consider the topological space $X = A \cup B$ that is shown in the figure below. Let $\varphi\colon X \to X$ be the map that is given by $z \mapsto z^2$ on A and that is given by reflection along the x-axis on B.

(a) Show that the Lefschetz number $\Lambda(\varphi, \mathbb{F}) = 0$ for every field $\mathbb{F}$.
(b) Show that any map ψ that is homotopic to φ actually has a fixed point.

Remark. It is easy to see that X admits a simplicial structure. Thus the exercise shows that the converse to the Lefschetz Fixed Point Theorem 97.9 does not hold.

Exercise 97.7.

(1) Let $A \in \mathrm{GL}(n, \mathbb{C})$ be a matrix. We denote by $\varphi_A\colon \mathbb{C}\mathrm{P}^{n-1} \to \mathbb{C}\mathrm{P}^{n-1}$ the induced map given by $\varphi_A([P]) := [A \cdot P]$.
   (a) Show that the Lefschetz number $\Lambda(\varphi_A) = n$.
   Hint. Use the Matrix Group Path-Component Proposition 2.37 (4). The super conscientious reader might also want to consult the discussion on page 426 to show that a certain map is indeed continuous.
   (b) Use (a) to show that A has an eigenvalue.
(2) What does the approach in (1) say about the existence of real eigenvalues of real matrices?

Exercise 97.8. Let $n \in \mathbb{N}_0$ be *even*.

(a) Show that the complex projective space $\mathbb{C}\mathrm{P}^n$ admits a self-map without fixed points.
Remark. In Exercise 121.10 we will prove the much more interesting converse, namely we will show that for every *odd* n every self-map of $\mathbb{C}\mathrm{P}^n$ has a fixed point.
(b) Does there exist a nowhere-vanishing vector field on $\mathbb{C}\mathrm{P}^n$?

Exercise 97.9. For which $n \in \mathbb{N}$ does the real projective space $\mathbb{R}\mathrm{P}^n$ admit a nowhere-vanishing vector field?

Exercise 97.10. Does the Klein bottle K admit two vector fields v and w such that at every point $P \in K$ the two vectors $v(P), w(P) \in \mathrm{T}_P K$ are linearly independent?

Exercise 97.11. In the figure on page 2124 we saw that the surface Σ of genus 2 supports a vector field with two zeros. What does such a vector field look like if we consider Σ as a submanifold of $\mathbb{R}^3$ in the usual way?

Exercise 97.12. Does the surface of genus 2 admit a vector field with a single zero?

Exercise 97.13. Let $m \in \mathbb{Z}$ be even.

(a) Show that there exists a map $f\colon S^1 \to S^1$ with Lefschetz number $\Lambda(f) = m$ and such that for every $x \in S^1$ we have $f(-x) = -f(x)$.
(b) Now prove (a) for higher-dimensional spheres.

Exercise 97.14. Let X be a finite CW-complex and let $\varphi\colon X \to X$ be a self-map. Furthermore let $p\colon \widetilde{X} \to X$ be a finite covering. By the Lift-to-Universal Coverings Proposition 61.13 we know that there exists a map $\widetilde{\varphi}\colon \widetilde{X} \to \widetilde{X}$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{X} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{f} & X. \end{array}$$

Show that

$$\Lambda(\widetilde{\varphi}\colon \widetilde{X} \to \widetilde{X}) \;=\; [\widetilde{X} : X] \cdot \Lambda(\varphi\colon X \to X).$$

Hint. Use cellular homology and use the Hopf Trace Formula, i.e. use Theorem 97.12.

Exercise 97.15. Let M be a compact topological manifold. Suppose we are given two compact codimension-zero submanifolds A and B such that $A \cap B = \partial A = \partial B$. Furthermore let $f\colon M \to M$ be a map that restricts to self-maps of A and B. Show that

$$\Lambda(f\colon M \to M) \;=\; \Lambda(f\colon A \to A) + \Lambda(f\colon B \to B) - \Lambda(f\colon A \cap B \to A \cap B).$$

Hint. Use the Mayer–Vietoris Theorem 78.9 for Manifolds and use the Hopf Trace Formula, i.e. use Theorem 97.12.
Remark. In the Topological Manifolds-Invariants Proposition 104.14 we will see that the homology groups of A, B and M are finitely generated and that there exists an n such that they vanish in dimension $> n$.

Exercise 97.16. Let M be a smooth manifold and let v be a vector field on M. Show that the zero set $\{x \in M \mid v(x) = 0\}$ is a closed subset of M.
Hint. Use Lemma 1.8 (2b).

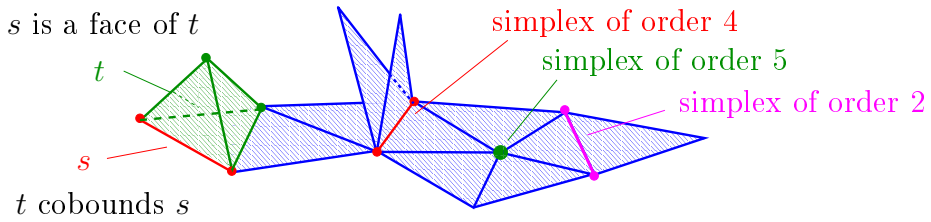
Exercise 97.17. A *Lie group* is a smooth manifold X with empty boundary together with a group structure such that the two maps

$$\begin{array}{ccc} X \times X & \to & X \\ (x, y) & \mapsto & x \cdot y \end{array} \qquad \text{and} \qquad \begin{array}{ccc} X & \to & X \\ x & \mapsto & x^{-1} \end{array}$$

are smooth. For example it is not difficult to show that the matrix groups $\mathrm{SO}(n)$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$ with the usual multiplication are Lie groups. Show that the Euler characteristic of any closed Lie group of dimension ≥ 1 is zero.

Exercise 97.18. For which compact connected 2-dimensional smooth manifolds M can you find a nowhere-vanishing vector field v with the additional property that for each $P \in \partial M$ we have $v(P) \in \mathrm{T}_P M$?
Remark. We had posed this question already as Exercise 23.11, but now you actually have the tools to give a complete answer.

98. Homology groups of pseudomanifolds and smooth manifolds



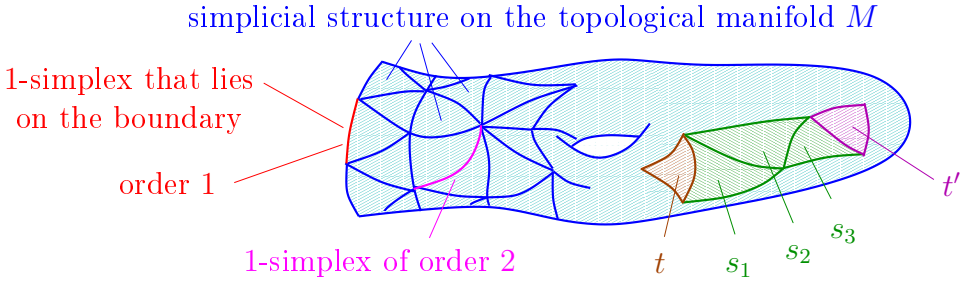
Let M be an n-dimensional smooth manifold. By the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a smooth simplicial structure. In the Smooth Manifolds-Invariants Proposition 96.6 we used this fact to show that for every $k > n$ we have $\mathrm{H}_k(M) = 0$. In this chapter we will squeeze more information out of the existence of a simplicial structure. In particular this will allow us to calculate $\mathrm{H}_n(M;\mathbb{Z})$ and it will allow us to make some statements regarding $\mathrm{H}_{n-1}(M;\mathbb{Z})$.

98.1. **The top-dimensional homology group of a pseudomanifold.** In this chapter we will see that any simplicial structure of an n-dimensional topological manifold has several special properties. This will lead us to the notion of an *n-dimensional pseudomanifold* which can be viewed as a simplicial analogue of a manifold. We will then prove several statements regarding the simplicial homology groups of an n-dimensional pseudomanifold. In the subsequent section we will then use the calculations from this chapter to prove the promised results on homology groups of smooth manifolds.
First we recall and introduce some definitions.

Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) Let t be a simplex of K. As on page 1979 we define a face of t to be a simplex s with $s \subset t$. In this setting we also say that t cobounds s.
(2) Let $s \in S$ be a k-simplex of K. We say s has order r, if there exist precisely r simplices of dimension $k+1$ which contain s as a face.

As before we sometimes use the same terms when we talk about topological realizations and simplicial complexes.



Proposition 98.1. (Manifold-Simplex Proposition) Let M be an n-dimensional topological manifold that is equipped with a simplicial structure.

(1) There is no simplex of dimension $> n$ and every simplex is the face of an n-simplex.
(2) The simplicial structure has finitely many simplices if and only if it has finitely many n-simplices.
(3) The simplicial structure on M restricts to a simplicial structure on the $(n-1)$-dimensional topological manifold ∂M. If M is a smooth manifold and if we are given a smooth simplicial structure, then the restriction of the simplicial structure to the smooth manifold ∂M is also a smooth simplicial structure.
(4) Let s be an $(n-1)$-simplex of M. Then

$$\text{order of } s \;=\; \begin{cases} 1, & \text{if } s \text{ lies on the boundary,} \\ 2, & \text{otherwise.} \end{cases}$$

(5) If M is connected, then given any two n-simplices t and t' there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of n-simplices such that any two consecutive simplices have a common $(n-1)$-dimensional face.

Remark.

(1) In Lemma 96.1 we gave a different proof why the maximal dimension of a simplex of a smooth simplicial structure of an n-dimensional smooth manifold equals n.

(2) A rather different proof of the Manifold-Simplex Proposition 98.1 (5) is given in [**Mun1984**, Corollary 65.2].

The key idea behind the proof of the Manifold-Simplex Proposition 98.1 is to squeeze the maximal amount of information out of the local homology groups. To do so we first recall the following definition from page 1655.

Definition. Given a topological space X and given a point $P \in X$ the relative homology group $\mathrm{H}_j(X, X \setminus \{P\})$ is called the n-th local homology group of X at the point P.

We recall the calculation of the local homology groups of a topological manifold.

Lemma 75.1. (Manifold-Local Homology Lemma) Let M be an n-dimensional topological manifold and let $P \in M$. For every $j \in \mathbb{N}_0$ we have

$$\mathrm{H}_j(M, M \setminus \{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M \setminus \partial M \text{ and } j = n, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. Since in a minute we will calculate a different local homology group it is perhaps helpful to remind us of the proof of the lemma. For simplicity we only consider the case that $P \in M \setminus \partial M$. In this case we can pick a chart $\Phi\colon U \to B^n$ for P with $\Phi(P) = 0$. We then have

$$\mathrm{H}_j(M, M\setminus\{P\}) \underset{\text{Excision Theorem 74.18}}{\leftarrow} \mathrm{H}_j(U, U\setminus\{P\}) \underset{\substack{\text{isomorphism by the long exact sequence in reduced homology of the pair } (B^n, B^n\setminus\{0\}) \text{ and the fact that } \widetilde{\mathrm{H}}_*(B^n) = 0 \text{ by page 1612}}}{\overset{\Phi_*}{\underset{\cong}{\longrightarrow}}} \mathrm{H}_j(B^n, B^n\setminus\{0\}) \underset{\uparrow}{\overset{\partial}{\longrightarrow}} \widetilde{\mathrm{H}}_{j-1}(B^n\setminus\{0\}) \underset{\substack{\text{isomorphism since } S^{n-1} \text{ is homotopy equivalent to } B^n\setminus\{0\}}}{\leftarrow} \widetilde{\mathrm{H}}_{j-1}(S^{n-1}).$$

The statement now follows from the calculation of the reduced homology groups of spheres given in Proposition 74.4. ∎

The next proposition calculates the local homology groups of a simplicial complex. This calculation is also interesting in its own right.

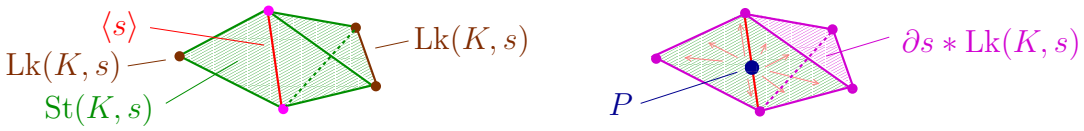
Proposition 98.2. Let $K = (V, S)$ be an abstract simplicial complex and let $P \in |K|$. By the Open Simplex Lemma 93.11 there exists a unique simplex $s \in S$ such that P is a point in the open simplex $\langle s \rangle$. We set $m := \dim(s)$. If $\mathrm{Lk}(K, s)$ is a finite simplicial complex, then for every $j \in \mathbb{N}_0$ we have[1202][1203]

$$\mathrm{H}_j(|K|, |K| \setminus \{P\}) \;\cong\; \widetilde{\mathrm{H}}_{j-1-m}(\mathrm{Lk}(K, s)).$$

Proof. We perform the following calculation:

$$\begin{array}{ccccc}
\mathrm{H}_j(|K|, |K| \setminus \{P\}) & \overset{\cong}{\leftarrow} & \mathrm{H}_j(\mathrm{St}(s), \mathrm{St}(s) \setminus \{P\}) & \overset{\cong}{\rightarrow} & \widetilde{\mathrm{H}}_{j-1}(\mathrm{St}(s) \setminus \{P\}) \\
& & \uparrow & & \uparrow \\
& & \widetilde{\mathrm{H}}_{j-1}(S^{m-1} * \mathrm{Lk}(s)) & \cong & \widetilde{\mathrm{H}}_{j-1-m}(\mathrm{Lk}(s)) \\
& & \uparrow & & \uparrow \\
& & \widetilde{\mathrm{H}}_{j-1}(\partial s * \mathrm{Lk}(s)) & \cong & \widetilde{\mathrm{H}}_{j-1}(\partial s * \mathrm{Lk}(s))
\end{array}$$

by the long exact sequence in reduced homology of the pair $(\mathrm{St}(s), \mathrm{St}(s) \setminus \{P\})$ and the observation, see the Link Star Lemma 94.5 (1f), that $\mathrm{St}(s)$ is contractible, which implies that its reduced homology vanishes



by the Link Star Lemma 94.5 (1d) we know that $\mathrm{St}(s)$ is a neighborhood, thus we can apply the Excision Theorem 74.18 (2)

by the Link Star Lemma 94.5 (1g) together with Homotopy Equivalence-H_*-Corollary 73.9

since s is an m-simplex we know by Simplex-Embedding Lemma 93.5 and the standard Simplex Homeomorphism Lemma 72.1 (3) that ∂s is homeomorphic to S^{m-1}

by Corollary 76.8 we have $\widetilde{\mathrm{H}}_{l+m}(S^{m-1} * X) \cong \widetilde{\mathrm{H}}_l(X)$ whenever X is compact and Hausdorff, we can apply this result since $\mathrm{Lk}(s)$ is by hypothesis finite

■

Now we can finally provide the proof of the Manifold-Simplex Proposition 98.1.

Proof of the Manifold-Simplex Proposition 98.1. Basically by definition of a simplicial structure it suffices to consider the case that the n-dimensional topological manifold M is the topological realization $M = |K|$ of some abstract simplicial complex $K = (V, S)$. Note that by the Topological Manifolds-Local Properties Lemma 18.8 we know that the topological manifold $M = |K|$ is regionally compact. Thus it follows from Proposition 94.6 that the abstract simplicial complex K is locally finite and that the link of any vertex is a finite simplicial complex. This implies in particular that we can apply Proposition 98.2 without worries.

(1) It suffices to prove the following claim.

Claim. Given any simplex s, the maximal dimension of a simplex that contains s is precisely given by n.

Proof. Let s be a simplex of K. As we mentioned in the beginning of the proof, we know that K is locally finite. This implies that there exists a simplex t of maximal dimension that contains s. We set $m := \dim(t)$. Now let $P \in \langle t \rangle$ be a point. We

[1202] It can happen that $\mathrm{Lk}(K, s) = \varnothing$. Recall that by definition we have $\widetilde{\mathrm{H}}_{-1}(\varnothing) \cong \mathbb{Z}$.

[1203] I do not know whether the statement holds in general without the condition that $\mathrm{Lk}(K, s)$ is finite.

calculate that

$$\begin{array}{ccccc} \mathbb{Z} & \cong & \widetilde{\mathrm{H}}_{-1}(\mathrm{Lk}(K,t)) & \cong & \mathrm{H}_m(|K|,|K|\backslash\{P\}) \\ & & \uparrow & & \downarrow \\ & & \text{since there are no simplices of dimension} > m \text{ which contain } t \text{ we see that } \mathrm{Lk}(K,t)=\varnothing & & \text{Manifold-Local Homology Lemma 75.1 applied to } |K|=M \end{array} \quad \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M\backslash\partial M \text{ and } m=n, \\ 0, & \text{otherwise.} \end{cases}$$

Comparing the left-hand side with the right-hand side shows that $m = n$. ⊞

(2) This statement is an almost immediate consequence of (1). Indeed, we only have to show that if K has finitely many n-simplices, then it has only finitely many simplices. But every n-simplex has only finitely many faces and by (1) we see that every simplex of K is the face of an n-simplex. Thus we are done.

(3) First note that if we are given a smooth simplicial structure on a smooth manifold that restricts to a simplicial structure on ∂M, then it follows easily from the definitions that this simplicial structure on ∂M is actually a smooth simplicial structure. Thus, to prove (3), it remains to show that the simplicial structure on $|K| = M$ restricts to a simplicial structure on the topological manifold ∂M.

If M is a smooth manifold, then we know by the Smooth Manifold Boundary Proposition 19.26 (3a) that ∂M is a closed subset of M. In the general case that M is a topological manifold the same statement follows from the Topological Manifold Boundary Proposition 75.2.

Now that we know that ∂M is a closed subset of M we obtain the desired statement from Lemma 93.13 together with the following claim.

Claim. Let s be an m-simplex of K. Either $\langle s\rangle \cap \partial M = \varnothing$ or $\langle s\rangle \subset \partial M$.

Proof. Let s be a simplex. For any point $P \in \langle s\rangle$ we perform almost the same calculation as in (1):

$$\begin{array}{ccccc} \widetilde{\mathrm{H}}_{n-1-m}(\mathrm{Lk}(K,s)) & \cong & \mathrm{H}_n(|K|,|K|\backslash\{P\}) \\ & & \downarrow \\ & & \text{Manifold-Local Homology Lemma 75.1 applied to } |K|=M \end{array} \quad \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M\backslash\partial M, \\ 0, & \text{otherwise.} \end{cases}$$

It follows from this calculation that $\langle s\rangle \cap \partial M = \varnothing$ if $\widetilde{\mathrm{H}}_{n-1-m}(\mathrm{Lk}(K,s)) \cong \mathbb{Z}$ and that $\langle s\rangle \subset \partial M$ if $\widetilde{\mathrm{H}}_{n-1-m}(\mathrm{Lk}(K,s)) = 0$. ⊞

(4) Let s be an $(n-1)$-simplex of M. We denote by r the order of s. We pick a point $P \in \langle s\rangle$. Similar to (1) we calculate that

$$\begin{array}{ccccc} \mathbb{Z}^{r-1} & \cong & \widetilde{\mathrm{H}}_0(\mathrm{Lk}(K,s)) & \cong & \mathrm{H}_n(|K|,|K|\setminus\{P\}) \\ & & \uparrow & & \downarrow \\ & & \text{since } s \text{ is an } (n-1)\text{-simplex and since there are no simplices of dimension} > n \text{ we see that } \mathrm{Lk}(K,s) & & \text{Lemma 75.1 applied to } |K|=M \\ & & \text{consists of } r \text{ points, the isomorphism now follows from the Reduced Homology Lemma 74.1 (5)} & & \end{array} \quad \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M\setminus\partial M, \\ 0, & \text{otherwise.} \end{cases}$$

Comparing the left-hand side with the right-hand side gives us the desired statement.

(5) Now we assume that M is in fact connected. We say that two n-simplices t and t' of K are *equivalent* if there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of n-simplices such

that any two consecutive simplices have a common $(n-1)$-dimensional face. Recall that our task is to show that any two n-simplices are equivalent in the above sense.

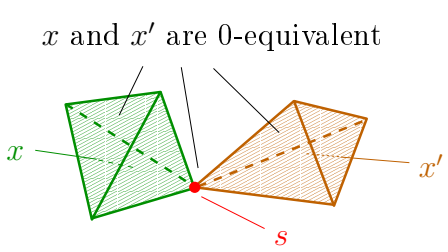
The key to doing so is the following claim:

Claim. Let t and t' be two n-simplices. If $t \cap t' \neq \varnothing$, then t and t' are actually equivalent in the above sense.

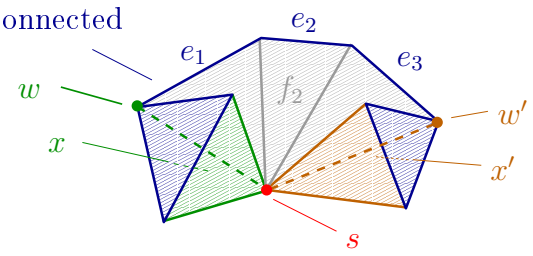
Proof. Given $m \in \{0, \dots, n-1\}$ we say that two n-simplices x and x' are *m-equivalent* if there exists a sequence $x = s_0, s_1, \dots, s_k = x'$ of n-simplices such that any two consecutive simplices have a common face of dimension $\geq m$. It suffices to show that if we are given $m \in \{0, \dots, n-2\}$ such that any two n-simplices in K are m-equivalent, then any two n-simplices in K are also $(m+1)$-equivalent. In fact evidently it suffices to show that if we are given two n-simplices x and x' which have an m-simplex s in common, then x and x' are $(m+1)$-equivalent. To do so we first note that since $\dim(x) > \dim(s)$ we can pick a vertex w of $x \cap \mathrm{Lk}(K, s)$ and similarly we can pick a vertex w' of $x' \cap \mathrm{Lk}(K, s)$.

Now we want to show that $\mathrm{Lk}(K, s)$ is connected. To do so we pick a point $P \in \langle s \rangle$ and we perform basically the same calculation as in the previous arguments:

$$\widetilde{\mathrm{H}}_0(\mathrm{Lk}(K,s)) \underset{\uparrow}{\cong} \widetilde{\mathrm{H}}_{m+1}(|K|, |K| \setminus \{P\}) = \widetilde{\mathrm{H}}_{m+1}(M, M \setminus \{P\}) \underset{\uparrow}{=} 0.$$



Proposition 98.2 applied to m-simplex s and $j = m+1$



by the Manifold-Local Homology Lemma 75.1 since $m \leq n-2$

It follows from this calculation together with the Reduced Homology Lemma 74.1 and Exercise 93.12 that the abstract simplicial complex $\mathrm{Lk}(K, s)$ is in fact connected in the sense of the definition on page 2013. This means in our setting that there exist 1-simplices $e_1, \dots, e_k \in S$ of $\mathrm{Lk}(K, s)$ such that the following holds:

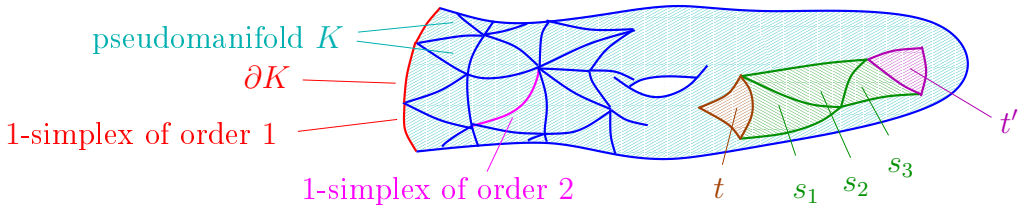
($*$) We have $w \in e_1$, for every $i \in \{1, \dots, k-1\}$ we have $e_i \cap e_{i+1} \neq \varnothing$ and we have $w' \in e_k$.

Let $i \in \{1, \dots, k\}$. Since e_i is a simplex in $\mathrm{Lk}(K, s)$ there exists a simplex f_i of K with $e_i \cup s \subset f_i$. By (1) we can in fact find an n-simplex $\widetilde{f}_i$ of K with $e_i \cup s \subset f_i \subset \widetilde{f}_i$. We set $\widetilde{f}_0 := x$ and $\widetilde{f}_{k+1} := x'$. Note that it follows from ($*$) that any two consecutive $\widetilde{f}_i$ and $\widetilde{f}_{i+1}$ have s and a vertex of $\mathrm{Lk}(K, s)$ in common, i.e. they have an $(m+1)$-simplex in common. This shows that x and x' are in fact $(m+1)$-connected. ⊞

We pick an equivalence class of n-simplices of K and we denote by J the subcomplex of K given by the union of the n-simplices in said equivalence class. Since J is a subcomplex we know by Lemma 93.8 that $|J|$ is a closed subset of $|K| = M$. Furthermore it follows from the claim together with Exercise 93.11 that $|J|$ is also

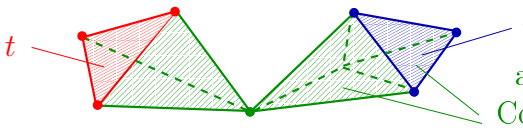
an open subset of $|K| = M$. By hypothesis $|K| = M$ is connected. Thus we see that $K = J$, which implies that any two n-simplices in K are in fact equivalent. ■

Our main goal is to say something meaningful about homology groups of smooth manifolds. The idea is to use the Manifold-Simplex Proposition 98.1 and the fact that we can calculate singular homology groups via simplicial homology groups. Since we will only use the information given by the Manifold-Simplex Proposition 98.1 it is convenient to introduce the following definition.



Definition. Let $n \in \mathbb{N}_0$. An n-dimensional pseudomanifold is a non-empty abstract simplicial complex K such the following conditions are satisfied:

(1) Every simplex of K is a face of an n-simplex of K.[1204]
(2) Every $(n-1)$-simplex has order one or two.
(3) Given any two n-simplices t and t' there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of n-simplices such that any two consecutive simplices have a common $(n-1)$-dimensional face.



Given a pseudomanifold K we define ∂K to be the subcomplex that is given by the union of all $(n-1)$-simplices of order 1. We say a pseudomanifold K is closed if $\partial K = \varnothing$ and if K is finite.

Examples.

(1) In the figure below we illustrate the definition of a 2-dimensional pseudomanifold.

(2) In the figure below we show an abstract simplicial complex that satisfies (1) and (2) but that does not satisfy (3). This example shows that Condition (3) is stronger than requiring ordinary connectedness.

abstract simplicial complex that satisfies Conditions (1) and (2) of a pseudomanifold but which does not satisfy Condition (3)

Remark.

(1) The definition of a pseudomanifold we give seems to be the one which is most frequently used, it goes back to work of Luitzen Brouwer [**Brou1976**, p. 477] in 1912.
(2) the Manifold-Simplex Proposition 98.1 says that if we are given a simplicial structure $(K, \Theta\colon |K| \to M)$ of a connected non-empty n-dimensional topological manifold M, then K is an n-dimensional pseudomanifold.
(3) In Exercise 98.4 we will show that if K is an n-dimensional pseudomanifold with $n \in \{1, 2\}$, then $|K|$ is a closed n-dimensional smooth manifold.

[1204] Note that this condition implies that K is necessarily n-dimensional.

(4) Let K be a finite n-dimensional pseudomanifold. As usual we denote by $\Sigma(K)$ the suspension as defined on page 2003. As we will see in Exercise 98.1, it follows very easily from the definitions that $\Sigma(K)$ is an $(n+1)$-dimensional pseudomanifold with $\partial\Sigma(K) = \Sigma(\partial K)$.

Now assume that the fundamental group $\pi_1(|K|)$ of the topological realization $|K|$ is non-trivial. It follows from the Simplicial Cone-Suspension Corollary 93.21 together with Lemma 96.19 that the topological realization $|\Sigma(K)|$ of the suspension $\Sigma(K)$ is not a topological manifold. This shows that for $n \geq 3$ not all n-dimensional pseudomanifolds arise from topological manifolds.

(5) In the literature there exist several, not always entirely equivalent, notions of a pseudomanifold. In general, as we just saw in (3), the topological realizations of pseudomanifolds are not topological manifolds. But many tools and results on topological manifolds can be generalized to the context of (topological realization of) pseudomanifolds, see e.g. [**KiW2006**, Chapter 4]. Also note that in the literature an n-dimensional pseudomanifold is sometimes called an *n-circuit*.

Next we recall and expand a definition from page 2038.

Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) Let $n \in \mathbb{N}_0$. An ordered n-simplex of K is an $(n+1)$-tuple $(v_0, \ldots, v_n) \in V^{n+1}$ such that $\{v_0, \ldots, v_n\} \in S$. We write $\lfloor (v_0, \ldots, v_n) \rfloor := \{v_0, \ldots, v_n\}$.

(2) An oriented n-simplex is a pair (ϵ, s) where $\epsilon \in \{\pm 1\}$ and s is an ordered n-simplex of K. As in (1) we write $\lfloor (\epsilon, s) \rfloor := \lfloor s \rfloor$ and we refer to $\lfloor (\epsilon, s) \rfloor$ as the underlying simplex. Sometimes we also say that (ϵ, s) is an orientation of the n-simplex s.

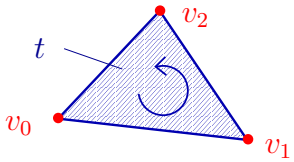
(3) We say two oriented n-simplices $(\mu, s = (v_0, \ldots, v_n))$ and $(\nu, t = (w_0, \ldots, w_n))$ are equivalent if

$$\mu \;=\; \nu \cdot \underset{\uparrow}{\operatorname{sign}}(\sigma) \qquad \text{where } \sigma \in \operatorname{Bij}\{0, \ldots, n\} \text{ with } v_i = w_{\sigma(i)} \text{ for } i = 0, \ldots, n.$$

sign of σ as defined on page 2035

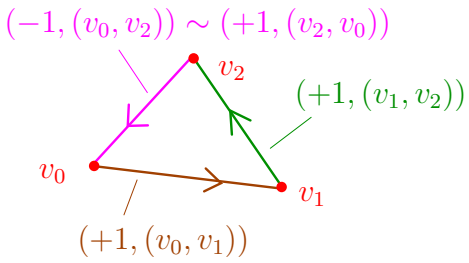
It follows immediately from Lemma 95.1 that this is indeed an equivalence relation on the set of oriented n-simplices.

(4) An orientation of an n-simplex s is an equivalence class of oriented n-simplices with underlying simplex s.



Definition. Let $K = (V, S)$ be an abstract simplicial complex and let $(\epsilon, t = (v_0, \ldots, v_n))$ be an oriented n-simplex. Let s be a codimension-one face of t. If v_i is the one vertex of t that is missing in s, then we define the induced orientation of s to be

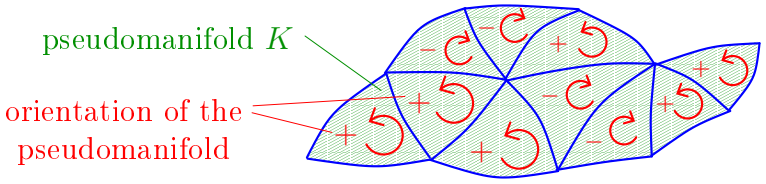
$$((-1)^i \cdot \epsilon, (v_0, \ldots, \widehat{v_i}, \ldots, v_n)).$$



Example. In the figure below we show the oriented 2-simplex $(+1, (v_0, v_1, v_2))$ together with the orientations induced on all of the three codimension-one faces.

Lemma 98.3. Let $K = (V, S)$ be an abstract simplicial complex, let t be a simplex of K and let s be a codimension-one face of t. Any two equivalent orientations of t induce equivalent orientations of s.

Proof. This statement follows easily from the properties of the sign of a bijection, see Lemma 95.1. We leave it to the reader to fill in the details. ∎



the oriented 2-simplex $(+1,(v_0,v_1,v_2))$ induces the following orientations of its codimension-one faces

Definition. Let K be an n-dimensional pseudomanifold.

(1) An orientation is a choice of an orientation for each n-simplex of K such that for any $(n-1)$-simplex s of order 2 the two cobounding n-simplices induce opposite orientations on s.

(2) We say K is orientable if K admits an orientation.

In the following we will study the simplicial homology groups of pseudomanifolds. Before we do so, let us recall the definition of simplicial homology that we gave on page 2036 and in Lemma 95.6.

Definition. Let $K=(V,S)$ be an abstract simplicial complex and let $n \in \mathbb{N}_0$. We set

$$\mathrm{C}_n^{\mathrm{simp}}(K) := \left\{ \begin{array}{c} \text{free abelian group generated} \\ \text{by all ordered } n\text{-simplices of } K \end{array} \right\} \Big/ (v_0,\ldots,v_n) \sim \mathrm{sign}(\sigma)\cdot(v_{\sigma(0)},\ldots,v_{\sigma(n)}).$$

In the discussion below, we will often not distinguish in the notation between an ordered simplex and the element it represents in $\mathrm{C}_k^{\mathrm{simp}}(K)$. The boundary map is given by

$$\begin{array}{rcl} \partial_n \colon \mathrm{C}_n^{\mathrm{simp}}(K) & \to & \mathrm{C}_{n-1}^{\mathrm{simp}}(K) \\ (v_0,\ldots,v_n) & \mapsto & \sum\limits_{i=0}^{n} (-1)^i \cdot (v_0,\ldots,v_{i-1},\widehat{v_i},v_{i+1},\ldots,v_n). \end{array}$$

Now we can provide the promised theorem.

Theorem 98.4. (Pseudomanifold Homology Theorem) Let K be an n-dimensional pseudomanifold. The following statements hold:

(1) We have an isomorphism as follows:

$$\mathrm{H}_n^{\mathrm{simp}}(K) \cong \left\{ \begin{array}{ll} \mathbb{Z}, & \text{if } K \text{ is closed and orientable,} \\ 0, & \text{otherwise.} \end{array} \right.$$

Furthermore, if K is closed and orientable, and if $\{(\epsilon_w, Y_w)\}_{w\in W}$ is an orientation of K (here W denotes the set of n-simplices of K), then a generator of $\mathrm{H}_n^{\mathrm{simp}}(K) \cong \mathbb{Z}$ is represented by the simplicial cycle $\sum\limits_{w\in W} \epsilon_w \cdot Y_w \in \mathrm{C}_n^{\mathrm{simp}}(K)$.

(2) If K is finite, then we also have an isomorphism as follows:

$$\mathrm{H}_{n-1}^{\mathrm{simp}}(K) \;\cong\; \begin{cases} \text{free abelian group}, & \text{if } K \text{ is orientable or if } \partial K \neq \varnothing, \\ \text{free abelian group} \oplus \mathbb{Z}_2, & \text{if } K \text{ is non-orientable and } \partial K = \varnothing. \end{cases}$$

(3) If K is finite, then

$$\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, \text{ if } K \text{ is closed, regardless whether or not } K \text{ is orientable,} \\ 0, \quad \text{otherwise.} \end{cases}$$

Furthermore, if K is in fact closed and if $Y_1, \ldots, Y_m$ is a set of ordered n-simplices of K such that for each n-simplex s there exists a unique $i \in \{1, \ldots, m\}$ with $s = \lfloor Y_i \rfloor$, then the unique non-zero element of $\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2) \cong \mathbb{F}_2$ is represented by the simplicial cycle $Y_1 \otimes 1 + \cdots + Y_m \otimes 1 \in \mathrm{C}_n^{\mathrm{simp}}(K;\mathbb{F}_2) = \mathrm{C}_n^{\mathrm{simp}}(K) \otimes \mathbb{F}_2$.

Theorem 98.4 leads us to the following definition.

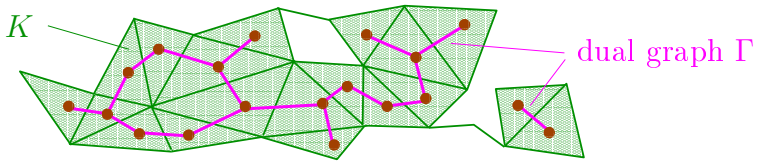
Definition. Let K be a closed n-dimensional pseudomanifold.

(1) If K is equipped with an orientation $\{(\epsilon_w, Y_w)\}_{w \in W}$, then we refer to the simplicial homology class

$$[K] \;:=\; \Big[\sum_{w \in W} \epsilon_w \cdot Y_w \Big] \;\in\; \mathrm{H}_n^{\mathrm{simp}}(K)$$

as the fundamental class of K.

(2) We refer to the unique non-zero element in $\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2) \cong \mathbb{F}_2$ as the $\mathbb{F}_2$-fundamental class $[K]_{\mathbb{F}_2}$.



For clarity we break the proof of Theorem 98.4 into three parts. For the proof of the first part it is convenient to introduce the following definitions which we will use on a few other occasions.

Definition. Let $K = (V, S)$ be an n-dimensional abstract simplicial complex such that every $(n-1)$-simplex has order ≤ 2.

(1) We denote by W the set of n-simplices of K.

(2) We denote by E_2 the set of $(n-1)$-simplices of order 2.

(3) Let $\Gamma = (W, E_2, \varphi)$ be the undirected abstract graph with vertex set W, with edge set E_2 and where $\varphi\colon E_2 \to \mathcal{P}(W)$ is the map that associates to each edge $e \in E_2$ the set $\{w \in W \,|\, e \text{ is a face of } w\}$. Note that for $e \in E_2$ the set $\varphi(e)$ has precisely two elements. This means that Γ is indeed an undirected abstract graph in the sense of the definition on page 313. We call Γ the dual graph of the abstract simplicial complex K. We refer to the figure below for an illustration.

Proof of Theorem 98.4 (1). Let K be an n-dimensional pseudomanifold. Our goal is to calculate $\mathrm{H}_n^{\mathrm{simp}}(K)$. We start out with the following easy but useful observation which

we will use throughout this proof without referring to it again explicitly:

$$\mathrm{H}_n^{\mathrm{simp}}(K) \underset{\uparrow}{=} \ker\big(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\big).$$

K has no simplices of dimension $n+1$, hence $\mathrm{C}_{n+1}^{\mathrm{simp}}(K) = 0$

To determine the right hand side of the above we need to introduce some notation.

(1) We denote by E the set of $(n-1)$-simplices of K. Furthermore we denote by E_1 the set of $(n-1)$-simplices of order 1 and similarly we denote by E_2 the set of $(n-1)$-simplices of order 2. Note that it follows from the hypothesis that K is an n-dimensional pseudomanifold that $E = E_1 \sqcup E_2$.

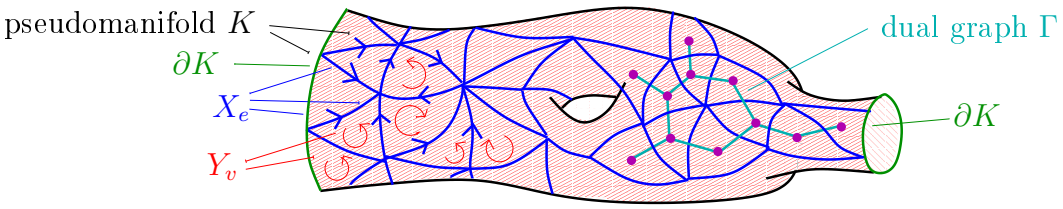
(2) We denote by W the set of n-simplices of K.

(3) Let $\Gamma = (W, E_2, \varphi)$ be the dual graph of K. Note that part (3) of the definition of a pseudomanifold implies that the undirected abstract graph Γ is connected in the sense of the definition on page 315.

(4) For each $(n-1)$-simplex $e \in E$ we pick, once and for all, an ordered $(n-1)$-simplex X_e with $\lfloor X_e \rfloor = e$. We use Lemma 95.5 to view $\{X_e\}_{e\in E}$ as a basis for $\mathrm{C}_{n-1}^{\mathrm{simp}}(K)$.

(5) We consider the two obvious projections

$$p_1\colon \overbrace{\bigoplus_{e\in E} \mathbb{Z}\cdot X_e}^{=\mathrm{C}_{n-1}^{\mathrm{simp}}(K)} \to \bigoplus_{e\in E_1} \mathbb{Z}\cdot X_e \quad \text{and} \quad p_2\colon \overbrace{\bigoplus_{e\in E} \mathbb{Z}\cdot X_e}^{=\mathrm{C}_{n-1}^{\mathrm{simp}}(K)} \to \bigoplus_{e\in E_2} \mathbb{Z}\cdot X_e$$



Since $E = E_1 \sqcup E_2$ we see for $s \in \mathrm{C}_{n-1}^{\mathrm{simp}}(K)$ that $s = 0$ if and only if $p_1(s) = 0$ and $p_2(s) = 0$.

Now suppose that for each $w \in W$ we are given an oriented n-simplex Y_w with $\lfloor Y_w \rfloor = w$. We introduce the following conventions.

(6) As above we use Lemma 95.5 to view $\{Y_w\}_{w\in W}$ as a basis for $\mathrm{C}_n^{\mathrm{simp}}(K)$.

(7) Given $e \in E$ and $w \in W$ we set[1205]

$$\mu_{ew} = \begin{cases} 0, & \text{if } e \text{ is not a face of } w, \\ +1, & \text{if } e \text{ is a face of } w \text{ and } [(+1, Y_w)] \text{ induces } [(+1, X_e)], \\ -1, & \text{if } e \text{ is a face of } w \text{ and } [(+1, Y_w)] \text{ induces } [(-1, X_e)]. \end{cases}$$

Claim 1. Given $\sum_{w\in W} a_w \cdot Y_w \in \mathrm{C}_n^{\mathrm{simp}}(K)$ we have

(a) $p_1\Big(\partial_n\Big(\sum_{w\in W} a_w \cdot Y_w\Big)\Big) = 0 \;\Leftrightarrow\;$ for all $w \in W$ that cobound an $e \in E_1$ we have $a_w = 0$

(b) $p_2\Big(\partial_n\Big(\sum_{w\in W} a_w \cdot Y_w\Big)\Big) = 0 \;\Leftrightarrow\;$ for all $w \neq w' \in W$ that cobound some $e \in E_2$ we have $\mu_{ew} \cdot a_w = -\mu_{ew'} \cdot a_{w'}$.

[1205] Note that if e is a face of w, then precisely one of the two cases does indeed occur.

Proof. We start out our proof of Claim 1 with the following calculation:

$$\partial_n\Big(\sum_{w\in W} a_w\cdot Y_w\Big) = \sum_{w\in W} a_w\cdot\partial_n(Y_w) = \sum_{w\in W} a_w\cdot \sum_{\substack{e\in E \text{ such that}\\ e \text{ is a face of } w}} \mu_{ew}\cdot X_e = \sum_{e\in E} X_e\cdot \sum_{\substack{w\in W \text{ such that}\\ e \text{ is a face of } w}} \mu_{ew}\cdot a_w.$$

↑ follows immediately from the definition of ∂_n, see page 2142, definition of induced orientations, see page 2141, and the above definition of μ_{ew}

Now we consider the two projections.

(a) Note that an element $s \in \mathrm{C}_{n-1}^{\mathrm{simp}}(K)$ lies in the kernel of p_1 if and only if for all $e \in E_1$ the X_e-coefficient of s vanishes. Thus let $e \in E_1$. Let $w \in W$ be the unique n-simplex that cobounds e. Using the above calculation we see that

$$X_e\text{–coefficient of } \partial_n\Big(\sum_{w\in W} a_w\cdot Y_w\Big) \;=\; \mu_{ew}\cdot a_w.$$

The promised result follows from this discussion.

(b) Next let $e \in E_2$. Let $w \neq w'$ be the two n-simplices that cobound e. Similar to the above we see that

$$X_e\text{–coefficient of } \partial_n\Big(\sum_{w\in W} a_w\cdot Y_w\Big) \;=\; \mu_{ew}\cdot a_w + \mu_{ew'}\cdot a_{w'}.$$

As in (a) we see that this calculation gives us the desired result.

Now note that Claim 1 follows almost immediately from the above discussion.

Claim 2. Every element $\sum_{w\in W} a_w\cdot Y_w$ that lies in the kernel of the map

$$\mathrm{C}_n^{\mathrm{simp}}(K) \xrightarrow{\partial_n} \mathrm{C}_{n-1}^{\mathrm{simp}}(K) = \bigoplus_{e\in E}\mathbb{Z}\cdot X_e \xrightarrow{p_2} \bigoplus_{e\in E_2}\mathbb{Z}\cdot X_e$$

has the property that for all $w, w' \in W$ we have $|a_w| = |a_{w'}|$.

Proof. We consider the map

$$\begin{array}{rcl} f\colon W & \to & \mathbb{N}_0 \\ w & \mapsto & |a_w|. \end{array}$$

It follows from Claim 1 that for every $e \in E_2$ and $w, w' \in \varphi(e)$ we have $|a_w| = |a_{w'}|$. Since the abstract graph (W, E_2, φ) is connected we obtain from Lemma 7.6 that $f\colon W \to \mathbb{N}_0$ is constant. ⊞

Claim 3. Given any $w_0 \in W$ the map

$$\begin{array}{rcl} \Theta_{w_0}\colon \ker\big(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\big) & \to & \mathbb{Z} \\ \sum_{w\in W} a_w\cdot Y_w & \mapsto & a_{w_0} \end{array}$$

is a monomorphism.

Proof. It is clear that the given map is a homomorphism. It follows immediately from Claim 2 that the map Θ_{w_0} is a monomorphism. ⊞

Now we can prove Statement (1) of the proposition.

(i) We need to show that if K is infinite, then $\mathrm{H}_n^{\mathrm{simp}}(K) = 0$. So suppose that K is infinite. It follows from the fact that K is finite-dimensional and the fact that every simplex is contained in an n-simplex that W is also infinite. Now let $\sum_{w\in W} a_w\cdot Y_w$

be an element in $\ker\big(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\big)$. Since W is infinite and since by definition every element in $\mathrm{C}_n^{\mathrm{simp}}(K)$ is a finite linear combination of ordered simplices we see that there exists a $w_0 \in W$ with $a_{w_0} = 0$. But then it follows from Claim 2 that $a_w = 0$ for all $w \in W$.

(ii) We need to show that if $\partial K \neq \varnothing$, then $\mathrm{H}_n^{\mathrm{simp}}(K) = 0$. Thus suppose that $\partial K \neq \varnothing$. By definition of ∂K this implies that $E_1 \neq \varnothing$. We pick some $e_0 \in E_1$. Let w_0 be the unique n-simplex that cobounds e_0. Now let $\sum_{w\in W} a_w \cdot Y_w$ be an element in $\ker\big(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\big)$. By Claim 1 we have $a_{w_0} = 0$. But then it follows from Claim 2 that $a_w = 0$ for all $w \in W$.

(iii) Now assume that $\mathrm{H}_n^{\mathrm{simp}}(K) \neq 0$. We need to show that K is actually orientable. To do so it suffices to prove the following claim.

Claim. If $\sum_{w\in W} a_w \cdot Y_w$ is a non-zero element in $\ker\big(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\big)$, then the orientations[1206] $\{(\mathrm{sign}(a_w), Y_w)\}_{w\in W}$ define an orientation of K.

Proof. Let $\sum_{w\in W} a_w \cdot Y_w$ be a non-zero element in $\ker\big(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\big)$. Let e be an $(n-1)$-simplex of order 2, i.e. let $e \in E_2$. Let $w \neq w'$ be the two cobounding n-simplices of e. By Claim 1 we know that $\mu_{ew} \cdot a_w = -\mu_{ew'} \cdot a_{w'}$. It follows from Claim 2 that we also have the equality $\mu_{ew} \cdot \mathrm{sign}(a_w) = -\mu_{ew'} \cdot \mathrm{sign}(a_{w'})$. But basically by definition that means that $(\mathrm{sign}(a_w), Y_w)$ and $(\mathrm{sign}(a_{w'}), Y_{w'})$ induce opposite orientations on the $(n-1)$-simplex e. ⊞

(iv) Finally we suppose that K is closed and orientable. Let $\{(\mu_w, Y_w)\}_{w\in W}$ be an orientation of K. We need to show that $\mathrm{H}_n^{\mathrm{simp}}(K) \cong \mathbb{Z}$ and that $\sum_{w\in W} \mu_w \cdot Y_w$ is a generator of $\mathrm{H}_n^{\mathrm{simp}}(K)$.

Since K is by definition non-empty we can pick some $w_0 \in W$. We consider the maps

$$\begin{array}{ccccc} \mathbb{Z} & \xrightarrow{\Psi} & \ker(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)) & \xrightarrow{\Theta_{w_0}} & \mathbb{Z} \\ r & \mapsto & r \cdot \sum_{w\in W} \mu_w \cdot Y_w & & \end{array}$$

It follows almost immediately from Claim 1 that the map Ψ to the left is well-defined, in the sense that it takes values in $\ker(\partial_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K))$. Furthermore it is clear that the composition $\Theta_{w_0} \circ \Psi$ is given by multiplication by μ_w, in particular the composition $\Theta_{w_0} \circ \Psi$ is an isomorphism. By Claim 3 we know that Θ_{w_0} is a monomorphism. It follows from this discussion that Ψ is an isomorphism. But that is exactly what we needed to show. ■

The proof of Statement (2) of Theorem 98.4 will require the following elementary lemma.

Lemma 98.5. Let A, B, C and D be abelian groups. We denote by $p_1\colon B \oplus C \to B$ the projection. Now suppose we are given an exact sequence

$$A \xrightarrow{\alpha} B \oplus C \xrightarrow{\varphi} D$$

[1206] Here recall that given a non-zero integer $a \in \mathbb{Z} \setminus \{0\}$ we denote by $\mathrm{sign}(a) := \frac{a}{|a|} \in \{\pm 1\}$ its sign. Also note that we know by hypothesis that at least one $a_w \neq 0$, but then it follows from Claim 2 that all $a_w \neq 0$, in particular it makes sense to consider the signs of the a_w.

of homomorphisms such that the following conditions are satisfied:

(1) the group $B/p_1(\alpha(A))$ is torsion,
(2) the group D is torsion-free,
(3) the map $p_1 \circ \alpha \colon A \to B$ is a monomorphism.

Then the map

$$\begin{array}{rcl} \Theta \colon B/p_1(\alpha(A)) \oplus \ker(C \xrightarrow{c \mapsto \varphi((0,c))} D) & \to & \dfrac{\ker(\varphi \colon B \oplus C \to D)}{\operatorname{im}(\alpha \colon A \to B \oplus C)} \\ ([b], c) & \mapsto & [(b,c)] \end{array}$$

is an isomorphism.

Proof. proof of Lemma 98.5] From our hypotheses (1) and (2) and the exactness of the sequence we easily deduce the following statement:

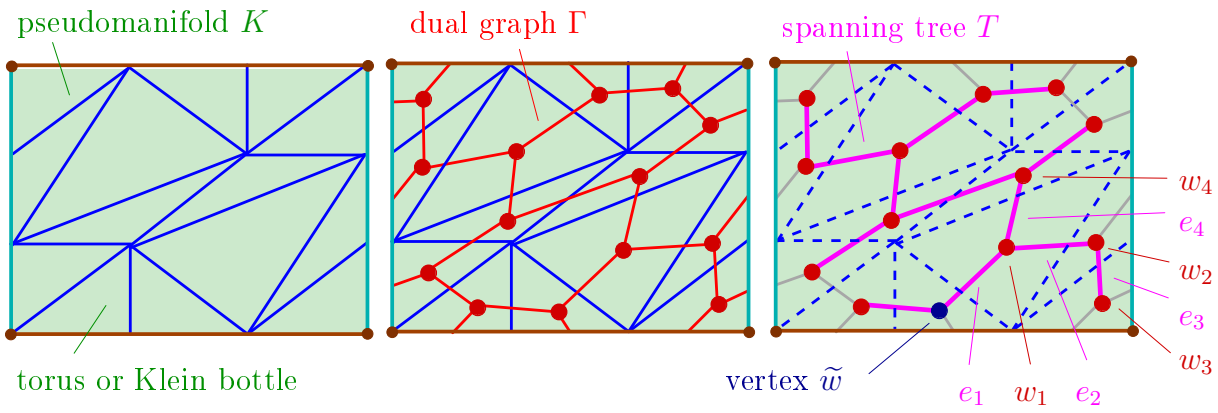
(∗) The map $B \xrightarrow{b \mapsto \varphi((b,0))} D$ is the zero map.

Note that (∗) implies that if $\varphi((b,c)) = 0$, then we also have $\varphi((0,c)) = 0$. From this observation it follows immediately that Θ is an epimorphism. Now suppose we are given $b \in B$ and $c \in \ker(C \to D)$ with $\Theta([b],c) = 0$. This means that there exists an $a \in A$ with $\alpha(a) = (b,c)$. By the exactness of the sequence and by (∗) we know that there exists an $\widetilde{a} \in A$ with $\alpha(\widetilde{a}) = (b,0)$. From (3) we obtain that $a = \widetilde{a}$. Thus we see that $(b,c) = \alpha(a) = \alpha(\widetilde{a}) = (b,0)$. This shows that $[b] = 0 \in B/p_1(\alpha(A))$ and $c = 0$. In other words, we have shown that Θ is a monomorphism. ■

We move on to the proof of Statement (2) of Theorem 98.4.

Proof of Theorem 98.4 (2). Let K be a finite n-dimensional pseudomanifold. Recall that we need to prove the following statements:

(a_1) If K is orientable and closed, then $\mathrm{H}^{\mathrm{simp}}_{n-1}(K)$ is a free abelian group.
(a_2) If $\partial K \neq \varnothing$, then $\mathrm{H}^{\mathrm{simp}}_{n-1}(K)$ is a free abelian group.
(b) If K is non-orientable and if $\partial K = \varnothing$, then $\mathrm{H}^{\mathrm{simp}}_{n-1}(K) \cong F \oplus \mathbb{Z}_2$ where F is a free abelian group.



In the following we will use freely the notation that we introduced in the proof of Statement (1). In particular we consider again the abstract graph $\Gamma = (W, E_2, \varphi)$. Since K is finite we know that Γ is finite, hence by the Spanning Tree Existence Proposition 7.10 (1) we know that there exists a spanning tree T of Γ. Recall that this means that T is connected, that $\chi(T) = 1$ and, by the Spanning Tree Existence Proposition 7.10 (2) it means that T contains every vertex. We pick $\widetilde{w} \in W$. By Lemma 7.8 we know that we can write $W = \{\widetilde{w}, w_1, \ldots, w_k\}$ and $E_2 = \{e_1, \ldots, e_k\}$ such that the following statements hold:

(1) For each $i \in \{1, \ldots, k\}$ the vertex w_i is an endpoint of the edge e_i.
(2) If some vertex w_i is an endpoint of some e_j, then $j \leq i$.

We introduce the following notation. We denote by

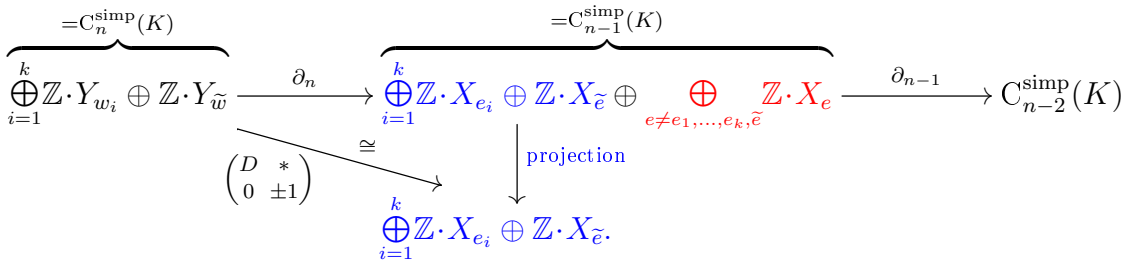
$$p_1 \colon \mathrm{C}^{\mathrm{simp}}_{n-1}(K) \to \bigoplus_{i=1}^{k} \mathbb{Z} \cdot e_i \quad \text{and} \quad p_2 \colon \mathrm{C}^{\mathrm{simp}}_{n-1}(K) \to \bigoplus_{e \in E \setminus \{e_1, \ldots, e_k\}}^{k} \mathbb{Z} \cdot e_i$$

the natural projections.
The key to the proof of Theorem 98.4 (2) is the following observation, which is an immediate consequence of Claim 1 together with the clever choice of $w_1, \ldots, w_k$ and $e_1, \ldots, e_k$.

Observation. The map $\bigoplus_{i=1}^{k}\mathbb{Z}\cdot w_i \xrightarrow{\partial_n} \mathrm{C}_{n-1}^{\mathrm{simp}}(K) \xrightarrow{p_1} \bigoplus_{i=1}^{k}\mathbb{Z}\cdot e_i$ is represented by a matrix of the form

$$D := \begin{pmatrix} \pm 1 & * & \dots & * \\ 0 & \pm 1 & * & \vdots \\ 0 & 0 & \pm 1 & * \\ 0 & 0 & 0 & \pm 1 \end{pmatrix}$$

(a_1) First we assume that K is orientable and closed. Let $\{(\epsilon_w, Y_w)\}_{w\in W}$ be an orientation of K. We set $\mu := \sum_{w\in W}\epsilon_w\cdot Y_w$. Since $\epsilon_{\widetilde{w}} \in \{\pm 1\}$ we see that $Y_{w_1},\dots,Y_{w_k},\mu$ is a basis for $\mathrm{C}_n^{\mathrm{simp}}(K)$. This time we consider the following maps



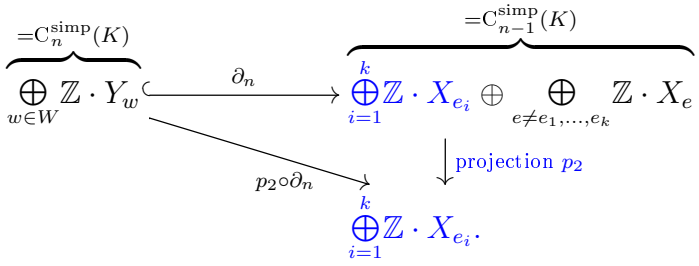
$$\begin{array}{ccccccc} \overbrace{\bigoplus_{i=1}^{k}\mathbb{Z}\cdot Y_{w_i}\oplus\mathbb{Z}\cdot\mu}^{=\mathrm{C}_n^{\mathrm{simp}}(K)} & \xrightarrow[\mu\mapsto 0]{\partial_n} & \overbrace{\bigoplus_{i=1}^{k}\mathbb{Z}\cdot X_{e_i}\oplus\bigoplus_{e\neq e_1,\dots,e_k}\mathbb{Z}\cdot X_e}^{=\mathrm{C}_{n-1}^{\mathrm{simp}}(K)} & \xrightarrow{\partial_{n-1}} & \mathrm{C}_{n-2}^{\mathrm{simp}}(K) \\ \downarrow \text{projection} & \nearrow \partial_n & \downarrow \text{projection } p_2 & & \\ \bigoplus_{i=1}^{k}\mathbb{Z}\cdot Y_{w_i} & \xrightarrow[\cong]{\text{matrix } D} & \bigoplus_{i=1}^{k}\mathbb{Z}\cdot X_{e_i}. & & \end{array}$$

As we already discussed in the proof of Statement (1), since K is closed we obtain from Claim 1 that $\partial_n(\mu) = 0$. Thus the image of ∂_n equals the image of the diagonal map. Furthermore, the bottom horizontal map is represented by the matrix D from the observation, in particular we see that the bottom horizontal map is an isomorphism. From Lemma 98.5 we now obtain the following isomorphism:

$$\underbrace{\ker\left(\bigoplus_{e\neq e_1,\dots,e_k}\mathbb{Z}\cdot X_e \xrightarrow{\partial_{n-1}} \mathrm{C}_{n-2}^{\mathrm{simp}}(K)\right)}_{\substack{\text{subgroup of a free abelian group thus by} \\ \text{Lemma 51.9 (3) it is a free abelian group}}} \xrightarrow{\cong} \underbrace{\frac{\ker\left(\mathrm{C}_{n-1}^{\mathrm{simp}}(K) \xrightarrow{\partial_{n-1}} \mathrm{C}_{n-2}^{\mathrm{simp}}(K)\right)}{\mathrm{im}\left(\mathrm{C}_n^{\mathrm{simp}}(K) \xrightarrow{\partial_n} \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\right)}}_{=\mathrm{H}_{n-1}^{\mathrm{simp}}(K)}.$$

(a_2) Now we assume that $\partial K \neq \varnothing$, i.e. we assume that $E_1 \neq \varnothing$. We pick an $\widetilde{e} \in E_1$. Let $\widetilde{w} \in W$ be the unique n-simplex that cobounds $\widetilde{e}$. We pick $w_1,\dots,w_k$ and $e_1,\dots,e_k$

accordingly. We consider the following maps



It follows easily from the Observation and Claim 1 that the diagonal map is an isomorphism. It now follows from Lemma 98.5 that

$$\underbrace{\ker\left(\bigoplus_{e\neq e_1,\dots,e_k,\widetilde{e}}\mathbb{Z}\cdot X_e\xrightarrow{\partial_{n-1}}\mathrm{C}_{n-2}^{\mathrm{simp}}(K)\right)}_{\substack{\text{subgroup of a free abelian group thus by}\\ \text{Lemma 51.9 (3) it is a free abelian group}}}\xrightarrow{\cong}\underbrace{\frac{\ker\left(\mathrm{C}_{n-1}^{\mathrm{simp}}(K)\xrightarrow{\partial_{n-1}}\mathrm{C}_{n-2}^{\mathrm{simp}}(K)\right)}{\mathrm{im}\left(\mathrm{C}_n^{\mathrm{simp}}(K)\xrightarrow{\partial_n}\mathrm{C}_{n-1}^{\mathrm{simp}}(K)\right)}}_{=\mathrm{H}_{n-1}^{\mathrm{simp}}(K)}.$$

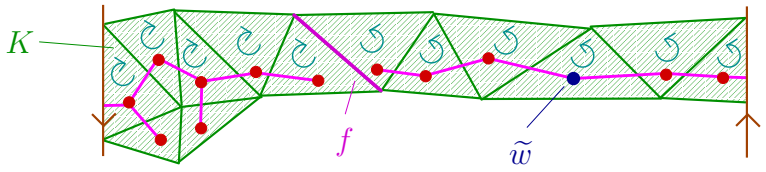
But the group on the right hand side is the subgroup of a finitely generated free abelian group, so it follows from Lemma 51.9 (3) that it is itself a finitely generated free abelian group.

(b) Finally we assume that K is closed and non-orientable. First we consider the following maps:

By our hypothesis that K is closed and non-orientable, together with Statement (1), we know that $\mathrm{H}_n^{\mathrm{simp}}(K)=0$. This means that the horizontal map is a monomorphism. On the other hand, for rank reasons the diagonal map $p_2\circ\partial_n$ has a kernel. In other words, there exists some non-zero $\mu=\sum_{w\in W}a_w\cdot Y_w\in\mathrm{C}_n^{\mathrm{simp}}(K)$ with $p_2(\partial_n(\mu))=0$. By Claim 2 we know that the value $|a_w|$ is constant. Thus after dividing by this constant (which is non-zero since μ is non-zero) we can arrange that each $|a_w|=1$.

Since K is by hypothesis closed, i.e. since each edge has order 2, we see, say by the calculation in the proof of Claim 1 or by direct inspection, that for each $e\in E$ the X_e-coefficient of $\partial_n(\mu)$ lies in $\{0,\pm 2\}$. Furthermore since ∂_n is a monomorphism we know that $\partial_n(\mu)\neq 0$. Thus there exists some $f\in E$ such that the f-coefficient of $\partial_n(\mu)$ equals ± 2. From $p_2(\partial_n(\mu))=0$ we obtain that $f\neq e_1,\dots,e_k$. Next we

consider the following maps:



$$\overbrace{\bigoplus_{i=1}^{k}\mathbb{Z}\cdot Y_{w_i}\oplus\mathbb{Z}\cdot\mu}^{=\mathrm{C}_n^{\mathrm{simp}}(K)}\xrightarrow{\partial_n}\overbrace{\bigoplus_{i=1}^{k}\mathbb{Z}\cdot X_{e_i}\oplus\mathbb{Z}\cdot X_f\oplus\bigoplus_{e\neq e_1,\dots,e_k,f}\mathbb{Z}\cdot X_e}^{=\mathrm{C}_{n-1}^{\mathrm{simp}}(K)}\xrightarrow{\partial_{n-1}}\mathrm{C}_{n-2}^{\mathrm{simp}}(K)$$

$$\begin{pmatrix} D & * \\ 0 & \pm 2 \end{pmatrix}\cong\bigoplus_{i=1}^{k}\mathbb{Z}\cdot X_{e_i}\oplus\mathbb{Z}\cdot X_f \quad\text{(projection)}$$

Finally we note that it follows from the above together with Lemma 98.5 that the following map is an isomorphism:

$$\underbrace{\ker\left(\bigoplus_{e\neq e_1,\dots,e_k,f}\mathbb{Z}\cdot X_e\to\mathrm{C}_{n-2}^{\mathrm{simp}}(K)\right)}_{\text{subgroup of a free abelian group thus by Lemma 51.9 (3) it is a free abelian group}}\oplus\underbrace{\mathbb{Z}^{k+1}\Big/\begin{pmatrix} D & * \\ 0 & \pm 2 \end{pmatrix}\mathbb{Z}^{k+1}}_{\cong\mathbb{Z}_2\text{ by the observation}}\to\underbrace{\frac{\ker\left(\mathrm{C}_{n-1}^{\mathrm{simp}}(K)\to\mathrm{C}_{n-2}^{\mathrm{simp}}(K)\right)}{\mathrm{im}\left(\mathrm{C}_{n}^{\mathrm{simp}}(K)\to\mathrm{C}_{n-1}^{\mathrm{simp}}(K)\right)}}_{=\mathrm{H}_{n-1}^{\mathrm{simp}}(K)}.$$

We have thus finished the proof of Theorem 98.4 (2). ■

Finally we get to the proof of the last statement of Theorem 98.4 (3).

Proof of Theorem 98.4 (3). Let K be a finite n-dimensional pseudomanifold. First we point out that it would be a fun exercise to modify the proof of (1) to obtain the promised result. But in these notes we will not pursue this approach. Instead we will do a little trick. First we consider the case that K is closed. In this case we perform the following calculation:

$$\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2)\ \cong\ \mathrm{H}_n^{\mathrm{simp}}(K)\otimes\mathbb{F}_2\oplus\mathrm{Tor}(\mathrm{H}_{n-1}^{\mathrm{simp}}(K),\mathbb{F}_2)\ \cong\ \begin{cases}\overbrace{\mathbb{Z}\otimes\mathbb{F}_2\oplus\mathrm{Tor}(\mathbb{Z}^l,\mathbb{F}_2)}^{\text{if } K \text{ is orientable}}\\ \underbrace{0\otimes\mathbb{F}_2\oplus\mathrm{Tor}(\mathbb{Z}^l\oplus\mathbb{Z}_2,\mathbb{F}_2)}_{\text{if } K \text{ is non-orientable}}\end{cases}\ \cong\ \mathbb{F}_2.$$

by the Algebraic Universal Coefficient Theorem 89.16 applied to the chain complex $\mathrm{C}_*^{\mathrm{simp}}(K)$ — by (1) and (3) — Tensor Lemma 89.3 and 89.15

Now suppose that $Y_1,\dots,Y_m$ is a set of ordered n-simplices of K such that for each n-simplex s of K there exists a unique $i\in\{1,\dots,m\}$ with $s=\lfloor Y_i\rfloor$. One easily verifies that the simplicial chain $Y_1\otimes 1+\cdots+Y_m\otimes 1\in\mathrm{C}_n^{\mathrm{simp}}(K;\mathbb{F}_2)=\mathrm{C}_n^{\mathrm{simp}}(K)\otimes\mathbb{F}_2$ is a simplicial cycle. Since it is non-zero we see that it equals necessarily the unique non-zero element of $\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2)=\ker(\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2)\to\mathrm{H}_{n-1}^{\mathrm{simp}}(K;\mathbb{F}_2))\cong\mathbb{F}_2$.

Finally if the pseudomanifold K is not closed, then the above approach shows almost immediately that $\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2)=0$. With a slight sigh of relief we note that we have now finally managed to prove all three statements of Theorem 98.4. ■

98.2. **The top-dimensional homology group of a smooth manifold.** As the reader surely expected, the main application of Theorem 98.4 is the following theorem which gives us lots of interesting extra information on the homology groups of smooth manifolds.

Theorem 98.6. (Smooth Manifold-Top Homology Theorem) Let M be a connected non-empty n-dimensional smooth manifold. The following statements hold:

(1) We have an isomorphism as follows:

$$\mathrm{H}_n(M;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ is closed and orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

(2) If M is compact, then we also have an isomorphism as follows:

$$\mathrm{H}_{n-1}(M;\mathbb{Z}) \cong \begin{cases} \text{free abelian group}, & \text{if } M \text{ is orientable or if } \partial M \neq \varnothing, \\ \text{free abelian group} \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable and closed.} \end{cases}$$

In both cases the free abelian group is finitely generated.

(3) If M is compact, then

$$\mathrm{H}_n(M;\mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } M \text{ is closed, regardless whether or not } M \text{ is orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

Examples.

(1) Let $k \in \mathbb{N}$. We consider $k \cdot \mathbb{R}\mathrm{P}^2$, i.e. we consider the connected sum of k copies of $\mathbb{R}\mathrm{P}^2$. By Exercise **??** we know that $k \cdot \mathbb{R}\mathrm{P}^2$ is non-orientable. In Proposition 80.10 we showed that

$$\mathrm{H}_1(\underbrace{k \cdot \mathbb{R}\mathrm{P}^2}_{=N_k};\mathbb{Z}) \cong \mathbb{Z}^{k-1} \oplus \mathbb{Z}_2 \quad \text{and} \quad \mathrm{H}_2(k \cdot \mathbb{R}\mathrm{P}^2;\mathbb{Z}) = 0.$$

This is reassuringly consistent with the Smooth Manifold-Top Homology Theorem 98.6.

(2) Recall that the Möbius band M is a compact non-orientable 2-dimensional smooth manifold with non-empty boundary. Since M is homotopy equivalent to S^1 we see that $\mathrm{H}_1(M;\mathbb{Z}) \cong \mathrm{H}_1(S^1;\mathbb{Z}) \cong \mathbb{Z}$. This example illustrates that in the Smooth Manifold-Top Homology Theorem 98.6 the "$\mathbb{Z}_2$"-term for a non-orientable smooth manifold only appears if M is closed.

(3) In Chapter 105 we will make sense of the notion of an orientable topological manifold. We will prove the generalization of the Smooth Manifold-Top Homology Theorem 98.6 to the setting of topological manifolds in Theorems 106.1, 106.2 and 106.3 and Proposition 106.22. These new results completely subsume the Smooth Manifold-Top Homology Theorem 98.6. Nonetheless it is worth covering the above proof since it is fairly geometric, whereas the latter proofs for topological manifolds are rather unintuitive.

Proof of the Smooth Manifold-Top Homology Theorem 98.6. Let M be a connected non-empty n-dimensional smooth manifold. Note that by the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a smooth simplicial structure $(K = (V,S), \Theta\colon |K| \to M)$. By the Manifold-Simplex Proposition 98.1 we know that K is an n-dimensional pseudomanifold. Evidently now we would like to apply Theorem 98.4 and call it a day.

But to do so we need to show that the hypotheses on the smooth manifolds do indeed match the corresponding hypotheses for pseudomanifolds. Let us start with the good news:

(1) By Lemma 93.9 (1) and the Simplicial Complex-Finiteness Proposition 93.12 we know that M is compact if and only if K is finite.
(2) From the Manifold-Simplex Proposition 98.1 (1), (3) and (4) we obtain that $\partial M = \varnothing$ if and only if $\partial K = \varnothing$.

Here is the bad news: We still have to relate the (non-) orientability of the smooth manifold M to the (non-) orientability of the abstract simplicial complex K. This will be done in the subsequent Proposition 98.7. ■

The following proposition gives us the last piece of the proof of the Smooth Manifold-Top Homology Theorem 98.6.

Proposition 98.7. (Pseudomanifold-Orientation Proposition) Let $n \in \mathbb{N}$ and let M be a connected non-empty n-dimensional smooth manifold.[1207] Furthermore let $(K = (V,S), \Theta\colon |K| \to M)$ be a smooth simplicial structure. The map

$$\left\{\begin{array}{c}\text{orientations of the smooth}\\ \text{manifold } M \text{ in the sense of the}\\ \text{definition on page 675}\end{array}\right\} \xrightarrow{\cong} \left\{\begin{array}{c}\text{orientations of the}\\ \text{pseudomanifold } K \text{ in the sense}\\ \text{of the definition on page 2142}\end{array}\right\}.$$

$$\begin{array}{rl} & \text{for each } n\text{-simplex } s \text{ we pick a corresponding}\\ & \text{ordered simplex } Y_s \text{ and we consider}\\ \text{orientation of } M \mapsto & \text{the oriented } n\text{-simplex } [(\epsilon_s, Y_s)] \text{ where}\\ & \epsilon_s = +1 \text{ if } \Theta \circ \Phi^{\leq}_{Y_s} : \mathring{\Delta}^n \to M \text{ is orientation-pres.}\\ & \epsilon_s = -1 \text{ if } \Theta \circ \Phi^{\leq}_{Y_s} : \mathring{\Delta}^n \to M \text{ is orientation-rev.}\end{array}$$

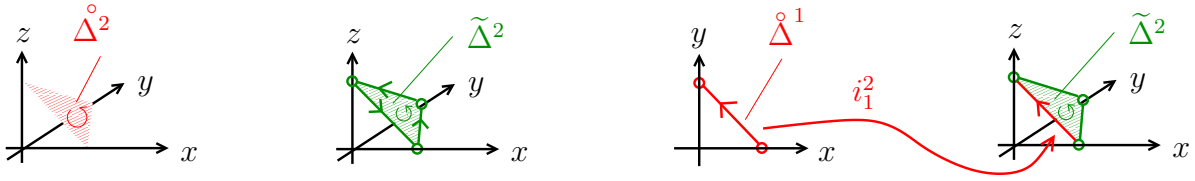
is a natural bijection.[1208] In particular the smooth manifold M is orientable if and only if the pseudomanifold K is orientable.

Proof of Proposition 98.7. In the following we will provide a proof of Proposition 98.7. To preserve the author's sanity we will skip a few technical calculations. We leave it to the reader to fill in the details.

Throughout the proof let M be a non-empty n-dimensional smooth manifold and let $(K = (V,S), \Theta\colon |K| \to M)$ be a smooth simplicial structure. First note that the case $n = 0$ is trivial, since every 0-dimensional smooth manifold and every 0-dimensional pseudomanifold is orientable. Thus in the following we assume that $n > 0$. Before we do anything else we recall and introduce a few definitions and we make a few basic comments regarding these definitions.

(a) Let $k \in \mathbb{N}_0$. On page 1581 we introduced

$$\mathring{\Delta}^k := \{(t_0, \ldots, t_k) \in \Delta^k \,|\, \text{all coordinates are non-zero}\}.$$



Now we also define

$$\widetilde{\Delta}^k := \{(t_0, \ldots, t_k) \in \Delta^k \,|\, \text{at least two coordinates are non-zero}\}.$$

[1207] We do not impose any other conditions, in particular neither do we assume that M is compact nor do we assume that $\partial M = \varnothing$.
[1208] We leave it to the reader to figure out what "natural" means in this context.

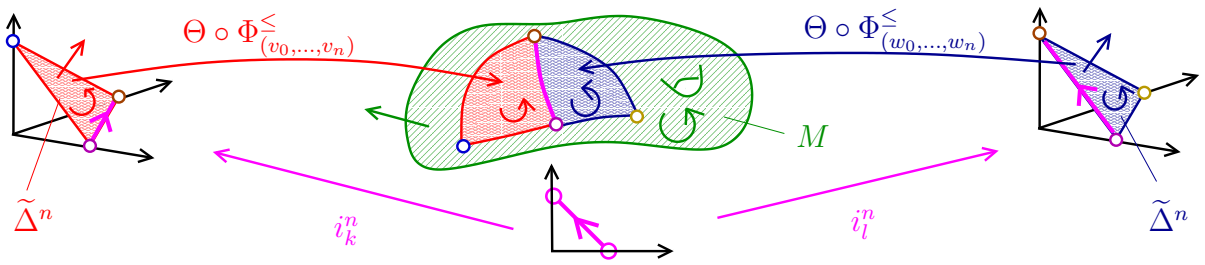
(b) Similar to the discussion on page 1581 we view $\mathring{\Delta}^k$ and $\widetilde{\Delta}^k$ in the obvious way[1209] as smooth manifolds. Note that $\mathring{\Delta}^k$ has no boundary and that the boundary of $\widetilde{\Delta}^k$ equals $\widetilde{\Delta}^k \cap \partial\Delta^k$. We equip the smooth manifolds $\mathring{\Delta}^k$ and $\widetilde{\Delta}^k$ with the orientation where for each $P \in \mathring{\Delta}^k$ a basis $v_1, \ldots, v_k$ of $\widetilde{\mathrm{T}}_P\mathring{\Delta}^k$ is positive if the vectors $\{(1, \ldots, 1), v_1, \ldots, v_k\}$ are a positive basis for $\mathbb{R}^{k+1}$. As always we endow the boundary $\partial\widetilde{\Delta}^k$ of the oriented smooth manifold $\widetilde{\Delta}^k$ with the orientation given by the Boundary Orientation Lemma 25.17.

(c) Note that for any $j \in \{0, \ldots, k\}$ the usual j-th face map $i^k_j \colon \Delta^{k-1} \to \Delta^k$ restricts to an embedding $i^k_j \colon \mathring{\Delta}^{k-1} \to \partial\widetilde{\Delta}^k \subset \widetilde{\Delta}^k$. Using the Basics-of-Orientations Lemma 25.13 (2) it is straightforward to verify that the map $i^k_j \colon \mathring{\Delta}^{k-1} \to \partial\widetilde{\Delta}^k$ is orientation-preserving if and only if j is even.

(d) Let $k \in \mathbb{N}_0$ and let $Y = (v_0, \ldots, v_k)$ be an ordered k-simplex of $K = (V, S)$. On page 1984 we introduced the corresponding characteristic map

$$\begin{aligned} \Phi^{\leq}_Y \colon \Delta^k = \left\{ (t_0, \ldots, t_k) \in \mathbb{R}^{k+1}_{\geq 0} \;\middle|\; \sum_{i=0}^k t_i = 1 \right\} &\to |K| \\ (t_0, \ldots, t_k) &\mapsto \sum_{i=0}^k t_i \cdot v_i. \end{aligned}$$

(e) It follows almost immediately from the definition of a "smooth" simplicial structure, see page 2082, that for every ordered k-simplex $Y = (v_0, \ldots, v_k)$ the map $\Theta \circ \Phi^{\leq}_Y \colon \widetilde{\Delta}^n \to M$ is an immersion.



Now we turn to the actual proof of the proposition.

First we assume that we are given an orientation of the smooth manifold M. We need to equip the pseudomanifold $K = (V, S)$ with a natural orientation. We say that an ordered n-simplex $Y = (v_0, \ldots, v_n)$ is *positive* if the map $\Theta \circ \Phi^{\leq}_Y \colon \mathring{\Delta}^n \to M$ is orientation-preserving in the sense of the definition on page 682. Since $n \geq 1$ we see easily that, by possibly swapping the order of two vertices, we can find for each n-simplex $s \in S$ a positive ordered n-simplex Y_s with $\lfloor Y_s \rfloor = s$. It remains to prove the following claim.

Claim 1. The oriented n-simplices $[(+1, Y_s)]$ form an orientation of the pseudomanifold K.

Proof. Let e be an $(n-1)$-simplex of K of order 2 and let s, t be the two n-simplices that cobound e. We need to show that the orientations $[(+1, Y_s)]$ and $[(+1, Y_t)]$ induce opposite orientations on e. We write $Y_s = (v_0, \ldots, v_n)$ and we write $Y_t = (w_0, \ldots, w_n)$. Let v_k be

[1209] Slightly more precisely, a smooth atlas for $\mathring{\Delta}^k$ is given by projection to the first k coordinates, and for $\widetilde{\Delta}^k$ we obtain a smooth atlas by the same projection and an affine linear map that sends points on a component of $\widetilde{\Delta}^k \cap \partial\Delta^k$ into the $(k-1)$-hyperplane.

the vertex missing in e and let w_l be the vertex missing in e. We consider the maps

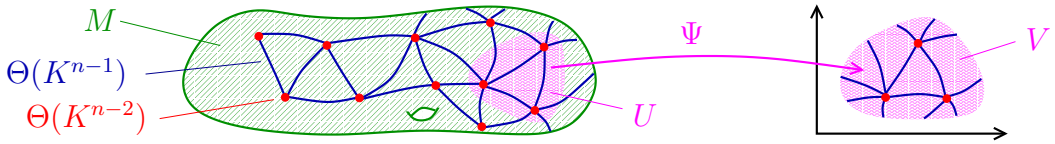
$$\mathring{\Delta}^{n-1} \xrightarrow{i^n_k} \widetilde{\Delta}^n \xrightarrow{\Theta\circ\Phi^{\leq}_{(v_0,\ldots,v_n)}} M \xleftarrow{\Theta\circ\Phi^{\leq}_{(w_0,\ldots,w_n)}} \widetilde{\Delta}^n \xleftarrow{i^n_l} \mathring{\Delta}^{n-1}.$$

The two maps $\mathring{\Delta}^{n-1} \to M$ are immersions and the images coincide, thus we obtain a self-diffeomorphism of $\mathring{\Delta}^{n-1}$. A little bit of thought, using (c) and using the Basics-of-Orientations Lemma 25.13 (2), shows that this map is orientation-preserving if and only if $k+l+1$ is even.[1210] Next we need to associate to each orientation of the pseudomanifold K an orientation of the smooth manifold M. Thus suppose we are given an orientation $\{(\mu_s, Y_s)\}_{s\in S}$ of the pseudomanifold K. Since $n > 0$ we can and will assume that for each n-simplex s we have $\mu_s = 1$.

Claim 2. The smooth manifold $M \setminus \Theta(K^{n-2})$ has a natural orientation.[1211]

Proof. Let $P \in M \setminus \Theta(K^{n-2})$. Since every $(n-1)$-simplex is the face of an n-simplex we see that there exists an n-simplex s with $P \in \Theta(|s|)$. Since $P \notin \Theta(K^{n-2})$ we see that there exists a $Q \in \widetilde{\Delta}^n$ such that $P = \Phi^{\leq}_{Y_s}(Q)$. Since $\Phi^{\leq}_{Y_s} \colon \widetilde{\Delta}^n \to M$ is an immersion we know that the induced map $\mathrm{T}_Q\widetilde{\Delta}^k \to \mathrm{T}_P M$ is an isomorphism. Thus it makes sense to equip $\mathrm{T}_P M$ with the image of the positive orientation of $\widetilde{\Delta}^n$ under the above isomorphism. We need to show that the definition of the orientation does not depend on the choice of s. If $P \in M \setminus \Theta(K^{n-1})$, then we know from Open Simplex Lemma 93.11 that s is unique, hence we are done. Otherwise there exists an $(n-1)$-simplex e such that $P \in \Theta(\langle e \rangle)$. If the order of e equals one, then s is again unique and again we are done. Finally if the order of e equals two, then it follows from the hypothesis that $\{(\mu_s, Y_s)\}_{s\in S}$ is an orientation of K. A reasonably elementary calculation shows that the orientation on $\mathrm{T}_P M$ does not depend on the choice of the cobounding n-simplex. Finally we note that it is fairly straightforward to show that these orientations of the tangent spaces define an orientation, in the sense of the definition on page 675, of the smooth submanifold $M \setminus \Theta(K^{n-2})$. ⊞

We move on to the next claim.



Claim 3. For every open connected subset U of M the following holds:

(a) The set $U \cap (M \setminus \Theta(K^{n-2}))$ is connected.
(b) The closure of $U \cap (M \setminus \Theta(K^{n-2}))$ equals U.

[1210] Also note that the fact that $\mathring{\Delta}^n$ is dense in $\widetilde{\Delta}^n$ implies that the map $\Theta \circ \Phi^{\leq}_{\widetilde{Y}} \colon \widetilde{\Delta}^n \to M$ is also orientation-preserving.

[1211] Note that by Lemma 93.8 we know that $M \setminus \Theta(K^{n-2})$ is an open subset of M, in particular it is a smooth submanifold of M.

Proof. For $i = 0, \ldots, n-2$ we set $N_i = U \cap (M \setminus \Theta(K^{i-1}))$ and we set $Y_i = \Theta(K^i) \cap N_i$. Note that for each $i \in \{1, \ldots, n-2\}$ we have $N_i = N_{i-1} \setminus Y_{i-1}$. It follows easily from the definition of a smooth simplicial structure together with Lemma 93.8 that each N_i is an n-dimensional smooth manifold and that each Y_i is a proper i-dimensional smooth submanifold of N_i. Since $i \leq n-2$ we obtain iteratively from the future Corollary 42.6 and the hypothesis that $N_0 = U$ is path-connected that each N_i is path-connected. Finally note that we know by Exercise 19.15 and the fact that $\dim(Y_i) = i < n = \dim(N_i)$ that the closure of $N_i \setminus Y_i$ is N_i. Note that the statements of Claim 3 follow almost immediately from these considerations.

Finally let $P \in M$. It follows quite easily from Claim (3a) that we can find a chart $\Psi\colon U \to V$ around P such that V is a connected open subset of $\mathbb{R}^n$ or $\mathbb{H}^n$ and such that Ψ is orientation-preserving for some $Q \in M \setminus \Theta(K^{n-2})$. Furthermore it follows from Claim (3a) and the Basics-of-Orientations Lemma 25.13 (2) that the restriction of Ψ to $U \setminus \Theta(K^{n-2})$ is orientation-preserving at every point. Now we equip all $Q \in U$ with the orientation induced by Ψ and the standard orientation of $\mathbb{R}^n$ respectively $\mathbb{H}^n$. It follows easily from Claim (3b) that these orientations do not depend on the choice of Ψ and that these orientations of the tangent spaces define an orientation of the smooth manifold M.

In the above discussion we constructed natural maps

$$\{\text{orientations of the smooth manifold } M\} \leftrightarrow \{\text{orientations of the pseudomanifold } K\}$$

in both directions. It follows reasonably easily from the definitions that the two maps are inverses of one another, thus both maps are natural bijections. ■

For manifolds with non-empty boundary the following theorem contains lots of extra information.

Theorem 98.8. Let M be a connected non-empty n-dimensional smooth manifold. The following statements hold:

(1) We have an isomorphism as follows:

$$\mathrm{H}_n(M, \partial M; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ is orientable and compact,} \\ 0, & \text{otherwise.} \end{cases}$$

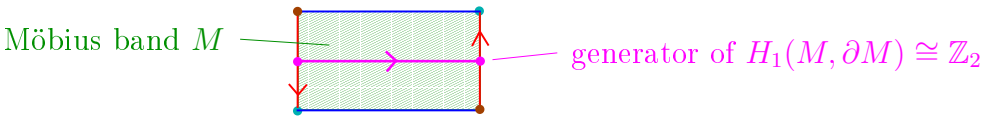
(2) If M is compact, then we also have an isomorphism as follows:

$$\mathrm{H}_{n-1}(M, \partial M; \mathbb{Z}) \cong \begin{cases} \text{free abelian group}, & \text{if } M \text{ is orientable,} \\ \text{free abelian group} \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable.} \end{cases}$$

In both cases the free abelian group is finitely generated.

(3) If M is compact, then we have $\mathrm{H}_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$.

Remark.



(1) Note that if M is a connected non-empty smooth manifold with $\partial M = \varnothing$, then the statements of Theorem 98.8 are contained in the Smooth Manifold-Top Homology Theorem 98.6.

(2) We will prove the generalization of the Smooth Manifold-Top Homology Theorem 98.6 to the setting of topological manifolds in Theorems 106.1 and 106.2 and Proposition 106.22.

Example. Let M be the Möbius band. Recall that M is a compact non-orientable 2-dimensional smooth manifold. In Exercise 74.7 we already saw that

$$\mathrm{H}_k(M, \partial M; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}_2, & \text{if } k = 1, \\ 0, & \text{otherwise.} \end{cases}$$

This calculation is of course consistent with Theorem 98.8.

Proof. Let M be a connected non-empty n-dimensional smooth manifold. We dealt with the case $\partial M = \varnothing$ in the Smooth Manifold-Top Homology Theorem 98.6 so we might as well assume that $\partial M \neq \varnothing$.

In the following we first sketch what we think should be the "correct" proof of Theorem 98.8 (1). Afterwards we will give the full details for an alternative proof.

(a) As before one uses the Smooth Manifold-Simplicial Structure Theorem 96.2 to equip M with some smooth simplicial structure $(K, \Theta\colon |K| \to M)$. It follows from the Manifold-Simplex Proposition 98.1 that K is an n-dimensional pseudomanifold such that ∂M corresponds precisely to ∂K.

(b) By the Simplicial-Singular Homology Isomorphism Lemma 95.30 we have a natural isomorphism $\mathrm{H}_n^{\mathrm{simp}}(K, \partial K) \xrightarrow{\cong} \mathrm{H}_n(|K|, |\partial K|; \mathbb{Z})$.

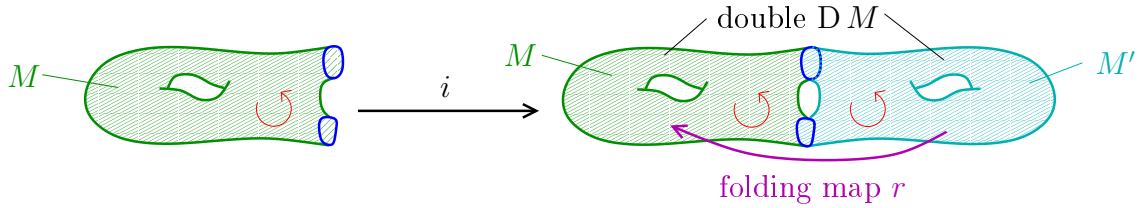
(c) It is fairly straightforward to modify the argument of Theorem 98.4 to show that one has an isomorphism

$$\mathrm{H}_n^{\mathrm{simp}}(K, \partial K) \cong \begin{cases} \mathbb{Z}, & \text{if } K \text{ is orientable and finite,} \\ 0, & \text{otherwise.} \end{cases}$$

(d) By Proposition 98.7 we know that M is orientable if and only if K is orientable. The desired Statement (1) now follows from the combination of all of the above.

The above approach is surely convincing and it is relatively straightforward to work out the details. Furthermore the same approach can also be employed to settle Statements (2) and (3).

Now we turn to our second approach to proving the proposition. This second approach has the advantage that this time we can provide all the details. Given M we consider its double $\mathrm{D}M = M \cup_{\partial M = \partial M'} M'$ where M' is a second copy of M. We refer to page 1667 for details and we refer to the figure below for an illustration. Recall that by the Doubling-Manifold Lemma 75.12 we know the following:



(a) The double $\mathrm{D}M$ is also an n-dimensional smooth manifold such that $M \subset \mathrm{D}M$ is a smooth submanifold.

(b) The boundary of the double $\mathrm{D}M$ is empty.

(c) M is orientable if and only if $\mathrm{D}M$ is orientable.

(d) M is connected if and only if $\mathrm{D}M$ is connected.

(e) M is compact if and only if $\mathrm{D}M$ is compact.

In the following we denote by $i\colon M \to \mathrm{D}M$ the natural inclusion and we denote by $r\colon \mathrm{D}M \to M$ the folding map that we introduced on page 1668. Given $k \in \mathbb{N}_0$ we consider the following maps:

$$\begin{array}{ccccccccccc} & & & & & & \mathrm{H}_k(M,\partial M) & & & & \\ & & & & & & \downarrow\cong & & & & \\ \ldots & \longrightarrow & \mathrm{H}_k(M) & \underset{r_*}{\overset{i_*}{\hookrightarrow}} & \mathrm{H}_k(\mathrm{D}M) & \longrightarrow & \mathrm{H}_k(\mathrm{D}M,M) & \xrightarrow{\partial} & \mathrm{H}_{k-1}(M) & \underset{r_*}{\overset{i_*}{\hookrightarrow}} & \mathrm{H}_{k-1}(\mathrm{D}M) \longrightarrow \ldots \end{array}$$

We make the following observations:

(f) The horizontal sequence is the long exact sequence in homology corresponding to the pair $(\mathrm{D}M, M)$.

(g) Since $r \circ i = \mathrm{id}_M$ we have $r_* \circ i_* = \mathrm{id}_{\mathrm{H}_k(M)}$, which implies that $i_*\colon \mathrm{H}_k(M) \to \mathrm{H}_k(\mathrm{D}M)$ is a monomorphism.

(h) By the Doubling-Manifold Lemma 75.12 we know that the vertical map is an isomorphism.

Next we recall some of our earlier calculations:

(i) Since $\partial M \neq \varnothing$ we obtain from the Smooth Manifold-Top Homology Theorem 98.6 that $\mathrm{H}_n(M) = 0$ and that $\mathrm{H}_{n-1}(M)$ is a free abelian group.

(j) By the Smooth Manifold-Top Homology Theorem 98.6 we have

$$\mathrm{H}_n(\mathrm{D}M) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } \mathrm{D}M \text{ is closed and orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

(k) By the Smooth Manifold-Top Homology Theorem 98.6 and since $\partial(\mathrm{D}M) = \varnothing$ we have

$$\mathrm{H}_{n-1}(\mathrm{D}M) \;\cong\; \begin{cases} \text{free abelian group}, & \text{if } \mathrm{D}M \text{ is orientable,} \\ \text{free abelian group} \oplus \mathbb{Z}_2, & \text{if } \mathrm{D}M \text{ is non-orientable.} \end{cases}$$

Now we turn to the actual proofs of the three statements of the proposition.

(1) By the above we have an exact sequence

$$0 \longrightarrow \underbrace{\mathrm{H}_n(M)}_{=0} \underset{r_*}{\overset{i_*}{\hookrightarrow}} \mathrm{H}_n(\mathrm{D}M) \longrightarrow \underbrace{\mathrm{H}_n(\mathrm{D}M, M)}_{\cong \mathrm{H}_n(M,\partial M)} \xrightarrow{\partial} 0.$$

The desired statement now follows from (a)–(h) together with (i) and (j).

(2) By the above we have an exact sequence:

$$0 \longrightarrow \underbrace{\mathrm{H}_{n-1}(M)}_{\text{free abelian}} \underset{r_*}{\overset{i_*}{\rightleftarrows}} \mathrm{H}_{n-1}(\mathrm{D}M) \longrightarrow \underbrace{\mathrm{H}_{n-1}(\mathrm{D}M, M)}_{\cong \mathrm{H}_{n-1}(M,\partial M)} \xrightarrow{\partial} 0.$$

Since $r_* \circ i_* = \mathrm{id}_{\mathrm{H}_{n-1}(M)}$ we obtain from Splitting Lemma 78.2 and the above discussion that $\mathrm{H}_{n-1}(\mathrm{D}M) \cong \mathrm{H}_{n-1}(M, \partial M) \oplus$ free abelian group. The desired statement follows from (a)–(h) together with (k) and Lemma 51.9.

(3) We can deduce this statement from the Smooth Manifold-Top Homology Theorem 98.6 (3) using a slight variation on the above arguments. Alternatively we can deduce (3) from (1) and (2) using the Universal Coefficient Theorem 89.17, the same way that we deduced the Smooth Manifold-Top Homology Theorem 98.6 (3) from the Smooth Manifold-Top Homology Theorem 98.6 (1) and (2). ■

98.3. **Homology groups of lens spaces.** In this section we will apply the results from the previous sections to complete the long overdue calculation of the homology groups of lens spaces.

Lemma 98.9. (Lens Space Homology Lemma) Let $p \in \mathbb{N}$ and let $q \in \mathbb{Z}$ be coprime to p. For the corresponding lens space $L(p, q)$ we have

$$\mathrm{H}_n(L(p,q); \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 3, \\ 0, & \text{if } n = 2 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases}$$

Remark. An alternative approach to computing the homology groups of lens spaces will be given in Exercise 146.2.

The calculation of this lemma is rather disappointing, it shows that homology groups cannot distinguish between two lens spaces of the form $L(p, q)$ and $L(p, r)$. In particular we have made no progress at all on Question 48.7.

Proof. We start out with the following observations:

(1) It follows from the Actions-Covering Proposition 48.9 and the definition of a lens space that $L(p, q)$ is finitely covered by S^3. It follows from $\chi(S^3) = 0$ together with Proposition 69.4 that $\chi(L(p, q)) = 0$.
(2) Note that on page 1075 we pointed out that every lens space $L(p, q)$ is a closed orientable connected 3-dimensional smooth manifold.
(3) We already know from the H_0-Proposition 72.5 that $\mathrm{H}_0(L(p, q)) \cong \mathbb{Z}$.
(4) By Corollary 84.6 we know that $\mathrm{H}_1(L(p, q)) \cong \mathbb{Z}_p$.
(5) By (2) and the Smooth Manifolds-Invariants Proposition 96.6 (or alternatively the Top-Homology Theorem 106.3) we know that $\mathrm{H}_n(L(p, q)) = 0$ for $n \geq 4$.
(6) By the Smooth Manifold-Top Homology Theorem 98.6 (1) and (2) (or alternatively by the Orientation-Top Homology Theorem 106.1) we know that $\mathrm{H}_3(L(p, q)) \cong \mathbb{Z}$.

Thus at the moment we are still missing $\mathrm{H}_2(L(p,q))$. Now note that

$$\operatorname{rank}\mathrm{H}_2(L(p,q)) \overset{\text{by the Euler Characteristic-H}_*\text{-Proposition 87.1}}{\downarrow} = \underbrace{\chi(L(p,q))}_{=0} - \underbrace{\operatorname{rank}\mathrm{H}_0(L(p,q))}_{=1} + \underbrace{\operatorname{rank}\mathrm{H}_1(L(p,q))}_{=0} + \underbrace{\operatorname{rank}\mathrm{H}_3(L(p,q))}_{=1} = 0.$$

Furthermore we know by the Smooth Manifold-Top Homology Theorem 98.6 (2) that $\mathrm{H}_2(L(p,q))$ is a finitely generated free abelian group. Therefore we see that $\mathrm{H}_2(L(p,q)) = 0$. ■

98.4. **The Poincaré Homology Sphere.** We start out with the following almost self-explanatory definition of a homology sphere.

Definition.

(1) We say that an n-dimensional topological manifold X is a topological homology n-sphere if for every $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(X;\mathbb{Z}) \cong \mathrm{H}_k(S^n;\mathbb{Z})$. Sometimes we also just say homology n-sphere.
(2) Sometimes, for disambiguation we also refer to such a topological manifold as an integral homology n-sphere.
(3) If X is actually a smooth manifold, then we refer to X as a smooth homology n-sphere.

Lemma 98.10. Let M be a smooth manifold. If M is a homology n-sphere, then M is closed, orientable and connected.

Proof. The lemma is an immediate consequence of the H_0-Proposition 72.5 and the Smooth Manifold-Top Homology Theorem 98.6. ■

It follows from the Topological 1-Dimensional Manifold Classification Theorem 22.1 and the Surface Classification Theorem 55.4 and the calculation of homology groups in Proposition 80.10 that for $n = 1, 2$ every homology n-sphere is homeomorphic to the standard sphere S^n. In 1900 Henri Poincaré [**Poi1900**],[**PGL1953**, p. 370] claimed that the same statement also holds for $n = 3$, i.e. he claimed that every homology 3-sphere is in fact homeomorphic to S^3.[1212] Shortly afterwards, in 1904, Henri Poincaré [**Poi1904, PGL1953**] himself found a counterexample to this claim. More precisely, he proved the following proposition.

Proposition 98.11. There exists a 3-dimensional smooth manifold M that is a homology 3-sphere, but such that $\pi_1(M)$ is a non-trivial group.

Remark. In Exercise 98.13 and in Proposition 141.5 we will prove the higher-dimensional analogue of Proposition 98.11.

Now we turn to the proof of Proposition 98.11. By now there are many proofs. In the following we will give Poincaré's example of such a smooth manifold. Later on in Exercise 100.4 we will give a different proof of Proposition 98.11.

[1212] In fact in [**PGL1953**, p. 498] he wrote "Pour ne pas trop allonger ce travail, je me bornerai à énoncer le théorème suivant dont la démonstration demanderait quelques développements: Tout polyèdre qui a tous ses nombres de Betti égaux Ã si et tous ses tableaux T_q bilatères est simplement connexe, c'est-à-dire homéomorphe à l'hypersphère.

To construct Poincaré's example we need to recall a few definitions and results from earlier on.

Definition.

(1) Let $z := 1 + \frac{\sqrt{5}}{2}$ be the golden ratio. As on page 1897 let D be the regular dodecahedron that is the convex hull of the 20 vertices

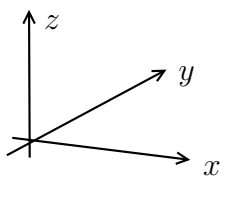
$$(\pm 1, \pm 1, \pm 1), \quad (0, \pm z, \pm \tfrac{1}{z}), \quad (\pm \tfrac{1}{z}, 0, \pm z), \quad \text{and} \quad (\pm z, \pm \tfrac{1}{z}, 0).$$

Furthermore let $\mathrm{Sym}(D)$ be the subgroup of $\mathrm{SO}(3)$ that preserves the regular dodecahedron, i.e. that preserves the set of these 20 vertices.

(2) Let $T := \{A \in \mathrm{M}(2 \times 2, \mathbb{C}) \,|\, A = \overline{A}^T \text{ and } \mathrm{tr}(A) = 0\}$. This is a 3-dimensional real vector space which we equip with the basis that is given by the matrices

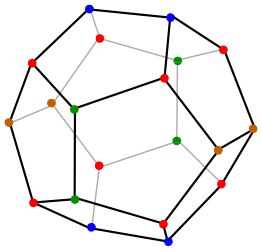
$$E_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad E_3 = \begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}.$$

Furthermore we equip T with the form $(A, B) \mapsto g(A, B) := \frac{1}{2} \mathrm{tr}\left(A\overline{B}^T\right)$. Next recall that on page 1819 we showed that the map $T \to \mathbb{R}^3$ given by $E_i \to e_i$ defines an isometry $(T, g) \to (\mathbb{R}^3, \langle\ ,\ \rangle)$ which we now use to make the identification $\mathrm{SIsom}(T, g) = \mathrm{SO}(3)$. Furthermore, in Lemma 83.1 we showed that the map



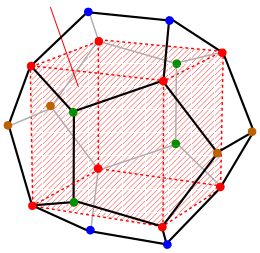
$$\begin{array}{rccl} q\colon & \mathrm{SU}(2) & \to & \mathrm{SIsom}(T, g) = \mathrm{SO}(3) \\ & A & \mapsto & (B \mapsto ABA^{-1}) \end{array}$$

is a well-defined group homomorphism, that it is an epimorphism and that the kernel is given by $\pm \mathrm{id}$.



(3) We make the identification $S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 \,|\, |z| = 1\}$, i.e. we view S^3 as the set of quaternions of length 1. By Proposition 92.2 (3) we know that the following map is a diffeomorphism and a group isomorphism:

$$\begin{array}{rccl} & f\colon S^3 & \to & \mathrm{SU}(2) \\ (z, w) = z + \mathrm{j} \cdot w & & \mapsto & \underbrace{\begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix}}_{\substack{\text{matrix that represents} \\ \text{left-multiplication by } z + \mathrm{j} \cdot w \text{ with} \\ \text{respect to the complex basis } \{1, \mathrm{j}\} \text{ of } \mathbb{H}}} \end{array}$$



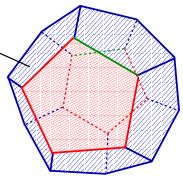
(4) We refer to $\Gamma := (q \circ f)^{-1}(\mathrm{Sym}(D)) \subset S^3$ as the binary icosahedral group.

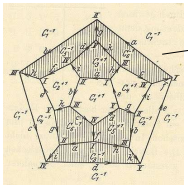
dodecahedron

inscribed cube

Remark. It might be a little confusing that we refer to Γ as the binary *icosahedral* group. As we discussed on page 1898, the symmetry group of a regular icosahedron I equals the

symmetry group of a regular dodecahedron D. Therefore in the above definition of the binary icosahedral group we could replace $\mathrm{Sym}(D)$ by $\mathrm{Sym}(I)$, which is more logical and more common. But since it is a little easier to describe $\mathrm{Sym}(D)$ geometrically we prefer to work with the regular dodecahedron.





Proposition 98.12.

(1) The binary icosahedral group Γ is a group with 120 elements.
(2) The binary icosahedral group Γ has trivial abelianization.
(3) The quotient $M := S^3/\Gamma$ is a smooth homology 3-sphere with non-trivial fundamental group.

Definition. The smooth manifold S^3/Γ is called the Poincaré Homology Sphere.

Remark. The Poincaré Homology Sphere is ubiquitous in topology and can be described in many different ways. The different avatars and also the history of the Poincaré Homology Sphere are discussed in detail in [**SeW1933**], [**Rolf1990**, Chapter 10.E], [**Vol2013**] and [**KSc1979**]. In fact [**KSc1979**] provides altogether *eight* different ways to construct the Poincaré Homology Sphere. In the following we outline a few of these alternative descriptions of the Poincaré Homology Sphere.

(1) In 1904, when Henri Poincaré discovered the eponymous sphere, he gave a different description in terms of gluing two "handlebodies". It is shown in [**SeW1933**] that this topological space is homeomorphic to the topological space we describe next in (2).
(2) Let D be the "solid" regular dodecahedron. Now identify each pentagon on the boundary with the opposite pentagon via a $\pi/5$ twist in the "clockwise" direction. As is explained in [**KSc1979**], the resulting topological space is in fact homeomorphic to the Poincaré Homology Sphere as we defined it above.

dodecahedron   description of the Poincaré homology sphere in [**?**]

(3) On page 3140 we will give two descriptions of the Poincaré Homology Sphere as the result of a "surgery" on a knot respectively a link.

Proof.

(1) Let $z := 1 + \frac{\sqrt{5}}{2}$ be the golden ratio. Recall that D is the polyhedron that is spanned by the 20 vertices

$$(\pm 1, \pm 1, \pm 1), \quad (0, \pm z, \pm \tfrac{1}{z}), \quad (\pm \tfrac{1}{z}, 0, \pm z), \quad \text{and} \quad (\pm z, \pm \tfrac{1}{z}, 0).$$

In the figures on page 1898 and on 2160 we show that one can inscribe five cubes $C_1, \ldots, C_5$ into the regular dodecahedron. As we already mentioned on page 1897, it is shown in [**Arm1988**, p. 40] that the map

$$\begin{array}{rcl} \mathrm{Sym}(D) & \to & A_5 \cong \text{positive permutations of } \{C_1, \ldots, C_5\} \\ A & \mapsto & (C_i \mapsto A \cdot C_i) \end{array}$$

is an isomorphism. We consider the maps : $\mathrm{SU}(2) \to \mathrm{SIsom}(T,g) = \mathrm{SO}(3)$ and $f\colon S^3 \to \mathrm{SU}(2)$ that we defined above and we recall that the binary icosahedral group is defined as $\Gamma := (q\circ f)^{-1}(\mathrm{Sym}(D)) \subset S^3$. As we mentioned above, in Lemma 83.1 we showed that $\ker(q\circ f) = \pm 1 \in S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 \,|\, |z| = 1\}$. Furthermore it follows from the SU(2)-SO(3)-Covering Theorem 83.2 (1) that $q\circ f$ is an epimorphism. Since $\mathrm{Sym}(D) \cong A_5$ has $\frac{1}{2}5! = 60$ elements and since $q\circ f$ has a kernel with two elements we see that Γ is a group with 120 elements.

(2) We need to show that the abelianization of Γ is trivial.[1212][1213] By (1) we know that the group $\Gamma \subset S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 \,|\, |z| = 1\}$ fits into a short exact sequence

$$1 \;\to\; \{\pm 1\} \;\xrightarrow{\rho}\; \Gamma \;\xrightarrow{q\circ f}\; \mathrm{Sym}(D) \;\to\; 1.$$

By the Abelianization Proposition 53.20 we get an induced exact sequence

$$\{\pm 1\} \;\xrightarrow{\rho}\; \Gamma_{\mathrm{ab}} \;\xrightarrow{q\circ f}\; (\mathrm{Sym}(D))_{\mathrm{ab}} \;\to\; 1.$$

Almost every algebra book worth its money shows that $A_5 \cong \mathrm{Sym}(D)$ is a simple group, see e.g. [**Bog2008**, Theorem 11.3]. This fact implies that the abelianization of $\mathrm{Sym}(D)$ is trivial. Thus it suffices to prove the following claim.

Claim. The quaternion $-1 \in S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 \,|\, |z| = 1\}$ represents the trivial element in Γ_{ab}.

Proof. First recall that a straightforward explicit calculation, which you and I carried out in Exercise 83.1 and on page 1960, shows that

$$(q\circ f)(\mathrm{i}) = q\begin{pmatrix} \mathrm{i} & 0 \\ 0 & -\mathrm{i}\end{pmatrix} = \underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1\end{pmatrix}}_{=:A} \text{ and } (q\circ f)(\mathrm{j}) = q\begin{pmatrix} 0 & -1 \\ 1 & 0\end{pmatrix} = \underbrace{\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1\end{pmatrix}}_{=:B}.$$

It follows immediately from the explicit description of the vertices of the regular dodecahedron D in (1) that the two matrices A and B to the right actually lie in $\mathrm{Sym}(D)$. Next note that it follows from the above calculation, that $\mathrm{i} = (q\circ f)^{-1}(A)$ and $\mathrm{j} = (q\circ f)^{-1}(B)$. In particular we see that $\mathrm{i},\mathrm{j} \in (q\circ f)^{-1}(\mathrm{Sym}(D)) = \Gamma$. By definition of the quaternion multiplication on page 1960 we have

$$[\mathrm{i},\mathrm{j}] \;=\; \underbrace{\mathrm{i}\cdot\mathrm{j}}_{=-\mathrm{j}\cdot\mathrm{i}} \cdot \mathrm{i}^{-1}\cdot\mathrm{j}^{-1} \;=\; -\mathrm{j}\cdot\mathrm{i}\cdot\mathrm{i}^{-1}\cdot\mathrm{j}^{-1} \;=\; -1.$$

We have thus shown that -1 is a commutator of elements in Γ. By definition of Γ_{ab} this implies that -1 represents indeed the trivial element in Γ_{ab}. ⊞

(3) Recall that it follows from Proposition 92.2 (3) that $\Gamma := (q\circ f)^{-1}(\mathrm{Sym}(D))$ is a finite subgroup of the *group* $S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 \,|\, |z| = 1\}$. Since subgroups act freely on groups we see that Γ acts freely on S^3. Since Γ is a finite subgroup it now follows from the Manifold Quotient-by-Group Action Proposition 19.32 that $M := S^3/\Gamma$ is a closed 3-dimensional smooth manifold. It remains to show that $M = S^3/\Gamma$ is a

[1213] An argument similar to our proof of (2) is also provided in [**Bre1993**, p. 354] and in [**Toen2017**, p. 133].

homology sphere. First we perform the following calculation:

$$\mathrm{H}_1(S^3/\Gamma) \overset{\text{by the Hurewicz Theorem 84.5}}{\cong} \pi_1(S^3/\Gamma)_{\mathrm{ab}} \overset{\text{by the Sphere-}\pi_1\text{-Proposition 47.13 and the Fundamental Group-via-Actions Theorem 48.16}}{\cong} \Gamma_{\mathrm{ab}} \overset{\text{by (2)}}{=} 0.$$

Next note that by the Smooth Manifolds-Invariants Proposition 96.6 we have $\mathrm{H}_i(M) = 0$ for $i \geq 4$. Furthermore note that by construction Γ is contained in $\mathrm{SU}(2)$. Thus we see that the action of Γ on S^3 is orientation-preserving.[1214] Therefore it follows from the Orientation-Action Proposition 25.19 that $M = S^3/\Gamma$ is actually orientable. This implies in turn by the Smooth Manifold-Top Homology Theorem 98.6 that $\mathrm{H}_3(M) \cong \mathbb{Z}$. Thus it remains to show that $\mathrm{H}_2(M) = 0$. By the Smooth Manifold-Top Homology Theorem 98.6 (2) we know that $\mathrm{H}_2(M)$ is a free abelian group. So it suffices to show that $b_2(M) = 0$. In fact we have

$$b_2(M) \overset{\text{since } b_0(M) = b_3(M) = 1 \text{ and } b_1(M) = 0}{=} \chi(M) \overset{\text{Proposition 69.4 and the Smooth Manifold-CW Structure Theorem 96.5}}{=} \frac{1}{k} \cdot \chi(S^3) \overset{\text{see page 1879}}{=} 0.$$

■

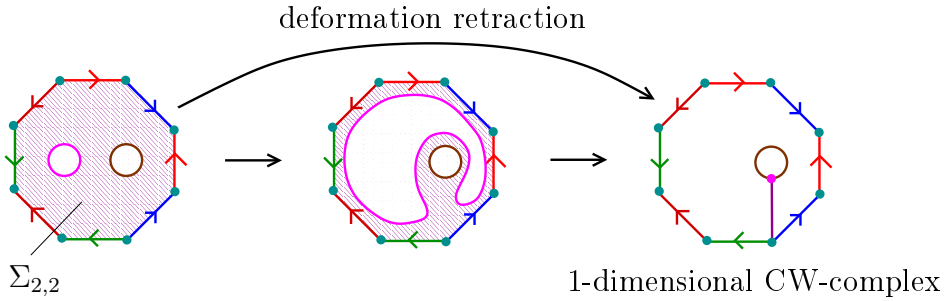
Remark. Let M be a homology 3-sphere with *finite* fundamental group. As is pointed out in [**Kerv1969**, p. 67], it follows from the work of Michio Suzuki [**Suz1955**] or alternatively John Milnor [**Miln1957b**] that $\pi_1(M)$ is isomorphic to the binary icosahedral group. In fact, it follows from the much more fancy Elliptisation Theorem **??** that such M is actually diffeomorphic to the Poincaré Homology Sphere.

We conclude this section with the statement of a conjecture that was formulated by Henri Poincaré [**PGL1953**, p. 498] [**Poi1904**].

Conjecture 98.13. (Poincaré Conjecture) If M is a homology 3-sphere that is simply connected, then M is homeomorphic to S^3.

We will discuss the Poincaré Conjecture and various variations thereof in Chapter **??**.

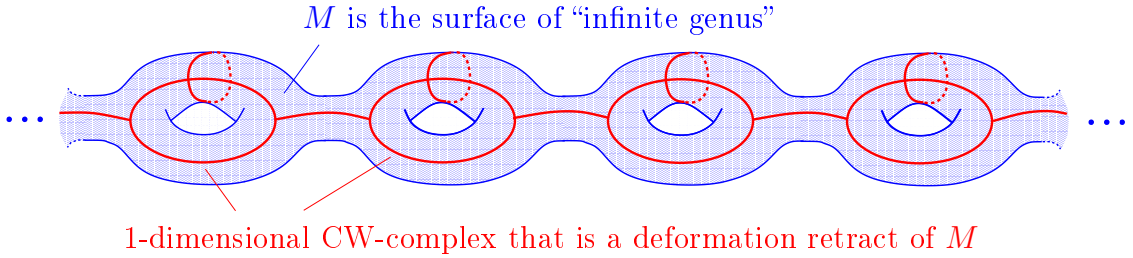
98.5. **The topology of smooth manifolds.** In this section we provide two results on the topology of smooth manifolds. Let us formulate our first result.



Proposition 98.14. (No Top-Cell Proposition) Let M be a connected non-empty n-dimensional smooth manifold. If M is non-compact or if M has non-empty boundary, then M is homotopy equivalent to an $(n-1)$-dimensional simplicial complex, in particular M is homotopy equivalent to an $(n-1)$-dimensional CW-complex.

Examples.

(1) Given $g \in \mathbb{N}_0$ and $k \in \mathbb{N}_0$ we denote as usual by $\Sigma_{g,k}$ the surface of genus g with k open disks removed. In the figure below we sketch a deformation retraction from $\Sigma_{2,2}$ to a CW-complex of Euler characteristic -4.
More generally, almost the same argument shows that $\Sigma_{g,k}$ with $k \geq 1$ admits a deformation retraction to a CW-complex with k 0-cells and $2g + 2(k-1)$ 1-cells, i.e. a 1-dimensional CW-complex of Euler characteristic $k - (2g + 2(k-1)) = -2g - k + 2$.



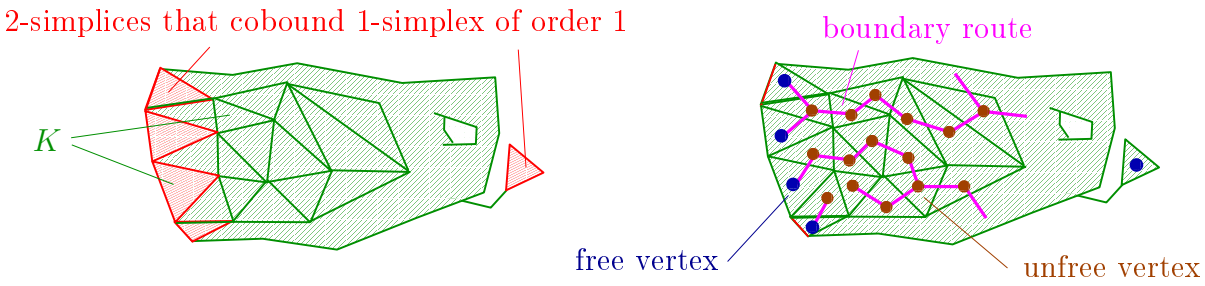
[1214] Since the action of Γ is free it follows also from Exercise 5.34 that the action is orientation-preserving.

Using the Quotient-by-Tree Proposition 69.8 (2) we also see that $\Sigma_{g,k}$ is homotopy equivalent to the wedge of $2g+k-1$ circles.

(2) The non-compact smooth manifold that is given by removing a point from the torus is easily seen to be homotopy equivalent to the wedge of two circles.

(3) In the figure below we show the surface M of infinite genus, which is non-compact, and a 1-dimensional CW-complex that is deformation retract of M. It is admittedly not overly obvious why the 1-dimensional CW-complex is indeed a deformation retract of M.

Remark. Let M be a compact connected n-dimensional smooth manifold with non-empty boundary. By the No Top-Cell Proposition 98.14 we now know that M is homotopy equivalent to a finite $(n-1)$-dimensional CW-complex which implies by the Homology-of-CW-Complex Proposition 80.6 that $\mathrm{H}_n(M)=0$ and that $\mathrm{H}_{n-1}(M)$ is a finitely generated free abelian group. This is of course consistent with the Smooth Manifold-Top Homology Theorem 98.6.



The proof of the No Top-Cell Proposition 98.14 requires some preparations.

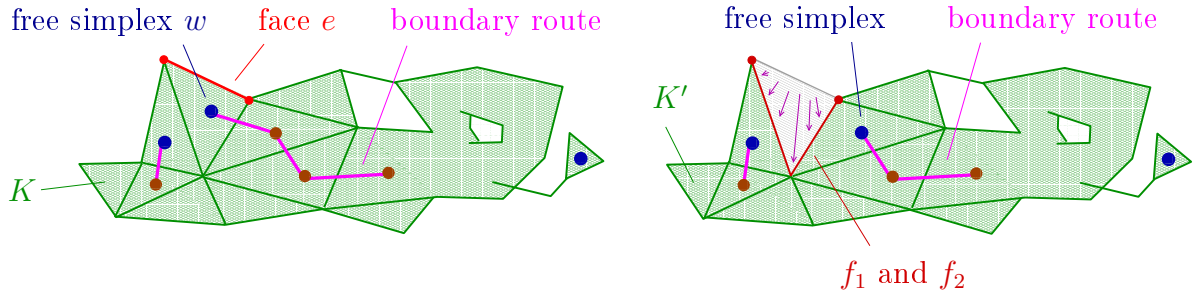
Definition. Let $K=(V,S)$ be an n-dimensional abstract simplicial complex such that every $(n-1)$-simplex has order ≤ 2. We denote by W the set of n-simplices and we denote by E the set of $(n-1)$-simplices.

(1) We say an n-simplex is free if it admits a codimension one face of order 1. Otherwise we say that the n-simplex is unfree.

(2) A boundary route is a subgraph $\widetilde{\Gamma}=(W,\widetilde{F},\varphi)$ of the dual graph[1215] $\Gamma=(W,E_2,\varphi)$ with the following property: every n-simplex of K, i.e. every vertex of the dual graph, is connected in $\widetilde{\Gamma}$ to a free n-simplex.

[1215] We refer to page 2143 for the definition of the dual graph.

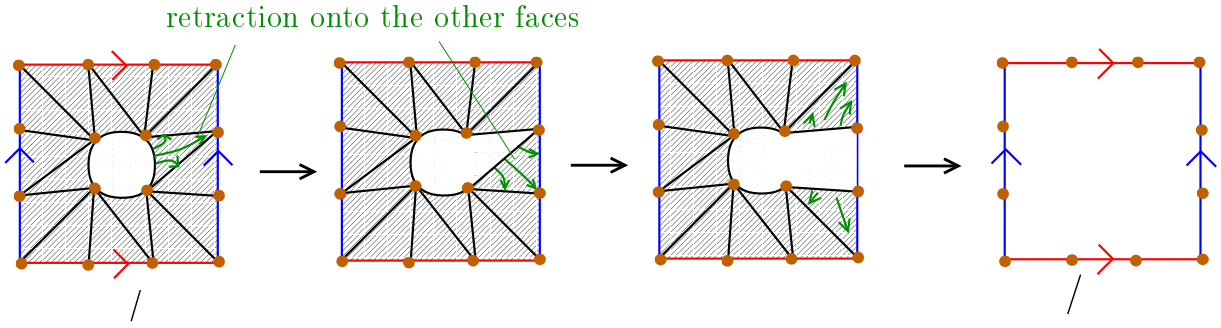
Lemma 98.15. Let $K = (V, S)$ be an n-dimensional abstract simplicial complex that admits a boundary route. There exists a subcomplex $K' = (V', S')$ of $K = (V, S)$ with the following three properties:



(1) $K' = (V', S')$ admits a boundary route.
(2) $|K'|$ is a deformation retract of $|K|$.
(3) The number of n-simplices of K' is less than the number of n-simplices of K.

Proof of Lemma 98.15. Let $K = (V, S)$ be an n-dimensional abstract simplicial complex that admits a boundary route $\widetilde{\Gamma} = (W, \widetilde{F}, \varphi)$. Since K is n-dimensional we know that it contains at least one n-simplex and since K admits a boundary route we see that there exists an n-simplex w that is free. By definition this means that w admits a codimension-one face e of order 1. We denote by $f_1, \ldots, f_n$ the remaining codimension-one faces of w. We set

$$K' \ := \ (V, S \setminus \{w, e\}).$$



Note that K' is indeed a subcomplex of K. A slight generalization of Exercise 15.13 shows that there exists a deformation retraction from $|w|$ to $\bigcup_{i=1}^{n} |f_i|$. It follows from Lemma 93.8 together with the Homotopy Stacking Lemma 14.3 that this deformation retraction together with the constant homotopy on $|K'|$ defines a deformation retraction from $|K|$ to $|K'|$.

Since every $(n-1)$-simplex of K has order ≤ 2 we see see that every n-simplex of K' that contains one of the f_i as a face is a free n-simplex of K'. Using this observation it is now straightforward to see a boundary route for K' is given by $(W \setminus \{w\}, \{\widetilde{f} \in \widetilde{F} \mid \widetilde{f} \not\subset w\}, \varphi)$. ■

Proof of the No Top-Cell Proposition 98.14 in the compact case. Let M be a compact connected non-empty n-dimensional smooth manifold with non-empty boundary. Recall that by the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a simplicial structure $(K = (V, S), \Theta\colon |K| \to M)$ such that ∂M is a subcomplex. We need to show that $|K|$ is homotopy equivalent to a finite $(n-1)$-dimensional simplicial complex.

Let $\Gamma = (W, E_2, \varphi)$ be the dual graph of K. By the Manifold-Simplex Proposition 98.1 (5) we know that Γ is connected. Thus it follows from the Spanning Tree Existence Proposition 7.10 (1) that Γ admits a spanning tree T. By definition T is connected and by the Spanning Tree Existence Proposition 7.10 we know that a spanning tree contains all vertices. Since $\partial M \neq \varnothing$ we know by the Manifold-Simplex Proposition 98.1 that $\partial K \neq \varnothing$. Thus we see that T is in fact a boundary route for K. This means that we can start up the machine given by Lemma 98.15. Iteratively applying Lemma 98.15 we get the desired deformation retraction. ■

simplicial structure for the surface of genus one with one boundary component

1-dimensional simplicial complex

Proof of the No Top-Cell Proposition 98.14 in the non-compact case. Let M be a non-compact connected n-dimensional smooth manifold. It follows from [**NR2004**, Theorem 2.2], or alternatively [**WhdJ1961b**, Lemma 2.1], together with Proposition 94.12 that M is homotopy equivalent to an $(n-1)$-dimensional simplicial complex.

We will not attempt to give a full proof of our own, but we will sketch an outline of a proof. Evidently we again use the fact that by the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that we can equip M with a simplicial structure $(K = (V, S), \Theta\colon |K| \to M)$. It is fairly straightforward to show that there exists a sequence $Y_1, Y_2, \ldots$ of non-empty subcomplexes of K with the following properties:

(1) The sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $Y_i \subset Y_{i+1}$.
(2) Each X_i is a finite n-dimensional pseudomanifold.
(3) We have $\bigcup\limits_{i\in\mathbb{N}} X_i = K$.

Now, with a considerable effort one can modify the above arguments used in the compact case to show that there exists a sequence of $(n-1)$-dimensional subcomplexes $X_i \subset Y_i$ with the following properties:

(4) For each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$.
(5) Each $|X_i|$ is a deformation retract of $|Y_i|$.

Finally we set $X := \bigcup\limits_{i\in\mathbb{N}} X_i$. Note that X is an $(n-1)$-dimensional subcomplex of Y. It remains to show that X is a deformation retract of Y.

We pick a base point $* \in$. Using the above one can show, reasonably easily, that the inclusion induced map $\pi_n(X, *) \to \pi_n(Y, *)$ is an isomorphism for every $n \in \mathbb{N}$. It follows from the Whitehead Deformation Retract Proposition 162.2[1216], which is a variation on the

[1216]My apologies for referring to a future result.

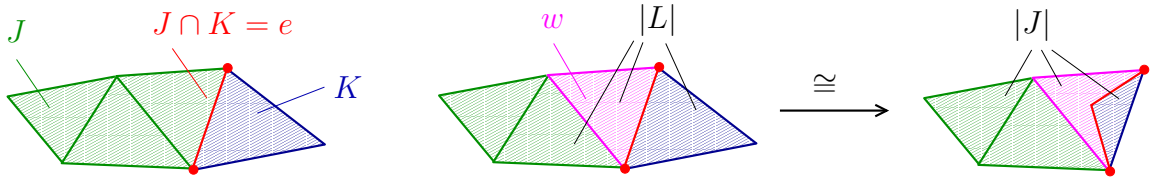
Whitehead Theorem 162.1, that X is indeed a deformation retract of Y. We leave it as a charming challenge to the reader to turn this idea into a rigorous proof. ■

We give a new proof of the following proposition.

Proposition 64.5. Let M be a connected 2-dimensional smooth manifold. If M is non-compact, then $\pi_1(M)$ is a free group.

Proof. Let M be a connected 2-dimensional smooth manifold that is non-compact. By the No Top-Cell Proposition 98.14 we know that M is homotopy equivalent to a 1-dimensional CW-complex. It follows from the Homotopy-π_1-Proposition 50.3 (2) and Proposition 69.9 (1) that $\pi_1(M)$ is a free group. ■

We conclude this chapter with the following proposition.



Proposition 98.16. (Single Top-Cell Proposition) Let M be a compact connected n-dimensional smooth manifold. There exists a CW-structure for M with a single n-cell.

Remark. For fans of small CW-complexes we also recall Proposition 70.4 which says that any 0-connected CW-complex X is homotopy equivalent to a CW-complex Y with a single 0-cell which has the property that for any $n \geq 2$ the number of n-cells of X equals the number of n-cells of Y.

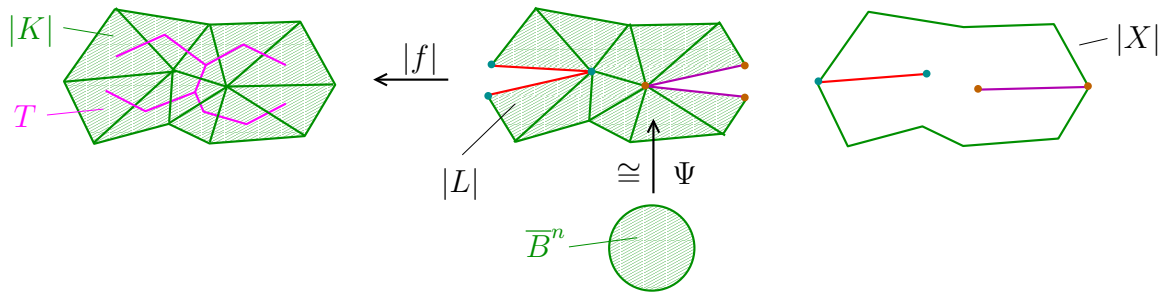
In the proof of the Single Top-Cell Proposition 98.16 we will make use of the following lemma.

Lemma 98.17. Let L be an n-dimensional pseudomanifold that contains two subcomplexes J and K. If K consists of a single n-simplex, if $J \cap K$ consists of a single $(n-1)$-simplex e and if e has order 1 in J, then there exists a homeomorphism $(|L|, |\partial L|) \to (|J|, |\partial J|)$ of pairs of topological spaces.

Sketch of a proof of Lemma 98.17. Let w be the one n-simplex of J that cobounds e. It is elementary, albeit ever-so-slightly painful, to write down an explicit homeomorphism $|w| \cup |K| \to |w|$ that is the identity on $|\partial w| \setminus (|\partial w| \cap |K|)$. Together with the identity on $|J| \setminus |w|$ this homeomorphism gives us the desired homeomorphism from $|L|$ to $|J|$. It follows almost immediately from the definitions that this homeomorphism restricts to a homeomorphism $|\partial L| \to |\partial J|$. We leave it to the reader to fill in the details. ■

Sketch of a proof of the Single Top-Cell Proposition 98.16. We sketch a proof of the proposition. The statement is also proved with fewer details but more authority in [**Mc2002**, Theorem 5.1].

Let M be a closed connected non-empty n-dimensional smooth manifold. By the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a simplicial structure $(K = (V, S), \Theta\colon |K| \to M)$. We need to show that $|K|$ admits a CW-structure with a single n-cell.



Let $\Gamma = (W, E_2, \varphi)$ be the dual graph of K. By the Manifold-Simplex Proposition 98.1 (5) we know that Γ is connected. Thus it follows from the Spanning Tree Existence Proposition 7.10 (1) that Γ admits a spanning tree T. Note that by the Spanning Tree Existence Proposition 7.10 (2) we know that T contains every vertex of Γ.

Let X be the subcomplex of K that is given by removing all n-simplices and by removing all $(n-1)$ that do not correspond to an edge of the spanning tree T. Note that X is an $(n-1)$-dimensional simplicial complex. Furthermore let L be the abstract simplicial complex that is given by the "disjoint union of the n-simplices of K and gluing them along the $(n-1)$-simplices corresponding to the edges of T". It is not difficult, but also not particularly instructive, to write down a completely rigorous definition of L. Note that L comes with a natural simplicial map $f\colon L \to K$.

Next note that using an induction argument based on Lemma 98.17, and which also makes use of the Standard Simplex Homeomorphism Lemma 72.1, it is rather straightforward to show that there exists a homeomorphism $\Psi\colon (\overline{B}^n, S^{n-1}) \to (\Delta^n, \partial\Delta^n) \to (|L|, |\partial L|)$. Finally, using the Compact-Hausdorff Proposition 2.17 (3) one can verify that the map

$$\begin{array}{rcl} & & \text{where } x \sim (\Psi \circ |f|)(x) \text{ for every } x \in S^{n-1} \\ & & \downarrow \\ (\overline{B}^n \sqcup |X|)/\!\sim & \to & |K| \\ [P] & \mapsto & \begin{cases} (\Psi \circ |f|)(P), & \text{if } P \in \overline{B}^n, \\ P, & \text{if } P \in |X| \subset |K| \end{cases} \end{array}$$

is a homeomorphism. The left-hand side admits an obvious CW-structure with a single n-cell. Thus we have shown that $|K|$ admits a CW-structure with a single n-cell. ∎

Exercises for Chapter 98.

Exercise 98.1. Let K be a finite n-dimensional pseudomanifold.

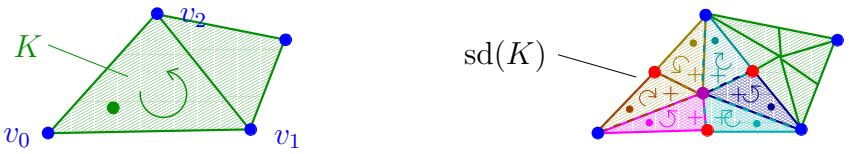
(a) Show that the suspension $\Sigma(K)$, as defined on page 2003, is an $(n+1)$-dimensional pseudomanifold.
(b) Show that if K is closed, then $\Sigma(K)$ is closed.
(c) Show that if K is orientable in the sense of the definition on page 2142, then $\Sigma(K)$ is orientable.

Exercise 98.2. Let K be an n-dimensional pseudomanifold such that ∂K is an $(n-1)$-dimensional pseudomanifold. Let $i\colon \partial K \to K$ be the inclusion map. We consider the cone $K \cup_{\partial K} \mathrm{Cone}(\partial K)$. Show that $\mathrm{Cone}(i\colon \partial K \to K)$ is a closed n-dimensional pseudomanifold.

Exercise 98.3. Let K be an m-dimensional pseudomanifold and let L be an n-dimensional pseudomanifold. We equip K and L with a total order and we define the product $K \times L$ as on page 1998.

(a) Show that $K \times L$ is an $(m+n)$-dimensional pseudomanifold.
(b) Show that $K \times L$ is closed if and only if both K and L are closed.
(c) Show that $K \times L$ is orientable if and only if both K and L are orientable.

Exercise 98.4.



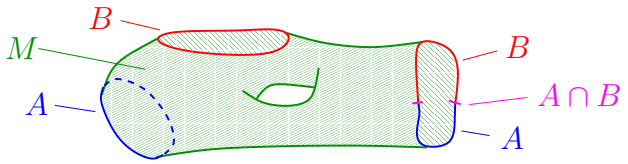
(a) Let K be a 1-dimensional pseudomanifold. Show that $|K|$ is a closed 1-dimensional smooth manifold.
(b) Let K be a 2-dimensional pseudomanifold. Show that $|K|$ is a closed 2-dimensional smooth manifold.

Remark. Part (a) is fairly straightforward. The proof of part (b) is more delicate. One way to prove part (b) is to imitate the proof, given in Propositions 18.7 and 19.18, that the surface Σ_g of genus g is closed 2-dimensional smooth manifold.

Exercise 98.5. Let $K = (V, S)$ be an n-dimensional pseudomanifold.

(a) Show that the barycentric subdivision $\mathrm{sd}(K)$ is an n-dimensional pseudomanifold.
(b) Suppose that K is equipped with an orientation. Let $t = \{\underline{s_0}, \ldots, \underline{s_n}\}$ be an n-simplex of $\mathrm{sd}(K)$. For $i = 0, \ldots, n$ we denote by v_i the vertex of s_i that is not contained in s_{i-1}. Let $\epsilon \in \{-1, 1\}$ be the sign such that $(\epsilon, (v_0, \ldots, v_n))$ matches the given orientation of K. We equip the n-simplex t of $\mathrm{sd}(K)$ with the orientation given by $(\epsilon, (\underline{s_0}, \ldots, \underline{s_n}))$. Show that the above orientations of the n-simplices of $\mathrm{sd}(K)$ define an orientation for $\mathrm{sd}(K)$.

We refer to the figure below for an illustration.



Exercise 98.6. Let M be a compact connected non-empty smooth manifold. Furthermore let $(K = (V, S), \Theta\colon |K| \to M)$ be a simplicial structure for M. Let Γ be the dual graph as defined on page 2143. Is there a relationship between the homology groups $\mathrm{H}_1(\Gamma; \mathbb{Z})$ and the groups $\mathrm{H}_1(M; \mathbb{Z})$ or $\mathrm{H}_1(M, \partial M; \mathbb{Z})$? For example is there a relationship between the ranks or the minimal number of generators?

Exercise 98.7. Let M be a compact orientable n-dimensional smooth manifold. Suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Show that $\mathrm{H}_{n-1}(M, A)$ is a free abelian group.

Exercise 98.8. Let M be a compact connected n-dimensional smooth manifold and let $p \neq 2$ be a prime. Determine $\mathrm{H}_n(M, \partial M; \mathbb{F}_p)$ and $\mathrm{H}_n(M; \mathbb{F}_p)$.

Exercise 98.9. Let $k, l \in \mathbb{N}$ and let $N_{k,l}$ be $N_k = k \cdot \mathbb{R}\mathrm{P}^2$ minus l open disks. Determine $\mathrm{H}_1(N_{k,l}, \partial N_{k,l}; \mathbb{Z})$.

Exercise 98.10. Let K be an infinite n-dimensional pseudomanifold such that $\partial K = \varnothing$. Show that $\mathrm{H}_{n-1}^{\mathrm{simp}}(K)$ is a free abelian group.
Remark. This exercise will require a serious effort.

Exercise 98.11. Let $p, q \in \mathbb{N}$ be coprime. Show that every orientation-reversing diffeomorphism of the lens space $L(p,q)$ has at least one fixed point.

Exercise 98.12. Let X be a connected 2-dimensional smooth manifold with infinite fundamental group (We do not assume that X is compact.) Show that X is aspherical, i.e. show that $\pi_i(X) = 0$ for $i \geq 2$.
Hint. First use the Hurewicz Theorem 85.5 and the results from this section to show that $\pi_2(X) = 0$.
Remark. This exercise gives in particular a new proof of the fact that given a surface Σ_g of genus $g \geq 1$ we have $\pi_i(\Sigma_g) = 0$ for $i \geq 2$. We had initially proved this statement on page 1575 using the rather difficult results from Chapter 66.

Exercise 98.13. Let M be a 3-dimensional smooth homology 3-sphere with non-trivial fundamental group.[1217] Furthermore let $n \geq 4$. We pick a smooth embedding $\varphi\colon \overline{B}^3 \to M$ and we consider $W := (M \setminus \varphi(B^3) \times \overline{B}^{n-3}$. By Proposition **??** we can equip W with the structure of an orientable n-dimensional smooth manifold. Show that the double $\mathrm{D}W$ is an n-dimensional smooth homology n-sphere with non-trivial fundamental group.

Exercise 98.14. Let Σ be a compact oriented connected 2-dimensional smooth manifold. We consider the product $N := \Sigma \times [0,1]$ and we consider the subset $A := \partial\Sigma \times [0,1] \subset N$. Let $\varphi\colon \Sigma \to \Sigma \times \{0\} \subset N$ be the obvious inclusion map. Now let $g\colon S \to N$ be a map from a compact oriented connected 2-dimensional smooth manifold with $g(\partial S) \subset A$ such that $\varphi_*([\Sigma]) = g_*([S])$. Show that $\chi(S) \leq \chi(\Sigma)$.
Remark. In a slightly simplified version the exercise says that the surface $\Sigma \times \{0\}$ is the "simplest" surface in N representing the homology class $[\Sigma \times \{0\}]$.

[1217] By Proposition 98.11 we know that such M exists.

99. Simplicial cohomology

In this chapter we will introduce the simplicial cohomology groups of an (ordered) abstract simplicial complex. This chapter can be seen as a continuation of our discussions of abstract simplicial complexes in Chapters 93, 94 and 95. The objects in this chapter are for the most part purely combinatorial and for the most part this chapter can be read independently of the chapters on singular cohomology. We will only make use of the purely algebraic statements in Sections 108.1, 108.2 and 108.3.
As for simplicial homology, the study of simplicial cohomology is great fun in its own right. But as we will see, it is also a very convenient tool for calculating singular cohomology groups and for determining the often intractable cup and cap products.
In Chapter 103 we will prove the Simplicial Poincaré Duality Theorem 103.4 for pseudo-manifolds, which gives us in particular a Poincaré Duality theorem for smooth manifolds.

99.1. **Simplicial chain complexes.** In the following section we will introduce simplicial cohomology groups. Before we do so it is convenient to recall several definitions and results on simplicial chain complexes.
We start out with the following definition from page 2036.

Definition. Let $K = (V, S)$ be an ordered abstract simplicial complex.[1218] Given $k \in \mathbb{N}_0$ we define

$$\mathrm{C}_k^{\mathrm{simp},\leq}(K) := \text{free abelian group generated by the set of } k\text{-simplices of } K.$$

Furthermore we consider the boundary map

$$\begin{aligned} \partial_k \colon \mathrm{C}_k^{\mathrm{simp},\leq}(K) &\to \mathrm{C}_{k-1}^{\mathrm{simp},\leq}(K) \\ \underbrace{\{v_0 < \cdots < v_k\}}_{\substack{\text{any } k\text{-simplex } s \text{ is uniquely} \\ \text{of the form } s = \{v_0,\dots,v_k\} \\ \text{with } v_0 < \cdots < v_k}} &\mapsto \sum_{i=0}^{k} (-1)^i \cdot \{v_0, \dots, v_{i-1}, \widehat{v_i}, v_{i+1}, \dots, v_k\}. \end{aligned}$$

By Lemma 95.2 we know that $(\mathrm{C}_*^{\mathrm{simp},\leq}(K), \partial_*)$ is a chain complex, thus we can define the corresponding simplicial homology groups $\mathrm{H}_*^{\mathrm{simp},\leq}(K)$.

The above definition is straightforward, but it does have the major disadvantage that it requires the choice of an order on K. In most situations there is no natural choice of an order. In the absence of an order we are led to the following more elaborate definition which initially we gave on page 2038 and in Lemma 95.6.

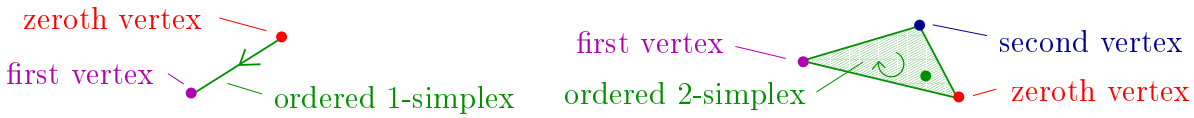
Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) Let $k \in \mathbb{N}_0$. An ordered k-simplex of K is a $(k+1)$-tuple $(v_0, \dots, v_k) \in V^{k+1}$ such that $\{v_0, \dots, v_k\}$ is a k-simplex of $K = (V, S)$. In the following we write $\lfloor (v_0, \dots, v_k) \rfloor := \{v_0, \dots, v_k\}$.

[1218] Recall that, according to the definition on page 1982, an *order* on an abstract simplicial complex (V, S) is a partial order on V that has the property that the restriction to each simplex is actually a total order.

(2) Let $k \in \mathbb{N}_0$. We define the k-th simplicial chain group

$$\mathrm{C}_k^{\mathrm{simp}}(K) := \begin{array}{c}\text{free abelian group on the set}\\ \text{of ordered } k\text{-simplices of } K\end{array} \Big/ \begin{array}{c}(v_0,\dots,v_k) - \mathrm{sign}(\sigma)\cdot(v_{\sigma(0)},\dots,v_{\sigma(k)})\\ \text{where } \sigma \in S_{k+1} = \mathrm{Bij}\{0,\dots,k\}\end{array}$$



(3) Given an ordered simplex $(v_0,\dots,v_k)$ we denote its image in $\mathrm{C}_k^{\mathrm{simp}}(K)$ by $[v_0,\dots,v_k]$.

(4) We consider the map

$$\begin{aligned}\partial_k \colon \mathrm{C}_k^{\mathrm{simp}}(K) &\to \mathrm{C}_{k-1}^{\mathrm{simp}}(K)\\ [v_0,\dots,v_k] &\mapsto \sum_{i=0}^{k} (-1)^i \cdot [v_0,\dots,v_{i-1},\widehat{v_i},v_{i+1},\dots,v_k].\end{aligned}$$

(5) By Lemma 95.6 we know that $(\mathrm{C}_*^{\mathrm{simp}}(K),\partial_*)$ is a chain complex, thus we can define the corresponding simplicial homology groups $\mathrm{H}_*^{\mathrm{simp}}(K)$.

Notation. In pictures we denote the ordering of the simplices of a 1-simplex in the obvious way by an arrow pointing from the first to the second vertex. Furthermore, given an ordered 2-simplex we indicate the first vertex by a dot and the ordering of the remaining vertices by an oriented 3/4-circle. We refer to the figure below for an illustration.

We recall the following lemma.

Lemma 95.6. Let K be an abstract simplicial complex. If we choose for each k-simplex $s \in S$ an ordered k-simplex $\widetilde{s}$ with $\lfloor \widetilde{s} \rfloor = s$, then the $[\widetilde{s}]$ form a basis for $\mathrm{C}_k^{\mathrm{simp}}(K)$.

We conclude this short section with the following proposition that combines several earlier statements on the relationship between the above two simplicial chain complexes and also the singular chain complex of the topological realization.

Proposition 99.1.

(1) Let $(K = (V,S), \leq)$ be an ordered abstract simplicial complex.

(a) We consider the following maps:

$$\begin{array}{ccccc}\mathrm{C}_k^{\mathrm{simp}}(K) & \xleftarrow{\Omega_{\leq,k}} & \mathrm{C}_k^{\mathrm{simp},\leq}(K) & \xrightarrow{\Theta_{\leq,k}} & \mathrm{C}_k(|K|)\\ [v_0,\dots,v_k] & \longleftarrow & s = \{v_0 < \cdots < v_k\} & \longmapsto & (\Phi_s^{\leq} \colon \Delta^k \to |K|).\end{array}$$

map given by sending e_i to v_i

The maps $\Omega_{\leq,k}$ to the left define a natural isomorphism of chain complexes whereas the maps $\Theta_{\leq,k}$ to the right define a natural chain homotopy equivalence.

(b) There exist maps

$$\pi_k \colon \mathrm{C}_k(|K|) \to \mathrm{C}_k^{\mathrm{simp},\leq}(K)$$

which have the following two properties:

(i) The maps π_k form a chain map which form a chain homotopy equivalence.

(ii) For each $k \in \mathbb{N}_0$ we have $\pi_k \circ \Theta_k = \mathrm{id}_{\mathrm{C}_k^{\mathrm{simp},\leq}(K)}$.

(2) Let K be an abstract simplicial complex and let "$\leq$" and "$\subseteq$" be two orders on K. The two chain maps

$$\begin{array}{ccccccc} & & \mathrm{C}_k^{\mathrm{simp}}(K) & \xrightarrow{\Omega^{-1}_{\leq,k}} & \mathrm{C}_k^{\mathrm{simp},\leq}(K) & \xrightarrow{\Theta_{\leq,k}} & \mathrm{C}_k(|K|) \\ \text{and} & & \mathrm{C}_k^{\mathrm{simp}}(K) & \xrightarrow{\Omega^{-1}_{\subseteq,k}} & \mathrm{C}_k^{\mathrm{simp},\subseteq}(K) & \xrightarrow{\Theta_{\subseteq,k}} & \mathrm{C}_k(|K|) \end{array}$$

are chain homotopic.

(3) Let G be an abelian group. The chain homotopy equivalence class of (2) induces a natural isomorphism

$$\Xi_{k*}\colon \mathrm{H}_k^{\mathrm{simp}}(K;G) \;\to\; \mathrm{H}_k(|K|;G).$$

Proof.

(1) (a) This statement is the combination of Lemma 95.8 and the Simplicial-Singular Chain Complex Theorem 95.25.

(b) It follows almost immediately from the definitions that for each $k \in \mathbb{N}_0$ the map $\mathrm{C}_k^{\mathrm{simp},\leq}(K) \to \mathrm{C}_k(|K|)$ is a monomorphism and that the image is a summand. The desired statement is now an immediate consequence of (a) and Proposition 81.5.

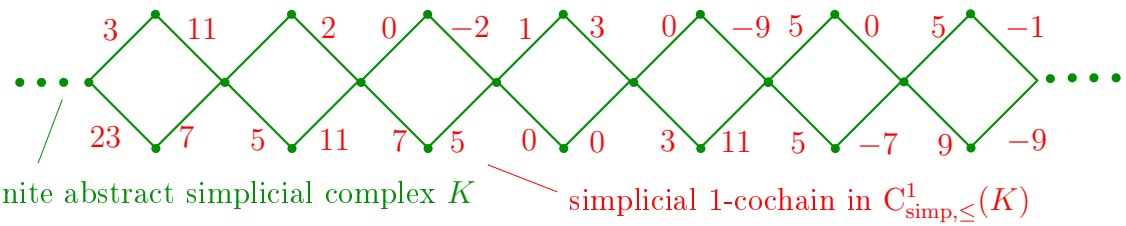
(2) This statement is the content of Lemma 95.26.

(3) It follows immediately from (2) and a slight generalization of Lemma 73.2 that any choice of order on K induces the same map on homology with G-coefficients, i.e. the map Ξ_{k*} is well-defined. It follows easily from (1) and Corollary 73.4 that the map Ξ_{k*} is a natural isomorphism. ■

99.2. **The definition of the simplicial cohomology groups.** In this section we will introduce the simplicial cohomology groups of an (ordered) abstract simplicial complex. The discussion in the previous section also shows that it will be necessary to consider two slightly different types of simplicial cohomology groups.
We start out with a decidedly dull definition.

Definition. Let K be an (ordered) abstract simplicial complex and let G be an abelian group. For each $k \in \mathbb{N}_0$ we write

$$\mathrm{C}^k_{\mathrm{simp}}(K;G) := \mathrm{Hom}(\mathrm{C}_k^{\mathrm{simp}}(K), G) \quad \text{and} \quad \mathrm{C}^k_{\mathrm{simp},\leq}(K;G) := \mathrm{Hom}(\mathrm{C}_k^{\mathrm{simp},\leq}(K), G).$$



Elements of $\mathrm{C}^k_{\mathrm{simp}}(K;G)$ and $\mathrm{C}^k_{\mathrm{simp},\leq}(K;G)$ are called simplicial k-cochains.

Remark. Let G be an abelian group, let K be an ordered abstract simplicial complex and let $k \in \mathbb{N}_0$.

(1) It follows from Lemma 108.1 that a simplicial k-cochain in $\mathrm{C}^k_{\mathrm{simp},\leq}(K;G)$ is the same data as assigning an element of G to *every* k-simplex. Note that in contrast to the setting of singular cochains one can actually hope to "see" simplicial cochains. For example see the figure below for a simple-minded illustration.

(2) In contrast, it follows easily from the Tensor Lemma 89.3 that a chain in $\mathrm{C}_k^{\mathrm{simp},\leq}(K) \otimes G$ is the same data as assigning an element of G to *finitely many* k-simplices.

Now we introduce the following notation.

Notation.

(1) Let K be an order abstract simplicial complex and let s be an ordered k-simplex. We denote by $s^*\colon \mathrm{C}_k^{\mathrm{simp},\leq}(K) \to \mathbb{Z}$ the map that is given by $s^*(s) = 1$ and $s^*(t) = 0$ for any k-simplex $t \neq s$.

(2) Let K be an abstract simplicial complex and let $s = (v_0, \ldots, v_k)$ be an ordered k-simplex. It follows immediately from the definitions that

$$\begin{array}{rcl} s^*\colon \mathrm{C}_k^{\mathrm{simp}}(K) & \to & \mathbb{Z} \\ [w_0, \ldots, w_k] & \mapsto & \begin{cases} 0, & \text{if } \{v_0, \ldots, v_k\} \neq \{w_0, \ldots, w_k\}, \\ \mathrm{sign}(\sigma), & \text{if there exists a } \sigma \in \mathrm{Bij}\{0, \ldots, k\} \\ & \qquad \text{with } w_i = v_{\sigma(i)} \text{ for } = 0, \ldots, k \end{cases} \end{array}$$

is well-defined, in other words, s^* is a well-defined cochain in $\mathrm{C}^k_{\mathrm{simp}}(K;\mathbb{Z})$.

In the following we will mostly study the simplicial cohomology of finite (ordered) abstract simplicial complexes. In this context the following lemma is very helpful.

Lemma 99.2. Let $k \in \mathbb{N}_0$.

(1) Let $K = (V, S)$ be an ordered abstract simplicial complex. If K is *finite*, then the set $\{s^* \mid s \text{ a } k\text{-simplex}\}$ is a basis for $\mathrm{C}^k_{\mathrm{simp},\leq}(K;\mathbb{Z})$.

(2) Let $K = (V, S)$ be an abstract simplicial complex. We choose for each k-simplex s an ordered k-simplex $\widetilde{s}$ with $\lfloor \widetilde{s} \rfloor = s$. If K is finite, then the $\widetilde{s}^*$ form a basis for $\mathrm{C}^k_{\mathrm{simp}}(K;\mathbb{Z})$.

Proof. This follows immediately from Lemma 108.1 together with the definition of $\mathrm{C}_k^{\mathrm{simp},\leq}(K)$ and together with Lemma 95.6. ■

Now that we have gained a little bit of familiarity with cochains let us move on to the definition of the simplicial cochain complex and the simplicial cohomology groups.

Definition. Let K be an abstract simplicial complex and let G be an abelian group. For each $k \in \mathbb{N}_0$ we refer to

$$\delta_k := \partial_{k+1}^*\colon \underbrace{\mathrm{Hom}(\mathrm{C}_k^{\mathrm{simp}}(K), G)}_{=\mathrm{C}^k_{\mathrm{simp}}(K;G)} \to \underbrace{\mathrm{Hom}(\mathrm{C}_{k+1}^{\mathrm{simp}}(K), G)}_{=\mathrm{C}^{k+1}_{\mathrm{simp}}(K;G)}$$

as the coboundary map. Any simplicial k-cochain in $\ker(\delta_k\colon \mathrm{C}^k_{\mathrm{simp}}(K;G) \to \mathrm{C}^{k+1}_{\mathrm{simp}}(K;G))$ is called a simplicial k-cocycle. We refer to the cochain complex

$$\ldots \leftarrow \mathrm{C}^{k+1}_{\mathrm{simp}}(K;G) \xleftarrow{\delta_k} \mathrm{C}^k_{\mathrm{simp}}(K;G) \xleftarrow{\delta_{k-1}} \mathrm{C}^{k-1}_{\mathrm{simp}}(K;G) \leftarrow \ldots \xleftarrow{\delta_0} \mathrm{C}^0_{\mathrm{simp}}(K;G) \leftarrow 0$$

as the simplicial cochain complex of K with G-coefficients. We define the k-th simplicial cohomology group of K with G-coelfficients as follows:

$$\mathrm{H}^k_{\mathrm{simp}}(K;G) := \mathrm{H}^k(\mathrm{C}^{\mathrm{simp}}_*(K);G) = \frac{\ker(\delta_k\colon \mathrm{C}^k_{\mathrm{simp}}(K;G) \to \mathrm{C}^{k+1}_{\mathrm{simp}}(K;G))}{\mathrm{im}(\delta_{k-1}\colon \mathrm{C}^{k-1}_{\mathrm{simp}}(K;G) \to \mathrm{C}^k_{\mathrm{simp}}(K;G))}.$$

If K is actually an ordered abstract simplicial complex, then we define the cochain complex $\mathrm{C}^*_{\mathrm{simp},\leq}(K;G)$ and the simplicial cohomology groups $\mathrm{H}^k_{\mathrm{simp},\leq}(K;G)$ in the obvious way.
Given a finite abstract simplicial complex it is just an elementary, albeit at times surprisingly intricate, problem in linear algebra to determine the simplicial cohomology groups and to give explicit examples of simplicial cocycles.

Example. We consider the "simplicial circle" C with vertex set $V = \{a, b, c\}$ shown in the figure below. We consider the ordered 1-simplices $s := (a, b)$, $t := (b, c)$ and $u := (c, a)$. We see that the simplicial chain complex $\mathrm{C}^{\mathrm{simp}}_*(C;\mathbb{Z})$ is of the following form:[1219]

$$\begin{array}{ccc} 0 \to \mathrm{C}^{\mathrm{simp}}_1(C) \xrightarrow{\partial_1} \mathrm{C}^{\mathrm{simp}}_0(C) \to 0 & \text{thus the dual} & 0 \leftarrow \mathrm{C}^1_{\mathrm{simp}}(C;\mathbb{Z}) \xleftarrow{\delta_0} \mathrm{C}^0_{\mathrm{simp}}(C;\mathbb{Z}) \leftarrow 0 \\ s \mapsto b - a & \text{chain complex} & u^* - s^* \leftarrow\!\shortmid\ a^* \\ t \mapsto c - b & \mathrm{C}^*_{\mathrm{simp}}(C;\mathbb{Z}) & s^* - t^* \leftarrow\!\shortmid\ b^* \\ u \mapsto a - c. & \text{is given by} & t^* - u^* \leftarrow\!\shortmid\ c^*. \end{array}$$

An elementary calculation shows that

$$\mathrm{H}^0_{\mathrm{simp}}(C;\mathbb{Z}) = \ker(\delta_0) = \mathbb{Z} \cdot (a^* + b^* + c^*).$$

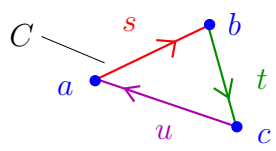
We turn to the slightly more tricky calculation of $\mathrm{H}^1_{\mathrm{simp}}(C;\mathbb{Z})$. First note that it is elementary to show that

$$\mathrm{im}\left(\delta_0\colon \mathrm{C}^0_{\mathrm{simp}}(C;\mathbb{Z}) \to \mathrm{C}^1_{\mathrm{simp}}(C;\mathbb{Z})\right) = \{k \cdot s^* + l \cdot t^* + m \cdot u^* \mid k + l + m = 0\}.$$

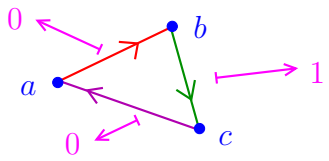
Now let us consider the cochain $\theta = t^*\colon \mathrm{C}^{\mathrm{simp}}_1(C) \to \mathbb{Z}$. (In other words, θ is the cochain that is given by $\theta(s) = 0$, $\theta(t) = 1$ and $\theta(u) = 0$.) An elementary argument, see e.g. Exercise 72.13, shows that the map

$$\begin{array}{ccc} \mathbb{Z} & \xrightarrow{\cong} & \mathrm{H}^1_{\mathrm{simp}}(C;\mathbb{Z}) = \mathrm{coker}(\delta_0) \\ n & \mapsto & n \cdot [\theta] \end{array}$$

is an isomorphism.[1220] Note that on several occasions throughout this chapter we will make use of the above simplicial cocycle $\theta = t^* \in \mathrm{C}^1_{\mathrm{simp}}(C;\mathbb{Z})$.



We state the next example as a lemma.



[1219] Usually it takes a while to get used to coboundaries. Thus let us show in detail that we have $\delta_0(a^*) = u^* - s^* \in \mathrm{C}^1_{\mathrm{simp}}(C;\mathbb{Z}) = \mathrm{Hom}(\mathrm{C}^{\mathrm{simp}}_1(C), \mathbb{Z})$. We need to show that $\delta_0(a^*) = u^* - s^*$ are the same homomorphism. By Lemma 95.6 we know that $\{s, t, u\}$ is a basis for $\mathrm{C}^{\mathrm{simp}}_1(C)$. So we need to show that the two homomorphisms take the same values on s, t and u. We calculate that

$$\delta_0(a^*)(s) \underset{\text{definition of } \delta_0}{=} a^*(\partial_1 s) \underset{\text{definition of } \partial_1}{=} a^*(b - a) = a^*(b) - a^*(a) = -1 = u^*(s) - s^*(s) = (u^* - s^*)(s).$$

The same way we proceed with t and u.

[1220] Of course there are many other choices of a cochain θ that would work. We picked this particular one since later on it works well in the pictures.

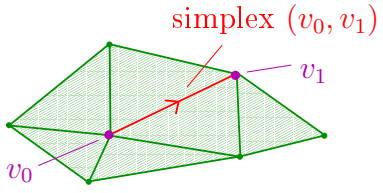
cocycle $\theta\colon \mathrm{C}_1^{\mathrm{simp}}(K) \to \mathbb{Z}$ represents a generator of $\mathrm{H}^1_{\mathrm{simp}}(K;\mathbb{Z})$

Lemma 99.3. Let G be an abelian group and let $K = (V, S)$ be an abstract simplicial complex.

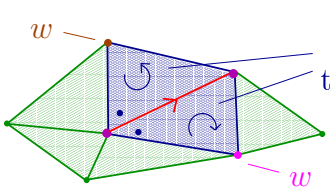
(1) Given any $g \in G$ the constant cochain $\varphi_g\colon \mathrm{C}_0^{\mathrm{simp}}(K) \to G$ given by $\varphi_g(v) = g$ for every $v \in V$ is a cocycle.
(2) If K is non-empty and connected in the sense of the definition on page 2013, then $\mathrm{H}^0_{\mathrm{simp}}(K;G) = \{\varphi_g \,|\, g \in G\}$. In particular $\mathrm{H}^0_{\mathrm{simp}}(K;G) \cong G$.

Proof.

(1) Let $g \in G$. We need to show that $\delta_0(\varphi_g) = 0 \in \mathrm{C}^1_{\mathrm{simp}}(K) = \mathrm{Hom}(\mathrm{C}_1^{\mathrm{simp}}(K), G)$. In other words, by definition of $\mathrm{C}_1^{\mathrm{simp}}(K)$ we need to show that for every ordered 1-simplex (v_0, v_1) of K we have $(\delta_0\varphi_g)([v_0, v_1]) = 0$. Indeed, we calculate that



$$\delta_0(\varphi_g)([v_0,v_1]) \underset{\text{definition of } \delta_0}{=} \varphi_g(\partial_1([v_0,v_1])) \underset{\text{definition of } \partial_1}{=} \varphi_g(v_1 - v_0) = \varphi_g(v_1) - \varphi_g(v_0) = g - g = 0.$$



(2) We will prove the second statement in Exercise 99.2. ∎

We conclude this section with the following explicit calculation of the coboundary map. This result will come in handy in the following chapter.

Lemma 99.4. Let $K = (V, S)$ be an abstract simplicial complex and let $(v_0, \ldots, v_k)$ be an ordered k-simplex of K. We have

$$\delta_k([v_0,\ldots,v_k]^*) = (-1)^{k+1} \cdot \sum_{\substack{w \in V \text{ such that} \\ \{v_0,\ldots,v_k,w\} \text{ is} \\ \text{a } (k+1)\text{-simplex}}} [v_0,\ldots,v_k,w]^* \in \mathrm{C}^{k+1}_{\mathrm{simp}}(K;\mathbb{Z}).$$

the coboundary $\delta_1([v_0, v_1]^*)$ sends these two ordered 2-simplices to $+1$ and all the other ones to zero

Proof. We need to show that both sides define the same map $\mathrm{C}^{\mathrm{simp}}_{k+1}(K) \to \mathbb{Z}$. Basically by definition of $\mathrm{C}^{\mathrm{simp}}_{k+1}(K)$ this means that we need to show both sides provide the same value for any given $[y_0, \ldots, y_{k+1}]$. So suppose we are given an ordered $(k+1)$-simplex $(y_0, \ldots, y_{k+1})$ of K. After possibly reordering the y_i we can arrange that there exists an $m \in \{0, \ldots, k\}$ such that $y_i = v_i$ for $i = 0, \ldots, m-1$ and such that $\{y_m, \ldots, y_{k+1}\} \cap \{v_m, \ldots, v_k\} = \varnothing$. We calculate that

$$\begin{array}{rcl}
(\delta_k([v_0,\dots,v_k]^*)([y_0,\dots,y_{k+1}]) & \overset{\text{definition of } \delta_k}{\overset{\downarrow}{=}} & [v_0,\dots,v_k]^*(\partial_{k+1}([y_0,\dots,y_{k+1}])) \overset{\text{definition of } \partial_{k+1}}{\overset{\downarrow}{=}} \\
& = & \sum_{i=0}^{k+1}(-1)^i\cdot[v_0,\dots,v_k]^*([y_0,\dots,\widehat{y_i},\dots,y_{k+1}]) \\
& = & \sum_{i=0}^{k+1}\begin{cases} 0, & \text{if } i<k+1 \text{ or if } m\neq k \\ (-1)^{k+1}, & \text{if } i=k+1 \text{ and if } m=k. \end{cases} \\
& \overset{\text{follows from the choice of } m}{\uparrow} &
\end{array}$$

It follows easily from the definitions that the cochain on the right hand side of the lemma leads to the same result. ■

99.3. **Properties of simplicial cohomology groups.** In the following lemma we will see that simplicial cohomology groups define contravariant functors. Before we can formulate that lemma let us recall a definition from Lemmas 95.3 and 95.7. Namely, given a simplicial map $f\colon K=(V,S)\to L=(W,T)$ between abstract simplicial complexes we consider the following chain map:

$$\begin{array}{rcl}
f_*\colon \mathrm{C}_k^{\mathrm{simp}}(K) & \to & \mathrm{C}_k^{\mathrm{simp}}(L) \\
[v_0,\dots,v_k] & \mapsto & \begin{cases} [f(v_0),\dots,f(v_k)], & \text{if } f(v_0),\dots,f(v_k) \text{ are pairwise different,} \\ 0, & \text{otherwise.} \end{cases}
\end{array}$$

When we are dealing with an order-preserving simplicial map between ordered abstract simplicial complexes, then we define the induced map $\mathrm{C}_k^{\mathrm{simp},\leq}(K)\to\mathrm{C}_k^{\mathrm{simp},\leq}(L)$ in the analogous way.

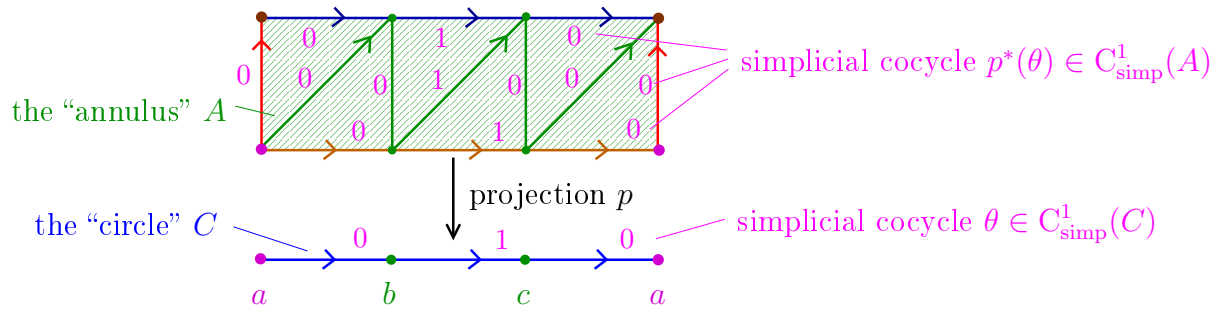
Lemma 99.5. Let $k\in\mathbb{N}_0$ and let G be an abelian group.

(1) The maps

$$\begin{array}{rcl}
(K,\leq) & \mapsto & \mathrm{H}^k_{\mathrm{simp},\leq}(K;G) \\
(f\colon(K,\leq)\to(L,\leq)) & \mapsto & \left(\begin{array}{rcl} f_*\colon \mathrm{H}^k_{\mathrm{simp},\leq}(K;G) & \to & \mathrm{H}^k_{\mathrm{simp},\leq}(L;G) \\ [\varphi\colon \mathrm{C}_k^{\mathrm{simp}}(K)\to G] & \mapsto & [\varphi\circ f_*] \end{array}\right)
\end{array}$$

define a contravariant functor from the category *OrdAbsSimpCplx* of ordered abstract simplicial complexes to the category *AbGroup* of abelian groups.

(2) The maps



$$\begin{array}{rcl}
K & \mapsto & \mathrm{H}^k_{\mathrm{simp}}(K;G) \\
(f\colon K\to L) & \mapsto & \left(\begin{array}{rcl} f_*\colon \mathrm{H}^k_{\mathrm{simp}}(K;G) & \to & \mathrm{H}^k_{\mathrm{simp}}(L;G) \\ [\varphi\colon \mathrm{C}_k^{\mathrm{simp}}(K)\to G] & \mapsto & [\varphi\circ f_*] \end{array}\right)
\end{array}$$

define a contravariant functor from the category *AbsSimpCplx* of abstract simplicial complexes to the category *AbGroup* of abelian groups.

Proof. The lemma is an immediate consequence of Lemmas 95.3, 95.7 and 108.8. ■

Example. In the figure below we show the "simplicial annulus" A together with the natural projection p to the simplicial circle C. Furthermore we also show the simplicial cocycle $\theta\in\mathrm{C}^1_{\mathrm{simp}}(C;\mathbb{Z})$ that we introduced on page 2175 and we show the corresponding cocycle $p^*(\theta)\in\mathrm{C}^1_{\mathrm{simp}}(A)$.

The following proposition relates the two flavors of simplicial cohomology groups to one another and it relates them to the singular cohomology groups of the topological realization.

Proposition 99.6. (Simplicial-Singular Cohomology Isomorphism Proposition) Let G be an abelian group.

(1) Let $(K, \leq)$ be an ordered abstract simplicial complex.

(a) The natural maps

$$\begin{aligned} \Theta^*_{\leq,k} \colon \mathrm{C}^k(|K|;G) &\to \mathrm{C}^k_{\mathrm{simp},\leq}(K;G) \\ (\varphi \colon \mathrm{C}_k(|K|) \to G) &\mapsto \left(\mathrm{C}^{\mathrm{simp}}_{k,\leq}(K) \xrightarrow{\Theta_{\leq,k}} \mathrm{C}_k(|K|) \xrightarrow{\varphi} G\right) \end{aligned}$$

are a cochain homotopy equivalence. In particular the maps induce natural isomorphisms

$$\Theta^*_{\leq,k} \colon \mathrm{H}^k(|K|;G) \to \mathrm{H}^k_{\mathrm{simp},\leq}(K;G)$$

(b) Every simplicial cocycle $\varphi \in \mathrm{C}^k_{\mathrm{simp},\leq}(K;G)$ "extends" to a singular cocycle of $\mathrm{C}^k(|K|;G)$. More precisely, there exists a cocycle $\psi \in \mathrm{C}^k(|K|;G)$ such that $\Theta^*_{\leq,k}(\psi) = \varphi$, i.e. such that $\psi \circ \Theta_{\leq,k} = \varphi \colon \mathrm{C}^{\mathrm{simp}}_k(K) \to G$.

(2) Let K be an abstract simplicial complex. We pick an order "$\leq$" for K. The composition of the two maps

$$\mathrm{H}^k(|K|;G) \xrightarrow{\Theta^*_{\leq}} \mathrm{H}^k_{\mathrm{simp},\leq}(K;G) \xrightarrow{\Omega^{-1}_{\leq,*}} \mathrm{H}^k_{\mathrm{simp}}(K;G)$$

does not depend on the choice of "$\leq$" and it defines a natural isomorphism

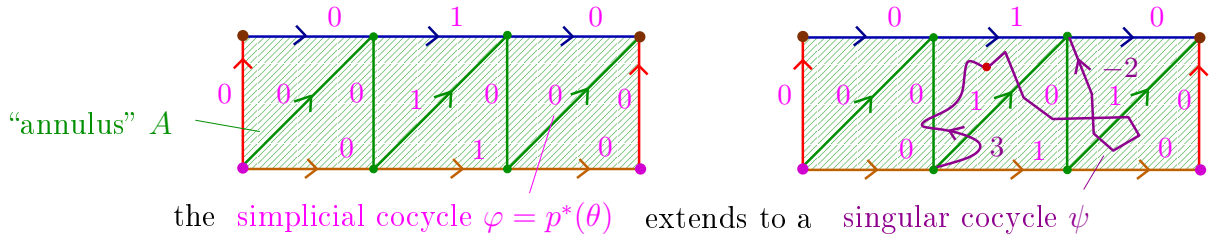
$$\Xi^*_k \colon \mathrm{H}^k(|K|;G) \to \mathrm{H}^k_{\mathrm{simp}}(K;G).$$

Proof.

(1) (a) This statement follows immediately from Proposition 99.1 (1) and the Dual Cochain Map Lemma 108.8.

(b) Let $\varphi \in \mathrm{C}^k_{\mathrm{simp},\leq}(K;G)$ be a simplicial cocycle. By Proposition 99.1 (2) there exist maps $\pi_k \colon \mathrm{C}_k(|K|) \to \mathrm{C}^{\mathrm{simp},\leq}_k(K)$ which have the following two properties:

(i) The maps π_k form a chain map.



(ii) For each $k \in \mathbb{N}_0$ we have $\pi_k \circ \Theta_k = \mathrm{id}_{\mathrm{C}^{\mathrm{simp},\leq}_k(K)}$.

We set $\psi := \pi^*_k(\varphi)$. By (i) this is a cocycle and by (ii) we have $\psi \circ \Theta_{\leq,k} = \varphi$.

(2) This statement follows immediately from Proposition 99.1 (1) and the Dual Cochain Map Lemma 108.8. ■

Example. Let us rephrase the statement of the Simplicial-Singular Cohomology Isomorphism Proposition 99.6 (1b). It says that given any simplicial cocycle $\varphi \in \mathrm{C}^k_{\mathrm{simp},\leq}(K;G)$

there exists a singular cocycle $\psi \in \mathrm{C}^k(|K|;G)$ with $[\Theta^*_{\leq,k}(\psi)] = [\varphi] \in \mathrm{H}^k_{\mathrm{simp},\leq}(K;G)$ and which, restricted to the singular simplices provided by the simplices of K, coincides with φ. We try to illustrate this statement in the figure below.

We continue with the following lemma which is just a special case of Lemma 109.6.

Lemma 99.7. Let G be an abelian group and let $k \in \mathbb{N}_0$.

(1) Given any abstract simplicial complex K the map

$$\begin{aligned} \langle\ ,\ \rangle\colon \mathrm{H}^k_{\mathrm{simp}}(K;G) \times \mathrm{H}^{\mathrm{simp}}_k(K) &\to G \\ ([\varphi],[\sigma]) &\mapsto \langle [\varphi],[c]\rangle_K := \varphi(\sigma), \end{aligned}$$

called the *Kronecker pairing*, is well-defined and bilinear.

(2) Given any simplicial map $f\colon K \to L$ between two abstract simplicial complexes, given any $\sigma \in \mathrm{H}^{\mathrm{simp}}_k(K)$ and given any $\varphi \in \mathrm{H}^k_{\mathrm{simp}}(L;G)$ we have

$$\langle f^*(\varphi),\sigma\rangle_K = \langle \varphi, f_*(\sigma)\rangle_L.$$

With the above lemma we can now formulate the following theorem which is an immediate consequence of the purely algebraic Universal Coefficient Theorem 110.11 for Cohomology Groups.

Theorem 99.8. (Universal Coefficient Theorem for Simplicial Cohomology) Let K be an abstract simplicial complex and let G be an abelian group. For each $k \in \mathbb{N}_0$ there exists a short exact sequence

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{Ext}(\mathrm{H}^{\mathrm{simp}}_{k-1}(K),G) & \longrightarrow & \mathrm{H}^k_{\mathrm{simp}}(K;G) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}^{\mathrm{simp}}_k(K),G) & \longrightarrow & 0 \\ & & & & \varphi & \mapsto & \begin{pmatrix} \mathrm{H}^{\mathrm{simp}}_k(K) \to G \\ \sigma \mapsto \langle \varphi,\sigma\rangle_K \end{pmatrix} & & \end{array}$$

which is natural in the abstract simplicial complex K and natural in the abelian group G. This short exact sequence splits and there exists therefore an isomorphism

$$\mathrm{H}^k_{\mathrm{simp}}(K;G) \cong \mathrm{Ext}(\mathrm{H}^{\mathrm{simp}}_{k-1}(K),G) \oplus \mathrm{Hom}(\mathrm{H}^{\mathrm{simp}}_k(K),G).$$

The analogous statement for ordered abstract simplicial complexes and the corresponding simplicial homology and cohomology groups also holds.

Remark.

(1) The Universal Coefficient Theorem 99.8 for Simplicial Cohomology is a double-edged sword. It allows us to compute the isomorphism types of simplicial cohomology groups in terms of the much more friendly simplicial homology groups. But it also says, somewhat disappointingly, that the isomorphism types of simplicial cohomology groups do not contain any information that is not already contained in the isomorphism types of the simplicial homology groups.

(2) The Universal Coefficient Theorem 99.8 for Simplicial Cohomology is also somewhat less powerful than it might appear. The theorem can be very convenient for determining the isomorphism types of simplicial cohomology groups. But if the Ext-terms are non-zero, then the theorem does not provide an approach to finding explicit cocycles representing cohomology classes.

99.4. **The simplicial cup product.** We had seen that one the remarkable features of singular cohomology is that it comes with a cup product and that it interacts with singular homology via the cap product. Before we attempt to introduce simplicial analogues let us remind us of the definitions from pages 2503, 2513 and 2551.

Definition.

(1) For $i = 0, \dots, n$ we write $v_i := (0, \dots, 1, 0, \dots, 0) \in \mathbb{R}^{n+1}$.

(2) For $a_0, \dots, a_k \in \Delta^n$ we consider the map

$$\begin{array}{rcl} [a_0, \dots, a_k] \colon \Delta^k & \to & \Delta^n \\ (\lambda_0, \dots, \lambda_k) & \mapsto & \sum_{j=0}^{k} \lambda_j \cdot a_j. \end{array}$$

(3) Let X be a topological space and let R be a commutative ring.

(a) Let $\varphi \in \mathrm{C}^p(X; R)$ and $\psi \in \mathrm{C}^q(X; R)$ be cochains. We define the cup product of φ and ψ to be the singular cochain

$$\begin{array}{rcl} \varphi \cup \psi \colon \mathrm{C}_{p+q}(X) & \to & R \\ (\sigma \colon \Delta^{p+q} \to X) & \mapsto & \underbrace{\varphi(\sigma \circ [v_0, \dots, v_p])}_{\in R} \cdot \underbrace{\psi(\sigma \circ [v_p, \dots, v_{p+q}])}_{\in R}. \end{array}$$

(b) Given a singular cochain $\varphi \in \mathrm{C}^k(X; R)$ and a singular simplex $\sigma \colon \Delta^n \to X$ with $k \leq n$ we define the cap product of φ and σ to be the singular chain

$$\varphi \cap \sigma := \underbrace{\varphi(\sigma \circ [v_0, \dots, v_k])}_{\in R} \cdot \underbrace{\sigma \circ [v_k, \dots, v_n]}_{\text{map } \Delta^{n-k} \to X}.$$

For $k > n$ we define $\varphi \cap \sigma = 0$.

In this and in the coming section we will introduce simplicial analogues of the above definitions. Evidently the idea is to imitate the above definitions and to define the cup and cap products on the level of simplicial (co-) chains. A short moment's thought shows that on the (co-) chain level one needs to work with *ordered* abstract simplicial complexes.
First we have the following definition which is clearly inspired by our second definition of the cup product in singular cohomology that we gave on page 2513.

Definition. Let $(K, \leq)$ be an ordered abstract simplicial complex and let R be a commutative ring. Given $\varphi \in \mathrm{C}^p_{\mathrm{simp},\leq}(K; R)$ and $\psi \in \mathrm{C}^q_{\mathrm{simp},\leq}(K; R)$ we consider the cup product

$$\begin{array}{rcl} \varphi \cup \psi \colon \mathrm{C}^{\mathrm{simp},\leq}_{p+q}(K) & \to & R \\ \{v_0 < \cdots < v_p < \cdots < v_{p+q}\} & \mapsto & \underbrace{\varphi(\{v_0 < \ldots < v_p\})}_{\in R} \cdot \underbrace{\psi(\{v_p < \ldots < v_{p+q}\})}_{\in R}. \end{array}$$

The following lemma is the analogue of Coboundary-Cup Product Lemma 114.2.

Lemma 99.9. (Coboundary-Cup Product Lemma) Let $(K, \leq)$ be an ordered abstract simplicial complex and let R be a commutative ring. Furthermore let $\varphi \in \mathrm{C}^p_{\mathrm{simp},\leq}(K;R)$ and $\psi \in \mathrm{C}^q_{\mathrm{simp},\leq}(K;R)$. Then

$$\delta(\varphi \cup \psi) \;=\; \delta\varphi \cup \psi \,+ (-1)^p \cdot \varphi \cup \delta\psi \;\in\; \mathrm{C}^{p+q+1}_{\mathrm{simp},\leq}(K;R).$$

In the following we will state several lemmas that are the simplicial counterparts of earlier results on the singular cup product. In most cases the proofs are, with an appropriate change of notation, basically identical. For sake of illustration we provide the proof of the Coboundary-Cup Product Lemma 99.9 and we invite the reader to compare the proof to the proof of the original Coboundary-Cup Product Lemma 114.2.

Proof. Let $\varphi \in \mathrm{C}^p_{\mathrm{simp},\leq}(K;R)$ and $\psi \in \mathrm{C}^q_{\mathrm{simp},\leq}(K;R)$ be simplicial cochains. We have to prove the following equality:

$$\delta(\varphi \cup \psi) \;=\; \delta\varphi \cup \psi \,+ (-1)^p \cdot \varphi \cup \delta\psi \;\in\; \mathrm{C}^{p+q+1}_{\mathrm{simp},\leq}(K;R) = \mathrm{Hom}(\mathrm{C}^{\mathrm{simp},\leq}_{p+q+1}(K), R).$$

So let $s = \{v_0 < \cdots < v_{p+q+1}\}$ be a simplicial $(p+q+1)$-simplex. We have the following three equalities in R:[1221]

$$\begin{aligned}
\text{(a) } (\delta(\varphi\cup\psi))(s) &= (\varphi\cup\psi)\Big(\sum_{j=0}^{p+q+1}(-1)^j\cdot\{v_0<\ldots<\widehat{v_j}<\ldots<v_{p+q+1}\}\Big)\\
&= \sum_{j=0}^{p}(-1)^j\cdot(\varphi\cup\psi)(\{v_0<\ldots<\widehat{v_j}<\ldots<v_{p+q+1}\})\\
&\quad + (-1)^p\cdot\sum_{k=1}^{q+1}(-1)^k\cdot(\varphi\cup\psi)(\{v_0<\ldots<\widehat{v_{k+p}}<\ldots<v_{p+q+1}\})\\
&= \sum_{j=0}^{p}(-1)^j\cdot\varphi(\{v_0<\ldots<\widehat{v_j}<\ldots<v_{p+1}\})\cdot\psi(\{v_p<\ldots<v_{p+q+1}\})\\
&\quad + (-1)^p\cdot\sum_{k=1}^{q+1}(-1)^k\cdot\varphi(\{v_0<\ldots<v_p\})\cdot\psi(\{v_p<\ldots<\widehat{v_k}<\ldots<v_{p+q+1}\}).\\
\text{(b) } (\delta\varphi\cup\psi)(s) &= (\delta\varphi)(\{v_0<\ldots<v_{p+1}\})\cdot\psi(\{v_p<\ldots<v_{p+q+1}\})\\
&= \varphi\Big(\sum_{j=0}^{p+1}(-1)^j\cdot\{v_0<\ldots<\widehat{v_j}<\ldots<v_{p+1}\}\Big)\cdot\psi(\{v_p<\ldots<v_{p+q+1}\})\\
&= \sum_{j=0}^{p+1}(-1)^j\cdot\varphi(\{v_0<\ldots<\widehat{v_j}<\ldots<v_{p+1}\})\cdot\psi(\{v_p<\ldots<v_{p+q+1}\})
\end{aligned}$$

and

$$\begin{aligned}
\text{(c) } (-1)^p\cdot(\varphi\cup\delta\psi)(s) &= (-1)^p\cdot\varphi(\{v_0<\ldots<v_p\})\cdot(\delta\psi)(\{v_p<\ldots<v_{p+q+1}\})\\
&= (-1)^p\cdot\varphi(\{v_0<\ldots<v_p\})\cdot\psi\Big(\sum_{k=0}^{q+1}(-1)^k\cdot\{v_p<\ldots<\widehat{v_k}<\ldots<v_{p+q+1}\}\Big)\\
&= (-1)^p\cdot\sum_{k=0}^{q+1}(-1)^k\cdot\varphi(\{v_0<\ldots<v_p\})\cdot\psi(\{v_p<\ldots<\widehat{v_k}<\ldots<v_{p+q+1}\}).
\end{aligned}$$

Now we observe that if we take the sum of (b) and (c), then the $(j = p+1)$-summand in (b) cancels with the $(k = 0)$-summand in (c). But after this observation it is obvious that the desired equality (b)+(c)=(a) holds. ■

[1221] Here in the argument we use on several occasions that for a simplicial n-cochain ϕ and an $(n+1)$-simplex $t = \{w_0 < \ldots < w_{n+1}\}$ we have by definition

$$(\delta_{n+1}\phi)(t) \;=\; \phi(\partial_n t) \;=\; \phi\Big(\sum_{l=0}^{n+1}(-1)^l\cdot\{w_0<\ldots<\widehat{w_l}<\ldots<w_{n+1}\}\Big).$$

In light of the Coboundary-Cup Product Lemma 99.9 it is now straightforward to see that the cup product descends to a map on simplicial cohomology.

Lemma 99.10. Let R be a commutative ring. For every ordered abstract simplicial complex $(K, \leq)$ the map

$$\begin{array}{rcl} \cup\colon \mathrm{H}^p_{\mathrm{simp},\leq}(K;R) \times \mathrm{H}^q_{\mathrm{simp},\leq}(K;R) & \to & \mathrm{H}^{p+q}_{\mathrm{simp},\leq}(K;R) \\ ([\varphi],[\psi])] & \mapsto & [\varphi] \cup [\psi] := [\varphi \cup \psi] \end{array}$$

is well-defined. We refer to this map again as the cup product.

Proof. This lemma follows almost immediately from the Coboundary-Cup Product Lemma 99.9. For more details we refer to the proof of Lemma 114.3. In that proof we just need to replace Coboundary-Cup Product Lemma 114.2 by the Coboundary-Cup Product Lemma 99.9. ■

The simplicial cup product is an interesting invariant in its own right and as we will see shortly, for finite abstract simplicial complexes it can be computed effectively. As for simplicial homology the question arises whether the isomorphism type of the simplicial cup product is an invariant of the topological realization. As we discussed in Sections 95.4 and 95.5, arguably the cleanest way of showing this is by proving that the simplicial cup product corresponds to the singular cup product. This is precisely what we will do in the first part of the following proposition, which can be viewed as an addendum to the Simplicial-Singular Cohomology Isomorphism Proposition 99.6.

Proposition 99.11. Let K be an abstract simplicial complex and let R be a commutative ring.

(1) Let "$\leq$" be an order on K. Let $\Theta_{\leq,k}\colon \mathrm{C}_k^{\mathrm{simp},\leq}(K) \to \mathrm{C}_k(|K|)$ be the natural chain map that we introduced in Proposition 99.1. The following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p(|K|;R) \times \mathrm{H}^q(|K|;R) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^{p+q}(|K|;R) \\ {\scriptstyle\Theta^*_\leq}\downarrow{\scriptstyle\cong} \quad {\scriptstyle\cong}\downarrow{\scriptstyle\Theta^*_\leq} & & {\scriptstyle\cong}\downarrow{\scriptstyle\Theta^*_\leq} \\ \mathrm{H}^p_{\mathrm{simp},\leq}(K;R) \times \mathrm{H}^q_{\mathrm{simp},\leq}(K;R) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^{p+q}_{\mathrm{simp},\leq}(K;R). \end{array}$$

(2) There exists a unique map

$$\mathrm{H}^p_{\mathrm{simp}}(K;R) \times \mathrm{H}^q_{\mathrm{simp}}(K;R) \xrightarrow{\quad\cup\quad} \mathrm{H}^{p+q}_{\mathrm{simp}}(K;R)$$

such that for every choice of order "$\leq$" for K the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p_{\mathrm{simp}}(K;R) \times \mathrm{H}^q_{\mathrm{simp}}(K;R) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^{p+q}_{\mathrm{simp}}(K;R) \\ {\scriptstyle\Omega^*_\leq}\downarrow{\scriptstyle\cong} \quad {\scriptstyle\cong}\downarrow{\scriptstyle\Omega^*_\leq} & & {\scriptstyle\cong}\downarrow{\scriptstyle\Omega^*_\leq} \\ \mathrm{H}^p_{\mathrm{simp},\leq}(K;R) \times \mathrm{H}^q_{\mathrm{simp},\leq}(K;R) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^{p+q}_{\mathrm{simp},\leq}(K;R). \end{array}$$

In other words, we can define the cup product on $\mathrm{H}^*_{\mathrm{simp}}(K;R)$ in a way that is independent of the choice of an order "$\leq$".

(3) The following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p(|K|;R) \times \mathrm{H}^q(|K|;R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(|K|;R) \\ {\scriptstyle \Xi_p^*}\downarrow{\scriptstyle \cong} \qquad {\scriptstyle \cong}\downarrow{\scriptstyle \Xi_q^*} & & {\scriptstyle \cong}\downarrow{\scriptstyle \Xi_{p+q}^*} \\ \mathrm{H}^p_{\mathrm{simp}}(K;R) \times \mathrm{H}^q_{\mathrm{simp}}(K;R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}_{\mathrm{simp}}(K;R). \end{array}$$

Remark. Let K be an abstract simplicial complex. In the presence of an order on K we have, by definition, a natural simplicial cup product on the cochain groups $\mathrm{C}^*_{\mathrm{simp},\leq}(K;R)$. In the absence of an order we do not have a natural simplicial cup product on the cochain groups $\mathrm{C}^*_{\mathrm{simp}}(K;R)$. But Proposition 99.11 says that we do have a natural simplicial cup product on the cohomology groups $\mathrm{H}^*_{\mathrm{simp}}(K;R)$.

Proof.

(1) It follows follows immediately from the definitions of the simplicial cup product and the definition of the singular cup product that we gave on page 2513 and that we recalled on page 2180 that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{C}^p(|K|;R) \times \mathrm{C}^q(|K|;R) & \xrightarrow{\cup} & \mathrm{C}^{p+q}(|K|;R) \\ {\scriptstyle \Theta_\leq^*}\downarrow \qquad \downarrow{\scriptstyle \Theta_\leq^*} & & \downarrow{\scriptstyle \Theta_\leq^*} \\ \mathrm{C}^p_{\mathrm{simp},\leq}(K;R) \times \mathrm{C}^q_{\mathrm{simp},\leq}(K;R) & \xrightarrow{\cup} & \mathrm{C}^{p+q}_{\mathrm{simp},\leq}(K;R). \end{array}$$

The desired statement follows immediately from this observation.

(2) Surely there is a heroic proof for this statement that does not involve singular cohomology. But to lessen the pain let us give a proof that makes the most use of our previous results. Thus we consider the following diagram:

$$\begin{array}{ccc} \mathrm{H}^p_{\mathrm{simp}}(K;R) \times \mathrm{H}^q_{\mathrm{simp}}(K;R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}_{\mathrm{simp}}(K;R) \\ {\scriptstyle (\Omega_\leq^{-1})_*}\uparrow{\scriptstyle \cong} \qquad {\scriptstyle \cong}\uparrow{\scriptstyle (\Omega_\leq^{-1})_*} & & {\scriptstyle \cong}\uparrow{\scriptstyle (\Omega_\leq^{-1})_*} \\ \mathrm{H}^p_{\mathrm{simp},\leq}(K;R) \times \mathrm{H}^q_{\mathrm{simp},\leq}(K;R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}_{\mathrm{simp},\leq}(K;R) \\ {\scriptstyle \Theta_\leq^*}\uparrow{\scriptstyle \cong} \qquad {\scriptstyle \cong}\uparrow{\scriptstyle \Theta_\leq^*} & & {\scriptstyle \cong}\uparrow{\scriptstyle \Theta_\leq^*} \\ \mathrm{H}^p(|K|;R) \times \mathrm{H}^q(|K|;R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(|K|;R). \end{array}$$

By Proposition 99.1 together with the Cochain Map Lemma 108.5 we see that the composition of the two vertical maps does not depend on the choice of "$\leq$". By (1) we know that the lower square commutes. Now we define the cup product on $\mathrm{H}^*_{\mathrm{simp}}(K;R)$ via the singular cup product and we see that it makes the upper square commute for any choice of "$\leq$".

(3) This statement follows immediately from the definition of the natural isomorphisms Ξ^*, see the Simplicial-Singular Cohomology Isomorphism Proposition 99.6 (3). ∎

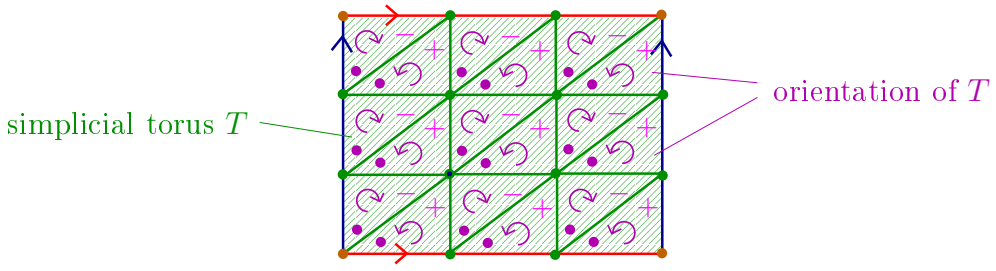
Remark. Proposition 99.11 shows in particular that if we are given a simplicial complex $(X, \Theta\colon |K| \to X)$, then we can compute the initially intractable singular cup product on $\mathrm{H}^*(X;R)$ via the simplicial cup product on $\mathrm{H}^*_{\mathrm{simp}}(K;\mathbb{R})$. If K is finite and explicitly given, then at least in principle one can compute the simplicial cup product on $\mathrm{H}^*_{\mathrm{simp}}(K;R)$ by brute force. This approach though is not a cure-all. For example given any $n \in \mathbb{N}$ we will want to determine the cup product on $\mathrm{H}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and $\mathrm{H}^*(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$. By the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that the complex projective spaces

$\mathbb{C}\mathrm{P}^n$ and the real projective spaces $\mathbb{R}\mathrm{P}^n$ admit simplicial structures. But we run into the following issues:

(1) It seems to be difficult to find explicit simplicial structures for the complex projective spaces $\mathbb{C}\mathrm{P}^n$. So we cannot even get started.
(2) Explicit simplicial structures for smooth manifolds tend to have many simplices. For example in Exercise 94.5 we gave an explicit simplicial structure for the real projective space $\mathbb{R}\mathrm{P}^n$ with $2^{n+1}-1$ vertices and it seems difficult to find simplicial structures with a significantly smaller number of vertices.

Later on, in Propositions 121.7 and 121.7 we will compute these cup products using the Simplicial Poincaré Duality Theorem 103.4.

To do calculations of cup products we need to deal with specific cohomology classes and in fact also with explicit cocycles. In the next lemma we will see that closed oriented pseudomanifolds are a rich source of interesting explicit cocycles. Before we can state this lemma it is convenient to recall some definitions from page 2142 and page 2143.



Definition. Let $K = (V, S)$ be an n-dimensional pseudomanifold.

(1) We denote by S_n the set of n-simplices of K.
(2) An orientation of an n-simplex s of K is an equivalence class of a pair $(\epsilon, \widetilde{s})$ where $\epsilon \in \{-1, 1\}$ and $\widetilde{s}$ is an ordered n-simplex with $\lfloor \widetilde{s} \rfloor = s$.
(3) An orientation of K is a choice of an orientation for each n-simplex of K such that for any $(n-1)$-simplex s of order 2 the two cobounding n-simplices induce opposite orientations on s.
(4) If K is a closed pseudomanifold that is equipped with an orientation $\{(\epsilon_w, Y_w)\}_{w \in S_n}$, then we refer to the simplicial homology class

$$[K] \;:=\; \Big[\sum_{w \in S_n} \epsilon_w \cdot Y_w \Big] \;\in\; \mathrm{H}_n^{\mathrm{simp}}(K)$$

as the fundamental class of K.

We illustrate the definitions for the simplicial torus in the figure below.

Now we can formulate the following lemma.

Lemma 99.12. Let $K = (V, S)$ be a closed connected n-dimensional pseudomanifold that is equipped with an orientation $\{(\epsilon_w, Y_w)\}_{w \in S_n}$ in the sense of the definition on page 2142.

(1) (a) For any $s, t \in S_n$ we have $[\epsilon_s \cdot Y_s^*] = [\epsilon_t \cdot Y_t^*] \in \mathrm{H}^n_{\mathrm{simp}}(K; \mathbb{Z})$. We refer to this cohomology class as the dual fundamental class $[K]^* \in \mathrm{H}^n_{\mathrm{simp}}(K; \mathbb{Z})$.
    (b) We have $\mathrm{H}^n_{\mathrm{simp}}(K; \mathbb{Z}) = \mathbb{Z} \cdot [K]^*$.
(2) We have $\langle [K]^*, [K] \rangle_K = 1$.

Proof.

(1) It follows from Theorem 98.4, and the discussion on page 2148 that the simplicial chain complex of K is of the form

$$0 \to \underbrace{\mathbb{Z}\cdot\Big[\sum_{w\in S_n}\epsilon_w\cdot Y_w\Big]\oplus\widetilde{C}_n}_{=\mathrm{C}_n^{\mathrm{simp}}(K)} \xrightarrow[\partial_n]{\begin{pmatrix}0 & D\\ 0 & 0\end{pmatrix}} \underbrace{\widetilde{C}_{n-1}\oplus\widehat{\mathrm{C}}_{n-1}}_{=\mathrm{C}_{n-1}^{\mathrm{simp}}(K)} \to \dots$$

such that $D\colon \widetilde{C}_n \to \widetilde{C}_{n-1}$ is an isomorphism. It follows easily that the map

$$\begin{array}{rcccc} \mathrm{H}^n_{\mathrm{simp}}(K;\mathbb{Z}) = \operatorname{coker}(\delta_{n-1}) & \to & \operatorname{Hom}\Big(\mathbb{Z}\cdot\Big[\sum\limits_{w\in S_n}\epsilon_w\cdot Y_w\Big],\mathbb{Z}\Big) & \to & \mathbb{Z}\\ \varphi & \mapsto & \text{restriction of } \varphi & & \\ & & & \varphi & \mapsto \quad \varphi\Big(\sum\limits_{w\in S_n}\epsilon_w\cdot Y_w\Big) \end{array}$$

is an isomorphism. The desired statements follow almost immediately from this observation.[1222]

(2) This statement follows immediately from the definitions. ∎

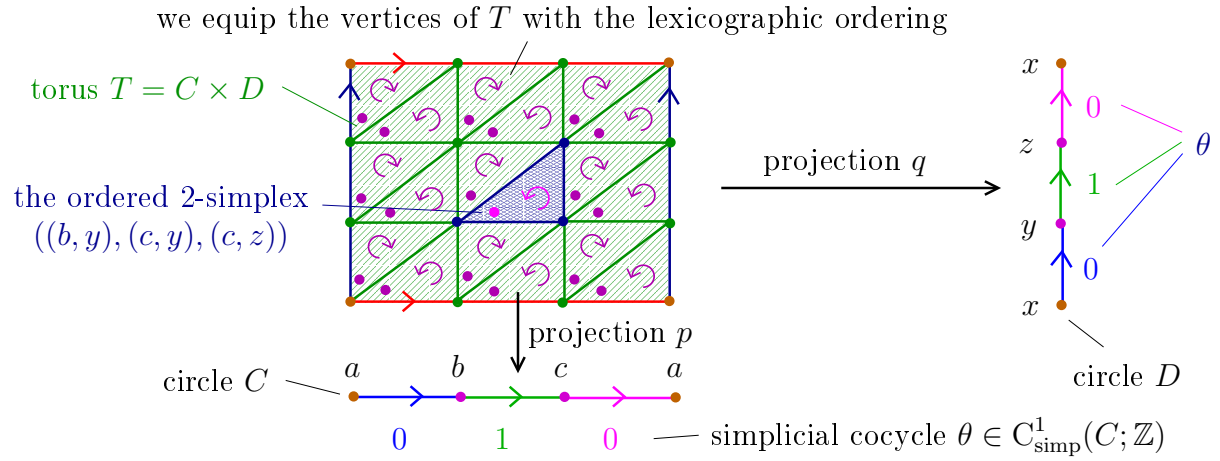
Now let us try to determine the simplicial cup product of the simplicial torus.

Example. We consider the simplicial circle C with vertex set $V = \{a, b, c\}$ and the simplicial circle $D = \{x, y, z\}$ with the obvious total order on the vertex sets. Furthermore we consider the simplicial torus $T = C \times D$, where we define the product as on page 1998. We equip T with the orientation shown in the figure on page 2184. We denote by $p\colon C\times D \to C$ and $q\colon C \times D \to D$ the natural projections. We equip the vertex set of $T = C \times D$ with the lexicographic ordering. In the figure below we show $T = C \times D$ together with the projections.

Let us first consider the simplicial cohomology of T. Let $\theta \in \mathrm{C}^1_{\mathrm{simp}}(C)$ be the simplicial cocycle that we introduced on page 2175. We have the following equalities:

$$\mathrm{H}^i_{\mathrm{simp}}(T;\mathbb{Z}) \;=\; \begin{cases} \mathbb{Z}\cdot[\text{constant cochain } v\mapsto 1], & \text{if } i=0,\\ \mathbb{Z}\cdot[p^*(\theta)]\oplus\mathbb{Z}\cdot[q^*(\theta)], & \text{if } i=1,\\ \mathbb{Z}\cdot[T]^*, & \text{if } i=2,\\ 0, & \text{if } i>2. \end{cases}$$

This can be obtained either through a slightly heroic linear algebra exercise, or, more systematically, through the combination of Lemma 99.12, the Simplicial Künneth Theorem 95.14 and the Universal Coefficient Theorem 99.8 for Simplicial Cohomology. Now we can calculate our first interesting simplicial cup product:



$$[p^*(\theta)]\cup[q^*(\theta)] \;=\; [p^*(\theta)\cup q^*(\theta)] \underset{\text{by inspection}}{=} [\overbrace{((b,y),(c,y),(c,z))}^{\text{ordered 2-simplex}}{}^*] \underset{\text{by Lemma 99.12}}{=} [T]^* \;\in\; \mathrm{H}^2_{\mathrm{simp}}(T;\mathbb{Z}).$$

[1222] The above argument is related to the content of Exercise 108.1.

Similar calculations gives us the following table for the cup product:[1223]

$$\begin{pmatrix} [p^*(\theta)] \cup [p^*(\theta)] & [p^*(\theta)] \cup [q^*(\theta)] \\ [q^*(\theta)] \cup [p^*(\theta)] & [q^*(\theta)] \cup [q^*(\theta)] \end{pmatrix} = \begin{pmatrix} 0 & [T]^* \\ -[T]^* & 0 \end{pmatrix}.$$

This is the simplicial analogue of the calculation performed in Lemma 114.14.

In the following we state several properties of the simplicial cup product that are the analogues of the corresponding properties of the singular cup product.

Proposition 99.13. Let $K = (V,S)$ be an abstract simplicial complex and let R be a commutative ring. The following statements hold:

(1) The cup product on $\mathrm{H}^*_{\mathrm{simp}}(K;R)$ is R-bilinear and associative.

(2) The abelian group $\mathrm{H}^*_{\mathrm{simp}}(K;R) = \bigoplus_{n\in\mathbb{N}_0} \mathrm{H}^n_{\mathrm{simp}}(K;R)$ together with the map

$$\cup\colon \mathrm{H}^*_{\mathrm{simp}}(K;R) \times \mathrm{H}^*_{\mathrm{simp}}(K;R) \to \mathrm{H}^*_{\mathrm{simp}}(K;R)$$

is a ring where the multiplicatively neutral element is given by

$$1_K \;:=\; \big[\text{map } V \to R \text{ given by } v \mapsto 1\big] \;\in\; \mathrm{H}^0_{\mathrm{simp}}(K;R).$$

Proof. We pick an order "$\leq$" for K. As in the proof of the Cup Product-Ring Proposition 114.7 we see that the cup product on the cochain level is associative. It now follows easily that all the given statements hold for $(\mathrm{H}^*_{\mathrm{simp},\leq}(K;R),\cup)$. By Proposition 99.11 (2) the statements now also hold for $(\mathrm{H}^*_{\mathrm{simp}}(K;R),\cup)$. ■

Proposition 99.14. Let K be an abstract simplicial complex and let R be a commutative ring. For any $\varphi \in \mathrm{H}^p_{\mathrm{simp}}(K;R)$ and any $\psi \in \mathrm{H}^q_{\mathrm{simp}}(K;R)$ we have

$$\varphi \cup \psi \;=\; (-1)^{pq} \cdot \psi \cup \varphi \;\in\; \mathrm{H}^{p+q}_{\mathrm{simp}}(K;R).$$

Proof. We pick an order "$\leq$" for K. By Proposition 99.11 (2) it suffices to prove the following claim.

[1223] In fact the remaining three entries of the matrix can also be obtained easily from Proposition 99.14 and Lemma 99.15.

Claim. For any $\varphi \in \mathrm{H}^p_{\mathrm{simp},\leq}(K;R)$ and $\psi \in \mathrm{H}^q_{\mathrm{simp},\leq}(K;R)$ we have

$$\varphi \cup \psi \;=\; (-1)^{pq} \cdot \psi \cup \varphi \;\in\; \mathrm{H}^{p+q}_{\mathrm{simp},\leq}(K;R).$$

Proof. The proof of the claim happens at the "cochain level". The argument is basically identical to the proof of the Cup Product-Commutativity Proposition 114.8. The only real difference is that one needs to replace the product topological space $\Delta^n \times [0,1]$ by the product of the ordered abstract simplicial complexes $D_n = (\{0,\ldots,n\}, \mathcal{P}(\{0,\ldots,n\}\backslash\{\varnothing\}))$ and $D_1 = (\{0,1\},\{\{0\},\{1\}\})$, as defined in the Simplicial Complex-Product Lemma 93.16. We leave it to the reader to make the necessary modifications to the argument. ■

Lemma 99.15. Let R be a commutative ring.

(1) Let $f\colon K \to L$ be a simplicial map between two abstract simplicial complexes. For any $\varphi \in \mathrm{H}^p_{\mathrm{simp}}(L;R)$ and $\psi \in \mathrm{H}^q_{\mathrm{simp}}(L;R)$ we have

$$f^*(\varphi) \cup f^*(\psi) \;=\; f^*(\varphi \cup \psi).$$

In particular the map

$$f^*\colon \mathrm{H}^*_{\mathrm{simp}}(L;R) \;\to\; \mathrm{H}^*_{\mathrm{simp}}(K;R)$$

is a homomorphism of graded rings which satisfies $f^*(1_L) = 1_K$.

(2) The maps

$$\begin{aligned} K &\mapsto (\mathrm{H}^*_{\mathrm{simp}}(K;R), \cup) \\ (f\colon K \to L) &\mapsto (f^*\colon \mathrm{H}^*_{\mathrm{simp}}(L;R) \to \mathrm{H}^*_{\mathrm{simp}}(K;R)) \end{aligned}$$

define a contravariant functor from the category $\mathcal{AbsSimpCplx}$ of abstract simplicial complexes to the category $\mathcal{GrRing}$ of graded rings.

Proof.

(1) Let $f\colon K = (V,S) \to L = (W,T)$ be a simplicial map between two abstract simplicial complexes. By Exercise 0.5 we can pick total orders "$\leq_K$" on K and "$\leq_L$" on L such that the map $f\colon V \to W$ is order-preserving. It follows basically immediately from the definitions that for $\varphi \in \mathrm{C}^p_{\mathrm{simp},\leq_L}(L;R)$ and $\psi \in \mathrm{C}^q_{\mathrm{simp},\leq_L}(L;R)$ we have the equality $f^*(\varphi) \cup f^*(\psi) = f^*(\varphi \cup \psi) \in \mathrm{C}^{p+q}_{\mathrm{simp},\leq_K}(K)$. The statements now follow from Proposition 99.11 (2).

(2) This statement follows from (1) together with Lemma 99.5 (2). ■

99.5. **The simplicial cap product.** In this section we will introduce the simplicial cap product. In contrast to the simplicial cup product it is perhaps less immediately clear what the simplicial cap product is good for. But it will have its moment of glory in Chapter 100 when we state and prove the Simplicial Poincaré Duality Theorem 103.4.

Definition. Let $(K,\leq)$ be an ordered abstract simplicial complex and let R be a commutative ring. Given an n-simplex $s = \{v_0 < \cdots < v_n\}$, given $k \leq n$ and given a simplicial cochain $\varphi \in \mathrm{C}^k_{\mathrm{simp},\leq}(K;R)$ we define

$$\varphi \cap s \;:=\; \underbrace{\varphi(\{v_0 < \cdots < v_k\})}_{\in R} \cdot \underbrace{\{v_k < \cdots < v_n\}}_{\in \mathrm{C}^{\mathrm{simp},\leq}_{n-k}(K)} \;\in\; \mathrm{C}^{\mathrm{simp},\leq}_{n-k}(K;R).$$

We extend this definition to simplicial R-chains and we obtain the cap product

$$\begin{array}{rcl} \cap\colon \mathrm{C}^k_{\mathrm{simp},\leq}(X;R) \times \mathrm{C}_n^{\mathrm{simp},\leq}(X;R) & \to & \mathrm{C}_{n-k}^{\mathrm{simp},\leq}(X;R) \\ \varphi \cap r \cdot \sigma & \mapsto & r \cdot \underbrace{(\varphi \cap \sigma)}_{\in R}. \end{array}$$

For $k > n$ we define the cap product to be the zero map.

The next lemma says that the cap product defines a map on simplicial (co-) homology.

Lemma 99.16. Let $(K, \leq)$ be an ordered abstract simplicial complex. Given any commutative ring R and given any $k, n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{H}^k_{\mathrm{simp},\leq}(K;R) \times \mathrm{H}_n^{\mathrm{simp},\leq}(K;R) & \to & \mathrm{H}_{n-k}^{\mathrm{simp},\leq}(K;R) \\ ([\varphi],[\sigma]) & \mapsto & [\varphi \cap \sigma] \end{array}$$

is well-defined.

Proof. The same argument as in the proof of Lemma 116.1 shows that given an n-simplex $s = \{v_0 < \cdots < v_n\}$, given $k \leq n$ and given any simplicial cochain $\varphi \in \mathrm{C}^k_{\mathrm{simp},\leq}(K;R)$ we have the following equality:

$$\partial(\varphi \cap \sigma) \;=\; (-1)^k \cdot (-\delta\varphi \cap \sigma \,+\, \varphi \cap \partial\sigma) \;\in\; \mathrm{C}_{n-k-1}(X;R).$$

As in the proof of Lemma 116.2 we see that the lemma follows easily from this equality. ∎

The next proposition is an analogue of Proposition 99.11.

Proposition 99.17. Let K be an abstract simplicial complex and let R be a commutative ring.

(1) Let "$\leq$" be an order on K. Let $\Theta_{\leq,k}\colon \mathrm{C}_k^{\mathrm{simp},\leq}(K) \to \mathrm{C}_k(|K|)$ be the natural chain map that we introduced in Proposition 99.1. The following diagram commutes:[1224]

$$\begin{array}{ccc} \mathrm{H}^p(|K|;R) \times \mathrm{H}_n(|K|;R) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-p}(|K|;R) \\ {\scriptstyle \Theta^*_\leq}\downarrow{\scriptstyle \cong} \quad {\scriptstyle \cong}\uparrow{\scriptstyle \Theta_*^\leq} & & {\scriptstyle \cong}\uparrow{\scriptstyle \Theta_*^\leq} \\ \mathrm{H}^p_{\mathrm{simp},\leq}(K;R) \times \mathrm{H}_n^{\mathrm{simp},\leq}(K;R) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-p}^{\mathrm{simp},\leq}(K;R). \end{array}$$

(2) There exists unique map

$$\mathrm{H}^p_{\mathrm{simp}}(K;R) \times \mathrm{H}_n^{\mathrm{simp}}(K;R) \xrightarrow{\quad\cap\quad} \mathrm{H}_{n-p}^{\mathrm{simp}}(K;R)$$

such that for any choice of order "$\leq$" for K the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p_{\mathrm{simp}}(K;R) \times \mathrm{H}_n^{\mathrm{simp}}(K;R) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-p}^{\mathrm{simp}}(K;R) \\ {\scriptstyle \Omega^*_\leq}\downarrow{\scriptstyle \cong} \quad {\scriptstyle \cong}\uparrow{\scriptstyle \Omega_*^\leq} & & {\scriptstyle \cong}\uparrow{\scriptstyle \Omega_*^\leq} \\ \mathrm{H}^p_{\mathrm{simp},\leq}(K;R) \times \mathrm{H}_n^{\mathrm{simp},\leq}(K;R) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-p}^{\mathrm{simp},\leq}(K;R). \end{array}$$

In other words, we can define the cap product on $\mathrm{H}^*_{\mathrm{simp}}(K;R)$ and $\mathrm{H}_*^{\mathrm{simp}}(K;R)$ in a way that is independent of the choice of an order "$\leq$".

(3) The following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p(|K|;R) \times \mathrm{H}_n(|K|;R) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-p}(|K|;R) \\ {\scriptstyle \Xi^*}\downarrow{\scriptstyle \cong} \qquad {\scriptstyle \cong}\uparrow{\scriptstyle \Xi_*} & & {\scriptstyle \cong}\uparrow{\scriptstyle \Xi_*} \\ \mathrm{H}^p_{\mathrm{simp}}(K;R) \times \mathrm{H}^{\mathrm{simp}}_n(K;R) & \xrightarrow{\quad\cap\quad} & \mathrm{H}^{\mathrm{simp}}_{n-p}(K;R). \end{array}$$

Sketch of proof.

(1) It follows almost immediately from the definition that the corresponding diagram on the level of simplicial (co-) chains commutes. This implies that the given diagram commutes.
(2) As in the proof of Proposition 99.11 (2) this statement follows from (1) together with Proposition 99.1, the Homotopy Equivalence-H_*-Corollary 73.9 and the Cochain Map Lemma 108.5.
(3) This statement follows immediately from the definition of the natural isomorphisms Ξ_* and Ξ^*, see Propositions 99.1 (3) and 99.6 (3). ■

Example. As on page 2185 we consider again the simplicial torus $T = C \times D$. We equip $T = (V, S)$ with the orientation $\{(\epsilon_w, Y_w)\}_{w \in S_2}$ shown in the figures on page 2184 and 2190 and we denote by $p\colon C \times D \to C$ the natural projection. Furthermore, we again make use of the simplicial cocycle $\theta \in \mathrm{C}^1_{\mathrm{simp}}(C;\mathbb{Z})$ that we first encountered on page 2175. We introduce the following extra notation:

(1) We denote by $j\colon D \to C \times D$ the simplicial map given by $v \mapsto (c, v)$.
(2) We denote by $\sigma := \{x,y\} + \{y,z\} + \{z,x\} \in \mathrm{C}^{\mathrm{simp},\leq}_1(D)$ the "obvious" simplicial cycle. Note that it represents the simplicial fundamental class $[D] \in \mathrm{H}^{\mathrm{simp},\leq}_1(D)$.

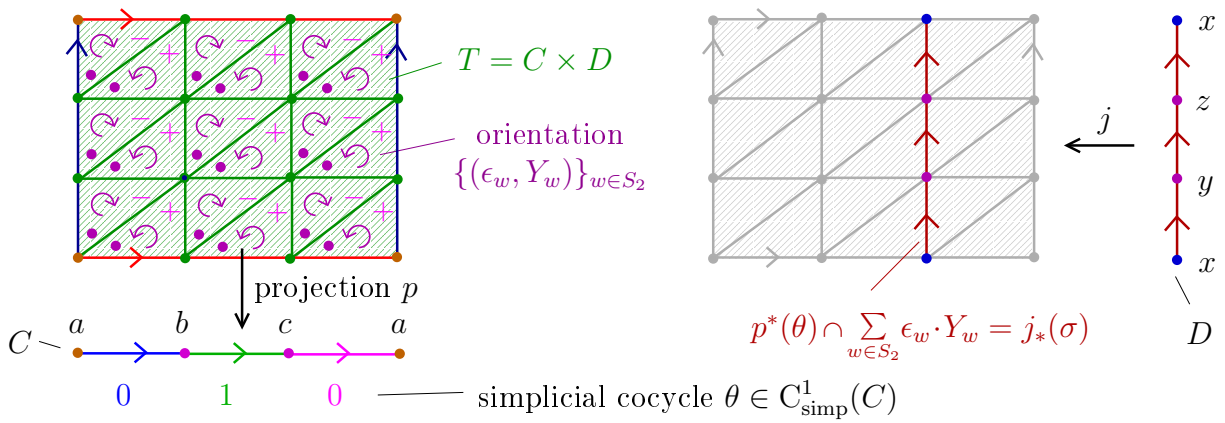
It follows immediately from the definitions that

$$p^*(\theta) \cap \sum_{w \in S_2} \epsilon_w \cdot Y_w \;=\; j_*(\sigma) \;\in\; \mathrm{C}^{\mathrm{simp},\leq}_1(C \times D)$$

thus in terms of (co-) homology we have

$$p^*([\theta]) \cap [T] \;=\; j_*([D]) \;\in\; \mathrm{H}^{\mathrm{simp},\leq}_1(C \times D).$$

We refer to the figure below for an illustration.



In the following we state three lemmas that summarize the key properties of the simplicial cap product. All of these statements are analogues of singular statements. First, the following lemma is an analogue of the Cap Product-Kronecker Lemma 116.4.

Lemma 99.18. Let K be a connected non-empty abstract simplicial complex. Given any $\varphi \in \mathrm{H}^p_{\mathrm{simp}}(K;R)$ and $\sigma \in \mathrm{H}^{\mathrm{simp}}_p(K;R)$ the following equality holds:

$$\varphi \cap \sigma \;=\; \langle \varphi, \sigma \rangle_K \;\in\; H^{\mathrm{simp}}_0(K;R) \underset{\uparrow}{=} R.$$

as in Exercise 95.3 there is a natural identification

[1224] Here the expression "the diagram commutes" is understood in the sense of the convention from page 2538.

Proof. First we pick an order "$\leq$" for the abstract simplicial complex K. Next we observe that the statement for $\varphi \in \mathrm{H}^p_{\mathrm{simp},\leq}(K;R)$ and $\sigma \in \mathrm{H}^{\mathrm{simp},\leq}_p(K;R)$ follows immediately from the definitions. Now the statement follows from Proposition 99.17 (2). ■

The following lemma relates the simplicial cup product to the simplicial cap product. It can be viewed as an analogue of the Cup-Cap Lemma 116.7.

Lemma 99.19. Let K be an abstract simplicial complex and let R be a commutative ring. For any $\varphi \in \mathrm{H}^p_{\mathrm{simp}}(K;R)$, any $\psi \in \mathrm{H}^q_{\mathrm{simp}}(K;R)$ and any $\sigma \in \mathrm{H}^{\mathrm{simp}}_n(K;R)$ we have

$$\varphi \cap (\psi \cap \sigma) \;=\; (\psi \cup \varphi) \cap \sigma \;\in\; \mathrm{H}^{\mathrm{simp}}_{n-p-q}(K;R).$$

Sketch of proof. We pick an order "$\leq$" for K. With basically the same, quite elementary, argument as in the proof of the Cup-Cap Lemma 116.7 we see that for any $\varphi \in \mathrm{H}^p_{\mathrm{simp},\leq}(K;R)$, any $\psi \in \mathrm{H}^q_{\mathrm{simp},\leq}(K;R)$ and any $\sigma \in \mathrm{H}^{\mathrm{simp},\leq}_n(K;R)$ we have

$$\varphi \cap (\psi \cap \sigma) \;=\; (\psi \cup \varphi) \cap \sigma \;\in\; \mathrm{H}^{\mathrm{simp},\leq}_{n-p-q}(K;R).$$

The desired statement now follows from Proposition 99.17 (2). ■

Finally we have the following analogue of the Cap Product-Naturality Lemma 116.8.

Lemma 99.20. Let R be a commutative ring and let $f\colon K \to L$ be a simplicial map between two abstract simplicial complexes. Given any $p, n \in \mathbb{N}_0$ the following diagram commutes

$$\begin{array}{ccccc} \mathrm{H}^p_{\mathrm{simp}}(K;R) & \times & \mathrm{H}^{\mathrm{simp}}_n(K;R) & \xrightarrow{\cap} & \mathrm{H}^{\mathrm{simp}}_{n-p}(K;R) \\ {\scriptstyle f^*}\uparrow & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ \mathrm{H}^p_{\mathrm{simp}}(L;R) & \times & \mathrm{H}^{\mathrm{simp}}_n(L;R) & \xrightarrow{\cap} & \mathrm{H}^{\mathrm{simp}}_{n-p}(L;R), \end{array}$$

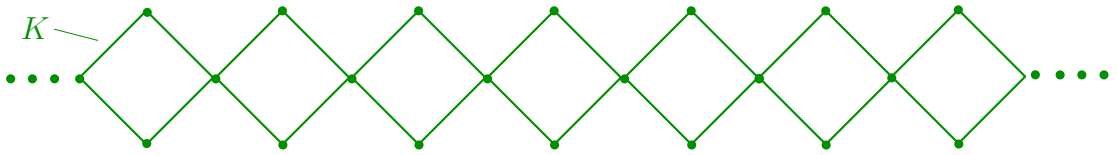
i.e. for any $\varphi \in \mathrm{H}^p_{\mathrm{simp}}(L;R)$ and any $\sigma \in \mathrm{H}^{\mathrm{simp}}_n(K;R)$ we have

$$\varphi \cap f_*(\sigma) \;=\; f_*(\underbrace{f^*(\varphi) \cap \sigma}_{\in \mathrm{H}^{\mathrm{simp}}_{n-p}(K;R)}) \;\in\; \mathrm{H}^{\mathrm{simp}}_{n-p}(L;R).$$

Proof. Let $f\colon K = (V,S) \to L = (W,T)$ be a simplicial map between two abstract simplicial complexes. By Exercise 0.5 we can pick total orders "$\leq_K$" on K and "$\leq_L$" on L such that the map $f\colon V \to W$ is order-preserving. It follows basically immediately from

the definitions that for any $\varphi \in \mathrm{C}^p_{\mathrm{simp},\leq L}(L;R)$ and $\sigma \in \mathrm{C}^{\mathrm{simp},\leq K}_n(K;R)$ we have the equality $f_*(\sigma) = f_*(f^*(\varphi)\cap\sigma)$. The promised statement now follows from Proposition 99.17 (2). ■

We conclude this chapter with a short calculation which in particular shows that at times simplicial cup products can be computed using simplicial cap products.



Example. Let us look one last time at the simplicial torus $T = C \times D$ with the natural projections $p\colon C \times D \to C$ and $q\colon C \times D \to D$. We will now see how we can obtain the simplicial cup product $p^*(\theta) \cup q^*(\theta)$, that we initially computed on page 2186, from the calculation of the simplicial cap product on page 2189. Indeed, under the natural identification $H_0^{\mathrm{simp}}(T;R) = R = H_0^{\mathrm{simp}}(D;R)$ from Exercise 95.3 we have the following equalities:

$$\begin{array}{lllll}
\langle p^*([\theta])\cup q^*([\theta]),[T]\rangle_T & \overset{\text{by Lemma 99.18}}{=} (p^*([\theta])\cup q^*([\theta]))\cap[T] & \overset{\text{Lemma 99.19}}{=} q^*([\theta])\cap(p^*([\theta])\cap[T]) & \overset{\text{see calculation on page 2189}}{=} q^*([\theta])\cap j_*([D]) & \\
= \langle q^*([\theta]), j_*([D])\rangle_T & = \langle [\theta], (q_*\circ j_*)([D])\rangle_D & = \langle [\theta],[D]\rangle_D & = 1. & \\
\uparrow & \uparrow & \uparrow & \uparrow & \\
\text{by Lemma 99.18} & \text{by Lemma 99.7 (2)} & \text{since } q\circ j = \mathrm{id}_D & \text{by definition of } \theta \text{ and } [D] &
\end{array}$$

In Chapter 100 we will state the Simplicial Poincaré Duality Theorem 103.4. Given a closed oriented PL-manifold K it allows for the calculation of simplicial cap products of the form $\varphi \cap [K]$. With tricks as above one can use this calculation of a simplicial cap product to determine several interesting simplicial cup products. In particular in Chapter 121 we will use this approach to calculate the (simplicial) cup products of the real and complex projective spaces.

Exercises for Chapter 99.

Exercise 99.1. We consider the abstract simplicial complex K shown in the figure below. Determine the isomorphism type of $\mathrm{H}^1_{\mathrm{simp}}(K;\mathbb{Z})$.

Exercise 99.2. Let $K = (V,S)$ be a non-empty abstract simplicial complex. We assume that K is connected. Recall that by the definition on page 2013 this means that given any $v, v' \in V$ there exist 1-simplices $s_0, \ldots, s_k \in S$ such that $v \in s_0$, such that for every $i \in \{0,\ldots,k-1\}$ we have $s_i \cap s_{i+1} \neq \varnothing$ and such that $v' \in s_k$. Now let G be an abelian group. Given any $g \in G$ we consider the simplicial cochain $\varphi_g\colon \mathrm{C}_0^{\mathrm{simp}}(K) \to G$ that is given by $\varphi_g(v) = g$ for every vertex $v \in V$. Show that the map

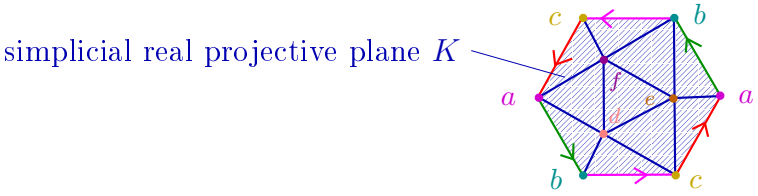
$$\begin{array}{ccc} G & \to & \mathrm{H}^0_{\mathrm{simp}}(K;G) \\ g & \mapsto & \varphi_g \end{array}$$

is a natural isomorphism.

Remark. This statement can be viewed is the cohomological analogue of Exercise 95.3.

Exercise 99.3. Let K be an abstract simplicial complex and let L be a subcomplex of K. Given an abelian group G and given $k \in \mathbb{N}_0$ we define

$$\mathrm{H}^k_{\mathrm{simp}}(K, L; G) \;:=\; \mathrm{H}^k(\mathrm{C}^{\mathrm{simp}}_*(K, L), G).$$



Show that there exists a natural isomorphism

$$\mathrm{H}^k_{\mathrm{simp}}(K, L; G) \;\cong\; \widetilde{\mathrm{H}}^k_{\mathrm{simp}}(\underbrace{K \cup_L \mathrm{Cone}(L)}_{\text{mapping cone of } L \to K}; G).$$

Exercise 99.4. In the figure below we show an abstract simplicial complex K whose topological realization $|K|$ is homeomorphic to the real projective plane $\mathbb{R}\mathrm{P}^2$.

(a) Show that for $i = 0, 1, 2$ we have $\mathrm{H}^i_{\mathrm{simp}}(K; \mathbb{F}_2) \cong \mathbb{F}_2$ and identify in each dimension a cocycle that represents the unique non-zero element.

(b) Compute the simplicial cup product $\mathrm{H}^1_{\mathrm{simp}}(K; \mathbb{F}_2) \times \mathrm{H}^1_{\mathrm{simp}}(K; \mathbb{F}_2) \xrightarrow{\cup} \mathrm{H}^2_{\mathrm{simp}}(K; \mathbb{F}_2)$. In other words, determine whether it is trivial or non-trivial.

Exercise 99.5. Let $g \in \mathbb{N}$. First pick a suitable abstract simplicial complex K that has the property that its topological realization is homeomorphic to the surface of genus g. Afterwards compute the cup product

$$\mathrm{H}^1_{\mathrm{simp}}(K; \mathbb{Z}) \times \mathrm{H}^1_{\mathrm{simp}}(K; \mathbb{Z}) \;\to\; \mathrm{H}^2_{\mathrm{simp}}(K; \mathbb{Z}).$$

Exercise 99.6. We consider the topological space

$$X = \overline{B}^2/\!\sim \qquad \text{where } z \sim z \cdot \exp(2\pi\,\mathrm{i}/3) \text{ for } z \in S^1.$$

(a) Determine the isomorphism types of $\mathrm{H}_i(X; \mathbb{F}_3)$ and $\mathrm{H}^i(X; \mathbb{F}_3)$.

(b) Give an explicit simplicial structure K for X.

(c) Compute the simplicial cup product $\mathrm{H}^1_{\mathrm{simp}}(K; \mathbb{F}_3) \times \mathrm{H}^1_{\mathrm{simp}}(K; \mathbb{F}_3) \xrightarrow{\cup} \mathrm{H}^2_{\mathrm{simp}}(K; \mathbb{F}_3)$.

100. The fundamental class of smooth manifolds

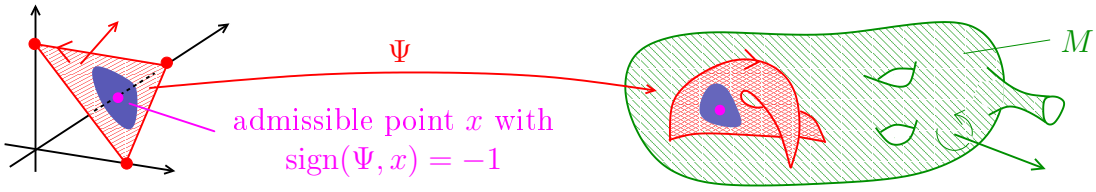
Let M be a compact *orientable* connected non-empty n-dimensional smooth manifold. By Theorem 98.8 we now know that we have $\mathrm{H}_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$. In this chapter we will see that a *choice of an orientation* naturally determines a generator $[M]$ of $\mathrm{H}_n(M, \partial M; \mathbb{Z})$, called the fundamental class of M. As the name already suggests, this homology class is of fundamental importance in the study of smooth manifolds.

100.1. **The definition of the fundamental class.** For our definition of fundamental classes we need to recall the following notation.

Notation. Let $n \in \mathbb{N}_0$. As on page 1581 we consider

$$\begin{aligned} \partial\Delta^n &:= \{(t_0, \dots, t_n) \in \Delta^n \,|\, \text{at least one coordinate is zero}\} \\ \mathring{\Delta}^n &:= \{(t_0, \dots, t_n) \in \Delta^n \,|\, \text{all coordinates are non-zero}\}. \end{aligned}$$

We view $\mathring{\Delta}^n$ as a smooth manifold and we equip it with the orientation defined on page 1581. Loosely speaking it is the orientation given by the "outward pointing vector $(1, \dots, 1)$".



We move on to the following somewhat technical definition.

Definition. Let M be an oriented n-dimensional smooth manifold and let $\Psi\colon \Delta^n \to M$ be a map.

(1) We say that a point $x \in \mathring{\Delta}^n$ is admissible for Ψ if $\Psi^{-1}(\Psi(x)) = \{x\}$ and if there exists an open connected neighborhood U of $x \in \mathring{\Delta}^n$ such that the map $\Psi|_U\colon U \to M$ is a smooth embedding.

(2) Given an admissible point x for Ψ we define

$$\mathrm{sign}(\Psi, x) = \begin{cases} +1, & \text{if } \Psi \text{ is orientation-preserving at } x, \\ -1, & \text{if } \Psi \text{ is orientation-reversing at } x. \end{cases}$$

Example. In many cases we will consider embeddings $\Psi\colon \Delta^n \to M$ such that the restriction of Ψ to $\mathring{\Delta}^n$ is a smooth embedding. In this case every point $x \in \mathring{\Delta}^n$ is admissible for Ψ, and we have

$$\mathrm{sign}(\Psi, x) = \begin{cases} +1, & \text{if } \Psi\colon \mathring{\Delta}^n \to M \text{ is orientation-preserving}, \\ -1, & \text{if } \Psi\colon \mathring{\Delta}^n \to M \text{ is orientation-reversing}. \end{cases}$$

Also note that it is clear that any non-empty smooth manifold admits such a smooth embedding.

The following theorem is the main technical result of this chapter.

Theorem 100.1. Let $n \in \mathbb{N}$ and let M be a compact oriented connected n-dimensional smooth manifold.

(1) For every $x \in M \setminus \partial M$ the inclusion induced map

$$\omega_x \colon \underbrace{\mathrm{H}_n(M, \partial M)}_{\cong \mathbb{Z} \text{ by Theorem 98.8}} \to \underbrace{\mathrm{H}_n(M, M \setminus \{x\})}_{\cong \mathbb{Z} \text{ by the Manifold-Local Homology Lemma 75.1}}$$

is an isomorphism.

(2) There exists a unique $[M] \in \mathrm{H}_n(M, \partial M)$ with the following property: For every map $\Psi \colon \Delta^n \to M$ and every admissible $x \in \mathring{\Delta}^n$ for Ψ we have the following equality in $\mathrm{H}_n(M, M \setminus \{\Psi(x)\})$:[1225][1226]

$$\underbrace{\omega_{\Psi(x)}}_{\text{map } \mathrm{H}_n(M,\partial M) \to \mathrm{H}_n(M, M\setminus\{\Psi(x)\}) \text{ as in (1)}}([M]) \quad = \quad \mathrm{sign}(\Psi, x) \cdot [\, \underbrace{\Psi \colon \Delta^n \to M}_{\in \mathrm{C}_n(M, M\setminus\{\Psi(x)\})} \,].$$

(3) The uniquely determined element $[M] \in \mathrm{H}_n(M, \partial M)$ from (2) is a generator, in particular we have $\mathrm{H}_n(M, \partial M) = \mathbb{Z} \cdot [M]$.

Proof of Theorem 100.1 (1) for closed manifolds. Let $n \in \mathbb{N}$ and let M be a closed oriented connected n-dimensional smooth manifold. By the Smooth Manifold-Simplicial Structure Theorem 96.2 we can pick a smooth simplicial structure $(K = (V, S), \lambda \colon |K| \to M)$ for the smooth manifold M. Since V is finite we can easily pick a total order "$\leq$" on the vertex set V.

In the following we will use the results from Section 98.1 to construct an explicit singular cycle in $\mathrm{C}_n(M)$ which represents a generator of $\mathrm{H}_n(M)$. We will use this cycle to prove (1). Afterwards we will show that the homology class $[M]$ that it represents actually has all the properties stated in (2).

In the following we will make heavy use of the objects we introduced in Section 98.1. Even if the reader might no longer be completely familiar with all the technical definitions, the overall flow of the argument should still be easy to follow. Without further ado, let us construct the promised singular cycle.

(a) Given an m-simplex s of K we consider the embedding

$$\begin{aligned} \Phi_s^{\leq} \colon \quad \Delta^m &\to |K| \\ (t_0, \ldots, t_m) &\mapsto \sum_{i=0}^{m} t_i \cdot \underbrace{i}_{\uparrow}\text{-th vertex of } s. \end{aligned}$$

here we use the total order on V to order the vertices of s

(b) We denote by $s_1, \ldots, s_k$ the n-simplices of K.

[1225] Note that by definition of a smooth embedding, see page 651, we know that $\Psi(x) \subset M \setminus \partial M$. This implies that we have an induced map $\mathrm{H}_n(M, \partial M) \to \mathrm{H}_n(M, M \setminus \{\Psi(x)\}$.

[1226] Since x is an admissible point for Ψ we know that $\Psi^{-1}(\Psi(x)) = \{x\}$. Note that this implies in particular that $\Psi(\partial \Delta^n) \subset M \setminus \{\Psi(x)\}$ which in turn implies that Ψ is a cycle in $\mathrm{C}_*(M, M \setminus \{\Psi(x)\})$.

(c) Let $i \in \{1, \dots, k\}$. It follows from the definition of a smooth simplicial structure, see page 2082, that the map $\lambda \circ \Phi^{\leq}_{s_i} \colon \mathring{\Delta}^n \to M$ is a smooth embedding. Now we set

$$\epsilon_i := \begin{cases} +1, & \text{if } \lambda \circ \Phi^{\leq}_{s_i} \colon \mathring{\Delta}^n \to M \text{ is orientation-preserving,} \\ -1, & \text{if } \lambda \circ \Phi^{\leq}_{s_i} \colon \mathring{\Delta}^n \to M \text{ is orientation-reversing.} \end{cases}$$

(d) By Proposition 98.7 we know that the oriented n-simplices $[(\epsilon_1, s_1)], \dots, [(\epsilon_k, s_k)]$ form an orientation, in the sense of the definition on page 2142, for the pseudo-manifold K.

(e) Next we consider the maps

$$\begin{array}{ccccccc} & & \text{isomorphism by Lemma 95.8} & & \text{chain homotopy equivalence by the Simplicial-Singular Chain Complex Theorem 95.25} & & \\ & & \downarrow & & \downarrow & & \\ \mathrm{C}_m^{\mathrm{simp}}(K) & \leftarrow & \mathrm{C}_m^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_m(|K|) & \xrightarrow{\lambda_*} & \mathrm{C}_m(M) \\ \underbrace{[v_0, \dots, v_m]}_{=[s]} & \mapsfrom & \underbrace{\{v_0 < \dots < v_m\}}_{=s} & \mapsto & \Phi^{\leq}_s & & \end{array}$$

(f) It follows from (d) together with Theorem 98.4 (1) that $\epsilon_1 \cdot [s_1] + \dots + \epsilon_k \cdot [s_k]$ is a cycle in the simplicial chain complex $\mathrm{C}^{\mathrm{simp}}_*(K)$ and we know that it represents a generator of $\mathrm{H}^{\mathrm{simp}}_n(K)$.

(g) It now follows from (e) and (f) that $c := \epsilon_1 \cdot \lambda \circ \Phi^{\leq}_{s_1} + \dots + \epsilon_k \cdot \lambda \circ \Phi^{\leq}_{s_k} \in \mathrm{C}_n(M)$ is a singular cycle in $\mathrm{C}_*(M)$ and that it represents a generator of $\mathrm{H}_n(M)$.

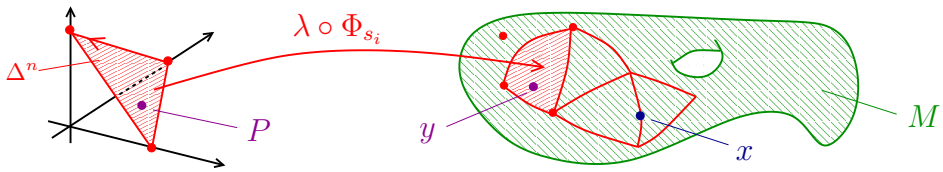
Now we turn to the actual proof of (1). As a reminder, recall that we need to prove the following claim.

Claim. For every $x \in M$ the map

$$\omega_x \colon \mathrm{H}_n(M) \to \mathrm{H}_n(M, M \setminus \{x\})$$

is an isomorphism.

Proof. First we take care of the special case of a point $y \in M$ which can be written as $y = (\lambda \circ \Phi^{\leq}_{s_i})(P)$ for some $i \in \{1, \dots, k\}$ and some $P \in \mathring{\Delta}^n$. We consider the following two maps:



$$\begin{array}{ccccccc} & & & & \text{isomorphism by the Manifold-Local Homology Lemma 75.1} & & \\ & & & & \downarrow & & =\mathbb{Z}\cdot[\mathrm{id}_{\Delta^n}], \text{by Exercise 76.1} \\ \mathrm{H}_n(M) & \xrightarrow{\omega_y} & \mathrm{H}_n(M, M \setminus \{y\}) & \xleftarrow[\cong]{(\lambda \circ \Phi^{\leq}_{s_i})_*} & \overbrace{\mathrm{H}_n(\Delta^n, \Delta^n \setminus \{P\})} & & . \\ [c] & \mapsto & [c] = [\lambda \circ \Phi^{\leq}_{s_i}] & \longleftarrow & [\mathrm{id}_{\Delta^n}] & & \\ & & \uparrow & & & & \\ & & \text{since all the other } \lambda \circ \Phi^{\leq}_{s_j} \text{ are zero in } \mathrm{C}_n(M, M \setminus \{y\}) & & & & \end{array}$$

The above data shows that the image of $[c]$ in $\mathrm{H}_n(M, M \setminus \{y\})$ equals the image of a generator of $\mathrm{H}_n(\Delta^n, \Delta^n \setminus \{P\})$. Since the map to the right is an isomorphism we see that the map $\omega_y \colon \mathrm{H}_n(M) \to \mathrm{H}_n(M, M \setminus \{y\})$ is an epimorphism. Since M is closed orientable connected and non-empty we know by Theorem 98.8 that the group to the left is also isomorphic to $\mathbb{Z}$. Thus we see that both groups are isomorphic to $\mathbb{Z}$ we see that the map ω_y is actually an isomorphism.

Now let $x \in M$ be any point. Since M is connected we obtain from Proposition 36.4 that there exists a diffeomorphism $f \colon M \to M$ with $f(x) = y$. Now we consider the following diagram:

$$\begin{array}{ccc} \mathrm{H}_n(M) & \xrightarrow{\omega_x} & \mathrm{H}_n(M, M\setminus\{x\}) \\ {\scriptstyle f_*}\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle f_*} \\ \mathrm{H}_n(M) & \xrightarrow[\cong]{\omega_y} & \mathrm{H}_n(M, M\setminus\{y\}). \end{array}$$

By the above we know that the bottom map is an isomorphism. Since f is a diffeomorphism the vertical maps are isomorphisms. Since the diagram commutes we see that the top horizontal map is also an isomorphism. ■

The proof of Theorem 100.1 (2) is a technically more intricate variation on the proof of Theorem 100.1 (1).

Proof of Theorem 100.1 (2) and (3) for closed manifolds. We continue with the notation of the proof of Theorem 100.1 (1). Note that the uniqueness part of Statement (2) is basically an immediate consequence of Statement (1). Thus to prove Statement (2) it remains to prove existence. In the following we will now show that

$$[M] := [c] = [\epsilon_1 \cdot \lambda \circ \Phi^{\leq}_{s_1} + \cdots + \epsilon_k \cdot \lambda \circ \Phi^{\leq}_{s_k}] \in \mathrm{H}_n(M)$$

has the desired properties. Before we do so, note though that in (1) we already saw that $[c]$ is a generator of $\mathrm{H}_n(M)$. Thus once we have shown that $[c]$ has the desired properties we have also shown Statement (3).

First let us now prove the following claim.

Claim. For every map $\Psi\colon \Delta^n \to M$ and every admissible $x \in \mathring{\Delta}^n$ we have

$$\omega_{\Psi(x)}([M]) = \mathrm{sign}(\Psi, x) \cdot [\underbrace{\Psi\colon \Delta^n \to M}_{\in \mathrm{C}_n(M, M\setminus\{\Psi(x)\})}].$$

Proof. Similar to the proof of the claim in Statement (1) we first deal with a special case. We pick an n-simplex s_i and we consider the corresponding map $\Upsilon := \lambda \circ \Phi^{\leq}_{s_i}\colon \Delta^n \to M$. Note that since we are given a smooth simplicial structure we know that the restriction of $\Upsilon = \lambda \circ \Phi^{\leq}_{s_i}\colon \Delta^n \to M$ to $\mathring{\Delta}^n$ is a smooth embedding. In particular any $x \in \mathring{\Delta}^n$ is admissible. Next note that we have the following equalities in $\mathrm{H}_n(M, M\setminus\{\Upsilon(x)\})$:

$$\omega_{\Upsilon(x)}([M]) \underset{\text{definition of } [M]}{=} [\epsilon_1 \cdot \lambda \circ \Phi^{\leq}_{s_1} + \cdots + \epsilon_k \cdot \lambda \circ \Phi^{\leq}_{s_k}] \underset{\text{since all other } \Phi^{\leq}_{s_j} \text{ are zero in } \mathrm{C}_n(M, M\setminus\{\Upsilon(x)\})}{=} [\epsilon_i \cdot \underbrace{\lambda \circ \Phi^{\leq}_{s_i}}_{=\Upsilon}] \underset{\text{since } \epsilon_i = \mathrm{sign}(\Upsilon, x)}{=} \mathrm{sign}(\Upsilon, x) \cdot [\Upsilon].$$

This concludes the proof of the claim for the special case $\Upsilon = \lambda \circ \Phi^{\leq}_{s_i}$ and any $x \in \mathring{\Delta}^n$.

Now we turn to the general case. Let $\Psi\colon \Delta^n \to M$ be a map and let $x \in \mathring{\Delta}^n$ be an admissible point. By definition we have $\Psi^{-1}(\Psi(x)) = \{x\}$ and by definition there exists an open connected neighborhood U of $x \in \mathring{\Delta}^n$ such that the map $\Psi|_U\colon U \to M$ is a smooth embedding. We pick an orientation-preserving embedding $\theta\colon \overline{B}^n \to U$ with $\theta(0) = x$.

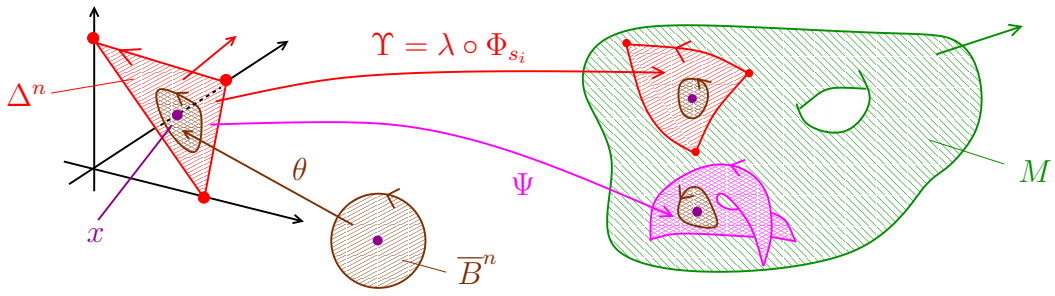
Next we consider the embedding $\widetilde{\Upsilon} := \Upsilon \circ \theta \colon \overline{B}^n \to M$, with $\Upsilon = \lambda \circ \Phi_{s_i}^{\leqslant}$ as above, and we consider the embedding $\widetilde{\Psi} = \Psi \circ \theta \colon \overline{B}^n \to M$. First we make the following assumption:

(∗) The maps $\widetilde{\Upsilon}$ and $\widetilde{\Psi}$ are both orientation-preserving embeddings or they are both orientation-reversing embeddings.

In this case it follows from the Smooth Ball Embedding Theorem 37.8 that there exists a diffeomorphism f of M with the following two properties:

(i) the map f is homotopic to the identity,
(ii) $f \circ \widetilde{\Upsilon} = \widetilde{\Psi}$.

We consider the following commutative diagram[1227]



$$\begin{array}{ccccc}
 & & \mathrm{H}_n(M, M\setminus\{\Upsilon(x)\}) & \xleftarrow[\cong]{\omega_{\Upsilon(x)}} & \mathrm{H}_n(M) \\
 & \overset{\Upsilon_*}{\nearrow} & \uparrow{\scriptstyle \widetilde{\Upsilon}_*} & & \\
\mathrm{H}_n(\Delta^n, \Delta^n\setminus\{x\}) & \xleftarrow[\theta_*]{\cong} & \mathrm{H}_n(\overline{B}^n, \overline{B}^n\setminus\{0\}) & & \\
 & \underset{\Psi_*}{\searrow} & \downarrow{\scriptstyle \widetilde{\Psi}_*} & & \\
 & & \mathrm{H}_n(M, M\setminus\{\Psi(x)\}) & \xleftarrow[\omega_{\Psi(x)}]{\cong} & \mathrm{H}_n(M).
\end{array}
\qquad
\begin{array}{ccc}
 & & \\
 & & \\
 & & \\
\cong & f_* & f_*{=}\mathrm{id} \\
 & & \\
 & & \\
 & &
\end{array}$$

We make the following observations and clarifications:

(a) It follows from (i) and from the Homotopic Maps-and-Homology Proposition 73.6 that the map $f_* \colon \mathrm{H}_n(M) \to \mathrm{H}_n(M)$ is the identity.
(b) Note that by Theorem 100.1 we know that the maps $\omega_{\Upsilon(x)}$ and $\omega_{\Psi(x)}$ are isomorphisms.
(c) Note that it follows immediately from the Excision Theorem 74.18 that the map $\theta_* \colon \mathrm{H}_n(\overline{B}^n, \overline{B}^n \setminus \{0\}) \to \mathrm{H}_n(\Delta^n, \Delta^n \setminus \{x\})$ is an isomorphism.
(d) By (c) we can now set $\sigma := \theta_*^{-1}([\mathrm{id}_{\Delta^n}]) \in \mathrm{H}_n(\overline{B}^n, \overline{B}^n \setminus \{0\})$.

We make the following observations:

$$\begin{array}{lrcll}
 & \omega_{\Upsilon(x)}([M]) & = & \mathrm{sign}(\Upsilon, x) \cdot [\Upsilon \colon \Delta^n \to M] & \text{by the above special case} \\
\Longrightarrow & \omega_{\Upsilon(x)}([M]) & = & \mathrm{sign}(\Upsilon, x) \cdot \widetilde{\Upsilon}_*(\sigma) & \text{by (d), since } \widetilde{\Upsilon}_* = \Upsilon_* \circ \theta_* \\
\Longrightarrow & \omega_{\Psi(x)}([M]) & = & \mathrm{sign}(\Upsilon, x) \cdot \widetilde{\Psi}_*(\sigma) & \text{by (a) and (b)} \\
\Longrightarrow & \omega_{\Psi(x)}([M]) & = & \mathrm{sign}(\Psi, x) \cdot \widetilde{\Psi}_*(\sigma) & \text{by (∗)} \\
\Longrightarrow & \omega_{\Psi(x)}([M]) & = & \mathrm{sign}(\Psi, x) \cdot [\Psi \colon \Delta^n \to M] & \text{by (d), since } \widetilde{\Psi}_* = \Psi_* \circ \theta_*.
\end{array}$$

[1227] Since Ψ is admissible we know that $\Psi^{-1}(\Psi(x)) = \{x\}$. This implies that Ψ does indeed induce a map $\Psi_* \colon \mathrm{H}_n(\Delta^n, \Delta^n \setminus \{x\}) \to \mathrm{H}_n(M, M \setminus \{\Psi(x)\})$.

Finally we suppose that $(*)$ does not hold. Let

$$\begin{aligned} \rho\colon \Delta^n &\to \Delta^n \\ (t_0, t_1, t_2, \dots, t_n) &\mapsto (t_1, t_0, t_2, \dots, t_n) \end{aligned}$$

be the map that swaps the first two coordinates. Since ρ is orientation-preserving we now see that $\widetilde{\Upsilon}$ and $\widetilde{\Psi} \circ \rho$ satisfy $(*)$. Now we see that

$$\begin{aligned} & & \omega_{(\Psi\circ\rho)(\rho(x))}([M]) &= \operatorname{sign}(\Psi\circ\rho, \rho(x)) \cdot \overbrace{[\Psi\circ\rho\colon \Delta^n \to M]}^{=\Psi_*(\rho_*[\mathrm{id}_{\Delta^n}])} && \text{since } \widetilde{\Upsilon} \text{ and } \widetilde{\Psi}\circ\rho \text{ satisfy } (*) \\ & & & & & \text{we can apply the above} \\ \implies & & \omega_{\Psi(x)}([M]) &= \operatorname{sign}(\Psi\circ\rho, \rho(x)) \cdot \Psi_*(-[\mathrm{id}_{\Delta^n}]) && \text{by Exercise 76.2} \\ \implies & & \omega_{\Psi(x)}([M]) &= (-\operatorname{sign}(\Psi, x)) \cdot \Psi_*(-[\mathrm{id}_{\Delta^n}]) && \text{since } \rho \text{ is orientation-reversing} \\ \implies & & \omega_{\Psi(x)}([M]) &= \operatorname{sign}(\Psi, x) \cdot \underbrace{[\Psi\colon \Delta^n \to M]}_{=\Psi_*([\mathrm{id}_{\Delta^n}])}. \end{aligned}$$

■

We have now proved Theorem 100.1 for all closed smooth manifolds. It remains to prove Theorem 100.1 for smooth manifold with non-empty boundary.

Proof of Theorem 100.1 for manifolds with non-empty boundary. Let M be a compact oriented connected n-dimensional smooth manifold with non-empty boundary. Let M' be another copy of M. We consider the double $\mathrm{D}M = M \cup_{\partial M = \partial M'} M'$ of M, as defined on page 1667. Since $\partial M \neq \varnothing$ we obtain from the Doubling-Manifold Lemma 75.12 that $\mathrm{D}M$ is a closed oriented n-dimensional smooth manifold such that the map $M \to \mathrm{D}M$ is an orientation-preserving embedding.

(1) Let $x \in M \setminus \partial M$. We consider the following commutative diagram:

$$\begin{array}{ccccc} \mathrm{H}_n(M, \partial M) & \xrightarrow{\cong} & \mathrm{H}_n(\mathrm{D}M, M') & \xleftarrow{\cong} & \mathrm{H}_n(\mathrm{D}M) \\ \downarrow & & & \searrow & \downarrow\cong \\ \mathrm{H}_n(M, M\setminus\{x\}) & & \xrightarrow{\qquad\cong\qquad} & & \mathrm{H}_n(\mathrm{D}M, \mathrm{D}M\setminus\{x\}). \end{array}$$

As we saw in the Doubling-Manifold Lemma 75.12 (6), it follows from the Excision Theorem 75.10 that the top left horizontal map is an isomorphism. Basically the same argument shows that the bottom horizontal map is an isomorphism. Furthermore note that in the proof of Theorem 98.8 we saw that the top right horizontal map is an isomorphism. By the above discussion of closed smooth manifolds we know that the right vertical map is an isomorphism. It now follows, as desired, that the left vertical map is also an isomorphism.

(2) By the discussion of the closed case we can consider the class $[\mathrm{D}M] \in \mathrm{H}_n(\mathrm{D}M)$. We define $[M] \in \mathrm{H}_n(M, \partial M)$ to be the preimage of $[\mathrm{D}M]$ under the composition of the above two horizontal isomorphisms. A slight variation on the argument provided in (1) now shows that $[M]$ has all the desired properties. We leave it to the reader to fill in the details. ■

Theorem 100.1 leads us to the following definition.

Definition. Let $n \in \mathbb{N}$ and let M be a compact oriented n-dimensional smooth manifold.

(1) We denote by $N_1, \ldots, N_k$ the components of M. Furthermore for $i = 1, \ldots, k$ we now denote by $[N_i] \in \mathrm{H}_n(N_i, \partial N_i)$ the homology class from Theorem 100.1. We refer to

$$[M] \;:=\; \sum_{i=1}^{k} [N_i] \;\in\; \mathrm{H}_n(M, \partial M) \;\underset{\uparrow}{=}\; \bigoplus_{i=1}^{k} \mathrm{H}_n(N_i, \partial N_i).$$

isomorphism given by Lemma 72.14

as the fundamental class of M.

(2) We refer to any cycle in $\mathrm{C}_n(M, \partial M)$ that represents the fundamental class $[M]$ as a fundamental cycle.

Remark. In Chapter 105 we will introduce the notion of an orientation on a topological manifold and on page 2351 we will introduce fundamental classes for oriented topological manifolds. After a few reinterpretations one sees that the Smooth-Topological Orientation Proposition 105.11 together with the Orientation-Top Homology Theorem 106.1 provide in particular an alternative proof of Theorem 100.1.

Conveniently enough, the proof of Theorem 100.1 actually gives an algorithm for determining explicit fundamental cycles.

Algorithm 100.2. Let $n \in \mathbb{N}$ and let M be a compact oriented non-empty n-dimensional smooth manifold.

(1) By the Smooth Manifold-Simplicial Structure Theorem 96.2 we can pick a smooth simplicial structure $(K = (V, S), |K| \xrightarrow{\lambda} M)$. Since V is finite we can pick a total order "$\leq$" on V.

(2) We denote by $s_1, \ldots, s_k$ the n-simplices of K.

(3) For $i \in \{1, \ldots, k\}$ we consider the characteristic map

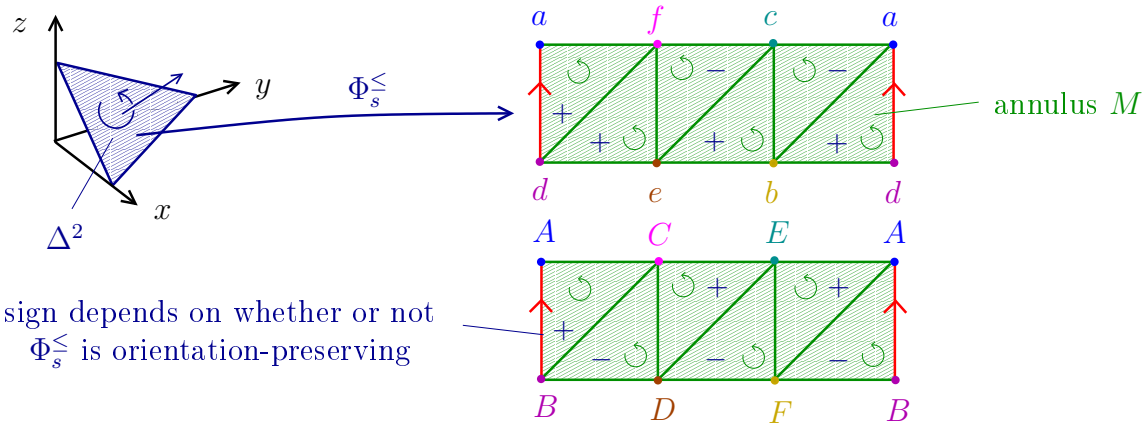
$$\begin{aligned} \Phi_{s_i}^{\leq} \colon \quad \Delta^n &\to |K| \\ (t_0, \ldots, t_n) &\mapsto \sum_{j=0}^{n} t_j \cdot \underset{\uparrow}{j}\text{-th vertex of } s_i \end{aligned}$$

we use the total order on V to order the vertices of s_i

and we set

$$\epsilon_i \;:=\; \begin{cases} +1, & \text{if } \lambda \circ \Phi_{s_i}^{\leq} \colon \mathring{\Delta}^n \to M \text{ is orientation-preserving,} \\ -1, & \text{if } \lambda \circ \Phi_{s_i}^{\leq} \colon \mathring{\Delta}^n \to M \text{ is orientation-reversing.} \end{cases}$$

(4) The cycle $\epsilon_1 \cdot \lambda \circ \Phi_{s_1}^{\leq} + \cdots + \epsilon_k \cdot \lambda \circ \Phi_{s_k}^{\leq} \in \mathrm{C}_n(M)$ is a fundamental cycle of M.



Proof. It is basically clear that it suffices to prove the validity of the algorithm for the *connected* case. Next note that if M is closed, then it follows immediately from the proof of Theorem 100.1 (1) that $\epsilon_1 \cdot \lambda \circ \Phi_{s_1}^{\leq} + \cdots + \epsilon_k \cdot \lambda \circ \Phi_{s_k}^{\leq} \in \mathrm{C}_n(M)$ is a cycle. Furthermore, in the proof of Theorem 100.1 (2) we saw that this cycle represents the fundamental class $[M] \in \mathrm{H}_n(M)$ of M. If M has non-empty boundary, then we equip the double $\mathrm{D}M$ with the simplicial structure given by "doubling" the simplicial structure of M. It is now straightforward to verify that the above algorithm also works in that case. We leave it to the reader to fill in the details. ∎

Example. In the figure below we consider the annulus $M = ([0, 3] \times [0, 1])/(0, y) \sim (3, y)$ equipped with an orientation and equipped with a smooth simplicial structure. In the

figure below we use two different ways to name the vertices, namely once the vertex set is $V = \{a, \dots, f\}$ and once it is $V = \{A, \dots, F\}$. In both cases we equip these sets with the obvious total order. We now see that the singular chains

$$\begin{aligned}
\mu = \; & +\Phi^{\leq}_{\{a,d,f\}} - \Phi^{\leq}_{\{d,e,f\}} + \Phi^{\leq}_{\{c,e,f\}} - \Phi^{\leq}_{\{b,c,e\}} + \Phi^{\leq}_{\{a,b,c\}} - \Phi^{\leq}_{\{a,b,d\}} \in \mathrm{C}_n(M, \partial M) \\
\nu = \; & +\Phi^{\leq}_{\{A,B,C\}} - \Phi^{\leq}_{\{B,C,D\}} + \Phi^{\leq}_{\{C,D,E\}} - \Phi^{\leq}_{\{D,E,F\}} + \Phi^{\leq}_{\{A,E,F\}} - \Phi^{\leq}_{\{A,B,F\}} \in \mathrm{C}_n(M, \partial M)
\end{aligned}$$

are both fundamental cycles of M.

Even though Algorithm 100.2 is very explicit, it also has some drawbacks. For example simplicial structures tend to have many simplices, which in the above algorithm leads to cycles with many summands. In a minute we will state a result that addresses this issue. But first let us prove a lemma which in particular says that, in order to show that we are given the fundamental class of a compact oriented *connected* smooth manifold, we only have to verify the defining property for a single choice of a map $\Psi\colon \Delta^n \to M$ and an admissible point $x \in \mathring{\Delta}^n$.

Lemma 100.3. (Fundamental Class-Characterization Lemma) Let M be a compact oriented non-empty n-dimensional smooth manifold and let $\varphi \in \mathrm{H}_n(M, \partial M)$. We denote by $N_1, \dots, N_k$ the components of M. The following statements are equivalent:

(1) φ is the fundamental class of M.

(2) For each $i \in \{1, \dots, k\}$ there exists a map $\Psi\colon \Delta^n \to N_i$ and an admissible point $x \in \mathring{\Delta}^n$ such that the following equality holds in $\mathrm{H}_n(M, M \setminus \{\Psi(x)\})$:

$$\underset{\text{map } \mathrm{H}_n(M,\partial M) \to \mathrm{H}_n(M, M\setminus\{\Psi(x)\})}{\omega_{\Psi(x)}(\varphi)} \;=\; \mathrm{sign}(\Psi, x) \cdot \underbrace{[\Psi\colon \Delta^n \to N_i \to M]}_{\in \mathrm{C}_n(M, M\setminus\{\Psi(x)\})}.$$

(3) For each $i \in \{1, \dots, k\}$ there exists a point $y \in N_i \setminus \partial_i N$ such that

$$\omega_y(\varphi) \;=\; \omega_y([M]).$$

Proof. A short moment of reflection shows that it suffices to prove the lemma in the case that M is connected. Next we note that the (1)⇒(2)-direction and (1)⇒(3)-direction are of course tautologies. We turn to the proof of the (2)⇒(1)-direction. We have the following

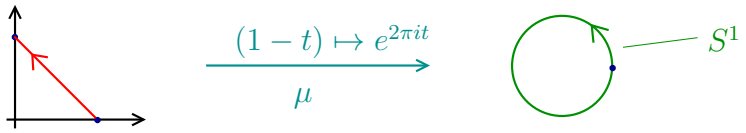
two equalities in $\mathrm{H}_n(M, M \setminus \{x\})$:

$$\omega_{\Psi(x)}(\varphi) \underset{\text{by hypothesis}}{\underset{\uparrow}{=}} \operatorname{sign}(\Psi, x) \cdot [\Psi\colon \Delta^n \to M] \underset{\text{by definition of } [M]}{\underset{\uparrow}{=}} \omega_{\Psi(x)}([M]).$$

Since we assume that M is connected we know by Theorem 100.1 that $\omega_{\Psi(x)}$ is an isomorphism. Thus it follows from the above that $\varphi = [M]$.

Finally we consider the (3)⇒(1)-direction. This statement follows again from the fact that ω_y is an isomorphism. ■

The following proposition now gives us a practical criterion for showing that a given cycle represents the fundamental class.



Proposition 100.4. (Fundamental Class-Criterion Proposition) Let M be a compact oriented connected n-dimensional smooth manifold. Let $r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m \in \mathrm{C}_n(M, \partial M)$ be a cycle. Suppose there exists a $j \in \{1, \ldots, m\}$ such that the following three conditions are satisfied:

(1) The map $\sigma_j\colon \mathring{\Delta}^n \to M$ is an orientation-preserving smooth embedding.[1228]
(2) There exists an $x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial\Delta^n)$ which is not contained in the image of any other $\sigma_i\colon \Delta^n \to M$.
(3) $r_j = 1$.

Then the cycle $r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m$ represents the fundamental class of the oriented smooth manifold, i.e. we have

$$[r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m] \;=\; [M] \;\in\; \mathrm{H}_n(M, \partial M).$$

Example. It follows easily from the Fundamental Class-Criterion Proposition 100.4 and our orientation convention, see page 681, that the singular 1-simplex $\mu\colon \Delta^1 \to S^1$ given by $\mu(1-t, t) = \exp(2\pi i t)$ represents the fundamental class of the oriented smooth manifold S^1.

Proof of the Fundamental Class-Criterion Proposition 100.4. Let M be a compact oriented connected n-dimensional smooth manifold, let $\sum_{i=1}^{m} r_i \cdot \sigma_i \in \mathrm{C}_n(M, \partial M)$ be a cycle and let $j \in \{1, \ldots, m\}$ such that conditions (1)–(3) above are satisfied. We pick $x \in \sigma_j(\mathring{\Delta}^n)$ as in (2). Now we see that we have the following equalities in $\mathrm{H}_n(M, M \setminus \{x\})$:

$$\omega_x([r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m]) \;=\; [\overbrace{r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m}^{\in \mathrm{C}_n(M, M\setminus\{x\})}] \underset{\text{since (2) implies that for } i \neq j \text{ we have } \sigma_i(\Delta^n) \subset M \setminus \{x\}}{\underset{\uparrow}{=}} [r_j \cdot \sigma_j] \;=\; [\sigma_j\colon \Delta^n \to M].$$

By hypothesis $\sigma_j\colon \Delta^n \to M$ restricts to an orientation-preserving embedding $\sigma_j\colon \mathring{\Delta}^n \to M$. Since $x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial\Delta^n)$ we see that x is an admissible point for σ_j. Thus all the

[1228] Note that we do *not* place any conditions on the restriction of σ_j to $\partial\Delta^n$.

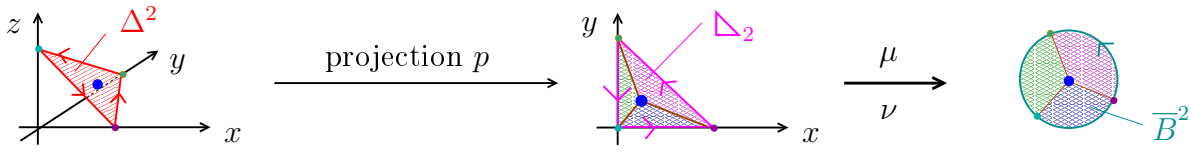
hypotheses of the Fundamental Class-Characterization Lemma 100.3 hold, and therefore we conclude from the Fundamental Class-Characterization Lemma 100.3 that the cycle $r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m \in \mathrm{C}_n(M, \partial M)$ is indeed a fundamental cycle of M. ■

100.2. **Examples of fundamental classes.** In this section we will give explicit cycles representing the fundamental classes of $\overline{B}^n$, of S^n and of surfaces of genus ≥ 1. At this stage it is convenient to recall the following notation.

Notation.

(1) We consider the projection

$$\begin{array}{rcl} p\colon \Delta^n & \to & \triangle_n := \left\{(t_1, \ldots, t_n) \in [0,1]^n \;\middle|\; \sum_{j=1}^{n} t_j \in [0,1]\right\} \\ (t_0, \ldots, t_n) & \mapsto & (t_0, \ldots, t_{n-1}). \end{array}$$



One can easily verify that the restriction $p\colon \overset{\circ}{\triangle}_n \to \overset{\circ}{\Delta}^n$ is orientation-preserving if and only if n is even.

(2) (a) Let $\mu\colon \triangle_n \to \overline{B}^n$ be the explicit homeomorphism with $\mu(\frac{1}{n+1}, \ldots, \frac{1}{n+1}) = 0$ that is given by the Convex-to-Ball Proposition 2.20 (2). Note that the restriction of μ to a map $\overset{\circ}{\triangle}_n \to B^n$ is not smooth. But it is easily seen to be an orientation-preserving smooth embedding on an open dense subset of $\overset{\circ}{\triangle}$.

(b) We denote by $\Phi\colon \Delta^n \to \triangle_n$ the natural projection. Given $P \in \overset{\circ}{\triangle}_n$ we consider the maps

$$\begin{array}{rcl} f_P\colon \overset{\circ}{\triangle}_n & \to & \mathbb{R}^n \\ (x_1, \ldots, x_n) & \mapsto & \frac{((x_1,\ldots,x_n)-P)}{x_1 \cdot \cdots \cdot x_n \cdot (1-x_1-\cdots-x_n)} \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{R}^n & \to & B^n \\ (x_1, \ldots, x_n) & \mapsto & \frac{x_1^2+\cdots+x_n^2}{1+x_1^2+\cdots+x_n^2} \cdot (x_1, \ldots, x_n) \end{array}$$

For $P = (\frac{1}{n+1}, \ldots, \frac{1}{n+1})$ we denote the homeomorphism by $\nu\colon \triangle_n \to \overline{B}^n$. In Exercise 72.2 we saw that this map has the very neat feature that the restriction $\overset{\circ}{\triangle}_n \to B^n$ is actually an orientation-preserving diffeomorphism.

The following lemma is an immediate consequence of the above and the Fundamental Class-Characterization Lemma 100.3.

Lemma 100.5. Let $n \in \mathbb{N}$. The cycles $(-1)^n \cdot (\mu \circ p\colon \Delta^n \to \overline{B}^n) \in \mathrm{C}_n(\overline{B}^n, S^{n-1})$ and $(-1)^n \cdot (\nu \circ p\colon \Delta^n \to \overline{B}^n) \in \mathrm{C}_n(\overline{B}^n, S^{n-1})$ are both representatives of the fundamental class $[\overline{B}^n] \in \mathrm{H}_n(\overline{B}^n, S^{n-1})$.

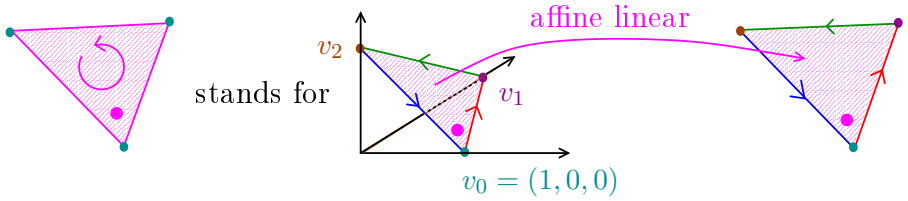
Let $n \in \mathbb{N}$. The eagle-eyed reader will have noticed that by now we have introduced the symbol $[S^n] \in \mathrm{H}_n(S^n)$ twice:

(1) On page 1677 we introduced the "standard generator" $[S^n] = [\alpha - \beta] \in \mathrm{H}_n(S^n)$. Here α is given by

$$\begin{array}{rcccl} \Delta^n & \xrightarrow{\mu \circ p} & \overline{B}^n & \to & S^n \subset \mathbb{R}^{n+1} = \mathbb{R}^n \times \mathbb{R} \\ & & x & \mapsto & \left(x, \sqrt{1 - \|x\|^2}\right) \end{array}$$

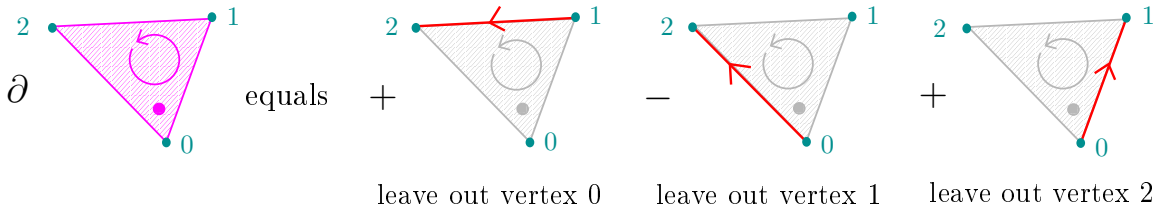
and $\beta\colon \Delta^n \to S^n$ is the composition of α with reflection in the hyperplane defined by $x_{n+1} = 0$.

(2) We endow S^n with the orientation introduced on page 681, namely given $P \in S^n$ we say a basis $v_1, \ldots, v_n$ of $\mathrm{T}_P M = \widetilde{\mathrm{T}}_P M$ is positive if $P, v_1, \ldots, v_n$ is a positive basis for $\mathbb{R}^{n+1}$. With this orientation of S^n we now also have the corresponding fundamental class $[S^n] \in \mathrm{H}_n(S^n)$.



Fortunately the next lemma says that our various sign conventions work out in such a way that the two definitions of $[S^n]$ agree.

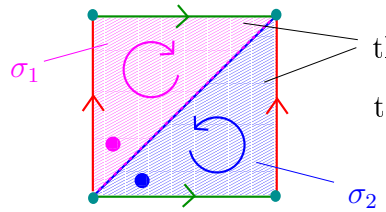
Lemma 100.6. Let $n \in \mathbb{N}$. The standard generator $[S^n] \in \mathrm{H}_n(S^n)$ that we introduced on page 1677 agrees with the fundamental class of the oriented smooth manifold S^n.



Proof. It follows from the above discussion, and some elementary arguments that the map $\alpha\colon \Delta^n \to S^n$ is an embedding and that it is an orientation-preserving embedding on an open subset of $\mathring{\Delta}^n$. The desired equality now follows almost immediately from the Fundamental Class-Criterion Proposition 100.4 applied to the cycle $\alpha - \beta$. ■

We move on to giving explicit representatives of fundamental classes for surfaces. This will require the introduction of more notation.

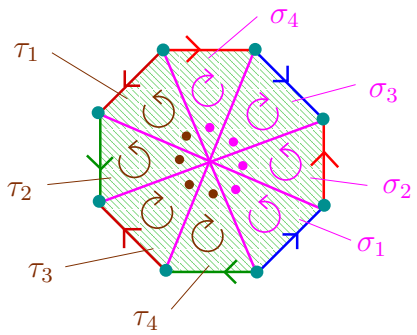
Notation. We will give many examples of fundamental classes of 2-dimensional smooth manifolds. Since we want to be very careful what singular simplex we mean by a given picture we adopt the following convention: A triangle T with a dot in a corner and a directional arrow in the center means the unique affine linear map $\Delta^2 \to T$ which sends $(1, 0, 0)$ to the vertex decorated with the dot and which respects the orientation of the vertices. We illustrate this notation in the figure below.



Convention. We also take some artistic liberties and allow triangles where the boundary is not given by segments and where the boundary consists of curves. In this case we expect that the boundary curves are parametrized with constant speed. Since the precise definition of the boundary of a singular 2-simplex is often a source of confusion we recall the definition in the figure below.

Example. In the figure below we show the torus $T = ([0, 1] \times [0, 1])/\!\sim$. We equip T with the orientation coming from the standard orientation on $(0, 1) \times (0, 1) \subset T$, which we can also view as an open subset of $\mathbb{R}^2$. In the figure we also show two singular 2-simplices σ_1

and σ_2. It is straightforward to verify that $-\sigma_1+\sigma_2$ is a cycle. (In the verification it is very helpful to keep the figure below in mind.) The summand σ_2 satisfies the conditions imposed in the Fundamental Class-Criterion Proposition 100.4, thus we see that $-\sigma_1+\sigma_2$ represents a fundamental class of T, in particular it represents a generator of $\mathrm{H}_2(T)$. This is of course the same cycle that we had already initially encountered on page 1589. We already saw in Lemma 78.11 (2) in a somewhat ad hoc argument that it represents a generator of $\mathrm{H}_2(T)$.



the torus T

the 2-cycle $-\sigma_1+\sigma_2 \in \mathrm{C}_2(T)$ represents the fundamental class of the torus

Examples. In the figure below we show the surface of genus 2 with eight singular 2-simplices $\sigma_1,\sigma_2,\sigma_3,\sigma_4$ and $\tau_1,\tau_2,\tau_3,\tau_4$. The interior of the octagon is an open subset of $\mathbb{R}^2$ and we equip the surface of genus 2 with the orientation coming from the standard orientation of $\mathbb{R}^2$. It is a fun exercise to verify that the singular 2-chain

$$\sigma_1+\sigma_2-\sigma_3-\sigma_4+\tau_1+\tau_2-\tau_3-\tau_4$$

is indeed a cycle. It follows easily from the Fundamental Class-Criterion Proposition 100.4 that the singular 2-chain is a fundamental cycle, i.e. it represents a fundamental class of the surface of genus 2.

$\sigma_1+\sigma_2-\sigma_3-\sigma_4$
$+\quad \tau_1+\tau_2-\tau_3-\tau_4$
is a cycle and represents the fundamental class

100.3. **Properties of the fundamental class.** In this section we will studies properties of the fundamental class. Before we can do so we will have plug a few holes in our definitions, namely we have not yet dealt with non-empty 0-dimensional manifolds and with the empty manifold.

First let us recall the following remark from page 675.

Definition. An orientation for a 0-dimensional smooth manifold M

Now we define the corresponding fundamental class.

Definition. Let $(M=\{P_1,\ldots,P_k\},\epsilon\colon M\to\{\pm1\})$ be a compact oriented non-empty 0-dimensional smooth manifold. The corresponding fundamental class $[M]$ is defined as the homology class

$$[M] := \sum_{i=1}^{k}\epsilon(P_i)\cdot[P_i] \in \mathrm{H}_0(M).$$

Finally let us consider the empty manifold. As we mentioned on page 514, basically by definition the empty set is a topological and smooth manifold of any dimension. Note that for the empty manifold $\varnothing$ we have the *equality* $\mathrm{H}_0(\varnothing) = \mathrm{H}_1(\varnothing) = \mathrm{H}_2(\varnothing) = \cdots = \{0\}$. This leads us to the following definition.

Definition. We define the fundamental class $[\varnothing]$ of the empty manifold to be $0 \in \{0\}$. Note that by the above the fundamental class $[\varnothing]$ is an element in every homology group of $\varnothing$.

Remark. The 0-dimensional oriented smooth manifolds and the empty manifold are a nuisance for a conscientious writer. In the following we will not always treat these cases explicitly and rely on the good will of the reader to deal with these on their own.

Now let us continue with serious mathematics. The following lemma tells us the behavior of the fundamental class under diffeomorphisms.

Lemma 100.7. Let $n \in \mathbb{N}_0$, let M and N be compact oriented connected n-dimensional smooth manifolds and let $f\colon M \to N$ be a diffeomorphism. We have[1229]

$$f_*([M]) \;=\; \begin{cases} [N], & \text{if } f \text{ is orientation-preserving,} \\ -[N], & \text{if } f \text{ is orientation-reversing.} \end{cases}$$

Proof. If $n = 0$, then the statement follows immediately from the definitions. As we will see, for $n \in \mathbb{N}$ the statement follows basically immediately from the definition property of the fundamental class. Indeed, we set $\epsilon := +1$ if f is orientation-preserving, otherwise we set $\epsilon := -1$. Let $\Psi\colon \Delta^n \to M$ be an embedding such that the map $\Psi\colon \mathring{\Delta}^n \to M$ is orientation-preserving. We pick some $x \in \mathring{\Delta}^n$. We consider the following commutative diagram:

$$\begin{array}{ccc} \mathrm{H}_n(M, \partial M) & \xrightarrow{\omega_{\Psi(x)}} & \mathrm{H}_n(M, M \setminus \{\Psi(x)\}) \\ \downarrow f_* & & \downarrow f_* \\ \mathrm{H}_n(N, \partial N) & \xrightarrow{\omega_{(f\circ\Psi)(x)}} & \mathrm{H}_n(N, N \setminus \{(f\circ\Psi)(x)\}). \end{array}$$

Now we see that

$$\begin{array}{rrcll} & \omega_{\Psi(x)}([M]) & = & \operatorname{sign}(\Psi, x) \cdot [\Psi], & \text{by definition of } [M] \\ \Longrightarrow & \omega_{(f\circ\Psi)(x)}(f_*([M])) & = & \operatorname{sign}(\Psi, x) \cdot [f \circ \Psi], & \text{since the diagram commutes} \\ \Longrightarrow & \omega_{(f\circ\Psi)(x)}(f_*([M])) & = & \epsilon \cdot \operatorname{sign}(f \circ \Psi, x) \cdot [f \circ \Psi], & \text{by definition of } \epsilon \\ \Longrightarrow & f_*([M] & = & \epsilon \cdot [N], & \text{by the Characterization Lemma 100.3.} \end{array}$$

■

Given an oriented smooth manifold M we denote, as usual, by $-M$ the same smooth manifold but with the opposite orientation. Now we can formulate the following lemma.

Lemma 100.8. For every compact oriented n-dimensional smooth manifold M we have

$$[-M] \;=\; -[M] \;\in\; \mathrm{H}_n(M, \partial M).$$

Proof. This statement follows basically immediately from Lemma 100.7 since the identity map $M \to -M$ is orientation-reversing. ■

[1229] Note that this statement now also makes sense for the empty manifold.

On page 689 we saw that the boundary of an oriented smooth manifold inherits a natural orientation. For compact smooth manifolds the following proposition gives the relationship between the fundamental class of the smooth manifold and of its boundary.

Proposition 100.9. (Fundamental Class-of-Boundary Proposition) Let M be a compact oriented n-dimensional smooth manifold with boundary. The connecting homomorphism

$$\partial\colon \mathrm{H}_n(M,\partial M) \;\to\; \mathrm{H}_{n-1}(\partial M)$$

of the long exact sequence in homology of the pair $(M,\partial M)$ has the property that

$$[M] \;\mapsto\; [\partial M].$$

Remark. In the Fundamental Class-of-Boundary Proposition 106.27 II we will prove the analogue of the Fundamental Class-of-Boundary Proposition 100.9 for topological manifolds.

Proof. Let M be a compact oriented n-dimensional smooth manifold with boundary components $N_1,\ldots,N_k$. By the Smooth Manifold-Simplicial Structure Theorem 96.2 the smooth manifold M admits a smooth simplicial structure $(K=(V,S),\lambda\colon |K|\to M)$. By the Manifold-Simplex Proposition 98.1 (3) we know that there exists a subcomplex $J=(U,R)$ of $=(V,S)$ such that $(J=(U,R),\lambda\colon |J|\to\partial M)$ is a smooth simplicial structure for ∂M. We pick some total order "$\leq$" on V. Next we introduce the following notation for K:

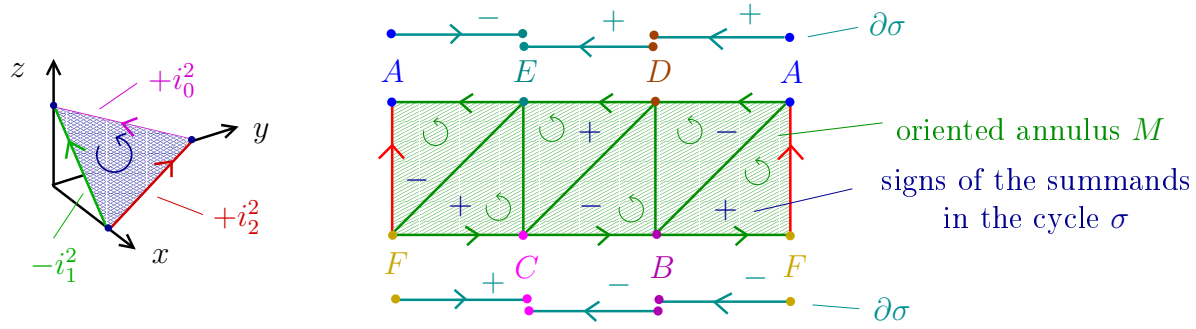
(1) We denote by S_n the set of n-simplices of K.
(2) For each $s\in S_n$ we denote by $\Phi_s^{\leq}\colon \Delta^n\to|K|$ the corresponding characteristic map.
(3) For each $s\in S_n$ we set

$$\epsilon_s \;:=\; \begin{cases} +1, & \text{if } \lambda\circ\Phi_s^{\leq}\colon \mathring{\Delta}^n\to M \text{ is orientation-preserving,}\\ -1, & \text{if } \lambda\circ\Phi_s^{\leq}\colon \mathring{\Delta}^n\to M \text{ is orientation-reversing.}\end{cases}$$

Next we introduce the analogous notions for the subcomplex J:

(4) We denote by R_{n-1} the set of $(n-1)$-simplices of R.
(5) For each $r\in R_{n-1}$ we denote by $\Psi_r^{\leq}\colon \Delta^{n-1}\to|J|$ the corresponding characteristic map.
(6) For each $r\in R_{n-1}$ we set

$$\mu_r \;:=\; \begin{cases} +1, & \text{if } \lambda\circ\Psi_r^{\leq}\colon \mathring{\Delta}^{n-1}\to\partial M \text{ is orientation-preserving,}\\ -1, & \text{if } \lambda\circ\Psi_r^{\leq}\colon \mathring{\Delta}^{n-1}\to\partial M \text{ is orientation-reversing.}\end{cases}$$



Now we see that

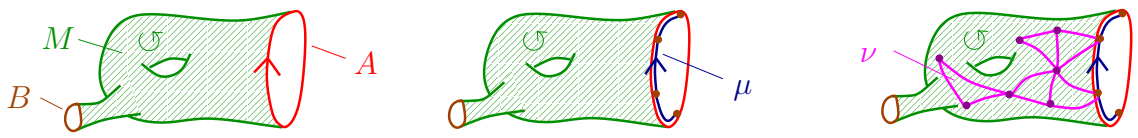
$$\partial[M] \overset{\text{Algorithm 100.2}}{=} \partial\Big[\sum_{s\in S_n} \epsilon_s \cdot \lambda \circ \Phi_s^{\leq}\Big] \overset{\text{Topological LES-Proposition 74.13}}{=} \Big[\sum_{s\in S_n} \epsilon_s \cdot \lambda \circ \partial_n(\Phi_s^{\leq})\Big] \overset{\text{definition of } \partial_n \colon \mathrm{C}_n(M) \to \mathrm{C}_{n-1}(M)}{=} \Big[\sum_{s\in S_n} \epsilon_s \cdot \lambda \circ \sum_{j=0}^{n} (-1)^j \cdot \Phi_s^{\leq} \circ i_j^n\Big]$$

since we are given a cycle in $\mathrm{C}_n(M, \partial M)$ the contributions of singular simplices for which the image does not lie in ∂M cancel

$$= \Big[\sum_{\substack{s\in S_n \text{ and } j\in\{0,\dots,n\} \\ \text{such that} \\ (\Phi_s^{\leq} \circ i_j^n)(\Delta^{n-1}) \subset \partial M}} (-1)^j \cdot \epsilon_s \cdot \lambda \circ \Phi_s^{\leq} \circ i_j^n\Big] = \Big[\sum_{r\in R} \mu_r \cdot \lambda \circ \Psi_r^{\leq}\Big] = [\partial M].$$

by the Manifold-Simplex Proposition 98.1 (4) we have a bijection of singular simplices that appear in the sums, furthermore the corresponding signs match by the discussion on page 2153 — Algorithm 100.2 ■

The following straightforward corollary says that we can "extend" fundamental cycles from the boundary to the total manifold.



Corollary 100.10. Let M be a compact oriented n-dimensional smooth manifold. Let A be a union of components of ∂M. We write $B := \partial M \setminus A$. We consider the map

$$\mathrm{C}_n(M, \partial M) \xrightarrow{\partial_n} \mathrm{C}_{n-1}(\partial M) \xrightarrow{\mathrm{id}} \mathrm{C}_{n-1}(A \sqcup B) \xrightarrow{\cong} \mathrm{C}_{n-1}(A) \oplus \mathrm{C}_{n-1}(B) \twoheadrightarrow \mathrm{C}_{n-1}(A).$$

$$=: \Theta_A$$

Given any fundamental cycle $\mu \in \mathrm{C}_{n-1}(A)$ there exists a chain $\nu \in \mathrm{C}_n(M)$ such that ν represents a fundamental cycle in $\mathrm{C}_n(M, \partial M)$ and such that $\Theta_A(\nu) = \mu$.

Proof. First note that it is basically clear that it suffices to prove the statement for the case $A = \partial M$. Next, pick a singular chain $\widetilde{\nu} \in \mathrm{C}_n(M)$ that represents a fundamental cycle in $\mathrm{C}_n(M, \partial M)$. By Propositions 100.9 and 74.13 we know that the cycles $\partial_n(\widetilde{\nu})$ and μ are homologous in $\mathrm{C}_{n-1}(\partial M)$. This means that there exists a $\sigma \in \mathrm{C}_n(\partial M)$ with $\partial\sigma = \partial_n(\widetilde{\nu}) - \mu$. Now we set $\nu := \widetilde{\nu} - \sigma \in \mathrm{C}_n(M)$. Since ν and $\widetilde{\nu}$ represent the same element in $\mathrm{C}_n(M, \partial M)$ we see that ν is also a fundamental cycle. Finally we note that by construction we have $\partial_n(\nu) = \partial_n(\widetilde{\nu}) - \partial_n(\sigma) = \mu$. ■

Next we record the following useful corollary to the Fundamental Class-of-Boundary Proposition 100.9.

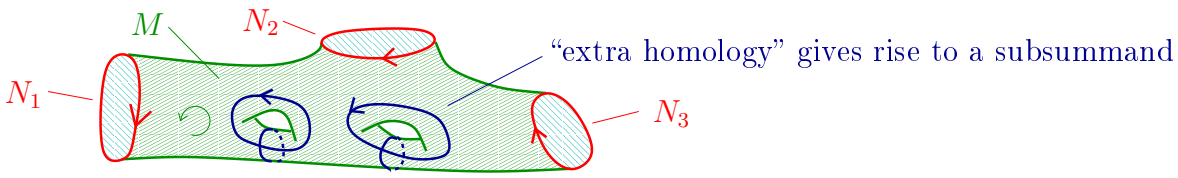
Corollary 100.11. (Fundamental Class-of-Boundary Corollary) Let M be a compact oriented connected n-dimensional smooth manifold. We denote by $i\colon \partial M \to M$ the inclusion map and we denote by $N_1, \ldots, N_k$ the components of ∂M.

(1) We have
$$\ker\big(i_*\colon \underbrace{\mathrm{H}_{n-1}(\partial M)}_{=\mathbb{Z}\cdot[N_1]\oplus\cdots\oplus\mathbb{Z}\cdot[N_k]} \to \mathrm{H}_{n-1}(M)\big) \;=\; \mathbb{Z}\cdot\underbrace{[\partial M]}_{\substack{\uparrow\\ \text{we have } [\partial M]=[N_1]+\cdots+[N_k]}} \subset \mathrm{H}_{n-1}(\partial M).$$

(2) Let $j \in \{1, \ldots, k\}$. We consider the following maps:
$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{H}_{n-1}(\partial M)/\mathbb{Z}\cdot[\partial M] & \xrightarrow{i_*} & \mathrm{H}_{n-1}(M) & \longrightarrow & \mathrm{coker}(\mathrm{H}_{n-1}(\partial M) \xrightarrow{i_*} \mathrm{H}_{n-1}(M)) & \longrightarrow & 0. \\ & & \cong\uparrow & & & & & & \\ & & \mathbb{Z}\cdot[N_1]\oplus\ldots\oplus\widehat{\mathbb{Z}\cdot[N_j]}\oplus\ldots\oplus\mathbb{Z}\cdot[N_k] & & & & & & \end{array}$$
The following two statements hold:
(a) The horizontal sequence is exact and it splits.
(b) The vertical map is an isomorphism.

(3) If M has precisely one boundary component, then $i_*\colon \mathrm{H}_{n-1}(\partial M) \to \mathrm{H}_{n-1}(M)$ is the zero map.

(4) The boundary ∂M is not a retract of M.



Remark.

(1) The special case that M is a 2-dimensional smooth manifold is foreshadowed by Exercise 80.14.

(2) In Proposition 74.7 we showed that the sphere $S^{n-1} = \partial\overline{B}^{n-1}$ is not a retract of the closed ball $\overline{B}^n$. the Fundamental Class-of-Boundary Corollary 100.11 (3) can thus be viewed as a generalization of Proposition 74.7 from $\overline{B}^n$ to the case of compact oriented connected smooth manifolds with non-empty boundary.

(3) In Corollary 106.28 we will extend the statement of the Fundamental Class-of-Boundary Corollary 100.11 to topological manifolds. Also note that in the Boundary Non-Retraction Proposition 31.3 we gave a very different proof of the Fundamental Class-of-Boundary Corollary 100.11.

Example. In the figure below we show a compact oriented n-dimensional smooth manifold with three boundary components N_1, N_2 and N_3. the Fundamental Class-of-Boundary Corollary 100.11 says that *any two* boundary components generate a *subsummand* of $\mathrm{H}_{n-1}(M)$. Furthermore in $\mathrm{H}_{n-1}(M)$ we have the equality $[N_1] + [N_2] + [N_3] = 0$.

Proof. Let M be a compact oriented n-dimensional smooth manifold. We denote by $i\colon \partial M \to M$ the inclusion map.

(1) Using the Fundamental Class-of-Boundary Proposition 100.9 and the long exact sequence in homology of the pair $(M, \partial M)$ we obtain that the following sequence is exact:

$$\underbrace{\mathrm{H}_n(M, \partial M)}_{=\mathbb{Z}\cdot[M] \text{ by Theorem 100.1}} \xrightarrow{[M]\mapsto[\partial M]} \mathrm{H}_{n-1}(\partial M) \xrightarrow{i_*} \mathrm{H}_{n-1}(M).$$

Statement (1) is now an immediate consequence.

(2) (a) It follows from (1) that the horizontal sequence is exact. By the Smooth Manifold-Top Homology Theorem 98.6 (2) the group $\mathrm{H}_{n-1}(M)$ is free abelian. It follows from Lemma 51.9 that the group $\operatorname{coker}(i_*\colon \mathrm{H}_{n-1}(\partial M) \to \mathrm{H}_{n-1}(M)) \cong \ker(\mathrm{H}_{n-1}(M) \to \mathrm{H}_{n-1}(M, \partial M))$ is also free abelian. It now follows from Lemma 78.1 that the short exact sequence splits.

(b) It follows immediately from $[\partial M] = [N_1] + \cdots + [N_k]$ that the vertical map is an isomorphism.

(3) Now we assume that ∂M has precisely one component. By Theorem 100.1 we now have $\mathrm{H}_{n-1}(\partial M) = \mathbb{Z} \cdot [\partial M]$. Thus this statement is now an immediate consequence of (1).

(4) Suppose there exists a retraction $r\colon M \to \partial M$, i.e. a map with $r \circ i = \mathrm{id}_{\partial M}$. We consider the following commutative diagram

$$\begin{array}{ccccc} & & \mathrm{H}_{n-1}(M) & & \\ & \overset{i_*}{\nearrow} & & \overset{r_*}{\searrow} & \\ \mathrm{H}_{n-1}(\partial M) & & \xrightarrow{(r\circ i)_*=\mathrm{id}} & & \mathrm{H}_{n-1}(\partial M). \end{array}$$

We just saw in (1) that i_* is not injective. But this leads immediately to a contradiction. ∎

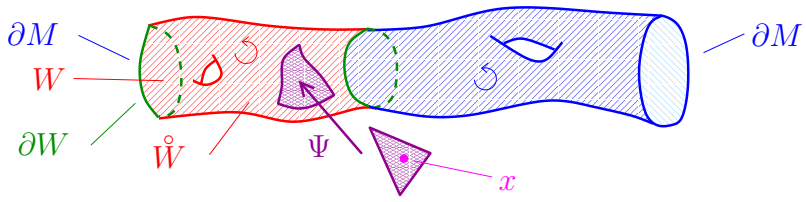
In the next lemma we study the fundamental classes of codimension-zero submanifolds.

Lemma 100.12. (Codimension Zero-Fundamental Class Lemma) Let M be a compact oriented n-dimensional smooth manifold. Furthermore let $W \subset M$ be a compact n-dimensional submanifold. We write $\mathring{W} = W \setminus \partial W$ and we equip W with the orientation given by the Basics-of-Orientations Lemma 25.13 (6). The following two statements hold:

(1) The inclusion induced map $\mathrm{H}_n(W, \partial W) \to \mathrm{H}_n(M, M \setminus \mathring{W})$ is an isomorphism.

(2) The images of the fundamental classes $[M] \in \mathrm{H}_n(M, \partial M)$ and $[W] \in \mathrm{H}_n(W, \partial W)$ under the maps

$$\mathrm{H}_n(M, \partial M) \longrightarrow \mathrm{H}_n(M, M \setminus \mathring{W}) \xleftarrow{\cong} \mathrm{H}_n(W, \partial W)$$



$\uparrow$ isomorphism by the Excision Theorem 75.10

agree.

Proof.

(1) The first statement is an immediate consequence of the Excision Theorem 75.10.

(2) We denote by $\Phi\colon \mathrm{H}_n(M, \partial M) \to \mathrm{H}_n(W, \partial W)$ the map given in Statement (2). We have to show that $\Phi([M])$ is the fundamental class for W. So let $\Psi\colon \Delta^n \to W$ be a

map and let $x \in \mathring{\Delta}^n$ be an admissible point. We consider the following commutative diagram

$$\begin{array}{ccccc}
 & & \overset{\Phi}{\curvearrowright} & & \\
\mathrm{H}_n(M, \partial M) & \longrightarrow & \mathrm{H}_n(M, M \setminus \mathring{W}) & \xleftarrow{\cong} & \mathrm{H}_n(W, \partial W) \\
\downarrow{\scriptstyle \omega_{\Psi(x)}} & & & & \downarrow{\scriptstyle \omega_{\Psi(x)}} \\
\mathrm{H}_n(M, M \setminus \{\Psi(x)\}) & & \xleftarrow[\text{isomorphism by the Excision Theorem 74.18}]{\cong} & & \mathrm{H}_n(W, W \setminus \{\Psi(x)\}) \\
 & {\scriptstyle \Psi_*} \nwarrow & & \nearrow {\scriptstyle \Psi_*} & \\
 & & \mathrm{H}_n(\Delta^n, \Delta^n \setminus \{x\}). & &
\end{array}$$

The desired statement now follows easily from the defining properties of fundamental classes and the above discussions. We leave the few remaining details to the reader. ■

One of the most popular approaches to computing the homology groups of some topological space X is to write X as the union $X = A \cup B$ of "simpler topological spaces A and B" in a suitable way and to use the Mayer–Vietoris Theorem 78.5. The catch of the Mayer–Vietoris Theorem 78.5 is that not only does one need to understand the homology groups of A, B and $A \cap B$, one also needs to understand the inclusion induced maps on homology groups, which can be quite difficult. Fortunately the Fundamental Class-of-Boundary Corollary 100.11 (2) now gives an interesting calculation of an inclusion induced map of homology groups. In the following two sections we will use the Fundamental Class-of-Boundary Corollary 100.11 (2) to study the homology groups of the connected sum of two smooth manifolds and to study the homology groups of knot complements.

100.4. **The homology groups of the connected sum of two smooth manifolds.** Let M and N be two compact oriented connected non-empty n-dimensional smooth manifolds. We recall the definition of the connected sum $M \# N$ that we gave on page **??**. First we pick an orientation-preserving smooth embedding $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and we pick an orientation-reversing smooth embedding $\psi\colon \overline{B}^n \to N \setminus \partial N$. Then we defined the connected sum of M and N as follows:

$$M \# N \;:=\; \big(M \setminus \varphi\big(B^n\big)\big) \sqcup \big(N \setminus \psi\big(B^n\big)\big) \,/\, \big\{\varphi(P) = \psi(P) \,\big|\, P \in S^{n-1}\big\}.$$

We refer to the Connected Sum-Proposition **??** for some key properties of $M \# N$. Recall that in the Connected Sum-π_1-Proposition 52.12 we showed that $\pi_1(M \# N)$ is isomorphic to the free product of $\pi_1(M)$ and $\pi_1(N)$. The following proposition says that a very similar result holds for the homology groups of $M \# N$.

Proposition 100.13. (Connected Sum-H_*-Proposition) Let M and N be two closed oriented connected non-empty n-dimensional smooth manifolds. For any $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(M\#N) \;\cong\; \begin{cases} \mathrm{H}_k(M) \oplus \mathrm{H}_k(N), & \text{if } k \neq 0, n, \\ \mathbb{Z}, & \text{if } k = 0, n. \end{cases}$$

Moreover, for $k \neq 0, n$ the inclusion maps induce isomorphisms

$$\mathrm{H}_k(M) \oplus \mathrm{H}_k(N) \;\xleftarrow{\cong}\; \mathrm{H}_k(M \setminus B^n) \oplus \mathrm{H}_k(N \setminus B^n) \;\xrightarrow{\cong}\; \mathrm{H}_k(M\#N)$$

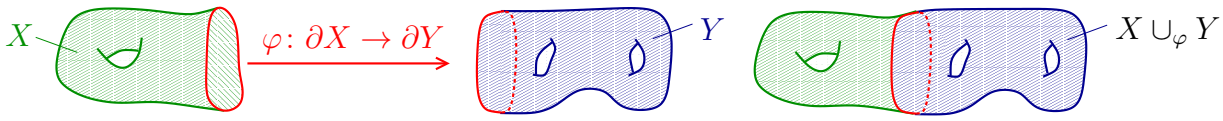
where $B^n \subset M$ and $B^n \subset N$ denote the open balls used in the definition of the connected sum of M and N.

Remark. In Exercise 100.8 we will consider the homology groups of $M\#N$ if we drop the condition that the smooth manifolds are closed.

The key to the proof of the Connected Sum-H_*-Proposition 100.13 is the following lemma.

Lemma 100.14. Let X and Y be two compact orientable connected n-dimensional smooth manifolds such that $\partial X \cong S^{n-1}$ and $\partial Y \cong S^{n-1}$. We pick a diffeomorphism $\varphi\colon \partial X \to \partial Y$.

(1) There exists an isomorphism



$$\mathrm{H}_n(X \cup_\varphi Y) \;\cong \mathbb{Z}.$$

Furthermore for every $k < n$ the inclusion maps $X \to X \cup_\varphi Y$ and $Y \to X \cup_\varphi Y$ induce an isomorphism

$$\widetilde{\mathrm{H}}_k(X) \oplus \widetilde{\mathrm{H}}_k(Y) \;\xrightarrow{\cong}\; \widetilde{\mathrm{H}}_k(X \cup_\varphi Y).$$

(2) In particular for the case that $Y = \overline{B}^n$ we obtain that for any $k < n$ the inclusion map $X \to X \cup_\varphi \overline{B}^n$ induces an isomorphism

$$\widetilde{\mathrm{H}}_k(X) \;\xrightarrow{\cong}\; \widetilde{\mathrm{H}}_k(X \cup_\varphi \overline{B}^n).$$

Proof of Lemma 100.14. The second statement is an immediate consequence of the first statement and the fact that for every $k < n$ we have $\widetilde{\mathrm{H}}_k(\overline{B}^n) = 0$. Thus it suffices to prove the first statement. To simplify the notation we write $S^{n-1} = \partial X = \partial Y$. We also write $Z = X \cup_\varphi Y$. It follows from the Mayer-Vietoris Theorem 78.9 for Manifolds[1230] that there exists a long exact sequence

$$\to \widetilde{\mathrm{H}}_k(S^{n-1}) \xrightarrow{i_*\oplus -i_*} \widetilde{\mathrm{H}}_k(X) \oplus \widetilde{\mathrm{H}}_k(Y) \xrightarrow{i_*+i_*} \widetilde{\mathrm{H}}_k(Z) \xrightarrow{\partial_k} \widetilde{\mathrm{H}}_{k-1}(S^{n-1}) \to \dots$$

where i always stands for the corresponding inclusion map. By Proposition 74.4 we have $\widetilde{\mathrm{H}}_n(S^n) \cong \mathbb{Z}$ and $\widetilde{\mathrm{H}}_k(S^n) = 0$ for $k \neq n$. We see immediately that for any $k < n$ the inclusion maps induce an isomorphism $\widetilde{\mathrm{H}}_k(X) \oplus \widetilde{\mathrm{H}}_k(Y) \to \widetilde{\mathrm{H}}_k(Z)$.

Now we turn to the n-th homology of Z. First note that by Theorem 98.8 we have $\widetilde{\mathrm{H}}_n(X) = \widetilde{\mathrm{H}}_n(Y) = 0$. Therefore the above long exact sequence gives rise to an exact

[1230] Note that here secretly we also used the Gluing-Smooth Manifolds-Proposition **??**

sequence

since S^{n-1} is the unique boundary component of X we deduce from Fundamental Class-of-Boundary Corollary 100.11 that the map $i_*\colon \widetilde{\mathrm{H}}_{n-1}(S^{n-1}) \to \widetilde{\mathrm{H}}_{n-1}(X)$ is the zero map, the same way we also see that the map $i_*\colon \mathrm{H}_{n-1}(S^{n-1}) \to \mathrm{H}_{n-1}(Y)$ is the zero map

$$\underbrace{\widetilde{\mathrm{H}}_n(X)\oplus\widetilde{\mathrm{H}}_n(Y)}_{=0 \text{ by Theorem 98.8}} \to \widetilde{\mathrm{H}}_n(Z) \xrightarrow{\partial_n} \underbrace{\widetilde{\mathrm{H}}_{n-1}(S^{n-1})}_{=\mathbb{Z}\cdot[S^{n-1}]} \xrightarrow{i_*\oplus -i_*} \widetilde{\mathrm{H}}_{n-1}(X)\oplus\widetilde{\mathrm{H}}_{n-1}(Y) \to \widetilde{\mathrm{H}}_{n-1}(Z) \to 0.$$

∂_n: isomorphism by the above

All the desired statements follow from the above data. ∎

Now we can easily provide the proof of the Connected Sum-H_*-Proposition 100.13.

Proof of the Connected Sum-H_*-Proposition 100.13. Let M and N be two closed oriented connected non-empty n-dimensional smooth manifolds. As required in the definition of the connected sum of M and N we pick an orientation-preserving smooth embedding $\varphi\colon \overline{B}^n \to M$ and we pick an orientation-reversing smooth embedding $\psi\colon \overline{B}^n \to N$. Recall that

$$M\#N \;=\; \big(M \setminus \varphi\big(B^n\big)\big) \sqcup \big(N \setminus \psi\big(B^n\big)\big) \,/\, \big\{\varphi(P) = \psi(P) \,\big|\, P \in S^{n-1}\big\}.$$

We write $X = M \setminus \varphi(B^n)$ and $Y = N \setminus \psi(B^n)$. Note that it follows immediately from Lemma 100.14 (1) that $\mathrm{H}_n(M\#N) = \mathrm{H}_n(X \cup_{S^{n-1}} Y) \cong \mathbb{Z}$. Now let $k < n$. Note that in this case we have

$$\mathrm{H}_k(M) \oplus \mathrm{H}_k(N) \;\xleftarrow{\cong}\; \mathrm{H}_k(\underbrace{M \setminus \varphi(B^n)}_{=X}) \oplus \mathrm{H}_k(\underbrace{N \setminus \psi(B^n)}_{=Y}) \;\xrightarrow{\cong}\; \mathrm{H}_k(M\#N)$$

Lemma 100.14 (1) applied to $M = X \cup_{S^{n-1}} \overline{B}^n$ and $N = Y \cup_{S^{n-1}} \overline{B}^n$

Lemma 100.14 (1) applied to $M\#N = X \cup_{S^{n-1}} Y$

∎

Examples.

(1) Let $T = S^1 \times S^1$ be the torus. In the figure on page **??** we saw that the connected sum $T\#T$ is diffeomorphic to the surface Σ_2 of genus 2. More generally, the same argument shows that the connected sum of g copies of the torus T is diffeomorphic to the surface Σ_g of genus g. Together with the calculation of the homology groups of the torus in Lemma 78.11 we now see that

$$\mathrm{H}_k(\Sigma_g) \;\cong\; \mathrm{H}_k(\underbrace{T\#\ldots\#T}_{g \text{ copies}}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, \\ \mathbb{Z}^{2g}, & \text{if } k = 1, \\ 0, & \text{if } k > 2. \end{cases}$$

This agrees of course with the result obtained in Proposition 80.10.

(2) We consider the complex manifold $\mathbb{C}\mathrm{P}^2$. On page 1772 we showed that

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^2) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \\ 0, & \text{otherwise.} \end{cases}$$

As always we equip $\mathbb{C}\mathrm{P}^2$ with the natural orientation coming from the Complex Manifold-Orientation Proposition 32.23. We can now form the connected sum $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$. It follows from the Connected Sum-H_*-Proposition 100.13 that

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 4, \\ \mathbb{Z} \oplus \mathbb{Z}, & \text{if } k = 2, \\ 0, & \text{otherwise.} \end{cases}$$

For the complex projective space $\mathbb{C}\mathrm{P}^2$ we use the common notation that we write $\overline{\mathbb{C}\mathrm{P}}^2$ instead of $-\mathbb{C}\mathrm{P}^2$. Since the homology groups do not depend on the orientation we have the same homology groups for $\overline{\mathbb{C}\mathrm{P}}^2$ and the calculation shows that the homology groups of $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ agree.

Recall that on page 1948 we showed, using the Künneth Theorem 90.8 that

$$\mathrm{H}_k(S^2 \times S^2) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 4, \\ \mathbb{Z} \oplus \mathbb{Z}, & \text{if } k = 2, \\ 0, & \text{otherwise.} \end{cases}$$

This fact, and our above calculations shows, that the homology groups of the connected sums $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$, $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ and of $S^2 \times S^2$ are all isomorphic. Furthermore, note that by Propositions 47.13, 48.20, 52.12 and the discussion on page 1533 we know that all of these topological spaces are simply connected. So this raises the following intriguing question.

Question 100.15. Are the closed 4-dimensional smooth manifolds $S^2 \times S^2$, $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ homeomorphic?

We will answer this question in Corollary 133.12 and Proposition 133.13.

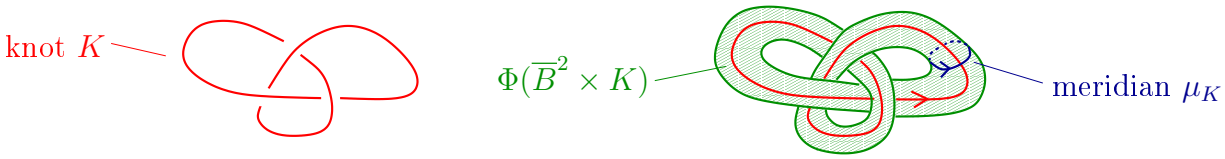
100.5. **Homology groups of knot complements.** We return to the ever-popular study of knots in S^3.

Definition. Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem **??** there exists a smooth embedding $\Phi\colon \overline{B}^2 \times K \to S^3$ such that $\Phi(0, P) = P$ for all $P \in K$. We refer to

$$X_K := S^3 \setminus \Phi(B^2 \times K)$$

as the exterior of K. If K is oriented, then we pick Φ to be orientation-preserving and, following the definition on page 1305, we refer to any oriented submanifold $\Phi(S^1 \times \{P\})$ as a meridian μ_K of K.

The following lemma gives us in particular the long-awaited calculation of the homology groups of knot complements.



Lemma 100.16. For any knot $K \subset S^3$ the following statements hold:

(1) The exterior X_K of the knot K is a compact orientable connected 3-dimensional smooth manifold and the boundary ∂X_K is diffeomorphic to the torus.
(2) The diffeomorphism type of X_K as an oriented smooth manifold does not depend on the choice of Φ.

(3) The exterior X_K is a deformation retract of the knot complement $S^3 \setminus K$.
(4) We pick an orientation for K. For every $n \in \mathbb{N}_0$ we have[1231]

$$\underset{\text{induced by the inclusion } X_K \to S^3 \setminus K}{\mathrm{H}_n(S^3 \setminus K) \xleftarrow[\uparrow]{\cong} \mathrm{H}_n(X_K)} = \begin{cases} 0, & \text{if } n \geq 2, \\ \mathbb{Z} \cdot [\mu_K], & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

where μ_K denotes a meridian of K.

Remark. In Lemma 78.13 we already showed that $\mathrm{H}_0(X_K) = \mathbb{Z}$ and that $\mathrm{H}_1(X_K) = \mathbb{Z} \cdot [\mu_K]$. In fact in the proof of Lemma 100.16 (4) below we will follow the same approach as in Lemma 78.13, except that now can overcome the hurdle which prevented us back then from computing all homology groups.

Proof. Let $K \subset S^3$ be an oriented knot and let $P \in K$. We pick a tubular neighborhood $\overline{B}^2 \times K$ for K and we pick $Q \in S^1$. We write $\mu_K = S^1 \times \{P\}$ and $\gamma = \{Q\} \times K$.

(1) This statement is basically a consequence of the Codimension-Zero Smooth Embedding Proposition 24.16.
(2) This statement is an immediate consequence of Proposition **??**.
(3) A deformation retraction from $S^3 \setminus K$ to X_K is given by the map

$$\begin{array}{rcl} (S^3 \setminus K) \times [0,1] & \to & X_K = S^3 \setminus (B^2 \times K) \\ (x,t) & \mapsto & \begin{cases} x, & \text{if } x \in Y = S^3 \setminus (\overline{B}^2 \times K), \\ (((1-t)r + t)\exp(\mathrm{i}\alpha), z), & \text{if } x = (r \cdot \exp(\mathrm{i}\alpha), z) \in \overline{B}^2 \times K. \end{cases} \end{array}$$

It follows easily from the Homotopy Stacking Lemma 14.3 and the Codimension-Zero Smooth Embedding Proposition 24.16 that this map is indeed continuous.
(4) First note that by the Homotopy Equivalence-H_*-Corollary 73.9, the Deformation Retract-Homotopy Equivalence Lemma 15.5 and by (3) we know that the inclusion $X_K \to S^3 \setminus K$ induces an isomorphism on all homology groups.

Now we proceed with almost the same argument as in the proof of Lemma 78.13. Namely, we consider the decomposition

$$S^3 = \underbrace{(S^3 \setminus (B^2 \times K))}_{=X_K} \cup_{S^1 \times K} (\overline{B}^2 \times K)$$

and we apply the Mayer-Vietoris Theorem 78.9 with reduced homology groups. We obtain the following long exact sequence:

$$\begin{array}{rcccccccc} \to & \mathrm{H}_3(\partial X_K) & \xrightarrow{i_*-i_*} & \mathrm{H}_3(X_K) & \oplus & \mathrm{H}_3(\overline{B}^2 \times K) & \xrightarrow{i_*+i_*} & \mathrm{H}_3(S^3) & \xrightarrow{\partial_3} \\ \to & \mathrm{H}_2(\partial X_K) & \xrightarrow{i_*-i_*} & \mathrm{H}_2(X_K) & \oplus & \mathrm{H}_2(\overline{B}^2 \times K) & \xrightarrow{i_*+i_*} & \mathrm{H}_2(S^3) & \xrightarrow{\partial_2} \\ \to & \mathrm{H}_1(\partial X_K) & \xrightarrow{i_*-i_*} & \mathrm{H}_1(X_K) & \oplus & \mathrm{H}_1(\overline{B}^2 \times K) & \xrightarrow{i_*+i_*} & \mathrm{H}_1(S^3) & \xrightarrow{\partial_1} 0. \end{array}$$

[1231] We will give an alternative approach to calculating these homology groups in Exercise 100.5.

Now we throw in everything we know about the above setting:

$$\begin{array}{ccccccccc}
\to & \underbrace{\mathrm{H}_3(\partial X_K)}_{=0} & \xrightarrow{i_*-i_*} & \mathrm{H}_3(X_K) & \oplus & \underbrace{\mathrm{H}_3(\overline{B}^2\times K)}_{=0} & \xrightarrow{i_*+i_*} & \underbrace{\mathrm{H}_3(S^3)}_{=\mathbb{Z}\cdot[S^3]} & \xrightarrow{\partial_3} \\
\to & \underbrace{\mathrm{H}_2(\partial X_K)}_{=\mathbb{Z}\cdot[\partial X_K]} & \xrightarrow{i_*-i_*} & \mathrm{H}_2(X_K) & \oplus & \underbrace{\mathrm{H}_2(\overline{B}^2\times K)}_{=0} & \xrightarrow{i_*+i_*} & \underbrace{\mathrm{H}_2(S^3)}_{=0} & \xrightarrow{\partial_2} \\
 & & \uparrow & & & & & & \\
 & & \text{by the Fundamental Class-of-Boundary Corollary 100.11 (2) this is the zero map} & & & & & & \\
\to & \underbrace{\mathrm{H}_1(\partial X_K)}_{=\mathbb{Z}\cdot[\mu_K]\oplus\mathbb{Z}\cdot[\gamma]} & \xrightarrow{i_*-i_*} & \mathrm{H}_1(X_K) & \oplus & \underbrace{\mathrm{H}_1(\overline{B}^2\times K)}_{=\mathbb{Z}\cdot[\gamma]} & \xrightarrow{i_*+i_*} & \underbrace{\mathrm{H}_1(S^3)}_{=0} & \xrightarrow{\partial_1} 0. \\
 & & \uparrow & & & & & & \\
 & & \text{we have } [\mu_K]\mapsto([\mu_K],0) \text{ and } [\gamma]\mapsto(?,[\gamma]) & & & & & &
\end{array}$$

Note that we obtain from the above discussion that the connecting homomorphism $\partial_3\colon \mathbb{Z}\cdot[S^3] = \mathrm{H}_3(S^3) \to \mathrm{H}_2(\partial X_K) = \mathbb{Z}\cdot[\partial X_K]$ is an epimorphism. Since every epimorphism $\mathbb{Z}\to\mathbb{Z}$ is necessarily an isomorphism we see that the connecting homomorphism is in fact an isomorphism. Thus we obtain that $\mathrm{H}_3(X_K) = \mathrm{H}_2(X_K) = 0$. At the lower end we obtain easily, as we explained in the proof of Lemma 78.13, that $\mathrm{H}_1(X_K) = \mathbb{Z}\cdot[\mu_K]$. ■

100.6. **The $\mathbb{F}_2$-fundamental class.** In this final section we introduce the $\mathbb{F}_2$-fundamental class for any compact (not necessarily orientable) smooth manifold. Truth be told, this notion will only play a fairly minor role in the subsequent chapters.

Now let M be a compact connected n-dimensional smooth manifold. Recall that by Theorem 98.8 (3) we know that, regardless of whether or not M is orientable, we have $\mathrm{H}_n(M,\partial M;\mathbb{F}_2)\cong\mathbb{F}_2$. This leads us to the following definition.

Definition. Let M be a compact n-dimensional smooth manifold. We denote by $N_1,\dots,N_k$ the components of M. We refer to

$$[M]_{\mathbb{F}_2} := \sum_{i=1}^{k} \text{the unique non-zero element of } \mathrm{H}_n(N_i,\partial N_i;\mathbb{F}_2) \in \underbrace{\mathrm{H}_n(M,\partial M;\mathbb{F}_2)}_{=\bigoplus_{i=1}^{k}\mathrm{H}_n(N_i,\partial N_i;\mathbb{F}_2)}$$

as the $\mathbb{F}_2$-fundamental class of M.

Remark. In the $\mathbb{F}_2$-Fundamental Class Corollary 106.5 we will generalize this notion to compact *topological* manifolds.

The following proposition is the "$\mathbb{F}_2$"-analogue of some of the results from Section 100.1.

Proposition 100.17. Let M be a compact n-dimensional smooth manifold.

(1) Let $(K=(V,S),\lambda\colon |K|\to M)$ be a smooth simplicial structure for M. We pick a total order "$\leq$" on V. We denote by $s_1,\dots,s_k$ the n-simplices of K. Furthermore for $i\in\{1,\dots,k\}$ we consider the characteristic map $\Phi^{\leq}_{s_i}\colon\Delta^n\to|K|$. With this notation the singular chain

$$\lambda\circ\Phi^{\leq}_{s_1}\otimes 1+\cdots+\lambda\circ\Phi^{\leq}_{s_k}\otimes 1 \in \mathrm{C}_n(M)\otimes\mathbb{F}_2 = \mathrm{C}_n(M;\mathbb{F}_2)$$

is a cycle which represents the $\mathbb{F}_2$-fundamental class of M.

(2) Let $x \in M \setminus \partial M$.
   (a) The image of the $\mathbb{F}_2$-fundamental class $[M]_{\mathbb{F}_2} \in \mathrm{H}_n(M, \partial M; \mathbb{F}_2)$ under the natural map $\mathrm{H}_n(M, \partial M; \mathbb{F}_2) \to \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{F}_2)$ is the unique non-trivial element.
   (b) If M is connected, then the natural map $\mathrm{H}_n(M, \partial M; \mathbb{F}_2) \to \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{F}_2)$ is an isomorphism.

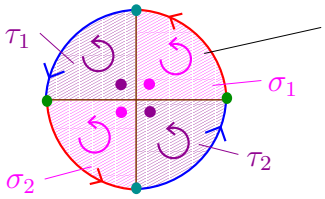
Sketch of proof. It is straightforward to see that it suffices to consider the case that M is connected. Furthermore, using a doubling argument one can fairly easily reduce the proof of the statement to the case of a closed n-dimensional smooth manifold M. Next note that a slight variation on the argument of Theorem 98.4 shows that

$$\sigma \;:=\; \lambda \circ \Phi^{\leq}_{s_1} \otimes 1 + \cdots + \lambda \circ \Phi^{\leq}_{s_k} \otimes 1 \;\in\; \mathrm{C}_n(M; \mathbb{F}_2)$$

is indeed a cycle in the chain complex $\mathrm{C}_*(M; \mathbb{F}_2) = \mathrm{C}_*(M) \otimes \mathbb{F}_2$. Next note that the argument of the proof of Theorem 100.1 (1) shows that for every $x \in M$ the natural map $\mathrm{H}_n(M; \mathbb{F}_2) \to \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{F}_2)$ sends $[\sigma]$ to the unique non-zero element. Furthermore note that by Theorem 98.8 (3) we know that $\mathrm{H}_n(M; \mathbb{F}_2) \cong \mathbb{F}_2$. Finally note that this implies that the natural map $\mathrm{H}_n(M; \mathbb{F}_2) \to \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{F}_2)$ is indeed an isomorphism and that $[\sigma]$ is indeed a generator of $\mathrm{H}_n(M; \mathbb{F}_2)$. ■

The following proposition is the $\mathbb{F}_2$-analogue of the Fundamental Class-Criterion Proposition 100.4.

Proposition 100.18. Let M be a compact connected n-dimensional smooth manifold. Let $(\sigma_1 + \cdots + \sigma_m) \otimes 1 \in \mathrm{C}_n(M, \partial M; \mathbb{F}_2) = \mathrm{C}_n(M, \partial M) \otimes \mathbb{F}_2$ be a cycle. Suppose there exists a $j \in \{1, \ldots, m\}$ such that the following two conditions are satisfied:



(1) The map $\sigma_j \colon \overset{\circ}{\Delta}{}^n \to M$ is a smooth embedding.
(2) There exists an $x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial \Delta^n)$ which is not contained in the image of any other $\sigma_i \colon \Delta^n \to M$.

Then the cycle $(\sigma_1 + \cdots + \sigma_m) \otimes 1$ represents the $\mathbb{F}_2$-fundamental class of M.

Proof. The proof of this proposition is almost the same as the proof of the Fundamental Class-Criterion Proposition 100.4. We leave it to the reader to make the necessary modifications. ■

Examples.

(1) Now we will give a representative for the $\mathbb{F}_2$-fundamental class for the real projective plane $\mathbb{R}\mathrm{P}^2$. More precisely, we consider the four singular simplices $\sigma_1, \sigma_2, \tau_1$ and τ_2 of $\mathbb{R}\mathrm{P}^2$ shown in the figure below, where we use a hopefully obvious variation on the notation introduced in the figure on page 2203. It is straightforward to see that the singular 2-chain $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in \mathrm{C}_2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ is a cycle. Using Proposition 100.18 we see that it represents the $\mathbb{F}_2$-fundamental class of the real projective plane.

projective plane $\mathbb{R}\mathrm{P}^2 = \overline{B}^2 / \sim$

the 2-cycle $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in \mathrm{C}_2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ represents the $\mathbb{F}_2$-fundamental class of the real projective plane

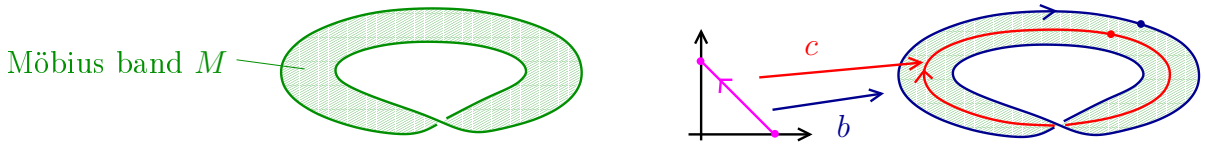
(2) In Exercise 100.13 we will write down a representative for the $\mathbb{F}_2$-fundamental class of the Klein bottle.

The following proposition is the analogue of the Fundamental Class-of-Boundary Proposition 100.9.

Proposition 100.19. Let M be a compact n-dimensional smooth manifold. The connecting homomorphism
$$\partial\colon \mathrm{H}_n(M, \partial M; \mathbb{F}_2) \ \to \ \mathrm{H}_{n-1}(\partial M; \mathbb{F}_2)$$
of the long exact sequence in homology with $\mathbb{F}_2$-coefficients of the pair $(M, \partial M)$ has the property that
$$[M]_{\mathbb{F}_2} \ \mapsto \ [\partial M]_{\mathbb{F}_2}.$$

Proof. The proof is the obvious modification of the previous proof. ∎

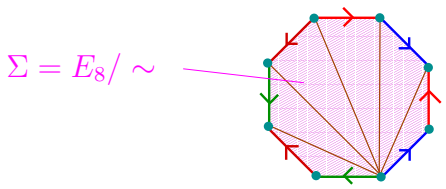
Finally we have the following analogue of the Fundamental Class-of-Boundary Corollary 100.11.



Corollary 100.20. Let M be a compact n-dimensional smooth manifold. We denote by $i\colon \partial M \to M$ the inclusion map.

(1) We have
$$\ker\big(i_*\colon \mathrm{H}_{n-1}(\partial M) \ \to \ \mathrm{H}_{n-1}(M)\big) \ = \ \mathbb{Z} \cdot [\partial M]_{\mathbb{F}_2} \ \in \ \mathrm{H}_{n-1}(\partial M; \mathbb{F}_2).$$
(2) If M has precisely one boundary component, then $i_*\colon \mathrm{H}_{n-1}(\partial M; \mathbb{F}_2) \to \mathrm{H}_{n-1}(M; \mathbb{F}_2)$ is the zero map.
(3) The boundary ∂M is not a retract of M.

Proof. Once again the proof is basically the same as the proof of the analogous statement for ordinary homology groups. ∎



Remark. It is perhaps instructive to consider the good old Möbius band M. We denote by $i\colon \partial M \to M$ the inclusion map. Furthermore let $[b] \in \mathrm{H}_1(M)$ and $[c] \in \mathrm{H}_1(\partial M)$ be the generators shown in the figure below. We end up with the following situation:
$$\begin{array}{ccc} \mathrm{H}_1(\partial M) & \xrightarrow{[b]\mapsto 2\cdot[c]} & \mathrm{H}_1(M) \\ \cong\downarrow{\scriptstyle [\sigma]\mapsto[\sigma\otimes 1]} & & \cong\downarrow{\scriptstyle [\sigma]\mapsto[\sigma\otimes 1]} \\ \mathrm{H}_1(\partial M; \mathbb{F}_2) & \xrightarrow{[b\otimes 1]\mapsto[2\cdot c\otimes 1]=[c\otimes 2]=0} & \mathrm{H}_1(M; \mathbb{F}_2). \end{array}$$

Note that the vertical maps are isomorphisms by the Universal Coefficient Theorem 89.17. We see that the top horizontal map is an injective map, in fact it is basically given by multiplication by 2. On the other hand we see that the bottom horizontal map is the zero map.

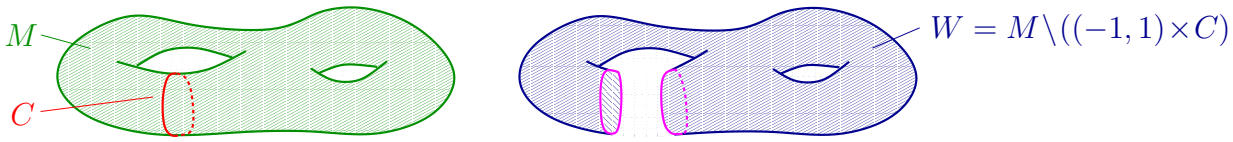
Exercises for Chapter 100.

Exercise 100.1. We consider the surface $\Sigma = E_8/\!\sim$ of genus two as shown in the figure below. Show that there exists a cycle of the form $\epsilon_1 \cdot \sigma_1 + \cdots + \epsilon_6 \cdot \sigma_6 \in \mathrm{C}_2(E_8/\!\sim)$ such that the images of the six singular simplices $\sigma_1, \ldots, \sigma_6$ are precisely the six triangles shown in the figure.

Exercise 100.2. Let M be a compact oriented connected n-dimensional smooth manifold with *at least two* boundary components. Let C be one of the boundary components. By the Fundamental Class-of-Boundary Corollary 100.11 we know that the inclusion induced map $i_*\colon \mathrm{H}_{n-1}(C) \to \mathrm{H}_{n-1}(M)$ admits a left-inverse, i.e. there exists a homomorphism $\varphi\colon \mathrm{H}_{n-1}(M) \to \mathrm{H}_{n-1}(C)$ such that $\varphi \circ i_* = \mathrm{id}_{\mathrm{H}_{n-1}(C)}$. Also note that in Lemma 55.13 we showed that in the case $n = 2$ a stronger statement holds, namely C is a retract of M. Is it true in general that C is necessarily a retract of M?

Exercise 100.3. Let M be a closed oriented connected n-dimensional smooth manifold and let $C \subset M$ be a closed oriented connected $(n-1)$-dimensional submanifold of M. We assume that C is non-separating. Recall that according to the definition on page 1246 this means that $M \setminus C$ is connected. By the Tubular Neighborhood Theorem **??** we can pick a tubular neighborhood $[-1,1] \times C$. We write $W := M \setminus ((-1,1) \times C)$.

(a) Show that there exists an exact sequence of the form



$$0 \;\to\; \mathrm{H}_{n-1}(\underbrace{M \setminus ((-1,1) \times C)}_{=W}) \;\to\; \mathrm{H}_{n-1}(M) \;\to\; \mathrm{H}_{n-2}(C) \;\to\; \ldots$$

Hint. Consider a Meyer–Vietoris sequence.

(b) Use (a) and Exercise 100.2 to show that the map $i_*\colon \mathrm{H}_{n-1}(C) \to \mathrm{H}_{n-1}(M)$ admits a left-inverse.

Remark. This implies in particular that $i_*([C])$ is a non-trivial element of $\mathrm{H}_{n-1}(M)$.

(c) Does the conclusion of (b) also hold if we replace the hypothesis that M is closed by the hypothesis that M is compact?

Exercise 100.4. Let $K = \gamma(S^1) \subset S^3$ be a knot and let $\Phi\colon \overline{B}^2 \times K \to S^3$ be a tubular map for K. As on page 2213 we refer to $X_K = S^3 \setminus \Phi(B^2 \times K)$ as the exterior of the knot K and we refer to $\mu_K = \Phi(S^1 \times \{P\})$ as a meridian of K. In Lemma 78.13, or alternatively

in Lemma 100.16, we saw that $[\mu_K]$, viewed as an element in $\mathrm{H}_1(X_K)$, is a generator of $\mathrm{H}_1(X_K)$.

(a) Show that there exists an $n \in \mathbb{Z}$ such that the curve

$$\begin{array}{rcl} S^1 & \to & \partial X_K = \Phi(S^1 \times K) \\ z & \mapsto & \Phi(z^n, \gamma(z)) \end{array}$$

represents a generator of $\ker(\mathrm{H}_1(\partial X_K) \to \mathrm{H}_1(X_K))$. We refer to the image of this curve as a *longitude* λ_K of K.

(b) Sketch longitudes for the three knots that are shown in the figure below.

(c) Now suppose that we are given two knots K and J. We define X_K, X_J, μ_K, μ_J and λ_K and λ_J as above. We pick a diffeomorphism $\varphi\colon \partial X_K \to \partial X_J$ with $\varphi_*(\mu_K) = \lambda_J$ and $\varphi_*(\lambda_K) = \mu_K$. We denote by $Y = X_K \cup_\varphi X_J$ the result of gluing X_K to X_J along the boundary. Show that Y is a homology sphere, i.e. show that $\mathrm{H}_1(Y) = \mathrm{H}_2(Y) = 0$ and $\mathrm{H}_3(Y) \cong \mathbb{Z}$.

Remark. If K and J are two non-trivial knots, then it follows from Proposition **??** (which in turn is a consequence of the famous Loop Theorem **??**) together with the Amalgamated Product-Monomorphism Proposition 53.24, that the fundamental group of Y is always non-trivial. This shows that Y is a homology sphere with non-trivial fundamental group. In other words we have now found an alternative proof of Proposition 98.11.

trivial knot trefoil figure-8 knot

Exercise 100.5. In this exercise we will consider an alternative approach to computing the homology groups of a knot complement. Let $K \subset S^3$ be a knot. We pick a tubular neighborhood $\overline{B}^2 \times K$ and we consider the exterior $X_K = S^3 \setminus (B^2 \times K)$. Now do the following:

(a) Show that the inclusion induced maps

$$\mathrm{H}_*(S^3, K) \xrightarrow{\cong} \mathrm{H}_*(S^3, \overline{B}^2 \times K) \xleftarrow{\cong} \mathrm{H}_*(X_K, \partial X_K)$$

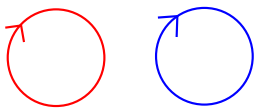
are both isomorphisms.

(b) Compute the homology groups of the pair $(X_K, \partial X_K)$.

(c) Determine, using (b), the homology groups of X_K.

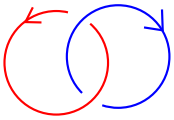
Exercise 100.6. We define an *m-component link* to be a 1-dimensional submanifold of S^3 that is diffeomorphic to the disjoint union of m copies of S^1. We pick a tubular neighborhood $\overline{B}^2 \times L$ and we define the exterior of L as $X_L := S^3 \setminus (B^2 \times L)$. We denote the components of L by $L_1, \ldots, L_m$. For each $i \in \{1, \ldots, m\}$ we pick a point $P_i \in L_i$ and we define $\mu_i := S^1 \times \{P_i\}$.

(a) Show that $\mathrm{H}_1(X_L) = \mathbb{Z} \cdot [\mu_1] \oplus \cdots \oplus \mathbb{Z} \cdot [\mu_m]$.



(b) Determine $\mathrm{H}_2(X_L)$.

Remark. There are basically two ways to go about doing this exercise, you can modify the proof of Lemma 100.16 or you could generalize the approach taken in Exercise 100.5.



Exercise 100.7.

(a) In the figure below we see two 2-component links, namely the unlink and the Hopf link. Are these two links isotopic?

(b) Let $L \subset S^3$ be an m-component link. Show that the weight of the group $\pi_1(S^3 \setminus L)$, as defined in Exercise 59.13, equals m.

2-component trivial link

Hopf link

Exercise 100.8. Let M and N be two oriented, connected n-dimensional smooth manifolds. We suppose that M is closed and that N has *non-empty* boundary. Express the homology groups of $M\#N$ in terms of the homology groups of M and N.

Exercise 100.9. Let $f\colon M \to N$ be a map between two compact orientable connected n-dimensional smooth manifolds with non-empty boundary. We assume that $f\colon \partial M \to \partial N$ is a homeomorphism. Show that f is a surjection.

Exercise 100.10. Let M be a compact oriented n-dimensional smooth manifold and let $p\colon \widetilde{M} \to M$ be a finite covering. By the Manifold Covering Proposition 49.2 we can equip $\widetilde{M}$ with the structure of a compact oriented smooth manifold such that $p\colon \widetilde{M} \to M$ is an orientation-preserving map. Let $p^*\colon \mathrm{H}_n(M) \to \mathrm{H}_n(\widetilde{M})$ be the transfer map that we introduced on page 1952. Show that $p^*([M]) = \left[\widetilde{M}\right] \in \mathrm{H}_n(\widetilde{M}, \partial\widetilde{M})$.

Exercise 100.11. Let Σ be a closed orientable connected 2-dimensional smooth manifold and let $f\colon \Sigma \to \Sigma$ be a diffeomorphism. We consider the corresponding mapping torus $M := \mathrm{Tor}(\Sigma, f)$. Note that we know by the Manifold-Mapping Torus Lemma 16.25 that M is a closed connected 3-dimensional smooth manifold.

(a) Suppose that if f is orientation-preserving, then $\mathrm{rank}(\mathrm{H}_2(M)) = \mathrm{rank}(\mathrm{H}_1(M))$.

(b) Suppose that if f is orientation-reversing, then $\mathrm{rank}(\mathrm{H}_2(M)) = \mathrm{rank}(\mathrm{H}_1(M)) - 1$.

Remark. You might want to use the Mapping Torus-Homology Proposition 78.20.

Exercise 100.12. Give examples of closed oriented connected non-empty smooth manifolds M and N of the same dimension such that $\pi_2(M\#N)$ is not isomorphic to $\pi_2(M) \oplus \pi_2(N)$.

Exercise 100.13. Give an example of a representative for the $\mathbb{F}_2$-fundamental class for the Klein bottle.

Exercise 100.14. Can you find a representative for the $\mathbb{F}_2$-fundamental class of $\mathbb{R}\mathrm{P}^2$ with two or three summands?

Exercise 100.15. Let $n \in \mathbb{N}$ and let M be a compact oriented n-dimensional smooth manifold. The image of the fundamental class $[M] \in \mathrm{H}_n(M, \partial M)$ under the natural map

$\mathrm{H}_n(M,\partial M) \to \mathrm{H}_n(M,\partial M;\mathbb{R})$ is called the *real fundamental class*, denoted by $[M]_{\mathbb{R}}$. Let $(K=(V,S),\Theta\colon |K| \to M)$ be a smooth simplicial structure. Given an ordered n-simplex $s=(v_0,\ldots,v_n)$ of K we denote by $\Phi_s\colon \Delta^n \to |K|$ the corresponding characteristic map given by $(t_0,\ldots,t_n) \mapsto t_0\cdot v_0 + \cdots + t_n \cdot v_n$.

(a) Show that

$$\sigma \;:=\; \sum_{\substack{s=(v_0,\ldots,v_n)\ \text{ordered } n\text{-simplex}\\ \text{such that } \Theta\circ\Phi_s\colon \mathring{\Delta}^n \to M\\ \text{is orientation-preserving}}} (\Theta\circ\Phi_s\colon \Delta^n \to M) \;\in\; \mathrm{C}_n(M)$$

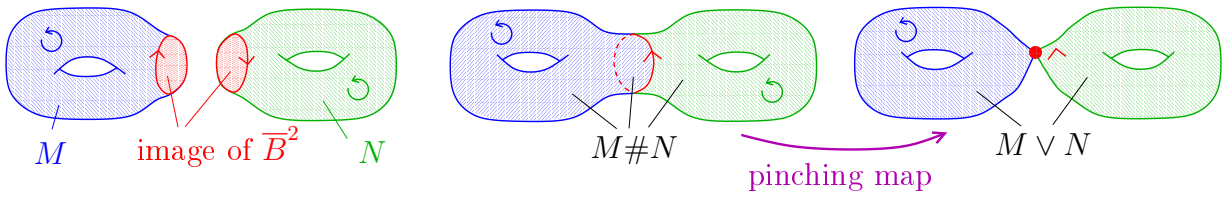
represents a cycle in $\mathrm{C}_n(M,\partial M)$.

(b) Show that $[\sigma]\otimes\frac{2}{n!} \in \mathrm{C}_n(M,\partial M;\mathbb{R}) = \mathrm{C}_n(M,\partial M)\otimes\mathbb{R}$ represents $[M]_{\mathbb{R}}$.

Exercise 100.16. Let $n\in\mathbb{N}$ and let M and N be two compact oriented connected non-empty n-dimensional smooth manifolds. We pick an orientation-preserving smooth embedding $\varphi\colon \overline{B}^n_2 \to M\setminus\partial M$ and furthermore we pick an orientation-reversing smooth embedding $\psi\colon \overline{B}^n_2 \to N\setminus\partial N$. We use φ and ψ to define the connected sum

$$M\#N \;:=\; \big(M\setminus\varphi\big(B^n\big)\big) \sqcup \big(N\setminus\psi\big(B^n\big)\big) \,/\, \big\{\varphi(P)=\psi(P)\,\big|\,P\in S^{n-1}\big\}.$$

We refer to the map



$$\begin{array}{rcl} p\colon M\#N & \to & M\vee N \\ P & \mapsto & \begin{cases} \varphi(x\cdot 2(t-1)), & \text{if } P=\varphi(x\cdot t) \text{ with } x\in S^{n-1} \text{ and } t\in[1,2] \\ \psi(x\cdot 2(t-1)), & \text{if } P=\psi(x\cdot t) \text{ with } x\in S^{n-1} \text{ and } t\in[1,2] \\ P, & \text{otherwise.} \end{cases} \end{array}$$

as the *pinching map*. Show that for $i=0,\ldots,n-1$ the induced map

$$p_*\colon \mathrm{H}_i(M\#N) \;\to\; \mathrm{H}_i(M\vee N)$$

is an isomorphism and that $p_*([M\#N]) = [M]+[N] \in \mathrm{H}_n(M\vee N) = \mathrm{H}_n(M)\oplus\mathrm{H}_n(N)$.

Remark. We leave it to the reader to show that for $M=N=S^n$ this pinching map is homotopic to the pinching map that we introduced on page 1565.

101. The degree of a map between oriented smooth manifolds II

In Chapters 38 and 39 we used Sard's Theorem 31.1 and several other tricks from differential topology to introduce the degree of a map between closed oriented connected non-empty smooth manifolds of the same dimension. In this chapter we will use a completely different approach to define the degree. The new approach is perhaps less intuitive, but since it builds on the machinery we have developed over the last chapters we can now quickly develop the theory of degrees.

101.1. **The definition of the degree of a map between compact smooth manifolds.** Let $n \in \mathbb{N}$ and let M be a compact oriented connected non-empty n-dimensional smooth manifold. Recall that in Theorem 100.1 and the Fundamental Class-Characterization Lemma 100.3 we proved that there exists a unique class $[M] \in \mathrm{H}_n(M, \partial M)$ such that the following holds:

(1) We have $\mathrm{H}_n(M, \partial M) = \mathbb{Z} \cdot [M]$.

(2) For every smooth embedding[1232] $\Psi\colon \Delta^n \to M$ and for every point $x \in \mathring{\Delta}^n$ with $\Psi^{-1}(\Psi(x)) = \{x\}$ we have the following equality in $\mathrm{H}_n(M, M \setminus \{\Psi(x)\})$:

$$\underset{\text{this is the natural map } \mathrm{H}_n(M,\partial M)\to\mathrm{H}_n(M,M\setminus\{\Psi(x)\}),\text{ which is in fact an isomorphism by Theorem 100.1 (1)}}{\omega_{\Psi(x)}([M])} \quad = \quad \operatorname{sign}(\Psi, x) \cdot [\, \underbrace{\Psi\colon \Delta^n \to M}_{\in \mathrm{C}_n(M, M\setminus\{\Psi(x)\})} \,].$$

In this short chapter we will explore the following definition.

Definition. Let $f\colon M \to N$ be a map between two compact oriented connected non-empty n-dimensional smooth manifolds. We assume that $f(\partial M) \subset \partial N$. We denote by $\deg(f) \in \mathbb{Z}$ the unique integer with

$$\underset{\text{since } f(\partial M) \subset \partial N \text{ we have an induced map } f_*\colon \mathrm{H}_n(M,\partial M) \to \mathrm{H}_n(N,\partial N)}{f_*([M])} \quad = \quad \deg(f) \cdot [N] \quad \in \quad \mathrm{H}_n(N, \partial N) = \mathbb{Z} \cdot [N].$$

We refer to $\deg(f)$ as the degree of f.

Remark.

(1) For a map $f\colon S^n \to S^n$ the above degree is, by definition, exactly the same as the degree that we defined on page 1684. Furthermore, if f is smooth and M and N are closed, then it follows from the Local-Global Degree Proposition 101.6 below that the above definition of the degree agrees with the definitions given on 899 on page 926.

(2) On page 2379 we will generalize the notion of degree from smooth manifolds to topological manifolds.

The following lemma generalizes several statements of the Sphere Degree Lemma 76.11.

Lemma 101.1. (Manifold Degree Lemma) Let $n \in \mathbb{N}$ and let L, M and N be compact oriented connected non-empty n-dimensional smooth manifolds.

(1) $\deg(\mathrm{id}_M) = 1$.

[1232] Recall that on page 2082 we defined what it means for a map $\Delta^n \to M$ to be a smooth embedding.

(2) For every map $f\colon M \to N$ such that $f(\partial M) \subset \partial N$ we have the following equality:[1233]
$$f_*([\partial M]) \;=\; \deg(f\colon M \to N) \cdot [\partial N] \;\in\; \mathrm{H}_{n-1}(\partial N).$$
In particular, if ∂M and ∂N are connected and non-empty, then we obtain the equality $\deg(f\colon \partial M \to \partial N) = \deg(f\colon M \to N)$.
(3) Let $f\colon M \to N$ be a map with $f(\partial M) \subset \partial N$. If f is not surjective, then $\deg(f) = 0$.
(4) Let $f, g\colon M \to N$ be two maps with $f(\partial M) \subset \partial N$ and $g(\partial M) \subset \partial N$. If f is homotopic to g, then $\deg(f) = \deg(g)$.
(5) For any two maps $f\colon L \to M$ and $g\colon M \to N$ with $f(\partial L) \subset \partial M$ and $g(\partial M) \subset \partial N$ we have $\deg(f \circ g) = \deg(f) \cdot \deg(g)$.

Proof.

(1) This statement is trivial.
(2) We consider the following diagram:
$$\begin{array}{ccc} \mathrm{H}_n(M, \partial M) & \xrightarrow[[M]\mapsto[\partial M], \text{ by the Fundamental Class-of-Boundary Proposition 100.9}]{\partial_n} & \mathrm{H}_{n-1}(\partial M) \\ \downarrow f_* & & f_* \downarrow \\ \mathrm{H}_n(N, \partial N) & \xrightarrow[[N]\mapsto[\partial N], \text{ by the Fundamental Class-of-Boundary Proposition 100.9}]{\partial_n} & \mathrm{H}_{n-1}(\partial N) \end{array}$$
where the horizontal maps are given by the connecting homomorphisms of the pairs $(M, \partial M)$ and $(N, \partial N)$. By the Topological LES-Proposition 74.13 we know that the connecting homomorphism are natural, in other words, the diagram commutes. The statement now follows from the Fundamental Class-of-Boundary Proposition 100.9.
(3) So let $f\colon M \to N$ be a non-surjective map with $f(\partial M) \subset \partial N$. We pick a point P in N that is not in the image of f. Note that $N \setminus \{P\}$ is an open subset of N. Thus, by the discussion on page 553, we can view it as an n-dimensional smooth manifold with $\partial(N \setminus \{P\}) = \partial N \cap (N \setminus \{P\}) = \partial N \setminus \{P\}$. Also note that it follows easily from $n \geq 1$ that $N \setminus \{P\}$ is non-compact.

Now we consider the following very simple commutative diagram:
$$\begin{array}{ccc} \mathrm{H}_n(M, \partial M) & \xrightarrow{\quad f_* \quad} & \mathrm{H}_n(N, \partial N) \\ & {\scriptstyle f_*} \searrow \quad \nearrow & \\ & \underbrace{\mathrm{H}_n(N \setminus \{P\}, \partial(N \setminus \{P\}))} & \end{array}$$
$= 0$ by the Smooth Manifold-Top Homology Theorem 98.6, since $N \setminus \{P\}$ is non-compact and connected

It follows immediately that $f_*\colon \mathrm{H}_n(M, \partial M) \to \mathrm{H}_n(N, \partial N)$ is the zero map.
(4) This statement follows immediately from the Homotopic Maps-and-Homology Proposition 73.6.
(5) Exactly as in the proof of the Sphere Degree Lemma 76.11 (4) we have
$$(g \circ f)_*([L]) \;=\; g_*(f_*([L])) \;=\; g_*(\deg(f) \cdot [M]) \;=\; \deg(g) \cdot \deg(f) \cdot [N].$$
This shows that $\deg(g \circ f) = \deg(g) \cdot \deg(f)$. ■

[1233] This statement can be viewed as a generalization of the Boundary Degree Proposition 39.6.

We move on to the following definition.

Definition. Let $f\colon M \to N$ be a smooth map between two smooth manifolds of the same dimension. Let $P \in M \setminus \partial M$. We say f is a local diffeomorphism at P if there exists an open neighborhood U of P such that $f|_U$ is an embedding.[1234]

The following proposition is much more interesting than the previous lemma. It gives in particular a practical criterion for a map to have degree ± 1.

Proposition 101.2. (Local-Global Degree Proposition 101.2 Let $n \in \mathbb{N}$ and let $f\colon M \to N$ be a map between two compact oriented connected non-empty n-dimensional smooth manifolds such that $f^{-1}(\partial N) = \partial M$. We suppose that there exists an $x \in M \setminus \partial M$ such that $f^{-1}(f(x)) = \{x\}$ and we suppose that f is a local diffeomorphism at x. Then

$$\deg(f) \;=\; \begin{cases} +1, & \text{if } f \text{ is orientation-preserving at } x \\ -1, & \text{if } f \text{ is orientation-reversing at } x. \end{cases}$$

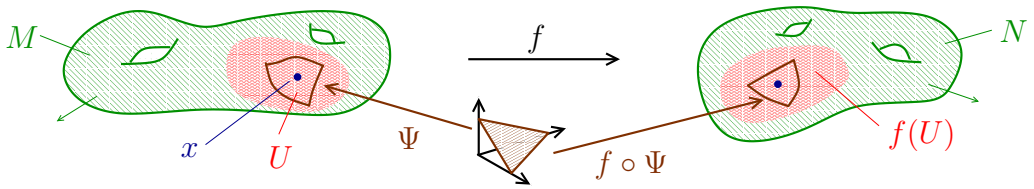
Proof. Let U be an open connected neighborhood of x such that $f\colon U \to N$ is an embedding. We set

$$\epsilon \;:=\; \begin{cases} +1, & \text{if } f\colon U \to N \text{ is orientation-preserving} \\ -1, & \text{if } f\colon U \to N \text{ is orientation-reversing.} \end{cases}$$

Note that we need to show that $\deg(f) = \epsilon$. Since $f^{-1}(\partial N) = \partial M$ we can pick a smooth embedding $\Psi\colon \Delta^n \to U$ such that $x \in \Psi(\mathring{\Delta}^n)$. Note that $\Psi^{-1}(x)$ is an admissible point for Ψ and note that it follows from our hypothesis $f^{-1}(f(x)) = \{x\}$ that $\Psi^{-1}(x)$ is also an admissible point for $f \circ \Psi$. We consider the following commutative diagram[1235]

$$\begin{array}{ccc} \mathrm{H}_n(M, \partial M) & \xrightarrow[\cong]{\omega_x} & \mathrm{H}_n(M, M \setminus \{x\}) \\ \downarrow{\scriptstyle f_*} & & {\scriptstyle f_*}\downarrow \\ \mathrm{H}_n(N, \partial N) & \xrightarrow[\cong]{\omega_{f(x)}} & \mathrm{H}_n(N, N \setminus \{f(x)\}). \end{array}$$

After these preparations we can now turn to the actual proof:



since $x \in \Psi(\mathring{\Delta}^n)$ and Ψ is an embedding we see that $\Psi\colon \Delta^n \to M$ defines an element of $\mathrm{H}_n(M, M\setminus\{x\})$

$$\begin{array}{rrcll} & \omega_x([M]) & = & \mathrm{sign}(\Psi, x) \cdot [\overset{\downarrow}{\Psi}\colon \Delta^n \to M] & \text{by definition of } [M] \\ \Rightarrow & f_*(\omega_x([M])) & = & \mathrm{sign}(\Psi, x) \cdot f_*([\Psi]) & \text{applying } f_* \\ \Rightarrow & \omega_{f(x)}(f_*([M])) & = & \mathrm{sign}(\Psi, x) \cdot [f \circ \Psi] & \text{since the diagram commutes} \\ \Rightarrow & \omega_{f(x)}(f_*([M])) & = & \epsilon \cdot \mathrm{sign}(f \circ \Psi, x) \cdot [f \circ \Psi] & \text{since } \mathrm{sign}(f \circ \Psi, x) = \epsilon \cdot \mathrm{sign}(\Psi, x) \\ \Rightarrow & \omega_{f(x)}(\deg(f) \cdot [N]) & = & \epsilon \cdot \omega_{f(x)}([N]) & \text{by definition of } \deg(f) \text{ and } [N] \\ \Rightarrow & \deg(f) \cdot [N] & = & \epsilon \cdot [N] & \text{by Theorem 100.1 (1)} \\ \Rightarrow & \deg(f) & = & \epsilon & \text{since } \mathrm{H}_n(N) = \mathbb{Z} \cdot [N]. \end{array}$$

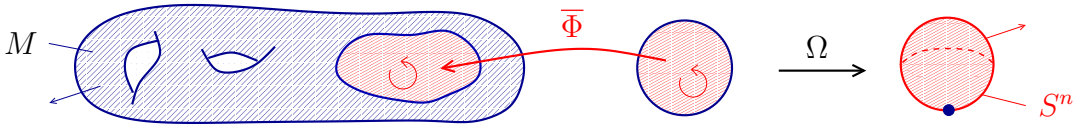
■

[1234] Note that it follows from the Smooth Invariance of Domain Theorem 19.13 that this definition of a "local diffeomorphism at a point" is consistent with the definition given on page 547.

[1235] Note that our hypothesis that $f^{-1}(f(x)) = \{x\}$ implies that $f(M \setminus \{x\}) \subset N \setminus \{f(x)\}$. Also note that $x \in M \setminus \partial M$ and $f(x) \in N \setminus \partial N$. In particular this implies that the various inclusion induced maps actually make sense.

101.2. **Properties of the degree.** We can now restate and reprove the Degree Realization Proposition 38.13 from earlier on.

Proposition 38.13 (Degree Realization Proposition) Let $n \in \mathbb{N}$ and let M be a closed oriented connected non-empty n-dimensional smooth manifold. Given any $k \in \mathbb{Z}$ there exists a smooth map $f\colon M \to S^n$ with $\deg(f) = k$.



Proof. [1236]The proof is almost identical to the proof we had given on page 911. Let M be a closed oriented connected non-empty n-dimensional smooth manifold and let $k \in \mathbb{Z}$. As we mentioned on page 1687, by Lemma 76.10 and the Suspension-Degree Lemma 76.12 there exists a map $g\colon S^n \to S^n$ of degree k. It follows from this fact and the Manifold Degree Lemma 101.1 (4) that it suffices to prove the following claim.

Claim. There exists a map $f\colon M \to S^n$ of degree $+1$.

Proof. First we pick an orientation-preserving smooth embedding $\Phi\colon \overline{B}^n \to M$. It follows fairly easily from the Twice Quotient Lemma 5.23 (2), and the Compact-Hausdorff Proposition 2.17 (3) together with the Compact Image Lemma 2.13 and the Quotient Hausdorff Lemma 5.21, that the induced map $\overline{\Phi}\colon \overline{B}^n/S^{n-1} \to M/(M \setminus \Phi(B^n))$ is a homeomorphism. We denote by $\Omega\colon \overline{B}^n/S^{n-1} \to S^n$ the explicit homeomorphism from the Ball-Quotient Sphere Lemma 5.20. By the Ball-Quotient Sphere Lemma 5.20 (3) this homeomorphism has the property that the restriction of Ω to B^n is in fact an orientation-preserving smooth embedding. We consider the map $f\colon M \to S^n$ that is given by

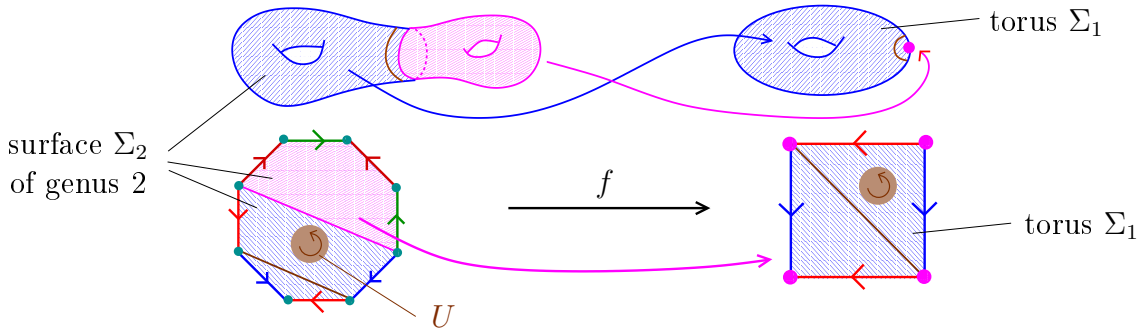
$$M \longrightarrow M/(M \setminus \Phi(B^n)) \xrightarrow{\overline{\Phi}^{-1}} \overline{B}/S^{n-1} \xrightarrow{\Omega} S^n.$$
$$=:f$$

It follows almost immediately from the Local-Global Degree Proposition 101.2 that f is a map of degree $+1$. ■

To put the previous proposition into context we recall the following theorem. It says that for maps to S^n the converse to the Manifold Degree Lemma 101.1 (3) holds.

Theorem 38.16. (Hopf Degree Theorem) Let M be a closed oriented connected non-empty n-dimensional smooth manifold and let $f, g\colon M \to S^n$ be two maps. If[1237] $\deg(f) = \deg(g)$, then the maps f and g are actually homotopic.

[1237]When we formulated the Hopf Degree Theorem 38.16 we used the definition of the degree that we gave on 899. On page 2222 we pointed out that it follows from the Local-Global Degree Proposition 101.6 that



For the record we also state the following open question, see [**Kir1997**, Problem 5.26], which was initially posed by Heinz Hopf.

Question 101.3. (Hopf) Let M be a closed orientable smooth manifold M. Is every map $f\colon M \to M$ of degree ± 1 a homotopy equivalence?

In the following discussion, given $g \in \mathbb{N}_0$, we denote as usual by Σ_g the surface of genus g. We move on to our next list of interesting examples of maps of no-zero degree.

Lemma 101.4. Let $k \in \mathbb{N}_0$. For every $g \geq k$ there exists a degree-one map from Σ_g to Σ_k.

Proof. We prove the lemma for $g = 2$ and $k = 1$. It should be clear how to modify the discussion for other values of $g \geq k$. Let us consider the map from the surface Σ_2 of genus two to the torus Σ_1 that is shown in the figure below. In fact in the figure below we show the map twice, on top we show a slightly informal description of the map, at the bottom we give a more formal description. Note that the hypotheses of the Local-Global Degree Proposition 101.2 are satisfied. Thus we see that $\deg(f) = 1$. ■

The following question, which extends Question 38.15, arises naturally.

Question 101.5. Suppose that $g < k$. Does there exist a degree-one map from Σ_g to Σ_k?

We will be able to give an answer to this question later on in Corollary 101.9.

But first let us move on to the next proposition, which is a generalization of the Local-Global Degree Proposition 101.2.

Proposition 101.6. (Local-Global Degree Proposition) Let $f\colon M \to N$ be a map between two compact oriented connected non-empty n-dimensional smooth manifolds such that $f^{-1}(\partial N) = \partial M$.

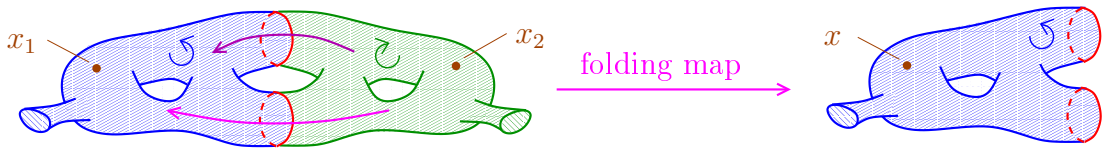
(1) Let $y \in N \setminus \partial N$ such that the following condition is satisfied:
   (∗) The preimage $f^{-1}(y)$ consists of finitely many points $x_1, \ldots, x_m$ and f is a local diffeomorphism around each x_i.

   Then
$$\deg(f) \;=\; \sum_{i=1}^{m} \begin{cases} +1, & \text{if } f \text{ is orientation-preserving at } x_i \\ -1, & \text{if } f \text{ is orientation-reversing at } x_i. \end{cases}$$

(2) If f is smooth, then every regular value in $N \setminus \partial N$ satisfies (∗).
(3) If f is smooth, then the set of regular values in $N \setminus \partial N$ has full measure in N.[1238]

[1238] the earlier definition of the degree agrees with the definition of the degree in terms of fundamental classes that we are using right now.

Remark. In Proposition 106.32 we state a result that generalizes the Local-Global Degree Proposition 101.6 (1) in the sense that we no longer demand that f is a local diffeomorphism around each x_i.



Example. Let M be a compact oriented n-dimensional smooth manifold and let W be the union of some components of ∂M. As on page 1667 we consider the double

$$\mathrm{D}_W M \;=\; (M \times \{1\}) \cup_{W\times\{1\}=W\times\{2\}} (M \times \{2\})$$

of M along W. By the Doubling-Manifold Lemma 75.12 we know that $\mathrm{D}_W M$ is naturally a compact oriented n-dimensional smooth manifold. We consider the folding map

$$\begin{array}{rcl} f\colon \mathrm{D}_W M & \to & M \\ [(P,i)] & \mapsto & P. \end{array}$$

If we take any $x \in M \setminus \partial M$, then we see that $f^{-1}(P)$ consists of precisely two points, namely $x_1 = [(x,1)]$ and $x_2 = [(x,2)]$. The folding map is an orientation-preserving local diffeomorphism around x_1 and it is an orientation-reversing local diffeomorphism around x_2. Thus we obtain from the Local-Global Degree Proposition 101.6 that the degree of the folding map is zero.

Since the two parts of the Local-Global Degree Proposition 101.6 are of very different nature we break the proof of the Local-Global Degree Proposition 101.6 into two parts.

Proof of the Local-Global Degree Proposition 101.6 (1). Let $f\colon M \to N$ be a map between two compact oriented connected non-empty n-dimensional smooth manifolds such that $f^{-1}(\partial N) = \partial M$. Let $y \in N \setminus \partial N$ such that $f^{-1}(y)$ consists of finitely many points $x_1, \ldots, x_m$ and such that f is a local diffeomorphism around each x_i.

For $i = 1, \ldots, m$ we pick an open connected neighborhood U_i of x_i such that $f\colon U_i \to N$ is an embedding. Note that we can arrange that for any $i \neq j$ we have $x_j \notin U_i$. For $i = 1, \ldots, m$ we set

$$\epsilon_i \;:=\; \begin{cases} +1, & \text{if } f\colon U_i \to N \text{ is orientation-preserving} \\ -1, & \text{if } f\colon U_i \to N \text{ is orientation-reversing.} \end{cases}$$

Note that we need to show that $\deg(f) = \epsilon_1 + \cdots + \epsilon_m$.

Let $i \in \{1, \ldots, m\}$. Since $y \in N \setminus \partial N$ and since by hypothesis we have $f^{-1}(\partial N) = \partial M$ we know that $x_i \in M \setminus \partial M$. Thus we can pick a smooth embedding $\Psi_i\colon \Delta^n \to U_i$ such

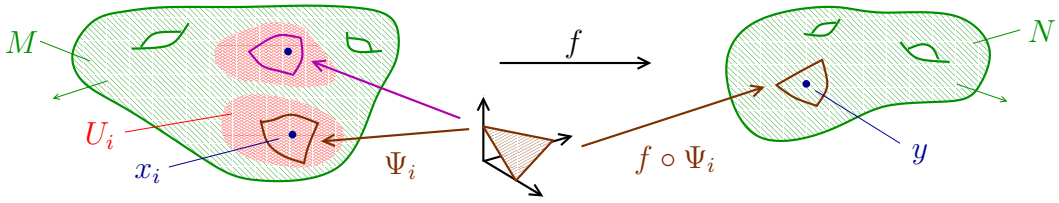
[1238] We refer to page 762 for the definition of a subset of full measure in N and, more usefully, we refer to Propositions 30.2 and 30.3 for the main properties of subsets of full measure.

that $x_i \in \Psi_i(\mathring{\Delta}^n)$. We consider the following commutative diagram

$$\begin{array}{ccc}
\mathrm{H}_n(M,\partial M) & \xrightarrow{\quad =:\mu \quad} & \mathrm{H}_n(M, M\setminus\{x_1,\dots,x_m\}) \\
\Big\downarrow{\scriptstyle f_*} & \searrow^{\oplus\omega_{x_i}} \quad \swarrow_{\oplus\nu_i}^{\cong} & \Big\downarrow{\scriptstyle f_*} \\
\mathrm{H}_n(N,\partial N) & \xrightarrow[\cong]{\omega_{f(x)}} & \mathrm{H}_n(N, N\setminus\{y\})
\end{array}
\qquad \bigoplus_{i=1}^m \mathrm{H}_n(M, M\setminus\{x_i\})$$

We make the following clarifications and observations:

(1) The map $\mu\colon \mathrm{H}_n(M,\partial M) \to \mathrm{H}_n(M, M\setminus\{x_1,\dots,x_m\})$ and furthermore all the maps $\nu_i\colon \mathrm{H}_n(M, M\setminus\{x_1,\dots,x_m\}) \to \mathrm{H}_n(M, M\setminus\{x_i\})$ are induced by the natural maps on the pairs of topological spaces. Note that here we use that $x_1,\dots,x_m \in M\setminus\partial M$, that $y \in N\setminus\partial N$ and that $f(\partial M)\subset \partial N$.



(2) It follows easily from the Excision Theorem 74.18, see also Exercise 75.1, that the diagonal map $\bigoplus_{i=1}^m \nu_i\colon \mathrm{H}_n(M, M\setminus\{x_1,\dots,x_m\}) \to \bigoplus_{i=1}^m \mathrm{H}_n(M, M\setminus\{x_i\})$ is an isomorphism.

(3) Let $i\in\{1,\dots,m\}$. Note that we arranged that $\Psi_i(\partial\Delta^n)\subset M\setminus\{x_1,\dots,x_m\}$. In particular $\Psi_i\colon \Delta^n \to M$ defines an element in $\mathrm{H}_n(M, M\setminus\{x_1,\dots,x_m\})$.

Now we see that

$$\begin{aligned}
& \bigoplus_{i=1}^m \omega_{x_i}([M]) = \bigoplus_{i=1}^m \operatorname{sign}(\Psi_i,x_i)\cdot[\Psi_i] && \text{by definition of } [M] \\
\Rightarrow\quad & \Big(\bigoplus_{i=1}^m \omega_{x_i}\Big)([M]) = \Big(\bigoplus_{i=1}^m \nu_i\Big)\Big(\sum_{j=1}^m \operatorname{sign}(\Psi_j,x_j)\cdot[\Psi_j]\Big) && \text{since } \nu_i([\Psi_j]) = \delta_{ij}\cdot[\Psi_i] \\
\Rightarrow\quad & \mu([M]) = \sum_{j=1}^m \operatorname{sign}(\Psi_j,x_j)\cdot[\Psi_j] && \text{since } \oplus\nu_i \text{ is an isomorphism and since the triangle commutes} \\
\Rightarrow\quad & f_*(\mu([M])) = \sum_{j=1}^m \operatorname{sign}(\Psi_j,x_j)\cdot f_*([\Psi_j]) && \text{applying } f_* \\
\Rightarrow\quad & \omega_{f(x)}(f_*([M])) = \sum_{j=1}^m \operatorname{sign}(\Psi_j,x_j)\cdot[f\circ\Psi_j] && \text{since the diagram commutes} \\
\Rightarrow\quad & \omega_{f(x)}(f_*([M])) = \sum_{j=1}^m \epsilon_j\cdot\operatorname{sign}(f\circ\Psi_j,x_j)\cdot[f\circ\Psi_j] && \text{since } \operatorname{sign}(f\circ\Psi_j,x_j)=\epsilon_j\cdot\operatorname{sign}(\Psi_j,x_j) \\
\Rightarrow\quad & \omega_{f(x)}(\deg(f)\cdot[N]) = \sum_{j=1}^m \epsilon_j\cdot\omega_{f(x)}([N]) && \text{by definition of } \deg(f) \text{ and } [N] \\
\Rightarrow\quad & \deg(f)\cdot[N] = \sum_{j=1}^m \epsilon_j\cdot[N] && \text{by Theorem 100.1 (1)} \\
\Rightarrow\quad & \deg(f) = \sum_{j=1}^m \epsilon_j && \text{since } \mathrm{H}_n(N,\partial N)=\mathbb{Z}\cdot[N].
\end{aligned}$$

■

Proof of the Local-Global Degree Proposition 101.6 (2) and (3). Let $f\colon M \to N$ be a smooth map between two compact oriented connected non-empty n-dimensional smooth manifolds M and N such that $f^{-1}(\partial N) = \partial M$.

(2) Let $y \in N \setminus \partial N$ be a regular value. It follows from Lemma 26.2 (2) that $f^{-1}(y)$ consists of finitely many points $x_1, \ldots, x_m$. Let $i \in \{1, \ldots, m\}$. Note that it follows from $f^{-1}(\partial N) = \partial M$ that $x_i \in M \setminus \partial M$. Since x_i is a regular point we obtain from Lemma 26.2 (1) that f is a local diffeomorphism around x_i.

(3) By Sard's Theorem 31.1 together with the Measure-Zero Properties Proposition 30.2 we know that the set of regular values of f that are contained in $N \setminus \partial N$ has full measure in N. ■

The following proposition gives us many examples of degrees of maps between smooth manifolds.

Proposition 101.7. (Covering Map-Degree Proposition) Let $p\colon \widetilde{M} \to M$ be a finite covering of compact oriented connected non-empty smooth manifolds. If p is orientation-preserving, then

$$\deg(p) \;=\; [\widetilde{M} : M].$$

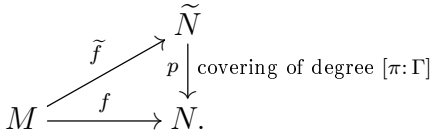
Proof. It turns out that there are two quick proofs for the proposition. In fact the desired statement follows immediately from the Local-Global Degree Proposition 101.6. Alternatively, if we denote by $p^*\colon \mathrm{H}_n(M, \partial M) \to \mathrm{H}_n(\widetilde{M}, \partial\widetilde{M})$ the transfer map that we introduced on page 1952, then we also see that

$$p_*([\widetilde{M}]) \underset{\text{Exercise 100.10}}{\uparrow} p_*(p^*([M])) \underset{\text{Transfer Map Proposition 91.1}}{\uparrow} [\widetilde{M} : M] \cdot [M].$$

■

The following proposition is the key to answering our ancient Question 38.15 and our much more recent Question 101.5.

Proposition 101.8. (Degree One-Epimorphism Proposition) Let $f\colon M \to N$ be a map between compact oriented connected non-empty n-dimensional smooth manifolds such that $f(\partial M) \subset \partial N$. If $\deg(f) = \pm 1$, then $f_*\colon \pi_1(M) \to \pi_1(N)$ is an epimorphism.



The statement of the Degree One-Epimorphism Proposition 101.8 is somewhat surprising, in so far as it takes as input fairly simple information, namely the induced map on n-th homology, which is an abelian group, and gives as output information about fundamental groups, which are usually much harder to deal with. Also it is a priori not clear why the homology in the maximal dimension should have any impact on fundamental groups.

Proof. Let $f\colon M \to N$ be a map between compact oriented connected non-empty n-dimensional smooth manifolds such that $f(\partial M) \subset \partial N$. We fix a base point $P \in M$ and we write $Q = f(P)$. Furthermore we write $\pi = \pi_1(N, Q)$ and $\Gamma = f_*(\pi_1(M, P))$.

By the Covering Existence Theorem 61.5[1239] there exists a path-connected covering $p\colon (\widetilde{N}, \widetilde{Q}) \to (N, Q)$ such that $p_*(\pi_1(\widetilde{N}, \widetilde{Q})) = \Gamma$ and such that $[\widetilde{N} : N] = [\pi : \Gamma]$. By the Manifold Covering Proposition 49.2 we can equip the covering space $\widetilde{N}$ with the structure of

[1239] Here we use that according to the discussion on pages 1352 any smooth manifold is locally simply connected.

a compact oriented smooth manifold such that the projection $p\colon \widetilde{N} \to N$ is an orientation-preserving map and such that we have $\partial\widetilde{N} = p^{-1}(\partial N)$. Since by design we know that $p_*(\pi_1(\widetilde{N}, \widetilde{Q})) = \Gamma = f_*(\pi_1(M, P))$ we obtain from the Map Lifting Criterion 61.2 that the map $f\colon (M, P) \to (N, Q)$ lifts to a map $\widetilde{f}\colon (M, P) \to (\widetilde{N}, \widetilde{Q})$. We can summarize the situation in the following simple commutative diagram

First suppose that Γ is a subgroup of π of infinite index. It follows immediately from $[\widetilde{N} : N] = [\pi : \Gamma]$ and Lemma 48.3 (5) that $\widetilde{N}$ is non-compact. Therefore we obtain from the Smooth Manifold-Top Homology Theorem 98.6 that $\mathrm{H}_n(\widetilde{N}) = 0$. But this shows that $f_* = p_* \circ \widetilde{f}_*\colon \mathrm{H}_n(M) \to \mathrm{H}_n(N)$ factors through the trivial group. Hence $\deg(f) = 0$. But this is a contradiction to our hypothesis that $\deg(f) = \pm 1$.

So now we know that Γ is necessarily a finite-index subgroup of π. It follows from $[\widetilde{N} : N] = [\pi : \Gamma]$ and Lemma 48.3 (4) that $\widetilde{N}$ is compact. Therefore, by the above we now know that $\widetilde{N}$ is a compact oriented connected n-dimensional smooth manifold. We deduce that

$$\pm 1 \;=\; \deg(f) \underset{\uparrow}{=} \deg(\widetilde{f}) \cdot \deg(p) \underset{\uparrow}{=} \deg(\widetilde{f}) \cdot [\widetilde{N} : N] \;=\; \deg(\widetilde{f}) \cdot [\Gamma\colon \pi].$$

Manifold Degree Lemma 101.1 — Covering Map-Degree Proposition 101.7

This shows that $[\Gamma\colon \pi] = 1$, i.e. $\Gamma = \pi$. ■

Now we can give a negative answer to Questions 38.15 and 101.5.

Corollary 101.9. Let $g, k \in \mathbb{N}_0$. If there exists a degree-one map from Σ_g to Σ_k, then $g \geq k$.

Proof. Suppose that there exists a degree-one map from Σ_g to Σ_k. By the Degree One-Epimorphism Proposition 101.8 we obtain an epimorphism $\pi_1(\Sigma_g) \to \pi_1(\Sigma_k)$. In particular we obtain an epimorphism from the abelianization $\pi_1(\Sigma_g)$ onto the abelianization of $\pi_1(\Sigma_k)$. By the Fundamental Group-of-Surfaces Proposition 54.5 the former is isomorphic to $\mathbb{Z}^{2g}$ and the latter is isomorphic to $\mathbb{Z}^{2k}$. It follows from the Rank Additivity Lemma 51.7 that $g \geq k$. ■

We conclude this chapter with several questions. Recall that it follows from Lemma 101.4 that there exists a degree-one map $S^2 \times S^2 \to S^4$. It is natural to ask whether the converse holds. This leads us to the following question which we will answer in Lemma 117.5.

Question 101.10. Does there exist a degree-one map from the 4-dimensional sphere S^4 to $S^2 \times S^2$?

Later, in Corollary 119.14, we will also address the following question.

Question 101.11. Does there exist a degree-one map from $S^1 \times S^2$ to $\mathbb{R}\mathrm{P}^3$?

It is also interesting to study degrees of self-maps of smooth manifolds. For example note that it follows from Lemmas 76.10 and the Suspension-Degree Lemma 76.12 that given any $k \in \mathbb{Z}$ and given any $n \in \mathbb{N}$ there exists a map $f\colon S^n \to S^n$ of degree k. Also note that it follows easily from the Covering Map-Degree Proposition 101.7 that the torus $T = S^1 \times S^1$

admits a self-map of any degree. This naturally leads us to the question whether similar phenomena hold for surfaces of higher genus.

Question 101.12.

(1) Let $g \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree -1?
(2) Let $g \geq 2$ and let $k \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree k?
(3) Does there exist a self-map $f\colon \mathbb{C}\mathrm{P}^2 \to \mathbb{C}\mathrm{P}^2$ of degree -1?

We will address the first question in Exercise 101.3 and we will address the last two questions later on in Proposition 114.17 and Corollary 121.10.
Finally we conclude this chapter with two conjectures that were formulated by Heinz Hopf in 1931. We refer to [**Hau1987, Neum1953**] for some more information and partial results.

Conjecture 101.13. (Hopf Conjecture) Let M be a closed oriented connected smooth manifold and let $f\colon M \to M$ be a map.

(1) If $\deg(f) = \pm 1$, then $f_*\colon \pi_1(M) \to \pi_1(M)$ is an isomorphism.
(2) If $\deg(f) = \pm 1$, then f is a homotopy equivalence.

Remark. Let M be a closed oriented connected smooth manifold and let $f\colon M \to M$ be a map with $\deg(f) = \pm 1$.

(1) By the Degree One-Epimorphism Proposition 101.8 we know that f_* is an epimorphism. Thus the Hopf Conjecture 101.13 (2) leads to the group-theoretic question, under what circumstances is a surjective automorphism of a group also injective. In particular this leads to the definition of a Hopfian group that we gave on page 1416.
(2) In Proposition **??** we will see that in general f is not homotopic to a homeomorphism. Thus in general "homotopy equivalence" is the best we can hope for. Note though that if M is in fact aspherical, see page 1861 for the definition, then the Borel Conjecture **??** predicts that f is actually homotopic to a homeomorphism.

Exercises for Chapter 101.

Exercise 101.1. Let M be a compact oriented n-dimensional smooth manifold with non-empty boundary. Show that there exists a map $f\colon M \to \overline{B}^n$ with $f(\partial M) \subset S^{n-1}$ of degree $+1$.
Remark. For $n \geq 2$ one can combine this result with Exercise 76.5 to get maps of arbitrary degree.

Exercise 101.2. Given an example of a map $f\colon M \to N$ between closed oriented connected non-empty n-dimensional smooth manifolds such that $f_*\colon \pi_1(M) \to \pi_1(N)$ is an epimorphism, but such that the degree of f is zero.

Exercise 101.3. Given $g \in \mathbb{N}$ we denote by Σ_g the surface of genus g.

(a) Let $g \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree -1?
(b) Let $g \geq 1$ and let $k \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree k?

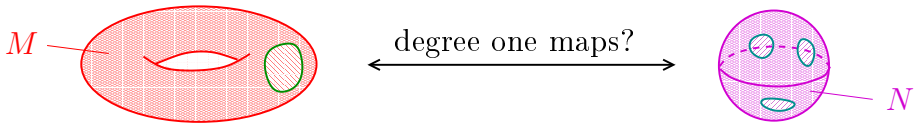
Exercise 101.4. Given $g \in \mathbb{N}$ we denote by Σ_g the surface of genus g. Show that if there exists a map $f\colon \Sigma_g \to \Sigma_k$ of non-zero degree, then $g \geq k$.

Exercise 101.5. Let $f\colon M \to N$ be a map between two closed oriented non-empty n-dimensional smooth manifolds. Suppose that there exists a compact smooth manifold W with $\partial W = M$ and a smooth map $g\colon W \to N$ with $g|_M = f$. Show that $\deg(f) = 0$.
Remark. This exercise is almost identical to Exercise 38.11, but now you should be able to give a much shorter proof.

Exercise 101.6. Let $f\colon M \to N$ be a map between two closed connected non-empty n-dimensional smooth manifolds. Furthermore let $p\colon \widetilde{N} \to N$ be a finite covering. As in the Topological-Pullback Lemma 56.16 we consider the pullback

$$\widetilde{M} \;:=\; f^*\widetilde{N} \;=\; \{(x,y) \in M \times \widetilde{N} \,|\, f(x) = p(y)\}$$

together with the following commutative diagram:



$$\begin{array}{ccc} \widetilde{M} & \xrightarrow{(x,y)\mapsto y} & \widetilde{N} \\ {\scriptstyle =:q}\downarrow{\scriptstyle (x,y)\mapsto x} & \overset{=:F}{\nearrow} & \downarrow{\scriptstyle p} \\ M & \xrightarrow{\quad f \quad} & N. \end{array}$$

Note that by the Topological-Pullback Lemma 56.16 (1) we know that q is again a covering with $\deg(q) = \deg(p)$.

(a) We suppose that M and N are oriented. We equip the smooth manifolds $\widetilde{M}$ and $\widetilde{N}$ with the corresponding orientations given by the Manifold Covering Proposition 49.2. Show that $\deg(F\colon \widetilde{M} \to \widetilde{N}) = \deg(f\colon M \to N)$.
(b) Suppose that the induced map $f_*\colon \mathrm{H}_n(M;\mathbb{F}_2) \to \mathrm{H}_n(N;\mathbb{F}_2)$ is an isomorphism. Show that $F_*\colon \mathrm{H}_n(\widetilde{M};\mathbb{F}_2) \to \mathrm{H}_n(\widetilde{N};\mathbb{F}_2)$ is also an isomorphism.

Exercise 101.7. Let M be the torus minus one open disk and let N be S^2 minus three open disks.

(a) Show that there is no degree one map $f\colon M \to N$.
(b) Show that there is no degree one map $g\colon N \to M$.

Exercise 101.8. Given $m \in \mathbb{N}$ we denote by N_m the non-orientable surface of genus m, as defined on page 266. Let $k \in \mathbb{N}$.

(a) Let $g \geq k$. Show that there exists a map $f\colon N_g \to N_k$ such that the induced map $\mathrm{H}_2(N_g;\mathbb{F}_2) \to \mathrm{H}_2(N_k;\mathbb{F}_2)$ is an isomorphism.
(b) Let $g < k$. Show that there does not exist a map $f\colon N_g \to N_k$ such that the induced map $\mathrm{H}_2(N_g;\mathbb{F}_2) \to \mathrm{H}_2(N_k;\mathbb{F}_2)$ is an isomorphism.
Remark. Recall that in Exercise 89.14 we saw that $\mathrm{H}_1(N_m;\mathbb{F}_2) \cong \mathbb{F}_2^m$.

Exercise 101.9. Let X be a topological space. Given $\varphi \in \mathrm{H}_k(X;\mathbb{R})$ we define

$$\|\varphi\|_{\mathbb{R}} \;:=\; \inf\Big\{ \sum_{i=1}^n |r_i| \,\Big|\, \sigma = \underbrace{\sum_{i=1}^n \sigma_i \otimes r_i}_{\text{with } \sigma_i \neq \sigma_j \text{ for } i \neq j} \text{ is a cycle with } [\sigma] = \varphi \in \mathrm{H}_k(X;\mathbb{R}) \Big\}.$$

In the following let M be a closed oriented connected non-empty n-dimensional smooth manifold M. Let $[M] \in \mathrm{H}_n(M)$ be the fundamental class and let $i\colon \mathrm{H}_1(M) \to \mathrm{H}_1(M;\mathbb{R})$ be the homomorphism from Lemma 89.7 (1). We define the *simplicial volume of* M as

$$\|M\|_{\mathbb{R}} \;:=\; \|i_*([M])\| \;\in \mathbb{R}_{\geq 0}.$$

(a) Show that $\|S^1\|_{\mathbb{R}} = 0$.

(b) Let $n \in \mathbb{N}_{\geq 2}$. What is $\|S^n\|_{\mathbb{R}}$?

(c) Let $f\colon M \to N$ be a map between closed oriented connected non-empty n-dimensional smooth manifolds. Show that

$$\|N\|_{\mathbb{R}} \;\leq\; \tfrac{1}{\deg(f)} \cdot \|M\|_{\mathbb{R}}$$

where $\deg(f)$ denotes the degree of f as defined on page 2222.

(d) Let M and N be two closed oriented connected non-empty n-dimensional smooth manifolds. We suppose that M and N are in fact homotopy equivalent. Show that $\|M\|_{\mathbb{R}} = \|N\|_{\mathbb{R}}$.

(e) Let N be a closed oriented non-empty n-dimensional smooth manifold. Furthermore let $p\colon M \to N$ be a d-fold covering. Show that $\|M\|_{\mathbb{R}} = d \cdot \|N\|_{\mathbb{R}}$.

(f) Let $g \in \mathbb{N}_0$. As usual we denote by Σ_g the surface of genus $g \geq 1$. Show that $\|\Sigma_g\|_{\mathbb{R}} \leq 2g - 2$.

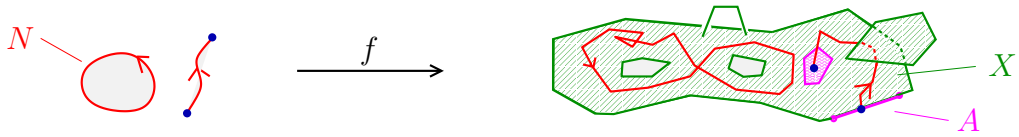
Hint. Make use of (f).

Remark. In [**Frig2017**, Corollary 7.5] or alternatively [**Thu1978**, Theorem 6.2] it is shown that we also have the reverse inequality, i.e. we have $\|\Sigma_g\|_{\mathbb{R}} = 2g - 2$.

Remark. The invariant $\|\varphi\|_{\mathbb{R}}$ is the "real analogue" of the invariant $\|\varphi\|_{\mathbb{Z}}$ introduced in Exercise 76.14.

102. Homology classes and smooth (sub-)manifolds

In Chapter 100 we saw that every compact oriented n-dimensional smooth manifold N comes naturally with a fundamental class $[N] \in \mathrm{H}_n(N, \partial N)$. In Chapters 100 and 101 we already saw several interesting applications of the fundamental class and we now feel like we have a good understanding of fundamental classes.



In this chapter we want to study to which degree homology classes can be understood in terms of fundamental classes. More precisely, we want to study the following two questions:

(1) Given a topological space X and a homology class $\varphi \in \mathrm{H}_n(X)$, can we always find a closed oriented n-dimensional smooth manifold N and a map $f\colon N \to X$ such that $f_*([N]) = \varphi$?
(2) If X is in fact a smooth manifold, can we find an $f\colon N \to X$ as in (1) that is actually a smooth embedding?

102.1. Realizing homology classes by smooth manifolds.

Let us start out with the following friendly definition.

Definition. Let X be a topological space, let $A \subset X$ be a subset and let $\varphi \in \mathrm{H}_n(X, A)$ be a homology class. We say φ can be realized by a smooth manifold if there exists a compact oriented n-dimensional smooth manifold N and a map $f\colon (N, \partial N) \to (X, A)$ such that $f_*([N]) = \varphi$.

Examples. Let (X, x_0) be a path-connected pointed topological space and let $n \in \mathbb{N}$. Recall that the Hurewicz homomorphism is defined as the map

$$\begin{array}{rcl} \Phi_{(X,x_0)}\colon \pi_n(X, x_0) & \to & \mathrm{H}_n(X) \\ [f\colon S^n \to X] & \mapsto & f_*([S^n]). \end{array}$$

Thus we see that every homology class that lies in the image of the Hurewicz homomorphism is realized by a smooth manifold. But as we remarked on page 1844, in general the Hurewicz homomorphism is certainly not an epimorphism.

In this and the subsequent section we want to study the following question.

Question 102.1. Let X be a topological space and let $A \subset X$ be a subset. For which $n \in \mathbb{N}_0$ can homology classes in $\mathrm{H}_n(X, A)$ be realized by smooth manifolds?

The case $n = 0$ is evidently trivial. So let us continue with the case $n = 1$.

Proposition 102.2. Let X be a topological space. Every class in $\mathrm{H}_1(X)$ is realized by a smooth manifold.

Proof. The proposition is basically an immediate consequence of Proposition 84.3. Nonetheless we prefer to do prove the proposition here "by hand", since this proof will also give us some ideas for how to approach the case of higher-dimensional homology classes.

Thus suppose we are given a homology class $\varphi \in \mathrm{H}_1(X)$. We pick a singular chain $c = a_1 \cdot \sigma_1 + \cdots + a_k \cdot \sigma_k \in \mathrm{C}_k(X)$ that represents φ. Note that we do not necessarily

demand that the σ_j are different. In fact note that by "taking multiple copies of the singular simplices σ_j" we can and will arrange that $a_j \in \{-1, 1\}$, $j = 1, \dots, k$. Next we will see that we can arrange that all $a_j = 1$. To do so, given a singular 1-simplex $\sigma\colon \Delta^1 \to X$ we denote by $\overline{\sigma}\colon \Delta^1 \to X$ the singular 1-simplex that is given by $\overline{\sigma}(t, 1-t) := \sigma(1-t, t)$. In Lemma 72.3 we saw that $-\sigma$ and $\overline{\sigma}$ are homologous. Thus, after replacing each summand $-\sigma_j$ by $\overline{\sigma}_j$ we can assume that all $a_j = 1$.

Next note that we have

$$0 \underset{\uparrow}{=} \partial_1(c) = \partial_1\Big(\sum_{j=1}^{k} \sigma_j\Big) \underset{\uparrow}{=} \sum_{j=1}^{k} \sigma_j(0,1) - \sigma_j(1,0) = \sum_{j=1}^{k} \sigma_j(0,1) + \sum_{j=1}^{k} -\sigma_j(1,0).$$

since c is a cycle — by definition of ∂_1, see also page 1585

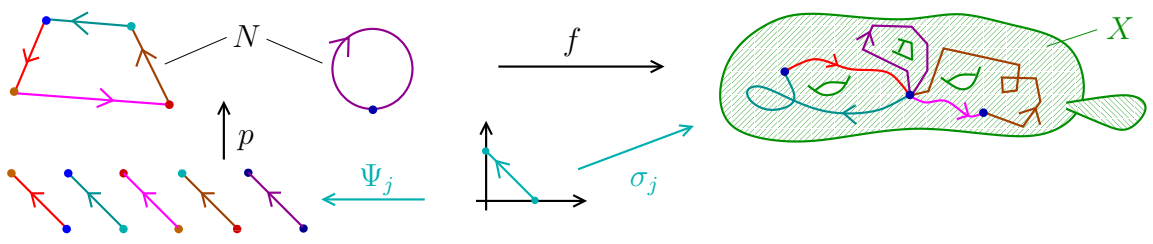
On the right hand side each "positive summand" needs to cancel with a "negative summand". As in the proof of Proposition 84.3 this means, see also Lemma 84.4, that there exists a permutation $\theta \in S_k$ such that for each $j \in \{1, \dots, k\}$ the "endpoint" $\sigma_j(0,1)$ of σ_j is just the "starting point" $\sigma_{\theta(j)}(1,0)$ of $\sigma_{\theta(j)}$. We introduce the following notation:

(1) We consider the topological space

$$N := (\{1, \dots, k\} \times \Delta^1)/\sim \quad \text{where for } j \in \{1, \dots, k\} \text{ we have } \sigma_j(0,1) \sim \sigma_{\theta(j)}(1,0).$$

(2) For $j = 1, \dots, k$ we denote by $\Psi_j\colon \Delta^1 \xrightarrow{x \mapsto (j,x)} \{1, \dots, k\} \times \Delta^1$ the j-th inclusion map.
(3) We denote by $p\colon \{1, \dots, k\} \times \Delta^1 \to N$ the projection .
(4) It follows immediately from the definitions and the Topological-Quotient Proposition 5.15 (1b) that the map

$$\begin{array}{rcl} f\colon N = (\{1, \dots, k\} \times \Delta^1)/\sim & \to & X \\ [(j,z)] & \mapsto & \sigma_j(z) \end{array}$$



is well-defined and continuous.

It is now straightforward to verify that N can be equipped with the structure of a closed 1-dimensional smooth manifold and that we can equip N with an orientation such that for each $j \in \{1, \dots, k\}$ the map $p \circ \Psi_j\colon \mathring{\Delta}^1 \to N$ is an orientation-preserving embedding. Finally we see that

$$f_*([N]) \underset{\uparrow}{=} f_*([p \circ \Psi_1 + \dots + p \circ \Psi_k]) \underset{\uparrow}{=} [\sigma_1 + \dots + \sigma_k] = c.$$

follows from the Fundamental Class-Criterion Proposition 100.4 applied to any of the maps $p \circ \Psi_j$ — by definition of f and $p \circ \Psi_j$

■

Evidently the idea now is to work our way up to higher dimensions. In fact we have the following proposition.

Proposition 102.3. (Realization-by-Surface Proposition) Let X be a topological space. Every class in $\mathrm{H}_2(X)$ is realized by a smooth manifold.

Proof. The basic idea of the proof of the Realization-by-Surface Proposition 102.3 is similar to the proof of Proposition 102.2. Nonetheless, ironing out the details is much more messy, hence we postpone the proof of the case $n = 2$ to Section 102.2. Alternatively see also [**Cal2009**, p. 3] for a quick sketch of the proof. ■

Remark. In Lemma 102.9 we will see that any naive attempt of generalizing the ideas behind the proofs of Propositions 102.2 and 102.3 to higher dimensions runs into serious problems.

We move on to the following proposition that summarizes a few generalities on realizing homology classes by smooth manifolds.

Proposition 102.4. Let $k \in \mathbb{N}$.

(1) Let X be a topological space and let $A \subset X$ be a subset. We suppose that X is path-connected. If $A = \varnothing$ or if $k \geq 2$, then every homology class in $\mathrm{H}_k(X, A)$ that can be realized by a smooth manifold can also be realized by a *connected* smooth manifold.

(2) Suppose that for every topological space X every homology class in $\mathrm{H}_k(X)$ can be realized by a smooth manifold. Then also for every pair (X, A) of topological spaces every relative homology class in $\mathrm{H}_k(X, A)$ can be realized by a smooth manifold.

Proof. In order not to disrupt the flow of the conversation too much we postpone the somewhat technical proof of Proposition 102.4 to Section 102.3. ■

Note that Propositions 102.2 and 102.3 together with Proposition 102.4 give us a complete, and affirmative, answer to Question 102.1 for the dimensions $k = 1$ and $k = 2$.

We move on to the following much more fancy theorem which was first proved by René Thom [**Tho1954b, Tho2007**] in 1954.[1240] The proof of the theorem uses methods that go well beyond our present abilities. We will not make use of the theorem.

Theorem 102.5. (Thom's Theorem I)

(1) If X is a topological space, then every homology class of dimension ≤ 6 can be realized by a smooth manifold.

(2) Given any $n \geq 7$ there exists a topological space X and a homology class in $\mathrm{H}_n(X)$ that is not realized by a smooth manifold.

(3) Given any $n \in \mathbb{N}_0$ there exists a $k \in \mathbb{N}$ such that for any topological space X and any homology class $\sigma \in \mathrm{H}_n(X)$ the class $k \cdot \sigma$ can be realized by a smooth manifold.

Remark. The statement of Thom's Theorem 102.5 solved what was known as the *Steenrod problem*, see [**Eil1949**, p. 257].

Proof. As mentioned before, the theorem is proved in [**Tho1954b**, Theorem III.3, III.4 and III.9]. A more modern account of the proof is given in Theorems IV.7.35, IV.7.36, IV.7.37 and IV.7.38 together with Remark IV.7.40 of [**Rudy1998**]. In fact the topological space

[1240] René Thom (1923-2002) was a French mathematician who received the Fields Medal in 1958. A short outline of the key ideas and contributions of René Thom can be found in [**Sul2004**]

X in (2) is given by the $(n-7)$-fold suspension of the Eilenberg-Maclane space $K(\mathbb{Z}_3, 2)$, which we will introduce later in Chapter 163. ■

For completeness we also mention $\mathbb{F}_2$-coefficients.

Theorem 102.6. (Thom's Theorem II) Let X be a path-connected topological space and let $A \subset X$ be a subset. Given any $\varphi \in \mathrm{H}_n(X, A; \mathbb{F}_2)$ there exists a compact connected n-dimensional smooth manifold N and a map $f\colon N \to X$ with $f(\partial N) \subset A$ such that $f_*([N]_{\mathbb{F}_2}) = \varphi$.

Proof. First let us consider the case $A = \varnothing$ and for the time being let us allow possibly disconnected smooth manifolds. In this setting, for $n = 1$ and $n = 2$ the statement follows from straightforward modifications of the proofs of Propositions 102.2 and 102.3. In fact, much more interestingly, the statement now holds in all dimensions by the above work of René Thom [**Tho1954b**, Theorem III.2], see also [**Rudy1998**, Theorem IV.7.33]. The statements about relative homology and connectedness follow from the obvious variations on Proposition 102.4. ■

We conclude this section with the following remark.

Remark.

(1) In Chapter 105 we will introduce the notion of an orientation of a topological manifold. Furthermore in Chapter 106 we will introduce the notion of the fundamental class $[N] \in \mathrm{H}_n(N, \partial N)$ of a compact oriented n-dimensional topological manifold N. It now makes sense to ask whether a homology class can be realized by a topological manifold. By [**Rudy1998**, Theorem IV.7.35 and Remark IV.3.740] there exist homology classes in any dimension ≥ 7 that cannot by realized by topological manifolds. But by [**Rudy1998**, Theorem IV.7.38] there do exist homology classes that can be realized by topological manifolds but which cannot be realized by smooth manifolds.

(2) Lowell Jones [**JonL1973**, Proposition 7.3] (see also Norman Levitt [**Levit1972**, Theorem 7.1]) showed that every homology class can be represented by a "Poincaré Duality space".

102.2. Proof of the Realization-by-Surface Proposition 102.3.

In this section we prove the following proposition from the last section.

Proposition 102.3. (Realization-by-Surface Proposition) Let X be a topological space. Every class in $\mathrm{H}_2(X)$ is realized by a smooth manifold.

The proof of the Realization-by-Surface Proposition 102.3 is modelled on the proof of Proposition 102.2. But, as we will see, the proof is technically more difficult.

We start out our proof with the more general setting of some n-dimensional class. Later on we will specialize to the case that $n = 2$. It is even worthwhile keeping the case $n = 1$ in mind, since even for $n = 1$ the argument below differs slightly from the argument provided in the proof of Proposition 102.2.

Thus let X be a topological space, let $n \in \mathbb{N}$ and let $c = a_1 \cdot \sigma_1 + \cdots + a_k \cdot \sigma_k$ be an n-dimensional singular chain in X. We do not necessarily demand that the σ_j are different. In fact note that by "taking multiple copies of the singular simplices σ_j" we can and will

arrange that $a_j \in \{-1,1\}$, $j = 1,\dots,k$.[1241] the Realization-by-Surface Proposition 102.3 is more difficult than the proof of Proposition 102.2. We set $T := \{1,\dots,k\} \times \{0,\dots,n\}$.

Now assume that c is a cycle. We see that we have the following equality in the free abelian group $\mathrm{C}_{n-1}(X)$:

$$0 \underset{\text{since } c \text{ is a cycle}}{=} \partial_1(c) = \partial_1\Big(\sum_{j=1}^{k} a_j \cdot \sigma_j\Big) = \sum_{j=1}^{k}\sum_{r=0}^{n} (-1)^r \cdot a_j \cdot \sigma_j \circ \underset{\text{here } i_r^n\colon \Delta^{n-1} \to \Delta^n \text{ is the } r\text{-th face map}}{i_r^n} = \sum_{(j,r)\in T} (-1)^r \cdot a_j \cdot \sigma_j \circ i_r^n.$$

It follows from Lemma 84.4 that there exists a decomposition $T = T_1 \sqcup T_2$ into two disjoint subsets together with a bijection

$$\begin{array}{rcl} \Theta = (\theta_1,\theta_2)\colon T_1 & \to & T_2 \\ (j,r) & \mapsto & \Theta(j,r) = (\theta_1(j,r),\theta_2(j,r)) \end{array}$$

such that the following condition is satisfied: For every $(j,r) \in T_1$ we have

$$\begin{array}{rcl} \sigma_j \circ i_r^n & = & \sigma_{\theta_1(j,r)} \circ i^n_{\theta_2(j,r)} \\ \text{and} \quad (-1)^r \cdot a_j & = & -(-1)^{\theta_2(j,r)} \cdot a_{\theta_1(j,r)}. \end{array}$$

Next we introduce some notation:

(1) We consider the topological space

$$Y(\Theta) := (\{1,\dots,k\} \times \Delta^n)/\sim \quad \begin{array}{l} \text{where for each } (j,r) \in T_1 \text{ and each } P \in \Delta^{n-1} \\ \text{we have } (j, i_r^n(P)) \sim (\theta_1(j,r), i^n_{\theta_2(j,r)}(P)). \end{array}$$

Informally speaking $Y(\Theta)$ is given by taking one n-simplex for each singular simplex σ_j and gluing these simplices along $(n-1)$-dimensional faces.[1242]

(2) For $j = 1,\dots,k$ we denote by $\Psi_j\colon \Delta^n \xrightarrow{x \mapsto (j,x)} \{1,\dots,k\} \times \Delta^n$ the j-th inclusion map.

(3) We denote by $p\colon \{1,\dots,k\} \times \Delta^n \to Y(\Theta)$ the projection .

(4) It follows immediately from the definitions and the Topological-Quotient Proposition 5.15 (1b) that the map

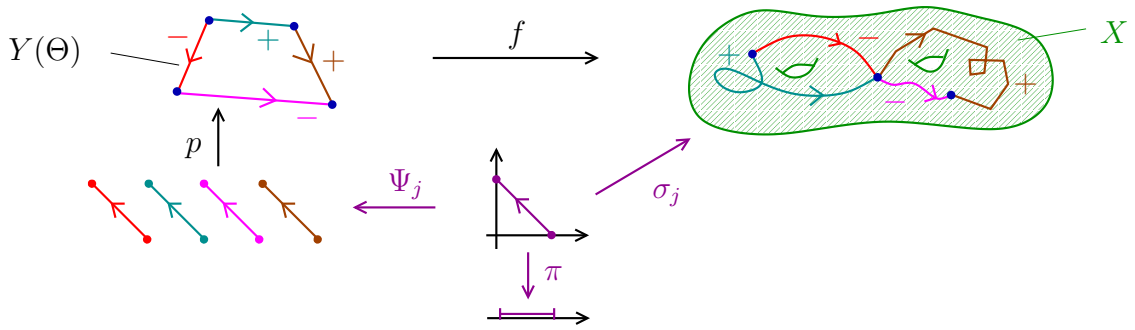
$$\begin{array}{rcl} f\colon Y(\Theta) = (\{1,\dots,k\} \times \Delta^n)/\sim & \to & X \\ [(j,P)] & \mapsto & \sigma_j(P) \end{array}$$

is well-defined and continuous.

(5) We set

$$\mu := \sum_{j=1}^{k} a_j \cdot p \circ \Psi_j \in \mathrm{C}_n(Y(\Theta)).$$

We can now formulate the following lemma.



Lemma 102.7.

(1) $\mu \in \mathrm{C}_n(Y(\Theta))$ is a cycle.

(2) $f_*([\mu]) = [c] \in \mathrm{H}_n(X)$.

[1241] Note that if n is even, then it follows from Exercise 72.12 that we cannot arrange that all a_j are of the same sign. This is one, but not the main, reason why the proof of

[1242] It might seem that $Y(\Theta)$ has an "obvious simplicial structure", but that is not necessarily the case, for example after gluing there might be two n-dimensional simplices that intersect in more than just one $(n-1)$-dimensional face.

Proof. First we show that μ is a cycle. This follows from the following straightforward calculation:

$$\begin{aligned}\partial\mu &= \partial\Big(\sum_{j=1}^{k} a_j \cdot p\circ\Psi_j\Big) = \sum_{j=1}^{k}\sum_{r=0}^{n}(-1)^r\cdot a_j\cdot p\circ\Psi_j\circ i_r^n = \sum_{(j,r)\in T}(-1)^r\cdot a_j\cdot p\circ\Psi_j\circ i_r^n\\
&= \sum_{(j,r)\in T_1}(-1)^r\cdot a_j\cdot p\circ\Psi_j\circ i_r^n + \sum_{(j,r)\in T_1}(-1)^{\theta_2(j,r)}\cdot a_{\theta_1(j,r)}\cdot p\circ\Psi_{\theta_1(j,r)}\circ i^n_{\theta_2(j,r)}\end{aligned}$$

since $T = T_1 \sqcup T_2$ and since $\Theta = (\theta_1,\theta_2)\colon T_1 \to T_2$ is a bijection

$$= \sum_{(j,r)\in T_1}\underbrace{(-1)^r\cdot a_j\cdot p\circ\Psi_j\circ i_r^n + (-1)^{\theta_2(j,r)}\cdot a_{\theta_1(j,r)}\cdot p\circ\Psi_{\theta_1(j,r)}\circ i^n_{\theta_2(j,r)}}_{=0 \text{ since } (-1)^r\cdot a_j = -(-1)^{\theta_2(j,r)}\cdot a_{\theta_1(j,r)} \text{ and } p\circ\Psi_j\circ i_r^n = p\circ\Psi_{\theta_1(j,r)}\circ i^n_{\theta_2(j,r)}\colon \Delta^{n-1}\to Y(\Theta)} = 0.$$

It follows immediately from the definitions that $f_*(\mu) = c \in \mathrm{C}_n(X)$. In particular we have $f_*([\mu]) = [c] \in \mathrm{H}_n(X)$. ∎

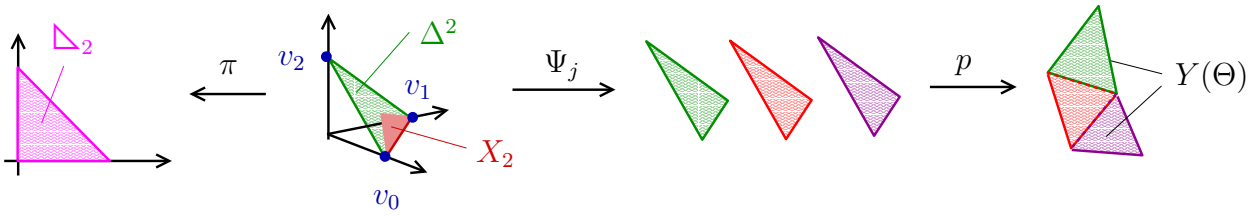
We move on to the next lemma, which together with Lemma 102.7 provides the long-desired proof of the Realization-by-Surface Proposition 102.3. Note that, as a bonus, we also obtain a new proof of Proposition 102.2.

Lemma 102.8. We continue with the above notation. If $n = 1$ or if $n = 2$, then the topological space $Y(\Theta)$ admits the structure of a closed oriented 2-dimensional smooth manifold such that $[\mu] \in \mathrm{H}_2(Y(\Theta))$ is the corresponding fundamental class.

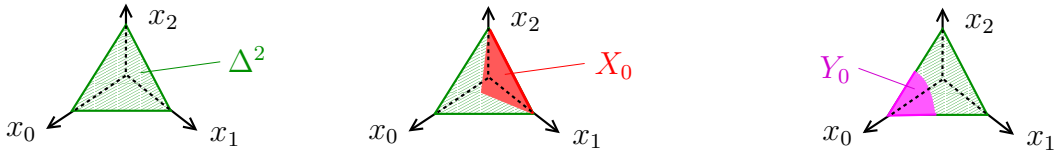
Remark. In Lemma 102.9 below we will see that for $n = 3$ the topological space $Y(\Theta)$ is in general not a topological manifold.

Sketch of a proof of Lemma 102.8. The proof of Lemma 102.8 for the case $n = 1$ is very elementary and thus left to the reader.

In the following we sketch a proof of Lemma 102.8 for the case $n = 2$. As we will see, the proof is quite similar to the proof, given in Propositions 18.7 and 19.18, that the surface Σ_g of genus g is indeed a closed orientable 2-dimensional smooth manifold.



First note that it follows easily from the Quotient-Compact Connected Lemma 5.16 (1) that $Y(\Theta)$ is compact. We leave it to the reader to verify, say using the Quotient Hausdorff Lemma 5.21, that $Y(\Theta)$ is Hausdorff.



Next we construct a finite atlas for $Y(\Theta)$. To do so we introduce the following notation:

- Let $\pi\colon \Delta^2 \to \triangle_2$ be the projection . Note that in the Standard Simplex Homeomorphism Lemma 72.1 we saw that π is a homeomorphism.
- We denote by $v_0 = (1,0,0)$, $v_1 = (0,1,0)$ and $v_2 = (0,0,1)$ the three vertices of Δ^2.

- Let $j \in \{0,1,2\}$. In the following will define two open subsets X_j and Y_j of Δ^2. In the subsequent definition we denote by w, w' the two vertices that are not equal to v_j. Now we introduce the following notation:
  - ▷ We denote by X_j the union of the open interval from w to w' and the open triangle in Δ^2 spanned by w, w' and the barycenter $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})$ of Δ^2.
  - ▷ We denote by Y_j the intersection of $\Delta^2 \subset \mathbb{R}^3$ with the open ball in $\mathbb{R}^3$ of radius $\frac{1}{2}$ around the j-th vertex v_j.

  We refer to the figures below for an illustration of the above definitions.

Next we sketch the construction of three types of charts for the topological space $Y(\Theta)$. We leave it to the reader to fill in the details in the discussions below.

(1) For each $j \in \{1, \dots, k\}$ we let $\alpha_j := \pi \circ \Psi_j^{-1} \circ p^{-1} \colon U_j := p(\mathring{\Delta}_j) \to V_j := \mathring{\Delta}_2 \subset \mathbb{R}^2$ be the "obvious" chart.

(2) Let $(j,r) \in T_1$. We write $\Theta(j,r) =: (j',r')$. Similar to the proof of the Surface-is-Topological Manifold Proposition 18.7 one can easily write down an explicit chart

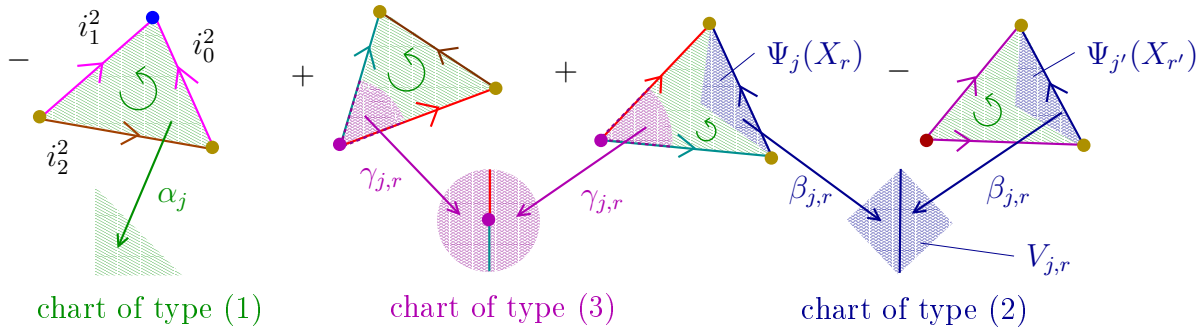
$$\beta_{j,r} \colon U_{j,r} := \underbrace{p(\Psi_i(X_r)) \cup p(\Psi_{j'}(X_{r'}))}_{\subset Y(\Theta)} \quad \to \quad V_{j,r} \subset \mathbb{R}^2$$

such that the maps $\beta_{j,r} \circ p \circ \Psi_j^{-1} \circ \pi^{-1} \colon \Delta_2 \to \mathbb{R}^2$ and $\beta_{j,r} \circ p \circ \Psi_{j'}^{-1} \circ \pi^{-1} \colon \Delta_2 \to \mathbb{R}^2$ are both affine linear and such that they are both orientation-preserving if and only if $(-1)^r \cdot a_j = 1$ and such that they are both orientation-reversing if and only if $(-1)^r \cdot a_j = -1$.

(3) Let $j \in \{1, \dots, k\}$ and let $r \in \{0,1,2\}$. An open neighborhood of $p(\Psi_j(v_r))$ is given by

$$\widetilde{U}_{j,r} \;:=\; \bigcup_{\substack{(j',r') \in T \text{ such that} \\ p(\Psi_{j'}(v_{r'})) = p(\Psi_j(v_r))}} p(\Psi_{j'}(Y_{r'})).$$

Again similar to the proof of Propositions 18.7 one can now write down an explicit chart $\gamma_{j,r} \colon \widetilde{U}_{j,r} \to B^2_{\frac{1}{2}}$ such that on each $p(\Psi_r(Y,s))$ the map is a concatenation of π, $(p \circ \Psi_r)^{-1}$, translation, rotation and a map of the form $\exp(\mathrm{i}t) \mapsto \exp(\mathrm{i}wt)$ for some $w \in \mathbb{R}_{\geq 0}$. In fact we can take $w = \frac{2\pi}{n}$ where $n \in \mathbb{N}$ is the number of terms (j',r') that appear in the above definition of $\widetilde{U}_{j,r}$.



We leave it to the reader to verify that all of these maps are homeomorphisms and that they form an atlas for $Y(\Theta)$. Note that by Lemma 18.2 (2) we now also know that $Y(\Theta)$

is second-countable. We have thus verified that $Y(\Theta)$ is a closed 2-dimensional topological manifold.

Next note that, as in the proof of Proposition 19.18, one can now verify easily that the transition maps between the given charts are indeed smooth and that they are orientation-preserving. Not surprisingly, once again we leave the details to the reader. Thus in summary we obtain from the above discussion, together with Lemmas 18.2 and 25.15, that $Y(\Theta)$ is a smooth manifold that is endowed with an orientation such that all charts are orientation-preserving.

Recall that in Lemma 102.7 we showed that $\mu = a_1 \cdot p \circ \Psi_1 + \cdots + a_k \cdot p \circ \Psi_k \in \mathrm{C}_2(Y(\Theta))$ is a cycle. It follows almost immediately from the Fundamental Class-Criterion Proposition 100.4 that μ represents the fundamental class of the closed oriented smooth manifold $Y(\Theta)$. ■

four simplices $\Delta_1, \Delta_2, \Delta_3, \Delta_4$ with gluings indicated by colors

We conclude this section with the following lemma which shows that the above approach will not work in higher dimensions.

Lemma 102.9. Given any $n \in \mathbb{N}_{\geq 3}$ there exists a topological space X together with a cycle $c = a_1 \cdot \sigma_1 + \cdots + a_k \cdot \sigma_k \in \mathrm{C}_n(X)$ such that for any choice of Θ the topological space $Y(\Theta)$ is not a closed topological manifold, let alone a closed smooth manifold.

Sketch of proof. Let $n \in \mathbb{N}_{\geq 3}$ and let M be the $(n-1)$-dimensional torus. Furthermore let $(K, \Xi\colon |K| \to M)$ be a smooth simplicial structure for M, which we know exists by the Smooth Manifold-Simplicial Structure Theorem 96.2, or by some more down-to-earth argument.

By Propositions 98.1 and 98.7 we know that K is a closed orientable $(n-1)$-dimensional pseudomanifold. Next we consider the suspension $\Sigma(K)$, as defined on page 2003. Note that by the Simplicial Cone-Suspension Corollary 93.21 we know that $X := |\Sigma(K)|$ is homeomorphic to $\Sigma(M)$.

Next recall that by the fairly straightforward Exercise 98.1 we know that $\Sigma(K)$ is a closed n-dimensional pseudomanifold that admits an orientation $\{(\epsilon_1, Y_1), \ldots, (\epsilon_k, Y_k)\}$. Now let $\varphi = \epsilon_1 \cdot Y_1 + \cdots + \epsilon_k \cdot Y_k \in \mathrm{C}_n^{\mathrm{simp}}(\Sigma(K))$ be the cycle from Theorem 98.4. Next note that after picking some total order on the vertex set of $\Sigma(K)$ we obtain from Lemmas 95.8 and the Simplicial-Singular Chain Complex Theorem 95.25 a corresponding singular cycle $c = a_1 \cdot \sigma_1 + \cdots + a_k \cdot \sigma_k \in \mathrm{C}_n(X) = \mathrm{C}_n(|\Sigma(K)|)$. We set $T := \{1, \ldots, k\} \times \{0, \ldots, n\}$. We leave it to the dedicated reader to verify that there is essentially only one choice of a decomposition $T = T_1 \sqcup T_2$ and a bijection $\Theta = (\theta_1, \theta_2)\colon T_1 \to T_2$ such that the condition

from page 2238 holds, i.e. such that for every $(j,r) \in T_1$ we have

$$\begin{aligned} \sigma_j \circ i_r^n &= \sigma_{\theta_1(j,r)} \circ i_{\theta_2(j,r)}^n \\ \text{and} \quad (-1)^r \cdot a_j &= -(-1)^{\theta_2(j,r)} \cdot a_{\theta_1(j,r)}. \end{aligned}$$

Furthermore we leave it to the reader to verify that $Y(\Theta)$ is actually homeomorphic to $|\Sigma(K)| \cong \Sigma(M)$.

Finally we point out that it follows from Exercise 76.8, together with the fact that $\mathrm{H}_1(M) = \mathrm{H}_1((S^1)^n) \neq 0$ and together with our hypothesis $n \geq 3$ that $X = |\Sigma(K)| \cong \Sigma(M)$ is not a closed topological manifold. ■

102.3. **Proof of Proposition 102.4.** The sole goal of this section is to prove Proposition 102.4. For convenience we prove the two parts of the proposition separately.

Proposition 102.4.

(1) Let $k \in \mathbb{N}$, let X be a topological space and let $A \subset X$ be a subset. We suppose that X is path-connected. If $A = \varnothing$ or if $k \geq 2$, then every homology class in $\mathrm{H}_k(X, A)$ that can be realized by a smooth manifold can also be realized by a *connected* smooth manifold.

Proof of Proposition 102.4 (1). To simplify the discussion we only consider the case that $A = \varnothing$. The case $A \neq \varnothing$ is proved in a completely analogous fashion, the only difference is that the notation becomes even more messy. We will point out though explicitly where we need that $k \geq 2$ for $A \neq \varnothing$.

Let X be a path-connected topological space and let $\theta \in \mathrm{H}_k(X)$ be a homology class. Suppose there exists a closed oriented k-dimensional smooth manifold W and a map $f\colon W \to X$ with $f_*([W]) = \theta$. If W is connected, then there is nothing to show. In the following we will deal with the case that W has precisely two components M and N. The general case is dealt with the same way.

We make the following preparations.

(1) As usual we denote by $\overline{B}_3^k \subset \mathbb{R}^k$ the closed ball of radius 3 around the origin. We pick an orientation-preserving smooth embedding $\varphi\colon \overline{B}_3^k \to M$ and we pick an orientation-reversing smooth embedding $\psi\colon \overline{B}_3^k \to N$. We write $P := \varphi(0)$ and $Q := \psi(0)$.

(2) We use the restrictions of φ and ψ to $\overline{B}^k$ to form, following the definition on page **??**, the connected sum $M\#N$, i.e. we consider

$$M\#N \;=\; ((M \setminus \varphi(B^k)) \sqcup (N \setminus \psi(B^k)))/\!\sim \qquad \text{where } \varphi(z) \sim \psi(z) \text{ for } z \in S^{k-1}.$$

(3) We recall a few statements from the Connected Sum-Proposition **??**:
   (a) The connected sum $M\#N$ is a closed k-dimensional smooth manifold which can be oriented in such a way that the two natural inclusions $M \setminus \varphi(B^k) \to M\#N$ and $N \setminus \psi(B^k) \to M\#N$ are both orientation-preserving smooth embeddings.
   (b) If $k \geq 2$ or if at least one of M or N is closed, then $M\#N$ is connected.
   Note though that for $A \neq \varnothing$ we have to deal with the connected sum of compact manifolds M and N that are not necessarily closed. So here the argument breaks down for $A \neq \varnothing$ and $k = 1$, since the connected sum of two copies of $\overline{B}^1$ is actually not connected.

(4) We consider the topological space $Z := (M \sqcup [-1,1] \sqcup N)/\sim$ where we make the identifications $P \sim -1$ and $1 \sim Q$.
(5) We denote by $i\colon M \to Z$ and $j\colon N \to Z$ the obvious maps. It is easy to see that they are in fact embeddings. Next we denote by $p\colon Z \to M$ the map that is given by the identity on M and which sends all other points to P. Similarly we define $q\colon Z \to N$.
(6) We consider the following maps:

$$\begin{array}{ccc} & & \mathrm{H}_k(M) \oplus \mathrm{H}_k(N) \\ & \overset{\text{isomorphism since inclusions are homotopy equivalences}}{\swarrow} & \qquad\qquad \searrow^{i_* \oplus j_*} \\ \mathrm{H}_k((M \sqcup [-1,1))/\sim) \oplus \mathrm{H}_k((N \sqcup (-1,1])/\sim) & \xrightarrow[\text{Mayer–Vietoris Theorem 78.5}]{\text{isomorphism by the}} & \mathrm{H}_k(Z). \end{array}$$

It follows that the right diagonal map $i_* \oplus j_*\colon \mathrm{H}_k(M) \oplus \mathrm{H}_k(N) \to \mathrm{H}_k(Z)$ is an isomorphism. It is now straightforward to see that the inverse of $i_* \oplus j_*$ is given by $p_* \oplus q_*\colon \mathrm{H}_k(Z) \to \mathrm{H}_k(M) \oplus \mathrm{H}_k(N)$.
(7) We consider the map

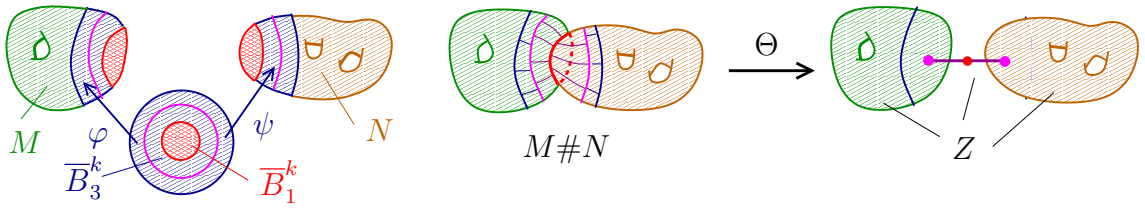
$$\begin{array}{rcl} \Theta\colon M\#N & \to & Z \\ x & \mapsto & \begin{cases} [x], & \text{if } x \in M \setminus \varphi(B_3^k), \\ [\varphi(3(r-2)\cdot y)], & \text{if } x = \varphi(r \cdot y) \text{ with } r \in [2,3] \text{ and } y \in S^{k-1}, \\ [-r+1], & \text{if } x = \varphi(r \cdot y) \text{ with } r \in [1,2] \text{ and } y \in S^{k-1}, \\ [r-1], & \text{if } x = \psi(r \cdot y) \text{ with } r \in [1,2] \text{ and } y \in S^{k-1}, \\ [\psi(3(r-2)\cdot y)], & \text{if } x = \psi(r \cdot y) \text{ with } r \in [2,3] \text{ and } y \in S^{k-1}, \\ [x], & \text{if } x \in N \setminus \psi(B_3^k). \end{cases} \end{array}$$

It follows easily from the Pasting Proposition 2.6 (2) that $\Theta\colon M\#N \to Z$ is actually continuous.
(8) It follows almost immediately from the Local-Global Degree Proposition 101.2 together with (3a) that the maps $p \circ \Theta\colon M\#N \to M$ and $q \circ \Theta\colon M\#N \to N$ both have degree one. In other words, we have the equality

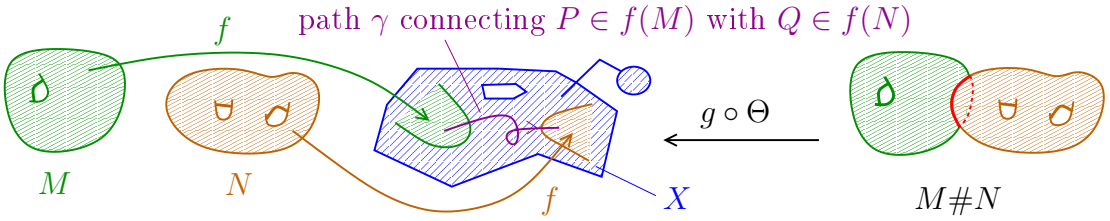
$$(p_* \oplus q_*)(\Theta_*([M\#N])) = [M] + [N] \in \mathrm{H}_k(M) \oplus \mathrm{H}_k(N) = \mathrm{H}_k(M \sqcup N) = \mathrm{H}_k(W).$$

(9) By hypothesis the topological space X is path-connected. This implies that there exists a path $\gamma\colon [-1,1] \to X$ with $\gamma(-1) = P$ and $\gamma(1) = Q$. Using γ we can extend the map $f\colon W = M \sqcup N \to X$ to a map $g\colon Z \to X$ in the obvious way.

By (3) the connected sum $M\#N$ is a closed oriented *connected* smooth manifold. Thus it remains to prove the following claim.



Claim. We have $(g \circ \Theta)_*([M\#N]) = \theta \in \mathrm{H}_k(X)$.



Proof. It follows from the above that we have the following diagram:

$$\begin{array}{ccccc} & & \mathrm{H}_k(M) \oplus \mathrm{H}_k(N) & \xrightarrow{=} & \mathrm{H}_k(M \sqcup N) = \mathrm{H}_k(W) \\ & & {\scriptstyle p_* \oplus q_*}\uparrow \cong \quad \cong \downarrow {\scriptstyle i_* \circ j_*} & \overset{f_*}{\searrow} & \downarrow {\scriptstyle f_*} \\ \mathrm{H}_k(M\#N) & \xrightarrow{\Theta_*} & \mathrm{H}_k(Z) & \xrightarrow{g_*} & \mathrm{H}_k(X). \end{array}$$

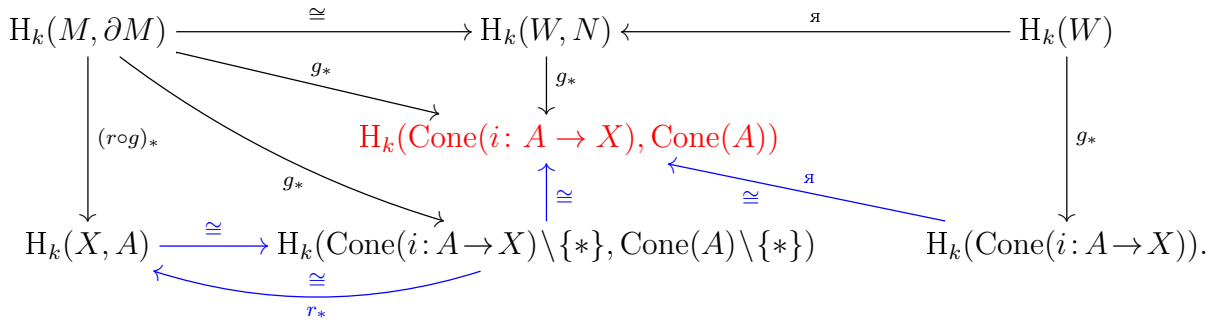
It follows from the definition of g together with (6) that the diagram commutes. Now we see that we have the following equalities in $\mathrm{H}_k(X)$:

$$(g\circ\Theta)_*([M\#N]) \underset{\text{by (8) and (6)}}{=} g_*(i_*([M])+j_*([N])) \underset{\text{since the diagram commutes}}{=} f_*([M])+f_*([N]) = f_*(\underbrace{[M\sqcup N]}_{=[W]}) = \theta. \qquad \blacksquare$$

We move on to the second statement of Proposition 102.4.

Proposition 102.4.

(2) Let $k\in\mathbb{N}$. Suppose that for every topological space X every homology class in $\mathrm{H}_k(X)$ can be realized by a smooth manifold. Then also for every pair (X,A) of topological spaces every relative homology class in $\mathrm{H}_k(X,A)$ can be realized by a smooth manifold.

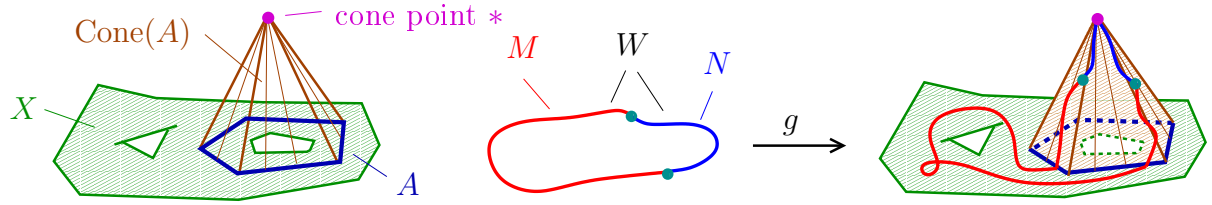


Proof. Let $k\in\mathbb{N}$. We make the following hypothesis:

(∗) For every topological space Y every homology class in $\mathrm{H}_k(Y)$ can be realized by a smooth manifold.

Now let (X,A) be a pair of topological spaces and let $\varphi\in\mathrm{H}_k(X,A)$ be a relative homology class. We denote by $i\colon A\to X$ the inclusion map. We consider the mapping cone

$$\mathrm{Cone}(i\colon A\to X) = (\underbrace{\mathrm{Cone}(A)}_{=(A\times[0,1])/A\times\{0\}}\sqcup X)/\!\sim \text{ where } [(a,1)]\sim i(a)=a \text{ for } a\in A.$$



We denote by $*[A\times\{0\}]\in\mathrm{Cone}(i\colon A\to X)$ the cone point. We consider the following diagram:

We make the following explanations, clarifications and observations:

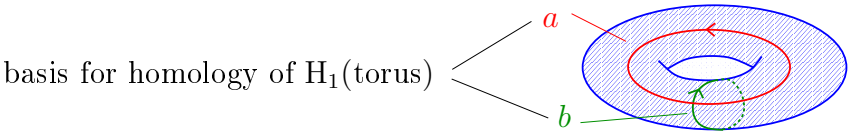
(1) By the Mapping Cone Basics Lemma 16.13 (2) and (3) we can and will view $\mathrm{Cone}(A)$ and X as subsets of $\mathrm{Cone}(i\colon A \to X)$.
(2) All maps that are not specified explicitly are inclusion induced maps.
(3) The maps я are the natural maps from absolute to relative homology.
(4) Note that by the Mapping Cone Basics Lemma 16.13 (6) there exists a natural deformation retraction from $\mathrm{Cone}(i\colon A \to X) \setminus \{*\}$ to X. We denote by $r\colon \mathrm{Cone}(i\colon A \to X) \setminus \{*\} \to X$ the corresponding retraction. Note that it restricts to a retraction from $\mathrm{Cone}(A) \setminus \{*\}$ to A.
(5) By the proof of the Mapping Cone-H_*-Lemma 78.15 we know that the four maps at the bottom, shown in blue, are isomorphisms.
(6) By (5) together with our hypothesis $(*)$ we know that there exists a closed oriented k-dimensional smooth manifold W and a map $g\colon W \to \mathrm{Cone}(i\colon A \to X)$ such that $я(g_*([W]))$ equals the image of our given class φ in the central red group $\mathrm{H}_k(\mathrm{Cone}(i\colon A \to X), \mathrm{Cone}(A))$.
(7) Since $\mathrm{Cone}(i\colon A \to X) \setminus \{*\})$ and $\mathrm{Cone}(A) \setminus A$ are open subsets that cover $\mathrm{Cone}(i)$ we obtain from Exercise 31.3 that there exist two compact codimension-zero submanifolds M and N of W such that $M \cup N = W$, $M \cap N = \partial M = \partial N$, such that $M \subset g^{-1}(\mathrm{Cone}(i\colon A \to X) \setminus \{*\})$ and such that $N \subset g^{-1}(\mathrm{Cone}(A) \setminus A)$.
(8) By (7) we have $g(N) \subset \mathrm{Cone}(A)$ and $g(\partial M) \subset \mathrm{Cone}(A)$. This implies that the two maps in relative homology denoted by g_*, namely the diagonal map to the left and the vertical map in the middle, actually do exist.
(9) By the Codimension Zero-Fundamental Class Lemma 100.12 (2) we know that the images of $[M]$ and $[W]$ in $\mathrm{H}_k(W, N)$ agree.

It is clear that the diagram commutes. It is now straightforward to verify that the compact oriented n-dimensional smooth manifold M together with the map $r \circ g\colon (M, \partial M) \to (X, A)$ has all the desired properties. ■

102.4. **Representing homology classes by submanifolds I.** In the previous sections we studied the following definition.

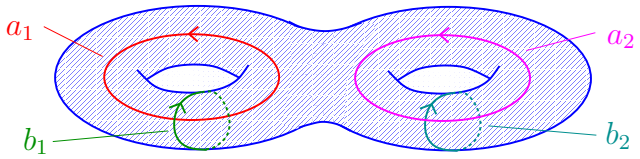
Definition. Let X be a topological space, let $A \subset X$ be a subset and let $\varphi \in \mathrm{H}_k(X, A)$ be a homology class. We say φ can be realized by a smooth manifold if there exists a compact oriented k-dimensional smooth manifold N and a map $f\colon (N, \partial N) \to (X, A)$ such that $f_*([N]) = \varphi$.

If the topological space X we are interested in is in fact a smooth manifold it is natural to ask whether one can actually find maps f that are smooth embeddings. This leads us to the following definition.



Definition. Let M be a smooth manifold and let A be a union of components of ∂M.

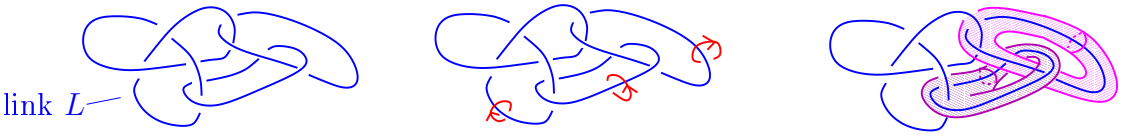
(1) Let N be a compact oriented proper k-dimensional submanifold of M with $\partial N \subset A$. By a slight abuse of notation, we denote by $[N]$ the image of the fundamental class $[N]$ under the inclusion induced map $\mathrm{H}_k(N, \partial N) \to \mathrm{H}_k(M, A)$.



(2) We say that a homology class $\varphi \in \mathrm{H}_k(M, A)$ is represented by a submanifold if there exists a compact oriented proper k-dimensional submanifold N with $\partial N \subset A$ such that $[N] = \varphi$.

Examples.

(1) We first consider the 2-dimensional torus $T = S^1 \times S^1$. Under the usual isomorphism $\mathrm{H}_1(S^1 \times S^1) \cong \mathbb{Z}^2$ the basis element $(1, 0)$ is represented by the oriented submanifold $S^1 \times \{1\}$ and the basis element $(0, 1)$ is represented by the oriented submanifold $\{1\} \times S^1$. This situation is illustrated in the figure below on the left.



(2) We consider the surface Σ_2 of genus 2. As in the figure on page **??** we view Σ_2 as the connected sum $T \# T$ of two tori. If we use the calculation on page 2212 to determine an isomorphism $\mathrm{H}_1(\Sigma_2) \cong \mathbb{Z}^4$, then it follows from (1) that the basis elements are represented by the submanifolds a_1, b_1, a_2, b_2 that are illustrated in the figure below.[1243] [1244]

basis for homology of H_1(surface of genus 2)

(3) Let $L = L_1 \cup \cdots \cup L_m$ be an m-component link in S^3. Those readers who solved Exercise 100.6 will see that the m meridians represent a basis for $\mathrm{H}_1(S^3 \setminus L) \cong \mathbb{Z}^m$ and that any choice of $m - 1$ tori $S^1 \times L_i$ represent a basis for $\mathrm{H}_2(S^3 \setminus L) \cong \mathbb{Z}^{m-1}$.

meridians represent basis for $\mathrm{H}_1(S^3 \setminus L)$

two out of three tori represent basis for $\mathrm{H}_2(S^3 \setminus L)$

(4) Any zero class $0 \in \mathrm{H}_k(M)$ is represented by the empty submanifold.

(5) We consider the complex projective space $\mathbb{C}\mathrm{P}^n$. We saw on page 1473 that for $k \leq n$ the map

[1243] Another point of view is that the submanifolds a_1, b_1, a_2, b_2 are given by deforming the curves x_1, y_1, x_2, y_2 that are shown in the figure on page 1225.

[1244] What do these submanifolds look like in the formal picture of the surface of genus 2 as the quotient $E_8/\sim$ of the Euclidean octagon?

$$\begin{array}{rcl} \mathbb{C}\mathrm{P}^k & \to & \mathbb{C}\mathrm{P}^n \\ [v_0 : \ldots : v_k] & \mapsto & [v_0 : \ldots : v_k : 0 : \ldots : 0] \end{array}$$

is a smooth embedding. We use this map to view $\mathbb{C}\mathrm{P}^k$ as a submanifold of $\mathbb{C}\mathrm{P}^n$. It follows from the discussion on page 1772 and the natural isomorphism of the Singular-Cellular H_*-Isomorphism Proposition 80.4 that

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^n) \cong \begin{cases} \mathbb{Z} \cdot [\mathbb{C}\mathrm{P}^i], & \text{if } k = 2i \text{ for some } i \in \{0, \ldots, n\}, \\ 0, & \text{otherwise.} \end{cases}$$

Put differently, the generators of the non-trivial homology groups of the complex projective space $\mathbb{C}\mathrm{P}^n$ are represented by the complex projective spaces $\mathbb{C}\mathrm{P}^i$ with $i = 0, \ldots, n$.

(6) Let M be a compact oriented connected k-dimensional smooth manifold. By Theorem 98.8 we have $\mathrm{H}_n(M, \partial M) = \mathbb{Z} \cdot [M]$. It follows from Lemma 100.8 that the classes $\pm[M]$ are represented by M, viewed as its own submanifold, equipped with the two possible orientations. Since M is connected we know by Exercise 19.19 that M admits no other non-empty n-dimensional proper submanifold. Thus we see that the classes $k \cdot [M]$ with $k \notin \{\pm 1\}$ are not represented by submanifolds.

For completeness' sake we state the following lemma.

Lemma 102.10. Let M be a smooth manifold, let A be a union of components of ∂M and let $\varphi \in \mathrm{H}_k(M, A)$. If N is a proper submanifold that represents φ, then ∂N represents the class $\partial_k(\varphi) \in \mathrm{H}_{k-1}(A)$ where $\partial_k \colon \mathrm{H}_k(M, A) \to \mathrm{H}_{k-1}(A)$ is the connecting homomorphism of the long exact sequence of the pair (M, A).

Proof. We consider the following diagram:

$$\begin{array}{ccc} \mathrm{H}_k(M, A) & \xrightarrow[\varphi \mapsto \partial_k(\varphi)]{\partial_k} & \mathrm{H}_{k-1}(A) \\ {\scriptstyle i_*}\uparrow & & \uparrow{\scriptstyle i_*} \\ \mathrm{H}_k(N, \partial N) & \xrightarrow[[N] \mapsto [\partial N]]{\partial_k} & \mathrm{H}_{k-1}(\partial N) \end{array}$$

where the horizontal maps are given by the connecting homomorphisms and where the vertical maps are induced by the inclusion maps. By the Topological LES-Proposition 74.13 we know that the connecting homomorphism are natural, in other words, the diagram commutes. The statement now follows from the Fundamental Class-of-Boundary Proposition 100.9. ∎

We are naturally lead to the following question which can be viewed as a refinement of Question 102.1 in the context of smooth manifolds.

Question 102.11. Let M be a smooth manifold and let A be a union of components of ∂M. For which $k \in \mathbb{N}_0$ can homology classes in $\mathrm{H}_k(M, A)$ be represented by submanifolds?

The following proposition, which can be viewed as analogue of Proposition 102.4 (2) says that the relative problem is equivalent to the absolute problem.

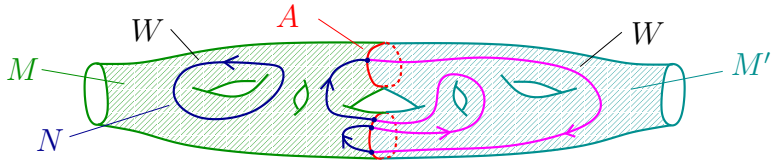
Proposition 102.12. Let $k \in \mathbb{N}$. Suppose that for every (orientable) n-dimensional smooth manifold every homology class in $\mathrm{H}_k(M)$ can be represented by a submanifold.

Then also for every (orientable) n-dimensional smooth manifold M and every union A of components of ∂M every relative homology class in $\mathrm{H}_k(M, A)$ can be represented by a submanifold.

Proof. Let A be the union of some components of ∂M and let $\sigma \in \mathrm{H}_k(M, A)$. Let M' be a second copy of M. As on page 1667 we consider the double of M along A, i.e. we consider $\mathrm{D}_A M = M \cup_{A=A'} M'$. Note that by the Doubling-Manifold Lemma 75.12 we know that $\mathrm{D}_A M$ is an (orientable) n-dimensional smooth manifold which contains A as a submanifold. Next let $D\colon \mathrm{H}_k(M, A) \to \mathrm{H}_k(\mathrm{D}_A M)$ be the doubling homomorphism given by the Doubling-Homology Lemma 75.16.

By our hypothesis there exists a closed oriented submanifold W of $\mathrm{D}_A M$ such that $[W] = D(\sigma)$. It follows from the Transversality Theorem 42.4 and the Homotopic Maps-and-Homology Proposition 73.6 that we can arrange that W is transverse to A. Now we set $N := W \cap M$. It follows from Exercise 42.8, which is a variation on the Submanifold Transversal Intersection Theorem 42.1, that N is a proper submanifold of W. It remains to prove the following claim.

Claim. We have $[N] = \sigma \in \mathrm{H}_k(M, A)$.



Proof. We denote by $i\colon W \to \mathrm{D}_A M$ the inclusion map. Now we consider the following diagram

$$\begin{array}{ccccc}
\mathrm{H}_k(N, \partial N) & \xrightarrow[\cong]{\alpha} & \mathrm{H}_n(W, W \setminus \mathring{N}) & \xleftarrow{\beta} & \mathrm{H}_k(W) \\
\downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle i_*} \\
\mathrm{H}_k(M, A) & \xrightarrow[\cong]{\gamma} & \mathrm{H}_k(\mathrm{D}_A M, M') & \xleftarrow{\delta} & \mathrm{H}_k(\mathrm{D}_A M).
\end{array}$$

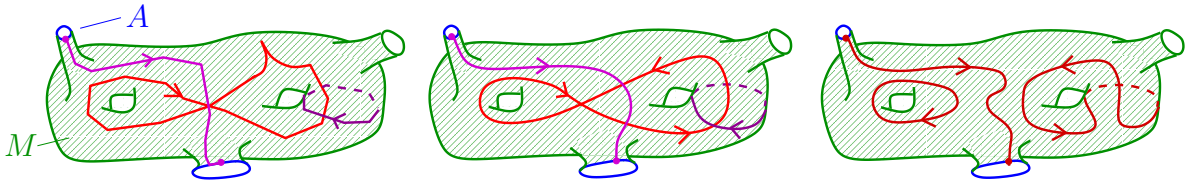
$$\mathrm{H}_k(M, A) \xrightarrow{\quad D \quad} \mathrm{H}_k(\mathrm{D}_A M)$$

Here α, β, γ and δ are the obvious maps. Now we make the following observations:

$$\begin{array}{rrcll}
 & i_*([W]) & = & D(\sigma) & \text{by choice of } W \\
\Longrightarrow & i_*(\beta([W])) & = & \delta(D(\sigma)) & \text{since the diagram commutes} \\
\Longrightarrow & i_*(\alpha([N]) & = & \gamma(\sigma) & \text{by Lemmas 100.12 and 75.16 (3)} \\
\Longrightarrow & \gamma(i_*([N])) & = & \gamma(\sigma) & \text{since the diagram commutes} \\
\Longrightarrow & i_*([N]) & = & \sigma & \text{since } \gamma \text{ is an isomorphism by the Excision Theorem 75.10}
\end{array}$$ ■

One obvious approach to Question 102.11 is as follows: in Section 102.1 we already saw that in many cases, given a class $\varphi \in \mathrm{H}_k(M, A)$, there exists a compact oriented k-dimensional smooth manifold N together with a map $f\colon (N, \partial N) \to (X, A)$ such that $f_*([N]) = \varphi$. The question now is the following: can we replace f by some proper embedding? The following proposition, which we will prove in Section 102.6, addresses this issue:

Proposition 102.13. Let $n \in \mathbb{N}$, let M be an n-dimensional smooth manifold and let A be a union of components of ∂M. Furthermore let N be a compact oriented k-dimensional smooth manifold and let $\varphi\colon (N, \partial N) \to (M, A)$ be a map.



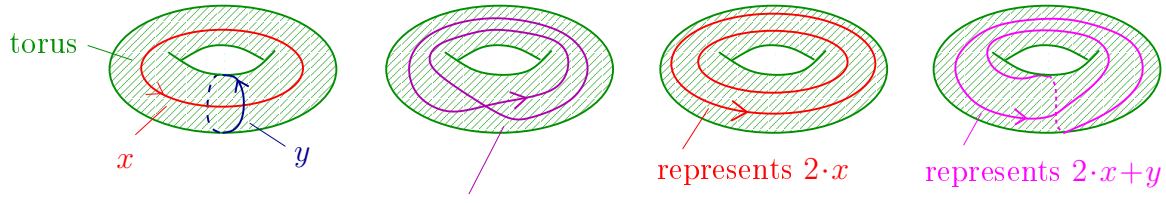
(1) If $n > 2k$, then $\varphi\colon (N, \partial N) \to (M, A)$ is homotopic, as a map of pairs of topological spaces, to a proper embedding $\psi\colon (N, \partial N) \to (M, A)$. In particular by the Smooth Embedding Theorem 24.10 (2) $\psi(N)$ is a proper submanifold of M and by Proposition 74.15 we have $\varphi_*([N]) = [\psi(N)] \in \mathrm{H}_k(M, A)$.

(2) If $n = 2k$, then there exists a compact oriented proper k-dimensional submanifold W of N with $\partial W \subset A$ such that $\varphi_*([N]) = [W] \in \mathrm{H}_k(M, A)$.[1245]

It is worth stating the following immediate corollary to Propositions 102.2 and 102.13.

Corollary 102.14. Let M be an m-dimensional smooth manifold with $m \geq 2$ and let A be the union of some components of ∂M. Given any homology class in $\sigma \in \mathrm{H}_1(M, A)$ there exists a compact oriented proper 1-dimensional submanifold P with $\partial P \subset A$ such that $[P] = \sigma$.

Example. Let M be a 2-dimensional smooth manifold and let $\sigma \in \mathrm{H}_1(M)$ be a homology class. For fun we illustrate in the figure below the three main steps in the proof of Proposition 102.13 in this special case.



by Proposition 102.2 we can represent the homology class by some map $\varphi\colon N \to M$

isotope to get smooth proper embedding without triple points

resolve intersections

Next we want to consider the question whether we can represent a homology class by a *connected* submanifold. For tori we have the following ambiguous answer.

Lemma 102.15. Let $T = S^1 \times S^1$ be the torus. We denote by $x = [S^1 \times \{1\}]$ and $y = [\{1\} \times S^1]$ the obvious basis for $\mathrm{H}_1(T)$. A non-zero class $r \cdot x + s \cdot y$ can be represented by a connected submanifold if and only if $\gcd(r, s) = 1$.

$2 \cdot x$ can be realized by a map from a connected manifold

Proof. We, i.e. you, will provide the proof in Exercise 102.4. For fun we will deal with the analogous problem for surfaces of higher genus in Exercise 102.5. ■

[1245] Note that we do not claim that W is diffeomorphic to N.

The following proposition, which can be viewed as an analogue of Proposition 102.4 (1), shows that in most settings we will not have troubles finding connected submanifolds. As for the previous proposition we postpone the proof to Section 102.7.

Proposition 102.16. Let $n \in \mathbb{N}$, let M be a connected n-dimensional smooth manifold and let A be a union of components of ∂M. Furthermore let N be a compact oriented k-dimensional submanifold with $\partial N \subset N$. We suppose that $n - k \geq 2$. If $n \geq 2$ or if $A = \varnothing$, then there exists a compact oriented *connected* submanifold W of M with $\partial W \subset A$ such that $[W] = [N] \in \mathrm{H}_k(M, A)$.

Remark. As we just saw in Lemma 102.15, in general the conclusion of Proposition 102.16 fails to hold if $k = n-1$. Note thought that in this setting some control over connectedness can be obtained using [**Tur2002**, Lemma 1.2].

The combination of Propositions 102.3, 102.13 and 102.16 gives us the following pretty corollary.

Corollary 102.17. Let M be an n-dimensional smooth manifold with $n \geq 4$ and let $A \subset \partial M$ be a union of boundary components. Every class in $\mathrm{H}_2(M, A)$ is represented by a connected submanifold.

Remark. Let M be a compact 4-dimensional smooth manifold and let $\sigma \in \mathrm{H}_2(M)$. By Corollary 102.17 it makes sense to the define the *genus of* σ:

$$\mathrm{genus}(\sigma) \ := \ \begin{array}{c}\text{minimal genus of a closed oriented connected} \\ \text{smooth submanifold } \Sigma \text{ of } M \text{ with } [\Sigma] = \sigma.\end{array}$$

As an example let us consider the 4-dimensional smooth manifold $\mathbb{C}\mathrm{P}^2$. By the discussion on page 2247 we know that $\mathrm{H}_2(\mathbb{C}\mathrm{P}^2) = \mathbb{Z} \cdot [\mathbb{C}\mathrm{P}^1]$. Let $n \in \mathbb{Z}$. We consider

$$W_n \ := \ \{[x : y : z] \in \mathbb{C}\mathrm{P}^2 \,|\, x^n + y^n + z^n = 0\}.$$

In Exercise 32.12 we showed that W_n is a closed 1-dimensional complex submanifold of the 2-dimensional complex manifold $\mathbb{C}\mathrm{P}^2$. In particular this shows that W_n is a closed 2-dimensional submanifold of $\mathbb{C}\mathrm{P}^2$. In Exercise 126.6 we will show that $[W_n] = n \cdot [\mathbb{C}\mathrm{P}^1]$. As is pointed out in [**GoS1999**, p. 38], it is a consequence of the "adjunction formula", that W_n is diffeomorphic to the surface of genus $\frac{1}{2}(n-1)(n-2)$. In particular we have the inequality $\mathrm{genus}(n \cdot [\mathbb{C}\mathrm{P}^1]) \leq \frac{1}{2}(n-1)(n-2)$. The Thom Conjecture predicted that equality holds. This conjecture was proved in 1994 by Peter Kronheimer and Tom Mrowka [**KrM1994**] using "Seiberg-Witten Theory". In general though it is still a very difficult problem to determine the genus of the homology class of a given smooth manifold.

Corollary 102.17 suffers from the rather annoying defect that it does not apply to the case of 3-dimensional smooth manifolds. Perhaps rather surprisingly this gets taken care of by coming "from the other direction", namely this case gets taken care of by the following proposition.

Proposition 130.4. Let M be a compact orientable n-dimensional smooth manifold and let $A \subset \partial M$ be a union of boundary components. Every class in $\mathrm{H}_{n-1}(M, A)$ can be represented by a submanifold.

Sketch of proof. As the number already suggests, we will not prove this statement in this chapter. In the following we will just provide the flavor of the argument which is meant

to serve as an amuse-bouche. For simplicity we assume that M is closed. Now suppose we are given a homology class $\sigma \in \mathrm{H}_{n-1}(M) = \mathrm{H}_{n-1}(M;\mathbb{Z})$. By the Poincaré Duality Theorem 119.1 we have an isomorphism $\mathrm{PD}_M \colon \mathrm{H}_{n-1}(M;\mathbb{Z}) \to \mathrm{H}^1(M;\mathbb{Z})$. Thus we obtain the Poincaré dual $\mathrm{PD}_M(\sigma) \in \mathrm{H}^1(M;\mathbb{Z})$. We will see that cohomology classes in $\mathrm{H}^1(M;\mathbb{Z})$ give rise to smooth maps $f \colon M \to K(\mathbb{Z},1) = S^1$. (Here $K(G,n)$ stands for an Eilenberg-Maclane space of type $K(G,n)$, the precise definition is irrelevant right now, except that in the discussion below it indicates some similarities between initially quite different looking arguments.) The desired submanifold is then given by the preimage of a regular value of f. ■

The analogue for codimension-two homology classes also holds:

Proposition ??. Let M be a compact orientable n-dimensional smooth manifold and let $A \subset \partial M$ be a union of boundary components. Every class in $\mathrm{H}_{n-2}(M,A)$ can be represented by a submanifold.

Sketch of proof. The logic of the proof is somewhat similar to the idea behind the proof of the Codimension-One Submanifold Existence Proposition 130.4. This time the Poincaré Duality Theorem 119.1 gives us an isomorphism $\mathrm{PD}_M \colon \mathrm{H}_{n-2}(M;\mathbb{Z}) \to \mathrm{H}^2(M;\mathbb{Z})$. Thus the given homology class in $\mathrm{H}_{n-2}(M;\mathbb{Z})$ corresponds to a cohomology class in $\mathrm{H}^2(M;\mathbb{Z})$. We will see that such cohomology classes give rise to maps $f \colon M \to K(\mathbb{Z},2) = \mathbb{C}\mathrm{P}^\infty$. Since M is compact we obtain a map $f \colon M \to \mathbb{C}\mathrm{P}^m$ for sufficiently large m. In this occasion the desired submanifold of M is given by the preimage of $\mathbb{C}\mathrm{P}^{m-1} \subset \mathbb{C}\mathrm{P}^m$. ■

Optimistically one might hope that the pattern of the previous two propositions extends to codimension-three homology classes. But Statement (2) of the following theorem shows that this is not the case.

Theorem 102.18. (Thom's Theorem III)

(1) Let M be a compact orientable n-dimensional smooth manifold and let A be a union of boundary components. Given $k \leq 6$ with $k < n$ every class in $\mathrm{H}_k(M,A)$ can be represented by a submanifold.
(2) There exists a 10-dimensional closed smooth manifold[1246] and a class in $\mathrm{H}_7(M)$ that cannot be represented by a submanifold.

Proof.

(1) First let us deal with the case that $A = \varnothing$. In this case, for $k \leq 5$ the statement can be found in [**Tho1954a**, Théorème 6] and also in [**Tho1954b**, Théorème II.27]. The statement for $k = 6$ can be found in the footnote on page 173 of [**Tho2007**]. The relative case now follows from the above together with Proposition 102.12.
(2) This statement was proved by Christian Bohr, Bernhard Hanke and Dieter Kotschick, see [**BHK2002**, Theorem 1]. Their work builds on earlier work of René Thom [**Tho1954b**, p. 62f]. ■

For completeness' sake we now also discuss homology with $\mathbb{F}_2$-coefficients. Given a compact (possibly non-orientable) proper k-dimensional submanifold N of a manifold M we

[1246] It follows from Statement (1) together with Propositions 130.4 and **??** that for a compact orientable n-dimensional smooth manifold of dimension $n \leq 9$ any homology class of dimension $< n$ can be represented by a submanifold. Thus the example in Statement (2) is "dimensionally minimal".

denote by $[N]_{\mathbb{F}_2}$ the image of the $\mathbb{F}_2$-fundamental class N under the inclusion induced map $\mathrm{H}_k(N, \partial N; \mathbb{F}_2) \to \mathrm{H}_k(M, \partial M; \mathbb{F}_2)$. We say N *represents the homology class* $[N]_{\mathbb{F}_2}$.
Surely it does not come as a surprise that we have the following analogue of Corollaries 102.14 and 102.17 for $\mathbb{F}_2$-coefficients. We will skip the proof since it is essentially the same.

Proposition 102.19. Let M be an n-dimensional smooth manifold and let $A \subset \partial M$ be a union of boundary components.

(1) If $n \geq 2$, then every class in $\mathrm{H}_1(M, A; \mathbb{F}_2)$ can be represented by a submanifold.
(2) If $n \geq 4$, then every class in $\mathrm{H}_2(M, A; \mathbb{F}_2)$ can be represented by a connected submanifold.

The following proposition is an analogue of the Codimension-One Submanifold Existence Proposition 130.4.

Proposition ??. Let M be a compact n-dimensional smooth manifold and let A be a union of boundary components. Every class in $\mathrm{H}_{n-1}(M, A; \mathbb{F}_2)$ can be represented by a submanifold.

Remark. This result will have its moment of glory when we will employ it in our proof, provided in Section **??**, that $\pi_{n+2}(S^n) \cong \mathbb{Z}_2$ for $n \geq 3$.

Sketch of proof. The proof of this proposition is quite similar to the proof of Proposition **??**. The Co-Homology Symmetry Theorem Theorem 119.6 with $\mathbb{F}_2$-coefficients gives us an isomorphism $\mathrm{PD}_M \colon \mathrm{H}_{n-1}(M; \mathbb{F}_2) \to \mathrm{H}^1(M; \mathbb{F}_2)$. Thus given the homology class in $\mathrm{H}_{n-1}(M; \mathbb{F}_2)$ corresponds to a cohomology class in $\mathrm{H}^1(M; \mathbb{F}_2)$. We will see that such cohomology classes give rise to maps $f \colon M \to K(\mathbb{F}_2, 1) = \mathbb{R}\mathrm{P}^\infty$. Since M is compact we obtain a map $M \to \mathbb{R}\mathrm{P}^m$ for sufficiently large m. Now the desired submanifold is given by the preimage of $\mathbb{R}\mathrm{P}^{m-1} \subset \mathbb{R}\mathrm{P}^m$. ∎

Remark. Note that this author is not aware of an analogue of Proposition **??**.

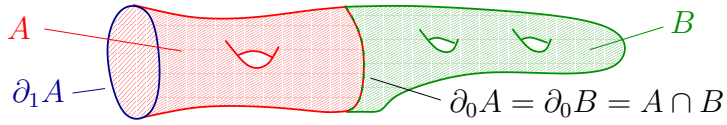
Finally let us see once again what René Thom has to say:

Theorem 102.20. (Thom's Theorem IV) Let M be a compact n-dimensional smooth manifold and let A be a union of boundary components.

(1) If $n \leq 5$, then any class in $\mathrm{H}_{n-2}(X, A; \mathbb{F}_2)$ can be represented by a submanifold.
(2) If $n \leq 7$, then any class in $\mathrm{H}_{n-3}(X, A; \mathbb{F}_2)$ can be represented by a submanifold.
(3) For $k \leq \lfloor \frac{n}{2} \rfloor$ any class in $\mathrm{H}_k(X, A; \mathbb{F}_2)$ can be represented by a submanifold.

Proof. In the case $A = \varnothing$ the three statements are precisely the content of [**Tho2007**, Théorème II.26]. The relative case follows from the $\mathbb{F}_2$-analogue of Proposition 102.12. Finally note that Statement (3) also follows from Theorem 102.5 together with the $\mathbb{F}_2$-analogue of Proposition 102.13 (2). ∎

We conclude this section with the following remark.



Remark. As we already mentioned on page 2237, later in Chapter 105 we will introduce the notion of an orientation of a topological manifold and in Chapter 106 we will introduce the notion of the fundamental class $[N] \in \mathrm{H}_n(N, \partial N)$ of a compact oriented n-dimensional topological manifold N. Thus it makes sense to ask which homology classes of a given topological manifold can be represented by submanifolds. This question is discussed in [**FNOP2019**].

In the remainder of this chapter we will provide the proofs of Proposition 102.13 and 102.16.

102.5. **Rearranging maps from smooth manifolds.** Let (X, A) be a pair of topological spaces. In this section we will state and prove a proposition which allows us to replace certain compact oriented smooth manifolds M and maps $f\colon (M, \partial M) \to (X, A)$ by a different compact oriented smooth manifold N together with a map $g\colon (N, \partial N) \to (X, A)$ such that $f_*([M]) = g_*([N])$. This procedure will come in handy in the proofs of Proposition 102.13 and 102.16.
The following definition is a special case of a more general concept introduced on page 570.

Definition. Let M be a compact n-dimensional smooth manifold. We say M is decomposed into submanifolds A and B if the following conditions hold:

(1) $M = A \cup B$.
(2) A and B are both compact n-dimensional submanifolds of M.
(3) We have $A \cap B = \partial_0 A = \partial_0 B$.

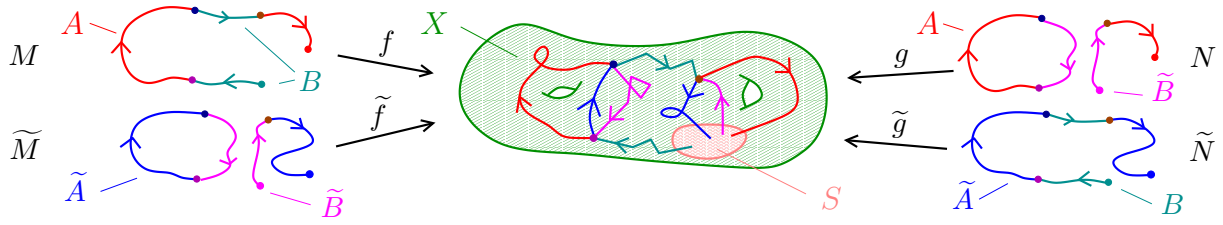
Now we can state the one result of this section.

Proposition 102.21. Let M and $\widetilde{M}$ be two compact oriented n-dimensional smooth manifolds. Suppose that M is decomposed into two submanifolds A and B and that $\widetilde{M}$ is decomposed into two submanifolds $\widetilde{A}$ and $\widetilde{B}$. We equip $A \cap B$ and $\widetilde{A} \cap \widetilde{B}$ with the orientation coming from A respectively $\widetilde{A}$. Suppose that we are given an orientation-preserving diffeomorphism $\Theta\colon A \cap B \to \widetilde{A} \cap \widetilde{B}$. Next we set

$$N := (A \sqcup \widetilde{B})/x \sim \Theta(x) \text{ for } x \in A \cap B \quad \text{and } \widetilde{N} := (\widetilde{A} \sqcup B)/\Theta(y) \sim y \text{ for } y \in A \cap B.$$

Note that it follows from the Gluing-Smooth Manifolds-Proposition **??** that N and $\widetilde{N}$ are both compact oriented n-dimensional smooth manifolds such that the obvious maps $A \to N$ and $\widetilde{A} \to \widetilde{N}$ are orientation-preserving embeddings. Next let (X, S) be a pair of topological space and furthermore let $f\colon (M, \partial M) \to (X, S)$ and $\widetilde{f}\colon (\widetilde{M}, \partial\widetilde{M}) \to (X, S)$ be two maps such that we have $\widetilde{f} \circ \Theta = f\colon A \cap B \to X$. We define[1247]

$$g\colon N = (A \sqcup \widetilde{B})/\sim \to X \qquad [P] \mapsto \begin{cases} f(P), & \text{if } P \in A, \\ \widetilde{f}(P), & \text{if } P \in \widetilde{B} \end{cases}$$



and

$$\widetilde{g}\colon \widetilde{N} = (\widetilde{A} \sqcup B)/\sim \to X \qquad [P] \mapsto \begin{cases} \widetilde{f}(P), & \text{if } P \in \widetilde{A}, \\ f(P), & \text{if } P \in B. \end{cases}$$

With this notation we have

$$f_*([M]) + \widetilde{f}_*([\widetilde{M}]) \;=\; g_*([N]) + \widetilde{g}_*([\widetilde{N}]) \;\in\; \mathrm{H}_n(X, S).$$

[1247] It follows from $\widetilde{f} \circ \Theta = f$ that both maps are continuous.

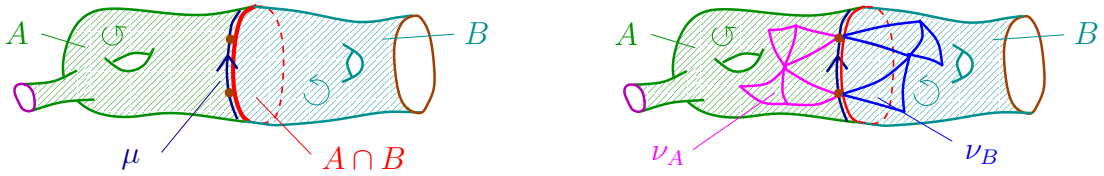
Proof. We pick a fundamental cycle $\mu \in \mathrm{C}_{n-1}(A \cap B)$ for the closed oriented $(n-1)$-dimensional smooth manifold $A \cap B$. We consider the map

$$\mathrm{C}_n(A, \partial A) \xrightarrow{\partial_n} \mathrm{C}_{n-1}(\overbrace{\partial_0 A \sqcup \partial_1 A}^{=\partial A}) \xrightarrow{\cong} \mathrm{C}_{n-1}(\overbrace{A \cap B}^{=\partial_0 A}) \oplus \mathrm{C}_{n-1}(\partial_1 A) \twoheadrightarrow \mathrm{C}_{n-1}(A \cap B).$$
$$\underbrace{\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad}_{=:\omega_A}$$

By Corollary 100.10 we know that there exists a singular chain $\nu_A \in \mathrm{C}_n(A)$ such that ν_A represents a fundamental cycle in $\mathrm{C}_n(A, \partial A)$ and such that $\omega_A(\nu_A) = \mu$. With the same notation we also obtain some $\nu_B \in \mathrm{C}_n(B)$ with $\omega_B(\nu_B) = \mu$.

Next we consider $\widetilde{\mu} := \Theta_*(\mu) \in \mathrm{C}_{n-1}(\widetilde{A} \cap \widetilde{B})$. As above we pick corresponding singular chains $\widetilde{\nu}_{\widetilde{A}} \in \mathrm{C}_n(\widetilde{A})$ and $\widetilde{\nu}_{\widetilde{B}} \in \mathrm{C}_n(\widetilde{B})$. Now we see that we have the following equalities in $\mathrm{H}_n(X, S)$:

it follows from $\omega_A(\nu_A) = \mu = \omega_B(\nu_B)$ that $\nu_A - \nu_B$ is a cycle in $\mathrm{C}_n(M, \partial M)$ using the Fundamental Class-Characterization Lemma 100.3 (3)⇒(1) one now can easily verify that $\nu_A - \nu_B$ is a fundamental cycle of M, the same argument shows that $\widetilde{\nu}_{\widetilde{A}} - \widetilde{\nu}_{\widetilde{B}}$ is a fundamental cycle of $\widetilde{M}$



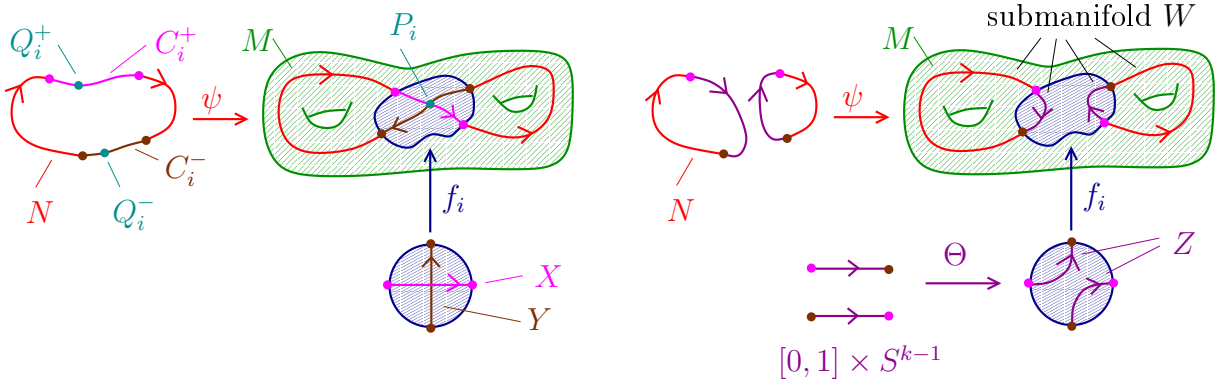
$$\begin{aligned}
f_*([M]) + \widetilde{f}_*([\widetilde{M}]) &\overset{\downarrow}{=} f_*([\nu_A - \nu_B]) + \widetilde{f}_*([\widetilde{\nu}_{\widetilde{A}} - \widetilde{\nu}_{\widetilde{B}}]) \qquad = [f_*(\nu_A) - f_*(\nu_B) + \widetilde{f}_*(\widetilde{\nu}_{\widetilde{A}}) - \widetilde{f}_*(\widetilde{\nu}_{\widetilde{B}})] \\
&= [f_*(\nu_A) - \widetilde{f}_*(\widetilde{\nu}_{\widetilde{B}}) + \widetilde{f}_*(\widetilde{\nu}_{\widetilde{A}}) - f_*(\nu_B)] \overset{\uparrow}{=} [f_*(\nu_A) - \widetilde{f}_*(\widetilde{\nu}_{\widetilde{B}})] + [\widetilde{f}_*(\widetilde{\nu}_{\widetilde{A}}) - f_*(\nu_B)]
\end{aligned}$$

it follows fairly easily from $\widetilde{f} \circ \Theta = f$ and $\widetilde{\mu} = \Theta_*(\mu)$ that $f_*(\nu_A) - \widetilde{f}_*(\widetilde{\nu}_{\widetilde{B}})$ and $\widetilde{f}_*(\widetilde{\nu}_{\widetilde{A}}) - f_*(\nu_B)$ are both cycles in $\mathrm{C}_n(X, S)$

$$= [g_*(\nu_A) - g_*(\widetilde{\nu}_{\widetilde{B}})] + [\widetilde{g}_*(\widetilde{\nu}_{\widetilde{A}}) - \widetilde{g}_*(\nu_B)] \;=\; g_*(\underbrace{[\nu_A - \widetilde{\nu}_B]}_{=[N]}) + \widetilde{g}_*(\underbrace{[\widetilde{\nu}_{\widetilde{A}} - \widetilde{\nu}_B]}_{=[\widetilde{N}]}).$$

$\uparrow$ by definition of g and $\widetilde{g}$

■



102.6. **Proofs of Proposition 102.13.** For the reader's convenience we recall the statement of Proposition 102.13.

Proposition 102.13. Let $n \in \mathbb{N}$, let M be an n-dimensional smooth manifold and let A be a union of components of ∂M. Furthermore let N be a compact oriented k-dimensional smooth manifold and let $\varphi\colon (N, \partial N) \to (M, A)$ be a map.

(1) If $n > 2k$, then $\varphi\colon (N, \partial N) \to (M, A)$ is homotopic, as a map of pairs of topological spaces, to a proper embedding $\psi\colon (N, \partial N) \to (M, A)$. In particular $\psi(N)$ is a proper submanifold of M and we have $\varphi_*([N]) = [\psi(N)] \in \mathrm{H}_k(M, A)$.

(2) If $n = 2k$, then there exists a compact oriented proper k-dimensional submanifold W of N with $\partial W \subset A$ such that $\varphi_*([N]) = [W] \in \mathrm{H}_k(M, A)$.

Proof. Let $n \in \mathbb{N}$, let M be an n-dimensional smooth manifold and let A be a union of components of ∂M. Furthermore let N be a compact oriented k-dimensional smooth manifold and let $\varphi\colon (N, \partial N) \to (M, A)$ be a map.

First let us consider the case $n > 2k$. In this case it follows from the Whitney Approximation Theorem 29.1 (3) together with Theorem **??** (2) that $\varphi\colon (N, \partial N) \to (M, A)$ is homotopic, as a map of pairs of topological spaces, to a proper embedding $\psi\colon (N, \partial N) \to (M, A)$. It follows from the Smooth Embedding Theorem 24.10 (2) that $\psi(N)$ is a proper submanifold of M and that $\psi\colon N \to \psi(N)$ is a diffeomorphism. Thus we see that

$$\varphi_*([N]) \underset{\substack{\uparrow \\ \text{Proposition 74.15}}}{=} \psi_*([N]) \underset{\substack{\uparrow \\ \text{since } \psi \text{ is a diffeomorphism}}}{=} [\psi(N)] \in \mathrm{H}_k(M, A).$$

Now let us deal with the much more subtle case $n = 2k$. From the Whitney Approximation Theorem 29.1 (3) together with Theorem **??** (1) we now obtain that the map φ is homotopic, as a map of pairs of topological spaces, to a proper immersion $\psi\colon N \to M$ which has furthermore the property that there exist points $P_1, \ldots, P_m$ in $M \setminus \partial M$ with the following properties:

(1) For each $i \in \{1, \ldots, m\}$ the preimage $\psi^{-1}(P_i)$ consists of precisely two points $Q_i^\pm$ which furthermore satisfy that $\psi_*(\mathrm{T}_{Q_i^+} N) + \psi_*(\mathrm{T}_{Q_i^-} N) = \mathrm{T}_{P_i}(M)$.

(2) The restriction of ψ to $N \setminus \{Q_1^\pm, \ldots, Q_m^\pm\}$ is injective.

In the following we write

$$X := \left\{ (x, 0) \in \overline{B}^{2k} \,\middle|\, x \in \overline{B}^k \right\} \quad \text{and} \quad Y := \left\{ (0, y) \in \overline{B}^{2k} \,\middle|\, y \in \overline{B}^k \right\}.$$

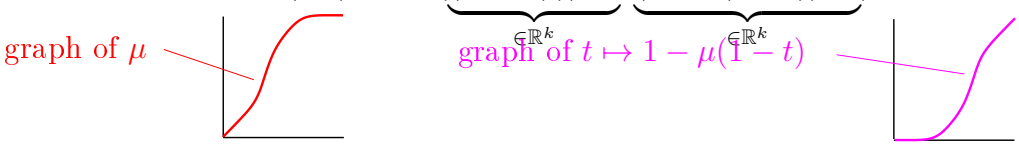
We view X and Y as submanifolds of $\overline{B}^{2k}$. We equip X and Y with the obvious orientation. It follows easily from the Smooth Embedding Theorem 24.10 (2) together with the Submanifold Transversal Intersection Theorem 42.1 (1) that we can find the following:

(1) Disjoint k-dimensional submanifolds $\mathrm{C}_1^{\pm}, \dots, \mathrm{C}_m^{\pm}$ of N such that for each $i \in \{1, \dots, m\}$ we have $Q_i^{\pm} \in \mathring{C}_i^{\pm} = \mathrm{C}_i^{\pm}$. Note that the restriction of ψ to any $\mathring{C}_i^{\pm}$ is in fact a smooth embedding.

(2) Disjoint embeddings $f_1, \dots, f_m \colon \overline{B}^{2k} \to M \setminus \partial M$ such that for each $i \in \{1, \dots, m\}$ we have

$$\psi(\mathrm{C}_i^+) \;=\; f_i(X), \quad \psi(\mathrm{C}_i^-) \;=\; f_i(Y), \quad \text{and } f_i(\overline{B}^{2k}) \cap \psi(N) \;=\; f_i(X) \cup f_i(Y).$$

Furthermore, after possibly precomposing the maps f_i with reflections in hyperplanes we can assume that the maps $X \to f_i(X) \overset{\psi}{\leftarrow} \mathrm{C}_i^+$ and $Y \to f_i(Y) \overset{\psi}{\leftarrow} \mathrm{C}_i^-$ are orientation-preserving.



Claim 1. There exists a proper smooth embedding $\Theta \colon [0,1] \times S^{k-1} \to \overline{B}^{2k}$ with the following three properties:

(1) For $t \in [0, \frac{1}{4}]$ and $z \in S^{k-1}$ we have $\Theta(t,z) = ((1-t)z, 0) \in \mathbb{R}^k \times \mathbb{R}^k$. Furthermore the map $\Theta_0 \colon \{0\} \times S^{k-1} \to S^{k-1} \times \{0\}$ is orientation-preserving.

(2) For $t \in [\frac{3}{4}, 1]$ and $z \in S^{k-1}$ we have $\Theta(t,z) = (0, t \cdot z) \in \mathbb{R}^k \times \mathbb{R}^k$. Furthermore the map $\Theta_0 \colon \{1\} \times S^{k-1} \to \{0\} \times S^{k-1}$ is orientation-reversing.

Proof. To prove the claim first note that, using the Smooth Transition Function Lemma 19.4 one can easily find a smooth function $\mu \colon [0,1] \to [0,1]$ such that $\mu(t) = t$ for $t \in [0, \frac{1}{4}]$, and such that $\mu(t) = 1$ for $t \in [\frac{3}{4}, 1]$ and such that $\mu'(t) > 0$ for any $t \in (0, \frac{3}{4})$. We leave it to the reader to verify that the following map has all the desired properties:

$$\begin{aligned} \Theta \colon [0,1] \times S^{k-1} &\to \overline{B}^{2k} \subset \mathbb{R}^k \times \mathbb{R}^k \\ (t,z) &\mapsto (\underbrace{(1-\mu(t)) \cdot z}_{\in \mathbb{R}^k}, \underbrace{(1-\mu(1-t)) \cdot z}_{\in \mathbb{R}^k}). \end{aligned}$$

⊞

Next we set $Z := \Theta([0,1] \times S^{k-1})$ and we set

$$W \;:=\; \psi\Big(\underbrace{N \setminus \bigcup_{i=1}^{m} (\mathring{C}_i^+ \cup \mathring{C}_i^-)}_{=:\widehat{N}}\Big) \cup \bigcup_{i=1}^{m} f_i(Z).$$

We leave it to the reader to verify that W is in fact a compact proper k-dimensional submanifold of M with $\partial W \subset A$ which can be oriented in such a way that the embedding $\psi \colon \widehat{N} \to W$ is orientation-preserving. It remains to prove the following claim.

Claim 2. We have $\varphi_*([N]) = [W] \in \mathrm{H}_k(X, A)$.

Proof. As usual we denote by $-W$ the same smooth manifold but with the opposite orientation. By Lemma 100.8 we have $[-W] = -[W]$. Thus it suffices to show that

$\varphi_*([N]) + [-W] = 0$. Now we perform the following calculation:

$$\varphi_*([N])+[-W] \overset{\text{by Proposition 74.15 since } \psi \text{ is homotopic to } \varphi}{\downarrow} = \psi_*([N])+[-W] = \psi_*\Big(\underbrace{\Big[\widehat{N} \cup \coprod_{i=1}^{m} (C_i^+ \cup C_i^-)\Big]}_{N}\Big) + \underbrace{\Big[-\psi(\widehat{N}) \cup - \coprod_{i=1}^{m} f_i(Z)\Big]}_{=W}$$

$$\overset{\text{Proposition 102.21}}{\downarrow} = \underbrace{(\psi \cup \psi)_*(\overbrace{[\widehat{N} \cup_{\partial_0 \widehat{N} = \partial_0 \widehat{N}} -\widehat{N}]}^{\text{the double } D_{\partial_0 \widehat{N}} \widehat{N}})}_{\substack{\text{the map } \psi \cup \psi \text{ factors through the} \\ \text{folding map } D_{\partial_0 \widehat{N}} \widehat{N} \to \widehat{N} \\ \text{which has degree zero by} \\ \text{the discussion on page 2227}}} + \sum_{i=1}^{m} \underbrace{(\psi \cup f_i)_*((Q_i^+ \cup Q_i^-) \cup Z)}_{\substack{= 0, \text{since } \psi \cup f_i \text{ takes values in } f_i(\overline{B}^{2k}) \\ \text{and since } \mathrm{H}_k(f_i(\overline{B}^{2k})) = 0}} = 0.$$

■

102.7. **The internal connected sum and the proof of Proposition 102.16.** We start with the slightly technical construction of an internal connected sum of two oriented submanifolds of a given smooth manifold. This construction is interesting in its own right, and it will be the key ingredient for the proof of Proposition 102.16.

Construction 102.22. Let M be a connected n-dimensional smooth manifold and let N_0 and N_1 be two compact oriented proper k-dimensional submanifolds of M. We suppose that $n - k \geq 2$. We pick points $P_0 \in N_0 \setminus \partial N_0$ and $P_1 \in N_1 \setminus \partial N_1$. We proceed with the following steps:

(1) Suppose we are given a smooth embedding $\gamma\colon [0,1] \to M \setminus \partial M$ with the following properties:
   (a) $\gamma(0) = P_0$ and $\gamma(1) = P_1$.
   (b) If we set $C := \gamma([0,1])$, then $C \cap N_0 = \{P_0\}$ and $C \cap N_1 = \{P_1\}$.
   (c) C hits N_0 and N_1 transversally, in the sense that $\mathrm{T}_{P_0} C \cap \mathrm{T}_{P_0} N_0 = \{0\}$ and $\mathrm{T}_{P_1} C \cap \mathrm{T}_{P_1} N_1 = \{0\}$.
   Note that it follows from Corollary 42.6 together with Theorem **??** that it follows from our hypothesis $n - k \geq 2$ that such γ always exists.

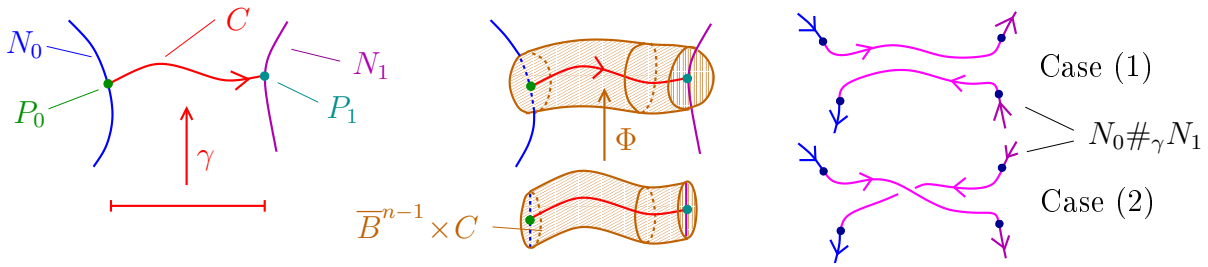
(2) Next we write $D := \{(x,0) \in \mathbb{R}^k \times \mathbb{R}^{n-1-k} \,|\, x \in \overline{B}^k\} \subset \overline{B}^{n-1}$. We challenge the courageous reader to show, say using a suitable variation on the Tubular Neighborhood Theorem **??**, that there exists an embedding $\Phi\colon \overline{B}^{n-1} \times C \to M$ such that $\Phi(\overline{B}^{n-1} \times C) \cap N_0 = \Phi(D \times \{P_0\})$ and such that $\Phi(\overline{B}^{n-1} \times C) \cap N_1 = \Phi(D \times \{P_1\})$.

(3) Using Exercise 19.12 one can easily find a smooth embedding $\Theta\colon S^{k-1} \times [0,1] \to \overline{B}^{k-1} \times C$ with the following two properties:
   (a) For $z \in S^{k-1}$ and $t \in [0, \frac{1}{4}]$ we have $\Theta(z,t) = ((1-t) \cdot z, P_0)$.
   (b) For $z \in S^{k-1}$ and $t \in [\frac{3}{4}, 1]$ we have $\Theta(z,t) = (t \cdot z, P_1)$.
   We set $Z := \Theta(S^{k-1} \times [0,1])$.

There are now two cases to consider.

Case (1) Among the two maps $\Phi\colon D \times \{P_0\} \to N_0$ and $\Phi\colon D \times \{P_1\} \to N_1$ one is orientation-preserving and one is orientation-reversing. In this case we set

$$N_0 \#_\gamma N_1 \;:=\; (N_0 \setminus \Phi(D \times \{P_0\})) \cup (N_1 \setminus \Phi(D \times \{P_1\}))) \cup \Phi(D \times C).$$



Case (2) If both maps $\Phi\colon D\times\{P_0\}\to N_0$ and $\Phi\colon D\times\{P_1\}\to N_1$ are orientation-preserving or if both are orientation-reversing then we add a "half-twist" to get us back into the game. More precisely, we consider the map [1248]

$$\begin{array}{rcl}\Omega\colon D\times C & \to & \overline{B}^{n-1}\times C\\ ((\underbrace{x_1,x_2,\ldots,x_k}_{\in\mathbb{R}^k},\underbrace{(0,0)}_{\in\mathbb{R}\times\mathbb{R}^{n-k-2}}),\gamma(t)) & \mapsto & ((\underbrace{\cos(t)\cdot x_1,x_2,\ldots,x_k}_{\in\mathbb{R}^k},\underbrace{(\sin(t)\cdot x_1,0)}_{\in\mathbb{R}\times\mathbb{R}^{n-k-2}}),\gamma(t)).\end{array}$$

Note that Ω is the identity on $D\times\{P_0\}$ and that Ω restricts to an orientation-reversing self-diffeomorphism of $D\times\{P_1\}$. Now we set

$$N_0\#_\gamma N_1 \;:=\; (N_0\setminus\Phi(D\times\{P_0\}))\cup(N_1\setminus\Phi(D\times\{P_1\}))\cup(\Phi\circ\Omega)(D\times C).$$

It is straightforward to verify that in both cases $N_0\#_\gamma N_1$ is a k-dimensional submanifold of M. Furthermore one sees easily that in both cases we can equip the smooth manifold $N_0\#_\gamma N_1$ with an orientation in such a way that the inclusions $N_0\setminus\Phi(D\times\{P_0\})\to N_0\#_\gamma N_1$ and $N_1\setminus\Phi(D\times\{P_1\})\to N_0\#_\gamma N_1$ are both orientation-preserving. We refer to $N_0\#_\gamma N_1$ as an *internal connected sum of* N_0 *and* N_1 *along* γ or as a *tubing of* N_0 *and* N_1 *along* γ.[1249]

The following lemma justifies the name "internal connected sum".

Lemma 102.23. We continue with the above notation. The internal connected sum $N_01\#_\gamma N_1$, viewed as a smooth manifold in its own right, is diffeomorphic to the connected sum $N_0\#N_1$.

Proof. The lemma can be proved fairly easily using the Smooth Collar Neighborhood Theorem 28.3 applied to $N_0\setminus\Phi(D\times\{P_0\})$ and $N_1\setminus\Phi(D\times\{P_1\})$. We leave it to the reader to fill in the details. ■

Example. In the figure below we show two disjoint oriented knots J and J. By definition both are submanifolds of S^3. We also show a path γ that connects K to J and we show a corresponding internal connected sum $K\#_\gamma J$. On page 1319 we introduced the connected sum $K\#J$. The resulting image, see e.g. the figure on page 1319 looks quite similar to what we see in the figure below. With some effort one can show that given any two oriented knots the corresponding connected sum $K\#J$ is smoothly isotopic to any internal connected sum $K\#_\gamma J$. In fact sometimes this approach is used as the definition of the connected sum of two oriented knots.

We recall the statement of proposition that we are actually supposed to prove.

[1248] Note that here we use again, in a most subtle way, our hypothesis $n-k\geq 2$.

[1249] The construction also depends on the choice of Φ and Θ. We do not claim that the isotopy type of $N_0\#_\gamma N_1$ is well-defined.

Proposition 102.16. Let $n \in \mathbb{N}$, let M be a connected n-dimensional smooth manifold and let A be a union of components of ∂M. Furthermore let N be a compact oriented k-dimensional submanifold with $\partial N \subset N$. We suppose that $n - k \geq 2$. If $n \geq 2$ or if $A = \varnothing$, then there exists a compact oriented *connected* submanifold W of M with $\partial W \subset A$ such that $[W] = [N] \in \mathrm{H}_k(M, A)$.

Sketch of proof. To simplify the notation we assume that N has precisely two components N_0 and N_1. As explained in Construction 102.22, since $n - k \geq 2$ we can perform an internal connected sum $N_0 \#_\gamma N_1$. As in the proof of Proposition 102.13 one can deduce, using Proposition 102.21, that $[N_0 \#_\gamma N_1] = [N_0] + [N_1] \in \mathrm{H}_k(M, A)$.

Next, as we pointed out in Lemma 102.23, the internal connected sum $N_0 \#_\gamma N_1$ is diffeomorphic to the connected sum $N_0 \# N_1$. If $n \geq 2$, then it follows immediately from the Connected Sum-Proposition **??** that the connected sum $N_0 \# N_1$ is connected. Finally, if $A = \varnothing$, then we know that both N_0 and N_1 are closed. Thus it follows again from the Connected Sum-Proposition **??** that $N_0 \# N_1$ is connected. ■

Exercises for Chapter 102.

Exercise 102.1. Let M be a closed 3-dimensional smooth manifold and let $\sigma \in \mathrm{H}_2(M)$ be a homology class. By the Realization-by-Surface Proposition 102.3 there exists a closed oriented 2-dimensional smooth manifold F and a map $\varphi\colon F \to M$ such that $\varphi_*([F]) = \varphi$. Can you modify the proof of Proposition 102.13 to show that there exists a closed oriented 2-dimensional smooth manifold G and an *embedding* $\psi\colon G \to M$ such that $\psi_*([G]) = \sigma$? Identify the issues you run into and try to resolve them.

Exercise 102.2. Let $n \in \mathbb{N}$. As on page 255 we consider the complex projective space $\mathbb{C}\mathrm{P}^n = (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\})$. By the discussion on page 1772 we know that

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k \in \{0, 2, \ldots, 2n\}, \\ 0, & \text{otherwise.} \end{cases}$$

We consider the map $f\colon \mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^n$ given by $f([z_0 : \cdots : z_n]) = [\overline{z}_0 : \cdots : \overline{z}_n]$. For each $k \in \{0, 2, \ldots, 2n\}$ determine the degree of the induced map $f_*\colon \mathrm{H}_k(\mathbb{C}\mathrm{P}^n) \to \mathrm{H}_k(\mathbb{C}\mathrm{P}^n)$.

Exercise 102.3. Let $g \in \mathbb{N}_0$. As usual we denote by Σ_g the surface of genus g. Let M be a smooth manifold and let $P \in M$. Now let $k \in \mathbb{N}_0$. Show that if there exists a map $f\colon \Sigma_k \to M \times \Sigma_g$ with $f_*([\Sigma_k]) = [\{P\} \times \Sigma_g] \in \mathrm{H}_2(M \times \Sigma_g)$, then $k \geq g$.

Exercise 102.4. Let $T = S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$ be the torus. We denote by $x = [S^1 \times \{1\}]$ and $y = [\{1\} \times S^1]$ the obvious basis for $\mathrm{H}_1(T)$. Let $(r, s) \neq (0, 0) \in \mathbb{Z}^2$. Show that the following two statements are equivalent:

(a) The homology class $r \cdot x + s \cdot y$ can be represented by a connected submanifold of T.

(b) $\gcd(r, s) = 1$.

Hint. For the "(a)⇒(b)"-direction you might want to use the classification of 2-dimensional smooth manifolds.

Exercise 102.5. Let $g \in \mathbb{N}$. We consider the surface Σ of genus g. Let $\varphi \neq 0 \in \mathrm{H}_1(\Sigma)$. Show that the following two statements are equivalent:

(a) φ can be represented by a connected submanifold of Σ.
(b) φ is a primitive class in $\mathrm{H}_1(\Sigma)$.

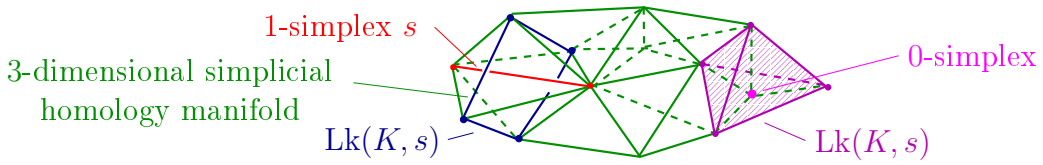
Remark. The case $g = 1$ is evidently just the content of Exercise 102.4.

103. The Simplicial Poincaré Duality Theorem

In this chapter we will prove one of the most beautiful and powerful theorems in the theory of abstract simplicial complexes, namely the Simplicial Poincaré Duality Theorem 103.4. This theorem has many applications, arguably the most interesting ones concern the singular (co-) homology groups of smooth manifolds.

103.1. **Simplicial Homology Manifolds.** To state the Simplicial Poincaré Duality Theorem we will need the following notion.

Definition.



(1) We say that an abstract simplicial complex L is an simplicial homology m-sphere if L is m-dimensional, if L is finite and if for every $i \in \mathbb{N}_0$ we have

$$\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(L) \cong \begin{cases} \mathbb{Z}, & \text{if } i = m, \\ 0, & \text{else.} \end{cases}$$

Furthermore we say that L is a simplicial homology ball if $\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(L) = 0$ for all $i \in \mathbb{N}_0$.

(2) We say that an abstract simplicial complex K is an n-dimensional simplicial homology manifold if K is n-dimensional, if K is finite and if for every $k \in \mathbb{N}_0$ and every k-simplex s of K the link $\mathrm{Lk}(K, s)$ is a simplicial homology $(n-1-k)$-sphere or if it is a simplicial homology ball.

(3) We say a simplicial homology manifold K is closed, if K is finite and if for every k-simplex s of K the link $\mathrm{Lk}(K, s)$ is a simplicial homology $(n-1-k)$-sphere.

Remark. Note that by the discussion on page 2042 the empty abstract simplicial complex is a simplicial homology (-1)-sphere. Furthermore it is a straightforward consequence of the Reduced Homology Lemma 95.10 (1) that the empty abstract simplicial complex is in fact the only simplicial homology (-1)-sphere. It follows in particular that every simplex in a closed n-dimensional simplicial homology manifold has dimension at most n.

The following lemma gives a reformulation of the definition of a simplicial homology manifold.

Lemma 103.1. Let K be an abstract simplicial complex. As always we denote by $\mathrm{sd}(K)$ its barycentric subdivision. The following two statements are equivalent:

(1) K is a closed n-dimensional simplicial homology manifold.

(2) For every vertex v[1250] of the barycentric subdivision $\mathrm{sd}(K)$ the link $\mathrm{Lk}(\mathrm{sd}(K), v)$ is a simplicial homology $(n-1)$-sphere.

Proof. The lemma follows immediately from the second part of the following claim.

[1250] It is worth remembering that by definition the vertices of $\mathrm{sd}(K)$ are precisely the barycenters of the simplices of K.

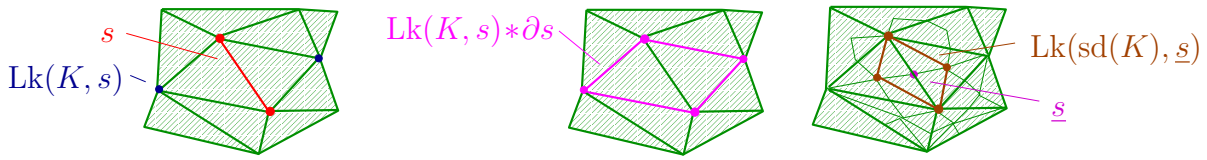
Claim. Let K be an abstract simplicial complex and let s be a k-simplex of K.

(a) There is a simplicial isomorphism $\mathrm{Lk}(K,s) * \partial s \cong \mathrm{Lk}(\mathrm{sd}(K), \underline{s})$.

(b) For each $i \in \mathbb{N}_0$ we have $\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(\mathrm{Lk}(K,s)) \cong \widetilde{\mathrm{H}}_{i+k}^{\mathrm{simp}}(\mathrm{Lk}(\mathrm{sd}(K), \underline{s}))$.

Proof.

(a) This statement is actually the content of Exercise 94.2. For the reader's convenience we sketch the proof. So let us consider the map



$$\begin{array}{rcl} \mathrm{Lk}(K,s) * \partial s & \to & \mathrm{Lk}(\mathrm{sd}(K), \underline{s}) \\ v & \mapsto & \begin{cases} s \setminus \{v\}, & \text{if } v \in \partial s, \\ \underline{s \sqcup \{v\}}, & \text{if } v \in \mathrm{Lk}(K,s). \end{cases} \end{array}$$

It is elementary to verify that this map on the level of vertices induces an isomorphism of abstract simplicial complexes.

(b) For any $i \in \mathbb{N}_0$ we have

$$\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(\mathrm{Lk}(K,s)) \underset{\uparrow}{\cong} \widetilde{\mathrm{H}}_{i+k}^{\mathrm{simp}}(\mathrm{Lk}(K,s) * \partial s) \underset{\uparrow}{\cong} \widetilde{\mathrm{H}}_{i+k}^{\mathrm{simp}}(\mathrm{Lk}(\mathrm{sd}(K), \underline{s})).$$

Join-Homology Lemma 95.13 (1) by (a) ■

Slightly annoyingly the notion of a "simplicial homology manifold" is now the third definition of a "manifold-like" structure on an abstract simplicial complex. Namely on page 2140 we introduced the notion of a pseudomanifold and on page 2093 we introduced the notion of a PL-manifold. For the reader's and also the author's convenience we now recall these two earlier notions. Thus let K be a finite non-empty abstract simplicial complex.

(1) K is a closed n-dimensional pseudomanifold if the following conditions are satisfied:
   (a) Every simplex of K is a face of an n-simplex of K.
   (b) Every $(n-1)$-simplex has order two, i.e. it is the face of precisely two n-dimensional faces.
   (c) Given any two n-simplices t and t' there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of n-simplices such that any two consecutive simplices have a common $(n-1)$-dimensional face.

(2) By the PL-Manifold Characterization Proposition 96.12 we know that K is a closed n-dimensional PL-manifold if and only if for every k-simplex $s \in S$ the link $\mathrm{Lk}(K,s)$ is a PL $(n-k-1)$-sphere, i.e. $|\mathrm{Lk}(K,s)|$ is PL-homeomorphic to the simplicial complex $\partial\Delta^{n-k}$.[1251]

The following proposition summarizes everything anybody ever wanted to know about the relationship between this new concept and our two earlier concepts.

[1251] By the Alexander-Newman Theorem 96.22 the notion of a PL-manifold is basically equivalent to the notion of a combinatorial manifold that we introduced on page 2104. Since the notion of a PL-manifold is more commonly used we stick in the discussion to PL-manifold even though the notion of a combinatorial manifold would be slightly more appropriate.

Proposition 103.2.

(1) A closed connected non-empty n-dimensional simplicial homology manifold K is a closed n-dimensional pseudomanifold with $\partial K = \varnothing$.
(2) There exists a closed pseudomanifold that is not a simplicial homology manifold.
(3) Every closed non-empty n-dimensional PL-manifold is a closed n-dimensional simplicial homology manifold.
(4) There exists a closed simplicial homology manifold that is not a PL-manifold.

Remark. Slightly more informally Proposition 103.2 can be summarized as follows:

$$\text{PL-manifold} \quad \overset{\Longrightarrow}{\not\Longleftarrow} \quad \text{simplicial homology manifold} \quad \overset{\Longrightarrow}{\not\Longleftarrow} \quad \text{pseudomanifold.}$$

Proof.

(1) Let K be a closed connected non-empty n-dimensional simplicial homology manifold. We want to show that K is a closed n-dimensional pseudomanifold. The well-versed reader will easily spot that arguments below are at times almost identical to the arguments provided in the proof of the Manifold-Simplex Proposition 98.1.

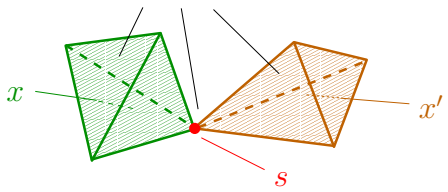
Let us prove that the three conditions of a pseudomanifold, which we recalled above, are satisfied.

(a) Let s be a k-simplex of K. By hypothesis $\widetilde{\mathrm{H}}^{\mathrm{simp}}_{n-k-1}(\mathrm{Lk}(K,s)) \neq 0$. This implies immediately that s is the face of an n-simplex.

(b) Let s be an $(n-1)$-simplex of K. By hypothesis $\widetilde{\mathrm{H}}^{\mathrm{simp}}_{0}(\mathrm{Lk}(K,s)) \cong \mathbb{Z}$, which implies by the Reduced Homology Lemma 95.10 that $\mathrm{H}^{\mathrm{simp}}_{0}(\mathrm{Lk}(K,s)) \cong \mathbb{Z}^2$. Recall that on page 2261 we pointed out that the maximal dimension of a simplex of K is n. Since s is $(n-1)$-dimensional we see that $\mathrm{Lk}(K,s)$ is a 0-dimensional simplicial complex. Now we see that it consists of precisely two vertices, which implies that there are precisely two n-simplices which contain s as a face.

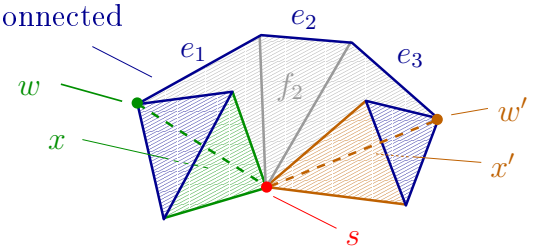
(c) We say that two n-simplices t and t' of K are *equivalent* if there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of n-simplices such that any two consecutive simplices have a common $(n-1)$-dimensional face. Recall that our task is to show that any two n-simplices are equivalent in the above sense.
The key to doing so is the following claim:

Claim. Let t and t' be two n-simplices. If $t \cap t' \neq \varnothing$, then t and t' are actually equivalent in the above sense.



Proof. Given $m \in \{0, \ldots, n-1\}$ we say that two n-simplices x and x' are *m-equivalent* if there exists a sequence $x = s_0, s_1, \ldots, s_k = x'$ of n-simplices such that any two consecutive simplices have a common face of dimension $\geq m$. It suffices to show that if we are given $m \in \{0, \ldots, n-2\}$ such that any two n-simplices in K are m-equivalent, then any two n-simplices in K are also $(m+1)$-equivalent. In fact evidently it suffices to show that if we are given two n-simplices x and x' which have an m-simplex s in common, then x and x' are $(m+1)$-equivalent. To do so we first note that since $\dim(x) > \dim(s)$ we can pick a vertex w of $x \cap \mathrm{Lk}(K,s)$ and similarly we can pick a vertex w' of $x' \cap \mathrm{Lk}(K,s)$.

By hypothesis we know that $\widetilde{\mathrm{H}}_0^{\mathrm{simp}}(\mathrm{Lk}(K,s)) = 0$. It follows from this fact together with the Reduced Homology Lemma 74.1 and Exercise 93.12 that the abstract simplicial complex $\mathrm{Lk}(K,s)$ is in fact connected. This means in our setting that there exist 1-simplices $e_1, \dots, e_k \in S$ of $\mathrm{Lk}(K,s)$ such that the following holds:



(∗) We have $w \in e_1$, for every $i \in \{1, \dots, k-1\}$ we have $e_i \cap e_{i+1} \neq \varnothing$ and we have $w' \in e_k$.

Let $i \in \{1, \dots, k\}$. Since e_i is a simplex in $\mathrm{Lk}(K,s)$ there exists a simplex f_i of K with $e_i \cup s \subset f_i$. By (a) we can in fact find an n-simplex $\widetilde{f}_i$ of K with $e_i \cup s \subset f_i \subset \widetilde{f}_i$. We set $\widetilde{f}_0 := x$ and $\widetilde{f}_{k+1} := x'$. Note that it follows from (∗) that any two consecutive $\widetilde{f}_i$ and $\widetilde{f}_{i+1}$ have s and a vertex of $\mathrm{Lk}(K,s)$ in common, i.e. they have an $(m+1)$-simplex in common. This shows that x and x' are in fact $(m+1)$-connected. ⊞

x and x' are 0-equivalent

$\mathrm{Lk}(K,s)$ is connected

Now let t and t' be any two n-simplices of K. By hypothesis K is connected. Together with (a) this implies easily that there exists a sequence of n-simplices $t = u_0, u_1, \dots, u_k = t'$ such that any two consecutive n-simplices share at least one vertex. By the claim any two consecutive n-simplices are equivalent. Hence t and t' are equivalent.

(2) Let K be a closed n-dimensional pseudomanifold. It follows from the discussion on page 2141 that the suspension $\Sigma(K) = K * \{\pm 1\}$ is a closed $(n+1)$-dimensional pseudomanifold. By the discussion on page 2018 we know that $\mathrm{Lk}(\Sigma(K), \{-1\}) = K$. Thus if $\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(K) \neq 0$ for two different dimensions, e.g. if $K = S_1 \times S_1$ is the simplicial torus, then $\Sigma(K)$ is not a simplicial homology manifold.

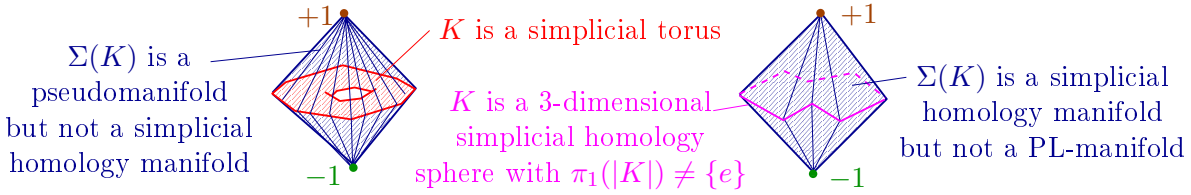
(3) Let K be a closed n-dimensional PL-manifold and let s be a k-simplex. We see that

$$\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(\mathrm{Lk}(K,s)) \underset{\uparrow}{\cong} \widetilde{\mathrm{H}}_i(|\mathrm{Lk}(K,s)|) \underset{\uparrow}{\cong} \widetilde{\mathrm{H}}_i(S^{n-k-1}) \cong \begin{cases} \mathbb{Z}, & \text{if } i = n-k-1, \\ 0, & \text{else.} \end{cases}$$

by the Simplicial-Singular Homology Isomorphism Theorem 95.23

since $\mathrm{Lk}(K,s)$ is a PL $(n-k-1)$-sphere we know that $|\mathrm{Lk}(K,s)|$ is homeomorphic to $\partial\Delta^{n-k}$ in particular $|\mathrm{Lk}(K,s)|$ is homeomorphic to S^{n-k-1}

(4) By Proposition 98.11 we know that there exists a closed orientable 3-dimensional smooth manifold Y that is a homology 3-sphere, but such that $\pi_1(Y)$ is a non-trivial group. By the Smooth Manifold-Simplicial Structure Theorem 96.2 and Theorem 96.15 we can equip Y with a PL-structure $(K, \Theta\colon |K| \to Y)$. We consider the suspension $\Sigma(K) = K * \{\pm 1\}$. We want to show that $\Sigma(K)$ is a closed 4-dimensional



simplicial homology manifold but that it is not a PL-manifold. It turns out that the simplices of $\Sigma(K) = K * \{\pm 1\}$ come in the following three flavors:

(a) Any k-simplex s of K is also a k-simplex of $\Sigma(K)$. We have, almost by definition, that $\mathrm{Lk}(\Sigma(K), s) = \Sigma(\mathrm{Lk}(K, s))$. It follows from this observation, together with (1) and the Join-Homology Lemma 95.13 (2) that $\mathrm{Lk}(\Sigma(K), s)$ is a simplicial homology $(3-k)$-sphere.

(b) Given a k-simplex s of K we obtain the $(k+1)$-simplices $s \cup \{-1\}$ and $s \cup \{1\}$ of $\Sigma(K)$. Note that it follows almost immediately from the various definitions that $\mathrm{Lk}(\Sigma(K), s \cup \{-1\}) = \mathrm{Lk}(K, s) = \mathrm{Lk}(\Sigma(K), s \cup \{1\})$. Thus we obtain from (1) that $\mathrm{Lk}(\Sigma(K), s \cup \{-1\})$ and $\mathrm{Lk}(\Sigma(K), s \cup \{1\})$ are both simplicial homology $(3-(k+1))$-spheres.

(c) Finally we need to consider the 0-simplices ± 1 of $\Sigma(K) = K * \{\pm 1\}$. As we discussed on page 2018, we have $\mathrm{Lk}(\Sigma(K), \{\pm 1\}) = K$. Since K is a homology 3-sphere we see that $\mathrm{Lk}(\Sigma(K), \{\pm 1\}) = K$ are simplicial homology 3-spheres. But since $\pi_1(|K|) = \pi_1(Y)$ is by construction a non-trivial group we see that $|\mathrm{Lk}(\Sigma(K), \{\pm 1\})| = |K|$ are not homeomorphic to the 3-sphere, let alone are $\mathrm{Lk}(\Sigma(K), \{\pm 1\})$ PL 3-spheres or PL-balls.

Thus we see that $\Sigma(K)$ is a 4-dimensional simplicial homology manifold, but $\Sigma(K)$ is not a PL-manifold. ■

We conclude this section with the following lemma.

Lemma 103.3. Let K be an abstract simplicial complex. If $|K|$ is an n-dimensional topological manifold with $\partial(|K|) = \varnothing$, then K is an n-dimensional simplicial homology manifold.

Proof. Let s be a k-simplex of K. We need to show that $\mathrm{Lk}(K, s)$ is a simplicial homology $(n-k-1)$-sphere. We pick a point P in the corresponding open simplex $\langle s \rangle$. We perform the following calculation:

$$\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(\mathrm{Lk}(K,s)) \underset{\uparrow}{\cong} \widetilde{\mathrm{H}}_{i+k+1}(|K|, |K| \setminus \{P\}) \underset{\uparrow}{\cong} \begin{cases} \mathbb{Z}, & \text{if } i+k+1 = n, \\ 0, & \text{else.} \end{cases}$$

by Proposition 98.2

by the Manifold-Local Homology Lemma 75.1, since $|K|$ is an n-dimensional topological manifold with $\partial(|K|) = \varnothing$

As a parenthetical remark we point out that alternatively we could have proved the lemma using Lemma 103.1 instead of using Proposition 98.2. ■

103.2. **The statement of the Simplicial Poincaré Duality Theorem.** Let K be a closed connected n-dimensional simplicial homology manifold. By Proposition 103.2 (1)

we know that K is in particular a closed n-dimensional pseudomanifold. In particular it makes sense to talk of orientations of K. We recall the notion of a fundamental class.

(1) If K is oriented, then by the definition on page 2143 we have a fundamental class $[K] \in \mathrm{H}_n^{\mathrm{simp}}(K)$. In the following, given a commutative ring R we denote by $[K]$ also the image of $[K]$ under the natural map $\mathrm{H}_n^{\mathrm{simp}}(K) \xrightarrow{[\sigma] \mapsto [\sigma \otimes 1_R]} \mathrm{H}_n^{\mathrm{simp}}(K;R)$.
(2) Regardless of whether or not K is orientable we defined on page 2143 the $\mathbb{F}_2$-fundamental class $[K]_{\mathbb{F}_2} \in \mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{F}_2)$.

The following theorem is the main theorem on simplicial (co-) homology groups of simplicial homology manifolds.

Theorem 103.4. (Simplicial Poincaré Duality Theorem) Let K be a closed n-dimensional simplicial homology manifold and let $k \in \mathbb{N}_0$. If K is orientable, then for every choice of orientation and every commutative ring R the map

$$\begin{array}{rcl} \mathrm{H}^k_{\mathrm{simp}}(K;R) & \to & \mathrm{H}^{\mathrm{simp}}_{n-k}(K;R) \\ \varphi & \mapsto & \varphi \cap [K] \end{array}$$

is an isomorphism. Regardless of whether or not K is orientable the map

$$\begin{array}{rcl} \mathrm{H}^k_{\mathrm{simp}}(K;\mathbb{F}_2) & \to & \mathrm{H}^{\mathrm{simp}}_{n-k}(K;\mathbb{F}_2) \\ \varphi & \mapsto & \varphi \cap [K]_{\mathbb{F}_2} \end{array}$$

is an isomorphism.

Remark. One might think or hope that the Simplicial Poincaré Duality Theorem 103.4 also holds for closed (orientable) pseudomanifolds, but as we will see in Exercise 103.1 this is not the case. Nonetheless, it turns out that on pseudomanifolds one can introduce more refined (co-) homology groups, namely intersection homology, that do satisfy an analogue of the Poincaré Duality Theorem. We refer to [**Ban2007**] for details.

The proof of the Simplicial Poincaré Duality Theorem 103.4 is evidently non-trivial and somewhat lengthy. Thus we will first draw several interesting conclusions before we head to the proof.

Example. Let K be a closed orientable n-dimensional simplicial homology manifold. Let us see what the Simplicial Poincaré Duality Theorem 103.4 tells us for $k = 1$. We have the following isomorphisms:

$$\begin{array}{ccccc} \mathrm{H}^{\mathrm{simp}}_{n-1}(K) & \cong & \mathrm{H}^1_{\mathrm{simp}}(K;\mathbb{Z}) & \cong & \mathrm{Hom}(\mathrm{H}_1^{\mathrm{simp}}(K),\mathbb{Z}) \oplus \mathrm{Ext}(\overbrace{\mathrm{H}_0^{\mathrm{simp}}(K)}^{\text{free abelian group by Exercise 95.3}},\mathbb{Z}) \\ \uparrow & & \uparrow & & \uparrow \\ \text{Poincaré Duality Theorem 103.4} & & & & \text{Universal Coefficient Theorem 99.8} \\ & \cong & \mathrm{Hom}(\mathrm{H}_1^{\mathrm{simp}}(K),\mathbb{Z}) & \cong & \mathrm{Hom}(\mathbb{Z}^k \oplus T,\mathbb{Z}) \;\cong\; \mathbb{Z}^k. \\ & & \uparrow & & \uparrow \\ & & \text{Ext-Calculation Lemma 14.5.6} & & \text{by Lemma 95.9 (1) we know that the group the group } \mathrm{H}_1^{\mathrm{simp}}(K) \text{ is finitely} \\ & & & & \text{generated, hence it is isomorphic to } \mathbb{Z}^k \oplus T \text{ for some } k \in \mathbb{N} \text{ and some finite group } T \end{array}$$

We have thus shown that $\mathrm{H}^{\mathrm{simp}}_{n-1}(K)$ is a free abelian group. In the more general setting of closed orientable pseudomanifolds we had obtained the same result in Theorem 98.4, but using a rather different argument.

Our richest source of simplicial homology manifolds are smooth manifolds. We obtain the following corollary to the Simplicial Poincaré Duality Theorem 103.4.

Theorem 103.5. (Poincaré Duality Theorem) Let M be a closed n-dimensional smooth manifold and let $k \in \mathbb{N}_0$. If M is orientable, then for every choice of orientation and every commutative ring R the map

$$\begin{array}{rcl} \mathrm{H}^k(M;R) & \to & \mathrm{H}_{n-k}(M;R) \\ \varphi & \mapsto & \varphi \cap [M] \end{array}$$

is an isomorphism. Regardless of whether or not M is orientable the map

$$\begin{array}{rcl} \mathrm{H}^k(M;\mathbb{F}_2) & \to & \mathrm{H}_{n-k}(M;\mathbb{F}_2) \\ \varphi & \mapsto & \varphi \cap [M]_{\mathbb{F}_2} \end{array}$$

is an isomorphism.

Proof. One can show easily (see e.g. the elementary future the Cup-Cap Disjoint Union Lemma 116.9) that we can assume that M is actually connected. Recall that by the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a smooth simplicial structure $(K = (V,S), f\colon |K| \to M)$. Without loss of generality we can assume that $|K| = M$. We denote by $\Xi_*\colon \mathrm{H}_k^{\mathrm{simp}}(K;R) \to \mathrm{H}_k(M;R)$ and $\Xi^*\colon \mathrm{H}^k(M;R) \to \mathrm{H}_k^{\mathrm{simp}}(K;R)$ the natural isomorphisms provided by Proposition 99.1 (1) and 99.6 (3). By Lemma 103.3 we know that K is a closed n-dimensional simplicial homology manifold.

Let us first deal with the case that M is equipped with a natural orientation. By Proposition 98.7 we know that the simplicial homology manifold K inherits an orientation. Next we consider the following diagram:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{simp}}(K;R) & \xrightarrow[\cong]{\cap[K]} & \mathrm{H}^{\mathrm{simp}}_{n-k}(K;R) \\ {\scriptstyle \Xi^*}\uparrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle \Xi_*} \\ \mathrm{H}^k(M;R) & \xrightarrow{\cap[M]} & \mathrm{H}^{\mathrm{simp}}_{n-k}(M;R). \end{array}$$

We make the following observations:

(1) By Algorithm 100.2 we know that $\Xi_*([K]) = [M]$.
(2) It follows from (1) and Proposition 99.17 (3) that the diagram commutes.
(3) The top horizontal map is an isomorphism by the Simplicial Poincaré Duality Theorem 103.4.

Since the vertical maps are isomorphisms we obtain from the above that the bottom horizontal map is, as promised, an isomorphism.

The proof for the statement regarding $\mathbb{F}_2$-coefficients is almost identical. We leave it to the reader to make the necessary straightforward modifications to the above argument. ■

There are many applications of the Poincaré Duality Theorem 103.5. In the following we will state two results. Since we have a predilection for smooth manifolds we state them in the context of smooth manifolds, but the statements also hold in the admittedly more general setting of simplicial homology manifolds.

Theorem 119.6. (Co-Homology Symmetry Theorem) Let M be a closed n-dimensional smooth manifold and let $k \in \mathbb{N}_0$.

(1) We have $\dim_{\mathbb{F}_2}(\mathrm{H}_k(M;\mathbb{F}_2)) = \dim_{\mathbb{F}_2}(\mathrm{H}_{n-k}(M;\mathbb{F}_2))$.
(2) If M is orientable, then for any field $\mathbb{F}$ we have $\dim_{\mathbb{F}}(\mathrm{H}_k(M;\mathbb{F})) = \dim_{\mathbb{F}}(\mathrm{H}_{n-k}(M;\mathbb{F}))$.

Proposition 119.7. The Euler characteristic of any closed odd-dimensional smooth manifold is zero.

As the reader will have noticed, the numbers of these results correspond to Chapter 119. In fact, in Chapter 119 we will prove a more general Poincaré Duality Theorem 119.1 that applies also to topological manifolds, possibly with boundary. In Section 119.2 we discuss many consequences of the Poincaré Duality Theorem 119.1. For closed smooth manifolds all statements in Section 119.2 can also be deduced from the above Poincaré Duality Theorem 103.5. In particular this way we obtain the above results. To avoid repetition, and for the sake of brevity, we do not spell out the proofs twice.

There are many other applications of the Poincaré Duality Theorem 103.5. Arguably one of the most interesting applications is that the Poincaré Duality Theorem 103.5 allows us to compute the cup product of the real and complex projective spaces. This will be done in Chapter 121.

Remark. The Poincaré Duality Theorem 103.5 has two significant limitations and one aesthetic issue.

(1) The theorem only deals with closed smooth manifolds. In fact the approach taken in the proof of Poincaré Duality Theorem 103.4 can be generalized, with some effort, to deal with compact (oriented) smooth manifolds with boundary. We refer to [**SZ1994**, Satz 14.8.8] for details.
(2) The Poincaré Duality Theorem 103.5 applies only to smooth manifolds. There is though some room for improvement. More precisely, the Simplicial Poincaré Duality Theorem 103.4 together with Lemma 103.3 shows that we have Poincaré Duality for any closed oriented topological manifold that admits a simplicial structure. But by Manolescu's Theorem 104.35 we know that for every $n \geq 5$ there exists a closed orientable n-dimensional topological manifold that does not admit a simplicial structure. Thus the Poincaré Duality Theorem 103.4 does not imply that Poincaré Duality holds for all closed topological manifolds.
(3) Even for smooth manifolds the proof of the Poincaré Duality Theorem 103.5 is aesthetically problematic since it makes use of the somewhat artificial choice of a simplicial structure.

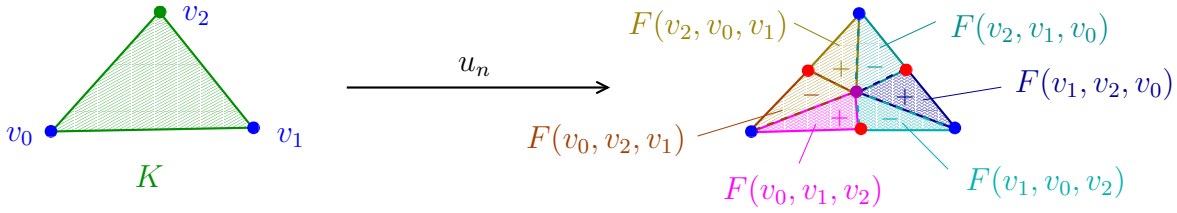
All three issues will be addressed by the Poincaré Duality Theorem 119.1 that we will state and prove in Chapter 119. Nonetheless, the (proof) of the Poincaré Duality Theorems 103.4 and 103.5 also have two advantages over the Poincaré Duality Theorem 119.1:

(1) The proofs in this chapter are much more visual, whereas the proof of the Poincaré Duality Theorem 119.1 is rather formal and it is difficult to get an intuition for "why" and "how" it works.
(2) More importantly, much later in Chapter **??** we will introduce a new invariant, namely Reidemeister torsion. The intermediate results in our proof of Poincaré Duality Theorem 103.4 will show that Reidemeister torsion of closed smooth manifolds is symmetric.

103.3. The barycentric subdivision.

The proof of the Simplicial Poincaré Duality Theorem 103.4 relies on a clever use of the barycentric subdivision of the simplicial homology

manifold. In this section we will recall the main definitions and statements on barycentric subdivisions which we will need later on in this chapter.
We recall the following definitions from pages 2014 and 2072.



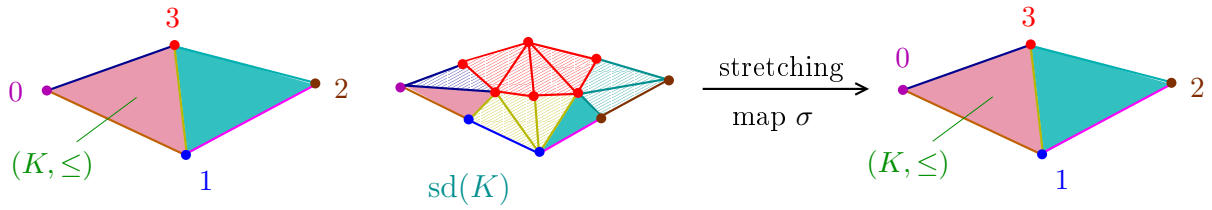
Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) For each k-simplex $s = \{v_0, \ldots, v_k\} \in S$ we define the barycenter of s to be the point
$$\underline{s} \;:=\; \sum_{v \in s} \frac{1}{\dim(s)+1} \cdot v \;=\; \frac{1}{k+1} \cdot v_0 + \cdots + \frac{1}{k+1} \cdot v_k \;\in\; \mathbb{R}^{(V)}.$$

(2) The barycentric subdivision of K is defined to be the following abstract simplicial complex:
$$\mathrm{sd}(K) \;=\; \big(\{\underline{s}\}_{s \in S}, \{\{\underline{s_0}, \ldots, \underline{s_k}\} \,|\, s_0 \subsetneq \cdots \subsetneq s_k\}\big).$$

(3) Given an ordered k-simplex $(v_0, \ldots, v_k)$ of K we consider the following ordered k-simplex of $\mathrm{sd}(K)$:
$$F(v_0, \ldots, v_k) \;:=\; \big(\underline{\{v_0\}}, \underline{\{v_0, v_1\}}, \ldots, \underline{\{v_0, \ldots, v_k\}}\big).$$

(4) Given an ordered k-simplex $s = (v_0, \ldots, v_k)$ of K we set
$$u_k(s) \;:=\; \sum_{\sigma \in \mathrm{Bij}\{0,\ldots,k\}} (-1)^{\mathrm{sign}(\sigma)} \cdot [F(v_{\sigma(0)}, \ldots, v_{\sigma(k)})] \;\in\; \mathrm{C}_k^{\mathrm{simp}}(\mathrm{sd}(K)).$$
We refer to the resulting map
$$\begin{array}{rcl} u_k \colon \mathrm{C}_k^{\mathrm{simp}}(K) & \to & \mathrm{C}_k^{\mathrm{simp}}(\mathrm{sd}(K)) \\ [s] & \mapsto & u_k(s) \end{array}$$
as the simplicial subdivision map. By the Chain Subdivision Lemma 95.41 (1) we know that these subdivision maps are actually well-defined and that they form a chain map.



Remark. Let $K = (V, S)$ be an abstract simplicial complex. Note that it follows easily from the definitions that given any n-simplex t of $\mathrm{sd}(K)$ there exists a unique ordered n-simplex $(v_0, \ldots, v_n)$ of K with $\lfloor F(v_0, \ldots, v_n) \rfloor = t$.

The following lemma shows that subdivision maps induce isomorphisms on simplicial (co-) homology groups.

Lemma 95.38. Let $(K, \leq)$ be an ordered abstract simplicial complex.

(1) There exists a unique simplicial map $\sigma \colon \mathrm{sd}(K) \to K$, called the *stretching map*, with the following property: given an n-simplex $s = \{v_0 < \cdots < v_n\}$ of K the map σ sends the corresponding vertex $\underline{s}$ of $\mathrm{sd}(K)$ to the vertex v_n of K.

The following lemma is an excerpt of the Chain Subdivision Lemma 95.41 together with a little dose of the Dual Cochain Map Lemma 108.8 (4).

Lemma 95.41. Let K be an abstract simplicial complex. We pick an order on K and we consider the corresponding stretching map $\sigma\colon \mathrm{sd}(K) \to K$.

(5) For every choice of some $k \in \mathbb{N}_0$ and of some abelian group G the two induced maps $u_*\colon \mathrm{H}_k^{\mathrm{simp}}(K; G) \to \mathrm{H}_k^{\mathrm{simp}}(\mathrm{sd}(K); G)$ and $u^*\colon \mathrm{H}^k_{\mathrm{simp}}(\mathrm{sd}(K); G) \to \mathrm{H}^k_{\mathrm{simp}}(K; G)$ are isomorphisms and the inverses are given by σ_* and σ^*.

Next we turn to barycentric subdivisions of pseudomanifolds. At this point it is convenient to introduce the following definition.

Definition. Let $K = (V, S)$ be a closed oriented n-dimensional pseudomanifold. Given an ordered n-simplex t of K we write

$$\mathrm{sign}(t) := \begin{cases} +1, & \text{if the oriented } n\text{-simplex } [(+1, t)] \text{ corresponds to the orientation,} \\ -1, & \text{otherwise.} \end{cases}$$

The following lemma contains everything anybody ever wanted to know about barycentric subdivisions of closed pseudomanifolds.

Lemma 103.6. Let $K = (V, S)$ be a closed n-dimensional pseudomanifold.

(1) The barycentric subdivision $\mathrm{sd}(K)$ is a closed n-dimensional pseudomanifold.

(2) Suppose that K is equipped with an orientation. Let t be an n-simplex of $\mathrm{sd}(K)$. As we pointed out on page 2269, there exists a unique ordered n-simplex $(v_0, \ldots, v_n)$ of K with $\lfloor F(v_0, \ldots, v_n) \rfloor = t$. We equip the n-simplex t of $\mathrm{sd}(K)$ with the orientation given by $(\mathrm{sign}(t), F(v_0, \ldots, v_n))$.
   (a) The above orientations of the n-simplices define an orientation for $\mathrm{sd}(K)$.
   (b) We have $u_*([K]) = [\mathrm{sd}(K)] \in \mathrm{H}_n^{\mathrm{simp}}(\mathrm{sd}(K))$.

(3) If K is oriented, then given any $k \in \mathbb{N}_0$ and given any commutative ring R the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{simp}}(K; R) & \xrightarrow{\cap [K]} & \mathrm{H}^{\mathrm{simp}}_{n-k}(K; R) \\ {\scriptstyle u^*}\uparrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle u_*} \\ \mathrm{H}^k_{\mathrm{simp}}(\mathrm{sd}(K); R) & \xrightarrow{\cap [\mathrm{sd}(K)]} & \mathrm{H}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K); R). \end{array}$$

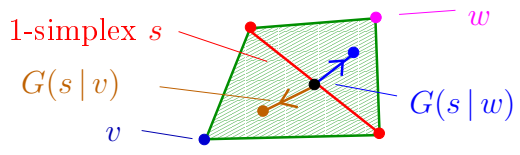
The analogues of (2) and (3) hold for arbitrary closed n-dimensional pseudomanifolds if we work with $\mathbb{F}_2$-coefficients and the simplicial $\mathbb{F}_2$-fundamental classes $[K]_{\mathbb{F}_2}$ and $[\mathrm{sd}(K)]_{\mathbb{F}_2}$.

Sketch of proof. Statements (1) and (2a) follow almost immediately from the definitions, the proof is outsourced to Exercise 98.5. Furthermore Statement (2b) can be deduced easily from the definition of the fundamental class on page 2143 and the definition of the subdivision map $u_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_n^{\mathrm{simp}}(\mathrm{sd}(K))$. We leave it to the reader to fill in the details.

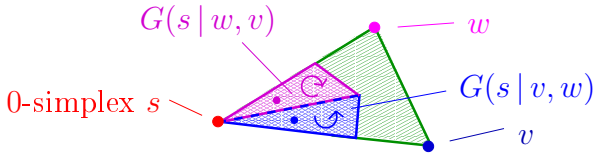
Next we turn to the proof of (3). We pick an order "$\leq$" on K and we denote by $\sigma\colon \mathrm{sd}(K) \to K$ the corresponding stretching map. Note that by the above the Chain Subdivision Lemma 95.41 (5) we know that $u_* = \sigma_*^{-1}$ and $u^* = (\sigma^*)^{-1}$. It follows that it suffices to show that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{simp}}(K;R) & \xrightarrow{\quad\cap[K]\quad} & \mathrm{H}^{\mathrm{simp}}_{n-k}(K;R) \\ {\scriptstyle\sigma^*}\downarrow{\scriptstyle\cong} & & {\scriptstyle\cong}\uparrow{\scriptstyle\sigma_*} \\ \mathrm{H}^k_{\mathrm{simp}}(\mathrm{sd}(K);R) & \xrightarrow{\cap[\mathrm{sd}(K)]} & \mathrm{H}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K);R). \end{array}$$

Now let $\varphi \in \mathrm{H}^k_{\mathrm{simp}}(K;R)$. We see that we have the following equalities:



$$\sigma_*(\sigma^*(\varphi) \cap [\mathrm{sd}(K)]) \underset{\substack{\uparrow\\ \text{by Lemma 99.20, here we use}\\ \text{that } \sigma\colon \mathrm{sd}(K)\to K \text{ is a simplicial map}}}{=} \varphi \cap \sigma_*([\mathrm{sd}(K)]) \underset{\substack{\uparrow\\ \text{by (2b)}}}{=} \varphi \cap [K].$$



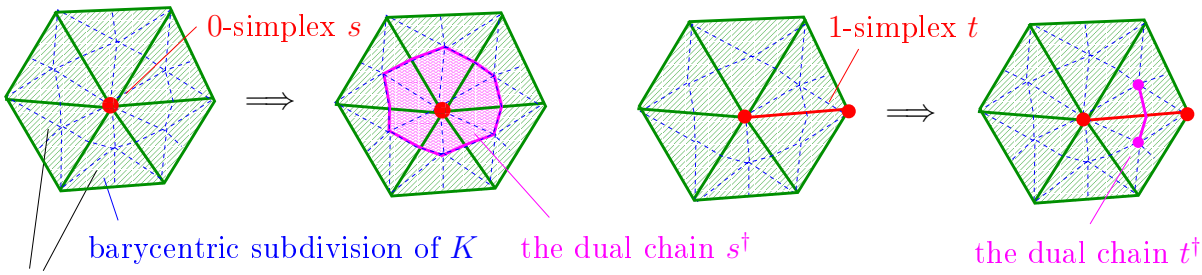
Finally we leave it to the reader to verify that the $\mathbb{F}_2$-analogues also hold. ∎

103.4. **The dual chain complex I.** In this section, given a pseudomanifold K, we will introduce the dual chain complex $\mathrm{D}^{\mathrm{simp}}_*(K)$. This is the main new concept needed for the proof of the Simplicial Poincaré Duality Theorem 103.4.

Definition. Let $K = (V, S)$, let $s \in S$ be a k-simplex and let $v_1, \ldots, v_l \in V$ such that $s \cup \{v_1, \ldots, v_l\}$ is a $(k+l)$-simplex of K. We set

$$G(s \,|\, v_1, \ldots, v_l) = \overbrace{\big(\underline{s}, \underline{s \cup \{v_1\}}, \ldots, \underline{s \cup \{v_1, \ldots, v_l\}}\big)}^{\text{ordered } l\text{-simplex of } \mathrm{sd}(K)}.$$

Remark. Note that for an ordered k-simplex $s = (v_0, \ldots, v_k)$ of K we have by definition $G(\{v_0\} \,|\, v_1, \ldots, v_k) = F(v_0, \ldots, v_k)$.



Definition. Let $K = (V, S)$ be a closed oriented n-dimensional pseudomanifold.

(1) Let $s = (v_0, \ldots, v_k)$ be an ordered k-simplex of K. We define the dual chain of s to be the following simplicial chain in $\mathrm{C}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K))$:

$$s^\dagger := \sum_{\substack{(v_{k+1}, \ldots, v_n) \in V^{n-k} \text{ such that} \\ \{v_0, \ldots, v_k, v_{k+1}, \ldots, v_n\} \in S_n}} \mathrm{sign}((v_0, \ldots, v_k, v_{k+1}, \ldots, v_n)) \cdot [\, \underbrace{G(s \,|\, v_{k+1}, \ldots, v_n)}_{\text{ordered } (n-k)\text{-simplex of } \mathrm{sd}(K)} \,].$$

(2) We define

$$\mathrm{D}^{\mathrm{simp}}_{n-k}(K) = \begin{array}{c}\text{subgroup of } \mathrm{C}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K)) \text{ generated by the } s^\dagger,\\ \text{where } s \text{ runs over all } k\text{-simplices of } K.\end{array}$$

part of the pseudomanifold K

Lemma 103.7. Let $K = (V, S)$ be a closed oriented n-dimensional pseudomanifold and let $k \in \mathbb{N}_0$.

(1) Given two ordered k-simplices s and $\widetilde{s}$ with $[s] = [\widetilde{s}] \in \mathrm{C}_k^{\mathrm{simp}}(K)$ we have $s^\dagger = \widetilde{s}^\dagger$.

(2) Let "$\leq$" be an order on $K = (V, S)$. The dual chains

$$\{s^\dagger \,|\, s = (v_0, \ldots, v_k) \text{ an ordered } k\text{-simplex of } K \text{ with } v_0 < \cdots < v_k\}$$

form a basis for $\mathrm{D}_{n-k}^{\mathrm{simp}}(K)$.

Proof. The first statement of the lemma follows easily from the definitions. Thus let us turn to the proof of the second statement. We pick an order "$\leq$" on $K = (V, S)$. We set

$$Y \;:=\; \{(v_0, \ldots, v_k) \in V^{k+1} \,|\, \{v_0, \ldots, v_k\} \in S_k \text{ and } v_0 < \cdots < v_k\}.$$

Recall that by the Manifold-Simplex Proposition 98.1 we know that in a closed n-dimensional pseudomanifold any simplex is the face of an n-simplex. It follows that given any $y = (v_0, \ldots, v_k) \in Y$ we can pick an ordered $(n-k)$-simplex $\widetilde{y} = (w_0, \ldots, w_{n-k})$ of K such that $v_k = w_0$, such that $\{v_0, \ldots, v_k = w_0, \ldots, w_{n-k}\} \in S_n$ and such that $w_1 < \cdots < w_{n-k}$. We make the following observation:

$(*)$ It follows easily from the definition of an order that for $y_1 \neq y_2 \in Y$ we have $\widetilde{y}_1 \neq \widetilde{y}_2$.

Now we consider the following maps:

$$\begin{array}{ccccc}
\bigoplus_{y \in Y} \mathbb{Z} \cdot y & \xrightarrow{y \mapsto y^\dagger} & \mathrm{D}_{n-k}^{\mathrm{simp}}(K) & \xhookrightarrow{\iota} & \mathrm{C}_{n-k}^{\mathrm{simp}}(\mathrm{sd}(K)) \\
\Big\downarrow{\scriptstyle y \,\updownarrow\, \widetilde{y}} & & & & \Big\uparrow{\scriptstyle \Phi} \;\; \Big\downarrow{\scriptstyle \Phi^{-1}} \\
\bigoplus_{\{\widetilde{y} \,|\, y \in Y\}} \mathbb{Z} \cdot \widetilde{y} & \xleftarrow[p]{\text{projection}} & \bigoplus_{\substack{(w_0, \ldots, w_{n-k}) \\ \text{ordered} \\ (n\text{-}k)\text{-simplex of } K}} \mathbb{Z} \cdot (w_0, \ldots, w_{n-k}) & & F(w_0, \ldots, w_{n-k}) \,\updownarrow\, (w_0, \ldots, w_{n-k})
\end{array}$$

We make the following observations:

(a) The right vertical map is an isomorphism. This follows from the observation, which we basically already mentioned on page 2269, that given any ordered $(n-k)$-simplex $(\underline{s}_0, \ldots, \underline{s}_{n-k})$ of $\mathrm{sd}(K)$ with $s_0 \subsetneq s_1 \subsetneq \cdots \subsetneq s_{n-k}$ there exists a unique ordered n-simplex $(w_0, \ldots, w_{n-k})$ of K with $F(w_0, \ldots, w_{n-k}) = (\underline{s}_0, \ldots, \underline{s}_{n-k})$.

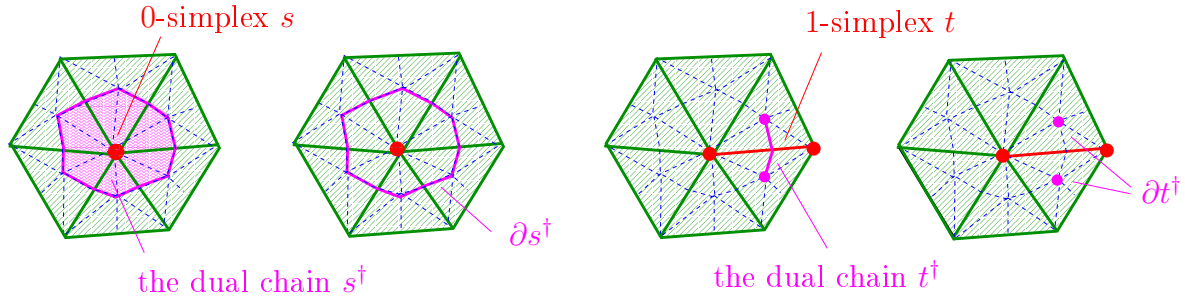
(b) It follows immediately from the definitions of the various maps that the diagram commutes.

Now we turn to the actual proof of the second statement of the lemma. First note that it follows from (1) that $\{y^\dagger\}_{y\in Y}$ form a generating set for $\mathrm{D}^{\mathrm{simp}}_{n-k}(K)$. Secondly note that it follows from (a) and (b) that the map $p\circ\Phi^{-1}\circ\iota\colon \mathrm{D}^{\mathrm{simp}}_{n-k}(K)\to \bigoplus_{\{\widetilde{y}\,|\,y\in Y\}}\mathbb{Z}\cdot\widetilde{y}$ sends $y^\dagger$ to $\widetilde{y}$. It follows from $(*)$ that the $\{y^\dagger\}_{y\in Y}$ are linearly independent. Thus we have shown that the given dual chains $\{y^\dagger\}_{y\in Y}$ are a basis for $\mathrm{D}^{\mathrm{simp}}_{n-k}(K)$. ■

To fully appreciate our next lemma it is worth recalling the following lemma.

Lemma 99.4. Let $K=(V,S)$ be an abstract simplicial complex. Given any ordered k-simplex $s=(v_0,\ldots,v_k)$ we have the following equality:

$$\delta_k([v_0,\ldots,v_k]^*) \;=\; (-1)^{k+1}\cdot \sum_{\substack{w\in V \text{ such that}\\ \{v_0,\ldots,v_k,w\} \text{ is}\\ \text{a } (k+1)\text{-simplex}}} [v_0,\ldots,v_k,w]^* \;\in\; \mathrm{C}^{k+1}_{\mathrm{simp}}(K;\mathbb{Z}).$$



Now we can state the promised lemma. Its statement perfectly matches the statement of Lemma 99.4.

Lemma 103.8. Let $K=(V,S)$ be an abstract simplicial complex that is an orientable n-dimensional pseudomanifold.

(1) Given any ordered k-simplex $s=(v_0,\ldots,v_k)$ we have the following equality:

$$\partial_{n-k}(\underbrace{[v_0,\ldots,v_k]^\dagger}_{\in \mathrm{C}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K))}) \;=\; \sum_{\substack{w\in V \text{ such that}\\ \{v_0,\ldots,v_k,w\}\in S_{k+1}}} [v_0,\ldots,v_k,w]^\dagger \;\in\; \mathrm{C}^{\mathrm{simp}}_{n-k-1}(\mathrm{sd}(K)).$$

(2) The groups $\mathrm{D}^{\mathrm{simp}}_*(K)$ form a subcomplex of $\mathrm{C}^{\mathrm{simp}}_*(\mathrm{sd}(K))$.

Proof. The second statement is an immediate consequence of the first statement. Thus we just need to prove the first statement. We start out with the following elementary observation.

Observation. Let $s=(v_0,\ldots,v_k)$ be some ordered k-simplex of K and furthermore let $(v_{k+1},\ldots,v_n)\in V^{n-k}$ such that $s\cup\{v_{k+1},\ldots,v_n\}=\{v_0,\ldots,v_k,v_{k+1},\ldots,v_n\}\in S_n$. Given any $i\in\{1,\ldots,n-k-1\}$ we have by definition

$$G(s\,|\,v_{k+1},..,v_n) \text{ with } i\text{-th vertex removed} = (\underline{s},..,\underline{s\cup\{v_{k+1},..,v_{k+i-1}\}},\underline{s\cup\{v_{k+1},..,v_{k+i+1}\}},..,\underline{s\cup\{v_{k+1},..,v_n\}}).$$

Furthermore it follows immediately from the definitions that we have

$$\begin{aligned} G(s\,|\,v_{k+1},..,v_n) \text{ with 0-th vertex removed} &= G(s\cup\{v_{k+1}\}\,|\,v_{k+2},\ldots,v_n)\\ G(s\,|\,v_{k+1},..,v_n) \text{ with } (n-k)\text{-th vertex removed} &= G(s\,|\,v_{k+1},v_{k+2},\ldots,v_{n-1}).\end{aligned}$$

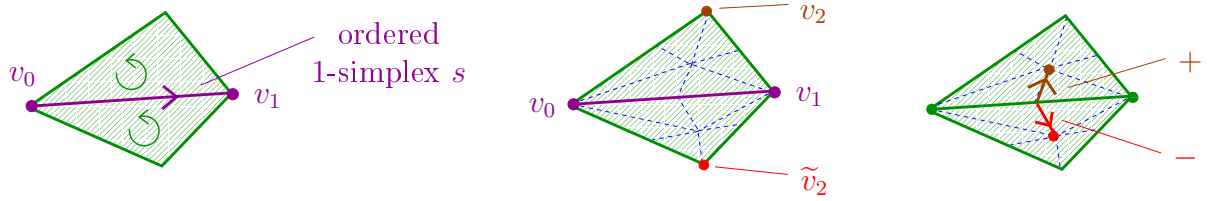
Now we turn to the actual proof of the first statement. Thus let $s = (v_0, \dots, v_k)$ be an ordered k-simplex of K. We see that

definition of $s^\dagger$ and definition of the simplicial boundary map

$$\partial s^\dagger \overset{\downarrow}{=} \sum_{\substack{(v_{k+1},\dots,v_n)\in V^{n-k} \text{ such that} \\ \{v_0,\dots,v_k,v_{k+1},\dots,v_n\}\in S_n}} \sum_{i=0}^{n-k} (-1)^i \cdot \operatorname{sign}(v_0,\dots,v_n) \cdot \begin{bmatrix} G(s \,|\, v_{k+1},\dots,v_n) \text{ with} \\ i\text{-th vertex removed} \end{bmatrix}$$

$$= \sum_{\substack{(v_{k+1},\dots,v_n)\in V^{n-k} \text{ such that} \\ \{v_0,\dots,v_k,v_{k+1},\dots,v_n\}\in S_n}} \sum_{i=0 \text{ or } i=n-k} (-1)^i \cdot \operatorname{sign}(v_0,\dots,v_n) \cdot \begin{bmatrix} G(s \,|\, v_{k+1},\dots,v_n) \text{ with} \\ i\text{-th vertex removed} \end{bmatrix}$$

given a fixed $(v_{k+1},\dots,v_n) \in V^{n-k}$ with $\{v_0,\dots,v_k,v_{k+1},\dots,v_n\} \in S_n$ and given $i \in \{1,\dots,n-k-1\}$ it follows almost immediately from the above observation that the contributions by $((v_{k+1},\dots,v_{k+i},v_{k+i+1},\dots,v_n),i)$ and $((v_{k+1},\dots,v_{k+i+1},v_{k+i},\dots,v_n),i+1)$ cancel, in other words, for $i = 1,\dots,n-k-1$ all terms cancel



$$= \sum_{\substack{(v_{k+1},\dots,v_n)\in V^{n-k} \text{ such that} \\ \{v_0,\dots,v_k,v_{k+1},\dots,v_n\}\in S_n}} \operatorname{sign}(v_0,\dots,v_n) \cdot \begin{bmatrix} G(s \,|\, v_{k+1},\dots,v_n) \text{ with} \\ 0\text{-th vertex removed} \end{bmatrix}$$

by definition of a closed pseudomanifold every $(n-1)$-simplex has order 2, since the pseudomanifold is oriented we obtain from the above observation that all contributions for $i = n-k$ cancel

$$= \sum_{\substack{v_{k+1}\in V \text{ such that} \\ \{v_0,..,v_k,v_{k+1}\}\in S_{k+1}}} \sum_{\substack{(v_{k+2},..,v_n)\in V^{n-k-1} \text{ such that} \\ \{v_0,..,v_k,v_{k+1},v_{k+2},..,v_n\}\in S_n}} \operatorname{sign}(v_0,..,v_n) \cdot [G(s \cup \{v_{k+1}\} \,|\, v_{k+2},..,v_n)]$$

follows from fact that any subset of a simplex is again a simplex, we also use the above observation to rewrite the summand

$$= \sum_{\substack{w\in V \text{ such that} \\ \{v_0,\dots,v_k,w\}\in S_{k+1}}} [v_0,\dots,v_k,w]^\dagger. \qquad \blacksquare$$

Using 103.8 we can now easily prove the following proposition which is one of the key steps in the proof of the Simplicial Poincaré Duality Theorem 103.4.

Proposition 103.9. Let $K = (V, S)$ be a closed oriented n-dimensional pseudomanifold.

(1) For each $k \in \mathbb{N}_0$ the map

$$\begin{array}{rccc} \Lambda\colon & \operatorname{Hom}(\mathrm{C}_k^{\mathrm{simp}}(K), \mathbb{Z}) & \to & \mathrm{D}_{n-k}^{\mathrm{simp}}(K) \\ & \sum_{i=1}^m a_i \cdot s_i^* & \mapsto & \sum_{i=1}^m a_i \cdot s_i^\dagger \end{array}$$

here s_i is a k-simplex of K and we define $s_i^* \colon \mathrm{C}^k_{\mathrm{simp}}(K) \to \mathbb{Z}$ as on page 2174

is a natural isomorphism of abelian groups.

(2) For each $k \in \mathbb{N}_0$ the following diagram commutes:

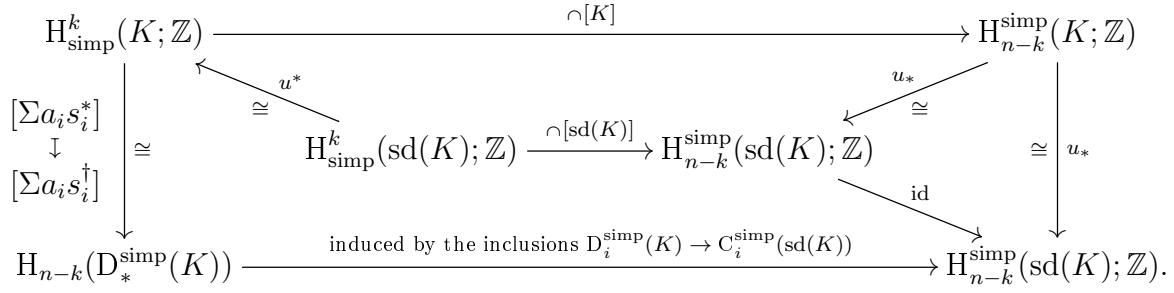
$$\begin{array}{ccc} \mathrm{Hom}(\mathrm{C}_k^{\mathrm{simp}}(K), \mathbb{Z}) & \xrightarrow[\Lambda]{s^* \mapsto s^\dagger} & \mathrm{D}_{n-k}^{\mathrm{simp}}(K) \\ \downarrow{\scriptstyle (-1)^k \cdot \delta_k = (-1)^k \cdot \partial_{k+1}^*} & & \downarrow{\scriptstyle \partial_{n-k}} \\ \mathrm{Hom}(\mathrm{C}_{\mathrm{simp}}^{k+1}(K), \mathbb{Z}) & \xrightarrow[\Lambda]{s^* \mapsto s^\dagger} & \mathrm{D}_{n-k-1}^{\mathrm{simp}}(K). \end{array}$$

(3) The maps

$$\begin{array}{rcl} \Lambda_* \colon \mathrm{H}_{\mathrm{simp}}^k(K; \mathbb{Z}) & \to & \mathrm{H}_{n-k}(\mathrm{D}_*^{\mathrm{simp}}(K)) \\ \left[\sum_{i=1}^m a_i \cdot s_i^*\right] & \mapsto & \left[\sum_{i=1}^m a_i \cdot s_i^\dagger\right] \end{array}$$

are well-defined and they are natural isomorphisms.

Proof.



(1) First note that K is by definition a finite abstract simplicial complex. Thus it follows immediately from Lemma 99.2 and Lemma 103.7 (2) that the maps Λ are isomorphisms. Basically by definition the maps Λ are natural.

(2) Let $k \in \mathbb{N}_0$ and let $s = (v_0, \ldots, v_k)$ be an ordered k-simplex of K. We calculate that

$$\partial_{n-k}(\Lambda(s)) = \partial_{n-k}([v_0, .., v_k]^\dagger) \overset{\text{Lemma 103.8}}{=} \sum_{\substack{w \in V \text{ such that} \\ \{v_0, \ldots, v_k, w\} \in S_{k+1}}} [v_0, \ldots, v_k, w]^\dagger \overset{\text{Lemma 99.4}}{=} (-1)^k \cdot \Lambda(\delta_k([v_0, .., v_k]^*).$$

(3) In (2) we showed that the maps Λ are cochain maps "up to sign", i.e. they are generalized cochain maps in the sense of the discussion on page 2398. As we pointed out on page 2398, this sign issue is completely irrelevant and we still get a well-defined map on cohomology groups. Furthermore, by (1) we know that the maps on each cochain level are isomorphisms, thus we get in fact an isomorphism of cohomology groups. ■

It is a good moment to keep stock of where we are in the proof of the Simplicial Poincaré Duality Theorem 103.4. Let K be a closed oriented n-dimensional simplicial homology manifold and let $k \in \mathbb{N}_0$. Let us consider the following diagram:

Our main goal is to show that the top horizontal map is an isomorphism. By now we already know the following:

(1) By Proposition 103.9 we now know that the left vertical map is an isomorphism.

(2) By the Chain Subdivision Lemma 95.41 we know that the subdivision maps u_* and u^* are isomorphisms.

(3) By Lemma 103.6 (3) we know that the upper quadrilateral commutes.

Thus to prove the core of the Simplicial Poincaré Duality Theorem 103.4 it remains to carry out the following steps:

(4) We need to show that the lower left part of the diagram commutes.

(5) We need to show that the bottom horizontal map is an isomorphism.

As we will see in a second, Step (4) follows from a fairly straightforward calculation. Step (5) is much more difficult and we postpone Step (5) to the next section. Note though that Step (5) is particularly interesting since so far we have only used that K is a closed n-dimensional pseudomanifold. We did not yet use the hypothesis that we are dealing with a simplicial homology manifold.

As promised, here is the lemma that takes care of Step (4).

Lemma 103.10. Given any closed oriented n-dimensional pseudomanifold K the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{simp}}(K;\mathbb{Z}) & \xleftarrow[\cong]{u^*} & \mathrm{H}^k_{\mathrm{simp}}(\mathrm{sd}(K);\mathbb{Z}) \\ {\scriptstyle [\Sigma a_i s_i^*]} \updownarrow {\scriptstyle [\Sigma a_i s_i^\dagger]} \Big\downarrow \cong & & \Big\downarrow {\scriptstyle \cap[\mathrm{sd}(K)]} \\ \mathrm{H}_{n-k}(\mathrm{D}^{\mathrm{simp}}_*(K)) & \longrightarrow & \mathrm{H}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K);\mathbb{Z}). \end{array}$$

Proof. Let $K = (V, S)$ be a closed oriented n-dimensional pseudomanifold. Given two k-simplices s and t of K we write $\underline{s} \leq \underline{t}$ if $s \subset t$. As we pointed out in Lemma 94.2, this order on the vertex set of $\mathrm{sd}(K)$ turns $\mathrm{sd}(K)$ naturally into an ordered abstract simplicial complex. In the following we use the natural isomorphisms $\mathrm{C}^{\mathrm{simp},\leq}_k(\mathrm{sd}(K)) \to \mathrm{C}^{\mathrm{simp}}_k(\mathrm{sd}(K))$ and $\mathrm{C}^k_{\mathrm{simp}}(\mathrm{sd}(K);\mathbb{Z}) \to \mathrm{C}^k_{\mathrm{simp},\leq}(\mathrm{sd}(K);\mathbb{Z})$ to identify these two (co-) chain complexes and throughout the proof we will work with $\mathrm{C}^{\mathrm{simp}}_k(\mathrm{sd}(K))$ and $\mathrm{C}^k_{\mathrm{simp}}(\mathrm{sd}(K))$.

We set

$$\mu := \sum_{\substack{(u_0,\dots,u_n) \text{ ordered} \\ n\text{-simplex of } K}} \mathrm{sign}(u_0,\dots,u_n) \cdot [\underline{\{u_0\}}, \underline{\{u_0,u_1\}}, \dots, \underline{\{u_0,\dots,u_n\}}] \in \mathrm{C}^{\mathrm{simp}}_n(\mathrm{sd}(K)).$$

It follows immediately from Lemma 103.6 and Theorem 98.4 that μ is a simplicial cycle that represents the simplicial fundamental class $[\mathrm{sd}(K)] \in \mathrm{H}^{\mathrm{simp}}_n(\mathrm{sd}(K))$.

Next we pick an order "$\leq$" on K and we denote by $\sigma\colon \mathrm{sd}(K) \to K$ the corresponding stretching map, as defined on page 2269. Recall that by the Chain Subdivision Lemma 95.41 we know that $\sigma^*\colon \mathrm{H}^k_{\mathrm{simp}}(K;\mathbb{Z}) \to \mathrm{H}^k_{\mathrm{simp}}(\mathrm{sd}(K);\mathbb{Z})$ and $u^*\colon \mathrm{H}^k_{\mathrm{simp}}(\mathrm{sd}(K);\mathbb{Z}) \to \mathrm{H}^k_{\mathrm{simp}}(K;\mathbb{Z})$ are inverses of one another. Thus it remains to prove the following claim.[1252]

[1252] Here, as on many other occasions we will use the remark on page 2046 to make the identification $\mathrm{C}^{\mathrm{simp}}_*(\mathrm{sd}(K)) = \mathrm{C}^{\mathrm{simp}}_*(\mathrm{sd}(K);\mathbb{Z})$.

Claim. The following diagram commutes:[1253]

$$\begin{array}{ccc} \mathrm{C}^k_{\mathrm{simp}}(K;\mathbb{Z}) & \xrightarrow{\quad\sigma^*\quad} & \mathrm{C}^k_{\mathrm{simp}}(\mathrm{sd}(K);\mathbb{Z}) \\ \Sigma a_i s_i^* \downarrow \Sigma a_i s_i^\dagger \;\cong & & \downarrow \cap\mu \\ \mathrm{D}^{\mathrm{simp}}_{n-k}(K) & \hookrightarrow & \mathrm{C}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K)). \end{array}$$

Proof. The verification of the claim consists of a careful, but at the end of the day elementary, calculation. Note that by Lemma 99.2 (2) it suffices to show that for every ordered k-simplex $s = (v_0, \dots, v_k)$ of K with $v_0 < \cdots < v_k$ we have the following equality:

$$\sigma^*(s^*) \cap \mu \;=\; s^\dagger \;\in\; \mathrm{C}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K)).$$

To verify this equality it is helpful to first do one specific calculation separately. Namely let $(z_0, \dots, z_k)$ be some other ordered k-simplex of S. We perform the following little calculation:

$$\sigma^*(s^*)([\underline{\{z_0\}}, \dots, \underline{\{z_0, \dots, z_k\}}]) \overset{\text{definition of } \sigma^*}{=} s^*(\sigma_*([\underline{\{z_0\}}, \dots, \underline{\{z_0, \dots, z_k\}}]))$$

$$= \begin{cases} (v_0, \dots, v_k)^*(z_0, \dots, z_k), & \text{if } z_0 < \dots < z_k, \\ 0, & \text{otherwise} \end{cases} = \begin{cases} 1, & \text{if } (v_0, \dots, v_k) = (z_0, \dots, z_k), \\ 0, & \text{otherwise.} \end{cases}$$

by the definition of the stretching map we see that $\{\sigma(\underline{\{z_0\}}), \dots, \sigma(\underline{\{z_0, \dots, z_k\}})\}$ is a k-simplex only if $z_0 < \cdots < z_k$, furthermore if $z_0 < \cdots < z_k$, then $\sigma(\underline{\{z_0\}}, \dots, \underline{\{z_0, \dots, z_k\}})) = (z_0, \dots, z_k)$

Now we can verify that $\sigma^*(s^*) \cap \mu = s^\dagger$. Indeed:

$$\sigma^*(s^*) \cap \mu \;=\; \sigma^*(s^*) \cap \Big(\sum_{\substack{(z_0,..,z_n) \text{ ordered} \\ n\text{-simplex of } K}} \mathrm{sign}(z_0,..,z_n) \cdot [\underline{\{z_0\}}, \underline{\{z_0, z_1\}}, .., \underline{\{z_0, .., z_n\}}] \Big)$$

(definition of μ)

by definition of the cap product, here we use that $\underline{\{z_0\}} < \underline{\{z_0, z_1\}} < \dots < \underline{\{z_0, .., z_n\}}$

$$= \sum_{\substack{(z_0,..,z_n) \text{ ordered} \\ n\text{-simplex of } K}} \mathrm{sign}(z_0,..,z_n) \cdot \sigma^*(s^*)([\underline{\{z_0\}}, .., \underline{\{z_0, .., z_k\}}]) \cdot \underbrace{[\underline{\{z_0, .., z_{k+1}\}}, .., \underline{\{z_0, .., z_n\}}]}_{= G(\{z_0,..,z_k\} \,|\, z_{k+1},..,z_n)}$$

$$= \sum_{\substack{(z_0,..,z_n) \text{ ordered} \\ n\text{-simplex of } K \text{ with} \\ (z_0,..,z_k) = (v_0,..,v_k)}} \mathrm{sign}(z_0,..,z_n) \cdot G(\underbrace{\{v_0,..,v_k\}}_{=s} \,|\, z_{k+1},..,z_n) \;=\; s^\dagger.$$

by the above calculation

by definition of $s^\dagger$, see page 2271

■

103.5. **The dual chain complex II.** As mentioned in the last section, the following proposition is the last major puzzle-piece in the proof of the Simplicial Poincaré Duality Theorem 103.4.

Proposition 103.11. Let K be a closed n-dimensional simplicial homology manifold.

(1) The inclusion map $\mathrm{D}^{\mathrm{simp}}_*(K) \to \mathrm{C}^{\mathrm{simp}}_*(\mathrm{sd}(K))$ is a chain homotopy equivalence.

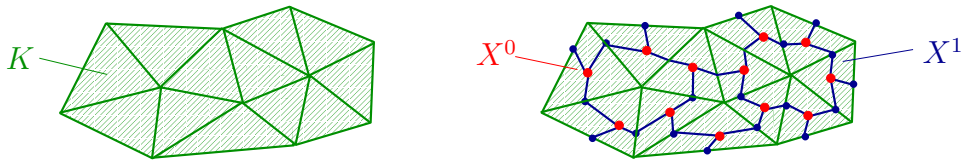
[1253] It follows from Proposition 103.9 and the formula in the proof of Lemma 99.16 that the two vertical maps are (co-) chain maps "up to the sign $(-1)^k$".

(2) For every abelian group G the induced maps $\mathrm{H}_k(\mathrm{D}^{\mathrm{simp}}_*(K)\otimes G)\to \mathrm{H}^{\mathrm{simp}}_k(\mathrm{sd}(K);G)$ are isomorphisms.

Remark.

(1) Note that in Proposition 103.11 we finally work with simplicial homology manifolds and not just with pseudomanifolds.
(2) Note that in Proposition 103.11 we do not demand that K is orientable.
(3) In Section 103.7 we will see that the dual chain complex $\mathrm{D}^{\mathrm{simp}}_*(K)$ can be viewed as the cellular chain complex of a "dual CW-structure" on $|K|$. The proof of Proposition 103.11 is in fact similar in spirit to the proof, given in the Singular-Cellular H_*-Isomorphism Proposition 80.4 and the Singular-Cellular Chain Complex Proposition 81.12 (2), that the cellular chain complex of a CW-complex X is chain homotopy equivalent to the singular chain complex of X.

Definition. Let $K=(V,S)$ be an n-dimensional abstract simplicial complex.



(1) Given $k\in\mathbb{N}_0$ we define

$$X^k := \begin{array}{c}\text{all simplices of } \mathrm{sd}(K) \text{ of the form } G(s\,|\,v_1,\ldots,v_l)\\ \text{where } s \text{ is a simplex of } S \text{ of dimension at least } n-k\end{array}$$

It follows immediately from the definitions that X^k can be viewed as a k-dimensional subcomplex of $\mathrm{sd}(K)$ and that $X^n=\mathrm{sd}(K)$.

(2) Let $k\in\mathbb{N}_0$. Similar to the discussion on page 1769 we consider the map

$$\begin{array}{rcl} d_k\colon \mathrm{H}^{\mathrm{simp}}_k(X^k,X^{k-1}) & \to & \mathrm{H}^{\mathrm{simp}}_k(X^{k-1},X^{k-2})\\ [\sigma] & \mapsto & [\partial_k(\sigma)].\\ \uparrow & & \\ \text{where } \sigma\in \mathrm{C}^{\mathrm{simp}}_k(X^k) & & \end{array}$$

The following lemma can be viewed as a partial analogue of the Skeleton-Homology Lemma 80.1.

Lemma 103.12. Let $K=(V,S)$ be a closed n-dimensional simplicial homology manifold and let $k\in\mathbb{N}_0$.

(1) For $i\neq k$ we have $\mathrm{H}^{\mathrm{simp}}_i(X^k,X^{k-1})=0$.
(2) The map

$$\begin{array}{rcl}\Theta\colon \mathrm{D}^{\mathrm{simp}}_k(K) & \to & \mathrm{H}^{\mathrm{simp}}_k(X^k,X^{k-1})\\ \sigma & \mapsto & [\sigma]\end{array}$$

is well-defined, i.e. every chain $\sigma\in\mathrm{D}^{\mathrm{simp}}_k(K)$ does indeed represent a cycle in $\mathrm{C}^{\mathrm{simp}}_k(X^k,X^{k-1})$. Furthermore the map Θ is an isomorphism.

(3) The maps Θ introduced in (2) define an isomorphism of chain complexes

$$(\mathrm{D}^{\mathrm{simp}}_k(K),\partial_k) \to (\mathrm{H}^{\mathrm{simp}}_k(X^k,X^{k-1}),d_k).$$

Proof. Let $K=(V,S)$ be a closed n-dimensional simplicial homology manifold. Given $l\in\mathbb{N}_0$ we denote by S_l the set of l-simplices of K. Given an $(n-k)$-simplex $s\in S_{n-k}$ we

define the following:[1254]

$$\begin{aligned} Z(s) &= \{ \text{ all simplices of } \mathrm{sd}(K) \text{ of the form } G(t \,|\, v_1, \ldots, v_l) \text{ with } s \subset t \} \subset X^k \\ \partial Z(s) &= \{ \text{ all simplices of } \mathrm{sd}(K) \text{ of the form } G(t \,|\, v_1, \ldots, v_l) \text{ with } s \subsetneq t \} \subset X^{k-1}. \end{aligned}$$

Claim 1. Let s be an $(n-k)$-simplex of K. Given any $l \in \mathbb{N}$ we have

$$\widetilde{\mathrm{H}}_l^{\mathrm{simp}}(Z(s)) = 0 \qquad \text{and} \qquad \widetilde{\mathrm{H}}_l^{\mathrm{simp}}(\partial Z(s)) \cong \begin{cases} \mathbb{Z}, & \text{if } l = k-1, \\ 0, & \text{otherwise.} \end{cases}$$

In particular $\partial Z(s)$ is a simplicial homology $(k-1)$-sphere.

Proof. Let s be an $(n-k)$-simplex of K. We start out with the following little observation:

(∗) Note that $Z(s)$ and $\mathrm{sd}(\partial s)$ are subcomplexes of $\mathrm{St}(\mathrm{sd}(K), \underline{s})$ and that $\partial Z(s)$ and $\mathrm{sd}(\partial s)$ are subcomplexes of $\mathrm{Lk}(\mathrm{sd}(K), \underline{s})$. It is now elementary to verify that the natural maps on the vertex sets induce simplicial isomorphisms

$$Z(s) * \mathrm{sd}(\partial s) \xrightarrow{\cong} \mathrm{St}(\mathrm{sd}(K), \underline{s}) \quad \text{and} \quad \partial Z(s) * \mathrm{sd}(\partial s) \xrightarrow{\cong} \mathrm{Lk}(\mathrm{sd}(K), \underline{s}).$$

We leave it to the reader to go over the details. It might be helpful to have a look at the figure on page 2279 to do a reality check.

Now let us turn to the actual calculation of the simplicial homology groups of $Z(s)$ and $\partial Z(s)$. Thus let $l \in \mathbb{N}_0$. We perform the following two calculations:

$$\widetilde{\mathrm{H}}_l^{\mathrm{simp}}(Z(s)) \underset{\uparrow}{=} \widetilde{\mathrm{H}}_{l+n-k}^{\mathrm{simp}}(Z(s) * \mathrm{sd}(\partial s)) \underset{\uparrow}{=} \widetilde{\mathrm{H}}_{l+n-k}^{\mathrm{simp}}(\overbrace{\mathrm{St}(\mathrm{sd}(K), \underline{s})}^{=\mathrm{Cone}(\mathrm{Lk}(\mathrm{sd}(K), \underline{s}))}) \underset{\uparrow}{=} 0.$$

since s is an $(n-k)$-simplex we obtain from the Chain Subdivision Lemma 95.41 that $\widetilde{\mathrm{H}}_{n-k-1}^{\mathrm{simp}}(\mathrm{sd}(\partial s)) \cong \mathbb{Z}$ and that $\widetilde{\mathrm{H}}_i^{\mathrm{simp}}(\mathrm{sd}(\partial s)) = 0$ for $i \neq n-k-1$, the statement now follows from Exercise 95.14

by (∗)

by the Link Star Lemma 94.5 together with the Cone Homology Lemma 95.11

$$\widetilde{\mathrm{H}}_l^{\mathrm{simp}}(\partial Z(s)) \underset{\downarrow}{=} \widetilde{\mathrm{H}}_{l+n-k}^{\mathrm{simp}}(\partial Z(s) * \mathrm{sd}(\partial s)) \underset{\downarrow}{=} \widetilde{\mathrm{H}}_{l+n-k}^{\mathrm{simp}}(\mathrm{Lk}(\mathrm{sd}(K), \underline{s})) \underset{\uparrow}{\cong} \begin{cases} \mathbb{Z}, \text{ if } l+n-k=n-1, \\ 0, \text{ otherwise.} \end{cases}$$

by our hypothesis that K is an n-dimensional simplicial homology manifold together with Lemma 103.1 we know that $\mathrm{Lk}(\mathrm{sd}(K), \underline{s})$ is an $(n-1)$-dimensional simplicial homology sphere ⊞

Claim 2. Let $k \in \mathbb{N}_0$. The map

$$\bigoplus_{s \in S_{n-k}} j_s \colon \bigoplus_{s \in S_{n-k}} \mathrm{C}_*^{\mathrm{simp}}(Z(s), \partial Z(s)) \to \mathrm{C}_*^{\mathrm{simp}}(X^k, X^{k-1}),$$

[1254] Note that it follows immediately from the definitions that $Z(s)$ are precisely the simplices that appear as summands in $s^\dagger \in \mathrm{C}_k^{\mathrm{simp}}(K)$ and that $\partial Z(s)$ are precisely the simplices that appear as summands in $\partial s^\dagger \in \mathrm{C}_{k-1}^{\mathrm{simp}}(K)$.

induced by the inclusions, is an isomorphism of chain complexes.

Proof. Since each of the inclusion induced maps $\mathrm{C}_*^{\mathrm{simp}}(Z(s), \partial Z(s)) \to \mathrm{C}_*^{\mathrm{simp}}(X^k, X^{k-1})$ is a chain map we see that the given map is indeed a chain map. Thus it suffices to show that the map is an isomorphism in each degree. Now let $l \in \mathbb{N}_0$. We consider the following diagram:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \bigoplus_{s \in S_{n-k}} \mathrm{C}_l^{\mathrm{simp}}(\partial Z(s)) & \xrightarrow{\alpha} & \bigoplus_{s \in S_{n-k}} \mathrm{C}_l^{\mathrm{simp}}(Z(s)) & \longrightarrow & \bigoplus_{s \in S_{n-k}} \mathrm{C}_l^{\mathrm{simp}}(Z(s), \partial Z(s)) & \longrightarrow & 0 \\
 & & \big\downarrow =:\varphi & & \big\downarrow =:\psi & & \big\downarrow & & \\
0 & \longrightarrow & \mathrm{C}_l^{\mathrm{simp}}(X^{k-1}) & \longrightarrow & \mathrm{C}_l^{\mathrm{simp}}(X^k) & \longrightarrow & \mathrm{C}_l^{\mathrm{simp}}(X^k, X^{k-1}) & \longrightarrow & 0. \\
 & & & & \big\downarrow p & & & & \\
 & & & & \bigoplus_{s \in S_{n-k}} \bigoplus_{(v_0, \ldots, v_l)} \mathbb{Z} \cdot G(s | v_0, \ldots, v_l) & & & &
\end{array}$$

We make the following clarifications and observations:

(a) The horizontal sequences are evidently exact.
(b) The vertical maps between the first and second row are induced by the inclusions $\partial Z(s) \to X^{k-1}$ and $Z(s) \to X^k$.
(c) It is basically clear that the middle vertical map ψ is an epimorphism.
(d) Let $G(t \,|\, v_0, \ldots, v_l)$ be an l-simplex in X^{k-1}. By definition of X^{k-1} this means that t is a simplex of K of dimension $\geq n - (k-1)$. For any $(n-k)$-simplex s with $s \subset t$ we have by definition that $G(t \,|\, v_0, \ldots, v_l)$ is a simplex of $\partial Z(s)$. This shows that the left vertical map φ is also an epimorphism.
(e) The vertical map p is the natural projection given by the fact that the bottom group is generated by a subset of the set of l-simplices of X^k.
(f) It follows easily from the definitions that $\ker(p \circ \psi) \subset \mathrm{im}(\alpha)$.
(g) It follows from (f) that $\ker(\psi) \subset \mathrm{im}(\alpha)$.

It now follows from (a), (b), (c) and (g) together with an elementary diagram chase, see Exercise 74.12, that the right vertical map is indeed an isomorphism. ⊞

Claim 3. For every ordered $(n-k)$-simplex s of K we have $\mathbb{Z} \cdot [s^\dagger] = \mathrm{H}_k^{\mathrm{simp}}(Z(s), \partial Z(s))$.

Proof. Let $s = (v_0, \ldots, v_{n-k})$ be an ordered $(n-k)$-simplex of K. By Proposition 103.2 we know that K is a closed n-dimensional pseudomanifold. By definition this implies that s is the face of an n-simplex. We pick vertices $w_1, \ldots, w_k$ of K such that $(v_0, \ldots, v_{n-k}, w_1, \ldots, w_k)$ is an n-simplex of K. Next we consider the following diagram:

$$\begin{array}{ccccccc}
\overbrace{\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(Z(s))}^{=0 \text{ by Claim 1}} & \longrightarrow & \mathrm{H}_k^{\mathrm{simp}}(Z(s), \partial Z(s)) & \xrightarrow[\cong]{\partial_k} & \overbrace{\widetilde{\mathrm{H}}_{k-1}^{\mathrm{simp}}(\partial Z(s))}^{\cong \mathbb{Z} \text{ by Claim 1}} & \longrightarrow & \overbrace{\widetilde{\mathrm{H}}_{k-1}^{\mathrm{simp}}(Z(s))}^{=0 \text{ by Claim 1}} \\
 & & \big\uparrow {\scriptstyle n \mapsto n \cdot [s^\dagger]} \quad =:\varphi & & \big\downarrow \iota & & \\
 & & \mathbb{Z} & \xleftarrow[\text{projection } p]{} & \widetilde{\mathrm{C}}_{k-1}^{\mathrm{simp}}(\partial Z(s)). & &
\end{array}$$

We make the following clarifications and observations:

(a) It follows from Claim 1 that the connecting homomorphism ∂_k on the top is an isomorphism.
(b) Note that $\partial Z(s)$ is a $(k-1)$-dimensional simplicial complex. Therefore we have the *inclusion* $\iota\colon \widetilde{\mathrm{H}}^{\mathrm{simp}}_{k-1}(\partial Z(s)) \to \widetilde{\mathrm{C}}^{\mathrm{simp}}_{k-1}(\partial Z(s))$.
(c) It follows immediately from the definitions that $\partial s^\dagger$ lies in $\mathrm{C}^{\mathrm{simp}}_{k-1}(\partial Z(s))$. In particular $s^\dagger$ defines an element $\mathrm{H}^{\mathrm{simp}}_k(Z(s), \partial Z(s))$. In other words, the vertical map φ is defined.
(d) We denote by $p\colon \mathrm{C}^{\mathrm{simp}}_{k-1}(\partial Z(s)) \to \mathbb{Z}$ the projection from the free abelian group $\mathrm{C}^{\mathrm{simp}}_{k-1}(\partial Z(s))$ onto the $G(s \cup \{w_{k+1}\} \mid w_{k+2}, \dots, w_n)$-coefficient.
(e) It follows easily from Lemma 103.8 (1) together with the various definitions that the map $p \circ \iota \circ \partial_k \circ \varphi\colon \mathbb{Z} \to \mathbb{Z}$ is multiplication by ± 1.
(f) By Claim 1 we have $\widetilde{\mathrm{H}}^{\mathrm{simp}}_{k-1}(\partial Z(s)) \cong \mathbb{Z}$.
(g) It follows easily from (d) and (e) that $\partial_k \circ \varphi$ is an isomorphism. Together with (1) we see that φ is an isomorphism. ⊞

As the reader will have noticed, the above claims basically take care of the three statements of the proposition:

(1) It follows from Claim 1 and 2 that for $i \neq k$ we have $\mathrm{H}^{\mathrm{simp}}_i(X^k, X^{k-1}) = 0$.
(2),(3) We consider the following diagram:

$$\begin{array}{ccccc}
\mathrm{D}^{\mathrm{simp}}_k(K) & \xrightarrow[\cong]{s^\dagger \mapsto [s^\dagger]} & \bigoplus_{s \in S_{n-k}} \mathrm{H}^{\mathrm{simp}}_k(Z(s), \partial Z(s)) & \xrightarrow[\cong]{} & \mathrm{H}^{\mathrm{simp}}_k(X^k, X^{k-1}) \\
\downarrow{\scriptstyle \partial_k} & & & & \downarrow{\scriptstyle d_k} \\
\mathrm{D}^{\mathrm{simp}}_{k-1}(K) & \xrightarrow[\cong]{s^\dagger \mapsto [s^\dagger]} & \bigoplus_{s \in S_{n-k+1}} \mathrm{H}^{\mathrm{simp}}_{k-1}(Z(s), \partial Z(s)) & \xrightarrow[\cong]{} & \mathrm{H}^{\mathrm{simp}}_{k-1}(X^{k-1}, X^{k-2}).
\end{array}$$

We make the following clarifications and observations:
(a) By Lemma 103.7 we know that the $\{s^\dagger\}_{s \in S_{n-l}}$ form a basis for each $\mathrm{D}^{\mathrm{simp}}_l(K)$.
(b) The composition of the horizontal maps equals the map Θ that is induced by the maps $\mathrm{D}^{\mathrm{simp}}_k(K) \to \mathrm{C}^{\mathrm{simp}}_k(X^k) \to \mathrm{C}^{\mathrm{simp}}_k(X^k, X^{k-1})$.
(c) It follows immediately from the definitions that the diagram commutes.
(d) By Claim 3 we know that the left horizontal maps are isomorphisms and by Claim 2 we know the right horizontal maps are isomorphisms.

This discussion shows that the maps

$$\begin{array}{rccc}
\Theta\colon & \mathrm{D}^{\mathrm{simp}}_k(K) & \to & \mathrm{H}^{\mathrm{simp}}_k(X^k, X^{k-1}) \\
& \sigma & \mapsto & [\sigma]
\end{array}$$

define an isomorphism $(\mathrm{D}^{\mathrm{simp}}_*(K), \partial_*) \to (\mathrm{H}^{\mathrm{simp}}_k(X^k, X^{k-1}), d_k)_{k \in \mathbb{N}_0}$ of chain complexes. ■

The following lemma is also a partial analogue of the Skeleton-Homology Lemma 80.1.

Lemma 103.13. Let $K = (V, S)$ be a closed n-dimensional simplicial homology manifold and let $k \in \mathbb{N}_0$.

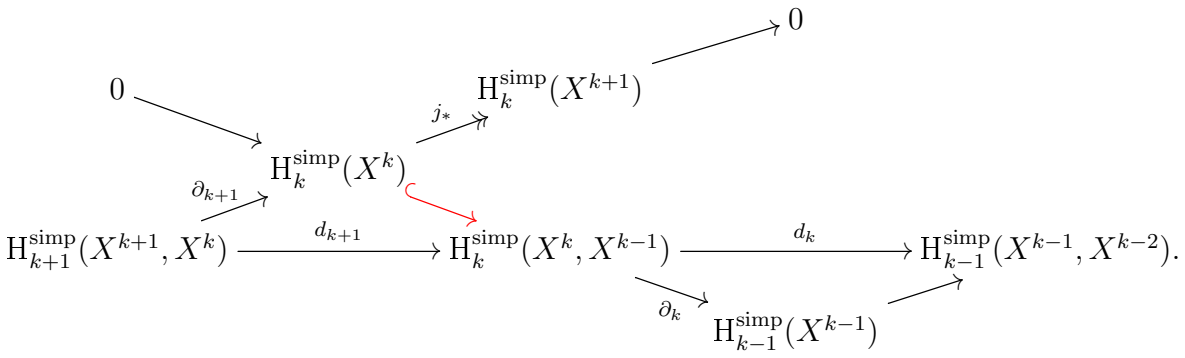
(1) For every $i > k$ we have $\mathrm{H}^{\mathrm{simp}}_i(X^k) = 0$.

(2) For every $i < k$ the inclusion induced map $\mathrm{H}_i^{\mathrm{simp}}(X^k) \to \mathrm{H}_i^{\mathrm{simp}}(\mathrm{sd}(K))$ is an isomorphism.

Proof.

(1) Note that X^k is an abstract simplicial complex of dimension k. It follows immediately from the definition of simplicial homology that $\mathrm{H}_i^{\mathrm{simp}}(K) = 0$ for $i > k$.
(2) We fix $i \in \mathbb{N}_0$. Let $m > i$. We consider the following excerpt from the long exact sequence in simplicial homology of the pair (X^{m+1}, X^m):

$$\dots \to \underbrace{\mathrm{H}_{i+1}^{\mathrm{simp}}(X^{m+1}, X^m)}_{=0 \text{ by Lemma 103.12 (1) since } i<m} \to \mathrm{H}_i^{\mathrm{simp}}(X^m) \to \mathrm{H}_i^{\mathrm{simp}}(X^{m+1}) \to \underbrace{\mathrm{H}_i^{\mathrm{simp}}(X^{m+1}, X^m)}_{=0 \text{ by Lemma 103.12 (1) since } i<m} \to \dots$$

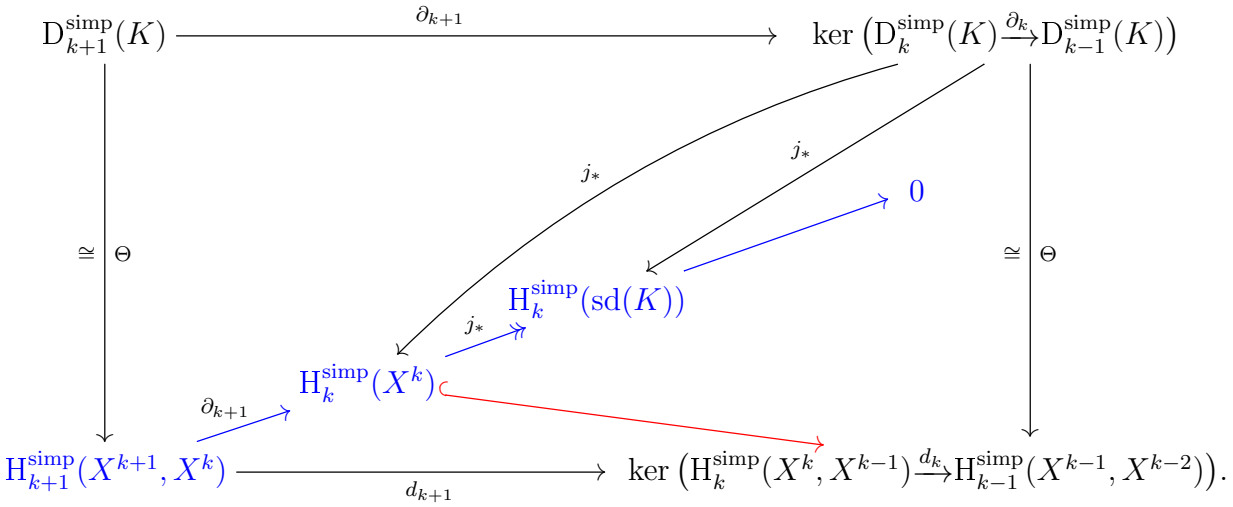


Now let $k > i$. The above discussion immediately implies that the following inclusion induced maps are isomorphisms: $\mathrm{H}_i^{\mathrm{simp}}(X^k) \xrightarrow{\cong} \mathrm{H}_i^{\mathrm{simp}}(X^{k+1}) \xrightarrow{\cong} \dots \xrightarrow{\cong} \mathrm{H}_i^{\mathrm{simp}}(X^n)$. The desired statement follows from the fact that $X^n = \mathrm{sd}(K)$. ■

Now we are finally in a position to provide the long overdue proof of Proposition 103.11.

Proof of Proposition 103.11. Let K be a closed n-dimensional simplicial homology manifold and let G be an abelian group. Recall that we need to prove the following two statements:

(1) The inclusion map $\mathrm{D}_*^{\mathrm{simp}}(K) \to \mathrm{C}_*^{\mathrm{simp}}(\mathrm{sd}(K))$ is a chain homotopy equivalence.
(2) The induced maps $\mathrm{H}_k(\mathrm{D}_*^{\mathrm{simp}}(K) \otimes G) \to \mathrm{H}_k^{\mathrm{simp}}(\mathrm{sd}(K); G)$ are isomorphisms.



Similarly to the proof of the Singular-Cellular H_*-Isomorphism Proposition 80.4 we consider the following diagram:

We make the following observations:

(1) It follows from Lemma 95.29, i.e. from the long exact sequence in simplicial homology, together with Lemma 103.12 (1) and Lemma 103.13 (1) that all diagonal sequences are exact.
(2) It follows from the definition of d_k that the map $\mathrm{H}_k^{\mathrm{simp}}(X^k) \to \mathrm{H}_k^{\mathrm{simp}}(X^k, X^{k-1})$ takes values in $\ker(d_k \colon \mathrm{H}_k^{\mathrm{simp}}(X^k, X^{k-1}) \to \mathrm{H}_{k-1}^{\mathrm{simp}}(X^{k-1}, X^{k-2}))$.

We move on to the main diagram of this proof:

We make the following clarification and observations:

(3) All the maps called j_* are induced by inclusions on the level of chain groups. In fact note that every map in the diagram is either induced by taking boundaries or it is induced by an inclusion. It follows almost immediately from this observation that the diagram commutes.

(4) The vertical maps are isomorphisms by Lemma 103.12.

(5) By (1) the map $\mathrm{H}^{\mathrm{simp}}_k(X^k) \to \ker(d_k \colon \mathrm{H}^{\mathrm{simp}}_k(X^k, X^{k-1}) \to \mathrm{H}^{\mathrm{simp}}_{k-1}(X^{k-1}, X^{k-2}))$ is a monomorphism.

(6) It follows from (1), together with Lemma 103.13, that the diagonal blue sequence

$$\mathrm{H}^{\mathrm{simp}}_{k+1}(X^{k+1}, X^k) \xrightarrow{\partial_{k+1}} \mathrm{H}^{\mathrm{simp}}_k(X^k) \xrightarrow{j_*} \mathrm{H}^{\mathrm{simp}}_k(\mathrm{sd}(K)) \to 0$$

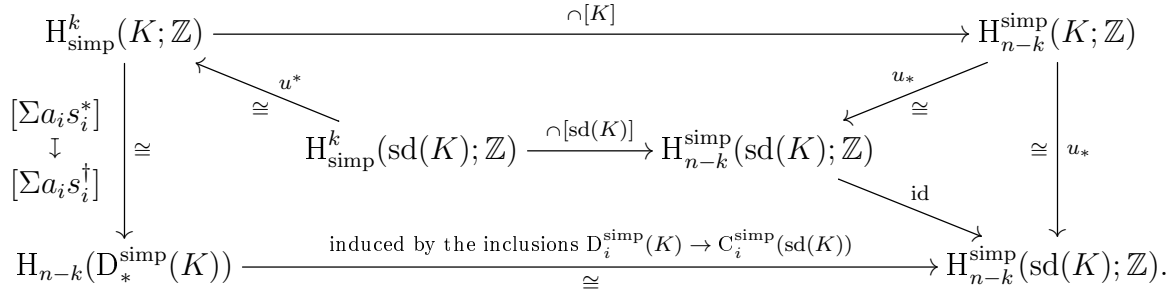
is exact.

An amusing little diagram chase now shows that the sequence

$$\mathrm{D}^{\mathrm{simp}}_{k+1}(K) \xrightarrow{\partial_{k+1}} \ker\left(\partial_k \colon \mathrm{D}^{\mathrm{simp}}_k(K) \to \mathrm{D}^{\mathrm{simp}}_{k-1}(K)\right) \xrightarrow{j_*} \mathrm{H}^{\mathrm{simp}}_k(\mathrm{sd}(K)) \to 0$$

is also exact. In other words we have proved the following statement:

(0) The inclusion map $\mathrm{D}^{\mathrm{simp}}_*(K) \to \mathrm{C}^{\mathrm{simp}}_*(\mathrm{sd}(K))$ induces for each $k \in \mathbb{N}_0$ an isomorphism $\mathrm{H}_k(\mathrm{D}^{\mathrm{simp}}_*(K)) \to \mathrm{H}^{\mathrm{simp}}_k(\mathrm{sd}(K))$.



Now let us turn to the two statements we actually need to prove.

(1) It follows from (0) and the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 that the chain map $\mathrm{D}^{\mathrm{simp}}_*(K) \to \mathrm{C}^{\mathrm{simp}}_*(\mathrm{sd}(K))$ is in fact a chain homotopy equivalence.

(2) Finally note that it follows either from (1), or from (0) together with the Algebraic Universal Coefficient Theorem 89.16 and the Five Lemma 74.10, that the maps $\mathrm{H}_k(\mathrm{D}^{\mathrm{simp}}_*(K); G) \to \mathrm{H}^{\mathrm{simp}}_*(\mathrm{sd}(K); G)$ are also isomorphisms. Alternatively we could have carried through the above arguments with G-coefficients without any hiccup. ■

103.6. **The proof of the Simplicial Poincaré Duality Theorem 103.4.** In this section we combine the results from the previous sections to finally provide the proof of the Simplicial Poincaré Duality Theorem 103.4. For the most part we are now just saying that the program, set out on page 2275 has been completed successfully.

Let K be a closed n-dimensional pseudomanifold. First we assume that K is orientable and that we are given an orientation for K. In the following we will only work with the commutative ring $R = \mathbb{Z}$. The proof for the general case is basically the same, except that one has to carry slightly more notation around. As on page 2275 we consider the following diagram:

In the last sections we have shown the following:

(1) By Proposition 103.9 we now know that the left vertical map is an isomorphism.
(2) By the Chain Subdivision Lemma 95.41 we know that the subdivision maps u_* and u^* are isomorphisms.
(3) By Lemma 103.6 (3) we know that the upper quadrilateral commutes.
(4) By Lemma 103.10 we know that the lower left part of the diagram commutes.
(5) Finally we now know by Proposition 103.11 that the bottom horizontal map is an isomorphism.

The combination of the above five statements implies that the map

$$\begin{array}{rcl} \mathrm{H}^k_{\mathrm{simp}}(K;\mathbb{Z}) & \to & \mathrm{H}^{\mathrm{simp}}_{n-k}(K;\mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [K] \end{array}$$

is, as promised and desired, an isomorphism.

Finally suppose that we are dealing with any closed n-dimensional pseudomanifold, in other words we drop the hypothesis that K is orientable. We need to show that the map

$$\begin{array}{rcl} \mathrm{H}^k_{\mathrm{simp}}(K;\mathbb{F}_2) & \to & \mathrm{H}^{\mathrm{simp}}_{n-k}(K;\mathbb{F}_2) \\ \varphi & \mapsto & \varphi \cap [K]_{\mathbb{F}_2} \end{array}$$

is an isomorphism. The argument is almost identical to the previous argument. In fact the only place where we ever really used the orientation was in the definition of $s^\dagger$ on page 2271 and the resulting map $\mathrm{C}^k_{\mathrm{simp}}(K;\mathbb{Z}) \to \mathrm{D}^{\mathrm{simp}}_k(K)$ that is given by $s^* \mapsto s^\dagger$. A little bit of thought shows that the same recipe defines a map $\mathrm{C}^k_{\mathrm{simp}}(K;\mathbb{F}_2) \to \mathrm{D}^{\mathrm{simp}}_k(K) \otimes \mathbb{F}_2$ and the argument of Proposition 103.9 shows that this map is actually an isomorphism of cochain complexes. In the remainder of the argument we did not really use the orientation, so these parts stay virtually untouched. For example Proposition 103.11 says that the maps $\mathrm{H}_{n-k}(\mathrm{D}^{\mathrm{simp}}_*(K) \otimes \mathbb{F}_2) \to \mathrm{H}^{\mathrm{simp}}_{n-k}(\mathrm{sd}(K);\mathbb{F}_2)$ are isomorphisms. We leave it to the reader to turn this sketch of a proof into a proper argument.

103.7. **The dual CW-structure of a smooth manifold.** Let M be a closed smooth manifold that is equipped with a smooth simplicial structure $(K = (V, S), \Theta\colon |K| \to M)$. Some of the figures above, e.g. the figures on pages 2272 and 2279, suggest that the dual chains correspond to an alternative decomposition of M into cells. As we will see shortly, that is indeed the case.
First we recall some of the notation that we introduced earlier.

Notation. Let $K = (V, S)$ be an n-dimensional pseudomanifold.

(1) Given $m \in \mathbb{N}_0$ we denote by S_m the set of m-simplices of K.
(2) Let $s \in S_m$ be an m-simplex and let $v_1, \ldots, v_l \in V$ such that $s \cup \{v_1, \ldots, v_l\} \in S_{m+l}$. As on page 2271 we consider the following ordered l-simplex of $\mathrm{sd}(K)$:
$$G(s \,|\, v_1, \ldots, v_l) \;:=\; \big(\underline{s}, \underline{s \cup \{v_1\}}, \ldots, \underline{s \cup \{v_1, \ldots, v_l\}}\big).$$
(3) Let $k \in \mathbb{N}_0$ and let $s \in S_{n-k}$ be an $(n-k)$-simplex. As on page 2279 we consider
$$Z(s) \;:=\; \{ \text{ all simplices of } \mathrm{sd}(K) \text{ of the form } G(t \,|\, v_1, \ldots, v_l) \text{ with } s \subset t\}.$$
Furthermore, as on page 2278 we consider the following:
$$X^k \;:=\; \text{the subcomplex of } \mathrm{sd}(K) \text{ given by all } Z(s) \text{ with } s \in S_{n-k}.$$

Now we can formulate the main result of this section.

Proposition 103.14. Let M be a closed n-dimensional smooth manifold. Furthermore let $(K = (V, S), \Theta\colon |K| \to M)$ be a smooth simplicial structure.

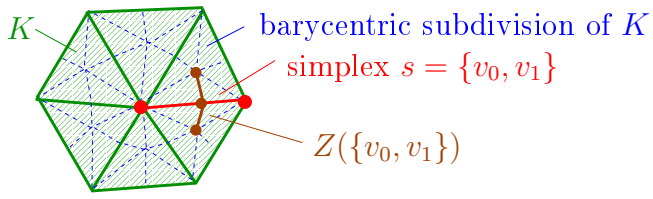
(1) For each $(n-k)$-simplex s we have a homeomorphism $|Z(s)| \cong \overline{B}^k$.
(2) There exists a CW-structure on M such that for each $k \in \mathbb{N}_0$ the following holds:
  (a) The k-cells are given by the $|Z(s)|$ with $s \in S_{n-k}$.
  (b) The k-skeleton is given by $|X^k|$.
(3) If we equip M with the CW-structure from (2), then there exists a natural isomorphism $\mathrm{D}_k^{\mathrm{simp}}(K) \to \mathrm{C}_k^{\mathrm{CW}}(M)$ of chain complexes.

We refer to the CW-structure described in Proposition 103.14 as the *dual* CW-*structure* of the smooth manifold. We refer to the figure below for an illustration.

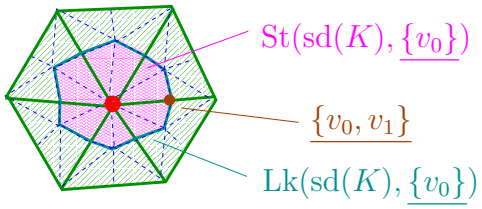
Sketch of proof. Let M be a closed n-dimensional smooth manifold. Furthermore let $(K = (V, S), \Theta\colon |K| \to M)$ be a smooth simplicial structure. Note that we know by Theorem 96.15 that $(K = (V, S), \Theta\colon |K| \to M)$ is a closed n-dimensional PL-manifold. This implies that we might as well prove the statement under the hypothesis that we are dealing with a closed n-dimensional PL-manifold. Furthermore note that it follows immediately from the definition of a PL-manifold, see page 2093, together with the SD-Lemma 94.3 that the barycentric subdivision $\mathrm{sd}(K)$ is also a closed n-dimensional PL-manifold.

Now let us turn to the proof of the three statement.

(1) One could prove this statement in one go, but it seems didactically opportune to first consider the two simplest cases.



(a) Let $s = \{v_0\}$ be a 0-simplex of K. We have the following homeomorphisms:



$$\begin{array}{ccccc} |Z(\{v_0\})| & = & |\operatorname{St}(\operatorname{sd}(K), \underline{\{v_0\}})| & = & |\text{ PL } n\text{-ball }| & \cong & \overline{B}^n. \\ \uparrow & & \uparrow & & \uparrow & & \\ \text{follows immediately} & & \text{by the PL-Manifold Characterization} & & \text{since PL-homeomorphic} & & \\ \text{from the definitions} & & \text{Proposition 96.12 since } \operatorname{sd}(K) \text{ is} & & \text{implies homeomorphic} & & \\ & & \text{an } n\text{-dimensional PL-manifold} & & & & \end{array}$$

(b) Next let $s = \{v_0, v_1\}$ be a 1-simplex of K. Note that

$$\begin{array}{ccccc} & & \text{by the PL-Manifold Characterization Proposition 96.12} & & \\ & & \text{since } \operatorname{sd}(K) \text{ is a closed } n\text{-dimensional PL-manifold} & & \\ |Z(\{v_0, v_1\})| & \overset{\downarrow}{=} & |\operatorname{St}(\operatorname{Lk}(\operatorname{sd}(K), \underline{\{v_0\}}), \underline{\{v_0, v_1\}})| & \overset{\downarrow}{=} & |\operatorname{St}(\text{PL } (n-1)\text{-sphere}, \underline{\{v_0, v_1\}})| \\ & & = |\operatorname{St}(\text{closed } (n-1)\text{-dimensional PL-manifold}, \underline{\{v_0, v_1\}})| & & \\ & & \uparrow & & \\ & & \text{as we pointed out on page 2093, it follows from Proposition 96.11 that a} & & \\ & & \text{PL } (n-1)\text{-sphere is a closed } (n-1)\text{-dimensional PL-manifold} & & \\ & \cong & |\text{PL } (n-1)\text{-ball}| & \cong & \overline{B}^{n-1}. \\ & \uparrow & & \uparrow & \\ & \text{PL-Manifold Characterization} & & \text{since PL-homeomorphic implies homeomorphic} & \\ & \text{Proposition 96.12} & & & \end{array}$$

(c) Finally let $s = \{v_0, \dots, v_k\}$ be any k-simplex of K. Similar to (b) we see that $Z(s)$ is the star of an iterated sequence of k links. Applying the PL-Manifold Characterization Proposition 96.12 multiple times we see that $Z(s)$ is homeomorphic to $\overline{B}^{n-k}$. We leave it to the reader to write down this notationally messy argument.

(2) This statement follows fairly immediately from (1). We leave it to the reader to fill in the details.

(3) Given each $k \in \mathbb{N}_0$ we consider the map

$$\begin{array}{ccccc} \mathrm{D}_k^{\mathrm{simp}}(K) & \to & \mathrm{H}_k^{\mathrm{simp}}(X^k, X^{k-1}) & \xrightarrow[\Xi]{\downarrow} & \mathrm{H}_k(|X^k|, |X^{k-1}|) = \mathrm{C}_k^{\mathrm{CW}}(M). \\ \sigma & \mapsto & [\sigma] & & \\ & & \text{natural isomorphism given by Lemma 95.30} & & \end{array}$$

Note that by Lemma 103.12 we know that the left maps are well-defined and that they form an isomorphism of chain complexes. We obtain immediately from the Simplicial-Singular Homology Isomorphism Lemma 95.30 (3) that the right maps also form an isomorphism of chain complexes. The composition of the two chain isomorphisms thus gives us the promised natural isomorphism of chain complexes. ■

Exercises for Chapter 103.

Exercise 103.1. Let T be the simplicial 2-dimensional torus. By Exercise 98.1 we know that the suspension $\Sigma(T)$ is a closed orientable 3-dimensional pseudomanifold. Show that the conclusion of the Simplicial Poincaré Duality Theorem 103.4 does not hold for $\Sigma(T)$.

Exercise 103.2. Let K be a simplicial complex. Show that K is an n-dimensional simplicial homology manifold if and only if the topological realization $|K|$ is an n-dimensional homology manifold. Recall by the definition on page 1672 a topological space X is called an n-dimensional homology manifold if for each $x \in X$ we have

$$\mathrm{H}_k(X, X \setminus \{x\}; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Exercise 103.3.

(a) Let M be a connected closed 3-dimensional smooth manifold. Show that if M is non-orientable, then $\mathrm{H}_1(M; \mathbb{Z})$ is infinite.
(b) Is the hypothesis in (a) that M is closed necessary?

Exercise 103.4. Let M and N be two closed orientable connected non-empty 3-dimensional smooth manifolds such that $\pi_1(M)$ is isomorphic to $\pi_1(N)$. Show that for all $i \in \mathbb{N}_0$ there exists an isomorphism $\mathrm{H}_i(M; \mathbb{Z}) \cong \mathrm{H}_i(N; \mathbb{Z})$.

Exercise 103.5. Let W be a closed orientable connected 4-dimensional smooth manifold with Euler characteristic $\chi(W) = -3$.

(a) Show that W admits a finite connected covering $\widetilde{W}$ with $\chi(\widetilde{W}) < -27$.
(b) Is the hypothesis in (a) that W is orientable necessary?

Exercise 103.6. Let M be a closed orientable connected odd-dimensional smooth manifold and let $f\colon M \to M$ be a map such that the induced map $f_*\colon \mathrm{H}_n(M) \to \mathrm{H}_n(M)$ is the identity. Show that the Lefschetz number

$$\Lambda(\varphi) \;=\; \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \mathrm{tr}(\varphi_*\colon \mathrm{H}_n(M) \to \mathrm{H}_n(M)),$$

equals zero.

Exercise 103.7. Let $n \in \mathbb{N}$ and let M be a closed oriented connected non-empty n-dimensional smooth manifold. Suppose that there exists a map $f\colon S^n \to M$ of degree ± 1, i.e. such that $f_*([S^n]) = [M] \in \mathrm{H}_n(M)$. Show that $\mathrm{H}_i(M) = 0$ for $i = 1, \ldots, n-1$.
Remark. In the Degree One-Epimorphism Proposition 101.8 we showed under the same hypotheses that we also have $\pi_1(M) = 0$.

Exercise 103.8.

(1) Give a suitable definition of an n-dimensional simplicial homology manifold *with boundary*.

(2) Let K be a connected orientable n-dimensional simplicial homology manifold with non-empty boundary ∂K. We consider $M := K \cup_{\partial K} \mathrm{Cone}(\partial K)$, i.e. we consider the simplicial mapping cone of the inclusion $L \to K$.

(a) Show that $M = K \cup_{\partial K} \mathrm{Cone}(\partial K)$ is a *closed* orientable n-dimensional pseudo-manifold.

(b) Show that

$$\mathrm{H}_i(\mathrm{D}_k(M)) \;\cong\; \begin{cases} 0, & \text{if } k = n, \\ \mathrm{H}_i^{\mathrm{simp}}(\mathrm{sd}(K)), & \text{otherwise.} \end{cases}$$

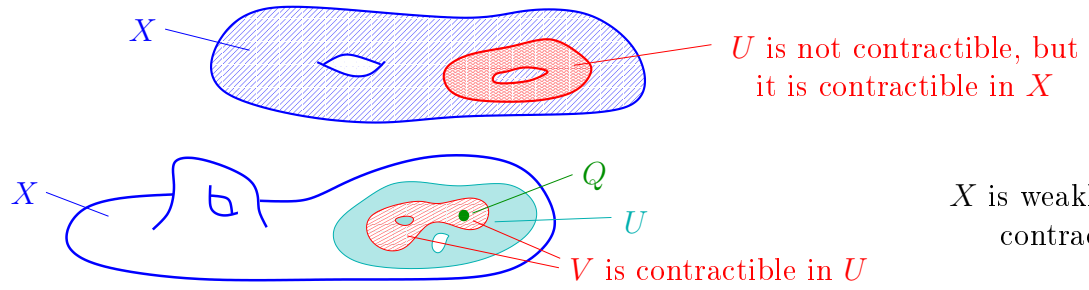
Remark. This is a non-trivial variation on Proposition 103.11.

(c) Use the above together with Proposition 103.9 and Exercise 99.3 to show that for every $i \in \mathbb{N}_0$ there exists a natural isomorphism $\mathrm{H}^i_{\mathrm{simp}}(K, \partial K; \mathbb{Z}) \to \mathrm{H}^{\mathrm{simp}}_{n-i}(K; \mathbb{Z})$.

Part X

Homology groups of topological manifolds

104. Borsuk's Theorem, ENRs and ANRs



In this chapter we will state and prove Borsuk's Theorem 104.3 which will give us many goodies:

(1) We can prove the Lefschetz Fixed Point Theorem also for CW-complexes and topological manifolds.[1255]
(2) We can get some control over the invariants of compact topological manifolds, for example we will be able to show that the homology groups of a compact topological manifold are finitely generated and that the fundamental groups are finitely presented.

104.1. **Neighborhood retracts.** We recall two definitions from pages 431 and 175 and we introduce two related definitions.

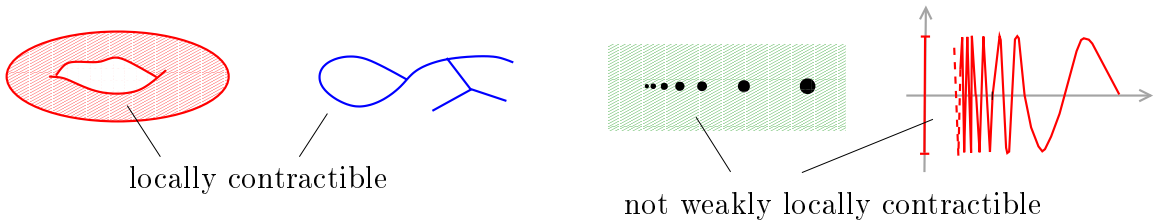
Definition. Let X be a topological space.

(1) We say X is contractible if X is homotopy equivalent to a point.
(2) We say X is locally contractible if given any $Q \in X$ and given any open neighborhood U of Q there exists an open neighborhood V of Q that is contained in U and that is contractible.
(3) We say that a subset U of X is contractible in X if the inclusion map $U \to X$ is homotopic to a constant map.[1256]
(4) We say X is weakly locally contractible if given any $Q \in X$ and given any open neighborhood U of Q there exists an open neighborhood V of Q that is contained in U and that is contractible in U.[1257]

Examples.

(1) It follows almost immediately from the definitions that a topological space that is locally contractible is also weakly locally contractible.
(2) By the Topological Manifolds-Local Properties Lemma 18.8 (1) every topological manifold is locally homeomorphic to some non-empty convex subset of $\mathbb{R}^n$. Since non-empty convex subsets are contractible we see that every topological manifold is locally contractible.

[1255] So far, in Chapter 97 we only proved the Lefschetz Fixed Point Theorem for simplicial complexes and smooth manifolds.



[1256] Note that the Contractibility Criterion Lemma 15.2 says that a topological space X is contractible if and only if the identity map is homotopic to a constant map.

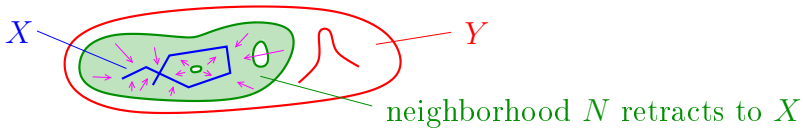
[1257] What we call a "weakly locally contractible" topological space is referred to in many books, see e.g. [**Bor1967, Saka2013**], as a "locally contractible" topological space. Since on page 175 we defined once and for all what it means that a topological space is "locally P" we stick with our more cumbersome name.

(3) In the CW-Complex Properties Proposition 68.10 (6) we showed that CW-complexes are locally contractible. In particular topological graphs are locally contractible. (Note that we had also shown in Exercise 61.1 that topological graphs are locally contractible.)
(4) It is easy to show that $\mathbb{R}^2 \setminus \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$ is not weakly locally contractible.
(5) It is an amusing little exercise to show that the Topologist's Sine Curve

$$\big\{(0,y) \,\big|\, y \in [-1,1]\big\} \cup \big\{(x, \sin(\tfrac{1}{x})) \,\big|\, x \in (0, \tfrac{1}{\pi}]\big\} \subset \mathbb{R}^2,$$

which we had initially introduced on page 164, is not weakly locally contractible.
(6) It is an equally amusing (but not entirely trivial) exercise to come up with a topological space that is weakly locally contractible but not locally contractible.

Next we recall the following definition from pages 433 and 1061.



Definition. Let X be a topological space. We say a subset $A \subset X$ is a retract of X if there exists a map $r\colon X \to A$ with $r(a) = a$ for all $a \in A$.

In our discussions of retracts the following two basically trivial observations will at times be helpful.

Observation 104.1. Let Z be a topological space and let K be a subset.
(1) Let $K \subset U \subset V \subset Z$ be subsets. If K is a retract of V, then K is also a retract of U.
(2) If K is a retract of a neighborhood, then it is also a retract of an open neighborhood.

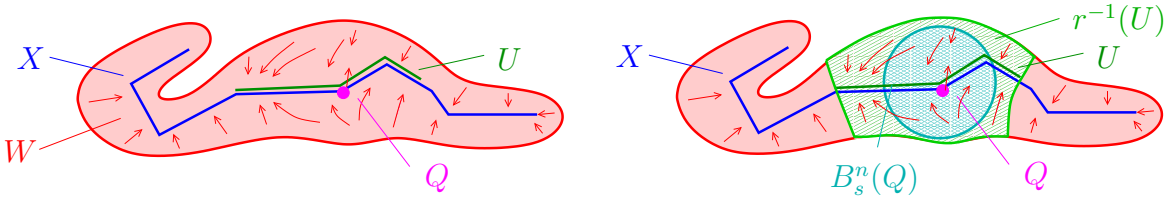
Proof. The first statement follows from the observation that the restriction of any retraction $r\colon V \to K$ to U is again a retraction. The second statement follows immediately from the first statement. ■

Definition. Let Y be a topological space and let X be a subset. We say X is a neighborhood retract in Y if there exists an open neighborhood N of X in Y such that X is a retract of N.[1258]

Examples.

[1258]By Observation 104.1 (2) this definition is equivalent to asking that there exists any neighborhood (not necessarily closed) that admits a retract to X. This formulation is often the definition of a neighborhood retract that is used in the literature. For our discussion it is convenient to already assume that the neighborhood is open.

(1) Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem **??** we know that there exists a tubular neighborhood $\overline{B}^2 \times K$ of K in S^3. Since $K = \{0\} \times K$ is evidently a retract of $\overline{B}^2 \times K$ we see that K is a neighborhood retract in S^3.
(2) Later on we will generalize (1) as follows. It is a consequence of the Regular Neighborhood Theorem 123.3, which is a fairly immediate consequence of the General Tubular Neighborhood Theorem **??**, that every compact proper submanifold X of a given smooth manifold M is a neighborhood retract in M.
(3) We will see in Exercise 104.2 that $X = \{0\} \cup \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$, viewed as a subset of $Y = \mathbb{R}$, is not a neighborhood retract.



We continue with the following fairly elementary lemma.

Lemma 104.2. Let $n \in \mathbb{N}_0$ and let X be a subset of $\mathbb{R}^n$. If X is a neighborhood retract in $\mathbb{R}^n$, then the topological space X is weakly locally contractible.

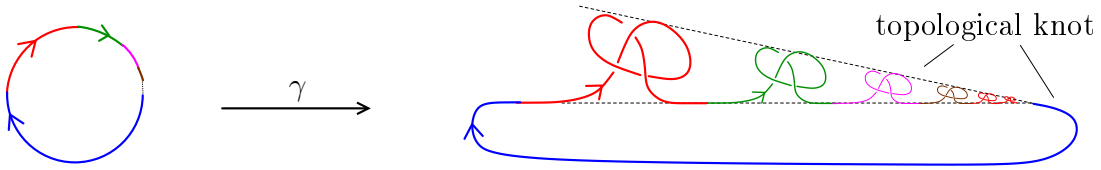
Proof. Let W be a neighborhood of X that admits a retraction $r\colon W \to X$. Let $Q \in X$ and let U be a neighborhood of Q in X. Since W is a neighborhood of X there exists an $s > 0$ such that $B_s^n(Q) \subset r^{-1}(U)$. We denote by $F\colon B_s^n(Q) \times [0,1] \to B_s^n(Q)$ the obvious homotopy from the identity to the constant map. Finally we consider the map

$$\begin{array}{rcl} (B_s^n(Q) \cap X) \times [0,1] & \to & U \\ (x,t) & \mapsto & r\big(\underbrace{F(x,t)}_{\in B_s^n(Q) \subset r^{-1}(U)}\big). \end{array}$$

Evidently this map is a homotopy from the identity to a constant map. In particular $V := B_s^n(Q) \cap X$ is contractible in U. ■

It is rather stunning that for closed subsets of $\mathbb{R}^n$ the converse to Lemma 104.2 holds. More precisely, the following theorem was proved by Karol Borsuk [**Bor1932**] in 1932.

Theorem 104.3. (Borsuk's Theorem) Let $n \in \mathbb{N}_0$ and let X be a closed subset of $\mathbb{R}^n$. If the topological space X is weakly locally contractible, then X is a neighborhood retract in $\mathbb{R}^n$.[1259]



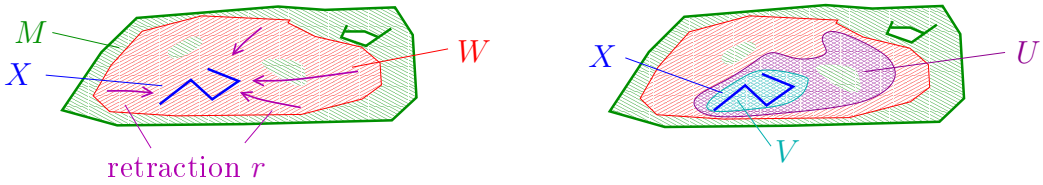
Remark.

(1) Borsuk's Theorem 104.3 can be viewed as a topological analogue of the Neighborhood Projection Theorem 28.1.
(2) Proofs of Borsuk's Theorem 104.3 are also given in [**Bre1993**, Theorem E.3] and [**Hat2002**, Theorem A.7].

Example. We define a *topological knot* to be the image of an embedding $\gamma\colon S^1 \to \mathbb{R}^3$. If the embedding is smooth, then we obtain the usual notion of a knot in $\mathbb{R}^3$. But once we drop

[1259] Is is perhaps worth stressing that the proposition does *not* claim that X is a *deformation retract* of a neighborhood of X.

smoothness one can get weird examples. For example, as we discussed on page 659, using the Compact-Hausdorff Proposition 2.17 (3) it is not difficult to show that the example shown in the figure below is indeed a topological knot.[1260]



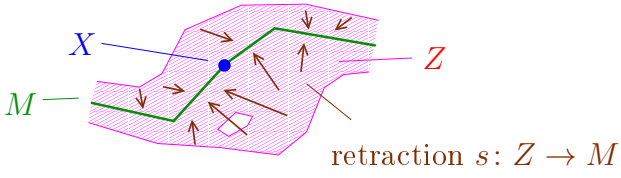
Evidently S^1 is locally contractible and by the Compact Image Lemma 2.13 together with the Compact-Closed Lemma 1.21 we know that $\gamma(S^1)$ is a closed subset of $\mathbb{R}^3$. Thus it follows from Borsuk's Theorem 104.3 that every topological knot is a neighborhood retract in $\mathbb{R}^3$. It is a mindboggling exercise to try to visualize a neighborhood of the above topological knot together with a retraction to $\gamma(S^1)$.

We conclude this discussion of Borsuk's Theorem 104.3 with a proposition that generalizes the statement of Borsuk's Theorem 104.3 from $\mathbb{R}^n$ to topological manifolds and that furthermore gives another rather technical conclusion. This second conclusion will play a significant role later on in our proof of the Generalized Alexander Duality Theorem 124.2.

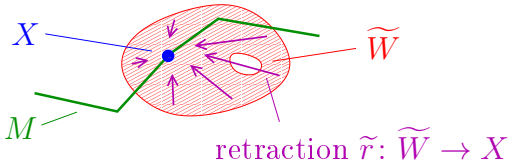
Proposition 104.4. Let M be a topological manifold and let $X \subset M$ be a closed subset that is weakly locally contractible.

(1) There exists an open neighborhood $W \subset M$ of X for which there exists a retraction $r\colon W \to X$.
(2) We can find W and r such that furthermore the following condition is satisfied: given any neighborhood U of X with $X \subset U \subset W$ there exists an open neighborhood V with $X \subset V \subset U$ such that the inclusion $i\colon V \to U$ and the retraction $r\colon V \to X \subset U$ are homotopic maps from V to U.

Proof. Let M be a topological manifold and let $X \subset M$ be a closed subset that is weakly locally contractible. By the Euclidean Embedding Theorem 27.1 there exists an $n \in \mathbb{N}$ and a proper embedding $f\colon M \to \mathbb{R}^n$.[1261] By the definition of a proper map, see page 650, this implies that $f(M)$ is a closed subset of $\mathbb{R}^n$. It follows from the elementary the Open -Closed Inclusion Lemma 2.10 that $f(X)$ is a closed subset of $\mathbb{R}^n$.



The above discussion shows that we only need to consider the case that M is a closed subset of $\mathbb{R}^n$ and that $X \subset M$ is a closed subset of $\mathbb{R}^n$. We now apply Borsuk's Theorem 104.3 not once, but twice:



[1260] It is also not difficult, but rather pointless, to write down such an embedding explicitly.
[1261] Note that one could also use the Euclidean Embedding Theorem 11.13 for Topological Spaces together with the Covering Dimension-of-Manifolds Proposition 27.7.

(a) Since M is a topological manifold we know by the Topological Manifolds-Local Properties Lemma 18.8 that M is weakly locally contractible. Since M is a closed subset of $\mathbb{R}^n$ we know by Borsuk's Theorem 104.3 that there exists an open neighborhood $Z \subset \mathbb{R}^n$ of M for which there exists a retraction $s\colon Z \to X$.

(b) Since X is weakly locally contractible we know again by Borsuk's Theorem 104.3 that there exists an open neighborhood $\widetilde{W} \subset \mathbb{R}^n$ of X for which there exists a retraction $\widetilde{r}\colon \widetilde{W} \to X$. After possibly replacing $\widetilde{W}$ by $\widetilde{W} \cap Z$ we can assume that $\widetilde{W} \subset Z$.

We set $W := \widetilde{W} \cap M$ and $r := \widetilde{r}|_W\colon W \to X$. By the definition of the subspace topology we know that W is indeed an open neighborhood of $X \subset M$. Thus we have proved (1).

Now let us show that the above W and r actually also satisfy Statement (2). Thus let U be a neighborhood of $X \subset M$ with $X \subset U \subset W$. By definition of the subspace topology there exists an open subset $\widetilde{U}$ of $\mathbb{R}^n$ with $U = \widetilde{U} \cap M$. After possibly replacing $\widetilde{U}$ by $\widetilde{U} \cap \widetilde{W} \cap s^{-1}(U)$ we might as well assume that $X \subset \widetilde{U} \subset \widetilde{W}$ and that $s(\widetilde{U}) \subset U$. We consider the homotopy

$$\begin{array}{rcl} \widetilde{F}\colon \widetilde{U} \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & (1-t)\cdot x + t \cdot \widetilde{r}(x) \end{array}$$

from the identity $\mathrm{id}_{\widetilde{U}}$ to the retraction $\widetilde{r}\colon \widetilde{U} \to X$. Note that this is a homotopy rel X.

Claim. There exists an open neighborhood $\widetilde{V}$ of $X \subset \mathbb{R}^n$, that is contained in $\widetilde{U}$, such that $\widetilde{F}(\widetilde{V} \times [0,1]) \subset \widetilde{U}$.

Proof. We consider the open subset $Y := \widetilde{F}^{-1}(\widetilde{U}) \subset \widetilde{U} \times [0,1]$. Since $X \subset \widetilde{U}$ and since $\widetilde{F}$ is a homotopy rel X we see that Y contains $X \times [0,1]$. Since $[0,1]$ is compact and since Y is open one sees, as in the proof of the Product Topology Properties Proposition 5.6, that for any $x \in X$ there exists an open neighborhood R_x of $x \in \widetilde{U}$ such that $R_x \times [0,1] \subset Y$. We set $\widetilde{V} := \bigcup_{x \in X} R_x$. This is an open neighborhood of $X \subset \mathbb{R}^n$ that is contained in $\widetilde{U}$ such that $\widetilde{F}(\widetilde{V} \times [0,1]) \subset \widetilde{U}$. ⊞

We set $V := \widetilde{V} \cap M$. By definition of the subspace topology this is an open neighborhood of X. Evidently $X \subset V \subset U$. Finally we consider the map

$$\begin{array}{rcl} F\colon U \times [0,1] & \to & M \\ (x,t) & \mapsto & \underbrace{s(\underbrace{\widetilde{F}(x,t)}_{\in \widetilde{U} \subset Z})}_{\in U}. \end{array}$$

Note that this map takes values in $s(\widetilde{U}) = U$. Furthermore note that this is a homotopy from $F_0 = i\colon V \to U$ to $F_1 = r\colon V \to U$. We have thus shown that W and r satisfy the desired condition. ■

104.2. **Proof of the Borsuk's Theorem 104.3.** Before we provide the proof of Borsuk's Theorem 104.3 it is convenient to introduce one definition and to prove one lemma.

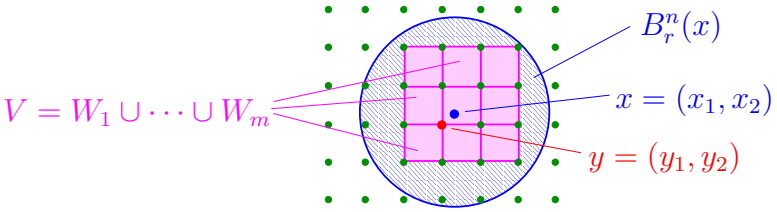
Definition. Let $k \in \mathbb{N}_0$ and let $n \in \mathbb{N}$. A $\frac{1}{2^k}$-cube is a subset C of $\mathbb{R}^n$ of the form

$$C \;=\; \left[\tfrac{a_1}{2^k}, \tfrac{a_1+1}{2^k}\right] \times \cdots \times \left[\tfrac{a_n}{2^k}, \tfrac{a_n+1}{2^k}\right] \quad \text{with } a_1, \ldots, a_n \in \mathbb{Z}.$$

Put differently, a $\frac{1}{2^k}$-cube is a cube in $\mathbb{R}^n$ with side length $\frac{1}{2^k}$ and where the coordinates of all vertices lie in $\frac{1}{2^k} \cdot \mathbb{Z}$.

Lemma 104.5. Let $x \in \mathbb{R}^n$ and let $r > 0$. If $k \in \mathbb{N}_0$ is chosen such that $\frac{1}{2^k} < \frac{1}{3\sqrt{n}} \cdot r$, then there exist finitely many $\frac{1}{2^k}$-cubes $W_1, \ldots, W_m$ such that

$$x \;\in\; \text{interior of } (W_1 \cup \cdots \cup W_m) \;\subset\; W_1 \cup \cdots \cup W_m \;\subset\; B_r^n(x).$$



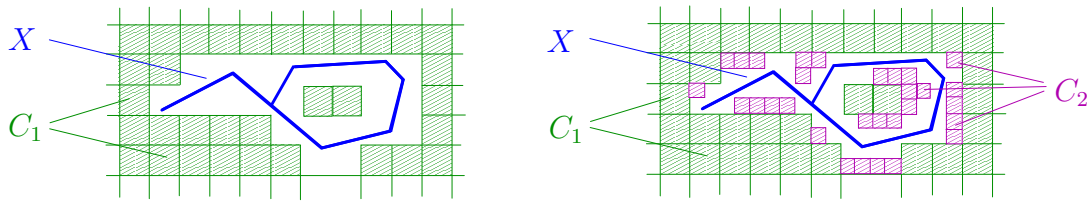
Proof. Let $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ and let $r > 0$. Furthermore let $k \in \mathbb{N}_0$ such that $\frac{1}{2^k} < \frac{1}{3\sqrt{n}} \cdot r$. We write $\epsilon = \frac{1}{2^k}$. For $i = 1, \ldots, n$ we denote by y_i the result of rounding x_i down to the closest number in $\mathbb{Z} \cdot \epsilon$. Clearly we have

$$(x_1, \ldots, x_n) \in \big[y_1, y_1{+}\epsilon\big] \times \cdots \times \big[y_n, y_n{+}\epsilon\big] \subset \text{interior of } \underbrace{\big[y_1{-}\epsilon, y_1{+}2\epsilon\big] \times \ldots \times \big[y_n{-}\epsilon, y_n{+}2\epsilon\big]}_{=:V}.$$

Since V is the union of finitely many ϵ-cubes it suffices to show that V is contained in $B_r^n(x)$. Thus let $y \in V$. We have

$$d(y,x) \underset{\substack{\uparrow \\ \text{since } x \in V}}{\leq} \text{diameter of } V \underset{\substack{\uparrow \\ \text{see page 285}}}{=} \sqrt{n} \cdot 3\epsilon \;=\; \sqrt{n} \cdot \frac{3}{2^k} \underset{\substack{\uparrow \\ \text{choice of } k}}{<} r$$

which means by definition that $y \in B_r^n(x)$. Thus we have shown that $V \subset B_r^n(x)$. ∎



Now we turn to the actual proof of Borsuk's Theorem 104.3

Proof of Borsuk's Theorem 104.3. Let X be a closed, weakly locally contractible subset of $\mathbb{R}^n$. By Observation 104.1 (2) it suffices to show that there exists a neighborhood W of X in $\mathbb{R}^n$ that admits a retraction $W \to X$. Evidently we only have to consider the case that X is non-empty. We introduce the following notation.

(1) We define C_1 to be the union of all 1-cubes that do not intersect X.
(2) We define C_2 to be the union of all $\frac{1}{2}$-cubes that do not intersect $\mathring{C}_1$ and that do not intersect X.
(3) We iterate this process, i.e. for any $k \geq 3$ we define C_n to be the union of all $\frac{1}{2^k}$-cubes that do not intersect the interior of $C_1 \cup \cdots \cup C_{k-1}$ and that do not intersect X.

Claim 1.

(1) We have $\bigcup_{k\in\mathbb{N}} C_k = \mathbb{R}^n \setminus X$.
(2) Given any $x_0 \in \mathbb{R} \setminus X$ there exists an open neighborhood U that intersects only finitely many cubes of $C_1, C_2, \ldots$.

Proof. Let $x_0 \in \mathbb{R}^n \setminus X$. Since X is closed we know that $\mathbb{R}^n \setminus X$ is open. This means that there exists an $r > 0$ such that $B_r^n(x_0) \subset \mathbb{R}^n \setminus X$. We pick $k \in \mathbb{N}_0$ such that $\frac{\sqrt{n}}{3\cdot 2^k} < r$. By Lemma 104.5 there exist finitely many $\frac{1}{2^k}$-cubes $W_1, \ldots, W_m$ such that

$$x_0 \in \underbrace{\text{interior of } W_1 \cup \cdots \cup W_m}_{:=U} \subset B_r^n(x).$$

This implies in particular that x_0 is contained in C_n or it is contained already in one of $C_1, \ldots, C_{k-1}$. Furthermore it is fairly easy to see that if U intersects a $\frac{1}{2^m}$-cube with $m \geq k$ it already intersects a $\frac{1}{2^k}$-cube. It follows from this observation and the iterative definition of the C_i that U intersects only finitely many cubes of $C_1, C_2, \ldots$. ⊞

We view each C_i as a CW-complex in the obvious way: the n-cells correspond precisely to the cubes and the lower dimensional cells correspond precisely to the faces of the cubes. For each k the union $C_1 \cup \cdots \cup C_n$ is also a CW-complex in an obvious way and finally we can also view the union $C := \bigcup_{k\in\mathbb{N}} C_k = \mathbb{R}^n \setminus X$ as a CW-complex. We leave it to the reader to verify, using Statement (2) of the claim and using Lemma 1.8 (2), that the topology on this CW-complex, given by the weak topology defined on page 1479, agrees with the usual subspace topology on $\mathbb{R}^n \setminus X$.

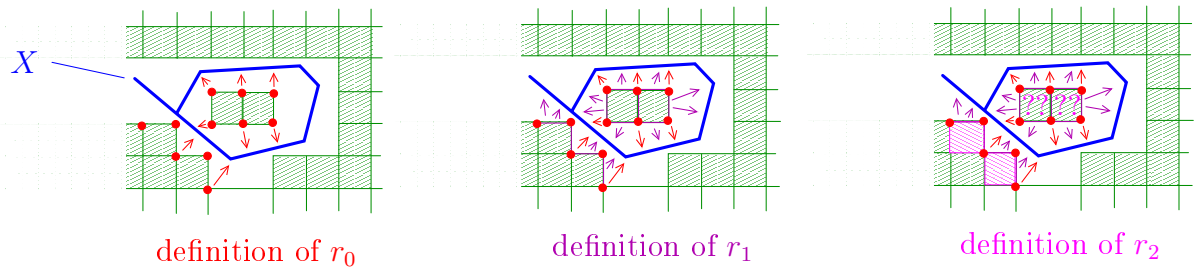
We continue with the following definition: given a cell σ of C and a map $f\colon \sigma \to X$ we define[12621263]

$$\rho(f) := \max\{d(z, f(z)) \,|\, z \in \sigma\}.$$

We start with the iterative definition of a subset of $\mathbb{R}^n$ together with a map to X.

(a) We denote by A_0 the 0-skeleton of C. Next we define a map $r_0\colon A_0 \to X$. Let $a \in A_0$. Since X is a closed subset of $\mathbb{R}^n$ it follows from the Distance-Minimizer Lemma 6.4 that we can find a point $r_0(a) \in X$ with $d(a, r_0(a)) = d(a, X)$.
(b) Now suppose inductively that we have defined a map $r_i\colon A_i \to X$ on a union A_i of some of the i-cells of C. We define the next set A_{i+1} and the corresponding map $r_{i+1}\colon A_{i+1} \to X$ as follows:
(b_1) Let σ be an $(i+1)$-cell of C for which r_i is defined on $\partial\sigma$. Suppose that r_i can be extended to a map $g\colon \sigma \to X$ that agrees with r_i on $\partial\sigma$. Then we pick a map

[1262]Given $a, b \in \mathbb{R}^n$ we denote by $d(a, b) = \|a - b\|$ the usual Euclidean distance.
[1263]Note that σ is compact, hence the maximum exists by the Compact Image Lemma 2.13 (2).



$r_{i+1}\colon \sigma \to X$ with $r_{i+1}|_{\partial\sigma} = r_i$ such that

$$\rho(r_{i+1}) \;\leq\; 2 \cdot \underbrace{\inf\{\rho(g) \,|\, g\colon \sigma \to X \text{ is a map with } g|_{\partial\sigma} = r_i|_{\partial\sigma}\}}_{\geq d(\sigma, X) \text{ which in turn is } > 0 \text{ by Lemma 6.3, here we use again that } X \subset \mathbb{R}^n \text{ is closed}}.$$

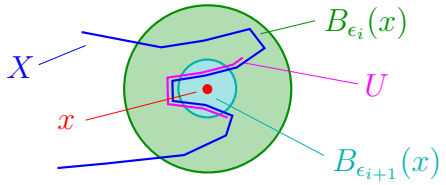
(b_2) We denote by A_{i+1} the union of all $(i+1)$-cells as in (b_1) and we define r_{i+1} on A_{i+1} as in (b_1).

(c) We set $A := \bigcup_{i\in\mathbb{N}} A_i \cup X$ and we define $r\colon A \to X$ to be the unique map that equals r_i on each A_i and that is the identity on X.

We refer to the figure below for an illustration. It remains to show that the set A is a

neighborhood of X and that the map $r\colon A \to X$ is continuous. Both statements follow from the following claim.

Claim 2. Given any $x \in X$ and any $\epsilon_0 > 0$ there exists an open neighborhood U of x that is contained in A and such that $\|\underbrace{r(x)}_{=x} - r(y)\| < \epsilon_0$ for all $y \in U$, i.e. such that $r(U) \subset B^n_{\epsilon_0}(x)$.

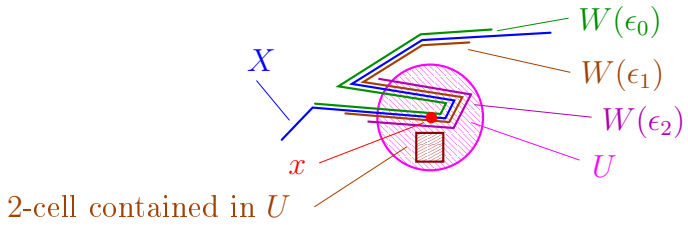


Proof. So let $x \in X$ and let $\epsilon_0 > 0$. We adopt the following notation: given $\mu > 0$ we write $W(\mu) = X \cap B^n_\mu(x)$.

Subclaim. We can find $\epsilon_1, \ldots, \epsilon_{2n}$ with the following two properties:

(1) for each $i \in \{0, \ldots, 2n-1\}$ we have $\epsilon_{i+1} < \frac{1}{3} \cdot \epsilon_i$,

(2) for every $i = 1, \ldots, 2n$ the subset $W(\epsilon_i)$ is contractible in $W(\epsilon_{i-1})$.



So suppose that we have already found $\epsilon_0, \ldots, \epsilon_i$ for some $i \in \{0, \ldots, 2n-1\}$ with the desired properties. Since X is weakly locally contractible we can find an open neighborhood U of x in X that is contained in $W(\epsilon_i)$ and that is contractible in $W(\epsilon_i)$. Since U is open there exists an $\epsilon_{i+1} < \frac{1}{3}\epsilon_i$ such that $W(\epsilon_{i+1}) \subset U$. Since U is contractible in $W(\epsilon_i)$ the subset $W(\epsilon_{i+1})$ is also contractible in $W(\epsilon_i)$. We refer to the figure below for an illustration. This concludes the proof of the subclaim.

We set $U := B^n_{\frac{1}{4}\epsilon_{2n}}(x)$. It suffices to prove the following two subclaims.

Subclaim 1. For each $i = 0, \dots, n$ the map r is defined for each i-cell σ of the CW-complex C that lies in U and for each such σ we have $r(\sigma) \subset W(\epsilon_{2n-2i})$.

Subclaim 2. The union of X with all cells of C that lie in U is a neighborhood of x.

First we prove Subclaim 1. We prove Subclaim 1 iteratively for $i = 0, 1, \dots, n$. We start out with $i = 0$. Thus we have to show that $r(U \cap A_0) \subset W(\epsilon_{2n})$. Therefore let $y \in U \cap A_0$. Then we have

$$d(x, r(y)) \underset{\uparrow}{\leq} d(x,y) + d(y, r_0(y)) \underset{\uparrow}{\leq} d(x,y) + d(y,x) = 2d(x,y) \underset{\uparrow}{<} 2 \cdot \tfrac{1}{4} \cdot \epsilon_{2n} = \tfrac{1}{2} \cdot \epsilon_{2n}.$$

triangle inequality and $r(y) = r_0(y)$ — by (a) since $x \in X$ — since $y \in U = B^n_{\frac{1}{4}\epsilon_{2n}}(x)$

But since $r(y) \in X$ this means precisely that $r(y) \in W(\epsilon_{2n}) = X \cap B^n_{\epsilon_{2n}}(x)$. This shows that Subclaim 1 holds for $i = 0$.

Now suppose that Subclaim 1 holds for some $i \in \{0, \dots, n-1\}$. Let σ be an $(i+1)$-cell of the CW-complex C inside U. Since $r(\partial\sigma) \subset W(\epsilon_{2n-2i})$ and since $W(\epsilon_{2n-2i})$ is contractible in $W_{2n-2i-1}$ it follows from the Convex-to-Ball Proposition 2.20 and the Homotopy-π_n-Proposition 71.7 (3) that we can extend $r|_{\partial\sigma} = r_i|_{\partial\sigma}$ to a map $s\colon \sigma \to W(\epsilon_{2n-2i-1})$. By definition of A_{i+1} this implies that $\sigma \subset A_{i+1}$. In particular r is defined on σ. It remains to show that $r(\sigma) \subset W(\epsilon_{2n-2i-2})$. Thus let $y \in \sigma$.

We have

$$d(x, r(y)) \underset{\uparrow}{\leq} d(x,y) + d(y, r_{i+1}(y)) \underset{\uparrow}{\leq} \tfrac{1}{4}\epsilon_{2n} + \rho(r_{i+1}) \underset{\uparrow}{\leq} \tfrac{1}{4}\epsilon_{2n} + 2 \cdot \inf\left\{ \rho(g) \,\middle|\, \begin{array}{c} g\colon \sigma \to X \text{ with} \\ g|_{\partial\sigma} = r_i|_{\partial\sigma} \end{array} \right\}.$$

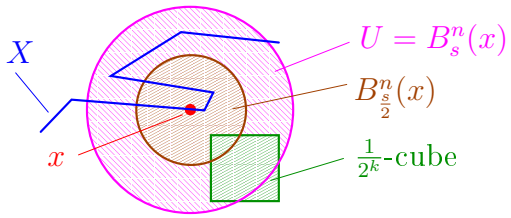
by the triangle inequality and since $r(y) = r_{i+1}(y)$ — since $y \in \sigma \subset U = B^n_{\frac{1}{4}\epsilon_{2n}}(x)$ and by definition of $\rho(r_{i+1})$ — by (b_1)

$$\underset{\uparrow}{\leq} \tfrac{1}{4}\epsilon_{2n} + 2 \cdot \underbrace{\max\{d(z, s(z)) \mid z \in \sigma\}}_{=\rho(s)} \underset{\uparrow}{\leq} \tfrac{1}{4}\epsilon_{2n} + 2 \cdot \max\{d(z,x) + d(x, s(z)) \mid z \in \sigma\}$$

since s is such a map — triangle inequality

$$\underset{\uparrow}{\leq} \tfrac{1}{4}\epsilon_{2n} + 2\big(\tfrac{1}{4}\epsilon_{2n} + \epsilon_{2n-2i-1}\big) = \tfrac{3}{4}\epsilon_{2n} + 2\epsilon_{2n-2i-1} \underset{\uparrow}{\leq} \tfrac{1}{12}\epsilon_{2n-2i-2} + \tfrac{2}{3}\epsilon_{2n-2i-2} \leq \epsilon_{2n-2i-2}.$$

since $\sigma \subset U = B^n_{\frac{1}{4}\epsilon_{2n}}(x)$ and since for each $z \in \sigma$ we have $s(z) \in W(\epsilon_{2n-2i-1}) \subset B^n_{\epsilon_{2n-2i-1}}(x)$ — since for each j we have $\epsilon_{j+1} \leq \frac{1}{3}\epsilon_j$



This concludes the proof that $r(\sigma) \subset W(\epsilon_{2n-2i-2})$. In particular this concludes the proof of Subclaim 1.

Finally it remains to prove Subclaim 2. We set $s = \frac{1}{4}\epsilon_{2n}$. As a reminder, we have to show that the union of X with all cells of C that lie in $B^n_s(x)$ is a neighborhood of x. Let W be a $\frac{1}{2^k}$-cube with $W \cap B^n_{\frac{s}{2}}(x) \neq \varnothing$ and $W \cap (\mathbb{R}^n \setminus B^n_s(x)) \neq \varnothing$. It follows that the diameter of W is at least $\frac{s}{2}$ which in turn implies that $\frac{\sqrt{n}}{2^k} \geq \frac{s}{2}$. We set $k_0 = \lfloor \ln_2(\frac{2\sqrt{n}}{s}) \rfloor$.

We see that

$$\begin{aligned}
&\text{union of } X \text{ with all cells of } C \text{ that lie in } B^n_s(x)\\
&\quad\supset \text{union of } X \text{ with all cubes of } C \text{ that lie in } B^n_s(x)\\
&\quad\supset B^n_s(x) \setminus \text{union of all cubes of } C \text{ that are not completely contained in } B^n_s(x)\\
&\qquad\uparrow \text{ since } \mathbb{R}^n \setminus X = C\\
&\quad= B^n_s(x) \setminus \text{union of all cubes of } C \text{ that are not completely contained in } B^n_s(x)\\
&\qquad\qquad \text{which do not contain the point } x \text{ but which intersect } B^n_{\frac{s}{s}}(x)\\
&\quad\supset B^n_s(x) \setminus \underbrace{\text{union of all } \tfrac{1}{2^k}\text{-cubes with } k \le k_0 \text{ of } C \text{ that are not contained in } B^n_s(x)}\\
&\qquad\uparrow \qquad\qquad \text{which do not contain the original point } x \text{ but which do intersect } B^n_{\frac{s}{s}}(x).}_{\text{finite union of cubes, hence a closed subset}}\\
&\quad \text{definition of } k_0
\end{aligned}$$

The last set is clearly an (open) neighborhood of x. But then the first set is also a neighborhood of x. This concludes the proof of Subclaim 2. ■

104.3. **Euclidean Neighborhood Retracts.** Borsuk's Theorem 104.3 has many applications. For example, much later, it will be a key ingredient in the proof of the Generalized Alexander Duality Theorem 124.2.
In this section we will discuss several fairly direct consequences of Borsuk's Theorem 104.3. For the following discussion it is convenient to introduce the following definition.

Definition. A topological space X is called a euclidean neighborhood retract (or short ENR) if there exists an embedding $f\colon X \to \mathbb{R}^n$ and an open neighborhood U of $f(X)$ such that $f(X)$ is a retract of U.

Remark. Let $i\colon X \to \mathbb{R}^n$ be an embedding of a topological space. The property of X being a retract of an open neighborhood, rather surprisingly, does not depend on the choice of the embedding. More precisely, [**tD2008**, Proposition 18.4.1] says the following. If X is an ENR, then given any embedding $f\colon X \to Y$ into a metric space Y there exists an open neighborhood U of $f(X)$ such that X is a retract of U. We will not make use of this pretty statement.

In the following we will mostly work with the following slight reformulation of Borsuk's Theorem.

Theorem 104.6. (Borsuk's Theorem) Let X be a topological space which is weakly locally contractible and which admits an embedding $f\colon X \to \mathbb{R}^n$.

(1) If $f(X)$ is closed, then X is an ENR.
(2) If X is regionally compact (e.g. if X is compact), then X is an ENR.

Proof.

(1) This statement follows immediately from Borsuk's Theorem 104.6.

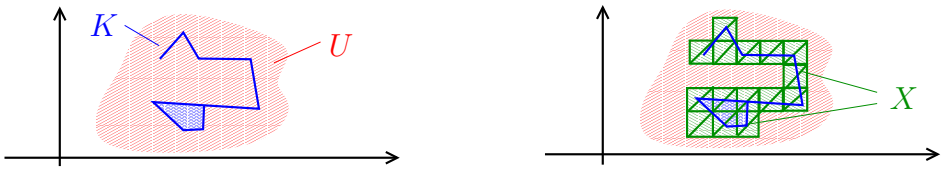
(2) Now assume that X is regionally compact. If X is compact, then we know of course by the Compact-Closed Lemma 1.21 (2) that $f(X)$ is compact and we can apply (1). Slightly more interestingly, if X is regionally compact, then we know by Exercise 104.6 that there exists an embedding $g\colon X \to \mathbb{R}^{n+1}$ such that $g(X)$ is a *closed* subset of $\mathbb{R}^{n+1}$. Thus we obtain again from (1) that X is an ENR. ■

Definition. Let X be a topological space and let $\mathcal{C}$ be a class of topological spaces (e.g. $\mathcal{C}$ could be the class of CW-complexes). We say X is a retract of an element in $\mathcal{C}$ if there exists a topological space $Y \in \mathcal{C}$, a map $i\colon X \to Y$ and a map $r\colon Y \to X$ with $r \circ i = \mathrm{id}_X$.[1264]

In this chapter our key interest in ENR and thus in Borsuk's Theorem 104.3 stems from the following fairly simple proposition.

Proposition 104.7. (ENR-Simplicial Complex Retract Proposition)

(1) If $K \subset \mathbb{R}^n$ is a compact neighborhood retract, then K is the retract of a finite n-dimensional simplicial complex.



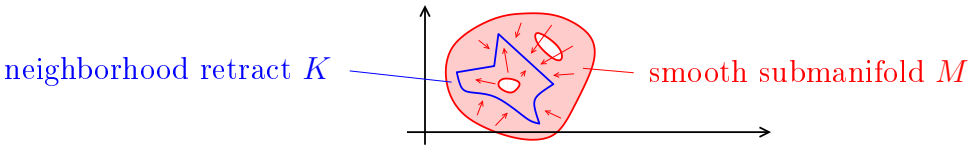
(2) Every compact ENR is a retract of a finite simplicial complex.

Proof.

(1) Let K be a compact subset of $\mathbb{R}^n$ which is a retract of some open neighborhood V. The idea is to define a simplicial complex X to be the union of finitely many sufficiently small cubes. To do so we set $r := d(K, \mathbb{R}^n \setminus V)$. Since K is compact and since $\mathbb{R}^n \setminus V$ is closed it follows from Lemma 6.3 that $r > 0$. We pick $k \in \mathbb{N}_0$ such that $\frac{1}{2^k} < \frac{1}{\sqrt{n}} \cdot r$. We denote by X the union of all $\frac{1}{2^k}$-cubes that intersect K. (See page 2295 for the definition of a $\frac{1}{2^k}$-cube.) Since K is compact we see that X is the union of finitely[1265] many $\frac{1}{2^k}$ cubes. The same argument as in the proof of Lemma 104.5 shows, by our choice of k, that each $\frac{1}{2^k}$-cube is contained in V.

We equip each cube with the canonical simplicial structure that we introduced on page 2000. As in Lemma 93.17 we see that the union of the cubes X also admits a simplicial structure. It follows from Observation 104.1 (1) that K is a retract of the finite simplicial complex X.

(2) This statement follows immediately from (1). ■



The statement of the following proposition is quite similar to the statement of the ENR-Simplicial Complex Retract Proposition 104.7, it just replaces simplicial complexes by smooth manifolds. We will not make much use of Proposition 104.8, except that it will come in handy at one occasion later on.

[1264] Note that Exercise 2.43 implies that such a map $i\colon X \to Y$ is necessarily an embedding.

[1265] Why is that? Why do we need only finitely many such cubes?

Proposition 104.8.

(1) If $K \subset \mathbb{R}^n$ is a compact neighborhood retract, then K is the retract of a compact n-dimensional smooth submanifold of $\mathbb{R}^n$.
(2) Every compact ENR is a retract of a compact smooth manifold.

Proof.

(1) Let K be a compact subset of $\mathbb{R}^n$ that is a retract of some open neighborhood V. Since V is an open subset of $\mathbb{R}^n$ it is in particular an n-dimensional smooth manifold. Therefore we can apply the Compact Submanifold Exhaustion Proposition 31.2 and we obtain a sequence $M_1, M_2, \dots$ of subsets of V with the following three properties:
   (a) the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $M_i \subset M_{i+1}$,
   (b) each M_i is a compact n-dimensional smooth submanifold of V,
   (c) we have $\bigcup_{i\in\mathbb{N}} \mathring{M}_i = V$ where $\mathring{M}_i := M_i \setminus \partial M_i$.

   We make the following observations:
   (i) By Lemma 120.1 (3) each $\mathring{M}_i$ is an open subset of V and thus also of $\mathbb{R}^n$.
   (ii) It follows from (a), (c) and (i), the hypothesis that K is compact and Lemma 2.12 that there exists an $i \in \mathbb{N}$ such that $f(K) \subset M_i$.
   (iii) Since V is an open subset of $\mathbb{R}^n$ every smooth submanifold of V is in fact also a smooth submanifold of $\mathbb{R}^n$.

   It follows from this discussion and property (2) and Observation 104.1 (1) that the smooth manifold $M := M_i$ has all the desired properties.
(2) This statement follows immediately from (1). ∎

The following proposition shows that many of our favorite topological spaces are ENRs.

Proposition 104.9. (Manifolds-ENR Proposition)

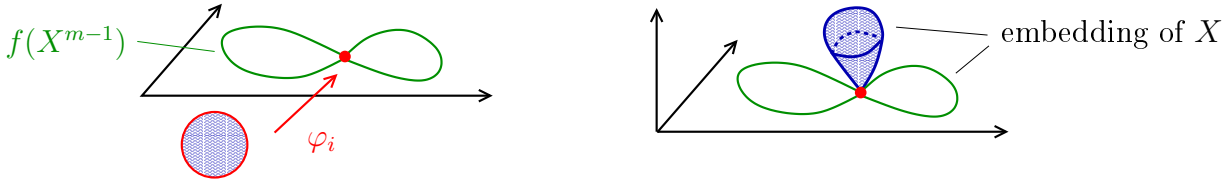
(1) Every topological manifold is an ENR.
(2) Every countable CW-complex that is regionally compact and finite-dimensional is an ENR.

Remark.

(1) By the CW-Complex Compactness Corollary 68.15 we know that a finite CW-complex is compact, in particular regionally compact. Thus the Manifolds-ENR Proposition 104.9 (2) implies that every finite CW-complex is an ENR.
(2) By Exercise 68.8 we know that a CW-complex is regionally compact if and only if it is locally finite.

The proof of the Manifolds-ENR Proposition 104.9 (2) relies very much on the following lemma which is perhaps interesting in its own right.

Lemma 104.10. Let X be a CW-complex. If X is countable, regionally compact and finite-dimensional, then X admits an embedding into some $\mathbb{R}^n$.



Remark. The special case of Lemma 104.10 provided by finite CW-complexes is precisely the content of Exercise 68.11.

Proof of Lemma 104.10. The theorem in its full generality is proved in [**FrPi1990b**, Theorem A]. In the discussion below we will only deal with the much simpler case that X is actually a finite CW-complex. We prove this case by induction on the dimension of the CW-complex X. The case $\dim(X) = -1$ is of course trivial. So suppose we already know the statement for all finite CW-complexes of dimension $\leq m-1$. Now let X be a finite m-dimensional CW-complex. As usual we denote by X^{m-1} the m-skeleton of X. We denote by $\varphi_1, \ldots, \varphi_k \colon S^{m-1} \to X^{m-1}$ the attaching maps of the m-cells of X. By induction there exists an $n \in \mathbb{N}_0$ and an embedding $f \colon X^{m-1} \to \mathbb{R}^n$. We consider the map

$$\overbrace{\left(X^{m-1} \sqcup \bigsqcup_{i=1}^{k} \overline{B}_i^m\right)/\sim}^{=X} \to \mathbb{R}^n \times \overbrace{\mathbb{R}^{m+1} \times \cdots \times \mathbb{R}^{m+1}}^{k \text{ copies}}$$

$$[x] \mapsto \begin{cases} (f(x), 0, \ldots, 0), & \text{if } x \in X^{m-1}, \\ (r \cdot f(\varphi_i(v)), 0, \ldots, \underbrace{rv \cdot (1-r), 1-r}_{\text{in the } i\text{-th } \mathbb{R}^{m+1}\text{-factor}}, \ldots, 0), & \text{if } x = r \cdot v \in \overline{B}_i^m \text{ where } \\ & r \in [0,1] \text{ and } v \in S^{m-1}. \end{cases}$$

It follows from Lemma 5.19 (2) that the somewhat risqué notation for points in $\overline{B}_i^m$ actually leads to a meaningful and continuous map on each $\overline{B}_i^m$. Note that from the Characteristic Maps Lemma 68.7 (4) we obtain that the overall map is continuous. Our hypothesis that X is a finite CW-complex implies by the CW-Complex Compactness Corollary 68.15 that X is compact. Finally it is elementary to verify that the map is actually injective. Thus, in summary, we can appeal to everybody's best friend, i.e. the Compact-Hausdorff Proposition 2.17 (2), to conclude the proof that this map is in fact an embedding. ■

Proof of the Manifolds-ENR Proposition 104.9.

(1) Just for fun we first give a separate, more down to earth argument, for the case of a closed smooth manifold M. By the Euclidean Embedding Theorem 27.1 and the Smooth Embedding Theorem 24.10 we can view M as a closed submanifold of some $\mathbb{R}^n$. Now we apply Theorem 28.1 to conclude that $M \subset \mathbb{R}^n$ admits an open neighborhood that retracts to M.

Now we turn to the general case. Thus let M be a topological manifold. By the Euclidean Embedding Theorem 27.1 we know that there exists an embedding $f \colon M \to \mathbb{R}^n$ such that $f(M)$ is a closed subset of $\mathbb{R}^n$. As we discussed on page 2290, every topological manifold is weakly locally contractible. Thus we can apply Borsuk's Theorem 104.6 to deduce that M is indeed an ENR.

(2) Let X be a CW-complex that is countable, regionally compact and finite-dimensional. By Lemma 104.10 we know that there exists an embedding $f\colon X \to \mathbb{R}^n$. Furthermore, as we discussed on page 2291, it follows almost immediately from the CW-Complex Properties Proposition 68.10 (6) that the CW-complex X is weakly locally contractible. Thus we can once again apply Borsuk's Theorem 104.6 (2) to conclude that X is an ENR. ■

Recall that in Theorem 97.9 and 97.10 we formulated and proved the Lefschetz Fixed Point Theorem in the realm of finite simplicial complexes and compact smooth manifolds. Our aim now is to extend the Lefschetz Fixed Point Theorem to compact ENRs. To do so we first need to convince ourselves that in this setting the Lefschetz number is actually defined. This follows from the following lemma.

Lemma 104.11. If X is a compact ENR, then for every field $\mathbb{F}$ the homology of X is $\mathbb{F}$-finite.

Proof. Let X be a compact ENR and let $\mathbb{F}$ be a field. It follows from Propositions 104.7 that X is a retract of a finite simplicial complex Y. Recall that this means that there exists a map $i\colon X \to Y$ and a map $r\colon Y \to X$ with $r \circ i = \mathrm{id}_X$.

(1) It follows from the Simplicial-Implies-CW Lemma 93.24 together with the Homology-of-CW-Complex Proposition 80.6 and the discussion on page 1915 that the homology of Y is $\mathbb{F}$-finite.
(2) It follows from the functoriality of homology groups and the fact that $r \circ i = \mathrm{id}_X$ that for every $k \in \mathbb{N}$ the map $r_*\colon \mathrm{H}_k(Y;\mathbb{F}) \to \mathrm{H}_k(X;\mathbb{F})$ is an epimorphism.

It follows immediately from (1) and (2) that the homology of X is $\mathbb{F}$-finite. ■

Now that we know that the Lefschetz number of every self-map of a compact ENR is defined we can now formulate the following theorem.

Theorem 104.12. (Lefschetz Fixed Point Theorem III) Let X be a compact ENR (e.g. X could be a compact topological manifold or a finite CW-complex) and let $\varphi\colon X \to X$ be a map. If the $\mathbb{F}$-Lefschetz number $\Lambda(\varphi, \mathbb{F})$ is non-zero for some field $\mathbb{F}$, then φ has a fixed point.

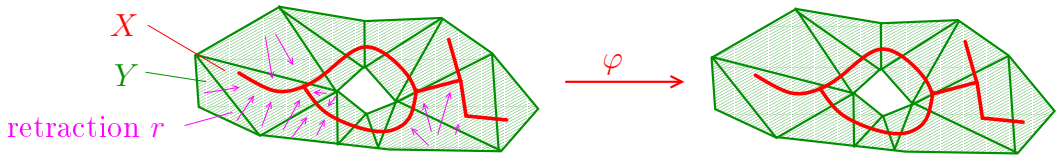
Remark.

(1) The above Lefschetz Fixed Point Theorem 104.12 together with the Manifolds-ENR Proposition 104.9 also gives a different, now totally self-contained, proof of the Lefschetz Fixed Point Theorem 97.10 for compact smooth manifolds.
(2) For compact orientable topological manifolds we will provide a generalization of the above Lefschetz Fixed Point Theorem 104.12 in the Lefschetz-Hopf Theorem 128.9.

Proof. Let X be a compact ENR. By the ENR-Simplicial Complex Retract Proposition 104.7 we know that X is a retract of a finite simplicial complex Y. Recall that this means that there exists a map $i\colon X \to Y$ and a map $r\colon Y \to X$ with $r \circ i = \mathrm{id}_X$. By the very harmless Exercise 2.43 we know that i is an embedding. Thus in the following we will view X as a subspace of Y. Now let $\varphi\colon X \to X$ be a map. We consider the map $i \circ \varphi \circ r\colon Y \to Y$.

Claim. We have $\Lambda(i \circ \varphi \circ r, \mathbb{F}) = \Lambda(\varphi, \mathbb{F})$.

Proof. Let $k \in \mathbb{N}_0$. We consider the following sequence of maps



$$0 \longrightarrow \ker(r_*) \hookrightarrow \mathrm{H}_k(Y;\mathbb{F}) \underset{i_*}{\overset{r_*}{\rightleftarrows}} \mathrm{H}_k(X;\mathbb{F}) \longrightarrow 0.$$

Note that we have the equality $r_* \circ i_* = (r \circ i)_* = \mathrm{id}_* = \mathrm{id}_{\mathrm{H}_k(X;\mathbb{F})}$. This observation implies that the horizontal sequence is exact and that it splits. As in Splitting Lemma 78.2 we see that this implies that we can write $\mathrm{H}_k(Y;\mathbb{F}) = i_*(\mathrm{H}_k(X;\mathbb{F})) \oplus \ker(r_*)$. With slightly suggestive notation we see that

$$\mathrm{tr}\left(\mathrm{H}_k(Y;\mathbb{F}) \xrightarrow{i_* \circ \varphi_* \circ r_*} \mathrm{H}_k(Y;\mathbb{F})\right) = \mathrm{tr}\Bigg(\underbrace{\begin{pmatrix}\mathrm{id}\\0\end{pmatrix}(\varphi_*)\begin{pmatrix}\mathrm{id} & 0\end{pmatrix}}_{=\begin{pmatrix}\varphi_* & 0\\0 & 0\end{pmatrix}}\Bigg) = \mathrm{tr}\left(\mathrm{H}_k(X;\mathbb{F}) \xrightarrow{\varphi_*} \mathrm{H}_k(X;\mathbb{F})\right).$$

The desired formula for the Lefschetz numbers follows immediately from this claim. ⊞

From our hypothesis, the claim and the Lefschetz Fixed Point Theorem 97.9 for simplicial complexes we obtain that $i \circ \varphi \circ r \colon Y \to Y$ admits a fixed point $y \in Y$. This fixed point y lies necessarily in the image of the last map, i.e. it lies in $i(X) = X$. It is clear that the point y is also a fixed point for φ. ■

Remark. In the possibly unlikely event that the reader wants to know more about ENRs we refer to [**Dol1980**, Chapter IV.8] for more information.

104.4. **Invariants of compact topological manifolds.** There are several ways how one can get a grip on the topology of a (compact) *smooth* manifold M:

(a) In Corollary 95.37 we used the fact that (compact) smooth manifolds admit good (finite) covers together with the Nerve Theorem 95.32 to show that M is weakly homotopy equivalent to a finite simplicial complex.

(b) In the Smooth Manifold-CW Structure Theorem 96.5 we used the fact that M is diffeomorphic to a smooth submanifold of some $\mathbb{R}^n$ to show that M actually admits a (finite) smooth simplicial structure.

(c) Later on, in the Morse Functions-Cells Proposition 138.6 and in the Smooth Manifold-CW-Homotopy Type 139.8, we will use "Morse theory" to show that M is homotopy equivalent to a (finite) CW-complex X with $\dim(X) \leq \dim(M)$.

These results, together with basic facts about invariants of finite CW-complexes, see the CW-Skeleton-π_1-Proposition 69.13 (3) and the Homology-of-CW-Complex Proposition 80.6 (2), imply the following excerpt of Proposition 96.6.

Proposition 96.6. (Smooth Manifolds-Invariants Proposition) Let M be a 0-connected smooth manifold.

(1) For any $k > n$ we have $\mathrm{H}_k(M) = 0$ and for every abelian group G we also have $\mathrm{H}_k(M; G) = 0$.
(2) The higher homotopy groups of M are countable.

Furthermore, if M is compact, then the following statements hold:

(3) The fundamental group of M is finitely presented.
(4) All homology groups of M are finitely generated abelian groups. Furthermore, given any field $\mathbb{F}$ the homology groups $\mathrm{H}_k(M; \mathbb{F})$ are finite-dimensional.

To the best of the author's understanding none of the above approaches (a), (b) and (c) can be carried over to topological manifolds.
It seems like the only tool we have for handling "the size" of invariants of compact topological manifolds is the following theorem, which is an immediate consequence of the Manifolds-ENR Proposition 104.9 together with the ENR-Simplicial Complex Retract Proposition 104.7.

Theorem 104.13. (Topological Manifold-Simplicial Complex Retract Theorem) Every compact topological manifold is a retract of a finite simplicial complex.

Fortunately this is enough to extend most of the results of Proposition 96.6:

Proposition 104.14. (Topological Manifolds-Invariants Proposition) Let M be a compact 0-connected topological manifold. The following statement holds:

(1) There exists an $l \in \mathbb{N}_0$ such that for every $k > l$ we have $\mathrm{H}_k(M) = 0$ and such that for every abelian group G we have $\mathrm{H}_k(M; G) = 0$.
(2) The higher homotopy groups of M are countable.
(3) The fundamental group of M is finitely presented.
(4) All homology groups $\mathrm{H}_k(M)$ are finitely generated abelian groups. Furthermore, given any field $\mathbb{F}$ the homology groups $\mathrm{H}_k(M; \mathbb{F})$ are finite-dimensional.

Remark.

(1) Let M be an n-dimensional topological manifold.
   (a) In the Top-Homology Theorem 106.3 we will see that in (1) we can take $l = \dim(M)$.
   (b) If M is in fact a smooth manifold, then the Smooth Manifold-Top Homology Theorem 98.6 allows us to compute the homology group $\mathrm{H}_n(M)$. In the Top-Homology Theorem 106.3 we will prove the analogous result without the hypothesis that M is smooth.
(2) the Topological Manifolds-Invariants Proposition 104.14 together with Lemma 96.8 often allows us to control the "size" of relative homology groups of a compact topological manifold. For example for a compact topological manifold M all relative homology groups $\mathrm{H}_k(M, \partial M)$ are finitely generated.
(3) We will deal with non-compact topological manifolds in Theorem 104.19 below.

Proof of the Topological Manifolds-Invariants Proposition 104.14. [1266] Let M be a compact 0-connected topological manifold, let $\mathbb{F}$ be a field, let G be an abelian group

[1266] The argument below is quite similar to the proof of Lemma 104.11.

and let $n \in \mathbb{N}$. We pick a base point $x_0 \in M$. It follows from Propositions 104.7 and 104.9 (1) that M is a retract of a finite simplicial complex Y. Recall that this means that there exists a map $i\colon M \to Y$ and a map $r\colon Y \to M$ with $r \circ i = \mathrm{id}_M$. We write $y_0 = i(x_0)$. Furthermore we denote the dimension of the simplicial complex by l. We make the following observations:

(a) By Proposition 94.9 we know that $\pi_n(Y, y_0)$ is countable.
(b) It follows from the Simplicial-Implies-CW Lemma 93.24 together with the CW-Skeleton-π_1-Proposition 69.13 that $\pi_1(Y, y_0)$ is finitely presented.
(c) It follows from the Simplicial-Implies-CW Lemma 93.24 together with the Homology-of-CW-Complex Proposition 80.6 and the discussion on page 1915 that the homology groups $\mathrm{H}_k(Y)$ are finitely generated, that the homology groups $\mathrm{H}_k(Y; \mathbb{F})$ are finite-dimensional and that $\mathrm{H}_k(Y) = 0$ and $\mathrm{H}_k(Y; G) = 0$ for $k > l$.

Now we turn to the invariants of M.

(1) Let $k \in \mathbb{N}_0$. It follows from the functoriality of homology groups and the fact that $r \circ i = \mathrm{id}_M$ that the maps $r_*\colon \mathrm{H}_k(Y) \to \mathrm{H}_k(M)$ and $\mathrm{H}_k(Y; G) \to \mathrm{H}_k(M; G)$ are epimorphisms. In particular if the groups to the left vanish, then so do the groups to the right. This observation together with (c) implies (1).
(4) The argument in (1) also shows that if $\mathrm{H}_k(Y)$ is finitely generated, then so is $\mathrm{H}_k(M)$. Similarly, if $\mathrm{H}_k(Y; \mathbb{F})$ is finite-dimensional, then so is $\mathrm{H}_k(M; \mathbb{F})$. Thus we see that (c) implies (4).
(2) As in (1) we see $r_*\colon \pi_n(Y, y_0) \to \pi_n(M, x_0)$ is an epimorphism. It follows from (a) and the Countability Lemma 0.8 that $\pi_n(M, x_0)$ is also countable.
(3) The logic of (1), (2) and (4) shows immediately that $\pi_1(M, x_0)$ is *finitely generated*. The statement that $\pi_1(M, x_0)$ is *finitely presented* requires a little more thought. More precisely, by the functoriality of fundamental groups we know that $\pi_1(M, x_0)$ is a *retract* of $\pi_1(Y, y_0)$. By (b) we know that the group $\pi_1(Y, y_0)$ is finitely presented. Thus we obtain from the purely group-theoretic the Finite Presentation-Retract Lemma 53.16 that $\pi_1(M, x_0)$ is also finitely presented. ■

Finally we can also say something non-trivial about possibly non-compact topological manifolds, namely we have the following analogue of Proposition 96.7.

Proposition 104.15. Let M be a 0-connected topological manifold.
(3′) The fundamental group of M is countable.
(4′) All homology groups $\mathrm{H}_k(M)$ are countable abelian groups. Furthermore, given any field $\mathbb{F}$ the dimension of each homology groups $\mathrm{H}_k(M; \mathbb{F})$ is countable.

Remark. In the Countable Fundamental Group Proposition 49.1 we already showed that fundamental groups of (possibly non-compact) topological manifolds are countable. But it seems difficult to adapt the approach of the Countable Fundamental Group Proposition 49.1 to deal with homology groups.

Proof. Let M be a 0-connected topological manifold. We pick $x_0 \in M$. By the Manifolds-ENR Proposition 104.9 we know that M is an ENR. Recall that this means that there exists an embedding $f\colon X \to \mathbb{R}^n$ and an open neighborhood U of $f(X)$ such that $f(X)$ is a retract of U.

Note that U is an open subset of $\mathbb{R}^n$. In particular U is a smooth manifold. It follows from Proposition 96.7 that $\pi_1(U, x_0)$ and all homology groups $\mathrm{H}_k(U)$ are countable.

As in the proof of the Topological Manifolds-Invariants Proposition 104.14 we see that $\pi_1(M, x_0)$ is isomorphic to a quotient of $\pi_1(U, x_0)$ and we see that each $\mathrm{H}_k(M)$ is isomorphic to a quotient of $\mathrm{H}_k(U)$. It follows from the above that $\pi_1(U, x_0)$ and all homology groups $\mathrm{H}_k(M)$ are countable. The same logic also applies to the homology groups $\mathrm{H}_k(M; \mathbb{F})$. ■

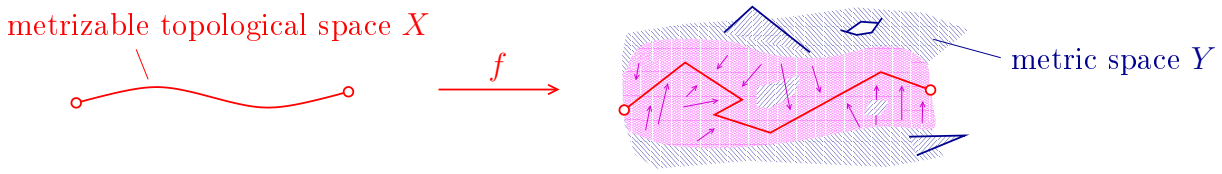
104.5. **ANRs and the homotopy type of topological manifolds.** In this section we will see in particular that all topological manifolds are homotopy equivalent to locally finite simplicial complexes, in particular, they are homotopy equivalent to CW-complexes. In contrast to the previous sections we will not attempt to prove the statements of this section, instead we try our best to give a good overview of the literature.
We start out with the following definition.

Definition. We say that a topological space X is dominated by a topological space Y if there exist maps $i\colon X \to Y$ and $r\colon Y \to X$ such that $r \circ i$ is homotopic to the identity id_X.

Example.

(1) If a topological space X is a retract of some topological space Y, then evidently X is dominated by Y.
(2) It follows from the ENR-Simplicial Complex Retract Proposition 104.7 together with the Manifolds-ENR Proposition 104.9 that every compact topological manifold and every finite CW-complex is dominated by a finite simplicial complex.

The following proposition is the most powerful result on dominations that we actually prove in these notes.



Proposition 162.8 (CW-Complex Domination Proposition). Let X be a topological space. If X is dominated by a CW-complex, then X is homotopy equivalent to a CW-complex.

Remark. Suppose a topological space X is a retract of some CW-complex Y. By the CW-Complex Domination Proposition 162.8 we now know that X is homotopy equivalent to a CW-complex. One might hope that X should actually admit the structure of a CW-complex. But in Exercise 104.5 we will see that in general this is *not* the case.

Proof. We will prove the CW-Complex Domination Proposition 162.8 in Section 162.3, using the Whitehead Theorem 162.1. Alternatively see the proofs of Theorems 104.19, 104.22 and 104.23 for alternative proofs. ■

It turns out that there exist several powerful generalizations of the CW-Complex Domination Proposition 162.8. To formulate these generalizations it is helpful to introduce the following definition.

Definition. A topological space X is called an absolute neighborhood retract (or short ANR) if X is metrizable and if the following condition is satisfied: whenever $f\colon X \to Y$ is an embedding into a metric space Y such that $f(X)$ is a closed subset of Y, then $f(X)$ is a neighborhood retract in Y.

Remark.

(1) Like in many other settings in the literature there exist various equivalent approaches to defining an ANR, see e.g. [**MaS1982**, Chaper I.3.1(ii)] and [**FrPi1990a**, Proposition A.6.2]. The definition above is the one given in [**FrPi1990a**, p. 281].

(2) Let X be an ANR. If X admits a closed embedding into some $\mathbb{R}^n$, then it follows immediately from the definitions that X is an ENR. Nonetheless, not every ANR is an ENR. For example we will see shortly that the disjoint union $X = \bigsqcup_{k\in\mathbb{N}} \overline{B}^k$ is an ANR, but it follows easily from the Topological Invariance of Domain Theorem 82.7 that X does not admit an embedding into any $\mathbb{R}^n$.

(3) Some references use a definition of an ANR which differs slightly from ours. More precisely, in [**Han1951**, p. 390] and [**Miln1959a**, p. 272] an ANR is supposed to satisfy the extra condition that it is separable, i.e. that it contains a countable subset that is dense. Note that in Exercise 9.8 we saw that a metrizable topological space is separable if and only if it is second-countable. Thus, since in these notes we are more familiar with the concept of second-countable topological spaces we will use that notion in the remainder of our discussion of ANRs.

(4) The theory of ANRs is developed in great detail in [**Hu1965, Bor1967, Chig1996**].

We will soon see what ANRs are good for. But first let us quote two theorems which give us many examples of ANRs.

Theorem 104.16. (Dugundji Extension Theorem) Let V be a real vector space and $\|-\|\colon V \to \mathbb{R}_{\geq 0}$ a norm on V. We equip V with the corresponding metric and we use this metric to view V as a topological space. With respect to this topology every convex subset of V is an ANR.[1267]

Example. The only consequence of the Dugundji Extension Theorem 104.16 that we will use is that every convex subset of some $\mathbb{R}^n$ is an ANR.

Proof. This theorem was proved by James Dugundji [**Dug1951**, Corollary 4.2] in 1952. A proof is also given in [**MaS1982**, Theorem I.3.1], [**Maye1989**, Theorem I.5.7] and [**Saka2013**, Theorem 6.1.1]. ■

Theorem 104.17. (Hanner's Theorem) Let X be a topological space which is second-countable and metrizable. If X is the union of a family $\{U_i\}_{i\in I}$ of open subsets such that each U_i is an ANR, then X itself is an ANR.

Proof. This theorem was proved by Olof Hanner [**Han1951**, Theorem 3.3] in 1950. An exposition of the proof is also given in [**Fera2004**, Theorem 2.77] and in [**Hu1965**, Theorem III.8.1]. ■

[1267] Note that there are no other hidden conditions on the subset except for convexity, in particular we do not demand that the subset is open, closed or compact.

Corollary 104.18. Every topological manifold is an ANR.

Proof. Let X be an n-dimensional topological manifold. By definition X is second-countable. By the Manifold Metrization Proposition 18.10 we know that X is metrizable. In the Topological Manifolds-Local Properties Lemma 18.8 (1) we showed that X is locally homeomorphic to some non-empty convex subset of $\mathbb{R}^n$. By the Dugundji Extension Theorem 104.16 every non-empty convex subset of $\mathbb{R}^n$ is an ANR. In other words, we have shown that X admits an open cover by ANRs. Thus we obtain from Hanner's Theorem 104.17 that X is indeed an ANR. ■

The following amazing theorem now tells us what ANRs are good for.

Theorem 104.19. Let X be a topological space. The following statements are equivalent:

(1) X is dominated by a countable CW-complex.
(2) X is homotopy equivalent to a countable CW-complex.
(3) X is homotopy equivalent to a countable simplicial complex.
(3′) X is homotopy equivalent to a countable simplicial complex that is locally finite.
(4) X is homotopy equivalent to an ANR which is second-countable.

Furthermore the following refinement of the equivalence of (2) and (3) holds: If X is homotopy equivalent to an n-dimensional countable CW-complex, then it is also homotopy equivalent to an n-dimensional countable simplicial complex, and vice versa.

Proof. The fact that all the statements are equivalent goes well beyond the scope of these notes. Thus we just give the necessary references. The implications (3′)⇒(3)⇒(2)⇒(1) are of course trivial. Next note that the equivalence of (2) and (3) is a consequence of the Simplicial-Implies-CW Lemma 93.24 and Proposition 94.12. As is explained in [**Miln1959a**, Theorem 1], the implication (1)⇒(3′) follows from work of James Whitehead [**WhdJ1950**, Theorem 24] and the implication (3′)⇒(4)⇒(1) follows from the work of Olof Hanner [**Han1951**, Corollary 3.5 and Theorem 6.1]. Alternatively we refer to [**FrPi1990a**, Theorem 5.2.1] or [**LW1969**, p. 137] for a proof that the five statements are equivalent. ■

The above results now give us several corollaries on topological manifolds.

Corollary 104.20.

(1) Every topological manifold is homotopy equivalent to a countable locally finite simplicial complex.
(2) The homology groups, the fundamental group and the higher homotopy groups of a 0-connected topological manifold are countable.

Remark. Let M be a 0-connected topological manifold. By Corollary 104.20 we now know that $\pi_1(M)$ is countable. A significantly more down-to-earth proof for this statement is given in [**Lee2000**, Proposition 7.21].

Proof.

(1) This statement follows from Corollary 104.18 together with Theorem 104.19 (4)⇒(3′) and the fact that topological manifolds are by definition second-countable.

(2) Let X be a 0-connected topological manifold. By (1) we know that X is homotopy equivalent to a 0-connected countable simplicial complex Y. It follows from Proposition 94.9 and the Simplicial-Implies-CW Lemma 93.24 together with the Homology-of-CW-Complex Proposition 80.6 that all homotopy groups[1268] and all homology groups of Y are countable. Finally note that it is a consequence of the Homotopy-π_n-Proposition 71.7 and the Homotopy Equivalence-H_*-Corollary 73.9 that the same statements hold for X. ■

By Proposition 86.15 we know that $\pi_2(S^1 \vee S^2)$ is isomorphic to $\mathbb{Z}^\infty$, in particular it is infinitely generated. This result, foreshadowed by our discussion on page 1573, shows that homotopy groups of finite CW-complexes can be infinitely generated. In Question 71.16 we asked, somewhat apprehensively, whether the homotopy groups of a countable CW-complex are necessarily countable. With a slight sigh of relief we can now give an affirmative answer to this question.

Proposition 104.21. If X is a CW-complex with countably many cells, then for any $n \in \mathbb{N}$ and any $x_0 \in X$ the group $\pi_n(X, x_0)$ is countable.

Proof. This follows from the combination of Theorem 104.19 (1)⇒(4) together with the Homotopy-π_n-Proposition 71.7 and Proposition 94.9. ■

Theorem 104.19 deals with (second-) countable objects. The following theorem is the analogue of Theorem 104.19 without any cardinality restrictions and, on the flip side, without any cardinality information.

Theorem 104.22. If X is a topological space, then the following statements are equivalent:

(1) X is dominated by a CW-complex.
(2) X is homotopy equivalent to a CW-complex.
(3) X is homotopy equivalent to a simplicial complex.
(4) X is homotopy equivalent to an ANR.

Proof. The implication "(1)⇒(2)" is precisely the statement of the CW-Complex Domination Proposition 162.8. The fact that (2) and (3) are equivalent is a consequence of the Simplicial-Implies-CW Lemma 93.24 and Proposition 94.12. The statement that in fact all four statements are equivalent is proved in [**FrPi1990a**, Theorem 5.2.1]. ■

Theorem 104.22, which gives no control of the "size" of the objects is not all that helpful. It is much more interesting to ask whether the analogue of Theorem 104.19 holds if we replace "countable" by "finite". In fact the following theorem holds.

Theorem 104.23. Let X be a topological space. The following statements are equivalent:

(2) X is homotopy equivalent to a finite CW-complex.
(3) X is homotopy equivalent to a finite simplicial complex.
(4) X is homotopy equivalent to a compact ANR.

Furthermore the following refinement of the equivalence of (2) and (3) holds: If X is homotopy equivalent to a finite n-dimensional CW-complex, then it is also homotopy equivalent to a finite n-dimensional simplicial complex, and vice versa.

[1268] For the fundamental group we could alternatively use the argument given on page 1537.

Proof. The fact that (2) and (3) are equivalent is a consequence of the Simplicial-Implies-CW Lemma 93.24 and Proposition 94.12. Next note that one can show, with some effort, that it is a consequence of the Dugundji Extension Theorem 104.16 that every finite simplicial complex is an ANR, we refer to [**LW1969**, p. 210] and [**HNV2004**, p. 472] for details. This observation gives us the implication (3)⇒(4). Finally the implication (4)⇒(2) was shown by James West [**Wes1977**] in 1977. ■

The attentive reader will have noticed that the dog that did not bark is the (1)⇒(2) implication. It turns out that there is a good reason why it did not bark. The following theorem, proved by C.T.C. Wall shows that in general the statement one would hope for is actually incorrect.

Theorem 104.24. There exists a topological space that is dominated by a finite CW-complex but that is not homotopy equivalent to a finite CW-complex.

Proof. The statement is proved in [**Wall1965a**, p. 66]. Alternatively see [**Var1989**, p. 163] and [**FeR2001**, Theorem 3.1]. More precisely, in [**Wall1965a, Var1989**] it is shown that to a topological space X that is dominated by a finite CW-complex one can associate an invariant in the "K-group $\widetilde{K}_0(\mathbb{Z}[\pi_1(X)])$" which vanishes if and only if X is homotopy equivalent to a finite CW-complex. It is shown in the above references that there exist examples where the invariant is indeed non-zero. Interestingly it is conjectured, see e.g. [**KrL2005**, p. 179], that the group $\widetilde{K}_0(\mathbb{Z}[\pi_1(X)])$ is zero, whenever $\pi_1(X)$ is a torsion-free group. ■

From this discussion we obtain the following corollary.

Corollary 104.25. Every compact topological manifold is homotopy equivalent to a finite simplicial complex.

Proof. This statement follows immediately from Corollary 104.18 together with Theorem 104.23 (4)⇒(3). A very different proof for the corollary was given by Rob Kirby and Larry Siebenmann in [**KSi1969**, Chapter III.2] and [**KSi1977**, p. 744]. ■

Let M be a (compact) n-dimensional topological manifold. By the above we now know that M is homotopy equivalent to a (finite) simplicial complex X. But the above results do not say anything about the dimension of the simplicial complex X. But it turns out, that at least for compact topological manifolds this can mostly be fixed.

Theorem 104.26.

(1) Every closed n-dimensional topological manifold is homotopy equivalent to a finite n-dimensional simplicial complex.
(2) Every compact connected n-dimensional topological manifold with non-empty boundary is homotopy equivalent to a finite $(n-1)$-dimensional simplicial complex.

Remark. It seems like a nice project to figure out whether Theorem 104.26 (2) can be generalized to non-compact topological manifolds.

Sketch of proof. First note that the 1-dimensional case follows immediately from the classification result proved in the Topological 1-Dimensional Manifold Classification Theorem 22.1. Furthermore the 2-dimensional case and the 3-dimensional case follow from

Radó's Theorem 104.29 and Moise's Theorem 104.30 below. Thus we can now assume that $n \geq 4$.

First note that by Theorem 104.22 (2)⇔(3) it suffices to prove the statement with simplicial complexes replaced by CW-complexes.

Next we cite the following theorem of C.T.C. Wall [**Wall1966a**, Corollary 5.1] (see also [**Wall1965a**, Theorem E] and [**Var1989**, Chapter 5.2]):

> **Wall's Finiteness Theorem.** *Let Y be a connected finite* CW*-complex such that there exists an $r \in \mathbb{N}_0$ such that all twisted cohomology groups $\mathrm{H}^s(Y;V)$ vanish for $s > r$. (The precise definition of twisted cohomology is irrelevant to our discussion, so stay with us.) Now* [**Wall1966a**, Corollary 5.1] *says that if these conditions are satisfied and if $r \geq 3$, then Y is homotopy equivalent to a finite r-*dimensional CW*-complex.*[1269]

Theorem 104.26 is now a consequence of Wall's Theorem and some reasonably standard facts in algebraic topology. In the discussion below we will outline the argument, the detailed proof for reducing Theorem 104.26 to Wall's Theorem is given in [**FNOP2019**, Theorem 4.1].

Now let X be a compact orientable n-dimensional topological manifold. It follows from Theorem 104.23 that X is homotopy equivalent to a finite CW-complex Y. It follows from "Poincaré Duality with twisted coefficients", see [**FNOP2019**, Theorem A.15], that for any $r \in \mathbb{N}_0$ and any $\mathbb{Z}[\pi_1(X, x_0)]$-left module V we have $\mathrm{H}^r(Y;V) \cong \mathrm{H}^r(X;V) \cong \mathrm{H}_{n-r}(X, \partial X; V)$. If $r > n$, i.e. if $n-r < 0$, then we have $\mathrm{H}_{n-r}(X, \partial X; V) = 0$. Furthermore, if X is connected and if $\partial X \neq 0$ and if $r = n$, i.e. if $n - r = 0$ we have, by an argument similar to the one given on page 1625, that $\mathrm{H}_{n-r}(X, \partial X; V) = 0$. The desired statement now follows from these calculations together with Wall's Theorem.

Finally we consider the case of a compact non-orientable n-dimensional topological manifold. The argument is basically the same, except that one needs Poincaré Duality for non-orientable manifolds. For untwisted coefficients this can be found in [**DaK2001**, Theorem 5.7]. For twisted coefficients this follows from an argument as in [**FNOP2019**, Theorem A.15], but it is conceivable that nobody ever bothered to work out the details. ■

We conclude this section with the following proposition which can be viewed as an analogue of the Single Top-Cell Proposition 98.16.

Proposition 104.27. Every closed connected non-empty n-dimensional topological manifold is homotopy equivalent to a finite n-dimensional CW-complex which has a single 0-cell and which has a single n-cell.

Proof. Let X be a closed connected non-empty n-dimensional topological manifold. We pick an embedding $\varphi\colon \overline{B}^n \to X$. It follows from Proposition 75.3 that $Y := X \setminus \varphi(B^n)$ is a compact connected non-empty n-dimensional topological manifold with $\partial Y = \varphi(S^{n-1})$. By Theorem 104.26 we know that there exists a finite $(n-1)$-dimensional CW-complex Z

[1269] To the best of my knowledge it seems to be unknown whether the statement holds for $r = 2$.

and a homotopy equivalence $h\colon Y \to Z$. We consider the following diagram:

$$\begin{array}{ccccc} \overline{B}^n & \xleftarrow{\quad i \quad} & S^{n-1} & \xrightarrow{\quad f \quad} & Y \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle h} \\ \overline{B}^n & \xleftarrow{\quad i \quad} & S^{n-1} & \xrightarrow{\quad \varphi\circ f \quad} & Z. \end{array}$$

Note that the diagram commutes, note that the vertical maps are homotopy equivalences and note that it follows from the Manifold Boundary-Cofibration Proposition 17.8 that the inclusion map $i\colon S^{n-1} \to \overline{B}^n$ is a closed cofibration. Thus it follows from the Homotopy Pushout Theorem 17.19 that the pushouts $\overline{B}^n \cup_{S^{n-1}} Y$ and $\overline{B}^n \cup_{S^{n-1}} Z$ are homotopy equivalent. By Lemma 5.36 the former pushout is homeomorphic to X. Furthermore by the CW-Complex Construction Lemma 68.32 the latter pushout admits a CW-structure with a single n-cell and no cells of dimension $> n$. Finally note that it follows from Proposition 70.4 that we can in fact find a CW-complex that is homotopy equivalent to X that contains not only a single n-cell but that also contains only a single 0-cell. ■

104.6. **Topological manifolds and CW-structures.** Recall that by the Smooth Manifold-CW Structure Theorem 96.5 we know that every smooth manifold admits a simplicial structure. By Corollaries 104.20 and 104.25 we now know that every (compact) topological manifold is homotopy equivalent to a (finite) CW-complex. The following question naturally arises.

Question 104.28.

(1) Does every topological manifold admit a simplicial structure?
(2) Does every topological manifold admit a CW-structure?

In the following we will survey what is known regarding Question 104.28. Let us start out with some positive statements.

Theorem 104.29. (Radó's Theorem) Every 2-dimensional topological manifold admits a PL-structure, in particular it admits a simplicial and a CW-structure.

Proof. In 1926 it was shown by Tibor Radó [**Rad1926**] that every 2-dimensional topological manifold admits a simplicial structure. It is elementary to see that the simplicial structure of any 1-dimensional topological manifold is in fact a PL-structure. It follows from the PL-Manifold Characterization Proposition 96.12 that the simplicial structure of any 2-dimensional topological manifold is in fact a PL-structure.

Note that we already mentioned the above result of Tibor Radó in the proof of the Surface-Smooth Structure Existence Theorem 55.5. We refer to that proof to alternative references. ■

Theorem 104.30. (Moise's Theorem) Every 3-dimensional topological manifold admits a PL-structure, in particular it admits a simplicial and a CW-structure.

Proof. This theorem was first proved in 1952 by Edwin Moise [**Moi1952**]. Alternative proofs are given in [**Moi1977**, p. 252 and 253], [**Moi1952**, Theorem 6], [**Bin1983**, Theorem XVIII.3.B], [**GNR2021**], [**Ham1976**, Theorem 2], [**Shal1984**]. ■

Now we turn to the higher dimensional setting. In this setting the stories between CW-structures and simplicial structures diverge. In the following we first consider CW-structures

on high-dimensional topological manifolds. It turns out that the 4-dimensional case is a no-show, in the sense that the following question is still open.

Question 104.31. Does every closed 4-dimensional topological manifold admit a CW-structure?

Once we move beyond dimension 4, the situation becomes somewhat clearer again.

Theorem 104.32. (Kirby-Quinn-Siebenmann Theorem) Every *closed* topological manifold of dimension ≥ 5 has a CW-structure.

Proof. For dimensions ≥ 6 this theorem was proved in the 1970s by Rob Kirby and Larry Siebenmann [**KSi1977**, Essay III.2]. In 1982 this result was extended to the 5-dimensional case by Frank Quinn [**Qu1982**, Theorem 2.3.1]. ■

Note that the Kirby-Quinn-Siebenmann Theorem 104.32 only deals with *closed* topological manifolds. The following question is still open.

Question 104.33. Let $n \in \mathbb{N}_{\geq 5}$. Does every *compact* n-dimensional topological manifold admit a CW-structure?

Now what about simplicial structures?

Theorem 104.34. There exists a closed 4-dimensional topological manifold that does not admit a simplicial structure.

Proof. This theorem was proved by Andrew Casson, see [**AkM1990**, page xvi], in the 1980s building on the work of Mike Freedman [**Fre1982**]. An account of the proof is also given in [**Sav2012**, Theorem 18.3]. ■

The question whether topological manifolds of dimension ≥ 5 admit a simplicial structure had been open for a very long time and it was finally resolved in 2013 by Ciprian Manolescu [**Man2016a**].

Theorem 104.35. (Manolescu's Theorem) For every $n \in \mathbb{N}_{\geq 5}$ there exists a closed n-dimensional topological manifold that does not admit a simplicial structure.

Proof. The theorem is proved in [**Man2016a**]. A more relaxed exposition of the key ideas of the proof is also given in [**Man2016b**]. Note that, as is explained in [**Man2016a, Man2016b**], in dimension 5 the examples are necessarily non-orientable, whereas for every $n \geq 5$ there exists a closed orientable n-dimensional topological manifold that does not admit a simplicial structure.[1270] ■

In the unlikely event that the reader got slightly confused by the various theorems and counterexamples we now summarize some of the key statements about the topology of

[1270] We will explain later on in Chapter 105 what it means for a topological manifold to be orientable.

compact topological manifolds in the following table:

	$n=1,2,3$	$n=4$	$n\geq 5$
each closed top. n-mfd. is homotopy equiv. to a finite CW-cplx.	✓	✓	✓
each closed top. n-mfd. admits a CW-structure	✓	?	✓
each compact top. n-mfd. is homotopy equ. to a finite CW-cplx.	✓	✓	✓
each compact top. n-manifold admits a CW-structure	✓	?	?
each compact top. n-manifold admits a simplicial structure	✓	✗	✗

Finally we note that we will discuss the existence and uniqueness of PL-structures and smooth structures on topological manifolds in greater detail in Chapter **??**.

104.7. **The Euler characteristic of compact topological manifolds.** The Euler characteristic of a finite CW-complex is one of the most convenient invariants and often it gives a convenient approach to calculating invariants of CW-complexes. As we just saw, it is not clear whether (compact) topological manifolds admit CW-structures. But fortunately we assembled just enough results on compact topological manifolds to be able to develop the theory of Euler characteristics of compact topological manifolds.
The first part of the following definition was already introduced on page 1932.

Definition.

(1) Given a pair (X,A) of topological spaces and $n\in\mathbb{N}_0$ we refer to

$$b_n(X,A) \;:=\; \operatorname{rank}(\mathrm{H}_n(X,A))$$

as the n-th Betti number of (X,A). For $A=\varnothing$ we write of course $b_n(X):=b_n(X,\varnothing)$.

(2) Let (X,A) be a pair of topological spaces. If all $b_n(X,A)$ are finite and if the sum $\sum_{n\in\mathbb{N}_0} b_n(X,A)$ is finite, then we define the Euler characteristic of (X,A) to be

$$\chi(X,A) \;:=\; \sum_{n\in\mathbb{N}_0}(-1)^n\cdot b_n(X,A).$$

For $A=\varnothing$ we write $\chi(X):=\chi(X,\varnothing)$.

Remark.

(1) It follows from the Euler Characteristic-H_*-Proposition 87.1 that for a finite CW-complex the above definition agrees with the original definition of the Euler characteristic of a finite CW-complex.

(2) Let X be a compact topological manifold and let A be a compact submanifold or let A be a union of components of ∂X. It follows from Propositions 75.2 (3) and (4) and the Topological Manifolds-Invariants Proposition 104.14 (0) and (4), together with Lemma 96.8, that the Euler characteristic $\chi(X,A)$ is defined.

It turns out that the formulas we proved before for the Euler characteristic of CW-complexes also hold for topological manifolds. More precisely, we have the following proposition, of which the first three statements are the analogue of Lemmas 87.8 and 87.5 and of Proposition 69.4 in our new context.

Proposition 104.36. (Manifold-χ-Proposition)

(1) Let X and Y be homotopy equivalent topological spaces. If the Euler characteristic is defined for one of the two topological spaces, then it is defined for the other topological space and we have
$$\chi(X) \;=\; \chi(Y).$$
(2) Let X be and Y be two compact topological manifolds, then
$$\chi(X \times Y) \;=\; \chi(X) \cdot \chi(Y).$$
(3) Let $X = Y \cup Z$ be a decomposition of a compact topological manifold into two compact submanifolds Y and Z such that $Y \cap Z$ is also a compact submanifold of X. Then the following equality holds
$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$
(4) Let X be a compact topological manifold and let $A \subset X$ be a subspace that is a compact topological manifold in its own right.[1271] Then
$$\chi(X, A) \;=\; \chi(X) \,-\, \chi(A).$$
Furthermore, for any field $\mathbb{F}$ we have
$$\chi(X, A) \;=\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(\mathrm{H}_i(X, A; \mathbb{F})).$$
(5) Let X be a compact topological manifold and let $p\colon \widetilde{X} \to X$ be a finite covering. Then
$$\chi(\widetilde{X}) \;=\; \big[\widetilde{X} : X\big] \cdot \chi(X).$$

Sketch of proof.

(1) This statement follows immediately from the Homotopy Equivalence-H_*-Corollary 73.9.
(2) This equality can be proved using the Künneth Theorem 90.7 for Chain Complexes. We will fill in the details in Exercise 104.9.
(3) We will not make use of this statement. Therefore we hide, with a good conscience, the proof in Exercise 104.10.
(4) Let X be a compact topological manifold and let $A \subset X$ be a subspace that is a compact topological manifold in its own right.
   (a) It follows immediately from considering the long exact sequence in homology of the pair (X, A) together with Lemma 87.4 that $\chi(X, A) = \chi(X) - \chi(A)$.
   (b) Let $\mathbb{F}$ be a field. Let Y be a compact topological manifold. From Corollary 104.25 we know that Y is homotopy equivalent to a finite CW-complex Z. We observe that

$$\chi(Y) \;\overset{\text{Homotopy Equivalence-H}_*\text{-Corollary 73.9}}{\underset{\text{see page 1915}}{=}}\; \chi(Z) \;\underset{\uparrow}{=}\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(\mathrm{H}_i(Z; \mathbb{F})) \;\underset{\uparrow}{=}\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(\mathrm{H}_i(Y; \mathbb{F})).$$
by the generalization of the Homotopy Equivalence-H_*-Corollary 73.9 to $\mathbb{F}$-coefficients, see page 1914

[1271] For example A could be compact submanifold or A could be a union of boundary components.

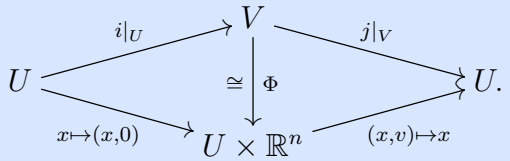
Using this observation we can now prove that

$$\chi(X,A) \underset{\text{by (a)}}{\underset{\uparrow}{=}} \chi(X) - \chi(A) \underset{\text{by the above observation}}{\underset{\uparrow}{=}} \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(\mathrm{H}_i(X;\mathbb{F})) - \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(\mathrm{H}_i(A;\mathbb{F}))$$
$$\underset{\text{by the long exact sequence of the pair } (X,A) \text{ with } \mathbb{F}\text{-coefficients and Lemma 87.3}}{\underset{\uparrow}{=}} \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(\mathrm{H}_i(X,A;\mathbb{F})).$$

(5) Let X be a compact topological manifold and let $p\colon \widetilde{X} \to X$ be a finite covering. Without loss of generality we can assume that X and $\widetilde{X}$ are connected. By Corollary 104.25 there exists a homotopy equivalence $f\colon X \to Y$, where Y is a finite CW-complex. By the Covering Existence Theorem 61.5 there exists a connected covering $q\colon \widetilde{Y} \to Y$ such that $q_*(\pi_1(\widetilde{Y})) = f_*(p_*(\pi_1(\widetilde{X})))$. Using the Map Lifting Criterion 61.2 one can now easily show that $f\colon X \to Y$ lifts to map $\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}$ and that this map is again a homotopy equivalence[1272]. Now we obtain that

$$\chi(\widetilde{X}) \underset{\text{by (1) since } \widetilde{X} \text{ and } \widetilde{Y} \text{ are homotopy equivalent}}{\underset{\uparrow}{=}} \chi(\widetilde{Y}) \underset{\text{Proposition 69.4 and Lemma 48.15}}{\underset{\uparrow}{=}} \big[\pi_1(Y) : q_*(\pi_1(\widetilde{Y}))\big] \cdot \chi(Y) \underset{\text{by (1) we have } \chi(Y) = \chi(X) \text{ since } X \text{ and } Y \text{ are homotopy equivalent}}{\underset{\uparrow}{\overset{\downarrow}{=}}} \big[\pi_1(X) : p_*(\pi_1(\widetilde{X}))\big] \cdot \chi(X)$$
$$\underset{\text{Lemma 48.15}}{\underset{\uparrow}{=}} \big[\widetilde{X} : X\big] \cdot \chi(X).$$

$\blacksquare$

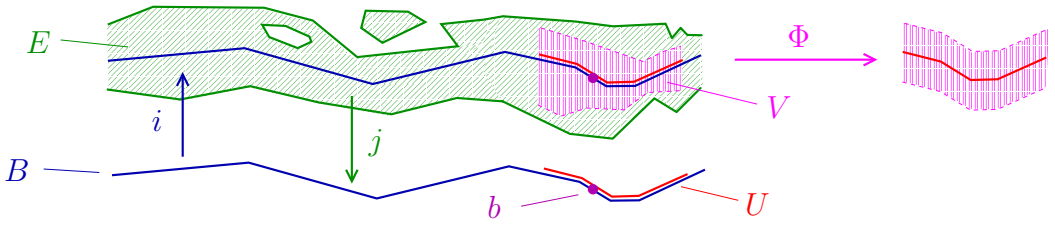


104.8. **Microbundles.** In this section we will give a short introduction to the concept of a normal microbundle of a submanifold of a topological manifold. A normal microbundle can be viewed as an analogue of the normal bundle of a smooth submanifold of a smooth manifold. We will not make use of microbundles. So this section we can safely be skipped.

We start out with the definition of a microbundle, which was introduced by John Milnor [**Miln1964a**, Chapter 2].

Definition. A microbundle consists of two topological spaces B and E and two maps $i\colon B \to E$ and $j\colon E \to B$ such that the following two conditions are satisfied:

(1) we have $j \circ i = \mathrm{id}_B$,



(2) for every $b \in B$ there exists an open neighborhood U of $b \in B$ and an open neighborhood V of $i(b) \in E$ with $i(U) \subset V$ and $j(V) \subset U$ and there exists a homeomorphism $\Phi\colon V \to U \times \mathbb{R}^n$ such that the following diagram commutes:

Such a map Φ is called a local trivialization.

[1272]Here the point is that not only the homotopy equivalences but also the homotopies lift to the covering spaces. We leave the details to the reader.

We refer to B as the base space of the microbundle, we refer to E as the total spaces of the microbundle and refer to n as the fiber dimension of the microbundle.[1273]

Examples.

(1) Every $\mathbb{R}^n$-bundle (in particular every vector bundle) is evidently a microbundle. But the notion of a microbundle is much less restrictive. For example we only have control over a neighborhood of $i(B) \subset E$ and the local trivializations do not have to be compatible in any way.

(2) Let M be a topological manifold. One can easily show, see also [**Miln1964a**, Lemma 2.1], that the maps

$$\begin{array}{rcl} i\colon M & \to & M \times M \\ x & \mapsto & (x,x) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} j\colon M \times M & \to & M \\ (x,y) & \mapsto & x \end{array}$$

form a microbundle. This microbundle is called the *tangent microbundle of* M.[1274] This definition and this name is inspired by the Total Tangent Space-Diagonal Embedding Proposition 45.16 which says given a closed smooth submanifold of $\mathbb{R}^n$ there exists a smooth embedding of the tangent bundle $\widetilde{\mathrm{T}}M$ into the product $M \times M$ with with $(x,0) \mapsto (x,x)$ for each $x \in M$.

As we just discussed, $\mathbb{R}^n$-bundles are microbundles. Somewhat surprisingly, in the settings we are interested in, every microbundle is essentially an $\mathbb{R}^n$-bundle.

Theorem 104.37. (Kister-Mazur Theorem) Let $i\colon B \to E$ and $j\colon E \to B$ be a microbundle. If B is a locally finite, finite dimensional simplicial complex or if B is a topological manifold, then there exists an open neighborhood U of $i(B) \subset E$ such that the restriction of j to U is an $\mathbb{R}^n$-bundle.

Proof. This theorem was proved by James Kister [**Kis1964**, Corollary 1 and Theorem 2] (see also [**Kis1963**]) and independently by Barry Mazur. The proof is also written up as [**Kupe2017b**, Theorem 3.7]. ■

Definition. Let X be a topological manifold and let Y be a submanifold of X. A normal microbundle of Y in X consists of a neighborhood U of $Y \subset X$ and a retraction $j\colon U \to M$ such that the inclusion $i\colon Y \to U$ and the retraction $j\colon U \to Y$ form a microbundle.

Remark.

(1) Note that if Y admits a normal microbundle, then Y is in particular a neighborhood retract in X in the sense of the definition on page 2291.

(2) A normal microbundle can be viewed as an analogue of the normal bundle of a smooth submanifold of a smooth manifold.

[1273] Using the local homology groups $\mathrm{H}_k(j^{-1}(b), j^{-1}(b), i(b))$ one can show that n is well-defined.

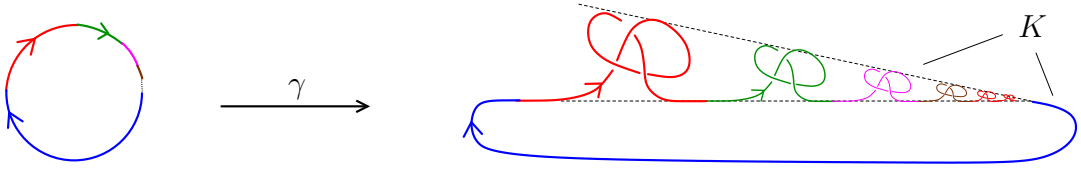
Colin Rourke and Brian Sanderson [**RS1968**, Theorem 3.12] gave an example of a topological submanifold of $S^9 \times S^{19}$ that is homeomorphic to S^{19} and that does not admit a normal microbundle. But fortunately the following theorem says that normal microbundles exist if the codimension of the submanifold is sufficiently large.

Theorem 104.38. Let X be an $(n+q)$-dimensional topological manifold and let Y be an n-dimensional proper submanifold of X. If there exists a $j \in \{0,1,2\}$ with $n \leq q+1+j$ and $q \geq 5+j$, then Y admits a normal microbundle restricting to a normal microbundle of $\partial N \subset \partial M$. Furthermore, if $n \leq q+j$, then this normal microbundle is unique up to isotopy.

Proof. This theorem is [**Ster1975**, Theorem 4.5]. ■

We will not develop the theory of microbundles any further. We refer to [**Scor2005**] and [**KSi1977**] for more information and the role they play in the study of topological manifolds.

Exercises for Chapter 104.



Exercise 104.1.

(1) Show that there are only countably many homotopy types of finite CW-complexes.
Hint. Use Theorem 104.23.
(2) Show that there are uncountably many homotopy types of countable CW-complexes.
(3) Let $k, n \in \mathbb{N}$.
   (a) Are there only finitely many homotopy types of k-dimensional CW-complexes with at most n cells?
   (b) Are there only finitely many homotopy types of k-dimensional simplicial complexes with at most n simplices?

Exercise 104.2. We consider $X = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$ as a subset of $Y = \mathbb{R}$. Show that there is no open neighborhood of X in Y that admits a retraction onto X.

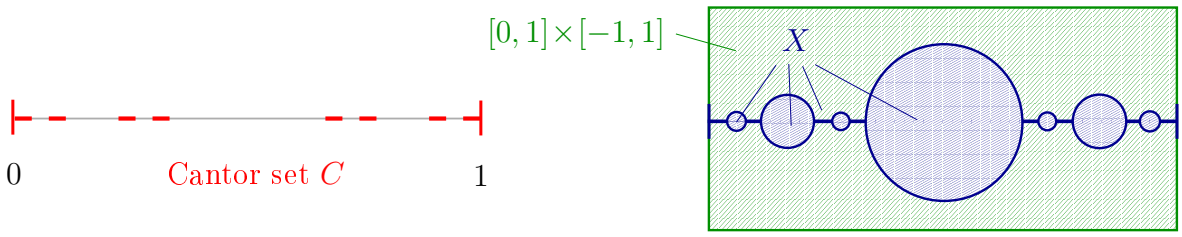
Exercise 104.3. We consider the embedding $\gamma\colon S^1 \to \mathbb{R}^3$ that is shown in the figure below. We set $K := \gamma(S^1)$.

(a) Show that $\pi_1(\mathbb{R}^3 \setminus K)$ is an infinitely generated group.
Remark. The rigor of the solution is bounded from above by the precision of the statement of the problem.
(b) What do you think are the homology groups of $\mathbb{R}^3 \setminus K$?
(c) Show that there is no neighborhood U of K that admits a deformation retraction to K.
Remark. Write to the author if you have a solution.

Exercise 104.4. Show that there exist embeddings $f\colon S^1 \to S^3$ which do not admit a tubular neighborhood, i.e. for which there is no map $\Phi\colon \overline{B}^2 \times S^1 \to S^3$ with $f(P) = \Phi(P, 0)$ for all $P \in S^1$.

Exercise 104.5. Let C be the Cantor set as defined on page 130. Note that basically by construction the complement of C in $[0,1]$ is the disjoint union of countably many open intervals $\{(a_n - \epsilon_n, a_n + \epsilon_n)\}_{n\in\mathbb{N}}$. We set

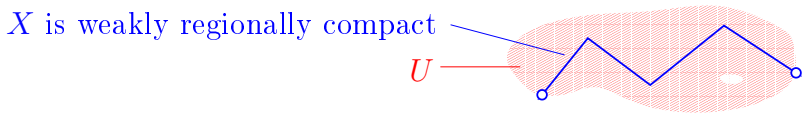
$$X \;:=\; \underbrace{\{(c,0) \in \mathbb{R}^2 \,|\, c \in C\}}_{=C\times\{0\}\subset\mathbb{R}^2} \cup \bigcup_{n\in\mathbb{N}} \overline{B}^2_{\epsilon_n}((a_n,0)) \;\subset\; \mathbb{R}^2.$$



(We refer to the figure below for an illustration.) In the following we will show that X is a retract of a finite CW-complex but that X itself is not a CW-complex.

(a) Show that X is a deformation retract of the CW-complex $[0,1] \times [-1,1] \subset \mathbb{R}^2$.
(b) Show that X is compact.

Given a path-connected topological space Y we define



$$S(Y) := \{y \in Y \,|\, Y \setminus \{y\} \text{ is not path-connected}\}.$$

(c) Show that $S(X) = \{(c,0) \,|\, c \in C \setminus \{0,1\}\}$.
(d) Let Y be a finite CW-complex. Show that $S(Y)$ has only finitely many path-components.
(e) Show that X does not admit the structure of a CW-complex.

Exercise 104.6. We say that a topological space X is *weakly regionally compact* if every point $x \in X$ admits a compact neighborhood. Now let $X \subset \mathbb{R}^n$ be a subset that is weakly regionally compact. In the following we will show that there exists an embedding $g\colon X \to \mathbb{R}^{n+1}$ such that $g(X)$ is a *closed* subset of $\mathbb{R}^{n+1}$.

(a) Show that there exists an open subset $U \subset \mathbb{R}^n$ with $U \cap \overline{X} = X$.
(b) We set $C := \overline{X} \setminus X = \overline{X} \setminus U$. Note that it follows from the Interior-Closure Lemma 1.9 that C is a closed subset of $\mathbb{R}^n$ and note that it follows from Lemma 6.3 that $d(x, C) > 0$ for every $x \in X$. Now we consider the map $f\colon X \to \mathbb{R}$ given by $x \mapsto d(x, C)$. Show that the map $g\colon X \to \mathbb{R}^{n+1}$ given by $x \mapsto (x, \frac{1}{f(x)})$ is an embedding such that $g(X)$ is a closed subset of $\mathbb{R}^{n+1}$.

Exercise 104.7. Let X be a compact space that is a retract of a finite simplicial complex X. Show that X is an ENR.
Remark. This is the, very easy, converse to the ENR-Simplicial Complex Retract Proposition 104.7.

Exercise 104.8. Let X be a compact space. Is $\mathrm{H}_1(X)$ necessarily finitely generated?

Exercise 104.9. Let X be and Y be two compact topological manifolds. Show that

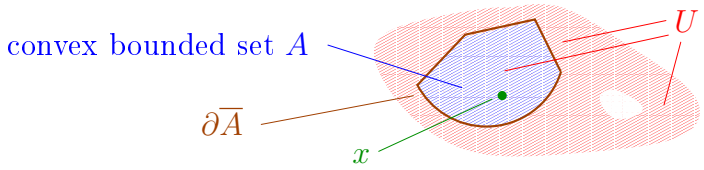
$$\chi(X \times Y) \;=\; \chi(X) \cdot \chi(Y).$$

Exercise 104.10. Let $X = Y \cup Z$ be a decomposition of a compact topological manifold into two compact submanifolds Y and Z such that $\partial Y = \partial Z$ is a submanifold of X. Show that

$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

105. Orientations of topological manifolds

In Section 25.2 we introduced the notion of an orientation of a smooth manifold. The basic idea is that an orientation of a smooth manifold is a "continuous" choice of orientations for each tangent space. Since topological manifolds do not come with tangent spaces there is no obvious extension of this definition of an orientation to the context of topological manifolds. In this chapter we will use "orientations of local homology groups" to introduce the concept of an orientation on a topological manifold.



105.1. **Relative homology and convex subsets of $\mathbb{R}^n$.** The next lemma is at first glance a little dull, but i will come in handy on several occasions later on in this chapter. In all likelihood it is best to have a quick glance at the statement and to move on to the next section.

Lemma 105.1. (Complement-of-Convex Homology Lemma) Let $n \in \mathbb{N}$, let U be an open subset of $\mathbb{R}^n$, let A be a convex bounded subset of U with $\overline{A} \subset U$ and let $x \in A$. Then for every abelian group G and every $i \in \mathbb{N}_0$ the following inclusion induced maps are isomorphisms:

$$\begin{array}{lrcl}
(1) & \mathrm{H}_i(\mathbb{R}^n \setminus A; G) & \to & \mathrm{H}_i(\mathbb{R}^n \setminus \{x\}; G) \\
(2) & \mathrm{H}_i(\mathbb{R}^n, \mathbb{R}^n \setminus A; G) & \to & \mathrm{H}_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}; G) \\
(3) & \mathrm{H}_i(U, U \setminus A; G) & \to & \mathrm{H}_i(U, U \setminus \{x\}; G).
\end{array}$$

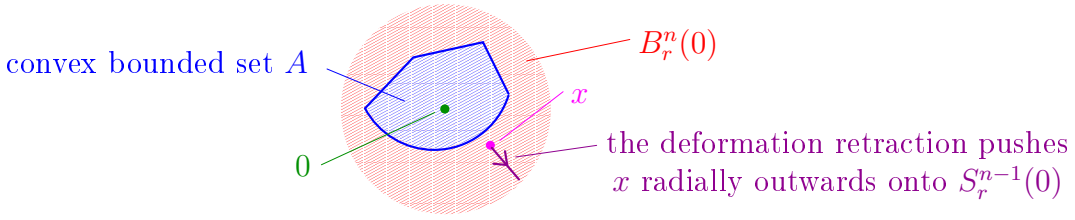
If $\mathring{A}$ is non-empty and if $x \in \mathring{A}$ is a point, then also the following inclusion induced maps are isomorphisms

$$\begin{array}{lrcl}
(4) & \mathrm{H}_i(\partial\overline{A}; G) & \to & \mathrm{H}_i(\mathbb{R}^n \setminus \{x\}; G) \\
(5) & \mathrm{H}_i(\mathbb{R}^n, \partial\overline{A}; G) & \to & \mathrm{H}_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}; G)
\end{array}$$

Proof. Let U be an open subset of $\mathbb{R}^n$, let A be a convex bounded subset of U with $\overline{A} \subset U$ and let $x \in A$. To simplify the notation we drop the coefficients G from the notation and without loss of generality we assume that $x = 0$. Now let $i \in \mathbb{N}_0$.

(1) We have to show that the inclusion induced map $\mathrm{H}_i(\mathbb{R}^n \setminus A) \to \mathrm{H}_i(\mathbb{R}^n \setminus \{0\})$ is an isomorphism. We had already stated this fact in Exercise 73.3. Now that we actually need the statement we give the full details.

Since A is bounded we can pick an $r > 0$ such that $A \subset B_r^n(0)$. We consider the following map:



$$\begin{array}{rcl}
F\colon (\mathbb{R}^n \setminus A) \times [0,1] & \to & \mathbb{R}^n \\
(x,t) & \mapsto & \begin{cases} x, & \text{if } x \in \mathbb{R}^n \setminus B_r^n(0), \\ x \cdot \underbrace{\big((1-t) + t \cdot \frac{r}{\|x\|}\big)}_{\geq 1 \text{ since } r > \|x\|}, & \text{if } x \in \overline{B}_r^n(0) \setminus A. \end{cases}
\end{array}$$

Note that if $y \notin A$, then it follows from the convexity of A and the fact that $0 \in A$, that for any $s \geq 1$ the point sy cannot lie in A either. This shows that the above map actually takes values in $\mathbb{R}^n \setminus A$.

Now it is obvious that the map F defines a deformation retraction from $\mathbb{R}^n \setminus A$ to $\mathbb{R}^n \setminus B_r^n(0)$.[1275] [1276] Clearly $\mathbb{R}^n \setminus B_r^n(0)$ is also a deformation retract of $\mathbb{R}^n \setminus \{0\}$. Now we consider the following commutative diagram of inclusion induced maps:

$$\begin{array}{ccc} \mathrm{H}_i(\mathbb{R}^n \setminus A) & \longrightarrow & \mathrm{H}_i(\mathbb{R}^n \setminus \{0\}) \\ & \nwarrow \quad \nearrow & \\ & \mathrm{H}_i(\mathbb{R}^n \setminus B_r^n(0)). & \end{array}$$

It follows from the Homotopy Equivalence-H_*-Corollary 73.9 and the above discussion that the two diagonal maps are isomorphisms. It follows that the horizontal map is also an isomorphism.

(2) Now we consider the following commutative diagram of long exact sequences

$$\begin{array}{ccccccccccc} \ldots \longrightarrow \mathrm{H}_i(\mathbb{R}^n \setminus A) & \longrightarrow & \mathrm{H}_i(\mathbb{R}^n) & \longrightarrow & \mathrm{H}_i(\mathbb{R}^n, \mathbb{R}^n \setminus A) & \longrightarrow & \mathrm{H}_{i-1}(\mathbb{R}^n \setminus A) & \longrightarrow & \mathrm{H}_{i-1}(\mathbb{R}^n) \to \ldots \\ \downarrow \cong & & \downarrow = & & \downarrow \cong & & \downarrow \cong & & \downarrow = \\ \ldots \to \mathrm{H}_i(\mathbb{R}^n \setminus \{x\}) & \to & \mathrm{H}_i(\mathbb{R}^n) & \to & \mathrm{H}_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) & \to & \mathrm{H}_{i-1}(\mathbb{R}^n \setminus \{x\}) & \to & \mathrm{H}_{i-1}(\mathbb{R}^n) \to \ldots \end{array}$$

By (1) the first and the fourth vertical maps are isomorphisms. The second and the fifth vertical map are the identity. It follows from the Five Lemma 74.10 that the middle vertical map is also an isomorphism.

(3) We consider the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}_i(U, U \setminus A) & \longrightarrow & \mathrm{H}_i(U, U \setminus \{x\}) \\ \downarrow & & \downarrow \\ \mathrm{H}_i(\mathbb{R}^n, \mathbb{R}^n \setminus A) & \longrightarrow & \mathrm{H}_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) \end{array}$$

of inclusion induced homomorphisms. Since $\overline{A} \subset U$ we deduce from the Excision Theorem 74.18 that the two vertical maps are isomorphisms. By (2) we know that the bottom horizontal map is an isomorphism. Hence the top horizontal map is also an isomorphism.

[1275] Note that the fact that $0 \in A$ and the convexity of A imply that for any $x \notin A$ and any $s \geq 1$ we have $s \cdot x \notin A$, in particular the map F does indeed take values in $\mathbb{R}^n \setminus A$.

[1276] As always, checking that a map is a deformation retraction also requires showing that the map is continuous. In this case the map is continuous by the Pasting Proposition 2.6 and the fact that $B_r^n(0) \setminus A$ is a closed subset of $\mathbb{R}^n \setminus A$.

Now we suppose that $\mathring{A}$ is non-empty and we suppose that x is a point in $\mathring{A}$. It follows from Exercise 1.23 that without loss of generality we can assume that $x = 0$ and that $A = \overline{A}$.

(4) Since A is compact, convex with non-empty boundary we can apply Lemma 14.2. Thus we now know that there exists an isotopy

$$F\colon A \times [0,1] \;\to\; \mathbb{R}^n$$

from the inclusion map $i\colon A \to \mathbb{R}^n$ to a homeomorphism $\varphi\colon A \to \overline{B}^n$ that has the following two properties:
(a) $F_1 = \varphi$ restricts to a homeomorphism $\partial A \to S^{n-1}$, and
(b) F has the property that $F(0,t) = 0$ for all $t \in [0,1]$.
Now we have the following diagram

$$\begin{array}{ccccc} & & \mathrm{H}_i(\partial A) & & \\ & \overset{\cong}{\swarrow}{\scriptstyle \varphi_*} & \downarrow{\scriptstyle \varphi_*} & \searrow{\scriptstyle (i|_{\partial A})_*} & \\ \mathrm{H}_i(S^{n-1}) & \xrightarrow[\cong]{} & \mathrm{H}_i(\mathbb{R}^n \setminus \{0\}) & \xrightarrow[=]{} & \mathrm{H}_i(\mathbb{R}^n \setminus \{0\}). \end{array}$$

Here all the unmarked maps are induced by inclusions. The right-hand triangle commutes by the Homotopy Equivalence-H_*-Corollary 73.9 since, by the above property (b), the isotopy F restricts to an isotopy $\partial A \times [0,1] \to \mathbb{R}^n \setminus \{0\}$. The left horizontal map is an isomorphism since S^{n-1} is a deformation retract of $\mathbb{R}^n \setminus \{0\}$. It is now clear that the right-hand diagonal map is also an isomorphism.

(5) With the same argument as in (2) we can reduce the proof of this statement to (4). ■

105.2. **The local homology of topological manifolds.** We recall the following definition from page 1655.

Definition. Given a topological space X and a point $x_0 \in X$ the homology groups $\mathrm{H}_n(X, X \setminus \{x_0\}; R)$ is called the n-local homology group of X at the point x_0.

In this section we will study the local homology of topological manifolds, in particular we want to gain a good understanding of generators of these groups.
Some of the following definitions and conventions we had already introduced earlier.

Definition. Let $n \in \mathbb{N}$.

(1) We equip $\mathbb{R}^n$ with the orientation given by the standard basis $e_1, \ldots, e_n$. With this orientation we can view any open subset of $\mathbb{R}^n$ as an oriented smooth manifold.

(2) We write

$$\partial\Delta^n \;=\; \bigcup_{i=0}^{n} \{(t_0, \ldots, t_n) \in \Delta^n \,|\, t_i = 0\}.$$

and we refer to $\mathring{\Delta}^n := \Delta^n \setminus \partial\Delta^n$ as the interior of Δ^n.

(3) As on page 1581 we say that a basis $\{v_1, \ldots, v_n\}$ for $\mathrm{T}_P\mathring{\Delta}^n$ is positive, if the ordered set of vectors $\{(1, \ldots, 1), v_1, \ldots, v_n\}$ is a positive basis for $\mathbb{R}^{n+1}$. This equips $\mathring{\Delta}^n$ with the structure of an oriented smooth manifold.

(4) Given a subset V of $\mathbb{R}^n$ we say that a map $f\colon V \to \mathbb{R}^k$ is affine linear if there exists a $P \in \mathbb{R}^k$ and a $k \times n$–matrix A such that $f(v) = P + Av$ for all $v \in V$.

orientations of the interiors of the standard simplices

Example. The projection

$$\begin{array}{rcl} p\colon \Delta^n & \to & \mathbb{R}^n \\ (x_1, \ldots, x_{n+1}) & \mapsto & (x_1, \ldots, x_n) \end{array}$$

is an injective affine linear map. One can easily verify that the restriction of this map to the interior $\mathring{\Delta}^n$ is orientation-preserving if and only if n is even.

projection is orientation-reversing projection is orientation-preserving

We continue with the following lengthy lemma.

Lemma 105.2. Let R be a commutative ring.

(1) For any $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(\Delta^n, \partial\Delta^n; R) \;=\; \begin{cases} 0, & \text{if } k \neq n, \\ R \cdot [\mathrm{id}_{\Delta^n} \otimes 1], & \text{if } k = n. \end{cases}$$

(2) Let $\Phi\colon \Delta^n \to \mathbb{R}^n$ be an injective affine linear map such that 0 lies in the image of $\mathring{\Delta}^n$ and such that the restriction of Φ to $\mathring{\Delta}^n$ is orientation-preserving. Then for any $k \in \mathbb{N}_0$ the induced map

$$\Phi_*\colon \mathrm{H}_k(\Delta^n, \partial\Delta^n; R) \;\to\; \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R)$$

is an isomorphism and this map does not depend on the choice of Φ.

(3) Let $P \in \mathbb{R}^n$. We pick $r > 0$ such that $B_r^n(0)$ contains P. Then for any $k \in \mathbb{N}_0$ the inclusion induced maps

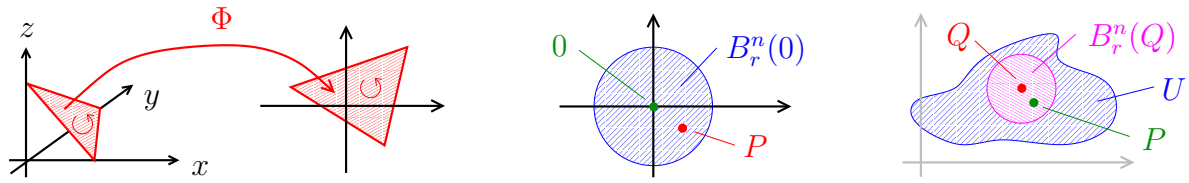
$$\mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \;\leftarrow\; \mathrm{H}_k\big(\mathbb{R}^n, \mathbb{R}^n \setminus B_r^n(0); R\big) \;\leftarrow\; \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$

are isomorphisms and the resulting isomorphism

$$\mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \;\xrightarrow{\cong}\; \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$

does not depend on the choice of r.

(4) Let $P \in \mathbb{R}^n$ be a point. If $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ is the reflection in an affine hyperplane through P, then the induced map



$$\rho_*\colon \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R) \to \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$

is given by multiplication by minus -1. The same conclusion also holds if we replace $\mathbb{R}^n$ by any open ball centered at P.

(5) Let $U \subset \mathbb{R}^n$ be an open set and let $\overline{B}_r^n(Q) \subset U$ be a closed ball. Then for any $P \in B_r^n(Q)$ the inclusion induced maps

$$\begin{array}{ccc} \mathrm{H}_k(U, U \setminus B_r^n(Q); R) & \longrightarrow & \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus B_r^n(Q); R) \\ \downarrow & & \downarrow \\ \mathrm{H}_k(U, U \setminus \{P\}; R) & \longrightarrow & \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R) \end{array}$$

are isomorphisms and they form a commutative diagram.

Proof.

(1) For $k \neq n$ the statement is proved the same way as Lemma 76.1. Next recall that in the Identity-is-Generator Lemma 76.2 (2) we saw that the identity map $\mathrm{id}\colon \Delta^n \to \Delta^n$ represents a generator of $\mathrm{H}_n(\Delta^n, \partial\Delta^n; \mathbb{Z}) \cong \mathbb{Z}$. Basically the same proof shows that for any commutative ring R the element $\mathrm{id}_{\Delta^n} \otimes 1 \in \mathrm{C}_n(\Delta^n, \partial\Delta^n; R)$ represents a generator of the homology group $\mathrm{H}_n(\Delta^n, \partial\Delta^n; R) \cong R$.

(2) Let $\Phi\colon \Delta^n \to \mathbb{R}^n$ be an injective affine linear map such that 0 lies in the image of $\mathring{\Delta}^n$ and such that the restriction of Φ to $\mathring{\Delta}^n$ is orientation-preserving. Note that it follows from the Compact-Hausdorff Proposition 2.17 (2) that Φ is an embedding.

Then we have the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}_k(\Delta^n, \partial\Delta^n; R) & \xrightarrow{\Phi_*} & \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R). \\ {\scriptstyle \Phi_*}\downarrow & & \uparrow \\ \mathrm{H}_k(\Phi(\Delta^n), \Phi(\partial\Delta^n); R) & \longrightarrow & \mathrm{H}_k(\mathbb{R}^n, \Phi(\partial\Delta^n); R) \end{array}$$

where the bottom and the right vertical map are induced by inclusions. Here the left vertical map is an isomorphism since Φ is an embedding.

Since Φ is an injective affine linear map we see that $\Phi(\Delta^n)$ is a convex subset of $\mathbb{R}^n$ with non-empty interior. By our hypothesis the point 0 lies in the interior of $\Phi(\Delta^n)$. It follows from the Complement-of-Convex Homology Lemma 105.1 (5) that the right vertical map is an isomorphism. Clearly $\Phi(\Delta^n) \to \mathbb{R}^n$ is a homotopy equivalence, hence it follows from Corollary 74.16 that the bottom horizontal map is an isomorphism. Since the diagram commutes we have thus now shown, as desired, that the top horizontal map is also an isomorphism.

If $\Psi\colon \Delta^n \to \mathbb{R}^n$ is another such injective affine linear orientation-preserving map, then it follows from elementary linear algebra that there exists some $P \in \mathbb{R}^n$ and a matrix A with *positive* determinant such that

$$\Phi \;=\; (v \mapsto P + A \cdot v) \circ \Psi\colon \Delta^n \to \mathbb{R}^n.$$

We write $\Omega = A \circ \Psi$. It suffices to show that Ψ and Ω and also Ω and Φ induce the same maps $\mathrm{H}_k(\Delta^n, \partial\Delta^n; R) \to \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R)$.

(a) By the Matrix Group Path-Component Proposition 2.37 (1) we know that $\{A \in \mathrm{GL}(n,\mathbb{R}) \mid \det(A) > 0\}$ is path-connected. This implies in particular that there exists a path $\gamma\colon [0,1] \to \mathrm{GL}(n,\mathbb{R})$ with $\gamma(0) = \mathrm{id}$ and $\gamma(1) = A$. We consider the map

$$\begin{aligned} F\colon \Delta^n \times [0,1] &\to \mathbb{R}^n \\ (Q,t) &\mapsto \gamma(t) \cdot \Psi(Q). \end{aligned}$$

Since by hypothesis we have $0 \notin \Phi(\partial\Delta^n)$ and since $\gamma(t)(0) = 0$ we see that $\gamma(t)(\partial\Delta^n) \subset \mathbb{R}^n \setminus \{0\}$ for all t. In particular we deduce that F defines a homotopy between Ψ and Ω as maps $(\Delta^n, \partial\Delta^n) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$. But by Proposition 74.15 this means that $\Psi_* = \Omega_*$ as maps on relative homology.

(b) Now we compare Ω and $\Phi = (w \mapsto P + w) \circ \Omega$. We consider the map

$$\begin{aligned} G\colon \Delta^n \times [0,1] &\to \mathbb{R}^n \\ (Q,t) &\mapsto (P \cdot t + \Omega(Q)). \end{aligned}$$

Note that $0 \in \Omega(\mathring{\Delta}^n) = A(\Psi(\mathring{\Delta}^n))$ and that $0 \in \Phi(\mathring{\Delta}^n)$ which implies by $\Phi = P + \Omega$ that $-P \in \Omega(\mathring{\Delta}^n)$. Since $\Omega(\mathring{\Delta}^n)$ is convex we see that G defines a homotopy between Ω and Φ as maps $(\Delta^n, \partial\Delta^n) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$. But again by Proposition 74.15 this means that $\Omega_* = \Phi_*$ as maps on relative homology.

(3) The fact that both inclusion induced maps are isomorphisms is an immediate consequence of the Complement-of-Convex Homology Lemma 105.1 (2). Now suppose we are given another such $s > 0$. Without loss of generality we can assume that $r \geq s$. We obtain the following commutative diagram:

$$\begin{array}{ccccc} & & \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus B_r^n(0); R) & & \\ & \overset{\cong}{\swarrow} & \downarrow & \overset{\cong}{\searrow} & \\ \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) & & & & \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R). \\ & \underset{\cong}{\nwarrow} & & \underset{\cong}{\nearrow} & \\ & & \mathrm{H}_k(\mathbb{R}^n, \mathbb{R}^n \setminus B_s^n(0); R) & & \end{array}$$

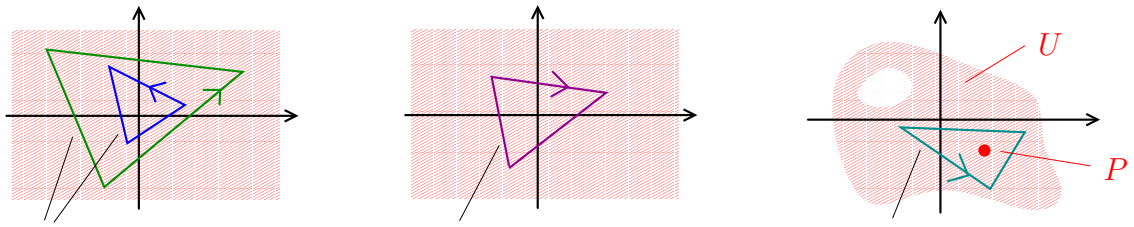
All maps are induced by inclusions, so the diagram commutes. By the Complement-of-Convex Homology Lemma 105.1 the diagonal maps are isomorphisms. It is now obvious that the composition of the top maps and the composition of the bottom maps agree.

(4) Let $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ be the reflection in an affine hyperplane V through a point P. We denote by $f\colon \mathbb{R}^n \to \mathbb{R}^n$ the map that is given by addition by P and furthermore we write $W = f^{-1}(V)$. Note that W goes through the origin. Finally we denote by $\sigma\colon \mathbb{R}^n \to \mathbb{R}^n$ the reflection in the hyperplane W. We consider the following diagram

$$\begin{array}{ccccccc} \mathrm{H}_{n-1}(S^{n-1}) \otimes R & \overset{\mu}{\underset{\cong}{\to}} & \mathrm{H}_{n-1}(S^{n-1}; R) & \xrightarrow{f_*} & \mathrm{H}_{n-1}(\mathbb{R}^n \setminus \{P\}; R) & \overset{\partial}{\underset{\cong}{\leftarrow}} & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R) \\ \downarrow{\scriptstyle \sigma_* \otimes \mathrm{id}} & & \downarrow{\scriptstyle \sigma_*} & & \downarrow{\scriptstyle \rho_*} & & \downarrow{\scriptstyle \rho_*} \\ \mathrm{H}_{n-1}(S^{n-1}) \otimes R & \overset{\mu}{\underset{\cong}{\to}} & \mathrm{H}_{n-1}(S^{n-1}; R) & \xrightarrow{f_*} & \mathrm{H}_{n-1}(\mathbb{R}^n \setminus \{P\}; R) & \overset{\partial}{\underset{\cong}{\leftarrow}} & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R). \end{array}$$

where μ is the natural map from page 1927 and where the right-hand horizontal maps are the connecting homomorphisms from the Topological LES-Corollary 74.14.

It follows from the Sphere Degree Lemma 76.11 that the vertical map on the left is given by multiplication by -1. It is straightforward to verify that the diagram commutes and that all horizontal maps are isomorphisms. Furthermore the horizontal maps on the top and bottom are identical. It thus follows that the vertical map on the right is also given by multiplication by -1.



(5) It is clear that the diagram commutes since all maps are induced by inclusions. The horizontal maps are isomorphisms by the Excision Theorem 74.18 and the vertical maps are isomorphisms by the Complement-of-Convex Homology Lemma 105.1. ■

Convention. We use the isomorphisms from Lemma 105.2 to identify the various relative homology modules. In particular, for any open set U of $\mathbb{R}^n$, any open ball $B_r(P)$ with $\overline{B}_r(P) \subset U$, any point $Q \in U$ and any commutative ring R we make the identifications

$$R = \mathrm{H}_n(\Delta^n, \partial\Delta^n; R) = \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) = \mathrm{H}_n(U, U \setminus B_r(P); R) = \mathrm{H}_n(U, U \setminus \{Q\}; R).$$

Furthermore, we refer to the image of the generator $[\mathrm{id}_{\Delta^n} \otimes 1] \in \mathrm{H}_n(\Delta^n, \partial\Delta^n; R)$ as the standard generator of the various relative homology modules.

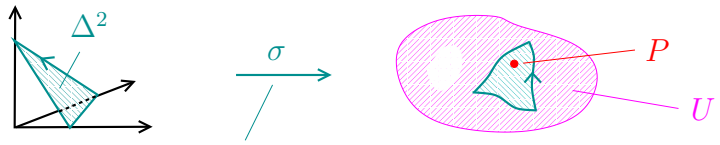
Example. We refer to the figure below for an illustration of representatives of the standard generators.[1277] Here, for simplicity, given a singular 2-simplex $\Delta^2 \to \mathbb{R}^2$ we only sketch the image of $\partial\Delta^2$ with the given orientation. Finally note that it follows from Lemma 105.2 (4) that the singular simplex illustrated in the middle of the figure below represents *minus* the standard generator.

standard generator for $\mathrm{H}_2(\mathbb{R}^2, \mathbb{R}^2 \setminus \{0\}; \mathbb{Z})$ | minus the standard generator | standard generator for $\mathrm{H}_2(U, U \setminus \{P\}; \mathbb{Z})$

Lemma 105.3. Let R be a commutative ring, let U be an open subset of $\mathbb{R}^n$, let $P \in U$ and let $\sigma\colon \Delta^n \to U$ be a singular n-simplex with the following properties:

(1) the point P lies in the image of $\mathring{\Delta}^n$,

(2) the restriction of σ to a map $\mathring{\Delta}^n \to U$ is a diffeomorphism onto its image.



Then $\sigma \otimes 1 \in \mathrm{C}_n(U) \otimes R$ represents a generator of $\mathrm{H}_n(U, U \setminus \{P\}; R)$.[1278] Furthermore, if

(3) the restriction of σ to a map $\mathring{\Delta}^n \to U$ is orientation-preserving,

then $\sigma \otimes 1$ represents the standard generator of $\mathrm{H}_n(U, U \setminus \{P\}; R)$.

[1277] At this occasion it is good to remember that if $\sigma\colon \Delta^k \to X$ is a map with $\sigma(\partial\Delta^n) \subset A$, then σ is a cycle in $\mathrm{C}_k(X, A)$, i.e. it represents a class in $\mathrm{H}_k(X, A)$.

[1278] Note that we do not make any assumptions on the behavior of σ restricted to $\partial\Delta^n$. If one looks very carefully, then one realizes that one has to convince oneself that $\sigma(\partial\Delta^n)$ is a subset of $U \setminus \{P\}$, i.e. one has to show that it follows from (1) and (2), that $P \notin \sigma(\partial\Delta^n)$. How can one prove this statement?

σ represents the standard generator of $\mathrm{H}_2(U, U \setminus \{P\}; \mathbb{Z})$

Proof. We denote by $Q \in \mathring{\Delta}^n$ the point with $\sigma(Q) = P$. To simplify the notation we work throughout the proof with the coefficients $R = \mathbb{Z}$. Using the fact that the inclusion induced map

$$\mathrm{H}_n(U, U \setminus \{P\}) \xrightarrow{\cong} \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\})$$

is an isomorphism by the Excision Theorem 74.18 we can without loss of generality assume that $U = \mathbb{R}^n$. As always we denote by $\mathrm{D}\sigma_Q \colon \mathrm{T}_Q \mathring{\Delta}^n \to \mathrm{T}_P U = \mathbb{R}^n$ the differential of σ at the point Q. We denote by

$$\begin{array}{rcl} f \colon \Delta^n & \to & \mathbb{R}^n \\ x & \mapsto & (\mathrm{D}\sigma_Q)\underbrace{(x - Q)}_{\in \mathrm{T}_Q \Delta^n} + P \end{array}$$

the linear approximation of σ at the point Q. We make the following two observations:

(1) Since $\sigma \colon \mathring{\Delta}^n \to U$ is a diffeomorphism onto its image we obtain that $\mathrm{D}\sigma_Q$ is an isomorphism of vector spaces, in particular f is an injective affine linear map.

(2) Basically the same argument as in the proof of Lemma 76.15 shows that there exists an open neighborhood V of Q in $\mathring{\Delta}^n$ such that the restrictions of σ and f to maps

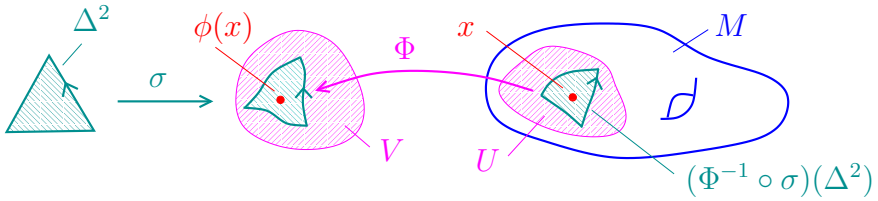
$$\sigma, f \colon (V, V \setminus \{Q\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{P\})$$

are homotopic.

Now consider the following diagram

$$\begin{array}{ccccccccc} \mathrm{H}_n(\Delta^n, \partial\Delta^n) & \longrightarrow & \mathrm{H}_n(\Delta^n, \Delta^n \setminus \{Q\}) & \longleftarrow & \mathrm{H}_n(V, V \setminus \{Q\}) & \xrightarrow{=} & \mathrm{H}_n(V, V \setminus \{Q\}) & \longrightarrow & \mathrm{H}_n(\Delta^n, \Delta^n \setminus \{Q\}) \\ \downarrow{\scriptstyle \sigma_*} & & \downarrow{\scriptstyle \sigma_*} & & \downarrow{\scriptstyle \sigma_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}) & \xrightarrow{=} & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}) & \xrightarrow{=} & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}) & \xrightarrow{=} & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}) & \xrightarrow{=} & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}). \end{array}$$

It is clear that the first two squares and the last square commute. Furthermore the third square commutes by the above observation (2) together with Proposition 74.15. As in the proof of Lemma 105.2 (2) we see that the last vertical map is an isomorphism. It now follows easily that $\sigma \in \mathrm{C}_n(\mathbb{R}^n)$ represents a generator of $\mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\})$.



Finally suppose that the restriction of σ to a map $\mathring{\Delta}^n \to U$ is orientation-preserving. In this case, by definition of orientation-preserving, the map f is also orientation-preserving, therefore by the above commutative diagram the singular n-simplex σ does indeed represent the standard generator of $\mathrm{H}_n(U, U \setminus \{P\})$. ∎

We continue with the following lemma which is almost identical to the Manifold-Local Homology Lemma 75.1.

Lemma 105.4. Let M be an n-dimensional topological manifold and let R be a commutative ring. Then for every $x \in M \setminus \partial M$ and any $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(M, M \setminus \{x\}; R) \;\cong\; \begin{cases} R, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Furthermore, if $\Phi\colon U \to V$ is a chart around x and if $\sigma\colon \Delta^n \to V$ represents a generator of $\mathrm{H}_n(V, V \setminus \{\Phi(x)\}; R)$, then $\Phi^{-1} \circ \sigma$ represents a generator of $\mathrm{H}_n(M, M \setminus \{x\}; R)$.

Remark. Let $n \in \mathbb{N}_0$. A topological space X that has the property that for each $x \in X$ we have

$$\mathrm{H}_k(X, X \setminus \{x\}; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise} \end{cases}$$

is often called a *k-dimensional homology manifold*. By Lemma 105.4 such topological spaces can be viewed as generalizations of closed topological manifolds.

Let Y be an homology n-sphere.[1279] By the Suspension-H_*-Proposition 76.7 we know that the suspension $\Sigma(Y)$ of Y is an $(n+1)$-dimensional homology manifold. On the other hand we saw in Exercise 76.9 that the suspension $\Sigma(Y)$ is *not* a topological manifold.[1280] Recall that the Double Suspension Theorem 96.18 says that the *double* suspension $\Sigma(\Sigma(Y))$ of any homology n-sphere is actually homeomorphic to S^{n+2}.

The proof of Lemma 105.4 is basically identical to the proof of the Manifold-Local Homology Lemma 75.1. We recall the argument just in case some readers might have forgotten.

Proof. Let M be an n-dimensional topological manifold, let R be a commutative ring and let $x \in M \setminus \partial M$. Since $x \notin \partial M$ we can pick a chart $\Phi\colon U \to V$ such that V is an open subset of $\mathbb{R}^n$. We write $y = \Phi(x)$. For any $k \in \mathbb{N}_0$ we then have

$$\mathrm{H}_k(M, M \setminus \{x\}; R) \;\underset{\uparrow}{\overset{\cong}{\longleftarrow}}\; \mathrm{H}_k(U, U \setminus \{x\}; R) \;\underset{\uparrow}{\overset{\Phi_*}{\underset{\cong}{\longrightarrow}}}\; \mathrm{H}_k(V, V \setminus \{y\}; R) \;\underset{\uparrow}{\overset{\cong}{\longrightarrow}}\; \begin{cases} R, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Excision Theorem 74.18 — since Φ is a homeomorphism — see Lemma 105.2 (5)

The last statement regarding generators now follows immediately from the above isomorphisms. ∎

[1279] Recall that by the definition on page 2159 an homology n-sphere is an n-dimensional topological manifold X such that for any $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(X; \mathbb{Z}) \cong \mathrm{H}_k(S^n; \mathbb{Z})$. On page 2161 we saw that there exists a smooth homology 3-sphere with non-trivial fundamental group, namely the Poincaré Homology Sphere.

[1280] To be super-precise we showed that it is not an $(n+1)$-dimensional topological manifold, but it follows easily from the Topological Manifold-Dimension Proposition 75.4 that if $\Sigma(Y)$ was a topological manifold it would need to be $(n+1)$-dimensional.

105.3. **R-Sections on topological manifolds.** In Section 25.2 we defined the notion of an oriented smooth manifold via orientations of the tangent spaces. The notion of a tangent space requires the smooth structure on a smooth manifold, put differently, topological manifolds do not come with tangent spaces. In the next section we will see that we can still define the notion of an orientation of a topological manifold. Furthermore we will see that for smooth manifolds this new notion of an orientation will be equivalent to the previous notion of an orientation.

The key to defining the new notion of orientation is the following, initially rather obscure definition.

Definition. Let M be an n-dimensional topological manifold and let R be a commutative ring.

(1) An R-section for M at $x \in M \setminus \partial M$ is an element $\mu_x \in \mathrm{H}_n(M, M \setminus \{x\}; R) \cong R$.

(2) Let $W \subset M$ and let $x \in W$. Given any $k \in \mathbb{N}_0$ we denote by ρ_x the natural map

$$\rho_x \colon \mathrm{H}_k(M, M \setminus W; R) \;\to\; \mathrm{H}_k(M, M \setminus \{x\}; R).$$

Given $\varphi \in \mathrm{H}_k(M, M \setminus W; R)$ we often write $\varphi_x := \rho_x(\varphi)$, i.e. the above map is also written as

$$\varphi \;\mapsto\; \varphi_x.$$

(3) Let A be a subset of $M \setminus \partial M$. (In the following we will mostly be interested in the case $A = M \setminus \partial M$). An R-section for M along A is a choice for each $x \in A$ of an R-section $\mu_x \in \mathrm{H}_n(M, M \setminus \{x\}; R)$ at x such that the following "continuity condition" is satisfied: for each $x \in A$ there exists an open neighborhood U of x in A and a homology class $\mu_U \in \mathrm{H}_n(M, M \setminus U; R)$ such that for each $y \in U$ the image of μ_U under the natural map

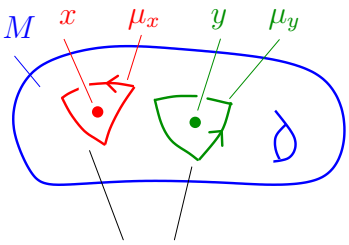
$$\rho_y \colon \mathrm{H}_n(M, M \setminus U; R) \;\to\; \mathrm{H}_n(M, M \setminus \{y\}; R)$$

equals μ_y.

(4) We denote by $\Gamma_R^A(M)$ the set of all R-sections of M along A.

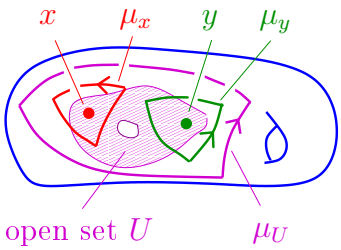
For $A = M \setminus \partial M$ we say "section" instead of "section along A" and we write $\Gamma_R(M)$ instead of $\Gamma_R^{M \setminus \partial M}(M)$.

Example. In the figure below we attempt to illustrate the definition of a $\mathbb{Z}$-section on a surface M. Here, for simplicity, given a singular 2-simplex $\Delta^2 \to M$ we only sketch the image of $\partial\Delta^2$ with the given orientation.

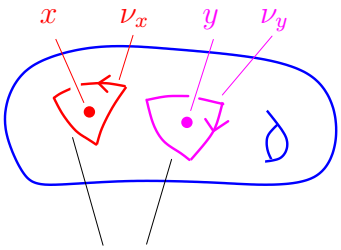


(1) In the figure below we show to the left two points x and y together with singular 2-simplices representing $\mu_x \in \mathrm{H}_2(M, M \setminus \{x\}; \mathbb{Z})$ and $\mu_y \in \mathrm{H}_2(M, M \setminus \{y\}; \mathbb{Z})$. Furthermore we sketch an open set U that contains x and y and we sketch a homology class $\mu_U \in \mathrm{H}_2(M, M \setminus U; \mathbb{Z})$ that gets sent to μ_x and μ_y via the natural maps[1281]

$$\mathrm{H}_n(M, M \setminus U; \mathbb{Z}) \xrightarrow{\rho_x} \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z}) \quad \text{and} \quad \mathrm{H}_n(M, M \setminus U; \mathbb{Z}) \xrightarrow{\rho_y} \mathrm{H}_n(M, M \setminus \{y\}; \mathbb{Z}).$$



In fact these $\mathbb{Z}$-sections at x and y form part of a $\mathbb{Z}$-section of M.



(2) In the figure below we show to the right two $\mathbb{Z}$-sections ν_x and ν_y that cannot be part of a $\mathbb{Z}$-section of M.

[1281] Note that in this example the group $\mathrm{H}_2(M, M \setminus U; \mathbb{Z})$ is not isomorphic to $\mathbb{Z}$, i.e. the two maps are not isomorphisms.

here the $\mathbb{Z}$-sections at the points correspond to a $\mathbb{Z}$-section on M

here the $\mathbb{Z}$-sections at the points do *not* come from a $\mathbb{Z}$-section on M

Lemma 105.5. Let M be an n-dimensional topological manifold and let R be a commutative ring.

(1) Given any subset $A \subset M \setminus \partial M$ the set $\Gamma_R^A(M)$ admits a unique R-module structure such that for each $y \in A$ the map $\Gamma_R^A(M) \to \mathrm{H}_n(M, M \setminus \{y\}; R)$ that is given by $\{\alpha_x\}_{x\in A} \mapsto \alpha_y$ is an R-module homomorphism.

(2) For every subset $A \subset M \setminus \partial M$ (often we will take $A = M \setminus \partial M$) the map

$$\begin{array}{rcl} \mathrm{H}_n(M, M \setminus A; R) & \to & \Gamma_R^A(M) \\ \alpha & \mapsto & \{\alpha_x\}_{x\in A} \end{array}$$

is a well-defined homomorphism of R-modules.

Remark. In the Homology-Section Theorem 106.10 we will see that in many settings the converse to Lemma 105.5 holds.

Proof.

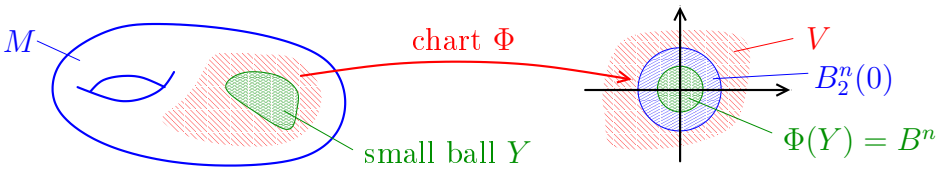
(1) We will prove this statement in Exercise 105.2.

(2) Let $A \subset M \setminus \partial M$ be a subset and let $\alpha \in \mathrm{H}_n(M, M \setminus A; R)$. Let $x \in A$. We need to show that there exists an open neighborhood U of x in A and a homology class $\varphi \in \mathrm{H}_n(M, M \setminus U; R)$ such that for each $y \in U$ we have $\rho_x(\varphi) = \alpha_x$. But this is trivial, we just take $U = A$ and $\varphi = \alpha$. ■

The following proposition contains much more interesting results on $\Gamma_R^A(M)$.

Proposition 105.6. (Sections Proposition) Let M be a topological manifold and let A be a *connected* subset of $M \setminus \partial M$.[1282]

(1) Let R be a commutative ring and let $\{\alpha_x\}_{x\in A}$ and $\{\beta_x\}_{x\in A}$ be two R-sections for M along A. If there exists an $x \in A$ with $\alpha_x = \beta_x$, then the two R-sections agree.



(2) Let $\{\alpha_x\}_{x\in A}$ be a $\mathbb{Z}$-section for M along M. Suppose there exists a $y \in A$, an $m \in \mathbb{Z}$ and a $\beta_y \in \mathrm{H}_n(M, M \setminus \{y\}; \mathbb{Z})$ such that $\alpha_y = m \cdot \beta_y$, then there exists a $\mathbb{Z}$-section $\{\beta_x\}_{x\in A}$ along A such that $\alpha_x = m \cdot \beta_x$ for every $x \in A$.

(3) Let $\{\alpha_x\}_{x\in A}$ be a $\mathbb{Z}$-section along A for M. If there exists a $y \in A$ such that α_y is a generator of $\mathrm{H}_n(M, M\setminus\{y\}; \mathbb{Z}) \cong \mathbb{Z}$, then α_x is a generator of $\mathrm{H}_n(M, M\setminus\{x\}; \mathbb{Z}) \cong \mathbb{Z}$ for every $x \in A$.

[1282] In some applications we will use that by Exercise 18.19 we know that if M is a connected topological manifold, then $M \setminus \partial M$ is also connected.

Before we provide the proof of the Sections Proposition 105.6 we need to prove one little lemma which in turn requires the following definition.

Definition. Let M be an n-dimensional topological manifold. We say that $Y \subset M$ is a small ball in M if there exists a chart $\Phi\colon U \to V$ such that $B_2^n(0) \subset V$ and such that $\Phi(Y) = B^n$.

Lemma 105.7. (Small Ball-Lemma) Let M be an n-dimensional topological manifold.

(1) Given any point $x \in M \setminus \partial M$ and any neighborhood U of x there exists a small ball contained in U that contains x.

Let R be a commutative ring.

(2) For any point y in a small ball Y and any $k \in \mathbb{N}_0$ the map

$$\rho_y\colon \mathrm{H}_k(M, M \setminus Y; R) \;\to\; \mathrm{H}_k(M, M \setminus \{y\}; R)$$

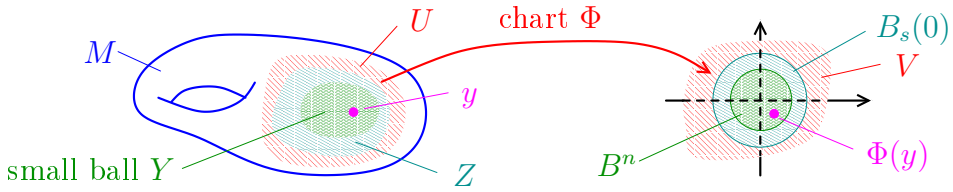
is an isomorphism.

(3) Let A be a subset of $M \setminus \partial M$, let $\{\alpha_x\}_{x\in A}$ be an R-section along A and let $x \in A$. There exists a small ball Y in $M \setminus \partial M$ that contains x and a $\varphi \in \mathrm{H}_k(M, M \setminus Y; R)$ such that for every $y \in Y \cap A$ we have $\rho_y(\varphi) = \alpha_y \in \mathrm{H}_n(M, M \setminus \{y\}; R)$.

Proof. Let M be an n-dimensional topological manifold.

(1) The proof of the first statement is elementary.

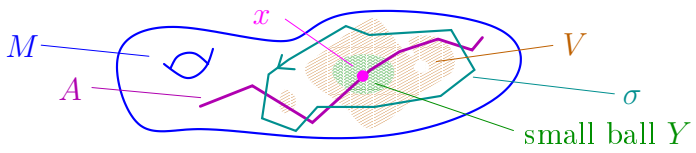
(2) Now let y be a point that is contained in a small ball Y. To simplify the notation we drop the commutative ring R from the notation. We consider the long exact sequence of the triple $(M, M \setminus \{y\}, M \setminus Y)$ given by the Topological LES-Corollary 74.14:



$$\to \mathrm{H}_k(M\setminus\{y\}, M\setminus Y) \to \mathrm{H}_k(M, M\setminus Y) \to \mathrm{H}_k(M, M\setminus\{y\}) \to \mathrm{H}_{k-1}(M\setminus\{y\}, M\setminus Y) \to$$

We see immediately that it suffices to show that all the relative homology groups $\mathrm{H}_k(M \setminus \{y\}, M \setminus Y)$ vanish. Since Y is a small ball we can pick a chart $\Phi\colon U \to V$ such that $B_2^n(0) \subset V$ and such that $\Phi(Y) = B^n$. We pick $s \in (1, 2)$ and we write $Z = \Phi^{-1}(B_s^n(0))$. Then

$$\mathrm{H}_k(M\setminus\{y\}, M\setminus Y) \xleftarrow[\uparrow]{\cong} \mathrm{H}_k(Z\setminus\{y\}, Z\setminus Y) \xrightarrow[\cong]{\Phi_*} \mathrm{H}_k(B_s^n(0)\setminus\{\Phi(y)\}, B_s^n(0)\setminus B^n) \underset{\uparrow}{=} 0.$$



Excision Theorem 74.18

by Corollary 74.16, since $B_s^n(0) \setminus B^n$ is a deformation retract of $B_s^n(0) \setminus \{\Phi(y)\}$

(3) Let A be a subset of M, let $\{\alpha_x\}_{x\in A}$ be an R-section along A and let $x \in A$. By definition of an R-section along A and by definition of the subspace topology there exists an open neighborhood V of $x \in M \setminus \partial M$ and a singular chain $\sigma \in \mathrm{C}_n(M;R)$ that represents a cycle in $\mathrm{C}_n(M, M \setminus (V \cap A);R)$ such that for each $y \in V \cap A$ we have $\alpha_y = \rho_y([\sigma]) \in \mathrm{H}_n(M, M \setminus \{y\};R)$.

Since σ represents a cycle in the relative chain complex $\mathrm{C}_*(M, M \setminus (V \cap A);R)$ we know that $\partial\sigma \in \mathrm{C}_{n-1}(M \setminus (V \cap A);R)$. It follows from the fact that Δ^{n-1} is compact together with the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 that there exists an open neighborhood $U \subset M$ of x with $U \subset V$ such that $\partial\sigma \in \mathrm{C}_{n-1}(M \setminus U;R)$. In other words, σ represents a cycle in $\mathrm{C}_n(M, M \setminus U)$. By (1) there exists a small ball Y with $x \in Y \subset U$. It follows immediately from the functoriality of homology groups that the homology class $[\sigma] \in \mathrm{H}_n(M, M \setminus Y;R)$ has all the desired properties. ■

Proof of the Sections Proposition 105.6. Let M be an n-dimensional topological manifold, let A be a connected subset of $M \setminus \partial M$ and let R be a commutative ring.

(1) Let $\{\alpha_x\}_{x\in A}$ and $\{\beta_x\}_{x\in A}$ be two R-sections for M along A. We assume that there exists a $z \in A$ with $\alpha_z = \beta_z$. We consider the R-section along A that is given by $\gamma_x = \alpha_x - \beta_x$ for $x \in A$. Next we consider the following two subsets of A:

$$V := \{y \in A \,|\, \gamma_y = 0\} \quad \text{and} \quad W := \{y \in A \,|\, \gamma_y \neq 0\}.$$

We need to show that $V = A$. Since V is by hypothesis non-empty and since A is connected it suffices to show that V and W are both open. In other words, it suffices to prove the following claim.

Claim. Let $x \in A$. There exists an open neighborhood U of x in A such that either γ_y is zero for every $z \in U$ or γ_y is non-zero for every $z \in U$.

Proof. Let $x \in A$. It follows immediately from the Small Ball-Lemma 105.7 (3) that there exists a small ball Y in $M \setminus \partial M$ that contains x and a $\varphi \in \mathrm{H}_k(M, M \setminus Y;R)$ such that for every $y \in Y \cap A$ we have $\rho_y(\varphi) = \alpha_y \in \mathrm{H}_n(M, M \setminus \{y\};R)$. Furthermore, note that by the Small Ball-Lemma 105.7 (2) we know that for every $y \in Y$ the map ρ_y is an isomorphism. But this implies that $\gamma_x = 0$ if and only if $\gamma_y = 0$ for all $y \in Y$. ⊞

(2) Let $n \in \mathbb{N}$. We start out with the following definition: Given an element g of a group G with $G \cong \mathbb{Z}$ we say that g is divisible by n if there exists an $h \in G$ with $n \cdot h = g$. In this case we write $g/n := h$. Note that h is well-defined since $G \cong \mathbb{Z}$.

Let $\{\alpha_x\}_{x\in A}$ be a $\mathbb{Z}$-section for M along A. Given $n \in \mathbb{N}$ we consider the two sets

$$\begin{aligned} V &:= \{y \in A \,|\, \alpha_y \text{ is divisible by } n\}, \qquad \text{and} \\ W &:= \{y \in A \,|\, \alpha_y \text{ is not divisible by } n\}. \end{aligned}$$

The same argument as in (1) one shows that V and W are open.

If V is non-empty, then $V = M \setminus \partial M$ and it is straightforward to verify that $\beta_y := \alpha_y/n$, $y \in A$, is in fact a $\mathbb{Z}$-section along A. We leave it to the reader to fill in the details.

(3) Let $\{\alpha_x\}_{x\in A}$ be a $\mathbb{Z}$-section for M along A. Let $y \in A$ be a point such that α_y is a generator of $\mathrm{H}_n(M, M\setminus\{y\}; \mathbb{Z}) \cong \mathbb{Z}$. Now let $z \in A$. If α_z is not a generator, then there exists a $\beta_z \in \mathrm{H}_n(M, M\setminus\{z\}; \mathbb{Z}) \cong \mathbb{Z}$ and some $n \geq 2$ such that $\alpha_z = n \cdot \beta_z$. By (2) we can extend β_z to a $\mathbb{Z}$-section $\{\beta_x\}_{x\in A}$ such that $\alpha_x = n \cdot \beta_x$ for every $x \in A$. But this implies that α_y is not a generator. So we have obtained a contradiction. ■

105.4. **Orientations of topological manifolds.** After the technical preparations from the last section we can now finally introduce the notion of an orientation of a topological manifold.

Definition. Let M be an n-dimensional topological manifold and let R be a commutative ring.

(1) An R-section for M at a point $x \in M \setminus \partial M$ that is in fact a generator of the R-module $\mathrm{H}_n(M, M \setminus \{x\}; R) \cong R$ is called an *R-orientation for M at $x \in M$*.

(2) An *R-section for M* that is an R-orientation at each point $x \in M \setminus \partial M$ is called an *R-orientation of M*.

(3) The topological manifold M is called *R-orientable* if it admits an R-orientation.

(4) Let M and N be two n-dimensional topological manifolds that are equipped with R-orientations $\{\alpha_x\}_{x\in M\setminus\partial M}$ and $\{\beta_x\}_{x\in N\setminus\partial N}$. Let $f\colon M \to N$ be a map that is a local homeomorphism. We say the map f is *orientation-preserving* if the following holds: for any open set $U \subset M$, such that $f\colon U \to f(U)$ is a homeomorphism and such that $f(U)$ is open, and any $x \in U \setminus \partial M$ the image of α_x under the map[1283] [1284] [1285]

these two maps are isomorphisms by the Excision Theorem 74.18

$$\mathrm{H}_n(M, M\setminus\{x\}) \xleftarrow[\cong]{\downarrow} \mathrm{H}_n(U, U\setminus\{x\}) \xrightarrow[\cong]{f_*} \mathrm{H}_n(f(U), f(U)\setminus\{f(x)\}) \xrightarrow[\cong]{\downarrow} \mathrm{H}_n(N, N\setminus\{f(x)\}).$$

equals $\beta_{f(x)}$. Otherwise we call f *orientation-reversing*.

Example. Let M be a 0-dimensional topological manifold. Note that for each $x \in M$ we have a natural isomorphism

$$\mathbb{Z} \xrightarrow[\uparrow]{n\mapsto n\cdot[x]} \mathrm{H}_n(\{x\}) \xrightarrow[\uparrow]{\cong} \mathrm{H}_0(M, M\setminus\{x\}).$$

H_0-Proposition 72.5 — inclusion induced

Thus we see that an orientation of a 0-dimensional topological manifold is basically the same as a map $M \to \{\pm 1\}$. In other words, we see that we have the same concept of an orientation as we remarked on page 675 for 0-dimensional smooth manifolds.

We leave the proof of the following lemma as an amusing exercise to the reader.

[1283] Since $f\colon U \to f(U)$ is a homeomorphism we have $f(U \setminus \{x\}) = f(U) \setminus \{f(x)\}$.

[1284] It follows from the fact that $f\colon U \to f(U)$ is a homeomorphism, the fact that $x \in U \setminus \partial U$ and the Topological Manifold Boundary Proposition 75.2 that $f(x) \notin \partial N$.

[1285] We suppress the R-coefficients from the notation for space reasons.

Lemma 105.8. Let M and N be two n-dimensional topological manifolds and furthermore let $f, g\colon M \to N$ be two homeomorphisms. If f and g are isotopic, then f is orientation-preserving if and only if g is orientation-preserving.

Before we start with the discussions of orientations in detail we get the following technical lemma out of the way.

Lemma 105.9. Let M be an-dimensional topological manifold.

(1) Let R be a commutative ring and let $A \subset M \setminus \partial M$ be a *connected* subset. If M is R-orientable, then for every $x \in M \setminus \partial M$ the map

$$\begin{array}{rcl} \Phi\colon \Gamma_R^A(M) & \to & \overbrace{\mathrm{H}_n(M, M \setminus \{x\}; R)}^{\cong R} \\ \{\alpha_y\}_{y\in A} & \mapsto & \alpha_x \end{array}$$

is an isomorphism of R-modules.

(2) If M is non-orientable and connected, then $\Gamma_{\mathbb{Z}}(M) = 0$.

Proof. Let M be a connected n-dimensional topological manifold.

(1) Let R be a commutative ring such that M is R-orientable. We pick an R-orientation $\{\mu_y\}_{y\in M\setminus\partial M}$ for M. Next let $A \subset M\setminus\partial M$ be a connected subset and let $x \in M\setminus\partial M$. By definition μ_x is a generator of the R-module $\mathrm{H}_n(M, M \setminus \{x\}; R) \cong R$, i.e. every element in $\mathrm{H}_n(M, M\setminus\{x\}; R)$ is of the form $r\cdot\mu_x$ for some unique $r \in R$. We consider the map

$$\begin{array}{rcl} \Psi\colon \mathrm{H}_n(M, M \setminus \{x\}; R) & \to & \Gamma_R^A(M) \\ r \cdot \mu_x & \mapsto & \{r \cdot \mu_y\}_{y\in A}. \end{array}$$

Evidently we have $\Phi \circ \Psi = \mathrm{id}$. It follows from our hypothesis that A is connected and from the Sections Proposition 105.6 (1) that $\Psi \circ \Phi$ is also the identity.

(2) Now we suppose that M admits a non-zero $\mathbb{Z}$-section $\{\alpha_x\}_{x\in M\setminus\partial M}$. We need to show that M is orientable. We pick $y \in M \setminus \partial M$ such that $\alpha_y \neq 0$. We pick a generator $\beta_y \in \mathrm{H}_n(M, M \setminus \{y\}; \mathbb{Z}) \cong \mathbb{Z}$. Then $\alpha_y = n \cdot \beta_y$ for some $n \in \mathbb{Z}$. It follows again from our hypothesis that M is connected and from the Sections Proposition 105.6 (2) that there exists a $\mathbb{Z}$-section $\{\beta_x\}_{x\in M\setminus\partial M}$ such that $\alpha_x = n \cdot \beta_x$ for all $x \in M \setminus \partial M$. It follows immediately from the Sections Proposition 105.6 (3) that $\{\beta_x\}_{x\in M\setminus\partial M}$ is an orientation for M. ■

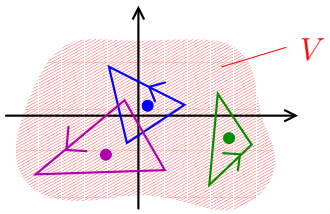
In the following lemma we collect some basic facts about $\mathbb{Z}$-orientations.

Lemma 105.10. Let M be a topological manifold.

(1) For any point $x \in M \setminus \partial M$ there exist precisely two $\mathbb{Z}$-orientations for M at x.

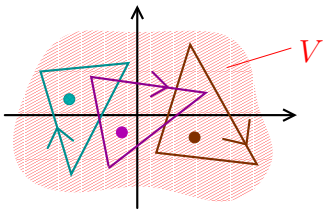
(2) If M is connected and orientable, then M admits precisely two $\mathbb{Z}$-orientations.

Proof. The first statement is an immediate consequence of the fact, proved in Lemma 105.4, that for any $x \in M \setminus \partial M$ we have $\mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z}) \cong \mathbb{Z}$. The second statement follows easily from the Sections Proposition 105.6 and the definitions. ■



Examples.

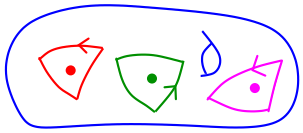
(1) Let V be a connected open subset of $\mathbb{R}^n$. For any $x \in V$ we define

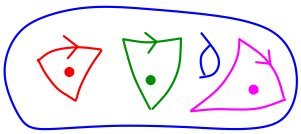


$$\mu_x \;:=\; \text{the standard generator of } \mathrm{H}_n(V, V \setminus \{x\}; \mathbb{Z}) \text{ as defined on page 2328.}$$

We claim that the μ_x define a $\mathbb{Z}$-orientation for V. Indeed, let $x \in V$. We pick an $r > 0$ such that $\overline{B}_r(x) \subset V$. We set $U := B_r(x)$. We denote by μ_U the standard generator of $\mathrm{H}_n(V, V \setminus U; \mathbb{Z})$ as defined on page 2328. It follows from Lemma 105.2 (5) that μ_U has the desired property. We refer to this $\mathbb{Z}$-orientation as the *standard $\mathbb{Z}$-orientation* of V.

By Lemma 105.10 (2) the topological manifold V admits precisely two different $\mathbb{Z}$-orientations. We have already given one orientation above. By Lemma 105.2 the other one is given by a reflection of the standard generators in hyperplanes. In the figure below we sketch the two different orientations of V.





standard generators
for $\mathrm{H}_2(V, V \setminus \{x\}; \mathbb{Z})$

the negative of the
standard generators

(2) In the figure below we sketch the two different orientations of the torus.

(3) Let R be a commutative ring. Recall that for $n \geq 1$ we denote by $[S^n] \in \mathrm{H}_n(S^n; \mathbb{Z})$ the standard generator that we introduced on page 1677. It follows from the Universal Coefficient Theorem 89.17 together with the Tor-Properties Lemma 89.15 (3) that the natural map

$$\mathrm{H}_n(S^n) \otimes R \ \to \ \mathrm{H}_n(S^n; R)$$

is an isomorphism. By a slight abuse of notation we denote by $[S^n]$ also the image of $[S^n] \otimes 1 \in \mathrm{H}_n(S^n; R)$ under the above map. Note that $[S^n] \in \mathrm{H}_n(S^n; R) \cong R$ is a generator. We refer to it as the *standard generator of* $\mathrm{H}_n(S^n; R)$. For any $x \in S^n$ it follows easily from the long exact sequence of homology groups with R-coefficients of the pair $(S^n, S^n \setminus \{x\})$ that the natural map

$$\mathrm{H}_n(S^n; R) \ \to \ \mathrm{H}_n(S^n, S^n \setminus \{x\}; R)$$

is an isomorphism. We denote by $\mu_x \in \mathrm{H}_n(S^n, S^n \setminus \{x\}; R)$ the image of $[S^n]$. By the above μ_x is an R-orientation at x. In fact all these R-orientations $\{\mu_x\}_{x \in S^n}$ define an R-orientation of S^n. Indeed, in the definition on page 2335 we just need to set $U = S^n$ and $\mu_U = [S^n] \in \mathrm{H}_n(S^n, \underbrace{S^n \setminus S^n}_{=\varnothing}; \mathbb{Z})$. We refer to this orientation of S^n as the *standard R-orientation of S^n*.

The following proposition shows in particular that for smooth manifolds the notion of orientability from page 675 agrees with the above notion of orientability.

Proposition 105.11. (Smooth-Topological Orientation Proposition)

(1) Give any smooth manifold M there exists a natural bijection

$$\left\{ \begin{array}{l} \text{orientations on } M \text{ in} \\ \text{the sense of page 675} \end{array} \right\} \xrightarrow{\cong} \{\, \mathbb{Z}\text{-orientations on } M \,\}$$

such that the following two statements hold:

(a) For any open subsets of some $\mathbb{R}^n$ the above bijections sends the standard orientation from page 675 to the above standard $\mathbb{Z}$-orientation.

(b) If $f\colon M \to N$ is a local diffeomorphism between oriented connected smooth manifolds, then the following two statements are equivalent:

(i) f preserves the orientations on M and N in the sense of page 675,

(ii) f preserves the $\mathbb{Z}$-orientations on M and N.

(2) Given an n-dimensional smooth manifold M we have

$$M \text{ is orientable in the sense of page 675} \iff M \text{ is } \mathbb{Z}\text{-orientable.}$$

In the proof of the Smooth-Topological Orientation Proposition 105.11 we will use the following lemma.

Lemma 105.12. Let $\Psi\colon V \to V'$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$. Then for any $x \in V$ we have

$$\begin{array}{c} \Psi \text{ preserves the standard} \\ \mathbb{Z}\text{-orientation of } V \text{ at the point } x \end{array} \iff \begin{array}{c} \Psi \text{ preserves the orientation of } V \text{ in the} \\ \text{sense of page 675 at the point } x. \end{array}$$

Proof. Let $\Psi\colon V \to V'$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$ and let $x \in V$. We write $x' = \Psi(x)$. Given $w \in \mathbb{R}^n$ we denote by t_w the translation $\mathbb{R}^n \to \mathbb{R}^n$ that is given by $v \mapsto v + w$. We set $\epsilon := 1$ if Ψ preserves the orientation of V in the sense of page 675 at the point x. Otherwise we set $\epsilon := -1$. We consider the following diagram

$$\begin{array}{ccccc} \mathrm{H}_n(V, V\backslash\{x\}; \mathbb{Z}) & \xleftarrow{t_{x*}} & \mathrm{H}_n(t_{-x}(V), t_{-x}(V)\backslash\{0\}) & \longrightarrow & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n\backslash\{0\}) \\ \downarrow{\scriptstyle \Psi_*} & & \downarrow{\scriptstyle (t_x \circ \Psi \circ t_{-x'})_*} & & \downarrow{\scriptstyle \cdot\epsilon} \\ \mathrm{H}_n(V', V'\backslash\{x'\}; \mathbb{Z}) & \xleftarrow{t_{x'*}} & \mathrm{H}_n(t_{-x}(V), t_{-x}(V)\backslash\{0\}) & \longrightarrow & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n\backslash\{0\}). \end{array}$$

We make the following observations:

(1) It follows easily from the definitions that each translation t_v is orientation-preserving in both senses of an orientation.

(2) It follows from the Local Diffeomorphism-Degree Proposition 76.14 together with (1) that the square at the right commutes.

(3) It is clear that the square at the left commutes.

(4) The statement of the lemma follows from (2) and (3). ∎

Sketch of the proof of Proposition 105.11. First, as we saw on page 2335, the case of 0-dimensional smooth manifolds is basically a tautology, at least as long as all statements are interpreted in a reasonable way. Thus in the following we assume that we are dealing with smooth manifolds of dimension ≥ 1.

Next note that Statement (2) is just a reader-friendly condensation of Statement (1). Thus we need to prove Statement (1). We define the promised natural bijections. Thus let M be an n-dimensional smooth manifold where $n \geq 1$. We first suppose that M is oriented in the sense of page 675. Let $x \in M \setminus \partial M$. We pick a chart $\Phi\colon U \to V$ around x

that is orientation-preserving in the sense of page 675. We define

$$\mu_x \;:=\; \Phi_*^{-1}\big(\text{standard generator of } \mathrm{H}_n(V, V\setminus\{\Phi(x)\};\mathbb{Z}) \text{ as defined on page 2328}\big).$$

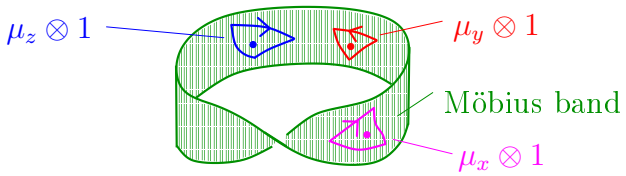
It follows from Lemma 105.12 that this definition does not depend on the choice of the orientation-preserving chart Φ. We claim that the classes $\{\mu_x\}_{x\in M\setminus\partial M}$ form a $\mathbb{Z}$-orientation for M. We only have to show that these classes satisfy the "continuity condition". We claim that for any $x \in M \setminus \partial$ a sufficiently small ball U containing x has the desired property. The proof of this fact is very similar to the arguments used in the proof of the Sections Proposition 105.6. We leave it to the reader to fill in the details.

Now we define the inverse map. So suppose we are given a $\mathbb{Z}$-orientation $\{\mu_x\}_{x\in M\setminus\partial M}$ for M. Note that by the Basics-of-Orientations Lemma 25.13 we only need to find an orientation for $M \setminus \partial M$. Thus let $x \in M \setminus \partial M$. We pick a chart $\Phi\colon U \to V$ around x such that V is connected. It follows from Lemma 105.2 that, after possibly reflecting V in a hyperplane, we can assume that Φ preserves the $\mathbb{Z}$-orientation at x, i.e. it sends the given $\mathbb{Z}$-orientation μ_x to the standard orientation of the open subset V of $\mathbb{R}^n$ that we introduced on page 2337. We define

$$\text{orientation of } \mathrm{T}_xM \;:=\; \Phi^*(\text{standard orientation of } \mathrm{T}_{\Phi(x)}V = \mathbb{R}^n).$$

It follows from Lemma 105.12 that this definition does not depend on the choice of Φ. As before, using small balls, one can show that this defines an orientation of M in the sense of page 675. We leave the verification of the details once again to the surely highly motivated reader.

It is basically clear, that by construction, the bijections have the desired properties (a) and (b). This concludes the proof of Statement (1). ■



Convention. the Smooth-Topological Orientation Proposition 105.11 says in particular that for smooth manifolds the notion of orientability that we introduced on page 675 agrees with the notion of $\mathbb{Z}$-orientability that we had just introduced. For $R = \mathbb{Z}$ we will therefore often drop the "R" from the definitions on page 2335, i.e. often we just say orientation at a point, orientation and orientable.

Remark. It follows basically from the definitions that under the equivalence of the Smooth-Topological Orientation Proposition 105.11 the orientations of S^n introduced on page 681 and page 2337 agree.

The following proposition shows that the notion of R-orientability is more flexible than the previous notion of orientability.

Proposition 105.13. ($\mathbb{F}_2$-Orientability Proposition) Every topological manifold is $\mathbb{F}_2$-orientable.

Example. The $\mathbb{F}_2$-Orientability Proposition 105.13 says in particular that the real projective plane, the Klein bottle and the Möbius band are $\mathbb{F}_2$-orientable.

Proof. Let M be an n-dimensional topological manifold. Let $x \in M \backslash \partial M$. By Lemma 105.4 we know that $\mathrm{H}_n(M, M \backslash \{x\}; \mathbb{F}_2) \cong \mathbb{F}_2$. We define μ_x to be the unique non-trivial element in $\mathrm{H}_n(M, M \setminus \{x\}; \mathbb{F}_2) \cong \mathbb{F}_2$. Using the Small Ball-Lemma 105.7 it is straightforward to show that the continuity condition is satisfied, in particular we have defined an $\mathbb{F}_2$-orientation on M. ■

Lemma 105.14. Let M be a topological manifold. If M is orientable, then it is R-orientable for any commutative ring R.

Proof. Let M be an n-dimensional orientable topological manifold and let R be a commutative ring. Let $x \in M \setminus \partial M$. It follows from the Universal Coefficient Theorem 89.17, together with the fact that $\mathrm{H}_{n-1}(M, M \setminus \{x\}; \mathbb{Z}) = 0$ obtained in Lemma 105.4, that the natural map

$$\begin{array}{rcl} \mu\colon \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z}) \otimes R & \to & \mathrm{H}_n(M, M \setminus \{x\}; R) \\ \sum\limits_{i=1}^{k} [\sigma_i] \otimes r_i & \mapsto & \Big[\sum\limits_{i=1}^{k} \sigma_i \otimes r_i\Big] \end{array}$$

is an isomorphism.

Now we pick an orientation $\{\alpha_x\}_{x \in M \setminus \partial M}$ for M. For each $x \in M \setminus \partial M$ we denote by $\widetilde{\alpha}_x \in \mathrm{H}_n(M, M \setminus \{x\}; R)$ the image of $\alpha_x \otimes 1$ under the above isomorphism. It is straightforward to verify that these generators $\{\widetilde{\alpha}_x\}_{x \in M \setminus \partial M}$ define an R-orientation for the topological manifold M. ■

We continue with the following proposition which is a variation on Propositions 49.4 and 49.5, which were formulated in the context of smooth manifolds.

Proposition 105.15. (Orientation Covering-Proposition)

(1) To each topological manifold M we can naturally[1286] associate an oriented topological manifold $\widetilde{M}$ together with a 2-fold covering $p\colon \widetilde{M} \to M$ and to each local homeomorphism $f\colon M \to N$ we can associate an orientation-preserving local homeomorphism $\widetilde{f}\colon \widetilde{M} \to \widetilde{N}$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow{\widetilde{f}} & \widetilde{N} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ M & \xrightarrow{f} & N. \end{array}$$

(2) Let M be a connected topological manifold and let $p\colon \widetilde{M} \to M$ be the 2-fold covering constructed in (1).

(a) If M is orientable, then there exists a unique orientation-preserving homeomorphism to $\Theta\colon \widetilde{M} \to M \sqcup -M$ such that the following diagram commutes:

$$\begin{array}{ccccc} \widetilde{M} & & \xrightarrow[\cong]{\Theta} & & M \sqcup -M \\ & {\scriptstyle p}\searrow & & \swarrow{\scriptstyle q} & \\ & & M & & \end{array}$$

where q is the obvious map given by the identity on each component of $M \sqcup -M$.

(b) If M is non-orientable, then $\widetilde{M}$ is connected.

(3) Let M be a topological manifold. The map

$$\begin{array}{rccl} \Xi_M\colon & \widetilde{M} & \to & \widetilde{M} \\ & x & \mapsto & \text{the unique other points of } p^{-1}(p(x)) \end{array}$$

is the unique orientation-reversing self-homeomorphism $\Xi_M\colon \widetilde{M} \to \widetilde{M}$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow[\cong]{\Xi_M} & \widetilde{M} \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle p} & \\ & M. & \end{array}$$

Furthermore, given a local homeomorphism $f\colon M \to N$ we have $\widetilde{f} \circ \Xi_M = \Xi_N \circ \widetilde{f}$.

(4) Let M be a connected non-orientable topological manifold. Suppose that we are given two connected 2-fold coverings $p\colon \widetilde{M} \to M$ and $q\colon \widehat{M} \to M$ such that $\widetilde{M}$ and $\widehat{M}$ are orientable. There exists a homeomorphism $\Phi\colon \widetilde{M} \to \widehat{M}$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{M} & \xrightarrow{\Phi} & \widehat{M} \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & M. & \end{array}$$

If $\widetilde{M}$ and $\widehat{M}$ are oriented, then there exists a unique orientation-preserving Φ as above.

Definition. Let M be a connected non-orientable topological manifold without boundary. We refer to the connected 2-fold covering $p\colon \widetilde{M} \to M$ which we construct in the proof the Orientation Covering-Proposition 105.15 as the orientation covering of M.

Given a non-orientable connected smooth manifold M with orientation cover $p\colon \widetilde{M} \to M$ we discussed in Proposition 49.7 at length the subgroup of $\pi_1(M)$ defined by $\pi_1(\widetilde{M})$. These results generalize without problems to the present setting of topological manifold. In particular we now have the following generalization of the definition from page 1114.

Definition. Let M be a connected topological manifold and let $x_0 \in M$.

(1) If M is non-orientable, then we refer to the epimorphism

$$w_1\colon \pi_1(M, x_0) \ \to \ \pi_1(M, x_0)/p_*(\pi_1(\widetilde{M}, \widetilde{x}_0)) = \mathbb{Z}_2,$$

which is given by the obvious analogue of Proposition 49.7, as the orientation character of M.

(2) If M is orientable, then we define the orientation character of M to be the trivial homomorphism $w_1\colon \pi_1(M, x_0) \to \mathbb{Z}_2$.

Sketch of proof. The proof is very similar to the proof of Propositions 49.4 and 49.5.

(1) Let M be a topological manifold.
   (a) For $x \in M \setminus \partial M$ we define an orientation at x to be a $\mathbb{Z}$-orientation for M at the point x.

[1286]Since the definition of $\widetilde{M}$ is a little more messy than in the case of smooth manifolds we prefer to hide it in the proof.

(b) Let $x \in \partial M$. An orientation-neighborhood for x is a triple (U, μ, x) where U is an open neighborhood of $x \in M$ and μ is a $\mathbb{Z}$-orientation on U. We say that two orientation-neighborhoods (U, μ, x) and (V, ν, x) are equivalent if the orientations μ and ν agree on $U \cap V$. For the purpose of this proof we define an orientation for x to be an equivalence class of orientation-neighborhoods for x.

We consider the set

$$\widetilde{M} := \{\mu_x \mid x \in M \text{ and } \mu_x \text{ is an orientation for } M \text{ at the point } x\}$$

and the projection $p\colon \widetilde{M} \to M$ that is given by $\mu_x \mapsto x$ for $x \in M \setminus \partial M$ and $[(U, \mu, x)] \mapsto x$ for $x \in \partial M$. It follows from Lemma 105.10 (1) that for every $x \in M \setminus \partial M$ the preimage $p^{-1}(x)$ has precisely two elements. We leave it to the reader to verify that for every $x \in \partial M$ the preimage $p^{-1}(x)$ also has precisely two elements.

We equip $\widetilde{M}$ with a topology similar to the proof of Proposition 49.4. It is then straightforward to see that $p\colon \widetilde{M} \to M$ is a 2-fold covering. Similar to the proof of Proposition 49.4 one can show that $\widetilde{M}$ admits a natural orientation.

Now let $f\colon M \to N$ be a local homeomorphism. We leave it to the reader to define the map $\widetilde{f}\colon \widetilde{M} \to \widetilde{N}$ that has the promised properties.[1287]

(2) The proof of this statement is almost identical to the proof of the Orientation Covering-Proposition 49.5 (2).

(3) The proof of this statement is identical to the very terse proof of the Orientation Covering-Proposition 49.5 (3).

(4) Not surprisingly the proof of this statement is also identical to the proof of the Orientation Covering-Proposition 49.5 (4).

We leave it to the reader to flesh out all the details. ■

Finally we conclude this section with the following corollary which is closely related to the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 49.8.

Corollary 105.16. (Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary) Let M be a connected topological manifold without boundary. If M is non-orientable, then there exists an epimorphism $\pi_1(M) \to \mathbb{Z}_2$.

Proof. The proof of the corollary is basically identical to the proof of the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 49.8, we just need to replace the Orientation Covering-Proposition 49.5 by the Orientation Covering-Proposition 105.15. ■

Remark. Many other results on orientations of smooth manifolds can now be extended to topological manifolds. For example the proof of the Orientation-Flipping Proposition 37.4 that we gave in Section 49.5 also applies verbatim to the setting of topological manifolds.. We leave it to the reader to work out the precise statements and proofs.

105.5. **Induced orientations.** In this final section we will show that various constructions of new topological manifolds out of a given oriented topological manifold are naturally equipped with orientations. For the most part the statements sound reasonable and familiar from the setting of smooth manifolds. Nonetheless, the constructions of the induced representations for topological manifolds are at times quite different from the constructions

[1287] It is obvious how to define the map if $\partial M = \partial N = \varnothing$. Dealing with the boundaries is slightly awkward.

of induced orientations for smooth manifolds. Truth be told, the reader will not miss out on much by just moving on to the next chapter.

Lemma 105.17. (Topological Manifold-Induced Orientation Lemma) Let R be a commutative ring and let M be a topological manifold that is equipped with an R-orientation.

(1) Let N be a topological manifold and let $f\colon N \to M$ be a map. If $f\colon N \setminus \partial N \to M$ is a local homeomorphism, then there exists a unique R-orientation on N such that f is orientation-preserving.
(2) If N is a submanifold of codimension zero (for example N could be an open subset of M), then N admits a unique R-orientation such that the inclusion map $N \to M$ is orientation-preserving.
(3) If $p\colon \widetilde{M} \to M$ is a covering, then there exists a unique orientation on $\widetilde{M}$ that turns p into an orientation-preserving map.

Proof. To simplify the notation we suppress the ring R from the notation. Thus let M be an n-dimensional topological manifold that is equipped with an orientation $\{\alpha_x\}_{x\in M\setminus\partial M}$.

(1) Let N be a topological manifold and let $f\colon N \to M$ be a local homeomorphism. Let $x \in N \setminus \partial N$. We pick an open neighborhood U of x such that $f\colon U \to f(U)$ is a homeomorphism and such that the image $f(U)$ is an open subset of M. We define $\beta_x \in \mathrm{H}_n(N, N\setminus\{x\}; R)$ to be the image of α_x under the map[1288]

$$\begin{array}{ccccccc} & & \text{these two maps are isomorphisms by the Excision Theorem 74.18} & & & & \\ & & \downarrow & & & & \downarrow \\ \mathrm{H}_n(M, M\setminus\{f(x)\}) & \xleftarrow{\cong} & \mathrm{H}_n(f(U), f(U)\setminus\{f(x)\}) & \xrightarrow[\cong]{f_*^{-1}} & \mathrm{H}_n(U, U\setminus\{x\}) & \xrightarrow{\cong} & \mathrm{H}_n(N, N\setminus\{x\}). \end{array}$$

We leave it to the reader to verify that these classes β_x define an orientation on N. By definition the map f is orientation-preserving with respect to the orientations on M and N. It is elementary to verify that the orientation on N is uniquely determined.
(2) This statement follows from (1) since the inclusion map of a codimension-zero submanifold is, basically by definition, a local homeomorphism.
(3) This statement also follows from (1) since a covering map is a local homeomorphism. ■

The following lemma, which can be viewed as an analogue of the Doubling-Manifold Lemma 75.12 (5), says in particular that the double of an R-orientable topological manifold is again R-orientable.

Lemma 105.18. (Double-Orientability Lemma) Let M be a connected topological manifold with non-empty boundary and let R be a commutative ring. Then

$$M \text{ is } R\text{-orientable} \iff \text{the double } \mathrm{D}M \text{ is } R\text{-orientable.}$$

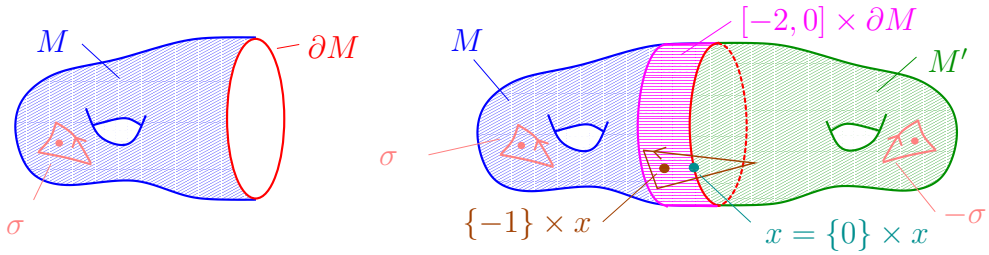
Furthermore, if M is equipped with an R-orientation, then $\mathrm{D}M$ admits a unique R-orientation such that the inclusion map $M \to \mathrm{D}M$ is orientation-preserving.

Sketch of proof. Let M be a connected topological manifold. In the following we write $\mathrm{D}M = (M \sqcup M')/\!\sim$ where M' is another copy of M. We apply the Topological Collar

[1288] Since $f\colon U \to f(U)$ is a homeomorphism we have $f(U \setminus \{x\}) = f(U) \setminus \{f(x)\}$. Furthermore it follows from the fact that $x \in U \setminus \partial U$ and the Topological Manifold Boundary Proposition 75.2 that $f(x) \notin \partial N$.

Neighborhood Theorem 75.5 to obtain a collar neighborhood $[-2,0]\times\partial M$ of ∂M in M. To simplify the notation we henceforth drop the coefficient ring R from the notation.

If $\mathrm{D}M$ is orientable, then it follows immediately from the Topological Manifold-Induced Orientation Lemma 105.17 that the submanifold M is also orientable.



Now suppose that M is equipped with an orientation $\{\mu_x\}_{x\in M\setminus\partial M}$. We define orientations for the points of $\mathrm{D}M$ in $M\setminus\partial M$, $M'\setminus\partial M'$ and in $\partial M=\partial M'$ separately.

(1) Given $x\in M\setminus\partial M$ we denote by α_x the image of μ_x under the inclusion induced isomorphism $\mathrm{H}_n(M,M\setminus\{x\})\to\mathrm{H}_n(\mathrm{D}M,\mathrm{D}M\setminus\{x\})$ given by the Excision Theorem 75.10.
(2) We denote by $r\colon \mathrm{D}M\to\mathrm{D}M$ the obvious homeomorphism given by interchanging the two copies of M in $\mathrm{D}M$. Given $x\in M'\setminus\partial M'$ we define $\alpha_x:=-r_*^{-1}(\alpha_{r(x)})$.
(3) Finally let $x\in\partial M$. We define $\alpha_x\in\mathrm{H}_n(\mathrm{D}M,\mathrm{D}M\setminus\{x\})$ to be the image of the class $\alpha_{\{-1\}\times x}\in\mathrm{H}_n(\mathrm{D}M,\mathrm{D}M\setminus(\{-1\}\times x))$, which we defined in (1), under the isomorphism

$$\mathrm{H}_n(\mathrm{D}M,\mathrm{D}M\setminus\{(-1,x)\}\xleftarrow[\uparrow]{\cong}\mathrm{H}_n(\mathrm{D}M,\mathrm{D}M\setminus([-1,0]\times\{x\}))\xrightarrow[\uparrow]{\cong}\mathrm{H}_n(\mathrm{D}M,\mathrm{D}M\setminus\overbrace{\{(0,x)\}}^{=x}).$$

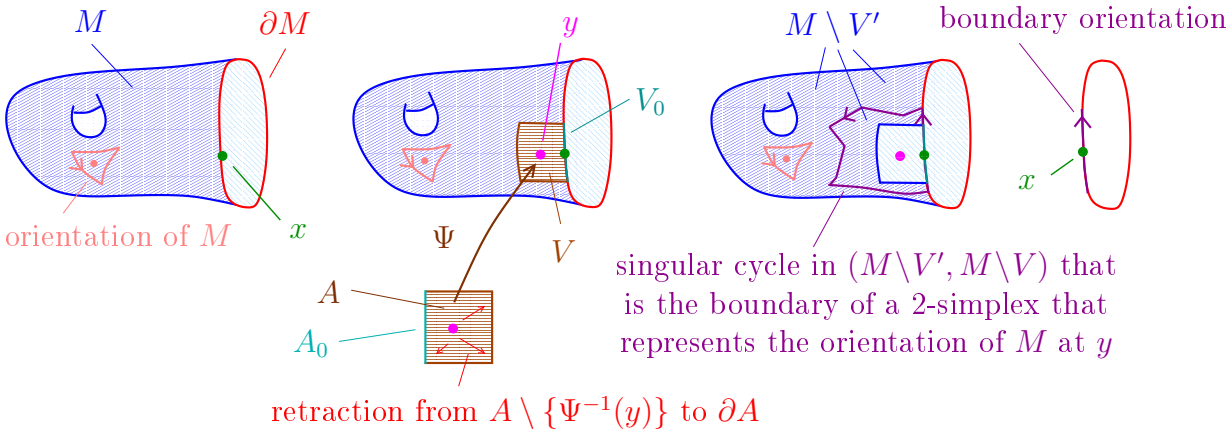
these maps are isomorphisms by an excision argument together with Complement-of-Convex Homology Lemma 105.1

We leave it as a slightly annoying exercise to the indefatigable reader to show that $\{\alpha_x\}_{x\in\mathrm{D}M}$ does indeed define an orientation on $\mathrm{D}M$. By construction of the orientation on $\mathrm{D}M$ the inclusion $M\to\mathrm{D}M$ is orientation-preserving. The uniqueness of the orientation on $\mathrm{D}M$ is a consequence of the Sections Proposition 105.6 (1) and of our hypothesis that M is connected. ∎

Finally let M be an n-dimensional topological manifold equipped with an orientation $\{\mu_x\}_{x\in M\setminus\partial M}$. Now we will see that the given orientation induces an orientation on ∂M.

Proposition 105.19. (Topological Manifold-Boundary Orientation Proposition) Let R be a commutative ring. Given any topological manifold M there exists a natural map

$$\{R\text{-orientations of } M\}\ \to\ \{R\text{-orientations of } \partial M\}.$$



Here natural means that if $f\colon M\to N$ is a homeomorphism, then the following diagram commutes:

$$\begin{array}{ccc}\{R\text{-orientations of } M\} & \longrightarrow & \{R\text{-orientations of } \partial M\}\\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*}\\ \{R\text{-orientations of } N\} & \longrightarrow & \{R\text{-orientations of } \partial N\}.\end{array}$$

Convention. If M is an R-oriented topological manifold, then invariably we will equip ∂M with the R-orientation provided by the construction in the proof of the Topological Manifold-Boundary Orientation Proposition 105.19.

Proof. To simplify the notation we will only deal with case $R = \mathbb{Z}$, which is anyway the only case we care about. We suppose we are given an orientation $\{\mu_y\}_{y\in M\setminus\partial M}$ for M. In the following we will define a natural orientation for ∂M.

We set $n := \dim(M)$ and we write $A = [0,1]\times[-1,1]^n$, we write $A_0 := \{0\}\times[-1,1]^{n-1}$ and we write $A' = (0,1)\times(-1,1)^{n-1}$. Now let $x \in \partial M$. Since M is a topological manifold and since $x \in \partial M$ we can pick a chart $\Phi\colon U \to [0,2)\times(-2,2)^{n-1}$ with $\Phi(x) = (0,0)$. We write $\Psi := \Phi^{-1}$. Furthermore we write $V = \Psi(A)$, $V_0 = \Psi(A_0)$ and we write $V' = \Psi(A')$. Finally we pick a point $y \in V'$.

We consider the following sequence of maps

$$\begin{array}{ccccc} \mathrm{H}_n(M, M\setminus\{y\}) & \xleftarrow{(1)} & \mathrm{H}_n\big(M, M\setminus V'\big) & \xrightarrow[(2)]{\partial} & \mathrm{H}_{n-1}(M\setminus V', (M\setminus V')\setminus\{x\}) \\ & & & & \uparrow{\scriptstyle (3)} \\ & & & & \mathrm{H}_{n-1}(V_0, V_0\setminus\{x\}) \xrightarrow[(4)]{} \mathrm{H}_{n-1}(\partial M, \partial M\setminus\{x\}). \end{array}$$

Here all the maps are induced by the obvious inclusions of pairs of topological spaces, except for the second map which is the connecting homomorphism of the long exact sequence of the triple $(M, M\setminus V', (M\setminus V')\setminus\{x\})$ that is provided by the Topological LES-Proposition 74.13.

Claim 1. All the maps in the above diagram are isomorphisms.

Proof. In the following we treat the four maps separately.

(1) It is elementary to see that $A\setminus\Psi^{-1}(y)$ is a deformation retract of ∂A. It follows that $M\setminus V'$ is a deformation retract of $M\setminus\{y\}$.[1289] We obtain from Corollary 74.16 that (1) an isomorphism.

[1289] Looking at the figure on page 2345 this statement sounds reasonable. But the statement nonetheless requires a proof. So let r be a deformation retraction from $A\setminus\Psi^{-1}(y)$ to ∂A. We consider the map

$$\begin{array}{rcl} s\colon (M\setminus\{y\})\times[0,1] & \to & M\setminus\{y\} \\ (P,t) & \mapsto & \begin{cases} P, & \text{if } P \notin V\setminus\{y\}, \\ \Psi(r(\Psi^{-1}(P),t)), & \text{if } P \in V\setminus\{y\}. \end{cases} \end{array}$$

(2) We consider the long exact sequence of the triple $(M, M \setminus V', (M \setminus V') \setminus \{x\})$ that is provided by the Topological LES-Proposition 74.13:

$$\begin{aligned} \mathrm{H}_n(M, (M \setminus V') \setminus \{x\}) \quad &\to \mathrm{H}_n(M, M \setminus V') \xrightarrow{\partial} \mathrm{H}_{n-1}(M \setminus V', M \setminus V) \to \\ \to \mathrm{H}_{n-1}(M, (M \setminus V') \setminus \{x\}). \end{aligned}$$

Similarly to (1) one sees that $(M \setminus V') \setminus \{x\}$ is a deformation retract of M. Therefore it follows from Corollary 74.16 that the groups at the two extremes are zero. In other words, the connecting homomorphism is an isomorphism.

(3) It follows quite easily from the Excision Theorem 74.18 that (3) is an isomorphism.

(4) Replace (3) by (4) in the previous sentence.

(5) The triangle is given by inclusion induced maps, hence it commutes. It now follows from (3) and (4) that (5) is also an isomorphism. ⊞

Given $x \in \partial M$ we now define $\nu_x \in \mathrm{H}_{n-1}(\partial M, \partial M \setminus \{x\})$ to be the image of the generator $\mu_y \in \mathrm{H}_n(M, M \setminus \{y\})$ under the above sequence of isomorphisms. We continue with our next claim.

Claim 2.

(1) The definition of ν_x is independent of the choice of y.

(2) The definition of ν_x is independent of the choice of Φ.

Proof.

(1) We need to show that for any $z \in \Psi(V')$ we have

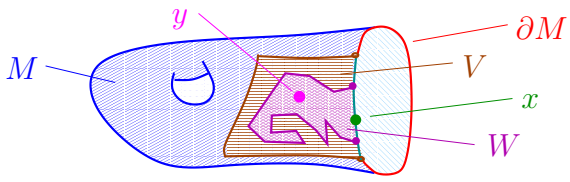
$$\begin{array}{c} \text{preimage of } \mu_y \text{ under the map} \\ \mathrm{H}_n(M, M \setminus V') \xrightarrow{\cong} \mathrm{H}_n(M, M \setminus \{y\}) \end{array} = \begin{array}{c} \text{preimage of } \mu_z \text{ under the map} \\ \mathrm{H}_n(M, M \setminus V') \xrightarrow{\cong} \mathrm{H}_n(M, M \setminus \{z\}). \end{array}$$

But this statement can be shown in a similar fashion as the Sections Proposition 105.6 (1). We leave it to the reader to fill in the details.

(2) Suppose we are given a different chart than Φ. We define W, W_0, W' in the obvious way. By possibly taking a third chart whose image lies in the intersection of V and W we can assume, without loss of generality, that $W \subset V$. (We refer to the figure below for an illustration.) Furthermore by (1) we can work with a point $y \in W$ for both charts. We consider the following diagram

$$\begin{array}{ccc} \mathrm{H}_n(M, M \setminus \{y\}) & \xleftarrow[(1)]{\cong} & \mathrm{H}_n\big(M, M \setminus V'\big) \\ \cong \uparrow (1) & \swarrow & \downarrow (2)\ \partial \\ \mathrm{H}_n\big(M, M \setminus W'\big) & \leftarrow & \mathrm{H}_{n-1}(M \setminus V', (M \setminus V') \setminus \{x\}) \\ (2)\ \partial \downarrow & \swarrow & \uparrow (3)\ \cong \\ \mathrm{H}_{n-1}(M \setminus W', (M \setminus W') \setminus \{x\}) & & \mathrm{H}_{n-1}(V_0, V_0 \setminus \{x\}) \\ (3)\ \uparrow \cong & \searrow & \downarrow (4) \\ \mathrm{H}_{n-1}(W_0, W_0 \setminus \{x\}) & \xrightarrow[(4)]{} & \mathrm{H}_{n-1}(\partial M, \partial M \setminus \{x\}). \end{array}$$

Note that $V \setminus \{y\}$ and $M \setminus \Psi(A')$ are closed subsets of $M \setminus \{y\}$. (Hmm, why is that?). It follows from the Homotopy Stacking Lemma 14.3 that the map s is continuous.



Here the two "outer paths" from the top left to the lower right correspond to the two "competing" definitions of ν_x. The dashed arrows are given by inclusions. We make the following observations:

(a) The triangle on top commutes since all maps are induced by inclusions.
(b) The upper parallelogram commutes since the connecting homomorphism is natural, see the Topological LES-Proposition 74.13 (3) for details.
(c) The lower parallelogram commutes since all the maps are induced by inclusions. (Note that the reversal of the direction of the arrow is not a typo.)
(d) The triangle on the bottom commutes since all maps are induced by inclusions.

We saw above that all maps (1), (2), (3) and (4) are isomorphisms. By going from the top to the bottom we see that all the dashed arrows are isomorphisms.

Since all pieces of the diagram commute and since all maps are isomorphisms we see that the total diagram commutes. This shows that the two "competing" definitions of ν_x agree. ⊞

Using Claim 1 it is now straightforward to show that the $\{\nu_x\}_{x\in\partial M}$ form an orientation for ∂M and that this orientation is natural. ■

Remark. Let M be an n-dimensional smooth manifold that is equipped with an orientation in the sense of Section 25.2. On page 689 and page 688 we had equipped the $(n-1)$-dimensional smooth manifold ∂M with an orientation in the sense of Section 25.2. If one takes the strenuous journey through all conventions and definitions one sees that the boundary orientations from page 689 and the proof of the Topological Manifold-Boundary Orientation Proposition 105.19 are compatible. More precisely, for any oriented n-dimensional M we have the following commutative "diagram"

$$\begin{array}{ccc} \text{oriented smooth manifold } M & \xmapsto{\text{take boundary}} & \text{oriented smooth manifold } \partial M \\ \Big\downarrow \text{Smooth-Topological Orientation Proposition 105.11} & & \Big\downarrow \text{Smooth-Topological Orientation Proposition 105.11} \\ \mathbb{Z}\text{-oriented smooth manifold } M & \xmapsto{\text{take boundary}} & \mathbb{Z}\text{-oriented smooth manifold } \partial M. \end{array}$$

Remark. Given topological manifolds M and N we can form the product $M \times N$. If M and N are oriented, then one would expect that $M \times N$ comes with a natural orientation. This is indeed the case, but the definition of this natural orientation requires more tools than we have at the moment. Thus we postpone the definition of the product orientation to Section 113.5.

Exercises for Chapter 105.

Exercise 105.1. We view $\mathbb{R}$ as a topological manifold and we equip it with the standard $\mathbb{Z}$-orientation that we had introduced on page 2337. Let $f\colon \mathbb{R} \to \mathbb{R}$ be a map that is a local homeomorphism and that is orientation-preserving. Show that f is strictly monotonously increasing.

Exercise 105.2. Let M be an n-dimensional topological manifold, let R be a commutative ring and let $A \subset M \setminus \partial M$ be a subset.

(a) Show that for R-sections $\{\alpha_x\}_{x\in A}$ and $\{\beta_x\}_{x\in A}$ along A the collection $\{\alpha_x + \beta_x\}_{x\in A}$ is also an R-section along A.

(b) Show that the set $\Gamma_R^A(M)$ admits a unique R-module structure such that for each $y \in A$ the map $\Gamma_R^A(M) \to \mathrm{H}_n(M, M \setminus \{y\}; R)$ given by $\{\alpha_x\}_{x\in A} \mapsto \alpha_y$ is an R-module homomorphism.

Exercise 105.3. Let M be an oriented n-dimensional topological manifold. Furthermore let $f, g\colon M \to M$ be two homeomorphisms. Show that if f is orientation-preserving and if g is homeotopic to f, then g is also orientation-preserving.
Remark. In the Smooth Isotopy-Orientation Proposition 34.2 we proved the analogue in the setting of smooth manifolds.

Exercise 105.4. Let M be an oriented n-dimensional topological manifold, let A and B be disjoint unions of boundary components of M and let $f\colon A \to B$ be a homeomorphism. We equip A and B with the boundary orientations, as defined in the Topological Manifold-Boundary Orientation Proposition 105.19.

(a) If f is orientation-reversing, then $M/a \sim f(a)$ admits an orientation such that the inclusion $M \setminus (A \cup B) \to M/a \sim f(a)$ is orientation-preserving.

(b) If M is connected and if f is not orientation-reversing, then $M/a \sim f(a)$ is non-orientable.

Remark. This is the long overdue proof of the Gluing-Topological Manifolds-Proposition 75.8 (6).

Exercise 105.5. Let M be a compact oriented 1-dimensional topological manifold. We equip ∂M with the orientation coming from the Topological Manifold-Boundary Orientation Proposition 105.19. Recall that on page 2335 we saw that an orientation on the 0-dimensional topological manifold ∂M is naturally the same as a map $\epsilon\colon \partial M \to \{\pm 1\}$. Show that

$$\sum_{P\in\partial M} \epsilon(P) \;=\; 0.$$

Remark. This exercise can be viewed as the analogue of the Boundary-of-Compact Smooth 1-Manifold Proposition 25.18 for topological manifolds.

106. The fundamental class of topological manifolds

In several previous chapters, e.g. in Chapter 96 and 98, we have assembled lots of information on homology groups of smooth manifolds. Let us recall some of the results. Thus let M be a connected n-dimensional smooth manifold.

(1) In the Smooth Manifolds-Invariants Proposition 96.6 (2) we saw, using the Smooth Manifold-CW Structure Theorem 96.5 , that $\mathrm{H}_i(M;\mathbb{Z}) = 0$ for $i > n$.
(2) Furthermore, in the Smooth Manifold-Top Homology Theorem 98.6 and Theorem 98.8 we showed that

$$\mathrm{H}_n(M;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ closed and orientable,} \\ 0, & \text{otherwise} \end{cases}$$

and

$$\mathrm{H}_n(M,\partial M;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ compact and orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

Furthermore, if M is compact and orientable, then we used (2) to define the corresponding fundamental class $[M] \in \mathrm{H}_n(M,\partial M;\mathbb{Z})$ which turned out to be very useful tool.
The key tool in proving the above statements was the fact, established in the Smooth Manifold-Simplicial Structure Theorem 96.2, that smooth manifolds admit simplicial structures. As we discussed in Section 104.6, in general topological manifolds do not admit simplicial structures, so if we want to replicate the above results for topological manifolds we will have to use a very different approach.
In this chapter we will indeed manage to reprove all of the above statements for topological manifolds. The advantage of the new approach is that it is more general, it covers topological manifolds, and that it does not require any extra topological input, i.e. it does not require the existence of a simplicial or cellular structure. The flip side of this chapters approach is that the proofs are arguably less intuitive.

106.1. **The fundamental class of an oriented topological manifold.** We recall the following notation that we introduced on page 2349.

Notation. Let M be a topological manifold, let R be a commutative ring and finally let $x \in M \setminus \partial M$. Given any $k \in \mathbb{N}_0$ we denote by ρ_x the obvious map

$$\rho_x \colon \mathrm{H}_k(M,\partial M;R) \to \mathrm{H}_k(M, M\setminus\{x\};R).$$

Given $\alpha \in \mathrm{H}_k(M,\partial M;R)$ we often write $\alpha_x := \rho_x(\alpha)$, i.e. the above map is also written as

$$\alpha \mapsto \alpha_x.$$

The following three theorems contain most of the main results of this chapter.

Theorem 106.1. (Orientation-Top Homology Theorem) Let M be a compact connected non-empty n-dimensional topological manifold. Then the following statements are equivalent:

(1) the topological manifold M is orientable,
(2) $\mathrm{H}_n(M,\partial M;\mathbb{Z}) \neq 0$,
(3) $\mathrm{H}_n(M,\partial M;\mathbb{Z}) \cong \mathbb{Z}$,

(4) for every $x \in M \setminus \partial M$ the map

$$\begin{array}{rcl} \rho_x \colon \mathrm{H}_n(M, \partial M; \mathbb{Z}) & \to & \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z}) \\ \alpha & \mapsto & \alpha_x \end{array}$$

is an isomorphism.

Theorem 106.2. (Top-$\mathbb{F}_2$-Homology Theorem) Let M be a compact connected non-empty n-dimensional topological manifold M. Then the following two statements hold:

(1) $\mathrm{H}_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$, and

(2) for every $x \in M \setminus \partial M$ the map

$$\begin{array}{rcl} \rho_x \colon \mathrm{H}_n(M, \partial M; \mathbb{F}_2) & \to & \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{F}_2) \\ \alpha & \mapsto & \alpha_x \end{array}$$

is an isomorphism.

Theorem 106.3. (Top-Homology Theorem) Let M be a connected non-empty n-dimensional topological manifold and let R be a commutative ring. The following three statements hold:

(1) For every $i > n$ we have $\mathrm{H}_i(M; R) = 0$ and $\mathrm{H}_i(M, \partial M; R) = 0$.

(2)
$$\mathrm{H}_n(M; R) \cong \begin{cases} R, & \text{if } M \text{ is closed and } R\text{-orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

(3)
$$\mathrm{H}_n(M, \partial M; R) \cong \begin{cases} R, & \text{if } M \text{ is compact and } R\text{-orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

Remark.

(1) As mentioned before, the above theorems generalize most of the results of the Smooth Manifolds-Invariants Proposition 96.6 (2), the Smooth Manifold-Top Homology Theorem 98.6 and Theorem 98.8 from smooth manifolds to topological manifolds.

(2) One might be tempted to consider the Top-Homology Theorem 106.3 (3) as "intuitively clear". After all, how could an n-dimensional object possibly have homology groups in higher dimensions? To shatter this belief, fix some $n \geq 2$. We consider the following subset of $\mathbb{R}^n$:[1290]

$$\begin{array}{rcl} X & := & \bigcup\limits_{n \in \mathbb{N}} n\text{-dimensional sphere of radius } \frac{1}{n} \text{ around } (\frac{1}{n}, 0, \ldots, 0) \\ & = & \bigcup\limits_{n \in \mathbb{N}} \{x \in \mathbb{R}^n \mid \|x - (\frac{1}{n}, 0, \ldots, 0)\| = \frac{1}{n^2}\}. \end{array}$$

In [**BaM1962**] it is shown, rather shockingly, that for every q with $q \equiv 1 \bmod (r-1)$ the group $\mathrm{H}_q(X; \mathbb{Q})$ is not only non-zero, it is even uncountable.

We will not immediately prove these three theorems, but we will first draw many conclusions, before we head towards the somewhat intricate proofs of the above three theorems.

[1290] As the reader will surely have noticed, this example can be viewed as a high-dimensional analogue of the Hawaiian Earings that we introduced in Exercise 56.1.

Definition. Let M be a compact n-dimensional topological manifold and let R be a commutative ring. An *R-fundamental class of M* is an element $\beta \in \mathrm{H}_n(M, \partial M; R)$ with the property that for any $x \in M \setminus \partial M$ the element $\beta_x \in \mathrm{H}_n(M, M \setminus \{x\}; R)$ is a generator. For $R = \mathbb{Z}$ we just say *fundamental class*.

Remark. Let M be a compact n-dimensional topological manifold and let R be a commutative ring.

(1) Let $[M]$ be a $\mathbb{Z}$-fundamental class for M. The image of $[M] \otimes 1$ under the natural map $\mu\colon \mathrm{H}_n(M; \mathbb{Z}) \otimes R \to \mathrm{H}_n(M; R)$ is an R-fundamental class. Indeed, let $x \in M \setminus \partial M$. From Lemma 89.7 (4) we obtain a commutative diagram

$$\begin{array}{ccc} \mathrm{H}_n(M; \mathbb{Z}) \otimes R & \xrightarrow{\mu} & \mathrm{H}_n(M; R) \\ \downarrow & & \downarrow \\ \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z}) \otimes R & \xrightarrow{\mu} & \mathrm{H}_n(M, M \setminus \{x\}; R) \end{array}$$

By Lemma 105.4 and the Universal Coefficient Theorem 89.17 the bottom horizontal map is an isomorphism. Since the image of the $\mathbb{Z}$-fundamental class $[M]$ under the obvious map $\mathrm{H}_n(M; \mathbb{Z}) \to \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z})$ is a generator it follows from the commutative diagram that the image of $\mu([M] \otimes 1)$ under the obvious map $\mathrm{H}_n(M; R) \to \mathrm{H}_n(M, M \setminus \{x\}; R)$ is indeed a generator.

(2) If M has connected components $M_1, \ldots, M_k$ and if for $i = 1, \ldots, k$ we are given R-fundamental classes $[M_i]_R \in \mathrm{H}_n(M_i, \partial M_i; R)$, then

$$\sum_{i=1}^{k} [M_i]_R \ \in \ \mathrm{H}_n(M, \partial M; R) = \bigoplus_{i=1}^{k} \mathrm{H}_n(M_i, \partial M_i; R)$$

is easily seen to be an R-fundamental class of M. The fundamental classes for the M_i are unique if and only if the fundamental class for M is unique.

Example. Let M be the empty topological space. As we mentioned on page 514, basically by definition the empty set is a topological manifold of any dimension. Note that for the empty manifold $\varnothing$ we have the *equality* $\mathrm{H}_0(\varnothing) = \mathrm{H}_1(\varnothing) = \mathrm{H}_2(\varnothing) = \cdots = \{0\}$. By definition this element 0 is a fundamental class of the empty manifold and it is evidently unique. We write $[\varnothing] := 0$. This is consistent with the discussion on page 2205.

The following corollary to the Orientation-Top Homology Theorem 106.1 says in particular that an orientation determines and is in turn uniquely determined by a fundamental class.

Corollary 106.4. (Fundamental Class-Corollary) Let M be a compact n-dimensional topological manifold.

(1) If $[M]$ is a fundamental class, then $\{[M]_x\}_{x \in M \setminus \partial M}$ defines an orientation for M.
(2) If $\{\alpha_x\}_{x \in M \setminus \partial M}$ is an orientation for M, then there exists a unique fundamental class $[M] \in \mathrm{H}_n(M, \partial M; \mathbb{Z})$ with $[M]_x = \alpha_x$ for all $x \in M \setminus \partial M$.

Furthermore, if M is connected, non-empty and orientable, then the following two statements hold:

(3) Every fundamental class $[M] \in \mathrm{H}_n(M, \partial M; \mathbb{Z})$ is a generator of $\mathrm{H}_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$.
(4) Every generator of $\mathrm{H}_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}^{1291}$ is a fundamental class.

Proof. Let M be a compact non-empty n-dimensional topological manifold. By considering the components of M separately we see that without loss of generality we can assume that M is connected. It is also clear that we only have to study the case that M is non-empty.

(1) Let $[M]$ be a fundamental class for the topological manifold M. It follows from Lemma 105.5 (2) that the homology classes $\{\rho_x([M])\}_{x\in M\setminus\partial M}$ form a section on M. By definition of a fundamental class each $\rho_x([M])$ is a generator. Therefore the section $\{\rho_x([M])\}_{x\in M\setminus\partial M}$ is indeed an orientation.

(2) Suppose we are given an orientation $\{\alpha_x\}_{x\in M\setminus\partial M}$ for M. By the Orientation-Top Homology Theorem 106.1 (1) $\Rightarrow$ (4) we know that for every $x \in M \setminus \partial M$ the map

$$\rho_x \colon \mathrm{H}_n(M, \partial M; \mathbb{Z}) \ \to \ \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z})$$

is an isomorphism. Now pick a $y \in M$. We write $[M] := \rho_y^{-1}(\alpha_y)$. Since ρ_y is an isomorphism the class $[M]$ is uniquely determined. So it remains to show that $[M]_x = \alpha_x$ for all $x \in M \setminus \partial M$. By Lemma 105.5 (2) the classes $\{[M]_x\}_{x\in M\setminus\partial M}$ form a $\mathbb{Z}$-section. It follows from the Sections Proposition 105.6 that $[M]_x = \alpha_x$ for all $x \in M \setminus \partial M$.

(3) This statement follows immediately from the definition of a fundamental class and the Orientation-Top Homology Theorem 106.1 (1) $\Rightarrow$ (4).

(4) The last statement is an immediate consequence of Lemma 105.5 (2) and the Orientation-Top Homology Theorem 106.1 (1) $\Rightarrow$ (4). ■

We also have the following corollary to the Top-$\mathbb{F}_2$-Homology Theorem 106.2 which deals with $\mathbb{F}_2$-coefficients.

Corollary 106.5. ($\mathbb{F}_2$-Fundamental Class Corollary) Let M be a compact, non-empty n-dimensional topological manifold.

(1) If M is connected, then[1292]

$$[M]_{\mathbb{F}_2} \ := \ \text{the unique non-zero element of } \mathrm{H}_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$$

is the unique $\mathbb{F}_2$-fundamental class of M.

(2) If M has connected components $M_1, \ldots, M_k$, then

$$[M]_{\mathbb{F}_2} \ := \ \sum_{i=1}^{k} [M_i]_{\mathbb{F}_2} \ \in \ \mathrm{H}_n(M, \partial M; \mathbb{F}_2) = \bigoplus_{i=1}^{k} \mathrm{H}_n(M_i, \partial M_i; \mathbb{F}_2)$$

is the unique $\mathbb{F}_2$-fundamental class of M.

Proof. It follows immediately from the Top-$\mathbb{F}_2$-Homology Theorem 106.2 (2) that the class $[M]_{\mathbb{F}_2}$ that we had just defined in (1) is indeed an $\mathbb{F}_2$-fundamental class for M and that it is unique. As we pointed out on page 2351, the second statement is an immediate consequence of the first statement. ■

Remark. Let R be a commutative ring. We consider the empty topological manifold $\varnothing$. Note that we have the equality of sets $\mathrm{H}_0(\varnothing; R) = \mathrm{H}_1(\varnothing; R) = \mathrm{H}_2(\varnothing; R) = \cdots = \{0\}$. As

[1291] Here we use that in the Orientation-Top Homology Theorem 106.1 we saw that for a compact orientable, non-empty n-dimensional topological manifold we have $\mathrm{H}_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$.

[1292] Here in the formulation we already use the Top-$\mathbb{F}_2$-Homology Theorem 106.2 (1) to guarantee that $\mathrm{H}_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$.

on page 2205 we now define the fundamental class $[\varnothing]$ of the empty topological manifold $\varnothing$ to be the unique element in the group $\mathrm{H}_0(\varnothing;R) = \mathrm{H}_1(\varnothing;R) = \mathrm{H}_2(\varnothing;R) = \cdots = \{0\}$.

Let M be a compact non-empty n-dimensional *smooth* manifold. On page 2215 we introduced the corresponding $\mathbb{F}_2$-fundamental class $[M]_{\mathbb{F}_2} \in \mathrm{H}_n(M,\partial M;\mathbb{F}_2)$. Furthermore, if M is in fact oriented, then on page 2199 we introduced the corresponding fundamental class $[M] \in \mathrm{H}_n(M,\partial M;\mathbb{Z})$. We will now see that the previous definitions are consistent with the definitions from this chapter.

First let us consider the case of $\mathbb{F}_2$-fundamental classes. This case is easy: it follows basically immediately from the $\mathbb{F}_2$-Fundamental Class Corollary 106.5 (1) that the two definitions actually agree.

Now let us assume that the smooth manifold M is oriented in the sense of Section 25.2. In Theorem 100.1 we defined the fundamental class $[M]$ in $\mathrm{H}_n(M,\partial M;\mathbb{Z})$. On the other hand, in the Smooth-Topological Orientation Proposition 105.11 we saw that the orientation of M also determines a $\mathbb{Z}$-orientation and thus we obtain a fundamental class $[M] \in \mathrm{H}_n(M,\partial M;\mathbb{Z})$ by the Fundamental Class-Corollary 106.4. Not surprisingly we will now see that these two definitions agree.

Lemma 106.6. The two definitions of the fundamental class of a compact oriented non-empty smooth manifold agree.

Remark. Let M be a compact oriented non-empty smooth manifold. In Algorithm 100.2 and the Fundamental Class-Criterion Proposition 100.4 we developed some techniques for finding explicit cycles representing the fundamental class of the oriented smooth manifold M. By Lemma 106.6 these approaches also work for finding explicit cycles representing the fundamental class of a smooth manifold that is equipped with a $\mathbb{Z}$-orientation.

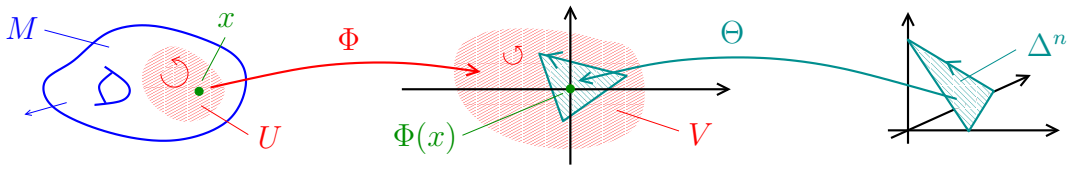
Proof. Let M be a compact n-dimensional smooth manifold that is oriented in the sense of Section 25.2. The case $n = 0$ is basically trivial. Hence we now only consider the case $n \geq 1$. As we will see, the lemma follows almost immediately from the definitions.

Now let us first recall the construction, in the proof of the Smooth-Topological Orientation Proposition 105.11, of the corresponding $\mathbb{Z}$-orientation of M. Let $x \in M \setminus \partial M$. We pick a chart $\Phi\colon U \to V$ around x that is orientation-preserving in the sense of page 675. We define

$$\mu_x \;:=\; \Phi_*^{-1}\big(\text{standard generator of } \mathrm{H}_n(V, V\setminus\{\Phi(x)\};\mathbb{Z}), \text{ as defined on page 2328}\big).$$

In the proof of the Smooth-Topological Orientation Proposition 105.11 we saw this definition of μ_x does not depend on the choice of the orientation-preserving chart. Furthermore we saw these classes $\{\mu_x\}_{x\in M\setminus\partial M}$ define a $\mathbb{Z}$-orientation for M.

We denote by $\alpha \in \mathrm{H}_n(M;\mathbb{Z})$ the fundamental class of Theorem 100.1. By definition of the fundamental class from the Fundamental Class-Corollary 106.4 it now remains to prove the following claim.



Claim. Given any $x \in M \setminus \partial M$ we have $\alpha_x = \mu_x \in \mathrm{H}_n(M, M\setminus\{x\})$.

Proof. Let $x \in M \setminus \partial M$. We pick a chart $\Phi\colon U \to V$ around x with $\Phi(x) = 0$ that is orientation-preserving. Furthermore let $\Theta\colon \Delta^n \to V$ be an affine linear map such that 0

lies in the image of $\Theta(\mathring{\Delta}^n)$ and which has the property that $\Theta\colon \mathring{\Delta}^n \to V$ is orientation-preserving. We see that

$$\alpha_x \underset{\text{follows from Theorem 100.1 and the fact that } \Phi^{-1}\circ\Theta \text{ is orientation-preserving}}{=} [\Phi^{-1}\circ\Theta\colon \Delta^n \to M] \overset{\text{[}\Theta\colon \Delta^n \to V\text{] is by definition a standard generator of } \mathrm{H}_n(V, V\setminus\{0\};\mathbb{Z})}{=} \Phi_*^{-1}([\text{standard generator of } \mathrm{H}_n(V, V\setminus\{0\};\mathbb{Z})]) = \mu_x.$$

■

We continue with the following two propositions which can be viewed as a generalizations of the Fundamental Class-Criterion Proposition 100.4 and 100.18.

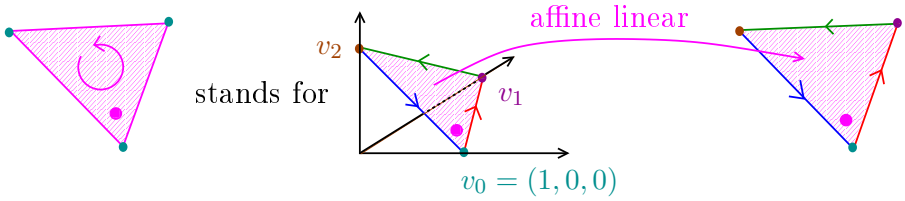
Proposition 106.7. Let M be a compact oriented connected n-dimensional topological manifold. Let $r_1\cdot\sigma_1 + \cdots + r_m\cdot\sigma_m \in \mathrm{C}_n(M,\partial M)$ be a cycle. Suppose there exists a $j\in\{1,\ldots,m\}$ such that the following three conditions are satisfied:

(1) The map $\sigma_j\colon \mathring{\Delta}^n \to M$ is an orientation-preserving embedding.[1293]
(2) There exists an $x\in\sigma_j(\Delta^n)\setminus\sigma_j(\partial\Delta^n)$ which is not contained in the image of any other $\sigma_i\colon \Delta^n\to M$.
(3) $r_j = 1$.

Then the cycle $r_1\cdot\sigma_1 + \cdots + r_m\cdot\sigma_m$ represents the fundamental class of the oriented topological manifold.

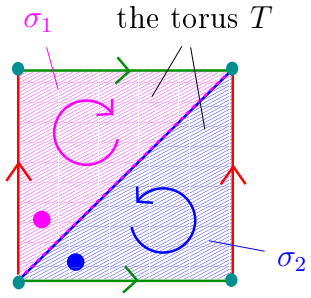
Proposition 106.8. Let M be a compact connected n-dimensional topological manifold. Let $(\sigma_1+\cdots+\sigma_m)\otimes 1 \in \mathrm{C}_n(M,\partial M;\mathbb{F}_2) = \mathrm{C}_n(M,\partial M)\otimes\mathbb{F}_2$ be a cycle. Suppose there exists a $j\in\{1,\ldots,m\}$ such that the following two conditions are satisfied:

(1) The map $\sigma_j\colon \mathring{\Delta}^n \to M$ is an embedding.
(2) There exists an $x\in\sigma_j(\Delta^n)\setminus\sigma_j(\partial\Delta^n)$ which is not contained in the image of any other $\sigma_i\colon \Delta^n\to M$.



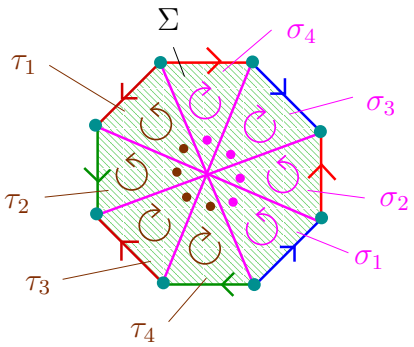
Then the cycle $(\sigma_1+\cdots+\sigma_m)\otimes 1$ represents the $\mathbb{F}_2$-fundamental class of M.

Proof. We leave it to the reader to modify the proofs of Propositions 100.4 and 100.18 to obtain the above result. ■

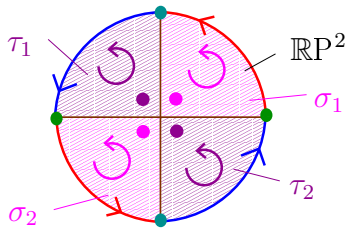


For the readers convenience we recall the discussion of cycles representing fundamental classes of the torus and the surface of genus 2 which we already gave in the figures on 2204 and 2204. There is always the outside chance that a reader decided to give Chapter 100 a pass.

Example. We will give some examples of fundamental classes of 2-dimensional topological manifolds. We use the notation from the figure below to indicate a singular simplex. In the figure below we now show cycles representing the fundamental classes of the torus



[1293] We equip Δ^n, and thus also its submanifold $\mathring{\Delta}^n$, with the $\mathbb{Z}$-orientation which is given by considering the orientation given by $[\mathrm{id}_{\Delta^n}]\in\mathrm{H}_n(\Delta^n,\Delta^n\setminus\{x\})$ for each $x\in\mathring{\Delta}^n$.



and the surface of genus 2 and we show a cycle representing the $\mathbb{F}_2$-fundamental class of $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/z \sim -z$.

$[T] = [-\sigma_1 + \sigma_2]$

$[\mathbb{R}\mathrm{P}^2]_{\mathbb{F}_2} = [(\sigma_1+\tau_1+\sigma_2+\tau_2)\otimes 1]$

$$[\Sigma] = [\sigma_1+\sigma_2-\sigma_3-\sigma_4+\tau_1+\tau_2-\tau_3-\tau_4]$$

106.2. **Lifts of sections on topological manifolds.** In this section we will prove the fundamental theorem of topological manifolds which lies at the heart of the proofs of Theorems 106.1, 106.2 and 106.3. Before we can state the lemma we introduce the following helpful notation.

Notation. Let M be a topological manifold without boundary, let R be a commutative ring and let $A \subset M$ be a subset.

(1) We write $\mathrm{H}_n(M|A;R) := \mathrm{H}_n(M, M\setminus A; R)$. Given a point $x \in M$ we use the obvious abbreviation $\mathrm{H}_n(M|x;R) := \mathrm{H}_n(M|\{x\};R)$.
(2) Given a homology class $\alpha \in \mathrm{H}_n(M|A;R)$ and a point $x \in A$ we denote by α_x the image of α under the obvious map $\mathrm{H}_n(M|A;R) \to \mathrm{H}_n(M|x;R)$.
(3) Let $\{\alpha_x\}_{x\in M}$ be an R-section on M and let $A \subset M$ be a subset. We call a class $\beta \in \mathrm{H}_n(M|A;R)$ a lift to A if for all $x \in A$ we have $\beta_x = \alpha_x$.
(4) As on page 2331 we denote by $\Gamma_R^A(M)$ the set of all R-sections of M along A.

The following lemma follows immediately from the definitions. But since we will refer to it on several occasions it is good to write it down.

Lemma 106.9. Let M be a topological manifold without boundary, let R be a commutative ring and let $A \subset B \subset M$ be subsets:

(1) Since $M\setminus B \subset M\setminus A$ we have an inclusion induced map $\mathrm{H}_n(M|B;R) \to \mathrm{H}_n(M|A;R)$.
(2) Let $\{\alpha_x\}_{x\in M}$ be an R-section on M. If $\mu_B \in \mathrm{H}_n(M|B;R)$ is a lift to B, then the image of μ_B under the above map $\mathrm{H}_n(M|B;R) \to \mathrm{H}_n(M|A;R)$ is a lift of the R-section to the subset A.

The following theorem is the main technical result of this chapter.

Theorem 106.10. (Homology-Section Theorem) Let M be an n-dimensional topological manifold with empty boundary and let $A \subset M$ be a compact subset. Let R be a commutative ring. Then the following hold:

(i) The map
$$\begin{array}{rcl} \mathrm{H}_n(M|A;R) & \to & \Gamma^A_M(R) \\ \varphi & \mapsto & \{\varphi_x\}_{x\in A} \end{array}$$
is an isomorphism. In other words, if $\{\alpha_x\}_{x\in A}$ is an R-section for M along A, then there exists a unique lift $\alpha^M_A = \alpha_A$ to A, i.e. there exists a unique homology class $\alpha^M_A = \alpha_A \in \mathrm{H}_n(M|A;R)$ such that for each $x \in A$ we have $\alpha_{A,x} = \alpha_x$.

(ii) For $i > n$ we have $\mathrm{H}_i(M|A;R) = 0$.

Remark. To avoid any nervousness later on we remark that the statements (i) and (ii) hold trivially for $A = \varnothing$ since $\mathrm{H}_n(M|\varnothing;R) = \mathrm{H}_n(M, M;R) = 0$.

Corollary 106.11. Let M be an n-dimensional topological manifold with empty boundary, let R be a commutative ring and let $A \subset M$ be a compact connected subset. If M is R-orientable, then for every $x \in A$ the map
$$\mathrm{H}_n(M, M\setminus A;R) \;\to\; \mathrm{H}_n(M, M\setminus\{x\};R) \;\underset{\uparrow}{\cong}\; R$$
isomorphic by Lemma 105.4
is an isomorphism.

Proof. We consider the following diagram:
$$\begin{array}{ccc} \mathrm{H}_n(M, M\setminus A;R) & \xrightarrow{\varphi\mapsto\varphi_x} & \mathrm{H}_n(M, M\setminus\{x\};R) \\ & {\scriptstyle \varphi\mapsto\{\varphi_x\}_{x\in A}} \searrow \quad \nearrow {\scriptstyle \{\varphi_x\}_{x\in A}\mapsto\varphi_x} & \\ & \Gamma^A_M(R) & \end{array}$$
The diagram commutes by definition. Since A is compact we know by the Homology-Section Theorem 106.10 (i) that the left diagonal map is an isomorphism. Furthermore, since A is connected we obtain from Lemma 105.9 that the right diagonal map is an isomorphism. Thus we see that the horizontal map is an isomorphism, as promised. ■

For later on we also record the following corollary to the Homology-Section Theorem 106.10 .

Corollary 106.12. Let M be an oriented n-dimensional topological manifold with empty boundary and let R be a commutative ring. We suppose that M is equipped with an R-orientation. We use the notation from the Homology-Section Theorem 106.10 .

(1) Let $K \subset L \subset M$ be compact subsets. We denote by $f_{KL}\colon (M, M\setminus L) \to (M, M\setminus K)$ the inclusion map of pairs. The map $f_{KL*}\colon \mathrm{H}_n(M, M\setminus L) \to \mathrm{H}_n(M, M\setminus K)$ sends α^M_L to α^M_K.

(2) Let U be an open subset of M and let $A \subset U$ be a compact subset. We use the Topological Manifold-Induced Orientation Lemma 105.17 to view U as an oriented topological manifold. If $i\colon U \to M$ denotes the inclusion map, then $i_*(\alpha^U_A) = \alpha^M_A$.

Proof. The lemma follows easily from the functoriality of homology groups and the uniqueness statement of the Homology-Section Theorem 106.10 . ■

Now we turn to the proof of the Homology-Section Theorem 106.10 . The very rough idea behind the proof of the fundamental theorem of topological manifolds can be summarized as follows:

(1) Using Mayer–Vietoris sequences we want to show that if the compact subsets A, B and $A \cap B$ have the desired properties, then so does $A \cup B$.
(2) Using charts we want to reduce the proof of the theorem to the case that $M = \mathbb{R}^n$.
(3) Finally for $M = \mathbb{R}^n$ we want to reduce the proof of the theorem to compact convex subsets A of $\mathbb{R}^n$.

The following lemmas give us the tools to put this idea into practice.

Lemma 106.13. Let M be an n-dimensional topological manifold, let R be a commutative ring and let A and B be two compact subsets of M. If the statements (i) and (ii) from the Homology-Section Theorem 106.10 hold for A, B and $A \cap B$, then they also hold for $A \cup B$.

Proof. Let M be an n-dimensional topological manifold, let R be a commutative ring and let A and B be two compact subsets of M such that A, B and $A \cap B$ satisfy statements (i) and (ii). To simplify the notation we drop R from the notation. We consider the inverted Mayer–Vietoris Sequence from Theorem 78.7

$$\cdots \to \overbrace{\mathrm{H}_{n+1}(M|A \cap B)}^{=0, \text{ by hypothesis on } A \cap B} \to \mathrm{H}_n(M|A \cup B) \xrightarrow[\alpha \mapsto (\alpha, -\alpha)]{\Phi} \mathrm{H}_n(M|A) \oplus \mathrm{H}_n(M|B) \xrightarrow[(\alpha, \beta) \mapsto \alpha + \beta]{\Psi} \mathrm{H}_n(M|A \cap B) \to \dots$$

Now we can prove that $A \cup B$ also satisfies statements (i) and (ii).

(ii) For $i > n$ the group $\mathrm{H}_i(M|A \cup B)$ is stuck, by our hypothesis on A, B and $A \cap B$, between groups that are zero, thus we see that $\mathrm{H}_i(M|A \cup B) = 0$ for $i > n$.

(i) Now suppose we are given a section $\{\alpha_x\}_{x \in M}$. We denote by α_A, α_B and $\alpha_{A \cap B}$ the unique lifts to A, B and $A \cap B$ given by our hypothesis. By Lemma 106.9 the images of α_A and α_B in $\mathrm{H}_n(M|A \cap B)$ are lifts to $A \cap B$. By the uniqueness of the lift $\alpha_{A \cap B}$ these images thus equal $\alpha_{A \cap B}$. By the exactness of the above sequence we see that $(\alpha_A, -\alpha_B) = \Phi(\alpha_{A \cup B})$ for some $\alpha_{A \cup B} \in \mathrm{H}_n(M|A \cup B)$. We claim that $\alpha_{A \cup B}$ is indeed a lift to $A \cup B$. So let $x \in A \cup B$. First we consider the case that $x \in A$. We have the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}_n(M|A \cup B) & \xrightarrow{[\alpha_{A \cup B} \mapsto \alpha_A]} & \mathrm{H}_n(M|A) \\ & \searrow & \downarrow \\ & & \mathrm{H}_n(M|x). \end{array}$$

We see that the image of $\alpha_{A \cup B}$ in $\mathrm{H}_n(M|x)$ is the image of α_A in $\mathrm{H}_n(M|x)$, hence it equals α_x. The same argument applies to the case that $x \in B$.

It remains to prove the uniqueness of the lift $\alpha_{A \cup B}$. If $\beta \in \mathrm{H}_n(M|A \cup B)$ is another lift, then it follows immediately from Lemma 106.9 and the uniqueness of α_A and α_B that $\Phi(\beta) = (\alpha_A, -\alpha_B)$. By the exactness of the sequence we see that we already have the equality $\alpha_{A \cup B} = \beta$ in $\mathrm{H}_n(M|A \cup B)$. ∎

Later on we will need the following variation on Lemma 106.13.

Lemma 106.14. Let M be an n-dimensional topological manifold, let R be a commutative ring. Let $\mathcal{A}$ be a family of compact subsets of M with the following two properties:

(1) Statements (i) and (ii) from the Homology-Section Theorem 106.10 hold for each $A \in \mathcal{A}$.
(2) The family $\mathcal{A}$ is closed under intersections, i.e. whenever $A, B \in \mathcal{A}$, then $A \cap B \in \mathcal{A}$.

Then the statements hold for all finite unions of elements in $\mathcal{A}$.

Proof. Given $k \in \mathbb{N}$ we write

$$\mathcal{U}_k := \{\text{all subsets of } M \text{ that are the union of at most } k \text{ subsets in } \mathcal{A}\}.$$

We claim that for every $k \in \mathbb{N}$ statements (i) and (ii) hold for all elements in $\mathcal{U}_k$. We prove this claim by induction on k.

(1) If $k = 1$, then the claim holds by hypothesis (1).
(2) Suppose that the claim holds for some k. Let $A_1, \dots, A_k, A_{k+1} \in \mathcal{A}$. We write $B = A_2 \cup \dots \cup A_{k+1}$. Note that

$$A_1 \cap B \;=\; A_1 \cap (A_2 \cup \dots \cup A_{k+1}) \;=\; \bigcup_{i=2}^{k+1} \underbrace{(A_1 \cap A_i)}_{\in \mathcal{A} \text{ by (2)}} \;\in \mathcal{U}_k.$$

Thus by induction hypothesis we see that the statements hold for A_1, B and also for $A_1 \cap B$. So the statements also hold for $A_1 \cup B = A_1 \cup \dots \cup A_{k+1}$ by Lemma 106.13. ■

Our next goal is to prove the Homology-Section Theorem 106.10 for $M = \mathbb{R}^n$. We will proceed in several steps.

Lemma 106.15. Let R be a commutative ring and let $\{\mu_x\}_{x \in \mathbb{R}^n}$ be an R-section on $\mathbb{R}^n$, let $A \subset \mathbb{R}^n$ be a convex bounded subset and let $\beta \in \mathrm{H}_n(\mathbb{R}^n | A; R)$. If $\mu_y = \beta_y$ for some $y \in A$, then $\mu_x = \beta_x$ for all $x \in A$, i.e. β is a lift to A.

Proof. The proof is very similar to the proof of the Sections Proposition 105.6. The following are the two key observations:

(1) a convex set is path-connected and thus connected,
(2) since A is convex, for any $x \in A$ and any $\epsilon > 0$ the intersection $A \cap B_\epsilon(x)$ is the intersection of two convex bounded sets, hence convex and bounded.

In the proof of the Sections Proposition 105.6 we now need to replace the Small Ball-Lemma 105.7 by the Complement-of-Convex Homology Lemma 105.1. We leave it to the reader to modify the proof of the Sections Proposition 105.6 to obtain a proof of Lemma 106.15. ■

Lemma 106.16. Statements (i) and (ii) from the Homology-Section Theorem 106.10 hold for $M = \mathbb{R}^n$, any commutative ring R and any convex compact subset A of $\mathbb{R}^n$.

Proof. Let A be a convex compact subset of $\mathbb{R}^n$ and let R be a commutative ring. As pointed out above, if $A = \varnothing$, then there is nothing to prove. Thus we can assume that $A \neq \varnothing$.

Now we can prove that A satisfies the statements (i) and (ii).

(i) Let $\{\alpha_x\}_{x\in\mathbb{R}^n}$ be a section for $\mathbb{R}^n$. Since $A \neq \varnothing$ we can pick a $y \in A$. We denote by $\alpha_A \in \mathrm{H}_n(\mathbb{R}^n|A)$ the preimage of α_y under the isomorphism

$$\mathrm{H}_n(\mathbb{R}^n|A;R) \;\to\; \mathrm{H}_n(\mathbb{R}^n|\{y\};R)$$

given by the Complement-of-Convex Homology Lemma 105.1. It follows from Lemma 106.15 that $\alpha_{A,x} = \alpha_x$ for all $x \in A$, i.e. we have shown that α_A is a lift to A. The uniqueness of the lift α_A follows again from the above isomorphism.

(ii) It follows the Complement-of-Convex Homology Lemma 105.1 and 75.1 that $\mathrm{H}_i(\mathbb{R}^n|A;R) = \mathrm{H}_i(\mathbb{R}^n|\{y\};R) = 0$ for every $i > n$. ■

Lemma 106.17. Every subset of $\mathbb{R}^n$ that is the union of finitely many convex compact sets satisfies the statements (i) and (ii) from the Homology-Section Theorem 106.10 .

Proof. We consider

$$\mathcal{A} := \{\text{all convex compact subsets of } \mathbb{R}^n\}.$$

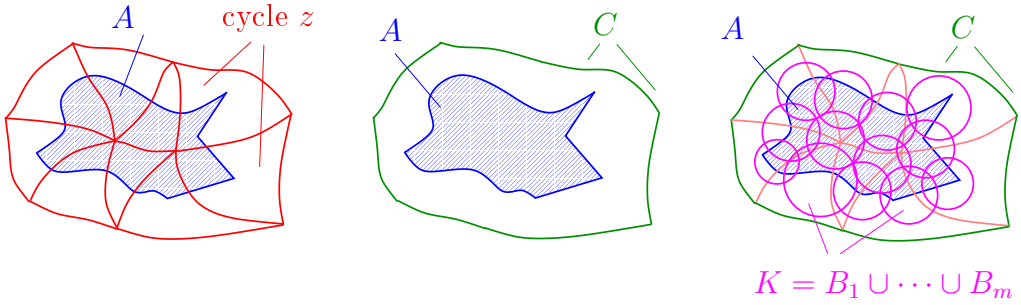
This family of subsets of $\mathbb{R}^n$ is closed under intersections.[1294] By Lemma 106.16 the two statements hold for each $A \in \mathcal{A}$. The lemma is now an immediate consequence of Lemma 106.14. ■

The following lemma is arguably the hardest step towards proving the fundamental theorem of topological manifolds.

Lemma 106.18. Statements (i) and (ii) from the Homology-Section Theorem 106.10 hold for $M = \mathbb{R}^n$, any commutative ring R and any compact subset A of $\mathbb{R}^n$.

Proof. To simplify the notation we again drop the R from the notation. Let $\{\alpha_x\}_{x\in\mathbb{R}^n}$ be a section for $\mathbb{R}^n$ and let $A \subset \mathbb{R}^n$ be an arbitrary compact set.

We first prove statement (i). We pick a closed ball B that contains A. We denote by $\alpha_B \in \mathrm{H}_n(\mathbb{R}^n|B)$ the lift constructed in Lemma 106.16. By Lemma 106.9 the image α_A of the class α_B under the map $\mathrm{H}_n(\mathbb{R}^n|B) \to \mathrm{H}_n(\mathbb{R}^n|A)$ is a lift to A. To complete the proof of statement (i) we still need to prove the uniqueness of α_A.



This uniqueness statement is equivalent to showing that if $\beta \in \mathrm{H}_n(\mathbb{R}^n|A)$ is a class such that $\beta_x = 0$ for all $x \in A$, then β is already zero. So let $\beta \in \mathrm{H}_n(\mathbb{R}^n|A)$. We pick a singular n-chain $z \in \mathrm{C}_n(\mathbb{R}^n)$ that represents β. We denote by $C \subset \mathbb{R}^n \setminus A$ the union of the images of the singular simplices appearing in $\partial z \subset \mathrm{C}_{n-1}(\mathbb{R}^n \setminus A)$. Note that C is the union of finitely many compact sets, hence C itself is compact.

Claim. There exist finitely many closed balls $B_1, \ldots, B_m$ with the following three properties:

(1) each B_i is contained in $\mathbb{R}^n \setminus C$,
(2) each B_i contains a point $x_i \in A$,
(3) we have $A \subset B_1 \cup \cdots \cup B_m$.

[1294] Here we use one of the most convenient properties of convex sets: the intersection of two convex sets is again convex.

Proof. Since C is compact and since $A \cap C = \varnothing$ we can find for each $x \in A$ an $r_x > 0$ with $B_{2r_x}(x) \subset \mathbb{R}^n \setminus C$. Since A is compact there exist finitely many points $x_1, \ldots, x_m$ in A such that A is contained in $B_{r_{x_1}}(x_1) \cup \cdots \cup B_{r_{x_m}}(x_m)$. It is now clear that $B_i := \overline{B}_{r_{x_i}}(x_i)$, $i = 1, \ldots, m$ have the desired property. We refer to the figure below for an illustration. ⊞

We write $K := B_1 \cup \cdots \cup B_m$. By (1) the singular n-chain $z \in \mathrm{C}_n(\mathbb{R}^n)$ also represents an element $\gamma \in \mathrm{H}_n(\mathbb{R}^n|K)$. Note that for each $x \in A$ we have a commutative diagram

$$\begin{array}{ccc} \mathrm{H}_n(\mathbb{R}^n|K) & \xrightarrow{\gamma=[z]\mapsto\beta=[z]} & \mathrm{H}_n(\mathbb{R}^n|A) \\ & {\scriptstyle \gamma\mapsto\gamma_x} \searrow \quad \swarrow {\scriptstyle \beta\mapsto\beta_x} & \\ & \mathrm{H}_n(\mathbb{R}^n|x). & \end{array}$$

It follows in particular from the commutative diagram that it suffices to show that we have $\gamma = 0 \in \mathrm{H}_n(\mathbb{R}^n|K)$. We do so as follows:

(1) By our hypothesis on β and by the above commutative diagram we know that for each $i \in \{1, \ldots, m\}$ we have $\gamma_{x_i} = \beta_{x_i} = 0$.
(2) Let $i \in \{1, \ldots, m\}$. Since $\gamma_{x_i} = 0$ and since B_i is convex and bounded it follows from Lemma 106.15 (applied to the zero section and to the image of $\gamma \in \mathrm{H}_n(\mathbb{R}^n|B_i)$) that $\gamma_x = 0$ for all $x \in B_i$.
(3) By (2) we know that $\gamma_x = 0$ for all $x \in K = B_1 \cup \cdots \cup B_m$.
(4) But now it follows from Lemma 106.17 that $\gamma = 0$.

This concludes the proof of statement (i).

Finally we need to show statement (ii) for A, i.e. we need to show that $\mathrm{H}_i(\mathbb{R}^n|A) = 0$ for $i > n$. So let $\beta \in \mathrm{H}_i(\mathbb{R}^n|A)$. As above we pick a singular n-chain $z \in \mathrm{C}_n(\mathbb{R}^n)$ that represents β. We define C, K and γ as above. By Lemma 106.17 we have $\gamma = 0 \in \mathrm{H}_i(\mathbb{R}^n|K)$. But as before this implies that also $\beta = 0 \in \mathrm{H}_i(\mathbb{R}^n|A)$. ■

Lemma 106.19. Let M be an n-dimensional topological manifold with empty boundary and let $A \subset M$ be a compact subset. If there exists a chart $\Phi \colon U \to \mathbb{R}^n$ such that A is contained in U, then statements (i) and (ii) hold for A.

Proof. The lemma is a fairly straightforward consequence of Lemma 106.18 and the fact that we have isomorphisms

$$\begin{array}{ccccc} \mathrm{H}_n(M, M \setminus A; R) & \xleftarrow{\cong} & \mathrm{H}_n(U, U \setminus A; R) & \xrightarrow{\Phi} & \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \Phi(A); R) \\ \uparrow & & \uparrow & & \uparrow \\ \text{Excision Theorem 74.18} & & & & \text{isomorphism since } \Phi \text{ is a homeomorphism} \end{array}$$

We leave it to the reader to fill in the details. ■

Now we can finally complete the proof of the Homology-Section Theorem 106.10 .

Proof of the Homology-Section Theorem 106.10 . Let M be an n-dimensional topological manifold with empty boundary. We consider

$$\mathcal{A} := \text{all compact subsets } A \text{ of } M \text{ for which there exists a chart } \Phi\colon U \to \mathbb{R}^n \text{ with } A \subset U.$$

By Lemma 106.19 statements (i) and (ii) hold for all subsets in $\mathcal{A}$. It is clear that $\mathcal{A}$ is closed under intersections. Thus it follows from Lemma 106.14 that the statements (i) and (ii) hold for all finite unions of sets in $\mathcal{A}$. Therefore it suffices to prove the following claim.

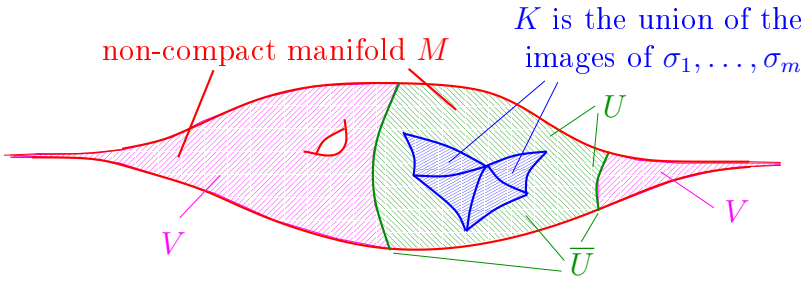
Claim. Every compact subset A of M is the union of finitely many sets in $\mathcal{A}$.

Proof. Let A be a compact subset of M. It is clear that given any point $x \in A$ there exists a chart $\Phi_x\colon U_x \to V_x$ around x such that the image is some open ball in $\mathbb{R}^n$. But since each open ball in $\mathbb{R}^n$ is homeomorphic to $\mathbb{R}^n$ we can find around each $x \in A$ a chart around x such that the image V_x equals $\mathbb{R}^n$. Now we write $A_x := A \cap \Phi_x^{-1}(\overline{B}_1^n(0))$ and $U'_x := \Phi_x^{-1}(B_1^n(0))$. Since A is compact we can find finitely many $x_1, \dots, x_m$ in A such that A is contained in $U'_{x_1} \cup \cdots \cup U'_{x_m}$. By construction the corresponding charts $\Phi_i := \Phi_{x_i}\colon U_{x_i} \to \mathbb{R}^n$ and the sets $A_i := A_{x_i}$ have the desired properties. ⊞

It follows from Lemma 106.19 that statements (i) and (ii) hold for all the A_i and for all arbitrary intersections of the A_i. But then Lemma 106.13 implies that they also hold for $A = A_1 \cup \cdots \cup A_m$. ■

106.3. **Proof of the Top-Homology Theorem 106.3.** Now we are in a position that we can provide the long-delayed proofs of Theorems 106.1, 106.2 and 106.3. We start out with the proof of the Top-Homology Theorem 106.3 since we will use that theorem in the proof of the Orientation-Top Homology Theorem 106.1.

The key extra ingredient in the proof of the Top-Homology Theorem 106.3 is the following proposition.



Proposition 106.20. Let M be a connected n-dimensional topological manifold and let R be a commutative ring. If M is non-compact and if $\partial M = \varnothing$, then $\mathrm{H}_k(M; R) = 0$ for every $k \geq n$.

Proof. Let M be a connected non-compact n-dimensional topological manifold such that $\partial M = \varnothing$, let R be a commutative ring and let $k \geq n$. Let $\alpha \in \mathrm{H}_k(M; R)$. We need to show that $\alpha = 0$. We represent α by a cycle $z = \sum_{i=1}^{m} \sigma_i \otimes r_i \in \mathrm{C}_k(M; R) = \mathrm{C}_k(M) \otimes R$. The union of the images of $\sigma_1, \dots, \sigma_m$ is a compact subset K of M. Since K is compact it follows from Exercise 106.1 that there exists an open subset $U \subset M$ that contains K and such that the closure $\overline{U}$ is compact. We consider the open subset $V = M \setminus \overline{U}$ and we consider the long exact sequence of the triple $(M, U \cup V, V)$, see the Topological LES-Corollary 74.14. It fits

into the following commutative diagram

$$\begin{array}{ccccccc} \ldots \longrightarrow \mathrm{H}_{k+1}(M, U\cup V; R) & \xrightarrow{\partial} & \mathrm{H}_k(U\cup V, V; R) & \longrightarrow & \mathrm{H}_k(M, V; R) & \longrightarrow & \ldots \\ & & \cong\uparrow & & \uparrow & & \\ & & \mathrm{H}_k(U; R) & \xrightarrow{[z]\mapsto[z]=\alpha} & \mathrm{H}_k(M; R). & & \end{array}$$

Here the left vertical map is an isomorphism since $U \cup V$ is the disjoint union of the open sets U and V.[1295]

Now we consider the modules to the top-left and top-right of the diagram. We have

$$\mathrm{H}_{k+1}(M, U\cup V; R) \;=\; \mathrm{H}_{k+1}(M|\overbrace{M\setminus(U\cup V)}^{=\overline{U}\setminus U}; R) \;\underset{\uparrow}{=}\; 0 \quad \text{if } k > n-1$$

by the Homology-Section Theorem 106.10 (ii) since M has no boundary and since $\overline{U}$ and $\overline{U}\setminus U$ are compact

$$\mathrm{H}_k(M, V; R) \;=\; \mathrm{H}_k(M|\underbrace{M\setminus V}_{=\overline{U}}; R) \qquad \underset{\downarrow}{=}\; 0 \quad \text{if } k > n.$$

After these preparations we come to the actual proof that $\alpha = [z] = 0 \in \mathrm{H}_k(M; R)$. We first consider the case $k > n$. We deduce from the above exact sequence and the above calculations that $\mathrm{H}_k(U; R) = 0$. But z represents an element in $\mathrm{H}_k(U; R)$. It follows that $[z] = 0$ in $\mathrm{H}_k(M; R)$.

Now we consider the case $k = n$. It follows from the above discussion that we have a commutative diagram

$$\begin{array}{ccc} \mathrm{H}_n(U\cup V, V; R) & \hookrightarrow & \mathrm{H}_n(M, V; R) \\ \cong\uparrow & & \uparrow \\ \mathrm{H}_n(U; R) & \xrightarrow{[z]\mapsto[z]=\alpha} & \mathrm{H}_n(M; R). \end{array}$$

Thus it suffices to show that the image of α in $\mathrm{H}_n(M, V; R)$ is zero. We showed in Lemma 105.5 (2) that $\{\alpha_x\}_{x\in M}$ is an R-section of M.[1296] Since M is non-compact we can find a point x outside of the compact set K. The class $\alpha_x \in \mathrm{H}_n(M, M\setminus\{x\}; R)$ is again represented by z which lies in $K \subset M\setminus\{x\}$. It is thus clear that $\alpha_x = 0 \in \mathrm{H}_n(M, M\setminus\{x\}; R)$. But since M is connected it follows from the Sections Proposition 105.6 (1) that $\{\alpha_x\}_{x\in M}$ is the zero section. Both the image of α in $\mathrm{H}_n(M, V; R)$ and the zero-class are lifts of the

[1295] One could at this point refer to the Excision Theorem 74.17 but this isomorphism follows already from the observation that $\mathrm{C}_*(U\cup V) = \mathrm{C}_*(U)\oplus\mathrm{C}_*(V)$ as chain complexes, since U and V are both open subsets of $U \cup V$.

[1296] Here we used a second time that M has no boundary.

zero section to $\mathrm{H}_n(M, V; R)$. By the Homology-Section Theorem 106.10 (i) both lifts agree, i.e. the image of α in $\mathrm{H}_n(M, V; R)$ is zero. ■

Now we can easily provide the proof of the Top-Homology Theorem 106.3.

Proof of the Top-Homology Theorem 106.3. Let M be a connected n-dimensional topological manifold and let R be a commutative ring. Recall that we need to prove the following three statements:

(1) (a) For every $i > n$ we have $\mathrm{H}_i(M; R) = 0$.
(b) For every $i > n$ we have $\mathrm{H}_i(M, \partial M; R) = 0$.

(2)
$$\mathrm{H}_n(M; R) \cong \begin{cases} R, & \text{if } M \text{ is closed and } R\text{-orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

(3)
$$\mathrm{H}_n(M, \partial M; R) \cong \begin{cases} R, & \text{if } M \text{ is compact and } R\text{-orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

Let us start out with the proof of (1) and (2). Note that (1b) is an immediate consequence of (1a), applied to M and ∂M, and the long exact sequence in homology of the pair $(M, \partial M)$. Thus it remains to prove (1a) and (2). In the following we prove (1a) and (2) together in one go. First suppose that M is not closed. The hypothesis that M is not closed means that M is not compact or that it has a non-empty boundary. If M is not compact without boundary, then we had just proved in Proposition 106.20 that $\mathrm{H}_i(M; R) = 0$ for $i \geq n$. If M has non-empty boundary, then we saw in Corollary 75.7 that M is homotopy equivalent to a non-compact n-dimensional topological manifold N without boundary. It follows from the Homotopy Equivalence-H_*-Corollary 73.9 and Proposition 106.20 that for any $i \geq n$ we have $\mathrm{H}_i(M; R) \cong \mathrm{H}_i(N; R) = 0$.

Now suppose that M is closed. Let $i \geq n$. We have

$$\mathrm{H}_i(M; R) = \mathrm{H}_i(M, \overbrace{M \setminus M}^{=\varnothing}; R) = \mathrm{H}_i(M|M; R) \underset{\uparrow}{\cong} \begin{cases} 0, & \text{if } i > n, \\ R, & \text{if } i = n. \end{cases}$$

by the Homology-Section Theorem 106.10 (ii) and Corollary 106.11 since M is compact and since M has no boundary

Now we turn to the proof of (3). If $\partial M = \varnothing$, then this is just the statement of (2). So let us now assume that $\partial M \neq \varnothing$. Similar to the proof of Theorem 98.8 we will prove (3) by reducing it to (2) via the doubling construction. We denote by $\mathrm{D}M$ the double of M as introduced on page 1667. We consider the following diagram:

$$\underbrace{\mathrm{H}_n(M)}_{=0} \xrightarrow{\iota_*} \mathrm{H}_n(\mathrm{D}M) \longrightarrow \mathrm{H}_n(\mathrm{D}M, M) \longrightarrow \mathrm{H}_{n-1}(M; R) \xhookrightarrow{\iota_*} \mathrm{H}_{n-1}(\mathrm{D}M)$$
$$\mathrm{H}_n(\mathrm{D}M) \underset{\cong}{\uparrow} \mathrm{H}_i(M, \partial M)$$

We make the following observations and clarifications:

- We denote by $\iota\colon M \to \mathrm{D}M$ the inclusion map.
- The top sequence is just the long exact sequence of the pair $(\mathrm{D}M, M)$.
- Since $\partial M \neq \varnothing$ we know by (2) that $\mathrm{H}_n(M) = 0$.

- The vertical map is induced by the inclusion and it is an isomorphism by the Excision Theorem 75.10 for Topological Manifolds, see also the Doubling-Manifold Lemma 75.12 (6).
- By Lemma 75.11 we have a retraction $r\colon \mathrm{D}M \to M$ such that $r \circ \iota = \mathrm{id}_M$. It follows from the functoriality of homology groups that $\iota_*\colon \mathrm{H}_{n-1}(M) \to \mathrm{H}_{n-1}(\mathrm{D}M)$ is a monomorphism.

In summary, we have shown that $\mathrm{H}_n(\mathrm{D}M) \cong \mathrm{H}_n(M, \partial M)$. The desired statement now follows from this observation, the calculation in (2) and the fact, see Lemmas 75.12 and 105.18, that M is compact and R-orientable if and only if $\mathrm{D}M$ is closed and R-orientable. ■

106.4. **Proof of Theorems 106.1 and 106.2.** The key to proving Theorems 106.1 and 106.2 is the following proposition which later on we will apply to $R = \mathbb{Z}$ and $R = \mathbb{F}_2$.

Proposition 106.21. Let M be a connected, compact n-dimensional topological manifold and let R be a commutative ring. Then the following hold:

(1) If M is R-orientable, then for any $x \in M \setminus \partial M$ the map

$$\mathrm{H}_n(M, \partial M; R) \;\to\; \mathrm{H}_n(M, M \setminus \{x\}; R) \;\underset{\text{isomorphic by Lemma 105.4}}{\overset{\cong}{\uparrow}}\; R$$

is an isomorphism.

(2) If M is non-orientable, then $\mathrm{H}_n(M, \partial M; \mathbb{Z}) = 0$.

Proof. Let M be a connected, compact n-dimensional topological manifold and let R be a commutative ring.

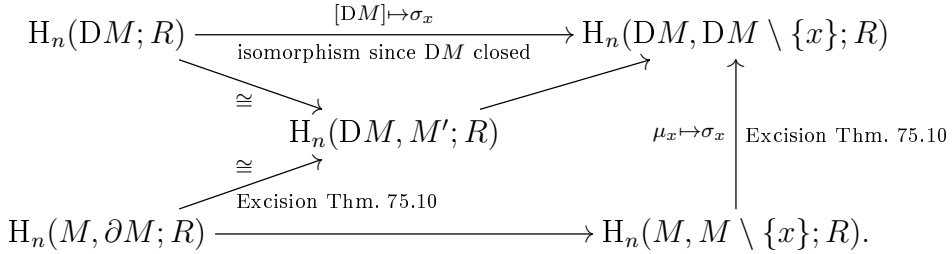
We first consider the case that M is actually closed. Recall that we denote by $\Gamma_R(M)$ the set of all R-sections of M. By Lemma 105.5 (2) we have a well-defined R-module homomorphism

$$\begin{aligned} \mathrm{H}_n(M; R) &\mapsto \Gamma_R(M) \\ \alpha &\mapsto \{\alpha_x\}_{x \in M}. \end{aligned}$$

Since M is closed we can apply the Homology-Section Theorem 106.10 (i) to the special case of the compact subset $A = M$ and we obtain that the above map is an isomorphism. The desired statements (1) and (2) now both follow from Lemma 105.9.

Now we consider the case that M is not closed, i.e. we suppose that $\partial M \neq \varnothing$. As usual we denote by $\mathrm{D}M$ the double of M. The idea now is to prove the desired statements for M by reducing them to the equivalent statements for the closed topological manifold $\mathrm{D}M$ that we had just proved.

As before we think of the double as $\mathrm{D}M = (M \sqcup M')/\sim$ where M' is another copy of M. We consider the maps



$$\underbrace{\mathrm{H}_n(M'; R)}_{=0 \text{ by Thm. } 106.3} \longrightarrow \mathrm{H}_n(\mathrm{D}M; R) \longrightarrow \mathrm{H}_n(\mathrm{D}M, M'; R) \longrightarrow \mathrm{H}_{n-1}(M'; R) \xrightarrow[\text{by } 75.13]{\text{injective}} \mathrm{H}_{n-1}(\mathrm{D}M; R)$$

$$\mathrm{H}_n(\mathrm{D}M, M'; R) \;\overset{\cong}{\uparrow}\; \mathrm{H}_n(M, \partial M; R), \qquad \text{with } \Phi \text{ from } \mathrm{H}_n(\mathrm{D}M; R) \text{ to } \mathrm{H}_n(M, \partial M; R),$$

where on the top we have written down the long exact sequence of the pair $(\mathrm{D}M, M')$. Note that the vertical map is an isomorphism by the Excision Theorem 75.10. The map Φ is defined to be the unique homomorphism that makes the triangle commute.

It follows immediately from the information provided in the above diagram that the map $\Phi\colon \mathrm{H}_n(\mathrm{D}M;R) \to \mathrm{H}_n(M,\partial M;R)$ is an isomorphism. Now we turn to the proof of the two statements of the proposition.

(1) Now suppose that M is R-orientable. Let $x \in M \setminus \partial M$. We consider the following diagram

Here all maps are the obvious inclusion induced maps. This implies that the diagram commutes. Since $\mathrm{D}M$ is closed and since it is R-orientable by the Double-Orientability Lemma 105.18 we know from the first part of the proof that the top horizontal map is an isomorphism. Furthermore by the above discussion we know that the top-left diagonal map is an isomorphism. Finally two of the maps are isomorphisms by the Excision Theorem 75.10. It now follows immediately that the bottom horizontal map is also an isomorphism. But that is exactly what we were supposed to show.

(2) If M is non-orientable, then it follows from the Double-Orientability Lemma 105.18 that the double $\mathrm{D}M$ is non-orientable either. We obtain that

$$\mathrm{H}_n(M,\partial M;\mathbb{Z}) \underset{\text{see above}}{\cong} \mathrm{H}_n(\mathrm{D}M;\mathbb{Z}) \underset{\substack{\text{since } \mathrm{D}M \text{ is closed and non-orientable and}\\ \text{since we have proved (1) in the closed case}}}{=} 0.$$

■

Remark. Note that the second statement of Proposition 106.21 only deals with integer coefficients. A more general statement is given by [**Hat2002**, Theorem 3.26]. This theorem says that if M is a closed connected n-dimensional topological manifold that is *not* R-orientable, then for any $x \in M$ the map $\rho_x\colon \mathrm{H}_n(M;R) \to \mathrm{H}_n(M, M\setminus\{x\};R) \cong R$ is injective with image $\{r \in R \mid 2r = 0\}$. For example for $R = \mathbb{Z}$ we have $\{r \in \mathbb{Z} \mid 2r = 0\} = \{0\}$, i.e. the map ρ_x is the zero map and by injectivity we have $\mathrm{H}_n(M;\mathbb{Z}) = 0$. In the case of closed topological manifolds we can thus view [**Hat2002**, Theorem 3.26] as a generalization of Proposition 106.21 (2). We will not make use of [**Hat2002**, Theorem 3.26].

Now we can finally provide the proofs of Theorems 106.1 and 106.2.

Proof of the Orientation-Top Homology Theorem 106.1. Let M be a compact connected non-empty n-dimensional topological manifold. We have to show that the following statements are equivalent:

(1) the topological manifold M is orientable,
(2) $\mathrm{H}_n(M,\partial M;\mathbb{Z}) \neq 0$,
(3) $\mathrm{H}_n(M,\partial M;\mathbb{Z}) \cong \mathbb{Z}$,
(4) for every $x \in M \setminus \partial M$ the map

$$\rho_x\colon \mathrm{H}_n(M,\partial M;\mathbb{Z}) \to \mathrm{H}_n(M, M\setminus\{x\};\mathbb{Z})$$

is an isomorphism.

We have (1) $\Rightarrow$ (4) by Proposition 106.21 (1) applied with $R = \mathbb{Z}$. Since M is non-empty we obtain from the Topological Manifold Boundary Proposition 75.2 (5) that there exists a point $x \in M \setminus \partial M$. Therefore we have (4) $\Rightarrow$ (3) by Lemma 105.4. Evidently we have (3) $\Rightarrow$ (2). Furthermore we have (2) $\Rightarrow$ (1) by Proposition 106.21 (2). ■

Proof of the Top-$\mathbb{F}_2$-Homology Theorem 106.2. Let M be a compact connected non-empty n-dimensional topological manifold. We have to show the following two statements:

(1) $\mathrm{H}_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$, and
(2) for every $x \in M \setminus \partial M$ the map

$$\rho_x \colon \mathrm{H}_n(M, \partial M; \mathbb{F}_2) \quad \to \quad \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{F}_2)$$

is an isomorphism.

By the $\mathbb{F}_2$-Orientability Proposition 105.13 we know that M admits an $\mathbb{F}_2$-orientation. Statement (2) follows immediately from this fact and Proposition 106.21 (1) applied to $R = \mathbb{F}_2$. As in the proof of the Orientation-Top Homology Theorem 106.1, the first statement is an immediate consequence of the second statement, together with the fact that there exists a point in $M \setminus \partial M$ and Lemma 105.4. ■

106.5. **Further properties of topological manifolds.** Let M be a compact n-dimensional topological manifold. With the Orientation-Top Homology Theorem 106.1 we now completely understand the n-dimensional homology of M. In this section we will obtain some results on the $(n-1)$-dimensional homology of M which generalize the results of the Smooth Manifold-Top Homology Theorem 98.6 (2) and Theorem 98.8 (2) from smooth manifolds to topological manifolds.

Proposition 106.22. Let M be a connected compact n-dimensional topological manifold.

$$\text{(1)} \qquad \mathrm{H}_{n-1}(M; \mathbb{Z}) \cong \begin{cases} \text{free abelian group}, & \text{if } M \text{ is orientable or if } \partial M \neq \varnothing, \\ \text{free abelian group} \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable and closed.} \end{cases}$$

$$\text{(2)} \quad \mathrm{H}_{n-1}(M, \partial M; \mathbb{Z}) \cong \begin{cases} \text{free abelian group}, & \text{if } M \text{ is orientable,} \\ \text{free abelian group} \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable.} \end{cases}$$

In all cases the free abelian group is finitely generated.

Remark.

(1) As a reality check it is good to recall the calculation of the homology groups of closed 2-dimensional topological manifolds that we gave in Proposition 80.10. There we showed for any $g \in \mathbb{N}_0$ and any $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_n(\Sigma_g) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ \mathbb{Z}, & \text{if } n = 2, \\ \mathbb{Z}^{2g}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0 \end{cases} \qquad \text{and} \qquad \mathrm{H}_n(k \cdot \mathbb{R}\mathrm{P}^2) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}_2 \oplus \mathbb{Z}^{k-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0, \end{cases}$$

where, as always, we denote by Σ_g the surface of genus g. Fortunately these calculations are coherent with Proposition 106.22.

(2) It follows immediately from the Universal Coefficient Theorem 89.17, the Orientation-Top Homology Theorem 106.1, Proposition 106.22 and the Tor-Properties Lemma 89.15 that for any closed orientable n-dimensional topological manifold and any abelian group G we have $\mathrm{H}_n(M;G) \cong G$.

In the proof of Proposition 106.22 we will use the following lemma which is an immediate consequence of the Finitely Generated Abelian Group Classification Theorem 51.4, and of the Tor-Properties Lemma 89.15.

Lemma 106.23. Let A be a finitely generated abelian group. Then the following holds:

$$A \text{ is a free abelian group} \iff \mathrm{Tor}(A, \mathbb{Z}_p) = 0 \text{ for all primes } p.$$

Now we can provide the proof of Proposition 106.22. First we consider Statement (1). For that statement we consider the two cases that the topological manifold is closed and that it has non-empty boundary separately.

Proof of Proposition 106.22 (1) I. Let M be a closed connected n-dimensional topological manifold. By the Topological Manifolds-Invariants Proposition 104.14 (4) we know that $\mathrm{H}_{n-1}(M;\mathbb{Z})$ is a finitely generated abelian group.

We first consider the case that M is orientable. We want to show that $\mathrm{H}_{n-1}(M;\mathbb{Z})$ is a free abelian group. By Lemma 106.23 it suffices to show that $\mathrm{Tor}(\mathrm{H}_{n-1}(M;\mathbb{Z}), \mathbb{F}_p) = 0$ for all primes p.

So let p be a prime. We have

$$\mathbb{F}_p \overset{\text{by Proposition 106.21 (1), since by Lemma 105.14 we know that } M \text{ is also } \mathbb{F}_p\text{-orientable}}{\cong} \mathrm{H}_n(M;\mathbb{F}_p) \overset{\text{UCT-Splitting Theorem 89.22}}{\cong} \mathrm{H}_n(M;\mathbb{Z}) \otimes \mathbb{F}_p \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(M;\mathbb{Z}), \mathbb{F}_p) \overset{\text{by the Orientation-Top Homology Theorem 106.1 (3) we have } \mathrm{H}_n(M;\mathbb{Z}) \cong \mathbb{Z}}{\cong} \mathbb{F}_p \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(M;\mathbb{Z}), \mathbb{F}_p).$$

It follows from Lemma 51.9 that $\mathrm{Tor}(\mathrm{H}_{n-1}(M;\mathbb{Z}), \mathbb{F}_p) = 0$.

Now we turn to the case that M is non-orientable. By the Orientation Covering-Proposition 105.15 there exists a connected 2-fold covering $q\colon \widetilde{M} \to M$ such that $\widetilde{M}$ is orientable. We consider the maps

$$\mathrm{H}_{n-1}(M;\mathbb{Z}) \xrightarrow{q^*} \mathrm{H}_{n-1}(\widetilde{M};\mathbb{Z}) \xrightarrow{q_*} \mathrm{H}_{n-1}(M;\mathbb{Z}), \qquad \cdot 2 \text{ (the composition)}$$

Here q^* denotes the transfer map that we introduced on page 1952 and q_* denotes of course the map induced by the projection q. By the Transfer Map Proposition 91.1 the composition of q^* and q_* is given by multiplication by 2. Put differently, the above diagram commutes.

Since $\widetilde{M}$ is orientable we obtain from the case that we had just proved that $\mathrm{H}_{n-1}(\widetilde{M};\mathbb{Z})$ is torsion-free. Now we see that

$$\text{torsion subgroup of } \mathrm{H}_{n-1}(M;\mathbb{Z}) \overset{\text{since } \mathrm{H}_{n-1}(\widetilde{M};\mathbb{Z}) \text{ is torsion-free}}{\subset} \ker(q^*) \subset \ker(q_* \circ q^*) \overset{\text{by the above commutative diagram}}{\subset} \{a \in \mathrm{H}_{n-1}(M;\mathbb{Z}) \mid 2a = 0\}.$$

From these inclusions and the classification of finitely generated abelian groups we obtain easily that $\mathrm{H}_{n-1}(M;\mathbb{Z}) \cong (\mathbb{Z}_2)^r \oplus \mathbb{Z}^k$ for some $r \in \mathbb{N}_0$ and some $k \in \mathbb{N}_0$.

It remains to show that $r = 1$. In light of the Tor-Properties Lemma 89.15 it suffices to show that we have $\mathrm{Tor}(\mathrm{H}_{n-1}(M;\mathbb{Z}), \mathbb{F}_2) \cong \mathbb{F}_2$. The argument is very similar to the

argument in the orientable case. More precisely, we have

$$\begin{array}{ccccccc} & & & \text{UCT-Splitting Theorem 89.22} & & & \\ & & & \downarrow & & & \\ \mathbb{F}_2 & \cong & \mathrm{H}_n(M;\mathbb{F}_2) & \cong & \mathrm{H}_n(M;\mathbb{Z}) \otimes \mathbb{F}_2 \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(M;\mathbb{Z}),\mathbb{F}_2) & \cong & 0 \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(M;\mathbb{Z}),\mathbb{F}_2). \\ & \uparrow & & & & \uparrow & \\ & \mathbb{F}_2\text{-Orientability Proposition 105.13} & & & & & \\ & \text{and the Top-}\mathbb{F}_2\text{-Homology Theorem 106.2} & & & \text{we have } \mathrm{H}_n(M;\mathbb{Z}) = 0 & & \end{array}$$

■

Now we deal with topological manifolds with non-empty boundary.

Proof of Proposition 106.22 (1) II. Let M be a connected, compact n-dimensional topological manifold with non-empty boundary. We need to show that $\mathrm{H}_{n-1}(M;\mathbb{Z})$ is a free abelian group. There are two approaches to the proof of this statement.

(1) We can imitate the proof of the closed case, or
(2) we reduce the proof of the proposition to the case of closed topological manifolds that we had just dealt with.

We will pursue the second approach. First recall that by the Double-Orientability Lemma 105.18 the double $\mathrm{D}M$ is orientable if and only if M is orientable.

We first consider the case that M is orientable. By Proposition 106.22 we know that $\mathrm{H}_{n-1}(\mathrm{D}M;\mathbb{Z})$ is a finitely generated free abelian group. It follows from Lemma 75.13 that the group $\mathrm{H}_{n-1}(M;\mathbb{Z})$ is isomorphic to a subgroup of $\mathrm{H}_{n-1}(\mathrm{D}M;\mathbb{Z})$, hence by Lemma 51.9 (3) it is also a finitely generated free abelian group.

Now we consider the case that M is non-orientable. We denote by M' a copy of M and as usual we denote by $\mathrm{D}M = M \cup_{\partial M = \partial M'} M'$ the double. From the Mayer–Vietoris Theorem 78.9 for Manifolds we obtain the following long exact sequence:

$$\cdots \to \mathrm{H}_n(\mathrm{D}M;\mathbb{Z}) \to \mathrm{H}_{n-1}(\partial M;\mathbb{Z}) \to \mathrm{H}_{n-1}(M;\mathbb{Z}) \oplus \mathrm{H}_{n-1}(M';\mathbb{Z}) \to \mathrm{H}_{n-1}(\mathrm{D}M;\mathbb{Z}) \to \dots$$

We make the following observations:

(1) By the Topological Manifold Boundary Proposition 75.2 (3) and (4) we know that ∂M is a closed $(n-1)$-dimensional topological manifold. Thus we obtain from the Orientation-Top Homology Theorem 106.1 that $\mathrm{H}_{n-1}(\partial M;\mathbb{Z})$ is isomorphic to a free abelian group $\mathbb{Z}^r$ for some $r \in \mathbb{N}_0$. (We do not have any control over the orientability of ∂M and the number of components of ∂M but this does not matter.)
(2) Since $\mathrm{D}M$ is non-orientable we know from the Orientation-Top Homology Theorem 106.1 that $\mathrm{H}_n(\mathrm{D}M;\mathbb{Z}) = 0$ and we know from Proposition 106.22 that $\mathrm{H}_{n-1}(\mathrm{D}M;\mathbb{Z}) \cong \mathbb{Z}^s \oplus \mathbb{Z}_2$ for some $s \in \mathbb{N}_0$.
(3) Since $M = M'$ we have $\mathrm{H}_{n-1}(M;\mathbb{Z}) = \mathrm{H}_{n-1}(M';\mathbb{Z})$. By the classification of finitely generated abelian groups we can pick an isomorphism $\mathrm{H}_{n-1}(M;\mathbb{Z}) \cong F \oplus T$ where F is a free abelian group and T is a torsion group.

We can thus rewrite the above sequence as follows:

$$0 \;\to\; \mathbb{Z}^r \;\xrightarrow{\varphi}\; F \oplus F \oplus T \oplus T \;\to\; \mathbb{Z}^s \oplus \mathbb{Z}_2 \;\to\; \dots$$

The map $\varphi\colon \mathbb{Z}^r \to F \oplus F \oplus T \oplus T$ is a monomorphism, but since $\mathbb{Z}^r$ is torsion-free and since T is finite we see that $\mathrm{im}(\varphi) \cap (T \oplus T)$ is trivial. But this implies that $T \oplus T$ is isomorphic to a subgroup of $\mathbb{Z}^s \oplus \mathbb{Z}_2$. But this is only possible if $T = 0$. This concludes the proof that $\mathrm{H}_{n-1}(M;\mathbb{Z})$ is a free abelian group. ■

Proof of Proposition 106.22 (2). First we note that by Propositions 75.2 (3) and (4) and 104.14 (4) together with Lemma 96.8 (1) we know that $\mathrm{H}_{n-1}(M,\partial M;\mathbb{Z})$ is finitely generated. Now there are two approaches to proving Statement (2):

(1) We can use basically exactly the argument as in the proof of Theorem 98.8 (2) to reduce, via a doubling construction, the study of relative homology groups to the study of absolute homology groups. The only difference is that we need to replace the Smooth Manifold-Top Homology Theorem 98.6 by Statement (1) of the present proposition.

(2) Alternatively we can adopt the argument of Statement (1). First we assume that M is orientable. By Lemma 106.23 it suffices to show that $\mathrm{Tor}(\mathrm{H}_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p)=0$ for all primes p. So let p be a prime. We have

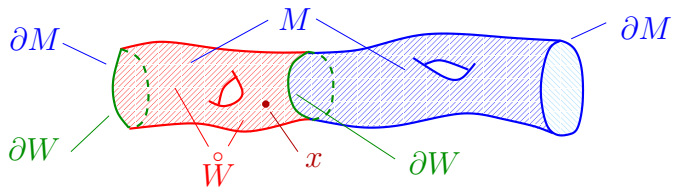
$$\begin{array}{ccccc} & & \overset{\text{UCT-Splitting Theorem 89.22}}{\downarrow} & & \\ \mathbb{F}_p & \cong \mathrm{H}_n(M,\partial M;\mathbb{F}_p) & \cong & \mathrm{H}_n(M,\partial M;\mathbb{Z})\otimes\mathbb{F}_p \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p) & \\ & & & \cong \mathbb{F}_p \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p). & \\ & \uparrow & & \uparrow & \\ & \text{by Proposition 106.21 (1), since by Lemma 105.14 } M \text{ is also } \mathbb{F}_p\text{-orientable} & & \text{by the Orientation-Top Homology Theorem 106.1 (3) we have } \mathrm{H}_n(M,\partial M;\mathbb{Z})\cong\mathbb{Z} & \end{array}$$

It follows from Lemma 51.9 that $\mathrm{Tor}(\mathrm{H}_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p)=0$. The case that M is non-orientable is very similar, we leave it to the reader to make the necessary modifications. ■

106.6. **The fundamental class and induced orientations.** In Section 105.5 we saw that an orientation on a topological manifold M induces orientations on codimension-zero submanifolds of M, on the boundary ∂M and on covering spaces of M. If M is compact, then M admits a fundamental class and we will see in this section how it is related to the fundamental classes of the various corresponding oriented topological manifolds.

First of all, in the Topological Manifold-Induced Orientation Lemma 105.17 we saw that a codimension-zero submanifold W of an oriented topological manifold M inherits an orientation. For compact topological manifolds the following lemma, which is the analogue of the Codimension Zero-Fundamental Class Lemma 100.12, shows the relationship between the corresponding fundamental classes.

Lemma 106.24. (Codimension Zero-Fundamental Class Lemma) Let M be a compact oriented n-dimensional topological manifold. Furthermore let $W\subset M$ be a compact non-empty codimension-zero submanifold. We write $\mathring{W}=W\setminus\partial W$. The following two statements hold:



(1) The inclusion induced map $\mathrm{H}_n(W,\partial W;\mathbb{Z})\to\mathrm{H}_n(M,M\setminus\mathring{W};\mathbb{Z})$ is an isomorphism.

(2) The image of the fundamental classes $[M]\in\mathrm{H}_n(M,\partial M;\mathbb{Z})$ and $[W]\in\mathrm{H}_n(W,\partial W;\mathbb{Z})$ under the maps

$$\mathrm{H}_n(M,\partial M;\mathbb{Z}) \longrightarrow \mathrm{H}_n(M,M\setminus\mathring{W};\mathbb{Z}) \longleftarrow \mathrm{H}_n(W,\partial W;\mathbb{Z})$$

agree.

Remark. In Lemma 120.4 we will generalize the Codimension Zero-Fundamental Class Lemma 106.24 to the case that W is a codimension-zero submanifold *with corner*.

Proof.

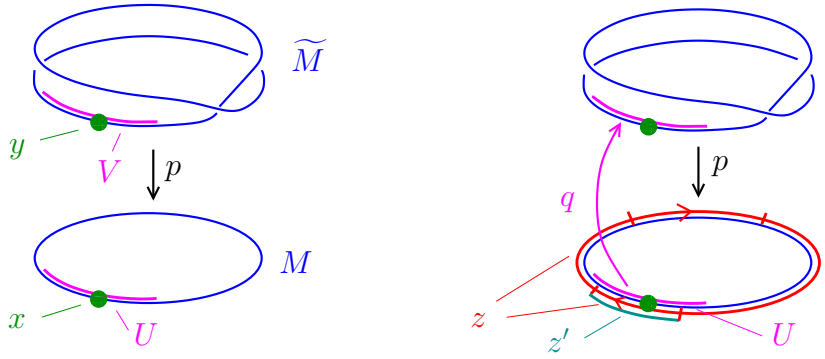
(1) The first statement is an immediate consequence of the Excision Theorem 75.10.

(2) We denote by $\Phi\colon \mathrm{H}_n(M, \partial M; \mathbb{Z}) \to \mathrm{H}_n(W, \partial W; \mathbb{Z})$ the map given in Statement (2). We have to show that $\Phi([M])$ is the fundamental class for W. But this follows immediately from the Fundamental Class-Corollary 106.4 and from considering for each $x \in W \setminus \partial W$ the following commutative diagram

$$\begin{array}{ccccc}
 & & \overset{\Phi}{\frown} & & \\
\mathrm{H}_n(M, \partial M; \mathbb{Z}) & \longrightarrow & \mathrm{H}_n(M, M \setminus \mathring{W}; \mathbb{Z}) & \overset{\cong}{\longleftarrow} & \mathrm{H}_n(W, \partial W; \mathbb{Z}) \\
\downarrow & \swarrow & & & \downarrow \\
\mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z}) & & \underset{\text{isomorphism by the Excision Theorem 74.18}}{\overset{\cong}{\longleftarrow}} & & \mathrm{H}_n(W, W \setminus \{x\}; \mathbb{Z}).
\end{array}$$

We leave the few remaining details to the reader. ■

In the Topological Manifold-Induced Orientation Lemma 105.17 (3) we showed that a covering space $\widetilde{M}$ of an oriented topological manifold M inherits an orientation from M. The following proposition can now be viewed as a generalization of Exercise 100.10 and the Covering Map-Degree Proposition 101.7.



Proposition 106.25. (Fundamental Class-Covering Proposition) Let M be a compact oriented non-empty n-dimensional topological manifold and let $p\colon \widetilde{M} \to M$ be a finite covering. We denote by $[M]$ the fundamental class of M and we denote by $p^*\colon \mathrm{H}_n(M; \mathbb{Z}) \to \mathrm{H}_n(\widetilde{M}; \mathbb{Z})$ the transfer map that we introduced on page 1952. $p^*([M])$ equals the fundamental class $\big[\widetilde{M}\big]$ of the oriented topological manifold $\widetilde{M}$ and we have $p_*\big(\big[\widetilde{M}\big]\big) = \big[\widetilde{M} : M\big] \cdot [M]$.

Proof. Let M be a compact n-dimensional topological manifold. To simplify the notation we assume that M is closed. Furthermore let $p\colon \widetilde{M} \to M$ be a finite covering and let $\{\mu_x\}_{x \in M}$ be an orientation for M. We denote by $\{\nu_x\}_{x \in \widetilde{M}}$ the orientation on $\widetilde{M}$ that we defined in the Topological Manifold-Induced Orientation Lemma 105.17 (3).

We want to show that $p^*([M])$ equals the fundamental class $\big[\widetilde{M}\big]$. By the Fundamental Class-Corollary 106.4 it suffices to show that for all $y \in \widetilde{M}$ we have $p^*([M])_y = \nu_y \in \mathrm{H}_n(\widetilde{M}, \widetilde{M} \setminus \{y\}; \mathbb{Z})$. So let $y \in \widetilde{M}$. We pick an open neighborhood V around y such that $U := p(V)$ is uniformly covered. We write $x = p(y)$ and we denote by $q\colon U \to V$ the inverse of the homeomorphism $p\colon V \to U$.

We pick a representative $z = a_1 \cdot \sigma_1 + \cdots + a_m \cdot \sigma_m \in \mathrm{C}_n(M)$ for $[M]$. By applying the Comfortable Covering Proposition 74.23 to the *open* cover of M given by $\{U, M \setminus \{x\}\}$ we

can arrange that the image of each σ_i lies in U or in $M \setminus \{x\}$. We denote by z' the sum of all summands in z such that the image of σ_i lies in U.

A moment's thought shows that in $\mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z})$ we have $[z] = [z']$ and that in $\mathrm{H}_n(\widetilde{M}, \widetilde{M} \setminus \{y\})$ we have $[p^*(z)] = [q_*(z')]$. From these observations we deduce that the following diagram commutes:

$$\begin{array}{ccccccc}
\mathrm{H}_n(M;\mathbb{Z}) & & \xrightarrow{\qquad\qquad p^* \qquad\qquad} & & & & \mathrm{H}_n(\widetilde{M};\mathbb{Z}) \\
\downarrow{\scriptstyle [M]=[z]\mapsto[z]=[z']=[\mu_x]} & & & & & & \downarrow{\scriptstyle [p^*z]\mapsto[p^*z]=[q_*(z')]} \\
\mathrm{H}_n(M, M\setminus\{x\};\mathbb{Z}) & \xleftarrow{\cong} & \mathrm{H}_n(U, U\setminus\{x\};\mathbb{Z}) & \xrightarrow[q_*]{\cong} & \mathrm{H}_n(V, V\setminus\{y\};\mathbb{Z}) & \xrightarrow{\cong} & \mathrm{H}_n(\widetilde{M}, \widetilde{M}\setminus\{y\};\mathbb{Z}).
\end{array}$$

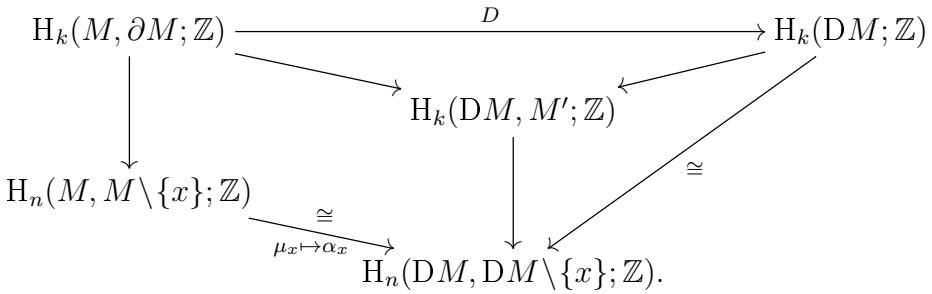
$$\mu_x \mapsto \nu_y$$

Note that the bottom horizontal maps to the left and right are isomorphisms by the Excision Theorem 74.18 and the middle horizontal map is an isomorphism since q is a homeomorphism. It follows from this diagram that we indeed have $p^*([M])_y = \nu_y$.

Finally we have

$$p_*\big([\widetilde{M}]\big) \underset{\text{by the above}}{=} p_*(p^*([M])) \underset{\text{Transfer Map Proposition 91.1}}{=} [\widetilde{M} : M] \cdot [M].$$

■



In the Double-Orientability Lemma 105.18 we saw that the double of an oriented topological manifold with non-empty boundary comes with a natural orientation. The following lemma following relates the various fundamental classes in this construction.

Lemma 106.26. Let M be a compact oriented n-dimensional topological manifold with non-empty boundary. If we equip $\mathrm{D}M$ with the orientation coming from the Double-Orientability Lemma 105.18, then

$$[\mathrm{D}M] \;=\; D([M]) \;\in\; \mathrm{H}_n(\mathrm{D}M;\mathbb{Z}),$$

where $D\colon \mathrm{H}_n(M, \partial M;\mathbb{Z}) \to \mathrm{H}_n(\mathrm{D}M;\mathbb{Z})$ denotes the doubling homomorphism that we introduced in the Doubling-Homology Lemma 75.16.

Proof. Let $\{\mu_x\}_{x \in M\setminus\partial M}$ be an orientation for M. We denote by $\{\alpha_x\}_{x\in \mathrm{D}M}$ the corresponding orientation for $\mathrm{D}M$ that we had constructed in the Double-Orientability Lemma 105.18. To simplify the notation we write $\mathrm{D}M = (M \sqcup M')/\!\sim$ where M' is a copy of M and we view M as a submanifold of the double. By the Topological Manifold Boundary Proposition 75.2 (5) there exists an $x \in M \setminus \partial M$. We consider the following diagram

Here all maps are the obvious maps for pairs of topological spaces. The lemma follows from the following observations:

(1) The top triangle commutes by the Doubling-Homology Lemma 75.16 (3). The parallelogram on the left and the triangle on the right commute by the functoriality of homology.
(2) The homomorphism to the bottom left is an isomorphism by the Excision Theorem 75.10 for topological Manifolds.
(3) The right diagonal map is an isomorphism by the Orientation-Top Homology Theorem 106.1.
(4) By definition $[M]$ gets sent to $\mu_x \in \mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z})$ and by definition μ_x gets sent to α_x. It follows from the commutativity of the diagram that $D([M])$ gets sent to α_x. But since the right diagonal map is an isomorphism it follows, from the definition of $[\mathrm{D}M]$, that $[\mathrm{D}M] = D([M])$. ■

In the Topological Manifold-Boundary Orientation Proposition 105.19 we saw that the boundary of an oriented topological manifold inherits a natural orientation. The following proposition can now be seen as a generalization of the Fundamental Class-of-Boundary Proposition 100.9 from smooth manifolds to topological manifolds.

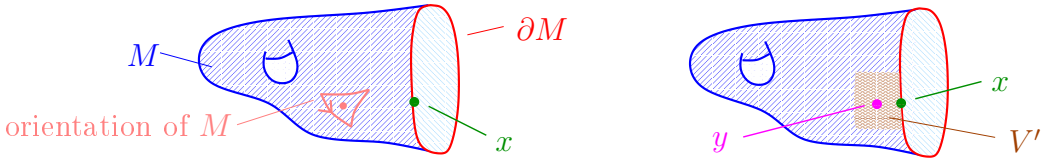
Proposition 106.27. (Fundamental Class-of-Boundary Proposition II) Let M be a compact n-dimensional topological manifold with non-empty boundary.

(1) We denote by $\partial_n \colon \mathrm{H}_n(M, \partial M; \mathbb{Z}) \to \mathrm{H}_{n-1}(\partial M; \mathbb{Z})$ the connecting homomorphism of the long exact sequence of the pair $(M, \partial M)$. If M is oriented, then[1297]
$$\partial_n([M]) \;=\; [\partial M] \;\in\; \mathrm{H}_{n-1}(\partial M; \mathbb{Z}).$$
(2) Similarly, for the connecting homomorphism $\partial_n \colon \mathrm{H}_n(M, \partial M; \mathbb{F}_2) \to \mathrm{H}_{n-1}(\partial M; \mathbb{F}_2)$ we have
$$\partial_n([M]_{\mathbb{F}_2}) \;=\; [\partial M]_{\mathbb{F}_2} \;\in\; \mathrm{H}_{n-1}(\partial M; \mathbb{F}_2).$$

Proof. As a health warning we point out that in this proof we make heavy use of the notation introduced in the Topological Manifold-Boundary Orientation Proposition 105.19. We only provide the proof of Statement (1); the proof of Statement (2) is almost identical.

Let $\{\mu_y\}_{y \in M \setminus \partial M}$ be the orientation of for M. Next let $x \in \partial M$. We pick a chart $\Phi \colon U \to [0, 2) \times (-2, 2)^{n-1}$ with $\Phi(x) = (0, 0)$. We write $V' = \Phi^{-1}((0, 1) \times (-1, 1)^{n-1})$.

[1297] Note that ∂M is a closed $(n-1)$-dimensional topological manifold by the Topological Manifold Boundary Proposition 75.2 (3) and (4).



Finally we pick a point $y \in V'$. We consider the following diagram:

$$\begin{array}{ccccccc}
 & & & \overset{\mu_y \mapsto \nu_x}{\curvearrowright} & & & \\
\mathrm{H}_n(M, M\backslash\{y\}) & \xleftarrow[\cong]{} & \mathrm{H}_n\big(M, M\backslash V'\big) & \xrightarrow[\cong]{\partial_n} & \mathrm{H}_{n-1}(M\backslash V', (M\backslash V')\backslash\{x\}) & \xleftarrow[\cong]{} & \mathrm{H}_{n-1}(\partial M, \partial M\backslash\{x\}) \\
\mu_y \updownarrow [M] & \nearrow & & & & \nwarrow & \nu_x \updownarrow [\partial M] \\
\mathrm{H}_n(M, \partial M) & & & \xrightarrow{\qquad\qquad\partial_n\qquad\qquad} & & & \mathrm{H}_{n-1}(\partial M).
\end{array}$$

We make the following observations and clarifications:

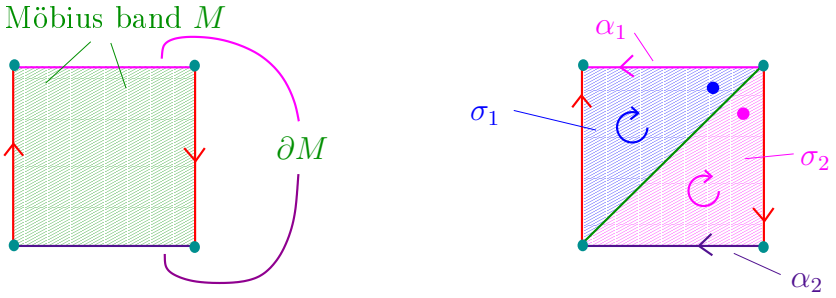
(1) All the unmarked maps are induced by the obvious inclusions of pairs of topological space.
(2) In the proof of the Topological Manifold-Boundary Orientation Proposition 105.19 we showed that the three horizontal blue maps on the top, connecting $\mathrm{H}_n(M, M\backslash\{y\})$ to $\mathrm{H}_{n-1}(\partial M, \partial M \setminus \{x\})$, are isomorphisms.
(3) By definition of the orientation $\{\nu_x\}_{x\in\partial M}$ of ∂M the composition of the top horizontal maps sends μ_x to ν_y.
(4) The maps ∂_n are the connecting homomorphism of the long exact sequence of the triple $(M, M \setminus V', (M\backslash V')\backslash\{x\})$ respectively of the pair $(M, \partial M)$.
(5) The triangles are given by inclusion induced maps, hence they both commute.
(6) Finally note that it follows from the naturality of the connecting homomorphisms, see the Topological LES-Proposition 74.13 (3), that the quadrilateral commutes.

It follows from the above and the defining property of $[M]$ that for any $x \in \partial M$ the image of $\partial_n([M]) \in \mathrm{H}_{n-1}(M)$ under the map $\mathrm{H}_{n-1}(\partial M) \to \mathrm{H}_{n-1}(\partial M, \partial M \setminus \{x\})$ equals ν_x. But that means that $\partial_n([M]) = [\partial M]$. ■

Remark. Given a compact oriented n-dimensional topological manifold the conclusion of the Fundamental Class-of-Boundary Proposition 106.27 can also be summarized in the following commutative "diagram"

$$\begin{array}{ccc}
\mathbb{Z}\text{-oriented topological manifold } M & \xmapsto{\text{take boundary}} & \mathbb{Z}\text{-oriented topological manifold } \partial M \\
\Big\downarrow \text{take fundamental class} & & \Big\downarrow \text{take fundamental class} \\
[M] & \xmapsto[\mathrm{H}_n(M,\partial M;\mathbb{Z})\to\mathrm{H}_{n-1}(\partial M;\mathbb{Z})]{\text{apply connecting homomorphism}} & \partial[M] = [\partial M].
\end{array}$$

Example. We will illustrate the Fundamental Class-of-Boundary Proposition 106.27 with the Möbius band M. By the $\mathbb{F}_2$-Orientability Proposition 105.13 and the Top-$\mathbb{F}_2$-Homology Theorem 106.2 it has an $\mathbb{F}_2$-fundamental class $[M] \in \mathrm{H}_2(M, \partial M; \mathbb{F}_2)$. In the figure below we consider the Möbius band with two singular 1-simplices α_1, α_2 and two singular 2-simplices



σ_1, σ_2. In this case we have

$$\partial\big(\underbrace{\sigma_1 + \sigma_2}_{=:\mu}\big) \;=\; \underbrace{\alpha_1 + \alpha_2}_{\in \mathrm{C}_1(\partial M)}.$$

In particular, $\mu \otimes 1$ is a cycle in $\mathrm{C}_2(M, \partial M; \mathbb{F}_2)$. It easily follows from Proposition 100.18 that $\mu \otimes 1$ represents the $\mathbb{F}_2$-fundamental class in $\mathrm{H}_2(M, \partial M; \mathbb{F}_2)$. Furthermore, if we denote by $\partial\colon \mathrm{H}_2(M, \partial M; \mathbb{F}_2) \to \mathrm{H}_1(\partial M; \mathbb{F}_2)$ the connecting homomorphism of the long exact sequence in $\mathbb{F}_2$-homology of the pair $(M, \partial M)$, then

$$\partial[M] \;=\; \partial[\mu \otimes 1] \;\underset{\text{Topological LES-Proposition 74.13}}{\uparrow}\; [\partial\mu \otimes 1] \;\underset{\text{by the above}}{\uparrow}\; \big[(\alpha_1 + \alpha_2) \otimes 1\big],$$

but the last class is clearly[1298] an $\mathbb{F}_2$-fundamental class for the circle ∂M.

The following corollary is the generalization of the Fundamental Class-of-Boundary Corollary 100.11 to the case of topological manifolds.

Corollary 106.28. Let M be a compact n-dimensional topological manifold. Then the following two statements hold:

(1) We have

$$\ker\big(\mathrm{H}_{n-1}(\partial M; \mathbb{F}_2) \to \mathrm{H}_{n-1}(M; \mathbb{F}_2)\big) \;=\; \mathbb{F}_2 \cdot [\partial M]_{\mathbb{F}_2} \;\in\; \mathrm{H}_{n-1}(\partial M; \mathbb{F}_2).$$

Furthermore, if M is oriented, then

$$\ker\big(\mathrm{H}_{n-1}(\partial M; \mathbb{Z}) \to \mathrm{H}_{n-1}(M; \mathbb{Z})\big) \;=\; \mathbb{Z} \cdot [\partial M] \;\in\; \mathrm{H}_{n-1}(\partial M; \mathbb{Z}).$$

(2) Let M be a compact n-dimensional topological manifold with non-trivial boundary. Then the boundary ∂M is not a retract of M.

Remark. In the Boundary Non-Retraction Proposition 31.3 we gave a very different proof of Corollary 106.28 (2) for smooth manifolds.

Proof. The proof is verbatim the same as the proof of the Fundamental Class-of-Boundary Corollary 100.11, the only difference in the proof is that we need to replace the Fundamental Class-of-Boundary Proposition 100.9 by the Fundamental Class-of-Boundary Proposition 106.27.

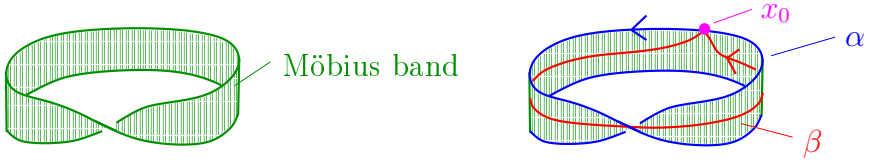
As a reminder, the first statement is proved using the long exact sequence in homology of the pair $(M, \partial M)$ together with the Fundamental Class-of-Boundary Proposition 106.27. The second statement follows from the first statement and the usual functoriality argument,

[1298] Why is this clear?

this time we employ the functoriality of homology with $\mathbb{F}_2$-coefficients and the fact that $[\partial M]_{\mathbb{F}_2}$ is non-zero. ■

Example. It follows from Corollary 106.28 that the boundary of the Möbius band M is not a retract of the Möbius band. A more down-to-earth proof is given as follows: we pick a base point $x_0 \in \partial M$ and we denote by α and β the loops shown in the figure below. Note that α represents a generator of $\pi_1(\partial M, x_0) \cong \mathbb{Z}$ and that β represents a generator of $\pi_1(M, x_0) \cong \mathbb{Z}$. We denote by $i\colon \partial M \to M$ the inclusion map. Note that $i_*([\alpha]) = 2 \cdot [\beta]$. If there was a retraction $r\colon M \to \partial M$, then we would obtain a commutative diagram

$$\begin{array}{ccc} & \pi_1(M,x_0) & \\ {\scriptstyle i_*}\nearrow & & \searrow{\scriptstyle r_*} \\ \pi_1(\partial M, x_0) & \xrightarrow[(r\circ i)_*]{} & \pi_1(\partial M, x_0) \end{array}$$

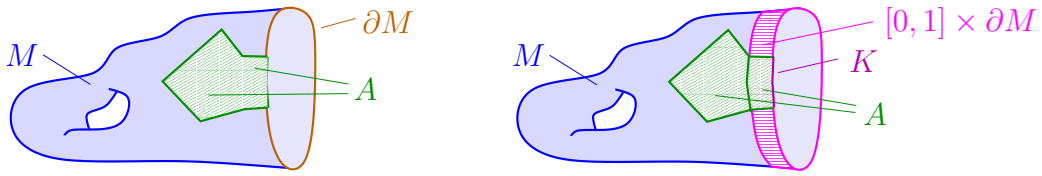


which by the above gives rise to the commutative diagram

$$\begin{array}{ccc} & \mathbb{Z} & \\ {\scriptstyle \cdot 2}\nearrow & & \searrow{\scriptstyle ??} \\ \mathbb{Z} & \xrightarrow[\mathrm{id}]{} & \mathbb{Z}, \end{array}$$

but such a commutative diagram cannot exist. Looking more carefully one sees that the two proofs that ∂M is not a retract of the Möbius band M are in some sense the same proof. More precisely, we have the following commutative diagram

$$\begin{array}{ccc} \mathbb{Z} = \pi_1(\partial M, x_0) & \xrightarrow{i_*} & \pi_1(M, x_0) = \mathbb{Z} \\ \downarrow & & \downarrow \\ \mathbb{Z} = \mathrm{H}_1(\partial M; \mathbb{Z}) & \xrightarrow{i_*} & \mathrm{H}_1(M; \mathbb{Z}) = \mathbb{Z} \\ \downarrow & & \downarrow \\ \mathbb{F}_2 = \mathrm{H}_1(\partial M; \mathbb{F}_2) & \xrightarrow{i_*} & \mathrm{H}_1(M; \mathbb{F}_2) = \mathbb{F}_2. \end{array}$$



Here the top vertical maps are given by the Hurewicz homomorphism from page 1832 and the bottom vertical maps are given by the map $[\alpha] \mapsto [\alpha \otimes 1]$ from page 1927. Since both maps are natural, see Proposition 84.2 (5) and page 1927, we see that the diagram commutes. The above observation that the top horizontal map is given by multiplication by 2 translates into the fact that the bottom horizontal map is the zero map.

Remark. In the Topological Product Orientation Proposition 113.10 we will deal with the difficult question of the fundamental class of a product of topological manifolds.

106.7. **Lifts of homology orientations for topological manifolds with boundary (∗).** In this very technical section we generalize the Homology-Section Theorem 106.10 (i) to the case of topological manifolds with boundary. Unless the reader is blessed with a surplus of energy it is best to skip this section.

Definition. Let M be a topological manifold. We say a compact subset $A \subset M$ is a product close to the boundary if there exists a collar neighborhood $[0,1] \times \partial M$ for the boundary ∂M and a compact subset $K \subset \partial M$ such that $A \cap ([0,1] \times \partial M) = [0,1] \times K$.

Remark. If M is a topological manifold with *empty boundary*, then every compact subset is in fact a product close to the boundary.

We leave the task of providing a proof of the following elementary lemma to the reader.

Lemma 106.29. Let M be a topological manifold and let $[0,1]\times\partial M$ be a collar neighborhood (which always exists by the topological Smooth Collar Neighborhood Theorem 75.5). Given any compact subset K of M there exists a compact subset A that contains K and that is a product close to the boundary.

Throughout this section we will need the following notation.

Notation. Given a subset A of a topological manifold M we write $A_\partial := A \cap (M \setminus \partial M)$. In other words, we have $A_\partial = A \setminus \partial M$. Note that $(M \setminus A) \cup \partial M = M \setminus A_\partial$.

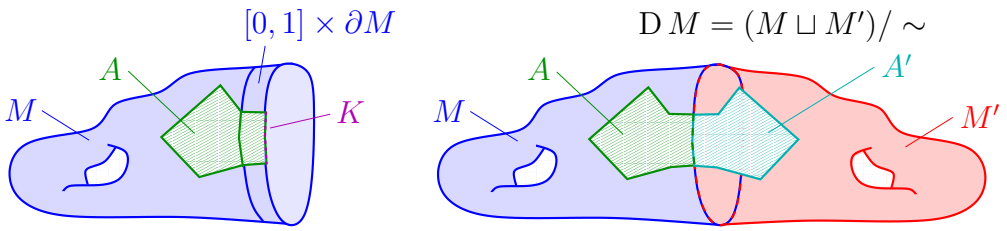
Now we can formulate the main result of this section.

Theorem 106.30. Let M be an n-dimensional topological manifold and let $A \subset M$ be a compact subset that is a product close to the boundary. Let R be a commutative ring. If $\{\alpha_x\}_{x\in M\setminus\partial M}$ is an R-section for M, then there exists a unique lift $\alpha_A^M = \alpha_A$ to A_∂, i.e. there exists a unique class $\alpha_A^M = \alpha_A \in \mathrm{H}_n(M, M \setminus A_\partial; R)$ such that for each $x \in A_\partial$ we have $\alpha_{A,x} = \alpha_x$.

Proof. Let M be an n-dimensional topological manifold and let R be a commutative ring. Furthermore let $A \subset M$ be a compact subset that is a product close to the boundary. We introduce the following notation and conventions:

(1) As usual we denote by $\mathrm{D}M$ the double of M. As before we think of the double as $\mathrm{D}M = (M \sqcup M')/\sim$ where M' is another copy of M. We recall that by the Doubling-Manifold Lemma 75.12 we know that $\mathrm{D}M$ is an n-dimensional topological manifold with empty boundary such that $M \subset \mathrm{D}M$ is a submanifold.

(2) By definition there exists a collar neighborhood $[0,1] \times \partial M$ for the boundary ∂M and a compact subset $K \subset \partial M$ such that $A \cap ([0,1] \times \partial M) = [0,1] \times K$.



(3) We denote by $DA = A \cup A' \subset \mathrm{D}M$ the double of A. As DA is the union of two compact sets we see that DA itself is compact.

(4) Given $t \in (0,1]$ we write $A_t := A \setminus ([0,t) \times K) = A \cap (M \setminus ([0,t) \times \partial M))$. It follows easily from the Compact-Closed Lemma 1.21 that A_t is again compact.

(5) It follows from the Excision Theorem 75.10 for topological manifolds that for any $P \in M \setminus \partial M$ the inclusion induced map

$$\mathrm{H}_n(M, M \setminus \{P\}; R) \;\to\; \mathrm{H}_n(\mathrm{D}M, \mathrm{D}M \setminus \{P\}; R)$$

is an isomorphism. We will use this isomorphism to identify these two homology groups.

The idea now is the same as in the proof of Proposition 106.21. Namely we want to prove the desired statement for M by reducing it to a corresponding statement for the topological manifold $\mathrm{D}M$ that has no boundary.

Claim. The inclusion induced map

$$\beta\colon \mathrm{H}_n(M, M \setminus A_\partial; R) \ \to \ \mathrm{H}_n(\mathrm{D}M, (M \setminus A) \cup M'; R)$$

is an isomorphism.

Proof. Recall that A is a product close to the boundary. Using this fact and using a gentle generalization of the Excision Theorem 75.10 for topological manifolds one can easily show that the inclusion induced map is an isomorphism. We leave it to the reader to fill in the details. ⊞

We denote by Φ the composition of the following two maps

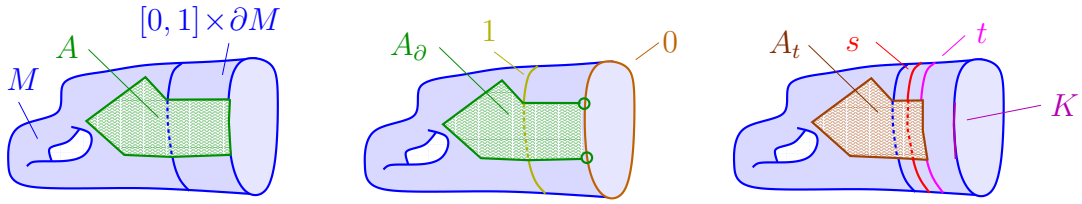
$$\mathrm{H}_n(\mathrm{D}M, \mathrm{D}M \setminus DA; R) \ \to \ \mathrm{H}_n(\mathrm{D}M, (M \setminus A) \cup M'; R) \xrightarrow{\beta^{-1}} \mathrm{H}_n(M, M \setminus A_\partial; R).$$

After all these preparations we now turn to the actual proof of the theorem. Thus let $\{\alpha_x\}_{x \in M \setminus \partial M}$ be an R-section for M. As in the proof of the Double-Orientability Lemma 105.18 we see that there exists an R-section $\{\alpha_x\}_{x \in \mathrm{D}M}$ for $\mathrm{D}M$ that restricts to the given R-section on M. By the Homology-Section Theorem 106.10 (i) there exists a lift $\mu_{DA} \in \mathrm{H}_n(\mathrm{D}M, \mathrm{D}M \setminus DA; R)$ of the R-section on $\mathrm{D}M$. We claim that $\Phi(\mu_{DA})$ is a lift for M. So let $P \in A_\partial$. We have the following commutative diagram

$$\begin{array}{ccccc}
 & & \overset{\Phi}{\frown} & & \\
\mathrm{H}_n(\mathrm{D}M, \mathrm{D}M \setminus DA; R) & \longrightarrow & \mathrm{H}_n(\mathrm{D}M, (M \setminus A) \cup M'; R) & \xleftarrow[\cong]{\beta} & \mathrm{H}_n(M, M \setminus A_\partial; R) \\
\downarrow & & \downarrow & & \downarrow \\
\mathrm{H}_n(\mathrm{D}M, \mathrm{D}M \setminus \{P\}; R) & \xrightarrow{\mathrm{id}} & \mathrm{H}_n(\mathrm{D}M, \mathrm{D}M \setminus \{P\}; R) & \xleftarrow{\cong} & \mathrm{H}_n(M, M \setminus \{P\}; R).
\end{array}$$

Since all maps are induced by inclusions of pairs of topological spaces we see that the diagram commutes. By definition of μ_{DA} the left-hand vertical map sends μ_{DA} to α_P. But this implies that the right-hand vertical map sends $\Phi(\mu_{DA})$ to $\alpha_P \in \mathrm{H}_n(M, M \setminus \{P\}; R)$.

Now we turn to the proof of the uniqueness of a lift. The following claim is the key to proving uniqueness.



Claim. Let $t \in (0,1)$. Note that $A_t \subset A_\partial$. The two inclusion induced maps

$$\begin{aligned}
\gamma\colon \mathrm{H}_n(M, M \setminus A_\partial; R) \ &\to \ \mathrm{H}_n(M, M \setminus A_t; R) \\
\delta\colon \mathrm{H}_n(M, M \setminus A_t; R) \ &\to \ \mathrm{H}_n(\mathrm{D}M, \mathrm{D}M \setminus A_t; R)
\end{aligned}$$

are isomorphisms.

Proof. It follows immediately from the Excision Theorem 75.10 for topological manifolds that the map δ is an isomorphism. Regarding the map γ, note that it follows from the long exact sequence of the triple $(M, M\setminus A_t, M\setminus A_\partial)$, see the Topological LES-Proposition 74.13, that it suffices to show that $\mathrm{H}_i(M\setminus A_t, M\setminus A_\partial; R) = 0$ for all i. We pick $s \in (t,1)$. We see that indeed we have

$$\mathrm{H}_i(M\setminus A_t, M\setminus A_\partial; R) \overset{\cong}{\underset{\text{by the Excision Theorem 74.17, here we excise everything in the complement of } ([0,s)\times\partial M)\cap A}{\longleftarrow}} \mathrm{H}_i(([0,s)\times\partial M)\setminus(K\times[t,s)), ([0,s)\times\partial M)\setminus((0,s)\times K); R) \underset{\text{follows from Corollary 74.16 since } ([0,s)\times\partial M)\setminus((0,s)\times K) \text{ is a deformation retract of } ([0,s)\times\partial M)\setminus([t,s)\times K}{=} 0. \quad \boxplus$$

Now let $\mu, \nu \in \mathrm{H}_n(M, M\setminus A_\partial; R)$ be two lifts of the R-section $\{\alpha_x\}_{x\in M\setminus\partial M}$. With the same arguments as before one can convince oneself easily of the fact that $\delta^{-1}(\gamma(\mu))$ and $\delta^{-1}(\gamma(\nu))$ are lifts of the R-section $\{\alpha_x\}_{x\in \mathrm{D}M}$. By the Homology-Section Theorem 106.10 these two lifts are identical. But then it follows from the claim that also $\mu = \nu$. ■

We conclude this long and tiring chapter with the following lemma that is a generalization of Corollary 106.12.

Lemma 106.31. Let M be an oriented n-dimensional topological manifold and let R be a commutative ring. We suppose that M is equipped with an R-orientation. We use the notation from Theorem 106.30.

(1) Let $K \subset L \subset M$ be compact subsets that are products close to the boundary. We denote by $f_{KL}\colon (M, M\setminus L) \to (M, M\setminus K)$ the inclusion map of pairs. The map $f_{KL*}\colon \mathrm{H}_n(M, M\setminus L) \to \mathrm{H}_n(M, M\setminus K)$ sends α_L^M to α_K^M.

(2) Let U be an open subset of M and let $A \subset U$ be a compact subset that is a product close to the boundary. We use the Topological Manifold-Induced Orientation Lemma 105.17 to view U as an oriented topological manifold. If $i\colon U \to M$ denotes the inclusion map, then $i_*(\alpha_A^U) = \alpha_A^M$.

Proof. The lemma follows easily from the functoriality of homology groups and the uniqueness statement of Theorem 106.30. ■

106.8. **The degree of a map between oriented topological manifolds.** Recall that on page 2222 we used the fundamental class to define the degree of a map between smooth manifolds. Now that we also managed to introduce the fundamental class for topological manifolds we can generalize the earlier definition to the setting of topological manifolds. More precisely, we have the following definition.

Definition. Let $f\colon M \to N$ be a map between two compact oriented connected non-empty n-dimensional topological manifolds. We assume that $f(\partial M) \subset \partial N$. We denote by $\deg(f) \in \mathbb{Z}$ the unique integer with

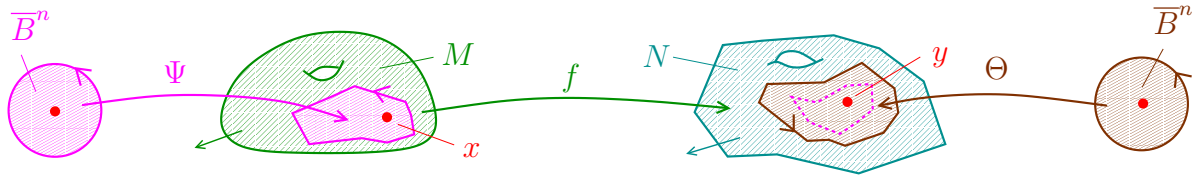
by the Fundamental Class-Corollary 106.4 (3)

$$f_*([M]) \;=\; \deg(f)\cdot[N] \;\in\; \mathrm{H}_n(N,\partial N) \;\overset{\downarrow}{=}\; \mathbb{Z}\cdot[N].$$

since $f(\partial M)\subset \partial N$ we have an induced map $f_*\colon \mathrm{H}_n(M,\partial M)\to \mathrm{H}_n(N,\partial N)$

We refer to $\deg(f)$ as the degree of f.

Remark.



(1) For a map $f\colon S^n\to S^n$ the above degree is, by definition, exactly the same as the degree that we defined on page 1684.
(2) Given a map between *smooth* manifolds it follows from Lemma 106.6 that the above definition of the degree agrees with the definition given on pages 2222.
(3) Given a *smooth* map between closed *smooth manifolds* it follows from Lemma 106.6 and the discussion below that the above definition of the degree agrees with the definition given on page 899.

In Propositions 76.21 and 101.6 we already saw that in some settings we can calculate the "global" degree of a map by "local" degrees. To formulate the analogue in our present setting we need the following straightforward definition.

Definition. Let $f\colon M\to N$ be a map between two oriented n-dimensional topological manifolds and let $x\in M\setminus\partial M$ such that $f(x)\in N\setminus\partial N$. We set $y:=f(x)$. We suppose that there exists an open neighborhood U of x such that $f(z)\neq f(x)$ for every $z\in U\setminus\{x\}$. We pick an embedding $\Psi\colon \overline{B}^n\to U\subset M$ with $\Phi(0)=x$ and we pick an embedding $\Theta\colon \overline{B}^n\to M$ with $\Psi(0)=y$ and with $f(\Psi(\overline{B}^n))\subset\Theta(\overline{B}^n)$. We assume that Ψ and Θ are either both orientation-preserving or they are both orientation-reversing. We define the local degree $\deg(f,x)$ as follows:

$$\deg(f,x) \;:=\; \deg\big((\Theta^{-1}\circ f\circ\Psi)_*\colon \mathrm{H}_n(\overline{B}^n,\overline{B}^n\setminus\{0\})\to \mathrm{H}_n(\overline{B}^n,\overline{B}^n\setminus\{0\})\big).$$

We leave it to the reader to verify that $\deg(f,x)$ is well-defined.

Remark.

(1) It is fairly straightforward to show that for $M=N=S^n$ the above local degree agrees with the definition given on page 1694.
(2) Let $f\colon M\to N$ be a map between two oriented n-dimensional topological manifolds. Let $x\in M\setminus\partial M$ be a point such that f is a local homeomorphism around x. It follows easily from the definitions that

$$\deg(f,x) \;=\; \begin{cases} +1, & \text{if } f \text{ is orientation-preserving at } x\\ -1, & \text{if } f \text{ is orientation-reversing at } x.\end{cases}$$

This observation, together with the Smooth-Topological Orientation Proposition 105.11 implies that for a smooth map $f\colon M\to N$ between smooth manifolds and a point

$x \in M \setminus \partial M$ at which f is a local diffeomorphism the above definition of the local degree agrees with the definition given on page 898.

It follows from the above remark that the following proposition is a generalization of the Local-Global Degree Propositions 76.21 and 101.6.

Proposition 106.32. (Local-Global Degree Proposition) Let $f\colon M \to N$ be a map between two closed oriented connected n-dimensional topological manifolds M and N and let $x \in M$. Let $y \in N$ such that $f^{-1}(y)$ consists of finitely many points $x_1, \dots, x_m$. Then

$$\deg(f\colon M \to N) \;=\; \sum_{i=1}^{m} \deg(f, x_i).$$

Proof of Proposition 106.32. The proof of the proposition is similar to the proofs of Propositions 76.21 and 101.6. Thus, in a vein attempt to keep these notes concise, we will not provide a proof. Instead we hope that the reader will take the baton and carry out the proof. ■

106.9. **Applications.** The results from this chapter makes it possible to read several sections which are placed in the part on simplicial complexes. For example, with the results from this chapter one can now read the following sections:

(1) Section 98.3, in which we calculate the homology groups of lens spaces.
(2) Section 98.4, in which we construct the Poincaré Homology Sphere.
(3) Section 100.4, in which we calculate the homology groups of the connected sum of two closed oriented smooth manifolds.
(4) Section 100.5, in which we calculate the homology groups of a knot complement.

Furthermore, using Lemma 106.6 and a little bit of mental agility one can also read Chapter 101, where we introduce and study the degree of a map between closed oriented connected non-empty smooth manifolds. Finally, Chapter 102, in which we discuss the question, which homology classes can be represented by (sub-) manifolds, is now also accessible to the reader.

Exercises for Chapter 106.

Exercise 106.1. Let M be a connected n-dimensional topological manifold without boundary and let K be a compact subset. Show that there exists an open subset $U \subset M$ that contains K and such that the closure $\overline{U}$ is compact.

Exercise 106.2. Let M be a closed orientable connected non-empty topological manifold of dimension $n \geq 3$. Now we know that $\mathrm{H}_n(M;\mathbb{Z}) \cong \mathbb{Z}$ and that $\mathrm{H}_{n-1}(M;\mathbb{Z})$ is torsion-free. Furthermore we know that $\mathrm{H}_0(M;\mathbb{Z}) \cong \mathbb{Z}$. Can we also say something about the other homology groups? More precisely, are there any restrictions on $\mathrm{H}_{n-2}(M;\mathbb{Z})$ or can any finitely generated abelian group be isomorphic to $\mathrm{H}_{n-2}(M;\mathbb{Z})$ for some such smooth manifold?

Exercise 106.3.

(a) Let M be a compact, connected n-dimensional topological manifold with non-empty boundary. Show that $\mathrm{H}_{n-1}(M;\mathbb{Z}) \cong \mathbb{Z}^k$ for some $k \in \mathbb{N}_0$.

Hint. You can use that we already obtained some results for closed smooth manifolds, in particular we have a good understanding of $\mathrm{H}_{n-1}(\mathrm{D}M;\mathbb{Z})$. You could start with the case that M is orientable and afterwards you could consider the case that M is non-orientable.

(b) Let M be a connected n-dimensional topological manifold. Suppose that M is non-compact. Does it follow that $\mathrm{H}_{n-1}(M;\mathbb{Z})$ is a free abelian group? It suffices to give a short justification for your answer.

Exercise 106.4. Let $X = S^1 \cup \{*\}$ be the topological space that is given by the circle "with two 1's", where the topology is defined in the same way as we defined the topology on the "line with two 0's" on page 122. It is straightforward to see that X is locally homeomorphic to open subsets of $\mathbb{R}$, in fact one can easily find a finite atlas for X. Furthermore we know by the Second Countability Lemma 9.1 (4) that X is second-countable. But X is not a topological manifold since it is not Hausdorff. The argument of Exercise 78.5 shows that $\mathrm{H}_1(X;\mathbb{F}_2) \cong \mathbb{F}_2^2$. This shows that in the proof of the Top-$\mathbb{F}_2$-Homology Theorem 106.2 at some point we must have used that topological manifolds are Hausdorff. Where did we make use of this fact?

Exercise 106.5. Let X be a topological space, let $n \in \mathbb{N}_0$ and let G be an abelian group.

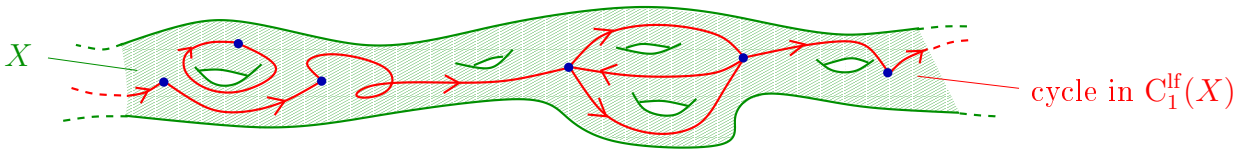
(1) A *locally finite singular n-chain* is a (possibly infinite) sum $\sum_{i\in I} a_i \cdot (\sigma_i \colon \Delta^n \to X)$ with $a_i \in \mathbb{Z}$, such that for every $x \in X$ there exists an open neighborhood U of x such that $\{i \in I \mid \sigma_i(\Delta^n) \cap U \neq \varnothing\}$ is finite. We define $\mathrm{C}_n^{\mathrm{lf}}(X)$ as the abelian group given by all locally finite singular n-chains. Note that the usual boundary map defines in an obvious way a boundary map $\mathrm{C}_n^{\mathrm{lf}}(X) \otimes G \to \mathrm{C}_{n-1}^{\mathrm{lf}}(X) \otimes G$. We define the *$n$-th locally finite homology group* $\mathrm{H}_n^{\mathrm{lf}}(X;G)$ to be the n-th homology of the corresponding chain complex.

(2) We consider the set $\mathcal{K}(X)$ of all compact subsets of X. The set $\mathcal{K}(X)$ together with the relation "$\subset$" defined by inclusion is a directed set since the union of two compact subsets is again compact. Given any two compact subsets $K \subset L$ we get an induced map $\mathrm{H}_n(X, X \setminus L; G) \to \mathrm{H}_n(X, X \setminus K; G)$. These homology groups form an *inverse* system over the directed set $(\mathcal{K}(X), \subset)$ and we can form the inverse limit[1299]

$$\overleftarrow{\mathrm{H}}_n(X;G) := \varprojlim_{K\in\mathcal{K}(X)} \mathrm{H}_n(X, X \setminus K; G).$$

In the following we will see that these two types of homology groups are often naturally isomorphic.

(a) Let *TopPropMap* be the category of topological spaces with proper maps, i.e. the objects are all topological spaces and the morphisms are continuous maps that are proper in the sense of the definition on page 180, i.e. maps such that preimage of compact sets are compact. Show that both homology groups define a covariant functor from *TopPropMap* to the category *AbGroup* of abelian groups.



(b) Give an explicit natural map $\mathrm{H}_n^{\mathrm{lf}}(X;G) \to \overleftarrow{\mathrm{H}}_n(X;G)$ which is the identity for all compact spaces.

[1299] To the best of my knowledge there is no established name for this natural object.

(c) We assume that there exists a nested sequence $K_1 \subset K_2 \subset \dots$ of compact subsets of X such that $X = \bigcup_{i\in\mathbb{N}} \mathring{K}_n$. Show that the natural map $\mathrm{H}_n^{\mathrm{lf}}(X;G) \to \overleftarrow{\mathrm{H}}_n(X;G)$ from (b) is an isomorphism.

(d) Let $k \in \mathbb{N}$. Compute $\mathrm{H}_n^{\mathrm{lf}}(\mathbb{R}^k;\mathbb{Z})$.

Remark. Locally finite homology is discussed in detail in[**HR1996**, p. 30-34] and [**Spa1993**]. Note that statement (c) is [**Spa1993**, Theorem 10.1], also see [**HR1996**, p 34] for a related result. For completeness sake we note that it follows with some effort from [**Bre1997**, Corollary V.12.21 and pages 288-292] that for suitable topological spaces these two homology groups are naturally isomorphic to Borel-Moore homology.

Exercise 106.6. Let M be a connected n-dimensional topological manifold with $\partial M = \varnothing$, let $K \subset M$ be a compact subset and let $x_0 \in K$ be a point.

(a) Show that there exists a *connected* compact subset $L \subset M$ with $K \subset L$.

(b) Show that the map

$$\begin{array}{rcl} \mathrm{Im}(\mathrm{H}_n(M, M\setminus L;\mathbb{Z}) \to \mathrm{H}_n(M, M\setminus K;\mathbb{Z})) & \to & \mathrm{H}_n(M, M\setminus\{x_0\};\mathbb{Z}) \\ [\sigma] & \mapsto & [\sigma] \end{array}$$

is an isomorphism.

Hint. Use Corollary 106.11.

Exercise 106.7. Let M be a connected orientable non-empty n-dimensional topological manifold such that $\partial M = \varnothing$. As in the above Exercise 106.5 we now consider the group $\overleftarrow{\mathrm{H}}_n(M;\mathbb{Z}) := \varprojlim_{K\in\mathcal{K}(M)} \mathrm{H}_n(M, M\setminus K;\mathbb{Z})$. Show that in our situation this group is naturally isomorphic to $\mathbb{Z}$. We refer to the corresponding natural generator as the fundamental class $[M] \in \overleftarrow{\mathrm{H}}_n(M;\mathbb{Z})$.

Hint. Use Exercise 106.6.

Exercise 106.8. Let X be a topological space. Given $\varphi \in \mathrm{H}_k(X;\mathbb{R})$ we define

$$\|\varphi\|_{\mathbb{R}} := \inf\Big\{ \sum_{i=1}^n |r_i| \;\Big|\; \sigma = \underbrace{\sum_{i=1}^n \sigma_i \otimes r_i}_{\text{with } \sigma_i \neq \sigma_j \text{ for } i\neq j} \text{ is a cycle with } [\sigma] = \varphi \in \mathrm{H}_k(X;\mathbb{R}) \Big\}.$$

In the following let M be a closed oriented connected non-empty n-dimensional topological manifold M. Let $[M] \in \mathrm{H}_n(M)$ be the fundamental class and let $i\colon \mathrm{H}_1(M) \to \mathrm{H}_1(M;\mathbb{R})$ be the homomorphism from Lemma 89.7 (1). We define the *simplicial volume of* M as

$$\|M\|_{\mathbb{R}} := \|i_*([M])\| \in \mathbb{R}_{\geq 0}.$$

(a) Show that $\|S^1\|_{\mathbb{R}} = 0$.

(b) Show that $\|(S^1)^2\|_{\mathbb{R}} = 0$.

(c) Let $f\colon M \to N$ be a map between closed oriented connected non-empty n-dimensional topological manifolds. Show that

$$\|N\|_{\mathbb{R}} \leq \frac{1}{\deg(f)} \cdot \|M\|_{\mathbb{R}}$$

where $\deg(f)$ denotes the degree of f as defined on page 2379.

(d) Let M and N be two closed oriented connected non-empty n-dimensional topological manifolds. We suppose that M and N are in fact homotopy equivalent. Show that $\|M\|_{\mathbb{R}} = \|N\|_{\mathbb{R}}$.

(e) Let N be a closed oriented non-empty n-dimensional topological manifold. Furthermore let $p\colon M \to N$ be a d-fold covering. Show that $\|M\|_{\mathbb{R}} = d \cdot \|N\|_{\mathbb{R}}$.

(f) Let M be a compact oriented n-dimensional topological manifold with non-empty connected boundary. Show that $\|M\| \geq \frac{1}{n+1} \cdot \|\partial M\|$.

Remark. For the most part this exercise is the "topological analogue" of Exercise 101.9.

Part XI

Singular Cohomology

107. Chirality

In this section we will take a short break from overly abstract concepts and we study chirality of objects in $\mathbb{R}^3$, knots and topological manifolds. We will run into several questions which will motivate us to develop new tools in the study of topological spaces.

107.1. **Chiral objects.** In physics or chemistry an object X in $\mathbb{R}^3$ is called *amphichiral* (or often short *achiral*) if it agrees with its mirror image, otherwise it is called *chiral*. To make this definition more precise we have to explain what we mean by "mirror image" and what we mean by "agree".
First of all, given a hyperplane $H \subset \mathbb{R}^3$ through the origin we denote by $\rho_H \colon \mathbb{R}^3 \to \mathbb{R}^3$ the reflection in the hyperplane H.[1300] Sometimes in this chapter we will extend ρ_H to a map from $S^3 = \mathbb{R}^3 \cup \{\infty\}$ to itself by setting $\rho_H(\infty) = \infty$.
The following lemma says that any two reflections in a hyperplane through the origin differ by multiplication by a matrix in SO(3).

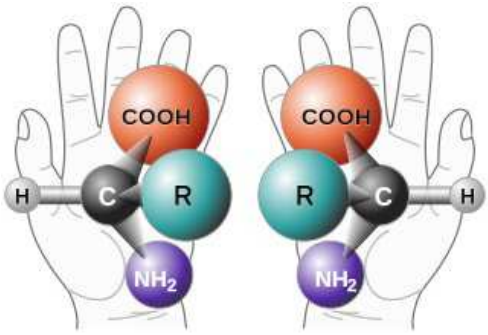
Lemma 107.1. If H and G are two hyperplanes in $\mathbb{R}^3$ through the origin, then there exists a matrix $A \in \mathrm{SO}(3)$ such that for all $v \in \mathbb{R}^3$ we have

$$\rho_G(v) \;=\; A \cdot \rho_H(v).$$

Sketch of proof. With respect to the standard basis of $\mathbb{R}^3$ the maps ρ_G and ρ_H are represented by orthogonal matrices P and Q with determinant -1. The matrix $A = PQ^{-1}$ then lies in SO(3) and for any $v \in \mathbb{R}^3$ we have $\rho_G(v) = Pv = A \cdot Qv = A \cdot \rho_H(v)$. ■

The above discussion leads us to the following definitions.

Definition. Let X be a subset of $\mathbb{R}^3$.



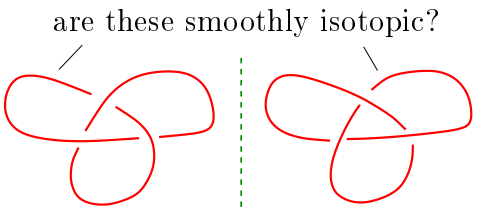
(1) We say another subset Y of $\mathbb{R}^3$ agrees with X if there exists a matrix $A \in \mathrm{SO}(3)$ and a point $P \in \mathbb{R}^3$ such that $X = A \cdot Y + P = \{A \cdot y + P \,|\, y \in Y\}$.
(2) For every hyperplane $H \subset \mathbb{R}^3$ we refer to $\rho_H(X)$ as the mirror image of X.[1301]
(3) We say X is amphichiral if its mirror image agrees with X, otherwise we say X is chiral.

Examples.

(1) Human hands are chiral, indeed, the left-hand does not agree with the right-hand. In fact the term chirality is derived from the Greek word for hand, $\chi\epsilon\iota\rho$.[1302]
(2) Many molecules are chiral, see e.g. the figure below for an example of a chiral molecule.[1303]

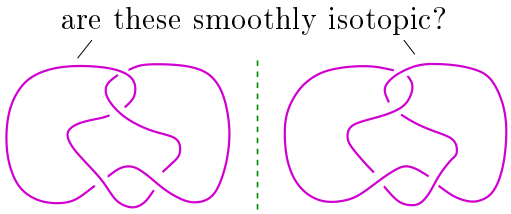
107.2. **Chiral knots.** Now we turn our focus to knots. We recall some of the relevant definitions from pages 1301 and 1315.

[1300] How is the reflection in a hyperplane defined?
[1301] To be precise, the definition of the mirror image depends on the choice of the hyperplane. By Lemma 107.1 reflections in two different hyperplanes differ by multiplication by a matrix in SO(3), i.e. the mirror images with respect to different hyperplanes agree in the above sense.
[1302] The same word is also the etymological root for the German word "Chirurg".
[1303] In fact, how can you show that the molecule is chiral?



source: https://en.wikipedia.org/wiki/Chirality

Definition.



(1) A knot is a 1-dimensional submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to S^1.

(2) Given a knot $K \subset S^3$ the reflection of K in any hyperplane of $\mathbb{R}^4$ is called mirror of K and denoted by K^{mir}. Note that in Exercise 59.1 we showed that, up to a smooth isotopy, the definition of K^{mir} does not depend on the choice of the hyperplane.

Example. In the figure below we show the trefoil and its mirror and we also show the figure-8 knot and its mirror. In both cases the question arises whether the original knot and its mirror are smoothly isotopic.

the trefoil K and its mirror K^{m}

the figure-8 knot J and its mirror J^{m}

Next we recall the following definition from page 1316.

Definition. We say that a knot K in $\mathbb{R}^3$ is amphichiral if it is smoothly isotopic to its mirror image, otherwise we call the knot K chiral.

Example. In the figure on page 1316 we showed that the figure-8 knot J is smoothly isotopic to its mirror image J^*, i.e. the figure-8 knot is amphichiral.

We recall the following question on which so far we have made zero progress.

Question 59.9. Is the trefoil chiral?

The question that naturally arises is, what does this discussion have to do with homology groups? How can we address this question using the tools of algebraic topology? In the following section we will turn Question 59.9 into a question about homology groups.

107.3. Chiral topological manifolds.

Definition. Let M be a compact oriented topological manifold. We say that M is amphichiral if M admits an orientation-reversing self-homeomorphism, otherwise we say that M is chiral.

In the next proposition, which is a variation on Lemma 100.7, we will give several criteria for a self-homeomorphism to be orientation-preserving.

Proposition 107.2. Let M be a compact oriented connected n-dimensional topological manifold and let $f\colon M \to M$ be a homeomorphism. Then the following three statements are equivalent:

(1) The map f is orientation-preserving in the sense of the definition on page 2335.

(2) There exists a point $x \in M \setminus \partial M$ and an open neighborhood U of x, e.g. $U = M$, such that[1304]
$$f_*(\underbrace{\text{orientation at } x}_{\in \mathrm{H}_n(U, U\setminus\{x\};\mathbb{Z})}) = \underbrace{\text{orientation at } f(x)}_{\in \mathrm{H}_n(f(U), f(U)\setminus\{f(x)\};\mathbb{Z})}.$$

(3) We have $f_*([M]) = [M]$.

Suppose M is in fact a smooth manifold and that f is a diffeomorphism. We equip M with the orientation in the sense of Section 25.2 coming from the Smooth-Topological Orientation Proposition 105.11. Then the above are equivalent to the following statement:

(4) The map f is orientation-preserving in the sense of Section 25.2.

Analogously the above statements also hold if in (1) and (4) we replace "orientation-preserving" by "orientation-reversing" and if in (2) and (3) we add a minus sign.

For the most part the proof of Proposition 107.2 boils down to the following lemma which is also useful in its own right.

Lemma 107.3. Let $f\colon M \to N$ be a map between compact oriented connected n-dimensional topological manifolds such that $f(\partial M) \subset \partial N$. Let $x \in M \setminus \partial M$ and let U be an open neighborhood of x with the property that f restricts to a homeomorphism $f\colon U \to f(U)$ and such that $f^{-1}(f(x)) = \{x\}$. Then
$$\begin{aligned}\deg(f\colon M \to N) &= \deg(f_*\colon \mathrm{H}_n(M, M\setminus\{x\};\mathbb{Z}) \to \mathrm{H}_n(N, N\setminus\{f(x)\};\mathbb{Z})\\ &= \deg(f_*\colon \mathrm{H}_n(U, U\setminus\{x\};\mathbb{Z}) \to \mathrm{H}_n(f(U), f(U)\setminus\{f(x)\};\mathbb{Z}).\end{aligned}$$

Proof. Let M and N be compact connected n-dimensional topological manifolds that are equipped with orientations $\{\mu_x\}_{x\in M\setminus\partial M}$ and $\{\nu_x\}_{x\in N\setminus\partial N}$. Furthermore let f, $x \in M \setminus \partial M$ and U as above. We consider the following commutative diagram
$$\begin{array}{ccc}
\mathrm{H}_n(M, \partial M;\mathbb{Z}) & \xrightarrow{\quad f_*\quad} & \mathrm{H}_n(N, \partial N;\mathbb{Z}) \\
\downarrow & & \downarrow \\
\mathrm{H}_n(M, M\setminus\{x\};\mathbb{Z}) & \xrightarrow{\quad f_*\quad} & \mathrm{H}_n(N, N\setminus\{f(x)\};\mathbb{Z}) \\
\uparrow & & \uparrow \\
\mathrm{H}_n(U, U\setminus\{x\};\mathbb{Z}) & \xrightarrow{\quad f_*\quad} & \mathrm{H}_n(f(U), f(U)\setminus\{f(x)\};\mathbb{Z}).
\end{array}$$

[1304] Recall that by the construction of the Topological Manifold-Induced Orientation Lemma 105.17 the orientation on M induces an orientation on any open subset.

We make the following observations:

(1) the top vertical maps are isomorphisms by the Orientation-Top Homology Theorem 106.1,
(2) the bottom vertical maps are isomorphisms by the Excision Theorem 74.18,
(3) it follows from the Fundamental Class-Corollary 106.4 that the vertical maps send the fundamental classes $[M]$ and $[N]$ to the orientations μ_x respectively $\nu_{f(x)}$.

The desired equalities follow easily from these observations.[1305] ■

Now we can also provide a proof for Proposition 107.2.

Sketch of a proof. The equivalence of (1), (2) and (3) follows quite easily from Lemma 107.3. Now suppose M that is in fact a smooth manifold and that f is a diffeomorphism. The equivalence of (2) and (4) is a straightforward consequence of Lemma 105.12 and the Excision Theorem 74.18. Once again we leave it to the reader to fill in the details. ■

Examples. Let $n \in \mathbb{N}_0$.

(1) It follows from the Sphere Degree Lemma 76.11 (6) that the map

$$\begin{array}{rcl} \rho\colon S^n & \to & S^n \\ (x_0, \dots, x_{n-1}, x_n) & \mapsto & (x_0, \dots, x_{n-1}, -x_n), \end{array}$$

i.e. the map that is given by reflection in the $x_n = 0$ hyperplane, is orientation-reversing. This shows that the sphere S^n is amphichiral.

(2) Let M be a closed, oriented topological manifold. It follows from (1) and the naturality of the Künneth Theorem 90.8 for topological spaces that the map

$$\begin{array}{rcl} S^n \times M & \to & S^n \times M \\ (x, P) & \mapsto & (\rho(x), P), \end{array}$$

is orientation-reversing. This shows that the product of the sphere S^n with any closed, oriented topological manifold is amphichiral.

Now we want to relate the notion of amphichiral knots to the notion of amphichiral smooth manifolds. Before we can do so we recall the following definition.

Definition. Let $K \subset \mathbb{R}^3$ be a knot. We pick a tubular neighborhood $\overline{B}^2 \times K$ as provided by the Tubular Neighborhood Theorem **??**. We refer to $X_K := S^3 \setminus (B^2 \times K)$ as the exterior of K.[1306]

The following proposition together with Proposition 107.2 now turns Question 59.9 into a question about topological spaces.

[1305] Where on earth did we use the hypothesis that $f^{-1}(f(x)) = \{x\}$?

[1306] As we pointed out in Lemma 100.16, the exterior X_K is a compact orientable smooth manifold and the diffeomorphism type of X_K as an oriented smooth manifold is well-defined, i.e. it is independent of the choice of the tubular neighborhood.

Proposition 107.4. Let $K \subset \mathbb{R}^3$ be a knot. If K is amphichiral, then the knot exterior X_K is also amphichiral.

Remark. We had just seen in Proposition 107.4 that the exterior of an amphichiral knot is amphichiral. The converse to that statement is also true, i.e. if the exterior of a knot is amphichiral, then the knot is also amphichiral. But this direction is much harder to prove. To the best of my knowledge it follows from a very difficult theorem by Cameron Gordon and John Luecke [**GL1989**, p. 371] from 1989.

Proof. Let $K \subset \mathbb{R}^3$ be an amphichiral knot. By the Tubular Neighborhood Theorem **??** we can pick a tubular neighborhood $\nu K = \overline{B}^2 \times K$. As on page 2213 we consider the knot exterior $X_K := S^3 \setminus (B^2 \times K)$. By Proposition 107.2 it suffices to show that there exists a homeomorphism $f\colon X_K \to X_K$ with $f_*([X_K]) = -[X_K]$.

We denote by ρ the reflection in a hyperplane of $\mathbb{R}^3$. As usual we extend ρ to a self-homeomorphism of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ by setting $\rho(\infty) = \infty$. We write $K^{\mathrm{mir}} = \rho(K)$ and $\nu K^{\mathrm{mir}} = \rho(\nu K)$. By hypothesis there exists a smooth isotopy from K^{mir} to K. By the Isotopy Extension Theorem 36.1 this smooth isotopy extends to a diffeotopy of S^3. This means that we have a smooth map

$$F\colon S^3 \times [0,1] \;\to\; S^3$$

such that $F_0 = \mathrm{id}$, such that each F_t is a diffeomorphism and such that $F_1(K^{\mathrm{mir}}) = K$. We write $\Phi := F_1\colon S^3 \to S^3$. Then $\Phi(\nu K^{\mathrm{mir}})$ is also a tubular neighborhood for K and by Proposition **??** there exists an orientation-preserving diffeomorphism $\Psi\colon S^3 \to S^3$ with $\Psi(\Phi(\nu K^{\mathrm{mir}})) = \nu K$. We write $f := \Psi \circ \Phi \circ \rho$.

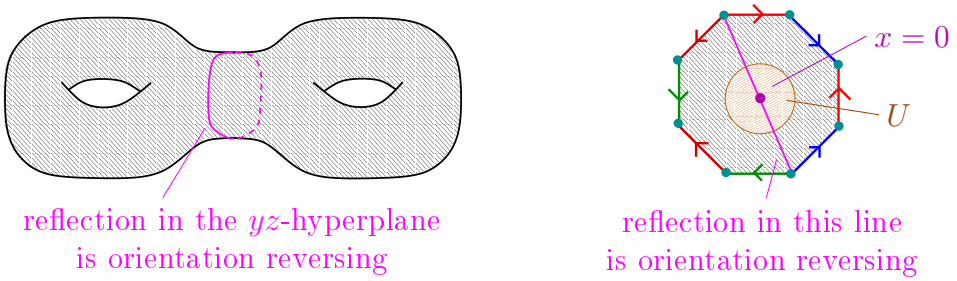
Now we consider the following commutative diagram

$$\begin{array}{ccccccc}
\mathrm{H}_3(S^3) & \xrightarrow{\rho_*} & \mathrm{H}_3(S^3) & \xrightarrow{\Phi_*} & \mathrm{H}_3(S^3) & \xrightarrow{\Psi_*} & \mathrm{H}_3(S^3) \\
\downarrow\cong & & \downarrow\cong & & \downarrow\cong & & \downarrow\cong \\
\mathrm{H}_3(S^3, \nu K) & \xrightarrow{\rho_*} & \mathrm{H}_3(S^3, \nu K^{\mathrm{mir}}) & \xrightarrow{\Phi_*} & \mathrm{H}_3(S^3, \Phi(\nu K^{\mathrm{mir}})) & \xrightarrow{\Psi_*} & \mathrm{H}_3(S^3, \nu K) \\
\uparrow\cong & & \uparrow\cong & & \uparrow\cong & & \uparrow\cong \\
\mathrm{H}_3(X_K, \partial X_K) & \xrightarrow{\rho_*} & \mathrm{H}_3(X_{K^{\mathrm{mir}}}, \partial X_{K^{\mathrm{mir}}}) & \xrightarrow{\Phi_*} & \mathrm{H}_3(\Phi(X_{K^{\mathrm{mir}}}), \Phi(\partial X_{K^{\mathrm{mir}}})) & \xrightarrow{\Psi_*} & \mathrm{H}_3(X_K, \partial X_K).
\end{array}$$

$$\overset{}{\underset{f_*=(\Psi\circ\Phi\circ\rho)_*}{\curvearrowright}}$$

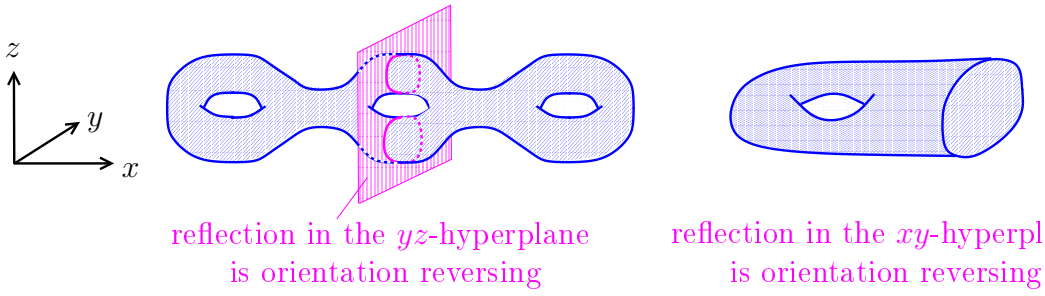
Here the upper left vertical map is an isomorphism by the long exact sequence of the pair $(S^3, \nu K)$ and the fact that $\mathrm{H}_i(\nu K) = 0$ for $i = 2, 3$ since $\nu K = K \times B^2$ is homotopy equivalent to S^1. Exactly the same argument shows that in fact all upper vertical maps are isomorphisms. The lower vertical maps are induced by the inclusion of pairs of topological spaces. All of them are isomorphisms by the Excision Theorem for Smooth Manifolds 75.10.

By Proposition 107.2 we are done once we have shown that the composition of three bottom horizontal maps is given by multiplication by -1. By the commutative diagram it suffices to prove the analogous statement for the composition of the top three horizontal maps. It follows from the Sphere Degree Lemma 76.11 (6) that the top-left horizontal map is given by multiplication by -1. It is a consequence of the Homotopic Maps-and-Homology Proposition 73.6 that the top-middle horizontal map is the identity, since Φ is homotopic



to the identity. Finally using Proposition 107.2 we see that the top-right horizontal map is the identity since Ψ is orientation-preserving. ■

Now we continue with our discussion of examples of amphichiral smooth manifolds.



Examples.

(1) We had just seen on page 2389 that topological manifolds of the type $S^n \times M$ are amphichiral. It follows that the torus $S^1 \times S^1$ is amphichiral.

(2) The surface of genus 2 is amphichiral. Pictorially an orientation-reversing self-homeomorphism is given by "reflection in the yz-plane", see the figure below. In the "octagon-picture" an orientation-reversing self-homeomorphism is given by the reflection f in the line illustrated in the figure below. It follows easily from Proposition 107.2 applied to the point $x = 0$ and U an open disk around x together with Lemma 105.2 that the map f is indeed orientation-reversing.

(3) All other compact oriented 2-dimensional smooth manifolds are also amphichiral. We show some of the orientation-reversing maps in the figure below. In Exercise 107.2 we will discuss how these maps can be described rigorously.

(4) Example (2) can also be generalized as follows: if M is a compact oriented topological manifold, then its double $\mathrm{D}M = (M \sqcup M')/\sim$ is amphichiral. Indeed, the map $f\colon \mathrm{D}M \to \mathrm{D}M$ that swaps the two copies of M is orientation-reversing. This follows immediately from the definition of the orientation of $\mathrm{D}M$ that we gave in the Double-Orientability Lemma 105.18.

The long list of examples of amphichiral smooth manifolds raises the following question.

Question 107.5. Are there compact oriented topological manifolds that are chiral?

We end this chapter with a short discussion of lens spaces. We recall the following definition.

Definition. Let $p \in \mathbb{N}$ and let $q \in \mathbb{N}$ be coprime to p. On page 1075 we defined the lens space

$$L(p,q) := S^3/\mathbb{Z}_p = \big\{(z_1,z_2) \in \mathbb{C}^2 \,\big|\, |z_1|^2 + |z_2|^2 = 1\big\}/(z_1,z_2) \sim (e^{2\pi \mathrm{i}/p} \cdot z_1, e^{2\pi \mathrm{i} q/p} \cdot z_2).$$

Furthermore, on page 1075 we had equipped $L(p,q)$ with the orientation which turns the natural projection $S^3 \to L(p,q)$ into an orientation-preserving map.

Now let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. In the Lens Spaces-Diffeomorphisms Lemma 48.6 we showed that if $q \equiv \pm r^{\pm 1} \bmod p$, then $L(p,q)$ and $L(p,r)$ are diffeomorphic.[1307] The following lemma is now a slight refinement of the Lens Spaces-Diffeomorphisms Lemma 48.6.

Lemma 107.6. Let $p \in \mathbb{N}$ and let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$.

(1) In the case that $q \equiv r^{\pm 1} \bmod p$ there exists an orientation-preserving diffeomorphism $L(p,q) \to L(p,r)$.
(2) On the other hand, if $q \equiv -r^{\pm 1} \bmod p$, then there exists an orientation-reversing diffeomorphism $L(p,q) \to L(p,r)$.

Proof. Let $p \in \mathbb{N}$ and let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. We suppose that $q \equiv \pm r^{\pm 1} \bmod p$. As in the proof of the Lens Spaces-Diffeomorphisms Lemma 48.6 we define a diffeomorphism

as follows:

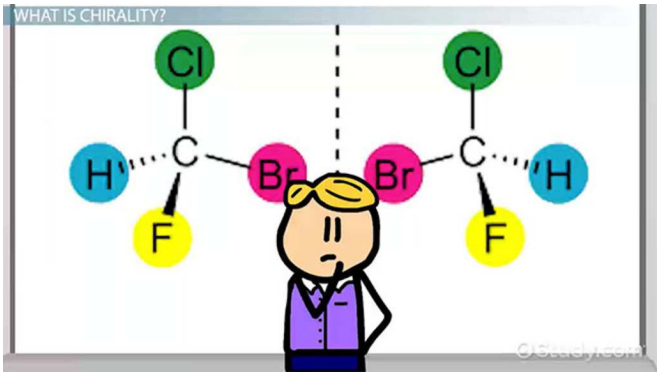
$$\begin{array}{lll} & \Phi\colon S^3 & \to \quad S^3 \\ \text{Case 1: } q \equiv r \bmod p. & (z_1,z_2) & \mapsto \quad (z_1,z_2) \\ \text{Case 2: } q \equiv -r \bmod p. & (z_1,z_2) & \mapsto \quad (z_1,\overline{z_2}) \\ \text{Case 3: } q \equiv r^{-1} \bmod p. & (z_1,z_2) & \mapsto \quad (z_2,z_1) \\ \text{Case 4: } q \equiv -r^{-1} \bmod p. & (z_1,z_2) & \mapsto \quad (z_2,\overline{z_1}) \end{array}$$

In all four cases it is straightforward to verify that the map descends to a diffeomorphism $L(p,q) \to L(p,r)$. It follows fairly easily from the Sphere Degree Lemma 76.11 and Proposition 107.2 that the diffeomorphism Φ is orientation-preserving in cases 1 and 3 and that it is orientation-reversing in cases 2 and 4.[1308] The lemma now follows from the fact that the projections $S^3 \to L(p,q)$ and $S^3 \to L(p,r)$ are orientation-preserving. ∎

Example. Note that $-2^{-1} \equiv -3 \equiv 2 \bmod 5$. Thus we obtain from Lemma 107.6 that there exists an orientation-reversing diffeomorphism $L(5,2) \to L(5,2)$, i.e. the lens space $L(5,2)$ is amphichiral.

The argument of the previous example does not work for the lens space $L(3,1)$. So the following question arises:

Question 107.7. Is the lens space $L(3,1)$ chiral?



With our present knowledge we are not able to answer Questions 59.9, 107.5 and 107.7. The key to answering these three questions will be the cohomology groups that we introduce in Chapter 108.

[1307] We still don't know whether the converse holds.

[1308] For example in case 3 the map is given by $(x_1,x_2,x_3,x_4) \mapsto (x_3,x_4,x_1,x_2)$ which is the composition of two reflections in hyperplanes, namely in the $x_1 = x_3$ and the $x_2 = x_4$ hyperplane.

Exercises for Chapter 107.

Exercise 107.1. Why is the molecule shown in the figure below chiral? How can you show rigorously that the two molecules left and right cannot be turned into one another using a translation and a matrix in SO(3)?

Exercise 107.2.

(a) Give a rigorous proof for the statement that the surface of genus 3 is amphichiral. More precisely, give a precise description of the surface of genus 3 (e.g. as a dodecagon with appropriate identifications) and indicate carefully an orientation-reversing self-homeomorphism.

(b) Do the same exercise for the genus 2 surface with two open disks removed.

Exercise 107.3. Which connected 1-dimensional topological manifolds are chiral?
Remark. In Exercise 43.16 we studied the 2-dimensional case.

108. The cohomology groups of a topological space

In this chapter we will introduce the cohomology groups $\mathrm{H}^k(X;G)$ of a topological space together with a choice of an abelian group G. These study of the cohomology will keep us busy for a very long time. For many mathematicians it takes a long time till they feel fully comfortable with cohomology group since elements of cohomology groups are much less visual than elements of homology groups. Perhaps, before we embark on our new adventure it is good quote John von Neumann who said

"In mathematics you don't understand things. You just get used to them."

108.1. The Hom-functor.

We start out with the following obvious notation.

Notation. Given a group A and an abelian group G we write

$$\mathrm{Hom}(A,G) \;=\; \{\text{all group homomorphisms } A \to G\}.$$

The set of homomorphisms $\mathrm{Hom}(A,G)$ has the structure of an abelian group with the sum of two homomorphisms $\varphi,\psi\colon A\to G$ given by the group homomorphism that is defined by $(\varphi+\psi)(a) := \varphi(a)+\psi(a)$.

Example. We leave it to the reader to provide a proof for the statement that for any $n\in\mathbb{N}$ and any abelian group G we have a natural isomorphism $\mathrm{Hom}(\mathbb{Z}_n,G)\cong\ker(G\xrightarrow{\cdot n}G)$. Note that this implies in particular that for any $m\in\mathbb{N}$ we have $\mathrm{Hom}(\mathbb{Z}_n,\mathbb{Z}_m)\cong\mathbb{Z}_{\gcd(n,m)}$.

On several occasions we will implicitly and explicitly use the following lemma which is an immediate consequence of Lemma 51.1.

Lemma 108.1. Let G be an abelian group. If S is a non-empty set, then the homomorphism[1309] [1310] [1311]

$$\begin{array}{rcl} \mathrm{Hom}(\mathbb{Z}^{(S)},G) & \to & \{\text{all maps from the set } S \text{ to } G\} \\ (\varphi\colon \mathbb{Z}^{(S)}\to G) & \mapsto & \begin{pmatrix} S & \to & G \\ s & \mapsto & \varphi(s) \end{pmatrix} \end{array}$$

is an isomorphism. In particular the map

$$\begin{array}{rcl} \mathrm{Hom}(\mathbb{Z},G) & \to & G \\ \varphi & \mapsto & \varphi(1) \end{array}$$

is an isomorphism.

[1309] Recall that on page 1147, given a non-empty set S we defined

$$\mathbb{Z}^S \;:=\; \text{all maps from } S \text{ to } \mathbb{Z}.$$

and we defined the free abelian group generated by S to be the subgroup

$$\mathbb{Z}^{(S)} \;:=\; \text{all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s\in S.$$

Following the notation introduced on page 1147 we view each $s\in S$ as an element in $\mathbb{Z}^{(S)}$.

[1310] Why do we write $\mathbb{Z}^{(S)}$ in the lemma? Should it not be $\mathbb{Z}^S$?

[1311] Note that the group structure on G turns both sides of the lemma into a group, so the given map clearly respects this group structure, i.e. the given map is a homomorphism.

Definition. Let G be an abelian group and let $f\colon A \to B$ be a group homomorphism. Then f induces a homomorphism

$$\begin{array}{rcl} f^*\colon \operatorname{Hom}(B,G) & \to & \operatorname{Hom}(A,G) \\ (\varphi\colon B \to G) & \mapsto & \begin{pmatrix} A & \to & G \\ a & \mapsto & \varphi(f(a)) \end{pmatrix}. \end{array}$$

Example. Let G be an abelian group.

(1) If A is a subgroup of a group B and if $i\colon A \to B$ is the inclusion map, then for each homomorphism $\varphi\colon B \to G$ the homomorphism $i^*\varphi\colon A \to G$ is just the restriction of φ to $A \subset B$.
(2) If S is a subset of a set T, then we have a natural inclusion $i\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ and it follows from Lemma 108.1 that the map $i^*\colon \operatorname{Hom}(\mathbb{Z}^{(T)}, G) \to \operatorname{Hom}(\mathbb{Z}^{(S)}, G)$ is an epimorphism. Indeed, we just extend the map $S \to G$ to a map $T \to G$ by assigning the trivial element in G to all elements in $T \setminus S$.

It follows immediately from the definitions that

$$(\mathrm{id}_A)_* = \mathrm{id}_{\operatorname{Hom}(A,G)}, \quad \text{for all groups } A$$

and

$$(g \circ f)^* = f^* \circ g^* \quad \text{for all homomorphisms } f\colon A \to B \text{ and } g\colon B \to C.$$

Put differently, given an abelian group G the maps

$$\begin{array}{rcl} A & \mapsto & \operatorname{Hom}(A,G) \\ (f\colon A \to B) & \mapsto & (f^*\colon \operatorname{Hom}(B,G) \to \operatorname{Hom}(A,G)) \end{array}$$

define a *contravariant* functor from the category of groups to the category of abelian groups.

Remark. If R is a commutative ring, for example if $R = \mathbb{Z}_n, R = \mathbb{Z}, R = \mathbb{Q}$ or $R = \mathbb{R}$, then for any group C the set of homomorphisms $\operatorname{Hom}(C,R)$ forms an R-module in an obvious way. More precisely, given a homomorphism $\varphi\colon C \to R$ and $r \in R$ we define $r\varphi$ to be the homomorphism given by $c \mapsto r \cdot \varphi(c)$. Now we see easily that the above maps $A \mapsto \operatorname{Hom}(A,R)$ and $f \mapsto f^*$ define a contravariant functor from the category of groups to the category of R-modules.

The following lemma might be familiar from linear algebra. We refer to [**Rot2009**, Theorem 2.32(i)] for more details.

Lemma 108.2. Let $\{A_i\}_{i\in I}$ be a family of groups and let G be an abelian group. Then the map

$$\begin{array}{rcl} \operatorname{Hom}\left(\bigoplus_{i\in I} A_i, G\right) & \to & \prod_{i\in I} \operatorname{Hom}(A_i,G) \\ f & \mapsto & \prod_{i\in I} f|_{A_i} \end{array}$$

is an isomorphism.

The following rather technical lemma will be used later on.

Lemma 108.3. Let $\{\{A_i\}_{i\in\mathbb{N}}, \{\varphi_{ij}\colon A_i \to A_j\}_{i\le j}\}$ be a direct system of groups and let G be an abelian group. Then

$$\{\{\operatorname{Hom}(A_i,G)\}_{i\in\mathbb{N}}, \{\varphi_{ij}^*\colon \operatorname{Hom}(A_j,G) \to \operatorname{Hom}(A_i,G)\}_{i\le j}\}$$

is an inverse system of abelian groups (or modules if G is a commutative ring), and we have a natural isomorphism

$$\operatorname{Hom}\left(\varinjlim A_i, G\right) \xrightarrow{\cong} \varprojlim \operatorname{Hom}(A_i, G)$$

of abelian groups (or modules if G is a commutative ring).

Proof. As so often for arguments regarding limits, the proof follows mostly from unraveling the definitions. We refer to [**Rot2009**, Proposition 5.26] for more details. ■

We continue with the following lemma which we will use on many occasions.

Lemma 108.4. Let

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of abelian groups and let G be an abelian group. If C is free abelian, then the dual sequence

$$0 \to \operatorname{Hom}(C, G) \xrightarrow{p^*} \operatorname{Hom}(B, G) \xrightarrow{i^*} \operatorname{Hom}(A, G) \to 0$$

is also exact.

Proof. It follows from the hypothesis that C is a free abelian and from Lemma 78.1 that the initial short exact sequence splits. But this means that, according to Splitting Lemma 78.2, that there exists an isomorphism $\Phi\colon B \to A \oplus C$ such that the following diagram commutes:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & A & \xrightarrow{\quad i \quad} & B & \xrightarrow{\quad p \quad} & C & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle \cong}{\scriptstyle \Phi} & & \downarrow{\scriptstyle =} & & \\
0 & \longrightarrow & A & \xrightarrow{a \mapsto (a,0)} & A \oplus C & \xrightarrow{(a,c) \mapsto c} & C & \longrightarrow & 0.
\end{array}$$

By applying the contravariant $\operatorname{Hom}(-, G)$ functor we obtain the upper half of the following commutative diagram:

$$\begin{array}{ccccccccc}
0 & \longleftarrow & \operatorname{Hom}(A,G) & \xleftarrow{\quad i^* \quad} & \operatorname{Hom}(B,G) & \xleftarrow{\quad p^* \quad} & \operatorname{Hom}(C,G) & \longleftarrow & 0 \\
 & & \uparrow{\scriptstyle =} & & \uparrow{\scriptstyle \cong}{\scriptstyle \Phi^*} & & \uparrow{\scriptstyle =} & & \\
0 & \longleftarrow & \operatorname{Hom}(A,G) & \xleftarrow{(a \mapsto (a,0))^*} & \operatorname{Hom}(A \oplus C, G) & \xleftarrow{((a,c) \mapsto c)^*} & \operatorname{Hom}(C,G) & \longleftarrow & 0 \\
 & & \uparrow{\scriptstyle =} & & \uparrow{\scriptstyle (f \oplus) \mapsto (a \oplus c \mapsto f(a) + g(c))} & & \uparrow{\scriptstyle =} & & \\
0 & \longleftarrow & \operatorname{Hom}(A,G) & \xleftarrow{f \oplus g \mapsto f} & \operatorname{Hom}(A,G) \oplus \operatorname{Hom}(C,G) & \xleftarrow{g \mapsto 0 \oplus g} & \operatorname{Hom}(C,G) & \longleftarrow & 0.
\end{array}$$

One can easily verify that the lower half of the diagram commutes. Furthermore it is evident that the bottom sequence is exact. Finally it is straightforward to see that the vertical maps are isomorphisms we obtain that the upper sequence is also exact. But that is exactly what we wanted to prove. ■

108.2. Cochain complexes.

Now we introduce the notion of a cochain complex and of its cohomology groups. A cochain complex is exactly the same as a chain complex except that the boundary map now increases the degree by one instead of lowering it by one.

Definition.

(1) A cochain complex is a sequence

$$\leftarrow D^n \xleftarrow{\delta_{n-1}} D^{n-1} \xleftarrow{\delta_{n-2}} \dots \xleftarrow{\delta_1} D^1 \xleftarrow{\delta_0} D^0 \leftarrow 0$$

of maps between abelian groups such that for all $i \in \mathbb{N}_0$ we have $\delta_{i+1} \circ \delta_i = 0$. We refer to the maps δ_* as coboundary maps.

(2) We define the n-th cohomology group of a cochain complex (D^*, δ_*) to be

$$\mathrm{H}^n(D) \ := \ \frac{\ker(\delta_n \colon D^n \to D^{n+1})}{\mathrm{im}(\delta_{n-1} \colon D^{n-1} \to D^n)}.$$

Example. In case the reader has seen differential forms already we can give an example. Given a smooth manifold M and given $n \in \mathbb{N}_0$ we write

$$\Omega^n(M) \ := \ \{\text{all smooth } n\text{-forms on } M\}.$$

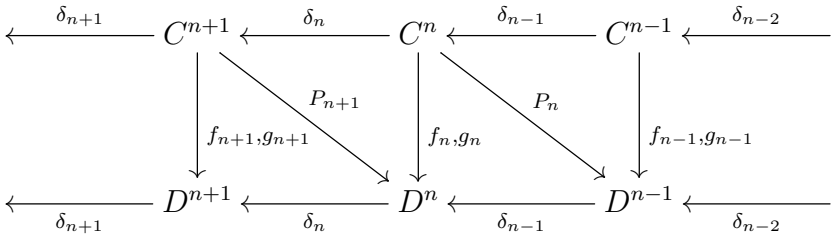
On page **??** we introduced the differentials $d_n \colon \Omega^n(M) \to \Omega^{n+1}(M)$. By the Differentials-on-Smooth Manifolds Proposition **??** we now obtain a cochain complex. The corresponding cohomology groups are called the de Rham cohomology groups of M. We studied this example in great detail in Chapter **??**.

Now we will see that most of the definitions and algebraic results for chain complexes can be generalized almost verbatim to cochain complexes.

Definition.

(1) A cochain map $f \colon C^* \to D^*$ between two cochain complexes consists of a family $\{f_n \colon \mathrm{C}^n \to D^n\}_{n \in \mathbb{N}_0}$ of maps that commute with the coboundary maps, i.e. such that for all $n \in \mathbb{N}_0$ we have

$$\underset{\delta_n \colon D^n \to D^{n+1}}{\delta_n} \circ f_n \ = \ f_{n+1} \circ \underset{\delta_n \colon \mathrm{C}^n \to C^{n+1}}{\delta_n} \colon \mathrm{C}^n \ \to \ D^{n+1}.$$



(2) Let $f, g \colon C^* \to D^*$ be two cochain maps between two cochain complexes C^* and D^*. A cochain homotopy $P = \{P_n\}_{n \in \mathbb{N}_0}$ between the cochain maps f and g consists of a family $\{P_n \colon \mathrm{C}^n \to D^{n-1}\}_{n \in \mathbb{N}_0}$ of maps such that for each $n \in \mathbb{N}_0$ we have

$$\delta_{n-1} \circ P_n + P_{n+1} \circ \delta_n \ = \ f_n - g_n.$$

If there exists a cochain homotopy between cochain maps f and g, then we say that f and g are cochain homotopic.

(3) A cochain map $f \colon C^* \to D^*$ between two cochain complexes C^* and D^* is called a cochain homotopy equivalence if there exists a cochain map $g \colon D^* \to C^*$ such that $f \circ g$ is cochain homotopic to id_{C^*} and $g \circ f$ is cochain homotopy to id_{D^*}.

Remark. For orientation we summarize in the following diagram all objects arising in the definition of a cochain homotopy:

The statements of the next lemma surely do not come as much of a surprise.

Lemma 108.5. (Cochain Map Lemma)

(1) If $f\colon C^* \to D^*$ is a cochain map between cochain complexes C^* and D^*, then the map
$$\begin{array}{rcl} f_*\colon \mathrm{H}^n(C) & \to & \mathrm{H}^n(D) \\ [c] & \mapsto & [f_n(c)] \end{array}$$
is well-defined.

(2) Two cochain maps that are cochain homotopic induce the same map on cohomology groups.

(3) Every cochain homotopy equivalence induces an isomorphism of cohomology groups.

(4) Cochain complexes together with the cochain maps form a category, called the category of cochain complexes.

Proof. The first statement is proved the same way as Lemma 72.7 and the second statement is proved the same way as Lemma 73.2. The proof of the third statement is basically the same as the proof of Corollary 73.4. Finally the last statement follows immediately from the definitions. ■

Remark. Let C^* and D^* be cochain complexes. On a few rare occasions we will need to deal with the following slight generalization of a cochain map. A *generalized cochain maps* is a family $\{f_n\colon \mathrm{C}^n \to D^n\}_{n\in\mathbb{N}_0}$ of maps that commute with the coboundary maps up to sign, i.e. such that for every $n \in \mathbb{N}_0$ there exists an $\epsilon \in \{-1, 1\}$ such that $\delta_n \circ f_n = f_{n+1} \circ \delta_n$. One can easily verify that the conclusion of the Cochain Map Lemma 108.5 (1) also holds for generalized cochain maps.

One of the most important algebraic constructions in homology theory was that we could associate to a short exact sequence of chain complexes a long exact sequence of homology groups. We have an almost identical construction for short exact sequences of cochain complexes and their cohomology groups. We will discuss this construction in detail:

Definition. Let
$$0 \to C^* \xrightarrow{f} B^* \xrightarrow{g} A^* \to 0$$
be a short exact sequence of cochain complexes. In particular for each $n \in \mathbb{N}_0$ we have a commutative diagram
$$\begin{array}{ccccccccc} 0 & \longrightarrow & C^{n+1} & \xrightarrow{f_{n+1}} & B^{n+1} & \xrightarrow{g_{n+1}} & A^{n+1} & \longrightarrow & 0 \\ & & \uparrow{\scriptstyle \delta_n} & & \uparrow{\scriptstyle \delta_n} & & \uparrow{\scriptstyle \delta_n} & & \\ 0 & \longrightarrow & C^n & \xrightarrow{f_n} & B^n & \xrightarrow{g_n} & A^n & \longrightarrow & 0 \end{array}$$

where the horizontal sequences are exact. Now we will define a connecting homomorphism

$$\delta\colon \mathrm{H}^n(A) \to \mathrm{H}^{n+1}(C).$$

The definition is almost verbatim the same as the definition on page 1620 of the connecting homomorphism in homology. More precisely, we perform the following steps:

(1) Let $z \in \mathrm{H}^n(A)$.
(2) We pick $\alpha \in A^n$ with $z = [\alpha]$.
(3) By the surjectivity of g_n we have $\alpha = g_n(\beta)$ for some $\beta \in B^n$.
(4) From the commutativity of the diagram and the exactness of the horizontal sequences we see that $\delta_n(\beta) = f_{n+1}(\gamma)$ for some uniquely determined $\gamma \in C^{n+1}$.
(5) We put $\delta_n(z) := [\gamma] \in \mathrm{H}^{n+1}(C)$.

The following proposition is now the obvious analogue of the Connecting Homomorphism Lemma 74.8 and the LES Proposition 74.9. We leave it to the reader to make the necessary changes to the proof.

Proposition 108.6. (Connecting Homomorphism Proposition)

(1) The connecting homomorphisms are well-defined and they are indeed homomorphisms.[1312]
(2) The connecting homomorphisms are natural in the sense that commuting diagrams of short exact sequences of cochain complexes give rise to commuting diagrams of cohomology groups involving the connecting homomorphisms.
(3) If

$$0 \to C^* \xrightarrow{f} B^* \xrightarrow{g} A^* \to 0$$

is a short exact sequence of cochain complexes, then

$$\cdots \to \mathrm{H}^n(C) \xrightarrow{f_*} \mathrm{H}^n(B) \xrightarrow{g_*} \mathrm{H}^n(A) \xrightarrow{\delta} \mathrm{H}^{n+1}(C) \xrightarrow{f_*} \mathrm{H}^{n+1}(B) \xrightarrow{g_*} \dots$$

forms an exact sequence.

Finally the following lemma says that cohomology commutes with direct sums and direct products. The proof of the lemma is identical to the proof of Lemma 72.13 that we did not give.

Lemma 108.7. If $\{C_a\}_{a\in A}$ is a family of cochain complexes, then the family of inclusion maps $C_a \to \bigoplus_{a\in A} C_a$, $a \in A$, and $C_a \to \prod_{a\in A} C_a$, $a \in A$, induce isomorphisms

$$\bigoplus_{a\in A} \mathrm{H}^n(C_a) \xrightarrow{\cong} \mathrm{H}^n\Big(\bigoplus_{a\in A} C_a\Big) \quad \text{and} \quad \prod_{a\in A} \mathrm{H}^n(C_a) \xrightarrow{\cong} \mathrm{H}^n\Big(\prod_{a\in A} C_a\Big).$$

108.3. **Dual cochain complexes.** Now we will present the arguably most important source of cochain complex.

Definition. Let

$$(C_*, \partial_*)\colon \quad \to C_{n+1} \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} \dots \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \to 0$$

[1312] Furthermore, if the cochain complexes are cochain complexes over a commutative ring R, then the connecting homomorphism is in fact an R-module homomorphism.

be a chain complex and let G be an abelian group. For each $n \in \mathbb{N}_0$ we write

$$\delta_n \;:=\; \partial_{n+1}^*\colon \operatorname{Hom}(C_n, G) \;\to\; \operatorname{Hom}(C_{n+1}, G).$$

We obtain the following cochain complex[1313]

$$\leftarrow \operatorname{Hom}(C_{n+1}, G) \xleftarrow{\delta_n} \operatorname{Hom}(C_n, G) \xleftarrow{\delta_{n-1}} \ldots \xleftarrow{\delta_1} \operatorname{Hom}(C_1, G) \xleftarrow{\delta_0} \operatorname{Hom}(C_0, G) \leftarrow 0.$$

We refer to it as cochain complex dual to (C_*, ∂_*) and we denote it by $\operatorname{Hom}(C_*, G)$. We define the n-th cohomology group of the chain complex (C_*, ∂_*) with G-coefficients as the cohomology of the cochain complex $(\operatorname{Hom}(C_*, G), \delta_*)$, i.e. we define

$$\mathrm{H}^n(C; G) \;:=\; \frac{\ker(\delta_n\colon \operatorname{Hom}(C_n, G) \to \operatorname{Hom}(C_{n+1}, G))}{\operatorname{im}(\delta_{n-1}\colon \operatorname{Hom}(C_{n-1}, G) \to \operatorname{Hom}(C_n, G))}.$$

Remark.

(1) We had just defined $\delta_n := \partial_{n+1}^*$, i.e. the coboundary map in the cochain complex is the dual of the boundary map in the chain complex. This is the same definition that is used in most books on algebraic topology, see e.g. [**Mun1984**, p. 251] or [**Hat2002**, p. 189]. In the book by Bredon [**Bre1993**, p. 321] the coboundary is defined as $\delta_n := (-1)^{n+1} \cdot \partial_{n+1}^*$.

The different conventions do not affect the definition of the cohomology groups, but they will affect the sign conventions in some formulas later on. In particular if one cites results from other books one needs to be careful about the sign conventions used.

(2) If R is a commutative ring and if (C_*, ∂_*) is a chain complex, then it follows immediately from the remark on page 2395 that the corresponding cohomology groups $\mathrm{H}^n(C; R)$ come naturally with the structure of R-modules.

Many of the statements about chain complexes and their homology groups hold in a slightly modified version also for cohomology groups. For example we have the following purely algebraic lemma.

Lemma 108.8. (Dual Cochain Map Lemma) Let G be an abelian group.

(1) Let $f = \{f_n\colon C_n \to D_n\}_{n\in\mathbb{N}_0}$ be a chain map between chain complexes C_* and D_*, then for each $n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} f^*\colon \operatorname{Hom}(D_n, G) & \to & \operatorname{Hom}(C_n, G) \\ (\varphi\colon D_n \to G) & \mapsto & \big(\underbrace{C_n \xrightarrow{f_n} D_n \xrightarrow{\varphi} G}_{=\varphi\circ f_n = f_n^*\varphi}\big) \end{array}$$

is a cochain map, in particular it induces a well-defined map

$$f^*\colon \mathrm{H}^n(D; G) \;\to\; \mathrm{H}^n(C; G).$$

(2) For each $n \in \mathbb{N}_0$ the maps

$$C_* \;\mapsto\; \mathrm{H}^n(C; G) \quad \text{and} \quad f \;\mapsto\; f^*$$

[1313] It follows the functoriality property of $\operatorname{Hom}(-, G)$ that $\delta_n \circ \delta_{n-1} = \partial_{n+1}^* \circ \partial_n^* = (\partial_n \circ \partial_{n+1})^* = 0$, i.e. this is indeed a cochain complex.

define a *contravariant* functor from the category $\mathcal{ChCplx}$ of chain complexes to the category $\mathcal{AbGroup}$ of abelian groups. (If G is a commutative ring, then this is in fact a functor to the category of G-modules.)

(3) Let $f, g\colon C_* \to D_*$ be two chain maps. If they are chain homotopic, then the induced cochain maps $f^*, g^*\colon \mathrm{Hom}(D_*, G) \to \mathrm{Hom}(C_*, G)$ are cochain homotopic and therefore the induced maps $f^*, g^*\colon \mathrm{H}^n(D; G) \to \mathrm{H}^n(C, G)$ are identical.

(4) If $f_*\colon C_* \to D_*$ is a chain homotopy equivalence, then for every $n \in \mathbb{N}_0$ the induced maps $f^*\colon \mathrm{H}^n(D; G) \to \mathrm{H}^n(C; G)$ are isomorphisms.

Proof.

(1) Let $f = \{f_n\colon C_n \to D_n\}_{n\in\mathbb{N}_0}$ be a chain map. This means that for each $n \in \mathbb{N}_0$ we have

$$f_{n-1} \circ \partial_n \;=\; \partial_n \circ f_n$$

which implies by the fact that $A \mapsto \mathrm{Hom}(A, G)$ is a *contravariant* functor that

$$\underbrace{\partial_n^*}_{=\delta_{n-1}} \circ f_{n-1}^* \;=\; f_n^* \circ \underbrace{\partial_n^*}_{=\delta_{n-1}}.$$

We have thus shown that f^* is a cochain map. The second statement follows immediately from the Cochain Map Lemma 108.5.

(2) This statement follows easily from the definitions.

(3) Let $\{P_n\colon C_n \to D_{n+1}\}_{n\in\mathbb{N}_0}$ be a chain homotopy $P = \{P_n\}_{n\in\mathbb{N}_0}$ between f and g. Recall that this means that for each $n \in \mathbb{N}_0$ we have

$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; f_n - g_n.$$

We set $Q_n := P_{n-1}^*\colon \mathrm{Hom}(D_n, G) \to \mathrm{Hom}(C_{n-1}, G)$. It follows again from the fact that $A \mapsto \mathrm{Hom}(A, G)$ is a *contravariant* functor that

$$\underbrace{P_n^*}_{=Q_{n+1}} \circ \underbrace{\partial_{n+1}^*}_{=\delta_n} + \underbrace{\partial_n^*}_{=\delta_{n-1}} \circ \underbrace{P_{n-1}^*}_{=Q_n} \;=\; f_n^* - g_n^*.$$

This shows that the maps $Q_n, n \in \mathbb{N}_0$ form a cochain homotopy. It follows from the Cochain Map Lemma 108.5 that the induced maps on cohomology groups agree.

(4) The last statement follows immediately from (2) and (3). ∎

In Lemma 89.7 (2) we basically saw that for any chain complex C_* and any homomorphism $f\colon A \to B$ of abelian groups the maps

$$\begin{array}{rcl} f_*\colon C_* \otimes A & \to & C_* \otimes B \\ \left[\sum_{i=1}^k \sigma_i \otimes a_i\right] & \mapsto & \left[\sum_{i=1}^k \sigma_i \otimes f(a_i)\right] \end{array}$$

form a chain map, in particular for each $n \in \mathbb{N}_0$ we obtain an induced map

$$f_*\colon \mathrm{H}_n(C_* \otimes A) \;\to\; \mathrm{H}_n(C_* \otimes B).$$

Similarly, it is straightforward to check that the maps

$$\begin{array}{rcl} f_*\colon \mathrm{Hom}(C_n, A) & \to & \mathrm{Hom}(C_n, B) \\ \varphi & \mapsto & f \circ \varphi \end{array}$$

define a cochain map, in particular we get for each $n \in \mathbb{N}_0$ an induced map

$$f_*\colon \mathrm{H}^n(C_*; A) \;\to\; \mathrm{H}^n(C_*; B)$$

The following lemma basically says that these maps have all the properties one could possibly hope for. The lemma can be viewed as a cohomological analogue of Lemma 89.7.

Lemma 108.9.

(1) Given a chain complex C_* and $n \in \mathbb{N}_0$ the maps

$$\begin{array}{rcl} A & \mapsto & \mathrm{H}^n(C_*; A) \\ (f\colon A \to B) & \mapsto & (f_*\colon \mathrm{H}^n(C_*; A) \to \mathrm{H}^n(C_*; B)) \end{array}$$

form a covariant functor from the category of abelian groups to the category of abelian groups. In other words, "cohomology is covariant in the coefficients".

(2) Given a group homomorphism $f\colon A \to B$ the induced maps f_* define a natural transformation from the contravariant functor $C_* \mapsto \mathrm{H}^n(C_*; A)$ to the contravariant functor $C_* \mapsto \mathrm{H}^n(C_*; B)$.

Proof. The two statements follow basically immediately from the definitions. ■

108.4. **The singular cohomology groups of topological spaces.** Now we apply the somewhat dry algebra from the last section to our favorite chain complex, namely the singular chain complex of a pair of topological spaces.

Definition. Let (X, A) be a pair of topological spaces and let G be an abelian group.

(1) For each $n \in \mathbb{N}_0$ we write

$$\mathrm{C}^n(X, A; G) := \mathrm{Hom}(\mathrm{C}_n(X, A), G) \text{ and } \delta_n := \partial_{n+1}^*\colon \mathrm{C}^n(X, A; G) \to \mathrm{C}^{n+1}(X, A; G).$$

We use the following notation:

(a) We refer to the elements of $\mathrm{C}^n(X, A; G)$ as singular n-cochains,

(b) we refer to the elements in the kernel of $\delta_n\colon \mathrm{C}^n(X, A; G) \to \mathrm{C}^{n+1}(X, A; G)$ as singular n-cocycles and

(c) we refer to the elements in the image of $\delta_{n-1}\colon \mathrm{C}^{n-1}(X, A; G) \to \mathrm{C}^n(X, A; G)$ as singular n-coboundaries.

When $n \in \mathbb{N}_0$ is understood then sometimes we just write δ instead of δ_n.

(2) We refer to the cochain complex

$$\ldots \leftarrow \mathrm{C}^{n+1}(X, A; G) \xleftarrow{\delta_n} \mathrm{C}^n(X, A; G) \xleftarrow{\delta_{n-1}} \mathrm{C}^{n-1}(X, A; G) \leftarrow \ldots \xleftarrow{\delta_0} C^0(X, A; G) \leftarrow 0$$

as the singular cochain complex of (X, A) with G-coefficients. We define the n-th singular cohomology group of (X, A) with G-coefficients[1314] as follows

$$\mathrm{H}^n(X, A; G) := \mathrm{H}^n(\mathrm{C}_*(X, A); G) = \frac{\ker(\delta_n\colon \mathrm{C}^n(X, A; G) \to \mathrm{C}^{n+1}(X, A; G))}{\mathrm{im}(\delta_{n-1}\colon \mathrm{C}^{n-1}(X, A; G) \to \mathrm{C}^n(X, A; G))}.$$

(3) If $A = \varnothing$ then we just write $\mathrm{C}^n(X; G) = \mathrm{C}^n(X, \varnothing; G)$ and similar for cohomology groups.

(4) If $G = \mathbb{Z}$ then often we drop the coefficients from the notation, e.g. often we write $\mathrm{H}^n(X, A) = \mathrm{H}^n(X, A; \mathbb{Z})$.

Remark. As we had already pointed out on page 2400, if R is a commutative ring, e.g. if $R = \mathbb{Z}_n, \mathbb{Z}, \mathbb{Q}, \mathbb{R}$ or $R = \mathbb{C}$, then the cohomology groups $\mathrm{H}^n(X, A; R)$ can in fact be viewed as R-modules and the coboundary maps are R-module homomorphisms.

[1314] In most cases we drop the adjective "singular" and we just talk of the n-th cohomology group of (X, A) with coefficients in G. We only refer to it as singular cohomology when we want to distinguish it from de Rham cohomology.

In the following we first discuss the definition and examples of the absolute cohomology groups $\mathrm{H}^*(X;G)$. A little later we will discuss the arguably even more confusing relative cohomology groups $\mathrm{H}^*(X,A;G)$. We start this discussion of absolute cohomology groups with the following remark.

Remark. Let G be an abelian group.

(1) Let X be a topological space and let $n \in \mathbb{N}_0$. We denote by $\mathrm{S}_n(X)$ the set of singular n-simplices. We then have natural identifications

$$\mathrm{C}^n(X;G) \;=\; \mathrm{Hom}(\mathrm{C}_n(X),G) \underset{\substack{\uparrow\\ \text{by definition } \mathrm{C}_n(X)=\mathbb{Z}^{(\mathrm{S}_n(X))}}}{=} \mathrm{Hom}\left(\mathbb{Z}^{(\mathrm{S}_n(X))},G\right) \underset{\substack{\uparrow\\ \text{identification given by Lemma 108.1}}}{=} \text{maps from } \mathrm{S}_n(X) \text{ to } G.$$

Put differently, a singular n-cochain is precisely the same as assigning to each singular n-simplex an element in G. We will use this bijection throughout the course without explicitly referring to it.

(2) Let X be a topological space. We recall that, following the discussion on page 1583, we can identify the singular 0-simplices in X with the points in X. According to the discussion in (1) we can now make the identification

$$\mathrm{C}^0(X;G) \;=\; \{\text{all maps from } X \text{ to } G\}.$$

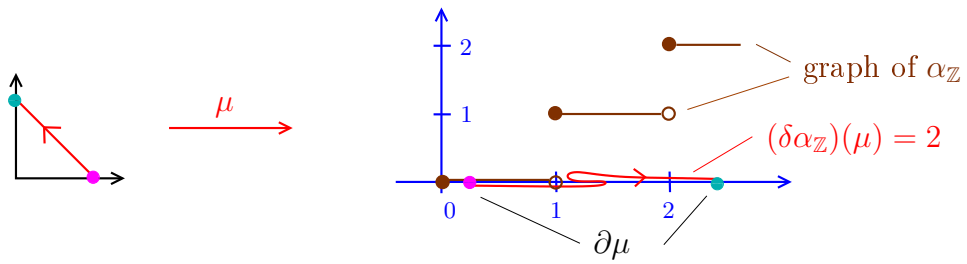
Before we develop the theory of cohomology groups in detail we first want to consider some explicit examples. As a starter we consider cochains and cocycles on the topological spaces $\mathbb{R}$ and S^1.

Examples.

(1) We start out with the topological space $X = \mathbb{R}$. We consider the two functions

$$\begin{array}{rcl} \alpha_{\mathbb{R}}\colon \mathbb{R} & \to & \mathbb{R} \\ x & \mapsto & x \end{array} \quad \text{and} \quad \begin{array}{rcl} \alpha_{\mathbb{Z}}\colon \mathbb{R} & \to & \mathbb{Z} \\ x & \mapsto & \lfloor x \rfloor := \max\{n \in \mathbb{Z} \,|\, n \le x\}. \end{array}$$

As pointed out above, these two functions define singular 0-cochains. We denote these 0-cochains again by $\alpha_{\mathbb{R}}$ and $\alpha_{\mathbb{Z}}$. For any singular 1-simplex $\mu\colon \Delta^1 \to \mathbb{R}$ we have



$$(\delta\alpha_{\mathbb{R}})(\mu) \underset{\substack{\uparrow\\ \text{definition of } \delta}}{=} \alpha_{\mathbb{R}}(\partial\mu) \underset{\substack{\uparrow\\ \text{see page 1585}}}{=} \alpha_{\mathbb{R}}(\mu(0,1)-\mu(1,0)) \underset{\substack{\uparrow\\ \text{definition of } \alpha_{\mathbb{R}}}}{=} \mu(0,1)-\mu(1,0)$$

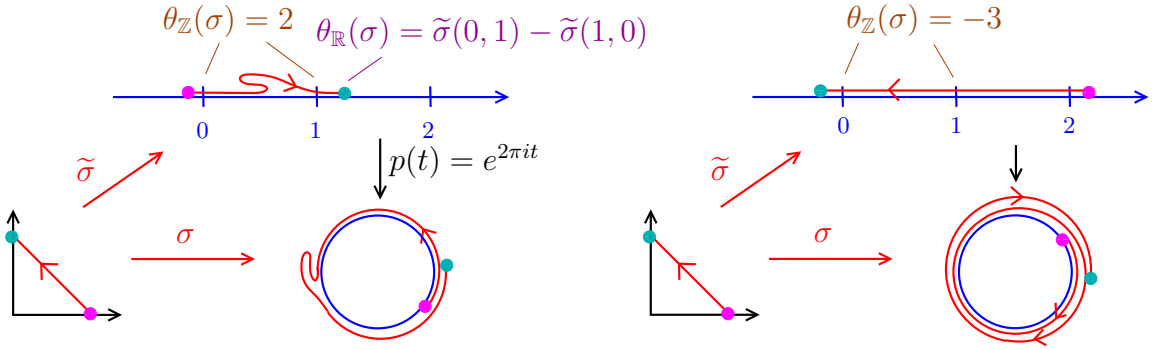
and, slightly more interesting, it follows immediately from the above discussion and the definition of $\alpha_{\mathbb{Z}}$ that

$$(\delta\alpha_{\mathbb{Z}})(\mu) \;=\; \alpha_{\mathbb{Z}}(\partial\mu) \;= \begin{cases} \#\{n \in \mathbb{Z} \,|\, \mu(1,0) < n \le \mu(0,1)\}, & \text{if } \mu(0,1) \ge \mu(1,0) \\ -\#\{n \in \mathbb{Z} \,|\, \mu(0,1) < n \le \mu(1,0)\}, & \text{if } \mu(1,0) \ge \mu(0,1). \end{cases}$$

In a somewhat informal way we can say that the cochain $\delta\alpha_{\mathbb{Z}}\colon \mathrm{C}_1(\mathbb{R}) \to \mathbb{Z}$ applied to a singular 1-simplex μ measures how many integers the simplex μ "crosses from left to right". We refer to the figure below for an illustration of $\delta\alpha_{\mathbb{Z}}$.

(2) Now we consider the topological space $X = S^1$. As usual we denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto \exp(2\pi\,\mathrm{i}t)$ the universal covering of S^1. Let $\sigma\colon \Delta^1 \to S^1$ be a singular 1-simplex. Since Δ^1 is simply connected it follows from the Covering Existence Theorem 61.5 that σ lifts to a map $\widetilde{\sigma}\colon \Delta^1 \to \mathbb{R}$. The lift is not unique, but it is straightforward

to see that any two lifts differ by addition by an integer. For a singular 1-simplex $\sigma\colon \Delta^1 \to S^1$ we pick a lift $\widetilde{\sigma}\colon \Delta^1 \to \mathbb{R}$ of σ and we define



$$\theta_{\mathbb{R}}(\sigma) \;:=\; (\delta\alpha_{\mathbb{R}})(\underset{\in C_1(\mathbb{R})}{\widetilde{\sigma}}) \;=\; \widetilde{\sigma}(0,1) - \widetilde{\sigma}(1,0)$$

and we also define

$$\theta_{\mathbb{Z}}(\sigma) \;:=\; (\delta\alpha_{\mathbb{Z}})(\widetilde{\sigma}) \;=\; \begin{cases} \#\{n \in \mathbb{Z} \,|\, \widetilde{\sigma}(1,0) < n \leq \widetilde{\sigma}(0,1)\}, & \text{if } \widetilde{\sigma}(0,1) \geq \widetilde{\sigma}(1,0) \\ -\#\{n \in \mathbb{Z} \,|\, \widetilde{\sigma}(0,1) < n \leq \widetilde{\sigma}(1,0)\}, & \text{if } \widetilde{\sigma}(1,0) \geq \widetilde{\sigma}(0,1). \end{cases}$$

Since any two lifts of σ differ by addition by an integer we see that $\theta_{\mathbb{R}}(\sigma)$ and $\theta_{\mathbb{Z}}(\sigma)$ are both well-defined, i.e. independent of the choice of the lift $\widetilde{\sigma}$. The definitions of $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are illustrated in the figure below.[1315]

As we had explained on page 2403, these two maps $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ actually define singular 1-cochains in $C^1, \mathbb{R})$ and $C^1; \mathbb{Z})$.

As an example we consider the singular 1-simplex

$$\mu\colon \Delta^1 \;\to\; S^1 \quad \text{that is defined by} \quad \mu(1-t,t) \;=\; \exp(2\pi i t).$$

A lift of μ to the above universal covering $\mathbb{R} \to S^1$ is given by the singular 1-simplex

$$\widetilde{\mu}\colon \Delta^1 \;\to\; \mathbb{R} \quad \text{that is defined by} \quad \widetilde{\mu}(1-t,t) \;=\; t.$$

It follows immediately from the definitions that $\theta_{\mathbb{R}}(\mu) = \theta_{\mathbb{Z}}(\mu) = 1$.

[1315] Here is an alternative description of the singular 1-cochain θ: We denote by $\Phi\colon [0,1] \to \Delta^1$ the homeomorphism that is given by $\Phi(t) = (1-t,t)$. Then for any singular 1-simplex $\sigma\colon \Delta^1 \to S^1$ we have

$$\theta_{\mathbb{R}}(\sigma) \;=\; \frac{1}{2\pi\,\mathrm{i}} \int\limits_{\sigma\circ\Phi} \frac{1}{z}\, dz,$$

where the right-hand side denotes the path integral of the holomorphic function $\frac{1}{z}$ over the continuous path $\sigma \circ \Phi\colon [0,1] \to S^1$. We leave it as an amusing exercise to verify this equality using complex analysis.

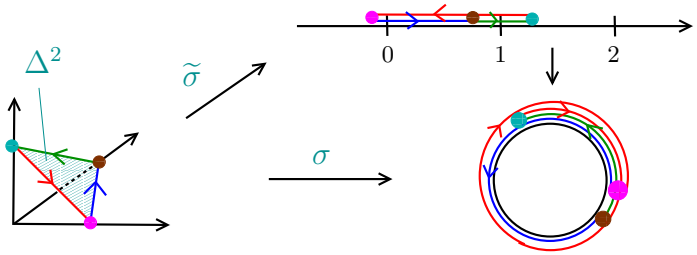
The following lemma shows that $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are actually quite interesting singular 1-cochains.

Lemma 108.10. We continue with the notation from the previous example.

(1) The singular 1-cochains $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are cocycles, in particular $\theta_{\mathbb{R}}$ defines an element in $\mathrm{H}^1(S^1;\mathbb{R})$ and $\theta_{\mathbb{Z}}$ defines an element in $\mathrm{H}^1(S^1;\mathbb{Z})$.

(2) The singular 1-cochain cochains $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are not the coboundary of a singular 0-cochain, i.e. the cohomology classes $[\theta_{\mathbb{R}}] \in \mathrm{H}^1(S^1;\mathbb{R})$ and $[\theta_{\mathbb{Z}}] \in \mathrm{H}^1(S^1;\mathbb{Z})$ are non-trivial.

Proof.



(1) We will first prove that the singular 1-cochain $\theta_{\mathbb{R}}$ is a cocycle. Thus we have to show that $\delta_1\theta_{\mathbb{R}} = 0 \in \mathrm{C}^2(S^1,\mathbb{R}) = \mathrm{Hom}(\mathrm{C}_2(S^1),\mathbb{R})$. So let $\sigma\colon \Delta^2 \to S^1$ be a singular 2-simplex. We have to show that $(\delta_1\theta_{\mathbb{R}})(\sigma) = \theta_{\mathbb{R}}(\partial\sigma) = 0$.

As before we denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto \exp(2\pi i t)$ the universal covering of S^1. Since Δ^2 is simply connected we can apply the Map Lifting Criterion 61.2 to obtain a lift of $\sigma\colon \Delta^2 \to S^1$ to a map $\widetilde{\sigma}\colon \Delta^2 \to \mathbb{R}$. We refer to the figure below for an illustration. Then

$$\theta_{\mathbb{R}}(\partial\sigma) \underset{\uparrow}{=} \theta_{\mathbb{R}}\Big(\sum_{j=0}^{2}(-1)^j \cdot \sigma \circ i_j^2\Big) \underset{\uparrow}{=} (\delta\alpha_{\mathbb{R}})\Big(\overbrace{\sum_{j=0}^{2}(-1)^j \cdot \widetilde{\sigma} \circ i_j^2}^{=\partial\widetilde{\sigma}}\Big) \underset{\uparrow}{=} \alpha_{\mathbb{R}}(\partial(\partial\widetilde{\sigma})) \underset{\uparrow}{=} 0.$$

definition of ∂ — by definition of $\theta_{\mathbb{R}}$ and since $\widetilde{\sigma} \circ i_j^2$ is a lift of $\sigma \circ i_j^2$ — by definition of $\delta\alpha_{\mathbb{R}}$ and $\partial\widetilde{\sigma}$ — since $\partial \circ \partial = 0$

Exactly the same argument applies to $\theta_{\mathbb{Z}}$.

(2) We still need to show that the singular 1-cochain cochains $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are not the coboundary of a singular 0-cochain. So let β be a singular 0-cochain. As usual we view β as a function $S^1 \to \mathbb{R}$. We consider again the singular 1-simplex $\mu\colon \Delta^1 \to S^1$ that is defined by $\mu(1-t,t) = \exp(2\pi i t)$. Then

$$(\delta_0\beta)(\mu) = \beta(\partial(\mu)) = \beta\big(\underbrace{\mu(0,1)}_{=1\in S^1} - \underbrace{\mu(1,0)}_{=1\in S^1}\big) = 0.$$

But in the previous example we saw that $\theta_{\mathbb{R}}(\mu) = \theta_{\mathbb{Z}}(\mu) = 1$. ■

Remark. Note that in Lemma 108.10 we have just given a mysteriously simple proof that $\mathrm{H}^1(S^1;\mathbb{R}) \neq 0$ and also that $\mathrm{H}^1(S^1;\mathbb{Z}) \neq 0$.

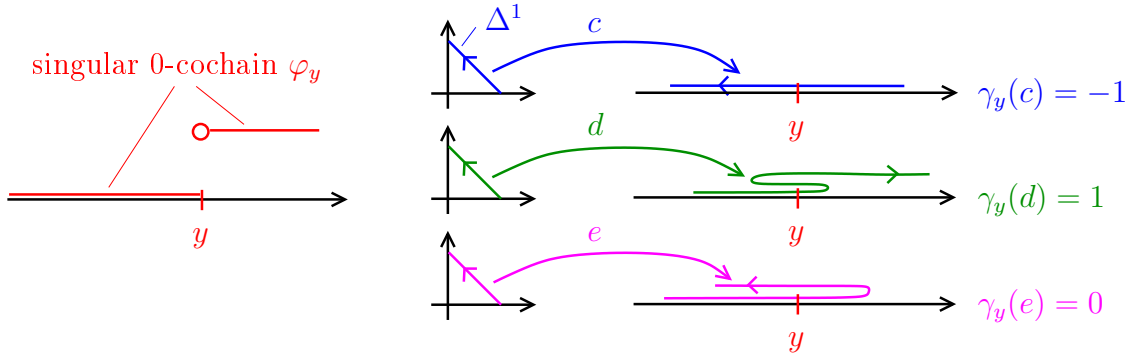
We continue with another example of cochains.

Example. We return to the topological space $X = \mathbb{R}$. We fix a point $y \in \mathbb{R}$. We consider the cochain

$$\begin{array}{rcl} \varphi_y\colon \mathrm{C}_0(\mathbb{R}) & \to & \mathbb{Z} \end{array}$$

that is determined by the function

$$\begin{array}{rcl} \mathbb{R} & \to & \mathbb{Z} \\ x & \mapsto & \begin{cases} 0, & \text{if } x \leq y, \\ 1, & \text{else.} \end{cases} \end{array}$$



For any singular 1-simplex $d\colon \Delta^1 \to X = \mathbb{R}$ we have

$$(\delta_0\varphi_y)(d) \;=\; \varphi_y(\partial d) \;\underset{\substack{\uparrow \\ \text{since } \partial d = 1\cdot d(0,1) + (-1)\cdot d(1,0) \\ \text{and since } \varphi_y\colon \mathrm{C}_0(\mathbb{R}) \to \mathbb{Z} \text{ is linear}}}{=}\; \varphi_y(d(0,1)) - \varphi_y(d(1,0)) \;=\; \begin{cases} 0, & \text{if } d(0,1), d(1,0) \leq y, \\ 0, & \text{if } d(0,1), d(1,0) \geq y, \\ 1, & \text{if } d(1,0) \leq y < d(0,1) \\ -1, & \text{if } d(0,1) \leq y < d(1,0). \end{cases}$$

In a slightly informal way we can say that the homomorphism $\delta_0\varphi_y\colon \mathrm{C}_1(\mathbb{R}) \to \mathbb{Z}$ applied to a singular 1-simplex d equals $+1$ if the simplex "crosses y from right to left" and it equals -1 if the simplex "crosses y from left to right". We will make use of this singular 1-cochain on several occasions, hence we give it its own notation, namely we write

$$\gamma_y \;:=\; \delta_0\varphi_y \;\in\; \mathrm{C}^1(\mathbb{R};\mathbb{Z}).$$

We illustrate the singular 1-cochain $\gamma_y = \delta_0\varphi_y \in \mathrm{C}^1(\mathbb{R};\mathbb{Z})$ in the figure below.

After this long discussion of explicit cochains and cohomology classes we want to turn to more general results. The only two instances where we could compute homology groups without any problems was the 0-th homology group of a path-connected space, see the H_0-Proposition 72.5, and the homology groups of a point, see the Single Point-Homology Lemma 72.6. Not surprisingly we can also deal with the same situations with cohomology groups.

First of all we have the following analogue of the H_0-Proposition 72.5.

Proposition 108.11. (H^0-Proposition) Let X be a non-empty path-connected topological space and let G be an abelian group. Then the map

$$\begin{array}{rcl} G & \to & \mathrm{H}^0(X;G) \\ g & \mapsto & [\text{0-cochain that assigns to each } x \in X \text{ the value } g] \end{array}$$

is a well-defined map that is in fact an isomorphism. For any point $P \in X$ an inverse is given by the map

$$\begin{array}{rcl} \mathrm{H}^0(X;G) & \to & G \\ [f] & \mapsto & f(P) \end{array}$$

Remark. At times we will use the isomorphism from the H^0-Proposition 108.11 to identify the 0-th cohomology $\mathrm{H}^0(X;G)$ of a path-connected topological space X with G.

Proof. We consider the "right-hand end" of the chain complex of $\mathrm{C}_*(X)$ and of the cochain complex $\mathrm{Hom}(\mathrm{C}_*(X),G)$:

$$\mathrm{C}_1(X) \xrightarrow{\partial_1} \mathrm{C}_0(X) \to 0 \quad \text{and} \quad \mathrm{Hom}(\mathrm{C}_1(X),G) \xleftarrow{\delta_0=\partial_1^*} \mathrm{Hom}(\mathrm{C}_0(X),G) \leftarrow 0.$$

Now we calculate that

$$\begin{aligned}
\mathrm{H}^0(X;G) &= \ker \left\{ \begin{array}{ccc} \mathrm{Hom}(\mathrm{C}_0(X),G) & \to & \mathrm{Hom}(\mathrm{C}_1(X),G) \\ (f\colon \mathrm{C}_0(X) \to G) & \mapsto & (f \circ \partial_1\colon \mathrm{C}_1(X) \to G) \end{array} \right\} \\
&\overset{\text{since the singular 1-simplices form a basis of } \mathrm{C}_1(X)}{\downarrow =} \\
&\{\text{maps } f\colon X \to G \mid \underbrace{f(\partial_1(\sigma))}_{=f(\sigma(0,1))-f(\sigma(1,0))} = 0 \text{ for all singular 1-simplices } \sigma\colon \Delta^1 \to X\} \\
&\overset{\text{by Lemma 108.1 we have the natural identification } \mathrm{Hom}(\mathrm{C}_0(X),G) = \text{maps from } X \text{ to } G}{\uparrow =} \\
&\text{all constant maps } X \to G \\
&\overset{\text{since } X \text{ is path-connected and since } \Delta^1 \cong [0,1]}{\uparrow =} \\
&G. \\
&\overset{\text{since } X \text{ is non-empty}}{\uparrow =}
\end{aligned}$$

The remaining statements of the proposition can be verified easily. ∎

The following lemma is an analogue of the Single Point-Homology Lemma 72.6.

Lemma 108.12. (Single Point-Cohomology Lemma) Let $X = \{x\}$ be a topological space that consists of a single point x. For any abelian group G we have

$$\mathrm{H}^n(X;G) = \left\{ \begin{array}{ll} 0, & \text{if } n \geq 1, \\ G, & \text{if } n = 0. \end{array} \right.$$

Proof. We outsource the proof to Exercise 108.3. ∎

We want to conclude this section with a short discussion of relative cohomology classes. Before we do so we make the following observations:

Observation.

(1) Given an abelian group C, a subgroup D and an abelian group G we have a natural isomorphism

$$\begin{array}{rcl} \mathrm{Hom}(C/D,G) & \xrightarrow{\cong} & \text{all homomorphisms } C \to G \text{ that vanish on } D \\ (\varphi\colon C/D \to G) & \mapsto & (C \to C/D \xrightarrow{\varphi} G). \end{array}$$

We will use this isomorphism to identify the groups left and right.

(2) If S is a set and T is a subset, then for any abelian group G the identification

$$\mathrm{Hom}(\mathbb{Z}^{(S)},G) = \text{all maps from } S \text{ to } G$$

from Lemma 108.1 restricts to an isomorphism

$$\left\{ f \in \mathrm{Hom}(\mathbb{Z}^{(S)},G) \,\middle|\, f \text{ vanishes on } \mathbb{Z}^{(T)} \right\} = \text{all maps } S \to G \text{ that are trivial on } T.$$

(3) It follows immediately from Lemma 108.1 and from (1) and (2) that given a pair of topological spaces (X,A) and an abelian group G we have for every $n \in \mathbb{N}_0$ a natural

isomorphism

$$\underbrace{\mathrm{Hom}(\mathrm{C}_n(X,A),G)}_{=\mathrm{C}^n(X,A;G)=\mathrm{Hom}(\mathrm{C}_n(X)/\mathrm{C}_n(A),G)} \;=\; \text{all maps } \mathrm{S}_n(X)\to G \text{ that are trivial on } \mathrm{S}_n(A).$$

We will often use this natural isomorphism to identify the left-hand side with the right-hand side.

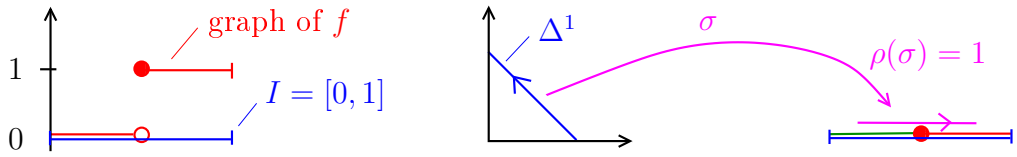
Examples.

(1) In Exercise 108.4 we will modify the argument of the H^0-Proposition 108.11 to show that for any path-connected topological space with non-empty subset A we have

$$\mathrm{H}^0(X,A;G) \;=\; 0 \quad \text{for any abelian group } G.$$

(2) We write $I=[0,1]$. In this example we want to construct a non-trivial element in $\mathrm{H}^1(I,\partial I)$. We consider the function

$$\begin{array}{rcl} f\colon I & \to & \mathbb{Z} \\ x & \mapsto & \begin{cases} 0, & \text{if } x\in[0,\frac{1}{2}) \\ 1, & \text{otherwise} \end{cases} \end{array}$$



which we use to define the singular 1-cochain

$$\begin{array}{rcl} \rho\colon \mathrm{C}_1(I) & \to & \mathbb{Z} \\ (\sigma\colon \Delta^1\to I) & \mapsto & f(\sigma(0,1))-f(\sigma(1,0)). \end{array}$$

Loosely speaking, similar to the singular 1-cochain φ_y from page 2406 the singular 1-cochain $\rho(\sigma)$ measures whether σ crosses $\frac{1}{2}$, and if yes, in what direction. We refer to the figure below for an illustration. Since Δ^1 is connected and since $\{0,1\}$ is discrete it follows from the Connected-to-Discrete Lemma 2.27 that any singular 1-simplex $\sigma\colon\Delta^1\to\partial I=\{0,1\}$ is constant. In particular in this case we have $\rho(\sigma)=0$. Thus we see, using the above observation, that ρ defines a map

$$\rho\colon \mathrm{C}_1(I,\partial I) \;\to\; \mathbb{Z}.$$

In Exercise 108.8 we will see that ρ is a singular 1-cocycle and that it defines a non-trivial element in $\mathrm{H}^1(I,\partial I;\mathbb{Z})$.

108.5. **Basic properties of cohomology groups.** Now we will see that maps between pairs of topological spaces induce maps on cohomology groups.

Definition. Let G be an abelian group and let $f\colon(X,A)\to(Y,B)$ be a map between pairs of topological spaces. Recall that f induces a chain map $f_*\colon\mathrm{C}_*(X,A)\to\mathrm{C}_*(Y,B)$. For each $n\in\mathbb{N}_0$ we denote by

$$f^*\colon \mathrm{H}^n(Y,B;G) \;\to\; \mathrm{H}^n(X,A;G)$$

the induced map of cohomology groups that we obtain from the Dual Cochain Map Lemma 108.8 (1).

Example. We will see in Exercise 108.6 that any map $f\colon X \to Y$ between two path-connected non-empty topological spaces induces an isomorphism $f^*\colon \mathrm{H}^0(Y;G) \to \mathrm{H}^0(X;G)$. A very similar argument shows that if Y is path-connected and X is non-empty, then $f^*\colon \mathrm{H}^0(Y;G) \to \mathrm{H}^0(X;G)$ is a monomorphism.

Notation. Let X be a topological space and let A be a subset. Furthermore let G be an abelian group. We denote by $i\colon A \to X$ the inclusion map. Sometimes we refer to $i^*\colon \mathrm{H}^n(X;G) \to \mathrm{H}^n(A;G)$ as the restriction map.

We summarize some basic properties of the induced maps in the following lemma.

Lemma 108.13. (Homotopic Maps-H*-Lemma) Let G be an abelian group and let $n \in \mathbb{N}_0$.

(1) The maps
$$\begin{array}{rcl}(X,A) & \mapsto & \mathrm{H}^n(X,A;G)\\ (f\colon (X,A)\to(Y,B)) & \mapsto & (f^*\colon \mathrm{H}^n(Y,B;G)\to \mathrm{H}^n(X,A;G))\end{array}$$
define a contravariant functor from the category of pairs of topological spaces to the category of abelian groups. (If G is a commutative ring, then this is in fact a functor to the category of G-modules.)

(2) Let $f,g\colon (X,A)\to(Y,B)$ be maps between pairs of topological spaces. If f and g are homotopic, then they induce the same maps
$$f^* = g^*\colon \mathrm{H}^n(Y,B;G) \to \mathrm{H}^n(X,A;G).$$

(3) If $f\colon X \to Y$ is a homotopy equivalence between two topological spaces, then the induced map
$$f^*\colon \mathrm{H}^n(Y;G) \xrightarrow{\cong} \mathrm{H}^n(X;G)$$
is an isomorphism. In particular the cohomology groups of homotopy equivalent topological spaces are isomorphic.

(4) Let X be a topological space, let $A \subset B$ be subsets of X and let $n \in \mathbb{N}_0$. If A is a deformation retract of B, then the inclusion induced map
$$\mathrm{H}^n(X,B;G) \to \mathrm{H}^n(X,A;G)$$
is an isomorphism. Similarly, if B is a deformation retract of X, then the inclusion induced map
$$\mathrm{H}^n(X,A;G) \to \mathrm{H}^n(B,A;G)$$
is an isomorphism.

Example. The Homotopic Maps-H*-Lemma 108.13 (4), together with the Single Point-Cohomology Lemma 108.12 and the discussion on page 432 implies that for any $n \geq 1$, any abelian group G and any $k \in \mathbb{N}_0$ we have
$$\mathrm{H}^n(\mathbb{R}^k;G) = \mathrm{H}^n\big(\overline{B}^k;G\big) = \mathrm{H}^n\big(B^k;G\big) = \mathrm{H}^n\big([0,1]^k;G\big) = \mathrm{H}^n\big(\Delta^k;G\big) = 0.$$

Proof.

(1) This statement follows immediately from the Dual Cochain Map Lemma 108.8 (2) together with the fact that the map $(X,A) \mapsto \mathrm{C}_*(X,A)$ defines a covariant functor

from the category *PairTop* of pairs of topological spaces to the category *ChCplx* of chain complexes.

(2) This statement is an immediate consequence of Proposition 74.15 together with Lemma 108.8 (3).

(3) This statement follows from (1) and (2).

(4) This statement is proved almost verbatim the same way as Corollary 74.16 (2a) and (2b). ■

Many of the statements about homology groups can be modified to give corresponding statements about cohomology groups. For example we have the following lemma.

Lemma 108.14. Let X be a topological space and let G be an abelian group.

(1) We denote by $\{X_j\}_{j\in J}$ the path-components of X. The inclusion maps $\iota_j\colon X_j \to X$, $j \in J$, induce an isomorphism

$$\prod_{j\in J} \iota_j^*\colon \mathrm{H}^n(X;G) \xrightarrow{\cong} \prod_{j\in J} \mathrm{H}^n(X_j;G).$$

(2) Suppose that X has finitely many path-components $X_1, \ldots, X_k$. If for $j = 1, \ldots, k$ we pick a point $P_j \in X_j$, then the map

$$\begin{array}{rcl} \mathrm{H}^0(X;G) & \to & G^k = \overbrace{G \times \cdots \times G}^{k \text{ times}} \\ [f] & \mapsto & (f(P_1), \ldots, f(P_k)) \end{array}$$

is an isomorphism.

Proof. Let X be a topological space with path-components $\{X_j\}_{j\in J}$ and let G be an abelian group. We have the following isomorphisms of cochain complexes:

$$\begin{array}{ccccc} \mathrm{Hom}(\mathrm{C}_*(X), G) & \xrightarrow{\left(\bigoplus_{j\in J} \iota_{j*}\right)^*} & \mathrm{Hom}\left(\bigoplus_{j\in J} \mathrm{C}_*(X_j), G\right) & \xrightarrow{\cong} & \prod_{j\in J} \mathrm{Hom}(\mathrm{C}_*(X_j), G). \\ \uparrow & & & & \uparrow \\ \text{Lemma 72.14} & & & & \text{Lemma 108.2} \end{array}$$

The first statement now follows easily from this observation together with the fact that cohomology commutes with direct products, see Lemma 108.7.

The second statement follows from the first statement together with the calculation of 0-th cohomology groups of path-connected topological spaces in the H^0-Proposition 108.11. ■

The following lemma is the analogue of the Topological LES-Proposition 74.13.

Lemma 108.15. (Cohomological LES-Lemma) Given a triple (X, B, A) of topological spaces and an abelian group G we obtain a long exact sequence

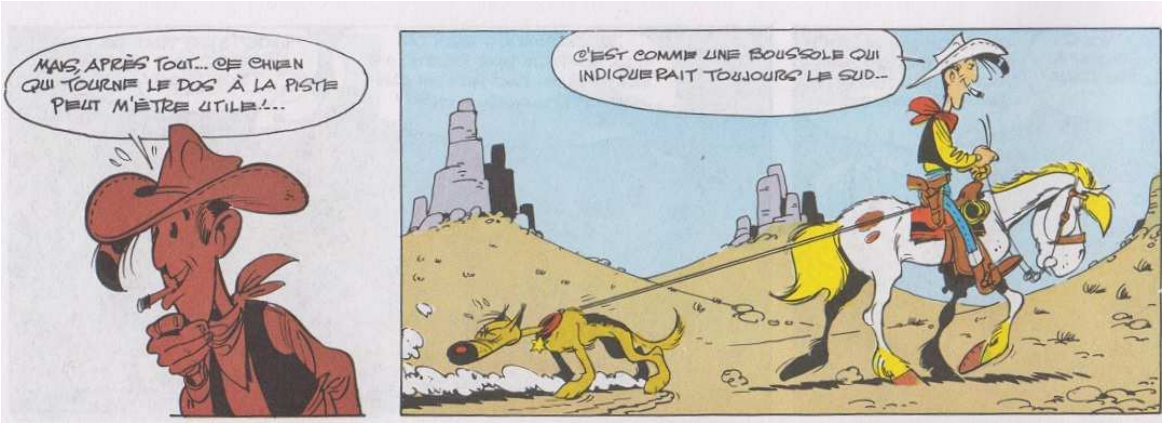
$$\ldots \xrightarrow{\delta_{n-1}} \mathrm{H}^n(X, B; G) \xrightarrow{p^*} \mathrm{H}^n(X, A; G) \xrightarrow{i^*} \mathrm{H}^n(B, A; G) \xrightarrow{\delta_n} \mathrm{H}^{n+1}(X, B; G) \xrightarrow{p^*} \ldots$$

hereby the maps are given as follows:

(1) p^* is the map induced by the map $p\colon (X, A) \to (X, B)$,

(2) i^* is the map induced by the map $i\colon (B, A) \to (X, A)$,

(3) the connecting homomorphism $\delta_n\colon \mathrm{H}^n(B,A;G) \to \mathrm{H}^{n+1}(X,B;G)$ is natural and it is given by the map



$$\begin{array}{rcl} \mathrm{H}^n(B,A;G) & \to & \mathrm{H}^{n+1}(X,B;G) \\ [f\colon \mathrm{C}_n(B,A)\to G] & \mapsto & \left[\begin{array}{rcl} \mathrm{C}_{n+1}(X,B) & \to & G \\ \sigma & \mapsto & f(q(\partial_n(\sigma))) \end{array}\right] \\ & & \uparrow \\ & & \text{with } \sigma \in \mathrm{C}_{n+1}(X) \end{array}$$

here $q\colon \mathrm{C}_n(X) \to \mathrm{C}_n(B)$ is the map given by sending all singular simplices that do not lie in B to zero.

Remark.

(1) An equivalent approach to expressing the connecting homomorphism is given as follows:
   (a) take a cocycle $f \in \mathrm{C}^n(B,A;G) = \mathrm{Hom}(\mathrm{C}_n(B,A),G)$,
   (b) denote by $\pi\colon \mathrm{C}_n(B) \to \mathrm{C}_n(B,A)$ the projection ,
   (c) denote by $\widetilde{f}$ the result of extending $f\circ\pi\colon \mathrm{C}_n(B) \to G$ to a map $\mathrm{C}_n(X) \to G$ by sending all singular simplices that do not lie in B to zero (sometimes we call $\widetilde{f}$ the *trivial extension* of $f\circ\pi$),
   (d) then consider the coboundary $\delta\widetilde{f} \in \mathrm{C}^{n+1}(X;G)$, since f is a cocycle it follows that $\delta\widetilde{f}$ actually defines an element in $\mathrm{C}^{n+1}(X,B;G)$ that we also denote by $\delta\widetilde{f}$, and which turns out to be a cocycle,
   (e) then $\delta[f] = [\delta\widetilde{f}] \in \mathrm{H}^{n+1}(X,B;G)$.

(2) One of the difficulties with the long exact sequence of cohomology groups is that all maps seem to point the wrong way. You should use the Lucky Luke approach to cohomology: if Rantanplan (i.e. your intuition) points one way, you should take the opposite direction.

(3) The most frequent application of the Cohomological LES-Lemma 108.15 is that given a pair (X,B) of topological spaces, i.e. given the triple $(X,B,\varnothing)$ and given an abelian group G we obtain a natural long exact sequence

$$\ldots \xrightarrow{\delta_{n-1}} \mathrm{H}^n(X,B;G) \xrightarrow{p^*} \mathrm{H}^n(X;G) \xrightarrow{i^*} \mathrm{H}^n(B;G) \xrightarrow{\delta_n} \mathrm{H}^{n+1}(X,B;G) \xrightarrow{p^*} \ldots$$

Proof. Let (X, B, A) be a triple of topological spaces. As in the proof of the Topological LES-Proposition 74.13 we note that

$$0 \;\to\; \mathrm{C}_*(B, A) \;\xrightarrow{i_*}\; \mathrm{C}_*(X, A) \;\xrightarrow{p_*}\; \mathrm{C}_*(X, B) \;\to\; 0$$

is a short exact sequence of chain complexes. Now let G be an abelian group. Recall that we pointed out on page 1625 that the chain groups $\mathrm{C}_*(X, B)$ are free abelian groups. Thus we deduce from Lemma 108.4 that the following induced sequence of cochain complexes is also exact:

$$0 \;\to\; \mathrm{Hom}(\mathrm{C}_*(X, B), G) \;\xrightarrow{p^*}\; \mathrm{Hom}(\mathrm{C}_*(X, A), G) \;\xrightarrow{i^*}\; \mathrm{Hom}(\mathrm{C}_*(B, A), G) \;\to\; 0.$$

The lemma now follows easily from the Connecting Homomorphism Proposition 108.6 and the construction of the connecting homomorphism. We leave the details to the reader. ■

Examples.

(1) Let X be a path-connected topological space and let A be any *non-empty* subset A of X. We denote by $i\colon A \to X$ the inclusion map. By the above remark we have a long exact sequence

$$0 \;\to\; \mathrm{H}^0(X, A; G) \;\to\; \mathrm{H}^0(X; G) \;\underset{\uparrow}{\xrightarrow{i^*}}\; \mathrm{H}^0(A; G) \;\to\; \dots$$

monomorphism, see page 2409

Thus it follows that $\mathrm{H}^0(X, A; G) = 0$. In Exercise 108.4 we will provide an alternative proof for this fact using only the definitions of cohomology groups.

(2) Let $b \in \mathbb{R}_{>0}$. We consider the long exact sequence in cohomology with $\mathbb{Z}$-coefficients of the pair $(\mathbb{R}, \mathbb{R} \setminus [-b, b])$. Together with (1) and Lemma 108.14 we obtain the following commutative diagram where the top horizontal sequence is exact:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{H}^0(\mathbb{R}; \mathbb{Z}) & \xrightarrow{i^*} & \mathrm{H}^0(\mathbb{R} \setminus [-b, b]; \mathbb{Z}) & \xrightarrow{\delta} & \mathrm{H}^1(\mathbb{R}, \mathbb{R} \setminus [-b, b]; \mathbb{Z}) & \longrightarrow & \mathrm{H}^1(\mathbb{R}; \mathbb{Z}) \\
 & & \downarrow{\scriptstyle [f] \mapsto f(-b-1)} & & \downarrow{\scriptstyle [f] \mapsto (f(-b-1), f(b+1))} & & & & \downarrow{\scriptstyle \mathrm{id}} \\
 & & \mathbb{Z} & \xrightarrow[m \mapsto (m,m)]{} & \mathbb{Z}^2 & & & & 0.
\end{array}$$

The cokernel of the bottom horizontal map is easily seen to be isomorphic to $\mathbb{Z}$ and it is generated by the element $(0, 1) \in \mathbb{Z}^2$. Put differently, the cokernel of the map $i^*\colon \mathrm{H}^0(\mathbb{R}; \mathbb{Z}) \to \mathrm{H}^0(\mathbb{R} \setminus [-b, b]; \mathbb{Z})$ is represented by the singular 0-cochain given by

$$\begin{array}{rcl}
\psi\colon \mathbb{R} \setminus [-b, b] & \to & \mathbb{Z} \\
x & \mapsto & \begin{cases} 0, & \text{if } x \le -b, \\ 1, & \text{if } x \ge b. \end{cases}
\end{array}$$

Now we want to determine $\delta\psi \in \mathrm{H}^1(\mathbb{R}, \mathbb{R} \setminus [-b, b]; \mathbb{Z})$. It is perhaps helpful to consider the following commutative diagram of short exact sequences:

$$\begin{array}{ccccccccc}
0 & \to & \mathrm{Hom}(\mathrm{C}_1(\mathbb{R}, \mathbb{R} \setminus [-b, b]), \mathbb{Z}) & \xrightarrow{p^*} & \mathrm{Hom}(\mathrm{C}_1(\mathbb{R}), \mathbb{Z}) & \xrightarrow{i^*} & \mathrm{Hom}(\mathrm{C}_1(\mathbb{R} \setminus [-b, b]), \mathbb{Z}) & \to & 0 \\
 & & \uparrow{\scriptstyle \delta_0} & & \uparrow{\scriptstyle \delta_0} & & \uparrow{\scriptstyle \boldsymbol{\delta_0}} & & \\
0 & \longrightarrow & \mathrm{Hom}(\mathrm{C}_0(\mathbb{R}, \mathbb{R} \setminus [-b, b], \mathbb{Z}) & \xrightarrow{p^*} & \mathrm{Hom}(\mathrm{C}_0(\mathbb{R}), \mathbb{Z}) & \xrightarrow{i^*} & \underbrace{\mathrm{Hom}(\mathrm{C}_0(\mathbb{R} \setminus [-b, b], \mathbb{Z})}_{\text{contains } \psi} & \longrightarrow & 0.
\end{array}$$

We start with the map $\psi\colon \mathbb{R} \setminus [-b,b] \to \mathbb{Z}$. We need to pick an extension to a map $\mathbb{R} \to \mathbb{Z}$. We might as well take the map $\varphi_0\colon \mathbb{R} \to \mathbb{Z}$ from page 2406. Then it follows from the discussion of the connecting homomorphism that the coboundary $\gamma_0 := \delta\varphi_0$ represents an element in $\mathrm{H}^1(\mathbb{R}, \mathbb{R} \setminus [-b,b]; \mathbb{Z})$, and that $\delta\psi = [\gamma_0]$ is a generator of $\mathrm{H}^1(\mathbb{R}, \mathbb{R} \setminus [-b,b]; \mathbb{Z}) \cong \mathbb{Z}$.

108.6. **Reduced cohomology groups.** We saw on several occasions that the reduced homology groups $\widetilde{\mathrm{H}}_k(X)$ of a non-empty topological space can be convenient for expressing calculations and results. In this last section we quickly introduce the reduced cohomology groups.

Definition. Let X be a topological space. By Lemma 72.4 (1) we know that the following is a chain complex

$$\begin{array}{ccccccccccc} \ldots & \xrightarrow{\partial_3} & \mathrm{C}_2(X) & \xrightarrow{\partial_2} & \mathrm{C}_1(X) & \xrightarrow{\partial_1} & \mathrm{C}_0(X) & \xrightarrow{\epsilon} & \mathbb{Z} & \to & 0. \\ & & & & & & \sum_{i=1}^k n_i\sigma_i & \mapsto & \sum_{i=1}^k n_i. & & \end{array}$$

Let G be an abelian group. In a fashion similar to reduced homology we now define the k-th reduced cohomology group $\widetilde{\mathrm{H}}^k(X;G)$ of X to be the k-th cohomology group of the above chain complex.

The following lemma is the analogue of Lemmas 74.1, 74.2 and 74.12. For brevity's sake we leave the proof to the reader.

Lemma 108.16. (Reduced Cohomology Lemma) Let G be an abelian group.

(1) Let $f\colon X \to Y$ be a map between two topological spaces. For every $n \in \mathbb{N}_0$ the map f induces a map $f^*\colon \widetilde{\mathrm{H}}^n(Y;G) \to \widetilde{\mathrm{H}}^n(X;G)$ in the obvious way. For every $n \in \mathbb{N}_0$ the maps

$$\begin{array}{ccc} X & \mapsto & \widetilde{\mathrm{H}}^n(X;G) \\ (f\colon X \to Y) & \mapsto & (f^*\colon \widetilde{\mathrm{H}}^n(Y;G) \to \widetilde{\mathrm{H}}^n(X;G)) \end{array}$$

define a contravariant functor from the category of topological spaces to the category of abelian groups.

(2) For each $n \in \mathbb{N}_0$ the maps

$$\begin{array}{ccc} \mathrm{H}^n(X;G) & \to & \widetilde{\mathrm{H}}^n(X;G) \\ [\varphi] & \mapsto & [\varphi] \end{array}$$

define a natural transformation from the contravariant functor $X \mapsto \mathrm{H}^n(X;G)$ to the contravariant functor that is given by $X \mapsto \widetilde{\mathrm{H}}^n(X;G)$.

(3) For each topological space the map

$$\begin{array}{ccc} G & \to & \mathrm{H}^0(X;G) \\ g & \mapsto & [\text{cochain that assigns to each singular 0-simplex the element } g] \end{array}$$

is well-defined. If X is non-empty, this map is a monomorphism that splits.

(4) If X is a non-empty topological space then the maps from (2) and (3) define a natural short exact sequence

$$0 \to G \to \mathrm{H}^n(X;G) \to \widetilde{\mathrm{H}}^n(X;G) \to 0$$

that splits.

(5) For every non-empty topological space X we have

$$\mathrm{H}^n(X;G) \;\cong\; \begin{cases} \widetilde{\mathrm{H}}^0(X;G) \oplus G, & \text{if } n = 0, \\ \widetilde{\mathrm{H}}^n(X;G), & \text{if } n \neq 0. \end{cases}$$

The isomorphism is natural for $n \geq 1$.

(6) If X is a topological space with $n \in \mathbb{N}$ path-components, then $\widetilde{\mathrm{H}}^0(X;G) \cong G^{n-1}$.

(7) Given a topological space X, a point $x_0 \in X$ and $n \in \mathbb{N}_0$ we consider the map

$$\mathrm{H}^n(X, \{x_0\}; G) \longrightarrow \mathrm{H}^n(X, \varnothing; G) \xrightarrow{=} \mathrm{H}^n(X;G) \longrightarrow \widetilde{\mathrm{H}}^n(X;G).$$

For any $n \in \mathbb{N}_0$ this map forms a natural isomorphism from the contravariant functor $(X, x_0) \mapsto \widetilde{\mathrm{H}}_n(X;G)$ to the contravariant functor $(X, x_0) \mapsto \mathrm{H}^n(X, x_0; G)$.

(8) Any homotopy equivalence between two topological spaces induces isomorphisms of reduced cohomology.

Finally the following lemma plays the role of the Topological LES-Corollary 74.14.

Lemma 108.17. Let X be a topological space and let $B \subset X$ be a non-empty subset. Then given any abelian group G there exists a natural long exact sequence

$$\ldots \xrightarrow{\delta_{n-1}} \mathrm{H}^n(X, B; G) \xrightarrow{p^*} \widetilde{\mathrm{H}}^n(X;G) \xrightarrow{i^*} \widetilde{\mathrm{H}}^n(B;G) \xrightarrow{\delta_n} \mathrm{H}^{n+1}(X, B; G) \xrightarrow{p^*} \ldots$$

Proof. The lemma follows immediately from the Cohomological LES-Lemma 108.15 applied to the triple $(X, B, \{P\})$ where P is a point in B, together with the Reduced Cohomology Lemma 108.16 (7). ■

108.7. **Isomorphic homology groups implies isomorphic cohomology groups.** In this short section we will see that the isomorphism type of cohomology groups cannot be used to extract more information from chain complexes than we already extracted from homology groups.

Proposition 108.18. Suppose $(\mathrm{C}_*, \partial_*)$ and (C'_*, ∂'_*) are two chain complexes of free abelian groups. Suppose that for each $n \in \mathbb{N}_0$ the homology groups $\mathrm{H}_n(C_*)$ and $\mathrm{H}_n(C'_*)$ are isomorphic. Then for each $n \in \mathbb{N}_0$ and any abelian group G the cohomology groups $\mathrm{H}^n(C;G)$ and $\mathrm{H}^n(C';G)$ are also isomorphic.

Proof. Suppose $(\mathrm{C}_*, \partial_*)$ and (C'_*, ∂'_*) are two chain complexes of free abelian groups. By our hypothesis there exist isomorphisms $\gamma_n \colon \mathrm{H}_n(C_*) \to \mathrm{H}_n(C'_*)$, $n \in \mathbb{N}_0$. By the Lift-to-Chain Map-Proposition 81.13 these isomorphisms can be realized by a chain map $f \colon C_* \to C'_*$. But by the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 this chain map is a chain homotopy equivalence. The statement of the proposition follows immediately from the Dual Cochain Map Lemma 108.8. ■

This proposition gives us a rather sobering corollary. It says that if our only goal is to distinguish (pairs of) topological spaces, then cohomology groups do not contain more information than homology groups.

Corollary 108.19. Let (X, A) and (Y, B) be topological spaces and let G be an abelian group. Then

$$\begin{array}{c}\mathrm{H}_n(X,A) \text{ and } \mathrm{H}_n(Y,B) \text{ are} \\ \text{isomorphic for all } n \in \mathbb{N}_0\end{array} \implies \begin{array}{c}\mathrm{H}^n(Y,B;G) \text{ and } \mathrm{H}^n(X,A;G) \text{ are} \\ \text{isomorphic for all } n \in \mathbb{N}_0.\end{array}$$

Proof. This corollary follows immediately from Proposition 108.18 and the observation from page 1625 that relative singular chain groups are free abelian groups. ■

The previous corollary does not specify how the isomorphism of the cohomology groups is given. If we already start out with a map $f\colon (X, A) \to (Y, B)$ that induces an isomorphism of homology groups, then we can be more precise, namely we have the following corollary which is similar in spirit to Corollary 89.18.

Corollary 108.20. Let $f\colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces and let G be an abelian group. Then

$$\begin{array}{c}\text{the induced map} \\ f_*\colon \mathrm{H}_n(X,A) \to \mathrm{H}_n(Y,B) \text{ is} \\ \text{an isomorphism for all } n \in \mathbb{N}_0\end{array} \implies \begin{array}{c}\text{the induced map} \\ f^*\colon \mathrm{H}^n(Y,B;G) \to \mathrm{H}^n(X,A;G) \text{ is} \\ \text{an isomorphism for all } n \in \mathbb{N}_0.\end{array}$$

Remark. In Proposition 110.13 we will see that the converse to Corollary 108.20 also holds.

Proof. Let $f\colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces and let G be an abelian group. If $f_*\colon \mathrm{H}_n(X, A) \to \mathrm{H}_n(Y, B)$ is an isomorphism for all $n \in \mathbb{N}_0$, then it follows from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 that $f_*\colon \mathrm{C}_*(X, A) \to \mathrm{C}_*(Y, B)$ is already a chain homotopy equivalence. (Here, as in the previous proof we use that relative singular chain groups are free abelian groups.) Now we get the desired conclusion from the Dual Cochain Map Lemma 108.8. ■

The upshot of this short section is that we will need to work to justify spending so many pages on cohomology.

Exercises for Chapter 108.

Exercise 108.1. Let $f\colon B \to C$ be a homomorphism between abelian groups such that $\mathrm{im}(f)$ is a summand of C. Let $\{k_1, \ldots, k_m\}$ be a generating set for $\ker(f)$. Finally suppose that we are given homomorphisms $\varphi_1, \ldots, \varphi_m\colon B \to \mathbb{Z}$ such that for all $i, j \in \{1, \ldots, m\}$ we have $\varphi_i(k_j) = \delta_{ij}$. Show that the map

$$\begin{array}{rcl}\Phi\colon \mathbb{Z}^m & \to & \mathrm{coker}(f\colon \mathrm{Hom}(C,\mathbb{Z}) \to \mathrm{Hom}(B,\mathbb{Z})) \\ e_i & \mapsto & [\varphi_i]\end{array}$$

is an isomorphism.

Exercise 108.2. Let $\varphi\colon C_1 \to C_0$ be a homomorphism between two finitely generated free abelian groups.

(a) Suppose that A is an $(n \times m)$-matrix that represents φ. Show that the transpose A^T represents the map $\varphi^*\colon \mathrm{Hom}(C_0, \mathbb{Z}) \to \mathrm{Hom}(C_1, \mathbb{Z})$.

(b) We consider the chain complex $C_* := 0 \to C_1 \xrightarrow{\varphi} C_0 \to 0$. Show that

$$\mathrm{Tor}(\mathrm{H}^1(C_*;\mathbb{Z})) \cong \mathrm{Tor}(\mathrm{H}_1(C)) \quad \text{and} \quad \mathrm{FH}^1(C_*;\mathbb{Z}) \cong \mathrm{FH}_1(C).$$

Remark. Statement (b) can be seen as a special case of the Universal Coefficient Theorem 110.11 for Cohomology Groups that we will prove later on.

Exercise 108.3. Let $X = \{x\}$ be a topological space that consists of a single point x. Show that for any abelian group G we have

$$\mathrm{H}^n(X;G) \;\cong\; \begin{cases} 0, & \text{if } n \geq 1, \\ G, & \text{if } n = 0. \end{cases}$$

Exercise 108.4. Let X be a path-connected topological space and let A be a non-empty subset of X. Show that

$$\mathrm{H}^0(X, A; G) \;=\; 0,$$

using only the definitions of cohomology groups.

Exercise 108.5. Let X be a path-connected topological space and let A and B be two disjoint non-empty subsets of X. Give an explicit example of a map $f\colon X \to \mathbb{Z}$ such that the map

$$\begin{array}{rcl} \mathrm{C}_1(X, A \cup B) & \to & \mathbb{Z} \\ [\sigma\colon \Delta^1 \to X] & \mapsto & f(\sigma((0,1)) - f(\sigma((1,0)) \end{array}$$

is cocycle that represents a non-zero element in $\mathrm{H}^1(X, A; \mathbb{Z})$.

Exercise 108.6. Show that any map $f\colon X \to Y$ between two path-connected non-empty topological spaces induces an isomorphism $f^*\colon \mathrm{H}^0(Y;G) \to \mathrm{H}^0(X;G)$.

Exercise 108.7. Let X be a topological space. Is the 0-th homology group $\mathrm{H}_0(X;\mathbb{Z})$ necessarily isomorphic to the 0-th cohomology group $\mathrm{H}^0(X;\mathbb{Z})$?

Exercise 108.8. We write $I = [0,1]$. As on page 2408 we consider the function

$$\begin{array}{rcl} f\colon I & \to & \mathbb{Z} \\ x & \mapsto & \begin{cases} 0, & \text{if } x \in [0, \frac{1}{2}) \\ 1, & \text{otherwise.} \end{cases} \end{array}$$

This map gives rise to the following singular 1-cochain:

$$\begin{array}{rcl} \rho\colon \mathrm{C}_1(I) & \to & \mathbb{Z} \\ (\sigma\colon \Delta^1 \to I) & \mapsto & f(\sigma(0,1)) - f(\sigma(1,0)). \end{array}$$

As we pointed out on page 2408, the map ρ actually defines a cochain $\rho\colon \mathrm{C}_1(I, \partial I) \to \mathbb{Z}$.

(a) Show that $\rho \in \mathrm{C}_1(I, \partial I)$ is a singular 1-cocycle.
(b) Show that ρ defines a non-trivial element in $\mathrm{H}^1(I, \partial I; \mathbb{Z})$.

Exercise 108.9. Let $X = \mathbb{R}^2$. We consider the singular 2-cochain $\varphi\colon \mathrm{C}_2(\mathbb{R}^2; \mathbb{F}_2)$ that is given by

$$\varphi(\sigma) \;:=\; \begin{cases} 1, & \text{if } (0,0) \text{ lies in the interior of the convex hull} \\ & \text{of the three points } \sigma(1,0,0), \sigma(0,1,0), \sigma(0,0,1), \\ 0, & \text{otherwise.} \end{cases}$$

Is φ a cocycle?

Exercise 108.10. Let $f\colon S^2 \to \mathbb{F}_2$ be a function such that $f(-x) = 1 - f(x)$ for all $x \in S^2$. Given a singular simplex $\tau\colon \Delta^1 \to S^2$ we write $\mu(\tau) = 0$ if f is constant on $\tau(\Delta^1)$ and otherwise we write $\mu(\tau) = 1$. We denote by $p\colon S^2 \to \mathbb{R}\mathrm{P}^2 = S^2/x \sim -x$ the projection . We consider the following cochain

$$\begin{array}{rcl} \varphi\colon \mathrm{C}_2(\mathbb{R}\mathrm{P}^2) & \to & \mathbb{F}_2 \\ (\sigma\colon \Delta^2 \to \mathbb{R}\mathrm{P}^2) & \mapsto & \begin{array}{c}\text{pick a lift } \widetilde{\sigma}\colon \Delta^2 \to S^2 \text{ of } \sigma \text{ and calculate} \\ \mu(\widetilde{\sigma} \circ i_0^2) + \mu(\widetilde{\sigma} \circ i_1^2) + \mu(\widetilde{\sigma} \circ i_2^2).\end{array} \end{array}$$

(a) Show that φ is well-defined, i.e. show that $\varphi(\sigma)$ does not depend on the choice of the lift $\widetilde{\sigma}$.
Remark. Note that if $\widetilde{\sigma}\colon \Delta^2 \to S^2$ is a lift of σ, then the only other one is given by $\nu \circ \widetilde{\sigma}$ where $\nu\colon S^2 \to S^2$ is the map defined by $\nu(x) = -x$ for all $x \in S^2$.
(b) Show that φ is a cocycle in $\mathrm{C}^2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$.
(c) Does φ represent a non-zero cohomology class?

Exercise 108.11. Suppose $(\mathrm{C}_*, \partial_*)$ and (C'_*, ∂'_*) are two chain complexes. We do *not* assume that the chain groups are necessarily free abelian groups. Suppose that for each $n \in \mathbb{N}_0$ the homology groups $\mathrm{H}_n(C_*)$ and $\mathrm{H}_n(\mathrm{C}'_*)$ are isomorphic. Does it follow that for each $n \in \mathbb{N}_0$ and any abelian group G the cohomology groups $\mathrm{H}^n(\mathrm{C}_*; G)$ and $\mathrm{H}^n(\mathrm{C}'_*; G)$ are also isomorphic?

109. Properties of cohomology groups

After the disappointment of Corollary 108.19 one might be tempted to drop cohomology groups and move on to a different subject. But later on we will see that cohomology groups can be very interesting after all. The key, as we will see, is that cohomology is a contravariant functor whereas homology is a covariant functor.
Therefore we now persevere with the study of cohomology groups. In this chapter we want to extend the following deep theorems and theories from the homological setup to the cohomological setting:

(1) The Excision Theorem 74.17,
(2) the isomorphism between singular homology and cellular homology from the Singular-Cellular H_*-Isomorphism Proposition 80.4,
(3) the Mayer-Vietoris Theorem 78.5.

These theorems will allow us in particular to give many more calculations of cohomology groups.

109.1. Excision theorems for cohomology groups.

We start out with the analogue of the Excision Theorem 74.17.

Theorem 109.1. (Excision Theorem for Cohomology Groups) Let X be a topological space and let G be an abelian group.

(1) Let $Z \subset A \subset X$ be subsets such that the closure of Z is contained in the interior of A. Then the inclusion
$$i\colon (X \setminus Z, A \setminus Z) \quad \to \quad (X, A)$$
induces for each $n \in \mathbb{N}_0$ an isomorphism
$$i^*\colon \mathrm{H}^n(X, A; G) \quad \xrightarrow{\cong} \quad \mathrm{H}^n(X \setminus Z, A \setminus Z; G).$$
(2) Let K be a subset of X and let U be a neighborhood of the closure of K (e.g. let X be Hausdorff, K compact and U open), then the inclusion $(U, U \setminus K) \to (X, X \setminus K)$ induces for each $n \in \mathbb{N}_0$ an isomorphism
$$\mathrm{H}^n(X, X \setminus K; G) \quad \xrightarrow{\cong} \quad \mathrm{H}^n(U, U \setminus K; G).$$

Proof.

(1) In the original Excision Theorem 74.17 we showed that the inclusion induced map
$$i_*\colon \mathrm{H}_n(X \setminus Z, A \setminus Z) \quad \to \quad \mathrm{H}_n(X, A)$$
is an isomorphism for every $n \in \mathbb{N}_0$. But then it follows immediately from Corollary 108.20 that the inclusion induced maps
$$i^*\colon \mathrm{H}^n(X, A; G) \quad \xrightarrow{\cong} \quad \mathrm{H}^n(X \setminus Z, A \setminus Z; G).$$
are also isomorphisms.
(2) By the same argument as in the proof of Theorem 74.18 one can easily deduce Statement (2) from Statement (1). ∎

Remark. Using Corollary 108.20 we also obtain the "cohomological" versions of the various other excision theorems, e.g. Theorems 74.18, 74.31 and 75.10. For example, let X be an m-dimensional topological manifold and let B be a compact m-dimensional submanifold of

X. We write $\mathring{B} := B \setminus \partial_0 B$.[1316] For every $n \in \mathbb{N}_0$ and any abelian group G the inclusion induced map

$$\mathrm{H}^n(X, B; G) \xrightarrow{\cong} \mathrm{H}^n\big(X \setminus \mathring{B}, \partial_0 B; G\big)$$

is an isomorphism.

Psychologically it is often helpful to replace relative homology groups by the homology groups of a quotient space. In the Homology-of-Quotients Proposition 74.20 we had seen that we can perform this switch for reasonable subsets. The following proposition does the same for cohomology groups.

Proposition 109.2. (Cohomology-of-Quotients Proposition) Let G be an abelian group. Let X be a topological space and let $A \subset X$ be a non-empty subset. We denote by $p\colon (X, A) \to (X/A, A/A)$ the natural projection. We consider the following map:

$$\widetilde{\mathrm{H}}^n(X/A; G) \xleftarrow[\cong]{\text{Reduced Cohomology Lemma 108.16 (7)}} \mathrm{H}^n(X/A, A/A; G) \xrightarrow{p^*} \mathrm{H}^n(X, A; G)$$

The following two statements hold:

(1) The composition of the above maps from left to right define a natural transformation from the contravariant functor $(X, A) \mapsto \widetilde{\mathrm{H}}^n(X, A)$ to the contravariant functor $(X, A) \mapsto \mathrm{H}^n(X, A; G)$.

(2) If A is a non-empty good subset[1317], then the above map $\widetilde{\mathrm{H}}^n(X/A; G) \to \mathrm{H}^n(X, A; G)$ is an isomorphism.

Proof. At this stage we have all the tools to rewrite the proof of the Homology-of-Quotients Proposition 74.20. In particular we can use the above Excision Theorem 109.1 for Cohomology Groups to replace the Excision Theorem 74.17. We leave it to the reader to verify that nothing goes wrong. ■

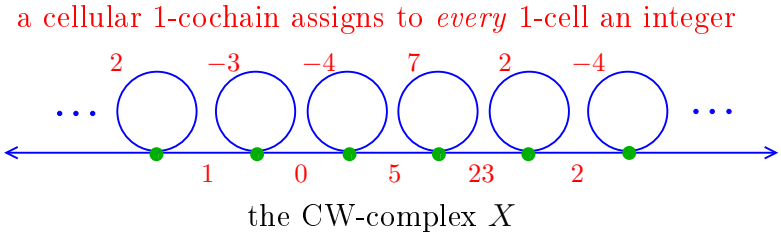
Example. Let G be an abelian group. From the calculation of the cohomology groups of finitely many points, see Lemmas 108.12 and 108.14, we obtain that

$$\mathrm{H}^k(S^0; G) \cong \begin{cases} G^2, & \text{if } k = 0, \text{ and} \\ 0, & \text{if } k \neq 0. \end{cases}$$

Similar to the proof of Proposition 74.4 we can use the Cohomology-of-Quotients Proposition 109.2 to calculate, via an induction argument, that for $n \geq 1$ we have

$$\mathrm{H}^k(S^n; G) \cong \begin{cases} G, & \text{if } k = 0 \text{ or } k = n, \text{ and} \\ 0, & \text{if } k \neq 0, n. \end{cases}$$

We will give an alternative calculation of the cohomology groups of spheres in the next section using cellular cohomology.



[1316] We refer to page 1658 for the definition of $\partial_0 B$.

[1317] Recall according to the definition on page 1613 this means that A is closed and that there exists an open neighborhood U of A in X such that A is a deformation retract of U.

109.2. **Cellular cohomology.** In Chapter 80 we introduced the cellular homology of a CW-complex. We saw that it is naturally isomorphic to singular homology and we saw that in many examples it is straightforward to compute cellular homology. Now we will repeat the trick and introduce cellular cohomology.
First we recall some definitions and some notation. Let X be a CW-complex.

(1) Recall that given $n \in \mathbb{N}_0$ we denote by X^n the n-skeleton of X.
(2) We write $\mathrm{C}_n^{\mathrm{CW}}(X) := \mathrm{H}_n(X^n, X^{n-1})$ and we denote by $d_n \colon \mathrm{C}_n^{\mathrm{CW}}(X) \to \mathrm{C}_{n-1}^{\mathrm{CW}}(X)$ the cellular boundary map from page 1769.
(3) We refer to
$$\ldots \xrightarrow{d_{n+1}} \mathrm{C}_{n+1}^{\mathrm{CW}}(X) \xrightarrow{d_{n+1}} \mathrm{C}_n^{\mathrm{CW}}(X) \xrightarrow{d_n} \mathrm{C}_{n-1}^{\mathrm{CW}}(X) \xrightarrow{d_{n-1}} \ldots$$
as the *cellular chain complex*.
(4) Let G be an abelian group. We remark that for a finite CW-complex we have
$$\mathrm{Hom}\left(\mathrm{C}_n^{\mathrm{CW}}(X), G\right) \underset{\uparrow}{\cong} \text{maps from the set of } n\text{-cells to } G \;=\; G^{\#\, n\text{-cells}}.$$
Lemmas 80.1 and 108.1
We refer to elements in $\mathrm{Hom}\left(\mathrm{C}_n^{\mathrm{CW}}(X), G\right)$ as *cellular n-cochains*.

Example. Given a CW-complex X an integral cellular 1-cochain in $\mathrm{Hom}\left(\mathrm{C}_1^{\mathrm{CW}}(X), \mathbb{Z}\right)$ assigns to *every* 1-cell an integer. We refer to the figure below for an illustration. In contrast an element in $\mathrm{C}_1^{\mathrm{CW}}(X)$ can be viewed as a formal linear combination of 1-cells which is the same as saying that an element in $\mathrm{C}_1^{\mathrm{CW}}(X)$ assigns a non-zero integer to only *finitely many* 1-cells.

the CW-complex X

Definition. Let G be an abelian group and let $n \in \mathbb{N}_0$.

(1) Let X be a CW-complex. We write $f_n := d_{n+1}^*$. We refer to
$$\cdots \leftarrow \mathrm{Hom}\left(\mathrm{C}_{n+1}^{\mathrm{CW}}(X), G\right) \xleftarrow{f_n} \mathrm{Hom}\left(\mathrm{C}_n^{\mathrm{CW}}(X), G\right) \leftarrow \mathrm{Hom}\left(\mathrm{C}_{n-1}^{\mathrm{CW}}(X), G\right) \xleftarrow{f_{n-1}} \ldots$$
as the cellular cochain complex. We define the n-th cellular cohomology group of X with G-coefficients as
$$\mathrm{H}_{\mathrm{CW}}^n(X; G) := \mathrm{H}^n\left(\mathrm{C}_*^{\mathrm{CW}}(X), G\right) = \frac{\ker\left(f_n \colon \mathrm{Hom}(\mathrm{C}_n^{\mathrm{CW}}(X), G) \to \mathrm{Hom}(\mathrm{C}_{n+1}^{\mathrm{CW}}(X), G)\right)}{\mathrm{im}\left(f_{n-1} \colon \mathrm{Hom}(\mathrm{C}_{n-1}^{\mathrm{CW}}(X), G) \to \mathrm{Hom}(\mathrm{C}_n^{\mathrm{CW}}(X), G)\right)}.$$
(2) If $f \colon X \to Y$ is a cellular map, then by Lemma 80.3 we get an induced chain map $f_* \colon \mathrm{C}_*^{\mathrm{CW}}(X) \to \mathrm{C}_*^{\mathrm{CW}}(Y)$ and thus we obtain from the Dual Cochain Map Lemma 108.8 (1) an induced map $f^* \colon \mathrm{H}_{\mathrm{CW}}^n(Y; G) \to \mathrm{H}_{\mathrm{CW}}^n(X; G)$.

For completeness' sake we jot down the following fairly self-evident lemma.

Lemma 109.3. Let G be an abelian group and let $n \in \mathbb{N}_0$. The maps

$$X \mapsto \mathrm{H}^n_{\mathrm{CW}}(X;G) \quad \text{and} \quad (f\colon X \to Y) \mapsto (f^*\colon \mathrm{H}^n_{\mathrm{CW}}(Y;G) \to \mathrm{H}^n_{\mathrm{CW}}(X;G))$$

define a contravariant functor from the category of CW-complexes to the category of abelian groups.

Proof. This lemma follows immediately from Lemmas 80.3 and 108.8 (2). ■

Perhaps not surprisingly we have the following theorem which plays a similar role as the Singular-Cellular H_*-Isomorphism Proposition 80.4.

Proposition 109.4. (Singular-Cellular H^*-Isomorphism Proposition) For every CW-complex X, any abelian group G and any $n \in \mathbb{N}_0$ there exists a natural isomorphism[1318]

$$\mathrm{H}^n(X;G) \xrightarrow{\cong} \mathrm{H}^n_{\mathrm{CW}}(X;G).$$

Remark. An alternative proof of this theorem is given in [**Hat2002**, p. 203].

First proof of Proposition 109.4. Let X be a CW-complex. Recall that on page 1801 we introduced the intermediate cellular chain complex that is given by

$$\mathrm{C}^{\mathrm{int}}_n(X) := \ker\big(\mathrm{C}_n(X^n) \xrightarrow{\partial} \mathrm{C}_{n-1}(X^n) \to \mathrm{C}_{n-1}(X^n, X^{n-1})\big) \quad \text{for } n \in \mathbb{N}_0.$$

We consider the two *natural* chain maps

$$i\colon \mathrm{C}^{\mathrm{int}}_*(X) \hookrightarrow \mathrm{C}_*(X) \quad \text{and} \quad p\colon \mathrm{C}^{\mathrm{int}}_*(X) \twoheadrightarrow \mathrm{C}^{\mathrm{CW}}_*(X),$$

which are given by the obvious inclusion and the obvious projection. In the Singular-Cellular Chain Complex Proposition 81.12 we had seen that these two chain maps are chain homotopy equivalences. Thus it follows from the Dual Cochain Map Lemma 108.8 (4) that we get isomorphisms

$$\mathrm{H}^n(X;G) = \mathrm{H}^n(\mathrm{C}_*(X);G) \xrightarrow[\cong]{i^*} \mathrm{H}^n(\mathrm{C}^{\mathrm{int}}_*(X);G) \xleftarrow[\cong]{p^*} \mathrm{H}^n(\mathrm{C}^{\mathrm{CW}}_*(X);G) = \mathrm{H}^n_{\mathrm{CW}}(X;G).$$

As pointed out above, the two chain maps i and p are natural. Therefore we see that the above isomorphism $\mathrm{H}^n(X;G) \to \mathrm{H}^n_{\mathrm{CW}}(X;G)$ is in fact natural. ■

Alternative proof of Proposition 109.4 without "natural". Let X be a CW-complex. We denote by $\mathrm{C}_* = \mathrm{C}_*(X)$ the singular chain complex and we denote by $D_* = \mathrm{C}^{\mathrm{CW}}_*(X)$ the cellular chain complex. In the Singular-Cellular H_*-Isomorphism Proposition 80.4 we showed that all the homology groups of the chain complexes C_* and D_* are isomorphic. It follows from Proposition 108.18 that for any abelian group G and any $n \in \mathbb{N}_0$ the cohomology groups $\mathrm{H}^n(X;G) = \mathrm{H}^n(\mathrm{C}_*;G)$ and $\mathrm{H}^n_{\mathrm{CW}}(X;G) = \mathrm{H}^n(D_*;G)$ are isomorphic. This approach to proving the Singular-Cellular H^*-Isomorphism Proposition 109.4 circumvents the use of the Singular-Cellular Chain Complex Proposition 81.12. But it is not clear how this approach can be used to show that there exists a *natural* isomorphism. Of course for many applications this is not an issue. ■

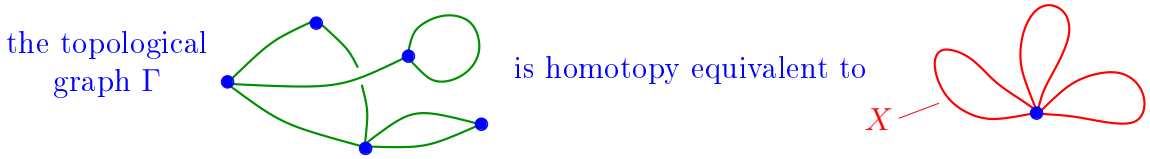
[1318]Here "natural" means that there exists a natural transformation between the contravariant functors $X \mapsto \mathrm{H}^n(X;G)$ and $X \mapsto \mathrm{H}^n_{\mathrm{CW}}(X;G)$ from the category of CW-complexes to the category of abelian groups.

Examples. Let G be an abelian group.

(1) We use cellular cohomology to once again compute the cohomology groups of spheres. As we saw on page 1472 we can view S^n, $n \geq 1$, as a CW-complex with one 0-cell and one other cell of dimension n. Furthermore the cellular boundary maps are the zero maps.[1319] Thus we see that the cellular chain complex is of the form

$$0 \to \mathbb{Z} \xrightarrow{0} \cdots \xrightarrow{0} \mathbb{Z} \to 0.$$

The dual cochain complex is then given by



$$0 \leftarrow \underbrace{\mathrm{Hom}(\mathbb{Z}, G)}_{=G} \xleftarrow{0} \cdots \xleftarrow{0} \underbrace{\mathrm{Hom}(\mathbb{Z}, G)}_{=G} \leftarrow 0.$$

Summarizing, precisely as on page 2419 we obtain that

$$\mathrm{H}^k(S^n; G) \cong \begin{cases} G, & \text{if } k = 0, n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) Let Γ be a connected finite topological graph. It follows from Proposition 50.15 (2) that Γ is homotopy equivalent to a CW-complex X with one 0-cell and $\chi(\Gamma) + 1$ 1-cells, see the figure below. The unique cellular boundary map in the cellular chain complex of X is zero by Lemma 80.7. Summarizing we see that for any $n \in \mathbb{N}_0$ we have

$$\mathrm{H}^n(\Gamma; G) \underset{\text{Homotopic Maps-H}^*\text{-Lemma 108.13}}{\overset{\uparrow}{\cong}} \mathrm{H}^n(X; G) \underset{\text{Singular-Cellular H}^*\text{-Isomorphism Proposition 109.4}}{\overset{\downarrow}{\cong}} \mathrm{H}^n_{\mathrm{CW}}(X; G) \underset{\text{since the coboundary map is zero}}{\overset{\uparrow}{\cong}} \mathrm{Hom}(\mathrm{C}^{\mathrm{CW}}_n(X); G) \cong \begin{cases} G, & \text{if } n=0, \\ G^{\chi(\Gamma)+1}, & \text{if } n=1, \\ 0, & \text{if } n \geq 2. \end{cases}$$

(3) Given $g \in \mathbb{N}_0$ and $m \in \mathbb{N}_0$ we denote by $\Sigma_{g,m}$ the surface of genus g minus m open disks. On page 2164 we had argued that for $m \geq 1$ the topological space $\Sigma_{g,m}$ is homotopy equivalent to the wedge of $2g + m - 1$ circles. The previous example, together with the Homotopic Maps-H*-Lemma 108.13, thus gives us the calculation of the cohomology groups of $\Sigma_{g,m}$ for $m \geq 1$.

(4) Let Σ_g be the surface of genus g. In the figure on page 1472 we showed that we can view Σ_g as a CW-complex with one 0-cell, $2g$ 1-cells and one 2-cell. On page 1780 we saw that the cellular boundary maps are all zero. Hence for any abelian group G and any $n \in \mathbb{N}_0$ we have

$$\mathrm{H}^n(\Sigma_g; G) \underset{\text{Singular-Cellular H}^*\text{-Isomorphism Proposition 109.4}}{\overset{\uparrow}{\cong}} \mathrm{H}^n_{\mathrm{CW}}(\Sigma_g; G) = \mathrm{Hom}\left(\mathrm{C}^{\mathrm{CW}}_n(\Sigma_g); G\right) \cong \begin{cases} G, & \text{if } n = 0 \text{ or } n = 2, \\ G^{2g}, & \text{if } n = 1, \text{ and} \\ 0, & \text{if } n \neq 0, 1, 2. \end{cases}$$

[1319] For $n \geq 2$ this follows by definition, for $n = 1$ this is a consequence of Lemma 80.7.

In all the examples so far the cohomology groups are isomorphic to the corresponding homology groups that we had calculated earlier. Now we will see an example where the homology and cohomology groups differ.

Examples.

(1) We consider the n-dimensional projective space $\mathbb{R}\mathrm{P}^n$. In the proof of Proposition 80.11 we saw that there exists a CW-structure on $\mathbb{R}\mathrm{P}^n$ such that the corresponding cellular chain complex is of the following form:

$$0 \to \underset{\substack{\uparrow \\ \text{degree } n}}{\mathbb{Z}} \xrightarrow{\cdot(1+(-1)^n)} \mathbb{Z} \to \ldots \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \to 0$$

which allowed us to compute the homology groups of $\mathbb{R}\mathrm{P}^n$. Now let G be an abelian group. We dualize this chain complex, i.e. we apply the functor $\mathrm{Hom}(-, G)$. Using the isomorphism $\mathrm{Hom}(\mathbb{Z}, G) \to G$ from Lemma 108.1 we see that the cochain complex is isomorphic to the following cochain complex:

$$0 \leftarrow G \xleftarrow{\cdot(1+(-1)^n)} G \leftarrow \ldots \xleftarrow{0} G \xleftarrow{\cdot 2} G \xleftarrow{0} G \leftarrow 0.$$

For $G = \mathbb{Z}$ we thus obtain from the Singular-Cellular H^*-Isomorphism Proposition 109.4 that for any $k \in \{0, \ldots, n\}$ we have

$$\mathrm{H}^k(\mathbb{R}\mathrm{P}^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is even and } k \neq 0, \\ 0, & \text{if } k \text{ is odd and } k \neq n, \\ \mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd} \end{cases} \quad \text{but } \mathrm{H}_k(\mathbb{R}\mathrm{P}^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is odd and } k \neq n, \\ 0, & \text{if } k \text{ is even and } k \neq 0, \\ \mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd} \end{cases}$$

where on the right-hand side we recall the calculation of the homology groups using the above cellular chain complex, see also Proposition 80.11. Therefore we see that for $n \geq 2$ the isomorphism types of the homology groups and the cohomology groups of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{Z}$-coefficients do *not* coincide.

(2) To add to the confusion we also compute the cohomology of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients. The corresponding dual cellular cochain complex is then given by

$$0 \to \mathbb{F}_2 \xleftarrow{0} \mathbb{F}_2 \leftarrow \ldots \leftarrow \mathbb{F}_2 \xleftarrow{\cdot 2=0} \mathbb{F}_2 \xleftarrow{0} \mathbb{F}_2 \to 0$$

and we see that

$$\mathrm{H}^k(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k = 0, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}$$

If we compare this result with the calculation on page 1916 of the homology of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients we see that we get the same result. More precisely, the homology groups and the cohomology groups of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients are isomorphic.

One can easily modify the above argument and apply it to $\mathbb{R}\mathrm{P}^\infty$, which we can view as a CW-complex with precisely one cell in each dimension, see 1480. We then obtain easily that for each $k \in \mathbb{N}_0$ we have

$$\mathrm{H}^k(\mathbb{R}\mathrm{P}^\infty; \mathbb{F}_2) \cong \mathbb{F}_2$$

(3) We recall that in Lemma 68.1 we showed that we can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex which admits exactly one cell in dimensions $0, 2, \ldots, 2n$ and which admits no odd-dimensional cells. It follows easily from the Singular-Cellular H^*-Isomorphism Proposition 109.4 that

$$\mathrm{H}^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

By Lemma 68.6 (2) we can view the infinite-dimensional complex projective space $\mathbb{C}\mathrm{P}^\infty$ as a CW-complex that has precisely one cell in each even dimension and no cells in odd dimensions. Using the Singular-Cellular H^*-Isomorphism Proposition 109.4 we obtain that

$$\mathrm{H}^k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k \text{ even}, \\ 0, & \text{if } k \text{ odd}. \end{cases}$$

Given $k < l \in \mathbb{N} \cup \{\infty\}$ we have an inclusion $\mathbb{C}\mathrm{P}^k \to \mathbb{C}\mathrm{P}^l$. Since the isomorphism of the Singular-Cellular H^*-Isomorphism Proposition 109.4 is natural and since the cellular chain complexes of $\mathbb{C}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^\infty$ agree up to the dimension $2n+1$ we obtain almost immediately that the inclusion induced maps $\mathrm{H}^k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \to \mathrm{H}^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ are actually isomorphisms up to dimension $2n$.

We conclude this section with the following fairly reasonably immediate corollary to the Singular-Cellular H^*-Isomorphism Proposition 109.4. This corollary can be viewed as an analogue of the Homology-of-CW-Complex Proposition 80.6 and Proposition 96.6.

Corollary 109.5. Let X be a topological space. Suppose we are in one of the following two situations:

(1) X is homotopy equivalent to a retract of a finite CW-complex,
(2) X is a compact topological manifold.

Then for every $n \in \mathbb{N}_0$ the cohomology group $\mathrm{H}^n(X;\mathbb{Z})$ is a finitely generated group.

Proof. Statement (2) is an immediate consequence of Statement (1) and the Topological Manifold-Simplicial Complex Retract Theorem 104.13. We will prove Statement (1) in Exercise 109.1. ■

109.3. **Explicit generators of cohomology groups.** In the previous section we had used cellular cohomology to compute the isomorphism types of the cohomology groups of many different topological spaces. But this calculation of the isomorphism types does not give us any explicit generators of the cohomology groups. For example on page 2404 we introduced a singular 1-cochain $\theta_{\mathbb{Z}} \colon \mathrm{C}_1(S^1) \to \mathbb{Z}$ and we showed in Lemma 108.10 that $\theta_{\mathbb{Z}}$ defines a non-zero cohomology class $[\theta_{\mathbb{Z}}] \in \mathrm{H}^1(S^1;\mathbb{Z})$. By the discussion on page 2422 we now also know that $\mathrm{H}^1(S^1;\mathbb{Z}) \cong \mathbb{Z}$, but we do not know whether $[\theta_{\mathbb{Z}}] \in \mathrm{H}^1(S^1;\mathbb{Z})$ is a generator.

On the other hand in earlier chapters we had obtained a pretty good understanding of generators of homology groups. The idea now is to translate information on homology groups to information on cohomology groups. The key tool relating homology and cohomology is given by the Kronecker pairing that we now introduce.

Lemma 109.6. Let C_* be a chain complex.

(1) Let G be an abelian group. The map

$$\begin{array}{rcl} \langle\ ,\ \rangle\colon \mathrm{H}^n(C;G) \times \mathrm{H}_n(C) & \to & G \\ ([\varphi],[c]) & \mapsto & \langle [\varphi],[c]\rangle := \underset{\uparrow}{\varphi(c)} \end{array}$$

here $\varphi \in \mathrm{Hom}(C_n, G)$ and $c \in C_n$, so $\varphi(c) \in G$ is defined

is well-defined and bilinear.[1320] In particular, if (X, A) is a pair of topological spaces, then the map

$$\begin{array}{rcl} \langle\ ,\ \rangle_X\colon \mathrm{H}^n(X,A;G) \times \mathrm{H}_n(X,A) & \to & G \\ ([\varphi],[c]) & \mapsto & \langle [\varphi],[c]\rangle_X := \varphi(c) \end{array}$$

is well-defined and bilinear. We refer to both pairings as the Kronecker pairing.[13211322]

(2) If $\varphi\colon G_1 \to G_2$ is a group homomorphism then the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^n(C;G_1) \times \mathrm{H}_n(C) & \xrightarrow{\langle -,-\rangle} & G_1 \\ \downarrow{\scriptstyle \varphi_* \times \mathrm{id}} & & \downarrow{\scriptstyle \varphi} \\ \mathrm{H}^n(C;G_2) \times \mathrm{H}_n(C) & \xrightarrow{\langle -,-\rangle} & G_2. \end{array}$$

(3) Let $f\colon C_* \to D_*$ be a chain map between two chain complexes and let G be an abelian group. Then for any $c \in \mathrm{H}_n(C)$ and $\varphi \in \mathrm{H}^n(D;G)$ we have

$$\langle f^*(\varphi), c\rangle \ = \ \langle \varphi, f_*(c)\rangle.$$

In particular, suppose that $f\colon (X,A) \to (Y,B)$ is a map between two pairs of topological spaces. Let $c \in \mathrm{H}_n(X,A)$ and let $\varphi \in \mathrm{H}^n(Y,B;G)$. Then

$$\langle f^*(\varphi), c\rangle_X \ = \ \langle \varphi, f_*(c)\rangle_Y.$$

Proof. Let C_* be a chain complex.

(1) Let G be an abelian group. Let $\varphi \in \mathrm{Hom}(C_n, G)$ be a cocycle and let $c \in C_n$ be a cycle. Furthermore let $\alpha \in \mathrm{Hom}(C_{n-1}, G)$ and let $d \in \mathrm{C}_{n+1}$. Then the following equalities hold in G:

$$(\varphi + \delta\alpha)(c) \underset{\substack{\uparrow \\ \text{definition of } \delta}}{=} \varphi(c) + \alpha(\partial c) \underset{\substack{\uparrow \\ \text{since } c \text{ is a cycle}}}{=} \varphi(c) \quad \text{and} \quad \varphi(c + \partial d) \underset{\substack{\uparrow \\ \text{definition of } \delta}}{=} \varphi(c) + (\delta\varphi)(d) \underset{\substack{\uparrow \\ \text{since } \varphi \text{ is a cocycle}}}{=} \varphi(c).$$

This calculation shows that the definition of the Kronecker pairing does not depend on the choices of the representatives of the cohomology and the homology classes. Finally note that it is clear that the Kronecker pairing is bilinear.

[1320] In general, given a commutative ring R a map $\Theta\colon U \times V \to W$ between R-modules is called *bilinear*, if for all $u, u' \in U$, $v, v' \in V$ and $r \in R$ we have

$$\begin{array}{rclcrcll} \Theta(u+u',v) & = & \Theta(u,v) + \Theta(u',v) & \text{and} & \Theta(ru,v) & = & r\Theta(u,v), & \text{and} \\ \Theta(u,v+v') & = & \Theta(u,v) + \Theta(u,v') & \text{and} & \Theta(u,rv) & = & r\Theta(u,v). & \end{array}$$

In our special case we consider the case of $\mathbb{Z}$-modules.

[1321] Often we drop the subscript X in the notation.

[1322] Leopold Kronecker (1823–1891) was a German mathematician who worked on number theory. I don't know how his name got attached to this pairing.

(2) This statement follows immediately from the definitions.
(3) The statement also follows immediately from the definitions. Indeed, if $[c] \in \mathrm{H}_n(C)$ and $[\varphi] \in \mathrm{H}^n(D;G)$, then

$$\langle f^*([\varphi]),[c]\rangle \;=\; \langle [f^*\varphi],[c]\rangle \;=\; (f^*\varphi)(c) \;=\; \varphi(f_*(c)) \;=\; \langle [\varphi],[f_*(c)]\rangle \;=\; \langle [\varphi], f_*([c])\rangle.$$

The statement regarding maps between pairs of topological spaces is an immediate consequence of the purely algebraic statement. ■

Now we state the lemma which will allow us in many situations to show that given cocycles form a basis for cohomology groups.

Lemma 109.7. (Kronecker-Basis Lemma) Let X be a topological space and let $n \in \mathbb{N}_0$. Suppose that $\mathrm{H}^n(X;\mathbb{Z})$ and $\mathrm{H}_n(X;\mathbb{Z})$ are free abelian groups of rank k and suppose we are given $\varphi_1,\ldots,\varphi_k \in \mathrm{H}^n(X;\mathbb{Z})$ and $c_1,\ldots,c_k \in \mathrm{H}_n(X;\mathbb{Z})$. If

$$\det\Big(\underbrace{\langle \varphi_i, c_j\rangle_{i,j=1,\ldots,k}}_{=\,k\times k\text{–matrix}}\Big) \;=\; \pm 1,$$

then $\varphi_1,\ldots,\varphi_k \in \mathrm{H}^n(X;\mathbb{Z})$ and $c_1,\ldots,c_k \in \mathrm{H}_n(X;\mathbb{Z})$ are both bases.

Example. Let $X = S^1$. We denote by $\theta_{\mathbb{Z}}\colon \mathrm{C}_1(S^1) \to \mathbb{Z}$ the singular 1-cocycle that we introduced on page 2404. We consider the singular cycle $\mu\colon \Delta^1 \to S^1$ that is given by $(1-t,t) \mapsto \exp(2\pi\,\mathrm{i}t)$. As on page 2404 we see that

$$\langle [\theta_{\mathbb{Z}}],[\mu]\rangle \;=\; \theta_{\mathbb{Z}}(\mu) \;=\; \alpha_{\mathbb{Z}}\left(\text{boundary of lift } \begin{array}{ccc} \widetilde{\mu}\colon \Delta^1 & \to & \mathbb{R} \\ (1-t,t) & \mapsto & t \end{array} \text{ of } \mu\right) \;=\; 1.$$

From Proposition 74.4 we know that $\mathrm{H}_1(S^1;\mathbb{Z}) \cong \mathbb{Z}$ and by the discussion on page 2419 we know that $\mathrm{H}^1(S^1;\mathbb{Z}) \cong \mathbb{Z}$. Therefore it follows from the Kronecker-Basis Lemma 109.7 that $[\theta_{\mathbb{Z}}] \in \mathrm{H}^1(S^1;\mathbb{Z})$ is in fact a generator.[1323] In particular we have an equality $\mathrm{H}^1(S^1;\mathbb{Z}) = \mathbb{Z}\cdot[\theta_{\mathbb{Z}}]$.

Remark. the Kronecker-Basis Lemma 109.7 is really quite generous, it gives us as output that both sets are bases. In particular to apply the lemma we do not even have to verify that the c_i form a basis.

The Kronecker-Basis Lemma 109.7 is an immediate consequence of the following purely algebraic lemma.

Lemma 109.8. Let A and B be two free abelian groups of rank k, let $a_1,\ldots,a_k \in A$ and let $b_1,\ldots,b_k \in B$. Furthermore let $\langle\ ,\ \rangle\colon A\times B \to \mathbb{Z}$ be a bilinear pairing. If

$$\det(\langle a_i,b_j\rangle_{i,j=1,\ldots,k}) \;=\; \pm 1,$$

then both $a_1,\ldots,a_k$ and $b_1,\ldots,b_k$ are bases.

Proof. We denote by S the free abelian group generated by the set $\{a_1,\ldots,a_k\}$ and we denote by T the free abelian group generated by the set $\{b_1,\ldots,b_k\}$. We denote by $i\colon S \to A$ and by $j\colon T \to B$ the obvious maps given by $a_i \mapsto a_i$ and $b_i \mapsto b_i$. We denote by

[1323] It also follows from the Kronecker-Basis Lemma 109.7 that the singular 1-simplex $\mu\colon \Delta^1 \to S^1$ represents a generator for $\mathrm{H}_1(S^1) \cong \mathbb{Z}$. We had obtained that result in Lemma 76.4.

$\Phi\colon A \to \operatorname{Hom}(B,\mathbb{Z})$ the homomorphism given by $a \mapsto (b \mapsto \langle a,b\rangle)$.[1324] The claim follows from the following three observations:

(1) Let $\gamma\colon G \to H$ be a homomorphism between two finitely generated free abelian groups of the same rank. Lemma 51.9 (5) says that if γ is an epimorphism, then γ it is already an isomorphism.

(2) We consider the following sequence of homomorphisms

$$S \xrightarrow{i} A \xrightarrow{\Phi} \operatorname{Hom}(B,\mathbb{Z}) \xrightarrow{j^*} \operatorname{Hom}(T,\mathbb{Z}).$$

With respect to the basis $a_1,\dots,a_k$ of S and the dual basis $b_1^*,\dots,b_k^*$ of $\operatorname{Hom}(T,\mathbb{Z})$ this linear map is represented by the matrix $\langle a_i,b_j\rangle_{i,j=1,\dots,k}$. Thus by our hypotheses this map is an isomorphism. Furthermore by our hypotheses each of the individual groups is a free abelian group of rank k.

(3) Since the map in (2) is an isomorphism it is in particular an epimorphism. Starting from the right and using (1) three times in a row we see that all maps are in fact isomorphisms. In particular we have $S = A$. The same argument turned around shows that $T = B$. ■

Now we will use the Kronecker-Basis Lemma 109.7 to determine explicit bases for the first cohomology groups of surfaces. We start out with the torus.

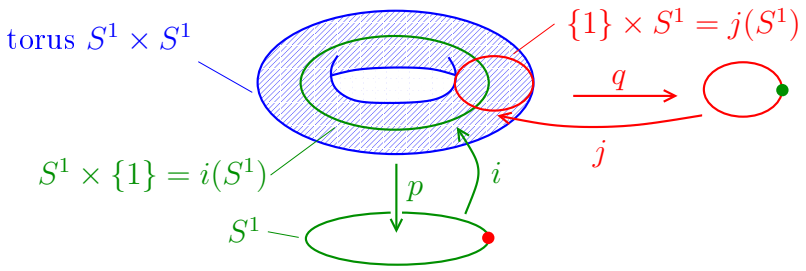
Lemma 109.9. We consider the two projection s

$$\begin{array}{rcl} p\colon S^1\times S^1 & \to & S^1 \\ (v,w) & \mapsto & v \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon S^1\times S^1 & \to & S^1 \\ (v,w) & \mapsto & w. \end{array}$$

Then $p^*([\theta_{\mathbb{Z}}])$ and $q^*([\theta_{\mathbb{Z}}])$ form a basis for $\mathrm{H}^1(S^1\times S^1;\mathbb{Z}) \cong \mathbb{Z}^2$.

Proof. We denote as usual by $\mu\colon \Delta^1 \to S^1$ our favorite singular 1-cycle of S^1 that is given by $\mu(1-t,t) = \exp(2\pi i t)$. For simplicity we write $\theta = \theta_{\mathbb{Z}}$. We denote by

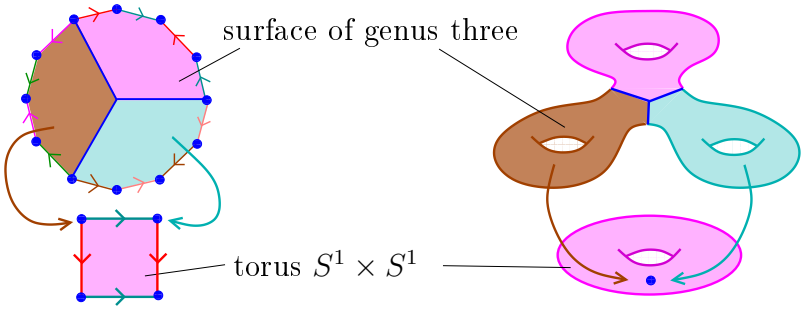
$$\begin{array}{rcl} i\colon S^1 & \to & S^1\times S^1 \\ z & \mapsto & (z,1) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon S^1 & \to & S^1\times S^1 \\ z & \mapsto & (1,z) \end{array}$$



the two obvious inclusion maps. We calculate that

$$\begin{pmatrix} \langle [p^*\theta],[i_*(\mu)]\rangle & \langle [p^*\theta],[j_*(\mu)]\rangle \\ \langle [q^*\theta],[i_*(\mu)]\rangle & \langle [q^*\theta],[j_*(\mu)]\rangle \end{pmatrix} \overset{\text{since } \langle [p^*\theta],[i_*(\mu)]\rangle = (p^*\theta)(i_*(\mu)) = \theta(p_*(i_*(\mu)))\text{ and similarly for the other terms}}{\downarrow} = \begin{pmatrix} \theta(p_*(i_*(\mu))) & \theta(p_*(j_*(\mu))) \\ \theta(q_*(i_*(\mu))) & \theta(q_*(j_*(\mu))) \end{pmatrix} \underset{\text{since } p\circ i = \mathrm{id} \text{ and } q\circ j = \mathrm{id} \text{ and since } p\circ j \equiv 1 \in S^1 \text{ and } q\circ i \equiv 1 \in S^1 \text{ here we denote by 1 also the constant singular 1-simplex given by } (1-t,t)\mapsto 1}{\uparrow} = \begin{pmatrix} \theta(\mu) & \theta(1) \\ \theta(1) & \theta(\mu) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

We know from Lemma 78.11 that $\mathrm{H}_1(S^1\times S^1;\mathbb{Z}) \cong \mathbb{Z}^2$. Furthermore we saw on page 2422 that $\mathrm{H}^1(S^1\times S^1;\mathbb{Z}) \cong \mathbb{Z}^2$. The above calculation, together with the Kronecker-Basis Lemma 109.7 shows that $p^*([\theta_{\mathbb{Z}}])$ and $q^*([\theta_{\mathbb{Z}}])$ form a basis for $\mathrm{H}^1(S^1\times S^1;\mathbb{Z})$. ■

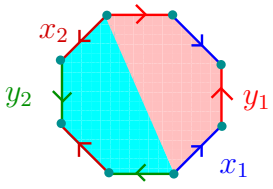


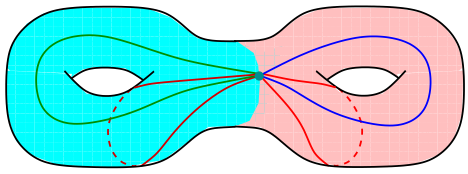
Together with the H^0-Proposition 108.11 we have now found explicit generators for the cohomology groups of the torus in dimensions 0 and 1. The following question arises:

[1324] The fact that $\langle\ ,\ \rangle$ is bilinear implies that $b \mapsto \langle a,b\rangle$ is a homomorphism and that $\Phi\colon A \to \operatorname{Hom}(B,\mathbb{Z})$ is a homomorphism.

Question 109.10. Can we find an explicit generator of $\mathrm{H}^2(S^1 \times S^1; \mathbb{Z}) \cong \mathbb{Z}$?

Now we turn to surfaces of higher genus. As usual, given $g \in \mathbb{N}$ we denote by Σ_g the surface of genus g. In the figure below we show projections $p_i \colon \Sigma_g \to S^1 \times S^1$, $i = 1, \dots, g$.[1325] The following lemma is a generalization of Lemma 109.9.





Lemma 109.11. We denote by $\alpha, \beta \in \mathrm{H}^1(S^1 \times S^1; \mathbb{Z})$ the basis given by Lemma 109.9. A basis for $\mathrm{H}^1(\Sigma_g; \mathbb{Z}) \cong \mathbb{Z}^{2g}$ is given by $p_i^*(\alpha), p_i^*(\beta)$, $i = 1, \dots, g$.

Proof. As we will see, the proof of the lemma is very similar to the proof of Lemma 109.9. For $i = 1, \dots, g$ we write $\varphi_i = p_i^*(\alpha)$ and $\psi_i := p_i^*(\beta)$. We consider the singular 1-cycles $x_1, \dots, x_g$ and $y_1, \dots, y_g$ that are indicated in the figure below. As in the proof of Lemma 109.9 it follows easily from the definitions that (for $g = 2$) we have

$$\begin{pmatrix} \langle \varphi_1, x_1 \rangle & \langle \varphi_1, y_1 \rangle & \langle \varphi_1, x_2 \rangle & \langle \varphi_1, y_2 \rangle \\ \langle \psi_1, x_1 \rangle & \langle \psi_1, y_1 \rangle & \langle \psi_1, x_2 \rangle & \langle \psi_1, y_2 \rangle \\ \langle \varphi_2, x_1 \rangle & \langle \varphi_2, y_1 \rangle & \langle \varphi_2, x_2 \rangle & \langle \varphi_2, y_2 \rangle \\ \langle \psi_2, x_1 \rangle & \langle \psi_2, y_1 \rangle & \langle \psi_2, x_2 \rangle & \langle \psi_2, y_2 \rangle \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

The lemma now follows immediately from the Kronecker-Basis Lemma 109.7. ∎

109.4. Excisive triads and the Mayer–Vietoris Theorem for cohomology groups.

Before we state and prove the Mayer–Vietoris Theorem for cohomology groups it is helpful to introduce the following definition.

[1325] In fact for $g = 2$ we already saw this map in the figure on page 1064.

Definition.

(1) A triad of topological spaces is a triple (X, A_1, A_2) where X is a topological space and where both A_1 and A_2 are subsets of X.[1326]

(2) A map $f\colon (X, A_1, A_2) \to (Y, B_1, B_2)$ of triads is a map $f\colon X \to Y$ with $f(A_1) \subset B_1$ and $f(A_2) \subset B_2$.

(3) Given a triad (X, A_1, A_2) of topological spaces we consider the following subgroup of $\mathrm{C}_n(A_1 \cup A_2)$:[1327]

$$\mathrm{C}_n^{\{A_1,A_2\}}(A_1 \cup A_2) := \left\{ \sum_{j=1}^{k} a_j \sigma_j \in \mathrm{C}_n(A_1 \cup A_2) \;\middle|\; \begin{array}{l} \text{for each } j \text{ there exists an } i \in \{1,2\} \\ \text{such that the image of } \sigma_j \text{ lies in } A_i \end{array} \right\}.$$

The usual boundary map on the groups $\mathrm{C}_*(A_1 \cup A_2)$ restricts to a boundary map on $\mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2)$, so we can view $\mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2)$ as a chain complex. We denote the corresponding homology groups by $\mathrm{H}_*^{\{A_1,A_2\}}(A_1 \cup A_2)$.

(4) We say a triad (X, A_1, A_2) is excisive if the inclusion map

$$\mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2) \;\to\; \mathrm{C}_*(A_1 \cup A_2)$$

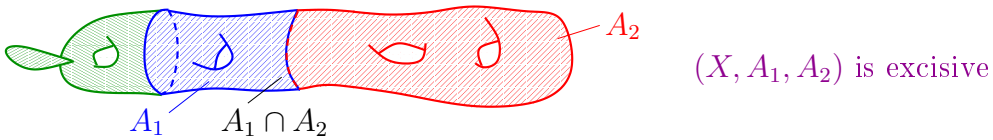
is a chain homotopy equivalence of chain complexes.

Example. In Exercise 109.2 we will see that the triad $(X, A_1, A_2) := (\mathbb{R}, (-\infty, 0], (0, \infty))$ is *not* excisive.

After this negative example we want to collect some positive examples of excisive triads.

Proposition 109.12. (Excisive Triad-Proposition) Let (X, A_1, A_2) be a triad of topological spaces. The triad is excisive if one of the following conditions is satisfied:

(1) $A_1 \subset A_2$ or $A_2 \subset A_1$,



(2) $A_1 = \varnothing$ or $A_2 = \varnothing$ or $A_1 = A_2$,

(3) $A_1 \cup A_2 = \mathring{A}_1 \cup \mathring{A}_2$ where we denote by $\mathring{A}_1$ and $\mathring{A}_2$ the interiors of A_1 and A_2 in $A_1 \cup A_2$,

(4) A_1 and A_2 are both open subsets of $A_1 \cup A_2$,

(5) $A_1 \cup A_2$ is a topological manifold and A_1 and A_2 are codimension-zero submanifolds which are both closed subsets and such that each component of $A_1 \cap A_2$ is a boundary component of A_1 and a boundary component of A_2,[1328]

(6) X is a CW-complex and A_1 and A_2 are both subcomplexes.

In the proof of the Excisive Triad-Proposition 109.12 we will need the following lemma which gives us several criteria for a triad to be excisive.

[1326] This definition should not be confused with the definition of a *triple* of topological spaces, which was defined as a triple (X, B, A) where X is a topological space and $A \subset B \subset X$ are subsets. In a triad we do not demand that the third set is contained in the second set.

[1327] The definition is basically the same as on page 1638 except that this time we do not demand that the interiors of A_1 and A_2 cover all of X.

[1328] In Exercise 109.5 we will state a generalization of this statement.

Lemma 109.13. (Excisive Characterization Lemma) Let (X, A_1, A_2) be a triad of topological spaces. The following statements are equivalent:

(1) the triad is excisive,
(2) for every $n \in \mathbb{N}_0$ the inclusion induced map
$$\mathrm{H}_n^{\{A_1,A_2\}}(A_1 \cup A_2) \;\to\; \mathrm{H}_n(A_1 \cup A_2)$$
is an isomorphism,
(3) for every $n \in \mathbb{N}_0$ the inclusion induced map
$$\mathrm{H}_n(A_1, A_1 \cap A_2) \;\to\; \mathrm{H}_n(A_1 \cup A_2, A_2)$$
is an isomorphism.

Now suppose that the triad is excisive.

(a) Given any abelian group G the statements (2) and (3) also hold for G-coefficients.
(b) Given any abelian group G the analogue of (2) also holds for cohomology groups, i.e. given any $n \in \mathbb{N}_0$ and given any abelian group G the inclusion induced map $\mathrm{H}^n(A_1 \cup A_2, A_2; G) \to \mathrm{H}^n(A_1, A_1 \cap A_2; G)$ is an isomorphism.

Proof. Let (X, A_1, A_2) be a triad of topological spaces. The equivalence of (1) and (2) is an immediate consequence of Corollary 73.4 and the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4.

Now we turn to the proof that (2) and (3) are equivalent. We write $Y = A_1 \cup A_2$. We consider the following sequences of chain complexes:

$$\begin{array}{ll}
\text{(I)} & 0 \;\to\; \mathrm{C}_*^{\{A_1,A_2\}}(Y) \;\to\; \mathrm{C}_*(Y) \;\to\; \mathrm{C}_*(Y)/\mathrm{C}_*^{\{A_1,A_2\}}(Y) \;\to\; 0 \\
\text{(II)} & 0 \;\to\; \underbrace{\mathrm{C}_*(A_1)/\mathrm{C}_*(A_1 \cap A_2)}_{=\mathrm{C}_*(A_1, A_1 \cap A_2)} \;\to\; \underbrace{\mathrm{C}_*(Y)/\mathrm{C}_*(A_2)}_{=\mathrm{C}_*(Y, A_2)} \;\to\; \mathrm{C}_*(Y)/\mathrm{C}_*^{\{A_1,A_2\}}(Y) \;\to\; 0.
\end{array}$$

The top sequence is exact by definition. It is easy to see that the bottom sequence is also exact. We can thus apply the LES Proposition 74.9 to get the corresponding long exact sequences of homology groups:

$$\begin{aligned}
&\text{(I)} \;\to \mathrm{H}_n\big(\mathrm{C}_*^{\{A_1,A_2\}}(Y)\big) \to \mathrm{H}_n(Y) \to \mathrm{H}_n\big(\mathrm{C}_*(Y)/\mathrm{C}_*^{\{A_1,A_2\}}(Y)\big) \xrightarrow{\partial} \mathrm{H}_{n-1}\big(\mathrm{C}_*^{\{A_1,A_2\}}(Y)\big) \to \\
&\text{(II)} \to \mathrm{H}_n(A_1, A_1 \cap A_2) \to \mathrm{H}_n(Y, A_2) \to \mathrm{H}_n\big(\mathrm{C}_*(Y)/\mathrm{C}_*^{\{A_1,A_2\}}(Y)\big) \xrightarrow{\partial} \mathrm{H}_{n-1}(A_1, A_1 \cap A_2) \to
\end{aligned}$$

But using these long exact sequences we see that

$$\text{(2) holds} \underset{\text{long exact sequence (I)}}{\iff} \mathrm{H}_n\big(\mathrm{C}_*(Y)/\mathrm{C}_*^{\{A_1,A_2\}}(Y)\big) = 0 \text{ for all } n \in \mathbb{N}_0 \underset{\text{long exact sequence (II)}}{\iff} \text{(3) holds.}$$

Finally we turn to the proofs of the addenda (a) and (b). Thus suppose that (X, A_1, A_2) is excisive and that G is an abelian group.

(a) The fact that the map in (2) is also an isomorphism with G-coefficients follows from basically the same argument as above. Furthermore, if (2) holds for G-coefficients, then again the same argument as above shows that also (3) holds with G-coefficients.
(b) This statement follows from the above "(1) $\Rightarrow$ (3)" implication together with Corollary 108.20. ∎

Now we turn to the proof of the Excisive Triad-Proposition 109.12.

Proof of the Excisive Triad-Proposition 109.12. Let (X, A_1, A_2) be a triad of topological spaces.

(1) If $A_1 \subset A_2$, then $\mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2) = \mathrm{C}_*(A_2) = \mathrm{C}_*(A_1 \cup A_2)$, so the triad is excisive. The same argument applies if $A_2 \subset A_1$.
(2) This case is just a special case of (1).
(3) If $A_1 \cup A_2 = \mathring{A}_1 \cup \mathring{A}_2$, then the desired statement follows immediately from Proposition 81.7.
(4) The case that A_1 and A_2 are both open subsets of $A_1 \cup A_2$ is a special case of (3).
(5) Suppose that $A_1 \cup A_2$ is a compact topological manifold and that A_1 and A_2 are submanifolds such that each component of $A_1 \cap A_2$ is a boundary component of A_1 and a boundary component of A_2. The Excision Theorem 75.10 for topological manifolds implies that for every $n \in \mathbb{N}_0$ the inclusion induced map

$$\mathrm{H}_n(A_1, A_1 \cap A_2) \;\to\; \mathrm{H}_n(A_1 \cup A_2, A_2)$$

is an isomorphism. By the Excisive Characterization Lemma 109.13 (3) $\Rightarrow$ (1) this implies that the triad (X, A_1, A_2) is excisive.
(6) Suppose that X is a CW-complex and that A_1 and A_2 are both subcomplexes. The proof of the Excision Theorem 75.10 for Topological Manifolds can easily be modified to give the corresponding statement for CW-complexes. More precisely, in the proof of the Excision Theorem 75.10 for Topological Manifolds we need to replace the Smooth Collar Neighborhood Theorem 28.3 by the CW-Complex Properties Proposition 68.10 (8). Furthermore we need to replace the Smooth Manifold Boundary Proposition 19.26 (3) by the Subcomplex Lemma 68.18 (2). We then proceed as in (5). We leave it to the reader to fill in the details. ■

Now we can formulate the following theorem, which in view of the Excisive Triad-Proposition 109.12 is a generalization of the various Mayer–Vietoris Theorems 78.5, 78.9, and 78.10 that we had formulated earlier.

Theorem 109.14. (Mayer–Vietoris Theorem) Given any excisive triad (X, A, B) with $X = A \cup B$ there exists a natural connecting homomorphism

$$\partial_n \colon \mathrm{H}_n(X) \;\to\; \mathrm{H}_{n-1}(A \cap B)$$

such that the following sequence[1329]

$$\cdots \to \mathrm{H}_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n(A) \oplus \mathrm{H}_n(B) \xrightarrow{i_A + i_B} \mathrm{H}_n(X) \xrightarrow{\partial_n} \mathrm{H}_{n-1}(A \cap B) \to \dots$$

is exact, where the various maps denoted by i are the obvious inclusion induced maps. The same connecting homomorphism and long exact sequence also exists for homology with coefficients in any abelian group G.

[1329] The fact that the connecting homomorphism is natural implies given a map $f \colon (X, A, B) \to (Y, C, D)$ of excisive triads with $X = A \cup B$ and $Y = C \cup D$ the following diagram commutes:

$$\begin{array}{ccccccccccc}
\dots & \longrightarrow & \mathrm{H}_n(A \cap B) & \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} & \mathrm{H}_n(A) \oplus \mathrm{H}_n(B) & \xrightarrow{i_A + i_B} & \mathrm{H}_n(X) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(A \cap B) & \longrightarrow & \dots \\
 & & \downarrow f_* & & \downarrow f_* & & \downarrow f_* & & \downarrow f_* & & \\
\dots & \longrightarrow & \mathrm{H}_n(C \cap D) & \xrightarrow{i_{C\cap D} \oplus -i_{C\cap D}} & \mathrm{H}_n(C) \oplus \mathrm{H}_n(D) & \xrightarrow{i_C + i_D} & \mathrm{H}_n(Y) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(C \cap D) & \longrightarrow & \dots
\end{array}$$

Proof. Let (X, A, B) be a triad with $X = A \cup B$. In the proof of the original Mayer–Vietoris Theorem 78.5 we showed that the sequence

$$0 \to \mathrm{C}_*(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{C}_*(A) \oplus \mathrm{C}_*(B) \xrightarrow{i_A + i_B} \mathrm{C}_*^{\{A,B\}}(X) \to 0$$

of chain maps is exact. We deduce from the LES Proposition 74.9 that we get a long exact sequence of the form

$$\cdots \to \mathrm{H}_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n(A) \oplus \mathrm{H}_n(B) \xrightarrow{i_A + i_B} \mathrm{H}_n^{\{A,B\}}(X) \xrightarrow{p_n} \mathrm{H}_{n-1}(A \cap B) \to \ldots$$

Recall that the connecting homomorphism is natural by the LES Proposition 74.9. Now we suppose that (X, A, B) is in fact excisive. By definition, and since $X = A \cup B$, this means that the inclusion map

$$\mathrm{C}_*^{\{A,B\}}(X) \quad \to \quad \mathrm{C}_*(X)$$

is a chain homotopy equivalence, hence for every $n \in \mathbb{N}_0$ it induces a natural isomorphism

$$\Phi_n \colon \mathrm{H}_n^{\{A,B\}}(X) \quad \xrightarrow{\cong} \quad \mathrm{H}_n(X).$$

For each $n \in \mathbb{N}_0$ we now replace $\mathrm{H}_n^{\{A,B\}}(X)$ by $\mathrm{H}_n(X)$ and we write $\partial_n := p_n \circ \Phi_n^{-1}$ and we finally get the desired natural long exact sequence.

The argument for homology with G-coefficients is very similar, see also page 1915. We leave the details to the dedicated reader. ■

We also have the following analogue for cohomology groups.

Theorem 109.15. (Mayer–Vietoris Theorem for Cohomology Groups) Let (X, A, B) be an excisive triad with $X = A \cup B$ and let G be an abelian group. Then there exists a natural[1330] long exact sequence

$$\cdots \to \mathrm{H}^n(X; G) \xrightarrow{i^* \oplus i^*} \mathrm{H}^n(A; G) \oplus \mathrm{H}^n(B; G) \xrightarrow{i^* \oplus -i^*} \mathrm{H}^n(A \cap B; G) \to \mathrm{H}^{n+1}(X; G) \to \ldots$$

where the maps i^* are the restrictions to the various subspaces.

Proof. Let (X, A, B) be an excisive triad with $X = A \cup B$ and let G be an abelian group. We start out with the following claim.

Claim. The inclusion map

$$\mathrm{C}_*^{\{A,B\}}(X) \quad \to \quad \mathrm{C}_*(X)$$

induces for each $n \in \mathbb{N}_0$ a natural isomorphism

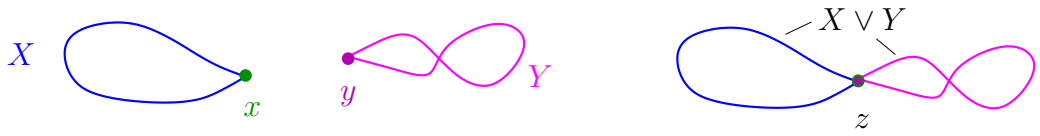
$$\mathrm{H}^n(X; G) \quad \to \quad \mathrm{H}^n\big(\mathrm{C}_*^{\{A,B\}}(X); G\big).$$

Proof. The claim follows immediately from the definition of an excisive triad together with the Dual Cochain Map Lemma 108.8 (3). ⊞

Now we turn to the actual proof of the Mayer–Vietoris Theorem for Cohomology Groups. Exactly as in the proof of the Mayer–Vietoris Theorem 109.14 we start out with the fact that the following sequence is exact:

$$0 \to \mathrm{C}_*(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{C}_*(A) \oplus \mathrm{C}_*(B) \xrightarrow{i_A + i_B} \mathrm{C}_*^{\{A,B\}}(X) \to 0.$$

The groups $\mathrm{C}_*^{\{A,B\}}(X)$ are clearly free abelian groups. Thus we deduce from Lemma 108.4 and the Connecting Homomorphism Proposition 108.6 that there exists a natural long exact



[1330] The meaning of "natural" is evidently totally analogous to the interpretation given in Footnote 1329.

sequence

$$\to \underbrace{\mathrm{H}^n\big(\mathrm{C}_*^{\{A,B\}}(X);G\big)}_{=\mathrm{H}^n(X;G)\ \text{by the claim}} \to \mathrm{H}^n(A;G)\oplus\mathrm{H}^n(B;G) \to \mathrm{H}^n(A\cap B;G) \to \underbrace{\mathrm{H}^{n+1}\big(\mathrm{C}_*^{\{A,B\}}(X);G\big)}_{=\mathrm{H}^{n+1}(X;G)\ \text{by the claim}} \to \quad \blacksquare$$

As an application of the Mayer–Vietoris Theorem 109.15 for Cohomology Groups we will determine the cohomology groups of the wedge of two topological spaces. We will not make use of this example.

Lemma 109.16. (Wedge Excisive Lemma) Let X and Y be topological spaces and let $x \in X$ and $y \in Y$ be good points.[1331] We use these points to define the wedge $X \vee Y$. Then $(X \vee Y, X, Y)$ is an excisive triad.

Proof. We denote by z the point in $X \vee Y$ that is given by identifying x with y. For each $k \in \mathbb{N}_0$ we consider the following diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{H}_k(Y,\{y\};\mathbb{Z}) & \longrightarrow & \mathrm{H}_k(X,\{x\};\mathbb{Z}) \oplus \mathrm{H}_k(Y,\{y\};\mathbb{Z}) & \longrightarrow & \mathrm{H}_k(X,\{x\};\mathbb{Z}) & \longrightarrow & 0 \\
 & & \downarrow{=} & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathrm{H}_k(Y,\{y\};\mathbb{Z}) & \longrightarrow & \mathrm{H}_k(X\vee Y,\{z\};\mathbb{Z}) & \longrightarrow & \mathrm{H}_k(X\vee Y, Y;\mathbb{Z}) & \longrightarrow & 0
\end{array}$$

where all the maps are the obvious maps. The top horizontal sequence is evidently exact. The bottom horizontal sequence is an excerpt from the long exact sequence of the triple $(\{y\} = \{z\}, Y, X \vee Y)$, see the Topological LES-Proposition 74.13. The excerpt shown is also exact since $(Y,\{y\})$ is a retract of $(X \vee Y,\{z\})$, which implies that for any $l \in \mathbb{N}_0$ the inclusion induced map $\mathrm{H}_l(Y,\{y\};\mathbb{Z}) \to \mathrm{H}_l(X \vee Y,\{z\};\mathbb{Z})$ is a monomorphism.

The middle vertical map in the above diagram is an isomorphism by the Wedge-H_*-Proposition 79.8 and the left vertical map is the identity. It follows from the Five Lemma 74.10 that the right vertical hand map is an isomorphism. We obtain from the Excisive Characterization Lemma 109.13 (3) $\Rightarrow$ (1) that $(X \vee Y, X, Y)$ is an excisive triad. $\blacksquare$

We prove the following proposition that is the analogue of the Wedge-H_*-Proposition 79.9.

Proposition 109.17. (Wedge-H^*-Proposition) Let $\{A_k\}_{k\in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. Let G be an abelian group. Given $j \in K$ we denote by

$$i_j\colon A_j \to \bigvee_{k\in K} A_k \quad \text{respectively} \quad p_j\colon \bigvee_{k\in K} A_k \to A_j$$

[1331] Recall that according to the definition on page 1171 we say that a point x in a topological space X is *good*, if $\{x\}$ is a closed subset and if there exists an open neighborhood U of x such that $\{x\}$ is a deformation retract of U.

the natural inclusion map respectively the natural projection that we introduced on page 1134. Then for every $n \in \mathbb{N}_0$ the map

$$\prod_{k\in K} i_k^* \colon \widetilde{\mathrm{H}}^n\Big(\bigvee_{k\in K} A_k; G\Big) \;\to\; \prod_{k\in K} \widetilde{\mathrm{H}}^n(A_k; G)$$

is an isomorphism where the inverse is given by

$$\prod_{k\in K} p_k^* \colon \prod_{k\in K} \widetilde{\mathrm{H}}^n(A_k; G) \;\to\; \widetilde{\mathrm{H}}^n\Big(\bigvee_{k\in K} A_k; G\Big)$$

Proof.

(1) First we consider the case we are given just two topological spaces. By the Wedge Excisive Lemma 109.16 we can use the Mayer–Vietoris Theorem 109.15 for Cohomology Groups to prove, completely analogously to the Wedge-H_*-Proposition 79.8, the desired statement.

(2) The case that we are dealing with finitely many topological spaces follows from (1) by induction.

(3) The case that K is infinite is more tricky. There are two possible approaches:

(a) In the proof of the Wedge-H_*-Proposition 79.9, that deals with the corresponding statement for homology groups, we gave two different proofs. The first proof generalizes to the present setting. It is not clear to me how the second proof can be generalized. But fortunately providing one proof is enough.[1332]

(b) Alternatively we can consider the map

$$\bigoplus_{k\in K} i_{k*} \colon \bigoplus_{k\in K} \widetilde{C}_n(A_k) \;\to\; \widetilde{C}_n\Big(\bigvee_{k\in K} A_k\Big).$$

By the Wedge-H_*-Proposition 79.9 this chain map induces an isomorphism of chain complexes. It follows from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 that this map is in fact a chain homotopy equivalence. It follows from the Dual Cochain Map Lemma 108.8 that the above map induces an isomorphism of dual cochain complexes. The desired statement now follows from throwing Lemmas 108.2 and 108.7 into the bargain. The same logic applies to the projections. ■

Recall that in the Suspension-H_*-Proposition 76.7 we showed that for any $k \in \mathbb{Z}$ and any topological space X we have a natural isomorphism

$$\Sigma_X \colon \widetilde{\mathrm{H}}_k(X) \;\xrightarrow{\cong}\; \widetilde{\mathrm{H}}_{k+1}(\Sigma(X)).$$

Not surprisingly we have a totally analogous statement in cohomology:

Lemma 109.18. (Suspension-H^*-Lemma) Let $k \in \mathbb{Z}$ and let G be an abelian group. Given any topological space X we have a natural isomorphism

$$\Sigma_X \colon \widetilde{\mathrm{H}}^k(\Sigma(X); G) \;\xrightarrow{\cong}\; \widetilde{\mathrm{H}}^{k+1}(X; G)$$

which has the property that for any $\varphi \in \mathrm{H}^k(X; G)$ and any $\sigma \in \mathrm{H}_k(X)$ we have

$$\langle \Sigma_X(\varphi), \Sigma_X(\sigma)\rangle_{\Sigma(X)} \;=\; \langle \varphi, \sigma\rangle_X \;\in\; G.$$

[1332] In fact the proof of the Wedge-H_*-Proposition 79.9 that we sketched in Exercise 79.2 can also be generalized to the present context.

Proof. The construction of the isomorphism Σ_X is basically the same as the construction of the corresponding isomorphism in cohomology. In the Suspension-H_*-Proposition 76.7 we just need to replace the Mayer–Vietoris Theorem 78.5 by the Mayer–Vietoris Theorem 109.15 for Cohomology Groups. We leave it to the reader to fill in the details. ■

Example. Let $n \in \mathbb{N}$. Let $\Sigma(S^n) \to S^{n+1}$ be the homeomorphism from page 452. On page 1683 we showed that

$$\Sigma_{S^n}([S^n]) \;=\; (-1)^{n+1} \cdot [S^{n+1}] \;\in\; \mathrm{H}_{n+1}(S^{n+1};\mathbb{Z}).$$

From the equality in the Suspension-H^*-Lemma 109.18 we obtain the corresponding equality

$$\Sigma_{S^n}([S^n]^*) \;=\; (-1)^{n+1} \cdot [S^{n+1}]^* \;\in\; \mathrm{H}^{n+1}(S^{n+1};\mathbb{Z}).$$

Exercises for Chapter 109.

Exercise 109.1. Let X be a topological space which is homotopy equivalent to a retract of a finite CW-complex. Show that for every $n \in \mathbb{N}_0$ the cohomology group $\mathrm{H}^n(X;\mathbb{Z})$ is a finitely generated group.

Exercise 109.2. Show that the triad $(X, A_1, A_2) := (\mathbb{R}, (-\infty, 0], (0, \infty))$ is *not* excisive.

Exercise 109.3. Use cellular cohomology to determine the isomorphism types of the cohomology groups of the Klein bottle with $\mathbb{F}_2$-coefficients, with $\mathbb{F}_3$-coefficients and with $\mathbb{Z}$-coefficients.

Exercise 109.4. Let $\{A_k\}_{k\in K}$ be a family of CW-complexes. Suppose that for each $k \in K$ suppose that we are given a point in the 0-skeleton of A_k. Provide a proof for the Wedge-H^*-Proposition 109.17 using cellular cohomology. More precisely, provide a proof along the following lines:

(a) Equip $X := \bigvee_{k\in K} A_k$ with the CW-structure provided by the CW-Complex Construction Lemma 68.32.
(b) Determine the relationship between the reduced cellular chain complexes of X and of the A_i.
(c) Make use of the Singular-Cellular Chain Complex Proposition 81.12.
(d) Make use of Lemmas 108.2 and 108.7.

Exercise 109.5. Let (X, A_1, A_2) be a triad of topological spaces. We suppose that $A_1 \cup A_2$ is a topological manifold and that A_1 and A_2 are codimension-zero submanifolds which are both closed subsets. Furthermore we suppose that we have $A_1 \cup A_2 = (A_1 \setminus \partial A_1) \cup (A_2 \setminus \partial A_2) \cup C$ where each component of C is a boundary component of A_1 and a boundary component of A_2. Show that (X, A_1, A_2) is an excisive triad.
Remark. This exercise is a generalization of the Excisive Triad-Proposition 109.12 (5).

110. The Universal Coefficient Theorems for Cohomology Groups

110.1. **The Ext group.** One of the questions that arises from the last chapter is, how can we explain the erratic relationship between homology groups and cohomology groups that we saw on page 2423. Furthermore it would be interesting to know whether given a chain complex one can determine the cohomology groups with G-coefficients from the usual homology group.

These questions are purely in the realm of algebra. More precisely, let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups and let G an abelian group. We want to find a connection between the cohomology groups $\mathrm{H}^*(C;G)$ and the homology groups $\mathrm{H}_*(C)$. This problem, and later on its solution, is very similar to the problem we faced in Chapter 89 where we showed that we can determine homology groups of a chain complex with G-coefficients from the usual homology group of the chain complex.

As usual we denote by $\mathcal{AbGroup}$ the category of abelian groups. On page 1918 we defined what it means for a *covariant* functor $F\colon \mathcal{AbGroup} \to \mathcal{AbGroup}$ to be exact, left-exact and right-exact. Basically the same way we can introduce these notions for *contravariant* functors $F\colon \mathcal{AbGroup} \to \mathcal{AbGroup}$.

Definition. A contravariant functor $F\colon \mathcal{AbGroup} \to \mathcal{AbGroup}$ is called left-exact[1333] if for all exact sequences

$$A \xrightarrow{i} B \xrightarrow{j} C \longrightarrow 0$$

of abelian groups the sequence

$$0 \longrightarrow F(C) \xrightarrow{F(j)} F(B) \xrightarrow{F(i)} F(A)$$

is also exact. Furthermore a contravariant functor $F\colon \mathcal{AbGroup} \to \mathcal{AbGroup}$ is called right-exact, if for all exact sequences

$$0 \longrightarrow A \xrightarrow{i} B \xrightarrow{j} C$$

the sequence

$$F(C) \xrightarrow{F(j)} F(B) \xrightarrow{F(i)} F(A) \longrightarrow 0$$

is also exact.

In Lemma 89.10 we saw that the covariant functor $-\otimes G$ is right-exact but that in general it is not left-exact. With the contravariant functor $\mathrm{Hom}(-,G)$ the situation is precisely the converse. More precisely, in the next lemma we will show that this functor is left-exact and immediately afterwards we will give an example that shows that the contravariant functor $\mathrm{Hom}(-,G)$ is in general not right-exact.

Lemma 110.1. (Hom-Left Exact Lemma) For any abelian group G the contravariant functor $\mathrm{Hom}(-,G)$ is left-exact.

Proof. Let G be an abelian group and let

$$A \xrightarrow{\alpha} B \xrightarrow{\beta} C \longrightarrow 0$$

be an exact sequence of abelian groups. We need to show that the sequence

$$0 \longrightarrow \mathrm{Hom}(C,G) \xrightarrow{\beta^*} \mathrm{Hom}(B,G) \xrightarrow{\alpha^*} \mathrm{Hom}(A,G)$$

[1333] Admittedly one could also refer to this definition as "right"-exact, since the direction changes. But the definition we give is the one which is commonly used in the literature.

is also exact. It is clear that β^* is injective and that $\alpha^* \circ \beta^* = (\beta \circ \alpha)^* = 0$, i.e. we have $\operatorname{im}(\beta^*) \subset \ker(\alpha^*)$. It remains to show that $\ker(\alpha^*) \subset \operatorname{im}(\beta^*)$. So let $f\colon B \to G$ be a homomorphism such that $\alpha^*(f) = 0$. We consider the following diagram:

$$\begin{array}{ccccccc} A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & C & \longrightarrow & 0. \\ & & \downarrow{\scriptstyle f} & \searrow^{\pi} & \uparrow{\scriptstyle \overline{\beta}}\ {\scriptstyle [b]\mapsto\beta(b)} & & \\ & & G & \xleftarrow[f(b)\hookleftarrow[b]]{\overline{f}} & B/\alpha(A) & & \end{array}$$

We make the following observations:

(1) Since $\alpha^*(f)$ we know that f vanishes on $\alpha(A)$. We denote by $\overline{f}\colon B/\alpha(A) \to G$ the resulting homomorphism given by $[b] \mapsto f(b)$.
(2) We denote $\pi\colon B \to B/\alpha(A)$ the projection.
(3) By the exactness of the original sequence the homomorphism β induces an isomorphism $\overline{\beta}\colon B/\alpha(A) \to C$.
(4) By construction the above diagram commutes.
(5) Now we see that $f = \overline{f} \circ \overline{\beta}^{-1} \circ \beta$, i.e. we have $f = \beta^*(\overline{f} \circ \overline{\beta}^{-1})$. ■

Now we give the example, promised above, that shows that the contravariant functor $\operatorname{Hom}(-, G)$ is in general not right-exact.

Example. We consider the chain complex

$$0 \to \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{p} \mathbb{Z}_2$$

where $p\colon \mathbb{Z} \to \mathbb{Z}_2$ denotes the natural projection. We apply the contravariant functor $\operatorname{Hom}(-, \mathbb{F}_2)$. The resulting cochain complex is of the form[1334]

$$\mathbb{F}_2 \xrightarrow[\cong]{p^*} \mathbb{F}_2 \xrightarrow[=0]{(\cdot 2)^*} \mathbb{F}_2 \to 0.$$

Since this cochain complex is not exact it follows that the functor $\operatorname{Hom}(-, \mathbb{F}_2)$ is not right-exact.

In Chapter 89.4 we introduced the torsion groups $\operatorname{Tor}(H, G)$ which "measure" to what degree the functor $- \otimes G$ fails to be a left-exact functor. The same way we now introduce the so called Ext-groups $\operatorname{Ext}(H, G)$ which "measure" to what degree the functor $\operatorname{Hom}(-, G)$ fails to be right-exact.

Definition. Let G and H be abelian groups. We denote by

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

the canonical free resolution from page 1922. We define the n-th G-Ext-group of H as

$$\operatorname{Ext}^n(H, G) := \mathrm{H}^n(F_*; G).$$

[1334]Here we use the identification $\operatorname{Hom}(\mathbb{Z}, G) = G$ from Lemma 108.1 and we use that multiplication by 2 is the zero endomorphism of $\mathbb{F}_2$.

Remark. Let $n \in \mathbb{N}_0$. On page 1923 we saw that $\mathrm{Tor}_n(H, G)$ is covariantly functorial in both G and H. Now we will see that the groups $\mathrm{Ext}_n(H, G)$ are contravariantly functorial in H and covariantly functorial in G:

(1) Let $\alpha\colon H \to H'$ be a homomorphism between abelian groups and let G be an abelian group. Then it follows from the Fundamental Theorem 81.1 of Homological Algebra together with the definition of the G-Ext groups that α induces a homomorphism

$$\begin{aligned} \alpha^*\colon \mathrm{Ext}^n(H', G) &\to \mathrm{Ext}^n(H, G). \\ \text{It is now straightforward to show that} & \\ H &\mapsto \mathrm{Ext}^n(H, G) \\ (\alpha\colon H \to H') &\mapsto (\alpha^*\colon \mathrm{Ext}^n(H', G) \to \mathrm{Ext}^n(H, G)) \end{aligned}$$

is a *contravariant* functor from the category of abelian groups to the category of abelian groups.

(2) On the other hand, if $\beta\colon G \to G'$ is a homomorphism between abelian groups then one sees easily that β induces a homomorphism

$$\begin{aligned} \beta_*\colon \mathrm{Ext}^n(H, G) &\to \mathrm{Ext}^n(H, G') \\ \text{Furthermore one can easily prove that} & \\ G &\mapsto \mathrm{Ext}^n(H, G) \\ (\beta\colon G \to G') &\mapsto (\beta_*\colon \mathrm{Ext}^n(H, G) \to \mathrm{Ext}^n(H, G')) \end{aligned}$$

is a *covariant* functor from the category of abelian groups to the category of abelian groups.

The following proposition is the analogue of the Tor-Free Resolution Proposition 89.12.

Proposition 110.2. (Ext-Free Resolution Proposition) Let G and H be abelian groups and let

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be a free resolution of H. Then for each $n \in \mathbb{N}_0$ there exists a canonical isomorphism

$$\mathrm{Ext}^n(H, G) \xrightarrow{\cong} \mathrm{H}^n(F_*, G).$$

In particular if

$$0 \to F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

is a free resolution of H of length one, then there exist canonical isomorphisms

$$\begin{aligned} \mathrm{Ext}^1(H, G) &\xrightarrow{\cong} \mathrm{coker}\left(\mathrm{Hom}(F_0, G) \xrightarrow{f_1^*} \mathrm{Hom}(F_1, G)\right) \\ \text{and} \quad \mathrm{Ext}^0(H, G) &\xrightarrow{\cong} \ker\left(\mathrm{Hom}(F_0, G) \xrightarrow{f_1^*} \mathrm{Hom}(F_1, G)\right) \end{aligned}$$

Proof. The proof is almost the same as the proof of the Tor-Free Resolution Proposition 89.12. We leave it to the reader to make the necessary changes. ■

In Lemma 89.14 we saw that the higher torsion groups of abelian groups vanish. The same statement, with basically the same proof, also holds for Ext groups. More precisely, we have the following corollary.

Corollary 110.3. For every choice of abelian groups G and H we have $\mathrm{Ext}^n(H, G) = 0$ for $n \geq 2$.

Proof. As we pointed out in the proof of Lemma 89.14 any abelian group H admits a free resolution of length 2:

$$0 \to F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0.$$

The corollary now follows immediately from the Ext-Free Resolution Proposition 110.2. ■

In the Tor_0–Lemma 89.13 we saw that the 0-th Torsion functor is an old acquaintance. More precisely we saw that for all abelian groups G and H there exists a natural isomorphism $\mathrm{Tor}_0(H,G) \xrightarrow{\cong} H \otimes G$. The following lemma gives us the analogous result for the 0-th Ext functor.

Lemma 110.4. Let G and H be abelian groups .There exists a natural[1335] isomorphism

$$\mathrm{Ext}^0(H,G) \xrightarrow{\cong} \mathrm{Hom}(H,G).$$

Proof. The proof of Lemma 110.4 is, not surprisingly, rather similar to the proof of the Tor_0–Lemma 89.13. Let G and H be abelian groups. Let

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be the canonical free resolution of H. We know from the Hom-Left Exact Lemma 110.1 that the sequence

$$(*) \qquad 0 \to \mathrm{Hom}(H,G) \xrightarrow{f_0^*} \mathrm{Hom}(F_0,G) \xrightarrow{f_1^*} \mathrm{Hom}(F_1,G)$$

is exact. Now we obtain the following isomorphism

$$\begin{aligned} \mathrm{Ext}_0(H,G) &\overset{\text{by definition}}{=} \mathrm{H}^0\big(\cdots \leftarrow \mathrm{Hom}(F_1,G) \xleftarrow{f_1^*} \mathrm{Hom}(F_0,G) \leftarrow 0\big) \\ &= \ker\big(\mathrm{Hom}(F_1,G) \xleftarrow{f_1^*} \mathrm{Hom}(F_0,G)\big) \xrightarrow[\text{isomorphism since } (*) \text{ is exact}]{f_0^*} \mathrm{Hom}(H,G). \end{aligned}$$

It is straightforward to verify that these isomorphisms are in fact natural. ■

Definition. Given abelian groups G and H we refer to

$$\mathrm{Ext}(H,G) := \mathrm{Ext}^1(H,G)$$

as *the* G-Ext-group of H.

Remark. Let G and H be two abelian groups. An *extension of H by G* is a short exact sequence of the form

$$0 \longrightarrow G \xrightarrow{\alpha} K \xrightarrow{\beta} H \longrightarrow 0.$$

[1335] Here by "natural" we mean that these isomorphisms define a natural isomorphism from the contravariant functor $H \mapsto \mathrm{Ext}^0(H,G)$ to the contravariant functor $H \mapsto \mathrm{Hom}(H,G)$ and that they also define a natural transformation from the covariant functor $G \mapsto \mathrm{Ext}^0(H,G)$ to the covariant functor $G \mapsto \mathrm{Hom}(H,G)$.

We say that two such extensions given by K and K' are *equivalent* if there exists a homomorphism $\varphi\colon K \to K'$ that makes the following diagram commute

$$\begin{array}{ccccccccc} 0 & \longrightarrow & G & \xrightarrow{\alpha} & K & \xrightarrow{\beta} & H & \longrightarrow & 0 \\ & & \downarrow{=} & & \downarrow{\varphi} & & \downarrow{=} & & \\ 0 & \longrightarrow & G & \xrightarrow{\alpha'} & K' & \xrightarrow{\beta'} & H & \longrightarrow & 0. \end{array}$$

In [**HS1997**, Theorem II.3.4] it is shown that there is a natural bijection from the set of equivalence classes of extensions of H by G with the set $\mathrm{Ext}(H,G)$. This fact is the origin of the name "Ext-group".

In light of Corollary 110.3 and Lemma 110.4 the remaining task is to compute the Ext-group $\mathrm{Ext}(H,G) = \mathrm{Ext}_1(H,G)$. The following lemma allows us in particular to determine the Ext-group for all finitely generated abelian groups.

Lemma 110.5. (Ext-Calculation Lemma) Let G, H and $G_1, \ldots, G_k, \mathrm{H}_1, \ldots, \mathrm{H}_k$ be abelian groups. The following statements hold:

(1) There exists a natural isomorphism

$$\mathrm{Ext}\left(\bigoplus_{i=1}^{k} \mathrm{H}_i, G\right) \;\cong\; \bigoplus_{i=1}^{k} \mathrm{Ext}(\mathrm{H}_i, G).$$

(2) There exists a natural isomorphism

$$\mathrm{Ext}\left(H, \bigoplus_{i=1}^{k} G_i\right) \;\cong\; \bigoplus_{i=1}^{k} \mathrm{Ext}(H, G_i).$$

(3) If H is a free abelian group, then $\mathrm{Ext}(H,G) = 0$.

(4) For all $n \in \mathbb{N}$ we have a natural isomorphism $\mathrm{Ext}(\mathbb{Z}_n, G) \cong G/nG$.

(5) If H is a finitely generated abelian group, then we have a natural isomorphism

$$\mathrm{Ext}(H,\mathbb{Z}) \cong \text{torsion subgroup of } H := \{h \in H \mid \text{there exists an } n \in \mathbb{N} \text{ with } nh = 0\}.$$

In particular $\mathrm{Ext}(H,\mathbb{Z})$ is a finite group.

(6) For $n, m \in \mathbb{N}$ we have $\mathrm{Ext}(\mathbb{Z}_n, \mathbb{Z}_m) \cong \mathbb{Z}_{\gcd(n,m)}$.

Remark.

(a) The first two statements of the lemma also generalize to the case of infinitely many groups, but some care needs to be taken. Indeed, some of the finite direct sums are secretly finite direct products and hence they generalize to infinite direct products. More precisely, the following holds:

(1′) If $\{\mathrm{H}_i\}_{i\in I}$ is a family of abelian groups and if G is an abelian group, then

$$\mathrm{Ext}\left(\bigoplus_{i\in I} \mathrm{H}_i, G\right) \;\cong\; \prod_{i\in I} \mathrm{Ext}(\mathrm{H}_i, G).$$

(2′) If H is an abelian group and if $\{G_i\}_{i\in I}$ is a family of abelian groups, then

$$\mathrm{Ext}\left(H, \prod_{i\in I} G_i\right) \;\cong\; \prod_{i\in I} \mathrm{Ext}(H, G_i).$$

We refer to [**Rot2009**, Propositions 7.21 and 7.22] for a proof. We will not make use of these more general statements.

(b) The statements of the Ext-Calculation Lemma 110.5 look very similar to the statements of the Tor-Properties Lemma 89.15. But there are some differences:
   (i) In the Tor-Properties Lemma 89.15 we saw that for every abelian group we have $\mathrm{Tor}(H, \mathbb{Z}) = 0$ whereas we have now shown in the Ext-Calculation Lemma 110.5 (5) that for every finite abelian group we have $\mathrm{Ext}(H, \mathbb{Z}) \cong H$.
   (ii) In the Tor-Properties Lemma 89.15 we saw that $\mathrm{Tor}(H, G) = 0$ not only whenever H is a free abelian group but also for all torsion-free abelian groups H. Here the situation is different, the statement of the Ext-Calculation Lemma 110.5 (3) does not generalize to torsion-free abelian groups. For example in [**Rot2009**, p. 428] it is shown that there exists an abelian group G such that $\mathrm{Ext}(\mathbb{Q}, G) \neq 0$. But this issue is of no concern to us.

Proof. The first three statements are proved almost the same way as we proved the Tor-Properties Lemma 89.15. We leave it to the reader to fill in the details. We turn to the final three statements.

(4) Let G be an abelian group and let $n \in \mathbb{N}$. We have

$$\mathrm{Ext}(\mathbb{Z}_n, G) \overset{\text{Ext-Free Resolution Proposition 110.2 applied to the free resolution } 0 \to \mathbb{Z} \xrightarrow{\cdot n} \mathbb{Z} \to \mathbb{Z}_n \to 0}{=} \mathrm{coker}\left(\mathrm{Hom}(\mathbb{Z}, G) \xrightarrow{(\cdot n)^*} \mathrm{Hom}(\mathbb{Z}, G)\right) \underset{\text{by the isomorphism } \mathrm{Hom}(\mathbb{Z}, G) = G \text{ given by } f \mapsto f(1)}{=} \mathrm{coker}\left(G \xrightarrow{\cdot n} G\right) = G/nG.$$

(5) This statement follows immediately from (1), (3) and (4) together with the Finitely Generated Abelian Group Classification Theorem 51.4.
(6) This statement follows immediately from (4) and the calculation on page 1922. ■

We have one more general result for calculating Ext-groups. Before we can state the result we need one more definition.

Definition. An abelian group G is called divisible if for every $g \in G$ and $n \in \mathbb{N}$ there exists an $h \in G$ with $n \cdot h = g$.

Examples.

(1) The groups $\mathbb{Q}, \mathbb{R}$ and $\mathbb{C}$ are divisible.
(2) Every quotient of a divisible group is easily seen to be divisible again. For example the quotient group $\mathbb{Q}/\mathbb{Z}$ is also divisible.[1336] This example also shows, using the notation of the definition, that h is not necessarily unique. For example, for $g = [0]$ and $n = 3$ we could take $h = [0]$ or $h = [\frac{1}{3}]$.
(3) The group $\mathbb{Z}$ is not divisible, and the only finite group that is divisible is the trivial group.

Proposition 110.6. Let G and H be abelian groups. If G is divisible, then $\mathrm{Ext}(H, G) = 0$.

In the proof of Proposition 110.6 it is useful to introduce the following notion.

Definition. An abelian group G is called injective if for all abelian groups A and B, every injective homomorphism $\varphi\colon B \to A$ and every homomorphism $\beta\colon B \to G$ there exists a

[1336] Odd as it may sound, this example will actually be important later in Section 148.4.

homomorphism $\alpha\colon A \to G$ such that the following diagram commutes

$$\begin{array}{ccccc} 0 & \longrightarrow & B & \overset{\varphi}{\hookrightarrow} & A \\ & & {\scriptstyle\beta}\downarrow & \swarrow_{\alpha} & \\ & & G. & & \end{array}$$

The following lemma shows why we are interested in injective groups.

Lemma 110.7. Let G and H be abelian groups. If G is injective, then $\mathrm{Ext}(H, G) = 0$.

Proof. Let H be an abelian group. As we pointed out in the proof of Lemma 89.14 the abelian group H admits a free resolution of length 2:

$$0 \to F_1 \xrightarrow{\varphi_1} F_0 \xrightarrow{\varphi_0} H \to 0.$$

By the Ext-Free Resolution Proposition 110.2 the group $\mathrm{Ext}(H, G)$ is isomorphic to the cokernel of the map

$$\mathrm{Hom}\begin{pmatrix} F_1 \\ \downarrow \\ G \end{pmatrix} \xleftarrow{\varphi_1^*} \mathrm{Hom}\begin{pmatrix} F_0 \\ \downarrow \\ G \end{pmatrix}.$$

But by definition of G being injective this map φ_1^* is in fact an epimorphism. Thus we have shown that $\mathrm{Ext}(H, G) = 0$. ■

To provide a proof for Proposition 110.6 it remains to prove the following proposition.

Proposition 110.8. Every abelian group that is divisible is also injective.

Remark. It is straightforward to prove the converse to Proposition 110.8, namely every injective abelian group is also divisible.

In the proof of Proposition 110.8 we will need Zorn's Lemma which we now recall for the reader's convenience.

Lemma 0.6. (Zorn's Lemma) Suppose a partially ordered set $(P, \leq)$ has the property that every chain has an upper bound in P. Then the set P contains at least one maximal element.

We also recall the definitions in the statement of Zorn's Lemma:

(1) A *partially ordered set* $(P, \leq)$ is a set together with a preorder $\leq$ (see page 1256) that has the property that $a \leq b$ and $b \leq a$ implies that $a = b$.
(2) A *chain* in P is a subset Q such that for any two elements $q, q' \in Q$ we have $q \leq q'$ or $q' \leq q$.
(3) An *upper bound* of a subset Q is an element $q \in Q$ such that $p \leq q$ for all $q \in Q$.
(4) A *maximal element* of a subset Q is an element $q \in Q$ such that there is no $r \in Q$ with $q < r$.[1337]

We refer to [**Cie1997**, Theorem 4.3.4] for a proof of Zorn's Lemma. Perhaps it is more fun to look at Zorn's Lemma in "The Simpsons", see

`http://www.simonsingh.net/Simpsons_Mathematics/zorns-lemma/`

Now we can give the proof of Proposition 110.8.

[1337] Aren't "upper bound" and "maximal element" the same?

Proof of Proposition 110.8. Let G be an abelian group that is divisible. Suppose we are given a diagram

$$\begin{array}{ccccc} 0 & \longrightarrow & B & \overset{\varphi}{\hookrightarrow} & A \\ & & \downarrow{\scriptstyle \beta} & \swarrow{\scriptstyle ?\,\alpha\,?} & \\ & & G. & & \end{array}$$

Since φ is a monomorphism we can assume that B is in fact a subgroup of A and that φ is the inclusion map.

We denote by P the set of all pairs (C_i, γ_i) where C_i is a subgroup of A which contains B and where $\gamma_i \colon \mathrm{C}_i \to G$ is a homomorphism such that $\gamma_i|_B = \beta$. This family of pairs is non-empty since (B, β) satisfies the required conditions. We define $(\mathrm{C}_i, \gamma_i) < (\mathrm{C}_j, \gamma_j)$ if $\mathrm{C}_i \subset \mathrm{C}_j$ and if $\gamma_j|_{\mathrm{C}_i} = \gamma_i$. Given a chain $(\mathrm{C}_j, \gamma_j)_{j \in J}$ in P we get an upper bound by setting

$$\begin{array}{rcl} C := \bigcup\limits_{j \in J} \mathrm{C}_j \text{ and } \gamma \colon C & \to & G \\ c & \mapsto & \gamma_j(c) \text{ if } j \in J \text{ with } c \in \mathrm{C}_j. \end{array}$$

Since $(\mathrm{C}_j, \gamma_j)_{j \in J}$ is a chain one can easily verify that C is in fact a subgroup of A which contains B and that γ is a homomorphism with $\gamma|_B = \beta$.

Therefore we can apply Zorn's Lemma to this family and we obtain a maximal pair (C_m, γ_m). It remains to prove the following claim.

Claim. We have $\mathrm{C}_m = A$.

Proof. Suppose that this is not the case. Then there exists an $a \in A \setminus \mathrm{C}_m$. We denote by $\langle\langle \mathrm{C}_m, a \rangle\rangle$ the subgroup of A generated by C_m and a, i.e. $\langle\langle \mathrm{C}_m, a \rangle\rangle$ is the smallest subgroup of A that contains C_m and a. To obtain a contradiction it suffices to show that there exists a homomorphism $\delta \colon \langle\langle \mathrm{C}_m, a \rangle\rangle \to G$ that extends γ_m. We distinguish two cases:

(1) If there exists no $n \in \mathbb{N}$ such that $n \cdot a \in \mathrm{C}_m$, then one can show easily that we have $\langle\langle \mathrm{C}_m, a \rangle\rangle = \mathrm{C}_m \oplus \langle a \rangle$. We extend γ_m to $\langle\langle \mathrm{C}_m, a \rangle\rangle = \mathrm{C}_m \oplus \langle a \rangle$ by setting $\delta(a) = 0$.

(2) Otherwise there exists a minimal $n \in \mathbb{N}$ such that $n \cdot a \in \mathrm{C}_m$. We denote by $r \in \mathbb{N}_0$ the order of $n \cdot a \in \mathrm{C}_m$. Here we say that the order is 0 if $n \cdot a \in \mathrm{C}_m$ has infinite order. We consider the maps

$$\begin{array}{ccccccccc} 0 & \to & \mathbb{Z}_r & \overset{\Phi}{\to} & \mathrm{C}_m \oplus \mathbb{Z}_{nr} & \overset{\Psi}{\to} & \langle\langle \mathrm{C}_m, a \rangle\rangle & \to & 0 \\ & & k & \mapsto & (k \cdot n \cdot a, -k \cdot n) & & & & \\ & & & & (c, l) & \mapsto & c + l \cdot a & & \end{array}$$

It is clear that Φ is injective and that $\Psi \circ \Phi = 0$. Note that the image of Ψ lies a priori in A, but it is straightforward to see that the image of Ψ is precisely $\langle\langle \mathrm{C}_m, a \rangle\rangle$. By definition of n we have that $\ker(\Psi) \subset \mathrm{im}(\Phi)$. Put differently, the sequence is exact. Since G is divisible there exists an $h \in G$ such that $n \cdot h = \gamma(n \cdot a)$. We denote by $\alpha \colon \mathrm{C}_m \oplus \mathbb{Z}_{nr} \to G$ the homomorphism that is given by setting $\alpha(c) = \gamma(c)$ for $c \in \mathrm{C}_m$ and $\alpha(k) = k \cdot h$ for $k \in \mathbb{Z}$. One can easily verify that $\mathrm{im}(\Phi)$ is contained in $\ker(\alpha)$. It is now straightforward to show that the homomorphism

$$\begin{array}{rcccl} \delta \colon \langle\langle \mathrm{C}_m, a \rangle\rangle & \to & (\mathrm{C}_m \oplus \mathbb{Z}_{nr}) / \mathrm{im}(\Phi) & \to & G \\ x & \mapsto & [\Psi^{-1}(x)] & & \\ & & [y] & \mapsto & \alpha(y) \end{array}$$

has the desired properties.

This concludes the proof of the claim and thus of the lemma. ■

The following proposition gives arguably slightly weird example.

Proposition 110.9. The group $\mathrm{Ext}(\mathbb{Q},\mathbb{Z})$ is isomorphic to the additive group $(\mathbb{R},+)$.

Remark. Note that this proposition is not totally pointless, for example it follows from the existence of Moore spaces, see the Moore Space Existence Proposition 79.11, that there exist topological spaces X with $\mathrm{H}_n(X) \cong (\mathbb{Q},+)$. Thus even unexpected abelian groups can appear in topology.

Proof. This proposition is proved in [**Wie1969**]. Alternatively the proposition is almost proved in [**Bre1997**, Lemma 14.8]. We also refer to [**Boar2010**] for the calculation of $\mathrm{Ext}(\mathbb{Q},\mathbb{Z})$. ■

This example also shows that Ext-groups can be quite large. In fact the following proposition holds.

Proposition 110.10. Let G be an abelian group. If G is not a finitely generated group, then $\mathrm{Hom}(G,\mathbb{Z})$ is uncountable or $\mathrm{Ext}(G,\mathbb{Z})$ is uncountable.

Proof. We will barely make use of this proposition, thus we refer to [**Hat2002**, Proposition 3.F.12] instead for a proof. ■

110.2. **The Universal Coefficient Theorem for Cohomology Groups.** Finally we want to explore the connection between the cohomology groups of a chain complex C and the usual homology groups of the chain complex. The key to relating homology groups to cohomology groups is given by the following evaluation homomorphism.

Definition. Let $(\mathrm{C}_*,\partial_*)$ be a chain complex and let G be an abelian group. We refer to the map[1338]

$$\begin{array}{rcl} \mathrm{ev}\colon \mathrm{H}^n(C;G) & \to & \mathrm{Hom}(\mathrm{H}_n(C),G) \\ [\varphi\colon \mathrm{C}_n \to G] & \mapsto & \left(\begin{array}{rcl} \mathrm{H}_n(C) & \to & G \\ [c] & \mapsto & \langle [\varphi],[c]\rangle = \varphi(c) \end{array} \right) \end{array}$$

as the evaluation homomorphism.

Remark. It follows immediately from Lemma 109.6 (3) that the evaluation homomorphisms in natural in the chain complex C_* in the sense that if $f\colon C_* \to D_*$ is a chain map, then for any $n \in \mathbb{N}_0$ and any abelian group G the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}^n(C;G) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_n(C),G) \\ {\scriptstyle f^*}\downarrow & & \downarrow{\scriptstyle (f_*)^*} \\ \mathrm{H}^n(D;G) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_n(D),G). \end{array}$$

Furthermore, it follows easily from the definitions that the evaluation map is natural in G, in the sense that if $\varphi\colon G_1 \to G_2$ is homomorphism of abelian groups, then for any $n \in \mathbb{N}_0$

[1338] This map is well-defined by Lemma 109.6.

and any chain complex C_* the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}^n(C;G_1) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_n(C),G_1) \\ \downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\ \mathrm{H}^n(C;G_2) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_n(C),G_2). \end{array}$$

Here the map on the left is the one we had introduced on page 2401.

Recall that in Lemma 78.8 we saw that $\mathrm{H}_2(\mathbb{R}\mathrm{P}^2;\mathbb{Z}) = 0$ and that on page 2423 we showed that $\mathrm{H}^2(\mathbb{R}\mathrm{P}^2;\mathbb{Z}) \cong \mathbb{Z}_2$. These calculations imply that the evaluation homomorphism $\mathrm{ev}\colon \mathrm{H}^n(X;G) \to \mathrm{Hom}(\mathrm{H}_n(X);G)$ is in general not a monomorphism. The following theorem relates homology groups and cohomology groups via the evaluation homomorphism and the Ext-groups.

Theorem 110.11. (Universal Coefficient Theorem for Cohomology Groups) Let $(\mathrm{C}_*,\partial_*)$ be a chain complex of free abelian groups and let G be an abelian group. For each $n \in \mathbb{N}_0$ there exists a map

$$\epsilon\colon\ \mathrm{Ext}(\mathrm{H}_{n-1}(C),G)\ \to\ \mathrm{H}^n(C;G)$$

which is natural in the chain complex C_* and natural in the abelian group G and which has the property that the following sequence is exact:

$$0\ \to\ \mathrm{Ext}(\mathrm{H}_{n-1}(C),G)\ \xrightarrow{\epsilon}\ \mathrm{H}^n(C;G)\ \xrightarrow{\mathrm{ev}}\ \mathrm{Hom}(\mathrm{H}_n(C),G) \to 0.$$

This short exact sequence splits and there exists therefore an isomorphism[1339]

$$\mathrm{H}^n(C;G)\ \cong\ \mathrm{Ext}(\mathrm{H}_{n-1}(C),G) \oplus \mathrm{Hom}(\mathrm{H}_n(C),G).$$

Before we provide the proof of the above Universal Coefficient Theorem for Cohomology Groups 110.11 let us formulate the most important application, namely let us apply it to the chain complex of a pair of topological spaces.

Theorem 110.12. (Universal Coefficient Theorem for Cohomology Groups) Let (X,A) be a pair of topological spaces and let G be an abelian group. For each $n \in \mathbb{N}_0$ there exists a map

$$\epsilon\colon\ \mathrm{Ext}(\mathrm{H}_{n-1}(X,A),G)\ \to\ \mathrm{H}^n(X,A;G)$$

which is natural in (X,A), which is natural in the abelian group G and which has the property that the following sequence is exact:

$$0\ \to\ \mathrm{Ext}(\mathrm{H}_{n-1}(X,A),G)\ \xrightarrow{\epsilon}\ \mathrm{H}^n(X,A;G)\ \xrightarrow{\mathrm{ev}}\ \mathrm{Hom}(\mathrm{H}_n(X,A),G) \to 0.$$

This short exact sequence splits and there exists therefore an isomorphism

$$\mathrm{H}^n(X,A;G)\ \cong\ \mathrm{Ext}(\mathrm{H}_{n-1}(X,A),G) \oplus \mathrm{Hom}(\mathrm{H}_n(X,A),G).$$

Remark. The Universal Coefficient Theorem 110.12 for Cohomology Groups is the analogue of the Algebraic Universal Coefficient Theorem 89.16 together with the UCT-Splitting Theorem 89.22.

[1339] Once again the two maps in the short exact sequence is natural, whereas the isomorphism is not natural. More precisely, the discussion on page 1935 can easily be modified to show that there exists no *natural* isomorphism

$$\mathrm{H}^n(C;G)\ \cong\ \mathrm{Ext}(\mathrm{H}_{n-1}(C),G) \oplus \mathrm{Hom}(\mathrm{H}_n(C),G).$$

We will discuss this issue in Exercise 110.1.

Proof of Theorem 110.12 assuming Theorem 110.11. As the reader will have noticed there is really not much to say, except that we recall that we pointed out on page 1625 that the chain groups $\mathrm{C}_n(X, A)$, $n \in \mathbb{N}_0$ are free abelian groups. ■

Remark.

(1) Here is one straightforward but interesting consequence to the Universal Coefficient Theorem 110.12 for Cohomology Groups. Given any pair (X, A) of topological spaces we see that

$$\mathrm{H}^1(X;\mathbb{Z}) \underset{\text{Universal Coefficient Theorem 110.12}}{\cong} \mathrm{Ext}(\mathrm{H}_0(X,A),\mathbb{Z}) \oplus \mathrm{Hom}(\mathrm{H}_1(X,A),\mathbb{Z}) \underset{\text{by the Ext-Calculation Lemma 110.5 and Corollary 72.15}}{=} \mathrm{Hom}(\mathrm{H}_1(X,A),\mathbb{Z}) \underset{\text{since } \mathrm{Hom}(G,\mathbb{Z}) \text{ is always torsion free}}{=} \text{torsion-free.}$$

(2) The Universal Coefficient Theorem 110.12 for Cohomology Groups implies in particular that topological spaces with isomorphic homology groups also have isomorphic cohomology groups. In other words, if our only goal is to distinguish homeomorphism types of topological spaces, then cohomology groups will not be of much help.

(3) The fact that cohomology groups are determined by homology groups is also immediate consequence of the combination of Propositions 81.13 and 81.4 together with the Cochain Map Lemma 108.5.

Now we turn to the proof of the purely algebraic Universal Coefficient Theorem 110.11 for Cohomology Groups. The proof is, perhaps not surprisingly, rather similar to the proofs of the Universal Coefficient Theorem 89.17 and the UCT-Splitting Proposition 89.21.

Proof. Let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups. For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \mathrm{im}(\partial_{n+1})$. Note that it follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that B_n and Z_n are free abelian groups.

As in the proof of the Universal Coefficient Theorem 89.17 we consider the following short exact sequence of vertical chain complexes:

$$\begin{array}{ccccccccc}
 & & \vdots & & \vdots & & \vdots & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & Z_n & \longrightarrow & \mathrm{C}_n & \xrightarrow{\partial_n} & B_{n-1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle 0} & & \downarrow{\scriptstyle \partial_n} & & \downarrow{\scriptstyle 0} & & \\
0 & \longrightarrow & Z_{n-1} & \longrightarrow & \mathrm{C}_{n-1} & \xrightarrow{\partial_{n-1}} & B_{n-2} & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & \vdots & & \vdots & & \vdots & &
\end{array}$$

Now let G be an abelian group. We apply the functor $\mathrm{Hom}(-, G)$ to the above short exact sequence of chain complexes and we obtain the following diagram:

$$\begin{array}{ccccccccc}
 & & \vdots & & \vdots & & \vdots & & \\
 & & \uparrow & & \uparrow & & \uparrow & & \\
0 & \longrightarrow & \mathrm{Hom}(B_{n-1}, G) & \xrightarrow{\partial_n^*} & \mathrm{Hom}(C_n, G) & \longrightarrow & \mathrm{Hom}(Z_n, G) & \longrightarrow & 0 \\
 & & \uparrow{\scriptstyle 0} & & \uparrow{\scriptstyle \partial_n^*} & & \uparrow{\scriptstyle 0} & & \\
0 & \longrightarrow & \mathrm{Hom}(B_{n-2}, G) & \xrightarrow{\partial_{n-1}^*} & \mathrm{Hom}(C_{n-1}, G) & \longrightarrow & \mathrm{Hom}(Z_{n-1}, G) & \longrightarrow & 0 \\
 & & \uparrow & & \uparrow & & \uparrow & & \\
 & & \vdots & & \vdots & & \vdots & &
\end{array}$$

This is again a sequence of cochain complexes. Since the Z_n are free abelian we obtain from Lemma 108.4 that the above horizontal sequences of cochain complexes are still exact. Therefore we can apply the Connecting Homomorphism Proposition 108.6 to obtain the following long exact sequence

$$\to \operatorname{Hom}(Z_{n-1}, G) \xrightarrow{d_n} \operatorname{Hom}(B_{n-1}, G) \to \mathrm{H}^n(C; G) \xrightarrow{\partial_n} \operatorname{Hom}(Z_n, G) \xrightarrow{d_{n-1}} \operatorname{Hom}(B_n, G) \to \dots$$

where the maps d_n are the connecting homomorphisms of the long exact sequence. One can show easily that the connecting homomorphism $d_n \colon \operatorname{Hom}(Z_n, G) \to \operatorname{Hom}(B_n, G)$ is the map $d_n = i_n^*$ where $i_n \colon B_n \to Z_n$ is the inclusion map. By the Break-into-SES Lemma 78.4 we obtain the following short exact sequence

$$0 \to \operatorname{coker}(\operatorname{Hom}(Z_{n-1},G) \to \operatorname{Hom}(B_{n-1},G)) \to \mathrm{H}^n(C;G) \to \ker(\operatorname{Hom}(Z_n,G) \to \operatorname{Hom}(B_n,G)) \to 0.$$

We have to show that the expressions left and right coincide with the desired expressions. Both equalities follow immediately from the Ext-Free Resolution Proposition 110.2 (together with Lemma 110.4 for the right-hand term) and the observation that for each $l \in \mathbb{N}_0$ a free resolution of $\mathrm{H}_l(C)$ is given by $0 \to B_l \xrightarrow{i_l} Z_l \to \mathrm{H}_l(C)$. We have thus shown the existence of the desired short exact sequence

$$0 \;\to\; \operatorname{Ext}(\mathrm{H}_{n-1}(C), G) \;\xrightarrow{\epsilon}\; \mathrm{H}^n(C; G) \;\xrightarrow{\mathrm{ev}}\; \operatorname{Hom}(\mathrm{H}_n(C), G) \to 0.$$

The statement that the homomorphism ϵ to the left is natural follows easily from the definitions and the Fundamental Theorem 81.1 (2) of Homological Algebra. We leave the verification of the details to the reader.

It remains to show that the above short exact sequence splits. By definitions this means that we need to construct a homomorphism $\eta \colon \operatorname{Hom}(\mathrm{H}_n(C), G) \to \mathrm{H}^n(C; G)$ such that $\mathrm{ev} \circ \eta$ is the identity on $\operatorname{Hom}(\mathrm{H}_n(C), G)$.

We consider again the short exact sequence

$$0 \;\to\; Z_n \;\hookrightarrow\; \mathrm{C}_n \;\xrightarrow{\partial_n}\; B_{n-1} \;\to\; 0.$$

Since B_{n-1} is a free abelian group we obtain from Lemmas 78.1 and 78.2 that there exists a homomorphism $p_n \colon \mathrm{C}_n \to Z_n$ such that p_n is the identity on $Z_n \subset C_n$.

In the proof of the UCT-Splitting Proposition 89.21 we showed that the following diagram commutes:

$$\begin{array}{ccccccccc}
\dots & \longrightarrow & \mathrm{C}_{n+1} & \xrightarrow{\partial_{n+1}} & \mathrm{C}_n & \xrightarrow{\partial_n} & \mathrm{C}_{n-1} & \xrightarrow{\partial_{n-1}} & \dots \\
 & & \downarrow\uparrow p_{n+1} & \searrow^{\partial_{n+1}} & \downarrow\uparrow p_n & \searrow^{\partial_n} & \downarrow\uparrow p_{n-1} & & \\
 & & Z_{n+1} & & Z_n & & Z_{n-1} & & \\
 & & \downarrow q_{n+1} & & \downarrow q_n & & \downarrow q_{n-1} & & \\
\dots & \longrightarrow & \underbrace{\mathrm{H}_{n+1}(C)}_{=Z_{n+1}/B_{n+1}} & \xrightarrow{0} & \underbrace{\mathrm{H}_n(C)}_{=Z_n/B_n} & \xrightarrow{0} & \underbrace{\mathrm{H}_{n-1}(C)}_{=Z_{n-1}/B_{n-1}} & \xrightarrow{0} & \dots
\end{array}$$

where the maps q_n are just the natural projections.

The top and the bottom horizontal sequences of the above diagram are chain complexes. Since the diagram commutes we see that the vertical maps from top to bottom are chain maps.

Now we apply the functor $\mathrm{Hom}(-,G)$ to the top and the bottom horizontal sequences and we obtain the following diagram of cochain complexes.

$$\begin{array}{ccccccccc}
\ldots & \longleftarrow & \mathrm{Hom}(C_{n+1},G) & \xleftarrow{\partial_{n+1}^*} & \mathrm{Hom}(C_n,G) & \xleftarrow{\partial_n^*} & \mathrm{Hom}(C_{n-1},G) & \longleftarrow & \ldots \\
 & & \uparrow{\scriptstyle (q_{n+1}\circ p_{n+1})^*} & & \uparrow{\scriptstyle (q_n\circ p_n)^*} & & \uparrow{\scriptstyle (q_{n-1}\circ p_{n-1})^*} & & \\
\ldots & \longleftarrow & \mathrm{Hom}(\mathrm{H}_{n+1}(C),G) & \xleftarrow{0} & \mathrm{Hom}(\mathrm{H}_n(C),G) & \xleftarrow{0} & \mathrm{Hom}(\mathrm{H}_{n-1}(C),G) & \longleftarrow & \ldots
\end{array}$$

The induced maps on the cohomology groups of these two cochain complexes give us a homomorphism

$$\eta\colon\ \mathrm{Hom}(\mathrm{H}_n(C),G) = \mathrm{H}^n(\text{lower sequence}) \ \to\ \mathrm{H}^n(\text{upper sequence}) = \mathrm{H}^n(C;G).$$

It remains to prove the following claim.

Claim. The composition $\mathrm{ev}\circ\eta$ is the identity on $\mathrm{Hom}(\mathrm{H}_n(C),G)$.

Proof. Let $\varphi\colon \mathrm{H}_n(C)\to G$ be homomorphism. We need to show that $(\mathrm{ev}\circ\eta)(\varphi)=\varphi$ in $\mathrm{Hom}(\mathrm{H}_n(C),G)$. So let $[\sigma]\in \mathrm{H}_n(C)$ with $\sigma\in Z_n$. Then

$$\big((\mathrm{ev}\circ\eta)(\varphi)\big)([\sigma]) \underset{\text{definition of ev}}{=} \langle \overbrace{\eta(\varphi)}^{\in \mathrm{H}^n(C;G)}, [\sigma]\rangle \underset{\text{definition of } \eta \text{ and } \langle\,,\,\rangle}{=} (\overbrace{\varphi\circ q_n\circ p_n}^{\in \mathrm{Hom}(C_n,G)})(\sigma) \underset{\text{since } p_n=\mathrm{id} \text{ on } Z_n}{=} (\varphi\circ q_n)(\sigma) \underset{\text{since } q_n(\sigma)=[\sigma]}{=} \varphi([\sigma]).$$

■

Example. We consider again the projective space $P := \mathbb{R}\mathrm{P}^2$. As a reminder, we showed on page 1725 that $\mathrm{H}_2(P)=0$, $\mathrm{H}_1(P)\cong\mathbb{Z}_2$ and $\mathrm{H}_0(P)\cong\mathbb{Z}$. It follows from the Universal Coefficient Theorem 110.12 and from the properties of the Ext-group that we had listed in the Ext-Calculation Lemma 110.5 that

$$\begin{array}{lllll}
\mathrm{H}^2(P;\mathbb{Z}) \cong \mathrm{Hom}(\mathrm{H}_2(P),\mathbb{Z}) \oplus \mathrm{Ext}(\mathrm{H}_1(P),\mathbb{Z}) & \cong \mathrm{Hom}(0,\mathbb{Z}) \oplus \mathrm{Ext}(\mathbb{Z}_2,\mathbb{Z}) & = 0\oplus\mathbb{Z}_2 = \mathbb{Z}_2 \\
\mathrm{H}^1(P;\mathbb{Z}) \cong \mathrm{Hom}(\mathrm{H}_1(P),\mathbb{Z}) \oplus \mathrm{Ext}(\mathrm{H}_0(P),\mathbb{Z}) & \cong \mathrm{Hom}(\mathbb{Z}_2,\mathbb{Z}) \oplus \mathrm{Ext}(\mathbb{Z},\mathbb{Z}) & = 0\oplus 0 = 0 \\
\mathrm{H}^0(P;\mathbb{Z}) \cong \mathrm{Hom}(\mathrm{H}_0(P),\mathbb{Z}) & \cong \mathrm{Hom}(\mathbb{Z},\mathbb{Z}) & \cong \mathbb{Z}
\end{array}$$

and

$$\begin{array}{lllll}
\mathrm{H}^2(P;\mathbb{Z}_2) \cong \mathrm{Hom}(\mathrm{H}_2(P),\mathbb{Z}_2)\oplus\mathrm{Ext}(\mathrm{H}_1(P),\mathbb{Z}_2) & \cong \mathrm{Hom}(0,\mathbb{Z}_2)\oplus\mathrm{Ext}(\mathbb{Z}_2,\mathbb{Z}_2) & = 0\oplus\mathbb{Z}_2 = \mathbb{Z}_2 \\
\mathrm{H}^1(P;\mathbb{Z}_2) \cong \mathrm{Hom}(\mathrm{H}_1(P),\mathbb{Z}_2)\oplus\mathrm{Ext}(\mathrm{H}_0(P),\mathbb{Z}_2) & \cong \mathrm{Hom}(\mathbb{Z}_2,\mathbb{Z}_2)\oplus\mathrm{Ext}(\mathbb{Z},\mathbb{Z}_2) & = \mathbb{Z}_2\oplus 0 = \mathbb{Z}_2 \\
\mathrm{H}^0(P;\mathbb{Z}_2) \cong \mathrm{Hom}(\mathrm{H}_0(P),\mathbb{Z}_2) & \cong \mathrm{Hom}(\mathbb{Z},\mathbb{Z}_2) & = \mathbb{Z}_2.
\end{array}$$

Fortunately this coincides with the calculations from page 2423.

Example. We return to the study of lens spaces. In the Lens Space Homology Lemma 98.9 we saw that

$$\mathrm{H}_n(L(p,q);\mathbb{Z}) \ \cong\ \begin{cases} \mathbb{Z}, & \text{if } n=0,3, \\ 0, & \text{if } n=2 \text{ or } n>3, \\ \mathbb{Z}_p, & \text{if } n=1. \end{cases}$$

As in the previous example we can now use the Universal Coefficient Theorem 110.12 and the Ext-Calculation Lemma 110.5 to compute the cohomology groups of $L(p,q)$. We leave

it to the reader to verify that[1340]

$$\mathrm{H}^n(L(p,q);\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0,3 \\ 0, & \text{if } n = 1 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 2. \end{cases}$$

This shows, as was already foreshadowed by Corollary 108.19, that cohomology groups also cannot distinguish between two lens spaces of the form $L(p,q)$ and $L(p,r)$. In particular we have not made any progress on Question 48.7 since the introduction of the fundamental group. All the extra invariants, namely higher homotopy groups, homology groups and cohomology groups (with any coefficients) have proved useless.

We conclude this section with the following proposition that gives in particular a converse to Corollary 108.20.

Proposition 110.13.

(1) Let C_* be a chain complex. The following two statements are equivalent:
   (a) $\mathrm{H}_k(C_*) = 0$ for all $k \in \mathbb{N}_0$.
   (b) $\mathrm{H}^k(C_*;\mathbb{Z}) = 0$ for all $k \in \mathbb{N}_0$.

(2) Let $f\colon D_* \to E_*$ be a chain map. The following two statements are equivalent:
   (a) All the induced map $f_*\colon \mathrm{H}_k(D_*) \to \mathrm{H}_k(E_*)$ are isomorphisms.
   (b) All the induced map $f^*\colon \mathrm{H}^k(E_*;\mathbb{Z}) \to \mathrm{H}^k(D_*;\mathbb{Z})$ are isomorphisms.

Proof.

(1) We start out with the following claim.

Claim. Let A be an abelian group. If A is non-trivial, then $\mathrm{Hom}(A,\mathbb{Z})$ or $\mathrm{Ext}(A,\mathbb{Z})$ is non-trivial.

Proof. Let A be a non-trivial abelian group. If A is finitely generated, then it follows from the Finitely Generated Abelian Group Classification Theorem 51.4 of Finitely Generated Abelian Groups together with the Ext-Calculation Lemma 110.5 that $\mathrm{Hom}(A,\mathbb{Z})$ or $\mathrm{Ext}(A,\mathbb{Z})$ is non-trivial. Furthermore, if A is infinitely generated, then the desired conclusion follows from Proposition 110.10. ⊞

The equivalence of (a) and (b) follows immediately from the claim together with the Universal Coefficient Theorem 110.11 for Cohomology Groups.

(2) Let $f\colon D_* \to E_*$ be a chain map. We denote by $(\mathrm{M}(f),\partial_*)$ the corresponding algebraic mapping cone as defined on page 1796. By the Mapping Cone-LES Lemma 81.8 there exists a long exact sequence of the form

$$\ldots \to \mathrm{H}_k(D_*) \xrightarrow{f_*} \mathrm{H}_k(E_*) \to \mathrm{H}_k(\mathrm{M}(f)) \to \mathrm{H}_{k-1}(D_*) \xrightarrow{f_*} \ldots$$

Basically the same argument also shows that there exists a long exact sequence of the form

$$\ldots \leftarrow \mathrm{H}^k(D_*;\mathbb{Z}) \xleftarrow{f^*} \mathrm{H}_k(E_*;\mathbb{Z}) \leftarrow \mathrm{H}_n(\mathrm{M}(f);\mathbb{Z}) \leftarrow \mathrm{H}_{n-1}(D_*;\mathbb{Z}) \xrightarrow{f^*} \ldots$$

Thus we see that the equivalence of (2a) and (2b) is an immediate consequence of the equivalence of (1a) and (1b) applied to $C_* = \mathrm{M}(f)$. ■

[1340]Note that the $\mathbb{Z}_p$ shifted from $n = 1$ in homology to $n = 2$ in cohomology.

110.3. Cohomology groups of topological manifolds.

Proposition 110.14. (Top-Cohomology Proposition) Let M be a connected n-dimensional topological manifold. Let G be an abelian group.

(1) Let $x \in M \setminus \partial M$. For $i \neq n$ we have $\mathrm{H}_i(M, M \setminus \{x\}; G) = 0$. Furthermore the map
$$\mathrm{ev}\colon \mathrm{H}^n(M, M \setminus \{x\}; G) \ \to \ \mathrm{Hom}(\mathrm{H}_n(M, M \setminus \{x\}; \mathbb{Z}), G)$$
is an isomorphism.
(2) If M is compact but not closed, then $\mathrm{H}^n(M; G) = 0$.
(3) If M is closed orientable and non-empty, then $\mathrm{H}^n(M; G) \cong G$.
(4) If M is closed non-orientable and non-empty, then $\mathrm{H}^n(M; G) \cong G/2G$.
(5) For any $k > n$ we have $\mathrm{H}^k(M; G) = 0$.

Proof. Let M be a compact connected n-dimensional topological manifold and let G be an abelian group.

(1) This statement follows immediately from Lemma 105.4 and the Universal Coefficient Theorem 110.12.
(2) We suppose that M has non-empty boundary. Then
$$\mathrm{H}^n(M; G) \ \underset{\text{Universal Coefficient Theorem 110.12}}{\overset{\uparrow}{\cong}} \ \mathrm{Hom}(\mathrm{H}_n(M; \mathbb{Z}), G) \oplus \mathrm{Ext}(\mathrm{H}_{n-1}(M; \mathbb{Z}), G) \ \underset{\substack{\text{by the Top-Homology Theorem 106.3 we have } \mathrm{H}_n(M; \mathbb{Z}) = 0 \text{ and} \\ \text{by Proposition 106.22 (1) we have } \mathrm{H}_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k \text{ for some } k \in \mathbb{N}_0}}{\overset{\uparrow}{=}} \ \mathrm{Ext}(\mathbb{Z}^k, G) \ \overset{\text{Ext-Calculation Lemma 110.5}}{\overset{\downarrow}{=}} \ 0.$$
(3) Suppose that M is closed orientable and non-empty. The argument is very similar to the proof of (2). We just need to use that we know from the Orientation-Top Homology Theorem 106.1 that $\mathrm{H}_n(M; \mathbb{Z}) \cong \mathbb{Z}$ and that from Proposition 106.22 (1) we know that $\mathrm{H}_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k$ for some k.
(4) Next suppose that M is closed non-orientable and non-empty. This time we use that we know from the Orientation-Top Homology Theorem 106.1 and Proposition 106.22 (2) that $\mathrm{H}_n(M; \mathbb{Z}) \cong 0$ and that $\mathrm{H}_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k \oplus \mathbb{Z}_2$ for some k. Here we also use the Ext-Calculation Lemma 110.5 (4) which says that $\mathrm{Ext}(\mathbb{Z}_2, G) \cong G/2G$.
(5) So let $k > n$. This time we use that by the Top-Homology Theorem 106.3 we know that $\mathrm{H}_k(M; \mathbb{Z}) = 0$ and that we know from Theorems 106.1 and 106.3 that $\mathrm{H}_{k-1}(M; \mathbb{Z})$ is either zero or isomorphic to $\mathbb{Z}$. The desired statement follows again from the Universal Coefficient Theorem 110.12 and the fact that by the Ext-Calculation Lemma 110.5 we have $\mathrm{Ext}(\mathbb{Z}, G) = 0$. ■

Lemma 110.15. (Dual Fundamental Class Lemma) Let M be a compact oriented connected non-empty n-dimensional topological manifold. Then we have $\mathrm{H}^n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$. Furthermore there exists a unique generator $[M]^* \in \mathrm{H}^n(M, \partial M; \mathbb{Z})$ which satisfies $\langle [M]^*, [M] \rangle_M = 1$.[1341]

Proof. Let M be a compact oriented connected n-dimensional non-empty topological manifold.

[1341] Here $[M] \in \mathrm{H}_n(M, \partial M; \mathbb{Z})$ denotes the fundamental class provided by the Fundamental Class-Corollary 106.4.

It follows from the Universal Coefficient Theorem 110.12 for Cohomology Groups together with Proposition 106.22 that the map

$$\mathrm{H}^n(M,\partial M;\mathbb{Z}) \xrightarrow{\mathrm{ev}} \mathrm{Hom}(\underbrace{\mathrm{H}_n(M,\partial M;\mathbb{Z})}_{=\mathbb{Z}\cdot[M]},\mathbb{Z})$$

is an isomorphism. By the Fundamental Class-Corollary 106.4 (3) we have the equality $\mathrm{H}_n(M,\partial M;\mathbb{Z}) = \mathbb{Z}\cdot[M]$. Hence there exists a unique element $[M]^* \in \mathrm{H}^n(M,\partial M;\mathbb{Z})$ with $\mathrm{ev}([M]^*)([M]) = 1$, i.e. with $\langle [M]^*, [M]\rangle_M = 1$. ■

Definition.

(1) Given a compact oriented connected non-empty n-dimensional topological manifold M we refer to the uniquely determined element $[M]^* \in \mathrm{H}^n(M,\partial M;\mathbb{Z})$ from the Dual Fundamental Class Lemma 110.15 as the dual fundamental class of M.

(2) Given a compact oriented n-dimensional non-empty topological manifold M with finitely many components $M_1,\ldots,M_k$ we define its dual fundamental class to be

$$[M]^* := [M_1]^* + \cdots + [M_k]^* \in \underbrace{\mathrm{H}^n(M_1,\partial M_1;\mathbb{Z}) \oplus \cdots \oplus \mathrm{H}^n(M_k,\partial M_k;\mathbb{Z})}_{=\mathrm{H}^n(M,\partial M;\mathbb{Z})}.$$

Example. We consider the smooth manifold S^1 with the usual orientation. We saw on page 2201 that the singular simplex $\mu\colon \Delta^1 \to S^1$ that is given by $(1-t,t) \mapsto \exp(2\pi\,\mathrm{i}t)$ represents the fundamental class of S^1. On page 2404 we introduced a cocycle $\theta_{\mathbb{Z}} \in \mathrm{C}^1;\mathbb{Z})$ and we had explicitly calculated that $\langle [\theta_{\mathbb{Z}}], [S^1]\rangle = \theta_{\mathbb{Z}}(\mu) = 1$. This shows immediately that $[\theta_{\mathbb{Z}}] \in \mathrm{H}^1(S^1;\mathbb{Z})$ is the dual fundamental class of S^1.

Later on we will need the following lemma.

Lemma 110.16. Let $f\colon M \to N$ be a map between closed oriented connected non-empty n-dimensional topological manifolds. Then

$$f^*([N]^*) \;=\; \deg(f)\cdot[M]^*.$$

Proof. Let $f\colon M \to N$ be a map between closed, oriented connected n-dimensional non-empty topological manifolds. It follows from the Dual Fundamental Class Lemma 110.15 that any class in $\varphi = \mathrm{H}^n(M;\mathbb{Z})$ is of the form $\varphi = k\cdot[M]^*$ for some $k \in \mathbb{Z}$ and it follows from $\langle [M]^*, [M]\rangle = 1$ and the bilinearity of the Kronecker pairing that $k = \langle \varphi, [M]\rangle_M$. In our case we have

$$\langle f^*([N]^*), [M]\rangle \underset{\uparrow}{=} \langle [N]^*, f_*([M])\rangle \underset{\uparrow}{=} \langle [N]^*, \deg(f)\cdot[N]\rangle \underset{\uparrow}{=} \deg(f)\cdot\underbrace{\langle [N]^*, [N]\rangle}_{=1} = \deg(f).$$

Lemma 109.6 (3) — by definition of $\deg(f)$ — since $\langle\,,\,\rangle$ is bilinear

It follows from the above discussion that $f^*([N]^*) = \deg(f)\cdot[M]^*$. ■

Next we record the following useful consequence of the Universal Coefficient Theorem 110.12 for Cohomology Groups:

Proposition 110.17. (First Cohomology Proposition) Let X be a path-connected topological space, let $x_0 \in X$ and let G be an abelian group. Then the Hurewicz homomorphism $\pi_1(X,x_0) \to \mathrm{H}_1(X)$ from page 1832 and the evaluation homomorphism

$\mathrm{ev}\colon \mathrm{H}^1(X;G) \to \mathrm{Hom}(\mathrm{H}_1(X);G)$ induce natural isomorphisms

$$\mathrm{H}^1(X;G) \overset{\cong}{\to} \mathrm{Hom}(\mathrm{H}_1(X);G) \overset{\cong}{\to} \mathrm{Hom}(\pi_1(X,x_0),G).$$

One often uses the natural isomorphisms from the First Cohomology Proposition 110.17 to identify these groups.

Proof. As we pointed out on page 2444 and Proposition 84.2 (5), both maps are natural. So it remains to show that both maps are isomorphisms.

We insert one extra map into the above sequence of maps to see that the maps are indeed isomorphisms:

$$\mathrm{H}^1(X;G) \underset{\uparrow}{\overset{\mathrm{ev}}{\longrightarrow}} \mathrm{Hom}(\mathrm{H}_1(X);G) \overset{\text{Hurewicz Theorem 84.5}}{\underset{\cong}{\downarrow}} \mathrm{Hom}(\pi_1(X,x_0)_{\mathrm{ab}},G) \underset{\uparrow}{\overset{\cong}{\longleftarrow}} \mathrm{Hom}(\pi_1(X,x_0),G).$$

isomorphism by Theorem 110.12 since $\mathrm{H}_0(X) \cong \mathbb{Z}$ by the H_0-Proposition 72.5

by the Abelianization Proposition 53.20 (2), since G is abelian

■

110.4. **Cohomology with field coefficients.** Before we continue we introduce a slight variation on the Kronecker pairing defined in Lemma 109.6:

Definition. Let C_* be a chain complex and let R be a commutative ring. We consider the map

$$\begin{array}{rcl} \langle\ ,\ \rangle\colon \mathrm{H}^n(C;R) \times \mathrm{H}_n(C;R) & \to & R \\ \left([\varphi], \left[\sum_{i=1}^k c_i \otimes a_i\right]\right) & \mapsto & \sum_{i=1}^k \varphi(c_i)\cdot a_i. \end{array}$$

We leave it to the reader to verify that this map is well-defined and bilinear. We refer to this pairing also as the Kronecker pairing.

The next proposition relates homology and cohomology with coefficients in a field $\mathbb{F}$.

Proposition 110.18. (Cohomology-Field Coefficients Proposition) Let (X,A) be a pair of topological spaces and let $\mathbb{F}$ be a field. The map

$$\begin{array}{rcl} \mathrm{ev}\colon \mathrm{H}^n(X,A;\mathbb{F}) & \to & \mathrm{Hom}_{\mathbb{F}}(\mathrm{H}_n(X,A;\mathbb{F}),\mathbb{F}) \\ \varphi & \mapsto & \left(\begin{array}{rcl} \mathrm{H}_n(X,A;\mathbb{F}) & \to & \mathbb{F} \\ \sigma & \mapsto & \langle\varphi,\sigma\rangle \end{array}\right) \end{array}$$

is a natural isomorphism of $\mathbb{F}$-vector spaces.[1342]

We postpone the proof of the Cohomology-Field Coefficients Proposition 110.18 to the next section. In most applications we are only interested in the following corollary to the Cohomology-Field Coefficients Proposition 110.18.

[1342] Note that "natural" makes sense since $(X,A) \mapsto \mathrm{H}^k(X,A;\mathbb{F})$ and $(X,A) \mapsto \mathrm{Hom}_{\mathbb{F}}(\mathrm{H}_k(X,A;\mathbb{F}),\mathbb{F})$ both define *contravariant* functors from the category of pairs of topological spaces to the category of $\mathbb{F}$-vector spaces.

Corollary 110.19. Let (X, A) be a pair of topological space and let $k \in \mathbb{N}_0$ such that $\mathrm{H}_k(X, A; \mathbb{Z})$ and $\mathrm{H}_{k-1}(X, A; \mathbb{Z})$ are finitely generated. (By the Topological Manifolds-Invariants Proposition 104.14 (4) we know if X and A are compact topological manifolds, then this condition is satisfied.)

(1) Given any field $\mathbb{F}$ the homology and cohomology groups $\mathrm{H}_k(X, A; \mathbb{F})$ and $\mathrm{H}^k(X, A; \mathbb{F})$ are finite-dimensional $\mathbb{F}$-vector spaces with

$$\dim_{\mathbb{F}}(\mathrm{H}_k(X, A; \mathbb{F})) \;=\; \dim_{\mathbb{F}}(\mathrm{H}^k(X, A; \mathbb{F})).$$

(2) For any subfield $\mathbb{F}$ of $\mathbb{C}$ we have

$$\dim_{\mathbb{F}}(\mathrm{H}_k(X, A; \mathbb{F})) \;=\; \dim_{\mathbb{F}}(\mathrm{H}^k(X, A; \mathbb{F})) \;=\; b_n(X, A).$$

Remark. Note that in Corollary 110.19 we only claim that the homology and cohomology groups are abstractly isomorphic. We do not claim that there is a natural isomorphism. In fact it does not make sense to ask for a natural isomorphism since the homology groups of a topological space X with $\mathbb{F}$-coefficients are covariant in X whereas the cohomology groups of X with $\mathbb{F}$-coefficients are contravariant in X.

Proof. First note that Statement (2) is an immediate consequence of Statement (1) and the discussion on page 1932. So let turn to the proof of Statement (1). To simplify the notation we only consider the case $A = \varnothing$. Let X be a topological space and let $k \in \mathbb{N}_0$ such that $\mathrm{H}_k(X; \mathbb{Z})$ and $\mathrm{H}_{k-1}(X; \mathbb{Z})$ are finitely generated. Let p be a prime number. By the Finitely Generated Abelian Group Classification Theorem 51.4 we can make the identifications

$$\mathrm{H}_{k-1}(X; \mathbb{Z}) \;=\; \mathbb{Z}^r \oplus \bigoplus_{i=1}^{\alpha} \mathbb{Z}_{a_i} \oplus \bigoplus_{i=1}^{\beta} \mathbb{Z}_{b_i} \quad \text{and} \quad \mathrm{H}_k(X; \mathbb{Z}) \;=\; \mathbb{Z}^s \oplus \bigoplus_{i=1}^{\gamma} \mathbb{Z}_{c_i} \oplus \bigoplus_{i=1}^{\delta} \mathbb{Z}_{d_i}$$

where all the a_i, b_i, c_i and d_i are non-zero, and where each a_i and each c_i is divisible by p and none of the b_i and d_i are divisible by p. We start out with the following claim:

Claim. We have

$$\dim_{\mathbb{F}}(\mathrm{H}_k(X, \mathbb{F})) \;=\; \begin{cases} s, & \text{if } \mathbb{F} \text{ is a field of characteristic zero,} \\ s + \alpha + \gamma, & \text{if } \mathbb{F} \text{ is a field of characteristic } p. \end{cases}$$

Proof. First assume that $\mathbb{F}$ is a field of characteristic zero. In this case we have

$$\mathrm{H}_k(X; \mathbb{F}) \;\underset{\uparrow}{\cong}\; \mathrm{H}_k(X; \mathbb{Z}) \otimes \mathbb{F} \;=\; \left(\mathbb{Z}^s \oplus \bigoplus_{i=1}^{\gamma} \mathbb{Z}_{c_i} \oplus \bigoplus_{i=1}^{\delta} \mathbb{Z}_{d_i}\right) \otimes \mathbb{F} \;\underset{\uparrow}{\cong}\; \mathbb{F}^s.$$

by Theorem 89.17 and the Tor-Properties Lemma 89.15 (4) since $\mathbb{F}$ is torsion-free — see page 1910

Now suppose that $\mathbb{F}$ is a field of characteristic p. We make the following observation. For any $n \in \mathbb{N}$ we have

$$\mathbb{Z}_n \otimes \mathbb{F} \underset{\uparrow}{=} \operatorname{coker}\left(\mathbb{F} \xrightarrow{\cdot n} \mathbb{F}\right) = \begin{cases} \mathbb{F}, & \text{if } p|n, \\ 0, & \text{else} \end{cases} \quad \text{and} \quad \operatorname{Tor}(\mathbb{Z}_n, \mathbb{F}) \underset{\uparrow}{=} \ker\left(\mathbb{F} \xrightarrow{\cdot n} \mathbb{F}\right) = \begin{cases} \mathbb{F}, & \text{if } p|n, \\ 0, & \text{else.} \end{cases}$$

Tensor Lemma 89.3 (3) — Tor-Properties Lemma 89.15 (6)

Then

$$\mathrm{H}_k(X; \mathbb{F}) \;\underset{\uparrow}{\cong}\; \mathrm{H}_k(X; \mathbb{Z}) \otimes \mathbb{F} \oplus \operatorname{Tor}(\mathrm{H}_{k-1}(X; \mathbb{Z}), \mathbb{F}) \;\underset{\uparrow}{\cong}\; \mathbb{F}^s \oplus \mathbb{F}^{\gamma} \oplus \mathbb{F}^{\alpha}.$$

by Theorem 89.17 — by the Tor-Properties Lemma 89.15, the discussion on page 1910 and the above observations

⊞

Now we have

$$\dim_{\mathbb{F}}(\mathrm{H}^k(X;\mathbb{F})) \underset{\uparrow}{=} \dim_{\mathbb{F}}(\mathrm{Hom}(\mathrm{H}_k(X;\mathbb{F}),\mathbb{F})) \underset{\uparrow}{=} \dim_{\mathbb{F}}(\mathrm{H}_k(X;\mathbb{F}))$$

Cohomology-Field Coefficients Proposition 110.18 since by the claim $\mathrm{H}_k(X;\mathbb{F})$ is finite-dimensional

We could also prove the equality $\dim_{\mathbb{F}}(\mathrm{H}^k(X;\mathbb{F})) = \dim_{\mathbb{F}}(\mathrm{H}_k(X;\mathbb{F}))$ without appealing to the Cohomology-Field Coefficients Proposition 110.18. Indeed, using Theorem 110.12, the fact that for any abelian group G we have $\mathrm{Hom}(\mathbb{Z}_n, G) \cong \ker(G \xrightarrow{\cdot n} G)$ and Proposition 110.6 one can easily compute $\dim_{\mathbb{F}}(\mathrm{H}^k(X;\mathbb{F}))$ and one ends up with the same calculation as in the above claim. We leave it to the reader to fill in the details. ■

110.5. **Proof of the Cohomology-Field Coefficients Proposition 110.18 (∗).** In this section we give the proof of the Cohomology-Field Coefficients Proposition 110.18. Before we can provide the proof we need to prepare the ground.

Let $\mathbb{F}$ be a field. We define a *chain complex over* $\mathbb{F}$ to be a chain complex (V_*, v_*) where all chain groups are $\mathbb{F}$-vector spaces and all boundary maps are $\mathbb{F}$-homomorphisms. For example, if $(\mathrm{C}_*, \partial_*)$ is a chain complex of abelian groups, then $(C_* \otimes \mathbb{F}, \partial_* \otimes \mathrm{id})$ is easily seen to be a chain complex over $\mathbb{F}$.

Given a chain complex (V_*, v_*) over the field $\mathbb{F}$ and given $n \in \mathbb{N}_0$ its n-homology

$$\mathrm{H}_n(V) \;:=\; \frac{\ker(v_n\colon V_n \to V_{n-1})}{\mathrm{im}(v_{n+1}\colon V_{n+1} \to V_n)}.$$

is an $\mathbb{F}$-vector space in a natural way.

We also define cochain complexes and cochain maps over $\mathbb{F}$ in the obvious way. For example, if (C_*, c_*) is a chain complex, then the dual cochain complex $(\mathrm{Hom}(\mathrm{C}_*(X,\mathbb{F})), c^*)$ is a cochain complex over $\mathbb{F}$.

Given a chain complex (V_*, v_*) over $\mathbb{F}$ we obtain a cochain complex by considering $(\mathrm{Hom}_{\mathbb{F}}(V_*;\mathbb{F}), v^*)$ and we define its n-th cohomology group to be the $\mathbb{F}$-vector space

$$\mathrm{H}^n(V;\mathbb{F}) \;:=\; \frac{\ker(v_{n+1}^*\colon \mathrm{Hom}_{\mathbb{F}}(V_n,\mathbb{F}) \to \mathrm{Hom}_{\mathbb{F}}(V_{n+1},\mathbb{F}))}{\mathrm{im}(v_n^*\colon \mathrm{Hom}_{\mathbb{F}}(V_{n-1},\mathbb{F}) \to \mathrm{Hom}_{\mathbb{F}}(V_n,\mathbb{F}))}.$$

Theorem 110.20. Let $\mathbb{F}$ be a field and let (V_*, v_*) be a chain complex over $\mathbb{F}$. Then the map

$$\begin{array}{rcl} \mathrm{ev}_{\mathbb{F}}\colon \mathrm{H}^k(V;\mathbb{F}) & \mapsto & \mathrm{Hom}_{\mathbb{F}}(\mathrm{H}_k(V),\mathbb{F}). \\ (\varphi\colon V_k \to \mathbb{F}) & \to & \begin{pmatrix} \mathrm{H}_k(V) & \to & \mathbb{F} \\ [c] & \mapsto & \varphi(c) \end{pmatrix} \end{array}$$

is well-defined and it is an isomorphism of $\mathbb{F}$-vector spaces.

Proof. This theorem is in fact identical to Theorem **??**. If the reader did not make it to Theorem **??**, then note that the proof of Theorem 110.20 is a variation, and mostly a simplification, of the proof of the Universal Coefficient Theorem 110.11 for Cohomology Groups. ■

We will also need the following lemma.

Lemma 110.21. Let C be an abelian group and let $\mathbb{F}$ be a field. Then the map[1343]

$$\begin{array}{rcl} \Phi_C\colon \operatorname{Hom}_{\mathbb{Z}}(C,\mathbb{F}) & \to & \operatorname{Hom}_{\mathbb{F}}(C\otimes\mathbb{F},\mathbb{F}) \\ (\varphi\colon C\to\mathbb{F}) & \mapsto & \left(\begin{array}{rcl} C\otimes\mathbb{F} & \to & \mathbb{F} \\ \sum\limits_{i=1}^{k} c_i\otimes a_i & \mapsto & \sum\limits_{i=1}^{k}\varphi(c_i)\cdot a_i \end{array}\right) \end{array}$$

is an isomorphism.

Proof. It is straightforward to verify that an inverse map to Φ_C is given by the following homomorphism of $\mathbb{F}$-vector spaces:

$$\begin{array}{rcl} \Psi_C\colon \operatorname{Hom}_{\mathbb{F}}(C\otimes\mathbb{F},\mathbb{F}) & \to & \operatorname{Hom}_{\mathbb{Z}}(C,\mathbb{F}) \\ (\varphi\colon C\otimes\mathbb{F}\to\mathbb{F}) & \mapsto & \big(C \xrightarrow{c\mapsto c\otimes 1} C\otimes\mathbb{F} \xrightarrow{\varphi} \mathbb{F}\big). \end{array}$$

■

Corollary 110.22. Let C_* be a chain complex and let $\mathbb{F}$ be a field. The maps

$$\Phi_{\mathrm{C}_k}\colon \operatorname{Hom}_{\mathbb{Z}}(C_k,\mathbb{F}) \to \operatorname{Hom}_{\mathbb{F}}(\mathrm{C}_k\otimes\mathbb{F},\mathbb{F}) \quad \text{with } k\in\mathbb{N}_0$$

from the previous lemma define an isomorphism of cochain complexes of $\mathbb{F}$-vector spaces, in particular for each $k\in\mathbb{N}_0$ they induce an isomorphism

$$\Phi\colon \mathrm{H}^k(C;\mathbb{F}) \to \mathrm{H}^k(C\otimes\mathbb{F};\mathbb{F})$$

of $\mathbb{F}$-vector spaces.

Proof. By Lemma 110.21 the maps Φ_{C_k}, $k\in\mathbb{N}_0$, are isomorphisms of the cochain vector spaces. It is straightforward to see that these maps are also cochain maps. ■

Now we can finally provide the proof of the Cohomology-Field Coefficients Proposition 110.18.

Proof of the Cohomology-Field Coefficients Proposition 110.18. Let (X,A) be a pair of topological spaces and let $\mathbb{F}$ be a field. We write $\mathrm{C}_* = \mathrm{C}_*(X,A)$. Given $k\in\mathbb{N}_0$ we consider the diagram

$$\begin{array}{ccc} & \mathrm{H}^k(C\otimes\mathbb{F};\mathbb{F}) & \\ {\scriptstyle\Phi}\nearrow & & \searrow{\scriptstyle \mathrm{ev}_{\mathbb{F}}} \\ \mathrm{H}^k(C;\mathbb{F}) & \xrightarrow[\mathrm{ev}]{} & \operatorname{Hom}_{\mathbb{F}}(\mathrm{H}_n(C\otimes\mathbb{F}),\mathbb{F}). \end{array}$$

It follows easily from the definitions that for any representative in $\mathrm{H}^k(C;\mathbb{F})$ the image under the composition of the two diagonal maps agrees with the image under the map ev. This implies that ev is well-defined and that the diagram commutes.

Also note that the left diagonal map is an isomorphism by Corollary 110.22 whereas the right diagonal map is an isomorphism by Theorem 110.20. In particular the bottom map is an isomorphism. But that is exactly what we had wanted to show. ■

[1343]Note that to the left we consider homomorphisms of $\mathbb{Z}$-modules, i.e. homomorphisms of abelian groups whereas to the right we consider homomorphisms of $\mathbb{F}$-vector spaces.

110.6. **Change of coefficients in cohomology.** Let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups and let G be an abelian group. By the Algebraic Universal Coefficient Theorem 89.16 we can relate the homology groups of $C_* \otimes G$ to the homology groups of C_*. Furthermore, by the Universal Coefficient Theorem for Cohomology Groups 110.11 we can relate the cohomology groups $\mathrm{H}^*(\mathrm{C}_*; G)$ to the homology groups $\mathrm{H}_*(C)$. The following question arises.

Question 110.23. Can we relate the cohomology groups $\mathrm{H}^*(C; G)$ to the cohomology groups $\mathrm{H}^*(C; \mathbb{Z})$?

It turns out that the question is slightly subtle. To formulate the answer we need the following lemma.

Lemma 110.24. Let G be an abelian group.

(1) For any abelian group H the map

$$\begin{array}{rcl} \mu\colon \mathrm{Hom}(H,\mathbb{Z}) \otimes G & \to & \mathrm{Hom}(H,G) \\ \sum_{i=1}^m \varphi_i \otimes g_i & \mapsto & \left(\begin{array}{ccc} H & \to & G \\ h & \mapsto & \sum_{i=1}^m \varphi_i(h) \cdot g_i \end{array} \right) \end{array}$$

is a well-defined *natural* homomorphism.

(2) Given a chain complex $(\mathrm{C}_*, \partial_*)$ the map

$$\begin{array}{rcl} \mathrm{H}^n(C;\mathbb{Z}) \otimes G & \stackrel{\mu}{\to} & \mathrm{H}^n(C;G) \\ \sum_{i=1}^m [\varphi_i] \otimes g_i & \mapsto & \sum_{i=1}^m [\mu(\varphi_i \otimes g_i)] \end{array}$$

is well-defined.

Proof. The proof is elementary and is left to the reader. ∎

The following theorem gives an affirmative answer to Question 110.23, albeit only under an extra hypothesis.

Theorem 110.25. (Universal Coefficient Theorem) Let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups and let G be an abelian group. We suppose that all cohomology groups $\mathrm{H}^n(\mathrm{C}_*; \mathbb{Z})$ are finitely generated. Then for each $n \in \mathbb{N}_0$ there exists a short exact sequence of the form

$$\begin{array}{ccccccccc} 0 & \to & \mathrm{H}^n(C;\mathbb{Z}) \otimes G & \stackrel{\mu}{\to} & \mathrm{H}^n(C;G) & \to & \mathrm{Tor}(\mathrm{H}^{n+1}(C;\mathbb{Z}), G) & \to & 0. \\ & & [\varphi] \otimes g & \mapsto & [\mu(\varphi \otimes g)] & & & & \end{array}$$

Furthermore the short exact sequence splits.[1344]

The key to proving the Universal Coefficient Theorem 110.25 is the following elementary but subtle lemma.

Lemma 110.26. Let G be an abelian group. If H is a free abelian group of *finite rank*, then the map

$$\mu\colon \mathrm{Hom}(H,\mathbb{Z}) \otimes G \to \mathrm{Hom}(H,G)$$

[1344] As always, the splitting is not natural. In fact in this theorem we do *not* even claim that the short exact sequence is natural. The reason is that the construction of the short exact sequence involves a choice of the chain complex D_* and we do not intend to discuss the question how that choice affects the map on the right hand side.

is an isomorphism.

Proof. Let $v_1, \dots, v_n$ be a basis for the finitely generated free abelian group H. We denote by $\varphi_1, \dots, \varphi_n$ the dual basis of $\mathrm{Hom}(H, \mathbb{Z})$. In other words, these are the homomorphisms that are uniquely determined by $\varphi_i(v_j) = \delta_{ij}$. We leave it to the reader to verify that the map

$$\begin{aligned} \nu\colon \mathrm{Hom}(H, G) &\to \mathrm{Hom}(H, \mathbb{Z}) \otimes G \\ \psi &\mapsto \sum_{i=1}^{n} \varphi_i \otimes \psi(v_i) \end{aligned}$$

is an inverse to the homomorphism μ. ■

We will also need the following lemma.

Lemma 110.27. Let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups. If all cohomology groups $\mathrm{H}^n(\mathrm{C}_*; \mathbb{Z})$ are finitely generated, then all homology groups $\mathrm{H}_n(C_*)$ are also finitely generated.

Proof of Lemma 110.27. Let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups such that all cohomology groups $\mathrm{H}^n(\mathrm{C}_*; \mathbb{Z})$ are finitely generated. By the Universal Coefficient Theorem 110.11 for Cohomology Groups there exists an isomorphism

$$\mathrm{H}^n(C; \mathbb{Z}) \cong \mathrm{Ext}(\mathrm{H}_{n-1}(C), \mathbb{Z}) \oplus \mathrm{Hom}(\mathrm{H}_n(C), \mathbb{Z}) \quad \text{for every } n \in \mathbb{N}_0.$$

We see that all the groups $\mathrm{Ext}(\mathrm{H}_{n-1}(C), \mathbb{Z})$ and $\mathrm{Hom}(\mathrm{H}_n(C), \mathbb{Z})$ are finitely generated, in particular they are countable. But by Proposition 110.10 this implies that all the homology groups $\mathrm{H}_n(C_*)$ are finitely generated. ■

Proof of the Universal Coefficient Theorem 110.25. Let G be an abelian group. Furthermore let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups such that all cohomology groups $\mathrm{H}^n(\mathrm{C}_*; \mathbb{Z})$ are finitely generated. It follows from Lemma 110.27 that all homology groups $\mathrm{H}_n(C_*)$ are also finitely generated. Thus we obtain from the Finite-Rank Chain Complex Lemma 81.14 that there exists a chain homotopy equivalence $h\colon C_* \to D_*$ from $(\mathrm{C}_*, \partial_*)$ to a chain complex (D_*, ∂_*) such that each chain group D_n is a finitely generated free abelian group. Now we consider the following diagram:

$$\begin{array}{ccccccccc}
0 \to & \overbrace{\mathrm{H}_n(\mathrm{Hom}(D_*, \mathbb{Z}))}^{=\mathrm{H}^n(D;\mathbb{Z}) \text{ by def.}} \otimes G & \xrightarrow{[\varphi]\otimes g \mapsto [\varphi \otimes g]} & \mathrm{H}_n(\mathrm{Hom}(D_*, \mathbb{Z}); G) & \to & \mathrm{Tor}(\overbrace{\mathrm{H}_{n+1}(\mathrm{Hom}(D_*, \mathbb{Z}))}^{=\mathrm{H}^{n+1}(D;\mathbb{Z}) \text{ by def.}}, G) & \to 0. \\
& \uparrow{=} & & \downarrow{\cong}\,\mu & & \uparrow{=} & & & \\
& \mathrm{H}^n(D; \mathbb{Z}) \otimes G & \xrightarrow{\mu} & \mathrm{H}_n(\mathrm{Hom}(D_*, G)) & & \mathrm{Tor}(\mathrm{H}^{n+1}(D; \mathbb{Z}), G) & & & \\
& \uparrow{=} & & \uparrow{=} & & \uparrow{=} & & & \\
& \mathrm{H}^n(D; \mathbb{Z}) \otimes G & \xrightarrow{\mu} & \mathrm{H}^n(D_*; G) & & \mathrm{Tor}(\mathrm{H}^{n+1}(D; \mathbb{Z}), G) & & & \\
& \downarrow{\cong}\,h^* & & \downarrow{\cong}\,h^* & & \downarrow{\cong}\,h^* & & & \\
& \mathrm{H}^n(C; \mathbb{Z}) \otimes G & \xrightarrow{\mu} & \mathrm{H}^n(C; G) & & \mathrm{Tor}(\mathrm{H}^{n+1}(C; \mathbb{Z}), G). & & &
\end{array}$$

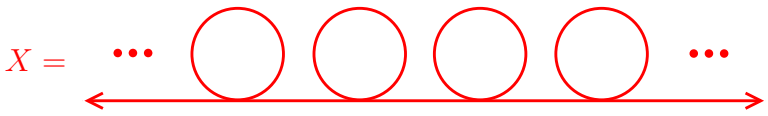
We make the following clarifications:

(1) The horizontal sequence on the top is the short exact sequence obtained from the Algebraic Universal Coefficient Theorem 89.16 which we applied to the chain complex $E_* = \mathrm{Hom}(D_{-*}, \mathbb{Z})$. We need to invert the sign of the degrees twice, thus we end up with the degree $n + 1 = -((-n) - 1)$ on the right hand side. We know by the UCT-Splitting Proposition 89.21 that the short exact sequence splits.

(2) It follows from Lemma 110.26 that the middle vertical map between the first two rows is an isomorphism. Here we use that each chain group of D_* is a free abelian group of finite rank.
(3) One can easily verify that the diagram commutes.
(4) By the Dual Cochain Map Lemma 108.8 (4) the bottom vertical maps are isomorphisms.

It is now clear that we obtain the desired short exact sequence. ■

The following theorem gives a practical "topological" version of the Universal Coefficient Theorem 110.25.



Theorem 110.28. (Universal Coefficient Theorem) Let X be a topological space and let G be an abelian group. If all homology groups $\mathrm{H}_n(X)$ of X are finitely generated (e.g. X could be a compact topological manifold or X could be a CW-complex that has only finitely many cells in each dimension[1345]), then for each $n \in \mathbb{N}_0$ there exists a short exact sequence of the form

$$\begin{array}{ccccccccc} 0 & \to & \mathrm{H}^n(X;\mathbb{Z}) \otimes G & \xrightarrow{\mu} & \mathrm{H}^n(X;G) & \to & \mathrm{Tor}(\mathrm{H}^{n+1}(X;\mathbb{Z}),G) & \to & 0. \\ & & [\varphi] \otimes g & \mapsto & [\mu(\varphi \otimes g)] & & & & \end{array}$$

Furthermore the short exact sequence splits.

Proof. This theorem follows immediately from applying the Universal Coefficient Theorem 110.25 to the singular chain complex of X. ■

Remark. In general the hypothesis on X that we put into the Universal Coefficient Theorem 110.28 cannot be dropped. For example consider the infinite string of circles X as shown in the figure below and we take $G = \mathbb{Q}$. By the Tor-Properties Lemma 89.15 (4) we know that all Tor-groups $\mathrm{Tor}(H, \mathbb{Q})$ vanish. In Exercise 110.10 we will see that the groups $\mathrm{H}^1(X;\mathbb{Z}) \otimes \mathbb{Q}$ and $\mathrm{H}^1(X;\mathbb{Q})$ are not isomorphic. This shows that in this setting the sequence stated in the Universal Coefficient Theorem 110.28 is not exact.

the groups
$H^1(X;\mathbb{Z}) \otimes \mathbb{Q}$ and $H^1(X;\mathbb{Q})$
are not isomorphic

The following lemma gives a convenient interpretation of the map μ appearing in the Universal Coefficient Theorem 110.28.

Lemma 110.29. Let X be a topological space, let G be an abelian group and let $f\colon \mathbb{Z} \to G$ be a homomorphism. The following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^n(X;\mathbb{Z}) & & \\ {\scriptstyle a \mapsto a \otimes f(1)}\downarrow & \searrow^{f_*} & \\ \mathrm{H}^n(X;\mathbb{Z}) \otimes G & \xrightarrow[\mu]{} & \mathrm{H}^n(X;G). \end{array}$$

[1345] By the Topological Manifolds-Invariants Proposition 104.14 (4) and the Homology-of-CW-Complex Proposition 80.6 (1) such topological spaces qualify.

Proof. The statement follows immediately from explicitly writing down the homomorphisms. ■

Example. Let $n \in \mathbb{N} \cup \{\infty\}$. We denote by $f\colon \mathbb{Z} \to \mathbb{Z}_2$ the obvious group homomorphism. It follows from the Universal Coefficient Theorem 110.28, from Lemma 110.29, from the calculations of the cohomology groups $\mathrm{H}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ on page 2424, and from the properties of Tor-groups, see the Tor-Properties Lemma 89.15, that for any $k \in \mathbb{N}_0$ the map $f_*\colon \mathrm{H}_*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to \mathrm{H}_*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2)$ is an epimorphism.

We conclude this chapter with the following lemma which unwittingly gets used frequently.

Lemma 110.30. We denote by $\varphi\colon \mathbb{Z} \to \mathbb{Q}$ the obvious inclusion. Let $n \in \mathbb{N}_0$.

(1) Let X be a topological space such that all homology groups are finitely generated. We suppose that $\mathrm{H}^n(X;\mathbb{Z})$ is a finitely generated free abelian group. If $v_1, \ldots, v_m$ is a basis of $\mathrm{H}^n(X;\mathbb{Z})$, then $\varphi_*(v_1), \ldots, \varphi_*(v_m)$ is a basis of $\mathrm{H}^n(X;\mathbb{Q})$.

(2) Let $f\colon X \to Y$ be a map between topological spaces. We suppose that all homology groups of X and Y are finitely generated and we suppose that $\mathrm{H}^n(X;\mathbb{Z})$ and $\mathrm{H}^n(Y;\mathbb{Z})$ are free abelian groups. We consider the following commutative diagram:

$$\begin{array}{ccc} \mathrm{H}^n(Y;\mathbb{Z}) & \xrightarrow{f^*} & \mathrm{H}^n(X;\mathbb{Z}) \\ {\scriptstyle\varphi_*}\downarrow & & \downarrow{\scriptstyle\varphi_*} \\ \mathrm{H}^n(Y;\mathbb{Q}) & \xrightarrow{f^*} & \mathrm{H}^n(X;\mathbb{Q}). \end{array}$$

Suppose $v_1, \ldots, v_r$ is a basis for $\mathrm{H}^n(X;\mathbb{Z})$ and that $w_1, \ldots, w_s$ is a basis for $\mathrm{H}^n(Y;\mathbb{Z})$. The matrix that represents $f^*\colon \mathrm{H}^n(Y;\mathbb{Z}) \to \mathrm{H}^n(X;\mathbb{Z})$ with respect to the given bases also represents $f^*\colon \mathrm{H}^n(Y;\mathbb{Q}) \to \mathrm{H}^n(X;\mathbb{Q})$ with respect to the bases $\varphi_*(v_1), \ldots, \varphi_*(v_r)$ and $\varphi_*(w_1), \ldots, \varphi_*(w_s)$.

Proof.

(1) This statement follows easily from the Universal Coefficient Theorem 110.28 together with the Tor-Properties Lemma 89.15 (4) and Lemma 110.29.

(2) The fact that the diagram commutes is an immediate consequence of Lemma 108.9. The remaining statement is just a psychologically helpful reinterpretation of the fact that the diagram commutes. ■

Exercises for Chapter 110.

Exercise 110.1. Let C_* be a chain complex of free abelian groups and let $n \in \mathbb{N}$. Show that there does not exist a *natural* isomorphism

$$\mathrm{H}^n(C;G) \;\cong\; \mathrm{Ext}(\mathrm{H}_{n-1}(C), G) \oplus \mathrm{Hom}(\mathrm{H}_n(C), G).$$

Exercise 110.2. Let $\{A_n\}_{n\in\mathbb{N}}$ be a sequence of finitely generated abelian groups. We assume that A_0 and A_1 are free abelian groups. Show that there exists a connected CW-complex X such that for any $n \in \mathbb{N}$ we have $\mathrm{H}^n(X;\mathbb{Z}) \cong A_n$.
Hint. Use Proposition 79.10.
Remark. The statement is not true if we drop the hypothesis that the groups are finitely generated, in fact as is shown in [**Luc1978**] (see also [**KaW1961**]) there is no topological space X with $\mathrm{H}^n(X;\mathbb{Z}) \cong \mathbb{Q}$ for some $n \in \mathbb{N}_0$.

Exercise 110.3. Let $(P, \leq)$ be a partially ordered set and let Q be a subset. Is an upper bound necessarily a maximal element? And conversely, is a maximal element necessarily an upper bound?

Exercise 110.4. Let X and Y are topological spaces. Suppose that $\mathrm{H}_n(X;\mathbb{Z}) \cong \mathrm{H}_n(Y;\mathbb{Z})$ for some $n \in \mathbb{N}_0$. Does it follow that $\mathrm{H}^n(X;\mathbb{Z})$ and $\mathrm{H}^n(Y;\mathbb{Z})$ are also isomorphic?

Exercise 110.5. Redo Exercise 109.3. More precisely, use the Universal Coefficient Theorem 110.12 for Cohomology Groups to determine the isomorphism types of the cohomology groups of the Klein bottle with $\mathbb{F}_2$-coefficients, with $\mathbb{F}_3$-coefficients and with $\mathbb{Z}$-coefficients.

Exercise 110.6. Give an explicit example of a cocycle $\varphi\colon \mathrm{C}_1(\mathbb{R}\mathrm{P}^2) \to \mathbb{F}_2$ that represents a generator of $\mathrm{H}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \cong \mathbb{F}_2$.

Exercise 110.7. Let M be a compact oriented connected n-dimensional topological manifold with connected non-empty boundary. Show that $\delta([\partial M]^*) = [M]^* \in \mathrm{H}^n(M, \partial M;\mathbb{Z})$ where δ denotes the connecting homomorphism in the long exact sequence of cohomology groups of the pair $(M, \partial M)$.
Hint. Use the Fundamental Class-of-Boundary Proposition 106.27.

Exercise 110.8.

(a) Let G and H be $\mathbb{Q}$-vector spaces. Let $\varphi\colon G \to H$ be a homomorphism of abelian groups. Show that φ is also a homomorphism of $\mathbb{Q}$-vector spaces.
(b) Show that the abelian groups $\mathbb{Q}$ and $\mathbb{Q}^2$ are not isomorphic.
(c) Show that the abelian groups $\mathbb{R}$ and $\mathbb{R}^2$ are isomorphic.
(d) Use (a) and (b), together with the existence of Moore spaces, see the Moore Space Existence Proposition 79.11, and together with the Universal Coefficient Theorem 110.12 for Cohomology Groups and Proposition 110.9 to conclude that there exist topological spaces X and Y such that $\mathrm{H}^n(X;\mathbb{Z}) \cong \mathrm{H}^n(Y;\mathbb{Z})$ for all $n \in \mathbb{N}_0$ but such that $\mathrm{H}_1(X;\mathbb{Z})$ is not isomorphic to $\mathrm{H}_1(Y;\mathbb{Z})$.

Remark. This exercise shows that in Corollary 108.19 the roles of homology and cohomology are not symmetric.

Exercise 110.9. Let H be a free abelian group and let G be an abelian group. As in Lemma 110.26 we consider the map

$$\begin{array}{ccc} \mathrm{Hom}(H,\mathbb{Z}) \otimes G & \to & \mathrm{Hom}(H,G) \\ \sum\limits_{i=1}^{m} \varphi_i \otimes g_i & \mapsto & \left(\begin{array}{ccc} H & \to & G \\ h & \mapsto & \sum\limits_{i=1}^{m} \varphi_i(h) \cdot g_i \end{array} \right). \end{array}$$

Show that this map is in general not an isomorphism.

Exercise 110.10. We consider the topological space X shown in the figure on page 2458. Show that the map

$$\mu\colon \mathrm{H}^1(X;\mathbb{Z}) \otimes \mathbb{Q} \to \mathrm{H}^1(X;\mathbb{Q})$$

from Lemma 110.24 is not an isomorphism.

Exercise 110.11. Show that there exists a topological space X such that the two groups $\mathrm{H}^1(X;\mathbb{Z}) \otimes \mathbb{Q}$ and $\mathrm{H}^1(X;\mathbb{Q})$ are not isomorphic.
Hint. You could make use of Proposition 79.10 to find unusual topological spaces.

Exercise 110.12. Let X be a topological space which is $\mathbb{Z}$-finite in the sense of the definition on page 2116, i.e. all homology groups $\mathrm{H}_i(X)$ are finitely generated abelian groups and all but finitely many homology groups $\mathrm{H}_i(X)$ are zero. Let $\varphi\colon X \to X$ be a map. Show that

$$\underbrace{\sum_{k\in\mathbb{N}_0} (-1)^k \cdot \mathrm{tr}(\varphi_*\colon \mathrm{H}_k(X;\mathbb{Z}) \to \mathrm{H}_k(X;\mathbb{Z}))}_{\text{Lefschetz number } \Lambda(\varphi) \text{ as defined on page 2116}} = \sum_{k\in\mathbb{N}_0} (-1)^k \cdot \mathrm{tr}(\varphi^*\colon \mathrm{H}^k(X;\mathbb{Z}) \to \mathrm{H}^k(X;\mathbb{Z})).$$

111. Cohomology groups and limits

111.1. **Direct limits of direct systems.** In the intermediate future direct limits of direct systems and inverse limits of inverse systems will play a large role. To fortify us for these discussions we recall the definitions and we prove some fairly elementary but useful lemmas regarding limits.
First we recall the following definition from page 1256.

Definition. A directed set is a set I together with a relation $\leq$ on I which satisfies the following three conditions:

(1) the relation is reflexive, i.e. for any $i \in I$ we have $i \leq i$.
(2) the relation is transitive, i.e. for any $i, j, k \in I$ we have
$$i \leq j \text{ and } j \leq k \implies i \leq k.$$
(3) for any $i, j \in I$ there exists a $k \in I$ with $i \leq k$ and $j \leq k$.

Examples.

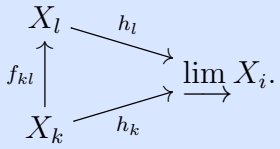
(a) Evidently the natural numbers $\mathbb{N}$ together with the usual "$\leq$" relation form a directed set $(\mathbb{N}, \leq)$.
(b) Let M be a set. We denote by $\mathcal{P}(M)$ the power set of M, i.e. the set of all subsets of M. Then the relation given by "$\subseteq$" turns $\mathcal{P}(M)$ into a directed set. To prove this claim it only remains to verify (3). But this also holds, since for any $X, Y \in \mathcal{P}(M)$, i.e. for any subsets X, Y of M we can take $Z = X \cup Y$ and we then have $X \subseteq Z$ and $Y \subseteq Z$.

Next we recall the following definition from page 1257.

Definition. Let $(I, \leq)$ be a directed set and let $\mathcal{C}$ be a category. A direct system over the directed set[1352] $(I, \leq)$ is a family of objects $\{X_i\}_{i \in I}$ in $\mathcal{C}$, together with a family of morphisms $\{f_{ij} \colon X_i \to X_j\}$ for all $i, j \in I$ with $i \leq j$ such that the following two conditions are satisfied:

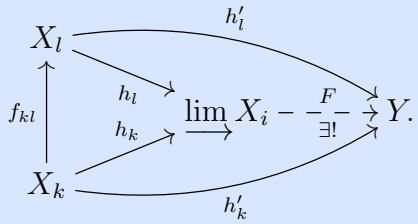
(1) $f_{ii} = \mathrm{id}_{X_i}$ for all $i \in I$,
(2) $f_{ik} = f_{jk} \circ f_{ij}$ for all $i, j, k \in I$ with $i \leq j \leq k$.

Example. Let $\mathcal{C}$ be a category and let
$$X_1 \xrightarrow{g_1} X_2 \xrightarrow{g_2} X_3 \xrightarrow{g_3} X_4 \xrightarrow{g_4} \dots$$
be a sequence of morphisms in the category $\mathcal{C}$. For $i \in \mathbb{N}_0$ we set $f_{ii} = \mathrm{id}$ and for $i \leq j$ we set $f_{ij} = g_{j-1} \circ \dots \circ g_{i+1} \circ g_i \colon X_i \to X_j$. It is clear that $(\{X_i\}_{i \in \mathbb{N}}, \{f_{ij}\}_{i \leq j})$ is a direct system over the directed set $(\mathbb{N}, \leq)$. By a slight abuse of notation we refer to such a sequence $(\{X_i\}_{i \in \mathbb{N}}, \{g_i \colon X_i \to X_{i+1}\}_{i \in \mathbb{N}})$ also as a direct system.



Finally we also recall the definition of a direct limit from page 1258.

Definition. Let $(I, \leq)$ be a directed set and let $\mathcal{C}$ be a category. Suppose we are given a direct system $(\{X_i\}_{i \in I}, \{f_{ij}\}_{i \leq j})$ in the category $\mathcal{C}$. A direct limit of the direct system is



[1352] On page 1257 we had also considered direct systems that are defined over preordered sets, but for the remainder of this course we are only interested in direct systems over directed sets.

an object $\varinjlim X_i$ in $\mathcal{C}$ together with morphisms $h_i\colon X_i \to \varinjlim X_i, i \in I$ in the category $\mathcal{C}$ such that the following two conditions are satisfied:

(1) For all $k \leq l$ we have $h_l \circ f_{kl} = h_k\colon X_k \to \varinjlim X_i$, i.e. for all $k \leq l$ the following diagram commutes

(2) If we are given another object Y and morphisms $h'_i\colon X_i \to Y, i \in I$ that satisfy (1), then there exists a unique morphism $F\colon \varinjlim X_i \to Y$ such that for all $k \leq l$ the following diagram commutes

As we pointed out on page 1258, the direct limit of direct system, if it exists, is in an appropriate sense unique up to isomorphism.

The following proposition is a variation on the Direct Limit Existence Proposition 56.1.

Proposition 111.1. (Direct Limit Existence Proposition) Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ be a direct system over one of the following categories:

(1) the category of abelian groups,
(2) the category of R-modules, where R is a commutative ring,
(3) the category of chain complexes,
(4) the category of cochain complexes.

Then[1353]

$$\varinjlim X_i \;:=\; \Big(\bigsqcup_{i\in I} X_i\Big)/\sim \quad \text{where } x \sim f_{ij}(x) \text{ for all } i \leq j,\ x \in X_i$$

with the obvious maps $X_i \to \varinjlim X_i$ is a direct limit. Here we view $\varinjlim X_i$ as a group as follows: if we are given $a \in X_i$ and $b \in X_j$, then by definition of a directed set there exists a $k \in I$ with $i \leq k$ and $j \leq k$, and we define[1354]

$$[a] + [b] \;:=\; \underbrace{\big[\underbrace{f_{ik}(a)}_{\in X_k} + \underbrace{f_{jk}(b)}_{\in X_k}\big]}_{\text{addition in } X_k} \;\in\; \varinjlim X_i.$$

Depending on the category we are dealing with we can also equip $\varinjlim X_i$ with an R-module structure or we can equip it with (co) boundary maps.

[1353] The construction of the direct limit that we gave in the Direct Limit Existence Proposition 56.1 was different, and arguably more complicated, since there we had considered direct systems over arbitrary preordered sets.

[1354] It is straightforward to verify that this definition does not depend on the choice of k.

Proof. This explicit construction of the direct limit was already given on page 1262. The proof of the proposition is a not overly exciting exercise in going through all the definitions. We leave this task to the reader. ■

Now we give three lemmas which will be helpful in getting direct limits "under control".

Lemma 111.2. Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system over I in one of the four categories that we had considered in the Direct Limit Existence Proposition 111.1. Then the following four statements hold:

(1) Every element in $\varinjlim X_i$ lies in the image of one of the maps $X_j \to \varinjlim X_i$.

(2) Let $a_j \in X_j$ and let $a_k \in X_k$. The images of a_j and a_k in $\varinjlim X_i$ agree if and only if there exists an $l \in I$ with $l \geq j$ and $l \geq k$ such that $f_{jl}(a_j) = f_{kl}(a_k) \in X_l$.

(3) Let $a_j \in X_j$. The image of a_j in $\varinjlim X_i$ is zero if and only if there exists a $k \geq j$ such that $f_{jk}(a_j) = 0 \in X_k$.

(4) If all maps $f_{ij}\colon X_i \to X_j$ are isomorphisms, then for any $j \in I$ the obvious map $X_j \to \varinjlim X_i$ is an isomorphism.

Proof.

(1) The first statement follows immediately from the explicit description of the direct limit given in the Direct Limit Existence Proposition 111.1.

(2) The second statement will be proved in Exercise 111.1. For the exercise it is useful to note that the symbol "$\sim$" in the definition of $\varinjlim X_i$ in the Direct Limit Existence Proposition 111.1 is only a relation and we really have to work with the equivalence relation generated by this relation, see page 258 for more information.

(3) The third statement is a special case of the second statement.

(4) The last statement will be proved in Exercise 111.1. ■

The second lemma is useful for simplifying calculations.

Lemma 111.3. (Limit-over-Subset Lemma) Let $(I, \leq)$ be a directed set. Furthermore let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system over I in one of the four categories that we had considered in the Direct Limit Existence Proposition 111.1. Let J be a subset of I such that $(J, \leq)$ is again a directed set.

(1) There exists a unique map

$$\varinjlim_{j\in J} X_j \longrightarrow \varinjlim_{i\in I} X_i$$

such that for any $j \in J$ the following diagram commutes:

$$\begin{array}{ccc} & X_j & \\ \swarrow & & \searrow \\ \varinjlim_{j\in J} X_j & \longrightarrow & \varinjlim_{i\in I} X_i. \end{array}$$

(2) If J has the property that given any $i \in I$ there exists a $j \in J$ with $i \leq j$, then the above map

$$\varinjlim_{j\in J} X_j \longrightarrow \varinjlim_{i\in I} X_i$$

is an isomorphism.

The first part of the lemma is just an immediate consequence of the definition of the direct limit over the directed set J. As we will see, the second statement is a fairly straightforward consequence of the next lemma. But it is also a good exercise to prove the above second statement "by hand".

The following definition is a generalization of the definition on page 1753.

Definition. Let $(I, \leq)$ and $(J, \leq)$ be directed sets.

(1) A morphism between the directed sets $(I, \leq)$ and $(J, \leq)$ is a map $\varphi\colon I \to J$ such that for any $i_1 \leq i_2$ in I we have $\varphi(i_1) \leq \varphi(i_2)$.

(2) A morphism $\varphi\colon I \to J$ is called cofinal if given any $j \in J$ there exists an $i \in I$ with $\varphi(i) \geq j$.

(3) Let $(\{K_i\}_{i\in I}, \{\chi_{i_1 i_2}\}_{i_1\leq i_2})$ and $(\{L_j\}_{j\in J}, \{\lambda_{j_1 j_2}\}_{j_1\leq j_2})$ be direct systems in one of the four categories that we had considered in the Direct Limit Existence Proposition 111.1. A homomorphism between the direct systems is a family $\{f_i\colon K_i \to L_{\varphi(i)}\}_{i\in I}$ of homomorphisms that has the property that for any $i_1 \leq i_2$ the following diagram commutes:

$$\begin{array}{ccc} K_{i_2} & \xrightarrow{f_{i_2}} & L_{\varphi(i_2)} \\ {\scriptstyle \chi_{i_1 i_2}}\uparrow & & \uparrow{\scriptstyle \lambda_{\varphi(i_1)\varphi(i_2)}} \\ K_{i_1} & \xrightarrow{f_{i_1}} & L_{\varphi(i_1)} \end{array}$$

(4) The maps $K_i \xrightarrow{f_i} L_{\varphi(i)} \to \varinjlim L_j$ induce, by the universal property of a direct limit, a map

$$\varinjlim_{i\in I} K_i \to \varinjlim_{j\in J} L_j$$

which is uniquely determined by the property that for any $i \in I$ the following diagram commutes

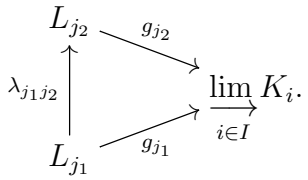
$$\begin{array}{ccc} K_i & \xrightarrow{f_i} & L_{\varphi(i)} \\ \downarrow & & \downarrow \\ \varinjlim_{i\in I} K_i & \longrightarrow & \varinjlim_{j\in J} L_j. \end{array}$$

Lemma 111.4. (Cofinal-Isomorphism Lemma) Let $\{f_i\colon K_i \to L_{\varphi(i)}\}_{i\in I}$ be a homomorphism between two direct systems $(\{K_i\}_{i\in I}, \{\chi_{i_1 i_2}\}_{i_1\leq i_2})$ and $(\{L_j\}_{j\in J}, \{\lambda_{j_1 j_2}\}_{j_1\leq j_2})$ in one of the four categories that we had considered in the Direct Limit Existence Proposition 111.1. Suppose the following two conditions are satisfied:

(1) the morphism $\varphi\colon I \to J$ is cofinal, and

(2) for each $i \in I$ the map $f_i\colon K_i \to L_{\varphi(i)}$ is an isomorphism.

Then the induced map



$$\varinjlim_{i\in I} K_i \to \varinjlim_{j\in J} L_j$$

is an isomorphism.

Sketch of proof. Let $j \in J$. Since $\varphi\colon I \to J$ is cofinal we can pick $i \in I$ with $f(i) \geq j$. We define

$$\begin{aligned} g_j\colon L_j &\to \varinjlim_{i\in I} K_i \\ x &\mapsto [f_i^{-1}(\lambda_{j,f(i)}(x))]. \end{aligned}$$

It is straightforward to verify that this map does *not* depend on the choice of i. Using this observation it is elementary to verify that for any $j_1 \leq j_2$ the following diagram commutes:

But by the universal property of the direct limit this implies that we get an induced

$$\varinjlim_{j\in J} L_j \to \varinjlim_{i\in I} K_i.$$

We leave it to the reader to verify that this map is an inverse to the map under consideration. ■

111.2. **Inverse limits of inverse systems.** We recall the following definition from page 1273.

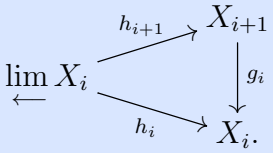
Definition. Let $(I, \leq)$ be a directed set and let $\mathcal{C}$ be a category. An inverse system in the category $\mathcal{C}$ over I is a family of objects $\{X_i\}_{i\in I}$ in $\mathcal{C}$, together with a family of morphisms $\{f_{ji}\colon X_j \to X_i\}$ for all $i, j \in I$ with $i \leq j$[1355] such that the following two conditions are satisfied:

(1)	f_{ii}	$=$	id_{X_i}	for all $i \in I$,
(2)	f_{ki}	$=$	$f_{ji} \circ f_{kj}$	for all $i, j, k \in I$ with $i \leq j \leq k$.

Example. Let $\mathcal{C}$ be a category and let

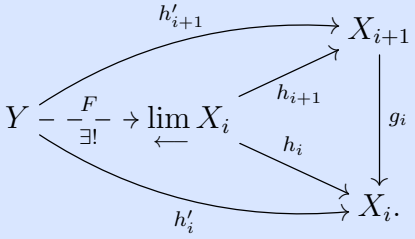
$$\ldots \xrightarrow{g_4} X_4 \xrightarrow{g_3} X_3 \xrightarrow{g_2} X_2 \xrightarrow{g_1} X_1$$

be a sequence of morphisms in the category $\mathcal{C}$. For $i \in \mathbb{N}$ we set $f_{ii} = \mathrm{id}$ and for $i \leq j$ we set $f_{ji} = g_i \circ \cdots \circ g_{j-1}\colon X_j \to X_i$. It is clear that $(\{X_i\}_{i\in I}, \{f_{ji}\}_{i\leq j})$ is an inverse system over the directed set $(\mathbb{N}, \leq)$. It is also clear that any inverse system over $(\mathbb{N}, \leq)$ arises that way. By a slight abuse of notation we refer to such a sequence $(\{X_i\}_{i\in\mathbb{N}}, \{g_i\colon X_{i+1} \to X_i\}_{i\in\mathbb{N}})$ also as an inverse system.



Using the convention from the previous example we can now reformulate in our context the original definition of an inverse limit from page 1273.

Definition. Let $(\{X_i\}_{i\in\mathbb{N}}, \{g_i\colon X_{i+1} \to X_i\}_{i\in\mathbb{N}})$ be an inverse system in a category $\mathcal{C}$. An inverse limit of the inverse system is an object $\varprojlim X_i$ in $\mathcal{C}$ together with morphisms



[1355] So in an inverse system, given $i \leq j$ we have a morphism $X_j \to X_i$, whereas in a direct system we had a morphism $X_i \to X_j$.

$h_i\colon \varprojlim X_i \to X_i$, $i \in I$, in the category $\mathcal{C}$ such that the following two conditions are satisfied:

(1) For all $i \in \mathbb{N}$ we have $g_i \circ h_{i+1} = h_i\colon \varprojlim X_i \to X_i$, i.e. for all $i \in \mathbb{N}$ the following diagram commutes

(2) If we are given another object Y and morphisms $h'_i\colon Y \to X_i$, $i \in \mathbb{N}$, that satisfy (1), then there exists a unique morphism $F\colon Y \to \varprojlim X_i$ such that for all $i \in \mathbb{N}$ the following diagram commutes

Throughout the remainder of this course we will only be interested in inverse systems over the directed set $(\mathbb{N}, \leq)$. In the following proposition we give an explicit description of inverse limits for this special case. The proposition can be viewed as a slight variation on the Inverse Limit Existence Proposition 56.15.

Proposition 111.5. (Inverse Limit Existence Proposition) Let $(\{X_i\}_{i\in\mathbb{N}}, \{g_i\colon X_{i+1} \to X_i\}_{i\in\mathbb{N}})$ be an inverse system over one of the following categories:

(1) the category of abelian groups,
(2) the category of R-modules, where R is a commutative ring,
(3) the category of chain complexes,
(4) the category of cochain complexes.

Then
$$\varprojlim X_i \;:=\; \Big\{(x_i)_{i\in\mathbb{N}} \in \prod_{i\in\mathbb{N}} X_i \;\Big|\; g_i(x_{i+1}) = x_i \text{ for all } i \in \mathbb{N}\Big\}$$
with the natural projections $\varprojlim X_i \to X_i$ is a direct limit.

Proof. This proposition is implicitly proved on page 1279. ■

Remark. the Inverse Limit Existence Proposition 111.5 can be summarized as saying that, under the hypothesis of the proposition, we have

$$\varprojlim X_i \;=\; \text{all infinite sequences } (x_1, x_2, x_3, \dots) \text{ of the form } \begin{array}{ccc} x_3 & \in & X_3 \\ \downarrow & & \downarrow g_2 \\ x_2 & \in & X_2 \\ \downarrow & & \downarrow g_1 \\ x_1 & \in & X_1. \end{array}$$

Example. For each $i \in \mathbb{N}$ we define $X_i := \mathbb{Z}^i$ and we denote by

$$\begin{array}{rcl} g_i\colon \mathbb{Z}^{i+1} & \to & \mathbb{Z}^i \\ (x_1, \dots, x_{i+1}) & \mapsto & (x_1, \dots, x_i) \end{array}$$

the projection . Then $(\{\mathbb{Z}^i\}_{i\in\mathbb{N}}, \{g_i\}_{i\in\mathbb{N}})$ forms an inverse system in the category of abelian groups. As we had already pointed out on page 1279, using the description of the inverse limit provided in the Inverse Limit Existence Proposition 111.5 one can show fairly easily that

$$\varprojlim_{i\in\mathbb{N}} \mathbb{Z}^i \;=\; \{(x_1, x_2, x_3, \dots) \mid x_j \in \mathbb{Z}\} \;\cong\; \mathbb{Z}^{\mathbb{N}}.$$

We conclude this section with the following analogue of the Direct Limit Stabilization Lemma 56.2.

Lemma 111.6. (Indirect Limit Stabilization Lemma) Let $f_n\colon X_n \to X_{n+1}$ be a sequence of morphisms in any category. Suppose there exists an $N \in \mathbb{N}$ such that all f_n for $n \geq N$ are isomorphisms. Then $\varprojlim X_n$ exists and the natural map $\varprojlim X_n \to X_N$ is an isomorphism.

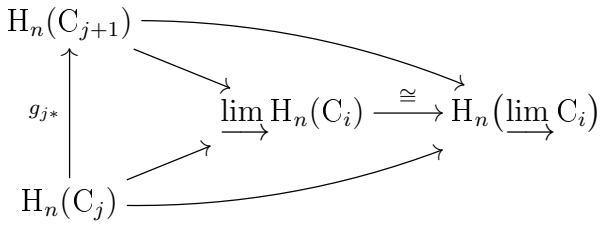
Proof. We leave it to the reader to prove this elementary lemma. ■

111.3. **Cohomology groups and inverse limits.** In Propositions 56.7 and 79.4 we saw that in favorable situations the fundamental group and the homology groups of a union of topological spaces are the direct limit of the corresponding fundamental groups and homology groups. In this section we will try to extend these results to cohomology groups. The results will not only be useful for computing cohomology groups, but they will also play an essential role in many proofs later on. For example the proof that de Rham cohomology is isomorphic to singular cohomology with real coefficients will build on the somewhat technical results of this section.
We recall that the Exhaustions-H_*-Proposition 79.4 was a consequence of the following two lemmas. The first lemma is of topological nature.

Lemma 79.5. (Exhaustion-Chain Complex Lemma) Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that every compact subset of X is already contained in one of the X_i. Then the chain complexes $\mathrm{C}_*(X_i), i \in \mathbb{N}$ together with the inclusion induced chain maps $\mathrm{C}_*(X_i) \to \mathrm{C}_*(X_j)$ for $i \leq j$ form a direct system of chain complexes. Furthermore the inclusion induced maps $\mathrm{C}_*(X_i) \to \mathrm{C}_*(X)$ induce an isomorphism

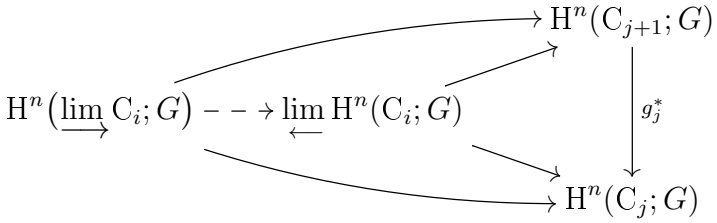
$$\varinjlim \mathrm{C}_*(X_i) \;\xrightarrow{\cong}\; \mathrm{C}_*(X)$$

of chain complexes.



The second lemma is purely algebraic.

Lemma 79.6. (Direct Limit-Homology Lemma) Let $(\{\mathrm{C}_i\}_{i\in\mathbb{N}}, \{g_i\colon \mathrm{C}_i \to \mathrm{C}_{i+1}\}_{i\in\mathbb{N}})$ be a direct system of chain complexes. Then for each $n \in \mathbb{N}_0$ we obtain an induced direct system $(\{\mathrm{H}_n(\mathrm{C}_i)\}_{i\in\mathbb{N}}, \{g_{i*}\}_{i\in\mathbb{N}})$ of abelian groups. Furthermore, given any $n \in \mathbb{N}_0$ the maps $\mathrm{H}_n(\mathrm{C}_i) \to \mathrm{H}_n\big(\varinjlim \mathrm{C}_i\big)$ induce an isomorphism



$$\varinjlim \mathrm{H}_n(\mathrm{C}_i) \;\xrightarrow{\cong}\; \mathrm{H}_n\big(\varinjlim \mathrm{C}_i\big).$$

Let $(\{\mathrm{C}_i\}_{i\in\mathbb{N}}, \{g_i\colon \mathrm{C}_i \to \mathrm{C}_{i+1}\}_{i\in\mathbb{N}})$ be a direct system of chain complexes. The last lemma can be summarized as follows: for every $j \in \mathbb{N}$ and any $n \in \mathbb{N}_0$ we have the following

diagram

Now we turn to cohomology groups. Let G be an abelian group. Whereas homology is a covariant functor, cohomology is a contravariant functor. This implies that from the above direct system of chain complexes we obtain for each $n \in \mathbb{N}_0$ an *inverse system* $(\{\mathrm{H}^n(\mathrm{C}_i; G)\}_{i\in\mathbb{N}}, \{g_i^*\colon \mathrm{H}^n(\mathrm{C}_{i+1}; G) \to \mathrm{H}^n(\mathrm{C}_i; G)\}_{i\in\mathbb{N}})$ of abelian groups. Furthermore the maps $\mathrm{C}_i \to \varinjlim \mathrm{C}_i$ induce maps $\mathrm{H}^n(\varinjlim \mathrm{C}_i; G) \to \mathrm{H}^n(\mathrm{C}_i; G)$. Put differently, for any $j \in \mathbb{N}$ we are in the following situation

where the dotted arrow exists by the definition of the inverse limit of the groups $\mathrm{H}^n(\mathrm{C}_i; G)$. The question is whether the dotted arrow is in fact an isomorphism, put differently, the following question arises.

Question 111.7. Let $(\{\mathrm{C}_i\}_{i\in\mathbb{N}}, \{g_i\colon \mathrm{C}_i \to \mathrm{C}_{i+1}\}_{i\in\mathbb{N}})$ be a direct system of chain complexes. Is the above map

$$\mathrm{H}^n\big(\varinjlim \mathrm{C}_i; \mathbb{Z}\big) \;\to\; \varprojlim \mathrm{H}^n(\mathrm{C}_i; \mathbb{Z})$$

always an isomorphism?

It turns out that this is not necessarily the case. To formulate the relationship between the two sides of the above question it is useful to rewrite the inverse limit from the Inverse Limit Existence Proposition 111.5. More precisely, given an inverse system $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ of abelian groups we consider the map

$$\begin{array}{rcl} \mu\colon \prod\limits_{i\in\mathbb{N}} D_i & \to & \prod\limits_{i\in\mathbb{N}} D_i \\ (x_i)_{i\in\mathbb{N}} & \mapsto & (x_i - g_i(x_{i+1}))_{i\in\mathbb{N}}. \end{array}$$

the Inverse Limit Existence Proposition 111.5 can be reformulated as saying that

$$\varprojlim D_i \;=\; \ker(\mu).$$

This leads us to the following definition.

Definition. Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups. Using the above notation we define[1356]

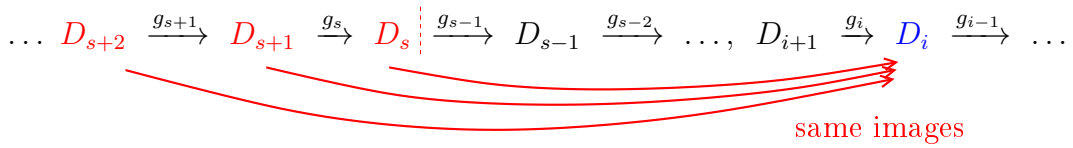
$$\varprojlim{}^1 D_i \;:=\; \operatorname{coker}(\mu).$$

Example. We consider the inverse system

$$D_*\colon \ \ldots \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \ \to 0.$$

In Exercise 111.2 we will see that $\varprojlim D_* = 0$ and $\varprojlim^1 D_* = 0$. Furthermore, we also consider the inverse system

$$E_*\colon \ \ldots \xrightarrow{\cdot 5} \mathbb{Z} \xrightarrow{\cdot 4} \mathbb{Z} \xrightarrow{3} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \ \to 0.$$



In Exercise 111.2 we will see that $\varprojlim^1 E_* \neq 0$. Furthermore in Exercise 111.3 we will see that this inverse system arises "in nature", i.e. we will see that there exists a nested sequence of topological spaces X_i such that for each $i \in \mathbb{N}$ we have $\mathrm{H}^1(X_i;\mathbb{Z}) \cong \mathbb{Z}$ and such that for each $i \in \mathbb{N}$ the map $\mathrm{H}^1(X_{i+1};\mathbb{Z}) \to \mathrm{H}^1(X_i;\mathbb{Z})$ is given by multiplication by $i+1$.

We cannot proceed without introducing the following somewhat technical definition.

Definition. We say an inverse system of abelian groups $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ satisfies the Mittag-Leffler condition if given any $i \in \mathbb{N}$ there exists an $n \geq i$ such that for all $s \geq n$ we have

$$\mathrm{im}(g_i \circ \cdots \circ g_{s-1}\colon D_s \to D_i) \ = \ \mathrm{im}(g_i \circ \cdots \circ g_{n-1}\colon D_n \to D_i).$$

.

Example. It is straightforward to verify that the above inverse system D_* satisfies the Mittag-Leffler condition whereas the above inverse system E_* does not satisfy the Mittag-Leffler condition.

In many situations one can ignore the precise definition of the Mittag-Leffler condition and instead one can appeal to the following lemma which in fact follows immediately from the definitions.

Lemma 111.8. Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups. If there exists an $m \in \mathbb{N}$ such that for all $i \in \mathbb{N}$ the map $g_i\colon D_{i+1} \to D_i$ is an epimorphism, then the inverse system satisfies the Mittag-Leffler condition.

Our main interest in the Mittag-Leffler condition arises from the fact that if a direct system satisfies this condition, then the pesky $\varprojlim^1$-limit vanishes.

Lemma 111.9. Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups. If this inverse system satisfies the Mittag-Leffler condition, then

$$\varprojlim^1 D_i \ = \ 0.$$

[1356] If R is a commutative ring and if $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ is an inverse system of R-modules, then $\varprojlim^1 D_i$ is also an R-module in an obvious way.

Proof. Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups that satisfies the Mittag-Leffler condition. This means that given given any $i \in \mathbb{N}$ there exists an $n(i) \geq i$ such that for all $s \geq n(i)$ we have

$$\operatorname{im}(g_i \circ \cdots \circ g_{s-1}\colon D_s \to D_i) \;=\; \operatorname{im}(g_i \circ \cdots \circ g_{n(i)-1}\colon D_{n(i)} \to D_i).$$

Without loss of generality we can assume that $n(i)$ is monotonously increasing in i. We have to show that the map

$$\begin{array}{rcl} \mu\colon \prod\limits_{i\in\mathbb{N}} D_i & \to & \prod\limits_{i\in\mathbb{N}} D_i \\ (x_i)_{i\in\mathbb{N}} & \mapsto & (x_i - g_i(x_{i+1}))_{i\in\mathbb{N}} \end{array}$$

is an epimorphism.

Given $j \geq i$ we now write $f_{ji} := g_i \circ \cdots \circ g_{j-1}\colon D_j \to D_i$. First we consider $(a_i)_{i\in\mathbb{N}} \in \prod\limits_{i\in\mathbb{N}} D_i$ with the property that for all $i \in \mathbb{N}$ we have $a_i \in \operatorname{im}(f_{n(i),i}\colon D_{n(i)} \to D_i)$. To show that $\{a_i\}_{i\in\mathbb{N}}$ lies in the image of μ it suffices to prove the following claim.

Claim 1. There exist $b_i \in \operatorname{im}(f_{n(i),i}\colon D_{n(i)} \to D_i)$ with $i \in \mathbb{N}$ such that for each i we have $a_i = b_i - g_i(b_{i+1})$.

Proof. We define the b_i inductively. We set $b_0 = a_0$. Suppose $b_0, \ldots, b_k$ are already defined with the desired properties. By our hypothesis we have $a_k \in \operatorname{im}(f_{n(k),k})$ and by our choice of b_k we have $b_k \in \operatorname{im}(f_{n(k),k})$. By the Mittag-Leffler condition and since we arranged that $n(k+1) \geq n(k)$ we have $\operatorname{im}(f_{n(k+1),k}) = \operatorname{im}(f_{n(k),k})$. Thus can we pick $c \in D_{n(k+1)}$ with $f_{n(k+1),k}(c) = a_k - b_k$. Now we put

$$b_{k+1} \;=\; -f_{n(k+1),k+1}(c).$$

Then

$$b_k - g_{k+1}(b_{k+1}) = b_k + g_{k+1}(f_{n(k+1),k+1}(c)) = b_k + \underbrace{(g_{k+1} \circ f_{n(k+1),k+1})}_{=f_{(n(k+1),k)}}(c) = b_k + (a_k - b_k) = a_k.$$

We have thus shown that $b_0, \ldots, b_{k+1}$ have the desired properties. ⊞

Now let $(b_i)_{i\in\mathbb{N}} \in \prod\limits_{i\in\mathbb{N}} D_i$ be an arbitrary element. For each $i \in \mathbb{N}$ we set

$$c_i \;=\; b_i + \sum_{j=i+1}^{n(i)} f_{j,i}(b_j).$$

Claim 2. For each $i \in \mathbb{N}$ we have $b_i - (c_i - g_i(c_{i+1})) \in \operatorname{im}(f_{n(i),i})$.

Proof. Let $i \in \mathbb{N}$. We have

$$\begin{aligned} b_i - (c_i - g_i(c_{i+1})) &= b_i - b_i - \sum_{j=i+1}^{n(i)} f_{j,i}(b_j) + g_i\Big(b_{i+1} + \sum_{j=i+2}^{n(i+1)} f_{j,i+1}(b_j)\Big) \\ &= -\sum_{j=i+1}^{n(i)} f_{j,i}(b_j) + f_{i+1,i}(b_{i+1}) + \sum_{j=i+2}^{n(i+1)} f_{j,i}(b_j) \;=\; \sum_{j=n(i)+1}^{n(i+1)} f_{j,i}(b_j). \end{aligned}$$

But by definition of $n(i)$ we know that for each $j \in \{n(i)+1, \ldots, n(i+1)\}$ we have $f_{j,i}(b_j) \in \operatorname{im}(f_{n(i),i})$. ⊞

It follows from the claim and the above discussion that $(b_i - (c_i - g_i(c_{i+1})))_{i\in\mathbb{N}}$ lies in the image of μ. Evidently $(c_i - g_i(c_{i+1}))_{i\in\mathbb{N}}$ lies in the image of μ. Since μ is a homomorphism we see that $(b_i)_{i\in\mathbb{N}}$ also lies in the image of μ. ■

We continue with the following definition.

Definition. Let R be a commutative ring and let $(X_i, f_i)_{i\in\mathbb{N}}$ and $(Y_i, g_i)_{i\in\mathbb{N}}$ be inverse systems of R-modules. A map of inverse systems from (X_i, f_i) to (Y_i, g_i) consists of a sequence of module homomorphisms $u_i\colon X_i \to Y_i$, $i \in \mathbb{N}$ such that for each i we have $g_i \circ u_i = u_{i-1} \circ f_i$.

Remark. Note that a map $u\colon (X_i, f_i) \to (Y_i, g_i)$ between two inverse systems induces a map $u_*\colon \varprojlim X_i \to \varprojlim Y_i$ and also a map $u_*\colon \varprojlim{}^1 X_i \to \varprojlim{}^1 Y_i$ in the obvious way.[1357]

Now we can formulate the following proposition.

Proposition 111.10. (Direct Limit-Cohomology Proposition) Let $(\{\mathrm{C}_i^*\}_{i\in\mathbb{N}}, \{f_i\colon \mathrm{C}_{i+1}^* \to \mathrm{C}_i^*\}_{i\in\mathbb{N}})$ be an inverse system of cochain complexes over $\mathbb{N}$. If for each $k \in \mathbb{N}_0$ the inverse system of cochain groups $\{\mathrm{C}_i^k\}_{i\in\mathbb{N}}$ satisfies the Mittag-Leffler condition, then there exists a natural[1358] short exact sequence of the form

$$0 \;\to\; \varprojlim_{i\in\mathbb{N}}{}^1 \mathrm{H}^{n-1}(\mathrm{C}_i^*) \;\to\; \mathrm{H}^n\big(\varprojlim_{i\in\mathbb{N}} \mathrm{C}_i^*\big) \;\to\; \varprojlim_{i\in\mathbb{N}} \mathrm{H}^n(\mathrm{C}_i^*) \;\to\; 0$$

where the right-hand map is the obvious map.[1359] If R is a commutative ring and if the C_i^* are cochain complexes of R-modules, then the maps in the short exact sequence are natural R-module homomorphisms.

Lemma 111.11. Given any short exact sequence

$$0 \;\to\; (X_i, f_i) \;\xrightarrow{u_i}\; (Y_i, g_i) \;\xrightarrow{v_i}\; (Z_i, h_i) \;\to\; 0$$

of inverse systems of abelian groups there exists a natural exact sequence

$$0 \to \varprojlim X_i \xrightarrow{u_*} \varprojlim Y_i \xrightarrow{v_*} \varprojlim Z_i \xrightarrow{\delta} \varprojlim{}^1 X_i \xrightarrow{u_*} \varprojlim{}^1 Y_i \xrightarrow{v_*} \varprojlim{}^1 Z_i \to 0.$$

If R is a commutative ring and if all cochain complexes and all maps are in the category of R-modules, then the maps in short exact sequence are natural R-module homomorphisms.

Proof. We consider the following commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \prod_{i\in\mathbb{N}} X_i & \xrightarrow{u} & \prod_{i\in\mathbb{N}} Y_i & \xrightarrow{v} & \prod_{i\in\mathbb{N}} Z_i & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \mu} & & \downarrow{\scriptstyle \mu} & & \downarrow{\scriptstyle \mu} & & \\
0 & \longrightarrow & \prod_{i\in\mathbb{N}} X_i & \xrightarrow{u} & \prod_{i\in\mathbb{N}} Y_i & \xrightarrow{v} & \prod_{i\in\mathbb{N}} Z_i & \longrightarrow & 0.
\end{array}$$

[1357] Whatever obvious means.

[1358] As so often it requires a few moments of pondering to figure out what "natural" is actually supposed to mean.

[1359] Here it takes a little effort to figure out what the "obvious" map actually is supposed to be. By definition an inverse limit of cochain complexes comes with cochain maps $\varprojlim \mathrm{C}_i^* \to \mathrm{C}_i^*$. Since cohomology of cochain complexes is covariant in cochain maps we get induced maps $\mathrm{H}^n(\varprojlim \mathrm{C}_i) \to \mathrm{H}^n(\mathrm{C}_i^*)$ which then, by definition of the inverse limit, give rise to a map $\mathrm{H}^n(\varprojlim \mathrm{C}_i) \to \varprojlim \mathrm{H}^n(\mathrm{C}_i^*)$.

The horizontal sequences are evidently exact. We can view the rows as chain complexes. The desired natural exact sequence now follows from theSnake Lemma that we proved in Exercise 74.9. ■

Proof of Proposition 111.10. Let $(\{\mathrm{C}_i^*\}_{i\in\mathbb{N}}, \{f_i\}_{i\in\mathbb{N}})$ be an inverse system of cochain complexes such that for each $k \in \mathbb{N}_0$ the inverse system of cochain groups $\{\mathrm{C}_i^k\}_{i\in\mathbb{N}}$ satisfies the Mittag-Leffler condition. In the following, given $m \in \mathbb{N}_0$ and $i \in \mathbb{N}$, we denote by $B_i^m = \mathrm{im}(\mathrm{C}_i^{m-1} \to \mathrm{C}_i^m)$ the image of the $(m-1)$-st coboundary map and we denote by $Z_i^m = \ker(\mathrm{C}_i^m \to \mathrm{C}_i^{m+1})$ the kernel of the m-th coboundary map. These give rise to the following two short exact sequences of inverse systems

$$\begin{array}{lccccccccc} \text{(i)} & & 0 & \to & B_i^m & \to & Z_i^m & \to & \mathrm{H}^m(\mathrm{C}_i) & \to & 0 \\ \text{(ii)} & & 0 & \to & Z_i^m & \to & C_i^m & \to & B_i^{m+1} & \to & 0. \end{array}$$

Let $m \in \mathbb{N}_0$. By our hypothesis the inverse systems $\{\mathrm{C}_i^m\}_{i\in\mathbb{N}}$ satisfy the Mittag-Leffler condition. It is straightforward to see that then the inverse system $\{B_i^m\}_{i\in\mathbb{N}}$ also satisfies the Mittag-Leffler condition. It follows from Lemma 111.9 that

$$\varprojlim{}^1 B_i^{m+1} \;=\; 0 \quad \text{and} \quad \varprojlim{}^1 C_i^m \;=\; 0.$$

(Here and throughout the proof all limits are taken over $i \in \mathbb{N}$.) Using this data we obtain from Lemma 111.11, applied to the two short exact sequences (i) and (ii) of inverse systems above, the following two exact sequences:

$$0 \to \varprojlim B_i^m \to \varprojlim Z_i^m \to \varprojlim \mathrm{H}^m(\mathrm{C}_i) \xrightarrow{\delta} \underbrace{\varprojlim{}^1 B_i^m}_{=0} \to \varprojlim{}^1 Z_i^m \to \varprojlim{}^1 \mathrm{H}^m(\mathrm{C}_i) \to 0$$

$$0 \to \varprojlim Z_i^m \to \varprojlim \mathrm{C}_i^m \to \varprojlim B_i^{m+1} \xrightarrow{\delta} \varprojlim{}^1 Z_i^m \to \underbrace{\varprojlim{}^1 \mathrm{C}_i^m}_{=0} \to \varprojlim{}^1 B_i^{m+1} \to 0.$$

From these sequence we deduce that the maps

$$\begin{array}{lcl} \text{(i)} & \varprojlim{}^1 Z_i^m \;\to\; \varprojlim{}^1 \mathrm{H}^m(\mathrm{C}_i) \\ \text{(ii)} & \varprojlim Z_i^m \;\to\; Z^m\big(\varprojlim \mathrm{C}_i\big) := \ker\big(\varprojlim \mathrm{C}_i^m \to \varprojlim B_i^{m+1}\big) \end{array}$$

are isomorphisms and that the following sequences are exact

$$\begin{array}{lccccccccc} \text{(i')} & & 0 & \to & \varprojlim B_i^m & \to & \varprojlim Z_i^m & \to & \varprojlim \mathrm{H}^m(\mathrm{C}_i) & \to & 0 \\ \text{(ii')} & & 0 & \to & \underbrace{B^m\big(\varprojlim \mathrm{C}_i\big)}_{=:\mathrm{im}(\varprojlim \mathrm{C}_i^{m-1} \to \varprojlim B_i^m)} & \to & \varprojlim B_i^m & \to & \varprojlim{}^1 Z_i^{m-1} & \to & 0. \end{array}$$

From (ii') and the isomorphism (ii) we obtain the inclusions

$$B^m\big(\varprojlim \mathrm{C}_i\big) \;\subset\; \varprojlim B_i^m \;\subset\; \varprojlim Z_i^m \;=\; Z^m\big(\varprojlim \mathrm{C}_i\big)$$

which gives rise to the short exact sequence[1360]

$$0 \to \underbrace{\frac{\varinjlim B_i^m}{B^m(\varinjlim \mathrm{C}_i)}}_{=\varinjlim {}^1\mathrm{H}^{m-1}(\mathrm{C}_i) \text{ by (ii') and (i)}} \to \underbrace{\frac{Z^m(\varinjlim \mathrm{C}_i)}{B^m(\varinjlim \mathrm{C}_i)}}_{=\mathrm{H}^m(\varinjlim \mathrm{C}_i) \text{ by def.}} \to \underbrace{\frac{\varinjlim Z_i^m}{\varinjlim B_i^m}}_{=\varinjlim \mathrm{H}^m(\mathrm{C}_i) \text{ by (i')}} \to 0.$$

■

111.4. The cohomology group of an ascending sequence of topological spaces.

The following proposition can be viewed as the analogue of the Exhaustions-H_*-Proposition 79.4 for cohomology groups.

Proposition 111.12. (Cohomology-via-Exhaustions Proposition) Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \ldots$ be a sequence of subsets such that $X = \bigcup_{i\in\mathbb{N}} X_i$ and such that one the following three conditions holds:

(1) every compact subset of X is contained in one of the X_i, or
(2) each X_i is open in X, or
(3) X is a CW-complex and each X_i is a subcomplex.

Then for any $n \in \mathbb{N}_0$ and any abelian group R there exists a natural short exact sequence

$$0 \to \varprojlim_{i\in\mathbb{N}} {}^1\mathrm{H}^{n-1}(X_i; R) \xrightarrow{\tau} \mathrm{H}^n(X; R) \to \varprojlim_{i\in\mathbb{N}} \mathrm{H}^n(X_i; R) \to 0$$

where the right-hand map is induced by the restriction maps $\mathrm{H}^n(X; R) \to \mathrm{H}^n(X_i; R)$. If R is a commutative ring, then all maps are R-module homomorphisms.

Remark. In many situations the term $\varprojlim^1 \mathrm{H}^{n-1}(X_i; R)$ will be zero. But it can be non-zero and one should view the proposition as a warning that in general it is not true that "limits commute with everything".

Proof. It follows easily from the Finiteness the CW-Complex-Finiteness Theorem 68.14 and Lemma 56.8 we only have to prove the proposition under the hypothesis (1). Therefore suppose that we are given a topological space X and subspaces $X_1 \subset X_2 \subset X_3 \subset \ldots$ with $X = \bigcup_{i\in\mathbb{N}} X_i$ and such that the following condition holds:

(1) every compact subset of X is contained in one of the X_i.

Furthermore let R be a commutative ring.

For $i \in \mathbb{N}$ we now consider the cochain complex $D_i^* := \mathrm{Hom}(\mathrm{C}_*(X_i), R)$ and for $i \in \mathbb{N}$ we denote by $f_i \colon D_{i+1}^* \to D_i^*$ the map that is induced by the inclusion $X_i \to X_{i+1}$.

Claim. For every choice of $k \in \mathbb{N}$ the inverse system of cochain groups that is given by $(\{D_i^k\}_{i\in\mathbb{N}}, \{f_i \colon D_{i+1}^k \to D_i^k\}_{i\in\mathbb{N}})$ satisfies the Mittag-Leffler condition.

Proof. Let $k \in \mathbb{N}_0$. By Lemma 111.8 it suffices to show that for every $i \in \mathbb{N}$ the map

$$D_{i+1}^k = \mathrm{Hom}(\mathrm{C}_n(X_{i+1}); R) \xrightarrow{f_i} \mathrm{Hom}(\mathrm{C}_n(X_i); R) = D_i^k$$

[1360] Here we use that a filtration $P \subset Q \subset R$ of three abelian groups induces a short exact sequence $0 \to Q/P \to R/P \to R/Q \to 0$.

is an epimorphism. Since $X_i \subset X_{i+1}$ we know that the set of singular chains in X_i is a subset of the set of singular chains in X_{i+1}. It follows from the discussion on page 2395 that the map $\mathrm{Hom}(\mathrm{C}_n(X_{i+1}); R) \to \mathrm{Hom}(\mathrm{C}_n(X_i); R)$ is indeed an epimorphism. ⊞

Let $n \in \mathbb{N}_0$. From the Direct Limit-Cohomology Proposition 111.10 we obtain the short exact sequence

$$0 \ \to \ \varprojlim{}^1 \mathrm{H}^{n-1}(D_i^*) \ \to \ \mathrm{H}^n\big(\varprojlim D_i^*\big) \ \to \ \varprojlim \mathrm{H}^n(D_i^*) \ \to \ 0$$

of R-modules. Let $i \in \mathbb{N}$. We make the following two observations:

(1) By definition we have $\mathrm{H}^k(D_i^*) = \mathrm{H}^k(X_i; R)$ for every $k \in \mathbb{N}_0$.

(2) We have natural isomorphisms

$$\varprojlim D_i^* \ \underset{\text{by definition of the } D_i}{=} \ \varprojlim \mathrm{Hom}(\mathrm{C}_*(X_i); R) \ \underset{\text{Lemma 108.3}}{=} \ \mathrm{Hom}\big(\varinjlim \mathrm{C}_*(X_i), R\big) \ \underset{\text{Lemma 79.5 and hypothesis (1)}}{=} \ \mathrm{Hom}(\mathrm{C}_*(X), R).$$

Combining all of the above we obtain our desired short exact sequence

$$0 \ \to \ \varprojlim{}^1 \mathrm{H}^{n-1}(X_i; R) \ \to \ \mathrm{H}^n(X; R) \ \to \ \varprojlim \mathrm{H}^n(X_i; R) \ \to \ 0.$$ ■

We provide a few examples for the above proposition.

Examples.

(1) As in Lemma 79.7 we consider the real line with infinitely many 2-dimensional spheres attached, i.e. we consider

$$X \ := \ (\mathbb{R} \cup S^2 \times \mathbb{Z})/\!\sim$$

where given $i \in \mathbb{Z}$ we identify $i \in \mathbb{R}$ with $((0,0,-1), i) \in S^2 \times \mathbb{Z}$. (See the figure below on the left.) Furthermore, given $k \in \mathbb{N}$ we consider the open subset

$$X_k \ := \ \big(\big(-k - \tfrac{1}{2}, k + \tfrac{1}{2}\big) \cup S^2 \times \{-k, \ldots, k\}\big)/\!\sim .$$

We leave it to the reader to verify that we can make the identifications[1361]

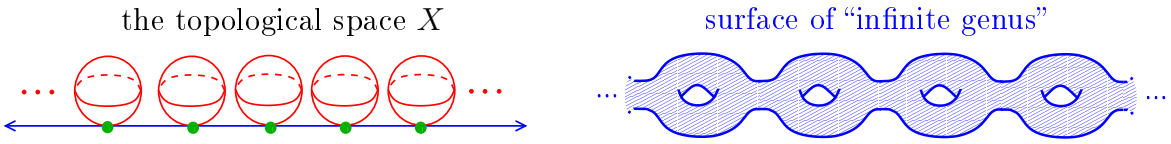
$$\mathrm{H}^n(X_k) \ = \ \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^{2k+1}, & \text{if } n = 2, \\ 0, & \text{else.} \end{cases}$$

such that for each $k \in \mathbb{N}$ the inclusion maps $X_k \to X_{k+1}$ induce the identity map on $\mathbb{Z} = \mathrm{H}^0(X_{k+1}) \to \mathrm{H}^0(X_k) = \mathbb{Z}$ and such that the inclusions induce the map

$$\begin{array}{rcl} \mathbb{Z}^{2k+3} = \mathrm{H}^2(X_{k+1}) & \to & \mathrm{H}^2(X_k) = \mathbb{Z}^{2k+1} \\ (a_1, \ldots, a_{2k+3}) & \mapsto & (a_2, \ldots, a_{2k+2}) \end{array}$$

It follows from Lemma 111.8 and the above calculations that for each $n \in \mathbb{N}_0$ the direct system of cohomology groups $\{\mathrm{H}^n(X_k)\}_{k \in \mathbb{N}}$ satisfies the Mittag-Leffler condition. We obtain that

$$\mathrm{H}^n(X) \ \underset{\substack{\text{Cohomology-via-Exhaustions} \\ \text{Proposition 111.12 and} \\ \text{Lemma 111.9}}}{=} \ \varprojlim \mathrm{H}^n(X_k) \ = \ \varprojlim \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^{2k+1}, & \text{if } n = 2, \\ 0, & \text{else} \end{cases} \ \underset{\text{see page 2468}}{=} \ \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^{\mathbb{N}}, & \text{if } n = 2, \\ 0, & \text{else.} \end{cases}$$



[1361] One possible approach to showing these statements is to use the Mayer–Vietoris Theorem 109.15 for Cohomology Groups.

Here we recall that $\mathbb{Z}^{\mathbb{N}} = \{(x_1, x_2, \dots) \mid x_i \in \mathbb{Z}\}$. Note that in Lemma 79.7 we saw that $\mathrm{H}_2(X) \cong \mathbb{Z}^{(\mathbb{N})}$. In this case we see that $\mathrm{H}_2(X) \ncong \mathrm{H}^2(X)$ since the former group is countable whereas the latter group is uncountable.[1362]

(2) We consider again the surface Σ_∞ of infinite genus that we had already encountered on page 1269 and in Lemma 80.4. (See also the figure below on the right.) Using a variation on example (1) and the proof of Lemma 56.11 one can show that

$$\mathrm{H}^n(\Sigma_\infty) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^{\mathbb{N}}, & \text{if } n = 1, \\ 0, & \text{if } n \geq 2. \end{cases}$$

We leave the task of providing full details to the valiant reader. Note that this shows that the first cohomology group is uncountable. In particular we see that the cohomology groups with $\mathbb{Z}$-coefficients of a non-compact smooth manifold do not need to be countable. This is in contrast to Proposition 96.7 where we showed that the homology groups with $\mathbb{Z}$-coefficients of a non-compact smooth manifold are always countable.

We conclude this chapter with the following variation on the Cohomology-via-Exhaustions Proposition 111.12. It can be viewed as the cohomological analogue of the Skeleton-Homology Lemma 80.1 (3).

Proposition 111.13. Let X be a CW-complex and let $n \in \mathbb{N}$. For every $k > n$ and every abelian group G the inclusion $i\colon X^k \to X$ induces an isomorphism

$$i^*\colon \mathrm{H}^n(X; G) \;\to\; \mathrm{H}^n(X^k; G).$$

Remark. We will give a very different proof of this proposition in Proposition **??**.

Proof. By the Cohomology-via-Exhaustions Proposition 111.12 there exists a natural short exact sequence

$$0 \;\to\; \varprojlim_{j\in\mathbb{N}}{}^1\mathrm{H}^{n-1}(X_j; G) \;\xrightarrow{\tau}\; \mathrm{H}^n(X; G) \;\to\; \varprojlim_{j\in\mathbb{N}} \mathrm{H}^n(X_j; G) \;\to\; 0$$

where the right-hand map is induced by the restriction maps $\mathrm{H}^n(X; G) \to \mathrm{H}^n(X_i; G)$. It follows immediately from the Indirect Limit Stabilization Lemma 111.6 and Lemma 111.8 that is suffices to prove the following claim.

Claim. For any $j \geq k > n$ the inclusion induced map $\mathrm{H}^n(X^j; G) \to \mathrm{H}^n(X^k; G)$ is an isomorphism.

Proof. It follows from the Skeleton-Homology Lemma 80.1, the Universal Coefficient Theorem 110.12 for Cohomology Groups that for every $m \geq n$ we have $\mathrm{H}^n(X^{m+1}, X^m; G) = 0$. Using the long exact sequence in cohomology of the pairs $(X^{m+1}, X^m), (X^{m+2}, X^m), \dots$

[1362] Of course we could have obtained the same observation from the Universal Coefficient Theorem 110.12 for Cohomology Groups.

one can now easily show that for any $j \geq k > n$ the inclusion induced map $\mathrm{H}^n(X^j; G) \to \mathrm{H}^n(X^k; G)$ is an isomorphism. ■

Exercises for Chapter 111.

Exercise 111.1. Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i \in I}, \{f_{ij} \colon X_i \to X_j\}_{i \leq j})$ be a direct system of abelian groups over I.

(a) Let $a_j \in X_j$ and let $a_k \in X_k$. Prove the following statement: if the images of a_j and a_k in $\varinjlim X_i$ agree, then there exists an $l \in I$ with $l \geq j$ and $l \geq k$ such that $f_{jl}(a_j) = f_{kl}(a_k) \in X_l$.

(b) Show that if all maps $f_{ij} \colon X_i \to X_j$ are isomorphisms, then for any $j \in I$ the obvious map $X_j \to \varinjlim X_i$ is an isomorphism.

Exercise 111.2. We consider the inverse systems

$$D_* \colon \ \ldots \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \ \to 0$$

and

$$E_* \colon \ \ldots \xrightarrow{\cdot 5} \mathbb{Z} \xrightarrow{\cdot 4} \mathbb{Z} \xrightarrow{3} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \ \to 0.$$

(a) Show that $\varprojlim D_* = 0$,

(b) show that $\varprojlim{}^1 D_* = 0$,

(c) show that $\varprojlim{}^1 E_* \neq 0$.

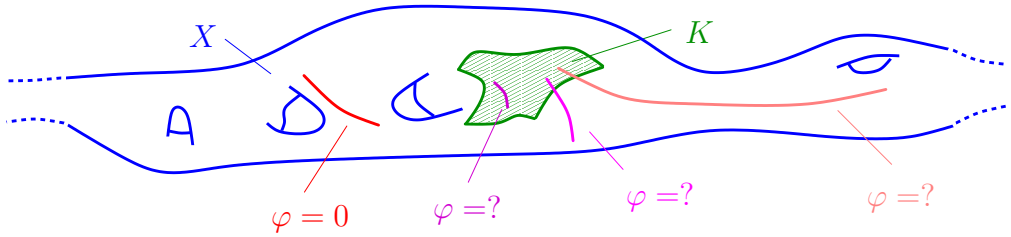
Exercise 111.3. Show that there exists a nested sequence of topological spaces X_i such that for each $i \in \mathbb{N}$ we have $\mathrm{H}^1(X_i; \mathbb{Z}) \cong \mathbb{Z}$ and such that for each $i \in \mathbb{N}$ the map $\mathrm{H}^1(X_{i+1}; \mathbb{Z}) \to \mathrm{H}^1(X_i; \mathbb{Z})$ is given by multiplication by $i + 1$.
Put differently, we want topological spaces and maps such that the inverse system

$$\mathrm{H}^1(X_4) \ \to \ \mathrm{H}^1(X_3) \ \to \ \mathrm{H}^1(X_2) \ \to \ \mathrm{H}^1(X_1)$$

is isomorphic to the inverse system E_* from Exercise 111.2.

112. Cohomology with compact support and bounded cohomology

112.1. The definition of cohomology with compact support and basic properties. In this section we introduce "cohomology with compact support", which is an interesting variation on the usual cohomology groups. Later on it will be a key tool in proving the Poincaré Duality Theorem, which is the most important result regarding homology and cohomology groups of topological manifolds.
We start out with the following definition.



Definition. Let X be a topological space and let G be an abelian group.

(1) Given a subset $A \subset X$ we say that a cochain $\varphi \in \mathrm{C}^i(X;G) = \mathrm{Hom}(\mathrm{C}_i(X), G)$ vanishes on A if $\varphi(c) = 0$ for all singular i-simplices $c\colon \Delta^i \to X$ in A, i.e. if φ vanishes on the image of $\mathrm{C}_i(A) \to \mathrm{C}_i(X)$.

(2) Given a subset $B \subset X$ we say that a cochain vanishes outside B if the cochain vanishes on $X \setminus B$.

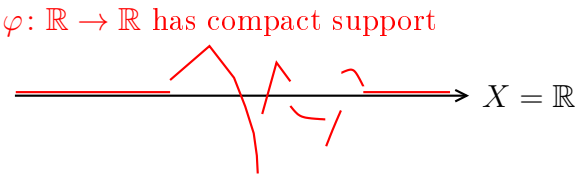
(3) We say that a cochain $\varphi \in \mathrm{C}^i(X;G) = \mathrm{Hom}(\mathrm{C}_i(X), G)$ has compact support if there exists a compact set $K \subset X$ such that φ vanishes outside of K. We denote the set of all i-cochains with compact support by $\mathrm{C}^i_{\mathrm{c}}(X;G)$.

φ is a cohomology class that vanishes outside of a compact subset K

Remark. Let X be a topological space and let G be an abelian group.

(1) Let A be a subset of X and let $n \in \mathbb{N}_0$. The inclusion $(X, \varnothing) \to (X, X \setminus A)$ induces an epimorphism $\mathrm{C}_n(X) \to \mathrm{C}_n(X, X \setminus A)$ and thus it also induces a monomorphism $\mathrm{C}^n(X, X \setminus A; G) \to \mathrm{C}^n(X;G)$. We have

$$\begin{aligned}\mathrm{im}(\mathrm{C}^n(X, X\setminus A; G) \to \mathrm{C}^n(X;G)) &= \text{all maps of the form } \mathrm{C}_n(X) \to \overbrace{\mathrm{C}_n(X, X\setminus A)}^{=\mathrm{C}_n(X)/\mathrm{C}_n(X\setminus A)} \to G \\ &= \{\varphi \in \mathrm{Hom}(\mathrm{C}_n(X), G) \,|\, \varphi \text{ vanishes on } X \setminus A\} \\ &= \{\varphi \in \mathrm{Hom}(\mathrm{C}_n(X), G) \,|\, \varphi \text{ vanishes outside } A\}.\end{aligned}$$



(2) On page 2403 we had made the identification

$$\mathrm{C}^0(X;G) \;=\; \{\text{maps from } X \text{ to } G\}.$$

With this identification we can now write

$$\mathrm{C}^0_{\mathrm{c}}(X;G) \;=\; \left\{ \text{maps } f\colon X \to G \,\middle|\, \begin{array}{c}\text{there exists a compact subset } K \\ \text{with } f|_{X\setminus K} \equiv 0\end{array} \right\}.$$

The first question that arises is whether cochains with compact support give again rise to cohomology groups. The following lemma shows in particular that this is indeed the case.

Lemma 112.1. Let X be a topological space and let G be an abelian group.

(1) A cochain $\varphi \in \mathrm{C}^i(X;G)$ has compact support if and only if there exists a compact subset K such that φ lies in the image of the map $\mathrm{C}^i(X, X \setminus K; G) \to \mathrm{C}^i(X;G)$.
(2) The set of cochains that have compact support form a subcomplex $(\mathrm{C}^*_{\mathrm{c}}(X;G);\delta)$ of the cochain complex $(\mathrm{C}^*(X;G);\delta)$.
(3) For any compact subset K of X the map $i_K\colon \mathrm{C}^*(X, X\setminus K;G) \to \mathrm{C}^*_{\mathrm{c}}(X;G)$ from (1) is a cochain map.

Proof. Let X be a topological space and let G be an abelian group. The first statement of the lemma follows immediately from the above remark.

We turn to the proof of the second statement.

Claim. Let $A, B \subset X$ be two subsets.

(a) If $\varphi \in \mathrm{C}^i(X;G)$ vanishes outside A and if $\psi \in \mathrm{C}^i(X;G)$ vanishes outside B, then for any $r, s \in \mathbb{Z}$ the linear combination $r\varphi + s\psi \in \mathrm{C}^i(X;G)$ vanishes outside the union $A \cup B$.
(b) If $\varphi \in \mathrm{C}^i(X;G)$ vanishes outside A, then $\delta\varphi \in \mathrm{C}^{i+1}(X;G)$ also vanishes outside A.

Proof. The first statement is obvious. Now we turn to the proof of the second statement. Suppose we are given a cochain $\varphi \in \mathrm{C}^i(X;G)$ that vanishes outside A. We need to show that $\delta\varphi \in \mathrm{C}^{i+1}(X;G)$ also vanishes outside A. So let c be a singular $(i+1)$-simplex in $X \setminus A$. Then

$$(\delta\varphi)(c) \;=\; \varphi(\partial c) \;=\; \sum_{j=0}^{n} (-1)^j \cdot \varphi(c \circ i_j^n) \;\underset{\uparrow}{=}\; 0.$$

image of each $c \circ i_j^n$ also lies in $X \setminus A$ and φ vanishes outside A

The second statement is now an immediate consequence of the above claim and the observation that given two compact subsets $K, L \subset X$ the union $K \cup L$ is again a compact subset of X.

Finally the last statement is an immediate consequence of the definitions. ∎

Definition. Let X be a topological space and let G be an abelian group. We define the n-th cohomology group with compact support $\mathrm{H}^n_{\mathrm{c}}(X;G)$ to be the cohomology of the cochain complex given by cochains with compact support, i.e. we define

$$\mathrm{H}^n_{\mathrm{c}}(X;G) \;:=\; \frac{\ker(\delta_n\colon \mathrm{C}^n_{\mathrm{c}}(X;G) \to \mathrm{C}^{n+1}_{\mathrm{c}}(X;G))}{\mathrm{im}(\delta_{n-1}\colon \mathrm{C}^{n-1}_{\mathrm{c}}(X;G) \to \mathrm{C}^n_{\mathrm{c}}(X;G))}.$$

Remark.

(1) If X is a compact space, then every cochain has compact support, in particular the cohomology groups with compact support are just the usual cohomology groups.

(2) Let X be a path-connected topological space. Then

$$\mathrm{H}^0_{\mathrm{c}}(X;G) \underset{\uparrow}{=} \left\{ X \xrightarrow{f} G \;\middle|\; \begin{array}{l} f \text{ is constant and there exists a} \\ \text{compact subset } K \text{ with } \varphi|_{X\setminus K} \equiv 0 \end{array} \right\} = \begin{cases} 0, & \text{if } X \text{ non-compact,} \\ G, & \text{if } X \text{ compact.} \end{cases}$$

see proof of the H^0-Proposition 108.11 and description of $\mathrm{C}^0_{\mathrm{c}}(X;G)$ on page 2478.

Example. We consider the topological space $X = \mathbb{R}$. As on page 2406 we consider the singular 0-cochain

$$\varphi_0 \colon \mathrm{C}_0(X) \;\to\; \mathbb{Z}$$

that is uniquely determined by the property that for any singular 0-simplex $x \in X$ we have

$$x \;\mapsto\; \begin{cases} 0, & \text{if } x \leq 0, \\ 1, & \text{if } x > 0. \end{cases}$$

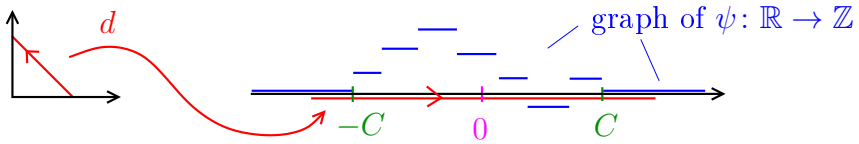
It is clear that this 0-cochain does *not have* compact support. As on page 2406 we also consider the coboundary $\gamma_0 := \delta\varphi_0 \in \mathrm{C}^1(\mathbb{R};\mathbb{Z})$. Since γ_0 is a coboundary, it is in particular a cocycle. By definition $\gamma_0 = \delta\varphi_0$ is uniquely determined by the property that for any singular 1-simplex $d\colon \Delta^1 \to \mathbb{R}$ we have

$$(\delta\varphi_0)(d) \;=\; \varphi_0(\partial d) \underset{\uparrow}{=} \varphi_0(d(0,1)) - \varphi_0(d(1,0)).$$

see page 1585

We claim that $\gamma_0 = \delta\varphi_0$ has compact support. In fact, we will now see that we can take K to be the compact set given by $K := \{0\}$. Indeed, if $d\colon \Delta^1 \to \mathbb{R}\setminus\{0\}$ is a singular 1-simplex, then it follows from the fact that Δ^1 is homeomorphic to the interval $[0,1]$ and the intermediate value theorem that either $d(0,1)$ and $d(1,0)$ both lie to the left of 0 or both lie to the right of 0. In both cases we obtain from the above formula that $\gamma_0(d) = (\delta\varphi_0)(d) = 0$. Thus we see that $\gamma_0 = \delta\varphi_0$ defines an element in $\mathrm{H}^1_{\mathrm{c}}(\mathbb{R})$.

Now we claim that $[\gamma_0] \in \mathrm{H}^1_{\mathrm{c}}(\mathbb{R};\mathbb{Z})$ is non-zero. This means that we have to show that there is no $\psi \in \mathrm{C}^0_{\mathrm{c}}(\mathbb{R};\mathbb{Z})$ with $\delta\psi = \gamma_0$. So let $\psi \in \mathrm{C}^0_{\mathrm{c}}(\mathbb{R};\mathbb{Z})$. Following the discussion on page 2478 we view ψ as a function $\mathbb{R} \to \mathbb{Z}$ which is zero outside of a compact subset of $\mathbb{R}$. This implies that there exists a $C \geq 0$ such that $\psi(x) = 0$ for all $x \notin [-C, C]$. Now we consider the singular 1-chain $d\colon \Delta^1 \to \mathbb{R}$ that is given by $d(1-t,t) = -2C + 4C \cdot t$ with $t \in [0,1]$. (See the figure below for an illustration.) Then we have



$$\gamma_0(d) \;=\; (\delta\varphi_0)(d) \;=\; \varphi_0(d(0,1)) - \varphi_0(d(1,0)) \;=\; \varphi_0(-2C) - \varphi_0(2C) \;=\; 0 - 1 \;=\; -1$$

but on the other hand we have

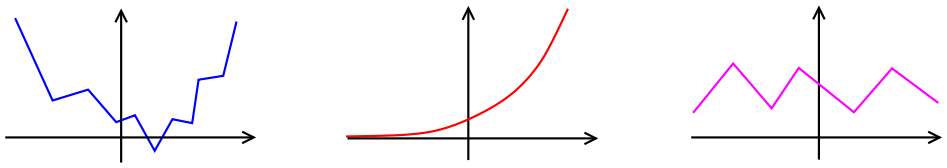
$$(\delta\psi)(d) \;=\; \psi(d(0,1)) - \psi(d(1,0)) \;=\; \psi(-2C) - \psi(2C) \underset{\uparrow}{=} 0 - 0 \;=\; 0.$$

since ψ is zero outside $[-C, C]$

This concludes the proof that $\gamma_0 = \delta\varphi_0$ is non-trivial in $\mathrm{H}^1_{\mathrm{c}}(\mathbb{R};\mathbb{Z})$.

The following lemma is an almost immediate consequence of Lemma 112.1 (1).

Lemma 112.2. Let X be a topological space and let G be an abelian group. Given any $\varphi \in \mathrm{H}^i_{\mathrm{c}}(X;G)$ there exists a compact subset K such that φ lies in the image of the map $\mathrm{H}^i(X, X \setminus K; G) \to \mathrm{H}^i_{\mathrm{c}}(X;G)$.



Proof. Let $[\varphi] \in \mathrm{H}^i_{\mathrm{c}}(X;G)$. By Lemma 112.1 (1) there exists a compact subset K such that φ lies in the image of the map $\mathrm{C}^i(X, X\setminus K; G) \to \mathrm{C}^i_{\mathrm{c}}(X;G)$. Since $\mathrm{C}^*(X, X\setminus K;G)$ can be viewed as a subcomplex of $\mathrm{C}^*_{\mathrm{c}}(X;G)$ we see that φ is also a cocycle in $\mathrm{C}^*(X, X \setminus K;G)$, in particular φ lies in the image of the map $\mathrm{H}^i(X, X \setminus K;G) \to \mathrm{H}^i_{\mathrm{c}}(X;G)$. ■

We conclude this section with the discussion of induced maps on cohomology groups with compact support.

Let $f\colon X \to Y$ be a map between topological spaces and let G be an abelian group. We saw that f induces a map $f^*\colon \mathrm{C}^*(Y;G) \to \mathrm{C}^*(X;G)$. But in general this map does *not* restrict to a map $f^*\colon \mathrm{C}^*_{\mathrm{c}}(Y;G) \to \mathrm{C}^*_{\mathrm{c}}(X;G)$. For example, if $f\colon \mathbb{R} \to \{P\}$ is the map that sends every point in $\mathbb{R}$ to the point P and if $\varphi\colon \mathrm{C}_0(\{P\}) \to \mathbb{Z}$ is the map given by $P \mapsto 1$, then $f^*\varphi\colon \mathrm{C}_0(\mathbb{R}) \to \mathbb{Z}$ corresponds to the map that takes the value 1 on all of $\mathbb{R}$, in particular it does not have compact support.

A moment of reflection shows that if we want to get induced maps on cohomology groups with compact support, we have to restrict ourselves to proper maps. For the reader's convenience we recall the definition from page 180.

Definition. A map $f\colon X \to Y$ between topological spaces is called proper if the preimage of every compact subset of Y is a compact subset of X.

Lemma 112.3. Let G be an abelian group.

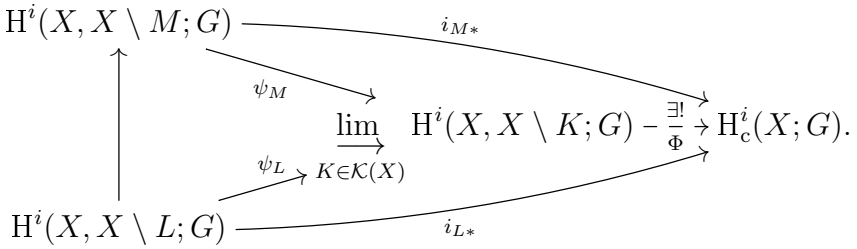
(1) Let $f\colon X \to Y$ be a map between topological spaces. If f is a proper map, then the cochain map $f^*\colon \mathrm{C}^*(Y;G) \to \mathrm{C}^*(X;G)$ restricts to a cochain map
$$f^*\colon \mathrm{C}^*_{\mathrm{c}}(Y;G) \to \mathrm{C}^*_{\mathrm{c}}(X;G).$$
In particular f^* induces a well-defined homomorphism
$$\mathrm{H}^*_{\mathrm{c}}(Y;G) \to \mathrm{H}^*_{\mathrm{c}}(X;G).$$

(2) The maps $X \mapsto \mathrm{H}^n_{\mathrm{c}}(X;G)$ and $f \mapsto f^*$ define a contravariant functor
$$\text{category } \mathit{TopPropMap} \text{ where objects are topological spaces and morphisms are proper maps} \to \text{category } \mathit{AbGroup} \text{ of abelian groups.}$$

(3) Homeomorphic topological spaces have isomorphic cohomology groups with compact support.

Proof. Let $f\colon X \to Y$ be a proper map and let G be an abelian group. Let $\varphi\colon \mathrm{C}_n(Y) \to G$ be a cocycle with compact support. We pick a compact subset K such that φ vanishes on $Y \setminus K$. Then $f^*\varphi$ vanishes on $f^{-1}(Y \setminus K) = X \setminus f^{-1}(K)$, i.e. $f^*\varphi$ vanishes outside of the

subset $f^{-1}(K)$. But $f^{-1}(K)$ is compact since f is proper. This concludes the proof of the first statement. The second statement and the third statement are obvious. ■



112.2. **Cohomology with compact support and direct limits.** Given a topological space X we consider the set $\mathcal{K}(X)$ of all compact subsets of X. The set $\mathcal{K}(X)$ together with the relation "$\subset$" defined by inclusion is a directed set since the union of two compact subsets is again compact. Furthermore, given any two compact subsets $K \subset L$ and any $i \in \mathbb{N}_0$ we get induced maps[1363]

$$\mathrm{H}^i(X, X \setminus K; G) \;\to\; \mathrm{H}^i(X, X \setminus L; G).$$

Since cohomology groups are contravariantly functorial we see that these cohomology groups form a *direct* system over the directed set $(\mathcal{K}(X), \subset)$ and we can form the direct limit

$$\varinjlim_{K \in \mathcal{K}(X)} \mathrm{H}^i(X, X \setminus K; G).$$

Recall that given any compact subset $K \subset X$ we have by Lemma 112.1 (3) a natural map $i_{K*} \colon \mathrm{H}^i(X, X \setminus K; G) \to \mathrm{H}^i_{\mathrm{c}}(X; G)$. Given compact subsets $L \subset M$ these maps give rise to the following commutative diagram:

Since this diagram commutes for all compact subsets $L \subset M$ we get the induced dotted arrow by the universal property of the direct limit.
The following proposition says that the above dotted arrow is in fact an isomorphism. This gives in particular an often convenient reformulation of the concept of cohomology with compact support.

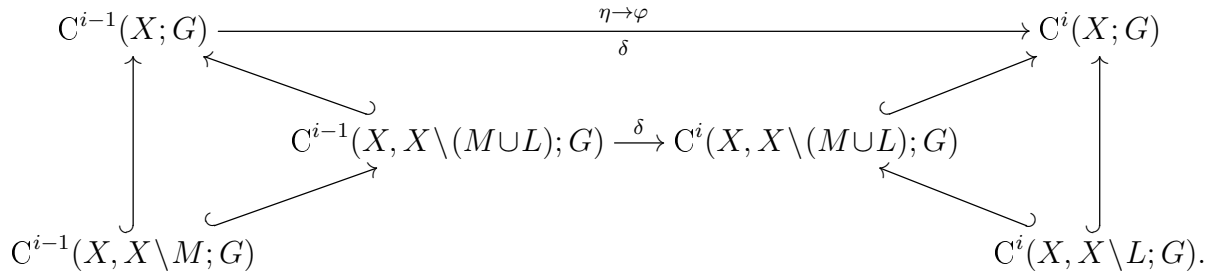
Proposition 112.4. ($\mathrm{H}^n_{\mathrm{c}}$-via-Direct Limits Proposition) Let X be a topological space and let G be an abelian group. Then the above map

$$\Phi \colon \varinjlim_{K \in \mathcal{K}(X)} \mathrm{H}^i(X, X \setminus K; G) \to \mathrm{H}^i_{\mathrm{c}}(X; G)$$

defines a natural isomorphism.[1364]

Proof. We need to show that the map Φ in the proposition is a bijection.

We first show that Φ is surjective. So let $\varphi \in \mathrm{H}^i_{\mathrm{c}}(X; G)$. By Lemma 112.2 there exists a compact subset L such that φ lies in the image of $\mathrm{H}^i(X, X \setminus L; G) \to \mathrm{H}^i(X; G)$. It



[1363]The most confusing part about cohomology is to figure out which way the maps go. In this case $K \subset L$ implies $X \setminus L \subset X \setminus K$ which means that we have a map of pairs $(X, X \setminus L) \to (X, X \setminus K)$ given by inclusion, which by the discussion on page 2408 implies that we do indeed get an induced map $\mathrm{H}^i(X, X \setminus K; G) \to \mathrm{H}^i(X, X \setminus L; G)$.

[1364]Here the term "natural" refers to the fact that both sides define a contravariant functor from the category where objects are topological spaces and morphisms are proper maps to the category of abelian groups.

follows immediately from the above commutative diagram that φ also lies in the image of $\Phi\colon \varinjlim \mathrm{H}^i(X, X \setminus K; G) \to \mathrm{H}^i_{\mathrm{c}}(X; G)$.

Now we show that the map Φ is injective. In the subsequent discussion, given a subset A of X, we identify the image of the monomorphism $\mathrm{C}^j(X, A; G) \to \mathrm{C}^j(X; G)$ with $\mathrm{C}^j(X, A; G)$, i.e. we view each $\mathrm{C}^j(X, A)$ as a subgroup of $\mathrm{C}^j(X)$.

Now suppose we are given an element c in the kernel of Φ. By Lemma 111.2 (1) we know that the element c lies in the image of some $\mathrm{H}^i(X, X \setminus L; G)$. We pick a representative $\varphi \in \mathrm{C}^i(X, X \setminus L; G)$. Since φ represents the zero class in $\mathrm{H}^i_{\mathrm{c}}(X; G)$ there exists a compactly supported $(i-1)$-cocycle η with $\delta\eta = \varphi$. We pick a compact subset M of X such that η vanishes on $X \setminus M$, i.e. according to the above notation and the discussion on page 2478 we have $\eta \in \mathrm{C}^{i-1}(X, X \setminus M)$. We consider the following commutative diagram:

It follows immediately from the diagram that in $\mathrm{C}^i(X, X \setminus (M \cup L); G)$ we have $\delta\eta = \varphi$, which shows that $[\varphi]$ represents the zero class in $\mathrm{H}^i(X, X \setminus (M \cup L); G)$. It follows from Lemma 111.2 (2) or alternatively from the commutative diagram from page 2482 that $\psi_L([\varphi]) = c$ is zero. ∎

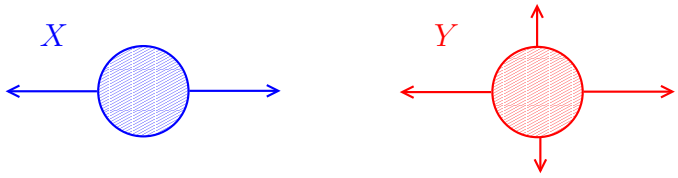
Example. Now we turn to a key example, namely for each $k \in \mathbb{N}_0$ we consider the cohomology with compact support $\mathrm{H}^k_{\mathrm{c}}(\mathbb{R}^n; \mathbb{Z})$ of $\mathbb{R}^n$. We have

$$\begin{array}{ccccc}
 & & & & \vdots \\
 & & & & \uparrow \\
 & \text{Proposition 112.4} & & \text{Limit-over-Subset Lemma 111.3} & \mathrm{H}^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_2(0); \mathbb{Z}) \\
 & \downarrow & & \downarrow & \uparrow \\
\mathrm{H}^k_{\mathrm{c}}(\mathbb{R}^n; \mathbb{Z}) & = & \varinjlim_{K \in \mathcal{K}(\mathbb{R}^n)} \mathrm{H}^k(\mathbb{R}^n, \mathbb{R}^n \setminus K; \mathbb{Z}) & = & \varinjlim_{s \in \mathbb{N}} \mathrm{H}^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_1(0); \mathbb{Z}) \\
 & & & & \uparrow \\
 & & & & \mathrm{H}^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_0(0); \mathbb{Z}) \\
 & \cong & \mathrm{H}^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_0(0); \mathbb{Z}) & \cong & \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases} \\
 & \uparrow & & \uparrow & \\
 & \text{by Corollary 74.16 (2) all vertical maps in the direct system are isomorphisms, hence we can apply Lemma 111.2} & & \text{same argument as in the proof of Lemma 105.4} &
\end{array}$$

We draw three interesting conclusions from this example:

(1) This example shows that cohomology with compact support can be used to show that the topological spaces $\mathbb{R}^n$ and $\mathbb{R}^m$ are not homeomorphic for $n \neq m$.

(2) The example also shows that cohomology with compact support, in contrast to basically all other invariants we have studied so far, is not the same for homotopy equivalent topological spaces.



(3) Finally we consider the case $n = 1$ in more detail. We consider again the singular 1-cochain $\gamma_0 := \delta\varphi_0$ from page 2406. On pages 2413 and 2480 we saw that γ_0 defines

an element in each $\mathrm{H}^1(\mathbb{R}, \mathbb{R} \setminus [-s,s]; \mathbb{Z})$ and an element in $\mathrm{H}^1_{\mathrm{c}}(\mathbb{R}; \mathbb{Z})$. Furthermore on page 2413 we saw that for each $s \in N$ the class $[\gamma_0] \in \mathrm{H}^1(\mathbb{R}, \mathbb{R} \setminus [-s,s]; \mathbb{Z})$ is a generator. The above argument now implies that $[\gamma_0] \in \mathrm{H}^1_{\mathrm{c}}(\mathbb{R}; \mathbb{Z})$ is also a generator.

Example. In Exercise 112.2 we will use cohomology with compact support to show that the topological spaces

$$X \;:=\; \overline{B}_1(0) \cup x\text{-axis} \quad \text{and} \quad Y \;:=\; \overline{B}_1(0) \cup x\text{-axis} \cup y\text{-axis}$$

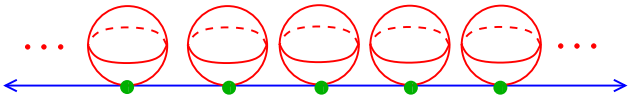
that are illustrated in the figure below are not homeomorphic.

In the previous examples cohomology with compact support turns out to be "bigger" than ordinary cohomology. But there are also examples "in the other direction":

Example. We consider again the topological space

$$X \;:=\; (\mathbb{R} \cup S^2 \times \mathbb{Z})/\!\sim$$

where given $i \in \mathbb{Z}$ we identify $i \in \mathbb{Z} \subset \mathbb{R}$ with $((0,0,-1), i) \in S^2 \times \mathbb{Z}$. In Exercise 112.6 we saw that



$$\mathrm{H}^2_{\mathrm{c}}(X) \;\cong\; \mathbb{Z}^{(\mathbb{N})},$$

in particular $\mathrm{H}^2_{\mathrm{c}}(X)$ is countable, whereas on page 2475 we saw that

$$\mathrm{H}^2(X) \;\cong\; \mathbb{Z}^{\mathbb{N}}$$

is uncountable.

the topological space X

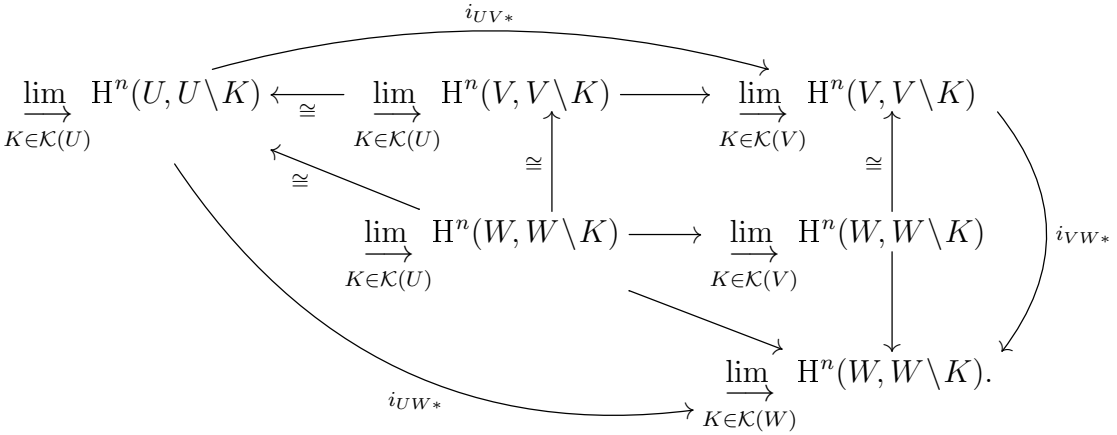
$\mathrm{H}^2(X) \cong \mathbb{Z}^{\mathbb{N}}$ but $\mathrm{H}^2_{\mathrm{c}}(X) \cong \mathbb{Z}^{(\mathbb{N})}$

In the following we will see the rather surprising fact that under fairly mild hypotheses an inclusion $U \to V$ of topological spaces induces for every $n \in \mathbb{N}_0$ a map $\mathrm{H}^n_{\mathrm{c}}(U) \to \mathrm{H}^n_{\mathrm{c}}(V)$ which "goes the same way".

Definition. Recall that given a topological space X we denote by $\mathcal{K}(X)$ the set of all compact subsets of X. Suppose U is an open subset of a topological space V and suppose that V is Hausdorff. We denote by $i_{UV*} = i_* \colon \mathrm{H}^n_{\mathrm{c}}(U) \to \mathrm{H}^n_{\mathrm{c}}(V)$ the composition of the following maps

$$\mathrm{H}^n_{\mathrm{c}}(U) \;\overset{\substack{\mathrm{H}^n_{\mathrm{c}}\text{-via-Direct Limits Proposition 112.4}\\ \downarrow}}{=}\; \varinjlim_{K \in \mathcal{K}(U)} \mathrm{H}^n(U, U \setminus K) \;\overset{\cong}{\leftarrow}\; \varinjlim_{K \in \mathcal{K}(U)} \mathrm{H}^n(V, V \setminus K) \;\to\; \varinjlim_{K \in \mathcal{K}(V)} \mathrm{H}^n(V, V \setminus K) \;\overset{\substack{\mathrm{H}^n_{\mathrm{c}}\text{-via-Direct Limits Proposition 112.4}\\ \downarrow}}{=}\; \mathrm{H}^n_{\mathrm{c}}(V).$$

by the Excision Theorem 74.18 (2) the map $\mathrm{H}^n(V, V \setminus K) \to \mathrm{H}^n(U, U \setminus K)$ is an isomorphism for every compact subset K of U



given by the Limit-over-Subset Lemma 111.3 (1) and fact that by the Compact Image Lemma 2.13 we have $\mathcal{K}(U) \subset \mathcal{K}(V)$

Note that, confusingly, the induced map on cohomology with compact support "goes the same direction" as the inclusion map $i\colon U \to V$.

Lemma 112.5. Given a topological space X that is Hausdorff the above construction defines for each $n \in \mathbb{N}_0$ a *covariant* functor

$$\begin{array}{c}\text{category where the objects are open subsets}\\ \text{of } X \text{ and where the morphisms are inclusions}\end{array} \to \begin{array}{c}\text{category of}\\ \text{abelian groups.}\end{array}$$

Proof. Let X be a topological space that is Hausdorff and let $U \subset V \subset W$ be open subsets. Let $n \in \mathbb{N}_0$. We have to show that $i_{UW*} = i_{VW*} \circ i_{UV*}\colon \mathrm{H}^n_{\mathrm{c}}(U) \to \mathrm{H}^n_{\mathrm{c}}(W)$. We consider the following diagram:

It follows from the explicit description of the direct limits in the Direct Limit Existence Proposition 111.1 and the uniqueness statement in the universal property of the direct limits that the two smaller triangles and the rectangle commute. Hence the diagram commutes and we get the desired statement. ■

We conclude this section with the following proposition.

Proposition 112.6. (Exhaustion-$\mathrm{H}^*_{\mathrm{c}}$-Proposition) Let X be a topological space that is Hausdorff. Let $X_i, i \in \mathbb{N}$ be a sequence of subsets such that the following holds:

(1) the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$,
(2) each X_i is open in X,
(3) and $X = \bigcup_{i\in\mathbb{N}} X_i$.

Then for any $n \in \mathbb{N}_0$ the above inclusion induced maps $\mathrm{H}^n_{\mathrm{c}}(X_i) \to \mathrm{H}^n_{\mathrm{c}}(X)$ induce an isomorphism

$$\varinjlim \underbrace{\mathrm{H}^n_{\mathrm{c}}(X_i)}_{\uparrow} \xrightarrow{\cong} \mathrm{H}^n_{\mathrm{c}}(X).$$

by Lemma 112.5 this is a direct system with the above inclusion induced maps

Proof. Using the $\mathrm{H}^n_{\mathrm{c}}$-via-Direct Limits Proposition 112.4 we see that we have to show that the map

$$\Phi\colon \varinjlim_{i\in\mathbb{N}} \varinjlim_{K\in\mathcal{K}(X_i)} \mathrm{H}^n(X_i, X_i \setminus K) \xrightarrow{\cong} \varinjlim_{K\in\mathcal{K}(X)} \mathrm{H}^n(X, X \setminus K)$$

is an isomorphism. We need to show that Φ is injective and surjective. The key to the proof of these two statements are the following observations:

(a) it follows from (1) and (2), together with Lemma 2.12, that every compact subset L of X is already contained in some X_i,
(b) it follows from the Excision Theorem 74.18 (2) that for each compact subset $L \subset X_i$ we get an inclusion induced isomorphism $\mathrm{H}^n(X, X \setminus L) \to \mathrm{H}^n(X_i, X_i \setminus L)$.

Now we prove that Φ is surjective, the proof that Φ is injective is fairly similar and we leave that part of the proof to the reader.

So let c be an element of the limit on the right-hand side. By Lemma 111.2 there exists a compact subset L of X and some $\varphi \in \mathrm{H}^n(X, X \setminus L)$ such that c is the image of φ under the map $\mathrm{H}^n(X, X \setminus L) \to \varinjlim \mathrm{H}^n(X, X \setminus K)$. By (a) there exists an $i \in \mathbb{N}$ with $L \subset X_i$. We consider the following commutative diagram

$$\begin{array}{ccc} \varinjlim_{i \in \mathbb{N}} \varinjlim_{K \in \mathcal{K}(X_i)} \mathrm{H}^n(X_i, X_i \setminus K) & \xrightarrow{\Phi} & \varinjlim_{K \in \mathcal{K}(X)} \mathrm{H}^n(X, X \setminus K) \\ \uparrow \beta & & \uparrow \\ \mathrm{H}^n(X_i, X_i \setminus L) & \xleftarrow[\cong]{\alpha} & \mathrm{H}^n(X, X \setminus L). \end{array}$$

The bottom horizontal map is an isomorphism by (b). Since the diagram is commutative we now see that $\Phi(\beta(\alpha(\varphi))) = c$. ∎

112.3. **Bounded cohomology** (∗). We had just seen that with a modest modification of the original definition of cohomology we obtain a new invariant which for non-compact spaces behaves quite differently from the usual cohomology groups.
In this section we will introduce another variation on cohomology, namely bounded cohomology. We will not make use of it later on, but it does play an important role in topology. A much more detail discussion of bounded cohomology is for example provided in [**Löh2010**].

Definition. Let X be a topological space.

(1) Let $C \in \mathbb{R}$. We say that a cochain $\rho \in \mathrm{C}_n(X;\mathbb{R}) = \mathrm{Hom}(\mathrm{C}_n(X), \mathbb{R})$ is C-bounded if for all singular n-simplices $\sigma\colon \Delta^n \to X$ we have $|\rho(\sigma)| \leq C$.
(2) We say that a cochain $\rho \in \mathrm{C}_n(X;\mathbb{R}) = \mathrm{Hom}(\mathrm{C}_n(X), \mathbb{R})$ is bounded if it is C-bounded for some $C \in \mathbb{R}$.
(3) Given $i \in \mathbb{N}_0$ we write

$$\mathrm{C}^n_{\mathrm{b}}(X;\mathbb{R}) \;:=\; \{\text{all bounded cochains in } \mathrm{C}^n(X;\mathbb{R})\}.$$

Examples.

(1) Let X be a topological space. The 0-cochain that assigns to each point $x \in X$ the same value $c \in \mathbb{R}$ is bounded.
(2) The singular 1-cochain $\theta_{\mathbb{R}} \in \mathrm{C}^1;\mathbb{R})$ defined on page 2404 is *not* bounded. Indeed, given $n \in \mathbb{N}$ we denote by $\mu_n\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $(1-t, t) \mapsto \exp(2\pi \mathrm{i} n t)$. It follows easily from the definition of $\theta_{\mathbb{R}}$ that $\theta_{\mathbb{R}}(\mu) = n$.

Lemma 112.7. Let X be a topological space. The bounded cochains $\mathrm{C}_\mathrm{b}^*(X)$ form a subcomplex of the cochain complex $(\mathrm{C}^*(X), \delta)$.

Proof. Suppose that $\rho \in \mathrm{C}^n(X;\mathbb{R})$ is a cochain that is C-bounded. For any $\varphi\colon \Delta^{n+1} \to X$ we obtain that

$$|(\delta\rho)(\varphi)| \;=\; |\rho(\partial\varphi)| \;\underset{\uparrow}{=}\; \left|\sum_{j=0}^{n+1}(-1)^j \cdot \rho(\varphi \circ i_j^{n+1})\right| \;\underset{\uparrow}{\leq}\; \sum_{j=0}^{n+1}|\rho(\varphi \circ i_j^{n+1})| \;\underset{\uparrow}{\leq}\; (n+2)\cdot C.$$

definition of ∂ and linearity of ρ — triangle inequality — since ρ is C-bounded

This shows that $\delta\rho$ is $C \cdot (n+2)$-bounded, in particular it is bounded. This shows that bounded cochains $\mathrm{C}_\mathrm{b}^*(X)$ form a subcomplex of the cochain complex $(\mathrm{C}^*(X), \delta)$. ■

This lemma leads us straight to the following definition.

Definition. Let X be a topological space and let $n \in \mathbb{N}_0$. The *n-th bounded cohomology group of X* is defined as

$$\mathrm{H}_\mathrm{b}^n(X;\mathbb{R}) \;:=\; \frac{\ker(\delta_n\colon \mathrm{C}_\mathrm{b}^n(X;\mathbb{R}) \to \mathrm{C}_\mathrm{b}^{n+1}(X;\mathbb{R}))}{\mathrm{im}(\delta_{n-1}\colon \mathrm{C}_\mathrm{b}^{n-1}(X;\mathbb{R}) \to \mathrm{C}_\mathrm{b}^n(X;\mathbb{R}))}.$$

Examples.

(1) The proof of the H^0-Proposition 108.11 can be used, without any changes, to show that 0-th bounded cohomology of a path-connected topological space agrees with 0-th cohomology with real coefficients.[1365]

(2) Every cochain on a topological space with finitely many points is bounded. Thus it follows from the Single Point-Cohomology Lemma 108.12 that for a topological space $\{x_0\}$ consisting of a single point x_0 we have

$$\mathrm{H}_\mathrm{b}^n(\{x_0\};\mathbb{R}) \;=\; \mathrm{H}^n(\{x_0\};\mathbb{R}) \;=\; \begin{cases} 0, & \text{if } n \geq 1, \\ \mathbb{R}, & \text{if } n = 0. \end{cases}$$

Proposition 112.8.

(1) Let $f\colon X$ *to* Y be a map between two topological spaces. The induced map $f^*\colon \mathrm{C}^*(Y;\mathbb{R}) \to \mathrm{C}^*(X;\mathbb{R})$ on singular cochains restricts to a cochain map $f^*\colon \mathrm{C}_\mathrm{b}^*(Y;\mathbb{R}) \to \mathrm{C}_\mathrm{b}^*(X;\mathbb{R})$. In particular the map f^* induces a map

$$f^*\colon \mathrm{H}_\mathrm{b}^n(Y;\mathbb{R}) \;\to\; \mathrm{H}_\mathrm{b}^n(X;\mathbb{R}).$$

(2) For each $n \in \mathbb{N}_0$ the maps $X \mapsto \mathrm{H}_\mathrm{b}^n(X;\mathbb{R})$ and $f \mapsto f^*$ define a contravariant functor from the category of topological spaces to the category of real vector spaces.

(3) Homotopic maps induce the same maps on bounded cohomology.

(4) If $f\colon X \to Y$ is a homotopy equivalence, then the induced map

$$f^*\colon \mathrm{H}_\mathrm{b}^n(Y;\mathbb{R}) \;\xrightarrow{\cong}\; \mathrm{H}_\mathrm{b}^n(X;\mathbb{R})$$

is in fact an isomorphism.

[1365] Is this statement also true for topological spaces that are not path-connected?

Proof.

(1) It is obvious that the pullback of a bounded cohomology class is again bounded. The first statement is an immediate consequence of this observation.

(2) This statement is obvious.

(3) Let $f, g\colon X \to Y$ be two maps between topological spaces X and Y. Furthermore let $F\colon X \times [0,1] \to Y$ be a homotopy between the maps f and g. As on page 1608 we define

$$P_n\colon \mathrm{C}_n(X) \;\to\; \mathrm{C}_{n+1}(Y)$$

to be the map that is given by

$$(\sigma\colon \Delta^n \to X) \;\mapsto\; \sum_{j=0}^{n} (-1)^j \cdot F \circ (\sigma \times \mathrm{id}_{[0,1]}) \circ \underbrace{[v_0, \dots, v_j, w_j, \dots, w_n]}_{\Delta^{n+1} \to \Delta^n \times [0,1]}.$$

In the proof of the Homotopic Maps-and-Homology Proposition 73.6 we saw that the maps P_n define a chain homotopy between f_* and g_*. It follows from this explicit description of P_n that for any cochain $\varphi \in \mathrm{C}^{n+1}(Y;\mathbb{R})$ that is C-bounded the chain $P^*\varphi \in \mathrm{C}^n(X;\mathbb{R})$ is $(n+1)\cdot C$-bounded, the map $P^*\colon \mathrm{C}^{n+1}(Y;\mathbb{R}) \to \mathrm{C}^n(X;\mathbb{R})$ restricts to a map $\mathrm{C}_\mathrm{b}^{n+1}(Y;\mathbb{R}) \to \mathrm{C}_\mathrm{b}^n(X;\mathbb{R})$. As in the proof of the Dual Cochain Map Lemma 108.8 (3) one sees easily that the maps P^* form a cochain homotopy between $f^*, g^*\colon \mathrm{C}_\mathrm{b}^*(Y;\mathbb{R}) \to \mathrm{C}_\mathrm{b}^*(X;\mathbb{R})$. The third statement now follows from the Cochain Map Lemma 108.5.

(4) This statement follows immediately from (2) and (3). ∎

So far it seems like bounded cohomology might be quite similar to usual cohomology with real coefficients. It turns out that this guess is dramatically misguided.
For example the following theorem was proved by Mikhail Gromov [**Grom1983**, p. 40], see also [**Iv1987**, Theorem 4.3].[1366]

Theorem 112.9. Let $f\colon X \to Y$ be a map between two connected CW-complexes. If the induced map $f_*\colon \pi_1(X) \to \pi_1(Y)$ is an epimorphism of fundamental groups such that the kernel $\ker(f_*\colon \pi_1(X) \to \pi_1(Y))$ is an amenable group, then for any $n \in \mathbb{N}_0$ the induced map

$$f^*\colon \mathrm{H}_\mathrm{b}^n(Y;\mathbb{R}) \;\xrightarrow{\cong}\; \mathrm{H}_\mathrm{b}^n(X;\mathbb{R})$$

is an isomorphism.

Remark. In the formulation of Theorem 112.9 we used the notion of an "amenable group". We will not give the definition of an "amenable group", instead we refer to [**Pie1984**] or [**CSC2010**, Section 4] for the definition. What matters to us are the following two facts:

(1) Groups that admit a finite index subgroup that is solvable are amenable, see [**Pie1984**, Propositions 13.3 and 13.4]. In particular finite groups and solvable groups are amenable.

(2) Groups that contain a free group on two generators are not amenable, see [**Pie1984**, Proposition 14.1].

Now we can formulate the following rather surprising corollary.

[1366] Mikhail Gromov (*1943) is a Russian-French mathematician who is easily one of the most influential geometers alive. He won the Abel prize in 2009.

Corollary 112.10. Let X be a connected CW-complex such that $\pi_1(X)$ is amenable, e.g. such that $\pi_1(X)$ is solvable. Then $\mathrm{H}_{\mathrm{b}}^n(X;\mathbb{R}) = 0$ for any $n \geq 1$.

Example. It follows from Corollary 112.10 that the higher bounded cohomology groups of the n-tori $(S^1)^n$, the spheres S^n and lens spaces all vanish. In particular this new invariant is also not useful in our attempt to answer Question 48.7.

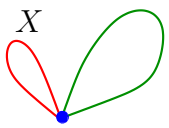
Proof. We consider the map $f\colon X \to \{x_0\}$ that is given by sending every point in X to the point x_0. Then for any $n \geq 1$ we have

$$\begin{array}{ccccc} \mathrm{H}_{\mathrm{b}}^n(X;\mathbb{R}) & \xrightarrow[\cong]{f^*} & \mathrm{H}_{\mathrm{b}}^n(\{x_0\};\mathbb{R}) & = & 0. \\ \uparrow & & \uparrow & & \\ \text{by Theorem 112.9 since} & & \text{see above example} & & \\ \ker(f_*) = \pi_1(X) \text{ is amenable} & & & & \end{array}$$

We have thus proved the desired result. ∎

The following vanishing result is in fact fairly easy to show, see e.g. [**Frig2017**, Chapter 2].

Lemma 112.11. For any CW-complex X we have $\mathrm{H}_{\mathrm{b}}^1(X;\mathbb{R}) = 0$.



On the other hand, if the fundamental group is not amenable, then we also see some totally unexpected behavior as is shown in the following proposition.

Proposition 112.12. Let X be the wedge of two circles. Then $\mathrm{H}_{\mathrm{b}}^2(X;\mathbb{R})$ and $\mathrm{H}_{\mathrm{b}}^3(X;\mathbb{R})$ are vector spaces of uncountable dimension.

Proof. The statement regarding $\mathrm{H}_{\mathrm{b}}^2(X;\mathbb{R})$ is proved in [**EF1997**]. An alternative fairly straightforward proof, using quasi-morphisms as introduced on page 1166, is given in [**Roll2009**, Corollary 2.3]. Furthermore the statement regarding $\mathrm{H}_{\mathrm{b}}^3(X;\mathbb{R})$ is proved in [**So1997**, Theorem 3]. ∎

Somewhat shockingly the following question is still open:

Question 112.13. Let X be the wedge of two circles. What are the bounded cohomology groups $\mathrm{H}_{\mathrm{b}}^k(X;\mathbb{R}) \neq 0$ for $k \geq 4$? Is any of the groups non-zero? Are all of them non-zero? Are all of them of uncountable dimension?

$$\begin{aligned} \dim(H_b^1(X;\mathbb{R})) &= 0 \\ \dim(H_b^2(X;\mathbb{R})) &= \infty \\ \dim(H_b^3(X;\mathbb{R})) &= \infty \\ \dim(H_b^4(X;\mathbb{R})) &= ??? \end{aligned}$$

Exercises for Chapter 112.

Exercise 112.1. We consider $X = \mathbb{R}$ and the singular 0-cochain

$$\varphi_0\colon \mathrm{C}_0(X) \to \mathbb{Z}$$

that is uniquely determined by the property that for any singular 0-simplex $x \in X = \mathbb{R}$ we have

$$x \mapsto \begin{cases} 1, & \text{if } x \leq 0, \\ 0, & \text{if } x > 0. \end{cases}$$

On page 2480 we saw that $\gamma_0 = \delta\varphi_0 \colon \mathrm{C}_1(\mathbb{R}) \to \mathbb{Z}$ defines a class in $\mathrm{H}^1_{\mathrm{c}}(\mathbb{R};\mathbb{Z})$. Prove, only using the definitions, that this class is non-zero.

Exercise 112.2. What is the cohomology with compact support of the topological spaces

$$X \;:=\; \overline{B}_1(0) \cup x\text{-axis} \quad \text{and} \quad Y \;:=\; \overline{B}_1(0) \cup x\text{-axis} \cup y\text{-axis}$$

that are illustrated in the figure on page 2484.

Exercise 112.3.

(a) Give an example of a path-connected topological space X such that $\mathrm{H}^1(X) = 0$ but such that $\mathrm{H}^1_{\mathrm{c}}(X) \cong \mathbb{Z}^{(\mathbb{N})}$. You do not have to justify why your example has the correct properties.

(b) Give an example of a path-connected topological space X such that $\mathrm{H}^2(X) = 0$ but such that $\mathrm{H}^2_{\mathrm{c}}(X) \cong \mathbb{Z}^3$. You do not have to justify why your example has the correct properties.

Exercise 112.4. Let X be a topological space. We consider the set $\mathcal{K}(X)$ of all compact subsets of X. The set $\mathcal{K}(X)$ together with the relation "$\subset$" defined by inclusion is a directed set since the union of two compact subsets is again compact. Given any two compact subsets $K \subset L$ we get an induced map $\mathrm{H}_n(X, X \setminus L; G) \to \mathrm{H}_n(X, X \setminus K; G)$. As in Exercise 106.5 we define

$$\overleftarrow{\mathrm{H}}_n(X;\mathbb{Z}) \;:=\; \varprojlim_{K \in \mathcal{K}(X)} \mathrm{H}_n(X, X \setminus K; \mathbb{Z}).$$

(a) Recall that on page 2479 we introduced cohomology group with compact support $\mathrm{H}^n_{\mathrm{c}}(X;\mathbb{Z}) = \mathrm{H}^n_{\mathrm{c}}(X;\mathbb{Z})$. Define a useful pairing $\mathrm{H}^n_{\mathrm{c}}(X) \times \overleftarrow{\mathrm{H}}_n(X;\mathbb{Z}) \to \mathbb{Z}$.
Remark. You could make use of Exercise 56.21.

(b) Use (a) to show that $\mathrm{H}^{\mathrm{lf}}_1(\mathbb{R}) \neq 0$.

Exercise 112.5. Let M be a *compact* topological manifold. We write $\mathring{M} = M \setminus \partial M$. The cohomology group $\mathrm{H}^n_{\mathrm{c}}(\mathring{M})$ is homeomorphic to some other cohomology group that might look more familiar. What is it? You do not have to justify your answer.

Exercise 112.6. Let us once again consider the topological space

$$X \;:=\; (\mathbb{R} \cup (S^2 \times \mathbb{Z}))/\!\sim$$

where given $i \in \mathbb{Z}$ we identify $i \in \mathbb{Z} \subset \mathbb{R}$ with $((0,0,-1), i) \in S^2 \times \mathbb{Z}$. On page 2475 we saw that $\mathrm{H}^2(X) \cong \mathbb{Z}^{\mathbb{N}}$. Show that $\mathrm{H}^2_{\mathrm{c}}(X) \cong \mathbb{Z}^{(\mathbb{N})}$.

Exercise 112.7. Show that for every path-connected topological space X the boundary cohomology $\mathrm{H}^1_b(X;\mathbb{R}) = 0$.

113. The Eilenberg-Zilber theorem and the cross product

In this chapter we will to try to find if one can define a "product" in singular homology and/or in singular cohomology. The key to doing so will be the Eilenberg-Zilber Theorem 90.4 that we had stated before without providing a proof. In this chapter we will give a slightly more precise statement and we provide the proof. In this chapter and in Chapter 114 we will see how it can be used to find product structures on homology and cohomology groups.

113.1. **The Eilenberg-Zilber theorem.** We start out by recalling and introducing some definitions.

Definition.

(1) Let $\mathcal{C} = (\mathrm{C}_*, \partial_*)$ and $\mathcal{C} = (\mathrm{C}'_*, \partial'_*)$ be two chain complexes. On page 1940 we defined the tensor product $\mathcal{C} \otimes \mathcal{C}'$ of the chain complexes where the n-th chain group is defined as

$$(\mathcal{C} \otimes \mathcal{C}')_n := \bigoplus_{p+q=n} \mathrm{C}_p \otimes \mathrm{C}'_q$$

and where the boundary homomorphisms are given by

$$\begin{array}{rcl} \partial^{\otimes} \colon (\mathcal{C} \otimes \mathcal{C}')_n & \to & (\mathcal{C} \otimes \mathcal{C}')_{n-1} \\ c_p \otimes c'_q & \mapsto & \partial c_p \otimes c'_q + (-1)^p \cdot c_p \otimes \partial' c'_q. \end{array}$$

(2) Given a point x in a topological space X we denote by x also the singular 0-simplex given by sending the unique point of Δ^0 to x.

(3) Given two topological spaces X and Y we refer to the maps

$$\begin{array}{rcl} \mathrm{C}_0(X) \otimes \mathrm{C}_0(Y) & \to & \mathrm{C}_0(X \times Y) \\ x \otimes y & \mapsto & (x, y) \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{C}_0(X \times Y) & \to & \mathrm{C}_0(X) \otimes \mathrm{C}_0(Y) \\ (x, y) & \mapsto & x \otimes y \end{array}$$

as the canonical maps. We refer to the identity maps on $\mathrm{C}_0(X) \otimes \mathrm{C}_0(Y)$ and on $\mathrm{C}_0(X \times Y)$ also as the canonical maps.

The following theorem is a slightly more precise formulation of the original Eilenberg-Zilber Theorem 90.4.

Theorem 113.1. (Eilenberg-Zilber Theorem)

(1) Given any topological spaces X and Y there exist natural chain maps

$$\begin{array}{rcl} \Upsilon \colon \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) & \to & \mathrm{C}_*(X \times Y) \\ \text{and} \quad \Theta \colon \mathrm{C}_*(X \times Y) & \to & \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y), \end{array}$$

which on the 0-level are the above canonical maps.

(2) The maps Υ and Θ are unique up to natural chain homotopies.[1367]

(3) The maps Υ and Θ are naturally[1368] chain homotopy inverses of one another.

We refer to the maps Υ and Θ as *Eilenberg-Zilber* maps. In the notation and our discussions we will usually ignore the fact that these maps are well-defined only up to a natural

[1367]Here "natural chain homotopy" means that given two such maps Υ and Υ' there exists a choice of chain homotopies $(\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y))_k \to \mathrm{C}_{k+1}(X \times Y)$, which is natural in X and Y, between Υ and Υ'. An analogous statement holds for maps Θ and Θ'.

[1368]Here "naturally" means that $\Upsilon \circ \Theta$ and $\Theta \circ \Upsilon$ are naturally homotopic to the identity maps, i.e. there exist natural chain homotopies from $\Upsilon \circ \Theta$ to the identity map and from $\Theta \circ \Upsilon$ to the identity map.

homotopy. We will only work with the properties of Υ and Θ stated in the theorem, so a different choice of maps Υ and Θ does not affect anything we say afterwards.

113.2. **Proof of the Eilenberg-Zilber Theorem 113.1.** The proof of the Eilenberg-Zilber Theorem 113.1 breaks up into three parts: we first construct Υ, then we construct Θ and finally we show that these maps are unique in the above sense and that they have the desired properties.
We start out with the following definition.

Definition. A topological space X is called acyclic if $\mathrm{H}_0(X;\mathbb{Z}) \cong \mathbb{Z}$ and if all higher homology groups are zero.

Example. In the Homotopy Equivalence-H_*-Corollary 73.9 we showed that every contractible topological space is acyclic. In particular every standard simplex Δ^n is contractible and thus acyclic. Furthermore, all products $\Delta^p \times \Delta^q$ of standard simplices are contractible and thus acyclic.[1369]

We also fix some notation.

Notation. Let X be a topological space and let $x \in X$. If $\sigma\colon \Delta^n \to Y$ is a singular n-simplex in a topological space Y, then we denote by $x \times \sigma\colon \Delta^n \to X \times Y$ the singular n-simplex given by $v \mapsto (x, \sigma(v))$. We use the analogous notation for the roles of X and Y swapped.

Now we can formulate the following theorem.

Theorem 113.2. (EZ-Construction Theorem) Given any two topological spaces X and Y and any $p, q \in \mathbb{N}_0$ there exists a homomorphism

$$\Upsilon_{p,q}\colon \mathrm{C}_p(X) \otimes \mathrm{C}_q(Y) \ \to \ \mathrm{C}_{p+q}(X \times Y)$$

such that the following conditions are satisfied:

(1) for $x \in X$ and $\sigma\colon \Delta^q \to Y$ we have $\Upsilon_{0,q}(x \otimes \sigma) = x \times \sigma$, the same statement also holds with the roles of X and Y swapped,

(2) the map $\Upsilon_{p,q}$ is natural, i.e. if $f\colon X' \to X$ and $g\colon Y' \to Y$ are maps between topological spaces, then for any $a \in \mathrm{C}_p(X')$ and any $b \in \mathrm{C}_q(Y')$ we have

$$(f \times g)_*(\underbrace{\Upsilon_{p,q}(a \otimes b)}_{\in \mathrm{C}_{p+q}(X' \times Y')}) \ = \ \underbrace{\Upsilon_{p,q}(f_*(a) \otimes g_*(b))}_{\in \mathrm{C}_{p+q}(X \times Y)},$$

(3) the maps $\Upsilon_{p,q}$ form a chain map, i.e. for any $a \in \mathrm{C}_p(X)$ and any $b \in \mathrm{C}_q(Y)$ we have

$$\partial(\Upsilon_{p,q}(a \otimes b)) \ = \ \underbrace{\Upsilon_{p-1,q}(\partial a \otimes b) + (-1)^p \cdot \Upsilon_{p,q-1}(a \otimes \partial b)}_{= \Upsilon(\partial^{\otimes}(a \otimes b))}.$$

Proof. We prove the existence of the maps $\Upsilon_{p,q}$ by induction on $p \cdot q$. For clarity we henceforth suppress the subscript from $\Upsilon_{p,q}$.

[1369] This can be seen in many ways, for example pick points $x \in \Delta^p$ and $y \in \Delta^q$, it is straightforward to show that there exists a deformation retraction r from Δ^p to $\{x\}$ and that there exists a deformation retraction s from Δ^q to $\{y\}$. But these two deformation retractions also define a deformation retraction from $\Delta^p \times \Delta^q$ to (x, y).

Clearly for $p = 0$ or $q = 0$ the maps from (1) have the properties (2) and (3). So now suppose that we are given $p, q \in \mathbb{N}_0$ with $p \cdot q > 0$ such that the maps Υ have been defined for all p', q' with $p' \cdot q' < p \cdot q$.

Given any $n \in \mathbb{N}_0$ we denote by $\mathrm{id}_n \colon \Delta^n \to \Delta^n$ the identity map. We first want to come up with a reasonable definition of $\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)$. If we want (3) to be satisfied we have to define $\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q) = z$ where $z \in \mathrm{C}_{p+q}(\Delta^p \times \Delta^q)$ satisfies

$$(*) \qquad \partial z \;=\; \Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q) + (-1)^p \cdot \Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q) \;\in\; \mathrm{C}_{p+q-1}(\Delta^p \times \Delta^q).$$

As we pointed out on page 2492, the product $\Delta^p \times \Delta^q$ is acyclic, in particular we have $\mathrm{H}_{p+q-1}(\Delta^p \times \Delta^q) = 0$, which means that every singular $(p+q-1)$-chain *that is a cycle* is in fact the boundary of some $(p+q)$-chain z. So we have to show that the right-hand side of $(*)$ is indeed a cycle. We compute that

$$\begin{aligned}
&\overbrace{\partial\big(\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q) + (-1)^p \cdot \Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q)\big)}^{\text{boundary of our hypothetical } \Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)} \overset{\text{linearity of } \partial}{\downarrow}{=}\; \partial(\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q)) + (-1)^p \cdot \partial(\Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q)) \\
&= \Upsilon(\underbrace{\partial\partial\,\mathrm{id}_p}_{=0} \otimes \mathrm{id}_q) + (-1)^{p-1} \cdot \Upsilon(\partial\,\mathrm{id}_p \otimes \partial\,\mathrm{id}_q) \\
&\quad + (-1)^p \cdot \Upsilon(\partial\,\mathrm{id}_p \otimes \partial\,\mathrm{id}_q) + (-1)^p \cdot (-1)^p \cdot \Upsilon(\mathrm{id}_p \otimes \underbrace{\partial\partial\,\mathrm{id}_q}_{=0}) = 0.
\end{aligned}$$

$\uparrow$ by our induction hypothesis we can apply the boundary formula (3) to $\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q)$ and $\Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q)$

This discussion gives us the definition of $\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q) := z$.

Now let X and Y be topological spaces and let $\varphi \colon \Delta^p \to X$ and $\psi \colon \Delta^q \to Y$ be singular simplices. If we want (2) to be satisfied then we have to define

$$\Upsilon(\underbrace{\varphi \otimes \psi}_{\in \mathrm{C}_p(X) \otimes \mathrm{C}_q(Y)}) \;:=\; (\varphi \times \psi)_*(\underbrace{\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)}_{\in \mathrm{C}_{p+q}(\Delta^p \times \Delta^q)}) \;\in\; \mathrm{C}_{p+q}(X \times Y).$$

We extend this map linearly to all of $\mathrm{C}_p(X) \otimes \mathrm{C}_q(Y)$. It follows almost immediately from the definition of Υ that the map Υ is natural in X and Y.

It remains to prove (3). This property holds basically by definition. But for completeness' sake we carry out the proof. So let $\varphi \colon \Delta^p \to X$ and $\psi \colon \Delta^q \to Y$ be singular simplices. We then have the following equality in $\mathrm{C}_{p+q-1}(X \times Y)$:

$$\begin{aligned}
\partial(\Upsilon(\varphi \otimes \psi)) \;&=\; \partial\big((\varphi \times \psi)_*(\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q))\big) \overset{\text{since } (\varphi \times \psi)_* \text{ is a chain map}}{\downarrow}{=}\; (\varphi \times \psi)_*(\partial(\overbrace{\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)}^{=z})) \\
&=\; (\varphi \times \psi)_*(\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q)) + (-1)^p \cdot (\varphi \times \psi)_*(\Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q)) \\
&\quad \uparrow \text{ by definition of } z \text{ and the linearity of } (\varphi \times \psi)_* \\
&=\; (\Upsilon(\varphi_*(\partial\,\mathrm{id}_p) \otimes \psi_*(\mathrm{id}_q))) + (-1)^p \cdot \Upsilon(\varphi_*(\mathrm{id}_p) \otimes \psi_*(\partial\,\mathrm{id}_q)) \\
&\quad \uparrow \text{ by induction we can apply the naturality of } \Upsilon \\
&=\; \Upsilon(\partial(\varphi) \otimes \psi) + (-1)^p \cdot \Upsilon(\varphi \otimes \partial\psi)) \\
&\quad \uparrow \text{ since } \varphi_* \text{ and } \psi_* \text{ are chain maps and since } \varphi_*(\mathrm{id}_p) = \varphi \text{ and } \psi_*(\mathrm{id}_q) = \psi
\end{aligned}$$

■

Now we turn to the construction of the second map in the Eilenberg-Zilber Theorem 113.1.

Theorem 113.3. (EZ-Inverse Theorem) Given any two topological spaces X and Y and any $k \in \mathbb{N}_0$ there exists a homomorphism

$$\Theta_k \colon \mathrm{C}_k(X \times Y) \ \to \ (\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y))_k \ = \ \bigoplus_{p+q=k} \mathrm{C}_p(X) \otimes \mathrm{C}_q(Y)$$

such that the following conditions are satisfied:

(1) the map Θ_0 is the canonical map on the 0-level, i.e. for every $x \in X$ and $y \in Y$ we have $\Theta_0((x,y)) = x \otimes y$,

(2) the map Θ_k is natural in X and Y, i.e. for any two maps $f \colon X' \to X$ and $g \colon Y' \to Y$ of topological spaces and any $c \in \mathrm{C}_k(X' \times Y')$ we have

$$\Theta_k((f \times g)_*(c)) \ = \ (f_* \otimes g_*)(\Theta_k(c)),$$

(3) the maps Θ_* form a chain map, i.e. for any $k \in \mathbb{N}_0$ we have

$$\partial_k^{\otimes} \circ \Theta_k \ = \ \Theta_{k-1} \circ \partial_k.$$

In the proof of the EZ-Inverse Theorem 113.3 we will need the following lemma.

Lemma 113.4. Let X and Y be two acyclic topological spaces. For every $k \geq 1$ we have

$$\mathrm{H}_k(\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)) \ = \ 0.$$

Furthermore we have an isomorphism

$$\begin{array}{rcl} \epsilon \colon \mathrm{H}_0(\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)) & \xrightarrow{\cong} & \mathbb{Z} \\ \Big[\sum_{i=1}^{k} \underbrace{a_i}_{\in \mathbb{Z}} \cdot \underbrace{x_i}_{\in X} \otimes \underbrace{y_i}_{\in Y} \Big] & \mapsto & \sum_{i=1}^{k} a_i. \end{array}$$

Proof. The lemma is an immediate consequence of our hypotheses, the H_0-Proposition 72.5 and the Künneth Theorem 90.7 for Chain Complexes. (Note that this Künneth Theorem is purely algebraic.) ■

Proof of the EZ-Inverse Theorem 113.3. As we will see the idea behind the proof of the EZ-Inverse Theorem 113.3 is very similar to the idea of the proof of Theorem 113.2. We start out with the outline of proof:

(a) We use (1) to define Θ_0,

(b) we suppose the map $\Theta_0, \ldots, \Theta_{k-1}$ are defined, we then use (3) to make an educated guess for $\Theta_k(d_k)$ where we consider
  (i) the topological spaces $X = Y = \Delta^k$ and
  (ii) the singular k-simplex $d_k \colon \Delta^k \to \Delta^k \times \Delta^k$ that is given by the diagonal map $d_k(x) = (x,x)$.

(c) we then use the naturality statement of (2) to define Θ_k for all topological spaces X and Y and all singular simplices in $\mathrm{C}_*(X \times Y)$.

Now we carry out the above program. First of all, given a 0-simplex (x,y) in $X \times Y$ we define $\Theta_0((x,y)) = x \otimes y$. Then we extend this definition linearly to get the desired map $\Theta_0 \colon \mathrm{C}_0(X \times Y) \to \mathrm{C}_0(X) \otimes \mathrm{C}_0(Y)$.

Now suppose we have already constructed the maps $\Theta_0, \ldots, \Theta_{k-1}$. We want to define Θ_k and we start out by defining $\Theta_k(d_k \colon \Delta^k \to \Delta^k \times \Delta^k)$. Since we need (3) to be satisfied we need to define $\Theta_k(d_k) := c$ where $c \in (\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k))_k$ satisfies $\partial_k^{\otimes}(c) = \Theta_{k-1}(\partial d_k)$.

In the chain complex $\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k)$ we calculate that

$$\partial^{\otimes}(\overbrace{\Theta_{k-1}(\partial_k(d_k))}^{\text{defined by induction}}) \;\underset{\text{by induction we can apply (3)}}{=}\; \Theta_{k-2}(\underbrace{\partial_{k-1}\partial_k}_{=0} d_k) \;=\; 0,$$

i.e. the chain $\Theta_{k-1}(\partial_k d_k) \in (\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k))_{k-1}$ is in fact a cycle. Since Δ^k is acyclic it follows immediately from Lemma 113.4 that this cycle is null-homologous. (For $k = 1$ one easily verifies, using the explicit description of Θ_0, that the cycle lies in the kernel of the isomorphism $\epsilon\colon \mathrm{H}_0(\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k)) \to \mathbb{Z}$.) This means that there exists a singular chain $c \in (\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k))_k$ with $\partial^{\otimes}(c) = \Theta_{k-1}(\partial_k d_k)$. We define $\Theta_k(d_k) := c$.

Now we define Θ_k for arbitrary topological spaces X and Y and an arbitrary singular k-simplex $\sigma\colon \Delta^k \to X \times Y$. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the natural projections. Note that we have a commutative diagram

$$\begin{array}{ccc} & & \Delta^k \times \Delta^k \\ & \overset{d_k}{\nearrow} & \big\downarrow {\scriptstyle (p\circ\sigma)\times(q\circ\sigma)} \\ \Delta^k & & \\ & \underset{\sigma}{\searrow} & X \times Y, \end{array}$$

i.e. we have $\sigma = ((p\circ\sigma)\times(q\circ\sigma))\circ d_k = ((p\circ\sigma)\times(q\circ\sigma))_*(d_k)$. For the naturality condition (2) to be satisfied we need to define

$$\Theta_k(\sigma) \;:=\; ((p\circ\sigma)_* \otimes (q\circ\sigma)_*)(\Theta_k(d_k)) \;\in\; (\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y))_k.$$

With this definition one readily verifies that the map Θ_k is natural in X and Y.

Finally we have to show that Θ_k satisfies the boundary formula (3). So as before let $\sigma\colon \Delta^k \to X \times Y$ be a singular k-simplex. Then

$$\begin{array}{lll} & \text{since } (p\circ\sigma)_* \otimes (q\circ\sigma)_*\colon \mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) & \\ \text{by definition of } \Theta_k(\sigma) & \text{is a chain map by Lemma 90.3} & \\ \partial^{\otimes}\Theta_k(\sigma) \overset{\downarrow}{=} \partial^{\otimes}\big(((p\circ\sigma)_* \otimes (q\circ\sigma)_*)(\Theta_k(d_k))\big) & \overset{\downarrow}{=} ((p\circ\sigma)_* \otimes (q\circ\sigma)_*)(\partial^{\otimes}\Theta_k(d_k)) & \\ = ((p\circ\sigma)_* \otimes (q\circ\sigma)_*)(\Theta_{k-1}(\partial d_k)) & = \Theta_{k-1}\big(((p\circ\sigma)\times(q\circ\sigma))_*(\partial d_k)\big) & \\ \uparrow \text{ by definition of } \Theta_k(d_k) & \uparrow \text{ by naturality of } \Theta_{k-1} & \\ = \Theta_{k-1}\partial\big(((p\circ\sigma)\times(q\circ\sigma))_*(d_k)\big) & = \Theta_{k-1}\partial\sigma. & \\ \uparrow \text{ since } ((p\circ\sigma)\times(q\circ\sigma))_* \text{ is a chain map} & \uparrow \text{ since } \sigma = ((p\circ\sigma)\times(q\circ\sigma))\circ d_k & \end{array}$$

We have now verified that Θ_k has all the desired properties. ∎

As we saw in the proofs of Theorem 113.2 and the EZ-Inverse Theorem 113.3, the natural chain maps $\Upsilon\colon \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y) \to \mathrm{C}_*(X\times Y)$ and $\Theta\colon \mathrm{C}_*(X\times Y) \to \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)$ depend on many choices. The next theorem says that different choices in the proofs lead to natural chain maps that are naturally homotopy equivalent to one another.

Theorem 113.5. Let X and Y be topological spaces. Any two natural chain maps

$$\mathrm{C}_*(X \times Y) \;\to\; \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)$$

that are the canonical maps on the 0-level are in fact naturally chain homotopic. The same conclusion also holds for any two natural chain maps

$$\mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)\to\mathrm{C}_*(X)\otimes\mathrm{C}_*(Y),\ \ \mathrm{C}_*(X\times Y)\to\mathrm{C}_*(X\times Y),\ \ \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)\to\mathrm{C}_*(X\times Y)$$

that are the canonical maps on the 0-level.

Proof. The proof of this theorem is in many ways quite similar to the proofs of the EZ-Construction Theorem 113.2 and the EZ-Inverse 113.3.

In the following we show the first statement. The proofs of the other three statements are very similar. So let

$$F,G\colon \mathrm{C}_*(X\times Y)\ \to\ \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)$$

be two natural chain maps that are the canonical maps on the 0-chains, i.e. which satisfy $F((x,y))=x\otimes y=G((x,y))$ for all $x\in X, y\in Y$. Given any $k\in\mathbb{Z}_{\geq -1}$ we have to define a map

$$P_k\colon \mathrm{C}_k(X\times Y)\ \to\ (\mathrm{C}_*(X)\otimes\mathrm{C}_*(Y))_{k+1}$$

that satisfies the following three properties:

(1) the map P_{-1} is the zero map,
(2) the map P_k is natural in X and Y,
(3) we have $\partial^{\otimes}\circ P_k+P_{k-1}\circ\partial=F-G$.

So suppose we have already defined the maps $P_{-1},\dots,P_{k-1}$ with $k\geq 0$. As before we denote by $d_k\colon\Delta^k\to\Delta^k\times\Delta^k$ the singular k-simplex that is given by the diagonal map $d_k(x):=(x,x)$. We first want to define $P_k(d_k)\in(\mathrm{C}_*(\Delta^k)\otimes\mathrm{C}_*(\Delta^k)_{k+1}$. In the chain complex $\mathrm{C}_*(\Delta^k)\otimes\mathrm{C}_*(\Delta^k)$ we calculate that

$$\begin{aligned}\partial^{\otimes}((F-G-P_{k-1}\partial)(d_k)) &= \partial^{\otimes}F(d_k)-\partial^{\otimes}G(d_k)-\partial^{\otimes}P_{k-1}(\partial d_k)\\ &\overset{\uparrow}{=} F(\partial d_k)-G(\partial d_k)-(F-G-P_{k-2}\partial)(\partial d_k)=P_{k-2}\partial\partial d_k=0.\end{aligned}$$

since F and G are chain maps and since inductively we know that $\partial^{\otimes}\circ P_{k-1}+P_{k-1}\circ\partial=F-G$

It follows from Lemma 113.4 that there exists a $(k+1)$-chain $c\in(\mathrm{C}_*(\Delta^k)\otimes\mathrm{C}_*(\Delta^k))_{k+1}$ with $\partial^{\otimes}(c)=(F-G-P_{k-1}\partial)(d_k)$. (For $k=0$ we need to show that $\epsilon((F-G)(d_0))=0$, to conclude this we need to use that F and G agree on 0-simplices.) We define $P_k(d_k):=c$.

Now let X and Y be two topological spaces and let $\sigma\in\mathrm{C}_k(X\times Y)$. As in the proof of the EZ-Construction Theorem 113.2 we denote by $p\colon X\times Y\to X$ and $q\colon X\times Y\to Y$ the natural projections and we set

$$P_k(\sigma)\ :=\ ((p\circ\sigma)_*\otimes(q\circ\sigma)_*)(P_k(d_k))\ \in\ (\mathrm{C}_*(X)\otimes\mathrm{C}_*(Y))_{k+1}.$$

Basically by definition this map is natural in X and Y. As in the proof of the EZ-Construction Theorem 113.2 one easily verifies that condition (3) is satisfied. ■

Now we can easily provide the proof of the Eilenberg-Zilber Theorem 113.1.

Proof of the Eilenberg-Zilber Theorem 113.1. We pick natural chain maps

$$\Upsilon\colon \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)\ \to\ \mathrm{C}_*(X\times Y)$$

and

$$\Theta\colon \mathrm{C}_*(X\times Y)\ \to\ \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)$$

as provided by the EZ-Construction Theorem 113.2 and the EZ-Inverse Theorem 113.3. These maps are the canonical maps on the 0-level. By Theorem 113.5 the maps Υ and Θ are thus unique up to a natural chain homotopy.

It remains to show that the maps Υ and Θ are naturally chain homotopy inverses of one another. The map $\Theta \circ \Upsilon \colon \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)$ is a natural chain map that is the canonical map on the 0-level. But this is also the case for the identity map. It follows from Theorem 113.5 that $\Theta \circ \Upsilon$ is naturally chain homotopic to the identity. The same argument shows that $\Upsilon \circ \Theta$ is naturally chain homotopic to the identity. ■

113.3. **The relative Eilenberg–Zilber map Υ.** In this short section we introduce a relative version of the Eilenberg–Zilber map Υ. We start out with the following elementary but essential remark.

Remark. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets. We denote by $i \colon A \to X$ and $j \colon B \to Y$ the inclusion maps. Then the diagram

$$\begin{array}{ccc} \mathrm{C}_*(A) \otimes \mathrm{C}_*(B) & \xhookrightarrow{i_* \otimes j_*} & \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) \\ \downarrow \Upsilon & & \downarrow \Upsilon \\ \mathrm{C}_*(A \times B) & \xhookrightarrow{(i \times j)_*} & \mathrm{C}_*(X \times Y) \end{array}$$

commutes by the naturality of Υ. In the following we do not explicitly mention the names of the various inclusion induced maps.

Proposition 113.6. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.

(1) The Eilenberg-Zilber map Υ induces a natural chain homotopy equivalence[1370]

$$\begin{array}{rcl} \mathrm{C}_*(X, A) \otimes \mathrm{C}_*(Y, B) & \to & \mathrm{C}_*(X \times Y)/(\mathrm{C}_*(A \times Y) + \mathrm{C}_*(X \times B)) \\ \sum_{i=1}^{n} [c_i] \otimes [d_i] & \mapsto & \sum_{i=1}^{n} [\Upsilon(c_i \otimes d_i)]. \end{array}$$

(2) The Eilenberg-Zilber map Υ descends to a well-defined chain map

$$\begin{array}{rcl} \mathrm{C}_*(X, A) \otimes \mathrm{C}_*(Y, B) & \to & \mathrm{C}_*(X \times Y, A \times Y \cup X \times B) \\ \sum_{i=1}^{n} [c_i] \otimes [d_i] & \mapsto & \sum_{i=1}^{n} \big[\Upsilon(c_i \otimes d_i)\big]. \end{array}$$

Proof. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.

(1) We consider the following diagram

$$\begin{array}{ccccccccc} 0 & \to & \mathrm{C}_*(A) \otimes \mathrm{C}_*(Y) & \to & \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) & \longrightarrow & \mathrm{C}_*(X, A) \otimes \mathrm{C}_*(Y) & \longrightarrow & 0 \\ & & \downarrow \Upsilon & & \downarrow \Upsilon & & \downarrow \Upsilon & & \\ 0 & \longrightarrow & \mathrm{C}_*(A \times Y) & \longrightarrow & \mathrm{C}_*(X \times Y) & \longrightarrow & \mathrm{C}_*(X \times Y)/\mathrm{C}_*(A \times Y) & \to & 0. \end{array}$$

The top sequence is given by tensoring a short exact sequence by the free abelian groups $\mathrm{C}_*(Y)$, Lemma 89.9 implies that the resulting sequence is again exact. The bottom sequence is exact by definition. The two left vertical maps are homotopy equivalences by Theorem 113.1 and the diagram commutes by the naturality of Υ, as explained in the remark preceding the proposition. Finally note that it follows from

[1370] Note that $\mathrm{C}_*(A \times Y) + \mathrm{C}_*(X \times B)$ is in fact a subcomplex of the chain complex $\mathrm{C}_*(X \times Y)$, so the right-hand side is indeed a chain complex.

the Two-Out-Of-Three-Homotopy Equivalence Corollary 81.6 that the right vertical map is also a chain homotopy equivalence.

We consider the following diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{C}_*(X,A)\otimes\mathrm{C}_*(B) & \longrightarrow & \mathrm{C}_*(X,A)\otimes\mathrm{C}_*(Y) & \longrightarrow & \mathrm{C}_*(X,A)\otimes\mathrm{C}_*(Y,B) & \longrightarrow & 0 \\ & & \downarrow\Upsilon & & \downarrow\Upsilon & & \downarrow\Upsilon & & \\ 0 & \longrightarrow & \mathrm{C}_*(X\times B)/\mathrm{C}_*(A\times B) & \longrightarrow & \mathrm{C}_*(X\times Y)/\mathrm{C}_*(A\times Y) & \longrightarrow & \dfrac{\mathrm{C}_*(X\times Y)}{\mathrm{C}_*(A\times Y)+\mathrm{C}_*(X\times B)} & \longrightarrow & 0. \end{array}$$

As above, it follows from the fact that each $\mathrm{C}_k(X,A)$ is a free abelian group and Lemma 89.9 that the top sequence is exact. It follows easily from[1371]

$$\mathrm{C}_*(X\times B)\cap\mathrm{C}_*(A\times Y) \;=\; \mathrm{C}_*((X\times B)\cap(A\times Y)) \;=\; \mathrm{C}_*(A\times B)$$

that the bottom sequence is also exact. The middle vertical map is a chain homotopy equivalence by the above discussion. Exactly the same argument also shows that the left vertical map is a chain homotopy equivalence. The diagram commutes by the naturality of Υ. It follows from the Two-Out-Of-Three-Homotopy Equivalence Corollary 81.6 that the right vertical map is also a homotopy equivalence.

(2) The second statement follows immediately from (1) together with the observation that $\mathrm{C}_*(A\times Y)+\mathrm{C}_*(X\times B)$ is a subcomplex of $\mathrm{C}_*(A\times Y\cup X\times B)$. ■

113.4. **The cross product on homology.** Recall that one of our goals is to find some type of product structure in homology or cohomology. We start our search for a product structure in homology, since we are more comfortable with homology groups.
The following definition already gives us some type of product structure on homology.

Definition. Let (X,A) and (Y,B) be two pairs of topological spaces. We refer to the map[1372]

$$\begin{array}{rcl} \times\colon \mathrm{H}_p(X,A)\otimes\mathrm{H}_q(Y,B) & \xrightarrow{\times} & \mathrm{H}_{p+q}(X\times Y, A\times Y\cup X\times B). \\ [c]\otimes[d] & \mapsto & [c]\times[d] := [\Upsilon(c\otimes d)] \end{array}$$

as the cross product.

In the following lemma we summarize some elementary properties of the cross product.

Lemma 113.7. (Cross Product Lemma)

(1) Let X and Y be two topological spaces and let $x\in X$ be a point. We denote by $f\colon Y\to X\times Y$ the map that is given by $y\mapsto(x,y)$ and we denote by $[x]\in\mathrm{H}_0(X)$ the homology class defined by x. Then for any $q\in\mathbb{N}_0$ the maps

$$\mathrm{H}_q(Y) \underset{f_*}{\overset{\sigma\mapsto[x]\times\sigma}{\rightrightarrows}} \mathrm{H}_q(X\times Y)$$

agree. The statement holds with the roles of X and Y reversed.

(2) The cross product is natural, i.e. if $f\colon(X,A)\to(X',A')$ and $g\colon(Y,B)\to(Y',B')$ are maps between pairs of topological spaces, then for any $p,q\in\mathbb{N}_0$ the following

[1371] Why does this equality of chain complexes hold?

[1372] Note that the map is well-defined by Lemmas 90.6 and 113.6 (2) and it is independent of the choice of Υ by Theorem 113.1 (2).

diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_p(X,A)\otimes\mathrm{H}_q(Y,B) & \xrightarrow{\times} & \mathrm{H}_{p+q}(X\times Y, A\times Y\cup X\times B) \\ \downarrow{\scriptstyle f_*} \quad \downarrow{\scriptstyle g_*} & & \downarrow{\scriptstyle (f\times g)_*} \\ \mathrm{H}_p(X',A')\otimes\mathrm{H}_q(Y',B') & \xrightarrow{\times} & \mathrm{H}_{p+q}(X'\times Y', A'\times Y'\cup X'\times B'). \end{array}$$

Proof. The lemma follows immediately from the definitions and the properties of Υ given in the EZ-Construction Theorem 113.2 (1) and (2). ■

We have the following variation on the Künneth Theorem 90.8 for topological spaces.

Theorem 113.8. (The Künneth Theorem) Let (X,A) and (Y,B) be pairs of topological spaces. We assume that one of the following two statements holds:

(1) A and B are open subsets (note that A and B can possibly be empty), or
(2) (X,A) and (Y,B) are pairs of CW-complexes.

Then for each $n\in\mathbb{N}$ there exists a natural short exact sequence

$$\begin{aligned} 0 \;\to\; \bigoplus_{p+q=n} \mathrm{H}_p(X,A)\otimes\mathrm{H}_q(Y,B) \;&\xrightarrow{\times}\; \mathrm{H}_n(X\times Y, A\times Y\cup X\times B) \\ &\to \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p(X,A),\mathrm{H}_q(Y,B)) \;\to\; 0. \end{aligned}$$

Furthermore the above short exact sequence splits.

Examples.

(1) Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold. Let $x\in M\setminus\partial M$ and let $y\in N\setminus\partial N$. Then it follows from the relative Künneth Theorem 113.8 (2), Lemma 105.4 and the Tor-Properties Lemma 89.15 that the cross product defines an isomorphism

$$\mathrm{H}_m(M,M\setminus\{x\})\otimes\mathrm{H}_n(N,N\setminus\{y\}) \xrightarrow{\times} \mathrm{H}_{m+n}(M\times N, \underbrace{(M\setminus\{x\})\times N\cup M\times(N\setminus\{y\})}_{=(M\times N)\setminus\{(x,y)\}}).$$

(2) Let X and Y be path-connected topological spaces. Let $x\in X$ and let $y\in Y$. We denote by $i\colon X\to X\times Y$ the inclusion map that is given by $i(x)=(x,y)$ and similarly we denote by $j\colon Y\to X\times Y$ the inclusion map that is given by $j(y)=(x,y)$. It follows from the H_0-Proposition 72.5, the Cross Product Lemma 113.7 (1) and the Künneth Theorem 113.8 that the map

$$i_*\oplus j_*\colon \mathrm{H}_1(X;\mathbb{Z})\oplus\mathrm{H}_1(Y;\mathbb{Z}) \;\to\; \mathrm{H}_1(X\times Y;\mathbb{Z})$$

is an isomorphism.[1373] Let G be any abelian group. Furthermore note that it follows easily from the above, the naturality of the Universal Coefficient Theorem 89.17 and the Tor-Properties Lemma 89.15 (3) that the map

$$i_*\oplus j_*\colon \mathrm{H}_1(X;G)\oplus\mathrm{H}_1(Y;G) \;\to\; \mathrm{H}_1(X\times Y;G)$$

is also an isomorphism.

[1373] We had given an alternative proof of this fact in Exercise 84.5.

Proof. We consider the following maps

$$0 \to \bigoplus_{p+q=n} \mathrm{H}_p(X,A)\otimes \mathrm{H}_q(Y,B) \to \mathrm{H}_n(\mathrm{C}_*(X,A)\otimes \mathrm{C}_*(Y,B)) \to \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p(X,A),\mathrm{H}_q(Y,B)) \to 0.$$
$$\downarrow \Upsilon$$
$$\mathrm{H}_n(\mathrm{C}_*(X\times Y)/(\mathrm{C}_*(A\times Y)+\mathrm{C}_*(X\times B)))$$
$$\downarrow$$
$$\mathrm{H}_n(\mathrm{C}_*(X\times Y)/\mathrm{C}_*(A\times Y\cup X\times B))$$
$$\downarrow =$$
$$\mathrm{H}_n(X\times Y, A\times Y\cup X\times B)$$

We first note that the top sequence is exact by the Künneth Theorem for Chain Complexes 90.7. (Here we use again that relative chain groups are free abelian groups.) Here the top vertical map is an isomorphism by Proposition 113.6. Recall that we assume that one of the following two statements holds:

(1) A and B are open subsets, or
(2) (X,A) and (Y,B) are pairs of CW-complexes.

We then know from the Excisive Triad-Proposition 109.12 (4) respectively (6) that the inclusion induced map

$$\underbrace{\mathrm{C}_*^{\{A\times Y, X\times B\}}(A\times Y\cup X\times B)}_{=\mathrm{C}_*(A\times Y)+\mathrm{C}_*(X\times B)} \to \mathrm{C}_*(A\times Y\cup X\times B)$$

is a chain homotopy equivalence. The same argument as in the proof of Corollary 74.16 shows that this piece of information implies that the second vertical map is indeed an isomorphism. It follows immediately from the definition of the cross product that the induced "diagonal map"

$$\bigoplus_{p+q=n} \mathrm{H}_p(X,A)\otimes \mathrm{H}_q(Y,B) \to \mathrm{H}_n(X\times Y, A\times Y\cup X\times B)$$

is precisely the cross product. ∎

113.5. **Product orientations of topological manifolds.** In this second to last section we want to consider products of topological manifolds. First let us recall the following fact.

Proposition 113.9. Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold. Then the following hold:

(1) The product $M\times N$ is an $(m+n)$-dimensional topological manifold.
(2) We have $\partial(M\times N) = (\partial M\times N)\cup(M\times \partial N)$.

Proof. This proposition follows from the combination of the Topological Manifold Product Proposition 18.4 and the Topological Manifold Boundary Proposition 75.2. ∎

The cross product, that we just introduced, allows us to formulate the following proposition.

Proposition 113.10. (Topological Product Orientation Proposition) Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold.

Suppose M is equipped with an orientation $\{\mu_x\}_{x\in M\setminus\partial M}$ and that N is equipped with an orientation $\{\nu_y\}_{y\in N\setminus\partial N}$.

(1) Given $(x,y)\in(M\times N)\setminus\partial(M\times N)$ we denote by $\rho_{(x,y)}$ the image of $\mu_x\otimes\nu_y$ under the isomorphism

$$\mathrm{H}_m(M,M\setminus\{x\})\otimes\mathrm{H}_n(N,N\setminus\{y\}) \xrightarrow{\times} \mathrm{H}_{m+n}(M\times N,(M\times N)\setminus\{(x,y)\})$$

from page 2499. Then these classes $\rho_{(x,y)}$ define an orientation on $M\times N$.

(2) Suppose both M and N are compact and connected, then the map

$$\mathrm{H}_m(M,\partial M)\otimes\mathrm{H}_n(N,\partial N) \xrightarrow{\times} \mathrm{H}_{m+n}(M\times N,\partial(M\times N))$$

given by the cross product is an isomorphism and it has the property that

$$[M]\times[N] \;=\; [M\times N] \;\in\; \mathrm{H}_{m+n}(M\times M,\partial(M\times N))$$

where $[M\times N]$ denotes the fundamental class of the compact topological manifold $M\times N$ equipped with the orientation defined in (1).

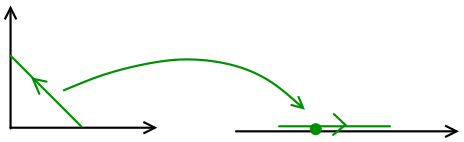
Proof. Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold.

(1) The first statement of the proposition is a straightforward consequence of the definitions and the naturality of the cross product, see the Cross Product Lemma 113.7. For completeness' sake we sketch the proof. To simplify the notation we assume that $\partial M=\partial N=\varnothing$. Now let $(x,y)\in M\times N$. We pick an open neighborhood U of x and a class $\mu_U\in\mathrm{H}_m(M,M\setminus U)$ and an open neighborhood V of y and a class $\nu_V\in\mathrm{H}_n(N,N\setminus V)$ as given by the definition on page 2331. By the naturality of the cross product we obtain the following commutative diagram

$$\begin{array}{ccc}
\mathrm{H}_m(M,M\setminus U)\times\mathrm{H}_n(N,N\setminus V) & \xrightarrow{\times} & \mathrm{H}_{m+n}(M\times N,M\times N\setminus(U\times V)) \\
{\scriptstyle \mu_U\mapsto\mu_x,\ \nu_V\mapsto\nu_y}\downarrow & & \downarrow \\
\mathrm{H}_m(M,M\setminus\{x\})\times\mathrm{H}_n(N,N\setminus\{y\}) & \xrightarrow[(\mu_x,\nu_y)\mapsto\rho_{(x,y)}]{\times} & \mathrm{H}_{m+n}(M\times N,M\times N\setminus\{(x,y)\}).
\end{array}$$

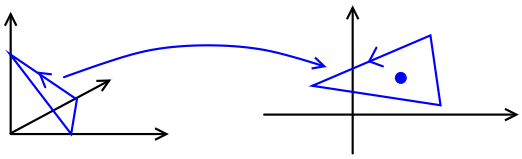
It is now straightforward to verify that $\phi_{U\times V}:=\mu_U\times\nu_V$ has the properties desired by the definition on page 2331.

(2) Now suppose that both M and N are compact. By the Product Topology Properties Proposition 5.6, the product $M\times N$ is then also compact. Now let $x\in M\setminus\partial M$ and let $y\in N\setminus\partial N$. By the Smooth Manifold Product Proposition 20.6 we have $(x,y)\in(M\times N)\setminus\partial(M\times N)$. Furthermore, by the Cross Product Lemma 113.7 we have the following commutative diagram



$$\begin{array}{ccc}
\mathrm{H}_m(M,\partial M)\otimes\mathrm{H}_n(N,\partial N) & \xrightarrow{\times} & \mathrm{H}_{m+n}(M\times N,\partial(M\times N)) \\
\downarrow & & \downarrow \\
\mathrm{H}_m(M,M\setminus\{x\})\otimes\mathrm{H}_n(N,N\setminus\{y\}) & \xrightarrow{\times} & \mathrm{H}_{m+n}(M\times N,M\times N\setminus\{(x,y)\}).
\end{array}$$

The vertical maps are isomorphisms by the Orientation-Top Homology Theorem 106.1. On page 2499 we saw that the bottom horizontal map is an isomorphism. It follows



that, as claimed, the top horizontal map is also an isomorphism. The statement regarding the fundamental classes is an immediate consequence of the commutativity of the diagram and the definitions. ■

Definition. Let M and N be oriented topological manifolds. We refer to the orientation on $M \times N$ defined in the Topological Product Orientation Proposition 113.10 (1) as the product orientation.

Remark. Recall that given any open subset $U \subset \mathbb{R}^k$, $k \in \mathbb{N}_0$, we introduced on page 2337 the standard orientation for U viewed as a topological manifold. (See also the figure below for a reminder.) The following lemma says that the above definition of the product orientation gives us the "expected" answer when we deal with open subsets of $\mathbb{R}^k$'s.

standard generator for $\mathbb{R}$

standard generator for $\mathbb{R}^2$

Proposition 113.11. Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open non-empty subsets. We equip U and V with the standard orientation. Then the product orientation of $U \times V$, defined above, agrees with the standard orientation of $U \times V \subset \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$.

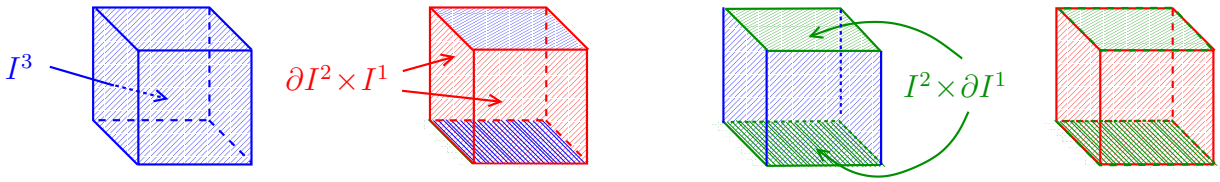
We postpone the proof of Proposition 113.11 to the next section.

Examples.

(1) Let M and N be two oriented smooth manifolds. We have the following diagram

$$\begin{array}{ccc} \text{oriented smooth manifolds } M, N & \overset{\substack{\text{Smooth-Topological}\\ \text{Orientation}\\ \text{Proposition 105.11}}}{\rightsquigarrow} & \text{oriented topological manifolds } M, N \\ \Big\downarrow \text{page 695} & & \Big\downarrow \text{see above} \\ \text{oriented smooth manifold } M \times N & \overset{\textit{Proposition } 105.11}{\rightsquigarrow} & \text{oriented topological manifold } M \times N. \end{array}$$

It follows fairly easily from Proposition 113.11 that this diagram commutes.



(2) We write $I = [-1, 1]$. We view I as a 1-dimensional topological manifold and we equip I with the orientation coming from $\mathbb{R}$. Given $k \in \mathbb{N}_0$ we write

$$\partial I^k \ := \ \{(x_1, \ldots, x_k) \,|\, \text{there exists an } i \text{ with } x_i = -1 \text{ or } x_i = 1\}.$$

Given any $m, n \in \mathbb{N}$ one sees easily that

$$\partial(I^m \times I^n) \ = \ (\partial I^m \times I^n) \cup (I^m \times \partial I^n) \ = \ \partial(I^{m+n}).$$

It follows from the Topological Manifold Product Proposition 18.4 and the above

discussion that we can view each $I^k = I \times \cdots \times I$ as a k-dimensional topological manifold with boundary given by the above subset ∂I^k. We equip I^k with the product orientation. It follows immediately from Proposition 113.11 that the orientation on the open subset $I^k \setminus \partial I^k \subset \mathbb{R}^k$ is the standard orientation.[1374] As usual we denote by $[I^k] \in \mathrm{H}_k(I^k, \partial I^k; \mathbb{Z})$ the fundamental class.

Now let $m, n \in \mathbb{N}_0$. We get a cross product

$$\overbrace{\mathrm{H}_m(I^m, \partial I^m)}^{=\mathbb{Z}\cdot[I^m]} \otimes \overbrace{\mathrm{H}_n(I^n, \partial I^n)}^{=\mathbb{Z}\cdot[I^n]} \quad \to \quad \overbrace{\mathrm{H}_{m+n}(I^{m+n}, \partial I^{m+n})}^{=\mathbb{Z}\cdot[I^{n+n}]}$$

which by the Topological Product Orientation Proposition 113.10 (2) has the property that

$$[I^m] \times [I^n] \quad = \quad [I^{m+n}].$$

113.6. **The shuffle product and the proof of Proposition 113.11** $(*)$**.** In this section we will provide the proof of Proposition 113.11. The difficulty in the proof is that the definition of the cross product relies on the map Υ from the EZ-Construction Theorem 113.2. We gave a non-constructive proof of the existence of the map Υ. In this section we give an *explicit* description of a map ∇ which has all the properties that we had asked for in the EZ-Construction Theorem 113.2. We will then use this map ∇ to prove Proposition 113.11. First we recall some notation from page 1584.

Notation. For $i = 0, \ldots, n$ we write

$$v_i \ := \ (0, \ldots, 1, 0, \ldots, 0) \ \in \ \mathbb{R}^{n+1}.$$

Furthermore for $a_0, \ldots, a_k \in \Delta^n$ we consider the map

$$\begin{array}{rcl} [a_0, \ldots, a_k] \colon \Delta^k & \to & \Delta^n \\ \sum_{j=0}^{k} \lambda_j \cdot v_j & \mapsto & \sum_{j=0}^{k} \lambda_j \cdot a_j. \end{array}$$

The map $[a_0, \ldots, a_k]$ thus sends the standard k-simplex Δ^k to the simplex "spanned by $a_0, \ldots, a_k$" in Δ^n.

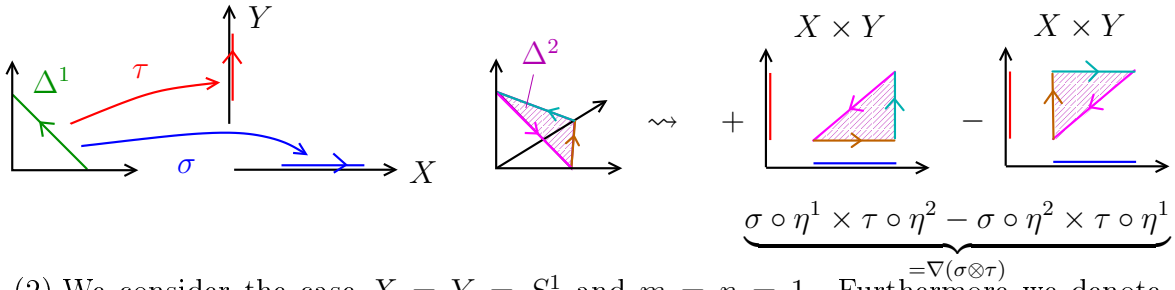
Definition. Let $m, n \in \mathbb{N}_0$.

(1) An (m,n)-shuffle is a pair (μ, ν) of disjoint sets of integers

$$1 \leq \mu_1 < \mu_2 < \cdots < \mu_m \leq m+n \quad \text{and} \quad 1 \leq \nu_1 < \nu_2 < \cdots < \nu_n \leq m+n.$$

We denote by $\mathrm{sign}(\mu, \nu)$ the sign of the permutation $(\mu_1, \ldots, \mu_m, \nu_1, \ldots, \nu_n)$. We denote by $\eta^\mu \colon \Delta^{m+n} \to \Delta^m$ the unique affine linear map which satisfies $\eta^\mu(v_i) = v_j$ for $\mu_j \leq i < \mu_{j+1}$.[1375] The same way we define $\eta^\nu \colon \Delta^{m+n} \to \Delta^n$.

[1374] Note that the homeomorphism $f \colon (I^k, \partial I^k) \to (\overline{B}^k, S^{k-1})$ from the Convex-to-Ball Proposition 2.20 (2) has the property that the restriction to a dense open subset of $I^k \setminus \partial I^k \to B^k$ is an orientation-preserving diffeomorphism. In particular this homeomorphism is thus an orientation-preserving homeomorphism from the oriented topological manifold I^k to the oriented topological manifold $\overline{B}^k$.



(2) Given two topological spaces X and Y we define

$$\begin{aligned} \nabla_{mn}\colon \mathrm{C}_m(X)\otimes \mathrm{C}_n(Y) &\to \mathrm{C}_{m+n}(X\times Y) \\ (\sigma\otimes\tau) &\mapsto \sum_{(\mu,\nu)} \operatorname{sign}(\mu,\nu)\cdot \underbrace{(\overbrace{\sigma\circ\eta^{\mu}}^{\Delta^{m+n}\to X}\times \overbrace{\tau\circ\eta^{\nu}}^{\Delta^{m+n}\to Y})}_{\text{map }\Delta^{m+n}\to X\times Y} \end{aligned}$$

where we take the sum over all (m,n)-shuffles.

Examples.

(1) We consider the case $X=Y=\mathbb{R}$ and $m=n=1$. There exist two $(1,1)$-shuffles, namely $\{\mu_1=1,\nu_1=2\}$ and $\{\mu_1=2,\nu_1=1\}$. Note that $\eta^1\colon\Delta^2\to\Delta^1$ equals the map $[v_0,v_1,v_1]$ and that $\eta^2\colon\Delta^2\to\Delta^1$ equals the map $[v_0,v_0,v_1]$. In the figure below we illustrate $\nabla_{11}(\sigma\otimes\tau)$ for two affine linear singular 1-simplices $\sigma\colon\Delta^1\to X=\mathbb{R}$ and $\tau\colon\Delta^1\to Y=\mathbb{R}$.

(2) We consider the case $X=Y=S^1$ and $m=n=1$. Furthermore we denote by $\mu\colon\Delta^1\to S^1$ the singular 1-simplex that is given by $\mu(1-t,t)=\exp(2\pi\,\mathrm{i}t)$. On page 2201 we saw that μ represents the fundamental class of S^1 with the standard orientation. Comparing the figures on page 2204 and on page 2504 we see that the shuffle $\nabla(\mu\otimes\mu)$ is precisely the usual representative for the fundamental class of the 2-dimensional torus $S^1\times S^1=([0,1]\times[0,1])/\!\sim$.

Proposition 113.12. The maps ∇ that we had just defined have all the properties that we had mentioned in the EZ-Construction Theorem 113.2, in other words, the maps $\nabla\colon \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)\to\mathrm{C}_*(X\times Y)$ are natural chain maps that on the 0-level equal the canonical maps that we introduced on page 2491.

Proof. It follows immediately from the definition that the maps ∇_{mn} are natural and that on the 0-level they agree with the canonical maps. It is elementary (albeit rather painful) to verify that these maps are chain maps. We refer to [**Dol1956**, p. 184] and [**EMc1953**] for details and proofs. ■

Now we can finally provide the proof of Proposition 113.11.

Proof of Proposition 113.11. It suffices to prove the statement for $U=\mathbb{R}^m$ and for $V=\mathbb{R}^n$. Given any $k\in\mathbb{N}_0$ we consider the singular chain $\sigma_k=(-1)^k\cdot[v_0,\ldots,v_k,0]$.

[1375] Here we implicitly use that $\mu_0=0$ and $\mu_{m+1}=m+n+1$.

(In plain English the singular simplex $[v_0, \ldots, v_k, 0]\colon \Delta^k \to \mathbb{R}^k$ is just given by the obvious projection.) We make the following observation:

(∗) Let $z \in \mathbb{R}^k$ be any point that lies in the interior of the image of σ_k. It follows from the discussion on page 2325 that the chain σ_k represents the standard generator of $\mathrm{H}_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{z\})$.

Next we consider the (m,n)-shuffle that is given by the sets $\mu_0 = \{1, \ldots, m\}$ and by $\nu_0 = \{m+1, \ldots, m+n\}$. It follows easily from the definitions that

$$\eta^{\mu_0} = [v_0, \ldots, v_m, \ldots, v_m]\colon \Delta^{m+n} \to \Delta^m \quad \text{and} \quad \eta^{\nu_0} = [v_m, \ldots, v_m, \ldots, v_{m+n}]\colon \Delta^{m+n} \to \Delta^n.$$

Also note that it is a straightforward consequence of the definitions that we have the following equality of singular $(m+n)$-chains in $\mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$:

$$(\sigma_m \circ \eta^{\mu_0}) \times (\sigma_n \circ \eta^{\nu_0}) \;=\; (-1)^m \cdot (-1)^n \cdot [v_0, \ldots, v_{m-1}, v_m, \ldots, v_{m+n-1}, 0] \;=\; \sigma_{m+n}.$$

We pick a point $(x,y) \in \mathbb{R}^m \times \mathbb{R}^n$ that lies in the interior of the image of σ_{m+n}. Note that x lies in the interior of the image of σ_m and that y lies in the interior of the image of σ_n.

It follows from the observation (∗), the definition of the product orientation on page 2502 and the Sections Proposition 105.6 (1) that it suffices to prove the following claim.

Claim. The following equality holds in $\mathrm{H}_{m+n}(\mathbb{R}^{m+n}, \mathbb{R}^{m+n} \setminus \{(x,y)\})$:

$$[\sigma_m] \times [\sigma_n] \;=\; [\sigma_{m+n}].$$

Proof. We have

$$\begin{aligned}
[\sigma_m] \times [\sigma_n] \;&\underset{\text{Proposition 113.12 and Theorem 113.5}}{\uparrow=}\; [\nabla_{mn}(\sigma_m \otimes \sigma_n)] \;\underset{\text{by definition}}{\uparrow=}\; \Big[\sum_{(\mu,\nu)} \operatorname{sign}(\mu,\nu) \cdot (\sigma_m \circ \eta^\mu \times \sigma_n \circ \eta^\nu)\Big] \\
&\underset{\text{for all other shuffles } (\mu,\nu) \text{ the point } (x,y) \text{ does not lie in the image of } \sigma_m \circ \eta^\mu \times \sigma_n \circ \eta^\nu}{\uparrow=}\; \Big[\underbrace{\operatorname{sign}(\mu_0,\nu_0)}_{=1} \cdot \underbrace{(\sigma_m \circ \eta^{\mu_0} \times \sigma_n \circ \eta^{\nu_0})}_{=\sigma_{m+n}}\Big] \;=\; [\sigma_{m+n}].
\end{aligned}$$

This concludes the proof of the claim and thus of the proposition. ∎

113.7. **The Acyclic Model Theorems.** In this section we will prove two "Acyclic Model Theorems" which on many occasions will allow us to construct maps and homotopies. We start out with the following fairly friendly Acyclic Model Theorem. We will need this particular Acyclic Model Theorem later on in Chapter 151 when we construct Steenrod operations.

Theorem 113.13. (Acyclic Model Theorem) Let $\mathcal{T}op$ be the category of topological spaces and let $\mathcal{C}$ be the category of generalized[1376] chain complexes. Let $G\colon \mathcal{T}op \to \mathcal{C}$ be a covariant functor. Furthermore let S be a natural transformation from the functor $X \mapsto \mathrm{C}_*(X)$ to the functor $X \mapsto G(X)$. If $\mathrm{H}_i(G(\Delta^k)) = 0$ for any $k \in \mathbb{N}_0$ and any $i \in \mathbb{N}_0$, then there exists a natural chain homotopy P from S to the zero map. In other words, for any topological space X and any $k \in \mathbb{N}$ there exists a natural map $P_X\colon \mathrm{C}_k(X) \to G_{k+1}(X)$, such that for any $k \in \mathbb{N}_0$ we have

$$\partial \circ P_X + P_X \circ \partial \;=\; S_X\colon \mathrm{C}_k(X) \;\to\; G_k(X).$$

[1376] Here "generalized" just means, see page 1592, that we also allow chain groups in negative degrees.

Sketch of proof. The proof of this theorem is very similar to the "naturally chain homotopic statement" of Theorem 113.5. First recall that the fact that S is a natural transformation means that for any topological space X we get a commutative diagram as follows:

$$\begin{array}{ccccccccccccc}
\ldots & \longrightarrow & \mathrm{C}_2(X) & \xrightarrow{\partial_2} & \mathrm{C}_1(X) & \xrightarrow{\partial_1} & \mathrm{C}_0(X) & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & \ldots \\
 & & \downarrow{\scriptstyle S} & & \downarrow{\scriptstyle S} & & \downarrow{\scriptstyle S} & & \downarrow{\scriptstyle S} & & \downarrow{\scriptstyle S} & & \\
\ldots & \longrightarrow & G_2(X) & \xrightarrow{\partial_2} & G_1(X) & \xrightarrow{\partial_1} & G_0(X) & \xrightarrow{\partial_0} & G_{-1}(X) & \xrightarrow{\partial_{-1}} & G_{-2}(X) & \xrightarrow{\partial_{-2}} & \ldots
\end{array}$$

Now we consider $\mathrm{id}_{\Delta^0} \in \mathrm{C}_0(\Delta^0)$. It is a cycle in the chain complex $\mathrm{C}_*(\Delta^0)$. Since the above diagram commutes we see that $S(\mathrm{id}_{\Delta^0})$ is also cycle in $G_0(\Delta^0)$. Since we assume that $\mathrm{H}_0(G(\Delta^0)) = 0$ we see that there exists some $\mu_1 \in G_1(\Delta^0)$ with $\partial_1(\mu_1) = S(\mathrm{id}_{\Delta^0})$. Now, given any topological space X we define

$$\begin{array}{rcl}
P_0 \colon \mathrm{C}_0(X) & \to & G_1(X) \\
\sum_{i=1}^m a_i \cdot \underset{\uparrow}{f_i} & \mapsto & \sum_{i=1}^m a_i \cdot f_{i*}(\mu_1). \\
\text{map } \Delta^0 \to X & &
\end{array}$$

We iterate this procedure. Namely suppose that for $i = 0, \ldots, k-1$ we have already constructed natural maps $P_i \colon \mathrm{C}_i(X) \to G_{i+1}(X)$ such that $\partial \circ P_i + P_{i-1} \circ \partial = S_i$ for $i = 0, \ldots, k-1$. For reference we consider the following diagram:

$$\begin{array}{ccccccccccc}
\ldots & \longrightarrow & \mathrm{C}_{k+1}(X) & \xrightarrow{\partial_{k+1}} & \mathrm{C}_k(X) & \xrightarrow{\partial_k} & \mathrm{C}_{k-1}(X) & \longrightarrow & \ldots \\
 & & \downarrow{\scriptstyle S_{k+1}} & \swarrow{\scriptstyle P_k} & \downarrow{\scriptstyle S_k} & \swarrow{\scriptstyle P_k - 1} & \downarrow{\scriptstyle S_{k-1}} & & \\
\ldots & \longrightarrow & G_{k+1}(X) & \xrightarrow[\partial_{k+1}]{} & G_k(X) & \xrightarrow[\partial_k]{} & G_{k-1}(X) & \xrightarrow{\partial_{k-1}} & \ldots
\end{array}$$

Next we need to construct a suitable map P_k. We calculate that

$$\begin{array}{rcl}
\partial_k((S_k - P_{k-1} \circ \partial)(\mathrm{id}_{\Delta^k})) & = & \partial S_k(\mathrm{id}_{\Delta^k}) - \partial P_{k-1}(\partial\, \mathrm{id}_{\Delta^k}) \\
 & \underset{\uparrow}{=} & S_{k-1}(\partial\, \mathrm{id}_{\Delta^k}) - (S_{k-1} - P_{k-2}\partial)(\partial\, \mathrm{id}_{\Delta^k}) \;=\; (P_{k-2} \circ \overbrace{\partial \circ \partial}^{=0})(\mathrm{id}_{\Delta^k}) \;= 0\,. \\
 & \text{since } S \text{ is a chain map and since } \partial \circ P_{k-1} + P_{k-2} \circ \partial = S_{k-1} &
\end{array}$$

Since we assume that $\mathrm{H}_k(G(\Delta^k)) = 0$ we see that there exists some $\mu_{k+1} \in G_{k+1}(\Delta^k)$ with $\partial_{k+1}(\mu_{k+1}) = (S_k - P_{k-1} \circ \partial)(\mathrm{id}_{\Delta^k})$. Now, given any topological space X we define

$$\begin{array}{rcl}
P_k \colon \mathrm{C}_k(X) & \to & G_{k+1}(X) \\
\sum_{i=1}^m a_i \cdot \underset{\uparrow}{f_i} & \mapsto & \sum_{i=1}^m a_i \cdot f_{i*}(\mu_{k+1}). \\
\text{map } \Delta^k \to X & &
\end{array}$$

Using the fact that S is natural one can easily verify that P_k has the desired properties. ∎

The above version of the Acyclic Model Theorem will not work for the situations that we need to deal with in the near future. There are two problems with the above Acyclic Model Theorem:

(1) On several occasions we will be interested in natural transformations of the form $\mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$, but for $X = \Delta^k$ the chain complexes to the right does

not satisfy the condition that the homology groups for $X = \Delta^k$ vanish in dimensions ≥ 0.

(2) We will also need to deal with situations where to the left we have more complicated chain complexes, e.g. we might want to study natural transformations of the type $\mathrm{C}_*(X) \times \mathrm{C}_*(X) \to \mathrm{C}_*(X \times X)$.

To formulate a version of the Acyclic Model Theorem that deals with the above two issues we need a few more definitions.

Definition.

(1) An augmented chain complex is a chain complex

$$(\mathrm{C}_*, \partial_*) = \ldots \xrightarrow{\partial_3} \mathrm{C}_2 \xrightarrow{\partial_2} \mathrm{C}_1 \xrightarrow{\partial_1} \mathrm{C}_0 \to 0$$

together with an epimorphism $\epsilon \colon \mathrm{C}_0 \to \mathbb{Z}$ such that $\epsilon \circ \partial_1 \colon \mathrm{C}_1 \to \mathbb{Z}$ is the zero map.

(2) We say that an augmented chain complex $((\mathrm{C}_*, \partial_*), \epsilon \colon \mathrm{C}_0 \to \mathbb{Z})$ is acyclic if the generalized chain complex

$$\ldots \xrightarrow{\partial_3} \mathrm{C}_2 \xrightarrow{\partial_2} \mathrm{C}_1 \xrightarrow{\partial_1} \mathrm{C}_0 \xrightarrow{\epsilon} \underset{\substack{\uparrow \\ \text{degree } -1}}{\mathbb{Z}} \to 0$$

is acyclic, i.e. if all homology groups are zero.

(3) Let $((\mathrm{C}_*, \partial_*), \epsilon)$ and $((\mathrm{C}'_*, \partial'_*), \epsilon')$ be two augmented chain complexes. A chain map of augmented chain complexes is a chain map $f_* \colon C_* \to \mathrm{C}'_*$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{C}_0 & \xrightarrow{\epsilon} & \mathbb{Z} \\ {\scriptstyle f_0}\downarrow & & \downarrow{\scriptstyle =} \\ \mathrm{C}'_0 & \xrightarrow{\epsilon'} & \mathbb{Z}. \end{array}$$

(4) We refer to the category $\mathcal{A}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{A}) &= \text{augmented chain complexes} \\ \mathrm{Mor}((C, \epsilon), (C', \epsilon')) &= \text{set of chain maps of augmented chain complexes from } (C, \epsilon) \text{ to } (C', \epsilon') \end{aligned}$$

as the category of augmented chain complexes.

Examples.

(1) Let X be a non-empty topological space. We denote by $\epsilon_X \colon C_0(X) \to \mathbb{Z}$ the augmentation map that we introduced on page 1590, i.e. ϵ_X is the map that sends each singular 0-simplex to 1. It follows from Lemma 72.4 (1) that $(C_*(X), \epsilon_X)$ is an augmented chain complex. If X is a contractible topological space, e.g. if $X = \Delta^k$, then it follows from the Reduced Homology Lemma 74.1 (7) that the corresponding augmented chain complex is acyclic.

(2) If (C_*, μ) and (D_*, ν) are two augmented chain complexes then the tensor product $C_* \otimes D_*$ of chain complexes, as defined in Lemma 90.2, together with the map

$$\begin{aligned} \mu \otimes \nu \colon (C_* \otimes D_*)_0 = C_0 \otimes D_0 &\to \mathbb{Z} \\ \sum_{i=1}^k c_i \otimes d_i &\mapsto \sum_{i=1}^k \mu(c_i) \cdot \nu(d_i) \end{aligned}$$

is easily seen to be an augmented chain complex.[1377]

Definition. We say a chain complex C_* is almost acyclic if $\mathrm{H}_i(C_*) = 0$ for $i \geq 1$ and if $\mathrm{H}_0(C_*) \cong \mathbb{Z}$.

Example. If X is a contractible topological space, then it follows from the Homotopy Equivalence-H_*-Corollary 73.9 that $\mathrm{C}_*(X)$ is almost acyclic.

Proposition 113.14. Let C_* and D_* be two chain complexes. If C_* and D_* are almost acyclic and if C_* is free, i.e. if each chain group C_n is a free abelian group, then $C_* \otimes D_*$ is also almost acyclic.

Proof. Let $n \in \mathbb{N}_0$. Since C_* is free we can apply the Künneth Theorem for Chain Complexes 90.7 which gives us the following short exact sequence:

$$0 \to \bigoplus_{p+q=n} \mathrm{H}_p(C_*) \otimes \mathrm{H}_q(D_*) \xrightarrow{\Theta} \mathrm{H}_n(C_* \otimes D_*) \to \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p(C_*), \mathrm{H}_q(D_*)) \to 0.$$

The proposition is an immediate consequence of this short exact sequence and of some very elementary statements regarding tensor products and torsion groups, see the Tensor Lemma 89.3 and 89.15. ■

The following lemma gives a convenient criterion for showing that augmented chain complexes are acyclic.

Lemma 113.15. Let $((\mathrm{C}_*, \partial_*), \epsilon)$ be an augmented chain complex. If the chain complex $(\mathrm{C}_*, \partial_*)$ is almost acyclic, then the augmented chain complex $((\mathrm{C}_*, \partial_*), \epsilon)$ is acyclic.

Proof. We denote by $\widetilde{C}_*$ the generalized chain complex

$$\ldots \xrightarrow{\partial_3} \mathrm{C}_2 \xrightarrow{\partial_2} \mathrm{C}_1 \xrightarrow{\partial_1} \mathrm{C}_0 \xrightarrow{\epsilon} \!\!\!\rightarrow \mathbb{Z} \longrightarrow 0.$$

We need to show that this chain complex is acyclic. It is clear that for $i \geq 1$ we have $\mathrm{H}_i(\widetilde{C}_*) = \mathrm{H}_i(C_*) = 0$. It remains to show that $\mathrm{H}_0(\widetilde{C}_*) = 0$. Since $\mathbb{Z}$ is a free abelian group and since $\epsilon\colon \mathrm{C}_0 \to \mathbb{Z}$ is an epimorphism we can pick a map $s\colon \mathbb{Z} \to \mathrm{C}_0$ with $\epsilon \circ s = \mathrm{id}_{\mathbb{Z}}$. As in the Reduced Homology Lemma 74.1 (4) one can easily show that the map

$$\begin{array}{rcl} \mathrm{H}_0(\widetilde{C}_*) \oplus \mathbb{Z} & \to & \mathrm{H}_0(C_*) \\ [\sigma] \oplus n & \mapsto & [\sigma] + s(n) \end{array}$$

is an isomorphism. Since $\mathrm{H}_0(C_*) \cong \mathbb{Z}$ it follows from Exercise 51.3 (b) (see also more generally Proposition 51.11) that $\mathrm{H}_0(\widetilde{C}_*) = 0$. ■

Definition. Let $\mathcal{K}$ be a category (in all applications $\mathcal{K}$ will be the category of non-empty topological spaces or the category of tuples of non-empty topological spaces) and let

[1377] Indeed, by definition $(C_* \otimes D_*)_1$ is generated by elements $c_1 \otimes d_0$ with $c_1 \in C_1$ and $d_0 \in D_0$ and by elements $c_0 \otimes d_1$ with $c_0 \in C_0$ and $d_1 \in D_1$. We calculate that

$$((\mu \otimes \nu) \circ \partial_1)(c_1 \otimes d_0) = (\mu \otimes \nu)(\partial c_1 \otimes d_0 + (-1)^1 \cdot c_1 \otimes \underbrace{\partial d_0}_{=0}) = (\mu \otimes \nu)(\partial c_1 \otimes d_0) = \mu(\partial c_1) \cdot \nu(d_0) = 0 \cdot \nu(d_0) = 0.$$

The same argument shows that $((\mu \otimes \nu) \circ \partial_1)(c_0 \otimes d_1) = 0$.

$F\colon \mathcal{K} \to \mathcal{A}$ be a covariant functor from $\mathcal{K}$ to the category $\mathcal{A}$ of augmented chain complexes. Let $\mathcal{M}$ be a collection of objects of $\mathcal{K}$.

(1) We say the functor F is acyclic relative to $\mathcal{M}$ if given any $X \in \mathcal{M}$ the augmented chain complex $F(X)$ is acyclic.
(2) We say the functor F is free relative to $\mathcal{M}$ if for each $k \in \mathbb{N}_0$ there exists $\mathcal{M}_k \subset \mathcal{M}$ and if for each $M \in \mathcal{M}_k$ there exists an element $\sigma_M \in F_k(M)$[1378] such that given any $X \in \mathcal{K}$ the following two statements hold:
   (a) The set
$$\{\underbrace{F(f)}_{\uparrow}(\sigma_M) \in F_k(X) \mid \ M \in \mathcal{M}_k \text{ and } f \in \operatorname{Mor}(M,X)\}$$
morphism $f\colon M \to X$ induces a homomorphism $F(f)\colon F_k(M) \to F_k(X)$
   is a basis for the abelian group $F_k(X)$.[1379]
   (b) The description of the set in (a) has no double elements, much more precisely, for $(M,f) \neq (M',f')$ we have $F(f)(\sigma_M) \neq F(f')(\sigma_{M'})$.

Remark. The objects in a collection $\mathcal{M}$ as in the previous definition are often called *models*.

The definition of "free relative to $\mathcal{M}$" is arguably somewhat intimidating. The following example should convince the reader that in practice it is not that bad.

Example. Let $\mathcal{K}$ be the category of non-empty topological spaces and let F be the covariant functor that assigns to each $X \in \mathcal{K}$ the augmented singular chain complex $(C_*(X), \epsilon_X)$. We consider
$$\mathcal{M} \ := \ \{\Delta^k \mid k \in \mathbb{N}_0\} \ = \ \text{the set of all standard simplices.}$$
We claim that F is acyclic and free relative to $\mathcal{M}$:

(1) By the Reduced Homology Lemma 74.1 (7) we know that for every $k \in \mathbb{N}_0$ we have $\widetilde{\mathrm{H}}_*(\Delta^k) = 0$. But by Lemma 113.15 this just means that $\mathcal{M}$ is acyclic relative to F.
(2) Let $k \in \mathbb{N}_0$. We set $\mathcal{M}_k = \{\Delta^k\}$ and we consider $\sigma_k = \mathrm{id}_{\Delta^k} \in \mathrm{C}_k(\Delta^k)$. Now recall that given any topological space X and given any $k \in \mathbb{N}_0$ we have
$$\begin{aligned} \mathrm{C}_k(X) &\overset{\text{by definition of } \mathrm{C}_k(X), \text{ see page 1583}}{=} \text{free abelian group generated by the set of singular } k\text{-simplices in } X \\ &= \text{free abelian group generated by the set of all maps } \underbrace{f\colon \Delta^k \to X}_{=f_*(\mathrm{id}_{\Delta^k})}. \end{aligned}$$
by definition of a singular k-simplex, see page 1583
   But this means that the set $\{f_*(\mathrm{id}_{\Delta^k})\}_{f\colon \Delta^k \to X}$ is a basis for $\mathrm{C}_k(X)$.

Now we can formulate the main theorem of this section.

Theorem 113.16. (Acyclic Model Theorem) Let $\mathcal{K}$ be a category with a collection of objects $\mathcal{M}$. Furthermore let $F, G\colon \mathcal{K} \to \mathcal{A}$ be two covariant functors from $\mathcal{K}$ to the

[1378] Here $F_k(M)$ is the k-chain group of the chain complex $F(M)$.
[1379] In particular this implies that each $F_k(X)$ is a free abelian group.

category of augmented chain complexes. If F is free relative to $\mathcal{M}$ and if G is acyclic relative to $\mathcal{M}$, then the following statements hold:

(1) There exists a natural transformation T from F to G. In other words, given any object X of $\mathcal{K}$ we have a chain map $T_X\colon F(X) \to G(X)$ of augmented chain complexes such that for any morphism $f\colon X \to Y$ in $\mathcal{K}$ the following diagram commutes:[1380]

$$\begin{array}{ccc} F(X) & \xrightarrow{F(f)} & F(Y) \\ {\scriptstyle T_X}\downarrow & & \downarrow{\scriptstyle T_Y} \\ G(X) & \xrightarrow{G(f)} & G(Y). \end{array}$$

(2) Given two natural transformations S_X and T_X from F to G there is a natural chain homotopy P_X between them.

Proof. The proof is, ultimately very much the same as the proof of Theorem 113.5. We decline to provide a proof and we follow the lead given by Munkres [**Mun1984**, p. 185], namely like Munkres we assign the proof as an exercise to the reader. Alternatively the reader can find the proof in [**Spa1995**, p. 169], [**Vic1994**, Theorem 5.3] or [**Dol1980**, p. 175]. ■

As an example for the Acyclic Model Theorem 113.16 we will prove a statement that we will anyway need shortly. To formulate the application we need the following definition.

Definition. A diagonal approximation is a natural chain map

$$\varphi\colon \mathrm{C}_*(X) \ \to \ \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$$

such that for each $x \in X$, viewed as a singular 0-simplex, we have

$$\varphi(x) \ = \ x \otimes x \ \in \ \underbrace{\mathrm{C}_0(X) \otimes \mathrm{C}_0(X)}_{=(\mathrm{C}_*(X)\otimes \mathrm{C}_*(X))_0}.$$

Proposition 113.17. (Diagonal Approximation Uniqueness Proposition) Given any two diagonal approximations Φ and Ψ there exists a natural chain homotopy equivalence between Φ and Ψ.

Proof. We let $\mathcal{K}$ be the category of non-empty topological spaces. As on page 2509 we consider the collection

$$\mathcal{M} \ := \ \{\Delta^k \,|\, k \in \mathbb{N}_0\} \ = \ \text{the set of all standard simplices.}$$

We consider the covariant functors[1381]

$$\begin{array}{rcl} F\colon \mathcal{K} & \to & \mathcal{A} \\ X & \mapsto & (\mathrm{C}_*(X), \epsilon_X) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{K} & \to & \mathcal{A} \\ X & \mapsto & (\mathrm{C}_*(X) \otimes \mathrm{C}_*(X), \epsilon_X \otimes \epsilon_X). \end{array}$$

Now let $\Phi, \Psi\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ be two diagonal approximations. By definition these are natural transformations from F to G. The hypothesis that Φ and Ψ are diagonal approximations implies that Φ and Ψ define chain maps of augmented chain complexes.

By the Acyclic Model Theorem 113.16 (2) it remains to prove the following claim.

[1380] Note that the zero map is *not* a chain map of augmented chain complexes, since it does not respect the augmentation.

[1381] It follows from the discussion on page 2507 that both F and G are indeed functors to the category of augmented chain complexes.

Claim.

(1) The functor F is free relative to $\mathcal{M}$.
(2) The functor G is acyclic relative to $\mathcal{M}$.

Proof.

(1) Conveniently enough we showed on page 2509 that F is free relative to $\mathcal{M}$.
(2) We need to show that given any $k \in \mathbb{N}_0$ the corresponding augmented chain complex $(\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k), \epsilon_X \otimes \epsilon_X)$ is acyclic. By Lemma 113.15 it suffices to show that the chain complex $\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k)$ is almost acyclic. But this is a consequence of the fact that $\mathrm{C}_*(\Delta^k)$ is almost acyclic, see page 2508, and Proposition 113.14. ■

Exercises for Chapter 113.

Exercise 113.1. Let M and N be topological manifolds and let $\varphi \in \mathrm{H}_k(M)$ and $\psi \in \mathrm{H}_l(N)$. If φ is realized by a closed oriented k-dimensional submanifold A and if ψ is realized by a closed oriented l-dimensional submanifold B, then the cross product $\varphi \times \psi \in \mathrm{H}_{k+l}(M \times N)$ is realized by the closed $(k+l)$-dimensional submanifold $A \times B$.

Exercise 113.2. Let X and Y be topological spaces. Show that for any $\sigma \in \mathrm{H}_0(X)$ and $\tau \in \mathrm{H}_0(X)$ we have

$$\epsilon_X(\sigma) \cdot \epsilon_Y(\tau) \;=\; \epsilon_{X \times Y}(\sigma \times \tau).$$

Here the maps ϵ are as always the various augmentation maps.

Exercise 113.3. Let M be the Möbius band. We consider the 3-dimensional topological manifold $M \times [0,1]$.

(a) What is the homeomorphism type of $\partial(M \times [0,1])$?
(b) Is the topological manifold $M \times [0,1]$ orientable?

Exercise 113.4. Let $f\colon A \to M$ and $g\colon B \to N$ be maps between closed oriented connected non-empty topological manifolds with $\dim(A) = \dim(M)$ and $\dim(B) = \dim(N)$. We consider the degree of maps between closed oriented connected non-empty topological manifolds of the same dimension as defined on page 2379. Show that

$$\deg(f \times g\colon A \times B) \;=\; \deg(f\colon A \to M) \cdot \deg(g\colon B \to N).$$

Remark. For smooth manifolds we gave a very very different proof in Exercise 38.17.

114. The cup product

114.1. **A first definition of the cup product.** Let X be a topological space. The cross product from page 2498 applied to the same topological spaces $X = Y$ gives us in particular the cross product[1382]

$$\begin{array}{rcl} \times\colon \overbrace{\mathrm{H}_p(\mathrm{C}_*(X)) \otimes \mathrm{H}_q(\mathrm{C}_*(X))}^{=\mathrm{H}_p(X)\otimes\mathrm{H}_q(X)} & \to & \mathrm{H}_{p+q}(\mathrm{C}_*(X)\otimes\mathrm{C}_*(X)) \xrightarrow{\Upsilon_*} \overbrace{\mathrm{H}_{p+q}(\mathrm{C}_*(X\times X))}^{=\mathrm{H}_{p+q}(X\times X)}. \\ [c]\otimes[d] & \mapsto & [c\otimes d]. \end{array}$$

This is very nice, but this construction does not give us a product on the homology groups of X itself, since we end up in the homology of a different topological space.
Now we try our luck with cohomology groups. Before we can study maps on cohomology groups we need a little bit of algebraic preparation.

Definition. Let $\mathcal{C}_*$ and $\mathcal{D}_*$ be chain complexes.

(1) Given $p, q \in \mathbb{N}_0$ we denote by

$$\Pi_{p,q}\colon (\mathcal{C}_* \otimes \mathcal{D}_*)_{p+q} = \bigoplus_{i+j=p+q} \mathcal{C}_i \otimes \mathcal{D}_j \to \mathcal{C}_p \otimes \mathcal{D}_q$$

the natural projection.

(2) Let R be a commutative ring. We denote by Ξ the map

$$\begin{array}{l} \mathrm{Hom}(\mathcal{C}_p, R)\times\mathrm{Hom}(\mathcal{D}_q, R) \to \mathrm{Hom}((\mathcal{C}\otimes\mathcal{D})_{p+q}, R) \\ (\varphi,\psi) \mapsto \left((\mathcal{C}_*\otimes\mathcal{D}_*)_{p+q} \xrightarrow{\Pi_{p,q}} \mathcal{C}_p\otimes\mathcal{D}_q \xrightarrow{\varphi\otimes\psi} R\otimes R \to R,\ a\otimes b \mapsto a\cdot b \right). \end{array}$$

Lemma 114.1. Let $\mathcal{C}_*$ and $\mathcal{D}_*$ be chain complexes. For any commutative ring R the map

$$\begin{array}{rcl} \mathrm{H}^p(\mathcal{C}_*; R) \times \mathrm{H}^q(\mathcal{D}; R) & \to & \mathrm{H}^{p+q}(\mathcal{C}_*\otimes\mathcal{D}_*; R) \\ ([\varphi],[\psi]) & \mapsto & [\Xi(\varphi,\psi)] \end{array}$$

is well-defined.

Proof. We leave the verification of the lemma to the reader. ∎

We return to topology. So let X be a topological space. We consider the map[1383]

$$\begin{array}{rcl} \overbrace{\mathrm{H}^p(X;\mathbb{Z})\otimes\mathrm{H}^q(X;\mathbb{Z})}^{=\mathrm{H}^p(X;\mathbb{Z})\otimes\mathrm{H}^q(X;\mathbb{Z})} & \xrightarrow{\Xi} & \mathrm{H}^{p+q}(\mathrm{C}_*(X)\otimes\mathrm{C}_*(X);\mathbb{Z}) \xrightarrow{\Theta^*} \overbrace{\mathrm{H}^{p+q}(\mathrm{C}_*(X\times X);\mathbb{Z})}^{=\mathrm{H}^{p+q}(X\times X;\mathbb{Z})}. \\ [\varphi]\otimes[\psi] & \mapsto & [\varphi\otimes\psi\circ\Pi_{p,q}]. \end{array}$$

Summarizing we get a map

$$\mathrm{H}^p(X;\mathbb{Z}) \otimes \mathrm{H}^q(X;\mathbb{Z}) \to \mathrm{H}^{p+q}(X\times X;\mathbb{Z})$$

which is sometimes called the *cross product on cohomology*. Again, this is nice, but exactly as in the case of the cross product on homology, we end up in the cohomology of $X \times X$, but we really would like to end up in the cohomology of X.

[1382] Here $\Upsilon\colon \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y) \to \mathrm{C}_*(X\times Y)$ denotes the Eilenberg-Zilber map from Theorem 113.1.

[1383] Here $\Theta\colon \mathrm{C}_*(X\times Y) \to \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y)$ denotes the Eilenberg-Zilber map from Theorem 113.1 (1). It follows from Theorem 113.1 (2) and the Dual Cochain Map Lemma 108.8 (3) that the definition below does not depend on the choice of Θ.

Now we have to find a way how to go back from the topological space $X \times X$ to the original space X. In general there does not exist an "interesting"[1384] map $X \times X \to X$. But, as we saw before, there does exist an interesting map in the opposite direction, namely the diagonal map

$$\begin{array}{rcl} d\colon X & \to & X \times X \\ x & \mapsto & (x,x). \end{array}$$

This diagonal map d induces a map

$$d_*\colon \mathrm{H}_*(X;\mathbb{Z}) \to \mathrm{H}_*(X \times X;\mathbb{Z})$$

on homology, and, much more interesting in our context, it also induces a map

$$d^*\colon \mathrm{H}^*(X \times X;\mathbb{Z}) \to \mathrm{H}^*(X;\mathbb{Z}).$$

on cohomology groups that goes in the "opposite direction". This discussion leads us to the following definition.

Definition. Let X be a topological space. We define the cup product[1385] on the cohomology groups of X as the composition of the following maps:

$$\mathrm{H}^p(X;\mathbb{Z}) \times \mathrm{H}^q(X;\mathbb{Z}) \to \mathrm{H}^p(X;\mathbb{Z}) \otimes \mathrm{H}^q(X;\mathbb{Z}) \xrightarrow{\Theta^* \circ \Xi} \mathrm{H}^{p+q}(X \times X;\mathbb{Z}) \xrightarrow{d^*} \mathrm{H}^{p+q}(X;\mathbb{Z}).$$

For the resulting pairing we use the notation

$$\begin{array}{rcl} \mathrm{H}^p(X;\mathbb{Z}) \times \mathrm{H}^q(X;\mathbb{Z}) & \to & \mathrm{H}^{p+q}(X;\mathbb{Z}) \\ (a,b) & \mapsto & a \mathbin{\widetilde{\cup}} b \end{array}$$

and we refer to $a \mathbin{\widetilde{\cup}} b$ as the cup product of a and b.

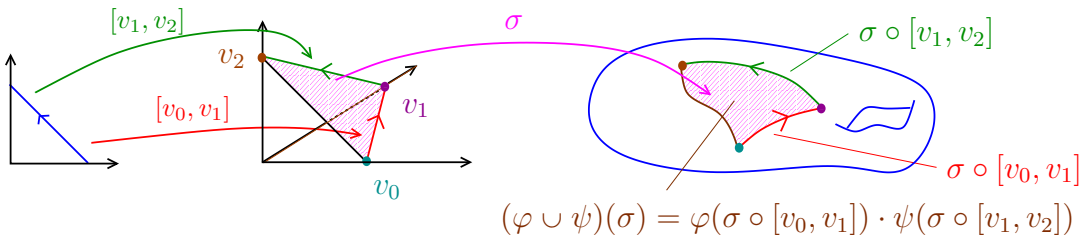
114.2. **An alternative definition of the cup product.** The definition of the cup product in the previous section was very natural and we could now develop the theory of the cup product using that definition. If one takes that route then one has to deal with the awkward fact that the Eilenberg-Zilber map Θ is not very explicit.
Now we give an alternative definition of the cup product which is more ad hoc, but which works surprisingly well in practice.

Definition. Let X be a topological space and let R be a commutative ring. Furthermore let $\varphi \in \mathrm{C}^p(X;R)$ and $\psi \in \mathrm{C}^q(X;R)$ be cochains. We define the cup product of φ and ψ to be the singular cochain[1386]

$$\varphi \cup \psi\colon \mathrm{C}_{p+q}(X) \to R$$

that is given by

$$(\sigma\colon \Delta^{p+q} \to X) \mapsto \underbrace{\varphi(\sigma \circ [v_0,\ldots,v_p])}_{\in R} \cdot \underbrace{\psi(\sigma \circ [v_p,\ldots,v_{p+q}])}_{\in R}.$$



The[1387] cup product thus defines a map

$$\cup\colon \mathrm{C}^p(X;R) \times \mathrm{C}^q(X;R) \to \mathrm{C}^{p+q}(X;R).$$

[1384]The projection from $X \times X$ onto one of the two factors does not count as "interesting", since it does not "mix" the two factors. In fact in Exercise 114.1 we will see that the map

$$\mathrm{H}_*(X) \otimes \mathrm{H}_*(X) \xrightarrow{\times} \mathrm{H}_*(X \times X) \xrightarrow{p_*} \mathrm{H}_*(X),$$

where $p\colon X \times X \to X$ denotes the projection on the first factor, is the zero map.
[1385]The name "cup product" comes from the notation "$a \mathbin{\widetilde{\cup}} b$" for the composition since $\cup$ looks like a cup.

Remark. The sign conventions for the cup product for cohomology classes $\varphi \in \mathrm{H}^p(X; R)$ and $\psi \in \mathrm{H}^q(X; R)$ differ in the literature. More precisely, given a topological space X and cochains $\varphi \in \mathrm{C}^p(X; R)$ and $\psi \in \mathrm{C}^q(X; R)$ the cup product $\varphi \cup \psi$, applied to a singular $(p+q)$-simplex $\sigma\colon \Delta^{p+q} \to X$ is defined as follows:

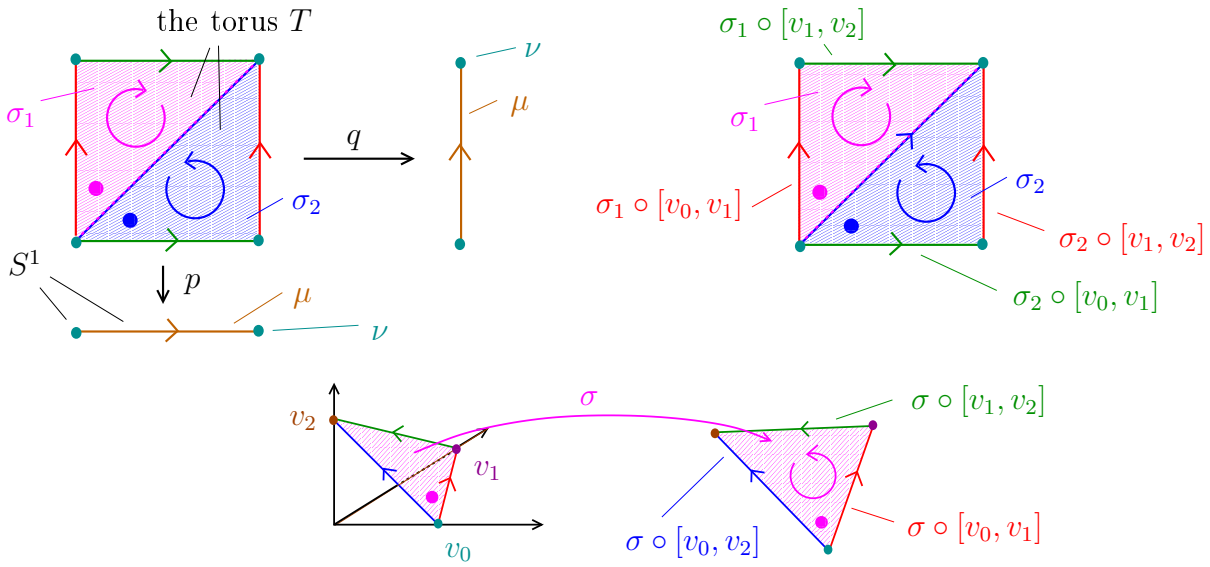
		$(\varphi \cup \sigma)(\sigma)$
(a)	Hatcher [**Hat2002**, p. 206]	$\varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])$
(b)	Bredon [**Bre1993**, p. 328]	$(-1)^{pq} \cdot \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])$
(c)	Dold [**Dol1956**, p. 222]	$(-1)^{pq} \cdot \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])$
(d)	Spanier [**Spa1995**, p. 251]	$\varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])$
(e)	Munkres [**Mun1984**, p. 288]	$\varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])$
(f)	Greenberg-Harper [**GrH1981**, p. 195]	$\varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])$

So we see that our sign convention agrees with the conventions of Hatcher, Spanier, Munkres and Greenberg-Harper, but they differ by the sign $(-1)^{pq}$ from the conventions used in Bredon and Dold.

Example. Since the second definition of the cup product is initially strange and not very intuitive we consider an example in slightly more detail. In the following we consider the torus $T = S^1 \times S^1 = ([0,1] \times [0,1])/\sim$ with the two singular 2-simplices σ_1 and σ_2 illustrated in the figure on page 2515 which we already saw in the figure on page 2204. We recall the following notation:

(1) we denote by p respectively q the projection $S^1 \times S^1 \to S^1$ onto the first respectively second factor,
(2) we denote by $\mu\colon \Delta^1 \to S^1$ the singular 1-simplex given by $\mu(1-t, t) = \exp(2\pi\,\mathrm{i}t)$,
(3) furthermore we denote by $\nu\colon \Delta^1 \to S^1$ the constant singular 1-simplex that is given by $\nu(1-t, t) = 1$.
(4) finally we recall that on page 2404 we introduced a cochain $\theta := \theta_{\mathbb{Z}} \in \mathrm{C}^1; \mathbb{Z})$ and we showed that $\theta(\mu) = 1$, also note that $\theta(\nu) = 0$.

[1386]Here, when we write $[v_0, \ldots, v_p]\colon \Delta^p \to \Delta^{p+q}$ and $[v_p, \ldots, v_{p+q}]\colon \Delta^q \to \Delta^{p+q}$, we use the notation from page 2503.
[1387]In the literature, given a singular n-simplex $\sigma\colon \Delta^n \to X$ one often writes ${}_p\lfloor\sigma = \sigma \circ [v_0, \ldots, v_p]$ and $\sigma\rfloor_p = \sigma \circ [v_{n-p}, \ldots, v_n]$.



We want to determine the values of $p^*(\theta) \cup q^*(\theta) \in \mathrm{C}^2(T;\mathbb{Z}) = \mathrm{Hom}(\mathrm{C}_2(T),\mathbb{Z})$ on the singular 2-simplices σ_1 and σ_2. We have

$$\begin{aligned}(p^*(\theta) \cup q^*(\theta))(\sigma_1) &= p^*(\theta)(\sigma_1 \circ [v_0,v_1]) \cdot q^*(\theta)(\sigma_1 \circ [v_1,v_2]) \\ &= \theta(\underbrace{p \circ \sigma_1 \circ [v_0,v_1]}_{=\nu}) \cdot \theta(\underbrace{q \circ \sigma_1 \circ [v_1,v_2]}_{=\nu}) \quad = \quad 0 \cdot 0 \quad = \quad 0.\end{aligned}$$

Much more interestingly we have

$$\begin{aligned}(p^*(\theta) \cup q^*(\theta))(\sigma_2) &= p^*(\theta)(\sigma_2 \circ [v_0,v_1]) \cdot q^*(\theta)(\sigma_2 \circ [v_1,v_2]) \\ &= \theta(\underbrace{p \circ \sigma_2 \circ [v_0,v_1]}_{=\mu}) \cdot \theta(\underbrace{q \circ \sigma_2 \circ [v_1,v_2]}_{=\mu}) \quad = \quad 1 \cdot 1 \quad = \quad 1.\end{aligned}$$

To aid the reader we also recall in the figure below the notation that we had initially introduced on page 2203 and that we use in the figure on page 2515.

The definition of the cup product on cochains might look strange and arbitrary. But the following lemma shows that it behaves well with respect to coboundary maps.

Lemma 114.2. (Coboundary-Cup Product Lemma) Let X be a topological space and let R be a commutative ring. Furthermore let $\varphi \in \mathrm{C}^p(X;R)$ and $\psi \in \mathrm{C}^q(X;R)$. Then

$$\delta(\varphi \cup \psi) \quad = \quad \delta\varphi \cup \psi \; + (-1)^p \cdot \varphi \cup \delta\psi \quad \in \quad \mathrm{C}^{p+q+1}(X;R).$$

Remark. Note that a similar looking statement holds for differential forms. More precisely, given a smooth manifold M and two differential forms $\omega \in \Omega^p(M)$ and $\eta \in \Omega^q(M)$ it follows from the Differentials-on-Smooth Manifolds Proposition **??** (1) that

$$d(\omega \wedge \eta) \quad = \quad d\omega \wedge \eta \; + \; (-1)^p \cdot \omega \wedge d\eta \quad \in \quad \Omega^{p+q+1}(M).$$

The (co-) boundary formula of Coboundary-Cup Product Lemma 114.2 is of course also very similar to the definition of the boundary map in the tensor product of two chain complexes.

Proof. The lemma follows from an elementary, albeit slightly confusing, calculation. Indeed, let $\varphi \in \mathrm{C}^p(X;R)$ and $\psi \in \mathrm{C}^q(X;R)$ be cochains. We have to prove the following

equality:

$$\delta(\varphi\cup\psi) \;=\; \delta\varphi\cup\psi \,+(-1)^p\cdot\varphi\cup\delta\psi \;\in\; \mathrm{C}^{p+q+1}(X;R)=\mathrm{Hom}(\mathrm{C}_{p+q+1}(X),R).$$

So let $\sigma\colon \Delta^{p+q+1}\to X$ be a singular $(p+q+1)$-simplex. We have the following three equalities in R:[1388]

$$\begin{aligned}
\text{(a)}\quad (\delta(\varphi\cup\psi))(\sigma) &= (\varphi\cup\psi)\Big(\sum_{j=0}^{p+q+1}(-1)^j\cdot\sigma\circ i_j^{p+q+1}\Big)\\
&= (\varphi\cup\psi)\Big(\sum_{j=0}^{p}(-1)^j\cdot\sigma\circ i_j^{p+q+1}\Big)+(\varphi\cup\psi)\Big(\sum_{j=p+1}^{p+q+1}(-1)^j\cdot\sigma\circ i_j^{p+q+1}\Big)\\
&= \sum_{j=0}^{p}(-1)^j\cdot(\varphi\cup\psi)(\sigma\circ i_j^{p+q+1})+(-1)^p\cdot\sum_{k=1}^{q+1}(-1)^k\cdot(\varphi\cup\psi)(\sigma\circ i_{k+p}^{p+q+1})\\
&= \sum_{j=0}^{p}(-1)^j\cdot\varphi(\underbrace{\sigma\circ[v_0,\dots,v_{p+1}]\circ i_j^{p+1}}_{\text{map }\Delta^p\to X})\cdot\psi(\underbrace{\sigma\circ[v_{p+1},\dots,v_{p+q+1}]}_{\text{map }\Delta^q\to X})\\
&\quad+(-1)^p\cdot\sum_{k=1}^{q+1}(-1)^k\cdot\varphi(\underbrace{\sigma\circ[v_0,\dots,v_p]}_{\text{map }\Delta^p\to X})\cdot\psi(\underbrace{\sigma\circ[v_p,\dots,v_{p+q+1}]\circ i_k^{q+1}}_{\text{map }\Delta^q\to X}).
\end{aligned}$$

$$\begin{aligned}
\text{(b)}\quad (\delta\varphi\cup\psi)(\sigma) &= (\delta\varphi)(\sigma\circ[v_0,\dots,v_{p+1}])\cdot\psi(\sigma\circ[v_{p+1},\dots,v_{p+q+1}])\\
&= \varphi\Big(\sum_{j=0}^{p+1}(-1)^j\cdot\underbrace{\sigma\circ[v_0,\dots,v_{p+1}]\circ i_j^{p+1}}_{\text{map }\Delta^p\to X}\Big)\cdot\psi(\underbrace{\sigma\circ[v_{p+1},\dots,v_{p+q+1}]}_{\text{map }\Delta^q\to X})\\
&= \sum_{j=0}^{p+1}(-1)^j\cdot\varphi(\sigma\circ[v_0,\dots,v_{p+1}]\circ i_j^{p+1})\cdot\psi(\sigma\circ[v_{p+1},\dots,v_{p+q+1}])
\end{aligned}$$

and

$$\begin{aligned}
\text{(c)}\quad (-1)^p\cdot(\varphi\cup\delta\psi)(\sigma) &= (-1)^p\cdot\varphi(\sigma\circ[v_0,\dots,v_p])\cdot(\delta\psi)(\sigma\circ[v_p,\dots,v_{p+q+1}])\\
&= (-1)^p\cdot\varphi(\underbrace{\sigma\circ[v_0,\dots,v_p]}_{\text{map }\Delta^p\to X})\cdot\psi\Big(\sum_{k=0}^{q+1}(-1)^k\cdot\underbrace{\sigma\circ[v_p,\dots,v_{p+q+1}]\circ i_k^{q+1}}_{\text{map }\Delta^q\to X}\Big)\\
&= (-1)^p\cdot\sum_{k=0}^{q+1}(-1)^k\cdot\varphi(\sigma\circ[v_0,\dots,v_p])\cdot\psi(\sigma\circ[v_p,\dots,v_{p+q+1}]\circ i_k^{q+1}).
\end{aligned}$$

Now we observe that if we take the sum of (b) and (c), then the $(j=p+1)$-summand in (b) cancels with the $(k=0)$-summand in (c). But after this observation it is obvious that the desired equality (b)+(c)=(a) holds. ■

Lemma 114.3. Let X be a topological space and let R be a commutative ring. Then the map

$$\begin{aligned}\cup\colon \mathrm{H}^p(X;R)\times\mathrm{H}^q(X;R) &\to \mathrm{H}^{p+q}(X;R)\\ ([\varphi],[\psi])] &\mapsto [\varphi]\cup[\psi]:=[\varphi\cup\psi]\end{aligned}$$

is well-defined.

Definition. We refer to the pairing of Lemma 114.3 also as the cup product.

As we will see, the proof of Lemma 114.3 is basically identical to the proof of Proposition **??**.

[1388]Here in the argument we use on several occasions that for a singular n-cochain ϕ and a singular $(n+1)$-simplex μ we have by definition

$$(\delta\phi)(\mu) \;=\; \phi(\partial\mu) \;=\; \phi\Big(\sum_{l=0}^{n+1}(-1)^l\cdot\mu\circ i_l^{n+1}\Big).$$

Proof. Let $\varphi \in \mathrm{C}^p(X;R)$ and $\psi \in \mathrm{C}^q(X;R)$ be cocycles.

(1) It follows immediately from Coboundary-Cup Product Lemma 114.2 that $\varphi \cup \psi$ is again a cocycle.

(2) If $\varphi' = \varphi + \delta\tau$ is another representative of $[\varphi]$, then

$$\varphi' \cup \psi - \varphi \cup \psi \underset{\uparrow}{=} (\varphi' - \varphi) \cup \psi = \delta\tau \cup \psi \underset{\uparrow}{=} \delta(\tau \cup \psi).$$

since "$\cup$" is clearly bilinear; by Coboundary-Cup Product Lemma 114.2 and since $\delta\psi = 0$

This shows that $\varphi \cup \psi$ and $\varphi' \cup \psi$ represent the same cohomology class, i.e. the cup product does not depend on the choice of the representative of the cohomology class of the first entry.

(3) The proof that the cup product does not depend on the choice of the representative of the second cohomology class is basically the same as the proof of (2). ■

The following proposition now says that the original definition of the cup product and the new definition actually agree.

Proposition 114.4. (Definitions-Cup Product Proposition) Let X be a topological space. Then for any $\varphi \in \mathrm{H}^p(X;\mathbb{Z})$ and any $\psi \in \mathrm{H}^q(X;\mathbb{Z})$ we have

$$\varphi \mathbin{\widetilde{\cup}} \psi = \varphi \cup \psi \in \mathrm{H}^{p+q}(X;\mathbb{Z}).$$

In the proof of the Definitions-Cup Product Proposition 114.4 we need the following definition and the subsequent lemma.

Definition. A diagonal approximation consists of a natural chain map

$$\Phi\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$$

for each topological space X, such that for each $x \in X$, viewed as a singular 0-simplex, the following equality holds in $(\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))_0 = \mathrm{C}_0(X) \otimes \mathrm{C}_0(X)$:

$$\Phi(x) = x \otimes x.$$

Example. Given any topological space X we denote by $d\colon X \to X \times X$ the diagonal map given by $d(x) = (x,x)$. Then the induced chain maps

$$\Theta \circ d_*\colon \mathrm{C}_*(X) \xrightarrow{d_*} \mathrm{C}_*(X \times X) \underset{\uparrow}{\xrightarrow{\Theta}} \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$$

Eilenberg-Zilber map from Theorem 113.1

form a diagonal approximation in the above sense.

The following lemma gives another diagonal approximation which will be very useful for doing actual calculations.

Lemma 114.5. (Alexander-Whitney Lemma) Given any topological space X we consider the map

$$\Delta\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$$

which for each singular n-simplex $\sigma\colon \Delta^n \to X$ is given by

$$\sigma \mapsto \sum_{p=0}^{n} \sigma \circ [v_0, \ldots, v_p] \otimes \sigma \circ [v_p, \ldots, v_n].$$

These maps form a diagonal approximation.

The diagonal approximation from the Alexander-Whitney Lemma 114.5 is called the *Alexander-Whitney diagonal approximation.* [13891390]

Proof. It follows almost immediately from the definition that the maps Δ are natural. Furthermore it is obvious that on the 0-chains the maps are of the desired form. It remains to show that for a given topological space X the maps actually form a chain map.

This follows from an elementary and uneventful calculation. For completeness' sake we provide the argument. Let $\mu\colon \Delta^n \to X$ be a singular n-simplex. Given $i_1, \ldots, i_r$ we write $[i_1, \ldots, i_r] := \mu \circ [v_{i_1}, \ldots, v_{i_r}]$. We also use the convention that the empty singular simplex $[\,]$ is 0. We calculate that

$$\begin{aligned}\Delta(\partial[0,\ldots,n]) &= \Delta\Big(\sum_{i=0}^{n}(-1)^i\cdot[0,\ldots,\widehat{i},\ldots n]\Big)\\ &= \underset{\uparrow}{\sum_{0\le p<i\le n}}(-1)^i\cdot[0,..,p]\otimes[p,..,\widehat{i},..,n]+\sum_{0\le i<q\le n}(-1)^i\cdot[0,..,\widehat{i},..,q]\otimes[q,..,n]\end{aligned}$$

in the second sum we secretly used the substitution $q = p+1$

and

$$\begin{aligned}\partial(\Delta[0,\ldots,n]) &= \partial\Big(\sum_{p=0}^{n}[0,\ldots,p]\otimes[p,\ldots,n]\Big)\\ &= \underset{\uparrow}{\sum_{0\le i\le p\le n}}(-1)^i\cdot[0,..,\widehat{i},..,p]\otimes[p,..,n]+\sum_{0\le p\le i\le n}(-1)^i\cdot[0,..,p]\otimes[p,..,\widehat{i},..,n].\end{aligned}$$

here we use the sign convention for the boundary in a tensor product

We see that the difference between the two terms equals

$$\begin{aligned}&\sum_{i=p}(-1)^i\cdot[0,\ldots,\widehat{i},\ldots,p]\otimes[p,\ldots,n]+\sum_{i=p}(-1)^i\cdot[0,\ldots,p]\otimes[p,\ldots,\widehat{i},\ldots,n]\\ =\ &\underset{\uparrow}{\sum_{i=1}^{n}}(-1)^i\cdot[0,\ldots,i-1]\otimes[i,\ldots,n]+\sum_{i=0}^{n-1}(-1)^i\cdot[0,\ldots,i]\otimes[i+1,\ldots,n]\end{aligned}$$

here we use that $[\,]=0$

$$= \sum_{i=1}^{n}(-1)^i\cdot[0,\ldots,i-1]\otimes[i,\ldots,n]+\sum_{j=1}^{n}(-1)^{j-1}\cdot[0,\ldots,j-1]\otimes[j,\ldots,n]\ =\ 0.$$

We have thus shown that Δ is indeed a chain map. ■

Proposition 114.6.

(1) There exist diagonal approximations.
(2) Given any two diagonal approximations Φ and Ψ there exists a natural chain homotopy equivalence between Φ and Ψ.

Proof.

(1) We had just given two examples of diagonal approximations.
(2) The uniqueness statement was proved in Proposition 114.6. ■

Now we are ready to provide the proof of the Definitions-Cup Product Proposition 114.4.

Proof of Proposition 114.4. We start out with the following claim.

[1389] James Alexander (1888-1971) was an American mathematician whom we had already met on page 1814.
[1390] Hassler Whitney (1907–1989) was an American mathematician. We will encounter him again later on.

Claim. For any two cochains $\varphi \in \mathrm{C}^p(X;\mathbb{Z})$ and $\psi \in \mathrm{C}^q(X;\mathbb{Z})$ we have[1391]

$$\varphi \cup \psi \;=\; (\varphi \otimes \psi) \circ \Pi_{p,q} \circ \Delta \;\in\; \mathrm{C}^{p+q}(X;\mathbb{Z}) = \mathrm{Hom}(\mathrm{C}_{p+q}(X),\mathbb{Z}).$$

Proof. We have to show that the two sides are the same maps $\mathrm{C}_{p+q}(X) \to \mathbb{Z}$. Therefore let $\sigma\colon \Delta^{p+q} \to X$ be a singular $(p+q)$-simplex. We calculate that

$$\begin{aligned}
(\varphi \otimes \psi \circ \Pi_{p,q} \circ \Delta)(\sigma) &\overset{\text{definition of the Alexander-Whitney diagonalization}}{\downarrow} \\
&= (\varphi \otimes \psi)\Big(\Pi_{p,q}\Big(\sum_{i+j=p+q} \overbrace{\sigma \circ [v_0,\dots,v_i] \otimes \sigma \circ [v_i,\dots,v_{p+q}]}^{\in \mathrm{C}_i(X)\otimes \mathrm{C}_j(X)}\Big)\Big) \\
&= (\varphi \otimes \psi)(\sigma \circ [v_0,\dots,v_p] \otimes \sigma \circ [v_q,\dots,v_{p+q}]) \\
&= \varphi(\sigma \circ [v_0,\dots,v_p]) \cdot \psi(\sigma \circ [v_p,\dots,v_n]) \\
&= (\varphi \cup \psi)(\sigma).
\end{aligned}$$

⊞

Now suppose that we are given cocycles $\varphi \in \mathrm{C}^p(X;\mathbb{Z})$ and $\psi \in \mathrm{C}^q(X;\mathbb{Z})$. We obtain the following equality in $\mathrm{H}^{p+q}(X;\mathbb{Z})$:[1392]

$$\begin{aligned}
[\varphi \smile \psi] \overset{\text{by definition}}{\downarrow} [(\varphi \otimes \psi)\circ\Pi_{p,q}\circ(\Theta\circ d_*)] &= (\Theta\circ d_*)^*\big(\overbrace{[(\varphi \otimes \psi)\circ\Pi_{p,q}]}^{\in \mathrm{H}^{p+q}(\mathrm{C}_*(X)\otimes \mathrm{C}_*(X))}\big) \\
&= \Delta^*\big([(\varphi \otimes \psi)\circ\Pi_{p,q}]\big) = [(\varphi \otimes \psi)\circ\Pi_{p,q}\circ\Delta] \overset{\text{by the claim}}{\uparrow} = [\varphi \cup \psi].
\end{aligned}$$

$\uparrow$ by Proposition 114.6 the maps $\Theta\circ d_*, \Delta\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X)\otimes\mathrm{C}_*(X)$ are chain homotopic so by the Dual Cochain Map Lemma 108.8 (3) they induce the same map on cohomology

We have thus obtained the desired equality of cohomology classes. ■

Henceforth we will mostly work with the second definition of the cup product. In the following proposition we summarize some of the key properties of the cup product.

Proposition 114.7. (Cup Product-Ring Proposition) Let X be a topological space and let R be a commutative ring.

(1) The cup product on $\mathrm{H}^*(X;R)$ is R-bilinear and associative.

(2) The abelian group $\mathrm{H}^*(X;R) = \bigoplus_{n\in\mathbb{N}_0} \mathrm{H}^n(X;R)$ together with the map

$$\cup\colon \mathrm{H}^*(X;R) \times \mathrm{H}^*(X;R) \to \mathrm{H}^*(X;R)$$

is a ring[1393] where the multiplicatively neutral element is given by

$$1_X \;:=\; \big[\text{constant map } X \to R \text{ given by } x \mapsto 1\big] \;\in\; \mathrm{H}^0(X;R).$$

Definition. Given a topological space X and given a commutative ring R we refer to $(\mathrm{H}^*(X;R), \cup)$ as the *R-cohomology ring of X*.

Proof. Let X be a topological space.

(1) It is clear from the second definition of the cup product that it is R-bilinear. It is also almost obvious, using the second definition, that the cup product is associative, but for completeness' sake we carry out the argument. Thus let $\alpha \in \mathrm{C}^p(X;R)$,

[1391] Here $\Delta\colon \mathrm{C}_{p+q}(X) \to (\mathrm{C}_*(X)\otimes\mathrm{C}_*(X))_{p+q}$ denotes the above Alexander-Whitney diagonalization.

[1392] Note that it follows from Lemma 114.1 that for two cocycles φ and ψ the composition $(\varphi\otimes\psi)\circ\Pi_{p,q}$ is indeed a cocycle, i.e. $(\varphi\otimes\psi)\circ\Pi_{p,q}$ defines an element in $\mathrm{H}^{p+q}(\mathrm{C}_*(X)\otimes\mathrm{C}_*(X);\mathbb{Z})$.

[1393] Recall that on page 98 we stated that in the lecture notes a ring is understood to be associative and it is understood to have a multiplicatively neutral element. We do not demand that a ring is commutative.

$\beta \in \mathrm{C}^q(X;R)$ and $\gamma \in \mathrm{C}^r(X;R)$ be cochains and let $\sigma\colon \Delta^{p+q+r} \to X$ be a singular simplex. Then

$$\begin{aligned}((\alpha \cup \beta) \cup \gamma)(\sigma) &= (\alpha \cup \beta)(\sigma \circ [v_0, \dots, v_{p+q}]) \cdot \gamma(\sigma \circ [v_{p+q}, \dots, v_{p+q+r}]) \\ &= \alpha(\sigma \circ [v_0, \dots, v_p]) \cdot \beta(\sigma \circ [v_p, \dots, v_{p+q}]) \cdot \gamma(\sigma \circ [v_{p+q}, \dots, v_{p+q+r}]) \\ &= (\alpha \cup (\beta \cup \gamma))(\sigma). \\ &\quad \uparrow \\ &\quad \text{same argument backwards}\end{aligned}$$

Thus we see that the cup product is already associative for cochains, so it is in particular associative for cohomology classes.

(2) Let $\eta\colon X \to R$ be the map that assigns to each point in X the value $1 \in R$. As usual we view η as a singular 0-cochain. It follows from the H^0-Proposition 108.11 that η is a 0-cocycle and that we obtain an element $1_X := [\eta] \in \mathrm{H}^0(X;R)$. It is clear from the definition that it is the neutral element with respect to the cup product. Together with (1) we have now shown that the cup product defines a ring structure on $\mathrm{H}^*(X;R)$. ■

Now that we have shown that $(\mathrm{H}^*(X;R), \cup)$ is a ring the question arises whether it is commutative or whether it is not commutative. It turns out that the answer lies somewhere in between. More precisely, we have the following proposition.

Proposition 114.8. (Cup Product-Commutativity Proposition) Let X be a topological space and let R be a commutative ring. For any $a \in \mathrm{H}^k(X;R)$ and $b \in \mathrm{H}^l(X;R)$ we have

$$a \cup b \;=\; (-1)^{kl} \cdot b \cup a.$$

Remark.

(1) The type of (non-) commutativity we encounter in the Cup Product-Commutativity Proposition 114.8 is the same as the one we encountered when we studied the wedge product of alternating forms and the wedge product on de Rham cohomology, see Lemma **??** and Proposition **??**.

(2) If $R = \mathbb{F}_2$, then we are in the pretty situation that $-1 = 1$, i.e. the cup product is commutative. Put differently, the $\mathbb{F}_2$-cohomology ring $\mathrm{H}^*(X;\mathbb{F}_2)$ of a topological space X is a commutative ring.

(3) The proof for the Cup Product-Commutativity Proposition 114.8 that we provide below is based on the second definition of the cup product. It is elementary but unfortunately unpleasant to read. Later, in Exercise 117.1, we will provide a different, more conceptual proof based on the first definition of the cup product.

Proof. We give a proof of the proposition following [**Hat2002**, p. 216-217]. In Hatcher's book more motivations for the steps in the proof are given.

So let $\varphi \in \mathrm{C}^k(X;R)$ and $\psi \in \mathrm{C}^l(X;R)$ be two cocycles. Given a singular n-simplex $\sigma\colon \Delta^n \to X$ we denote by $\overline{\sigma}$ the singular n-simplex obtained from σ by precomposing σ with the affine linear map $[v_n, \dots, v_0]\colon \Delta^n \to \Delta^n$ that reverses the order of the vertices. Furthermore we write $\epsilon_n = (-1)^{n(n+1)/2}$. We note that for any $m, n \in \mathbb{N}_0$ an elementary calculation shows that $\epsilon_{m+n} = (-1)^{mn} \cdot \epsilon_m \epsilon_n$ and that $\epsilon_1 = -1$.

Claim. The maps

$$\begin{array}{rcl}\rho\colon \mathrm{C}_n(X) & \to & \mathrm{C}_n(X)\\ \sigma & \mapsto & \epsilon_n\cdot\overline{\sigma}\end{array}$$

form a chain map that is chain homotopic to the identity.

We first show that the claim actually implies the statement of the proposition. Thus let $[\varphi]\in \mathrm{H}^k(X;R)$ and $[\psi]\in \mathrm{H}^l(X;R)$. Since by the claim ρ is chain homotopic to the identity it follows from the Dual Cochain Map Lemma 108.8 that the induced map $\rho^*\colon \mathrm{C}^*(X;R)\to \mathrm{C}^*(X;R)$ induces the identity on cohomology groups. So to deduce the statement of the proposition it suffices to show that

$$\rho^*(\psi\cup\varphi) \;=\; (-1)^{kl}\cdot\rho^*\varphi\cup\rho^*\psi \;\in\; \mathrm{C}^{k+l}(X;R).$$

Now let σ be a $(k+l)$-chain. Then

$$\begin{array}{rcl}(\rho^*(\psi\cup\varphi))(\sigma) & = & (\psi\cup\varphi)(\rho_*(\sigma)) \;=\; (\psi\cup\varphi)(\epsilon_{k+l}\cdot\sigma\circ[v_{k+l},\dots,v_0])\\ & = & \epsilon_{k+l}\cdot\psi(\sigma\circ[v_{k+l},\dots,v_k])\cdot\varphi(\sigma\circ[v_k,\dots,v_0])\\ & = & (-1)^{kl}\cdot\varphi(\epsilon_k\cdot\sigma\circ[v_k,\dots,v_0])\cdot\psi(\epsilon_l\cdot\sigma\circ[v_{k+l},\dots,v_k])\\ & & \uparrow\\ & & \text{since } \epsilon_{k+l}=(-1)^{kl}\cdot\epsilon_k\cdot\epsilon_l \text{ and since } R \text{ is a } \textit{commutative} \text{ ring}\\ & = & (-1)^{kl}\cdot(\rho^*\varphi\cup\rho^*\psi)(\sigma).\end{array}$$

We have thus shown the statement of the proposition modulo the claim.

Proof. It is straightforward to verify that ρ is a chain map, indeed, for any singular n-simplex σ we have

$$\begin{array}{rcl}\partial\rho(\sigma) & = & \partial(\epsilon_n\cdot\sigma\circ[v_n,\dots,v_0]) \;=\; \epsilon_n\cdot\sum_{i=0}^{n}(-1)^i\cdot\sigma\circ[v_n,\dots,\widehat{v_{n-i}},\dots,v_0],\\ \rho\partial(\sigma) & = & \rho\Big(\sum_{i=0}^{n}(-1)^i\cdot\sigma\circ[v_0,\dots,\widehat{v_i},\dots,v_n]\Big) \;\underset{\uparrow}{=}\; \epsilon_{n-1}\cdot\sum_{j=0}^{n}(-1)^{n-j}\cdot\sigma\circ[v_n,\dots,\widehat{v_{n-j}},\dots,v_0].\\ & & \qquad\qquad \text{definition of } \rho \text{ and substitution } j=n-i\end{array}$$

From $\epsilon_n=(-1)^n\cdot\epsilon_{n-1}$ we now obtain that $\partial\rho=\rho\partial$, i.e. we have shown that ρ is a chain map.

We still have to show that ρ is chain homotopic to the identity. We proceed with ideas similar to the ideas used in the proof of the Homotopic Maps-and-Homology Proposition 73.6. As in that proof, given $i\in\{0,\dots,n\}$ we write

$$\begin{array}{rcl}v_i & := & (0,\dots,1,0,\dots,0)\times\{0\} \;\in\; \mathbb{R}^{n+1}\times\{0\},\\ \text{and}\qquad w_i & := & (0,\dots,1,0,\dots,0)\times\{1\} \;\in\; \mathbb{R}^{n+1}\times\{1\}.\end{array}$$

We justify the reassignment of v_i to a different point by saying that we identify Δ^n with $\Delta^n\times\{0\}\in\mathbb{R}^{n+1}\times\mathbb{R}$. We denote by $\pi\colon\Delta^n\times[0,1]\to\Delta^n$ the projection . We consider the map

$$\begin{array}{rcl}P\colon \mathrm{C}_n(X) & \to & \mathrm{C}_{n+1}(X)\\ \sigma & \mapsto & \sum_{i=0}^{n}(-1)^i\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,w_i].\end{array}$$

Now we want to show that $\partial P+P\partial=\rho-\mathrm{id}$. We calculate

$$\begin{array}{rcl}(P\partial)(\sigma) & = & \sum_{i<j}(-1)^i(-1)^j\cdot\epsilon_{n-i-1}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,\widehat{w_j},\dots,w_i]\\ & & +\sum_{i>j}(-1)^{i-1}(-1)^j\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,\widehat{v_j},\dots,v_i,w_n,\dots,w_i],\end{array}$$

On the other hand we have

$$\begin{aligned}(\partial P)(\sigma) &= \sum_{j\le i}(-1)^i(-1)^j\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,\widehat{v_j},\dots,v_i,w_n,\dots,w_i]\\ &\quad+\sum_{j\ge i}(-1)^i(-1)^{i+1+n-j}\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,\widehat{w_j},\dots,w_i].\end{aligned}$$

Now using that $\epsilon_{n-i}=(-1)^{n-i}\epsilon_{n-i-1}$ we see that the sum over the $j\neq i$ terms agrees precisely with $-P\partial$ calculated above (with the roles of i and j reversed). It remains to show that the sum over the $i=j$ terms equals $(\rho-\mathrm{id})(\sigma)$. This is indeed the case since

$$\begin{aligned}&\text{sum of the } i=j \text{ summands in the above formula for } (\partial P)(\sigma)\\ &= \epsilon_n\cdot(\sigma\circ\pi)\circ[w_n,\dots,w_0]+\sum_{i=1}^{n}\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_{i-1},w_n,\dots,w_i]\\ &\quad+\sum_{i=0}^{n-1}(-1)^{n+i+1}\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,w_{i+1}]-(\sigma\circ\pi)\circ[v_0,\dots,v_n]\\ &\underset{\uparrow}{=}\ \epsilon_n\cdot(\sigma\circ\pi)\circ[w_n,\dots,w_0]-(\sigma\circ\pi)\circ[v_0,\dots,v_n] \;=\; (\rho-\mathrm{id})(\sigma).\end{aligned}$$

in the second sum we substitute $j=i+1$, we obtain a new sign $(-1)^{n+j}\epsilon_{n-j+1}=-\epsilon_{n-j}$, thus we see that the two sums over i cancel

We have now completed the proof that $\partial P+P\partial=\rho-\mathrm{id}$, in particular we have shown the claim and thus also the proposition. ■

Let $k\in\mathbb{N}$ be odd. It follows from the Cup Product-Commutativity Proposition 114.8 that given any topological space X and any $\varphi\in\mathrm{H}^k(X;\mathbb{Z})$ we have $\varphi\cup\varphi=-(1)^{k\cdot k}\cdot\varphi\cup\varphi$, put differently, we have $2\cdot(\varphi\cup\varphi)=0$. Thus we see that $\varphi\cup\varphi$ is 2-torsion. The next lemma makes the amusing observation that for $k=1$ this "square" is in fact always zero.

Lemma 114.9. Let X be a topological space. For any $\varphi\in\mathrm{H}^1(X;\mathbb{Z})$ we have $\varphi\cup\varphi=0$.

Remark. Note that there is no higher-dimensional analogue of Lemma 114.9. For example on [**Hat2002**, p. 403] it is shown that given any odd k with $k\ge 3$ there exists a cohomology class $\gamma\in\mathrm{H}^k(\mathbb{R}\mathrm{P}^\infty\times\mathbb{R}\mathrm{P}^\infty;\mathbb{Z})$ with $\gamma^m\neq 0$ for all $m\in\mathbb{N}$.

Proof. Let X be a topological space and let $\varphi\in\mathrm{C}^1(X;\mathbb{Z})$ be a cocycle. We need to show that $\varphi\cup\varphi\in\mathrm{C}^2(X;\mathbb{Z})$ is a coboundary. We consider the 1-dimensional cochain

$$\begin{aligned}\mu\colon \mathrm{C}_1(X) &\to \mathbb{Z}\\ (\sigma\colon\Delta^1\to X) &\mapsto \tfrac{1}{2}(\underbrace{\varphi(\sigma)-\varphi(\sigma)^2}_{\in 2\mathbb{Z}}).\end{aligned}$$

that is determined by

It remains to prove the following claim.

Claim. We have $\varphi\cup\varphi=\delta\mu\colon \mathrm{C}_2(X)\to\mathbb{Z}$.

Proof. We only need to prove this equality for singular 2-simplices. So suppose we are given $\tau\colon\Delta^2\to X$. Given $j\in\{0,1,2\}$ we write $i_j=i_j^2\colon\Delta^1\to\Delta^2$. Note that

$$(*)\qquad \varphi(\tau\circ i_0)-\varphi(\tau\circ i_1)+\varphi(\tau\circ i_2) \;=\; \varphi(\partial\tau) \underset{\substack{\uparrow\\ \text{definition of }\delta\varphi}}{=} (\delta\varphi)(\tau) \underset{\substack{\uparrow\\ \text{since }\varphi\text{ is a cocycle}}}{=} 0.$$

Now we compute that

$$\begin{aligned}(\delta\mu)(\tau) &= \mu(\partial\tau) = \mu\big((\tau\circ i_0)-(\tau\circ i_1)+(\tau\circ i_0)\big)\\ &= \tfrac{1}{2}\big(\varphi(\tau\circ i_0)-\varphi(\tau\circ i_1)+\varphi(\tau\circ i_2)+\varphi(\tau\circ i_0)^2-\varphi(\tau\circ i_1)^2+\varphi(\tau\circ i_2)^2\big)\\ &= \tfrac{1}{2}\big(\varphi(\tau\circ i_0)^2-(\varphi(\tau\circ i_0)+\varphi(\tau\circ i_2))^2+\varphi(\tau\circ i_2)^2\big)\\ &\quad\uparrow\\ &\quad\text{by }(*)\text{ we have }\varphi(\tau\circ i_1)=\varphi(\tau\circ i_0)+\varphi(\tau\circ i_2)\\ &= \varphi(\tau\circ i_2)\cdot\varphi(\tau\circ i_0) = (\varphi\cup\varphi)(\tau).\\ &\quad\uparrow\qquad\qquad\uparrow\\ &\quad\text{elementary algebra}\qquad\text{definition of the cup-product}\end{aligned}$$

This concludes the proof of the claim and thus of the lemma. ■

We continue with the following lemma that shows that the cup product behaves well under maps between topological spaces.

Lemma 114.10. (Cup Product-Naturality Lemma) Let R be a commutative ring.

(1) Let $f\colon X\to Y$ be a map between topological spaces. For any $c\in \mathrm{H}^p(Y;R)$ and any $d\in \mathrm{H}^q(Y;R)$ we have
$$f^*(c)\cup f^*(d) = f^*(c\cup d).$$
In particular the map
$$f^*\colon \mathrm{H}^*(Y;R) \to \mathrm{H}^*(X;R)$$
is a homomorphism of graded rings[1394] which satisfies $f^*(1_Y)=1_X$.

(2) The maps
$$\begin{aligned} X &\mapsto (\mathrm{H}^*(X;R),\cup)\\ (f\colon X\to Y) &\mapsto (f^*\colon \mathrm{H}^*(Y;R)\to \mathrm{H}^*(X;R))\end{aligned}$$
define a contravariant functor from the category *Top* of topological spaces to the category *GrRing* of graded rings.

Proof. The lemma follows basically immediately from the definitions. But for completeness' sake we write down the proof. So let $c=[\varphi]\in \mathrm{H}^p(Y;R)$ and let $b=[\psi]\in \mathrm{H}^q(Y;R)$. Furthermore let $\sigma\colon \Delta^{p+q}\to X$ be a singular $(p+q)$-chain. Then

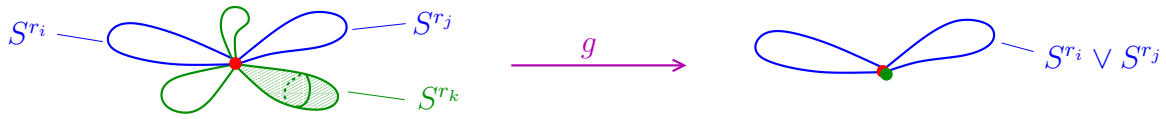
$$\begin{aligned}(f^*\varphi\cup f^*\psi)(\sigma) &= (f^*\varphi)(\sigma\circ[v_0,\dots,v_p])\cdot(f^*\psi)(\sigma\circ[v_p,\dots,v_{p+q}])\\ &= \varphi(f\circ(\sigma\circ[v_0,\dots,v_p]))\cdot\psi(f\circ(\sigma\circ[v_p,\dots,v_{p+q}]))\\ &= \varphi((f\circ\sigma)\circ[v_0,\dots,v_p))\cdot\psi((f\circ\sigma)\circ[v_p,\dots,v_{p+q}])\\ &= (\varphi\cup\psi)(f\circ\sigma) = (f^*(\varphi\cup\psi))(\sigma).\end{aligned}$$

Finally note that it follows immediately from the definitions of 1_X, 1_Y and f^* that we have the equality $f^*(1_Y)=1_X$. Statement (2) follows immediately from Statement (1) and the fact that cohomology groups with R-coefficients form a contravariant functor of abelian groups. ■

We can use the Cup Product-Naturality Lemma 114.10 to calculate the cup product of the wedge of finitely many spheres.

Lemma 114.11. For any wedge of finitely many spheres all cup products in degrees ≥ 1 are zero.

[1394] Recall that a *graded ring* is a ring R together with a decomposition $R=\bigoplus_{n\in\mathbb{N}_0} R_n$ such that for any $m,n\in\mathbb{N}_0$ the multiplication map restricts to a map $R_m\times R_n\to R_{m+n}$. A homomorphism $f\colon R\to S$ between graded rings is a ring homomorphism with $f(R_n)\subset S_n$ for all $n\in\mathbb{N}_0$



Proof. Let $S^{r_1} \vee \cdots \vee S^{r_k}$ be the wedge of finitely many spheres and let R be a commutative ring. For each $i \in \{1, \ldots, k\}$ we denote by $p_i \colon S^{r_1} \vee \cdots \vee S^{r_k} \to S^{r_i}$ the natural projection. By the Wedge-H*-Proposition 109.17 we know that for every $n \in \mathbb{N}$ the map

$$p_1^* \oplus \cdots \oplus p_k^* \colon \mathrm{H}^n(S^{r_1}; R) \oplus \cdots \oplus \mathrm{H}^n(S^{r_k}; R) \xrightarrow{\cong} \mathrm{H}^n(S^{r_1} \vee \cdots \vee S^{r_k}; R)$$

is an isomorphism. It remains to show that for any choice of $i, j \in \{1 \ldots, k\}$ with $r_i > 0$ and $r_j > 0$ we have $p_i^*([S^{r_i}]^*) \cup p_j^*([S^{r_j}]^*) = 0$. We prove the statement for $i \neq j$. The proof of the statement for $i = j$ is basically the same. So suppose that $i \neq j$. We denote by $g \colon S^{r_1} \vee \cdots \vee S^{r_k} \to S^{r_i} \vee S^{r_j}$ the natural projection and we denote by $q_i \colon S^{r_i} \vee S^{r_j} \to S^{r_i}$ and $q_j \colon S^{r_j} \vee S^{r_j} \to S^{r_j}$ the natural projections. Then

$$p_i^*([S^{r_i}]^*) \cup p_j^*([S^{r_j}]^*) \underset{\text{since } q_i \circ g = p_i \text{ and } q_j \circ g = p_j}{\overset{\uparrow}{=}} g^*(q_i^*([S^{r_i}]^*)) \cup g^*(q_j^*([S^{r_j}]^*)) \underset{\text{Cup Product-Naturality Lemma 114.10}}{\overset{\uparrow}{=}} g^*(\overbrace{q_i^*([S^{r_i}]^*) \cup q_j^*([S^{r_j}]^*)}^{\in \mathrm{H}^{r_i + r_j}(S^{r_i} \vee S^{r_j}) = 0}) = 0.$$

We have thus proved that all cup products in degrees ≥ 1 are zero. ∎

Later on, after we will have found methods for computing the cup product, we will often use the following corollary to show that certain topological spaces are not homotopy equivalent.

Corollary 114.12. Let X and Y be topological spaces. If X and Y are homotopy equivalent, then for any commutative ring R there exists an isomorphism

$$(\mathrm{H}^*(Y; R), \cup) \xrightarrow{\cong} (\mathrm{H}^*(X; R), \cup)$$

of graded rings.

Proof. Let $f \colon X \to Y$ be a homotopy equivalence. In the Homotopic Maps-H*-Lemma 108.13 we saw that the induced maps $f^* \colon \mathrm{H}^n(Y; R) \to \mathrm{H}^n(X; R)$ on cohomology *groups* are isomorphisms. But it follows from the Cup Product-Naturality Lemma 114.10 that these isomorphisms preserve the ring structure, i.e. the map f^* is in fact an isomorphism of graded rings. ∎

114.3. **The cup product of the torus.** Evidently our goal now is to determine the cup product of some of our favorite different topological spaces. We start out with two elementary observations regarding the cup product.

Observation 114.13. Let R be a commutative ring.

(1) Let X be a path-connected topological space. It follows from the H^0-Proposition 108.11 that $\mathrm{H}^0(X; R) = R \cdot 1_X$. For any $r \cdot 1_X \in \mathrm{H}^0(X; R)$ and $\varphi \in \mathrm{H}^k(X; R)$ we have

$$(r \cdot 1_X) \cup \varphi \underset{\text{since } \cup \text{ is } R\text{-bilinear}}{\overset{\uparrow}{=}} r \cdot (1_X \cup \varphi) \underset{\text{Cup Product-Ring Proposition 114.7}}{\overset{\uparrow}{=}} r \cdot \varphi \underset{\text{same argument backwards}}{\overset{\uparrow}{=}} \varphi \cup (r \cdot 1_X).$$

(2) If M is an m-dimensional topological manifold, then for any p, q with $p+q > m$ the cup product $\mathrm{H}^p(M;R) \times \mathrm{H}^q(M;R)$ is zero, since it takes values in the group $\mathrm{H}^{p+q}(M;R)$, which is zero by the Top-Homology Theorem 106.3.
(3) By the Cup Product-Ring Proposition 114.7 the cup product is R-bilinear, so it suffices to determine the cup product on a generating system.

In this section we want to determine the cup product on the torus $T = S^1 \times S^1$. By Observation 114.13 it remains to determine the cup product

$$\cup\colon \mathrm{H}^1(T;\mathbb{Z}) \times \mathrm{H}^1(T;\mathbb{Z}) \ \to\ \mathrm{H}^2(T;\mathbb{Z}).$$

We first need to understand the cohomology groups $\mathrm{H}^1(T;\mathbb{Z})$ and $\mathrm{H}^2(T;\mathbb{Z})$ explicitly. We recall some notation and results from before:

(1) We denote by p respectively q the projection $S^1 \times S^1 \to S^1$ onto the first respectively second factor. Furthermore, we recall that on page 2404 we introduced a cochain $\theta := \theta_{\mathbb{Z}} \in \mathrm{C}^1;\mathbb{Z})$, we showed in Lemma 108.10 that θ is a cocycle and we showed on page 2426 that θ represents a generator of $\mathrm{H}^1(S^1;\mathbb{Z})$.
(2) In Lemma 109.9 we showed that $\mathrm{H}^1(T;\mathbb{Z}) \cong \mathbb{Z}^2$ and that the two cohomology classes $\alpha := p^*([\theta])$ and $\beta := q^*([\theta])$ form a basis for $\mathrm{H}^1(S^1 \times S^1;\mathbb{Z})$.
(3) On page 2204 we showed that the cycle $-\sigma_1 + \sigma_2$, with the notation from the figure on page 2204, represents the fundamental class of T.
(4) In Lemma 109.9 and 110.15 we showed that

$$\begin{array}{rcl} \mathrm{H}^2(T;\mathbb{Z}) & \to & \mathbb{Z} \\ [\varphi] & \mapsto & \langle \varphi, [T] \rangle = \varphi(-\sigma_1 + \sigma_2) \end{array}$$

is in fact an isomorphism. We will use this isomorphism to make the identification $\mathrm{H}^2(T;\mathbb{Z}) = \mathbb{Z}$.

By Oberservation 114.13 (3) and the above discussion it suffices to determine all entries in the following matrix

$$\begin{pmatrix} \langle \alpha \cup \alpha, [T] \rangle & \langle \alpha \cup \beta, [T] \rangle \\ \langle \beta \cup \alpha, [T] \rangle & \langle \beta \cup \beta, [T] \rangle \end{pmatrix}.$$

Now we determine these four entries separately.

(1) We first consider the entry $\langle \alpha \cup \beta, [T] \rangle$. Fortunately we already did all the work on page 2515, more precisely, we have

$$\langle \alpha \cup \beta, [T] \rangle = (p^*\theta \cup q^*\theta)(-\sigma_1 + \sigma_2) = (p^*\theta \cup q^*\theta)(-\sigma_1) + (p^*\theta \cup q^*\theta)(\sigma_2) \underset{\uparrow}{=} 0 + 1 = 1.$$

see calculations on page 2515

(2) We could do the same argument as in (1) with α and β reversed. But it is easier to apply the Cup Product-Commutativity Proposition 114.8 which gives us that $\beta \cup \alpha = (-1)^{1 \cdot 1} \cdot \alpha \cup \beta = -\alpha \cup \beta = -1$.
(3) There are many different ways for showing that $\alpha \cup \alpha = 0$:
  (a) We could do the calculation as in (1), but that is the least efficient approach.
  (b) We could use the symmetry from the Cup Product-Commutativity Proposition 114.8 to argue that $\alpha \cup \alpha = -\alpha \cup \alpha$, and hence $\alpha \cup \alpha = 0$ since $\mathrm{H}^2(T;\mathbb{Z})$ is torsion-free.
  (c) We could just use Lemma 114.9 and remove all the fun.

(d) We can also argue that

$$\langle \alpha \cup \alpha, [T] \rangle \;=\; \langle [p^*\theta] \cup [p^*\theta], [T] \rangle \;\underset{\uparrow}{=}\; \langle p^*([\theta] \cup [\theta]), [T] \rangle \;\underset{\uparrow}{=}\; 0.$$

Cup Product-Naturality Lemma 114.10 since $[\theta] \cup [\theta] \in \mathrm{H}^2(S^1;\mathbb{Z}) = 0$

(4) The same way as in (3) we see that $\beta \cup \beta = 0$.

Summarizing we have proved the following lemma.

Lemma 114.14. Let T be the 2-dimensional torus. We use the above notation. The cup product $\mathrm{H}^1(T;\mathbb{Z}) \times \mathrm{H}^1(T;\mathbb{Z}) \to \mathrm{H}^2(T;\mathbb{Z})$ with respect to the basis α, β of $\mathrm{H}^1(T;\mathbb{Z})$ and the identification $\mathrm{H}^2(T;\mathbb{Z}) = \mathbb{Z} \cdot [T]^* = \mathbb{Z}$[1395]is given by the matrix

$$\begin{pmatrix} \alpha \cup \alpha & \alpha \cup \beta \\ \beta \cup \alpha & \beta \cup \beta \end{pmatrix} \;=\; \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Thus we have shown that the cup product on cohomology is in general non-zero and that it is in general not commutative.

Remark.

(1) We have just shown that the 2-cocycle $p^*(\theta) \cup q^*(\theta) \in \mathrm{C}^2(T;\mathbb{Z})$ represents a generator of $\mathrm{H}^2(T;\mathbb{Z})$. We have thus answered Question 109.10.

(2) We have now performed enough calculations to see that the cohomology rings contain more information than the homology or the cohomology groups. More precisely, it follows from Lemma 78.11 and Propositions 74.4 and 79.8 that for the 2-dimensional torus $S^1 \times S^1$ and for $S^1 \vee S^1 \vee S^2$ we have

$$\mathrm{H}_i(S^1 \times S^1;\mathbb{Z}) \;\cong\; \mathrm{H}_i(S^1 \vee S^1 \vee S^2;\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0, 2, \\ \mathbb{Z}^2, & \text{if } i = 1, \\ 0, & \text{if } i \geq 3. \end{cases}$$

We deduce from the Universal Coefficient Theorem 110.12 for Cohomology Groups that $S^1 \times S^1$ and $S^1 \vee S^1 \vee S^2$ also have isomorphic cohomology groups. In Lemma 114.14 we saw that the cup product on $\mathrm{H}^1(S^1 \times S^1;\mathbb{Z})$ is non-zero, whereas we showed in Lemma 114.11 that the cup product on $\mathrm{H}^1(S^1 \vee S^1 \vee S^2;\mathbb{Z})$ is zero.[1396]

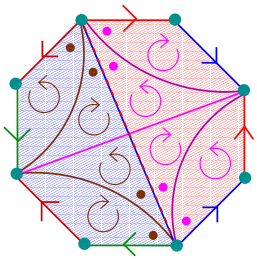
We conclude this section with the following slightly subtle lemma.

Lemma 114.15. Let $f\colon T \to T$ be a homeomorphism of the torus $T = S^1 \times S^1$. If f is orientation-preserving, then

$$\det\big(f_*\colon \mathrm{H}_1(T;\mathbb{Z}) \to \mathrm{H}_1(T;\mathbb{Z})\big) \;=\; \det\big(f^*\colon \mathrm{H}^1(T;\mathbb{Z}) \to \mathrm{H}^1(T;\mathbb{Z})\big) \;=\; +1.$$

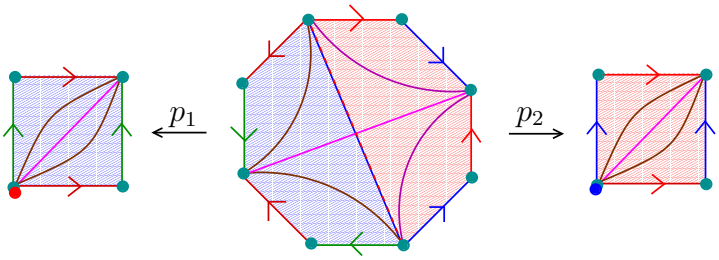
Conversely, if f is orientation-reversing, then both determinants equal -1.

Proof. In Exercise 114.2 we will use the above calculation of the cup product of the torus to prove the lemma. ■



[1395]Here $[T]^* \in \mathrm{H}^2(T;\mathbb{Z})$ denotes the dual fundamental class that we introduced on page 2451, it is uniquely determined by $\langle [T]^*, [T] \rangle = 1$.

[1396]Of course we do not need to use cup products to distinguish the torus $S^1 \times S^1$ and the wedge $S^1 \vee S^1 \vee S^2$, this can already be done using fundamental groups. Nonetheless it is encouraging to see that we found a new way to prove this statement.



114.4. **The cup product of the surface of genus 2.** In this section we calculate the cup product for the surface Σ of genus 2. By Observation 114.13 it remains to determine the cup product

$$\mathrm{H}^1(\Sigma;\mathbb{Z}) \times \mathrm{H}^1(\Sigma;\mathbb{Z}) \ \to \ \mathrm{H}^2(\Sigma;\mathbb{Z})$$

on a basis of $\mathrm{H}^1(\Sigma;\mathbb{Z})$. We recall that on page 2428 we introduced for $i = 1, 2$ a map $p_i \colon \Sigma \to T = S^1 \times S^1$. We refer to the figure below on the right for a reminder of the definition of the maps. We denote by $\alpha, \beta \in \mathrm{H}^1(T;\mathbb{Z})$ the basis from Lemma 109.9 that

fundamental class of Σ

projections from Σ to the torus

we had also used in the previous section.
In Lemma 109.11 we saw that the map

$$p_1^* \oplus p_2^* \colon \mathrm{H}^1(T;\mathbb{Z}) \oplus \mathrm{H}^1(T;\mathbb{Z}) \ \to \ \mathrm{H}^1(\Sigma;\mathbb{Z})$$

is an isomorphism. We deduce that a basis for $\mathrm{H}^1(\Sigma;\mathbb{Z}) \cong \mathbb{Z}^4$ is given by $\alpha_i := p_i^*(\alpha)$, $\beta_i := p_i^*(\beta)$, $i = 1, 2$. Now we can use the definition of the cup product and the explicit description of a representative of the fundamental class $[\Sigma] \in \mathrm{H}_2(\Sigma;\mathbb{Z})$ in the figure above on the left (see also the figure on page 2204 for a more detailed discussion) to compute the cup product $\mathrm{H}^1(\Sigma;\mathbb{Z}) \times \mathrm{H}^1(\Sigma;\mathbb{Z}) \to \mathrm{H}^2(\Sigma;\mathbb{Z}) = \mathbb{Z}$.
A not particularly exciting calculation leads us eventually to the following lemma.[1397]

Lemma 114.16. Let Σ be the surface of genus 2. We use the above notation. The cup product $\mathrm{H}^1(\Sigma;\mathbb{Z}) \times \mathrm{H}^1(\Sigma;\mathbb{Z}) \to \mathrm{H}^2(\Sigma;\mathbb{Z})$ with respect to the basis $\alpha_1, \beta_1, \alpha_2, \beta_2$ of $\mathrm{H}^1(\Sigma;\mathbb{Z})$ and the identification $\mathrm{H}^2(\Sigma;\mathbb{Z}) = \mathbb{Z} \cdot [\Sigma]^* = \mathbb{Z}$ is given by the matrix

$$\begin{pmatrix} \alpha_1 \cup \alpha_1 & \alpha_1 \cup \beta_1 & \alpha_1 \cup \alpha_2 & \alpha_1 \cup \beta_2 \\ \beta_1 \cup \alpha_1 & \beta_1 \cup \beta_1 & \beta_1 \cup \alpha_2 & \beta_1 \cup \beta_2 \\ \alpha_2 \cup \alpha_1 & \alpha_2 \cup \beta_1 & \alpha_2 \cup \alpha_2 & \alpha_2 \cup \beta_2 \\ \beta_2 \cup \alpha_1 & \beta_2 \cup \beta_1 & \beta_2 \cup \alpha_2 & \beta_2 \cup \beta_2 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}$$

An analogous statement holds for any surface of genus $g \geq 1$, i.e. the cup product on the first cohomology of the surface of genus $g \geq 1$ can be represented by a block diagonal matrix consisting of g copies of $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$.

Remark. In the next section we will obtain a more conceptual proof of Lemma 114.16.

Before we continue with more calculations of cup products we return to a question that we had asked earlier on.

[1397] We have to evaluate the cup products of the explicit 1-cochains on the eight singular 2-simplices illustrated in the figure above. It is straightforward to see that all 16 cup products evaluate to zero on the four central singular 2-simplices. For the remaining cup products the calculation is almost the same as for the torus on page 2515.

Question 101.12.
(2) Let $g \geq 2$ and let $k \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree k?[1398]

Now we have the tools to answer this question. In this context it is useful to introduce the following definition.

Definition. A closed oriented connected non-empty topological manifold M is called flexible if given any $k \in \mathbb{Z}$ there exists a map $f\colon M \to M$ of degree k.

Example. In Lemma 76.10 we saw that S^1 is flexible. The combination of this fact with the Degree-Suspension Lemma 76.12 shows that in fact any sphere S^n, $n \geq 1$ is flexible.

Now we can determine which closed oriented connected 2-dimensional smooth manifolds are flexible. More precisely, we have the following proposition which gives a negative answer to Question 101.12 (2).

Proposition 114.17. Let $g \geq 1$. We denote by Σ_g the surface of genus g.
(1) The torus $\Sigma_1 = S^1 \times S^1$ is flexible.
(2) For $g \geq 2$ the surface Σ_g is not flexible. In fact if $k \neq -1, 0, 1$, then there is no map $\Sigma_g \to \Sigma_g$ of degree k.

Proof.

(1) We first show that the torus $S^1 \times S^1$ is flexible. So let $k \in \mathbb{Z}$. We consider the map $f\colon S^1 \to S^1$ that is given by $z \mapsto z^k$. We claim that $f \times \mathrm{id}\colon S^1 \times S^1 \to S^1 \times S^1$ has degree k. In fact by the naturality of the short exact sequence of the Künneth-Theorem 90.8 we have a commutative diagram

$$\begin{array}{ccc} \mathrm{H}_1(S^1) \otimes \mathrm{H}_1(S^1) & \xrightarrow[\cong]{\Theta} & \mathrm{H}_2(S^1 \times S^1) \\ \downarrow{\scriptstyle f_* \otimes \mathrm{id}} & & \downarrow{\scriptstyle (f \times \mathrm{id})_*} \\ \mathrm{H}_1(S^1) \otimes \mathrm{H}_1(S^1) & \xrightarrow[\cong]{\Theta} & \mathrm{H}_2(S^1 \times S^1) \end{array}$$

where the horizontal maps are isomorphisms. By Lemma 76.10 the map on the left is given by multiplication by k. Hence the map on the right is also given by multiplication by k.

(2) Now let $g \geq 2$ and let $f\colon \Sigma_g \to \Sigma_g$ be a map of degree $k \neq 0$. We have to show that $k \in \{\pm 1\}$. We write $\pi := \pi_1(\Sigma_g)$. We start out with the following claim.

Claim. The map $f_*\colon \pi \to \pi$ is an epimorphism.

Proof. First note that the argument in the proof of the Degree One-Epimorphism Proposition 101.8 shows that $f_*(\pi)$ is a finite-index subgroup of π. (Here we used that $k \neq 0$.) We denote by $n \in \mathbb{N}$ the index of the subgroup $f_*(\pi) \subset \pi$. In the proof of Proposition 64.17 we used the multiplicativity of the Euler characteristic under finite covers to show that the abelianization of $f_*(\pi)$ is isomorphic to $\mathbb{Z}^{2n\cdot(g-1)+2}$. On the other hand the epimorphism $\pi \to f_*(\pi)$ induces evidently an epimorphism of

[1398] Recall that if $f\colon M \to N$ is a map between two closed, oriented connected, non-empty n-dimensional topological manifolds, then the degree $\deg(f) \in \mathbb{Z}$ is defined as the unique integer $\deg(f)$ that satisfies $f_*([M]) = \deg(f) \cdot [N]$.

the abelianization of π onto the abelianization of $f_*(\pi)$, i.e. we have an epimorphism from $\mathbb{Z}^{2g}$ onto $\mathbb{Z}^{2n\cdot(g-1)+2}$. Since $g \geq 2$ this is only possible if $n = 1$. ⊞

Claim. The map $f^*\colon \mathrm{H}^1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}^1(\Sigma_g;\mathbb{Z})$ is an isomorphism.

Proof. By the first claim we know that the map $f_*\colon \pi \to \pi$ is an epimorphism. It follows from the naturality of the Hurewicz Isomorphism, see Propositions 84.3 and 84.2 (5), that the map $f_*\colon \mathrm{H}_1(\Sigma_g) \to \mathrm{H}_1(\Sigma_g)$ is also an epimorphism. But any epimorphism from a finitely generated abelian group to itself is in fact an isomorphism[1399], so we see that $f_*\colon \mathrm{H}_1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}_1(\Sigma_g;\mathbb{Z})$ is in fact an isomorphism. By the First Cohomology Proposition 110.17 the evaluation homomorphism $\mathrm{ev}\colon \mathrm{H}^1(\Sigma_g;\mathbb{Z}) \cong \mathrm{Hom}(\mathrm{H}_1(\Sigma_g;\mathbb{Z}),\mathbb{Z})$ is a natural isomorphism, i.e. we have a commutative diagram

$$\begin{array}{ccc} \mathrm{H}^1(\Sigma_g;\mathbb{Z}) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_1(\Sigma_g;\mathbb{Z}),\mathbb{Z}) \\ \big\downarrow{\scriptstyle f^*} & & \cong\big\downarrow{\scriptstyle (f_*)^*} \\ \mathrm{H}^1(\Sigma_g;\mathbb{Z}) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_1(\Sigma_g;\mathbb{Z}),\mathbb{Z}). \end{array}$$

The right-hand map is an isomorphism, it follows from the commutative diagram that the left-hand map $f^*\colon \mathrm{H}^1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}^1(\Sigma_g;\mathbb{Z})$ is also an isomorphism. ⊞

By Lemma 114.16 we know that there exist $a, b \in \mathrm{H}^1(\Sigma_g;\mathbb{Z})$ with $a \cup b = [\Sigma_g]^*$. Since $f^*\colon \mathrm{H}^1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}^1(\Sigma_g;\mathbb{Z})$ is an isomorphism we can in particular find cohomology classes $c, d \in \mathrm{H}^1(\Sigma_g;\mathbb{Z})$ with $f^*(c) = a$ and $f^*(d) = b$. Now we have

$$[\Sigma_g]^* = a \cup b = f^*(c) \cup f^*(d) \underset{\uparrow}{=} f^*(c \cup d) \overset{\downarrow}{=} f^*(m \cdot [\Sigma_g]^*) \underset{\uparrow}{=} \deg(f) \cdot m \cdot [\Sigma_g]^*.$$

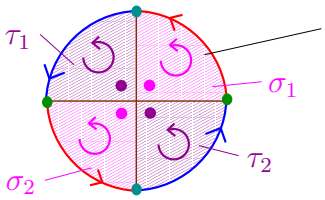
since $c \cup d \in \mathrm{H}^2(\Sigma_g;\mathbb{Z})$ and since $[\Sigma_g]^* \in \mathrm{H}^2(\Sigma_g;\mathbb{Z})$ is a generator such an m exists

Cup Product-Naturality Lemma 114.10 — by Lemma 110.16 we have $f^*([\Sigma_g]^*) = \deg(f) \cdot [\Sigma_g]^*$

Evidently this is only possible if $\deg(f) \in \{\pm 1\}$. ■

114.5. **The cup product of the real projective plane (∗).** Now we want to understand the cup product in the $\mathbb{F}_2$-cohomology of the real projective plane $\mathbb{R}\mathrm{P}^2$. Recall that on page 2423 we saw that $\mathrm{H}^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$[1400] for $i = 0, 1, 2$ and that the $\mathbb{F}_2$-cohomology vanishes in all other dimensions. By Observation 114.13 it remains to determine the cup product on the first cohomology.

To compute the cup product we need to get a good understanding of the cohomology groups. Recall that on page 2216 we had seen that $(\sigma_1+\sigma_2+\tau_1+\tau_2)\otimes 1 \in \mathrm{C}_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ is a representative of the $\mathbb{F}_2$-fundamental class $[\mathbb{R}\mathrm{P}^2]$ of $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$.[1401] (See the figure below for the definition of $\sigma_1, \sigma_2, \tau_1$ and τ_2.) It follows from the Cohomology-Field Coefficients Proposition 110.18 and the above that the map



$$\begin{array}{rcl} \eta\colon \mathrm{H}^2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) & \to & \mathbb{F}_2 \\ [\varphi \in \mathrm{C}^2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)] & \mapsto & [\varphi(\sigma_1)+\varphi(\sigma_2)+\varphi(\tau_1)+\varphi(\tau_2)] \end{array}$$

[1399] Why is that?

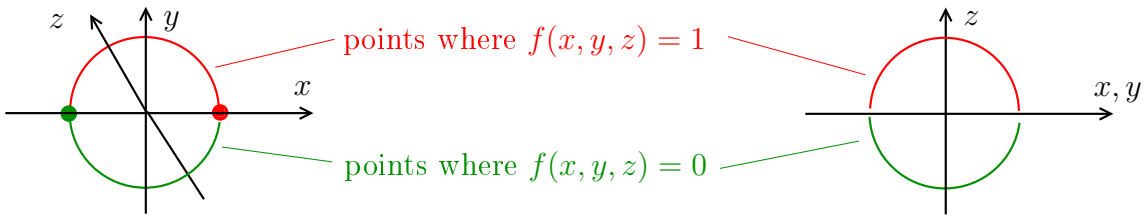
[1400] Why is it safe to write $\mathrm{H}^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$? Would it not be much more appropriate to write $\mathrm{H}^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \cong \mathbb{F}_2$?

[1401] Here we use the identification $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$ from page 258.

is an isomorphism.

projective plane $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$

the 2-cycle $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in \mathrm{C}_2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ represents the $\mathbb{F}_2$-fundamental class of the real projective plane



Now we also need to find an explicit representative of $x \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$. We will find such a representative in a similar fashion to the construction of the singular 1-cocycle $\theta_{\mathbb{Z}} \in \mathrm{H}^1(S^1; \mathbb{Z})$ on page 2404. More precisely, we consider the map

$$\begin{array}{rcl} f\colon S^2 & \to & \mathbb{F}_2 \\ (x,y,z) & \mapsto & \begin{cases} 1, & \text{if } (z>0) \text{ or } (z=0 \text{ and } y>0) \text{ or } (z=y=0 \text{ and } x=1), \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

Note that for any point $P \in S^2$ we have $f(-P) = 1 - f(P)$.[1402] For a singular 1-simplex $\sigma\colon \Delta^1 \to \mathbb{R}\mathrm{P}^2$ we pick a lift $\widetilde{\sigma}\colon \Delta^1 \to S^2$ of σ and we define

$$\varphi(\sigma) \;:=\; f\big(\widetilde{\sigma}(0,1)\big) - f\big(\widetilde{\sigma}(1,0)\big) \;\in\; \mathbb{F}_2.$$

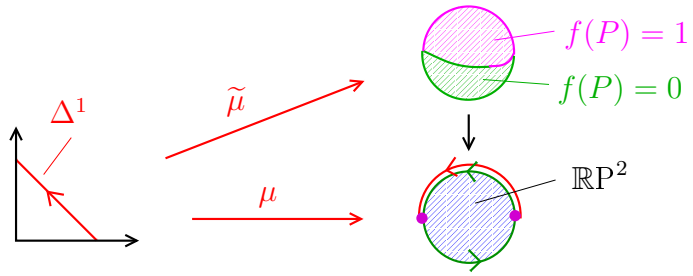
We refer to the figure below for an illustration.

Note that φ is well-defined since the only other lift of σ is given by multiplying $\widetilde{\sigma}$ by -1,[1403] but then it follows from $f(-P) = 1 - f(P)$ that the difference of the evaluations at the endpoints does not change. (Here we use that we work with $\mathbb{F}_2$-coefficients instead of $\mathbb{Z}$-coefficients.) The argument of Lemma 108.10 can easily be adapted to show that the singular 1-cochain $\varphi\colon \mathrm{C}_1(\mathbb{R}\mathrm{P}^2) \to \mathbb{F}_2$ is a cocycle.

Example. We consider the map $\mu\colon \Delta^1 \to \mathbb{R}\mathrm{P}^2 = S^2/\sim$ given by $\mu(1-t,t) = [\exp(\pi \mathrm{i} t)]$. Then $\mu \in \mathrm{C}_1(\mathbb{R}\mathrm{P}^2)$. Thus we can apply the Kronecker pairing $\mathrm{H}^1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2) \times \mathrm{H}_1(\mathbb{R}\mathrm{P}^2) \to \mathbb{F}_2$ from Lemma 109.6 to $[\varphi] \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ and $[\mu] \in \mathrm{H}_1(\mathbb{R}\mathrm{P}^2)$ and we calculate that

$$\langle [\varphi], [\mu] \rangle \;=\; \varphi(\mu) \;\underset{\uparrow}{=}\; f(\exp(\pi \mathrm{i})) - f(\exp(0)) \;=\; 1 \in \mathbb{F}_2.$$

since a lift of $\mu(1-t,t) = [\exp(\pi \mathrm{i} t)]$ to S^2 is given by $\widetilde{\mu}(1-t,t) = \exp(\pi \mathrm{i} t)$



Since this is non-zero we have now actually shown two statements at once: the cohomology class $[\varphi] \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ is non-zero and we have also certified that the homology class $[\mu] \in \mathrm{H}_1(\mathbb{R}\mathrm{P}^2)$ is non-zero.[1404]

Now we have the tools to prove the following lemma.

[1402] In fact for the subsequent discussion any map $f\colon S^2 \to \mathbb{F}_2$ with this property would work. We just picked this example for concreteness.

[1403] Why is that true?

[1404] Do you know any other methods for showing that $[\mu] \neq 0 \in \mathrm{H}_1(\mathbb{R}\mathrm{P}^2)$?

Lemma 114.18. Under the identifications $\mathrm{H}^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$ the cup product

$$\begin{array}{rcl} \cup\colon \mathrm{H}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \times \mathrm{H}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) & \to & \mathrm{H}^2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \\ \mathbb{F}_2 \times \mathbb{F}_2 & \to & \mathbb{F}_2 \\ (a,b) & \mapsto & a \cdot b. \end{array}$$

is given by

Remark. Note that the calculation in Lemma 114.18 that the statement of Lemma 114.9 does not hold for $\mathbb{F}_2$-coefficients.

Proof. By the discussion above it suffices to show that $\eta([\varphi] \cup [\varphi]) \neq 0$. Put differently, by definition of η we need to show that

$$(\varphi \cup \varphi)(\sigma_1) + (\varphi \cup \varphi)(\sigma_2) + (\varphi \cup \varphi)(\tau_1) + (\varphi \cup \varphi)(\tau_2) \;=\; 1 \;\in \mathbb{F}_2.$$

In Exercise 114.4 we will determine all four summands and we will see that the sum is indeed 1. ■

The above calculation of the cup product of the real projective plane $\mathbb{R}\mathrm{P}^2$ is very explicit and hands on, but not very conceptual. Later on, in the Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16, we will give a very different calculation of the cup product on $\mathbb{F}_2$-cohomology of all real projective spaces $\mathbb{R}\mathrm{P}^n$.

Exercises for Chapter 114.

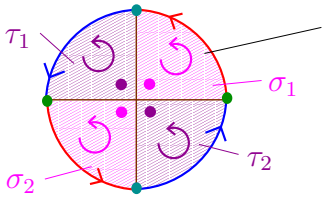
Exercise 114.1. Let X be a topological space. We consider the map

$$\Phi\colon \mathrm{H}_*(X) \otimes \mathrm{H}_*(X) \xrightarrow{\times} \mathrm{H}_*(X \times X) \xrightarrow{p_*} \mathrm{H}_*(X)$$

where $p\colon X \times X \to X$ denotes the projection on the first factor. Show that Φ is the trivial map.

Exercise 114.2. Let $f\colon T \to T$ be a homeomorphism of the torus $T = S^1 \times S^1$. Show that if f orientation-preserving, then the following two statements hold:

(a) $f_*\colon \mathrm{H}_1(T;\mathbb{Z}) \to \mathrm{H}_1(T;\mathbb{Z})$ has determinant one,
(b) $f^*\colon \mathrm{H}^1(T;\mathbb{Z}) \to \mathrm{H}^1(T;\mathbb{Z})$ has determinant one.



Exercise 114.3.

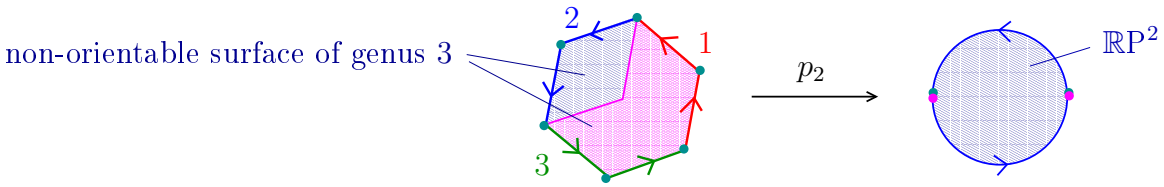
(a) Use cup products to show that there is no map $f\colon S^1 \times S^1 \to S^2$ of degree one, i.e. there is no map that induces an isomorphism on second homology.
(b) Given $g \in \mathbb{N}_0$ we denote by Σ_g the surface of genus g. Let $g < k$. Use cup product to show that there is no degree-one map from Σ_g to Σ_k.

Remark. This exercise shows that cup products can also be used to answer Question 101.5. Note that in Corollary 101.9 we used the fundamental class to prove the above statements.

Exercise 114.4. We consider $\mathbb{R}\mathrm{P}^2 = S^2/\!\sim$ which we identify with $\overline{B}^2/\!\sim$ via the homeomorphism that is induced by the projection $S^2 \to \overline{B}^2$. Let $\varphi \in \mathrm{C}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ be the cocycle that we defined on page 2530. Determine *each of the four summands* in the sum

$$(\varphi \cup \varphi)(\sigma_1) + (\varphi \cup \varphi)(\sigma_2) + (\varphi \cup \varphi)(\tau_1) + (\varphi \cup \varphi)(\tau_2).$$

projective plane $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$



the 2-cycle $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in \mathrm{C}_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ represents the $\mathbb{F}_2$-fundamental class of the real projective plane

Exercise 114.5. Let K be the Klein bottle.

(a) Is the cup product $\mathrm{H}^1(K;\mathbb{Z}) \times \mathrm{H}^1(K;\mathbb{Z}) \to \mathrm{H}^2(K;\mathbb{Z})$ is trivial?
(b) Show that the cup product $\mathrm{H}^1(K;\mathbb{F}_2) \times \mathrm{H}^1(K;\mathbb{F}_2) \to \mathrm{H}^2(K;\mathbb{F}_2)$ is non-trivial.

Exercise 114.6. Let $k \in \mathbb{N}$. We denote by N_k the non-orientable surface of genus k as defined on page 266. For $i = 1, \dots, k$ we denote by $p_i \colon N_k \to \mathbb{R}\mathrm{P}^2$ the map that is illustrated in the figure below.

(a) Show that the map $p_1^* \oplus \cdots \oplus p_k^* \colon \mathrm{H}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \oplus \cdots \oplus \mathrm{H}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \to \mathrm{H}^1(N_k;\mathbb{F}_2)$ is an isomorphism.
Hint. You could use cellular cohomology.
(b) Let $x \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ be the unique non-trivial element. For $i = 1, \dots, k$ we write $y_i = p_i^*(x)$. Furthermore we denote by $[N_k]^* \in \mathrm{H}^2(N_k;\mathbb{F}_2)$ the unique non-trivial element. Show that for any $i, j \in \{1, \dots, k\}$ we have $y_i \cup y_j = \delta_{ij} \cdot [N_k]^*$.
(c) Let $g < k$. Use cup product to show that there is no map $f \colon N_g \to N_k$ that induces an isomorphism $f_* \colon \mathrm{H}_2(N_g;\mathbb{F}_2) \to \mathrm{H}_2(N_k;\mathbb{F}_2)$.
Remark. This statement is the non-orientable analogue of Exercise 114.3. Note that we had proved this statement in Exercise 101.8 using an alternative approach. Both are fun!

Exercise 114.7. Given a matrix $A \in \mathrm{M}(n \times n, \mathbb{F}_2)$ we define the bilinear form

$$\begin{array}{rccc} \lambda(A) \colon & \mathbb{F}_2^n \times \mathbb{F}_2^n & \to & \mathbb{F}_2 \\ & (v, w) & \mapsto & v^T A w. \end{array}$$

We consider the two matrices $P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $Q = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ over $\mathbb{F}_2$. Next we consider the torus $T = S^1 \times S^1$ and the Klein bottle $K = N_2$. By a slight variation on Lemma 114.14 and by Exercise 114.6 we know that the cup products $\mathrm{H}^1(T;\mathbb{F}_2) \times \mathrm{H}^1(T;\mathbb{F}_2) \to \mathrm{H}^2(T;\mathbb{F}_2)$ and $\mathrm{H}^1(K;\mathbb{F}_2) \times \mathrm{H}^1(K;\mathbb{F}_2) \to \mathrm{H}^2(K;\mathbb{F}_2)$ are isometric to $\lambda(P)$ respectively $\lambda(Q)$.

(a) Show that the forms $\lambda(P)$ and $\lambda(Q)$ are not isometric.

(b) Show that there is no map $f\colon T \to K$ such that the map $f_*\colon \mathrm{H}_2(T;\mathbb{F}_2) \to \mathrm{H}_2(K;\mathbb{F}_2)$ is an isomorphism.

Remark. This approach gives an alternative, and arguably more systematic solution, to Exercise 114.7.

115. The relative cup product

Our goal in this chapter is to introduce a relative version of the cup product. More precisely, given an excisive triad (X, A, B) and a commutative ring R we will introduce a cup product

$$\mathrm{H}^p(X, A; R) \times \mathrm{H}^q(X, B; R) \xrightarrow{\quad\cup\quad} \mathrm{H}^{p+q}(X, A \cup B; R)$$

that is functorial in an appropriate sense and that equals the previous definition of the cup product for the special case that $A = B = \varnothing$. This relative cup product will help us in determining the cup products of wedges of topological spaces and of the suspension of a topological space. Also it will help us to determine the mysterious sounding Lusternik-Schnirelmann category.

115.1. **Definition of the relative cup product.** In this section we will work a lot with relative cochains. Before we do so we recall the following convention from page 2407.

Convention.

(1) Given an abelian group C, a subgroup D and an abelian group G we have a natural isomorphism

$$\begin{array}{rcl} \mathrm{Hom}(C/D, G) & \xrightarrow{\cong} & \{f\colon C \to G \,|\, f \text{ vanishes on } D\} \\ (\varphi\colon C/D \to G) & \mapsto & (C \to C/D \xrightarrow{\varphi} G). \end{array}$$

We will use this isomorphism to identify the groups left and right.

(2) In particular, given a pair of topological spaces (X, A), a commutative ring R and $n \in \mathbb{N}_0$ we make the identification

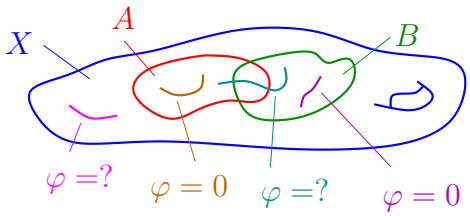
$$\mathrm{C}^n(X, A; R) \xrightarrow{\cong} \{f\colon \mathrm{C}_n(X) \to R \,|\, f(\sigma) = 0 \text{ for all } \sigma\colon \Delta^n \to A\}.$$

The definition of the relative cup product requires some preparation. We start out with the following definition.

Definition. Let (X, A, B) be a triad of topological spaces. As in the definition on page 2429 we write

$$\mathrm{C}_n^{\{A,B\}}(A \cup B) := \left\{ \sum_{j=1}^{k} n_j \sigma_j \in \mathrm{C}_n(A \cup B) \;\middle|\; \begin{array}{c} \text{for each } j \text{ the image of } \sigma_j \\ \text{lies in } A \text{ or it lies in } B \end{array} \right\}$$

The usual boundary map on the groups $\mathrm{C}_*(A \cup B)$ restricts to a boundary map on the groups $\mathrm{C}_*^{\{A,B\}}(A \cup B)$. Given a commutative ring R we consider



$$\mathrm{C}^n(X, \{A, B\}; R) := \ker\left(\mathrm{C}^n(X; R) \to \mathrm{Hom}\Big(\underbrace{\mathrm{C}_n^{\{A,B\}}(A \cup B)}_{\text{subgroup of } \mathrm{C}_n(X)}, R\Big)\right).$$

This is again a cochain complex and we denote the corresponding cohomology groups by $\mathrm{H}^*(X, \{A, B\}; R)$.

Remark. With the above notation we could write that

$$\mathrm{C}^n(X, \{A, B\}; R) = \{\varphi\colon \mathrm{C}_n(X) \to R \,|\, \varphi(\sigma) = 0 \text{ for any } \sigma\colon \Delta^n \to A \text{ and any } \sigma\colon \Delta^n \to B\}.$$

The definition of $\mathrm{C}^n(X, \{A, B\}; R)$ is illustrated in the figure below.

$$\varphi \in \mathrm{H}^1(X, \{A, B\}; R)$$

Lemma 115.1. Let (X, A, B) be an excisive triad of topological spaces. Given any commutative ring R the natural[1405] map

$$\mathrm{C}^*(X, A \cup B; R) \quad \to \quad \mathrm{C}^*(X, \{A, B\}; R)$$

induces for every $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}^n(X, A \cup B; R) \quad \xrightarrow{\cong} \quad \mathrm{H}^n(X, \{A, B\}; R).$$

Proof. We have the following commutative diagram of short exact sequences of chain complexes

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{C}_*^{\{A,B\}}(A \cup B) & \longrightarrow & \mathrm{C}_*(X) & \longrightarrow & \dfrac{\mathrm{C}_*(X)}{\mathrm{C}_*^{\{A,B\}}(A \cup B)} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow{\scriptstyle =\mathrm{id}} & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{C}_*(A \cup B) & \longrightarrow & \mathrm{C}_*(X) & \longrightarrow & \mathrm{C}_*(X, A \cup B) & \longrightarrow & 0. \end{array}$$

It is clear that the groups in the first and second column are free abelian. On page 1625 we already remarked that relative chain groups are free abelian, and the same same argument shows that the top right group is free abelian, in fact a basis is given by all singular simplices of X that are not contained in A or B. By our hypothesis the triad (X, A, B) is excisive. By definition this means that the left vertical map is a chain homotopy equivalence. The middle vertical map is the identity. It follows from this discussion together with the Two-Out-Of-Three-Homotopy Equivalence Corollary 81.6 that the right vertical map is also a chain homotopy equivalence.

Recall that by the convention on page 2534 we have an identification

$$\mathrm{Hom}\left(\frac{\mathrm{C}_n(X)}{\mathrm{C}_n^{\{A,B\}}(A \cup B)}, R\right) \;=\; \mathrm{C}^n(X, \{A, B\}; R).$$

The lemma follows from the above vertical chain homotopy equivalence, the above observation and the Dual Cochain Map Lemma 108.8. ∎

The following lemma is the motivation for introducing the rather technical cohomology modules $\mathrm{H}^*(X; \{A, B\}; R)$.

Lemma 115.2. Let (X, A, B) be a triad of topological spaces and let R be a commutative ring. Then the map

$$\begin{array}{rcl} \mathrm{C}^p(X, A; R) \times \mathrm{C}^q(X, B; R) & \to & \mathrm{C}^{p+q}(X, \{A, B\}; R) \\ (\varphi, \psi) & \mapsto & \left[\begin{array}{rcl} \mathrm{C}_{p+q}(X) & \to & R \\ \sigma & \mapsto & \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \end{array}\right]. \end{array}$$

[1405] What is the "natural" map?

is well-defined and it induces an R-bilinear map

$$\cup\colon \mathrm{H}^p(X,A;R)\times \mathrm{H}^q(X,B;R) \;\to\; \mathrm{H}^{p+q}(X,\{A,B\};R).$$

Proof. The lemma follows easily from the following claim.

Claim. Given $\varphi\in \mathrm{C}^p(X,A;R)$ and $\psi\in \mathrm{C}^q(X,B;R)$ the homomorphism

$$\begin{array}{rcl} \mathrm{C}_{p+q}(X) & \to & R \\ (\sigma\colon \Delta^{p+q}\to X) & \mapsto & \varphi(\sigma\circ[v_0,\dots,v_p])\cdot\psi(\sigma\circ[v_p,\dots,v_{p+q}]) \end{array}$$

lies actually in $\mathrm{C}^{p+q}(X,\{A,B\})$.

Proof. By the remark on page 2534 we have to show that the above cochain vanishes on all singular $(p+q)$-simplices that lie entirely in A or that lie entirely in B. But this is clear:

(1) given $\sigma\colon \Delta^{p+q}\to A$ the first factor $\varphi(\sigma\circ[v_0,\dots,v_p])$ is necessarily zero since we have $\varphi\in \mathrm{C}^p(X,A;R)$, and similarly,
(2) given $\sigma\colon \Delta^{p+q}\to B$ the second factor $\psi(\sigma\circ[v_p,\dots,v_{p+q}])$ is necessarily zero since we have $\psi\in \mathrm{C}^q(X,B;R)$.

This concludes the proof of the claim and thus also of the lemma. ∎

Definition. Let (X,A,B) be an excisive triad of topological spaces and let R be a commutative ring. We refer to the composition

$$\mathrm{H}^p(X,A;R)\times \mathrm{H}^q(X,B;R) \xrightarrow{(c,d)\mapsto c\cup d} \mathrm{H}^{p+q}(X,\{A,B\};R) \xleftarrow[\uparrow]{\cong} \mathrm{H}^{p+q}(X,A\cup B;R)$$

isomorphism by Lemma 115.1

again as a cup product (or sometimes as a relative cup product) and we denote it as usual by the "$\cup$"-symbol.

Remark. Let X be a topological space, let $A,B\subset X$ be subsets and let R be a commutative ring. Suppose that $\mathrm{C}_*^{\{A,B\}}(A\cup B)=\mathrm{C}_*(A\cup B)$. (This is for example the case if $A=B=\varnothing$ or more generally, if A is a subset of B or if B is a subset of A.) Then the above definition of the cup product is just the "naive" definition given by

$$\begin{array}{rcl} \mathrm{C}^p(X,A;R)\times \mathrm{C}^q(X,B;R) & \to & \mathrm{C}^{p+q}(X,A\cup B;R) \\ (\varphi,\psi) & \mapsto & \left(\begin{array}{rcl} \mathrm{C}_{p+q}(X,A\cup B) & \to & R \\ \sigma & \mapsto & \underbrace{\varphi(\sigma\circ[v_0,\dots,v_p])}_{\in R}\cdot\underbrace{\psi(\sigma\circ[v_p,\dots,v_{p+q}])}_{\in R} \end{array}\right). \end{array}$$

In the following we summarize a few properties of the relative cup product. We start out with the obvious generalization of the Cup Product-Commutativity Proposition 114.8.

Proposition 115.3. (Cup Product-Commutativity Proposition) Let (X,A,B) be an excisive triad of topological spaces and let R be a commutative ring. For every $\varphi\in \mathrm{H}^k(X,A;R)$ and $\psi\in \mathrm{H}^l(X,B;R)$ we have

$$\varphi\cup\psi \;=\; (-1)^{kl}\cdot\psi\cup\varphi \;\in\; \mathrm{H}^{k+l}(X,A\cup B;R).$$

Proof. In Exercise 115.1 we will see that a modification of the proof of the Cup Product-Commutativity Proposition 114.8 provides us with a proof of the Cup Product-Commutativity Proposition 115.3. ∎

Note that the first part of following proposition is a generalization of the Cup Product-Naturality Lemma 114.10.

Proposition 115.4. (Cup Product-Naturality Proposition)

(1) Let (X, A, B) and (Y, C, D) be two excisive triads and let R be a commutative ring. Let $f\colon (X, A, B) \to (Y, C, D)$ be a map. Then for all $p, q \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p(Y, C; R) \times \mathrm{H}^q(Y, D; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(Y, C \cup D; R) \\ \downarrow{\scriptstyle f^* \times f^*} & & \downarrow{\scriptstyle f^*} \\ \mathrm{H}^p(X, A; R) \times \mathrm{H}^q(X, B; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(X, A \cup B; R). \end{array}$$

(2) Let (X, A, B) be an excisive triad. If $\varphi\colon R \to S$ is a homomorphism between commutative rings, then for all $p, q \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p(X, A; R) \times \mathrm{H}^q(X, B; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(X, A \cup B; R) \\ \downarrow{\scriptstyle \varphi_* \times \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\ \mathrm{H}^p(X, A; S) \times \mathrm{H}^q(X, B; S) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(X, A \cup B; S). \end{array}$$

Here the vertical maps are the maps defined on page 2401.

Proof.

(1) It follows easily from the definitions that the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}^p(Y, C; R) \times \mathrm{H}^q(Y, D; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(Y, \{C, D\}; R) & \xleftarrow{\cong} & \mathrm{H}^{p+q}(Y, C \cup D; R) \\ \downarrow{\scriptstyle f^* \times f^*} & & \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*} \\ \mathrm{H}^p(X, A; R) \times \mathrm{H}^q(X, B; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(X, \{A, B\}; R) & \xleftarrow{\cong} & \mathrm{H}^{p+q}(X, A \cup B; R). \end{array}$$

The desired statement follows immediately from this observation.

(2) This statement follows, similar to (1), basically immediately from the definitions. ■

We record a particularly useful special case of the Cup Product-Naturality Proposition 115.4 (1) as a corollary.

Corollary 115.5. (Cup Product-Naturality Corollary) Let (X, A, B) be an excisive triad and let R be a commutative ring. Then the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p(X, A; R) \times \mathrm{H}^q(X, B; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(X, A \cup B; R) \\ \downarrow & & \downarrow \\ \mathrm{H}^p(X; R) \times \mathrm{H}^q(X; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(X; R). \end{array}$$

In particular, if $\alpha \in \mathrm{H}^p(X; R)$ lies in the image of $\mathrm{H}^p(X, A; R)$ and if $\beta \in \mathrm{H}^q(X; R)$ lies in the image of $\mathrm{H}^q(X, B; R)$ and if $A \cup B = X$, then $\alpha \cup \beta = 0$.

Proof. The first part of the corollary follows immediately from the Cup Product-Naturality Proposition 115.4 (1) applied to the obvious map $f\colon (X, \varnothing, \varnothing) \to (X, A, B)$ of excisive triads.

We turn to the proof of the second part. We denote by $\sigma\colon \mathrm{H}^p(X, A; R) \to \mathrm{H}^p(X; R)$, $\tau\colon \mathrm{H}^p(X, B; R) \to \mathrm{H}^p(X; R)$ and by $\upsilon\colon \mathrm{H}^{p+q}(X, A \cup B; R) \to \mathrm{H}^{p+q}(X; R)$ the obvious maps.

Let $\widehat{\alpha} \in \mathrm{H}^p(X, A; R)$ and $\widehat{\beta} \in \mathrm{H}^q(X, B; R)$. We write $\alpha = \sigma(\widehat{\alpha})$ and $\beta = \tau(\widehat{\beta})$. We suppose that $A \cup B = X$. Then

$$\alpha \cup \beta \;=\; \sigma(\widehat{\alpha}) \cup \tau(\widehat{\beta}) \;\underset{\text{by the commutative diagram}}{=}\; \upsilon\big(\widehat{\alpha} \cup \widehat{\beta}\big) \;\underset{\substack{\text{since } \widehat{\alpha} \cup \widehat{\beta} \text{ lies in the group} \\ \mathrm{H}^{p+q}(X, A \cup B; R) = \mathrm{H}^{p+q}(X, X; R) = 0}}{=}\; \upsilon(0) \;=\; 0.$$

■

Before we state the next lemma we introduce one more convention.

Convention. Let A, B, C, D, X and Y be sets, let $f\colon C \to A$, $g\colon B \to D$ and $\mu\colon X \to Y$ be maps and let $\varphi\colon A \times B \to X$ and $\psi\colon C \times D \to Y$ be maps. We say that the diagram

$$\begin{array}{ccc} A \times B & \xrightarrow{\varphi} & X \\ {\scriptstyle f}\uparrow \quad \downarrow{\scriptstyle g} & & \quad {\scriptstyle \mu}\downarrow \\ C \times D & \xrightarrow{\psi} & Y \end{array}$$

commutes, if for all $c \in C$ and $b \in B$ we have

$$\psi(c, g(b)) \;=\; \mu(\varphi(f(c), b)).$$

A similar convention holds with the directions of f and g reversed. Furthermore, if we are dealing with group homomorphisms, then there is an obvious notion of "commutes up to a given sign".

Using this convention we can now formulate our next lemma.

Lemma 115.6. (Cup Product-Connecting Homomorphism Lemma) Let (X, A) be a pair of topological spaces and let R be a commutative ring. We denote by $i\colon A \to X$ the inclusion map and we denote by δ the connecting homomorphisms in the long exact sequence in cohomology corresponding to the pair (X, A). For any $p, q \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^q(A; R) \times \mathrm{H}^p(A; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(A; R) \\ {\scriptstyle \delta}\downarrow \quad \uparrow{\scriptstyle i^*} & & \quad \downarrow{\scriptstyle \delta} \\ \mathrm{H}^{q+1}(X, A; R) \times \mathrm{H}^p(X; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q+1}(X, A; R) \end{array}$$

and the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}^p(A; R) \times \mathrm{H}^q(A; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(A; R) \\ {\scriptstyle i^*}\uparrow \quad \downarrow{\scriptstyle \delta} & & \quad \downarrow{\scriptstyle \delta} \\ \mathrm{H}^p(X; R) \times \mathrm{H}^{q+1}(X, A; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q+1}(X, A; R) \end{array}$$

up to the sign $(-1)^p$.

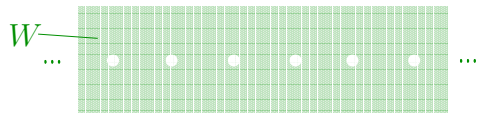
Remark. In Lemma 132.18 we will formulate a generalization of the Cup Product-Connecting Homomorphism Lemma 115.6.

Proof. For no particular reason we prove the second statement. The first statement can either be proved the same way or it can be deduced from the second statement using the Cup Product-Commutativity Proposition 115.3. We pick cocycles $\varphi \in \mathrm{C}^p(X; R)$ and $\psi \in \mathrm{C}^q(A; R)$. In the following we denote by $\widetilde{\psi}\colon \mathrm{C}^q(X) \to R$ the extension of ψ that is defined to be zero on all singular k-simplices that do not lie in the subset A. We have the

following equalities:

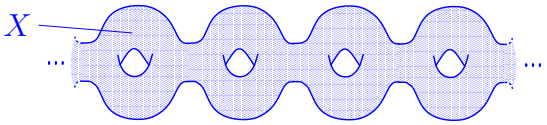
$$\begin{array}{lllll}
\delta([i^*\varphi]\cup[\psi]) & = \delta([i^*\varphi\cup\psi]) & \overset{\text{by the discussion of the connecting homomorphism in the remark on page 2411 and since } \varphi\cup\psi \text{ is the trivial extension of } i^*\varphi\cup\psi\colon \mathrm{C}_{p+q}(A)\to R \text{ to a homomorphism } \mathrm{C}_{p+q}(X)\to R}{=} [\delta(\varphi\cup\widetilde{\psi})] & \overset{\text{Coboundary-Cup Product Lemma 114.2}}{=} [\delta\varphi\cup\widetilde{\psi}+(-1)^p\cdot(\varphi\cup\delta\widetilde{\psi})] \\
= (-1)^p\cdot[\varphi\cup\delta\widetilde{\psi}] & = (-1)^p\cdot([\varphi]\cup[\delta\widetilde{\psi}]) & = (-1)^p\cdot([\varphi]\cup\delta[\psi]). & \\
\text{since } \varphi \text{ is a cocycle} & & \text{again by the remark on page 2411} &
\end{array}$$

This equality implies that the diagram commutes up to the sign $(-1)^p$. ■



Finally, recall that on page 2479 we introduced cohomology with compact support $\mathrm{H}^*_{\mathrm{c}}(X;\mathbb{Z})$. For the insatiable reader we also provide the definition of the cup product on cohomology with compact support.

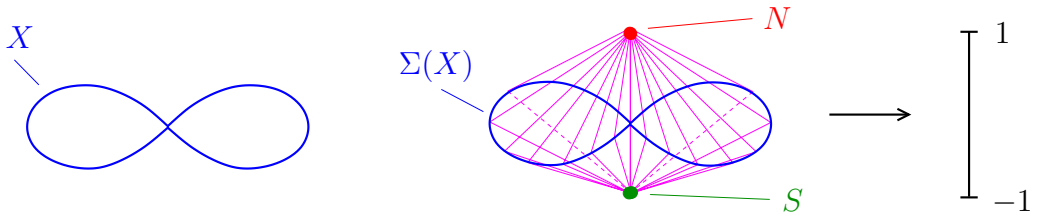
Definition. Let X be a topological space, let $\varphi\in\mathrm{H}^k_{\mathrm{c}}(X;\mathbb{Z})$ and let $\psi\in\mathrm{H}^l_{\mathrm{c}}(X;\mathbb{Z})$. Recall that by Lemma 112.2 there exists a compact subset $K\subset X$ and a cohomology class $\widetilde{\varphi}\in\mathrm{H}^k(X,X\setminus K;\mathbb{Z})$ such that the image of $\widetilde{\varphi}$ in $\mathrm{H}^k_{\mathrm{c}}(X;\mathbb{Z})$ equals φ. Analogously we find a compact set L and $\widetilde{\psi}\in\mathrm{H}^l(X,X\setminus L;\mathbb{Z})$. We define



$$\varphi\cup\psi \;:=\; \text{the image of } \varphi\cup\psi\in\mathrm{H}^{k+l}(X,X\setminus(K\cup L)) \text{ in } \mathrm{H}^{k+l}_{\mathrm{c}}(X;\mathbb{Z}).$$

It follows easily from the Cup Product-Naturality Corollary 115.5 that this definition does not depend on any of the choices. We refer to $\varphi\cup\psi$ as the cup product in cohomology with compact support.

The cup product on cohomology with compact support can be very useful for tackling non-compact spaces. For example in Exercise 115.5 we will make of use of the cup product on cohomology with compact support to show that the topological manifold $W=\mathbb{R}^2\setminus\{(n,0)\,|\,n\in\mathbb{Z}\}$ is not homeomorphic to the surface X of infinite genus that is shown in the figure below. On a more theoretical side we will make of the above definition in Theorem 127.9 when we will learn how to compute cup products on topological manifolds by "intersecting cycles".



cup product on $\mathrm{H}^*_{\mathrm{c}}(W;\mathbb{Z})$ is trivial

cup product on $\mathrm{H}^*_{\mathrm{c}}(X;\mathbb{Z})$ is non-trivial

115.2. **Calculations using the relative cup product.** In this section we will use the Cup Product-Naturality Proposition 115.4 (1) to calculate cup products of several topological spaces. We start out with the suspension $\Sigma(X)=(X\times[-1,1])/\sim$ of a topological space X. We refer to page 451 for the precise definition and we refer to the figure below for a reminder.

The following lemma shows that the cup product of the suspension of a topological space is quite dull.

Lemma 115.7. (Suspension-Cup Product Lemma) Let X be a path-connected topological space and let R be a commutative ring.

(1) We have

$$\mathrm{H}^k(\Sigma(X);R) \;\cong\; \begin{cases} R, & \text{if } k=0,\\ 0, & \text{if } k=1,\\ \mathrm{H}^{k-1}(X;R), & \text{if } k\geq 2. \end{cases}$$

(2) For any $k,l\geq 1$ the cup product

$$\mathrm{H}^k(\Sigma(X);R)\times \mathrm{H}^l(\Sigma(X);R) \;\to\; \mathrm{H}^{k+l}(\Sigma(X);R)$$

is the zero map.

Proof. We denote by $p\colon X\times[-1,1]\to\Sigma(X)$ the natural projection. We denote by $N:=[X\times\{1\}]$ the "North Pole" and we denote by $S:=[X\times\{-1\}]$ the South Pole. We refer to the figure above for an illustration. We write $U=\Sigma(X)\setminus\{S\}$ and $V=\Sigma(X)\setminus\{N\}$. By the same argument as in the Cone Contractibility Lemma 16.7 that U admits deformation retraction from U to the North Pole N. This shows that U is contractible. The same argument shows that V is contractible.

(1) Note that U and V are open subsets of $\Sigma(X)$.[1406] It follows from the Excisive Triad-Proposition 109.12 (4) that $(\Sigma(X),U,V)$ is excisive. Therefore we can apply the Mayer–Vietoris Theorem 109.15 for Cohomology Groups and we obtain the following long exact sequence

$$\ldots\to\mathrm{H}^i(\Sigma(X);R)\to\mathrm{H}^i(U;R)\oplus\mathrm{H}^i(V;R)\to\mathrm{H}^i(U\cap V;R)\to\mathrm{H}^{i+1}(\Sigma(X);R)\to\ldots$$

The desired isomorphism now follows easily from the above long exact sequence and the following:
(a) above we had observed that U and V are contractible,
(b) the intersection $U\cap V$ is homeomorphic to $X\times(-1,1)$, in particular it is homotopy equivalent to X,
(c) Lemmas 108.14 and 108.12 and the discussion of induced maps on 0-th cohomology on page 2409.

(2) Now let $k,l\geq 1$. It follows immediately from the long exact sequence of cohomology groups corresponding to the pair $(\Sigma(X),U)$, the fact that U is homotopy equivalent to a point (together with Lemmas 108.12 and 108.13) that the inclusion induced map $\mathrm{H}^k(\Sigma(X),U;R)\to\mathrm{H}^k(\Sigma(X);R)$ is an isomorphism. Evidently the same also holds if we replace U by V.

By the Cup Product-Naturality Corollary 115.5, and the fact that $(\Sigma(X),U,V)$ is excisive, we have the following commutative diagram

[1406] Why is that?

$$\begin{array}{ccc} \mathrm{H}^k(\Sigma(X), U; R) \times \mathrm{H}^l(\Sigma(X), V; R) & \xrightarrow{\cup} & \mathrm{H}^{k+l}(\Sigma(X), \overbrace{U \cup V}^{=\Sigma(X)}; R) \\ \downarrow\cong & & \downarrow \\ \mathrm{H}^k(\Sigma(X); R) \times \mathrm{H}^l(\Sigma(X); R) & \xrightarrow{\cup} & \mathrm{H}^{k+l}(\Sigma(X); R). \end{array}$$

Since $U \cup V = \Sigma(X)$ we see that the cohomology group on the top-right is zero. Furthermore, since the vertical map on the left is an isomorphism we see that the cup product on the bottom is zero. ■

Let X and Y be two topological spaces and let $x \in X$ and $y \in Y$ be good points. (See page 1171 for the definition of a good point.) We use these points to define the wedge $X \vee Y$ of X and Y. Furthermore let R be a commutative ring. We denote by $p\colon X \vee Y \to X$ and $q\colon X \vee Y \to Y$ the natural projections. By the Wedge-H*-Proposition 109.17 we know that for every $n \in \mathbb{N}$ the map

$$p^* \oplus q^*\colon \mathrm{H}^n(X; R) \oplus \mathrm{H}^n(Y; R) \xrightarrow{\cong} \mathrm{H}^n(X \vee Y; R)$$

is an isomorphism. The following lemma determines the cup product of $X \vee Y$ in terms of the cup products of X and Y. It can be viewed as a generalization of Lemma 114.11.

Lemma 115.8. (Wedge-Cup Product Lemma) We continue with the above notation. Then for any $\alpha, \beta \in \mathrm{H}^*(X; R)$ and $\varphi, \psi \in \mathrm{H}^*(Y; R)$ in degrees ≥ 1 the following statements hold in $\mathrm{H}^*(X \vee Y; R)$:

$\cup$	$p^*(\beta)$	$q^*(\psi)$
$p^*(\alpha)$	$p^*(\alpha \cup \beta)$	0
$q^*(\varphi)$	0	$q^*(\varphi \cup \psi)$

Proof. The statement regarding the "diagonal" terms of the table follows immediately from the Cup Product-Naturality Lemma 114.10. It remains to prove that the off-diagonal terms are zero. We show that the top-right entry is zero. The proof that the bottom-left entry is zero is basically identical.

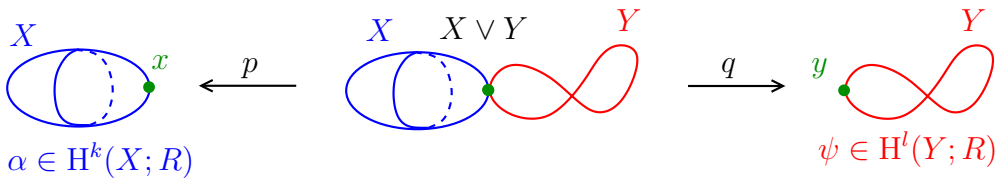
Thus let $\alpha \in \mathrm{H}^k(X; R)$ and $\psi \in \mathrm{H}^l(Y; R)$ with $k, l \geq 1$. We view X and Y as subsets of $X \vee Y$. We denote by $f\colon (X \vee Y, \varnothing) \to (X \vee Y, X)$ and $g\colon (X \vee Y, \varnothing) \to (X \vee Y, Y)$ the two inclusion maps of pairs of topological spaces.

Claim. There exist $\widetilde{\alpha} \in \mathrm{H}^k(X \vee Y, Y; R)$ with $g^*(\widetilde{\alpha}) = p^*(\alpha)$ and $\widetilde{\psi} \in \mathrm{H}^l(X \vee Y, X; R)$ with $f^*(\widetilde{\psi}) = q^*(\psi)$.

Proof. To prove the claim we consider the following two diagrams[1407]

$$\begin{array}{ccc} \mathrm{H}^k(X \vee Y; R) & \xleftarrow{g^*} & \mathrm{H}^k(X \vee Y, Y; R) \\ {\scriptstyle p^*}\uparrow & & \downarrow \\ \mathrm{H}^k(X; R) & \longleftarrow & \mathrm{H}^k(X, \{x\}; R) \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{H}^l(X \vee Y; R) & \xleftarrow{f^*} & \mathrm{H}^l(X \vee Y, X; R) \\ {\scriptstyle q^*}\uparrow & & \downarrow \\ \mathrm{H}^l(Y; R) & \longleftarrow & \mathrm{H}^l(Y, \{y\}; R). \end{array}$$

Here the maps that are unlabeled are induced by the obvious inclusions. It is easy to verify that the diagrams commute. It follows easily from the long exact sequence in cohomology



[1407]Recall that in $X \vee Y$ the points x and y get identified, so we can view x as an element in Y and we can view y as an element in X.

of a pair of topological spaces that the two bottom horizontal maps are isomorphisms. Recall that in the Wedge Excisive Lemma 109.16 we showed that the triad $(X \vee Y, X, Y)$ is excisive. Therefore it follows from the Excisive Characterization Lemma 109.13 that the vertical maps on the right are isomorphisms. The claim is an immediate consequence of these observations. ⊞

Since, as we had just seen, the triad $(X \vee Y, X, Y)$ is excisive we can apply the Cup Product-Naturality Corollary 115.5 and we obtain that

$$p^*(\alpha) \cup q^*(\psi) \;=\; g^*(\widetilde{\alpha}) \cup f^*(\widetilde{\psi}) \underset{\uparrow}{=} 0.$$

by the Cup Product-Naturality Corollary 115.5 since $X \cup Y = X \vee Y$ ■

Example. Now we can also give a new proof of Lemma 114.16, more precisely, we can give a new and somewhat more conceptual proof of the calculation of the cup product of the surface Σ of genus 2. First we recall that on page 2428 we introduced two projections $p_i \colon \Sigma \to T_i = S^1 \times S^1$ for $i = 1, 2$. It follows easily from Lemma 107.3 that these projections are degree-one maps, i.e. they send the fundamental class $[\Sigma]$ to the fundamental class $[T_i]$. In Lemma 109.11 we saw that the map

$$p_1^* \oplus p_2^* \colon \mathrm{H}^1(T_1; \mathbb{Z}) \oplus \mathrm{H}^1(T_2; \mathbb{Z}) \;\to\; \mathrm{H}^1(\Sigma; \mathbb{Z})$$

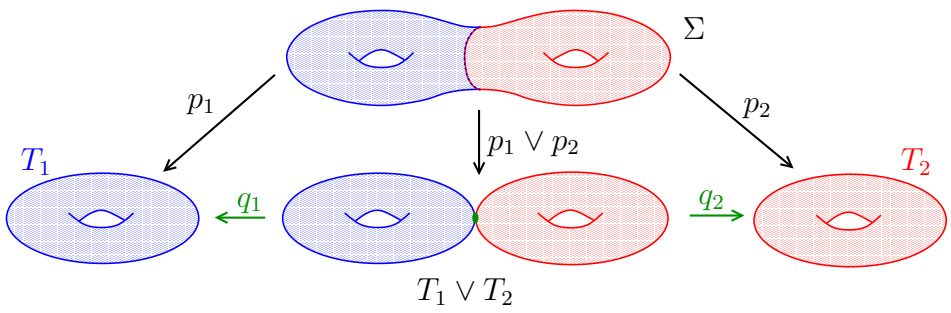
is an isomorphism. We make the following observations:

(1) Let $\varphi, \psi \in \mathrm{H}^1(T_i; \mathbb{Z})$, $i = 1, 2$. Then

$$\langle \varphi \cup \psi, [T_i] \rangle_{T_i} \underset{\uparrow}{=} \langle \varphi \cup \psi, p_{i*}([\Sigma]) \rangle_{T_i} \underset{\uparrow}{=} \langle p_i^*(\varphi \cup \psi), [\Sigma] \rangle_{\Sigma} \underset{\uparrow}{=} \langle p_i^*(\varphi) \cup p_i^*(\psi), [\Sigma] \rangle_{\Sigma}.$$

since p_i is of degree one — Lemma 109.6 (3) — Cup Product-Naturality Lemma 114.10

(2) We denote by $q_i \colon T_1 \vee T_2 \to T_i$, $i = 1, 2$ the obvious projections. The two projections p_1, p_2 give rise to a map $p_1 \vee p_2 \colon \Sigma \to T_1 \vee T_2$ which has the property that $q_i \circ (p_1 \vee p_2) = p_i$, $i = 1, 2$. (See the figure below for an illustration.) Now let $\varphi_1 \in \mathrm{H}^1(T_1; \mathbb{Z})$ and $\varphi_2 \in \mathrm{H}^1(T_2; \mathbb{Z})$. Then



$$p_1^*(\varphi_1) \cup p_2^*(\varphi_2) \underset{\uparrow}{=} (p_1 \vee p_2)^*(q_1^*(\varphi_1) \cup q_2^*(\varphi_2)) \underset{\uparrow}{=} (p_1 \vee p_2)^*(0) \;=\; 0.$$

by the Cup Product-Naturality Lemma 114.10, since $q_i \circ (p_1 \vee p_2) = p_i$ — Wedge-Cup Product Lemma 115.8

Precisely the same proof shows also that $p_2^*(\varphi_2) \cup p_1^*(\varphi_1) = 0$.

These two claims, together with the previous calculation of the cup product on the torus $T = S^1 \times S^1$, see Lemma 114.14, give a new proof of Lemma 114.16.

115.3. **The Lusternik-Schnirelmann category.** We start out with the following definition.

Definition. Let M be an m-dimensional smooth manifold.

(1) A parametrization for M is a smooth map $\Psi\colon V \to M$ with the following properties:
   (a) the domain V is either an open ball in $\mathbb{R}^m$, or an open rectangle, or all of $\mathbb{R}^m$,[1408]
   (b) the map Ψ is a diffeomorphism onto its image.

(2) We say a family $\{\Psi_i\colon V_i \to M\}_{i\in I}$ of parametrizations covers M if $\bigcup_{i\in I} \Psi_i(V_i) = M$.

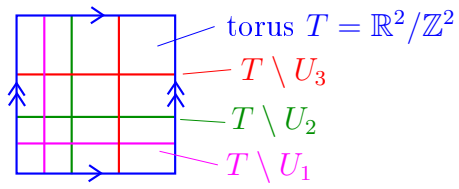
The following slightly vague question arises:

Question 115.9. For a given smooth manifold M, how many parametrizations do we need to cover all of M?

Examples.

(1) Let $N = (0, \dots, 0, 1)$ be the North Pole and let $S = (0, \dots, 0, -1)$ be the South Pole of the n-dimensional sphere S^n. We can cover S^n by the two open subsets $S^n \setminus \{N\}$ and $S^n \setminus \{S\}$. Stereographic projection, see the figure on page 155, gives rise to two diffeomorphisms $\Phi_1\colon S^n \setminus \{N\} \to \mathbb{R}^n$ and $\Phi_2\colon S^n \setminus \{S\} \to \mathbb{R}^n$. The inverses of these two maps define parametrizations that cover S^n.

Since S^n is not diffeomorphic to any of the admissible domains of a parametrization we see that the above collection of parametrizations is optimal in the sense that we cannot parametrize S^n with fewer parametrizations.



(2) We consider the n-torus $(S^1)^n = \mathbb{R}^n/\mathbb{Z}^n$. We denote by $p\colon \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ the projection . We pick real numbers $0 < s_1 < s_2 < \cdots < s_{n+1} < 1$. For $i = 1, \dots, n+1$ we consider the map

$$\begin{array}{rccc} \Psi_i\colon & \overbrace{(s_i, s_i+1)\times\ldots\times(s_i, s_i+1)}^{=:V_i} & \to & \mathbb{R}^n/\mathbb{Z}^n \\ & (t_1, \dots, t_n) & \mapsto & p(t_1, \dots, t_n). \end{array}$$

For $i = 1, \dots, n+1$ we write $U_i = \Psi_i(V_i)$. It is straightforward to see that the maps $\Psi_1, \dots, \Psi_{n+1}$ are parametrizations that cover $\mathbb{R}^n/\mathbb{Z}^n$.[1409] We illustrate the images of the parametrizations for the 2-torus in the figure below.

[1408] The condition on V sounds slightly arbitrary, and it is, but it is reasonable that for practical purposes one prefers domains that are "easy to describe".

[1409] Hmm, why is it true that $U_1 \cup \cdots \cup U_{n+1} = \mathbb{R}^n/\mathbb{Z}^n$?

(3) For $i = 1, \ldots, n+1$ we consider the map

$$\begin{array}{rcl} \Psi_i \colon \mathbb{R}^n & \to & \mathbb{R}\mathrm{P}^n = (\mathbb{R}^{n+1} \setminus \{0\})/\sim \\ (x_1, \ldots, x_n) & \mapsto & \underbrace{[x_1 : \ldots : x_{i-1} : 1 : x_i : \ldots : x_n]}_{\text{point in } \mathbb{R}\mathrm{P}^n \text{ represented by } (x_1, \ldots, x_{i-1}, 1, x_i, \ldots, x_n)}. \end{array}$$

It is straightforward to see that the maps $\Psi_1, \ldots, \Psi_{n+1}$ are parametrizations that cover the real projective space $\mathbb{R}\mathrm{P}^n$.

(4) Almost the same construction as in (3) shows that we can cover the complex projective space $\mathbb{C}\mathrm{P}^n = (\mathbb{C}^{n+1} \setminus \{0\})/\sim$ by $n+1$ parametrizations such that the domain of each parametrization is diffeomorphic to $\mathbb{C}^n \cong \mathbb{R}^{2n}$.

The following question is now a more precise version of Question 115.9.

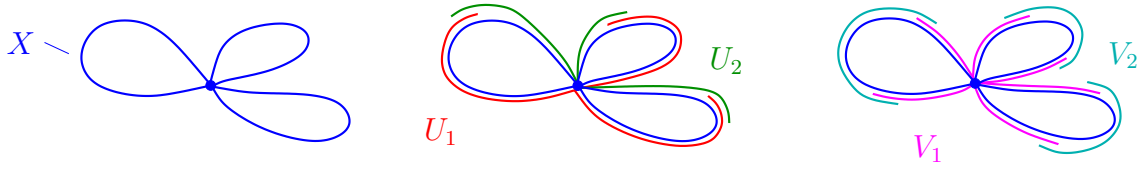
Question 115.10.

(1) Can we cover $(S^1)^n$ by fewer than $n+1$ parametrizations?
(2) Can we cover $\mathbb{R}\mathrm{P}^n$ by fewer than $n+1$ parametrizations?
(3) Can we cover $\mathbb{C}\mathrm{P}^n$ by fewer than $n+1$ parametrizations?

In the remainder of this chapter we will study a generalization of these questions and we will see how cup products can be used to approach this question and its generalizations. We will eventually answer Question 115.10 in Corollary 117.23 and Proposition 121.18.
Now we will generalize this discussion to arbitrary topological spaces by introducing the following definition.

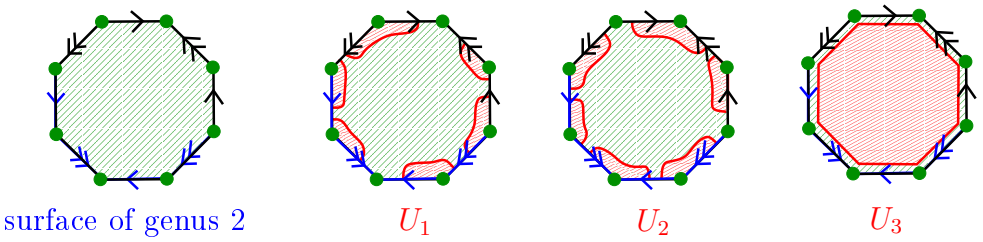
Definition.

(1) We say that a map $f \colon Y \to X$ between topological spaces is null-homotopic if it is homotopic to a constant map.
(2) The Lusternik-Schnirelmann category $\mathrm{cat}(X)$[1410] of a topological space X is defined as the smallest $n \in \mathbb{N}_0$ such that there exists an open cover $U_1, \ldots, U_{n+1}$ of X such that each inclusion map $U_i \to X$ is null-homotopic.[14111412] If no such n exists, then we define $\mathrm{cat}(X) = \infty$.



Remark.

[1410]The word "category" with its modern meaning was first used by Eilenberg-Maclane [**EMc1945**] in 1945. On the other hand the term "Lusternik-Schnirelmann category" was already established by 1941, see [**Fox1941**].
[1411]Recall that according to the definition on page 418 a map $f \colon U \to X$ is called null-homotopic if it is homotopic to a constant map.
[1412]Note the fairly well-hidden "+1" in the subscript of U_{n+1}. Sometimes, especially in the older literature the Lusternik-Schnirelmann category is defined without the adjustment given by the "+1".



(1) Suppose that a given smooth manifold M can be covered by $n+1$ parametrizations. Since the domain of a parametrization is contractible and since a parametrization is a diffeomorphism onto its image we see that $\mathrm{cat}(M) \leq n$.[1413]
(2) The sets U_i in the definition of the Lusternik-Schnirelmann category do not have to be contractible, for example if X itself is contractible, then for any subset $U \subset X$ the inclusion map $U \to X$ is null-homotopic.
(3) The Lusternik-Schnirelmann category plays an important role in topological robotics, see e.g. [**Far2008**] for more details.

Examples.

(1) For a non-empty topological space X we have $\mathrm{cat}(X) = 0$ if and only if $\mathrm{id}\colon X \to X$ is null-homotopic, i.e. if X is contractible.
(2) The above discussion of parametrizations of S^n together with Statement (1) shows that $\mathrm{cat}(S^n) = 1$.
(3) (a) In the figure below we consider the wedge X of $n \geq 1$ circles together with two open covers $X = U_1 \cup U_2$ and also $X = V_1 \cup V_2$. Note that all the inclusion maps $U_i \to X$ and also $V_i \to X$ are null-homotopic. So this gives us two separate proofs that $\mathrm{cat}(X) \leq 1$. Together with Statement (1) this shows that we have $\mathrm{cat}(X) = 1$.
(b) Using the obvious generalization of the sets V_1 and V_2 shown in the figure below one can easily show that the Lusternik-Schnirelmann category of any non-empty wedge of spheres has Lusternik-Schnirelmann category equal to 1.

(4) The discussion preceding Question 115.10 gives us the inequalities $\mathrm{cat}((S^1)^n) \leq n$, $\mathrm{cat}(\mathbb{R}\mathrm{P}^n) \leq n$ and also $\mathrm{cat}(\mathbb{C}\mathrm{P}^n) \leq n$.
(5) For any $g \geq 2$ the surface Σ of genus g satisfies $\mathrm{cat}(\Sigma) \leq 2$, see the figure below for an illustration in the case $g = 2$.

We move on to more general statements.

Proposition 115.11. Let X and Y be topological spaces. If X and Y are homotopy equivalent, then $\mathrm{cat}(X) = \mathrm{cat}(Y)$.

[1413] Hmm, why is the image of a parametrization an open subset of the smooth manifold?

Proof. We outsource the proof of the proposition to Exercise 115.9. Alternatively the diffident reader is referred to [**CLOT2003**, Theorem 1.30] for the proof. ■

The following proposition gives interesting upper bounds for many examples. In particular it gives a unified approach to the above Examples (3)-(5).

Proposition 115.12.
(1) If X is a connected n-dimensional simplicial complex X, then $\operatorname{cat}(X) \leq n$.
(2) If X is a connected n-dimensional CW-complex, then $\operatorname{cat}(X) \leq n$.
(3) If X is a connected n-dimensional smooth manifold, then $\operatorname{cat}(X) \leq n$.
(4) If X is a connected n-dimensional topological manifold, then $\operatorname{cat}(X) \leq n$.

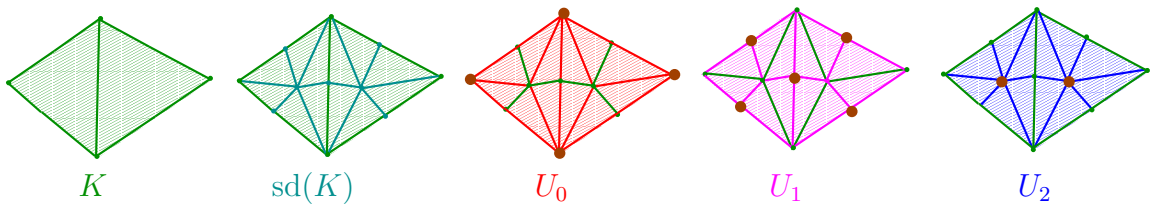
In the proof of Proposition 115.12 we make use of the following lemma.

Lemma 115.13. Let X be a topological space and let $U \subset X$ be a subset with components $\{U_i\}_{i \in I}$. If each inclusion $U_i \to X$ is null-homotopic and if X is path-connected, then the inclusion $U \to X$ is also null-homotopic.

Proof. By hypothesis there exists for each $i \in I$ a $P_i \in X$ such that the inclusion map $U_i \to X$ is homotopic to the constant map which sends all points in U_i to P_i. Now pick $Q \in X$. Since X is path-connected we can find paths that connect the P_i to Q. Using these paths we can construct a homotopy from the inclusion map $U \to X$ to the constant map that sends all points to Q. ■

Proof.

(1) We only have to deal with the case that $X = |K|$ is the topological realization of a connected n-dimensional abstract simplicial complex. We consider the barycentric subdivision $\operatorname{sd}(K)$ as defined in Lemma 94.2. By the SD-Lemma 94.3 (3d) we know that the topological realization $|\operatorname{sd}(K)|$ is homeomorphic to $|K|$. Thus it suffices to show that $\operatorname{cat}(|\operatorname{sd}(K)|) \leq n$. For $i = 0, \ldots, n$ we set



$$S_i \;:=\; \text{set of } i\text{-simplices of } K \qquad \text{and} \qquad U_i \;=\; \bigcup_{s \in S_i} \mathring{\operatorname{St}}(\operatorname{sd}(K), \underline{s}).$$

In other words, U_i is the union of the open stars in the barycentric subdivision corresponding to the vertices of the barycentric subdivision that are given by the barycenters of the i-simplices of K. We fix $i \in \{0, \ldots, n\}$. We make the following observations:
(a) By the Link Star Lemma 94.5 (1d) we know that each $\mathring{\operatorname{St}}(\operatorname{sd}(K), \underline{s})$ is contractible.
(b) It follows easily from the Link Star Lemma 94.5 (3) that for any two $s \neq t \in S_i$ we have $\mathring{\operatorname{St}}(\operatorname{sd}(K), s) \cap \mathring{\operatorname{St}}(\operatorname{sd}(K), t) = \varnothing$.

It follows almost immediately from (a) and (b), together with Lemma 115.13 that the inclusion $U_i \to |\operatorname{sd}(K)|$ is null-homotopic.

Furthermore it follows from the Link Star Lemma 94.5 (2b) that the U_i, $i = 0, \ldots, n$ form an open cover of $|\operatorname{sd}(K)|$. Thus we shown that $\operatorname{cat}(|\operatorname{sd}(K)|) \leq n$.

(2) By Proposition 94.12 we know that every connected n-dimensional CW-complex is homotopy equivalent to a connected n-dimensional simplicial complex. Thus the statement follows from (1) together with Proposition 115.11.

(3) Let X be a connected n-dimensional smooth manifold X. By the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that X has the structure of an n-dimensional simplicial complex. Thus the statement follows from (1).
(4) Let X be a connected n-dimensional smooth manifold. There are two different approach to showing that $\mathrm{cat}(X) \leq n$:
   (a) By the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that X has the structure of an n-dimensional simplicial complex. Thus the statement follows from (1).
   (b) In the proof of the Small Atlas Proposition 27.8 we implicitly showed that X admits an atlas $\{\Phi_i \colon U_i \to V_i\}_{i=1,\ldots,n+1}$ with $n+1$ charts with the property that for each component C of any U_i the map $\Phi_i|_C \colon C \to V_i$ factors through a contractible set. Since X is connected we see that each Φ_i is homotopic to a constant map.
(5) Let X be a connected n-dimensional topological manifold. There are again two different approaches to showing that $\mathrm{cat}(X) \leq n$:
   (a) At least if X is compact, then by Theorem 104.26 we know that X is homotopy equivalent to a connected n-dimensional simplicial complex. So the statement follows again from (1) together with Proposition 115.11.
   (b) The approach of (4a) also works in the topological context. ■

Remark. If X and Y are two connected CW-complexes with finite Lusternik-Schnirelmann categories, then $\mathrm{cat}(X \times Y) \leq \mathrm{cat}(X) + \mathrm{cat}(Y)$, see e.g. [**Fox1941**, Theorem 9] or [**CLOT2003**, Theorem 1.37]. The Ganea Conjecture from 1971 predicted that for any CW-complex X one has $\mathrm{cat}(X \times S^n) = \mathrm{cat}(X) + \mathrm{cat}(S^n) = \mathrm{cat}(X) + 1$. But this conjecture was eventually disproved by Norio Iwase [**Iw1998, Iw2002**] in 1998.

As we saw in the above examples and Proposition 115.12, one can obtain an upper bound on the Lusternik-Schnirelmann category of a given topological space by writing down explicit open subsets. To obtain lower bounds on the Lusternik-Schnirelmann category we introduce the following definition.

Definition. Given a topological space X we define its cup length $\mathrm{cl}(X) \in \mathbb{N}_0 \cup \{\infty\}$ as follows:

$$\mathrm{cl}(X) := \max\left\{ n \in \mathbb{N}_0 \,\middle|\, \begin{array}{c}\text{there exists a commutative ring } R \text{ and } R\text{-cohomology} \\ \text{classes } x_1, \ldots, x_n \text{ in degrees} \geq 1 \text{ with } x_1 \cup \cdots \cup x_n \neq 0\end{array} \right\}.$$

Examples.

(1) If X is an n-dimensional CW-complex, then it follows immediately from the Singular-Cellular H^*-Isomorphism Proposition 109.4 that $\mathrm{cl}(X) \leq n$.

(2) In Lemma 114.14 and Lemma 114.16 we saw that for any surface Σ of genus $g \geq 1$ there exist $x, y \in \mathrm{H}^1(\Sigma; \mathbb{Z})$ with $x \cup y \neq 0$, which together with (1) shows that $\mathrm{cl}(\Sigma) = 2$.
(3) In Lemma 114.18 we saw that there exists an $x \in \mathrm{H}_1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ with $x \cup x \neq 0$, which shows that $\mathrm{cl}(\mathbb{R}\mathrm{P}^2) = 2$.

The following proposition shows that the cup length is a lower bound on the Lusternik-Schnirelmann category.

Proposition 115.14. For every topological space X we have

$$\mathrm{cl}(X) \ \leq \ \mathrm{cat}(X).$$

Example. It follows immediately from Proposition 115.14 and the above examples that

$$\mathrm{cat}(S^1 \times S^1) \ = \ \mathrm{cat}(\text{surface of genus } g \geq 2) \ = \ \mathrm{cat}(\mathbb{R}\mathrm{P}^2) \ = \ 2.$$

Proof. Let X be a topological space, let R be a commutative ring and let $x_j \in \mathrm{H}^{s_j}(X; R)$, $j = 1, \ldots, n$ be cohomology classes in dimensions $s_j \geq 1$ such that $x_1 \cup x_2 \cup \cdots \cup x_n \neq 0$. We have to show that $\mathrm{cat}(X) \geq n$.

Thus let $k \leq n$ and let $U_1, \ldots, U_k$ be open subsets in X with $U_1 \cup \cdots \cup U_k = X$ such that each inclusion map $U_i \to X$ is null-homotopic. We have to show that $U_1 \cup \cdots \cup U_k$ is a *proper* subset of X.

Claim. For any $j \in \{1, \ldots, k\}$ the obvious map $\rho_j \colon \mathrm{H}^{s_j}(X, U_j; R) \to \mathrm{H}^{s_j}(X; R)$ is in fact an isomorphism.

Proof. By our hypothesis the inclusion map $i_j \colon U_j \to X$ is null-homotopic, it follows that the restriction map $i_j^* \colon \mathrm{H}^k(X; R) \to \mathrm{H}^k(U_j; R)$ is the zero map for $k \geq 1$ and an epimorphism for $k = 0$.[1414] We deduce from this observation, the long exact sequence of cohomology groups corresponding to the pair (X, U_j) and the fact that $s_j \geq 1$ that the obvious map $\rho_j \colon \mathrm{H}^{s_j}(X, U_j; R) \to \mathrm{H}^{s_j}(X; R)$ is in fact an isomorphism. ⊞

Given $j \in \{1 \ldots, k\}$ we write $y_j := \rho_j^{-1}(x_j) \in \mathrm{H}^{s_j}(X, U_j; R)$ and we set $s = s_1 + \cdots + s_k$. By the Cup Product-Naturality Corollary 115.5[1415] we have the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}^{s_1}(X, U_1; R) \times \cdots \times \mathrm{H}^{s_k}(X, U_k; R) & \xrightarrow{\cup} & \mathrm{H}^{s}(X, U_1 \cup \cdots \cup U_k; R) \\ \Big\downarrow {\scriptstyle (y_1, \ldots, y_k)} \atop {\scriptstyle \downarrow} \atop {\scriptstyle (x_1, \ldots, x_k)} & & \Big\downarrow \\ \mathrm{H}^{s_1}(X; R) \times \cdots \times \mathrm{H}^{s_k}(X; R) & \xrightarrow{\cup} & \mathrm{H}^{s}(X; R). \end{array}$$

By our hypotheses the cup product $x_1 \cup \cdots \cup x_k$ is non-zero, which then implies, by the commutativity of the diagram, that the cup product $y_1 \cup \cdots \cup y_k$ is also non-zero. But this implies that the group $\mathrm{H}^s(X, U_1 \cup \cdots \cup U_k; R)$ is non-zero, which in turn implies that $U_1 \cup \cdots \cup U_k$ is a proper subset of X. ■

[1414] This can be seen as follows: the map $i_j \colon U_j \to X$ is homotopic to a constant map that takes the value $P_j \in X$. We denote by $c_j \colon U_j \to \{P_j\}$ the constant map and we denote by $k_j \colon \{P_j\} \to X$ the inclusion map. We statement now follows from $i_j^* = (k_j \circ c_j)^* = c_j^* \circ k_j^*$ and Lemmas 108.13 and 108.12.

[1415] Strictly speaking Corollary 115.5 was formulated for the cup product of two terms, but one can easily reduce the general case of k terms to the special case of 2 terms.

Proposition 115.14 gives us a tool to attack Question 115.10. In fact we saw right after Proposition 115.14 that we can now answer the question for the 2-dimensional torus $(S^1)^2$ and the real projective plane $\mathbb{R}\mathrm{P}^2$.
The following questions naturally arise:

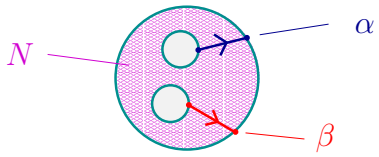
Question 115.15.
(1) What is the $\mathbb{Z}$-cohomology ring of $(S^1)^n$?
(2) What is the $\mathbb{F}_2$-cohomology ring of $\mathbb{R}\mathrm{P}^n$?
(3) What is the $\mathbb{Z}$-cohomology ring of $\mathbb{C}\mathrm{P}^n$?

We will answer these questions in Propositions 117.22, 121.16 and 121.7.
There are many other questions that we cannot answer in these notes, in fact which are still open. As an example we conclude this introduction to the Lusternik-Schnirelmann category of a topological space with the following conjecture which is formulated as a question in [**Rudy2017**, Question 1.1].

Conjecture 115.16. (Rudyak Conjecture) Let M and N be two closed oriented connected n-dimensional topological manifolds. If there exists a map $f\colon M \to N$ of degree one, then $\mathrm{cat}(M) \geq \mathrm{cat}(N)$.

Exercises for Chapter 115.

Exercise 115.1. Let (X, A, B) be an excisive triad of topological spaces and let R be a commutative ring. Show that for every $\varphi \in \mathrm{H}^k(X, A; R)$ and $\psi \in \mathrm{H}^l(X, B; R)$ the following equality holds:



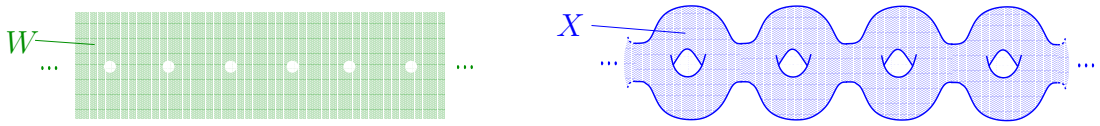
$$\varphi \cup \psi \;=\; (-1)^{kl} \cdot \psi \cup \varphi \;\in\; \mathrm{H}^{k+l}(X, A \cup B; R).$$

Hint. Evidently you should study the proof of the Cup Product-Commutativity Proposition 114.8 carefully.

Exercise 115.2. Let M be the torus minus one open disk. Show that the cup product $\mathrm{H}^1(M, \partial M; \mathbb{Z}) \times \mathrm{H}^1(M, \partial M; \mathbb{Z}) \to \mathrm{H}^2(M, \partial M; \mathbb{Z})$ is non-trivial.
Hint. Reduce this statement to the calculation of the cup product of the torus.

Exercise 115.3. Let N be the disk $\overline{B}^2$ minus two open disks.

(a) Show that the two homology classes $\alpha, \beta \in \mathrm{H}_1(N, \partial N; \mathbb{Z})$ shown in the figure below are a basis for $\mathrm{H}_1(N, \partial N; \mathbb{Z}) \cong \mathbb{Z}^2$.
(b) We denote by $\varphi, \psi \in \mathrm{H}^1(N, \partial N; \mathbb{Z}) = \mathrm{Hom}(\mathrm{H}_1(N, \partial N; \mathbb{Z}), \mathbb{Z})$ the basis dual to α, β. Show that $\alpha \cup \beta = 0 \in \mathrm{H}^2(N, \partial N; \mathbb{Z})$.
Hint. Show that there exist open subsets A and B with the following properties:
(i) $\partial N \subset A$ and $\partial N \subset B$.
(ii) $A \cup B = N$.
(iii) φ lies in the image of $\mathrm{H}^1(N, A; \mathbb{Z}) \to \mathrm{H}^1(N, \partial N; \mathbb{Z})$ and ψ lies in the image of $\mathrm{H}^1(N, B; \mathbb{Z}) \to \mathrm{H}^1(N, \partial N; \mathbb{Z})$.
(c) Show that the cup product $\mathrm{H}^1(N, \partial N; \mathbb{Z}) \times \mathrm{H}^1(N, \partial N; \mathbb{Z}) \to \mathrm{H}^2(N, \partial N; \mathbb{Z})$ is the zero map.



Exercise 115.4. Let M be the torus minus one open disk and let N be the disk $\overline{B}^2$ minus two open disks. Use the calculations from Exercise 115.2 and 115.3 to show that there is no degree one map $g\colon N \to M$.
Remark. This gives an alternative solution to Exercise 101.7 (b).

Exercise 115.5. As in Exercise 115.5 we consider $W = \mathbb{R}^2 \setminus \{(n,0)\,|\,n \in \mathbb{Z}\}$ and we consider the surface X of infinite genus that is shown in the figure below.

(a) Show that the cup product $\mathrm{H}^1_{\mathrm{c}}(W;\mathbb{Z}) \times \mathrm{H}^1_{\mathrm{c}}(W;\mathbb{Z}) \to \mathrm{H}^2_{\mathrm{c}}(W;\mathbb{Z})$, that we defined on page 2539, is the zero map.
(b) Show that the cup product $\mathrm{H}^1_{\mathrm{c}}(X;\mathbb{Z}) \times \mathrm{H}^1_{\mathrm{c}}(X;\mathbb{Z}) \to \mathrm{H}^2_{\mathrm{c}}(X;\mathbb{Z})$ is non-zero.
Hint. You could use the pairing $\mathrm{H}^2_{\mathrm{c}}(X;\mathbb{Z}) \times \mathrm{H}^{\mathrm{lf}}_2(X) \to \mathbb{Z}$ from Exercise 106.5 to detect that an element in $\mathrm{H}^2_{\mathrm{c}}(X;\mathbb{Z})$ is non-zero.
(c) Show that X and W are not homeomorphic.
(d) Does this argument imply that X and W are not homotopy equivalent?

Remark. In Exercise 55.14 we showed the weaker statement that W and X, viewed as 2-dimensional smooth manifolds, are not diffeomorphic.

Exercise 115.6. Let X and Y be non-empty topological spaces. Show that we have the following lower bound on the cup length of $X \times Y$:

$$\mathrm{cl}(X \times Y) \;\geq\; \max\{\mathrm{cl}(X), \mathrm{cl}(Y)\}.$$

Exercise 115.7. Let X and Y be topological spaces. Show that if X and Y are homotopy equivalent, then the cup lengths of X and Y agree, i.e. we have $\mathrm{cl}(X) = \mathrm{cl}(Y)$.

Exercise 115.8. Determine the Lusternik-Schnirelmann category for all compact (not necessarily connected) 2-dimensional smooth manifolds.

Exercise 115.9. Let X and Y be topological spaces. Show that if X and Y are homotopy equivalent, then $\mathrm{cat}(X) = \mathrm{cat}(Y)$.

116. The cap product

In this chapter we introduce the cap product that relates the homology and the cohomology groups. It can be viewed as a generalization of the Kronecker pairing. Initially it might not be clear that the cap product is good for, but later on we will see that it plays an essential role in many calculations and in the formulation of the Poincaré Duality Theorem.

116.1. **The definition of the cap product and calculations.** We start out by introducing a convention that simplifies our notation later on.

Convention. Let R be a commutative ring and let S be a non-empty set. We consider

$$R^{(S)} \ := \ \text{all maps from } S \text{ to } R \text{ which are non-zero for only finitely many } s \in S$$

with the obvious R-module structure. We refer to $R^{(S)}$ as the free R-module generated by S. For example, the free $\mathbb{Z}$-module generated by S is precisely the same as the free abelian group generated by S. We use the same convention as on page 1147 to identify elements in $R^{(S)}$ with finite formal linear combinations $r_1s_1+\cdots+r_ks_k$ where $r_1,\ldots,r_k \in R$ and $s_1,\ldots,s_k \in S$. By the Tensor Lemma 89.3 the map

$$\begin{array}{rcl} \mathbb{Z}^{(S)} \otimes R & \to & R^{(S)} \\ \sum_{i=1}^n n_i \cdot s_i \otimes r_i & \mapsto & \sum_{i=1}^n \underbrace{n_i r_i}_{\in R} \cdot s_i \end{array}$$

is an isomorphism. We use this isomorphism to identify the left-hand side with the right-hand side. In particular, given a topological space X and given $k \in N_0$ we write

$$\mathrm{C}_k(X;R) \ := \ \mathbb{Z}^{S_k(X)} \otimes R \ = \ R^{S_k(X)} \ = \ \left\{ \sum_{i=1}^n r_i \cdot \sigma_i \,\middle|\, r_1,\ldots,r_n \in R \text{ and } \sigma_i \colon \Delta^k \to X \right\},$$

where $S_k(X)$ denotes the set of singular k simplices in X.

The following definition is inspired by the second definition of the cup product that we gave on page 2513.

Definition. Let X be a topological space and let R be a commutative ring. Given a singular cochain $\varphi \in \mathrm{C}^k(X;R)$ and a singular simplex $\sigma \colon \Delta^l \to X$ with $k \leq l$ we define the cap product as[1416]

$$\varphi \cap \sigma \ := \ \underbrace{\varphi(\sigma \circ [v_0,\ldots,v_k])}_{\in R} \cdot \underbrace{\sigma \circ [v_k,\ldots,v_l]}_{\text{map } \Delta^{l-k} \to X}.$$

We extend this definition to singular R-chains and we obtain the cap product

$$\begin{array}{rcl} \cap \colon \mathrm{C}^k(X;R) \times \mathrm{C}_l(X;R) & \to & \mathrm{C}_{l-k}(X;R) \\ \varphi \cap r \cdot \sigma & \mapsto & r \cdot \underbrace{(\varphi \cap \sigma)}_{\in R}. \end{array}$$

For $k > l$ we define the cap product to be the zero map.

As for the cup product, the first thing we want to verify is that this map on the cochain and chain level defines a map on the level of cohomology groups and homology groups. The key to doing so is the following elementary lemma.

[1416] Here we use, as usual, the notation from page 2503.

Lemma 116.1. Let X be a topological space and let R be a commutative ring. Furthermore let $\varphi \in \mathrm{C}^k(X;R)$ and let $\sigma \in \mathrm{C}_l(X;R)$. Then

$$\partial(\varphi \cap \sigma) \;=\; (-1)^k \cdot (-\delta\varphi \cap \sigma \;+\; \varphi \cap \partial\sigma) \;\in\; \mathrm{C}_{l-k-1}(X;R).$$

In particular this implies that $\varphi \cap \partial\sigma$ and $\delta\varphi \cap \sigma$ are homologous.

Proof. For $k > l$ the statement is trivial. So assume that $k \leq l$. Clearly it suffices to prove the equality for the case that $\sigma\colon \Delta^l \to X$ is a singular l-simplex. This case follows from an elementary calculation. Indeed, we have

$$\begin{aligned}
\text{(a)} \qquad \varphi \cap \partial\sigma \;&=\; \sum_{i=0}^{k} (-1)^i \cdot \varphi(\sigma \circ [v_0, \ldots, \widehat{v_i}, \ldots, v_{k+1}]) \cdot \sigma \circ [v_{k+1}, \ldots, v_l] \\
&\qquad + \sum_{i=k+1}^{l} (-1)^i \cdot \varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_k, \ldots, \widehat{v_i}, \ldots, v_l] \\
\text{(b)} \qquad \delta\varphi \cap \sigma \;&=\; \sum_{i=0}^{k+1} (-1)^i \cdot \varphi(\sigma \circ [v_0, \ldots, \widehat{v_i}, \ldots, v_{k+1}]) \cdot \sigma \circ [v_{k+1}, \ldots, v_l] \\
\text{(c)} \qquad (-1)^k \cdot \partial(\varphi \cap \sigma) \;&=\; \sum_{i=k}^{l} (-1)^i \cdot \varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_k, \ldots, \widehat{v_i}, \ldots, v_l].
\end{aligned}$$

Note that the summand of (b) corresponding to $i = k+1$ equals *minus* the summand of (c) corresponding to $i = k$. Adding (b) and (c) and comparing it to (a) we see that

$$\varphi \cap \partial\sigma \;=\; \delta\varphi \cap \sigma + (-1)^k \cdot \partial(\varphi \cap \sigma)$$

which gives the desired equality. ∎

The following lemma says that "$\cap$" descends to a map on homology and cohomology.

Lemma 116.2. Let X be a topological space and let R be a commutative ring. Then for any $k, l \in \mathbb{N}_0$ the map

$$\begin{array}{ccc} \mathrm{H}^k(X;R) \times \mathrm{H}_l(X;R) & \to & \mathrm{H}_{l-k}(X;R) \\ ([\varphi],[\sigma]) & \mapsto & [\varphi \cap \sigma] \end{array}$$

is well-defined and R-bilinear.

We refer to the pairing from Lemma 116.2 as the *cap product*.[1417]

Proof. For $k > l$ the statement is trivial. So assume that $k \leq l$. The statement now follows easily from Lemma 116.1. Indeed, let $\varphi \in \mathrm{C}^k(X;R)$ be a cocycle and let $\sigma \in \mathrm{C}_l(X;R)$ be a cycle.

(1) It follows from Lemma 116.1 that $\varphi \cap \sigma$ is a cycle, i.e. it represents a homology class.
(2) If $\sigma' = \sigma + \partial\tau$ is another representative of $[\sigma]$, then

$$\varphi \cap \sigma - \varphi \cap \sigma' \;=\; \varphi \cap (\sigma - \sigma') \;=\; \varphi \cap \partial\tau \;\underset{\uparrow}{=}\; \pm\partial(\varphi \cap \tau).$$

by Lemma 116.1 and since $\delta\varphi = 0$

This shows that $\varphi \cap \sigma$ and $\varphi \cap \sigma'$ represent the same homology class, i.e. the cap product does not depend on the choice of the representative of the homology class.

[1417] The name "cap product" comes from the notation "$a \cap b$" for the composition since $\cap$ looks like, just a little bit, like the "a" in cap. The other reason is that the cup product was first introduced, and mathematicians needed a different name for a somewhat related object. Also mathematicians are well-known for their great sense of humor.

(3) The proof that the cap product does not depend on the choice of representative of the cohomology class is basically the same as the proof of (2).

This shows that the map is well-defined. It is clear that the map is indeed R-bilinear. ■

Remark. We already saw on page 2514 that the definition of the cup product in the literature is not uniform. Rather depressingly, the situation is even worse for the cap product, there is an endless variety of definitions of the cap product in the literature. More precisely, given a cochain $\varphi \in \mathrm{C}^k(X;R)$ and a singular simplex $\sigma\colon \Delta^l \to X$ the following definitions of $\varphi \cap \sigma$ can be found in the literature:[1418]

		$\varphi \cap \sigma$
(a)	Hatcher [**Hat2002**, p. 239]	$\varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, v_l]$
(b)	Bredon [**Bre1993**, p. 335]	$(-1)^{k(l-k)} \cdot \varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, v_l]$
(c)	Dold [**Dol1956**, p. 335]	$(-1)^{k(l-k)} \cdot \sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$
(d)	Spanier [**Spa1995**, p. 254]	$\sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$
(e)	Munkres [**Mun1984**, p. 389]	$\sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$

To the best of my understanding, see [**Spa1995**, p. 250], the singular chains

$$\varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, v_l] \quad \text{and} \quad (-1)^{k(l-k)} \cdot \sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$$

are homologous. This shows that on the level of homology and cohomology groups the definition (a), which is also our definition, agrees with (c), but that the sign differs for (b), (d) and (e). For the most part this is not an issue, but one needs to be careful when one cites formulas from the literature. For example, as we had already mentioned on page 2400, Bredon [**Bre1993**] defined the coboundary map as

$$\delta_k^{\mathrm{Br}} \;:=\; (-1)^{k+1} \cdot \partial_{k+1}^* \;=\; (-1)^{k+1} \cdot \delta_k$$

and as we saw above, the cap product is also defined differently. Thus our Lemma 116.1, which says that for $\varphi \in \mathrm{C}^k(X;R)$ and $\sigma\colon \Delta^l \to X$ we have

$$\partial(\varphi \cap \sigma) \;=\; (-1)^k \cdot (\varphi \cap \partial\sigma \;-\; \delta\varphi \cap \sigma)$$

becomes the following equality in [**Bre1993**, Proposition VI.5.1]:[1419]

$$\partial(\varphi \cap \sigma) \;=\; (-1)^k \cdot \varphi \cap \partial\sigma \;+\; \delta^{\mathrm{Br}}(\varphi) \cap \sigma.$$

The following lemma follows immediately from the definitions.

Lemma 116.3. Let X be a topological space and let R be a commutative ring. Then for any $\sigma \in \mathrm{H}_k(X;R)$ we have

$$1_X \cap \sigma \;=\; \sigma.$$

For future applications we state the special case $k = l$ in the cap product in the following lemma.

[1418]The definition of the cap product given by Greenberg-Harper in [**GrH1981**, p. 205] agrees with our definition, *except*, that they use a different notation, namely they cap a homology class with a cohomology class instead of capping a cohomology class with a homology class. In other words, in our setting they write $\sigma \cap \varphi$ instead of $\varphi \cap \sigma$.

[1419]The lesson you should draw is that if you ever have to write algebraic topology lectures notes, stick to a single book and do not try to mix books.

Lemma 116.4. (Cap Product-Kronecker Lemma) Let X be a topological space and let R be a commutative ring.

(1) The composition

$$\mathrm{H}^k(X;R) \times \mathrm{H}_k(X;R) \xrightarrow{\cap} \mathrm{H}_0(X;R) \xrightarrow[\text{from page 1914}]{\text{augmentation } \epsilon} R$$

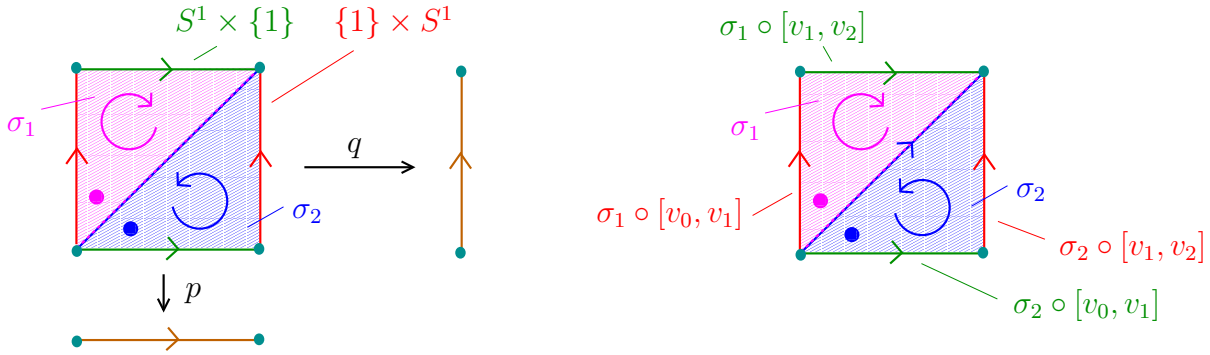
is precisely the Kronecker pairing from pages 2425 and 2452.

(2) If X is path-connected, and if we make the usual identification $\mathrm{H}_0(X;R) = R$ given by the augmentation map, see the H_0-Proposition 72.5, then for any $\varphi \in \mathrm{H}^k(X;R)$ and $\sigma \in \mathrm{H}_k(X;R)$ we have

$$\varphi \cap \sigma \;=\; \langle \varphi, \sigma \rangle \;\in\; R.$$

Proof. Both statements follow immediately from recalling all the relevant definitions. ■

Example. We consider some examples of the cap product in detail to get some feeling for what it does.



(1) Let $T = S^1 \times S^1 = ([0,1] \times [0,1])/\!\sim$ be the torus. We recall the following notations and results that we have by now used on many occasions. (We refer to the figure below for some of the notation.)

(a) We denote by σ_1, σ_2 the singular 2-simplices from the figure below. As we pointed out on page 2204, the singular 2-chain $-\sigma_1 + \sigma_2$ is a representative of the fundamental class $[T]$.

(b) We denote by p respectively q the projection $S^1 \times S^1 \to S^1$ onto the first respectively second factor.

(c) We denote by $\theta := \theta_{\mathbb{Z}} \in \mathrm{C}^1;\mathbb{Z})$ the singular 1-cocycle that we introduced on page 2404.

(d) As before we denote by $\mu\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $\mu(1-t,t) = \exp(2\pi\,\mathrm{i}t)$. By the discussion on page 2201 we know that μ represents the fundamental class $[S^1]$ of S^1 equipped with the standard orientation. By a slight abuse of notation we also denote by $[1 \times S^1]$ the image of the fundamental class under the monomorphism $\mathrm{H}_1(1 \times S^1;\mathbb{Z}) \to \mathrm{H}_1(S^1 \times S^1;\mathbb{Z})$.

We calculate that

$$p^*(\theta) \cap \sigma_1 \;=\; \underbrace{p^*(\theta)(\sigma_1 \circ [v_0, v_1])}_{=\theta(p\circ\sigma_1\circ[v_0,v_1])=0} \cdot \sigma_1 \circ [v_1, v_2] \;=\; 0$$

and similarly we calculate that

$$p^*(\theta) \cap \sigma_2 \;=\; \underbrace{p^*(\theta)(\sigma_2 \circ [v_0, v_1])}_{=\theta(p\circ\sigma_2\circ[v_0,v_1])=1} \cdot \sigma_2 \circ [v_1, v_2] \;= \sigma_2 \circ [v_1, v_2] = 1 \times \mu.$$

Putting these calculations together we obtain that

$$[p^*(\theta)] \cap [T] \;=\; [p^*(\theta) \cap (-\sigma_1 + \sigma_2)] \;=\; [1 \times S^1].$$

Basically the same calculation shows that

$$[q^*(\theta)] \cap [T] \;=\; [q^*(\theta) \cap (-\sigma_1 + \sigma_2)] \;=\; -[S^1 \times 1].$$

So we see that the map

$$\cap[T] \colon \mathrm{H}^1(T; \mathbb{Z}) \;\to\; \mathrm{H}_1(T; \mathbb{Z})$$

is non-trivial, in fact we have just shown that this map satisfies

$$\begin{array}{rcl} [p^*(\theta)] & \mapsto & [1 \times S^1] \\ [q^*(\theta)] & \mapsto & -[S^1 \times 1] \end{array}$$

which shows that "capping with the fundamental class" is in this case an isomorphism.

(2) In Exercise 116.2 we will deal with the surface Σ of genus 2 and there we will also see that the map

$$\cap[\Sigma] \colon \mathrm{H}^1(\Sigma; \mathbb{Z}) \;\to\; \mathrm{H}_1(\Sigma; \mathbb{Z})$$

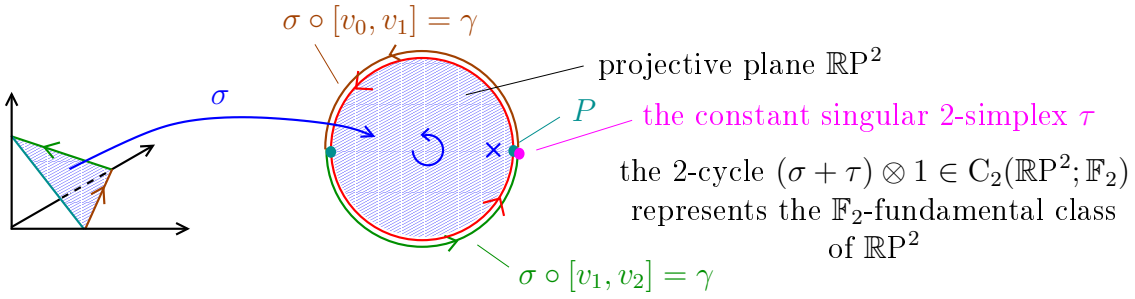
is an isomorphism.

(3) Finally we consider again the real projective plane $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$. We introduce the following notation:

(a) We denote by $\varphi \in \mathrm{C}^1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ the cocycle that we introduced on page 2530.

(b) We denote by $\gamma \colon \Delta^1 \to \mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$ the singular 1-simplex that is given by $\gamma(t, 1-t) = [\exp(\pi i t)]$. Note that γ is a cycle in $\mathrm{C}_1(\mathbb{R}\mathrm{P}^2)$ and note that $\varphi(\gamma) = 1$.

(c) In the figure on page 2216 we already saw a representative for the $\mathbb{F}_2$-fundamental class, but we will work with a different one that is "smaller" and that is shown in the figure below. In the figure below we see the singular 2-simplex σ that sends the face $[v_0, v_2]$ to a point P and the singular 2-simplex τ that sends all points on Δ^2 to P. It is straightforward to see that $(\sigma + \tau) \otimes 1 \in \mathrm{C}_2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ is a cycle. Using Proposition 100.18 we see that it represents the $\mathbb{F}_2$-fundamental class of $\mathbb{R}\mathrm{P}^2$.



It is straightforward to see that

$$[\varphi] \cap [\mathbb{R}\mathrm{P}^2] \;=\; [\varphi] \cap [(\sigma + \tau) \otimes 1] \;=\; [\underbrace{\varphi \cap \sigma}_{=\gamma} \otimes 1 + \underbrace{\varphi \cap \tau}_{=0} \otimes 1] \;=\; [\gamma \otimes 1]$$

We saw on page 2530 that $[\gamma \otimes 1]$ is the unique non-trivial element of $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$. Thus in this case we see that the map

$$\cap[\mathbb{R}\mathrm{P}^2] \colon \mathrm{H}^1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2) \;\to\; \mathrm{H}_1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$$

is also an isomorphism.

Remark. In the last three examples we saw for the closed 2-dimensional smooth manifolds $F = S^1 \times S^1$, $F = \Sigma$, $F = \mathbb{R}\mathrm{P}^2$ and for $R = \mathbb{Z}$ respectively $R = \mathbb{F}_2$ that the map

$$- \cap [F]_R \colon \mathrm{H}^1(F; R) \ \to \ \mathrm{H}_1(F; R)$$

is an isomorphism. In Chapter 119 we will see that it is not a coincidence. More precisely we will see that this observation can be generalized to all closed topological manifolds.

116.2. **The relative cap product and more properties of the cap product.** After considering the various examples of the cap product we continue with developing the theory. Similar to the case of the cup product, we intend to extend the notion of cap product to relative homology and cohomology groups. As in the case of the cup product it requires some delicate footwork to get to the right notion of a relative cap product. We start out with the following rather technical definition.

Definition. Let (X, A, B) be a triad of topological spaces and let R be a commutative ring. We write

$$\mathrm{C}_n(X, \{A, B\}; R) \ := \ \frac{\mathrm{C}_n(X) \otimes R}{\mathrm{C}_n^{\{A,B\}}(A \cup B) \otimes R}.$$

The boundary map on $\mathrm{C}_*(X; R)$ descends to a boundary map on $\mathrm{C}_*(X, \{A, B\}; R)$ which we can thus view as a chain complex. We denote the corresponding homology groups by $\mathrm{H}_*(X, \{A, B\}; R)$.

This technical definition allows us to define a first version of a relative cap product.

Lemma 116.5. Let (X, A, B) be a triad of topological spaces, let $k \leq l$ and let R be a commutative ring. Then the map

$$\begin{aligned} \cap \colon \mathrm{C}^k(X, A; R) \times \mathrm{C}_l(X, \{A, B\}; R) \ &\to \ \mathrm{C}_{l-k}(X, B; R) \\ (\varphi, [\sigma \colon \Delta^l \to X]) \ &\mapsto \ \big[\underbrace{\varphi(\sigma \circ [v_0, \dots, v_k])}_{\in R} \cdot \underbrace{\sigma \circ [v_k, \dots, v_l]}_{\text{map } \Delta^{l-k} \to X}\big] \end{aligned}$$

is well-defined and it descends to a map

$$\cap \colon \mathrm{H}^k(X, A; R) \times \mathrm{H}_l(X, \{A, B\}; R) \ \to \ \mathrm{H}_{l-k}(X, B; R)$$

that is R-bilinear.

Proof. We first show that the cap product on (co-) chains is well-defined. By definition of

$$\mathrm{C}_n(X, \{A, B\}; R) \ := \ \frac{\mathrm{C}_n(X) \otimes R}{\mathrm{C}_n^{\{A,B\}}(A \cup B) \otimes R} \ = \ \frac{\mathrm{C}_n(X) \otimes R}{\mathrm{C}_n(A) \otimes R + \mathrm{C}_n(B) \otimes R}$$

we have to show that if we are given a singular l-simplex $\sigma\colon \Delta^l \to X$ such that

(1) the image of σ lies in A, or
(2) the image of σ lies in B,

then the product $\varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_0, \ldots, v_k]$ is zero in $\mathrm{C}_{l-k}(X, B; R)$. But this is indeed the case:

(1) first, if the image of σ lies in A, then it follows immediately from the hypothesis that φ lies in $\mathrm{C}^k(X, A; R)$ that $\varphi(\sigma \circ [v_0, \ldots, v_k]) = 0$, and
(2) if the image of σ lies in B, then the image of $\sigma \circ [v_0, \ldots, v_k]$ also lies in B. Hence the term is zero in $\mathrm{C}_{l-k}(X, B; R)$.

This concludes the proof of the first part of the lemma.

The argument that the map on (co-) chain complexes descends to a map on the level of homology and cohomology groups is the same as in the proof of Lemma 116.2. It is obvious that the map $\cap$ is R-bilinear. ■

Evidently we are not very interested in the group $\mathrm{H}_n(X, \{A, B\}; R)$. The following lemma allows us to replace this group by the much more agreeable group $\mathrm{H}_n(X, A \cup B; R)$, at least for reasonable triads.

Lemma 116.6. If (X, A, B) is an excisive triad of topological spaces, then given any commutative ring R the obvious map

$$\mathrm{C}_*(X, \{A, B\}; R) \quad \to \quad \mathrm{C}_*(X, A \cup B; R)$$

induces for every $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n(X, \{A, B\}; R) \quad \xrightarrow{\cong} \quad \mathrm{H}_n(X, A \cup B; R).$$

Proof. In the proof of Lemma 115.1 we already showed that the map

$$\mathrm{C}_*(X, \{A, B\}) \ \to \ \mathrm{C}_*(X, A \cup B)$$

on chain complexes is a chain homotopy equivalence. By tensoring all maps and chain homotopies with R we see that the map

$$\mathrm{C}_*(X, \{A, B\}; R) \ \to \ \mathrm{C}_*(X, A \cup B; R)$$

is also a chain homotopy equivalence. The second statement is then an immediate consequence of Corollary 73.4. ■

Lemma 116.6 leads to the following definition.

Definition. Let (X, A, B) be an excisive triad of topological spaces, let $k \leq l$ and let R again be a commutative ring. We refer to the map

$$\mathrm{H}^k(X, A; R) \times \mathrm{H}_l(X, A \cup B; R) \quad \xleftarrow[\uparrow]{\cong} \quad \mathrm{H}^k(X, A; R) \times \mathrm{H}_l(X, \{A, B\}; R) \quad \xrightarrow[\uparrow]{\cap} \quad \mathrm{H}_{l-k}(X, B; R)$$

isomorphism given by Lemma 116.6 — map from Lemma 116.5

as the cap product (sometimes we refer to it as the relative cap product) that we also denote by "$\cap$". For $k > l$ we define the cap product to be the zero map.

Remark. In many examples, e.g. if $A = \varnothing$, or $B = \varnothing$ or $A = B$, then the slightly mysterious first map in the definition of the cap product is just the identity. In particular,

for any subset A of X we obtain cap products

$$\mathrm{H}^k(X;R) \ \times \ \mathrm{H}_l(X,A;R) \ \stackrel{\cap}{\longrightarrow} \ \mathrm{H}_{l-k}(X,A;R)$$

and

$$\mathrm{H}^k(X,A;R) \ \times \ \mathrm{H}_l(X,A;R) \ \stackrel{\cap}{\longrightarrow} \ \mathrm{H}_{l-k}(X;R)$$

and both of them are induced, on the (co-) chain level, by the formula

$$(\varphi, \sigma\colon \Delta^l \to X) \quad \mapsto \quad \varphi(\sigma\circ[v_0,\dots,v_k])\cdot\sigma\circ[v_k,\dots,v_l].$$

This observation also shows that we can easily generalize the Cap Product-Kronecker Lemma 116.4 to the relative case in the obvious way. For example, if X is path-connected, and if we make the usual identification $\mathrm{H}_0(X;\mathbb{Z}) = \mathbb{Z}$ given by the augmentation map, see the H_0-Proposition 72.5, then for any $\varphi \in \mathrm{H}^k(X,A;\mathbb{Z})$ and $\sigma \in \mathrm{H}_k(X,A;\mathbb{Z})$ we have

$$\varphi\cap\sigma \ = \ \langle\varphi,\sigma\rangle \ \in \ \mathbb{Z}.$$

For the record we point out that it follows from this observation and the Dual Fundamental Class Lemma 110.15 that if M is a compact oriented path-connected n-dimensional topological manifold, then for any point $P \in M$ we have

$$[M]^* \cap [M] \ = \ [P]$$

and $[M]^*$ is the only element in $\mathrm{H}^n(M,\partial M;\mathbb{Z}) \cong \mathbb{Z}$ that has that property.

Example. Let $X = S^1 \times [0,1]$ be the annulus. In the figure below we show two singular 2-simplices σ_1, σ_2. It follows easily from the Fundamental Class-Criterion Proposition 100.4 that $-\sigma_1+\sigma_2$ represents the fundamental class $[X] \in \mathrm{H}_2(X,\partial X;\mathbb{Z})$ of the annulus X with the usual orientation. We denote by $p\colon X \to [0,1]$ the projection . As on page 2408 we consider the function

$$\begin{array}{rcl} f\colon [0,1] & \to & \mathbb{Z} \\ x & \mapsto & \left\{ \begin{array}{ll} 0, & \text{if } x \in [0,\frac{1}{2}) \\ 1, & \text{otherwise} \end{array} \right. \end{array}$$

which we use to define the singular 1-cochain

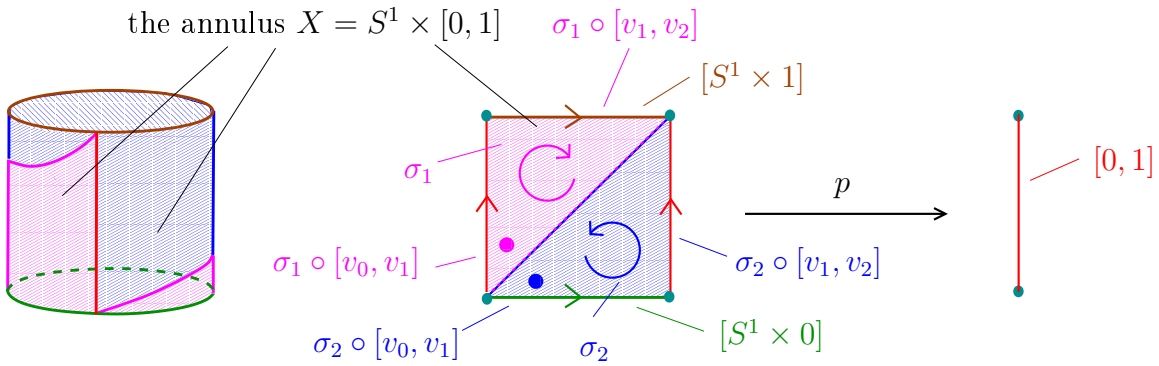
$$\begin{array}{rcl} \rho\colon \mathrm{C}_1([0,1]) & \to & \mathbb{Z} \\ (\sigma\colon \Delta^1 \to [0,1]) & \mapsto & f(\sigma(0,1)) - f(\sigma(1,0)). \end{array}$$

It follows from the discussion on page 2408 that $p^*(\rho) \in \mathrm{C}^1(X,\partial X;\mathbb{Z})$ is a cochain, thus it represents an element in $\mathrm{H}^1(X,\partial X;\mathbb{Z})$. We calculate that

$$\begin{array}{rcl} [p^*(\rho)]\cap\sigma_1 & = & \underbrace{p^*(\sigma_1\circ[v_0,v_1])}_{=1}\cdot\underbrace{\sigma_1\circ[v_1,v_2]}_{=[S^1\times 1]} \ = \ [S^1\times 1] \\ [p^*(\rho)]\cap\sigma_2 & = & \underbrace{p^*(\sigma_2\circ[v_0,v_1])}_{=0}\cdot\sigma_2\circ[v_1,v_2] \ = \ 0. \end{array}$$

Adding up we see that

$$[p^*(\rho)]\cap[X] \ = \ [p^*(\rho)\cap(-\sigma_1+\sigma_2)] \ = \ -[S^1\times 1].$$



Since the inclusion $S^1\times 1 \to X$ is a homotopy equivalence we see that $\mathrm{H}_1(X;\mathbb{Z}) \cong \mathbb{Z}$ and that $[S^1\times 1]$ is a generator. A straightforward argument, e.g. using the long exact sequence of the pair $(X,\partial X)$, shows that $\mathrm{H}^1(X,\partial X;\mathbb{Z}) \cong \mathbb{Z}$. The above calculation thus shows that the map

$$\begin{array}{rcl} \mathrm{H}^1(X,\partial X;\mathbb{Z}) & \to & \mathrm{H}_1(X;\mathbb{Z}) \\ \varphi & \mapsto & \varphi\cap[X] \end{array}$$

is an epimorphism. Since both groups are isomorphic to $\mathbb{Z}$ we see that the map is in fact an isomorphism and as a bonus we obtain that $[\rho] \in \mathrm{H}^1(X, \partial X; \mathbb{Z})$ is a generator. In Exercise 116.3 we will show that the map

$$\begin{array}{ccc} \mathrm{H}^1(X;\mathbb{Z}) & \to & \mathrm{H}_1(X, \partial X; \mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [X] \end{array}$$

is also an isomorphism.

The following lemma relates the cup product to the cap product.

Lemma 116.7. Cup-Cap Lemma Let X be a topological space and let R be a commutative ring.

(1) Let $\varphi \in \mathrm{C}^k(X;R)$, $\psi \in \mathrm{C}^l(X;R)$ and let $\sigma \in \mathrm{C}_n(X;R)$. Then[1420]
$$\varphi \cap (\psi \cap \sigma) \ = \ (\psi \cup \varphi) \cap \sigma \ \in \ \mathrm{C}_{n-k-l}(X;R).$$

(2) If $A \subset X$ is a subset and $C, D \in \{\varnothing, A\}$ we have for any $\varphi \in \mathrm{H}^k(X, C; R)$, any $\psi \in \mathrm{H}^l(X, D; R)$ and any $\sigma \in \mathrm{H}_n(X, C \cup D; R)$ that
$$\varphi \cap (\psi \cap \sigma) \ = \ (\psi \cup \varphi) \cap \sigma \ \in \ \mathrm{H}_{n-k-l}(X;R).$$

(3) If $A \subset X$ is a subset and $C, D \in \{\varnothing, A\}$ we have for any $\varphi \in \mathrm{H}^k(X, C; R)$, any $\psi \in \mathrm{H}^l(X, D; R)$ and any $\sigma \in \mathrm{H}_{k+l}(X, C \cup D; R)$ that
$$\langle \varphi, \psi \cap \sigma \rangle \ = \ \langle \psi \cup \varphi, \sigma \rangle \ \in \ R.$$

[1420]Note that on the right-hand side it says $(\psi \cup \varphi) \cap \sigma$ instead of $(\varphi \cup \psi) \cap \sigma$. In fact if one picks a different sign convention for the cap product this sign goes away. For example with the sign conventions used by Bredon, see [**Bre1993**, Chapter 5], the equation becomes
$$\varphi \cap (\psi \cap \sigma) \ = \ (\varphi \cup \psi) \cap \sigma$$
which looks much more appealing. Once we consider (co-) homology classes we obtain from the Cup Product-Commutativity Proposition 114.8 that the difference between these two expressions $(\psi \cup \varphi) \cap \sigma$ and $(\varphi \cup \psi) \cap \sigma$ is just a factor of $(-1)^{kl}$.

Proof. The case $k+l>n$ is trivial. So suppose that $k+l\leq n$.

(1) So let $\varphi\in \mathrm{C}^k(X;R)$, $\psi\in \mathrm{C}^l(X;R)$. It suffices to consider the case that $\sigma\colon \Delta^n\to X$ is a singular n-simplex. We have

$$\begin{aligned}\varphi\cap(\psi\cap\sigma) &= \varphi\cap\big(\psi(\sigma\circ[v_0,\ldots,v_l])\cdot\sigma\circ[v_l,\ldots,v_n]\big)\\ &= \psi(\sigma\circ[v_0,\ldots,v_l])\cdot\varphi\cap(\sigma\circ[v_l,\ldots,v_n])\\ &= \psi(\sigma\circ[v_0,\ldots,v_l])\cdot\varphi(\sigma\circ[v_l,\ldots,v_{l+k}])\cdot\sigma\circ[v_{l+k},\ldots,v_n]\\ &= (\psi\cup\varphi)(\sigma\circ[v_0,\ldots,v_{l+k}])\cdot\sigma\circ[v_{l+k},\ldots,v_n]\\ &= (\psi\cup\varphi)\cap\sigma.\end{aligned}$$

(2) The statement regarding the (co-) homology classes follows almost immediately from the above result on (co-) chains obtained in (1).

(3) This statement follows immediately from (2) together with the Cap Product-Kronecker Lemma 116.4. ■

Now suppose we are given a map of excisive triads of topological spaces. We get induced maps on homology and cohomology and the following lemma tells us the relationship of these induced maps and the cap product.

Lemma 116.8. (Cap Product-Naturality Lemma) Let R be a commutative ring.

(1) If $f\colon (X,A,B)\to(\widetilde{X},\widetilde{A},\widetilde{B})$ is a map between two excisive triads, then for any $k,l\in\mathbb{N}_0$ the following diagram commutes[1421]

$$\begin{array}{ccccc}\mathrm{H}^k(X,A;R) & \times & \mathrm{H}_l(X,A\cup B;R) & \xrightarrow{\cap} & \mathrm{H}_{l-k}(X,B;R)\\ {\scriptstyle f^*}\uparrow & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*}\\ \mathrm{H}^k(\widetilde{X},\widetilde{A};R) & \times & \mathrm{H}_l(\widetilde{X},\widetilde{A}\cup\widetilde{B};R) & \xrightarrow{\cap} & \mathrm{H}_{l-k}(\widetilde{X},\widetilde{B};R),\end{array}$$

i.e. for any $\varphi\in\mathrm{H}^k(\widetilde{X},\widetilde{A};R)$ and any $\sigma\in\mathrm{H}_l(X,A\cup B;R)$ we have

$$\varphi\cap f_*(\sigma) \;=\; f_*(\underbrace{f^*(\varphi)\cap\sigma}_{\in\mathrm{H}_{l-k}(X,B;R)}) \;\in\; \mathrm{H}_{l-k}(\widetilde{X},\widetilde{B};R).$$

(2) Let X and $\widetilde{X}$ be path-connected topological spaces and let $B\subset X$ and $\widetilde{B}\subset\widetilde{X}$ be subsets. If $f\colon(X,B)\to(\widetilde{X},\widetilde{B})$ is a map, then for any $\varphi\in\mathrm{H}^k(\widetilde{X},\widetilde{B};R)$ and any $\sigma\in\mathrm{H}_k(X,B;R)$ we have

$$\varphi\cap f_*(\sigma) \;=\; f^*(\varphi)\cap\sigma \;\in\; \underbrace{\mathrm{H}_0(X;R)=R=\mathrm{H}_0(\widetilde{X};R)}_{\substack{\text{identification from}\\ \text{the H}_0\text{-Proposition 72.5}}}.$$

Remark. Note that by the Cap Product-Kronecker Lemma 116.4 (1) we can view the above as a generalization of Lemma 109.6 (3).

Proof. The first statement follows immediately from the definitions. We leave the details to the skeptical reader. The second statement is an immediate consequence of the first statement. ■

[1421] Here "the diagram commutes" is understood in the sense of the convention from page 2538.

The next lemma says that cup and cap products behave in the obvious way with respect to the path-components.

Lemma 116.9. (Cup-Cap Disjoint Union Lemma) Let X be a topological space and let R be a commutative ring. We denote by $\{X_j\}_{j\in J}$ the path-components of X. By Lemmas 72.14 and 108.14 the inclusion maps $\iota_j\colon X_j \to X$, $j \in J$, induce for any $n \in \mathbb{N}_0$ isomorphisms

$$\Phi := \bigoplus_{j\in J}(\iota_j)_*\colon \bigoplus_{j\in J}\mathrm{H}_n(X_j;G) \xrightarrow{\cong} \mathrm{H}_n(X;G)$$

and

$$\Psi := \prod_{j\in J}\iota_j^*\colon \mathrm{H}^n(X;G) \xrightarrow{\cong} \prod_{j\in J}\mathrm{H}^n(X_j;G).$$

Then the following two statements hold:

(1) For any $i \neq j$ and any $\alpha \in \mathrm{H}^m(X_i;R)$ and $\beta \in \mathrm{H}^n(X_j;R)$ we have
$$\Psi^{-1}(\alpha) \cup \Psi^{-1}(\beta) = 0.$$
(2) For any $i \neq j$ and any $\alpha \in \mathrm{H}^m(X_i;R)$ and $\beta \in \mathrm{H}_n(X_j;R)$ we have
$$\Psi^{-1}(\alpha) \cap \Phi(\beta) = 0.$$

The same type of statements hold for cup and cap products on relative (co-) homology groups.

Proof. The statements in the lemma follow easily from the definitions. Therefore we leave the proof of the lemma to the reader. ■

In the next lemma of the chapter we relate the relative cap product to (co-) boundary maps on (co-) homology. More precisely, we have the following lemma which is similar in spirit to the Cup Product-Connecting Homomorphism Lemma 115.6.

Lemma 116.10. (Cap Product-Connecting Homomorphism Lemma) Let R be a commutative ring.

(1) Let (X, B, A) be a triple of topological spaces. For any $n, k \in \mathbb{N}_0$ the following diagram commutes:
$$\begin{array}{ccc} \mathrm{H}^k(B,A;R) \times \mathrm{H}_{n-1}(B,A;R) & \xrightarrow{\cap} & \mathrm{H}_{n-k-1}(B;R) \\ \downarrow{\scriptstyle \delta} & \uparrow{\scriptstyle \partial} & \downarrow{\scriptstyle i_*} \\ \mathrm{H}^{k+1}(X,B;R) \times \mathrm{H}_n(X,B;R) & \xrightarrow{\cap} & \mathrm{H}_{n-k-1}(X;R). \end{array}$$
Here $i\colon B \to X$ denotes the inclusion map and δ and ∂ denote the connecting homomorphisms in the long exact sequences in (co-) homology corresponding to the triple (X, B, A).
(2) Let (X, A, B) be an excisive triad and let $n \in \mathbb{N}_0$. Note that by the Excisive Characterization Lemma 109.13 the map $j_*\colon \mathrm{H}_{n-1}(B, A\cap B;R) \to \mathrm{H}_{n-1}(A\cup B, A;R)$ is an isomorphism. For any $k \in \mathbb{N}_0$ the following diagram commutes up to the sign

$(-1)^{k+1}$:

$$\begin{array}{ccc}
\mathrm{H}^k(X,A;R)\times\mathrm{H}_n(X,A\cup B;R) & \xrightarrow{\ \cap\ } & \mathrm{H}_{n-k}(X,B;R) \\
{\scriptstyle i^*}\downarrow \quad {\scriptstyle \partial}\downarrow & & \\
\mathrm{H}^k(A\cup B,A;R)\times\mathrm{H}_{n-1}(A\cup B,A;R) & & \Big\downarrow{\scriptstyle \partial} \\
{\scriptstyle j^*}\downarrow\cong \quad {\scriptstyle (j_*)^{-1}}\downarrow\cong & & \\
\mathrm{H}^k(B,A\cap B;R)\times\mathrm{H}_{n-1}(B,A\cap B;R) & \xrightarrow{\ \cap\ } & \mathrm{H}_{n-k-1}(B;R).
\end{array}$$

Here $i\colon (A\cup B,A)\to(X,A)$ and $j\colon (B,A\cap B)\to(A\cup B,A)$ denote the inclusion maps and ∂ denotes the connecting homomorphisms in the long exact sequences in homology corresponding to the triple $(X,A\cup B,A)$ respectively the pair (X,B).

Proof.

(1) We pick $\psi\in\mathrm{H}^k(B,A;R)$ and $\tau\in\mathrm{H}_n(B,A;R)$. We make the following observations:
   (a) We can find $\sigma\in\mathrm{C}_n(B;R)$ such that the image of σ in $\mathrm{C}_n(B,A;R)$ is a cycle that represents τ.
   (b) We can pick a singular cochain $\varphi\in\mathrm{C}^k(B;R)=\mathrm{Hom}(\mathrm{C}_k(B),R)$ that vanishes on $\mathrm{C}_k(A)$ and such that the corresponding element in $\mathrm{C}^k(B,A;R)$ represents ψ. We denote by $\widetilde{\varphi}\colon \mathrm{C}_k(X)\to R$ the extension of φ that is defined to be zero on all singular k-simplices that do not lie in B.

   We have the following equalities:

$$\delta\psi\cap\tau \underset{\uparrow}{=} \left[\delta\widetilde{\varphi}\right]\cap[\sigma] \overset{\downarrow}{=} \left[\delta\widetilde{\varphi}\cap\sigma\right] \underset{\uparrow}{=} [\widetilde{\varphi}\cap\partial\sigma] = [\varphi\cap\partial\sigma] \overset{\downarrow}{=} [\varphi]\cap[\partial\sigma] \underset{\uparrow}{=} \psi\cap\partial\tau.$$

by the discussion of relative cap products on page 2558

Cohomological LES-Lemma 108.15 and the discussion on page 2411

by Lemma 116.1 the classes $\delta\varphi\cap\sigma$ and $\varphi\cap\partial\sigma$ are homologous

Topological LES Proposition 74.13

   This equality implies that the diagram commutes.[1422]

(2) We pick $\psi\in\mathrm{H}^k(X,A;R)$ and $\tau\in\mathrm{H}_n(X,A\cup B;R)$. We make the following observations:
   (a) It follows immediately from our hypothesis that the triad (X,A,B) is excisive together with Lemma 116.6 that we can find $\sigma\in\mathrm{C}_n(X;R)$ such that $\partial\sigma=\alpha+\beta$ with $\alpha\in\mathrm{C}_{n-1}(A;R)$ and $\beta\in\mathrm{C}_{n-1}(B;R)$ and such that the image of σ in $\mathrm{C}_n(X,A\cup B;R)$ is a cycle that represents τ.
   (b) As on page 2534 we make the identification

$$\mathrm{C}^k(X,A;R) \xrightarrow{=} \text{ all homomorphisms } \mathrm{C}_k(X)\to R \text{ that vanish on } \mathrm{C}_k(A).$$

   We can pick a singular cochain $\varphi\in\mathrm{C}^k(X;R)=\mathrm{Hom}(\mathrm{C}_k(X),R)$ that vanishes on $\mathrm{C}_k(A)$ and such that the corresponding element in $\mathrm{C}^k(X,A;R)$ is a cocycle that represents ψ. Note that $\delta\varphi=0$.

[1422] With the various quotient groups, lifts, extensions, inclusions and so on it is admittedly quite tricky to figure out in between where any of the equalities hold.

We have the following equalities:

$$\begin{array}{lcll}
\partial(\psi\cap\tau) & \overset{\text{choice of } \sigma \text{ and definition of relative cap product}}{=} & \partial([\varphi\cap\sigma]) \overset{\text{Topological LES-Proposition 74.13}}{=} [\partial(\varphi\cap\sigma)] & \overset{\text{Lemma 116.1}}{=} (-1)^k\cdot[-\delta\varphi\cap\sigma+\varphi\cap\partial\sigma] \\
& \overset{\uparrow}{=} & (-1)^k\cdot[\varphi\cap\alpha+\varphi\cap\beta]) & \overset{\uparrow}{=} (-1)^k\cdot[\varphi\cap\beta]) \\
& & \text{since } \delta\varphi=0 \text{ and } \partial\sigma=\alpha+\beta & \text{since } \varphi \text{ vanishes on } \mathrm{C}_k(A) \text{ and since } \alpha\circ[v_0,\dots,v_k]\in\mathrm{C}_k(A) \\
& \overset{\uparrow}{=} & (-1)^k\cdot([j^*i^*\varphi]\cap j_*^{-1}(\partial[\sigma])). & \\
& & \text{by the Topological LES-Proposition 74.13 we have } j_*([\beta])=\partial[\sigma] &
\end{array}$$

This equality implies that the diagram commutes. ■

As we had mentioned before, a frequently used trick in the study of topological manifolds is to replace a topological manifold with non-empty boundary by its double. When doing this trick the following lemma can at times be useful.

Lemma 116.11. Let M be a topological manifold. We denote by $r\colon \mathrm{D}M\to M$ the folding map from page 1668 and given $l\in\mathbb{N}_0$ we denote by $D\colon \mathrm{H}_l(M,\partial M;\mathbb{Z})\to\mathrm{H}_l(\mathrm{D}M;\mathbb{Z})$ the doubling homomorphism that we introduced in the Doubling-Homology Lemma 75.16. Then for any $\phi\in\mathrm{H}^k(M;\mathbb{Z})$ and any $\sigma\in\mathrm{H}_l(M,\partial M;\mathbb{Z})$ we have

$$r^*\phi\cap D(\sigma) \;=\; D(\phi\cap\sigma) \;\in\; \mathrm{H}_{l-k}(\mathrm{D}M;\mathbb{Z}).$$

Proof. We will show that the desired equality actually holds already on the (co-) chain level. So let $\phi\in\mathrm{C}^k(M;\mathbb{Z})$ and let $\sigma\colon\Delta^l\to M$ be a singular l-simplex. If $k>l$, then both sides of the lemma are trivially zero. Hence we can assume that $k\le l$. For $i=1,2$ we denote by $j_i\colon M\to M\times\{i\}\subset\mathrm{D}M$ the obvious map. Then

$$\begin{array}{lcll}
r^*\phi\cap D(\sigma) & \overset{\text{by definition of } D(\sigma)}{\overset{\downarrow}{=}} & r^*\phi\cap(j_1\circ\sigma-j_2\circ\sigma) & \overset{\text{since } \cap \text{ is bilinear}}{\overset{\downarrow}{=}} r^*\phi\cap j_1\circ\sigma - r^*\phi\cap j_2\circ\sigma \\
& = & \phi(\underbrace{r\circ j_1\circ\sigma}_{=\sigma}\circ[v_0,\dots,v_k])\cdot j_1\circ\sigma\circ[v_k,\dots,v_l] - \phi(\underbrace{r\circ j_2\circ\sigma}_{=\sigma}\circ[v_0,\dots,v_k])\cdot j_2\circ\sigma\circ[v_k,\dots,v_l] & \\
& \overset{\uparrow}{=} & \text{definition of cap product and definition of } r^*\phi & \\
& = & \phi(\sigma\circ[v_0,\dots,v_k])\cdot j_1\circ(\sigma\circ[v_k,\dots,v_l]) - \phi(\sigma\circ[v_0,\dots,v_k])\cdot j_2\circ(\sigma\circ[v_k,\dots,v_l]) & \\
& = & j_{1*}(\phi\cap\sigma) - j_{2*}(\phi\cap\sigma) \;=\; D(\phi\cap\sigma). & \\
& \overset{\uparrow}{=} & \text{definition of } j_{1*},\, j_{2*} \text{ and the cap product} &
\end{array}$$

■

Exercises for Chapter 116.

Exercise 116.1. Let $X=S^1\vee S^2$. We denote by $p\colon X\to S^1$ and $q\colon X\to S^2$ the natural projections and we denote by $i\colon S^1\to X$ and $j\colon S^2\to X$ the obvious inclusion maps. Determine $p^*([\theta_{\mathbb{Z}}])\cap j_*([S^2])$.

Exercise 116.2. We denote by Σ the surface of genus two. Furthermore we denote by $p_1,p_2\colon\Sigma\to T=S^1\times S^1$ the two projections and we denote by $p,q\colon S^1\times S^1\to S^1$ the projection onto the first respectively the second factor. As usual we write $\alpha=p^*(\theta)$ and $\beta=q^*(\theta)$. We saw that $[p_1^*(\alpha)],[p_1^*(\beta)],[p_2^*(\alpha)],[p_2^*(\beta)]$ form a basis for $\mathrm{H}^1(\Sigma;\mathbb{Z})$.

Furthermore we denote by $x_1, y_1, x_2, y_2 \in \mathrm{H}_1(\Sigma;\mathbb{Z})$ the standard basis. For each of the four basis elements of $\mathrm{H}^1(\Sigma;\mathbb{Z})$ determine the cap product with $[\Sigma]$ in terms of the basis for $\mathrm{H}_1(\Sigma;\mathbb{Z})$.
Remark. This exercise is not as bad as it might sound initially.

Exercise 116.3. We consider the annulus $X = S^1 \times [0,1]$. Determine the following map:

$$\begin{array}{rcl} \mathrm{H}^1(X;\mathbb{Z}) & \to & \mathrm{H}_1(X, \partial X;\mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [X] \end{array}$$

More precisely, give a basis for $\mathrm{H}^1(X;\mathbb{Z})$ and $\mathrm{H}_1(X,\partial X;\mathbb{Z})$ and express the map $- \cap [X]$ in terms of that basis.

Exercise 116.4. Let X be a topological space and let $k, l \in \mathbb{N}_0$. We consider the cohomology with compact support group $\mathrm{H}^k_{\mathrm{c}}(X;\mathbb{Z})$ and as in Exercise 106.5 we consider the group

$$\overleftarrow{\mathrm{H}}_l(X;\mathbb{Z}) \;:=\; \varprojlim_{K \in \mathcal{K}(X)} \mathrm{H}_n(X, X \setminus K; G).$$

Show that there exists a natural cap product

$$\cap \colon \mathrm{H}^k_{\mathrm{c}}(X;\mathbb{Z}) \times \overleftarrow{\mathrm{H}}_l(X;\mathbb{Z}) \;\to\; \mathrm{H}_{l-k}(X;\mathbb{Z})$$

that equals the usual cap product if X is compact.
Remark. Use the description of cohomology with compact support that is provided by the $\mathrm{H}^n_{\mathrm{c}}$-via-Direct Limits Proposition 112.4.

117. The Product Theorem and the Künneth Theorem for cohomology

In this chapter we will deal with the cup and cap product of product topological spaces. In particular at the end of the chapter we will have determined the cup product of the product $S^m \times S^n$ of two spheres and of the n-dimensional torus $(S^1)^n$. Furthermore we will have determined the Lusternik-Schnirelmann category of the n-dimensional torus.

117.1. **The Product Theorem.** The following theorem relates the cross product to the cap product and the cup product.

Theorem 117.1. (Product Theorem) Let (X, A) and (Y, B) be two pairs of topological spaces such that the triad $(X \times Y, A \times Y, X \times B)$ is excisive. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the natural projections. Furthermore let[1423] $A_1, A_2 \in \{\varnothing, A\}$ and let $B_1, B_2 \in \{\varnothing, B\}$. Then for any $\alpha \in \mathrm{H}^k(X, A_1; \mathbb{Z})$, $\mu \in \mathrm{H}_m(X, A_1 \cup A_2; \mathbb{Z})$, $\beta \in \mathrm{H}^l(Y, B_1; \mathbb{Z})$ and $\nu \in \mathrm{H}_n(Y, B_1 \cup B_2; \mathbb{Z})$ we have the equality[1424]

$$\big(p^*(\alpha) \cup q^*(\beta)\big) \cap (\mu \times \nu) = (-1)^{\deg(\alpha)\cdot\deg(\beta)+\deg(\beta)\cdot\deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu)$$

in $\mathrm{H}_{m+n-k-l}(X \times Y, X \times B_2 \cup A_2 \times Y; \mathbb{Z})$.

Remark. Even though the equality in the Product Theorem 117.1 is easy to write down, it is much harder to figure out in which (co-) homology groups the various objects actually live. In fact the equality is understood as follows:

$$\Big(\underbrace{\underbrace{p^*(\alpha)}_{\in \mathrm{H}^k(X\times Y, A_1\times Y)} \cup \underbrace{q^*(\beta)}_{\in \mathrm{H}^l(X\times Y, X\times B_1)}}_{\in \mathrm{H}^{k+l}(X\times Y, A_1\times Y \cup X\times B_2)}\Big) \cap \overbrace{(\mu\times\nu)}^{\text{lies in } \mathrm{H}_{m+n}(X\times Y, (A_1\cup A_2)\times Y \cup X\times(B_1\cup B_2))} = (-1)^{\deg(\alpha)\cdot\deg(\beta)+\deg(\beta)\cdot\deg(\mu)} \cdot \underbrace{\underbrace{(\alpha \cap \mu)}_{\in \mathrm{H}_{m-k}(X, A_2)} \times \underbrace{(\beta \cap \nu)}_{\in \mathrm{H}_{n-l}(Y, B_2)}}_{\in \mathrm{H}_{m+n-k-l}(X\times Y, X\times B_2 \cup A_2\times Y)}.$$

In this formula we have to ensure that all products are in fact defined. This follows easily from the Excisive Triad-Proposition 109.12, our hypothesis that $A_1, A_2 \in \{\varnothing, A\}$ and $B_1, B_2 \in \{\varnothing, B\}$ and our hypothesis that the triad $(X \times Y, A \times Y, X \times B)$ is excisive.

Remark.

(1) The condition in the Product Theorem 117.1 that the triad $(X \times Y, A \times Y, X \times B)$ needs to be excisive is arguably a little awkward. By the Excisive Triad-Proposition 109.12 this condition is satisfied if we are in one of the following situations:
   (a) $A = \varnothing$ or $B = \varnothing$,
   (b) (X, A) and (Y, B) are pairs of CW-complexes,

[1423] By $A_1, A_2 \in \{\varnothing, A\}$ we mean that $A_1 = \varnothing$ or $A_1 = A$ and that $A_2 = \varnothing$ or $A_2 = A$.

[1424] Here, and throughout this section, we denote by p also the map of pairs $(X \times Y, A \times Y) \to (X, A)$ given by projection onto the first factor and we denote by q the map of pairs $(X \times Y, X \times B) \to (Y, B)$ given by projection onto the second factor.

(c) $(X, A) = (X, \partial X)$ and $(Y, B) = (Y, \partial Y)$ where X and Y are topological manifolds,[1425]

(d) A and B are open subsets of X respectively Y.

(2) In fact a more general statement of the Product Theorem 117.1 holds if we deal with excisive triads (X, A_1, A_2) and (Y, B_1, B_2) and (co-) homology classes $\alpha \in \mathrm{H}^k(X, A_1; \mathbb{Z})$, $\mu \in \mathrm{H}_m(X, A_2; \mathbb{Z})$, $\beta \in \mathrm{H}^l(Y, B_1; \mathbb{Z})$ and $\nu \in \mathrm{H}_n(Y, B_2; \mathbb{Z})$. But some care needs to be taken to see which other triads need to be excisive to ensure that all the cap and cup products are defined. We will not attempt to formulate this more general statement and we will not make use of it. (See also [**Dol1956**, p. 240 and p. 244] for a few more details.)

(3) The cross product is defined the same way in all of the usual text books in algebraic topology. But we saw on pages 2514 and 2553 that in the literature different sign conventions are used for the cup product and the cap product. These also lead to different formulations of the Product Theorem 117.1. More precisely, given topological spaces X and Y and $\alpha \in \mathrm{H}^k(X; \mathbb{Z})$, $\mu \in \mathrm{H}_m(X; \mathbb{Z})$, $\beta \in \mathrm{H}^l(Y; \mathbb{Z})$ and $\nu \in \mathrm{H}_n(Y; \mathbb{Z})$ the following equations can be found in the literature:

[**Bre1993**, p. 337] $(p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) = (-1)^{\deg(\beta)\cdot\deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu)$

[**Dol1956**, p. 240] $(p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) = (-1)^{\deg(\beta)\cdot\deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu)$

[**Spa1995**, p. 255] $(p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) = (-1)^{\deg(\alpha)\cdot(\deg(\nu)-\deg(\beta))} \cdot (\alpha \cap \mu) \times (\beta \cap \nu).$

With the aforementioned sign conventions the formulas of Dold and Spanier are consistent with our formula, whereas the formula of Bredon differs from the formula of Dold and Spanier by the term $(-1)^{\deg(\alpha)\cdot\deg(\nu)+\deg(\beta)\cdot\deg(\mu)}$.[1426][1427]

(4) The conclusion of the Product Theorem 117.1 also holds, with verbatim the same proof, if throughout we replace $\mathbb{Z}$-coefficients by $\mathbb{F}_2$-coefficients.

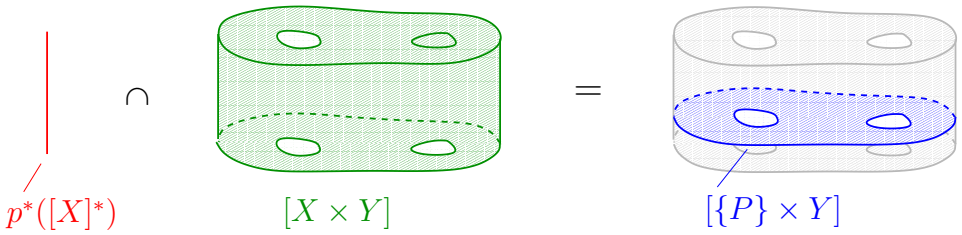
The proof of the Product Theorem 117.1 is somewhat lengthy and technical. Therefore we first discuss some consequences of Theorem 117.1 which will then hopefully convince us that it is worth the effort to prove Theorem 117.1.

The following is one of the key calculations of the cup product and the cap product. As we will see later, many other calculations can be reduced to this calculation.

[1425] Let X be an m-dimensional topological manifold and let Y be an n-dimensional smooth manifold. It follows from Propositions 18.4 and 75.2 that $W := \partial(X \times Y) = \partial X \times Y \cup X \times \partial Y$ is an $(m + n - 1)$-dimensional topological manifold. It is straightforward to verify that $\partial X \times Y$ and $X \times \partial Y$ are submanifolds of W such that

$$(\partial X \times Y) \cap (X \times \partial Y) = \partial X \times \partial Y = \partial(\partial X \times Y) = \partial(X \times \partial Y).$$

Therefore it follows from the Excisive Triad-Proposition 109.12 (5) that the triad $(X \times Y, \partial X \times Y, X \times \partial Y)$ is excisive.



[1426] Mathematicians with a long experience of teaching cohomology groups sidestep all issues with signs by working with $\mathbb{F}_2$-coefficients, see [**Hau2014**].

[1427] We leave it to the never-flagging enthusiasm of the reader to figure out whether the formulas agree with the one given by Greenberg-Harper [**GrH1981**, p. 262].

Proposition 117.2. (Fundamental Class-Product Proposition) Let X be a compact oriented connected m-dimensional topological manifold and let Y be a compact oriented connected n-dimensional topological manifold. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the natural projections. Then the following two statements hold:

(1)
$$\underbrace{p^*([X]^*)}_{\in \mathrm{H}^m(X\times Y,\partial X\times Y)} \cup \underbrace{q^*([Y]^*)}_{\in \mathrm{H}^n(X\times Y,X\times\partial Y)} = \underbrace{[X\times Y]^*}_{\in \mathrm{H}^{m+n}(X\times Y,\partial(X\times Y))}.$$

(2) If $P \in X$ and $Q \in Y$ are points, then[1428]
$$\overbrace{p^*([X]^*)}^{\in \mathrm{H}^m(X\times Y,\partial X\times Y)} \cap \overbrace{[X\times Y]}^{\in \mathrm{H}_{m+n}(X\times Y,\partial(X\times Y))} = \overbrace{[\{P\}\times Y]}^{\in \mathrm{H}_n(X\times Y,X\times\partial Y)}$$
and similarly
$$\underbrace{q^*([Y]^*)}_{\in \mathrm{H}^n(X\times Y,X\times\partial Y)} \cap \underbrace{[X\times Y]}_{\in \mathrm{H}_{m+n}(X\times Y,\partial(X\times Y))} = (-1)^{mn} \cdot \underbrace{[X\times\{Q\}]}_{\in \mathrm{H}_m(X\times Y,\partial X\times Y)}.$$

Remark. As we pointed out above, the conclusion of the Product Theorem 117.1 also holds if we work with $\mathbb{F}_2$-coefficients. It follows easily that there is also an $\mathbb{F}_2$-coefficient analogue of the Fundamental Class-Product Proposition 117.2.

Example. If we apply the Fundamental Class-Product Proposition 117.2 (2) to $X = S^1$ and $Y = S^1$ we see that
$$p^*([S^1]^*) \cap [S^1 \times S^1] = [1 \times S^1] \quad \text{and} \quad q^*([S^1]^*) \cap [S^1 \times S^1] = -[S^1 \times 1].$$
This matches our down-to-earth calculation from page 2555.

Proof. Let X be a compact oriented connected m-dimensional topological manifold and let Y be a compact oriented connected n-dimensional topological manifold. Furthermore let P be a point in X and let Q be a point in Y. We start out with the following two observations:

(a) For any compact oriented connected k-dimensional topological manifold M and any point $R \in M$ we obtain from the discussion on page 2558 that $[M]^* \cap [M] = [R]$ and that $[M]^*$ is the unique element in $\mathrm{H}^k(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$ with $[M]^* \cap [M] = [R]$ in $\mathrm{H}_0(M; \mathbb{Z}) = \mathbb{Z} \cdot [R]$.

(b) By the Topological Product Orientation Proposition 113.10 we have $[X \times Y] = [X] \times [Y]$.

[1428]Here we use the following suggestive notation: We can view $\{P\} \times Y$ as a submanifold of $X \times Y$. It is canonically homeomorphic to Y, thus can view $\{P\} \times Y$ as a compact oriented topological manifold. We denote by $[\{P\} \times Y]$ its fundamental class, and by a slight abuse of notation we also denote by $[\{P\} \times Y]$ the image of the fundamental class under the inclusion $\{P\} \times Y \to X \times Y$.

Now we turn to the actual proof of the two statements.

(1) We perform the following calculation in $\mathrm{H}_0(X \times Y; \mathbb{Z})$:

$$\begin{array}{ccccc} & & & \overset{\text{observation (b)}}{\downarrow} & \\ & (p^*([X]^*) \cup q^*([Y]^*)) \cap ([X \times Y]) & \overset{}{=} & (p^*([X]^*) \cup q^*([Y]^*)) \cap ([X] \times [Y]) & \\ \overset{}{=} & (-1)^{mn+mn} \cdot ([X]^* \cap [X]) \times ([Y]^* \cap [Y]) & \overset{}{=} & [P] \times [Q] & \overset{}{=} [(P,Q)]. \\ \uparrow & & & \uparrow & \uparrow \\ \text{by Theorem 117.1 applied} & & & \text{observation (a)} & \text{see the Cross Product Lemma 113.7 (2)} \\ \text{to } (X, A_1, A_2) = (X, \partial X, \partial X) & & & & \\ \text{and } (Y, B_1, B_2) = (Y, \partial Y, \partial Y) & & & & \end{array}$$

This implies, by observation (a), that $p^*([X]^*) \cup q^*([Y]^*) = [X \times Y]^*$.

(2) Let $P \in X$. Then

$$\begin{array}{ccccc} p^*([X]^*) \cap ([X \times Y]) & \overset{}{=} & (p^*([X]^*) \cup q^*(1_Y)) \cap ([X] \times [Y]) & & \\ \uparrow & & & & \\ \text{by the Cup Product-Naturality Proposition 115.4 (1) we have } q^*(1_Y) = 1_{X \times Y} \text{ and} & & & & \\ \text{by observation (b) we have } [X \times Y] = [X] \times [Y] & & & & \\ \overset{}{=} & ([X]^* \cap [X]) \times (1_Y \cap [Y]) & \overset{}{=} & [P] \times [Y] & \overset{}{=} [\{P\} \times Y]. \\ \uparrow & & \uparrow & & \uparrow \\ \text{by Theorem 117.1 applied to } (Y, B_1, B_2) = (Y, \varnothing, \partial Y) & & \text{by Lemma 116.3} & & \text{Cross Product} \\ \text{note that here we use that } 1_Y \text{ lies in } \mathrm{H}^0(Y; \mathbb{Z}) & & \text{and observation (a)} & & \text{Lemma 113.7 (2)} \end{array}$$

This proves the first equality of (2). Now let $Q \in Y$. Then, very similar to the above, we have

$$\begin{aligned} q^*([Y]^*) \cap ([X \times Y]) &= (p^*(1_X) \cup q^*([Y]^*)) \cap ([X] \times [Y]) \\ &= (-1)^{mn} \cdot (1_X \cap [X]) \times ([Y]^* \cap [Y]) \\ &= (-1)^{mn} \cdot [X] \times [Q] = (-1)^{mn} \cdot [X \times \{Q\}]. \end{aligned}$$

■

Using the Fundamental Class-Product Proposition 117.2 (1) we can now easily compute the cup product of the product $S^m \times S^n$ of two spheres.

Lemma 117.3. Let $m, n \in \mathbb{N}$. We denote by $p\colon S^m \times S^n \to S^m$ and by $q\colon S^m \times S^n \to S^n$ the two natural projections. Let $1 \in \mathrm{H}^0(S^m \times S^n; \mathbb{Z})$ be the neutral element from the Cup Product-Ring Proposition 114.7.

(1) The cohomology of $S^m \times S^n$ is given as follows:

$$\mathrm{H}^*(S^m \times S^n; \mathbb{Z}) = \mathbb{Z} \cdot 1 \oplus \mathbb{Z} \cdot p^*([S^m]^*) \oplus \mathbb{Z} \cdot q^*([S^n]^*) \oplus \mathbb{Z} \cdot [S^m \times S^n]^*.$$

(2) The multiplication table for the cup product is given by

$\cup$	1	$p^*([S^m]^*)$	$q^*([S^n]^*)$	$[S^m \times S^n]^*$
1	1	$p^*([S^m]^*)$	$q^*([S^n]^*)$	$[S^m \times S^n]^*$
$p^*([S^m]^*)$	$p^*([S^m]^*)$	0	$[S^m \times S^n]^*$	0
$q^*([S^n]^*)$	$q^*([S^n]^*)$	$(-1)^{mn} \cdot [S^m \times S^n]^*$	0	0
$[S^m \times S^n]^*$	$[S^m \times S^n]^*$	0	0	0.

Here the table shows the cup product of the term in the first column with the term in the first row (and not the other way round).

Remark.

(1) For $m = n = 1$, i.e. for the torus $S^1 \times S^1$ we had calculated the cup product in Lemma 114.14.

(2) If we use the Fundamental Class-Product Proposition 117.2 (1) with $\mathbb{F}_2$-coefficients then we can also determine the cup product on $\mathrm{H}^*(S^m \times S^n; \mathbb{F}_2)$ and we obtain basically the same result.

Proof.

(1) Using Proposition 74.4, the Künneth Theorem 90.8 for topological spaces and the Universal Coefficient Theorem 110.12 for Cohomology Groups one can easily determine the isomorphism type of $\mathrm{H}^*(S^m \times S^n; \mathbb{Z})$. Furthermore, using the Kronecker-Basis Lemma 109.7 and the homology classes given by the fundamental classes of S^m, S^n and $S^m \times S^n$ it is straightforward to verify that the given cohomology classes do indeed form a basis for $\mathrm{H}^*(S^m \times S^n; \mathbb{Z})$.

(2) By Observation 114.13 it remains to show that the red-colored and the blue-colored entries are correct.

(a) First we consider the red-colored entries. We have

$$p^*([S^m]^*) \cup p^*([S^m]^*), \underset{\uparrow}{=} p^*([S^m]^* \cup [S^m]^*) \underset{\uparrow}{=} p^*(0) = 0.$$

Cup Product-Naturality Lemma 114.10 — since $[S^m]^* \cup [S^m]^* \in \mathrm{H}^{2m}(S^m; \mathbb{Z}) = 0$

The same argument also shows that $q^*([S^n]^*) \cup q^*([S^n]^*) = 0$.

(b) We turn to the blue-colored entries. We calculate that

$$(-1)^{mn} \cdot q^*([S^n]^*) \cup p^*([S^m]^*) \underset{\uparrow}{=} p^*([S^m]^*) \cup q^*([S^n]^*) \underset{\uparrow}{=} [S^m \times S^n]^*.$$

Cup Product-Commutativity Proposition 114.8 — Fundamental Class Product Proposition 117.2 (1) ■

In the following we consider the wedge $X := S^2 \vee S^2 \vee S^4$ and we consider the product $Y := S^2 \times S^2$. It follows from Lemma 78.11 and Propositions 74.4 and 79.8 and the Universal Coefficient Theorem 110.12 for Cohomology Groups that $X = S^2 \vee S^2 \vee S^4$ and $Y = S^2 \times S^2$ have isomorphic homology and cohomology groups. Furthermore one obtains easily from Propositions 47.13, 48.20 and 52.3 that both X and Y are simply connected. It is quite easy to show that $X = S^2 \vee S^2 \vee S^4$ and $Y = S^2 \times S^2$ are not homeomorphic. Indeed, suppose there exists a homeomorphism $\phi\colon S^2 \vee S^2 \vee S^4 \to S^2 \times S^2$. We denote by P we wedge point of $X = S^2 \vee S^2 \vee S^4$ and we write $Q = f(P)$. Then $X \setminus \{P\}$ and $Y \setminus \{Q\}$ would also be homeomorphic. But the former topological space has three path-components whereas the latter has just one path-component.[1429] We refer to the figure below for a dimensionally reduced illustration.

The following lemma is much deeper than the above discussions.

Lemma 117.4. The topological spaces $S^2 \vee S^2 \vee S^4$ and $S^2 \times S^2$ are not even homotopy equivalent.

[1429] How can you prove rigorously that given any point $Q \in S^2 \times S^2$ the complement $S^2 \times S^2 \setminus \{Q\}$ is still path-connected?

Proof. We had just seen in Lemma 117.3 that there exist cohomology classes α and β in $\mathrm{H}^2(S^2 \times S^2; \mathbb{Z})$ with $\alpha \cup \beta \neq 0$. On the other hand in Lemma 114.11 we saw that the cup product

$$\cup\colon \mathrm{H}^2(S^2 \vee S^2 \vee S^4; \mathbb{Z}) \times \mathrm{H}^2(S^2 \vee S^2 \vee S^4; \mathbb{Z}) \ \to\ \mathrm{H}^4(S^2 \vee S^2 \vee S^4; \mathbb{Z})$$

is the zero-map. It follows from Corollary 114.12 that the topological spaces $S^2 \vee S^2 \vee S^4$ and $S^2 \times S^2$ are not homotopy equivalent. ■

In the Degree Realization Proposition 38.13 we saw that there exists a degree-one map from $S^2 \times S^2$ onto the 4-dimensional sphere S^4. In Question 101.10 we had asked whether there exists a degree-one map from the 4-dimensional sphere S^4 to $S^2 \times S^2$. Now we can answer this question in the negative.

Lemma 117.5. There is no map $f\colon S^4 \to S^2 \times S^2$ of non-zero degree.

Proof. Let $f\colon S^4 \to S^2 \times S^2$ be a map. We have to show that $\deg(f) = 0$. By Lemma 110.16 it suffices to show that $f^*([S^2 \times S^2]^*) = 0$. In Lemma 117.3 we showed that there exist cohomology classes $a, b \in \mathrm{H}^2(S^2 \times S^2; \mathbb{Z})$ such that $a \cup b = [S^2 \times S^2]^* \in \mathrm{H}^4(S^2 \times S^2; \mathbb{Z})$. It follows that

$$\begin{array}{ccccccc} f^*([S^2 \times S^2]^*) & = & f^*(a \cup b) & = & f^*(a) \cup f^*(b) & = & 0 \cup 0 \ = 0. \\ & & \uparrow & & \uparrow & & \uparrow \\ & & \text{since } [S^2 \times S^2]^* = a \cup b & & \text{Cup Product-Naturality Lemma} & & \text{since } f^*(a), f^*(b) \in \mathrm{H}^2(S^4; \mathbb{Z}) = 0 \end{array}$$

■

117.2. **Proof of the Product Theorem 117.1.** Now that we are fully convinced of the value of Theorem 117.1 it is time to actually provide a proof thereof.
Initially we introduced only the tensor product $C_* \otimes D_*$ of two chain complexes C_* and D_*. The definition of the boundary map in the tensor product $C_* \otimes D_*$ is *not* symmetric in the two terms. But it is straightforward to see that the tensor product of chain complexes is associative. More precisely, given chain complexes $\mathrm{C}^1_*, \ldots, \mathrm{C}^k_*$ the boundary map on the tensor product $\mathrm{C}^1_* \otimes \cdots \otimes \mathrm{C}^k_*$ is always determined by

$$\partial(c_1 \otimes c_2 \otimes \cdots \otimes c_k) \ = \ \sum_{i=1}^{k} (-1)^{\deg(c_1)+\cdots+\deg(c_{i-1})} \cdot c_1 \otimes \cdots \otimes \partial c_i \otimes \cdots \otimes c_k,$$

regardless of the way how one breaks the tensor product into the tensor product of pairs of two chain complexes.
The following lemma is basically the same as Lemma 90.3, but we state it here for the convenience of the reader.

Lemma 117.6. Let $f_i\colon \mathrm{C}^i_* \to D^i_*$, $i = 1, \ldots, k$ be chain maps between chain complexes. The map

$$f_1 \otimes \cdots \otimes f_k\colon \mathrm{C}^1_* \otimes \cdots \otimes \mathrm{C}^k_* \ \to\ D^1_* \otimes \cdots \otimes D^k_*$$

that is determined by

$$c_1 \otimes \cdots \otimes c_k \ \mapsto\ f(c_1) \otimes \cdots \otimes f(c_k)$$

is also a chain map.

Remark. Even the definition of $f_1 \otimes \cdots \otimes f_k$ is, oddly enough, not the same everywhere. For example [**Bre1993**, p. 315] adds a sign to the map.

Proof. Since in the proof of the Product Theorem 117.1 there are lots of steps later on which can make us nervous, let us convince ourselves that the statement is indeed correct. We have

$$\begin{aligned}\partial\big((f_1\otimes\ldots\otimes f_k)(c_1\otimes\ldots\otimes c_k)\big) &= \partial(f_1(c_1)\otimes\ldots\otimes f_k(c_k)) \\ &= \sum_{i=1}^{k}(-1)^{\deg(f_1(c_1))+\cdots+\deg(f_{i-1}(c_{i-1}))}\cdot f_1(c_1)\otimes\ldots\otimes\overbrace{f_i(\partial c_i)}^{=\partial f_i(c_i)}\otimes\ldots\otimes f_k(c_k) \\ &= (f_1\otimes\ldots\otimes f_k)\Big(\sum_{i=1}^{k}(-1)^{\deg(c_1)+\cdots+\deg(c_{i-1})}\cdot c_1\otimes\ldots\partial c_i\otimes\ldots\otimes c_k\Big) \\ &\quad\uparrow \\ &\quad\text{since } \deg(f_i(c_i))=\deg(c_i) \\ &= (f_1\otimes\ldots\otimes f_k)(\partial(c_1\otimes\ldots\otimes c_k)).\end{aligned}$$

■

Note though that the naive swapping of two factors in the tensor product of two chain complexes is not necessarily a chain map. But we have the following lemma.

Lemma 117.7. Let A_* and B_* be chain complexes. The unique map

$$\tau\colon A_*\otimes B_* \;\to\; B_*\otimes A_*$$

that for $a\in A_k$ and $b\in B_l$ is given by

$$a\otimes b \;\mapsto\; (-1)^{kl}\cdot b\otimes a$$

is a chain map.

Remark. In Exercise 117.1 we will see that we can use Lemma 117.7 to give a new proof of the Cup Product-Commutativity Proposition 114.8, i.e. we can give a new proof that the cup product is (anti-) commutative.

Proof. The difficult bit about the lemma is coming up with the statement. The verification is now almost trivial. So let $a\in A_k$ and $b\in B_l$. Then we have

$$\begin{aligned}\tau(\partial(a\otimes b)) &= \tau\big(\partial a\otimes b+(-1)^k\cdot a\otimes\partial b\big) \\ &= (-1)^{(k-1)l}\cdot b\otimes\partial a+(-1)^{k+k(l-1)}\cdot\partial b\otimes a \\ &= \partial((-1)^{kl}\cdot b\otimes a) \;=\; \partial(\tau(a\otimes b)).\end{aligned}\qquad\begin{aligned}&= \tau(\partial a\otimes b)+(-1)^k\cdot\tau(a\otimes\partial b) \\ &= (-1)^{kl}\cdot\partial b\otimes a+(-1)^{l+kl}\cdot b\otimes\partial a\end{aligned}$$

■

Now we have to introduce a plethora of new definitions and notations.

Notation.

(1) We denote by $\mathbb{Z}$ also the chain complex given by the group $\mathbb{Z}$ in degree zero and where all other chain groups are zero.

(2) Given a chain complex C_* and $k\in\mathbb{N}_0$ we denote by $\mathrm{C}_*[k]$ the chain complex which is the result of "shifting C_* by k to the left", i.e. it is the chain complex for which the m-th chain groups $(\mathrm{C}_*[k])_m$ is given by C_{m-k}.[1430] For example, $\mathbb{Z}[3]$ is the following chain complex:

$$\ldots \;\to\; 0 \;\to\; \underset{\substack{\uparrow\\ \text{degree 3}}}{\mathbb{Z}} \;\to\; 0 \;\to\; 0 \;\to\; 0.$$

(3) If $\alpha\colon C_*\to D_*$ is a chain map, then for any $k\in\mathbb{N}_0$ we denote by $\alpha[k]\colon \mathrm{C}_*[k]\to D_*[k]$ the obvious shift of the chain map. Evidently this is again a chain map.

(4) Let C_* be a chain complex and let $k\in\mathbb{N}_0$.

(a) Given a cocycle $\varphi\colon \mathrm{C}_k\to\mathbb{Z}$ we denote by $\Pi_k(\varphi)\colon C_*\to\mathbb{Z}[k]$ the map that is given by φ on C_n and zero on all other chain groups.

(b) Conversely, given a chain map $\psi\colon C_* \to \mathbb{Z}[k]$ we denote by $\psi_k\colon \mathrm{C}_k \to \mathbb{Z}$ the map that is the k-th map of the chain map.

Lemma 117.8. Let C_* be a chain complex and let $k \in \mathbb{N}_0$. The following statements hold:

(1) Let $\varphi\colon \mathrm{C}_k \to \mathbb{Z}$ be a cocycle. The map $\Pi_k(\varphi)\colon C_* \to \mathbb{Z}[k]$ is a chain map.
(2) Let $\psi\colon C_* \to \mathbb{Z}[k]$ be a chain map. The map $\psi_k\colon \mathrm{C}_k \to \mathbb{Z}$ is a cocycle.
(3) Let $\alpha, \beta\colon C_* \to \mathbb{Z}[k]$ be chain maps. If α and β are chain homotopic, then α_k and β_k are cohomologous.

Proof.

(1) Let $\varphi\colon \mathrm{C}_k \to \mathbb{Z}$ be a cocycle. We consider the following diagram:

$$\begin{array}{ccccccccc} \dots & \longrightarrow & \mathrm{C}_{k+1} & \xrightarrow{\partial} & \mathrm{C}_k & \xrightarrow{\partial} & \mathrm{C}_{k-1} & \longrightarrow & \dots \\ & & \downarrow & & \downarrow{\scriptstyle \varphi} & & \downarrow & & \\ \dots & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \dots . \end{array}$$

The hypothesis that φ is a cocycle means that $\delta\varphi = \varphi \circ \partial = 0$, which implies immediately that $\Pi_k(\varphi)$ is a chain map.

(2) The proof of Statement (2) is almost the same as the proof of Statement (1).

(3) Let $\alpha, \beta\colon C_* \to \mathbb{Z}[k]$ be chain maps and let $\{P_m\colon \mathrm{C}_m \to \mathbb{Z}[k]_{m+1}\}_{m\in\mathbb{N}_0}$ be a chain homotopy between α and β. We summarize all relevant maps in the following diagram:

$$\begin{array}{ccccccccc} \dots & \longrightarrow & \mathrm{C}_{k+1} & \xrightarrow{\partial} & \mathrm{C}_k & \xrightarrow{\partial} & \mathrm{C}_{k-1} & \longrightarrow & \dots \\ & & \downarrow & \swarrow_{P_k} & \downarrow{\scriptstyle \alpha_k-\beta_k} & \swarrow_{P_{k-1}} & \downarrow & & \\ \dots & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \dots . \end{array}$$

By definition of a chain homotopy we obtain that $\alpha_k - \beta_k = P_{k-1} \circ \partial$. But this means that $\alpha_k - \beta_k = \delta P_{k-1}$, i.e. α_k and β_k are cohomologous. ■

Lemma 117.9. Let C_* be a chain complex and let $k \in \mathbb{Z}$. The maps

$$\begin{array}{rcl} \eta_m\colon (\mathbb{Z}[k] \otimes \mathrm{C}_*)_m = \mathbb{Z} \otimes \mathrm{C}_{m-k} & \to & (\mathrm{C}_*[k])_m = \mathrm{C}_{m-k} \\ a \otimes c_{m-k} & \mapsto & (-1)^{k(m-k)} \cdot a \cdot c_{m-k} \end{array}$$

form an isomorphism

$$\eta\colon \mathbb{Z}[k] \otimes \mathrm{C}_* \xrightarrow{\cong} \mathrm{C}_*[k]$$

of chain complexes.

Example. Let $k, l \in \mathbb{N}_0$. The chain map

$$\eta\colon \mathbb{Z}[k] \otimes \mathbb{Z}[l] \to \mathbb{Z}[k+l]$$

is determined by the fact that for $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$ and $b \in (\mathbb{Z}[l])_l = \mathbb{Z}$ we have

$$\eta(a \otimes b) = (-1)^{kl} \cdot a \cdot b.$$

[1430] Once again, conventions in the literature differ. It is fairly common to define the boundary maps on $\mathrm{C}_*[k]$ to be the boundary maps of C_* multiplied by $(-1)^k$, see e.g. [**Weib1994**, p. 10].

Proof. It follows from the Tensor Lemma 89.3 (3) that each η_m is an isomorphism. But we still need to verify that the maps η_m form a chain map $\eta\colon \mathbb{Z}[k] \otimes C_* \to \mathrm{C}_*[k]$. Thus let $k \in \mathbb{N}_0$, let $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$ and let $c_{m-k} \in \mathrm{C}_{m-k}$. Then

$$\begin{array}{rcccl} & & \text{since } a \text{ is of degree } k \text{ and since } \partial a = 0 & & \text{since } \partial c_{m-k} \text{ is of degree } m-k-1 \\ \eta_{m-1}(\partial(a \otimes c_{m-k})) & \overset{\downarrow}{=} & \eta_{m-1}((-1)^k \cdot a \otimes \partial c_{m-k}) & \overset{\downarrow}{=} & (-1)^k \cdot (-1)^{k(m-1-k)} \cdot a \cdot \partial c_{m-k} \\ & = & \partial((-1)^{k(m-k)} \cdot a \cdot c_{m-k}) & = & \partial(\eta_m(a \otimes c_{m-k})). \end{array}$$

It follows immediately that the maps η_m form a chain map. ■

Notation.

(1) Given topological spaces X and Y we denote by $\Upsilon\colon \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) \to \mathrm{C}_*(X \times Y)$ and $\Theta\colon \mathrm{C}_*(X \times Y) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)$ the chain maps from the Eilenberg-Zilber Theorem 113.1.

(2) Given a topological space W we denote by $\Delta_W\colon \mathrm{C}_*(W) \to \mathrm{C}_*(W) \otimes \mathrm{C}_*(W)$ the Alexander-Whitney diagonalization from page 2518. Recall that Δ_W is also a chain map.

In the following two lemmas we will reinterpret the cup product and the cap product as chain maps.

Lemma 117.10. Let W be a topological space and let $\alpha \in \mathrm{C}^k(W;\mathbb{Z})$ and $\beta \in \mathrm{C}^l(W;\mathbb{Z})$ be cocycles. Then we have the following equality of chain maps:

$$(-1)^{kl} \cdot \Pi_{k+l}\underbrace{(\alpha \cup \beta)}_{\text{cocycle in } \mathrm{C}^{k+l}(W;\mathbb{Z})} = \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Delta_W\colon \mathrm{C}_*(W) \to \mathbb{Z}[k+l].$$

Proof. We introduce the following notation:

(1) We denote by $\mu\colon \mathbb{Z} \otimes \mathbb{Z} \to \mathbb{Z}$ the obvious isomorphism of abelian groups given by $\mu(a \otimes b) = a \cdot b$.

(2) We denote by $\Pi_{k,l}\colon (\mathrm{C}_*(W) \otimes \mathrm{C}_*(W))_{k+l} \to \mathrm{C}_k(W) \otimes \mathrm{C}_l(W)$ the natural projection.

In the proof of the Definitions-Cup Product Proposition 114.4 on page 2519 we showed that

$$\alpha \cup \beta = \mu \circ (\alpha \otimes \beta) \circ \Pi_{k,l} \circ \Delta_W\colon \mathrm{C}_{k+l}(W) \to \mathbb{Z}.$$

The lemma follows immediately from this equality and the following claim.

Claim. [1431]

$$(-1)^{kl} \cdot \mu \circ (\alpha \otimes \beta) \circ \Pi_{k,l} = \underbrace{(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)))_{k+l}}_{\substack{\text{the restriction to the } (k+l)\text{-th chain group of the} \\ \text{chain map } \mathrm{C}_*(W) \otimes \mathrm{C}_*(W) \to \mathbb{Z}[k] \otimes \mathbb{Z}[l] \to \mathbb{Z}[k+l] \\ a \otimes b \mapsto (-1)^{kl} \cdot ab}}\colon (\mathrm{C}_*(W) \otimes \mathrm{C}_*(W))_{k+l} \to \mathbb{Z}.$$

Proof. Let $\sigma_i \in \mathrm{C}_i(W)$ and $\sigma_j \in \mathrm{C}_j(W)$ with $i + j = k + l$. If $(i,j) \neq (k,l)$, then both maps are zero. So now suppose that $(i,j) = (k,l)$. Then it is clear that both maps send $\sigma_k \otimes \sigma_l$ to $(-1)^{kl} \cdot \alpha(\sigma_k) \cdot \beta(\sigma_l)$. (Note that the sign $(-1)^{kl}$ for the map on the right-hand side stems from the definition of the chain map η.) ■

[1431] Here, given two chain complexes $\mathcal{C}_*$ and $\mathcal{D}_*$ the map $\Pi_{k,l}\colon \mathcal{C}_* \otimes \mathcal{D}_* \to \mathcal{C}_k \otimes \mathcal{B}_l$ is the natural projection that we introduced on page 2512.

Given a topological space W and given $\varphi \in \mathrm{C}^k(W;\mathbb{Z})$ we obtain for each $m \in \mathbb{N}_0$ a map

$$\begin{array}{rcl} \varphi \cap -\colon \mathrm{C}_m(W) & \to & \mathrm{C}_{m-k}(W) = (\mathrm{C}_*(W)[k])_m \\ \sigma & \mapsto & \varphi \cap \sigma. \end{array}$$

Unfortunately in general these maps do *not* form a chain map from the chain complex $\mathrm{C}_*(W)$ to the chain complex $\mathrm{C}_*(W)[k]$. This motivates introducing the following slight variation on the cap product.

Definition. Let W be a topological space. Given $\varphi \in \mathrm{C}^m(W;\mathbb{Z})$ and given $\sigma \in \mathrm{C}_n(W)$ we define[1432]

$$\varphi \mathbin{\widetilde{\cap}} \sigma \ := \ (-1)^{m(n-m)} \cdot \varphi \cap \sigma.$$

In particular for $m = n$ we have $\varphi \mathbin{\widetilde{\cap}} \sigma = \varphi \cap \sigma$.

Lemma 117.11. Let W be a topological space.

(1) If $\varphi \in \mathrm{C}^m(W;\mathbb{Z})$ is a cocycle, then the map

$$\begin{array}{rcl} \varphi \mathbin{\widetilde{\cap}} -\colon \mathrm{C}_*(W) & \to & \mathrm{C}_*(W)[m] \\ \sigma & \mapsto & \varphi \mathbin{\widetilde{\cap}} \sigma \end{array}$$

is a chain map.

(2) If $\varphi, \psi \in \mathrm{C}^m(W;\mathbb{Z})$ are cohomologous cocycles, then the chain maps $\varphi \mathbin{\widetilde{\cap}} -$ and $\psi \mathbin{\widetilde{\cap}} -$ are chain homotopic.

Proof. Let W be a topological space. We start out with the following claim.

Claim. For any cochain $\tau \in \mathrm{C}^l(W;\mathbb{Z})$ and any chain $\mu \in \mathrm{C}_n(W;\mathbb{Z})$ we have

$$\partial(\tau \mathbin{\widetilde{\cap}} \mu) \ = \ (-1)^{l+n} \cdot \delta\tau \mathbin{\widetilde{\cap}} \mu + \tau \mathbin{\widetilde{\cap}} \partial\mu.$$

Proof. The claim is an immediate consequence of Lemma 116.1. Since we are worried about signs we write down the detailed calculation. We have

$$\begin{aligned} \partial(\tau \mathbin{\widetilde{\cap}} \mu) &\underset{\text{definition of } \widetilde{\cap}}{\uparrow=} (-1)^{l(n-l)} \cdot \partial(\tau \cap \mu) \underset{\text{Lemma 116.1}}{\uparrow=} (-1)^{l(n-l)} \cdot (-1)^l \cdot (-\delta\tau \cap \mu + \tau \cap \partial\mu) \\ &= (-1)^{l(n-l)+l} \cdot \big(- (-1)^{(l+1)\cdot(n-l-1)} \cdot \delta\tau \mathbin{\widetilde{\cap}} \mu + (-1)^{l\cdot(n-l-1)} \cdot \tau \mathbin{\widetilde{\cap}} \partial\mu \big) \\ &= (-1)^{l+n} \cdot \delta\tau \mathbin{\widetilde{\cap}} \mu + \tau \mathbin{\widetilde{\cap}} \partial\mu. \end{aligned}$$

⊞

Now we turn to the actual proof of the two statements.

(1) Let $\varphi \in \mathrm{C}^m(W;\mathbb{Z})$ be a cocycle. Furthermore let $\sigma \in \mathrm{C}_n(W)$. By the definition of the cap product and by definition of the shifting of chain complexes we have $\varphi \cap \sigma \in \mathrm{C}_{n-m}(W) = (\mathrm{C}_*(W)[m])_n$. This shows that $\varphi \mathbin{\widetilde{\cap}} -$ preserves degrees. It remains to show that the map $\varphi \mathbin{\widetilde{\cap}} -$ commutes with the boundary maps. But this is an immediate consequence of the above claim and the fact that φ is a cocycle.

(2) So let $\varphi, \psi \in \mathrm{C}^m(W;\mathbb{Z})$ be cocycles. We assume they are cohomologous which means that there exists a $\tau \in \mathrm{C}^{m-1}(W;\mathbb{Z})$ such that $\varphi = \psi + \delta\tau$. For any $k \in \mathbb{N}_0$ we consider the map

$$\begin{array}{rcl} P_k\colon \mathrm{C}_k(W) & \to & (\mathrm{C}_*(W)[m])_{k+1} = \mathrm{C}_{k-m+1}(W) \\ \sigma & \mapsto & (-1)^{m+k} \cdot \tau \mathbin{\widetilde{\cap}} \sigma. \end{array}$$

[1432] If we compare this definition with the discussion on page 2553 we see that the definition of $\widetilde{\cap}$ is precisely the definition of the cap product in Bredon [**Bre1993**] and Dold [**Dol1956**].

We calculate that for any $\sigma \in \mathrm{C}_k(W)$ we have

$$\begin{aligned} \varphi \mathbin{\widetilde{\cap}} \sigma - \psi \mathbin{\widetilde{\cap}} \sigma \;&=\; \delta\tau \mathbin{\widetilde{\cap}} \sigma \;\overset{\text{by the claim}}{\overset{\downarrow}{=}}\; (-1)^{m+k} \cdot \partial(\tau \mathbin{\widetilde{\cap}} \sigma) + (-1)^{m+k-1} \cdot \tau \mathbin{\widetilde{\cap}} \partial\sigma \\ &=\; (\partial \circ P_k)(\sigma) + (P_{k-1} \circ \partial)(\sigma). \end{aligned}$$

This shows that the maps $\{P_k\}_{k\in\mathbb{N}_0}$ form a chain homotopy between the chain maps $\varphi \mathbin{\widetilde{\cap}} -$ and $\psi \mathbin{\widetilde{\cap}} -$. ■

In the proof of Theorem 117.1 we will also need the following reformulation of the cap product.

Proposition 117.12. Let W be a topological space and let $\varphi \in \mathrm{C}^m(W;\mathbb{Z})$ be a cocycle. Then we have the following equality of chain maps

$$\varphi \mathbin{\widetilde{\cap}} - \;=\; \eta \circ (\Pi_m(\varphi) \otimes \mathrm{id}) \circ \Delta_W \colon \mathrm{C}_*(W) \;\to\; \mathrm{C}_*(W)[m].$$

Proof. Let W be a topological space, let $\varphi \in \mathrm{C}^m(W)$ be a cocycle and let $\sigma\colon \Delta^n \to W$ be a singular n-simplex. We have the following equalities in $\mathrm{C}_*(W)[m]_n = \mathrm{C}_{n-m}(W)$:

$$\begin{aligned} \big(\eta \circ (\Pi_m(\varphi) \otimes \mathrm{id}) \circ \Delta_W\big)(\sigma) \;&\overset{\text{definition of the Alexander-Whitney diagonalization}}{\overset{\downarrow}{=}}\; \eta\Big((\Pi_m(\varphi) \otimes \mathrm{id})\Big(\sum_{j=0}^{n} \sigma \circ [v_0,\dots,v_j] \otimes \sigma \circ [v_j,\dots,v_n]\Big)\Big) \\ &=\; \eta\big(\underbrace{\varphi(\sigma \circ [v_0,\dots,v_m])}_{\in \mathbb{Z}[m]_m} \otimes \underbrace{\sigma \circ [v_m,\dots,v_n]}_{\in \mathrm{C}_{n-m}}\big) \\ &\overset{\text{by definition of the chain map } \Pi_m(\varphi)\otimes\mathrm{id}\colon \mathrm{C}_*(W)\otimes\mathrm{C}_*(W)\to\mathbb{Z}[m]\otimes\mathrm{C}_*(W)}{\uparrow} \\ &=\; (-1)^{m(n-m)} \cdot \underbrace{\varphi(\sigma\circ[v_0,\dots,v_m])\cdot\sigma\circ[v_m,\dots,v_n]}_{=\varphi\cap\sigma} \;=\; \varphi \mathbin{\widetilde{\cap}} \sigma. \\ &\qquad\uparrow \text{ definition of } \eta \text{ in Lemma 117.9} \qquad\qquad \uparrow \text{ definition of } \mathbin{\widetilde{\cap}} \text{ on page 2574} \end{aligned}$$

We have thus verified that the desired equality holds. ■

The following statement is just the definition of the cross product.

Tautology 117.13. Let X and Y two topological spaces. For any $[\mu] \in \mathrm{H}_m(X;\mathbb{Z})$ and $[\nu] \in \mathrm{H}_n(Y;\mathbb{Z})$ we have

$$[\mu] \times [\nu] \;=\; [\Upsilon(\mu \otimes \nu)].$$

We need one more slightly delicate chain map before we can finally turn to the proof of the Product Theorem 117.1.

Lemma 117.14. Let C_* and D_* be chain complexes and let $k, l \in \mathbb{N}_0$. The map

$$\Psi_{k,l}\colon \mathrm{C}_*[k] \otimes D_*[l] \;\to\; (C_* \otimes D_*)[k+l]$$

which is defined by the property that for $c_m \in \mathrm{C}_m$ and $d_n \in D_n$ we have

$$c_m \otimes d_n \;\mapsto\; (-1)^{k(l+n)} \cdot c_m \otimes d_n.$$

is an isomorphism of chain complexes.

Proof. First note that it is clear that $\Psi_{k,l}$ preserves degrees and that on each degree it is an isomorphism. It remains to show that the map $\Psi_{k,l}$ is a chain map. Let $c_m \in \mathrm{C}_m$ and

$d_n \in D_n$. We calculate that

$$\begin{aligned}
\Psi_{k,l}(\partial(c_m \otimes d_n)) &\overset{\text{since } c_m \text{ has degree } m+k \text{ in } \mathrm{C}_*[k]}{\downarrow} \\
&= \Psi_{k,l}(\partial c_m \otimes d_n + (-1)^{m+k} \cdot c_m \otimes \partial d_n) \\
&= (-1)^{k(l+n)} \cdot \partial c_m \otimes d_n + (-1)^{m+k} \cdot (-1)^{k(l+n-1)} \cdot c_m \otimes \partial d_n \\
&= (-1)^{k(l+n)} \cdot (\partial c_m \otimes d_n + (-1)^m \cdot c_m \otimes \partial d_n) \underset{\text{since } c_m \text{ has degree } m \text{ in } C_*}{\overset{\uparrow}{=}} (-1)^{k(l+n)} \cdot \partial(c_m \otimes d_n) \\
&= \partial((-1)^{k(l+n)} \cdot c_m \otimes d_n)) = \partial(\Psi_{k,l}(c_m \otimes d_n)).
\end{aligned}$$

This calculation implies that $\Psi_{k,l}$ is a chain map. ■

The following theorem is the main technical result of this section. As we will see shortly, the Product Theorem 117.1 is a straightforward consequence of Theorem 117.15.

Theorem 117.15. Let X and Y be topological spaces. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the projection s. Let $\alpha \in \mathrm{C}^k(X;\mathbb{Z})$ and $\beta \in \mathrm{C}^l(Y;\mathbb{Z})$ be cocycles. Then the chain maps

$$(-1)^{kl} \cdot ((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} -) \circ \Upsilon \quad \text{and} \quad \Upsilon[k+l] \circ \Psi_{k,l} \circ (\alpha \mathbin{\widetilde{\cap}} - \otimes \beta \mathbin{\widetilde{\cap}} -)$$

from $\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)$ to $\mathrm{C}_*(X \times Y)[k+l]$ are chain homotopic.

Proof. Let X and Y be topological spaces and let $\alpha \in \mathrm{C}^k(X;\mathbb{Z})$ and $\beta \in \mathrm{C}^l(Y;\mathbb{Z})$ be cocycles. We consider the following diagram of chain maps

$$\begin{array}{ccccc}
\mathrm{C}_*X \otimes \mathrm{C}_*Y & \xrightarrow{\Upsilon} & \mathrm{C}_*(X\times Y) & \xrightarrow{\Delta_{X\times Y}} & \mathrm{C}_*(X\times Y)\otimes\mathrm{C}_*(X\times Y) \\
\downarrow{\scriptstyle \Delta_X\otimes\Delta_Y} & & & & \downarrow{\scriptstyle \Theta\otimes\mathrm{id}} \\
\mathrm{C}_*X\otimes\mathrm{C}_*X\otimes\mathrm{C}_*Y\otimes\mathrm{C}_*Y & \xrightarrow{\mathrm{id}\otimes\tau\otimes\mathrm{id}} & \mathrm{C}_*X\otimes\mathrm{C}_*Y\otimes\mathrm{C}_*X\otimes\mathrm{C}_*Y & \xrightarrow{\mathrm{id}\otimes\mathrm{id}\otimes\Upsilon} & \mathrm{C}_*X\otimes\mathrm{C}_*Y\otimes\mathrm{C}_*(X\times Y) \\
\downarrow{\scriptstyle \Pi_k(\alpha)\otimes\mathrm{id}\otimes\Pi_l(\beta)\otimes\mathrm{id}} & & \downarrow{\scriptstyle \Pi_k(\alpha)\otimes\Pi_l(\beta)\otimes\mathrm{id}\otimes\mathrm{id}} & & \downarrow{\scriptstyle \Pi_k(\alpha)\otimes\Pi_l(\beta)\otimes\mathrm{id}} \\
\mathbb{Z}[k]\otimes\mathrm{C}_*X\otimes\mathbb{Z}[l]\otimes\mathrm{C}_*Y & \xrightarrow{\mathrm{id}\otimes\tau\otimes\mathrm{id}} & \mathbb{Z}[k]\otimes\mathbb{Z}[l]\otimes\mathrm{C}_*X\otimes\mathrm{C}_*Y & \xrightarrow{\mathrm{id}\otimes\mathrm{id}\otimes\Upsilon} & \mathbb{Z}[k]\otimes\mathbb{Z}[l]\otimes\mathrm{C}_*(X\times Y) \\
\downarrow{\scriptstyle \eta\otimes\eta} & & \downarrow{\scriptstyle \eta\otimes\mathrm{id}\otimes\mathrm{id}} & & \downarrow{\scriptstyle \eta\otimes\mathrm{id}} \\
 & & \mathbb{Z}[k+l]\otimes(\mathrm{C}_*X\otimes\mathrm{C}_*Y) & \xrightarrow{\mathrm{id}\otimes\Upsilon} & \mathbb{Z}[k+l]\otimes\mathrm{C}_*(X\times Y) \\
 & & \downarrow{\scriptstyle \eta} & & \downarrow{\scriptstyle \eta} \\
\mathrm{C}_*X[k]\otimes\mathrm{C}_*Y[l] & \xrightarrow{\Psi_{k,l}} & (\mathrm{C}_*X\otimes\mathrm{C}_*Y)[k+l] & \xrightarrow{\Upsilon[k+l]} & \mathrm{C}_*(X\times Y)[k+l].
\end{array}$$

Claim 1. The above diagram commutes up to chain homotopies.

Proof. We consider the various smaller squares and rectangles.

(1) The two paths along the top rectangle from the top-left corner to the bottom-right corner are both natural chain maps. Furthermore, both have the property that for $x \in X$ and $y \in Y$ the element $x \otimes y \in \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)$ gets sent to $x \otimes y \otimes (x, y)$ in $\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) \otimes \mathrm{C}_*(X \times Y)$. In particular both paths agree on the 0-level.

It follows from Acyclic Model Theorem 113.16 (2) that the rectangle commutes up to a chain homotopy. More precisely, we apply the Acyclic Model Theorem 113.16 as follows:

(a) We take $\mathcal{C}$ to be the category of tuples (X, Y) of topological spaces.

(b) We consider the two functors $F\colon (X,Y) \mapsto (\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y), \epsilon_X \otimes \epsilon_Y)$ and $G\colon (X,Y) \mapsto (\mathrm{C}_*(X \times Y), \epsilon_{X\times Y})$.
(c) We take $\mathcal{M} = \{\Delta^k \times \Delta^l\}_{k,l\in\mathbb{N}_0}$.
(d) We consider the two natural transformations that are given by the two extremal paths in the diagram (shifted downward in degrees).

(2) It is clear that the two squares between the second and the third row commute.
(3) It is straightforward to verify that the two squares at the bottom right commute.
(4) It remains to consider the big square to the bottom left of the diagram. Starting with $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$, $b \in \mathrm{C}_m(X)$, $c \in (\mathbb{Z}[l])_l = \mathbb{Z}$ and $d \in \mathrm{C}_n(Y)$ and keeping in mind the sign conventions of Lemmas 117.7, 117.9 and 117.14 we get the following results for $a \otimes b \otimes c \otimes d$:
(a) going down-right gives $(-1)^{km} \cdot (-1)^{ln} \cdot (-1)^{k(l+n)} \cdot ac \cdot (b \otimes d)$,
(b) going right-down-down gives $(-1)^{ml} \cdot (-1)^{kl} \cdot (-1)^{(k+l)(m+n)} \cdot ac \cdot (b \otimes d)$.
One easily verifies that the signs agree. So we see that the bottom left square also commutes. ⊞

In light of the previous claim it suffices to prove the following claim.

Claim 2.
(1) the "left-bottom route" equals the chain map $\Upsilon[k+l] \circ \Psi_{k,l} \circ ((\alpha \mathbin{\widetilde{\cap}} -) \otimes (\beta \mathbin{\widetilde{\cap}} -))$,
(2) the "top-right route" is chain homotopic to $(-1)^{kl} \cdot ((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} -) \circ \Upsilon$.

Proof. We start out with the proof of Statement (1). First we note that

$$(\alpha \mathbin{\widetilde{\cap}} -) \otimes (\beta \mathbin{\widetilde{\cap}} -) \underset{\text{by Proposition 117.12}}{\overset{\uparrow}{=}} (\eta \circ (\Pi_k(\alpha) \otimes \mathrm{id}) \circ \Delta_X) \otimes (\eta \circ (\Pi_l(\beta) \otimes \mathrm{id}) \circ \Delta_Y) \underset{\text{follows from the observation that for chain maps } a,b,c \text{ and } d \text{ we have } (a\circ b)\otimes(c\circ d) = (a\otimes b)\circ(c\otimes d)}{\overset{\uparrow}{=}} (\eta \otimes \eta) \circ ((\Pi_k(\alpha) \otimes \mathrm{id} \otimes \Pi_l(\beta) \otimes \mathrm{id})) \circ (\Delta_X \otimes \Delta_Y).$$

If we compose this equality with $\Upsilon[k+l] \circ \Psi_{k,l}$ then we obtain the "bottom left route" in the above diagram. This concludes the proof of Statement (1).

We continue with the proof of Statement (2). In that proof we will make use of the following subclaim.

Subclaim. The two cocycles[1433]
$$(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l} \quad \text{and} \quad (-1)^{kl} \cdot p^*(\alpha) \cup q^*(\beta)$$
in $\mathrm{C}^{k+l}(X \times Y; \mathbb{Z})$ are cohomologous.

We consider the following diagram

$$\begin{array}{ccccc} \mathrm{C}_{k+l}(X\times Y) & \hookrightarrow & \mathrm{C}_*(X\times Y) & \xrightarrow{\Theta} & \mathrm{C}_*(X)\otimes\mathrm{C}_*(Y) \\ & & \downarrow{\scriptstyle \Delta_{X\times Y}} & \nearrow{\scriptstyle p_*\otimes q_*} & \downarrow{\scriptstyle \Pi_k(\alpha)\otimes\Pi_l(\beta)} \\ & & \mathrm{C}_*(X\times Y)\otimes\mathrm{C}_*(X\times Y) & \xrightarrow[\Pi_k(p^*(\alpha))\otimes\Pi_l(q^*(\beta))]{} & \mathbb{Z}[k]\otimes\mathbb{Z}[l] \xrightarrow[\eta]{} \mathbb{Z}[k+l]. \end{array}$$

[1433] Recall that $\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta$ is a chain map $\mathrm{C}_*(X \times Y) \to \mathbb{Z}[k+l]$. Furthermore recall that the map $(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l}\colon \mathrm{C}_{k+l}(X \times Y) \to (\mathbb{Z}[k+l])_{k+l} = \mathbb{Z}$ is the $(k+l)$-th map of the chain map.

Note that by the above discussion all maps except for the top left map are chain maps. It follows immediately from the definitions that the bottom triangle of chain maps commutes "on the nose". The top triangle of chain maps commutes, up to a chain homotopy, by Theorem 113.5.[1434] It follows from Lemma 117.8 (3) that the restrictions of these two chain maps to maps $\mathrm{C}_{k+l}(X \times Y) \to \mathbb{Z} = \mathbb{Z}[k+l]$ are cohomologous cochains. But the restriction of the "top route" equals evidently the left-hand side of the subclaim. On the other hand, by Lemma 117.10 the restriction of the "bottom route" equals the right-hand side of the subclaim. This concludes the proof of the subclaim.

Now we see that

$$
\begin{aligned}
(-1)^{kl} \cdot ((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} -) \circ \Upsilon
&\overset{\text{above subclaim and Lemma 117.11 (2)}}{\simeq} \big((\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l} \mathbin{\widetilde{\cap}} -\big) \circ \Upsilon \\
&= \eta \circ \big(\Pi_{k+l}((\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l}) \otimes \mathrm{id}\big) \circ \Delta_{X\times Y} \circ \Upsilon \\
&\quad \uparrow \text{Proposition 117.12 applied to the } (k+l)\text{-cocycle } (\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l} \\
&= \eta \circ \big(\Pi_{k+l}((\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)))_{k+l}) \circ \Theta \otimes \mathrm{id}\big) \circ \Delta_{X\times Y} \circ \Upsilon \\
&\quad \uparrow \text{since for every chain map } \Omega\colon \mathrm{C}_*(X) \times \mathrm{C}_*(Y) \to \mathbb{Z}[k+l] \text{ we} \\
&\quad \text{have } \Pi_{k+l}((\Omega \circ \Theta)_{k+l}) = \Pi_{k+l}(\Omega_{k+l}) \circ \Theta \text{ as maps } \mathrm{C}_*(X \times Y) \to \mathbb{Z}[k+l], \\
&\quad \text{applies this observation to } \Omega = \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \\
&= \eta \circ ((\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta) \otimes \mathrm{id}) \circ \Delta_{X\times Y} \circ \Upsilon \\
&\quad \uparrow \text{here we use the equality of chain maps} \\
&\quad \Pi_{k+l}((\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)))_{k+l}) = \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta))\colon \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) \to \mathbb{Z}[k+l] \\
&\quad \text{which is obvious once one unravels the definitions} \\
&= \text{the "top right route" in the above diagram.} \\
&\quad \uparrow \text{follows from } (f \otimes \mathrm{id}) \circ (g \otimes \mathrm{id}) = (g \circ f) \otimes \mathrm{id}
\end{aligned}
$$

This concludes the proof of the claim and thus also of the theorem. ∎

Now we can finally provide the proof of Theorem 117.1.

Proof of Theorem 117.1. To simplify the notation we only consider the special case that $A = B = \varnothing$. For the general case one needs to take more care, we refer to [**Dol1956**, p. 240 and p. 244] for details. So let X and Y be two topological spaces. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the projection s. Let $[\alpha] \in \mathrm{H}^k(X;\mathbb{Z})$, $[\beta] \in \mathrm{H}^l(Y;\mathbb{Z})$ and let $[\mu] \in \mathrm{H}_m(X;\mathbb{Z})$ and $[\nu] \in \mathrm{H}_n(Y;\mathbb{Z})$. We have to show that

$$
\Big(\underbrace{[p^*(\alpha)]}_{\in \mathrm{H}^k(X\times Y)} \cup \underbrace{[q^*(\beta)]}_{\in \mathrm{H}^l(X\times Y)}\Big) \cap \underbrace{\big([\mu] \times [\nu]\big)}_{\in \mathrm{H}_{m+n}(X\times Y)} = (-1)^{kl+lm} \cdot \underbrace{([\alpha] \cap [\mu])}_{\in \mathrm{H}_{m-k}(X)} \times \underbrace{([\beta] \cap [\nu])}_{\in \mathrm{H}_{n-l}(Y)}
$$

[1434] More precisely, given $x \in X$ and $y \in Y$ both routes along the triangle send (x, y) to $x \otimes y$. Furthermore both routes are natural chain maps. Thus we can apply Theorem 113.5.

We have the following equality in $\mathrm{H}_{m+n-k-l}(X\times Y)$:

$$\begin{aligned}
(p^*([\alpha])\cup q^*([\beta]))\cap([\mu]\times[\nu]) &\overset{\text{Tautology 117.13 and the definition of } \widetilde{\cap}\text{, see page 2574}}{=} (-1)^{(k+l)(m+n-k-l)}\cdot([p^*\alpha\cup q^*\beta])\ \widetilde{\cap}\ [\Upsilon(\mu\otimes\nu)]\\
&= (-1)^{(k+l)(m+n-k-l)}\cdot(((p^*\alpha\cup q^*\beta)\ \widetilde{\cap}\ -)\circ\Upsilon)_*([\mu\otimes\nu])\\
&= (-1)^{(k+l)(m+n-k-l)}\cdot((-1)^{kl}\cdot\Upsilon[k+l]\circ\Psi_{k,l}\circ(\alpha\ \widetilde{\cap}\ -\otimes\beta\ \widetilde{\cap}\ -))_*([\mu\otimes\nu])\\
&\overset{\text{by Theorem 117.15 and the fact that chain homotopic maps induce the same map on homology groups}}{=}\\
&= (-1)^{(k+l)(m+n-k-l)}\cdot(-1)^{kl}\cdot\Big[\Upsilon[k+l]\circ\Psi_{k,l}\circ\Big(\underbrace{\alpha\ \widetilde{\cap}\ \mu}_{\substack{=(-1)^{k(m-k)}\cdot\alpha\cap\mu\\ \in \mathrm{C}_{m-k}(X)[k]}}\otimes\underbrace{\beta\ \widetilde{\cap}\ \nu}_{\substack{=(-1)^{l(n-l)}\cdot\beta\cap\nu\\ \in \mathrm{C}_{n-l}(Y)[l]}}\Big)\Big]\\
&= (-1)^{(k+l)(m+n-k-l)}\cdot(-1)^{kl}\cdot(-1)^{k(l+n-l)}\cdot(-1)^{k(m-k)}\cdot(-1)^{l(n-l)}\cdot\big[\Upsilon(\alpha\cap\mu\otimes\beta\cap\nu)\big]\\
&\overset{\text{definition of } \Psi_{k,l}\text{, see page 2575, and of the shifting from } \Upsilon \text{ to } \Upsilon[k+l]}{=}\\
&= (-1)^{kl+lm}\cdot[\alpha\cap\mu\times\beta\cap\nu] = (-1)^{kl+lm}\cdot([\alpha]\cap[\mu]\times[\beta]\cap[\nu]).\\
&\overset{\text{cleaning up signs and Tautology 117.13}}{}
\end{aligned}$$

■

117.3. **The Künneth Theorem for cohomology groups.** Given two topological spaces X and Y the Künneth Theorem 113.8 for topological spaces determines the homology groups of $X\times Y$ in terms of the homology groups of X and Y. The following proposition gives us, under some mild hypothesis, a similar answer for cohomology groups.

Theorem 117.16. (The Künneth Theorem for cohomology groups) Let X and Y be two topological spaces. We denote by $p\colon X\times Y\to X$ and $q\colon X\times Y\to Y$ the natural projections. If all the homology groups of X are finitely generated[1435], then given any $n\in\mathbb{N}_0$ there exists a short exact sequence

$$0\to\bigoplus_{k+l=n}\mathrm{H}^k(X;\mathbb{Z})\otimes\mathrm{H}^l(Y;\mathbb{Z})\to\mathrm{H}^n(X\times Y;\mathbb{Z})\to\bigoplus_{k+l=n+1}\mathrm{Tor}(\mathrm{H}^k(X;\mathbb{Z}),\mathrm{H}^l(Y;\mathbb{Z}))\to 0$$
$$\varphi\otimes\psi\mapsto p^*\varphi\cup q^*\psi$$

which is natural with respect to the topological spaces X and Y. If all the homology groups of Y are also finitely generated, then the short exact sequence splits (albeit not naturally).

Remark. Let X and Y be two topological spaces. In the literature the map

$$\begin{aligned}\mathrm{H}^k(X;\mathbb{Z})\times\mathrm{H}^l(Y;\mathbb{Z}) &\to \mathrm{H}^{k+l}(X\times Y;\mathbb{Z})\\ (\varphi,\psi) &\mapsto p^*\varphi\cup q^*\psi\end{aligned}$$

is often referred to as the *cohomology cross product* and it is written as $\varphi\times\psi := p^*\varphi\cup q^*\psi$. We will not make use of this notation.

The proof of the theorem rests on a purely algebraic theorem that, given two chain complexes $\mathcal{C}$ and $\mathcal{C}'$, relates the cohomology groups of $\mathcal{C}$ and $\mathcal{C}'$ to the cohomology groups of $\mathcal{C}\otimes\mathcal{C}'$. Before we can state the theorem we need to introduce one more definition, which is closely related to the definitions introduced on page 2512.

[1435] By this we mean that for every $k\in\mathbb{N}_0$ the abelian group $\mathrm{H}_k(X;\mathbb{Z})$ is finitely generated.

Definition. Let $\mathcal{C}$ and $\mathcal{C}'$ be two chain complexes and let $p, q \in \mathbb{N}_0$.

(1) We denote by
$$\Pi_{p,q}\colon (\mathcal{C}_* \otimes \mathcal{C}'_*)_{p+q} = \bigoplus_{i+j=p+q} \mathrm{C}_i \otimes \mathrm{C}'_j \;\to\; \mathrm{C}_p \otimes \mathrm{C}'_q$$
the natural projection.

(2) We denote by $\mu\colon \mathbb{Z} \otimes \mathbb{Z} \to \mathbb{Z}$ the obvious isomorphism given by $\mu(a \otimes b) = ab$.

(3) We consider the map:
$$\begin{aligned}\Xi_{p,q}\colon \mathrm{Hom}(\mathrm{C}_p, \mathbb{Z}) \otimes \mathrm{Hom}(\mathrm{C}'_q, \mathbb{Z}) \;&\to\; \mathrm{Hom}\left((\mathcal{C} \otimes \mathcal{C}')_{p+q}, \mathbb{Z}\right)\\ \varphi_p \otimes \varphi'_q \;&\mapsto \left(\bigoplus_{i+j=p+q} \mathrm{C}_i \otimes \mathrm{C}'_j \xrightarrow{\Pi_{p,q}} \mathrm{C}_p \otimes \mathrm{C}'_q \xrightarrow{\varphi_p \otimes \varphi'_q} \mathbb{Z} \otimes \mathbb{Z} \xrightarrow{\mu} \right).\end{aligned}$$

(4) It is straightforward to verify that the map $\Xi_{p,q}$ induces a well-defined map on cohomology groups, i.e. that the map
$$\begin{aligned}\Xi_{p,q}\colon \mathrm{H}^p(\mathcal{C}; \mathbb{Z}) \otimes \mathrm{H}^q(\mathcal{C}'; \mathbb{Z}) \;&\to\; \mathrm{H}^{p+q}(\mathcal{C} \otimes \mathcal{C}'; \mathbb{Z})\\ ([\varphi_p] \otimes [\varphi'_q]) \;&\mapsto\; [\Xi_{p,q}(\varphi_p \otimes \varphi'_q)]\end{aligned}$$
is well-defined. Furthermore it follows immediately from the definition that $\Xi_{p,q}$ is natural[1436] with respect to $\mathcal{C}$ and $\mathcal{C}'$.

Now we can state the promised purely algebraic theorem.

Theorem 117.17. (The Künneth Theorem for cochain complexes) Let $\mathcal{C}$ and $\mathcal{C}'$ be chain complexes. If $\mathcal{C}$ is a free chain complex and if all homology groups of $\mathcal{C}$ are finitely generated, then for every $n \in \mathbb{N}_0$ there exists a short exact sequence
$$0 \to \bigoplus_{p+q=n} \mathrm{H}^p(\mathcal{C}; \mathbb{Z}) \otimes \mathrm{H}^q(\mathcal{C}'; \mathbb{Z}) \xrightarrow{\Xi_{p,q}} \mathrm{H}^n(\mathcal{C} \otimes \mathcal{C}'; \mathbb{Z}) \to \bigoplus_{p+q=n+1} \mathrm{Tor}(\mathrm{H}^p(\mathcal{C}; \mathbb{Z}), \mathrm{H}^q(\mathcal{C}; \mathbb{Z})) \to 0$$
which is natural with respect to $\mathcal{C}$ and $\mathcal{C}'$. If all the chain groups of $\mathcal{C}'$ are also free abelian and all the homology groups of $\mathcal{C}'$ are also finitely generated, then the short exact sequence splits (albeit not naturally).

In the proof of the Künneth Theorem 117.17 for cochain complexes we need one technical lemma. To state the lemma we recall that on page 1940 we introduced the tensor product of two chain complexes. Basically the same definition also allows us to define the tensor product of two cochain complexes. With this preamble we can formulate the next lemma.

Lemma 117.18. Let $\mathcal{C}_*$ and $\mathcal{C}'_*$ be two chain complexes. We assume that all chain groups of $\mathcal{C}$ are finitely generated free abelian groups. Then the map
$$\begin{aligned}\Omega\colon \mathrm{Hom}(\mathcal{C}_*, \mathbb{Z}) \otimes \mathrm{Hom}(\mathcal{C}'_*, \mathbb{Z}) \;&\to\; \mathrm{Hom}(\mathcal{C}_* \otimes \mathcal{C}'_*, \mathbb{Z})\\ (\varphi_p\colon \mathrm{C}_p \to \mathbb{Z}) \otimes (\varphi'_q\colon C'_q \to \mathbb{Z}) \;&\mapsto\; (\mu \circ (\varphi_p \otimes \varphi'_q) \circ \Pi_{p,q}\colon (\mathcal{C}_* \otimes \mathcal{C}'_*)_{p+q} \to \mathbb{Z})\end{aligned}$$
is an isomorphism of cochain complexes.

[1436] In this case this means that for chain maps $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ the following diagram commutes:
$$\begin{array}{ccc}\mathrm{H}^p(\mathcal{D}; \mathbb{Z}) \otimes \mathrm{H}^q(\mathcal{D}'; \mathbb{Z}) & \xrightarrow{\Xi_{p,q}} & \mathrm{H}^{p+q}(\mathcal{D} \otimes \mathcal{D}'; \mathbb{Z})\\ \downarrow{\scriptstyle f^* \otimes (f')^*} & & \downarrow{\scriptstyle (f \otimes f')^*}\\ \mathrm{H}^p(\mathcal{C}; \mathbb{Z}) \otimes \mathrm{H}^q(\mathcal{C}'; \mathbb{Z}) & \xrightarrow{\Xi_{p,q}} & \mathrm{H}^{p+q}(\mathcal{C} \otimes \mathcal{C}'; \mathbb{Z}).\end{array}$$

Proof. We start out the proof of the lemma with the following elementary well-known observation:

(∗) For finitely many abelian groups $A_1, \dots, A_k$ we have a canonical isomorphism

$$\operatorname{Hom}(A_1 \oplus \cdots \oplus A_k, \mathbb{Z}) \;=\; \operatorname{Hom}(A_1, \mathbb{Z}) \oplus \cdots \oplus \operatorname{Hom}(A_k, \mathbb{Z}).$$

Now we turn to the actual proof of the lemma. It is elementary to verify that the map Ω is in fact a cochain map. So it remains to show that for every $n \in \mathbb{N}_0$ the map

$$\begin{aligned} \bigoplus_{p+q=n} \operatorname{Hom}(\mathrm{C}_p, \mathbb{Z}) \otimes \operatorname{Hom}(C'_q, \mathbb{Z}) &\to \operatorname{Hom}\Big(\bigoplus_{p+q=n} \mathrm{C}_p \otimes \mathrm{C}'_q, \mathbb{Z}\Big) \\ \varphi_p \otimes \varphi'_q &\mapsto \mu \circ (\varphi_p \otimes \varphi'_q) \circ \Pi_{p,q} \end{aligned}$$

is an isomorphism. Applying (∗) to the right-hand side we see that it suffices to prove the following claim.

Claim. For every choice of $p, q \in \mathbb{N}_0$ the map

$$\begin{aligned} \operatorname{Hom}(\mathrm{C}_p, \mathbb{Z}) \otimes \operatorname{Hom}(C'_q, \mathbb{Z}) &\to \operatorname{Hom}(\mathrm{C}_p \otimes C'_q, \mathbb{Z}) \\ \varphi_p \otimes \varphi'_q &\mapsto \mu \circ (\varphi_p \otimes \varphi'_q) \end{aligned}$$

is an isomorphism.

Proof. Let $p, q \in \mathbb{N}_0$. By our hypothesis on $\mathcal{C}_*$ the chain group C_p is a finitely generated free abelian group. Therefore we can find a basis $a_1, \dots, a_k$ for C_p. We denote by $\widehat{a}_1, \dots, \widehat{a}_k$ the dual basis of $\operatorname{Hom}(\mathrm{C}_p, \mathbb{Z})$. We can thus write

$$\operatorname{Hom}(\mathrm{C}_p, \mathbb{Z}) = \bigoplus_{i=1}^{k} \mathbb{Z} \cdot \widehat{a}_i \quad \text{and} \quad \mathrm{C}_p \otimes \mathrm{C}'_q = \bigoplus_{i=1}^{k} \mathbb{Z} \cdot a_i \otimes \mathrm{C}'_q.$$

Applying (∗) to the above decompositions and both sides of the claim one sees easily that the given homomorphism is an isomorphism. ■

Now we can finally prove the Künneth Theorem 117.17 for cochain complexes.

Proof of the Künneth Theorem 117.17 for cochain complexes. We only provide an outline of the proof. Let $\mathcal{C} = (\mathrm{C}_*, c_*)$ and $\mathcal{C}' = (\mathrm{C}'_*, c'_*)$ be chain complexes such that all the chain groups C_n are free abelian groups and such that all the homology groups $\mathrm{H}_k(\mathcal{C}; \mathbb{Z})$ are finitely generated.

The idea is that one can turn any cochain complex into a chain complex by reversing the signs in the degrees. Thus one can try to reduce the theorem to the Künneth Theorem 90.7. Towards the end of the proof we need to insert Lemma 117.18 to make everything work.

The proof proceeds in three steps:

(1) Since $\mathcal{C}$ is a free chain complex and since all homology groups of $\mathcal{C}$ are finitely generated we can use the Finite-Rank Chain Complex Lemma 81.14 to replace $\mathcal{C}$ by a chain complex such that all chain groups are finitely generated free abelian groups.

(2) Given $n \in \mathbb{Z}_{\leq 0}$ we write $E_n := \operatorname{Hom}(\mathrm{C}_{-n}, \mathbb{Z})$, $e_n := \partial^*_{-n+1} \colon E_n \to E_{n-1}$ and similarly we write $E'_n := \operatorname{Hom}(\mathcal{C}'_{-n}, \mathbb{Z})$ and $e'_n := \partial^*_{-n+1} \colon E'_n \to E'_{n-1}$. It follows immediately from the definitions that $\mathcal{E}_* := (E_*, e_*)$ and $\mathcal{E}'_* := (E'_*, e'_*)^*)$ form chain complexes in negative degrees. (We defined chain complexes to be given by chain groups indexed by $n \in \mathbb{N}_0$ but evidently the same theory also works for chain groups indexed by $\mathbb{Z}$ and $\mathbb{Z}_{\leq 0}$.) Since the groups E_n are free abelian we can apply the Künneth Theorem 90.7

(which also applies to chain complexes in non-positive degrees) to obtain for each $n \in \mathbb{Z}_{\leq 0}$ a natural short exact sequence

$$0 \to \bigoplus_{p+q=n} \mathrm{H}_p(\mathcal{E}) \otimes \mathrm{H}_q(\mathcal{E}') \to \mathrm{H}_n(\mathcal{E} \otimes \mathcal{E}') \to \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p(\mathcal{E}), \mathrm{H}_q(\mathcal{E}')) \to 0.$$
$$[\varphi] \otimes [\psi] \quad :$$

Put differently, for each $n \in \mathbb{N}_0$ we have a natural short exact sequence

$$0 \to \bigoplus_{-p-q=n} \underbrace{\mathrm{H}_{-p}(\mathcal{E})}_{=\mathrm{H}^p(\mathcal{C};\mathbb{Z})} \otimes \underbrace{\mathrm{H}_{-q}(\mathcal{E}')}_{=\mathrm{H}^q(\mathcal{E}';\mathbb{Z})} \to \mathrm{H}_{-n}(\mathcal{E} \otimes \mathcal{E}') \to \bigoplus_{-p-q=n+1} \mathrm{Tor}(\underbrace{\mathrm{H}_{-p}(\mathcal{E})}_{=\mathrm{H}^p(\mathcal{C};\mathbb{Z})}, \underbrace{\mathrm{H}_{-q}(\mathcal{E}')}_{=\mathrm{H}^p(\mathcal{C};\mathbb{Z})}) \to 0.$$

(3) For each $n \in \mathbb{N}_0$ we have isomorphisms

$$\mathrm{H}_{-n}(\mathcal{E}_* \otimes \mathcal{E}'_*) = \mathrm{H}^n(\mathcal{E}_{-*} \otimes \mathcal{E}'_{-*}) = \mathrm{H}^n\big(\overbrace{\mathrm{Hom}(\mathcal{C}_*, \mathbb{Z})}^{=\mathcal{E}_{-*}} \otimes \overbrace{\mathrm{Hom}(\mathcal{C}'_*, \mathbb{Z})}^{=\mathcal{E}'_{-*}}\big) \xrightarrow{\Omega} \mathrm{H}^n(\mathcal{C}_* \otimes \mathcal{C}'_*; \mathbb{Z}).$$
$$\uparrow \text{ by definition} \qquad \uparrow \text{ by definition} \qquad \uparrow \text{ by Lemma 117.18 and our hypothesis on } \mathcal{C}_*$$

We use this isomorphism to replace the middle term of the second short exact sequence in (2) and we obtain the desired short exact sequence.

Finally suppose that all the chain groups of $\mathcal{C}'$ are also free abelian and that all the homology groups of $\mathcal{C}'$ are also finitely generated. As in (1) we can use the Finite-Rank Chain Complex Lemma 81.14 to replace $\mathcal{C}$ by a chain complex such that all chain groups are finitely generated free abelian groups. It follows that $\mathcal{E}_*$ is a free chain complex which implies, by the last statement of the Künneth Theorem 90.7, that the short exact sequence splits. ■

Now we are in a position to prove the Künneth Theorem 117.16 for cohomology groups.

Proof of the Künneth Theorem 117.16 for cohomology groups. Let X and Y be two topological spaces such that all the homology groups of X are finitely generated. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the natural projections. Throughout the proof we use all the definitions that we introduced in Section 117.2.

It follows from the Eilenberg-Zilber Theorem 113.1, together with comparing the conclusion of the Künneth Theorem 117.17 for cochain complexes with the desired statement of the Künneth Theorem 117.16 for cohomology groups, that it remains to prove the following claim.

Claim. For any $k, l \in \mathbb{N}_0$ the map

$$\begin{aligned} \mathrm{H}^k(X;\mathbb{Z}) \otimes \mathrm{H}^l(Y;\mathbb{Z}) &\to \mathrm{H}^{k+l}(X \times Y;\mathbb{Z}) \\ [\alpha] \otimes [\beta] &\mapsto [p^*\alpha \cup q^*\beta] \end{aligned}$$

agrees with the map that is given by

$$[\alpha] \otimes [\beta] \mapsto [(\alpha \otimes \beta) \circ \Pi_{k,l} \circ \Theta].$$

Proof. Let $\alpha \in \mathrm{C}^k(X;\mathbb{Z})$ and $\beta \in \mathrm{C}^l(Y;\mathbb{Z})$ be cocycles. We have to show that the two cocycles

$$\underbrace{p^*\alpha \cup q^*\beta}_{=:\aleph} \quad \text{and} \quad \underbrace{(\alpha \otimes \beta) \circ \Pi_{k,l}}_{=:\beth} \circ \Theta$$

are cohomologous.

As usual, given a topological space W we denote by $\epsilon_W\colon \mathrm{C}_0(W) \to \mathbb{Z}$ the augmentation map. Clearly ϵ_W is a cocycle so by Lemma 117.8 (2) we can extend ϵ_W to a chain map

$\mathrm{C}_*(W) \to \mathbb{Z}$ which, by a slight abuse of notation, we also denote by ϵ_W. It follows from the Eilenberg-Zilber Theorem 113.1, Theorem 117.15 and Lemma 117.8 (2) that the maps

$$\underbrace{(-1)^{kl} \cdot \epsilon_{X\times Y}[k+l] \circ ((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} -)}_{=:\aleph'}\colon \mathrm{C}_{k+l}(X \times Y) \to \mathbb{Z}[k+l] = \mathbb{Z}$$

and

$$\underbrace{\epsilon_{X\times Y}[k+l] \circ \Upsilon[k+l] \circ \Psi_{k,l} \circ (\alpha \mathbin{\widetilde{\cap}} - \otimes \beta \mathbin{\widetilde{\cap}} -)}_{=:\beth'} \circ \Theta\colon \mathrm{C}_{k+l}(X \times Y) \to \mathbb{Z}[k+l] = \mathbb{Z}$$

are cocycles that are cohomologous. It remains to prove the following two subclaims.

Subclaim. We have

$$\aleph' = (-1)^{kl} \cdot \aleph\colon \mathrm{C}_{k+l}(X \times Y) \to \mathbb{Z}.$$

Let $\sigma \in \mathrm{C}_{k+l}(X \times Y)$. Then

$$\aleph'(\sigma) \underset{\uparrow}{=} (-1)^{kl} \cdot \epsilon_{X\times Y}((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} \sigma) \underset{\uparrow}{=} (-1)^{kl} \cdot (p^*\alpha \cup q^*\beta)(\sigma) = (-1)^{kl} \cdot \aleph(\sigma).$$

under the identification $\mathbb{Z}[k+l] = \mathbb{Z}$ we have $\epsilon_{X\times Y}[k+l] = \epsilon_{X\times Y}$

by definition of $\widetilde{\cap}$, see page 2574, together with the Cap Product-Kronecker Lemma 116.4 (1)

This concludes the proof of the subclaim.

Subclaim. We have

$$\beth' = (-1)^{kl} \cdot \beth\colon (\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y))_{k+l} \to \mathbb{Z}.$$

We have to show that both sides take the same value on any tensor product of the form $\sigma_i \otimes \sigma_j$ with $i+j = k+l$ and $\sigma_i \in \mathrm{C}_i(X)$ and let $\sigma_j \in \mathrm{C}_j(Y)$. It follows easily from the definition that both sides are zero for $\sigma_i \otimes \sigma_j$ with $(i,j) \neq (k,l)$. So let $\sigma_k \in \mathrm{C}_k(X)$ and let $\sigma_l \in \mathrm{C}_l(Y)$. Then

$$\begin{aligned}
\beth'(\sigma_k \otimes \sigma_l) &\underset{\uparrow}{=} (\epsilon_{X\times Y} \circ \Upsilon)[k+l] \circ \Psi_{k,l} \circ (\alpha \mathbin{\widetilde{\cap}} \sigma_k \otimes \beta \mathbin{\widetilde{\cap}} \sigma_l) \\
&\quad \text{since } \epsilon_{X\times Y}[k+l] \circ \Upsilon[k+l] = (\epsilon_{X\times Y} \circ \Upsilon)[k+l] \\
&\underset{\uparrow}{=} (-1)^{kl} \cdot (\epsilon_X \otimes \epsilon_Y) \circ (\alpha \cap \sigma_k \otimes \beta \cap \sigma_l) && \underset{\uparrow}{=} (-1)^{kl} \cdot \alpha(\sigma_k) \cdot \beta(\sigma_l) \\
&\quad \text{we use } \epsilon_{X\times Y} \circ \Upsilon = \epsilon_X \otimes \epsilon_Y\colon (\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y))_0 \to \mathbb{Z} \otimes \mathbb{Z} = \mathbb{Z}, && \text{by the Cap Product-Kronecker Lemma 116.4} \\
&\quad \text{definition of } \Psi_{k,l} \text{ in Lemma 117.14 and the definition of } \widetilde{\cap} \text{ on page 2574} \\
&= (-1)^{kl} \cdot ((\alpha \otimes \beta) \circ \Pi_{k,l})(\sigma_k \otimes \sigma_l) && = (-1)^{kl} \cdot \beth(\sigma_k \otimes \sigma_l).
\end{aligned}$$

This concludes the proof of the second subclaim, thus also of the claim and therefore also of the theorem. ∎

117.4. **The cohomology ring of product topological spaces.** In this section we will determine the cohomology ring of the m-dimensional torus $(S^1)^m$ and more generally, under some mild technical hypothesis, we will determine the cohomology ring of a product $X \times Y$ of topological spaces in terms of the cohomology rings of X and Y.
We recall the following definition.

Definition.

(1) A graded ring is a ring R together with a decomposition $R = \bigoplus_{n\in\mathbb{N}_0} R_n$ such that for any $m, n \in \mathbb{N}_0$ the multiplication map restricts to a map $R_m \times R_n \to R_{m+n}$. We say that an element r of R that lies in some R_n is homogeneous and we refer to $\deg(r) := n$ as the degree of r.

(2) A homomorphism $\varphi\colon A \to B$ between graded rings is a ring homomorphism that preserves the gradings, i.e. that satisfies $\varphi(A_n) \subset B_n$ for all $n \in \mathbb{N}_0$.
(3) A graded ring $R = \bigoplus_{n\in\mathbb{N}_0} R_n$ such that for any two homogeneous elements a and b the equality $a \cdot b = (-1)^{\deg(a)\cdot\deg(b)} \cdot b \cdot a$ holds is called a superalgebra.

Examples.

(1) the Cup Product-Commutativity Proposition 114.8 says in particular that for any topological space X the cohomology ring $(\mathrm{H}^*(X;\mathbb{Z}), \cup)$ is a superalgebra. Furthermore the Cup Product-Naturality Lemma 114.10 implies that for any map $f\colon X \to Y$ the induced map $f^*\colon \mathrm{H}^*(Y;\mathbb{Z}) \to \mathrm{H}^*(X;\mathbb{Z})$ is a homomorphism of superalgebras.
(2) The polynomial ring $\mathbb{F}_2[a] = \bigoplus_{i\in\mathbb{N}_0} \mathbb{F}_2 \cdot a^i$ is a superalgebra if we equip the ring with the grading that is determined by setting $\deg(a^i) := i$.
(3) The polynomial ring $\mathbb{Z}[x] = \bigoplus_{i\in\mathbb{N}_0} \mathbb{Z} \cdot x^i$ is a superalgebra if we equip the ring with the grading that is determined by setting $\deg(x^i) := 2i$.
(4) More generally, the polynomial ring $\mathbb{Z}[x_1, \ldots, x_k]$ in k variables $x_1, \ldots, x_k$ can be viewed as a superalgebra by setting $\deg(x_1^{r_1} \cdot \cdots \cdot x_k^{r_k}) = 2(r_1 + \cdots + r_k)$.
(5) The ring $\mathbb{Z}[x]/(x^2) = \mathbb{Z} \oplus \mathbb{Z} \cdot x$ is a superalgebra by viewing elements in $\mathbb{Z}$ as elements of degree 0 and by viewing elements in $\mathbb{Z} \cdot x$ as elements of degree 1. Note that the map
$$\begin{array}{rcl} \mathbb{Z}[x]/(x^2) & \to & \mathrm{H}^*(S^1;\mathbb{Z}) \\ a \cdot 1 + b \cdot x & \mapsto & a \cdot 1_{S^1} + b \cdot [S^1]^* \end{array}$$
is an isomorphism of superalgebras.
(6) We consider the ring
$$\Lambda[x_1, \ldots, x_k] := \mathbb{Z}[x_1, \ldots, x_k]/\text{ideal generated by } x_1^2, \ldots, x_k^2, \{x_i x_j + x_j x_i\}_{i,j=1,\ldots,k}.$$
In this ring we use the symbol "$\wedge$" for multiplication instead of "$\cdot$". For example for any $i, j \in \{1, \ldots, k\}$ we have $x_i \wedge x_i = 0$ and $x_i \wedge x_j = -x_j \wedge x_i$. This ring can be viewed in a unique way as a superalgebra such that $\deg(x_j) = 1$ for $j = 1, \ldots, k$. The ring $\Lambda[x_1, \ldots, x_k]$ is often referred to as the *exterior algebra on generators* $x_1, \ldots, x_k$, see e.g. [**Hat2002**, p. 217] and [**Mac1975**, p. 183].[1437] We leave it as an amusing exercise to verify that $\Lambda[x_1, \ldots, x_k]$ is a free abelian group of rank 2^k where a basis is given by
$$\{x_{n_1} \wedge \cdots \wedge x_{n_l} \,|\, n_1 < \cdots < n_l\}.$$

In Exercise 110.2 we saw that any sequence $\{A_n\}_{n\geq 1}$ of finitely generated abelian groups, with A_1 torsion-free, can appear as the sequence of cohomology groups $\mathrm{H}^*(X;\mathbb{Z})$ of some CW-complex. It is natural to ask whether any superalgebra structure can be realized as

[1437] If we replace the $\mathbb{Z}$-coefficients by $\mathbb{R}$-coefficients we obtain a ring that we denote by $\Lambda_{\mathbb{R}}[x_1, \ldots, x_k]$. This ring is isomorphic to the ring $\wedge^*(\mathbb{R}^k)^* = \bigoplus_{j=0}^{k} \wedge^j (\mathbb{R}^k)^*$ of alternating forms on $\mathbb{R}^k$, where the ring structure on $\wedge^*(\mathbb{R}^k)^*$ is given by the wedge product of alternating forms. More precisely a ring isomorphism is given by
$$\begin{array}{rcl} \Lambda_{\mathbb{R}}[x_1, \ldots, x_k] & \to & \wedge^*(\mathbb{R}^k)^* \\ x_{i_1} \wedge \cdots \wedge x_{i_r} & \to & dy_{i_1} \wedge \cdots \wedge dy_{i_r} \end{array}$$
where $dy_i\colon \mathbb{R}^k \to \mathbb{R}$ is the projection onto the i-th coordinate.

the cohomology ring of a topological space. More precisely, we have the following question, to which we will return later with Proposition 152.6.

Question 117.19. Let $R = \bigoplus_{n\in\mathbb{N}_0} R_n$ be superalgebra such that ${}_0 \cong \mathbb{Z}$, R_1 is torsion-free and such that all R_n are finitely generated. Does there exist a topological space X such that $(\mathrm{H}^*(X;\mathbb{Z}), \cup)$ is isomorphic to R?

Since there is not much to say right now about this question we continue with the next definition.

Definition. The tensor product of two superalgebras $A = \bigoplus_{n\in\mathbb{N}_0} A_n$ and $B = \bigoplus_{n\in\mathbb{N}_0} B_n$ is defined as the graded abelian group

$$A \otimes B := \bigoplus_{n\in\mathbb{N}_0} \underbrace{\bigoplus_{p+q=n} A_p \otimes B_q}_{=:(A\otimes B)_n}$$

where for $a_k \in A_k, a_l \in A_l, b_m \in B_m$ and $b_n \in B_n$ the multiplication is given by

$$(a_k \otimes b_l) \cdot (a_m \otimes b_n) := (-1)^{lm} \cdot a_k \cdot a_m \otimes b_l \cdot b_n.$$

Lemma 117.20.

(1) The tensor product of two superalgebras is again a superalgebra.

(2) The tensor product of superalgebras is associative, i.e. for any three superalgebras A, B and C the map

$$\begin{array}{rcl} (A \otimes B) \otimes C & \to & A \otimes (B \otimes C) \\ (a \otimes b) \otimes c & \mapsto & a \otimes (b \otimes c) \end{array}$$

that is induced by

is an isomorphism of superalgebras.

It follows immediately from Lemma 117.20 (2) that we can ignore parentheses when we consider the tensor product of several superalgebras.

Proof. Let A, B and C be superalgebras and let $a_k \in A_k, a_l \in A_l, b_m \in B_m$ and $b_n \in B_n$.

(1) We have the following equalities:

$$\begin{aligned} (a_k \otimes b_l)\cdot(a_m \otimes b_n) &= (-1)^{lm} \cdot a_k \cdot a_m \otimes b_l \cdot b_n = (-1)^{lm+km+ln} \cdot a_m \cdot a_k \otimes b_n \cdot b_l \\ &= (-1)^{lm+km+ln+kn} \cdot (a_m \otimes b_n) \cdot (a_k \otimes b_l) \\ &= (-1)^{(m+n)(k+l)} \cdot (a_m \otimes b_n) \cdot (a_k \otimes b_l) \\ &= (-1)^{\deg(a_m\otimes b_n)\cdot\deg(a_k\otimes b_l)} \cdot (a_m \otimes b_n) \cdot (a_k \otimes b_l). \end{aligned}$$

It follows immediately that $A \otimes B$ is again a superalgebra.

(2) It suffices to show that the indicated map is a homomorphism of superalgebras. Thus let $c_r \in \mathrm{C}_r$ and $c_s \in \mathrm{C}_s$. Then

$$\begin{aligned} ((a_k \otimes b_l) \otimes c_r)\cdot((a_m \otimes b_n) \otimes c_s) &= (-1)^{r(m+n)} \cdot ((a_k \otimes b_l)\cdot(a_m \otimes b_n)) \otimes (c_r \cdot c_s) \\ &= (-1)^{r(m+n)+lm} \cdot (a_k \cdot a_m \otimes b_l \cdot b_n \otimes c_r \cdot c_s) \\ &= (-1)^{m(l+r)} \cdot (a_k \cdot a_m \otimes (b_l \otimes c_r) \cdot (b_n \otimes c_s)) \\ &= (a_k \otimes (b_l \otimes c_r)) \cdot (a_m \otimes (b_n \otimes c_s)). \end{aligned}$$

■

Examples.

(1) As above we view the polynomial rings $\mathbb{F}_2[a]$ and $\mathbb{F}_2[b]$ as superalgebras by setting $\deg(a^i) = \deg(b^i) = i$. We consider the map

$$\begin{array}{rcl} \mathbb{F}_2[a] \otimes \mathbb{F}_2[b] & \to & \mathbb{F}_2[a,b] \\ a^r \otimes b^s & \mapsto & a^r \cdot b^s. \end{array}$$

Using the Tensor Lemma 89.3 (1) it is straightforward to show that this map is an isomorphism of abelian groups. One can easily verify that the map is a homomorphism of superalgebras. Summarizing we have convinced ourselves that this map is in fact an isomorphism of superalgebras.

(2) As before we view the polynomial rings $\mathbb{Z}[x_j]$, $j = 1, \ldots, k$ as superalgebras with $\deg(x_j^i) = 2i$. We consider the map

$$\begin{array}{rcl} \mathbb{Z}[x_1] \otimes \cdots \otimes \mathbb{Z}[x_k] & \to & \mathbb{Z}[x_1, \ldots, x_k] \\ x_1^{r_1} \otimes \cdots \otimes x_k^{r_k} & \mapsto & x_1^{r_1} \cdot \cdots \cdot x_k^{r_k}. \end{array}$$

The same argument as in (1) shows that this map is an isomorphism of superalgebras.

(3) As above we view the rings $\mathbb{Z}[x_j]/(x_j^2)$ as superalgebras with $\deg(x_j) = 1$. We leave it as an amusing exercise to verify that the map

$$\begin{array}{rcl} \mathbb{Z}[x_1]/(x_1^2) \otimes \cdots \otimes \mathbb{Z}[x_k]/(x_k^2) & \to & \Lambda[x_1, \ldots, x_k] \\ x_1^{r_1} \otimes \cdots \otimes x_k^{r_k} & \mapsto & x_1^{r_1} \wedge \cdots \wedge x_k^{r_k} \end{array}$$

is an isomorphism of superalgebras.

The following proposition explains our sudden interest in tensor products of superalgebras.

Proposition 117.21. (Cohomology Ring-of-Product Proposition) Let X and Y be two topological spaces. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the natural projections.

(1) The map

$$\begin{array}{rcl} \Phi\colon \mathrm{H}^*(X;\mathbb{Z}) \otimes \mathrm{H}^*(Y;\mathbb{Z}) & \to & \mathrm{H}^*(X \times Y;\mathbb{Z}) \\ \varphi \otimes \psi & \mapsto & p^*\varphi \cup q^*\psi \end{array}$$

is a homomorphism of superalgebras.

(2) If all the homology groups of X are finitely generated and torsion-free, then the homomorphism from (1) is in fact an isomorphism.

Proof. Let X and Y be two topological spaces.

(1) Let $\varphi_k \in \mathrm{H}^k(X;\mathbb{Z})$, $\psi_l \in \mathrm{H}^l(Y;\mathbb{Z})$, $\varphi_m \in \mathrm{H}^m(X;\mathbb{Z})$ and $\psi_n \in \mathrm{H}^n(Y;\mathbb{Z})$. Then

$$\begin{array}{ll} \overbrace{\Phi\big((-1)^{lm} \cdot (\varphi_k \cup \varphi_m) \otimes (\psi_l \cup \psi_n)\big)}^{=\Phi((\varphi_k \otimes \psi_l) \cdot (\varphi_m \otimes \psi_n))} & = (-1)^{lm} \cdot p^*(\varphi_k \cup \varphi_m) \cup q^*(\psi_l \cup \psi_n) \\ = (-1)^{lm} \cdot (p^*(\varphi_k) \cup p^*(\varphi_m) \cup q^*(\psi_l) \cup q^*(\psi_n)) & = \underbrace{p^*(\varphi_k) \cup q^*(\psi_l) \cup p^*(\varphi_m) \cup q^*(\psi_n)}_{=\Phi(\varphi_k \otimes \psi_l) \cup \Phi(\varphi_m \otimes \psi_n))}. \\ \uparrow & \uparrow \\ \text{Cup Product-Commutativity Proposition 114.8} & \text{Cup Product-Naturality Lemma 114.10} \end{array}$$

It follows immediately that Φ is a homomorphism of superalgebras.

(2) Now suppose that all the homology groups of X are finitely generated and torsion-free. This hypothesis allows us to apply the Künneth Theorem 117.16 for cohomology

groups and we obtain the following short exact sequence:

$$0 \to \bigoplus_{k+l=n} \mathrm{H}^k(X;\mathbb{Z}) \otimes \mathrm{H}^l(Y;\mathbb{Z}) \to \mathrm{H}^n(X \times Y;\mathbb{Z}) \to \bigoplus_{k+l=n+1} \mathrm{Tor}(\mathrm{H}^k(X;\mathbb{Z}), \mathrm{H}^l(Y;\mathbb{Z})) \to 0.$$
$$\varphi \otimes \psi \mapsto p^*\varphi \cup q^*\psi$$

Since the homology groups of X are torsion-free we obtain from the Universal Coefficient Theorem 110.12 for Cohomology Groups that the cohomology groups $\mathrm{H}^k(X;\mathbb{Z})$ are also torsion-free. But by the Tor-Properties Lemma 89.15 this implies that all the Tor-terms on the right-hand side of the short exact sequence vanish. ■

The following proposition in particular provides an answer to Question 115.15 (1).

Proposition 117.22. (Cohomology Ring-of-Torus Proposition) Let $n \in \mathbb{N}_0$. We denote by $T = (S^1)^n$ the n-dimensional torus. For $i = 1, \ldots, n$ we denote by $p_i \colon T \to S^1$ the projection onto the i-th factor. Then there exists a unique isomorphism

$$\psi \colon \Lambda[x_1, \ldots, x_n] \to \mathrm{H}^*(T;\mathbb{Z})$$

of superalgebras which has the property that for each $i \in \{1, \ldots, n\}$ we have

$$\psi(x_i) = p_i^*([S^1]^*).$$

Proof. We consider the following isomorphism of superalgebras

$$\Lambda[x_1, \ldots, x_n] \xleftarrow[\uparrow]{\cong} \mathbb{Z}[x_1]/(x_1^2) \otimes \ldots \otimes \mathbb{Z}[x_k]/(x_k^2) \xrightarrow[\uparrow]{\cong} \mathrm{H}^*(S^1;\mathbb{Z}) \otimes \ldots \otimes \mathrm{H}^*(S^1;\mathbb{Z}) \xrightarrow[\uparrow]{\cong} \mathrm{H}^*((S^1)^n;\mathbb{Z}).$$

isomorphism from page 2586 — isomorphism from page 2584 — Cohomology Ring-of-Product Proposition 117.21

It is clear from the definitions of the various maps that the map from left to right sends each x_i to $p_i^*([S^1]^*)$. The composition of the isomorphisms thus gives us the desired isomorphism. The uniqueness follows immediately from the fact that the x_i generate $\Lambda[x_1, \ldots, x_n]$ as a ring. ■

The following corollary gives in particular a negative answer to Question 115.10.

Corollary 117.23. For the n-dimensional torus $T = (S^1)^n$ the Lusternik-Schnirelmann category $\mathrm{cat}(T)$ equals n.

Proof. Given any $n \in \mathbb{N}_0$ we have

$$n \overset{\text{see page 2545}}{\underset{\downarrow}{\geq}} \text{Lusternik-Schnirelmann category } \mathrm{cat}((S^1)^n) \overset{\text{by Proposition 115.14}}{\underset{\downarrow}{\geq}} \text{cup length } \mathrm{cl}((S^1)^n) \underset{\uparrow}{\geq} n.$$

by the Cohomology Ring-of-Torus Proposition 117.22 there exists
somorphism $\psi \colon \Lambda[x_1, \ldots, x_n] \to \mathrm{H}^*((S^1)^n;\mathbb{Z})$ of graded rings,
furthermore by the discussion on page 2584 we know that $x_1 \wedge \cdots \wedge x_n \neq 0$,
since ψ is an isomorphism we deduce that $\psi(x_1) \cup \cdots \cup \psi(x_n) \neq 0$, i.e. $\mathrm{cl}((S^1)^n) \geq n$ ■

We conclude this chapter with the following variation on the Cohomology Ring-of-Product Proposition 117.21.

Proposition 117.24. Let X and Y be two topological spaces. We denote by $p \colon X \times Y \to X$ and $q \colon X \times Y \to Y$ the natural projections. If all the homology groups of X are finitely generated, then the map

$$\Phi \colon \mathrm{H}^*(X;\mathbb{F}_2) \otimes \mathrm{H}^*(Y;\mathbb{F}_2) \to \mathrm{H}^*(X \times Y;\mathbb{F}_2)$$
$$\varphi \otimes \psi \mapsto p^*\varphi \cup q^*\psi$$

is an isomorphism of superalgebras.

In the proof of Proposition 117.24 we will need the following theorem which is a variation on the Künneth Theorem 117.17 for cochain complexes.

Theorem 117.25. Let $\mathcal{C}$ and $\mathcal{C}'$ be chain complexes. If $\mathcal{C}$ is a free chain complex and if all homology groups of $\mathcal{C}$ are finitely generated, then for every $n \in \mathbb{N}_0$ there exists a natural isomorphism

$$\bigoplus_{k+l=n} \mathrm{H}^k(\mathcal{C};\mathbb{F}_2) \otimes \mathrm{H}^l(\mathcal{C}';\mathbb{F}_2) \xrightarrow{\Xi} \mathrm{H}^n(\mathcal{C} \otimes \mathcal{C}';\mathbb{F}_2).$$

The proof of Theorem 117.25 is evidently very similar to the proof of the Künneth Theorem 117.17 for cochain complexes. We refer to [**Mun1984**, Theorem 60.6] for a proof.

Proof of Proposition 117.24. The proof is almost the same as the proof of the Cohomology Ring-of-Product Proposition 117.21. More precisely, we first note that if in the proof of the Künneth Theorem 117.16 for cohomology groups we replace the Künneth Theorem 117.17 for cochain complexes by Theorem 117.25 we obtain that the map

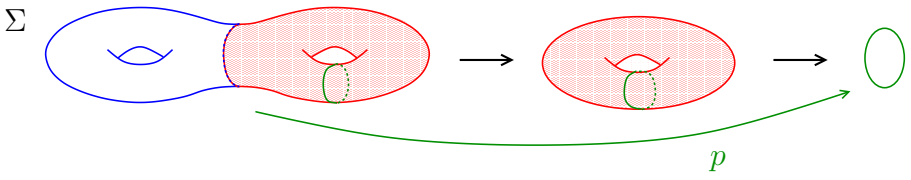
$$\begin{aligned} \bigoplus_{k+l=n} \mathrm{H}^k(X;\mathbb{F}_2) \otimes \mathrm{H}^l(Y;\mathbb{F}_2) &\to \mathrm{H}^n(X \times Y;\mathbb{F}_2) \\ \varphi \otimes \psi &\mapsto p^*\varphi \cup q^*\psi \end{aligned}$$

is an isomorphism. But the same argument as in the proof of the Cohomology Ring-of-Product Proposition 117.21 shows that this map is in fact a homomorphism of superalgebras. ■

Exercises for Chapter 117.

Exercise 117.1. Let X be a topological space. Recall that the Cup Product-Commutativity Proposition 114.8 says that for any $a \in \mathrm{H}^k(X;\mathbb{Z})$ and $b \in \mathrm{H}^l(X;\mathbb{Z})$ we have

$$a \cup b \;=\; (-1)^{kl} \cdot b \cup a.$$



Provide a proof of this statement using the original definition of the cup product from page 2513 and using Lemma 117.7.

Exercise 117.2. Let $g \in \mathbb{N}$ and denote by Σ_g the surface of genus g. Show that the Lusternik-Schnirelmann category of $S^1 \times \Sigma_g$ is greater or equal than three.

Exercise 117.3. Let Σ be the surface of genus 2, let $q\colon \Sigma \times S^1 \to \Sigma$ be the projection and let $p\colon \Sigma \to S^1$ be the map shown in the figure below. Determine the cap product

$$q(p^*([S^1]^*)) \cap [\Sigma \times S^1] \;\in\; \mathrm{H}_2(\Sigma \times S^1;\mathbb{Z})$$

up to sign.

Exercise 117.4. Let $n \in \mathbb{N}_0$. We write $T := (S^1)^n$. Let $\varphi\colon T \to T$ be map. We pick a basis for $\mathrm{H}_1(T) \cong \mathbb{Z}^n$ and we denote by A the $(n \times n)$-matrix that represents the map $\varphi_*\colon \mathrm{H}_1(T) \to \mathrm{H}_1(T)$ with respect to the given basis. Show that

$$\underbrace{\sum_{k=0}^{n} (-1)^k \cdot \mathrm{tr}(\varphi_*\colon \mathrm{H}_k(T) \to \mathrm{H}_k(T))}_{\text{Lefschetz number } \Lambda(\varphi)} \;=\; \det(\mathrm{id} - A).$$

Hint. Use the cohomological reformulation of the Lefschetz number given in Exercise 110.12 and use the Cohomology Ring-of-Torus Proposition 117.22.
Remark. It follows from this calculation together with the Lefschetz Fixed Point Theorem 97.9 that unless 1 is an eigenvalue of A the map φ has a fixed point.

Exercise 117.5. Let $n \in \mathbb{N}$ and let W be a compact orientable $(n+1)$-dimensional topological manifold such that ∂W is homeomorphic to the n-torus $(S^1)^n$. Show that the inclusion induced map $\mathrm{H}_1(\partial W; \mathbb{Z}) \to \mathrm{H}_1(W; \mathbb{Z})$ is not an injection.
Hint. Consider the cup product on $(S^1)^n$ and consider the interplay of the fundamental classes of ∂W and W.

Exercise 117.6. Given $n \in \mathbb{N}$ we denote by $p\colon S^n \times S^n \to S^n$ and $q\colon S^n \times S^n \to S^n$ the two obvious projections. Let $\varphi \in \mathrm{H}^n(S^n; \mathbb{Z})$ be a generator. We know, for example by the Cohomology Ring-of-Product Proposition 117.21, that $p^*(\varphi)$ and $q^*(\varphi)$ form a basis for $\mathrm{H}^n(S^n \times S^n; \mathbb{Z})$. Given a map $f\colon S^n \times S^n \to S^n \times S^n$ we denote by $A(f)$ the matrix representing the automorphism f^* of $\mathrm{H}^n(S^n \times S^n; \mathbb{Z})$ with respect to the basis $p^*(\varphi)$ and $q^*(\varphi)$.

(a) Let $B \in \mathrm{SL}(2, \mathbb{Z})$. Show that there exists a homeomorphism $f\colon S^1 \times S^1 \to S^1 \times S^1$ with $A(f) = B$.
Hint. Use the Action-on-Torus Homology Lemma 84.7.

(b) Now let $f\colon S^n \times S^n \to S^n \times S^n$ be a homeomorphism. Show that if n is even, then $A(f)$ is given by one of the following eight matrices

$$\begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & \pm 1 \\ \pm 1 & 0 \end{pmatrix}.$$

118. The relationship between de Rham cohomology and singular cohomology

In this chapter we want to find the connection between the de Rham cohomology groups from Chapter **??** and the singular cohomology groups that we defined in Chapter 108. To avoid a repetitive use of suffixes we will use the following convention.

Convention. In this chapter by a "manifold" we always mean a smooth manifold *without boundary*, unless we say explicitly otherwise.

118.1. **Smooth cohomology theories.** To a smooth manifold M we can associate the singular cohomology groups $\mathrm{H}^i(M;\mathbb{R})$ and also the de Rham cohomology groups $\mathrm{H}^i_{\mathrm{dR}}(M)$. Rereading the chapters on these cohomology groups one notices many common features, for example they both satisfy a Mayer–Vietoris type theorem. Now we want to put both cohomologies in a common framework.

Definition. A smooth cohomology theory is a contravariant functor[14381439]

$$\begin{array}{rcl} \mathcal{H}^*\colon \text{category of smooth manifolds} & \to & \text{category of } \mathbb{N}_0\text{-graded real vector spaces} \\ M & \mapsto & \mathcal{H}^*(M) = \bigoplus_{n\in\mathbb{N}_0} \mathcal{H}^n(M) \\ (f\colon M\to N) & \mapsto & \{f^* = \mathcal{H}^n(f)\colon \mathcal{H}^n(N)\to\mathcal{H}^n(M)\}_{n\in\mathbb{N}_0} \end{array}$$

that satisfies the following three axioms:

(1) (Smooth homotopy invariance) Let $f,g\colon M\to N$ be smooth maps between smooth manifolds. If f and g are smoothly homotopic, then for all $n\in\mathbb{N}_0$ we have

$$\mathcal{H}^n(f) = \mathcal{H}^n(g)\colon \mathcal{H}^n(N) \;\to\; \mathcal{H}^n(M).$$

(2) (Mayer–Vietoris sequence) If M is a smooth manifold and U and V are open subsets such that $M = U\cup V$, then there exists a natural long exact sequence of the form

$$\ldots \to \mathcal{H}^k(M) \xrightarrow{j_U^*\oplus -j_V^*} \mathcal{H}^k(U)\oplus\mathcal{H}^k(V) \xrightarrow{i_U^*+i_V^*} \mathcal{H}^k(U\cap V) \xrightarrow{\delta} \mathcal{H}^{k+1}(M) \to \ldots$$

where $j_U\colon U\to M$, $j_V\colon V\to M$, $i_U\colon U\cap V\to U$ and $i_V\colon U\cap V\to V$ denote the inclusion maps.

(3) (Limit property) Let M be a smooth manifold and let $\{U_i\}_{i\in\mathbb{N}}$ be a sequence of open subsets that satisfy the following three conditions:
   (a) for each $i\in\mathbb{N}$ the closure $\overline{U}_i$ of U_i is compact,
   (b) for each $i\in\mathbb{N}$ we have $U_i\subset U_{i+1}$, and
   (c) $M = \bigcup_{i\in\mathbb{N}} U_i$.
   Then for every $n\in\mathbb{N}_0$ there exists a natural short exact sequence

$$0 \;\to\; \varprojlim{}^1\, \mathcal{H}^{n-1}(U_i) \;\xrightarrow{\tau}\; \mathcal{H}^n(M) \;\to\; \varprojlim \mathcal{H}^n(U_i) \;\to\; 0$$

   where the right-hand map is induced by the maps $\mathcal{H}^n(M)\to\mathcal{H}^n(U_i)$ which in turn are induced by the inclusions $U_i\to M$.

[1438] Given a smooth map $f\colon M\to N$ the contravariant functor provides for each $n\in\mathbb{N}_0$ a morphism $\mathcal{H}^n(f)\colon\mathcal{H}^n(N)\to\mathcal{H}^n(M)$. As usual, when there is no danger of confusion we just write f^* instead of $\mathcal{H}^n(f)$.

[1439] We refer to page 1935 for the definition of the category of $\mathbb{N}_0$-graded real vector spaces.

This time it is easy to give examples for our new definition.

Proposition 118.1.
(1) Singular cohomology with real coefficients is a smooth cohomology theory.
(2) De Rham cohomology is a smooth cohomology theory.

Proof.

(1) It follows from the Homotopic Maps-H*-Lemma 108.13, the Mayer–Vietoris Theorem 109.15, together with the Excisive Triad-Proposition 109.12 and the Cohomology-via-Exhaustions Proposition 111.12 (1), that singular cohomology with real coefficients is a smooth cohomology theory.
(2) It follows from the Homotopic Maps-De Rham Cohomology Proposition **??**, Theorem **??** and the De Rham Cohomology-via-Exhaustions Proposition 118.2, which we will prove in the next section, that de Rham cohomology is a smooth cohomology theory. ■

To show that de Rham cohomology is indeed a smooth cohomology theory we will need to prove the following proposition, which is very similar in nature to the Cohomology-via-Exhaustions Proposition 111.12 for singular cohomology.

Proposition 118.2. (De Rham Cohomology-via-Exhaustions Proposition) Let M be a smooth manifold and let $\{U_i\}_{i\in\mathbb{N}}$ be a sequence of open subsets of M that satisfy the following three conditions:
(1) for each $i \in \mathbb{N}$ the closure $\overline{U}_i$ of U_i is compact,
(2) for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and
(3) $M = \bigcup_{i\in\mathbb{N}} U_i$.
Then for every $n \in \mathbb{N}_0$ there exists a natural short exact sequence

$$0 \;\to\; \varprojlim{}^1 \mathrm{H}^{n-1}_{\mathrm{dR}}(U_i) \;\xrightarrow{\tau}\; \mathrm{H}^n_{\mathrm{dR}}(M) \;\to\; \varprojlim \mathrm{H}^n_{\mathrm{dR}}(U_i) \;\to\; 0$$

where the right-hand map is induced by the obvious maps $\mathrm{H}^n_{\mathrm{dR}}(M) \to \mathrm{H}^n_{\mathrm{dR}}(U_i)$.

Proof. For each $k \in \mathbb{N}_0$ we consider the inverse system

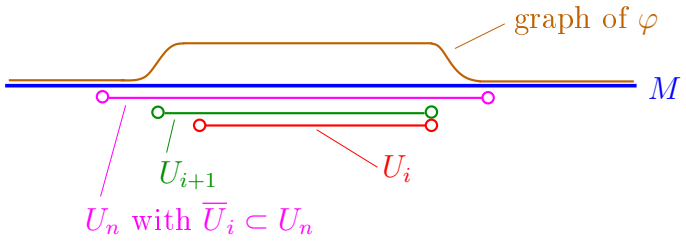
$$\Omega^k(U_1) \;\leftarrow\; \Omega^k(U_2) \;\leftarrow\; \Omega^k(U_3) \;\leftarrow\; \dots$$

where all the maps are induced by the inclusion, put differently, they are all restriction maps.

Claim. The inverse system satisfies the Mittag-Leffler condition from page 2470.

Proof. Given any $j \geq i$ we denote by $\rho_{ji}\colon \Omega^k(U_j) \to \Omega^k(U_i)$ the restriction map. Now let $i \in \mathbb{N}$. We have to show that there exists an $n \geq i$ such that for all $r \geq n$ we have

$$\operatorname{im}\big(\rho_{ri}\colon \Omega^k(U_r) \to \Omega^k(U_i)\big) \;=\; \operatorname{im}\big(\rho_{ni}\colon \Omega^k(U_n) \to \Omega^k(U_i)\big).$$



Since $\overline{U}_i$ is compact, since the U_j are nested and since $\overline{U}_i$ is contained in the union of all U_j there exists an n such that $\overline{U}_i \subset U_n$. We refer to the figure below for an illustration. We claim that n has the desired property. So let $r \geq n$. We have to show that

$$\operatorname{im}(\rho_{ri}\colon \Omega^k(U_r) \to \Omega^k(U_i)) \;=\; \operatorname{im}(\rho_{ni}\colon \Omega^k(U_n) \to \Omega^k(U_i)).$$

Clearly we have the inclusion "$\subset$". It remains to prove the reverse inclusion. So suppose $\eta \in \Omega^k(U_i)$ is the restriction of some $\mu \in \Omega^k(U_n)$. Note that U_n and $M \setminus \overline{U}_i$ form an open cover for M. It follows immediately from the Manifold-Partitions of Unity Existence Theorem 21.1 that there exists a smooth function $\varphi\colon M \to \mathbb{R}$ with $\varphi|_{\overline{U}_i} \equiv 1$ and such that $\operatorname{supp}(\varphi) \subset U_n$. Let $r \geq n$. We see that

$$\eta = \mu|_{U_i} \underset{\substack{\uparrow \\ \text{since } \varphi \equiv 1 \text{ on } U_i}}{=} (\varphi \cdot \mu)|_{U_i} = \overbrace{\epsilon(\varphi \cdot \mu, U_r)}^{\text{smooth by Lemma ??}}|_{U_i}.$$

We have thus shown that η is also the restriction of some smooth form on U_r. ⊞

By the claim we can apply the Direct Limit-Cohomology Proposition 111.10 to the inverse system $(\{\Omega^*(U_i)\}_{i\in\mathbb{N}}, \{\rho_{ij}\}_{i\geq j})$ of cochain complexes over $\mathbb{N}$ and we obtain the short exact sequence

$$0 \to \underbrace{\varprojlim_{i\in\mathbb{N}}{}^{1} \mathrm{H}^{n-1}(\Omega^*(U_i))}_{=\mathrm{H}^{n-1}_{\mathrm{dR}}(U_i)} \to \underbrace{\mathrm{H}^n\Big(\overbrace{\varprojlim_{i\in\mathbb{N}} \Omega^*(U_i)}^{=\Omega^*(M), \text{ see page 1280}} \Big)}_{=\mathrm{H}^n_{\mathrm{dR}}(M)} \to \underbrace{\varprojlim_{i\in\mathbb{N}} \mathrm{H}^n(\Omega^*(U_i))}_{=\mathrm{H}^n_{\mathrm{dR}}(U_i)} \to 0.$$

We have thus obtained the desired short exact sequence. ■

118.2. **Isomorphisms between smooth cohomology theories.** One might now be optimistic and hope that smooth cohomology theories are necessarily isomorphic. As it stands this thought though is too optimistic. For example other smooth cohomology theories are given by $\mathcal{H}^n(M) = 0$ for all $n \in \mathbb{N}_0$ or by $\mathcal{H}^n(M) = \mathrm{H}^{n+5}(M;\mathbb{R})$ or by $\mathcal{H}^n(M) = \mathrm{H}^n(M;\mathbb{R}) \oplus \mathrm{H}^n(M;\mathbb{R})$. This shows that if we want to prove that smooth cohomology theories are isomorphic we have to add some extra hypotheses, for example we could demand that the 0-th cohomology groups of a point are isomorphic.

Notation. In the following $\star$ denotes the topological space consisting of a single point. Evidently $\star$ is a 0-dimensional smooth manifold.

On page 203 we introduced the notion of a natural transformation between two contravariant functors. For the reader's convenience recall the definition since it will play an essential role in the following discussion.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories and let $F, G\colon \mathcal{C} \to \mathcal{D}$ be two contravariant functors. A natural transformation between the contravariant functors F and G assigns to each object $X \in \mathrm{Ob}(\mathcal{C})$ a morphism $\Phi_X\colon F(X) \to G(X)$ in $\mathcal{D}$ such that for each morphism

$f\colon X \to Y$ in $\mathcal{C}$ the following diagram commutes:

$$\begin{array}{ccc} F(Y) & \xrightarrow{F^*(f)} & F(X) \\ {\scriptstyle \Phi_Y}\downarrow & & \downarrow{\scriptstyle \Phi_X} \\ G(Y) & \xrightarrow{G^*(f)} & G(X). \end{array}$$

If all the maps Φ_X are isomorphisms we also say it is a natural isomorphism.

Example. Given $n \in \mathbb{N}_0$ we consider the two contravariant functors $X \mapsto \mathrm{H}^n(X;\mathbb{Z})$ and $X \mapsto \mathrm{Hom}(\mathrm{H}_n(X),\mathbb{Z})$ from the category of topological spaces to the category of abelian groups. It follows from the discussion on page 2444 that the evaluation homomorphisms $\mathrm{ev}\colon \mathrm{H}^n(X;\mathbb{Z}) \to \mathrm{Hom}(\mathrm{H}_n(X),\mathbb{Z})$ define a natural transformation between the two contravariant functors, i.e. given any map $f\colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^n(Y;\mathbb{Z}) & \xrightarrow{f^*} & \mathrm{H}^n(X;\mathbb{Z}) \\ {\scriptstyle \mathrm{ev}}\downarrow & & \downarrow{\scriptstyle \mathrm{ev}} \\ \mathrm{Hom}(\mathrm{H}_n(Y),\mathbb{Z}) & \xrightarrow{f^*} & \mathrm{Hom}(\mathrm{H}_n(X),\mathbb{Z}). \end{array}$$

With this notation and this definition we can now formulate the following theorem.

Theorem 118.3. (Smooth Cohomology Theory Isomorphism Theorem) Let $\mathcal{H}^*$ and $\mathcal{K}^*$ be smooth cohomology theories and let $t\colon \mathcal{H}^* \to \mathcal{K}^*$ be a natural transformation. Suppose t has the following three properties:

(i) the natural transformation t is compatible with the connecting homomorphism in the Mayer-Vietoris sequence, i.e. with the obvious notation we always have a commutative diagram

$$\begin{array}{ccccccccc} \ldots \longrightarrow \mathcal{H}^n(M) & \xrightarrow{j_U^*\oplus -j_V^*} & \mathcal{H}^n(U)\oplus\mathcal{H}^n(V) & \xrightarrow{i_U^*+i_V^*} & \mathcal{H}^n(U\cap V) & \xrightarrow{\delta} & \mathcal{H}^{n+1}(M) \longrightarrow \ldots \\ \downarrow{\scriptstyle t} & & \downarrow{\scriptstyle t\oplus t} & & \downarrow{\scriptstyle t} & & \downarrow{\scriptstyle t} \\ \ldots \longrightarrow \mathcal{K}^n(M) & \xrightarrow{j_U^*\oplus -j_V^*} & \mathcal{K}^n(U)\oplus\mathcal{K}^n(V) & \xrightarrow{i_U^*+i_V^*} & \mathcal{K}^n(U\cap V) & \xrightarrow{\delta} & \mathcal{K}^{n+1}(M) \longrightarrow \ldots \end{array}$$

(ii) the natural transformation t is compatible with the map τ appearing in the limit property, i.e. with the obvious notation we always have a commutative diagram[1440]

$$\begin{array}{ccccccccc} 0 \longrightarrow & \varprojlim{}^1\,\mathcal{H}^{n-1}(U_i) & \xrightarrow{\tau} & \mathcal{H}^n(M) & \longrightarrow & \varprojlim \mathcal{H}^n(U_i) & \longrightarrow 0 \\ & \downarrow{\scriptstyle t} & & \downarrow{\scriptstyle t} & & \downarrow{\scriptstyle t} & \\ 0 \longrightarrow & \varprojlim{}^1\,\mathcal{K}^{n-1}(U_i) & \xrightarrow{\tau} & \mathcal{K}^n(M) & \longrightarrow & \varprojlim \mathcal{K}^n(U_i) & \longrightarrow 0, \end{array}$$

(iii) for all $n \in \mathbb{N}_0$ the map $t^n(\star)\colon \mathcal{H}^n(\star) \to \mathcal{K}^n(\star)$ is an isomorphism.

Then for every smooth manifold M and every $n \in \mathbb{N}_0$ the map

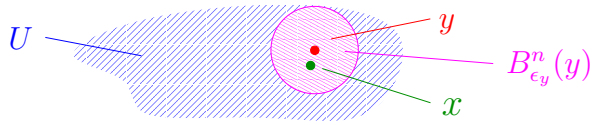
$$t\colon \mathcal{H}^n(M) \to \mathcal{K}^n(M)$$

is an isomorphism.

[1440] Note that the left and right vertical maps are given by the remark on page 2472.

The proof of the Smooth Cohomology Theory Isomorphism Theorem 118.3 rests on the following useful little lemma, which incidentally also solves Exercise 1.30.

Lemma 118.4. (Rational Open Balls Lemma)



(1) Every open subset of $\mathbb{R}^n$ is the union of open balls of the form $B^n_\epsilon(x)$ where ϵ is rational and $x \in \mathbb{Q}^n$.
(2) Every open subset of $\mathbb{R}^n$ is the union of countably many open balls.

Proof of Lemma 118.4.

(1) Let U be an open subset of $\mathbb{R}^n$. For $x \in U$ we set $\mu_x := \sup\{\mu \in [0,1] \mid B^n_\mu(x) \subset U\}$. The hypothesis that U is open implies that $\mu_x > 0$. We pick a rational number $\epsilon_x \in (\frac{1}{2}\mu_x, \mu_x)$. Note that $B^n_{\epsilon_x}(x) \subset U$. It remains to prove the following claim.

Claim. The subset U is the union of all $B^n_{\epsilon_x}(x)$ with $x \in U \cap \mathbb{Q}^n$.

Proof. Let $y \in U$. Since $\mathbb{Q}^n$ is dense in $\mathbb{R}^n$ we can pick $x \in U \cap \mathbb{Q}^n$ with $\|x-y\| < \frac{1}{4}\epsilon_y$. Note that this is equivalent to saying that $y \in B^n_{\frac{1}{4}\epsilon_y}(x)$. Thus it remains to prove that $B^n_{\frac{1}{4}\epsilon_y}(x) \subset B^n_{\epsilon_x}(x)$. Recall that we pointed out above that $B^n_{\epsilon_y}(y) \subset U$. Since $\|x-y\| < \frac{1}{4}\epsilon_y$ we have by the triangle inequality that $B^n_{\frac{3}{4}\epsilon_y}(x) \subset B^n_{\epsilon_y}(y)$. Thus $B^n_{\frac{3}{4}\epsilon_y}(x) \subset U$. By definition of μ_x this implies that $\frac{3}{4}\epsilon_y \leq \mu_x$. Hence we have $\frac{1}{4}\epsilon_y \leq \frac{3}{8}\epsilon_y \leq \frac{1}{2}\mu_x \leq \epsilon_x$. But then we also have $B^n_{\frac{1}{4}\epsilon_y}(x) \subset B^n_{\epsilon_x}(x)$, as desired. ⊞

(2) This statement follows immediately from (1). ■

Proof of Theorem 118.3. Let $\mathcal{H}^*$ and $\mathcal{K}^*$ be smooth cohomology theories, which means they both satisfy

(α) smooth homotopy invariance,
(β) the Mayer-Vietoris sequence,
(γ) the limit property.

Furthermore let $t\colon \mathcal{H}^* \to \mathcal{K}^*$ be a natural transformation that has the above properties (i), (ii) and (iii). We need to prove the following statement:

Statement. Let $m \in \mathbb{N}_0$. For every m-dimensional smooth manifold M and every $n \in \mathbb{N}_0$ the map

$$t^n(M)\colon \mathcal{H}^n(M) \to \mathcal{K}^n(M)$$

is an isomorphism.

We start out with the following two observations:

(A) Suppose M is an m-dimensional smooth manifold and U and V are open subsets with $M = U \cup V$. If all t^n are isomorphisms for U, V and $U \cap V$, then it follows from (β), (i) and the Five Lemma 74.10 that all the t^n are therefore isomorphisms for M.
(B) Let M be an m-dimensional smooth manifold and let $\{U_i\}_{i\in\mathbb{N}}$ be a sequence of open subsets that satisfy the following three conditions:
 (a) for each $i \in \mathbb{N}$ the closure $\overline{U}_i$ of U_i is compact,

(b) for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and
(c) $M = \bigcup_{i\in\mathbb{N}} U_i$.

If all the t^n are isomorphisms for all U_i, then it follows from (γ) and the Five Lemma 74.10 that all the t^n are therefore isomorphisms for M.

After these preparations we will prove the desired statement in four easy steps:

(1) Let M be an open convex subset of $\mathbb{R}^m$. We pick an inclusion $f\colon \star \to M$. As in the proof of the Poincaré Lemma **??** we see that f is a smooth homotopy equivalence. Given $n \in \mathbb{N}_0$ we consider the diagram

$$\begin{array}{ccc} \mathcal{H}^n(M) & \xrightarrow{f^*} & \mathcal{H}^n(\star) \\ {\scriptstyle t}\downarrow & & \cong\downarrow{\scriptstyle t} \\ \mathcal{K}^n(M) & \xrightarrow{f^*} & \mathcal{K}^n(\star). \end{array}$$

The diagram commutes since t is a natural transformation. It follows easily from (α) that the horizontal maps are isomorphisms. By (iii) the right vertical map is also an isomorphism. It follows that the left vertical map is, as desired, an isomorphism

(2) We claim that t is an isomorphism for every subset M of $\mathbb{R}^m$ that is the union of k open convex subsets of $\mathbb{R}^m$. We prove this by induction on the number k of open convex subsets:
   (a) If $k = 1$, then M itself is an open convex subset of $\mathbb{R}^m$, hence the statement follows from (1).
   (b) Suppose the statement holds whenever M is the union of $k-1$ open convex subsets. Now let M be the union of k open convex subsets $U_1, \ldots, U_k$. We write $V = U_1 \cup \cdots \cup U_{k-1}$. By induction the statement holds for V and also for U_k. Furthermore since the intersection of two convex open subsets is again convex and open we see that $V \cap U_k = (U_1 \cap U_k) \cup \cdots \cup (U_{k-1} \cap U_k)$ is the union of $k-1$ open convex subsets, i.e. by induction the statement holds for $V \cap U_k$. But then it follows from (A) that the statement also holds for U.

(3) Let M be an open subset of $\mathbb{R}^m$. By the Rational Open Balls Lemma 118.4 we can write M as the union of countably many open balls $B_i, i \in \mathbb{N}$. For $i \in \mathbb{N}$ we define $U_i := \bigcup_{j\le i} B_j$. By (2) the statement holds for each U_i, but then it follows from (B) that the statement holds for M.

(4) Finally let M be any m-dimensional smooth manifold. We say a subset W of M is *small* if it is open, if $\overline{W}$ is compact and if W is contained in the domain of some chart for M. We make the following observations:
   (a) Since $\mathcal{H}$ and $\mathcal{K}$ are diffeomorphism invariants we obtain from (2) that the statement holds for every small subset of W (viewed as a smooth manifold in its own right).
   (b) The same induction argument as in (2) shows that the statement holds for finite unions of small subsets (here the key observation is that the intersection of two small subsets is again small).[1441]

[1441]Here we implicitly use the following statement: if A and B are subsets of M such that $\overline{A}$ and $\overline{B}$ are compact, then $\overline{A \cap B}$ and $\overline{A \cup B}$ are also compact. We will prove this statement in Exercise 118.2.

(c) Finally it follows easily from the fact that the smooth manifold M is second-countable, the existence of charts around every point and Lemma 1.30 that there exist small sets $W_i, i \in \mathbb{N}$ which cover M. As in (3) we consider $U_i := \bigcup_{j \leq i} W_j$. We had just seen in (b) that the statement holds for all the U_i. But then it follows from (B) that the statement holds for M. ■

118.3. **Smooth singular cohomology.** One might think that it follows immediately from Proposition 118.1 and the Smooth Cohomology Theory Isomorphism Theorem 118.3 (together with the calculations of the cohomology groups of a point in the Single Point-Cohomology Lemma 108.12 and on page **??**) that the singular real valued cohomology and the de Rham cohomology groups of smooth manifolds are always isomorphic.
But recall that to apply the Smooth Cohomology Theory Isomorphism Theorem 118.3 we need to find a natural transformation

$$t\colon \text{de Rham cohomology} \quad \to \quad \text{real valued singular cohomology}$$

that has the property that

$$\mathrm{H}^n_{\mathrm{dR}}(\star) \quad \xrightarrow{\cong} \quad \mathrm{H}^n(\star;\mathbb{R}) \qquad \text{for all } n \in \mathbb{N}_0.$$

Here is an idea: in Section **??** we had seen that given a compact oriented n-dimensional smooth manifold W and a smooth differential n-form ω on W there exists an integral

$$\int_W \omega \ \in \ \mathbb{R}$$

that has many good properties. So given some smooth manifold M (with no restrictions on the dimension) we could try to define a map

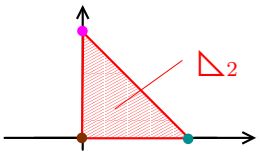
$$\begin{array}{rcl} t\colon \Omega^n(M) & \to & \mathrm{Hom}(\mathrm{C}_n(M);\mathbb{R}) \\ \omega & \mapsto & \left(\begin{array}{rcl} \mathrm{C}_n(M) & \to & \mathbb{R} \\ \sum_{i=1}^k a_i \cdot (f_i\colon \Delta^n \to M) & \mapsto & \sum_{i=1}^k a_i \cdot \int_{\Delta^n} f_i^*\omega \end{array} \right). \end{array}$$

Unfortunately, there are several problems with this "definition":

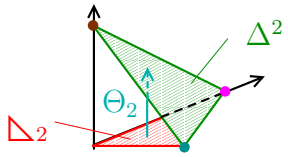
(1) The first question that arises is the following: what does it mean to integrate a form over Δ^n? After all, it is not clear in what sense Δ^n is a smooth manifold. With some luck that should not be too much of an issue, since Δ^n is clearly pretty close to being a smooth manifold.
(2) Let us suppose that we have resolved (1). Now let $f\colon \Delta^n \to M$ be a singular n-chain. If the map f is not smooth, then $f^*\omega$ just does not make any sense.[1442]
(3) After fixing the previous issues, why should t be a cochain map?

Arguably the most serious issue is (2). The only way around it is to only work with smooth singular simplices. Let us recall the following definitions.

[1442]Recall that if $f\colon N \to M$ is a smooth map between smooth manifolds and ω is a smooth differential n-form on M, then $f^*\omega$ is defined to be the differential n-form that for $v_1, \ldots, v_n \in \mathrm{T}_P N$ has the value



$$(f^*\omega)_P(v_1, \ldots, v_n) \ = \ \omega_{f(P)}(\mathrm{D}f_P(v_1), \ldots, \mathrm{D}f_P(v_n)).$$



But if f is not differentiable, then there is no differential $\mathrm{D}f_P\colon \mathrm{T}_P N \to \mathrm{T}_{f(P)} M$.

Definition. Let $n \in \mathbb{N}_0$.

(1) As in the Standard Simplex Homeomorphism Lemma 72.1 we consider the planar simplex
$$\triangle_n := \left\{(t_1, \ldots, t_n) \in \mathbb{R}^n_{\geq 0} \;\middle|\; \sum_{i=1}^n t_i \in [0,1]\right\}.$$

(2) In the Standard Simplex Homeomorphism Lemma 72.1 we saw that the map[1443]
$$\begin{aligned} \Theta_n \colon \triangle_n &\to \Delta^n \\ (t_1, \ldots, t_n) &\mapsto \left(t_1, \ldots, t_n, 1 - \sum_{i=1}^n t_i\right) \end{aligned}$$
is a homeomorphism.

Now we turn to smooth manifolds. Continuing with the above definition we can now introduce the notion of a smooth singular simplex.

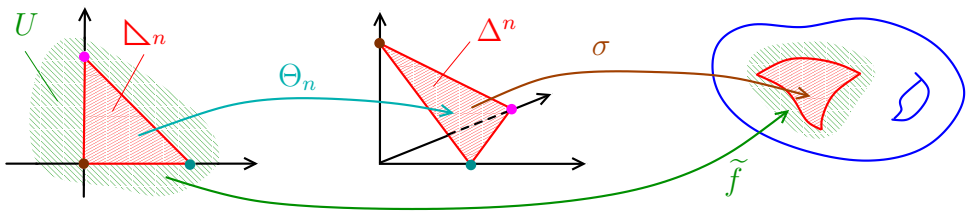
Definition. Let M be a smooth manifold.

(3) Recall that by the definition on page 549 a map $f \colon \triangle_n \to M$ is smooth if given any $a \in \triangle_n$ there exists an open neighborhood U in $\mathbb{R}^n$ of a and a smooth map $\widetilde{f} \colon U \to M$ which coincides with f on A. We define the differential of f at $a \in \triangle_n$ to be the differential of $\widetilde{f}$.[1444]

(4) We say a singular n-simplex $\sigma \colon \Delta^n \to M$ is smooth if the map $\sigma \circ \Theta_n \colon \triangle_n \to M$ is smooth. We illustrate the definition in the figure below.

(5) We write
$$\mathrm{C}_n^{\text{smooth}}(M) := \begin{array}{c}\text{the free abelian group generated by the} \\ \text{set of smooth singular } n\text{-simplices in } M.\end{array}$$
This is a subgroup of $\mathrm{C}_n(M)$ and it is straightforward to verify that the boundary map $\partial_n \colon \mathrm{C}_n(M) \to \mathrm{C}_{n-1}(M)$ restricts to a map $\partial_n \colon \mathrm{C}_n^{\text{smooth}}(M) \to \mathrm{C}_{n-1}^{\text{smooth}}(M)$.

(6) Given an abelian group G we write
$$\mathrm{C}^n_{\text{smooth}}(M; G) := \mathrm{Hom}\left(\mathrm{C}_n^{\text{smooth}}(M), G\right)$$
and we define $\delta_n \colon \mathrm{C}^n_{\text{smooth}}(M; G) \to \mathrm{C}^{n+1}_{\text{smooth}}(M; G)$ as the map $\delta_n := \partial_{n+1}^*$.



(7) We define the n-th smooth singular cohomology group of a smooth manifold M with G-coefficients as
$$\mathrm{H}^n_{\text{smooth}}(M; G) := \frac{\ker\left(\delta_n \colon \mathrm{C}^n_{\text{smooth}}(M; G) \to \mathrm{C}^{n+1}_{\text{smooth}}(M; G)\right)}{\mathrm{im}\left(\delta_{n-1} \colon \mathrm{C}^{n-1}_{\text{smooth}}(M; G) \to \mathrm{C}^n_{\text{smooth}}(M; G)\right)}.$$

Remark.

(1) Let $f \colon M \to N$ be a *smooth* map between two smooth manifolds. Evidently the induced map $f_* \colon \mathrm{C}^n(M) \to \mathrm{C}^n(N)$ restricts to a map $f_* \colon \mathrm{C}_n^{\text{smooth}}(M) \to \mathrm{C}_n^{\text{smooth}}(N)$. In particular we get an induced map $f^* \colon \mathrm{C}^n_{\text{smooth}}(N, G) \to \mathrm{C}^n_{\text{smooth}}(M, G)$. Thus we

[1443] Put differently, Θ_n is the inverse of the obvious projecton map $\Delta^n \to \triangle_n$.

[1444] It is straightforward to verify that this definition does not depend on the choice of U and $\widetilde{f}$.

obtain for each $n \in \mathbb{N}_0$ an induced map

$$f^* \colon \mathrm{H}^n_{\mathrm{smooth}}(N; G) \ \to \ \mathrm{H}^n_{\mathrm{smooth}}(M; G).$$

(2) Every map $\Delta^n \to \star$ is smooth, so there is no difference between ordinary singular cohomology and smooth singular cohomology for smooth manifold $\star$.

Proposition 118.5. Smooth singular cohomology with real coefficients is a smooth cohomology theory.

Sketch of proof. We need to verify that smooth singular cohomology with real coefficients satisfies the properties of a smooth cohomology theory.

(0) It is clear that smooth singular cohomology with real coefficients is a contravariant functor from the category of smooth manifolds to the category of $\mathbb{N}_0$-graded real vector spaces.

(1) Suppose $f, g \colon M \to N$ are two smooth maps between two smooth manifolds and suppose we are given a *smooth* homotopy F between f and g. Some thought shows that the chain homotopy

$$P_n \colon \mathrm{C}_n(M) \ \to \ \mathrm{C}_{n+1}(N), \quad n \in \mathbb{N}_0$$

from the proof of the Homotopic Maps-and-Homology Proposition 73.6 restricts to a chain homotopy

$$\mathrm{C}^{\mathrm{smooth}}_n(M) \ \to \ \mathrm{C}^{\mathrm{smooth}}_{n+1}(N), \quad n \in \mathbb{N}_0.$$

Now we can once again appeal to the Dual Cochain Map Lemma 108.8 to conclude that the induced maps on smooth singular cohomology are the same.

(2) Let M be a smooth manifold and let U and V be open subsets with $M = U \cup V$. The key to proving the existence of the Mayer–Vietoris sequence for ordinary singular cohomology was to show that the inclusion map

$$\mathrm{C}^{\{U,V\}}_*(M) \ \to \ \mathrm{C}_*(M)$$

is a chain homotopy equivalence. This in turn we showed using the Comfortable Covering Proposition 74.23. In the proof of the Comfortable Covering Proposition 74.23 we introduced the subdivision maps

$$u_n \colon \mathrm{C}_n(M) \ \to \ \mathrm{C}_n(M), \quad n \in \mathbb{N}_0.$$

It follows immediately from the definitions that these maps restrict to maps

$$u_n \colon \mathrm{C}^{\mathrm{smooth}}_n(M) \ \to \ \mathrm{C}^{\mathrm{smooth}}_n(M), \quad n \in \mathbb{N}_0.$$

Using this observation the proof of the existence of a Mayer–Vietoris sequence for smooth singular cohomology is otherwise identical to the proof for ordinary singular cohomology.

(3) The limit property is proved the same way as the Cohomology-via-Exhaustions Proposition 111.12 (1). We only have to replace the fact, proved in the Exhaustion-Chain Complex Lemma 79.5 that $\mathrm{C}_*(M) = \varinjlim \mathrm{C}_*(U_i)$ by the observation that the same argument as in the Exhaustion-Chain Complex Lemma 79.5 shows that $\mathrm{C}_*^{\mathrm{smooth}}(M) = \varinjlim \mathrm{C}_*^{\mathrm{smooth}}(U_i)$. ■

Now we can easily show that smooth singular cohomology with real coefficients and ordinary singular cohomology with real coefficients are naturally isomorphic. More precisely, we have the following proposition.

Proposition 118.6. There exists a natural isomorphism from smooth singular cohomology with real coefficients to ordinary singular cohomology with real coefficients. In particular for any smooth manifold M and any $n \in \mathbb{N}_0$ we have a natural isomorphism

$$\mathrm{H}^n(M;\mathbb{R}) \xrightarrow{\cong} \mathrm{H}^n_{\mathrm{smooth}}(M;\mathbb{R}).$$

Proof. For any smooth manifold M we have the natural inclusion

$$\mathrm{C}_*^{\mathrm{smooth}}(M) \to \mathrm{C}_*(M)$$

which evidently respects the boundary maps. These maps thus give rise to natural maps

$$\mathrm{C}^*(M;\mathbb{R}) \to \mathrm{C}^*_{\mathrm{smooth}}(M;\mathbb{R})$$

which respect the coboundary maps. Thus we obtain a natural map

$$t(M)\colon \mathrm{H}^*(M;\mathbb{R}) \to \mathrm{H}^*_{\mathrm{smooth}}(M;\mathbb{R}).$$

As we pointed out above, for $\star$ there is no difference between smooth and ordinary singular cohomology, i.e.

$$t(\star)\colon \mathrm{H}^*(\star;\mathbb{R}) \to \mathrm{H}^*_{\mathrm{smooth}}(\star;\mathbb{R})$$

is an isomorphism. Since the natural transformation is induced by the inclusion map it follows easily that the natural transformation is compatible with the connecting homomorphism in the Mayer-Vietoris sequence and that it is compatible with the map τ appearing in the limit property. The proposition now follows immediately from the Smooth Cohomology Theory Isomorphism Theorem 118.3. ■

Now we also want to relate smooth singular cohomology to de Rham cohomology. The key for doing so is the following definition and the subsequent proposition.

Definition.

(1) Given $x \in \triangle_n$ we define $\widetilde{\mathrm{T}}_x\triangle_n := \mathbb{R}^n$. Using this definition it makes sense to talk of smooth n-forms on $\triangle_n$.

(2) Given a smooth n-form α on $\triangle_n$ we define[1445]

$$\int_{\triangle_n} \alpha := \int_{x\in\triangle_n} \alpha_x(e_1,\ldots,e_n)\,d\lambda.$$

(3) Let M be a smooth manifold and let $f\colon \triangle_n \to M$ be a smooth map. Since $\triangle$ is regular closed, i.e. since it equals the closure of its interior, we obtain from the argument of Lemma 19.2 that it makes sense to consider the map $\mathrm{D}f_x\colon \mathbb{R}^n \to \mathrm{T}_{f(x)}M$ for all $x \in \triangle_n$.

(4) Given a smooth manifold M, given a smooth differential n-form ω on M and a smooth singular n-simplex $\sigma\colon \Delta^n \to M$ we use (1), (2) and (3) to define[1446]

$$\int_\sigma \omega \;:=\; (-1)^n \cdot \int_{\triangle_n} (\sigma \circ \Theta_n)^*(\omega).$$

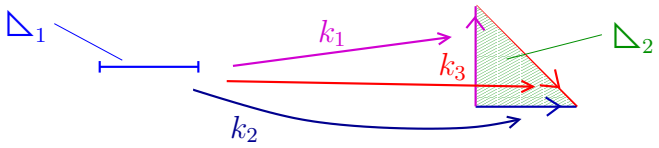
We extend this definition linearly to define the integral of the smooth differential n-form ω over a smooth singular n-chain $\sum_{i=1}^{k} a_i \circ \sigma_i$.

Proposition 118.7. (Stokes-for-Simplices Proposition) Let M be a smooth manifold, let ω be a smooth differential $(n-1)$-form on M and let $\sigma\colon \Delta^n \to M$ be a smooth singular n-simplex. Then[1447]

$$\int_\sigma d\omega \;=\; \int_{\partial\sigma} \omega.$$

All the hard work for the proof of the Stokes-for-Simplices Proposition 118.7 is done in the following lemma.

Lemma 118.8. For $i = 1, \ldots, n$ we consider the map



$$\begin{array}{rcl} k_i\colon \triangle_{n-1} & \to & \triangle_n \\ (x_1, \ldots, x_{n-1}) & \to & (x_1, \ldots, x_{i-1}, 0, x_i, \ldots, x_{n-1}). \end{array}$$

Furthermore we consider the map

$$\begin{array}{rcl} k_{n+1}\colon \triangle_{n-1} & \to & \triangle_n \\ (x_1, \ldots, x_{n-1}) & \to & (x_1, \ldots, x_{n-1}, 1 - x_1 - \cdots - x_{n-1}) \end{array}$$

Given any smooth $(n-1)$-form α on $\triangle_n$ we have

$$\int_{\triangle_n} d\alpha \;=\; \sum_{i=1}^{n} (-1)^i \cdot \int_{\triangle_{n-1}} k_i^*\alpha + (-1)^{n+1} \cdot \int_{\triangle_{n-1}} k_{n+1}^*\alpha.$$

Proof. Let α be a smooth $(n-1)$-form on $\triangle_n$ By the Alternating Forms-Basis Proposition **??** we can write

$$\alpha \;=\; \sum_{j=1}^{n} f_j \cdot dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^n$$

where $f_1, \ldots, f_n\colon \triangle_n \to \mathbb{R}$ are smooth functions. First let us calculate the differential of the n-form $d\alpha$.

[1445] The Lebesgue integral is defined since $\triangle_n$ is a compact subset of $\mathbb{R}^n$ and since the integrand is continuous.

[1446] Recall that on page 1581 we had equipped $\mathring{\Delta}^n$ with an orientation. The factor $(-1)^n$ is motivated by the fact that the restriction of the map $\Theta_n\colon \triangle_n \to \Delta^n$ to the interiors is orientation-preserving if and only if n is even.

[1447] Note that on the left we integrate a smooth differential n-form over a smooth singular n-simplex and that on the right we integrate a smooth $(n-1)$-form over a smooth singular $(n-1)$-chain.

Claim 1. For each $x \in \Delta_n$ we have

$$(d\alpha)_x(e_1, \ldots, e_n) \;=\; \sum_{i=1}^{n} (-1)^{i-1} \cdot \frac{\partial f_i}{\partial x_i}(x).$$

Proof. We performed the calculation already in the proof of Stokes' Theorem **??**. But there is no harm done in doing so again. So let us do so:

$$d\alpha \;\overset{\text{see definition on page ??}}{\downarrow}\; \sum_{j=1}^{n} df_j \cdot dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^n \;\overset{\text{1-Form-via-}dx^i\text{-Lemma ??}}{\downarrow}\; \sum_{j=1}^{n} \sum_{j=1}^{n} \frac{\partial f_j}{\partial x_j} \cdot dx^j \wedge dx^1 \wedge \cdots \wedge \widehat{dx^i} \wedge \cdots \wedge dx^n$$

$$= \sum_{j=1}^{n} (-1)^i \cdot \frac{\partial f_j}{\partial x_j} \cdot dx^1 \wedge \cdots \wedge dx^i \wedge \cdots \wedge dx^n$$

$$\uparrow \text{ follows from } dx^i \wedge dx^i = 0 \text{ and } dx^i \wedge dx^j = -dx^j \wedge dx^i$$

Thus for each $x \in \Delta_n$ we have

$$(d\alpha)_x(e_1, \ldots, e_n) \;=\; \sum_{i=1}^{n} (-1)^{i-1} \cdot \frac{\partial f_i}{\partial x_i}(x) \cdot \underbrace{(dx^1 \wedge \cdots \wedge dx^n)(e_1, \ldots, e_n)}_{=1} \;=\; \sum_{i=1}^{n} (-1)^{i-1} \cdot \frac{\partial f_i}{\partial x_i}(x).$$

⊞

We adopt the following notation: given $i \in \{1, \ldots, n\}$ and given $x \in \mathbb{R}^n$ we denote by $\varphi_i(x) \in \mathbb{R}^{i-1}$ the first $i-1$ coordinates and we denote by $\psi_i(x) \in \mathbb{R}^{n-i}$ the last $n-i$ coordinates. Furthermore we denote by $|x|$ the sum of the coordinates of x. Now we see that

$$\int_{\Delta_n} d\alpha \;=\; \int_{x \in \Delta_n} (d\alpha)_x(e_1, \ldots, e_n) \;=\; \sum_{i=1}^{n} (-1)^{i-1} \cdot \int_{x \in \Delta_n} \frac{\partial f_i}{\partial x_i}(x)\, d\lambda \;\overset{\text{Fubini Theorem ??}}{\downarrow}\; =$$

$$= \sum_{i=1}^{n} (-1)^{i-1} \cdot \int_{s \in \Delta_{n-1}} \underbrace{\int_{x_i=0}^{x_i=1-|s|} \frac{\partial f_i}{\partial x_i}(\varphi_i(s), x_i, \psi_i(s))\, dx_i}_{\substack{\text{can be calculated using the} \\ \text{Fundamental Theorem of Calculus}}} d\lambda$$

$$= \sum_{i=1}^{n} (-1)^{i-1} \cdot \int_{s \in \Delta_{n-1}} (f_i(\varphi_i(s), 1-|s|, \psi_i(s)) - f_i(\varphi_i(s), 0, \psi_i(s))\, d\lambda$$

$$= \sum_{i=1}^{n} (-1)^{i-1} \cdot \int_{s \in \Delta_{n-1}} \underbrace{f_i(\varphi_i(s), 0, \psi_i(s))}_{=k_i(s)}\, d\lambda + \sum_{i=1}^{n} (-1)^{i-1} \cdot \int_{s \in \Delta_{n-1}} (f_i(\varphi_i(s), 1-|s|, \psi_i(s))\, d\lambda.$$

It remains to recognize the terms. We will do so in the following two claims.

Claim 2. Given any $i \in \{1, \ldots, n\}$ we have

$$\int_{s \in \Delta_{n-1}} f_i(k_i(s))\, d\lambda \;=\; \int_{\Delta_{n-1}} k_i^* \alpha.$$

Proof. We calculate that

$$\begin{aligned}\int_{\Delta_{n-1}} k_i^*\alpha &= \int_{s\in\Delta_{n-1}} (k_i^*\alpha)_s(e_1,\dots,e_{n-1})\,d\lambda = \int_{s\in\Delta_{n-1}} \alpha_{k_i(s)}(k_{i*}(e_1),\dots,k_{i*}(e_{n-1}))\,d\lambda\\ &= \int_{s\in\Delta_{n-1}} \sum_{j=1}^{n} f_j(k_i(s))\cdot \underbrace{(dx^1\wedge\cdots\wedge\widehat{dx^j}\wedge\cdots\wedge dx^n)(e_1,\dots,\widehat{e_i},\dots,e_{n-1})}_{=\delta_{ij}\text{, where }\delta_{ij}\text{ denotes the Kronecker delta}}\,d\lambda\\ &= \int_{s\in\Delta_{n-1}} f_i(k_i(s))\,d\lambda.\end{aligned}$$

⊞

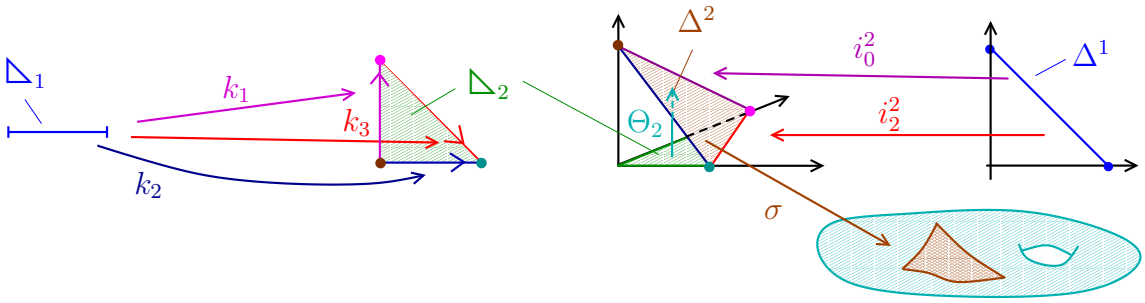
Claim 3. $\displaystyle\sum_{i=1}^{n}\int_{s\in\Delta_{n-1}} (-1)^{i-1}\cdot f_i(\varphi_i(s),1-|s|,\psi_i(s))\,d\lambda = (-1)^{n+1}\cdot\int_{\Delta_{n-1}} k_{n+1}^*\alpha.$

Proof. We calculate that

$$\begin{aligned}\int_{\Delta_{n-1}} k_{n+1}^*\alpha &= \int_{s\in\Delta_{n-1}} (k_{n+1}^*\alpha)_s(e_1,\dots,e_{n-1})\,d\lambda = \int_{s\in\Delta_{n-1}} \alpha_{k_{n+1}(s)}(k_{n+1,*}(e_1),\dots,k_{n+1,*}(e_{n-1}))\,d\lambda\\ &= \int_{s\in\Delta_{n-1}} \sum_{j=1}^{n} f_j(k_{n+1}(s))\cdot\underbrace{(dx^1\wedge\cdots\wedge\widehat{dx^j}\wedge\cdots\wedge dx^n)(e_1-e_n,\dots,e_{n-1}-e_n)}_{=(-1)^{n-j}}\,d\lambda\\ &= \sum_{j=1}^{n}\int_{s\in\Delta_{n-1}} (-1)^{n-j}\cdot f_j(k_{n+1}(s))\,d\lambda = \sum_{j=1}^{n}\int_{s\in\Delta_{n-1}} (-1)^{n-j}\cdot f_j\underbrace{(\varphi_n(s),1-|s|,\psi_n(s))}_{=k_{n+1}(s)}\,d\lambda\\ &= \sum_{j=1}^{n}\int_{s\in\Delta_{n-1}} (-1)^{n-j}\cdot f_j(\varphi_j(s),1-|s|,\psi_j(s))\,d\lambda.\end{aligned}$$

↑ follows from the Lebesgue Transformation Theorem ?? applied to the diffeomorphism that swaps the j-th and the n-th coordinate

This calculation of course implies the claim. ■



Proof of the Stokes-for-Simplices Proposition 118.7. Let M be a smooth manifold, let ω be a smooth differential $(n-1)$-form on M and let $\sigma\colon\Delta^n\to M$ be a smooth singular n-simplex. For $j\in\{0,\dots,n\}$ we consider as usual the map

$$\begin{aligned} i_j^n\colon\Delta^{n-1} &\to \Delta^n\\ (t_0,\dots,t_{n-1}) &\mapsto (t_0,\dots,t_{j-1},0,t_j,\dots,t_{n-1}).\end{aligned}$$

The proposition follows from the following calculation:

$$\begin{aligned}\int_\sigma d\omega &\overset{\text{by the definition on page 2600}}{=} (-1)^n\cdot\int_{\Delta_n}(\sigma\circ\Theta_n)^*(d\omega) \overset{\text{by the Differentials-on-Smooth Manifolds Proposition ??}}{=} (-1)^n\cdot\int_{\Delta_n} d((\sigma\circ\Theta_n)^*(\omega)) \overset{\text{Lemma 118.8 applied to }\alpha=(\sigma\circ\Theta_n)^*(d\omega)}{=}\\ &= \sum_{j=1}^{n}(-1)^{n+i}\cdot\int_{\Delta_{n-1}}\underbrace{k_j^*((\sigma\circ\Theta_n)^*(\omega))}_{(\sigma\circ\Theta_n\circ k_j)^*(\omega)} + (-1)^{2n+1}\cdot\int_{\Delta_{n-1}}\underbrace{k_{n+1}^*((\sigma\circ\Theta_n)^*(\omega))}_{(\sigma\circ\Theta_n\circ k_j)^*(\omega)}\\ &= (-1)^{n-1}\cdot\sum_{l=0}^{n}(-1)^l\cdot\int_{\Delta_{n-1}}(\sigma\circ i_l^n\circ\Theta_{n-1})^*(\omega) = (-1)^{n-1}\cdot\sum_{l=0}^{n}(-1)^l\cdot\int_{\sigma\circ i_l^n}\omega = \int_{\partial\sigma}\omega.\end{aligned}$$

↑ since $\Theta_n\circ k_j = i_{j+1}^{n-1}\circ\Theta_{n-1}\colon\Delta_{n-1}\to\Delta^n$; ↑ by the definition on page 2600; ↑ by definition of $\partial\sigma$ ■

118.4. **The isomorphism between singular and de Rham cohomology.** After the preparations in the previous sections we can now easily prove the theorem that we had been aiming for.

Theorem 118.9. (De Rham Theorem) There exists a natural isomorphism $u = u_M$ from de Rham cohomology to singular cohomology with real coefficients. In particular for any smooth manifold M and any $k \in \mathbb{N}_0$ we have a natural isomorphism

$$u_M \colon \mathrm{H}^k_{\mathrm{dR}}(M) \xrightarrow{\cong} \mathrm{H}^k(M;\mathbb{R})$$

which has the property that for any closed differential k-form ω and any smooth singular k-chain σ that is a cycle we have

$$\big\langle \underbrace{u_M([\omega])}_{\in \mathrm{H}^k(M;\mathbb{R})}, \underbrace{[\sigma]}_{\in \mathrm{H}_k(M;\mathbb{Z})} \big\rangle_M = \int_\sigma \omega.$$

(Here we stress, that according to the convention from page 2590 it is understood that the smooth manifolds have empty boundary.)

Remark. A rather different proof for Theorem 118.9 is given in [**War1983**, p. 205] and [**Ram2005**, Chapte 4.6]. More precisely, in [**War1983, Ram2005**] the equivalence of de Rham cohomology and real valued singular cohomology is proved by relating both to another type of cohomology theory, namely sheaf cohomology. We also refer to [**BoT1982**, Theorems 8.9 and 15.8], [**Dup1978**, Theorem 1.15], [**Lau2011**, Section 6.7.6] and [**Ful1995**, Section 15C] for other proofs.

Proof. We denote by s the natural isomorphism from real-valued singular cohomology to real-valued smooth singular cohomology that we had constructed in the proof of Proposition 118.6.

Now we construct a natural isomorphism t from de Rham cohomology to real-valued smooth singular cohomology. For any smooth manifold M and any $k \in \mathbb{N}_0$ we have, by the above discussion, a map

$$\begin{array}{rcl} \Omega^k(M) & \to & \mathrm{C}^k_{\mathrm{smooth}}(M;\mathbb{R}) \\ \omega & \mapsto & \begin{pmatrix} \mathrm{C}^{\mathrm{smooth}}_k(M) & \to & \mathbb{R} \\ \sigma & \mapsto & \int_\sigma \omega \end{pmatrix} \end{array}$$

Note that it follows basically immediately from the definitions that this map is natural in M. Next note that it is an immediate consequence of the Stokes-for-Simplices Proposition 118.7 that for given M all these maps together form a cochain map $\Omega^*(M) \to \mathrm{C}^*_{\mathrm{smooth}}(M;\mathbb{R})$.

Summarizing we see that we have constructed a natural map

$$t(M)\colon \mathrm{H}^*_{\mathrm{dR}}(M) \;\to\; \mathrm{H}^*_{\mathrm{smooth}}(M;\mathbb{R}).$$

Furthermore, in the special case of $M = \star$ the map

$$t(\star)\colon \mathrm{H}^*_{\mathrm{dR}}(\star) \;\to\; \mathrm{H}^*_{\mathrm{smooth}}(\star;\mathbb{R})$$

is easily seen to be an isomorphism. Once one has unraveled all the definitions it becomes apparent that this natural transformation is compatible with the connecting homomorphism in the Mayer-Vietoris sequence and that it is compatible with the map τ appearing in the limit property. Now we obtain from the Smooth Cohomology Theory Isomorphism Theorem 118.3 that t is a natural isomorphism from de Rham cohomology to real-valued smooth singular cohomology.

Finally we set $u := s^{-1} \circ t$. By the above u is a natural isomorphism from de Rham cohomology to singular cohomology with real coefficients. It follows easily from the definitions of s and t that for any closed differential k-form ω and any smooth singular k-chain σ that is a cycle we have

$$\langle \underbrace{u([\omega])}_{\in \mathrm{H}^k(M;\mathbb{R})}, \underbrace{[\sigma]}_{\in \mathrm{H}_k(M;\mathbb{Z})} \rangle_M \;=\; \int_\sigma \omega. \qquad \blacksquare$$

The following proposition summarizes a few useful properties of the natural isomorphism $u_M\colon \mathrm{H}^k_{\mathrm{dR}}(M) \to \mathrm{H}^k(M;\mathbb{R})$ from the above de Rham Theorem 118.9.

Proposition 118.10.

(1) Let M be a closed oriented connected n-dimensional smooth manifold. Furthermore let $\omega \in \Omega^n(M)$ be a smooth differential n-form.
   (a) We have $\langle u_M([\omega]), [M]\rangle_M \;=\; \int_M \omega$.
   (b) If $\int_M \omega = 1$, then $u_M([\omega]) = [M]^* \in \mathrm{H}^n(M;\mathbb{R})$ where $[M]^*$ denotes the dual fundamental class that we introduced on page 2451.

(2) Let $f\colon M \to N$ be a smooth map between closed oriented connected n-dimensional smooth manifolds and let ω be a smooth differential n-form on N with $\int_N \omega = 1$. Then

$$\int_M f^*\omega \;=\; \underbrace{\deg(f\colon M \to N)}_{\text{as defined on page 2222 or page 2379}}.$$

Proof.

(1) (a) Let M be a closed oriented connected n-dimensional smooth manifold and let $\omega \in \Omega^n(M)$ be a smooth differential n-form. As we explained in Algorithm 100.2, there exist smooth singular simplices $\varphi_1, \ldots, \varphi_k\colon \Delta^n \to M$ with the following properties:

- We have $\bigcup_{i=1}^{k} \varphi_i(\Delta^n) = M$.
- For any $i, j \in \{1, \ldots, k\}$ we have $\varphi_i(\Delta^n) \cap \varphi_j(\Delta^n) = \varphi_i(\partial\Delta^n) \cap \varphi_j(\partial\Delta^n)$.
- If for each $\in \{1, \ldots, k\}$ we set $\epsilon_i = +1$ if φ_i is orientation-preserving and $\epsilon_i = -1$ otherwise, then the singular chain $\sigma := \epsilon_1 \cdot \varphi_1 + \cdots + \epsilon_k \cdot \varphi_k$ is a singular cycle that represents the fundamental class $[M]$.

As above we denote by $\Theta_n\colon \triangle_n \to \Delta^n$ the inverse of the obvious projecton map. We calculate that

$$\int_M \omega \overset{\text{follows fairly easily from (i)– (ii) and our orientation conventions}}{=} \sum_{i=1}^{k}(-1)^n \cdot \epsilon_i \cdot \int_{\triangle_n} (\varphi_i \circ \Theta_n)^*(\omega) \overset{\text{see definition on page 2600}}{=} \int_\sigma \omega \overset{\text{by Theorem 118.9}}{=} \langle u_M([\omega]), [M]\rangle_M.$$

(b) This statement follows immediately from (a) and the definition of the dual fundamental class.

(2) Let $f\colon M \to N$ be a smooth map between closed oriented connected n-dimensional smooth manifolds and let ω be a smooth differential n-form on N with $\int_N \omega = 1$.

$$\begin{array}{lllll} \int_M f^*\omega & \overset{\text{by (1a)}}{=} \langle u_M(f^*([\omega])), [M]\rangle_M & \overset{\text{since } u \text{ are } \textit{natural} \text{ isomorphisms}}{=} \langle f^*(u_N([\omega])), [M]\rangle_M & \overset{\text{Lemma 109.6 (3)}}{=} \langle u_N([\omega]), f_*([M])\rangle_N & \\ & \overset{\text{by definition of } \deg(f)}{=} \deg(f) \cdot \langle u_N([\omega]), [N]\rangle_N & \overset{\text{by (1a)}}{=} \deg(f) \cdot \int_N \omega & \overset{\text{by choice of } \omega}{=} \deg(f). & \end{array}$$

■

Theorem 118.9 allows us to transport information from de Rham cohomology to real-valued singular cohomology and vice-versa. For example the many computational techniques that we had developed, e.g. cellular cohomology, for singular cohomology can now be used to calculate isomorphism types of de Rham cohomology groups. In particular we can easily prove the following corollary.

Corollary 118.11. If M is a closed, oriented connected, non-empty n-dimensional smooth manifold, then the map

$$\begin{array}{rcl} \mathrm{H}^n_{\mathrm{dR}}(M) & \to & \mathbb{R} \\ [\omega] & \mapsto & \int_M \omega \end{array}$$

is an isomorphism.

Proof. By the Top Dimension-de Rham-Integration Proposition **??** the map is well-defined and it is an epimorphism. On the other hand, by the Top-Cohomology Proposition 110.14 and Theorem 118.9 we know that $\mathrm{H}^n_{\mathrm{dR}}(M) \cong \mathbb{R}$, which implies that the map is an isomorphism. ■

118.5. **Realizing cohomology classes by maps to S^1.** We start out this section with the following definition.

Definition. Let G be a group, let Y be a topological space and let $y_0 \in Y$ be a point with an identification $\pi_1(Y, y_0) = G$. Given another topological space X and $x_0 \in X$ we say that a homomorphism $\varphi\colon \pi_1(X, x_0) \to G = \pi_1(Y, y_0)$ is realized by a map $g\colon X \to Y$ if $g(x_0) = y_0$ and if $g_* = \varphi$. If there is no danger of confusion we will drop the base points from the notation.

In the following we will mostly discuss the case $G = \mathbb{Z}$ and $Y = S^1$. Before we can continue we introduce the following conventions.

Convention.

(1) We use the diffeomorphism $\mathbb{R}/\mathbb{Z} \to S^1$ given by $[t] \mapsto \exp(2\pi i t)$ to make the identification $\mathbb{R}/\mathbb{Z} = S^1$.
(2) By Proposition 48.17 we have an isomorphism $\mathbb{Z} \to \pi_1(S^1, 1)$ given by sending 1 to the equivalence class of the loop $t \mapsto \exp(2\pi i t)$. We use this isomorphism to make the identification $\pi_1(\mathbb{R}/\mathbb{Z}, 0) = \pi_1(S^1, 1) = \mathbb{Z}$.
(3) Let X be a path-connected topological space and let $x_0 \in X$. As shown in the First Cohomology Proposition 110.17 we can use the Hurewicz homomorphism and the evaluation homomorphism to make the identifications $\mathrm{H}^1(X;\mathbb{Z}) = \mathrm{Hom}(\mathrm{H}_1(X);\mathbb{Z}) = \mathrm{Hom}(\pi_1(X, x_0), \mathbb{Z})$.

Now we can formulate the following question.

Question 118.12. Let X be a path-connected topological space that is "reasonable", e.g. that is a smooth manifold or a CW-complex. Let $x_0 \in X$ be a base point. Can every homomorphism $\varphi\colon \pi_1(X, x_0) \to \mathbb{Z} = \pi_1(S^1, 1)$ be realized by a map $(X, x_0) \to (S^1, 1)$?

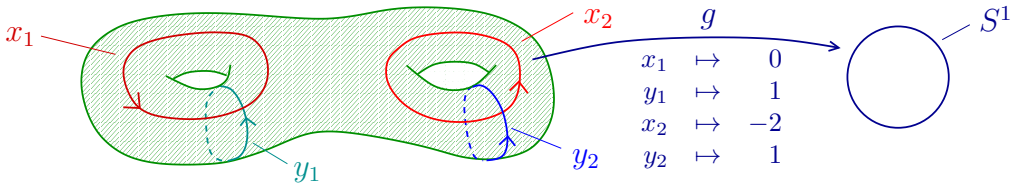
The following proposition gives an affirmative answer if X is a smooth manifold.

Proposition 118.13. (Maps-to-S^1 Proposition) Let M be a connected smooth manifold (here for once we allow M to have boundary) and let P be a base point.

(1) Every class $\phi \in \mathrm{H}^1(M;\mathbb{Z}) = \mathrm{Hom}(\pi_1(M, P), \mathbb{Z})$ can be realized by a smooth map $g\colon M \to S^1$ with $g(P) = 1$.
(2) We suppose that $\partial M = \varnothing$. If $f, g\colon M \to S^1$ are two smooth maps with $g(P) = 1$, such that $f_* = g_*\colon \pi_1(M, P) \to \pi_1(S^1, 1)$, then f and g are homotopic.
(3) Let $\phi \in \mathrm{H}^1(M;\mathbb{Z})$ and let $P \in \partial M$. If $f\colon \partial M \to S^1$ is a smooth map that realizes $\phi|_{\partial M}$, then there exists a smooth map $g\colon M \to S^1$ with $g|_{\partial M} = f$ that realizes ϕ.

Remark.

(1) Sometimes the following reformulation of the Maps-to-S^1 Proposition 118.13 is quite useful: Let M be a connected smooth manifold and let P be a base point. Given any $\phi \in \mathrm{H}^1(M;\mathbb{Z})$ there exists a smooth map $g\colon M \to S^1$ and a generator $\psi \in \mathrm{H}^1(S^1;\mathbb{Z})$ with $\phi = g^*(\psi)$.
(2) the Maps-to-S^1 Proposition 118.13 (2) can be viewed as a partial converse to the Homotopic Maps-De Rham Cohomology Proposition **??**.
(3) Later on, in the Maps-to-K(π, n)-Proposition 163.15 we will prove an analogue of the Maps-to-S^1 Proposition 118.13 for CW-complexes. This will allows in Proposition 163.20 to give a new proof of the Maps-to-S^1 Proposition 118.13.



Examples.

(1) We consider the torus $T = S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$ and we make the usual identification $\mathrm{H}_1(T;\mathbb{Z}) = \mathbb{Z}^2$. We consider the cohomology classes in $\mathrm{H}^1(T;\mathbb{Z}) = \mathrm{Hom}(\mathrm{H}_1(T), \mathbb{Z})$ that are given by

$$\begin{array}{rcl} \phi\colon \mathrm{H}_1(T;\mathbb{Z}) = \mathbb{Z}^2 & \to & \mathbb{Z} \\ (m, n) & \mapsto & m \end{array} \quad \text{and} \quad \begin{array}{rcl} \psi\colon \mathrm{H}_1(T;\mathbb{Z}) = \mathbb{Z}^2 & \to & \mathbb{Z} \\ (m, n) & \mapsto & n. \end{array}$$

These two cohomology classes are evidently realized by the projection $S^1 \times S^1 \to S^1$ onto the first, respectively the second factor. In Exercise 118.3 the goal will be to give an example of an explicit map $g\colon T \to S^1$ that realizes the homomorphism $\varphi\colon \mathrm{H}_1(T;\mathbb{Z}) = \mathbb{Z}^2 \to \mathbb{Z}$ given by $\varphi(m, n) = 6m + 4n$.

(2) In the figure below we consider the surface Σ of genus 2. As we saw on page 1781, the oriented curves x_1, y_1, x_2, y_2 represent a basis for $\mathrm{H}_1(\Sigma)$. We consider some random epimorphism $\phi\colon \mathrm{H}_1(\Sigma) \to \mathbb{Z}$, e.g. we could consider the epimorphism $\phi\colon \mathrm{H}_1(\Sigma) \to \mathbb{Z}$ that is given by $\phi(x_1) = 0$, $\phi(y_1) = 1$, $\phi(x_2) = -2$ and $\phi(y_2) = 1$. By the Maps-to-S^1 Proposition 118.13 we know that ϕ can be realized by some map $g\colon \Sigma \to S^1$. But can one "visualize" such a map? We will return to this question on page 2840.

We break the proof of the Maps-to-S^1 Proposition 118.13 into three parts.

Proof of the Maps-to-S^1 Proposition 118.13 (1). Let M be a connected smooth manifold. We first assume that M has no boundary. We start out with the following definition. Let ω be a smooth differential 1-form on M and let $\gamma\colon [a,b] \to M$ be a piecewise smooth path. We pick $a = t_0 < t_1 < \cdots < t_n = b$ such that the restriction of γ to each subinterval $[t_i, t_{i+1}]$ is smooth. We define

$$\int\limits_{[a,b]} \gamma^*\omega \;=\; \sum_{i=0}^{n-1} \int\limits_{[t_i,t_{i+1}]} \gamma^*\omega.$$

It follows immediately from the Form Integration Proposition **??** (6) that this definition does not depend on the choice of the subdivision.

After this preparation we start with the actual proof of the proposition. We fix a base point $P \in M$. Furthermore let $\phi \in \mathrm{H}^1(M;\mathbb{Z}) = \mathrm{Hom}(\pi_1(M,P),\mathbb{Z})$. We denote by u the natural isomorphism from de Rham cohomology to singular cohomology with real coefficients from Theorem 118.9. We pick a smooth closed differential 1-form ω on M with $u([\omega]) = \phi$.

Claim. Let $\delta\colon [0,1] \to M$ be a piecewise smooth loop in P. Then

$$\int\limits_{[0,1]} \delta^*\omega \;=\; \phi\Big(\underbrace{[\delta]}_{\in \pi_1(M,P)}\Big) \;\in\; \mathbb{R}.$$

Proof. Let $\delta\colon [0,1] \to M$ be a piecewise smooth loop in P. One can show easily that after possibly performing an orientation-preserving reparametrization we can write $\delta = \delta_1 * \cdots * \delta_k$ as a product of smooth paths $\delta_i\colon [0,1] \to M$, $i = 1, \ldots, k$. As in the definition of the Hurewicz homomorphism we use the map $t \mapsto (1-t, t)$ to make the identification $[0,1] = \Delta^1$. Using this identification we view each δ_i also as a smooth 1-simplex. In particular we have $\delta_1 + \cdots + \delta_k \in \mathrm{C}_1^{\mathrm{smooth}}(M)$. Then

$$\int\limits_{[0,1]} \delta^*\omega \;\underset{\text{by the definitions and by the Form Integration Proposition ?? (1) and (6)}}{=}\; \int\limits_{\delta_1+\cdots+\delta_k} \omega \;\underset{\text{by Theorem 118.9 since } u([\omega]) = \phi}{=}\; \langle \phi, [\delta_1 + \cdots + \delta_k] \rangle \;\underset{\text{via the identification } \mathrm{H}^1(M;\mathbb{Z}) = \mathrm{Hom}(\pi_1(M,P),\mathbb{Z})}{=}\; \phi([\delta]).$$

⊞

We define

$$\begin{array}{rcl} g\colon M & \to & S^1 = \mathbb{R}/\mathbb{Z} \\ Q & \mapsto & \left[\int\limits_{[0,1]} \gamma^*\omega\right] \quad \text{where } \gamma \text{ is a smooth path}^{1448} \text{ from } P \text{ to } Q. \end{array}$$

We claim that the map g has the required properties. It remains to prove the following four statements:

(1) The map g is well-defined.
(2) We have $g(P) = [0] \in \mathbb{R}/\mathbb{Z}$.
(3) The map g is smooth.
(4) We have $g_* = \phi\colon \pi_1(M,P) \to \pi_1(S^1,1) = \mathbb{Z}$.

Now we turn to the proofs of the statements.

(1) Let Q in M. Suppose we are given two piecewise smooth paths β and γ from the base point P to Q. (See the left of the figure below for an illustration.) Then

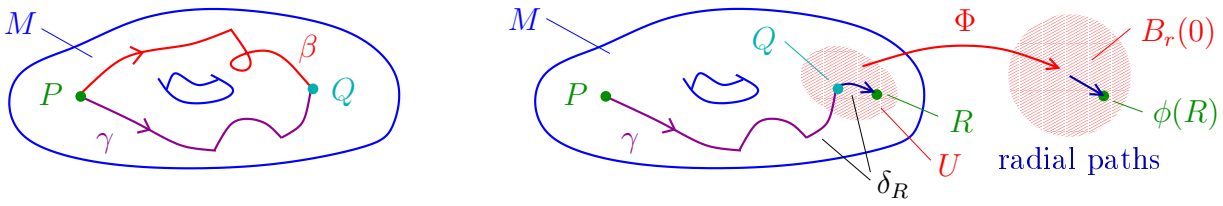
$$\int\limits_{[0,1]} \beta^*\omega - \int\limits_{[0,1]} \gamma^*\omega \quad \underset{\text{follows from the definitions and the Form Integration Proposition ?? (1) and (6)}}{=} \quad \int\limits_{[0,1]} (\beta * \overline{\gamma})^*\omega \quad \underset{\text{by the above claim, since } \beta * \overline{\gamma} \text{ is a piecewise smooth loop}}{=} \quad \phi([\beta * \overline{\gamma}]) \ \in \ \mathbb{Z}.$$

This shows that g is indeed well-defined.

(2) We determine $g(P)$ by taking the constant path from P to P. It follows immediately from the definition of g that $g(P) = [0] \in \mathbb{R}/\mathbb{Z}$.

(3) Let $Q \in M$. We need to show that g is smooth in an open neighborhood of Q. We pick a path γ from P to Q. We pick a chart $\Phi\colon U \to B_r(0)$ around Q with $\Phi(Q) = 0$. Given a point $R \in U$ we denote by δ_R the piecewise smooth path that is given by the concatenation of the following two paths:
   (a) the path γ from P to Q,
   (b) the "radial path" from Q to R that corresponds, under the diffeomorphism Φ, to the radial path from 0 to $\Phi(R) \in B_r(0)$.

   (See the right of the figure below for an illustration.) Using these paths δ_R it is now relatively straightforward to show that g is smooth in U. We leave the verification of the details to the reader.



(4) Suppose we are given an element in $\pi_1(M,P)$. By the Smooth Path-Connectivity Proposition 19.29 (1) we can represent this element by a smooth loop $\delta\colon [0,1] \to M$. We have the following equality:

$$\begin{array}{rl} & \overset{\text{by the Fundamental Group-via-Actions Theorem 48.16}}{\downarrow} \\ g_*([\delta]) & = \text{endpoint of the lift of } g\circ\delta\colon [0,1] \to \mathbb{R} \text{ to the universal covering } \mathbb{R} \text{ of } \mathbb{R}/\mathbb{Z} \\ & = \text{endpoint of the lift of the path } t \mapsto \left[\int\limits_{[0,t]} \delta^*\omega\right] \text{ to the universal covering } \mathbb{R} \\ & = \text{endpoint of the path } t \mapsto \int\limits_{[0,t]} \delta^*\omega \ = \ \text{the point } \int\limits_{[0,1]} \delta^*\omega \ = \ \phi([\delta]). \\ & \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \underset{\text{by the above claim}}{\uparrow} \end{array}$$

[1448] By the Smooth Path-Connectivity Proposition 19.29 (2) any two points on a connected smooth manifold.

We have thus shown that $g_* = \phi\colon \pi_1(M,P) \to \pi_1(S^1,1) = \mathbb{Z}$.

This concludes the proof of the theorem in the case that M has empty boundary.

Finally let M be a smooth manifold with non-empty boundary. To deal with this case we consider $W := M \cup (\partial M \times [0,1))$ where we make the obvious identification of $P = P \times \{0\}$ for $P \in \partial M$. Using the Smooth Collar Neighborhood Theorem 28.3 one can easily verify that W is a smooth manifold such that M is a submanifold and such that W has no boundary. Evidently M is a deformation retract of W. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3 (2) that the induced map $i_*\colon \pi_1(M,P) \to \pi_1(W,P)$ is an isomorphism. Now let $\phi \in \operatorname{Hom}(\pi_1(M,P),\mathbb{Z})$. By the previously considered case we can realize $\phi \circ (i_*)^{-1}\colon \pi_1(W,P) \to \mathbb{Z}$ by a smooth map $g\colon W \to S^1$. The restriction of g to M has all the desired properties. ■

Proof of the Maps-to-S^1 Proposition 118.13 (2). We suppose that $\partial M = \varnothing$. In the following let $f, g\colon M \to S^1 = \mathbb{R}/\mathbb{Z}$ be two smooth maps with $g(P) = 1$, such that we have the equality $f_* = g_*\colon \pi_1(M,P) \to \pi_1(S^1,1)$. We need to show that f and g are homotopic. Let ω be the standard closed differential 1-form on $S^1 = \mathbb{R}/\mathbb{Z}$. We set $\alpha := f^*\omega$ and $\beta := g^*\omega$.

Claim. There exists a closed differential 1-form ψ on $M \times [0,1]$ such that the restriction to $M \times \{0\} = M$ equals α and such that the restriction to $M \times \{1\} = M$ equals β.

Proof. First note that it follows from the fact that $f_* = g_*$ and from the natural isomorphisms $\mathrm{H}^1_{\mathrm{dR}}(M) = \mathrm{H}^1(M;\mathbb{R}) = \operatorname{Hom}(\pi_1(M,P),\mathbb{R})$ that $[\alpha] = f^*([\omega]) = g^*([\omega]) = [\beta] \in \mathrm{H}^1_{\mathrm{dR}}(M)$. By definition this means that there exists a 0-form φ on M with $d\varphi = \alpha - \beta$. Next let $p\colon M \times [0,1] \to M$ and $q\colon M \times [0,1] \to [0,1]$ be the natural projection. Furthermore let $h\colon [0,1] \to [0,1]$ be a map that is zero close to 0 and one close to 1. On $M \times [0,1]$ we consider the 1-form that given by $\psi := p^*\alpha - d(q^*h \cdot \varphi)$. It follows from the Differentials-on-Smooth Manifolds Proposition **??** (2) that ψ is closed. We calculate that

$$\psi = p^*\alpha - d(q^*h \cdot \varphi) \underset{\text{by Proposition ?? (1)}}{=} p^*\alpha - (q^*(dh) \cdot \varphi + q^*h \cdot d\varphi) = p^*\alpha - \overbrace{q^*(dh)}^{=0 \text{ on } M\times\{0\} \text{ and } M\times\{1\}} \cdot \varphi - \underbrace{q^*h \cdot d\varphi}_{= 0 \text{ on } M\times\{0\} \text{ and } = p^*\alpha - p^*\beta \text{ on } M\times\{1\}}.$$

⊞

Next note that, as in the proof of Statement (1), the closed 1-form ψ gives rise to a map $F\colon M \times [0,1] \to S^1$. It follows fairly easily from the definitions that $F_0 = f$ and $F_1 = g$. We leave it to the reader to fill in the details. ■

Proof of the Maps-to-S^1 Proposition 118.13 (3). Let $\phi \in \mathrm{H}^1(M;\mathbb{Z})$, let $P \in \partial M$ and let $f\colon \partial M \to S^1$ be a smooth map that realizes $\phi|_{\partial M}$. By the Smooth Collar Neighborhood Theorem 28.3 we can pick a collar neighborhood $[0,1] \times \partial M$. We set

$W := M \setminus ([0,1) \times \partial M)$ and we equip it with the base point $(P,1)$. By the Basics-of-Collars Lemma 28.4 (1) we know that W is an n-dimensional smooth manifold with $\partial W = \{1\} \times M$. By the Maps-to-$S^1$ Proposition 118.13 (1) there exists a smooth map $h\colon W \to S^1$ which realizes $\phi|_W$. It is now straightforward to see that under the obvious isomorphism $\{0\} \times M \to \{1\} \times M$ the maps $f_*\colon \mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(S^1;\mathbb{Z})$ and $h_*\colon \mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(S^1;\mathbb{Z})$ agree. At this point we can conclude from the Maps-to-S^1 Proposition 118.13 (2) that there exists a smooth map $F\colon [0,1] \times \partial M \to S^1$ such that $F_0 = f$ and $F_1 = h|_{\{1\}\times M}$.

Note that by definition of a collar neighborhood and by the Basics-of-Collars Lemma 28.4 we know that $[0,1] \times \partial M$ and W are closed subsets of M. Thus we obtain from the Pasting Proposition 2.6 (2) that the two maps F and g combine to a continuous map $h\colon M \to S^1$.

Since h is smooth on $[0,1] \times \partial M$ we obtain from the Whitney Approximation Theorem 29.1 that h is homotopic rel $\{0\} \times \partial M$ to a smooth map $g\colon M \to S^1$. This map now has all the desired properties. ■

Of course one can ask many variations on Question 118.12. Since arbitrary topological spaces can be quite weird we restrict ourselves in the following questions to CW-complexes.

Question 118.14. Let X be a connected CW-complex.

(1) Let $g \geq 1$ and let Σ_g be the surface of genus $g \geq 1$. Can every homomorphism $\pi_1(X) \to \pi_1(\Sigma_g)$ be realized by a map $X \to \Sigma_g$?

(2) Can every homomorphism $\pi_1(X) \to \pi_1\Big(\bigvee_{i=1}^{k} S^1\Big) = \langle x_1, \ldots, x_k \rangle$ be realized by a map $X \to \bigvee_{i=1}^{k} S^1$?

(3) Can every homomorphism $\pi_1(X) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}\mathrm{P}^2)$ be realized by a map $X \to \mathbb{R}\mathrm{P}^2$?

118.6. **Rewriting products $M \times S^1$.** the Maps-to-S^1 Proposition 118.13 (1) has many consequences. For example in the Codimension-One Submanifold Existence Proposition 130.4 we will use it to show that for a given compact orientable n-dimensional smooth manifold M any class in $\mathrm{H}_{n-1}(M;\mathbb{Z})$ can be represented by a submanifold. In this section we will give a different application, namely we will see that in many situations one can find interesting ways to rewrite a product $M \times S^1$ where M is a closed connected smooth manifold.
To formulate that application it is convenient to recall the following definition from page 467.

Definition. Let X be a topological space and let $f\colon X \to X$ be a map. We refer to

$$\mathrm{Tor}(X,f) \;:=\; (X \times [0,1])/\!\sim \qquad \text{where } (x,0) \sim (f(x),1) \text{ for all } x \in X,$$

as the mapping torus of (X,f). We refer to the map

$$\begin{array}{rccc} q\colon \mathrm{Tor}(X,f) = (X \times [0,1])/(x,0) \sim (f(x),1) & \to & S^1 \\ [(x,t)] & \mapsto & \exp(2\pi i t) \end{array}$$

as the natural projection onto S^1.

Throughout this section we also use the following notation.

Notation. We denote by $\Theta\colon \mathrm{H}_1(S^1) \to \mathbb{Z}$ the isomorphism given by $\Theta([S^1]) = 1$.

Now we can state the main result of this section.

Proposition 118.15. Let M be a closed connected manifold and let $\phi\colon \mathrm{H}_1(M\times S^1;\mathbb{Z})\to\mathbb{Z}$ be an epimorphism. We set $k = k(\phi) := \phi([\{*\}\times S^1])$. If $k\neq 0$, then there exists a $|k|$-fold covering $p\colon \widetilde{M}\to M$ and a deck transformation $f\colon \widetilde{M}\to\widetilde{M}$ together with a diffeomorphism[1449] $\Xi\colon \mathrm{Tor}(\widetilde{M},f)\to M\times S^1$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_1(\mathrm{Tor}(\widetilde{M},f);\mathbb{Z}) & \xrightarrow{\quad\Xi_*\quad} & \mathrm{H}_1(M\times S^1;\mathbb{Z}) \\ & {\scriptstyle \Theta\circ q_*}\searrow \quad \swarrow{\scriptstyle \phi} & \\ & \mathbb{Z}. & \end{array}$$

Here the diagonal map to the left is induced by the natural projection.

Remark.

(1) Proposition 118.15 can be viewed as a "manifold analogue" of the group-theoretic statement of Exercise 50.19.

(2) One mathematician once called products "slippery". Indeed, as we will see in the examples below, Proposition 118.15 shows that many products have alternative descriptions.

Examples.

(1) Let M be a closed connected non-empty smooth manifold and let $\psi\colon \mathrm{H}_1(M;\mathbb{Z})\to\mathbb{Z}$ be a homomorphism. We apply Proposition 118.15 to the epimorphism

$$\begin{array}{rcl} \phi\colon \mathrm{H}_1(M\times S^1;\mathbb{Z}) = \mathrm{H}_1(M;\mathbb{Z})\oplus \mathrm{H}_1(S^1;\mathbb{Z}) & \to & \mathbb{Z} \\ (\sigma, n\cdot[S^1]) & \mapsto & \psi(\sigma)+n. \end{array}$$

Note that we have $k = k(\phi) = 1$. This implies that the map $p\colon \widetilde{M}\to M$ is a covering of degree 1. By the Covering Uniqueness Theorem 61.9 we can assume that $\widetilde{M} = M$ and that $p = \mathrm{id}$. Note that the only deck transformation of the 1-fold covering $\mathrm{id}\colon M\to M$ is the identity. Thus we obtain from Proposition 118.15 that there exists a diffeomorphism $\Xi\colon M\times S^1\to M\times S^1$ such that the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}_1(M\times S^1;\mathbb{Z}) & \xrightarrow{\quad\Xi_*\quad} & \mathrm{H}_1(M\times S^1;\mathbb{Z}) \\ & {\scriptstyle \Theta\circ q_*}\searrow \quad \swarrow{\scriptstyle \phi} & \\ & \mathbb{Z}, & \end{array}$$

where $q\colon M\times S^1\to S^1$ denotes the natural projection. Note that if $\psi\colon \mathrm{H}_1(M;\mathbb{Z})\to\mathbb{Z}$ is non-zero, then Ξ_* is not the identity. Summarizing, we have now shown that if $\mathrm{H}^1(M;\mathbb{Z}) = \mathrm{Hom}(\mathrm{H}_1(M;\mathbb{Z}),\mathbb{Z})\neq 0$, then $M\times S^1$ can be decomposed as a product in more than one way.

(2) Let Σ be the surface of some genus $g\in\mathbb{N}_{\geq 2}$ and let $\phi\colon \mathrm{H}_1(\Sigma\times S^1;\mathbb{Z})\to\mathbb{Z}$ be an epimorphism such that $k = k(\phi)\neq 0$. It follows from Proposition 118.15, together with the Subgroups-of-Surface Groups Proposition 64.6 (1) or alternatively with Lemma 87.9, that $\Sigma\times S^1$ is diffeomorphic to a mapping torus of the form $\mathrm{Tor}(\widetilde{\Sigma},f)$ where $\widetilde{\Sigma}$ is a surface of genus $|k|\cdot(g-1)+1$. In particular we obtain the

[1449] By the Manifold-Mapping Torus Lemma 16.25 the mapping torus $\mathrm{Tor}(\widetilde{M},f)$ naturally has the structure of a smooth manifold.

slightly mind boggling statement that the product $\Sigma \times S^1$ can also be viewed as a mapping torus of a self-diffeomorphism of a surface of arbitrarily high genus.

Proof. First we pick points $* \in M$ and $* \in S^1$ and we denote by $j_1 \colon M \xrightarrow{x \mapsto (x,*)} M \times S^1$ and $j_2 \colon S^1 \xrightarrow{z \mapsto (*,z)} M \times S^1$ the corresponding inclusions. Note that by the Maps-to-S^1 Proposition 118.13 (1) there exists a smooth map $g \colon M \to S^1$ such that the map $\mathrm{H}_1(M) \xrightarrow{g_*} \mathrm{H}_1(S^1) \xrightarrow{\Theta} \mathbb{Z}$ equals $\phi \circ j_{1*} \colon \mathrm{H}_1(M) \to \mathbb{Z}$. Now let us consider the following pullback diagram:

$$\begin{array}{ccc} \widetilde{M} := \{(x,z) \in M \times S^1 \mid g(x) = z^k\} & \xrightarrow{(x,z) \mapsto z} & S^1 \\ \Big\downarrow{\scriptstyle (x,z) \mapsto x} & & \Big\downarrow{\scriptstyle z \mapsto z^k} \\ M & \xrightarrow{\qquad g \qquad} & S^1. \end{array}$$

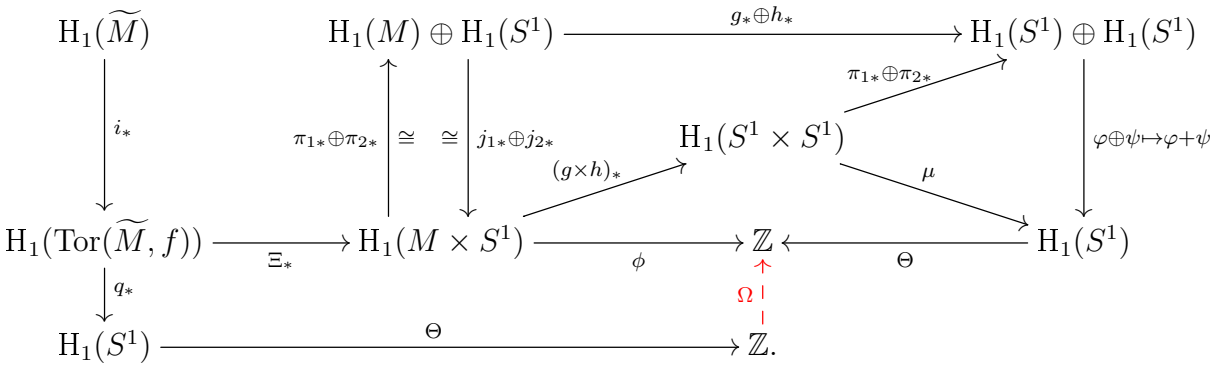
By the Topological-Pullback Lemma 56.16 we know that $p \colon \widetilde{M} \to M$ is a k-fold covering. The map

$$\begin{array}{rcl} f \colon \widetilde{M} & \to & \widetilde{M} \\ (x,z) & \mapsto & (x, \exp(-2\pi\,\mathrm{i}/k) \cdot z) \end{array}$$

is evidently a deck transformation. Next we consider the following diagram:

$$\begin{array}{ccc} \widetilde{M} \times S^1 & \xrightarrow{((x,z),w) \mapsto ((x,z), z^{-1} \cdot w)} & \widetilde{M} \times S^1 \\ \Big\downarrow{\scriptstyle ((x,z),\exp(2\pi\,\mathrm{i}\,t)) \mapsto [((x,z), k \cdot t \bmod \mathbb{Z})]} & & \Big\downarrow{\scriptstyle ((x,z),w) \mapsto (x,w)} \\ \mathrm{Tor}(\widetilde{M}, f) & \xrightarrow[\Xi]{[((x,z),t)] \mapsto (x, z^{-1} \cdot \exp(2\pi\,\mathrm{i}\,t/k))} & M \times S^1. \end{array}$$

We make the following observations:



(1) One can easily verify that the bottom map is in fact well-defined and that the diagram commutes.
(2) It is pretty clear that the top map is a diffeomorphism.[1450]
(3) It is straightforward to show that the vertical maps are local diffeomorphisms and they are degree k coverings.

It follows from the above together with Exercise 49.4 that the bottom map is also a diffeomorphism. It remains to prove the following claim.

Claim. We have $\phi \circ \Xi_* = \Theta \circ q_* \colon \mathrm{H}_1(\mathrm{Tor}(\widetilde{M}, f)) \to \mathbb{Z}$.

[1450] The reader might note that the top map is the restriction of the map $(M \times S^1) \times S^1 \to (M \times S^1) \times S^1$ given by the same formula, which is clearly a diffeomorphism, to the submanifold $\widetilde{M} \times S^1$ of $(M \times S^1) \times S^1$.

Proof. We consider the following diagram:

We make the following clarifications and observations:

(1) The map $i\colon \widetilde{M} \to \mathrm{Tor}(\widetilde{M}, f))$ is the natural inclusion given by $x \mapsto [(x, 0)]$.
(2) The map $\mu\colon S^1 \times S^1 \to S^1$ is the multiplication map.
(3) In both settings we denote by π_1 and π_2 the projection onto the first respectively second factor.
(4) The map $h\colon S^1 \to S^1$ is given by $z \mapsto z^k$. Note that by Lemma 76.10 we know that $h_*\colon \mathrm{H}_1(S^1) \to \mathrm{H}_1(S^1)$ is given by multiplication by k.
(5) It follows from Exercise 84.5, or alternatively from the discussion on page 2499, that the vertical maps in the middle are isomorphisms and inverses of one another.
(6) The upper left triangle commutes by the functoriality of homology groups.
(7) The triangle to the right commutes by Exercise 84.4.
(8) The big rectangle to the right commutes by the choice of g and h.
(9) It follows from (5), (6), (7) and (8) that the triangle at the bottom commutes.
(10) Recall that any point $(x, z) \in \widetilde{M}$ satisfies by definition $g(x) = z^k$. It now follows immediately that the map $(g \times h) \circ \mu \circ \Xi \circ i\colon \widetilde{M} \to S^1$ is the constant map.
(11) It follows from (9) and (10) that $\phi \circ \Xi_* \circ i_*\colon \mathrm{H}_1(\widetilde{M}) \to \mathbb{Z}$ is the zero map.
(12) By the Mapping Torus-Homology Lemma 78.22 we know that the vertical sequence to the left is exact.
(13) It follows from (10) and (11) that the vertical map Ω exists.
(14) We pick $(x, z) \in \widetilde{M}$. We use the homeomorphism from the Mapping Torus-of-Homeomorphism Lemma 16.28 to make the identification $\mathrm{Tor}(\widetilde{M}, f) = (\widetilde{M} \times \mathbb{R})/(w, t) \sim (f(w), t + 1)$. Now we consider the singular 1-cycle

$$\begin{array}{rcl} \sigma\colon \Delta^1 & \to & \mathrm{Tor}(\widetilde{M}, f) = (\widetilde{M} \times \mathbb{R})/(w, t) \sim (f(w), t + 1) \\ (1 - t, t) & \mapsto & [((x, z), kt)]. \end{array}$$

It follows immediately from the definitions that $(\phi \circ \Xi_*)([\sigma]) = k$ and $(\Theta \circ q_*)([\sigma]) = k$. Thus we have $\Omega(k) = k$. Since $k \neq 0$ we see that $\Omega = \mathrm{id}$. ∎

118.7. **The wedge product of differential forms** (∗). For a real vector space V we introduced in the Wedge Product the Wedge Product Proposition **??** the bilinear wedge

product

$$\wedge^k V^* \times \wedge^l V^* \ \to \ \wedge^{k+l} V^*.$$

Given a smooth manifold M we can define this wedge product for each tangent space $V = \mathrm{T}_P M$. As we saw in Lemma **??** we have a bilinear map

$$\wedge\colon \Omega^k(M) \times \Omega^l(M) \ \to \ \Omega^{k+l}(M).$$

Let M be a smooth manifold. We recall that in Proposition **??** we saw that the map

$$\begin{array}{rcl} \wedge\colon \mathrm{H}^k_{\mathrm{dR}}(M) \times \mathrm{H}^l_{\mathrm{dR}}(M) & \to & \mathrm{H}^{k+l}_{\mathrm{dR}}(M) \\ ([\omega],[\sigma]) & \mapsto & [\omega] \wedge [\sigma] := [\omega \wedge \sigma] \end{array}$$

is well-defined and that it has many nice properties.
At this point it is helpful to introduce the following definition.

Definition.

(1) A graded ring is a ring[1451] R together with a direct sum decomposition[1452] $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ into subgroups such that for any $m, n \in \mathbb{N}_0$ the multiplication map restricts to a map

$$R_m \times R_n \ \to \ R_{m+n}.$$

(2) A graded ring $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ such that for any two homogeneous elements a and b the equality $a \cdot b = (-1)^{\deg(a) \cdot \deg(b)} \cdot b \cdot a$ holds is called a superalgebra.[1453]

(3) Let $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ and $S = \bigoplus_{n \in \mathbb{N}_0} S_n$ be two graded rings. A morphism between the two graded rings is a ring homomorphism $\varphi\colon R \to S$ such that for any $n \in \mathbb{N}_0$ we have $\varphi(R_n) \subset S_n$.

(4) We define the category $\mathcal{GrRing}$ of graded rings to be the category where the objects are graded rings and the morphisms are morphisms of graded rings. Similarly we define the category of graded superalgebras.

Example. We consider the polynomial ring $R = \mathbb{Q}[x]$. We can view this ring as a graded ring by defining $R_n := \mathbb{Q} \cdot x^n$ for $n \in \mathbb{N}_0$.

Recall that for a given smooth manifold M we write

$$\mathrm{H}^*_{\mathrm{dR}}(M) \ = \ \bigoplus_{i=0}^{\infty} \mathrm{H}^i_{\mathrm{dR}}(M).$$

We consider the following map

$$\begin{array}{rcl} \wedge\colon \mathrm{H}^*_{\mathrm{dR}}(M) \times \mathrm{H}^*_{\mathrm{dR}}(M) & \to & \mathrm{H}^*_{\mathrm{dR}}(M) \\ \left(\sum_{i=0}^{\infty} x_i, \sum_{i=0}^{\infty} y_i\right) & \mapsto & \sum_{i,j=0}^{\infty} x_i \wedge y_j. \end{array}$$

where it is understood that each x_i and y_i is homogeneous of degree i.

[1451] Here we mean by a ring an abelian group together with a multiplicative structure which is associative, distributive and that admits a multiplicatively neutral element. We do not demand that a ring is commutative.

[1452] In particular, R viewed as an abelian group is $\mathbb{N}_0$-graded.

[1453] The word "algebra" in our context is justified by the fact that any ring is a $\mathbb{Z}$-algebra. We could also have referred to such an object as a superring, but this terminology seems to be uncommon.

The following proposition summarizes the key features of the wedge product on de Rham cohomology.

Proposition 118.16. The maps

$$\begin{array}{rcl} M & \mapsto & (\mathrm{H}^*_{\mathrm{dR}}(M), \wedge) \\ (f\colon M \to N) & \mapsto & (f^*\colon \mathrm{H}^*_{\mathrm{dR}}(N) \to \mathrm{H}^*_{\mathrm{dR}}(M)) \end{array}$$

define a contravariant functor from the category of smooth manifolds to the category of graded superalgebras.

Proof.

(1) First note that it follows almost immediately from Proposition **??** that for a given smooth manifold M the wedge product turns $\mathrm{H}^*_{\mathrm{dR}}(M)$ into a graded superalgebra. It follows immediately from the definitions that the multiplicatively neutral element in de Rham cohomology is hereby the 0-dimensional cohomology class that is represented by the constant function $f\colon M \to \mathbb{R}$, $x \mapsto 1$.

(2) If $f\colon M \to N$ is a smooth map between smooth manifolds, then it follows immediately from the definitions that for any choice of $\omega \in \Omega^k(N)$ and $\sigma \in \Omega^l(N)$ the following equality holds:

$$(f^*\omega \wedge f^*\sigma) \;=\; f^*(\omega \wedge \sigma).$$

Therefore the smooth map f induces a morphism $f^*\colon \mathrm{H}^*_{\mathrm{dR}}(N) \to \mathrm{H}^*_{\mathrm{dR}}(M)$ of graded rings. ∎

Example. We consider the differential 1-forms dx and dy on $\mathbb{R}^2$ which are given by[1454] $dx(v,w) = v$ and $dy(v,w) = w$. Furthermore we identify the 2-torus T with the quotient space $\mathbb{R}^2/\mathbb{Z}^2$ and we denote the projection $\mathbb{R}^2 \to T = \mathbb{R}^2/\mathbb{Z}^2$ by p. It is straightforward to see that dx and dy induce differential 1-forms on T.[1455] We denote these also by dx and dy.[1456] The 1-forms dx and dy are closed, i.e. $d(dx) = d(dy) = 0$.[1457] Thus they define cohomology classes $[dx], [dy] \in \mathrm{H}^1_{\mathrm{dR}}(T)$. A straightforward calculation, see e.g. [**Frie2016a**, p. 248], shows that if we integrate the 2-form $dx \wedge dy$ on T with the standard orientation, then we obtain 1. It follows from the Top Dimension-de Rham-Integration Proposition **??** that $[dx \wedge dy] = [dx] \wedge [dy]$ is a non-trivial element in $\mathrm{H}^2_{\mathrm{dR}}(T)$.

From the fact that $\mathrm{H}^*_{\mathrm{dR}}(T)$ is a superalgebra we know that

$$[dx] \wedge [dy] \;=\; (-1)^{1\cdot 1} \cdot [dy] \wedge [dx] \;=\; -[dy] \wedge [dx].$$

Since this wedge product is non-zero we see that $(\mathrm{H}^*_{\mathrm{dR}}(T), \wedge)$ is a non-commutative ring.

This discovery of a ring structure on de Rham cohomology raises the question whether one can also define such a ring structure using singular cohomology and whether such a ring structure exists on singular cohomology for more general spaces. We will answer these questions in Chapter 113.

[1454] As always we identify $\mathrm{T}_P\mathbb{R}^2$ with $\mathbb{R}^2$.

[1455] Details are given in [**Frie2016a**, p. 248].

[1456] More precisely, we showed that there exists a unique 1-form dx on T such that for each point $P \in \mathbb{R}^2$ and $v \in \mathrm{T}_P\mathbb{R}^2$ we have $dx_P(v) = dx_{p(P)}(p_*(v))$. Of course the same statement also holds for dy.

[1457] This is clear for dx and dy viewed as differential 1-forms on $\mathbb{R}^2$. But the projection $p\colon \mathbb{R}^2 \to T = \mathbb{R}^2/\mathbb{Z}^2$ is a local diffeomorphism. Since the differential commutes with smooth maps, see the Differentials-on-Smooth Manifolds Proposition **??** (2), we also see that $d(dx) = d(dy) = 0$ on $\mathbb{R}^2/\mathbb{Z}^2$.

Exercises for Chapter 118.

Exercise 118.1. Let $\mathcal{H}^*$ be a smooth cohomology theory with $\mathcal{H}^n(\star) = 0$ for $n \geq 1$. We denote by $f\colon S^1 \to S^1$ the map that is given by $(x, y) \mapsto (x, -y)$. Show, only using the axioms of a smooth cohomology theory, that $f^*\colon \mathcal{H}^1(S^1) \to \mathcal{H}^1(S^1)$ is given by multiplication by -1.

Exercise 118.2. Let M be a smooth manifold. Show that if A and B are subsets of M such that $\overline{A}$ and $\overline{B}$ are compact, then $\overline{A \cap B}$ and $\overline{A \cup B}$ are also compact.

Exercise 118.3. We make the usual identification $\pi_1(\mathbb{R}^2/\mathbb{Z}^2) = \mathbb{Z}^2$. We consider the homomorphism $\phi\colon \mathbb{Z}^2 = \pi_1(\mathbb{R}^2/\mathbb{Z}^2) \to \mathbb{Z}$ given by $\phi((1,0)) = 6$ and $\phi((0,1)) = 4$. Provide an *explicit* map $f\colon \mathbb{R}^2/\mathbb{Z}^2 \to S^1$ such that $f_* = \phi$.

Exercise 118.4. Let M be a smooth manifold and let $\phi \in \mathrm{H}^1(M; \mathbb{Z})$. Show that $\phi \cup \phi = 0$.

Exercise 118.5. Let M be a smooth manifold and let A be a union of components of ∂M. We define

$$\mathrm{C}^k_{\mathrm{dr}}(M, A) \;:=\; \{\varphi \in \Omega^k(M) \,|\, \text{there exists a neighborhood } U \text{ of } A \text{ such that } \varphi|_U \equiv 0\}.$$

(a) Show that the usual differential $d\colon \mathrm{C}^k_{\mathrm{dR}}(M) \to \mathrm{C}^{k+1}_{\mathrm{dR}}(M)$ restricts to a coboundary map $d\colon \mathrm{C}^k_{\mathrm{dR}}(M, A) \to \mathrm{C}^{k+1}_{\mathrm{dR}}(M, A)$. We refer to resulting cohomology groups by $\mathrm{H}^k_{\mathrm{dR}}(M, A)$.

(b) Show that there exists a natural connecting homomorphism $\delta\colon \mathrm{H}^k_{\mathrm{dR}}(A) \to \mathrm{H}^{k+1}_{\mathrm{dR}}(X, A)$ which gives rise to a long exact sequence

$$\ldots \longrightarrow \mathrm{H}^k_{\mathrm{dR}}(M, A) \longrightarrow \mathrm{H}^k_{\mathrm{dR}}(M) \longrightarrow \mathrm{H}^k_{\mathrm{dR}}(A) \xrightarrow{\delta} \mathrm{H}^{k+1}_{\mathrm{dR}}(M, A) \longrightarrow \ldots$$

(c) Show that there exists a natural isomorphism $u\colon \mathrm{H}_k(M, A) \to$ such that the following diagram commutes:

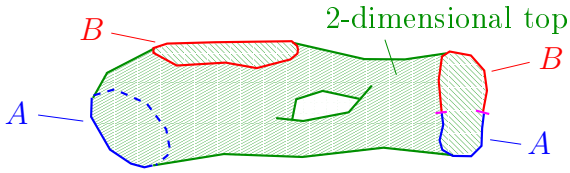
$$\begin{array}{ccccccccc}
\ldots \longrightarrow & \mathrm{H}^k(M, A; \mathbb{R}) & \longrightarrow & \mathrm{H}^k(M; \mathbb{R}) & \longrightarrow & \mathrm{H}^k(A; \mathbb{R}) & \xrightarrow{\delta} & \mathrm{H}^{k+1}(M, A; \mathbb{R}) & \longrightarrow \ldots \\
& \cong \downarrow u & & \cong \downarrow u & & \cong \downarrow u & & \cong \downarrow u & \\
\ldots \longrightarrow & \mathrm{H}^k_{\mathrm{dR}}(M, A) & \longrightarrow & \mathrm{H}^k_{\mathrm{dR}}(M) & \longrightarrow & \mathrm{H}^k_{\mathrm{dR}}(A) & \xrightarrow{\delta} & \mathrm{H}^{k+1}_{\mathrm{dR}}(M, A) & \longrightarrow \ldots
\end{array}$$

(d) Let $\varphi \in \mathrm{H}^1(M, A; \mathbb{Z})$. Show that there exists a smooth map $f\colon M \to S^1$ that vanishes on an open neighborhood of U and which has the property that the induced map $f_*\colon \mathrm{H}_1(M, A; \mathbb{Z}) \to \mathrm{H}_1(S^1) = \mathbb{Z}$ equals the given cohomology class $\varphi \in \mathrm{H}^1(M, A; \mathbb{Z}) = \mathrm{Hom}(\mathrm{H}_1(M, A; \mathbb{Z}), \mathbb{Z})$.
Remark. This statement is the analogue of the Maps-to-S^1 Proposition 118.13 (1).

Part XII

Poincaré Duality

119. The Topological Poincaré Duality Theorem



In Chapter 103 we stated and proved the Simplicial Poincaré Duality Theorem 103.4 and we saw that it gives rise to the Poincaré Duality Theorem 103.5 for closed smooth manifolds. As discussed on page 2268, that approach has its limitations. We will rectify this by proving in this chapter the Poincaré Duality Theorem 119.1, which in particular has the advantage that it also applies to topological manifolds.

119.1. **The Poincaré Duality Theorem.** The following theorem is by far the most important theorem regarding homology and cohomology groups of topological manifolds.

Theorem 119.1. (Poincaré Duality Theorem) Let M be a compact, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. We denote by $[M] \in \mathrm{H}_n(M, \partial M; R)$ the R-fundamental class. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ the map[1458]

$$\begin{array}{rcl} \mathrm{H}^k(M, A; R) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(M, B; R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

is an isomorphism.

for all commutative rings R we have $\mathrm{H}^k(M, A; R) \xrightarrow{\cong} \mathrm{H}_{2-k}(M, B; R)$

We proceed as follows: in this section and the next section we discuss several special cases and applications of the Poincaré Duality Theorem 119.1. In the final two sections of the chapter we will then provide a rigorous, but arguably less intuitive proof, of the theorem. In the coming chapters we will then use the Poincaré Duality Theorem 119.1 to prove many more statements.

Notation. The isomorphism of the Poincaré Duality Theorem 119.1 is called the Poincaré Duality isomorphism. We denote it and its inverse both by PD_M, i.e. with the notation of the Poincaré Duality Theorem 119.1 we have the isomorphism[1459]

$$\begin{array}{rcl} \mathrm{PD}_M \colon \mathrm{H}^k(M, A; R) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(M, B; R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

together with the inverse

$$\mathrm{PD}_M \colon \mathrm{H}_{n-k}(M, B; R) \xrightarrow{\cong} \mathrm{H}^k(M, A; R).$$

[1458] Recall that the Excisive Triad-Proposition 109.12 (5) implies that (M, A, B) is an excisive triad. In particular, following the definition of the relative cap product on page 2557, we obtain a relative cap product

$$\mathrm{H}^k(M, A; R) \times \underbrace{\mathrm{H}_n(M, \overbrace{A \cup B}^{=\partial M}; R)}_{\text{contains } [M]} \xrightarrow{\cap} \mathrm{H}_{n-k}(X, B; R).$$

This shows that the map in the Poincaré Duality Theorem is in fact defined.

The isomorphisms PD_M thus allow us to go back and forth between homology and cohomology of an R-oriented topological manifold.

Remark. Let M be a compact n-dimensional topological manifold.

(1) the $\mathbb{F}_2$-Orientability Proposition 105.13 says that M is $\mathbb{F}_2$-orientable, i.e. the duality statement holds with $\mathbb{F}_2$-coefficients without any further assumptions on M.
(2) If M is in fact orientable, then it follows from Lemma 105.14 that M is R-orientable for any commutative ring R. In particular the duality statement holds for any commutative ring.
(3) The two most important instances of A and B are that we have either $A = \varnothing$ or $A = \partial M$. Under the hypothesis of the Poincaré Duality Theorem 119.1 we then get isomorphisms

$$\begin{array}{ccc} \mathrm{H}^k(M;R) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(M,\partial M;R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{H}^k(M,\partial M;R) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(M;R) \\ \sigma & \mapsto & \sigma \cap [M]. \end{array}$$

(4) For topological manifolds with non-empty boundary the Poincaré Duality Theorem is sometimes also called the *Poincaré-Lefschetz Duality Theorem*.

Examples.

(1) Let P be a point in M and suppose that M is connected. As we pointed out on page 2558, we have $[M]^* \cap [M] = [P] \in \mathrm{H}_0(M;\mathbb{Z})$. Therefore we obtain that $\mathrm{PD}_M([P]) = [M]^*$.
(2) Earlier we had already performed several explicit calculations which can be viewed as special case of the Poincaré Duality Theorem 119.1:
   (a) On page 2555 we saw explicitly that for any surface Σ the map
   $$- \cap [\Sigma] \colon \mathrm{H}^1(\Sigma;\mathbb{Z}) \to \mathrm{H}_1(\Sigma;\mathbb{Z})$$
   is an isomorphism. On page 2555 we had obtained similar results for $\mathbb{R}\mathrm{P}^2$ with $\mathbb{F}_2$-coefficients.
   (b) On page 2559 we saw explicitly that for the annulus $X = S^1 \times [0,1]$ the map
   $$- \cap [X] \colon \mathrm{H}^1(X;\mathbb{Z}) \to \mathrm{H}_1(X,\partial X;\mathbb{Z})$$
   is an isomorphism.
(3) It is instructive to consider the case $k = 0$ of the Poincaré Duality Theorem 119.1. We obtain for a compact connected non-empty n-dimensional topological manifold that
$$\mathrm{H}_n(M,\partial M;\mathbb{Z}) \cong \mathrm{H}^0(M;\mathbb{Z}) \underset{\uparrow}{\cong} \mathbb{Z} \quad \& \quad \mathrm{H}_n(M;\mathbb{Z}) \cong \mathrm{H}^0(M,\partial M;\mathbb{Z}) \underset{\uparrow}{\cong} \begin{cases} \mathbb{Z}, & \text{if } \partial M = \varnothing, \\ 0, & \text{if } \partial M \neq \varnothing. \end{cases}$$
H^0-Proposition 108.11 — see the H^0-Proposition 108.11 and page 2408
   This calculation is consistent with the results from the Orientation-Top Homology Theorem 106.1 and the Top-Homology Theorem 106.3.

We formulate our last example as a proposition.

[1459] When M is understood, then we drop it from the notation.

Proposition 119.2. (Poincaré Duality-Products Proposition) Let M and N be two compact oriented connected topological manifolds. Furthermore let $x_0 \in M$ and $y_0 \in N$.

(a) We denote by $p\colon M \times N \to M$ and $q\colon M \times N \to N$ the obvious projections.

(b) We denote by $i\colon M \xrightarrow{x \mapsto (x,y_0)} M \times N$ and $j\colon N \xrightarrow{y \mapsto (x_0,y)} M \times N$ the obvious inclusions.

(c) We equip $M \times N$ with the product orientation introduced in the Topological Product Orientation Proposition 113.10.

(d) We work with the decomposition $\partial(M \times N) = (\partial M \times N) \cup (M \times \partial N)$.

(e) We write $m = \dim(M)$ and $n = \dim(N)$.

The following equalities hold:

$$\begin{aligned} \mathrm{PD}_{M\times N}(i_*([M])) &= (-1)^{mn} \cdot q^*([N]^*) &&\in \mathrm{H}^m(M\times N, M\times\partial N;\mathbb{Z}) \\ \mathrm{PD}_{M\times N}(j_*([N])) &= p^*([M]^*) &&\in \mathrm{H}^n(M\times N, M\times\partial N;\mathbb{Z}) \\ \mathrm{PD}_{M\times N}(i_*([M])) \cup \mathrm{PD}_{M\times N}(j_*([N])) &= [M\times N]^* &&\in \mathrm{H}^{m+n}(M\times N, \partial(M\times N);\mathbb{Z}). \end{aligned}$$

Proof. By the Fundamental Class-Product Proposition 117.2 (2) we have

$$p^*([M]^*) \cap [M\times N] = i_*([M]) \quad \text{and} \quad q^*([N]^*) \cap [M\times N] = (-1)^{mn} \cdot j_*([N]).$$

The first two promised equalities follow from these two calculations and the definition of the Poincaré Duality isomorphisms. The third equality is verified in the following little calculation:

$$\begin{aligned} \mathrm{PD}_{M\times N}(i_*([M])) \cup \mathrm{PD}_{M\times N}(j_*([N])) &\overset{\text{by the first two equalities}}{=} (-1)^{mn} \cdot q^*([N]^*) \cup p^*([M]^*) \\ &= (-1)^{mn} \cdot (-1)^{mn} \cdot p^*([M]^*) \cup q^*([N]^*) \\ &\overset{\text{by the Cup Product-Commutativity Property}}{=} [M\times N]^*. \end{aligned}$$

by the Fundamental Class-Product Proposition

119.2. **Consequences of the Poincaré Duality Theorem 119.1.** In this section we give several more or less immediate corollaries to the Poincaré Duality Theorem 119.1. If we restrict ourselves to closed smooth manifolds, then the statements below can also be deduced from the Poincaré Duality Theorem 103.5 that we proved in the last chapter. We start out with the following proposition.

Proposition 119.3. Let M be a compact orientable n-dimensional topological manifold and suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. For every $k \in \mathbb{N}_0$ there exists an isomorphism[1460]

$$\mathrm{H}_{n-k}(M, A;\mathbb{Z}) \cong \underset{\uparrow}{\mathrm{FH}_k}(M, B;\mathbb{Z}) \oplus \underset{\uparrow}{\mathrm{Tor}}(\mathrm{H}_{k-1}(M, B;\mathbb{Z})).$$

given an abelian group G we denote by $\mathrm{Tor}(G)$ its torsion-subgroup and we denote by $\mathrm{F}G := G/\mathrm{Tor}(G)$ the maximal torsion-free quotient

Proof. We have the following isomorphisms

$$\begin{aligned} \mathrm{H}_{n-k}(M, A;\mathbb{Z}) &\overset{\text{Poincaré Duality Theorem 119.1}}{\cong} \mathrm{H}^k(M, B;\mathbb{Z}) \overset{\text{Universal Coefficient Theorem 110.12}}{\cong} \mathrm{Hom}(\mathrm{H}_1(M, B),\mathbb{Z}) \oplus \mathrm{Ext}(\mathrm{H}_{k-1}(M, B;\mathbb{Z}),\mathbb{Z}) \\ &\cong \mathrm{FH}_k(M, B;\mathbb{Z}) \oplus \mathrm{Tor}(\mathrm{H}_{k-1}(M, B;\mathbb{Z})). \end{aligned}$$

follows from the Ext-Calculation Lemma 110.5 (5) and the fact that by Lemma 96.8 together with Topological Manifolds-Invariants Proposition 104.14 (4) we know that the homology groups $\mathrm{H}_i(M, B;\mathbb{Z})$ are finitely generated abelian groups

[1460] It is worth stressing that this isomorphism is not natural.

■

Example. Let $p, q \in \mathbb{N}$ be coprime. In this example we consider the corresponding lens space $L(p,q) = S^3/\mathbb{Z}_p$ as defined and discussed on page 1075. Note that $L(p,q)$ is a closed orientable 3-dimensional smooth manifold. In the Lens Space Homology Lemma 98.9 we computed the following homology groups:

$$\begin{array}{rcl} \mathrm{H}_3(L(p,q);\mathbb{Z}) & \cong & \mathbb{Z} \\ \mathrm{H}_2(L(p,q);\mathbb{Z}) & \cong & 0 \\ \mathrm{H}_1(L(p,q);\mathbb{Z}) & \cong & \mathbb{Z}_p \\ \mathrm{H}_0(L(p,q);\mathbb{Z}) & \cong & \mathbb{Z}. \end{array}$$

Fortunately this data is indeed consistent with Proposition 119.3.

The following straightforward corollary to the previous proposition gives in particular a new proof to the Smooth Manifold-Top Homology Theorem 98.6 (2) and Proposition 106.22.

Corollary 119.4. Let M be a compact orientable n-dimensional topological manifold and suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Then the homology groups $\mathrm{H}_{n-1}(M, A; \mathbb{Z})$ and $\mathrm{H}_{n-1}(M, B; \mathbb{Z})$ are free abelian groups.

Proof. We have

$$\mathrm{H}_{n-1}(M,A;\mathbb{Z}) \overset{\text{Proposition 119.3}}{\cong} \underbrace{\mathrm{FH}_1(M,B)}_{\text{free abelian group}} \oplus \underbrace{\mathrm{Ext}(\overbrace{\mathrm{H}_0(M,B)}^{\text{free abelian group}},\mathbb{Z})}_{=0 \text{ by the Ext-Calculation Lemma 110.5}}$$

■

Let X be a topological space X and let $n \in \mathbb{N}_0$. Recall that on page 1882 we defined the n-th Betti number of X as $b_n(X) := \mathrm{rank}(\mathrm{H}_n(X))$. With this definition we have the following immediate corollary to Proposition 119.3.

Corollary 119.5. (Betti Number Symmetry Corollary) Let M be a closed orientable n-dimensional topological manifold. Given any $k \in \mathbb{N}_0$ we have $b_{n-k}(M) = b_k(M)$.

Remark. Henri Poincaré [**Poi1895, Poi2010, PGL1953**, Chapter 9], formulated the conclusion of the Betti Number Symmetry Corollary 119.5 in a distinctly more elegant way: in his seminal paper "analysis situs", published in 1895, he wrote

> "[...] pour une variété fermé les nombres de Betti
> également distants des extrêmes sont égaux".

In fact when Henri Poincaré first developed what became known as Poincaré Duality he thought that for any closed orientable connected n-dimensional smooth manifold the groups $\mathrm{H}_k(M;\mathbb{Z})$ and $\mathrm{H}_{n-k}(M;\mathbb{Z})$ are isomorphic. A Danish mathematician, Poul Heegaard [**Hee1898**], pointed out to him that this is not true in general, for example as we just saw, for the lens space $L(p,q)$ we have by the Lens Space Homology Lemma 98.9 that $\mathrm{H}_1(L(p,q);\mathbb{Z}) \cong \mathbb{Z}_p$ but $\mathrm{H}_2(L(p,q);\mathbb{Z}) = 0$. Shortly afterwards Henri Poincaré [**Poi1900**] came up with the correct formulation of Poincaré Duality, namely the one given in Proposition 119.3.

Next let us consider (co-) homology groups with field coefficients. In this context we have the following almost immediate consequence of the Poincaré Duality Theorem 119.1.

Theorem 119.6. (Co-Homology Symmetry Theorem) Let M be a compact n-dimensional topological manifold and let $k \in \mathbb{N}_0$.

(1) We have[1461]

$$\begin{aligned} \dim_{\mathbb{F}_2}(\mathrm{H}_k(M;\mathbb{F}_2)) &= \dim_{\mathbb{F}_2}(\mathrm{H}_{n-k}(M,\partial M;\mathbb{F}_2)) \\ \text{and} \quad \dim_{\mathbb{F}_2}(\mathrm{H}^k(M;\mathbb{F}_2)) &= \dim_{\mathbb{F}_2}(\mathrm{H}^{n-k}(M,\partial M;\mathbb{F}_2)). \end{aligned}$$

(2) If M is orientable, then for any field $\mathbb{F}$ we have

$$\begin{aligned} \dim_{\mathbb{F}}(\mathrm{H}_k(M;\mathbb{F})) &= \dim_{\mathbb{F}}(\mathrm{H}_{n-k}(M,\partial M;\mathbb{F})) \\ \text{and} \quad \dim_{\mathbb{F}}(\mathrm{H}^k(M;\mathbb{F})) &= \dim_{\mathbb{F}}(\mathrm{H}^{n-k}(M,\partial M;\mathbb{F})). \end{aligned}$$

Remark. In the De Rham Cohomology Symmetry Corollary **??** we proved the analogous statement in terms of dimensions of de Rham cohomology groups.

Proof. Let M be a compact n-dimensional topological manifold. We have

$$\begin{aligned} \dim_{\mathbb{F}_2}(\mathrm{H}_k(M;\mathbb{F}_2)) &\underset{\text{Theorem 119.1}}{=} \dim_{\mathbb{F}_2}(\mathrm{H}^{n-k}(M,\partial M;\mathbb{F}_2)) \\ &\underset{\text{Cohomology-Field Coefficients Proposition 110.18}}{=} \dim_{\mathbb{F}_2}(\mathrm{Hom}(\mathrm{H}_{n-k}(M,\partial M;\mathbb{F}_2),\mathbb{F}_2)) \\ &\underset{\substack{\text{since Propositions 104.14 (4) and 75.2 (3) and (4) together with Lemma 96.8} \\ \text{imply that } \mathrm{H}_{n-k}(M,\partial M;\mathbb{F}_2) \text{ is finite-dimensional}}}{=} \dim_{\mathbb{F}_2}(\mathrm{H}_{n-k}(M,\partial M;\mathbb{F}_2)). \end{aligned}$$

The proofs of all other statements are basically the same. ■

Example. We consider the real projective space $\mathbb{R}\mathrm{P}^n$. On page 1930 we had determined that

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k = 0,\ldots,n, \\ 0, & \text{otherwise.} \end{cases}$$

So the homology groups with $\mathbb{F}_2$-coefficients are in particular symmetric, which is exactly what the above Co-Homology Symmetry Theorem 119.6 with $\mathbb{F}_2$-coefficients predicts.

Remark. Let M be a compact n-dimensional topological manifold and let $\mathbb{F}$ be a field. In the Topological Manifolds-Invariants Proposition 104.14 (4) we had mentioned that all homology groups $\mathrm{H}_k(M;\mathbb{F})$ are finite-dimensional. But this proof relied on the slightly mysterious Topological Manifold-Simplicial Complex Retract Theorem 104.13. Now we can give an alternative argument if M is closed and orientable. Indeed, we have

$$\mathrm{H}_k(M;\mathbb{F}) \underset{\text{this follows from the Poincaré Duality Theorem 119.1}}{\cong} \mathrm{H}^{n-k}(M;\mathbb{F}) \overset{\text{Cohomology-Field Coefficients Proposition 110.18}}{\cong} \mathrm{H}_{n-k}(M;\mathbb{F})^* \underset{}{\cong} \mathrm{H}^k(M;\mathbb{F})^* \overset{}{\cong} (\mathrm{H}_k(M;\mathbb{F})^*)^*.$$

(Here, as always given an $\mathbb{F}$-vector space V we denote by $V^* = \mathrm{Hom}_{\mathbb{F}}(V,\mathbb{F})$ its dual vector space.) But by [**Jacb1953**, p. 244-248] (see also [**DF2004**, Chapter 11.4]) a vector space V is isomorphic to its double dual $(V^*)^*$ if and only if the vector space is finite-dimensional.

Using the Co-Homology Symmetry Theorem Theorem 119.6 we obtain the following pretty proposition.

[1461]The statement implies of course that $\mathrm{H}^k(M;\mathbb{F})$ and $\mathrm{H}^{n-k}(M,\partial M;\mathbb{F})$ are isomorphic. We prefer to state the result in terms of dimensions to stress that the isomorphism is not natural.

Proposition 119.7. (Odd-Dimensional Manifold-Euler Characteristic Proposition) For every compact odd-dimensional topological manifold M we have

$$\chi(M) \ = \ \tfrac{1}{2}\chi(\partial M).$$

In particular if M is closed, then $\chi(M) = 0$.

Remark.

(1) In the Odd-Dimensional Manifold-Euler Characteristic Lemma 45.4 we showed that the smooth Euler characteristic of a closed orientable odd-dimensional smooth manifold is zero.
(2) In Corollary 140.5 we will use handle decompositions to give an alternative proof of the Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7 in the setting of closed smooth manifolds.

Proof. Let M be a compact topological manifold of dimension $2n+1$. Then

$$\begin{array}{lll}
\chi(M) & = \sum_{i=0}^{2n+1}(-1)^i\cdot\dim_{\mathbb{F}_2}(\mathrm{H}_i(M;\mathbb{F}_2)) & = \sum_{i=0}^{2n+1}(-1)^i\cdot\dim_{\mathbb{F}_2}(\mathrm{H}_{2n+1-i}(M,\partial M;\mathbb{F}_2)) \\
\uparrow & & \uparrow \\
\text{Manifold-}\chi\text{-Proposition 104.36 (4)} & & \text{by the Co-Homology Symmetry Theorem 119.6} \\
= -\sum_{j=0}^{2n+1}(-1)^j\cdot\dim_{\mathbb{F}_2}(\mathrm{H}_j(M,\partial M;\mathbb{F}_2)) & = -\chi(M,\partial M) & = -\chi(M)+\chi(\partial M). \\
\uparrow & \uparrow & \uparrow \\
\text{follows from the substitution } j=2n+1-i & \text{Manifold-}\chi\text{-Proposition 104.36 (4)} & \\
\text{together with the fact that } (-1)^{2n+1}=-1 & &
\end{array}$$

Summarizing we have shown that $\chi(M) = -\chi(M) + \chi(\partial M)$. The desired equality follows from solving for $\chi(M)$. ■

the Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7 raises the following question: what can we say about Euler characteristics of closed even-dimensional topological manifolds. By the classification of closed oriented connected 2-dimensional topological manifolds, see the Surface Classification Theorem 55.4, we know that the Euler characteristic of such a topological manifold is even. In higher dimensions there is evidently much more freedom for constructing topological manifolds.

Question 119.8. Let $n \geq 4$ be even. Is every integer the Euler characteristic of a closed orientable connected n-dimensional topological manifold?

Using the Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7 we easily obtain the following surprising (?) corollary.

Corollary 119.9.

(1) If M is a closed even-dimensional topological manifold that is homeomorphic to the boundary of a compact topological manifold, then $\chi(M)$ is even.
(2) Let n be even. The topological manifolds $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$ are not homeomorphic to the boundary of a compact topological manifold.

Remark. In Exercise 119.5 we will study the question, whether the Klein bottle is homoemorphic to the boundary of a compact 3-dimensional topological manifold M. It follows from the CW-structure on page 1471 that the Euler characteristic of the Klein bottle K is zero, therefore Corollary 119.9 (1) does not obstruct the existence of such an M.

Proof.

(1) Let M is a closed even-dimensional topological manifold that is homeomorphic to the boundary of a compact topological manifold W. Since W is odd-dimensional we obtain from the Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7 that $\chi(M) = \chi(\partial W) = 2 \cdot \chi(W) \in 2 \cdot \mathbb{Z}$.

(2) This statement follows from Statement (1) together with the fact, shown on page 1879, that $\chi(\mathbb{R}\mathrm{P}^n) = \frac{1}{2}(1 + (-1)^n)$ and that $\chi(\mathbb{C}\mathrm{P}^n) = n + 1$. ■

Note that in the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 49.8 we showed that if N is a non-orientable topological manifold, then $\pi_1(N)$ admits an epimorphism onto $\mathbb{Z}_2$.[1462] It follows from the Hurewicz Theorem 84.5 that there exists also an epimorphism $\mathrm{H}_1(N;\mathbb{Z}) \to \mathbb{Z}_2$. For closed 3-dimensional topological manifolds the following Lemma 119.10 is thus a considerable strengthening of the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 49.8.

Lemma 119.10. Let M be a connected closed 3-dimensional topological manifold. If M is non-orientable, then $\mathrm{H}_1(M;\mathbb{Z})$ is infinite.

Proof. Let M be a connected closed 3-dimensional topological manifold. We have

$$0 \overset{\text{Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7}}{=} \chi(M) \overset{\text{see page 2315}}{=} \sum_{n\in\mathbb{N}_0} (-1)^n \cdot b_n(M) \overset{\text{Theorems 106.1 and 106.3}}{=} b_0(M) - b_1(M) + b_2(M) \overset{\text{by the } \mathrm{H}_0\text{-Proposition 72.5}}{=} 1 - b_1(M) + b_2(M).$$

This equality can only hold if $b_1(M) > 0$, i.e. if $\mathrm{H}_1(M;\mathbb{Z})$ is infinite. ■

Definition. Let $f\colon M \to N$ be a map between closed, oriented connected non-empty n-dimensional topological manifolds. We consider the following diagram of maps:

$$\begin{array}{ccc} \mathrm{H}_k(M;\mathbb{Z}) & \underset{\cap[M]}{\overset{\mathrm{PD}_M}{\rightleftarrows}} & \mathrm{H}^{n-k}(M;\mathbb{Z}) \\ \downarrow{\scriptstyle f_*} & & \uparrow{\scriptstyle f^*} \\ \mathrm{H}_k(N;\mathbb{Z}) & \underset{\cap[N]}{\overset{\mathrm{PD}_N}{\rightleftarrows}} & \mathrm{H}^{n-k}(N;\mathbb{Z}). \end{array}$$

We refer to

$$\begin{array}{rcl} f^!\colon \mathrm{H}_k(N;\mathbb{Z}) & \to & \mathrm{H}_k(M;\mathbb{Z}) \\ \sigma & \mapsto & f^*(\mathrm{PD}_N(\sigma)) \cap [M] \end{array}$$

as the Umkehr map of f.[14631464]

The following lemma shows that in some circumstances the Umkehr map is just the transfer map that we introduced on page 1952.

[1462] If in the proof of the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 49.8 we replace the Orientation Covering-Proposition 49.5 by the Orientation Covering-Proposition 105.15 we see that the statement also holds for non-orientable topological manifolds.

[1463] This map is indeed called "Umkehr map" in English. The name stems from the fact that it is a map on homology that "goes the wrong way".

[1464] Wikipedia writes: "In category theory [...] certain unusual functors are denoted $f^!$ and $f_!$, with the exclamation mark used to indicate that they are exceptional in some way. They are thus accordingly sometimes called shriek maps, with "shriek" being slang for an exclamation mark [...]."

Lemma 119.11. Let $p\colon \widetilde{N} \to N$ be a finite cover of a closed, oriented, non-empty n-dimensional topological manifold. If we equip $\widetilde{N}$ with the orientation given by the Topological Manifold-Induced Orientation Lemma 105.17 (3), then for any $k \in \mathbb{N}_0$ the Umkehr map $p^!\colon \mathrm{H}_k(N;\mathbb{Z}) \to \mathrm{H}_k(\widetilde{N};\mathbb{Z})$ equals the transfer map p^*.

Proof. We start our proof with the following claim.

Claim 1. Let $r \leq s$. Given any singular simplex $\sigma\colon \Delta^s \to N$ and any cochain $\phi \in \mathrm{C}^r(N;\mathbb{Z})$ we have

$$p^*(\phi) \cap p^*(\sigma) \;=\; p^*(\phi \cap \sigma).$$

Proof. We write $m = [\widetilde{N} : N]$. We denote by $\widetilde{\sigma}_1, \ldots, \widetilde{\sigma}_m$ the lifts of σ. Then

$$\begin{aligned} p^*(\phi) \cap p^*(\sigma) \;&=\; p^*(\phi) \cap \sum_{i=1}^m \widetilde{\sigma}_i \;=\; \sum_{i=1}^m p^*(\phi)(\widetilde{\sigma}_i \circ [v_0,\ldots,v_r]) \cdot \widetilde{\sigma}_i \circ [v_r,\ldots,v_s] \\ &= \sum_{i=1}^m \phi((p_* \circ \widetilde{\sigma}_i) \circ [v_0,\ldots,v_r]) \cdot \widetilde{\sigma}_i \circ [v_r,\ldots,v_s] \\ &\underset{\uparrow}{=} p^*\big(\phi(\sigma \circ [v_0,\ldots,v_r]) \cdot \sigma \circ [v_r,\ldots,v_s]\big) \;=\; p^*(\phi \cap \sigma) \end{aligned}$$

since $p_* \circ \widetilde{\sigma}_i = \sigma$ and since $\widetilde{\sigma}_i \circ [v_0,\ldots,v_r]$, $i = 1,\ldots,m$ are the lifts of $\sigma \circ [v_0,\ldots,v_r]$ ⊞

Now we turn to the actual proof of the lemma. We pick an n-cycle τ that is a representative for the fundamental class $[N] \in \mathrm{H}_n(N;\mathbb{Z})$ of N. By the Fundamental Class-Covering Proposition 106.25 we know that $p^*(\tau)$ represents the fundamental class of $\widetilde{N}$. By definition of the Umkehr map it suffices to prove the following claim.

Claim 2. For any cocycle $\phi \in \mathrm{C}^l(N;\mathbb{Z})$ we have

$$f^*(\phi) \cap p^*(\tau) \;=\; p^*(\phi \cap \tau).$$

Proof. This claim is an immediate consequence of the first claim. ■

We continue with the following useful and typical application of the Poincaré Duality Theorem 119.1.

Proposition 119.12. (Homotopy Sphere-Characterization Proposition) Let $n \geq 2$. Give a closed connected n-dimensional topological manifold X the following statements are equivalent:

(1) X is $\lfloor \frac{n}{2} \rfloor$-connected,
(2) X is $(n-1)$-connected,
(3) $\pi_1(X)$ is trivial and $\mathrm{H}_i(X;\mathbb{Z}) = 0$ for $i = 2,\ldots,n-1$,
(4) $\pi_1(X)$ is trivial and $\mathrm{H}_i(X;\mathbb{Z}) = 0$ for $i = 2,\ldots,\lfloor \frac{n}{2} \rfloor$.

Definition. A closed connected n-dimensional topological manifold M that satisfies any of the four equivalent statements in Proposition **??** is called a homotopy n-sphere. If M is actually a smooth manifold, then we refer to M as a smooth homotopy n-sphere.

Remark. In Corollaries 153.15 and Proposition **??** we will give alternative characterizations of homotopy spheres.

Proof. We have (1) ⇒ (4) by the Hurewicz Corollary 85.7. We can easily show that (4) ⇒ (3) by applying the Poincaré Duality Theorem 119.1 (here we use that X is orientable by

the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 105.16) and the Universal Coefficient Theorem 110.12 for Cohomology Groups.[1465] The conclusion (3) $\Rightarrow$ (2) is again the Hurewicz Corollary 85.7 and finally (2) $\Rightarrow$ (1) is trivial. ■

Finally we want to study degree-one maps between topological manifolds. We recall that on page 2379 we defined the degree of a map $f\colon M \to N$ between closed, oriented connected non-empty n-dimensional topological manifolds to be the unique integer $\deg(f) \in \mathbb{Z}$ with $f_*([M]) = \deg(f) \cdot [N]$. We had obtained the following results:

(1) In the Degree Realization Proposition 38.13 we showed that for any closed oriented non-empty n-dimensional topological manifold M there exists a degree-one map $M \to S^n$.[1466]
(2) In the Degree One-Epimorphism Proposition 101.8 we saw that if $\deg(f) = \pm 1$, then $f_*\colon \pi_1(M) \to \pi_1(N)$ is an epimorphism.
(3) In Lemma 117.5 we had used cup products to show that there does not exist a map $f\colon S^4 \to S^2 \times S^2$ of non-zero degree.

Now we add the following proposition to our list on results on the non-existence of degree-one maps.

Proposition 119.13. (Umkehr Map Proposition) Let $f\colon M \to N$ be a map between closed oriented non-empty n-dimensional topological manifolds. For every $k \in \mathbb{N}_0$ the following statements hold:

(1) The map $f_* \circ f^!$ is multiplication by $\deg(f)$.
(2) Suppose that f is a map of degree ± 1.
  (a) The map $f^!\colon \mathrm{H}_k(N;\mathbb{Z}) \to \mathrm{H}_k(M;\mathbb{Z})$ splits.
  (b) The image $f^!(\mathrm{H}_k(N;\mathbb{Z}))$ is a subsummand of $\mathrm{H}_k(M;\mathbb{Z})$, i.e. there exists a subgroup Q of $\mathrm{H}_k(M;\mathbb{Z})$ such that $\mathrm{H}_k(M;\mathbb{Z}) = f^!(\mathrm{H}_k(N;\mathbb{Z})) \oplus Q$.
  (c) There exists an isomorphism $\mathrm{H}_k(M;\mathbb{Z}) \cong \mathrm{H}_k(N;\mathbb{Z}) \oplus Q$ for some finitely generated abelian group Q.

Proof. Let $f\colon M \to N$ be a between closed oriented non-empty n-dimensional topological manifolds. We write $d = \deg(f)$. Let $\sigma \in \mathrm{H}_k(N;\mathbb{Z})$. We have

$$(f_* \circ f^!)(\sigma) \underset{\text{definition of } f^!}{=} f_*\big(f^*(\mathrm{PD}_N(\sigma)) \cap [M]\big) \underset{\substack{\text{Cap Product-Naturality} \\ \text{Lemma 116.8}}}{=} \mathrm{PD}_N(\sigma) \cap f_*([M]) \underset{\text{by definition of } d=\deg(f)}{=} d \cdot \mathrm{PD}_N(\sigma) \cap [N] \underset{\text{definition of } \mathrm{PD}_N}{=} d \cdot \sigma.$$

The second statement of the lemma follows from combining the first statement with the Splitting Lemma 78.2. ■

It follows from remark (2) above that there is no degree-one map from $\mathbb{R}\mathrm{P}^3$ to $S^1 \times S^2$. In Question 101.11 we had asked whether there exists a degree-one map from $S^1 \times S^2$ to $\mathbb{R}\mathrm{P}^3$. Now we can give a negative answer.

Corollary 119.14. There is no degree-one map from $S^1 \times S^2$ to $\mathbb{R}\mathrm{P}^3$.

[1465] Note that the proof of (4) $\Rightarrow$ (3) is almost identical to the proof of Lemma 148.1.

[1466] Basically the same proof, together with say the Orientation-Top Homology Theorem 106.1 (4) and an excision argument, shows that the same statement also holds for topological manifolds. We leave it to the reader to fill in the details.

Proof. The corollary follows immediately from the Umkehr Map Proposition 119.13 and the observation that the group $\mathrm{H}_1(\mathbb{R}\mathrm{P}^3;\mathbb{Z}) \cong \mathbb{Z}_2$ is not a subsummand of $\mathrm{H}_1(S^1 \times S^2;\mathbb{Z}) \cong \mathbb{Z}$. ■

We conclude this long list of applications of the Poincaré Duality Theorem 119.1 with the following result.

Corollary 119.15. Let $n \in \mathbb{N}_{\geq 2}$ and let M be a closed oriented connected n-dimensional topological manifold. If there exists a degree one map $f\colon S^n \to M$, then M is a homotopy n-sphere.

Proof. Let $f\colon S^n \to M$ be a degree one map. Recall that by the Degree One-Epimorphism Proposition 101.8 we know that $f_*\colon \pi_1(S^n) \to \pi_1(M)$ is an epimorphism. Thus we see that M is simply connected. Furthermore it follows from the Umkehr Map Proposition 119.13 that for $i = 2, \ldots, n-1$ the homology group $\mathrm{H}_i(M;\mathbb{Z})$ is isomorphic to a subgroup of $\mathrm{H}_i(S^n;\mathbb{Z})$. Since the latter is zero we obtain from the Homotopy Sphere-Characterization Proposition 119.12 that M is indeed a homotopy sphere. ■

119.3. **The proof of the Poincaré Duality Theorem 119.1 for topological manifolds without boundary.** In this section we will prove the Poincaré Duality Theorem 119.1 for closed topological manifolds. More precisely, we will prove the following theorem.

Theorem 119.16. Let M be a closed, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. We denote by $[M] \in \mathrm{H}_n(M;R)$ the R-fundamental class. Then for each $k \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{PD}_M\colon \mathrm{H}^k(M;R) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(M;R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

is an isomorphism.

In order to simplify the notation a little bit we will work throughout the section with $R = \mathbb{Z}$. The proof for other commutative rings is verbatim the same.

The key idea is somewhat similar to the strategy of the proof of the Homology-Section Theorem 106.10 . More precisely, using a Mayer–Vietoris argument and a limit argument we want to reduce the proof eventually to the fairly trivial case of an open ball in $\mathbb{R}^n$.
To carry out the above strategy we need a version of Poincaré Duality for every topological manifold (not necessarily compact) with empty boundary. Formulating this generalized Poincaré Duality Theorem requires some preparations. First we recall some definitions and results from earlier on:

(1) Given a topological space X we denote by $\mathcal{K}(X)$ the set of all compact subsets of X. Let $k \in \mathbb{N}_0$. By the $\mathrm{H}^n_{\mathrm{c}}$-via-Direct Limits Proposition 112.4 we have an identification

$$\varinjlim_{K \in \mathcal{K}(X)} \mathrm{H}^k(X, X \setminus K) \;=\; \mathrm{H}^k_{\mathrm{c}}(X).$$

(2) Let M be an n-dimensional topological manifold with empty boundary. If M is equipped with an orientation $\{\mu_x\}_{x \in M}$, then we saw in the Homology-Section Theorem 106.10 (i) that given any compact subset K of M there exists a unique class

$\mu_K^M \in \mathrm{H}_n(M, M \setminus K)$ such that for any $x \in K$ the image of μ_K^M under the map

$$\mathrm{H}_n(M, M \setminus K) \;\to\; \mathrm{H}_n(M, M \setminus \{x\})$$

equals the given orientation μ_x at x. If M is understood, then we drop it from the notation, i.e. we just write μ_K instead of μ_K^M.

Lemma 119.17. Let M be an oriented n-dimensional topological manifold with empty boundary.

(1) Let $K \subset L \subset M$ be compact subsets. We denote by $f_{KL} \colon (M, M \setminus L) \to (M, M \setminus K)$ the inclusion map of pairs.
   (a) The map $f_{KL*} \colon \mathrm{H}_n(M, M \setminus L) \to \mathrm{H}_n(M, M \setminus K)$ sends μ_L to μ_K.
   (b) For any $k \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k(M, M \setminus K) & \xrightarrow{\cap \mu_K} & \mathrm{H}_{n-k}(M). \\ \downarrow{\scriptstyle f_{KL}^*} & & \\ \mathrm{H}^k(M, M \setminus L) & \xrightarrow{\cap \mu_L} & \end{array}$$

(2) For any $k \in \mathbb{N}_0$ there exists a unique map

$$\mathrm{PD}_M \colon \mathrm{H}_{\mathrm{c}}^k(M) \;\to\; \mathrm{H}_{n-k}(M)$$

such that for each compact subset $K \subset M$ the following diagram commutes[1467]

$$\begin{array}{ccc} \mathrm{H}^k(M, M \setminus K) & \xrightarrow{\cap \mu_K} & \mathrm{H}_{n-k}(M). \\ & \searrow \quad \nearrow_{\mathrm{PD}_M} & \\ & \mathrm{H}_{\mathrm{c}}^k(M) & \end{array}$$

Proof. Let M be an oriented n-dimensional topological manifold with empty boundary.

(1) (a) This is precisely Corollary 106.12 (1).
   (b) Let $\varphi \in \mathrm{H}^k(M, M \setminus K)$. We see that

$$\varphi \cap \mu_K \underset{\text{part (1a)}}{=} \varphi \cap f_{KL*}(\mu_L) \underset{\text{Cap Product-Naturality Lemma 116.8}}{=} f_{KL}^*(\varphi) \cap \mu_L.$$

   But this means precisely that the diagram under consideration commutes.

(2) This statement follows immediately from (1b) and the universal property of the direct limit. ∎

We will prove the following generalization of Theorem 119.16.[1468] This more general version of Poincaré Duality will not only be useful for the divide-et-impera approach to the proof of Theorem 119.16, but it will also be of interest in its own right later on.

Theorem 119.18. (Non-Compact PD Theorem) Let M be an oriented n-dimensional topological manifold with empty boundary. Then for each $k \in \mathbb{N}_0$ the map

$$\mathrm{PD}_M \colon \mathrm{H}_{\mathrm{c}}^k(M) \;\xrightarrow{\cong}\; \mathrm{H}_{n-k}(M)$$

[1467] Note that for a class $\varphi \in \mathrm{H}^k(M, M \setminus K)$ and $\mu_K \in \mathrm{H}_n(M, M \setminus K)$ the cap product $\varphi \cap \mu_K$ does indeed lie in $\mathrm{H}_{n-k}(M)$.

[1468] Why is it a generalization of Theorem 119.16?

from Lemma 119.17 is an isomorphism.

Example. Let M be an oriented connected, non-empty n-dimensional topological manifold with empty boundary. Then

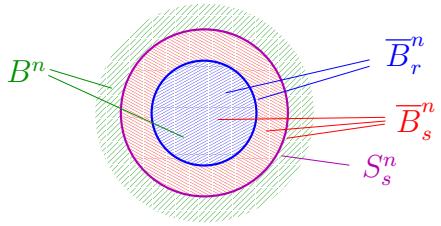
$$\begin{array}{ccc} \mathrm{H}_n(M;\mathbb{Z}) & \cong & \mathrm{H}^0_{\mathrm{c}}(M;\mathbb{Z}) \\ & & \uparrow \\ & & \text{the Non-Compact PD Theorem 119.18 see page 2480} \end{array} \qquad \begin{array}{c} \cong \\ \uparrow \end{array} \begin{cases} \mathbb{Z}, & \text{if } M \text{ is compact,} \\ 0, & \text{if } M \text{ is non-compact.} \end{cases}$$

This calculation is consistent with the results obtained in Theorems 106.1 and 106.3.

Remark.

(1) Let M be an oriented connected, non-empty n-dimensional topological manifold with empty boundary. Following the convention introduced on page 2618 we denote the inverse of the isomorphism $\mathrm{PD}_M \colon \mathrm{H}^k_{\mathrm{c}}(M) \xrightarrow{\cong} \mathrm{H}_{n-k}(M)$ also by PD_M.

(2) Given a possibly non-compact oriented topological manifold without boundary the Non-Compact PD Theorem 119.18 allows us to relate singular homology to cohomology with compact support. There is also a different version of Poincaré Duality that relates singular cohomology to a different flavor of homology, namely Borel-Moore homology. We refer to [**Greenb1967**], [**Bre1997**, Chapter V.9] and [**PS2008**, p. 332] for details.



As a warm up for the proof of the Non-Compact PD Theorem 119.18 we will deal with the case $M = B^n$ by hand.[1469] More precisely, we will prove the following lemma.

Lemma 119.19. For each $k \in \mathbb{N}_0$ the map

$$\mathrm{PD}_{B^n} \colon \mathrm{H}^k_{\mathrm{c}}(B^n) \xrightarrow{\cong} \mathrm{H}_{n-k}(B^n)$$

is an isomorphism.

Proof. Let $k \in \mathbb{N}_0$. Given any $s \in (0,1)$ we write $\overline{B}^n_s := \{x \in \mathbb{R}^n \mid \|x\| \leq s\}$ and we also write $S^{n-1}_s := \partial \overline{B}^n_s$. For the remainder of the proof we fix $0 < r < s < 1$. We denote by $i \colon (\overline{B}^n_s, S^n_s) \to (B^n, B^n \setminus \overline{B}^n_r)$ the inclusion map of pairs.

We consider the following diagram:

$$\begin{array}{ccccc} \mathrm{H}^k\big(\overline{B}^n_s, S^n_s\big) & \xleftarrow{i^*} & \mathrm{H}^k\big(B^n, B^n \setminus \overline{B}^n_r\big) & \longrightarrow & \mathrm{H}^k_{\mathrm{c}}(B^n) \\ \downarrow{\scriptstyle \cap[\overline{B}^n_s]} & & \downarrow{\scriptstyle \cap \mu_{\overline{B}^n_r}} & & \downarrow{\scriptstyle \mathrm{PD}_{B^n}} \\ \mathrm{H}_{n-k}\big(\overline{B}^n_s\big) & \xrightarrow{i_*} & \mathrm{H}_{n-k}(B^n) & \xrightarrow{\mathrm{id}} & \mathrm{H}_{n-k}(B^n). \end{array}$$

[1469] We use the convention that any n-dimensional submanifold of $\mathbb{R}^n$ is equipped with the orientation induced from the standard orientation of $\mathbb{R}^n$, see the Topological Manifold-Induced Orientation Lemma 105.17.

The lemma is an immediate consequence of the following claim.

Claim.

(1) The diagram commutes,
(2) the left vertical map is an isomorphism, and
(3) all horizontal maps are isomorphisms.

Proof.

(1) The square on the right commutes by definition of PD_{B^n}. So it remains to show that the square on the left commutes. Thus let $\varphi \in \mathrm{H}^k(B^n, B^n \setminus \overline{B}^n_r)$. We have

$$i_*\big(i^*\varphi \cap [\overline{B}^n_s]\big) \;=\; \varphi \cap i_*([\overline{B}^n_s]) \qquad\qquad = \;\varphi \cap \mu_{\overline{B}^n_r} \;\in\; \mathrm{H}_{n-k}(B^n).$$

$\uparrow$ Cap Product-Naturality Lemma 116.8 $\qquad\qquad$ $\uparrow$ since the images of $[\overline{B}^n_s]$ and $\mu_{\overline{B}^n_r}$ in $\mathrm{H}_n(B^n, B^n \setminus \{0\})$ agree

(2) We consider the left vertical map of the diagram. Clearly both groups are zero for $k \neq n$. Evidently a generator for $\mathrm{H}^n(\overline{B}^n_s, S^n_s)$ is given by the dual fundamental class $[\overline{B}^n_s]^*$. Since $\overline{B}^n_s$ is path-connected we see, following the discussion on page 2558, that $[\overline{B}^n_s]^* \cap [\overline{B}^n_s] = \langle [\overline{B}^n_s]^*, [\overline{B}^n_s] \rangle = 1 \in \mathrm{H}_0(\overline{B}^n_s) = \mathbb{Z}$. In particular the left vertical map is an isomorphism.

(3) It follows easily from Corollary 74.16 and the Homotopic Maps-H*-Lemma 108.13 that the left horizontal maps are isomorphisms. It remains to show that the top right horizontal map is an isomorphism. We consider the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}^k(B^n, B^n \setminus \overline{B}^n_r) & \longrightarrow & \varinjlim_{K \in \mathcal{K}(B^n)} \mathrm{H}^k(B^n, B^n \setminus K) = \mathrm{H}^k_{\mathrm{c}}(B^n). \\ & \searrow \quad \nearrow & \\ & \varinjlim_{t \in (0,1)} \mathrm{H}^k(B^n, B^n \setminus \overline{B}^n_t) & \end{array}$$

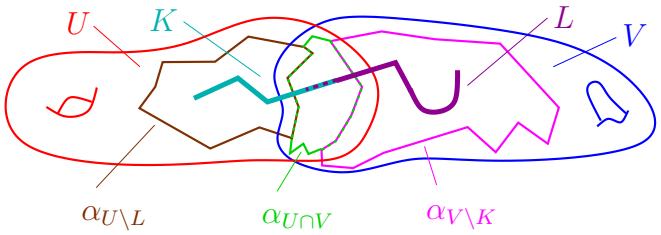
We make the following two observations:

(a) Every compact subset of B^n is contained in a closed ball $\overline{B}^n_t$ with $t \in (0,1)$. Therefore it follows from the Limit-over-Subset Lemma 111.3 that the right diagonal map is an isomorphism.
(b) It follows easily from Lemmas 108.13 and 111.2 (4) that the left diagonal map is an isomorphism.

These two observations together imply that the horizontal map is also an isomorphism. ∎

In the proof of the Non-Compact PD Theorem 119.18 we will need the following two lemmas.

Lemma 119.20. (Compact Subset Decomposition Lemma) Let M be a topological manifold and let U, V be open subsets such that $M = U \cup V$. Then given any compact subset $C \subset M$ there exist compact subsets $K \subset U$ and $L \subset V$ such that $C = K \cup L$.



Proof. Let M be an n-dimensional topological manifold and let U, V be open subsets with $M = U \cup V$. Furthermore let C be a compact subset of M. Using charts one can easily show that given any point $x \in C$ there exists a compact set A_x with the following properties:

(1) the point x lies in the interior of A_x,
(2) if $x \in U$ then the set A_x is contained in U,
(3) if $x \in V$ then the set A_x is contained in V.

It follows from (1), the fact that the sets A_x cover all of C together with the hypothesis that C is compact that there exist finitely many $y_1, \ldots, y_r \in C$ with $C \subset \mathring{A}_{y_1} \cup \cdots \cup \mathring{A}_{y_r}$. One can now easily verify that $K := \bigcup_{y_i \in U} (A_{y_i} \cap C)$ and $L := \bigcup_{y_i \in V} (A_{y_i} \cap C)$ have the desired properties. ■

Lemma 119.21. (Fundamental Cycle Decomposition Lemma) Let M be a compact oriented n-dimensional topological manifold and let U, V be open subsets of M such that $M = U \cup V$ and let $K \subset U$ and $L \subset V$ be compact subsets. Then there exist singular n-chains $\alpha_{U\setminus L}$, $\alpha_{U\cap V}$ and $\alpha_{V\setminus K}$ in $U \setminus L$, $U \cap V$ and $V \setminus K$ such that the following three equalities hold:

(a)	$\mu^M_{K\cup L}$	$=$	$[\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}]$	in $\mathrm{H}_n(M, M \setminus (K \cup L))$
(b)	$\mu^{U\cap V}_{K\cap L}$	$=$	$[\alpha_{U\cap V}]$	in $\mathrm{H}_n(U \cap V, U \cap V \setminus (K \cap L))$
(c)	μ^U_K	$=$	$[\alpha_{U\setminus L} + \alpha_{U\cap V}]$	in $\mathrm{H}_n(U, U \setminus K)$.

Proof. We pick a representative $\alpha \in \mathrm{C}_n(M)$ for $\mu^M_{K\cup L}$. Note that the open sets $U \setminus L, U \cap V$ and $V \setminus K$ cover M. It follows from Lemmas 74.27 and 74.30 that there exist singular chains $\alpha_{U\setminus L}$, $\alpha_{U\cap V}$ and $\alpha_{V\setminus K}$ in $U \setminus L$, $U \cap V$ and $V \setminus K$ such that α is homologous in $\mathrm{C}_k(M)$ to $\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}$. The chains are in particular homologous in $\mathrm{C}_k(M, M \setminus (K \cup L))$ which implies that (a) holds.[1470] Next note that we have

$$\mu^M_{K\cap L} \underset{\text{Lemma 119.17}}{\uparrow\!=} \text{image of } \mu^M_{K\cup L} = [\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}] \underset{\text{since } \alpha_{U\setminus L}, \alpha_{V\setminus K} \text{ lie in } \mathrm{C}_n(M \setminus (K \cap L))}{\uparrow\!=} [\alpha_{U\cap V}] \in \mathrm{H}_n(M, M \setminus (K \cap L)).$$

[1470] Why is $\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}$ a cycle in $\mathrm{C}_*(M, M \setminus (K \cup L))$?

But $\alpha_{U\cap V}$ lies in $U\cap V$, therefore it follows from Corollary 106.12 (2) that $\mu_{K\cap L}^{U\cap V} = [\alpha_{U\cap V}]$ in $\mathrm{H}_n(U\cap V, U\cap V\setminus(K\cap L))$. We have thus verified (b).

Finally the proof of equality (c) is basically the same as the proof of equality (b). ■

Throughout the remainder of this section we will make use of the following notation.

Notation. Let $k\in\mathbb{N}_0$ and let X be a topological space.

(1) Given any subset A of X we denote by $i_*\colon \mathrm{H}_k(A)\to\mathrm{H}_k(X)$ and $i^*\colon \mathrm{H}_k(X)\to\mathrm{H}_k(A)$ the inclusion induced map.

(2) Suppose that X is Hausdorff and that U is an open subset of X. Then we denote by $i\colon \mathrm{H}^k_{\mathrm{c}}(U)\to\mathrm{H}^k_{\mathrm{c}}(X)$ the map defined by

$$\mathrm{H}^k_{\mathrm{c}}(U) = \varinjlim_{K\in\mathcal{K}(U)} \mathrm{H}^k(U, U\setminus K) \xleftarrow{\cong} \varinjlim_{K\in\mathcal{K}(U)} \mathrm{H}^k(X, X\setminus K) \to \varinjlim_{K\in\mathcal{K}(X)} \mathrm{H}^k(X, X\setminus K) = \mathrm{H}^k_{\mathrm{c}}(X).$$

We refer to Lemma 112.5 for the proof that these inclusion maps are covariantly functorial with respect to compositions of inclusions.

We recall the following notation and convention:

Convention. Let X be a topological space, let A be a subset and let $k\in\mathbb{N}_0$. As on page 2534 we make the identification

$$\mathrm{C}^k(X,A) \xrightarrow{=} \text{ all homomorphisms } \mathrm{C}_k(X)\to\mathbb{Z} \text{ that vanish on } \mathrm{C}_k(A).$$

Furthermore, given another subset B of X we write

$$\mathrm{C}^k(X,\{A,B\}) := \text{ all homomorphisms } \mathrm{C}_k(X)\to\mathbb{Z} \text{ that vanish on } \mathrm{C}_k(A) \text{ and on } \mathrm{C}_k(B).$$

If A and B are open subsets of X then we use the isomorphism

$$\mathrm{H}^k(X, A\cup B) \xrightarrow{\cong} \mathrm{H}^k(X,\{A,B\})$$

from Lemma 115.1 to identify the two groups.

In the proof of the Non-Compact PD Theorem 119.18 we will also need the following "inverted" Mayer–Vietoris Theorem, which is very similar to Theorem 78.7.

Theorem 119.22. (Inverted Mayer–Vietoris Theorem for Cohomology groups) Let X be a topological space and let A and B be open subsets.

(1) For every $n\in\mathbb{N}_0$ and every cochain $\varphi\in\mathrm{C}^n(X, A\cup B)$ there exist $\varphi_A\in\mathrm{C}^n(X,A)$ and $\varphi_B\in\mathrm{C}^n(X,B)$ such that $\varphi_A+\varphi_B=\varphi$.

(2) For all $n\in\mathbb{N}_0$ there exists a unique homomorphism

$$\delta\colon \mathrm{H}^n(X, A\cap B) \to \mathrm{H}^{n+1}(X, A\cup B)$$

which has the following property: for every $\varphi_A\in\mathrm{C}^n(X,A)$ and $\varphi_B\in\mathrm{C}^n(X,B)$ such that $\varphi_A+\varphi_B$ is a cocycle in $\mathrm{C}^n(X, A\cap B)$ we have

$$\delta([\varphi_A+\varphi_B]) = [\delta\varphi_A] = -[\delta\varphi_B] \in \mathrm{H}^{n+1}(X,\{A,B\}) = \mathrm{H}^{n+1}(X, A\cup B).$$

(3) The sequence

$$\begin{aligned}\ldots \to \mathrm{H}^n(X, A\cup B) &\xrightarrow{i^*\oplus -i^*} \mathrm{H}^n(X,A)\oplus\mathrm{H}^n(X,B) \xrightarrow{i^*\oplus i^*} \mathrm{H}^n(X, A\cap B)\\ &\xrightarrow{\delta} \mathrm{H}^{n+1}(X, A\cup B) \to \ldots\end{aligned}$$

is exact.

Proof. We start out with the following two observations:

(1) It is straightforward to verify that the following sequence of cochain maps between cochain complexes is exact:

$$0 \to \mathrm{C}^*(X, \{A, B\}) \xrightarrow{i^* \oplus -i^*} \mathrm{C}^*(X, A) \oplus \mathrm{C}^*(X, B) \xrightarrow{i^* \oplus i^*} \mathrm{C}^*(X, A \cap B) \to 0.$$

(2) Since the subsets A and B are open we know from the Excisive Triad-Proposition 109.12 (4) that the triad (X, A, B) is excisive. Therefore it follows from Lemma 115.1 that the obvious map $\mathrm{C}^*(X, A \cup B) \to \mathrm{C}^*(X, \{A, B\})$ induces for every $n \in \mathbb{N}_0$ an isomorphism $\mathrm{H}^n(X, A \cup B) \xrightarrow{\cong} \mathrm{H}^n(X, \{A, B\})$.

With these two observations it is straightforward to modify the proof of Theorem 78.5 to obtain the theorem. We leave it to the reader to fill in the details. ■

The key to the proof of the Non-Compact PD Theorem 119.18 is the following proposition.

Proposition 119.23. Let M be an oriented n-dimensional topological manifold with empty boundary that is the union of two open sets U and V. Then there exists a diagram

$$\begin{array}{ccccccccc}
\ldots \longrightarrow & \mathrm{H}^k_{\mathrm{c}}(U \cap V) & \xrightarrow{i \oplus -i} & \mathrm{H}^k_{\mathrm{c}}(U) \oplus \mathrm{H}^k_{\mathrm{c}}(V) & \xrightarrow{i+i} & \mathrm{H}^k_{\mathrm{c}}(M) & \longrightarrow & \mathrm{H}^{k+1}_{\mathrm{c}}(U \cap V) & \longrightarrow \ldots \\
& \downarrow{\scriptstyle \mathrm{PD}_{U \cap V}} & & \downarrow{\scriptstyle \mathrm{PD}_U \oplus \mathrm{PD}_V} & & \downarrow{\scriptstyle \mathrm{PD}_M} & & \downarrow{\scriptstyle \mathrm{PD}_{U \cap V}} & \\
\ldots \longrightarrow & \mathrm{H}_{n-k}(U \cap V) & \xrightarrow{i \oplus -i} & \mathrm{H}_{n-k}(U) \oplus \mathrm{H}_{n-k}(V) & \xrightarrow{i+i} & \mathrm{H}_{n-k}(M) & \longrightarrow & \mathrm{H}_{n-k-1}(U \cap V) & \longrightarrow \ldots
\end{array}$$

with the following properties:

(1) the first two squares commute, the third square commutes up to the sign $(-1)^{k+1}$,
(2) the lower exact sequence is the long exact Mayer–Vietoris sequence for $M = U \cup V$,
(3) the upper horizontal sequence is also exact.

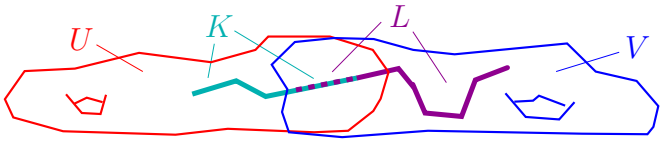
Proof. Let M be an oriented n-dimensional topological manifold with empty boundary. Throughout the proof, given any two subsets $X \subset Y$ and $i \in \mathbb{N}_0$ we write as before $\mathrm{H}^i(Y|X) := \mathrm{H}^i(Y, Y \setminus X)$. We note that if U is open and $K \subset U$ is compact we obtain a map

$$- \cap \mu^U_K \colon \mathrm{H}^k(U|K) \to \mathrm{H}_{n-k}(U).$$

Now let let U and V be open subsets with $M = U \cup V$. Furthermore let $K \subset U$ and $L \subset V$ be compact subsets. We consider the following diagram

$$\begin{array}{ccccccccc}
\ldots \to & \mathrm{H}^k(M|K \cap L) & \to & \mathrm{H}^k(M|K) \oplus \mathrm{H}^k(M|L) & \longrightarrow & \mathrm{H}^k(M|K \cup L) & \xrightarrow{\delta} & \mathrm{H}^{k+1}(M|K \cap L) & \to \ldots \\
& \downarrow{\scriptstyle \cong} & & \downarrow{\scriptstyle \cong} & & & & \downarrow{\scriptstyle \cong} & \\
& \mathrm{H}^k(U \cap V|K \cap L) & & \mathrm{H}^k(U|K) \oplus \mathrm{H}^k(V|L) & & \downarrow{\scriptstyle \cap \mu^M_{K \cup L}} & & \mathrm{H}^{k+1}(U \cap V|K \cap L) & \\
& \downarrow{\scriptstyle \cap \mu^{U \cap V}_{K \cap L}} & & \downarrow{\scriptstyle \cap \mu^U_K \oplus \cap \mu^V_L} & & & & \downarrow{\scriptstyle \cap \mu^{U \cap V}_{K \cap L}} & \\
\ldots \to & \mathrm{H}_{n-k}(U \cap V) & \longrightarrow & \mathrm{H}_{n-k}(U) \oplus \mathrm{H}_{n-k}(V) & \longrightarrow & \mathrm{H}_{n-k}(M) & \xrightarrow{\partial} & \mathrm{H}_{n-k-1}(U \cap V) & \to \ldots
\end{array}$$

which we now explain in more detail:



(1) We write $A = M \setminus K$ and $B = M \setminus L$. The upper horizontal sequence is the inverted Mayer–Vietoris Sequence for cohomology groups from Theorem 119.22.
(2) The lower horizontal sequence is the Mayer-Vietoris sequence coming from Theorem 78.5, corresponding to the decomposition $M = U \cup V$.

(3) The three vertical maps on the top are induced by inclusions of pairs of topological spaces, they are isomorphisms by the Excision Theorem 109.1 for Cohomology Groups.

The following is the key claim of the proof.

Claim. The first two rectangles commute and the third rectangle commutes up to the sign $(-1)^{k+1}$.

$M = U \cup V$

Before we prove the claim we show that it implies our lemma. For each group appearing in the above diagram we take the direct limit over the directed set[1471]

$$\mathcal{K}(U,V) \;=\; \{(K,L) \mid K \text{ compact subset of } U \text{ and } L \text{ compact subset of } V\}$$

and we consider the induced maps of direct limits that were introduced on page 1753. We make the following remarks regarding this new diagram:

(1) Using the Cofinal-Isomorphism Lemma 111.4 one can show that the groups that we obtain taking the direct limit over $\mathcal{K}(U,V)$ are naturally isomorphic to the corresponding cohomology groups with compact support. We carry out the argument for two groups:

$$\varinjlim_{(K,L)\in\mathcal{K}(U,V)} \mathrm{H}^k(U\cap V|K\cap L) \;=\; \varinjlim_{C\in\mathcal{K}(U\cap V)} \mathrm{H}^k(U\cap V|C) \;=\; \mathrm{H}^k_{\mathrm{c}}(U\cap V).$$

$\uparrow$ we apply the Cofinal-Isomorphism Lemma 111.4 to the cofinal morphism of directed sets given by $(K,L)\mapsto K\cap L$

and

$$\varinjlim_{(K,L)\in\mathcal{K}(U,V)} \mathrm{H}^k(M|K\cup L) \;=\; \varinjlim_{C\in\mathcal{K}(M)} \mathrm{H}^k(M|C) \;=\; \mathrm{H}^k_{\mathrm{c}}(M).$$

$\uparrow$ we apply the Cofinal-Isomorphism Lemma 111.4 to the morphism of directed sets given by $(K,L)\mapsto K\cup L$, this morphism is cofinal by the Compact Subset Decomposition Lemma 119.20

All other cases are treated in a very similar fashion.

(2) By the functoriality of direct limits, and since the signs in the commutativity do not depend on K and L, the new diagram also commutes (up to the same signs).

(3) Using (2) and the definition of the "PD-maps" in Lemma 119.17 one can easily verify that the direct limit of the diagram does indeed give rise to the diagram specified in the statement of the lemma.

(4) the Direct Limit-Exactness Proposition 79.2 says that the direct limit of exact sequences is again exact.

All these remarks put together show that the direct limit of the above diagram gives rise precisely to the diagram that we claimed exists and that all claimed statements are satisfied. This concludes the proof that the claim implies the lemma.

[1471] We view $\mathcal{K}(U,V)$ as a directed set given by the relation $(K,L)\leq(K',L')$ if $K\subset K'$ and $L\subset L'$. It is clear that each of the groups in the diagram forms a direct system with respect to this directed set.

Proof. Now we turn to the actual proof of the claim. We show in three separate subclaims that the three rectangles commute. The proof of the first two subclaims consists of a clever usage of the Cap Product-Naturality Lemma 116.8. The proof of the third subclaim is much more sophisticated since it relies on understanding the connecting homomorphisms in the Mayer-Vietoris sequences in (co-) homology.

Subclaim 1. The first rectangle of the diagram on page 2633 commutes.

So we need to show that the following diagram commutes:

$$\begin{array}{ccc}
\mathrm{H}^k(M, M\setminus(K\cap L)) & \xrightarrow{i\oplus -i} & \mathrm{H}^k(M, M\setminus K)\oplus \mathrm{H}^k(M, M\setminus L) \\
\downarrow\cong & \searrow^{i\oplus -i} & \downarrow\cong \\
\mathrm{H}^k(U\cap V, (U\cap V)\setminus(K\cap L)) & & \mathrm{H}^k(U, U\setminus K)\oplus \mathrm{H}^k(V, V\setminus L) \\
\downarrow\cap\mu^{U\cap V}_{K\cap L} & & \downarrow\cap\mu^U_K\oplus\cap\mu^V_L \\
\mathrm{H}_{n-k}(U\cap V) & \xrightarrow{i\oplus -i} & \mathrm{H}_{n-k}(U)\oplus \mathrm{H}_{n-k}(V).
\end{array}$$

Evidently the triangle commutes. We note that the remaining pentagon breaks up into the "direct sum" of two diagrams. By symmetry reasons it suffices to consider the left-hand summands. So let $\phi\in \mathrm{H}^k(M, M\setminus(K\cap L))$. We consider the following diagram of maps between pairs of topological spaces

$$\begin{array}{ccc}
(U\cap V, (U\cap V)\setminus(K\cap L)) & \xrightarrow{\alpha} & (U, U\setminus(K\cap L)) \\
\downarrow{\scriptstyle f\circ\alpha} & \swarrow_{f} & \uparrow{\scriptstyle \beta} \\
(M, M\setminus(K\cap L)) & \xleftarrow[f\circ\beta]{} & (U, U\setminus K).
\end{array}$$

With this notation we need to show that

$$\alpha_*\big((f\circ\alpha)^*(\phi)\cap\mu^{U\cap V}_{K\cap L}\big) \;=\; (f\circ\beta)^*(\phi)\cap\mu^U_K.$$

But this is indeed the case, since

$$\begin{array}{ccccc}
\alpha_*\big(\underbrace{(f\circ\alpha)^*}_{=\alpha^*\circ f^*}(\phi)\cap\mu^{U\cap V}_{K\cap L}\big) & = & f^*(\phi)\cap\alpha_*(\mu^{U\cap V}_{K\cap L}) & = & f^*(\phi)\cap\mu^U_{K\cap L} \\
& & \uparrow & & \uparrow \\
& & \text{Cap Product-Naturality Lemma 116.8} & & \text{by Corollary 106.12 we have } \alpha_*(\mu^{U\cap V}_{K\cap L})=\mu^U_{K\cap L} \\
& & = \quad \beta_*\big((f\circ\beta)^*(\phi)\cap\mu^U_K\big) & = & (f\circ\beta)^*(\phi)\cap\mu^U_K \\
& & \uparrow & & \uparrow \\
& & \text{same argument backwards with the roles of } \alpha \text{ and } \beta \text{ exchanged} & & \text{since } \beta \text{ is on the first coordinate the identity}
\end{array}$$

This concludes the proof of Subclaim 1.

Subclaim 2. The second rectangle of the diagram on page 2633 commutes.

The proof of that subclaim is very similar to the proof of the previous subclaim. Thus we leave it to the reader to fill in the details.

Subclaim 3. The third rectangle of the diagram on page 2633 commutes up to the sign $(-1)^{k+1}$.

As a reminder, we need to show that the following diagram commutes up to the sign $(-1)^{k+1}$:

$$\begin{array}{ccccc} \mathrm{H}^k(M, M\setminus(K\cup L)) & \xrightarrow{\delta} & \mathrm{H}^{k+1}(M, M\setminus(K\cap L)) & \xrightarrow{\cong} & \mathrm{H}^{k+1}(U\cap V, (U\cap V)\setminus(K\cap L)) \\ \downarrow{\scriptstyle \cap\mu_{K\cup L}} & & & & \downarrow{\scriptstyle \cap\mu_{K\cap L}} \\ \mathrm{H}_{n-k}(M) & & \xrightarrow{\qquad\qquad\partial\qquad\qquad} & & \mathrm{H}_{n-k-1}(U\cap V). \end{array}$$

So let $[\varphi] \in \mathrm{H}^k(M, M\setminus(K\cup L)) = \mathrm{H}^k(M, A\cap B)$. We start out with the following preparations:

(1) By Theorem 119.22 (1) we can find $\varphi_A \in \mathrm{C}^k(M, A)$ and $\varphi_B \in \mathrm{C}^k(M, B)$ such that $\varphi = \varphi_A + \varphi_B$.

(2) By the Fundamental Cycle Decomposition Lemma 119.21 there exist singular chains $\alpha_{U\setminus L}$, $\alpha_{U\cap V}$ and $\alpha_{V\setminus K}$ in $U\setminus L$, $U\cap V$ and $V\setminus K$ such that the following three equalities hold:

(2a) $\mu_{K\cup L} = [\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}]$ in $\mathrm{H}_n(M, M\setminus(K\cup L))$

(2b) $\mu_{K\cap L}^{U\cap V} = [\alpha_{U\cap V}]$ in $\mathrm{H}_n(U\cap V, (U\cap V)\setminus(K\cap L))$

(2c) $\mu_K^U = [\alpha_{U\setminus L} + \alpha_{U\cap V}]$ in $\mathrm{H}_n(U, U\setminus K)$.

After these preparations we obtain the following equalities in $\mathrm{H}_{n-k-1}(U\cap V)$:[1472]

$$\begin{array}{l} \text{maps in the rectangle applied clockwise} \\ \text{to some } [\varphi]\in \mathrm{H}^k(M, M\setminus(K\cup L)) \end{array} = \delta[\varphi]\cap\mu_{K\cap L}^{U\cap V} \overset{\text{Theorem 119.22 and (2b)}}{=} [\delta\varphi_A \cap \alpha_{U\cap V}]$$

$$= [\varphi_A\cap\partial\alpha_{U\cap V}] = [\varphi_A\cap\partial\alpha_{U\cap V} - \underbrace{\varphi_A\cap\partial(\alpha_{U\cap V}+\alpha_{U\setminus L})}_{=0}] = [-\varphi_A\cap\partial\alpha_{U\setminus L}]$$

Lemma 116.1; note that (2c) implies that $\partial(\alpha_{U\cap V}+\alpha_{U\setminus L})$ is a singular chain in $U\setminus K$, but φ_A vanishes on singular chains in $A = M\setminus K$

$$= [-\varphi_A\cap\partial\alpha_{U\setminus L} - \underbrace{\varphi_B\cap\partial\alpha_{U\setminus L}}_{=0}] = [-(\varphi_A+\varphi_B)\cap\partial\alpha_{U\setminus L}] = [-\varphi\cap\partial\alpha_{U\setminus L}]$$

since φ_B vanishes on singular chains in $B = M\setminus L$; since $\varphi = \varphi_A + \varphi_B$

$$= [(-1)^{k+1}\cdot\partial(\varphi\cap\alpha_{U\setminus L})] = (-1)^{k+1}\cdot\partial[\underbrace{(\varphi\cap\alpha_{U\setminus L})}_{\in \mathrm{C}_{n-k}(U)} + \underbrace{(\varphi\cap\alpha_{U\cap V}+\varphi\cap\alpha_{V\setminus K})}_{\in \mathrm{C}_{n-k}(V)}]$$

by Lemma 116.1 and since $\delta\varphi = 0$; by the definition of the connecting homomorphism ∂ in the Mayer–Vietoris sequence, see Theorem 78.5 (1)

$$= (-1)^{k+1}\cdot\partial\big([\varphi]\cap\mu_{K\cup L}^M\big) = (-1)^{k+1}\cdot \text{maps in the rectangle applied counterclockwise to } [\varphi].$$

by equality (2a)

This concludes the proof of Subclaim 3, thus of the claim and thus also of the lemma. ■

Proposition 119.23 actually contains an interesting and useful statement which is worth jotting down separately.

[1472] The maps δ and ∂ written in blue are the connecting homomorphisms in the Mayer–Vietoris sequences.

Lemma 119.24. Let M be an oriented n-dimensional topological manifold with empty boundary and let U be an open subset of M. We denote by $i\colon U \to M$ the inclusion. For any $k \in \mathbb{N}_0$ the following two diagrams commute:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{c}}(U) & \xrightarrow{i_*} & \mathrm{H}^k_{\mathrm{c}}(M) \\ \downarrow{\scriptstyle \mathrm{PD}_U} & & \downarrow{\scriptstyle \mathrm{PD}_M} \\ \mathrm{H}_{n-k}(U) & \xrightarrow{i_*} & \mathrm{H}_{n-k}(M) \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{H}_k(U) & \xrightarrow{i_*} & \mathrm{H}_k(M) \\ \downarrow{\scriptstyle \mathrm{PD}_U} & & \downarrow{\scriptstyle \mathrm{PD}_M} \\ \mathrm{H}^{n-k}_{\mathrm{c}}(U) & \xrightarrow{i_*} & \mathrm{H}^{n-k}_{\mathrm{c}}(M). \end{array}$$

Proof. The statement that the diagram on the left commutes for any k is contained in Proposition 119.23 (1). Since the maps PD_U and PD_M are isomorphisms the statement that the diagram on the right commutes is just a reformulation of the fact that the diagrams on the left commutes. ■

Now we turn to the actual proof of the Non-Compact PD Theorem 119.18.

Proof of the Non-Compact PD Theorem 119.18. We fix a dimension n. Throughout this proof by a "manifold" we mean an oriented n-dimensional topological manifold without boundary. We say *Poincaré Duality holds for a manifold M* if for each $k \in \mathbb{N}_0$ the map

$$\mathrm{PD}_M\colon \mathrm{H}^k_{\mathrm{c}}(M) \;\to\; \mathrm{H}_{n-k}(M)$$

from Lemma 119.17 is an isomorphism. Our goal is to show that Poincaré Duality holds for all manifolds.

We start out with the following claim.

Claim 1. Let W be a manifold.

(A) If Poincaré Duality holds for W equipped with an orientation, then it also holds for any other orientation of W.
(B) If W is homeomorphic to a manifold for which Poincaré Duality holds, then Poincaré Duality also holds for W.
(C) Suppose that W is the union of two open subsets U and V. If Poincaré Duality holds for U, V and $U \cap V$, then it also holds for W.
(D) If W is the union of a nested sequence $U_1 \subset U_2 \subset \ldots$ of open subsets such that Poincaré Duality holds for each U_i, then it also holds for W.

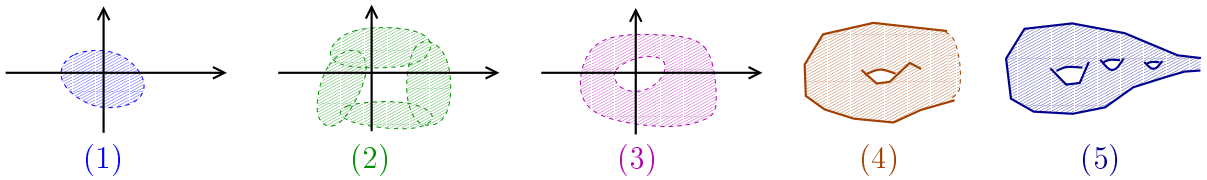
Proof. So let W be a manifold.

(A) Clearly it suffices to consider the case that W is path-connected. By Lemma 105.10 the path-oriented connected manifold W admits only one other orientation, namely the reverse orientation. Evidently Poincaré Duality also holds for that orientation.
(B) If we have an orientation-preserving homeomorphism, then this statement is obvious. For a non-orientation-preserving homeomorphism this statement follows from (A).
(C) If all maps $\mathrm{PD}_U, \mathrm{PD}_V$ and $\mathrm{PD}_{U\cap V}$ are isomorphisms, then it follows immediately from Proposition 119.23 and the Five Lemma 74.10 that also each PD_W is an isomorphism, i.e. Poincaré Duality holds for $W = U \cup V$.
(D) Let $k \in \mathbb{N}_0$. We suppose that for every $i \in \mathbb{N}$ the map $\mathrm{PD}_{U_i}\colon \mathrm{H}^k_{\mathrm{c}}(U_i) \to \mathrm{H}_{n-k}(U_i)$ is an isomorphism. Using Lemmas 116.8 and 119.17 it is straightforward to verify that

for any $i \leq j$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_{\mathrm{c}}^{k}(U_i) & \xrightarrow{\mathrm{PD}_{U_i}} & \mathrm{H}_{n-k}(U_i) \\ \downarrow & & \downarrow \\ \mathrm{H}_{\mathrm{c}}^{k}(U_j) & \xrightarrow{\mathrm{PD}_{U_j}} & \mathrm{H}_{n-k}(U_j). \end{array}$$

We obtain isomorphisms



$$\begin{array}{ccccccc} \mathrm{H}_{\mathrm{c}}^{k}(W) & = & \varinjlim \mathrm{H}_{\mathrm{c}}^{k}(U_i) & \xrightarrow{\varinjlim \mathrm{PD}_{U_i}} & \varinjlim \mathrm{H}_{n-k}(U_i) & = & \mathrm{H}_{n-k}(W). \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \text{Exhaustion-H}_{\mathrm{c}}^{*}\text{-Proposition 112.6} & & \text{isomorphism by our hypothesis and since the above diagram commutes} & & & & \text{Exhaustions-H}_{*}\text{-Proposition 79.4} \end{array}$$

We leave it to the reader to verify that the map from left to right is indeed given by PD_W. ⊞

The following claim completes the proof of the theorem.

Claim 2.

(1) Poincaré Duality holds for every open bounded convex subset of $\mathbb{R}^n$.
(2) For every $m \in \mathbb{N}$ Poincaré Duality holds for the union of m open bounded convex subsets of $\mathbb{R}^n$.
(3) Poincaré Duality holds for every open subset of $\mathbb{R}^n$.
(4) For every $m \in \mathbb{N}$ Poincaré Duality holds for all manifolds that admit an atlas with m charts.
(5) Poincaré Duality holds for all manifolds.

Proof.

(1) Let M be an open bounded convex subset of $\mathbb{R}^n$. By the Convex-to-Ball Proposition 2.20 (1) there exists a homeomorphism $M \to B^n$. It follows from Lemma 119.19 and (B) that Poincaré Duality also holds for M.
(2) We prove the claim by induction on m. By (1) we know that the statement holds for $m = 1$. Now suppose it holds for all unions of $m-1$ open bounded convex subsets of $\mathbb{R}^n$. Let M be the union of m open bounded convex subsets $U_1, \ldots, U_m$. We set $V = U_1 \cup \cdots \cup U_{m-1}$. By our hypothesis and by induction the statement holds for U_m, for V and also for $V \cap U_m = (U_1 \cap U_m) \cup \cdots \cup (U_{m-1} \cap U_m)$, which is the union of $(m-1)$ open bounded convex subsets.[1473] Hence by (C) the statement also holds for

$$M \;=\; V \cup U_m \;=\; (U_1 \cup \cdots \cup U_{m-1}) \cup U_m.$$

[1473]Here we once again use the convenient fact that the intersection of two convex sets is convex.

(3) Let M be an arbitrary open subset of $\mathbb{R}^n$. By the Rational Open Balls Lemma 118.4 we can write M as the union of countably many open balls $B_i, i \in \mathbb{N}$. For $i \in \mathbb{N}$ we set $U_i := \bigcup_{j \leq i} B_j$. By (2) Poincaré Duality holds for each $U_i \in \mathbb{N}$. But then it follows from (D) that Poincaré Duality also holds for M.

(4) We prove this statement by induction on m. The case $m = 1$ is taken care of by (3) and (B). Now suppose Poincaré Duality holds for all manifolds that admit an atlas with $m-1$ charts. Let M be a manifold that admits an atlas $\{\phi_i \colon U_i \to V_i\}_{i=1,\ldots,m}$ with m charts. We write $U = U_1 \cup \cdots \cup U_{m-1}$ and $V = U_m$. Both are open subsets of a manifold, hence they are also manifolds. Furthermore U and V are manifolds that admit an atlas with $m-1$ charts respectively one chart. Similarly $U \cap V = (U_1 \cap U_m) \cup \cdots \cup (U_{m-1} \cap U_m)$ is a manifold that admits an atlas with $m-1$ charts. By induction Poincaré Duality holds for U, V and $U \cap V$. Thus by (C) Poincaré Duality also holds for M itself.

(5) Finally let M be any manifold. By the Countable Covering Lemma 9.2 we know that M admits a countable atlas $\{\Phi_j \colon U_j \to V_j\}_{j \in \mathbb{N}}$. For $i \in \mathbb{N}$ we set $X_i := \bigcup_{j \leq i} U_j$. By (4) Poincaré Duality holds for each X_i. It follows from (D) that Poincaré Duality also holds for M. ■

119.4. **The proof of Poincaré Duality for topological manifolds with boundary.** Now we will finally prove the general statement of the Poincaré Duality Theorem 119.1. For the reader's convenience we recall the statement.

Theorem 119.1. (Poincaré Duality Theorem) Let M be a compact, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. We denote by $[M] \in \mathrm{H}_n(M, \partial M; R)$ the R-fundamental class. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ the map

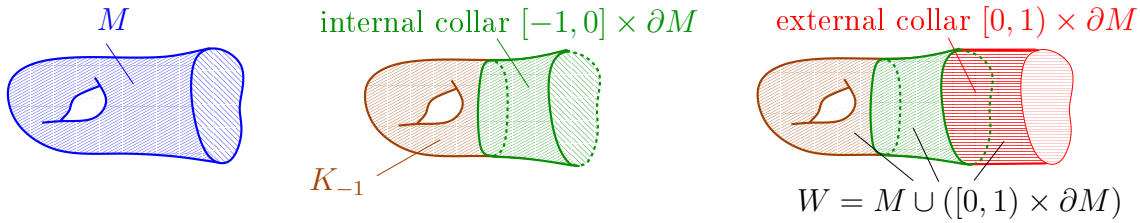
$$\begin{array}{ccc} \mathrm{H}^k(M, A; R) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(M, B; R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

is an isomorphism.

Proof of Theorem 119.1 for $A = \partial M$ and $B = \varnothing$. In this proof we consider the case that $A = \partial M$ and $B = \varnothing$. To simplify the notation we will once again only consider the case that $R = \mathbb{Z}$. The proof of the general case is basically the same. We introduce the following objects:

(i) From the Topological Collar Neighborhood Theorem 75.5 we obtain a collar neighborhood $[-1, 0] \times \partial M$ of $\partial M = \{0\} \times M$. We refer to it as the "internal collar".

(ii) We define



$$W := M \cup ([0, 1) \times \partial M)/\sim \qquad \text{with } x \sim (x, 0) \text{ for every } x \in \partial M.$$

Sometimes $[0, 1) \times \partial M$ is called an *external collar of* M. Furthermore, given any $t \in [-1, 1)$ we write

$$K_t := (M \setminus ([-1, 0] \times \partial M)) \cup ([-1, t] \times \partial M)/\sim .$$

(iii) We denote by $i\colon X \to W$ the obvious map. By the Topological Pushout-Maps Lemma 5.34 (3) and (4) this map is a closed embedding. We will use this to view X as a closed subset of W. Note that it follows easily from the Homotopy Pushout Lemma 14.9 that $X = i(X)$ is a deformation retract of W.

(iv) We denote by $i\colon (X, \partial X) \to (W, W \setminus K_{-1})$ the inclusion map.

By elementary arguments and using the Topological Manifold Boundary Proposition 75.2 (1) one can easily show the following statements:

(A) W is an n-dimensional topological manifold with empty boundary.

(B) W admits an orientation such that M is a submanifold and such that $M \to W$ is orientation-preserving.

(C) Every K_t is a compact subset of W and given any compact subset K of W there exists a $t \in [-1, 1)$ with $K \subset K_t$.

We denote by $i\colon (M, \partial M) \to (W, W \setminus K_{-1})$ the obvious inclusion map. We obtain the following diagram:

$$\begin{array}{ccccc} \mathrm{H}^k(M, \partial M) & \xleftarrow{i^*} & \mathrm{H}^k(W, W \setminus K_{-1}) & \longrightarrow & \mathrm{H}^k_{\mathrm{c}}(W) \\ \downarrow{\scriptstyle \cap [M]} & & \downarrow{\scriptstyle \cap \mu_{K_t}} & & \downarrow{\scriptstyle \mathrm{PD}_W} \\ \mathrm{H}_{n-k}(M) & \xrightarrow{i_*} & \mathrm{H}_{n-k}(W) & \xrightarrow{\mathrm{id}} & \mathrm{H}_{n-k}(W). \end{array}$$

It remains to prove the following claim which resembles closely the claim in the proof of Lemma 119.19.

Claim. The following three statements hold:

(1) the diagram commutes,

(2) the right vertical map is an isomorphism, and

(3) all horizontal maps are isomorphisms.

Proof.

(1) The right-hand square commutes by definition of PD_W. Using (B) we can apply the same argument as in the proof of the claim in Lemma 119.19 to show that the left-hand square commutes.

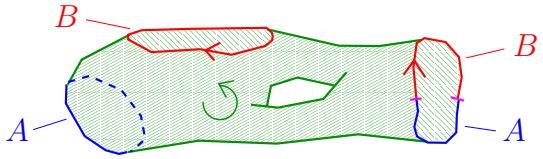
(2) the Non-Compact PD Theorem 119.18 implies that the right vertical map is an isomorphism.

(3) It follows easily from the discussion in (iii) together with Corollary 74.16 and the Homotopic Maps-H*-Lemma 108.13 that the left horizontal maps are isomorphisms. Note that the bottom right horizontal map is the identity. Thus it remains to show that the top right horizontal map is an isomorphism. Similar to the proof

of Lemma 119.19 we consider the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}^k(W, W \setminus K_{-1}) & \longrightarrow & \varinjlim_{K \in \mathcal{K}(W)} \mathrm{H}^k(W, W \setminus K) = \mathrm{H}^k_{\mathrm{c}}(W). \\ & \searrow \quad \nearrow & \\ & \varinjlim_{t \in [-1,1)} \mathrm{H}^k(W, W \setminus K_t) & \end{array}$$

We make the following two observations:



(a) By (C) every compact subset of W is contained in some K_t. Therefore it follows from the Limit-over-Subset Lemma 111.3 that the right diagonal map is an isomorphism.

(b) It follows easily from Lemmas 108.13 and 111.2 (4) that the left diagonal map is an isomorphism.

These two observations together imply that the horizontal map is also an isomorphism.

This concludes the proof of the claim and it concludes the proof of the Poincaré Duality Theorem 119.1 in the special case that $A = \partial M$ and $B = \varnothing$. ■

Proof of Theorem 119.1 for the general case. Now we finally consider the general case of Theorem 119.1. So we suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. We recall that by the Excisive Triad-Proposition 109.12 (5) we know that the triad (M, A, B) is excisive. In this proof, once again we simplify the notation and we only work with $\mathbb{Z}$-coefficients.

We equip ∂M and then also B with the orientations coming from the Topological Manifold-Boundary Orientation Proposition 105.19 and the Topological Manifold-Induced Orientation Lemma 105.17. We consider the following diagram

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \mathrm{H}^k(M, \partial M) & \longrightarrow & \mathrm{H}^k(M, A) & \longrightarrow & \mathrm{H}^k(\partial M, A) & \xrightarrow{\delta} & \mathrm{H}^{k+1}(M, \partial M) & \longrightarrow & \ldots \\ & & \cong \downarrow -\cap[M] & & \downarrow -\cap[M] & & \cong \downarrow i^* & & \cong \downarrow -\cap[M] & & \\ & & & & & & \mathrm{H}^k(B, \partial B) & & & & \\ & & & & & & \cong \downarrow -\cap[B] & & & & \\ \ldots & \longrightarrow & \mathrm{H}_{n-k}(M) & \longrightarrow & \mathrm{H}_{n-k}(M, B) & \xrightarrow{\partial} & \mathrm{H}_{n-k-1}(B) & \longrightarrow & \mathrm{H}_{n-k-1}(M) & \longrightarrow & \ldots \end{array}$$

We make the following observations:

(1) The top horizontal sequence is the long exact sequence in cohomology of the triple $(M, \partial M, A)$ provided by the Cohomological LES-Lemma 108.15.

(2) The bottom horizontal sequence is the long exact sequence in homology of the pair (M, B) provided by the Topological LES-Corollary 74.14.

(3) The above vertical map $i^*\colon \mathrm{H}^k(\partial M, A) \to \mathrm{H}^k(B, \partial B)$ is induced by the inclusion $i\colon (B, \partial B) \to (\partial M, A)$. It is an isomorphism by the Excisive Triad-Proposition 109.12 (5) together with the Excisive Characterization Lemma 109.13 (3).
(4) The other maps decorated with "$\cong$" are isomorphisms by the special case of the Poincaré Duality Theorem 119.1 that we have already dealt with.

By the Five Lemma 74.10 it remains to prove the following claim.

Claim. The above diagram commutes up to signs, more precisely:
(1) the first rectangle commutes,
(2) the second rectangle commutes up to the sign $(-1)^k$,
(3) the third rectangle commutes.

Proof. We consider the three rectangles separately.

(1) We consider the following diagram:

$$\begin{array}{ccc}
\mathrm{H}^k(M, \partial M) \times \mathrm{H}_n(M, \partial M) & \xrightarrow{\cap} & \mathrm{H}_{n-k}(M) \\
{\scriptstyle =}\uparrow \quad \downarrow{\scriptstyle =} & & \downarrow \\
\mathrm{H}^k(M, \partial M) \times \mathrm{H}_n(M, \partial M) & \xrightarrow{\cap} & \mathrm{H}_{n-k}(M, B) \\
\downarrow \quad \uparrow{\scriptstyle =} & & {\scriptstyle =}\uparrow \\
\mathrm{H}^k(M, A) \times \mathrm{H}_n(M, \partial M) & \xrightarrow{\cap} & \mathrm{H}_{n-k}(M, B).
\end{array}$$

We can convince ourselves that the diagram commutes by applying the Cap Product-Naturality Lemma 116.8 to the maps $(M, \partial M, \varnothing) \to (M, \partial M, B)$ and $(M, A, B) \to (M, \partial M, B)$ of excisive triads. It follows easily from this observation that the first rectangle of the claim commutes.

Before we continue with the discussion of the other two rectangles we need to make one remark. We denote by $j\colon (B, \partial B) \to (\partial M, A)$ the inclusion map and we denote by $\partial\colon \mathrm{H}_n(M, \partial M) \to \mathrm{H}_{n-1}(\partial M, A)$ the connecting homomorphism in the long exact sequence of the triple $(M, \partial M, A)$. It follows from the Fundamental Class-of-Boundary Proposition 106.27 (1), the Codimension Zero-Fundamental Class Lemma 106.24 and the remark on page 1629 that the following equality holds

$$(*) \qquad j_*([B]) \;=\; \partial[M] \in \mathrm{H}_{n-1}(\partial M, A).$$

Now we continue with the proof of the claim.

(2) We apply the Cap Product-Connecting Homomorphism Lemma 116.10 (2) to the excisive triad (M, A, B). (Recall that $A \cup B = \partial M$ and $A \cap B = \partial B$.) We obtain that for any $k \in \mathbb{N}_0$ the following diagram commutes up to the sign $(-1)^k$:

$$\begin{array}{ccc}
\mathrm{H}^k(M, A) \times \mathrm{H}_n(M, \partial M) & \xrightarrow{\cap} & \mathrm{H}_{n-k}(M, B) \\
{\scriptstyle i^*}\downarrow \quad {\scriptstyle \partial}\downarrow & & \\
\mathrm{H}^k(\partial M, A) \times \mathrm{H}_{n-1}(\partial M, A) & & \Big\downarrow \partial \\
{\scriptstyle j^*}\downarrow \cong \quad {\scriptstyle (j_*)^{-1}}\downarrow \cong & & \\
\mathrm{H}^k(B, \partial B) \times \mathrm{H}_{n-1}(B, \partial B) & \xrightarrow{\cap} & \mathrm{H}_{n-k-1}(B).
\end{array}$$

Together with $(*)$ we obtain that the second rectangle of the claim does indeed commute up to the sign $(-1)^k$.

(3) We consider the following diagram:

$$\begin{array}{ccccc}
\mathrm{H}^k(B,\partial B) \times \mathrm{H}_{n-1}(B,\partial B) & \xrightarrow{\cap} & \mathrm{H}_{n-k-1}(B) \\
\uparrow{\scriptstyle i^*} & \downarrow{\scriptstyle i_*} & \downarrow{\scriptstyle i_*} \\
\mathrm{H}^k(\partial M,A) \times \mathrm{H}_{n-1}(\partial M,A) & \xrightarrow{\cap} & \mathrm{H}_{n-k-1}(\partial M) \\
\downarrow{\scriptstyle \delta} & \uparrow{\scriptstyle \partial} & \downarrow{\scriptstyle i_*} \\
\mathrm{H}^{k+1}(M,\partial M) \times \mathrm{H}_n(M,\partial M) & \xrightarrow{\cap} & \mathrm{H}_{n-k-1}(M).
\end{array}$$

The upper part of this diagram commutes by the Cap Product-Naturality Lemma 116.8 applied to the map $(B,\partial B,\varnothing) \to (\partial M,A,\varnothing)$ between excisive triads. The lower part commutes by the Cap Product-Connecting Homomorphism Lemma 116.10 (1) applied to the triple $(M,\partial M,A)$. This discussion, together with $(*)$, implies that the third rectangle of the diagram in the claim commutes.

This concludes the proof of the claim and thus also of the Poincaré Duality Theorem 119.1. ■

Remark. It follows from the Poincaré Duality Theorem 119.1 and Corollary 114.12 that if X is a topological space that is homotopy equivalent to a closed orientable n-dimensional topological manifold, then there exists a $\phi \in \mathrm{H}_n(X;\mathbb{Z})$ such that for any $k \in \mathbb{N}_0$ the map

$$- \cap \phi \colon \mathrm{H}^k(X;\mathbb{Z}) \ \to \ \mathrm{H}_{n-k}(X;\mathbb{Z})$$

is an isomorphism. One can ask to what degree the converse holds. Namely, if say a CW-complex X admits such a ϕ, is X homotopy equivalent to a closed orientable topological manifold? We will discuss this question on page **??**.

We conclude this section with two propositions that relate Poincaré Duality on a manifold to Poincaré Duality on its boundary.

Proposition 119.25. Let M be a compact n-dimensional topological manifold with non-empty boundary. Let R be a commutative ring. We suppose that M is R-oriented. We equip the boundary ∂M with the R-orientation given by the Topological Manifold-Boundary Orientation Proposition 105.19. As usual we denote by $[M] \in \mathrm{H}_n(M,\partial M;R)$ and $[\partial M] \in \mathrm{H}_{n-1}(\partial M;R)$ the corresponding R-fundamental classes. We consider the following diagram:

$$\begin{array}{ccccccccc}
\ldots \to \mathrm{H}^k(M,\partial M;R) & \longrightarrow & \mathrm{H}^k(M;R) & \longrightarrow & \mathrm{H}^k(\partial M;R) & \xrightarrow{\delta} & \mathrm{H}^{k+1}(M,\partial M;R) & \to \ldots \\
\cong\downarrow{\scriptstyle -\cap[M]} & & \cong\downarrow{\scriptstyle -\cap[M]} & & \cong\downarrow{\scriptstyle -\cap[\partial M]} & & \cong\downarrow{\scriptstyle -\cap[M]} & \\
\ldots \longrightarrow \mathrm{H}_{n-k}(M;R) & \longrightarrow & \mathrm{H}_{n-k}(M,\partial M;R) & \to & \mathrm{H}_{n-k-1}(\partial M;R) & \longrightarrow & \mathrm{H}_{n-k-1}(M;R) & \xrightarrow{\partial} \ldots
\end{array}$$

where the horizontal sequences are the long exact sequences in (co-) homology of the pair $(M,\partial M)$. (Note that the vertical maps are isomorphisms by Theorem 119.1.) The first and the third square commute, furthermore the second square commutes up to the sign $(-1)^k$.

Proof. We had implicitly proved the proposition in the above proof of the Poincaré Duality Theorem 119.1 applied to the special case that $A = \varnothing$ and $B = \partial M$. ■

Finally we have the following proposition.

Proposition 119.26. Let M be a compact, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. We denote by $[M] \in \mathrm{H}_n(M, \partial M; R)$ the R-fundamental class. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. We consider the following two diagrams:

$$\begin{array}{ccc} \mathrm{H}_k(M, A; R) & \xrightarrow{\partial} & \mathrm{H}_k(A; R) \\ {\scriptstyle \mathrm{PD}_M}\downarrow & & \downarrow{\scriptstyle \mathrm{PD}_A} \\ \mathrm{H}^{n-k}(M, B; R) & \xrightarrow{w^*} & \mathrm{H}^{n+1-k}(A, \partial A; R) \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{H}_k(A, \partial A; R) & \xrightarrow{w_*} & \mathrm{H}_k(M, B; R) \\ {\scriptstyle \mathrm{PD}_A}\downarrow & & \downarrow{\scriptstyle \mathrm{PD}_M} \\ \mathrm{H}^{n-k}(A; R) & \xrightarrow{\delta} & \mathrm{H}^{n+1-k}(M, A; R). \end{array}$$

The first diagram commutes up to multiplication by $(-1)^k$ whereas the second commutes as it is.

Proof. We already showed on page 2642 that the first diagram commutes up to multiplication by $(-1)^k$. The fact that the second diagram commutes is a fairly straightforward consequence of the Cap Product-Connecting Homomorphism Lemma 116.10. We leave it to the reader to fill in the details. ■

Exercises for Chapter 119.

Exercise 119.1. Let M be a closed 0-connected n-dimensional topological manifold. We suppose there exists an $(n+1)$-dimensional topological manifold N such that for every $i \in \{1, \ldots, n\}$ we have $\widetilde{\mathrm{H}}_i(N) \cong \mathrm{H}_{i-1}(M)$. Show that M is a homology n-sphere, i.e. show that $\mathrm{H}_i(M) \cong \mathrm{H}_i(S^n)$ for all $i \in \mathbb{N}_0$.
Remark. In view of the Suspension-H_*-Proposition 76.7 this exercise can be viewed as a variation on Exercise 76.8.

Exercise 119.2. Let M and N be two closed orientable connected non-empty 3-dimensional topological manifolds such that $\pi_1(M)$ is isomorphic to $\pi_1(N)$. Show that for all $i \in \mathbb{N}_0$ there exists an isomorphism $\mathrm{H}_i(M; \mathbb{Z}) \cong \mathrm{H}_i(N; \mathbb{Z})$.
Remark. This exercise is almost identical to Exercise 103.4.

Exercise 119.3.

(a) Let M be an n-dimensional closed orientable connected topological manifold such that $\pi_1(M)$ is isomorphic to the permutation group S_5. What can you say about $\mathrm{H}^{n-1}(M; \mathbb{Z})$? Does the answer depend on whether or not M has boundary?
(b) Let M be a non-compact orientable topological manifold. Show that the group $\mathrm{H}_{n-1}(M, \partial M; \mathbb{F}_2)$ is non-zero.

Exercise 119.4. Let $p\colon \widetilde{N} \to N$ be a finite covering of a closed, oriented n-dimensional topological manifold. We equip $\widetilde{N}$ with the orientation given by the Topological Manifold-Induced Orientation Lemma 105.17

(a) Let $r \leq s$. Show that given any singular simplex $\sigma\colon \Delta^s \to N$ and any cochain $\phi \in \mathrm{C}^r(N;\mathbb{Z})$ we have

$$p^*(\phi) \cap p^*(\sigma) \;=\; p^*(\phi \cap \sigma).$$

Here p^* for homology classes denotes the transfer map.

(b) Show that for any $k \in \mathbb{N}_0$ the Umkehr map $p^!\colon \mathrm{H}_k(N;\mathbb{Z}) \to \mathrm{H}_k(\widetilde{N};\mathbb{Z})$ equals the transfer map p^*.
Hint. the Fundamental Class-Covering Proposition 106.25 might be useful.

Exercise 119.5. Is the Klein bottle the boundary of a compact 3-dimensional topological manifold?

Exercise 119.6.

(a) Let M be a topological manifold and let U, V be open subsets such that $M = U \cup V$. Show that given any compact subset $C \subset M$ there exist compact subsets $K \subset U$ and $L \subset V$ such that $C = K \cup L$.

(b) Does statement (a) hold for any topological space?

Exercise 119.7. Let M be a closed connected 4-dimensional topological manifold that is simply connected and with $\chi(M) = 2$. What can you say about the homeomorphism type of M?

Exercise 119.8.

(a) Let W be a closed orientable connected 4-dimensional topological manifold with $\chi(W) = -3$. Show that W admits a finite connected covering $\widetilde{W}$ with $\chi(\widetilde{W}) < -27$.

(b) Is the hypothesis in (a) that W is orientable necessary?

Remark. This exercise is almost identical to Exercise 103.5.

Exercise 119.9. Let M be a closed 4-dimensional topological manifold.

(a) Show that if M is simply connected, then there exist at most finitely many isomorphism classes of finite groups which can act discretely on M.

(b) Is the hypothesis in (a) that M is simply connected necessary?

Exercise 119.10. Let M be a compact orientable 4-dimensional topological manifold with $\partial M = A \sqcup B$ where A and B are two connected 3-dimensional topological manifolds with $\mathrm{H}_1(A;\mathbb{Z})$ finite. We suppose that the inclusion induced map $\mathrm{H}_1(A;\mathbb{Z}) \to \mathrm{H}_1(M;\mathbb{Z})$ is an epimorphism. Show that the inclusion induced map $\mathrm{H}_1(B;\mathbb{Z}) \to \mathrm{H}_1(M;\mathbb{Z})$ is a monomorphism.

Exercise 119.11. Let M be a closed orientable connected odd-dimensional topological manifold and let $f\colon M \to M$ be a map such that the induced map $f_*\colon \mathrm{H}_n(M) \to \mathrm{H}_n(M)$ is an isomorphism. Show that the Lefschetz number

$$\Lambda(\varphi) \;=\; \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \mathrm{tr}(\varphi_*\colon \mathrm{H}_n(M) \to \mathrm{H}_n(M)),$$

equals zero.
Remark. This exercise is almost identical to Exercise 103.6.

Exercise 119.12. Let M be a closed oriented connected n-dimensional topological manifold. Furthermore let $i \in \{0, \dots, n\}$ and let $v_1, \dots, v_m$ be a basis of $\mathrm{FH}^i(M;\mathbb{Z})$. Show that there exists a basis $\widetilde{v}_1, \dots, \widetilde{v}_m$ of $\mathrm{FH}^{n-i}(M;\mathbb{Z})$ such that for any $k, l \in \{1, \dots, m\}$ we have $\langle v_k \cup \widetilde{v}_l, [M]\rangle = \delta_{kl}$.

Exercise 119.13. Let M be a compact oriented connected n-dimensional topological manifold. We say M is an *n-dimensional homotopy ball* if $\pi_i(M) = 0$ for $i \geq 1$ and if $\pi_1(\partial M) = \{e\}$. Show that if M is an n-dimensional homotopy ball, then ∂M is an homotopy $(n-1)$-sphere, as defined in Exercise 119.13.

Exercise 119.14. Let $n \in \mathbb{N}_{\geq 2}$ and let M be a compact oriented connected n-dimensional topological manifold. Suppose that there exists a degree one map $f\colon (\overline{B}^n, S^{n-1}) \to (M, \partial M)$. Show that M is an n-dimensional homotopy ball.

Exercise 119.15. Let M be a compact oriented connected n-dimensional topological manifold. Let Y be a boundary component of M which is homeomorphic to S^{n-1}. Show that either $[Y] \neq 0 \in \pi_{n-1}(M)$ or M is a homotopy ball, as defined in Exercise 119.13.
Hint. Show that if $[Y] = 0$, then there exists a degree one map $(\overline{B}^n, S^{n-1}) \to (M, Y)$. Now use Exercise 119.14.

Exercise 119.16. Let $f\colon M \to N$ be a homeomorphism between two compact oriented connected n-dimensional topological manifolds and let A, B be two compact $(n-1)$-dimensional submanifolds of ∂M with $A \cup B = \partial M$, $A \cap B = \partial A = \partial B$. Show that for any $\sigma \in \mathrm{H}_k(M, A)$ we have

$$f^*(\mathrm{PD}_N(f_*(\sigma)) \;=\; \begin{cases} \mathrm{PD}_M(\sigma), & \text{if } \sigma \text{ is orientation-preserving,} \\ -\mathrm{PD}_M(\sigma), & \text{if } \sigma \text{ is orientation-reversing.} \end{cases}$$

Remark. This exercise consists mostly of collecting fairly standard facts.

Exercise 119.17. Let M be an oriented connected non-empty n-dimensional topological manifold. As in Exercise 106.5 we consider the group $\overleftarrow{\mathrm{H}}_n(M;\mathbb{Z}) := \varprojlim \mathrm{H}_n(M, M \setminus K; G)$. In Exercise 106.7 we showed that $\overleftarrow{\mathrm{H}}_n(M;\mathbb{Z})$ is isomorphic to $\mathbb{Z}$ and we showed that there exists a natural generator $[M]$. Let $k \in \mathbb{N}_0$.

(a) Let $\cap\colon \mathrm{H}_{\mathrm{c}}^{n-k}(M;\mathbb{Z}) \times \overleftarrow{\mathrm{H}}_n(M;\mathbb{Z}) \to \mathrm{H}_k(M;\mathbb{Z})$ be the natural cap product that we introduced in Exercise 116.4. Show that the map $\mathrm{H}_{\mathrm{c}}^{n-k}(M;\mathbb{Z}) \to \mathrm{H}_k(M;\mathbb{Z})$ given by capping with $[M]$ defines an isomorphism.
Remark. Use Lemma 119.17.

(b) Now let $f\colon M \to N$ be a proper map between two connected orientable non-empty n-dimensional topological manifolds. Since f is proper we obtain by Exercise 106.5 an induced map $f_*\colon \overleftarrow{\mathrm{H}}_k(M;\mathbb{Z}) \to \overleftarrow{\mathrm{H}}_k(N;\mathbb{Z})$. We define $\deg(f) \in \mathbb{Z}$ via the equality $f_*([M]) = \deg(f) \cdot [N]$. Furthermore, using (a), we can define the Umkehr map $f^!\colon \overleftarrow{\mathrm{H}}_k(N;\mathbb{Z}) \to \overleftarrow{\mathrm{H}}_k(M;\mathbb{Z})$. Show that the map $f^! \circ f_*\colon \mathrm{H}_k(M;\mathbb{Z}) \to \mathrm{H}_k(M;\mathbb{Z})$ is given by multiplication by $\deg(f)$.

Remark. The goal of this exercise is to generalize the ideas and concepts behind the Umkehr Map Proposition 119.13 to the setting of non-compact topological manifolds.

Exercise 119.18. Recall that given a topological space X we defined on page 2547 its *cup length* $\mathrm{cl}(X) \in \mathbb{N}_0 \cup \{\infty\}$ as follows:

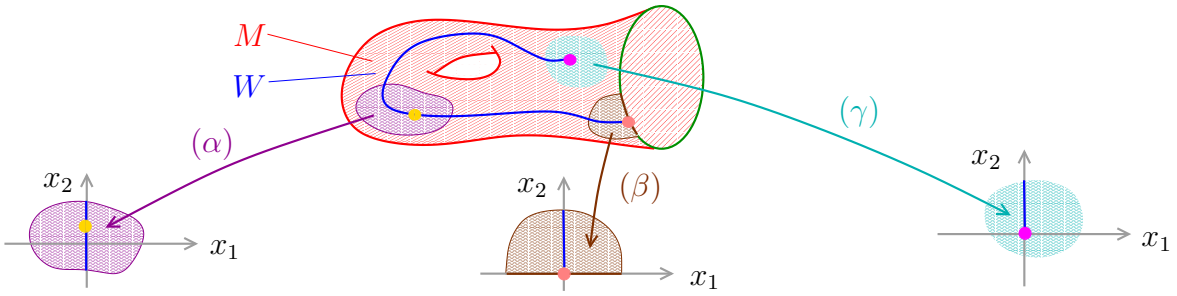
$$\mathrm{cl}(X) \;:=\; \max\left\{ n \in \mathbb{N}_0 \;\middle|\; \begin{array}{c} \text{there exists a commutative ring } R \text{ and } R\text{-cohomology} \\ \text{classes } x_1, \ldots, x_n \text{ in degrees} \geq 1 \text{ with } x_1 \cup \cdots \cup x_n \neq 0 \end{array} \right\}.$$

Let M and N be two closed oriented connected n-dimensional topological manifolds. Show that if there exists a map $f\colon M \to N$ of degree one, then $\mathrm{cl}(M) \geq \mathrm{cl}(N)$.
Remark. At least in spirit this exercise is related to the Rudyak Conjecture 115.16.

Exercise 119.19. Let M be a closed simply connected 4-dimensional topological manifold. Show that $\mathrm{H}_1(M;\mathbb{Z}) = 0$, $\mathrm{H}_3(M;\mathbb{Z}) = 0$ and show that $\mathrm{H}_2(M;\mathbb{Z})$ is torsion-free.

Exercise 119.20. Let X and Y be compact oriented connected non-empty n-dimensional topological manifolds and let $f\colon X \to Y$ be a map of degree one. Does it follow that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_k(X;\mathbb{Z}) & \xrightarrow{\quad f_* \quad} & \mathrm{H}_k(Y;\mathbb{Z}) \\ {\scriptstyle \mathrm{PD}_X}\big\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\big\downarrow{\scriptstyle \mathrm{PD}_Y} \\ \mathrm{H}^{n-k}(X;\mathbb{Z}) & \xleftarrow{\quad f^* \quad} & \mathrm{H}^{n-k}(Y;\mathbb{Z})\,? \end{array}$$



Exercise 119.21. Let M be a compact orientable n-dimensional topological manifold. Determine the homology groups of the double $\mathrm{D}M$ in terms of the homology groups of M.
Remark. It is tempting to use Mayer–Vietoris sequences, but this will most likely not lead very far. At some stage in the calculation it will be helpful to use the Poincaré Duality Theorem 119.1.

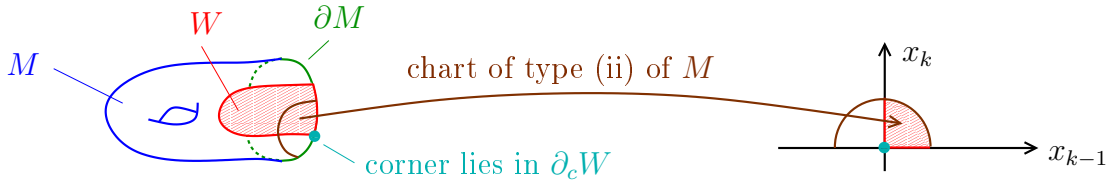
Exercise 119.22. Let M be a compact orientable 3-dimensional topological manifold such that $\mathrm{H}_1(M;\mathbb{Z})$ is torsion-free. We denote by $i\colon \partial M \to M$ the inclusion. Show that there exists a subgroup G of $\mathrm{H}_1(M;\mathbb{Z})$ such that $\mathrm{H}_1(M;\mathbb{Z}) = i_*(\mathrm{H}_1(\partial M;\mathbb{Z})) \oplus G$.

120. Poincaré Duality and codimension-zero submanifolds

In this short chapter we will study the interplay between Poincaré Duality on a given compact topological manifold M and on a given codimension-zero submanifold W of M. Later on, in the applications of this chapter's results, we will also deal with submanifolds with corner, so we will use this opportunity to finally introduce the notion of a submanifold with corner. The results and concepts of this chapter we will be used on several occasions. Nonetheless it is safe to skip this chapter and to move on to the next, significantly more entertaining, chapter.

120.1. **Submanifolds with corner.** Recall that on page 524 we defined what it means for a subset W of a manifold M to be a submanifold, namely it means that given any $P \in W$ there is a chart for M of one of the three types (α), (β) and (γ) that are defined properly on page 524 and that are sketched in the figure below.

Now we introduce the more general notion of a submanifold with corner.



Definition. Let M be an n-dimensional topological manifold. We say a subset $W \subset M$ is a k-dimensional submanifold with corner[1474] if for every $P \in W$ there exists a chart of the type (α), (β) and (γ) from page 524 or if

(δ) there exists a chart $\Phi\colon U \to V$ of type (ii)[1475] for M such that

$$\Phi(U \cap W) \subset \{(0,\dots,0,x_1,\dots,x_k)\,|\,x_1,\dots,x_k \in \mathbb{R} \text{ with } x_{k-1} \geq 0 \text{ and } x_k \geq 0\}$$

and with $\Phi(P) \in \{(0,\dots,0,x_1,\dots,x_{k-2},0,0)\,|\,x_1,\dots,x_{k-2} \in \mathbb{R}\}$.

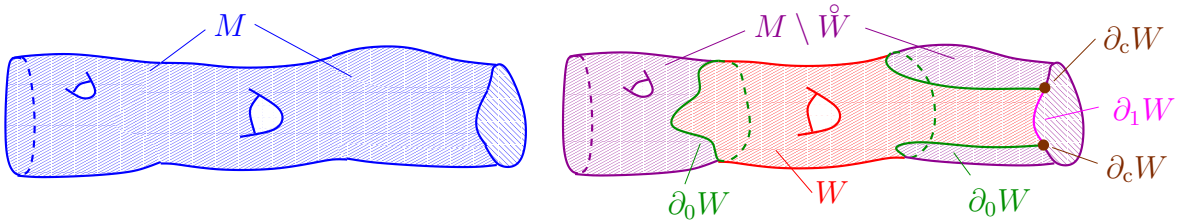
If M is an n-dimensional smooth manifold, then we demand that the charts come from the maximal smooth atlas. We refer to the set of points in W that admit a chart of type (δ) as the corner set of W and we denote it by $\partial_c W$.

Remark. Throughout these lecture notes we will only consider submanifolds with corner of codimension *zero*. But the concept can of course also play a role for other codimensions.

[1474] Often in the literature such objects are called "submanifold with corners". Following [**Wall2016**, p. 30] we write "submanifold with corner" instead.

[1475] See page 511 for the definition of a chart of type (ii).

The following lemma also introduces a notation that we will use throughout these notes.



Lemma 120.1. Let M be an n-dimensional topological manifold and let W be a compact codimension-zero submanifold with corner. We write

$$\partial_0 W \;:=\; W \cap \overline{M \setminus W} \quad \text{and} \quad \partial_1 W \;:=\; W \cap \partial M.$$

The following five statements hold:

(1) The subset W itself is an n-dimensional topological manifold.
(2) The boundary of the topological manifold W equals $\partial_0 W \cup \partial_1 W$. Furthermore $\partial_0 W$ and $\partial_1 W$ are $(n-1)$-dimensional submanifolds of the boundary ∂W such that
$$\partial_0 W \cap \partial_1 W \;=\; \partial(\partial_0 W) \;=\; \partial(\partial_1 W) \;=\; \partial_{\mathrm{c}} W.$$
(3) The set $\mathring{W} := W \setminus \partial_0 W$ is the interior of W in M, in particular $\mathring{W}$ is an open subset of M.
(4) The subset $M \setminus \mathring{W}$ is a codimension-zero submanifold of M with corner given by $\partial_{\mathrm{c}}(M \setminus \mathring{W}) = \partial_{\mathrm{c}} W$. Furthermore $\partial_0(M \setminus \mathring{W}) = \partial_0 W$ and $\partial_1(M \setminus \mathring{W}) = \overline{\partial M \setminus \partial_1 W}$.
(5) $\partial_0 W$ is a proper submanifold of M, in the sense of the definition on page 525.

The analogous statements also hold if we replace "topological" by "smooth".

Remark. Let M be a topological manifold and let W be a submanifold in the sense of the definition on page 524. Evidently it is also a submanifold with corner. Furthermore note that it follows from Proposition 75.3 (1) together with Lemma 120.1 that $\partial_{\mathrm{c}} W = \varnothing$.

Sketch of proof. In the proof that W itself is a (topological) manifold we only have to worry about the corners. But for these we can use the approach taken in Proposition **??** to find a (smooth) atlas. The remaining statements follow reasonably easily from the Topological Manifold Boundary Proposition 75.2 and the definitions. We leave the slightly annoying task of filling in the details to the reader. ■

In the following we will generalize a few results on codimension-zero submanifolds to codimension-zero submanifolds with corner. It is unlikely that the reader's pulse will quicken while reading the remainder of this section.
First we have the following variation on the Excision Theorem 75.10 for Topological Manifolds.

Theorem 120.2. (Excision Theorem for Submanifolds with Corner) Let M be an n-dimensional topological manifold and let W be a compact codimension-zero submanifold of M with corner. We write $\mathring{W} := W \setminus \partial_0 W$. For every $k \in \mathbb{N}_0$ and every abelian group G

the inclusion induced maps

$$\begin{array}{lrcl} \text{(a)} & \mathrm{H}_k(W, \partial_0 W; G) & \xrightarrow{\cong} & \mathrm{H}_k(M, M \setminus \mathring{W}; G) \\ \text{(b)} & \mathrm{H}_k(W, \partial W; G) & \xrightarrow{\cong} & \mathrm{H}_k(M, \underbrace{(M \setminus \mathring{W}) \cup \partial M}_{(M \setminus \mathring{W}) \cup \partial_1 W}; G) \\ \text{(c)} & \mathrm{H}_k(W, \partial_1 W; G) & \xrightarrow{\cong} & \mathrm{H}_k(W \cup \partial M, \partial M; G) \end{array}$$

are isomorphisms. Similarly, all maps in cohomology "in the other direction" are also isomorphisms.

Proof. We will prove the statements on homology groups with $\mathbb{Z}$-coefficients in Exercise 120.2. The statement for homology with G-coefficients and the statement for cohomology with G-coefficients are an immediate consequence of the above together with Corollaries 89.18 and 108.20. ■

We turn to the topic of orientations and fundamental classes. First we have the following lemma which generalizes the Topological Manifold-Induced Orientation Lemma 105.17 (2).

Lemma 120.3. Let R be a commutative ring and let M be a topological manifold that is equipped with an R-orientation. If W is a codimension-zero submanifold of M with corner, then W admits a unique R-orientation such that the inclusion map $N \to M$ is orientation-preserving.

Proof. This statement follows immediately from the Topological Manifold-Induced Orientation Lemma 105.17 (1). ■

Convention. Let M be a topological manifold and let W be a codimension-zero submanifold with corner. If M is oriented, then we equip W with the orientation coming from Lemma 120.3.

The following lemma is a generalization of the Codimension Zero-Fundamental Class Lemma 106.24.

Lemma 120.4. Let M be a compact oriented n-dimensional topological manifold. Furthermore let $W \subset M$ be a compact non-empty codimension-zero submanifold *with corner*. We write $\mathring{W} = W \setminus \partial W$. The following two statements hold:

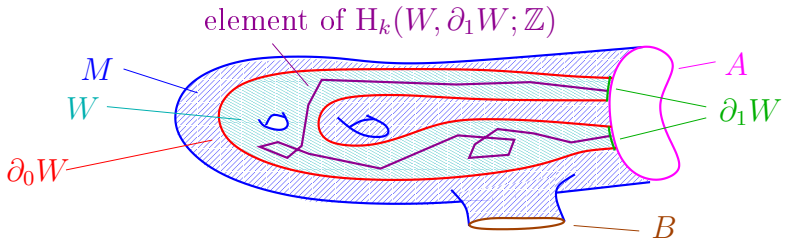
(1) The inclusion induced map $\mathrm{H}_n(W, \partial W; \mathbb{Z}) \to \mathrm{H}_n(M, (M \setminus \mathring{W}) \cup \partial_1 W; \mathbb{Z})$ is an isomorphism.

(2) The image of the fundamental classes $[M] \in \mathrm{H}_n(M, \partial M; \mathbb{Z})$ and $[W] \in \mathrm{H}_n(W, \partial W; \mathbb{Z})$ under the maps

$$\mathrm{H}_n(M, \partial M; \mathbb{Z}) \longrightarrow \mathrm{H}_n(M, (M \setminus \mathring{W}) \cup \partial_1 W; \mathbb{Z}) \underset{\substack{\uparrow \\ \text{isomorphism by the Excision Theorem 120.2 (2)}}}{\longleftarrow} \mathrm{H}_n(W, \partial W; \mathbb{Z})$$

agree.

Proof. The proof of Lemma 120.4 is basically identical to the proof of the Codimension Zero-Fundamental Class Lemma 106.24. ■



120.2. **Poincaré Duality and codimension-zero submanifolds.** The following lemma says that given a homology class in a codimension-zero submanifold W of some topological manifold M we can apply Poincaré Duality in M or W and essentially we end up with the same result.

Lemma 120.5. (Codimension-Zero Submanifold-PD Lemma) Let M be a compact oriented n-dimensional topological manifold and let W be a compact codimension-zero with corner. We equip W with the induced orientation from the Topological Manifold-Induced Orientation Lemma 105.17. We write $\mathring{W} = W \setminus \partial_0 W$.[1476] Furthermore let A and B be disjoint unions of components of ∂M with $\partial M = A \cup B$ and $\partial_1 W \subset A$. We fix the following notation:

(1) We denote by w the obvious map $(W, \partial_1 W) \to (M, A)$ and also the obvious map $(W, \partial_0 W) \to (M, M \setminus \mathring{W})$,
(2) we denote by $p\colon (M, B) \to (M, M \setminus \mathring{W})$ the obvious map.

Then for every $k \in \mathbb{N}_0$ the following diagram commutes[14771478]

$$\begin{array}{ccccc} \mathrm{H}_k(W, \partial_1 W; \mathbb{Z}) & \xrightarrow{\mathrm{PD}_W} & \mathrm{H}^{n-k}(W, \partial_0 W; \mathbb{Z}) & \xrightarrow[\cong]{(w^*)^{-1}} & \mathrm{H}^{n-k}(M, M \setminus \mathring{W}; \mathbb{Z}) \\ \downarrow{\scriptstyle w_*} & & & & \downarrow{\scriptstyle p^*} \\ \mathrm{H}_k(M, A; \mathbb{Z}) & & \xrightarrow{\qquad\qquad\mathrm{PD}_M\qquad\qquad} & & \mathrm{H}^{n-k}(M, B; \mathbb{Z}). \end{array}$$

In the proof of Lemmas 120.5 and 120.6 will use the full force of the Cap Product-Naturality Lemma 116.8 applied to excisive triads. Since this can be seriously confusing we recall the general statement of the lemma, before we provide the proof of the Codimension-Zero Submanifold-PD Lemma 120.5.

Lemma 116.8. Let $f\colon (X, A, B) \to (\widetilde{X}, \widetilde{A}, \widetilde{B})$ be a map between two excisive triads. Then for any choice of $\varphi \in \mathrm{H}^{n-k}(\widetilde{X}, \widetilde{A}; \mathbb{Z})$ and $\sigma \in \mathrm{H}_m(X, A \cup B; \mathbb{Z})$ we have

$$\begin{array}{c} f_*\colon \mathrm{H}_m(X, A \cup B) \to \mathrm{H}_m(\widetilde{X}, \widetilde{A} \cup \widetilde{B}) \qquad f^*\colon \mathrm{H}^{n-k}(\widetilde{X}, \widetilde{A}) \to \mathrm{H}^{n-k}(X, A) \\ \varphi \cap \underset{\downarrow}{f_*}(\sigma) \;=\; \underset{\uparrow}{f_*}(\underset{\downarrow}{f^*}(\varphi) \cap \sigma) \;\in\; \mathrm{H}_k(\widetilde{X}, \widetilde{B}; \mathbb{Z}). \\ f_*\colon \mathrm{H}_k(X, B) \to \mathrm{H}_k(\widetilde{X}, \widetilde{B}) \end{array}$$

Proof of the Codimension-Zero Submanifold-PD Lemma 120.5. By definition of the isomorphisms PD_W and PD_M, proving the lemma is equivalent to proving that the

[1476] Recall that by Proposition 75.3 the set $\mathring{W} = W \setminus \partial_0 W$ is indeed the interior of W in M.
[1477] Here we use that by the Excision Theorem 120.2 we know that $w\colon (W, \partial_0 W) \to (M, M \setminus \mathring{W})$ induces an isomorphism on cohomology groups.
[1478] Note that by Lemma 120.1 we can apply the Poincaré Duality Theorem 119.1 to obtain that $\cap[W]\colon \mathrm{H}^{n-k}(W, \partial_1 W; \mathbb{Z}) \to \mathrm{H}_k(W, \partial_0 W; \mathbb{Z})$ is an isomorphism. We denote its inverse by PD_W.

following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}_k(W,\partial_1 W;\mathbb{Z}) & \xleftarrow[\cong]{\cap[W]} & \mathrm{H}^{n-k}(W,\partial_0 W;\mathbb{Z}) & \xleftarrow[w^*]{\cong} & \mathrm{H}^{n-k}(M,M\setminus \mathring{W};\mathbb{Z}) \\ \downarrow{\scriptstyle w_*} & & & & \downarrow{\scriptstyle p^*} \\ \mathrm{H}_k(M,A;\mathbb{Z}) & \xleftarrow[\cong]{\cap[M]} & & & \mathrm{H}^{n-k}(M,B;\mathbb{Z}). \end{array}$$

In the following we use the following notation:

(1) We write $\widehat{W} := W \setminus \partial W$.
(2) We denote the map $(W,\partial W) \to (M, M\setminus \widehat{W})$ by w as well
(3) We denote the map $(M,\partial M) \to (M, M\setminus \widehat{W})$ by p as well.

Now let $\beta \in \mathrm{H}^{n-k}(M, M\setminus \mathring{W};\mathbb{Z})$. We have the following equality in $\mathrm{H}_k(M,A;\mathbb{Z})$:

$$\begin{array}{ccccccc} w_*(w^*(\beta)\cap[W]) & \underset{\uparrow}{=} & \beta\cap w_*([W]) & \underset{\uparrow}{=} & \beta\cap p_*([M]) & \underset{\uparrow}{=} & p_*(\overbrace{p^*(\beta)\cap[M]}^{\in \mathrm{H}_k(M,A)}) \underset{\uparrow}{=} p^*(\beta)\cap[M]. \\ \text{Cap Product-Naturality} & & \text{by Lemma 120.4 we have } p_*([M]) = w_*([W]) \in \mathrm{H}_m(M, M\setminus\widehat{W}) & & \text{Cap Product-Naturality} & & \text{since } p\colon (M,A)\to(M,A) \\ \text{Lemma 116.8 applied to the map} & & \downarrow & & \text{Lemma 116.8 applied to the map} & & \text{is id we have } p_* = \mathrm{id}_* = \mathrm{id} \\ w\colon (W,\partial_0 W,\partial W)\to(M, M\setminus\mathring{W}, M\setminus\widehat{W}) & & & & p\colon (M,B,A)\to(M,M\setminus\mathring{W},A) & & \end{array}$$

We have thus shown that the above diagram does indeed commute. ■

We conclude this short introduction to submanifolds with corner with the following lemma that also relates Poincaré Duality in a topological manifold M to Poincaré Duality in a compact submanifold W with corner.

Lemma 120.6. Let M be a compact oriented n-dimensional topological manifold and let W be a compact codimension-zero submanifold with corner. Furthermore let A and B be disjoint unions of components of ∂M with $\partial M = A \cup B$. We fix the following notation:

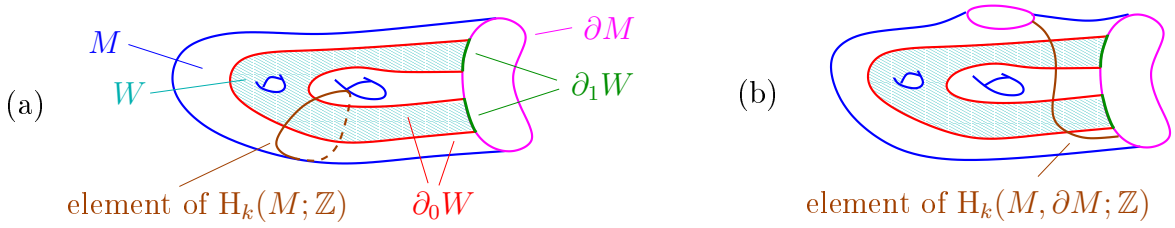
(1) we set $C := \partial_1 W \cap A$ and $D := (\partial_1 W \cap B) \cup \partial_0 W$,
(2) we set $\mathring{W} := W \setminus \partial_0 W$,
(3) the obvious maps $(W,C)\to(M,A)$ and $(W,D)\to(M,(M\setminus\mathring{W})\cup B)$ are denoted by w, and
(4) we denote by $p\colon (M,B)\to(M,M\setminus\mathring{W})$ the obvious map.

Then for every $k\in\mathbb{N}_0$ the following diagram commutes [1479]

$$\begin{array}{ccccc} \mathrm{H}_k(M,B;\mathbb{Z}) & & \xrightarrow{\mathrm{PD}_M} & & \mathrm{H}^{n-k}(M,A;\mathbb{Z}) \\ \downarrow{\scriptstyle p_*} & & & & \downarrow{\scriptstyle w^*} \\ \mathrm{H}_k(M,(M\setminus\mathring{W})\cup B;\mathbb{Z}) & \xrightarrow[\cong]{(w_*)^{-1}} & \mathrm{H}_k(W,D;\mathbb{Z}) & \xrightarrow{\mathrm{PD}_W} & \mathrm{H}^{n-k}(W,C;\mathbb{Z}). \end{array}$$

Example. We continue with the notation from the previous lemma. If we set $A := \partial M$ and $B := \varnothing$, then $C = \partial_1 W$ and $D = \partial_0 W$ and we obtain that the following diagram

[1479] We use that $w\colon (W,D)\to(M,(M\setminus\mathring{W})\cup B)$ induces an isomorphism on cohomology. This follows from a slight generalization of the Excision Theorem 120.2.



commutes:

$$\text{(a)}\qquad \begin{array}{ccccc} \mathrm{H}_k(M;\mathbb{Z}) & & \xrightarrow{\quad\mathrm{PD}_M\quad} & & \mathrm{H}^{n-k}(M,\partial M;\mathbb{Z}) \\ \downarrow{\scriptstyle p_*} & & & & \downarrow{\scriptstyle w^*} \\ \mathrm{H}_k(M, M\setminus \mathring{W};\mathbb{Z}) & \xrightarrow[\cong]{(w_*)^{-1}} & \mathrm{H}_k(W,\partial_0 W;\mathbb{Z}) & \xrightarrow{\mathrm{PD}_W} & \mathrm{H}^{n-k}(W,\partial_1 W;\mathbb{Z}). \end{array}$$

Furthermore, if we set $A := \varnothing$ and $B := \partial M$, then $C = \varnothing$ and $D = \partial W$, and we see that the following diagram commutes:

$$\text{(b)}\qquad \begin{array}{ccccc} \mathrm{H}_k(M,\partial M;\mathbb{Z}) & & \xrightarrow{\quad\mathrm{PD}_M\quad} & & \mathrm{H}^{n-k}(M;\mathbb{Z}) \\ \downarrow{\scriptstyle p_*} & & & & \downarrow{\scriptstyle w^*} \\ \mathrm{H}_k(M,(M\setminus \mathring{W})\cup\partial M;\mathbb{Z}) & \xrightarrow[\cong]{(w_*)^{-1}} & \mathrm{H}_k(W,\partial W;\mathbb{Z}) & \xrightarrow{\mathrm{PD}_W} & \mathrm{H}^{n-k}(W;\mathbb{Z}). \end{array}$$

These two important special cases are illustrated in the figure below.

Proof. We set $\widehat{W} := W \setminus (\partial_0 W \cup C)$. Note that $M \setminus \widehat{W} = (M \setminus \mathring{W}) \cup B$. By definition of the isomorphisms PD_W and PD_M, proving the lemma is equivalent to proving that the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}_k(M,B;\mathbb{Z}) & & \xleftarrow[\cong]{\cap[M]} & & \mathrm{H}^{n-k}(M,A;\mathbb{Z}) \\ \downarrow{\scriptstyle p_*} & & & & \downarrow{\scriptstyle w^*} \\ \mathrm{H}_k(M, M\setminus \widehat{W};\mathbb{Z}) & \xleftarrow[\cong]{w_*} & \mathrm{H}_k(W,D;\mathbb{Z}) & \xleftarrow{\cap[W]} & \mathrm{H}^{n-k}(W,C;\mathbb{Z}). \end{array}$$

So let $\beta \in \mathrm{H}^{n-k}(M,A;\mathbb{Z})$. We have the following equalities in $\mathrm{H}_k(M, M\setminus \mathring{W};\mathbb{Z})$:

$$\begin{array}{ccccc} p_*(\beta\cap[M]) & = & \beta\cap p_*([M]) & = & \beta\cap w_*([W]) \\ \uparrow & & \uparrow & & \uparrow \\ \text{Cap Product-Naturality Lemma 116.8 applied to the map } p\colon (M,A,B)\to(M,A,M\setminus\widehat{W}) \text{ of excisive triads} & & \text{by Lemma 120.4 we have } p_*([M])=w_*([W]) \text{ in } \mathrm{H}_n(M,(M\setminus\mathring{W})\cup\partial M) & & \text{Cap Product-Naturality Lemma 116.8 applied to the map } w\colon (W,C,D)\to(M,A,M\setminus\widehat{W}) \text{ of excisive triads} \end{array} = w_*(w^*(\beta)\cap[W]).$$

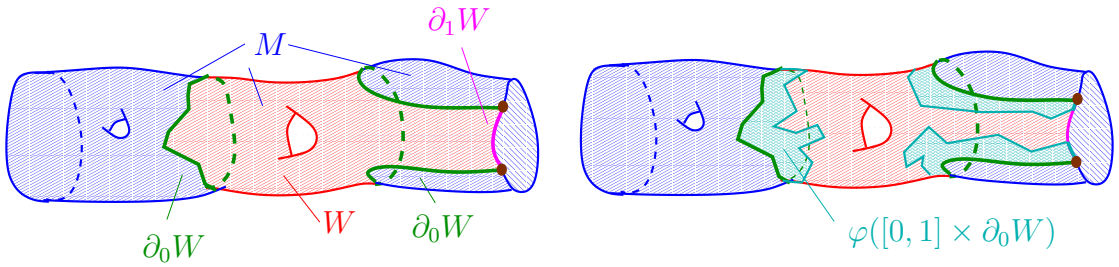
■

Exercises for Chapter 120.

Exercise 120.1. Let M be an n-dimensional topological manifold and let W be a compact codimension-zero submanifold of M with corner. Show that there exists an embedding $\varphi\colon [0,1]\times\partial_0 W \to W$ with the following two properties:

(1) For every $x \in \partial_0 W$ we have $\varphi(0,x) = x$.

(2) For every $t \in [0,1]$ and every $x \in \partial_c W = \partial(\partial_0 W)$ we have $\varphi(t,x) \in \partial_1 W$.



Hint. Adapt the proof of the Topological Collar Neighborhood Theorem 75.5.

Exercise 120.2. Let M be an n-dimensional topological manifold and let W be a compact codimension-zero submanifold of M with corner. We write $\mathring{W} := W \setminus \partial_0 W$. Show that for every $k \in \mathbb{N}_0$ the inclusion induced maps

$$\begin{array}{lrcl} \text{(a)} & \mathrm{H}_k(W, \partial_0 W) & \xrightarrow{\cong} & \mathrm{H}_k(M, M \setminus \mathring{W}) \\ \text{(b)} & \mathrm{H}_k(W, \partial W) & \xrightarrow{\cong} & \mathrm{H}_k(M, (M \setminus \mathring{W}) \cup \partial M) \\ \text{(c)} & \mathrm{H}_k(W, \partial_1 W) & \xrightarrow{\cong} & \mathrm{H}_k(W \cup \partial M, \partial M) \end{array}$$

are isomorphisms.

Remark. This exercise is a variation on the Excision Theorem 75.10 for Topological Manifolds. You might want to use Exercise 120.1.

Part XIII

Applications of Poincaré Duality

121. The cup product of projective spaces

In this chapter we will use the Poincaré Duality Theorem 119.1 to determine the cup product on $\mathrm{H}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and $\mathrm{H}^*(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$. These calculations will allow us to prove several interesting consequences which at first glance have very little to do with cup products.

121.1. **Non-singular pairings and the cup product.** Before we start drawing more conclusions from the Poincaré Duality Theorem 119.1 we need to introduce some purely algebraic definitions.

Definition. Let R be a commutative ring and let V, W and S be R-modules.

(1) A pairing on $V \times W$ is a map
$$\varphi\colon V \times W \ \to \ S$$
such that for all $v, v' \in V$ and $W, w' \in W$ we have $\varphi(v+v', w) = \varphi(v,w) + \varphi(v',w)$ and $\varphi(v, w+w') = \varphi(v,w) + \varphi(v,w')$.[1480]

(2) A pairing is called R-bilinear if it is R-linear in V and if it is R-linear in W.[1481]

(3) We say that an R-bilinear pairing $\langle\ ,\ \rangle\colon V \times W \to S$ is non-singular if the induced maps
$$\begin{array}{ccc} V & \to & \mathrm{Hom}_R(W,S) \\ v & \mapsto & \begin{pmatrix} W & \to & S \\ w & \mapsto & \langle v,w\rangle \end{pmatrix} \end{array} \quad \text{and} \quad \begin{array}{ccc} W & \to & \mathrm{Hom}_R(V,S) \\ w & \mapsto & \begin{pmatrix} V & \to & S \\ v & \mapsto & \langle v,w\rangle \end{pmatrix} \end{array}$$
are isomorphisms. Otherwise we say that the R-bilinear pairing is singular.

We start out with the following elementary lemma.

Lemma 121.1. (Non-Singularity Lemma) Let R be a commutative ring. Let V and W be free R-modules of the same finite rank and let
$$\langle\ ,\ \rangle\colon V \times W \to R$$
be an R-bilinear pairing.

(1) We denote by n the rank of V. Let $v_1, \ldots, v_n$ be a basis for V and let $w_1, \ldots, w_n$ be a basis for W. Then the following statement holds:
$$\text{the pairing } \langle\ ,\ \rangle \text{ is non-singular} \quad \Longleftrightarrow \quad \det(\langle v_i, w_j\rangle)_{i,j=1,\ldots,n}) \text{ is a unit of } R.$$

(2) Suppose V and W are of rank one. If v and w are generators of V respectively W, then the following statement holds:
$$\text{the pairing } \langle\ ,\ \rangle \text{ is non-singular} \quad \Longleftrightarrow \quad \langle v,w\rangle \text{ is a unit of the ring } R.$$

Proof. The second statement is evidently just a special case of the first statement. So it suffices to prove the first statement. Let $v_1, \ldots, v_n$ be a basis for V and let $w_1, \ldots, w_n$ be a basis for W. We denote by $v_1^*, \ldots, v_n^* \in \mathrm{Hom}(V,R)$ and $w_1^*, \ldots, w_n^* \in \mathrm{Hom}(W,R)$ the dual bases. We consider the maps
$$\begin{array}{ccc} V & \to & \mathrm{Hom}_R(W,R) \\ v & \mapsto & \begin{pmatrix} W & \to & R \\ w & \mapsto & \langle v,w\rangle \end{pmatrix} \end{array} \quad \text{and} \quad \begin{array}{ccc} W & \to & \mathrm{Hom}_R(V,R) \\ w & \mapsto & \begin{pmatrix} V & \to & R \\ v & \mapsto & \langle v,w\rangle \end{pmatrix} \end{array}.$$

[1480] In most examples we will be interested in $S = R$, but later on we will, oddly enough, also develop a fondness for $R = \mathbb{Z}$ and $S = \mathbb{Q}/\mathbb{Z}$.

[1481] Note that a pairing is by definition always $\mathbb{Z}$-bilinear.

Since $\langle\ ,\ \rangle$ is R-bilinear both maps are R-homomorphisms. Furthermore, it is straightforward to show that with respect to these bases both the R-homomorphisms are represented by the transpose of the matrix $(\langle v_i, w_j\rangle_{i,j=1,\dots,n})$. The lemma is an immediate consequence of this observation. ■

Remark. The proof of the Non-Singularity Lemma 121.1 shows that if V and W are free R-modules of finite rank, then the pairing is non-singular if and only if either of the two maps $V \to \mathrm{Hom}(W, R)$ or $W \to \mathrm{Hom}(V, R)$ is an isomorphism.[1482]

Now we return to topology.

Proposition 121.2. (Manifold-Non Singularity Proposition) Let M be a closed n-dimensional topological manifold and let $k \in \mathbb{N}_0$.

(1) Suppose M is oriented with fundamental class $[M]$. If $\mathrm{H}_{k-1}(M;\mathbb{Z})$ and $\mathrm{H}_{n-k-1}(M;\mathbb{Z})$ are torsion-free, then the cup product pairing
$$\begin{array}{rcl} \mathrm{H}^k(M;\mathbb{Z}) \times \mathrm{H}^{n-k}(M;\mathbb{Z}) & \to & \mathbb{Z} \\ (\varphi, \psi) & \mapsto & \langle \varphi \cup \psi, [M]\rangle \end{array}$$
is non-singular.

(2) Let $\mathbb{F}$ be a field. If M is $\mathbb{F}$-oriented with fundamental class $[M]$, then for any $k \in \mathbb{N}_0$ the cup product pairing
$$\begin{array}{rcl} \mathrm{H}^k(M;\mathbb{F}) \times \mathrm{H}^{n-k}(M;\mathbb{F}) & \to & \mathbb{F} \\ (\varphi, \psi) & \mapsto & \langle \varphi \cup \psi, [M]\rangle \end{array}$$
is non-singular.

Proof. Let M be a closed n-dimensional topological manifold and let $k \in \mathbb{N}_0$.

(1) We suppose that M is oriented with fundamental class $[M]$ and we suppose that $\mathrm{H}_{k-1}(M;\mathbb{Z})$ and $\mathrm{H}_{n-k-1}(M;\mathbb{Z})$ are torsion-free. It follows from the Topological Manifolds-Invariants Proposition 104.14 (4), our hypothesis on $\mathrm{H}_{k-1}(M;\mathbb{Z})$ and $\mathrm{H}_{n-k-1}(M;\mathbb{Z})$, the classification of finitely generated abelian groups, the Ext-Calculation Lemma 110.5 (3) and the Universal Coefficient Theorem 110.12 that $\mathrm{H}_{k-1}(M;\mathbb{Z})$, $\mathrm{H}_{n-k-1}(M;\mathbb{Z})$, $\mathrm{H}^k(M;\mathbb{Z})$ and $\mathrm{H}^{n-k}(M;\mathbb{Z})$ are finitely generated free abelian groups. Therefore by the remark on page 2657 it suffices to show that the map
$$\begin{array}{rcl} \Omega\colon \mathrm{H}^{n-k}(M;\mathbb{Z}) & \to & \mathrm{Hom}(\mathrm{H}^k(M;\mathbb{Z}),\mathbb{Z}) \\ \psi & \mapsto & (\varphi \mapsto \langle \varphi \cup \psi, [M]\rangle) \end{array}$$
is an isomorphism. We start out with the following claim.

Claim. The following diagram commutes:[1483]
$$\begin{array}{ccc} \mathrm{H}^{n-k}(M;\mathbb{Z}) & \xrightarrow{\quad\Omega\quad} & \mathrm{Hom}(\mathrm{H}^k(M;\mathbb{Z}),\mathbb{Z}). \\ & {\scriptstyle \mathrm{ev}}\searrow \quad \nearrow{\scriptstyle (\cap[M])^*} & \\ & \mathrm{Hom}_{\mathbb{Z}}(\mathrm{H}_{n-k}(M;\mathbb{Z}),\mathbb{Z}) & \end{array}$$

[1482] Is the hypothesis on V and W necessary to draw this conclusion?

[1483] The right diagonal is the dual map corresponding to the map $\mathrm{H}^k(M;\mathbb{Z}) \xrightarrow{\cap[M]} \mathrm{H}_{n-k}(M;\mathbb{Z})$.

Proof. Note that for any $\psi \in \mathrm{H}^{n-k}(M;\mathbb{Z})$ and any $\varphi \in \mathrm{H}^k(M;\mathbb{Z})$ the following equalities hold in $\mathbb{Z}$:

$$\Omega(\psi)(\varphi) \underset{\substack{\uparrow \\ \text{by definition of } \Omega \text{ and the} \\ \text{Cap Product-Kronecker Lemma 116.4}}}{=} (\varphi \cup \psi) \cap [M] \overset{\substack{\downarrow \\ \text{Cup-Cap Lemma 116.7}}}{=} \psi \cap (\varphi \cap [M]) \underset{\substack{\uparrow \\ \text{Cap Product-Kronecker Lemma 116.4}}}{=} \langle \psi, \varphi \cap [M] \rangle = \mathrm{ev}(\psi)(\varphi \cap [M]).$$

But this observation immediately shows that the diagram commutes. ⊞

We need to show that in the above diagram the horizontal map is an isomorphism. By the claim it suffices to show that the two diagonal maps are isomorphisms. The left diagonal map is an isomorphism by the Universal Coefficient Theorem 110.12 for Cohomology Groups together with the Ext-Calculation Lemma 110.5 (3) and the fact, pointed out above, that $\mathrm{H}_{n-k-1}(M;\mathbb{Z})$ is free abelian. Furthermore the second map is an isomorphism by the Poincaré Duality Theorem 119.1.

(2) Now let $\mathbb{F}$ be a field. We suppose that M is $\mathbb{F}$-oriented with corresponding fundamental class $[M]$. By the Cohomology-Field Coefficients Proposition 110.18 the map

$$\begin{array}{rcl} \mathrm{ev}\colon \mathrm{H}^k(M;\mathbb{F}) & \to & \mathrm{Hom}_{\mathbb{F}}(\mathrm{H}_k(M;\mathbb{F}),\mathbb{F}) \\ \varphi & \mapsto & \left(\begin{array}{rcl} \mathrm{H}_k(M;\mathbb{F}) & \to & \mathbb{F} \\ \sigma & \mapsto & \langle \varphi, \sigma \rangle \end{array} \right) \end{array}$$

is a natural isomorphism of $\mathbb{F}$-vector spaces. The proof of (2) is now basically the same as the proof of (1). ■

The following corollary will be surprisingly effective in determining cup products on topological manifolds.

Corollary 121.3. (Rank One-PD Corollary) Let M be a closed connected n-dimensional topological manifold and let $k \in \mathbb{N}_0$.

(1) Suppose that M is oriented and that $\mathrm{H}_{k-1}(M;\mathbb{Z})$ and $\mathrm{H}_{n-k-1}(M;\mathbb{Z})$ are torsion-free. Furthermore suppose that $\mathrm{H}^k(M;\mathbb{Z}) \cong \mathbb{Z}$ and $\mathrm{H}^{n-k}(M;\mathbb{Z}) \cong \mathbb{Z}$. If $\varphi \in \mathrm{H}^k(M;\mathbb{Z})$ and $\psi \in \mathrm{H}^{n-k}(M;\mathbb{Z})$ are generators, then

$$\varphi \cup \psi \;=\; \epsilon \cdot [M]^* \;\in\; \mathrm{H}^n(M;\mathbb{Z})$$

for some $\epsilon \in \{-1, 1\}$.

(2) Let $\mathbb{F}$ be a field such that M is $\mathbb{F}$-orientable. Suppose that $\mathrm{H}^k(M;\mathbb{F}) \cong \mathbb{F}$ and $\mathrm{H}^{n-k}(M;\mathbb{F}) \cong \mathbb{F}$. If $\varphi \in \mathrm{H}^k(M;\mathbb{F})$ and $\psi \in \mathrm{H}^{n-k}(M;\mathbb{F})$ are non-zero, then $\varphi \cup \psi$ is non-zero in $\mathrm{H}^n(M;\mathbb{F}) \cong \mathbb{F}$.

Proof. Let M be a closed connected n-dimensional topological manifold and let $k \in \mathbb{N}_0$.

(1) By our hypothesis and by the Manifold-Non Singularity Proposition 121.2 (1) the cup product pairing

$$\begin{array}{rcl} \mathrm{H}^k(M;\mathbb{Z}) \times \mathrm{H}^{n-k}(M;\mathbb{Z}) & \to & \mathbb{Z} \\ (\varphi, \psi) & \mapsto & \langle \varphi \cup \psi, [M] \rangle \end{array}$$

is non-singular. It follows from this fact and the Non-Singularity Lemma 121.1 (2) that $\langle \varphi \cup \psi, [M] \rangle = \pm 1$. But by the Dual Fundamental Class Lemma 110.15 this just means that $\varphi \cup \psi \in \mathrm{H}^n(M;\mathbb{Z})$ is a generator.

(2) This proof is almost identical to the proof of (1), we just need to replace the Manifold-Non Singularity Proposition 121.2 (1) by the Manifold-Non Singularity Proposition 121.2 (2). ■

Example. Let $m \neq n \in \mathbb{N}$. As on many earlier occasions we denote by $p\colon S^m \times S^n \to S^m$ and by $q\colon S^m \times S^n \to S^n$ the two natural projections. Let $1 \in \mathrm{H}^0(S^m \times S^n;\mathbb{Z})$ be the neutral element from the Cup Product-Ring Proposition 114.7. In Lemma 117.3 we showed that the cohomology of $S^m \times S^n$ is given as follows:

$$\mathrm{H}^*(S^m \times S^n;\mathbb{Z}) \;=\; \mathbb{Z} \cdot 1 \oplus \mathbb{Z} \cdot p^*([S^m]^*) \oplus \mathbb{Z} \cdot q^*([S^n]^*) \oplus \mathbb{Z} \cdot [S^m \times S^n]^*.$$

It follows from the Rank One-PD Corollary 121.3 (1)[1484] that $p^*([S^m]^*) \cup q^*([S^n]^*) = \pm[S^m \times S^n]^*$. This result recovers (up to the sign indeterminacy) the calculation of the non-trivial cup product on $S^m \times S^n$ that we had initially performed in Lemma 117.3 using the somewhat mysterious Product Theorem 117.1. In Exercise 121.4 we will see, that with slightly more effort, one can also prove the same type of result for $m = n$.

Next we consider the topological spaces $S^2 \vee S^4$ and $\mathbb{C}\mathrm{P}^2$. It follows from Propositions 47.13 and 52.3 and the discussion on page 1533 that $S^2 \vee S^4$ and $\mathbb{C}\mathrm{P}^2$ are both simply connected. Furthermore it follows from Propositions 74.4 and 79.8, the calculation on page 1772 and the Universal Coefficient Theorem 110.12 for Cohomology Groups that for any $k \in \mathbb{N}_0$ we have

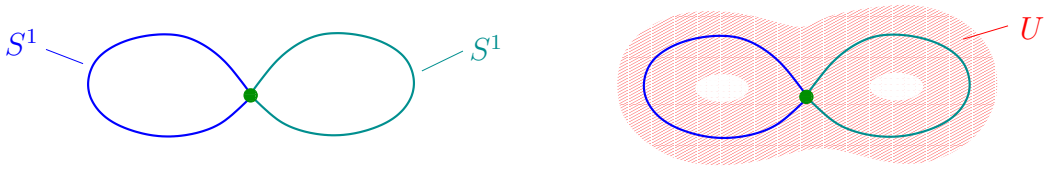
$$\mathrm{H}_k(S^2 \vee S^4;\mathbb{Z}) \cong \mathrm{H}^k(S^2 \vee S^4;\mathbb{Z}) \cong \mathrm{H}^k(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \cong \mathrm{H}_k(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0,2,4, \\ 0, & \text{otherwise.} \end{cases}$$

We can thus view $S^2 \vee S^4$ as a (co-) homological doppelgänger to $\mathbb{C}\mathrm{P}^2$.
Using the Rank One-PD Corollary 121.3 (1) we can easily prove the following lemma which implies in particular that $S^2 \vee S^4$ is not homotopy equivalent to $\mathbb{C}\mathrm{P}^2$.

Lemma 121.4. The topological space $S^2 \vee S^4$ is not homotopy equivalent to any closed topological manifold.

Proof. Let X be a closed topological manifold whose homology and cohomology groups are isomorphic to the corresponding groups of $S^2 \vee S^4$. It follows from the above calculation of homology groups, our hypothesis that X is compact, from Propositions 72.5 and 106.22 and Theorems 106.1 and 106.3 that X is a closed oriented closed connected 4-dimensional topological manifold. But then the Rank One-PD Corollary 121.3 (1) implies that the cup product

$$\mathrm{H}^2(X;\mathbb{Z}) \times \mathrm{H}^2(X;\mathbb{Z}) \;\to\; \mathrm{H}^4(X;\mathbb{Z})$$



is non-zero. On the other hand in Lemma 114.11 we saw that the cup product

$$\cup\colon \mathrm{H}^2(S^2 \vee S^4;\mathbb{Z}) \times \mathrm{H}^2(S^2 \vee S^4;\mathbb{Z}) \;\to\; \mathrm{H}^4(S^2 \vee S^4;\mathbb{Z})$$

is the zero-map. By Corollary 114.12 and the above calculation of the cup product of X this implies that $S^2 \vee S^4$ and X are not homotopy equivalent. ■

[1484] Of course here we also use the fact, with which we are very familiar by now, that the homology groups of $S^m \times S^n$ are torsion-free.

Remark. One can ask whether the adjective "closed" in Lemma 121.4 is necessary. It turns out that this is the case. In fact every wedge of finitely many spheres can be viewed as a deformation retract of an open subset of a sufficiently high-dimensional $\mathbb{R}^n$. For the wedge $S^1 \vee S^1$ we sketch the argument in the figure below. With slightly more care one can also show that this wedge of finitely many spheres is also a deformation retract of some compact n-dimensional smooth manifold of $\mathbb{R}^n$. We leave it to the reader to provide a formal proof for these statements.

open neighborhood U admits a deformation retraction onto $S^1 \vee S^1$

We conclude this section with the following application to de Rham cohomology. We will not make use of it later on.

Corollary 121.5. If M is a closed oriented n-dimensional smooth manifold, then for any $k \in \mathbb{N}_0$ the $\mathbb{R}$-bilinear pairing

$$\begin{array}{rcl} \mathrm{H}^k_{\mathrm{dR}}(M) \times \mathrm{H}^{n-k}_{\mathrm{dR}}(M) & \to & \mathbb{R} \\ ([\varphi],[\psi]) & \mapsto & \displaystyle\int_M \varphi \wedge \psi \end{array}$$

is non-singular.

Since there is no "de Rham homology" the above corollary is usually called the Poincaré Duality Theorem for de Rham cohomology.

Remark. Evidently there are also more direct proofs of Corollary 121.5 that take place within the setting of de Rham cohomology. We refer to [**BoT1982**, p. 44] or alternatively [**War1983**, Theorem 6.13] for such a proof.

Proof. It is straightforward to see that it suffices to deal with the case that M is connected. Theorem **??** and Proposition 118.10 give us the following commutative diagram with vertical isomorphisms:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{dR}}(M) \times \mathrm{H}^{n-k}_{\mathrm{dR}}(M) & \xrightarrow{(\varphi,\psi)\mapsto \int_M \varphi\wedge\psi} & \mathbb{R} \\ \cong\downarrow \quad \downarrow\cong & & \downarrow= \\ \mathrm{H}^k(M;\mathbb{R}) \times \mathrm{H}^{n-k}(M;\mathbb{R}) & \xrightarrow{(\varphi,\psi)\mapsto\langle\varphi\cup\psi,[M]\rangle} & \mathbb{R}. \end{array}$$

By the Manifold-Non Singularity Proposition 121.2 (2) the $\mathbb{R}$-bilinear pairing on the bottom is non-singular. Thus the $\mathbb{R}$-bilinear pairing on the top is also non-singular. ■

121.2. **The cup product of $\mathbb{C}\mathrm{P}^n$ and applications.** In this section we apply our acquired wisdom to the complex projective spaces $\mathbb{C}\mathrm{P}^n$. Recall that in the Complex Projective Space-is-Complex Manifold Lemma 32.16 we showed that $\mathbb{C}\mathrm{P}^n$ is a closed $2n$-dimensional smooth manifold that comes with a natural orientation. Thus we will always view $\mathbb{C}\mathrm{P}^n$ as

an *oriented* smooth manifold. In particular $\mathbb{C}\mathrm{P}^n$ comes with a canonical fundamental class $[\mathbb{C}\mathrm{P}^n] \in \mathrm{H}_{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and a canonical dual fundamental class $[\mathbb{C}\mathrm{P}^n]^* \in \mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$.
An astute observer might already have noticed that the Rank One-PD Corollary 121.3 (1) can be used to compute the cup product on $\mathrm{H}^*(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$. In fact in this section we will use the Rank One-PD Corollary 121.3 (1) and the naturality of the cup product to compute the cohomology ring of any complex projective space $\mathbb{C}\mathrm{P}^n$. Throughout this section, given $m \leq n$ we will view $\mathbb{C}\mathrm{P}^m$ as a submanifold of $\mathbb{C}\mathrm{P}^n$ via the smooth embedding

$$\begin{array}{rcl} i\colon \mathbb{C}\mathrm{P}^m & \to & \mathbb{C}\mathrm{P}^n \\ [z_0 : \cdots : z_m] & \mapsto & [z_0 : \cdots : z_m : 0 : \cdots : 0]. \end{array}$$

We prepare the ground with the following elementary lemma.

Lemma 121.6.

(1) For every $n \in \mathbb{N}$ and every $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\cong\; \mathrm{H}^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) Let $m \leq n$. We denote by $i\colon \mathbb{C}\mathrm{P}^m \to \mathbb{C}\mathrm{P}^n$ the inclusion map. For any $k \leq 2m$ the induced maps $i_*\colon \mathrm{H}_k(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) \to \mathrm{H}_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and $i^*\colon \mathrm{H}^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to \mathrm{H}^k(\mathbb{C}\mathrm{P}^m;\mathbb{Z})$ are isomorphisms.

Proof. First we recall that in Lemma 68.1 we showed that we can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex which admits exactly one cell in dimensions $0, 2, \ldots, 2n$ and which admits no cells in any other dimension. Furthermore we saw that the CW-structure can be chosen in such a way that for $k \in \{0, \ldots, n\}$ the $(2k+1)$-skeleton on $\mathbb{C}\mathrm{P}^n$ equals $\mathbb{C}\mathrm{P}^k$.

Furthermore recall that by Propositions 80.4 we know that singular and cellular homology are *naturally* isomorphic. Together with the above discussion of the CW-structures it follows that for every $n \in \mathbb{N}$ and every $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\xrightarrow{\cong}\; \mathrm{H}_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise} \end{cases}$$

and that for every $m \leq n$ the inclusion induced maps $i_*\colon \mathrm{H}_k(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) \to \mathrm{H}_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ are isomorphisms for $k \leq 2m$.

In the Singular-Cellular H^*-Isomorphism Proposition 109.4 we had also seen that singular and cellular cohomology are naturally isomorphic. So the same logic applies to cohomology groups. ∎

We also introduce the following notation.

Notation.

(1) Let X be a topological space, let R be a commutative ring and let $\varphi \in \mathrm{H}^k(X;R)$. We define $\varphi^0 = 1_X$ and given any $n \in \mathbb{N}$ we define

$$\varphi^n \;=\; \underbrace{\varphi \cup \cdots \cup \varphi}_{n \text{ times}} \;\in\; \mathrm{H}^{kn}(X;R).$$

(2) Recall that we denote by $[\mathbb{C}\mathrm{P}^1]^* \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^1;\mathbb{Z})$ the dual fundamental class of $\mathbb{C}\mathrm{P}^1$. For any $n \geq 1$ we denote by $i\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^n$ the above inclusion map. By Lemma 121.6

we can define $x := (i^*)^{-1}([\mathbb{C}\mathrm{P}^1]^*) \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$. We refer to $x \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ as the standard generator.

Now we have the tools to determine the cup product of all complex projective spaces.

Proposition 121.7. (Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition) Let $n \in \mathbb{N}$.

(1) For every $k \in \{0,\dots,n\}$ the k-th power $x^k \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ is a generator.
(2) If we view $\mathbb{Z}[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 2$, then the obvious map
$$\mathbb{Z}[x]/(x^{n+1}) \;\to\; (\mathrm{H}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}),\cup)$$
is an isomorphism of superalgebras.

Proof. It follows immediately from the definitions and the Cup Product-Commutativity Proposition 114.8 that the map in (2) is a homomorphism of superalgebras. This observation, together with Lemma 121.6, shows that (2) is a consequence of (1). Thus it remains to prove (1)

We prove (1) by induction on n. Evidently the statement holds for $n = 1$. Now suppose it holds for some $n-1$ with $n \geq 2$. We denote by $i\colon \mathbb{C}\mathrm{P}^{n-1} \to \mathbb{C}\mathrm{P}^n$ the inclusion map. Note that $i^*(x) = x \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^{n-1};\mathbb{Z})$. It follows easily from Lemma 121.6 together with the Cup Product-Naturality Lemma 114.10 and our induction hypothesis that for each $k \in \{1,\dots,n-1\}$ the cohomology class $x^k \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ is a generator. It remains to show that $x^n \in \mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ is also a generator. This is an immediate consequence of the Rank One-PD Corollary 121.3 (1), applied to the generator $\varphi := x \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ and the generator $\psi := x^{n-1} \in \mathrm{H}^{2(n-1)}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$. ■

The previous proof leaves it open whether nor not $x^n \in \mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ equals the dual fundamental class $[\mathbb{C}\mathrm{P}^n]^*$. We formulate this as a question which we will answer later in the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11, when we will have obtained more tools for calculating cup products.

Question 121.8. Let $n \in \mathbb{N}$. Does the n-th power $x^n \in \mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ equal the dual fundamental class $[\mathbb{C}\mathrm{P}^n]^*$?

In Lemma 121.4 we had in particular shown that $\mathbb{C}\mathrm{P}^2$ is not homotopy equivalent to its (co-) homological doppelgänger $S^2 \vee S^4$. On page 1949 we pointed out that $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ is another example of a pair of topological spaces that cannot be distinguished using the fundamental group and using homology groups. This motivated us to ask in Question 90.9 whether the topological spaces $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ are homeomorphic. Now we can answer the question in the negative, in fact we can prove an even stronger result.

Corollary 121.9. The topological spaces $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ are not homotopy equivalent.

Proof. In Lemma 117.3 we saw that the cup product
$$\mathrm{H}^2(S^2 \times S^4;\mathbb{Z}) \times \mathrm{H}^2(S^2 \times S^4;\mathbb{Z}) \;\to\; \mathrm{H}^4(S^2 \times S^4;\mathbb{Z})$$
is zero, whereas we saw in the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 that the cup product
$$\mathrm{H}^2(\mathbb{C}\mathrm{P}^3;\mathbb{Z}) \times \mathrm{H}^2(\mathbb{C}\mathrm{P}^3;\mathbb{Z}) \;\to\; \mathrm{H}^4(\mathbb{C}\mathrm{P}^3;\mathbb{Z})$$
is non-zero. It follows from Corollary 114.12 that $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ are not homotopy equivalent. ■

We recall the following definition from page 2388.

Definition. Let M be a compact oriented topological manifold. We say that M is amphichiral if M admits an orientation-reversing self-homeomorphism, otherwise we say that M is chiral.

On page 2391 we saw that many smooth manifolds are amphichiral, for example we showed that all compact oriented 2-dimensional topological manifolds are amphichiral.
In Question 107.5 we had asked whether there exist compact oriented topological manifolds that are chiral. Now we will see that the complex projective space $\mathbb{C}\mathrm{P}^2$ is chiral. This gives an affirmative answer to Question 107.5. Note that the following corollary also gives a negative answer to Question 101.12 (3).

Corollary 121.10. The smooth manifold $\mathbb{C}\mathrm{P}^2$ is chiral, i.e. there does not exist a self-homeomorphism $f\colon \mathbb{C}\mathrm{P}^2 \to \mathbb{C}\mathrm{P}^2$ with $f_*([\mathbb{C}\mathrm{P}^2]) = -[\mathbb{C}\mathrm{P}^2]$.

Remark. In Exercise 121.5 we will discuss for which $n \in \mathbb{N}$ the complex projective space $\mathbb{C}\mathrm{P}^n$ is chiral.

Proof. As usual we denote by $x \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ the standard generator. By the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 we know that $x \cup x \in \mathrm{H}^4(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ is a generator. This implies that $x \cup x = \epsilon \cdot [\mathbb{C}\mathrm{P}^2]^*$ for some $\epsilon \in \{-1, 1\}$.

Now let $f\colon \mathbb{C}\mathrm{P}^2 \to \mathbb{C}\mathrm{P}^2$ be a self-homeomorphism. Since we want to show that $\mathbb{C}\mathrm{P}^2$ is chiral we need to show that $f_*([\mathbb{C}\mathrm{P}^2]) = [\mathbb{C}\mathrm{P}^2] \in \mathrm{H}_4(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$, or equivalently, that $f^*([\mathbb{C}\mathrm{P}^2]^*) = [\mathbb{C}\mathrm{P}^2]^* \in \mathrm{H}^4(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$.

Now we see that

$$\begin{aligned}
f^*([\mathbb{C}\mathrm{P}^2]^*) &= \epsilon \cdot f^*(x \cup x) \underset{\text{Cup Product-Naturality Lemma 114.10}}{=} \epsilon \cdot (f^*(x) \cup f^*(x)) \underset{\substack{f^*(x) \text{ is also a generator of } \mathrm{H}^2(\mathbb{C}\mathrm{P}^4;\mathbb{Z}),\\ \text{hence } f^*(x) = \eta \cdot x \text{ for some } \eta \in \{-1,1\}}}{=} \epsilon \cdot (\eta \cdot x \cup \eta \cdot x) \\
&\underset{\cup \text{ is bilinear}}{=} \epsilon \cdot \eta^2 \cdot (x \cup x) \underset{\text{since } \eta \in \{-1,1\}}{=} \epsilon \cdot (x \cup x) = [\mathbb{C}\mathrm{P}^2]^*.
\end{aligned}$$

■

Next we turn to the calculation of the cohomology ring of the infinite-dimensional complex projective space $\mathbb{C}\mathrm{P}^\infty = \varinjlim \mathbb{C}\mathrm{P}^n$.

Lemma 121.11.

(1) For every $k \in \mathbb{N}$ we have

$$\mathrm{H}^k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong \mathrm{H}_k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k \text{ is even,} \\ 0, & \text{if } k \text{ is odd.} \end{cases}$$

(2) Let $n \in \mathbb{N}$. We denote by $i\colon \mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^\infty$ the inclusion map. For any $k \leq 2n$ the induced maps $i_*\colon \mathrm{H}_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to \mathrm{H}_k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$ and $i^*\colon \mathrm{H}^k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \to \mathrm{H}^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ are isomorphisms.

Proof. The statements in (1) and (2) regarding homology groups follow from the discussion on page 1772. The statements in (1) and (2) regarding cohomology groups then follow from the Universal Coefficient Theorem 110.12 for Cohomology Groups. ■

Remark. One could also prove the lemma using Lemma 121.6 and a suitable generalization of the Cohomology-via-Exhaustions Proposition 111.12.

Notation. We denote by $i\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^\infty$ the inclusion map. By Lemma 121.11 we can set $x := (i^*)^{-1}([\mathbb{C}\mathrm{P}^1]^*) \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$. We refer to x as the standard generator of $\mathrm{H}^2(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$.

Proposition 121.12. (Cup Product-$\mathbb{C}\mathrm{P}^\infty$-Proposition)

(1) For every $k \in \mathbb{N}$ the k-th power $x^k \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong \mathbb{Z}$ is a generator.

(2) If we view $\mathbb{Z}[x]$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 2$, then the obvious map

$$\mathbb{Z}[x] \;\to\; (\mathrm{H}^*(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}), \cup)$$

is an isomorphism of superalgebras.

Proof. Exactly as in the proof of the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 we see that (2) is a consequence of (1). Thus it remains to prove (1) So let $k \in \mathbb{N}$. We consider the inclusion map $j\colon \mathbb{C}\mathrm{P}^k \to \mathbb{C}\mathrm{P}^\infty$. By the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 and the Cup Product-Naturality Lemma 114.10 we know that $j^*(x^k) = j^*(x)^k = x^k \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^k;\mathbb{Z})$ is a generator. It follows from Lemma 121.11 that $x^k \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$ is also a generator. ■

Remark. It follows from the Cohomology Ring-of-Product Proposition 117.21 and the discussion on page 2586 that for each $k \in \mathbb{N}$ we also have an isomorphism

$$(\mathrm{H}^*(\underbrace{\mathbb{C}\mathrm{P}^\infty \times \ldots \times \mathbb{C}\mathrm{P}^\infty}_{k \text{ copies}};\mathbb{Z}), \cup) \;\cong\; \mathbb{Z}[x_1, \ldots, x_k]$$

of superalgebras. Here $x_1, \ldots, x_k$ are given by preimages of the standard generator of the group $\mathrm{H}^2(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$ under the k natural projections.

The fact that so far we worked with $\mathbb{Z}$-coefficients was mostly irrelevant. In fact most of the results carry over, with obvious modifications, to the cohomology groups $\mathrm{H}^*(\mathbb{C}\mathrm{P}^n;R)$ where R is an arbitrary commutative ring. For future reference we state the following proposition.

Proposition 121.13. Let $n \in \mathbb{N}$.

(1) For every every $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2) \;\cong\; \mathrm{H}^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2) \;\cong\; \begin{cases} \mathbb{Z}_2, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) We denote by $x \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2)$ the unique non-trivial element. If we view the ring $\mathbb{Z}_2[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 2$, then the obvious map

$$\mathbb{Z}_2[x]/(x^{n+1}) \;\to\; (\mathrm{H}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2), \cup)$$

is an isomorphism of superalgebras.

The obvious analogues for $\mathbb{C}\mathrm{P}^\infty$ also hold.

Proof. This proposition can be proved in an almost identical way as the Cup Product-$\mathbb{C}\mathrm{P}^\infty$-Proposition 121.12. Alternatively we can deduce the proposition from the Cup Product-$\mathbb{C}\mathrm{P}^\infty$-Proposition 121.12, the Universal Coefficient Theorem 110.25, Lemma 110.29 and the Cup Product-Naturality Proposition 115.4 (2). We leave it to the impeccably conscientious reader to fill in the details. ■

Towards the end of this section we recall the definition of a retract. Thus let A be a subset of a topological space X. We denote by $i\colon A \to X$ the inclusion map. Recall that we say that A is a *retract* of X if there exists a map $r\colon X \to A$ such that $r \circ i = \mathrm{id}_A$. It follows immediately from the functoriality of homology groups and Splitting Lemma 78.2 that for each k the group $\mathrm{H}_k(A;\mathbb{Z})$ is a subsummand of $\mathrm{H}_k(X;\mathbb{Z})$.
Let $m < n$. In Question 85.4 we had asked whether $\mathbb{C}\mathrm{P}^m \subset \mathbb{C}\mathrm{P}^n$ is a retract of $\mathbb{C}\mathrm{P}^n$. Note that Lemma 121.6 shows that a study of homology groups does not preclude that for $m < n$ the complex projective space $\mathbb{C}\mathrm{P}^m$ is a retract of $\mathbb{C}\mathrm{P}^n$. Nonetheless, the final result of the section gives a negative answer to Question 85.4, i.e. we show that $\mathbb{C}\mathrm{P}^m$ is not a retract of $\mathbb{C}\mathrm{P}^n$.

Proposition 121.14. If $1 \leq m < n$, then $\mathbb{C}\mathrm{P}^m \subset \mathbb{C}\mathrm{P}^n$ is not a retract of $\mathbb{C}\mathrm{P}^n$.

Proof. Let $1 \leq m < n$. We denote by $i\colon \mathbb{C}\mathrm{P}^m \to \mathbb{C}\mathrm{P}^n$ the inclusion map. Suppose there exists a retraction $r\colon \mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^m$. We denote by $x \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ the standard generator. We have

$$x^n \underset{\text{by Lemma 121.6 the map } i^*\colon \mathrm{H}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to \mathrm{H}^2(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) \text{ is an isomorphism, together with } i^* \circ r^* = (r \circ i)^* = \mathrm{id} \text{ we obtain that } r^* \circ i^* = \mathrm{id}}{=} (r^*(i^*(x)))^n \overset{\text{Cup Product-Naturality Lemma 114.10}}{=} r^*(i^*(x)^n) \underset{\text{note that } n > m \text{ implies that } i^*(x)^n \text{ lies in the trivial group } \mathrm{H}^n(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) = 0}{=} r^*(0) = 0 \in \mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}).$$

But this calculation contradicts the fact shown in the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 that $x^n \neq 0$. ∎

121.3. **The cup product of $\mathbb{R}\mathrm{P}^n$ and applications.** In this section we intend to determine the cup product of the real projective space $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients. Evidently the approach will be very similar to the one taken in the previous section. First we recall that on page 564 we saw that the real projective space $\mathbb{R}\mathrm{P}^n$ is a closed n-dimensional smooth manifold. Given $m \leq n$ we will view $\mathbb{R}\mathrm{P}^m$ as a submanifold of $\mathbb{R}\mathrm{P}^n$ via the smooth embedding

$$\begin{array}{rcl} i\colon \mathbb{R}\mathrm{P}^m & \to & \mathbb{R}\mathrm{P}^n \\ [x_0 : \cdots : x_m] & \mapsto & [x_0 : \cdots : x_m : 0 : \cdots : 0]. \end{array}$$

The following lemma plays the role of Lemma 121.6.

Lemma 121.15.

(1) For every $n \in \mathbb{N}$ we have

$$\mathrm{H}^k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k = 0, 1, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) Let $m \leq n$. For any $k \leq m$ the induced maps $i_*\colon \mathrm{H}_k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2) \to \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ and $i^*\colon \mathrm{H}^k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \to \mathrm{H}^k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2)$ are isomorphisms.

Proof. The calculation of the isomorphism types of the (co-) homology groups and of the induced maps on homology is basically the same as in the proof of Lemma 121.15. The argument that determines the induced map on $\mathbb{F}_2$-cohomology is slightly different. This time we use the Cohomology-Field Coefficients Proposition 110.18 which gives us the

following commutative diagram:

$$\begin{array}{ccc} \mathrm{H}^k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2),\mathbb{F}_2) \\ \downarrow i^* & & \downarrow i^* \\ \mathrm{H}^k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(\mathrm{H}_k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2),\mathbb{F}_2). \end{array}$$

As we had just pointed out, the maps on the right are isomorphisms for $k \leq m$. It follows that the maps on the left are also isomorphisms for $k \leq m$. ■

Notation. Given $n \in \mathbb{N}$ we denote by $x \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ the unique non-trivial element.

The following proposition is the analogue of the Cup Product-$\mathbb{C}\mathrm{P}^n$ Proposition 121.7 and the Cup Product-$\mathbb{C}\mathrm{P}^\infty$ Proposition 121.12.

Proposition 121.16. (Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition) Let $n \in \mathbb{N}$.

(1) For every $k \in \{0,\ldots,n\}$ the k-th power $x^k \in \mathrm{H}^k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \mathbb{F}_2$ is non-trivial.
(2) If we view $\mathbb{F}_2[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 1$, then the obvious map
$$\mathbb{F}_2[x]/(x^{n+1}) \;\to\; (\mathrm{H}^*(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2),\cup)$$
is an isomorphism of superalgebras.
(3) If we view $\mathbb{F}_2[x]$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 1$, then the obvious map
$$\mathbb{F}_2[x] \;\to\; (\mathrm{H}^*(\mathbb{R}\mathrm{P}^\infty;\mathbb{F}_2),\cup)$$
is an isomorphism of superalgebras.

Proof. First recall that the $\mathbb{F}_2$-Orientability Proposition 105.13 implies that any topological manifold, in particular $\mathbb{R}\mathrm{P}^n$, is $\mathbb{F}_2$-orientable. With this observation the proof of the proposition is basically identical to the proofs of the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 and 121.12. We just need to replace Lemma 121.6 by Lemma 121.15 and we need to replace the Rank One-PD Corollary 121.3 (1) by the Rank One-PD Corollary 121.3 (2). ■

Remark.

(1) In principle one could have tried to compute the cup product on $\mathbb{R}\mathrm{P}^n$ using the same approach that we had taken in Section 114.5. More precisely, suppose one has found an explicit $\mathbb{F}_2$-fundamental class σ for $\mathbb{R}\mathrm{P}^n$. We denote by $\varphi \in \mathrm{C}^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ the 1-cocycle from page 2530. Now we know from the Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16 that $\langle \varphi^n, \sigma\rangle = 1$. But more interestingly, if one shows with an explicit calculation that $\langle \varphi^n, \sigma\rangle = 1$, then this gives a new and elementary proof of the Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16.
(2) We have just computed the cup product on $\mathrm{H}^*(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$. We leave it as a highly instructive exercise to use the same approach to determine the cup product on $\mathrm{H}^*(\mathbb{R}\mathrm{P}^n;\mathbb{Z})$. This cup product is also determined, using a somewhat different approach, in [**Hat2002**, p. 214].
(3) In Corollary 119.14 we showed that there is no map $S^1 \times S^2$ to $\mathbb{R}\mathrm{P}^3$ of degree one, thus giving a negative answer to Question 101.11. On page 2569 and in the Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16 we had determined the cup product of $S^1 \times S^2$ and

$\mathbb{R}\mathrm{P}^3$ on cohomology with $\mathbb{F}_2$-coefficients. Using an argument similar to the proof of Lemma 117.5 one can easily give an alternative proof of Corollary 119.14.

For completeness' sake we mention the following analogue of Proposition 121.14.

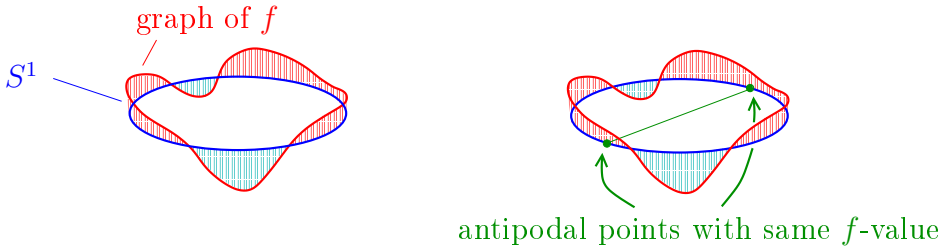
Proposition 121.17. If $1 \leq m < n$, then $\mathbb{R}\mathrm{P}^m \subset \mathbb{R}\mathrm{P}^n$ is not a retract of $\mathbb{R}\mathrm{P}^n$.

Proof. The proof is totally analogous to the proof of Proposition 121.14. In the proof we just need to replace Lemma 121.6 by Lemma 121.15. ■

Remark. We can also give an alternative proof of Proposition 121.17 using higher homotopy groups. More precisely, let $1 \leq m < n$. By Proposition 71.10 together with the Coverings-π_n-Proposition 71.13 we know that $\pi_m(S^n) = 0$. Furthermore by Lemma 85.2 together with the Coverings-π_n-Proposition 71.13 we know that $\pi_m(S^m) \neq 0$. Since higher homotopy groups are functorial, see Proposition 71.6, we can use the standard argument, see e.g. the proof of Lemma 47.16, to show that $\mathbb{R}\mathrm{P}^m$ is not a retract of $\mathbb{R}\mathrm{P}^n$.

One of the many consequences of our calculations from this chapter is that we can now calculate the Lusternik-Schnirelmann category for $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$. More precisely, we have the following proposition that gives a complete answer to Question 115.10.

Proposition 121.18. For any $n \in \mathbb{N}_0$ we have $\mathrm{cat}(\mathbb{R}\mathrm{P}^n) = \mathrm{cat}(\mathbb{C}\mathrm{P}^n) = n$.



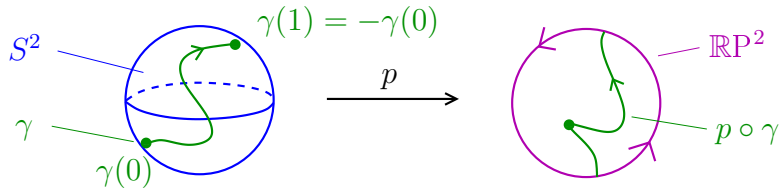
Proof. Given any $n \in \mathbb{N}_0$ we have

$$n \underset{\text{see page 2544}}{\geq} \mathrm{cat}(\mathbb{R}\mathrm{P}^n) \underset{\text{Proposition 115.14}}{\geq} \overbrace{\text{cup length cl}(\mathbb{R}\mathrm{P}^n)}^{\text{see page 2547 for the definition}} \underset{\text{Cup Product-}\mathbb{R}\mathrm{P}^n\text{-Proposition 121.16}}{\geq} n.$$

The same argument also works for $\mathbb{C}\mathrm{P}^n$, we just need to replace Propositions 121.16, by Propositions 121.7. ■

We conclude this section with an alternative proof for the Borsuk-Ulam Theorem. First we recall the statement of the Borsuk-Ulam Theorem.

Theorem 39.8. (Borsuk-Ulam Theorem) For every map $f\colon S^n \to \mathbb{R}^n$ there exists a pair of antipodal points x and $-x$ on S^n with $f(x) = f(-x)$.



Remark. As we have pointed out on numerous occasions, the Borsuk-Ulam Theorem 39.8 has many beautiful applications, in particular the Lusternik-Schnirelmann Theorem 40.1, the Ham-Sandwich Theorem 40.2, Pfister's Level Theorem 40.9 and the Necklace Theorem 40.11.

In the new proof of the Borsuk-Ulam Theorem below we will need the following Lemma.

Lemma 121.19.

(1) Let $k \geq 2$. As usual we denote by $p\colon S^k \to \mathbb{R}\mathrm{P}^k$ the natural projection. If $\gamma\colon [0,1] \to S^k$ is a path with $\gamma(1) = -\gamma(0)$, then $p \circ \gamma$ represents the unique non-trivial element in $\pi_1(\mathbb{R}\mathrm{P}^k)$.

(2) Let $k, l \geq 2$. Furthermore let $h\colon \mathbb{R}\mathrm{P}^k \to \mathbb{R}\mathrm{P}^l$ be a map. If $h_*\colon \pi_1(\mathbb{R}\mathrm{P}^k) \to \pi_1(\mathbb{R}\mathrm{P}^l)$ has non-trivial image, then the induced maps $h_*\colon \mathrm{H}_1(\mathbb{R}\mathrm{P}^k; \mathbb{F}_2) \to \mathrm{H}_1(\mathbb{R}\mathrm{P}^l; \mathbb{F}_2)$ and $h^*\colon \mathrm{H}^1(\mathbb{R}\mathrm{P}^l; \mathbb{F}_2) \to \mathrm{H}^1(\mathbb{R}\mathrm{P}^k; \mathbb{F}_2)$ are also isomorphisms.

Proof of Lemma 121.19. First we recall that for $k \geq 2$ we know from Corollary 48.18 that $\pi_1(\mathbb{R}\mathrm{P}^k) \cong \mathbb{Z}_2$.

(1) The first statement is an immediate consequence of Lemma 48.15 (1) and the fact that $\pi_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$.

(2) Since $k, l \geq 2$ both fundamental groups are isomorphic to $\mathbb{Z}_2$. In particular if $h_*\colon \pi_1(\mathbb{R}\mathrm{P}^k) \to \pi_1(\mathbb{R}\mathrm{P}^l)$ has non-trivial image, then this map is already an isomorphism. It follows from the naturality of the Hurewicz homomorphism, see Proposition 84.2 (5), together with the Hurewicz Theorem 84.5 that the induced map $h_*\colon \mathrm{H}_1(\mathbb{R}\mathrm{P}^k; \mathbb{F}_2) \to \mathrm{H}_1(\mathbb{R}\mathrm{P}^l; \mathbb{F}_2)$ is also an isomorphism. Finally note that it follows from the naturality of the isomorphisms in the First Cohomology Proposition 110.17 that the induced map $h^*\colon \mathrm{H}^1(\mathbb{R}\mathrm{P}^l; \mathbb{F}_2) \to \mathrm{H}^1(\mathbb{R}\mathrm{P}^k; \mathbb{F}_2)$ is also an isomorphism. ■

Proof of the Borsuk-Ulam 39.8 for $n \geq 2$. Let us suppose that there exists a map $f\colon S^n \to \mathbb{R}^n$ such that for any $x \in S^n$ we have that $f(x) \neq f(-x)$. We consider the map

$$\begin{array}{rcl} g\colon S^n & \to & S^{n-1} \\ x & \mapsto & \frac{f(x)-f(-x)}{\|f(x)-f(-x)\|}. \end{array}$$

By our hypothesis this map is defined. It is clear that $g(-x) = -g(x)$ for all $x \in S^n$. Therefore this map g descends to a map

$$\begin{array}{rcl} h\colon \mathbb{R}\mathrm{P}^n & \to & \mathbb{R}\mathrm{P}^{n-1} \\ [x] & \mapsto & [g(x)] \end{array}$$

i.e. we get the following commutative diagram

$$\begin{array}{ccc} S^n & \xrightarrow{\quad g \quad} & S^{n-1} \\ \downarrow{\scriptstyle p} & & \downarrow{\scriptstyle q} \\ \mathbb{R}\mathrm{P}^n & \xrightarrow{[x]\mapsto h(x):=[g(x)]} & \mathbb{R}\mathrm{P}^{n-1} \end{array}$$

where p and q denote the natural projections.[1485]

[1485]The map $q \circ g\colon S^n \to \mathbb{R}\mathrm{P}^{n-1}$ is continuous. It follows from the Topological-Quotient Proposition 5.15 (1b) that the map h is also continuous.

Claim. The map $h^*\colon \mathrm{H}^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \to \mathrm{H}^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ is an isomorphism.

Proof. By Lemma 121.19 (2) we only have to show that $h_*\colon \pi_1(\mathbb{R}\mathrm{P}^n) \to \pi_1(\mathbb{R}\mathrm{P}^{n-1})$ has non-trivial image. Let $\gamma\colon [0,1] \to S^n$ be a path with $\gamma(1) = -\gamma(0)$. Note that $p\circ\gamma\colon [0,1] \to \mathbb{R}\mathrm{P}^n$ is a loop. We calculate that

$$h_*([p\circ\gamma]) \;=\; [h\circ p\circ\gamma] \;\overset{\text{by the above commutative diagram}}{\overset{\downarrow}{=}}\; [q\circ(g\circ\gamma)] \qquad \underset{\uparrow}{\neq}\; e \;\in \pi_1(\mathbb{R}\mathrm{P}^{n-1}).$$

by Lemma 121.19 (1) since $(g\circ\gamma)(1) = g(\gamma(1)) = g(-\gamma(0)) = -g(\gamma(0)) = -(g\circ\gamma)(0)$ ⊞

We denote by $y \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ and $x \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ the unique non-trivial elements. We have the following equality in $\mathrm{H}^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$:[1486]

$$0 \;\overset{\text{Cup Product-}\mathbb{R}\mathrm{P}^n\text{-Proposition 121.16}}{\overset{\downarrow}{\neq}}\; x^n \;\underset{\text{by the claim}}{\underset{\uparrow}{=}}\; (h^*(y))^n \;\overset{\text{Cup Product-Naturality Lemma 114.10}}{\overset{\downarrow}{=}}\; h^*(y^n) \;\underset{\text{Cup Product-}\mathbb{R}\mathrm{P}^n\text{-Proposition 121.16}}{\underset{\uparrow}{=}}\; h^*(0) \;=\; 0.$$

We have thus obtained the desired contradiction. ■

121.4. **The cup product of quaternionic and octonionic projective spaces.** In this very short section we discuss the cup product of the quaternionic projective spaces $\mathbb{H}\mathrm{P}^n$ that we introduced on page 1970. We will also calculate the cup product of the octonionic projective plane $\mathbb{O}\mathrm{P}^2$ that we defined on page 1972. These calculations might not sound all that interesting, but later in Chapter 122 we will use them to show that certain homotopy groups of spheres are non-trivial.

The following proposition is the only, and thus also the most interesting, result of this section. The statement is of course, in light of the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7, entirely predictable.

Proposition 121.20.

(1) Given any $n \in \mathbb{N}$ there exists an isomorphism

$$\mathbb{Z}[z]/(z^{n+1}) \;\to\; (\mathrm{H}^*(\mathbb{H}\mathrm{P}^n;\mathbb{Z}),\cup)$$

of superalgebras, where z is an element of degree 4.

(2) There exists an isomorphism

$$\mathbb{Z}[z]/(z^3) \;\to\; (\mathrm{H}^*(\mathbb{O}\mathrm{P}^2;\mathbb{Z}),\cup)$$

of superalgebras, where z is an element of degree 8.

In both cases the obvious analogues with $\mathbb{Z}$ replaced by $\mathbb{Z}_2$ also hold.

Proof.

(1) Let $n \in \mathbb{N}_0$. By the Quaternion-Projective Space Lemma 92.9 we know that $\mathbb{H}\mathrm{P}^n$ is a $4n$-dimensional closed orientable smooth manifold which admits a CW-structure that has exactly one cell in the dimensions $0, 4, 8, \ldots, 4n$. The proof of the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 can be used, with very minor modifications, to prove the desired result.

[1486] The argument is very similar to the argument in the proof of Proposition 121.14.

(2) In the Octonion Plane Proposition 92.10 (3) we showed that the octonionic projective plane $\mathbb{O}\mathrm{P}^2$ is a closed orientable 16-dimensional smooth manifold which admits a CW-structure with precisely one cell in dimensions 0, 8 and 16, and which has no other cells. Once again the proof of the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 clinches the deal. ■

Propositions 121.7 and 121.20 do raise a few questions, which can be viewed as a more specific versions of Question 117.19. The first question we formulate asks whether we can realize polynomial rings in other degrees.

Question 121.21. Let m be an even number and $n \in \mathbb{N}$. Does there exist a topological space X such that $(\mathrm{H}^*(X;\mathbb{Z}), \cup)$ is isomorphic to $\mathbb{Z}[z]/(z^{n+1})$ where z is now an element of degree m?

The following question is even more specific, it asks whether there exists a "cohomological $\mathbb{O}\mathrm{P}^3$.

Question 121.22. Does there exist a topological space X such that $(\mathrm{H}^*(X;\mathbb{Z}), \cup)$ is isomorphic to $\mathbb{Z}[z]/(z^4)$ where z is now an element of degree 8?

It will not take the reader very long to see that a negative answer to Question 121.22 would also tragically give a negative answer to Question 92.11.

121.5. **Division algebras.** We recall that on page 1959 we defined a *real division algebra* to be an algebra over $\mathbb{R}$ such that for all $a \neq 0$ and $b \in A$ there exists an $x \in A$ with $a \cdot x = b$ and a $y \in A$ with $y \cdot a = b$. In Section 92.1 we gave several examples of real division algebras, namely $\mathbb{R}$, the complex numbers $\mathbb{C}$, the quaternions $\mathbb{H}$ (which are not commutative) and the Cayley Octonions $\mathbb{O}$ (which are neither commutative nor associative). These real division algebras are defined over $\mathbb{R}^n$ with $n = 1, 2, 4$ and 8.
These dimensions are powers of 2 and the following theorem, which was first proved by Heinz Hopf [**Hopf1940a**] in 1940, shows that this is not a coincidence.

Theorem 121.23. (Hopf 1940) If $\mathbb{R}^n$ admits the structure of a real division algebra, then n is a power of 2.

In the proof of Theorem 121.23 we will need the following lemma which is interesting in its own right.

Lemma 121.24. Let $k \in \mathbb{N}$. We denote by $\varphi \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^k;\mathbb{F}_2)$ the unique non-trivial element. We denote by p and q the two natural projections $\mathbb{R}\mathrm{P}^k \times \mathbb{R}\mathrm{P}^k \to \mathbb{R}\mathrm{P}^k$ and we write $\alpha = p^*(\varphi)$ and $\beta = q^*(\varphi)$. Then the obvious homomorphism

$$\mathbb{F}_2[\alpha,\beta]/(\alpha^{k+1},\beta^{k+1}) \;\to\; \mathrm{H}^*(\mathbb{R}\mathrm{P}^k \times \mathbb{R}\mathrm{P}^k;\mathbb{F}_2)$$

of superalgebras is an isomorphism.

Proof. The lemma is an immediate consequence of Propositions 121.16 and 117.24 and the discussion on page 2586. ■

Proof of Theorem 121.23. Let "$*$" be a real division algebra structure on $\mathbb{R}^n$. We want to show that n is a power of 2. Since 1 and 2 are powers of 2 we can assume that $n \geq 3$.

As in the proof of Theorem 92.4 we consider the map

$$\begin{array}{rcl} \widetilde{f}\colon S^{n-1}\times S^{n-1} & \to & S^{n-1} \\ (x,y) & \mapsto & \widetilde{f}(x,y) := \dfrac{x*y}{\|x*y\|}. \end{array}$$

We make the following observations:

(1) In the proof of Theorem 92.4 we already showed, using the hypothesis that "$*$" defines a division algebra, that this map is well-defined, i.e. that we never divide by zero.
(2) In the proof of Theorem 92.4 we had also shown that the map $\widetilde{f}$ is continuous.
(3) Since "$*$" defines in particular an algebra we have

$$\widetilde{f}(-x,y) = -\widetilde{f}(x,y) \quad \text{and} \quad \widetilde{f}(x,-y) = -\widetilde{f}(x,y) \quad \text{for any } x,y\in S^{n-1}.$$

From (3) it follows that the above map $\widetilde{f}$ descends to a map[1487]

$$\begin{array}{rcl} f\colon \mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ [\widetilde{x}],[\widetilde{y}] & \mapsto & \big[\widetilde{f}(x,y)\big]. \end{array}$$

We pick a point $z\in S^{n-1}$. We consider the inclusion maps

$$\begin{array}{rcl} i\colon \mathbb{R}\mathrm{P}^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1} \\ x & \mapsto & (x,[z]) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon \mathbb{R}\mathrm{P}^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1} \\ x & \mapsto & ([z],x). \end{array}$$

Our first goal is to prove the following claim.

Claim 1. The map

$$(f\circ i)_*\colon \mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \to \mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$$

is an isomorphism. The same conclusion holds with i_* replaced by j_*.

Proof. We provide the proof for the first statement. The proof with i_* replaced by j_* is basically the same. By Lemma 121.19 (2) it suffices to show that the map

$$(f\circ i)_*\colon \pi_1(\mathbb{R}\mathrm{P}^{n-1}) \to \pi_1(\mathbb{R}\mathrm{P}^{n-1})$$

has non-trivial image. We introduce the following notation:

(1) We denote by $\pi\colon S^{n-1}\to\mathbb{R}\mathrm{P}^{n-1}$ the natural projection.
(2) We pick a path $\gamma\colon[0,1]\to S^{n-1}$ with $\gamma(1)=-\gamma(0)$. Note that $\pi\circ\gamma\colon[0,1]\to\mathbb{R}\mathrm{P}^{n-1}$ is a loop.
(3) We denote by $\widetilde{i}$ the inclusion map $S^{n-1}\to S^{n-1}\times S^{n-1}$ that is given by $\widetilde{i}(x)=(x,z)$.

Note that we get the following commutative diagram

$$\begin{array}{ccccccc} [0,1] & \xrightarrow{\gamma} & S^{n-1} & \xrightarrow{\widetilde{i}} & S^{n-1}\times S^{n-1} & \xrightarrow{\widetilde{f}} & S^{n-1} \\ & & \downarrow{\scriptstyle\pi} & & \downarrow{\scriptstyle\pi\times\pi} & & \downarrow{\scriptstyle\pi} \\ & & \mathbb{R}\mathrm{P}^{n-1} & \xrightarrow{i} & \mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1} & \xrightarrow{f} & \mathbb{R}\mathrm{P}^{n-1}. \end{array}$$

Finally we note that

$$(f\circ i)_*([\pi\circ\gamma]) = [f\circ i\circ\pi\circ\gamma] \overset{\text{by the above commutative diagram}}{=} \big[\pi\circ(\widetilde{f}\circ\widetilde{i}\circ\gamma)\big] \neq e \in \pi_1(\mathbb{R}\mathrm{P}^{n-1}).$$

this follows from Lemma 121.19 (1) since the following equality holds:
$(\widetilde{f}\circ\widetilde{i}\circ\gamma)(1)=\widetilde{f}(\gamma(1),z)=\widetilde{f}(-\gamma(0),z)=-\widetilde{f}(\gamma(0),z)=-(\widetilde{f}\circ\widetilde{i}\circ\gamma)(0)$

[1487] The argument of Footnote 1485 shows that f is continuous.

⊞

We denote by $\varphi \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ the unique non-trivial element. Furthermore, as so often we denote by p and q the two natural projections $\mathbb{R}\mathrm{P}^{n-1} \times \mathbb{R}\mathrm{P}^{n-1} \to \mathbb{R}\mathrm{P}^{n-1}$. Finally we write $\alpha = p^*(\varphi)$ and $\beta = q^*(\varphi) \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$.

Claim 2. The following equality holds

$$f^*(\varphi) \;=\; \alpha + \beta \;\in\; \mathrm{H}^1(\mathbb{R}\mathrm{P}^{n-1} \times \mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2).$$

Proof. We start out the proof of the claim with the following three observations:

(1) The Cohomology-Field Coefficients Proposition 110.18 says that for any topological space W the map

$$\begin{array}{rcl} \mathrm{ev}\colon \mathrm{H}^1(W;\mathbb{F}_2) & \to & \mathrm{Hom}(\mathrm{H}_1(W;\mathbb{F}_2),\mathbb{F}_2) \\ \psi & \mapsto & (\sigma \mapsto \langle \psi, \sigma\rangle) \end{array}$$

is an isomorphism.

(2) Let $x \in \mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ be the unique non-trivial element. By the discussion on page 2499 the map

$$\begin{array}{rcl} \mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \oplus \mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) & \to & \mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \\ a \oplus b & \mapsto & i_*(a) \oplus j_*(b) \end{array}$$

is an isomorphism. In particular we see that $\mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ is generated by $i_*(x)$ and $j_*(x)$.

(3) Since $\mathrm{H}^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ and $\mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ both contain a unique non-trivial element, namely φ and x, we obtain from Observation (1) that $\mathrm{ev}(\varphi)(x) = \langle \varphi, x\rangle = 1$.

It follows from (1) and (2) that it suffices to show that $\mathrm{ev}(f^*(\varphi))$ and $\mathrm{ev}(\alpha+\beta)$ agree on $i_*(x)$ and $j_*(y)$. In fact we have

$$\mathrm{ev}(f^*(\varphi))(i_*(x)) \underset{\text{by definition}}{=} \langle f^*(\varphi), i_*(x)\rangle \underset{\text{Lemma 109.6 (3)}}{=} \langle \varphi, f_*(i_*(x))\rangle \underset{\substack{\text{by Claim 1 since } x \text{ is unique non-zero element of } \mathrm{H}_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)}}{=} \langle \varphi, x\rangle \underset{\text{observation (3)}}{=} 1.$$

We also calculate that

$$\mathrm{ev}(\alpha+\beta)(i_*(x)) \underset{\text{by definition}}{=} \langle p^*\varphi + q^*\varphi, i_*(x)\rangle \underset{\text{Lemma 109.6 (3)}}{=} \langle \varphi, p_*(i_*(x))\rangle + \langle \varphi, q_*(i_*(x))\rangle \underset{\text{since } p\circ i = \mathrm{id} \text{ and } q\circ i \text{ is a constant map}}{=} \langle \varphi, x\rangle \;=\; 1.$$

We have thus shown that $\mathrm{ev}(f^*(\varphi))$ and $\mathrm{ev}(\alpha+\beta)$ agree on $i_*(x)$. The same argument also works with $i_*(x)$ replaced by $j_*(y)$. ⊞

Using Lemma 121.24 we can and will make the identification

$$\mathrm{H}^*(\mathbb{R}\mathrm{P}^{n-1} \times \mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \;=\; \mathbb{F}_2[\alpha,\beta]/(\alpha^n,\beta^n).$$

Using this identification we see that

$$0 = f^*(0) \underset{\substack{\text{by the Cup Product-}\mathbb{R}\mathrm{P}^n\text{-Proposition 121.16,} \\ \text{since } \varphi \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)}}{=} f^*(\varphi^n) \overset{\substack{\text{by Cup Product-Naturality Lemma 114.10} \\ \downarrow}}{=} (f^*(\varphi))^n \underset{\text{by the previous claim}}{=} (\alpha+\beta)^n = \sum_{k=0}^{n}\binom{n}{k}\cdot\alpha^k\beta^{n-k} \underset{\text{since } \alpha^n=\beta^n=0}{=} \sum_{k=1}^{n-1}\binom{n}{k}\cdot\alpha^k\beta^{n-k}.$$

This equality holds in the polynomial ring $\mathbb{F}_2[\alpha,\beta]/(\alpha^n,\beta^n)$. In this ring the $n-1$ monomials $\alpha\beta^{n-1}, \alpha^2\beta^{n-2}, \dots, \alpha^{n-1}\beta$ are linearly independent over the field $\mathbb{F}_2$. This implies that for $k = 1, \dots, n-1$ we have $\binom{n}{k} \equiv 0 \bmod 2$. Thus it remains to prove the following purely algebraic claim.

Claim 3. If $n \in \mathbb{N}$ satisfies that $\binom{n}{k} \equiv 0 \bmod 2$ for $k = 1, \dots, n-1$, then n is a power of 2.

Proof. We can and will write n as a sum $n = n_1 + \cdots + n_r$ where each n_i is a power of 2 and with $n_1 < \cdots < n_r$. In the polynomial ring $\mathbb{F}_2[x]$ we obtain that

$$1 + x^n \overset{\text{by our hypothesis}}{\downarrow} = \sum_{k=0}^{n} \binom{n}{k} x^k = (1+x)^n \overset{\text{since } n = n_1 + \cdots + n_r}{\downarrow} = (1+x)^{n_1} \cdot \cdots \cdot (1+x)^{n_r}$$
$$= (1+x^{n_1}) \cdot \cdots \cdot (1+x^{n_r}) \overset{\text{since } n_1 < \cdots < n_r}{\uparrow} = 1 + x^{n_1} + \text{higher powers.}$$
$$\overset{\text{since each } n_i \text{ is a power of 2 and since in } \mathbb{F}_2[x] \text{ we have } (a+b)^2 = a^2 + b^2}{\uparrow}$$

But this is only possible if $n = n_1$, i.e. if n itself is a power of 2. ■

In fact, with more fancy topological methods one can actually strengthen the previous theorem to obtain the following theorem which gives a complete answer to Question 92.7. Unfortunately the proof is well beyond the scope of these modest lecture notes.

Theorem 121.25. (Bott-Kervaire-Milnor 1958) Every finite-dimensional division algebra over $\mathbb{R}$ is of dimension 1,2, 4 or 8.

Proof. The theorem was first proved using topological methods by Michel Kervaire [**Kerv1958**] and John Milnor [**Miln1958a**, Corollary 1], building on the "Bott Periodicity Theorem" proved by Raoul Bott [**Bot1957, Bot1959**].[1488] Full details for the proof can also be found in [**Hat2**, Theorem 2.16]. As of right now there is no purely algebraic proof for the statement. ■

Remark. One might ask whether any finite-dimensional division algebra over $\mathbb{R}$ is isomorphic to $\mathbb{R}, \mathbb{C}, \mathbb{H}$ or $\mathbb{O}$. The statement holds under the stronger hypothesis that the algebra is "normed" or "alternative". We refer to [**BD1973**, p. 73], [**EHHKMNPR1991**, p. 262] and [**Baez2001**] for results in this direction. As is shown in [**Hat2002**, p. 59], [**Bruc1944, Osb1962**], without any extra hypotheses one cannot expect a uniqueness statement.

Exercises for Chapter 121.

Exercise 121.1. Let R be a commutative ring, let V be an R-module and let $\varphi\colon V \times V \to R$ be a symmetric R-bilinear pairing. Given a submodule $W \subset V$ we obtain a symmetric R-bilinear pairing $\varphi\colon W \times W \to R$ by restricting φ to $W \times W$.

(a) Show that if φ is non-degenerate, then it does not necessarily follow that $\varphi|_W$ is non-degenerate.

[1488] We will discuss the statement of the Bott Periodicity Theorem in Section 156.4.

(b) Let $\langle -,-\rangle\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ be the usual Euclidean pairing. Show that for every $\mathbb{R}$-vector subspace $W \subset \mathbb{R}^n$ the corresponding pairing $W \times W \to \mathbb{R}$ is non-singular.

(c) Let $\langle -,-\rangle\colon \mathbb{Z}^n \times \mathbb{Z}^n \to \mathbb{Z}$ be the usual Euclidean pairing. Show that for a $\mathbb{Z}$-submodule $W \subset \mathbb{Z}^n$ the corresponding pairing $W \times W \to \mathbb{Z}$ is non-degenerate and show that in general it is not non-singular.

Exercise 121.2. Let V and W be free $\mathbb{Z}$-modules of finite rank, i.e. V and W are free abelian groups. Furthermore let $\lambda\colon V \times W \to \mathbb{Z}$ be a pairing. Recall that we say that λ is *non-singular* if the induced maps

$$\begin{array}{ccc} V & \to & \mathrm{Hom}_{\mathbb{Z}}(W,\mathbb{Z}) \\ v & \mapsto & \left(\begin{array}{ccc} W & \to & \mathbb{Z} \\ w & \mapsto & \lambda(v,w) \end{array}\right) \end{array} \quad \text{and} \quad \begin{array}{ccc} W & \to & \mathrm{Hom}_{\mathbb{Z}}(V,\mathbb{Z}) \\ w & \mapsto & \left(\begin{array}{ccc} V & \to & \mathbb{Z} \\ v & \mapsto & \lambda(v,w) \end{array}\right) \end{array}$$

are isomorphisms. We say that the pairing is *non-degenerate*, if the two maps are monomorphisms.

(a) Let $v_1,\dots,v_n$ be a basis for V. Show that the following two statements are equivalent:
  (i) There exists some basis $w_1,\dots,w_n$ for W such that $\lambda(v_i,w_j) = \delta_{ij}$ for every choice of $i,j \in \{1,\dots,n\}$.[1489]
  (ii) The pairing λ is non-singular.

(b) Suppose that λ is non-degenerate. Show that V and W have the same rank.

(c) Suppose that V and W are of rank n and suppose we are given $v_1,\dots,v_n \in V$ and $w_1,\dots,w_n \in W$ such that $\det(\lambda(v_i,w_j)) = \pm 1$. Show that $v_1,\dots,v_n$ is a basis for V and that $w_1,\dots,w_n$ is a basis for W.

Exercise 121.3. Let V be a free $\mathbb{Z}$-module of finite rank, i.e. V is a free abelian group. Let $\varphi\colon V \times V \to \mathbb{Z}$ be a form. Given a subgroup $U \subset V$ we write

$$U^{\perp} \;=\; \{v \in V \mid \varphi(u,v) = 0 \text{ for all } u \in U\}.$$

We suppose that the form φ is non-singular. Show that for any subgroup $U \subset V$ we have $\mathrm{rank}(U^{\perp}) = \mathrm{rank}(V) - \mathrm{rank}(U)$.

Exercise 121.4. Let $m,n \in \mathbb{N}$. We denote by $p\colon S^m \times S^n \to S^m$ and by $q\colon S^m \times S^n \to S^n$ the two natural projections. Use Poincaré Duality to show that

$$p^*([S^m]^*) \cup q^*([S^n]^*) \;=\; \pm[S^m \times S^n]^*.$$

Put differently, you should show the equality without using the Product Theorem 117.1.

Exercise 121.5. For which $n \in \mathbb{N}$ is the complex projective space $\mathbb{C}\mathrm{P}^n$ chiral, i.e. for which $n \in \mathbb{N}$ does $\mathbb{C}\mathrm{P}^n$ admit an orientation-reversing self-homeomorphism?

Exercise 121.6. Does there exist a degree one map from $\mathbb{C}\mathrm{P}^2$ to $S^2 \times S^2$?

Exercise 121.7. Is $S^3 \vee \mathbb{R}\mathrm{P}^2$ homotopy equivalent to a smooth manifold?

Exercise 121.8. Show that there exists a connected CW-complex X with base point x_0 and a homomorphism $\varphi\colon \pi_1(X,x_0) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}\mathrm{P}^2,*)$ which cannot be realized by a map $g\colon X \to \mathbb{R}\mathrm{P}^2$, i.e. such that there is no map $f\colon X \to \mathbb{R}\mathrm{P}^2$ with $f(x_0) = *$ such that $f_* = \varphi$. *Remark.* This gives a negative answer to Question 118.14 (3).

[1489] The basis $w_1,\dots,w_n$ is in fact unique.

Exercise 121.9.

(a) Let $n \in \mathbb{N}$ and let M be a closed orientable $2n$-dimensional smooth manifold. Suppose that M admits a CW-structure with precisely three cells. Show that M has precisely one cell in dimensions 0, n and $2n$.

(b) Show that there is no closed orientable 6-dimensional smooth manifold that has only three cells.

(c) In (a) and (b), do we really need to assume that M is orientable?

Exercise 121.10. Let $n \in \mathbb{N}_0$ and let $\varphi\colon \mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^n$ be map.

(a) Show that there exists a $d \in \mathbb{Z}$ such that

$$\underbrace{\sum_{k=0}^{2n} (-1)^k \cdot \operatorname{tr}(\varphi_*\colon \mathrm{H}_k(\mathbb{C}\mathrm{P}^n) \to \mathrm{H}_k(\mathbb{C}\mathrm{P}^n))}_{\text{Lefschetz number } \Lambda(\varphi)} \;=\; 1 + \sum_{l=1}^{n} d^l.$$

Hint. Use the cohomological reformulation of the Lefschetz number given in Exercise 110.12.

(b) Suppose n is odd. Use the Lefschetz Fixed Point Theorem 97.9 to show that φ admits a fixed point.

Remark. In Exercise 97.8 we showed that for any even $n \in \mathbb{N}_0$ there exists a self-map of $\mathbb{C}\mathrm{P}^n$ with no fixed points.

Exercise 121.11. Let $n \in \mathbb{N}_{\geq 2}$ and let $\varphi\colon S^2 \to S^2$ be a map of degree n. We consider $X := \operatorname{Cone}(S^2 \xrightarrow{\varphi} S^2 = \mathbb{C}\mathrm{P}^1 \subset \mathbb{C}\mathrm{P}^2)$ and $Y := \operatorname{Cone}(S^2 \xrightarrow{\varphi} S^2) \vee S^4$.

(a) Show that the cohomology rings of X and Y with $\mathbb{Z}$-coefficients are isomorphic.

(b) Show that the cohomology rings of X and Y with $\mathbb{Z}$-coefficients are not isomorphic.

122. The Hopf invariant

In previous chapters we have seen that the introduction and the calculation of the cup product allowed us to answer many questions on topological spaces that we could not deal with before. In this section we want to use the cup product to address the following question that we formulated a long time ago.

Question 71.18. Does the Hopf map $H\colon S^3 \to S^2$ represent a non-trivial element in the homotopy group $\pi_3(S^2)$?

In this chapter we will use the calculation of the cup product of $\mathbb{C}\mathrm{P}^2$ to give an affirmative answer to this question. Furthermore we will use the quaternions and octonions to define higher dimensional analogues of the Hopf map which also represent non-trivial elements in homotopy groups of spheres.

122.1. The Hopf map is not null-homotopic.

First we recall the definition of the Hopf map. On page 258 we gave an explicit identification $\mathbb{C}\mathrm{P}^1 = S^2$. Furthermore on page 1576 we made the following definition.

Definition. We refer to the map[1490]

$$\begin{array}{rcl} H\colon S^3 = \{(z_1,z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ (z_1,z_2) & \mapsto & [z_1 : z_2] \end{array}$$

as the Hopf map.

Since the Hopf map is so much fun we will introduce two higher-dimensional analogues of the Hopf map. More precisely, we will repeat the trick with $\mathbb{C}$ replaced by the quaternions $\mathbb{H}$ and the octonions $\mathbb{O}$. First we point out that we can use the homeomorphisms from the Quaternion-Projective Space Lemma 92.9 (2) and the Octonion Plane Proposition 92.10 (2) to make the identifications $\mathbb{H}\mathrm{P}^1 = S^4$ and $\mathbb{O}\mathrm{P}^1 = S^8$. Now we can introduce the quaternionic and octonionic Hopf maps.

Definition. We refer to

$$\begin{array}{rcl} H_{\mathbb{H}}\colon S^7 = \{(z_1,z_2) \in \mathbb{H}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^4 = \mathbb{H}\mathrm{P}^1 \\ (z_1,z_2) & \mapsto & [z_1 : z_2] \end{array}$$

as the quaternionic Hopf map and we refer to

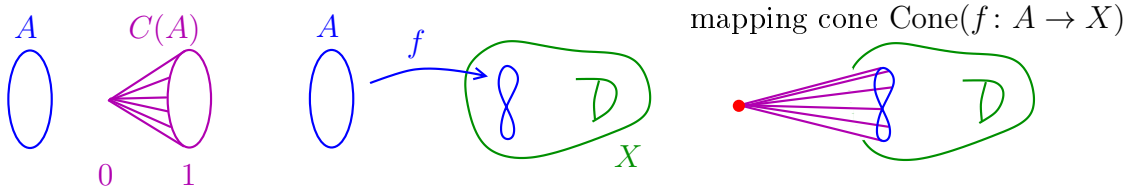
$$\begin{array}{rcl} H_{\mathbb{O}}\colon S^{15} = \{(z_1,z_2) \in \mathbb{O}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^8 = \mathbb{O}\mathrm{P}^1 \\ (z_1,z_2) & \mapsto & [z_1 : z_2] \end{array}$$

as the octonionic Hopf map.

The idea for answering Question 71.18 is to translate this question about maps to a question about topological spaces for which we can then bring our new invariants to bear. To carry out this approach we recall the following definitions from earlier on:

Definition.

(1) On page 450 we defined the cone of a topological space A to be the topological space $\mathrm{Cone}(A) := (A \times [0,1])/\sim$ where $(a,0) \sim (a',0)$ for all $a, a' \in A$.



[1490] See also the figure on page 1577 for an illustration of the map.

(2) On page 457 we defined the mapping cone of a map $f\colon A \to X$ between topological spaces as

$$\text{Cone}(f\colon A \to X) \;:=\; (\text{Cone}(A) \cup X)/\!\sim$$

where $(a,1) \sim f(a)$ for all $a \in A$.

Both definitions are illustrated in the figure below.

Examples.

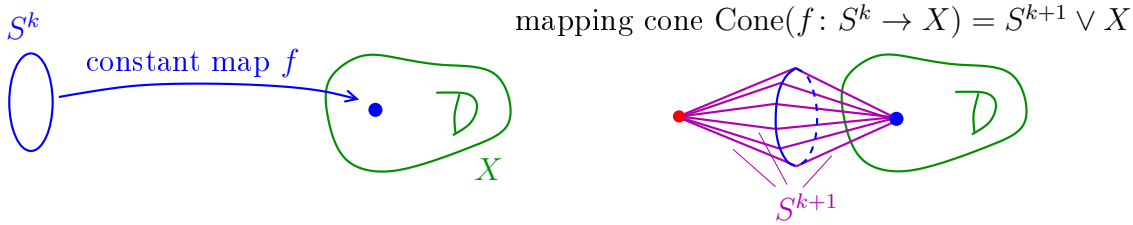
(1) It follows from the Compact-Hausdorff Proposition 2.17 (3) and the Topological-Quotient Proposition 5.15 (1b) that the map

$$\begin{array}{rcl} \text{Cone}(S^{n-1}) & \to & \overline{B}^n \\ [(P,t)] & \mapsto & t \cdot P \end{array}$$

is a homeomorphism. We use this homeomorphism to identify $\text{Cone}(S^{n-1})$ with $\overline{B}^n$. In particular, if X is a topological space and if $f\colon S^{n-1} \to X$ is a map, then we get an identification

$$\text{Cone}(f\colon S^{n-1} \to X) \;=\; \overline{B}^n \cup_f X.$$

It follows immediately from this observation that any finite CW-complex can be viewed as an iterated mapping cone (where we start out with a finite discrete set).



(2) In Exercise 122.1 we will see that the mapping cone of the map $f\colon S^1 \to S^1$ that is given by $f(z) = z^2$ is a topological space that we are very familiar with.

The next lemma gives us another elementary but oddly useful example.

Lemma 122.1. (Mapping Cone-of-Constant Map Lemma) If $f\colon S^k \to X$ is a constant map, then there exists a homeomorphism

$$\text{Cone}(f\colon S^k \to X) \;\xrightarrow{\cong}\; S^{k+1} \vee X,$$

where we perform the wedge for suitable points in S^{k+1} and X.

Proof. Suppose $f\colon S^k \to X$ is a constant map. It follows easily from the example on page 2677 and the homeomorphism $\overline{B}^{k+1}/S^k \cong S^{k+1}$ from the Ball-Quotient Sphere Lemma 5.20 that $\text{Cone}(f\colon S^k \to X)$ is homeomorphic to a wedge $S^{k+1} \vee X$. We leave it to the reader to fill in the details. ∎

The following lemma gives a particularly interesting example of a mapping cone.

Lemma 122.2. (Mapping Cone-of-Hopf Map Lemma) There exist homeomorphisms

$$\begin{array}{lrcl} (1) & \mathrm{Cone}(H\colon S^3 \to S^2) & \cong & \mathbb{C}\mathrm{P}^2 \\ (2) & \mathrm{Cone}(H_{\mathbb{H}}\colon S^7 \to S^4) & \cong & \mathbb{H}\mathrm{P}^2 \\ (3) & \mathrm{Cone}(H_{\mathbb{O}}\colon S^{15} \to S^8) & \cong & \mathbb{O}\mathrm{P}^2. \end{array}$$

Proof.

(1) In Lemma 68.1 we saw that $\mathbb{C}\mathrm{P}^2$ is a CW-complex that is obtained from the CW-complex $\mathbb{C}\mathrm{P}^1 = S^2$ by attaching a 4-cell. The attaching map $S^3 \to \mathbb{C}\mathrm{P}^1$ of the 4-cell is precisely the Hopf map. This observation, together with the discussion on page 2677, already implies the statement. For completeness' sake we give the argument more explicitly and in more detail. We consider the maps[1491]

$$\begin{array}{rcl} f\colon \mathrm{Cone}(S^3) & \to & \mathbb{C}\mathrm{P}^2 \\ [(z_0,z_1),r] & \mapsto & [r\cdot z_0 : r\cdot z_1 : 1-r] \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{C}\mathrm{P}^1 & \to & \mathbb{C}\mathrm{P}^2 \\ [z_0:z_1] & \mapsto & [z_0:z_1:0]. \end{array}$$

It follows immediately from the definitions together with the Topological-Quotient Proposition 5.15 (1b) that these two maps define a continuous map

$$\underbrace{\mathrm{Cone}(H\colon S^3 \to S^2)}_{=(\mathrm{Cone}(S^3)\cup\mathbb{C}\mathrm{P}^1)/\sim} \to \mathbb{C}\mathrm{P}^2.$$

One can easily verify that this map is a bijection. Furthermore, using the Compact-Hausdorff Proposition 2.17 (3) and the Projective Spaces-Compact+Hausdorff Proposition 5.30 one sees that the map is in fact a homeomorphism.

(2) The proof of (2) is basically identical to the proof of (1).

(3) Implicitly we mostly proved this statement in the proof of the Octonion Plane Proposition 92.10. Alternatively we also refer to [**Lackm2012**, p. 4] for details. ■

Now we can finally answer Question 71.18 in the affirmative. More precisely we have the following theorem. The statement regarding the "classical" Hopf map was first proved by Heinz Hopf [**Hopf1931**] in 1931.

Theorem 122.3.

(1) The Hopf map $H\colon S^3 \to S^2$ represents a non-trivial element in the third homotopy group $\pi_3(S^2)$.

(2) We have $[H_{\mathbb{H}}] \neq 0 \in \pi_7(S^4)$.

(3) We have $[H_{\mathbb{O}}] \neq 0 \in \pi_{15}(S^8)$.

Proof. First we prove (1). Recall that for two topological spaces X and Y we write $X \simeq Y$ if they are homotopy equivalent. We have

$$\begin{array}{ccccccc} \mathrm{Cone}(\text{Hopf map } H) & \cong & \mathbb{C}\mathrm{P}^2 & \not\simeq & S^2 \vee S^4 & \cong & \mathrm{Cone}(\text{constant map}). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Mapping Cone-of-Hopf Map Lemma 122.2 (1)} & & \text{Lemma 121.4} & & \text{Mapping Cone-of-Constant Map Lemma 122.1} & \end{array}$$

But by the Mapping Cone Inclusion Lemma 16.16 this means that the Hopf map is not homotopic to the constant map. In particular the Hopf map $H\colon S^3 \to S^2$ represents a non-trivial element in the homotopy group $\pi_3(S^2)$.

[1491] It follows from the Topological-Quotient Proposition 5.15 (1b) and the Topological-Quotient Proposition 5.15 (1a) that these two maps are continuous.

The proof of the other two statements is quite similar. We again use the Mapping Cone-of-Hopf Map Lemma 122.2 and we use the calculations of the cup products of $\mathbb{H}\mathrm{P}^2$ and $\mathbb{O}\mathrm{P}^2$, see Proposition 121.20, to conclude that the mapping cones of the quaternionic and octonionic Hopf maps are not homotopy equivalent to a wedge of spheres. ■

122.2. **The Hopf invariant.** It is natural to ask how far we can push the methods of Theorem 122.3 to gain more insight into homotopy groups of spheres. In this section, given $n \geq 2$ we will introduce the Hopf invariant

$$\mathrm{Hopf}\colon \pi_{2n-1}(S^n) \;\to\; \mathbb{Z}$$

which satisfies $\mathrm{Hopf}(H) = \pm 1$, $\mathrm{Hopf}(H_{\mathbb{H}}) = \pm 1$ and $\mathrm{Hopf}(H_{\mathbb{O}}) = \pm 1$.
The idea behind the definition of the Hopf invariant is straightforward. Namely, given $n \in \mathbb{N}_{\geq 2}$ and given a map $f\colon S^{2n-1} \to S^n$ we consider again the corresponding mapping cone $\mathrm{Cone}(f\colon S^{2n-1} \to S^n)$. We will see in Lemma 122.5 that it follows from the fact that $n \geq 2$ that we have $\mathrm{H}^n(\mathrm{Cone}(f);\mathbb{Z}) \cong \mathbb{Z}$ and $\mathrm{H}^{2n}(\mathrm{Cone}(f);\mathbb{Z}) \cong \mathbb{Z}$. We will equip $\mathrm{H}^{2n}(\mathrm{Cone}(f);\mathbb{Z})$ with a "preferred generator". We pick a generator $\varphi \in \mathrm{H}^n(\mathrm{Cone}(f);\mathbb{Z})$ and we define $\mathrm{Hopf}(f)$ to be the unique integer that satisfies

$$\varphi \cup \varphi \;=\; \mathrm{Hopf}(f) \cdot \text{preferred generator} \;\in\; \mathrm{H}^{2n}(\mathrm{Cone}(f);\mathbb{Z}).$$

To carry out this program we need to carefully study the cohomology groups of a mapping cone. Recall that in the Mapping Cone-H_*-Lemma 78.17 we saw that the homology groups of a mapping cone fit naturally into a long exact sequence of homology groups. The following lemma shows that the analogous statement also holds for the cohomology groups of a mapping cone.

Lemma 122.4. (Mapping Cone-H^*-Lemma) Let R be a commutative ring.

(1) Let $f\colon A \to X$ be a map between topological spaces.
   (a) We denote by $j(f)\colon X \to \mathrm{Cone}(f) = (\mathrm{Cone}(A) \sqcup X)/\!\sim$ the obvious inclusion map.
   (b) We denote by U the image of $A \times [0, \frac{3}{4})$ in $\mathrm{Cone}(f)$ and we denote by V the complement of the image of $A \times [0, \frac{1}{4}]$. (See also the figure below.) We consider the following diagram

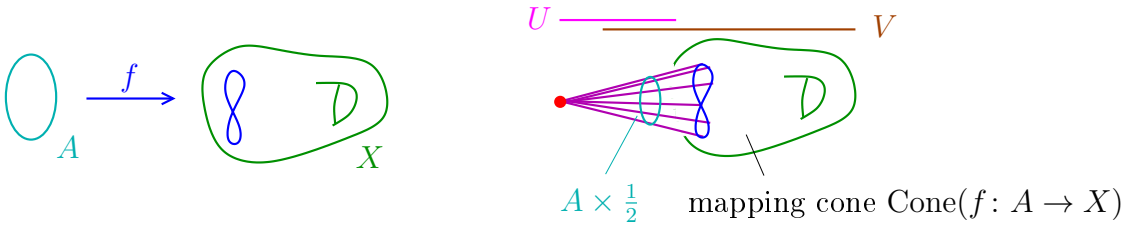
$$\begin{array}{ccccccc} \ldots \longrightarrow \mathrm{H}^{k-1}(U\cap V;R) & \xrightarrow{\delta} & \mathrm{H}^k(\mathrm{Cone}(f);R) & \longrightarrow & \mathrm{H}^k(U;R)\oplus \mathrm{H}^k(V;R) & \longrightarrow & \ldots \\ \downarrow{=} & \nearrow_{=:\delta^{k-1}(f)} & & & & & \\ \mathrm{H}^{k-1}(A;R). & & & & & & \end{array}$$

   Here the top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 109.15 for Cohomology Groups[1492] and the vertical map comes from the obvious identifications $\mathrm{H}^{k-1}(U\cap V;R) = \mathrm{H}^{k-1}(A\times\frac{1}{2};R) = \mathrm{H}^{k-1}(A;R)$. From the above diagram we obtain the map

$$\delta^{k-1}(f)\colon \mathrm{H}^{k-1}(A;R) \;\to\; \mathrm{H}^k(\mathrm{Cone}(f);R).$$

The following sequence is exact

$$\ldots \to \widetilde{\mathrm{H}}^k(\mathrm{Cone}(f);R) \xrightarrow{j(f)^*} \mathrm{H}^k(X;R) \xrightarrow{f^*} \mathrm{H}^k(A;R) \xrightarrow{\delta^k(f)} \widetilde{\mathrm{H}}^{k+1}(\mathrm{Cone}(f);R) \to \ldots$$



(2) The connecting homomorphism in (1) is natural. In particular given any commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{f} & X \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{A} & \xrightarrow{\widetilde{f}} & \widetilde{X} \end{array}$$

of maps between topological spaces the following diagram commutes:

$$\begin{array}{ccccccccc} \ldots \to \widetilde{\mathrm{H}}^k(\mathrm{Cone}(f);R) & \xrightarrow{j(f)^*} & \mathrm{H}^k(X;R) & \xrightarrow{f^*} & \mathrm{H}^k(A;R) & \xrightarrow{\delta^k(f)} & \widetilde{\mathrm{H}}^{k+1}(\mathrm{Cone}(f);R) & \to \ldots \\ \uparrow & & {\scriptstyle\psi^*}\uparrow & & {\scriptstyle\varphi^*}\uparrow & & \uparrow & \\ \ldots \to \widetilde{\mathrm{H}}^k(\mathrm{Cone}(\widetilde{f});R) & \xrightarrow{j(\widetilde{f})^*} & \mathrm{H}^k(\widetilde{X};R) & \xrightarrow{\widetilde{f}^*} & \mathrm{H}^k(\widetilde{A};R) & \xrightarrow{\delta^k(\widetilde{f})} & \widetilde{\mathrm{H}}^{k+1}(\mathrm{Cone}(\widetilde{f});R) & \to \ldots \end{array}$$

Here the vertical maps between the cohomology groups of the mapping cones are induced by the maps from the Mapping Cone Functor Lemma 16.14 (3).

Proof. The proof is basically identical to the proof of the Mapping Cone-H_*-Lemma 78.17. The meticulous reader who filled in the details of the proof of the Mapping Cone-H_*-Lemma 78.17 will have no troubles working out the details of the present proof. ■

Lemma 122.5. Let $f\colon S^m \to S^n$ be a map. If $m \geq n+1$ and $n \geq 1$, then the maps

$$\mathrm{H}^n(\mathrm{Cone}(f);\mathbb{Z}) \xrightarrow{j(f)^*} \mathrm{H}^n(S^n;\mathbb{Z})$$

and

$$\mathrm{H}^m(S^m;\mathbb{Z}) \xrightarrow{\delta^m(f)} \mathrm{H}^{m+1}(\mathrm{Cone}(f);\mathbb{Z})$$

are isomorphisms and all other reduced cohomology groups of $\mathrm{Cone}(f)$ are zero. An analogous statement holds for homology groups. In particular we have isomorphisms

$$\mathrm{H}_k(\mathrm{Cone}(f\colon S^m \to S^n);\mathbb{Z}) \cong \mathrm{H}^k(\mathrm{Cone}(f\colon S^m \to S^n);\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, n, m+1, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. The lemma is an almost immediate consequence of the Mapping Cone-H^*-Lemma 122.4 and the calculation of the cohomology groups of spheres, see page 2422. For $n = 1$ one also needs to invoke Exercise 108.6. ■

[1492]Note that U and V are open subsets of $\mathrm{Cone}(f)$. Thus it follows from the Excisive Triad-Proposition 109.12 that we can in fact apply the theorem.

Throughout this section we use the notation that we had already introduced in the formulation of the Mapping Cone-H*-Lemma 122.4. More precisely, given a map $f\colon A \to X$ between two topological spaces we denote by $j(f)\colon X \to \mathrm{Cone}(f) = (\mathrm{Cone}(A) \cup X)/\sim$ the obvious inclusion map and furthermore we denote by $\delta^{k-1}(f)\colon \mathrm{H}^{k-1}(A;\mathbb{Z}) \to \mathrm{H}^k(\mathrm{Cone}(f);\mathbb{Z})$ the coboundary map in the long exact sequence in cohomology of the Mapping Cone-H*-Lemma 122.4.
Now we are finally in a position to turn the idea from page 2679 into a proper definition.

Definition. Let $f\colon S^{2n-1} \to S^n$ be a map with $n \geq 2$. The Hopf invariant $\mathrm{Hopf}(f)$ is defined to be the unique integer that satisfies[1493]

$$\underbrace{(j(f)^*)^{-1}([S^n]^*)}_{\substack{\text{generator of}\\ \mathrm{H}^n(\mathrm{Cone}(f);\mathbb{Z})}} \cup \underbrace{(j(f)^*)^{-1}([S^n]^*)}_{\substack{\text{generator of}\\ \mathrm{H}^n(\mathrm{Cone}(f);\mathbb{Z})}} = \mathrm{Hopf}(f) \cdot \underbrace{\delta^{2n-1}(f)([S^{2n-1}]^*)}_{\substack{\text{generator of}\\ \mathrm{H}^{2n}(\mathrm{Cone}(f);\mathbb{Z})}}$$

in $\mathrm{H}^{2n}(\mathrm{Cone}(f);\mathbb{Z}) \cong \mathbb{Z}$.

Remark.

(1) In the definition of the Hopf invariant we could have squared any of the two generators of $\mathrm{H}^n(\mathrm{Cone}(f);\mathbb{Z}) \cong \mathbb{Z}$, since the sign ambiguity goes away with the square.
(2) It follows immediately from the (anti-) commutativity of the cup product, see the Cup Product-Commutativity Proposition 114.8, that the Hopf invariant is zero for all odd n.

Example.

(1) As usual we denote by $H\colon S^3 \to S^2$ the Hopf map. In the Mapping Cone-of-Hopf Map Lemma 122.2 we showed that the mapping cone $\mathrm{Cone}(H)$ is homeomorphic to $\mathbb{C}\mathrm{P}^2$. By Lemma 122.5 we know that $(j(H)^*)^{-1}([S^2]^*) \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ and $\delta^3(f)([S^3]^*) \in \mathrm{H}^4(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ are generators. It follows from the calculation of the cup product on $\mathbb{C}\mathrm{P}^2$, see the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7, that $\mathrm{Hopf}(H) = -1$ or $\mathrm{Hopf}(H) = 1$.[1494]
(2) Using Proposition 121.20 one can show, by the same argument as in (1), that the Hopf invariants of the quaternionic Hopf map $H_{\mathbb{H}}\colon S^7 \to S^4$ and the octonionic Hopf map $H_{\mathbb{O}}\colon S^{15} \to S^8$ are equal to ± 1.

Lemma 122.6. Let $n \geq 2$ and let $f_0, f_1\colon S^{2n-1} \to S^n$ be two maps. If f_0 and f_1 are homotopic, then $\mathrm{Hopf}(f_0) = \mathrm{Hopf}(f_1)$.

Proof. Let $H\colon S^{2n-1} \times [0,1] \to S^n$ be a homotopy between f_0 and f_1. We denote by $i_0, i_1\colon S^{2n-1} \to S^{2n-1} \times [0,1]$ the two obvious inclusion maps. We obtain the following two commutative diagrams

$$\begin{array}{ccc} S^{2n-1} & \xrightarrow{f_0} & S^n \\ {\scriptstyle i_0}\downarrow & & \downarrow{\scriptstyle =} \\ S^{2n-1}\times[0,1] & \xrightarrow{H} & S^n \end{array} \qquad \text{and} \qquad \begin{array}{ccc} S^{2n-1} & \xrightarrow{f_1} & S^n \\ {\scriptstyle i_1}\downarrow & & \downarrow{\scriptstyle =} \\ S^{2n-1}\times[0,1] & \xrightarrow{H} & S^n. \end{array}$$

[1493] Here we implicitly use that in Lemma 122.5 we showed that $j(f)^*$ and $\delta^{2n-1}(f)$ are isomorphisms.
[1494] With more care one can show that in fact $\mathrm{Hopf}(H) = 1$, but this is irrelevant for our purpose.

By the Mapping Cone Functor Lemma 16.14 (3) the diagrams give rise to inclusion maps $\Xi_0\colon \operatorname{Cone}(f_0) \to \operatorname{Cone}(H)$ and $\Xi_1\colon \operatorname{Cone}(f_1) \to \operatorname{Cone}(H)$. From the Mapping Cone-H*-Lemma 122.4 we obtain the following commutative diagram of long exact sequences:

$$\begin{array}{ccccccccc}
\ldots \to \widetilde{\mathrm{H}}^k(\operatorname{Cone}(f_0)) & \xrightarrow{j(f_0)^*} & \mathrm{H}^k(S^n) & \xrightarrow{f_0^*} & \mathrm{H}^k(S^{2n-1}) & \xrightarrow{\delta} & \widetilde{\mathrm{H}}^{k+1}(\operatorname{Cone}(f_0)) \to \ldots \\
\uparrow{\scriptstyle \Xi_0^*} & & \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle \cong\, i_0^*} & & \uparrow{\scriptstyle \Xi_0^*} \\
\ldots \to \widetilde{\mathrm{H}}^k(\operatorname{Cone}(H)) & \xrightarrow{j(H)^*} & \mathrm{H}^k(S^n) & \xrightarrow{\mathrm{H}^*} & \mathrm{H}^k(S^{2n-1}\times[0,1]) & \xrightarrow{\delta} & \widetilde{\mathrm{H}}^{k+1}(\operatorname{Cone}(H)) \to \ldots \\
\downarrow{\scriptstyle \Xi_1^*} & & \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \cong\, i_1^*} & & \downarrow{\scriptstyle \Xi_1^*} \\
\ldots \to \widetilde{\mathrm{H}}^k(\operatorname{Cone}(f_1)) & \xrightarrow{j(f_1)^*} & \mathrm{H}^k(S^n) & \xrightarrow{f_1^*} & \mathrm{H}^k(S^{2n-1}) & \xrightarrow{\delta} & \widetilde{\mathrm{H}}^{k+1}(\operatorname{Cone}(f_1)) \to \ldots
\end{array}$$

Note that the vertical maps between the cohomology groups of the mapping cones are isomorphisms. This can be shown using the Five Lemma 74.10, or alternatively, in a more fancy way using the Mapping Cone Inclusion Lemma 16.16.

Next we consider the generator $\Theta := (i_0^*)^{-1}([S^{2n-1}]^*) = (i_1^*)^{-1}([S^{2n-1}]^*)$ of the group $\mathrm{H}^{2n-1}(S^{2n-1}\times[0,1];\mathbb{Z})$. We define a number $\operatorname{Hopf}(H)$ via the equality

$$(j(H)^*)^{-1}([S^n]^*) \cup (j(H)^*)^{-1}([S^n]^*) \;=\; \operatorname{Hopf}(H)\cdot\delta^{2n-1}(H)(\Theta)$$

in $\mathrm{H}^{2n}(\operatorname{Cone}(H);\mathbb{Z}) \cong \mathbb{Z}$. Finally we apply the above commutative diagram and we apply the Cup Product-Naturality Lemma 114.10 to the maps $\Xi_0\colon \operatorname{Cone}(f_0) \to \operatorname{Cone}(H)$ and $\Xi_1\colon \operatorname{Cone}(f_1) \to \operatorname{Cone}(H)$ and we see that $\operatorname{Hopf}(f_0) = \operatorname{Hopf}(H) = \operatorname{Hopf}(f_1)$. ■

Definition. It follows from Lemma 122.6 that for each $n \geq 2$ the map

$$\begin{array}{rcl} \pi_{2n-1}(S^n,*) & \to & \mathbb{Z} \\ [f] & \mapsto & \operatorname{Hopf}(f) \end{array}$$

is well-defined. This map is called the Hopf invariant.

Our next proposition says that the Hopf invariant is a homomorphism. This is arguably somewhat surprising since at first glance the definition of the Hopf variant, given by squaring an element, does not look particularly like a linear map.

Proposition 122.7. For any $n \geq 2$ the Hopf invariant $\operatorname{Hopf}\colon \pi_{2n-1}(S^n,*) \to \mathbb{Z}$ is a homomorphism.

Together with the calculation of the Hopf invariant for the Hopf maps H, $H_{\mathbb{H}}$ and $H_{\mathbb{O}}$ on page 2681 we obtain the following immediate corollary to Proposition 122.7.

Corollary 122.8. The Hopf invariants

$$\begin{array}{lrcl} (1) & \operatorname{Hopf}\colon \pi_3(S^2) & \to & \mathbb{Z} \\ (2) & \operatorname{Hopf}\colon \pi_7(S^4) & \to & \mathbb{Z} \\ (3) & \operatorname{Hopf}\colon \pi_{15}(S^8) & \to & \mathbb{Z} \end{array}$$

are epimorphisms.

The technically slightly dicey proof of Proposition 122.7 will require the remainder of this section. The reader is cordially invited to skip the argument and to jump to the much more entertaining content of the next section.

Our proof[1495] of Proposition 122.7 will require a few preparations. First of all, on several occasions we will need the following construction.

Construction 122.9. Suppose we are given the following commutative diagram of topological spaces:

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{Y}. \end{array}$$

Then, as discussed in the Mapping Cone Functor Lemma 16.14 (3), we obtain an induced map

$$\begin{array}{rcl} \mathrm{Cone}(f\colon X \to Y) & \to & \mathrm{Cone}(f\colon \widetilde{X} \to \widetilde{Y}) \\ [P] & \mapsto & \begin{cases} [(\varphi(x), t)], & \text{if } P = (x,t) \text{ with } x \in X,\ t \in [0,1], \\ [\psi(y)], & \text{if } P = y \text{ with } y \in Y \end{cases} \end{array}$$

By the Mapping Cone Functor Lemma 16.14 (4) the map fits into the following commutative diagram:

$$\begin{array}{ccccc} Y & \xhookrightarrow{j} & \mathrm{Cone}(f\colon X \to Y) & \xrightarrow{p} & \Sigma(X) \\ {\scriptstyle\psi}\downarrow & & \downarrow & & \downarrow{\scriptstyle\Sigma(\varphi)} \\ \widetilde{Y} & \xhookrightarrow{j} & \mathrm{Cone}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) & \xrightarrow{p} & \Sigma(\widetilde{X}) \end{array}$$

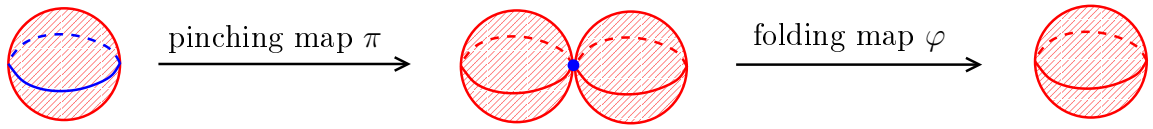
where the horizontal maps to the left are the inclusions maps i that we introduced in the Mapping Cone Basics Lemma 16.13 (2) and where the horizontal maps p on the right are given by the projection and the homeomorphism from the Mapping Cone Basics Lemma 16.13 (4).

Finally we will need the following slight reinterpretation of the Hopf invariant.

Lemma 122.10. Let $f\colon S^{2n-1} \to S^n$ be a map. We denote by $j\colon S^n \to \mathrm{Cone}(f)$ the inclusion map and we denote by $p\colon \mathrm{Cone}(f) \to \mathrm{Cone}(f)/S^n = \Sigma(S^{2n-1})$ the map given by the projection and homeomorphism from the Mapping Cone Basics Lemma 16.13 (4). Then

$$(j^*)^{-1}([S^n]^*) \cup (j^*)^{-1}([S^n]^*) \;=\; \mathrm{Hopf}(f) \cdot p^*(\Sigma([S^{2n-1}]^*)) \;\in\; \mathrm{H}^{2n}(\mathrm{Cone}(f); \mathbb{Z}).$$

Proof of Lemma 122.10. The statement follows basically immediately from the discussion on page 2435[1496] and the cohomological analogue of Lemma 78.19. ∎

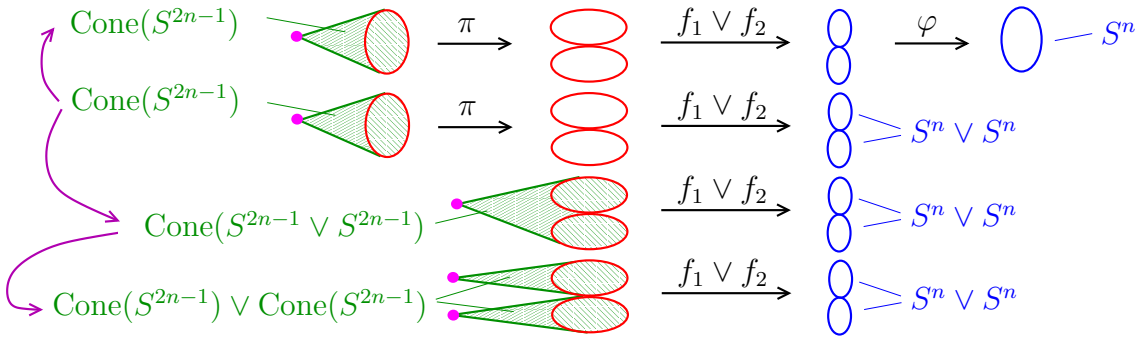


Proof of Proposition 122.7. We start out with a few preparations.

(1) Given a pointed topological space (X, x_0) we define $X \vee X$ by identifying two copies of X along the base point. We refer to the map $\varphi\colon X \vee X \to X$ which is given by the identity on either of the two copies as the *folding map*.
(2) Let $k \in \mathbb{N}_{\geq 2}$. On page 1565 we introduced a pinching map $\pi\colon S^k \to S^k \vee S^k$. The precise definition is rather irrelevant to us right now. What matters is that we saw on page 1566 that given any pointed topological space (X, x_0) and given any two

[1495] Our proof is based on the proof in [**MTa1968**, p. 35]. An alternative proof is sketched in [**Stro2011**, p. 557].
[1496] Note that here we use the convenient fact that $(-1)^{(2n-1)+1} = +1$. In reality the sign is largely irrelevant, as long as we can be sure that the sign depends only on n.

maps $f_1, f_2 \colon (S^k, *) \to (X, x_0)$ we have



$$[f_1 * f_2] \;=\; \left[S^k \xrightarrow{\pi} S^k \vee S^k \xrightarrow{f_1 \vee f_2} X \vee X \xrightarrow{\varphi} X\right] \;\in\; \pi_k(X, x_0).$$

Now we turn to our actual situation. Let $n \in \mathbb{N}_{\geq 2}$. Suppose we are given two maps $f_1, f_2 \colon (S^{2n-1}, *) \to (S^n, *)$. For $i = 1, 2$ we consider the following diagram

$$\begin{array}{ccccc}
S^n & \xrightarrow{j} & \mathrm{Cone}(\varphi \circ (f_1 \vee f_2) \circ \pi \colon S^{2n-1} \to S^n) & \xrightarrow{p} & \Sigma S^{2n-1} \\
{\scriptstyle\varphi}\uparrow & & \uparrow{\scriptstyle\varphi} & & \uparrow{\scriptstyle=} \\
S^n \vee S^n & \xrightarrow{j} & \mathrm{Cone}((f_1 \vee f_2) \circ \pi \colon S^{2n-1} \to S^n \vee S^n) & \xrightarrow{p} & \Sigma S^{2n-1} \\
{\scriptstyle=}\downarrow & & \downarrow{\scriptstyle\psi} & & \downarrow{\scriptstyle\Sigma(\pi)} \\
S^n \vee S^n & \xrightarrow{j} & \mathrm{Cone}(f_1 \vee f_2 \colon S^{2n-1} \vee S^{2n-1} \to S^n \vee S^n) & \xrightarrow{p} & \Sigma(S^{2n-1} \vee S^{2n-1}) \\
{\scriptstyle=}\uparrow & & \uparrow{\scriptstyle\Xi} & & \uparrow{\scriptstyle\Omega} \\
S^n \vee S^n & \xrightarrow{j \vee j} & \mathrm{Cone}(f_1 \colon S^{2n-1} \to S^n) \vee \mathrm{Cone}(f_2 \colon S^{2n-1} \to S^n) & \xrightarrow{p \vee p} & \Sigma S^{2n-1} \vee \Sigma S^{2n-1} \\
{\scriptstyle q_i}\downarrow & & \downarrow{\scriptstyle q_i} & & \downarrow{\scriptstyle q_i} \\
S^n & \xrightarrow{j} & \mathrm{Cone}(f_i \colon S^{2n-1} \to S^n) & \xrightarrow{p} & \Sigma S^{2n-1}.
\end{array}$$

The top three vertical maps are illustrated in the figure below.

We make the following clarifications:

(1) The horizontal maps to the left are the inclusions maps j introduced in the Mapping Cone Basics Lemma 16.13 (2) and the horizontal maps p on the right are given by the projection and the homeomorphism from the Mapping Cone Basics Lemma 16.13 (4).

(2) The vertical maps between the first and the second and between the second and the third row are obtained from Construction 122.9 applied to the following two commutative diagrams

$$\begin{array}{ccc}
S^{2n-1} & \xrightarrow{(f_1 \vee f_2) \circ \pi} & S^n \vee S^n \\
{\scriptstyle=}\downarrow & & \downarrow{\scriptstyle\varphi} \\
S^{2n-1} & \xrightarrow{\varphi \circ (f_1 \vee f_2) \circ \pi} & S^n
\end{array}
\qquad \text{and} \qquad
\begin{array}{ccc}
S^{2n-1} & \xrightarrow{(f_1 \vee f_2) \circ \pi} & S^n \vee S^n \\
{\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle=} \\
S^{2n-1} \vee S^{2n-1} & \xrightarrow{f_1 \vee f_2} & S^n \vee S^n.
\end{array}$$

In particular we see that the four upper squares commute.

(3) Next we consider the two diagrams

$$\begin{array}{ccc} S^{2n-1} & \xrightarrow{\quad f_i \quad} & S^n \\ \downarrow & & \downarrow \\ S^{2n-1} \vee S^{2n-1} & \xrightarrow{f_1 \vee f_2} & S^n \vee S^n \end{array}$$

which are given by the injections into the first respectively second factor. By Construction 122.9 these diagrams give rise to two sequences of maps. We "wedge" the two sequences and we obtain the vertical maps from the fourth to the third row.

(4) At the bottom, in each column the map q_i is the projections onto the i-th factor.

Next we apply the cohomology functor $X \mapsto \mathrm{H}^k(X) = \mathrm{H}^k(X;\mathbb{Z})$ with $k = n$ and $k = 2n$ to the above diagram (except that at the bottom we consider both maps q_1 and q_2). We obtain the following commutative diagram:[1497]

$$\begin{array}{ccccc}
\mathrm{H}^k(S^n) & \xleftarrow[\cong]{j^*} & \mathrm{H}^k(\mathrm{Cone}(\varphi\circ(f_1\vee f_2)\circ\pi : S^{2n-1}\to S^n)) & \xleftarrow[\cong]{p^*} & \mathrm{H}^k(\Sigma S^{2n-1}) \\
{\scriptstyle\varphi^*}\uparrow & & \downarrow{\scriptstyle\varphi^*} & & \downarrow{\scriptstyle =} \\
\mathrm{H}^k(S^n\vee S^n) & \xleftarrow[\cong]{j^*} & \mathrm{H}^k(\mathrm{Cone}((f_1\vee f_2)\circ\pi : S^{2n-1}\to S^n\vee S^n)) & \xleftarrow[\cong]{p^*} & \mathrm{H}^k(\Sigma S^{2n-1}) \\
{\scriptstyle =}\uparrow & & \uparrow{\scriptstyle\psi^*} & & \uparrow{\scriptstyle\Sigma(\pi)^*} \\
\mathrm{H}^k(S^n\vee S^n) & \xleftarrow[\cong]{j^*} & \mathrm{H}^k(\mathrm{Cone}(f_1\vee f_2 : S^{2n-1}\vee S^{2n-1}\to S^n\vee S^n)) & \xleftarrow[\cong]{p^*} & \mathrm{H}^k(\Sigma(S^{2n-1}\vee S^{2n-1})) \\
{\scriptstyle =}\downarrow & & \cong\downarrow{\scriptstyle\Xi^*} & & \cong\downarrow{\scriptstyle\Omega^*} \\
\mathrm{H}^k(S^n\vee S^n) & \xleftarrow[\cong]{(j\vee j)^*} & \mathrm{H}^k(\mathrm{Cone}(f_1)\vee\mathrm{Cone}(f_2)) & \xleftarrow[\cong]{(p\vee p)^*} & \mathrm{H}^k(\Sigma S^{2n-1}\vee\Sigma S^{2n-1}) \\
{\scriptstyle q_1^*\oplus q_2^*}\uparrow\cong & & \cong\uparrow{\scriptstyle q_1^*\oplus q_2^*} & & \cong\uparrow{\scriptstyle q_1^*\oplus q_2^*} \\
\mathrm{H}^k(S^n)\oplus\mathrm{H}^k(S^n) & \xleftarrow[\cong]{j_1^*\oplus j_2^*} & \mathrm{H}^k(\mathrm{Cone}(f_1))\oplus\mathrm{H}^k(\mathrm{Cone}(f_2)) & \xleftarrow[\cong]{p_1^*\oplus p_2^*} & \mathrm{H}^k(\Sigma S^{2n-1})\oplus\mathrm{H}^k(\Sigma S^{2n-1}).
\end{array}$$

We make the following observations:

(1) It follows almost immediately from the Mapping Cone-H*-Lemma 122.4 that the horizontal maps to the left are isomorphisms in degree n. Since these isomorphisms are only in degree n they are colored in red.

(2) It follows easily from the Mapping Cone-H*-Lemma 122.4 and the cohomological analogue of Lemma 78.19 that the horizontal maps to the right are isomorphisms for $k = 2n$. Since these isomorphisms are only in degree $2n$ they are colored in green.

(3) Similar to the calculation in Exercise 79.1 we see that the map Ω^* is an isomorphism.

(4) It follows from (1), (2) and (3) that the map Ξ^* is an isomorphism.

(5) The vertical maps at the very bottom are induced by the natural projections. The maps are isomorphisms by the Wedge-H*-Proposition 109.17.

Next we denote by $\alpha = [S^n]^* \in \mathrm{H}^n(S^n)$ the dual fundamental class. Furthermore we write $\beta = ([\Sigma([S^{2n-1}]^*)]) \in \mathrm{H}^{2n}(\Sigma S^{2n-1})$.

Claim 1. We have $\varphi^*(\alpha) = q_1^*(\alpha) + q_2^*(\alpha)$ and $((\Sigma(\pi)^* \circ (\Omega^*)^{-1})(q_1^*(\beta) + q_2^*(\beta)) = \beta$.

Proof. We leave it to the reader to verify this claim.

[1497] Any reader who knows of a program which can automatically turn the latex-code for a diagram of topological spaces into the latex-code for the corresponding diagram of cohomology groups should contact me urgently.

The key calculation takes place in the fourth row. More precisely, we have the following claim.

Claim 2. The following equality holds in $\mathrm{H}^{2n}(\mathrm{Cone}(f_1) \vee \mathrm{Cone}(f_2))$:

$$\big((j \vee j)^*\big)^{-1}(q_1^*(\alpha) + q_2^*(\alpha))\big)^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot (p \vee p)^*(q_1^*(\beta) + q_2^*(\beta)).$$

Proof. We calculate that

$$\begin{array}{l}
\big((j \vee j)^{*-1}(q_1^*\alpha + q_2^*\alpha)\big)^2 \overset{\text{since } j_i \circ q_i = q_i \circ (j \vee j)\colon S^n \vee S^n \to \mathrm{Cone}(f_i\colon S^{2n-1} \to S^n)}{=} \big(q_1^*(j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha)\big) \cup \big(q_1^*(j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha)\big) \\
\underset{\text{by the Suspension-Cup Product Lemma 115.7 the ``mixed'' terms are zero}}{=} q_1^*(j_1^{*-1}\alpha) \cup q_1^*(j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha) \cup q_2^*(j_2^{*-1}\alpha) \underset{\text{Cup Product-Naturality Lemma 114.10}}{=} q_1^*(j_1^{*-1}\alpha \cup j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha \cup j_2^{*-1}\alpha) \\
\underset{\text{by the reinterpretation of } \mathrm{Hopf}(f_1) \text{ and } \mathrm{Hopf}(f_2) \text{ given in Lemma 122.10}}{=} q_1^*(\mathrm{Hopf}(f_1) \cdot p_1^*(\beta)) + q_2^*(\mathrm{Hopf}(f_2) \cdot p_2^*(\beta)) \underset{\text{since } p_i \circ q_i = q_i \circ (p \vee p)\colon\ \mathrm{Cone}(f_1) \vee \mathrm{Cone}(f_2) \to \Sigma S^{2n-1}}{=} (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot (p \vee p)^*(q_1^*(\beta) + q_2^*(\beta)).
\end{array}$$

⊞

It follows from $[f_1 * f_2] = [\varphi \circ (f_1 \vee f_2) \circ \pi]$, the definition of α and β and the reinterpretation of the Hopf invariant given in Lemma 122.10, that it remains to prove the following claim.

Claim 3. The following equality holds in the first row:

$$((j^*)^{-1}(\alpha))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*(\beta).$$

Proof. The idea is of course to push the equality from Claim 2 through the above commutative diagram towards the top. The key tool hereby is the naturality of the cup product, see the Cup Product-Naturality Lemma 114.10. First we note that it follows from the Cup Product-Naturality Lemma 114.10 and the fact that φ^* is an isomorphism in degree $2n$ that it remains to prove that the following equality holds in the second row:

$$(*) \qquad (j^*)^{-1}(\varphi^*(\alpha))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*(\beta).$$

To prove this equality we note that it follows from Claims 1 and 2 together with the Cup Product-Naturality Lemma 114.10 that the following equality holds in the third row:

$$((j^*)^{-1}(\varphi^*(\alpha)))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*((\Omega^*)^{-1}(q_1^*(\beta) + q_2^*(\beta))).$$

Again, using the Cup Product-Naturality Lemma 114.10 we see that the following equality holds in the second row:

$$((j^*)^{-1}(\varphi^*(\alpha)))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*(\underbrace{\Sigma(\pi)^*((\Omega^*)^{-1}(q_1^*(\beta) + q_2^*(\beta)))}_{=\beta \text{ by Claim 1}}).$$

But using Claim 1 we see that this is precisely the desired equality that we formulated in $(*)$. ■

122.3. **The Hopf invariant and multiplication maps.** By a *multiplication map* we mean any map of the form $f\colon S^k \times S^k \to S^k$. In this section we will see that such multiplication maps give rise to potentially interesting maps $\Theta_f\colon S^{2k+1} \to S^k$. In the key calculation of this section we show how we can determine the Hopf invariant $\mathrm{Hopf}(\Theta_f)$ directly in terms of homological data of the original map f.

We start out with recalling the following not terribly inspired definition from Exercise 76.20.

Definition. Let $n \in \mathbb{N}$ and let $f\colon S^n \times S^n \to S^n$ be a map. We pick $x_0, y_0 \in S^n$. We define the bidegree of f as[1498]

$$\operatorname{bideg}(f) := (p,q) \text{ where } p := \deg\begin{pmatrix} S^n & \to & S^n \\ x & \mapsto & f(x,y_0) \end{pmatrix} \text{ and } q := \deg\begin{pmatrix} S^n & \to & S^n \\ y & \mapsto & f(x_0,y) \end{pmatrix}.$$

Examples.

(1) The map $f\colon S^1 \times S^1 \to S^1$ that is given by complex multiplication has bidegree $(1,1)$. This can be seen as follows: taking $x_0 = y_0 = 1$, we see that the two maps $S^1 \to S^1$ given by $z \mapsto f(z,1)$ and $z \mapsto f(1,z)$ are in fact the identity.
(2) The same argument as in (1) shows that the quaternion multiplication $S^3 \times S^3 \to S^3$ is a map of bidegree $(1,1)$ and that the octonion multiplication $S^7 \times S^7 \to S^7$ is also a map of bidegree $(1,1)$.
(3) Let $n \in \mathbb{N}$ and let $f\colon S^n \times S^n \to S^n$ be a map of bidegree (p,q). Furthermore let $\varphi, \psi\colon S^n \to S^n$ two maps. It follows almost immediately from the definitions that the bidegree of the map $(x,y) \mapsto f(\varphi(x), \psi(y))$ equals $(p \cdot \deg(\varphi), q \cdot \deg(\psi))$.

The previous example shows that the division algebras $\mathbb{C}$, $\mathbb{H}$ and $\mathbb{O}$ give rise to maps of bidegree $(1,1)$. This result can be generalized to all division algebras.

Lemma 122.11. Let $n \in \mathbb{N}_{\geq 2}$. If $\mathbb{R}^n$ admits the structure of a division algebra[1499], then there exists a map $S^{n-1} \times S^{n-1} \to S^{n-1}$ of bidegree (p,q) where both p and q are odd.

Proof. Let $*$ be the multiplication map of a division algebra on $\mathbb{R}^n$. As in the proof of Theorem 92.4 we consider the map

$$\begin{array}{rcl} f\colon S^{n-1} \times S^{n-1} & \to & S^{n-1} \\ (x,y) & \mapsto & f(x,y) := \dfrac{x*y}{\|x*y\|}. \end{array}$$

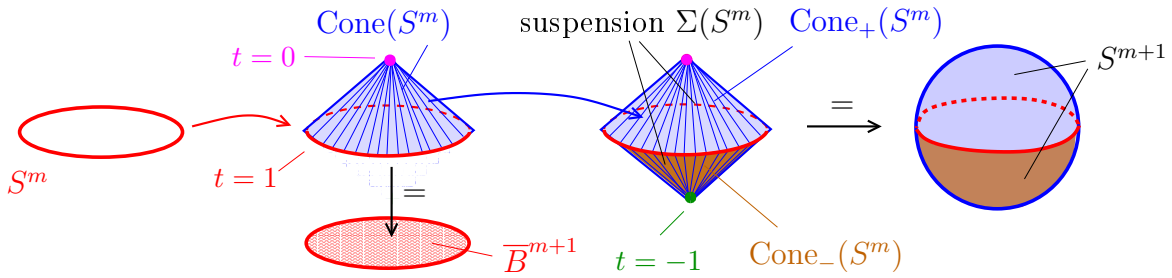
In the proof of Theorem 92.4 we already showed, using the hypothesis that "$*$" defines a division algebra, that this map is well-defined and that it is continuous. Now we pick a point $\star \in S^{n-1}$ and we consider the maps

$$\begin{array}{rcl} \varphi\colon S^{n-1} & \to & S^{n-1} \\ x & \mapsto & f(x,\star) \end{array} \quad \text{and} \quad \begin{array}{rcl} \psi\colon S^{n-1} & \to & S^{n-1} \\ y & \mapsto & f(\star,y). \end{array}$$

It follows easily from the fact that $*$ is the multiplication of a real algebra that for all $z \in S^{n-1}$ we have $\varphi(-z) = -\varphi(z)$ and $\psi(-z) = -\psi(z)$. By the Odd Degree Proposition 91.3 this implies that $\deg(\varphi)$ and $\deg(\psi)$ are odd. Conveniently enough that is exactly what he had set out to show. ∎

[1498] In Exercise 76.20 (a) we saw that the definition does not depend on the choice of x_0 and y_0.

[1499] Recall that by the definition on page 1959 a division algebra is an algebra that has left and right inverses. We do not assume that division algebras are associative and we do not assume that they preserve the scalar product.



Before we continue we recall a few conventions that we had introduced along the way. Most of them are also illustrated in the figure below.

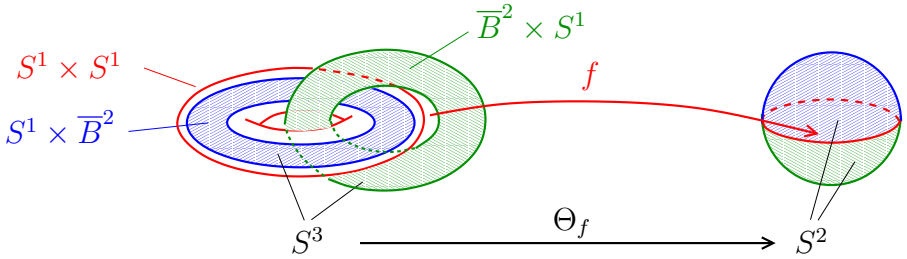
(1) Given a topological space we consider the cone $\mathrm{Cone}(X)$, the suspension $\Sigma(X)$ and we consider the two copies $\mathrm{Cone}_{\pm}(X)$ of the cone in the suspension.[1500]

(2) Let $m \in \mathbb{N}_0$. Note that by the discussion on page 450 we can make the identification $\mathrm{Cone}(S^m) = \overline{B}^{m+1}$ and by the discussion on page 452 we can make the identification $\Sigma(S^m) = S^{m+1}$.

(3) Let $m, n \in \mathbb{N}_0$. By the discussion on page 263 we can make the identification

$$(S^m \times \overline{B}^{n+1}) \cup_{\mathrm{id}_{S^m \times S^n}} (\overline{B}^{m+1} \times S^n) \xrightarrow{=} S^{m+n+1}.$$

Now we can move on to the promised construction of potentially interesting maps between spheres.



Definition. Let $f\colon S^p \times S^q \to S^r$ be a map. We consider the maps

$$\begin{array}{rcl} S^p \times \mathrm{Cone}(S^q) & \to & \mathrm{Cone}_+(S^r) \\ (P, [(Q,t)]) & \mapsto & [(f(P,Q), 1-t)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{Cone}(S^p) \times S^q & \to & \mathrm{Cone}_-(S^r) \\ ([(P,t)], Q) & \mapsto & [(f(P,Q), t-1)]. \end{array}$$

We will see in Exercise 122.2 that these two maps are continuous. We leave the task of showing that these two maps are continuous to the reader. Evidently the two maps agree on the overlap $S^p \times S^q$. Thus by the Topological Pushout Proposition 5.33 (1b) these two maps define a continuous map

$$\Theta_f\colon \underbrace{(S^p \times \mathrm{Cone}(S^q)) \cup_{S^p \times S^q} (\mathrm{Cone}(S^p) \times S^q) = S^{p+q+1}}_{=(S^p \times \overline{B}^{q+1}) \cup_{S^p \times S^q} (\overline{B}^{p+1} \times S^q)} \to \underbrace{\Sigma(S^r)}_{=S^{r+1}}.$$

We refer to the figure below for a moderately successful attempt at illustrating the map Θ_f.

Example.

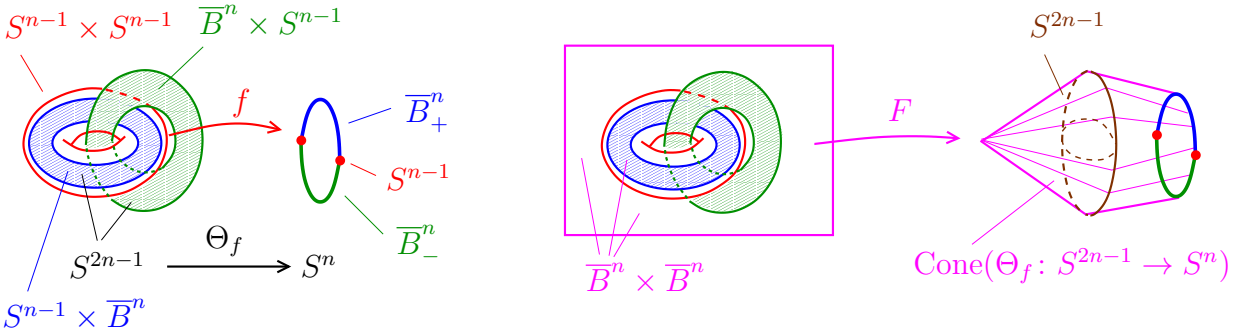
[1500] Here we implicitly use the Cone-Suspension Basics Lemma 16.8.

(1) Again we consider the map $f\colon S^1 \times S^1 \to S^1$ that is given by complex multiplication. We obtain by the above construction a map $\Theta_f\colon S^3 \to S^2$. The heroically inclined reader will surely rise to the challenge of showing that this map is homotopic to the Hopf map.[1501]
(2) Similarly to (1) one can show that the quaternion multiplication $S^3 \times S^3 \to S^3$ gives rise to the quaternionic Hopf map $S^7 \to S^4$ and that the octonion multiplication $S^7 \times S^7 \to S^7$ gives rise to the quaternionic Hopf map $S^{15} \to S^8$.

Given a map $f\colon S^{n-1} \times S^{n-1} \to S^{n-1}$ the next proposition computes the Hopf invariant of Θ_f in terms of the bidegree of f.

Proposition 122.12. Let $n \in \mathbb{N}_{\geq 2}$. If $f\colon S^{n-1} \times S^{n-1} \to S^{n-1}$ is a map of bidegree (r, s), then the induced map $\Theta_f\colon S^{2n-1} \to S^n$ has Hopf invariant $\pm rs$.[1502]

Proof. We make the following preparations:



(1) Throughout the proof all cohomology groups are understood to be with $\mathbb{Z}$-coefficients.
(2) To simplify the notation we write $\mathrm{C}(\Theta_f)$ instead of $\mathrm{Cone}(\Theta_f)$.
(3) By the Mapping Cylinder Basics Lemma 16.10 we know that the inclusion $S^n \to \mathrm{C}(\Theta_f\colon S^{2n-1} \to S^n)$ is actually an embedding, thus we can identify S^n with its image in $\mathrm{C}(\Theta_f)$.
(4) We denote by $\overline{B}^n_+$ the upper hemisphere of S^n and we denote by $\overline{B}^n_-$ the lower hemisphere of S^n.
(5) By the discussion on page 450 we can make the identification

$$\overline{B}^n \times \overline{B}^n \;=\; \overline{B}^{2n} \;=\; \mathrm{Cone}\Big(\underbrace{(S^{n-1} \times \overline{B}^n) \cup_{S^{n-1}\times S^{n-1}} (\overline{B}^n \times S^{n-1})}_{=S^{2n-1}}\Big).$$

We denote by

$$F\colon \overline{B}^n \times \overline{B}^n \;\to\; \mathrm{C}(\Theta_f\colon S^{2n-1} \to S^n) \;=\; \underbrace{\mathrm{Cone}(S^{2n-1})}_{=\overline{B}^n\times\overline{B}^n=\overline{B}^{2n}} \cup_{\Theta_f} S^n$$

the obvious map which is given by the identification $\overline{B}^n \times \overline{B}^n = \mathrm{Cone}(S^{2n-1})$ followed by the projection.

[1501] To be on the safe side, let us more cautiously say that the map Θ_f is either homotopic to the Hopf map or that it is homotopic to the composition of the Hopf map with a reflection in a hyperplane.
[1502] We leave it to the sign aficionados to determine the correct sign.

Next we pick generators for various cohomology groups:

(1) We denote by $x \in \mathrm{H}^n(\mathrm{C}(\Theta_f))$ and $z \in \mathrm{H}^{2n}(\mathrm{C}(\Theta_f))$ the generators that are given in the definition of the Hopf invariant, see page 2681.
(2) The long exact sequence in cohomology of the pair $(\mathrm{C}(\Theta_f), \overline{B}^n_\pm)$ shows that the maps $\mathrm{H}^n(\mathrm{C}(\Theta_f), \overline{B}^n_\pm) \to \mathrm{H}^n(\mathrm{C}(\Theta_f))$ are isomorphisms. Let $x_\pm \in \mathrm{H}^n(\mathrm{C}(\Theta_f), \overline{B}^n_\pm)$ be the generators that correspond to x under the given isomorphisms.
(3) We denote by $[S^{n-1}]^* \in \mathrm{H}^{n-1}(S^{n-1})$ and $[\overline{B}^n]^* \in \mathrm{H}^n(\overline{B}^n, S^{n-1})$ the standard dual generators. For $i = 1, 2$ we denote by $p_i \colon \overline{B}^n \times \overline{B}^n \to \overline{B}^n$ the projection onto the first respectively second coordinate. We write

$$\begin{aligned} y_1 &= p_1^*([\overline{B}^n]^*) \in \mathrm{H}^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \quad \text{and} \\ y_2 &= p_2^*([\overline{B}^n]^*) \in \mathrm{H}^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}). \end{aligned}$$

The following claim contains the key calculation of the proof.

Claim. The map F induces the following maps on relative cohomology:

$$\begin{array}{lrcl} \text{(i)} & \mathrm{H}^n(\mathrm{C}(\Theta_f), \overline{B}^n_+) & \xrightarrow{F^*} & \mathrm{H}^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \\ & x_+ & \mapsto & \pm r \cdot y_1 \\ \text{(ii)} & \mathrm{H}^n(\mathrm{C}(\Theta_f), \overline{B}^n_-) & \xrightarrow{F^*} & \mathrm{H}^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}) \\ & x_- & \mapsto & \pm s \cdot y_2. \end{array}$$

Proof. Before we turn to the actual calculation we make the following two preparations:

(a) We point out that the restrictions of F to various subsets gives us the following commutative diagram

$$\begin{array}{ccc} \overline{B}^n \times \overline{B}^n & \xrightarrow{F} & \mathrm{C}(\Theta_f) \\ \uparrow & & \uparrow \\ \overline{B}^n \times S^{n-1} & \xrightarrow{\Theta_f} & \overline{B}^n_- \\ \uparrow & & \uparrow \\ S^{n-1} \times S^{n-1} & \xrightarrow{f} & S^{n-1}. \end{array}$$

(b) We pick a point $* \in S^{n-1}$.

To provide the actual proof of the claim we consider the following diagram:

$$\begin{array}{ccccc} \mathrm{H}^n(\mathrm{C}(\Theta_f)) & \xleftarrow{\cong} & \mathrm{H}^n(\mathrm{C}(\Theta_f), \overline{B}^n_+) & \xrightarrow{F^*} & \mathrm{H}^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \\ \downarrow \cong & & \downarrow & & \downarrow \cong \\ \mathrm{H}^n(S^n) & \xleftarrow{\cong} & \mathrm{H}^n(S^n, \overline{B}^n_+) \xrightarrow[\text{exc.}]{\cong} & \mathrm{H}^n(\overline{B}^n_-, S^{n-1}) & \xrightarrow{\Theta_f^*} \mathrm{H}^n(\overline{B}^n \times *, S^{n-1} \times *) \\ & & \cong \uparrow \delta & & \delta \uparrow \cong \\ & & \mathrm{H}^{n-1}(S^{n-1}) & \xrightarrow[[S^{n-1}]^* \mapsto r \cdot [S^{n-1} \times *]^*]{f^*} & \mathrm{H}^{n-1}(S^{n-1} \times *). \end{array}$$

We make the following clarifications and observations:

(1) The maps that are not specified are induced by the obvious inclusions of (pairs) of topological spaces.

(2) The inclusion induced maps that are decorated by "$\cong$" are isomorphisms for the following reasons:
   (a) by the long exact sequence in cohomology for the corresponding pair,
   (b) the maps are induced by a homotopy equivalence,
   (c) by the long exact sequence provided by the Mapping Cone-H*-Lemma 122.4,
   (d) by an appropriate version of the Excision Theorem, see the remark on page 2418.
(3) The quadrilateral to the left commutes since all maps are induced by inclusions.
(4) It follows from (2) and (3) that the diagonal map is an isomorphism.
(5) The triangle towards the center commutes since all maps are induced by inclusions.
(6) It follows from (2), (4) and (5) that the middle vertical map is an isomorphism.
(7) The squares to the right commute by the commutative diagram shown in (a) and by the naturality of the connecting homomorphisms.
(8) The connecting homomorphisms δ are easily seen to be isomorphisms since the other groups in the corresponding long exact sequence are zero.
(9) Basically by the definition of the bidegree of the map f the bottom horizontal map is given by $[S^{n-1}]^* \mapsto r \cdot [S^{n-1} \times *]^*$.

The above arguments show that the vertical maps of the blue part of the diagram are isomorphisms. Since the bottom map is given by multiplication by r we see that the top map, with whatever choice of generators is also given by multiplication by $\pm r$. This concludes the proof of part (i) of the claim. The proof of part (ii) is evidently basically the same. ⊞

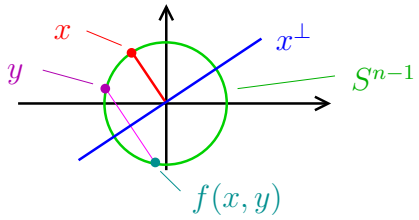
Finally we consider the following diagram

$$\begin{array}{ccccc}
\mathrm{H}^n(\mathrm{C}(\Theta_f)) & \xleftarrow[\cong]{\substack{x \leftarrow\!\shortmid x_- \\ x \leftarrow\!\shortmid x_+}} & \mathrm{H}^n(\mathrm{C}(\Theta_f), \overline{B}^n_-) & \xrightarrow[F^*]{\substack{x_- \mapsto \pm r \cdot y_1 \\ x_+ \mapsto \pm s \cdot y_2}} & \mathrm{H}^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \\
\times & & \times & & \times \\
\mathrm{H}^n(\mathrm{C}(\Theta_f)) & & \mathrm{H}^n(\mathrm{C}(\Theta_f), \overline{B}^n_+) & & \mathrm{H}^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}) \\
\cup \downarrow {\scriptstyle (x,x) \mapsto x^2 = \mathrm{Hopf}(\Theta_f) \cdot z} & & \downarrow \cup & & \cup \downarrow {\scriptstyle (y_1, y_2) \mapsto y_1 \cup y_2 = [\overline{B}^n \times \overline{B}^n]^*} \\
\mathrm{H}^{2n}(\mathrm{C}(\Theta_f)) & \xleftarrow[\cong]{} & \mathrm{H}^{2n}(\mathrm{C}(\Theta_f), S^n) & \xrightarrow[\cong]{F^*} & \mathrm{H}^{2n}(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1} \cup S^{n-1} \times \overline{B}^n).
\end{array}$$

$$\pm z \leftarrow\!\shortmid [\overline{B}^n \times \overline{B}^n]^*$$

We make the following comments:

(1) It follows almost immediately from the Excisive Triad-Proposition 109.12 (5) that $(\mathrm{C}(\Theta_f), \overline{B}^n_-, \overline{B}^n_+)$ and $(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n, \overline{B}^n \times S^{n-1})$ are excisive triads. Thus we see that the relative cup product in the center and to the right are actually defined.
(2) It follows from the naturality of the cup product, see the Cup Product-Naturality Proposition 115.4, that the two squares commute.
(3) By the Fundamental Class-Product Proposition 117.2 (1) we have $y_1 \cup y_2 = p_1^*([\overline{B}^n]) \cup p_2^*([\overline{B}^n]) = [\overline{B}^n \times \overline{B}^n]^*$.
(4) By the above claim we know that the top right horizontal map is in fact given by $x_- \mapsto \pm r \cdot y_1$ and $x_+ \mapsto \pm s \mapsto s \cdot y_2$.
(5) Since the bottom horizontal maps are isomorphisms we see that going right to left the generator $[\overline{B}^n \times \overline{B}^n]^*$ gets sent to $\pm z$.



It follows immediately from the above comments that $\mathrm{Hopf}(\Theta_f) = \pm r \cdot s$. ■

Since the Hopf invariant gives us a homomorphism $\pi_{2n-1}(S^n) \to \mathbb{Z}$ we are now interested in finding interesting maps $S^{n-1} \times S^{n-1} \to S^{n-1}$. Perhaps somewhat surprisingly it is not that hard to find interesting maps.

Proposition 122.13. Given any *even* $n \in \mathbb{N}$ the map

$$\begin{aligned} f\colon S^{n-1} \times S^{n-1} &\to S^{n-1} \\ (x,y) &\mapsto y - 2 \cdot \langle x,y\rangle \cdot x = \text{reflection of } y \text{ in the hyperplane } x^\perp \end{aligned}$$

has bidegree $(2,-1)$.

Proof. We need to show that the given map $f\colon S^{n-1} \times S^{n-1} \to S^{n-1}$ has bidegree $(2,-1)$. The proof of this statement naturally breaks up into two parts.

(1) We take $y_0 = (1,0,\ldots,0)$. We consider the map $\varphi\colon S^{n-1} \to S^{n-1}$ that is given by $x \mapsto (x,y_0)$. Note that $\varphi^{-1}((1,0,\ldots,0)) = (\pm 1,0,\ldots,0)$. Using this observation together with the Local-Global Degree Proposition 76.21 and Proposition 76.20 one can easily show that the degree of the map $x \mapsto (x,y_0)$ equals $1+(-1)^{n-2}$. Since n is by hypothesis even we see that the degree equals two.

(2) We take $x_0 = (1,0,\ldots,0)$. The corresponding $S^{n-1} \to S^{n-1}$, $y \mapsto (x_0,y)$ is the reflection in a hyperplane, hence it follows from the Sphere Degree Lemma 76.11 that the map has degree -1. ∎

The combination of Propositions 122.7 and 122.13 gives us the following interesting corollary.

Corollary 122.14. Given any even $n \in \mathbb{N}$ there exists an epimorphism $\pi_{2n-1}(S^n) \to \mathbb{Z}$.

As always in mathematics, every result opens up lots of new questions. Here are a few:

Question 122.15.

(1) We have now seen that there exists an epimorphism $\pi_3(S^2) \to \mathbb{Z}$. Is this map an isomorphism?

(2) We have now seen that there exists an epimorphism $\pi_7(S^4) \to \mathbb{Z}$. Is this map an isomorphism?

We will provide the answer to Question 122.15 (1) in Theorem 155.10 and we will see the answer to Question 122.15 (2) in Theorem 159.10 (1).

Question 122.15 points to a problem: we have now developed some tools for showing that certain homotopy groups of spheres are non-trivial, but we have no tools yet for computing any interesting homotopy groups. We will partially rectify this problem in Chapter 159.

Here is another question. We delay the answer to Theorem 160.1.

Question 122.16. Given any $n \in \mathbb{N}$ we know by Lemma 85.2 and Corollary 122.14 that $\pi_n(S^n)$ and $\pi_{4n-1}(S^{2n})$ admit an epimorphism onto $\mathbb{Z}$. Are there are any other homotopy groups of spheres that admit an epimorphism onto $\mathbb{Z}$?

In light of Lemma 122.11 and Proposition 122.13 the following question becomes interesting:

Question 122.17. For which $n \in \mathbb{N}_{\geq 2}$ does there exist a map $f\colon S^{2n-1} \to S^n$ such that $\mathrm{Hopf}(f) = 1$?[1503]

We will see the complete answer to Question 122.17 in Theorems 152.10 and 152.11. Initially one might not appreciate Question 122.17. But rather mysteriously it is not that hard to come up with maps of Hopf degree 2, but it is strikingly difficult to come up with maps of Hopf degree 1. To underline our point we conclude this chapter with another construction of a map of Hopf degree 2.

Example. Let $n \in \mathbb{N}$. We start out with the following two reminders:

(1) We can view S^n as a CW-complex with one 0-cell and one n-cell. In particular, if we denote by S^n_a and S^n_b two copies of S^n then we view S^n_a as a CW-complex with one 0-cell P and one n-cell that we denote by S^n_a. Similarly we view S^n_b as a CW-complex with one 0-cell Q and one n-cell S^n_b.
(2) Given two finite CW-complexes X and Y we introduced on page 1497 the product CW-structure on $X \times Y$. Recall that the n-cells of $X \times Y$ correspond precisely to products $e_x \times f_y$ where e_x is a p-cell of X and f_y is an $(n-p)$-cell of Y.

It follows from (1) and (2) that we can view $S^n_a \times S^n_b$ as a CW-complex with one 0-cell (P, Q), two n-cells $S^n_a \times \{Q\}$ and $\{P\} \times S^n_b$ and one $2n$-cell $S^n_a \times S^n_b$. We consider the maps

$$S^{2n-1} \xrightarrow{\varphi} \overbrace{S^n_a \times \{Q\} \cup \{P\} \times S^n_b}^{=S^n_a \vee S^n_b} \xrightarrow{p} S^n.$$

φ: attaching map of the $2n$-cell to the $(2n-1)$-skeleton of $S^n_a \times S^n_b$ which is precisely $S^n_a \times \{Q\} \cup \{P\} \times S^n_b$

p: obvious projection on $S^n_a \times \{Q\}$ and $\{P\} \times S^n_b$

The composition of the maps φ and p defines a map $f\colon S^{2n-1} \to S^n$. It is clear from the

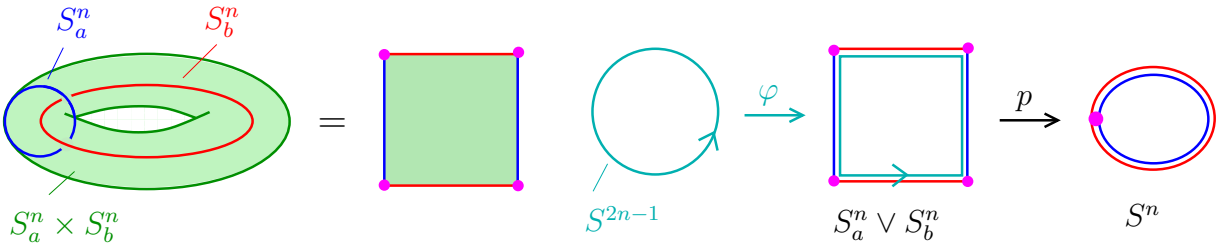


figure above that this map is not very interesting for $n = 1$. But using fairly elementary arguments one can show that for all even n we have $\mathrm{Hopf}(f) = \pm 2$. We refer to [**Hat2002**, p. 428] or [**Vic1994**, p. 138] for details. Alternatively we leave it as a brain teaser for the reader to perform this calculation.

[1503]Note that Propositions 122.7 and 122.13 tell us that this question is equivalent to the question, for which $n \in \mathbb{N}$ does there exist a map $f\colon S^{2n-1} \to S^n$ such that $\mathrm{Hopf}(f)$ is odd?

Exercises for Chapter 122.

Exercise 122.1. What is the homeomorphism type of the mapping cone of the map $S^1 \to S^1$ given by $z \mapsto z^2$?
Hint. It is a topological space that we are quite familiar with.

Exercise 122.2. Let $f\colon S^p \times S^q \to S^r$ be a map. (As always, f is understood to be continuous.) Show that the map

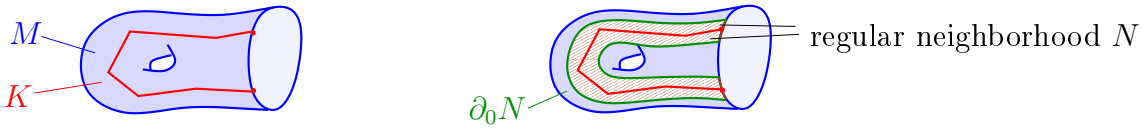
$$\begin{array}{rcl} S^p \times \mathrm{Cone}(S^q) & \to & \mathrm{Cone}(S^r) \\ (P, [(Q,t)]) & \mapsto & [(f(P,Q),t)] \end{array}$$

is continuous.
Hint. Use the Whitehead Quotient Theorem 13.4 and Lemma 13.5 (2).

Exercise 122.3. Let $f\colon S^k \times S^k \to S^k$ be the projection onto the first factor. Show that the corresponding map $\Theta_f\colon S^{2k+1} \to S^{k+1}$, that is defined on page 2688, is homotopic to a constant map.
Hint. The exercise is very easy.

Exercise 122.4. Let $n \in \mathbb{N}$ be even and let $a, b \in \mathbb{Z}$. Show that if at least one of a or b is even, then there exists a map $S^{n-1} \times S^{n-1} \to S^{n-1}$ of bidegree (a, b).

123. Regular neighborhoods and the Basic Alexander Duality Theorem



In this chapter we will study the Alexander Duality Theorem which, given a "reasonable" subset X of S^n relates the homology groups of $S^n \setminus X$ to the cohomology groups of X.

123.1. **Regular neighborhoods.** In this section we will introduce the notion of a regular neighborhood of a compact subset of a topological manifold. This notion is a variation on the eponymous concept that we defined on page 2096 and it is a variation on the notion of a tubular neighborhood that we encountered on page **??**.

Definition. Let M be an m-dimensional topological manifold and let K be a compact subset. A regular neighborhood of K is an m-dimensional compact submanifold N with corner of M with the following properties:

(1) K is contained in the interior $\mathring{N}$ of N,
(2) K is a deformation retract of N,
(3) $\partial_0 N$ is a deformation retract of $N \setminus K$.

We refer to $\mathring{N}$ as an open regular neighborhood of K.

Example. Let M be a PL-manifold and let $K \subset M \setminus \partial M$ be a subcomplex. In Section 96.3 we defined the regular neighborhood $N_K(M)$ of K in M. By the Simplicial Regular Neighborhood Proposition 96.13 we know that $N_K(M)$ does indeed have the properties demanded in the above definition of a regular neighborhood. In other words, by the Simplicial Regular Neighborhood Proposition 96.13 we know that K has a regular neighborhood in the above sense.

We continue this section with the following lemma which can be viewed as a generalization of Lemma 100.16 (3).

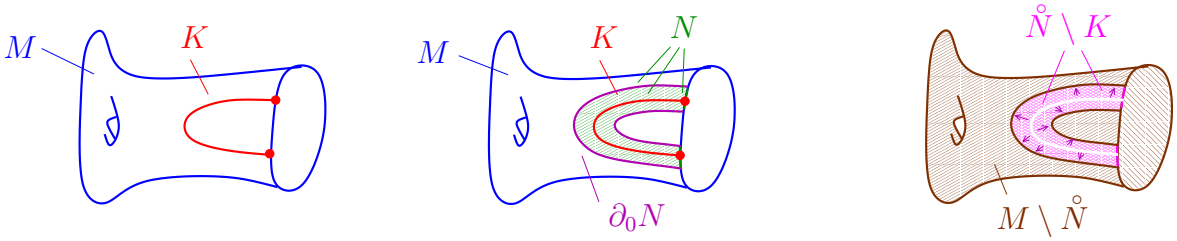
Lemma 123.1. Let K be a compact subset of a topological manifold M. If N is a regular neighborhood of K, then the following statements hold:

(1) $M \setminus \mathring{N}$ is a deformation retract of $M \setminus K$.
(2) The inclusion $M \setminus \mathring{N} \to M \setminus K$ is a homotopy equivalence, in particular it induces an isomorphism of homotopy groups (for suitable base points) and homology groups.
(3) $M \setminus \mathring{N}$ is path-connected if and only if $M \setminus K$ is path-connected.
(4) The inclusion map $M \setminus \mathring{N} \to M \setminus K$ induces isomorphisms of fundamental groups and (co-) homology groups.

Proof.

(1) By definition of a regular neighborhood there exists a deformation retraction r from $N \setminus K$ to $\partial_0 N$. We extend this deformation retraction to all of $M \setminus K$ in the obvious

way. More precisely, we consider the map



$$\begin{aligned} f\colon (M \setminus K) \times [0,1] &\to M \setminus K \\ (P,t) &\mapsto \begin{cases} P, & \text{if } P \notin N, \\ r(P,t), & \text{if } P \in N \setminus K. \end{cases} \end{aligned}$$

Using the Homotopy Stacking Lemma 14.3 and the Codimension-Zero Smooth Embedding Proposition 24.16 one can easily show that this map is indeed continuous. Once continuity is verified it is straightforward to show that f is indeed a deformation retraction from $M \setminus K$ to $M \setminus \mathring{N}$.

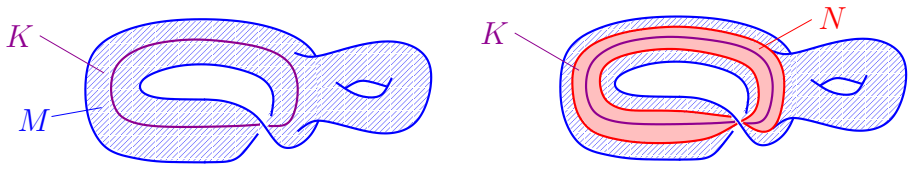
(2) It follows from (1) and the Deformation Retract-Homotopy Equivalence Lemma 15.5 that the inclusion is a homotopy equivalence. The statement regarding homotopy groups and homology groups follow from the Homotopy-π_n-Proposition 71.7 (2) and the Homotopy Equivalence-H_*-Corollary 73.9.

(3) This statement follows from (2) and the π_0-Homotopy Equivalence Lemma 15.3.

(4) This last statement follows from (2) together with the Homotopy-π_1-Proposition 50.3 (2), the Homotopy Equivalence-H_*-Corollary 73.9 and the Homotopic Maps-H^*-Lemma 108.13 (3). ■

The following corollary, which in the literature is often used implicitly or explicitly, gives one application of the theory of regular neighborhoods.

Lemma 123.2. Let M be a compact topological manifold and let $K \subset M$ be a compact subset. If K admits a regular neighborhood, then the following two statements hold:



(1) the fundamental group $\pi_1(M \setminus K)$ is finitely presented, and
(2) for each $k \in \mathbb{N}_0$ the homology group $\mathrm{H}_k(M \setminus K; \mathbb{Z})$ is finitely generated.

Proof. Note that by Lemma 123.1 the topological space $M \setminus K$ is homotopy equivalent to $M \setminus \mathring{N}$. Since M is compact it follows from Lemma 120.1 (3) that $M \setminus \mathring{N}$ is also compact. Furthermore, by Lemma 120.1 (4) we know that $M \setminus \mathring{N}$ is an n-dimensional topological manifold. Summarizing we have seen that $M \setminus \mathring{N}$ is a compact n-dimensional topological manifold. The lemma now follows from the Topological Manifolds-Invariants Proposition 104.14 and Lemma 123.1 (4). ■

In the Tubular Neighborhood Theorem **??** we showed that if M is an orientable smooth manifold, then every closed 1-dimensional submanifold admits a trivial tubular neighborhood, which is easily seen to be a regular neighborhood. It is thus natural to guess that something similar should also hold for higher-dimensional submanifolds. In fact we have the following theorem.

Theorem 123.3. (Regular Neighborhood Theorem) Let M be a smooth manifold. Every compact proper submanifold of M admits a regular neighborhood.

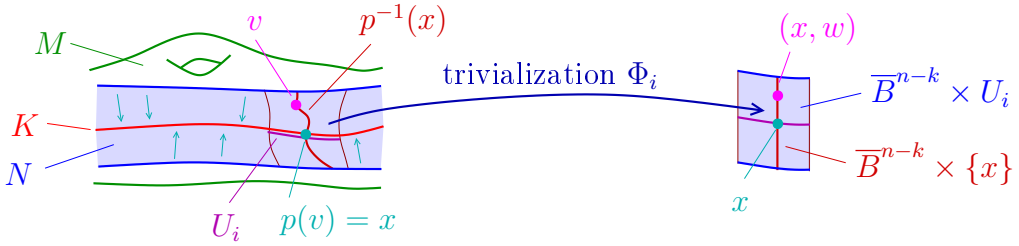
An outline of the proof will be sketched in the next section.

The following proposition finally implies Theorem 123.3.

Proposition 123.4. Let M be a smooth manifold and let K be a compact proper submanifold of M. Every tubular neighborhood of K is also a regular neighborhood of K.

Proof. Let M be an n-dimensional smooth manifold and let K be a compact proper k-dimensional submanifold of M. Let $(N, p\colon N \to K)$ be a tubular neighborhood of K. Recall that this means that the following three statements are satisfied:

(1) N is a compact codimension-zero submanifold with corner of M that is a neighborhood of K.
(2) The map $p\colon N \to K$ is a linear $\overline{B}^{n-k}$-bundle such that for all $x \in K$ we have $p(x) = x$. We denote by $\{(U_i, \Phi_i\colon p^{-1}(U_i) \to \overline{B}^{n-k} \times U_i)\}_{i\in I}$ the corresponding family of trivializations.
(3) We have $\partial_1 N = p^{-1}(\partial K)$, put differently, we have $\partial M \cap N = p^{-1}(\partial M \cap K)$.



We start out the actual proof of the proposition with the following definition and construction. Let $v \in N$. We write $x := p(v)$. We pick an $i \in I$ with $p(v) \in U_i$ and we write $\Phi_i(v) = (w, x)$ where $w \in \overline{B}^m$.

(1) Given $s \in [0,1]$ we write $\varphi_s(v) := \Phi_i^{-1}(s \cdot w, x)$.
(2) Suppose $v \notin K$. This is equivalent to saying that $w \neq 0$. Then given $t \in [0,1]$ we write $\psi_t(v) := \Phi_i^{-1}\big((1-t)\cdot w + t \cdot \frac{w}{\|w\|}, x\big)$.

We leave it to the reader to verify that these definitions are independent of the choice of the trivialization Φ_i.[1504] From this independence it also follows easily that the maps

$$\begin{array}{rcl} \Phi\colon N \times [0,1] & \to & N \\ (v,s) & \mapsto & \varphi_s(v) \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon (N \setminus K) \times [0,1] & \to & N \setminus K \\ (v,t) & \mapsto & \psi_t(v) \end{array}$$

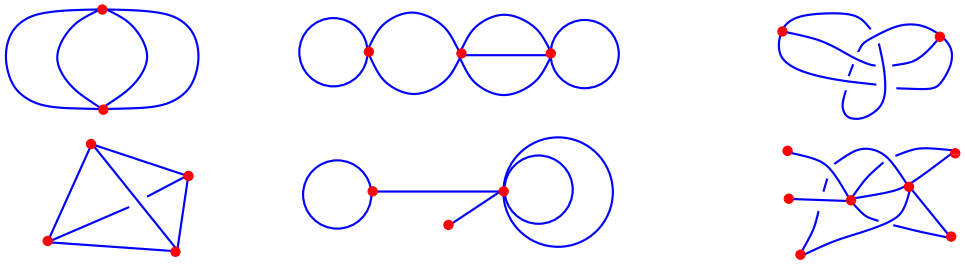
are continuous.[1505] We refer to the figure below for an illustration of the definition of Φ and Ψ. Finally recall that by definition of a regular neighborhood we have to prove the

following claim.

[1504] At this point it is essential that we work with a linear $\overline{B}^{n-k}$-bundle.

[1505] Evidently we only have to show continuity locally. So let $v \in N$. We can pick a trivialization that contains x and then it follows immediately from the definitions that the maps Φ and Ψ are continuous in the neighborhood of x corresponding to the trivialization.

Claim.



(1) K is contained in the interior of N,
(2) K is a deformation retract of N,
(3) $\partial_0 N$ is a deformation retract of $N \setminus K$.

Proof.

(1) By definition of a neighborhood we know that K is contained in the interior of N.
(2) The above map $\Phi\colon N \times [0,1] \to N$ is easily seen to be a deformation retraction from N to K.
(3) The above map $\Psi\colon (N \setminus K) \times [0,1] \to N \setminus K$ is easily seen to be a deformation retraction from $N \setminus K$ to $\partial_0 N$.

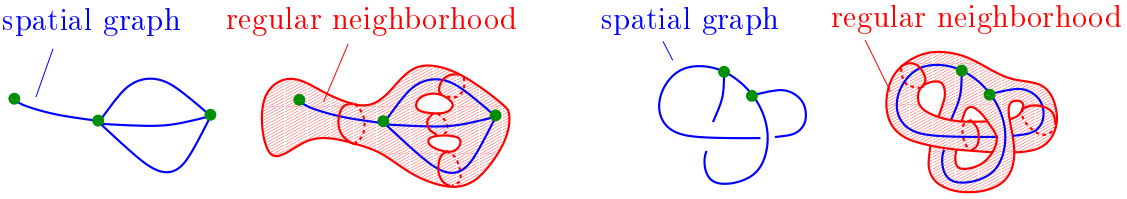
This concludes the proof of the claim and thus also of the proposition. ■

123.2. **Spatial graphs.** Note that in the definition of a regular neighborhood we did not demand that K is a submanifold, in particular K could a priori be any subset. As we will see in Exercise 123.1 it is not difficult to come up with compact subsets of even just $\mathbb{R}$ which do not admit regular neighborhoods. On the other hand one might hope that reasonable subsets of some $\mathbb{R}^n$ admit regular neighborhoods. For example consider the "spatial graphs" shown in the figure below. It seems reasonable to expect that these actually admit regular neighborhoods.

To make sense of this hunch we first need a definition of a "spatial graph" which captures the above examples. A first attempt might be to attempt to define a "a spatial" as the image of an embedding of a (say finite) topological into $\mathbb{R}^3$. But ever since on page 2293 and in Exercise 104.4 we learned of wild knots and its strange behaviors we know that we need some control over such embeddings to end up with reasonable objects.
Some leisurely thinking leads us to the following definition is modelled on the notion of a topological graph that we introduced on page 310.

Definition. A spatial graph is a triple $(G = (V, E, i, t), \Theta\colon |G| \to \mathbb{R}^3)$ where the following holds:

(1) The quadruple $G = (V, E, i, t)$ is a finite abstract graph.
(2) The map $\Theta\colon |G| \to \mathbb{R}^3$ is an embedding of the topological realization $|G|$ into $\mathbb{R}^3$.
(3) For every edge e with characteristic map $\Phi_e\colon [0,1] \to |G|$ the following statements hold:
   (a) The map $f := \Theta \circ \Phi_e\colon [0,1] \to \mathbb{R}^3$ is smooth. Note that by the Smooth Functions on Compact Interval Proposition 19.5 this means that the derivative f' is defined on all of $(0,1)$ and that it extends continuously to a map $f'\colon [0,1] \to \mathbb{R}^3$.



(b) The first derivative $f'(t)$ is non-zero for all $t \in [0,1]$,

Sometimes we just refer to $\Theta(|G|)$ as a "spatial graph" and we just ignore the extra data involved in the proper definition of a spatial graph.

Example. It should hopefully be clear that the examples sketched in the figure on page 2698 are spatial graphs.

Now we can formulate the following proposition.

Proposition 123.5. Every finite spatial graph G in $\mathbb{R}^3$ admits a regular neighborhood.

Proof. This proposition is proved in [**FrH2018, FrH2019**]. Note that in [**FrH2018, FrH2019**] it is also shown that there is a type of regular neighborhood which is unique in an appropriate sense. ■

123.3. **The Basic Alexander Duality Theorem.** We start out with the basic Alexander Duality Theorem which will be surprisingly easy to prove and which is already very helpful.

Theorem 123.6. (Alexander Duality Theorem) Let K be a compact non-empty subset of S^n that admits a regular neighborhood in the sense of the definition on page 2695. For any $i \in \mathbb{N}_0$ there exist isomorphisms

(a) $\quad \widetilde{\mathrm{H}}_i(S^n \setminus K;\mathbb{Z}) \cong \widetilde{\mathrm{H}}^{n-i-1}(K;\mathbb{Z})$

and

(b) $\quad \widetilde{\mathrm{H}}^i(S^n \setminus K;\mathbb{Z}) \cong \widetilde{\mathrm{H}}_{n-i-1}(K;\mathbb{Z}).$

By the Regular Neighborhood Theorem 123.3 this conclusion holds for any closed non-empty submanifold of S^n. In this particular case the isomorphisms are natural.

Proof. Let K be a compact non-empty subset of S^n that admits a regular neighborhood N. We first consider statement (a) and the case that $i > 0$. In this case we have the following isomorphisms:

$$\begin{array}{ccccc}
\widetilde{\mathrm{H}}_i(S^n \setminus K;\mathbb{Z}) & \xleftarrow{\cong} & \widetilde{\mathrm{H}}_i(S^n \setminus \mathring{N};\mathbb{Z}) & \xleftarrow{\cong} & \mathrm{H}^{n-i}(S^n \setminus \mathring{N}, \partial N;\mathbb{Z}) \xleftarrow{\cong} \mathrm{H}^{n-i}(S^n, N;\mathbb{Z}) \\
 & & \uparrow & & \\
 & & \widetilde{\mathrm{H}}^{n-i-1}(N;\mathbb{Z}) & \xrightarrow{\cong} & \widetilde{\mathrm{H}}^{n-i-1}(K;\mathbb{Z}).
\end{array}$$

Poincaré Duality Theorem 119.1 applied to $S^n \setminus \mathring{N}$, which is a compact smooth manifold by Lemma 120.1 (4)

Lemmas 123.1 and 108.16 (8)

Excision Theorem 74.18

by the long exact sequence in reduced cohomology of the pair (S^n, N), see Lemma 108.17 here we use that $i > 0$

by the Reduced Cohomology Lemma 108.16 (8) since K is a deformation retract of N

The case $i = 0$ is proved almost the same way. Thus we leave it to the reader to verify this case. This concludes the proof of (a). The proof of the existence of the isomorphism (b) is basically identical.

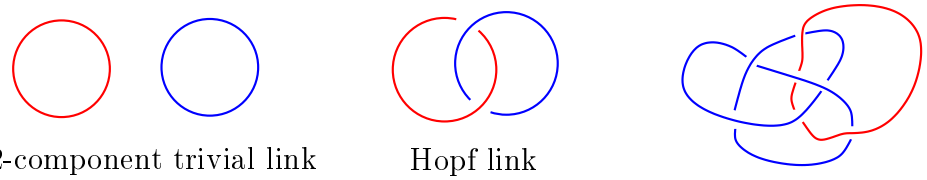
Finally suppose that K is a closed non-empty submanifold of S^n. It follows from the General Tubular Neighborhood Theorem **??** and Proposition 123.4 that we can take a tubular neighborhood as a regular neighborhood. By Proposition **??** tubular neighborhoods are unique in an appropriate sense which then allows us to get a natural isomorphism. ■

Remark.

(1) The argument in the proof of the Alexander Duality Theorem 123.6 implies in particular that given any compact, non-empty n-dimensional submanifold W of S^n there exists an isomorphism
$$\widetilde{\mathrm{H}}_i(S^n \setminus \mathring{W}; \mathbb{Z}) \cong \widetilde{\mathrm{H}}^{n-i-1}(W; \mathbb{Z}).$$

(2) In Alexander Duality Theorem 123.6 we explicitly do not write "natural" isomorphism. The isomorphism that we construct in the proof depends on the choice of a regular neighborhood. It is not clear to me whether two regular neighborhoods are necessarily in any way "equivalent".

In practice we often like to consider objects that lie in $\mathbb{R}^n$ instead of S^n. The following variation on the Alexander Duality Theorem 123.6 deals with this situation.



Corollary 123.7. Let K be a compact non-empty subset of $\mathbb{R}^n$. If K admits a regular neighborhood, then for any $i \in \mathbb{N}_0$ we have an isomorphism
$$\widetilde{\mathrm{H}}_i(\mathbb{R}^n \setminus K) \cong \mathrm{H}^{n-i-1}(K).$$
By the Regular Neighborhood Theorem 123.3 this conclusion holds for any compact submanifold of $\mathbb{R}^n$.

Proof. Let K be a compact non-empty subset of $\mathbb{R}^n$ that admits a regular neighborhood N in $\mathbb{R}^n$. Recall that N is by definition compact. It follows easily that N is also a regular neighborhood for K in S^n. Now let $i \in \mathbb{N}_0$. Then
$$\widetilde{\mathrm{H}}^{n-i-1}(K) \underset{\substack{\uparrow \\ \text{Alexander Duality Theorem 123.6 which we can apply since } K \text{ admits a regular neighborhood in } S^n}}{\cong} \widetilde{\mathrm{H}}_i(S^n \setminus K) \underset{\substack{\uparrow \\ \text{see Exercise 78.12}}}{\cong} \begin{cases} \widetilde{\mathrm{H}}_i(\mathbb{R}^n \setminus K), & \text{if } i \neq n-1, \\ \widetilde{\mathrm{H}}_{n-1}(\mathbb{R}^n \setminus K) \oplus \mathbb{Z}, & \text{if } i = n-1. \end{cases}$$

The corollary now follows from Lemmas 108.16 and 51.9 (1). ■

In the remainder of this section we discuss a few applications of the Alexander Duality Theorem 123.6. The following definition generalizes the notion of a knot.

Definition. Let $m \in \mathbb{N}_0$. An m-component link is a 1-dimensional submanifold of S^3 that is diffeomorphic to the disjoint union of m circles.[1506]

2-component trivial link Hopf link

The following lemma computes the homology groups of a link complement. It can be viewed as a generalization of Lemma 100.16 (4).

Lemma 123.8. For any m-component link L in S^3 we have

$$\mathrm{H}_i(S^3 \setminus L; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}^{m-1}, & \text{if } i = 2, \\ \mathbb{Z}^m, & \text{if } i = 1, \\ \mathbb{Z}, & \text{if } i = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. Let L be an m-component link. We calculate that

$$\widetilde{\mathrm{H}}_i(S^3 \setminus L; \mathbb{Z}) \;\underset{\substack{\uparrow \\ \text{Alexander Duality Theorem 123.6}}}{\cong}\; \widetilde{\mathrm{H}}^{2-i}(L; \mathbb{Z}) \;\cong\; \widetilde{\mathrm{H}}^{2-i}(\underbrace{S^1 \sqcup \cdots \sqcup S^1}_{m\text{-copies}}; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}^{m-1}, & \text{if } i = 2, \\ \mathbb{Z}^m, & \text{if } i = 1, \\ 0, & \text{otherwise.} \end{cases}$$

The lemma follows from this calculation together with the Reduced Cohomology Lemma 108.16 (5). ■

For any 2-component link $L = K_1 \cup K_2$, for example for any of the links shown in the figure on page 2701, we see that

$$\mathrm{H}_1(S^3 \setminus L; \mathbb{Z}) \;\cong\; \mathbb{Z}^2 \quad \text{and} \quad \mathrm{H}_2(S^3 \setminus L; \mathbb{Z}) \;\cong\; \mathbb{Z}.$$

The problem with this calculation is that we do not obtain any understanding of what the homology classes "look like". It seems reasonable to guess, along the lines of Lemma 100.16, that the first homology group is generated by the two meridians. But (a), we do not know how to prove it, and (b), we have no idea what a generator of the second homology group looks like. So the following question arises:

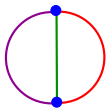
Question 123.9. Given a link L, what are explicit bases for the homology groups of $S^3 \setminus L$?

We will return to this question in Lemma 131.19. We continue with another example.

Examples.

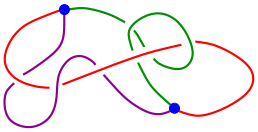
(1) We consider the connected topological graph G with two vertices and three edges that is illustrated in the figure below on the left. On the right of the figure we show a spatial graph G' in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is homeomorphic to G. We have the

[1506] Sometimes, to distinguish this notion from the higher-dimensional analogue that we define on page ?? we refer to such a link in S^3 as a *classical link*.



following isomorphisms:

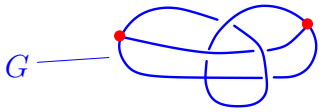
$$\widetilde{\mathrm{H}}_i(S^3 \setminus G'; \mathbb{Z}) \;\cong\; \widetilde{\mathrm{H}}^{2-i}(G'; \mathbb{Z}) \;\cong\; \widetilde{\mathrm{H}}^{2-i}(G; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}^2, & \text{if } i = 1, \\ 0, & \text{otherwise.} \end{cases}$$



by Proposition 123.5 we can apply Alexander Duality Theorem 123.6

similar to Lemma 87.12

In this case it is also rather unclear what a basis of $\mathrm{H}_1(S^3 \setminus G; \mathbb{Z})$ should look like. Later, on page 2873, we will find an explicit basis for $\mathrm{H}_1(S^3 \setminus G; \mathbb{Z})$.



graph G

the spatial graph G' in $S^3 = \mathbb{R}^3 \cup \{\infty\}$

(2) Let G be the spatial graph that is shown in the figure below and that we already considered in Exercise 123.3.

The same argument as in (1) shows that $\mathrm{H}_1(S^3 \setminus G; \mathbb{Z}) \cong \mathbb{Z}^2$. Together with the Hurewicz Theorem 84.5 and Exercise 78.12 we see that $\pi_1(\mathbb{R}^3 \setminus G)_{\mathrm{ab}} \cong \mathbb{Z}^2$. This gives an answer to Exercise 123.3 (b) is $\mathbb{Z}^2$.

We conclude this section with the following variation on the above Alexander Duality Theorem 123.6. It will come in handy at times. But arguably it is best to study it only when it is actually needed.

Theorem 123.10. (Alexander Duality Theorem) Let $n \in \mathbb{N}_0$ and let $j \in \{0, \dots, n\}$. Given any compact oriented n-dimensional smooth manifold X which has the property that $\mathrm{H}_j(X; \mathbb{Z}) = \mathrm{H}_{j+1}(X; \mathbb{Z}) = 0$ and given any compact proper submanifold G of X there exist natural isomorphisms

$$\alpha_G \colon \mathrm{H}_j(X \setminus G; \mathbb{Z}) \xrightarrow{\cong} \mathrm{H}^{n-j-1}(G, \partial G; \mathbb{Z}) \quad \text{and} \quad \alpha_G \colon \mathrm{H}^j(X \setminus G; \mathbb{Z}) \xrightarrow{\cong} \mathrm{H}_{n-j-1}(G, \partial G; \mathbb{Z})$$

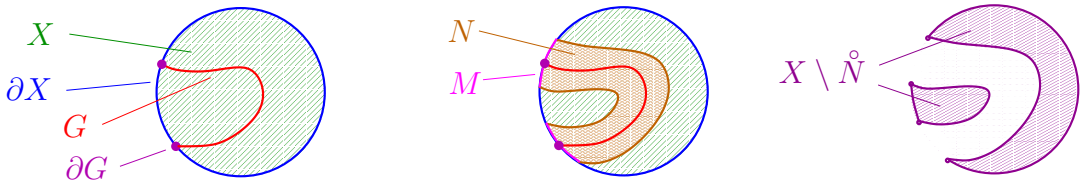
such that the following conditions are satisfied:

(1) If $X = S^n$, then the isomorphisms are precisely the isomorphisms from the Alexander Duality Theorem 123.6.
(2) The isomorphisms decompose in the obvious way if X is disconnected.
(3) If W is a compact oriented n-dimensional smooth manifold with

$$\mathrm{H}_j(W; \mathbb{Z}) \;=\; \mathrm{H}_{j+1}(W; \mathbb{Z}) \;=\; \mathrm{H}_j(\partial W; \mathbb{Z}) \;=\; \mathrm{H}_{j+1}(\partial W; \mathbb{Z}) \;=\; 0,$$

and if F is a compact proper submanifold of W, then we have commutative diagrams

$$\begin{array}{ccc} \mathrm{H}_j(W\setminus F;\mathbb{Z}) & \xrightarrow[\alpha_F]{\cong} & \mathrm{H}^{n-j-1}(F,\partial F;\mathbb{Z}) \\ {\scriptstyle i_*}\uparrow & & \uparrow{\scriptstyle \delta} \\ \mathrm{H}_j(\partial W\setminus \partial F;\mathbb{Z}) & \xrightarrow[\alpha_{\partial F}]{\cong} & \mathrm{H}^{n-j-2}(\partial F;\mathbb{Z}) \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{H}^j(W\setminus F;\mathbb{Z}) & \xrightarrow[\alpha_F]{\cong} & \mathrm{H}_{n-j-1}(F,\partial F;\mathbb{Z}) \\ {\scriptstyle i^*}\downarrow & & \downarrow{\scriptstyle \partial} \\ \mathrm{H}^j(\partial W\setminus \partial F;\mathbb{Z}) & \xrightarrow[\alpha_{\partial F}]{\cong} & \mathrm{H}_{n-j-2}(\partial F;\mathbb{Z}) \end{array}$$



where we denote by $i\colon \partial W\setminus\partial F \to W\setminus F$ the inclusion map and where the right-hand vertical maps are the connecting homomorphisms of the long exact sequences in (co-) homology of the pair $(F,\partial F)$.

Example. The above Alexander Duality Theorem 123.10 will be applied later on to the smooth manifolds $W=[0,1]\times S^n$ and to $W=\overline{B}^n$. For example, suppose that F is a connected properly embedded surface in $\overline{B}^4$ such that $\partial F = K$ is a knot. We can apply the Alexander Duality Theorem 123.10 for $j=1$. Together with Proposition 119.25 we obtain the following commutative diagram:

$$\begin{array}{ccccc} \mathrm{H}_1(\overline{B}^4\setminus F;\mathbb{Z}) & \xrightarrow[\cong]{\alpha_F} & \mathrm{H}^2(F,K;\mathbb{Z}) & \xrightarrow[\cong]{-\cap[F]} & \mathrm{H}_0(F;\mathbb{Z}) \\ {\scriptstyle i_*}\uparrow & & \uparrow{\scriptstyle \delta} & & \downarrow{\scriptstyle i_*} \\ \mathrm{H}_1(S^3\setminus K;\mathbb{Z}) & \xrightarrow[\cong]{\alpha_K} & \mathrm{H}^1(K;\mathbb{Z}) & \xrightarrow[\cong]{-\cap[K]} & \mathrm{H}_0(K;\mathbb{Z}). \end{array}$$

The right hand vertical map is of course an isomorphism and both groups are isomorphic to $\mathbb{Z}$. Now we see that both groups on the left are isomorphic to $\mathbb{Z}$ and that the inclusion induced map is an isomorphism.

Sketch of proof. Let $n\in\mathbb{N}_0$ and let $j\in\{0,\dots,n\}$. Let X be a compact orientable n-dimensional smooth manifold with $\mathrm{H}_j(X;\mathbb{Z})=\mathrm{H}_{j+1}(X;\mathbb{Z})=0$ and let G be a compact proper submanifold of X. We pick a tubular neighborhood N for G as provided by the General Tubular Neighborhood Theorem **??**. Recall that N is a submanifold with corner. We define $\mathring{N}$ as in Lemma 120.1. We write $M := N\cap\partial X$. Note that M is a tubular neighborhood for $\partial F\subset\partial X$. We consider the following diagram

$$\begin{array}{ccccccc} \mathrm{H}_j(X\setminus\mathring{N}) & \xleftarrow[\mathrm{PD}]{\cong} & \mathrm{H}^{n-j}(X\setminus\mathring{N},\partial(X\setminus\mathring{N})) & \xleftarrow[\mathrm{exc}]{\cong} & \mathrm{H}^{n-j}(X,N\cup\partial X) & \xleftarrow[\delta]{\cong} & \mathrm{H}^{n-j-1}(N\cup\partial X,\partial X) \\ \cong\downarrow & & & & & & {\scriptstyle \mathrm{exc}}\uparrow{\scriptstyle \cong} \\ & & & & & & \mathrm{H}^{n-j-1}(N,M) \\ & & & & & & \downarrow\cong \\ \mathrm{H}_j(X\setminus G) & & \xrightarrow{\quad =:\alpha_G \quad} & & & & \mathrm{H}^{n-j-1}(G,\partial G). \end{array}$$

We make the following comments:

(a) All maps where no map is specified are induced by inclusions. It follows from Proposition 123.4, together with the Homotopy Equivalence-H_*-Corollary 73.9 and the Homotopic Maps-H^*-Lemma 108.13 (4) that the vertical inclusion maps to the left and bottom right are isomorphisms.

(b) The two maps that are decorated with "exc" are inclusion induced maps that are isomorphisms by "excision". We leave it to the reader to verify that these inclusion maps are indeed isomorphisms. As an example, if $\partial X = \varnothing$, then it follows from the Excision Theorem 74.18 that the top "exc"-map is an isomorphism.

(c) The map on the top right indicated by "δ" is the connecting homomorphism of the long exact sequence in cohomology of the triple $(X, N \cup \partial X, \partial X)$. By our hypothesis we have $\mathrm{H}_j(X;\mathbb{Z}) = \mathrm{H}_{j+1}(X;\mathbb{Z}) = 0$. By the Poincaré Duality Theorem 119.1 this implies that $\mathrm{H}^{n-j}(X, \partial X;\mathbb{Z}) = \mathrm{H}^{n-j-1}(X, \partial X;\mathbb{Z}) = 0$, which in turn implies that the connecting homomorphism $\delta\colon \mathrm{H}^{n-j-1}(N \cup \partial X, \partial X;\mathbb{Z}) \to \mathrm{H}^{n-j}(X, N \cup \partial X;\mathbb{Z})$ is an isomorphism.

We have now seen that all maps in the diagram are isomorphisms. Thus we can define α_G to be the map on the bottom. A priori the definition of α_G depends on the choice of the tubular neighborhood N. But by Proposition **??** tubular neighborhoods are unique in an appropriate sense. This implies that isomorphisms do not depend on the choice of the tubular neighborhood.

First note that Statement (1) is basically clear once one compares the definitions. Next note that Statement (2) follows from all the usual results for the behavior of invariants under the disjoint union. Finally we turn to the proof of Statement (3). Let W be a compact oriented n-dimensional smooth manifold with

$$(*) \qquad \mathrm{H}_j(W;\mathbb{Z}) = \mathrm{H}_{j+1}(W;\mathbb{Z}) = \mathrm{H}_j(\partial W;\mathbb{Z}) = \mathrm{H}_{j+1}(\partial W;\mathbb{Z}) = 0.$$

Furthermore let F be a compact proper submanifold of W. We pick a tubular neighborhood N for F. We define $\mathring{N}$ as above. We write $M := N \cap \partial W$. Note that M is a tubular neighborhood for ∂F. We consider the following diagram

$$\begin{array}{ccccccc}
\mathrm{H}_j(W\backslash\mathring{N}) & \xleftarrow[\mathrm{PD}]{\cong} & \mathrm{H}^{n-j}(W\backslash\mathring{N}, \partial(W\backslash\mathring{N})) & \xleftarrow[\mathrm{exc}]{\cong} & \mathrm{H}^{n-j}(W, N\cup\partial W) & \xleftarrow[\delta]{\cong} & \mathrm{H}^{n-j-1}(N\cup\partial W, \partial W) \\
\downarrow \cong & & & & & & \uparrow \cong \\
\mathrm{H}_j(W\backslash F) & & & & & & \mathrm{H}^{n-j-1}(N, M) \\
& & & & & & \downarrow \cong \\
\mathrm{H}_j(W\backslash F) & & \xrightarrow{\qquad\qquad\alpha_F\qquad\qquad} & & & & \mathrm{H}^{n-j-1}(F, \partial F) \\
i_* \uparrow & & & & & & \delta \uparrow \\
\mathrm{H}_j(\partial W\backslash F) & & \xrightarrow{\qquad\qquad\alpha_{\partial F}\qquad\qquad} & & & & \mathrm{H}^{n-j-2}(\partial F) \\
\cong \uparrow & & & & & & \uparrow \cong \\
\mathrm{H}_j(\partial W\backslash\mathring{M}) & \xleftarrow[\mathrm{PD}]{\cong} & \mathrm{H}^{n-j}(\partial W\backslash\mathring{M}, \partial M) & \xleftarrow[\mathrm{exc}]{\cong} & \mathrm{H}^{n-j-1}(\partial W, M) & \xleftarrow[\delta]{\cong} & \mathrm{H}^{n-j-2}(M).
\end{array}$$

We make the following observations:

(1) By our hypothesis $(*)$ and the discussion above the horizontal maps α_G and $\alpha_{\partial G}$ are defined.
(2) One can easily see that the bottom "$\cup$" of the diagram is indeed the map $\alpha_{\partial F}$.
(3) If one ignores the blue arrows, then the brave reader can verify that the diagram does indeed commute.

This concludes the proof of Statement (3) for the diagram to the left. Basically the same argument also takes care of the proof of the diagram to the right. ■

123.4. **Immersions and smooth embeddings of smooth manifolds into $\mathbb{R}^n$ II.** We can now provide a new proof of the following proposition.

Proposition 43.12. (Smooth Codimension-One Orientability Proposition) Let N be a closed n-dimensional connected smooth manifold. If N is non-orientable, then there is no smooth embedding of N into $\mathbb{R}^{n+1}$.

Proof. Let N be a closed n-dimensional connected non-orientable smooth manifold. Suppose that N can be embedded into $\mathbb{R}^{n+1}$. We can thus view N as a submanifold of $\mathbb{R}^{n+1}$. We obtain that

$$\mathbb{Z}_2 \overset{\text{Top-Cohomology Proposition 110.14}}{\underset{\cong}{\downarrow}} \mathrm{H}^n(N;\mathbb{Z}) \underset{\text{Alexander Duality Theorem 123.7}}{\underset{\uparrow}{\cong}} \widetilde{\mathrm{H}}_0(\mathbb{R}^{n+1}\setminus N;\mathbb{Z}) \underset{\text{H}_0\text{-Proposition 72.5}}{\underset{\uparrow}{\cong}} \mathbb{Z}^{\text{number of path-components of } \mathbb{R}^{n+1}\setminus N \text{ minus } 1}.$$

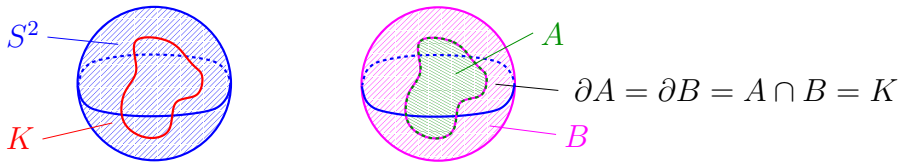
But this is absurd. We have thus obtained the desired contradiction. ■

It is worth recalling the following almost immediately corollary to Proposition 43.12. This corollary gives in particular a negative answer to Question 24.13 (2).

Corollary 43.13. Neither $\mathbb{R}\mathrm{P}^2$ nor the Klein bottle admit a smooth embedding into $\mathbb{R}^3$.

Proof. By the Surface Non-Orientability Lemma 25.20 we know that $\mathbb{R}\mathrm{P}^2$ and the Klein bottle are both non-orientable. Since both are closed 2-dimensional smooth manifolds it follows from the Smooth Codimension-One Orientability Proposition 43.12 that neither $\mathbb{R}\mathrm{P}^2$ nor the Klein bottle admit a smooth embedding into $\mathbb{R}^3$. ■

We recall the following related question.



Question 27.5. Given $n \in \mathbb{N}$, what is the minimal $k \in \mathbb{N}$ such that $\mathbb{R}\mathrm{P}^n$ admits a (topological) smooth embedding into $\mathbb{R}^k$?

Recall that it follows from the Real Projective Space Orientability Lemma 25.21, or alternatively from the Orientation-Top Homology Theorem 106.1 and the calculation of the homology groups of $\mathbb{R}\mathrm{P}^n$ in Proposition 80.11, that $\mathbb{R}\mathrm{P}^n$ is orientable if and only if n is odd. In particular it follows from the Smooth Codimension-One Orientability Proposition 43.12 that for n even it is not possible to embed $\mathbb{R}\mathrm{P}^n$ into S^{n+1}. But this raises the question, whether for n odd one can embed $\mathbb{R}\mathrm{P}^n$ into S^{n+1}. It turns out that this is also not the case:

Proposition 123.11. If $n \in \mathbb{N}_{\geq 2}$, then there is no smooth embedding from $\mathbb{R}\mathrm{P}^n$ into S^{n+1}.

In the proof of Proposition 123.11 we will need the following lemma which is interesting in its own right.

Lemma 123.12. If K is a closed orientable connected $(n-1)$-dimensional smooth submanifold of the smooth manifold S^n, then there exist two compact n-dimensional submanifolds A and B of S^n such that $A \cap B = \partial A = \partial B = K$.

Proof. First we note that by Proposition **??** the submanifold K admits a tubular neighborhood $[-1,1] \times K$. Our hypothesis that K is connected implies that $[-1,0] \times K$ and $[0,1] \times K$ are also connected.

We first calculate that

$$\mathrm{H}_0(S^n \setminus K;\mathbb{Z}) \underset{\text{Reduced Homology Lemma 74.1 (4a)}}{\cong} \widetilde{\mathrm{H}}_0(S^n \setminus K;\mathbb{Z}) \oplus \mathbb{Z} \underset{\text{Alexander Duality Theorem 123.6}}{\cong} \mathrm{H}^{n-1}(K;\mathbb{Z}) \oplus \mathbb{Z} \underset{\text{Orientation-Top Homology Theorem 106.1}}{\cong} \mathbb{Z} \oplus \mathbb{Z}.$$

It follows from the H_0-Proposition 72.5 that $S^n \setminus K$ has precisely two path-components A' and B'. Since $[-1,0] \times K$ is connected and since it is contained in $S^n \setminus K = A' \cup B'$ it follows that $[-1,0] \times K$ is either contained in A' or it is contained in B'. Without loss of generality we can assume that $[-1,0] \times K$ is contained in A'.

Claim. The subset $[0,1] \times K$ is contained in B'.

Proof. We consider the set $A'' := A' \cup [-1,1] \times K$. Note that $S^n = A'' \cup B'$. Since both A'' and B' are open and since S^n is connected it follows that $A'' \cap B' \neq \varnothing$. But this implies that $[0,1] \times K \cap B' \neq \varnothing$. But since $[0,1] \times K$ is connected we see that $[0,1] \times K$ is contained in B'. ⊞

We set $A := A' \cup K = A' \cup [-1,0] \times K$ and $B := B' \cup K = B' \cup [0,1] \times K$. It is easy to show that A and B are compact submanifolds of S^n such that $A \cap B = \partial A = \partial B = K$. ■

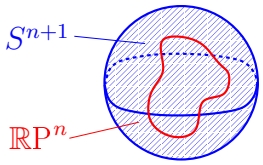
Proof of Proposition 123.11. As we had discussed just before the proposition, it remains to deal with the case that n is odd. So suppose that $n \geq 3$ is odd and that there exists a smooth embedding of $\mathbb{R}\mathrm{P}^n$ into S^{n+1}. We identify $\mathbb{R}\mathrm{P}^n$ with its image under the smooth embedding, i.e. we view $\mathbb{R}\mathrm{P}^n$ as a submanifold of S^{n+1}. Note it follows from $n \geq 3$ and the discussion on page 2419 that $\mathrm{H}^1(S^n;\mathbb{F}_2) = \mathrm{H}^2(S^n;\mathbb{F}_2) = 0$.

Since n is odd we know that $\mathbb{R}\mathrm{P}^n$ is orientable. Thus we can apply Lemma 123.12 which tells us that there exist two compact $(n+1)$-dimensional submanifolds A and B of S^{n+1} with $A \cap B = \partial A = \partial B = K$. We denote by $i\colon \mathbb{R}\mathrm{P}^n \to A$ and by $j\colon \mathbb{R}\mathrm{P}^n \to B$ the inclusion maps. As usual we denote by $x \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \mathbb{F}_2$ the unique generator.

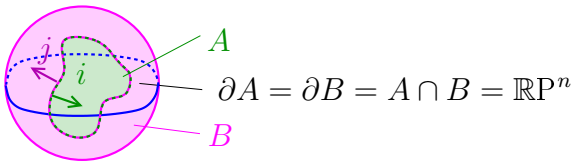
By the Excisive Triad-Proposition 109.12 (5) we can apply the Mayer–Vietoris Theorem 109.15 for Cohomology Groups to $S^{n+1} = A \cup B$ and we obtain the long exact sequence

$$\cdots \to \underbrace{\mathrm{H}^1(S^{n+1};\mathbb{F}_2)}_{=0 \text{ since } n \geq 3} \to \mathrm{H}^1(A;\mathbb{F}_2) \oplus \mathrm{H}^1(B;\mathbb{F}_2) \xrightarrow{i^*+j^*} \underbrace{\mathrm{H}^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)}_{=\mathbb{F}_2 \cdot x} \to \underbrace{\mathrm{H}^2(S^{n+1};\mathbb{F}_2)}_{=0 \text{ since } n \geq 3} \to \dots$$

Thus we see that the map $i^* + j^* \colon \mathrm{H}^1(A;\mathbb{F}_2) \oplus \mathrm{H}^1(B;\mathbb{F}_2) \to \mathrm{H}^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \mathbb{F}_2 \cdot x$ is an isomorphism. Without loss of generality we can assume that i^* is non-trivial which means that there exists an $a \in \mathrm{H}^1(A;\mathbb{F}_2)$ with $i^*(a) = x$. We have



$$i^*(a^n) \underset{\text{Cup Product-Naturality Lemma 114.10}}{\overset{\uparrow}{=}} (i^*(a))^n = x^n \underset{\text{Cup Product-}\mathbb{R}\mathrm{P}^n\text{-Proposition 121.16}}{\overset{\uparrow}{\neq}} 0 \in \mathrm{H}^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2).$$



In particular the map $i^* \colon \mathrm{H}^n(A;\mathbb{F}_2) \to \mathrm{H}^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ is non-zero. Now we consider the other end of the above Mayer-Vietoris sequence and we obtain the exact sequence

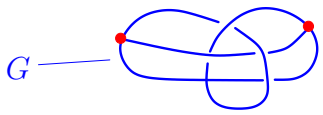
$$\mathrm{H}^n(A;\mathbb{F}_2) \oplus \mathrm{H}^n(B;|!\mathbb{F}_2) \xrightarrow{i^*+j^*} \overbrace{\mathrm{H}^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)}^{=\mathbb{F}_2 \cdot x^n} \to \overbrace{\mathrm{H}^{n+1}(S^{n+1};\mathbb{F}_2)}^{\cong \mathbb{F}_2} \to \underbrace{\mathrm{H}^{n+1}(A;\mathbb{F}_2) \oplus \mathrm{H}^{n+1}(B;\mathbb{F}_2)}_{\substack{\text{both are zero by the Top-Cohomology Proposition 110.14,} \\ \text{since } A \text{ and } B \text{ are compact, connected} \\ (n+1)\text{-dimensional smooth manifolds} \\ \text{with non-empty boundary}}}.$$

$$a^n \oplus 0 \qquad \mapsto \quad x^n$$

Thus we see that the map on the left is an epimorphism and that the group on the right is trivial. But then the fact that $\mathrm{H}^{n+1}(S^{n+1};\mathbb{F}_2) \neq 0$ shows that the sequence cannot possibly be exact. We have thus obtained the desired contradiction. ■

Remark. The above proposition does not give a complete answer to Question 27.5, we have only shown that $\mathbb{R}\mathrm{P}^n$ cannot embed into S^{n+1}. More lower bounds on the minimal dimension of some $\mathbb{R}^k$ into which we can embed $\mathbb{R}\mathrm{P}^n$ have been obtained by Michael Atiyah [**At1961**].

Exercises for Chapter 123.

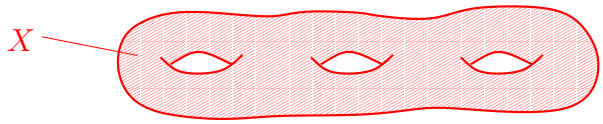


Exercise 123.1. Show that the subset $K := \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$ of $\mathbb{R}$ does not admit a regular neighborhood.

Exercise 123.2. Let G and G' be two spatial graphs in $\mathbb{R}^3$ with regular neighborhoods $N(G)$ and $N(G')$. Which of the following two implications is correct?

$$G \text{ and } G' \text{ are isotopic} \iff N(G) \text{ and } N(G') \text{ are isotopic?}$$

Exercise 123.3. We consider the spatial graph G shown in the figure below.



(a) Determine a presentation for $\pi_1(\mathbb{R}^3 \setminus G)$.
(b) What is the abelianization of $\pi_1(\mathbb{R}^3 \setminus G)$?

Exercise 123.4. Let $X \subset S^3$ be a closed orientable connected 2-dimensional submanifold. We view S^3 as a subset of S^4 in the usual way.

(a) Determine the homology groups of $S^4 \setminus X$.

(b) Now let $X \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be the surface shown in the figure below. Give an example of a closed curve in $S^4 \setminus X$ that is not null-homotopic.

Exercise 123.5. This exercise is a continuation of Exercise 123.4.

(a) Let $X \subset S^n$ be a closed submanifold. We view S^n as a subset of S^{n+1} in the usual way. Show that $S^{n+1} \setminus X$ is homotopy equivalent to $\Sigma(S^n \setminus X)$. (Here $\Sigma(S^n \setminus X)$ denotes the suspension of $S^n \setminus X$.)
Remark. You will need to use at some point that X is a "reasonable subset", e.g. that X is a closed submanifold. The statement does not hold for all subsets of S^n.

(b) Again let $X \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be the surface shown in the figure above. As above we view it as a submanifold of S^4. Determine $\pi_1(S^4 \setminus X)$.

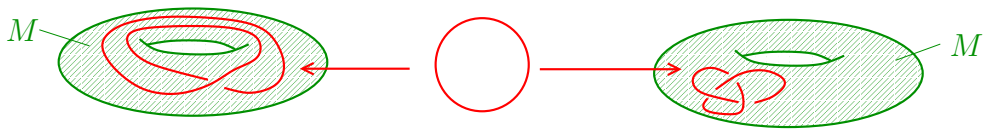
Exercise 123.6.

(a) Let F be an orientable connected 2-dimensional smooth manifold with non-empty boundary and let $i\colon F \to \mathbb{R}^3$ be an injective map. Is the complement $\mathbb{R}^3 \setminus F$ necessarily path-connected?

(b) Let F be an orientable connected surface non-compact 2-dimensional smooth manifold with empty boundary and let $i\colon F \to S^3$ be an injective map. Is the complement $S^3 \setminus F$ necessarily path-connected?

Exercise 123.7. Let M be a closed orientable n-dimensional smooth manifold.

(a) Let $A \subset M$ be a proper submanifold. Show that for each $k \in \mathbb{N}_0$ we have an isomorphism
$$\mathrm{H}^k(M \setminus A) \;\cong\; \mathrm{H}_{n-k}(M, A).$$



(b) Let $A \subset B \subset M$ be proper submanifolds. Show that for each $k \in \mathbb{N}_0$ we have an isomorphism
$$\mathrm{H}^k(M \setminus A, M \setminus B) \;\cong\; \mathrm{H}_{n-k}(B, A).$$
Hint. Use long exact sequences of triples.

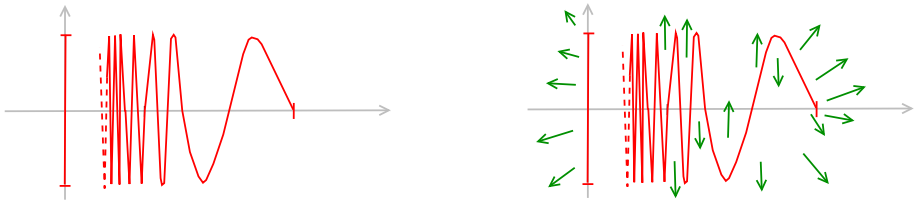
Exercise 123.8. Let M be an n-dimensional smooth manifold and let $\varphi\colon S^1 \to M$ be a smooth embedding. By the Smooth Embedding Theorem 24.10 we know that $\varphi(S^1)$ is a smooth submanifold that is diffeomorphic to S^1.

(a) We suppose that $\mathrm{H}_2(M) = 0$ and that $\mathrm{H}_1(M)$ is torsion-free. (For example M could be the solid torus $\overline{B}^2 \times S^1$.) Compute the isomorphism types of the homology groups of $M \setminus \varphi(S^1)$.

(b) Under the hypothesis of (a) show that the isomorphism type of $\mathrm{H}_*(M \setminus \varphi(S^1))$ does not depend on the choice of the smooth embedding φ.

(c) Provide examples that show that in (b) the hypothesis $\mathrm{H}_2(M) = 0$ cannot be dropped and provide examples that show that the hypothesis that $\mathrm{H}_1(M)$ is torsion-free cannot be dropped.

Exercise 123.9. Let $n \in \mathbb{N}$. Show that there is no smooth embedding of the complex projective space $\mathbb{C}\mathrm{P}^n$ into $\mathbb{R}^{2n+1}$.



124. The Generalized Alexander Duality Theorem

In this chapter we will formulate and proof a signification generalization of the Alexander Duality Theorem 123.6. Note that the proof of the Generalized Alexander Duality Theorem makes use of Borsuk's Theorem 104.3.

124.1. **The generalized Alexander Duality Theorem.** In a bout of optimism one might hope that the statement of Alexander Duality Theorem 123.6 holds for any (compact) subset of S^n. But this is not the case. More precisely, once again we consider the Topologist's Sine Curve

$$X \;=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\}\,\cup\,\big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\tfrac{1}{\pi}]\big\}\;\subset\;\mathbb{R}^2$$

that we had initially introduced on page 164. It is fairly straightforward to see that X is a closed subset of $\mathbb{R}^2$. Evidently X is bounded. Thus the Heine-Borel Theorem 1.24 implies that X is in fact a compact subset of $\mathbb{R}^2$ and thus of $S^2=\mathbb{R}^2\cup\{\infty\}$. Back on page 164 we saw that X is not path-connected, which by the H^0-Proposition 108.11 and Lemma 108.14 implies that $\widetilde{\mathrm{H}}^0(X;\mathbb{Z})\neq 0$. On the other hand, with some effort one can show that there exists a deformation retraction from $S^2\setminus X=(\mathbb{R}^2\setminus X)\cup\{\infty\}$ to ∞, which implies that $\mathrm{H}_1(S^2\setminus X;\mathbb{Z})=0$. But this shows that $\widetilde{\mathrm{H}}_1(S^2\setminus X;\mathbb{Z})\ncong\widetilde{\mathrm{H}}^0(X;\mathbb{Z})$.

X is not path-connected $\qquad$ $S^2\setminus X$ is contractible

We formulated Alexander Duality Theorem 123.6 for smooth submanifolds of S^n. We will now generalize this statement in two ways:

(1) Instead of only considering S^n we will now also allow topological homology spheres.
(2) Instead of smooth submanifolds we will now consider compact weakly locally contractible subsets.

We now recall these definitions in reverse order. First we recall the following definition from page 2290.

Definition. Let X be a topological space. We say X is weakly locally contractible if given any $Q\in X$ and given any open neighborhood U of Q there exists an open neighborhood V of Q that is contained in U such that the inclusion $V\to U$ is homotopic to a constant map.

Next we recall the following definition from page 2159.

Definition. We say that an n-dimensional topological manifold X is a topological homology n-sphere if for every $k\in\mathbb{N}_0$ we have $\mathrm{H}_k(X;\mathbb{Z})\cong\mathrm{H}_k(S^n;\mathbb{Z})$.

The following lemma is a generalization of Lemma 98.10.

Lemma 124.1. Let M be a topological manifold. If M is a topological homology n-sphere, then M is closed, orientable and connected.

Proof. The lemma is an immediate consequence of the H_0-Proposition 72.5 and the Top-Homology Theorem 106.3. ■

Now we can formulate our main theorem of the chapter which, by Lemma 104.2, is a significant generalization of the earlier Alexander Duality Theorem 123.6 (a).

Theorem 124.2. (Generalized Alexander Duality Theorem) Let $n \geq 2$, let Σ be a topological homology n-sphere and let $X \subsetneq \Sigma$ be a weakly locally contractible, non-empty compact subset of Σ. Given any $j \in \mathbb{N}_0$ and given any abelian group G we have a natural isomorphism

$$\Theta_X \colon \widetilde{\mathrm{H}}_j(\Sigma \setminus X; G) \xrightarrow{\cong} \widetilde{\mathrm{H}}^{n-j-1}(X; G).$$

Here "natural" means, that if $X \subset Y \subsetneq \Sigma$ are two weakly locally contractible, non-empty compact subset of Σ, then given any $j \in \mathbb{N}_0$ and given any abelian group G we have the following commutative diagram:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_j(\Sigma \setminus X; G) & \xrightarrow[\cong]{\Theta_X} & \widetilde{\mathrm{H}}^{n-j-1}(X; G) \\ \downarrow & & \downarrow \\ \widetilde{\mathrm{H}}_j(\Sigma \setminus Y; G) & \xrightarrow[\cong]{\Theta_Y} & \widetilde{\mathrm{H}}^{n-j-1}(Y; G), \end{array}$$

here the left vertical map is induced by the inclusion $\Sigma \setminus X \to \Sigma \setminus Y$ and the right vertical map is induced by the inclusion $X \to Y$.

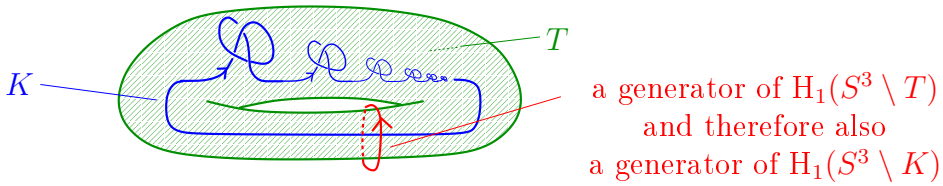
Example. In the figure below we show a subset $K \subset S^3$ that is, as we saw on page 659, homeomorphic to S^1. In Proposition 124.17 we will show that K does not admit a regular neighborhood in the sense of the definition on page 2695.[1507] In particular Alexander Duality Theorem 123.6 does not apply to $K \subset S^3$.

On the other hand K is homoemorphic to S^1, thus it is weakly locally contractible and we see that Generalized Alexander Duality Theorem 124.2 applies. We see that

$$\widetilde{\mathrm{H}}_j(S^3 \setminus K; \mathbb{Z}) \underset{\uparrow}{\xrightarrow{\cong}} \widetilde{\mathrm{H}}^{2-j}(K; \mathbb{Z}) \cong \widetilde{\mathrm{H}}^{2-j}(S^1; \mathbb{Z}) \underset{\uparrow}{\cong} \begin{cases} \mathbb{Z}, & \text{if } j = 1, \\ 0, & \text{otherwise.} \end{cases}$$

isomorphism Θ_K from the Generalized Alexander Duality Theorem 124.2

by the calculation on page 2419 together with the Reduced Cohomology Lemma 108.16



We have thus shown that $\mathrm{H}_1(S^3 \setminus K; \mathbb{Z}) \cong \mathbb{Z}$. But from the above isomorphism it is difficult to specify an explicit generator for $\mathrm{H}_1(S^3 \setminus K; \mathbb{Z})$. We will do so using the naturality of the isomorphism Θ_K. Namely, we consider the "standard solid torus" $T \subset S^3$ that is shown in the figure below. We denote by $i \colon K \to T$ the inclusion map. By the naturality of the isomorphism of the Generalized Alexander Duality Theorem 124.2 we obtain the following

[1507] In Theorem 124.13 we will show the related result, that K is not a topological submanifold of S^3.

commutative diagram:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_j(\Sigma \setminus K;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_K} & \widetilde{\mathrm{H}}^{n-j-1}(K;\mathbb{Z}) \\ \downarrow & & \downarrow i^* \\ \widetilde{\mathrm{H}}_j(\Sigma \setminus T;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_T} & \widetilde{\mathrm{H}}^{n-j-1}(T;\mathbb{Z}). \end{array}$$

Each map $i_*\colon \mathrm{H}_*(K;\mathbb{Z}) \to \mathrm{H}_*(T;\mathbb{Z})$ is an isomorphism.[1508] It follows from Corollary 108.20 that the map $i^*\colon \mathrm{H}^1(K;\mathbb{Z}) \to \mathrm{H}^1(T;\mathbb{Z})$ is also an isomorphism. It follows from the above commutative diagram that the inclusion induced map $\widetilde{\mathrm{H}}_1(\Sigma \setminus K;\mathbb{Z}) \to \mathrm{H}_1(\Sigma \setminus T;\mathbb{Z})$ is an isomorphism. But it is straightforward to specify a generator for $\widetilde{\mathrm{H}}_1(\Sigma \setminus K;\mathbb{Z})$.

Remark.

(1) We leave it to the reader to determine – say using search engines provided by California based companies – whether the obvious generalization of Alexander Duality Theorem 123.6 (b) holds.

(2) The Generalized Alexander Duality Theorem 124.2 can be generalized even further. More precisely, an analogous statement also holds for any compact subset K of S^n, e.g. the Topologist's Sine Curve. But hereby one needs to replace the usual singular cohomology on the right-hand side by the *Čech cohomology* of K. We refer to [**Hat2002**, p. 256], [**Dol1980**, Theorem VIII.7.2], [**Bre1993**, Corollary VI.8.7], [**Mass1981b**] or [**Pra2007**, p. 271] for more details.

We will provide the proof of the Generalized Alexander Duality Theorem 124.2 in the next section. For the time being we discuss some special cases and consequences.
For most applications of Alexander Duality we will actually need the following straightforward consequence of the above theorem.

Theorem 124.3. (Alexander Duality Theorem for Topological Manifolds) Let $n \geq 2$, let Σ be a topological homology n-sphere and let X be a compact, non-empty k-dimensional topological manifold. If $f\colon X \to \Sigma$ is an injective map, then for any $j \in \mathbb{N}_0$ and any abelian group G we have a natural isomorphism

$$\widetilde{\mathrm{H}}_j(\Sigma \setminus f(X);G) \xrightarrow{\cong} \widetilde{\mathrm{H}}^{n-j-1}(X;G),$$

which is natural in sense of the previous theorem.

[1508] There are many ways of seeing this. For example let $f\colon S^1 \to K$ be a homeomorphism and let $p\colon T \to S^1$ be the obvious homotopy equivalence. We only need to worry about homology in dimension one since all other reduced homology groups vanish. One can easily show, say using Proposition 76.20, that $(p \circ i \circ f)_*\colon \mathrm{H}_*(K;\mathbb{Z}) \to \mathrm{H}_*(T;\mathbb{Z})$ is an isomorphism. But then $i_*\colon \mathrm{H}_*(K;\mathbb{Z}) \to \mathrm{H}_*(T;\mathbb{Z})$ is also an isomorphism.

Proof. Let $f\colon X \to \Sigma$ be an injective map from a compact, non-empty k-dimensional topological manifold to a topological homology n-sphere Σ with $k < n$. It is a consequence of the Compact-Hausdorff Proposition 2.17 (3) that $f\colon X \to f(X)$ is a homeomorphism. From $k < n$ and the Topological Manifold-Dimension Proposition 75.4 it follows that $f(X) \neq \Sigma$. We have the following isomorphisms:

$$\widetilde{\mathrm{H}}_j(\Sigma \setminus f(X); G) \xrightarrow[\uparrow]{\cong} \widetilde{\mathrm{H}}^{n-j-1}(f(X); G) \xrightarrow{\cong} \widetilde{\mathrm{H}}^{n-j-1}(X; G).$$

we can apply the Generalized Alexander Duality Theorem 124.2 since by the Topological Manifolds-Local Properties Lemma 18.8 we know that $f(X)$ is weakly locally contractible, and since $f(X) \neq \Sigma$ ■

Examples.

(1) Let $n \geq 2$ and let $k < n$. Furthermore let $f\colon S^k \to S^n$ be an injective map. We obtain that

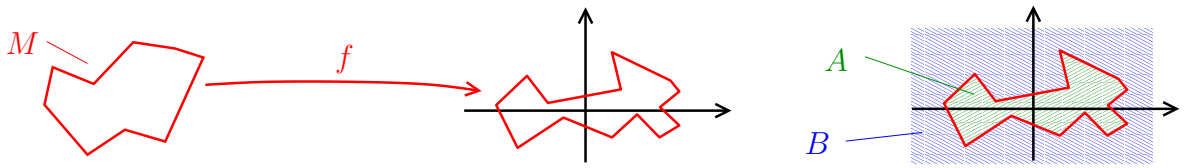
$$\widetilde{\mathrm{H}}_j\big(S^n \setminus f(S^k); \mathbb{Z}\big) \underset{\text{Theorem 124.3}}{\cong} \widetilde{\mathrm{H}}^{n-j-1}(S^k; \mathbb{Z}) \underset{\text{see page 2422 and the Reduced Cohomology Lemma 108.16}}{\cong} \begin{cases} \mathbb{Z}, & \text{if } j = n-k-1, \\ 0, & \text{otherwise.} \end{cases}$$

This calculation gives a new proof for the Sphere Complement-H_*-Theorem 82.1 (2). Basically the same approach also gives a new proof of the Sphere Complement-H_*-Theorem 82.1 (1). Finally note that this calculation gives an answer to Exercise 104.3 (b).

(2) Let $n \geq 2$, let X be a compact connected non-empty $(n-1)$-dimensional topological manifold with $\partial X \neq \varnothing$ and let $f\colon X \to S^n$ be an injective map. We see that

$$\widetilde{\mathrm{H}}_0\big(S^n \setminus f(X); \mathbb{Z}_2\big) \underset{\substack{\text{Alexander Duality} \\ \text{Theorem 124.3}}}{\cong} \widetilde{\mathrm{H}}^{n-1}(X; \mathbb{Z}_2) \underset{\text{since } n \geq 2}{\cong} \mathrm{H}^{n-1}(X; \mathbb{Z}_2) \underset{\substack{\text{Poincaré Duality} \\ \text{Theorem 119.1}}}{\cong} \mathrm{H}_0(X, \partial X; \mathbb{Z}_2) \underset{\substack{\text{since } X \text{ is connected} \\ \text{and since } \partial X \neq \varnothing}}{=} 0.$$

It follows from the analogue of the Reduced Homology Lemma 74.1 (5) for $\mathbb{Z}_2$-coefficients that $S^n \setminus f(X)$ is path-connected.



Corollary 124.4. (Generalized Jordan–Brouwer Separation Theorem) Let $n \in \mathbb{N}_{\geq 2}$, let M be an $(n-1)$-dimensional closed connected non-empty topological manifold and let $f\colon M \to \mathbb{R}^n$ be an injective map.

(1) The complement $\mathbb{R}^n \setminus f(M)$ has precisely two path-components, one of which is bounded and one which is unbounded.
(2) If A and B are these path-components, then $\partial A = \partial B = A \cap B = f(M)$.

Remark. The Generalized Jordan–Brouwer Separation Theorem 124.4 we first proved by James Alexander [**Al1922**, p. 348] in 1922. It is a generalization of the Generalized Smooth Jordan-Brouwer Separation Theorem 43.10 (1) and the Jordan–Brouwer Separation Theorem 82.2.

Proof. [1509] Let $n \in \mathbb{N}_{\geq 2}$, let M be an $(n-1)$-dimensional closed connected non-empty topological manifold and let $f\colon M \to \mathbb{R}^n$ be an injective map.

[1509] The proof of the Generalized Jordan–Brouwer Separation Theorem 124.4 is very similar to the Jordan–Brouwer Separation Theorem 82.2. The biggest difference is that we need to replace the Sphere

(1) We use the embedding $\mathbb{R}^n \to \mathbb{R}^n \cup \{\infty\} = S^n$ to view $\mathbb{R}^n$ as a subspace of S^n. Now we see that

$$\begin{array}{ccccccc} & & \text{see Exercise 78.12} & & \text{Alexander Duality Theorem 124.3} & & \text{since } n \geq 2 \\ & & \downarrow & & \downarrow & & \downarrow \\ \widetilde{\mathrm{H}}_0(\mathbb{R}^n \setminus f(M); \mathbb{Z}_2) & \cong & \widetilde{\mathrm{H}}_0(S^n \setminus f(M); \mathbb{Z}_2) & \cong & \widetilde{\mathrm{H}}^{n-1}(M; \mathbb{Z}_2) & \cong & \mathrm{H}^{n-1}(M; \mathbb{Z}_2) \\ & \cong & \mathrm{H}_0(M; \mathbb{Z}_2) & \cong & \mathbb{Z}_2. & & \\ & & \uparrow & & \uparrow & & \end{array}$$

by the Poincaré Duality Theorem 119.1 which we can apply since M is closed

by the analogue of the H_0-Proposition 72.5, since M connected and non-empty

It follows from the analogue of the Reduced Homology Lemma 74.1 (5) for $\mathbb{Z}_2$-coefficients that $\mathbb{R}^n \setminus f(M)$ has precisely two path-components. It remains to show that precisely one of them is unbounded.

Since M is compact there exists an $r \in \mathbb{R}$ such that $f(M) \subset B^n_r$. It is elementary to show that $\mathbb{R}^n \setminus B^n_r$ is path-connected. It follows that $\mathbb{R}^n \setminus B^n_r$ is contained in one of the two path-components. This shows that precisely one path-component is unbounded.

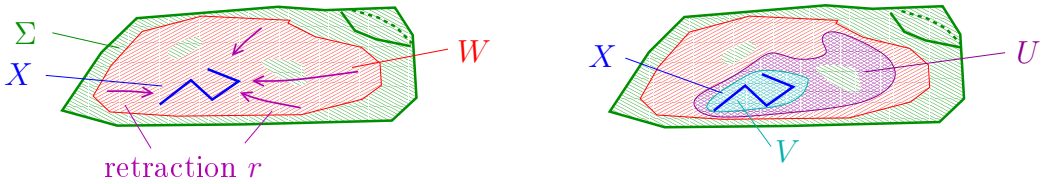
(2) First note that it follows from the Compact Image Lemma 2.13 and 1.21 that $\mathbb{R}^n \setminus f(M)$ is open. In particular, as we remarked on page 176, $\mathbb{R}^n \setminus f(M)$ is locally path-connected. It follows easily that A and B are both open subsets of $\mathbb{R}^n$.

Claim. We have $\overline{A} = A \cup f(M)$.

Proof. Since B is open we know that $A \cup f(M) = \mathbb{R}^n \setminus B$ is closed. By definition of $\overline{A}$ this implies that $\overline{A} \subset A \cup f(M)$. Now let $P \in A \cup f(M)$. We need to show that $P \in \overline{A}$. Suppose that this is not the case. By the Interior-Closure Lemma 1.9 we know that $\overline{A}$ is closed. Thus our assumption that $P \notin \overline{A}$ implies that there exists an open subset $U \subset \mathbb{R}^n$ with $P \in U \subset \mathbb{R}^n \setminus \overline{A}$. Using a chart one can show that there exists a subspace $D \subset M$, which is a compact $(n-1)$-dimensional topological manifold, such that $M \setminus D \subset f^{-1}(U)$, i.e. such that $f(M \setminus D) \subset U$. We now obtain the following equalities:

$$\begin{array}{ccccc} \underbrace{\mathbb{R}^n \setminus f(D)} & = & A \sqcup B \sqcup (f(M) \setminus f(D)) & \overset{\downarrow}{=} & A \sqcup (B \cup (U \cap \mathbb{R}^n \setminus f(D)). \\ \text{path-connected by the discussion on page 2713 and Exercise 78.12} & & & & \uparrow \\ & & & & \text{disjoint union since } U \cap A = \varnothing \end{array}$$

since $f(M) \setminus f(D) = f(M \setminus D) \subset U$



We have thus written the path-connected space $\mathbb{R}^n \setminus f(D)$ as the disjoint union of the two open non-empty sets A and $B \cup (U \cap \mathbb{R}^n \setminus f(D))$. But by the Path-Connected Implies Connected Corollary 2.23 this is not possible. We have thus obtained a contradiction. ∎

Complement-H_*-Theorem 82.1 by the Alexander Duality Theorem for Topological Manifolds 124.3. There are a few other subtle changes though.

124.2. **Proof of the Generalized Alexander Duality Theorem 124.2.** Before we can provide the proof of the Generalized Alexander Duality Theorem 124.2. let us recall the following proposition which is a consequence of Borsuk's Theorem 104.3. The proposition will be crucial input in our proof of the Generalized Alexander Duality Theorem 124.2.

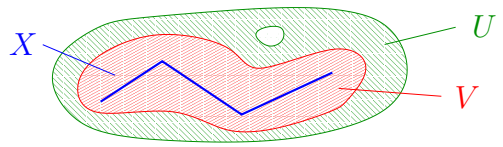
Proposition 104.4. Let Σ be a topological manifold and let $X \subset \Sigma$ be a closed subset that is weakly locally contractible.

(1) There exists an open neighborhood $W \subset \Sigma$ of X for which there exists a retraction $r\colon W \to X$.
(2) We can find W and r such that furthermore the following condition is satisfied: given any neighborhood U of X with $X \subset U \subset W$ there exists an open neighborhood V with $X \subset V \subset U$ such that the inclusion $i\colon V \to U$ and the retraction $r\colon V \to X \subset U$ are homotopic maps from V to U.

We now turn to the proof of the Generalized Alexander Duality Theorem 124.2. We first deal with the case $j \neq 0$. Afterwards we will deal with the case $j = 0$, which is quite similar, but slightly different.

Proof of the Generalized Alexander Duality Theorem 124.2 for $j \neq 0$. Let $n \geq 2$ and let Σ be a topological homology n-sphere. Furthermore let $X \subsetneq \Sigma$ be a weakly locally contractible, non-empty compact subset of Σ. Note that to simplify the notation we work throughout the proof with the abelian group $G = \mathbb{Z}$.

We recall the following definition:



(1) Given a topological space Y we denote by $\mathcal{K}(Y)$ the set of all compact subsets of Y. Given $K, L \in \mathcal{K}(Y)$ we write $K \leq L$ if $K \subset L$. The set $\mathcal{K}(X)$ together with the relation "$\leq$" is a directed set since the union of two compact subsets is again compact.

We also introduce a new definition and notation:

(2) We denote by $\mathcal{N}(X)$ the set of all open neighborhoods of X. Given $U, V \in \mathcal{N}(X)$ we write $U \leq V$ if $V \subset U$. (Note the reversal of V and U.) The set $\mathcal{N}(X)$ together with the relation "$\leq$" is a directed set since the intersection of two open neighborhoods of X is again an open neighborhood of X.[1510]
(3) Given any subsets $A \subset B$ of Σ we denote by $i_{A,B}\colon A \to B$ the inclusion map.
(4) It follows from our definition of "$\leq$" on $\mathcal{N}(X)$ that for any $m \in \mathbb{N}_0$ the cohomology groups $\{\widetilde{\mathrm{H}}^m(U)\}_{U \in \mathcal{N}(X)}$ together with the inclusion induced maps form a *direct* system of abelian groups.

We continue with the key technical part of the proof of the theorem.

[1510] Here the idea is that the neighborhoods "approximate" X, in particular $U \leq V$ means that V is a "better approximation of X", which just means that $V \subset U$.

we have $U \leq V$ and $i^*_{V,U} \colon \widetilde{\mathrm{H}}^m(U) \to \widetilde{\mathrm{H}}^m(V)$

Claim. For every $m \in \mathbb{N}_0$ the map

$$\Phi \colon \varinjlim_{U \in \mathcal{N}(X)} \widetilde{\mathrm{H}}^m(U) \to \widetilde{\mathrm{H}}^m(X),$$

that is induced by the restriction maps $i^*_{X,U} \colon \widetilde{\mathrm{H}}^m(U) \to \widetilde{\mathrm{H}}^m(X)$, is an isomorphism.

Proof. By our hypothesis we know that X is compact and weakly locally contractible. Since Σ is a topological manifold we know by Proposition 104.4 that there exists an open neighborhood $W \subset \Sigma$ of $X \subset \Sigma$ and a retraction $r \colon W \to X$ such that furthermore the following condition is satisfied:

(∗) Given any neighborhood U of X with $X \subset U \subset W$ there exists an open neighborhood V with $X \subset V \subset U$ such that the inclusion map $i_{V,U} \colon V \to U$ and the retraction $r \colon V \to X \subset U$ are homotopic maps from V to U.

Next we consider the following commutative diagram

$$\begin{array}{ccc} & \widetilde{\mathrm{H}}^m(W) & \\ {\scriptstyle i^*_{X,W}} \swarrow & & \searrow {\scriptstyle r^*} \\ \varinjlim_{U \in \mathcal{N}(X)} \widetilde{\mathrm{H}}^m(U) & \xrightarrow[\Phi]{} & \widetilde{\mathrm{H}}^m(X). \end{array}$$

From $(i^*_{X,W} \circ r^*) = (r \circ i_{X,W})^* = \mathrm{id}^*_X$ we deduce that the map $i^*_{X,W}$ is an epimorphism. It follows that the horizontal map Φ is also an epimorphism. It remains to show that Φ is a monomorphism.

By Lemma 111.2 (3) it remains to show that for any $U \in \mathcal{N}(X)$ there exists a $V \in \mathcal{N}(X)$ with $U \leq V$, i.e. with $V \subset U$, such that

$$\ker\left(i^*_{X,U} \colon \widetilde{\mathrm{H}}^m(U) \to \widetilde{\mathrm{H}}^m(X)\right\} \subset \ker\left(i^*_{V,U} \colon \widetilde{\mathrm{H}}^m(U) \to \widetilde{\mathrm{H}}^m(V)\right).$$

So let $U \in \mathcal{N}(X)$. After possibly replacing U by $U \cap W$ we can without loss of generality assume that $U \subset W$.

By (∗) there exists an open neighborhood V with $X \subset V \subset U$ such that the inclusion $i_{V,U} \colon V \to U$ and the retraction $r \colon V \to X \subset U$ are homotopic maps from V to U.

We consider the following diagram

$$\begin{array}{ccc} \widetilde{\mathrm{H}}^m(U) & \xrightarrow{\quad i^*_{X,U} \quad} & \widetilde{\mathrm{H}}^m(X) \\ & {\scriptstyle r^*} \searrow \quad \swarrow {\scriptstyle r^*} & \\ {\scriptstyle i^*_{V,U}} \searrow & & \swarrow \\ & \widetilde{\mathrm{H}}^m(V). & \end{array}$$

Since the two maps $i_{V,U} \colon V \to U$ and $r \colon V \to X \subset U$ are homotopic it follows from the Homotopic Maps-H*-Lemma 108.13 that the two maps $i^*_{V,U}$ and r^* from $\widetilde{\mathrm{H}}^m(U)$ to

$\widetilde{\mathrm{H}}^m(V)$ agree. Since r is the identity on X we see that $r\colon U \to X \subset V$ equals the map $i_{X,U} \circ r\colon U \to X$. This shows that the diagram commutes. It follows immediately from these observations that V has the desired property. ⊞

Now we can finally turn to the actual proof of the theorem. First let $j \neq 0$. The desired isomorphism will be given by a sequence of natural isomorphisms as follows:

$$\begin{aligned}\mathrm{H}_j(\Sigma\backslash X) \underset{(1)}{\overset{\cong}{\leftarrow}} \mathrm{H}_{\mathrm{c}}^{n-j}(\Sigma\backslash X) &\underset{(2)}{\overset{\cong}{\leftarrow}} \varinjlim_{K\in\mathcal{K}(\Sigma\backslash X)} \mathrm{H}^{n-j}(\Sigma\backslash X, \overbrace{(\Sigma\backslash X)\backslash K}^{=(\Sigma\backslash K)\backslash X}) \underset{(3)}{\overset{\cong}{\leftarrow}} \varinjlim_{U\in\mathcal{N}(X)} \mathrm{H}^{n-j}(\Sigma\backslash X, U\backslash X)\\ &\underset{(4)}{\overset{\cong}{\leftarrow}} \varinjlim_{U\in\mathcal{N}(X)} \mathrm{H}^{n-j}(\Sigma, U) \underset{(5)}{\overset{\cong}{\leftarrow}} \varinjlim_{U\in\mathcal{N}(X)} \widetilde{\mathrm{H}}^{n-j-1}(U) \underset{(6)}{\overset{\cong}{\rightarrow}} \widetilde{\mathrm{H}}^{n-j-1}(X).\end{aligned}$$

We explain the natural isomorphisms in more detail:

(1) Since X is compact we know from the Compact-Closed Lemma 1.21 (2) that $\Sigma \setminus X$ is an open subset of $\Sigma \setminus X$. In particular $\Sigma \setminus X$ is also an n-dimensional topological manifold and via the Topological Manifold-Induced Orientation Lemma 105.17 it inherits an orientation from Σ. Also note that it follows from the Topological Manifold Boundary Proposition 75.2 that $\Sigma \setminus X$ has no boundary. After this preamble the first isomorphism is the Poincaré Duality isomorphism from the Non-Compact PD Theorem 119.18 corresponding to the oriented topological manifold $\Sigma \setminus X$. By Lemma 119.24 this isomorphism is natural.

(2) The second isomorphism is provided by the $\mathrm{H}_{\mathrm{c}}^n$-via-Direct Limits Proposition 112.4.

(3) Recall that the X is by hypothesis a compact subset of Σ. By the Compact-Closed Lemma 1.21 (2) this implies that X is a closed subset of S^3. This observation implies that the map $\mathcal{N}(X) \to \mathcal{K}(\Sigma \setminus X)$ given by $U \mapsto \Sigma \setminus U$ is an isomorphism of directed sets which gives us an isomorphism of direct systems. The third isomorphisms is an immediate consequence of this fact.

(4) For any open neighborhoods U and V of X with $U \leq V$, i.e. with $V \subset U$, we have a commutative diagram

$$\begin{array}{ccc}\mathrm{H}^{n-j}(\Sigma\backslash X, V\backslash X) & \longleftarrow & \mathrm{H}^{n-j}(\Sigma, V)\\ \uparrow & & \uparrow\\ \mathrm{H}^{n-j}(\Sigma\backslash X, U\backslash X) & \longleftarrow & \mathrm{H}^{n-j}(\Sigma, U)\end{array}$$

where all the maps are induced by the obvious inclusions of pairs of topological spaces. It follows from the Excision Theorem 109.1 for Cohomology Groups that the horizontal maps are isomorphisms. The desired isomorphism of direct limits is now an immediate consequence of the Cofinal-Isomorphism Lemma 111.4.

(5) For any open neighborhoods U and V of X with $U \leq V$, i.e. with $V \subset U$, we have a commutative diagram

$$\begin{array}{ccc}\mathrm{H}^{n-j}(\Sigma, V) & \xleftarrow{\delta} & \widetilde{\mathrm{H}}^{n-j-1}(V)\\ \uparrow & & \uparrow\\ \mathrm{H}^{n-j}(\Sigma, U) & \xleftarrow{\delta} & \mathrm{H}^{n-j-1}(U)\end{array}$$

where the vertical maps are induced by the obvious inclusions and where the horizontal maps are the connecting homomorphisms of the long exact sequences in reduced cohomology provided by Lemma 108.17. Since $j \geq 1$ we obtain from these long exact sequences and the calculation of the cohomology groups of Σ that the horizontal maps are in fact isomorphisms. As in (4) we appeal to the Cofinal-Isomorphism Lemma 111.4 to obtain the desired isomorphism of direct limits.

(6) The last map is the isomorphism of the above claim.

This concludes the proof of the construction of an isomorphism

$$\Theta_X \colon \widetilde{\mathrm{H}}_j(\Sigma \setminus X; G) \xrightarrow{\cong} \widetilde{\mathrm{H}}^{n-j-1}(X; G).$$

Finally let $X \subset Y \subsetneq \Sigma$ be two weakly locally contractible, non-empty compact subset of Σ. As we more or less discussed, the isomorphisms (1)–(6) that we just constructed are all natural with respect to inclusions. Thus we obtain the following commutative diagram:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_j(\Sigma \setminus X) & \xrightarrow[\cong]{\Theta_X} & \widetilde{\mathrm{H}}^{n-j-1}(X) \\ \downarrow & & \downarrow \\ \widetilde{\mathrm{H}}_j(\Sigma \setminus Y) & \xrightarrow[\cong]{\Theta_Y} & \widetilde{\mathrm{H}}^{n-j-1}(Y), \end{array}$$

We leave it to the reader to double-check this claim. ■

Proof of the Generalized Alexander Duality Theorem 124.2 for $j = 0$. It still remains to deal with the case $j = 0$. The argument is almost entirely the same as for $j \neq 0$. In particular we can again construct the maps (1)–(6). In the case $= 0$ all of the above maps (1)–(6) are still isomorphisms, except for map (5). To address this issue we consider the following diagram:

$$\begin{array}{ccccccc} \mathrm{H}_0(\Sigma\setminus X) & \xrightarrow[\cong]{(1)} & \mathrm{H}^n_{\mathrm{c}}(\Sigma\setminus X) & \xrightarrow[\cong]{(2),(3)} & \varinjlim_{U\in\mathcal{N}(X)} \mathrm{H}^n(\Sigma\setminus X, U\setminus X) & \xrightarrow[\cong]{(4)} & \varinjlim_{U\in\mathcal{N}(X)} \mathrm{H}^n(\Sigma, U) \\ \downarrow & & \downarrow & & \cong\downarrow & & \downarrow \\ \mathrm{H}_0(\Sigma) & \xrightarrow[\cong]{(1)} & \mathrm{H}^n_{\mathrm{c}}(\Sigma) & \xrightarrow[\cong]{(2),(3)} & \varinjlim_{U\in\mathcal{N}(X)} \mathrm{H}^n(\Sigma, U) & \xrightarrow[\cong]{(4)} & \varinjlim_{U\in\mathcal{N}(X)} \mathrm{H}^n(\Sigma). \end{array}$$

Here the second vertical map is the inclusion induced map defined by Lemma 112.5. The first and the fourth vertical maps are the obvious inclusion induced maps. Furthermore the third vertical map is the inverse of the isomorphism which is induced by the isomorphisms $\mathrm{H}^n(\Sigma, U) \to \mathrm{H}^n(\Sigma\setminus X, U\setminus X)$ that are given by the Excision Theorem 109.1 for Cohomology Groups. The top horizontal maps are precisely the above maps (1), (2), (3) and (4). The bottom horizontal maps are defined completely analogously with $X = \varnothing$. Since the maps defined in (1), (2), (3) and (4) are natural we see that the diagram commutes. It follows

that

induced by the natural map $\varkappa\colon \widetilde{\mathrm{H}}_0(\Sigma\backslash X) \to \widetilde{\mathrm{H}}_0(\Sigma\backslash X)$ it follows from Lemma 74.2 that this map is in fact an isomorphism — by the above commutative diagram

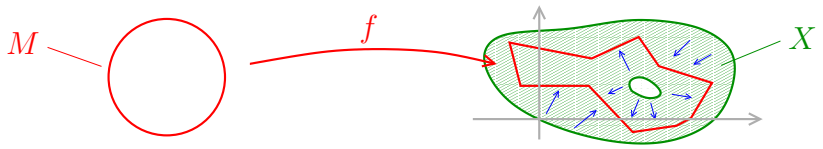
$$\begin{array}{ccccc} \widetilde{\mathrm{H}}_0(\Sigma\backslash X) & \overset{\cong}{\to} & \ker(\mathrm{H}_0(\Sigma\backslash X) \to \mathrm{H}_0(\Sigma)) & \overset{\cong}{\to} & \ker\left(\varinjlim \mathrm{H}^n(\Sigma, U) \to \varinjlim \mathrm{H}^n(\Sigma)\right) \\ & \overset{\cong}{\leftarrow} & \varinjlim \ker(\mathrm{H}^n(\Sigma, U) \to \mathrm{H}^n(\Sigma)) & \overset{\cong}{\leftarrow} & \varinjlim \widetilde{\mathrm{H}}^{n-1}(U) \quad \overset{\cong}{\to} \quad \widetilde{\mathrm{H}}^{n-1}(X). \\ & & \uparrow & & \uparrow \qquad\qquad \uparrow \end{array}$$

Direct Limit-(Co-)-Kernel Corollary 79.3 — by the long exact sequence of Lemma 108.17 and since $n \geq 2$ — by the claim

This concludes the proof of the construction of an isomorphism

$$\Theta_X\colon \widetilde{\mathrm{H}}_j(\Sigma \setminus X; G) \overset{\cong}{\to} \widetilde{\mathrm{H}}^{n-j-1}(X; G).$$

We leave the task of verifying naturality to the reader. ■



124.3. **Consequences of the Generalized Alexander Duality Theorem 124.2.** The following proposition is the topological analogue of the Smooth Codimension-One Orientability Proposition 43.12 which we proved on pages 1002 and 2705.

Proposition 124.5. (Topological Codimension-One Orientability Proposition) Let M be a closed connected n-dimensional topological manifold. If M is non-orientable, then there is no *topological* embedding of M into $\mathbb{R}^{n+1}$.

Proof. The proof of the Topological Codimension-One Orientability Proposition 124.5 is verbatim the same as the proof of the Smooth Codimension-One Orientability Proposition 43.12, we only need to replace the original Alexander Duality Theorem 123.6 by the Alexander Duality Theorem 124.3 for Topological Manifolds.

We also give an alternative argument that does not require the slightly obscure Generalized Alexander Duality Theorem 124.2. Thus let M be a closed connected n-dimensional topological manifold which admits an embedding $f\colon M \to \mathbb{R}^{n+1}$. We have to show that M is orientable. As usual we view $\mathbb{R}^{n+1}$ as a subset of S^{n+1}. We make the following observations:

(1) It follows from Borsuk's Theorem 104.6 together with Proposition 104.8 (1) that there exists a compact $(n+1)$-dimensional smooth submanifold X of $\mathbb{R}^{n+1}$ that contains $f(M)$ and such that there exists a retraction $r\colon X \to f(M)$. In the following we denote by $i\colon f(M) \to X$ the inclusion map.
(2) Since $r \circ i = \mathrm{id}_{f(M)}$ we see that the map $r^*\colon \mathrm{H}^n(f(M); \mathbb{Z}) \to \mathrm{H}^n(X; \mathbb{Z})$, induced by the retraction, is a monomorphism.
(3) By the remark on page 2700 there is an isomorphism $\mathrm{H}^n(X; \mathbb{Z}) \cong \mathrm{H}_0(S^{n+1} \setminus X; \mathbb{Z})$. It follows in particular from the H_0-Proposition 72.5 that $\mathrm{H}^n(X; \mathbb{Z})$ is a free abelian group.
(4) It follows from (2) and (3) that $\mathrm{H}^n(f(M); \mathbb{Z})$ is a torsion-free abelian group.
(5) Since $f\colon M \to f(M)$ is a homeomorphism we obtain from (4) that $\mathrm{H}^n(M; \mathbb{Z})$ is a torsion-free abelian group.
(6) We deduce from (5) and the Top-Cohomology Proposition 110.14 that the closed connected n-dimensional topological manifold M is orientable. ■

In Question 24.13 (3) we asked whether $\mathbb{R}\mathrm{P}^2$ or the Klein bottle admit an embedding into $\mathbb{R}^3$. We can now give a negative answer.

Corollary 124.6. Neither $\mathbb{R}\mathrm{P}^2$ nor the Klein bottle admit an embedding into $\mathbb{R}^3$.

Proof. By the Surface Non-Orientability Lemma 25.20 we know that $\mathbb{R}\mathrm{P}^2$ and the Klein bottle are both non-orientable as smooth manifolds. It follows from the Smooth-Topological Orientation Proposition 105.11 that both are also non-orientable as topological manifolds. Since both are closed 2-dimensional topological manifolds it follows from the Topological Codimension-One Orientability Proposition 124.5 that neither $\mathbb{R}\mathrm{P}^2$ nor the Klein bottle admit an embedding into $\mathbb{R}^3$. ■

The following proposition is a strengthening of Proposition 123.11.

Proposition 124.7. If $n \in \mathbb{N}_{\geq 2}$, then there is no embedding of $\mathbb{R}\mathrm{P}^n$ into S^{n+1}.

Proof. First let n be even. In this case we know by the Real Projective Space Orientability Lemma 25.21 and the Smooth-Topological Orientation Proposition 105.11 that $\mathbb{R}\mathrm{P}^n$ is non-orientable. Thus the result is an immediate consequence of the Topological Codimension-One Orientability Proposition 124.5.

Now let n be odd. This case is significantly harder and it was first proved by René Thom [**Tho1952**, p. 180] in 1952. We cannot provide the argument. But it seems like the argument of Thom is somewhat reminiscent of the argument in the proof of Proposition 123.11. So suppose there exists an embedding $f\colon \mathbb{R}\mathrm{P}^n \to S^{n+1}$. It follows from the H_0-Proposition 72.5, the Generalized Alexander Duality Theorem 124.2 and the fact that $\mathrm{H}^n(\mathbb{R}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ (here we use that n is odd), that $S^{n+1} \setminus f(\mathbb{R}\mathrm{P}^n)$ consists of two path components. We denote the closures of the path components by A and B. The problem is that the triad (S^{n+1}, A, B) is in general not excisive so we cannot apply the Mayer–Vietoris Theorem 109.15 for Cohomology Groups. The idea in the proof is to replace usual singular cohomology by Alexander-Spanier cohomology for which the above triad is excisive. We refer to [**Mass1978a**, Chapter 8] or [**Mass1978b**] for an introduction to Alexander-Spanier cohomology and we refer to [**Mass1978a**, Theorem II.8.15] for the proof that in this setting the above triad is excisive. ■

124.4. **Generalized Alexander Duality Theorem for Homology Balls.** We have the following obvious analogue of the definition of a homology sphere.

Definition. We say that an n-dimensional topological manifold X is a topological homology n-ball if X is compact and if for every $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(X;\mathbb{Z}) \cong \mathrm{H}_k(\overline{B}^n;\mathbb{Z})$.

Lemma 124.8. If X is a topological homology n-ball, then ∂X is a topological homology $(n-1)$-sphere.

Proof. Let X be a topological homology n-ball. Note that this implies in particular that $\mathrm{H}_1(X;\mathbb{Z}) = 0$. Therefore it follows from the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 105.16 together with the Hurewicz Theorem 85.5 that X is orientable.

At this state this lemma follows easily from the Poincaré Duality Theorem 119.1 and the long exact sequence in homology of the pair $(X, \partial X)$. We will fill in the details in Exercise 124.2. ■

We can now formulate the following variation on the Generalized Alexander Duality Theorem 124.2.

Theorem 124.9. (Generalized Alexander Duality Theorem for Balls) Let $n \geq 2$, let B be an n-dimensional homology ball and let $X \neq B$ be a non-empty compact subset of B. We write $\partial X := X \cap \partial B$. If X and ∂X are weakly locally contractible, then given any $j \in \mathbb{N}_0$ we have a natural isomorphism

$$\Theta_X \colon \widetilde{\mathrm{H}}_j(B \setminus X;\mathbb{Z}) \xrightarrow{\cong} \widetilde{\mathrm{H}}^{n-j-1}(X, \partial X;\mathbb{Z}).$$

Here natural means that if we are given $X \subset Y \subset B$ that both satisfy the above conditions, then the following diagram commutes:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_j(B \setminus Y;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_Y} & \mathrm{H}^{n-j-1}(Y, \partial Y;\mathbb{Z}) \\ \downarrow & & \downarrow \\ \widetilde{\mathrm{H}}_j(B \setminus X;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_X} & \mathrm{H}^{n-j-1}(X, \partial X;\mathbb{Z}), \end{array}$$

where the vertical maps are induced by the inclusions $B \setminus Y \to B \setminus X$ and $X \to Y$.

Proof. One could try to imitate the proof of the Generalized Alexander Duality Theorem 124.2, but instead we will do a little trick to reduce most of the statement to the Generalized Alexander Duality Theorem 124.2.

Let $X \subsetneq B$ be a non-empty compact subset of B such that X and $\partial X := X \cap \partial B$ are both weakly locally contractible.

Let $X \subsetneq B$ be a weakly locally contractible compact non-empty subset. We consider

$$K := (X \times \{0\}) \cup \underbrace{(\partial X \times [0,1]) \cup (B \times \{1\})}_{=:Y} \subset \underbrace{(B \times \{0\}) \cup (\partial B \times [0,1]) \cup (B \times \{1\})}_{=\partial(B \times [0,1])}.$$

Claim 1. The topological space K is again weakly locally contractible.

Proof. This claim can be proved easily by considering the following cases:

(1) The points $(x,0)$ with $x \notin \partial X$ and $(x,0)$ with $x \in \partial X$.
(2) The points (x,t) with $t \in (0,1)$.
(3) The points $(x,1)$ with $x \in B \setminus \partial B$ and $(x,1)$ with $x \in \partial B$.

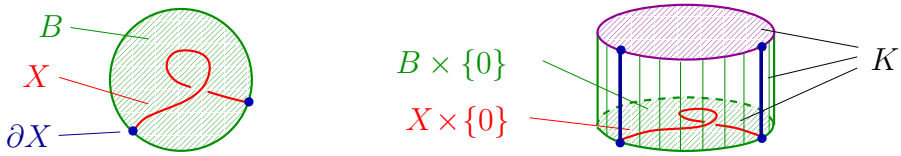
The first cases can be dealt with easily using the fact that X is weakly locally contractible. For the second case we need to use that ∂X is weakly locally contractible. The third case can be dealt with without any assumptions on X. ⊞

Now we consider the following maps

$$\begin{array}{ccccc}
\widetilde{\mathrm{H}}_j(B\setminus X) & \xrightarrow[\cong]{\text{(a)}} & \widetilde{\mathrm{H}}_j((B\times 0)\setminus(X\times\{0\})) & \xrightarrow[\cong]{\text{(b)}} & \widetilde{\mathrm{H}}_j(\partial(B\times[0,1])\setminus K) \\
\downarrow\cong & & \downarrow\cong & & \text{(c)}\downarrow\cong \\
\mathrm{H}^{n-j-1}(X,\partial X) & \xleftarrow[\text{(e)}]{\cong} & \mathrm{H}^{n-j-1}(K,Y) & \xleftarrow[\text{(d)}]{\cong} & \widetilde{\mathrm{H}}^{n-j-1}(K).
\end{array}$$

We make the following observations regarding the various maps:

(a) This map is induced by the obvious homeomorphism.



(b) This map is an isomorphism since $(B\times 0)\setminus(X\times\{0\})$ is a deformation retract of $\partial(B\times[0,1])\setminus K$.

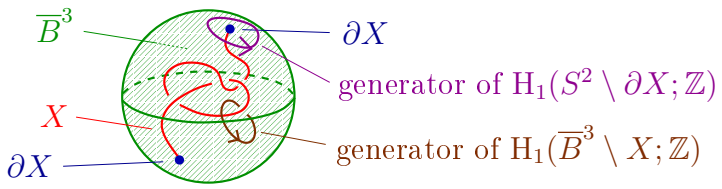
(c)
- It follows from the Künneth Theorem 90.8 together with the Topological Manifold Product Proposition 18.4 that $B^n\times[0,1]$ is a topological homology $(n+1)$-ball with boundary $(\partial B^n\times[0,1])\cup(B^n\times\{0,1\})$. It follows from Lemma 124.8 that $\partial(B^n\times[0,1])$ is a topological homology n-sphere.
- In Claim 1 we just showed that K is again weakly locally contractible.
- By the above we can appeal to the Generalized Alexander Duality Theorem 124.2 to obtain a natural isomorphism.

(d) This map is an isomorphism since Y is contractible.

(e) This map is an isomorphism by a suitable variation on the Excision Theorem 109.1.

The combination of the above gives us a natural vertical isomorphism Θ_X to the left. The proof of the naturality of Θ_X follows from the fact that all the isomorphisms we considered are natural under inclusions.

■



Theorem 124.10. (Generalized Alexander Duality Theorem for Balls) Let $n\geq 2$, let B be an n-dimensional homology ball and let $X\neq B$ be a non-empty compact subset of B. We write $\partial X := X\cap\partial B$. If X and ∂X are weakly locally contractible, non-empty compact subset of B, then given any $j\in\mathbb{N}_0$ we have a natural isomorphism

$$\Theta_X\colon \widetilde{\mathrm{H}}_j(B\setminus X;\mathbb{Z}) \xrightarrow{\cong} \widetilde{\mathrm{H}}^{n-j-1}(X,\partial X;\mathbb{Z}).$$

such that the following diagram commutes

$$\begin{array}{ccc}
\widetilde{\mathrm{H}}_{j-1}(\partial B\setminus\partial X;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_{\partial X}} & \widetilde{\mathrm{H}}^{n-j-1}(\partial X;\mathbb{Z}) \\
{\scriptstyle i_*}\downarrow & & \downarrow{\scriptstyle \delta} \\
\widetilde{\mathrm{H}}_j(B\setminus X;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_X} & \mathrm{H}^{n-j-1}(X,\partial X;\mathbb{Z}),
\end{array}$$

up to a sign that depends only on j and n.[1511] Here the bottom map is the isomorphism given in the proof of the Generalized Alexander Duality Theorem 124.2.

Proof. We consider

$$\widetilde{K} := (B \times \{0\}) \cup \underbrace{(\partial X \times [0,1]) \cup (B \times \{1\})}_{=:Y} \subset \underbrace{(B \times \{0\}) \cup (\partial B \times [0,1]) \cup (B \times \{1\})}_{=\partial(B \times [0,1])}.$$

By the naturality of the isomorphism from the Generalized Alexander Duality Theorem 124.2 we obtain the following commutative diagram:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_j(\partial(B \times [0,1]) \setminus \widetilde{K}) & \longrightarrow & \widetilde{\mathrm{H}}_j(\partial(B \times [0,1]) \setminus K) \\ {\scriptstyle (c)}\downarrow\cong & & {\scriptstyle (c)}\downarrow\cong \\ \widetilde{\mathrm{H}}^{n-j-1}(\widetilde{K}) & \longrightarrow & \widetilde{\mathrm{H}}^{n-j-1}(K). \end{array}$$

■

In the next section we will make use of the following lemma.

Corollary 124.11. Let $n \geq 2$ and let B be a topological n-dimensional homology ball and let $f\colon \overline{B}^k \to B$ be a proper embedding, i.e. f is an embedding with $f^{-1}(\partial B) = S^{k-1}$. We denote by $i\colon \partial B \setminus f(S^{k-1}) \to B \setminus f(\overline{B}^k)$ the inclusion map. The following two statements hold:

(1) The maps $i_*\colon \mathrm{H}_j(\partial B \setminus f(S^{k-1})) \to \mathrm{H}_j(B \setminus f(\overline{B}^k))$ are all isomorphisms.
(2) For each j we have

$$\mathrm{H}_j(B \setminus f(\overline{B}^k)) \cong \begin{cases} \mathbb{Z}, & \text{if } j = 0, n-k-1, \\ 0, & \text{else.} \end{cases}$$

Proof. By hypothesis $f\colon \overline{B}^k \to B$ is a proper embedding. Since $\overline{B}^k$ is evidently weakly locally contractible we see that $f(\overline{B}^k)$ is also weakly locally contractible. Thus we obtain from the Generalized Alexander Duality Theorem 124.10 for Balls that for any $j \in \mathbb{N}_0$ we have an isomorphism

$$\widetilde{\mathrm{H}}_j(B \setminus f(\overline{B}^k); \mathbb{Z}) \xrightarrow{\cong} \widetilde{\mathrm{H}}^{n-j-1}(\overline{B}^k, S^{k-1}; \mathbb{Z}).$$

such that the following diagram commutes

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_{j-1}(\partial B \setminus f(S^{k-1}); \mathbb{Z}) & \xrightarrow{\cong} & \widetilde{\mathrm{H}}^{n-j-1}(S^{k-1}); \mathbb{Z}) \\ {\scriptstyle i_*}\downarrow & & \downarrow{\scriptstyle \delta} \\ \widetilde{\mathrm{H}}_j(B \setminus f(\overline{B}^k); \mathbb{Z}) & \xrightarrow{\cong} & \mathrm{H}^{n-j-1}(\overline{B}^k, S^{k-1}; \mathbb{Z}), \end{array}$$

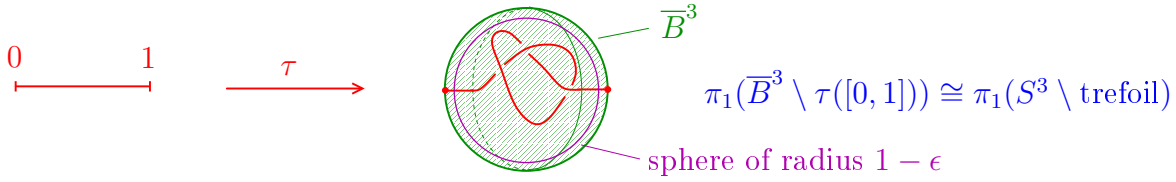
up to a sign. We make the following observations:

[1511] I will not embarrass myself by trying to guess the sign.

(a) It follows from the Single Point-Cohomology Lemma 108.12 and 108.13 that the reduced cohomology groups of $\overline{B}^k$ vanish.
(b) It follows from (a) and from the long exact sequence of reduced cohomology groups, see Lemma 108.17, that the vertical maps to the right are isomorphisms. Together with the commutativity of the diagram this implies Statement (1).
(c) On page 2419 we calculated the cohomology groups of S^{k-1}. Together with Lemma 108.17 and the above isomorphisms we obtain a proof for Statement (2). ■

Theorem 124.12. (Generalized Alexander Duality Theorem for Balls) Let $n \geq 2$, let B be an n-dimensional homology ball and let $X \neq B$ be a non-empty compact subset of B. We write $\partial X := X \cap \partial B$. We suppose that X and ∂X are weakly locally contractible, non-empty compact subsets of B. If ∂X is a smooth submanifold of ∂B and it has a collar in B, then the following diagram commutes

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_{j-1}(\partial B \setminus \partial X;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_{\partial X}} & \widetilde{\mathrm{H}}^{n-j-1}(\partial X;\mathbb{Z}) \\ \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle \delta} \\ \widetilde{\mathrm{H}}_{j}(B \setminus X;\mathbb{Z}) & \xrightarrow[\cong]{\Theta_{X}} & \mathrm{H}^{n-j-1}(X,\partial X;\mathbb{Z}), \end{array}$$



up to a sign that depends only on j and n.[1512] Here the bottom map is the isomorphism given in the proof of the Generalized Alexander Duality Theorem 124.2.

124.5. **Wild arcs and wild knots.** In this section we will use the Generalized Alexander Duality Theorem for Balls 124.12 to prove the following theorem.

Theorem 124.13. There exists an embedding $\gamma\colon S^1 \to S^3$ such that $\gamma(S^1) \subset S^3$ is not a topological manifold.

The construction of such a map $\gamma\colon S^1 \to S^3$ requires some preparations. We start out with the following lemma.

Lemma 124.14. There exists a proper smooth embedding $\tau\colon [0,1] \to \overline{B}^3$ with the following two properties:
(1) there exists an $\epsilon > 0$ such that $\tau(t) = (2t-1, 0, 0)$ for $t \in [0, \frac{\epsilon}{2}]$ and $t \in [1-\frac{\epsilon}{2}, 1]$ and such that $\tau^{-1}(\{x \in \overline{B}^3 \mid \|x\| > 1-\epsilon\}) = [0, \frac{\epsilon}{2}] \cup [1-\frac{\epsilon}{2}, 1]$,
(2) $\pi_1(\overline{B}^3 \setminus \tau([0,1]))$ is non-abelian.

Sketch of proof. Let $T \subset S^3$ be the trefoil, as defined on page 1312. In Proposition 59.6 we showed that $\pi_1(S^3 \setminus T)$ is non-abelian. In the proof of Proposition 59.14 we showed

[1512] I will not embarrass myself by trying to guess the sign.

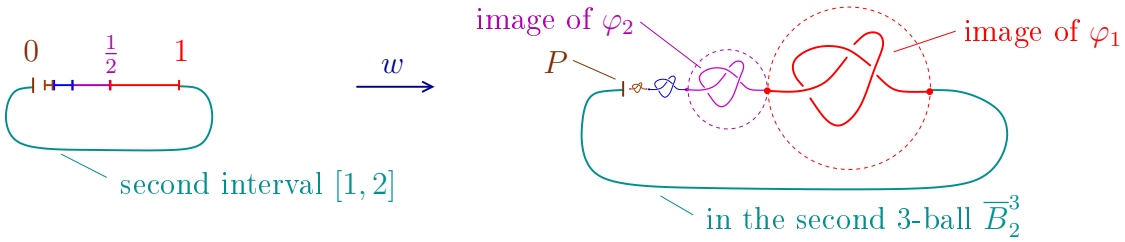
that T gives rise to a desired proper smooth embedding $\tau\colon [0,1] \to \overline{B}^3$ that satisfies (a) and such that $\pi_1(\overline{B} \setminus \tau([0,1])) \cong \pi_1(S^3 \setminus T)$ ■

Our goal is to construct an embedding $f\colon S^1 \to S^3$ such that $f(S^1)$ is not a topological submanifold of S^3. To simplify the notation we will use the homeomorphisms from the Ball-Quotient Sphere Lemma 5.20 and pages261 to make the identifications $[0,2]/0 \sim 2 = S^1$ and $\overline{B}^3_1 \cup_{S^2_1 = S^2_2} \overline{B}^3_2 = S^3$.

Notation.

(1) For the remainder of this section we fix a proper smooth embedding $\tau\colon [0,1] \to \overline{B}^3$ as in Lemma 124.14.

(2) Given $n \in \mathbb{N}$ we consider the smooth embedding



$$\begin{array}{rcl} \varphi_n\colon \overline{B}^3 & \to & B^3 \subset \overline{B}^3 \\ x & \mapsto & (-1 + \frac{3}{2^n}, 0, 0) + \frac{1}{2^n} \cdot x. \end{array}$$

(3) We consider the map

$$w\colon \overbrace{[0,2]/0 \sim 2}^{=S^1} \to \overbrace{\overline{B}^3_1 \cup_{S^2_1 = S^2_2} \overline{B}^3_2}^{=S^3}$$

$$t \mapsto \begin{cases} (-1,0,0) \in \overline{B}^3_1, & \text{if } t = 0, \\ \varphi_n(\tau(\underbrace{2^{n-1} \cdot (t - \frac{1}{2^n})}_{\in (0,1]})) \in \overline{B}^3_1, & \text{if } t \in (\frac{1}{2^n}, \frac{1}{2^{n-1}}] \text{ for some } n \in \mathbb{N}, \\ (3 - 2t, 0, 0) \in \overline{B}^3_2, & \text{if } t \in [1,2]. \end{cases}$$

(4) We set $W := w(S^1)$ and we write $P := w([0])$.

The following proposition immediately implies Theorem 124.13.

Proposition 124.15. Let $w\colon S^1 \to S^3$ be the above map.

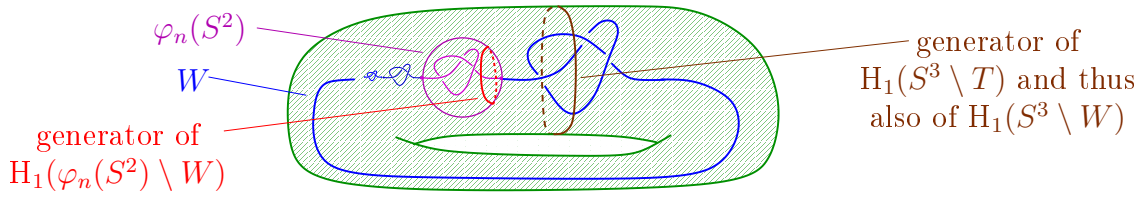
(1) The map $w\colon S^1 \to S^3$ is an embedding.

(2) There is no submanifold chart, in the sense of the definition on page 524, for the subset $W := w(S^1) \subset S^3$ around $P = w([0])$. In particular $W = w(S^1)$ is not a submanifold of S^3.

Our proof of Proposition 124.15 crucially relies on the following lemma, which is a direct descendant of the Generalized Alexander Duality Theorem 124.2.

Lemma 124.16. For any $n \in \mathbb{N}$ the inclusion induced map

$$\mathrm{H}_1(\varphi_n(S^2) \setminus W) \to \mathrm{H}_1(S^3 \setminus W)$$



is an isomorphism.

Proof. As the reader will see short, the proof of Lemma 124.16 is almost identical to the argument on page 2711 where we identified a generator for $\mathrm{H}_1(S^3 \setminus W)$. For peace of mind we provide the argument.

Let $n \in \mathbb{N}$. We denote by T the "standard solid torus" in $S^3 = \overline{B}^3_1 \cup_{S^2_1 = S^2_2} \overline{B}^3_2$ that is given by the points $(x, y, z) \in \overline{B}_i$ in each ball with $y^2 + z^2 \leq \frac{1}{2}$. Note that $W \subset T$. We denote by $i \colon W \to T$ the inclusion map. By the naturality of the isomorphism of the Generalized Alexander Duality Theorem 124.2 we have the following commutative diagram:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_j(\Sigma \setminus X; G) & \xrightarrow[\cong]{\Theta_X} & \widetilde{\mathrm{H}}^{n-j-1}(X; G) \\ \downarrow & & \downarrow \\ \widetilde{\mathrm{H}}_j(\Sigma \setminus Y; G) & \xrightarrow[\cong]{\Theta_Y} & \widetilde{\mathrm{H}}^{n-j-1}(Y; G), \end{array}$$

here the left vertical map is induced by the inclusion $\Sigma \setminus X \to \Sigma \setminus Y$ and the right vertical map is induced by the inclusion $X \to Y$. ■

Our proof of Proposition 124.15 relies also on the following earlier proposition.

Proposition 53.24. (Amalgamated Product-Monomorphism Proposition) Let $\alpha \colon G \to A$ and $\beta \colon G \to B$ be two group homomorphisms. We denote by $A *_G B$ the corresponding amalgamated product as defined on page 1209. If α and β are both monomorphisms, then the natural homomorphisms $A \to A *_G B$ and $B \to A *_G B$ are also both monomorphisms.

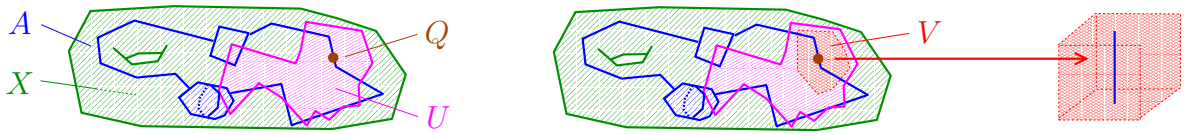
Proof of Proposition 124.15. First we provide the proof of Statement (1). Using the ϵ-δ-criterion from the Metric Continuity Proposition 2.8 one can easily show that the map $[0, 1] \to S^3$, induced by f, is continuous. It is clear that the corresponding map $[1, 2] \to S^3$ is continuous. It follows from the Pasting Pasting Proposition 2.6 together with the Topological-Quotient Proposition 5.15 (1b) that the given map $f \colon S^1 \to S^3$ is continuous. It now follows from the Compact-Hausdorff Proposition 2.17 (2) that $f \colon S^1 \to S^3$ is actually an embedding.

Now we turn to the proof of Statement (2). We start out with the following harmless general claim.

Claim 1. Let X be an n-dimensional topological manifold, let $A \subset X$ be a subset and let $Q \in A$. If there exists a submanifold chart of type (α) for $A \subset X$ and $Q \in A$, then given any open neighborhood U of $Q \in A$ there exists a neighborhood V with the following properties:

(1) $A \in V \subset U$,

(2) V is homeomorphic to $\overline{B}^3$,



(3) either $V = A \cap V$ or $V \setminus (A \cap V)$ is non-empty and path-connected with abelian $\pi_1(V \setminus (A \cap V))$.[1513]

Proof. It follows almost immediately from the definition of a chart for A and Q that given any open neighborhood U of $Q \in A$ there exists a neighborhood V with $A \in V \subset U$ such that the pair $(V, A \cap V)$ is homeomorphic to the pair $([-1,1]^n, \{0\} \times [-1,1]^k)$. If $n = k$, then $V = A \cap V$. If $k < n$, then we see that

$$\pi_1(V \setminus (A \cap V)) \;\cong\; \pi_1([-1,1]^n \setminus (\{0\} \times [-1,1]^k) \;\underset{\uparrow}{\cong}\; \pi_1(S^{n-k-1}) \;\underset{\uparrow}{\cong}\; \begin{cases} \mathbb{Z}, & \text{if } n-k=2, \\ 0, & \text{otherwise.} \end{cases}$$

topological spaces are homotopy equivalent — Propositions 48.17 and 47.13

By the Convex-to-Ball Proposition 2.20 we know that $[-1,1]^n$ is homeomorphic to $\overline{B}^n$. Thus V has indeed all the desired properties. ⊞

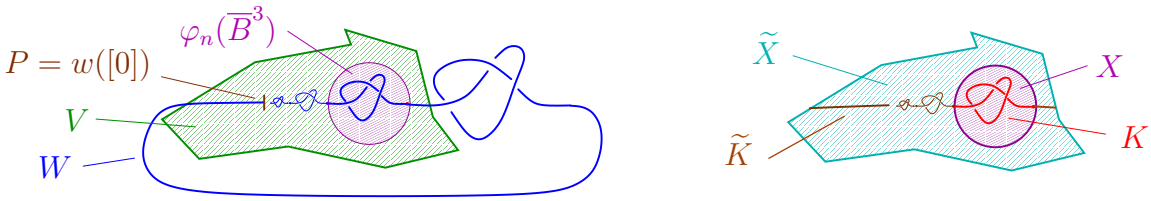
Note that S^1 and S^3 are topological manifolds with empty boundary. It follows from the Topological Manifold Boundary Proposition 75.2 that neither $\mathbb{R}$ nor $\mathbb{R}^3$ admits a chart of type (i) in the sense of the definition on page 511. This implies that if there exists a submanifold, it has to be a chart of type (α). It follows from this discussion, together with Claim 1, that it suffices to prove the following claim.

Claim 2. For every path-connected neighborhood V of $P \in S^3$, that is homeomorphic to $\overline{B}^3$, the fundamental group $\pi_1(V \setminus (W \cap V))$ is non-abelian.

Proof. Let V be a path-connected open neighborhood of $P \in S^3$ that is homeomorphic to $\overline{B}^3$. Since V is a neighborhood of $P = w([0])$ there exists an $n \in \mathbb{N}$ such that $\varphi_n(\overline{B}^3) \subset V$. We pick an $\epsilon > 0$ as in Lemma 124.14.

(1) By the Topological Invariance of Domain Theorem 82.7 we know that $\varphi_n(B^3)$ is an open subset of S^3.
(2) Note that $S^2_{1-\epsilon}$ is a submanifold of B^3 that intersects $\tau([0,1])$ transversally in two points.
(3) Note that $\overline{B}^3_{1-\epsilon}$ is a codimension-zero submanifold of B^3.
(4) It follows from (a) and (c) that $\varphi_n(\overline{B}^3_{1-\epsilon})$ is a codimension-zero submanifold of B^3.
(5) It follows from Proposition 75.3 and (d) that $S^3 \setminus \varphi_n(\overline{B}^3_{1-\epsilon})$ is also a codimension-zero submanifold of B^3. In particular it is a topological manifold in its own right.

We introduce the following notation:



(1) We write $X := \varphi_n(\overline{B}^3_{1-\epsilon})$, $\widetilde{X} := V \setminus \varphi(B^3_{1-\epsilon})$ and $Y := \varphi_n(S^2_{1-\epsilon})$,
(2) We write $K := W \cap X$, $\widetilde{K} := K \cap \widetilde{X}$ and $L := K \cap Y$.

[1513] Since $V \setminus (A \cap V)$ is path-connected we know by the Base Point Independence Corollary 47.11 that the isomorphism type of the fundamental group does not depend on the choice of the base point.

We now see that

follows from the Seifert–van Kampen Theorem for Topological Manifolds 54.4

$$\pi_1(V \setminus (W \cap V)) \overset{\cong}{\downarrow} \pi_1(X \setminus K) *_{\pi_1(Y \setminus L)} \pi_1(\widetilde{X} \setminus \widetilde{K}).$$

We know that $\pi_1(X \setminus K)$ is non-abelian. To conclude that $\pi_1(V \setminus (W \cap V))$ is non-abelian, it suffices by the Amalgamated Product-Monomorphism Proposition 53.24 to show that the two maps $\pi_1(Y \setminus L) \to \pi_1(X \setminus K)$ and $\pi_1(Y \setminus L) \to \pi_1(\widetilde{X} \setminus \widetilde{K})$ are monomorphisms. Since $\pi_1(Y \setminus L) \cong \mathbb{Z}$ it suffices to show that the maps $\mathrm{H}_1(Y \setminus L) \to \mathrm{H}_1(X \setminus K)$ and $\mathrm{H}_1(Y \setminus L) \to \mathrm{H}_1(\widetilde{X} \setminus \widetilde{K})$ are monomorphisms. In the former case that follows easily from Corollary 124.11.

Now consider $\widetilde{X}$. As discussed above, we know that $\widetilde{X}$ is a compact 3-dimensional topological manifold in its own right. Furthermore, by the Generalized Alexander Duality Theorem 124.12 for Balls we know that $\widetilde{X}$ is a homology 3-ball. (In all likelihood $\widetilde{X}$ is in fact homeomorphic to $\overline{B}^3$, in fact we even know that $\pi_1(\widetilde{X}) = 0$, but from what we know we cannot conclude so.)

But now it follows again from Corollary 124.11 that the map $\mathrm{H}_1(Y \setminus L) \to \mathrm{H}_1(\widetilde{X} \setminus \widetilde{K})$ is an isomorphism. ■

Proposition 124.17. The subset $W := w(S^1) \subset S^3$ does not admit a regular neighborhood in the sense of the definition on page 2695.

Sketch of proof. $\pi_1(S^3 \setminus W)$ is infinitely generated. One can see this by exhausting $S^3 \setminus W$ by sets where swallow all but finitely many balls and then do a limit argument. But this contradicts Lemma 123.1. ■

Exercises for Chapter 124.

Exercise 124.1. The Generalized Alexander Duality Theorem 124.2 was formulated for $n \geq 2$. What is the correct statement for $n = 1$?

Exercise 124.2. Let X be a topological homology n-ball. Show that ∂X is a topological homology $(n-1)$-sphere.

Exercise 124.3. We say an embedding $\varphi\colon [0,1] \to \mathbb{R}^3$ is tame if there exists a homeomorphism $f\colon \mathbb{R}^3 \to \mathbb{R}^3$ such that $f(\varphi(t)) = (t,0,0)$ for all $t \in [0,1]$. In the figure below we show the images of three embeddings $\alpha, \beta, \gamma\colon [0,1] \to \mathbb{R}^3$.

(a) Show that α is tame.
(b) Show that β is tame.
(c) Show that γ is not tame.

(d) Let $\delta\colon [0,1] \to \mathbb{R}^3$ be an embedding that is also a smooth map. Is δ tame?
Remark. Note that a smooth embedding, as defined on page 652, is more than just an embedding that is a smooth map.

Exercise 124.4. In the figure below we show two subsets X and Y of $\mathbb{R}^3$ that are homeomorphic to the compact interval $[0,1]$. Which of the fundamental groups $\pi_1(\mathbb{R}^3 \setminus X)$ and $\pi_1(\mathbb{R}^3 \setminus Y)$ is abelian and which is non-abelian?

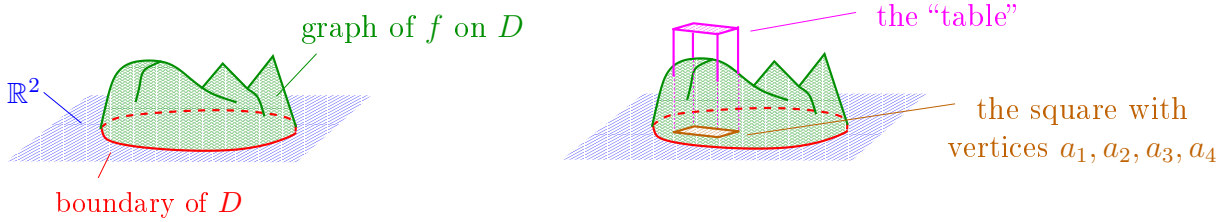
125. Applications of cohomology groups

In this chapter we give two applications of cohomology groups, namely we prove the table theorem and we address two special cases of the square peg problem. Neither of these applications can count as a "real life" application, but at least in both cases cohomology, Poincaré Duality and Alexander duality get used to prove statements which initially have absolutely no connection to cohomology theory at all.

125.1. **The Table Theorem ❀.** As a warm-up we start out with the fairly elementary but charming Wobbly Table Theorem. In the vernacular it says that given a wobbly table we can rotate it around its center, by an angle of at most $\frac{\pi}{2}$, such that eventually all four legs touch the ground. Slightly more precisely, it can be formulated as follows:

Theorem 125.1. (Wobbly Table Theorem) Let $f\colon \mathbb{C} = \mathbb{R}^2 \to \mathbb{R}$ be a function, let $x \in \mathbb{C}$ and let $z \in \mathbb{C} \setminus \{0\}$. There exists a $\theta \in [0, \frac{\pi}{2}]$ such that

$$f(x + e^{\mathrm{i}\theta} \cdot z) \;=\; f(x + e^{\mathrm{i}(\theta+\frac{\pi}{2})} \cdot z) \;=\; f(x + e^{\mathrm{i}(\theta+\pi)} \cdot z) \;=\; f(x + e^{\mathrm{i}(\theta+\frac{3\pi}{2})} \cdot z).$$



Proof. The theorem is a fairly elementary consequence of the Intermediate Value Theorem from real analysis. Filling in the details is your task in Exercise 125.1. Alternatively the reader can look at [**Loy2017**, p. 289] for a proof. ■

Our goal in this section is to prove a much more fancy theorem. More precisely we will prove the following "Table Theorem" which was first formulated and proved by Roger Fenn [**Fen1970**] in 1970.

Theorem 125.2. (Table Theorem) Let $D \subset \mathbb{R}^2$ be a compact convex non-empty subset and let $f\colon \mathbb{R}^2 \to \mathbb{R}$ be a map such that $f(x) \geq 0$ for all $x \in D$ and such that $f(x) = 0$ for all $x \notin D$. Given any $d \in \mathbb{R}_{>0}$ there exist four points $a_1, a_2, a_3, a_4 \in \mathbb{R}^2$ with the following properties:

(1) the points form a square of side length d,
(2) the center of the square lies in D,
(3) we have $f(a_1) = f(a_2) = f(a_3) = f(a_4)$.

In other words, the Table Theorem 125.2 says that any given square table can be placed on the ground defined by the graph of f, such that all four legs lie on the ground, such that the table is horizontal and such that the center of the table is located in D.

Remark. In [**Meye1981**] it is shown that in the formulation of the Table Theorem 125.2 one cannot drop the hypothesis that D is convex.

The proof of the Table Theorem 125.2 will require the remainder of this section. Throughout the section we fix a compact convex non-empty subset $D \subset \mathbb{R}^2$ and we fix a function

$f\colon \mathbb{R}^2 \to \mathbb{R}$ such that $f(x) \geq 0$ for all $x \in D$ and such that $f(x) = 0$ for all $x \notin D$. Let $d \in \mathbb{R}_{>0}$. We make the following elementary observations and preparations:

(i) Since we can rescale D we can and will without loss of generality assume that $d = 1$.
(ii) If the interior of D is the empty set, then the function f is necessarily the zero function[1514]. Thus the conclusion of the Table Theorem 125.2 holds trivially.
(iii) It follows from (ii) that henceforth we can assume that the interior of D is non-empty. Note that the Convex-to-Ball Proposition 2.20 implies that there exists a homeomorphism of pairs $(D, \partial D) \xrightarrow{\cong} (\overline{B}^2, S^1)$.
(iv) After a translation we can and will assume that the origin $(0, 0)$ is contained in the interior of D.
(v) As always we will make the identification $\mathbb{R}^2 = \mathbb{C}$, in particular we will work a lot with the multiplication "$\cdot\, i$", i.e. with "rotation by $\frac{\pi}{2}$".
(vi) If there exists a square in $\mathbb{R}^2$ of side length $d = 1$ with center in D, such that the f-value at all of the four vertices is zero, then we have evidently found the desired table. Thus we can henceforth assume that for any square of side length $d = 1$ with center in D the f-value of at least one vertex is non-zero.

In the following discussion we will at times take a few liberties with mathematical language, but these liberties will not infringe on the rigor of the argument.

We start out with introducing the following notation, which gives us a convenient way for parameterizing the set of all squares with side length $d = 1$ and whose center lies in D.

Notation.

(1) We consider the map[1515]

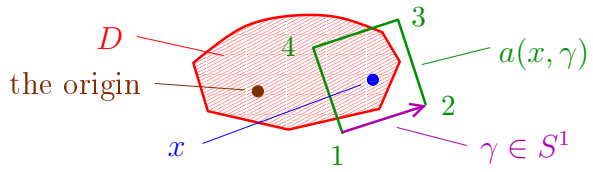
$$\begin{array}{rcl} a\colon D \times S^1 & \to & \mathbb{R}^2 \times \mathbb{R}^2 \times \mathbb{R}^2 \times \mathbb{R}^2 \\ & & \text{the four vertices } a_1, a_2, a_3, a_4 \text{ of the unique square} \\ (x, \gamma) & \mapsto & \text{with center } x \text{ such that } a_2 - a_1 = \gamma \text{ and} \\ & & \text{such that } a_1, a_2, a_3, a_4 \text{ are ordered in the} \\ & & \text{counterclockwise direction.} \end{array}$$

This definition is illustrated in the figure below.

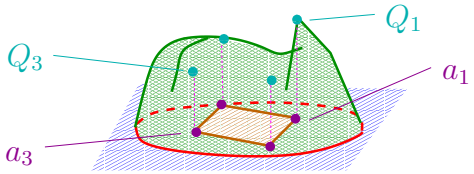
(2) We also consider the closely related map

$$\begin{array}{rcl} Q\colon D \times S^1 & \to & \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3 \\ (x, \gamma) & \mapsto & \text{the points } Q_1, Q_2, Q_3, Q_4 \text{ on the graph corresponding to } a(x, \gamma). \end{array}$$

When $(x, \gamma) \in D \times S^1$ is understood from the context, then we drop it at times from the notation. In other words, often we write a_i instead of $a_i(x, \gamma)$ and we write Q_i instead of $Q_i(x, \gamma)$.



One of the key ideas behind the proof of the Table Theorem 125.2 is to split Condition (3) of the Table Theorem 125.2 into two separate statements. Namely we note that the condition



(3) $f(a_1) = f(a_2) = f(a_3) = f(a_4)$,

is satisfied precisely if the following two conditions are satisfied:

[1514] Why is that?

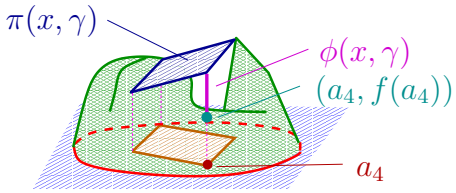
[1515] We leave the task of writing down an explicit formula to the reader. Once the formula is written down it is clear that a is actually continuous.

(3a) the points $\underbrace{(a_1, f(a_1))}_{=Q_1}, \ldots, \underbrace{(a_4, f(a_4))}_{=Q_4}$ lie on a plane,

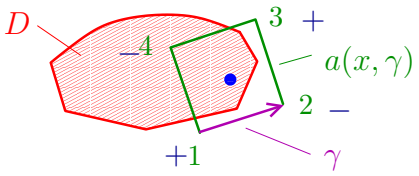
(3b) the plane from (3a) is horizontal.

The trick now is to encode these two statements in a clever way. We will do so by introducing two maps.

Definition.



(1) Given $(x,\gamma) \in D^2 \times S^1$ we denote by $\pi(x,\gamma)$ the plane through the three points $Q_1(x,\gamma), Q_2(x,\gamma)$ and $Q_3(x,\gamma)$.



(2) We consider the map[1516]

$$\begin{array}{rcl} \phi\colon D \times S^1 & \to & \mathbb{R} \\ (x,\gamma) & \mapsto & \underbrace{x_3\text{-value of the plane } \pi(x,\gamma) \text{ at } a_4(x,\gamma) \text{ minus } f(a_4(x,\gamma))}_{=f(a_1)+f(a_3)-f(a_2)-f(a_4)} \end{array}$$

The definition of this map is illustrated in the figure below. Note that $\phi(x,\gamma) = 0$ if and only if the corresponding points Q_1, Q_2, Q_3, Q_4 lie on a plane.

(3) We set $A := \{(x,\gamma) \in D \times S^1 \mid \phi(x,\gamma) = 0\}$.

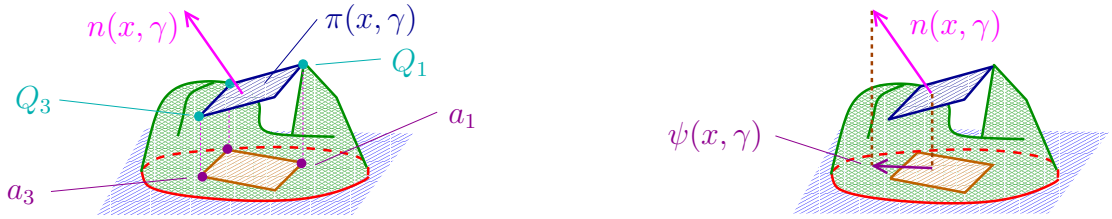
Definition.

(1) Given $(x,\gamma) \in D^2 \times S^1$ we denote by $n(x,\gamma) \in \mathbb{R}^3$ the unique vector that is normal to $\pi(x,\gamma)$, that has unit length and that has positive x_3-coordinate. This definition is illustrated in the figure below on the left.

(2) We consider the map

$$\begin{array}{rcl} \psi\colon D \times S^1 & \to & \mathbb{R}^2 \\ (x,\gamma) & \mapsto & \text{projection of } n(x,\gamma) \text{ onto the } x_1x_2\text{-plane.} \end{array}$$

[1516] Note that the equality



$$a_4 = a_2 + (a_3 - a_2) + \underbrace{(a_4 - a_3)}_{=a_1-a_2} = a_2 + (a_1 - a_2) + (a_3 - a_2) = a_1 + a_3 - a_2,$$

together with the fact that the x_3-coordinate of the plane $\pi(x,\gamma)$ is an affine function on $\mathbb{R}^2$, implies that

$$x_3\text{-coordinate of the plane } \pi(x,\gamma) \text{ at } a_4 \;=\; f(a_1) + f(a_3) - f(a_2).$$

The definition of this map is illustrated on the right hand side of the figure below. Note that $\psi(x,\gamma)=0$ if and only if the plane $\pi(x,\gamma)$ is horizontal.

(3) We set $B := \{(x,\gamma)\in D\times S^1 \,|\, \psi(x,\gamma)=0\}$.

Remark. The Wobbly Table Theorem 125.1 implies that given any $x\in D$ there exist at least four $\gamma\in S^1$ with $(x,\gamma)\in A$. In particular the set A is more complicated than in our subsequent illustrations.

We make the following elementary observation.

Observation 125.3. To prove the Table Theorem 125.2 it suffices to show that $A\cap B\neq\varnothing$.

In the following two lemmas we collect some properties of the two maps ϕ and ψ.

Lemma 125.4. The map $\phi\colon D\times S^1\to\mathbb{R}$ has the following properties:

(1) The map $\phi\colon D\times S^1\to\mathbb{R}$ is continuous.
(2) For any $(x,\gamma)\in D\times S^1$ we have $\phi(x,i\cdot\gamma)=-\phi(x,\gamma)$.
(3) Given $(x,\gamma)\in D\times S^1$ the following statements are equivalent:
  (a) $\phi(x,\gamma)=0$,
  (b) $\phi(x,i\cdot\gamma)=0$,
  (c) (x,γ) lies in A,
  (d) the corresponding points Q_1,Q_2,Q_3,Q_4 lie on a plane.

Proof.

(1) As we pointed out above, we have

$$\phi(x,\gamma) \;=\; f(\underbrace{a_1(x,\gamma)}_{\text{odd vertex}}) + f(\underbrace{a_3(x,\gamma)}_{\text{odd vertex}}) - f(\underbrace{a_2(x,\gamma)}_{\text{even vertex}}) - f(\underbrace{a_4(x,\gamma)}_{\text{even vertex}}).$$

It follows from the continuity of f and the continuity of $(x,\gamma)\mapsto a_i(x,\gamma)$ that ϕ is indeed continuous.

(2) Note that for any $(x,y)\in D\times S^1$ and any $j\in\{1,2,3,4\}$ we have the equality $a_j(x,i\cdot\gamma)=a_{j+1}(x,\gamma)$. In particular the odd/even vertices corresponding to $(x,i\cdot\gamma)$ are precisely the even/odd vertices corresponding to (x,γ). It follows immediately from this observation and the explicit formula for ϕ given in (1) that the equality $\phi(x,i\cdot\gamma)=-\phi(x,\gamma)$ holds.

(3) This statement follows immediately from (2) and the definition of A. ∎

Next we turn to the study of the map $\psi\colon D \times S^1 \to \mathbb{R}^2$. In the formulation of the next lemma we need the following definition.

Definition. We say that $v, w \in \mathbb{R}^2$ are parallel if one of v, w is zero or if there exists an $\lambda \in \mathbb{R}_{>0}$ such that $v = \lambda w$.

Lemma 125.5. The map $\psi\colon D \times S^1 \to \mathbb{R}^2$ has the following properties:

(1) The map $\psi\colon D \times S^1 \to \mathbb{R}$ is continuous.
(2) If $(x, \gamma) \in A$, then $\psi(x, \gamma) = \psi(x, i^k \cdot \gamma)$ for any $k \in \mathbb{Z}$.
(3) Let $x \in \partial D$ and let $\gamma \in S^1$. If $(x, \gamma) \in A$, then the vector $\psi(x, \gamma)$ is not parallel to $-x$.

Sketch of proof.

(1) Let $(x, \gamma) \in D \times S^1$. Basic linear algebra shows that

$$\psi(x,\gamma) = \begin{array}{l}\text{the vector in } \mathbb{R}^3 \text{ that is obtained as follows:}\\ (1)\ \text{perform the cross product } (Q_3(x,\gamma)-Q_2(x,\gamma))\times(Q_1(x,\gamma)-Q_2(x,\gamma))\\ (2)\ \text{normalize the vector from (1) to length one}^{1517}\\ (3)\ \text{project the vector from (2) onto the } xy\text{-plane.}\end{array}$$

It follows immediately from this observation that ψ is continuous.
