Introduction 84

Part I. General Topology 85
0. Preliminaries 86
1. Topological spaces: basic definitions and properties 107
2. Continuity 141
3. Categories, functors and natural transformations 194
4. Products and Coproducts – Limits and colimits 211
5. Constructions of topological spaces 224
6. Topology of metric spaces 283
7. Graphs 307
8. Urysohn's Lemma and the Tietze Extension Theorem 326
9. Second-countable topological spaces and the Urysohn Metrization Theorem 337
10. Paracompact spaces and partitions of unity 354
11. The covering dimension of topological spaces 369
12. The compact-open topology 392
13. Mixing product and quotient topologies 404

Part II. Basics of homotopy theory 417
14. Homotopies 418
15. Homotopy equivalences and homotopy equivalent topological spaces 430
16. Joins, mapping cones, cylinders and tori 446
17. Cofibrations 477

Part III. Topological and smooth manifolds 509
18. Topological manifolds 511
19. Smooth manifolds 531
20. Smooth manifolds with corner 579
21. Partitions of unity on manifolds 586
22. 1-dimensional manifolds and the long line 600
23. Tangent spaces of smooth manifolds 620
24. The Inverse Mapping Theorem and the Smooth Embedding Theorem 645
25. Orientations of smooth manifolds 668
26. The Regular Value Theorem 701
27. The Euclidean Embedding Theorem 718
28. The Neighborhood Projection Theorem and Smooth Collar Neighborhoods 732
29. The Whitney Approximation Theorem 749
30. Subsets of measure zero 762

31. Sard's Theorem 777
32. Complex manifolds 789

Part IV. Differential topology 809
33. Smooth homotopies 811
34. Classification of certain diffeomorphisms up to diffeotopy 830
35. The Flow Theorem 844
36. The Isotopy Extension Theorem 861
37. Orientation-preserving and orientation-reversing loops 880
38. The degree of a map between oriented smooth manifolds I 898
39. Degrees for smooth manifolds with boundary and the Borsuk-Ulam Theorem 924
40. Applications of the Borsuk-Ulam Theorem 937
41. Regular homotopies and the Whitney-Graustein Theorem 952
42. The transversality theorem 967
43. The algebraic intersection number 988
44. Linking numbers 1007
45. The smooth Euler characteristic and the Smooth Poincaré-Hopf Theorem 1017

Part V. Fundamental Groups 1043
46. How can we show that two topological spaces are (not) homeomorphic? 1044
47. The fundamental group 1048
48. Fundamental groups and coverings 1067
49. Coverings of smooth and topological manifolds 1103
50. Homotopies and fundamental groups 1123
51. Basics of group theory 1147
52. The basic Seifert–van Kampen Theorem 1168
53. Presentations of groups and amalgamated products 1191
54. The general Seifert–van Kampen Theorem 1217
55. The classification of compact 2-dimensional manifolds I 1233
56. Limits 1256
57. The HNN-Seifert–van Kampen Theorem 1290
58. Introduction to knot theory 1301
59. An excursion into knot theory 1308
60. Decision problems 1346

Part VI. The universal covering 1351
61. The existence of universal coverings 1352
62. The deck transformation group 1383
63. Topics in covering theory 1399

64. Coverings of topological graphs and applications to group theory 1409
65. Hyperbolic geometry 1426
66. The universal covering of surfaces 1439
67. Related constructions in algebraic geometry and Galois theory 1463

Part VII. CW-complexes 1467
68. CW-complexes I: Definitions, basic properties and constructions 1468
69. CW-complexes II: Fundamental groups 1515
70. CW-complexes III: Advanced properties 1535

Part VIII. Singular Homology 1559
71. Higher homotopy groups: a primer 1560
72. The homology groups of a topological space 1581
73. Homology and homotopies 1602
74. The Excision Theorem 1611
75. Applications and variations of the Excision Theorem 74.17 1655
76. Homology and self-maps of spheres 1674
77. The covering dimension of topological spaces II 1708
78. The Mayer–Vietoris sequence and its applications 1715
79. Homology groups and direct limits 1753
80. Cellular homology 1767
81. The Fundamental Theorem of Homological Algebra 1791
82. The Jordan-Brouwer Separation Theorem 1809
83. Topological robotics ❀ 1819
84. The Hurewicz Theorem in dimension one 1831
85. The Hurewicz Theorem in higher dimensions 1842
86. Applications of the Hurewicz Theorem 1863
87. The Euler characteristic 1879
88. Applications of the Euler characteristic (∗) 1893
89. Homology with coefficients 1907
90. The Künneth Theorem 1940
91. Applications of homology groups 1951
92. Division algebras and generalized projective spaces 1959

Part IX. Simplicial Complexes 1977
93. Simplicial complexes: Definition, examples and basic properties 1978
94. The Simplicial Approximation Theorem 2014
95. Simplicial homology 2035
96. Simplicial and PL-structures on manifolds 2081

97. The Lefschetz Fixed Point Theorem 2113
98. Homology groups of pseudomanifolds and smooth manifolds 2135
99. Simplicial cohomology 2171
100. The fundamental class of smooth manifolds 2193
101. The degree of a map between oriented smooth manifolds II 2222
102. Homology classes and smooth (sub-)manifolds 2234
103. The Simplicial Poincaré Duality Theorem 2261

Part X. Homology groups of topological manifolds 2289
104. Borsuk's Theorem, ENRs and ANRs 2290
105. Orientations of topological manifolds 2322
106. The fundamental class of topological manifolds 2349

Part XI. Singular Cohomology 2385
107. Chirality 2386
108. The cohomology groups of a topological space 2394
109. Properties of cohomology groups 2418
110. The Universal Coefficient Theorems for Cohomology Groups 2436
111. Cohomology groups and limits 2462
112. Cohomology with compact support and bounded cohomology 2478
113. The Eilenberg-Zilber theorem and the cross product 2491
114. The cup product 2512
115. The relative cup product 2534
116. The cap product 2551
117. The Product Theorem and the Künneth Theorem for cohomology 2565
118. The relationship between de Rham cohomology and singular cohomology 2590

Part XII. Poincaré Duality 2617
119. The Topological Poincaré Duality Theorem 2618
120. Poincaré Duality and codimension-zero submanifolds 2648

Part XIII. Applications of Poincaré Duality 2655
121. The cup product of projective spaces 2656
122. The Hopf invariant 2676
123. Regular neighborhoods and the Basic Alexander Duality Theorem 2695
124. The Generalized Alexander Duality Theorem 2710
125. Applications of cohomology groups 2730
126. The cup product and algebraic intersection numbers 2747
127. Intersections of cycles and the cup product 2775

128. The Lefschetz-Hopf Theorem 2799
129. The Poincaré-Hopf Theorem 2818
130. Homology, cohomology and submanifolds 2833
131. Applications to knot theory 2853
132. The intersection form I: Definition and calculations 2877
133. The intersection form II: Algebra and some topology 2906
134. The Intersection Form III: The Novikov Additivity Theorem 2926
135. The intersection form IV: 4-dimensional manifolds 2939

Part XIV. Handle Structures and Morse Theory 2949
136. Handle decompositions of smooth manifolds 2950
137. Morse functions 2973
138. Morse theory I: Closed smooth manifolds 2988
139. Morse theory II: The Relative Handle Decomposition Theorem 3001
140. Handle homology and the Morse inequalities 3011
141. Constructing smooth manifolds using handles 3030
142. The classification of compact 2-dimensional smooth manifolds II 3044

Part XV. Bundles 3057
143. Vector Bundles 3058
144. Cobordisms 3088
145. Pontryagin classes and the Hirzebruch Signature Theorem 3102

Part XVI. 3-dimensional Manifolds 3113
146. Handlebodies and Heegaard splittings of 3-dimensional smooth manifolds 3114
147. Surgeries on 3-dimensional smooth manifolds 3131
148. The linking pairing on rational homology spheres 3143
149. Branched coverings and chiral knots 3173
150. The cobordism groups of rational homology spheres 3188

Part XVII. Steenrod operations 3199
151. Steenrod Operations 3200
152. The Adem relations 3223

Part XVIII. Homotopy Theory and Eilenberg-Maclane Spaces 3237
153. Relative homotopy groups 3238
154. Fibrations 3263
155. Fiber bundles 3298
156. Homotopy groups of Lie groups 3316

157. Thom-Pontryagin Theory I: The basics 3341
158. Thom-Pontryagin Theory II: The Freudenthal Suspension Theorem 3365
159. Thom-Pontryagin Theory III: The groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ and $\Omega_2^{\mathrm{fr}}(\mathbb{R}^{n+2})$ 3382
160. Summary of homotopy groups of spheres 3392
161. The CW-Approximation Theorem 3396
162. The Whitehead Theorem 3408
163. Eilenberg-Maclane Spaces 3426
164. Invariants obtained through Eilenberg-Maclane spaces 3465

Part XIX. (Co-) homology with twisted and local coefficients 3497
165. Modules over rings 3499
166. Homological algebra over rings 3518
167. Twisted (co-) homology 3532
168. Calculations and examples of twisted (co-) homology 3555
169. Universally excisive triads and Mayer-Vietoris sequences 3571
170. Twisted cellular (co-) homology 3582
171. The cup and cap-product on twisted (co-) homology 3600
172. Poincaré Duality with twisted coefficients 3611
173. Twisted intersection pairings 3631
174. Local coefficients 3643
175. (Co-) homology with local coefficients 3655

Bibliography 43
Introduction 84

Part I. General Topology 85
0. Preliminaries 86
0.1. Basic set theory 86
0.2. Relations and equivalence relations on sets 89
0.3. Orders on sets 91
0.4. The cardinality of sets 94
0.5. Conventions for (linear) algebra 98
0.6. The Cauchy-Schwarz Inequality 99
0.7. Normed vector spaces 101
0.8. Metric spaces 103
Exercises for Chapter 0 104
1. Topological spaces: basic definitions and properties 107
1.1. Topological spaces 107
1.2. Basic definitions 110
1.3. The subspace topology 112
1.4. Covers of topological spaces 114
1.5. The interior and the closure of a subset 116
1.6. The Hausdorff property 121
1.7. Convergence of sequences 124
1.8. Compact topological spaces 125
1.9. Bases of a topology 131
Exercises for Chapter 1 136
2. Continuity 141
2.1. Continuous maps 141
2.2. The Compact-Image Lemma 149
2.3. Homeomorphisms 151
2.4. Convex subsets 157
2.5. The two notions of connected spaces 161

2.6. The (path-) components of a topological space . . . 166
2.7. The (path-) components of matrix groups . . . 171
2.8. Local and regional properties . . . 175
2.9. Proper maps and closed embeddings . . . 180
Exercises for Chapter 2 . . . 182
3. Categories, functors and natural transformations . . . 194
3.1. Definition and examples of categories . . . 194
3.2. Functors . . . 199
3.3. Natural transformations . . . 203
3.4. Equivalence of categories . . . 207
Exercises for Chapter 3 . . . 208
4. Products and Coproducts – Limits and colimits . . . 211
4.1. Products . . . 211
4.2. Coproducts . . . 213
4.3. Limits . . . 216
4.4. Colimits . . . 219
Exercises for Chapter 4 . . . 221
5. Constructions of topological spaces . . . 224
5.1. The product of topological spaces . . . 224
5.2. Properties of products of topological spaces I . . . 229
5.3. Properties of products of topological spaces II . . . 233
5.4. The disjoint union of topological spaces . . . 236
5.5. Quotients of topological spaces . . . 240
5.6. Group actions on topological spaces . . . 248
5.7. Projective spaces . . . 255
5.8. The pushout in the topological category . . . 258
5.9. Surfaces . . . 263
5.10. Topological groups . . . 267
5.11. Continuity of zeros . . . 268
Exercises for Chapter 5 . . . 271
6. Topology of metric spaces . . . 283
6.1. Distance in metric spaces . . . 283
6.2. The Lebesgue Lemma . . . 285
6.3. Uniformly continuous maps . . . 287
6.4. Complete metric spaces . . . 288
6.5. Space-filling curves . . . 292
6.6. The Baire Category Theorem . . . 295
6.7. Baire spaces and completely metrizable spaces . . . 299

6.8. Application of the Baire Category Theorem 6.16 to sequences of maps 300
Exercises for Chapter 6 303
7. Graphs 307
7.1. Abstract graphs and topological graphs 307
7.2. Undirected abstract graphs and their topological realizations 312
7.3. Trees 315
7.4. Topological valence 319
7.5. Quotients of abstract graphs 321
Exercises for Chapter 7 322
8. Urysohn's Lemma and the Tietze Extension Theorem 326
8.1. Normal topological spaces 326
8.2. Urysohn's Lemma 328
8.3. The Tietze Extension Theorem 331
Exercises for Chapter 8 334
9. Second-countable topological spaces and the Urysohn Metrization Theorem 337
9.1. Second-countable topological spaces 337
9.2. The Urysohn Metrization Theorem 339
9.3. Regular topological spaces 343
9.4. Separation Axioms 346
Exercises for Chapter 9 350
10. Paracompact spaces and partitions of unity 354
10.1. Paracompact spaces 354
10.2. Partitions of unity 360
10.3. The Neighborhood Embedding Theorem 363
Exercises for Chapter 10 367
11. The covering dimension of topological spaces 369
11.1. The definition of the covering dimension of a topological space 369
11.2. Basic properties of the covering dimension 372
11.3. The Covering Dimension Refinement Theorem 379
11.4. The Euclidean Embedding Theorem for Topological Spaces 381
Exercises for Chapter 11 389
12. The compact-open topology 392
Exercises for Chapter 12 402
13. Mixing product and quotient topologies 404
13.1. Mixing product and quotient topologies: a disturbing example 404
13.2. Whitehead's Quotient Theorem 407
13.3. Proof of the Whitehead Quotient Theorem 13.4 410
13.4. Mixing product and quotient topologies II (∗) 413

Part II. Basics of homotopy theory 417
14. Homotopies 418
14.1. Homotopic maps 418
14.2. Homotopies on quotients and pushouts 424
Exercises for Chapter 14 427
15. Homotopy equivalences and homotopy equivalent topological spaces 430
15.1. Homotopy equivalent topological spaces 430
15.2. Deformation retractions 433
15.3. Homotopies and homotopy equivalences for pairs of topological spaces 439
15.4. The set of homotopy classes of maps between topological spaces 440
Exercises for Chapter 15 442
16. Joins, mapping cones, cylinders and tori 446
16.1. The join of two topological spaces 446
16.2. The cone and suspension of a topological space 449
16.3. Mapping cylinder and mapping cone 453
16.4. The mapping cone of a suspension 464
16.5. The mapping torus 467
Exercises for Chapter 16 474
17. Cofibrations 477
17.1. Cofibrations: definition and basic examples 477
17.2. Properties of cofibrations 482
17.3. "Real-life" Examples of cofibration 485
17.4. Products and cofibrations 488
17.5. Push-outs and cofibrations 494
17.6. Proof of Theorem 17.19 498
Exercises for Chapter 17 507

Part III. Topological and smooth manifolds 509
18. Topological manifolds 511
18.1. Topological manifolds: definition and examples 511
18.2. Surfaces are topological manifolds 517
18.3. Properties of topological manifolds 520
18.4. Submanifolds 524
Exercises for Chapter 18 528
19. Smooth manifolds 531
19.1. Smooth functions on subsets of $\mathbb{R}^n$ 531
19.2. Taylor's Theorem 534
19.3. The differential of a smooth map 535

19.4. Special topics in the theory of smooth functions 539
19.5. Smooth manifolds 541
19.6. Smooth maps between smooth manifolds 546
19.7. Submanifolds of smooth manifolds 549
19.8. Topological properties of smooth manifolds 554
19.9. The Smooth Path-Connectivity Proposition 558
19.10. Products of smooth manifolds I 560
19.11. Manifolds and group actions 562
19.12. Codimension-Zero submanifolds and decompositions of smooth manifolds 567
Exercises for Chapter 19 572
20. Smooth manifolds with corner 579
20.1. Definition of smooth manifolds with corner 579
20.2. Products of smooth manifolds II 583
Exercises for Chapter 20 585
21. Partitions of unity on manifolds 586
21.1. Existence on partitions of unity on manifolds 586
21.2. Proof of the Manifold-Partitions of Unity Existence Theorem 21.1 589
21.3. Paracompactness and second-countability 592
21.4. Smooth extensions and approximations 594
Exercises for Chapter 21 599
22. 1-dimensional manifolds and the long line 600
22.1. The classification of 1-dimensional topological manifolds 600
22.2. The classification of 1-dimensional smooth manifolds 608
22.3. Interlude: The order topology 609
22.4. The long line 611
22.5. Proof of Theorem 22.13 614
Exercises for Chapter 22 618
23. Tangent spaces of smooth manifolds 620
23.1. Tangent spaces of smooth submanifolds of $\mathbb{R}^k$ 620
23.2. Smooth manifolds and functors 626
23.3. Tangent spaces of smooth manifolds 627
23.4. The relationship between the definitions of tangent spaces 634
23.5. Alternative construction of tangent spaces 637
23.6. Vector fields 638
Exercises for Chapter 23 641
24. The Inverse Mapping Theorem and the Smooth Embedding Theorem 645
24.1. The Inverse Mapping Theorem 645
24.2. The Local Graph Lemma 649

24.3. Immersions and smooth embeddings 650
24.4. The Smooth Embedding Theorem 655
24.5. Immersions and smooth embeddings of smooth manifolds into $\mathbb{R}^n$ I 660
24.6. Immersions among smooth manifolds of the same dimension 663
Exercises for Chapter 24 664
25. Orientations of smooth manifolds 668
25.1. Orientations of real vector spaces I 668
25.2. Orientations of smooth manifolds 674
25.3. Orientations of submanifolds of $\mathbb{R}^n$ and unit normal fields 677
25.4. Orientation-preserving and reversing maps 682
25.5. Boundary orientation 688
25.6. Orientations and group actions 690
25.7. Products of smooth manifolds and orientations 693
Exercises for Chapter 25 696
26. The Regular Value Theorem 701
26.1. Regular values 701
26.2. The Fundamental Theorem of Algebra ❀ 704
26.3. The Regular Value Theorem 706
26.4. Matrix groups as smooth manifolds 711
Exercises for Chapter 26 715
27. The Euclidean Embedding Theorem 718
27.1. The statement of the Euclidean Embedding Theorem 718
27.2. Proof of the Euclidean Embedding Theorem 27.1 in the compact case 722
27.3. The covering dimension of topological manifolds 725
27.4. Proof of the Euclidean Embedding Theorem 27.1 in the non-compact case 727
Exercises for Chapter 27 729
28. The Neighborhood Projection Theorem and Smooth Collar Neighborhoods . . . 732
28.1. The Neighborhood Projection Theorem 732
28.2. Statement of the Smooth Collar Neighborhood Theorem 736
28.3. Proof of the Smooth Collar Neighborhood Theorem 28.3 742
Exercises for Chapter 28 747
29. The Whitney Approximation Theorem 749
29.1. The statement of the Whitney Approximation Theorem 749
29.2. Consequences of the Whitney Approximation Theorem 29.1 753
29.3. More consequences of the Whitney Approximation Theorem 29.1 756
Exercises for Chapter 29 760
30. Subsets of measure zero 762
30.1. Sets of measure zero and the Weak Whitney Embedding Theorem 762

30.2. Proof of Propositions 30.1, 30.2 and 30.3 764
30.3. The Weak Whitney Embedding Theorem 768
30.4. The Mini-Fubini Theorem 773
Exercises for Chapter 30 775
31. Sard's Theorem 777
31.1. Sard's Theorem 777
31.2. Applications of Sard's Theorem 782
31.3. The Brouwer Fixed Point Theorem I 784
Exercises for Chapter 31 787
32. Complex manifolds 789
32.1. Holomorphic functions 789
32.2. Biholomorphisms in the one-dimensional setting 794
32.3. Holomorphic maps in the higher-dimensional setting 796
32.4. Complex manifolds 797
32.5. The natural orientation of a complex manifold 803
Exercises for Chapter 32 805

Part IV. Differential topology 809
33. Smooth homotopies 811
33.1. Smooth homotopies 811
33.2. Smooth isotopies of (sub-) manifolds 817
33.3. Examples of smooth homotopies 818
33.4. Homogeneous topological spaces 821
33.5. The Flattening Lemma 826
Exercises for Chapter 33 827
34. Classification of certain diffeomorphisms up to diffeotopy 830
34.1. Diffeotopies and orientations 831
34.2. Diffeotopies of $\mathbb{R}^n$ and smooth embeddings of balls into $\mathbb{R}^n$ 833
34.3. Smooth homotopies and diffeotopies of S^1 836
Exercises for Chapter 34 841
35. The Flow Theorem 844
35.1. Statement of the Flow Theorem 844
35.2. Proof of the Flow Theorem 35.1 848
35.3. Proof of the Flow Fixed Point Theorem 35.4 854
35.4. Appendix I: Zeros of vector fields 855
35.5. Appendix II: Dealing with non-compact smooth manifolds 855
35.6. Moving points on smooth manifolds 858
Exercises for Chapter 35 858

36. The Isotopy Extension Theorem . . . 861
36.1. The statement of the Isotopy Extension Theorem . . . 861
36.2. Consequences of the Isotopy Extension Theorem 36.1 . . . 863
36.3. Proof of the Isotopy Extension Theorem 36.1 I: Preparations . . . 865
36.4. Proof of the Isotopy Extension Theorem 36.1 II: Closed smooth manifolds 870
36.5. Proof of the Isotopy Extension Theorem 36.1 III: The general case . . . 873
Exercises for Chapter 36 . . . 877
37. Orientation-preserving and orientation-reversing loops . . . 880
37.1. Orientation-preserving reversing and orientation-reversing loops . . . 880
37.2. Orientation flipping diffeotopies I . . . 885
37.3. The Smooth Ball Embedding Theorem . . . 888
37.4. The Lower-Dimensional Smooth Ball Embedding Theorem . . . 893
Exercises for Chapter 37 . . . 895
38. The degree of a map between oriented smooth manifolds I . . . 898
38.1. The definition of the degree of a map between closed smooth manifolds . . 898
38.2. Proof of Theorem 38.1, 38.3 and 38.4 . . . 900
38.3. Calculations of the degree . . . 905
38.4. Applications of the degree . . . 908
38.5. The Hopf Theorem . . . 910
38.6. Proof of the Hopf Degree Theorem 38.16 . . . 913
Exercises for Chapter 38 . . . 919
39. Degrees for smooth manifolds with boundary and the Borsuk-Ulam Theorem 924
39.1. Extension of degrees to smooth manifolds with boundary . . . 924
39.2. The Boundary Degree Proposition . . . 927
39.3. The Borsuk-Ulam Theorem . . . 929
Exercises for Chapter 39 . . . 934
40. Applications of the Borsuk-Ulam Theorem . . . 937
40.1. The Ham-Sandwich Theorem . . . 937
40.2. The chromatic number of Kneser graphs . . . 941
40.3. The level of a commutative ring . . . 945
40.4. The Necklace Theorem . . . 947
Exercises for Chapter 40 . . . 950
41. Regular homotopies and the Whitney-Graustein Theorem . . . 952
41.1. Regular homotopies . . . 952
41.2. Proof of Proposition 41.3 . . . 958
41.3. Proof of the "if"-statement of the Whitney-Graustein Theorem 41.7 . . . 960
Exercises for Chapter 41 . . . 965
42. The transversality theorem . . . 967

42.1. The Transversal Intersection Theorem . . . 967
42.2. The Transversal Preimage Theorem . . . 971
42.3. The Transversality Theorem . . . 976
42.4. Proof of the Transversality Theorem 42.4 . . . 978
42.5. Proof of the Transversality Theorem 42.5 . . . 980
Exercises for Chapter 42 . . . 985
43. The algebraic intersection number . . . 988
43.1. The Algebraic intersection number between a submanifold and a map . . . 988
43.2. The Intersection Number Homotopy Invariance Theorem . . . 992
43.3. The $\mathbb{Z}_2$-algebraic intersection number . . . 996
43.4. The Smooth Jordan-Brouwer Separation Theorem . . . 998
Exercises for Chapter 43 . . . 1003
44. Linking numbers . . . 1007
Exercises for Chapter 44 . . . 1015
45. The smooth Euler characteristic and the Smooth Poincaré-Hopf Theorem . . . 1017
45.1. The smooth Euler characteristic . . . 1017
45.2. Zeros of vector fields . . . 1020
45.3. The total tangent space and vector fields . . . 1024
45.4. The total tangent space and the diagonal . . . 1028
45.5. The Smooth Poincaré–Hopf Theorem . . . 1031
45.6. Applications of the Smooth Poincaré–Hopf Theorem 45.17 . . . 1033
45.7. The Gauß map I . . . 1036
Exercises for Chapter 45 . . . 1039

Part V. Fundamental Groups . . . 1043
46. How can we show that two topological spaces are (not) homeomorphic? . . . 1044
47. The fundamental group . . . 1048
47.1. Path-homotopy classes of paths . . . 1048
47.2. The fundamental group of a pointed topological space . . . 1054
47.3. The fundamental group as functor . . . 1060
Exercises for Chapter 47 . . . 1065
48. Fundamental groups and coverings . . . 1067
48.1. Coverings of topological spaces . . . 1067
48.2. Group actions and covering spaces . . . 1073
48.3. Lifting of paths . . . 1078
48.4. Lifting of path-homotopies . . . 1080
48.5. Group actions and fundamental groups . . . 1085
48.6. The fundamental group of the product of two topological spaces . . . 1091

48.7. The Fundamental Theorem of Algebra and the Borsuk-Ulam Theorem ❀1094
Exercises for Chapter 48 . . . 1096
49. Coverings of smooth and topological manifolds . . . 1103
49.1. Fundamental groups of topological manifolds . . . 1103
49.2. Manifold structures on coverings of manifolds . . . 1104
49.3. The orientation covering of a non-orientable smooth manifold . . . 1108
49.4. The orientation character . . . 1112
49.5. Orientation flipping diffeotopies II . . . 1118
Exercises for Chapter 49 . . . 1120
50. Homotopies and fundamental groups . . . 1123
50.1. Closed oriented curves and fundamental groups . . . 1123
50.2. The fundamental groups of homotopy equivalent topological spaces . . . 1124
50.3. The fundamental group of mapping tori . . . 1127
50.4. The boundary of 2-dimensional topological manifolds . . . 1129
50.5. The wedge of pointed topological spaces . . . 1132
50.6. Topological graphs . . . 1136
50.7. Homotopy classes of loops . . . 1141
Exercises for Chapter 50 . . . 1142
51. Basics of group theory . . . 1147
51.1. Free abelian groups and finitely generated abelian groups . . . 1147
51.2. The free product of groups . . . 1154
51.3. An alternative definition of the free product of groups . . . 1160
51.4. The Grushko-Neumann Theorem . . . 1162
Exercises for Chapter 51 . . . 1164
52. The basic Seifert–van Kampen Theorem . . . 1168
52.1. The formulation of the basic Seifert–van Kampen Theorem . . . 1168
52.2. Proof of the Seifert–van Kampen Theorem 52.2 . . . 1177
52.3. More examples: surfaces and the connected sum of smooth manifolds . . . 1182
Exercises for Chapter 52 . . . 1187
53. Presentations of groups and amalgamated products . . . 1191
53.1. Basic definitions in group theory . . . 1191
53.2. Presentations of groups . . . 1192
53.3. Tietze transformations . . . 1196
53.4. The Andrews-Curtis Conjecture . . . 1202
53.5. The abelianization of a group . . . 1203
53.6. The amalgamated product of groups I . . . 1207
53.7. The amalgamated product of groups II . . . 1212
Exercises for Chapter 53 . . . 1214

54. The general Seifert–van Kampen Theorem 1217
54.1. The formulation of the general Seifert–van Kampen Theorem 1217
54.2. The fundamental groups of surfaces 1220
54.3. Non-orientable surfaces 1226
54.4. Fundamental groups of high-dimensional smooth manifolds 1227
Exercises for Chapter 54 1230
55. The classification of compact 2-dimensional manifolds I 1233
55.1. Surfaces with boundary 1233
55.2. The Surface Classification Theorem 1236
55.3. Non-compact 2-dimensional smooth manifolds 1240
55.4. Retractions onto boundary components of 2-dimensional smooth manifolds 1241
55.5. Curves on surfaces 1246
Exercises for Chapter 55 1251
56. Limits 1256
56.1. Preordered and directed sets 1256
56.2. The direct limit of a direct system 1257
56.3. The direct limit in the topological category 1262
56.4. Fundamental groups and direct limits 1264
56.5. The surface of "infinite genus" 1269
56.6. The inverse limit of an inverse system 1273
56.7. The profinite completion of a group 1283
Exercises for Chapter 56 1284
57. The HNN-Seifert–van Kampen Theorem 1290
Exercises for Chapter 57 1299
58. Introduction to knot theory 1301
59. An excursion into knot theory 1308
59.1. One more avatar of spheres 1308
59.2. The fundamental group of the complement of the trefoil 1311
59.3. The mirror image of a knot 1315
59.4. The connected sum of oriented submanifolds and knots 1317
59.5. Knot diagrams 1321
59.6. The Wirtinger presentation 1328
59.7. The Reidemeister-Schreier process 1335
59.8. High-dimensional knots 1337
Exercises for Chapter 59 1340
60. Decision problems 1346
Exercises for Chapter 60 1349

Part VI. The universal covering 1351
61. The existence of universal coverings 1352
61.1. Local properties of topological spaces 1352
61.2. Lifting maps to coverings 1353
61.3. Semi-locally simply connected spaces 1357
61.4. Existence of covering spaces 1358
61.5. Proof of the Covering Existence Theorem 61.5 1360
61.6. Uniqueness of covering spaces 1368
61.7. The universal covering 1371
Exercises for Chapter 61 1377
62. The deck transformation group 1383
Exercises for Chapter 62 1397
63. Topics in covering theory 1399
63.1. Self-diffeomorphisms of S^1 1399
63.2. Complex one-dimensional tori 1400
63.3. Complex logarithms 1401
63.4. Preimages of subsets under coverings 1402
63.5. Covering spaces of surfaces 1405
Exercise for Chapter 63 1407
64. Coverings of topological graphs and applications to group theory 1409
64.1. Coverings of topological graphs 1409
64.2. Fundamental group of countable topological graphs 1410
64.3. Subgroups of free groups 1411
64.4. Subgroups of surface groups 1413
64.5. Residually finite groups and Hopfian groups 1415
Exercises for Chapter 64 1423
65. Hyperbolic geometry 1426
65.1. Hyperbolic space 1426
65.2. Angles in Riemannian manifolds 1432
65.3. The distance metric of a Riemannian manifold 1434
65.4. The hyperbolic distance function 1436
Exercises for Chapter 65 1438
66. The universal covering of surfaces 1439
66.1. Hyperbolic surfaces 1439
66.2. More hyperbolic structures on the surfaces of genus $g \geq 2$p 1443
66.3. More examples of hyperbolic surfaces 1444
66.4. The universal covering of surfaces 1448
66.5. Proof of Theorem 66.9 I 1449

66.6. Proof of Theorem 66.9 II 1452
66.7. Fundamental groups of surfaces 1456
66.8. Picard's Theorem ❀ 1457
66.9. Triangle groups 1459
Exercises for Chapter 66 1461
67. Related constructions in algebraic geometry and Galois theory 1463
67.1. The fundamental group of an algebraic variety 1463
67.2. Galois theory 1465

Part VII. CW-complexes 1467
68. CW-complexes I: Definitions, basic properties and constructions 1468
68.1. Definition of finite-dimensional CW-complexes and examples 1468
68.2. Two topologies on $\mathbb{R}^\infty$ 1474
68.3. Infinite-dimensional CW-complexes 1478
68.4. Homotopies on infinite CW-complexes 1482
68.5. Properties of CW-complexes 1484
68.6. The Finiteness Theorem for CW-complexes 1490
68.7. Cellular maps 1492
68.8. Subcomplexes 1493
68.9. Products of CW-complexes I 1497
68.10. Products of CW-complexes II 1499
68.11. A convenient category of topological spaces 1501
68.12. Constructions of more CW-complexes 1506
68.13. Coverings of CW-complexes 1510
Exercises for Chapter 68 1512
69. CW-complexes II: Fundamental groups 1515
69.1. Fundamental groups of CW-complexes 1515
69.2. The Euler characteristic of a CW-complex 1519
69.3. The fundamental group of 1-dimensional CW-complexes 1520
69.4. Fundamental groups of CW-complexes 1527
Exercises for Chapter 69 1534
70. CW-complexes III: Advanced properties 1535
70.1. The Homotopy Extension Theorem 1535
70.2. Proof of the Homotopy Extension Theorem 70.1 1539
70.3. Dropping base points 1542
70.4. Combining infinitely many homotopies and the telescope construction 1545
70.5. The Cellular Approximation Theorem 1548
70.6. Proof of Proposition 70.17 (∗) 1552

Exercises for Chapter 70 1556

Part VIII. Singular Homology 1559
71. Higher homotopy groups: a primer 1560
71.1. Definition of the higher homotopy groups 1560
71.2. Alternative descriptions of homotopy groups 1564
71.3. Properties and basic calculations of higher homotopy groups 1567
71.4. Covering spaces and higher homotopy groups 1572
71.5. Are there any higher homotopy groups that are non-trivial? 1576
Exercises for Chapter 71 1578
72. The homology groups of a topological space 1581
72.1. Singular chains 1581
72.2. Definition of the homology groups of a topological space 1584
72.3. First calculations of homology groups 1589
72.4. Algebraic chain complexes 1591
72.5. The functoriality of homology groups 1593
72.6. Direct products and direct sums (∗) 1595
72.7. The homology groups of a direct sum 1596
Exercises for Chapter 72 1598
73. Homology and homotopies 1602
73.1. Chain homotopies 1602
73.2. Homology and homotopic maps 1604
Exercises for Chapter 73 1610
74. The Excision Theorem 1611
74.1. Reduced homology groups 1611
74.2. Long exact sequences 1613
74.3. The homology groups of spheres 1616
74.4. The Brouwer Fixed Point Theorem II 1617
74.5. Basic homological algebra 1619
74.6. Relative homology groups 1624
74.7. The Excision Theorem 1632
74.8. The proof of the Excision Theorem 74.17: the idea 1637
74.9. The proof of the Excision Theorem 74.17: the full details 1637
74.10. Excision for CW-complexes 1649
Exercises for Chapter 74 1649
75. Applications and variations of the Excision Theorem 74.17 1655
75.1. The local homology groups of a topological space 1655
75.2. The topology of topological manifolds 1656

75.3. The Topological Collar Neighborhood Theorem 1659
75.4. Variations on the Excision Theorem 74.17 1664
75.5. The double of topological and smooth manifolds 1667
Exercises for Chapter 75 1671
76. Homology and self-maps of spheres 1674
76.1. Explicit generators of relative homology groups 1674
76.2. The standard generator of $\mathrm{H}_n(S^n)$ 1677
76.3. Suspensions and homology groups 1681
76.4. The degree of a self-map of a sphere 1684
76.5. The local degree I 1690
76.6. The local degree II 1693
76.7. Proof of the Standard Generator-Relationship Proposition 76.5 1700
Exercises for Chapter 76 1703
77. The covering dimension of topological spaces II 1708
Exercises for Chapter 77 1714
78. The Mayer–Vietoris sequence and its applications 1715
78.1. Split exact sequences 1715
78.2. The Mayer–Vietoris sequence 1718
78.3. Applications of the Mayer–Vietoris sequence 1722
78.4. The Mayer–Vietoris Theorem for manifolds and CW-complexes 1725
78.5. The homology groups of the torus and the Klein bottle 1728
78.6. The first homology group of a knot complement 1732
78.7. The homology groups of a mapping cone $(*)$ 1735
78.8. The homology groups of a mapping torus $(*)$ 1741
Exercises for Chapter 78 1746
79. Homology groups and direct limits 1753
79.1. Direct limits and induced maps 1753
79.2. The homology groups of a nested sequence of topological spaces 1754
79.3. The homology groups of the wedge of topological spaces 1757
79.4. Moore spaces 1761
Exercises for Chapter 79 1765
80. Cellular homology 1767
80.1. The definition of cellular homology 1767
80.2. The relationship between cellular and singular homology 1771
80.3. The cellular boundary maps 1776
80.4. The homology groups of 2-dimensional smooth manifolds 1782
80.5. The homology groups of real projective spaces 1785
Exercises for Chapter 80 1787

81. The Fundamental Theorem of Homological Algebra 1791
81.1. The Fundamental Theorem of Homological Algebra 1791
81.2. Quasi-isomorphisms are chain homotopy equivalences 1794
81.3. Proof of Propositions 81.4 and 81.5 1796
81.4. Singular and cellular chain complexes 1800
81.5. Abstractly isomorphic homology groups 1805
Exercises for Chapter 81 1808
82. The Jordan-Brouwer Separation Theorem 1809
Exercises for Chapter 82 1817
83. Topological robotics ❀ 1819
83.1. The matrix groups SO(3) and SU(2) 1819
83.2. The belt trick ❀ 1823
83.3. The plate trick ❀ 1825
83.4. Topological robotics ❀ 1826
83.5. Linkages ❀ 1828
Exercises for Chapter 83 1830
84. The Hurewicz Theorem in dimension one 1831
Exercises for Chapter 84 1840
85. The Hurewicz Theorem in higher dimensions 1842
85.1. The Hurewicz homomorphism in higher dimensions 1842
85.2. The group structure on $\pi_n(X, x_0)$ 1847
85.3. The proof of the Hurewicz Theorem 85.5 1851
Exercises for Chapter 85 1861
86. Applications of the Hurewicz Theorem 1863
86.1. The social choice problem ❀ 1863
86.2. The degree of a self-map of a sphere II 1868
86.3. Paths acting on homotopy groups 1868
86.4. Group rings 1872
86.5. Homotopy groups of $S^1 \vee S^2$ 1874
Exercises for Chapter 86 1877
87. The Euler characteristic 1879
87.1. The Euler characteristic and homology groups 1879
87.2. Properties of the Euler characteristic 1883
87.3. Groups acting on spheres and surfaces 1887
87.4. Topological graphs $(*)$ 1888
Exercises for Chapter 87 1889
88. Applications of the Euler characteristic $(*)$ 1893
88.1. Building a leather football ❀ 1893

88.2. Platonic solids ❀ 1894
88.3. Planar graphs ❀ 1900
Exercises for Chapter 88 1905
89. Homology with coefficients 1907
89.1. The tensor product of abelian groups 1907
89.2. The homology groups of a topological space with coefficients 1912
89.3. Exact functors 1917
89.4. The G-torsion of an abelian group 1920
89.5. The Universal Coefficient Theorem 1927
89.6. Splittings of the Universal Coefficient Theorem 1932
89.7. The Eilenberg-Steenrod axioms for homology $(*)$ 1935
Exercises for Chapter 89 1937
90. The Künneth Theorem 1940
90.1. The tensor product of chain complexes 1940
90.2. The Eilenberg-Zilber Theorem 1941
90.3. The Künneth Theorem for chain complexes 1944
90.4. The Künneth Theorem for topological spaces 1947
Exercises for Chapter 90 1949
91. Applications of homology groups 1951
91.1. Persistent homology ❀ 1951
91.2. The transfer map 1952
91.3. The Borsuk-Ulam Theorem 1956
92. Division algebras and generalized projective spaces 1959
92.1. Division algebras 1959
92.2. Commutative division algebras 1967
92.3. Quaternionic and octonionic projective spaces 1970
Exercises for Chapter 92 1975

Part IX. Simplicial Complexes 1977
93. Simplicial complexes: Definition, examples and basic properties 1978
93.1. Abstract simplicial complexes 1978
93.2. Ordered abstract simplicial complexes 1982
93.3. The topological realization of an abstract simplicial complex 1982
93.4. Simplicial complexes 1994
93.5. The product of (abstract) simplicial complexes 1998
93.6. The simplicial join of (abstract) simplicial complexes 2001
93.7. Linear simplicial complexes 2005
93.8. Simplicial structures and CW-structures I 2007

Exercises for Chapter 93 . . . 2012
94. The Simplicial Approximation Theorem . . . 2014
94.1. The barycentric subdivision . . . 2014
94.2. Stars and links in simplicial complexes . . . 2018
94.3. The Simplicial Approximation Theorem . . . 2024
94.4. Mapping cylinders and mapping cones of simplicial maps . . . 2027
94.5. Simplicial structures and CW-structures II . . . 2029
Exercises for Chapter 94 . . . 2033
95. Simplicial homology . . . 2035
95.1. Simplicial homology of an ordered abstract simplicial complex . . . 2035
95.2. Simplicial homology . . . 2037
95.3. The Simplicial Künneth Theorem . . . 2046
95.4. The topological invariance of simplicial homology I . . . 2047
95.5. The topological invariance of simplicial homology II . . . 2052
95.6. Relative simplicial homology . . . 2059
95.7. The Nerve Theorem . . . 2061
95.8. The simplicial subdivision map . . . 2068
Exercises for Chapter 95 . . . 2076
96. Simplicial and PL-structures on manifolds . . . 2081
96.1. Simplicial structures on smooth manifolds . . . 2081
96.2. PL-manifolds . . . 2090
96.3. Regular Neighborhoods . . . 2095
96.4. The interplay between topological, smooth and PL-manifolds . . . 2098
96.5. Stellar subdivisions and the Alexander-Newman Theorem . . . 2101
96.6. Combinatorial manifolds and Pachner's Theorem . . . 2104
Exercises for Chapter 96 . . . 2111
97. The Lefschetz Fixed Point Theorem . . . 2113
97.1. The trace of an endomorphism . . . 2113
97.2. The Lefschetz number . . . 2115
97.3. The formulation of the Lefschetz Fixed Point Theorems . . . 2117
97.4. Proof of the Lefschetz Fixed Point Theorem 97.9 . . . 2118
97.5. Vector fields on smooth manifolds . . . 2123
97.6. The Borsuk-Ulam Theorem II ❀ . . . 2127
Exercises for Chapter 97 . . . 2132
98. Homology groups of pseudomanifolds and smooth manifolds . . . 2135
98.1. The top-dimensional homology group of a pseudomanifold . . . 2135
98.2. The top-dimensional homology group of a smooth manifold . . . 2151
98.3. Homology groups of lens spaces . . . 2158

98.4. The Poincaré Homology Sphere . . . 2159
98.5. The topology of smooth manifolds . . . 2163
Exercises for Chapter 98 . . . 2168
99. Simplicial cohomology . . . 2171
99.1. Simplicial chain complexes . . . 2171
99.2. The definition of the simplicial cohomology groups . . . 2173
99.3. Properties of simplicial cohomology groups . . . 2177
99.4. The simplicial cup product . . . 2180
99.5. The simplicial cap product . . . 2187
Exercises for Chapter 99 . . . 2191
100. The fundamental class of smooth manifolds . . . 2193
100.1. The definition of the fundamental class . . . 2193
100.2. Examples of fundamental classes . . . 2202
100.3. Properties of the fundamental class . . . 2204
100.4. The homology groups of the connected sum of two smooth manifolds . . . 2210
100.5. Homology groups of knot complements . . . 2213
100.6. The $\mathbb{F}_2$-fundamental class . . . 2215
Exercises for Chapter 100 . . . 2218
101. The degree of a map between oriented smooth manifolds II . . . 2222
101.1. The definition of the degree of a map between compact smooth manifolds . . . 2222
101.2. Properties of the degree . . . 2225
Exercises for Chapter 101 . . . 2231
102. Homology classes and smooth (sub-)manifolds . . . 2234
102.1. Realizing homology classes by smooth manifolds . . . 2234
102.2. Proof of the Realization-by-Surface Proposition 102.3 . . . 2237
102.3. Proof of Proposition 102.4 . . . 2242
102.4. Representing homology classes by submanifolds I . . . 2245
102.5. Rearranging maps from smooth manifolds . . . 2253
102.6. Proofs of Proposition 102.13 . . . 2254
102.7. The internal connected sum and the proof of Proposition 102.16 . . . 2257
Exercises for Chapter 102 . . . 2259
103. The Simplicial Poincaré Duality Theorem . . . 2261
103.1. Simplicial Homology Manifolds . . . 2261
103.2. The statement of the Simplicial Poincaré Duality Theorem . . . 2265
103.3. The barycentric subdivision . . . 2268
103.4. The dual chain complex I . . . 2271
103.5. The dual chain complex II . . . 2277
103.6. The proof of the Simplicial Poincaré Duality Theorem 103.4 . . . 2284

103.7. The dual CW-structure of a smooth manifold . . . 2285
Exercises for Chapter 103 . . . 2287

Part X. Homology groups of topological manifolds . . . 2289
104. Borsuk's Theorem, ENRs and ANRs . . . 2290
104.1. Neighborhood retracts . . . 2290
104.2. Proof of the Borsuk's Theorem 104.3 . . . 2295
104.3. Euclidean Neighborhood Retracts . . . 2299
104.4. Invariants of compact topological manifolds . . . 2304
104.5. ANRs and the homotopy type of topological manifolds . . . 2307
104.6. Topological manifolds and CW-structures . . . 2313
104.7. The Euler characteristic of compact topological manifolds . . . 2315
104.8. Microbundles . . . 2317
Exercises for Chapter 104 . . . 2319
105. Orientations of topological manifolds . . . 2322
105.1. Relative homology and convex subsets of $\mathbb{R}^n$ . . . 2322
105.2. The local homology of topological manifolds . . . 2324
105.3. R-Sections on topological manifolds . . . 2331
105.4. Orientations of topological manifolds . . . 2335
105.5. Induced orientations . . . 2342
Exercises for Chapter 105 . . . 2347
106. The fundamental class of topological manifolds . . . 2349
106.1. The fundamental class of an oriented topological manifold . . . 2349
106.2. Lifts of sections on topological manifolds . . . 2355
106.3. Proof of the Top-Homology Theorem 106.3 . . . 2361
106.4. Proof of Theorems 106.1 and 106.2 . . . 2364
106.5. Further properties of topological manifolds . . . 2366
106.6. The fundamental class and induced orientations . . . 2369
106.7. Lifts of homology orientations for topological manifolds with boundary (∗) . . . 2375
106.8. The degree of a map between oriented topological manifolds . . . 2378
106.9. Applications . . . 2380
Exercises for Chapter 106 . . . 2380

Part XI. Singular Cohomology . . . 2385
107. Chirality . . . 2386
107.1. Chiral objects . . . 2386
107.2. Chiral knots . . . 2386
107.3. Chiral topological manifolds . . . 2387

Exercises for Chapter 107 2393
108. The cohomology groups of a topological space 2394
108.1. The Hom-functor 2394
108.2. Cochain complexes 2396
108.3. Dual cochain complexes 2399
108.4. The singular cohomology groups of topological spaces 2402
108.5. Basic properties of cohomology groups 2408
108.6. Reduced cohomology groups 2413
108.7. Isomorphic homology groups implies isomorphic cohomology groups . . . 2414
Exercises for Chapter 108 2415
109. Properties of cohomology groups 2418
109.1. Excision theorems for cohomology groups 2418
109.2. Cellular cohomology 2420
109.3. Explicit generators of cohomology groups 2424
109.4. Excisive triads and the Mayer–Vietoris Theorem for cohomology groups 2428
Exercises for Chapter 109 2435
110. The Universal Coefficient Theorems for Cohomology Groups 2436
110.1. The Ext group 2436
110.2. The Universal Coefficient Theorem for Cohomology Groups 2444
110.3. Cohomology groups of topological manifolds 2450
110.4. Cohomology with field coefficients 2452
110.5. Proof of the Cohomology-Field Coefficients Proposition 110.18 (∗) 2454
110.6. Change of coefficients in cohomology 2456
Exercises for Chapter 110 2459
111. Cohomology groups and limits 2462
111.1. Direct limits of direct systems 2462
111.2. Inverse limits of inverse systems 2466
111.3. Cohomology groups and inverse limits 2468
111.4. The cohomology group of an ascending sequence of topological spaces . 2474
Exercises for Chapter 111 2477
112. Cohomology with compact support and bounded cohomology 2478
112.1. The definition of cohomology with compact support and basic properties 2478
112.2. Cohomology with compact support and direct limits 2482
112.3. Bounded cohomology (∗) 2486
Exercises for Chapter 112 2489
113. The Eilenberg-Zilber theorem and the cross product 2491
113.1. The Eilenberg-Zilber theorem 2491
113.2. Proof of the Eilenberg-Zilber Theorem 113.1 2492

113.3. The relative Eilenberg–Zilber map Υ 2497
113.4. The cross product on homology 2498
113.5. Product orientations of topological manifolds 2500
113.6. The shuffle product and the proof of Proposition 113.11 (∗) 2503
113.7. The Acyclic Model Theorems 2505
Exercises for Chapter 113 2511
114. The cup product 2512
114.1. A first definition of the cup product 2512
114.2. An alternative definition of the cup product 2513
114.3. The cup product of the torus 2524
114.4. The cup product of the surface of genus 2 2527
114.5. The cup product of the real projective plane (∗) 2529
Exercises for Chapter 114 2531
115. The relative cup product 2534
115.1. Definition of the relative cup product 2534
115.2. Calculations using the relative cup product 2539
115.3. The Lusternik-Schnirelmann category 2542
Exercises for Chapter 115 2549
116. The cap product 2551
116.1. The definition of the cap product and calculations 2551
116.2. The relative cap product and more properties of the cap product 2556
Exercises for Chapter 116 2563
117. The Product Theorem and the Künneth Theorem for cohomology 2565
117.1. The Product Theorem 2565
117.2. Proof of the Product Theorem 117.1 2570
117.3. The Künneth Theorem for cohomology groups 2579
117.4. The cohomology ring of product topological spaces 2583
Exercises for Chapter 117 2588
118. The relationship between de Rham cohomology and singular cohomology . . 2590
118.1. Smooth cohomology theories 2590
118.2. Isomorphisms between smooth cohomology theories 2592
118.3. Smooth singular cohomology 2596
118.4. The isomorphism between singular and de Rham cohomology 2603
118.5. Realizing cohomology classes by maps to S^1 2605
118.6. Rewriting products $M \times S^1$ 2610
118.7. The wedge product of differential forms (∗) 2613
Exercises for Chapter 118 2616

Part XII. Poincaré Duality 2617
119. The Topological Poincaré Duality Theorem 2618
119.1. The Poincaré Duality Theorem 2618
119.2. Consequences of the Poincaré Duality Theorem 119.1 2620
119.3. The proof of the Poincaré Duality Theorem 119.1 for topological manifolds without boundary 2627
119.4. The proof of Poincaré Duality for topological manifolds with boundary 2639
Exercises for Chapter 119 2644
120. Poincaré Duality and codimension-zero submanifolds 2648
120.1. Submanifolds with corner 2648
120.2. Poincaré Duality and codimension-zero submanifolds 2650
Exercises for Chapter 120 2653

Part XIII. Applications of Poincaré Duality 2655
121. The cup product of projective spaces 2656
121.1. Non-singular pairings and the cup product 2656
121.2. The cup product of $\mathbb{C}\mathrm{P}^n$ and applications 2660
121.3. The cup product of $\mathbb{R}\mathrm{P}^n$ and applications 2665
121.4. The cup product of quaternionic and octonionic projective spaces 2669
121.5. Division algebras 2670
Exercises for Chapter 121 2673
122. The Hopf invariant 2676
122.1. The Hopf map is not null-homotopic 2676
122.2. The Hopf invariant 2679
122.3. The Hopf invariant and multiplication maps 2686
Exercises for Chapter 122 2694
123. Regular neighborhoods and the Basic Alexander Duality Theorem 2695
123.1. Regular neighborhoods 2695
123.2. Spatial graphs 2698
123.3. The Basic Alexander Duality Theorem 2699
123.4. Immersions and smooth embeddings of smooth manifolds into $\mathbb{R}^n$ II ... 2705
Exercises for Chapter 123 2707
124. The Generalized Alexander Duality Theorem 2710
124.1. The generalized Alexander Duality Theorem 2710
124.2. Proof of the Generalized Alexander Duality Theorem 124.2 2715
124.3. Consequences of the Generalized Alexander Duality Theorem 124.2 2719
124.4. Generalized Alexander Duality Theorem for Homology Balls 2720
124.5. Wild arcs and wild knots 2724
Exercises for Chapter 124 2728

125. Applications of cohomology groups 2730
125.1. The Table Theorem ❀ 2730
125.2. The square-peg problem ❀ 2742
Exercises for Chapter 125 2745
126. The cup product and algebraic intersection numbers 2747
126.1. Algebraic intersection numbers of submanifolds 2747
126.2. The cup product and algebraic intersection numbers 2752
126.3. Proof of the Intersection Number-via-Cup Product Theorem 126.5 2757
126.4. Algebraic intersection numbers of complex submanifolds 2765
126.5. Applications to complex projective spaces 2766
126.6. Higher dimensional analogue of Theorem 126.5 2769
Exercises for Chapter 126 2771
127. Intersections of cycles and the cup product 2775
127.1. The algebraic intersection number of maps of topological manifolds 2775
127.2. Transverse intersection points of maps 2781
127.3. Intersections of cycles 2785
127.4. Proof of Theorem 127.9 2786
127.5. The algebraic $\mathbb{F}_2$-intersection number $(*)$ 2796
Exercises for Chapter 127 2798
128. The Lefschetz-Hopf Theorem 2799
128.1. The Lefschetz number as an intersection number 2799
128.2. The Lefschetz-Hopf Theorem I 2805
128.3. The Lefschetz-Hopf Theorem II 2809
Exercises for Chapter 128 2817
129. The Poincaré-Hopf Theorem 2818
129.1. The index of a zero of a vector field 2818
129.2. The Poincaré-Hopf Theorem 2823
129.3. The Gauß map II 2829
Exercises for Chapter 129 2831
130. Homology, cohomology and submanifolds 2833
130.1. Codimension one submanifolds 2833
130.2. Representing homology classes by submanifolds II 2836
130.3. The basic Thom-Pontryagin Theory 2839
130.4. Cyclic coverings of manifolds 2843
130.5. Curves on 2-dimensional smooth manifolds $(*)$ 2847
Exercises for Chapter 130 2849
131. Applications to knot theory 2853
131.1. The longitude of a knot 2853

131.2. Detecting non-invertible and chiral knots . . . 2856
131.3. Seifert surfaces . . . 2859
131.4. Linking numbers . . . 2862
131.5. Alexander duality and linking numbers (∗) . . . 2872
Exercises for Chapter 131 . . . 2874
132. The intersection form I: Definition and calculations . . . 2877
132.1. Pairings and forms . . . 2877
132.2. The definition of the intersection form of topological manifolds . . . 2880
132.3. Properties of the intersection form . . . 2882
132.4. The intersection form and degree-one maps . . . 2885
132.5. The connected sum of topological manifolds . . . 2886
132.6. The intersection form and the connected sum operation . . . 2890
132.7. The asymmetric intersection pairings . . . 2893
132.8. The reduced intersection form . . . 2901
Exercises for Chapter 132 . . . 2903
133. The intersection form II: Algebra and some topology . . . 2906
133.1. Non-singular anti-symmetric forms . . . 2907
133.2. Interlude: Sphere-packing . . . 2910
133.3. Non-singular symmetric forms over the real numbers . . . 2912
133.4. Non-singular symmetric forms over the integers . . . 2918
133.5. Forms over $\mathbb{F}_2$ . . . 2922
Exercises for Chapter 133 . . . 2924
134. The Intersection Form III: The Novikov Additivity Theorem . . . 2926
134.1. Statement of the Novikov Additivity Theorem . . . 2926
134.2. Proof of the Novikov Additivity Theorem I . . . 2927
134.3. Proof of the Novikov Additivity Theorem II . . . 2930
134.4. Proof of the Novikov Additivity Theorem III . . . 2936
Exercises for Chapter 134 . . . 2937
135. The intersection form IV: 4-dimensional manifolds . . . 2939
135.1. The K3-surface and Rokhlin's Theorem . . . 2939
135.2. The work of Michael Freedman and Simon Donaldson . . . 2942
Exercises for Chapter 135 . . . 2948

Part XIV. Handle Structures and Morse Theory . . . 2949
136. Handle decompositions of smooth manifolds . . . 2950
136.1. Handle attachments . . . 2950
136.2. Handle decompositions . . . 2954
136.3. Handle rearrangements . . . 2956

136.4. Dual handle decomposition . . . 2959
136.5. Handle attachments: Connectedness and orientability . . . 2962
136.6. Handle attachments: Algebraic invariants . . . 2964
136.7. Handle attachments: Invariants of the boundary . . . 2966
136.8. Handle decompositions and CW-structures . . . 2968
Exercises for Chapter 136 . . . 2970
137. Morse functions . . . 2973
137.1. Non-degenerate critical points . . . 2973
137.2. Existence of Morse functions . . . 2979
137.3. The gradient vector field . . . 2981
Exercises for Chapter 137 . . . 2986
138. Morse theory I: Closed smooth manifolds . . . 2988
138.1. The Smooth Manifold-Product Theorem . . . 2988
138.2. The Handle Addition Theorem . . . 2990
138.3. The Handle Decomposition Theorem . . . 2995
138.4. Reeb's Theorem . . . 2998
Exercises for Chapter 138 . . . 3000
139. Morse theory II: The Relative Handle Decomposition Theorem . . . 3001
139.1. Relative Handle Decompositions . . . 3001
139.2. Morse functions for smooth manifolds with boundary . . . 3005
139.3. The Relative Handle Decomposition Theorem . . . 3007
139.4. Constructing Morse functions from handle decompositions . . . 3008
139.5. Handle decompositions of topological manifolds . . . 3010
Exercises for Chapter 139 . . . 3010
140. Handle homology and the Morse inequalities . . . 3011
140.1. Handle homology . . . 3011
140.2. The boundary maps in the handle chain complex . . . 3017
140.3. The Morse inequalities . . . 3021
Exercises for Chapter 140 . . . 3027
141. Constructing smooth manifolds using handles . . . 3030
141.1. Finite presentations of groups and handle decompositions . . . 3030
141.2. Integral homology spheres and homotopy spheres . . . 3032
141.3. Handle decompositions and CW-structures . . . 3036
Exercises for Chapter 141 . . . 3042
142. The classification of compact 2-dimensional smooth manifolds II . . . 3044
142.1. Handle decompositions of 2-dimensional smooth manifolds . . . 3044
142.2. The classification of compact 2-dimensional smooth manifolds . . . 3050
Exercises for Chapter 142 . . . 3054

Part XV. Bundles 3057
143. Vector Bundles 3058
143.1. Vector bundles 3058
143.2. Constructing vector bundles via transition maps 3066
143.3. The pullback of vector bundles 3068
143.4. The Grassmannian manifolds 3074
143.5. Trivializations of a vector bundle 3077
143.6. Classifying space 3078
143.7. The Whitney sum of vector bundles 3079
143.8. Linear algebra on vector bundles 3079
143.9. Vector bundles over spheres 3082
Exercises for Chapter 143 3086
144. Cobordisms 3088
144.1. The cobordism rings 3088
Exercises for Chapter 144 3100
145. Pontryagin classes and the Hirzebruch Signature Theorem 3102
145.1. Pontryagin classes 3102
145.2. Pontryagin classes as invariants of smooth manifolds 3104
145.3. Pontryagin numbers and the signature 3105
Exercises for Chapter 145 3112

Part XVI. 3-dimensional Manifolds 3113
146. Handlebodies and Heegaard splittings of 3-dimensional smooth manifolds 3114
146.1. Heegaard splittings of 3-dimensional smooth manifolds 3114
146.2. Fundamental groups of 3-dimensional smooth manifolds 3119
146.3. The mapping class group of 2-dimensional smooth manifolds 3122
Exercises for Chapter 146 3130
147. Surgeries on 3-dimensional smooth manifolds 3131
147.1. The Lickorish-Wallace Theorem 3131
147.2. Dehn surgery along knots 3134
147.3. Dehn surgery along links 3139
Exercises for Chapter 147 3141
148. The linking pairing on rational homology spheres 3143
148.1. Rational homology spheres 3143
148.2. The Bockstein homomorphisms 3144
148.3. The cup product and the cap product with coefficients 3146
148.4. The linking pairing on odd-dimensional rational homology spheres 3150
148.5. Proofs of Propositions 148.16 and 148.17 3153

148.6. Linking pairings of lens spaces ... 3155
148.7. The proof of the Lens Space-Linking Pairing Proposition 148.20 ... 3157
148.8. Computing the linking pairing by intersecting singular simplices ... 3163
148.9. Linking pairings and intersection forms ... 3164
Exercises for Chapter 148 ... 3171
149. Branched coverings and chiral knots ... 3173
149.1. Branched coverings ... 3173
149.2. The hyperelliptic involution and branched coverings of surfaces ... 3176
149.3. Branched coverings of 3-dimensional smooth manifolds ... 3179
149.4. Branched coverings defined by knots ... 3181
Exercises for Chapter 149 ... 3186
150. The cobordism groups of rational homology spheres ... 3188
Exercises for Chapter 150 ... 3196

Part XVII. Steenrod operations ... 3199
151. Steenrod Operations ... 3200
151.1. The axioms of Steenrod operations ... 3200
151.2. Steenrod operations and connecting homomorphisms ... 3204
151.3. Steenrod operations and suspensions ... 3208
151.4. Proof of the Steenrod Theorem 151.2 I ... 3212
151.5. Proof of the Steenrod Theorem 151.2 II ... 3217
Exercises for Chapter 151 ... 3222
152. The Adem relations ... 3223
152.1. Application of the Adem relations to homotopy groups of spheres ... 3223
152.2. Decomposing Steenrod operations and the Hopf invariant revisited ... 3228
152.3. The Steenrod cyclic reduced powers ... 3234
Exercises for Chapter 152 ... 3236

Part XVIII. Homotopy Theory and Eilenberg-Maclane Spaces ... 3237
153. Relative homotopy groups ... 3238
153.1. The definition of relative homotopy groups ... 3238
153.2. The long exact homotopy sequence of a pair ... 3243
153.3. Paths acting on relative homotopy groups ... 3247
153.4. Alternative description of relative homotopy groups ... 3250
153.5. Connected (pairs of) topological spaces ... 3252
153.6. The relative Hurewicz Theorem ... 3254
153.7. Excision for relative homotopy groups? ... 3260
Exercises for Chapter 153 ... 3261
154. Fibrations ... 3263

154.1. Definition and examples of fibrations . . . 3263
154.2. The homotopy fiber of a fibration . . . 3266
154.3. The long exact homotopy sequence of a Serre fibration . . . 3271
154.4. Proof of the Fibration-LES Theorem 154.7 . . . 3274
154.5. The path space fibration . . . 3279
154.6. Every map can be replaced by a fibration . . . 3286
154.7. Adjoint functors . . . 3291
Exercises for Chapter 154 . . . 3295
155. Fiber bundles . . . 3298
155.1. The definition of fiber bundles . . . 3298
155.2. Hopf fibrations arising from complex and quaternionic projective spaces 3306
155.3. The Hopf fibration arising from the octonions (∗) . . . 3310
Exercises for Chapter 155 . . . 3314
156. Homotopy groups of Lie groups . . . 3316
156.1. Topological groups and Lie groups . . . 3316
156.2. The homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ . . . 3320
156.3. Spin groups . . . 3325
156.4. The Bott Periodicity Theorem . . . 3329
156.5. H-spaces . . . 3333
156.6. The Eckmann-Hilton Theorem . . . 3338
Exercises for Chapter 156 . . . 3339
157. Thom-Pontryagin Theory I: The basics . . . 3341
157.1. The generalized Thom-Pontryagin construction . . . 3341
157.2. The Thom-Pontryagin construction and homotopy groups . . . 3344
157.3. The thickened cobordism groups and the Thom-Pontryagin Theorem . . . 3350
157.4. The calculation of the thickened cobordism group $\Omega_1^{\mathrm{th}}(\mathbb{R}^3)$ . . . 3355
157.5. The linking number . . . 3360
157.6. The Hopf invariant and the thickened cobordism group $\Omega_{2n-1}^{\mathrm{th}}(\mathbb{R}^{4n-1})$ . . . 3361
Exercises for Chapter 157 . . . 3363
158. Thom-Pontryagin Theory II: The Freudenthal Suspension Theorem . . . 3365
158.1. The framed cobordism group . . . 3365
158.2. The Freudenthal Suspension Theorem . . . 3370
158.3. Framed internal surgery . . . 3375
158.4. Suspension and the Hopf invariant . . . 3377
Exercise for Chapter 158 . . . 3380
159. Thom-Pontryagin Theory III: The groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ and $\Omega_2^{\mathrm{fr}}(\mathbb{R}^{n+2})$ . . . 3382
159.1. The calculation of the framed cobordism groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ for $n \geq 3$ . . . 3382
159.2. Further results obtained using the Thom-Pontryagin approach . . . 3390

Exercises for Chapter 159 3391
160. Summary of homotopy groups of spheres 3392
Exercises for Chapter 160 3395
161. The CW-Approximation Theorem 3396
161.1. Modifying CW-complexes 3396
161.2. Weak homotopy equivalences and the CW-Approximation Theorem 3402
Exercises for Chapter 161 3407
162. The Whitehead Theorem 3408
162.1. The Whitehead Theorem 3408
162.2. Homotopy classification of lens spaces 3413
162.3. Topological spaces dominated by CW-complexes 3417
162.4. Highly connected CW-complexes 3418
162.5. Elementary collapses 3420
Exercises for Chapter 162 3423
163. Eilenberg-Maclane Spaces 3426
163.1. The definition and basic examples of Eilenberg-Maclane Spaces 3426
163.2. Killing higher homotopy groups 3430
163.3. Existence of Eilenberg-Maclane Spaces 3434
163.4. Uniqueness of Eilenberg-Maclane Spaces 3440
163.5. First applications of Eilenberg-Maclane spaces 3449
163.6. Eilenberg–Maclane spaces and the social choice problem ❀ 3452
163.7. An extension of the Hurewicz Theorem 85.5 3453
Exercises for Chapter 163 3460
164. Invariants obtained through Eilenberg-Maclane spaces 3465
164.1. The homotopy category of topological spaces 3465
164.2. The homotopy category of pointed topological spaces 3467
164.3. Eilenberg-Maclane spaces give rise to invariants of topological spaces . . 3476
164.4. Alternative description of the group structure 3485
164.5. Functoriality 3486
164.6. Basic calculations 3490
164.7. Product structures 3491
Exercises for Chapter 164 3494

Part XIX. (Co-) homology with twisted and local coefficients 3497
165. Modules over rings 3499
165.1. Modules over rings 3500
165.2. Homomorphisms between modules 3502
165.3. Rings with involution 3502

165.4. Free modules . . . 3503
165.5. Modules over group rings I. Basics . . . 3506
165.6. Modules over group rings II: Finite dimensional representations . . . 3508
165.7. The tensor product over rings . . . 3510
165.8. Modules over skew fields and PIDS . . . 3515
Exercises for Chapter 165 . . . 3516
166. Homological algebra over rings . . . 3518
166.1. Chain complexes over rings . . . 3518
166.2. Cochain complexes over rings . . . 3519
166.3. Free resolutions . . . 3521
166.4. Free imitations of chain complexes . . . 3523
166.5. Connecting homomorphisms . . . 3527
166.6. Homological algebra over skew fields . . . 3527
166.7. Tor-modules . . . 3529
166.8. Ext-modules . . . 3530
Exercises for Chapter 166 . . . 3531
167. Twisted (co-) homology . . . 3532
167.1. Basics of covering theory . . . 3532
167.2. Definition of twisted (co-) homology . . . 3535
167.3. Functoriality . . . 3541
167.4. Excision for (co-) homology with twisted coefficients . . . 3546
167.5. Homotopic maps and (co-) homology with twisted coefficients . . . 3547
Exercises for Chapter 167 . . . 3553
168. Calculations and examples of twisted (co-) homology . . . 3555
168.1. (Co-) homology with twisted coefficients in degree 0 . . . 3555
168.2. Twisted homology and homology of covering spaces . . . 3557
168.3. Twisted cohomology and cohomology of finite-index coverings . . . 3561
168.4. Twisted (co-) homology groups of lens spaces . . . 3563
168.5. Replacing the universal covering . . . 3564
168.6. The Bockstein sequence and non-orientable topological manifolds . . . 3566
Exercises for Chapter 168 . . . 3569
169. Universally excisive triads and Mayer-Vietoris sequences . . . 3571
169.1. Universally excisive triads . . . 3571
169.2. Internal twisted (co-) homology . . . 3573
169.3. Mayer-Vietoris Theorems for (co-) homology with twisted coefficients . . . 3576
Exercises for Chapter 169 . . . 3581
170. Twisted cellular (co-) homology . . . 3582
170.1. Twisted cellular (co-) homology . . . 3582

170.2. The interaction between twisted cellular and singular (co-) homology . . 3586
170.3. Twisted (co-) homology of compact CW-complexes and manifolds 3593
Exercises for Chapter 170 3597
171. The cup and cap-product on twisted (co-) homology 3600
171.1. Algebraic preparations 3600
171.2. The cup product on twisted cohomology 3601
171.3. The cap product on twisted (co-) homology 3605
172. Poincaré Duality with twisted coefficients 3611
172.1. Statement of the Poincaré Duality Theorem with twisted coefficients . . . 3611
172.2. The proof of Theorem 172.1 for topological manifolds without boundary 3613
172.3. The proof of Poincaré Duality for topological manifolds with boundary 3625
Exercises for Chapter 172 3630
173. Twisted intersection pairings 3631
173.1. Definition of twisted intersection pairings 3631
173.2. Twisted signatures 3639
173.3. Twisted invariants and finite covers 3639
Exercises for Chapter 173 3642
174. Local coefficients 3643
174.1. Local coefficients 3643
174.2. Local coefficient systems and modules over group rings 3645
174.3. Pullbacks of local coefficient systems 3647
174.4. Local coefficient systems and homotopies 3650
174.5. Tensor products of local coefficient systems 3653
Exercises for Chapter 174 3654
175. (Co-) homology with local coefficients 3655
175.1. Homology with local coefficients 3655
175.2. Cohomology with local coefficients 3661
175.3. Cup product with local coefficients 3666
175.4. Cap product with local coefficients 3668
175.5. Excision with local coefficients 3669
175.6. The interaction between twisted (co-) homology and (co-) homology with local coefficients 3670
175.7. Poincaré Duality with local coefficients 3670

Introduction

These are the lecture notes for a sequence of courses on algebraic and geometric topology at the University of Regensburg that started in the winter term of 2016/17 and ended in the summer term 2022. A new sequence is starting in the winter term of 2022/23 and the hope is to revise some of the lecture notes and to add some material (e.g. tubular neighborhoods, de Rham cohomology, bundles, characteristic classes, Reidemeister torsion).

Some references point to future material that is either not written yet or not presentable yet. If you have any comments, especially if you find mistakes or typos, please let me know.

sfriedl@gmail.com

Part I

General Topology

0. Preliminaries

In this preliminary chapter we introduce some concepts and results from set theory and linear algebra which we will use throughout these notes, but which otherwise have little to do with topology itself. The reader might want to skip this chapter and directly move to the next chapter.

0.1. **Basic set theory.** Throughout these notes we work with "naive set theory". Like many working mathematicians this author does not want to get drawn into a discussion about what a set really is. Furthermore, when we describe sets we sometimes use creative notation and language. The hope is that the language is chosen in such a way that any good-willed reader will understand what is meant.

In this short section we recall a few basic definitions and results from set theory which will frequently use throughout these notes. Usually we will not refer to the statements explicitly, unless it helps to clarify an argument.

First we introduce the following notation which should mostly be standard.

Notation.

(1) We write $\mathbb{N}_0 := \{0, 1, 2, 3, \dots\}$ and $\mathbb{N} := \{1, 2, 3, \dots\}$.
(2) We denote by $\varnothing$ the empty set.
(3) Given a set X we write $A \subset X$ if A is a subset of X and we write $A \subsetneq X$ if A is a subset of X with $A \neq X$.
(4) Given a set X we denote by $\mathcal{P}(X)$ its power set, i.e. $\mathcal{P}(X)$ is the set of all subsets of X.
(5) Given a map $f\colon X \to Y$ between sets and given a subset $A \subset Y$ we write
$$f^{-1}(A) \;=\; \{x \in X \mid f(x) \in A\}.$$
Furthermore, given $y \in Y$ we write $f^{-1}(y) := f^{-1}(\{y\})$.[1]

Definition. Let X be a set. A family of subsets of X consists of a set I and a map $f\colon I \to \mathcal{P}(X)$.

Remark. When it comes to families of subsets we often use suggestive notation, e.g. we might write "let $\{U_i\}_{i\in I}$ be a family of subsets of X", which just means that I is a set and the map $I \to \mathcal{P}(X)$ is denoted by $i \mapsto U_i$.

Convention. Let X be a set. We will view any subset $\mathcal{U} \subset \mathcal{P}(X)$ as a family of subsets of X via the index set $I = \mathcal{U}$ and the map $I = \mathcal{U} \to \mathcal{P}(X)$ given by $U \mapsto U$. This convention might sound silly, but it will be useful on many occasions.

We continue with two of the most important definitions of set theory.

Definition. Let $\{U_i\}_{i\in I}$ be a family of subsets of a given set X. We write
$$\begin{aligned} \bigcup_{i\in I} U_i &= \{x \in X \mid \text{ there exists an } i \in I \text{ with } x \in X_i\} \\ \bigcap_{i\in I} U_i &= \{x \in X \mid \text{ for every } i \in I \text{ we have } x \in X_i\}. \end{aligned}$$

[1] Purists might decry this notation, but it does make notation much more readable.

In particular, if $I = \varnothing$, then $\bigcup_{i\in I} U_i = \varnothing$ and $\bigcap_{i\in I} U_i = X$.[2]

Notation. Let $\{U_i\}_{i\in I}$ be a family of subsets of a given set X. If for any $i \neq j \in I$ we have $U_i \cap U_j = \varnothing$, then at times we write

$$\bigsqcup_{i\in I} U_i \;:=\; \bigcup_{i\in I} U_i.$$

The very first statement of these notions are e Morgan's Laws from elementary set theory.

Lemma 0.1. (De Morgan's Laws) Let X be a set and let $\{A_i\}_{i\in I}$ be a family of subsets of X. If given a subset $B \subset X$ we denote its complement by $B^c := X \setminus B$, then

$$\Big(\bigcap_{i\in I} A_i\Big)^c \;=\; \bigcup_{i\in I} A_i^c \quad \text{and} \quad \Big(\bigcup_{i\in I} A_i\Big)^c \;=\; \bigcap_{i\in I} A_i^c.$$

Or equivalently, in a more cumbersome notation, we have

$$X \setminus \Big(\bigcap_{i\in I} A_i\Big) \;=\; \bigcup_{i\in I} (X \setminus A_i) \quad \text{and} \quad X \setminus \Big(\bigcup_{i\in I} A_i\Big) \;=\; \bigcap_{i\in I} (X \setminus A_i).$$

Proof. The lemma follows easily from the definitions and elementary logic. ■

The following lemma concerns the interaction between operations on sets and maps between sets.

Lemma 0.2. (Image-Preimage Lemma) Let $f\colon X \to Y$ be a map between two sets X and Y. Then

(1)	for every subset $U \subset X$ we have	U	$\subset$	$f^{-1}(f(U))$
	furthermore, if f is injective[3], then we have	U	$=$	$f^{-1}(f(U))$
(2)	for every subset $V \subset Y$ we have	V	$\supset$	$f(f^{-1}(V))$
	furthermore, if f is surjective, then we have	V	$=$	$f(f^{-1}(V))$
(3)	for every family $\{U_i\}_{i\in I}$ of subsets of X we have	$f\Big(\bigcup_{i\in I} U_i\Big)$	$=$	$\bigcup_{i\in I} f(U_i)$
(4)	for every family $\{U_i\}_{i\in I}$ of subsets of X we have	$f\Big(\bigcap_{i\in I} U_i\Big)$	$\subset$	$\bigcap_{i\in I} f(U_i)$
(5)	for every subset $U \subset X$ we have	$f(X \setminus U)$	$\supset$	$f(X) \setminus f(U)$
	furthermore, if $f^{-1}(f(U)) = U$, then we have	$f(X \setminus U)$	$=$	$f(X) \setminus f(U)$
(6)	for every family $\{V_i\}_{i\in I}$ of subsets of Y we have	$f^{-1}\Big(\bigcup_{i\in I} V_i\Big)$	$=$	$\bigcup_{i\in I} f^{-1}(V_i)$
(7)	for every family $\{V_i\}_{i\in I}$ of subsets of Y we have	$f^{-1}\Big(\bigcap_{i\in I} V_i\Big)$	$=$	$\bigcap_{i\in I} f^{-1}(V_i)$
(8)	for every subset $V \subset Y$ we have	$f^{-1}(Y \setminus V)$	$=$	$X \setminus f^{-1}(V)$.

Proof. The lemma follows again from the definitions and elementary logic. ■

Definition.

[2] This simple observation will be useful at times.

[3] As a totally irrelevant side remark we would like to point out that the fundamental terms "surjective", "injective" and "bijective" are actually fairly recent additions to the mathematical language. They were first introduced on page 80 of Nicolas Bourbaki's "Théorie des ensembles" first published in 1954, see [**Bou1954**]. The reader who has not read the biography of the great mathematician Nicolas Bourbaki is strongly encouraged to do so.

(1) Given finitely many sets $X_1, \ldots, X_m$ we define the product of $X_1, \ldots, X_n$ to be

$$X_1 \times \cdots \times X_n \ := \ \{(x_1, \ldots, x_n) \,|\, \text{ for } i = 1, \ldots, n \text{ we have } x_i \in X_i\}.$$

(2) Given a set X and given $n \in \mathbb{N}$ we write

$$X^n \ := \ \underbrace{X \times \cdots \times X}_{n \text{ times}}.$$

With this notation we can also formulate the following addendum to the above lemmas.

Lemma 0.3. Let X be a set and let $\{A_i\}_{i \in I}$ and $\{B_j\}_{j \in J}$ be two families of subsets of X. Then

$$\left(\bigcup_{i \in I} A_i \right) \cap \left(\bigcup_{j \in J} B_j \right) \ = \ \bigcup_{(i,j) \in I \times J} (A_i \cap B_j).$$

Proof. The lemma follows - surprise! - easily from the definitions and elementary logic. ■

We turn to the product of not just finitely many sets but the product of a family of sets.

Definition. Let $\{X_i\}_{i \in I}$ be a family of sets. The product of these sets is defined as the set[4] [5]

$$\prod_{i \in I} X_i \ := \ \left\{ f \colon I \to \bigcup_{i \in I} X_i \,\middle|\, \text{ for every } i \in I \text{ we have } f(i) \in X_i \right\}.$$

Furthermore, given a set X and a set I we write

$$X^I \ := \ \prod_{i \in I} X_i.$$

In this lecture notes we will use the Axiom of Choice, even though for the most part it is rather irrelevant. We refer to [**Je1973**] for a detailed discussion of the Axiom of Choice.

Axiom of Choice 0.1. For every family of sets $\{X_i\}_{i \in I}$ the product $\prod_{i \in I} X_i$ is non-empty.

We conclude this section with one last piece of notation.

Notation.

(1) If $\{A_i\}_{i \in I}$ is a family of sets, then we define the disjoint union as the set

$$\bigsqcup_{i \in I} A_i \ := \ \bigcup_{i \in I} (A_i \times \{i\}).$$

(2) If $I = \{1, \ldots, k\}$, then we write $A_1 \sqcup \cdots \sqcup A_k := \bigsqcup_{i=1}^{k} A_i$.

(3) We use obvious variations on (1) and (2), for example given sets A and B we refer to

$$A \sqcup B \ := \ (A \times \{1\}) \cup (B \times \{2\})$$

as the disjoint union of A and B

Remark. Let $\{U_i\}_{i \in I}$ be a family of subsets of a given set X such that for any $i \neq j \in I$ we have $U_i \cap U_j = \varnothing$. The expression $\bigsqcup_{i \in I} U_i$ now describes two different sets, namely it describes the subset of X defined on page 87 and it describes the disjoint union as defined above. There is a natural bijection between these two sets and thus we will freely go back and forth between these notations. In practice should not pose any problems.

[4] This definition is now possibly beyond the realm of "naive set theory", since it is perhaps a little unclear what the union of arbitrary sets is supposed to mean.

[5] If $I = \{1, \ldots, n\}$ then we will not distinguish between $X_1 \times \cdots \times X_n$ and $\prod_{i \in \{1, \ldots, n\}} X_i$.

0.2. **Relations and equivalence relations on sets.** We start out with recalling the notion of a relation.

Definition. A relation on a set S is a subset of $S \times S$.

The definition of a relation in its full generality is pretty useless. It becomes more interesting once we introduce several adjectives.

Definition. Let S be a set and let $R \subset S \times S$ be a relation on S.

(1) The relation is called reflexive, if for every $s \in S$ we have $(s, s) \in R$.
(2) The relation is called transitive, if for every $(s, t), (t, u) \in R$ we also have $(s, u) \in R$.
(3) The relation is called symmetric, if for every (s, t) in R we also have $(t, s) \in R$.

We adopt the following notation.

Notation. Let S be a set and let $R \subset S \times S$ be a relation on S. Given $x, y \in S$ we write $x \, R \, y$ if and only if $(x, y) \in R$.[6]

Example. We consider the set $\mathbb{R}$ together with the relation

$$\leq \ := \ \{(x, y) \in \mathbb{R}^2 \,|\, y - x \text{ is not negative}\}.$$

One can easily verify that this relation $\leq$ is reflexive and transitive, but that it is not symmetric. Note that given $x, y \in \mathbb{R}$ the above expression "$x \leq y$" has the usual meaning that we are all used to.

Most of the relations that we will consider are going to be reflexive and transitive. There is a big difference though in the roles of symmetric and non-symmetric relations. Let us consider the symmetric ones first. We will turn to the (possibly) non-symmetric relations in the next section.

Definition. An equivalence relation on a set S is a relation that is reflexive, transitive and symmetric.

Convention. Equivalence relations on a set S are almost invariably denoted by "$\sim$" or some variation thereof.

To practice our conventions and notations, the three properties of an equivalence relation "$\sim$" on a set S are precisely the following three statements:

(1) for any $s \in S$ we have $s \sim s$ (reflexivity),
(2) for any $s, t, u \in S$ with $s \sim t$ and $t \sim u$ we have $s \sim u$ (transitivity),
(3) for any $s, t \in S$ with $s \sim t$ we also have $t \sim s$ (symmetry).

We continue with the following definition.

Definition. Let S be a set together with an equivalence relation "$\sim$". An equivalence class of $(S, \sim)$ is a subset C of S with the following three properties:

(1) the subset is non-empty,
(2) given any two $s, t \in C$ we have $s \sim t$, and
(3) given $s \in C$ and $t \in S$ with $s \sim t$ we have $t \in C$.

We refer to [**Halm1960**, Section 7] for a confirmation of the above definitions.

The following lemma summarizes the key properties of equivalence classes.

[6] Most relations are denoted by symbols like "$\sim$", "$\leq$", "$\cong$".

Lemma 0.4. (Equivalence Class Lemma) Let S be a set together with an equivalence relation "$\sim$".

(1) Every element of S is contained in a unique equivalence class, namely
$$[s] := \{t \in S \,|\, t \sim s\}.$$
(2) Two equivalence classes are either disjoint or the same.

Proof. Surely the reader will have seen the proof of the lemma before. Nonetheless we give the proof, in particular to highlight the fact that we do indeed need the symmetry condition.

(1) Let $s \in S$. Since $\sim$ is reflexive we see that $s \in [s]$. Thus it remains to show that $[s] := \{t \in S \,|\, t \sim s\}$ is indeed an equivalence class.
   (a) We already showed that $s \in [s]$, in particular we see that $[s]$ is non-empty.
   (b) Let $t, t' \in [s]$. By definition this means that $t \sim s$ and $t' \sim s$. By symmetry we $s \sim t'$. By transitivity we deduce from $t \sim s$ and $s \sim t'$ that $t \sim t'$.
   (c) Let $t \in [s]$ and suppose that $t \sim u$. Since by definition we have $s \sim t$ we obtain from transitivity that $s \sim u$, i.e. we see that $u \in [s]$.

(2) Let C and D be two equivalence classes. We suppose that $C \cap D \neq \varnothing$. Thus there exists an $x \in C \cap D$. We need to show that $C = D$. Thus let $d \in D$. By Condition (2) of an equivalence class applied to D we know that $x \sim d$. By condition (1) of an equivalence class, applied to C, we see that $d \in C$. Thus we have shown that $D \subset C$. Evidently the same argument shows that $C \subset D$. ∎

Throughout these notes we adopt the following standard notation.

Notation. Let S be a set together with an equivalence relation "$\sim$".

(1) We denote by $S/\!\sim$ the set of equivalence classes.
(2) Given $s \in S$ we denote by $[s]$ the unique equivalence class that contains $[s]$.
(3) We refer to the map
$$\begin{array}{rccc} p\colon X & \to & X/\!\sim \\ x & \mapsto & [x] \end{array}$$
as the natural projection.

Example. Let $n \in \mathbb{N}$. We consider the set $\mathbb{Z}$ together with the equivalence relation that is given by
$$x \sim y \quad :\Longleftrightarrow \quad (x-y) \text{ is divisible by } n.$$
There are exactly n equivalence classes, namely
$$\begin{array}{rcl} [0] & = & \{\ldots, -2n, -n, 0, n, 2n, 3n, \ldots\} \\ [1] & = & \{\ldots, 1-2n, 1-n, 1, 1+n, 1+2n, 1+3n, \ldots\} \\ & \vdots & \\ [n-1] & = & \{\ldots, -2n-1, -n-1, -1, n-1, 2n-1, 3n-1, \ldots\}. \end{array}$$
To the despair of many of my cultured friends we write $\mathbb{Z}_n := \mathbb{Z}/\!\sim$.

Lemma 0.5. (Quotient-Factorization Lemma) Let $\sim$ be an equivalence relation on a set X. We denote by $p\colon X \to X/\sim$ the natural projection. Let $f\colon X \to Y$ be a map to

some set Y with the property that $f(x) = f(y)$ whenever $x \sim y$. Then the map

$$\begin{array}{rccc} g\colon & X/\!\sim & \to & Y \\ & [x] & \mapsto & f(x) \end{array}$$

is well-defined and it is the unique map $g\colon X/\!\sim \to Y$, such that $f = g \circ p$, i.e. such that the following diagram of maps commutes:

$$\begin{array}{ccc} X & \xrightarrow{p} & X/\!\sim \\ & \searrow^{f} & \downarrow g \\ & & Y. \end{array}$$

Proof. Let $\sim$ be an equivalence relation on a set X and let $f\colon X \to Y$ be a map with the property that $f(x) = f(y)$ whenever $x \sim y$. Let a be an element of $X/\!\sim$. By definition there exists an $x \in X$ with $a = [x]$. We set

$$g(a) \;:=\; f(x).$$

Evidently this definition does not depend on the choice of x. The map g satisfies $f = g \circ p$. Since the projection $X \to X/\!\sim$ is surjective we see that g is uniquely determined by this property. ■

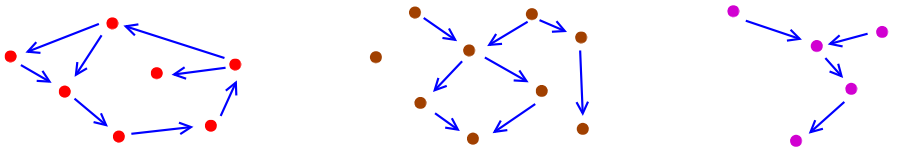
We will now see that every relation gives rise to an equivalence relation.

Definition. Let S be a set and let R be a relation on S. We say $x, y \in S$ are equivalent, if there exists a sequence $x_0, \ldots, x_k$ of elements in S such that $x = x_0$, $x_k = y$ and such that for each $i \in \{0, \ldots, k-1\}$ we have $x_i \, R \, x_{i+1}$ or $x_{i+1} \, R \, x_i$. It is straightforward to verify that "$\sim$" defines an equivalence relation on S. We refer to it as the equivalence relation generated by the relation R.

Example. We consider the set $S = \mathbb{R}$ and the relation that is defined by $x \, R \, y$ if and only $y = x + 1$. The equivalence relation generated by R is the equivalence relation that is given by $x \sim y$ if and only $x - y \in \mathbb{Z}$.

Convention. At times we are a little sloppy in our notation and we do not distinguish in our notation between a relation and the equivalence relation it generates.

0.3. **Orders on sets.** In this section we turn our gaze towards relations which are not required to be symmetric. We have the following harmless definition.



Definition.

(1) A relation "$\leq$" on a set S is called antisymmetric if $a \leq b$ and $b \leq a$ implies $a = b$.
(2) A relation that is reflexive, transitive and antisymmetric is called a partial order.
(3) A set together with a partial order is called a partially ordered set.
(4) Let "$\leq$" be a partial order on a set A. Given $a, b \in A$ we write $a < b$ if $a \leq b$ and if $a \neq b$.
(5) Let $(A, \leq)$ and $(B, \leq)$ be two partially ordered sets. A map $f\colon A \to B$ is called order-preserving, if for every two elements $a_1, a_2 \in A$ with $a_1 \leq a_2$ we also have $f(a_1) \leq f(a_2)$.[7]

(6) We say that two partially ordered sets $(A, \leq)$ and $(B, \leq)$ have the same order type if there exists a bijection $f\colon A \to B$ which is order-preserving and such that the inverse $f^{-1}\colon B \to A$ is also order-preserving.

Example.

(1) Let X be a subset of $\mathbb{R}$ and denote by $\leq$ the usual "less or equal" relation on the real numbers. Then $(X, \leq)$ is a partially ordered set.
(2) We equip $\mathbb{R} \cup \{\pm\infty\}$ with the relation $\leq$ that is given by the usual relation on $\mathbb{R}$ together with $-\infty \leq a \leq \infty$ for any $a \in \mathbb{R}$. This turns $\mathbb{R} \cup \{\pm\infty\}$ into a partially ordered set.
(3) Let M be a set. Recall that we denote by $\mathcal{P}(M)$ the power set of M, i.e. the set of all subsets of M. Then "being a subset", i.e. the relation given by "$\subset$", is a partial order on $\mathcal{P}(M)$.
(4) Let X be a set. The trivial partial order $\leq_{\text{tr}}$ is the partial order where $x \leq_{\text{tr}} y$ if and only if $x = y$.
(5) We consider the three reflexive transitive relations that are illustrated in the figure below. Here it is understood that $P \leq Q$ if there exists a "directed path" from Q to P.
   (a) The example on the left has a "loop". Given any two points P, Q on the loop we have $P \leq Q$ and $Q \leq P$, hence this example is not a partial order.
   (b) This example is a partial order.
   (c) This example is also a partial order.

Example (a) Example (b) Example (c)

The following construction lets us build new examples of partially ordered sets out of given ones.

Definition. Let $(A, \leq)$ and $(B, \leq)$ be two partially ordered sets. Given (a, b) and (a', b') in $A \times B$ we define[8]

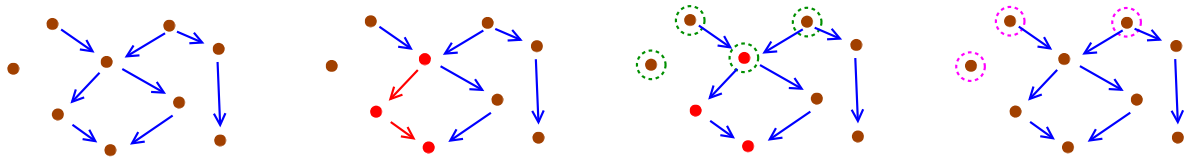
$$(a, b) < (a', b') \quad :\Longleftrightarrow \quad \text{either } a < a' \text{ or } a = a' \text{ and } b < b'$$

and we define $(a, b) \leq (a', b')$ if either $(a, b) = (a', b')$ or $(a, b) < (a', b')$. One can easily verify that "$\leq$" is a partial order on $A \times B$. We refer to this partial order on $A \times B$ as the lexicographic order on $A \times B$.

We need a few more definitions before we can state the first non-trivial result.

Definition. Let $(P, \leq)$ be a partially ordered set.

(1) A chain in P is a subset Q such that for any two elements $q, q' \in Q$ we have $q \leq q'$ or $q' \leq q$.



[7]Note that "order-preserving" does not mean that $a_1 < a_2$ implies $f(a_1) < f(a_2)$.
[8]Note that if $a < a'$, then we do not demand that $b \leq b'$.

(2) An upper bound of a subset Q is an element $p \in P$ such that $q \leq p$ for all $q \in Q$.
(3) A maximal element of a subset Q is an element $q \in Q$ such that there is no $r \in Q$ with $q < r$.

We define the notion of a lower bound and a minimal element in the obvious analogous way.

Example.

(1) In the figure below we once again consider the partially ordered set in the middle of the previous figure. We show a chain, we show upper bounds for the chain and we show maximal elements for P.

partially ordered set P | chain Q | upper bounds for the chain Q | maximal elements of the set P

(2) We consider the interval $P = [0, \infty)$ with the usual partial ordering. Every subset is a chain, but not every subset has an upper bound. For example P does not have an upper bound.
(3) We consider the interval $P = (-\infty, 0]$ with the usual partial ordering. Every subset is a chain and 0 is an upper bound for every subset furthermore it is a maximal element of P.

Next we formulate Zorn's Lemma. Its modest name conceals its true importance in mathematics.

Lemma 0.6. (Zorn's Lemma) Suppose a partially ordered set $(P, \leq)$ has the property that every chain has an upper bound in P. Then the set P contains at least one maximal element.

Remark.

(1) Zorn's Lemma even made it into "The Simpsons", see

`http://www.simonsingh.net/Simpsons_Mathematics/zorns-lemma/`

(2) The lemma is named after Max Zorn [**Zo1935**] who published a proof in 1935. In fact the same statement was already proved by Casimir Kuratowski [**Kura1922**] in 1922.

Proof. A nice discussion of the proof and its historical context is given in [**Sti2013**, Section 7.2]. Alternatively see also [**Cie1997**, Theorem 4.3.4] and [**Je1973**, p. 9] for a proof, assuming the Axiom of Choice 0.1. In fact, as is shown in [**Sti2013**, p. 154] or alternatively [**Je1973**, Theorem 2.1], Zorn's Lemma is equivalent to the Axiom of Choice 0.1. ■

We continue with the next adjective that we can associate to a relation.

Definition.

(1) A relation "$\leq$" on a set S is called connex if for every $a, b \in S$ we have $a \leq b$ or $b \leq a$.

(2) A partial order that is connex is called a total order.
(3) A set together with a total order is called a totally ordered set.

Examples.

(1) Evidently the usual "$\leq$"-relation on $\mathbb{R}$ is connex.
(2) None of the partial orders considered in the figure on page 92 is connex.
(3) Given two totally ordered sets $(A, \leq)$ and $(B, \leq)$ one can show easily that the lexicographic order on $A \times B$ is again a total order.

Finally we introduce one last type of partial orders.

Definition.

(1) A total order $\leq$ on a set S is called a well-order if every non-empty subset T has a minimal element.
(2) A set together with a well-order is called a well-ordered set.

Examples.

(1) The usual order on $\mathbb{Q}$ is a total order but it is not a well-order, for example the subset $T := \{x \in \mathbb{Q} \,|\, x > 2\}$ does not have a minimal element. But since $\mathbb{Q}$ is in bijection to $\mathbb{N}$ we see that $\mathbb{Q}$ admits a well-order.
(2) The usual order on $\mathbb{R}$ is a total order but it is not a well-order. It is a priori not so clear how one can define a well-order on $\mathbb{R}$.
(3) Given two well-ordered sets $(A, \leq)$ and $(B, \leq)$ one can again show easily that the lexicographic order on $A \times B$ is a well-order.

Perhaps somewhat shockingly the following theorem, due to Ernst Zermelo [**Zer1904**], says that every set admits a well-ordering.

Theorem 0.7. (Well-Ordering Theorem) Every set admits a well-order.

Proof. We refer to [**Cie1997**, Theorem 4.3.3] or alternatively to [**Je1973**, p. 9] for a proof assuming the Axiom of Choice 0.1.In fact, as for Zorn's Lemma it is shown in [**Je1973**, Theorem 2.1] that the Well-Ordering Theorem is equivalent to the Axiom of Choice 0.1. ■

0.4. **The cardinality of sets.** In this section we introduce the notion of the cardinality of a set.

Definition.

(1) We say that two given sets S and T are equinumerous if there exists a bijection $\varphi\colon S \to T$.[9]
(2) Given a set S we define the cardinality $\#S$ of S as the equinumerosity equivalence class of S in the class of all sets. Put differently we have

$$\#S \;:=\; \text{class of all sets } T \text{ that are equinumerous with } S.$$

(3) If S is a finite set, then we write $\#S = n$ for the unique $n \in \mathbb{N}_0$ which satisfies $\#S = \#\{1, \ldots, n\}$. If S infinite, then sometimes we write $\#S = \infty$[10]. At times we also write $|S| \in \mathbb{N}_0 \cup \{\infty\}$ instead of $\#S \in \mathbb{N}_0 \cup \{\infty\}$.

(4) Let S be a set. If $\#S = n$ for some $n \in \mathbb{N}_0$ or if $\#S = \#\mathbb{N}$, then we say that S is countable, otherwise we say that S is uncountable.

Example. We have $\#(\mathbb{R} \setminus \{0\}) = \#\mathbb{R}$. Indeed a bijection is given by

$$\begin{array}{rcl} \mathbb{R} \setminus \{0\} & \to & \mathbb{R} \\ x & \mapsto & \begin{cases} x, & \text{if } x \in \mathbb{R} \setminus \mathbb{N}_0, \\ x - 1, & \text{if } x \in \mathbb{N}. \end{cases} \end{array}$$

Remark. Another way of putting the definition of cardinality is that given two sets S and T we have $\#S = \#T$ if and only if there exists a bijection from S to T.

The following lemma gets used on many occasions in these lecture notes.

Lemma 0.8. (Countability Lemma)

(1) Every subset of a countable set is again countable.
(2) Let S be a countable set and let $f\colon S \to T$ be a map. The image $f(S)$ is again countable.
(3) The union of countably many countable sets is again countable.
(4) Let T be a set and let S be a subset such that $T \setminus S$ is countable. Then S is countable if and only if T is countable.
(5) The product of finitely many countable sets is again countable.
(6) If S is a finite set and if T is a countable set, then the set of maps from S to T is also countable.

Example. We consider the map

$$\begin{array}{rcl} \mathbb{Z} \times \mathbb{N} & \to & \mathbb{Q} \\ (m, n) & \mapsto & \frac{m}{n}. \end{array}$$

Evidently this map is surjective. It follows from the Countability Lemma 0.8 (2) and (5) that $\mathbb{Q}$ is countable.

Sketch of proof.

(1) After excluding the trivial case that S is finite and the case that T is finite one sees that one has to prove the following: given any infinite subset T of $\mathbb{N}$ there exists a bijection $\varphi\colon \mathbb{N} \to T$. Such a bijection is given by defining $\varphi(i)$ as the i-th smallest element of T.
(2) Let S be a countable set and let $f\colon S \to T$ be a map. We only really need to consider the case that $S = \mathbb{N}$ and that $f(S)$ is infinite. In this case the bijection $\varphi\colon \mathbb{N} \to f(S)$ is given by defining $\varphi(1) = f(1)$ and by defining iteratively

$$\varphi(i+1) \ := \ \left\{ f(k) \,\middle|\, \begin{array}{c} k \in \mathbb{N} \text{ is the smallest number such} \\ \text{that } f(k) \notin \{\varphi(1), \ldots, \varphi(i)\} \end{array} \right\}.$$

(3) It is fairly straightforward, albeit notationally slightly messy to give a direct proof. For completeness we refer to [**Cie1997**, Corollary 5.2.6] for a proof.
(4) This statement follows immediately from (2) and (3).

[9] It follows immediately from the definitions that being equinumerous defines an equivalence relation on the class of all sets.

[10] This notation is a little risque. The sets $\mathbb{N}$ and $\mathbb{R}$ are both infinite, but in Corollary 0.10 we will see that $\mathbb{N}$ and $\mathbb{R}$ are not equinumerous. Thus we write $\#\mathbb{N} = \infty$ and $\#\mathbb{R} = \infty$, but $\#\mathbb{N} \neq \#\mathbb{R}$.

(5) By induction and by ignoring the rather dull case of finite sets it remains to show that $\mathbb{N}_0 \times \mathbb{N}_0$ is countable. This can be shown by the well-known argument sketched in the figure below.

(6) Let $S = \{v_1, \ldots, v_n\}$ be a finite set and let T be a countable set. We have an obvious bijection between T^n and the set of maps from S to T. Thus it follows from (5) that the set of maps from S to T is countable. ■

We move on to the next definition.

Definition. Let S and T be two sets.

(1) We write $\#S \leq \#T$ if there exists an injection $\varphi\colon S \to T$.
(2) We write $\#S < \#T$ if $\#S \leq \#T$ but $\#S \neq \#T$.

Example. It follows from the Countability Lemma 0.8 (1) that a set S is countable if and only if $\#S \leq \#\mathbb{N}$.

The following theorem was first proved by Georg Cantor [**Cant1892**]. The ration of significance of the statement to length of the proof seems to be unbeatable.

Theorem 0.9. (Cantor's Theorem) Recall that given a set X we denote by $\mathcal{P}(X)$ its power set, i.e. the set of all subsets of X. For every X we have $\#X < \#\mathcal{P}(X)$.

Proof. First note that the map

$$\begin{array}{rcl} X & \to & \mathcal{P}(X) \\ x & \mapsto & \{x\} \end{array}$$

is evidently injective, hence $\#X \leq \#\mathcal{P}(X)$. Now let $f\colon X \to \mathcal{P}(X)$ be a map. We have to show that it cannot be surjective. We consider the set

$$Y \;:=\; \{x \in X \,|\, x \notin f(x)\}.$$

We claim that Y is not in the range of f. Indeed, if there did exist a $z \in X$ with $f(z) = Y$, then we would have

$$z \in Y \quad \underset{\text{by definition of } Y}{\overset{\uparrow}{\iff}} \quad z \notin f(z) \quad \underset{\text{since } f(z) = Y}{\overset{\uparrow}{\iff}} \quad z \notin Y.$$

We have thus obtained a contradiction. ■

Corollary 0.10. The set $\mathbb{R}$ of real numbers is uncountable.

Proof. [11] We consider the maps

$$\begin{array}{rcl} f\colon \mathcal{P}(\mathbb{N}) & \to & \{\mathbb{Z}_2\}^{\mathbb{N}} \\ X & \mapsto & \left(\begin{array}{rcl} \mathbb{N} & \to & \mathbb{Z}_2 \\ k & \mapsto & \left\{ \begin{array}{ll} 1, & \text{if } k \in X \\ 0, & \text{otherwise} \end{array} \right. \end{array} \right) \end{array}$$

and

$$\begin{array}{rcl} g\colon \{\mathbb{Z}_2\}^{\mathbb{N}} & \to & \mathbb{R} \\ f & \mapsto & \sum_{k=1}^{\infty} \frac{f(k)}{3^k} \end{array}$$

[11] There are many proofs that the real numbers are uncountable. Perhaps the most beautiful and astounding proof that $\mathbb{Q}$ is countable is given via the amazing Farey sequence, see [**Hat2021**, Chapter 3].

One can easily verify that $f\colon \mathcal{P}(\mathbb{N}) \to \{\mathbb{Z}_2\}^{\mathbb{N}}$ is a bijection and that $g\colon \{\mathbb{Z}_2\}^{\mathbb{N}} \to \mathbb{R}$ is injective. Thus it follows from Cantor's Theorem 0.9 together with the Countability Lemma 0.8 (1) that $\mathbb{R}$ is uncountable. ■

Now we can formulate the final result of this chapter.

Theorem 0.11. (Bernstein-Schröder)[12] Let S and T be two sets. Then

$$\#S \leq \#T \quad \text{and} \quad \#T \leq \#S \quad \Longrightarrow \quad \#S = \#T.$$

Example. Let U be a non-empty subset of $\mathbb{R}$ which contains an open interval (a, b) with $a < b$. Then $\#U = \#\mathbb{R}$. Indeed, the inclusion $U \to \mathbb{R}$ is of course injective, thus we see that $\#U \leq \#\mathbb{R}$. Furthermore the map $\varphi\colon (a, b) \to \mathbb{R}$ given by $x \mapsto \frac{x}{(x-a)(x-b)}$ defines a bijection between (a, b) and $\mathbb{R}$. Thus $\mathbb{R} \xrightarrow{\varphi^{-1}} (a, b) \to U$ is also an injection. This means that $\#\mathbb{R} \leq \#U$. Therefore it follows from the Bernstein-Schröder-Theorem 0.11 that there exists a bijection from U to $\mathbb{R}$.

Proof. Let $f\colon A \to B$ and $g\colon B \to A$ be two injective maps between two sets A and B. Without loss of generality we can assume that A and B are disjoint.[13] We denote by $\sim$ the equivalence relation on $A \sqcup B$ that is generated by $a \sim f(a)$ for $a \in A$ and by $b \sim g(b)$ for $b \in B$. Note that if $a \in A$ lies in the image of g, then by the injectivity of g there exists a unique element $g^{-1}(a) \in B$ and we have $a \sim g^{-1}(a)$. The same remark works with the roles of f and g reversed.

Claim. For each equivalence class I there exists a bijection $A \cap I \to B \cap I$.

Proof. So let I be an equivalence class and let $a \in A \cap I$.[14] The subset $I \subset A \sqcup B$ consists of all elements equivalent to a. The equivalence class I is then of one of the following three types:[15]

			A	B	A	B	A	B		
(1)	a'	$\dots$	$f^{-1}(g^{-1}(a))$,	$g^{-1}(a)$,	a,	$f(a)$,	$g(f(a))$,	$f(g(f(a))$,	$\dots$	with $a' \in A \setminus g(B)$
(2)	b'	$\dots$	$f^{-1}(g^{-1}(a))$,	$g^{-1}(a)$,	a,	$f(a)$,	$g(f(a))$,	$f(g(f(a))$,	$\dots$	with $b' \in B \setminus f(A)$
(3)	$\dots$	$\dots$	$f^{-1}(g^{-1}(a))$,	$g^{-1}(a)$,	a,	$f(a)$,	$g(f(a))$,	$f(g(f(a))$,	$\dots$	

In case (1) the map f defines a bijection $A \cap I \to B \cap I$, in case (2) the map g^{-1} defines a bijection $A \cap I \to B \cap I$ and in case (3) both f and g^{-1} define a bijection $A \cap I \to B \cap I$.

Proof.

Recall that by the Equivalence Class Lemma 0.4 we know that equivalence classes always give a disjoint decomposition of a set. In our case, if I_j, $j \in J$ denote the set of

[12] The theorem was initially stated by Georg Cantor without a proof and it was first proved by Felix Bernstein (1878-1956) and Ernst Schröder (1841-1902) in 1896. Sometimes it is also called the Cantor-Bernstein-Schröder Theorem.

[13] If A and B are not disjoint, then we replace A by $A' = A \times \{0\}$ and B by $B' = B \times \{1\}$, then A' and B' are disjoint, since any two elements in A' and B' now have different second coordinate.

[14] There always exists an $a \in A \cap I$. Indeed, I is by definition non-empty. If it contains an element in A we are done. Otherwise it contains an element in $b \in B$, but then it also contains $g(b) \in A$, since $b \sim g(b)$.

[15] Note that we do not claim that the elements in the given sequences are distinct, for example $f\colon A \to B$ could be a bijection and $g = f^{-1}$ its inverse, then the equivalence class consists only of the two elements a and $g(a)$.

equivalence classes of $\sim$ on $A \sqcup B$, then we have

$$A \sqcup B = \bigsqcup_{j \in J} I_j \quad \text{and therefore also} \quad A = \bigsqcup_{j \in J} (A \cap I_j) \text{ and } B = \bigsqcup_{j \in J} (B \cap I_j).$$

Since for each $j \in J$ we have a bijection $A \cap I_j \to B \cap I_j$ we get a bijection $A \to B$. ■

Remark. The *continuum hypothesis*, first formulated by Georg Cantor in 1878, states that there exists no set S with $\#\mathbb{Q} < \#S < \#\mathbb{R}$. Any attempt at proving this statement relies on first of all making precise what "sets" are supposed to be or what axioms they are supposed to satisfy. As wikipedia writes "the answer to this problem is independent of ZFC set theory (that is, Zermelo-Fraenkel set theory with the Axiom of Choice 0.1 included), so that either the continuum hypothesis or its negation can be added as an axiom to ZFC set theory, with the resulting theory being consistent if and only if ZFC is consistent." This independence was proved in 1963 by Paul Cohen for which he obtained a Fields medal in 1966. More useful information can as always be found on wikipedia:

`https://en.wikipedia.org/wiki/Continuum_hypothesis`

0.5. **Conventions for (linear) algebra.** Next we want to introduce the notion of rings. Since the definition of a "ring" in the literature can differ considerably let us state precisely what we mean by a ring in these notes.

Definition.

(1) A ring is a triple $(R, +\colon R \times R \to R,\ \cdot\ \colon R \times R \to R)$ where $(R, +)$ is an abelian group and such that the following conditions are satisfied:
   (a) the multiplication "$\cdot$" is associative,
   (b) the multiplication "$\cdot$" is distributive,
   (c) there exists a multiplicatively neutral element $1 = 1_R$ with $1 \neq 0$.

(2) A ring R is called commutative, if given any $r, s \in R$ we have $r \cdot s = s \cdot r$.

(3) A ring homomorphism between two rings $(R, +, \cdot)$ and $(S, +, \cdot)$ is a map $R \to S$ that preserves the additive and multiplicative structures and that sends 1_R to 1_S.

(4) A field is a commutative ring such that every non-zero element has a multiplicative inverse.

Remark. Recall that "associative" means that for any $a, b, c \in R$ we have $(a \cdot b) \cdot c = a \cdot (b \cdot c)$. It is well-known that this means that we can unambiguously define the product of finitely many elements using any choice of parentheses. Even though this statement is completely familiar, if one thinks about it, one realizes that this requires a proof. Such a proof is for example provided in [**DF2004**, p. 19].

We move on to the next definition.

Definition. Let R be a commutative ring.

(1) Let M be an R-module. A basis for M is a subset $\mathcal{B} \subset M$ such that every element in M can be written uniquely as a linear combination of elements in $\mathcal{B}$.

(2) An R-module is called free if it admits a basis.

(3) Let V and W be two free R-modules which are equipped with finite bases $\mathcal{B} = \{b_1, \ldots, b_m\}$ and $\mathcal{C} = \{c_1, \ldots, c_n\}$ and let $\varphi\colon V \to W$ be an R-homomorphism. We

refer to the unique $(n \times m)$-matrix $P = (p_{ij})$ with $\varphi(v_i) = \sum_{j=1}^{n} p_{ji} \cdot w_j$ as the matrix representing φ with respect to the bases $\mathcal{B}$ and $\mathcal{C}$.

The previous definition is the standard definition well-known from earlier courses in linear algebra. Towards the end of the notes we will work with module homomorphisms over non-commutative rings. At that point we will see that at times it is convenient to switch to a different convention.

One of the problems haunting anybody trying to write coherent lecture notes are the "extreme cases" of the empty set and 0-dimensional vector spaces. In an attempt to avoid some issues from occurring we introduce the following convention.

Convention. The determinant of a 0×0-matrix over a ring R is $1_R \in R$.

We conclude this chapter with the following definition.

Definition. Let R be a commutative domain. Given an R-module M we define

$$\operatorname{rank}(M) \quad := \quad \dim_{K(R)}(M \otimes_R K(R))$$

($\otimes_R$: tensor product over R as defined in Section 165.7)

where $K(R)$ denotes the quotient field of R.

0.6. The Cauchy-Schwarz Inequality.

Definition. Let R be a commutative ring and let V and W be R-modules.

(1) A pairing on $V \times W$ is a map
$$\varphi\colon V \times W \ \to \ R$$
such that for all $v, v', w, w' \in W$ we have $\varphi(v + v', w) = \varphi(v, w) + \varphi(v', w)$ and $\varphi(v, w + w') = \varphi(v, w) + \varphi(v, w')$.

(2) A pairing is called R-bilinear if for all $\lambda \in R$ and all $v \in V$ and $w \in W$ we have $\varphi(\lambda \cdot v, w) = \lambda \cdot \varphi(v, w)$ and $\varphi(v, \lambda \cdot w) = \varphi(v, w) \cdot \lambda$.

(3) We say that an R-bilinear pairing $\varphi\colon V \times V \to S$ is symmetric if $\varphi(v, w) = \varphi(w, v)$ for all $v, w \in V$.

We now specialize to the case that the ring R are the real numbers.

Definition. Let V be a real vector space.

(1) We say a pairing φ is positive-definite if $\varphi(v, v) > 0$ for all $v \in V \setminus \{0\}$.

(2) We say a pairing φ is positive-semidefinite if $\varphi(v, v) \geq 0$ for all $v \in V \setminus \{0\}$.

Example. Let $n \in \mathbb{N}_0$. The standard pairing on $\mathbb{R}^n$ is given by

$$\begin{aligned} \langle -, - \rangle\colon \mathbb{R}^n \times \mathbb{R}^n \ &\to \ \mathbb{R} \\ (v, w) \ &\mapsto \ \sum_{i=1}^{n} v_i \cdot w_i. \end{aligned}$$

Here we use the standard convention that for $v \in \mathbb{R}^n$ we denote by $v_1, \ldots, v_n$ its coordinates. This standard pairing on $\mathbb{R}^n$ is evidently positive-definite.

Proposition 0.12. (Cauchy-Schwarz Inequality) Let V be a real vector space and let

$$\begin{aligned} \varphi\colon V \times V \ &\to \ \mathbb{R}_{\geq 0} \\ (v, w) \ &\mapsto \ \varphi(v, w) \end{aligned}$$

be an $\mathbb{R}$-bilinear form.

(1) If φ is positive semidefinite, then for any $v, w \in V$ we have
$$\varphi(v,w)^2 \ \leq \ \varphi(v,v) \cdot \varphi(w,w).$$
(2) Now suppose that φ is positive-definite. In this equality in (1) holds if and only if v and w are linearly dependent.

Proof. First we just assume that φ is positive semidefinite. Let $v, w \in V$. Given $t \in \mathbb{R}$ we consider
$$f(t) \ := \ \varphi(v + t \cdot w, v + t \cdot w) \underset{\substack{\uparrow \\ \text{since } \varphi \text{ is } \mathbb{R}\text{-bilinear and symmetric}}}{=} \varphi(v,v) + 2t \cdot \varphi(v,w) + t^2 \cdot \varphi(w,w).$$

Since φ is positive semidefinite we see that f assumes only non-negative values. This implies that f assumes a minimum, which in turn implies that there exists a $t_0 \in \mathbb{R}$ with $f'(t_0) = 0$. It follows from the second description of $f(t)$ that
$$f'(t) \ = \ 2 \cdot \varphi(v,w) + 2t \cdot \varphi(w,w).$$
This implies that $t_0 \cdot \varphi(w,w) = -\varphi(v,w)$. Now note that
$$\begin{aligned} \varphi(v + t_0 \cdot w, v + t_0 \cdot w) \cdot \varphi(w,w) \ &= \ \varphi(w,w) \cdot \varphi(v,v) + 2\overbrace{t_0 \cdot \varphi(w,w)}^{=-\varphi(v,w)} \cdot \varphi(v,w) + \overbrace{t_0^2 \cdot \varphi(w,w) \cdot \varphi(w,w)}^{=\varphi(v,w)^2} \\ &\underset{\substack{\uparrow \\ \text{follows from } t_0 \cdot \varphi(w,w) = -\varphi(v,w)}}{=} \varphi(w,w) \cdot \varphi(v,v) - \varphi(v,w) \cdot \varphi(v,w). \end{aligned}$$

Since φ is positive semidefinite we see that $\varphi(v + t_0 \cdot w, v + t_0 \cdot w) \cdot \varphi(w,w) \geq 0$. It follows from the little calculation above that $\varphi(v,w)^2 \leq \varphi(v,v) \cdot \varphi(w,w)$.

Now suppose that $\varphi(v,w)^2 = \varphi(v,v) \cdot \varphi(w,w)$. This implies, by the above calculation, that $\varphi(v + t_0 \cdot w, v + t_0 \cdot w) \cdot \varphi(w,w) = 0$. Since φ is positive-definite this means that $v + t_0 \cdot w = 0$ or $w = 0$. In either case, v, w are linearly dependent. ■

On one occasion we will need the following corollary to the Cauchy-Schwarz Inequality 0.12.

Corollary 0.13. (Cauchy-Schwarz Inequality) Given $v_1, \ldots, v_n \in \mathbb{R}^n$ and given $w_1, \ldots, w_n \in \mathbb{R}$ we have the following inequality:
$$(v_1 \cdot w_1 + \cdots + v_n \cdot w_n)^2 \ \leq \ (v_1^2 + \cdots + v_n^2) \cdot (w_1^2 + \cdots + w_n^2).$$

Proof. The statement follows immediately from the Cauchy-Schwarz Inequality 0.12 applied to the standard pairing on $\mathbb{R}^n$. ■

Finally on some occasions we will need a variation of the Cauchy-Schwarz Inequality 0.12 where we work with pairings over $\mathbb{C}$. This leads us to the following definitions.

Definition. Let V be a complex vector space.

(1) A pairing $\varphi\colon V \times V \to \mathbb{C}$ is called $\mathbb{C}$-sesquilinear if for all $\lambda \in \mathbb{C}$ and all $v, w \in V$ we have $\varphi(\lambda \cdot v, w) = \lambda \cdot \varphi(v,w)$ and $\varphi(v, \lambda \cdot w) = \varphi(v,w) \cdot \overline{\lambda}$.
(2) A $\mathbb{C}$-sesquilinear pairing $\varphi\colon V \times V \to \mathbb{C}$ is called hermitian if $\varphi(v,w) = \overline{\varphi(w,v)}$ for all $v, w \in V$.
(3) We say a pairing φ is positive-definite if $\varphi(v,v) \in \mathbb{R}_{>0}$ for all $v \in V \setminus \{0\}$.
(4) We say a pairing φ is positive-semidefinite if $\varphi(v,v) \in \mathbb{R}_{\geq 0}$ for all $v \in V \setminus \{0\}$.

Example. Let $n \in \mathbb{N}_0$. The standard hermitian pairing on $\mathbb{C}^n$ is given by

$$\begin{array}{rccl} \langle -,- \rangle \colon & \mathbb{C}^n \times \mathbb{C}^n & \to & \mathbb{R} \\ & (v,w) & \mapsto & \sum_{i=1}^{n} v_i \cdot \overline{w}_i. \end{array}$$

This standard pairing on $\mathbb{C}^n$ is evidently positive-definite.

Notation. Given $z = x + y\mathrm{i} \in \mathbb{C}$ with $x, y \in \mathbb{R}$ we write $|z| := \sqrt{x^2 + y^2} = \sqrt{z \cdot \overline{z}}$.

Proposition 0.14. (Cauchy-Schwarz Inequality) Let V be a complex vector space and let

$$\begin{array}{rccl} \varphi \colon & V \times V & \to & \mathbb{R}_{\geq 0} \\ & (v,w) & \mapsto & \varphi(v,w) \end{array}$$

be a hermitian form.

(1) If φ is positive semidefinite, then for any $v, w \in V$ we have

$$|\varphi(v,w)|^2 \leq \varphi(v,v) \cdot \varphi(w,w).$$

(2) Now suppose that φ is positive-definite. In this case equality in (1) holds if and only if v and w are linearly dependent.

Proof. The proof is very similar to the proof of the above Cauchy-Schwarz Inequality 0.14. We leave it to the reader to make the necessary minor modifications. ∎

0.7. **Normed vector spaces.** We continue with another definition from linear algebra.

Definition. Let V be a real vector space. A norm on V is a map $\| - \| \varphi \colon V \to \mathbb{R}_{\geq 0}$ that satisfies the following three properties:

(1) For every $v \in V$ we have $\|v\| = 0 \iff v = 0$.
(2) For every $v \in V$ and $\lambda \in \mathbb{R}$ we have $\|\lambda \cdot v\| = |\lambda| \cdot \|v\|$.
(3) For every $v, w \in V$ we have $\|v + w\| \leq \|v\| + \|w\|$.

Lemma 0.15. Let V be a vector space. If $\langle -,- \rangle \colon V \times V \to \mathbb{R}_{\geq 0}$ is a positive definite $\mathbb{R}$-linear pairing, then the map

$$\begin{array}{rccl} & V \times V & \to & \mathbb{R}_{\geq 0} \\ & v & \mapsto & \|v\| := \sqrt{\langle v, v \rangle} \end{array}$$

is a norm.

Proof. It is straightforward to verify that the first two properties of a norm are satisfied. It remains to prove the third property. Given $v, w \in \mathbb{R}^n$ we see that

$$\begin{array}{rcl} \|v+w\|^2 & = & \langle v+w, v+w \rangle \overset{\text{follows from the } \mathbb{R}\text{-bilinearity of } \langle -,- \rangle}{=\!=\!=} \langle v,v \rangle + \langle v,w \rangle + \langle w,v \rangle + \langle w,w \rangle \overset{\text{since } \langle w,v \rangle = \langle v,w \rangle}{=\!=\!=} \langle v,v \rangle + 2 \cdot \langle v,w \rangle + \langle w,w \rangle \\ & \underset{\text{by the Cauchy-Schwarz Inequality 0.13 we have } \langle v,w \rangle^2 \leq \langle v,v \rangle \cdot \langle w,w \rangle}{\leq} & \langle v,v \rangle + 2 \cdot \sqrt{\langle v,v \rangle \cdot \langle w,w \rangle} + \langle w,w \rangle = \left(\sqrt{\langle v,v \rangle} + \sqrt{\langle w,w \rangle} \right)^2 = (\|v\| + \|w\|)^2. \end{array}$$

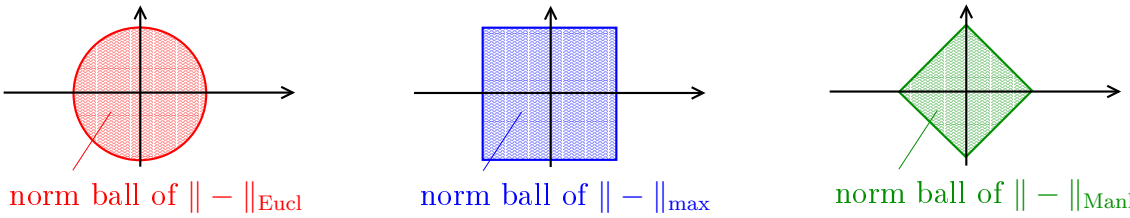
By taking square roots on both sides we obtain that $\|v + w\| \leq \|v| + \|w\|$. ∎

Definition. The standard pairing on $\mathbb{R}^n$ gives rise to the Euclidean norm

$$\begin{array}{rcl} \|-\|_{\text{Eucl}}\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ v = (v_1, \ldots, v_n) & \mapsto & \sqrt{\langle v, v, \rangle} = \sqrt{v_1^2 + \cdots + v_n^2} \end{array}.$$

Usually, when there is no source of confusion, we just write $\|v\|$ instead of $\|v\|_{\text{Eucl}}$.
We now give more examples of norms $\mathbb{R}^n$.

Example. In Exercise 0.12 we will see that the following maps are norms and we will see that for $n \geq 2$ they do *not* arise from a positive definite $\mathbb{R}$-bilinear pairing:



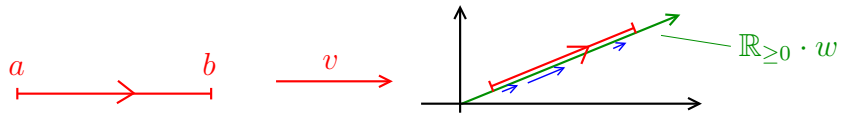
$$\underbrace{\begin{array}{rcl} \|-\|_{\max}\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x_1, \ldots, x_n) & \mapsto & \max\{|x_1|, \ldots, |x_n|\} \end{array}}_{\text{maximum norm}} \quad \text{and} \quad \underbrace{\begin{array}{rcl} \|-\|_{\text{Manh}}\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x_1, \ldots, x_n) & \mapsto & \sum_{i=1}^{n} |x_i|. \end{array}}_{\text{Manhattan norm}}$$

Since the human brain is equipped with a great image processor it is usually helpful to turn an abstract definition into an image. The key to doing so in the present context is given by the following definition.

Definition. Given a norm $\|-\|\colon V \to \mathbb{R}_{\geq 0}$ we define

$$\text{norm ball of } \|-\| \;:=\; \{v \in V \mid \|v\| \leq 1\}.$$

Example. In the figure below we show the norm balls of the Euclidean norm, the maximum norm and the Manhattan norm.



We conclude our sections on norms with the following lemma which we will use on several occasions.

Lemma 0.16. (Integral Inequality Lemma) For every continuous map $v\colon [a,b] \to \mathbb{R}^n$ the following inequality of real numbers holds:

$$\left\| \int_a^b v(t)\, dt \right\| \;\leq\; \int_a^b \|v(t)\|\, dt.$$

Furthermore equality holds if and only if u there exists a $w \in \mathbb{R}^n$ and a map $\lambda\colon [a,b] \to \mathbb{R}_{\geq 0}$ such that for every $t \in [a,b]$ we have $v(t) = \lambda(t) \cdot w$.

Proof. We first show that the inequality holds. We set

$$u \;:=\; \int_a^b v(t)\, dt \quad \in\; \mathbb{R}^n.$$

If $\|u\| = 0$, then there is nothing to show. Thus we might as well assume that $\|u\| > 0$. We obtain the following (in-) equalities:

$$\begin{aligned}
\|u\| \cdot \left\| \int_a^b v(t)\,dt \right\| \;=\; \|u\|^2 \;=\; \langle u, u\rangle \;&=\; \left\langle u, \int_a^b v(t)\,dt \right\rangle \\
&=\; \left\langle (u_1,\dots,u_n), \left(\int_a^b v_1(t)\,dt, \dots, \int_a^b v_n(t)\,dt \right) \right\rangle \\
&=\; \sum_{i=1}^n u_i \cdot \int_a^b v_i(t)\,dt \;=\; \int_a^b \sum_{i=1}^n u_i \cdot v_i(t)\,dt \\
&=\; \int_a^b \langle u, v(t)\rangle\,dt \;\underset{\uparrow}{\leq}\; \int_a^b \|u\| \cdot \|v(t)\|\,dt \;=\; \|u\| \cdot \int_a^b \|v(t)\|\,dt.
\end{aligned}$$

by the Cauchy-Schwarz Inequality 0.12 we know that
for any $x, y \in \mathbb{R}^n$ we have $\langle x, y\rangle \leq \|x\| \cdot \|y\|$

The desired inequality follows from canceling $\|u\|$.

Now we turn to the "furthermore statement". In fact this statement follows from the above considerations together with the "furthermore statement" of Proposition 0.12. We leave it to the reader to fill in the details. ■

0.8. **Metric spaces.** Finally we recall the notion of a metric space which is most likely familiar from an earlier course on real analysis.

Definition. A metric space is a pair (X, d) consisting of a set X and a metric d on X, i.e. a map

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} := \{x \in \mathbb{R} \mid x \geq 0\} \\ (x, y) & \mapsto & d(x, y) \end{array}$$

with the following properties:

(1)		$d(x,y)$	$=$	$0 \iff x = y$	
(2)	for all $x, y \in X$ we have	$d(x,y)$	$=$	$d(y,x)$	(symmetry)
(3)	for all $x, y, z \in X$ we have	$d(x,z)$	$\leq$	$d(x,y) + d(y,z)$	(triangle inequality).

Sometimes we refer to $d(x, y)$ as the distance between x and y.

The following lemma shows that any norm on a vector space V give rise to a metric on V.

Lemma 0.17. Let V be a real vector space and let $\| - \| : V \to \mathbb{R}_{\geq 0}$ be a norm. Then

$$\begin{array}{rcl} V \times V & \to & \mathbb{R}_{\geq 0} \\ (v, w) & \mapsto & d(v, w) := \|v - w\| \end{array}$$

is a metric on V.

Proof. The three properties of a metric follow easily from the three properties of a norm. For example, given $v, w \in V$ we see that

$$d(v,w) \;=\; \|v - w\| \;=\; \|(-1) \cdot (w - v)\| \;\underset{\uparrow}{=}\; |-1| \cdot \|w - v\| \;=\; \|w - v\| \;=\; d(w,v).$$

property (2) of a norm

The other two properties of a metric are verified in a similar fashion. ■

It follows from Lemma 0.17 that the Euclidean norm $\| - \|_{\text{Eucl}}$ gives rise to a metric, called the Euclidean metric. This is perhaps the most frequently used example of a metric.

Definition. Given $x, y \in \mathbb{R}^n$ we set

$$d(x,y) \;:=\; \|x-y\| \quad \text{where} \quad \|z\| \;=\; \|(z_1,\dots,z_n)\| \;:=\; \sqrt{z_1^2+\cdots+z_n^2}\,.$$

We refer to the map

$$\begin{array}{rcl} d\colon \mathbb{R}^n \times \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & d(x,y) \end{array}$$

as the Euclidean metric on $\mathbb{R}^n$.[16]. Usually we consider $\mathbb{R}^n$ as a metric space with respect to this Euclidean metric, unless we say something else.

Of course there are many other examples of metrics. In the following we will see two examples, the first one corresponds to the Manhattan norm and the other one is an example of a metric that does not come from a norm.

Example. Let $n \in \mathbb{R}^n$. We fix a point $P \in \mathbb{R}^n$. Besides the ever-popular Euclidean metric on $\mathbb{R}^n$ we can also consider the following two metrics:

$$\begin{array}{rcl} d_{\text{Manh}}\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ ((x_1,\dots,x_n),(y_1,\dots,y_n)) & \mapsto & \sum_{i=1}^{n} |x_i - y_i| \end{array} \qquad \text{and} \qquad \begin{array}{rcl} d_{\text{SNCF}}\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & \|x-P\| + \|y-P\|. \end{array}$$

The metric d_{Manh} is called the Manhattan metric since it measures the distance between two points if one can go only vertically (avenues) and horizontally (streets). The metric d_{SNCF} is called the SNCF metric since it models the distance in France where every train between two points necessarily has to go through Paris.

In Exercise 0.14 we will see that both maps do indeed form metrics on $\mathbb{R}^n$. Furthermore we will see in Exercise 0.14 that the SNCF-metric does not arise from a norm.

Manhattan metric

SNCF-metric

Of course there are many other examples of metric spaces. The last definition shows that we can define a metric on any set.

Definition. Let X be a set. The map

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & \begin{cases} 0, & \text{if } x = y, \\ 1, & \text{if } x \neq y \end{cases} \end{array}$$

defines a metric on X called the trivial metric.

Exercises for Chapter 0.

[16] It follows from Lemma 0.15 together with Lemma 0.17 that this is indeed a metric on $\mathbb{R}^n$.

Exercise 0.1. Show that for statements (1), (2), (4) and (5) of the Image-Preimage Lemma 0.2 there are indeed examples such that the stated inclusion is indeed a strict inclusion. More precisely:

(a) Give an example of a map $f\colon X \to Y$ and a subset $U \subset X$ such that $U \subsetneq f^{-1}(f(U))$.
(b) Give an example of a map $f\colon X \to Y$ and a subset $V \subset Y$ such that $f(f^{-1}(f(V))) \subsetneq V$.
(c) Give an example of a map $f\colon X \to Y$ and a family $\{U_i\}_{i\in I}$ of subsets of X such that

$$f\Big(\bigcap_{i\in I} U_i\Big) \;\subsetneq\; \bigcap_{i\in I} f(U_i)$$

(d) Give an example of a map $f\colon X \to Y$ and a subset $U \subset X$ such that we have $f(X) \setminus f(U) \subsetneq f(X \setminus U)$.

Exercise 0.2. Let $f\colon X \to Y$ be a map between two sets. Let $A \subset X$ and let $B \subset Y$ be two subsets. Prove the following equivalence of statements:

$$f(A) \subset B \qquad \Longleftrightarrow \qquad A \subset f^{-1}(B).$$

Exercise 0.3. Let $f\colon X \to Y$ be a map between two sets. Let $A \subset X$ and let $B \subset Y$. Show that

$$f(A \cap f^{-1}(B)) \;=\; f(A) \cap B.$$

Exercise 0.4. Let $(V, \leq)$ be a totally ordered set of cardinality $n \in \mathbb{N}$. We equip the set $\{1, \ldots, n\}$ with the usual total order $\leq$. Show that there exists a *unique* order-preserving bijection $\{1, \ldots, n\} \to V$.

Exercise 0.5. Let $f\colon X \to Y$ be a map between two sets. Show that there exist total orders "$\leq_X$" on X and "$\leq_Y$" on Y such that the map f is order-preserving.

Exercise 0.6. Show that there exists an uncountable well-ordered set $(X, \leq)$ such that for every $y \in X$ the set $\{x \in X \,|\, x \leq y\}$ is countable.

Exercise 0.7. We consider $\mathbb{N}$ and $\mathbb{Z}$ with the usual partial order $\leq$.

(a) Does the lexicographically ordered set $\mathbb{N} \times \mathbb{N}$ have the same order type as $\mathbb{N}$?
(b) Does the lexicographically ordered set $\mathbb{Z} \times \mathbb{Z}$ have the same order type as $\mathbb{Z}$?

Exercise 0.8. We consider the half-open interval $[0, 1)$, the set $\mathbb{R}_{\geq 0}$ and the set $\mathbb{N}_0$, each equipped with the usual partial order $\leq$.

(a) Show that the lexicographically ordered set $[0, 1) \times \mathbb{N}_0$ has the same order type as $\mathbb{R}_{\geq 0}$.
(b) Show that the lexicographically ordered set $\mathbb{N}_0 \times [0, 1)$ does not have the same order type as $\mathbb{R}_{\geq 0}$.

Exercise 0.9.

(a) Let $n \in \mathbb{N}$. Show that $\mathbb{R}$ and $\mathbb{R}^n$ have the same cardinality.
(b) Show that $\mathbb{R}$ and $\mathbb{R}^{\mathbb{N}}$ have the same cardinality.

Exercise 0.10. Show that $\mathcal{P}(\mathbb{N})$ and $\mathbb{R}$ have the same cardinalitiy.
Hint. Use the Bernstein-Schröder Theorem 0.11.

Exercise 0.11. Let X be a set and let $\mathcal{P}(X)$ be the power set. Given $A, B \in \mathcal{P}(X)$ we define the symmetric difference

$$A \triangle B \;:=\; (A \setminus B) \cup (B \setminus A).$$

What axioms of a ring does $(\mathcal{P}(X), \triangle, \cap)$ satisfy?

Exercise 0.12. We consider the following two maps:

$$\begin{array}{rcl} \|-\|_{\max}\colon \mathbb{R}^k n \to & \mathbb{R}_{\geq 0} & \\ (x_1,\ldots,x_n) & \mapsto & \max\{|x_1|,\ldots,|x_n|\} \end{array} \quad \text{and} \quad \begin{array}{rcl} \|-\|_{\text{Manh}}\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x_1,\ldots,x_n) & \mapsto & \sum_{i=1}^{n} |\, x_i|. \end{array}$$

(a) Show that both maps define norms on $\mathbb{R}$.
(b) We now suppose that $n \geq 2$. Show that the norms do not arise from a positive definite $\mathbb{R}$-bilinear pairing, i.e. show that there is no positive-definite $\mathbb{R}$-bilinear pairing $\varphi\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ such that for all $v \in \mathbb{R}^n$ we have $\|v\|_{\max} = \sqrt{\varphi(v,v)}$ and similarly for $\|-\|_{\text{Manh}}$.

Exercise 0.13. Let V be a real vector space Recall that given a norm $n|\colon V \to \mathbb{R}_{\geq 0}$ its norm ball is defined as $B(n) := \{v \in V \,|\, n(v) \leq 1\}$. Show that a norm is determined by its norm ball.

Exercise 0.14. Let $n \in \mathbb{N}$. We fix a point $P \in \mathbb{R}^n$ and we consider the maps

$$\begin{array}{rcl} d_M\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ ((x_1,\ldots,x_n),(y_1,\ldots,y_n)) & \mapsto & \sum_{i=1}^{n} |x_i - y_i| \end{array} \quad \text{and} \quad \begin{array}{rcl} d_S\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & \|x-P\| + \|y-P\| \end{array}$$

which on page 104 we called the Manhattan metric respectively the SNCF metric.

(a) Show that both maps define metrics on $\mathbb{R}^n$.
(b) Show that there is no norm $\|-\|$ on $\mathbb{R}^n$ such that $d_S(v,w) = \|v-w\|$ for all $v, w \in \mathbb{R}^n$.

1. Topological spaces: basic definitions and properties

In this chapter we give the definition of topological spaces, we provide many examples and we discuss a long list of basic properties. Many of these results might well be familiar to the reader. Nonetheless we attempt to give a fairly complete list of basic statements so that later on we have a firm common foundation to work with.

1.1. Topological spaces.

In this section we give the definition of a topological space and we discuss some very basic definitions and statements. Presumably most readers will have seen this material. Throughout these lecture notes, in the proofs, we strive for giving precise references to earlier results. The main exceptions are the lemmas from this Section 1.1. Usually we use them without referring to them explicitly.
The following definition will keep us occupied for the rest of these notes.

Definition.

(1) Let X be a set. A topology on X is a subset $\mathcal{T}$ of the power set $\mathcal{P}(X)$[17] with the following properties:
   (a) the empty set and the entire set X lie in $\mathcal{T}$,
   (b) the intersection of *finitely many* sets in $\mathcal{T}$ is again a set in $\mathcal{T}$,
   (c) the union of *arbitrarily many* sets in $\mathcal{T}$ is again a set in $\mathcal{T}$.
   The sets in $\mathcal{T}$ are called open with respect to $\mathcal{T}$. If $\mathcal{T}$ is understood from the context, then we just say open.
(2) A topological space is a pair $(X, \mathcal{T})$, where X is a set and $\mathcal{T}$ is a topology on X.

Remark.

(1) Usually we suppress the topology from the notation, e.g. usually we just write "let X be a topological space".
(2) If X is a topological space, then the properties of a topology imply immediately the following three statements:
   (a) the empty set and the entire set X are open,
   (b) the intersection of *finitely many* open sets is again open,
   (c) the union of *arbitrarily many* open sets is again open.
(3) It took mathematicians several decades to settle on the above definition, the long and tortuous history of the definition of a topological space is presented in [**Moo2008**].

We start out with some very basic examples of topological spaces.

Examples.

(1) Let X be a set, then $\mathcal{T} = \{\varnothing, X\}$ is a topology on X. This topology is sometimes called the trivial topology on X.
(2) Let X be a set. Then $\mathcal{T} = \mathcal{P}(X)$ is also a topology on X. In other words, $\mathcal{T}$ is the topology such that every subset of X is open. This topology is usually referred to as the discrete topology on X. Sometimes we say that a topological space is discrete, if the topology is indeed the discrete topology.

[17] In more humble words, $\mathcal{T}$ is a set of subsets of X.

(3) Let X be a set.
   (a) We define $\mathcal{T} \subset \mathcal{P}(X)$ as follows:

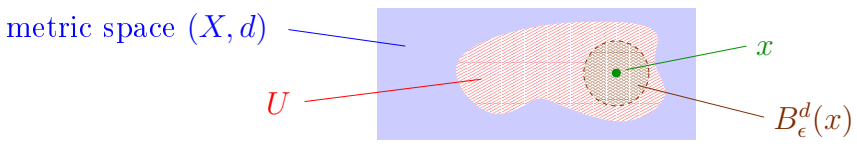
$$U \in \mathcal{T} \iff \text{either } U = \varnothing \text{ or } U \text{ is the complement of a finite subset of } X.$$

   It follows easily from de Morgan's Laws 0.1, that $\mathcal{T}$ is a topology on X. We refer to it as the cofinite topology. Sometimes this topology is also called the finite-complement topology.
   (b) Similarly we can define the cocountable topology $\mathcal{T} \subset \mathcal{P}(X)$ as follows:

$$U \in \mathcal{T} \iff \text{either } U = \varnothing \text{ or } U \text{ is the complement of a countable subset of } X.$$

   It follows from de Morgan's Laws together with the Countability Lemma 0.8 that this is a topology on X.
(4) Let X be the empty set. Together with $\mathcal{T} = \{\varnothing\}$ this is a topological space, called the empty topological space. It is a never ending source of counterexamples to carelessly formulated statements.
(5) (a) Let $X = \{*\}$ be a set with a single element $*$. It follows immediately from the definition of a topology there is a unique topology on $X = \{*\}$, namely the topology given by $\mathcal{T} = \{\varnothing, \{*\}\}$. Together with the empty set this is the only case where the topology is already determined by the set.
   (b) Given a set $X = \{a, b\}$ with two elements it is straightforward to see that there exist four distinct topologies on X. More precisely, there is the trivial and the discrete topology, and there are the two topologies where precisely one of the subsets $\{a\}$ and $\{b\}$ is open. The latter two topologies correspond to the Sierpiński space which we will discuss in greater detail in Exercise 2.22.
   Not surprisingly the number of topologies on a finite set grows rapidly with the cardinality of the set, we refer to **[KR1970, BMc2002]** for details.

Recall that on page 103 we introduced the notion of a metric space. We will now see that metric spaces give rise to topological spaces. To do so we will need the following notation.



Notation. Let (X, d) be a metric space. Given $x \in X$ and $r \in \mathbb{R}$ we write

$$B_r^d(x) := \{y \in X \mid d(x, y) < r\}$$

If the metric d is understood from the context, then sometimes we drop it from the notation.

The following lemma shows that metric spaces give rise to topological spaces.

Lemma 1.1. (Metric-Topology Lemma) Let (X, d) be a metric space. A subset U of X is called open if for every $x \in U$ there exists an $\epsilon > 0$ such that $B_\epsilon^d(x)$ is contained in U. These open sets define a topology on X.

Proof.

(1) It is clear that the empty set and X itself are open.

(2) Suppose $U_1, \dots, U_k$ are open subsets of X. We need to show that the intersection $U_1 \cap U_2 \cap \dots \cap U_k$ is also open. Thus let $x \in U_1 \cap U_2 \cap \dots \cap U_k$. For each $i \in \{1, \dots, k\}$ there exists an $\epsilon_i > 0$ with $B_{\epsilon_i}(x) \subset U_i$. We set $\epsilon := \min\{\epsilon_1, \dots, \epsilon_k\}$. Then

$$\begin{array}{ccccc} B_\epsilon(x) & \subset & B_{\epsilon_1}(x) \cap \dots \cap B_{\epsilon_k}(x) & \subset & U_1 \cap U_2 \cap \dots \cap U_k. \\ & \uparrow & & \uparrow & \\ & \text{since } \epsilon \leq \epsilon_i & & \text{since } B_{\epsilon_i}(x) \subset U_i & \end{array}$$

(3) Let $\{U_i\}_{i \in I}$ be a family of open sets. We want to show that $\bigcup_{i \in I} U_i$ is also open. Thus let $x \in \bigcup_{i \in I} U_i$. This means that there exists an $i \in I$ with $x \in U_i$. Since U_i is open there exists an $\epsilon > 0$ with $B_\epsilon(x) \subset U_i$. Thus we have

$$B_\epsilon(x) \subset U_i \subset \bigcup_{i \in I} U_i.$$ ■

Definition. Let (X, d) be a metric space.

(1) We refer to the topology introduced in Metric-Topology Lemma 1.1 as the metric topology.
(2) Unless we say something else we always view (X, d) with the metric topology.

Example. Let X be a set and let $d\colon X \times X \to \mathbb{R}_{\geq 0}$ be the trivial metric that we introduced on page 104. It is straightforward to see that the corresponding metric topology is the discrete topology.

Convention. Let $n \in \mathbb{N}$.

(1) Unless we say something else we consider $\mathbb{R}^n$ as a metric space with the Euclidean metric given by

$$d(x, y) := \|x - y\| \quad \text{where} \quad \|z\| = \|(z_1, \dots, z_n)\| := \sqrt{z_1^2 + \dots + z_n^2}.$$

Furthermore, unless we say something else we equip $\mathbb{C}^n$ with the metric given by[18]

$$d(x, y) := \|x - y\| \quad \text{where} \quad \|z\| = \|(z_1, \dots, z_n)\| := \sqrt{z_1 \cdot \overline{z_1} + \dots + z_n \cdot \overline{z_n}}.$$

(2) In particular, unless we say explicitly otherwise, we equip $\mathbb{R}^n$ with the topology arising from the Euclidean metric and we $\mathbb{C}^n$ with the topology arising from the above metric. We call these the Euclidean topologies on $\mathbb{R}^n$ and $\mathbb{C}^n$.

We have now seen that metrics give rise to topologies. In general different metrics will give rise to different topologies, for example the Euclidean metric and the trivial metric on $\mathbb{R}^n$ give rise to wildly different topologies. But different metrics might also give rise to the same topology. This leads us to the following definition.

Definition. Let X be a set. We say that two metrics d and e on X are equivalent if they give rise to the same topology.

[18] It follows from the observation that $(x + \mathrm{i}y) \cdot \overline{x + \mathrm{i}y} = (x + \mathrm{i}y) \cdot (x - \mathrm{i}y) = x^2 + y^2$ that the metric on $\mathbb{C}^n$ is the Euclidean metric on $\mathbb{C}^n = \mathbb{R}^{2n}$ in slight disguise. In particular it is indeed a metric.

Lemma 1.2. (Equivalent Metric Lemma) Let X be a set and suppose that we have two metrics d and e on X such that the following two conditions are satisfied:

(1) For each $x \in X$ and each $\mu > 0$ there exists a $\nu > 0$ with $B^e_\nu(x) \subset B^d_\mu(x)$.

(2) For each $x \in X$ and each $\nu > 0$ there exists a $\mu > 0$ with $B^d_\mu(x) \subset B^e_\nu(x)$.

Then the two metrics are equivalent.

Example. Let $n \in \mathbb{R}^n$ and let $P \in \mathbb{R}^n$. On page 104 we introduced the following metrics:

$$\begin{array}{rcl} d_{\text{Manh}} \colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ ((x_1,\ldots,x_n),(y_1,\ldots,y_n)) & \mapsto & \sum_{i=1}^{n} |x_i - y_i| \end{array} \qquad \text{and} \qquad \begin{array}{rcl} d_{\text{SNCF}} \colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & \|x-P\| + \|y-P\|. \end{array}$$

In Exercise 1.7 we will see that the Manhattan metric is equivalent to the Euclidean metric and we will see that the SNCF-metric is not equivalent to the Euclidean metric.

Proof. We need to show that a set $U \subset X$ which is open with respect to d is open with respect to e and vice versa. So suppose that U is open with respect to d. We need to show that U is open with respect to e, i.e. we need to show that for each $x \in U$ there exists a $\nu > 0$ with $B^e_\nu(x) \subset U$. Thus let $x \in U$. Since U is open with respect to d there exists a $\mu > 0$ such that $B^d_\mu(x) \subset U$. By hypothesis there exists a $\nu > 0$ such that $B^e_\nu(x) \subset B^d_\mu(x)$. This ν has the desired property. The same argument evidently also works with the roles of d and e reversed. ■

Metric spaces are popular source of examples of topological spaces. This leads us to the following definition.

Definition. A topological space X is called metrizable if there exists a metric d on X such that the given topology agrees with the topology coming from d.

Even though many interesting topological spaces are indeed metrizable, we will see in Exercise 1.1 that a finite topological space is metrizable if and only if the topology is discrete.

1.2. Basic definitions.

We proceed with the next definition.

Definition. Let X be a topological space. We say a subset A of X is closed if the complement $X \setminus A$ is open.

Example. By an *interval* we mean any subset of $\mathbb{R}$ of the form

$$\begin{array}{rcll} (a,b) & := & \{x \in \mid a < x < b\} & \text{where } a,b \in \mathbb{R} \cup \{\pm\infty\} \\ (a,b] & := & \{x \in \mid a < x \leq b\} & \text{where } a \in \mathbb{R} \cup \{-\infty\} \text{ and } b \in \mathbb{R} \text{ with } a < b \\ [a,b) & := & \{x \in \mid a \leq x < b\} & \text{where } a \in \mathbb{R} \text{ and } b \in \mathbb{R} \cup \{\infty\} \text{ with } a < b \\ [a,b] & := & \{x \in \mid a \leq x \leq b\} & \text{where } a,b \in \mathbb{R} \text{ with } a \leq b. \end{array}$$

The intervals of the form (a,b), $(-\infty,b)$ and (a,∞) with $a,b \in \mathbb{R}$ are open subsets of $\mathbb{R}$ and the intervals of the form $[a,b]$, $(-\infty,b]$ and $[a,\infty)$ with $a,b \in \mathbb{R}$ are closed subsets of $\mathbb{R}$. Note that $\varnothing$ and $\mathbb{R}$ are also intervals, they are both open and closed in $\mathbb{R}$.

The following lemma mirrors the remark on page 107.

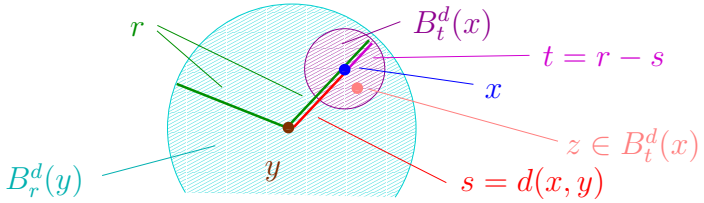
Lemma 1.3. Let X be a topological space.

(1) the empty set and the entire set X are closed,

(2) the intersection of *arbitrarily many* closed sets is again closed,
(3) the union of *finitely many* closed sets is again closed.

Proof. The lemma is an immediate consequence of the definition of a topology and de Morgan's Laws 0.1. ■

Remark. Let X be a set. If we specify what we mean by closed sets such that the three properties of Lemma 1.3 are satisfied, then it follows once again from de Morgan's Laws that the complements of the closed sets define a topology.



The following proposition gives us important examples of closed and open subsets.

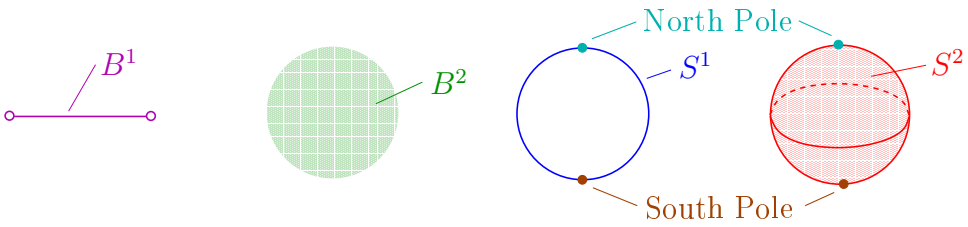
Proposition 1.4. Let (X, d) be a metric space, let $y \in X$ and let $r \in \mathbb{R}$.
(1) the set $B_r^d(y) := \{x \in X \mid d(x, y) < r\}$ is open in X,
(2) the set $\overline{B}_r^d(y) := \{x \in X \mid d(x, y) \leq r\}$ is closed in X,
(3) the set $S_r^d(y) := \{x \in X \mid d(x, y) = r\}$ is closed in X.

Proof. Let (X, d) be a metric space, let $y \in X$ and let $r \in \mathbb{R}$.
(1) Let $x \in B_r^d(y)$. We set $s := d(x, y)$. By definition of $B_r^d(y)$ we have $s < r$. We set $t := r - s$. Since $t > 0$ it suffices to show that $B_t^d(x) \subset B_r^d(y)$. Thus let $z \in B_t^d(x)$. We see that

$$d(y, z) \underset{\substack{\uparrow \\ \text{triangle inequality}}}{\leq} d(x, y) + d(x, z) < s + t = r.$$

Thus we see that $z \in B_r^d(y)$, which is what we needed to show.

(2) Almost the same argument as in (1) shows that $X \setminus \overline{B}_r(y)$ is open, which implies that $\overline{B}_r(y)$ is closed.
(3) We have $X \setminus S_r^d(y) = B_r^d(y) \cup (X \setminus \overline{B}_r(y))$. By (1) and (2) we see that $X \setminus S_r^d(y)$ is the union of two open sets, thus by the third property of a topological space we see that $X \setminus S_r^d(y)$ is open, thus $S_r^d(y)$ is indeed closed. ■



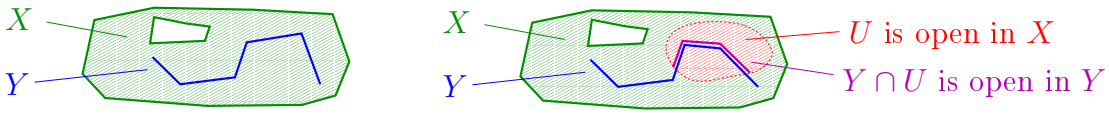
The most frequent application of Proposition 1.4 is to the metric space $\mathbb{R}^n$. Thus we introduce the following notation.

Notation. Let $n \in \mathbb{N}_0$. Given $y \in \mathbb{R}^n$ and $r \in \mathbb{R}$ we write[19] [20]

$$\begin{array}{rcll} B_r^n(y) & := & \{x \in \mathbb{R}^n \mid \|x - y\| < r\} & \text{called open } n\text{-ball} \\ \overline{B}_r^n(y) & := & \{x \in \mathbb{R}^n \mid \|x - y\| \leq r\} & \text{called closed } n\text{-ball} \\ S_r^{n-1}(y) & := & \{x \in \mathbb{R}^n \mid \|x - y\| = r\} & \text{called } (n-1)\text{-sphere.} \end{array}$$

We adopt the following conventions:
(1) A 2-ball is often called a disk and a 1-sphere is often referred to as a circle.
(2) If the parameter n is clear from the context we sometimes drop it from the notation.

(3) If $y = 0$, then we drop y from the notation and if $r = 1$, then we drop r from the notation.
(4) Sometimes we write rB^n instead of $B^n_r(0)$ and sometimes we write $r\overline{B}^n$ instead of $\overline{B}^n_r(0)$.
(5) We refer to the point $(0, \ldots, 0, 1) \in S^n = \{x \in \mathbb{R}^{n+1} \,|\, \|x\| = 1\}$ as the North Pole of S^n and we refer to the point $(0, \ldots, 0, -1) \in S^n = \{x \in \mathbb{R}^{n+1} \,|\, \|x\| = 1\}$ as the South Pole of S^n.



1.3. **The subspace topology.** The next definition gives us a rich source of new examples of topological spaces.

Definition. Let $(X, \mathcal{T})$ be a topological space and let $Y \subset X$ be a subset. It follows almost immediately from Lemma 0.3 that

$$\mathcal{S} := \{Y \cap U \,|\, U \in \mathcal{T}\}$$

is a topology on Y. We refer to $\mathcal{S}$ as the subspace topology on Y induced by Y.

Convention.
(1) Unless we say something else, we consider each subset Y of $\mathbb{R}^n$ always as a topological space with respect to the subspace topology.
(2) Let $(X, \mathcal{T})$ be a topological space and let $Y \subset X$ be a subset. If Y is indeed equipped with the subspace topology, then sometimes we refer to Y as a subspace of X.

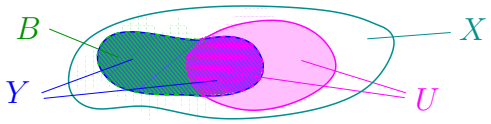
We continue with the following useful lemma.

Lemma 1.5. (Neighborhood Openness Criterion) Let X be a topological space and let $Y \subset X$ be a subset. We equip Y with the subspace topology.

(1) $V \subset Y$ is open in $Y \iff$ there exists an open subset $U \subset X$ with $V = U \cap Y$
(2) $B \subset Y$ is closed in $Y \iff$ there exists a closed subset $A \subset X$ with $B = A \cap Y$.

Proof. The first statement is just a reformulation of the definition of the subspace topology. We turn to the proof of the second statement. Now let $B \subset Y$. Elementary set theory

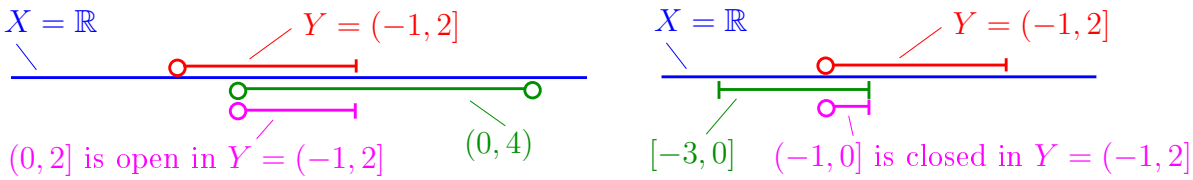
[19] These definitions also make sense for $r < 0$, in that case all of the sets are the empty set. Also note that for $n = 0$ we obtain that $S^{n-1}_r(y) = S^{-1}_r(y) = \varnothing$.
[20] Of course one cannot easily sketch the 3-sphere S^3. But it is worth pointing out that in some form it has been around for a while. In [**Lip2014**, Chapter 2] and [**Petn1979**] the argument is made that the universe in Dante's Divina Commedia is precisely the 3-sphere.



shows that for any subset U of X we have

$$(*) \qquad U \cap Y = Y \setminus B \iff Y \setminus (U \cap Y) = B \iff (X \setminus U) \cap Y = B.$$

Now the second statement is basically obvious. Indeed, we have



$$\begin{aligned} B \text{ is closed in } Y &\iff Y \setminus B \text{ is open in } Y \\ &\iff \text{there exists } U \subset Y \text{ open with } U \cap Y = Y \setminus B \\ &\underset{\text{by } (*)}{\iff} \text{there exists } U \subset Y \text{ open with } (X \setminus U) \cap Y = B \\ &\iff \text{there exists } A \subset Y \text{ closed with } A \cap Y = B. \end{aligned}$$

■

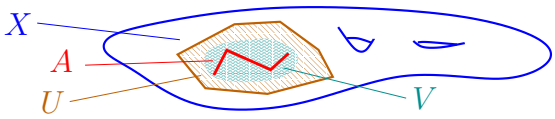
Example. We consider $Y = (-1, 2]$ equipped with the subspace topology coming from $\mathbb{R}$.

(1) The Neighborhood Openness Criterion 1.5 (1) implies that $V = (0, 2]$ is an open subset of Y, since we can write $V = (0, 4) \cap Y$ and $(0, 4)$ is an open subset of $\mathbb{R}$.
(2) The Neighborhood Openness Criterion 1.5 (2) implies that $B = (-1, 0]$ is a closed subset of Y, since we can write $B = [-3, 0] \cap Y$ and $[-3, 0]$ is a closed subset of $\mathbb{R}$.

We conclude this short discussion of the subspace topology with the following lemma which subconsciously gets used all the time.

Lemma 1.6. Let X be a topology space and let $Z \subset Y \subset X$ be two subsets. The following two topologies are the same:

(1) The subspace topology on Z induced by X.
(2) The subspace topology on Z induced by the subspace topology on Y, which is in turn induced by X.



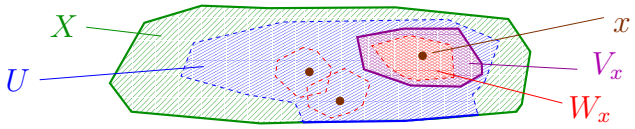
Proof. This lemma follows almost immediately from the definitions. ■

We continue with the next basic definition.

Definition. Let X be a topological space.

(1) Let $A \subset X$ be a subset. We say $U \subset X$ is a neighborhood of A if there exists an open set V such that $A \subset V \subset U$. We say U is an open neighborhood of A, if U is furthermore open. This definition is illustrated in the figure below.
(2) An (open) neighborhood of a point $x \in X$ is an (open) neighborhood of $\{x\}$.

Example. If $X = \mathbb{R}$ and $A = [0, 2)$, then $U = (-1, 3]$ and $V = (-2, \infty)$ are neighborhoods of A in X.



The following lemma gives a useful criterion for showing that a given subset is open.

Lemma 1.7. (JH-Lemma[21]) Let X be a topological space and let $U \subset X$ be a subset. If for every $x \in U$ there exists a neighborhood V of x that is contained in U, then U is open.

Proof. Let X be a topological space and let $U \subset X$ be a subset. Suppose that for every $x \in U$ there exists a neighborhood V_x of x that is contained in U. By definition of a neighborhood there exists for each $x \in U$ an open subset W_x with $x \in W_x \subset V_x$. We see that

$$U = \bigcup_{x \in U} \{x\} \subset \bigcup_{x \in U} W_x \underset{\text{since each } W_x \text{ is contained in } U}{\subset} U.$$

It follows that $U = \bigcup_{x \in U} W_x$, i.e. U is the union of open subsets of X, thus by the third property of a topology, U itself is open. ■

1.4. **Covers of topological spaces.** On many occasions it will be useful to "break" a topological space into smaller pieces. This leads us to the following definition.

Definition. Let X be a topological space.

(1) A cover[22] of a subset $A \subset X$ is a family[23] $\{U_i\}_{i \in I}$ of subsets of X with $A \subset \bigcup_{i \in I} U_i$.
(2) We say a cover $\{U_i\}_{i \in I}$ is open if each U_i is open. Similarly we define a closed cover.
(3) We say a cover $\{U_i\}_{i \in I}$ is finite if I is finite. Otherwise we say that the cover is infinite.
(4) We say a family $\{U_i\}_{i \in I}$ of subsets is locally finite if each $x \in X$ admits an open neighborhood W such that $\{i \in I \,|\, U_i \cap W \neq \varnothing\}$ is finite.

Example. In the figure below we sketch on the right a closed cover $\{U_i\}_{i \in I}$ of $X = \mathbb{R}^2$ which has the property that each $x \in X$ is contained in only finitely many U_i, but which nonetheless fails to be locally finite.

The following lemma is crucial for many arguments.

[21] A student, let's call him JH, pointed out to me in an earlier version of these notes, that I was implicitly frequently using the statement of this lemma.
[23] What we call a "cover" is often also called a "covering". We reserve the name "covering" for a completely different concept that we will introduce on page 1067.
[23] Recall that according to the definition on page 86 a family of subsets of a given set X consists of a set I and a map $f\colon I \to \mathcal{P}(X)$. We also recall the convention from page 86 which says that we will view any subset $\mathcal{U} \subset \mathcal{P}(X)$ as a family of subsets of X via the index set $I = \mathcal{U}$ and the map $I = \mathcal{U} \to \mathcal{P}(X)$ given by $U \mapsto U$.

locally finite closed cover of $X = \mathbb{R}^2$ not locally finite

Lemma 1.8. Let X be a topological space and let M be a subset of X.

(1) Let $\{U_i\}_{i\in I}$ be an open cover of X. The following two statements hold:
   (a) M is open if and only if each intersection $M \cap U_i$ is open in U_i,
   (b) M is closed if and only if each intersection $M \cap U_i$ is closed in U_i.

(2) Let $\{A_i\}_{i\in I}$ be a locally finite closed cover of X. (In most applications we will deal with a finite closed cover.) The following two statements hold:
   (a) M is open if and only if each intersection $M \cap A_i$ is open in A_i,
   (b) M is closed if and only if each intersection $M \cap A_i$ is closed in A_i.

Example. Let X be a topological space and let $\{A_i\}_{i\in I}$ be a family of closed subsets of X. If the family is locally finite, then it follows from Lemma 1.8 (2b) together with Lemma 1.3 (2) that $\bigcup\limits_{i\in I} A_i$ is also a closed subset of X.

Remark. Note that in Lemma 1.8 we allow an arbitrary family of open subsets but we only allow a finite family of closed subsets. One can easily see that this restriction is necessary. For example, consider $X = \mathbb{R}$ and the infinite family $\{A_i\}_{i\in I}$ of closed subsets of $X = \mathbb{R}$ given by all subsets consisting of a single point. Let $M \subset \mathbb{R}$ be a subset. For each $i \in I$ the intersection $M \cap A_i$ is either the empty set or all of A_i, in particular the intersection $M \cap A_i$ is closed in A_i. But of course there is no reason why M should be a closed subset of $\mathbb{R}$.

Proof. Let X be a topological space and let M be a subset of X.

(1) Let $\{U_i\}_{i\in I}$ be an open cover of X. The "only if"-directions of (a) and (b) are an immediate consequence of the Neighborhood Openness Criterion 1.5 (1). It remains to prove the "if"-directions.

   (a) Suppose that for every $i \in I$ the intersection $M \cap U_i$ is an open subset of U_i. By definition of the subspace topology this means that for each $i \in I$ there exists an open subset Z_i of X with $Z_i \cap U_i = M \cap U_i$. We have

$$M \underset{\substack{\uparrow \\ \text{since } \bigcup_{i\in I} U_i = X}}{=} \bigcup_{i\in I} (M \cap U_i) = \bigcup_{i\in I} \overbrace{(Z_i \cap U_i)}^{\text{intersection of open subsets of } X\text{, hence open in } X} \underset{\substack{\uparrow \\ \text{union of open subsets, hence open}}}{=} \text{open subset of } X.$$

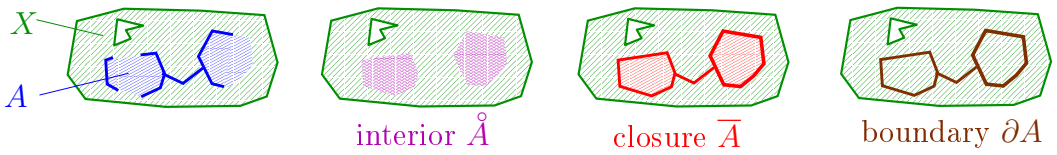
   (b) Now suppose that each intersection $M \cap U_i$ is closed in U_i. In other words, each set $U_i \setminus (M \cap U_i)$ is open in U_i. Since $(X \setminus M) \cap U_i = U_i \setminus (M \cap U_i)$ we obtain from (a) that $X \setminus M$ is open in X. In other words, M is closed in X.

(2) First note that, as in (1) it remains to prove the "if"-directions.

(b) First we deal with the case that we are given a finite closed cover $\{A_i\}_{i=1,\dots,m}$ of X such that for each i the intersection $M \cap A_i$ is a closed subset of A_i. It follows from the Neighborhood Openness Criterion 1.5 (2) that for each $i \in \{1, \dots, m\}$ there exists a closed subset Z_i of X with $Z_i \cap A_i = M \cap A_i$. We have

$$M \underset{\substack{\uparrow \\ \text{since } A_1 \cup \dots \cup A_m = X}}{=} \bigcup_{i=1}^{m} (M \cap A_i) = \bigcup_{i=1}^{m} \overbrace{(Z_i \cap A_i)}^{\substack{\text{intersection of closed subsets of } X, \text{ hence closed in } X}} \underset{\substack{\uparrow \\ \text{union of finitely many closed subsets, hence closed}}}{=} \text{closed subset of } X$$

Now suppose that we are given a locally finite closed cover $\{B_i\}_{i \in I}$ of X such that for each $i \in I$ the intersection $M \cap B_i$ is a closed subset of B_i. Since the cover is locally finite there exists for each $x \in X$ an open neighborhood W_x such that $I_x := \{i \in I \,|\, W_x \cap B_i \neq \varnothing\}$ is finite. Since $\{W_x \cap B_i\}_{i \in I_x}$ is a finite closed cover of W_x we obtain from the above that $M \cap W_x$ is closed. But since $\{W_x\}_{x \in X}$ is an open cover of X we obtain from (1b) that M is a closed subset of X.



(a) As in (1) we can reduce the proof of (a) to the proof of (b). ■

1.5. The interior and the closure of a subset.

Definition. Let X be a topological space and let A be a subset of X. We make the following two definitions:[24]

$$\text{interior } \mathring{A} := \begin{array}{c}\text{union of all open sets of } X \\ \text{that are contained in } A\end{array} \qquad \text{closure } \overline{A} := \begin{array}{c}\text{intersection of all closed sets} \\ \text{of } X \text{ that contain } A\end{array}$$

Sometimes, to avoid confusion, we will also write $\operatorname{int}(A)$ for the interior of a subset A. Furthermore we define the boundary of A in X as $\partial A := \overline{A} \setminus \mathring{A}$.

In the following we will state general properties of the interior, the closure and the boundary of a subset. Evidently the point is not to memorize the following lemmas. Instead they are meant as a resource to turn to, when one is dealing with these objects. Therefore it is warmly recommended to move on to the next section and to return to the present section when the need arises.

Lemma 1.9. (Interior-Closure Lemma) Let X be a topological space and let A be a subset of X.

(1) The interior $\mathring{A}$ is an open subset of X.
(2) The closure $\overline{A}$ of A is a closed subset of X.
(3) We have $\mathring{A} \subset A \subset \overline{A}$.
(4) A is open $\iff \mathring{A} = A$.
(5) A is closed $\iff \overline{A} = A$.
(6) We have $\mathring{A} = A \setminus \partial A$ and $\overline{A} = A \cup \partial A$.

(7) If we set $B := X \setminus A$, then the following statements hold:

$$\begin{array}{lrcl} \text{(a)} & \overline{B} & = & X \setminus \mathring{A}, \\ \text{(b)} & \mathring{B} & = & X \setminus \overline{A}, \\ \text{(c)} & \partial B & = & \partial A. \end{array}$$

Proof.

(1) The union of arbitrarily many open sets is, by definition of a topology, again an open set. Thus the interior $\mathring{A}$ is an open subset of X.

(2) In Lemma 1.3 we saw that the intersection of arbitrarily many closed sets is again a closed set. It follows immediately that the closure $\overline{A}$ is a closed subset of X.

(3) This statement follows immediately from the definitions.

(4) The "$\Leftarrow$"-statement follows immediately from (1). We turn the proof of the "$\Rightarrow$"-statement. Given any subset $A \subset X$ we always have $\mathring{A} \subset A$. If A is open, then by definition we also have $A \subset \mathring{A}$. Thus we see that $\mathring{A} = A$.

(5) The "$\Leftarrow$"-statement follows immediately from (2). We turn the proof of the "$\Rightarrow$"-statement. Given any subset $A \subset X$ we always have $A \subset \overline{A}$. If A is closed, then by definition we also have $\overline{A} \subset A$. Thus we see that $\overline{A} = A$.

(6) We note that:

$$\begin{array}{rcccccl} A \setminus \partial A & = & A \setminus (\overline{A} \setminus \mathring{A}) & = & A \setminus (A \setminus \mathring{A}) & = & \mathring{A}. \\ & & \uparrow & & \uparrow & & \\ & & \text{definition of } \partial A & & \text{since } \mathring{A} \subset A \subset \overline{A} & & \\ & & \downarrow & & \downarrow & & \\ \text{and} \quad A \cup \partial A & = & A \cup (\overline{A} \setminus \mathring{A}) & = & \overline{A}. & & \end{array}$$

(7) We set $B := X \setminus A$. First we prove (a):

$$\overline{B} \overset{\text{definition of closure}}{\downarrow} = \bigcap_{\substack{Y \subset X \text{ closed} \\ \text{with } B \subset Y}} Y \overset{\text{substitution } U = X \setminus Y}{\downarrow} = \bigcap_{\substack{U \subset X \text{ open} \\ \text{with } U \subset A}} (X \setminus U) \overset{\text{de Morgan's Laws 0.1}}{\downarrow} = X \setminus \bigcup_{\substack{U \subset X \text{ open} \\ \text{with } U \subset A}} U \overset{\text{definition of interior}}{\downarrow} = X \setminus \text{interior of } A.$$

Next note that (b) is an immediate consequence of (a). Finally note that (c) is an immediate consequence of (a) and (b). ■

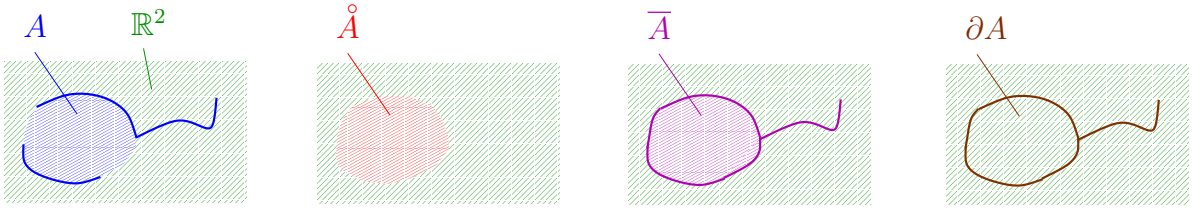
The above definition of the interior and the closure of a subset is succinct and precise. But just by using the definition it is perhaps difficult to find the interior and the closure of a given subset of a topological space. In many situations the following lemma takes care of that difficulty.

Lemma 1.10. Let X be a topological space and let A be a subset of X. We have the following three equalities:

$$\begin{array}{lrcl} (1) & \mathring{A} & = & \{x \in A \mid \text{there exists a neighborhood } U \text{ of } x \text{ that is contained in } A\} \\ (2) & \overline{A} & = & \{x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A\} \\ (3) & \partial A & = & \{x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A \\ & & & \qquad \text{and one point that does not lie in } A\} \end{array}$$

The same statements also hold with "neighborhood" replaced by "open neighborhood".

Proof. The proof of the lemma is Exercise 1.6. ■



Examples.

(1) We consider the topological space $X = \mathbb{R}$ and the subset $A = [-1, 2)$. Using Lemma 1.10 one can easily see that the interior of A is the open interval $(-1, 2)$ and that the closure of A is the closed interval $[-1, 2]$. Furthermore $\partial A = \{-1, 2\}$.

(2) Let $x \in \mathbb{R}^n$ and $r \in \mathbb{R}$. We view $B_r^n(x)$, $\overline{B}_r^n(x)$ and $S_r^{n-1}(x)$ as subsets of $\mathbb{R}^n$. Using Lemma 1.10 one can show fairly easily that

$$\overline{B_r^n(x)} = \overline{B}_r^n(x), \quad \operatorname{int}(\overline{B}_r^n(x)) = B_n^r(x), \quad \partial\overline{B}_r^n(x) = \partial B_r^n(x) = \partial S_r^{n-1}(x) = S_r^{n-1}(x).$$

(3) In the figure below we show a subset of $\mathbb{R}^2$, and we also show its interior $\mathring{A}$, its closure $\overline{A}$ and its boundary ∂A.

(4) It is rather unfortunate that the notations $\mathring{A}$, $\overline{A}$ and ∂A hide the role of X. For example let us consider $A = [0, 2]$. If we view it as a subset of $X = \mathbb{R}$, then $\partial A = \partial[0, 2] = \{0, 2\}$. On the other hand, if we view $A = [0, 2]$ as a subset of $X = \mathbb{R}_{\geq 0}$, then $\partial A = \partial[0, 2] = \{2\}$. This ambiguity in the notation can sometimes be a source of confusion. Thus it would be more appropriate to specify the role of X in the above notation. But mathematicians, as all humans, tend to be lazy and thus tend to simplify the notation.

(5) We consider $X = \mathbb{R}$ and the subset $A = \mathbb{Q}$. Using Lemma 1.10 one can easily show, using standard facts about real numbers, that $\mathring{\mathbb{Q}} = \varnothing$ and that $\overline{\mathbb{Q}} = \mathbb{R}$. The same conclusion also holds for $Q = \mathbb{R} \setminus \mathbb{Q}$.

Finally we consider the relationship between closures and interiors under taking unions and intersections. As the following examples show, this is a tricky topic.

Example. Throughout we work with the topological space $X = \mathbb{R}$.

(1) Let $A = \mathbb{Q}$ and $B = \mathbb{R} \setminus \mathbb{Q}$. We see that

$$\begin{aligned} \text{interior of } \underbrace{\mathbb{Q} \cup (\mathbb{R} \setminus \mathbb{Q})}_{=\mathbb{R}} &= \mathbb{R} \neq \varnothing = \underbrace{\text{interior of } \mathbb{Q}}_{=\varnothing} \cup \underbrace{\text{interior of } \mathbb{R} \setminus \mathbb{Q}}_{=\varnothing} \\ \text{closure of } \underbrace{\mathbb{Q} \cap (\mathbb{R} \setminus \mathbb{Q})}_{=\mathbb{R}} &= \varnothing \neq \mathbb{R} = \underbrace{\text{closure of } \mathbb{Q}}_{=\mathbb{R}} \cap \underbrace{\text{closure of } \mathbb{R} \setminus \mathbb{Q}}_{=\mathbb{R}}. \end{aligned}$$

This discussion shows that taking interiors does not commute even with just taking *finite* unions and analogously that taking closures does not even commute with taking *finite* intersections.

(2) We consider the subsets $[0, \frac{1}{n})$ and $[0, 1 - \frac{1}{n})$ of $\mathbb{R}$. Now we see that

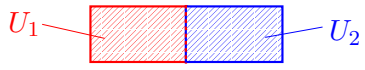
$$\text{interior of } \bigcap_{n\in\mathbb{N}} [0, \tfrac{1}{n}) = \text{interior of } \{0\} = \varnothing \subsetneq \{0\} = \bigcap_{n\in\mathbb{N}} \underbrace{\text{interior of } [0, \tfrac{1}{n})}_{=[0,\frac{1}{n})}$$

$$\text{closure of } \bigcup_{n\in\mathbb{N}} [0, 1-\tfrac{1}{n}) = \text{closure of } [0,1) = [0,1] \supsetneq [0,1) = \bigcup_{n\in\mathbb{N}} \underbrace{\text{closure of } [0, 1-\tfrac{1}{n})}_{=[0,1-\frac{1}{n})}$$

These examples show that taking interiors does not commute even with taking infinite intersections and analogously that taking closures does not commute with taking infinite unions.

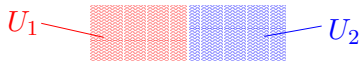
After this exhaustive list of counter examples the reader will be relieved to see that one can in fact formulate a lemma regarding the interaction of interiors and closures with unions and intersections.

Lemma 1.11. Let X be a topological space and let $\{U_i\}_{i\in I}$ be a family of subsets. The following inclusions hold:



(1a) $\text{interior of } \bigcup_{i\in I} U_i \supset \bigcup_{i\in I} \mathring{U}_i$ and (1b) $\text{closure of } \bigcap_{i\in I} U_i \subset \bigcap_{i\in I} \overline{U_i}$

(2a) $\text{interior of } \bigcap_{i\in I} U_i \subset \bigcap_{i\in I} \mathring{U}_i$ and (2b) $\text{closure of } \bigcup_{i\in I} U_i \supset \bigcup_{i\in I} \overline{U_i}$.



Furthermore, if the family $\{U_i\}_{i\in I}$ is locally finite (e.g. if it is finite), then the following equalities hold:

(3a) $\text{interior of } \bigcap_{i\in I} U_i = \bigcap_{i\in I} \mathring{U}_i$ and (3b) $\text{closure of } \bigcup_{i\in I} U_i = \bigcup_{i\in I} \overline{U_i}$.

Example. In the figure below we show two subsets U_1, U_2 of $\mathbb{R}^2$ such that the inclusions in Lemma 1.11 (1a) and (1b) are actually proper inclusions.

interior of $U_1 \cup U_2 \supsetneq \mathring{U}_1 \cup \mathring{U}_2$

closure of $U_1 \cap U_2 \subsetneq \overline{U}_1 \cup \overline{U}_2$

Proof.

(1a) By the Interior-Closure Lemma 1.9 we know that each $\mathring{U}_i$ is open. Therefore $\bigcup_{i\in I} \mathring{U}_i$ is open. Evidently this set is contained in $\bigcup_{i\in I} U_i$. By definition of the interior the set $\bigcap_{i\in I} \mathring{U}_i$ is now also contained in the interior of $\bigcup_{i\in I} U_i$.

(1b) It is straightforward to prove (1b) directly. In the following we show alternatively, that (1b) is in fact a formal consequence of (1a). Indeed, we have

$$\begin{array}{ccccc} \text{closure of } \bigcap_{i\in I} U_i & \overset{\text{Interior-Closure Lemma 1.9 (7)}}{\downarrow =} & X \setminus \text{interior of } \Big(X \setminus \bigcap_{i\in I} U_i\Big) & \overset{\text{de Morgan's Laws 0.1}}{\downarrow =} & X \setminus \text{interior of } \Big(\bigcup_{i\in I} (X \setminus U_i)\Big) \\ & \overset{\text{follows from (1a)}}{\uparrow \subset} & X \setminus \bigcup_{i\in I} \text{interior of } (X \setminus U_i) & \overset{\text{de Morgan's Laws 0.1}}{\uparrow =} & \bigcap_{i\in I} X \setminus \text{interior of } (X \setminus U_i) \overset{\text{Interior-Closure Lemma 1.9 (7)}}{\uparrow =} \bigcap_{i\in I} \overline{U}_i. \end{array}$$

(2a) The interior V of $\bigcap_{i\in I} U_i$ is an open subset which is contained in each U_i. By definition of the interior of U_i we see that V is contained in each $\mathring{U}_i$. The promised inclusion is an immediate consequence of this observation.

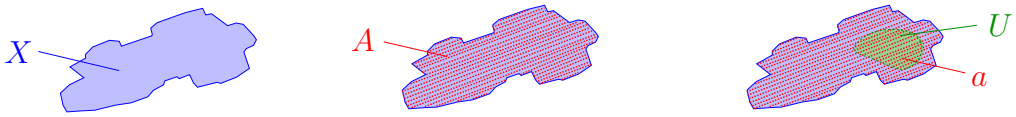
(2b) The closure A of $\bigcup_{i\in I} U_i$ is a closed set that contains each U_i. By definition of the closure of U_i we see that A contains each $\overline{U}_i$. The promised inclusion is an immediate consequence of this observation. observation.

We now assume that the family $\{U_i\}_{i\in I}$ is locally finite.

(3a) By (2a) We already know that the "$\subset$"-inclusion holds. Thus it suffices to prove the "$\supset$"-inclusion. By definition of the interior it suffices to show that $\bigcap_{i\in I} \mathring{U}_i$ is open. By Lemma 1.8 it remains to prove the following claim.

Claim. For each $x \in \bigcap_{i\in I} \mathring{U}_i$ there exists an open neighborhood W of $x \in X$ such that $W \subset \bigcap_{i\in I} \mathring{U}_i$.

Proof. Let $x \in \bigcap_{i\in I} \mathring{U}_i$. Since $\{U_i\}_{i\in I}$ is a locally finite family of open subsets there exists an open neighborhood V of x such that $J := \{i \in I \,|\, V \cap U_i = \varnothing\}$ is finite. We see that



$$W \;:=\; \underbrace{V \cap \bigcap_{i\in J} \mathring{U}_i}_{\substack{\text{intersection of finitely}\\ \text{many open sets}}} \;=\; \bigcap_{i\in J} (V \cap \mathring{U}_i) \;\subset\; \underbrace{\bigcap_{i\in I} (V \cap \mathring{U}_i)}_{\uparrow \text{ by definition of } J} \;\subset\; \bigcap_{i\in I} \mathring{U}_i.$$

Since the intersection of finitely many open sets is open we see that W is an open neighborhood of $x \in X$. Thus we are done.

(3b) By the same argument as in the proof of (1b) we can use de Morgan's Laws 0.1 to reduce the proof of (3b) to the proof of (3a). ■

We conclude this section with the discussion of the following definition, which will show up every now and then.

Definition. Let X be a topological space. We say a subset A of X is dense in X if every open non-empty subset U of X contains a point $a \in A$.

Example.

(1) Let $n \in \mathbb{N}$. It follows from basic facts in real analysis that $A = \mathbb{Q}^n$ is a dense subset of $X = \mathbb{R}^n$.

(2) It is very tempting to think that dense *open* subsets of say $X = [0,1]$ must be "almost the whole set". But the following example might dent one's optimism. First we pick a bijection $f\colon \mathbb{N} \to \mathbb{Q} \cap [0,1]$. For $i \in \mathbb{N}$ we write $x_i := f(i)$. We consider the set

$$U \;:=\; \bigcup_{i\in\mathbb{N}} \underbrace{(x_i - \tfrac{1}{3^i}, x_i + \tfrac{1}{3^i}) \cap [0,1]}_{\text{open in } [0,1]} \;\subset\; [0,1].$$

The same argument as in (1) shows that U is a dense subset of $[0,1]$. Since U is the union of open subsets we see that U is also an open subset of $[0,1]$. On the other hand its Lebesgue measure satisfies

$$\mathrm{vol}(U) = \mathrm{vol}\left(\bigcup_{i\in\mathbb{N}} \left(x_i - \tfrac{1}{3^i}, x_i + \tfrac{1}{3^i}\right) \cap [0,1]\right) \leq \sum_{i\in\mathbb{N}} \mathrm{vol}\left((x_i - \tfrac{1}{3^i}, x_i + \tfrac{1}{3^i})\right) \leq \sum_{i\in\mathbb{N}} \frac{2}{3^i} = \frac{2}{3}.$$

Thus we have shown that the Lebesgue measure of U is less than the Lebesgue measure of $[0,1]$. So by no means can one reasonably claim that the dense open U subset is "almost all of $[0,1]$".

(3) Here is an immediate, perhaps not entirely serious application of topology to the eternal problem for how to capture a lion in the desert [**Barr1981**]: We give the desert the *leonine topology*, in which a subset is closed if it is the whole desert or if it contains no lions.[25] The set of lions is now a dense subset.[26] Now put an open cage in the desert. By density it contains a lion. Once we shut the cage we have caught the lion![27]

In the following we relate the notions of closure and interiors to some of notions that we had introduced earlier.

Lemma 1.12. Let X be a topological space and let $A \subset X$ be a subset. The following three statements are equivalent:

(1) A is dense in X.
(2) We have $\overline{A} = X$.
(3) The interior of $X \setminus A$ is empty.

Proof. Let $A \subset X$. The equivalence of (2) and (3) is a consequence of the Interior-Closure Lemma 1.9. Thus it remains to show that (1) and (3) are equivalent. In fact we have

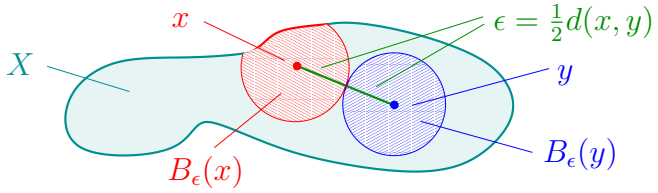
$$\begin{aligned} A \text{ is dense} &\iff \text{for every open non-empty subset } U \text{ of } X \text{ we have } U \cap A \neq \varnothing \\ &\iff \text{for every open non-empty subset } U \text{ of } X \text{ we have } U \subsetneq X \setminus A \\ &\iff \text{there is no open non-empty subset } U \text{ of } X \text{ with } U \subset X \setminus A \\ &\iff \text{the interior of } X \setminus A \text{ is empty.} \end{aligned}$$

■

1.6. The Hausdorff property.

Definition.

(1) We say a topological space X is Hausdorff, if given any two distinct points $x \neq y$ there exist disjoint open neighborhoods U of x and V of y.
(2) A Hausdorff space is a topological space that is Hausdorff.[28]



[25] Why is this a topology?
[26] Why is that?
[27] This and many other mathematical approaches to hunting lions can be found in [**Boas1995**].
[28] We use this language for all other properties of topological spaces, for example we will soon introduce the very important notion of a compact topological space. We will often write "let X be a compact space" instead of the more precise "let X be a compact topological space".

The following proposition, which very likely is well-known to most readers, says that topological spaces arising from metric spaces are Hausdorff.

Proposition 1.13. Let (X, d) be a metric space. The corresponding topological space is Hausdorff.

Proof. Let $x, y \in X$ be two different points. We set $\epsilon := \frac{1}{2}d(x, y)$. It follows from Proposition 1.4 that $U := B_\epsilon(x)$ and $V := B_\epsilon(y)$ are neighborhoods of x respectively y. An elementary argument using the triangle inequality shows that U and V are disjoint. ■

We now introduce two more examples of topological spaces. Both are of the type "$\mathbb{R}^n$ together with an extra point". These two topological spaces are often good candidates for (counter-) examples in topology.

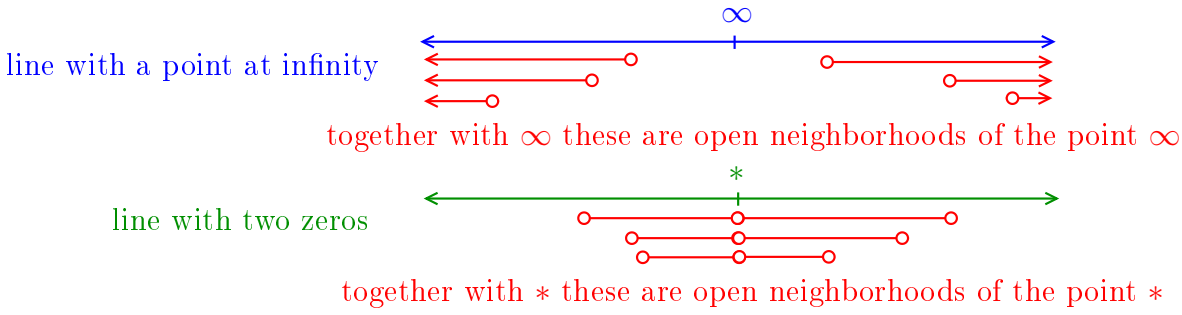
Definition.

(1) Let $n \in \mathbb{N}$. We consider the set

$$X := \mathbb{R}^n \cup \{\infty\},$$

i.e. X consists of $\mathbb{R}^n$ and an extra point ∞. We say $U \subset X$ is open, if both of the following two conditions are satisfied:
(a) for each point $x \in U \cap \mathbb{R}^n$ there exists an $\epsilon > 0$ such that $B_\epsilon(x) \subset U$,
(b) if $\infty \in U$, then there exists a $C > 0$ such that $\{x \in \mathbb{R}^n \mid \|x\| > C\} \subset U$.
It is straightforward to see that this defines indeed a topology on X. We refer to $\mathbb{R}^n \cup \{\infty\}$ as $\mathbb{R}^n$ with a point at infinity. For $n = 1$ we refer to $\mathbb{R} \cup \{\infty\}$ also as the line with a point at infinity.

(2) We consider the set



$$X := \mathbb{R} \cup \{*\},$$

i.e. X consists of $\mathbb{R}$ and an extra point $*$. We say $U \subset X$ is open, if the following two conditions are satisfied:
(a) for each point $x \in U \cap \mathbb{R}$ there exists an $\epsilon > 0$ such that $(x - \epsilon, x + \epsilon) \subset U$,
(b) if $* \in U$, then there exists an $\epsilon > 0$ such that $(-\epsilon, 0) \cup (0, \epsilon) \subset U$.
One can easily verify that this is indeed a topology on X. We refer to this topological space as the line with two zeros.

Even though the "line with two zeros" looks at first glance similar to the "line with a point at infinity", the next example shows that they are strikingly different topological spaces.

Example. In Exercise 1.18 we will see that "$\mathbb{R}^n$ with a point at infinity" is Hausdorff and that on the other hand "the line with two zeros" is not Hausdorff.

The following lemma is basically trivial, but since it gets used on many occasions it is still worth spelling it out.

Lemma 1.14. Let X be a topological space and let A be a subset of X. If X is Hausdorff, then A is also Hausdorff.

Proof. The lemma follows almost immediately from the definitions. ■

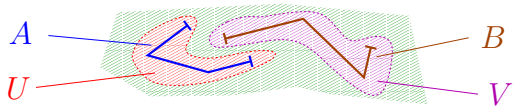
The following gives us a modest but still quite useful consequence of being Hausdorff.

Lemma 1.15. (Points-in-Hausdorff Space Lemma) Let X be a topological space.

(1) If X is Hausdorff, then for every $x \in X$ the corresponding subset $\{x\}$ is closed.
(2) If X is Hausdorff, then for every $x \neq y \in X$ there exists an open neighborhood U of x such that $y \notin \overline{U}$.

Proof. Let X be a topological space which is Hausdorff.

(1) Let $x \in X$. Since X is Hausdorff we know that for every $y \neq x$ there exist open disjoint neighborhoods U_y of x and V_y of y. Note that



$$X \setminus \{x\} = \bigcup_{y \in X \setminus \{x\}} \{y\} \underset{\substack{\uparrow \\ \text{since } y \in V_y}}{\subset} \bigcup_{y \in X \setminus \{x\}} V_y \underset{\substack{\uparrow \\ \text{since } x \notin V_y}}{\subset} X \setminus \{x\}.$$

Thus we see that the inclusions are equalities. Since each V_y is open we see that $X \setminus \{x\}$ is the union of open sets, in particular $X \setminus \{x\}$ is open. In other words, $\{x\}$ is a closed subset of X.

(2) Let $x \neq y \in X$. Since X is Hausdorff there exist disjoint open neighborhoods U of x and V of y. Since $U \subset X \setminus V$ and since $X \setminus V$ is closed we obtain from the definition of the closure that $\overline{U} \subset X \setminus V$. In particular $y \notin \overline{U}$. ■

There are many variations on the definition of the Hausdorff property. We will discuss some of these in Chapters 8 and 9, and especially in Section 9.4. For the time being we just want to introduce one variation on being Hausdorff:

Definition. A topological space X is called normal if any two disjoint closed subsets A and B of X can be separated by open neighborhoods, i.e. if there exist disjoint open neighborhoods U of A and V of B.

We will discuss this notion of begin normal in greater detail in Section 8.1. For the time being we only want to prove the following lemma and a corollary, both of which can be quite useful.

Lemma 1.16. (Compact Hausdorff Spaces-Normal Lemma) Every compact Hausdorff space is normal.

Proof. Let X be a Hausdorff space. We start out with the following claim.

Claim. Let B be a compact subspace of X. Given any $a \in X \setminus B$ there exists an open neighborhood U_a of $a \in X$ and an open neighborhood V_a of B that are disjoint.

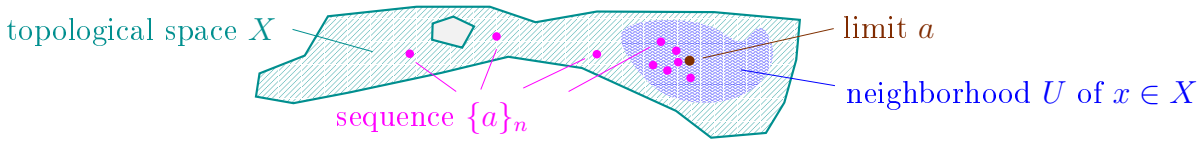
Proof. Let $a \in A$. Since X is Hausdorff we can find for any $b \in B$ disjoint open neighborhoods R_b and S_b of a and b. Furthermore, since B is compact there exist $b_1, \ldots, b_n \in B$ such that $B \subset S_{b_1} \cup \cdots \cup S_{b_n}$. The open sets

$$U_a := R_{b_1} \cap \cdots \cap R_{b_n} \quad \text{and} \quad V_a := S_{b_1} \cup \cdots \cup S_{b_n}$$

have the desired properties. ⊞

Now assume that X is also compact. We need to show that X is normal. Thus let A and B be two disjoint closed subsets of X. Note that the Compact-Closed Lemma 1.21 (1) implies that A and B are also compact.

Since B is compact we can apply the above claim to every $a \in A \subset X \setminus B$ and B. In the following we use the notation of the above claim. Since A is compact we can find $a_1, \ldots, a_m \in A$ such that $A \subset U_{a_1} \cup \cdots \cup U_{a_m}$. The open sets



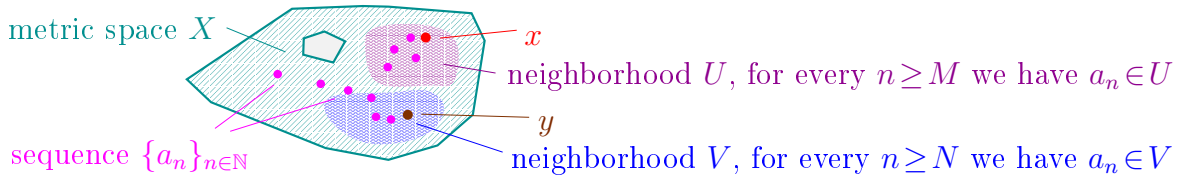
$$U := U_{a_1} \cup \cdots \cup U_{a_m} \quad \text{and} \quad V := V_{a_1} \cap \cdots \cap V_{a_m}$$

have the desired properties. ■

1.7. **Convergence of sequences.** In this short section we will introduce the notion of convergence of a sequence of points in a topological spaces and we will see how the Hausdorff property comes in handy. We will barely make use of the results of this section. For a reader who is used to analysis it is often quite natural to argue with limits. But when it comes to topological spaces it is in most cases more elegant to avoid arguing with limits.

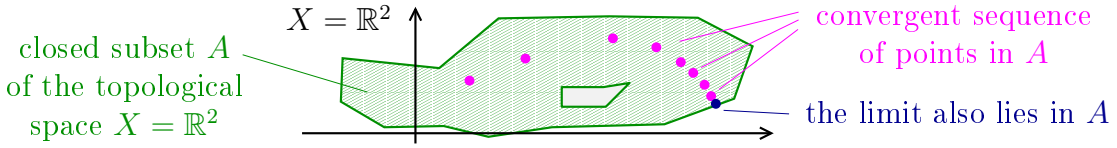
After this preamble, let us finally introduce the notion of a convergent sequence in a topological space.

Definition. Let X be a topological space. We say that a sequence $\{a_n\}_{n\in\mathbb{N}}$ converges if there exists an $a \in X$ such that for every neighborhood U of a there exists an $N \in \mathbb{N}$ such that for all $n \geq N$ we have $a_n \in U$. We refer to a as a limit of the sequence.



Example. We consider the line with two zeros, i.e. the topological space $X = \mathbb{R} \cup \{*\}$ defined above. The sequence $a_n = \frac{1}{n}$ converges, more or less evidently with limit 0. But strikingly enough, it follows easily from the definitions that the sequence also converges to $*$. Thus we see that the limit is not unique.

Lemma 1.17. (Unique Limit Lemma) Let X be a topological space. If X is Hausdorff, then every convergent sequence in X has a unique limit.



Proof. Assume there exists a sequence $\{a_n\}_{n\in\mathbb{N}}$ in X that converges to two different points x and y. Since X is Hausdorff there exist disjoint neighborhoods U and V of x and y. By our hypothesis we know the following:

- There exists an $M \in \mathbb{N}$ such for every $n \geq M$ we have $a_n \in U$.
- There exists an $N \in \mathbb{N}$ such for every $n \geq N$ we have $a_n \in V$.

But this means that for $n \geq \max\{M, N\}$ have to lie in U and V at the same time. But that is not possible and we have thus obtained a contradiction. ■

Lemma 1.18. (Closed Subset Limit Lemma) Let X be a topological space, let $A \subset X$ be a closed subset and let $\{a_n\}_{n\in\mathbb{N}}$ be a sequence of points in A. Every limit of the sequence lies in A.

Proof. We suppose that the sequence has a limit $x \in X \setminus A$. Since A is closed we know that $U := X \setminus A$ is open. But if we now apply the definition of a limit to this open neighborhood $U = X \setminus A$ of x we see that almost all of the a_n have to lie in $U = X \setminus A$. We have thus obtained a contradiction. ■

1.8. **Compact topological spaces.** In this section we introduce the notion of compactness. Usually it takes a while till one appreciates the brilliance of the definition.

Definition. We say a topological space X is compact if for each open cover $\{U_i\}_{i\in I}$ of X there exist finitely many indices $i_1, \ldots, i_k \in I$ such that

$$X = U_{i_1} \cup \cdots \cup U_{i_k}.$$

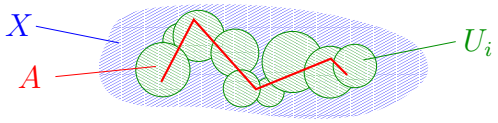
Remark. The introduction of the notion of compact space by Pavel Alexandrov and Pavel Urysohn [**AU1929**] in 1929 shows that often in mathematics the really clever thing is not necessarily the proofs, but coming up with just the right definition. It is difficult to exaggerate the role of compactness in topology.

Example.

(1) Every finite topological space (regardless of the topology) is compact, since there exist only finitely many distinct open subsets. This simple example can sometimes be quite useful.
(2) We consider the topological space $X = \mathbb{R}$. The sets $\{(-n, n)\}_{n\in\mathbb{N}}$ form an open cover of $X = \mathbb{R}$, but evidently we cannot cover $X = \mathbb{R}$ by finitely many of these sets. This shows that $X = \mathbb{R}$ is not compact.

In the following we will often use the following convention.

Convention. Let P be a property of a topological space (e.g. being discrete, Hausdorff, compact). We say that a subset Y of a topological space X has the property P if Y, equipped with the subspace topology, has the property P.



Examples.

(1) The set $\mathbb{Z} \subset \mathbb{R}$ is easily seen to be a discrete subset.
(2) Any finite set of a topological space is, by the above, a compact subset.

Frequently and often subconsciously the following elementary lemma is employed.

Lemma 1.19. (Compact Subspace Covering Lemma) Let X be a topological space, let $A \subset X$ be a subset and let $\{U_i\}_{i\in I}$ be an open cover of the subset $A \subset X$. If A is compact, then there exist finitely many indices $i_1, \ldots, i_k \in I$ such that

$$A \subset U_{i_1} \cup \cdots \cup U_{i_k}.$$

Proof. Given $i \in I$ we set $V_i := U_i \cap A$. By definition of the subspace topology each V_i is an open subset of A. Thus $\{V_i\}_{i\in I}$ is an open cover of A. Since A is compact there exist $i_1, \ldots, i_k \in I$ with $A = V_{i_1} \cup \cdots \cup V_{i_k}$. But this implies that $A \subset U_{i_1} \cup \cdots \cup U_{i_k}$. ■

We continue with the following frequently employed lemma.

Lemma 1.20. (Compact-Union-Intersection Lemma) Let X be a topological space.
(1) The union of finitely many compact subsets of X is again a compact subset.
(2) If X is Hausdorff, then the intersection of arbitrarily many compact subsets of X is again a compact subset.

Remark. Note that in the Compact-Union-Intersection Lemma 1.20 we cannot drop the hypothesis that X is Hausdorff. For example consider the set $X = \mathbb{N} \cup \{x_0, x_1\}$ where we equip $\mathbb{N}$ with the discrete topology and where the only other open sets are $\mathbb{N} \cup \{x_i\}$ and $\mathbb{N} \cup \{x_0, x_1\}$. The subsets $A_0 = \mathbb{N} \cup \{x_0\}$ and $A_1 = \mathbb{N} \cup \{x_1\}$ are easily seen to be compact, but the intersection $A_0 \cap A_1$ is certainly not compact.

Proof.

(1) This statement follows easily from the definitions, we leave it to the reader to fill in the details.

(2) Let $\{A_i\}_{i\in I}$ be a family of compact subsets of X. We pick $j \in I$. By the Compact-Closed Lemma 1.21 (2) know that each $A_i \cap A_j$ is a closed subset of A_i. Thus $\bigcap_{i\in I}(A_i \cap A_j)$ is a closed subset of the compact space A_j. Hence $\bigcap_{j\in I} A_i$ is compact by (1) Compact-Closed Lemma 1.21. ■

Before we give some more interesting examples of compact spaces we want to discuss a few properties of compact spaces and compact subsets. The following lemma is frequently used, often subconsciously, in topology.

Lemma 1.21. (Compact-Closed Lemma) Let X be a topological space.
(1) If X is compact, then any closed subset of X is also compact.
(2) Let $A \subset X$ be a compact subset. If X is Hausdorff, then A is a closed subset of X.

Example.

(1) Let X be a topological space. As we pointed out on page 126, any finite subset of X is compact. Thus if X is Hausdorff, then it follows from the Compact-Closed Lemma 1.21 (2) that any finite subset of X, in particular any point in X, is a closed subset of X. Thus we have found a new proof for the Points-in-Hausdorff Space Lemma 1.15 (1).
(2) Let X be a topological space, let A be a closed subset and let K be a compact subset of X. It follows from the Compact-Closed Lemma 1.21 (1) that $A \cap K$ is also compact. This simple observation will get used frequently.
(3) We consider the topological space $X = \{0, 1\}$ that is equipped with the trivial topology $\{\varnothing, X\}$. The subset $A = \{0\}$ is evidently compact, but it is not a closed subset of X. This shows that in the formulation of Compact-Closed Lemma 1.21 (2) we cannot drop the hypothesis that X is Hausdorff.

Proof.

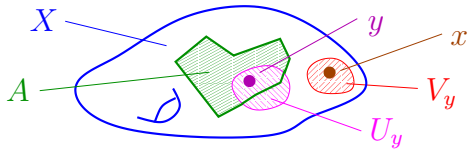
(1) Let X be a compact space and let A be a closed subset. Let $\{U_i\}_{i\in I}$ be an open cover of A. By definition of the subset topology there exists for every $i \in I$ an open subset V_i of X such that $U_i = V_i \cap A$. Since A is closed the complement $X \setminus A$ is open. The open subsets $\{V_i\}_{i\in I}$ together with $X \setminus A$ are an open cover of X. Since X is compact we can cover X by finitely many of these open sets. But then we can also cover A by finitely many of the U_i.

(2) Let X be a Hausdorff space and let $A \subset X$ be a compact subset. We want to show that $X \setminus A$ is open. By the JH-Lemma 1.7 it suffices to prove the following claim.

Claim. Let $x \in X \setminus A$. Then there exists an open neighborhood V of x that is contained in $X \setminus A$.

Proof. We apply the Hausdorff property to x and every $y \in A$. For every $y \in A$ we obtain disjoint open neighborhoods U_y of y and V_y of x. Evidently we have

$$A = \bigcup_{y\in A} \{y\} \subset \bigcup_{y\in A} (U_y \cap A) \subset A.$$



Thus we see that $\{U_y \cap A\}_{y\in A}$ is an open cover of A. Since A is compact there exist $y_1, \ldots, y_k \in A$ such that

$$A = \bigcup_{i=1}^{k} (U_{y_i} \cap A).$$

Now we consider

$$V := \bigcap_{i=1}^{k} V_{y_i}.$$

Since V is the intersection of finitely many open sets, it is open itself. Furthermore V does not intersect any of the U_{y_i}, $i = 1, \ldots, k$. This implies that V is disjoint from $A \subset U_{y_1} \cup \cdots \cup U_{y_k}$. ■

Before we move on to giving more interesting examples of compact spaces we state and prove the following elementary lemma.

Lemma 1.22. (Compact-Discrete Lemma)

(1) Every discrete space that is compact is finite.
(2) Let X be a compact space and let A be a closed subset. If A is discrete, then A is finite.

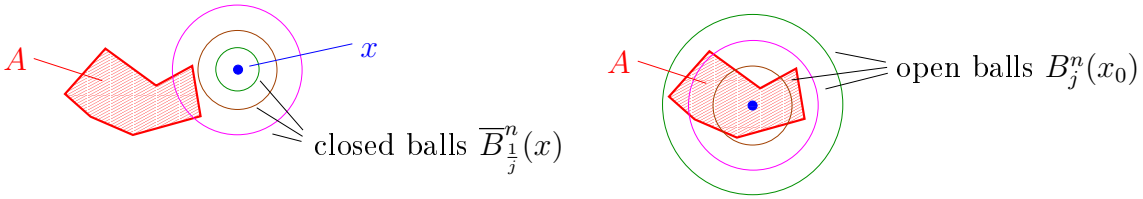
Remark. Note that the conclusion of the Compact-Discrete Lemma 1.22 (2) does not necessarily hold, if we drop the hypothesis that A is closed. For example, consider the topological space $X = [0, 1]$. The subset $A := \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$ is a discrete subset, but evidently it is not finite.

Proof.

(1) Let X be a discrete space. Each point thus defines an open set. Evidently X is covered by all the open sets given by the points in X. Since X is compact we can cover X by finitely many of those open sets. But this means that X contains only finitely many points.
(2) Let X be a compact space and let A be a closed subset. It follows from the Compact-Closed Lemma 1.21 (1) that A is also compact. So if A is discrete, then it follows from (1) that A is finite. ■

We continue with the following almost self-explanatory definition.

Definition. Let (X, d) be a metric space. A subset A of $\mathbb{R}^n$ is called bounded if there exists a $C \geq 0$ such that for all $x_0, x_1 \in A$ we have $d(x_0, x_1) \leq C$.



Example. Let X be a metric space, let $y \in X$ and let $r \geq 0$. It follows easily from the triangle inequality that the balls $B_r^d(y)$, $\overline{B}_r^d(y)$ and the sphere $S_r^d(y)$ are bounded.

Lemma 1.23. Let (X, d) be a metric space and let $A \subset X$ be a subset. If A is compact, then A is closed and it is bounded.

Proof. Let (X,d) be a metric space and let $A \subset X$ be a subset.

(1) We want to show that $X \setminus A$ is open. Let $x \in X \setminus A$. We need to show that there exists an $\epsilon > 0$ with $B^d_\epsilon(x) \subset X \setminus A$. Given $j \in \mathbb{N}$ we consider the subset $U_j = X \setminus \overline{B}^d_{\frac{1}{j}}(x)$. By Proposition 1.4 we know that the U_j are open. Evidently these open sets cover A. Since A is compact we obtain from the Compact Subspace Covering Lemma 1.19 that there exist $j_1, \dots, j_k \in \mathbb{N}$ with $A \subset U_{j_1} \cup \dots \cup U_{j_k}$. We set $\epsilon := \min\{\frac{1}{j_1}, \dots, \frac{1}{j_k}\}$. We obtain that $A \subset X \setminus \overline{B}^d_\epsilon(x)$. Thus we have found the desired ϵ.

(2) We need to show that A is bounded. If A is empty, then there is nothing to show. Now suppose that A is non-empty. We pick $x_0 \in A$. It follows from the triangle inequality that it suffices to show that there exists an $R \geq 0$ with $A \subset \overline{B}^d_R(x_0)$. We consider the open subsets $U_j = B^d_j(x_0)$ with $j \in \mathbb{N}$. Evidently these sets cover A. Since A is compact we obtain again from the Compact Subspace Covering Lemma 1.19 that there exist $j_1, \dots, j_k \in \mathbb{N}$ such that $A \subset U_{j_1} \cup \dots \cup U_{j_k}$. We set $R := \max\{j_1, \dots, j_k\}$. We obtain that $A \subset B^d_R(x_0) \subset \overline{B}^d_R(x_0)$. We have thus found the desired R. ∎

The ever-popular Heine-Borel Theorem says that for the metric space $X = \mathbb{R}^n$ mercifully the converse to Lemma 1.23 holds.

Theorem 1.24. (Heine-Borel) A subset of $\mathbb{R}^n$ is compact if and only if it is bounded and closed.

In the following we first provide several examples before we turn to the chore of proving the Heine-Borel Theorem.

Example.

(1) Let $y \in \mathbb{R}^n$ and $r \geq 0$. It follows from the Heine-Borel Theorem 1.24 and Proposition 1.4 that the closed ball $\overline{B}^n_r(y)$ and the sphere $S^{n-1}_r(y)$ are compact.

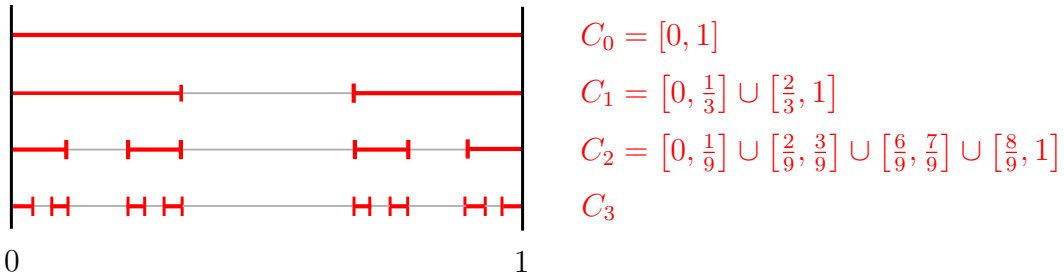
(2) It is an amusing exercise, see Exercise 1.18, to show, using the Heine-Borel Theorem 1.24, that "$\mathbb{R}^n$ with a point at infinity" is compact.

(3) It is an equally entertaining exercise, see Exercise 1.18, to show that the "line with two zeros" is not compact.

(4) Since the concepts of being bounded and closed are initially much more intuitive than being compact it is not uncommon that many, especially students, like to replace "compact" by "bounded and closed". But this equality only holds for subsets of $\mathbb{R}^n$, it does not hold for other metric spaces. For example, the set $[0,1] \cap \mathbb{Q}$ is a bounded and closed subset of the metric space $(\mathbb{Q}, d(x,y) = |x-y|)$, but as we will see in Exercise 1.26, it is not compact. Furthermore in Exercise 1.27 we will see that in general the conclusion of the Heine-Borel Theorem 1.24 does not hold for the infinite-dimensional real vector space

$$\mathbb{R}^\infty := \{(x_1, x_2, \dots) \in \mathbb{R}^{\mathbb{N}} \,|\, \text{there exists an } i \in \mathbb{N} \text{ such that } x_j = 0 \text{ for } j \geq i\}$$

equipped with the obvious generalization of the Euclidean metric.



Our final example deserves to be introduced as a proper definition.

Definition. We set $C_0 := [0,1]$. Iteratively we now define sets $C_2, C_3, \ldots$ as follows:

$$C_i \;:=\; \underbrace{\{\tfrac{1}{3}\cdot x \,|\, x \in C_{i-1}\}}_{=\frac{1}{3}\cdot C_{i-1}} \;\cup\; \underbrace{\{\tfrac{2}{3}+\tfrac{1}{3}\cdot x \,|\, x \in C_{i-1}\}}_{=\frac{2}{3}+\frac{1}{3}\cdot C_{i-1}}.$$

Note that each C_i consists of 2^i closed intervals of length $\frac{1}{3^i}$ and that we obtain C_i from C_{i-1} by removing the "open middle third" of each interval. We define

$$\text{Cantor set } C \;:=\; \bigcap_{i\in\mathbb{N}_0} C_i.$$

Lemma 1.25. The Cantor set is compact.

Proof. Each C_i is the union of 2^i closed intervals, hence each C_i is closed. It follows from Lemma 1.3 that C itself is a closed subset of $\mathbb{R}$. It is evidently bounded, hence the Heine-Borel Theorem 1.24 implies that the Cantor set is compact. ■

The following proposition is the key ingredient in the proof of the Heine-Borel Theorem 1.24.

Proposition 1.26. (Hyperrectangle-Compact Proposition) Let $n \in \mathbb{N}$ and let $a_i < b_i$, $i = 1, \ldots, n$ be real numbers. The hyperrectangle

$$\underbrace{[a_1,b_1] \times \ldots \times [a_n,b_n]}_{:=\{(x_1,\ldots,x_n)\in\mathbb{R}^n \,|\, x_i\in[a_i,b_i] \text{ for } i=1,\ldots,n\}} \;\subset\; \mathbb{R}^n$$

is compact.

Proof. To simplify the notation we only treat the case $n = 1$. The general case is treated in a very similar fashion.[29] To simplify the notation further we assume that $a = 0$ and $b = 1$. Thus we will now show that $I := [0,1]$ is compact. In an attempt at a proof by contradiction we suppose that I is not compact. This means that there exists an open cover $\{U_j\}_{j\in J}$ such that I cannot be covered by finitely many of the U_j.

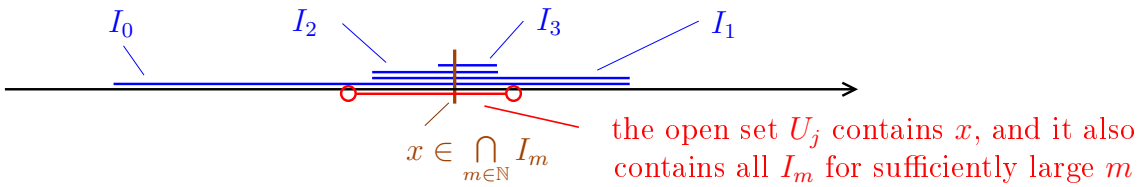
Claim 1. There exists a sequence of closed intervals

$$I \;=\; I_0 \;\supset\; I_1 \;\supset\; I_2 \;\supset\; \ldots$$

such that for any $m \in \mathbb{N}_0$ the following two conditions hold:

(1) I_m cannot be covered by finitely many of the U_j,
(2) the length of I_m equals 2^{-m}.

[29] The full details are for example provided in [**RudiW1976**, Theorem 2.4.1]. Alternatively one can also use the Product Topology Properties Proposition 5.6 (2).



Proof. We prove the claim by induction. We set $I_0 := I$. Suppose we have already found $I_0, I_1, \ldots, I_m$. We divide the interval I_m into two closed intervals I' and I'' of half the length. Since I_m cannot be covered by finitely many U_j it follows that at least one of the intervals I' and I'' cannot be covered by finitely many U_j either. We declare such interval to be I_{m+1}. ⊞

Claim 2. There exists an $x \in I$ with $x \in \bigcap_{m\in\mathbb{N}} I_m$.

Proof. For every $m \in \mathbb{N}$ we pick an $a_m \in I_m$. For any $m \geq n$ we know that a_m and a_n both lie in I_n. In particular

$$|a_m - a_n| \;\leq\; \text{length of } I_n \;=\; \frac{1}{2^n}.$$

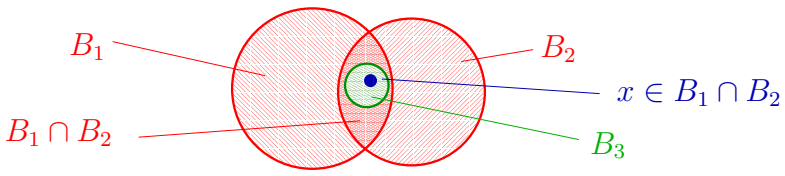
It follows that $(a_m)_{m\in\mathbb{N}}$ is a Cauchy sequence of real numbers. Since $\mathbb{R}$ is complete we know that the sequence converges. We denote by x the limit of this Cauchy sequence. We want to show that $x \in \bigcap_{m\in\mathbb{N}} I_m$. Put differently, we want to show that for every $m \in \mathbb{N}$ we have $x \in I_m$. Thus let $m \in \mathbb{N}$. For all $n \geq m$ we have $a_n \in I_n \subset I_m$. In particular, $(a_n)_{n\geq m}$ is a sequence that converges in I_m. Since I_m is closed we know by the Closed Subset Limit Lemma 1.18 that $\lim_{n\to\infty} a_n \in I_m$. ⊞

Since $\{U_j\}_{j\in J}$ is an open cover of I there exists a $j \in J$ with $x \in U_j$. Since U_j is open there exists an $\epsilon > 0$ with $(x-\epsilon, x+\epsilon) \cap I \subset U_j$. We pick $m \in \mathbb{N}$ with $2^{-m} < \epsilon$. Now note that

$$I_m \underset{\substack{\uparrow\\ \text{since } x\in I_m \text{ and since}\\ \text{length of } I_m \text{ equals } 2^{-m}}}{\subset} [x-2^{-m}, x+2^{-m}] \cap I \underset{\substack{\uparrow\\ \text{choice of } m}}{\subset} (x-\epsilon, x+\epsilon) \cap I \underset{\substack{\uparrow\\ \text{choice of } U_j}}{\subset} U_j$$

i.e. I_m is contained in a unique U_j. But this contradicts property (1) of the intervals $I_m, m \in \mathbb{N}$. ■

Now we can finally give the proof of the Heine-Borel Theorem 1.24.



Proof of the Heine-Borel Theorem 1.24. In light of Lemma 1.23 we only need to show that if A is a bounded and closed subset of $\mathbb{R}^n$, then it is compact. Since A is bounded there exists a $C \geq 0$ such that $A \subset [-C, C]^n$. By the Hyperrectangle-Compact Proposition 1.26 we know that $A \subset [-C, C]^n$ is compact. Since A is closed in $\mathbb{R}^n$ it follows from the Neighborhood Openness Criterion 1.5 that is also a closed subset of $[-C, C]^n$. It follows from the Compact-Closed Lemma 1.21 that A itself is compact. ■

1.9. **Bases of a topology.** We start out with the following definition.

Definition. Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$ be a subset of the power set of X. We say $\mathcal{B}$ has the basis property if the following two conditions are satisfied:

(B1) For every $x \in X$ there exists a $B \in \mathcal{B}$ with $x \in B$.

(B2) Given any $B_1, B_2 \in \mathcal{B}$ and given any $x \in B_1 \cap B_2$ there exists a $B_3 \in \mathcal{B}$ such that $x \in B_3$ and $B_3 \subset B_1 \cap B_2$.

Example. Let (X, d) be a metric space. It follows from an elementary argument, see e.g. the proof of Proposition 1.4 (1), that the set of all open balls

$$\mathcal{B} \;=\; \{\text{all balls } B_r(x) \text{ with } r > 0 \text{ and } x \in X\} \;\subset\; \mathcal{P}(X)$$

satisfies (B1) and (B2).

The following lemma justifies our sudden interest in this new definition.

Lemma 1.27. (Topology-from-Basis Lemma) Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$. We define

$$\mathcal{T}(\mathcal{B}) \;:=\; \{V \subset X \,|\, \text{for every } x \in V \text{ there exists a } B \in \mathcal{B} \text{ with } x \in B \subset V\}.$$

If $\mathcal{B}$ has the basis property, then $\mathcal{T}(\mathcal{B})$ is a topology on X.

Definition. Let X be a set.

(1) If $\mathcal{B} \subset \mathcal{P}(X)$ has the basis property, then we refer to $\mathcal{T}(\mathcal{B})$ as the topology on X generated by $\mathcal{B}$.

(2) Conversely, if $\mathcal{T}$ is a given topology on X and if $\mathcal{B} \subset \mathcal{P}(X)$ has the basis property and if $\mathcal{T} = \mathcal{T}(\mathcal{B})$, then we say that $\mathcal{B}$ is a basis of the topology $\mathcal{T}$ of X.

Examples.

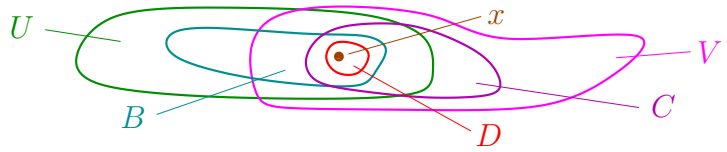
(1) If (X, d) is a metric space, then the topology generated by the set of all open balls, is by definition precisely the metric topology we already introduced on page 109.

(2) Let X be a set and let $\mathcal{T}$ be a topology on X. It follows easily from the definitions that $\mathcal{T}$ has the basis property. Furthermore it follows from the JH-Lemma 1.7 that the topology generated by $\mathcal{T}$ is in fact $\mathcal{T}$.

(3) Let $n \in \mathbb{N}$ and let $\mathbb{R}^n \cup \{\infty\}$ be the topological space defined on page 122. It follows immediately from the definition of the topology that a basis for the topological space $\mathbb{R}^n \cup \{\infty\}$ is given by

$$\mathcal{B} \;=\; \big\{B_r^n(x) \,\big|\, r > 0 \text{ and } x \in \mathbb{R}^n\big\} \;\cup\; \big\{\{\infty\} \cup (\mathbb{R}^n \setminus \overline{B}_C^n) \,\big|\, C \in \mathbb{R}\big\}.$$

For completeness we provide the elementary proof of the Topology-from-Basis Lemma 1.27, which turns out to be quite similar to the proof of the Metric-Topology Lemma 1.1.



Proof. Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$. We write

$$\mathcal{T} \;:=\; \mathcal{T}(\mathcal{B}) \;:=\; \{V \subset X \,|\, \text{for every } x \in V \text{ there exists a } B \in \mathcal{B} \text{ with } x \in B \subset V\}.$$

We need to show that $\mathcal{T}$ satisfies the three properties (1), (2) and (3) in the definition of a topological space, see page 107.

(1) First we need to show that $\varnothing, X \in \mathcal{T}$. It is clear that the empty set $\varnothing$ lies in $\mathcal{T}$. Furthermore given any $x \in X$ there exists by (B1) a $B \in \mathcal{B}$ with $x \in B$. Thus it follows from the definitions that $X \in \mathcal{T}$.

(2) We need to show that the intersection of finitely many sets in $\mathcal{T}$ is again a set in $\mathcal{T}$.
First we consider the case of two sets in $\mathcal{T}$. Thus let $U, V \in \mathcal{T}$. We need to show that $U \cap V \in \mathcal{T}$. Let $x \in U \cap V$. Since U and V lie in $\mathcal{T}$ there exist $B, C \in \mathcal{B}$ with $x \in B \subset U$ and $x \in C \subset V$. By (B2) there exists a $D \in \mathcal{B}$ with $x \in D$ and $D \subset B \cap C$. In particular we have $x \in D \subset U \cap V$. This shows that $U \cap V \in \mathcal{T}$.

Now let $U_1, \ldots, U_k$ be sets in $\mathcal{T}$. Using the above statement and an elementary induction argument we see that $U_1 \cap \cdots \cap U_k$ lies in $\mathcal{T}$ as well.

(3) Let $U_j, j \in J$ be a family of sets in $\mathcal{T}$. We need to show that the union $\bigcup_{j \in J} U_j$ lies in $\mathcal{T}$. Thus let $x \in \bigcup_{j \in J} U_j$. This means that there exists a $k \in J$ with $x \in U_k$. Since $U_k \in \mathcal{T}$ there exists a $B_x \in \mathcal{B}$ with $x \in B_x \subset U_k$. But then we also have

$$x \in B_x \subset U_k \subset \bigcup_{j \in J} U_j.$$

■

The following lemma can be used to show that two topologies on a given set agree.

Lemma 1.28. (Subbasis Lemma) Let X be a set and let $\mathcal{S}$ and $\mathcal{T}$ be topologies for X. Suppose that $\mathcal{C}$ is a basis for $\mathcal{T}$. (As discussed above we could take $\mathcal{C} = \mathcal{T}$.) If for every $x \in X$ and every $V \in \mathcal{C}$ there exists a $U \in \mathcal{S}$ with $x \in U \subset V$, then $\mathcal{T} \subset \mathcal{S}$.

Example. Let $n \in \mathbb{N}$. We consider the two metrics

$$\begin{array}{rcl} \mathbb{R}^n \times \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (v, w) & \mapsto & \|v - w\| \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathbb{R}^n \times \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (v, w) & \mapsto & \max\{|v_i - w_i| \,|\, i \in \{1, \ldots, n\}\}. \end{array}$$

The former is the Euclidean metric that we introduced on page 104. We refer to the second metric as the *maximum's metric*. We leave it as a task to the dedicated reader to show, using the Subbasis Lemma 1.28, that the two topologies on $\mathbb{R}^n$ agree.

Proof. It follows immediately from the JH-Lemma 1.7 that any set in $\mathcal{C}$ is open in $\mathcal{S}$. But then, once again using the JH-Lemma 1.7 we see that any set in $\mathcal{T}$ is open in $\mathcal{S}$, i.e. $\mathcal{T} \subset \mathcal{S}$. ■

Sometimes the following two lemmas can be useful.

Lemma 1.29. Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$. If $\mathcal{B}$ has the basis property, then

$$V \subset X \text{ is open with respect to } \mathcal{T}(\mathcal{B}) \iff V \text{ is the union of sets in } \mathcal{B}.$$

Proof of Lemma 1.29. We first prove the "$\Leftarrow$"-direction. Thus let V be the union of sets in $\mathcal{B}$. Since sets in $\mathcal{B}$ are open with respect to $\mathcal{T}(\mathcal{B})$ and since $\mathcal{T}(\mathcal{B})$ is a topology we see that $V \in \mathcal{T}(\mathcal{B})$.

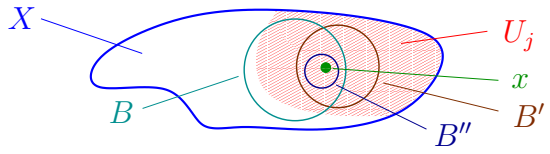
Now we prove the "$\Rightarrow$"-direction. Thus we suppose that $V \subset X$ is open with respect to $\mathcal{T}(\mathcal{B})$. For each $x \in V$ there exists, by definition of $\mathcal{T}(\mathcal{B})$, a set $B_x \in \mathcal{B}$ with $x \in B_x \subset V$. We see that

$$V = \bigcup_{x\in V}\{x\} \subset \bigcup_{x\in V} B_x \subset V, \quad \text{thus it follows that } V = \bigcup_{x\in V} B_x. \qquad \blacksquare$$

Lemma 1.30. Let $\mathcal{B}$ be a basis for the topology of a topological space X. Furthermore let $\{U_j\}_{j\in J}$ be an open cover of X, i.e. $\{U_j\}_{j\in J}$ is a family of open sets with $\bigcup_{j\in J} U_j = X$. Then

$$\{B \in \mathcal{B} \,|\, \text{ there exists some } j \in J \text{ with } B \subset U_j\}$$

is also a basis for the topology of X.



Proof. We set

$$\mathcal{C} := \{B \in \mathcal{B} \,|\, \text{ there exists some } j \in J \text{ with } B \subset U_j\}.$$

Since $\mathcal{C} \subset \mathcal{B}$ we have $\mathcal{T}(\mathcal{C}) \subset \mathcal{T}(\mathcal{B})$. It remains to show the reverse inclusion $\mathcal{T}(\mathcal{B}) \subset \mathcal{T}(\mathcal{C})$. It follows easily from the JH-Lemma 1.7 that it suffices to show that $\mathcal{B} \subset \mathcal{T}(\mathcal{C})$. In other words, it suffices to prove the following claim.

Claim. Given any $x \in X$ and any $B \in \mathcal{B}$ with $x \in B$ there exists a $C \in \mathcal{C}$ such that $x \in C \subset B$.

Proof. So let $x \in X$ and let $B \in \mathcal{B}$ with $x \in B$. By hypothesis there exists a j such that $x \in U_j$. Since U_j is open and since $\mathcal{B}$ is a basis for the topology of X there exists a $B' \in \mathcal{B}$ with $x \in B' \subset U_j$. By (B2) there exists a $B'' \subset B$ with $x \in B''$ and $B'' \subset B \cap B' \subset U_j$. So we are done since by definition we have $B'' \in \mathcal{C}$. $\blacksquare$

Example. We consider the topological space $\mathbb{R}^n$. As we pointed out on page 132, the set of open balls $\mathcal{B} = \{B_r^n(x) \,|\, r > 0 \text{ and } x \in \mathbb{R}^n\}$ is a basis for the topology of $\mathbb{R}^n$. We denote by $\mathcal{U}$ the family of all open sets that are contained in an open ball of radius 1. Then the open sets in $\mathcal{U}$ cover $\mathbb{R}^n$. It follows from Lemma 1.30 that

$$\{B_r^n(x) \,|\, r \in (0,1) \text{ and } x \in \mathbb{R}^n\}$$

is also a basis for $\mathbb{R}^n$.

The following lemma gives us in particular another source of topologies.

Lemma 1.31. Let X be a set. For any $\mathcal{C} \subset \mathcal{P}(X)$ the set

$$\mathcal{B}(\mathcal{C}) := \begin{array}{c}\text{all subsets of } X \text{ that can be written as} \\ \text{intersections of a finite family of sets in } \mathcal{C}\end{array}$$

has the basis property.

Proof.

(1) On page 87 we pointed out that if we take the empty family of subsets of X, then the intersection is all of X. In other words, we see that $X \in \mathcal{B}(\mathcal{C})$. It follows that $\mathcal{B}(\mathcal{C})$ satisfies (B1).

(2) It is easy to verify that $\mathcal{B}(\mathcal{C})$ satisfies (B2). $\blacksquare$

The previous lemma leads us to the following definition.

Definition. Let X be a set and let $\mathcal{C} \subset \mathcal{P}(X)$.

(1) We define $\mathcal{B} = \mathcal{B}(\mathcal{C})$ as in Lemma 1.31 and we refer to $\mathcal{T}(\mathcal{B})$ as the topology generated by $\mathcal{C}$.
(2) Conversely, if $\mathcal{T}$ is a topology on X and if the topology generated by $\mathcal{C}$ agrees with $\mathcal{T}$, then we say that $\mathcal{C}$ is a subbasis for $\mathcal{T}$.

Example.

(1) Let $\mathcal{C}$ be the set of all intervals in $\mathbb{R}$ of length one. One can easily verify that $\mathcal{C}$ generates the usual topology on $\mathbb{R}$.
(2) It follows easily from the definitions that a basis of a given topology is also a subbasis of the topology.

The following lemma gives us a convenient characterization of (sub-) bases for a given topology.

Lemma 1.32. (Basis Characterization Lemma) Let X be a topological space and let $\mathcal{C}$ be a family of subsets of X.

(1) The following two statements are equivalent:
   (a) Every $C \in \mathcal{C}$ is open and given any open set U and given any $x \in U$ there exists a $C \in \mathcal{C}$ with $x \in C \subset U$.
   (b) $\mathcal{C}$ is a basis for the topology of X.
(2) Suppose $\mathcal{B}$ is a basis for the topology of X. The following two statements are equivalent:
   (a) Every $C \in \mathcal{C}$ is open and given any $x \in X$ and given any $B \in \mathcal{B}$ there exist finitely many $C_1, \ldots, C_m \in \mathcal{C}$ with $x \in C_1 \cap \cdots \cap C_m \subset B$.
   (b) $\mathcal{C}$ is a subbasis for the topology of X.

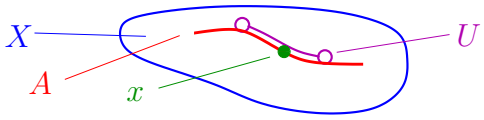
Example. In Exercise 1.8 we will show, using the Basis Characterization Lemma 1.32, that the set of open *rational* intervals forms a basis for the usual topology on $\mathbb{R}$. In particular $\mathbb{R}$ has a countable basis for its topology.

Proof.

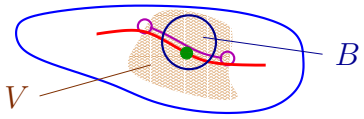
(1) We denote by $\mathcal{T}$ the topology of X. The implication (b) $\Rightarrow$ (a) follows immediately from the definitions. So let us turn to the proof of (a) $\Rightarrow$ (b). First we show that $\mathcal{C}$ has the basis property:
   (B1) If we apply the property of $\mathcal{C}$ to $U = X$ then we obtain immediately that given any $x \in X$ there exists a $C \in \mathcal{C}$ with $x \in C$.
   (B2) Let $x \in C_1 \cap C_2$ with $C_1, C_2 \in \mathcal{C}$. Since C_1 and C_2 are open the intersection $U = C_1 \cap C_2$ is also open. It follows from the hypothesis on $\mathcal{C}$, applied to U, that there exists a $C \in \mathcal{C}$ with $x \in C \subset C_1 \cap C_2$.

   Let $\mathcal{S}$ be the topology on X that is generated by $\mathcal{C}$. We need to show that $\mathcal{S} = \mathcal{T}$.

   First we show the inclusion $\mathcal{S} \subset \mathcal{T}$. Since all sets in $\mathcal{C}$ are open with respect to $\mathcal{T}$ it follows from Lemma 1.29 that $\mathcal{S} \subset \mathcal{T}$.



Finally we show the reverse inclusion $\mathcal{T} \subset \mathcal{S}$. Thus let $U \in \mathcal{T}$. We need to show that $U \in \mathcal{S}$. Thus let $x \in U$. By our hypothesis there exists a $C \in \mathcal{C}$ with $x \in C \subset U$. Therefore by definition we have $U \in \mathcal{S}$. We have thus shown that $\mathcal{T} \subset \mathcal{S}$.

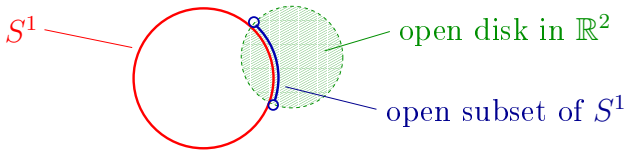


(2) We leave the verification of this statement to the reader. ■

We conclude this section with the following not terribly inspiring lemma.

Lemma 1.33. Let X be a topological space and let $A \subset X$ be a subset. If $\mathcal{B}$ is a basis for the topology of X, then $\{B \cap A \,|\, B \in \mathcal{B}\}$ is a basis for the topology of A, equipped with the subspace topology.

Proof. We prove the lemma using the Basis Characterization Lemma 1.32 (1). Thus let $U \subset A$ be an open subset in A and let $x \in U$. By definition of the subspace topology there exists an open subset $V \subset X$ of X with $U = V \cap A$. Since $\mathcal{B}$ is a basis for the topology of X there exists a $B \in \mathcal{B}$ with $x \in B \subset V$. This implies that $x \in B \cap A \subset V \cap A = U$. It follows from the Basis Characterization Lemma 1.32 (1) that $\{B \cap A \,|\, B \in \mathcal{B}\}$ is indeed a basis for the topology of A. ■



Example. We consider $$S^1 \;=\; \{(x,y) \in \mathbb{R}^2 \,|\, x^2 + y^2 = 1\} \;\subset\; \mathbb{R}^2.$$

As we saw on page 132, a basis for the topology on $\mathbb{R}^2$ is given by

$$\mathcal{B} \;=\; \{B_r(x,y) \,|\, (x,y) \in \mathbb{R}^2 \text{ and } r > 0\}.$$

The intersection of such an open ball with S^1 is an "open interval on S^1", i.e. it is a subset of the form $\{\exp(\mathrm{i}\varphi) \,|\, \varphi \in (a,b)\}$. It follows from Lemma 1.33 that these "open intervals" form a basis for the topology on S^1.

Exercises for Chapter 1.

Exercise 1.1. Let X be a finite set. Show that a topology $\mathcal{T}$ on X is metrizable if and only if it is the discrete topology.

Exercise 1.2. Recall that a topological space X is called *metrizable* if there exists a metric d on X such that the given topology agrees with the topology coming from d. We say that a metric space (X,d) is *complete* if every Cauchy sequence in (X,d) converges. Furthermore we say that a topological space X is *completely metrizable* if there exists a complete metric d on X such that the given topology agrees with the topology coming from d.

(a) Is $(0,1)$ completely metrizable?
(b) Is $\mathbb{Q}$ completely metrizable?

Exercise 1.3. Let (X,d) be a metric space and let $A \subset X$ be a subset. The restriction of the metric $d\colon X \times X \to \mathbb{R}_{\geq 0}$ to the map $d\colon A \times X \to \mathbb{R}_{\geq 0}$ defines a metric on A. We equip the metric spaces (X,d) and (A,d) with the corresponding topologies $\mathcal{X}$ and $\mathcal{A}$ as defined in Metric-Topology Lemma 1.1. Show that the topology $\mathcal{A}$ on A is the subspace topology of $A \subset X$ as defined on page 112.

Exercise 1.4. Let X be a set and let $\mathcal{S}, \mathcal{T}$ be two topologies on X. We assume that the following statements hold:

(1) For each $U \in \mathcal{S}$ there exists a $V \in \mathcal{T}$ with $V \subset U$.
(2) For each $V \in \mathcal{T}$ there exists a $U \in \mathcal{S}$ with $U \subset V$.

Does it follow that $\mathcal{S} = \mathcal{T}$?

Exercise 1.5. Let $X \subset \mathbb{R}^n$.

(a) Show that if the subspace topology on X is the discrete topology, then X is countable.
(b) Show that the converse to (a) does not hold.

Exercise 1.6. Let X be a topological space and let A be a subset of X. Show that the following three equalities hold:

$$\begin{array}{lrcl}
(1) & \mathring{A} & = & \{x \in A \mid \text{there exists a neighborhood } U \text{ of } x \text{ that is contained in } A\} \\
(2) & \overline{A} & = & \{x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A\} \\
(3) & \partial A & = & \{x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A \\
 & & & \qquad \text{and one point that does not lie in } A\}
\end{array}$$

Exercise 1.7. Let $n \in \mathbb{N}$. We fix a point $P \in \mathbb{R}^n$ and we consider the maps

$$\begin{array}{rcl} d_M\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ ((x_1,\ldots,x_n),(y_1,\ldots,y_n)) & \mapsto & \sum_{i=1}^{n} |x_i - y_i| \end{array} \quad \text{and} \quad \begin{array}{rcl} d_S\colon \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & \|x-P\| + \|y-P\| \end{array}$$

which on page 104 we called the Manhattan metric respectively the SNCF metric.

(a) Show that the Manhattan metric is equivalent to the Euclidean metric, i.e. show that they define the same topology on $\mathbb{R}^n$.
(b) Show that the SNCF metric is not equivalent to the Euclidean metric.

Exercise 1.8.

(a) Show that the open *rational* intervals, i.e. the open intervals (a,b) with $a,b \in \mathbb{Q}$, form a basis for the usual topology on $\mathbb{R}$.
(b) Let $n \in \mathbb{N}_0$. Show that the set of open balls $B_r(x)$ with $r \in \mathbb{Q}_{>0}$ and $x \in \mathbb{Q}^n$ form a basis for the usual topology on $\mathbb{R}^n$.

Exercise 1.9. Let U be an open subset of $\mathbb{R}^2$. Is it true that the interior of $\overline{U}$ equals U?

Exercise 1.10. Let $\{U_i\}_{i \in I}$ be a family of subsets. If I is finite, then we know by Lemma 1.11 that the following two equalities hold:

$$\text{(a)} \quad \text{interior of } \bigcap_{i \in I} U_i = \bigcap_{i \in I} \mathring{U}_i \qquad \text{and} \qquad \text{(b)} \quad \text{closure of } \bigcup_{i \in I} U_i = \bigcup_{i \in I} \overline{U_i}.$$

Do these equalities also hold if I is infinite?

Exercise 1.11. Are the topological spaces $\mathbb{Q}$ and $\mathbb{Q} \setminus \{0\}$ (equipped with the subspace topology coming from $\mathbb{R}$) homeomorphic?

Exercise 1.12. Is every open subset of $\mathbb{R}$ the disjoint union of countably many open intervals?

Exercise 1.13. Let $\{U_s\}_{s \in S}$ be an open cover of the interval $[0,1]$. Show that there exist $0 = t_0 < t_1 < \cdots < t_{k-1} < t_k$ such that each interval $[t_i, t_{i+1}]$ is contained in one of the U_s.
Remark. Note that we do not assume that the U_s are connected.

Exercise 1.14. Let (X,d) be a compact metric space. A rather surprising theorem, see **[Gros1964]** or alternatively **[Ris2006]**, says that there exists a unique $r \in \mathbb{R}_{\geq 0}$ such that for any finite sequence of points $x_1, \ldots, x_n \in X$ there exists an $x' \in X$ with $\frac{1}{n}\sum_{i=1}^{n} d(x_i, x') = r$. This number is called the *rendezvous value of* (X,d).

(a) Determine the rendezvous value of the interval $X = [0,1]$ equipped with the metric $d(x,y) = |x-y|$.
(b) Determine the rendezvous value of the circle $X = S^1$ equipped with the Euclidean metric of $\mathbb{R}^2$.

Exercise 1.15. Let X be a Hausdorff space, let $x_1, \ldots, x_k$ be distinct points in X and let $U_1, \ldots, U_k$ be neighborhoods of $x_1, \ldots, x_k$. Show that there exist disjoint open neighborhoods $V_1, \ldots, V_k$ of $x_1, \ldots, x_k$.

Exercise 1.16. Let X be a topological space that is Hausdorff.

(a) Let $K_1 \supset K_2 \supset K_3 \supset \ldots$ be a sequence of non-empty compact subsets. Show that $\bigcap_{n \in \mathbb{N}} K_n$ is also non-empty.
(b) Does the conclusion of (a) hold, if we only assume that the K_n are closed?

Exercise 1.17. Let X be a topological space that is Hausdorff and let $x, y \in X$ be two distinct points. Can you always find open neighborhoods U of x and V of y such that the closures are disjoint, i.e. such that $\overline{U} \cap \overline{V} = \varnothing$?

Exercise 1.18.

(a) Show that "$\mathbb{R}^n$ with a point at infinity" is Hausdorff and compact.
(b) Show that "the line with two zeros" is neither Hausdorff nor compact.

Exercise 1.19. Let X be a topological space.

(1) A point $x_0 \in X$ is called *isolated* if $\{x_0\}$ itself is an open subset.
(2) Let $U \subset X$ be a subset. We say $x \in X$ is an *accumulation point of* U, if every neighborhood of x contains a point in $U \setminus \{x\}$.

With these definitions we can formulate our exercise:

(a) Let $x \in U$. Show that x is an accumulation point of U if and only if x is not isolated in U, in the sense of the definition on page 235.
(b) We denote by $A(U)$ the accumulation points of U and we denote by $I(U)$ the isolated points of U. Show that the closure $\overline{U}$ equals $A(U) \cup I(U)$.
(c) Let $f, g \colon X \to \mathbb{R}$ be maps which agree on U. Show that for every accumulation point x of U we also have $f(x) = g(x)$.

Remark. In the literature accumulation points are sometimes also called limit points or cluster points.

Exercise 1.20. Given $a, b \in \mathbb{N}$ we define

$$U_a(b) \ := \ \{b + n \cdot a \in \mathbb{N} \,|\, n \in \mathbb{Z}\} \ \subset \ \mathbb{N}.$$

Furthermore we set

$$\mathcal{C} \ := \ \{U_p(b) \,|\, p, b \in \mathbb{N} \text{ and } p \text{ prime}\} \ \subset \ \mathcal{P}(\mathbb{N}).$$

The topology $\mathcal{T}$ on $\mathbb{N}$ generated by $\mathcal{C}$ is called the *prime integer topology*.

(a) Show that $(\mathbb{N}, \mathcal{T})$ is Hausdorff.

(b) A topological space X is called *regular* if given any $P \in X$ and given any closed subset $A \subset X$ with $x \notin A$ there exist disjoint open subsets U and V with $P \in U$ and $A \subset V$. Show that $(\mathbb{N}, \mathcal{T})$ is not regular.

Exercise 1.21. Given $a \in \mathbb{Z} \setminus \{0\}$ and $b \in \mathbb{Z}$ we define

$$S(a, b) \ := \ \{a \cdot n + b \,|\, n \in \mathbb{Z}\} \ = \ a \cdot \mathbb{Z} + b.$$

We say that $U \subset \mathbb{Z}$ is open if for every $x \in U$ there exists a subset $S(a, b)$ as above with $x \in S(a, b) \subset U$. We denote by $\mathcal{T}$ the set of all open subsets of $\mathbb{Z}$.

(a) Show that $\mathcal{T}$ is a topology on $\mathbb{Z}$. (This topology is called the *evenly spaced integer topology* on $\mathbb{Z}$).

(b) Show that each set of the form $S(a, b)$ is also closed.

(c) Let P be the set of prime numbers. Show that $\mathbb{Z} \setminus \{-1, 1\} = \bigcup_{p \in P} S(p, 0)$.

(d) Show that there exist infinitely many primes.

Remark. This proof that there exist infinitely many primes was found by Harry Furstenberg [**Furs1955**] in 1955.

Exercise 1.22. Let X be a topological space, let $A \subset X$ be a closed subset and let $K \subset X$ be a compact subset. Show that $A \cap K$ is also compact.

Exercise 1.23. Let X be a topological space and let $A \subset X$ be a subset.

(a) We suppose that X is Hausdorff. Show that $\partial A = \partial \overline{A}$.

(b) Does the conclusion in (a) also hold if X is not Hausdorff?

Exercise 1.24. Let X be a topological space.

(a) Show that the intersection of finitely many open and dense subsets is again open and dense.

(b) Show that the intersection of countably many open and dense subsets is in general not dense.

Exercise 1.25. Let X be a topological space. We say a subset $U \subset X$ is *large* if U is open and dense.

(a) Show that the intersection of finitely many large subsets of X is again large.

(b) Is it true that the intersection of countably many large subsets of X is necessarily large?

Exercise 1.26. Show that the topological space $[0, 1] \cap \mathbb{Q}$, equipped with the subspace topology coming from $\mathbb{R}$, is not compact.

Exercise 1.27. We consider

$$\mathbb{R}^\infty := \{(x_1, x_2, \dots) \in \mathbb{R}^{\mathbb{N}} \mid \text{there exists an } i \in \mathbb{N} \text{ such that } x_j = 0 \text{ for } j \geq i\}.$$

We equip $\mathbb{R}^\infty$ with the Euclidean metric

$$\begin{array}{rcl} d\colon \mathbb{R}^\infty \times \mathbb{R}^\infty & \to & \mathbb{R}^\infty \\ ((x_1, x_2, \dots), (y_1, y_2, \dots)) & \mapsto & \sqrt{\sum_{i \in \mathbb{N}} |x_i - y_i|^2}. \end{array}$$

Show that $(\mathbb{R}^\infty, d)$ is not compact.

Exercise 1.28. Let X be a topological space. Recall that a subset $A \subset X$ is called *precompact in* X if the closure $\overline{A}$ is compact. Let X be a subset of some topological space Y and let $A \subset X$ be a precompact subspace.

(a) Show that A is not necessarily precompact in Y.
(b) Show that if Y is Hausdorff, then A is in fact precompact in Y.

Remark. Dealing with closures can be quite subtle. For example, it seems to me that for (b) you want to use the Neighborhood Openness Criterion 1.5 (2) at some point.

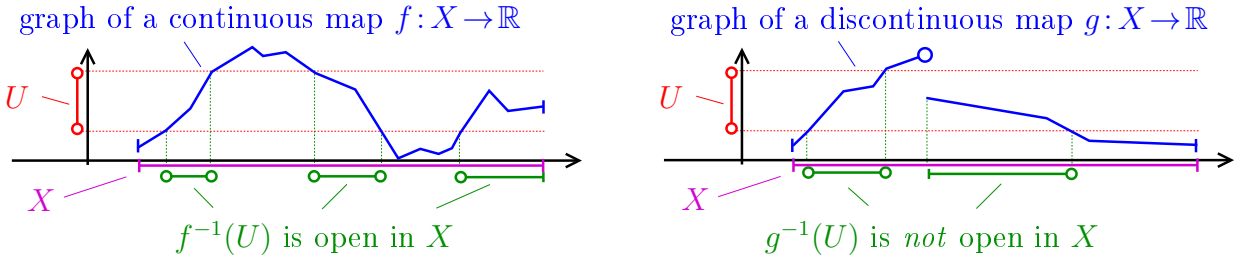
Exercise 1.29. Let X be a topological space. We say that a family $\{A_i\}_{i \in I}$ of subsets has the *finite intersection property* if given any finite collection of indices $i_1, \dots, i_r \in I$ the corresponding intersection $A_{i_1} \cap \dots \cap A_{i_r}$ is non-empty.

(a) We assume that X is a compact space and that all the A_i are closed subsets. Show that $\bigcap_{i \in I} A_i \neq \varnothing$.
(b) Show that in (a) we cannot drop the hypothesis that X is compact.

Exercise 1.30. Show that every open subset of $\mathbb{R}^n$ is the union of countably many open balls.

Exercise 1.31. Let X be a Hausdorff space, let A be a subset of X and let B be a compact subset of X. Show that if $A \cap B = \varnothing$, then there exists an open subset U of X with $A \subset U$ and $U \cap B = \varnothing$.

Hint. Look at the (proof of) the Compact Hausdorff-Normal Lemma 1.16.



2. Continuity

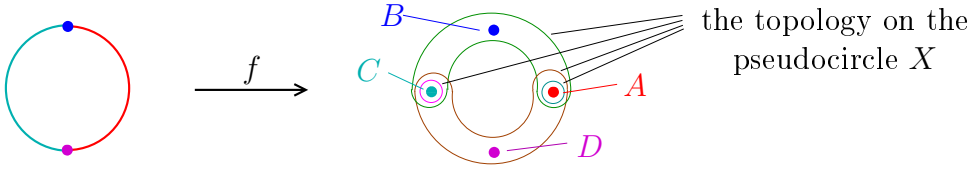
2.1. **Continuous maps.** The following is the key definition in the context of topological spaces.

Definition. We say a map $f\colon X \to Y$ between two topological spaces X and Y is continuous, if for each open set U in Y the preimage $f^{-1}(U)$ is open in X. Otherwise the map is called discontinuous.

Examples.

(1) For subsets $X \subset \mathbb{R}$ and maps $\mathbb{R} \to \mathbb{R}$ we see in the figure below that the above definition of continuous matches our intuition.

(2) Let X and Y be two topological spaces. If Y is equipped with the trivial topology or if X is equipped with the discrete topology, then every map $f\colon X \to Y$ is continuous.



(3) We consider the set $X = \{A, B, C, D\}$ where the topology is given by the set

$$\mathcal{T} := \{\varnothing, \{A\}, \{C\}, \{A, C\}, \{A, B, C\}, \{A, C, D\}, X\}.$$

We refer to this to topological spaces as the *pseudocircle*. It follows easily from the definitions that the map

$$\begin{array}{rcl} f\colon S^1 & \to & X \\ \exp(it) & \mapsto & \begin{cases} A, & \text{if } t \in (-\frac{\pi}{4}, \frac{\pi}{4}), \\ B, & \text{if } t = \frac{\pi}{4}, \\ C & \text{if } t \in (\frac{\pi}{4}, \frac{3\pi}{4}), \\ D & \text{if } t = \frac{3\pi}{4}. \end{cases} \end{array}$$

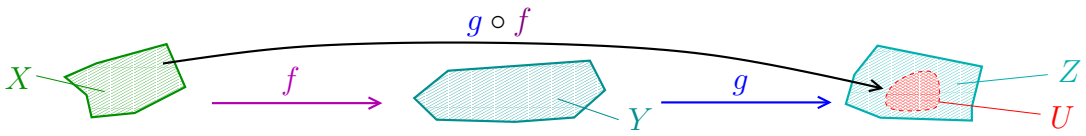
is continuous.

(4) Let X and Y be topological spaces and let $y \in Y$. The constant map

$$\begin{array}{rcl} c_y\colon X & \to & Y \\ x & \mapsto & y \end{array}$$

is continuous since the preimage of any set in Y is either $\varnothing$ or all of X. This simple example will come in handy on many occasions.

Lemma 2.1.



(1) If $f\colon X \to Y$ and $g\colon Y \to Z$ are two continuous maps between topological spaces, then the composition $g \circ f\colon X \to Z$ is also continuous.
(2) Let X be a topological space and let A be a subset. If we equip A with the subspace topology, then the inclusion map $i\colon A \to X$ is continuous.
(3) Let $f\colon X \to Y$ be a continuous map between topological spaces and let A be a subset. If we equip A with the subspace topology, then the restriction of f to the map $f|_A\colon A \to Y$ is also continuous.
(4) Let $f\colon X \to Y$ be a continuous map. If $Z \subset Y$ is a subset with $f(X) \subset Z$, then the map $f\colon X \to Z$ is also continuous.

Proof.

(1) Let $f\colon X \to Y$ and $g\colon Y \to Z$ be two continuous maps between topological spaces. We need to show that the composition $g \circ f\colon X \to Z$ is also continuous. Let $U \subset Z$ be an open subset. Then

$$(g \circ f)^{-1}(U) \;=\; f^{-1}(g^{-1}(U)) \;\underset{\uparrow}{=}\; f^{-1}(\text{the open set } g^{-1}(U)) \;\underset{\uparrow}{=}\; \text{open}.$$

since g is continuous and U is open; since f is continuous

(2) This statement follows immediately from the definitions.
(3) This statement is an immediate consequence of (1) and (2) since the restriction of f to A is precisely the same as $f \circ i$ where $i\colon A \to X$ denotes the inclusion.
(4) For clarity we denote by $g\colon X \to Z$ the map given by $x \mapsto f(x)$. Let $U \subset Z$ be an open subset. We need to show that $g^{-1}(U)$ is an open subset of X. By definition of the subspace topology there exists an open subset $V \subset X$ with $U = Z \cap V$. Thus we see that

$$g^{-1}(U) \;=\; g^{-1}(Z \cap V) \;\underset{\uparrow}{=}\; f^{-1}(Z \cap V) \;\underset{\uparrow}{=}\; f^{-1}(V) \;\underset{\uparrow}{=}\; \text{open subset of } X.$$

definition of g; since $f(X) \subset Z$; since f is continuous

■

We continue with several examples of continuous maps.

Lemma 2.2. Let $n \in \mathbb{N}$.

(1) For each $i \in \{1, \dots, n\}$ the projection

$$\begin{array}{rcl} \mathbb{R}^n & \to & \mathbb{R} \\ (x_1, \dots, x_n) & \mapsto & x_i \end{array}$$

is continuous.
(2) Let $f = (f_1, \dots, f_n)\colon X \to \mathbb{R}^n$ be a map from a topological space X to $\mathbb{R}^n$. Then f is continuous if and only if each $f_i\colon X \to \mathbb{R}$ is continuous.

Proof. We leave the slightly messy proof of the lemma to the reader. ■

Lemma 2.3. Let X be a topological space. If $f\colon X \to \mathbb{R}$ and $g\colon X \to \mathbb{R}$ are continuous maps, then the maps

$$\begin{array}{lll} X \to \mathbb{R} & X \to \mathbb{R} & X \to \mathbb{R} \\ x \mapsto f(x)+g(x) & x \mapsto f(x)\cdot g(x) & x \mapsto \max\{f(x),g(x)\} \end{array} \qquad \begin{array}{l} X \to \mathbb{R} \\ x \mapsto \min\{f(x),g(x)\} \end{array}$$

are also continuous.

Example. Let A be a real $(m\times n)$–matrix. It follows easily from Lemma 2.2 (1), Lemma 2.1 (1) and Lemma 2.3 that the following map is continuous:

$$\begin{array}{rcl} f\colon \mathbb{R}^n & \to & \mathbb{R}^m \\ v & \mapsto & A \cdot v. \end{array}$$

Proof. In Exercise 2.31 we will show that the maps

$$\begin{array}{rcl} \alpha\colon \mathbb{R}^2 & \to & \mathbb{R} \\ (x,y) & \mapsto & x+y \end{array} \quad \text{and} \quad \begin{array}{rcl} \beta\colon \mathbb{R}^2 & \to & \mathbb{R} \\ (x,y) & \mapsto & x\cdot y \end{array}$$

are continuous. The map $x \mapsto f(x)+g(x)$ equals the map

$$X \xrightarrow{x\mapsto(f(x),g(x))} \mathbb{R}^2 \xrightarrow{\alpha} \mathbb{R}.$$

By Lemma 2.2 (2) the first map is continuous. By the above we know that α is continuous. From Lemma 2.1 (1) we deduce that the map $f+g$ is continuous. The same argument also takes care of the map $x \mapsto f(x)\cdot g(x)$. Finally note that for any $a, b \in \mathbb{R}$ we have

$$\max\{a,b\} \;=\; \tfrac{1}{2}(a+b+|a-b|) \quad \text{and} \quad \min\{a,b\} \;=\; \tfrac{1}{2}(a+b-|a-b|).$$

Using this observation one can now easily show, by a slight modification of the previous arguments, that the maps $x \mapsto \max\{f(x),g(x)\}$ and $x \mapsto \min\{f(x),g(x)\}$ are continuous. ■

At times it is also useful to have a characterization of continuous maps in terms of closed sets.

Lemma 2.4. (Continuity-via-Closed Subsets Lemma) A map $f\colon X \to Y$ between two topological spaces X and Y is continuous if and only if for each closed set A in Y the preimage $f^{-1}(A)$ is closed in X.

Proof. This lemma is a straightforward consequence of the Image-Preimage Lemma 0.2 (8) and the definitions. We leave it to the reader to fill in the details. ■

For completeness' sake we also state the following lemma.

Lemma 2.5. (Closure-Interior Mapping Lemma) Let $f\colon X \to Y$ be a map between topological spaces.

(1) The following statements are equivalent:
   (a) The map is continuous.
   (b) For every subset $B \subset Y$ we have $f^{-1}(\overline{B}) \subset \overline{f^{-1}(B)}$.
   (c) For every subset $B \subset Y$ we have $f^{-1}(\mathring{B}) \subset$ interior of $f^{-1}(B)$.
   The analogous statement hold with the closures replaced by the interiors.

(2) If f is continuous, then the following statements hold:
   (a) For every subset $A \subset X$ we have $\overline{f(\overline{A})} = \overline{f(A)}$.

(b) For every subset $A \subset X$ we have $\operatorname{int}(f(\operatorname{int} A)) = \operatorname{int}(f(A))$.

Proof.

(1) We prove (a) $\Rightarrow$ (b). Thus we assume that $f\colon X \to Y$ is continuous. Let $B \subset Y$. By the Continuity-via-Closed Subsets Lemma 2.4 we know that $f^{-1}(\overline{B})$ is a closed subset of X that contains $f^{-1}(B)$. By the definition of the closure this means that $f^{-1}(\overline{B}) \subset \overline{f^{-1}(B)}$. We will prove the remaining statements in Exercise 2.11.

(2) (a) Evidently we have $f(A) \subset f(\overline{A})$. Thus we have $\overline{f(A)} \subset \overline{f(\overline{A})}$. We now show the reverse inclusion $\overline{f(\overline{A})} \subset \overline{f(A)}$. Since $\overline{f(A)}$ is a closed subset it suffices to show that $f(\overline{A}) \subset \overline{f(A)}$. Let Z be a closed subset of Y that contains $f(A)$. We need to show that $f(\overline{A}) \subset Z$. First note that we have $f(A) \subset Z$. Thus we see that $A \subset f^{-1}(f(A)) \subset f^{-1}(Z)$. Since Z is closed and f is continuous we obtain from the Continuity-via-Closed Subsets Lemma 2.4 that $f^{-1}(Z)$ is closed. Thus we have $\overline{A} \subset f^{-1}(Z)$. This finally implies that $f(\overline{A}) \subset f(f^{-1}(Z)) \subset Z$.

(b) Evidently we have $f(\operatorname{int}(A)) \subset f(A)$. Thus we have $\operatorname{int}(f(\operatorname{int}(A))) \subset \operatorname{int}(f(A))$. We now show the reverse inclusion $\operatorname{int}(f(A)) \subset \operatorname{int}(f(\operatorname{int}(A)))$. Since $\operatorname{int}(f(\operatorname{int} A))$ is an open subset it suffices to show that $\operatorname{int}(f(A)) \subset f(\operatorname{int}(A))$. Let U be an open subset subset of Y that is contained in $f(A)$. We need to show that $U \subset f(\operatorname{int}(A))$. We have $f^{-1}(U) \subset f^{-1}(f(A)) \subset A$. Since f is continuous we know that $f^{-1}(U)$ is an open subset of X. Thus we see that $f^{-1}(U) \subset \operatorname{int}(A)$. Since U is contained in the image of X we see that $U = f(f^{-1}(U))$. In summary we see that $U = f(f^{-1}(U)) \subset f(\operatorname{int}(A))$. ■

By Lemma 2.1 (3) we know that the restriction of a continuous map to any subset is still continuous. The following lemma can be viewed as a converse: if "enough" restrictions of a given map are continuous, then the original map is also continuous.
Initially the main application of Lemma 2.7 is the following proposition which we will use abundantly.

Proposition 2.6. (Pasting Proposition) Let $f\colon X \to Y$ be a map between topological spaces.

(1) If there exists an open subsets $\{W_i\}_{i\in I}$ of X such that each restriction $f|_{W_i}$ is continuous, then f itself is continuous.

(2) If there exists a *locally finite* closed cover $\{A_i\}_{i\in I}$ of X such that each restriction $f|_{A_i}$ is continuous, then f itself is continuous.

In practice often the following variation on (2) gets used:

(2′) If X is Hausdorff and if there exists a locally finite cover $\{A_i\}_{i\in I}$ of X such that each A_i is compact and such that each restriction $f|_{A_i}$ is continuous, then f itself is continuous.

Remark.

(1) In practice the Pasting Proposition 2.6 (2) often gets used in the following way: Suppose we are given two topological spaces X and Y and closed subsets $A_1, \ldots, A_m$ of X such that $X = A_1 \cup \cdots \cup A_m$. Furthermore we are given continuous maps

$f_i\colon A_i \to Y$, $i = 1, \dots, m$. If the f_i agree on the overlaps, then the map

$$\begin{array}{ccl} X & \to & Y \\ P & \mapsto & f_i(P) \quad \text{if } P \in A_i \end{array}$$

is well-defined and it follows from the Pasting Proposition 2.6 (2) that it is continuous.

(2) Note that in Pasting Proposition 2.6 (1) we are allowed to deal with arbitrarily many open subsets whereas in Pasting Proposition 2.6 (2) we are restricted to finitely many closed subsets. It is clear that Pasting Proposition 2.6 (2) cannot be generalized to arbitrarily many closed subsets, after all, the restriction of a map $f\colon \mathbb{R} \to \mathbb{R}$ to any one-point subset $\{x\} \subset \mathbb{R}$ is continuous, but clearly not every map $f\colon \mathbb{R} \to \mathbb{R}$ is continuous.

The proof of the Pasting Proposition 2.6 rests on the shoulders of the following lemma, which will at times also be of independent interest.

Auxiliary Lemma 2.7. Let X be a topological space and let $\{X_i\}_{i\in I}$ be a family of subsets. The following two statements are equivalent:

(1) A subset $U \subset X$ is open if each $U \cap X_i$ is open in X_i.
(2) A subset $U \subset X$ is closed if each $U \cap X_i$ is closed in X_i.

Furthermore, if (1) or equivalently (2) holds, then also the following statement holds:

(3) A map $f\colon X \to Y$ to some topological space Y is continuous if each restriction $f|_{X_i}\colon X_i \to Y$ is continuous.

Proof of Lemma 2.7.

(1)$\Rightarrow$(2) We assume that (1) holds. Now let $U \subset X$ be a subset. We have

$$\begin{array}{l} \text{for every } i \in I \text{ the set} \\ X_i \cap U \text{ is closed in } X_i. \end{array} \quad \begin{array}{l} \overset{\text{since } (X\setminus U)\cap X_i = X_i \setminus (X_i \cap U)}{\downarrow} \\ \Longrightarrow \quad \text{for every } i \in I \text{ the set} \\ \quad\ (X\setminus U)\cap X_i \text{ is open in } X_i \\ \Longrightarrow \ X \setminus U \text{ is open in } X \implies U \text{ is closed in } X. \\ \overset{\text{since (1) holds}}{\uparrow} \end{array}$$

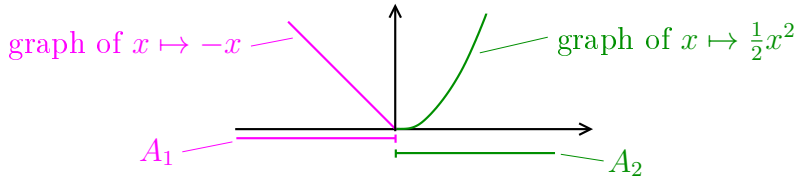
(2)$\Rightarrow$(1) This proof is basically the same as the above argument.

(1)$\Rightarrow$(3) Let $f\colon X \to Y$ be a map to some topological space Y. We suppose that each $f|_{X_i}$ is continuous. Let $U \subset Y$ be an open subset. We need to show that $f^{-1}(U)$ is an open subset of X. By (1) it suffices to show that each intersection $f^{-1}(U) \cap X_i$ is an open subset of X_i. But this follows from the observation that $f^{-1}(U) \cap X_i = (f|_{X_i})^{-1}(U)$ and the hypothesis that $f|_{X_i}$ is continuous. ■

Proof of the Pasting Proposition 2.6. Let $f\colon X \to Y$ be a map between topological spaces.

(1) This statement follows immediately from the combination of Lemma 1.8 (1a) and Lemma 2.7.
(2) Similar to (1) this statement follows immediately from the combination of Lemma 1.8 (2a) and Lemma 2.7.
(2′) This statement follows from (2) and the Compact-Closed Lemma 1.21 (2). ■

The notion of continuity is of course already familiar from earlier analysis courses. The following proposition shows that for maps between metric spaces the earlier "$\epsilon-\delta$"–definition of continuity agrees with the above definition of continuity.



Proposition 2.8. (Metric Continuity Proposition) Let $f\colon X \to Y$ be a map between metric spaces. Then the following holds:

$$f \text{ is continuous} \quad \Longleftrightarrow \quad \forall_{x\in X}\ \forall_{\epsilon>0}\ \exists_{\delta>0}\ \forall_{x'\in B_\delta(x)}\ d(f(x),f(x')) < \epsilon.$$

Remark. We use the Metric Continuity Proposition 2.8 to import from real analysis the various continuous functions on $\mathbb{R}$ and $\mathbb{C}$, e.g. polynomials, trigonometric functions and the exponential function. The replacement of the classic "$\epsilon - \delta$"–definition of continuity by the definition in terms of open sets can even be helpful in the context of real analysis. For example, let us consider the function

$$\begin{array}{rcl} f\colon \mathbb{R} & \to & \mathbb{R} \\ x & \mapsto & \begin{cases} \frac{1}{2}x^2, & \text{if } x \geq 0, \\ -x, & \text{if } x \leq 0. \end{cases} \end{array}$$

With the "$\epsilon - \delta$"–definition it is slightly annoying to prove continuity at 0. But applying Pasting Proposition 2.6 (2) to the closed subsets $A_1 = (-\infty, 0]$ and $A_2 = [0, \infty)$ it is totally evident that this function is continuous.

The previous remark leads us straight to the following convention.

Convention. The purist will correctly complain that the definition of the map in the previous remark is irregular, since the two cases treated in the definition of the map f are not disjoint. Nonetheless, on numerous occasions we will use such irregular definitions, usually to highlight the fact that we can use Pasting Proposition 2.6 to show that the map is continuous.

The proof of the Metric Continuity Proposition 2.8 requires some preparations. In particular it builds on the following proposition that frequently makes it much easier to show that a given map is continuous.

Proposition 2.9. (Subbasis-Continuity Proposition) Let $f\colon X \to Y$ be a map between topological spaces. Let $\mathcal{C}$ be a subbasis for the topology of Y (e.g. $\mathcal{C}$ could be a basis for the topology). Then the following holds

$$f \text{ is continuous} \quad \Longleftrightarrow \quad \text{for each } C \in \mathcal{C} \text{ the preimage } f^{-1}(C) \text{ is open in } X.$$

Proof of the Subbasis-Continuity Proposition 2.9. Let $f\colon X \to Y$ be a map between topological spaces and let $\mathcal{C}$ be a subbasis for the topology of Y. As in Lemma 1.31 we denote by $\mathcal{B} := \mathcal{B}(\mathcal{C})$ all subsets of Y that can be obtained by intersecting finitely many sets of $\mathcal{C}$.

The "⇒"-direction of the proposition follows from the observation that elements of a subbasis are in fact open. Thus let us turn to the "⇐"-direction. Now we assume that for each $C \in \mathcal{C}$ the preimage $f^{-1}(C)$ is open in X. We start out with a little observation. Suppose we are given $C_1, \ldots, C_k \in \mathcal{C}$, then

$$f^{-1}(C_1 \cap \cdots \cap C_k) \overset{\text{Image-Preimage Lemma 0.2}}{=} \underbrace{f^{-1}(C_1)}_{\text{open in } X} \cap \cdots \cap \underbrace{f^{-1}(C_k)}_{\text{open in } X}$$

is also open in X. This shows, by definition, that for each $B \in \mathcal{B} = \mathcal{B}(\mathcal{C})$ the preimage $f^{-1}(B)$ is open in X.

Now we turn to the actual proof that f is continuous. Thus let $U \subset Y$ be an open subset. By Lemma 1.29 there exists a family $\{B_j\}_{j \in J}$ of sets in $\mathcal{B}$ with

$$U = \bigcup_{j \in J} B_j.$$

Then we see that

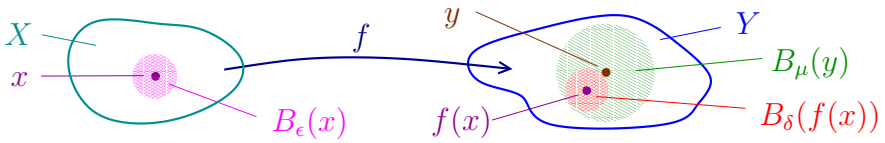
$$f^{-1}(U) = f^{-1}\Big(\bigcup_{j \in J} B_j\Big) \overset{\text{Image-Preimage Lemma 0.2}}{=} \underbrace{\bigcup_{j \in J} \underbrace{f^{-1}(B_j)}_{\text{open in } X}}_{\substack{\text{union of open} \\ \text{sets, thus open in } X}}.$$

■

Now that we have the Subbasis-Continuity Proposition 2.9 under the belt we can easily provide a proof of the Metric Continuity Proposition 2.8.

Proof of the Metric Continuity Proposition 2.8. Let $f\colon X \to Y$ be a map between metric spaces. We need to show that

$$f \text{ is continuous} \iff \forall_{x \in X} \forall_{\epsilon > 0} \exists_{\delta > 0} \forall_{y \in B_\delta(x)} d(f(x), f(y)) < \epsilon.$$



We prove the two directions separately:

"⇒" Let $x \in X$ and let $\epsilon > 0$. We consider $V := f^{-1}(B_\epsilon(f(x))) \subset X$. Since f is continuous we know that V is open. By the definition of the topology on a metric space there exists a $\delta > 0$ such that $B_\delta(x) \subset V$. This delta has the desired property.

"⇐" On page 132 we saw that the open balls form a basis for the topology of metric spaces. Thus by the Subbasis-Continuity Proposition 2.9 it suffices to show that if $y \in Y$ and $\mu > 0$, then $f^{-1}(B_\mu(y))$ is an open subset of X. By the definition of the topology on X it suffices to prove the following claim.

Claim. Given any $x \in f^{-1}(B_\mu(y))$ there exists an $\epsilon > 0$ with $B_\epsilon(x) \subset f^{-1}(B_\mu(y))$.

Proof. We set $\delta = \mu - d(f(x), y)$. Note that $\delta > 0$. By the triangle inequality we have $B_\delta(f(x)) \subset B_\mu(y)$. Furthermore by our hypothesis on f there exists an $\epsilon > 0$ such that $f(B_\epsilon(x)) \subset B_\delta(f(x))$. Thus we see that $B_\epsilon(x) \subset f^{-1}(B_\mu(y))$. ■

We continue with the following straightforward definition.

Definition. Let $f\colon X \to Y$ be a map between topological spaces.
(1) We say f is open if the image of every open subset of X is open in Y.
(2) We say f is closed if the image of every closed subset of X is closed in Y.

Examples.

(1) The projection $\mathbb{R}^2 \to \mathbb{R}$ given by $(x, y) \mapsto x$ is easily seen to be an open map, but it is not a closed map.[30]
(2) On the other hand the inclusion $i\colon \mathbb{R} \to \mathbb{R}^2$, $i(x) = (x, 0)$ is evidently not an open map, but it is a closed map.

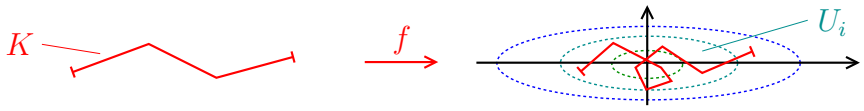
Lemma 2.10. (Open-Closed Inclusion Lemma) Let X be a topological space.
(1) If $U \subset X$ is an open subset, then the inclusion map $i\colon U \to X$ is open.
(2) If $A \subset X$ is a closed subset, then the inclusion map $i\colon A \to X$ is closed.

Proof.

(1) Suppose that V is an open subset of U. By definition of the subspace topology there exists an open subset $W \subset X$ with $V = U \cap W$. But then $i(V) = V = U \cap W$ is the intersection of two open subsets of X, thus it is an open subset of X.
(2) The proof of this statement is analogous to the proof of Statement (1), we just not to appeal to the Neighborhood Openness Criterion 1.5 (2) to make the necessary adjustments. ■

We have the following analogue to the Subbasis-Continuity Proposition 2.9.

Lemma 2.11. Let $f\colon X \to Y$ be a map between topological spaces. Let $\mathcal{C}$ be a subbasis for the topology of X (e.g. $\mathcal{C}$ could be a basis for the topology). Then the following holds:



$$f \text{ is open} \quad \Longleftrightarrow \quad \text{for each } C \in \mathcal{C} \text{ the image } f(C) \text{ is open in } Y.$$

Proof. The logic of the proof is very similar to the proof of the Subbasis-Continuity Proposition 2.9. Eventually the proof boils down to Lemma 1.29 and the Image-Preimage Lemma 0.2. ■

On many occasions we will use the following elementary lemma.

Lemma 2.12. Let $f\colon K \to X$ be a continuous map from a compact space K to a topological space X.[31] Suppose there exists a sequence $U_1, U_2, \ldots$ of subsets of X with the following properties:
(1) each U_i is open,
(2) the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$,
(3) we have $X = \bigcup_{i \in \mathbb{N}} U_i$.
Then there exists a $k \in \mathbb{N}$ with $f(K) \subset U_k$.

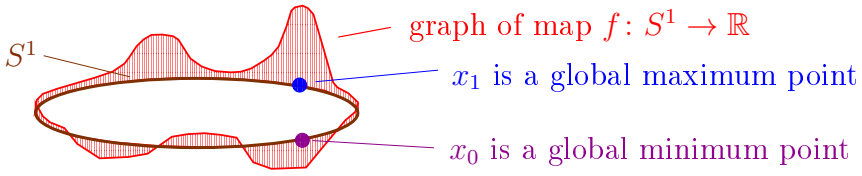
[30] Why is not a closed map?
[31] A common application is that K is a compact subset of X and f is the inclusion map.

Proof. For $i \in \mathbb{N}$ we write $V_i = f^{-1}(U_i)$. Since f is continuous it follows from (1) that each V_i is an open subset of K. By (3) the V_i cover all of K. Since K is compact there exist $i_1, \ldots, i_n \in \mathbb{N}$ such that $K = V_{i_1} \cup \cdots \cup V_{i_n}$. We set $k := \max\{i_1, \ldots, i_n\}$. Since the U_i are nested the V_i are also nested. It follows that K is already contained in V_k, put differently, $f(K)$ is contained in U_k. ■

In most instances we are dealing with continuous maps. Since constantly writing and reading "continuous maps" is tiresome for the author and the reader we adopt throughout the remainder of these lecture notes the following convention:

Convention. Henceforth any map between two topological spaces is assumed to be continuous, unless we say explicitly otherwise.

2.2. **The Compact-Image Lemma.** The first statement of the following lemma is perhaps the most important feature of compact spaces.



Lemma 2.13. (Compact Image Lemma)

(1) Let $f\colon X \to Y$ be a continuous map. If X is compact, then $f(X)$ is also compact.

(2) Let $f\colon X \to \mathbb{R}$ be a continuous map. If X is compact and non-empty, then f assumes its maximum and its minimum, i.e. there exist $x_0, x_1 \in X$ such that

$$f(x_0) \;\leq\; f(x) \;\leq\; f(x_1) \quad \text{for all } x \in X.$$

(3) Let $f\colon X \to Y$ be a continuous map. If X is compact and if Y is Hausdorff, then $f(X)$ is a closed subset of Y.

Example. Let X be a topological space, let Y be a subset and let $K \subset Y$ be another subset. If K is a compact subset of Y, then K is also a compact subset of X. This elementary observation follows immediately from the Compact Image Lemma 2.13 and the fact, observed above, that inclusion maps are continuous.

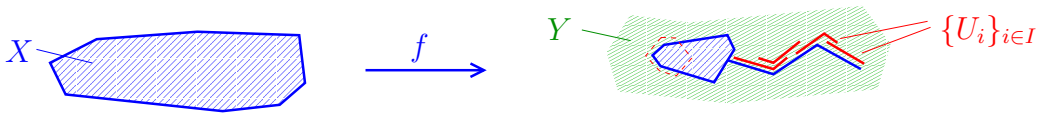
Remark. The statement of the Compact Image Lemma 2.13 (1) is really quite astounding. More precisely, we already saw that the image of an open set under a continuous map is not necessarily open. Similarly, the image of a closed set under a continuous map is not necessarily closed. For example consider the inclusion map $i\colon X = (0,1] \to Y = \mathbb{R}$. Evidently X is a closed subset of itself, but $i(X)$ is not a closed subset of $\mathbb{R}$. We will discuss such examples in more detail in Exercise 2.29.

Proof.

(1) Let $\{U_i\}_{i\in I}$ be an open cover of the topological space $f(X)$. We need to show that $f(X)$ is contained in the union of finitely many U_i's. We have

$$X \underset{\uparrow}{=} f^{-1}(f(X)) \subset f^{-1}\Big(\bigcup_{i\in I} U_i\Big) \underset{\uparrow}{=} \bigcup_{i\in I} f^{-1}(U_i).$$

Image-Preimage Lemma 0.2 (1) — Image-Preimage Lemma 0.2 (6)



By hypothesis the map $f\colon X \to Y$ is continuous. It follows from the elementary Lemma 2.1 that the map $f\colon X \to f(X)$ is also continuous, in particular each $f^{-1}(U_i)$ is an open subset of X. This observation together with the above discussion shows that $\{f^{-1}(U_i)\}_{i\in I}$ is an open cover of X. Since X is compact there exist $i_1, \dots, i_k \in I$ such that

$$X = f^{-1}(U_{i_1}) \cup \dots \cup f^{-1}(U_{i_k}).$$

Therefore

$$\begin{aligned} f(X) &= f\left(f^{-1}(U_{i_1}) \cup \dots \cup f^{-1}(U_{i_k})\right) \\ &\underset{\uparrow}{=} f\left(f^{-1}(U_{i_1})\right) \cup \dots \cup f\left(f^{-1}(U_{i_k})\right) \underset{\uparrow}{\subset} U_{i_1} \cup \dots \cup U_{i_k}. \end{aligned}$$

Image-Preimage Lemma 0.2 (3) — Image-Preimage Lemma 0.2 (2)

(2) It follows from (1) and the Heine-Borel Theorem 1.24 that $f(X) \subset \mathbb{R}$ is bounded and closed. Since X is non-empty we thus see that $y_0 := \inf(f(X))$ and $y_1 := \sup(f(X))$ exist and they lie in $f(X)$. Any choice of points $x_0 \in f^{-1}(y_0)$ and $x_1 \in f^{-1}(y_1)$ have the desired properties.

(3) This statement is an immediate consequence of the Compact-Closed Lemma 1.21 (1) and the first statement. ■

The Compact Image Lemma 2.13 is one of the results that we will cite most often. In the remainder of this section we want to give a first application to the study of norms on finite-dimensional real vector spaces. This result is somewhat tangential to the main story of the lecture notes, but it falls into the category of "nice to know".

For the reader's convenience let us recall the following definition from page 101.

Definition. Let V be a real vector space. A norm on V is a map $n\colon V \to \mathbb{R}_{\geq 0}$ that satisfies the following three properties:

(1) For every $v \in V$ we have $n(v) = 0 \iff v = 0$.
(2) For every $v \in V$ and $\lambda \in \mathbb{R}$ we have $n(\lambda \cdot v) = |\lambda| \cdot n(v)$.
(3) For every $v, w \in V$ we have $n(v + w) \leq n(v) + n(w)$.

Recall that in Lemma 0.17 and Metric-Topology Lemma 1.1 we saw that a norm gives rise to a metric and hence to a topology.

Definition. Let V be a real vector space. We say that two norms n and $\widetilde{n}$ on V are equivalent if there exist $c, C \in \mathbb{R}_{>0}$ such that for all $v \in V$ we have

$$c \cdot n(v)| \leq \widetilde{n}(v) \leq C \cdot n(v).$$

Lemma 2.14. Let V be a real vector space.

(1) The notion of "equivalence" of norms on V is indeed an equivalence relation.
(2) Equivalent norms give rise to the same topology on V

Proof. The first statement is basically trivial. The second statement follows from the elementary the Equivalent Metric Lemma 1.2. ■

The following proposition is the promised result on norms on finite-dimensional real vector spaces.

Proposition 2.15. (Norm Equivalence Proposition) Any two norms on a finite-dimensional real vector space are equivalent.

Remark. In Exercise 2.5 we will see that the analogous statement for infinite-dimensional vector spaces does not necessarily hold.

Proof. Evidently it suffices to consider $\mathbb{R}^k$. Furthermore note that by Lemma 2.14 it suffices to show that every norm n on $\mathbb{R}^k$ is equivalent to the Euclidean norm $\|-\|$. As usual we denote by $e_1, \dots, e_k$ the standard basis of $\mathbb{R}^k$. We set

$$C \ := \ \sqrt{n(e_1)^2 + \cdots + n(e_k)^2}.$$

Note that $C > 0$.

Claim 1. For every $v \in \mathbb{R}^k$ we have $n(v) \leq C \cdot \|v\|$.

Proof. Let $v = (v_1, \dots, v_k) \in \mathbb{R}^k$. We see that

$$\begin{aligned} n(v) \ = \ n(v_1 \cdot e_1 + \cdots + v_k \cdot e_k) &\overset{\text{since } n \text{ is a norm}}{\leq} |v_1| \cdot n(e_1) + \cdots + |v_k| \cdot n(e_k) \\ &\underset{\text{Cauchy-Schwarz Inequality 0.13 applied to } |v_1|, \dots, |v_k| \text{ and } n(e_1), \dots, n(e_k)}{\leq} \sqrt{(v_1^2 + \cdots + v_k^2) \cdot (n(e_1)^2 + \cdots + n(e_k)^2)} \ = \ \|v\| \cdot C. \end{aligned}$$

⊞

Since n is a norm it follows from Claim 1 that $n \colon \mathbb{R}^k \to \mathbb{R}$ is continuous with respect to the standard topology on $\mathbb{R}^k$ given by the Euclidean norm. By the Heine-Borel Theorem 1.24 we know that $S^{n-1} = \{v \in \mathbb{R}^k \,|\, \|v\| = 1\}$ is compact. Therefore we know by the Compact Image Lemma 2.13 that there exists a $u \in S^{n-1}$ such that $n(u) \leq n(w)$ for all $w \in S^{n-1}$. Note that by Property (1) of the norm n we know that $n(u) > 0$. We set $c := \frac{1}{n(u)}$. Evidently $c > 0$. At this stage it remains to prove the following claim.

Claim 2. For every $v \in \mathbb{R}^k$ we have $\|v\| \leq c \cdot n(v)$.

Proof. Let $v \in \mathbb{R}^k$. If $v = 0$, then there is nothing to show. So suppose that $v \neq 0$. We see that

$$\|v\| \ \underset{\text{definition of } c}{=} \ \|v\| \cdot c \cdot n(u) \ \underset{\text{choice of } u}{\leq} \ \|v\| \cdot c \cdot n\Big(\frac{v}{\|v\|}\Big) \ \underset{\text{since } n \text{ is a norm}}{=} \ c \cdot n(v).$$

■

2.3. Homeomorphisms.

We introduce the main objects of interest of this section.

Definition.

(1) We say a map $f\colon X \to Y$ between two topological spaces X and Y is a homeomorphism if the following three properties are satisfied:
   (a) f is continuous,
   (b) f is bijective,
   (c) the inverse map $f^{-1}\colon Y \to X$ is also continuous.
   If there exists a homeomorphism between X and Y we say that X and Y are homeomorphic and sometimes we write $X \cong Y$.

(2) We say a map $f\colon X \to Y$ between two topological spaces X and Y is an embedding if $f\colon X \to f(X)$, where $f(X)$ is equipped with the subspace topology, is a homeomorphism. We say the embedding is closed if $f(X)$ is a closed subset of Y and we say the embedding is open if $f(X)$ is an open subset of Y.

Remark.

(1) If two topological spaces are homeomorphic, then they have the same topological properties, i.e. they share all properties that are defined purely in terms of the topology. For example, if X and Y are homeomorphic, then X is Hausdorff if and only if Y is Hausdorff, X is compact if and only if Y is compact and so on.

(2) It follows from the Open -Closed Inclusion Lemma 2.10 that an open (respectively closed) embedding is also an open (respectively closed) map.

Convention. At times we refer to a topological space that is homeomorphic to a ball or to a sphere also as a ball or a sphere.

Before we turn to our first examples we introduce some standard notation.

Notation. Given $n_0 \in \mathbb{N}$ we write

$$\begin{array}{lcll} S^n_{\geq 0} & := & \{(x_1,\dots,x_{n+1}) \in S^n \mid x_{n+1} \geq 0\} & \text{the upper hemisphere} \\ S^n_{\leq 0} & := & \{(x_1,\dots,x_{n+1}) \in S^n \mid x_{n+1} \leq 0\} & \text{the lower hemisphere} \\ S^n_{=0} & := & \{(x_1,\dots,x_{n+1}) \in S^n \mid x_{n+1} = 0\} & \text{the equator.} \end{array}$$

Similarly we define

$$\begin{array}{lcl} B^n_{\geq 0} & := & \{(x_1,\dots,x_n) \in B^n \mid x_n \geq 0\} \\ B^n_{\leq 0} & := & \{(x_1,\dots,x_n) \in B^n \mid x \leq 0\} \end{array}$$

Finally, the same way we also define $\overline{B}^n_{\geq 0}$ and $\overline{B}^n_{\leq 0}$.

Examples.

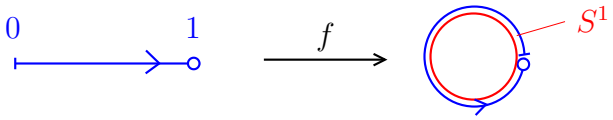
(1) The maps

$$\begin{array}{rcl} \varphi\colon \overline{B}^n & \to & S^n_{\geq 0} \\ x & \mapsto & \left(x, \sqrt{1-\|x\|^2}\right) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} p\colon S^n_{\geq 0} & \to & \overline{B}^n \\ (x_1,\dots,x_n,x_{n+1}) & \mapsto & (x_1,\dots,x_n) \end{array}$$

are easily seen to be continuous and inverses to one another. Thus both maps are homeomorphisms. The same way we see that the lower hemisphere is also homeomorphic to the closed ball $\overline{B}^n$.

(2) Let $A \in \mathrm{GL}(n,\mathbb{R})$ be an invertible real matrix. It follows from the discussion on page 143 that the map $\mathbb{R}^n \to \mathbb{R}^n$ given by multiplication by A is a homeomorphism. This simple observation has a useful consequence: Let V be an n-dimensional real vector space. We pick an isomorphism $\varphi\colon \mathbb{R}^n \to V$ and we equip V with the unique topology that turns φ into a homeomorphism. By the above discussion this definition of a topology does not depend on the choice of φ. Unless we say something else any finite-dimensional real vector space will be equipped with this topology. Note that with these topologies any isomorphism between real vector spaces of the same finite dimension is also a homeomorphism.

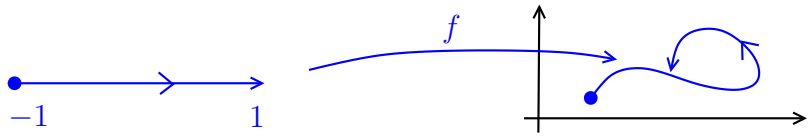
(3) Let $n \in \mathbb{N}$. It follows immediately from the definitions of the standard metrics on $\mathbb{R}^{2n}$ and $\mathbb{C}^n$ that the map



$$\begin{array}{rcl} \mathbb{R}^{2n} & \to & \mathbb{C}^n \\ (x_1, y_1, \ldots, x_n, y_n) & \mapsto & (x_1 + \mathrm{i}y_1, \ldots, x_n + \mathrm{i}y_n) \end{array}$$

is an isometry of metric metric spaces. Recall that on page 109 we defined the standard topology on $\mathbb{R}^{2n}$ and $\mathbb{C}^n$ to be the metric topology corresponding to the standard metrics. Thus we see that the above map is a homeomorphism. We will use this homeomorphism to freely go back and forth between $\mathbb{C}^n$ and $\mathbb{R}^{2n}$.

(4) We consider the map



$$\begin{array}{rcl} f\colon [0,1) & \to & S^1 \\ t & \mapsto & \exp(2\pi \mathrm{i} t). \end{array}$$

The map f is a continuous bijection but it is not a homeomorphism. One can see this by either directly showing that f^{-1} is not continuous or by noting that $[0,1)$ is not compact whereas S^1 is compact. The importance of this example cannot be overestimated. It is an unfortunate fact of life that all too often one writes down a continuous map $f\colon X \to Y$ between topological spaces, checks that it is a bijection, and walks away under the warm, but mistaken, impression that one now has found a homeomorphism.

f is a continuous bijection but not a homeomorphism

(5) To drive home the point we made in (3) we show in the figure below an injective continuous map $f\colon [-1,1) \to \mathbb{R}^2$ which is *not* an embedding. Especially once we move to more abstract topological spaces it is easy to loose track of the fact that an injective homeomorphism is not necessarily an embedding.

In many situations one is given an explicit continuous bijection $f\colon X \to Y$ between two topological spaces and one would like to show that f is in fact a homeomorphism. Unfortunately usually it is very painful to write down the explicit inverse map $f^{-1}\colon Y \to X$, let alone to verify that it is continuous. Fortunately we have several results which often help us in circumventing this difficulty.

Lemma 2.16. (Open-Injective Map Lemma) Let $f\colon X \to Y$ be a map between topological spaces that is continuous. We assume that f is open or that f is closed.

(1) If f is an injection, then f is an open (respectively closed) embedding.
(2) If f is a bijection, then f is a homeomorphism.

Proof. Let $f\colon X \to Y$ be a map between topological spaces that is continuous

(2) We assume that f is a bijection. Furthermore we now assume that f is open. We want to show that f is a homeomorphism. It remains to show that $g := f^{-1}\colon Y \to X$ is continuous. Thus let $U \subset X$ be an open set. We need to show that $g^{-1}(U)$ is an open subset of Y. But this is obvious, since $g^{-1}(U) = f(U)$ is an open subset since we assume that f is an open map.

    Now suppose that the map f is closed. The proof is almost identical to the above argument, except that now we have to use the continuity criterion provided by the Continuity-via-Closed Subsets Lemma 2.4.

(1) We assume that f is an injection and we assume that f is open. We write $Z := f(X)$. Since $f\colon X \to Y$ is open it follows basically immediately from the definition of the subspace topology that $f\colon X \to Z$ is also open. Thus we obtain from (2) that f is an embedding. Furthermore, since f is open we see that f is an open embedding. The proof in the case that f is closed is basically identical. ■

Example. Let U be an open subset of $\mathbb{R}$ and let $f\colon U \to \mathbb{R}$ be a strictly monotonously increasing map, i.e. for any $x < y$ in U we have $f(x) < f(y)$. Note that open intervals form a basis for the topology of U. By the Intermediate Value Theorem the image of an open interval under f is again an open interval. Thus it follows from Lemma 2.11 that $f\colon U \to \mathbb{R}$ is an open map. The Open-Injective Map Lemma 2.16 implies that $f\colon U \to f(U)$ is a homeomorphism.

The next proposition is certainly one of the most frequently used results in topology.

Proposition 2.17. (Compact-Hausdorff Proposition) Let $f\colon X \to Y$ be a continuous map between topological spaces. If X is compact and if Y is Hausdorff, then the following statements hold:

(1) The map $f\colon X \to Y$ is closed.
(2) If f is an injection, then f is a closed embedding.
(3) If f is a bijection, then f is a homeomorphism.

Remark.

(1) On page 153 we gave an example of a continuous bijective map $f\colon [0,1) \to S^1$ that is not a homeomorphism,. This shows that we cannot drop the condition that X is compact from the proposition. But what about the "Hausdorff condition"? In Exercise 2.42 we will come up with an example of a bijective continuous map $f\colon X \to Y$ between two topological spaces where X is compact but such that f is nonetheless not a homeomorphism.
(2) If X is non-compact, then it is often a major nuisance to try to show that a given map $f\colon X \to Y$ is in fact a closed embedding. Later on, in the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19 and the Proper-Closed Proposition 2.43 we give two criteria

which can often be used to show that an injective continuous map starting from a non-compact space to a Hausdorff space is a closed embedding after all.

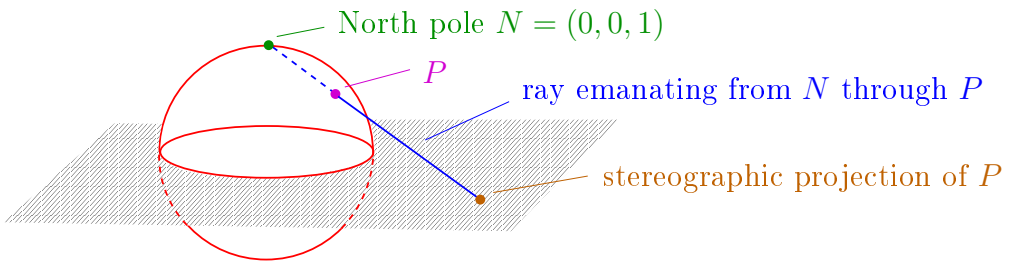
Proof. Let $f\colon X \to Y$ be a continuous map between topological spaces. We assume that X is compact and that Y is Hausdorff.

(1) Let A be a closed subset of X. We need to show that $f(A)$ is a closed subset of Y. In fact we see that

$$A \subset X \text{ closed} \underset{\substack{\uparrow\\ \text{by the Compact-Closed Lemma 1.21 since } X \text{ is compact}}}{\Longrightarrow} A \text{ is compact} \underset{\substack{\uparrow\\ \text{by the Compact Image Lemma 2.13 (1)}}}{\Longrightarrow} f(A) \text{ is compact} \underset{\substack{\uparrow\\ \text{by the Compact-Closed Lemma 1.21 (2) since } Y \text{ is Hausdorff}}}{\Longrightarrow} f(A) \subset Y \text{ is closed.}$$

(2) If f is an injection, then it follows immediately from (1) together with the Open -Injective Map Lemma 2.16 (1) that f is a closed embedding.

(3) This follows immediately from (2). ∎



We formulate our first application of the Compact-Hausdorff Proposition 2.17 (3) as a lemma.

Lemma 2.18. Let $n \in \mathbb{N}$. We consider the map

$$\begin{array}{rcl} \Phi\colon S^n & \to & \mathbb{R}^n \cup \{\infty\} \\ (x_1, \ldots, x_{n+1}) & \mapsto & \begin{cases} \left(\frac{x_1}{1-x_{n+1}}, \ldots, \frac{x_n}{1-x_{n+1}}\right), & \text{if } x_{n+1} < 1, \\ \infty, & \text{if } x_{n+1} = 1. \end{cases} \end{array}$$

where we equip $\mathbb{R}^n \cup \{\infty\}$ with the topology that we introduced on page 122. We refer to Φ as the stereographic projection. This map has the following properties:

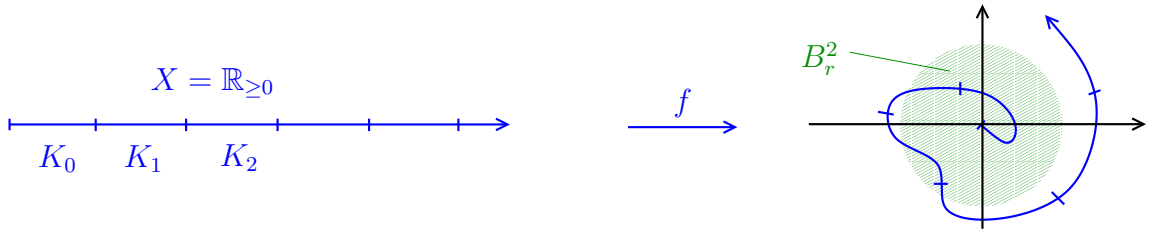
(1) The map Φ sends the North Pole $N = (0, \ldots, 0, 1) \in S^n$ to ∞.
(2) For any $P \in S^n$ that does not equal the North Pole N the point $\Phi(P) \in \mathbb{R}^n$ is the unique point such that the ray emanating from N and that goes through P intersects the plane $\mathbb{R}^n \times \{0\}$ in $(\Phi(P), 0)$.
(3) For any $(v_1, \ldots, v_n, 0) \in S^n \cap (\mathbb{R}^n \times \{0\})$ we have $\Phi(v_1, \ldots, v_n, 0) = (v_1, \ldots, v_n)$.
(4) The map Φ is continuous.
(5) The map Φ is a homeomorphism.
(6) The restriction of Φ to a map $S^n \setminus \{N\} \to \mathbb{R}^n$ is also a homeomorphism.

Convention. Let $n \in \mathbb{N}$. On many occasions we will use the homeomorphism from Lemma 2.18 to make the identification $S^n = \mathbb{R}^n \cup \{\infty\}$. In particular we have the identification $S^2 = \mathbb{C} \cup \{\infty\}$.

Proof.

(1) This statement follows immediately from the definition of Φ.
(2) This statement follows from an elementary calculation which we leave to the reader.
(3) This statement follows immediately from the definition of Φ.
(4) We will prove this statement in Exercise 2.47.
(5) We leave it to the reader to verify that Φ is a bijection. Note that S^n is compact by the Heine-Borel Theorem 1.24. Furthermore note that on page 122 we pointed out that $\mathbb{R}^n \cup \{\infty\}$ is Hausdorff. Hence it follows from the Compact-Hausdorff Proposition 2.17 (3) that Φ is a homeomorphism.
(6) This statement follows immediately from (5). ■

The existence of non-compact spaces is one of those unfortunate facts of life. As we saw, in general the conclusion of the Compact-Hausdorff Proposition 2.17 does not hold if the domain is non-compact. The following proposition gives us a criterion for an injective map to be a closed embedding which will deal with most cases that we will encounter.



Proposition 2.19. (Closed Embedding-to-$\mathbb{R}^n$ Proposition) Let X be a topological space, let $n \in \mathbb{N}$ and let $f\colon X \to \mathbb{R}^n$ be an injective continuous map. Furthermore suppose that X is the union of compact subsets $\{K_i\}_{i\in I}$ such that the following condition is satisfied:

($*$) Given any $r > 0$ there exist only finitely many $i \in I$ with $f(K_i) \cap \overline{B}^n_r \neq \varnothing$.

Then f is a closed embedding.

Remark. Later we will prove the Proper-Closed Proposition 2.43 which gives a more general criterion for an injective map to be a closed embedding. On page 182 we will use it to give a different, arguably more conceptual proof of the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19.

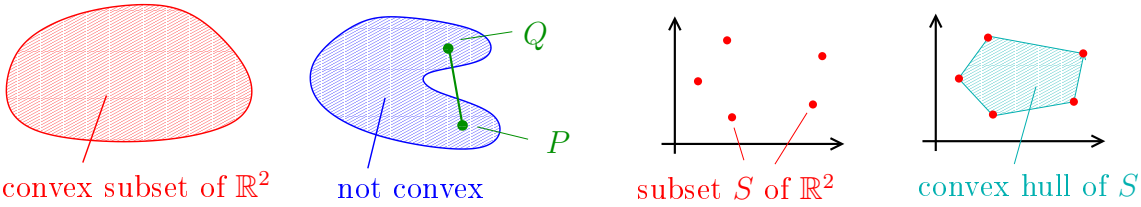
Example. Let $X = \mathbb{R}_{\geq 0}$. We consider the "outward spiraling" map $f\colon X \to \mathbb{R}^2$ that is sketched in the figure below. Given $i \in \mathbb{N}_0$ we set $K_i := [i, i+1]$. These compact subsets cover all of $X = \mathbb{R}_{\geq 0}$ and they satisfy the condition ($*$) of the proposition. Thus we obtain from the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19 that the map f is a closed embedding.

Proof. By the Open -Injective Map Lemma 2.16 (1) it remains to show that the map $f\colon X \to \mathbb{R}^n$ is closed. Thus let A be a closed subset of X. We need to show that $f(A)$ is a closed subset of $\mathbb{R}^n$. Given $s \in \mathbb{N}_0$ we consider $C_s := \overline{B}^n_{s+1} \setminus B^n_s$. Clearly $\{C_s\}_{s\in\mathbb{N}_0}$ is a

locally finite closed cover of $\mathbb{R}^n$. By Lemma 1.8 (2b) it suffices to show that each $C_s \cap f(A)$ is closed in $\mathbb{R}^n$. Thus let $s \in \mathbb{N}_0$. By hypothesis we know that $J := \{i \in I \,|\, f(K_i) \cap \overline{B}_s^n \neq \varnothing\}$ is a finite set. Now we see that

$$\begin{array}{lcccl} C_s \cap f(A) & = & C_s \cap f\Big(\bigcup_{i\in I} K_i\Big) & \overset{\downarrow}{=} & C_s \cap f\Big(\bigcup_{j\in J} K_j\Big) \quad \overset{\downarrow}{=} \quad C_s \cap f(\text{compact subset}) \\ & = & C_s \cap \text{compact subset of } \mathbb{R}^n & = & C_s \cap \text{closed subset of } \mathbb{R}^n \quad = \quad \text{closed subset of } C_s. \\ & \uparrow & & \uparrow & \uparrow \end{array}$$

definition of J; by the Compact-Union-Intersection Lemma 1.20 (1), since each K_j is compact, and since J is finite



Compact Image Lemma 2.13; Compact-Closed Lemma 1.21; definition of subspace topology ■

2.4. **Convex subsets.** We start out with the definition of a convex subset.

Definition.

(1) We say that a subset $A \subset \mathbb{R}^n$ is convex, if for every two points P and Q in A the segment $\overline{PQ} := \{t \cdot P + (1-t) \cdot Q \,|\, t \in [0,1]\}$ also lies in A.

(2) Given a subset S of $\mathbb{R}^k$ the convex hull of S is defined as the intersection of all convex subsets of $\mathbb{R}^k$ that contain S. Since the intersection of convex sets is again convex we see that the convex hull of S is a convex subset of $\mathbb{R}^n$.

convex subset of $\mathbb{R}^2$ | not convex | subset S of $\mathbb{R}^2$ | convex hull of S

Examples.

(1) For any point $x \in \mathbb{R}^n$ and any $\epsilon > 0$ the open ball $B_\epsilon^n(x)$ is convex. Indeed, let $P, Q \in B_\epsilon^n(x)$. Then for any $t \in [0,1]$ we have

$$\begin{array}{rcll} \|t\cdot P + (1-t)\cdot Q - x\| & = & \|t\cdot(P-x) + (1-t)\cdot(Q-x)\| & \\ & \underset{\uparrow}{\leq} & t\cdot\|P-x\| + (1-t)\cdot\|Q-x\| & \underset{\uparrow}{<} \; t\cdot\epsilon + (1-t)\cdot\epsilon = \epsilon. \end{array}$$

triangle inequality and homogeneity of $\|-\|$; since $P, Q \in B_\epsilon^n(x)$

We have thus shown that $t \cdot P + (1-t) \cdot Q \in B_\epsilon^n(x)$. Basically the same way one shows that the closed ball $\overline{B}_\epsilon^n(x)$ is also convex.

(2) It is straightforward to verify that any hyperrectangle $[a_1, b_1] \times \cdots \times [a_n, b_n]$ is convex.

(3) In Exercise 2.38 we will show that the convex hull of points $P_1, \ldots, P_n \in \mathbb{R}^k$ is given by the set

$$\Big\{\sum_{i=1}^n t_i \cdot P_i \,\Big|\, t_1, \ldots, t_n \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^n t_i = 1\Big\}.$$

(4) One of the most useful properties of convex subsets is that the intersection of arbitrarily many convex subsets is, basically by definition, again convex.

The following proposition gives a useful criterion for showing that subsets of $\mathbb{R}^n$ are homeomorphic to an open or to a closed ball.

Proposition 2.20. (Convex-to-Ball Proposition)

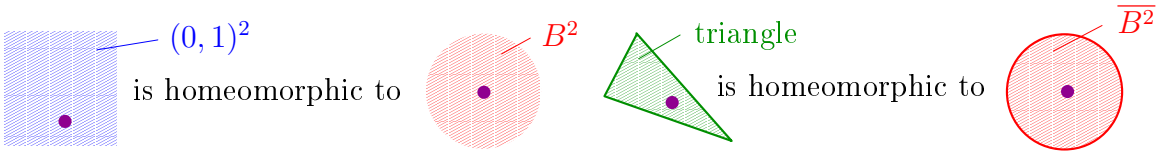
(1) Let A be a bounded *open* convex subset of $\mathbb{R}^n$ and let $Q \in A$.[32] We consider the map

$$\begin{array}{rcl} \rho_A \colon A \setminus \{Q\} & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & \sup\left\{ \|r \cdot x\| \,\middle|\, r \in \mathbb{R}_{>0} \text{ and } r \cdot (x-Q) + Q \in A \right\}. \end{array}$$

This map is well-defined in the sense that the supremum exists for each $x \in A \setminus \{Q\}$. Furthermore the map ρ_A is continuous and the map

$$\begin{array}{rcl} f_Q \colon A & \to & B^n \\ x & \mapsto & \begin{cases} (x-Q) \cdot \frac{1}{\rho_A(x)}, & \text{if } x \neq Q, \\ 0, & \text{if } x = Q. \end{cases} \end{array}$$

is a homeomorphism with $f_Q(Q) = 0$.



(2) Let A be a bounded *closed*[33] convex subset of $\mathbb{R}^n$. If Q is a point in the interior[34] of A, then the same expression as in (1) defines a homeomorphism[35]

$$f_Q \colon A \to \overline{B}^n = \{x \in \mathbb{R}^n \mid \|x\| \leq 1\}$$

with the following properties:

(a) the homeomorphism f_Q sends Q to the origin,

(b) the homeomorphism f_Q restricts to a homeomorphism $\partial A \to S^{n-1}$.

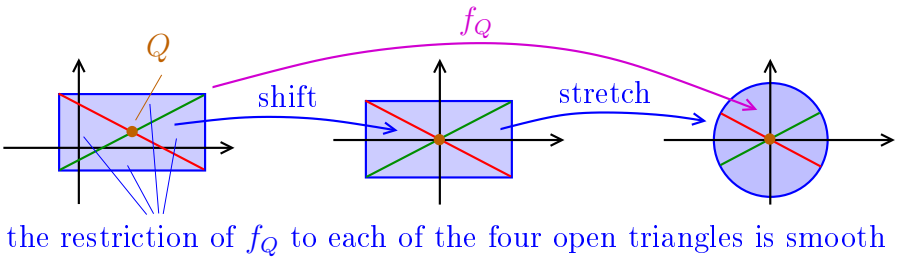
Example.

(1) For $i = 1, \ldots, n$ let $a_i < b_i$ be real numbers. We consider the "hyperrectangle" $[a_1, b_1] \times \cdots \times [a_n, b_n]$. It follows from the discussion on page 157 and from the Hyperrectangle-Compact Proposition 1.26 that the hyperrectangle is convex and compact. The Convex-to-Ball Proposition 2.20 (2) gives us an explicit homeomorphism

$$f_Q \colon [a_1, b_1] \times \cdots \times [a_n, b_n] \to \overline{B}^n$$

that sends the boundary of the hyperrectangle to the sphere S^{n-1} and that sends the "midpoint" $Q := (\frac{a_1+b_1}{2}, \ldots, \frac{a_n+b_n}{2})$ to the origin. Throughout this course we will use this homeomorphism to identify the left-hand side with the right-hand side. It follows easily from the explicit description of f_Q that the restriction of f_Q to each open cone on a side is smooth.[36]

---

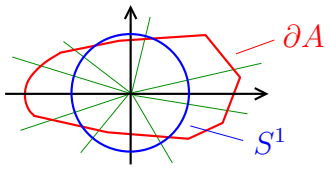


[32] The statement becomes slightly more readable if one sets $Q = 0$.

[33] Of course "bounded and closed" is in this instance, by the Heine-Borel Theorem 1.24 equivalent to "compact". In this instance we prefer to talk of "bounded closed" to stress the analogy to Statement (1) of the lemma.

[34] Note that the interior might well be empty, i.e. such a point Q might not exist.

[35] This says in particular that if A is a bounded closed convex subset of $\mathbb{R}^n$ with *non-empty interior*, then A is homeomorphic to $\overline{B}^n$.



[36] We leave it to the reader to make it precise what "open cone on a side" means. We will make use of this observation only once, and then it should be clear what we mean.

(2) Let A be a bounded convex subset of $\mathbb{R}^n$ such that the origin 0 lies in the interior of A. The Convex-to-Ball Proposition 2.20, applied to $Q = 0$, implies in particular that the map

$$\begin{array}{rcl} f\colon \partial A & \to & S^{n-1} \\ x & \mapsto & \frac{x}{\|x\|} \end{array}$$

is a homeomorphism. This statement is illustrated in the figure below.

Remark. The reader might be familiar with the concept of a diffeomorphism. In the Star Shaped-Diffeomorphism Type Theorem **??** we will show that every open convex subset of $\mathbb{R}^n$ is in fact diffeomorphic to $\mathbb{R}^n$, and thus diffeomorphic to B^n. The diffeomorphism that we will provide in that later instance is, in contrast to the above proposition, not explicit.

The proof of the Convex-to-Ball Proposition 2.20 relies on the following lemma.

Lemma 2.21. Let A be a bounded closed convex subset of $\mathbb{R}^n$ such that the origin 0 lies in the interior of A.

(1) The map $\rho_A\colon A \setminus \{0\} \to \mathbb{R}_{\geq 0}$ defined in the Convex-to-Ball Proposition 2.20 is continuous.

(2) The map

$$\begin{array}{rcl} f_0\colon A & \to & \overline{B}^n \\ x & \mapsto & \begin{cases} x \cdot \frac{1}{\rho_A(x)}, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0 \end{cases} \end{array}$$

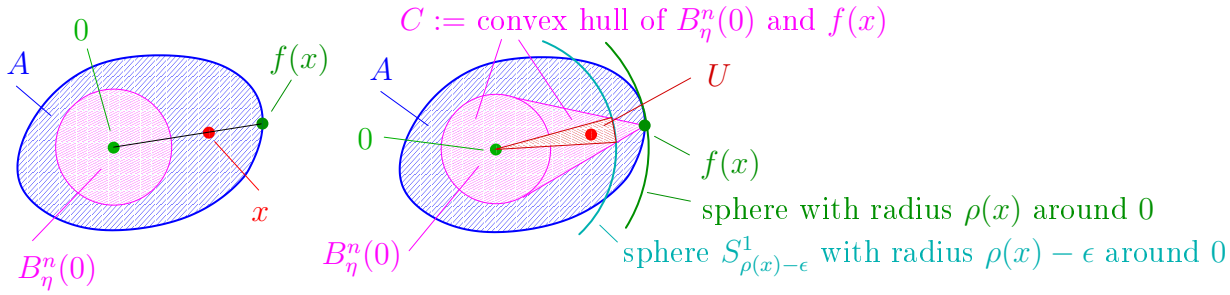
is continuous and it satisfies $f_0^{-1}(S^{n-1}) = \partial A$.

Proof of Lemma 2.21. We start out with the following claim.

Claim. The map $\rho_A\colon A \setminus \{0\} \to \mathbb{R}$ is defined, it is continuous, it is bounded from above and it is bounded from below by 1.

Proof. Since A is bounded it follows that ρ_A is defined and that it is bounded from above. It follows from the definition of ρ_A that ρ_A is bounded from below by 1. Therefore it remains to show that ρ_A is continuous. Now let $x \in A \setminus \{0\}$ and let $\epsilon > 0$. It suffices to show the following two statements:

(1) there exists a neighborhood U of $x \in A \setminus \{0\}$ with $\rho_A(y) > \rho_A(x) - \epsilon$ for all $y \in U$,



(2) there exists a neighborhood V of $x \in A \setminus \{0\}$ with $\rho_A(y) < \rho_A(x) + \epsilon$ for all $y \in V$.

We first show the existence of U. After possibly replacing ϵ by $\min\{\frac{1}{2}\rho_A(x), \epsilon\}$ we can suppose that $\epsilon \in (0, \rho_A(x))$.

Since A is closed we have $f_0(x) \in A$. Since 0 lies in the interior of A there exists an $\eta > 0$ such that $B^n_\eta(0) \subset A$. Since A is convex, the convex hull C of $B^n_\eta(0) \cup \{f_0(x)\}$ is still contained[37] in A. Furthermore, since $B^n_\eta(0)$ is open it is straightforward to see that $C' := C \setminus \{f_0(x)\}$ is an open subset of $\mathbb{R}^n$. We denote by $S^{n-1}_{\rho_A(x)-\epsilon}$ the sphere of radius $\rho_A(x) - \epsilon$ around 0. The point $x \cdot \frac{\rho_A(x)-\epsilon}{\|x\|}$ lies on $S^{n-1}_{\rho_A(x)-\epsilon}$ and it lies in C'. Since C' is open there exists an open neighborhood U' on $S^{n-1}_{\rho_A(x)-\epsilon}$ that is contained in C'. We set

$$U \;:=\; \{r \cdot z \,|\, z \in U' \text{ and } r \in (0,1)\}.$$

This is an open neighborhood of x and for any $y \in U$ we have $(\rho_A(x)-\epsilon)\cdot y \in A$, i.e. for any $y \in A$ we have $\rho_A(y) \geq \rho_A(x) - \epsilon$. Thus we have shown that the desired neighborhood U exists. The existence of V is proved in a very similar way. We refer to [**Berger2009**, Chapter 11.3] for full details. ⊞

From the continuity of ρ_A it follows that f is continuous on $A \setminus \{0\}$. From the fact that ρ_A is bounded it follows easily that f_Q is continuous in 0. Finally one can easily verify, using the convexity of A, that $f_0^{-1}(S^{n-1}) = \partial A$. We leave it to the reader to fill in the details. ■

Proof of the Convex-to-Ball Proposition 2.20.

(2) Let A be a bounded closed convex subset of $\mathbb{R}^n$ and let Q be a point in the interior of A. After a translation we can assume that $Q = 0$ is the origin, in particular we can assume that the origin 0 lies in the interior of A. By Lemma 2.21 we know that the map $\rho_A \colon A \setminus \{0\} \to \mathbb{R}_{\geq 0}$ is defined and continuous. Next we consider the map

$$\begin{array}{rcl} f_0 \colon A & \to & \overline{B}^n \\ x & \mapsto & \begin{cases} x \cdot \frac{1}{\rho_A(x)}, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0. \end{cases} \end{array}$$

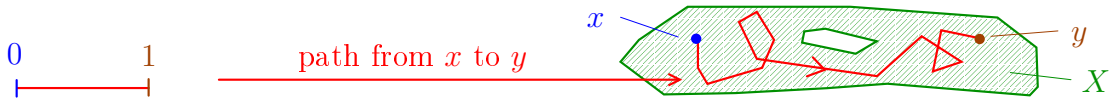
It is straightforward to verify that this map is bijective[38] and by Lemma 2.21 we know that f_0 is continuous and that $f_0^{-1}(S^{n-1}) = \partial A$. Note that our hypothesis on A and

[37] Why is that the case?

[38] It follows easily from the convexity of A, the hypothesis that $\mathring{A} \neq \varnothing$ and the definition of f_0 that for each $v \in S^{n-1}$ the map f_0 restricts to a bijection on the "ray defined by v", i.e. it restricts to a bijection

$$A \cap \{r \cdot v \,|\, r \in \mathbb{R}_{>0}\} \;\to\; \overline{B}^n \cap \{r \cdot v \,|\, r \in \mathbb{R}_{>0}\}.$$

the Heine-Borel Theorem 1.24 imply that A is compact. Thus we obtain from the Compact-Hausdorff Proposition 2.17 (3) that f_0 is in fact a homeomorphism. Finally note that it follows from $f_0^{-1}(S^{n-1}) = \partial A$ that f_0 restricts to a homeomorphism $\partial A \to S^{n-1}$.



(1) We denote by $C = \overline{A}$ the closure of A. Since A is open and convex we know by Exercise 2.8 that $A = \mathring{C}$. One verifies fairly easily that C is convex. It is clear that C is bounded and it follows from the Interior-Closure Lemma 1.9 that C is closed. One verifies easily that the map f_0 defined for $C = \overline{A}$ restricts to the map f_0 defined for A. Thus it follows from (2) that the map $f_0 \colon C = \overline{A} \to \overline{B}^n$ is a homeomorphism and it restricts to a homeomorphism $f_0 \colon \mathring{C} \to B^n$. Since $\mathring{C} = A$ we get the desired homeomorphism. ■

2.5. **The two notions of connected spaces.** In this section we will see that there are two notions of connectedness of a topological space. As we will see, for most "reasonable" topological spaces the two notions mercifully coincide. We start out with the more obvious definition.

Definition.

(1) Let X be a topological space. A path is a map $p \colon [0,1] \to X$. Often we say that p is a path from $p(a)$ to $p(b)$.

(2) We say that a topological space X is path-connected if given any two points x and y there exists a path from x to y.

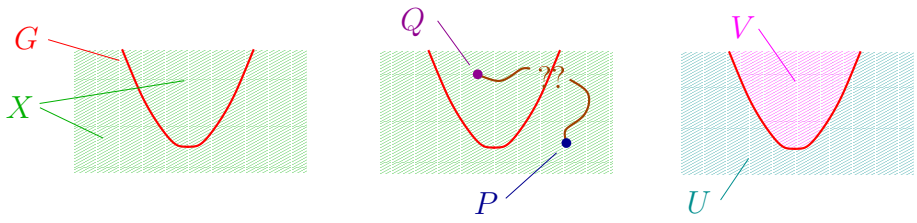
Before we discuss examples let us immediately provide the other, less obvious definition of connectedness.

Definition. We say that a topological space X is connected if the following holds[39]

$$\text{if } X = U \sqcup V \text{ is the disjoint union of open sets } U, V \quad \Longrightarrow \quad X = U \text{ or } X = V.$$

A topological space which is not connected is called disconnected.

Example.



(1) It follows basically from the definitions that any convex subset of some $\mathbb{R}^n$ is path-connected. But it is much less clear whether say $\mathbb{R}^n$ is connected in the above sense.

(2) Next let $G \subset \mathbb{R}^2$ be the graph of the function $f \colon \mathbb{R} \to \mathbb{R}$ given by $x \mapsto x^2$. As in the figure below we consider the complement $X = \mathbb{R}^2 \setminus G$. It is pretty clear that X is not path-connected, surely there is no path from a point P below G to a point above G. But how can one show the non-existence of such a path?[40] But it is clear that X is not connected, since X is the disjoint union of the two open non-empty sets $U := \{(x,y) \in \mathbb{R}^2 \,|\, y < x^2\}$ and $V := \{(x,y) \in \mathbb{R}^2 \,|\, y > x^2\}$.

(3) It follows from the Intermediate Value Theorem that the rational numbers $\mathbb{Q}$ are not path-connected. But $\mathbb{Q}$ is also not connected, for example we can write the topological

[39] Recall that we write $X = U \sqcup V$ if X is the disjoint union of U and V, i.e. if $X = U \cup V$ and if $U \cap V = \varnothing$.

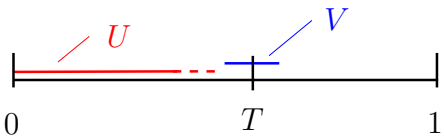
[40] The fact that such a path does not exist can be shown, with some dexterity, using real analysis. How?

space $\mathbb{Q}$ as the disjoint union of the two open non-empty subsets $\{x \in \mathbb{Q} \,|\, x^2 < 2\}$ and $\{x \in \mathbb{Q} \,|\, x^2 > 2\}$.

So we see that both notions of connectedness have their advantages and disadvantages. It is often easy to show that a given topological space is path-connected but it can be a pain to show that a given topological space is not path-connected. With connectedness it is precisely the other way round.

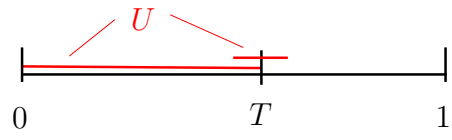
It is basically obvious that any interval is path-connected. But as we will see, it takes some effort to show that the interval $[0,1]$ is connected.

Proposition 2.22. (Interval-Connectedness Proposition) The interval $[0,1]$ is connected.



Proof. Let U and V be two disjoint open subsets of $[0,1]$ with $U \cup V = [0,1]$. Without loss of generality we can assume that $0 \in U$. We want to show that $U = [0,1]$. We consider

$$A \;:=\; \big\{t \in [0,1] \,\big|\, [0,t] \subset U\big\}.^{41}$$



The set A contains 0, hence it is non-empty. Evidently the set is bounded thus we can consider $T := \sup A$. We need to show that $T = 1$ and that $T \in U$.

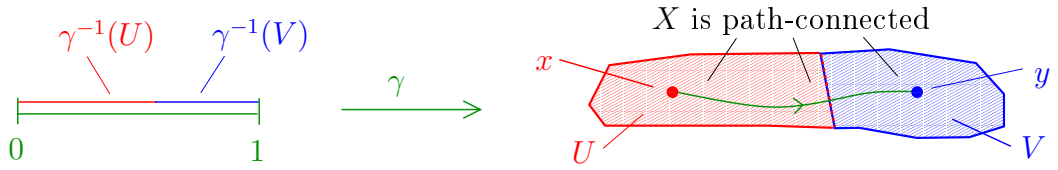
First let us suppose that $T \notin U$. This implies that $T \in V$. Since V is open it follows that there exists an $\epsilon > 0$ such that $(T-\epsilon, T+\epsilon) \cap [0,1]$ is also contained in V. In particular we have $(T-\epsilon, T+\epsilon) \cap A = \varnothing$ which implies that $\sup A \leq T - \epsilon$. Thus we have obtained a contradiction.

Now we know that $T \in U$. We still need to show that $T = 1$. Since U is open it follows that there exists an $\epsilon > 0$ such that $(T-\epsilon, T+\epsilon) \cap [0,1] \subset U$. Thus $[0, T+\epsilon) \cap [0,1] \subset U$. In light of the definition of T that is only possible if $T = 1$. ■

if $T \in V$ then $(T-\epsilon, T+\epsilon) \cap [0,1]$ is also contained in V

since $T \in U$ we see that $[0, T+\epsilon) \cap [0,1]$ is contained in U

Corollary 2.23. (Path-Connected Implies Connected Corollary) Every path-connected topological space is also connected.



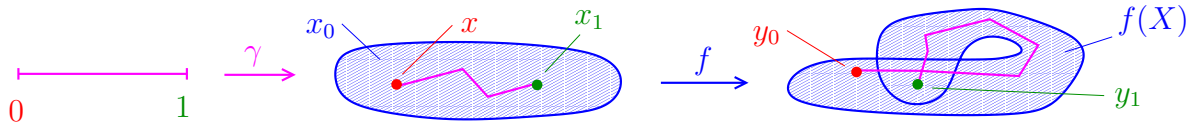
[41] Put differently,

$$A \;=\; \text{the set of all } t \in [0,1] \text{ such that the interval } [0,t] \text{ is contained in } U.$$

Remark.

(1) It follows from the Path-Connected Implies Connected Corollary 2.23 that in fact every interval is connected.
(2) In Exercise 2.18 we will prove the converse to (1), namely we will show that every connected subset of $\mathbb{R}$ is actually an interval.

Proof. Let X be a topological space that is path-connected. Suppose that X is not connected. This means that there exist disjoint open non-empty subsets U and V with $X = U \cup V$. Since U and V are non-empty we can find points $x \in U$ and $y \in V$. Since X is path-connected there exists a path $\gamma\colon [0,1] \to X$ with $\gamma(0) = x$ and $\gamma(1) = y$. Then $\gamma^{-1}(U) \cup \gamma^{-1}(V)$ is a decomposition of $[0,1]$ into two disjoint open non-empty subsets. But that is a contradiction to the Interval-Connectedness Proposition 2.22. ■



Lemma 2.24. (Image-Connected Lemma) Let $f\colon X \to Y$ be a map between topological spaces.

(1) If X is path-connected, then $f(X)$ is also path-connected.
(2) If X is connected, then $f(X)$ is also connected.

Proof.

(1) We suppose that X is path-connected. Let $y_0 = f(x_0)$ and $y_1 = f(x_1)$ be two points in $f(X)$. Since X is path-connected there exists a path $\gamma\colon [0,1] \to X$ from x_0 to x_1. But then $f \circ \gamma\colon [0,1] \to f(X)$ is a path from $f(x_0)$ to $f(x_1)$.

(2) We suppose that $f(Y)$ is disconnected. This means that there exist disjoint open non-empty subsets U and V of $f(Y)$ with $f(Y) = U \cup V$. By the Image-Preimage Lemma 0.2 we know that $f^{-1}(U)$ and $f^{-1}(V)$ are also disjoint and we know that $X = f^{-1}(U) \cup f^{-1}(V)$. By definition of a continuous map $f^{-1}(U)$ and $f^{-1}(V)$ are open. Finally, since $U, V \subset f(X)$ we see that $f^{-1}(U)$ and $f^{-1}(V)$ are non-empty. Thus we have shown that X is also disconnected. ■

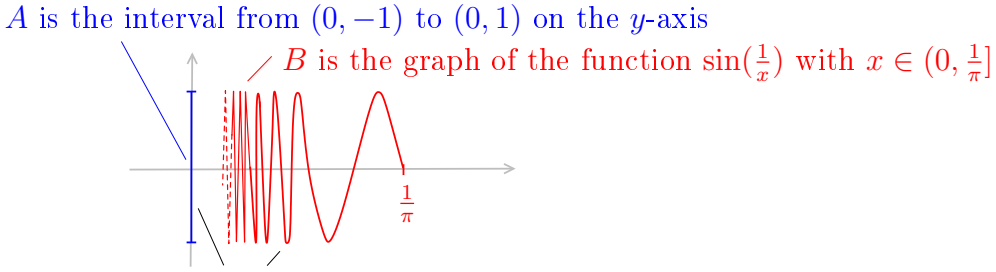
In the following lemma we show that most of the topological spaces that we had encountered so far are path-connected and connected. We will use this lemma on numerous occasions without explicitly referring to it.

Lemma 2.25. (Ball-Sphere-Connected Lemma)

(1) Let $n \geq 1$. Every open ball $B_r^n(y)$, every closed ball $\overline{B}_r^n(y)$ and $\mathbb{R}^n$ are path-connected and connected.

(2) Every sphere $S_r^n(y)$ with $n \geq 1$ is path-connected and connected.

Proof. By the Path-Connected Implies Connected Corollary 2.23 it suffices to show that all these topological spaces are path-connected.



(1) It follows from the example on page 157 that all balls (open or closed) and $\mathbb{R}^n$ are convex. But as we already pointed out on page 161, convex subsets are basically by definition path-connected.
(2) We will show in Exercise 2.55 that spheres of dimension ≥ 1 are path-connected. ■

For better or worse, the converse to the Path-Connected Implies Connected Corollary 2.23 is not always correct.

Example. The *Topologist's Sine Curve* is defined as the following topological space

$$X \;:=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\} \cup \big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2,$$

equipped with the subspace topology. In other words, the Topologist's Sine Curve is the union of the graph of $x \mapsto \sin(\frac{1}{x})$ for $x \in (0,\pi]$ and an interval on the y-axis. It is a very instructive exercise, see Exercise 2.48, to show that X is connected and it is an equally instructive exercise to show that X is *not* path-connected.

the Topologist's Sine Curve $X = A \cup B$ is connected but not path-connected

Remark. The fact that an example of a topological space that is connected but not path-connected is so "wild" indicates that perhaps for most "reasonable" spaces the two notions of connectedness and path-connectedness agree. In fact in basically all examples of topological spaces that we encounter throughout these notes the two notions of connectedness will agree.

By a clever use of the notion of connectedness one can sometimes prove statements which at first glance have nothing to do with connectedness. For example we can now prove the following lemma.

Lemma 2.26. Let $n \in \mathbb{N}_{\geq 2}$.

(1) The topological spaces $\mathbb{R}$ and $\mathbb{R}^n$ are not homeomorphic.
(2) The topological spaces $[0,1]$ and $[0,1]^n$ are not homeomorphic.

Remark.

(1) The statement of Lemma 2.26 is not overly surprising. But note that in Theorem 6.13 we will see that for any $n \in \mathbb{N}$ there exists a *surjective* map $[0,1] \to [0,1]^n$.
(2) Later on, in Proposition 74.6, we will study the question whether for $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ can be homeomorphic.

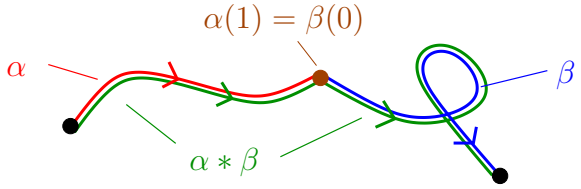
Proof.

(1) Let us suppose that there exists a homeomorphism $f\colon \mathbb{R} \to \mathbb{R}^n$. Let $P \in \mathbb{R}$ be a point. Then f restricts to a homeomorphism from $\mathbb{R} \setminus \{P\}$ to $\mathbb{R}^2 \setminus \{f(P)\}$. The topological space $\mathbb{R}\setminus\{P\} = (-\infty, P)\cup(P, \infty)$ is not path-connected[42], while one can easily verify that $\mathbb{R}^n \setminus \{f(P)\}$ is path-connected. But as we remarked on page 152, homeomorphic spaces have the same topological properties. In particular two homeomorphic spaces are either both path-connected or they are both not path-connected. Thus we have obtained a contradiction.

(2) The proof of this statement is fairly similar to the proof of (1). We leave it to the reader to fill in the details. ■

We continue with the following elementary but useful lemma.

Lemma 2.27. (Connected-to-Discrete Lemma) Every map $f\colon X \to Y$ from a connected space X to a discrete space is constant.



Remark. One could argue that the Connected-to-Discrete Lemma 2.27 is the lemma in topology that is most relevant to real life. More precisely, an immediate consequence of the Connected-to-Discrete Lemma 2.27 is that any *non-constant* map $(a, b) \to A$ from an interval to a finite set is not continuous. This is of huge significance since humanity likes to squeeze a real-parameter (e.g. time, intelligence, performance) into a finite set of values (e.g. historical stages, grades in school and exams, hired-or-fired). Any such function is non-continuous and hence very problematic.

Proof. We need to show that for any $x \in X$ we have $f(\{x\}) = f(X)$. Since Y is a discrete space we know that $\{f(x)\}$ and $Y \setminus \{f(x)\}$ are open subsets of Y. The preimages $U := f^{-1}(f(x))$ and $V := f^{-1}(Y \setminus \{f(x)\})$ are also open and they are evidently disjoint. Since U is non-empty and since X is connected we see that $V = \varnothing$. But this means that f is constant. ■

Before we continue we introduce the concatenation of two paths.

Definition. Let X be a topological space and let $\alpha\colon [0,1] \to X$ and $\beta\colon [0,1] \to X$ be two paths with $\alpha(1) = \beta(0)$. We define the concatenation of α and β as the path $\alpha * \beta$ which is given by[43]

$$\begin{array}{rcl} \alpha * \beta\colon [0,1] & \to & X \\ t & \mapsto & \begin{cases} \alpha(2t), & \text{if } t \in \left[0, \frac{1}{2}\right] \\ \beta(\frac{1}{2} + (2t-1)), & \text{if } t \in \left(\frac{1}{2}, 1\right]. \end{cases} \end{array}$$

The concatenation of paths will play a major role throughout these notes, especially when we introduce the fundamental group of a pointed topological space. In a more humble

[42] Why is this topological space not path-connected? How can one show this?

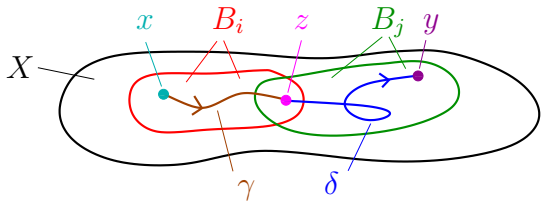
[43] It follows from the Pasting Proposition 2.6 (2) and our hypothesis $\alpha(1) = \beta(0)$ that $\alpha * \beta\colon [0,1] \to X$ is a continuous map.

fashion it also plays a minor role in the proof of the following lemma, which gives a criterion for the union of (path-) connected subsets to be (path-) connected.

Lemma 2.28. (Union Connected Lemma) Let X be a topological space and let $\{B_i\}_{i\in I}$ be a family of subsets such that the intersection $\bigcap_{i\in I} B_i$ is non-empty.

(1) If each B_i, $i \in I$ is path-connected, then $\bigcup_{i\in I} B_i$ is path-connected.

(2) If each B_i, $i \in I$ is connected, then $\bigcup_{i\in I} B_i$ is connected.



Remark. In Exercise 6.11 we will provide a partial converse to the Union Connected Lemma 2.28.

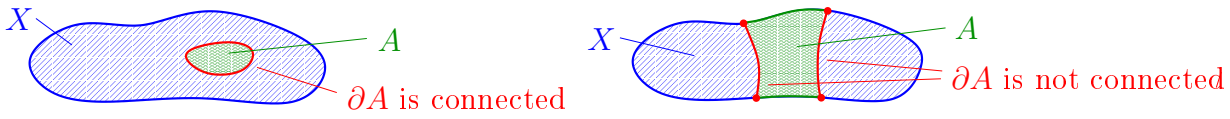
Proof. Let X be a topological space and let $\{B_i\}_{i\in I}$ be a family of subsets such that the intersection $\bigcap_{i\in I} B_i$ contains a point z. We write $Z := \bigcup_{i\in I} B_i$.

(1) We suppose that each B_i, $i \in I$ is path-connected. So let $x, y \in Z$. There exists an $i \in I$ with $x \in B_i$ and there exists a $j \in I$ with $y \in B_j$. Since B_i and B_j are path-connected we can pick a path $\gamma\colon [0,1] \to B_i$ from x to z and we can pick a path $\delta\colon [0,1] \to B_j$ from z to y. Note that the concatenation of the paths γ and δ is a path from x to y.

(2) We suppose that each B_i, $i \in I$ is connected. We write $Z = U \sqcup V$ where U and V are open subsets. Without loss of generality we can assume that $z \in U$. For each $i \in I$ we have a decomposition $B_i = (U \cap B_i) \sqcup (V \cap B_i)$ into disjoint open subsets (here we use the definition of the subspace topology). Since B_i is connected and since $U \cap B_i \neq \varnothing$ we see that $B_i = U \cap B_i$. Thus we have shown that

$$U = \bigcup_{i\in I}(B_i \cap U) = \bigcup_{i\in I} B_i = Z. \qquad \blacksquare$$

Sometimes it is also useful to have criteria which show that removing a subset does not change connectedness.



Lemma 2.29. (Complement Connected Lemma) Let X be a topological space and let $A \subset X$ be a subset.

(1) If X is path-connected and if ∂A is path-connected, then $X \setminus \mathring{A}$ is also path-connected.

(2) If X is connected and if ∂A is connected, then $X \setminus \mathring{A}$ is also connected.

Proof. We will prove the Complement Connected Lemma 2.29 in Exercise 2.50. $\blacksquare$

2.6. **The (path-) components of a topological space.** This section is a follow-up on the previous section. Let us start with the following simple-minded definition.

Definition. Let x and y be two points in a topological space X. We say that the points x and y are path-equivalent, if there exists a map $\gamma\colon [0,1] \to X$ with $\gamma(0) = x$ and $\gamma(1) = y$.

Lemma 2.30. For every topological space X the notion of path-equivalence is indeed an equivalence relation.

Proof. All properties of an equivalence relation are trivial except possibly for transitivity. The fact that path-equivalence is transitive can be shown by concatenating paths. More precisely, if $\alpha\colon [0,1] \to X$ is a path from $P = \alpha(0)$ to $Q = \alpha(1)$ and if $\beta\colon [0,1] \to X$ is a path from $Q = \beta(0)$ to $R = \beta(1)$, then the concatenation $\alpha * \beta\colon [0,1] \to X$ is a path from P to R. ■

Definition. Let X be a topological space.

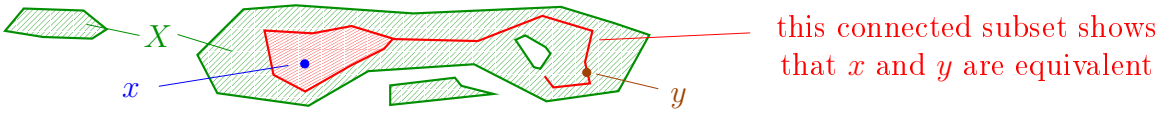
(1) We call the path-equivalence classes of points the path-components of X.
(2) We denote by $\pi_0(X)$ the set of path-components of X.[44] Furthermore we write $\pi_0(X) = 0$ if X is non-empty and if it consists of a single path-component.

Example. It is a straightforward consequence of the Intermediate Value Theorem that each point in $\mathbb{Q}$ is in fact already a path-component of $\mathbb{Q}$.

Lemma 2.31. (Path-Component Lemma) Let X be a topological space.

(1) As a set, X is the disjoint union of its path-components.
(2) Each path-component of X is path-connected.
(3) Each path-component C of X is a maximal path-connected subset, i.e. if $C \subsetneq D$, then D is not path-connected.
(4) Let A be a subset of X.
   (a) If no point in A is path-equivalent to a point in $X \setminus A$, then A is the union of path-components of X.
   (b) If A is path-connected, then A is contained in a path-component of X.
   (c) If A is path-connected and if no point in A is path-equivalent to a point in $X \setminus A$, then A is a path-component of X.

Proof. The lemma follows immediately from the definitions and basic properties of equivalence relations, see the Equivalence Class Lemma 0.4. We leave it to the reader to fill in the few remaining details. ■



Example. We consider the topological space $\mathbb{R} \setminus \{0\}$. The subsets $\mathbb{R}_{<0}$ and $\mathbb{R}_{>0}$ are evidently path-connected. It follows from the Intermediate Value Theorem that no point in $\mathbb{R}_{<0}$ is path-equivalent to a point in $\mathbb{R}_{>0}$. Thus it follows from the Path-Component Lemma 2.31 (4c) that $\mathbb{R}_{<0}$ and $\mathbb{R}_{>0}$ are the path-components of $\mathbb{R} \setminus \{0\}$.

[44] The notation "$\pi_0(X)$" might look rather odd at the moment, but it will become clearer later on, when we introduce the fundamental groups and the higher homotopy groups, why this is a perfectly sensible notation. At that point the weird definition of "$\pi_0(X) = 0$" will start making more sense.

Our goal now is to define the "components" of a topological space that should play the same role as the path-components, i.e. we want to introduce the notion of "components" such that the statements of the Path-Component Lemma 2.31 hold, but with "path-connected" replaced by "connected" and "path-component" replaced by "component".

We start out with the following definition.

Definition. Let x and y be two points in a topological space X. We say that the points x and y are equivalent, if there exists a connected subset of X that contains both x and y.

Lemma 2.32. For every topological space X the above notion of equivalence is indeed an equivalence relation.

Proof. All properties of an equivalence relation are trivial except for transitivity. So suppose that x and y are equivalent and that y and z are equivalent. By definition there exists a connected subset A that contains x and y and there exists a connected subset B that contains y and z. By the Union Connected Lemma 2.28 (2) the union $A \cup B$ is connected and it thus follows that x and z are equivalent. ■

Definition. Let X be a topological space. We call the equivalence classes of points on X the components of X.

Examples.

(1) In Exercise 2.48 we will show that the Topologist's Sine Curve, that we illustrated in the figure on page 164, has two path-components but only a single component.
(2) We consider $X = \mathbb{Q}$ with the subspace topology coming from $\mathbb{R}$. In Exercise 2.23 we show that the only connected subsets of $\mathbb{Q}$ are the subsets consisting of at most a point. It follows that the components of $\mathbb{Q}$ are precisely the one-point subsets.

The following is in particular the promised analogue of the Path-Component Lemma 2.31.

Lemma 2.33. (Component Lemma) Let X be a topological space.

(1) As a set X is the disjoint union of its components.
(2) Each component of X is connected.
(3) Each component C of X is a maximal connected subset of X, i.e. if $C \subsetneq D$, then D is not connected.
(4) Let A be a subset of X.
    (a) If C is a component of X, then $A \cap C$ is a union of components of A.
    (b) If A is closed and open in X, then A is the union of components of X.
    (c) If A is closed and open in X and if A is connected, then A is a component of X.
(5) Each component of X is the union of path-components of X.

Example. We consider the topological space $\mathbb{R} \setminus \{0\}$. The subsets $\mathbb{R}_{<0}$ and $\mathbb{R}_{>0}$ are evidently path-connected. By the Path-Connected Implies Connected Corollary 2.23 we know that $\mathbb{R}_{<0}$ and $\mathbb{R}_{>0}$ are also connected. Since these two subsets are closed and open

in $\mathbb{R} \setminus \{0\}$ we deduce from the Component Lemma 2.33 (4c) that the two subsets are the components of $\mathbb{R} \setminus \{0\}$.

Proof. Let X be a topological space.

(1) This statement is clear since components are defined to be equivalence classes, see also the Equivalence Class Lemma 0.4.

(2) Now let C be a component of X. We pick $c \in C$. For each $d \in C$ there exists by definition a connected subset Y_d of X that contains c and d. We have

$$C = \bigcup_{c \in C} \{c\} \subset \bigcup_{c \in C} Y_c \underset{\uparrow}{\subset} C \quad \text{which implies that} \quad C = \bigcup_{c \in C} Y_c.$$

by definition all points in Y_d are equivalent to c, thus we have $Y_d \subset C$

It follows from the Union Connected Lemma 2.28 (2) that C is connected.

(3) This statement follows immediately from the definitions.

(4) Let A be a subset of X.
   (a) Let C be a component of X. Note that if two points of A are equivalent in A, then they are also equivalent in X. This implies that no point in $A \cap C$ is equivalent to a point of $A \setminus (A \cap C)$. The statement now follows from (1) applied to A.
   (b) Suppose that A is closed and open. Let C be a component of X. Note that $A \cap C$ is a subset of C that is closed and open. By (2) we know that C is connected, hence we see that either $A \cap C = \varnothing$ or $A \cap C = C$. This shows that A is precisely the union of all the components of X that A intersects.
   (c) This statement follows immediately from (b).

(5) Let C be a component of X and let P be a component of X with $P \cap C \neq \varnothing$. We need to show that $P \subset X$. We do so as follows:
   (a) Note that P is connected by the Path-Connected Implies Connected Corollary 2.23.
   (b) It follows from (a) and the Union Connected Lemma 2.28 that $P \cup C$ is connected.
   (c) It follows from (b) and (3) that $P \cup C \subset C$. This of course implies that $P \subset C$. ■

We continue our discussion of the components of a topological space with the following, possibly slightly counterintuitive, lemma.

Lemma 2.34. (Components-are-Closed Lemma) Let X be a topological space.

(1) Every component of X is a closed subset of X.

(2) If X has only finitely many components, then each component is also an open subset of X.[45]

Example. We consider $X = \mathbb{Q}$. As we mentioned on page 168, in this case every point is already a component. We see that every component is closed, but in this case no component is an open subset. Therefore we cannot drop the condition on the number of components in the second statement of the lemma.

[45] In the Locally Path-Connected Lemma 2.40 we give a criterion which often can be used to show that components are in fact open.

Proof. Let X be a topological space.

(1) Let C be a component of X. We need to show that $X \setminus C$ is open. By the JH-Lemma 1.7 it suffices to show that every $P \in X \setminus C$ admits a neighborhood that does not intersect C. Thus let $P \in X \setminus C$. By the Component Lemma 2.33 (3) we know that $C \cup \{P\}$ is not connected. Therefore there exists a decomposition $C \cup \{P\} = U \sqcup V$ with U and V open subsets such that both U and V are non-empty. Without loss of generality $C \cap U \neq \varnothing$. Since C is connected and since $C = (U \cap C) \sqcup (V \cap C)$ we see that $C = U \cap C$. Since V is also non-empty we see that $V = \{P\}$. By the definition of the subspace topology that means that there exists an open subset W of X such that $W \cap (C \cup \{P\}) = V = \{P\}$. But this shows that W is an open neighborhood of P that does not intersect C. We have thus shown that the complement of C is open.

(2) Now suppose that X has only finitely many components. Let C be a component of X. We already know from (1) that C is closed. By definition the complement of C is the union of all other components. Since there are only finitely many and since they are closed by (1) it follows that the complement of C is closed, i.e. C is open. ■

Remark. Let X be a topological space. We say that the points x and y are *quasi-equivalent*, if the following holds

$$\text{if } X = U \sqcup V \text{ is the disjoint union with } U, V \text{ open } \implies \text{ either } x, y \in U \text{ or } x, y \in V.$$

It is straightforward to see that this indeed an equivalence relation on X. The equivalence classes of this equivalence relation are called *quasi-components*. It follows immediately from the definitions that components are contained in quasi-components. But the notions are different, for example it is shown in [**SS1978**, p. 137] that there exist topological spaces such that quasi-components are not connected. We will not make use of the concept of quasi-equivalence and quasi-components.

We conclude this section with the following lemma that can be viewed as a generalization of the Image-Connected Lemma 2.24 and Lemmas 2.27.

Lemma 2.35. Let $f\colon X \to Y$ be a map between two topological spaces.

(1) Let C be a (path)-component C of Y. The preimage $f^{-1}(C)$ is the union of (path)-components of X.
(2) Let B be a (path)-component B of X. There exists a (path)-component C of Y with $f(B) \subset C$.

Proof.

(1) We only need to show that if a point $a \in f^{-1}(C)$ is (path-) equivalent to a point $b \in X$, then a and b are (path-) equivalent. If a and b are (path-) equivalent, then as in the Image-Connected Lemma 2.24 we see that $f(a)$ and $f(b)$ are (path-) equivalent, thus $f(a)$ and $f(b)$ both lie in C. Therefore a and b both lie in $f^{-1}(C)$.
(2) This statement is proved by the same elementary argument as in (1). ■

2.7. **The (path-) components of matrix groups.** In this section we will discuss the (path-) connectedness of certain matrix groups over $\mathbb{R}$ and over $\mathbb{C}$. First we introduce the main players.

Notation. Given a commutative ring R we write

$$\begin{aligned} \mathrm{GL}(n,R) &:= \{A \in \mathrm{M}(n\times n,R) \,|\, \det(A) \text{ a multiplicative unit in } R\} \\ \mathrm{SL}(n,R) &:= \{A \in \mathrm{M}(n\times n,R) \,|\, \det(A) = 1\}. \end{aligned}$$

For $\mathbb{K} = \mathbb{R}$ we have the following extra definitions:

$$\begin{aligned} \mathrm{GL}_+(n,\mathbb{R}) &:= \{A \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, \det(A) > 0\} \\ \mathrm{GL}_-(n,\mathbb{R}) &:= \{A \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, \det(A) < 0\} \\ \mathrm{O}(n) &:= \{A \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, A^TA = \mathrm{id}\} \\ \mathrm{SO}(n) &:= \mathrm{O}(n) \cap \mathrm{SL}(n,\mathbb{R}) = \{A \in \mathrm{M}(n\times n,\mathbb{R}) \,|\, A^TA = \mathrm{id} \text{ and } \det(A) = 1\}. \end{aligned}$$

Furthermore for $\mathbb{K} = \mathbb{C}$ we have the following extra definitions:

$$\begin{aligned} \mathrm{U}(n) &:= \{A \in \mathrm{M}(n\times n,\mathbb{C}) \,|\, \overline{A}^TA = \mathrm{id}\} \\ \mathrm{SU}(n) &:= \mathrm{U}(n) \cap \mathrm{SL}(n,\mathbb{C}) = \{A \in \mathrm{M}(n\times n,\mathbb{C}) \,|\, \overline{A}^TA = \mathrm{id} \text{ and } \det(A) = 1\}. \end{aligned}$$

The following convention explains in what sense these matrix groups are topological spaces.

Convention. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Given $m, n \in \mathbb{N}$ we make the identification

$$\mathrm{M}(m\times n,\mathbb{K}) = \mathbb{K}^{m\cdot n}$$

by "juxtaposing" the rows of the matrix. We equip $\mathbb{K}^{m\cdot n}$ and thus also $\mathrm{M}(m\times n,\mathbb{K})$ with the standard topology that we introduced on page 109. We equip each subset of $\mathrm{M}(m\times n,\mathbb{K})$ with the corresponding subspace topology that we introduced on page 112.

Lemma 2.36. (Matrix Group Lemma) Let $n \in \mathbb{N}$.

(1) $\mathrm{GL}(n,\mathbb{R})$, $\mathrm{GL}_+(n,\mathbb{R})$ and $\mathrm{GL}_-(n,\mathbb{R})$, are open subsets of $\mathrm{M}(n\times n,\mathbb{R})$.
(2) $\mathrm{SL}(n,\mathbb{R})$, $\mathrm{O}(n)$ and $\mathrm{SO}(n)$, are closed subsets of $\mathrm{M}(n\times n,\mathbb{R})$.
(3) $\mathrm{O}(n)$ is compact.
(4) $\mathrm{GL}(n,\mathbb{C})$ is an open subset of $\mathrm{M}(n\times n,\mathbb{C})$.
(5) $\mathrm{SL}(n,\mathbb{C})$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$, are closed subsets of $\mathrm{M}(n\times n,\mathbb{C})$.
(6) $\mathrm{U}(n)$ is compact.

Remark. We will generalize the Matrix Group Lemma 2.36 (1) in Exercise 2.41.

Proof. We consider the following two maps

$$\det\colon \begin{array}{ccc} \mathrm{M}(n\times n,\mathbb{R}) & \to & \mathbb{R} \\ A & \mapsto & \det(A) \end{array} \quad \text{and} \quad \varphi\colon \begin{array}{ccc} \mathrm{M}(n\times n,\mathbb{R}) & \to & \mathbb{R} \\ A & \mapsto & A^T\cdot A. \end{array}$$

It follows from the Leibniz formula and the rather elementary Lemmas 2.2 and 2.3 that both maps are continuous.

(1) It follows from the above that $\mathrm{GL}(n,\mathbb{R}) = \det^{-1}(\mathbb{R}\setminus\{0\})$, $\mathrm{GL}_+(n,\mathbb{R}) = \det^{-1}((0,\infty))$ and $\mathrm{GL}_-(n,\mathbb{R}) = \det^{-1}((-\infty,0))$ are open subset of $\mathrm{M}(n\times n,\mathbb{R})$.
(2) It follows from the above and the Continuity-via-Closed Subsets Lemma 2.4 that $\mathrm{SL}(n,\mathbb{R}) = \det^{-1}(\{1\})$, $\mathrm{O}(n) = \varphi^{-1}(\{\mathrm{id}\})$ and $\mathrm{SO}(n) = \mathrm{SL}(n,\mathbb{R}) \cap \mathrm{O}(n,\mathbb{R})$ are closed subsets of $\mathrm{M}(n\times n,\mathbb{R})$.

(3) Note that each column of an orthogonal matrix has norm one. This implies that $\mathrm{O}(n) \subset \mathbb{R}^{n^2}$ is a bounded subset of $\mathrm{M}(n \times n, \mathbb{R}) = \mathbb{R}^{n^2}$. Thus it follows from the Heine-Borel Theorem 1.24 that $\mathrm{O}(n)$ is compact.

The proofs of Statements (4), (5) and (6) are almost identical to the above proofs. ■

The following proposition will hopefully quench the reader's thirst for information on the (path-) connectedness of the matrix groups.

Proposition 2.37. (Matrix Group Path-Component Proposition) Let $n \in \mathbb{N}$.

	topological space	path-components
(1)	$\mathrm{GL}(n, \mathbb{R})$	path-components are $\mathrm{GL}_+(n, \mathbb{R})$ and $\mathrm{GL}_-(n, \mathbb{R})$
(2)	$\mathrm{SL}(n, \mathbb{R})$	path-connected
(3)	$\mathrm{O}(n)$	path-components are $\mathrm{SO}(n)$ and $\mathrm{O}(n) \cap \mathrm{GL}_-(n, \mathbb{R})$
(4)	$\mathrm{GL}(n, \mathbb{C})$	path-connected
(5)	$\mathrm{SL}(n, \mathbb{C})$	path-connected
(6)	$\mathrm{U}(n)$	path-connected
(7)	$\mathrm{SU}(n)$	path-connected.

Furthermore the path-components are also the components.

Remark.

(1) In Exercise 156.12 we will provide a somewhat different proof of some of the statements of the Matrix Group Path-Component Proposition 2.37. An alternative proof of the Matrix Group Path-Component Proposition 2.37 is also given in [**Bak2002**, Chapter 9.2].

(2) In the Matrix Groups (Smooth) Deformation Retract Propositions 15.7 and 33.10 we collect more information on the relationships between the topological spaces that are given by the various matrix groups.

In the proof of the Matrix Group Path-Component Proposition 2.37 we will make use of the Gram-Schmidt Orthogonalization Process which we now recall.

Lemma 2.38. (Gram-Schmidt Orthogonalization Process) Let V be a real vector space and let $\langle\, , \rangle \colon V \times V \to \mathbb{R}$ be a positive-definite symmetric $\mathbb{R}$-bilinear[46] form. Given $v \in V$ we write $\|v\| := \sqrt{\langle v, v \rangle}$. Let $v_1, \ldots, v_n$ be a basis of V. We consider the following sequence of n-tuples of vectors in V:[47]

$$
\begin{aligned}
&u_{0,1}, .., u_{0,n} := v_1, .., v_n \\
&u_{1,1}, .., u_{1,n} := \frac{v_1}{\|v_1\|}, \|v_1\| \cdot v_2, v_2, .., v_n \\
&\qquad\vdots \qquad\qquad\qquad \vdots \\
&u_{i,1}, .., u_{i,n} := u_{i-1,1}, .., u_{i-1,i-1}, \frac{z}{\|z\|}, \|z\| \cdot v_{i+1}, v_{i+2}, .., v_n \text{ with } z := v_i - \sum_{j=1}^{i-1} \langle v_i, u_{i-1,j} \rangle \cdot u_{i-1,j} \\
&\qquad\vdots \qquad\qquad\qquad \vdots \\
&u_{n,1}, .., u_{n,n} := u_{n-1,1}, .., u_{n-1,n-1}, \frac{z}{\|z\|} \qquad\qquad \text{with } z := v_n - \sum_{j=1}^{n-1} \langle v_n, u_{n-1,j} \rangle \cdot u_{n-1,j}.
\end{aligned}
$$

This sequence has the following properties:

(1) For each $i \in \{1, \ldots, n\}$ the vectors $\{u_{i,1}, \ldots, u_{i,n}\}$ form a basis of V.

(2) For each $i \in \{1, \ldots, n-1\}$ the base change matrix from the basis $v_1, \ldots, v_n$ to the basis $u_{i,1}, \ldots, u_{i,n}$ has determinant 1.
(3) The base change matrix from the basis $v_1, \ldots, v_n$ to the basis $u_{n,1}, \ldots, u_{n,n}$ has positive determinant.
(4) For each $i \in \{1, \ldots, n\}$ the vectors $u_{i,1}, \ldots, u_{i,i}$ are orthonormal.
(5) If $v_1, \ldots, v_n$ are orthonormal, then the sequence of n-tuples of vectors is constant, i.e. for any $i, j \in \{1, \ldots, n\}$ we have $u_{i,j} = v_j$.

The analogous statement also holds if we are dealing with a positive-definite hermitian $\mathbb{C}$-sesquilinear form over a complex vector space.

Proof. The lemma follows from elementary arguments which we leave to the readers who suffer from linear algebra withdrawal syndrome. ■

Now we turn to the actual proof of the Matrix Group Path-Component Proposition 2.37. In fact we break the proof of the Matrix Group Path-Component Proposition 2.37 into two parts. First we consider the matrix groups defined over $\mathbb{R}$, afterwards we consider the matrix groups defined over $\mathbb{C}$.

Proof for the Matrix Group Path-Component Proposition 2.37 (1), (2) and (3). The proof of the three statements rests mostly on the following three claims.

Claim 1. Given any matrix $A \in \mathrm{GL}_+(n, \mathbb{R})$ there exists a path $\alpha\colon [0,1] \to \mathrm{GL}_+(n, \mathbb{R})$ with $\alpha(0) = A$ and with $\alpha(1) \in \mathrm{SL}(n, \mathbb{R})$.

Proof. Let $A \in \mathrm{GL}_+(n, \mathbb{R})$. Since $\det(A) > 0$ we can consider the path that is given by $\alpha(t) = \det(A)^{-t/n} \cdot A$. Evidently $\alpha(0) = A$ and one can easily verify that $\det(\alpha(1)) = 1$ ⊞

Claim 2. Given any $A \in \mathrm{SL}(n, \mathbb{R})$ there exists a path $\beta\colon [0,1] \to \mathrm{SL}(n, \mathbb{R})$ with $\beta(0) = A$ and $\beta(1) \in \mathrm{SO}(n)$.

Proof. We apply the Gram-Schmidt Orthonormalization Process 2.38 to the column vectors $v_1, \ldots, v_n$ of the matrix $A \in \mathrm{SL}(n, \mathbb{R})$. For $i = 0, \ldots, n$ we obtain sets of vectors $u_{i,1}, \ldots, u_{i,n} \in \mathbb{R}^n$. For $i = 0, \ldots, n$ we write $A_i := (u_{i,1} \ \ldots \ u_{i,n}) \in \mathrm{M}(n \times n, \mathbb{R})$. By construction $A_0 = A$. Note that it follows from Properties (1), (2), (3) and (4) stated in the Gram-Schmidt Orthonormalization Process, together with the fact that the determinant of an orthogonal matrix is ± 1, that each matrix A_i lies in $\mathrm{SL}(n, \mathbb{R})$ and that $A_n \in \mathrm{SO}(n)$.

Let $i \in \{1, \ldots, n\}$. We will now show that there exists path in $\mathrm{SL}(n, \mathbb{R})$ from A_{i-1} to A_i. To simplify the notation we write $u_1, \ldots, u_n$ instead of $u_{i-1,1}, \ldots, u_{i-1,n}$. First we consider the path

$$\begin{aligned} \varphi\colon [0,1] &\to \mathrm{SL}(n, \mathbb{R}) \\ t &\mapsto \left(u_1 \ \ldots \ u_{i-1} \ \ \frac{u_i}{\lambda(t)} \ \ \lambda(t) \cdot u_{i+1} \ \ u_{i+2} \ \ldots \ u_n\right) \text{ where } \lambda(t) = (1-t) + t \cdot \|u_i\|. \end{aligned}$$

[46] Recall that according, to the definition that we gave on page 99, we say that a symmetric $\mathbb{R}$-bilinear form $\langle -, - \rangle\colon V \times V \to \mathbb{R}$ is positive-definite if for every $v \neq 0$ we have $\langle v, v \rangle > 0$.

[47] Our formulation is more complicated than the standard formulation of the Gram-Schmidt Orthogonalization Process. The reason is that we want to have control over the base change matrices. This is important when we show, in the proof of the Matrix Group Path-Component Proposition 2.37 (2), that $\mathrm{SL}(n, \mathbb{R})$ is path-connected.

We write $\widetilde{u}_i := \frac{u_i}{\|u_i\|}$ and $\widetilde{u}_{i+1} := \|u_i\| \cdot u_{i+1}$. Next we consider the path

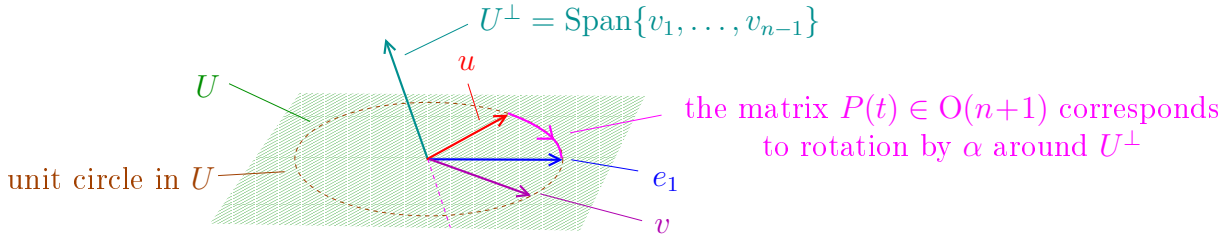
$$\begin{array}{rcl} \psi\colon [0,1] & \to & \mathrm{SL}(n,\mathbb{R}) \\ t & \mapsto & \left(u_1 \ \dots \ u_{i-1} \ \ \frac{z(t)}{\|z(t)\|} \ \ \|z(t)\| \cdot \widetilde{u}_{i+1} \ \dots \ u_n\right) \text{ where } z(t) = \widetilde{u}_i - t \cdot \sum_{j=1}^{i-1} \langle \widetilde{u}_i, u_j \rangle \cdot u_j. \end{array}$$

Note that $\varphi(0) = A_{i-1}$ and note that $\varphi(1) = \psi(0)$. A short moment's thought shows that $\psi(1) = A_n$. Thus the concatenation of the paths φ and ψ is a path in $\mathrm{SL}(n,\mathbb{R})$ from A_{i-1} to A_i. The concatenation of these finitely many paths is the desired path $\beta\colon [0,1] \to \mathrm{SL}(n,\mathbb{R})$ from A to the orthogonal matrix $A_n \in \mathrm{SO}(n)$. ⊞

Claim 3. Given any $A \in \mathrm{SO}(n)$ there exists a path $\gamma\colon [0,1] \to \mathrm{SO}(n)$ with $\gamma(0) = A$ and $\gamma(1) = \mathrm{id}_n$.

Proof. We prove this claim by induction on n. The case $n = 1$ is clear since $\mathrm{SO}(1)$ consists of precisely the matrix $(1) = \mathrm{id}_1$. Now suppose that the statement holds for some $n \geq 1$. Let $A \in \mathrm{SO}(n+1)$. We denote by $u \in \mathbb{R}^{n+1}$ the first column of the matrix A. We write $e_1 = (1, 0, \dots, 0) \in \mathbb{R}^{n+1}$. Since $n + 1 \geq 2$ there exists a vector $v \in \mathbb{R}^{n+1}$ with $\|v\| = 1$, such that $u \perp v$ and such that $e_1 \in \mathrm{span}\{u, v\}$. We set $U := \mathrm{span}\{u, v\}$. Since u and v are orthonormal there exists an $\alpha \in \mathbb{R}$ such that $e_1 = \cos(\alpha) \cdot u + \sin(\alpha) \cdot v$. We extend u, v to an orthonormal basis $u, v, w_1, \dots, w_{n-1}$. Given $t \in [0,1]$ we consider the matrix

$$P(t) \ := \ Q \cdot \underbrace{\begin{pmatrix} \cos(\alpha \cdot t) & -\sin(\alpha \cdot t) & 0 \\ \sin(\alpha \cdot t) & \cos(\alpha \cdot t) & 0 \\ 0 & 0 & \mathrm{id}_{n-1} \end{pmatrix}}_{\in \mathrm{O}(n+1)} \cdot Q^{-1} \qquad \text{where } Q = \underbrace{(u \ v \ w_1 \ \dots \ w_{n-1})}_{\in \mathrm{O}(n+1)}.$$



Next we consider the path

$$\begin{array}{rcl} \gamma\colon [0,1] & \to & \mathrm{SO}(n+1) \\ t & \mapsto & P(t) \cdot A. \end{array}$$

Evidently $\gamma(0) = A$. An elementary calculation shows that the first column of the matrix $\gamma(1) \in \mathrm{SO}(n+1)$ equals e_1. Since $\gamma(1)$ is orthogonal this implies that there exists an $\widetilde{A} \in \mathrm{SO}(n)$ with

$$\gamma(1) \ = \ \begin{pmatrix} 1 & 0 \\ 0 & \widetilde{A} \end{pmatrix}.$$

By induction hypothesis there exists a path $\widetilde{\delta}\colon [0,1] \to \mathrm{SO}(n)$ from $\widetilde{A}$ to id_n. By "adding a 1 at the top left" this path $\widetilde{\delta}$ gives rise to a path δ in $\mathrm{SO}(n+)$ from $\gamma(1)$ to id_{n+1}. The concatenation of the two paths γ and δ is the promised path in $\mathrm{SO}(n+1)$ from A to id_{n+1}. ⊞

Now we turn to the actual proofs of the statements (1), (2) and (3) of the Matrix Group Path-Component Proposition 2.37.

(1) It follows from Claims 1, 2 and 3, together with the fact that path-equivalence is an equivalence relation, that $\mathrm{GL}_+(n,\mathbb{R})$ is path-connected. Next note that multiplication by a matrix in $\mathrm{GL}(n,\mathbb{R})$ with negative determinant gives rise to a homeomorphism $\mathrm{GL}_+(n,\mathbb{R}) \to \mathrm{GL}_-(n,\mathbb{R})$. Thus it follows that $\mathrm{GL}_-(n,\mathbb{R})$ is also path-connected.

Next we consider the map $f\colon \mathrm{GL}(n,\mathbb{R}) \to \mathbb{R}\setminus\{0\}$ that is given by the determinant. On page 167 we saw that $\mathbb{R}_{<0}$ and $\mathbb{R}_{>0}$ are the path-components of $\mathbb{R}\setminus\{0\}$. It follows from the above together with Lemma 2.35 that $\mathrm{GL}_-(n,\mathbb{R}) = f^{-1}(\mathbb{R}_{<0})$ and $\mathrm{GL}_+(n,\mathbb{R}) = f^{-1}(\mathbb{R}_{>0})$ are the path-components of $\mathrm{GL}(n,\mathbb{R})$.

This discussion, together with the Path-Connected Implies Connected Corollary 2.23 and the Component Lemma 2.33 shows that $\mathrm{GL}_-(n,\mathbb{R})$ and $\mathrm{GL}_+(n,\mathbb{R})$ are also the components of $\mathrm{GL}(n,\mathbb{R})$.

(2) It follows from Claims 2 and 3 that $\mathrm{SL}(n,\mathbb{R})$ is path-connected. By the Path-Connected Implies Connected Corollary 2.23 this implies that $\mathrm{SL}(n,\mathbb{R})$ is connected.

(3) It follows from Claim 3 that $\mathrm{SO}(n,\mathbb{R})$ is path-connected. By basically the same argument as in (1) we see that $\mathrm{O}(n)$ has precisely two path-components, namely $\mathrm{SO}(n)$ and $\mathrm{O}(n)\cap\mathrm{GL}_-(n,\mathbb{R})$, and by the same argument as above one sees that these are also the components of $\mathrm{O}(n)$. ■

Now we turn to the proof of Proposition 2.37 for the matrix groups that are defined over $\mathbb{C}$.

Proof of Proposition 2.37 (4), (5), (6) and (7).

Claim 4.

(1) Given any $A \in \mathrm{GL}(n,\mathbb{C})$ there exists a path $\delta\colon [0,1] \to \mathrm{GL}(n,\mathbb{C})$ with $\gamma(0) = A$ and $\gamma(1) \in \mathrm{SL}(n,\mathbb{C})$.

(2) If $A \in \mathrm{U}(n)$, then we can find such a path that takes values in $\mathrm{U}(n)$.

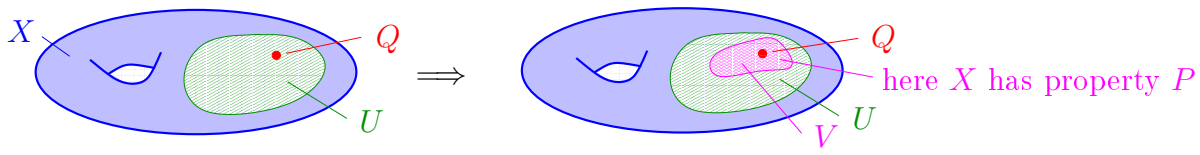
Proof. Let $A \in \mathrm{GL}(n,\mathbb{C})$. We pick $r \in \mathbb{R}_{>0}$ and $\varphi \in \mathbb{R}$ with $\det(A) = r\cdot\exp(\mathrm{i}\varphi)$. The map

$$\begin{array}{rcl} \delta\colon [0,1] & \to & \mathrm{GL}(n,\mathbb{C}) \\ t & \mapsto & r^{-t/n}\cdot\exp(-\mathrm{i}\varphi\cdot t/n)\cdot A \end{array}$$

is a path from A to a matrix in $\mathrm{SL}(n,\mathbb{C})$. If $A \in \mathrm{U}(n)$, then $r = 1$ and we see that the path takes values in $\mathrm{U}(n)$. ⊞

Using Claim 4 one sees that it suffices to show that $\mathrm{SL}(n,\mathbb{C})$ and $\mathrm{SU}(n)$ are connected. This is achieved by making straightforward modifications to the Claims 2 and 3 that we considered in the proof of the real case. We leave it to the reader to fill in the details. ■

2.8. Local and regional properties.



As so often, let us start out with a definition.

Definition. Let P be a property of topological spaces and let X be a topological space.

(1) We say X is regionally P if given any $Q \in X$ and any neighborhood U of Q there exists a neighborhood V of Q that is contained in U that has the property P.

(2) We say X is locally P if given any $Q \in X$ and any neighborhood U of Q there exists an *open* neighborhood V of Q that is contained in U that has the property P.

Note that by definition a topological space that is locally P is also regionally P.

Warning. Our usage of the expression "locally P" is non-standard. In fact most textbooks, see e.g. **[Hat2002, Bre1993, Rot1988]**, define "locally P" as what we call "regionally P". (Note though that, as is apparent from **[Mun1975**, p. 161], in **[Mun1975]** our notion of "locally P" is being used.) The property that we now call "locally P" does not seem to have an established name. For our purpose it is useful to give names to both concepts since both have their uses and justifications. Later on we will also introduce notion of a local property of a map, in this context most books implicitly or explicitly seem to work with open neighborhoods. Thus it seems reasonable to us to use the word "local" whenever we deal with open neighborhoods and to rename the concept when any neighborhood is allowed.

Examples.

(1) Every open subset of $\mathbb{R}^n$ is locally path-connected. Indeed, suppose A is an open subset of $\mathbb{R}^n$. Let $Q \in A$ and let U be a neighborhood of Q in A. Then there exists an $\epsilon > 0$ such that $B^n_\epsilon(x) \subset U$. The ϵ-ball $B^n_\epsilon(x)$ is of course path-connected.
(2) The topological space $X = (-2, 1) \cup [3, 6] \subset \mathbb{R}$ with the usual topology is not path-connected but it is locally path-connected.[48] On the other hand $X = \mathbb{Q}$ is not even locally path-connected.
(3) The line with two zeros, i.e. the topological space $\mathbb{R} \cup \{*\}$ with the topology from page 122, is not Hausdorff, but one can easily show that $\mathbb{R} \cup \{*\}$ is locally Hausdorff.

The following lemma can at times be useful.

Lemma 2.39. Let P be a property of topological spaces and let X be a topological space. If X is locally P, then the open subsets of X that have P form a basis for the topology of X.

Proof. This lemma follows immediately from the Basis Characterization Lemma 1.32 (1). ■

The following lemma is the key to showing that for "reasonable" topological spaces the notions of being connected and being path-connected are actually the same.

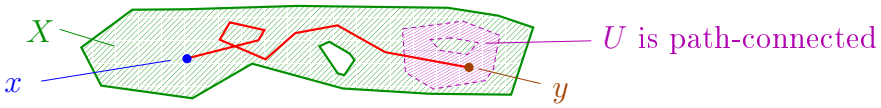
Lemma 2.40. (Locally Path-Connected Lemma) Let X be a topological space.

(1) If X is locally path-connected, then the following statements hold:
  (a) X is connected if and only if X is path-connected.
  (b) The components of X are precisely the path-components of X.
(2) If X is locally path-connected, then it is also locally connected.
(3) If X is locally connected, then every component of X is a closed and an open subset of X.[49]

[48] Why is that?

[49] Recall that on page 168 we saw that for the topological space $X = \mathbb{Q}$ every point defines a component. Thus in general components are, very annoyingly, not necessarily open.

Proof.



(1) First note that if X is path-connected, then we know by the Path-Connected Implies Connected Corollary 2.23 that X is connected. This gives us the cheap "if"-direction of (a).

We now assume that X is locally path-connected. Note that the "only if"-direction of (a) is a special case of (b). Thus it remains to prove (b). We start out with the following claim.

Claim 1. Each path-component is open.

Proof. Let P be a path-component. We pick $x \in X$. To show that P is open it suffices by the JH-Lemma 1.7 to show that each $y \in P$ admits a neighborhood that is contained in P.

Thus let $y \in P$. We pick a path $p\colon [0,1] \to X$ with $p(0) = x$ and $p(1) = y$. Since X is locally path-connected there exists an open neighborhood U of y that is path-connected. It follows from the Image-Connected Lemma 2.24 (1) together with the Union Connected Lemma 2.28 that $p([0,1]) \cup U$ is path-connected. It follows from the Path-Component Lemma 2.31 (4b) that $p([0,1]) \cup U \subset P$. Finally note that since U is open we know that $p([0,1]) \cup U$ is a neighborhood of x. ⊞

Claim 2. Each path-component is closed.

Proof. By Claim 1 we now know that each path-component is open. Since the complement of a path-component is the union of path-components and since the union of open sets is open we see that each path-component is also closed. ⊞

Now let C be a component of X. By the Component Lemma 2.33 (2) and (5) we know that C is connected and that it is the union of a family of path-component $\{P_i\}_{i\in I}$. By Claim 1 and Claim 2 we know that each P_i is open and connected. But since C is connected this implies that I consists of a single element, i.e. C is a path-component of X.

(2) This statement follows from the Path-Connected Implies Connected Corollary 2.23.

(3) Let C be a component of X. By the Components-are-Closed Lemma 2.34 we know that C is a closed subset of X. We now assume that X is locally connected. We want to show that C is an open subset of X. By the Neighborhood Openness Criterion 1.5 it suffices to show that each $x \in C$ admits an open neighborhood that is contained in C. Thus let $x \in C$. Since X is locally connected we see that there exists an open neighborhood U of $x \in X$ such that U is connected. It follows immediately from the definition of a component, see page 168, that every point in U is also contained in x. ■

In the following we discuss the notion of being regionally compact.

Examples.

(1) Every open subset of $\mathbb{R}^n$ is regionally compact. Indeed, suppose A is an open subset of $\mathbb{R}^n$. Let $Q \in A$ and let U be a neighborhood of Q in A. Then there exists an

$\epsilon > 0$ such that $B_\epsilon^n(x) \subset U$. The closed ϵ-ball $\overline{B}_{\frac{\epsilon}{2}}^n(x)$ is a neighborhood of x and it is compact by the Heine-Borel Theorem 1.24.

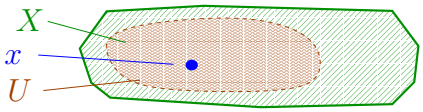
(2) Similar to (1) one can easily show that every interval is regionally compact. In fact later on we will mostly need the fact that the interval $[0, 1]$ is regionally compact.

In Exercise 2.58 we will see that there exists a topological space that is compact but not regionally compact. The following lemma shows that this slightly unintuitive phenomenon cannot occur if we restrict ourselves to topological spaces that are Hausdorff.

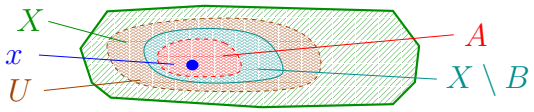
Lemma 2.41. Let X be a Hausdorff space.

(1) If X is compact, then X is also regionally compact.

(2) If given any point $P \in X$ there exists a compact neighborhood of P, then X is regionally compact.



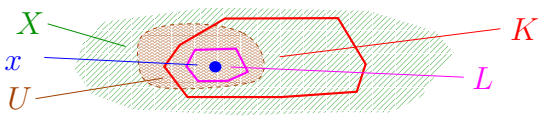
Proof.



(1) Let X be a compact Hausdorff space. We need to show that X is regionally compact. Thus let $x \in X$ and let U be an neighborhood of x.

Claim. There exists an open neighborhood A of x with $\overline{A} \subset U$.

Proof. Note that it follows from the hypothesis that X is Hausdorff and the Points-in-Hausdorff Space Lemma 1.15 that $\{x\}$ is a closed subset of X. Furthermore note that by the Compact Hausdorff Spaces-Normal Lemma 1.16 we know that the compact Hausdorff X is normal. Thus we can separate the closed subsets $\{x\}$ and $X \setminus \mathring{U}$ by open neighborhoods A and B. More precisely, there exist disjoint open neighborhoods A of $\{x\}$ and B of $X \setminus \mathring{U}$.

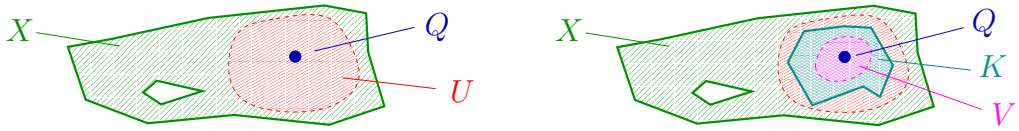


It remains to show that $\overline{A} \subset U$. Note that $A \subset X \setminus B \subset U$. Since B is open we know that $X \setminus B$ is closed. By definition of the closure $\overline{A}$ we have $\overline{A} \subset X \setminus B$. ⊞

Finally note, since $\overline{A}$ is a closed subset of the compact space X we know by the Compact-Closed Lemma 1.21 (1) that $\overline{A}$ is compact. We are done.

(2) Let X be a Hausdorff space such that every $P \in X$ admits a compact neighborhood. We need to show that X is regionally compact. Thus let $P \in X$ and let U be a neighborhood of P. By hypothesis we know that P admits a compact neighborhood K. By (1) we know that K is regionally compact, which implies that there exists a compact neighborhood L of $P \in K$ with $P \in L \subset U \cap K$. ■

Our next definition is a closely related concept.



Definition. Let X be a topological space. A subset $A \subset X$ is called precompact if the closure $\overline{A}$ is compact.

Lemma 2.42. Let X be a Hausdorff space that is regionally compact.

(1) Given any $Q \in X$ and given any open neighborhood U of Q there exists an open neighborhood V of Q such that $\overline{V}$ is compact and such that $Q \in V \subset \overline{V} \subset U$.
(2) X is locally precompact.

Proof. Let X be a Hausdorff space that is regionally compact.

(1) Let $Q \in X$ and let U be a neighborhood of Q. Since X is regionally compact we know that there exists a compact neighborhood K of Q with $K \subset U$. Since K is a neighborhood of Q we know that there exists an open neighborhood V of Q with $Q \in V \subset K$. Since X is Hausdorff we know by the Compact-Closed Lemma 1.21 (2) that K is a closed subset of X. Hence $\overline{V} \subset K$. Since $\overline{V}$ is a closed subset of the compact space K we obtain from the Compact-Closed Lemma 1.21 (1) that $\overline{V}$ is compact.

(2) It follows immediately from (1) that X is locally precompact. ■

We conclude the discussion of regionally compact spaces with another health warning.

Warning. Recall that what we call "regionally P" is usually called "locally P". Even more confusing, in the literature frequently "usually compact" is used with different definitions. For example in [**HY1988**, p. 71] and [**Dug1966**, p. 237] a topological space is called "regionally compact" if every point admits an open neighborhood such that its closure is compact. Furthermore in [**SS1978**, p. 20], [**Bre1993**, p. 31] and [**Jos1983**, p. 266] a topological space is called "regionally compact" if every point is contained in a compact neighborhood. The latter two notions of "regionally compact" are in general different, see e.g. [**SS1978**, Example 52]. Furthermore note that for the above two concepts of "regionally compact" every compact space is already regionally compact. But as we mentioned above, in Exercise 2.58 we will see that there exists a compact space that is not regionally compact topological. Nonetheless, it is a "metatheorem" that all concepts of "locally compact" in the literature agree for Hausdorff spaces and they agree with our notion of "regionally compact".

In the following definition we turn from properties of topological spaces to properties of maps.

Definition. Let P be a property of maps between topological spaces and let $f\colon X \to Y$ be a map between topological spaces.

(1) We say that $f\colon X \to Y$ is locally P at $x \in X$ if there exists an open neighborhood U of x and an open neighborhood V of $f(x)$ such that $f\colon U \to V$ has the property P.
(2) We say that f is locally P if it is locally P at any $x \in X$.

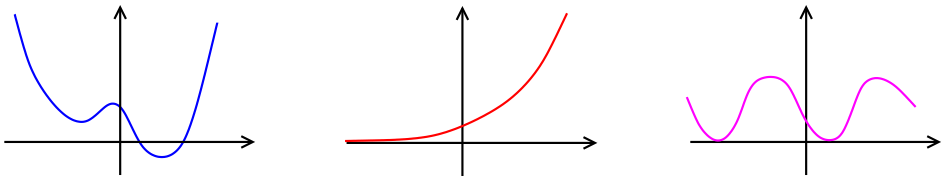
Example.

(1) One easily verifies that the map $f\colon \mathbb{R} \to \mathbb{R}$ given by $f(x) = x^2$ is a local homeomorphism at all points $x \neq 0$.

(2) The map

$$\begin{array}{rccl} p\colon & \mathbb{R} & \to & S^1 \\ & t & \mapsto & \exp(2\pi\,\mathrm{i}t) \end{array}$$

is a local homeomorphism. Indeed, let $t \in \mathbb{R}$. We set $U = (t-\frac{1}{2}, t+\frac{1}{2})$ and $V = p(U)$. The restriction of p to $p\colon U \to V$ is continuous and a bijection. Furthermore it is not difficult to show that p is an open map, see also Exercise 2.36. It follows from the Open -Injective Map Lemma 2.16 (2) that $p\colon U \to V$ is a homeomorphism.



(3) The statement of the Pasting Proposition 2.6 can be reformulated as saying that a map between two topological spaces is continuous, if it is locally continuous.

2.9. **Proper maps and closed embeddings.** Perhaps the best loved result in topology is the Compact-Hausdorff Proposition 2.17 (3) which says that a bijective continuous map $f\colon X \to Y$ is actually a homeomorphism if X is compact and Y is Hausdorff. In this section we will prove a result which at times can deal with the case that X is non-compact. First we need to introduce the following definition which will appear time and again.

Definition. A map $f\colon X \to Y$ between topological spaces is called proper if the preimage of every compact subset of Y is a compact subset of X.

Example.

(1) In the figure below we show graphs of maps $\mathbb{R} \to \mathbb{R}$, some of the maps are proper and some are not proper.

map is proper map is not proper map is not proper

(2) A map from a non-compact space to a compact space *cannot* be proper. In particular inclusion maps are not necessarily proper, for example the inclusion $i\colon (0,1) \to [-2,2]$ is not proper.

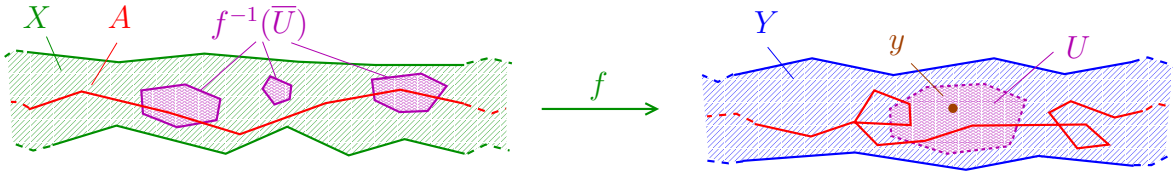
(3) Evidently every homeomorphism is proper.

(4) It follows easily from the Compact-Closed Lemma 1.21 (1) and (2) that every map from a compact space to a Hausdorff space is proper.

Now we can formulate and prove the following variation on the Compact-Hausdorff Proposition 2.17.

Proposition 2.43. (Proper-Closed Proposition) Let $f\colon X \to Y$ be a map from a topological space X to a topological space Y. We assume that Y is Hausdorff and regionally compact.

(1) If f is proper, then $f\colon X \to Y$ is a closed map.



(2) The following two statements are equivalent:

  (a) The map $f\colon X \to Y$ is injective and proper.

  (b) The map $f\colon X \to Y$ is a closed embedding.

Proof.

(1) Let $A \subset X$ be a closed subset. We need to show that $f(A)$ is a closed subset of Y. By the JH-Lemma 1.7 it suffices to show that every $y \in Y \setminus f(A)$ admits an open neighborhood V with $V \subset Y \setminus f(A)$ or equivalently with $V \cap f(A) = \varnothing$. Thus let $y \in Y$. The proof proceeds in the following steps, which are mostly forced on us:
- Since Y is regionally compact and Hausdorff we know by Lemma 2.42 that y admits an open neighborhood U such that the closure $\overline{U}$ is compact.
- Since f is proper we know that $f^{-1}(\overline{U})$ is compact.
- Since A is a closed subset we obtain from the Compact-Closed Lemma 1.21 (1) that $A \cap f^{-1}(\overline{U})$ is also compact.
- By the Compact Image Lemma 2.13 we know that $f(A \cap f^{-1}(\overline{U}))$ is compact.
- By the elementary Exercise 0.3 we know that $f(A \cap f^{-1}(\overline{U})) = f(A) \cap \overline{U}$.
- Since Y is Hausdorff we obtain immediately from the Compact-Closed Lemma 1.21 (2) that $f(A \cap f^{-1}(\overline{U})) = f(A) \cap \overline{U}$ is a closed subset of Y.
- Therefore $V := U \setminus (f(A) \cap \overline{U}) = U \setminus f(A)$ is an open neighborhood of $y \in Y$ that does not intersect $f(A)$.

(2) First we prove the "(a)⇒(b)"-direction. Thus we assume that $f\colon X \to Y$ is injective and proper. Since Y is Hausdorff and regionally compact we know by Statement (1) that $f\colon X \to Y$ is a closed map. Since f is furthermore injective we obtain from the Compact-Hausdorff Proposition 2.17 that $f\colon X \to Y$ is indeed a closed embedding.

Now we prove the "(b)⇒(a)"-direction. We only need to show that $f\colon X \to Y$ is proper. Thus let $K \subset Y$ be a compact subset.
- Since $f\colon X \to Y$ is a closed map we know by the Compact-Closed Lemma 1.21 (1) that $K \cap f(X)$ is also compact.
- Since $f\colon X \to f(X)$ is a homeomorphism we know that $f^{-1}(K \cap f(X))$ is compact.
- Since $f^{-1}(K \cap f(X)) = f^{-1}(K)$ we have indeed shown that $f^{-1}(K)$ is compact. ■

We can use the Proper-Closed Proposition 2.43 to give a new proof of the following popular proposition.

Proposition 2.19. (Closed Embedding-to-$\mathbb{R}^n$ Proposition) Let X be a topological space, let $n \in \mathbb{N}$ and let $f\colon X \to \mathbb{R}^n$ be an injective continuous map. Furthermore suppose that X is the union of compact subsets $\{K_i\}_{i \in I}$ such that the following condition is satisfied:

(∗) Given any $r > 0$ there exist only finitely many $i \in I$ with $f(K_i) \cap \overline{B}_r^n \neq \varnothing$.

Then f is a closed embedding.

For the new proof of the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19 we will need the following lemma, which often simplifies the task of showing that a certain map is proper.

Auxiliary Lemma 2.44. Let $f\colon X \to Y$ be a map between two topological spaces. We suppose that Y is Hausdorff.

(1) We suppose that we are given a family $\{L_j\}_{j\in J}$ of compact subsets of Y such that each compact subset of Y is contained in some L_j. If each $f^{-1}(L_j)$ is compact, then f is proper.

(2) Suppose that X is covered by compact subsets $\{K_i\}_{i\in I}$. Let $L \subset Y$ be compact. If there exist only finitely many $i \in I$ with $f(K_i) \subset L$, then $f^{-1}(L)$ is compact.

Proof of Lemma 2.44.

(1) Let L be a compact subset of Y. By hypothesis there exists a $j \in J$ with $L \subset L_j$. Note that

$$\begin{array}{rcl} f^{-1}(L) & \overset{\text{since } L\subset L_j}{\underset{\downarrow}{=}} & f^{-1}(L\cap L_j) \overset{\text{Image-Preimage Lemma 0.2 (7)}}{\underset{\downarrow}{=}} f^{-1}(L)\cap f^{-1}(L_j) \\ & & = \text{ closed subset } \cap \text{ compact subset } \underset{\uparrow}{=} \text{ compact.} \end{array}$$

since Y is Hausdorff we know by the Compact-Closed Lemma 1.21 that L is closed, therefore $f^{-1}(L)$ is closed, furthermore by hypothesis we know that $f^{-1}(L_j)$ is compact

by the Compact-Closed Lemma 1.21

(2) Let $L \subset Y$ be a compact subspace with the property that there exist only finitely many $i \in I$ with $f(K_i) \subset L$. Note that

$$\begin{array}{rcl} f^{-1}(L) & = & f^{-1}(L)\cap \bigcup_{i\in I \text{ with } f(K_i)\subset L} K_i \\ & \underset{\uparrow}{=} & \text{closed subset } \cap \text{ compact subset } \underset{\uparrow}{=} \text{ compact.} \end{array}$$

since Y is Hausdorff we know by the Compact-Closed Lemma 1.21 that L is closed, therefore $f^{-1}(L)$ is closed, furthermore by the Compact-Union-Intersection Lemma 1.20 we know that union of finitely many compact subspaces is again compact

by the Compact-Closed Lemma 1.21

■

Proof of Proposition 2.19. (Closed Embedding-to-$\mathbb{R}^n$ Proposition)] Since $\mathbb{R}^n$ is Hausdorff it follows from Lemma 2.44 (2) that for each $r > 0$ the preimage $f^{-1}(\overline{B}^n_r)$ is compact. It follows from Lemma 2.44 (1) that f is actually proper. On page 178 we pointed out that $\mathbb{R}^n$ is regionally compact. We now obtain from the Proper-Closed Proposition 2.43 that f is in fact a closed embedding. ■

Exercises for Chapter 2.

Exercise 2.1.

(a) Let X be a topological space that is locally connected. Show that the continuous maps $f\colon X \to \mathbb{R}$ that are locally constant are precisely the maps that are constant on all of the components of X.

(b) Show that the conclusion in (a) does not necessarily hold if we drop the hypothesis that X is locally connected.

Exercise 2.2. We consider

$$\mathcal{B} \;:=\; \{[a,b) \,|\, a,b \in \mathbb{R}\} \;\subset\; \mathcal{P}(\mathbb{R}).$$

It is clear that $\mathcal{B}$ has the basis property introduced on page 132. Let $\mathcal{T} := \mathcal{T}(\mathcal{B})$ be the topology generated by $\mathcal{B}$. This topology on $\mathbb{R}$ is called the *lower limit topology* and the topological space $(\mathbb{R}, \mathcal{T})$ is called the *Sorgenfrey line*.

(a) Let $\mathcal{S}$ be the standard topology on $\mathbb{R}$. Which, if any, of the two identity maps $(\mathbb{R}, \mathcal{S}) \to (\mathbb{R}, \mathcal{T})$ and $(\mathbb{R}, \mathcal{T}) \to (\mathbb{R}, \mathcal{S})$ is continuous?
(b) Determine the closure of the intervals $(1, \sqrt{2})$ and $(\sqrt{2}, 3)$ in the Sorgenfrey line.
(c) Is the Sorgenfrey line path-connected?
(d) Is the Sorgenfrey line regionally compact?

Exercise 2.3. Let X be a set, let Y be a topological space and let $f\colon X \to Y$ be a map. Now suppose that we are given two topologies $\mathcal{T}$ and $\mathcal{T}'$ on X such that $f\colon (X, \mathcal{T}) \to Y$ and $f\colon (X, \mathcal{T}') \to Y$ are local homeomorphisms. Show that $\mathcal{T} = \mathcal{T}'$.
Hint. Use the Pasting Proposition 2.6.

Exercise 2.4.

(a) Show that every self-homeomorphism of B^1 extends to a self-homeomorphism of $\overline{B}^1$.
(b) Give an example self-homeomorphism of B^2 that does not extend to a self-homeomorphism of $\overline{B}^2$.

Exercise 2.5. Let $C([0,1])$ be the real vector space of continuous maps from the interval $[0,1]$ to $\mathbb{R}$. We consider the

$$\text{supremum norm } s(f) := \sup\{|f(x)| \,|\, x \in [0,1]\} \quad \text{and the integral norm} \quad i(f) := \int_0^1 |f(x)|\, dx.$$

We denote the topologies corresponding to these norms by $\mathcal{S}$ and $\mathcal{I}$. Show that one topology is contained in the other and show that the two topologies are not the same.
Remark. This shows in particular that the identity map $\mathrm{id}\colon (C([0,1], \mathcal{S}) \to (C([0,1], \mathcal{I})$ is not a homeomorphism.

Exercise 2.6. Let $f\colon [a,b] \to \mathbb{R}$ be a continuous map. Show that if f is injective, then $f([a,b])$ is an interval with endpoints $f(a)$ and $f(b)$ and show that the map $f\colon [a,b] \to f([a,b])$ is a homeomorphism.
Hint. Use the Intermediate Value Theorem.

Exercise 2.7. Let $C([0,1])$ be the real vector space of continuous maps from the interval $[0,1]$ to $\mathbb{R}$ and let $C^1([0,1])$ be the real vector space of continuously differentiable maps from the interval $[0,1]$ to $\mathbb{R}$. In this exercise we equip both vector spaces with the supremum norm $s(f) := \sup\{f(x) \,|\, x \in [0,1]\}$. We consider the two maps

$$\begin{array}{rcl} D\colon C^1([0,1]) & \to & C([0,1]) \\ f & \mapsto & f' \end{array} \qquad \text{and} \qquad \begin{array}{rcl} I\colon C^1([0,1]) & \to & C([0,1]) \\ f & \mapsto & \left(x \mapsto \int_0^x f(t)\, dt\right). \end{array}$$

Note that D and I are inverses of one another, in particular both are isomorphisms of real vector spaces.

(a) Show that I is continuous.
(b) Show that D is not continuous.

Remark. This exercise shows that integration is usually a well-behaved operation whereas differentiation can be problematic.
Remark. This exercise is a variation on Exercise 2.5.

Exercise 2.8. Let U be an open subset of $\mathbb{R}^n$. We denote by $C = \overline{U}$ the closure of U.

(a) Suppose that U is convex. Show that $U = \mathring{C}$.
(b) Given an example of an open subset U of $\mathbb{R}^n$ where $U \neq \mathring{C}$.

Exercise 2.9. Let V be a finite-dimensional real vector space. Recall that given a norm $n\colon V \to \mathbb{R}_{\geq 0}$ its norm ball is defined as the subset $B(n) := \{v \in V \mid n(v) \leq 1\}$.

(a) Show that for any norm $n\colon V \to \mathbb{R}_{\geq 0}$ the norm ball $B(n)$ is a convex subset with non-empty interior.
(b) Show that for any convex subset $C \subset \mathbb{R}^n$ with non-empty interior there exists a norm $n\colon V \to \mathbb{R}_{\geq 0}$ with $B(n) = C$.

Exercise 2.10. Let $n \in \mathbb{N}$. Show that there are precisely $n + 2$ homeomorphism types of compact convex subsets of $\mathbb{R}^n$.
Remark. Use the Convex-to-Ball Proposition 2.20 (2).

Exercise 2.11. Let $f\colon X \to Y$ be a map between topological spaces.

(a) Show that the following statements are equivalent:
  (i) The map is continuous.
  (ii) For every subset $B \subset Y$ we have $f^{-1}(\overline{B}) \subset \overline{f^{-1}(B)}$.
  (iii) For every subset $B \subset Y$ we have $f^{-1}(\mathring{B}) \subset$ interior of $f^{-1}(B)$.
  Remark. We showed (i)⇒(ii) in the Closure-Interior Mapping Lemma 2.5.
(b) Given an example of a continuous map $f\colon X \to Y$ that shows that in general we do not have an equality in (ii).
(c) Given an example of a continuous map $f\colon X \to Y$ that shows that in general we do not have an equality in (iii).

Exercise 2.12. Does there exist a continuous map $f\colon S^2 \to S^2$ with a single fixed point, i.e. with a unique point x such that $f(x) = x$?

Exercise 2.13. Let (X, d) and (Y, e) be two metric spaces and let $\varphi\colon X \to Y$ be a map.

(a) Suppose that there exists some $C > 0$ such that for every choice of $x, x' \in X$ we have $e(\varphi(x), \varphi(x')) < C \cdot d(x, x')$. Show that d is continuous.
(b) Suppose that there exists some $c > 0$ such that for every choice of $x, x' \in X$ we have $e(\varphi(x), \varphi(x')) > c \cdot d(x, x')$. Furthermore suppose that φ is surjective. Does it follow that d is open?

Exercise 2.14. Let (a, b) be an interval and let $f\colon (a, b) \to X$ be a map to a topological space. Let $(a_n)_{n\in\mathbb{N}}$ and $(b_n)_{n\in\mathbb{N}}$ be sequences of real numbers in (a, b) such that $\lim\limits_{n\to\infty} a_n = a$ and such that $\lim\limits_{n\to\infty} b_n = b$. We suppose that the restriction of f to each $[a_n, b_n]$ is continuous. Show that f itself is continuous.
Remark. An analogous statement also holds if we deal with a half-open interval $[a, b)$.

Exercise 2.15. Let (X, d) be a metric space and let A be a subset of X. Show that the map

$$\begin{array}{rcl} A & \to & [0,1] \\ a & \mapsto & \min\{1, \sup\{r \in \mathbb{R}_{\geq 0} \,|\, B_r(a) \subset A\}\} \end{array}$$

is continuous.

Exercise 2.16. Let X be a set and let d and e be two metrics on X that are equivalent, i.e. that induce the same topology on X. We use this common topology to view X as a topological space.

(a) Suppose that X is compact. Show that given any $\mu > 0$ there exists a $\nu > 0$ such that the following conclusion holds:

$$d(x,y) < \mu \qquad \Longrightarrow \qquad e(x,y) < \nu.$$

(b) Let $\alpha\colon X \to \mathbb{R}_{>0}$ be a map. Show that there exists a map $\beta\colon X \to \mathbb{R}_{>0}$ such that the following conclusion holds:

$$d(x,y) < \alpha(x,y) \qquad \Longrightarrow \qquad e(x,y) < \beta(x,y).$$

Remark. As always all maps are understood to be continuous.

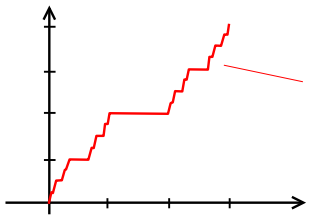
Hint. Use Exercise 2.15

Exercise 2.17. Let C be the Cantor set as defined on page 130.

(a) Show that for every $x \in C$ there exists a unique sequence $a_1, a_2, \ldots$ of elements of $\{0,1\}$ such that

$$x = \sum_{k=1}^{\infty} \frac{2a_k}{3^k}.$$

(b) We define the *Cantor function* as follows:



$$\begin{array}{rcl} c\colon [0,1] & \to & [0,1] \\ x & \mapsto & \begin{cases} \sum_{k=1}^{\infty} \frac{a_k}{2^k}, & \text{if } x = \sum_{k=1}^{\infty} \frac{2a_k}{3^k} \in C, \\ \sup\{c(y) \,|\, y \in C \text{ and } y \leq x\}, & \text{if } x \notin C. \end{cases} \end{array}$$

Show that the Cantor function is continuous.

(c) Show that the Cantor function is surjective.

(d) Show that the Cantor set is uncountable.

Remark. The graph of the Cantor function is sometimes called the *Devil's Staircase*.

Exercise 2.18. Show that every connected non-empty subset of $\mathbb{R}$ is an interval.

Exercise 2.19. Let X be a topological space and let $A \subset X$ be a subset.

(a) Show that if A is connected, then so is its closure $\overline{A}$.

(b) If A is path-connected, does it follow, that its closure $\overline{A}$ is also path-connected?

Exercise 2.20. Let X be a topological space and let $A \subset X$ be a subspace. We say that A *can be disconnected in* X if there exist disjoint open subsets U and V of X such that $U \cap A \neq \varnothing$, $V \cap A \neq \varnothing$ and $A \subset U \cup V$.

(a) Show that if X is a metric space, then any disconnected subspace A can be disconnected in X.
(b) Give an example of a topological space and a disconnected subspace A that cannot be disconnected in X.

Exercise 2.21.

(a) Show that every self-homeomorphism of $\mathbb{R}$ is monotonously increasing or monotonously decreasing.
(b) Is every self-homeomorphism of $\mathbb{Q}$ is monotonously increasing or monotonously decreasing?

Exercise 2.22. Let $X = \{0, 1\}$ be the set with two elements which we equip with the topology $\mathcal{T} = \{\varnothing, X, \{0\}\}$. The topological space $X = (X, \mathcal{T})$ is called the *Sierpiński space*.

(a) Is every continuous maps $X \to \mathbb{R}$ constant?
(b) Is every continuous map $\mathbb{R} \to X$ constant?
(c) Is X Hausdorff?
(d) Is X connected?
(e) Is X path-connected?
(f) Determine all self-homeomorphisms of X.

Exercise 2.23. We consider $X = \mathbb{Q}$ with the subspace topology coming from $\mathbb{R}$. Show that the only connected subsets of $\mathbb{Q}$ are the subsets consisting of at most a point.

Exercise 2.24. Let $f\colon X \to Y$ be a continuous map between topological spaces, let $U \subset X$ be a subset and let $A \subset Y$ be a subset.

(a) Suppose that A is closed and suppose that $f(U) \subset A$. Show that $f(\overline{U}) \subset A$.
(b) Suppose that A is open and that $A \subset f(U)$. Show that $A \subset f(\mathring{U})$.

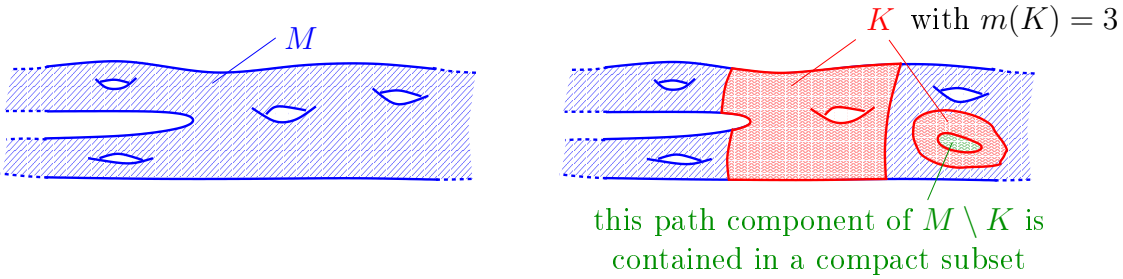
Exercise 2.25. Let X be a topological space. We say a subset $A \subset X$ is a *retract of* X if there exists a *retraction* $r\colon X \to A$, i.e. a continuous map with $r(a) = a$ for all $a \in A$. (Evidently we demand that r is continuous).

(a) Suppose that X is Hausdorff. Show that A is a closed subset of X.
(b) Show that the conclusion of (a) does not necessarily hold if we do not assume that X is Hausdorff.

Exercise 2.26. Let $f\colon (X, \mathcal{S}) \to (Y, \mathcal{T})$ be a (possibly non-continuous) map between two topological spaces.

(a) Show that if f is continuous, then for every $(x_n)_{n\in\mathbb{N}}$ sequence in X we have
$$\lim_{n\to\infty} x_n = x \qquad \Longrightarrow \qquad \lim_{n\to\infty} f(x_n) = f(x).$$
(b) We suppose that for every sequence $(x_n)_{n\in\mathbb{N}}$ in X we have
$$\lim_{n\to\infty} x_n = x \qquad \Longrightarrow \qquad \lim_{n\to\infty} f(x_n) = f(x).$$

(i) Give an example where this condition is satisfied but f is not continuous.
(ii) A topological space is called *first-countable*, if for every $x \in X$ there exists a countable family of open neighborhoods $\{U_i\}_{i\in I}$ of x such that each open neighborhood of x contains at least one U_i. Show that if X is first-countable, then f is continuous.



Exercise 2.27. Let X be a topological space. Given a compact subset $K \subset X$ we define $m(K)$ to be the number of non-compact path-components of $X \setminus K$ that are *not* contained in a compact subset of X. We refer to

$$\mathrm{End}(X) \;:=\; \max\{m(K) \,|\, K \text{ is a compact subset of } X\} \in \mathbb{N}_0 \cup \{\infty\}$$

as the *number of ends of* X.

(a) Given $n \in \mathbb{N}$ determine $m(\mathbb{R}^n)$.
Remark. This exercise shows that $\mathbb{R}$ is not homeomorphic to $\mathbb{R}^2$.
(b) Can you find connected spaces with arbitrarily large number of ends?

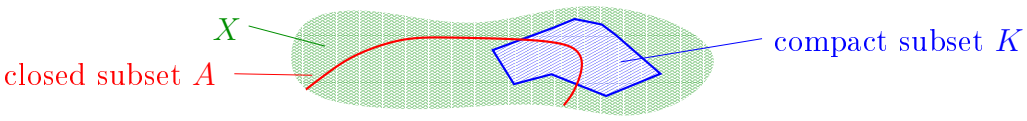
Remark. We will introduce the "ends" of a topological space in Exercise 56.13. We will see that what we now call the "number of ends" equals the cardinality of the set of ends.

Exercise 2.28. Let $C \subset \mathbb{R}$ be the Cantor set. We equip C with the subspace topology. Determine the components of C.

Exercise 2.29. Let $f\colon X \to Y$ be a continuous map between topological spaces. By the Compact Image Lemma 2.13 we know that the image of a compact subset of X under f is a compact subset of Y.

(a) Give an example of a continuous map $f\colon \mathbb{R} \to \mathbb{R}$ and an open subset $U \subset \mathbb{R}$ such that $f(U)$ is not an open subset of $\mathbb{R}$.
(b) Give an example of a continuous map $f\colon \mathbb{R} \to \mathbb{R}$ and a closed subset $U \subset \mathbb{R}$ such that $f(U)$ is not a closed subset of $\mathbb{R}$.

Exercise 2.30. In this exercise we will see that for maps between subsets of $\mathbb{R}^2$ the notions of "open", "closed" and "continuous" are completely independent. More precisely for (a)-(f) provide an example of a map $\varphi\colon X \to Y$ between subsets of $\mathbb{R}^2$, equipped with the subspace topology coming from $\mathbb{R}^2$, that have the stated property.



(a) The map φ is open but neither closed nor continuous.
(b) The map φ is closed but neither open nor continuous.
(c) The map φ is continuous but neither open nor closed.
(d) The map φ is continuous and open but not closed.
(e) The map φ is continuous and closed but not open.

(f) The map φ is open and closed but not continuous.

Exercise 2.31. Show that the maps

$$\begin{array}{rcl} \alpha\colon \mathbb{R}^2 & \to & \mathbb{R} \\ (x,y) & \mapsto & x+y \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \beta\colon \mathbb{R}^2 & \to & \mathbb{R} \\ (x,y) & \mapsto & x\cdot y \end{array}$$

are continuous.

Exercise 2.32. Let $f\colon X \to Y$ be a continuous map from a topological space X to some metric space Y, e.g. $Y = \mathbb{R}^n$. Let $P \in Y$ be a point that is not contained in $f(X)$. We suppose that X is compact. Show that there exists an $r > 0$ such that $B_r(P) \cap f(X) = \varnothing$.

Exercise 2.33. Let $f, g\colon X \to Y$ be two continuous maps between topological spaces.

(a) Suppose that Y is Hausdorff. Show that $\{x \in X \mid f(x) = g(x)\}$ is a closed subset of X.

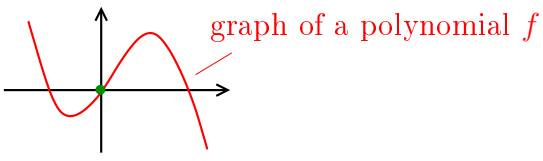
(b) Show that the conclusion of (a) does not necessarily hold if we do not assume that Y is Hausdorff.

(c) Show that if f and g agree on a subset A and if Y is Hausdorff, then f and g also agree on the closure $\overline{A}$ of A.

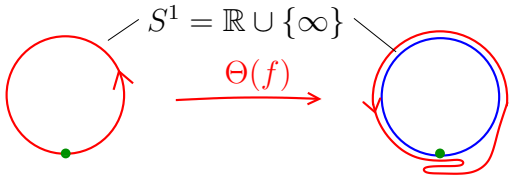
Exercise 2.34. Let $\mathbb{R}^n \cup \{\infty\}$ be "$\mathbb{R}^n$ with a point at infinity". Let $v \in \mathbb{R}^n$. Show that the map

$$\begin{array}{rcl} \mathbb{R}^n \cup \{\infty\} & \to & \mathbb{R}^n \cup \{\infty\} \\ Q & \mapsto & \begin{cases} Q+v, & \text{if } Q \in \mathbb{R}^n, \\ \infty, & \text{if } Q = \infty \end{cases} \end{array}$$

is continuous.



Exercise 2.35. Let f be a complex polynomial of degree ≥ 1. Show that the map

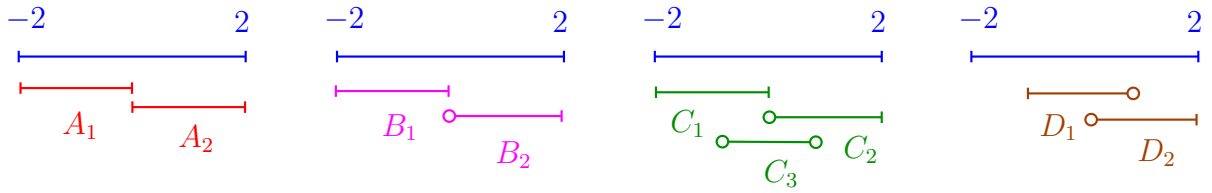


$$\begin{array}{rcl} \Theta(f)\colon \mathbb{C} \cup \{\infty\} & \to & \mathbb{C} \cup \{\infty\} \\ t & \mapsto & \begin{cases} f(t), & \text{if } t \in \mathbb{C}, \\ \infty, & \text{if } t = \infty \end{cases} \end{array}$$

is continuous.

Remark. By Lemma 2.18 we can make the identification $S^2 = \mathbb{C} \cup \{\infty\}$. Thus we see that complex polynomials of degree ≥ 1 give rise to interesting self-maps of S^2.

Remark. The analogous statement also holds for a polynomial f with real coefficients, it gives rise to a self-map $\Theta(f)$ of $\mathbb{R} \cup \{\infty\} = S^1$.



Exercise 2.36. We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R} & \to & S^1 \\ t & \mapsto & \exp(2\pi\,\mathrm{i}t) \end{array}$$

(a) Show that f is an open map.
(b) Is f also a closed map?

Exercise 2.37. Let X be a set and let $\{A_i\}_{i\in I}$ be a family of subsets. Suppose that each A_i is equipped with a topology.

(a) We say $U \subset X$ is open if for each $i \in I$ the intersection $U \cap A_i$ is an open subset of A_i. Show that this defines a topology on X.
(b) We consider the set $X = [-2, 2]$.
  (i) We consider the subsets $A_1 = [-2, 0]$ and $A_2 = [0, 2]$.
  (ii) We consider the subsets $B_1 = [-2, 0]$ and $B_2 = (0, 2]$.
  (iii) We consider the subsets $C_1 = [-2, 0]$, $C_2 = (0, 2]$ and $C_3 = (-1, 1)$.
  (iv) We consider the subsets $D_1 = [-1, 1)$ and $D_2 = (0, 2]$.
  For each of these four settings we equip the subsets with the obvious topology and we equip $X = [-2, 2]$ with the corresponding topology. Describe the resulting four topological spaces. Are these topological spaces that we are familiar with?

Exercise 2.38. Let $P_1, \ldots, P_n \in \mathbb{R}^k$.

(a) Show that the convex hull of the set $\{P_1, \ldots, P_n\}$ is given by the set

$$\left\{ \sum_{i=1}^{n} t_i \cdot P_i \,\middle|\, t_1, \ldots, t_n \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^{n} t_i = 1 \right\}.$$

Note: We make no hypothesis on the points $P_1, \ldots, P_n$, in particular some of them could be identical and we do not assume say that the vectors $P_2 - P_1, \ldots, P_n - 1$ are linearly independent.
(b) Show that the set in (a) is compact.
(c) Is the convex hull of a compact subset of $\mathbb{R}^k$ necessarily compact?
(d) Is the convex hull of an open subset of $\mathbb{R}^k$ necessarily an open subset?

Exercise 2.39. Let $f, g\colon X \to Y$ be two maps between two topological spaces. Let $A \subset X$ be a subset such that f and g agree on A. Show that if A is dense, if Y is Hausdorff and if f and g are continuous, then f and g agree on all of X.

Exercise 2.40.

(a) Show that the half-open interval $[0, 1)$ and the open interval $(0, 1)$ are not homeomorphic.
(b) Is the topological space $[0, 1) \cap \mathbb{Q}$ homeomorphic to the topological space $(0, 1) \cap \mathbb{Q}$?

Exercise 2.41. Let $m, n \in \mathbb{N}$.

(a) Let $A = (a_1 \ldots a_n) \in \mathrm{M}(m \times n, \mathbb{R}) = (\mathbb{R}^m)^n$. Show that A has rank m if and only there exist $k_1, \ldots, k_m \in \{1, \ldots, n\}$ with $\det(a_{k_1} \ldots a_{k_m}) \neq 0$.
(b) Show that the set of matrices of rank m is an open subset of $\mathrm{M}(m \times n, \mathbb{R})$.
Remark. In the Matrix Group Lemma 2.36 we dealt with the case $m = n$.

Exercise 2.42. Give an example of a bijective continuous map $f\colon X \to Y$ between two topological spaces where X is compact but such that f is nonetheless not a homeomorphism.

Exercise 2.43. Let X and Y be topological spaces and let $i\colon X \to Y$ be a map. We suppose that there exists a map $r\colon Y \to X$ with $r \circ i = \mathrm{id}_X$. Show that i is an embedding.

Exercise 2.44. Let $f\colon [0,1] \to \mathbb{R}$ be a continuous function. Let $a < b$ be two real numbers. Show that f can only go finitely many times from a to b. More precisely, show that it is not possible to find numbers $x_1 < y_1 < x_2 < y_2 < x_3 < y_3 < \ldots$ in $[0,1]$ such that for each $i \in \mathbb{N}$ we have $f(x_i) = a$ and we have $f(y_i) = b$.

Exercise 2.45. Let $A \in \mathrm{M}(m \times n, \mathbb{R})$. We define the *norm of* A as follows:

$$\|A\| \;:=\; \max\{\|Av\| \mid v \in S^{n-1}\} \;\in\; \mathbb{R}_{\geq 0}.$$

(Note that by the Compact Image Lemma 2.13 (2) it does indeed make sense to take the maximum.)

(a) Show that for all $v \in \mathbb{R}^n$ we have $\|Av\| \leq \|A\| \cdot \|v\|$.
(b) (i) Show that for all $A, B \in \mathrm{M}(m \times n, \mathbb{R})$ we have $\|A + B\| \leq \|A\| + \|B\|$.
(ii) Show that for any $A \in \mathrm{M}(m \times n, \mathbb{R})$ and $\lambda \in \mathbb{R}$ we have $\|\lambda \cdot A\| = |\lambda| \cdot \|A\|$.
Note that this shows that $\| - \|$ turns $\mathrm{M}(m \times n, \mathbb{R})$ into a normed vector space.
(c) Show that for $A \in \mathrm{O}(n)$ we have $\|A\| = 1$.
(d) Show that for $A \in \mathrm{M}(l \times m, \mathbb{R})$ and $B \in \mathrm{M}(m \times n, \mathbb{R})$ we have $\|A \cdot B\| \leq \|A\| \cdot \|B\|$.
(e) Give examples of matrices $A, B \in \mathrm{M}(m \times m, \mathbb{R})$ with $\|A \cdot B\| \neq \|A\| \cdot \|B\|$.
(f) Show that for $A \in \mathrm{GL}(n, \mathbb{R})$ we have $\|A^{-1}\| = \|A\|^{-1}$.
(g) Let $A \in \mathrm{GL}(n, \mathbb{R})$ be an invertible matrix. Show that there exists a $\lambda > 0$ such that $\|Av\| \geq \lambda \cdot \|v\|$ for all $v \in \mathbb{R}^n$.
(h) Show that the map

$$\begin{array}{rcl} \mathrm{M}(m \times n, \mathbb{R}) & \to & \mathbb{R}_{\geq 0} \\ A & \mapsto & \|A\| \end{array}$$

is continuous.
(i) Let $f\colon [a,b] \to \mathrm{M}(m \times n, \mathbb{R})$ be a continuous map. Show that

$$\Big\| \int_a^b A(t)\, dt \Big\| \;\leq\; \int_a^b \|A(t)\|\, dt.$$

Hint. Make use of the Integral Inequality Lemma 0.16.

Exercise 2.46. Let A be an invertible real $(m \times m)$–matrix. Show that the map

$$\begin{array}{rcl} \mathbb{R}^m \cup \{\infty\} & \to & \mathbb{R}^m \cup \{\infty\} \\ x & \mapsto & \begin{cases} A \cdot x, & \text{if } x \in \mathbb{R}^m, \\ \infty, & \text{if } x = \infty \end{cases} \end{array}$$

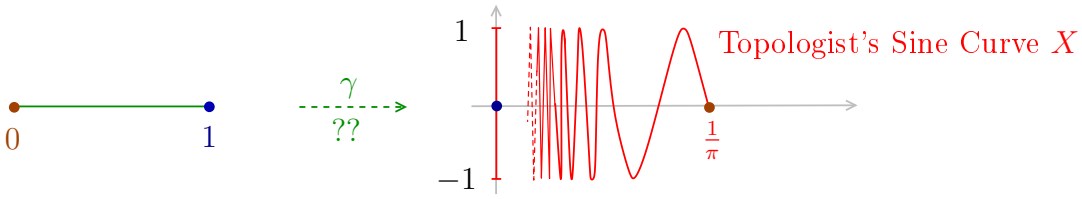
is continuous.
Hint. Use Exercise 2.45 (g).

Exercise 2.47. Let $n \in \mathbb{N}$. We consider the stereographic projection

$$\begin{array}{rcl} \Phi\colon S^n & \to & \mathbb{R}^n \cup \{\infty\} \\ (x_1, \ldots, x_{n+1}) & \mapsto & \begin{cases} \left(\frac{x_1}{1-x_{n+1}}, \ldots, \frac{x_n}{1-x_{n+1}}\right), & \text{if } x_{n+1} < 1, \\ \infty, & \text{if } x_{n+1} = 1 \end{cases} \end{array}$$

that we introduced in Lemma 2.18. Show that Φ is continuous.

Exercise 2.48. We consider the Topologist's Sine Curve



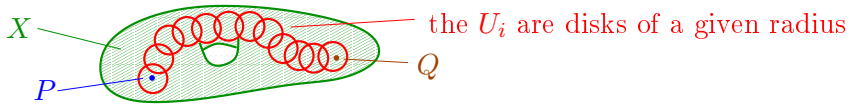
$$X \;:=\; \left\{(0,y)\,\middle|\, y \in [-1,1]\right\} \cup \left\{(x, \sin(\tfrac{1}{x}))\,\middle|\, x \in (0, \tfrac{1}{\pi}]\right\} \;\subset\; \mathbb{R}^2.$$

which we introduced on page 164.

(a) Show that X is connected.

(b) Show that there does not exist a continuous map $\gamma\colon [0,1] \to X$ with $\gamma(0) = (\frac{1}{\pi}, 0)$ and with $\gamma(1) = (0,0)$.
Hint. Assume such a map exists. We denote by $q\colon X \to \mathbb{R}$ the projection onto the second coordinate. Use the Intermediate Value Theorem to construct sequences $(a_n)_{n\in\mathbb{N}}$ and $(b_n)_{n\in\mathbb{N}}$ in $[0,1]$ which both converge to the same number but such that for each $n \in \mathbb{N}$ we have $q(\gamma(a_n)) = -1$ and $q(\gamma(b_n)) = +1$.
Remark. This exercise implies of course that X is *not* path-connected.

(c) Show that X has two path components.



Exercise 2.49. Let X be a topological space and let $\mathcal{U} \subset \mathcal{P}(X)$ be an open cover of X. Show that the following two statements are equivalent:

(1) The topological space X is connected.

(2) Given any two points $P, Q \in X$ there exist $U_0, \ldots, U_k \in \mathcal{U}$ with $P \in U_0$, $Q \in U_k$, with $U_i \cap U_{i+1} \neq \varnothing$ for $i = 0, \ldots, k-1$ and such that $U_i \cap U_j = \varnothing$ whenever $|i-j| \geq 2$.

Remark. Some people refer to this statement as the *Sausage Lemma*.

Exercise 2.50. Let X be a topological space and let $A \subset X$ be a subset.

(a) Suppose that X is path-connected and that ∂A is path-connected. Show that $X \setminus \mathring{A}$ is also path-connected.

(b) Suppose that X is connected and that ∂A is connected. Show that $X \setminus \mathring{A}$ is also connected.

Remark. This exercise is the content of the Complement Connected Lemma 2.29.

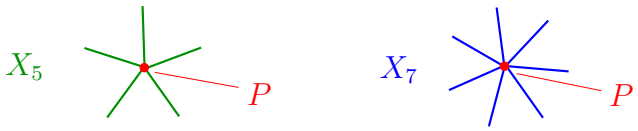
Exercise 2.51. We set $K := \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$. The *K-topology* on $\mathbb{R}$ is defined as the topology $\mathcal{K}$ that is generated by the open intervals (a, b) and by all sets of the form $(a, b) \setminus K$ where $a, b \in \mathbb{R}$.

(a) Show that $(\mathbb{R}, \mathcal{K})$ is connected.
(b) Show that $(\mathbb{R}, \mathcal{K})$ is not path-connected, more precisely, show that it has precisely two path-components, namely $(-\infty, 0]$ and $(0, \infty)$.

Exercise 2.52. Let X be a topological space and let $A \subset X$ be a subset. Show that if A is connected, then its closure $\overline{A}$ is also connected.

Exercise 2.53. A topological space X is called *arc-connected* if given any two points $P, Q \in X$ there exists a map $f\colon [0, 1] \to X$ with $f(0) = P$, $f(1) = Q$ and which has the property that f is an embedding.[50]

(a) Show that the line with two zeros is not arc-connected.
(b) Let $n \geq 2$ and let X be the "$\mathbb{R}^n$ with two origins", which is defined in the hopefully obvious way. Is X arc-connected?



Remark. A rather amazing (non-trivial!) theorem says that any topological space that is path-connected *and which is Hausdorff* is in fact arc-connected. We refer to [**Will1970**, Corollary 31.6], [**Enge1989**, p. 381] and [**HY1988**, p. 118 and p. 129] for a proof of this statement.

Exercise 2.54.

(a) Let $n \in \mathbb{N}_{\geq 3}$. We consider

$$X_n \;:=\; \{r \cdot \exp(2\pi\,\mathrm{i}t \cdot \tfrac{k}{n}) \,|\, r \in [0, 1) \text{ and } k \in \{0, \ldots, n-1\}\}.$$

We write $P := 0$. Show that every self-homeomorphism $f\colon X_n \to X_n$ preserves P.
(b) Does the statement in (a) also hold for $n = 1$ and/or $n = 2$?

Exercise 2.55.

(a) Let $n \geq 1$. Show that the sphere S^n is path-connected.
Remark. This is the content of the Ball-Sphere-Connected Lemma 2.25 (2).
(b) Is the line with two zeros connected?

Exercise 2.56. A subset of a topological space is sometimes called *clopen* if it is open and closed. Let $n \in \mathbb{N}$. Determine all clopen subsets of $\mathbb{R}^n$.

Exercise 2.57. Let X be a path-connected subset of $\mathbb{R}^2$. Is it also necessarily regionally path-connected?

[50] Sometimes, see e.g. [**Will1970, Enge1989**], such topological spaces are also called *arcwise connected*. Rather confusingly some other books, e.g. [**Bre1993**], use the term *arcwise connected* for what we call path-connected. The lesson is, that in any given book one always should look up the definitions.

Exercise 2.58. We consider the set $X = (0, 1)$ with the topology where the open sets are precisely the sets $\varnothing, X$ and the intervals $(0, 1 - \frac{1}{n})$. Show that X is compact and show that X is not regionally compact.

Exercise 2.59. Let X be a topological space. We consider the set $X^* := X \cup \{\infty\}$. We say $U \subset X^*$ is open if one of the following conditions is satisfied:

(1) U is an open subset of X, or
(2) $\infty \in U$ and there exists a compact subset K of X such that $U = X^* \setminus K$.

The inclusion $c\colon X \to X^*$ is called the *Alexandroff extension*. Show that the following statements hold:

(a) The open sets do indeed define a topology on X.
(b) The map c is continuous and open.
(c) Show that the topological space X^* is compact.
(d) Show that if X is non-compact, then $c(X) \subset X^*$ is dense.
(e) Show that X^* is Hausdorff if and only if X is Hausdorff and regionally compact.

Remark. The topological space X^* is called the *one-point compactification of* X or *Alexandroff compactification of* X.[51]

Remark. One can show easily that the one-point compactification of $\mathbb{R}^n$ equals the "$\mathbb{R}^n$ with a point at infinity" that we introduced on page 122.

Exercise 2.60. Let $X = \mathbb{N}$ with the discrete topology. Show that the one-point compactification of X, as defined in Exercise 2.59, is homeomorphic to a subset of $\mathbb{R}$.

Exercise 2.61. Give an example of a subspace of $\mathbb{R}^2$ that is path-connected but that is not locally path-connected.

Exercise 2.62. Let X be a topological space.

(a) Let $f\colon X \to \mathbb{R}^n$ and $g\colon X \to \mathbb{R}^n$ be two maps. We assume that f is proper and we assume that there exists an $\epsilon \in \mathbb{R}$ such that for every $x \in X$ we have $\|f(x) - g(x)\| < \epsilon$. Show that g is also proper.
(b) Does the conclusion of (a) hold if we replace the metric space $(\mathbb{R}^n, d(x, y) := \|x - y\|)$ by any other metric space (Y, d)?

[51] Some authors use the expression "one-point compactification" only if X is non-compact, Hausdorff and regionally compact.

3. Categories, functors and natural transformations

In the last chapter we introduced the concept of topological spaces, we studied several natural examples and we discussed various basic concepts. We will now take a short break from discussing topological spaces.

In this chapter we introduce the notion of a category, of a functor and of a natural transformation that many readers will already have encountered in different courses. In the following chapter we will introduce the notions of (co-) products and (co-) limits in categories. These notions might initially appear to be rather abstract, but they play an essential role in topology and they are regularly used in all branches of pure mathematics. These concepts will also guide us for how to proceed with the discussion of topological spaces.

Nonetheless, readers who want to learn more about topological spaces as quickly as possible can also safely skip these two chapters. Having a background in categories is helpful for the later chapters on topological spaces, but not completely essential.

3.1. Definition and examples of categories.

Definition. A category $\mathcal{C}$ consists of the following data:

(1) A class[52] $\mathrm{Ob}(\mathcal{C})$, the elements of which are called the objects of the category.

(2) For each pair (X, Y) of objects there exists a set[53] [54] $\mathrm{Mor}_{\mathcal{C}}(X, Y)$, the elements of which are called the morphisms from X to Y.

(3) For any three objects X, Y and Z we are provided a map

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{C}}(X,Y) \times \mathrm{Mor}_{\mathcal{C}}(Y,Z) & \to & \mathrm{Mor}_{\mathcal{C}}(X,Z) \\ (f,g) & \mapsto & g \circ f, \end{array}$$

that satisfies the following axioms:

(A) (associativity): For every $f \in \mathrm{Mor}_{\mathcal{C}}(W,X), g \in \mathrm{Mor}_{\mathcal{C}}(X,Y)$ and $h \in \mathrm{Mor}_{\mathcal{C}}(Y,Z)$ we have

$$(h \circ g) \circ f \;=\; h \circ (g \circ f) \;\in\; \mathrm{Mor}_{\mathcal{C}}(W,Z).$$

(B) (identity): For every object X there exists a morphism $\mathrm{id}_X \in \mathrm{Mor}_{\mathcal{C}}(X,X)$ with the property that

$$\begin{array}{rcll} \mathrm{id}_X \circ f & = & f & \text{for all } W \in \mathrm{Ob}(\mathcal{C}) \text{ and all } f \in \mathrm{Mor}_{\mathcal{C}}(W,X), \quad \text{and} \\ f \circ \mathrm{id}_X & = & f & \text{for all } Y \in \mathrm{Ob}(\mathcal{C}) \text{ and all } f \in \mathrm{Mor}_{\mathcal{C}}(X,Y). \end{array}$$

Before we give a long list of examples let us first state a lemma which will look familiar from a basic algebra course.

---

[52] As many "working mathematicians" the author has a slightly guilty conscience for not knowing what a "set" and what a "class" is. Therefore the reader is referred to **[Cie1997, FPr1985]** for details. Truth be told, most mathematicians learn from logicians at some point when to say "class" instead of "set", but many mathematicians do not know exactly what they are doing at that point.

[53] One could ask why $\mathrm{Mor}_{\mathcal{C}}(X,Y)$ has to be a set, why not just a class? To the best of my knowledge the axioms on morphisms that we write down also make sense if $\mathrm{Mor}_{\mathcal{C}}(X,Y)$ is only required to be a class. Here's a long discussion which gives a satisfactory answer to people in category theory:

`http://mathoverflow.net/questions/48810/why-need-the-morphisms-to-form-a-set`

I myself do not understand the answer.

[54] If the category is clear from the context, then we just write $\mathrm{Mor}(X,Y)$ instead of $\mathrm{Mor}_{\mathcal{C}}(X,Y)$.

Lemma 3.1. Let $\mathcal{C}$ be a category. For every object $X \in \mathrm{Ob}(\mathcal{C})$ there exists a *unique* morphism $\mathrm{id}_X \in \mathrm{Mor}_{\mathcal{C}}(X,X)$ with the property that

(i) $\mathrm{id}_X \circ f = f$ for all $W \in \mathrm{Ob}(\mathcal{C})$ and all $f \in \mathrm{Mor}_{\mathcal{C}}(W,X)$,
(ii) $f \circ \mathrm{id}_X = f$ for all $X \in \mathrm{Ob}(\mathcal{C})$ and all $f \in \mathrm{Mor}_{\mathcal{C}}(X,Y)$.

Proof. The existence of id_X is given by property (3B) of a category. Now suppose that $I \in \mathrm{Mor}_{\mathcal{C}}(X,X)$ has the same property. Then we have

$$\mathrm{id}_X \underset{\substack{\uparrow \\ \text{property (i) of } I \text{ applied to } f=\mathrm{id}_X}}{=} I \circ \mathrm{id}_X \underset{\substack{\uparrow \\ \text{property (ii) of } \mathrm{id}_X \text{ applied to } f=I}}{=} I.$$

■

Lemma 3.1 allows us to introduce the following definition.

Definition. Let $\mathcal{C}$ be a category and let $X \in \mathrm{Ob}(\mathcal{C})$. We refer to the morphism that is uniquely defined in Lemma 3.1 as the identity morphism id_X.

In the following we introduce all kinds of categories. Many of those will be faithful companions throughout these notes.

Definition.

(a) We refer to the category $\mathcal{Set}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{Set}) &:= \text{all sets}, \\ \mathrm{Mor}(X,Y) &:= \text{all maps from } X \text{ to } Y, \end{aligned}$$

together with the usual composition of maps as the category of sets.

(b) We refer to the category $\mathcal{Top}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{Top}) &:= \text{all topological spaces}, \\ \mathrm{Mor}(X,Y) &:= C(X,Y) := \text{all continuous maps from } X \text{ to } Y, \end{aligned}$$

with the usual composition of maps[55] as the category of topological spaces.

(c) Let $\mathbb{K}$ be a field. We refer to the category $\mathcal{Vec}_{\mathbb{K}}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{Vec}_{\mathbb{K}}) &:= \text{all } \mathbb{K}\text{-vector spaces}, \\ \mathrm{Mor}(X,Y) &:= \mathrm{Hom}_{\mathbb{K}}(X,Y) = \text{all } \mathbb{K}\text{-homomorphisms from } X \text{ to } Y, \end{aligned}$$

with the usual composition of homomorphisms as the category of $\mathbb{K}$-vector spaces.

(d) We refer to the category $\mathcal{Group}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{Group}) &:= \text{all groups}, \\ \mathrm{Mor}(X,Y) &:= \mathrm{Hom}(X,Y) = \text{all group homomorphisms from } X \text{ to } Y, \end{aligned}$$

with the usual composition of group homomorphisms as the category of groups. Similarly we define the category $\mathcal{AbGroup}$ of abelian groups.

(e) We refer to the category $\mathcal{Ring}$ with[56]

$$\begin{aligned} \mathrm{Ob}(\mathcal{Ring}) &:= \text{all rings}, \\ \mathrm{Mor}(R,S) &:= \mathrm{Hom}(R,S) = \text{all ring homomorphisms from } R \text{ to } S, \end{aligned}$$

with the usual composition of ring homomorphisms as the category of rings. Similarly we define the category $\mathcal{CRing}$ of commutative rings.

(f) A pair of sets is a pair (X, A), where X is a set and A is a subset of X. We refer to the category $\mathcal{PairSet}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{PairSet}) &:= \text{all pairs of sets,} \\ \mathrm{Mor}((X,A),(Y,B)) &:= \text{all maps } f \text{ from } X \text{ to } Y \text{ with } f(A) \subset B \end{aligned}$$

with the usual composition of maps as the category of pairs of sets. With the same approach we could also introduce the category of pairs of groups and so on.

The name "morphisms" suggests that morphisms are necessarily maps. But as we will see in the following two examples, this is not necessarily always the case.

Example.

(g) We consider the category $\mathcal{C}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{C}) &:= \text{all sets,} \\ \mathrm{Mor}(X,Y) &:= \begin{cases} \{\mathrm{id}_X\}, & \text{if } X = Y \\ \varnothing, & \text{if } X \neq Y. \end{cases} \end{aligned}$$

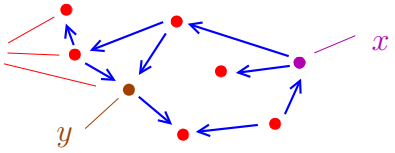
The composition map only needs to be defined if $X = Y = Z$[57], and in this case we define $\mathrm{id}_X \circ \mathrm{id}_X := \mathrm{id}_X$. One can easily convince oneself that this defines a category.

(h) Let G be an arbitrary group. We consider the category $\mathcal{C}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{C}) &:= \text{the set with the unique element } *, \\ \mathrm{Mor}(*,*) &:= G. \end{aligned}$$

We define

$$\begin{aligned} \mathrm{Mor}(*,*) \times \mathrm{Mor}(*,*) &\to \mathrm{Mor}(*,*) \\ (f,g) &\mapsto g \circ f := \underbrace{g \cdot f}_{\text{multiplication in } G} \end{aligned}$$



via the group structure on $\mathrm{Mor}(*,*) = G$. The axioms of a category can be easily deduced from the group axioms of G.

(i) Let $(P, \leq)$ be a partially ordered set, as defined on page 91. We fix a set $\{*\}$ consisting of a single element. We define the order category $\mathcal{Order}_{(P,\leq)}$ that is given by

$$\begin{aligned} \mathrm{Ob}(\mathcal{Order}_{(P,\leq)}) &= P \\ \mathrm{Mor}(x,y) &= \begin{cases} \{*\}, & \text{if } x \leq y, \\ \varnothing, & \text{otherwise.} \end{cases} \end{aligned}$$

together with the only possible way to compose morphisms.

partially ordered set where $a \geq b$ if a is connected to b via a sequence of arrows

$\mathrm{Mor}(x,y) = \{*\}$
$\mathrm{Mor}(y,x) = \varnothing$
$\mathrm{Mor}(x,x) = \varnothing$
$\mathrm{Mor}(y,y) = \{*\}$

The following definition is almost self-explanatory.

[56] We refer to page 98 for our definition of a ring.

[57] If $X \neq Y$ then $\mathrm{Mor}(X,Y) = \varnothing$, but then $\mathrm{Mor}(X,Y) \times \mathrm{Mor}(Y,Z)$ is also the empty set for any Z.

Definition. Let $\mathcal{C}$ be a category. A subcategory is a category $\mathcal{D}$ such that $\mathrm{Ob}(\mathcal{D}) \subset \mathrm{Ob}(\mathcal{C})$ and such that for each $X, Y \in \mathrm{Ob}(\mathcal{D})$ we have $\mathrm{Mor}_{\mathcal{D}}(X,Y) \subset \mathrm{Mor}_{\mathcal{C}}(X,Y)$. We say $\mathcal{D}$ is a full subcategory if for each $X, Y \in \mathrm{Ob}(\mathcal{D})$ we have $\mathrm{Mor}_{\mathcal{D}}(X,Y) = \mathrm{Mor}_{\mathcal{C}}(X,Y)$.

Examples.

(1) The category *AbGroup* of abelian groups is a full subcategory of the category of groups *Group*.
(2) Let $\mathcal{C}$ be the category where the objects are groups but where the only morphisms are group isomorphisms. This is a subcategory of *Group*, but it is certainly not a full subcategory of *Group*.

Definition. Let $\mathcal{C}$ be a category.

(1) An object $X \in \mathrm{Ob}(\mathcal{C})$ is called initial if for each object $Y \in \mathrm{Ob}(\mathcal{C})$ there exists a unique morphism from X to Y.
(2) An object $X \in \mathrm{Ob}(\mathcal{C})$ is called terminal if for each object $Y \in \mathrm{Ob}(\mathcal{C})$ there exists a unique morphism from Y to X.

Example.

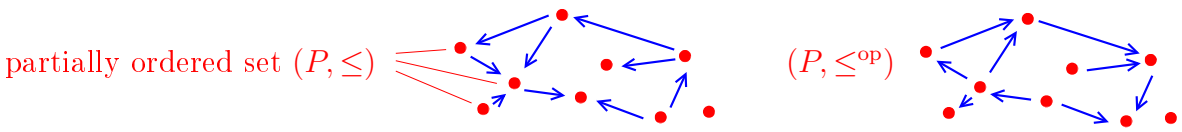
(1) In the category *Set* of sets an initial object is given by the empty set and a terminal object is given by any set consisting of a single element. Similarly in the category *Top* of topological spaces an initial object is given by the empty topology space and a terminal object is given by an topological space consisting of a single element.
(2) In the category *Group* of groups any group consisting of a single element is an initial and also a terminal object. The same applies to the category *AbGroup* of abelian groups and the analogous statement holds in the category $\mathcal{Vec}_{\mathbb{K}}$ of vector spaces over a field $\mathbb{K}$.

Lemma 3.2. Let $\mathcal{C}$ be a category.

(1) If an initial object exists, then it is unique up to isomorphism.
(2) If a terminal object exists, then it is unique up to isomorphism.

Proof. The statements follow easily from the definition. We will fill in the details in Exercise 3.4. ■

Next we introduce the dual of a category $\mathcal{C}$. The idea is very simple, we keep the objects, but we "invert the direction of the morphisms". This simple concept can be very convenient in future discussions.



Definition. Let $\mathcal{C}$ be a category. The opposite category $\mathcal{C}^{\mathrm{op}}$ of $\mathcal{C}$ is defined as the category where

$$\begin{aligned} \mathrm{Ob}(\mathcal{C}^{\mathrm{op}}) &:= \mathrm{Ob}(\mathcal{C}) \\ \mathrm{Mor}_{\mathcal{C}^{\mathrm{op}}}(X,Y) &:= \mathrm{Mor}_{\mathcal{C}}(Y,X) \end{aligned}$$

with the composition given by $f \circ_{\mathcal{C}^{\mathrm{op}}} g = g \circ_{\mathcal{C}} f$.

Example.

(1) Let $(P, \leq)$ be a partially ordered set. We consider the corresponding order category $\mathcal{O}rder_{(P,\leq)}$. The dual of the order category $\mathcal{O}rder_{(P,\leq)}$ is the order category corresponding to the partially ordered set $(P, \leq^{\mathrm{op}})$ where $x \leq^{\mathrm{op}} y$ if and only if $y \leq x$.

(2) For any category $\mathcal{C}$ we evidently have $(\mathcal{C}^{\mathrm{op}})^{\mathrm{op}} = \mathcal{C}$.
(3) Let X be the initial object of a category $\mathcal{C}$. It follows easily from the definitions that it is also the terminal object of the category $\mathcal{C}^{\mathrm{c}}$.

We conclude this introduction to categories and morphisms with the following definition and a short discussion thereof.

Definition. Let $\mathcal{C}$ be a category.
(1) In the following we call a morphism $f \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ invertible if there exists a morphism $g \in \mathrm{Mor}_{\mathcal{C}}(Y, X)$ such that $f \circ g = \mathrm{id}_Y$ and $g \circ f = \mathrm{id}_X$. Sometimes we refer to invertible morphisms also as isomorphisms.
(2) We denote by $\mathrm{Mor}_{\mathcal{C}}(X, Y)_{\mathrm{inv}}$ the set of all invertible morphisms.

Examples.
(1) In the category of vector spaces the invertible morphisms are precisely the isomorphisms which are familiar from linear algebra.
(2) In the category considered in (g) every morphism is an isomorphism. In fact categories in which every morphism is an isomorphism are called groupoids.

Lemma 3.3. Let $\mathcal{C}$ be a category.
(1) Let $X, Y \in \mathrm{Ob}(\mathcal{C})$ and let $f \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$. If $g \in \mathrm{Mor}_{\mathcal{C}}(Y, X)$ is a morphism with $f \circ g = \mathrm{id}_Y$ and if $\widetilde{g} \in \mathrm{Mor}_{\mathcal{C}}(Y, X)$ is a morphism with $\widetilde{g} \circ f = \mathrm{id}_X$, then $g = \widetilde{g}$.
(2) Let $X, Y \in \mathrm{Ob}(\mathcal{C})$ and let $g, \widetilde{g} \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ with $f \circ g = \mathrm{id}_Y$ and $g \circ f = \mathrm{id}_X$ and with $f \circ \widetilde{g} = \mathrm{id}_Y$ and $\widetilde{g} \circ f = \mathrm{id}_X$. Then $g = \widetilde{g}$.
(3) Let $X \in \mathrm{Ob}(\mathcal{C})$. The set of invertible morphisms $\mathrm{Mor}_{\mathcal{C}}(X, X)_{\mathrm{inv}}$ forms a group under the composition of morphisms.

Proof.
(1) We have

$$g \underset{\substack{\uparrow \\ \text{defining property of } \mathrm{id}_X}}{=} \mathrm{id}_X \circ g \underset{\substack{\uparrow \\ \text{defining property of } g}}{=} (\widetilde{g} \circ f) \circ g \underset{\substack{\uparrow \\ \text{associativity of } \circ}}{=} \widetilde{g} \circ (f \circ g) \underset{\substack{\uparrow \\ \text{defining property of } \widetilde{g}}}{=} \widetilde{g} \circ \mathrm{id}_Y \underset{\substack{\uparrow \\ \text{defining property of } \mathrm{id}_Y}}{=} \widetilde{g}.$$

(2) This statement follows immediately from (1).
(3) Let $X \in \mathrm{Ob}(\mathcal{C})$. first note that by definition $\mathrm{Mor}_{\mathcal{C}}(X, X)$ is actually a set. Next note that by definition of a category we can compose any two morphisms that lie in $\mathrm{Mor}_{\mathcal{C}}(X, X)$. It follows easily from the associativity of "$\circ$" that the composition of two invertible morphisms is again invertible. It now follows from Properties (3A) and (3B) of a category that $\mathrm{Mor}_{\mathcal{C}}(X, X)_{\mathrm{inv}}$ forms a group. ∎

Definition. Let $\mathcal{C}$ be a category, let $X, Y \in \mathrm{Ob}(\mathcal{C})$ and let $f \in \mathrm{Mor}_{\mathcal{C}}(X, Y)_{\mathrm{inv}}$ be an invertible morphism. By Lemma 3.3 there exists a *unique* morphism $g \in \mathrm{Mor}_{\mathcal{C}}(Y, X)$ with

$f \circ g = \mathrm{id}_Y$ and $g \circ f = \mathrm{id}_X$. We refer to this morphism as the inverse of f and usually we denote it by f^{-1}.

Lemma 3.4. Let $\mathcal{C}$ be a category and let $f \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ be an invertible morphism. For every $Z \in \mathrm{Ob}(\mathcal{C})$ the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{C}}(Y, Z) & \to & \mathrm{Mor}_{\mathcal{C}}(X, Z) \\ g & \mapsto & g \circ f \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{Mor}_{\mathcal{C}}(Z, X) & \to & \mathrm{Mor}_{\mathcal{C}}(Z, Y) \\ g & \mapsto & f \circ g \end{array}$$

are bijections.

Proof. One can easily show that precomposition respectively postcomposition with the inverse morphism f^{-1} defines inverses to the given maps. ∎

3.2. **Functors.** In this section we introduce the all-important notions of covariant and contravariant functors.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories. A covariant functor $F \colon \mathcal{C} \to \mathcal{D}$ consists of a map

$$F \colon \mathrm{Ob}(\mathcal{C}) \to \mathrm{Ob}(\mathcal{D})$$

and for all $X, Y \in \mathrm{Ob}(\mathcal{C})$ a map

$$F \colon \mathrm{Mor}_{\mathcal{C}}(X, Y) \to \mathrm{Mor}_{\mathcal{D}}(F(X), F(Y)),$$

such that the following axioms are satisfied:

(F1) For all $X \in \mathrm{Ob}(\mathcal{C})$ we have $F(\mathrm{id}_X) = \mathrm{id}_{F(X)}$.

(F2) For all $\phi \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ and all $\psi \in \mathrm{Mor}_{\mathcal{C}}(Y, Z)$ the following equality holds

$$F(\psi \circ \phi) = F(\psi) \circ F(\phi) \in \mathrm{Mor}_{\mathcal{D}}(F(X), F(Z)).$$

Convention. For a covariant functor F and $\phi \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ we often write ϕ_* instead of $F(\phi)$. The first axiom (F1) then becomes $(\mathrm{id}_X)_* = \mathrm{id}_{F(X)}$ and the second axiom (F2) becomes $(\psi \circ \phi)_* = \psi_* \circ \phi_*$.

Examples.

(1) The map

$$\begin{array}{rcl} F \colon \mathrm{Ob}(\mathcal{V}ec_{\mathbb{R}}) & \to & \mathrm{Ob}(\mathcal{S}et) \\ (V, +, \cdot) & \mapsto & V, \\ \mathrm{Mor}_{\mathcal{V}ec_{\mathbb{R}}}(V, W) & \to & \mathrm{Mor}_{\mathcal{S}et}(V, W) \\ (\varphi \colon V \to W) & \mapsto & (\varphi \colon V \to W) \end{array}$$

together with the maps

defines a covariant functor from the category $\mathcal{V}ec_{\mathbb{R}}$ of real vector spaces to the category $\mathcal{S}et$ of sets. This example can be generalized to many contexts. Functors of this type are colloquially called *forgetful functor*.

(2) Given any category there is the identity functor with the obvious definition.

(3) Let $\mathcal{Top}$ be the category of topological spaces and let $\mathcal{Set}$ be the category of sets. It follows easily from follows easily from Lemma 2.35 (2) that the map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{Top}) & \to & \mathrm{Ob}(\mathcal{Set}) \\ X & \mapsto & \pi_0(X) := \text{set of path-components of } X, \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{Top}}(X,Y) & \to & \mathrm{Mor}_{\mathcal{Set}}(\pi_0(X),\pi_0(Y)) \\ f & \mapsto & \begin{pmatrix} \pi_0(X) & \to & \pi_0(Y) \\ C & \mapsto & f(C) \end{pmatrix} \end{array}$$

is a covariant functor from the category $\mathcal{Top}$ of topological spaces to the category $\mathcal{Set}$ of sets.

The next lemma says that covariant functors can be composed in an obvious way.

Lemma 3.5. Let $\mathcal{C}$, $\mathcal{D}$ and $\mathcal{E}$ be three categories and let $F\colon \mathcal{C} \to \mathcal{D}$ and $G\colon \mathcal{D} \to \mathcal{E}$ be covariant functors. The map

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{C}) & \to & \mathrm{Ob}(\mathcal{E}) \\ X & \mapsto & G(F(X)) \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{C}}(X,Y) & \to & \mathrm{Mor}_{\mathcal{E}}(G(F(X)),G(F(Y))) \\ (\varphi\colon X \to Y) & \mapsto & G(F(\varphi))\colon G(F(X)) \to G(F(Y)) \end{array}$$

is a covariant functor from $\mathcal{C}$ to $\mathcal{E}$. We denote this functor by $G \circ F$.

Proof. The lemma follows easily from the definitions. ∎

Example. We consider the covariant functors $F\colon \mathcal{Set} \to \mathcal{PairSet}$ and $G\colon \mathcal{PairSet} \to \mathcal{Set}$ that are given by

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{Set}) & \to & \mathrm{Ob}(\mathcal{PairSet}) \\ X & \mapsto & (X,\varnothing) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathrm{Ob}(\mathcal{PairSet}) & \to & \mathrm{Ob}(\mathcal{Set}) \\ (X,A) & \mapsto & X \end{array}$$

together with the obvious maps on morphisms. The composition $G \circ F$ is just the identity functor on $\mathcal{Set}$ and the composition $F \circ G$ is the covariant functor that sends (X,A) to $(X,\varnothing)$.

We state our next example of a covariant functor as a lemma.

Lemma 3.6. Let $\mathcal{D}$ be a category and let $\mathcal{Set}$ be the category of sets. Furthermore let $W \in \mathrm{Ob}(\mathcal{D})$. The map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{D}) & \to & \mathrm{Ob}(\mathcal{Set}) \\ X & \mapsto & \mathrm{Mor}_{\mathcal{D}}(W,X) \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{D}}(Y,Z) & \to & \mathrm{Mor}_{\mathcal{Set}}(\mathrm{Mor}_{\mathcal{D}}(W,Y),\mathrm{Mor}_{\mathcal{D}}(W,Z)) \\ \phi & \mapsto & \begin{pmatrix} \mathrm{Mor}_{\mathcal{D}}(W,Y) & \to & \mathrm{Mor}_{\mathcal{D}}(W,Z) \\ g & \mapsto & \phi \circ g \end{pmatrix} \end{array}$$

is a covariant functor.

Proof. The statement follows easily from the axioms of a category. ∎

Example. The example of a covariant functor in Lemma 3.6 comes with many variations, for example if $\mathrm{Mor}_{\mathcal{D}}(W,X)$ has more structure than that of a set. For instance let W be a

real vector space. Then the above map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{V}ec_{\mathbb{R}}) & \to & \mathrm{Ob}(\mathcal{V}ec_{\mathbb{R}}) \\ V & \mapsto & \underbrace{\mathrm{Hom}_{\mathbb{R}}(W,V)}_{\text{real vector space}}, \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{V}ec_{\mathbb{R}}}(U,V) & \to & \mathrm{Mor}_{\mathcal{V}ec_{\mathbb{R}}}(F(U),F(V)) \\ (\phi\colon U \to V) & \mapsto & \begin{pmatrix} \mathrm{Hom}_{\mathbb{R}}(W,U) & \to & \mathrm{Hom}_{\mathbb{R}}(W,V) \\ g & \mapsto & \phi \circ g \end{pmatrix} \end{array}$$

defines a covariant functor from the category $\mathcal{V}ec_{\mathbb{R}}$ of real vector spaces to itself.

We also have the following definition which looks almost the same as the previous definition.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories. A contravariant functor $F\colon \mathcal{C} \to \mathcal{D}$ consists of a map

$$F\colon \mathrm{Ob}(\mathcal{C}) \to \mathrm{Ob}(\mathcal{D})$$

and for all $X, Y \in \mathrm{Ob}(\mathcal{C})$ a map

$$\mathrm{Mor}_{\mathcal{C}}(X,Y) \to \mathrm{Mor}_{\mathcal{D}}(F(Y),F(X))$$

such that the following axioms are satisfied:

(F1) For all $X \in \mathrm{Ob}(\mathcal{C})$ we have $F(\mathrm{id}_X) = \mathrm{id}_{F(X)}$.
(F2) For all $\phi \in \mathrm{Mor}_{\mathcal{C}}(X,Y)$ and all $\psi \in \mathrm{Mor}_{\mathcal{C}}(Y,Z)$ we have

$$F(\psi \circ \phi) = F(\phi) \circ F(\psi) \in \mathrm{Mor}_{\mathcal{D}}(F(Z),F(X)).$$

The definition of a contravariant functor looks very much the same as the definition of a covariant functor. The difference is that a contravariant functor "reverses the direction of morphisms" and the orders of $F(\psi)$ and $F(\phi)$ in the second axiom are swapped.

Convention. For a contravariant functor F and $\phi \in \mathrm{Mor}_{\mathcal{C}}(X,Y)$ we often write ϕ^* instead of $F(\phi)$. The first axiom then becomes $(\mathrm{id}_X)^* = \mathrm{id}_{F(X)}$ and the second axiom becomes $(\psi \circ \phi)^* = \phi^* \circ \psi^*$.

We state our first example as a lemma, namely we have the following analogue of Lemma 3.6.

Lemma 3.7. Let $\mathcal{D}$ be a category and let $\mathcal{S}et$ be the category of sets. Furthermore let $W \in \mathrm{Ob}(\mathcal{D})$. The map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{D}) & \to & \mathrm{Ob}(\mathcal{S}et) \\ X & \mapsto & \mathrm{Mor}_{\mathcal{D}}(X,W) \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{D}}(Y,Z) & \to & \mathrm{Mor}_{\mathcal{S}et}(\mathrm{Mor}_{\mathcal{D}}(Z,W),\mathrm{Mor}_{\mathcal{D}}(Y,W)) \\ f & \mapsto & \begin{pmatrix} \mathrm{Mor}_{\mathcal{D}}(Z,W) & \to & \mathrm{Mor}_{\mathcal{D}}(Y,W) \\ g & \mapsto & g \circ f \end{pmatrix} \end{array}$$

is a contravariant functor.

Proof. Again the statement follows easily from the axioms of a category. ∎

Examples. Lemma 3.7 can be viewed as the mother of all contravariant functors. As in the case of Lemma 3.6 it spawns many variations if $\mathrm{Mor}_{\mathcal{D}}(X,W)$ has more structure than just being a set.

(1) The map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{Set}) & \to & \mathrm{Ob}(\mathcal{Vec}_{\mathbb{R}}) \\ X & \mapsto & \mathrm{Map}(X,\mathbb{R}) := \underbrace{\text{set of maps } X \to \mathbb{R}}_{\text{vector space in the obvious way}}, \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{Set}}(X,Y) & \to & \mathrm{Mor}_{\mathcal{Vec}_{\mathbb{R}}}(\mathrm{Map}(Y,\mathbb{R}),\mathrm{Map}(X,\mathbb{R})) \\ (\phi\colon X \to Y) & \mapsto & \begin{pmatrix} \mathrm{Map}(Y,\mathbb{R}) & \to & \mathrm{Map}(X,\mathbb{R}) \\ f & \mapsto & f\circ\phi \end{pmatrix} \end{array}$$

is a contravariant functor from the category $\mathcal{Set}$ of sets to the $\mathcal{Vec}_{\mathbb{R}}$ of real vector spaces.

(2) The map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{Vec}_{\mathbb{R}}) & \to & \mathrm{Ob}(\mathcal{Vec}_{\mathbb{R}}) \\ V & \mapsto & V^* := \mathrm{Hom}_{\mathbb{R}}(V,\mathbb{R}) =: \text{dual vector space of } V, \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{Vec}_{\mathbb{R}}}(U,V) & \to & \mathrm{Mor}_{\mathcal{Vec}_{\mathbb{R}}}(V^*,U^*) \\ (\phi\colon U \to V) & \mapsto & \begin{pmatrix} \mathrm{Hom}_{\mathbb{R}}(V,\mathbb{R}) & \to & \mathrm{Hom}_{\mathbb{R}}(U,\mathbb{R}) \\ f & \mapsto & f\circ\phi \end{pmatrix} \end{array}$$

is a contravariant functor from the category $\mathcal{Vec}_{\mathbb{R}}$ of real vector spaces to itself.

We have the following analogue of Lemma 3.5, but note that it comes with a twist.

Lemma 3.8. Let $\mathcal{C}$, $\mathcal{D}$ and $\mathcal{E}$ be three categories.

(1) Let $F\colon \mathcal{C} \to \mathcal{D}$ and $G\colon \mathcal{D} \to \mathcal{E}$ be *two contravariant functors*. The map

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{C}) & \to & \mathrm{Ob}(\mathcal{E}) \\ X & \mapsto & G(F(X)) \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{C}}(X,Y) & \to & \mathrm{Mor}_{\mathcal{E}}(G(F(X)),G(F(Y))) \\ (\varphi\colon X \to Y) & \mapsto & F(G(\varphi))\colon G(F(X)) \to G(F(Y)) \end{array}$$

is a *covariant functor* from the category $\mathcal{C}$ to the category $\mathcal{E}$.

(2) Similarly we can define the composition of a covariant functor with a contravariant functor and we obtain a contravariant functor.

Proof. The lemma again follows easily from the definitions. Nonetheless it is worth going through the argument to make sue that all maps actually make sense and go into the desired direction. ■

The following lemma shows that contravariant functors are covariant functors in disguise.

Lemma 3.9. If

$$\begin{array}{c} F\colon \mathcal{C} \to \mathcal{D} \\ X \mapsto F(X) \\ (X \xrightarrow{\varphi} Y) \mapsto (F(Y) \xrightarrow{F(\varphi)} F(X)) \end{array}$$

is a contravariant functor between two categories, then

$$\begin{array}{c} \mathcal{C} \to \mathcal{D}^{\mathbf{c}} \\ X \mapsto F(X) \\ (X \xrightarrow{\varphi} Y) \mapsto (F(Y) \xrightarrow{F(\varphi)} F(X)) \end{array}$$

is a covariant functor. The same statement also holds with the roles of "covariant" and "contravariant" swapped.

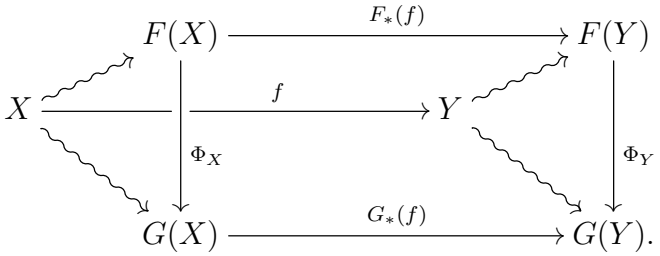
Proof. As so often in category theory, the statement follows immediately from the definitions. ■

Lemma 3.9 can be useful for developing the general study of functors. When we work with "real life" categories, then personally we find that Lemma 3.9 is not all that useful and we prefer to work with both notions of functors.
We conclude this section with the following basically obvious lemma.

Lemma 3.10. Every functor (regardless of whether it is covariant or contravariant) sends invertible morphisms to invertible morphisms.

3.3. **Natural transformations.** In this section we introduce the notion of a natural transformation between two functors. This topic might eventually look even more esoteric, but once one keeps one's eyes open one realizes that the mathematical world is stuffed with natural transformations and natural isomorphisms. They just suffer from the sad fate that often they do not recognized as such.
After this long preamble, let us give the definition of natural transformations.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories and let $F, G\colon \mathcal{C} \to \mathcal{D}$ be two covariant functors.



(1) A natural transformation between the functors F and G assigns to each $X \in \mathrm{Ob}(\mathcal{C})$ a morphism $\Phi_X\colon F(X) \to G(X)$ in $\mathcal{D}$ such that for each morphism $f\colon X \to Y$ in $\mathcal{C}$ the following diagram commutes:

$$\begin{array}{ccc} F(X) & \xrightarrow{F_*(f)} & F(Y) \\ {\scriptstyle \Phi_X}\downarrow & & \downarrow{\scriptstyle \Phi_Y} \\ G(X) & \xrightarrow{G_*(f)} & G(Y). \end{array}$$

(2) If for every $X \in \mathrm{Ob}(\mathcal{C})$ the morphism $\Phi_X\colon F(X) \to G(X)$ is an isomorphism, then we refer to the natural transformation as a natural isomorphism. In this case, given $X \in \mathrm{Ob}(\mathcal{C})$ we often say that $F(X)$ and $G(X)$ are naturally isomorphic.[58]

The same way we can of course also define the notion of a natural transformation and a natural isomorphism between two contravariant functors.

Remark. The notion of a natural transformation can also be summarized in the following diagram:

[58] In the literature the words "natural isomorphism" and "canonical isomorphism" are often used indiscriminately, but whereas the expression "natural isomorphism" has a precise meaning, the expression "canonical isomorphism" is not a well-defined mathematical concept. However, in the lecture notes we will on occasions write that "some object exists canonically". This means that in the proof we show the existence of the object by giving an explicit construction that does not rely on any choices.

Here the wiggly arrows are not morphisms but they are just meant to remind us which objects a functor associates to the objects X and Y.

Now we will see that we have encountered natural transformations and natural isomorphisms much more often than one might have initially thought.

Examples.

(1) Let *CRing* be the category of commutative rings and let *Group* be the category of groups. Let $n \in \mathbb{N}$. We consider the covariant functors

$$\begin{array}{rcl} F\colon \mathcal{CRing} & \to & \mathcal{Group} \\ R & \mapsto & \mathrm{GL}(n,R) \end{array} \quad \text{and} \quad \begin{array}{rcl} G\colon \mathcal{CRing} & \to & \mathcal{Group} \\ R & \mapsto & R^* := \text{units in } R. \end{array}$$

For each commutative ring R we consider the group homomorphism

$$\begin{array}{rcl} \Phi_R\colon \mathrm{GL}(n,R) & \to & R^* \\ A & \mapsto & \det(A). \end{array}$$

We claim that these group homomorphisms define a natural transformation from F to G. Thus let $f\colon R \to S$ be a homomorphism between commutative rings and let $A \in F(R)$, i.e. $A = (a_{ij})$ is a matrix in $\mathrm{GL}(n,R)$. We have

$$\begin{aligned} \Phi_S(F_*(f)(A)) &= \det((f(a_{ij}))_{i,j=1,\dots,n}) \overset{\text{Leibniz formula}}{\underset{\downarrow}{=}} \sum_{\sigma\in S_n} \operatorname{sign}(\sigma)\cdot\prod_{i=1}^{n} f(a_{i,\sigma(i)}) \\ &\underset{\substack{\uparrow \\ f \text{ is a ring homomorphism}}}{=} f\Big(\sum_{\sigma\in S_n} \operatorname{sign}(\sigma)\cdot\prod_{i=1}^{n} a_{i,\sigma(i)}\Big) \underset{\substack{\uparrow \\ \text{Leibniz formula}}}{=} f(\det(A)) = G_*(f)(\Phi_R(A)). \end{aligned}$$

But that means, by definition, that the Φ_R define a natural transformation from F to G.

(2) Let $\mathbb{K}$ be a field. We consider again the category $\mathcal{Vec}_{\mathbb{K}}$ of vector spaces over $\mathbb{K}$. By Lemma 3.8 we have a covariant functor $F\colon \mathcal{Vec}_{\mathbb{K}} \to \mathcal{Vec}_{\mathbb{K}}$ that is given by the maps

$$\begin{array}{rcl} V & \mapsto & (V^*)^* \\ (f\colon V \to W) & \mapsto & ((f^*)^*\colon (V^*)^* \to (W^*)^*). \end{array}$$

For each real vector space V we denote by Φ_V the homomorphism

$$\begin{array}{rcl} V & \to & (V^*)^* \\ v & \mapsto & \left(\begin{array}{rcl} V^* & \to & \mathbb{K} \\ (\varphi\colon V \to \mathbb{K}) & \mapsto & \varphi(v) \end{array}\right). \end{array}$$

It is straightforward to verify that these maps define a natural transformation from the identity functor $\mathrm{id}\colon \mathcal{Vec}_{\mathbb{K}} \to \mathcal{Vec}_{\mathbb{K}}$ to the functor $F\colon \mathcal{Vec}_{\mathbb{K}} \to \mathcal{Vec}_{\mathbb{K}}$. We will discuss this example in greater detail in Exercise 3.4.

(3) Let $\mathbb{K}$ be a field. We denote by *Epi* the following category:

- The objects are epimorphisms $\varphi\colon V \to W$ between vector spaces over $\mathbb{K}$.

- A morphism between objects $\varphi\colon V \to W$ and $\varphi'\colon V' \to W'$ consists of two $\mathbb{K}$-linear maps $\alpha\colon V \to V'$ and $\beta\colon W \to W'$ such that the following diagram commutes:

$$\begin{array}{ccc} V & \xrightarrow{\varphi} & W \\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\beta} \\ V' & \xrightarrow{\varphi'} & W'. \end{array}$$

  The composition of two morphisms (α, β) and $(\widetilde{\alpha}, \widetilde{\beta})$ is defined as $(\widetilde{\alpha} \circ \alpha, \widetilde{\beta} \circ \beta)$, provided $\widetilde{\alpha} \circ \alpha$ and $\widetilde{\beta} \circ \beta$ are defined.

The following maps define covariant functors from the category $\mathcal{E}pi$ to the category $\mathcal{V}ec_{\mathbb{K}}$ of vector spaces over $\mathbb{K}$:

$$\begin{array}{rcl} F\colon \mathcal{E}pi & \to & \mathcal{V}ec_{\mathbb{K}} \\ (\varphi\colon V \to W) & \mapsto & V/\ker(\varphi) \\ (\alpha, \beta) & \mapsto & \begin{pmatrix} V/\ker(\varphi) & \to & V'/\ker(\varphi') \\ [v] & \mapsto & [\alpha(v)] \end{pmatrix} \end{array} \quad \text{and} \quad \begin{array}{rcl} G\colon \mathcal{E}pi & \to & \mathcal{V}ec_{\mathbb{K}} \\ (\varphi\colon V \to W) & \mapsto & W \\ (\alpha, \beta) & \mapsto & \beta. \end{array}$$

The maps

$$\begin{array}{rcl} V/\ker(\varphi) & \to & W \\ [v] = v + \ker(\varphi) & \mapsto & \varphi(v) \end{array}$$

form a natural isomorphism from the functor F to the functor G.

(4) We consider the covariant functors

$$\begin{array}{rcl} F\colon \mathcal{R}ing & \to & \mathcal{R}ing \\ R & \mapsto & \mathbb{Z} \\ (f\colon R \to S) & \mapsto & (\mathrm{id}\colon \mathbb{Z} \to \mathbb{Z}) \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{id}\colon \mathcal{R}ing & \to & \mathcal{R}ing \\ R & \mapsto & R \\ (f\colon R \to S) & \mapsto & (f\colon R \to S). \end{array}$$

For each commutative ring R we consider the ring homomorphism

$$\begin{array}{rcl} \Phi_R\colon \mathbb{Z} & \to & R \\ n & \mapsto & n \cdot 1_R. \end{array}$$

Note by our definition of a ring homomorphism on page 98 it follows that for each ring homomorphism $f\colon R \to S$ we have $f(1_R) = 1_S$. This implies that the following diagram commutes:

$$\begin{array}{ccc} F(R) = \mathbb{Z} & \xrightarrow{F_*(f)=\mathrm{id}} & \mathbb{Z} = F(S) \\ {\scriptstyle\Phi_R}\downarrow & & \downarrow{\scriptstyle\Phi_S} \\ \mathrm{id}(R) = R & \xrightarrow{\mathrm{id}_*(f)=f} & S = \mathrm{id}(S). \end{array}$$

But this shows that the ring homomorphisms Φ_R define a natural transformation from the covariant functor F to the identity functor id. Thus, given a commutative ring, we refer to this ring homomorphism $\mathbb{Z} \to R$ as the *natural ring homomorphism*.

Perhaps in this instance it is also important to give a "non-example".

Non-Example. Let $\mathcal{FGAbGroup}$ be the category of finitely generated abelian groups. Given an abelian group A we denote by $\mathrm{Tor}(A) := \{g \in A \mid \text{there exists an } n \in \mathbb{N} \text{ with } n \cdot g = 0\}$

its torsion subgroup and we denote by $\mathrm{F}A := A/\operatorname{Tor}(A)$ the so maximal torsion-free quotient. We consider the following two covariant functors that are given by[59]

$$\begin{array}{rcl} F\colon \mathcal{FGAbGroup} & \to & \mathcal{FGAbGroup} \\ A & \mapsto & A \end{array} \quad \text{and} \quad \begin{array}{rcl} G\colon \mathcal{FGAbGroup} & \to & \mathcal{FGAbGroup} \\ A & \mapsto & \operatorname{Tor}(A) \oplus \mathrm{F}A \end{array}$$

together with the obvious maps on morphisms. It follows from the Finitely Generated Abelian Group Classification Theorem 51.4 that for any finitely generated abelian group A the groups $F(A) = A$ and $G(A) = \operatorname{Tor}(A) \oplus \mathrm{F}A$ are isomorphic. Now we claim that nonetheless there is *no* natural isomorphism between F and G. Indeed, suppose there was such a natural isomorphism Φ. Let us consider the group $A = \mathbb{Z}_2 \oplus \mathbb{Z}$ and the homomorphism

$$\begin{array}{rcl} f\colon A = \mathbb{Z}_2 \oplus \mathbb{Z} & \to & \mathbb{Z}_2 \oplus \mathbb{Z} = A \\ ([a], b) & \mapsto & ([b], 0). \end{array}$$

Since we assume that Φ is a natural isomorphism we obtain the following commutative diagram

$$\begin{array}{ccc} F(A) & \xrightarrow[\cong]{\Phi_A} & G(A) \\ {\scriptstyle F(f)}\downarrow & & \downarrow{\scriptstyle G(f)} \\ F(A) & \xrightarrow[\cong]{\Phi_A} & G(A) \end{array} \quad \text{which specializes in our setting to the following commutative diagram} \quad \begin{array}{ccc} \mathbb{Z}_2 \oplus \mathbb{Z} & \xrightarrow[\cong]{\Phi_A} & \mathbb{Z}_2 \oplus \mathbb{Z} \\ {\scriptstyle F(f)=f}\downarrow & & \downarrow{\scriptstyle G(f)=0} \\ \mathbb{Z}_2 \oplus \mathbb{Z} & \xrightarrow[\cong]{\Phi_A} & \mathbb{Z}_2 \oplus \mathbb{Z}. \end{array}$$

Note that the vertical map to the left is non-trivial whereas a close inspection shows that the vertical map to the right is trivial. But this collides with the statement that the horizontal maps are isomorphisms and that the diagram commutes.

On many occasions we, and many authors, say that a certain map is "natural". This means that the map is in fact a natural transformation between two suitable functors between two suitable categories. Sometimes it takes some thought to figure out what the right context is.

Example. Let G be a group and let A and B be normal subgroups of G with $A \subset B$. The Third Isomorphism Theorem in group theory, see [**Hun1980**, Corollary 5.10], says that the map

$$\begin{array}{rcl} \Phi_{(G,A,B)}\colon G/B & \to & (G/A)/(B/A) \\ g \cdot B & \mapsto & (g \cdot A) \cdot B/A \end{array}$$

is an isomorphism. This isomorphism is a natural isomorphism in the following sense. We consider the category $\mathcal{TripGr}$ of triples of groups which is defined as follows:

- The objects are the triples (G, A, B) where G is a group and A and B are normal subgroups of G with $A \subset B$.
- The morphisms from (G, A, B) to (G', A', B') are the homomorphisms $\varphi\colon G \to G'$ with $\varphi(A) \subset A'$ and $\varphi(B) \subset B'$.

[59] Let us explain why G is in fact a covariant functor. Let $f\colon A \to B$ be a homomorphism between two finitely generated abelian groups. Since a homomorphism sends torsion elements to torsion elements we see that f restricts to a homomorphism $\operatorname{Tor}(A) \to \operatorname{Tor}(B)$. This also implies that f descends to a homomorphism $\mathrm{F}\,A = A/\operatorname{Tor}(A) \to \mathrm{F}\,B = B/\operatorname{Tor}(B)$. Summarizing we see that $f\colon A \to B$ induces a homomorphism $G(f)\colon G(A) = \operatorname{Tor}(A) \oplus \mathrm{F}\,A \to G(B) = \operatorname{Tor}(B) \oplus \mathrm{F}\,B$.

We consider the two functors

$$\begin{array}{rcl} F\colon \mathcal{TripGr} & \to & \mathcal{Group} \\ (G,A,B) & \mapsto & G/B \end{array} \quad \text{and} \quad \begin{array}{rcl} G\colon \mathcal{TripGr} & \to & \mathcal{Group} \\ (G,A,B) & \mapsto & (G/A)/(B/A). \end{array}$$

One can easily verify that the above isomorphisms $\Phi_{(G,A,B)}$ from the third Isomorphism Theorem define a natural isomorphism from F to G.

All of the above examples of natural transformations are perhaps not particularly impressive. But as we will see, the concept of a natural transformation will eventually become one of the key notions in this course.

3.4. Equivalence of categories.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories.

(1) An equivalence of the categories $\mathcal{C}$ and $\mathcal{D}$ is a tuple (F, G, μ, ν) where $F\colon \mathcal{C} \to \mathcal{D}$ and $G\colon \mathcal{D} \to \mathcal{C}$ are two covariant functors and $\mu\colon G \circ F \to \mathrm{id}_{\mathcal{C}}$ and $\nu\colon F \circ G \to \mathrm{id}_{\mathcal{D}}$ are natural isomorphisms.
(2) A weak equivalence of the categories $\mathcal{C}$ and $\mathcal{D}$ is a covariant functor $F\colon \mathcal{C} \to \mathcal{D}$ that admits a covariant functor $G\colon \mathcal{D} \to \mathcal{C}$ and two natural isomorphisms $\mu\colon G \circ F \to \mathrm{id}_{\mathcal{C}}$ and $\nu\colon F \circ G \to \mathrm{id}_{\mathcal{D}}$ such that (F, G, μ, ν) is an equivalence of categories.[60]
(3) We say $\mathcal{C}$ and $\mathcal{D}$ are equivalent categories, if there exists an equivalence of categories.

Remark. Given a weak equivalence F of categories $\mathcal{C}$ and $\mathcal{D}$ the corresponding G, μ, ν are not uniquely defined.

Proposition 3.11. (Weak Equivalence of Categories Proposition) Let $\mathcal{C}$ and $\mathcal{D}$ be two categories and let $F\colon \mathcal{C} \to \mathcal{D}$ be a covariant functor. The following two statements are equivalent:

(1) The functor $F\colon \mathcal{C} \to \mathcal{D}$ is a weak equivalence of categories.
(2) The following three statements hold:
   (a) The functor F is full, i.e. for any two objects C_1, C_2 of the category $\mathcal{C}$ the map $\mathrm{Mor}_{\mathcal{C}}(C_1, C_2) \to \mathrm{Mor}_{\mathcal{D}}(F(C_1), F(C_2))$ is surjective.
   (b) The functor F is faithful, i.e. for any two objects C_1, C_2 of the category $\mathcal{C}$ the map $\mathrm{Mor}_{\mathcal{C}}(C_1, C_2) \to \mathrm{Mor}_{\mathcal{D}}(F(C_1), F(C_2))$ is injective.
   (c) The functor F is essentially surjective (or *dense*), i.e. each object D in the category $\mathcal{D}$ is isomorphic to an object of the form $F(C)$ where C is an object of the category $\mathcal{C}$.

Proof. The "(1) $\Rightarrow$ (2)"-direction is elementary. The "(2) $\Rightarrow$ (1)" builds on the Axiom of Choice 0.1 and can be proved "by hand" with a little bit of an effort. The details are worked out in [**Rie2016**, Theorem 1.5.9]. ■

Example. Let $\mathcal{C}$ be the category given by the objects $\{\mathbb{R}^n \mid n \in \mathbb{N}_0\}$, where the morphisms $\mathrm{Mor}_{\mathcal{C}}(\mathbb{R}^m, \mathbb{R}^n)$ are all real $(n \times m)$-matrices and where composition of morphisms is given by multiplication of matrices. Furthermore let $\mathcal{D}$ be the category where the objects are all finite dimensional real vector spaces and where the morphisms are all homomorphisms. It

[60] In other words, a weak equivalence of categories is the same as an equivalence of categories, except that G, μ and ν are not part of the date. In particular an equivalence of categories exists if and only if a weak equivalence of categories exists.

follows easily from Proposition 3.11 and very elementary linear algebra that the obvious functor $\mathcal{C} \to \mathcal{D}$ is an equivalence of categories.

We conclude this section with the following lemma that will come in handy at times.

Lemma 3.12. Let $F\colon \mathcal{C} \to \mathcal{D}$ be a weak equivalence of categories between two categories and let $V\colon \mathcal{C} \to \mathcal{V}$ be a covariant functor.

(1) There exists a covariant functor $W\colon \mathcal{D} \to \mathcal{V}$ such that $W \circ F$ is naturally isomorphic to V.
(2) If $W\colon \mathcal{D} \to \mathcal{V}$ and $\widetilde{W}\colon \mathcal{D} \to \mathcal{V}$ are two covariant functors such that $W \circ F$ and $\widetilde{W} \circ F$ are naturally isomorphic to V, then W and $\widetilde{W}$ are naturally isomorphic.

Proof. Proofs in basic category theory are almost invariably elementary and a little dull. Thus we outsource the proof to Exercise 3.8. ■

Exercises for Chapter 3.

Exercise 3.1. Let $\mathcal{C}$ be a category.

(1) A morphism $g \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ is called a *monomorphism* if for every two morphisms $f_1, f_2 \in \mathrm{Mor}_{\mathcal{C}}(W, X)$ with $g \circ f_1 = g \circ f_2$ we also have $f_1 = f_2$.
(2) A morphism $g \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ is called an *epimorphism* if for every two morphisms $h_1, h_2 \in \mathrm{Mor}_{\mathcal{C}}(Y, Z)$ with $h_1 \circ g = h_2 \circ g$ we also have $h_1 = h_2$.

We consider these notions in two different categories.

(a) Show that in the category *AbGroup* of abelian groups the monomorphisms are precisely the injective homomorphisms and that the epimorphisms are precisely the surjective homomorphisms.
Remark. The same statements also hold in the category *Group* of all groups. The proof for monomorphisms is straightforward, but the proof for epimorphisms is non-trivial, we refer to [**Lin1970**] and [**Pare1970**, p. 16] for details.
(b) Show that in the category *Ring* of rings the inclusion $\mathbb{Z} \to \mathbb{Q}$ is an epimorphism.
(c) An abelian group G is called *divisible* if for every $g \in G$ and $n \in \mathbb{N}$ there exists an $h \in G$ with $n \cdot h = g$. We define the category of divisible abelian groups in the obvious way. Show that in this category the obvious homomorphism $\mathbb{Q} \to \mathbb{Q}/\mathbb{Z}$ is a monomorphism.

Exercise 3.2. Let $\mathcal{C}$ be a category. We recall the following definition from Exercise 3.1:

(1) A morphism $g \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ is called a *monomorphism* if for every two morphisms $f_1, f_2 \in \mathrm{Mor}_{\mathcal{C}}(W, X)$ with $g \circ f_1 = g \circ f_2$ we also have $f_1 = f_2$.
(2) A morphism $g \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ is called an *epimorphism* if for every two morphisms $h_1, h_2 \in \mathrm{Mor}_{\mathcal{C}}(Y, Z)$ with $h_1 \circ g = h_2 \circ g$ we also have $h_1 = h_2$.

Now solve the following two exercises:

(a) Show that in the category *Top* of topological spaces a monomorphism is not necessarily injective.
(b) Show that in the category *Top* of topological spaces an epimorphism is not necessarily surjective.

Exercise 3.3. Let $\mathbb{K}$ be a field. Given a $\mathbb{K}$-vector space V we write $V^* := \mathrm{Hom}_{\mathbb{K}}(V, \mathbb{K})$. Given a homomorphism $f\colon V \to W$ we denote by $f^*\colon W^* \to V^*$ the dual map. As on page 204 we consider the covariant functor $F\colon \mathcal{V}ec_{\mathbb{K}} \to \mathcal{V}ec_{\mathbb{K}}$ F that is given by the maps

$$\begin{array}{rcl} V & \mapsto & (V^*)^* \\ (f\colon V \to W) & \mapsto & ((f^*)^*\colon (V^*)^* \to (W^*)^*). \end{array}$$

Furthermore for each $\mathbb{K}$-vector space V we denote by Φ_V the homomorphism

$$\begin{array}{rcl} V & \to & (V^*)^* \\ v & \mapsto & \left(\begin{array}{rcl} V^* & \to & \mathbb{K} \\ (\varphi\colon V \to \mathbb{K}) & \mapsto & \varphi(v) \end{array} \right). \end{array}$$

On page 204 we saw that the maps Φ_V define a natural transformation from $F\colon \mathcal{V}ec_{\mathbb{K}} \to \mathcal{V}ec_{\mathbb{K}}$ to the identity morphism $\mathrm{id}\colon \mathcal{V}ec_{\mathbb{K}} \to \mathcal{V}ec_{\mathbb{K}}$.

(a) Show that the maps Φ_V are in general not isomorphisms.
(b) We denote by $\mathcal{V}ec_{\mathbb{K}}^{\mathrm{fin}}$ the full subcategory of $\mathcal{V}ec_{\mathbb{K}}$ that is given by the finite dimensional $\mathbb{K}$-vector spaces. Note that F restricts to a covariant functor $\mathcal{V}ec_{\mathbb{K}}^{\mathrm{fin}} \to \mathcal{V}ec_{\mathbb{K}}^{\mathrm{fin}}$. Show that this functor is naturally isomorphic to the identity functor.

Exercise 3.4.

(a) Let $\mathcal{C}$ be a category. Show that if an initial object exists, then it is unique up to isomorphism.
(b) Which of the following categories admits an initial object and which ones admit a terminal object?
  (i) The category *Ring* of rings.
  (ii) The full subcategory *Field* of the category *Ring* that consists only of fields.
  (iii) Let $(P, \leq)$ be a partially order set. We consider the corresponding order category $\mathcal{O}rder_{(P,\leq)}$.
(c) Give an example of a category that contains an initial object but not a terminal object.
(d) Give an example of a category that contains a terminal object but that does not contain an initial object.

Exercise 3.5. Let $\mathbb{K}$ be a field. We denote by $\mathcal{V}ec_{\mathbb{K}}^n$ the category where the objects are all vector spaces over $\mathbb{K}$ of dimension n and where the morphisms are isomorphisms of vector spaces. We consider the following two covariant functors:

$$\begin{array}{rcl} F\colon \mathcal{V}ec_{\mathbb{K}}^n & \to & \mathcal{V}ec_{\mathbb{K}}^n \\ V & \mapsto & \mathbb{K}^n \\ (\varphi\colon V \to W) & \mapsto & (\mathrm{id}\colon \mathbb{K}^n \to \mathbb{K}^n) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{V}ec_{\mathbb{K}}^n & \to & \mathcal{V}ec_{\mathbb{K}}^n \\ V & \mapsto & V \\ (\varphi\colon V \to W) & \mapsto & (\varphi\colon V \to W). \end{array}$$

Are the two functors naturally isomorphic?

Exercise 3.6. Let $\mathbb{K}$ be a field, let W be a $\mathbb{K}$-vector space and let $U, V \subset W$ be vector subspaces. In what sense is the isomorphism

$$\begin{array}{rcl} V/(U \cap V) & \to & (U+V)/U \\ v + U \cap V & \mapsto & v + U \end{array}$$

a natural isomorphism?

Exercise 3.7. Let $G = (G, *)$ be a group. We define the *opposite group* $G^{\mathrm{op}} = (G, *^{\mathrm{op}})$ as the group

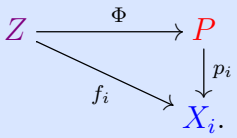
$$\begin{array}{rcl} G \times G & \to & G \\ (g, h) & \mapsto & g *^{\mathrm{op}} h := h * g. \end{array}$$

(a) Show that the maps $G \mapsto G^{\mathrm{op}}$ and $f \mapsto f$ define a covariant functor from the category *Group* of groups to itself.

(b) Show that the functor in (a) is naturally isomorphic to the identity functor on the category *Group* of groups.

Exercise 3.8. Let $F\colon \mathcal{C} \to \mathcal{D}$ be an equivalence of categories between two categories and let $V\colon \mathcal{C} \to \mathcal{V}$ be a covariant functor.

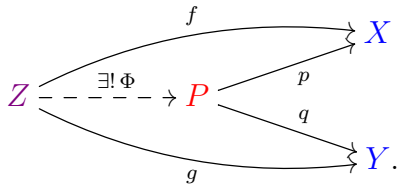
(1) Show that there exists a covariant functor $W\colon \mathcal{D} \to \mathcal{V}$ such that $W \circ F$ is naturally isomorphic to V.



(2) Let $W\colon \mathcal{D} \to \mathcal{V}$ and $\widetilde{W}\colon \mathcal{D} \to \mathcal{V}$ be two covariant functors such that $W \circ F$ and $\widetilde{W} \circ F$ are naturally isomorphic to V. Show that W and $\widetilde{W}$ are naturally isomorphic.

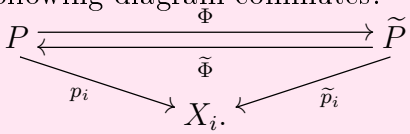
4. Products and Coproducts – Limits and colimits

In this chapter we will continue with our general discussion of categories. First we will introduce the notion of products and coproducts. Afterwards we will discuss the even more general notions of limits and colimits. These notions will guide us in our exploration of topological spaces.



4.1. Products.

Definition. Let $\mathcal{C}$ be a category and let $\{X_i\}_{i\in I}$ be a family of objects in $\mathcal{C}$. A product of $\{X_i\}_{i\in I}$ in the category $\mathcal{C}$ is an object $P \in \mathrm{Ob}(\mathcal{C})$ together with a family of morphisms $\{p_i\colon P \to X_i\}_{i\in I}$ such that the following universal property is satisfied: Whenever we are given a $Z \in \mathrm{Ob}(\mathcal{C})$ and a family of morphisms $\{f_i\colon Z \to X_i\}_{i\in I}$ there exists a unique morphism $\Phi\colon Z \to P$ such that for each $i \in I$ we have $f_i = p_i \circ \Phi$, i.e. such that the following diagram commutes:[61]



Example. Let $\mathcal{C}$ be a category.

(1) Let $X, Y \in \mathrm{Ob}(\mathcal{C})$ be two objects. A product of X and Y in the category $\mathcal{C}$ is some object $P \in \mathrm{Ob}(\mathcal{C})$ together with two morphisms $p\colon P \to X$ and $q\colon P \to Y$ such that the following universal property is satisfied: Whenever we are given an object $Z \in \mathrm{Ob}(\mathcal{C})$ and two morphisms $f\colon Z \to X$ and $g\colon Z \to Y$ there exists a unique morphism $\Phi\colon Z \to P$ such that $f = p \circ \Phi$ and $g = q \circ \Phi$. The situation is summarized in the following diagram:

(2) If we take the empty family of objects in $\mathcal{C}$, then it follows easily from the definitions that the corresponding product is a terminal object in the category $\mathcal{C}$.

Lemma 4.1. (Product Uniqueness Lemma) Let $\mathcal{C}$ be a category and let $\{X_i\}_{i\in I}$ be a family of objects in $\mathcal{C}$. If we are given two products $(P, \{p_i\colon P \to X_i\}_{i\in I})$ and $(\widetilde{P}, \{\widetilde{p}_i\colon \widetilde{P} \to X_i\}_{i\in I})$ then the universal properties of both products define uniquely determined isomorphisms $\Phi\colon P \to \widetilde{P}$ and $\widetilde{\Phi}\colon \widetilde{P} \to P$ which are inverses of one another and such that for each $i \in I$ the following diagram commutes:

[61] Sometimes we refer to P also as the *categorical product* of $\{X_i\}_{i\in I}$ if we want to distinguish it from the usual set-theoretic product.

Proof. The lemma follows easily from the definitions. We will work out the details in Exercise 4.1. ■

Notation. Let $\mathcal{C}$ be a category. Let $\{X_i\}_{i\in I}$ be a family of objects in $\mathcal{C}$ such that a product exists.

(1) We usually denote the product by $\prod_{i\in I} X_i$ and we refer to the morphisms $\prod_{i\in I} X_i \to X_i$ as natural projections. Furthermore, given morphisms $f_i\colon Z \to X_i$ we denote the corresponding morphism $Z \to \prod_{i\in I} X_i$ by $\prod_{i\in I} f_i$.

(2) If $I = \{1, \dots, k\}$, then often we denote the product by $X_1 \times \cdots \times X_k$. Furthermore given morphisms $f_i\colon Z \to X_i$, $i = 1, \dots, k$ we denote the corresponding morphism $Z \to X_1 \times \cdots \times X_k$ by $(f_1, \dots, f_k)$.

Lemma 4.2. (Product-Sets-and-Groups Lemma)

(1) Let *Set* be the category of sets and let $\{X_i\}_{i\in I}$ be a family of sets. The product in *Set* is precisely the product

$$\prod_{i\in I} X_i \ := \ \left\{ f\colon I \to \bigcup_{i\in I} X_i \,\middle|\, \text{for every } i \in I \text{ we have } f(i) \in X_i \right\}$$

as defined on page 88, together with the obvious maps to X_i that is given by $f \mapsto f(i)$.

(2) Let *Group* be the category of groups and let $\{X_i\}_{i\in I}$ be a family of groups. The product in *Group* is the set

$$\prod_{i\in I} X_i \ = \ \left\{ f\colon I \to \bigcup_{i\in I} X_i \,\middle|\, \text{for every } i \in I \text{ we have } f(i) \in X_i \right\}$$

as in (1), which we now view as a group by the obvious multiplication, together with the obvious homomorphisms to X_i.

(3) The same approach as in (2) also applies to the category *AbGroup* of abelian groups and the category $\mathcal{V}ec_{\mathbb{K}}$ of vector spaces over a fixed field $\mathbb{K}$.

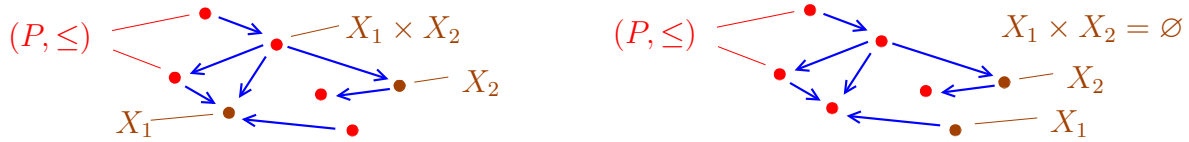
Proof.

(1) So let $Z \in \mathrm{Ob}(\mathcal{S}et)$ and let $\{f_i\colon Z \to X_i\}_{i\in I}$ be a family of maps between sets. We define

$$\begin{array}{rcl} \Phi\colon Z & \to & \prod_{i\in I} X_i \\ z & \mapsto & \begin{pmatrix} I & \to & \bigcup_{i\in I} X_i \\ i & \mapsto & f_i(z) \end{pmatrix}. \end{array}$$

It follows immediately from the definition that for each $i \in I$ we have $f_i = p_i \circ \Phi$. It remains to show that Φ is unique. So let $\Psi\colon Z \to \prod_{i\in I} X_i$ be a map such that for each $i \in I$ we have $f_i = p_i \circ \Psi$. We need to show that $\Phi = \Psi$, i.e. we need to show that for each $z \in Z$ and $i \in I$ we have $\Phi(z)(i) = \Psi(z)(i) \in X_i$. But this follows from the observation that $\Phi(z)(i) = p_i(\Phi(z)) = f_i(z) = p_i(\Psi(z)) = \Psi(z)(i) \in X_i$.

(2) The same argument as in (1) also works for *Group*.



(3) The argument of (2) also works in (3). ■

After these examples one might assume that one gets the hang of the product in categories. The following examples might rob the reader of this illusion.

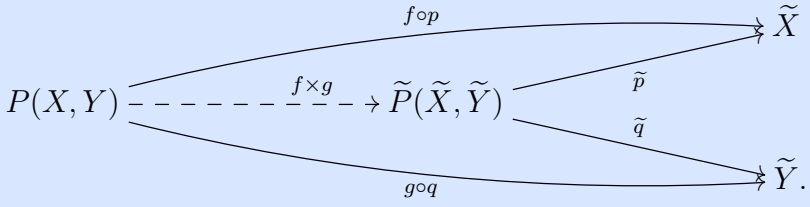
Example.

(1) Let $(P, \leq)$ be a partially ordered set. We consider the corresponding order category $\mathcal{Order}_{(P,\leq)}$ as defined on page 196. Given a family $\{X_i\}_{i\in I}$ of objects in $\mathcal{Order}_{(P,\leq)}$, i.e. given a family $\{X_i\}_{i\in I}$ of elements of P, one can easily show that

$$\prod_{i\in I} X_i \;:=\; \begin{cases} \text{the smallest } Y \in P \text{ such that } X_i \leq Y \text{ for all } i \in I, \text{ if such } Y \text{ exists} \\ \varnothing \qquad\quad \text{if no such } Y \text{ exists.} \end{cases}$$

(2) We introduce a new category. A *pointed set* is a pair (X, x_0), where X is a set and x_0 is a point in X. We refer to the category $\mathcal{PSet}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{PSet}) &:= \text{all pointed sets,} \\ \mathrm{Mor}((X,x_0),(Y,y_0)) &:= \text{all maps } f \text{ from } X \text{ to } Y \text{ with } f(x_0) = y_0 \end{aligned}$$

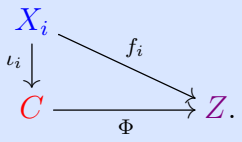


with the usual composition of maps as the *category of pointed sets*. Now let (X, x_0) and (Y, y_0) be two pointed sets. In Exercise 4.6 we will see that the product of (X, x_0) and (Y, y_0) in the category $\mathcal{PSet}$ is given by the set

$$(X \times Y)/\underbrace{((X \times \{y_0\}) \cup (\{x_0\} \times Y))}_{\substack{\text{the points in this subset get} \\ \text{identified to a single point } *}} \quad \text{together with the point} \quad *$$

and the obvious morphisms to (X, x_0) and (Y, y_0).

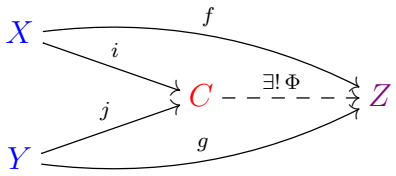
We conclude our discussion of products with the following notation.



Notation. Let $\mathcal{C}$ be a category. Furthermore let $f\colon X \to \widetilde{X}$ and $g\colon Y \to \widetilde{Y}$ be two morphisms in $\mathcal{C}$. If $(P(X,Y), p\colon P \to X, q\colon P(P,X) \to Y)$ is a product of X and Y and if $(\widetilde{P}(\widetilde{X},\widetilde{Y}), \widetilde{p}\colon \widetilde{P}(\widetilde{X},\widetilde{Y}) \to \widetilde{X}, \widetilde{q}\colon \widetilde{P}(\widetilde{X},\widetilde{Y} \to \widetilde{Y})$ is a product of $\widetilde{X}$ and $\widetilde{Y}$, then there exists a unique morphism $f \times g$ that makes the following diagram commute

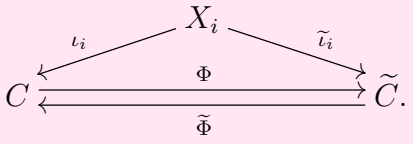
4.2. **Coproducts.** We now reverse the direction of the morphisms in the definition of a product and we obtain a new interesting definition.

Definition. Let $\mathcal{C}$ be a category and let $\{X_i\}_{i\in I}$ be a family of objects in $\mathcal{C}$. A coproduct of $\{X_i\}_{i\in I}$ in the category $\mathcal{C}$ is an object $C \in \mathrm{Ob}(\mathcal{C})$ together with a family of morphisms $\{\iota_i\colon X_i \to C\}_{i\in I}$ such that the following property is satisfied: Whenever we are given a $Z \in \mathrm{Ob}(\mathcal{C})$ and a family of morphisms $\{f_i\colon X_i \to Z\}_{i\in I}$ there exists a unique morphism



$\Phi\colon C \to Z$ such that for each $i \in I$ we have $f_i = \Phi \circ \iota_i$, i.e. such that the following diagram commutes:[62]

Remark. Note that by definition coproducts in $\mathcal{C}$ are products in the opposite category $\mathcal{C}^{\text{op}}$. So we did not introduce a new concept at all.



Example. Let $\mathcal{C}$ be a category.

(1) Let $X, Y \in \text{Ob}(\mathcal{C})$ be two objects. A coproduct of X and Y in the category $\mathcal{C}$ is some object $C \in \text{Ob}(\mathcal{C})$ together with two morphisms $i\colon X \to C$ and $j\colon Y \to C$ such that the following universal property is satisfied: Whenever we are given an object $Z \in \text{Ob}(\mathcal{C})$ and two morphisms $f\colon X \to Z$ and $g\colon Y \to Z$ there exists a unique morphism $\Phi\colon C \to Z$ such that $f = \Phi \circ i$ and $g = \Phi \circ j$. The situation is summarized in the following diagram:

(2) If we take the empty family of objects in $\mathcal{C}$, then it follows easily from the definitions that the corresponding coproduct is an initial object in the category $\mathcal{C}$.

Lemma 4.3. (Coproduct Uniqueness Lemma) Let $\mathcal{C}$ be a category and let $\{X_i\}_{i\in I}$ be a family of objects in $\mathcal{C}$. If we are given two coproducts $(C, \{\iota_i\colon X_i \to C\}_{i\in I})$ and $(\widetilde{C}, \{\widetilde{\iota}_i\colon X_i \to \widetilde{C}\}_{i\in I})$, then there exist unique isomorphisms $\Phi\colon C \to \widetilde{C}$ and $\widetilde{\Phi}\colon \widetilde{C} \to C$ which are inverses of one another and such that for each $i \in I$ the following diagram commutes:

Proof. The lemma is just a reformulation of the Product Uniqueness Lemma 4.1 since coproducts in $\mathcal{C}$ are products in the opposite category $\mathcal{C}^{\text{c}}$. Alternatively the statement also follows easily from the definitions. ∎

Notation. Let $\mathcal{C}$ be a category. Let $\{X_i\}_{i\in I}$ be a family of objects in $\mathcal{C}$ such that a coproduct exists. Often[63] we denote the coproduct by $\coprod_{i\in I} X_i$ and we refer to the morphisms $X_i \to \coprod_{i\in I} X_i$ as natural injections.[64]

[63] In fact, as we will see shortly, in many settings we will see that the coproduct already has an established different notation.

[63] The name *natural injection* is somewhat unfortunate since in general for a morphism it makes no sense to say that is injective. Even if there is a reasonable notion of injective, the natural injection does not

Lemma 4.4. (Coproduct-Sets-and-Abelian Groups Lemma)

(1) Let *Set* be the category of sets and let $\{X_i\}_{i\in I}$ be a family of sets. The coproduct in *Set* is the disjoint union

$$\bigsqcup_{i\in I} X_i \;:=\; \bigcup_{i\in I}(A_i \times \{i\}),$$

as defined on page 88, together with the natural injections of the X_i.

(2) Let *AbGroup* be the category of *abelian* groups and let $\{X_i\}_{i\in I}$ be a family of groups. The coproduct in *AbGroup* is given by

$$\bigoplus_{i\in I} X_i \;:=\; \left\{ (g_i)_{i\in I} \in \prod_{i\in I} X_i \,\middle|\, \text{all but finitely many } g_i \text{ are trivial} \right\}$$

together with the group homomorphisms

$$\begin{array}{rcl} X_i & \to & \bigoplus_{i\in I} X_i \\ x & \mapsto & \left(\begin{array}{lcl} I & \to & \bigcup_{i\in I} X_i \\ j & \mapsto & \begin{cases} x_i, & \text{if } i = j, \\ 0_{X_j}, & \text{if } i \neq j. \end{cases} \end{array} \right) \end{array}$$

(3) The same approach as in (2) also applies to the category $\mathcal{V}ec_{\mathbb{K}}$ of vector spaces over a fixed field $\mathbb{K}$.

Notation. Let $\{X_i\}_{i\in I}$ be objects in the category *AbGroup* of abelian groups. We write

$$\bigoplus_{i\in I} X_i \;:=\; \left\{ (g_i)_{i\in I} \in \prod_{i\in I} X_i \,\middle|\, \text{all but finitely many } g_i \text{ are trivial} \right\}$$

and we refer to it as the direct sum of the X_i. We proceed similarly with objects in the category $\mathcal{V}ec_{\mathbb{K}}$ of vector spaces over a fixed field $\mathbb{K}$.

Remark. In Exercise 4.7 we will see that the construction of the Coproduct-Sets-and-Abelian Groups Lemma 4.4 does *not* give the coproduct in the category *Group* of all groups. It turns out that for the construction of the coproduct in the category *Group* will require a more clever construction.

Proof.

(1) So let $Z \in \mathrm{Ob}(\mathcal{S}et)$ and let $\{f_i \colon X_i \to Z\}_{i\in I}$ be a family of maps between sets. We define

$$\begin{array}{rcl} \Phi \colon \bigsqcup_{i\in I} X_i & \to & Z \\ (z_i, i) & \mapsto & f_i(z_i). \end{array}$$

It follows immediately from the definition that for each $i \in I$ we have $f_i = \Phi \circ \iota_i$. It remains to show that Φ is unique. So let $\Psi \colon \bigsqcup_{i\in I} X_i \to Z$ be a map such that for each $i \in I$ we have $f_i = \Psi \circ \iota_i$. We need to show that $\Phi = \Psi$, i.e. we need to show that for each $i \in I$ and each $x_i \in X_i$ we have $\Phi((x_i, i)) = \Psi((x_i, i)) \in Z$. But this follows from the observation that $\Phi((x_i, i)) = \Phi(\iota_i(x_i)) = f_i(z) = \Psi(\iota_i(x_i)) = \Psi((x_i, i)) \in Z$.

need to be injection. On the other hand, in all examples we ever care about the natural injection will be an injective map.

(2) Let a $Z \in \mathrm{Ob}(\mathcal{AbGroup})$ and let$\{f_i \colon X_i \to Z\}_{i\in I}$ be a family of homomorphisms. We set

$$\begin{aligned} \Phi \colon \Big\{(g_i)_{i\in I} \in \prod_{i\in I} X_i \,\Big|\, \text{all but finitely many } g_i \text{ are trivial}\Big\} &\to Z \\ (g_i)_{i\in I} &\mapsto \prod_{\substack{i\in I \text{ with} \\ g_i \neq e}} f_i(g_i). \end{aligned}$$

Note that this map makes sense since we take the product only of finitely elements of Z. Furthermore note that this map is a homomorphism since we work with the category of abelian groups.

It follows immediately from the definition that for each $i \in I$ we have $f_i = \Phi \circ \iota_i$. It remains to show that Φ is unique. So let Ψ be another homomorphism such that for each $i \in I$ we have $f_i = \Psi \circ \iota_i$. We need to show that $\Phi = \Psi$. So suppose we are given $(g_i)_{i\in I} \in \prod_{i\in I} X_i$ such that there exist only finitely many $i_1, \dots, i_k \in I$ such that the corresponding group element is non-trivial. Then

$$\Phi((g_i)_{i\in I}) = \Phi\Big(\prod_{r=1}^{k} \iota_{i_r}(g_{i_r})\Big) = \prod_{r=1}^{k} \Phi(\iota_{i_r}(g_{i_r})) = \prod_{r=1}^{k} f_{i_r}(g_{i_r}) \underset{\text{same argument backwards}}{\uparrow} = \Psi((g_i)_{i\in I}).$$

(3) This statement is proved the same way as we proved (2). ■

4.3. Limits.

Definition. Let $(P, \leq)$ be a partially ordered set and let $\mathcal{C}$ be a category. A diagram in $\mathcal{C}$ over $(P, \leq)$ is a covariant functor from the order category $\mathcal{Order}_{(P,\leq)}$ to $\mathcal{C}$.

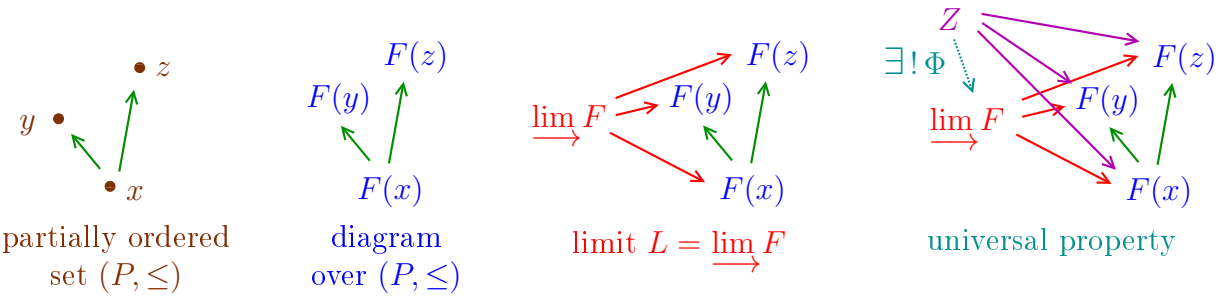
Remark. In plain English a diagram in a category $\mathcal{C}$ over a partially ordered set $(P, \leq)$ is the following data:

(1) for each $x \in P$ we are given any object $F(x) \in \mathcal{C}$,
(2) for each $x < y$ we are given a morphism $F(x) \to F(y)$,
(3) if $x < y < z$, then the following diagram needs to commute:

$$\begin{array}{ccc} F(x) & \longrightarrow & F(z). \\ & \searrow \quad \nearrow & \\ & F(y) & \end{array}$$

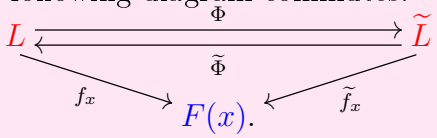
Example.

(1) We consider the partially ordered set $(P, \leq_{\mathrm{tr}})$ that is given by a set P with the trivial partial order $\leq_{\mathrm{tr}}$, i.e. $x \leq_{\mathrm{tr}} y$ if and only if $x = y$. In this setting a diagram over $(P, \leq_{\mathrm{tr}})$ is the same data as a family of objects $\{X_i\}_{i\in P}$.
(2) We consider the partially ordered set $(\mathbb{N}, \leq)$. In this setting a diagram over $(\mathbb{N}, \leq)$ is the same data as a sequence



$$X_1 \xrightarrow{\varphi_1} X_2 \xrightarrow{\varphi_2} X_3 \xrightarrow{\varphi_3} \dots$$

of morphisms $\varphi_i \colon X_i \to X_{i+1}$. For $i < j$ the morphisms $X_i \to X_j$ are understood to be given by $\varphi_{j-1} \circ \dots \circ \varphi_{i+1} \circ \varphi_i$.



Definition. Let $(P, \leq)$ be a partially ordered set, let $\mathcal{C}$ be a category and let F be a diagram in $\mathcal{C}$ over $(P, \leq)$. A limit of F consists of an object $L \in \mathrm{Ob}(\mathcal{C})$ together with morphisms $f_x \colon L \to F(x)$ for each $x \in P$ such that the following two conditions are satisfied:

(1) For any $x \leq y$ we have $f_y = F(x \to y) \circ f_x \colon L \to F(x)$.
(2) The following universal property holds: If Z is an object in $\mathcal{C}$ and if we are given morphisms $g_x \colon Z \to F(x)$ for each $x \in P$ such that (1) is satisfied, then there exists a unique morphism $\Phi \colon Z \to L$ such that $g_x = f_x \circ \Phi$ for all $x \in P$.

If a limit exists, then often we denote it by $\varinjlim F$, or by sensible variations thereof.

Lemma 4.5. (Limit Uniqueness Lemma) Let $(P, \leq)$ be a partially ordered set, let $\mathcal{C}$ be a category and let F be a diagram in $\mathcal{C}$ over $(P, \leq)$. Suppose that we are given two limits $(L, \{f_x \colon L \to F(x)\}_{x \in P})$ and $(\widetilde{L}, \{\widetilde{f}_x \colon \widetilde{L} \to F(x)\}_{x \in P})$. Then there exist uniquely determined isomorphisms $\Phi \colon L \to \widetilde{L}$ and $\widetilde{\Phi} \colon \widetilde{L} \to L$ which are inverses of one another and such that for each $x \in P$ the following diagram commutes:

Proof. As in the case of the Product Uniqueness Lemma 4.1 the proof follows easily from the definitions. ∎

Example.

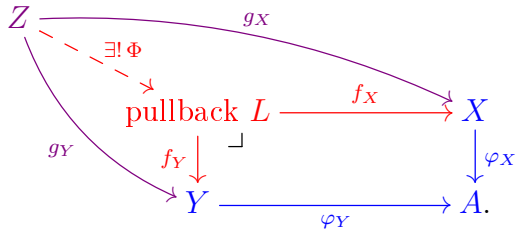
(1) If we consider a trivial partially ordered set $(P, \leq_{\mathrm{tr}})$, then the limit is by definition precisely the product.
(2) We consider $(\mathbb{N}, \leq)$ and we consider a diagram in the category $\mathcal{S}et$ of sets where each $\varphi_i \colon X_i \to X_{i+1}$ is an inclusion of subsets of a given set Y. In Exercise 4.8 we will see that in this case the limit is the union of the X_i.

We conclude this discussion of limits with a particularly frequently used special case.

Definition.

(1) We consider the set $P = \{0, x, y\}$ with the partial order that is given by the trivial relations $0 \leq 0, x \leq x, y \leq y$ and the non-trivial relations $x \leq 0$ and $y \leq 0$:

the partially ordered set



$$\begin{array}{ccc} & & x \\ & & \downarrow \\ y & \longrightarrow & 0 \end{array}$$

gives rise to the pullback diagram

$$\begin{array}{ccc} & & F(x) \\ & & \downarrow{\scriptstyle \varphi_x} \\ F(y) & \xrightarrow{\varphi_y} & F(0). \end{array}$$

(2) The limit of a pullback diagram is called a pullback.

Remark. The following diagram summarizes the definition of a pullback:

(1) We start out with a pullback diagram.
(2) The pullback L comes with morphisms $f_X \colon L \to X$ and $f_Y \colon L \to Y$ such that the rectangle commutes.
(3) If we are given an object Z of $\mathcal{C}$ with morphisms $g_X \colon Z \to X$ and $g_Y \colon Z \to Y$ such that the outer big quadrilateral commutes, then there exists a unique morphism $\Phi \colon Z \to L$ that makes the diagram commute.

Here the symbol "$\lrcorner$" indicates that L is the pullback of the diagram.

Example. We consider the following pullback diagram in the category of groups:

$$\begin{array}{ccc} & & G \\ & & \downarrow{\scriptstyle \varphi} \\ \{e\} & \longrightarrow & H \end{array}$$

one can easily show that the corresponding pullback is given by

$$\begin{array}{ccc} \ker(\varphi) & \longrightarrow & G \\ \downarrow & \lrcorner & \downarrow{\scriptstyle \varphi} \\ \{e\} & \longrightarrow & H \end{array}$$

Lemma 4.6. (Pullback Lemma) Let $\mathcal{C}$ be a category.

(1) Let

$$\begin{array}{ccc} L & \xrightarrow{f_X} & X \\ {\scriptstyle f_Y}\downarrow & \lrcorner & \downarrow{\scriptstyle \varphi_X} \\ Y & \xrightarrow[\varphi_Y]{} & A. \end{array}$$

be a pullback.
(a) If φ_X is an isomorphism, then so is the "opposite" morphism f_Y.
(b) If φ_Y is an isomorphism, then so is the "opposite" morphism f_X.

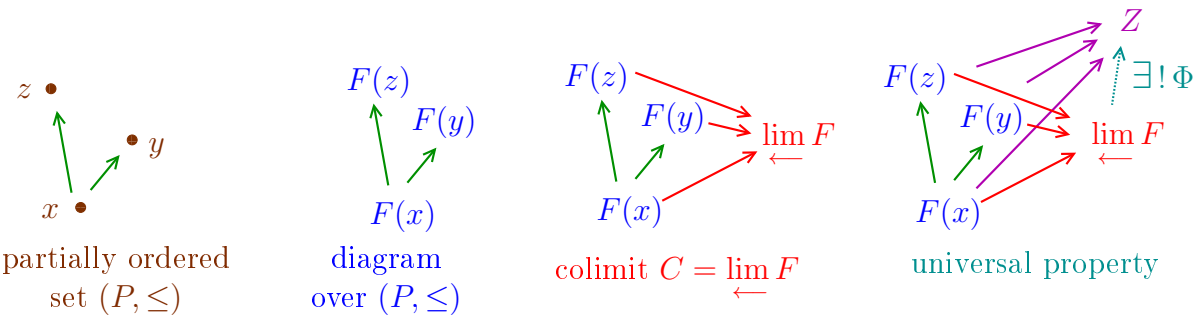
(2) If we are given pullbacks

$$\begin{array}{ccc} L & \xrightarrow{f_X} & X \\ {\scriptstyle f_Y}\downarrow & \lrcorner & \downarrow{\scriptstyle \varphi_X} \\ Y & \xrightarrow{\varphi_Y} & A \end{array} \quad \text{and} \quad \begin{array}{ccc} X & \xrightarrow{\theta} & Z \\ {\scriptstyle \varphi_X}\downarrow & \lrcorner & \downarrow{\scriptstyle \psi_Z} \\ A & \xrightarrow{\psi_A} & B \end{array}$$

then the composition

$$\begin{array}{ccc} L & \xrightarrow{\theta \circ f_X} & Z \\ {\scriptstyle f_y}\downarrow & \lrcorner & \downarrow{\scriptstyle \psi_Z} \\ Y & \xrightarrow{\psi_A \circ \varphi_Y} & B \end{array}$$

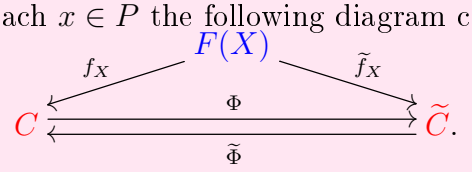
is also a pullback.



Proof. All statements follow from purely formal arguments which do not become clearer by writing them down. Thus we leave it to the reader to go through the argument. ■

4.4. **Colimits.** In this section we introduce the notion of a colimit, which is very similar to the notion of a limit, except that the directions of the morphisms are reversed.

Definition. Let $(P, \leq)$ be a partially ordered set, let $\mathcal{C}$ be a category and let F be a diagram in $\mathcal{C}$ over $(P, \leq)$. A colimit of F consists of an object $C \in \mathrm{Ob}(\mathcal{C})$ together with morphisms $f_x \colon F(x) \to C$ for each $x \in P$ such that the following two conditions are satisfied:



(1) For any $x \leq y$ we have $f_y = F(x \to y) \circ f_x \colon F(x) \to C$.
(2) The following universal property holds: If Z is an object in $\mathcal{C}$ and if we are given morphisms $g_x \colon F(x) \to Z$ for each $x \in P$ such that (1) is satisfied, then there exists a unique morphism $\Phi \colon C \to Z$ such that $g_x = f_x \circ \Phi$ for all $x \in P$.

If a colimit exists, then often we denote it by $\varinjlim F$, or by sensible variations thereof.

Not surprisingly we have the following analogue of the Limit Uniqueness Lemma 4.5.

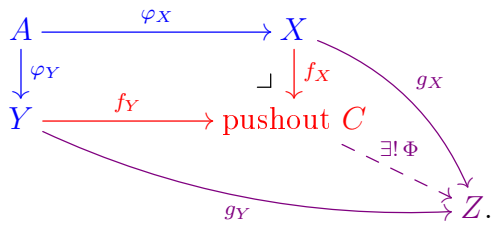
Lemma 4.7. (Colimit Uniqueness Lemma) Let $(P, \leq)$ be a partially ordered set, let $\mathcal{C}$ be a category and let F be a diagram in $\mathcal{C}$ over $(P, \leq)$. Suppose that we are given two colimits $(C, \{f_x \colon F(x) \to C\}_{x \in P})$ and $(\widetilde{C}, \{\widetilde{f}_x \colon F(X) \to \widetilde{C}\}_{x \in P})$. Then there exist uniquely determined isomorphisms $\Phi \colon C \to \widetilde{C}$ and $\widetilde{\Phi} \colon \widetilde{C} \to C$ which are inverses of one another and such that for each $x \in P$ the following diagram commutes:

Proof. As always the proof follows easily from the definitions. ■

Example.

(1) If we consider a trivial partially ordered set $(P, \leq_{\mathrm{tr}})$, then the colimit is by definition precisely the coproduct.
(2) We consider $(\mathbb{N}, \leq)$ and we consider a diagram in the category *Set* of sets where each $\varphi_i \colon X_i \to X_{i+1}$ is an inclusion of subsets of a given set Y. In Exercise 4.8 we will see that in this case the colimit is the intersection of the X_i.

Next we introduce the analogue of the pullback.



Definition.

(1) We consider the set $P = \{0, x, y\}$ with the partial order that is given by the trivial relations $0 \leq 0, x \leq x, y \leq y$ and the non-trivial relations $0 \leq x$ and $0 \leq y$:

the partially ordered set $\begin{array}{ccc} 0 & \longrightarrow & x \\ \downarrow & & \\ y & & \end{array}$ gives rise to the pushout diagram $\begin{array}{ccc} F(0) & \xrightarrow{\varphi_x} & F(x) \\ \downarrow{\scriptstyle \varphi_y} & & \\ F(y) & & \end{array}$

(2) The colimit of a pushout diagram is called a pushout.

Remark. The following diagram summarizes the definition of a pushout:

(1) We start out with a pushout diagram.
(2) The pushout C comes with morphisms $f_X \colon X \to C$ and $f_Y \colon Y \to C$ such that the rectangle commutes.
(3) If we are given Z with morphisms $g_X \colon X \to Z$ and $g_Y \colon Y \to Z$ such that the big quadrilateral commutes, then there exists a unique morphism $\Phi \colon C \to Z$ that makes the diagram commute.

Here the symbol "⌟" indicates that C is the pushout of the diagram.

Remark. Note that by definition coproducts in $\mathcal{C}$ are products in the opposite category $\mathcal{C}^{\mathrm{op}}$. So we did not introduce a new concept at all.

Example. Let G be a group and let A be a normal subgroup. We consider the following pushout diagram in the category of groups:

$\begin{array}{ccc} A & \longrightarrow & \{e\} \\ \downarrow & & \\ G & & \end{array}$ one can easily show that the corresponding pushout is given by $\begin{array}{ccc} A & \longrightarrow & \{e\} \\ \downarrow & & \downarrow \\ G & \longrightarrow & G/A. \end{array}$

In Exercise 4.9 we will consider a generalization of this situation.

We conclude this section with the following analogue of the Pullback Lemma 4.6.

Lemma 4.8. (Pushout Lemma) Let $\mathcal{C}$ be a category.

(1) Let

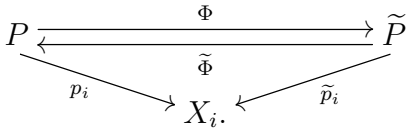
$$\begin{array}{ccc} A & \xrightarrow{\varphi_X} & X \\ \downarrow{\scriptstyle \varphi_Y} & & \downarrow{\scriptstyle f_X} \\ Y & \xrightarrow{f_Y} & C. \end{array}$$

be a pushout.

(a) If φ_X is an isomorphism, then so is the "opposite" morphism f_Y.

(b) If φ_Y is an isomorphism, then so is the "opposite" morphism f_X.

(2) If we are given pushouts



$$\begin{array}{ccc} A & \xrightarrow{\varphi_X} & X \\ {\scriptstyle \varphi_Y}\downarrow & \lrcorner & \downarrow{\scriptstyle f_X} \\ Y & \xrightarrow{f_Y} & L \end{array} \quad \text{and} \quad \begin{array}{ccc} X & \xrightarrow{\theta} & Z \\ {\scriptstyle f_X}\downarrow & \lrcorner & \downarrow{\scriptstyle g_Z} \\ L & \xrightarrow{g_L} & W \end{array} \quad \text{then the composition} \quad \begin{array}{ccc} A & \xrightarrow{\theta\circ\varphi_X} & Z \\ {\scriptstyle \varphi_Y}\downarrow & \lrcorner & \downarrow{\scriptstyle g_Z} \\ Y & \xrightarrow{g_L\circ f_Y} & W \end{array}$$

is also a pushout.

Proof. Again all statements follow from purely formal arguments which do not become clearer by writing them down. Thus we leave it to the reader to go through the argument. ■

Exercises for Chapter 4.

Exercise 4.1. Let $\mathcal{C}$ be a category and let $\{X_i\}_{i\in I}$ be a family of objects in $\mathcal{C}$. Suppose we are given two products $(P, \{p_i\colon P \to X_i\}_{i\in I})$ and $(\widetilde{P}, \{\widetilde{p}_i\colon \widetilde{P} \to X_i\}_{i\in I})$. Show that there exist uniquely determined isomorphisms $\Phi\colon P \to \widetilde{P}$ and $\widetilde{\Phi}\colon \widetilde{P} \to P$ which are inverses of one another and such that for each $i \in I$ the following diagram commutes:

Remark. This exercise is the content of the Product Uniqueness Lemma 4.1.

Exercise 4.2. Show that the category *Field* of fields does not admit products.

Exercise 4.3. Let *Metric* be the category of metric spaces where the objects are metric spaces and the morphisms are continuous maps.

(a) Do any two metric spaces X, Y admit a product in *Metric*?
(b) Do any two metric spaces X, Y admit a coproduct in *Metric*?

Exercise 4.4. Let $(P, \leq)$ be a partially ordered set. We consider the corresponding order category $\mathit{Order}_{(P,\leq)}$ as defined on page 196. What is the coproduct of a family $\{X_i\}_{i\in I}$ of objects in $\mathit{Order}_{(P,\leq)}$, if it exists.

Exercise 4.5. Does the coproduct of the rings $\mathbb{Z}_2$ and $\mathbb{Z}_3$ in the category *Ring* of rings exist, and if yes, what is it?

Exercise 4.6. A *pointed set* is a pair (X, x_0), where X is a set and x_0 is a point in X. We refer to the category *PSet* with

$$\begin{array}{rcl} \mathrm{Ob}(\mathit{PSet}) & := & \text{all pointed sets,} \\ \mathrm{Mor}((X,x_0),(Y,y_0)) & := & \text{all maps } f \text{ from } X \text{ to } Y \text{ with } f(x_0) = y_0 \end{array}$$

with the usual composition of maps as the *category of pointed sets*.

(a) Does the category of pointed sets admit an initial and a terminal object?

(b) Let (X, x_0) and (Y, y_0) be two pointed sets. Show that a product of (X, x_0) and (Y, y_0) in the category $\mathcal{PSet}$ is given by the set

$$(X \times Y)/\underbrace{((X \times \{y_0\}) \cup (\{x_0\} \times Y))}_{\substack{\text{the points in this subset get} \\ \text{identified to a single point } *}} \quad \text{together with the point} \quad *$$

and the obvious morphisms to (X, x_0) and (Y, y_0).

(c) Let (X, x_0) and (Y, y_0) be two pointed sets. What is the coproduct of (X, x_0) and (Y, y_0)?

Exercise 4.7. We consider the category $\mathcal{Group}$ of all groups. Show that in general for two groups A, B the product $A \times B$ is not the coproduct in the category $\mathcal{Group}$.
Remark. This exercise shows that the construction in the Coproduct-Sets-and-Abelian Groups Lemma 4.4 does not provide the coproduct in the category $\mathcal{Group}$.

Exercise 4.8. We consider the partially ordered set $(\mathbb{N}, \leq)$. Let Y be a set. Furthermore let $X_1 \subset X_2 \subset \ldots$ be a nested sequence of subsets of Y. For each $i \in \mathbb{N}$ we denote by $\varphi_i \colon X_i \to X_{i+1}$ the inclusion. The X_i and φ_i define a diagram over $(\mathbb{N}, \leq)$.

(a) Show that the limit of this diagram equals the union of the X_i.

(b) Show that the colimit of this diagram equals the intersection of the X_i.

Exercise 4.9. Let $\varphi \colon A \to G$ be a group homomorphism. What is the pushout of the following pushout diagram in the category of groups:

$$\begin{array}{ccc} A & \longrightarrow & \{e\} \\ {\scriptstyle\varphi}\downarrow & & \\ G & & \end{array}$$

Exercise 4.10. We consider the category $\mathcal{AbGroup}$ of abelian groups.

(a) Show that pullbacks always exist.

(b) Show that pushouts always exist.

Exercise 4.11. Let

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ {\scriptstyle g}\downarrow & \lrcorner & \downarrow{\scriptstyle r} \\ C & \xrightarrow{s} & X. \end{array}$$

be a pushout in the category $\mathcal{Set}$ of sets.

(a) We suppose that $f \colon A \to B$ is injective. Show that the opposite map $s \colon C \to X$ is also injective.

(b) If $f \colon A \to B$ is surjective, does it follow that the opposite map $s \colon C \to X$ is also surjective?

Exercise 4.12. Let $\mathcal{C}$ be some category. We consider the following commutative diagram of morphisms in $\mathcal{C}$:

$$\begin{array}{ccccc} A & \xrightarrow{\varphi} & B & \xrightarrow{\psi} & C \\ \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\gamma} \\ A' & \xrightarrow{\varphi'} & B' & \xrightarrow{\psi'} & C'. \end{array}$$

We suppose that the big rectangle forms a pushout square.

(a) We suppose that the square to the left is a pushout square. Show that the square to the right is also a pushout square.
(b) We suppose that the square to the right is a pushout square. Is the square to the left also a pushout square?

5. Constructions of topological spaces

In Chapter 4 we introduced the concepts of (co-) products and more generally (co-) limits in categories. In this chapter we will see how these concepts play out in the category of topological spaces.

5.1. The product of topological spaces.

In this section we will see that the category of topology spaces has products. It is convenient to recall the following definition from page 88.

Definition. Let $\{X_i\}_{i\in I}$ a family of sets. The product of these sets is defined as the set

$$\prod_{i\in I} X_i \;:=\; \left\{ f\colon I \to \bigcup_{i\in I} X_i \;\middle|\; \text{for every } i\in I \text{ we have } f(i)\in X_i \right\}.$$

Proposition 5.1. (Topological-Product Proposition) Let $\{X_i\}_{i\in I}$ be a family of topological spaces. We set

$$\mathcal{B} \;:=\; \left\{ \prod_{i\in I} U_i \;\subset\; \prod_{i\in I} X_i \;\middle|\; \begin{array}{ll} (1) & \text{each } U_i \text{ is open in } X_i \text{ and} \\ (2) & \text{there exist only finitely many } i\text{'s with } U_i \neq X_i \end{array} \right\}.$$

The following statements hold:

(0) The set $\mathcal{B}$ has the basis property that we introduced on page 132.

(1) (a) For any $i\in I$ the map

$$\begin{array}{rcl} p_i\colon \prod_{i\in I} X_i & \to & X_i \\ f & \mapsto & f(i) \end{array}$$

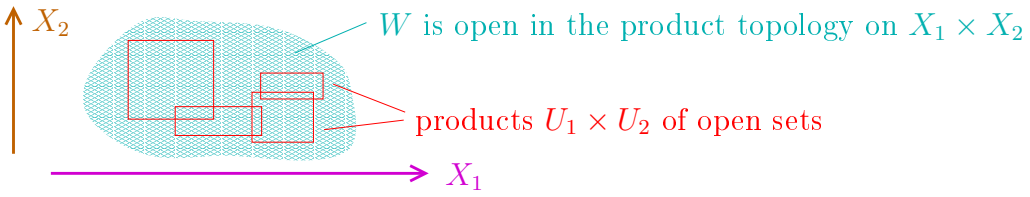
is continuous with respect to the topology from (0).

(b) Given a topological space Z and given a family $\{f_i\colon Z\to X_i\}_{i\in I}$ of continuous maps the map

$$\begin{array}{rcl} F\colon Z & \to & \prod_{i\in I} X_i \\ z & \mapsto & \begin{pmatrix} I & \to & \bigcup_{i\in I} X_i \\ i & \mapsto & f_i(z) \end{pmatrix}. \end{array}$$

is continuous with respect to the topology from (0).

(2) The topological space $\prod_{i\in I} X_i$ together with the natural projections p_i is a product (in the sense of the definition on page 211 of $\{X_i\}_{i\in I}$ in the category $\mathcal{T}op$ of topological spaces.



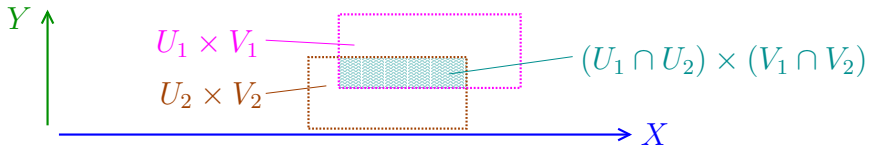
Example. It is worth considering the case we will use most frequently, namely the case that we are given finitely many topological spaces. Thus let $X_1,\dots,X_k$ be topological spaces. In this case the product topology on $X_1\times\cdots\times X_k$ is the topology on $X_1\times\cdots\times X_k$ that is generated by

$$\mathcal{B} \;=\; \{U_1\times\cdots\times U_k \,|\, \text{ each } U_i \text{ is open in } X_i\}.$$

Proof. Let $\{X_i\}_{i\in I}$ be a family of topological spaces.

(0) We need to verify that

$$\mathcal{B} \;:=\; \left\{ \prod_{i\in I} U_i \;\subset\; \prod_{i\in I} X_i \;\middle|\; \begin{array}{ll} (1) & \text{each } U_i \text{ is open in } X_i \text{ and} \\ (2) & \text{there exist only finitely many } i\text{'s with } U_i \neq X_i \end{array} \right\}$$



satisfies the conditions (B1) and (B2) formulated on page 132.

(B1) Evidently we have $\prod_{i\in I} X_i \in \mathcal{B}$. It follows immediately that $\mathcal{B}$ satisfies (B1).

(B2) Let $\prod_{i\in I} U_i$ and $\prod_{i\in I} V_i$ be two sets in $\mathcal{B}$. Then

$$\prod_{i\in I} U_i \;\cap\; \prod_{i\in I} V_i \;=\; \prod_{i\in I} \underbrace{(U_i \cap V_i)}_{\substack{\text{only finitely many} \\ \text{are} \neq X_i}}$$

is again a set in $\mathcal{B}$. Thus $\mathcal{B}$ also satisfies (B2).

(1) (a) It follows immediately from the definitions that the projection maps p_i are continuous with respect to the given topology.

(b) Suppose we are given a topological space Z and continuous maps $f_i\colon Z \to X_i$. We denote by $F\colon Z \to \prod_{i\in I} X_i$ the map that is given by $z \mapsto (i \mapsto f_i(z))$. We claim that F is continuous. By the Subbasis-Continuity Proposition 2.9 it suffices to verify that the preimage of any set in $\mathcal{B}$ is open. So let $\prod_{i\in I} U_i$ be a set in $\mathcal{B}$. By definition there exists a finite set $J \subset I$ such that $U_i = X_i$ for any $i \notin J$. Then

$$F^{-1}\Big(\prod_{i\in I} U_i\Big) \;=\; \bigcap_{i\in I} f_i^{-1}(U_i) \;=\; \bigcap_{j\in j} \underbrace{f_j^{-1}(U_j)}_{\text{open in } Z} \;=\; \begin{array}{c}\text{intersection of } \textit{finitely} \\ \text{many open subsets of } Z.\end{array}$$

This concludes the proof that F is continuous.

(2) Let Z be a topological space and let $\{f_i\colon Z \to X_i\}_{i\in I}$ be a family of continuous maps. It follows from the Product-Sets-and-Groups Lemma 4.2 that the map

$$\begin{array}{rcl} \Phi\colon Z & \to & \prod_{i\in I} X_i \\ z & \mapsto & (f_i(z))_{i\in I} \end{array}$$

is the unique map (of sets) $\Phi\colon Z \to \prod_{i\in I} X_i$ such that for each $i \in I$ we have $f_i = p_i \circ \Phi$. In (1b) we just showed that this map is fortunately continuous, so this shows that there exists a unique continuous map $\Phi\colon Z \to \prod_{i\in I} X_i$ such that for each $i \in I$ we have $f_i = p_i \circ \Phi$. This shows that the topological space $\prod_{i\in I} X_i$ together with the natural projections p_i is a product of $\{X_i\}_{i\in I}$ in the category $\mathcal{T}op$ of topological spaces. ■

Definition. Let $\{X_i\}_{i\in I}$ a family of topological spaces. We refer to the topology on the set $\prod_{i\in I} X_i$ that we defined in the Topological-Product Proposition 5.1 (0) as the product topology on $\prod_{i\in I} X_i$.

Example. It follows from the Topological-Product Proposition 5.1 (1a) and (1b) that given any topological space X the

diagonal map $\begin{array}{rcl} d\colon X & \to & X\times X \\ x & \mapsto & (x,x) \end{array}$ and the projection $\begin{array}{rcl} p\colon X\times X & \to & X \\ (x,y) & \mapsto & x \end{array}$

are continuous. Since $p\circ d = \mathrm{id}_X$ we see that $d\colon X\to X\times X$ is an embedding. This fact will come in handy on many occasions.

The following remark can be viewed as a sibling of the future Remark 5.17.

Remark 5.2. We consider maps in and out of a product space $X_1\times X_2$:

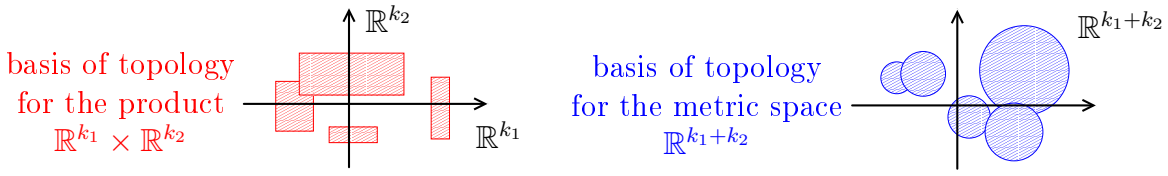
(1) The Topological-Product Proposition 5.1 gives us an easy to show that a given map $X\to X_1\times X_2$ to a product space is continuous. More precisely, by the Topological-Product Proposition 5.1 (1b) we "just" need to show that the two coordinate maps $X\to X_1$ and $X\to X_2$ are continuous.

(2) There is usually no easy way to show that a map $X_1\times X_2\to X$ out of a product space is continuous.

The following lemma gives us a reinterpretation of the product topology in some of the most frequently studied cases.

Lemma 5.3. (Product Metric Lemma)

(1) Let $(X_1,d_1),\dots,(X_m,d_m)$ be metric spaces. We define the product metric d on $X_1\times\cdots\times X_m$ as follows:



$$d((x_1,\dots,x_m),(y_1,\dots,y_m)) \;:=\; \sum_{i=1}^{m} d_i(x_i,y_i).$$

The product topology on $X_1\times\cdots\times X_m$ agrees with the metric topology coming from the product metric.

(2) Let $k_1,\dots,k_m\in\mathbb{N}_0$. The map

$$\begin{array}{ccc} \overbrace{\mathbb{R}^{k_1}\times\cdots\times\mathbb{R}^{k_m}}^{\text{product of Euclidean topologies}} & \to & \overbrace{\mathbb{R}^{k_1+\cdots+k_m}}^{\text{Euclidean topology}} \\ ((x_1,\dots,x_{k_1}),\dots,(x_1,\dots,x_{k_m})) & \mapsto & (x_1,\dots,x_{k_1},\dots,x_1,\dots,x_{k_m}) \end{array}$$

is a homeomorphism. The analogous statement also holds if we replace "$\mathbb{R}$" by "$\mathbb{C}$".

Remark. As we just pointed out, by design the product topology is set up in such a way that it is usually easy to show that a map into a product is continuous. On the other hand, except for the projections there is no obvious way to show that a map out of a product of

topological spaces is continuous. This is where the Product Metric Lemma 5.3 comes in. If we want to show that a map out of the product topological space $\mathbb{R}^k \times \mathbb{R}^l$ is continuous, it suffices to show that the map from $\mathbb{R}^{k+l}$ is continuous, which is often easier, since we can use the tools that we acquired in analysis.

Proof.

(1) This statement can be proved using the Subbasis Lemma 1.28. We will fill in the details in Exercise 5.1.

(2) Note that it follows from (1) that it suffices to show that the product metric on $\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_m}$ and the Euclidean metric on $\mathbb{R}^{k_1+\cdots+k_m}$ define the same topology. This in turn follows easily from the Equivalent Metric Lemma 1.2. We leave it to the reader to fill in the details. ■

Convention. Henceforth, given $k_1, \ldots, k_m \in \mathbb{N}_0$ we will always identify the product topological space $\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_m}$ with $\mathbb{R}^{k_1+\cdots+k_m}$. In particular, given $X_i \subset \mathbb{R}^{k_i}$, $i = 1, \ldots, m$, we view $X_1 \times \cdots \times X_m$ as a subspace of $\mathbb{R}^{k_1+\cdots+k_m}$.

Example. It follows almost immediately from the definition of the topology on the matrix $\mathrm{M}(r \times s, \mathbb{R})$ on page 171, the examples on page 141 and the Product Metric Lemma 5.3 (2) that for any $k, l, m \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{M}(k \times l, \mathbb{R}) \times \mathrm{M}(l \times m, \mathbb{R}) & \to & \mathrm{M}(k \times m, \mathbb{R}) \\ (A, B) & \mapsto & A \cdot B \end{array}$$

is continuous. The same also applies to matrices over $\mathbb{C}$.

After these examples let us turn to the study of the more formal properties of the product topology. On several occasions we will use, consciously or unconsciously, the following lemma.

Lemma 5.4. (Product Topology-Basics Lemma)

(1) Let $\{Y_i\}_{i \in I}$ be a family of topological spaces.

(a) Let $j \in I$ and for $k \neq j$ let $y_k \in Y_k$. The inclusion map

$$\begin{array}{rcl} Y_i & \to & \prod\limits_{i \in I} Y_i \\ y & \mapsto & \left(\begin{array}{rcl} I & \to & \bigcup\limits_{i \in I} X_i \\ i & \mapsto & \begin{cases} y, & \text{if } i = j, \\ y_j & \end{cases} \end{array} \right). \end{array}$$

is continuous and it is an embedding.[64]

(b) If $f_i \colon Y_i \to Z_i$, $i \in I$ are continuous maps between topological spaces, then the map

$$\begin{array}{rcl} \prod\limits_{i \in I} f_i \colon \prod\limits_{i \in I} Y_i & \to & \prod\limits_{i \in I} Z_i \\ (y_i)_{i \in I} & \mapsto & (f(y_i))_{i \in I} \end{array}$$

is continuous.

(2) If we are given families of topological spaces $\{\{X_i\}_{i \in I_j}\}_{j \in J}$, then the obvious map

$$\prod_{j \in J} \left(\prod_{i \in I_j} X_i \right) \to \prod_{i \in \bigsqcup_{j \in J} I_j} X_i$$

is a homeomorphism.

(3) If $\{X_i\}_{i\in I}$ is a family of topological spaces and if for each $i \in I$ we are given a basis $\mathcal{B}_i$ of the topological space X_i, then

$$\mathcal{C} \;=\; \left\{ \prod_{i\in I} U_i \;\subset\; \prod_{i\in I} X_i \;\middle|\; \begin{array}{ll} (1) & \text{each } U_i \neq X_i \text{ is contained in } \mathcal{B}_i \text{ and} \\ (2) & \text{there exist only finitely many } i\text{'s with } U_i \neq X_i \end{array} \right\}$$

is a basis for $\prod_{i\in I} X_i$. If I is finite, then we can restrict ourselves to the case that the U_i are always in $\mathcal{B}_i$.

(4) The product topology commutes with subspace topology. More precisely, let $\{X_i\}_{i\in I}$ be a family of topological spaces and for each $i \in I$ let A_i be a subset. Then the subspace topology of $\prod_{i\in I} A_i \subset \prod_{i\in I} X_i$ agrees with product topology on $\prod_{i\in I} A_i$

Example.

(1) On page 135 we saw that the *rational* intervals form a basis for the usual topology on $\mathbb{R}$. It follows from the Product Topology-Basics Lemma 5.4 (4) that the set $\mathcal{B}$ of rational hyperrectangles, i.e. that the set

$$\mathcal{B} \;=\; \{\text{hyperrectangle } [a_1, b_1] \times \cdots \times [a_k, b_k] \,|\, a_1, \ldots, a_k, b_1, \ldots, b_k \in \mathbb{Q}\} \;\subset\; \mathcal{P}(\mathbb{R}^k)$$

forms a basis for the standard topology on $\mathbb{R}^k$. It follows from this observation together with the Countability Lemma 0.8 (5) that $\mathbb{R}^k$ admits a basis for the topology that consists of only countably many sets.

(2) Let $s_1, \ldots, s_n \in \mathbb{N}_0$. We set $s = s_1 + \cdots + s_n$. It follows from the Product Topology-Basics Lemma 5.4 (4) and the Product Metric Lemma 5.3 (2) that we can view $B^{s_1} \times \cdots \times B^{s_n}$ as a subspace of $\mathbb{R}^s$. By definition this is an open subset of $\mathbb{R}^s$ and one verifies easily that it is convex and bounded. Thus it follows from the Convex-to-Ball Proposition 2.20 that there exists a canonical homeomorphism $B^{s_1} \times \cdots \times B^{s_n}$ to the ball B^s that sends $(0, \ldots, 0)$ to the origin. The same statement holds for the corresponding closed balls.

Proof.

(1) (a) This statement follows from the Topological-Product Proposition 5.1 (1b) and the observation that the identity map and the constant map are both continuous.

(b) It follows from Lemma 2.1 and the Topological-Product Proposition 5.1 (1a) that the maps $\prod_{i\in I} Y_i \to Z_j$ given by $(y_i)_{i\in I} \mapsto f_j(y_j)$ are continuous. Thus it follows from Topological-Product Proposition 5.1 (1b) that the given map is continuous.

(2) It now follows from the Topological-Product Proposition 5.1 (1b) that the given map $Y_1 \times \cdots \times Y_k \to Z_1 \times \cdots \times Z_k$ is continuous.

(3) The main idea is to prove the lemma using the Basis Characterization Lemma 1.32 (1). First note that by definition the maps in $\mathcal{C}$ are open. Next let $W \subset \prod_{i\in I} X_i$ be an open subset and let $(x_i)_{i\in I} \in W$. By definition of the product topology there exist open sets $V_i \subset X_i$, $i \in I$ such that $X_i = V_i$ for all but finitely many $i \in I$ and

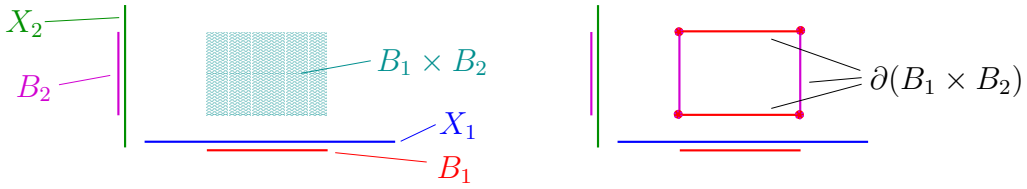
[64] Recall that "embedding" means that the map is a homeomorphism onto its image, in our setting this means that the inclusion map defines a homeomorphism $Y_i \to \{y_1\} \times \cdots \times \{y_{i-1}\} \times Y_i \times \{y_{i+1}\} \times \cdots \times \{y_k\}$.

such that $(x_i)_{i\in I} \subset \prod_{i\in I} V_i \subset W$. Since $\mathcal{B}_i$ is a basis for X_i we see that for each i with $V_i \neq X_i$ there exists a $U_i \in \mathcal{B}_i$ with $x \in U_i \subset V_i$. For all other i we set $U_i = V_i = X_i$. It follows that

$$(x_i)_{i\in I} \in \prod_{i\in I} U_i, \subset \prod_{i\in I} V_i \subset W.$$

We deduce from the Basis Characterization Lemma 1.32 (1) that the given set $\mathcal{C}$ is indeed a basis for $\prod_{i\in I} X_i$. ■

Example. Let X be a topological space and let $\{P\}$ be the topological space consisting of a single point P (note that $\{P\}$ has a unique topological structure!). It follows from the Product Topology-Basics Lemma 5.4 (1a) that the natural bijection $X \to X \times \{P\}$ is a homeomorphism. On many occasions we will use this homeomorphism to make the identification $X = X \times \{P\}$.



5.2. **Properties of products of topological spaces I.** Throughout these notes we will almost invariably only work with the product of finitely many topological spaces. In this section we will therefore discuss properties of the product of finitely many topological spaces. This simplifies some of the arguments and it makes the notation arguably more natural. In the following section we will, for completeness sake, also discuss some of the properties of products of arbitrarily many topological spaces.

Lemma 5.5. (Product-of-Subsets Lemma) Let $X_1, \ldots, X_k$ be topological spaces.

(1) If $A_i \subset X_i$, $i = 1, \ldots, k$ are closed subsets, then $A_1 \times \cdots \times A_k$ is a closed subset of $X_1 \times \cdots \times X_k$.

(2) Let $B_i \subset X_i$, $i = 1, \ldots, k$ be subsets. The following equalities hold:

$$\begin{aligned}
\text{closure of } B_1\times\ldots\times B_k \text{ in } X_1\times\ldots\times X_k &= \overline{B}_1\times\ldots\times\overline{B}_k\\
\text{interior of } B_1\times\ldots\times B_k \text{ in } X_1\times\ldots\times X_k &= \mathring{B}_1\times\ldots\times\mathring{B}_k\\
\text{boundary of } B_1\times\ldots\times B_k \text{ in } X_1\times\ldots\times X_k &= \bigcup_{i=1}^{k} (\overline{B}_1\times\ldots\times\partial B_i\times\ldots\times\overline{B}_k).
\end{aligned}$$

Proof.

(1) We have

$$(X_1 \times \cdots \times X_k) \setminus (A_1 \times \cdots \times A_k) \overset{\text{basic set theory}}{=} \bigcup_{i=1}^{k} \underbrace{X_1 \times \cdots \times (X_i \setminus A_i) \times \cdots \times X_k}_{\text{open in } X_1\times\cdots\times X_k \text{ since } A_i \text{ is closed}}.$$

Thus we see that $(X_1 \times \cdots \times X_k) \setminus (A_1 \times \cdots \times A_k)$ is the intersection of finitely many open sets, i.e. the set itself is open, which implies by definition that $A_1 \times \cdots \times A_k$ is closed.

(2) We will verify this statement in Exercise 5.8. ■

The next proposition deals with some of our favorite properties of topological spaces.

Proposition 5.6. (Product Topology Properties Proposition) Let $X_1, \ldots, X_k$ be non-empty topological spaces.

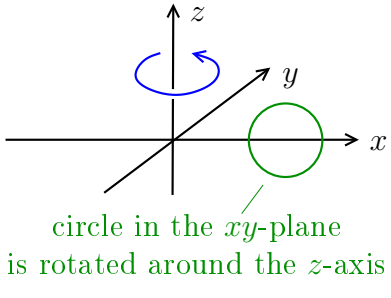
(1) The product $X_1 \times \cdots \times X_k$ is Hausdorff if and only if each X_i is Hausdorff.
(2) The product $X_1 \times \cdots \times X_k$ is compact if and only if each X_i is compact.
(3) The product $X_1 \times \cdots \times X_k$ is (path)-connected if and only if each X_i is (path)-connected.

Remark. The Product Topology Properties Proposition 5.6 (2) also shows how the case $n = 1$ in the Hyperrectangle-Compact Proposition 1.26 implies the general case of the Hyperrectangle-Compact Proposition 1.26.

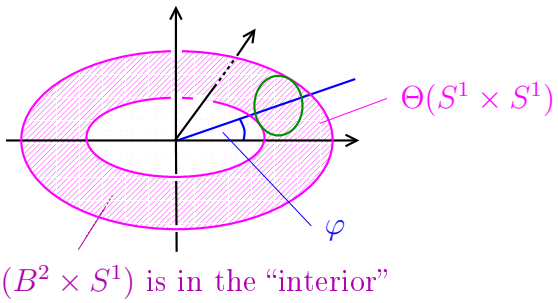
Before we head to the proof of the Product Topology Properties Proposition 5.6 let us first discuss some examples in detail.

Definition.

(1) We refer to $(S^1)^n$ as the n-dimensional torus. For $n = 2$ we just say the torus.
(2) We refer to $S^1 \times \overline{B}^2$ as the solid torus and we refer to $S^1 \times B^2$ as the open solid torus.



We deduce from the Product Topology Properties Proposition 5.6 that the n-dimensional torus $(S^1)^n$ and the solid torus $S^1 \times \overline{B}^2$ are compact.

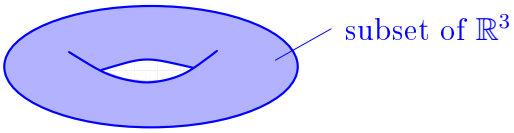


The following lemma allows us to view (solid) tori as subspaces of $\mathbb{R}^3$.

Lemma 5.7. We consider the map[65]

$$\begin{array}{rcl} \Theta\colon \mathbb{R}^2 \times S^1 & \to & \mathbb{R}^3 \\ ((x,y),\exp(\mathrm{i}\varphi)) & \mapsto & \underbrace{\begin{pmatrix} \cos\varphi & -\sin\varphi & 0 \\ \sin\varphi & \cos\varphi & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{\text{rotation around } z\text{-axis}} \cdot \underbrace{\begin{pmatrix} 1+\frac{1}{2}x \\ 0 \\ -\frac{1}{2}y \end{pmatrix}}_{\substack{\text{describes circle} \\ \text{in } xz\text{-plane}}} \end{array}$$

The restrictions of Θ to $S^1 \times S^1$, $\overline{B}^2 \times S^1$ and $B^2 \times S^1$ are embeddings.



Proof. It follows easily from the example on page 227 that the map $\Theta\colon S^1 \times \mathbb{R}^2 \to \mathbb{R}^3$ is continuous. An elementary argument shows that the restriction of Θ to $\overline{B}^2 \times S^1$ is injective. Since the solid torus $\overline{B}^2 \times S^1$ is compact we obtain from the Compact-Hausdorff

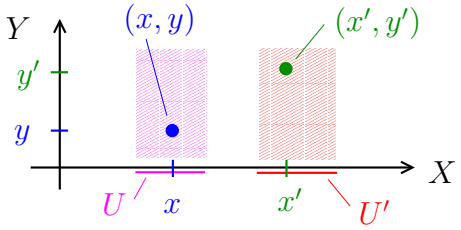
[65] The map is chosen in such a way that it is orientation-preserving (we will introduce the notions of orientation and orientation-preserving later on page 682) and such that $\Theta(\{(0,0)\} \times S^1) = S^1 \times \{0\}$.

Proposition 2.17 (3) that the restriction of Θ to $\Theta\colon \overline{B}^2 \times S^1 \to \Theta(S^1 \times \overline{B}^2)$ is a homeomorphism. But then it follows also that the restrictions of Θ to $S^1 \times S^1$ and $B^2 \times S^1$ are embeddings. ■

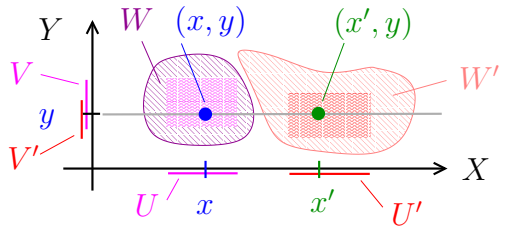
Remark. Lemma 5.7 allows us to view (solid) tori as subspaces of $\mathbb{R}^3$. We refer to the images under these maps as the *standard* (*solid*) (*open*) *torus in* $\mathbb{R}^3$. Unfortunately, in a picture, it is hard to distinguish between tori, solid tori and open solid tori.

$S^1 \times S^1$ is homeomorphic to 

Now the time of procrastination is over, we need to provide the proof of the Product Topology Properties Proposition 5.6.



Proof of the Product Topology Properties Proposition 5.6 (1). By induction we only have to deal with the case $k = 2$. Thus let X and Y be two non-empty topological spaces.

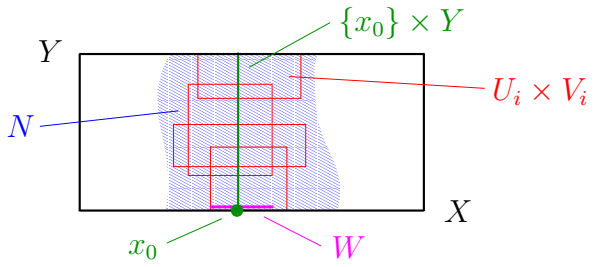


First we deal with the "$\Leftarrow$"-direction of Statement (1). Thus we assume that X and Y are Hausdorff. Let (x, y) and (x', y') be two distinct points in $X \times Y$. Without loss of generality we can assume that $x \neq x'$. By our hypothesis there exist open neighborhoods U of x and U' of x' with $U \cap U' = \varnothing$. Note that

$$(U \times Y) \cap (U' \times Y) \;=\; (U \cap U') \times Y \;=\; \varnothing \times Y \;=\; \varnothing.$$

By definition of the product topology the sets $U \times Y$ and $U' \times Y$ are open in $X \times Y$. We have thus found disjoint open neighborhoods of (x, y) and (x', y'). Therefore $X \times Y$ is Hausdorff. (This argument is sketched in the figure below to the left.)

Now we deal with the "$\Rightarrow$"-direction of Statement (1). Therefore we suppose that $X \times Y$ is Hausdorff. We want to show that X is Hausdorff. Thus let x and x' be two different points in X. Since Y is non-empty there exists a $y \in Y$. Furthermore, since $X \times Y$ is Hausdorff there exist disjoint open neighborhoods W and W' of (x, y) and (x', y). By definition of the product topology there exist open neighborhoods U of x and U' of x' and open neighborhoods V of y and V' of y such that $(U \times V) \cap (U' \times V') = \varnothing$. In particular we see that $(U \times \{y\}) \cap (U' \times \{y\}) = \varnothing$. But this implies that $U \cap U' = \varnothing$. This implies that U and U' are disjoint open neighborhoods of x and x'. Thus we have shown that X is Hausdorff. (This argument is sketched in the figure below to the right.) The proof that Y is also Hausdorff is evidently basically the same. ■



Proof of the Product Topology Properties Proposition 5.6 (2). As in the proof of Statement (1) we only need to deal with the case $k = 2$. Thus let X and Y be two non-empty topological spaces. The "$\Rightarrow$"-direction of Statement (2) is fortunately elementary: if $X \times Y$ is compact, then it follows immediately from the Topological-Product Proposition 5.1 (1a) and the Compact Image Lemma 2.13 (1).
Next we deal with "$\Leftarrow$"-direction of Statement (2). This is by far the hardest part of the proposition. So we now assume that X and Y are both compact. We need to show that $X \times Y$ is compact. We start out with the following claim.

Claim. Let $x_0 \in X$. If N is an open set of $X \times Y$ that contains $\{x_0\} \times Y$, then there exists a neighborhood W of $x_0 \in X$ such that $W \times Y \subset N$.

Proof. By definition of the product topology there exist sets of the form $U_i \times V_i$, $i \in I$ with the following properties:

(1) each U_i is open in X and each V_i is open in Y,
(2) each U_i contains x_0, i.e. for each i we have $\{x_0\} \times V_i \subset U_i \times V_i$,
(3) each $U_i \times V_i$ is contained in N,
(4) $\{x_0\} \times Y$ is contained in the union of the $U_i \times V_i$.

Since $\{x_0\} \times Y$ is compact we can arrange that I is a finite set, i.e. we can assume that $I = \{1, \ldots, n\}$. We set $W = U_1 \cap \cdots \cap U_n$. This is an open subset of X that contains x_0. It follows immediately from (3) and the definition of W that $W \times Y \subset N$. ⊞

Now we turn to the actual proof that $X \times Y$ is compact. Thus suppose we are given an open cover $\{A_i\}_{i \in I}$ of $X \times Y$. Let $x \in X$. Since Y is compact there exists a finite set $I(x) \subset I$ such that $\{x\} \times Y \subset \bigcup_{i \in I(x)} A_i$. By the above claim there exists an open neighborhood $W(x)$ of x such that $W(x) \times Y \subset \bigcup_{i \in I(x)} A_i$.

All these open sets $\{W(x)\}_{x \in X}$ are an open cover of X. Since X is compact there exist $x_1, \ldots, x_k \in X$ such that $X = W(x_1) \cup \cdots \cup W(x_k)$. But then we see that

$$X \times Y \;=\; (W(x_1) \cup \cdots \cup W(x_k)) \times Y \;=\; \bigcup_{j=1}^{k} W(x_j) \times Y \;\subset\; \bigcup_{j=1}^{k} \bigcup_{i \in I(x_j)} A_i \;\subset\; X \times Y.$$

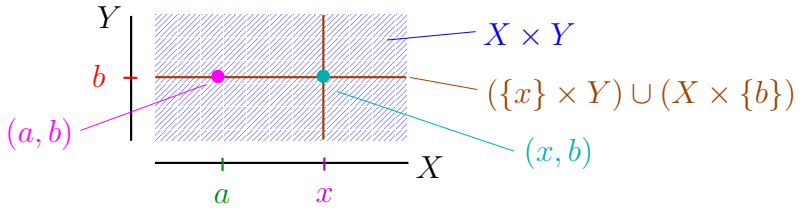
Thus we have successfully covered $X \times Y$ by finitely many sets in the given open cover. ■

Proof of the Product Topology Properties Proposition 5.6 (3). As in the proof of Statement (1) we only need to deal with the case $k = 2$. Thus let X and Y be two non-empty topological spaces.

The "$\Rightarrow$"-direction of Statement (3) is once again basically elementary, Indeed, if $X \times Y$ is (path)-connected, then it follows immediately from the Image-Connected Lemma 2.24

applied to the projections $X \times Y \to X$ and $X \times Y \to Y$, that X and Y are (path)-connected.[66]

Next we deal with "$\Leftarrow$"-direction of Statement (3). First we suppose that X and Y are path-connected. We need to show that $X \times Y$ is also path-connected. Thus let (x, y) and (x', y') be two points in $X \times Y$. Since X is path-connected we can find a path $p\colon [0,1] \to X$ from x to x' and similarly we can find a path $q\colon [0,1] \to Y$ from y to y'. Then



$$\begin{array}{rcl} [0,1] & \to & X \times Y \\ t & \mapsto & \begin{cases} (p(2t), y), & \text{if } t \in [0, \frac{1}{2}], \\ (x', q(2t-1)), & \text{if } t \in (\frac{1}{2}, 1] \end{cases} \end{array}$$

is a path from (x, y) to (x', y').[67]

Finally suppose that X and Y are connected. We want to show that $X \times Y$ is also connected. We pick $a \in X$ and $b \in Y$. Let $x \in X$. Note that the subsets $\{x\} \times Y$ and $X \times \{b\}$ are connected by our hypothesis. Since these have the point (x, b) in common we deduce from the Union Connected Lemma 2.28 (2) that $(\{x\} \times Y) \cup (X \times \{b\})$ is also connected. Note that

$$X \times Y = \bigcup_{x \in X} (\{x\} \times Y) \cup (X \times \{b\}).$$

All the sets on the right are connected and they have the point (a, b) in common. Thus it follows again from the Union Connected Lemma 2.28 (2) that the union on the right-hand side is connected. ■

5.3. **Properties of products of topological spaces II.** In this section we now return to the study of the product of arbitrarily many topological spaces. We will not bother with formulating the generalization of the Product-of-Subsets Lemma 5.5. Instead we jump straight to the following generalization of the Product Topology Properties Proposition 5.6.

Proposition 5.8. (Product Topology Properties Proposition) Let $\{X_i\}_{i \in I}$ be a family of non-empty topological spaces.

(1) The product $\prod_{i \in I} X_i$ is Hausdorff if and only if each X_i is Hausdorff.

(2) The product $\prod_{i \in I} X_i$ is compact if and only if each X_i is compact.

(3) The product $\prod_{i \in I} X_i$ is (path)-connected if and only if each X_i is (path)-connected.

[66] Note that the projections are surjective since we assume that X and Y are non-empty.

[67] It follows from the Topological-Product Proposition 5.1 (1b) and the Pasting Proposition 2.6 (2) that this map is indeed continuous.

Proof. The proof of all statements of the Product Topology Properties Proposition 5.8 is basically the same as the proof of the corresponding statements of the Product Topology Properties Proposition 5.6, *except*, for the "if"-direction of the Product Topology Properties Proposition 5.8 (2). This proof is now considerably harder and thus the proposition gets upgraded to a theorem, which we formulate below. ■

Theorem 5.9. (Tychonoff's Theorem[68]) The product of arbitrarily many compact spaces is again a compact space.

Remark. The theorem has its origin in the work of Andrey Tikhonov [**Tyc1935**]. The spelling for the theorem is due to the fact that Tikhonov initially published in German and his name got transcribed from the Cyrillic alphabet to the Latin alphabet as Tychonoff.

Sketch of proof. We will not really make use of Tychonoff's Theorem, therefore we limit ourselves to a proof for $I = \mathbb{N}$. Thus let $\{X_i\}_{i\in\mathbb{N}}$ be a family of compact spaces. Furthermore let $\{U_j\}_{j\in J}$ be a family of open sets of $\prod\limits_{i\in\mathbb{N}} X_i$ such that we cannot cover $\prod\limits_{i\in\mathbb{N}} X_i$ by finitely many sets in the given open cover $\{U_j\}_{j\in J}$. We need to show that $\{U_j\}_{j\in J}$ is not a cover of $\prod\limits_{i\in\mathbb{N}} X_i$. In other words, we need to show that $\bigcup\limits_{j\in J} U_j$ is a proper subset of $\prod\limits_{i\in\mathbb{N}} X_i$.

Claim 1. There exist $x_i \in X_i$, $i \in \mathbb{N}$ with the following property: Given any $k \in \mathbb{N}$ and given any open neighborhoods V_i of x_i, $i = 1, \dots, k$ the product

$$V_1 \times \cdots \times V_k \times X_{k+1} \times X_{k+2} \times \dots$$

cannot be covered by finitely many sets in the given open cover.

Proof. Suppose that for some $k \in \mathbb{N}_0$ we have already found $x_i \in X_i$, $i = 1, \dots, k$ with the desired properties. Suppose there is no such $x_{k+1} \in X_{k+1}$. This means that for every $y \in X_{k+1}$ there exist open neighborhoods $V_1^y, \dots, V_k^y, V_y^y$ of $x_1, \dots, x_k, y$ such that $\underbrace{V_1^y \times \cdots \times V_k^y \times V_y^y}_{=:W^y} \times X_{k+2} \times \dots$ can be covered by finitely many of the U_j, i.e. there exists a finite subset $J_y \subset J$ such that $W^y \times X_{k+2} \times \cdots \subset \bigcup\limits_{j\in J_y} U_j$.

Note that $\{W^y\}_{y\in V_{k+1}}$ is an open cover of $X_1 \times \cdots \times X_{k+1}$. By the original Product Topology Properties Proposition 5.6 (2) we know that $X_1 \times \cdots \times X_{k+1}$, as the product of *finitely many* compact topological spaces is compact. This implies that there exists a finite subset $Y \subset V_{k+1}$ such that $\bigcup\limits_{y\in Y} W_y = X_1 \times \cdots \times X_{k+1}$. But this means that

$$\begin{aligned}\prod_{i\in\mathbb{N}} X_i \;&=\; (X_1 \times \cdots \times X_{k+1}) \times \prod_{i=k+2}^{\infty} X_i \;=\; \Big(\bigcup_{y\in Y} W_y\Big) \times \prod_{i=k+2}^{\infty} X_i \\ &= \bigcup_{y\in Y} \Big(W_y \times \prod_{i=k+2}^{\infty} X_i\Big) \;\subset\; \bigcup_{y\in Y} \bigcup_{j\in J_y} U_j.\end{aligned}$$

Recall that Y is finite and that each J_y is finite. We have thus obtained contradiction to our hypothesis that $\prod\limits_{i\in\mathbb{N}} X_i$ cannot be covered by finitely many of the U_j. ⊞

The following claim concludes the proof of the theorem for $I = \mathbb{N}$.

Claim 2. The point $(x_1, x_2, \dots) \in \prod\limits_{i\in\mathbb{N}} X_i$ does not lie in any of the U_j.

Proof. Suppose there exists a $j \in J$ with $(x_1, x_2, \dots) \in U_j$. By definition of the topology on $\prod_{i\in\mathbb{N}} X_i$, (see the Topological-Product Proposition 5.1 (0) together with the Topology-from-Basis Lemma 1.27) there exists a $k \in \mathbb{N}$ and open neighborhoods V_i of x_i, $i = 1, \dots, k$ such that

$$V_1 \times \cdots \times V_k \times X_{k+1} \times X_{k+2} \times \dots \subset U_j.$$

But by construction of $(x_1, x_2, \dots)$ this is impossible. ⊞

The proof of the general case of the Tychonoff Theorem can be done in a very similar way by equipping the index set I with a total order, which we can do by the Well-Ordering Theorem 0.7. We refer to [**Wri1994**] for details. Alternatively proofs of Tychonoff's Theorem are provided in most textbooks on general topology, see e.g. [**Mun1975**, Chapter 5.1] or [**Jä2005**, Chapter X]. A particularly concise proof is also given in [**Chf1992**]. Note that all proofs of the Tychonoff Theorem rely on the Axiom of Choice 0.1, in fact, as is shown in [**Je1973**, p. 26] or [**BTT2020**, Theorem 3.14], the Tychonoff Theorem is equivalent to the Axiom of Choice 0.1. ■

We continue with a very instructive example.

Example. We equip $\{0, 2\}$ with the discrete topology. We consider the map

$$\begin{aligned} \varphi\colon \prod_{i\in\mathbb{N}} \{0,2\} &\to C = \text{Cantor set from page 130} \\ (f\colon \mathbb{N} \to \{0,2\}) &\mapsto \sum_{i=1}^{\infty} \frac{f(i)}{3^i}. \end{aligned}$$

It is elementary to see that φ takes values in C. It is a refreshing exercise, left to the enthusiastic reader, to show that φ is a bijection. The left-hand side is compact by Tychonoff's Theorem 5.9 and the right-hand is evidently Hausdorff. In Exercise 5.21 we verify that φ is continuous. It thus follows from the Compact-Hausdorff Proposition 2.17 (3) that φ is a homeomorphism.

Initially the definition of the Cantor set is nicely explicit, but the definition looks rather arbitrary. The previous example gives a much more natural definition of the Cantor set, viewed as a topological space. Amazingly there exists a characterization of the Cantor set, up to homeomorphism, in terms of basic topological properties. To state the proposition we need two easy definitions.

Definition. Let X be a topological space. A point $x_0 \in X$ is called isolated if $\{x_0\}$ itself is an open subset.

Examples.

(1) We consider $X = \{\frac{1}{n} \mid n \in \mathbb{N}\} \cup \{0\}$. The only point in X that is not isolated is 0.
(2) One can easily verify that no point in the Cantor set is isolated.
(3) It follows immediately from the definitions that no point in $\prod_{i\in\mathbb{N}} \{0, 2\}$ is isolated.
(4) The topological spaces $\mathbb{Q}$ and $\mathbb{Q} \setminus \{0\}$ equipped with the subspace topology coming from $\mathbb{R}$ do not contain any isolated points.
(5) Let X be a topological space. If every point is isolated, then by definition X has the discrete topology. If X is furthermore finite, then it follows from the Compact-Discrete Lemma 1.22 (1) that X is finite.

Definition. A topological space X is called totally disconnected if the only connected subsets are the empty set and the subsets consisting of a single point.

Example. The following topological spaces are totally disconnected:

(1) Discrete spaces.
(2) The Cantor set.T
(3) the infinite product $\prod_{i\in\mathbb{N}}\{0,2\}$.
(4) The topological spaces $\mathbb{Q}$ and $\mathbb{Q}\setminus\{0\}$ equipped with the subspace topology coming from $\mathbb{R}$.

Here (1) is obvious and (4) was dealt with in Exercise 2.23. We will deal with the remaining two examples in Exercise 5.22.

We conclude this section with the following amusing proposition.

Proposition 5.10. Let X be a topological space that is compact and totally disconnected. If X contains no isolated points, then X is homeomorphic to the Cantor set.

Proof. We will not make use of the proposition, hence we will not prove it. A proof is for example given in [**Val2013**, Theorem 7.8] or [**Will1970**, Theorem 30.3]. ■

Example. By the above examples Proposition 5.10 implies not only that the Cantor set is homeomorphic to $\prod_{i\in\mathbb{N}}\{0,2\}$ but also to $\mathbb{Q}$ and $\mathbb{Q}\setminus\{0\}$. In particular we obtain the weird result that $\mathbb{Q}$ and $\mathbb{Q}\setminus\{0\}$ are homeomorphic.[69]

5.4. **The disjoint union of topological spaces.** In this section we will discuss the coproduct in the category of topological spaces. Before we get to topological spaces it is worth recalling the following definitions from page 88 and the Coproduct-Sets-and-Abelian Groups Lemma 4.4.

Definition. Let $\{A_i\}_{i\in I}$ be a family of sets.

(1) We define the disjoint union as the set

$$\bigsqcup_{i\in I} A_i := \bigcup_{i\in I}(A_i\times\{i\}).$$

As usual we take some liberties with the notation if we have finitely many sets.

(2) Given $i\in I$ we refer to the map $A_i\to\bigsqcup_{i\in I}A_i$ given by $a\mapsto(a,i)$ as the natural injection.

In the Coproduct-Sets-and-Abelian Groups Lemma 4.4 we saw that the disjoint union, together with the obvious natural injections, gives us the coproduct in the category of sets. In a second we will see that a very similar statement holds in the context of the category of topological spaces. But before we get to this point, let us introduce the following convention.

Convention. Let $\{A_i\}_{i\in I}$ be a family of sets. For any $i\in I$ we use the natural injection $A_i\to\bigsqcup_{i\in I}A_i$ to think of A_i as a subset of the disjoint union.

[69] In Exercise 1.11 you were challenged to prove directly that $\mathbb{Q}$ and $\mathbb{Q}\setminus\{0\}$ are homeomorphic?

Definition. Let $\{X_i\}_{i\in I}$ be a family of of topological spaces. The disjoint union topology on the disjoint union $\bigsqcup_{i\in I} X_i$ is defined by the condition that $U \subset \bigsqcup_{i\in I} X_i$ is open if and only if for each $i \in I$ the intersection $X_i \cap U$ is an open subset of X_i.[70]

The following proposition is the analogue of the Topological-Product Proposition 5.1.

Proposition 5.11. (Topological-Coproduct Proposition) Let $\{X_i\}_{i\in I}$ be a family of topological spaces. We equip the disjoint union $\bigsqcup_{i\in I} X_i$ with the disjoint union topology. For each $i \in I$ we denote by $\iota_i \colon X_i \to \bigsqcup_{i\in I} X_i$ the natural injection.

(1) (a) Each ι_i is continuous.
   (b) If Z is a topological space and if $\{f_i \colon X_i \to Z\}_{i\in I}$ is a family of continuous maps, then the map
$$\begin{array}{rcl} \bigsqcup_{i\in I} X_i & \to & Z \\ (x,i) & \mapsto & f_i(x) \end{array}$$
   is continuous.
(2) The topological space $\bigsqcup_{i\in I} X_i$ together with the natural injections ι_i is a coproduct of $\{X_i\}_{i\in I}$ in the category $\mathcal{T}op$ of topological spaces.

Proof.

(1) Both statements follow immediately from writing down the definitions.
(2) Let Z be a topological space and let $\{f_i \colon X_i \to Z\}_{i\in I}$ be a family of continuous maps. By the definition of the coproduct on page 214 we have to show that there exists a *unique* continuous map $\Phi \colon \bigsqcup_{i\in I} X_i \to Z$ such that for each $i \in I$ we have $f_i = \Phi \circ \iota_i$. In (1b) we defined such a map Φ and we saw that it is continuous. It remains to prove uniqueness. The proof of uniqueness is basically identical to the argument in the proof of the Coproduct-Sets-and-Abelian Groups Lemma 4.4 (1) where we dealt with the coproduct in the category of sets. ■

Convention. Let $\{X_i\}_{i\in I}$ be a family of topological spaces. Unless we say something else we equip the disjoint union $\bigsqcup_{i\in I} X_i$ with the disjoint union topology. We refer to this topological space as the disjoint union of the X_i.[71]

Lemma 5.12. Let $\{X_i\}_{i\in I}$ be a family of topological spaces.

(1) A subset $A \subset \bigsqcup_{i\in I} X_i$ is closed if and only if for each $i \in I$ the intersection $A \cap X_i$ is a closed subset of X_i.
(2) For each $i \in I$ the natural injection $\iota_i \colon X_i \to \bigsqcup_{i\in I} X_i$ is an embedding which is open and closed.

Proof.

---

[70] It follows very very easily from the definitions that this defines a topology on the set $\bigsqcup_{i\in I} X_i$.

[71] It would perhaps make more sense to refer to $\bigsqcup_{i\in I} X_i$ as the coproduct of the X_i. But we prefer to stick to the more classical name.

(1) The lemma follows immediately from the definition of the disjoint union topology together with Lemma 2.7.
(2) Let $i \in I$. It follows easily from the definition of the subspace topology that the natural injection $\iota_i \colon X_i \to \bigsqcup_{i\in I} X_i$ is an open map. Furthermore it follows from (1) that the natural injection is a closed map. It now follows from the Open -Injective Map Lemma 2.16 that the natural injection is an embedding which is open and closed. ■

The following lemma plays the role of the Product Topology Properties Proposition 5.6.

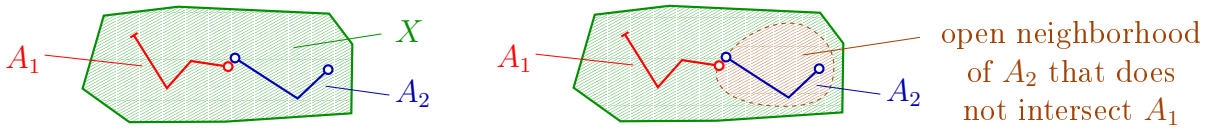
Lemma 5.13. (Disjoint Union Topology-Properties Lemma) Let $\{X_i\}_{i\in I}$ be a family of topological spaces.

(1) The disjoint union $\bigsqcup_{i\in I} X_i$ is Hausdorff if and only if each X_i is Hausdorff.
(2) The disjoint union $\bigsqcup_{i\in I} X_i$ is compact if and only if each X_i is compact and if there are only finitely many $i \in I$ such that $X_i \neq \varnothing$.
(3) The (path-) components of the disjoint union $\bigsqcup_{i\in I} X_i$ are precisely the (path-) components of the X_i.

Proof.

(1) This statement follows easily from the definitions
(2) We first prove the "if"-direction. Thus we assume that each X_i is compact and that there are only finitely many $i_1, \ldots, i_k \in I$ such that the corresponding topological space is non-empty. Let $\{U_j\}_{j\in J}$ be an open cover of $\bigsqcup_{i\in I} X_i$. Since each X_i is compact we can find for each $i \in I$ a finite subset $J_i \subset J$ such that $\bigsqcup_{j\in J_i} (U_j \cap X_i) = X_i$. It is now clear that $X = \bigcup_{r=1}^{k} \bigsqcup_{j\in J_{i_r}} U_j$.

We turn to the proof of the "only if"-direction. Thus we assume that $\bigsqcup_{i\in I} X_i$ is compact. It follows from the Disjoint Union Topology-Properties Lemma 5.13 (2) together with the Compact-Closed Lemma 1.21 (1) that each X_i is compact. Since the $\{X_i\}_{i\in I}$ form an open cover of the compact topological space $\bigsqcup_{i\in I} X_i$ we see that there exists a finite subset $J \subset I$ with $\bigsqcup_{j\in J} X_j = \bigsqcup_{i\in I} X_i$. In particular $X_i = \varnothing$ for $i \notin J$.
(3) This statement follows without too much effort from the Component Lemma 2.33. ■



The following lemma gives a criterion for showing that a union of subspaces is homeomorphic to the disjoint union of the subspaces.

Lemma 5.14. (Disjoint Union Embedding Lemma) Let X be a topological space and let $\{A_i\}_{i\in I}$ be a family of disjoint subsets of X. The following two statements are equivalent:

(1) For each $i \in I$ there exists an open neighborhood of $A_i \subset X$ that does not intersect any of the A_j with $j \neq i$.[72]
(2) The map

$$\begin{array}{ccc} \overbrace{\bigsqcup_{i\in I} A_i}^{\text{disjoint union topology}} & \to & \overbrace{\bigcup_{i\in I} A_i}^{\text{subspace of } X} \\ (a,i) & \mapsto & a \end{array}$$

is a homeomorphism.

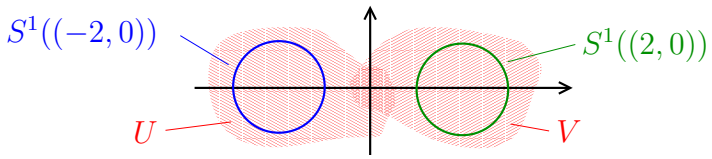
Proof. First we point out that the given map

$$\begin{array}{rccc} \Phi\colon & \bigsqcup_{i\in I} A_i & \to & \bigcup_{i\in I} A_i \\ & (a,i) & \mapsto & a \end{array}$$

is a bijection since the A_i are disjoint subsets of X. Since the inclusion maps $A_i \to \bigcup_{i\in I} A_i$ are continuous it follows from the Topological-Coproduct Proposition 5.11 that the above map Φ is continuous.

We first prove (1)⇒(2). Thus we assume that for each $i \in I$ there exists an open neighborhood V_i of $A_i \subset X$ that does not intersect any of the A_j with $j \neq i$. We need to show that Φ is a homeomorphism. By the above discussion and the Open-Injective Map Lemma 2.16 it remains to show that Φ is open. Thus let U be an open subset of $\bigsqcup_{i\in I} A_i$. By definition of the disjoint union topology each $A_i \cap U$ is an open subset of A_i. By the definition of the subspace topology on A_i this means that there exists an open subset W_i of X with $A_i \cap U = A_i \cap W_i$. We now see that

$$\begin{array}{rcccl} \Phi(U) & = & \Phi\Big(\bigsqcup_{i\in I}(A_i\cap U)\Big) & \overset{\text{definition of }\Phi}{=} & \bigsqcup_{i\in I}(A_i\cap U) \overset{\text{since } A_i\subset V_i \text{ and since } A_j\cap V_i=\varnothing \text{ for } i\neq j}{=} \bigsqcup_{i\in I}((A_i\cap U)\cap V_i) \\ & = & \bigsqcup_{i\in I}((A_i\cap(V_i\cap W_i)) & = & \Big(\bigcup_{i\in I} A_i\Big)\cap\Big(\bigcup_{j\in J}(V_j\cap W_j\Big). \\ & & \uparrow \text{choice of } W_i & & \uparrow \text{since } A_i\subset V_i\cap W_i \text{ and since } A_i\cap(V_j\cap W_j)=\varnothing \text{ for } i\neq j \end{array}$$



Since $\bigcup_{j\in J}(V_j\cap W_j)$ is an open subset of X we obtain, by definition of the subspace topology, that U is indeed an open subset of $\bigcup_{i\in I} A_i$.

Finally we prove (2)⇒(1). Thus we suppose that Φ is a homeomorphism. Let $i \in I$. Evidently A_i is an open subset of $\bigsqcup_{j\in I} A_j$. Thus $\Phi(A_i) = A_i$ is an open subset of $\bigcup_{j\in I} A_j$. By definition of the subspace topology this means that there exists an open subset V_i such that $V_i \cap \bigcup_{j\in J} A_j = A_i$. But this means that V_i is an open neighborhood V_i of $A_i \subset X$ that does not intersect any other A_j. ■

[72] Of course this hypothesis is satisfied if the A_i are disjoint open subsets of X.

Examples.

(1) Using Lemma 5.14 one can easily verify that the topological space $S^1 \sqcup S^1$ is homeomorphic to the topological space $S^1((-2,0)) \cup S^1((2,0)) \subset \mathbb{R}^2$.

(2) Using Lemma 5.14 one can also easily show that the topological space $[-1,0] \sqcup (0,1]$ is homeomorphic to $[-2,-1] \cup (0,1] \subset \mathbb{R}$. But note that the topological space $[-1,0] \sqcup (0,1]$ is not homeomorphic to $[-1,1]$ since the former is non-compact whereas the latter is compact.

(3) Let X be a topological space and let $\{X_i\}_{i \in I}$ be its set of components. Note that the Component Lemma 2.33 (1) says that as a set we have $X = \bigsqcup_{i \in I} X_i$, thus the natural map $\bigsqcup_{i \in I} X_i \to X$ is a bijection.

(a) If I is finite, then we know by the Components-are-Closed Lemma 2.34 that each X_i is closed and open, thus it follows from the Disjoint Union Embedding Lemma 5.14 that the natural map $\bigsqcup_{i \in I} X_i \to X$ is in fact a homeomorphism.

(b) If I is infinite, this logic does not necessarily apply. An easy counterexample is given by $X = \mathbb{Q}$, where, as saw on page 168, the components are precisely the one-point subsets.

5.5. **Quotients of topological spaces.** On page 89 we recalled the notion of an equivalence relation. We recall the following notation from page 90.

Notation. Let $\sim$ be an equivalence relation $\sim$ on a set X.

(1) Given $x \in X$ we denote by $[x]$ the unique equivalence class that contains x.

(2) We refer to the map

$$\begin{array}{rccc} p\colon & X & \to & X/\!\sim \\ & x & \mapsto & [x] \end{array}$$

as the natural projection.

(3) If $f\colon X \to Y$ is a map with the property that $f(x) = f(y)$ whenever $x \sim y$, then by the Quotient-Factorization Lemma 0.5 the map

$$\begin{array}{rccc} g\colon & X/\!\sim & \to & Y \\ & [x] & \mapsto & f(x) \end{array}$$

is well-defined and it is the unique map $g\colon X/\!\sim \to Y$, such that $f = g \circ p$, i.e. such that the following diagram of maps commutes:

$$\begin{array}{ccc} X & \xrightarrow{p} & X/\!\sim \\ & \searrow^{f} & \downarrow g \\ & & Y. \end{array}$$

We refer to this map g as the induced map.

The following proposition is the analogue of the Topological-Product Proposition 5.1 and of the Topological-Coproduct Proposition 5.11.

Proposition 5.15. (Topological-Quotient Proposition) Let $\sim$ be an equivalence relation on a topological space X. We denote by $p\colon X \to X/\sim$ the natural projection from X onto the set of equivalence classes $X/\sim$. The following statements hold:

(0) (a) The set
$$\mathcal{T} := \{U \subset X/\sim \mid p^{-1}(U) \text{ is open in } X\}$$
is a topology on $X/\sim$.[73]

(b) A subset $A \subset X/\sim$ is closed if and only if the preimage $p^{-1}(A)$ is closed in X.

(1) (a) The natural projection $p\colon X \to X/\sim$ is continuous.

(b) Let Y be a topological space and let $f\colon X \to Y$ be a continuous map with the property that $f(x) = f(y)$ whenever $x \sim y$. The induced map
$$\begin{array}{rccc} g\colon & X/\sim & \to & Y \\ & [x] & \mapsto & f(x) \end{array}$$
is also continuous.

(2) If Z is a topological space and if $q\colon X \to Z$ is a map such that the pair (Z, q) has the same properties as $(X/\sim, p)$ as formulated in (1a) and (1b), then there exists a unique homeomorphism $\Phi\colon X/\sim \to Z$ with $q = \Phi \circ p$.

Proof. Let $\sim$ be an equivalence relation on a topological space X.

(1) (a) This statement follows easily from the Image-Preimage Lemma 0.2 (6) and (7).

(b) This statement follows easily from the Image-Preimage Lemma 0.2 (8).

(2) (a) It follows immediately from the definition of the topology on $X/\sim$ that the natural projection $p\colon X \to X/\sim$ is continuous.

(b) Let $f\colon X \to Y$ be a continuous map such that $f(x) = f(y)$ whenever $x \sim y$. We need to show that the induced map $g\colon X/\sim \to Y$ is continuous as well. Let $U \subset Y$ be open. We need to show that $g^{-1}(U) \subset X/\sim$ is open. By definition of the quotient topology we need to show that $p^{-1}(g^{-1}(U))$ is open in X. We observe that
$$p^{-1}(g^{-1}(U)) \;=\; (g \circ p)^{-1}(U) \underset{\text{by the commutative diagram}}{\overset{\uparrow}{=}} f^{-1}(U) \underset{\text{since } f \text{ continuous}}{\overset{\uparrow}{=}} \text{open subset}\,.$$
We have thus shown that g is continuous.

(3) Let Z be a topological space and let $q\colon X \to Z$ be a map such that the following conditions are satisfied:

(a′) The map q is continuous.

(b′) Whenever we are given a topological space Y and a continuous map $f\colon X \to Y$ with the property that $f(x) = f(y)$ whenever $x \sim y$, then there exists a unique continuous map $h\colon Z \to Y$ with $h \circ q = f$.

We apply (b) and (a′) to obtain a continuous map $\Phi\colon X/\sim \to Z$ with $q = \Phi \circ p$. Furthermore we apply (a) and (b′) to obtain a continuous map $\Psi\colon Z \to X/\sim$ with $p = \Psi \circ p$. It follows from the uniqueness statement of the Quotient-Factorization Lemma 0.5 that $\Psi \circ \Phi = \mathrm{id}_{X/\sim}$ and it follows from the uniqueness statement of (b′) that $\Phi \circ \Psi = \mathrm{id}_Z$. ∎

[73] In other words, $U \subset X/\sim$ is open if and only if $p^{-1}(U) \subset X$ is open.

The following definition will not come as a surprise.

Definition. Let $\sim$ be an equivalence relation on a topological space X. We refer to the topology on $X/\sim$ from the Topological-Quotient Proposition 5.15 (0a) as the quotient topology and we refer to $X/\sim$ as a quotient space of X.

Definition. Let $f\colon X \to Y$ be a map as in the Topological-Quotient Proposition 5.15 (1b).

(1) We refer to the map $g\colon X/\sim \to Y$ as the induced map.
(2) At times we denote the induced map by $\overline{f}$. Sometimes, when there is no danger of confusion we denote the induced map just by f itself.
(3) Sometimes we also say that the map $f\colon X \to Y$ descends to a map $X/\sim \to Y$.

Lemma 5.16. (Quotient-Compact Connected Lemma) Let $\sim$ be an equivalence relation on a topological space X.

(1) If X is compact, then $X/\sim$ is also compact.
(2) If X is (path)-connected, then $X/\sim$ is also (path)-connected.

Proof.

(1) This statement follows immediately from (3) and from the Compact Image Lemma 2.13.
(2) This statement follows immediately from (3) together with the Image-Connected Lemma 2.24. ■

The following remark can be viewed as a sibling of Remark 5.2.

Remark 5.17. We consider maps in and out of a quotient space $X/\sim$:

(1) In practice it is usually easy to show that a given map $X/\sim \to Y$ out of the quotient space is continuous. More precisely, in practice it is often fairly clear that the map $X \to X/\sim \to Y$ is continuous, but then it follows from the Topological-Quotient Proposition 5.15 (1b) that the original map $X/\sim \to Y$ is continuous.
(2) There is usually no easy way to show that a map $Y \to X/\sim$ to a quotient space is continuous, unless the map factors through the projection $X \to X/\sim$.

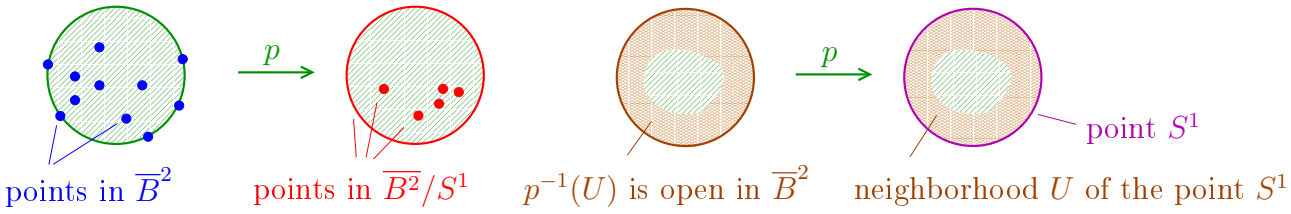
We continue with a particularly important source of quotient spaces.

Definition. Let X be a topological space and let $A \subset X$ be a subset.

(1) (a) First we suppose that A is a non-empty subset. For $P, Q \in X$ we define

$$P \sim Q \quad :\Longleftrightarrow \quad P = Q \text{ or } P, Q \text{ both lie in } A.$$

This is easily seen to be an equivalence relation on X. We write $X/A := X/\sim$ and we always equip X/A with the quotient topology. We refer to X/A as the quotient of X by A. Note that $A \subset X$ is an equivalence class, thus it defines a point X/A. In an attempt to avoid confusion we write $[A]$ for the point in X/A that is given by the equivalence class A.



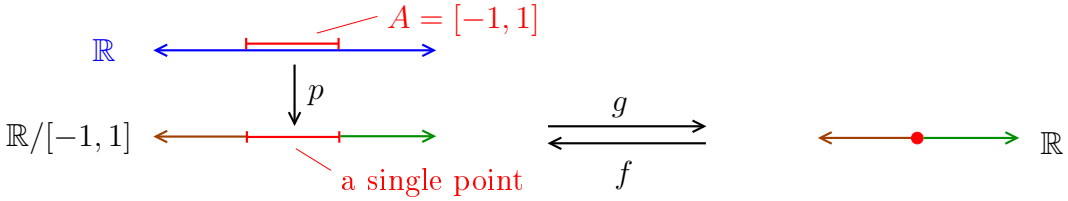
(b) If $A = \varnothing$ is the empty set, then we define $X/\varnothing := X \sqcup \{\varnothing\}$, i.e. $X/\varnothing$ equals the disjoint union of the topological space X with the topological space consisting of a single point $\varnothing$. For consistency we denote this point by $[A] = [\varnothing]$ as well. Note that $\varnothing/\varnothing$ is the topological space consisting of the single point $\{\varnothing\}$.[74]

(2) We refer to the obvious map $p\colon X \to X/A$ as the natural projection .

Remark. Let us attempt to digest the definition of X/A. As a set X/A corresponds precisely to the points in $X \setminus A$ together with the point $[A]$. Furthermore, by definition of the quotient topology a set $U \subset X/A$ is open if and only if $p^{-1}(U)$ is an open subset of X. Note that given any subset $Z \subset X/A = (X \setminus A) \cup \{[A]\}$ we have[75]

$$p^{-1}(Z) = \begin{cases} Z, & \text{if } [A] \notin Z, \\ Z \cup A, & \text{if } [A] \in Z. \end{cases}$$

This shows that the open sets in X/A correspond precisely to the open sets of X that lie in $X \setminus A$ and the open sets of X that contain A.



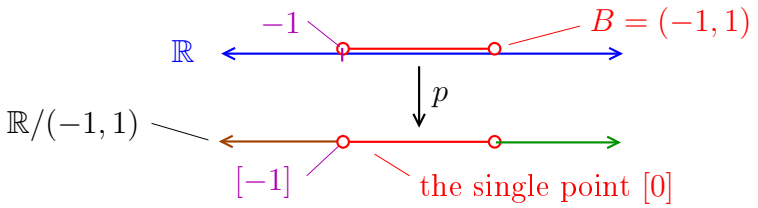
Examples.

(1) We consider the quotient of $X = \mathbb{R}$ by the compact interval $A = [-1, 1]$. This example has two interesting features:

- The quotient $X/A = \mathbb{R}/[-1, 1]$ is actually homeomorphic to an old favorite, namely one can easily verify that the maps

$$f : \mathbb{R} \to \mathbb{R}/[-1,1] \quad x \mapsto \begin{cases} [x+1], & \text{if } x \geq 0 \\ [x-1], & \text{if } x < 0 \end{cases} \quad \& \quad g : \mathbb{R}/[-1,1] \to \mathbb{R} \quad P \mapsto \begin{cases} x-1, & \text{if } P = [x] \text{ with } x \geq 1 \\ x+1, & \text{if } P = [x] \text{ with } x < -1 \end{cases}$$

  are continuous and inverses of one another.
- Above we saw that projections $X \to X/\sim$ are basically by definition, continuous. One might think that projections should also be open. But in this example the projection $p\colon X = \mathbb{R} \to X/A = \mathbb{R}/[-1, 1]$ is *not* an open map, for example it follows immediately from the previous remark that the image of the open set $(-1, 1) \subset \mathbb{R}$ is not an open subset of $\mathbb{R}/[-1, 1]$.



(2) We consider the quotient of $X = \mathbb{R}$ by the open interval $B = (-1, 1)$. We denote by $p\colon \mathbb{R} \to \mathbb{R}/(-1, 1)$ the projection . Even though this example looks very similar

[74]The reader will have spotted that the case $A = \varnothing$ is a major nuisance. It is conceivable that later on in proofs we will subconsciously suppress this special case. Whenever this occurs we leave it to the reader to deal with the case $A = \varnothing$ separately.

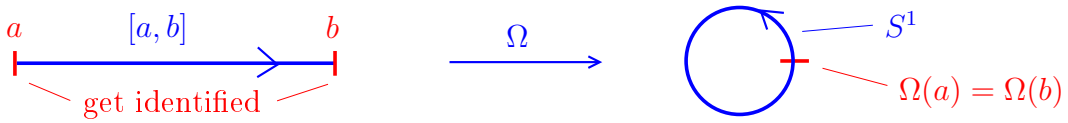
[75]In an attempt to lighten the notation, given $x \in X \setminus A$ we do not distinguish between the point $x \in X \setminus A$ and the equivalence class $\{x\} \subset X$.

to the previous one, it shows very different behavior. For example it turns out that the quotient $X/B = \mathbb{R}/(-1,1)$ is not Hausdorff. More precisely we consider the two points $[-1]$ and $[0]$ in $\mathbb{R}/(-1,1)$. The previous remark shows that any open neighborhood U of $[-1]$ in $\mathbb{R}/(-1,1)$ has the property that $p^{-1}(U)$ is an open subset of $\mathbb{R}$ that contains -1. In particular $p^{-1}(U)$ has non-empty intersection with B. But this implies that $U = p(p^{-1}(U))$ contains the point $[0]$. Thus $[-1]$ and $[0]$ cannot be separated by open neighborhoods.[76]

The following lemma is elementary but useful. On numerous occasions it will allow us to slightly shift our point of view.

Lemma 5.18. Let X be a topological space and let $A \subset X$ be a subset. Furthermore let Y be another topological space and let $y_0 \in Y$. The map

$$\Phi\colon \left\{\begin{array}{c}\text{set of continuous maps } f\colon X \to Y \\ \text{such that } f(A) = \{y_0\}\end{array}\right\} \to \left\{\begin{array}{c}\text{set of continuous maps } f\colon X/A \to Y \\ \text{such that } f([A]) = y_0\end{array}\right\}$$
$$(f\colon X \to Y) \mapsto (\overline{f}\colon X/A \to Y)$$



is well-defined and it is a bijection.

Proof. It follows from the Topological-Quotient Proposition 5.15 (1b) that given a continuous map $f\colon X \to Y$ with $f(A) = \{y_0\}$ the corresponding map $\overline{f}\colon X/A \to Y$ is continuous. This shows that the map Φ is well-defined. It is clear that Φ is injective. Finally suppose we are given a map $g\colon X/A \to Y$ with $g([A]) = y_0$. We denote by $f\colon X \to X/A \to Y$ the map that is given by precomposing g with the natural projection $X \to X/A$. It follows from the Topological-Quotient Proposition 5.15 (1a) that f is continuous. Clearly we have $\Phi(f) = g$. This shows that Φ is also a surjection. ■

Example. Let $a < b$ be two real numbers. It follows easily from the Quotient-Compact Connected Lemma 5.16 (1), the Topological-Quotient Proposition 5.15 (1b) and the Compact-Hausdorff Proposition 2.17 (3) that the map

$$\Omega\colon [a,b]/\{a,b\} \to S^1$$
$$[t] \mapsto \exp\left(i \cdot \tfrac{2\pi(t-a)}{b-a}\right)$$

is a homeomorphism.

We continue with the following innocuous lemma.

[76] Note that in the Quotient Hausdorff Lemma 5.21 we will give a criterion that ensures that the quotient of a topological space is Hausdorff.

Lemma 5.19.

(1) The map

$$\begin{array}{rcl} ([0,1]\times S^n)/(\{0\}\times S^n) & \to & \overline{B}^{n+1} \\ [(r,v)] & \mapsto & r\cdot v \end{array}$$

is a homeomorphism.

(2) Let X be a topological space and let $f\colon [0,1]\times S^n \to X$ be a continuous map. If $f(0,v)=f(0,w)$ for all $v,w\in S^n$, then the map

$$\begin{array}{rcl} \overline{B}^{n+1} & \to & X \\ r\cdot v & \mapsto & f(r,v) \text{ with } r\in[0,1] \text{ and } v\in S^n \end{array}$$

is well-defined and continuous.

Proof.

(1) It follows from the Topological-Quotient Proposition 5.15 (1b) that the given map is continuous. It is basically clear that the map is a bijection. The left-hand side is compact by the Topological-Quotient Proposition 5.15 (1b) (4). It follows from the Compact-Hausdorff Proposition 2.17 (3) that the map is a homeomorphism.

(2) It follows from the hypothesis that the map is well-defined. It follows from (1) and the Topological-Quotient Proposition 5.15 (1b) that the map is continuous. ■

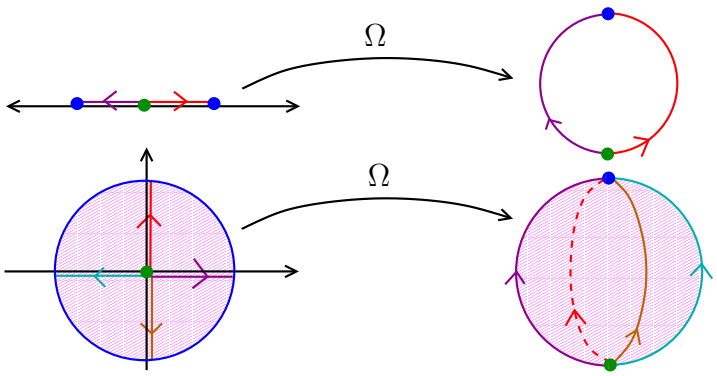
We record our next example as a lemma.

Lemma 5.20. (Ball-Quotient Sphere Lemma) The map

$$\begin{array}{rcl} \Omega\colon \overline{B}^n/S^{n-1} & \to & S^n \\ [r\cdot v] & \mapsto & \underbrace{\begin{pmatrix} 0 & (-1)^{n-1} & \dots \\ 0 & 0 & \mathrm{id}_{n-1} \\ -1 & \dots & 0 \end{pmatrix}}_{\in \mathrm{SO}(n+1)} \cdot \underbrace{\begin{pmatrix} \cos(\pi r) \\ \sin(\pi r)\cdot v \end{pmatrix}}_{\in \mathbb{R}\times\mathbb{R}^n=\mathbb{R}^{n+1}} \text{ with } r\in[0,1] \text{ and } v\in S^{n-1} \end{array}$$

is a homeomorphism. (Note that for $n=1$ and $n=2$ this homeomorphism is illustrated in the figure below.) This homeomorphism has the following properties:

(1) The map Ω sends the point $[S^{n-1}]\in \overline{B}^n/S^{n-1}$ to the North Pole $(0,\dots,0,1)$.



(2) The map Ω sends the origin to the South Pole $(0,\dots,0,-1)$.

(3) The map $B^n \to \overline{B}^n/S^{n-1} \xrightarrow{\Omega} S^n$ is a smooth embedding in the sense of the definition on page 652. Furthermore, if we equip B^n and S^n with the standard orientations from page 677 and page 681, then the smooth embedding is orientation-preserving in the sense of the definition on page 682.[77]

Proof. It follows from Lemma 5.19, the Topological-Quotient Proposition 5.15 (1b) and the Compact-Hausdorff Proposition 2.17 (3) that the map $\Omega\colon \overline{B}^n/S^{n-1}\to S^n$ is a homeomorphism. It is clear that $\Omega([S^{n-1}])=(0,\dots,0,1)$ and that $\Omega(0)=(0,\dots,0,-1)$.

Thus it remains to prove Statement (3). To show smoothness it is convenient to rewrite the definition of Ω. First note that by elementary real analysis we know that there exists a smooth map $f\colon \mathbb{R}\to\mathbb{R}$ such that for any $x\neq 0$ we have $f(x)=\frac{\sin(\pi\cdot x)}{x}$. One can now

[77] We hope that the reader is not too fazed by the fact that we use some expressions that we will introduce only later. But we think it is useful to state all properties of Ω now.

easily verify that the map $\Omega\colon \overline{B}^n/S^{n-1} \to S^n$ has the following, in some sense cleaner, description:

$$\begin{array}{rcl} \Omega\colon \overline{B}^n/S^{n-1} & \to & S^n \\ [w] & \mapsto & \underbrace{\begin{pmatrix} 0 & (-1)^{n-1} & \dots \\ 0 & 0 & \mathrm{id}_{n-1} \\ -1 & \dots & 0 \end{pmatrix}}_{\in \mathrm{SO}(n+1)} \cdot \underbrace{\begin{pmatrix} \cos(\pi \cdot \|w\|) \\ f(\|w\|) \cdot w \end{pmatrix}}_{\in \mathbb{R}\times\mathbb{R}^n = \mathbb{R}^{n+1}} \quad \text{with } w \in \overline{B}^n. \end{array}$$

It is now clear that the map $B^n \to \overline{B}^n/S^{n-1} \xrightarrow{\Omega} S^n$ is smooth. One can easily verify that the differential at each $w \in B^n$ is invertible, i.e. the map $B^n \to S^n$ is an immersion in the sense of the definition on page 651. Using the above one can also easily verify that $B^n \to S^n$ is an embedding. In summary, we have shown that the map $B^n \to S^n$ is a smooth embedding.

It remains to show that the smooth embedding $B^n \to S^n$ is orientation-preserving. By the Basics-of-Orientations Lemma 25.13 it suffices to show that the map is orientation-preserving at the origin. At the origin the standard basis $e_1, \dots, e_n$ of $\widetilde{\mathrm{T}}_0 B^n = \mathbb{R}^n$ is a positive basis. An elementary calculation shows that it gets sent to the basis $(-1)^{n-1} \cdot e_1, e_2, \dots, e_n$ of the tangent space of S^n at $\Phi(0) = -e_{n+1}$. Since $\det(-e_{n+1}\ (-1)^{n-1} \cdot e_1\ e_2 \dots e_n) > 0$ we see, by the definition on page 681 of the standard orientation on S^n, that $(-1)^{n-1} \cdot e_1, e_2, \dots, e_n$ is a positive basis of the tangent space of S^n at $\Phi(0) = -e_{n+1}$. We have thus shown that the smooth embedding $B^n \to S^n$ is orientation-preserving at the origin and thus everywhere. ■

We conclude this section with a rather technical discussion. Namely, on page 244 we saw that the quotient of a topological space that is Hausdorff is not necessarily again Hausdorff. It is pretty clear that if one puts enough conditions on the equivalence relation, then one can avoid such misdemeanor. This leads us to the following definition.

Definition. Let X be a topological space and let $\sim$ be an equivalence relation on X. Recall that an equivalence relation is, by the definition on page 89, a subset of $X \times X$ with suitable properties. We say that $\sim$ is closed if $\sim$ is a closed subset of $X \times X$.

Now we can formulate the next lemma.

Lemma 5.21. (Quotient Hausdorff Lemma) Let X be a topological space that is Hausdorff and compact. If $\sim$ is a closed relation, then $X/\sim$ is Hausdorff.

Proof. Let X be a topological space that is Hausdorff and compact and let $\sim$ be a closed relation. For psychological reasons we denote by $G \subset X \times X$ the subset given by the relation $\sim$. By hypothesis we know that G is a closed subset of $X \times X$. We denote by $p\colon X \to X/\sim$ the projection. We start out with the following claim.

Claim. Given any closed subset C of X the projection $p(C)$ is a closed subset of $X/\sim$.

Proof. Let C be a closed subset of X. We need to show that $p^{-1}(p(C))$ is closed in X. We denote by $p_1, p_2\colon X \times X \to X$ the projection onto the first respectively the second factor. Then one easily sees that

$$p^{-1}(p(C)) \;=\; \{y \in X \,|\, \text{there exists an } x \in C \text{ with } y \sim x\} \;=\; p_2(p_1^{-1}(C) \cap G).$$

Note that $p_1^{-1}(C) = C \times X$ is the product of two closed subsets of X, hence it follows from the Product-of-Subsets Lemma 5.5 that $p_1^{-1}(C) = C \times X$ is a closed subset of $X \times X$. Furthermore by our hypothesis G is a closed subset of $X \times X$. Thus we see that $p_1^{-1}(C) \cap G$ is closed. By the Product Topology Properties Proposition 5.6 (2) and our hypothesis on X we know that $X \times X$ is compact. It follows from the Compact-Closed Lemma 1.21 (1) that $p_1^{-1}(C) \cap G$ is a compact subset of $X \times X$. It is now a consequence of the Compact Image Lemma 2.13 (1) that $p_2(p_1^{-1}(C) \cap G)$ is a compact subset of X. But since X is Hausdorff we obtain from the Compact-Closed Lemma 1.21 (2) that $p_2(p_1^{-1}(C) \cap G)$ is also a closed subset of X. ⊞

Now let $[x], [y] \in X/\sim$ be two disjoint points in $X/\sim$. Since X is Hausdorff we know from the Compact-Closed Lemma 1.21 (2) that $\{x\}$ and $\{y\}$ are closed subsets of X. By the claim we see that $\{[x]\}$ and $\{[y]\}$ are closed subsets of $X/\sim$. Since the projection $p\colon X \to X/\sim$ is continuous we see that $p^{-1}([x])$ and $p^{-1}([y])$ are two disjoint closed subsets of X. Since X is compact and Hausdorff we know by the Compact Hausdorff Spaces-Normal Lemma 1.16 that X is normal, i.e. that there exist open disjoint neighborhoods U and V of $p^{-1}([x])$ and $p^{-1}([y])$. We write $U' = X \setminus U$ and $V' = X \setminus V$. These are now closed subsets of X. By the claim their images are closed subsets of $X/\sim$. Now we see that $(X/\sim) \setminus p(U')$ and $(X/\sim) \setminus p(V')$ are the desired open disjoint sets containing $[x]$ respectively $[y]$. ■

We conclude this section on quotient spaces with three technical lemmas.

Lemma 5.22. Let X be a topological space and let $\sim$ be an equivalence relation on X. Furthermore let $\mathcal{B}$ be a basis of the topology of X. If the projection $p\colon X \to X/\sim$ is an open map, then

$$p(\mathcal{B}) \;=\; \{p(B) \,|\, B \in \mathcal{B}\}$$

is a basis for the topology of $X/\sim$.

Proof. First note that the sets in $p(\mathcal{B})$ are indeed open subsets of $X/\sim$ since we assume that the projection is open. We use the criterion provided by the Basis Characterization Lemma 1.32 (1) to show that $p(\mathcal{B})$ is a basis for the topology of $X/\sim$. Thus let $U \subset X/\sim$ be an open set and let $y \in U$. We need to show that there exists a $B \in \mathcal{B}$ with $y \in p(B) \subset U$.

We choose an $x \in X$ with $p(x) = y$. Since $\mathcal{B}$ is a basis for the topology of X and since $p^{-1}(U)$ is open in X there exists by the Basis Characterization Lemma 1.32 (1) a $B \in \mathcal{B}$ with $x \in B \subset p^{-1}(U)$. But then we also have that $y = p(x) \in p(B) \subset p(p^{-1}(U)) = U$. ■

A careful reading of these notes shows that the following lemma gets used on many occasions without giving its due credit.

Lemma 5.23. (Twice Quotient Lemma)

(1) Let X be a topological space and let $\sim_1$ be an equivalence relation on X. Furthermore let $\sim_2$ be an equivalence relation on $X/\!\sim_1$. Given $x, y \in X$ we define

$$x \sim y \quad :\Longleftrightarrow \quad [x]_{\sim_1} \sim_2 [y]_{\sim_1}.$$

Then the following two statements hold:

(a) "$\sim$" is an equivalence relation.

(b) The map

$$\begin{array}{rcl} X/\!\sim & \to & (X/\!\sim_1)/\!\sim_2 \\ [x] & \mapsto & [[x]_{\sim_1}]_{\sim_2} \end{array}$$

is a homeomorphism.

(2) Let $f\colon X \to Y$ be a map between two topological spaces and let $\sim_X$ and $\sim_Y$ be equivalence relations on X respectively Y. If $x_1 \sim_x x_2$ implies that $f(x_1) \sim_y f(x_2)$, then the map

$$\begin{array}{rcl} X/\!\sim_X & \to & Y/\!\sim_Y \\ [x] & \mapsto & [f(x)] \end{array}$$

is well-defined and continuous.

Proof.

(1) We leave the proof of this lemma as a gift to our dear reader.

(2) It follows from the Topological-Quotient Proposition 5.15 (1a) that the map $X \xrightarrow{f} Y \xrightarrow{y \mapsto [y]} Y/\!\sim_Y$ is continuous. It follows from our hypothesis on f and the Topological-Quotient Proposition 5.15 (1b) that this map descends to a continuous map $X/\!\sim_X \to Y/\!\sim_Y$. ∎

5.6. **Group actions on topological spaces.** We continue with the following definition that eventually will provide a rich source of examples of topological spaces.

Definition. Let X be a set and let G be a group with trivial element e.

(1) An action of G on X is a map

$$\begin{array}{rcl} G \times X & \to & X \\ (g, x) & \mapsto & g \cdot x \end{array}$$

with the following properties

$$\begin{array}{rcll} e \cdot x & = & x, & \text{for all } x \in X, \\ g \cdot (h \cdot x) & = & (g \cdot_G h) \cdot x, & \text{for all } x \in X \text{ and } g, h \in G. \end{array}$$

($g \cdot (h \cdot x)$: the outer $\cdot$ is the group action, the inner $\cdot$ is the group action; $g \cdot_G h$: multiplication in the group G)

(2) The action is called free, if $g \cdot x = x$ for some $x \in X$ implies that $g = e$.

(3) We say G acts transitively, if for every x and y in X there exists a $g \in G$ with $g \cdot x = y$.

(4) If X is a topological space, then we say that the action is continuous, if for every $g \in G$ the map

$$\begin{array}{rcl} X & \to & X \\ x & \mapsto & g \cdot x \end{array}$$

is continuous.[78]

Remark. Sometimes what we call an "action" is referred to as a "left-action". A "right-action" is exactly the same as a left-action except that the second property gets replaced by $g \cdot (h \cdot x) = (h \cdot_G g) \cdot x$. Or, more intuitively, a right-action is a map $X \times G \to X$ such that we have $(x \cdot h) \cdot g = x \cdot (h \cdot_G g)$. Basically all the statements and definitions that we give for left-actions carry over, with minuscule modifications, to the setting of right-actions.

Examples.

(1) Given any group G the map

$$\begin{array}{rcl} G \times G & \to & G \\ (g, h) & \mapsto & ghg^{-1} \end{array}$$

defines an action of G on itself. Let G be a non-trivial group. Considering $h = e$ we see that this action is not free and it is also straightforward to see that the action is not transitive.

(2) Let $\mathbb{F}$ be a field and let V be a k-dimensional vector space over $\mathbb{F}$. We denote by B the set of all ordered bases of V. The map

$$\begin{array}{rcl} \mathrm{GL}(k, \mathbb{F}) \times B & \to & B \\ \big((a_{ij})_{i,j=1,\dots,k}, (v_1, \dots, v_k)\big) & \mapsto & \Big(\sum\limits_{i=1}^{k} a_{i1} v_i, \dots, \sum\limits_{i=1}^{k} a_{ik} v_i\Big) \end{array}$$

is a transitive action. It is an amusing linear algebra exercise to figure out under what circumstances this action is free.

(3) The group $G = \mathbb{Z}^n$ acts on $X = \mathbb{R}^n$ by addition. This action is evidently free and continuous but it is not transitive.

We continue with the following definition.

Definition. Let X be a set and let G be a group that acts on X. One can easily verify that

$$x \sim y \quad :\Longleftrightarrow \quad \text{there exists a } g \in G \text{ such that } g \cdot x = y$$

is an equivalence relation on X. We write[79]

$$X/G \;:=\; X/\!\sim .$$

If X is a topological space, then we view X/G as a topological space equipped with the quotient topology.

Lemma 5.24. (Group-Action Projection Lemma) Let X be a topological space and let G be a group that acts on X.

(1) The projection $p\colon X \to X/G$ is continuous.
(2) We suppose that G acts continuously on X.
   (a) The projection p is open.

[78] If the action is continuous, then the map $x \mapsto g \cdot x$ is in fact a homeomorphism with inverse map given by $x \mapsto g^{-1} \cdot x$.

[79] It is arguably more logical to write $G\backslash X$ since we are dealing with a left-action and to reserve the notation X/G for right-actions. We stick to X/G since it is closer to our language "X mod G" and since we will not deal with right-actions at all.

(b) If $A \subset X$ is a closed subset with $G \cdot A = A$, then $p(A)$ is a closed subset of X/G.

Remark. Note that even if G acts continuously on a topological space, it is not true in general that the projection $p\colon X \to X/G$ is closed. For example, let $X = \mathbb{R}$ and $G = \mathbb{Z}$ with the additive action on $\mathbb{R}$. The set $A := \{n + \frac{1}{n} \,|\, n \in \mathbb{Z}\}$ is a closed subset of $X = \mathbb{R}$, but using the Topological-Quotient Proposition 5.15 (0b) one can easily show that $p(A)$ is not a closed subset of $X/G = \mathbb{R}/\mathbb{Z}$.

Proof.

(1) The first statement follows immediately from the Topological-Quotient Proposition 5.15 (1a).

(2) Now we assume that G acts continuously on X.

(a) Let $U \subset X$ be an open subset. We need to show that $p(U)$ is open in X/G. Thus we need to show that $p^{-1}(p(U))$ is an open subset of X. It follows easily from the definitions that

$$p^{-1}(p(U)) \;=\; \bigcup_{g \in G} g \cdot U.$$

Since G acts continuously the map $x \mapsto g \cdot x$ is a homeomorphism. Thus we see that $p^{-1}(p(U))$ is the union of open sets, thus it is open itself.

(b) Let $A \subset X$ be a closed subset with $G \cdot A = A$. We see that

$$(X/G) \setminus p(A) \;\underset{\substack{\uparrow\\ \text{by the Image-Preimage Lemma 0.2 (5), since } G\cdot A = A \\ \text{implies that } p^{-1}(p(A)) = A}}{=}\; p(X \setminus A) \;\underset{\substack{\uparrow\\ \text{since } A \text{ closed}}}{=}\; p(\text{open set of } X) \;\underset{\substack{\uparrow\\ \text{by (2a)}}}{=}\; \text{open subset of } X/G.$$

But this means that $p(A)$ is indeed a closed subset of X/G. ∎

The following lemma discusses one example in greater detail.

Lemma 5.25. The map

$$\begin{array}{rcl} \mathbb{R}^n/\mathbb{Z}^n & \to & (S^1)^n \\ [(t_1, \ldots, t_n)] & \mapsto & \big(\exp(2\pi \mathrm{i} t_1), \ldots, \exp(2\pi \mathrm{i} t_n)\big) \end{array}$$

is a homeomorphism.

Convention. Often we use the homeomorphism of Lemma 5.25 to make the identification $\mathbb{R}^n/\mathbb{Z}^n = (S^1)^n$.

Proof. We start out with the following observations:

(1) The map is continuous by the Topological-Product Proposition 5.1 (1b) and. the Topological-Quotient Proposition 5.15 (1b). Furthermore it is straightforward to see that it is a bijection.

(2) The obvious map $[0,1]^n \to \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ is continuous and it is easily seen to be surjective. By the Hyperrectangle-Compact Proposition 1.26 we know that $[0,1]^n$ is compact. It follows from the Compact Image Lemma 2.13 that $\mathbb{R}^n/\mathbb{Z}^n$ is compact.

(3) From the Product Topology Properties Proposition 5.6 we obtain that $(S^1)^n$ is Hausdorff.

Now it follows from the Compact-Hausdorff Proposition 2.17 (3) that the given map is indeed a homeomorphism. ∎

We continue with more examples of group actions and the resulting quotient topological spaces. The first example doubles as a definition

Definition. Let $X = S^n$ and $G = \{\pm 1\}$. The map

$$\begin{array}{rcl} \{\pm 1\} \times S^n & \to & S^n \\ (\epsilon, P) & \mapsto & \epsilon \cdot P \end{array}$$

defines an action that is free and continuous. We refer to the quotient space $S^n/\{\pm 1\}$ as the n-dimensional real projective space $\mathbb{R}\mathrm{P}^n$. [80][81]

We continue with one more example of a group action.

Example. Let $X = \mathbb{R}$ and $G = \{\pm 1\}$. The map

$$\begin{array}{rcl} \{\pm 1\} \times \mathbb{R} & \to & \mathbb{R} \\ (\epsilon, x) & \mapsto & \epsilon \cdot x \end{array}$$

defines an action that is continuous. But this action is not free, since $(-1) \cdot 0 = 0$, but -1 is not the trivial element in the group $G = \{\pm 1\}$. In Exercise 5.29 we will show that $\mathbb{R}/\{\pm 1\}$ is homeomorphic to the half-open interval $[0, \infty)$.

We formulate the next example as a lemma.

Lemma 5.26. (Orthogonal Action Lemma) Let $n \in \mathbb{N}_0$.

(1) The maps

$$\begin{array}{rcl} \mathrm{O}(n+1) \times S^n & \to & S^n \\ (A, v) & \mapsto & A \cdot v \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{O}(n+1) \times \overline{B}^{n+1} & \to & \overline{B}^{n+1} \\ (A, v) & \mapsto & A \cdot v \end{array}$$

define continuous actions of $\mathrm{O}(n+1)$ on S^n and on $\overline{B}^{n+1}$.

(2) The action of $\mathrm{SO}(n+1)$ on S^n is free if and only if $n = 1$.

(3) The action of $\mathrm{O}(n+1)$ on S^n is transitive.

(4) If $n \geq 1$, then the action of $\mathrm{SO}(n+1)$ on S^n is also transitive.

(5) Let $k \in \{0, \ldots, n\}$. The obvious action of $\mathrm{SO}(n)$ on the set of k-dimensional vector subspaces of $\mathbb{R}^n$ is transitive.

We can use the above to draw the following two conclusions:

(6) For every $P \in S^n$ the complement $S^n \setminus \{P\}$ is homeomorphic to $\mathbb{R}^n$.

(7) Given any $x, y \in S^n$ there exists a homeomorphism $\varphi \colon \overline{B}^{n+1} \to \overline{B}^{n+1}$, which restricts to a homeomorphism $S^n \to S^n$, with $\varphi(x) = y$

Proof. Statements (1) and (2) can be verified easily.

We turn to the proof of Statements (3) and (4). The statements fall in the realm of linear algebra, but for the reader's convenience we provide the argument. First we prove Statement (3). It suffices to show that given any $v \in S^n$ there exists an $A \in \mathrm{O}(n+1)$ with $A \cdot e_1 = v$. To produce such a matrix we find vectors $v_2, \ldots, v_{n+1}$ such that $v, v_2, \ldots, v_{n+1}$ form a basis for $\mathbb{R}^{n+1}$. We apply the Gram-Schmidt Orthonormalization Process 2.38 to the ordered basis $(v, v_2, \ldots, v_{n+1})$. Since $\|v\| = 1$ this process leaves the first vector invariant

[80] For $n = 2$ we sometimes refer to $\mathbb{R}\mathrm{P}^2$ as the real projective plane.

[81] In Exercise 5.25 we will show that $\mathbb{R}\mathrm{P}^1$ is homeomorphic to S^1.

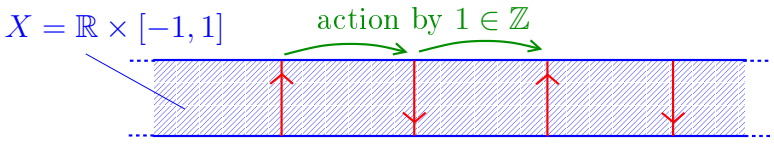
and we obtain an orthonormal basis $(v, \widetilde{v}_2, \dots, \widetilde{v}_{n+1})$. We denote by A the orthogonal matrix with columns given by $v, \widetilde{v}_2, \dots, \widetilde{v}_{n+1}$. Clearly $A \cdot e_1 = v$.

We turn to the proof of Statement (4). We argue as in Statement (3). The only difference is, that if $\det(A) = -1$ and if $n \geq 1$, then we replace $\widetilde{v}_2$ by $-\widetilde{v}_2$, and now we are happy.

We move on to the proof of Statement (5). Now let $k \in \{0, \dots, n\}$ and let $V, W \subset \mathbb{R}^n$ be two k-dimensional vector subspaces of $\mathbb{R}^n$. The case $k = n$ is trivial. So we can assume that $k \in \{0, \dots, n-1\}$. By the Gram-Schmidt Orthogonalization Process 2.38 we can pick orthogonal bases $v_1, \dots, v_k$ and $w_1, \dots, w_k$. It suffices to show that for $i = 1, \dots, k$ there exists an $A_i \in \mathrm{SO}(n)$ such that $A \cdot v_j = \pm w_j$ for $j = 1, \dots, i$. These matrices $A_1, \dots, A_k$ can be found iteratively by applying (4) to the vectors v_j and w_j in the orthogonal complement of $v_1, \dots, v_{j-1}$, which has dimension $n - (j-1) \geq n - (k-1) \geq n - ((n-1)-1) \geq 2$.

Next note that Statement (6) follows from Statement (3) together with Lemma 2.18. Finally Statement (7) follows from Statements (1) and (3). ■

We consider our next example in greater detail.



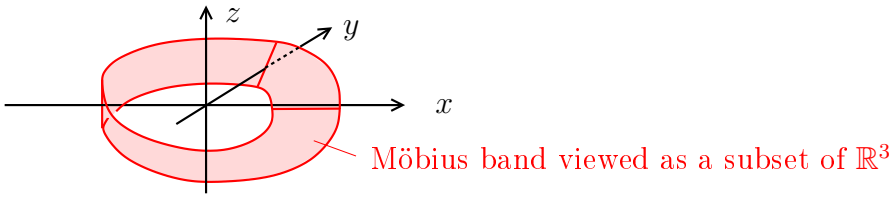
Definition.

(1) Let $X = \mathbb{R} \times [-1, 1]$ and $G = \mathbb{Z}$. The map

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n, (x, y)) & \mapsto & (x + n, (-1)^n \cdot y) \end{array}$$

defines an action that is free and continuous. We refer to the quotient $X/\mathbb{Z}$ as the Möbius band. The same argument as in the proof of Lemma 5.25 shows that the Möbius band is compact.

(2) On occasion we will also be interested in the open Möbius band which is basically defined as above, except that we define it as the quotient of $\mathbb{R} \times (-1, 1)$ instead of the quotient of $\mathbb{R} \times [-1, 1]$.



Remark. The name "Möbius band" conjures up a certain picture. We will now see that our name is justified. Given $\varphi, \psi \in \mathbb{R}$ and $r \in [-1, 1]$ we set

$$A(\varphi) := \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad v(r, \psi) := \begin{pmatrix} 2 + r \cdot \sin(\psi) \\ 0 \\ r \cdot \cos(\psi) \end{pmatrix}.$$

We consider the map

$$\begin{array}{rcl} \Psi \colon (\mathbb{R} \times [-1,1])/\mathbb{Z} & \to & \mathbb{R}^3 \\ [(\varphi, r)] & \mapsto & A(2\pi \cdot \varphi) \cdot v\big(r, \pi\varphi\big). \end{array}$$

The argument of Lemma 5.25 shows that Ψ is an embedding. Thus the Möbius band, defined abstractly as above, is indeed homeomorphic to a subset of $\mathbb{R}^3$ that looks like what we had in mind.

If X is a Hausdorff space and if G acts continuously on X, then it is unfortunately not necessarily true that X/G itself is Hausdorff. For example, consider the obvious action of $G = (\mathbb{Q}, +)$ on $X = \mathbb{R}$. It is a moderately insightful exercise, see Exercise 5.27, to verify that the quotient space $\mathbb{R}/\mathbb{Q}$ is not Hausdorff.
This example leads us to the following definition.

Definition. Let X be a topological space and let G be a group that acts on X. We say that G acts properly if for every two points x and y in X there exist open neighborhoods U of x and V of y such that the set $\{g \in G \,|\, gU \cap V \neq \varnothing\}$ is finite.[82]

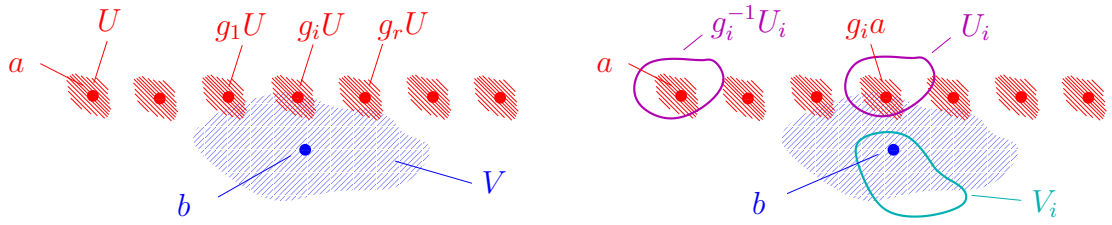
Examples.

(1) The action of any finite group is proper by definition.
(2) One can show easily that the action of $\mathbb{Z}$ on $\mathbb{R} \times [-1, 1]$ that we had considered on page 252 to define the Möbius band, is proper.
(3) It is straightforward to show that the action of $\mathrm{O}(n+1)$ on S^n from the Orthogonal Action Lemma 5.26 is not proper.

Proposition 5.27. (Group Action-Hausdorff Quotient Proposition) Let G be a group that acts on a topological space X. If X is Hausdorff and if the action is proper and continuous, then the quotient space X/G is also Hausdorff.

Example. Note that it follows from the Group Action-Hausdorff Quotient Proposition 5.27 and the above examples that the real projective spaces $\mathbb{R}\mathrm{P}^n/\{\pm 1\}$ and the Möbius band $(\mathbb{R} \times [-1, 1])/\mathbb{Z}$ are Hausdorff.

Unless one has an insatiable appetite for technical proofs it is best to move on to the next section.



The proof of the Group Action-Hausdorff Quotient Proposition 5.27 relies on the following two lemmas.

Lemma 5.28. Let G be a group that acts continuously and properly on a topological space. If X is Hausdorff, then given any two points a and b in X there exist open neighborhoods A of a and B of b with the following property: for every $g \in G$ with $ga \neq b$ we also have $gA \cap B = \varnothing$.

Proof of Lemma 5.28. Let G be a group that acts continuously and properly on a topological space X that is Hausdorff. Let a and b be two points in X. Since G acts properly on X there exist open neighborhoods U of a and V of b such that $\{g \in G \,|\, gU \cap V \neq \varnothing\}$ is a finite set. We denote the elements of this finite set by $g_1, \ldots, g_r$. We set

$$I \;:=\; \{i = 1, \ldots, r \,|\, g_i a \neq b\}.$$

[82] The notion of a "proper action" is defined in different ways by different authors.

Since X is Hausdorff we can find for every $i \in I$ an open neighborhood U_i of $g_i a$ and an open neighborhood V_i of b such that $U_i \cap V_i = \varnothing$. We set

$$A \;:=\; U \cap \bigcap_{i\in I} g_i^{-1}U_i \quad \text{and} \quad B \;:=\; V \cap \bigcap_{i\in I} V_i.$$

The sets A and B are the intersection of finitely many open subsets,[83] thus they are open. In particular A is an open neighborhood of a and B is an open neighborhood of b.

Now one can easily verify that A and B have the desired properties. Indeed, let $g \in G$ with $ga \neq b$. If $g \notin \{g_1, \dots, g_r\}$, then $gU \cap V = \varnothing$, therefore $gA \cap B = \varnothing$. On the other hand, if $g \in \{g_1, \dots, g_r\}$, then there exists an $i \in I$ with $g = g_i$. It follows that $g_i(g_i^{-1}U_i) \cap V_i = U_i \cap V_i = \varnothing$, hence $g_i A \cap B = \varnothing$. ∎

Lemma 5.29. Let G be a group that acts on a set X. We denote by $p\colon X \to X/G$ the projection. Let A and B be subsets of X. Then

$$p(A) \cap p(B) \;=\; \varnothing \quad \Longleftrightarrow \quad \text{for every } g \in G \text{ we have } gA \cap B = \varnothing,$$

or equivalently,

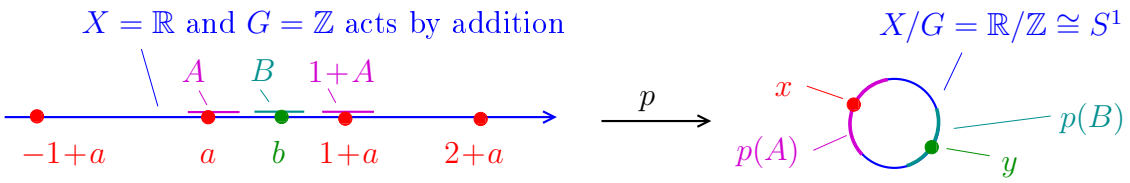
$$p(A) \cap p(B) \;\neq\; \varnothing \quad \Longleftrightarrow \quad \text{there exists a } g \in G \text{ with } gA \cap B \neq \varnothing.$$

Proof of Lemma 5.29. We prove the second statement. The first statement is easily seen to be equivalent to the second statement. Note that

$$\begin{aligned} p(A) \cap p(B) \;\neq\; \varnothing \;&\Longleftrightarrow\; \text{there exist } a \in A \text{ and } b \in B \text{ with } p(a) = p(b) \in X/G \\ &\Longleftrightarrow\; \text{there exist } a \in A,\ b \in B \text{ and } g \in G \text{ with } ga = b \\ &\Longleftrightarrow\; \text{there exists a } g \in G \text{ with } gA \cap B \neq \varnothing. \end{aligned}$$

∎

Now we turn to the actual proof of the Group Action-Hausdorff Quotient Proposition 5.27.



Proof of the Group Action-Hausdorff Quotient Proposition 5.27. Let G be a group that acts on a topological space X. We assume that X is Hausdorff and that the action is proper and continuous. We want to show that the quotient space X/G is also Hausdorff. We denote by $p\colon X \to X/G$ the projection .

Let x and y be two distinct points in X/G. We pick a and b in X with $p(a) = x$ and $p(b) = y$. Since $p(a) = x \neq y = p(b)$ we see that for every $g \in G$ we have $ga \neq b$. By Lemma 5.28 there exist open neighborhoods A of a and B of b such that $gA \cap B = \varnothing$ for every $g \in G$. It follows from Lemma 5.29 that $p(A)$ and $p(B)$ are disjoint.

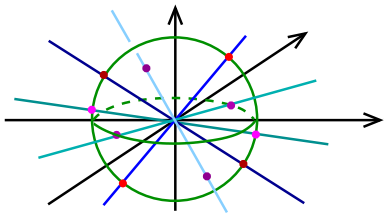
Since A and B are open it follows from the Group-Action Projection Lemma 5.24 that $p(A)$ and $p(B)$ are open subsets of X/G, in particular they are open neighborhoods of

[83] Here we use that G acts continuously, since this implies that the sets $h^{-1} \cdot U_i$ are also open.

$x = p(a)$ and $y = p(b)$. We have thus found the desired disjoint open neighborhoods of x and y in X/G. ■

5.7. **Projective spaces.** Let $n \in \mathbb{N}$. On page 251 we introduced the real projective space $\mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\}$. In this section we will give an alternative definition and we will introduce the complex projective spaces. Even though these projective spaces appear initially rather arbitrary they will on several occasions play an essential role in these notes.

Convention. Let $X = \mathbb{R}^{n+1} \setminus \{0\}$ and let $G = \mathbb{R} \setminus \{0\}$, where we view G as a group via multiplication. The map



$$\begin{array}{rcl} (\mathbb{R} \setminus \{0\}) \times (\mathbb{R}^{n+1} \setminus \{0\}) & \to & \mathbb{R}^{n+1} \setminus \{0\} \\ (r, P) & \mapsto & r \cdot P \end{array}$$

defines an action that is free and continuous. It is straightforward to see that the map

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\} & \to & (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \\ [P] & \mapsto & [P] \end{array}$$

defines a homeomorphism[84]. We will use this homeomorphism to make the identification $\mathbb{R}\mathrm{P}^n = (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\})$.

$(\mathbb{R}^3 \setminus \{0\})/(\mathbb{R} \setminus \{0\})$ is the "set of lines through 0"

$\mathbb{R}\mathrm{P}^2 = S^2/x \sim -x$ is the "set of pairs of antipodal points on S^2"

Our new point of view on real projective spaces has the advantage that we can create a different class of examples of topological spaces by replacing $\mathbb{R}$ by $\mathbb{C}$. More precisely, this discussion leads us to the following definition:

Definition. Let $X = \mathbb{C}^{n+1} \setminus \{0\}$ and let $G = \mathbb{C} \setminus \{0\}$. The map

$$\begin{array}{rcl} (\mathbb{C} \setminus \{0\}) \times (\mathbb{C}^{n+1} \setminus \{0\}) & \to & \mathbb{C}^{n+1} \setminus \{0\} \\ (z, P) & \mapsto & z \cdot P \end{array}$$

defines an action that is free and continuous. The quotient space $(\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\})$ is called the n-dimensional complex projective space $\mathbb{C}\mathrm{P}^n$.

In our treatments of real and complex projective spaces we will often use the following notation.

[84] For example an inverse is given by the map $(\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \to S^n/\{\pm 1\}$ that is defined by $[x] \mapsto [\frac{x}{\|x\|}]$. More precisely, it follows from the Topological-Quotient Proposition 5.15 (1b) and the Topological-Quotient Proposition 5.15 (1a) that both maps are continuous. Clearly they are inverses of one another.

Notation. Let $n \in \mathbb{N}_0$. For $(x_0, \ldots, x_n) \in \mathbb{R}^{n+1} \setminus \{0\}$ we denote by $[x_0 : \ldots : x_n]$ the corresponding point in $\mathbb{R}\mathrm{P}^n$. We also use the same notation for points in complex projective spaces.

The following lemma shows that real and complex projective spaces have some of our favorite properties.

Proposition 5.30. (Projective Spaces-Compact+Hausdorff Proposition) The real projective and the complex projective spaces are compact and Hausdorff.

Example. Let $n \in \mathbb{N}_0$ and let $m \leq n$. We consider the maps

$$\begin{array}{rcl} i\colon \mathbb{R}\mathrm{P}^m & \to & \mathbb{R}\mathrm{P}^n \\ [x_0 \colon \ldots \colon x_m] & \mapsto & [x_0 \colon \ldots \colon x_m \colon 0 \colon \ldots \colon 0] \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon \mathbb{C}\mathrm{P}^m & \to & \mathbb{C}\mathrm{P}^n \\ [z_0 \colon \ldots \colon z_m] & \mapsto & [z_0 \colon \ldots \colon z_m \colon 0 \colon \ldots \colon 0]. \end{array}$$

It follows from the Twice Quotient Lemma 5.23, the Projective Spaces-Compact+Hausdorff Proposition 5.30 and the Compact-Hausdorff Proposition 2.17 (2) that both maps are embeddings. Sometimes we will use these maps to view $\mathbb{R}\mathrm{P}^m$ as a subset of $\mathbb{R}\mathrm{P}^n$ and similarly we will view $\mathbb{C}\mathrm{P}^m$ as a subspace of $\mathbb{C}\mathrm{P}^n$.

In the proof of the Projective Spaces-Compact+Hausdorff Proposition 5.30 it is convenient to have the following description of complex projective spaces.

Auxiliary Lemma 5.31. Let $n \in \mathbb{N}_0$. We make the identification

$$S^{2n+1} \;=\; \{(z_1, \ldots, z_{n+1}) \in \mathbb{C}^{n+1} \,|\, |z_1|^2 + \cdots + |z_{n+1}|^2 = 1\}.$$

We consider the action

$$\begin{array}{rcl} S^1 \times S^{2n+1} & \to & S^{2n+1} \\ (w, (z_1, \ldots, z_{n+1})) & \mapsto & (w \cdot z_1, \ldots, w \cdot z_{n+1}). \end{array}$$

The maps

$$\begin{array}{l} f\colon S^{2n+1}/S^1 \to \mathbb{C}\mathrm{P}^n \\ [z_1, \ldots, z_{n+1}] \mapsto [z_1 \colon \ldots \colon z_{n+1}] \end{array} \quad \text{and} \quad \begin{array}{l} p\colon \mathbb{C}\mathrm{P}^n \to S^{2n+1}/S^1 \\ [z_1 \colon \ldots \colon z_{n+1}] \mapsto \left[\frac{1}{\sqrt{|z_1|^2 + \cdots + |z_{n+1}|^2}}(z_1, \ldots, z_{n+1})\right] \end{array}$$

are continuous and inverses of one another, in particular both maps are homeomorphisms. We will use these maps to make the identification $\mathbb{C}\mathrm{P}^n = S^{2n+1}/S^1$.

Proof. Lemma 5.31] It follows easily from the definition of the quotient topology on the complex projective space $\mathbb{C}\mathrm{P}^n = (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\})$ and from the Topological-Quotient Proposition 5.15 (1a) together with the Topological-Quotient Proposition 5.15 (1b) that both maps are continuous. It is easy to verify that the maps are inverses of one another. ■

Proof of the Projective Spaces-Compact+Hausdorff Proposition 5.30. Let $n \in \mathbb{N}$. It follows from the Compact Image Lemma 2.13 and the Group Action-Hausdorff Quotient Proposition 5.27 that the real projective space $\mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\}$ is compact and Hausdorff.

For the complex projective space $\mathbb{C}\mathrm{P}^n$ we need to work just a little harder. Throughout the remainder of this proof we will use the identification $\mathbb{C}\mathrm{P}^n = S^{2n+1}/S^1$ from Lemma 5.31. Note that since S^{2n+1} is compact it follows again from the Compact Image Lemma 2.13 that $\mathbb{C}\mathrm{P}^n = S^{2n+1}/S^1$ is compact.

It remains to show that $\mathbb{C}\mathrm{P}^n = S^{2n+1}/S^1$ is Hausdorff. A direct argument is sketched in Exercise 5.44. In the following we will provide a less direct but more general argument.

Note that it follows from the Quotient Hausdorff Lemma 5.21 that S^{2n+1}/S^1 is Hausdorff once we have shown that the equivalence relation is closed. Thus we need to show that

$$G \;=\; \{(v_1, v_2) \in S^{2n+1} \times S^{2n+1} \,|\, \text{there exists } w \in S^1 \text{ with } w \cdot v_1 = v_2\},$$

is a closed subset of $S^{2n+1} \times S^{2n+1}$. Note that G is the image of the map

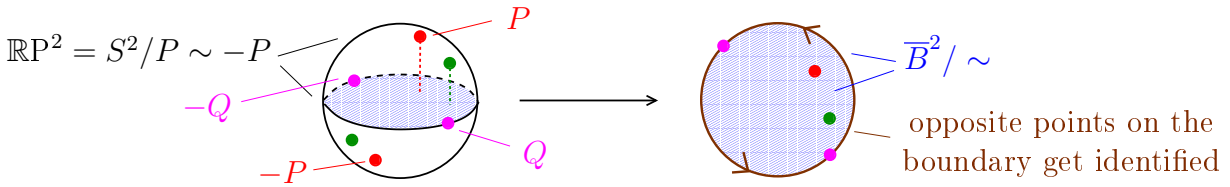
$$\begin{array}{rcl} \Phi\colon S^{2n+1} \times S^1 & \to & S^{2n+1} \times S^{2n+1} \\ (v, w) & \mapsto & (v, w \cdot v). \end{array}$$

This map is continuous and the left-hand side is compact by the Product Topology Properties Proposition 5.6 (2). Thus the image of Φ is compact by the Compact Image Lemma 2.13. By the Product Topology Properties Proposition 5.6 (1) we know that $S^{2n+1} \times S^{2n+1}$ is Hausdorff. Thus we obtain from the Compact-Closed Lemma 1.21 that the image of Φ is a closed subset of $S^{2n+1} \times S^{2n+1}$. ■

In the following lemma we give alternative descriptions of $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^1$ that will be used on many occasions.

Lemma 5.32.

(1) Let $n \in \mathbb{N}$. If we denote by $\sim$ the equivalence relation on $\overline{B}^n$ that is generated by $P \sim -P$ for $P \in S^{n-1} = \partial\overline{B}^n$, then the map



$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\} & \xrightarrow{\cong} & \overline{B}^n/\!\sim \\ [(x_1, \ldots, x_n, x_{n+1})] & \mapsto & \begin{cases} [(x_1, \ldots, x_n)], & \text{if } x_{n+1} \geq 0, \\ [-(x_1, \ldots, x_n)], & \text{if } x_{n+1} < 0 \end{cases} \end{array}$$

is a homeomorphism.

(2) The map

$$\begin{array}{rcl} \mathbb{C}\mathrm{P}^1 & \to & \mathbb{C} \cup \{\infty\} = \mathbb{R}^2 \cup \{\infty\} \\ [z_0 : z_1] & \mapsto & \begin{cases} z_0 \cdot z_1^{-1}, & \text{if } z_1 \neq 0, \\ \infty, & \text{if } [z_0 : z_1] = [1 : 0] \end{cases} \end{array}$$

is a homeomorphism. Similarly we see that $\mathbb{R}\mathrm{P}^1$ is homeomorphic to $\mathbb{R} \cup \{\infty\}$.

Proof. First note that one can easily verify that both maps are actually well-defined and that they are bijections. Next we explain why the two maps are continuous:

(1) By the Topological-Quotient Proposition 5.15 (1b) it suffices to show that the corresponding map $S^n \to \overline{B}^n/\!\sim$ is continuous. One can easily verify that the restriction to the closed subsets $S^n_{\geq 0}$ and $S^n_{\leq 0}$ are continuous. Thus it follows from the Pasting Pasting Proposition 2.6 (2) that the map $S^n \to \overline{B}^n$ is continuous.

(2) It follows again from the Topological-Quotient Proposition 5.15 (1b) that it suffices to show that the corresponding map $\Theta\colon \mathbb{C}^2 \setminus \{(0,0\} \to \mathbb{C} \cup \{\infty\}$ is continuous. Note that for any $C \in \mathbb{R}$ we have

$$\Theta^{-1}(\text{complement of } \overline{B}^n_C) \;=\; \{(z_0, z_1) \in \mathbb{C}^2 \setminus \{(0,0)\} \,|\, |z_0| > |z_1|\}$$

which is an open subset of $\mathbb{C}^2 \setminus \{(0,0)\}$. It follows quite easily from this discussion together with the Subbasis-Continuity Proposition 2.9 and together with the discussion of the basis of $\mathbb{R}^2 \cup \{\infty\}$ on page 132 that the map Θ is continuous.

By the Projective Spaces-Compact+Hausdorff Proposition 5.30 we know that each $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$ is compact. Using the Quotient Hausdorff Lemma 5.21 one can show that $\overline{B}^n/\sim$ is Hausdorff. Furthermore we know from Exercise 1.18 that $\mathbb{R}^2 \cup \{\infty\}$ is Hausdorff. Thus it follows from the Compact-Hausdorff Proposition 2.17 (3) that both maps are homeomorphisms. ■

Convention.

(1) On many occasions we will use the homeomorphism from Lemma 5.32 to make the identification $\mathbb{R}\mathrm{P}^n = \overline{B}^n/\sim$.

(2) In Lemma 2.18 we gave an explicit homeomorphism $S^2 \to \mathbb{R}^2 \cup \{\infty\}$. Combining this homeomorphism with the homeomorphism from Lemma 5.32 we obtain a homeomorphism $S^2 \to \mathbb{C}\mathrm{P}^1$ which we will often use to make the identification $S^2 = \mathbb{C}\mathrm{P}^1$. Note that under this identification the North Pole $(0,0,1) \in S^2$ corresponds to the point $[1:0] \in \mathbb{C}\mathrm{P}^1$.

We conclude this short section on projective spaces with two somewhat tangential remarks.

Remark.

(1) Here is a fun fact: if we consider $\mathbb{C}\mathrm{P}^2/\sim$, where $\sim$ denotes the equivalence relation defined by complex conjugation, i.e. where $[z:w] \sim [\overline{z}:\overline{w}]$, then the quotient space is homeomorphic (in fact diffeomorphic in a suitable sense) to S^4. This statement is known as the Arnold–Kuiper–Massey Theorem, see e.g. [**?, ?, ?**].

(2) The definition of projective spaces makes sense for any field, even for fields of non-zero characteristic. For example, if $\mathbb{F}$ is a field of characteristic p we can still define the set $\mathbb{F}\mathrm{P}^n = (\mathbb{F}^{n+1} \setminus \{0\})/(\mathbb{F} \setminus \{0\})$. A priori this is just a set, but together with the Zariski topology, see [**Har1992**, Lecture 2] or [**SKKT2000**, Chapter 1], it actually becomes an unusual, but interesting topological space.
For any field the map

$$\begin{array}{rcl} \mathbb{F}\mathrm{P}^n = (\mathbb{F}^{n+1} \setminus \{0\})/(\mathbb{F} \setminus \{0\}) & \to & \{\text{all one-dimensional subspaces of } \mathbb{F}^{n+1}\} \\ [v] & \mapsto & \mathbb{F} \cdot v \end{array}$$

is a bijection. Thus we can view $\mathbb{F}\mathrm{P}^n$ as the set of all lines through the origin.

5.8. **The pushout in the topological category.** In this section we consider a particularly important special case of a quotient topology which deserves its own section. Before we delve into topology we recall the following definition.

Definition. Suppose we are given a relation $\sim$ on a set X. We say $x, y \in X$ are equivalent if there exists a sequence $x = x_1, \ldots, x_k = y$ of elements in X such that for all $i = 1, \ldots, k-1$ the following holds: either $x_i \sim x_{i+1}$ or $x_{i+1} \sim x_i$. We write again $x \sim y$ if x and y are equivalent. It is straightforward to see that this is now indeed an equivalence relation. We say it is generated by the initial relation.

Example. The relations $x \sim (x+1)$ with $x \in \mathbb{R}$ on $\mathbb{R}$ generate the familiar equivalence relation $x \sim y \Leftrightarrow x - y \in \mathbb{Z}$.

Definition. Let $f\colon X \to Y$ and $g\colon X \to Z$ be two maps between topological spaces. We define

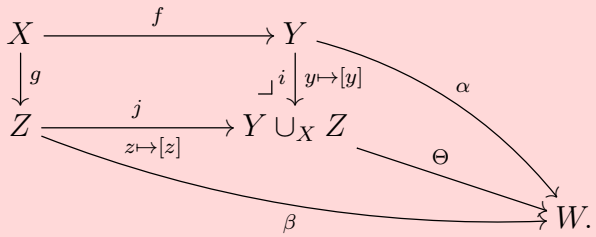
$$Y \cup_X Z \;:=\; (Y \sqcup Z)/\!\sim \qquad \text{where } f(x) \sim g(x) \text{ for all } x \in X.$$

We refer to $Y \cup_X Z$ as the pushout of f and g. Furthermore we refer to the maps

$$\begin{array}{rcl} i\colon Y & \to & Y \cup_X Z \\ y & \mapsto & [y] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} j\colon Z & \to & Y \cup_X Z \\ z & \mapsto & [z] \end{array}$$

as the two natural maps.

The notion of a pushout will play an important role throughout the lecture notes. We first summarize some key properties of pushouts, afterwards we will discuss an important special case.



Proposition 5.33. (Topological Pushout Proposition) Let $f\colon X \to Y$ and $g\colon X \to Z$ be two maps between topological spaces. The following statements hold:

(1) (a) The natural maps $i\colon Y \to Y \cup_X Z$ and $j\colon Z \to Y \cup_X Z$ are continuous.

(b) Suppose we are given two maps $\alpha\colon Y \to W$ and $\beta\colon Z \to W$ to some topological space W such that $\alpha \circ f = \beta \circ g\colon X \to W$. The map

$$\begin{array}{rcl} \Theta\colon Y \cup_X Z & \to & W \\ [P] & \mapsto & \begin{cases} \alpha(x) & \text{if } P = [y] \text{ for some } y \in Y, \\ \beta(y) & \text{if } P = [z] \text{ for some } z \in Z \end{cases} \end{array}$$

is well-defined and it is the unique map $h\colon Y \cup_X Z \to W$ with $\Theta \circ i = \alpha$ and $\Theta \circ j = \beta$. Furthermore, if α and β are continuous, then Θ is also continuous. In particular we obtain the following commutative diagram:

(2) The topological space $Y \cup_X Z$ with the natural maps $Y \to Y \cup_X Z$ and $Z \to Y \cup_X Z$ is the pushout in the sense of the definition on page 220.

Proof. Throughout the proof we denote by $p\colon Y \sqcup Z \to Y \cup_X Z$ the natural projection.

(1) (a) It follows from the Topological-Coproduct Proposition 5.11 (1a) and the Topological-Quotient Proposition 5.15 (1a) that the natural maps $i\colon Y \to Y \cup_X Z$ and $j\colon Z \to Y \cup_X Z$ are continuous.

(b) This statement is an immediate consequence of the definitions and the Topological-Quotient Proposition 5.15 (1b).

(2) This statement follows easily from the definitions and Statement (1). We leave it to the reader to fill in the details. ∎

Lemma 5.34. (Topological Pushout-Maps Lemma) Let $f\colon X \to Y$ and $g\colon X \to Z$ be two maps between topological spaces. We obtain the following commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \downarrow{\scriptstyle g} & \lrcorner & \downarrow{\scriptstyle i}\ {\scriptstyle y\mapsto[y]} \\ Z & \xrightarrow[z\mapsto[z]]{j} & Y \cup_X Z. \end{array}$$

The following statements hold:

(1) If f is a homeomorphism, then the "opposite map" j is a homeomorphism.
(2) If f is injective, then the "opposite map" j is injective. The same statement holds for "surjective" and "bijective".[85]
(3) If f is an embedding, then the "opposite map" j is an embedding.
(4) Suppose that at least one of the two maps f or g is injective.
   (α) If the image of f is a closed subset of Y, then the image of the "opposite map" j is a closed subset of $Y \cup_X Z$.
   (β) If the image of g is a closed subset of Z, then the image of the "opposite map" i is a closed subset of $Y \cup_X Z$.
   Both statements also hold with "closed" replaced by "open".

By symmetry the statements in (1), (2) and (3) hold also for g and its "opposite map" i.

Proof. Throughout the proof we denote by $p\colon Y \sqcup Z \to Y \cup_X Z$ the natural projection.

(1) Suppose $f\colon X \to Y$ is a homeomorphism. It follows immediately from the Pushout Lemma 4.8 (1) that $j\colon Z \to Y \cup_X Z$ is a homeomorphism.
(2) Let $z \in Z$. It follows basically from the definitions that the set of elements in Z that are equivalent to z with respect to the equivalence relation "$\sim$" on $Y \sqcup Z$ equals precisely

$$\bigcup_{k\in\mathbb{N}_0} \underbrace{g(f^{-1}(f(g^{-1}(\dots g(f^{-1}(f(g^{-1}(}_{\text{applied } k \text{ times}}\{z\}))))\dots)))).$$

If f is injective, then it follows immediately from the Image-Preimage Lemma 0.2 (1) and (2) that this set consists precisely of the element z. In other words, the map j is injective. The proof for "surjective" is very similar.
(3) We suppose that $f\colon X \to Y$ is an embedding. By the Topological Pushout Proposition 5.33 we know that j is continuous and by (1) we know that $j\colon Z \to Y \cup_X Z$ is injective. By the Open -Injective Map Lemma 2.16 (2) and by definition of the subspace topology on $j(U)$ it remains to prove the following claim.

Claim. If U is an open subset of Z, then there exists an open subset W of $Y \cup_X Z$ such that $j(U) = W \cap j(Z)$.

Proof. Let U be an open subset of Z. Since g is continuous we know that $g^{-1}(U)$ is an open subset of X. Since f is an embedding we know that there exists an open subset $V \subset Y$ with $f(g^{-1}(U)) = f(X) \cap V$. We set $W := p(U \sqcup V)$. A short argument shows that $p^{-1}(W) = U \sqcup V$. Thus it follows from the definition of the quotient

[85] This statement is very close to the content of Exercise 4.11.

topology and the disjoint union topology that W is indeed an open subset of $Y \cup_X Z$. Basically by construction we have $j(U) = W \cap j(Z)$. ⊞

(4) Without loss of generality we can assume that f is injective. The statements for "closed" follow almost immediately from the following observations:
- By the Topological-Quotient Proposition 5.15 (0b) a subset W of $Y \cup_X Z$ is closed if and only if $p^{-1}(W)$ is closed.
- Since f is injective it follows from the argument in (2a) that
$$p^{-1}(i(Y)) = Y \sqcup g(X) \quad \text{and} \quad p^{-1}(j(Z)) = f(g^{-1}(Z)) \sqcup Z = f(X) \sqcup Z.$$
- By Lemma 5.12 a subset $U \sqcup V$ of $Y \sqcup Z$ is closed if and only if U and V are closed.

The proof for "open" is basically the same. ■

Proposition 5.35. (Pushout Properties Proposition) Let $f\colon X \to Y$ and $g\colon X \to Z$ be two maps between topological spaces.

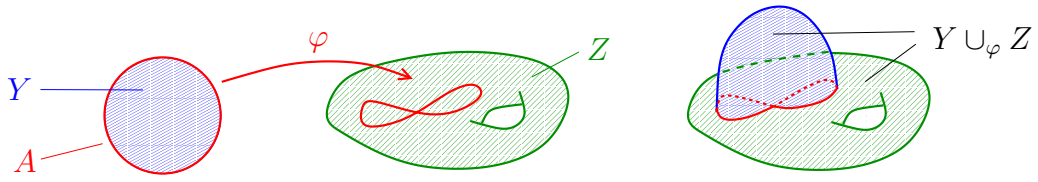
(1) If Y and Z are compact, then so is the pushout $Y \cup_X Z$.
(2) If Y and Z are (path-) connected and if X is non-empty, then so is the pushout $Y \cup_X Z$.

Proof.

(1) If Y and Z are compact, then it follows from the Disjoint Union Topology-Properties Lemma 5.13 (2) and the Quotient-Compact Connected Lemma 5.16 (1) that $Y \cup_X Z$ is compact.
(2) If Y and Z are (path-) connected, then it follows easily from the Image-Connected Lemma 2.24 and the Union Connected Lemma 2.28 that $Y \cup_X Z$ is also (path-) connected. ■

Example. Let $n \in \mathbb{N}_0$. We consider the maps[86]
$$\begin{array}{rcl} g_\pm\colon \overline{B}^n = \overline{B}^n_\pm & \to & S^n \\ (x_1, \dots, x_n) & \mapsto & \big((-1)^n \cdot x_1, \dots, x_n, \pm\sqrt{1 - x_1^2 - \dots - x_n^2}\big). \end{array}$$
It follows from the Topological Pushout Proposition 5.33 (1b) that the map
$$\begin{array}{rcl} \overline{B}^n_+ \cup_{S^{n-1}} \overline{B}^n_- & \to & S^n \\ [P] & \mapsto & \begin{cases} g_+(P), & \text{if } P \in \overline{B}^n_+, \\ g_-(P), & \text{if } P \in \overline{B}^n_- \end{cases} \end{array}$$
is continuous. One can easily verify that it is a bijection. It follows from the the Pushout Properties Proposition 5.35 (1) combined with the Compact-Hausdorff Proposition 2.17 (3) that the map is a homeomorphism. We use this homeomorphism to make the identification $\overline{B}^n_+ \cup_{S^{n-1}} \overline{B}^n_- = S^n$.[87]

Now, as promised we will discuss an important class of pushouts, namely where the map $f\colon X \to Y$ is just the inclusion of a subset. This leads us to the following definition.



[86] We put in the superfluous looking sign $(-1)^n$ for the following reason: once we have introduced orientations of smooth manifolds and once we have introduced the standard orientations of $\overline{B}^n$ and S^n this sign assures us that the map $g_+\colon \overline{B}^n \to S^n$ is orientation-preserving and it means that $g_-\colon \overline{B}^n \to S^n$ is orientation-reversing.

[87] In Exercise **??** we will see that we can also identify $\overline{B}^n_+ \cup_{S^{n-1}} \overline{B}^n_-$ and S^n as "smooth manifolds".

Definition. Let Y and Z be topological spaces, let $A \subset Y$ be a subset and let $\varphi\colon A \to Z$ be a continuous map. (Note that φ does not need to be injective.) We write

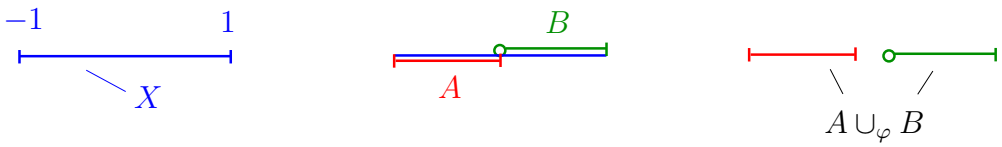
$$Y \cup_\varphi Z \;:=\; Y \cup_{\varphi\colon A \to Z} Z \;:=\; (Y \sqcup Z)/\!\sim$$

where $\sim$ is the equivalence relation generated by $a \sim \varphi(a)$ for $a \in A$. We call $Y \cup_\varphi Z$ the topological space obtained by gluing Y to Z via the map f.

Example. Let Y be a topological space and let A be a subset of Y. If Z is the topological space that consists of a single point, then there exists evidently precisely one map $\varphi\colon A \to Z$ and it follows basically immediately from the definitions that $Y \cup_\varphi Z$ is homeomorphic to Y/A.

The following lemma is quite subtle and gets used, often inadvertently, on many occasions.

Lemma 5.36. Let X be a topological space and let A and B be two subsets of X with $X = A \cup B$. We denote by $\varphi\colon A \cap B \to A \cap B$ the identity map. We suppose that one of the following two conditions hold:



(1) Both subsets A and B are closed.
(2) Both subsets A and B are open.

Then the map

$$\begin{array}{rcl} A \cup_{\varphi\colon A\cap B \to A\cap B} B & \to & X \\ [x] & \mapsto & x \end{array}$$

is a homeomorphism.

Remark. In general the conclusion of the lemma does not hold without some assumptions on A and B. For example, consider $X = [-1, 1]$ together with the subsets $A = [-1, 0]$ and $B = (0, 1]$. In this case $A \cap B = \varnothing$, thus $A \cup_\varphi B$ is the disjoint union of A and B. It follows from the Disjoint Union Topology-Properties Lemma 5.13 (2) and the Heine-Borel 1.24 Theorem that $A \sqcup B$ is not compact. On the other hand $X = [-1, 1]$ is compact by the Heine-Borel 1.24. Thus the two topological spaces $A \cup_\varphi B$ and X are not homeomorphic.

Proof. Let X be a topological space and let A and B be two subsets of X with $X = A \cup B$. We denote by $\varphi\colon A \cap B \to A \cap B$ the identity map. In the following we consider the case that A and B are both closed subsets of X. The case that both A and B are open subsets is dealt with in almost entirely the same way.

It follows from the Topological Pushout Proposition 5.33 (1b) that the given map $h\colon A \cup_{\varphi\colon A\cap B \to A\cap B} B \to X$ is continuous. Furthermore, basically by definition the map h is

a bijection. By the Open -Injective Map Lemma 2.16 (2) it remains to show that the map h is closed. Thus let $W \subset A \cup_\varphi B$ be a closed subset. Note that $h(W) = (W \cap A) \cup (W \cap B)$. It follows from the Topological-Quotient Proposition 5.15 (0b), applied to the projection

$$A \sqcup B \ \to \ A \cup_\varphi B = (A \sqcup B)/\!\sim,$$

that $A \cap W$ is closed in A and that $B \cap W$ is closed in B. Since A and B are by hypothesis closed in X we obtain from the Open -Closed Inclusion Lemma 2.10 (2) that $A \cap W$ and $B \cap W$ are closed in X. Therefore $h(W) = (W \cap A) \cup (W \cap B)$ is a closed subset of X. ■

We conclude this section with an amusing description of spheres. We introduce the following notation:

(1) We write $I = [-1, 1]$.
(2) It follows from the Product-of-Subsets Lemma 5.5 (2) that given $k \in \mathbb{N}_0$ we have

$$\partial I^k \ = \ \{(x_1, \ldots, x_k) \in I^k \mid \text{ at least one } x_i \text{ lies in } \{\pm 1\}\}.$$

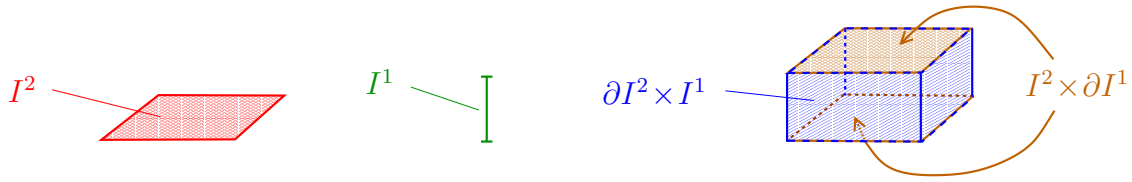
(3) We recall that given $k \in \mathbb{N}_0$ there exists by the Convex-to-Ball Proposition 2.20 a canonical homeomorphism

$$\varphi_k \colon (\overline{B}^k, S^{k-1}) \ \xrightarrow{\cong} \ (I^k, \partial I^k)$$

with $\varphi_k(0) = 0$.

Now let $m, n \in \mathbb{N}_0$. An elementary set-theoretic argument shows that

$$((\partial I^m) \times I^n) \ \cup \ (I^m \times \partial I^n) \ = \ \partial I^{m+n}$$



and the two subsets to the left coincide in $(\partial I^m) \times (\partial I^n)$. It follows from Lemma 5.36 that the inclusions induce a homeomorphism

$$((\partial I^m) \times I^n) \cup_{\mathrm{id}_{\partial I^m \times \partial I^n}} (I^m \times \partial I^n) \ \xrightarrow{\cong} \ \partial I^{m+n}.$$

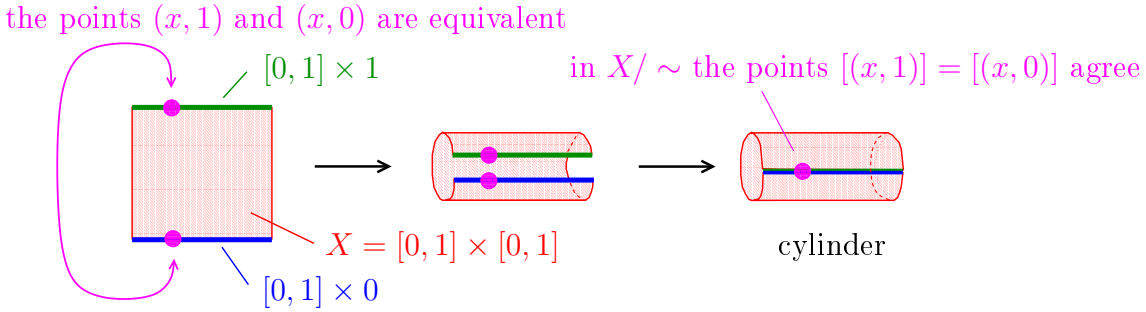
Together with the above homeomorphisms we obtain a canonical homeomorphism

$$(S^{m-1} \times \overline{B}^n) \cup_{\mathrm{id}_{S^{m-1} \times S^{n-1}}} (\overline{B}^m \times S^{n-1}) \ \xrightarrow{\cong} \ S^{m+n-1}.$$

For example, if we take $m = n = 2$, then we see that we can write S^3 as the union of two solid tori. We will discuss this particular case in greater detail later in Section 59.1.

5.9. **Surfaces.** In this section we introduce some of my favorite topological spaces, namely surfaces.

(1) We consider $X = [0, 1] \times [0, 1] \subset \mathbb{R}^2$ and the equivalence relation which is generated by



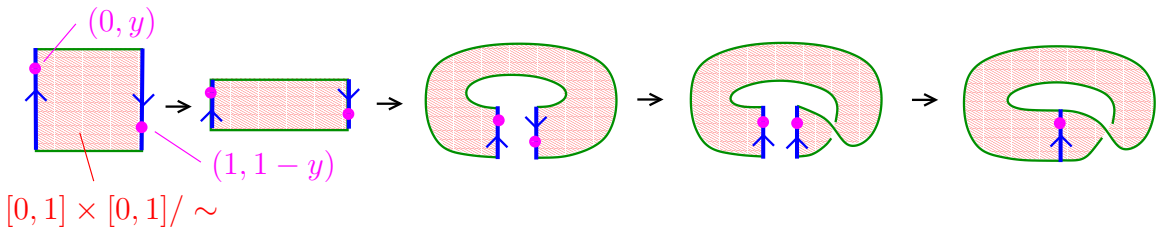
$$(x, 0) \ \sim \ (x, 1) \quad \text{for all } x \in [0, 1].$$

The quotient topological space $X/\!\sim$ is obtained from the square $X = [0, 1] \times [0, 1]$ by identifying each point on the upper edge with the corresponding point on the lower

edge. Put differently, "we glue the upper edge to the lower edge". Using the Compact-Hausdorff Proposition 2.17 (3) one can easily show that the map

$$\begin{array}{rcl} X/\sim & \to & S^1 \times [0,1] \\ [(s,t)] & \mapsto & \big(\exp(2\pi\,\mathrm{i}t), s\big) \end{array}$$

is a homeomorphism. We refer to $X/\sim$ and also to $S^1 \times [0,1]$ as the cylinder or the annulus. Sometimes we refer to $S^1 \times (0,1)$, which is homeomorphic to $(0,1) \times [0,1]/\sim$, as the open cylinder or open annulus.



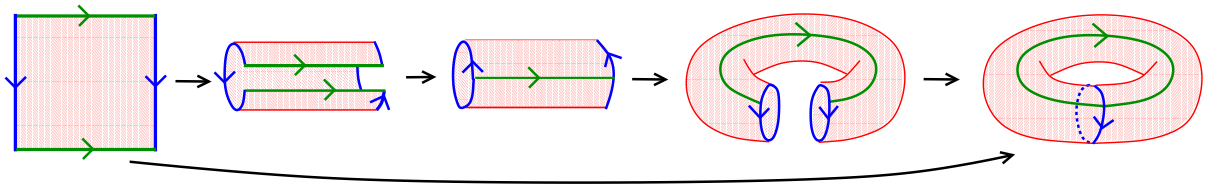
(2) Now we consider $X = [0,1] \times [0,1] \subset \mathbb{R}^2$, this time with the equivalence relation which is generated by

$$(0,y) \sim (1,1-y) \quad \text{for all } y \in [0,1].$$

The quotient space $X/\sim$ is obtained from the square X by gluing the edge on the left to the edge on the right, but this time "we glue the edges with a twist". We will now see that this topological space is homeomorphic to the Möbius band as defined on page 252. We consider the map

$$\begin{array}{rcl} ([0,1] \times [0,1])/\sim & \to & (\mathbb{R} \times [-1,1])/\mathbb{Z} \\ [(x,y)] & \mapsto & [(x, 2y-1)] \end{array}$$

The left-hand side is compact by the Quotient-Compact Connected Lemma 5.16 (1) and the right-hand side is Hausdorff by the Group Action-Hausdorff Quotient Proposition 5.27 and the discussion on page 253. The map is clearly continuous and a bijection. Thus it follows from the ever-popular the Compact-Hausdorff Proposition 2.17 (3) that the map is a homeomorphism. We will use this homeomorphism to identify $([0,1] \times [0,1])/\sim$ with the Möbius band. It is straightforward to see that this homeomorphism restricts to a homeomorphism from $([0,1] \times (0,1))/(0,y) \sim (1,1-y)$ to the open Möbius band $(\mathbb{R} \times (-1,1))/\sim$.



(3) Now we consider again $X = [0,1] \times [0,1] \subset \mathbb{R}^2$, but this time with the equivalence relation which is generated by

$$(x,0) \sim (x,1) \quad \text{for all } x \in [0,1]$$

and by

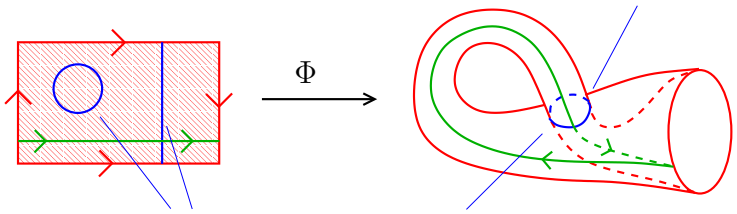
$$(0,y) \sim (1,y) \quad \text{for all } y \in [0,1].$$

Put differently, we obtain the quotient topological space $X/\sim$ by gluing the top edge to the bottom edge and the left-hand edge to the right-hand edge, each time without adding a twist. The figure below illustrates that the quotient space $X/\sim$ is indeed a torus. As in the previous example one can show that the inclusion $X \to \mathbb{R}^2$ descends

by gluing of the opposite edges of a square we obtain a torus

to a homeomorphism $X/\sim \to \mathbb{R}^2/\mathbb{Z}^2$. In other words, we can make the identification $\mathbb{R}^2/\mathbb{Z}^2 = ([0,1] \times [0,1])/\sim$

(4) Now we consider $X = [0,1] \times [0,1] \subset \mathbb{R}^2$, this time with the equivalence relation which is generated by



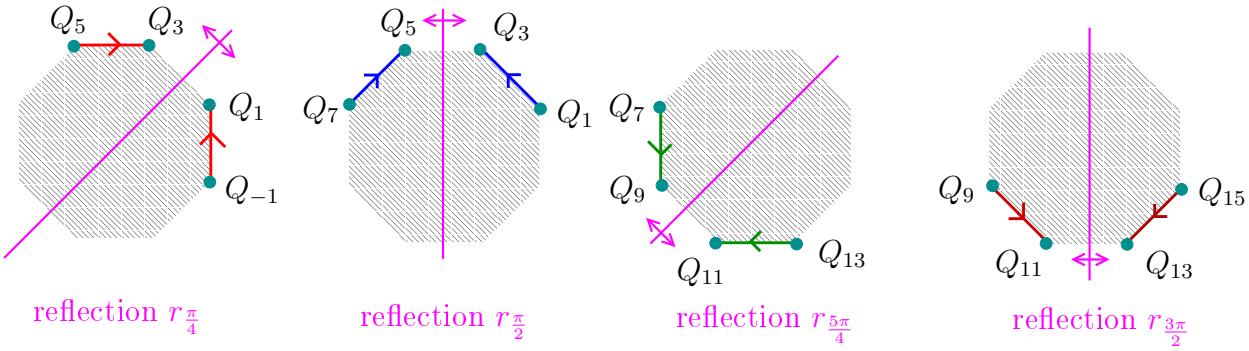
$$(x,0) \sim (x,1) \quad \text{for all } x \in [0,1]$$

and by

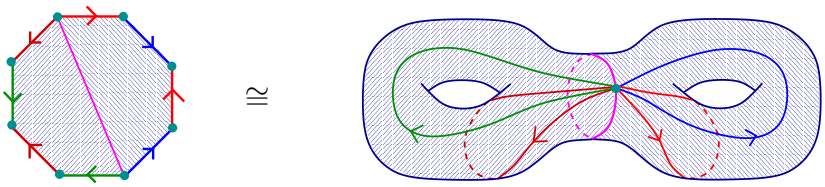
$$(0,y) \sim (1,1-y) \quad \text{for all } y \in [0,1].$$

Thus we obtain the quotient space $X/\sim$ by gluing the upper edge to the lower edge and by gluing the edge on the left to the edge on the right with a twist. The resulting topological space is called the Klein bottle. In the figure below we show the Klein bottle to the left. Furthermore we indicate a map from the Klein bottle to $\mathbb{R}^3$. This particular map is not injective.

the given map from the Klein bottle to $\mathbb{R}^3$ has a self-intersection

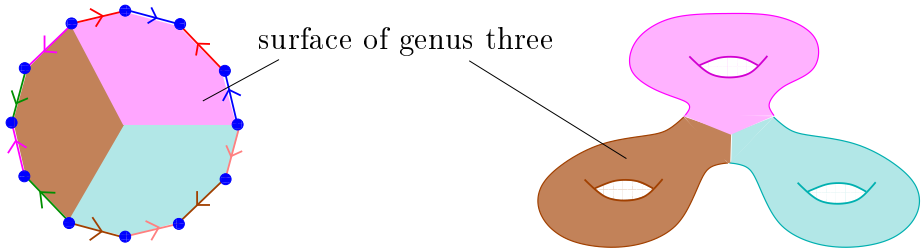


the images of these two circles are the same



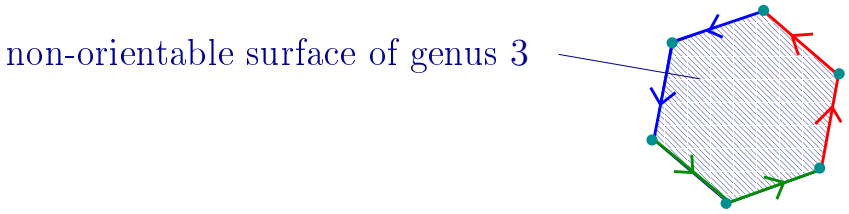
(5) We denote by E_8 the regular octagon in $\mathbb{C}$ with the vertices $Q_k = \exp(2\pi \mathrm{i} k/16)$ where $k = 1, 3, \ldots, 15$, i.e. E_8 is the convex hull of these eight points in $\mathbb{R}^2$. Given two points $A, B \in \mathbb{R}^2 = \mathbb{C}$ we denote by $\overline{AB}$ the Euclidean segment from A to B. Furthermore, given $\varphi \in \mathbb{R}$ we denote by $r_\varphi \colon \mathbb{C} \to \mathbb{C}$ the reflection in the Euclidean line $\{t \exp(\mathrm{i}\varphi) \mid t \in \mathbb{R}\}$. We denote by $\sim$ the equivalence relation on E_8 which is generated by

$$P \in \overline{Q_{2k-1}Q_{2k+1}} \;\sim\; r_{2\pi(2k+2)/16}(P) \;\in\; \overline{Q_{2k+3}Q_{2k+5}}$$



for $k = 0, 1, 4, 5$. We refer to the topological space $E_8/\sim$ as the surface of genus 2. Furthermore, in the figure below we indicate how $E_8/\sim$ is related to the actual

"physical" surface of genus 2 in $\mathbb{R}^3$. The same way we can define the surface Σ_g of



genus g for any $g \geq 3$. More precisely, we take a regular $4g$-gon in $\mathbb{C}$ and for $j = 1, \ldots, g$ we identify the $(4j+1)$-st edge with the $(4j+3)$-rd edge and the $(4j+2)$-nd edge with the $(4j+4)$-th edge. Here each identification is given by a reflection.

Finally we refer to the sphere S^2 as the surface of genus 0 and we refer to the torus $S^1 \times S^1$ as the surface of genus 1.

(6) Given $g \in \mathbb{N}_{\geq 2}$ we consider the regular $2g$-gon E_{2g} with the identification of the boundary segments shown in the figure below. We refer to this topological space as the non-orientable surface N_g of genus g. (Later on in the Surface Non-Orientability Lemma 25.20 we will see why N_g deserves its epithet.) Furthermore, we refer to the real projection place $\mathbb{R}\mathrm{P}^2$ as the non-orientable surface of genus 1. In Exercise 5.50 we will see that the Klein bottle is homeomorphic to the non-orientable surface of genus 2. Furthermore, as a sneak preview, let us point out that later in Lemma **??** we will see that N_g is diffeomorphic to the connected sum of g copies of $\mathbb{R}\mathrm{P}^2$.

We have now introduced many examples of topological spaces, some of them, for example the Möbius band, the torus and the surface of genus 2, can easily be pictured as subsets of "our universe", i.e. they can be viewed as subsets of $\mathbb{R}^3$. This raises the following question.

Question 5.37. Can the real projective space $\mathbb{R}\mathrm{P}^2$ and the Klein bottle, or more generally the non-orientable surfaces of some genus ≥ 3, be viewed[88] as subsets of $\mathbb{R}^3$?

5.10. **Topological groups.** Now that we notion of the product topology we can introduce the notion of a topological group. This notion does not play an essential role in the lecture notes, but it will pup up every now and then.

Definition. A topological group is a topological space X together with a group structure, such that the two maps[89]

$$\begin{array}{ccc} X\times X & \to & X \\ (x,y) & \mapsto & x\cdot y \end{array} \quad \text{and} \quad \begin{array}{ccc} X & \to & X \\ x & \mapsto & x^{-1} \end{array}$$

are continuous.

The most basic example of a topological group is given by taking any group and equipping it with the discrete topology. As we will see in Lemma 5.39 (2), somewhat surprisingly even this banal example can turn out to be interesting.

The following lemma gives us much more interesting examples of topological groups.

Lemma 5.38. For any $n \in \mathbb{N}$ the matrix groups $\mathrm{GL}(n,\mathbb{R})$ and $\mathrm{GL}(n,\mathbb{C})$ are topological groups.

Proof. As we pointed out on page 227, matrix multiplication is continuous. Furthermore, basic linear algebra, see e.g. [**HJa2013**, Chapter 0.8.2], says that taking the inverse is given by the map

$$\begin{array}{ccc} \mathrm{GL}(n,\mathbb{R}) & \to & \mathrm{GL}(n,\mathbb{R}) \\ A & \mapsto & \frac{1}{\det(A)} \cdot \underbrace{\begin{array}{c}\text{matrix whose } (i,j)\text{-entry is given by taking the determinant} \\ \text{of the matrix that is obtained from } A \text{ by removing} \\ \text{the } i\text{-th column and the } j\text{-th row of } A.\end{array}}_{=\text{called the adjugate of } A} \end{array}$$

But this map is clearly continuous. This shows that $\mathrm{GL}(n,\mathbb{R})$ is a topological group. Basically the same argument also shows that $\mathrm{GL}(n,\mathbb{C})$ is a topological group. ∎

After this first list of examples let us formalize the setting a little bit by introducing the category of topological groups.

Definition. We refer to the category $\mathcal{TopGr}$ with

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{TopGr}) & := & \text{all topological groups,} \\ \mathrm{Mor}(X,Y) & := & \text{all homomorphisms from } X \text{ to } Y \text{ that are continuous,} \end{array}$$

with the usual composition of maps as the category of topological groups.

We obtain more examples of topological groups by taking subgroups and products:

[88] The word "view" is intentionally vague.

[89] Here we evidently equip $X \times X$ with the product topology.

Lemma 5.39.

(1) Let X be a topological group and let Y be a subgroup. If we equip Y with the subspace topology, then Y is also a topological group.

(2) Let $\{X_i\}_{i\in I}$ be a family of topological groups. If we equip $\prod_{i\in I} X_i$ with the product topology and the obvious group structure, then it is again a topological group.

Proof.

(1) This statement follows immediately from Lemma 2.1 together with the Product Topology-Basics Lemma 5.4 (4).

(2) This statement follows easily from the Topological-Product Proposition 5.1 and the Product Topology-Basics Lemma 5.4 (2). ■

Example. It follows from Lemmas 5.38 and 5.39 (1) that $\mathrm{SL}(n,\mathbb{R})$, $\mathrm{O}(n)$, $\mathrm{SO}(n)$, $\mathrm{GL}(n,\mathbb{C})$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$ are topological groups.

Lemma 5.40. Let G be a topological group.

(1) Given any $g \in G$ the two maps

$$\begin{array}{rcl} l_g\colon G & \to & G \\ h & \mapsto & g\cdot h \end{array} \quad \text{and} \quad \begin{array}{rcl} r_g\colon G & \to & G \\ h & \mapsto & h\cdot g \end{array}$$

are continuous.

(2) If G is a topological group, then any two path-components of G are homeomorphic.

Proof.

(1) The map l_g is the composition of the two maps

$$\begin{array}{rcl} G & \to & G\times G \\ h & \mapsto & (g,h) \end{array} \quad \text{and} \quad \begin{array}{rcl} G\times G & \to & G \\ (x,y) & \mapsto & x\cdot y. \end{array}$$

The first map is continuous by the Product Topology-Basics Lemma 5.4 (1) and the second map is continuous since G is a topological group. Thus l_g itself is continuous. The same argument shows that r_g is continuous.

(2) Let X, Y be two path-components of G. We pick $x \in X$ and $y \in Y$. We consider the map $\varphi\colon G \to G$ given by $g \mapsto yx^{-1}g$. By (1) we know that φ is continuous. Furthermore it follows from Lemma 2.35 that $\varphi(X) \subset Y$.

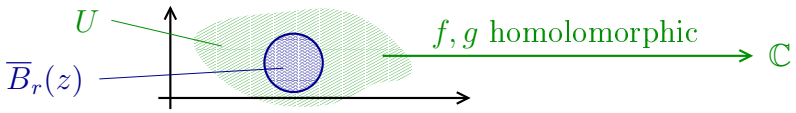
We also consider the map $\psi\colon G \to G$ given by $g \mapsto xy^{-1}g$. The same argument as above shows that ψ is continuous and that $\psi(Y) \subset X$. Clearly φ and ψ are inverses of one another. But this implies that φ and ψ are homeomorphisms between X and Y. ■

5.11. **Continuity of zeros.** We conclude this long chapter with a slightly peripheral discussion on the zeros of complex polynomials. This discussion shows in particular that group actions can appear in unexpected situations. We start out with the following slightly vague question.

Question 5.41. Let $n \in \mathbb{N}$. Do the zeros of a polynomial of degree n vary continuously with the coefficients of the polynomial?

The first question is, what does it mean that the "zeros of a polynomial" vary "continuously"? What are the topological spaces involved so that we can talk about continuity? The following proposition kills two birds at once: it makes the question precise and it gives a complete answer.

Proposition 5.42. (Zeros Continuity Proposition) Let $n \in \mathbb{N}$. We consider the action by the permutation group S_n on $\mathbb{C}^n$ that is given by permuting the coordinates. The map[90]



$$\begin{array}{rcl} f\colon \mathbb{C}^n & \to & \mathbb{C}^n/S_n \\ (v_0,\dots,v_{n-1}) & \mapsto & \left[\begin{array}{c} \text{set of zeros of the polynomial} \\ v_0 + v_1\cdot z + \dots + v_{n-1}\cdot z^{n-1} + z^n, \\ \text{counted with multiplicities} \end{array}\right] \end{array}$$

is continuous, in fact it is a homeomorphism.

Remark. For $n = 1, 2, 3, 4$ one can hope to prove the Zeros Continuity Proposition 5.42 by the formulas for determining zeros of polynomials of degree n. But since no such formula exists for general polynomials of higher degree this approach is doomed for $n \geq 5$.

The proof of the Zeros Continuity Proposition 5.42 makes use Rouché's Theorem from complex analysis.

Theorem 5.43. (Rouché's Theorem) Let $U \subset \mathbb{C}$ be an open set. Furthermore let $f, g\colon U \to \mathbb{C}$ be two holomorphic[91] functions and let $z \in U$ and $r \in \mathbb{R}_{>0}$ be such that $\overline{B}_r(z) = \{w \in \mathbb{C} \,|\, |w - z| \leq r\}$ is contained in U. If for all $w \in \partial\overline{B}_r(z)$ we have the inequality $|g(w)| < |f(w)|$, then f and $f + g$ have the same number of zeros (counted with multiplicities) within the open disk $B_r(z)$.

Proof. This theorem is proved in every self-respecting book on complex analysis, see e.g. [**Lang1999**, Theorem VI.1.6]. ■

Example. We consider $f(z) = z^5$ and the disk $\overline{B}_1(0)$. The polynomial $f(z)$ has one zero of multiplicity five in $\overline{B}_1(0)$. For any $a, b \in \mathbb{C}$ with $|a| + |b| < 1$ we have $|az + b| < |z^5|$ for all points $z \in \partial\overline{B}_1(0) = S^1$. Thus by Rouché's Theorem 5.43 we see that for such a, b the polynomial $z^5 + az + b$ also has five zeros (counted with multiplicities) in $\overline{B}_1(0)$.

We will also need the following definition:

Definition. Given $w = [(w_1,\dots,w_n)]$ and $z = [(z_1,\dots,z_n)]$ in $\mathbb{C}^n/S_n$ we define

$$d(w,z) \;:=\; \min_{\sigma\in S_n} \max_{1\leq j\leq n} \big|w_j - z_{\sigma(j)}\big|.$$

The following lemma summarizes two key statements regarding the above definition.

[90] Slightly more rigorously the map f is defined as follows: given $(v_0,\dots,v_{n-1}) \in \mathbb{C}^n$ we define $f(v_0,\dots,v_{n-1}) := [(\alpha_1,\dots,\alpha_n)]$ where $\alpha_1,\dots,\alpha_n \in \mathbb{C}$ are determined uniquely (up to reordering) by the condition that $v_0 + v_1 z + \dots + v_{n-1}z^{n-1} + z^n = (z-\alpha_1)\cdot\dots\cdot(z-\alpha_n) \in \mathbb{C}[z]$.

[91] We will introduce the notion of a holomorphic function on page 789. But at this point it suffices to know that polynomial functions are holomorphic.

Lemma 5.44.

(1) The map

$$\begin{array}{rcl} d\colon \mathbb{C}^n/S_n \times \mathbb{C}^n/S_n & \to & \mathbb{R}_{\geq 0} \\ (w,z) & \mapsto & d(w,z) \end{array}$$

is a metric on $\mathbb{C}^n/S_n$.

(2) The topology defined by the metric d on $\mathbb{C}^n/S_n$ agrees with the quotient topology on $\mathbb{C}^n/S_n$.

Proof. We hand over the task providing the proof of the lemma to the surely very meticulous reader. ■

Now we are in a position to prove the Zeros Continuity Proposition 5.42.

Proof of the Zeros Continuity Proposition 5.42. Recall that we need to show that the map

$$\begin{array}{rcl} f\colon \mathbb{C}^n & \to & \mathbb{C}^n/S_n \\ (v_0,\ldots,v_{n-1}) & \mapsto & \left[\begin{array}{c} \text{set of zeros of the polynomial} \\ v_0 + v_1\cdot z + \cdots + v_{n-1}\cdot z^{n-1} + z^n, \\ \text{counted with multiplicities} \end{array}\right] \end{array}$$

is a homeomorphism. To do so we consider the map[92]

$$\begin{array}{rcl} g\colon \mathbb{C}^n/S_n & \to & \mathbb{C}^n \\ [(\alpha_1,\ldots,\alpha_n)] & \mapsto & \text{coefficients of the polynomial } (z-\alpha_1)\cdot\cdots\cdot(z-\alpha_n). \end{array}$$

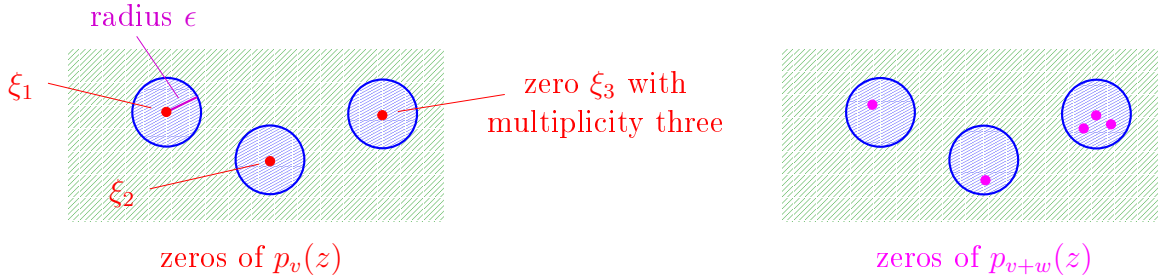
It is straightforward to check that g is continuous and that f and g are inverses of one another.

It remains to show that f is continuous. We introduce the following definitions: We denote by d the above metric on $\mathbb{C}^n/S_n$. It follows from Lemma 5.44 that we can view f as a map between the two metric spaces $(\mathbb{C}^n, \|-\|)$ and $(\mathbb{C}^n/S_n, d)$. Therefore it follows from the Metric Continuity Proposition 2.8 that it suffices to prove the following claim.

Claim.
$$\forall_{v\in\mathbb{C}^n}\ \forall_{\epsilon>0}\ \exists_{\delta>0}\ \forall_{\substack{w\in\mathbb{C}^n \text{ with} \\ \|w\|<\delta}}\quad d(f(v), f(v+w)) < \epsilon.$$

Proof. Before we start with the proof of the claim we introduce the following definition: Given $v = (v_0,\ldots,v_{n-1}) \in \mathbb{C}^n$ we denote by $p_v(z) := v_0 + v_1\cdot z + \cdots + v_{n-1}\cdot z^{n-1} + z^n$ the corresponding polynomial. Now we turn to the actual proof of the claim. Thus let $v = (v_0,\ldots,v_{n-1}) \in \mathbb{C}^n$ and let $\epsilon > 0$. We denote by $\xi_1,\ldots,\xi_k$ the *distinct* zeros of the corresponding polynomial $p_v(z)$. (Note that if $p_v(z)$ has zeros of higher multiplicity, then $k < n$.) After possibly replacing ϵ by a smaller non-negative number we can assume, without loss of generality, that $\epsilon < \frac{1}{2}\cdot|\xi_i - \xi_j|$ for all $i \neq j$.

We denote by Γ the union of the circles of the radius ϵ around $\xi_1,\ldots,\xi_k$. Furthermore we set



$$\eta \ := \ \inf_{z\in\Gamma} |p_v(z)| \ \in \ \mathbb{R}_{>0}.$$

[92] Slightly more precisely the map g is defined as follows: given $[(\alpha_1,\ldots,\alpha_n)] \in \mathbb{C}^n/S_n$ we have $f([(\alpha_1,\ldots,\alpha_n)]) = (v_0,\ldots,v_{n-1})$ where $v_0,\ldots,v_{n-1} \in \mathbb{C}$ are uniquely determined by the condition that $v_0 + v_1 z + \cdots + v_{n-1}z^{n-1} + z^n = (z-\alpha_1)\cdot\cdots\cdot(z-\alpha_n) \in \mathbb{C}[z]$.

It is elementary to show that there exists a $\delta > 0$ such that for all $w = (w_0, \ldots, w_{n-1}) \in \mathbb{C}^n$ such that $\|w\| < \delta$ we have

$$|w_0 + w_1 \cdot z + \cdots + w_{n-1} \cdot z^{n-1}| \ < \ \eta \quad \text{for all } z \in \Gamma.$$

We claim that this δ has the desired property. Thus let $w \in \mathbb{C}^n$ with $|w| < \delta$. It follows from the definition of δ and Rouché's Theorem 5.43 that the polynomials $p_v(z)$ and $p_{v+w}(z)$ have the same number of zeros (counted with multiplicities) in the disks $B_\epsilon(\xi_1), \ldots, B_\epsilon(\xi_k)$. This means that the zeros of $p_v(z)$ and can be matched up with the zeros of $p_{v+w}(z)$ such that each zero is less then ϵ removed from its match. This statement implies immediately that $d(f(v), f(v+w)) < \epsilon$. ■

Remark. With some effort one can also prove the Zeros Continuity Proposition 5.42 without using Rouché's Theorem 5.43. We outline the key steps, using the notation that we introduced in the above proof of Proposition 5.42.

(1) Note that by the Open -Injective Map Lemma 2.16 (2) it suffices to show that the map $g\colon \mathbb{C}^n/S_n \to \mathbb{C}^n$ is open.
(2) By Lemma 2.11 it suffices to show that for each $\epsilon > 0$ and each $z \in \mathbb{C}^n/S_n$ the image of the open ball $B_\epsilon(z) \subset (\mathbb{C}^n/S_n, d)$ under g is open.
(3) Thus let $\epsilon > 0$ and $z \in \mathbb{C}^n/S_n$.
(4) We pick $C \in \mathbb{R}_{\geq 0}$ such that $g(\overline{B}_\epsilon(z)) \subset B_C(0) \subset \mathbb{C}^n$.
(5) There exists a $D \in \mathbb{R}_{\geq 0}$ such that for any $v \in \mathbb{C}^n$ which satisfies $\|v\| \leq C$ we have $f(v) \in B_D(0) \subset \mathbb{C}^n/S_n$. (This statement requires some unraveling and a little bit of thought. It can be proved using Rouché's Theorem 5.43, but with a worse bound it can also be proved by hand.)
(6) Note that by the Compact-Hausdorff Proposition 2.17 (3) we know that g restricted to $\overline{B}_D(0) \to g(\overline{B}_D(0))$ is a homeomorphism. Thus $g(B_\epsilon(z))$ is an open subset of $g(\overline{B}_D(0))$.
(7) By (5) and (6), and since f and g are inverses of one another, we know that $g(B_\epsilon(z))$ is also open in $B_D(0)$. But $B_D(0)$ is an open subset of $\mathbb{C}^n$, hence $g(B_\epsilon(z))$ is also open in $\mathbb{C}^n$.

Exercises for Chapter 5.

Exercise 5.1. Let $(X_1, d_1), \ldots, (X_m, d_m)$ be metric spaces. We define the product metric d on $X_1 \times \cdots \times X_m$ as follows:

$$d((x_1, \ldots, x_m), (y_1, \ldots, y_m)) \ := \ \sum_{i=1}^{m} d_i(x_i, y_i).$$

Show that the product topology on $X_1 \times \cdots \times X_m$ agrees with the metric topology coming from the product metric.

Exercise 5.2. Let $C \subset \mathbb{R}$ be the Cantor set, as defined on page 130. Is the disjoint union $C \sqcup C$ homeomorphic to C itself?

Exercise 5.3.

(a) Let $\mathcal{C}$ be a category $\mathcal{C}$ that admits products and coproducts. Let X, Y, A be objects of $\mathcal{C}$. Show that there exists a natural map $(X \times A) \amalg (Y \times A) \to (X \amalg Y) \times A$.

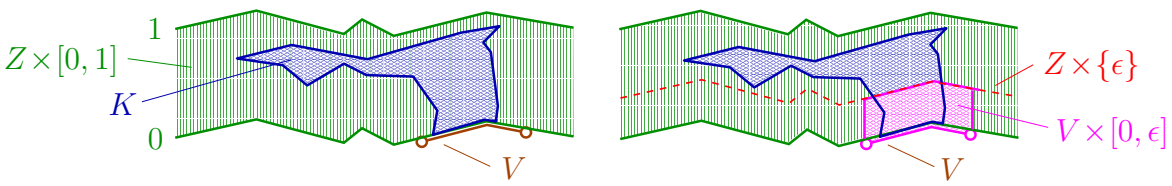
(b) Show that the product topology is "distributive" with respect to the disjoint union topology. More precisely, let X and Y be two topological spaces and let A be another topological space. Show that the natural map $(X \times A) \sqcup (Y \times A) \to (X \sqcup Y) \times A$ from (a) is a homeomorphism.

(c) Show that the statement of (b) is not a consequence of the formal properties of products and coproducts. More precisely give an example of a category $\mathcal{C}$ that admits products and coproducts and objects X, Y, A of $\mathcal{C}$ such that the natural map $(X \times A) \amalg (Y \times A) \to (X \amalg Y) \times A$ is not an isomorphism.

Exercise 5.4. Let X be a topological space and let I be a set. We equip I with the discrete topology. Show that the natural map

$$\begin{array}{ccc} \overbrace{\bigsqcup_{i \in I} X}^{\text{disjoint union topology}} & \to & \overbrace{X \times I}^{\text{product topology}} \\ (x, i) & \mapsto & (x, i) \end{array}$$

is a homeomorphism.



Exercise 5.5. Show that there are non-homeomorphic topological spaces A and B and a non-empty topological space X such that $A \times X$ is homeomorphic to $B \times X$.
Hint. you could take $A = \{0\}$ and $B = \{0, 1\}$.

Exercise 5.6. Let X be a topological space. We consider the "diagonal"

$$\Delta \ := \ \{(x, x) \in X \times X \,|\, x \in X\}.$$

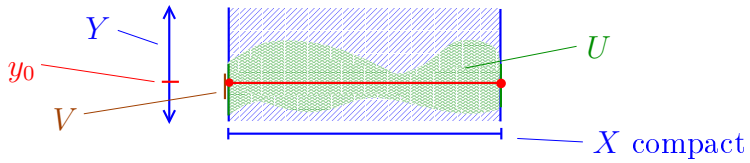
We equip $X \times X$ with the product topology and we equip Δ with the subspace topology. Show that the map $X \to \Delta$ given by $x \mapsto (x, x)$ is a homeomorphism.

Exercise 5.7. Let Z be a topological space and let $K \subset Z \times [0, 1]$ be a compact subset. Furthermore let $V \subset Z$ be an open subset such that $(K \cap (Z \times \{0\}) \subset V \times \{0\}$. Show that there exists an $\epsilon > 0$ such that $K \cap (Z \times [0, \epsilon]) = K \cap (V \times [0, \epsilon])$.

Exercise 5.8. Let $X_1, \ldots, X_k$ be topological spaces and let $B_i \subset X_i$, $i = 1, \ldots, k$ be subsets. Show that the following equalities hold:

(a) closure of $B_1 \times \ldots \times B_k$ in $X_1 \times \ldots \times X_k$ $= \overline{B}_1 \times \ldots \times \overline{B}_k$

(b) interior of $B_1 \times \ldots \times B_k$ in $X_1 \times \ldots \times X_k$ $= \mathring{B}_1 \times \ldots \times \mathring{B}_k$



(c) boundary of $B_1 \times \ldots \times B_k$ in $X_1 \times \ldots \times X_k$ $= \bigcup_{i=1}^{k} \overline{B}_1 \times \ldots \times \partial B_i \times \ldots \times \overline{B}_k$.

Remark. This exercise provides the proof of the Product-of-Subsets Lemma 5.5.

Exercise 5.9. Let X and Y be topological spaces, let $y_0 \in Y$ and let U be an open subset of $X \times Y$ that contains $X \times \{y_0\}$.

(a) We assume that X is compact. Show that there exists an open neighborhood V of y_0 such that $X \times V \subset U$.
Remark. This statement is sometimes called the *Tube Lemma*.

(b) Show that the conclusion of (a) in general does not hold if we do not assume that X is compact.

Exercise 5.10. Let X and Y be topological spaces and let $W \subset X \times Y$ be an open subset.

(a) Let $y \in Y$. Show that $U_y := \{x \in X \,|\, (x, y) \in W\}$ is an open subset of X.

(b) Show that the natural projection $p\colon X \times Y \to X$ is an open map.

(c) Let K be a compact subset of Y. Show that $U := \{x \in X \,|\, \{x\} \times K \subset W\}$ is an open subset of X.

Exercise 5.11. Let X and Y be topological spaces and let $K \subset X \times Y$ be a compact subset. Let $y \in Y$. We set $K_y := \{x \in X \,|\, (x, y) \in K\}$.

(a) Show that if Y is Hausdorff, then K_y is a compact subspace of X.

(b) Show that in general it is not true that K_y is a compact subspace of X.

Exercise 5.12. Let X and Y be topological spaces.

(a) Show that if X is compact, then the natural projection $p\colon X \times Y \to Y$ is a closed map.
Remark. This exercise is related to Exercise 5.9.

(b) Give an example that shows that in general in (b) we cannot drop the hypothesis that X is compact.

Somewhat surprisingly, the converse to (a) holds. More precisely, if a topological space X has the property, that for any other topological space Y the projection $p\colon X \times Y \to Y$ is a closed map, then X is actually compact. This non-trivial statement is sometimes known as the *Kuratowski-Mrówka Theorem*, it was first proved by Stanislaw Mrówka [**Mró1959**, p. 21] in 1959. See also [**Herl1996**, p. 3] for a proof and see [**Enge1989**, Theorem 3.1.16] for a proof under the extra hypothesis that X is Hausdorff.

Exercise 5.13. Let $S := (\mathbb{R}, \mathcal{T})$ be the Sorgenfrey line that we introduced on page 182. We refer to the product $S \times S$ as the *Sorgenfrey plane*.

(a) Show that the diagonal $\Delta := \{(x, x) \,|\, x \in \mathbb{R}\}$ is a closed subset of the Sorgenfrey plane.

(b) Show that the subspace topology on the anti-diagonal $A := \{(x, -x) \,|\, x \in \mathbb{R}\}$ is the discrete topology.

Exercise 5.14. Let $\{X_i\}_{i \in I}$ be a family of topological spaces. The *box topology* on the set $\prod\limits_{i \in I} X_i$ is the topology that is generated by the set

$$\Big\{ \prod_{i \in I} U_i \,\Big|\, U_i \subset X_i \text{ open} \Big\}.$$

(a) Show that the product of compact topological spaces, equipped with the box topology, is not necessarily compact.

(b) Let X be a topological space. We equip $X^{\mathbb{N}} = \prod\limits_{i \in \mathbb{N}} X$ with the box topology. Is the diagonal map

$$\begin{array}{ccc} X & \to & X^{\mathbb{N}} \\ x & \mapsto & (x, x, \dots) \end{array}$$

continuous?

Exercise 5.15. Let $X \subset \mathbb{R}^n$ be a compact convex non-empty subset. Show that there exists a $k \in \mathbb{N}_0$ such that X is homeomorphic to $\overline{B}^k$.

Exercise 5.16. Let $\{X_i\}_{i \in I}$ be a family of topological spaces.

(a) Suppose that for each $i \in I$ we are given a closed subset $A_i \subset X_i$. If I is finite, then it follows from the Product-of-Subsets Lemma 5.5 that $\prod\limits_{i \in I} A_i$ is a closed subset of $\prod\limits_{i \in I} X_i$. Does this conclusion also hold if I is infinite?

(b) Let $\{X_i\}_{i \in I}$ be a family of topological spaces. Suppose that for each $i \in I$ we are given a subset $A_i \subset X_i$. Show that

$$\prod_{i \in I} \overline{A_i} \;=\; \overline{\prod_{i \in I} A_i} \;\subset\; \prod_{i \in I} X_i.$$

Exercise 5.17. Let X and Y be topological spaces and let $M \subset X \times Y$ be a compact subset. Show that there exist compact subsets $K \subset X$ and $L \subset Y$ such that $M \subset K \times L$.

Exercise 5.18. Let X and Y be two topological spaces. Show that the product topology on $X \times Y$ is the smallest topology that has the property that the two natural projections $X \times Y \to X$ and $X \times Y \to Y$ are continuous.

Exercise 5.19. Let A be the annulus and let M be the Möbius band. Are the product topological spaces $A \times [0, 1]$ and $M \times [0, 1]$ homeomorphic?

Exercise 5.20. Let X be a topological space that is compact and Hausdorff. Furthermore let $f \colon X \to X$ be a map. We denote by $F := \{x \in X \,|\, f(x) = x\}$ the fixed point set of f. Show that F is a discrete subset of X if and only if F is finite.

Exercise 5.21. Show "by hand" that the map

$$\begin{aligned} \varphi\colon \prod_{i\in\mathbb{N}} \{0,2\} &\to C = \text{Cantor set from page 130} \\ (f\colon \mathbb{N}\to\{0,2\}) &\mapsto \sum_{i=1}^{\infty} \frac{f(i)}{3^i}, \end{aligned}$$

which we defined on page 235, is continuous.

Exercise 5.22.

(a) Show that the Cantor set is totally disconnected.

(b) Show that $\prod_{i\in\mathbb{N}} \{0,2\}$ is totally disconnected.

Exercise 5.23. Let X be a topological space.

(a) Show that the following two statements are equivalent:
   (i) X is Hausdorff,
   (ii) the diagonal $\Delta = \{(x,x) \mid x \in X\}$ is a closed subset of $X \times X$.

(b) Let $A \subset X$ be a subset that admits a retraction $r\colon X \to A$.
   (i) We denote by $f\colon X \to X \times X$ the map that is given by $x \mapsto (x, r(x))$. Show that f is continuous and that $f^{-1}(\Delta) = A$.
   (ii) Show that if X is Hausdorff, then A is closed.
   Remark. This gives a new solution of Exercise 2.25 (1).

Exercise 5.24. Let C be the Cantor set as defined on page 130. We recall two facts:

(1) On page 235 we showed that C is homeomorphic to the product $\{0,1\}^{\mathbb{N}}$.

(2) In Exercise 2.17 we showed that there exists a surjective map $\varphi\colon C \to [0,1]$.

Use the above to prove the following statements:

(a) The Cantor set C is homeomorphic to $C \times C$.

(b) Any continuous map $C \to \mathbb{R}$ extends to a continuous map $[0,1] \to \mathbb{R}$.
   Remark. This statement follows from the Tietze Extension Theorem 8.5. But it also allows for an elementary proof.

(c) Use the above statements to conclude that there exists a surjective continuous map $[0,1] \to [0,1] \times [0,1]$.
   Remark. Such a map is called a *space-filling curve*. We will provide alternative constructions of space-filling curves in Theorem 6.13 and Exercise 6.15.

Exercise 5.25.

(a) Show that the real projective space $\mathbb{R}\mathrm{P}^1$ is homeomorphic to S^1.

(b) Do you think that the real projective space $\mathbb{R}\mathrm{P}^2 = (\mathbb{R}^3 \setminus \{0\})/(\mathbb{R} \setminus \{0\})$ is homeomorphic to S^2? As of now we lack the tools to answer this question. Nonetheless, what do you think the answer will be?

Exercise 5.26. Let $\sim$ be an equivalence relation on a topological space X. Furthermore let $f\colon X \to Y$ be a map with the property that $f(x) = f(y)$ whenever $x \sim y$. Show that if $f\colon X \to Y$ is an open map, then the induced map $X/\!\sim \to Y$ is also an open map.

Exercise 5.27. Let the group $(\mathbb{Q}, +)$ act on the topological space $\mathbb{R}$ by addition. Show that the quotient topology on $\mathbb{R}/\mathbb{Q}$ is actually the trivial topology.
Remark. This of course shows in particular that $\mathbb{R}/\mathbb{Q}$ is not Hausdorff.

Exercise 5.28. We consider the map

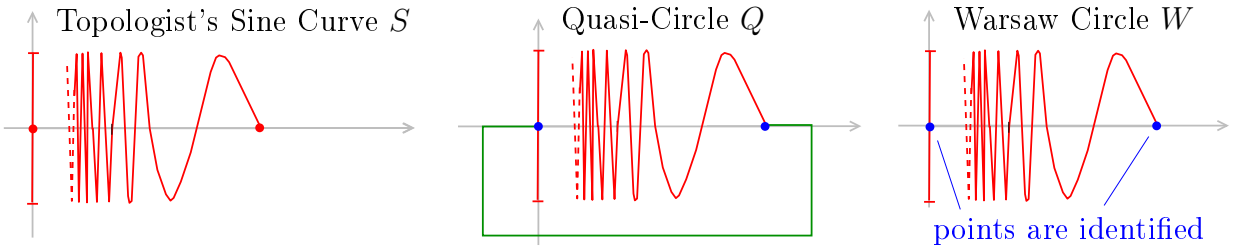
$$\begin{array}{rcl} f\colon [0,1) & \to & \mathbb{R}/\mathbb{Z}. \\ x & \mapsto & [x]. \end{array}$$

Give an example of an subset of $[0,1)$ such that $f(U)$ not open in $\mathbb{R}/\mathbb{Z}$.

Exercise 5.29. Show that the topological space $\mathbb{R}/\{\pm 1\} = \mathbb{R}/x \sim -x$ is homeomorphic to the half-open interval $[0,\infty)$.

Exercise 5.30. Let

$$S \;:=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\} \cup \big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2$$



be the "Topologist's Sine Curve" from page 164.

- We turn the Topologist's Sine curve into the *Quasi-Circle* Q by connecting the point $(0,0)$ with $(\frac{1}{\pi},0)$ via the green curve shown in the figure below.
- We refer to quotient space $W := S/(0,0)\sim(\frac{1}{\pi},0)$ as the *Warsaw Circle*.

Now perform the following tasks:

(a) Show that the Topologist's Sine Curve, the Quasi-Circle and the Warsaw Circle are compact.
(b) Show that the Warsaw Circle is homeomorphic to the Quasi-Circle.
(c) Show that the Warsaw Circle and the Quasi-Circle are path-connected.

Remark. The Warsaw Circle is sometimes also called the *Polish Circle*.

Exercise 5.31. Let $n\in\mathbb{N}$.

(a) Let $p\colon \mathbb{R}^n\setminus\{0\}\to S^{n-1}$ be the map given by $x\mapsto \frac{x}{\|x\|}$. Show that the preimage of a dense subset of S^{n-1} is a dense subset of $\mathbb{R}^n\setminus\{0\}$.
(b) Let $q\colon S^{n-1}\to \mathbb{R}\mathrm{P}^{n-1}$ be the projection . Show that the preimage of a dense subset of $\mathbb{R}\mathrm{P}^{n-1}$ is a dense subset of S^{n-1}.

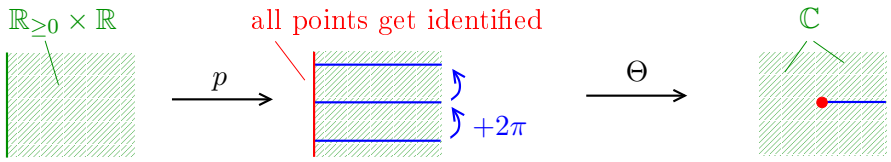
Exercise 5.32. Let $\sim$ be the equivalence relation on $\mathbb{R}_{\geq 0}\times\mathbb{R}$ that is generated by

(1) $(0,\varphi)\sim(0,\varphi')$ for all $\varphi,\varphi'\in\mathbb{R}$ and by
(2) $(r,\varphi)\sim(r,\varphi+k\cdot 2\pi)$ for all $r\in\mathbb{R}_{\geq 0}$, $\varphi\in\mathbb{R}$ and $k\in\mathbb{Z}$.

We equip $(\mathbb{R}_{\geq 0}\times\mathbb{R})/\!\sim$ with the quotient topology.

(a) Show that the map

$$\begin{array}{rcl} \Theta\colon (\mathbb{R}_{\geq 0}\times\mathbb{R})/\!\sim & \to & \mathbb{C} \\ [(r,\varphi)] & \mapsto & r\cdot\exp(\mathrm{i}\varphi) \end{array}$$

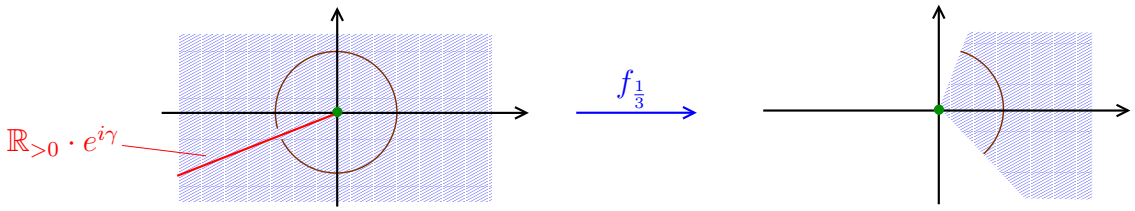


is a homeomorphism.
Hint. To show that the map is a homeomorphism you might want to use the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19.

(b) Let $f\colon \mathbb{R}_{\geq 0} \times \mathbb{R} \to X$ be a continuous map to some topological space X such that $f(P) = f(Q)$ whenever $P \sim Q$. Show that the map

$$\begin{array}{rcl} \mathbb{C} & \to & X \\ r \cdot \exp(\mathrm{i}\varphi) & \mapsto & f(r, \varphi) \end{array}$$

is continuous.



Remark. This exercise is a variation on Lemma 5.19.

Exercise 5.33. Let $\gamma \in \mathbb{R}$ and let $s \in \mathbb{R}$. We consider the map

$$\begin{array}{rcl} f_s\colon \mathbb{C} \setminus \{t \cdot \exp(\mathrm{i}\gamma) \,|\, t \in \mathbb{R}_{>0}\} & \to & \mathbb{C} \\ r \cdot \exp(\mathrm{i}\varphi) & \mapsto & r \cdot \exp(\mathrm{i}\varphi \cdot s). \end{array}$$

(a) Show that f_s is well-defined and continuous.
(b) Suppose that $s \neq 0$. Show that f_s is a local homeomorphism. (See the discussion on page 179 for the definition of a local homeomorphism.)

Exercise 5.34.

(a) Show that any matrix $A \in \mathrm{O}(2n)$ with $\det(A) = -1$ has 1 as an eigenvalue.
Hint. Show that if $\lambda \in \mathbb{C}$ is an eigenvalue of A, then so is $\overline{\lambda}$.
(b) Let $G \subset \mathrm{O}(2n)$ be a subgroup that acts freely on S^{2n-1}. Show that G is contained in $\mathrm{SO}(2n)$.
(c) Show that the analogue of (b) does not hold for subgroups of $G \subset \mathrm{O}(2n-1)$.

Exercise 5.35. Let $n \in \mathbb{N}$ and let $\varphi\colon S^n \to S^n$ be a homeomorphism. We consider the map

$$\begin{array}{rcl} \Phi\colon \overline{B}^{n+1} & \to & \overline{B}^{n+1} \\ x & \mapsto & \begin{cases} \|x\| \cdot \varphi(\frac{x}{\|x\|}), & \text{if } x \neq 0, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

(a) Show that Φ is continuous.
(b) Show that Φ is a homeomorphism.
(c) Give any example of a *diffeomorphism* $\varphi\colon S^n \to S^n$ such that the corresponding map $\Phi\colon \overline{B}^{n+1} \to \overline{B}^{n+1}$ is *not* a diffeomorphism.

Hint. You might want to use Lemma 5.19.

Remark 1. The fact that we can extend φ to a homeomorphism of $\overline{B}^{n+1}$ is sometimes

referred to as the Alexander trick. We will get to know a more fancy Alexander trick later on page 421.

Remark 2. We have thus shown that every *homeomorphism* of S^n extends to a *homeomorphism* of $\overline{B}^{n+1}$. In contrast, in Proposition **??** we will see that exists a *diffeomorphism* $\varphi\colon S^6 \to S^6$ that does not extend to a *diffeomorphism* of $\overline{B}^7$.

Exercise 5.36. Given $v, w \in \mathbb{R}^2 \setminus \{(0,0)\}$ we define

$$\sphericalangle(v,w) := \text{unique } \varphi \in (-\pi,\pi] \text{ such that } w = r \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} \cdot v \text{ for some } r \in \mathbb{R}_{>0}.$$

(a) Show that the map

$$\begin{array}{rcl} \Phi\colon (\mathbb{R}^2 \setminus \{(0,0)\}) \times (\mathbb{R}^2 \setminus \{(0,0)\}) & \to & (-\pi,\pi] \\ (v,w) & \mapsto & \sphericalangle(v,w) \end{array}$$

is not continuous.

(b) Show that the map

$$\begin{array}{rcl} \Phi\colon (\mathbb{R}^2 \setminus \{(0,0)\}) \times (\mathbb{R}^2 \setminus \{(0,0)\}) & \to & \mathbb{R}/2\pi\mathbb{Z} \\ (v,w) & \mapsto & [\sphericalangle(v,w)] \end{array}$$

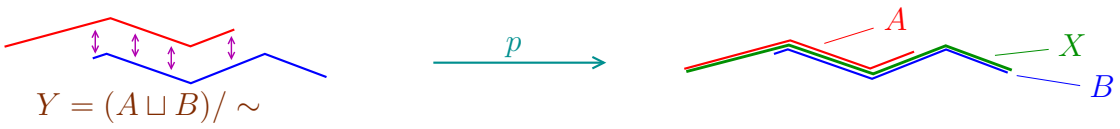
is continuous. (Here $\mathbb{R}/2\pi\mathbb{Z}$ denotes the quotient of the topological space $\mathbb{R}$ by the group $(2\pi\mathbb{Z},+)$.)

Exercise 5.37. We consider the following subsets of $[0,1]$:

$$A = \{0, \tfrac{1}{3}, \tfrac{2}{3}, 1\}, \quad B = \{\tfrac{1}{n} \mid n \in \mathbb{N}\} \quad \text{and} \quad C = \{0\} \cup B.$$

(a) Show that the quotient $[0,1]/A$ is homeomorphic to a subset of $\mathbb{R}^2$.
(b) Is the quotient $[0,1]/B$ homeomorphic to a subset of $\mathbb{R}^2$?
(c) Is the quotient $[0,1]/C$ homeomorphic to a subset of $\mathbb{R}^2$?

Exercise 5.38. Let X be topological space and let A and B be two subsets with $A \cup B = X$. We write $C := A \cap B$. We consider the disjoint union $A \sqcup B = (A \times \{1\}) \cup (B \times \{2\})$ and we consider $Y = (A \sqcup B)/\!\sim$ where for each $c \in C$ we identify the point $(c,1) \in A \times \{1\}$ with the corresponding point $(c,2) \in B \times \{2\}$. We consider the map



$$p\colon Y = (A \sqcup B)/\!\sim \ \to \ X$$

that is given by

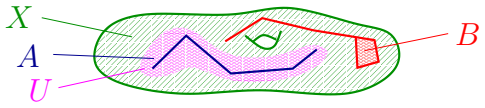
$$\begin{array}{rcll} [(a,1)] & \mapsto & a & \text{for } a \in A, \\ [(b,2)] & \mapsto & b & \text{for } b \in B. \end{array}$$

(a) Is the map p necessarily continuous?
(b) Is the map p necessarily open?
(c) Suppose that A and B are open subsets of X. Show that p is a homeomorphism.

Remark. The fact that p is not necessarily a homeomorphism can lead to nasty surprises.

Exercise 5.39. Let Σ be the surface of genus 4.

(a) Show that Σ admits a free and continuous action by $\mathbb{Z}_2$.
(b) Show that Σ admits a free and continuous action by $\mathbb{Z}_3$.
(c) Show that Σ admits a free and continuous action by $\mathbb{Z}_6$.



Remark. In Proposition 87.11 we will see that if a finite group G admits a free and continuous action on Σ, then the order of G divides 6.

Exercise 5.40. Give an example of maps $f\colon X \to Y$ and $X \to Z$ between infinite topological spaces such that the pushout $Y \cup_X Z$ consists of a single point.

Exercise 5.41. Let X be a topological space and let $A \subset X$ be a subset. We denote by $\{*\}$ the topological space with a single point. Let $i\colon A \to X$ be the inclusion map and let $p\colon A \to \{*\}$ be the unique map there is. Show that the corresponding pushout $X \cup_A \{*\}$ is homeomorphic to the quotient X/A.
Remark. Note that we also allow the case $A = \varnothing$.

Exercise 5.42. Let X be a topological space and let A and B be two disjoint subsets. We equip A with the subspace topology and we equip X/B with the quotient topology. We denote by $i\colon A \to X$ the inclusion map and we denote by $p\colon X \to X/B$ the projection.

(a) Show that the map $p \circ i\colon A \to X/B$ is continuous and injective.
(b) Show that the map $p \circ i\colon A \to X/B$ is not necessarily an embedding.
(c) Suppose that there exists an open subset $U \subset X$ with $A \subset U$ and $U \cap B = \varnothing$. Show that the map $p \circ i\colon A \to X/B$ is an embedding.

Exercise 5.43. Similar to the definition of the Möbius band on page 252 we consider the action of the group $G = \mathbb{Z}$ on $X = \mathbb{R} \times \{-1, 1\}$ that is given by

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times \{-1,1\}) & \to & \mathbb{R} \times \{-1,1\} \\ (n, (x,y)) & \mapsto & (x+n, (-1)^n \cdot y). \end{array}$$

Show that $X/G = X/\mathbb{Z}$ is homeomorphic to S^1.

Exercise 5.44. We consider the map

$$\begin{array}{rcl} (\mathbb{C} \setminus \{0\}) \times (\mathbb{C}^{n+1} \setminus \{0\}) & \to & \mathbb{C}^{n+1} \setminus \{0\} \\ (z, P) & \mapsto & z \cdot P. \end{array}$$

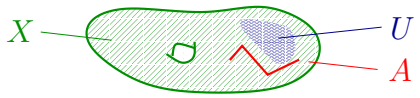
By definition we have $\mathbb{C}\mathrm{P}^n := (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\})$.

(1) Show that the obvious map $p\colon \mathbb{C}^{n+1} \setminus \{0\} \to \mathbb{C}\mathrm{P}^n$ is open.
(2) In the Projective Spaces-Compact+Hausdorff Proposition 5.30 we showed that $\mathbb{C}\mathrm{P}^n$ is Hausdorff. In this exercise we want to give a more direct, down-to-earth proof that $\mathbb{C}\mathrm{P}^n$ is Hausdorff. Thus let $[x], [y] \in \mathbb{C}\mathrm{P}^n$ be two disjoint points. Let $\langle -, - \rangle$ be the standard hermitian inner product on $\mathbb{C}^{n+1}$ that we introduced on page 101. We consider

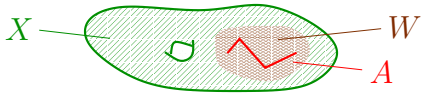
$$U_x = \big\{ z \in \mathbb{C}^{n+1} \setminus \{0\} \,\big|\, |\langle z, y\rangle| < |\langle z, x\rangle| \big\} \;\&\; U_y = \big\{ z \in \mathbb{C}^{n+1} \setminus \{0\} \,\big|\, |\langle z, x\rangle| < |\langle z, y\rangle| \big\}.$$

(a) Show that U_x and U_y are open subsets of $\mathbb{C}^{n+1} \setminus \{0\}$.

(b) Show that $p(U_x)$ and $p(U_y)$ are disjoint. (Note that they are open by (1) and (2a).)
(c) Show that $[x] \in p(U_x)$ and $[y] \in p(U_y)$.
Hint. Use the Cauchy-Schwarz Inequality 0.14.



Exercise 5.45. We consider the map



$$\begin{array}{rcl} f\colon \mathbb{R}^2 & \to & \mathbb{R}\mathrm{P}^2 \\ (x,y) & \mapsto & [x:y:1]. \end{array}$$

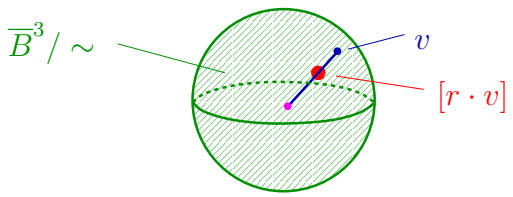
(a) Show that f is an embedding, i.e. show that f is a homeomorphic onto its image.
(b) What is the closure of $f(\mathbb{Z}^2) \subset \mathbb{R}\mathrm{P}^2$?

Exercise 5.46. Let X be a topological space and let A be a closed subset of X.

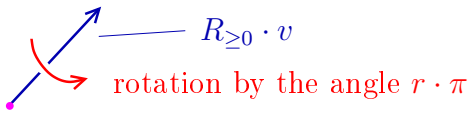
(a) Show that for every open subset $U \subset X \setminus A$ the obvious map $U \to X/A$ is an open embedding.
(b) Show that for every open neighborhood W of A the map $W \setminus A \to (W/A) \setminus (A/A)$ is a homeomorphism.
(c) Show that in (a) and (b) we cannot drop the hypothesis that A is closed.

(a) 

(b) 



Exercise 5.47. Let $\sim$ be the equivalence relation on $\overline{B}^3$ that is generated by $x \sim -x$ for $x \in S^2$. We consider the map

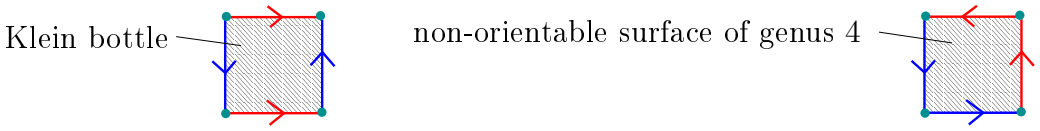


$$\begin{array}{rcl} F\colon \overline{B}^3/\!\sim & \to & \mathrm{SO}(3) \\ [\underbrace{r \cdot v}_{r \in [0,1] \text{ and } v \in S^2}] & \mapsto & \text{matrix in SO(3) which represents rotation by the angle } \pi \cdot r \\ & & \text{around the axis } \mathbb{R}_{\geq 0} \cdot v \text{ where the rotation} \\ & & \text{direction is given by the right-hand rule} \end{array}$$

We refer to the figure below for an illustration.

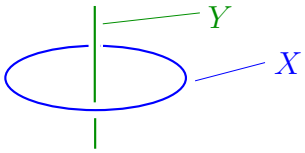
(a) Give a rigorous description of F and show that F is continuous.
(b) Use your linear algebra skills to show that F is a bijection.
(c) Show that F is a homeomorphism.

Remark. On page 258 we showed that $\overline{B}^3/\!\sim$ is homeomorphic to $\mathbb{R}\mathrm{P}^3$. Thus in combination we have just shown the amusing and surprising fact that $\mathbb{R}\mathrm{P}^3$ is homeomorphic to SO(3). We will give a different proof of this fact later on in the SU(2)-SO(3)-Covering Theorem 83.2.



Exercise 5.48. We say a group G *acts discretely* on a topological space X, if it acts continuously and if for each $x \in X$ there exists an open neighborhood U such that we have $U \cap gU$ for all $g \neq e$. Can the group $\mathbb{Z}$ act discretely on S^2?

Exercise 5.49. Let X be a Hausdorff space and let G be a group that acts discretely on X. (See Exercise 5.48 for the notion of a discrete action.) Furthermore let K be a compact subset of X.

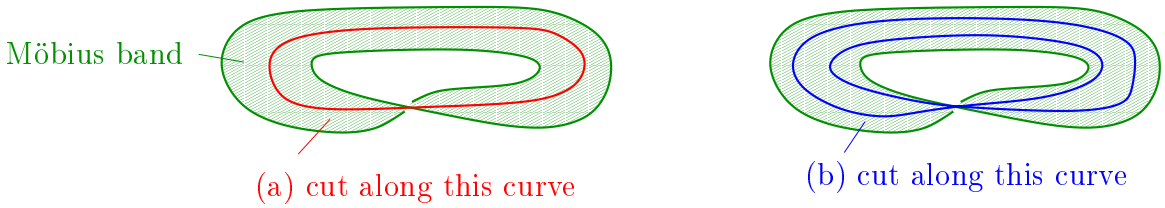


(a) We assume that X is regionally compact. Show that $\{g \in G \,|\, gK \cap K \neq \varnothing\}$ is finite.
(b) Does the conclusion of (a) also hold if we drop the hypothesis that X is regionally compact? This statement is [**Scot1978**, Lemma 1.2].

Exercise 5.50. Show that the Klein bottle, as defined on page 265, is homeomorphic to the non-orientable surface N_2 of genus 2, as defined on page 266.

Exercise 5.51. Show that for any choice of $m, n \in \mathbb{N}_0$ there exists a homeomorphism $\overline{B}^m * \overline{B}^n \xrightarrow{\cong} \overline{B}^{m+n+1}$.

Exercise 5.52. We let $X = S^1$ be the standard circle in the xy-plane of $\mathbb{R}^3$ and we let Y be the circle in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is given by the z-axis together with the point $\{\infty\}$. Show that we can "continuously" connect every point on X to every point Y such that the paths fill out S^3. In other words, try to visualize the fact that $S^1 * S^1 \cong X * Y$ is homeomorphic to S^3.



Exercise 5.53. Construct the Möbius band $M = ([0,1] \times [0,1])/(0,y) \sim (1, 1-y)$ by gluing two of the opposite sides of a strip of paper with a twist.

(a) Cut M along the central curve, i.e. start cutting at the point $[(0, \frac{1}{2})]$ and continue along the Möbius band till you reach the starting point. What topological space do you obtain that way?
(b) Start cutting at the point $[(0, \frac{1}{3})]$ and continue along the Möbius band till you reach the starting point. What topological space do you obtain that way?
(c) Let $n \in \mathbb{N}$. Start cutting a $[(0, \frac{1}{n})]$ and continue along the Möbius band till you reach the starting point. What topological space do you obtain that way?

Exercise 5.54. Let G be a topological group. We denote by X the set of subgroups of G that are closed subsets. We consider the following types of subsets of G:

$$\begin{aligned} \text{Miss} &:= \{H \in X \,|\, \text{there exists a compact subset } K \subset G \text{ with } H \cap K = \varnothing\}, \\ \text{Hit} &:= \{H \in X \,|\, \text{there exists an open subset } U \subset G \text{ with } H \cap U \neq \varnothing\}. \end{aligned}$$

The topology on X that is generated by Miss and Hit is called the *Chabauty topology on* X, see [**Chab1950**].

(a) Show that the Chabauty topology is Hausdorff.
(b) Let $G = \mathbb{R}$.
  (i) Determine the closed subgroups of $G = \mathbb{R}$.
  (ii) Show that in this case X, equipped with the Chabauty topology, is homeomorphic to $[0, 1]$.

6. Topology of metric spaces

In this chapter we will discuss several topics that are germane to metric spaces. For the reader's convenience we recall the definition of a metric space from page 103.

Definition. A metric space is a pair (X, d) consisting of a set X and a metric d on X, i.e. a map

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} := \{x \in \mathbb{R} \,|\, x \geq 0\} \\ (x, y) & \mapsto & d(x, y) \end{array}$$

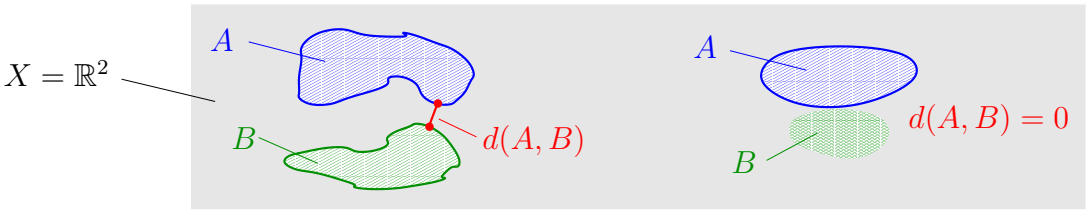
with the following properties:

(1)		$d(x,y)$	$=$	0	$\iff$ $x = y$	
(2)	for all $x, y \in X$ we have	$d(x,y)$	$=$	$d(y,x)$		(symmetry)
(3)	for all $x, y, z \in X$ we have	$d(x,z)$	$\leq$	$d(x,y) + d(y,z)$		(triangle inequality).

Example. The most familiar example of a metric space is given by $X = \mathbb{R}^n$ equipped with the euclidean metric.

As always we equip a metric space (X, d) with the topology that we introduced in Lemma 1.1 and we equip $X \times X$ with the product topology that we introduced on page 224. With these conventions it now makes sense to formulate the following lemma.

Lemma 6.1. (Metric-is-Continuous Lemma) Let (X, d) be a metric space. The metric $d\colon X \times X \to \mathbb{R}_{\geq 0}$ is continuous.



Proof. We prove the lemma in Exercise 6.2. ∎

6.1. Distance in metric spaces.

Definition. Let X be a metric space. Given two non-empty subsets A and B we refer to

$$d(A, B) \;:=\; \inf\{d(a, b) \,|\, a \in A \text{ and } b \in B\}$$

as the distance between A and B. If $A = \{a\}$ consists of a single point, then we write $d(a, B) := d(\{a\}, B)$.

Example. If two subsets A and B intersect, then we evidently have $d(A, B) = 0$. But in general the converse does not hold. For example if we consider $X = \mathbb{R}$, then

$$d\big(\underbrace{\text{open interval } (0,1)}_{=A}, \underbrace{\text{closed interval } [1,2]}_{=B}\big) \;=\; 0,$$

but evidently the intervals $A = (0, 1)$ and $B = [1, 2]$ do not intersect.

The reader might justly suspect that the phenomenon of the last example is due to the fact that one of the subspaces is not compact. In fact the next two lemmas, which will play a useful role time and again, confirms this suspicion.

Lemma 6.2. (Distance-to-Subspace Lemma) Let X be a metric space and let $B \subset X$ be a non-empty subset.

(1) The map
$$\begin{array}{rcl} X & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & d(x,B) := \inf\{d(x,b) \,|\, b \in B\} \end{array}$$
is continuous.

(2) If B is closed, then given $x \in X$ we have
$$d(x,B) = 0 \qquad \Longleftrightarrow \qquad x \in B.$$

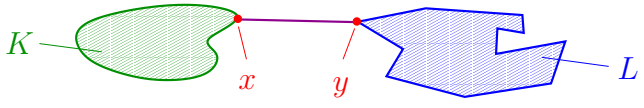
Proof. We will prove Statement (1) in Exercise 6.5. Thus we can immediately proceed to the proof of Statement (2). Let B be a closed subset of X. If $x \in B$, then evidently $d(x,B) = 0$. Now suppose that $x \notin B$. Since B is closed we know that $X \setminus B$ is open. This implies that there exists an $\epsilon > 0$ such that $B_\epsilon(x) \subset X \setminus B$. But this implies that $d(x,B) \geq \epsilon$. ■

Lemma 6.3. Let X be a metric space and let K and L be two non-empty disjoint subsets. If one of the two subsets is compact and if the other subset is a closed subset of X, then $d(K,L) > 0$.

Proof. We can assume that K is compact and that L is a closed subset of X. We consider the map
$$\begin{array}{rcl} K & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & d(x,L). \end{array}$$
By the Distance-to-Subspace Lemma 6.2 we know that the map is continuous. Since K is compact we know by the Compact Image Lemma 2.13 (1) that f assumes a minimum, i.e. there exists an $x \in K$ such that for all $y \in K$ we have $d(x,L) \leq d(y,L)$. This implies that

$$d(K,L) \underset{\text{by definition}}{=} \inf\{d(y,L) \,|\, y \in K\} \underset{\text{by choice of } x}{=} d(x,L) \overset{\text{by the Distance-to-Subspace Lemma 6.2 (2), since } L \text{ closed}}{>} 0.$$

■

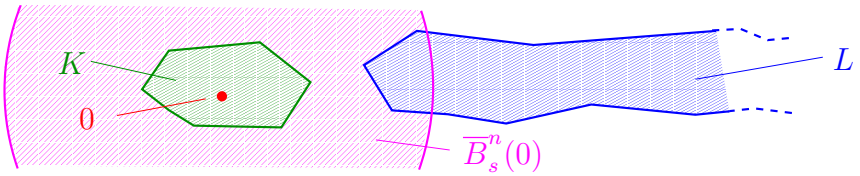


Sometimes it is nice to know that points of minimal distance exist. This leads us to the following lemma.

Lemma 6.4. (Distance-Minimizer Lemma) Let X be a metric space and let K and L be two non-empty subsets. We assume that one of the following holds:

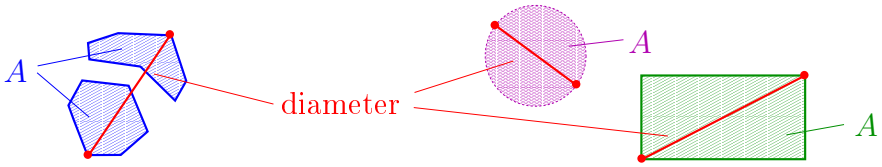
(i) Both K and L are compact, or

(ii) $X = \mathbb{R}^n$, K is compact and L is a closed subset of $X = \mathbb{R}^n$.



There exist $x \in K$ and $y \in L$ with $d(x,y) = d(K,L)$.

Proof. First we suppose that we are in the setting (i). Thus let K and L be two non-empty compact subsets of X. By the Product Topology Properties Proposition 5.6 we know

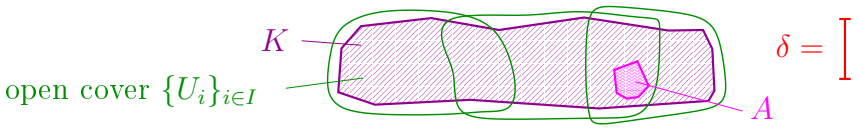


that $K \times L$ is compact. By the Metric-is-Continuous Lemma 6.1 we know that the metric $d\colon K \times L \to \mathbb{R}_{\geq 0}$ is continuous. It follows from the above, together with the fact that $K \times L$ is non-empty and the Compact Image Lemma 2.13 (2) that $d\colon K \times L \to \mathbb{R}_{\geq 0}$ assumes a minimum at some point $(x, y) \in K \times L$. But this means precisely that $d(x, y) = d(K, L)$.

Now suppose that we are in the setting (ii). We will reduce this case to the setting (i). To do so we set $s := \max\{\|x\| \,|\, x \in K\} + 1 + d(K, L)$. Next we set $L' := L \cap \overline{B}^n_s(0)$. Note that it follows from the hypothesis that L is closed and the Heine-Borel Theorem 1.24 together with the Compact-Closed Lemma 1.21 (2) that L' is compact. We leave it to the reader to verify that it follows easily from the choice of s and the triangle inequality that $L' \neq \varnothing$ and that $d(K, L') = d(K, L)$. We apply (i) to $X = \mathbb{R}^n$ together with the compact subsets K and L'. We obtain $x \in K$ and $y \in L' \subset L$ with $d(x, y) = d(K, L') = d(K, L)$. ■

6.2. **The Lebesgue Lemma.** In this section we intend to formulate and prove the Lebesgue Lemma. Despite its humble name it does actually play an important role in topology. The formulation of the Lebesgue Lemma requires the following definition.

Definition. Let X be a metric space. The diameter of a non-empty subset A of X is defined as $\operatorname{diam}(A) := \sup\{d(a, b) \,|\, a, b \in A\} \in \mathbb{R}_{\geq 0} \cup \{\infty\}$.
To avoid any issues later on we also define $\operatorname{diam}(\varnothing) := 0$.



Example.

(1) Let (X, d) be a metric space, let $x \in X$ and $r \in \mathbb{R}_{\geq 0}$. Using the triangle inequality one can easily show that $\operatorname{diam}(\overline{B}^d_r(x)) = \operatorname{diam}(B^d_r(x)) \leq 2r$. Furthermore, if we consider balls in some $\mathbb{R}^n$, then it is straightforward to see that the above inequality is in fact an equality.

(2) We consider the metric space $(\mathbb{R}^n, d_{\text{Eucl}})$. We leave it to the reader to show that

$$\operatorname{diam}\big(\text{hyperrectangle } [a_1, b_1] \times \cdots \times [a_n, b_n]\big) = \sqrt{(b_1 - a_1)^2 + \cdots + (b_n - a_n)^2}.$$

Lemma 6.5. (Lebesgue Lemma) Let K be a compact metric space and let $\{U_i\}_{i \in I}$ be an open cover of K. There exists a $\delta > 0$ such that for every subset A of K with $\operatorname{diam}(A) < \delta$ there exists an $i \in I$ with $A \subset U_i$.

Remark. Any $\delta > 0$ that has the property stated in the Lebesgue Lemma is usually called a *Lebesgue number*.

Proof. Since K is compact we can cover K with finitely many of the U_i's. Put differently, without loss of generality we can assume that $I = \{1, \dots, n\}$ is a finite set.

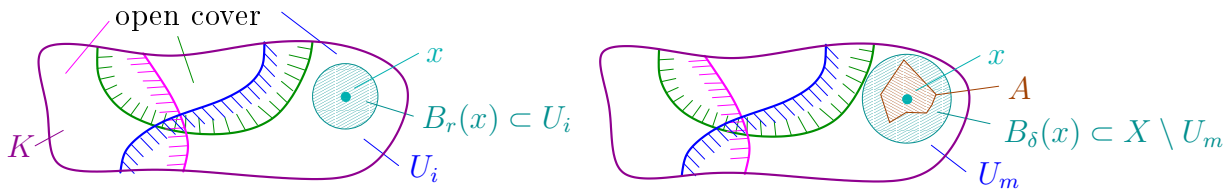
If there exists an $i \in \{1, \dots, n\}$ with $K = U_i$, then any $\delta > 0$ has the desired property. Now suppose that this is not the case, i.e. we suppose that for every i we have $U_i \subsetneq K$.

Claim 1. The map

$$\begin{array}{rcl} f\colon K & \to & \mathbb{R} \\ x & \mapsto & f(x) := \frac{1}{n} \cdot \sum_{i=1}^{n} d(x, \underbrace{K \setminus U_i}_{\neq \varnothing}) \end{array}$$

is continuous and positive for every $x \in K$.

Proof. By the Distance-to-Subspace Lemma 6.2 (1) we know that f is continuous. Now let $x \in K$. We want to show that $f(x) > 0$. Since $K = U_1 \cup \dots \cup U_n$ there exists an i with $x \in U_i$. Since U_i is open and since $x \in U_i$ we obtain from the Distance-to-Subspace Lemma 6.2 (2) that $d(x, K \setminus U_i) > 0$. Evidently this implies that $f(x) > 0$. ⊞



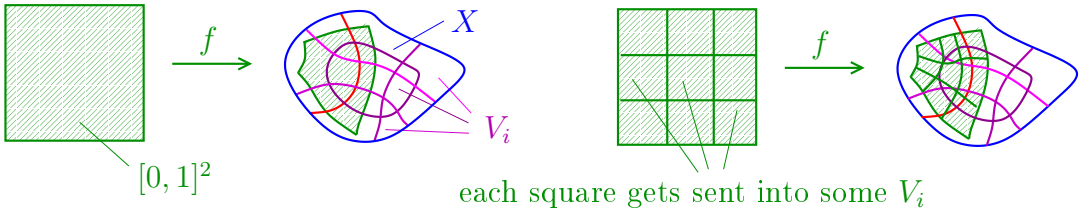
Since f is continuous and since K is compact it follows from the Compact Image Lemma 2.13 that the map f has a global minimum δ on K. It follows from Claim 1 that this minimum δ is greater than 0. Now we want to show that this δ has the desired property. More precisely, we want to prove the following claim.

Claim 2. Let A be a subset of K. If $\operatorname{diam}(A) < \delta$, then there exists an $i \in \{1, \dots, n\}$ with $A \subset U_i$.

Proof. If $A = \varnothing$, then there is nothing to show. If $A \neq \varnothing$, then we pick $x \in A$. We choose an $m \in \{1, \dots, n\}$ such that $d(x, K \setminus U_m)$ is maximal. We want to show that $A \subset U_m$. Since the diameter of A is less than δ we have $A \subset B_\delta(x)$. Thus it suffices to show that $B_\delta(x) \subset U_m$. Put differently, we need to show that $d(x, K \setminus U_m) \geq \delta$. Indeed we have

$$d(x, K \setminus U_m) \underset{\substack{\uparrow \\ \text{since } d(x,K\setminus U_m) \geq d(x,K\setminus U_i)}}{\geq} \frac{1}{n} \cdot \sum_{i=1}^{n} d(x, K \setminus U_i) = f(x) \underset{\substack{\uparrow \\ \text{by the choice of } \delta}}{\geq} \delta.$$

■



In many cases the following corollary is even more useful.

Corollary 6.6. (Lebesgue Corollary) Let $f\colon [0,1]^n \to X$ be a map from the cube $[0,1]^n$ to a topological space X and let $\{V_i\}_{i\in I}$ be an open cover of X. Then there exists an $N > 0$ such that for any $a_1, \ldots, a_n \in \{0, \ldots, N-1\}$ there exists an $i \in I$ such that

$$f\big(\big[\tfrac{a_1}{N}, \tfrac{a_1+1}{N}\big] \times \cdots \times \big[\tfrac{a_n}{N}, \tfrac{a_n+1}{N}\big]\big) \subset V_i.$$

More pictorially speaking the corollary says that if $f\colon [0,1]^n \to X$ is a map, and if we are given an open cover of X, then we can always find a small grid on the cube, such that each cube of the grid gets mapped into one of the open sets cover X.

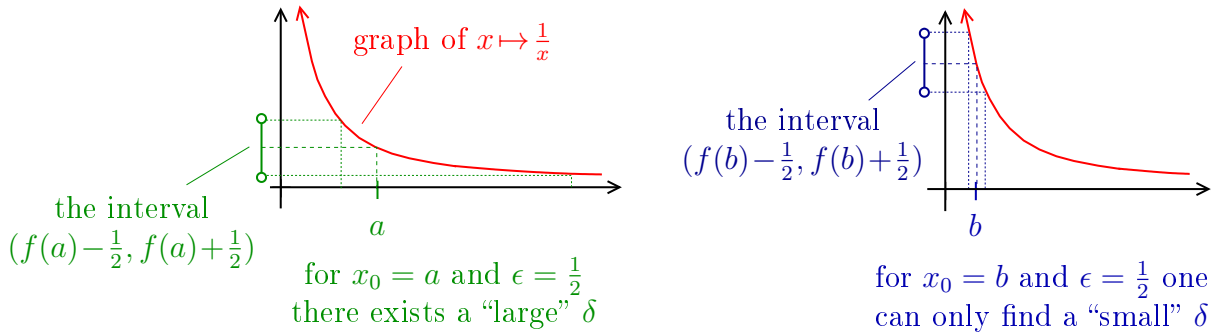
Proof. Let $f\colon [0,1]^n \to X$ be a map from the cube $[0,1]^n$ to a topological space X and let $\{V_i\}_{i\in I}$ be an open cover of X. By the Hyperrectangle-Compact Proposition 1.26 we know that $[0,1]^n$ is compact. Thus we can apply Lemma 6.5 to the open cover $U_i := f^{-1}(V_i)$, $i \in I$ of $[0,1]^n$ and we obtain a $\delta > 0$ such that for each subset A of $[0,1]^n$ with $\operatorname{diam}(A) < \delta$ there exists an $i \in I$ with $A \subset U_i = f^{-1}(V_i)$, which means that $f(A) \subset V_i$. It follows from the example on page 285 that the diameter of the cube of side length $\frac{1}{m}$ equals $\frac{\sqrt{n}}{m}$. Thus we see that for any $N \in \mathbb{N}_0$ with $N \geq \frac{\sqrt{n}}{\delta}$ any cube of side length $\frac{1}{N}$ has diameter less than δ. ∎

6.3. **Uniformly continuous maps.** In this section we introduce the concept of uniformly continuous maps that the reader might be familiar with from a course on real analysis. We will show that a continuous map $X \to Y$ between metric spaces is actually uniformly continuous. This is a rather technical result which we will make use of only once, namely in Section 70.6 when we discuss "CW-complexes". Most readers will be best served by passing on to the next section.

Definition. Let $f\colon X \to Y$ be a map between two metric spaces X and Y. By the Metric Continuity Proposition 2.8 we know that

$$f \text{ is continuous} \iff \underset{x\in X}{\forall}\ \underset{\epsilon>0}{\forall}\ \underset{\delta>0}{\exists}\ \underset{y\in B_\delta(x)}{\forall}\ d(f(x),f(y)) < \epsilon.$$

Now we define



$$f \text{ is uniformly continuous} :\iff \underset{\epsilon>0}{\forall}\ \underset{\delta>0}{\exists}\ \underset{x\in X}{\forall}\ \underset{y\in B_\delta(x)}{\forall}\ d(f(x),f(y)) < \epsilon.$$

Example. The map

$$\begin{array}{rcl} f\colon (0,\infty) & \to & \mathbb{R} \\ x & \mapsto & \frac{1}{x} \end{array}$$

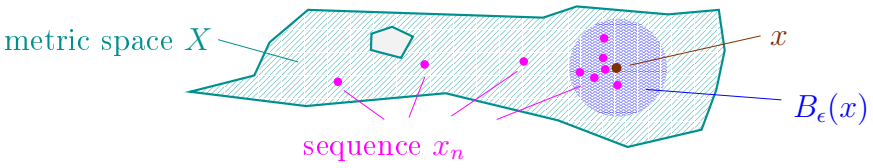
is not uniformly continuous. For example for $\epsilon = \frac{1}{2}$ there is no "universal" δ that works for all $x \in (0,\infty)$.

Proposition 6.7. Let $f\colon X \to Y$ be a continuous map between two metric spaces. If X is compact, then f is uniformly continuous.

Proof. Let $f\colon X \to Y$ be a continuous map between two metric spaces and let $\epsilon > 0$. The "$\Leftarrow$"-direction of the Metric Continuity Proposition 2.8 tells us in particular that given any $P \in X$ there exists a $\delta(P) > 0$ such that for all $y \in B_{\delta(P)}(P)$ we have $d(f(P), f(y)) < \frac{\epsilon}{2}$. Since the open balls $B_{\delta(P)/2}(x)$ form an open cover of X and since X is compact there exist $P_1, \ldots, P_k \in X$ such that $B_{\delta(P_1)/2}(P_1) \cup \cdots \cup B_{\delta(P_1)/2}(P_1) = X$. We claim that

$$\delta \;:=\; \min\left\{\frac{\delta(P_1)}{2}, \ldots, \frac{\delta(P_k)}{2}\right\}$$

has the desired properties. Thus let $x, y \in X$ with $d(x,y) < \delta$. There exists a $j \in \{1, \ldots, k\}$ with $x \in B_{\delta(P_j)/2}(P_j)$. From the triangle inequality and from $d(x,y) < \delta \le \frac{\delta(P_j)}{2}$ we obtain that $y \in B_{\delta(P_j)}(P_j)$. It follows that



$$d(f(x), f(y)) \underset{\text{triangle inequality}}{\overset{\uparrow}{\le}} d(f(P_j), f(x)) + d(f(P_j), f(y)) \underset{\text{since } x \in B_{\delta(P_j)}(P_j) \text{ and } y \in B_{\delta(P_j)}(P_j)}{\overset{\uparrow}{<}} \frac{\epsilon}{2} + \frac{\epsilon}{2} \;=\; \epsilon.$$

We have thus shown that δ does indeed have the desired properties. ∎

6.4. **Complete metric spaces.** On page 124 we defined for any topological space X what it means for a sequence of points in X to converge to some other point. In metric spaces the following lemma gives an alternative characterization of convergent sequences.

Lemma 6.8. Let (X,d) be a metric space and let $(x_n)_{n\in\mathbb{N}}$ be a sequence in X. For each $x \in X$ we have

$$\begin{array}{c}x \text{ is a limit of the sequence } (x_n)_{n\in\mathbb{N}} \\ \text{according to the definition on page 124}\end{array} \quad\Longleftrightarrow\quad \underset{\epsilon>0}{\forall}\ \underset{N\in\mathbb{N}}{\exists}\ \underset{n\ge N}{\forall}\ \underbrace{d(x_n, x) < \epsilon.}_{\text{i.e. } x_n \in B_\epsilon(x)}$$

Proof. We need to show

$$\underset{\text{neighborhoods } U \text{ of } x}{\forall}\ \underset{N\in\mathbb{N}}{\exists}\ \underset{n\ge N}{\forall}\ x_n \in U \quad\Longleftrightarrow\quad \underset{\epsilon>0}{\forall}\ \underset{N\in\mathbb{N}}{\exists}\ \underset{n\ge N}{\forall}\ \underbrace{d(x_n, x) < \epsilon.}_{\text{i.e. } x_n \in B_\epsilon(x)}$$

Evidently that is just a dull routine exercise which is best left to the reader's office mate. ∎

Definition. By Proposition 1.13 we know that metric spaces are Hausdorff. It follows from the Unique Limit Lemma 1.17 that if a sequence $(x_n)_{n\in\mathbb{N}}$ in a metric space X converges, then its limit is unique. Thus it makes sense to denote its limit by $\lim_{n\to\infty} x_n \in X$.

Definition. Let X be a metric space. A sequence $(x_n)_{n\in\mathbb{N}}$ in X is called Cauchy sequence if

$$\forall_{\epsilon>0}\ \exists_{N\in\mathbb{N}}\ \forall_{m,n\geq N}\ d(x_n,x_m)<\epsilon.$$

One can easily show that every convergent sequence is a Cauchy sequence. In general the converse does of course not hold though. For example, if we consider the metric space $(\mathbb{R}\setminus\{0\}, d(x,y)=|x-y|)$, then we see that the sequence $x_n=\frac{1}{n}$ is a Cauchy sequence, but it does not converge in the metric space $\mathbb{R}\setminus\{0\}$.

Definition. We say that a metric space (X,d) is complete if every Cauchy sequence in (X,d) converges. Otherwise we say that (X,d) is incomplete.

Examples.

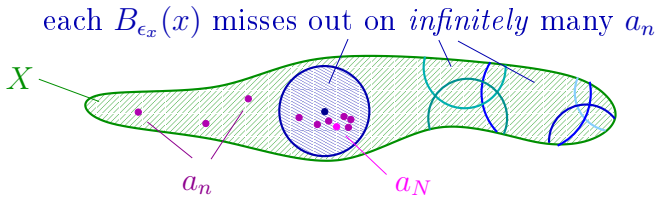
(1) It is one of the defining properties of the real numbers that the metric space given by $\mathbb{R}$ and the usual metric $d(x,y)=|x-y|$ is complete.
(2) It follows without too much sweat from (1) that the metric space given by $\mathbb{R}^n$ and the Euclidean metric is complete.

Lemma 6.9. (Closed Subspace-Completeness Lemma) Let (X,d) be a complete metric space. If $A\subset X$ is a closed subset, then (A,d) is also complete.

Proof. Let $(a_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in (A,d). Since (X,d) is complete we know that $(a_n)_{n\in\mathbb{N}}$ converges to some point $x\in X$. But since A is closed we obtain from the Closed Subset Limit Lemma 1.18 that $x\in A$. ■

Proposition 6.10. (Compact-Complete Proposition) Every compact metric space is complete.

Proof. Let (X,d) be a compact metric space and let $(a_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in (X,d). We want to show that the sequence converges, i.e. we want to show that



$$\exists_{x\in X}\ \forall_{\epsilon>0}\ \exists_{N\in\mathbb{N}}\ \forall_{n\geq N}\ a_n\in B_\epsilon(x).$$

Let us assume that no such x exists. Thus we negate the above statement and we obtain that

$$\forall_{x\in X}\ \exists_{\epsilon_x>0}\ \forall_{N\in\mathbb{N}}\ \exists_{n\geq N}\ a_n\notin B_{\epsilon_x}(x).$$

Evidently the family $\{B_{\epsilon_x}(x)\}_{x\in X}$ of subsets is an open cover of X. Since X is compact it follows from the Lebesgue Lemma 6.5 that there exists a $\mu>0$ such that any subset A of X of diameter less than μ is contained in some $B_{\epsilon_x}(x)$.

Since $(a_n)_{n\in\mathbb{N}}$ is a Cauchy sequence there exists an $N\in\mathbb{N}$ such that for all $m,n\geq N$ we have $d(a_m,a_n)<\frac{\mu}{4}$. This means in particular that for all $m\geq N$ we have $d(a_N,a_m)<\frac{\mu}{4}$. It follows from the triangle inequality that the diameter of the set $A:=\{a_n\,|\,n\geq N\}$ is $\leq\frac{\mu}{2}<\mu$. By the above there exists an $x\in X$ such that $A\subset B_{\epsilon_x}(x)$. But this means that for all $n\geq N$ we have $a_n\in B_{\epsilon_x}(x)$. But this contradicts the defining property of ϵ_x. ■

The following lemma shows that one can replace a metric by a bounded metric without affecting the topology.

Lemma 6.11. Let (M,d) be a metric space.

(1) The map

$$\begin{array}{rcl} \widetilde{d}\colon M\times M & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & \widetilde{d}(x,y) := \min\{1, d(x,y)\} \end{array}$$

also defines a metric on M.

(2) This new metric $\widetilde{d}$ induces the same topology as d on M.

(3) (M,d) is complete if and only if $(M,\widetilde{d})$ is complete.

Proof. All three statements are elementary and they follow easily from the definitions. We refrain from boring the reader with details. ∎

Notation. Let (M,d) be a metric space and let X be a topological space. We denote by $C(X,M)$ the set of continuous maps from X to M.

Proposition 6.12. Let (M,d) be a metric space and let X be a non-empty topological space. The map

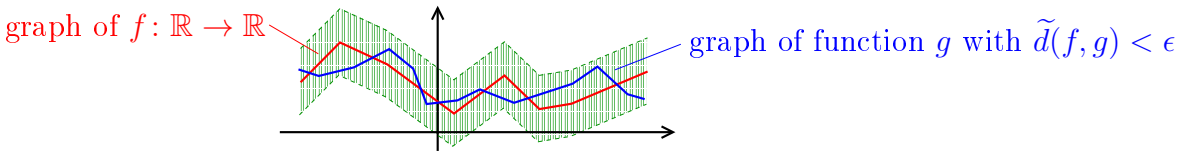
$$\begin{array}{rcl} \widetilde{d}\colon C(X,M)\times C(X,M) & \to & \mathbb{R}_{\geq 0} \\ (f,g) & \mapsto & \widetilde{d}(f,g) := \sup \underbrace{\left\{\widetilde{d}(f(x),g(x)) \,|\, x\in X\right\}}_{\text{non-empty and bounded}} \end{array}$$

has the following properties:

(1) The map $\widetilde{d}$ defines a metric on $C(X,M)$.

(2) If X is compact, then the map

$$\begin{array}{rcl} d\colon C(X,M)\times C(X,M) & \to & \mathbb{R}_{\geq 0} \\ (f,g) & \mapsto & d(f,g) := \sup \underbrace{\left\{d(f(x),g(x)) \,|\, x\in X\right\}}_{\substack{\text{non-empty and bounded} \\ \text{by the Compact Image Lemma 2.13}}} \end{array}$$



is also a metric on $C(X,M)$ which is equivalent, in the sense of the definition on page 109 to the above metric $\widetilde{d}$

(3) If (M,d) is complete, then given any Cauchy sequence $(f_n)_{n\in\mathbb{N}}$ in $(C(X,M),\widetilde{d})$ the map

$$\begin{array}{rcl} f\colon X & \to & M \\ x & \mapsto & \lim\limits_{n\to\infty} f_n(x) \end{array}$$

exists (i.e. each limit exists), it is a continuous map (i.e. it defines an element of $C(X,M)$) and in the metric space $(C(X,M),\widetilde{d})$ it is the limit of the sequence $(f_n)_{n\in\mathbb{N}}$.

(4) If (M,d) is complete, then so is $(C(X,M),\widetilde{d})$.

Remark. The proposition might be familiar from a real analysis course, at least for the case that $X\subset\mathbb{R}^n$ and $M=\mathbb{R}$. The proof of the general case does not differ one iota from the special case.

Proof. The first statement follows easily from the definitions and the properties of the supremum. We leave it to the reader to fill in the details. The second statement follows easily from the definitions and the Equivalent Metric Lemma 1.2. Furthermore the last statement is contained in the third statement.

Thus it remains to prove the third statement of the proposition. Let $(f_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in $(C(X,M),\widetilde{d})$. The following three claims imply the third statement of the proposition.

Claim 1. For each $x\in X$ the sequence $(f_n(x))_{n\in\mathbb{N}}$ converges.

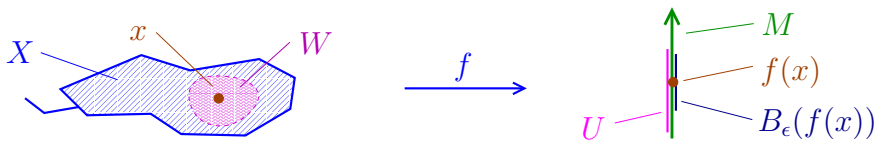
Proof. Let $x\in X$. Note that we have $\widetilde{d}(f_n(x),f_m(x))\leq\widetilde{d}(f_n,f_m)$. Thus we see that $(f_n(x))_{n\in\mathbb{N}}$ is a Cauchy sequence in the metric space $(M,\widetilde{d})$. By our hypothesis (M,d) is complete. By Lemma 6.11 we know that $(M,\widetilde{d})$ is also complete, thus the sequence $(f_n(x))_{n\in\mathbb{N}}$ converges in $(M,\widetilde{d})$ to a point which we call $f(x)$. ⊞

We can now consider the map

$$\begin{array}{rcl} f\colon X & \to & M \\ x & \mapsto & \lim\limits_{n\to\infty} f_n(x). \end{array}$$

Claim 2. $$\forall_{\epsilon>0}\ \exists_{N\in\mathbb{N}}\ \forall_{n\geq N}\ \forall_{x\in X}\ \widetilde{d}(f_n(x),f(x))<\epsilon.$$

Proof. Let $\epsilon>0$. Since $(f_n)_{n\in\mathbb{N}}$ is a Cauchy sequence in $(C(X,M),\widetilde{d})$ we know that there exists an $N\in\mathbb{N}$ such that for each $m,n\geq N$ we have $\widetilde{d}(f_n,f_m)<\frac{\epsilon}{2}$. Now let $n\geq N$ and let $x\in X$. We see that



$$\widetilde{d}(f_n(x),f(x)) \;=\; \widetilde{d}\Big(f_n(x),\lim_{m\to\infty}f(x_m)\Big) \;\overset{\text{by continuity of metrics, see the Metric-is-Continuous Lemma 6.1, and Exercise 2.26}}{=}\; \lim_{m\to\infty}\underbrace{\widetilde{d}(f_n(x),f_m(x))}_{\leq\widetilde{d}(f_n,f_m)<\frac{\epsilon}{2}} \;\leq\; \frac{\epsilon}{2} \;<\; \epsilon.$$

⊞

Claim 3. The map $f\colon X\to M$ is continuous.

Proof. Let $U\subset M$ be an open subset. We need to show that $f^{-1}(U)$ is open. By the JH-Lemma 1.7 it suffices to show that for every $x\in f^{-1}(U)$ there exists an open neighborhood W of $x\in X$ with $f(W)\subset U$. Thus let $x\in f^{-1}(U)$. Since $U\subset M$ is open there exists an $\epsilon>0$ such that $B_\epsilon(f(x))\subset U$.

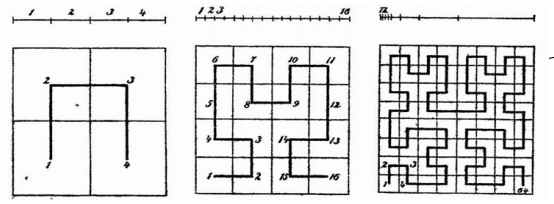
Next note that by Claim 2 and by definition of $\widetilde{d}$ there exists an $n\in\mathbb{N}$ such that for every $x\in X$ we have $d(f_n(x),f(x))<\frac{\epsilon}{3}$. Furthermore, by hypothesis $f_n\colon X\to M$ is continuous,

which implies that there exists an open neighborhood W of x with $f_n(W) \subset B_{\frac{\epsilon}{3}}(f_n(x))$. Now we see that for each $y \in W$ we have

$$d(f(x), f(y)) \leq \underbrace{d(f(x), f_n(x))}_{\leq \frac{\epsilon}{3} \text{ by choice of } n} + \underbrace{d(f_n(x), f_n(y))}_{\leq \frac{\epsilon}{3} \text{ by choice of } W} + \underbrace{d(f_n(y), f(y))}_{\leq \frac{\epsilon}{3} \text{ by choice of } n} < \epsilon.$$

But this means precisely that $f(W) \subset B_\epsilon(f(x)) \subset U$. ■

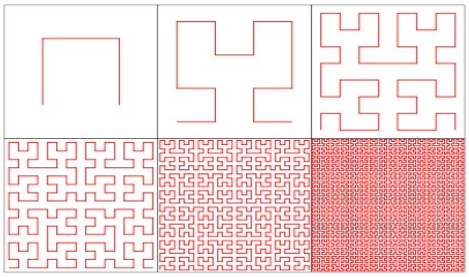
6.5. **Space-filling curves.** The goal of this section is to prove the following, possibly rather counterintuitive theorem.



Theorem 6.13. (Space-Filling Curve Theorem) For every $m \in \mathbb{N}$ there exists a map[93] $f\colon [0,1] \to [0,1]^m$ that is surjective.

Definition. Let $m \geq 2$. A surjective map from $[0,1]$ to $[0,1]^m$ is called a space-filling curve.[94]

Remark.

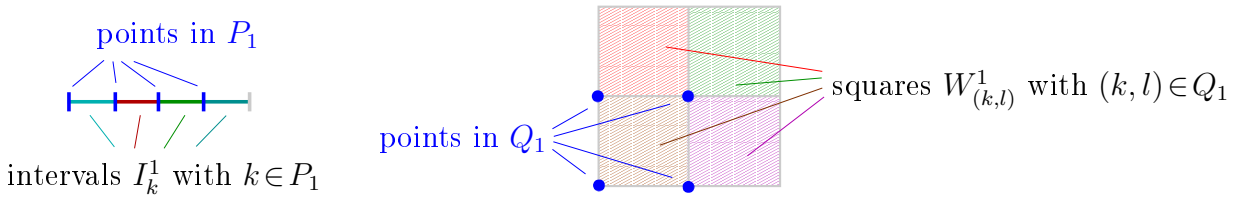


(1) The first example of a space-filling curve was provided by Giuseppe Peano [**Pean1890**] in 1890. Shortly afterwards David Hilbert [**Hilb1891**] gave the first "pictorial" description of a space-filling curve, see the figure below. Nowadays there are many many constructions of space-filling curves. In fact two such constructions are given in Exercises 5.24 and 5.24. Further constructions are considered in [**Sag1994**, Theorem 2.1] and [**Bad2013**].

(2) In Exercise 6.13 we will use the Space-Filling Curve Theorem 6.13 to show that for every $n \in \mathbb{N}$ there exists a surjective map $\mathbb{R} \to \mathbb{R}^n$.

first stages in the construction
of the Hilbert space-filling curve

– [**Hilb1891**]



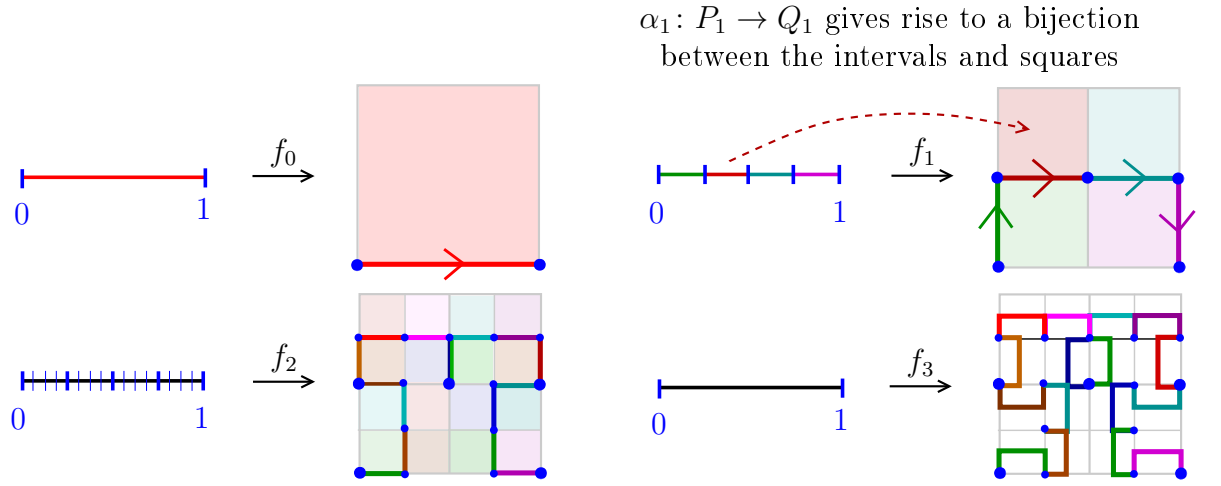
Proof of Theorem 6.13 for $m = 2$**.** For $n \in \mathbb{N}$ we set

$P_n := \{0, \frac{1}{4^n}, \ldots, \frac{4^n-1}{4^n}\}$ and for $k \in P_n$ we set $I_k^n := [k, k + \frac{1}{4^n}]$,

$Q_n := \{0, \frac{1}{2^n}, .., \frac{2^n-1}{2^n}\} \times \{0, \frac{1}{2^n}, .., \frac{2^n-1}{2^n}\}$ and for $(k,l) \in Q_n$ we set $W_{(k,l)}^n := [k, k+\frac{1}{2^n}] \times [l, l+\frac{1}{2^n}]$.

[93] Just to make things clear, here we demand of course as always that f is continuous.

[94] The same name is also used for obvious variations on this concept.



Claim 1. For $n = 0, 1, 2, \ldots$ we can find a bijection $\alpha_n \colon P_n \to Q_n$ and a (continuous) map $f_n \colon [0,1] \to [0,1] \times [0,1]$ such that the following conditions are satisfied:

(a) For each $n \in \mathbb{N}_0$ and each $k \in P_n$ we have $f_n(I_k^n) \subset W_{\alpha_n(k)}^n$.

(b) For each $n \in \mathbb{N}_0$ and each $k \in P_n$ the two endpoints of the interval I_k^n get sent to adjacent vertices of the square $W_{\alpha_n(k)}^n$.

(c) For each $n \geq m \in \mathbb{N}$ and each $k \in P_m$ and $l \in P_l$ with $I_k^n \subset I_l^m$ we have the inclusion $f_n(I_k^n) \subset W_{\alpha_m(l)}^m$.[95]

Proof. We define the maps iteratively.

- For $n = 0$ we have $P_1 = \{0\}$ and $Q_n = \{(0,0)\}$, thus we let $\alpha_0 \colon P_1 \to Q_0$ be the unique bijection. Furthermore we set

$$\begin{array}{rcl} f_1 \colon I_1^0 = [0,1] & \to & W_{(1,1)}^0 = [0,1] \times [0,1] \\ t & \mapsto & (t,0). \end{array}$$

  It is clear that (a) and (b) are satisfied.

- Now suppose that we have constructed bijections $\alpha_0, \ldots, \alpha_n$ and maps $f_0, \ldots, f_n$ with the desired properties. Next we need to construct the bijection $\alpha_{n+1} \colon P_{n+1} \to Q_{n+1}$ and the map $f_{n+1} \colon [0,1] \to [0,1] \times [0,1]$.

  Our first goal is, given $j \in P_n$, to define f_{n+1} on $I_j^n = [j, j + \frac{1}{4^n}]$ and to define α_{n+1} on $j, j + \frac{1}{4^{n+1}}, j + \frac{2}{4^{n+1}}, j + \frac{3}{4^{n+1}} \in P_{n+1}$. We write $\alpha_n(j) =: (k,l) \in Q_n$. It follows easily from (b) that we can find a bijection

$$\alpha_{n+1} \colon \{j, j+\tfrac{1}{4^{n+1}}, j+\tfrac{2}{4^{n+1}}, j+\tfrac{3}{4^{n+1}}\} \to \{(k,l), (k+\tfrac{1}{2^{n+1}}, l), (k, l+\tfrac{1}{2^{n+1}}), (k+\tfrac{1}{2^{n+1}}, l+\tfrac{1}{2^{n+1}})\}$$

[95] Note that Condition (a) is the special case of (c) with $n = m$ and $l = k$. But It seems to us that it is easier to first digest (a) and then to try to digest (c).

and a map $f_{n+1}\colon I_j^n \to W_k^n$ with the following three properties:
(1) The map $f_{n+1}\colon I_j^n \to W_k^n$ agrees with the map f_n on the endpoints.
(2) Each interval $I^{n+1}_{j+\frac{i}{4^{n+1}}}$ gets sent to the square $W^{n+1}_{\alpha_{n+1}(j+\frac{i}{4^{n+1}})}$.
(3) The endpoints of each interval $I^{n+1}_{j+\frac{i}{4^{n+1}}}$ get sent to adjacent vertices of the square $W^{n+1}_{\alpha_{n+1}(j+\frac{i}{4^{n+1}})}$.

This can be done in a systematic way[96] (as is shown in the figure above) but does not have to be so (as is shown in the figure below). We will not clutter the pages with writing down explicit maps. These maps $f_{n+1}\colon I_j^n \to [0,1]\times[0,1]$ agree on the endpoints.

f_n sends endpoints to adjacent vertices f_{n+1} sends endpoints to adjacent vertices

Therefore it follows from the Pasting Proposition 2.6 that they define a continuous map $f_{n+1}\colon [0,1] \to [0,1]\times[0,1]$. Furthermore the bijections α_{n+1} combined give a bijection $\alpha_{n+1}\colon P_{n+1} \to Q_{n+1}$. We leave it to the reader to verify that f_{n+1} and α_{n+1} have the desired properties. ⊞

As above we consider the set $C([0,1],[0,1]\times[0,1])$ of continuous maps from $[0,1]$ to $[0,1]\times[0,1]$. We view this as a metric space with respect to the metric

$$d(f,g) \;:=\; \sup\{\|f(t)-g(t)\|_{\text{Eucl}} \,|\, t\in[0,1]\}$$

that we introduced in Proposition 6.12 (2).

Claim 2. The sequence $(f_n)_{n\in\mathbb{N}_0}$ of maps $[0,1]\to[0,1]\times[0,1]$ is a Cauchy sequence in the metric space $C([0,1],[0,1]\times[0,1])$.

Proof. Let $\epsilon>0$. We pick $N\in\mathbb{N}_0$ with $\frac{1}{2^N}<\frac{\epsilon}{2}$. Let $m,n\geq N$. For any $t\in[0,1]$ we have

$$\|f_m(t)-f_n(t)\|_{\text{Eucl}} \;\underset{\uparrow}{\leq}\; \text{diameter of square of side length } \tfrac{1}{2^N} \;\underset{\uparrow}{=}\; \sqrt{2}\cdot\tfrac{1}{2^N} \;\underset{\uparrow}{<}\; \tfrac{\epsilon}{\sqrt{2}}.$$

it follows from Property (c) that for $m,n\geq N$ and $t\in[0,1]$ $f_m(t), f_n(t)$ are contained in a square of side length $\frac{1}{2^N}$ — see page 285 — choice of N

This implies that for $m,n\geq N$ we have $d(f_m,f_n)\leq\frac{\epsilon}{\sqrt{2}}<\epsilon$. ⊞
It follows from Claim 2 together with Proposition 6.12 that the resulting map

$$\begin{array}{rcl} f\colon [0,1] & \to & [0,1]\times[0,1] \\ t & \mapsto & f(t)=\lim\limits_{n\to\infty} f_n(t) \end{array}$$

is continuous.[97]

[96] In fact one can easily see that α_{n+1} is uniquely determined. A canonical way of defining f_{n+1} is now given by connecting the endpoints via a line segment.
[97] Note though that f is nowhere differentiable.

Claim 3. The image of the map $f\colon [0,1] \to [0,1] \times [0,1]$ is dense.

Proof. Let U be an open subset of $[0,1] \times [0,1]$. We need to show that $f([0,1]) \cap U \neq \varnothing$. It follows from an elementary argument, similar to the discussion on page 228, that there exists an $N \in \mathbb{N}_0$ and a $(k,l) \in Q_N$ such that $W^N_{(k,l)} \subset U$. By Property (a) there exists an $x \in [0,1]$ with $f_N(x) \in W^N_{(k,l)}$. By Property (c) we know that for each $n \geq N$ we have $f_n(x) \in W^N_{(k,l)}$. Since $W^N_{(k,l)}$ is closed we obtain from the Closed Subset Limit Lemma 1.18 that $f(x) = \lim\limits_{n\to\infty} f_n(x) \in W^N_{(k,l)} \subset U$. We have thus shown that $f([0,1]) \cap U \neq \varnothing$. ⊞

Claim 4. The map $f\colon [0,1] \to [0,1] \times [0,1]$ is surjective.

Proof. Since $[0,1]$ is compact and since $[0,1]\times[0,1]$ is Hausdorff we obtain from the Compact Image Lemma 2.13 together with the Compact-Closed Lemma 1.21 (2) that $f([0,1])$ is a closed subset of $[0,1] \times [0,1]$. By Claim 3 we know that $f([0,1])$ is dense in $[0,1] \times [0,1]$. It follows immediately from the definition of a dense subset that the only closed subset that is dense is the total space. Thus we have shown that $f([0,1]) = [0,1] \times [0,1]$. ■

Proof of Theorem 6.13 for $m \geq 2$. We need to show that for each $n \geq 2$ there exists a surjective map $[0,1] \to [0,1]^m$. We prove this statement by induction on m. By the above we know that there exists a surjective map $f\colon [0,1] \to [0,1]^2$. Now suppose we have found a surjective map $\varphi\colon [0,1] \to [0,1]^m$ for some $m \geq 2$. The map[98]

$$[0,1] \xrightarrow{f} [0,1] \times [0,1] \xrightarrow{\mathrm{id}\times\varphi} [0,1] \times [0,1]^m = [0,1]^{m+1}$$

is evidently surjective. ■

Let $m \geq 2$. Recall that in Lemma 2.26 we showed that $[0,1]$ and $[0,1]^m$ are not homeomorphic. By the Compact-Hausdorff Proposition 2.17 (3) this implies that there is no map $[0,1] \to [0,1]^m$ that is surjective and injective. Nonetheless, the following variation on the Space-Filling Curve Theorem 6.13 holds:

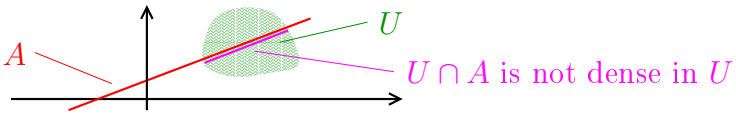
Proposition 6.14. There exists an *injective* map $f\colon [0,1] \to [0,1]^2$ such that $f([0,1])$ has non-zero 2-dimensional Lebesgue measure.

Remark. An injective map $f\colon S^1 \to [0,1]^2$ such that $f([0,1])$ has non-zero 2-dimensional Lebesgue measure is called an *Osgood curve*.

Proof. In 1903 William Osgood [**Osg1903**] and Henri Lebesgue [**Leb1903**] independently showed that there exist injective maps $f\colon [0,1] \to [0,1]^2$ such that $f([0,1])$ has non-zero 2-dimensional Lebesgue measure. Many more examples of such maps are given in [**Sag1994**, Chapter 8.2]. In Exercise 6.14 we will see how this fact can be used to find injective maps $g\colon S^1 \to [0,1]^2$ such that $g(S^1)$ has non-zero 2-dimensional Lebesgue measure. ■

6.6. **The Baire Category Theorem.** The formulation of the Baire Category Theorem requires the following basic definition.

[98] Note that it follows from THE Product Topology-Basics Lemma 5.4 (3) that the middle map is indeed continuous.

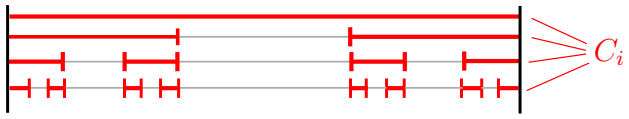


Definition. Let X be a topological space and let $A \subset X$.

(1) As on page 120 we say A is dense in X if every open non-empty subset of X has a non-empty intersection with A.

(2) We say A is nowhere dense in X if there is no open non-empty subset U of X such that $U \cap A$ is dense in U.

Examples.



(1) Let $A \subset \mathbb{R}^n$ be an affine hyperplane of codimension ≥ 1. In Exercise 6.16 we will see that A is a nowhere dense subset of $\mathbb{R}^n$.

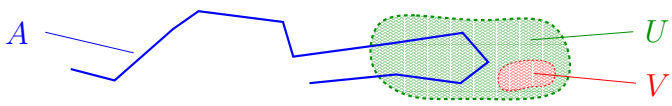
(2) In the following we recall the definition of the Cantor set from page 130. We set $C_0 := [0,1]$ and iteratively we define sets C_i, $i \in \mathbb{N}$ as follows:

$$C_i \;:=\; \tfrac{1}{3} \cdot C_{i-1} \cup \left(\tfrac{2}{3} + \tfrac{1}{3} \cdot C_{i-1}\right).$$

The Cantor set is defined as the intersection $C := \bigcap_{i \in \mathbb{N}_0} C_i$. Note that for $i \in \mathbb{N}_0$ the set C_i does not contain an interval of length $> \frac{1}{3^i}$. It follows that the Cantor set is nowhere dense. On the other hand we saw in Exercise 2.17 that the Cantor set is uncountable. This shows that $\mathbb{R}$ contains an uncountable nowhere dense subset.

We have the following analogue to Lemma 1.12.

Lemma 6.15. Let X be a topological space and let $A \subset X$ be a subset. The following two statements are equivalent:



(1) A is a nowhere dense in X.

(2) The interior of the closure $\overline{A}$ is the empty set, or more succinctly, if $\operatorname{int}(\overline{A}) = \varnothing$.

Proof. We have the following equivalences of statements:

$$\begin{aligned}
& A \text{ is nowhere dense in } X \\
\iff & \forall_{\varnothing \neq U \subset X \text{ open}} \quad U \cap A \text{ is not dense in } U \\
\iff & \forall_{\varnothing \neq U \subset X \text{ open}} \; \exists_{\varnothing \neq V \subset U \text{ open}} \quad A \cap V = \varnothing \\
\iff & \forall_{\varnothing \neq U \subset X \text{ open}} \; \exists_{\varnothing \neq V \subset U \text{ open}} \quad A \subset (X \setminus V) \\
\iff & \forall_{\varnothing \neq U \subset X \text{ open}} \; \exists_{B \subsetneq X \text{ closed with } X \setminus U \subset B} \quad A \subset B \qquad \text{substitution } B = X \setminus V \text{ or } V = X \setminus B \\
\iff & \forall_{\varnothing \neq U \subset X \text{ open}} \; \exists_{C \subset X \text{ closed with } A \subset C} \quad U \not\subset C \qquad \text{substitution } C = (X \setminus U) \cup B \text{ or } B = C \\
\iff & \text{the interior of the closure } \overline{A} \text{ is the empty set.}
\end{aligned}$$

∎

Theorem 6.16. (Baire Category Theorem) Let X be one of the following:
(1) X is a complete metric space, or
(2) X is a regionally compact Hausdorff space.[99]
Then the union of countably many nowhere dense subsets of X has empty interior.

Remark. The Baire Category Theorem 6.16 has its origins in the work of René-Louis Baire [**Bai1899**]. The name of the theorem predates the advent of category theory. In particular the theorem has absolutely nothing to do with category theory.

Examples.

(1) It follows from the Baire Category Theorem 6.16 (1) and the example on page 296 that the union of countably many affine hyperplanes of $\mathbb{R}^n$ of codimension ≥ 1 has empty interior.
(2) The union of countable many nowhere dense sets might well be dense. For example take $X = \mathbb{R}$ and let $\varphi\colon \mathbb{N} \to \mathbb{Q}$ be a bijection. Then the sets $A_n := \{\varphi(n)\}$ are nowhere dense, but the union of the A_ns's is $\mathbb{Q}$, which is of course dense.

To clarify the exposition we prove the two cases of the Baire Category Theorem separately.

Proof of Theorem 6.16 for complete metric spaces. After possibly taking duplicates we only have to deal with the case that we have a countably *infinite* family $\{A_i\}_{i\in\mathbb{N}}$ of nowhere dense subsets of X. We need to show that no open non-empty subset U of X is contained in $\bigcup_{i\in\mathbb{N}} A_i$. Thus let U be an open non-empty subset of X. Our goal now is to find a point x in $U \setminus \bigcup_{i\in\mathbb{N}} A_i$.

Claim 1. There exists a sequence of open non-empty subsets $V_1, V_2, V_3, \ldots$ of X with the following three properties:
(0) $V_1 = U$,
(1) for each $i \in \mathbb{N}$ we have $\overline{V}_{i+1} \subset V_i \setminus \overline{A}_i$, and
(2) for each $i \in \mathbb{N}_{\geq 2}$ we have $\operatorname{diam}(V_i) \leq 2^{-i}$.

Proof. We construct the sequence iteratively. We set $U = V_1$ and we suppose that we have already constructed $V_1, \ldots, V_i$. Since A_i is nowhere dense and since V_i is non-empty and open we know by Lemma 6.15 that $V_i \setminus \overline{A}_i$ is non-empty. By the Interior-Closure Lemma 1.9 we know that $\overline{A}_i$ is a closed subset. Thus we see that $V_i \setminus \overline{A}_i$ is in fact an open non-empty subset of X. Therefore there exists an open ball $B_\epsilon(x) \subset V_i \setminus \overline{A}_i$. We can arrange that

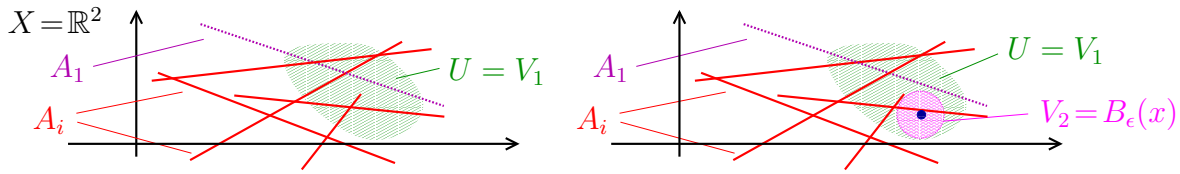
[99] We will only make us of Statement (1). Nonetheless it is nice to have the second statement. It is a fun little exercise to show that the two hypothesis given in Statements (1) and (2) are independent of one another.

$\epsilon \leq \frac{1}{2^i}$. We set $V_{i+1} = B_{\frac{\epsilon}{2}}(x)$. One can now easily verify that $V_1, \ldots, V_{i+1}$ have the desired properties:

(1) Since $\overline{B}_{\frac{\epsilon}{2}}(x)$ is closed we see that $\overline{V}_{i+1} \subset \overline{B_{\frac{\epsilon}{2}}(x)} = \overline{B}_{\frac{\epsilon}{2}}(x) \subset B_\epsilon(x) \subset V_i \setminus \overline{A}_i$.

(2) By the discussion on page 285 we have $\operatorname{diam}(V_{i+1}) = \dim(B_{\frac{\epsilon}{2}}(x)) = 2 \cdot \frac{\epsilon}{2} \leq 2^{-i}$. ⊞

Let $i \in \mathbb{N}$. Since V_i is non-empty we can pick a point $x_i \in V_i$. Note that $\{x_i\}_{i\in\mathbb{N}}$ is a Cauchy sequence since for $2 \leq i \leq j$ we have $d(x_i, x_j) \leq \operatorname{diam}(V_i) \leq 2^{-i}$. By hypothesis the metric space (X, d) is complete. This means that the Cauchy sequence $\{x_i\}_{i\in\mathbb{N}}$ has a limit point $x \in X$.



Claim 2. The point x lies in each $\overline{V}_i$.

Proof. Let $i \in \mathbb{N}$. By construction we know that for all $n \geq i$ we have $x_n \in \overline{V}_i$. Since $\overline{V}_i$ is closed we obtain from the Closed Subset Limit Lemma 1.18 that $x \in \overline{V}_i$. ⊞

Finally note that

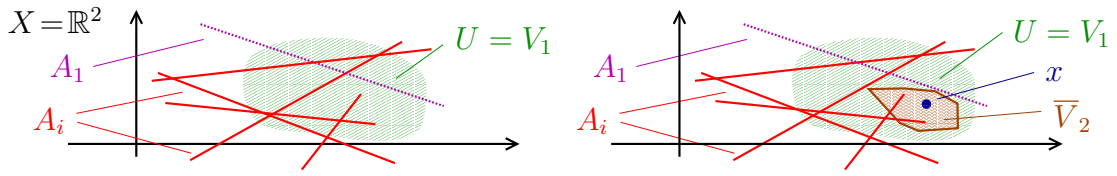
$$\begin{array}{ccccccccc} x & \in & \bigcap_{i\in\mathbb{N}} \overline{V}_{i+1} & \subset & \bigcap_{i\in\mathbb{N}} (V_i \setminus \overline{A}_i) & \subset & \bigcap_{i\in\mathbb{N}} (U \setminus A_i) & \subset & U \setminus \bigcup_{i\in\mathbb{N}} A_i. \\ & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ & \text{by the above} & & \text{by construction of } V_{i+1} & & \text{since } V_i \subset U & & \text{de Morgan's Laws 0.1} & \end{array}$$

This shows that $U \not\subset \bigcup_{i\in\mathbb{N}} A_i$. ■

Proof of Theorem 6.16 for regionally compact Hausdorff spaces. As in the previous setting we need to show that if $\{A_i\}_{\in\mathbb{N}}$ is a family of nowhere dense subsets and if U is an open non-empty subset U of X, then $U \cap \bigcup_{i\in\mathbb{N}} A_i \neq \varnothing$. Thus let U be an open non-empty subset of X.

Claim. There exists a sequence of open non-empty subsets $V_1, V_2, V_3, \ldots$ with the following three properties:

(0) $V_1 = U$,



(1) for each $i \in \mathbb{N}$ we have $\overline{V}_{i+1} \subset V_i \setminus \overline{A}_i$, and

(2) for each $i \in \mathbb{N}_{\geq 2}$ the subspace $\overline{V}_i$ is compact.

Proof. We construct the sequence iteratively. We set $U = V_1$ and we suppose that we have already constructed $V_1, \ldots, V_i$. Since A_i is nowhere dense and since V_i is open we know by Lemma 6.15 that $V_i \setminus \overline{A}_i$ is non-empty. Since $\overline{A}_i$ is a closed subset we see that $V_i \setminus \overline{A}_i$ is in fact an open non-empty subset of X. We pick $x \in V_i \setminus \overline{A}_i$. Since X is regionally compact and Hausdorff we know by Lemma 2.42 (1) that there exists an open neighborhood V_{i+1} of x such that $\overline{V}_{i+1}$ is compact and such that $\overline{V}_{i+1}$ is contained in $V_i \setminus \overline{A}_i$. Evidently $V_1, \ldots, V_{i+1}$ have the desired properties. ⊞

We make the following observations:

(1) The intersection of finitely many $\overline{V}_i$ is non-empty by construction.

(2) Since each $\overline{V}_i$ is closed and since X is Hausdorff we obtain from the Compact-Closed Lemma 1.21 that each $\overline{V}_i$ is a closed subset of $\overline{V}_1$.

Since $\overline{V}_1$ is compact it follows from the above, together with Exercise 1.29[100] that $\bigcap_{i\in\mathbb{N}} \overline{V}_i$ is non-empty. As in the previous case we note that we have $\bigcap_{i\in\mathbb{N}} \overline{V}_i \subset U \setminus \bigcup_{i\in\mathbb{N}} \overline{A}_i$. This shows that $U \subsetneq \bigcup_{i\in\mathbb{N}} \overline{A}_i$. ■

6.7. **Baire spaces and completely metrizable spaces.** The Baire Category Theorem 6.16 motivates several definitions.

Definition. A topological space that has the property that the union of countably many nowhere dense subsets of X has empty interior is called a Baire space.

Lemma 6.17. (Baire Space Characterization Lemma) Let X be a topological space. The following two statements are equivalent:

(1) X is a Baire space.

(2) For each countable collection of open dense subsets $\{U_n\}_{n\in\mathbb{N}}$ the intersection $\bigcap_{n\in\mathbb{N}} U_n$ is dense.

Proof. We have the following equivalences of statements:

X is a Baire space

$\iff$ for every family $\{W_n\}_{n\in\mathbb{N}}$ of nowhere dense subsets the interior of $\bigcup_{n\in\mathbb{N}} W_n$ is $\varnothing$

$\overset{6.15}{\iff}$ for every family $\{W_n\}_{n\in\mathbb{N}}$ of subsets with $\operatorname{int}(\overline{W}_n) = \varnothing$ the interior of $\bigcup_{n\in\mathbb{N}} W_n$ is $\varnothing$

$\overset{1.9(2)}{\iff}$ for every family $\{A_n\}_{n\in\mathbb{N}}$ of closed subsets with $\operatorname{int}(A_n) = \varnothing$ the interior of $\bigcup_{n\in\mathbb{N}} A_n$ is $\varnothing$

$\underset{U_n=X\setminus A_n}{\overset{1.12}{\iff}}$ for every family $\{U_n\}_{n\in\mathbb{N}}$ of dense open subsets the interior of $\bigcup_{n\in\mathbb{N}} (X \setminus U_n)$ is $\varnothing$

$\overset{1.12}{\iff}$ for every family $\{U_n\}_{n\in\mathbb{N}}$ of dense open subsets the subset $X \setminus \bigcup_{n\in\mathbb{N}} (X \setminus U_n)$ is dense

$\overset{0.1}{\iff}$ for every family $\{U_n\}_{n\in\mathbb{N}}$ of dense open subsets the intersection $\bigcap_{n\in\mathbb{N}} U_n$ is dense. ■

Lemma 6.18. If X is a Baire space, then every open subset V is also a Baire space.

Proof. The statement follows easily from the Open -Closed Inclusion Lemma 2.10 and the definitions. We leave it to the reader to fill in the details. ■

Definition. A topological space X is called completely metrizable if there exists a *complete* metric d on X such that the given topology agrees with the topology coming from d.

[100] The content Exercise 1.29 is frankly just reformulation of the definition of a compact space using de Morgan's Laws 0.1.

Example.

(1) By the Compact-Complete Proposition 6.10 we know that every compact metrizable space is already completely metrizable.
(2) The metric space $(\mathbb{R}, d^{\text{eucl}})$ is of course complete, hence $\mathbb{R}$ is completely metrizable.
(3) If a topological space X is homeomorphic to a completely metrizable topological space, then X is evidently also completely metrizable.
(4) We consider $X = (-1, 1)$. If we equip $(-1, 1)$ with the usual Euclidean metric d^{eucl}, then $((-1, 1), d^{\text{eucl}})$ is of course not complete. But the map $(-1, 1) \to \mathbb{R}$ given by $t \mapsto \tan(\frac{\pi}{2}t)$ is a homeomorphism. Thus it follows from (2) and (3) that $(-1, 1)$ is completely metrizable.

With these definitions we can now reformulate the Baire Category Theorem 6.16 (1).

Theorem 6.16 (Baire Category Theorem)
(1) If X is a topological space that is completely metrizable, then X is a Baire space.

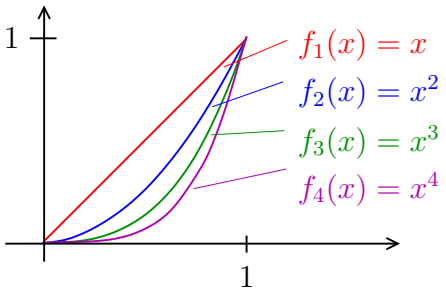
We conclude this section with the following amusing corollary. It is an amusing exercise to try to prove the corollary from scratch, i.e. without appealing to the Baire Category Theorem 6.16 (1).

Corollary 6.19. The topological space $\mathbb{Q}$ is metrizable but not completely metrizable.

Proof. Evidently $\mathbb{Q}$ is metrizable. But $\mathbb{Q}$ is not a Baire space. This can be seen as follows. Since $\mathbb{Q}$ is countable there exists a bijection $\varphi\colon \mathbb{N} \to \mathbb{Q}$. For each $n \in \mathbb{N}$ we set $U_n := \{\varphi(n)\}$. Each U_n is nowhere dense, but $\bigcup_{n\in\mathbb{N}} U_n = \mathbb{Q}$. So we have found a countably many nowhere dense subsets such that the interior of the union is non-empty. Since $\mathbb{Q}$ is not a Baire space it follows from the Baire Category Theorem 6.16 (1) that $\mathbb{Q}$ is not completely metrizable. ■

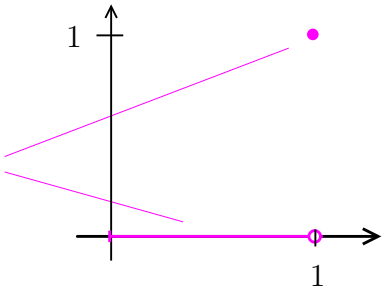
6.8. Application of the Baire Category Theorem 6.16 to sequences of maps.

We conclude this chapter with an application of the Baire Category Theorem 6.16 to analysis. We will not make use of the concepts and results of this section. But hopefully Proposition 6.20 gives the reader an idea of what the Baire Category Theorem 6.16 "is good for" in analysis.



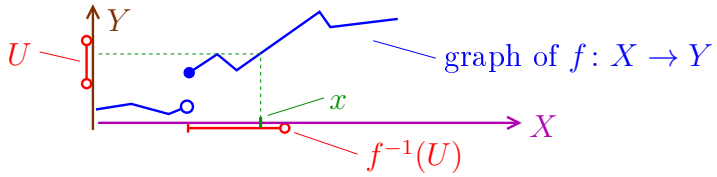
Definition. Let X be a topological space and let Y be a Hausdorff space. Furthermore let $\{f_n\colon X \to Y\}_{n\in\mathbb{N}}$ be a sequence of continuous maps. We say the sequence $(f_n)_{n\in\mathbb{N}}$ converges pointwise, if for each $x \in X$ the sequence $(f_n(x))_{n\in\mathbb{N}}$ converges in Y. We refer to the map[101]

$$\begin{array}{ccc} X & \to & Y \\ x & \mapsto & \lim\limits_{n\to\infty} f_n(x) \end{array}$$



as the limit map.

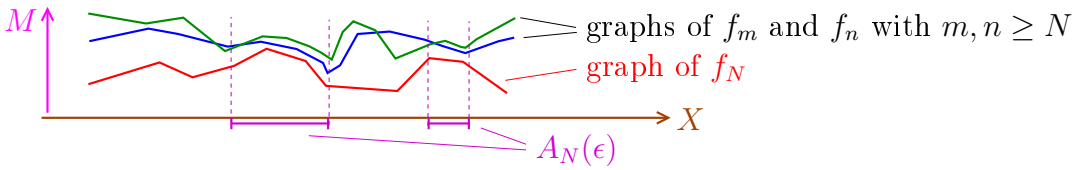
Example. A popular way to shock students in a real analysis course is to show that the limit map of a pointwise convergent sequence of continuous maps is not necessarily continuous.



[101] Since Y is Hausdorff we know by the Unique Limit Lemma 1.17 that we can unambiguously talk about the limit of the sequence $(f_n(x))_{n\in\mathbb{N}}$.

the sequence of maps $f_n(x) = x^n$ converges pointwise, but the limit map is not continuous at $x=1$

Definition. Let $f\colon X \to Y$ be a map between two topological spaces X and Y and let $x \in X$. We say f is continuous at the point $x \in X$, if for each open neighborhood U of $f(x) \in Y$ the preimage $f^{-1}(U)$ is a neighborhood of $x \in X$.



Remark. It follows easily from the JH-Lemma 1.7 that a map $f\colon X \to Y$ is continuous at every point $x \in X$ if and only if f is continuous in the sense of the definition on page 141.

The following proposition shows that the set of discontinuities of a limit map cannot get completely out of hand.

Proposition 6.20. Let X be a topological space, let (M, d) be a metric space and let $(f_n\colon X \to M)_{n\in\mathbb{N}}$ be a sequence of continuous maps which converges pointwise. If X is a Baire space, then the set of points at which the limit map $f\colon X \to M$ is continuous is dense in X.

Proof. Given $N \in \mathbb{N}$ and $\epsilon > 0$ we set

$$A_N(\epsilon) \;:=\; \{x \in X \,|\, d(f_m(x), f_n(x)) \le \epsilon \text{ for all } m, n \ge N\}$$

Claim 1.

(a) Each $A_N(\epsilon)$ is closed.

(b) $\bigcup_{N\in\mathbb{N}} A_N(\epsilon) = X$.

Proof.

(a) Note that $A_N(\epsilon) \;=\; \bigcap_{m,n\ge N} (d \circ ((f_m, f_n)\colon X \to M \times M)\colon X \to \mathbb{R})^{-1}([-\epsilon, \epsilon])$.

By the Metric-is-Continuous Lemma 6.1 we know that d is continuous. It follows from this description that $A_N(\epsilon)$ is closed.

(b) Let $x \in X$. By hypothesis $(f_n(x))_{n\in\mathbb{N}}$ is a convergent sequence. This implies that it is in particular a Cauchy sequence, which by definition implies that there exists an $N \in \mathbb{N}$ such that $x \in A_N(\epsilon)$. ⊞

Given $\epsilon > 0$ we set

$$U(\epsilon) \ := \ \bigcup_{N\in\mathbb{N}} \text{interior of } A_N(\epsilon).$$

By hypothesis X is a Baire space. Thus it follows from the Baire Space Characterization Lemma 6.17 that it suffices to prove the following claim.

Claim 2.

(a) For each $\epsilon > 0$ the set $U(\epsilon)$ is open and dense in X.

(b) The map f is continuous at every point in $\bigcap_{m\in\mathbb{N}} U(\frac{1}{m})$.

Proof.

(a) Since interiors of subsets are open we see that $U(\epsilon)$ is open. To show that $U(\epsilon)$ is dense it suffices, by definition of $U(\epsilon)$, to show that for each open subset $V \subset X$ there exists an $N \in \mathbb{N}$ such that $V \cap \text{int}(A_N(\epsilon)) \neq \varnothing$. Thus let $V \subset X$ be an open subset.

(i) It follows from Claim 1 (a) that each $V \cap A_N(\epsilon)$ is a closed subset of V.

(ii) Since X is a Baire space and since $V \subset X$ is open we know by Lemma 6.18 that V itself is a Baire space.

(iii) By Claim 1 (b) we know that the sets $V \cap A_N(\epsilon)$ form a cover of V. Since V is a Baire space we see that not all $V \cap A_N(\epsilon)$ can be nowhere dense in V. In other words there exists an $N \in \mathbb{N}$ such that $V \cap A_N(\epsilon)$ is not nowhere dense in V.

(iv) By Lemma 6.15 we know that the interior of the closure of $V \cap A_N(\epsilon)$ in V is non-empty.

(v) By (i) and (iv) we know that the interior of $V \cap A_N(\epsilon)$ is non-empty.

In summary, we have shown that there exists an $N \in \mathbb{N}$ such that $V \cap A_N(\epsilon)$ contains a subset $W \subset V$ that is open in V. Since V is open in X it follows from the elementary the Open -Closed Inclusion Lemma 2.10 that W is open in X. In particular we see that W is contained in the interior of $A_N(\epsilon)$.

(b) Let $x \in \bigcap_{m\in\mathbb{N}} U(\frac{1}{m})$. We need to show that f is continuous at the point x. It follows easily from the definition, see page 301, that it suffices to show that for every $\epsilon > 0$ there exists a neighborhood W of x such that for all $y \in W$ we have $d(f(x), f(y)) < \epsilon$. We make a few preparations:

(i) We pick $k \in \mathbb{N}$ with $\frac{1}{k} < \frac{\epsilon}{3}$.

(ii) Note that we know for free that $x \in U(\frac{1}{k})$. Therefore there exists an $n \in \mathbb{N}$ such that $x \in \text{int}(A_n(\frac{1}{k}))$.

(iii) Since f_n is continuous and since $\text{int}(A_n(\frac{1}{k}))$ there exists a neighborhood W of $x \in X$ with $W \subset A_n(\frac{1}{k})$ such that $d(f_n(x), f_n(y)) < \frac{\epsilon}{3}$ for all $y \in W$.

Now we see that for all $z \in W$ we have

$$d(f(z), f_n(z)) = \Big(\lim_{m\to\infty} f_m(z), f_n(z)\Big) \overset{\text{by continuity of metrics, see the Metric-is-Continuous Lemma 6.1, and Exercise 2.26}}{\overset{\downarrow}{=}} \lim_{m\to\infty} \underbrace{d(f_m(z), f_n(z))}_{\substack{< \frac{1}{k} \text{ for } m \geq n \text{ since} \\ z \in W \subset A_n(\frac{1}{k})}} \leq \frac{1}{k} < \frac{\epsilon}{3}.$$

Finally note that for all $y \in W$ we have the following (in-) equalities:

$$d(f(x), f(y)) \overset{\text{triangle inequality}}{\overset{\downarrow}{=}} \underbrace{d(f(x), f_n(x))}_{\substack{< \frac{\epsilon}{3} \text{ by the above,} \\ \text{since } x \in W}} + \underbrace{d(f_n(x), f_n(y))}_{\substack{< \frac{\epsilon}{3}, \text{ since } y \in W, \\ \text{see (iii)}}} + \underbrace{d(f_n(y), f(y))}_{\substack{< \frac{\epsilon}{3} \text{ by the above,} \\ \text{since } y \in W}} < \epsilon.$$

■

Remark. The Baire Category Theorem 6.16 has many other applications to analysis. For example one can use it to show that "most" continuous maps $\mathbb{R} \to \mathbb{R}$ are nowhere differentiable. We refer to [**JP2015**, Chapter 7] or alternatively to [**Ross2013**, Theorem 38.3] for details.

Exercises for Chapter 6.

Exercise 6.1. Let (X, d) be a metric space, let $K \subset X$ be a compact subspace and let U be an open neighborhood of $K \subset X$. Show that there exists an $r > 0$ such that for each $x \in K$ we have $B_r(x) \subset U$.

Exercise 6.2. Let (X, d) be a metric space. Show that the map

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} \\ (x, y) & \mapsto & d(x, y) \end{array}$$

is continuous.

Exercise 6.3. Let (X, d) be a metric space. We suppose that X is compact. Furthermore let $f\colon X \to X$ be a map with $f(x) \neq x$ for all $x \in X$. Show that there exists an $\epsilon > 0$ such that $d(f(x), x) \geq \epsilon$ for all $x \in X$.

Exercise 6.4. Let (X, d) be a metric space and let $f\colon X \to \mathbb{R}$ be a continuous map. We now define

$$\begin{array}{rcl} \widetilde{d}\colon X \times X & \to & \mathbb{R}_0 \\ (x, y) & \mapsto & d(x, y) + |f(x) - f(y)|. \end{array}$$

Show that $\widetilde{d}$ is a metric and show that $\widetilde{d}$ induces the same topology as d.

Exercise 6.5. Let (X, d) be a metric space and let $B \subset X$ be a non-empty subset. Show that the map

$$\begin{array}{rcl} X & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & d(x, B) := \inf\{d(x, b) \,|\, b \in B\} \end{array}$$

is continuous.

Exercise 6.6. Suppose that X is a metrizable topological space. Show that given any closed set $A \subset X$ there exists a map $f\colon X \to \mathbb{R}$ such that $f^{-1}(0) = A$.
Hint. Use the Distance-to-Subspace Lemma 6.2.

Exercise 6.7. Show that the statement of the Distance-Minimizer Lemma 6.4 does not generalize to general metric spaces. More precisely, give an example of a metric space X, a compact subset $K \subset X$ and a closed subset $L \subset X$ such that there do not exist $x \in K$ and $y \in L$ with $d(x, y) = d(K, L)$.

Exercise 6.8. Let (X, d) be a metric space. We denote by $\mathcal{P}(X)$ its power set. We consider the map

$$\begin{array}{rcl} d\colon \mathcal{P}(X) \setminus \{\varnothing\} \times \mathcal{P}(X) \setminus \{\varnothing\} & \to & \mathbb{R}_{\geq 0} \\ (A, B) & \mapsto & d(A, B). \end{array}$$

Which properties of a metric does this map satisfy?

Exercise 6.9. We consider the metric space $X = \mathbb{R}$. Let K and L be two closed non-empty disjoint subsets of $\mathbb{R}$. Is it necessarily true that $d(K, L) > 0$?

Exercise 6.10. Let X be a metric space and let A, B be two non-empty subsets of X. Suppose that $\operatorname{diam}(A) + \operatorname{diam}(B) < d(A, B)$. Show that $A \cap B = \varnothing$.

Exercise 6.11. Let X be a topological space and let $\{B_i\}_{i \in I}$ be a family of *open* subsets such that the intersection $Y := \bigcap_{i \in I} B_i$ is non-empty.

(a) We suppose that X and Y are path-connected. Show that each B_i is path-connected.
Hint. Use the Lebesgue Lemma 6.5.
(b) We suppose that X and Y are connected. Show that each B_i is connected.
(c) Show that statements (a) and (b) are wrong if we drop the hypothesis that the B_i are open.
(d) Do statements (a) and (b) hold if each B_i is a closed subset?

Remark. This statement can be viewed as a partial converse to the Union Connected Lemma 2.28.

Exercise 6.12. Let $A \subset \mathbb{R}^n$ be a subset. We equip A with the usual Euclidean metric. Show that A is complete if and only if A is a closed subset of $\mathbb{R}^n$.

Exercise 6.13. Show that for for every $n \in \mathbb{N}$ there exists a surjective map $\mathbb{R} \to \mathbb{R}^n$.

Exercise 6.14. Recall that by Proposition 6.14 we know that there exists an injective map $f\colon [0,1] \to [0,1]^2$ be an injective map such that $f([0,1])$ has non-zero 2-dimensional Lebesgue measure. Show that there exists an injective map $g\colon S^1 \to [0,1]^2$ such that $g(S^1)$ has non-zero 2-dimensional Lebesgue measure.

Exercise 6.15. Let $f\colon \mathbb{R} \to [0,1]$ be a continuous map that satisfies the following three conditions:

(1) for every $t \in \mathbb{R}$ we have $f(t+2) = f(t)$,

(2) for every $t \in [0, \frac{1}{3}]$ we have $f(t) = 0$,
(3) for every $t \in [\frac{2}{3}, 1]$ we have $f(t) = 1$.

Given $t \in \mathbb{R}$ we set

$$\varphi(t) := \sum_{n=1}^{\infty} 2^{-n} \cdot f(3^{2n-1} \cdot t), \qquad \psi(t) := \sum_{n=1}^{\infty} 2^{-n} \cdot f(3^{2n} \cdot t).$$

Prove the following two statements:

(a) The maps $\varphi, \psi \colon \mathbb{R} \to \mathbb{R}$ are continuous.
(b) The map $t \mapsto (\varphi(t), \psi(t))$ is a surjection $[0,1] \to [0,1] \times [0,1]$.
(c) Let $n \in \mathbb{N}$. How can you modify the above construction of maps to get a space-filling curve $[0,1] \to [0,1]^n$?

Remark. This explicit description of a space-filling curve was found by Isaac Schoenberg [**Schoe1938**]. It nicely complements the constructions given in Exercise 5.24 and the Space-Filling Curve Theorem 6.13.

Exercise 6.16. Show that every affine hyperplane in $\mathbb{R}^n$ of codimension ≥ 1 is nowhere dense.

Exercise 6.17. The Baire Category Theorem 6.16 (1), together with Lemma 6.15, implies that $\mathbb{R}$ cannot be written as a countable union of *closed* subsets having empty interiors. Show that this conclusion does not hold, if the subsets are not required to be closed.

Exercise 6.18. Let X be a topological space.

(a) Show that the union of finitely many nowhere dense subsets is again nowhere dense.
(b) Is the union of countably many nowhere dense necessarily nowhere dense?

Exercise 6.19. Show that the conclusion of the Baire Category Theorem 6.16 does not necessarily hold for incomplete metric spaces. More precisely, provide an example of a metric space X, a countable family $\{U_i\}_{i \in I}$ of nowhere dense subsets such that the union $\bigcup_{i \in I} U_i$ has non-empty interior.

Exercise 6.20. Let (M, d) be a complete metric space with no isolated points. Show that the set M is uncountable.
Remark. Recall that a point $x_0 \in X$ is called *isolated* if $\{x_0\}$ itself is an open subset.

Exercise 6.21. Let $f \colon (0,1) \to \mathbb{R}$ be an infinitely differentiable function such that for each $x \in (0,1)$ there exists an $n \in \mathbb{N}_0$ such that $f^{(n)}(x) = 0$. We want to show that f is a polynomial function. In the following we outline a proof by contradiction. Suppose that f is not a polynomial function.

(a) We consider the sets

$$\begin{aligned} S_n &:= \{x \in (0,1) \mid f^{(n)}(x) = 0\} \\ X &:= \left\{ x \in (0,1) \,\middle|\, \begin{array}{c} \text{there is no open neighborhood of } x \in (0,1) \text{ on} \\ \text{which } f \text{ is a polynomial function} \end{array} \right\} \end{aligned}$$

Show that S_n and X are closed and show that X has no isolated points.
(b) Apply the Baire Category Theorem 6.16 (1) to the covering $\{X \cap S_n\}_{n \in \mathbb{N}}$ of X to show that there exists an open interval (a, b) and an $n \in \mathbb{N}$ such that $(a, b) \cap X \neq \varnothing$ and such that $(a, b) \cap X \subset S_n$.

(c) Show that $(a,b) \cap X \subset S_m$ for all $m \geq n$.
Hint. Use that every point in X is an accumulation point and use the definition of derivatives.
(d) Let (s,t) be a maximal interval in $X \setminus (a,b)$. Note that f is described by a polynomial function of some degree d on (s,t). Use the fact that at least one of s,t lies in X to show that $d < n$.
Hint. Consider the d-th derivative.
(e) Use (d) to show that $f^{(n)} = 0$ on (a,b).
(f) Argue why (e) is a contradiction to $(a,b) \cap X$ being non-empty.

Remark. This statement was first proved in [**CSB1954**]. The details for this challenging exercise are worked out in [**Ross2013**, Theorem 38.5].

Exercise 6.22. We say that a map $f\colon \mathbb{R} \to \mathbb{R}$ is *nowhere monotonic* if there is no open non-empty subset $U \subset \mathbb{R}$ such that $f|_U\colon U \to \mathbb{R}$ is monotonic. Show that the set of nowhere monotonic maps is dense in the topological space $C(\mathbb{R},\mathbb{R})$.

Exercise 6.23. Give an example of a sequence $\{f_n\colon [0,1] \to \mathbb{R}\}_{n\in\mathbb{N}}$ of continuous maps that converges pointwise and such that the limit map $f\colon [0,1] \to \mathbb{R}$ is discontinuous at infinitely many points.

Exercise 6.24. Let $f\colon \mathbb{R} \to \mathbb{R}$ be a continuous map with the following property: for each $x \in \mathbb{R}_{>0}$ we have $\lim\limits_{n\to\infty} f(nx) = 0$. Show that $\lim\limits_{n\to\infty} f(x) = 0$.
Hint.
(a) Let $\epsilon > 0$. We set $D_n := \{x \in \mathbb{R}_{>0} \,|\, |f(mx)| \leq \epsilon \text{ for all } m \geq n\}$. Use the Baire Category Theorem 6.16 (1) to show that there exists an $n_0 \in \mathbb{N}$ such that D_{n_0} has non-empty interior.
(b) Use (a) to show that there exists an $r > 0$ such that $|f(x)| < \epsilon$ for all $x > r$.

Exercise 6.25. A topological space that has the property that every sequence admits a convergent subsequence is called *sequentially compact*.

(a) Show that every compact metric space is sequentially compact.
Remark. In fact a metric space is compact if and only if it is compact. The "only if"-direction is shown in [**Mun1975**, §28].
Remark. This exercise can be viewed as a generalization of the Bolzano-Weierstraß-theorem from real analysis.
(b) By Tychonoff's Theorem 5.9 we know that $[0,1]^{\mathbb{N}}$ is compact. Show that $[0,1]^{\mathbb{N}}$ is not sequentially compact.

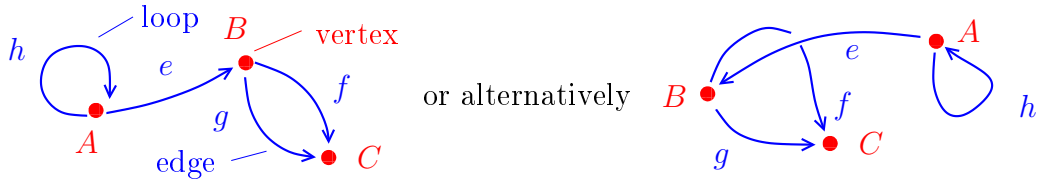
Exercise 6.26. Let X be a metric space. We say that a map $f\colon X \to X$ is an *isometry* if for every $x,y \in X$ we have $d(f(x),f(y)) = d(x,y)$. Show that if $f\colon X \to X$ is an isometry and if X is compact, then f is a homeomorphism.
Hint. It is clear that f is injective. By the Compact-Hausdorff Proposition 2.17 (3) it suffices to show that f is a surjection. Suppose that there exists an $a \in X \setminus f(X)$. There exists an $\epsilon > 0$ with $B_\epsilon(a) \subset X \setminus f(X)$. We consider the sequence given by $x_0 := a$ and $x_{n+1} = f(x_n)$ for $n \in \mathbb{N}_0$. Show that for every $m \neq n$ we have $d(x_m,x_n) > \epsilon$. Why is this not possible?

7. Graphs

In this chapter we will first introduce the purely combinatorial concept of an (undirected) abstract graph. Afterwards we introduce the corresponding topological realizations. These notions are of interest for various reasons. Abstract graphs are ubiquitous in mathematics and at times they will also play a useful role in our discussions. The corresponding topological realizations form fairly simple, but nonetheless interesting examples of topological spaces.

7.1. Abstract graphs and topological graphs.

We start out with the following rather abstract definition.



Definition. An abstract graph G is a quadruple (V, E, i, t) where V is a set, E is a set and $i, t\colon E \to V$ are maps from E to V.

(1) The elements of V are called the vertices of G and the elements of E are called the edges of G.
(2) Given $e \in E$ the point $i(e)$ is called the initial point of e and $t(e)$ is called the terminal point of e. We refer to $i(e)$ and $t(e)$ as the endpoints of e.
(3) We say an edge $e \in E$ is a loop if $i(e) = t(e)$. Otherwise we call e a non-loop.
(4) We say G is finite (countable) if both V and E are finite (countable).

Remark. The origins of graph theory go back to Leonhard Euler[**Eul1736**] and his work in 1736 on the problem on the seven bridges of Königsberg, see Exercise 7.2.

Examples.

(A) We take $V = \{A, B, C\}$ and $E = \{e, f, g, h\}$. Furthermore let $i\colon E \to V$ be the map that is defined by $i(e) = A$, $i(f) = B$, $i(g) = B$ and $i(h) = A$ and let $t\colon E \to V$ be the map that is defined by $t(e) = B$, $t(f) = C$, $t(g) = C$ and $t(h) = A$. The quadruple (V, E, i, t) is an abstract graph. We can try to visualize such an abstract graphs by drawing a point for each vertex and by drawing an arrow for each edge e that points from the initial point $i(e)$ to the endpoint $t(e)$.

(B) Let $a, b \in \mathbb{Z}$. We denote by $G_{a,b} = (V, E, i, t)$ the abstract graph with vertex set $V = \mathbb{Z}$, edge set $E = \mathbb{Z} \times \{0, 1\}$ and where $i(n, 0) = i(n, 1) = n$ and $t(n, 0) = n + a$ and $t(n, 1) = n + b$. We leave it to the reader to draw visualizations of $G_{a,b}$ for different values of a and b.

The above figure already indicates that abstract graphs give rise to topological space. The following definition is already somewhat topology-like.

Definition. We say that an abstract graph (V, E, i, t) is connected if for every two vertices $v \neq w \in V$ there exist vertices $v = v_0, v_1, \ldots, v_n = w$ and edges $e_0, \ldots, e_{n-1}$ such that for each $i \in \{0, \ldots, n-1\}$ the endpoints of e_i are v_i and v_{i+1}.

Examples. We want to determine whether or not the above examples (A) and (B) of abstract graphs are connected.

(A) This abstract graph is connected, for example if we take $v = A$ and $w = C$, then $v_0 = A$, $v_1 = B$ and $v_2 = C$ and $e_0 = e$ and $e_1 = f$ have the desired property.

(B) Let $a, b \in \mathbb{Z}$. Basically by definition the abstract graph $G_{a,b}$ is connected if and only if for every two integers $x, y \in \mathbb{Z}$ there exist $n, m \in \mathbb{Z}$ such that $x - y = ma + nb$. Elementary number theory says that this is the case if and only if a and b are coprime.

Definition.

(1) Let $G = (V, E, i\colon E \to V, t\colon E \to V)$ and $G' = (V', E', i'\colon E' \to V', t'\colon E' \to V')$ be two abstract graphs in the sense of the definition on page 307. We define a morphism $G \to G'$ of abstract graphs to be a pair $(\alpha\colon V \to V', \beta\colon E \to E')$ of maps such that for each $e \in E$ we have $i'(\beta(e)) = \alpha(i(e))$ and $t'(\beta(e)) = \alpha(t(e))$.

(2) We refer to the category $\mathcal{AbsGraph}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{AbsGraph}) &:= \text{all abstract graphs,} \\ \mathrm{Mor}(G, G') &:= \text{all maps from } G \text{ to } G' \text{ in the above sense} \end{aligned}$$

with the usual composition of maps as the category of abstract graphs.

Example. The maps

$$\begin{aligned} (V, E, i\colon E \to V, t\colon E \to V) &\mapsto (V, E, t\colon E \to V, i\colon E \to V) \\ (f\colon G \to G') &\mapsto (f\colon G \to G') \end{aligned}$$

defines a covariant functor from the category $\mathcal{AbsGraph}$ to itself. The effect on each abstract graph is that it swaps the roles of the initial points and the endpoints. Pictorially speaking the functor "inverts the orientations of the arrows".

Surely the reader is bothered by the absence of topology. We will change this sorry state of affairs by introducing the topological realization of a graph. The idea is, basically, that the topological realization of an abstract graph $G = (V, E, i, t)$ is given by one point for each vertex $v \in V$ and one interval for each edge $e \in E$ with endpoints given by $i(e)$ and $t(e)$. The definition below is the formalization of that idea.

Definition. Let $G = (V, E, i, t)$ be an abstract graph.

(1) We define the topological realization of G as the topological space

$$|G| := \big(V \sqcup (E \times [0,1])\big)/\!\sim \quad \text{where for any } e \in E \text{ we have } (e,0) \sim i(e) \text{ and } (e,1) \sim t(e).$$

$\uparrow$ here E is equipped with the *discrete* topology

Note that on many occasions we will use implicitly that by Exercise 5.4 we know that $[0,1] \times E = \coprod_{e \in E} [0,1]$.

(2) Given $e \in E$ we refer to the map $\Phi_e\colon [0,1] \xrightarrow{x \mapsto (e,x)} \{e\} \times [0,1] \to |G|$ as the characteristic map of the edge e.

(3) Let $e \in E$. By a slight abuse of language we refer to $|e| = \Phi_e([0,1])$ also as an edge of $|G|$. Furthermore we refer to $\langle e \rangle := \Phi_e((0,1))$ as an open edge of $|G|$.

Before we attempt to give a better intuition for the definition of the topological realization we need to get the following lemma out of the way.

Lemma 7.1. (Abstract Graph-Topological Realization Lemma) Let $G = (V, E, i, t)$ be an abstract graph.

(1) The obvious map $V \to |G|$ is an inclusion and the image is a discrete subset of $|G|$.
(2) $|G|$ is Hausdorff.
(3) Let $e \in E$.
   (a) The map $\Phi_e \colon [0,1] \to |G|$ is continuous and closed.
   (b) The map $\Phi_e \colon (0,1) \to |G|$ is an open embedding.
   (c) If $i(e) = t(e)$, then Φ_e induces a homeomorphism $[0,1]/0 \sim 1 \to |e|$.
   (d) If $i(e) \neq t(e)$, then Φ_e restricts to a homeomorphism $[0,1] \to |e|$.

   The same statements (a), (b), (c) and (d) also hold for the map $\widetilde{\Phi}_e \colon [0,1] \to |G|$ given by $t \mapsto \Phi_e(1-t)$. This map satisfies $\widetilde{\Phi}_e(0) = t(e)$ and $\widetilde{\Phi}_e(1) = i(e)$. For convenience we sometimes refer to $\widetilde{\Phi}_e$ also as a *characteristic map of the edge* e.
(4) G is finite if and only if $|G|$ is compact.
(5) The following statements are equivalent:
   (a) G is connected,
   (b) given any two distinct vertices v, v' there exists an embedding $\gamma \colon [0,1] \to |G|$ with $\gamma(0) = v$, $\gamma(1) = v'$ and such that $\gamma([0,1]) \subset |G|$ is the union of edges,
   (c) the topological realization $|G|$ is path-connected,
   (d) the topological realization $|G|$ is connected.

Proof.

(1) This statement follows fairly easily from the definitions of the quotient topology and the disjoint union topology. We leave it to the reader to fill in the details.
(2) Ditto.
(3) Let $e \in E$.
   (a) It follows immediately from Lemma 5.12 (2) and the Topological-Quotient Proposition 5.15 (1a) that Φ_e is continuous. Furthermore it follows easily from the definitions together with Lemma 5.12 and the Topological-Quotient Proposition 5.15 (1a) that Φ_e is closed.
   (b) One can easily verify that $\Phi_e \colon (0,1) \to |G|$ is injective and that it is an open map. Thus it follows from the Open -Injective Map Lemma 2.16 that it is an embedding.
   (c) We suppose that $i(e) = t(e)$. It follows easily from the Twice Quotient Lemma 5.23 that Φ_e induces a continuous map $[0,1]/0 \sim 1 \to |e|$ and that this map is a bijection. It follows from (2) and the Compact-Hausdorff Proposition 2.17 (3) that the map $\Phi_e \colon [0,1]/0 \sim 1 \to |e|$ is in fact a homeomorphism.
   (d) Now we suppose that $i(e) \neq t(e)$. In this case the map is clearly injective. Thus it follows from (2) together with the Compact-Hausdorff Proposition 2.17 (3) that $\Phi_e \colon [0,1] \to |e|$ is a homeomorphism.

   The statements regarding $\widetilde{\Phi}_e$ follow from the fact that the map $t \mapsto 1-t$ is a homeomorphism of $[0,1]$.

(4) First assume that G is finite. First note that it follows almost immediately from the Disjoint Union Topology-Properties Lemma 5.13 (2) together with the Compact Image Lemma 2.13 that $|G|$ is compact. Conversely, in Exercise 7.5 we will show that any compact subset of the topological realization of a graph is contained in the topological realization of a finite graph contained in G. This statement immediately implies that if $|G|$ is finite, then G is finite.

(5) We will prove this statement in Exercise 7.4. ■

The following lemma makes the unsurprising assertion that the above assignment of a topological space to an abstract simplicial complex is functorial.

Lemma 7.2. The following two statements hold:

(1) Let $G = (V, E, i, t)$ and $G' = (V', E', i', t')$ be two abstract graphs. Furthermore let $f := (\alpha\colon V \to V', \beta\colon E \to E')$ be a map between the two abstract graphs. Recall that, by the definition on page 308, this means that for each $e \in E$ we have the equalities $i'(\beta(e)) = \alpha(i(e))$ and $t'(\beta(e)) = \alpha(t(e))$. Now we consider the following map between the topological realizations of G and G':

$$\begin{array}{rcl} & \text{where } (e,0)\sim i(e) \text{ and } (e,1)\sim t(e) & \text{similarly } (e,0)\sim i'(e) \text{ and } (e,1)\sim t'(e) \\ |f|\colon |G| = \big(V \sqcup (E\times[0,1])\big)\big/\overset{\downarrow}{\sim} & \to & |G'| = \big(V' \sqcup (E'\times[0,1])\big)\big/\overset{\downarrow}{\sim} \\ [x] & \mapsto & \begin{cases} \alpha(x), & \text{if } x \in V, \\ (\beta(e), t), & \text{if } x = (e,t) \in E\times[0,1]. \end{cases} \end{array}$$

This map $|f|\colon |G| \to |G'|$ is well-defined and continuous.

(2) The map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{AbsGraph}) & \to & \mathrm{Ob}(\mathcal{Top}) \\ G & \mapsto & |G|, \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{AbsGraph}}(G, G') & \to & \mathrm{Mor}_{\mathcal{Top}}(|G|, |G'|) \\ f & \mapsto & |f| \end{array}$$

is a covariant functor from the category $\mathcal{AbsGraph}$ of abstract graphs to the category $\mathcal{Top}$ of topological spaces.

Proof.

(1) It follows almost immediately from the definitions that the map is well-defined. We leave it to the reader to verify, e.g. using the Twice Quotient Lemma 5.23, that the map is continuous.

(2) This statement follows easily from the definitions. ■

Even though the above definition of the topological realization of an abstract graph is a perfectly fine, rigorous and precise definition, it is perhaps not the most intuitive definition. It would be much more fun to work with topological spaces that we can "see". This leads us to the following definition.

Definition. A topological graph is a triple $(X, G = (V, E, i, t), \Theta\colon |G| \to X)$ where the following holds:

(1) X is a topological space,

(2) $G = (V, E, i, t)$ is an abstract graph,

(3) $\Theta\colon |G| \to X$ is a homeomorphism between the topological realization $|G|$ of G and the topological space X.

Given a topological graph $(X, G = (V, E, i, t), \Theta\colon |G| \to X)$ we introduce the following extra definitions:

(1) Given $v \in V$ we refer to $\Theta(v)$ as a vertex of the topological graph.
(2) Given $e \in E$ we refer to $\Theta(|e|)$ as an edge of the topological graph. Given a loop e we refer to $|e|$ as a loop of the topological graph.
(3) We refer to the abstract graph $G = (V, E, i, t)$ as the underlying abstract graph.
(4) Sometimes we refer, somewhat incorrectly, to X as a topological realization of G.

Sometimes we will just say that X is a topological graph. Furthermore on occasions we will suppress $G = (V, E, i, t)$ and $\Theta\colon |G| \to X$ from the notation.

The following lemma gives us a way to construct topological graphs with a given underlying abstract graph.

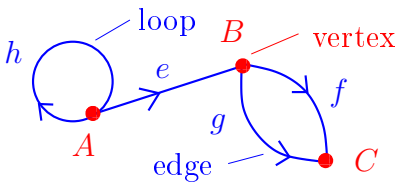
Lemma 7.3. Let $G = (V, E, i, t)$ be an abstract graph and let $n \in \mathbb{N}_0$. Suppose we are given the following data:

(1) An injective map $\alpha\colon V \to \mathbb{R}^n$.
(2) For each $e \in E$ we are given a map $\beta_e\colon [0,1] \to \mathbb{R}^n$ which is injective on $(0,1)$ and which satisfies $\beta_e(0) = \alpha(i(e))$ and $\beta_e(1) = \alpha(t(e))$.
(3) For $e \neq f \in E$ we have $\beta_e((0,1)) \cap \beta_f((0,1)) = \varnothing$.

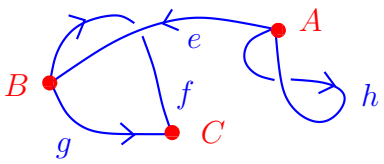
If G is infinite, then we also demand that the following condition is satisfied:

(4) For every $r \in \mathbb{R}_{\geq 0}$ there exist only finitely many $v \in V$ with $\alpha(v) \cap B_r^n(0) \neq \varnothing$ and there exist only finitely many $e \in E$ with $\beta_e([0,1]) \cap B_r^n(0) \neq \varnothing$.

Then the following map is a closed embedding:

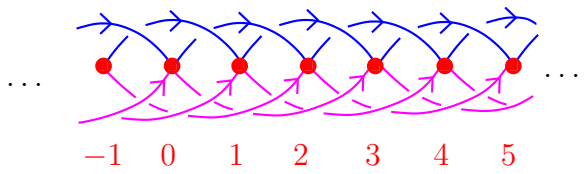


$$\begin{array}{rcl} |G| = \big(V \sqcup (E \times [0,1])\big)/\overset{\downarrow}{\sim} & \to & \mathbb{R}^n \\ & & \text{where } (e,0) \sim i(e) \text{ and } (e,1) \sim t(e) \\ [x] & \mapsto & \begin{cases} \alpha(x), & \text{if } x \in V, \\ \beta_e(t), & \text{if } x = (e,t) \in E \times [0,1]. \end{cases} \end{array}$$



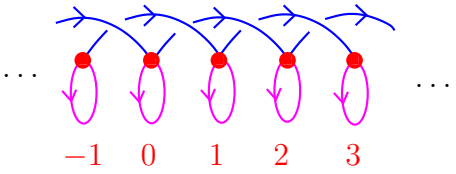
Proof. It follows easily from our hypotheses that the map is well-defined and that it is an injection. Furthermore we obtain from the Topological-Quotient Proposition 5.15 (1b) that the map is continuous. If G is finite, then it follows from the Abstract Graph-Topological Realization Lemma 7.1 together with the Compact-Hausdorff Proposition 2.17 (3) that the given map $|G| \to \mathbb{R}^n$ is an embedding. In the general case the same conclusion follows from the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19. ■

Examples. We return to the two examples of abstract graphs that we gave on page 307.



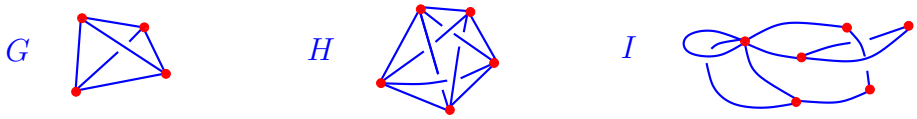
(A) As on page 307 we consider $V = \{A, B, C\}$ and $E = \{e, f, g, h\}$ together with the maps $i, t\colon E \to V$ given by $i(e) = A$, $i(f) = B$, $i(g) = B$ and $i(h) = A$ and given by $t(e) = B$, $t(f) = C$, $t(g) = C$ and $t(h) = A$. In the figure below we show two topological realizations[102] of this abstract graph.

[102] Here evidently we use the slightly sloppy language from above. More precisely, we do not show the actual topological realization $|G|$ but we show a topological graph X such that the underlying abstract graph equals G.



(B) Let $a, b \in \mathbb{Z}$. As on page 307 we consider the abstract graph with vertex set $V = \mathbb{Z}$, edge set $\mathbb{Z} \times \{0, 1\}$ and where $i(n, 0) = i(n, 1) = n$ and $t(n, 0) = n + a$ and $t(n, 1) = b$. In the figure below we show topological realizations of the graphs $G_{2,3}$ and $G_{0,2}$.

topological realization of $G_{2,3}$



topological realization of $G_{0,2}$

In Exercise 7.9 we will see that given any finite abstract graph G there exists an embedding of $|G|$ into $\mathbb{R}^3$. (Alternatively see [**CELR1994**, p. 2] or [**Mun1975**, p. 309] for a proof of this fact). We conclude this section with the following question.

Question 7.4. Let G be a finite abstract graph. Does there necessarily exist an embedding of $|G|$ into $\mathbb{R}^2$?

Example. We consider the finite abstract graphs G, H and I that are (implicitly) illustrated in the figure below. Do their topological realizations admit embeddings into $\mathbb{R}^2$?

Surely the answer to Question 7.4 must be no, but it is not clear how one can prove this statement rigorously. We will return to this question in Section 88.3.

7.2. **Undirected abstract graphs and their topological realizations .** In this section we will introduce the notion of an undirected abstract graph and the corresponding topological realizations. In many settings undirected abstract graphs are more suitable than the abstract graphs from the previous section. But as we will see, the topological realization of an undirected abstract graph is more unwieldy. Thus in these notes we will mostly work with abstract graphs and we will leave it to the reader to generalize some of the later results to the setting of undirected abstract graphs.

Without further ado, here is the definition.

Definition. An undirected abstract graph G is a triple (V, E, φ) where V is a set, E is a set and φ is a map

$$\varphi\colon E \to \{\text{subsets of } V \text{ with one or two elements}\}.$$

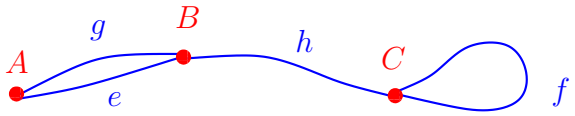
Similar to the discussion on page 307 we introduce the following extra definitions:

(1) The elements of V are called the vertices of G and the elements of E are called the edges of G.
(2) We say an edge $e \in E$ is a loop if $\#\varphi(e) = 1$. Otherwise we call e a non-loop.
(3) Given $e \in E$ the points in $\varphi(e)$ are called the endpoints of e.
(4) We say G has multi-edges if there exist distinct edges e and e' with $\varphi(e) = \varphi(e')$.
(5) We say G is finite (countable) if both V and E are finite (countable).

Example. We take V to be the set of all subway stations in München and we take E to be the set of all segments of the subway system. The map φ then assigns to each $e \in E$ the two stations that are connected by the segment e. The triple (V, E, φ) is an undirected abstract graph.

The following definition is the analogue of the definition on page 308.

Definition.



(1) Let $G = (V, E, \varphi\colon E \to \mathcal{P}(V))$ and $G' = (V', E', \varphi'\colon E' \to \mathcal{P}(V'))$ be two undirected abstract graphs. We define a morphism $G \to G'$ between the two undirected abstract graphs to be a pair $(\alpha\colon V \to V', \beta\colon E \to E')$ of maps such that for every $e \in E$ we have the equality $\varphi'(\beta(e)) = \alpha(\varphi(e))$.
(2) We refer to the category $\mathcal{UndirAbsGraph}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{UndirAbsGraph}) &:= \text{all undirected abstract graphs,} \\ \mathrm{Mor}(G, G') &:= \text{all maps from } G \text{ to } G' \text{ in the above sense} \end{aligned}$$

with the hopefully obvious composition of maps as the category of undirected abstract graphs.

Example.

(1) Let $V = \{A, B, C\}$, $E = \{e, f, g, h\}$ and $\varphi(e) = \{A, B\}$ and let $\varphi\colon E \to \mathcal{P}(V)$ be the map that is given by $\varphi(f) = \{C\}$, and $\varphi(g) = \{A, B\}$ and $\varphi(h) = \{B, C\}$. This defines an undirected abstract graph with loop f and multi-edges. As before we can visualize such an undirected abstract graph by drawing points for the vertices and by either drawing a segment that either connects the two endpoints of an edge or by drawing a loop if the edge has a single endpoint.

(2) Let $\mathcal{AbsGraph}$ be the category of abstract graphs and let $\mathcal{UndirAbsGraph}$ be the category of undirected abstract graphs. It follows easily from the definitions that the map

$$\begin{aligned} F\colon \mathrm{Ob}(\mathcal{AbsGraph}) &\to \mathrm{Ob}(\mathcal{UndirAbsGraph}) \\ (V, E, i\colon E \to V, t\colon E \to V) &\mapsto \begin{pmatrix} V, E, & E & \to & \mathcal{P}(V) \\ & e & \mapsto & \{i(e), t(e)\} \end{pmatrix} \end{aligned}$$

together with the hopefully obvious maps from the morphisms in *AbsGraph* to the morphisms in *UndirAbsGraph* is a covariant functor from the category *AbsGraph* of abstract graphs to the category *UndirAbsGraph* of undirected abstract graphs.[103]

Now comes the slightly intimidating definition of the topological realization of an undirected abstract graph.

Definition. Let $G = (V, E, \varphi)$ be an undirected abstract graph. We define the topological realization of G as the topological space[104]

$$|G| \;:=\; \Big(V \;\sqcup \bigsqcup_{\substack{e\,\in\,E\\ \#\varphi(e)\,=\,1}} [0,1] \;\sqcup \bigsqcup_{\substack{e\,\in\,E\\ \#\varphi(e)\,=\,2}} [0,1]\times \mathrm{Bij}(\{0,1\},\varphi(e))\Big)\Big/\!\sim$$

where $\sim$ is generated by the following two relations:

(1) For each $e \in E$ with $\#\varphi(e) = 1$ we identify 0 and 1 in the corresponding copy of $[0,1]$ with the unique point $\varphi(e) \in V$.

(2) For each $e \in E$ with $\#\varphi(e) = 2$ we make the following identifications:
   (a) For each $\gamma \in \mathrm{Bij}(\{0,1\}, \varphi(e))$ we set $(0,\gamma) \sim \gamma(0)$ and $(1,\gamma) \sim \gamma(1)$.
   (b) For $\alpha \neq \beta \in \mathrm{Bij}(\{0,1\}, \varphi(e))$ and each $t \in [0,1]$ we set $(t,\alpha) \sim (1-t,\beta)$.

Example. Using a variation on Lemma 7.3, or alternatively using Lemma 7.5 below one can see that the subset of $\mathbb{R}^2$ shown in the figure below is a topological realization of the subway system of München.

Lemma 7.5. Let $G = (V, E, i, t)$ be an abstract graph. As above we consider the undirected abstract graph $\widetilde{G} = (V, E, \varphi)$ where $\varphi\colon E \to \mathcal{P}(V)$ is the map that is given by

[103] It follows from the Axiom of Choice 0.1 that given any undirected abstract graph G there exists an abstract graph G' with $F(G') = G$.

[104] Let $e \in E$ be a vertex with $\#\varphi(e) = 2$. Note that in this case $\mathrm{Bij}(\{0,1\}, \varphi(e))$ has precisely two elements. The problem is that there is no "preferred" bijection, so we need to consider both in our definition.

$\varphi(e) = \{i(e), t(e)\}$. The map

$$\begin{aligned} \Theta_G\colon |G| &\to |\widetilde{G}| \\ [x] &\mapsto \begin{cases} [x], & \text{if } x \in V, \\ [t \in [0,1]_e], & \text{if } x = (e,t) \in E \times [0,1] \text{ with } i(e) = t(e), \\ [(t,\gamma)], & \text{if } x = (e,t) \in E \times [0,1] \text{ with } i(e) \neq t(e), \text{ where } \gamma \text{ is} \\ & \text{given by } \gamma(0) = i(e),\ \gamma(1) = t(e) \end{cases} \end{aligned}$$

is a homeomorphism.

Proof. It follows fairly easily from the definitions that the map is well-defined and a bijection. Furthermore one can deduce easily from the Twice Quotient Lemma 5.23 that the map is continuous. Working directly with the definitions one sees that the map is open. In summary it follows from the Open -Injective Map Lemma 2.16 that the map is indeed a homeomorphism. ■

Remark. Perhaps by now it has become clear why the definition of the topological realization of an *undirected* abstract graph is more painful than the definition of the topological realization of an abstract graph. In both cases we want to attach one interval for each edge. If we are given maps $i, t\colon E \to V$, then we have a preferred way of doing so. If we are only given a map $\varphi\colon E \to \mathcal{P}(V)$ none of the two ways is preferred, thus we need to attach an interval in both ways and then we need to "anti-identify" the two intervals.

The following definition is almost verbatim the same as the definition of a connected abstract graph that we provided on page 307.

Definition. We say that an undirected abstract graph (V, E, φ) is connected if for every two vertices $v \neq w \in V$ there exist vertices $v = v_0, v_1, \ldots, v_n = w$ and edges $e_0, \ldots, e_{n-1}$ such that for each $i \in \{0, \ldots, n-1\}$ the endpoints of e_i are v_i and v_{i+1}.

The following totally elementary lemma can be viewed as an analogue of the Connected-to-Discrete Lemma 2.27.

Lemma 7.6. Let $G = (V, E, i, t)$ be an abstract graph or let $G = (V, E, \varphi)$ be an undirected abstract graph. Let $f\colon V \to X$ be a map to some set X such that for any $e \in E$ the values of f on the endpoints of e agree. If G is connected, then f is constant.

Proof. This lemma follows almost immediately from the definitions. ■

7.3. **Trees.** In this last section we study a basic but surprisingly useful class of abstract graphs.

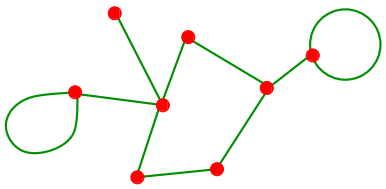
Definition. Let $G = (V, E, i, t)$ be an abstract graph or let (G, V, φ) be an undirected abstract graph.

(1) If G is finite, then we refer to

$$\chi(G) \;=\; \#V - \#E \;=\; \text{number of vertices} - \text{number of edges}$$

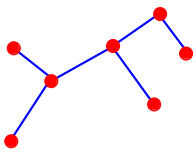
as the Euler characteristic of G.

(2) A tree is a finite connected abstract graph with Euler characteristic 1.



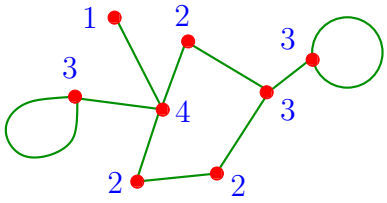
(3) (a) If $G = (V, E, i, t)$ is an abstract graph, then the valence of a vertex v is defined as

$$\text{valence}(v) \;:=\; \#\{e \in E \,|\, i(e) = v\} + \#\{e \in E \,|\, t(e) = v\}.$$



(b) If $G = (V, E, \varphi)$ is an undirected abstract graph, then the valence of a vertex v is defined as

$$\begin{aligned}\text{valence}(v) \quad := \quad & \#\{e \in E \,|\, v \in \varphi(e) \text{ and } \#\varphi(e) = 2\} \\ & +2 \cdot \#\{e \in E \,|\, v \in \varphi(e) \text{ and } \#\varphi(e) = 1\}.\end{aligned}$$



In a slightly less formal way, the valence of a vertex v is the number of edges at v, but hereby we have to count any loop at v twice, since it "goes twice into v".

Euler characteristic of G equals $\chi(G) = 8 - 10 = -2$

example of a tree

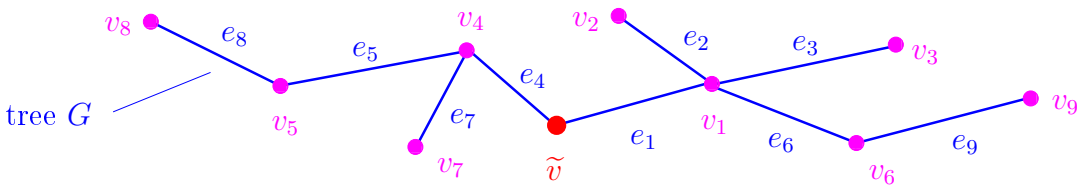
valences of the vertices

Lemma 7.7. Let $G = (V, E, i, t)$ be an abstract graph or let $G = (V, E, \varphi)$ be an undirected abstract graph. If G is a tree and if G has at least one edge, then G admits at least two vertices of valence one.

Proof. We prove Lemma 7.7 for abstract graphs, the proof for undirected abstract graphs is verbatim the same. Thus let $G = (V, E, i, t)$ be a tree that has at least one edge. Since G has at least one edge and since it is by definition connected, we see that the tree G does not have a vertex of valence 0. We calculate that

$$\begin{aligned}\sum_{\text{vertex } v} \underbrace{\text{valence}(v)}_{\geq 1} \quad &= \quad \sum_{\text{vertex } v} (\#\{e \in E \,|\, i(e) = v\} + \#\{e \in E \,|\, t(e) = v\}) \\ &= \quad 2 \cdot \#\text{ edges} \quad = \quad 2 \cdot \#\text{vertices} - 2.\end{aligned}$$

each edge contributes 2 to the sum — since $\chi(T) = 1$



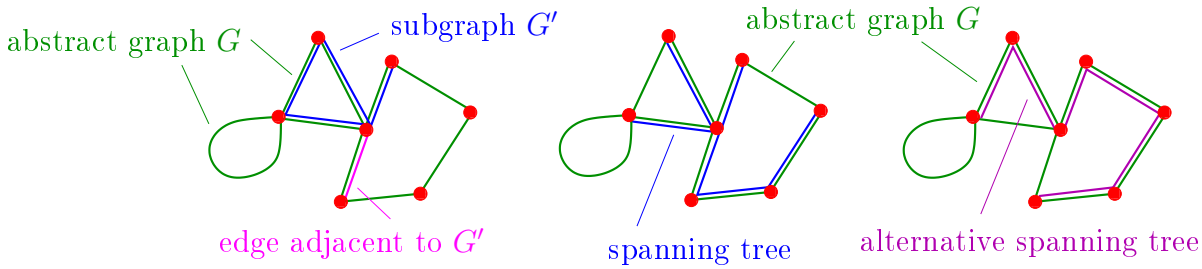
Recall that we just observed that the valence of each vertex is at least one. Thus the above equality can only hold if there are at least two vertices with valence one. ∎

On one occasion the following lemma will come in handy.

Lemma 7.8. Let $G = (V, E, i, t)$ be an abstract graph and let $\widetilde{v} \in V$ be a vertex. If G is a tree, then there exist distinct edges $e_1, \ldots, e_k$ and distinct vertices $v_1, \ldots, v_k$ with the following properties:

(1) We have $V = \{\widetilde{v}, v_1, \ldots, v_k\}$ and $E = \{e_1, \ldots, e_k\}$.
(2) For each $i \in \{1, \ldots, k\}$ the vertex v_i is an endpoint of the edge e_i.
(3) If some vertex v_i is an endpoint of some e_j, then $i \leq j$.

The same statement also holds for undirected abstract graphs.



Proof. For abstract graphs we will provide the proof of the corollary in Exercise 7.7. For undirected abstract graphs the proof is verbatim the same. ■

Now we provide a few more definitions on (undirected) abstract graphs.

Definition. Let $G = (V, E, i, t)$ be an abstract graph.

(1) A subgraph of $G = (V, E, i, t)$ is an abstract graph $G' = (V', E', i', t')$ such that $V' \subset V$ and $E' \subset E$ are subsets such that $i' = i|_{E'}$ and $t' = t|_{E'}$. If G' is a tree, then we refer to G' as a subtree. Since i' and t' are determined by V' and E' we often suppress both of them from the notation.
(2) We say an edge $e \in E$ is adjacent to a subgraph G' if e has two endpoints where one of the endpoints lies on G' and the other does not.
(3) A spanning tree for G is a subgraph that is a tree and which does not admit an adjacent edge.

For undirected abstract graphs we introduce the obvious analogues of the above notions.

Remark. Let $G = (V, E, i, t)$ be an abstract graph.

(1) Every $v \in V$ gives rise to the rather trivial subgraph with a single vertex v and no edge.
(2) If an edge e of E is adjacent to some subgraph G', then it is not part of the subgraph. Indeed, by definition of a subgraph, for any edge that is part of the subgraph also its endpoints have to lie in the subgraph.
(3) The example of the figure above shows that an abstract graph usually has many different spanning trees.
(4) A spanning tree is often also called a *maximal tree*.

The following lemma summarizes a few basic properties of subgraphs.

Lemma 7.9. Let $G = (V, E, i, t)$ be an abstract graph and let $G' = (V', E', i', t')$ be a subgraph.

(1) The inclusions $V' \to V$ and $E' \to E$ define a map $\iota\colon G' \to G$ of abstract graphs in the sense of the definition on page 308.
(2) The induced map $|\iota|\colon |G'| \to |G|$ between the topological realization is a closed embedding.

In the following we will sometimes use (2) to view $|G'|$ as a closed subset of $|G|$.

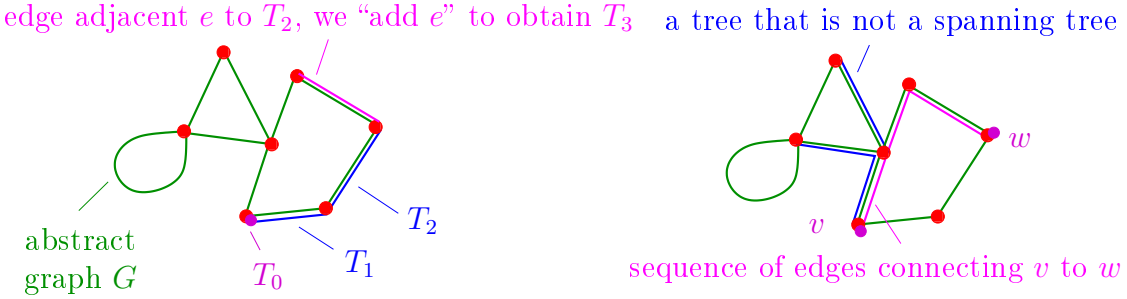
Proof.

(1) This statement follows immediately from the definitions.
(2) By the discussion on page 310 we know that the map $|\iota|$ is continuous. By the Open -Injective Map Lemma 2.16 it remains to show that $|\iota|$ is a closed map. We leave it to

the reader to show, using Lemma 5.12 and the Topological-Quotient Proposition 5.15 (1a), that $|\iota|$ is closed. ■

We conclude this section with the following proposition.

Proposition 7.10. (Spanning Tree Existence Proposition) Let $G = (V, E, i, t)$ be a finite connected non-empty abstract graph.

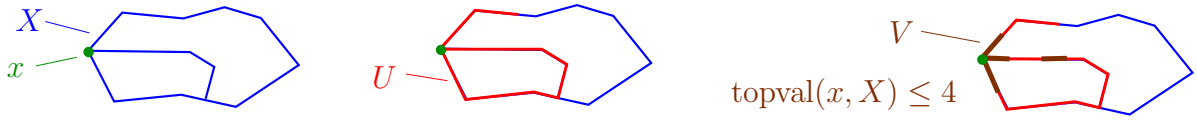


(1) The graph G admits a spanning tree.
(2) Every spanning tree of G contains all vertices of G.

The same statement also holds for undirected abstract graphs.

Remark. On page 1520 we will generalize the notion of a (spanning) tree to infinite abstract graphs and in the Spanning Tree Existence Proposition 69.7 we will prove a generalization of the Spanning Tree Existence Proposition 7.10 to infinite abstract graphs.

Proof. In the following we provide the proof for abstract graphs. The proof for undirected abstract graphs is verbatim the same. Thus let $G = (V, E, i, t)$ be a finite connected abstract graph.



(1) We pick a vertex $v \in V$. We define $T_0 = \{v\}$ and view T_0 as a subtree of G. Now we construct iteratively a sequence of subtrees $T_0 \subset T_1 \subset \dots$ as follows: Suppose we have a subtree $T_i = (V_i, E_i)$. If there exists an edge $e \in E$ that is adjacent to T_i, then we "add e to T_i", more precisely, we define $T_{i+1} = (V_i \cup \varphi(e), E_i \cup e)$. Note that by definition of an adjacent edge we just added precisely one edge and precisely one vertex to T_i. Thus we see that $\chi(T_{i+1}) = \chi(T_i) = \dots = \chi(T_0) = 1$, i.e. T_{i+1} is indeed a subtree. Since G is finite this process stops after finitely many steps. Let T be the final subtree of our sequence. Note that by definition T is in fact a spanning tree. This argument is illustrated in the figure below on the left.
(2) Let T be a subgraph of G that is a tree. Suppose that there exists a vertex w that does not lie in T. We will show that T is not a spanning tree. Let v be a vertex in T. Since G is connected there exists a sequence of edges $e_0, \dots, e_n$ with the following properties:
   (a) v is a vertex of e_0,
   (b) for each $i \in \{0, \dots, n-1\}$ a vertex of e_i is also a vertex of e_{i+1}, and
   (c) w is a vertex of e_n.
   Then there exists an $i \in \{0, \dots, n-1\}$ such that a vertex of e_i lies in T and the other one does not. But then e_i is an edge adjacent to T. This shows that T was not a spanning tree. This argument is illustrated in the figure below on the right. ■

7.4. **Topological valence.** On page 315 we introduced the valence of a vertex in an (undirected) abstract graph. In this section we introduce an analogue for points of topological spaces.

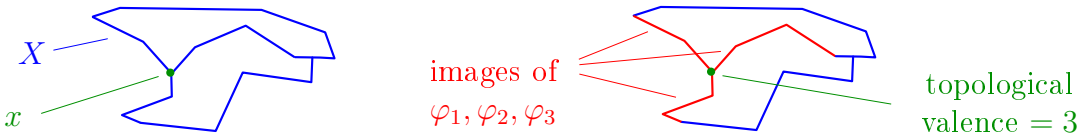
Definition. Let X be a topological space and let $x \in X$. We define the topological valence of x as

$$\operatorname{topval}(x, X) := \min \left\{ n \in \mathbb{N} \cup \{\infty\} \;\middle|\; \begin{array}{c} \text{for every open neighborhood } U \text{ of } x \text{ there} \\ \text{exists an open neighborhood } V \text{ of } x \text{ with } V \subset U \\ \text{such that } V \setminus \{x\} \text{ has at least } n \text{ components} \end{array} \right\}.$$

The following lemma summarizes a few basic properties about the topological valence of points.

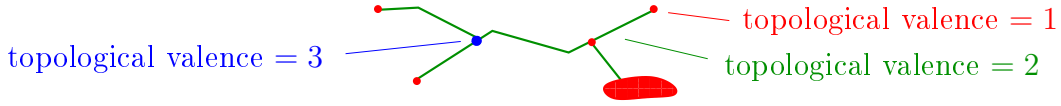
Lemma 7.11. Let X be a topological space and let $x \in X$.

(1) For every neighborhood W of x we have $\operatorname{topval}(x, W) = \operatorname{topval}(x, X)$.
(2) For every homeomorphism $f\colon X \to Y$ we have $\operatorname{topval}(x, X) = \operatorname{topval}(f(x), f(X))$.



Proof. The lemma follows immediately from the definitions. ∎

The following proposition allows for the calculation of the valence in many interesting settings.



Proposition 7.12. (Topological Valence Determination Proposition) Let X be a Hausdorff space and let $x \in X$ be a point. We now suppose that there exist embeddings $\varphi_1, \ldots, \varphi_n\colon [0,1] \to X$ with the following properties:

(a) $\varphi_1(0) = \cdots = \varphi_n(0) = x$,
(b) the images $\varphi_i((0,1])$, $i = 1, \ldots, n$ are pairwise disjoint,
(c) $\varphi_1([0,1]) \cup \cdots \cup \varphi_n([0,1])$ is a neighborhood of x.

Then $\operatorname{topval}(X, x) = n$.

Example. Let I be an interval that consists of more than one point. It follows easily from the Topological Valence Determination Proposition 7.12 that the points in the interior of I have topological valence 2 and that the endpoints of I, if they are included, have topological valence 1. This observation implies for example that the half-open interval $[0,1)$ and the open interval $(0,1)$ are not homeomorphic. This gives in particular a solution to Exercise 2.40.

Proof. We start out with the following claim.

Claim. There exists a $\lambda \in (0,1]$ such that for every $\epsilon \in (0,\lambda]$ the following holds:
(1) For each $i \in \{1,\dots,n\}$ the set $\varphi_i((0,\epsilon))$ is open in X.
(2) For each $i \in \{1,\dots,n\}$ the set $\varphi_i((0,\epsilon))$ is closed in $\varphi_1((0,\epsilon)) \cup \dots \cup \varphi_n((0,\epsilon))$.
(3) $\varphi_1([0,\epsilon)) \cup \dots \cup \varphi_n([0,\epsilon))$ is an open neighborhood of x.

Proof. Note that by Hypothesis (c) we know that there exists an open neighborhood W of x that is contained $\varphi_1([0,1]) \cup \dots \cup \varphi_n([0,1])$. By looking at the preimages of W under the maps $\varphi_1,\dots,\varphi_n$ we see that there exists a $\lambda \in (0,1]$ such that $\varphi_1([0,\lambda]),\dots,\varphi_n([0,\lambda])$ are contained in W. Now let $\epsilon \in (0,\lambda]$.

(1) Note that

$$\varphi_i((0,\epsilon)) \;=\; W \cap \Big(X \setminus \Big(\underbrace{\varphi_i([\epsilon,1]) \cup \bigcup_{j\neq i} \varphi_j([0,1])}_{\text{compact by the Compact Image Lemma 2.13, since } X \text{ is Hausdorff we obtain from the Compact-Closed Lemma 1.21 (2), that the set is closed}} \Big)\Big).$$

choice of x and Hypothesis (b)

Thus we see that $\varphi_i((0,\epsilon))$ is an open subset of X.
(2) This statement follows immediately from (1).
(3) Almost the same argument as in (1) also implies (3). ⊞

We now turn to the actual proof that $\operatorname{topval}(x,x) = n$. First we want to show that $\operatorname{topval}(X,x) \leq n$. Thus let U be a neighborhood of x. There exists a $\mu \in (0,\epsilon)$ such that for each $i \in \{1,\dots,n\}$ we have $\varphi_i((0,\mu)) \subset U$. By the above claim we know that $V := \varphi_1([0,\mu)) \cup \dots \cup \varphi_1([0,\mu))$ is an open neighborhood of X. Next note that $V \setminus \{x\}$ consists of the n open and closed sets $\varphi_1((0,\mu)),\dots,\varphi_n((0,\mu))$. By the Path-Connected Implies Connected Corollary 2.23 we know that each of these sets is connected. Thus we obtain from the Component Lemma 2.33 (4c) that $V \setminus \{x\}$ has precisely n components.

Now let us show that $\operatorname{topval}(X,x) \geq n$. We set $U := \varphi_1((0,\epsilon)),\dots,\varphi_n((0,\epsilon))$. Let V be an open neighborhood of x that is contained in U. For each $i \in \{1,\dots,n\}$ we know that $\varphi_i^{-1}([0,\epsilon]) \cap V$ is open and that it contains 0. This implies that $\varphi_i^{-1}((0,\epsilon]) \cap (V \setminus \{x\})$ is also non-empty. By (2) this set is open and closed in $V \setminus \{x\}$. It follows from the Component Lemma 2.33 (4b) that $V \setminus \{x\}$ has at least n components. ■

The final proposition of this section shows that given an undirected abstract graph the valence of a vertex agrees with the topological valence of the corresponding point on the topological realization.

Proposition 7.13.
(1) Let $G = (V,E,\varphi)$ be an undirected abstract graph. For every vertex $v \in V$ we have

$$\operatorname{valence}(v) \;=\; \operatorname{topval}(v,|G|) \;\in\; \mathbb{N}_0 \cup \{\infty\}.$$

(2) If $f\colon X = |G| \to Y = |H|$ is a homeomorphism between the topological realizations of undirected abstract graphs G and H that sends vertices to vertices, then this homeomorphism preserves valences, viewed as numbers in $\mathbb{N}_0 \cup \{\infty\}$.

Remark. An alternative proof of Proposition 7.13 will be given in Exercises 75.2 and 75.9.

Proof.

(1) If the valence(v) is finite, then the statement follows easily from the Topological Valence Determination Proposition 7.12. We leave it to the reader to modify the argument if valence(v) is infinite.
(2) This statement follows immediately from (1) and Lemma 7.11 (2). ■

7.5. **Quotients of abstract graphs.** We conclude this chapter on graphs with the definition and discussion of quotients of abstract graphs and the corresponding topological realizations.

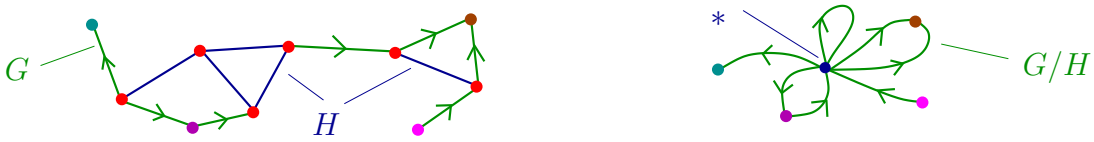
Definition. Let $G = (V, E, i, t)$ be an abstract graph and let $H = (W, F)$ be a non-empty subgraph.

(1) We define $\sim$ to be the equivalence relation generated by $v \sim v'$ if v and v' are both vertices in H. We denote by $*$ the equivalence class defined by the vertices in H.
(2) We denote by $\rho\colon V \to V/\!\sim$ the map given by $v \mapsto [v]$.
(3) Finally we define the abstract graph

$$G/H \;:=\; (V/\!\sim, E \setminus F, \rho \circ i\colon E \setminus F \to V/\!\sim, \rho \circ t\colon E \setminus F \to V/\!\sim).$$

We refer to G/H as the quotient of the abstract graph G by the abstract graph H.

The following lemma summarizes a few properties of the abstract graph G/H.



Lemma 7.14. (Quotient Abstract Graph Lemma) Let $G = (V, E, i, t)$ be an abstract graph and let $H = (W, F)$ be a non-empty subgraph. We continue with the above notation.

(1) We have $\chi(G/H) = \chi(G) - \chi(H) + 1$.
(2) We consider the map

$$p\colon |G| = (V \sqcup (E \times [0,1]))/\overset{\text{where } (e,0)\sim i(e) \text{ and } (e,1)\sim t(e)}{\sim} \to |G/H| = (V/\!\sim \sqcup ((E \setminus F) \times [0,1]))/\overset{\text{similarly } (e,0)\sim \rho(i(e)) \text{ and } (e,1)\sim \rho(t(e))}{\sim}$$

$$[x] \mapsto \begin{cases} [*], & \text{if } x \in |H|, \\ [\rho(x)], & \text{if } x \in V, \\ [(e,t)], & \text{if } x = (e,t) \text{ with } e \in E \setminus F \text{ and } t \in [0,1]. \end{cases}$$

This map has the following two properties:
(a) The map $p\colon |G| \to |G/H|$ is well-defined and continuous.
(b) If the abstract graph G is finite, then the map $p\colon |G| \to |G/H|$ descends to a homeomorphism[105] $|G|/|H| \to |G/H|$.

Proof.

(1) We calculate that

$$\chi(G/H) = \#(V/\!\sim) - \#(E \setminus F) = (\#V - \#W + 1) - (\#E - \#F) = \chi(G) - \chi(H) + 1.$$

[105]Note that it follows from Lemma 7.9 (2) that it is legitimate to view $|H|$ as a subset of $|G|$.

(2) (a) Once one has entangled all the definitions one sees that the map is indeed well-defined and one sees, using the Twice Quotient Lemma 5.23, that the map is indeed continuous.

(b) Since the abstract graph G is finite we know by the Abstract Graph-Topological Realization Lemma 7.1 (4) and the Compact Image Lemma 2.13 that $|G|/|H|$ is compact. Furthermore, by the Abstract Graph-Topological Realization Lemma 7.1 (2) we know that $|G/H|$ is Hausdorff. It is very elementary to show that the induced map $p\colon |G|/|H| \to |G/H|$ is a bijection. Thus we obtain from the Compact-Hausdorff Proposition 2.17 (3) that $p\colon |G|/|H| \to |G/H|$ is a homeomorphism. ■

Exercises for Chapter 7.

Exercise 7.1. We consider the category *AbsGraph* of abstract graphs. Let X, Y be abstract graphs.

(a) Does the product of X and Y exist in the category *AbsGraph*?
(b) Does the coproduct of X and Y exist in the category *AbsGraph*?

Exercise 7.2. In the below we see the seven bridges of Königsberg. Is it possible to cross all seven bridges in a walk without crossing a single bridge twice?

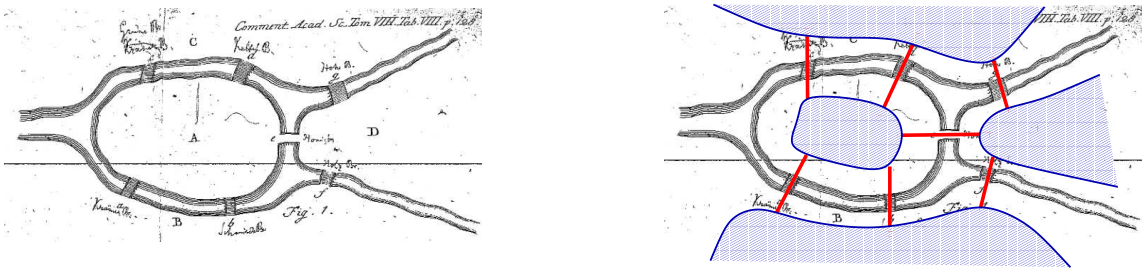


Illustration from Euler's paper [**Eul1736**]

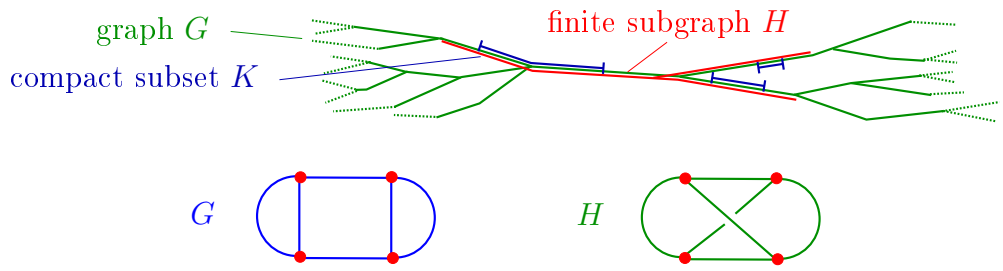


Exercise 7.3. Let $G = (V, E, \varphi)$ and $G' = (V', E', \varphi')$ be two undirected abstract graphs. If the topological realizations $|G|$ and $|G'|$ are homeomorphic, does it follow that the undirected abstract graphs G and G' are isomorphic?

Exercise 7.4. Let G be an abstract graph. Show that the following are equivalent:

(a) G is connected,
(b) given any two distinct vertices v, v' there exists an embedding $\gamma\colon [0,1] \to |G|$ with $\gamma(0) = v$, $\gamma(1) = v'$ and such that $\gamma([0,1]) \subset |G|$ is the union of edges,
(c) the topological realization $|G|$ is path-connected,
(d) the topological realization $|G|$ is connected.

Exercise 7.5. Let G be an abstract graph and let $K \subset |G|$ be compact subset. Show that there exists a finite subgraph H of G with $K \subset |H|$.

Exercise 7.6. Are the two topological graphs G and H shown in the figure below homeomorphic?

Exercise 7.7. Let $G = (V, E, i, t)$ be an abstract graph and let $\widetilde{v} \in V$ be a vertex. We suppose that G is a tree. Show that there exist distinct edges $e_1, \ldots, e_k$ and distinct vertices $v_1, \ldots, v_k$ with the following properties:

(1) We have $V = \{\widetilde{v}, v_1, \ldots, v_k\}$ and $E = \{e_1, \ldots, e_k\}$.
(2) For each $i \in \{1, \ldots, k\}$ the vertex v_i is an endpoint of the edge e_i.
(3) If some vertex v_i is an endpoint of some e_j, then $i \leq j$.

We refer to the figure on page 316 for an illustration.

Exercise 7.8. Let $G = (V, E, i, t)$ be a countable connected non-empty abstract graph. We pick a vertex $v \in V$. Show that there exists a sequence $\{G_j = (V_j, E_j, i, t)\}_{j \in \mathbb{N}}$ of subgraphs with the following properties:

(1) Each G_j is finite and connected.
(2) Each G_j contains v.
(3) We have $G = \bigcup\limits_{j \in \mathbb{N}} G_j$ in the sense that $V = \bigcup\limits_{j \in \mathbb{N}} V_j$ and $E = \bigcup\limits_{j \in \mathbb{N}} G_j$.

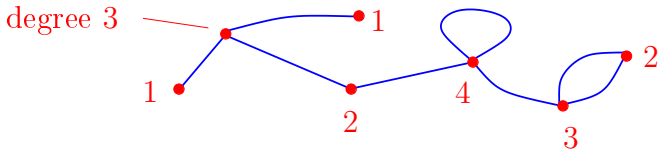
Exercise 7.9.

(a) Let $A \subset \mathbb{R}^3$ be a finite set. We say the points in A are in *general position* if no distinct three points in A are collinear and if no four points in A are coplanar. Show that if $t_1 < \cdots < t_k$ are real numbers, then the points

$$\{(t_i, t_i^2, t_i^3) \,|\, i = 1, \ldots, k\}$$

are in general position.

(b) Show that given any finite abstract graph G there exists an embedding of the topological realization $|G|$ into $\mathbb{R}^3$.



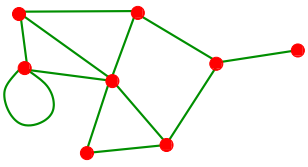
Exercise 7.10. As above let $\mathcal{Top}$ be the category of topological spaces, let $\mathcal{AbsGraph}$ be the category of abstract graphs and let $\mathcal{UndirAbsGraph}$ be the category of undirected abstract graphs. In Lemma 7.2 we defined a functor $|-|$ from $\mathcal{AbsGraph}$ to $\mathcal{Top}$. Furthermore on page 313 we defined a functor F from $\mathcal{AbsGraph}$ to $\mathcal{UndirAbsGraph}$ such that for any abstract graph the homeomorphism $\Theta_G \colon |G| \to |F(G)|$ between the topological realizations is a homeomorphism.

Is it possible to define a functor Ψ from $\mathcal{UndirAbsGraph}$ to $\mathcal{Top}$ such that the homeomorphisms Θ_G are natural?
Remark. Beware of loops.

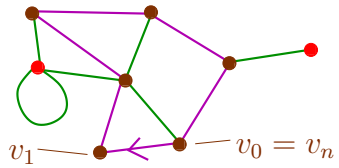
Exercise 7.11. Let $G = (V, E, i, t)$ be a finite abstract graph. The degree of a vertex v is defined as

$$\deg(v) \;:=\; \#\{e \in E \,|\, i(e) = v\} + \#\{e \in E \,|\, t(e) = v\}.$$

Show that the number of vertices of odd degree is even.
Remark. This statement is known as the *Handshaking Lemma*, the name comes from the observation that the statement means that at an event where some people shake hands, an even number of people have shaken an odd number of other people's hands.

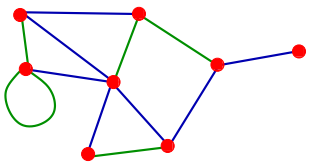


Exercise 7.12. We consider the topological space $X = \mathbb{Q}$. What is the topological valence $\operatorname{topval}(0, \mathbb{Q})$?



Exercise 7.13. Let $G = (V, E, \varphi)$ be an unoriented abstract graph. First we introduce some definitions.

(1) A *circuit of length* n in G is a sequence of vertices $v_0, v_1, v_2, \ldots, v_n = v_0$ such that the vertices $v_0, \ldots, v_{n-1}$ are distinct and such for each $i \in \{0, \ldots, n-1\}$ there exists an $e \in E$ with $\varphi(e) = \{v_i, v_{i+1}\}$.
(2) We say G is a *tree* if G is connected and if G contains no circuits.
(3) We say a subgraph $T \subset G$ is a *spanning tree* if T is a tree and if T contains all vertices of G.



Now we can state the actual problems.

(a) Show that for a finite unoriented abstract graph the above definition of a tree is equivalent to the definition on page 315.
(b) Show that for a finite unoriented abstract graph the above definition of a spanning tree is equivalent to the definition on page 317.
(c) Show that every connected unoriented abstract graph G admits a spanning tree.
Hint. Apply Zorn's Lemma 0.6 to the set of trees in G with the partial order given by inclusion.

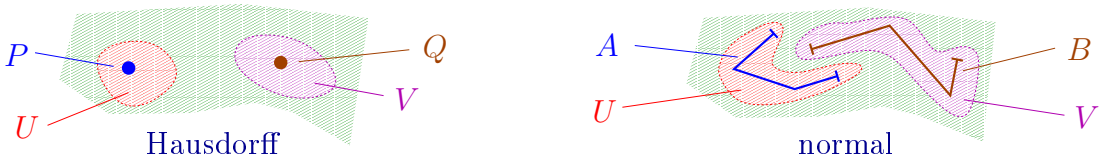
unoriented abstract graph G

circuit C

example of a spanning tree

Exercise 7.14. Let $G = (V, E, \varphi)$ be an unoriented abstract graph and let π be a group. A *π-action on G* is a homomorphism $\Phi\colon \pi \to \operatorname{Aut}(G)$. We say $v \in V$ is a *fixed vertex of the π-action* if for every $g \in \pi$ we have $\Phi(g)(v) = v$.

(a) Let T be an unoriented abstract graph that is a tree in the sense of the definition on page 324. Show that there exists a finite subtree $\widetilde{T}$ such that the π-action restricts to a π-action on $\widetilde{T}$.
(b) Let π be a finite group that acts on an undirected finite tree $\widetilde{T}$. Show that this action admits a fixed vertex.



Remark. You can prove the statement by induction on $\#T$. You can perform the induction step by considering the vertices of valency ≥ 2.

8. Urysohn's Lemma and the Tietze Extension Theorem

In this chapter we state and prove Urysohn's Lemma and the Tietze Extension Theorem. For the most part the proofs of the results we stated so far are fairly straightforward and could be assigned as (at times slightly challenging) homework exercises. The results of this chapter are the first really non-trivial statements.

8.1. **Normal topological spaces.** Recall that according to the definition on page 121 a topological space X is called *Hausdorff* if any two distinct points $P \neq Q$ can be separated by disjoint open subsets, i.e. if there exist disjoint open neighborhoods U of P and V of Q. As we will see in the following two chapters, and especially in Section 9.4, there are many variations on this definition. In this chapter we will mostly care about the following concept, which we already introduced on page 123.

Definition. A topological space X is called normal if any two disjoint closed subsets A and B of X can be separated by open neighborhoods, i.e. if there exist disjoint open neighborhoods U of A and V of B.

Remark.

(1) Note that the definitions of a normal topological space can differ slightly in the literature. For example [**Mun1975**, p. 195] imposes the extra condition that one-point sets are closed.
(2) Let X be a normal topological space. If every one-point subset is closed, then X is also Hausdorff.[106] But, as we will see in Exercise 8.1, without this condition there do in fact exist normal spaces that are not Hausdorff.
(3) Let X be the line with two zeros that we introduced on page 122. One can easily verify that every one-point subset is closed. We saw that X is not Hausdorff. Thus it follows from (2) that X is not normal either.
(4) In Exercise 8.3 we will give an example of a topological space that is Hausdorff but which is not normal.
(5) It follows easily from the Open -Closed Inclusion Lemma 2.10 (2) that any closed subset of a normal space is again normal. A topological space that has the property that every subspace is normal is called *hereditarily normal*. As we will see in Proposition 9.12 together with Exercise 9.18, there exist normal spaces that are not hereditarily normal.

For the reader's convenience we recall the Compact Hausdorff Spaces-Normal Lemma 1.16. Together with the subsequent the Metric Spaces are Normal Proposition 8.1 it provides us with a long list of examples of normal spaces.

[106] On page 349 we define a T_0-*space* to be a topological space that has the property that each one-point subset is closed.

Lemma 1.16. (Compact Hausdorff-Normal Lemma) Every compact Hausdorff space is normal.

The following proposition gives us an often convenient approach to showing that a topological space is normal. It implies, among many other things, that every subspace of some $\mathbb{R}^n$ is normal.

Proposition 8.1. (Metric Spaces-Normal Proposition) Let (X, d) be a metric space. If we equip X with the corresponding topology, then X is normal.

Proof. Let (X, d) be a metric space. We recall the following notation from page 283: given $x \in X$ and given a non-empty subset C of X we write

$$d(x, C) \ := \ \inf\{d(x, c) \,|\, c \in C\}.$$

If C is closed, then we know by the Distance-to-Subspace Lemma 6.2 (2) that $d(x, C) = 0$ if and only if $x \in C$.

Now let A and B be two disjoint closed subsets of X. If one of A or B is empty, then the desired disjoint neighborhoods are given by the empty set and X. Thus it remains to consider the case that both A and B are non-empty.

In our context, since A and B are disjoint and closed, we conclude from the above that for every $x \in X$ we have $d(x, A) + d(x, B) > 0$. Thus it makes sense to consider the map

$$\begin{array}{rcl} X & \to & \mathbb{R} \\ x & \mapsto & \dfrac{d(x, A)}{d(x, A) + d(x, B)}. \end{array}$$

By the Distance-to-Subspace Lemma 6.2 (1) we know that f is continuous. Evidently $f|_A \equiv 0$ and $f|_B \equiv 1$. It follows that $U := f^{-1}((-\infty, \frac{1}{4}))$ and $V := f^{-1}((\frac{3}{4}, \infty))$ have the desired properties. ■

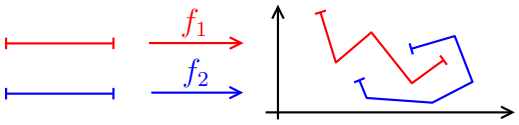
The following lemma, which is an analogue of the Points-in-Hausdorff Space Lemma 1.15, contains a convenient and frequently used property of normal spaces.

Lemma 8.2. (Normal-Open-Closed-Neighborhood Lemma) Let X be a topological space and let $A \subset X$ be a closed subset and $U \subset X$ be an open subset with $A \subset U$. If X is normal, then there exists an open subset $V \subset X$ with $A \subset V \subset \overline{V} \subset U$.

Proof. Let X be a topological space, let $A \subset X$ be a closed subset and let $U \subset X$ be an open subset with $A \subset U$. We set $B := X \setminus U$. This is a closed subset with $A \cap B = \varnothing$. Since X is normal there exist disjoint neighborhoods V of A and W of B. It remains to show that $\overline{V} \subset U$. In fact we have $V \subset X \setminus W \subset U$. But since W is open we know that $X \setminus W$ is closed. By definition of the closure $\overline{V}$ we have $\overline{V} \subset X \setminus W$. ■

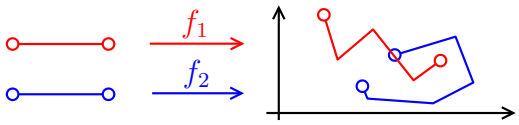
Remark. The combination of the Paracompact-Criterion Lemma 10.2 and Dieudonné's Theorem 10.5 gives us many more examples of normal topological spaces.

We conclude this short introduction to normal topological spaces with the following lemma which often gets used subconsciously.



Lemma 8.3. Let Y be a normal space.

(1) Let $A_1, \dots, A_k \subset Y$ be disjoint subsets. If the A_i are all closed, then the natural map $A_1 \sqcup \dots \sqcup A_k \to A_1 \cup \dots \cup A_k$ is a homeomorphism.



(2) Let $X_1, \dots, X_k$ be compact spaces and let $\varphi_i \colon X_i \to Y$ be embeddings with disjoint images. If Y is Hausdorff, then the map

$$\coprod_{i=1}^{k} f_i \colon \coprod_{i=1}^{k} X_i \;\to\; Y$$

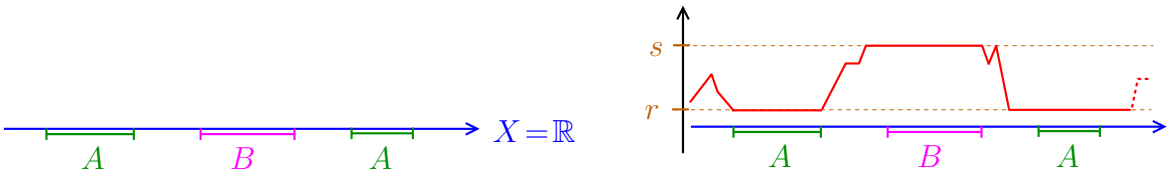
is an embedding.

$f_1 \sqcup f_2 \colon X_1 \sqcup X_2 \to \mathbb{R}^2$ is an embedding

$f_1 \sqcup f_2 \colon X_1 \sqcup X_2 \to \mathbb{R}^2$ is *not* an embedding

Proof. Let Y be a normal space.

(1) Let $A_1, \dots, A_k \subset Y$ be closed disjoint subsets. Note that for any $i \in \{1, \dots, k\}$ the union of the A_j with $i \neq j$ is a finite union of closed subsets, thus it is a closed subset itself. Since X is normal we see that there exists an open neighborhood of A_i that does not intersect any of the other A_j. It follows from this observation and the Disjoint Union Embedding Lemma 5.14 that the natural map $A_1 \sqcup \dots \sqcup A_k \to A_1 \cup \dots \cup A_k$ is a homeomorphism.



(2) Since $X_1, \dots, X_k$ are compact and since Y is in particular Hausdorff we know by the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 (2) that the images $\varphi_1(X_1), \dots, \varphi_k(X_k)$ are closed subsets of Y. It now follows from (1) that $\coprod_{i=1}^{k} f_i \colon \coprod_{i=1}^{k} X_i \to Y$ is indeed an embedding. ■

8.2. **Urysohn's Lemma.** In this section we will state and prove Urysohn's Lemma. Despite its modest name it is actually very much non-trivial.

Lemma 8.4. (Urysohn's Lemma) Let X be a topological space. The following two statements are equivalent:

(1) For any two disjoint closed subsets A and B and any $r < s \in \mathbb{R}$ there exists a continuous map $f \colon X \to [r, s]$ with $f|_A \equiv r$ and $f|_B \equiv s$.

(2) X is normal.

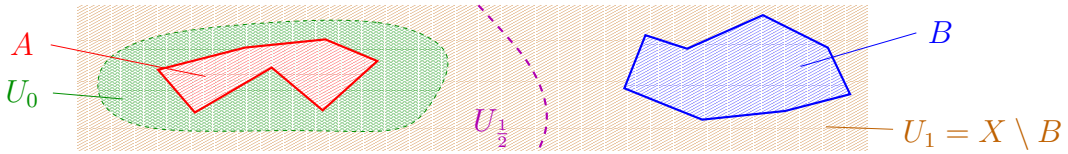
The statement of Urysohn's Lemma 8.4 is really quite amazing, just using the existence of suitable open subsets it builds up an interesting map.

Remark.

(1) Urysohn's Lemma 8.4 was first proved by Paul Urysohn [**Ury1925a**, p. 290] in 1924. The paper was finished three days before Paul Urysohn died in a swimming accident [**Gron2010**].
(2) A very nice motivation for the standard proof is given in [**Jä2005**, p. 109]. A somewhat different proof, using the Cantor function from page 185, is given in [**Cîr2021**].
(3) Note that Statement (1) in Urysohn's Lemma 8.4 does *not* say that there exists a continuous map $f\colon X \to [r,s]$ with $f^{-1}(r) = A$ and $f^{-1}(s) = B$. In fact, as we will see in Exercise 8.4, in general we cannot demand to find such a map on a normal space.
(4) The proof of the Metric Spaces-Normal Proposition 8.1 shows that the conclusion of Urysohn's Lemma 8.4 holds trivially for metric spaces.
(5) Urysohn's Lemma 8.4 motivates the interest in normal spaces. The combination of the Paracompact-Criterion Lemma 10.2 and the Dieudonné Theorem 10.5 shows that every topological space that is regionally compact, "second-countable" and Hausdorff is normal. In many settings this result will be strong enough to conclude that a given topological space is normal.
(6) In Lemma 21.7 we will prove a "smooth" version of Urysohn's Lemma 8.4.

Proof. The "(1)⇒(2)"-implication is straightforward. Indeed, suppose that A and B are two disjoint closed subsets of X. If (1) holds, then there exists a continuous function $f\colon X \to [0,1]$ with $f|_A \equiv 0$ and $f|_B \equiv 1$. Then $U := f^{-1}((-\infty, \frac{1}{2}))$ and $V := f^{-1}((\frac{1}{2}, \infty))$ have the desired properties.

The "(2)⇒(1)"-implication is the non-trivial direction of Urysohn's Lemma and its proof will occupy the remainder of the proof. Let A and B be two disjoint closed subsets. An elementary rescaling argument shows that it suffices to deal with the case $r = 0$ and $s = 1$, i.e. it suffices to show that there exists a continuous map $f\colon X \to [0,1]$ with $f|_A \equiv 0$ and $f|_B \equiv 1$.



Claim 1. We set $P = [0,1] \cap \mathbb{Q}$. There exists a family $\{U_s\}_{s\in P}$ of open subsets of X with the following three properties:

(i) $A \subset U_0$,
(ii) for each $p \in P$ with $p < 1$ we have $U_p \subset X \setminus B$,
(iii) for each $s,t \in P$ with $s < t$ we have $\overline{U}_s \subset U_t$.

Proof. Since P is countable there exists a bijection $\varphi\colon \mathbb{N}_0 \to P$. We can arrange that $\varphi(0) = 0$ and $\varphi(1) = 1$. We set $U_1 := X \setminus B$. Since B is closed we know that U_1 is

open. Since X is normal and since A is closed we obtain from the Normal-Open-Closed-Neighborhood Lemma 8.2 that there exists an open neighborhood U_0 of A with $\overline{U}_0 \subset U_1$. Now suppose that for some $n \geq 1$ we have already defined $U_{\varphi(0)}, U_{\varphi(1)}, \ldots, U_{\varphi(n)}$ with the required properties. We set $P_n = \{\varphi(0), \ldots, \varphi(n)\}$ and we set $y := \varphi(n+1)$. Since $\varphi(0) = 0$ and $\varphi(1) = 1$ we see that $y \in (0,1)$. Since P_n is a finite subset of $[0,1]$ and since $\varphi(0) = 0$ and $\varphi(1) = 1$ we see that the set P_n contains a largest number x less than $y = \varphi(n+1)$ and it contains a smallest number z larger than $y = \varphi(n+1)$.

Note that our induction hypothesis implies that $\overline{U}_x \subset U_z$. Thus, since X is normal, we obtain from the Normal-Open-Closed-Neighborhood Lemma 8.2 that there exists an open subset U_y with $\overline{U}_x \subset U_y \subset \overline{U}_y \subset U_z$. One can now easily verify that $U_{\varphi(0)}, U_{\varphi(1)}, \ldots, U_{\varphi(n)}, U_{\varphi(n+1)}$ have the required properties. ⊞

For each $p \in (-\infty, 0) \cap \mathbb{Q}$ we set $U_p := \varnothing$ and for each $p \in (1, \infty) \cap \mathbb{Q}$ we set $U_p := X$. Next we consider

$$\begin{array}{rcl} f\colon X & \to & \mathbb{R} \\ x & \mapsto & \inf\{p \in \mathbb{Q} \,|\, x \in U_p\}. \end{array}$$

It follows easily from Properties (i) and (ii) that $f|_A \equiv 0$, that $f|_B \equiv 1$ and that f takes values in $[0,1]$. Thus it remains to prove that f is continuous. The proof of continuity requires some preparations.

Claim 2. Let $r \in \mathbb{Q}$.

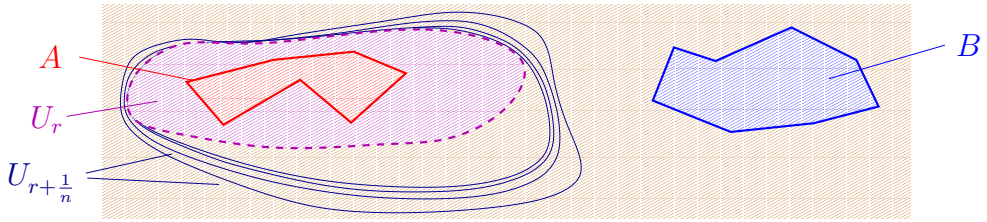
$$\begin{array}{llll} \text{(a)} & x \in \overline{U}_r \implies f(x) \leq r & \text{(a')} & f(x) > r \;\Rightarrow\; x \notin \overline{U}_r. \\ \text{(b)} & x \notin U_r \implies f(x) \geq r & \text{(b')} & f(x) < r \;\Rightarrow\; x \in U_r. \end{array}$$

Proof. Statements (a') and (b') are evidently just reformulations of Statements (a) and (b). Statements (a) and (b) are trivial if $r < 0$ or $r > 1$. Now assume that $r \in P = [0,1] \cap \mathbb{Q}$. In this case the statements follow from the following straightforward arguments:

$$\begin{array}{lcl} & \overset{\text{by Property (iii)}}{\Longrightarrow} & \overset{\text{by definition of infimum and since } P \text{ is dense in } [0,1]}{\Longrightarrow} \\ x \in \overline{U}_r & \Longrightarrow & x \in U_s \text{ for every } s \in P \text{ with } s > r \;\Longrightarrow f(x) \leq r \\ x \notin U_r & \Longrightarrow & x \notin U_s \text{ for every } s \in P \text{ with } s < r \;\Longrightarrow f(x) \geq r. \end{array}$$ ⊞

Claim 3. Given any $r \in \mathbb{Q}$ we have

$$f^{-1}([0,r]) = \bigcap_{n\in\mathbb{N}} \overline{U}_{r+\frac{1}{n}} \qquad \text{and} \qquad f^{-1}([0,r)) = \bigcup_{n\in\mathbb{N}} U_{r-\frac{1}{n}}.$$



Proof. Let $r \in \mathbb{Q}$. We see that

$$\begin{array}{lcl} f^{-1}([0,r]) & = & f^{-1}\Big(\bigcap_{n\in\mathbb{N}} [0, r+\frac{1}{n})\Big) \overset{\text{Image-Preimage Lemma 0.2 (7)}}{=} \bigcap_{n\in\mathbb{N}} f^{-1}([0,r+\frac{1}{n})) \overset{\text{by Claim 2 (b')}}{\subset} \bigcap_{n\in\mathbb{N}} U_{r+\frac{1}{n}} \subset \bigcap_{n\in\mathbb{N}} \overline{U}_{r+\frac{1}{n}} \\ & \subset & \bigcap_{n\in\mathbb{N}} f^{-1}([0,r+\frac{1}{n}]) = f^{-1}\Big(\bigcap_{n\in\mathbb{N}} [0,r+\frac{1}{n}]\Big) = f^{-1}([0,r]). \\ & \uparrow \text{ by Claim 2 (a)} & \uparrow \text{ Image-Preimage Lemma 0.2 (7)} \end{array}$$

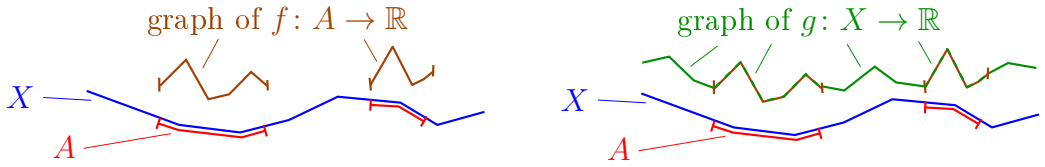
Note that at the beginning and at the end we have the same set. Thus all inclusions have to be equalities. Therefore we obtain the first equality of the claim. The proof of the second equality is very similar to the proof of the first equality. For completeness' sake we carry out the argument:

$$\begin{array}{ccccccc} f^{-1}([0,r)) & = & f^{-1}\Big(\bigcup_{n\in\mathbb{N}}[0,r-\frac{1}{n})\Big) & \overset{\text{Image-Preimage Lemma 0.2 (6)}}{\downarrow =} & \bigcup_{n\in\mathbb{N}} f^{-1}([0,r-\frac{1}{n})) & \overset{\text{by Claim 2 (b')}}{\downarrow \subset} & \bigcup_{n\in\mathbb{N}} U_{r-\frac{1}{n}} \subset \bigcup_{n\in\mathbb{N}} \overline{U}_{r-\frac{1}{n}} \\ & \subset & \bigcup_{n\in\mathbb{N}} f^{-1}([0,r-\frac{1}{n}]) & = & f^{-1}\Big(\bigcup_{n\in\mathbb{N}}[0,r-\frac{1}{n}]\Big) & = & f^{-1}([0,r)). \\ & \underset{\text{by Claim 2 (a)}}{\uparrow} & & \underset{\text{Image-Preimage Lemma 0.2 (6)}}{\uparrow} & & & \end{array}$$

As above we deduce the desired equality. ⊞

Claim 4. The map $f\colon X \to \mathbb{R}$ is continuous.

Proof. On page 135 we pointed out that the set of rational intervals forms a basis for the topology of $\mathbb{R}$. It follows from the Subbasis-Continuity Proposition 2.9 that it suffices to show that for every choice of $c, d \in \mathbb{Q}$ the preimage $f^{-1}((c,d))$ is open. Thus let $c, d \in \mathbb{Q}$. We see that



$$f^{-1}((c,d)) \overset{\text{by the Image-Preimage Lemma 0.2 (8) and since } f(X)\subset[0,1]}{\downarrow =} f^{-1}([0,d)) \setminus f^{-1}([0,c]) \overset{\text{by Claim 3}}{\downarrow =} \underbrace{\bigcup_{n\in\mathbb{N}} U_{d-\frac{1}{n}}}_{\substack{\text{open, since each} \\ U_p \text{ is open}}} \setminus \underbrace{\bigcap_{n\in\mathbb{N}} \overline{U}_{c+\frac{1}{n}}}_{\substack{\text{closed by} \\ \text{Lemmas 1.9 (2)} \\ \text{and 1.3 (2)}}}.$$

■

8.3. **The Tietze Extension Theorem.** Using Urysohn's Lemma 8.4 we can now prove the following major theorem.

Theorem 8.5. (Tietze Extension Theorem) Let X be a topological space, let $A \subset X$ be a closed subset and let $f\colon A \to \mathbb{R}$ be a continuous map. If X is normal, then there exists a continuous map $g\colon X \to \mathbb{R}$ with $g|_A = f$. If A is non-empty then one can find such g such that

$$\inf g(X) = \inf f(A) \in \mathbb{R}\cup\{-\infty\} \quad \text{and} \quad \sup g(X) = \sup f(A) \in \mathbb{R}\cup\{\infty\}.$$

Remark.

(1) The Tietze Extension Theorem was first proved for metric spaces by Heinrich Tietze [**Tie1915**] in 1915. The extension to normal topological spaces was proved by Paul Urysohn [**Ury1925a**, p. 293].
(2) Let X be a topological space and let A and B be two disjoint closed subsets. We consider the map on $A \sqcup B$ that is given by $f|_A \equiv 0$ and $f|_B \equiv 1$. By the Pasting Proposition 2.6 we know that f is continuous. If X is normal, then we can extend f by the Tietze Extension Theorem 8.5 to a continuous map on all of X. This shows that the Tietze Extension Theorem 8.5 is an extension of Urysohn's Lemma 8.4.
(3) In Exercise 8.10 we will see, borrowing some ideas from (2), that the Tietze Extension Theorem 8.5 is optimal in the sense, that if the conclusion holds for a topological space X, then X is normal.
(4) In Proposition 21.9 we will prove a "smooth" version of the Tietze Extension Theorem 8.5.

For many applications the following formulation of the Tietze Extension Theorem 8.5 is more convenient.

Theorem 8.6. (Tietze Extension Theorem) Let X be a topological space and let A be a closed subset of X. Suppose that for $i = 1, \ldots, n$ we are given a closed interval $I_i \subset \mathbb{R}$ and suppose that we are given a map $f\colon A \to I_1 \times \cdots \times I_n \subset \mathbb{R}^n$. If X is normal, then there exists a continuous map $g\colon X \to I_1 \times \cdots \times I_n$ with $g|_A = f$.

Proof. We apply the earlier Tietze Extension Theorem 8.5 to the various coordinate functions $f_k\colon A \to I_k$, $k = 1, \ldots, n$ and we find maps $g_1, \ldots, g_k\colon X \to \mathbb{R}$ with the same infima and suprema as $f_1, \ldots, f_k$. But since each I_k is closed we see that the infima and suprema lie in the corresponding I_k. This shows that each g_k takes again values in I_k. ■

The proof of the Tietze Extension Theorem 8.5 relies on the following proposition.

Proposition 8.7. Let X be a non-empty topological space. First we introduce some notation: given a bounded map[107] $g\colon X \to \mathbb{R}$ we set

$$\|g\| \;:=\; \sup\{|g(x)| \,|\, x \in X\} \;\in\; \mathbb{R}.$$

Let $(g_n\colon X \to \mathbb{R})_{n\in\mathbb{N}}$ be a sequence of bounded maps. If $\sum_{n=1}^{\infty} \|g_n\| < \infty$, then for each $x \in X$ the series $\sum_{n=1}^{\infty} g_n(x)$ converges in $\mathbb{R}$ and the map $x \mapsto \sum_{n=1}^{\infty} g_n(x)$ is continuous.

Proof of Proposition 8.7. Let X be a non-empty topological space. As in Proposition 6.12 we consider the set $C(X, \mathbb{R})$ of continuous maps $X \to \mathbb{R}$ and given $f, g \in C(X, \mathbb{R})$ we write again

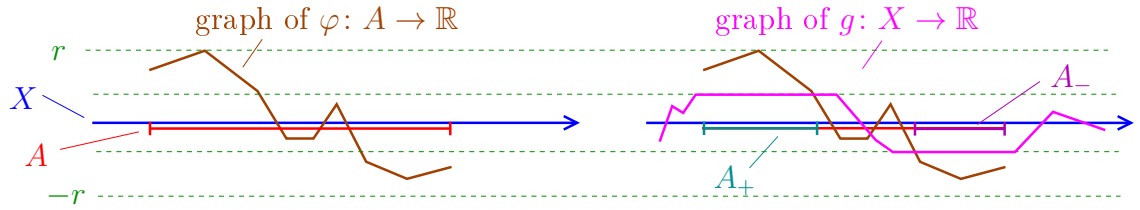
$$\widetilde{d}(f, g) \;=\; \sup\big\{\, \min\{|f(x) - g(x)|, 1\} \,\big|\, x \in X\big\}.$$

[107] We say $g\colon X \to \mathbb{R}$ is bounded if there exists a $C \in \mathbb{R}$ such that $|g(x)| \leq C$ for all $x \in X$.

Now let $(g_n\colon X \to \mathbb{R})_{n\in\mathbb{N}}$ be a sequence of bounded maps such that $\sum_{n=1}^{\infty} \|g_n\| < \infty$. Note that for each $k \geq l \in \mathbb{N}$ we have

$$\widetilde{d}\Big(\sum_{n=1}^{k} g_n\,,\sum_{n=1}^{l} g_n\Big) \;\leq\; \Big\|\sum_{n=1}^{k} g_n \;-\; \sum_{n=1}^{l} g_n\Big\| \;=\; \Big\|\sum_{n=l+1}^{k} g_n\Big\| \;\underset{\substack{\uparrow\\ \text{triangle inequality}}}{\leq}\; \sum_{n=l+1}^{k} \|g_n\|.$$

It follows easily from this observation and from the hypothesis that the series $\sum_{n=1}^{\infty} \|g_n\|$ converges in $\mathbb{R}$ that the partial sums $\sum_{n=1}^{k} g_k$ define a Cauchy sequence in $(C(X,\mathbb{R}),\widetilde{d})$. The desired statements now follow from Proposition 6.12. ■



Proof of the Tietze Extension Theorem 8.5 if f is bounded. Let X be a topological space which is normal and let $A \subset X$ be a closed subset. If X is empty, then there is nothing to show. Thus we can assume that X is non-empty. Given a bounded map $\psi\colon X \to \mathbb{R}$ we write again

$$\|\psi\| \;:=\; \sup\{|\psi(x)|\,|\,x \in X\} \;\in\; \mathbb{R}.$$

Claim. Let $r \in \mathbb{R}_{\geq 0}$. Given any continuous map $\varphi\colon A \to [-r,r]$ there exists a continuous map $g\colon X \to \mathbb{R}$ such that

$$\|g\| \leq \tfrac{1}{3}\cdot r \qquad \text{and such that} \qquad |\varphi(a) - g(a)| \;\leq\; \tfrac{2}{3}\cdot r \qquad \text{for all } a \in A.$$

Proof. We set $A_- = \varphi^{-1}([-r,-\frac{1}{3}r])$, $A_0 = \varphi^{-1}([-\frac{1}{3}r,\frac{1}{3}r])$ and $A_+ = \varphi^{-1}([\frac{1}{3}r,r])$. Since A_- and A_+ are disjoint closed subsets of X it follows from Urysohn's Lemma 8.4 that there exists a continuous map $g\colon X \to [-\frac{1}{3}r,\frac{1}{3}r]$ such that $g|_{A_-} \equiv -\frac{1}{3}r$ and $g|_{A_+} \equiv \frac{1}{3}r$. In particular we have $\|g\| \leq \frac{1}{3}r$. Now let $a \in A$. In each of the three cases $a \in A_-$, $a \in A_0$ and $a \in A_+$ one can easily verify, using the triangle inequality, that $|\varphi(a)-g(a)| \leq \frac{2}{3}\cdot r$. ⊞

Now let $f\colon A \to \mathbb{R}$ be a bounded map. This means that there exists an $s \geq 0$ such that f takes values in $[-s,s]$. Thus we can apply the claim to $\varphi = f$ and $r = s$. We obtain a continuous map $g_1\colon X \to \mathbb{R}$ such that

$$\|g_1\| \;\leq\; \tfrac{1}{3}\cdot s \qquad \text{and} \qquad |f(a) - g_1(a)| \;\leq\; \tfrac{2}{3}\cdot s \qquad \text{for all } a \in A.$$

Next we apply the claim to the map $\varphi = f - g_1$ and $r = \frac{2}{3}\cdot s$. We obtain a continuous map $g_2\colon X \to \mathbb{R}$ such that

$$\|g_2\| \;\leq\; \tfrac{1}{3}\cdot\tfrac{2}{3}\cdot s \qquad \text{and} \qquad |\underbrace{(f(a) - g_1(a))}_{=\varphi(a)} - g_2(a)| \;\leq\; (\tfrac{2}{3})^2\cdot s \;\text{ for all } a \in A.$$

Iterating this procedure we obtain a sequence of continuous maps $g_1, g_2, \ldots : X \to \mathbb{R}$ such that for each $n \in \mathbb{N}$ we have

$$\|g_n\| \;\leq\; \tfrac{1}{3}\cdot(\tfrac{2}{3})^{n-1}\cdot s \qquad \text{and} \qquad |f(a) - g_1(a) - \cdots - g_n(a)| \;\leq\; (\tfrac{2}{3})^n\cdot s \;\text{ for all } a \in A.$$

Note that $\sum_{n=1}^{\infty} \|g_n\| \leq \sum_{n=1}^{\infty} \frac{1}{3} \cdot (\frac{2}{3})^{n-1} \cdot s = \frac{1}{3} \cdot s \cdot \sum_{n=0}^{\infty} (\frac{2}{3})^n = s < \infty$. Thus it follows from Proposition 8.7 that the map

$$\begin{array}{rcl} X & \to & \mathbb{R} \\ x & \mapsto & g(x) := \sum_{n=1}^{\infty} g_n(x) \end{array}$$

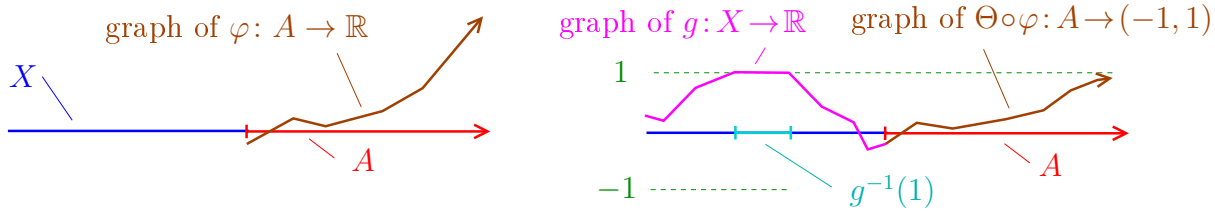
is defined and continuous. Next note that for any $a \in A$ we have

$$|f(a)-g(a)| = \left|f(a)-\sum_{n=1}^{\infty} g_n(a)\right| = \left|f(a)-\lim_{n\to\infty}\sum_{k=1}^{n} g_k(a)\right| = \lim_{n\to\infty} \underbrace{\left|f(a)-\sum_{k=1}^{n} g_k(a)\right|}_{\leq (\frac{2}{3})^n \cdot s \text{ by the second property}} = 0.$$

In other words, the maps g and f agree on A.

Finally assume that A is non-empty. Since $f\colon X \to \mathbb{R}$ is by hypothesis bounded it makes sense to set $a := \inf f(A) \in \mathbb{R}$ and to set $b := \sup f(A) \in \mathbb{R}$. By Lemma 2.3 we know that the map

$$x \mapsto \min(\max(g(x), a), b)$$



is continuous. Evidently this map has all the desired properties. ∎

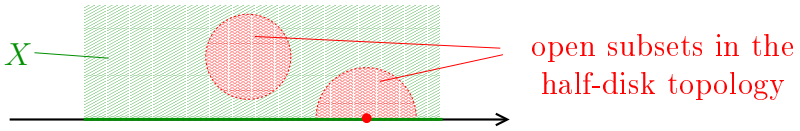
Proof of the Tietze Extension Theorem 8.5 if f is unbounded. Let X be a topological space which is normal, let $A \subset X$ be a closed subset and let $f\colon A \to \mathbb{R}$ be a possibly unbounded continuous map.

We pick a homeomorphism $\Theta\colon \mathbb{R} \to (-1,1)$, e.g. we could pick $x \mapsto \frac{2}{\pi} \cdot \arctan(x)$. The map $\Theta \circ f\colon A \to \mathbb{R}$ is bounded and continuous. By the previous case of the Tietze Extension Theorem we know that there exists a continuous map $g\colon X \to [-1,1]$ which agrees with $\Theta \circ f$ on A. If $g(X) \subset (-1,1)$, then $\Theta^{-1} \circ g\colon X \to \mathbb{R}$ is the desired extension of f.

It remains to consider the case that $g^{-1}(-1) \cup g^{-1}(1)$ is non-empty. Note that A and $g^{-1}(-1) \cup g^{-1}(1)$ are two disjoint closed subsets of X. Therefore we can apply Urysohn's Lemma 8.4 and we obtain a continuous map $\gamma\colon X \to [0,1]$ with $\gamma|_A \equiv 1$ and which vanishes on $g^{-1}(-1) \cup g^{-1}(1)$. The map $x \mapsto \gamma(x) \cdot g(x)$ takes values in $(-1,1)$. The map $x \mapsto \Theta^{-1}(\gamma(x) \cdot g(x))$ is therefore well-defined and it is a continuous extension of $f\colon A \to \mathbb{R}$ to all of X.

By basically the same argument as in the bounded case we can arrange that f and g have the same infimum and the same supremum. ∎

Exercises for Chapter 8.



Exercise 8.1. Give an example of a topological space that is normal but which is not Hausdorff.

Exercise 8.2. Let Y be a topological space and let $X_1, \ldots, X_k$ be disjoint closed subsets of Y. Show that if Y is normal, then the X_i are contained in disjoint open subsets.

Exercise 8.3. We consider the upper half-plane $X := \{(x, y) \in \mathbb{R}^2 \,|\, y \geq 0\}$ together with the *half-disk topology* $\mathcal{H}$ which is generated by the usual open disks $B_r(x, y)$ with $r < y$ and the subsets of the form

$$\{(x, 0)\} \;\cup\; (B_r(x, 0) \cap \{(x, y) \in \mathbb{R}^2 \,|\, y > 0\}).$$

(a) Show that $(X, \mathcal{H})$ is Hausdorff.
(b) Show that $(X, \mathcal{H})$ is not normal.

Exercise 8.4. Give an example of a normal topological space X and two closed subsets A and B such that there exists no continuous map $f\colon X \to \mathbb{R}$ with $A = f^{-1}(0)$ and $B = f^{-1}(1)$.

Exercise 8.5. Show that every topological graph, as defined on page 310, is normal.

Exercise 8.6. Let $S := (\mathbb{R}, \mathcal{T})$ be the Sorgenfrey line that we introduced on page 182.

(a) Show that the Sorgenfrey line is normal.

As in Exercise 5.13 we refer to the product $S \times S$ as the *Sorgenfrey plane*.

(b) Show that $A := \{(x, -x) \,|\, x \in \mathbb{Q}\}$ and $B := \{(x, -x) \,|\, x \in \mathbb{R} \setminus \mathbb{Q}\}$ are closed subsets of the Sorgenfrey plane.
Remark. You could make use of Exercise 5.13.
(c) Show that the Sorgenfrey plane is not normal.

Exercise 8.7. Let $A \subset \mathbb{R}^n$ be a subset. Show that if A is not closed, then there exists a continuous map $f\colon A \to \mathbb{R}$ which cannot be extended to a continuous map on all of $\mathbb{R}^n$.

Exercise 8.8. Let X be a topological space that is normal. Let $U_1, \ldots, U_m$ be open subsets such that $X = \bigcup_{i=1}^{m} U_i$. Show that there exist open subsets $V_i \subset U_i$ such that $\overline{V}_i \subset U_i$ and such that $X = \bigcup_{i=1}^{m} V_i$.
Remark. A much stronger version of the statement of this exercise can be found in [**Dug1966**, Theorem VII.6.1] or alternatively in [**Grote1969**, Satz 43].

Exercise 8.9. Let X be a metric space.

(a) Let $A, B \subset X$ be two disjoint closed subsets of X. Does there exist a continuous map $f\colon X \to [0, 1]$ such that $A = f^{-1}(0)$ and $B = f^{-1}(1)$?
(b) Let $A, B \subset X$ be two disjoint open subsets of X. Does there exist a continuous map $f\colon X \to \mathbb{R}$ and disjoint open intervals I and J such that $A = f^{-1}(I)$ and $B = f^{-1}(J)$?
(c) Let $A, B \subset X$ be two subsets of X such that $\overline{A} \cap B = \varnothing$ and $A \cap \overline{B} = \varnothing$. Do there exist disjoint open neighborhoods U of A and V of B?

Exercise 8.10. Let X be a topological space that satisfies the conclusion of the Tietze Extension Theorem 8.5, i.e. we assume that given any closed subset A of X and given any

continuous map $f\colon A \to \mathbb{R}$ there exists a continuous map $g\colon X \to \mathbb{R}$ with $g|_A = f$. Show that X is normal.

9. Second-countable topological spaces and the Urysohn Metrization Theorem

In this chapter we will first introduce the notion of a second-countable topological space. This notion is used in the formulation of the Urysohn Metrization Theorem. Depending on the reader's taste, even more importantly, the notion of a second-countable topological space plays an essential role in the definition of topological manifolds on page 511.

9.1. Second-countable topological spaces.

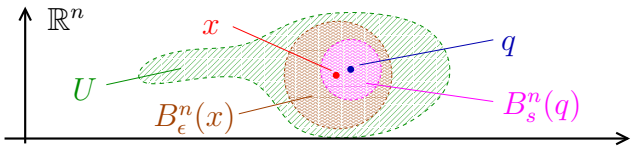
Recall that on page 132 we introduced the notion of a basis of a topological space. With this notion we can define what it means for a topological space to be second-countable.

Definition. A topological space is called second-countable if there exists a countable basis for the topology.

Non-Example. Of course not every topological space is second-countable. For example consider the uncountable set $\mathbb{R}$, but for once equipped with the discrete topology $\mathcal{D}$. It follows easily from the definitions that $X = (\mathbb{R}, \mathcal{D})$ is *not* second-countable. There are also more subtle examples, for example we will see in Exercise 9.6 that there exist *compact* topological spaces that are not second-countable. Furthermore in Theorem 22.13 we will see that there exists a path-connected space that is not second-countable.

Using the next lemma we will see that many of the topological spaces that we are interested in are actually second-countable.

Lemma 9.1. (Second Countability Lemma)



(1) For every $n \in \mathbb{N}_0$ the topological space $\mathbb{R}^n$ is second-countable.
(2) If X is a topological space that is second-countable, then every subspace is also second-countable.
(3) (a) If $X_1, \dots, X_k$ are topological spaces that are second-countable, then $X_1 \times \cdots \times X_k$ is second-countable.
    (b) Let $\{X_i\}_{i \in I}$ be a countable family of topological spaces. If each X_i is second-countable, then $\prod_{i \in I} X_i$ is also second-countable.
(4) Let X be a topological space. If there exists a countable family of open subsets $\{U_i\}_{i \in I}$ such that $\bigcup_{i \in I} U_i = X$ and such that each U_i is second-countable, then X itself is second-countable.
(5) Let X be a topological space and let $\sim$ be an equivalence relation on X. If X is second-countable and if the projection $X \to X/\!\sim$ is an open map, then $X/\!\sim$ is also second-countable.

Proof.

(1) This statement is basically the content of Exercise 1.8. For completeness' sake we provide the argument. Let $n \in \mathbb{N}_0$. We denote by $\mathcal{B}$ the set of all open balls around points in $\mathbb{Q}^n$ with rational radii. By the Countability Lemma 0.8 we know that $\mathcal{B}$ is countable. Thus it remains to show that $\mathcal{B}$ is a basis for the standard topology on $\mathbb{R}^n$. Note that each set in $\mathcal{B}$ is an open subset of $\mathbb{R}^n$. By the definition of the basis of a topology, see page 132, it now suffices to prove the following claim.

Claim. Given any open subset $U \subset \mathbb{R}^n$ and given any $x \in U$ there exists a $B \in \mathcal{B}$ with $x \in B \subset U$.

Proof. Let $U \subset \mathbb{R}^n$ be an open subset and let $x \in U$. Since U is open there exists an $\epsilon > 0$ such that $B^n_\epsilon(x) \subset U$. Since $\mathbb{Q}$ is dense in $\mathbb{R}$ there exists a $q \in \mathbb{Q}^n$ with $\|x - q\| < \frac{1}{3}\epsilon$. Next we pick an $s \in \mathbb{Q}$ with $s \in (\frac{1}{3}\epsilon, \frac{2}{3}\epsilon)$. A straightforward argument, using the triangle inequality, shows that $x \in B^n_s(q) \subset B^n_\epsilon(x) \subset U$. ⊞

(2) This statement follows from Lemma 1.33 and the Countability Lemma 0.8 (3).

(3) (a) This statement follows from the Product Topology-Basics Lemma 5.4 (3) and the Countability Lemma 0.8 (5).

(b) This statement follows from the Product Topology-Basics Lemma 5.4 (3) and the Countability Lemma 0.8 (3) and (5).

(4) For each U_i we pick a countable basis $\mathcal{B}_i$ of the topology of U_i. Using the Basis Characterization Lemma 1.32 it is straightforward to verify that $\bigcup_{i \in I} \mathcal{B}_i$ is a basis for the topology of X. By the Countability Lemma 0.8 (2) this is a countable set.

(5) This statement follows from Lemma 5.22 and the Countability Lemma 0.8 (3). ■

The following lemma gives us a convenient property of second-countable topological spaces.

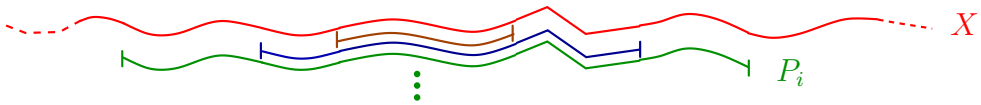
Lemma 9.2. (Countable Covering Lemma) Let X be a topological space and let $\{U_i\}_{i \in I}$ be an open cover of X. If X is second-countable, then there exists a countable subset $J \subset I$ with $X = \bigcup_{j \in J} U_j$.

Proof. Let $\mathcal{B}$ be a countable basis for the topology of X. We write

$$\mathcal{B}' := \{V \in \mathcal{B} \,|\, V \subset U_i \text{ for some } i \in I\}.$$

Given $V \in \mathcal{B}'$ we pick $j \in I$ with $V \subset U_j$. It follows from the Countability Lemma 0.8 (1) that the set $J \subset I$ of all such j is countable. It remains to show that $X = \bigcup_{j \in J} U_j$.

Thus let $x \in X$. By hypothesis there exists an $i \in I$ with $x \in U_i$. Since $\mathcal{B}$ is a basis for the topology of X there exists a $V \in \mathcal{B}$ with $x \in V \subset U_i$. Note that $V \in \mathcal{B}'$. But this implies that $x \in U_j$ for some $j \in J$. ■



We conclude this introduction to second-countable topological spaces with the discussion of exhaustions of topological spaces, which play a role later on.

Definition. Let X be a topological space. We say that a sequence $\{P_i\}_{i \in \mathbb{N}}$ of subsets of X is an exhaustion if the following two conditions are satisfied:

(1) We have $X = \bigcup_{i \in \mathbb{N}} P_i$.

(2) For each $i \in \mathbb{N}$ we have $\overline{P}_i \subset \overset{\circ}{P}_{i+1}$.

We say that the exhaustion is compact, if each P_i is compact.

Example. A compact exhaustion of $\mathbb{R}^n$ is given by $P_i := \overline{B}_i^n(0)$ with $i \in \mathbb{N}$.

Lemma 9.3. (Compact Exhaustion Lemma) Let X be a topological space which is second countable, Hausdorff and regionally compact.

(1) There exists an exhaustion of X by compact subsets.
(2) Given any compact subset $K \subset X$ there exists an open neighborhood P of K such that the closure $\overline{P}$ is compact.

Remark. In the Exhaustion Function Lemma 10.7 we will prove a refinement of the Compact Exhaustion Lemma 9.3 (1).

Proof.

(1) First recall that on page 178 we said that a subset $A \subset X$ is *precompact in* X if the closure $\overline{A}$ of A in X is compact. By hypothesis we know that X is regionally compact and Hausdorff. It follows from Lemma 2.42 that X is locally precompact, which implies by Lemma 2.39 that the topology of X admits a basis of precompact open subsets. Since X is second-countable we know by the Countable Covering Lemma 9.2 that X is in fact covered by a countable family $\{U_i\}_{i\in\mathbb{N}}$ of precompact open subsets. It remains to prove the following claim.

Claim. There exists a sequence $\{K_i\}_{i\in\mathbb{N}}$ of compact subsets of X such that for each $i \in \mathbb{N}$ we have $U_i \subset K_i$ and such that for each $i \geq 2$ we have $K_{i-1} = \overline{K}_{i-1} \subset \mathring{K}_i$.

Proof. We set $K_1 := \overline{U}_1$. Suppose we have already constructed $K_1, \ldots, K_n$ with the above properties. Since K_n is compact there exists an $r \in \mathbb{N}$ with $K_n \subset U_1 \cup \cdots \cup U_r$. We set

$$K_{n+1} := \overline{U}_1 \cup \cdots \cup \overline{U}_r \cup \overline{U}_{n+1}.$$

Since the $U_1, \ldots, U_r, U_{n+1}$ are precompact, their closures are by definition compact. Thus it follows from the Compact-Union-Intersection Lemma 1.20 that K_{n+1} is compact. Evidently $U_{n+1} \subset K_{n+1}$. Finally observe that

$$\overline{K}_n \underset{\uparrow}{=} K_n \subset U_1 \cup \cdots \cup U_r \subset \mathring{K}_{n+1} \subset K_{n+1}.$$

since X is Hausdorff we know by the Compact-Closed Lemma 1.21 (2) that compact subsets are closed

By iterating this procedure we get the desired sequence.

(2) Let K be a compact subset of X. We continue with the notation from (1). The sets $\mathring{K}_n$ form an open cover of K. Since K is compact and since we have $\mathring{K}_n \subset \mathring{K}_{n+1}$ we see that there exists an $n \in \mathbb{N}$ with $K \subset \mathring{K}_n$. But K_n is compact, thus we are done. ∎

9.2. **The Urysohn Metrization Theorem.** In this section we will state and prove a major consequence of Urysohn's Lemma 8.4, namely the Urysohn Metrization Theorem. Before we can state the theorem, let us recall the following definition from page 110.

Definition. A topological space X is called metrizable if there exists a metric d on X such that the given topology agrees with the topology coming from d.

For second-countable topological spaces the following theorem gives a complete characterization of metrizability.

Theorem 9.4. (Urysohn Metrization Theorem) Let X be a topological space. If X is second-countable, then the following two statements are equivalent:

(1) X is normal and every one-point subset is closed[108].
(2) X is metrizable.

Remark.

(1) The Urysohn Metrization Theorem 9.4 was proved by Paul Urysohn in 1924. Urysohn's proof was written up posthumously by Paul Alexandroff [**Ury1925b**].
(2) The later Completely Metrizable Criterion Proposition 10.8 can often be used to show that a given topological space is in fact completely metrizable.
(3) In Exercise 9.21 we will show that a compact metrizable space is second-countable.

The proof of the Urysohn Metrization Theorem 9.4 relies on a proposition which is interesting in its own right. To formulate this proposition we need to introduce or recall the following notation.

Notation. We write

$$\mathbb{R}^{\mathbb{N}} := \{\text{all maps } \mathbb{N} \to \mathbb{R}\} = \{(x_1, x_2, \dots) \,|\, \text{all } x_i \in \mathbb{R}\}.$$

We equip $\mathbb{R}^{\mathbb{N}}$ with the product topology introduced on page 226, namely this is the topology which is defined by the condition that a basis for the topology is given by the sets

$$U_1 \times \cdots \times U_k \times \mathbb{R} \times \mathbb{R} \times \dots \quad \subset \mathbb{R}^{\mathbb{N}}$$

where $U_1, \dots, U_k$ are open sets in $\mathbb{R}$.

Proposition 9.5. The topological space $\mathbb{R}^{\mathbb{N}}$ is metrizable.

Proof. Throughout the proof we adopt the following notation:

- Given $a, b \in \mathbb{R}$ we write $d(a,b) := \min\{|b-a|, 1\}$.
- Given $x \in \mathbb{R}^{\mathbb{N}}$ we denote by $x_1, x_2, \dots$ the "coordinates" of x.
- Given $x, y \in \mathbb{R}^{\mathbb{N}}$ we set[109]

$$D(x,y) := \sup_{k\in\mathbb{N}}\{\tfrac{1}{k} \cdot d(x_k, y_k)\} \in \mathbb{R}.$$

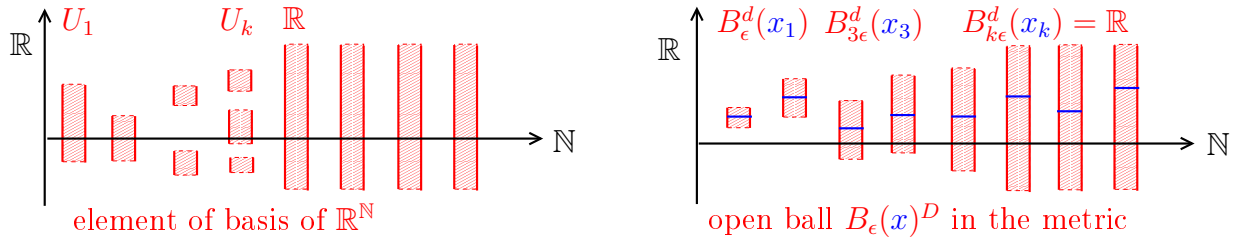
Claim 1. The map D defines a metric on $\mathbb{R}^{\mathbb{N}}$.

Proof. It is clear that D is symmetric and that $D(x,y) = 0$ if and only if $x = y$. Thus it remains to prove the triangle inequality. Let $x, y, z \in \mathbb{R}^{\mathbb{N}}$. We have

$$D(x,z) = \sup_{k\in\mathbb{N}}\{\tfrac{1}{k}\cdot d(x_k,z_k)\} \underset{\uparrow}{\leq} \sup_{k\in\mathbb{N}}\{\tfrac{1}{k}\cdot d(x_k,y_k) + \tfrac{1}{k}\cdot d(y_k,z_k)\} \underset{\uparrow}{\leq} D(x,y) + D(y,z).$$

follows from the straightforward observation that d is a metric

by definition of the supremum



⊞

[108] By the Points-in-Hausdorff Space Lemma 1.15 (1) this condition is satisfied if X is Hausdorff.

[109] By definition of d we see that the set $\{\frac{1}{k}\cdot d(x_k, y_k) \,|\, k \in \mathbb{N}\}$ is bounded by 1. It follows that the supremum does in fact exist.

It remains to prove the following claim.

Claim 2. The topology defined by the metric D equals the product topology on $\mathbb{R}^{\mathbb{N}}$.

Proof. First we show that the metric topology is contained in the product topology. Thus let $U \subset \mathbb{R}^{\mathbb{N}}$ be open in the metric topology. We want to show that U is open in the product topology. By the JH-Lemma 1.7 it suffices to show that for each $x \in U$ there exists a set V, which is open in the product topology, with $x \in V \subset U$. Note that since U is open in the metric topology we know that there exists an $\epsilon > 0$ with $B^D_\epsilon(x) \subset U$. We pick $n \in \mathbb{N}$ with $\frac{1}{n} < \epsilon$ and we set

$$V \;=\; (x_1 - \epsilon, x_1 + \epsilon) \times \cdots \times (x_n - \epsilon, x_n + \epsilon) \times \mathbb{R} \times \mathbb{R} \times \ldots \qquad \subset\; \mathbb{R}^{\mathbb{N}}.$$

It follows easily from the definitions that $V \subset B^D_\epsilon(x)$. By the above discussion we know that V is open in the product topology. Thus we have verified that U is open in the product topology.

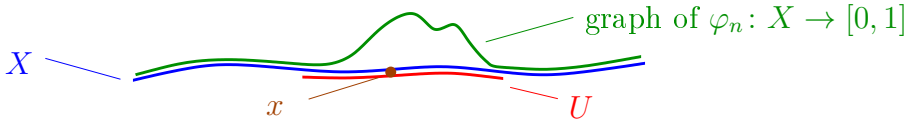
Now we need to show that the product topology is contained in the metric topology. By the Subbasis Lemma 1.28 it suffices to show that for each subset

$$U \;:=\; U_1 \times \cdots \times U_k \times \mathbb{R} \times \mathbb{R} \times \ldots \qquad (\text{where } U_1, \ldots, U_k \text{ are open sets in } \mathbb{R})$$

and each $x \in U$ there exists an open set V of the metric topology with $x \in V \subset U$. Note that since the U_i are open we know that for $i = 1, \ldots, k$ there exists a $\mu_i \in (0, 1)$ with $(x_i - \mu_i, x_i + \mu_i) \subset U_i$. We set

$$\epsilon \;:=\; \min\left\{\tfrac{\mu_1}{1}, \tfrac{\mu_2}{2}, \ldots, \tfrac{\mu_k}{k}\right\}.$$

It follows easily from the definitions that $V := B^D_\epsilon(x) \subset U$. ∎

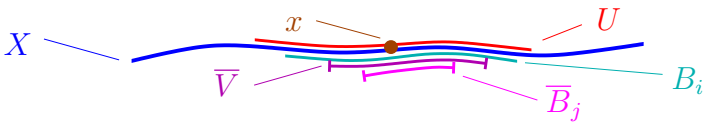


Now we can finally provide the proof of the Urysohn Metrization Theorem 9.4.

Proof of the Urysohn Metrization Theorem 9.4. Let X be a topological space which is second-countable. The "(2)⇒(1)"-direction is basically clear. Indeed, if X is metrizable, then it follows from Proposition 1.13 that X is Hausdorff which in turn implies by the Points-in-Hausdorff Space Lemma 1.15 (1) that every one-point subset is closed. Furthermore by the Metric Spaces-Normal Proposition 8.1 we know that X is normal.

We turn to the proof of the significantly more interesting "(1)⇒(2)"-direction. Thus we now assume that X is normal and that every one-point set is closed.

> The idea, at this stage not very surprising, is to attempt to find an embedding $\Phi\colon X \to \mathbb{R}^{\mathbb{N}}$ and to use the fact that by Proposition 9.5 we know that $\mathbb{R}^{\mathbb{N}}$ is metrizable. A map $\Phi\colon X \to \mathbb{R}^{\mathbb{N}}$ is basically the same as a sequence of maps $\{\varphi_n\colon X \to \mathbb{R}\}_{n\in\mathbb{N}}$.



Claim 1. There exists a family $\{\varphi_n\colon X \to [0,1]\}_{n\in\mathbb{N}}$ of maps with the following property: for each $x \in X$ and each open neighborhood U of x there exists an $n \in \mathbb{N}$ such that $\varphi_n(x) = 1$ and such that $\varphi_n|_{X\setminus U} \equiv 0$.

Proof. Since X is by hypothesis second-countable there exists a countable basis $\{B_j\}_{j\in J}$ for the topology of X. For every choice of $i, j \in J$ with $\overline{B}_i \subset B_j$ we can and will apply Urysohn's Lemma 8.4[110] to the disjoint closed subsets $\overline{B}_i$ and $X \setminus B_j$ and we obtain a map $g_{i,j}\colon X \to [0,1]$ with $g_{i,j}|_{\overline{B}_i} \equiv 1$ and $g_{i,j}|_{X\setminus B_j} \equiv 0$. Since J is countable we know by the Countability Lemma 0.8 that the set

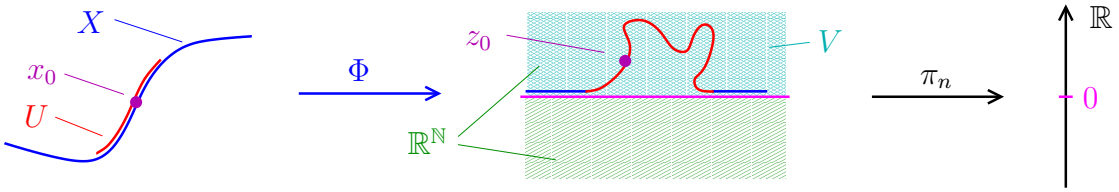
$$K \;:=\; \{(i,j) \in J \times J \,|\, \overline{B}_i \subset B_j\} \;\subset J \times J$$

is again countable, thus in bijection with a subset of $\mathbb{N}$. Therefore it remains to show that these maps $\{g_{i,j}\}_{(i,j)\in K}$ have the desired properties. Now let $x \in X$ and let U be a neighborhood of x. By definition of a basis of the topology there exists a $j \in J$ with $x \in B_j \subset U$. By hypothesis X is normal and every one-point subset is closed. Therefore we obtain from the Normal-Open-Closed-Neighborhood Lemma 8.2 an open subset V of X with $x \in V \subset \overline{V} \subset B_j$. By definition of a basis there exists an $i \in J$ with $x \in B_i \subset V$. But then we also have $\overline{B}_i \subset \overline{V} \subset B_j$. Note that the map $g_{i,j}$ satisfies $g_{i,j}(x) = 1$ and it vanishes on $X \setminus B_j$. From $B_j \subset U$ we obtain that $g_{i,j}$ vanishes in particular on $X \setminus U$. ⊞

We consider the product $\mathbb{R}^{\mathbb{N}} = \prod_{n\in\mathbb{N}} \mathbb{R}$, equipped with the product topology. By Proposition 9.5 we know that $\mathbb{R}^{\mathbb{N}}$ is metrizable. Thus it suffices to prove the following claim.

Claim 2. The map

$$\begin{array}{rccc} \Phi\colon & X & \to & \mathbb{R}^{\mathbb{N}} \\ & x & \mapsto & (\varphi_1(x), \varphi_2(x), \dots) \end{array}$$



is an embedding, i.e. it is a homeomorphism onto its image.

Proof. It follows immediately from the continuity of the φ_n and the Topological-Product Proposition 5.1 that Φ is continuous. Next we show that Φ is injective. Thus let $x \neq y$ be two points in X. Since X is normal and since each one-point set is closed there exists an open neighborhood U of x that does not contain y. By construction there exists an $n \in \mathbb{N}$ with $\varphi_n(x) = 1$ and with $\varphi_n(y) = 0$. This shows that Φ is injective.

We have now shown that Φ is an injective continuous map. We want to show that Φ is actually a homeomorphism onto its image. By the Open -Injective Map Lemma 2.16 it now suffices to show that Φ is an open map.

[110] Here we use our hypothesis that X is normal

Thus let $U \subset X$ be an open subset. We need to show that $\Phi(U)$ is open in $\Phi(X)$. By the JH-Lemma 1.7 it remains to show that for every $z_0 \in \Phi(U)$ there exists an open set $W \subset \Phi(U)$ with $z_0 \in W \subset \Phi(U)$. We pick $x_0 \in U$ with $\Phi(x_0) = z_0$. By construction there exists an $n \in \mathbb{N}$ with $\varphi_n(x_0) = 1$ and with $\varphi_n|_{X \setminus U} \equiv 0$. We denote by $\pi_n \colon \mathbb{R}^{\mathbb{N}} \to \mathbb{R}$ the projection onto the n-th coordinate. By the Topological-Product Proposition 5.1 we know that π_n is continuous.

We set $V := \pi_n^{-1}((0, \infty))$ and we set $W := V \cap \Phi(X)$. By definition of the subspace topology we know that W is open in $\Phi(X)$. It remains to show that $z_0 \in W$ and that $W \subset \Phi(U)$.

- It follows from $\pi_n(z_0) = (\pi_n \circ \Phi)(x_0) = \varphi_n(x_0) = 1 > 0$ that $z_0 \in W$.
- Let $z \in W$. We denote by $x \in X$ the unique element with $\Phi(x) = z$. Note that $\pi_n(z) = (\pi_n \circ \Phi)(x) = \varphi_n(x) > 0$. Since $\varphi_n|_{X \setminus U} \equiv 0$ we see that $x \in U$. In particular $z = \Phi(x) \in \Phi(U)$. ■

9.3. **Regular topological spaces.** It turns out that one can formulate the Urysohn Metrization Theorem 9.4 with an a priori weaker hypothesis. This weaker hypothesis is used in most formulations of the Urysohn Metrization Theorem 9.4 in the literature. Therefore, for completeness' sake we will discuss this weaker hypothesis, even though we will not really make use of the results of this section.
We start out with the following notion.

Definition. A topological space X is called regular if given any $x \in X$ and given any closed subset $A \subset X$ there exist disjoint open subsets U and V with $x \in U$ and $A \subset V$.

Remark.

(1) Note that in the definition of a regular topological space we do not demand, in contrast say to [**Mun1975**, p. 195], that one-point sets are closed.
(2) In Section 9.4 we will discuss the relationship between the various "separation axioms", i.e. between the notions "Hausdorff", "regular" and "'normal".

We have the following analogue of Lemmas 1.15 and 8.2.

Lemma 9.6. (Regular-Open-Closed-Neighborhood Lemma) Let X be a topological space, let $x \in X$ and let $U \subset X$ be an open neighborhood of x. If X is regular, then there exists an open subset V with $x \in V \subset \overline{V} \subset U$.

Proof. The proof of the lemma is almost identical to the proof of the Normal-Open-Closed-Neighborhood Lemma 8.2. For peace of mind we nonetheless provide the argument. Let U be an open neighborhood of x. We set $B := X \setminus U$. This is a closed subset with $x \notin B$. Since X is regular there exist disjoint neighborhoods V of x and W of B. It remains to show that $\overline{V} \subset U$. In fact we have $V \subset X \setminus W \subset U$. But since W is open we know that $X \setminus W$ is closed. By definition of $\overline{V}$ we have $\overline{V} \subset X \setminus W$. ■

The following proposition, together with the previous remark shows that for a large class of topological spaces the notions of being regular and normal coincide.

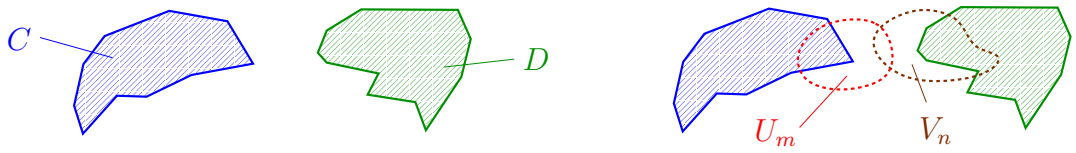
Proposition 9.7. Let X be a topological space. If X is regular and if X is second-countable, then X is also normal.

Proof. Let X be a topological space that is regular and that is second-countable. The latter condition means that there exists a countable basis $\{B_j\}_{j\in J}$ for the topology of X. Now let C and D be two disjoint closed subsets of X.

Claim 1. There exist open subsets $\{U_m\}_{m\in\mathbb{N}}$ such that $C \subset \bigcup_{m\in\mathbb{N}} U_m \subset \bigcup_{m\in\mathbb{N}} \overline{U}_m \subset X \setminus D$.

Proof. Since J is countable we know that the set $\{j \in J \,|\, \overline{B}_j \subset X\setminus D\} \subset J$ is also countable. It remains to show that the union of the corresponding B_j covers C. Thus let $c \in C$. Since X is regular and since D is closed we know by the Regular-Open-Closed-Neighborhood Lemma 9.6 that there exists an open neighborhood U of c such that $\overline{U} \subset X \setminus D$. By definition of a basis of the topology there exists a $j \in J$ with $c \in B_j \subset U$. By construction $\overline{B}_j \subset \overline{U} \subset X \setminus D$, thus j lies in the given index set. ⊞

We swap the roles of C and D in the previous claim and we obtain open subsets $\{V_n\}_{n\in\mathbb{N}}$ such that $D \subset \bigcup_{n\in\mathbb{N}} V_n \subset \bigcup_{n\in\mathbb{N}} \overline{V}_n \subset X \setminus C$. Note that we do not know whether $\bigcup_{m\in\mathbb{N}} U_m$ and $\bigcup_{n\in\mathbb{N}} V_n$ are disjoint. Thus we have to go into extra time and do some more work. Given $m, n \in \mathbb{N}$ we now set



$$\widetilde{U}_m \;:=\; U_m \;\setminus\; \underbrace{\bigcup_{i=1}^{m} \overline{V}_i}_{\substack{\textit{finite}\text{ union of}\\ \text{closed subsets}}} \qquad \text{and} \qquad \widetilde{V}_n \;:=\; V_n \;\setminus\; \underbrace{\bigcup_{i=1}^{n} \overline{U}_i}_{\substack{\textit{finite}\text{ union of}\\ \text{closed subsets}}}.$$

Since the *finite* union of closed subsets is closed we see that the subsets $\widetilde{U}_m$ and $\widetilde{V}_n$ are open. Furthermore, since each $\overline{V}_i$ is disjoint from C we see that the $\widetilde{U}_m$ cover C. Similarly we see that the $\widetilde{V}_n$ cover D. It remains to prove the following claim.

Claim 2. The open sets $\bigcup_{m\in\mathbb{N}} \widetilde{U}_m$ and $\bigcup_{n\in\mathbb{N}} \widetilde{V}_n$ are disjoint.

Proof. It suffices to show that for each $m, n \in \mathbb{N}$ we have $\widetilde{U}_m \cap \widetilde{V}_n = \varnothing$. If $m \leq n$, then we have by construction that even $\widetilde{U}_m \cap \overline{V}_n = \varnothing$. Similarly, if $n \leq m$, we have by construction that even $\widetilde{V}_n \cap \overline{U}_m = \varnothing$. ■

Now we can give the standard formulation of the Urysohn Metrization Theorem.

Theorem 9.8. (Urysohn Metrization Theorem) Let X be a topological space. If X is second-countable, the following two statements are equivalent:

(1) X is regular and every one-point subset is closed.
(2) X is metrizable.

Proof. Let X be a topological space which is second-countable.

First we consider again the basically trivial "(2)⇒(1)"-direction. If X is metrizable, then it follows from Proposition 1.13 that X is Hausdorff which in turn implies by the Points-in-Hausdorff Space Lemma 1.15 (1) that every one-point subset is closed. Furthermore by the Metric Spaces-Normal Proposition 8.1 we know that X is normal. Since one-point subsets are closed this also implies that X is regular.

Now we consider the "(1)⇒(2)"-direction. Thus we assume that X is regular and that every one-point subset is closed. Since X is second-countable it follows from Proposition 9.7 that X is normal. Thus it follows from the "(1)⇒(2)"-direction of the original Urysohn Metrization Theorem 9.4 that X is metrizable. ■

The Urysohn Metrization Theorems 9.4 and 9.8 give a satisfactory characterization of metrizable topological spaces among all second-countable topological spaces.

For completeness' sake we state the following theorem which gives, rather astonishingly, a complete characterization of metrizable topological spaces among all topological spaces:

Theorem 9.9. (Nagata-Smirnov Metrization Theorem) Let X be a topological space. The following two statements are equivalent:

(1) X is metrizable.
(2) The following three conditions are satisfied:
  (a) X is regular.
  (b) X is Hausdorff.
  (c) The topology of X admits a basis that is the union of countably many locally finite families of subsets of X.In other words, there exists a countable set I and for each $i \in I$ there exists a locally finite family $\mathcal{B}_i$ of subsets of X such that $\bigcup_{i\in I}\mathcal{B}_i$ is a basis for the topology of X.

Remark. The theorem was proved independently by Junichi Nagata [**Naga1950**] and Yurii Smirnov [**Smi1951**]. A variation on the metrization theorem was proved by R. H. Bing [**Bin1951**].[111]

Example.

[111]The first and middle name of Bing are "R." and "H.".

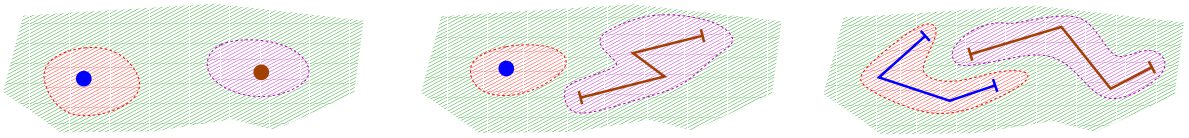
(1) Let X be a topological space that is second-countable, i.e. it admits a countable basis $\{U_i\}_{i\in I}$ of the topology. We set $\mathcal{B}_i := \{U_i\} \subset \mathcal{P}(X)$ and we see that condition (c) is satisfied. This shows that the Nagata-Smirnov Metrization Theorem 9.9 implies the Urysohn Metrization Theorem 9.8.

(2) Let X be a set that is equipped with the discrete topology. The family of all one-point subsets is locally finite. Thus, if we set $I := \{*\}$ and $\mathcal{B}_* := \{\{x\}\}_{x\in X}\}$, then we see that X satisfies Properties (a), (b) and (c), thus X is metrizable. In fact in this case it is easy to provide an explicit example of a metric, namely we just need to consider the discrete metric that is given by

$$d(x,y) \;:=\; \begin{cases} 0, & \text{if } x = y, \\ 1, & \text{if } x \neq y. \end{cases}$$

Proof. Despite its beauty we will not make use of the Nagata-Smirnov Metrization Theorem. We use this as an excuse for not providing the proof. The theorem is of course proved in the original sources [**Naga1950**] and Yurii Smirnov [**Smi1951**]. A textbook proof is given in [**Mun1975**, Chapters 6.2 and 6.3], [**Enge1989**, Theorem 4.4.7] and [**Pat2009**, Chapter 7.3]. ■

9.4. **Separation Axioms.** We have now introduced the properties of being Hausdorff, normal and regular. Each such property states to what degree points and closed subsets can be separated by open subsets. The limitless imagination of mathematicians has produced many variations on these separation axioms. In this section we will state, for reference, several other time-honored separation axioms, even though we will not really make use of the axioms that we introduce in this section.



Definition. Let X be a topological space. Let A and B be two subsets of X. We say A and B are separated by subsets U and V if $A \subset U$ and $B \subset V$ and if $U \cap V = \varnothing$. We use the obvious extensions of these definitions if we are dealing with points instead of subsets.

With these definitions we can reformulate the definitions of being "Hausdorff", "regular" and "normal":

(1) A topological X is *Hausdorff* precisely if any two distinct points can be separated by open neighborhoods.

(2) A topological X is *regular* precisely if every point x can be separated from every closed subset A with $x \notin A$ by open neighborhoods.

(3) A topological X is *normal* if any two disjoint closed subsets of X can be separated by open neighborhoods.

Hausdorff regular normal

Definition. Let X be a topological space. Let A and B be two subsets of X.

(1) We say that A and B are separated by a map if there exists a continuous map $f\colon X \to \mathbb{R}$ such that $f|_A \equiv 0$ and $f|_B \equiv 1$.

(2) We say that A and B are precisely separated by a map if there exists a continuous map $f\colon X \to \mathbb{R}$ such that $f^{-1}(0) = A$ and $f^{-1}(1) = B$.

We use the obvious extensions of these definitions if we are dealing with points instead of subsets.

By Urysohn's Lemma 8.4 we know that given a topological space X the following two statements are equivalent:

(1) Any two disjoint closed subsets can be separated by open neighborhoods.
(2) Any two disjoint closed subsets can be separated by maps.

It is less clear whether these statements are equivalent to the following statement:

(3) Any two disjoint closed subsets can be *precisely* separated by maps.

This leads us to the following refinement of the notion of being normal.

Definition. A topological space is called perfectly normal if any disjoint closed subsets can be precisely separated by a map.

Example. In the proof of the Metric Spaces-Normal Proposition 8.1 we implicitly showed that metric spaces are perfectly normal.

For some purposes it is convenient to work with a reformulation of being "perfectly normal and Hausdorff". To do so we will need the following definition.

Definition. Let X be a topological space. We say a subset is a G_δ-subset if it is the intersection of countably many open subsets.

Lemma 9.10. Let X be a Hausdorff space. The following three statements are equivalent:

(1) X is perfectly normal.
(2) For every closed subset $A \subset X$ there exists a map $f\colon X \to [0,1]$ with $A = f^{-1}(0)$.
(3) X is normal and every closed subset of X is a G_δ-subset.

Remark. In many, arguably most, textbooks, e.g. [**Kel1975**, p. 134], [**SS1978**, p. 16] and [**Jos1983**, p. 187], the characterization of Lemma 9.10 (3) is used for the definition of a perfectly normal topological space.

Proof. First we prove the "(1)⇒(2)"-direction. Let A be some closed subset of X. If $A = X$, then we can take f to be the constant map. Now suppose that $A \subsetneq X$. We pick $x \in X \setminus A$. Since X is Hausdorff we know by the Points-in-Hausdorff Space Lemma 1.15 that $\{x\}$ is a closed subset. Since X is perfectly normal there exists a map $f\colon X \to [0,1]$ with $A = f^{-1}(0)$ and with $\{x\} = f^{-1}(1)$.

We turn to the proof of the "(2)⇒(1)"-direction. Let A and B be two disjoint closed subsets. By hypothesis there exists a map $f\colon X \to [0,1]$ with $A = f^{-1}(0)$ and a map $g\colon X \to [0,1]$ with $B = g^{-1}(0)$. Since A and B are disjoint we see that for every $x \in X$ we have $f(x) + g(x) > 0$. As in the proof of the Metric Spaces-Normal Proposition 8.1 we can consider the map

$$\begin{array}{rccc} h\colon & X & \to & [0,1] \\ & x & \mapsto & \dfrac{f(x)}{f(x)+g(x)}. \end{array}$$

Evidently $A = h^{-1}(0)$ and $B = h^{-1}(0)$.

Next we prove the "(2)⇒(3)"-direction. It follows from the "(2)⇒(1)"-direction that X is normal. Thus it suffices to prove that every closed subset of X is a G_δ-subset. Now let A

be a closed subset of X. By hypothesis there exists a map $f\colon X \to [0,1]$ with $A = f^{-1}(0)$. We now see that

$$A \;=\; f^{-1}(0) \;=\; f^{-1}\Big(\bigcap_{n\in\mathbb{N}} [0,\tfrac{1}{n})\Big) \;=\; \bigcap_{n\in\mathbb{N}} \underbrace{f^{-1}([0,\tfrac{1}{n}))}_{\text{open subset of } X}.$$

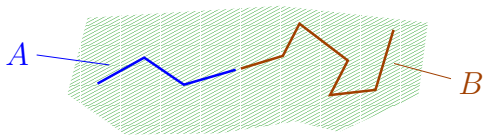
Image-Preimage Lemma 0.2 (7)

Finally we provide the proof of the "(3)⇒(2)"-direction. Thus we assume that X is normal and we assume that every closed subset of X is a G_δ-subset. Let A be a closed subset of X. By hypothesis there exists a countable family $\{U_n\}_{n\in\mathbb{N}}$ of open subsets such that $A = \bigcap_{n\in\mathbb{N}} U_n$. Let $n \in \mathbb{N}$. Since X is normal and since A and $X \setminus U_n$ are disjoint we obtain from Urysohn's Lemma 8.4 a continuous map $f_n\colon X \to [0,1]$ with $f_n|_A \equiv 0$ and $f_n|_{X\setminus U_n} \equiv 1$. It follows from Proposition 6.12 that the map

$$\begin{aligned} f\colon X &\to [0,1] \\ x &\mapsto \sum_{n\in\mathbb{N}} \frac{1}{2^n}\cdot f_n(x) \end{aligned}$$

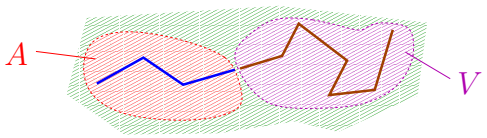
is continuous. Furthermore note that

$$X \setminus A \;=\; X \setminus \bigcap_{n\in\mathbb{N}} U_n \;=\; \bigcup_{n\in\mathbb{N}} \underbrace{(X\setminus U_n)}_{\text{here } f_n \equiv 1}.$$



It follows almost immediately from this observation that $f^{-1}(0) = A$. ■

Since this was so much fun we want to introduce one more variation on being normal. For this we need the following definition.

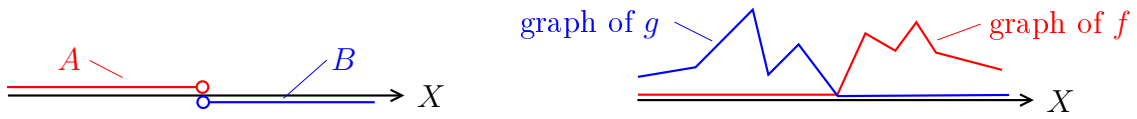


Definition. Let X be a topological space. We say two subsets A and B are separate if $A \cap \overline{B} = \varnothing$ and if $\overline{A} \cap B = \varnothing$.[112]

Example. Let $X = \mathbb{R}$. The subsets $A = (-1,0)$ and $B = (0,1)$ are separate.

Definition. A topological space is called completely normal if separate subsets are separated by open neighborhoods.

A and B are separate



completely normal

Lemma 9.11. Let X be a topological space. If X is perfectly normal, then it is also completely normal.

Proof. Let X be a perfectly normal Hausdorff space and let A and B be two separate subsets of X. By Lemma 9.10 and the Interior-Closure Lemma 1.9 (2) there exist maps $f\colon X \to [0,1]$ and $g\colon X \to [0,1]$ with $f^{-1}(0) = \overline{A}$ and $g^{-1}(0) = \overline{B}$. We consider the map $h = f - g$. By construction $A \subset h^{-1}((-\infty,0))$ and $B \subset h^{-1}((0,\infty))$. ■

[112] Evidently disjoint closed subsets are separate.

Definition. Let X be a topological space. We say two points x and y are topologically indistinguishable if x and y have the same neighborhoods, i.e. if a subset $U \subset X$ is a neighborhood of x if and only if it is a neighborhood of y. Otherwise we say that the points are topologically distinguishable.

Example. If X is a set that is equipped with the trivial topology $\{\varnothing, X\}$, then any two points are topologically indistinguishable.

We can now formulate the following hierarchy of separations axioms, which has its origins in the work of Heinrich Tietze [**Tie1923**].[113]

Definition. Given a topological space X we introduce the following separability axioms:

T_0	Kolmogorov	distinct points are topologically distinguishable
T_1	Fréchet	every one-point subset is closed
T_2	Hausdorff	distinct points are separated by open neighborhoods
$T_{2\frac{1}{2}}$	Urysohn	distinct points are separated by closed neighborhoods
T_3	regular Hausdorff	X is Hausdorff & every point x is separated from any closed subset A with $x \notin A$ by open neighborhoods
$T_{3\frac{1}{2}}$	Tychonoff	X is Hausdorff & every point x is separated from every closed closed subset A with $x \notin A$ by a map
T_4	normal Hausdorff	X is Hausdorff & disjoint closed subsets are separated by open neighborhoods
T_5	completely normal Hausdorff	X is Hausdorff & separate subsets are separated by open neighborhoods
T_6	perfectly normal Hausdorff	X is Hausdorff & disjoint closed subsets are precisely separated by a map.

We say X is a T_i-space if the corresponding condition is satisfied.

Remark.

(1) Note that the definitions can differ slightly in the literature, for example in [**vQu2001**, Chapter 6] and in [**SS1978**, Section 2] the T_3 and the T_4-axiom is stated without the Hausdorff condition. The advantage of the above definition is that the separability axioms are increasingly stronger. More precisely, in Proposition 9.12 we will see that for T_i and T_j in the list with $i < j$ every T_j-space is also a T_i-space.

(2) In Exercise 9.18 we give an alternative characterization of complete normal Hausdorff spaces.

[113] The "T" in the names of the separation axioms goes back to the German word "Trennungsaxiom".

Proposition 9.12. For every two axioms T_i and T_j with $i < j$ in the above definition the following holds:

(1) If a topological space is a T_j-space, then it is also a T_i-space.
(2) There exists a topological space that is T_i but not T_j.

Remark. Proposition 9.12 says in particular that the obvious analogue of Urysohn's Lemma 8.4 for regular spaces does *not* hold. More precisely, Proposition 9.12 says in particular that there exists a topological space X which satisfies T_3 but does not satisfy $T_{3\frac{1}{2}}$. In plain English this means that the topological space X has the following two properties:

(1) X is regular space X and every one-point subset is closed.
(2) There exists a point $x \in X$ and a closed subset $A \subset X$ with $x \notin A$ such that there is no continuous map $f\colon X \to \mathbb{R}$ with $f(x) = 0$ and $f|_A \equiv 1$.

Proof.

(1) In the Points-in-Hausdorff Space Lemma 1.15 we showed that in a Hausdorff space every one-point subset is closed. In most cases this shows that for $i < j$ a T_j-space is also a T_i-space. The implications "$T_6 \Rightarrow T_5$" and "$T_{3\frac{1}{2}} \Rightarrow T_3$" rely on the simple observation, which we already used in the easy direction of Urysohn's Lemma 8.4, that if two subsets can be separated by a map, then they can also be separated by open subsets. Perhaps the only implication which is not entirely obvious is why a T_6-space is a T_5-space. Fortunately this implication follows immediately from Lemma 9.11.
(2) The following list of examples, exercises and references provides us with the promised topological spaces:

T_0	but not	T_1	Sierpiński space, see Exercise 2.22
T_1	but not	T_2	line with two zeros, see page 122
T_2	but not	$T_{2\frac{1}{2}}$	see Exercise 9.15
$T_{2\frac{1}{2}}$	but not	T_3	see Exercise 9.16 or alternatively Exercise 8.3
T_3	but not	$T_{3\frac{1}{2}}$	see [**SS1978**, Example 91]
$T_{3\frac{1}{2}}$	but not	T_4	see Exercise 9.17
T_4	but not	T_5	see [**SS1978**, Examples 87 and 105]
T_5	but not	T_6	see [**SS1978**, Example 32].

Many more examples regarding these and other separation axioms are discussed in [**SS1978**], which is a never-ending source of amusing topological spaces. ■

Exercises for Chapter 9.

Exercise 9.1. Let X be a topological space. Show that if X is second-countable, then X has only countably many components.

Exercise 9.2. Let X be a topological space. Show that if X is second-countable, then every locally finite open cover $\{U_i\}_{i\in I}$ of X is countable.

Exercise 9.3. Let $n \in \mathbb{N}$. We equip $\mathbb{R}^n$ with the standard topology $\mathcal{T}$.

(a) Show that the open balls with rational centers and rational radii, i.e. the set

$$\mathcal{C} \;:=\; \{B_r^n(q) \,|\, r \in \mathbb{Q}_{\geq 0} \text{ and } q \in \mathbb{Q}^n\},$$

is a basis for the topological space $\mathbb{R}^n$.

(b) Use (a) to show that for the cardinality of $\mathcal{T}$ we have $\#\mathcal{T} \leq \#\mathcal{P}(\mathbb{Q})$.

(c) Use the Bernstein-Schröder Theorem 0.11 to show that $\#\mathcal{T} = \#\mathcal{P}(\mathbb{Q})$.

Remark. By Exercise 0.10 we know that $\#\mathcal{P}(\mathbb{Q}) = \#\mathbb{R}$ and by Exercise 0.10 we know that $\#\mathbb{R} < \#\mathcal{P}(\mathbb{R})$. Evidently $\#\mathcal{P}(\mathbb{R}) \leq \#\mathcal{P}(\mathbb{R}^n)$. In summary we have thus shown that $\#\mathcal{T} < \#\mathcal{P}(\mathbb{R}^n)$. Informally speaking this means that open sets are "rare" among all subsets of $\mathbb{R}^n$.

Exercise 9.4. Given a non-empty subset $I \subset \mathbb{R}$ we denote by $C^b(I, \mathbb{R})$ the set of all bounded continuous maps $I \to \mathbb{R}$ and given $f \in C^b(I, \mathbb{R})$ we set

$$\|f\| \ := \ \sup\{|f(x)| \,|\, x \in I\}.$$

Note that $(C^b(I, \mathbb{R}), \|-\|)$ is a metric space. We will equip $C^b(I, \mathbb{R})$ with the corresponding topology.

(a) Show that if I is a compact interval, then $C^b(I, \mathbb{R})$ is second-countable.

(b) Show that if I is a non-compact interval, then $C^b(I, \mathbb{R})$ is not second-countable.

Exercise 9.5. Let X be a topological space that admits a compact exhaustion $\{P_i\}_{i\in\mathbb{N}}$ in the sense of the definition of page 338. Suppose that X is connected. Show that there exists also a compact exhaustion $\{Q_i\}_{i\in\mathbb{N}}$ such that each Q_i is connected.

Exercise 9.6. Let I be an uncountable set. Show that $[0, 1]^I$ is not second-countable.
Remark. By the Tychonoff Theorem 5.9 we know that $[0, 1]^I$ is compact. Thus the exercise shows that there exist compact spaces that are not second-countable.

Exercise 9.7. Let $S := (\mathbb{R}, \mathcal{T})$ be the Sorgenfrey line that we introduced on page 182. Show that the Sorgenfrey line is not second-countable.

Exercise 9.8. A topological space is called *separable* if it admits a subset that is countable and dense.

(a) Show that every second-countable topological space is separable.

(b) Let X be a set. We equip X with the cofinite topology that we defined on page 108.
(i) Show that X is separable.
(ii) Suppose that X is uncountable. Show that X is not second-countable.
Remark. This example is taken from [**SS1978**, Example 19].

(c) Let X be a topological space that is separable *and* Hausdorff. Show that X is second-countable.

Exercise 9.9. A topological space is called *separable* if it admits a subset that is countable and dense.

(a) Show that the Sorgenfrey line S, which we introduced on page 182, and the Sorgenfrey plane $S \times S$ are separable.

(b) Show that the diagonal $\Delta = \{(x, x) \in S \times S \,|\, x \in S\}$ is not separable.
Hint. Use Exercise 5.13.

Remark. This exercise shows that in general separability is not inherited by subsets.

Exercise 9.10. Let (X, d) be a metric space. Show that the corresponding topological space is second-countable if and only if X admits a countable dense subset.

Exercise 9.11. Show that every regionally compact Hausdorff space is regular.

Exercise 9.12. Let X be the *Sierpiński space* which we introduced on page 186, i.e. let $X = \{0,1\}$ be the set with two elements which we equip with the topology $\mathcal{T} = \{\varnothing, X, \{0\}\}$. Show that X is regular and show that X is not normal.

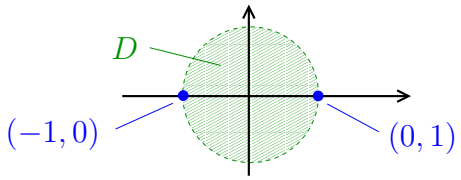
Exercise 9.13. Show that the product of two regular topological spaces is again regular.
Remark. Together with Exercise 8.6 we see that the Sorgenfrey plane is regular but not normal. One can easily show that the Sorgenfrey plane is Hausdorff. Thus we see that the Sorgenfrey plane is an example of a topological space that is T_3 but not T_4.

Exercise 9.14. Provide an example of a topological space that is not T_0.

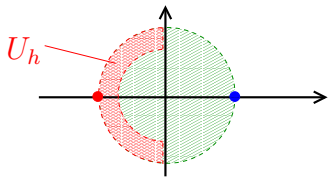
Exercise 9.15. Let $D := B_1^2(0) \subset \mathbb{R}^2$ be the open disk of radius 1 centered on the origin and let

$$X \;:=\; D \cup \{(-1,0)\} \cup \{(0,1)\}.$$

We equip X with the topology that is generated by the following subsets:



- For every $P \in D$ and every $r > 0$ we consider $B_r^2(P) \cap X$.
- For every $h \in (0,1)$ we consider the sets



$$\begin{aligned} U_h &:= \{(x,y) \in D \,|\, x < 0 \text{ and } x^2 + y^2 > h\} \cup \{(0,-1)\} \\ V_h &:= \{(x,y) \in D \,|\, x > 0 \text{ and } x^2 + y^2 > h\} \cup \{(0,1)\}. \end{aligned}$$

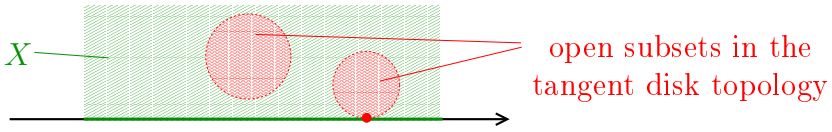
The following two exercises show that $(X, \mathcal{T})$ is T_2 but not $T_{2\frac{1}{2}}$.

(a) Show that $(X, \mathcal{T})$ is Hausdorff.
(b) Show that the points $(0,-1)$ and $(0,1)$ cannot be separated by closed neighborhoods.

Remark. This exercise also solves Exercise 1.17.

Exercise 9.16. We set $K := \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$. As in Exercise 2.51 we define the *K-topology* on $\mathbb{R}$ as the topology $\mathcal{K}$ that is generated by the open intervals (a,b) and by all sets of the form $(a,b) \setminus K$ where $a, b \in \mathbb{R}$.

(a) Show that $(\mathbb{R}, \mathcal{K})$ is Hausdorff.
(b) Show that $(\mathbb{R}, \mathcal{K})$ is Urysohn.
(c) Show that $(\mathbb{R}, \mathcal{K})$ is not regular.
Hint. First show that K is closed in $(\mathbb{R}, \mathcal{K})$.



Remark. The exercises show that $(\mathbb{R}, \mathcal{K})$ is $T_{2\frac{1}{2}}$ but not T_3.

Exercise 9.17. We consider the upper half-plane $X := \{(x,y) \in \mathbb{R}^2 \,|\, y \geq 0\}$ together with the *tangent disk topology* $\mathcal{D}$, i.e. the topology which is generated by the usual open disks $B_r(x,y)$ with $r < y$ and the subsets $B_y(x,y) \cup \{(0,x)\}$.

(a) Show that $(X, \mathcal{D})$ is Hausdorff.
(b) Show that $(X, \mathcal{D})$ is Tychonoff.

(c) Show that $(X, \mathcal{D})$ is not normal.
Hint. Show that $\{(x,0) \mid x \in \mathbb{Q}\}$ and $\{(x,0) \mid x \notin \mathbb{Q}\}$ are closed subsets.

Remark. The exercises show that $(X, \mathcal{D})$ is $T_{3\frac{1}{2}}$ but not T_4.

Exercise 9.18. Let X be a Hausdorff space. Show that the following two statements are equivalent:

(1) X is T_5, i.e. X is completely normal and Hausdorff.
(2) X is *hereditarily normal*, i.e. if every subspace of X is normal.

Exercise 9.19. Let X be a perfectly normal topological space and let $A \subset X$ be a closed subset. By Lemma 9.10 we know that if X is Hausdorff, then there exists a map $f\colon X \to [0,1]$ with $A = f^{-1}(0)$. Do we need the hypothesis that X is Hausdorff?

Exercise 9.20. We consider the set

$$H \;:=\; \prod_{n\in\mathbb{N}} [0, \tfrac{1}{n}] \;=\; \big\{(x_1, x_2, \dots) \,\big|\, \text{for every } n \in \mathbb{N} \text{ we have } x_n \in [0, \tfrac{1}{n}]\big\}$$

with the metric

$$d(x,y) \;:=\; \sqrt{\sum_{n=1}^{\infty} (x_n - y_n)^2}.$$

This metric space, and the corresponding topological space, are called the *Hilbert Cube*.

(a) Show that d is defined, i.e. show that the series converges and show that d does indeed define a metric on H.
(b) Show that the Hilbert Cube, viewed as a topological space, is homeomorphic to the product space $[0,1]^{\mathbb{N}}$.
Remark. By Tychonoff's Theorem 5.9 this implies that the Hilbert Cube is compact.
(c) Let X be a metric space that is second-countable.[114] Show that there exists an embedding $f\colon X \to H$ of topological spaces.
Hint. Reread the proof of the Urysohn Metrization Theorem 9.4.
Remark. Statements (b) and (c) imply that any second-countable metric space admits an embedding, as a topological space, into a *compact* metrizable topological space.
(d) Show that every compact second-countable topological space is homeomorphic to a closed subset of the Hilbert Cube.

Exercise 9.21. Let X be a compact metrizable space.

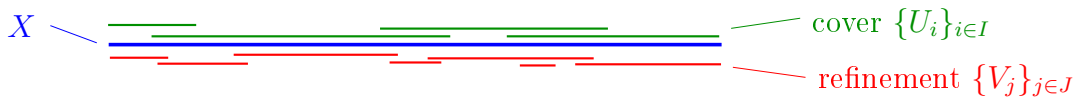
(a) Show that X is second-countable.
Hint. Use the fact that given any $n \in \mathbb{N}$ there exists a finite subset $A_n \subset X$ with $\bigcup_{a\in A_n} B_{\frac{1}{n}}(a) = X$.

(b) Show that X is regionally compact.

[114] In Exercise 9.8 we showed that a metric space is second-countable if and only if it is separable. With this reformulation Statement (c) is commonly used in the literature.

10. Paracompact spaces and partitions of unity

10.1. **Paracompact spaces.** We recall the following definitions from page 114.

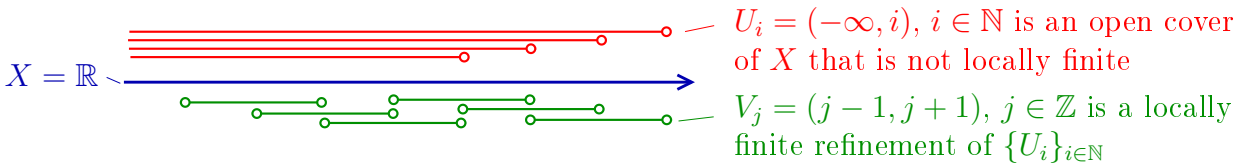


Definition. Let X be a topological space.

(1) A cover of a subset $A \subset X$ is a family $\{U_i\}_{i\in I}$ of subsets of X with $A \subset \bigcup_{i\in I} U_i$.
(2) We say a cover $\{U_i\}_{i\in I}$ is open if each U_i is open.
(3) We say a family $\{U_i\}_{i\in I}$ of subsets is locally finite if each $x \in X$ admits an open neighborhood W such that $\{i \in I \,|\, U_i \cap W \neq \varnothing\}$ is finite.

We add one and a half definitions in the context of covers.

Definition. Let X be a topological space and let $\{U_i\}_{i\in I}$ and $\{V_j\}_{j\in J}$ be two covers of X.



(1) We say that $\{V_j\}_{j\in J}$ is a refinement of $\{U_i\}_{i\in I}$ if each V_j is contained in some U_i.
(2) If furthermore each V_j is open, then we say that $\{V_j\}_{j\in J}$ is an open refinement of $\{U_i\}_{i\in I}$.

Now we can give the key definition of this chapter, which was introduced by Jean Dieudonné in [**Die1944**, p. 66].

Definition. A topological space is called paracompact if every open cover admits a locally finite open refinement.

Remark. Many books, e.g. [**Bre1993**, Definition I.12.3] and [**Kel1975**, p. 156] demand that a paracompact space is also Hausdorff.

As the name suggests, paracompact spaces are somewhat related to compact spaces. It is clear that a compact space is paracompact. The following lemma gives a useful example of a topological space that is not compact, but which is nonetheless paracompact.

Lemma 10.1. For every $n \in \mathbb{N}_0$ the topological space $\mathbb{R}^n$ is paracompact.

Proof. Let $\{U_i\}_{i\in I}$ be an open cover of $\mathbb{R}^n$. Let $m \in \mathbb{N}$. We consider

$$\begin{aligned} \text{the closed annulus} \quad A_m &:= \{x \in \mathbb{R}^n \,|\, m \leq \|x\| \leq m+1\} \\ \text{the open annulus} \quad W_m &:= \{x \in \mathbb{R}^n \,|\, m-1 < \|x\| < m+2\}. \end{aligned}$$

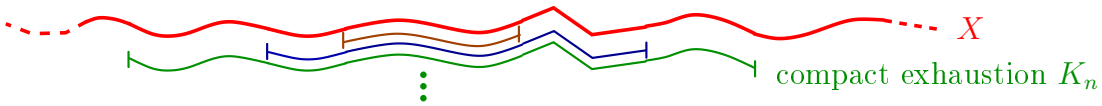
By the Heine-Borel Theorem 1.24 we know that A_m is compact. Therefore there exists a finite subset $J_m \subset I$ such that the sets $\{U_j\}_{j\in J_m}$ form an open cover of A_m. One can now easily verify that

$$\{W_m \cap U_j\}_{m\in\mathbb{N}_0, j\in J_m}$$

is a locally finite open refinement of the open cover $\{U_i\}_{i\in I}$. ∎

In fact, according to the principle "what properties of $\mathbb{R}^n$ did we really use?" we can generalize the above lemma to the following statement.

Lemma 10.2. (Paracompact-Criterion Lemma) Let X be a topological space. If X is second countable, Hausdorff and regionally compact, then X is also paracompact.



Remark. It follows from the discussion on pages 178 and 228 that Lemma 10.1 is actually a special case of the Paracompact-Criterion Lemma 10.2.

Proof. Let X be a topological space that is second countable, Hausdorff and regionally compact. We want to show that X is paracompact. Thus let $\{U_i\}_{i\in I}$ be an open cover of X.

By the Compact Exhaustion Lemma 9.3 (1) there exists a sequence of compact subsets $\{K_n\}_{n\in\mathbb{N}}$ of X such that the following two conditions are satisfied:

(1) for every $n \in \mathbb{N}$ we have $K_n \subset \overset{\circ}{K}_{n+1}$,
(2) we have $X = \bigcup_{n\in\mathbb{N}} K_n$.

We set $K_0 = \varnothing$. Let $n \in \mathbb{N}$. Since K_n is compact we obtain from the elementary the

Compact Subspace Covering Lemma 1.19 that there exists a finite subset $J_n \subset I$ such that the sets $\{U_j\}_{j\in J_n}$ form an open cover of K_n. One can now easily verify that[115]

$$\{(\overset{\circ}{K}_{n+1} \setminus K_{n-1}) \cap U_j\}_{n\in\mathbb{N}, j\in J_n}$$

is a locally finite open refinement of the open cover $\{U_i\}_{i\in I}$. ■

The following lemma can be viewed as an analogue of the Compact-Closed Lemma 1.21 (1). In combination with Lemmas 10.1 and 10.2 this new lemma gives us already a long list of paracompact spaces.

Lemma 10.3. (Closed Subset-Paracompact Lemma) Let X be a paracompact space. Every closed subset of X is also paracompact.

Remark. As is shown in [**Mun1975**, p. 254], in general a subspace of a paracompact space need not be paracompact.

Proof. The proof of the Closed Subset-Paracompact Lemma 10.3 is almost identical to the proof of the Compact-Closed Lemma 1.21 (1). Indeed, let X be a paracompact space and let $A \subset X$ be a closed subset. Let $\{U_i\}_{i\in I}$ be an open cover of A. By definition of the subspace topology there exists for each $i \in I$ an open subset V_i of X such that $U_i = V_i \cap A$. Since A is a closed subset of X we see that $\{V_i\}_{i\in I}$ together with $X \setminus A$ is an open cover of X. Since X is paracompact there exists a locally finite open refinement $\{W_j\}_{j\in J}$ of this cover of X. Evidently $\{W_j \cap A\}_{j\in J}$ is a locally finite open refinement of our original cover $\{U_i\}_{i\in I}$ of A. ■

[115] Since K_{n-1} is compact and since X is Hausdorff we obtain from the Compact-Closed Lemma 1.21 that K_{n-1} is a closed subset. Thus it follows that $\overset{\circ}{K}_{n+1} \setminus K_{n-1}$ is an open subset of X.

We conclude our initial list of examples of paracompact spaces with the following difficult theorem. We will not make use of it and thus we will not provide the proof.

Theorem 10.4. (Stone's Theorem) Every metric space is paracompact.

Proof. The theorem was first proved by Arthur Stone [**Stone1948**] in 1948. A much shorter proof can be found in [**RudiM1969**]. Alternatively a proof is given in [**Mun1975**, Theorem 41.4]. ■

Remark. As we will see, most topological spaces that are of interest to us, are in fact paracompact. For example we just saw that Stone's Theorem shows that metrizable topological spaces are paracompact. Furthermore in the Manifold Paracompact-Normal Proposition 18.9 (1) we will see, using the Paracompact-Criterion Lemma 10.2 that "topological manifolds" are paracompact. Furthermore in the CW-Complex Paracompactness Proposition 68.13 and in the Simplicial-Implies-CW Lemma 93.24 we will see that "CW-complexes" and "simplicial complexes" are paracompact. Nonetheless, elementary topological psychology tells us that surely not every topological space is paracompact. Indeed in Proposition 22.14 we will see that the "long line", that we will define on page 613, is not paracompact.

Next we recall the following definition from page 123.

Definition. A topological space X is called normal if any two disjoint closed subsets A and B of X are separated by open neighborhoods, i.e. if there exist disjoint open neighborhoods U of A and V of B.

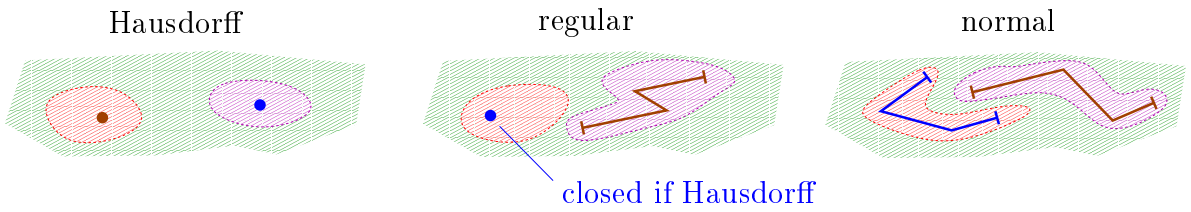
In the Compact Hausdorff Spaces-Normal Lemma 1.16 (2) we showed that every compact Hausdorff space is normal. The following theorem, which is originally due to Jean Dieudonné [**Die1944**, Théorème 1], generalizes this result from compact to paracompact spaces.

Theorem 10.5. (Dieudonné's Theorem) Every paracompact Hausdorff space is normal.

The proof of Dieudonné's Theorem 10.5 rests on the following technical but useful lemma.

Lemma 10.6. (Closure-of-Locally Finite Cover Lemma) Let X be a topological space. If $\{U_i\}_{i\in I}$ is a locally finite cover of X, then $\{\overline{U}_i\}_{i\in I}$ is also a locally finite cover of X.

Proof of Lemma 10.6. Let X be a topological space and let $\{U_i\}_{i\in I}$ is a locally finite cover of X. The lemma follows immediately from the definitions and the following claim.



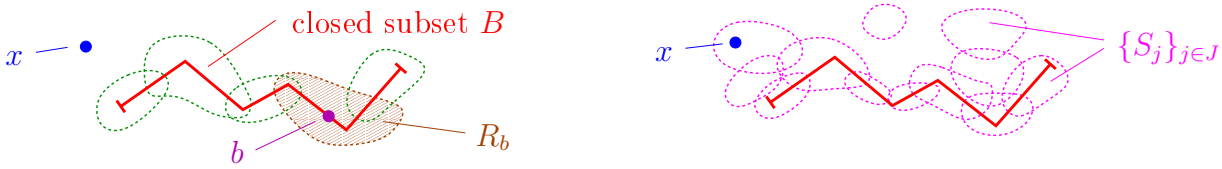
Claim. If W and U are two disjoint open subsets of X, then $\overline{U} \cap W = \varnothing$.

Proof. Let W and U be two disjoint open subsets of X. This means that U is contained in the closed subset $X \setminus W$. By definition of the closure this implies that $\overline{U} \subset X \setminus W$. In particular $\overline{U} \cap W = \varnothing$. ■

Proof of Dieudonné's Theorem 10.5. First recall that, according to the definition on page 343, a topological space X is called *regular* if given any $x \in X$ and given any closed

subset $B \subset X$ there exist disjoint open subsets U and V with $x \in U$ and $B \subset V$. Now let X be a paracompact Hausdorff space. In the following claim we first use paracompactness to upgrade from Hausdorff to regular.

Claim. The topological space X is regular.



Proof. Let $x \in X$ and let $B \subset X$ be a closed subset. Since X is Hausdorff it follows from the Points-in-Hausdorff Space Lemma 1.15 (2) that we can find for each $b \in B$ an open neighborhood R_b of $b \in X$ such that $x \notin \overline{R}_b$. The open sets $\{R_b\}_{b\in B}$ together with the open set $X \setminus B$ form an open cover of X. Since X is paracompact there exists a locally finite open refinement $\{S_j\}_{j\in J}$ of this cover. We set

$$U := X \setminus \bigcup_{j\in J \text{ with } S_j\cap B\neq\varnothing} \overline{S}_j \qquad \text{and} \qquad V := \bigcup_{j\in J \text{ with } S_j\cap B\neq\varnothing} S_j.$$

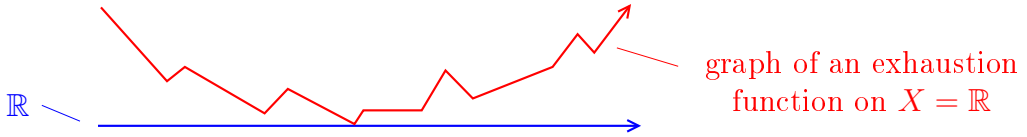
We make the following observations:

- Evidently we have $U \cap V = \varnothing$.
- Since the S_j are an open cover of X we see that V is an open neighborhood of B.
- We claim that $x \in U$. If $j \in J$ with $S_j \cap B \neq \varnothing$, then we see that S_j is contained in one of the R_b's, since it cannot be contained in $X \setminus B$. Since $\overline{S}_j \subset \overline{R}_b$ we see that $x \notin \overline{S}_j$. This implies that $x \in U$.
- We need to show that U is open. Note that by construction the family $\{S_j\}_{j\in J}$ is locally finite. Next note that it follows from the Closure-of-Locally Finite Cover Lemma 10.6 that $\{\overline{S}_j\}_{j\in J}$ is also a locally finite family of subsets of X. By Lemma 1.3 (2b) we know that the union of a locally finite collection of closed subsets is again closed. This shows that U is open.

We have thus shown that U and V are disjoint open neighborhoods of x and B. ⊞

In the remainder we will use the argument of the claim to use paracompactness to upgrade from "regular" to "normal". Thus let A and B be two disjoint closed subsets of X. By the claim we know that X is regular. By the Regular-Open-Closed-Neighborhood Lemma 9.6 this implies that for each $a \in A$ there exists an open neighborhood R_a of a such that $\overline{R}_a \subset X \setminus B$.

The open sets $\{R_a\}_{a\in A}$ together with the open set $X \setminus A$ form an open cover of X. Since X is paracompact there exists a locally finite open refinement $\{S_j\}_{j\in J}$ of this cover.



We set

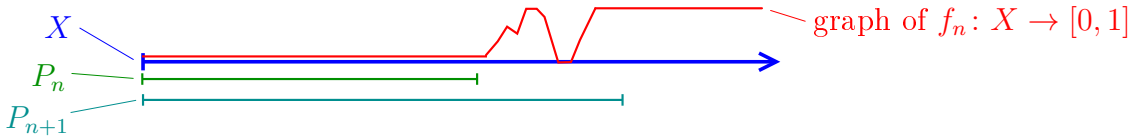
$$U := \bigcup_{j\in J \text{ with } S_j\cap A\neq\varnothing} S_j \qquad \text{and} \qquad V := X \setminus \bigcup_{j\in J \text{ with } S_j\cap A\neq\varnothing} \overline{S}_j.$$

By basically the same argument as above we see that U is an open neighborhood of A, that V is an open neighborhood of B and that $U \cap V = \varnothing$. ■

We conclude this section with a short discussion of exhaustion functions.

Definition. Let X be a topological space. An exhaustion function is a map $f\colon X \to \mathbb{R}_{\geq 0}$ such that for every $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of X.[116]

Lemma 10.7. (Exhaustion Function Lemma) Let X be a topological space. If X is second countable, Hausdorff and regionally compact, then X admits an exhaustion function.



Remark. The Exhaustion Function Lemma 10.7 can be viewed as a refinement of the Compact Exhaustion Lemma 9.3 (1).

Proof. Let X be a topological space which is second countable, Hausdorff and regionally compact. By the Compact Exhaustion Lemma 9.3 (1) we know that X admits an exhaustion by compact subsets. In other words we know that there exists a sequence $\{P_n\}_{n\in\mathbb{N}}$ of compact subsets of X such that the following two conditions are satisfied:

(1) We have $X = \bigcup_{n\in\mathbb{N}} P_n$.

(2) For each $n \in \mathbb{N}$ we have[117] $P_n \subset \mathring{P}_{n+1}$.

Furthermore, the combination of the Paracompact-Criterion Lemma 10.2 and Dieudonné's Theorem 10.5 shows that X is normal. Since X is Hausdorff we know by the Compact-Closed Lemma 1.21 that each P_n is closed. Furthermore, by (2) we know that for each $n \in \mathbb{N}$ the closed sets P_n and $X \setminus \mathring{P}_{n+1}$ are disjoint. Since X is normal we obtain from Urysohn's Lemma 8.4 for each $n \in \mathbb{N}$ a map $f_n\colon X \to [0,1]$ such that $f_n|_{P_n} \equiv 0$ and $f_n|_{X\setminus\mathring{P}_{n+1}} \equiv 1$.

Claim 1. The sets $U_n = \{x \in X \mid f_n(x) \neq 0\}_{n\in\mathbb{N}}$ are a locally finite open cover of X.

Proof. Evidently each $U_n = f_n^{-1}((0,1])$ is open. Now let $x \in X$ be a point. According to the definition on page 114 we need to show that x admits an open neighborhood W such

[116] One can easily show that a map $X \to \mathbb{R}_{\geq 0}$ is an exhaustion function if and only if it is proper in the sense of the definition on page 180.

[117] Here we use the Compact-Closed Lemma 1.21 (2) which tells us that every compact subspace of our Hausdorff space X is a closed subset.

that W is contained in only finitely many U_n's. By (1) and (2) we know that x is contained in some open subset $\mathring{P}_k$. By (2) and by construction we know that $f_n(y) = 0$ for all $y \in P_k$ and all $n \geq k+1$. ⊞

By the claim it makes sense to consider the map

$$\begin{aligned} f\colon X &\to \mathbb{R}_{\geq 0} \\ x &\mapsto \sum_{k\in\mathbb{N}} f_n(x). \end{aligned}$$

Furthermore it follows from the Pasting Proposition 2.6 that f is continuous. It remains to prove the following claim.

Claim 2. For every $c \in \mathbb{R}$ the preimage $f^{-1}([0,c])$ is compact.

Proof. Let $c \in \mathbb{R}$. We pick $N \in \mathbb{N}$ with $N \geq c$. Then

$$\begin{aligned} f^{-1}([0,c]) &= f^{-1}([0,c]) \cap f^{-1}([0,N]) \\ &\subset f^{-1}([0,c]) \cap P_{N+1} \;=\; \text{closed subset} \cap \text{compact subset}. \end{aligned}$$

$\uparrow$ since $f(x) \geq N+1$ for all $x \in X \setminus \mathring{P}_{N+1}$

It follows from the Compact-Closed Lemma 1.21, see also the elementary Exercise 1.22, that $f^{-1}([0,c])$ is indeed compact. ■

Let X be a topological space that is second countable, Hausdorff and regionally compact. By the Paracompact-Criterion Lemma 10.2 we know that X is paracompact. It follows from Dieudonné's Theorem 10.5 that X is normal. Since X is second-countable, normal and Hausdorff it follows from the elementary the Points-in-Hausdorff Space Lemma 1.15 (1) and the much less elementary Urysohn Metrization Theorem 9.4 that X is metrizable. The concept of exhaustion functions allows us to prove the following proposition which upgrades the conclusion from "metrizable" to "completely metrizable".

Proposition 10.8. (Completely Metrizable Criterion Proposition) Let X be a topological space. If X is second countable, Hausdorff and regionally compact, then it is completely metrizable.

Proof. Let X be a topological space that is second countable, Hausdorff and regionally compact. As we just discussed, it follows from the Paracompact-Criterion Lemma 10.2, Dieudonné's Theorem 10.5, the Points-in-Hausdorff Space Lemma 1.15 (1) and the Urysohn Metrization Theorem 9.4 that X is metrizable.

Now let d be a metric on X which induces the given topology on X. Since X is second countable, Hausdorff and regionally compact we know by the Exhaustion Function Lemma 10.7 that X admits an exhaustion function, i.e there exists a map $f\colon X \to \mathbb{R}_{\geq 0}$ such that for every $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of X.

We now define

$$\begin{aligned} \widetilde{d}\colon X \times X &\to \mathbb{N}_0 \\ (x,y) &\mapsto d(x,y) + |f(x) - f(y)|. \end{aligned}$$

It follows from Exercise 6.4 that $\widetilde{d}$ is a metric and that $\widetilde{d}$ induces again the given topology.

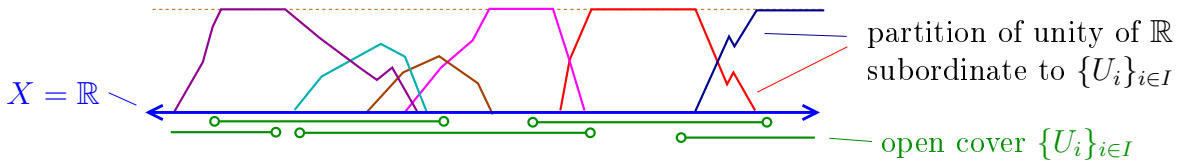
Now let $(x_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in $(X, \widetilde{d})$. It follows immediately from the definition of $\widetilde{d}$ that there exists a $c \in \mathbb{R}_{\geq 0}$ such that $|f(x_n)| \leq c$ for all $n \in \mathbb{N}$. In other words, the sequence $(x_n)_{n\in\mathbb{N}}$ takes place in the compact subspace $f^{-1}([0,c])$. But by the

Compact-Complete Proposition 6.10 we know that any Cauchy sequence in a compact metric space converges. ■

10.2. **Partitions of unity.** In this section we introduce the notion of a "partition of unity" and we will see that for Hausdorff spaces the existence of suitable partitions of unity is equivalent to being paracompact. On numerous occasions we will see that "partitions of unity" are very useful for building interesting maps "out of" a given topological space.

Definition. Let X be a topological space.

(1) The support of a map $f\colon X \to \mathbb{R}$ is defined as



$$\operatorname{supp}(f) \;:=\; \overline{\{x \in X \mid f(x) \neq 0\}}.$$

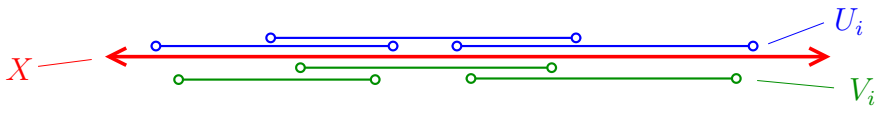
(2) A partition of unity on X is a family of maps[118] $\{f_i\colon X \to [0,1]\}_{i\in I}$ with the following properties:
   (a) For each $x \in X$ there exists an open neighborhood U of x such that f_i vanishes on U for all but finitely many i.[119]
   (b) For every $x \in X$ we have[120]

$$\sum_{i\in I} f_i(x) \;=\; 1.$$

(3) Let $\{U_i\}_{i\in I}$ be an open cover. A partition of unity subordinate to the open cover $\{U_i\}_{i\in I}$ is a partition of unity $\{f_j\colon X \to [0,1]\}_{j\in J}$ such that for each $j \in J$ there exists an $i \in I$ with $\operatorname{supp}(f_j) \subset U_i$.

Example. In the figure below we consider the topological space $X = \mathbb{R}$ together with some open cover $\{U_i\}_{i\in I}$ and we illustrate a partition of unity subordinate to this open cover.

The following is the most interesting and useful theorem of this chapter.



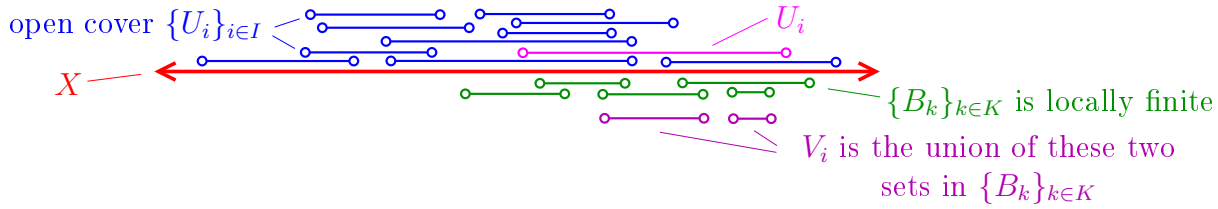
Theorem 10.9. (Paracompact-Partition of Unity Theorem) Let X be a topological space that is *Hausdorff*. The following three statements are equivalent:

(1) The topological space X is paracompact.
(2) For every open cover $\{U_i\}_{i\in I}$ of X we can find a partition of unity subordinate to the open cover $\{U_i\}_{i\in I}$.
(3) For every open cover $\{U_i\}_{i\in I}$ of X we can find a partition of unity $\{f_i\colon X \to [0,1]\}_{i\in I}$ such that for every $i \in I$ we have $\operatorname{supp}(f_i) \subset U_i$.

[118] As always, all maps are assumed to be continuous.
[119] If U is a subset on which a map $f\colon X \to \mathbb{R}$ vanishes, and if U is open, then it follows from the definition of the closure that $\operatorname{supp}(f) \cap U = \varnothing$. This observation shows that (a) implies that for each $x \in X$ there exist only finitely many $i \in I$ such that $x \in \operatorname{supp}(f_i)$.
[120] Note that by (a) there are only finitely many non-zero summands, hence the expression on the left-hand side makes sense even if I is infinite.

The proof of the "(1)⇒(3)"-direction of the Paracompact-Partition of Unity Theorem 10.9 rests on the shoulders of the following lemma which is interesting in its own right.

Lemma 10.10. (Shrinking Lemma) Let X be a paracompact Hausdorff space and let $\{U_i\}_{i\in I}$ be an open cover of X. There exists a locally finite open cover $\{V_i\}_{i\in I}$ of X such that for each $i \in I$ we have $\overline{V}_i \subset U_i$.



Proof of the Shrinking Lemma 10.10. Let X be a paracompact Hausdorff space and let $\{U_i\}_{i\in I}$ be an open cover of X. We define $\mathcal{A}$ to be the set of all open subsets A of X such that the closure $\overline{A}$ is contained in some subset U_i of the given open cover.

Claim 1. The sets in $\mathcal{A}$ form an open cover of X.

Proof. Since X is paracompact and Hausdorff we obtain from Dieudonné's Theorem 10.5 that X is normal. Furthermore since X is Hausdorff we know by the Points-in-Hausdorff Space Lemma 1.15 that every one-point subset of X is closed. It follows from these facts, together with the Normal-Open-Closed-Neighborhood Lemma 8.2, that given any U_i and given any $x \in U_i$ there exists an open subset A of X with $x \in A \subset \overline{A} \subset U_i$. Note that $A \in \mathcal{A}$. Since the U_i form an open cover of X we now see that the sets in $\mathcal{A}$ also form an open cover of X. ⊞

Since X is paracompact there exists a locally finite open cover $\{B_k\}_{k\in K}$ of X that is a refinement of $\mathcal{A}$. Note that every B_k is contained in some set in $\mathcal{A}$. Thus for every $k \in K$ we can and will pick an $f(k) \in I$ with $\overline{B}_k \subset U_{f(k)}$. Given $i \in I$ we set

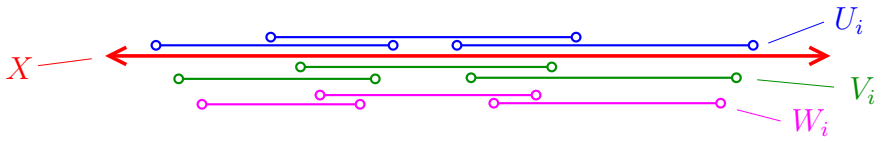
$$V_i := \bigcup_{k\in K \text{ with } f(k)=i} B_k.$$

Claim 2. For each $i \in I$ we have $\overline{V}_i \subset U_i$.

Proof. Let $i \in I$. We see that

$$\overline{V}_i = \overline{\bigcup_{k\in K \text{ with } f(k)=i} B_k} = \bigcup_{k\in K \text{ with } f(k)=i} \overline{B}_k \subset U_i.$$

(The first $=$: follows from Lemma 1.11 (3b) since $\{B_k\}_{k\in K}$ is locally finite. The $\subset$: by definition of $f\colon K \to I$ we know that for each $k \in K$ with $f(k) = i$ we have $\overline{B}_k \subset U_i$.) ⊞



It remains to prove the following claim.

Claim 3. The family $\{V_i\}_{i\in I}$ is locally finite.

Proof. Let $x \in X$. Since $\{B_k\}_{k\in K}$ is locally finite there exists an open neighborhood W of $x \in X$ such that W has non-empty intersection with only finitely many B_k. Suppose that the corresponding indices are $k_1, \dots, k_m \in K$. If $W \cap V_i \neq \varnothing$, then by definition of V_i there exists a $k \in K$ with $f(k) = i$ and with $W \cap B_k \neq \varnothing$, but this implies that $i \in \{f(k_1), \dots, f(k_m)\}$. ■

Proof of the Paracompact-Partition of Unity Theorem 10.9. The "(2)⇒(1)"-direction is basically trivial. Indeed let $\{U_i\}_{i\in I}$ be an open cover of X. By hypothesis there exists a partition of unity $\{f_j \colon X \to [0,1]\}_{j\in J}$ subordinate to the open cover $\{U_i\}_{i\in I}$. It follows immediately from the definitions that $\{f_j^{-1}((0,\infty))\}_{j\in J}$ is a locally finite open cover that is a refinement of $\{U_i\}_{i\in I}$.

The "(3)⇒(2)"-direction is utterly trivial. Thus it remains to prove the "(1)⇒(3)"-direction. Let $\{U_i\}_{i\in I}$ be an open cover of X. By applying the Shrinking Lemma 10.10 twice we obtain locally finite open covers $\{V_i\}_{i\in I}$ and $\{W_i\}_{i\in I}$ such that for each $i \in I$ we have $\overline{W}_i \subset V_i \subset \overline{V}_i \subset U_i$.

Since X is paracompact and Hausdorff we know by Dieudonné's Theorem 10.5 that X is normal. Now let $i \in I$. Since X is normal we can apply Urysohn's Lemma 8.4 to the disjoint closed subsets $\overline{W}_i$ and $X \setminus V_i$ and we obtain a continuous map $g_i \colon X \to \mathbb{R}$ with $g|_{\overline{W}_i} \equiv 1$ and $g|_{X\setminus V_i} \equiv 0$.

Claim. For each $x \in X$ there exists an open neighborhood U of x such that g_i vanishes on U for all but finitely many i.

Proof. For every $i \in I$ we have $\{x \in X \mid g_i(x) \neq 0\} \subset V_i$. The claim now follows from the fact that the cover $\{V_i\}_{i\in I}$ is locally finite. ⊞

By the claim it makes sense to consider the map

$$\begin{array}{rcl} g \colon X & \to & \mathbb{R} \\ x & \mapsto & g(x) := \sum_{i\in I} g_i(x). \end{array}$$

It follows from the claim and the Pasting Proposition 2.6 that g is continuous. Furthermore note that it follows from the fact that the $\{W_i\}_{i\in I}$ form a cover of X and that $g_i|_{W_i} \equiv 1$ that for every $x \in X$ we have $g(x) > 0$. Therefore given $i \in I$ it makes sense to consider the map

$$\begin{array}{rcl} f_i \colon X & \to & \mathbb{R} \\ x & \mapsto & \frac{g_i(x)}{g(x)}. \end{array}$$

The maps f_i add up to the constant function 1. Together with the claim it follows that the maps $\{f_i\}_{i\in I}$ form a partition of unity.

Finally let $i \in I$. As we mentioned above, we have $\{x \in X \mid f_i(x) \neq 0\} \subset V_i$. It follows that $\operatorname{supp}(f_i) \subset \overline{V}_i \subset U_i$. ■

The following, slightly technical proposition, sometimes makes it possible to find a suitable *countable* open cover. We will only make use of it once, namely much later, when we study vector bundles. For the time being it is surely best to just ignore it.

Proposition 10.11. (Countable Cover Proposition) Let X be a topological space and let $\{U_i\}_{i\in I}$ be an open cover of X. If X is paracompact and Hausdorff, then there exists a *countable* locally finite open cover $\{V_j\}_{j\in J}$ such that each component of any V_j is contained in some U_i.

Proof. Since X is paracompact it follows from the Paracompact-Partition of Unity Theorem 10.9 that there exists a partition of unity $\{f_i\colon X \to [0,1]\}_{i\in I}$ such that for each $i \in I$ we have $\operatorname{supp}(f_i) \subset U_i$. Given a finite non-empty subset $S \subset I$ we define

$$V_S \;:=\; \{x \in X \,|\, f_s(x) > f_i(x) \text{ for all } s \in S \text{ and all } i \notin s\}.$$

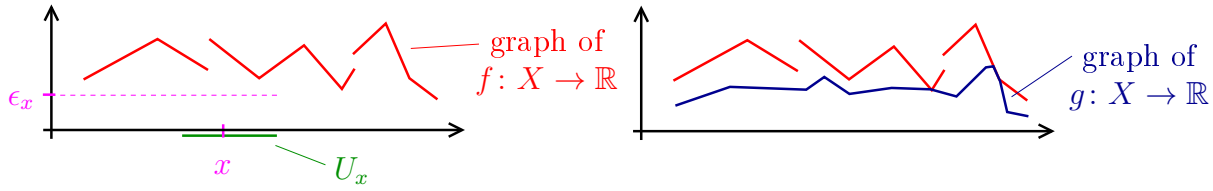
Claim 1.

(1) Each V_S is open.
(2) Each $x \in X$ is contained in some V_S.
(3) Each V_S is contained in some U_i.
(4) For finite non-empty subsets S and T of I we have $V_S \subset V_T$ if and only if $S \subset T$.

Proof.

(1) Let $S \subset I$ be finite and non-empty. We need to show that V_S is open. By the JH-Lemma 1.7 it suffices to show that given any $x \in V_S$ there exists an open neighborhood U of x such that $V_S \cap U$ is open. Thus let $x \in V_S$. By definition of a partition of unity there exists a neighborhood U on which all but finitely many of the functions f_i vanish. We set $T := \{i \in I \setminus S \,|\, f_i(x) \neq 0\}$. We see that

$$V_S \cap U \;=\; \bigcap_{t\in T}\bigcap_{s\in S} \underbrace{\{x \in X \,|\, f_s(x) > f_t(x)\}}_{=(f_t-f_s)^{-1}((-\infty,0))}.$$



This is the intersection of finitely many open sets, thus open.
(2) Let $x \in X$. By definition of a partition of unity the set $S = \{i \in I \,|\, f_i(x) > 0\}$ is finite and non-empty. Evidently we have $x \in V_S$.
(3) Let $S \subset I$ be a finite non-empty subset. Given any $i \in S$ we have $V_S \subset \operatorname{supp}(f_i) \subset U_i$.
(4) This statement follows immediately from the definitions. ⊞

Now given $n \in \mathbb{N}_0$ we set $V_n := \bigcup_{\#S=n} V_S \subset X$. It follows from the above that the V_S with $\#S = n$ are disjoint and open. Therefore we deduce from the Component Lemma 2.33 (4b) that each component of V_n is contained in some V_S which in turn, as we saw above, is contained in some U_i. It is now clear that the family $\{V_n\}_{n\in\mathbb{N}_0}$ has all the desired properties. ■

10.3. **The Neighborhood Embedding Theorem.** We conclude this chapter with the Neighborhood Embedding Theorem which shows that under favorable circumstances one can extend an embedding from a closed subset to an open neighborhood.
Before we discuss the Neighborhood Embedding Theorem let us first state and prove a lemma, which is of independent interest, but which often gets used in conjunction with the Neighborhood Embedding Theorem.

Lemma 10.12. Let X be a topological space and let $f\colon X \to \mathbb{R}$ be a map (not necessarily continuous) with the property that for every $x \in X$ there exists an open neighborhood U_x

of x and an $\epsilon_x > 0$ such that for each $y \in U_x$ we have $f(y) \geq \epsilon_x$. If X is paracompact, then there exists a continuous map $g\colon X \to (0, \infty)$, such that for all $x \in X$ we have $g(x) \leq f(x)$.

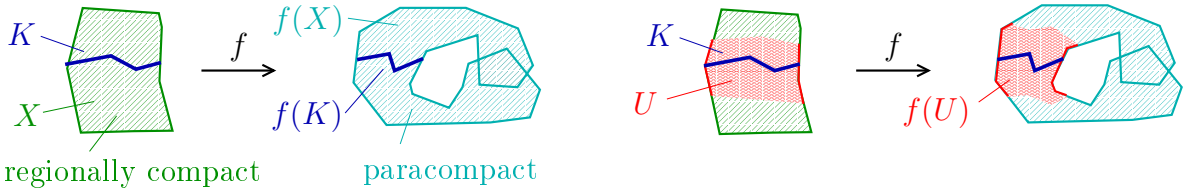
Proof. Since X is paracompact we know by the Paracompact-Partition of Unity Theorem 10.9 that we can pick a partition of unity $\{\varphi_x\}_{x \in X}$ such that for each $x \in X$ we have $\operatorname{supp}(\varphi_x) \subset U_x$. We set

$$g := \sum_{x \in X} \varphi_x \cdot \epsilon_x.$$

As always it follows from the Pasting Proposition 2.6 that g is continuous. Since each $\epsilon_x > 0$ we see that $g(y) > 0$ for all $y \in X$. Finally, for every $y \in X$ we have

$$g(y) = \sum_{x \in X} \varphi_x(y) \cdot \epsilon_x \leq \sum_{x \in X \text{ with } y \in U_x} \varphi_x(y) \cdot \epsilon_x \leq \sum_{x \in X \text{ with } y \in U_x} \varphi_x(y) \cdot f(y) = f(y).$$

$\uparrow$ since $\operatorname{supp}(\varphi_x) \subset U_x$; $\uparrow$ property of ϵ_x; $\uparrow$ since $\{\varphi_x\}_{x \in X}$ is a partition of unity and since $\operatorname{supp}(\varphi_x) \subset U_x$



In summary, we have shown that $g(y) \leq f(y)$ for all $y \in X$. ■

Now we turn our attention to the actual hero of this section.

Theorem 10.13. (Neighborhood Embedding Theorem) Let $f\colon X \to Y$ be a map between two topological spaces and let $K \subset X$ be a subset. We assume that the following conditions are satisfied.

(1) The restriction of f to $f\colon K \to Y$ is an embedding.
(2) K is a closed subset of X and $f(K)$ is a closed subset of Y.
(3) The map $f\colon X \to Y$ is a local homeomorphism at each $P \in K$.
(4) The topological space X is regionally compact.
(5) The topological space Y is paracompact.

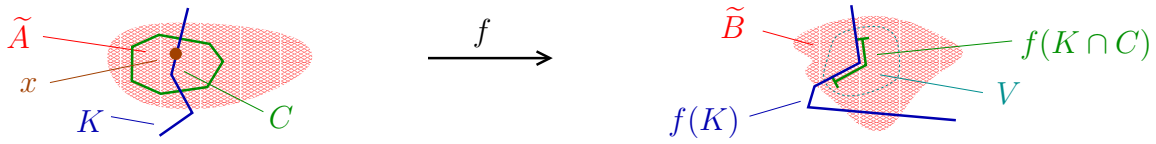
Then there exists an open neighborhood U of K such that the restriction of f to $f\colon U \to Y$ is an embedding and such that $f(U)$ is an open subset of Y.

Remark.

(1) This very useful theorem is based on [**Lang1985**, p. 97], [**Kos1993**, Lemma 9.2] and [**God1973**, p. 150]. Writing down the proof of the Neighborhood Embedding Theorem caused countless hours of pain for the author.
(2) The Neighborhood Embedding Theorem 21.13 gives the corresponding statement for smooth manifolds.

Proof. We start out with the first of several claims.

Claim 1. For each $x \in K$ there exists an open neighborhood A_x of $x \in X$ and an open neighborhood B_x of $f(x) \in Y$ such that $f|_{A_x} \colon A_x \to B_x$ is a homeomorphism and such that $f^{-1}(B_x \cap f(K)) = A_x \cap K$.



Proof. Let $x \in K$. Since f is a local homeomorphism at $x \in K$ we know that there exists an open neighborhood $\widetilde{A}$ of $x \in X$ and an open neighborhood $\widetilde{B}$ of $f(x) \in Y$ such that $f|_{\widetilde{A}} \colon \widetilde{A} \to \widetilde{B}$ is a homeomorphism.

Since X is regionally compact there exists a compact subset $C \subset X$ with $x \in C \subset \widetilde{A}$. Furthermore, since $K \subset X$ is closed we see that $K \cap C$ is a closed subset of C. It follows from the Compact-Closed Lemma 1.21 that $K \cap C$ is also compact. Next we consider $f(K \cap C)$. By the Compact Image Lemma 2.13 we know that $f(K \cap C)$ is compact. Since Y is paracompact it is in particular Hausdorff. Thus we obtain from the Compact-Closed Lemma 1.21 that $f(K \cap C)$ is a closed subset of Y.

Next note that $K \cap (X \setminus \widetilde{A})$ is a closed subset of K. Since f is an embedding we see that $f(K \cap (X \setminus \widetilde{A}))$ is a closed subset of $f(K)$. Since $f(K)$ is a closed subset of Y we obtain from the Open -Closed Inclusion Lemma 2.10 (2) that $f(K \cap (X \setminus \widetilde{A}))$ is a closed subset of Y.

Since f is in particular injective we see that the two closed subsets $f(K \cap C)$ and $f(K \cap (X \setminus \widetilde{A}))$ are actually closed disjoint. Since Y is paracompact we know by Dieudonné's Theorem 10.5 that Y is normal. Thus there exist disjoint open neighborhoods V of $f(K \cap C)$ and W of $f(K \cap (X \setminus \widetilde{A}))$.

We set $B_x := \widetilde{B} \cap V$ and we set $A_x := \widetilde{A} \cap f^{-1}(B_x)$. Basically by construction these have the desired properties. ⊞

Claim 2. There exists a family of open subsets $\{U_i\}_{i \in I}$ of X with the following properties:

(a) The maps $f|_{U_i} \colon U_i \to V_i = f(U_i)$ are homeomorphisms.
(b) For each $i \in I$ we have $f_i^{-1}(V_i \cap f(K)) = U_i \cap K$.
(c) The sets $\{V_i\}_{i \in I}$ form a locally finite open cover of $f(K)$ in the sense that given any $y \in f(K)$ there exists an open neighborhood $\widetilde{W}$ of $y \in Y$ such that $\widetilde{W}$ has non-empty intersection with only finitely many V_i.

Proof. For each $x \in K$ we pick A_x and B_x as in Claim 1. Note that the sets $\{B_x\}_{x \in K}$ form an open cover of $f(K)$. By hypothesis $f(K)$ is a closed subset of Y. Thus the sets $\{B_x\}_{x \in K}$ and $Y \setminus f(K)$ form an open cover of Y. Since Y is paracompact it follows from the Paracompact-Partition of Unity Theorem 10.9 that we can find a *locally finite* open cover $\{V_i\}_{i \in I'}$ that is a refinement of the given open cover of Y. In particular each V_i is contained in some B_x or it is contained in $Y \setminus f(K)$. We set $I := \{i \in I' \mid V_i \text{ is contained in some } B_x\}$. For each $i \in I$ we set $U_i = f^{-1}(V_i)$. These sets have, almost by definition, the desired properties. ⊞

For each $i \in I$ we write $f_i := f|_{U_i} \colon U_i \to V_i$ and we write $g_i := f_i^{-1} \colon V_i \to U_i$. It follows from the hypothesis that Y is paracompact and that $f(K)$ is a closed subset, by the argument of the Paracompact-Partition of Unity Theorem 10.9 that there exists an open cover $\{D_i\}_{i \in I}$ of $f(K) \subset Y$ such that for each $i \in I$ we have $\overline{D}_i \subset V_i$.

Claim 3. Let $y \in f(K)$. There exists a subset $W_y \subset Y$ with the following properties:

(a) $\{i \in I \,|\, \overline{D}_i \cap W_y \neq \varnothing\}$ is finite.
(b) W_y is an open neighborhood of $y \in Y$.
(c) If $\overline{D}_i \cap W_y \neq \varnothing$, then $W_y \subset V_i$.
(d) For each $i, j \in I$ with $\overline{D}_i \cap W_y \neq \varnothing$ and $\overline{D}_j \cap W_y \neq \varnothing$ we have[121] $g_i|_{W_y} = g_j|_{W_y}$.

Proof. Let $y \in f(K)$. Since the open cover $\{V_i\}_{i \in I}$ is locally finite and since for each $i \in I$ we have $\overline{D}_i \subset V_i$ we know that there exists an open neighborhood $\widetilde{W}$ of $y \in Y$ such that $J := \{i \in I \,|\, \overline{D}_i \cap \widetilde{W} \neq \varnothing\}$ is finite. We set $\widetilde{J} := \{j \in J \,|\, y \in \overline{D}_j\}$ and we set

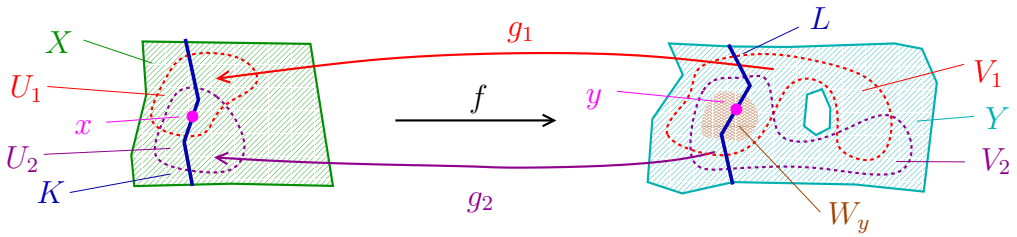
$$W_y \;:=\; \Big(\widetilde{W} \setminus \bigcup_{j \,\in\, J \text{ with } y \,\notin\, \overline{D}_j} \overline{D}_j\Big) \cap f\Big(\bigcap_{j \in \widetilde{J}} U_j\Big).$$

We claim that W_y has the desired properties:

(a) By construction $\{i \in I \,|\, \overline{D}_i \cap W_y \neq \varnothing\}$ is finite.
(b) First we make the following observations:
- We pick some $i \in \widetilde{J}$. Note that $\bigcap_{j \in \widetilde{J}} U_j$ is the intersection of finitely many open subsets of Y. It follows that it is an open subset of U_i. Since $f \colon U_i \to V_i$ is a homeomorphism and since V_i is an open subset of Y we obtain, using the elementary the Open -Closed Inclusion Lemma 2.10, that $f\Big(\bigcap_{j \in \widetilde{J}} U_j\Big)$ is an open subset of Y.
- The set W_y is thus obtained by removing a finite number of closed sets from $\widetilde{W}$ and by taking afterwards the intersection with an open subset of Y.

This discussion shows that W_y is an open subset of Y.

It remains to show that $y \in W_y$. Since $f \colon K \to Y$ is an embedding there exists a unique $x \in K$ with $f(x) = y$. It remains to show that for each $j \in \widetilde{J}$ we have $x \in U_j$. Thus let $j \in \widetilde{J}$. By definition we have $y \in \overline{D}_j \subset V_j$. By Property (b) of Claim 2 we have $f_j^{-1}(V_j \cap f(K)) = U_j \cap K$. It follows that $f_j^{-1}(y) \in U_j \cap K$, which means that $f_j^{-1}(y) = x$. Thus we have shown that $x \in U_j$.



(c) Suppose that we have an $i \in I$ with $\overline{D}_i \cap W_y \neq \varnothing$. By construction of W_y we have $y \in \overline{D}_i$. This in turn implies that $i \in \widetilde{J}$ which then implies, by construction, that $W_y \subset f(U_i) = V_i$.

(d) Now let $Q \in W_y$. Let $i \in I$ with $\overline{D}_i \cap W_y \neq \varnothing$.
- By definition $g_i(Q)$ is the unique element $P \in U_i$ with $f(P) = Q$.
- In (c) we just saw that $i \in \widetilde{J}$.
- By construction of W_y we have $Q \in f\Big(\bigcap_{j \in \widetilde{J}} U_j\Big)$.

[121] Note that it follows from (c) that g_i and g_j are defined on W_y.

- Since $i \in \widetilde{J}$ and since $f\colon U_i \to Y$ is injective we obtain from the above that $P \in \bigcap_{j\in\widetilde{J}} U_j$.

In summary we have shown that $g_i(Q)$ is the unique $P \in \bigcap_{j\in\widetilde{J}} U_j$ with $f(P) = Q$. But this shows that $g_i(Q)$ is independent of the choice of $i \in J$. ⊞

Next we set

$$V := \bigcup_{y\in f(K)} W_y \qquad \text{and} \quad U := \bigcup_{y\in f(K)} \bigcup_{i\in I} g_i(W_y \cap D_i).$$

Since each W_y is open we see that V is an open neighborhood of $f(K)$. Furthermore, each $W_y \cap D_i$ is an open subset of V_i and thus each $g_i(W_y \cap D_i)$ is an open subset of U_i, in particular also of X. This shows that U is an open subset of X. Finally, since the D_i form an open cover of Y we see that U contains K. Thus we have shown that U is an open neighborhood of K.

The following claim now shows the desired statement, namely it shows that the restriction of f to $f\colon U \to Y$ is an embedding such that $f(U)$ is an open subset of Y.

Claim 4. The map

$$\begin{array}{rcl} g\colon V & \to & U \\ Q & \mapsto & g_i(Q) \text{ where } i \in I \text{ is chosen such that } Q \in D_i \end{array}$$

is well-defined, continuous and it satisfies $f \circ g = \mathrm{id}_V$ and $g \circ f = \mathrm{id}_U$.

Proof. It follows almost immediately from Claim 3 (d) that g is well-defined in the sense, that $g(Q)$ does not depend on the choice of $i \in I$. Furthermore, basically by definition of U we see that $g(V) \subset U$.

Next, note that on each subset $D_i \cap V$ the map g is given by the continuous map g_i. Since the $D_i \cap V$ are an open cover of V we obtain from the Pasting Proposition 2.6 that g is continuous.

Basically by definition we have $f \circ g = \mathrm{id}_V$. It remains to show that $g \circ f = \mathrm{id}_U$. Thus let $P \in U$. By definition P is of the form $g_i(Q) \subset U_i$ for some $Q \in W_y \cap D_i$. This implies that $f(P) = f(g_i(Q)) = Q \in W_y \cap D_i$. By definition we have $g(f(P)) = g_i(f(P))$. But $g_i(f(P))$ is the unique element of U_i which gets mapped to $f(P)$ under f. This element is P. We have thus shown that $g(f(P)) = P$. ■

Exercises for Chapter 10.

Exercise 10.1. Let X be a topological space and let $\{U_i\}_{i\in I}$ be an open cover of X. Show that if there exists a partition of unity subordinate to the open cover $\{U_i\}_{i\in I}$, then there exists a partition of unity $\{f_i\colon X \to [0,1]\}_{i\in I}$ such that for every $i \in I$ we have $\mathrm{supp}(f_i) \subset U_i$.

Remark. For Hausdorff spaces this is precisely the (2)⇒(3)-direction of the Paracompact-Partition of Unity Theorem 10.9. But even for Hausdorff spaces it is worth providing a direct proof.

Exercise 10.2. Let X be a paracompact space and let Y be a compact space. Show that the product $X \times Y$ is also paracompact.

Exercise 10.3. Let $S := (\mathbb{R}, \mathcal{T})$ be the Sorgenfrey line that we introduced on page 182. Show that the Sorgenfrey line is Hausdorff and paracompact.
Remark. We consider the product $S \times S$, which is often called the *Sorgenfrey plane*. Since S is Hausdorff we know by the Product Topology Properties Proposition 5.6 that the Sorgenfrey plane $S \times S$ is also Hausdorff. In Exercise 8.6 we saw that the Sorgenfrey plane $S \times S$ is not normal. It follows from these two observations, together with Dieudonné's Theorem 10.5, that the Sorgenfrey plane $S \times S$ is not paracompact. This shows that the property of being paracompact is not preserved under taking products.

Exercise 10.4. Give an example of a paracompact space X together with an open cover $\{U_i\}_{i \in I}$ such that there is no subset $J \subset I$ such that $\{U_i\}_{i \in J}$ is a locally finite open cover of X.

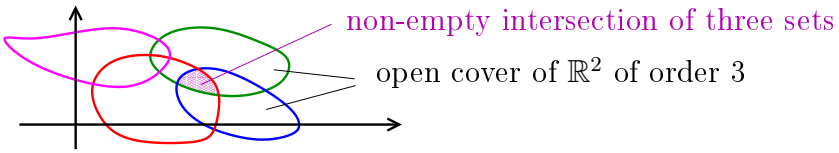
Exercise 10.5.

(a) Show that every discrete space is paracompact.
(b) Provide an example of a map $f\colon X \to Y$ such that X is paracompact, but such that the image $f(X)$ is not paracompact.

Remark. This exercise shows that the Compact Image Lemma 2.13 cannot be generalized from compact spaces to paracompact spaces.

11. The covering dimension of topological spaces

In this chapter we introduce the covering dimension of a topological space. This topic is not essential for the main flow of the lecture notes, but it is interesting and amusing in its own right. The most difficult result of this chapter is the Euclidean Embedding Theorem 11.13 for Topological Spaces which shows that, under reasonably mild extra hypotheses, a topological space of covering dimension m admits a closed embedding into $\mathbb{R}^{2m+1}$. Later in Chapter 27 we will use some of the results of this chapter to show that every (possibly non-compact) "topological manifold" admits a closed embedding into some $\mathbb{R}^n$ and every "smooth manifold" admits a "smooth embedding" into some $\mathbb{R}^n$. The exposition of this chapter is based on [**Mun1975**, Chapter 50] and [**Flo2020**].

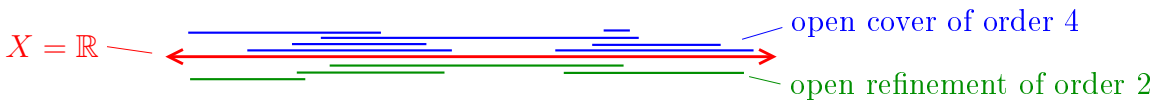


11.1. The definition of the covering dimension of a topological space.

Definition. Let X be a set and let $m \in \mathbb{N}_0$. A family $\{U_i\}_{i\in I}$ of subsets of X has order m if the following two statements hold:

(1) There exists $J \subset I$ with $\#J = m$ such that $\bigcap_{j\in J} U_j \neq \varnothing$.

(2) For every $J \subset I$ with $\#J > m$ we have $\bigcap_{j\in J} U_j = \varnothing$.



If no such m exists, then we say that the family has infinite order.

Definition. Let X be a topological space. If X is non-empty, then we refer to

$$\operatorname{cdim}(X) \;:=\; \min\left\{ m \in \mathbb{N}_0 \cup \{\infty\} \;\middle|\; \begin{array}{l}\text{every open cover of } X \text{ admits an}\\ \text{open refinement of order} \leq m+1\end{array} \right\}$$

as the[122] covering dimension of X. If X is empty, then we set $\operatorname{cdim}(X) := -1$.

Remark. The above definition of the covering dimension of a topological space is equivalent to the definition given in [**Mun1975**, Chapter 50].[123] In many other books, e.g.

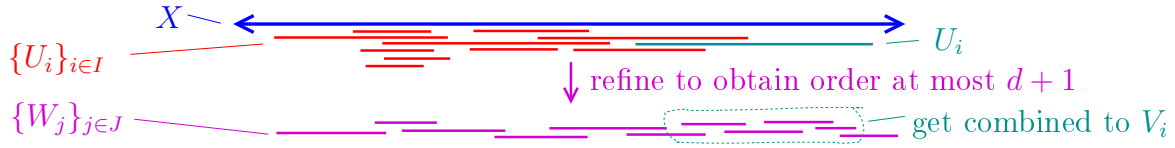
[122] In the mathematical literature the words "cover" and "covering" often get used indiscriminately. In these notes we usually reserve the word "cover" for the concept introduced on page 114 and we reserve the word "covering" for the concept that we will introduce on page 1067. Thus it would make more sense to call the present concept "cover dimension". But since this term is not used at all in the literature we stick to the slightly illogical name "covering dimension".

[123] The definition is not entirely the same as the definition in [**Mun1975**, Chapter 50] since we consider families of subsets (where we allow repetitions), whereas [**Mun1975**, Chapter 50] works with subsets of the power set of X, in other words, families of subsets without repetition. Nonetheless, elementary logic shows that the definition of covering dimension that we give results in the same covering dimension as in [**Mun1975**, Chapter 50].

[**Enge1995**, p. 42], [**Pear1975**, p. 111] and [**Char2019**, p. 10], the covering dimension is defined by considering finite covers only. For many topological spaces these two notions agree, for example in [**Enge1995**, Proposition 3.2.2] it is shown that the two notions agree for paracompact spaces.

The following trivial lemma, which is an immediate consequence of the definitions, says that the covering dimension is a homeomorphism invariant.

Lemma 11.1. Let X and Y be two topological spaces. If X and Y are homeomorphic, then $\operatorname{cdim}(X) = \operatorname{cdim}(Y)$.



The next lemma simplifies life and the notation in applications significantly.

Lemma 11.2. Let X be a topological space with covering dimension $d := \operatorname{cdim}(X) \in \mathbb{N}_0$. Given any open cover $\{U_i\}_{i\in I}$ there exists an open cover $\{V_i\}_{i\in I}$ of order $\leq d+1$ such that for each $i \in I$ we have $V_i \subset U_i$.

Proof. Let $\{U_i\}_{i\in I}$ be an open cover of X. Since $d := \operatorname{cdim}(X) \in \mathbb{N}_0$ we know that there exists an open refinement $\{W_j\}_{j\in J}$ of order $\leq d+1$. Since $\{W_j\}_{j\in J}$ is a refinement for the original cover we see that for each $j \in J$ we can pick an $i(j) \in I$ such that $W_j \subset U_{i(j)}$. Given $i \in I$ we set

$$V_i \;=\; \bigcup_{j\,\in\, J \text{ with } i(j)\,=\,i} W_j \quad\subset\; U_i.$$

Evidently the family $\{V_i\}_{i\in I}$ is an open cover of X that is a refinement of the original cover $\{U_i\}_{i\in I}$. It remains to show that the cover $\{V_i\}_{i\in I}$ has order $\leq d+1$. So let $x \in X$. Since $\{W_j\}_{j\in J}$ has order $\leq d+1$ we see that $\#\{j \in J \,|\, x \in W_j\} \leq d+1$. But then it follows follows that $\#\{i \in I \,|\, x \in V_i\} \leq d+1$. ∎

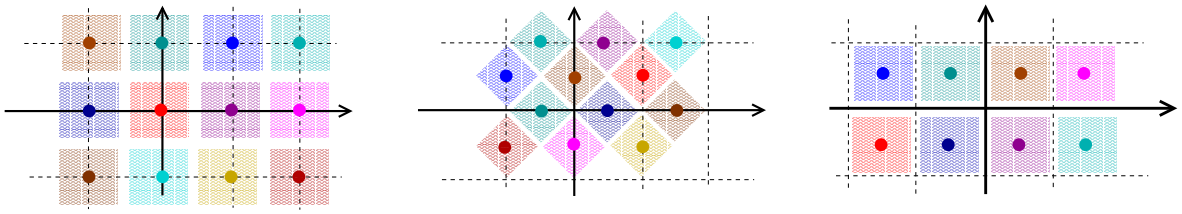
The following theorem hopefully justifies somewhat the term covering *dimension*.

Theorem 11.3. Let $n \in \mathbb{N}_0$. For every compact subspace $X \subset \mathbb{R}^n$ we have $\operatorname{cdim}(X) \leq n$.

Auxiliary Lemma 11.4. Let $n \in \mathbb{N}_0$. There exists an open cover $\{V_j\}_{j\in J}$ of $\mathbb{R}^n$ of order $n+1$ such that for each $j \in J$ we have $\operatorname{diam}(V_j) \leq \sqrt{n}$.

Remark. The proof we give of Lemma 11.4 is rather ad hoc. We will give an alternative proof using simplicial complexes in Exercise 94.8.

Proof of Lemma 11.4. Let $x = (x_1, \ldots, x_n) \in (\frac{1}{2}\cdot\mathbb{Z})^n$.



- We set $R_x := \{i \in \{1,\ldots,n\} \,|\, x_i \in \mathbb{Z} + \frac{1}{2}\}$ (the "rational coordinates" of x)
- We set

$$V(x) \;:=\; x + \left\{ \sum_{i=1}^{n} e_i \cdot \lambda_i \;\middle|\; \begin{array}{l} \text{for } i \in R_x \text{ we have } \lambda_i \in (-\frac{1}{2}, \frac{1}{2}), \\ \text{for } i \notin R_x \text{ we have } |\lambda_i| < \max\{\frac{1}{2} - |\lambda_j| \,|\, j \in R_x\} \end{array} \right\}$$

Given $d \in \{0,\ldots,n\}$ we consider the following families of open subsets of $\mathbb{R}^n$:

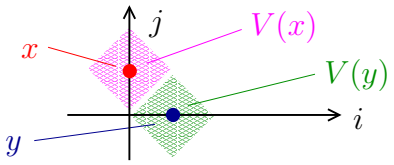
$$\mathcal{V}_d \;:=\; \{V(x)\}_{x\in X_d} \qquad \text{where} \qquad X_d \;:=\; \{x \in (\tfrac{1}{2}\cdot\mathbb{Z})^n \,|\, \#R_x = d\}.$$

We claim that $\mathcal{V}_0 \cup \cdots \cup \mathcal{V}_d$ has the desired properties.

open sets in $\mathcal{V}_0$ open sets in $\mathcal{V}_1$ open sets in $\mathcal{V}_2$

It remains to prove the following claim.

Claim.



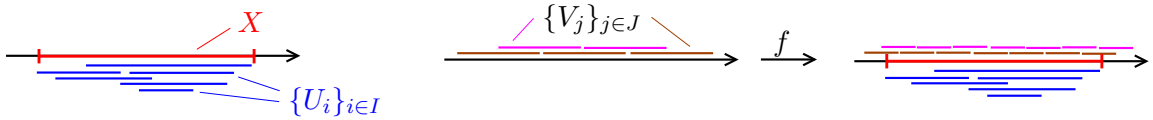
(1) Each $V(x)$ is an open subset of $\mathbb{R}^n$ with $\operatorname{diam}(V(x)) \leq \sqrt{n}$.
(2) $\mathcal{V}$ is a cover of $\mathbb{R}^n$.
(3) For every $d \in \{0, \ldots, n\}$ the sets in $\mathcal{V}_d$ are disjoint.

Proof.

(1) Let $x = (x_1, \ldots, x_n) \in (\frac{1}{2} \cdot \mathbb{Z})^n$. It is rather elementary to verify that $V(x)$ is open. We leave it to the reader to fill in the details. Furthermore note that for each $y = (y_1, \ldots, y_n) \in V(x)$ and each $i \in \{1, \ldots, n\}$ we have $y_i \in (x_i - \frac{1}{2}, x_i + \frac{1}{2})$. This implies that $\operatorname{diam}(V(x)) \leq \sqrt{n}$.
(2) Let $y = (y_1, \ldots, y_n) \in \mathbb{R}^n$. For $i = 1, \ldots, n$ we set

$$x_i := \begin{cases} y_i, & \text{if } y_i \in \mathbb{Z}, \\ \lfloor y_i \rfloor + \frac{1}{2}, & \text{if } y_i \notin \mathbb{Z} \end{cases}$$

and we set $x = (x_1, \ldots, x_n)$ Note that for $i \in \{1, \ldots, n\}$ with $y_i \notin \mathbb{Z}$ we have $i \in R_x$ and $y_i \in (x_i - \frac{1}{2}, x_i + \frac{1}{2})$. It is now clear that $y \in V(x)$.
(3) Let $d \in \{0, \ldots, n\}$ and let $x = (x_1, \ldots, x_n), y = (y_1, \ldots, y_n) \in X_d$ with $x \neq y$.
- If there exists an $i \in \{1, \ldots, n\}$ with $|x_i - y_i| \geq 1$, then it follows from considering the i-th coordinate that $V(x) \cap V(y) = \varnothing$.
- Suppose there exists no $i \in \{1, \ldots, n\}$ with $|x_i - y_i| \geq 1$. Since $x \neq y$ we see that $R_x \neq R_y$. Since $\#R_x = \#R_y$ we see that there exists an $i \in \{1, \ldots, n\}$ with $i \in R_x$ and $i \notin R_y$ and there exists a $j \in \{1, \ldots, n\}$ with $j \notin R_x$ and $j \in R_y$. It is now elementary to see that the points in $V(x)$ and $V(y)$ differ in the i-th or the j-th coordinate. ■



Proof of Theorem 11.3. Let $X \subset \mathbb{R}^n$ be a compact subspace and let $\mathcal{U} = \{U_i\}_{i \in I}$ be an open cover of X. We equip X with the usual Euclidean metric coming from $\mathbb{R}^n$.[124] Since X is compact it follows from the Lebesgue Lemma 6.5 that there exists a $\delta > 0$ such that for every subset A of X with $\operatorname{diam}(A) < \delta$ there exists an $i \in I$ with $A \subset U_i$.

[124] By Exercise 1.3 we know that this metric gives the topology of X.

By Lemma 11.4 there exists an open cover $\mathcal{V} = \{V_j\}_{j\in J}$ of order $\leq n+1$ such that for each $j \in J$ we have $\operatorname{diam}(V_j) \leq \sqrt{n}$. We consider the homeomorphism

$$\begin{array}{rccc} f\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ x & \mapsto & \frac{\delta}{2\sqrt{n}} \cdot x. \end{array}$$

It is clear that $\{f(V_j) \cap X\}_{j\in J}$ is an open cover of X of order $\leq n+1$ such that for each $j \in J$ we have $\operatorname{diam}(f(V_j) \cap X) \leq \delta$. But then it follows from the choice of δ that this is an open cover subordinate to the original open cover $\mathcal{U} = \{U_i\}_{i\in I}$ of X. ■

11.2. **Basic properties of the covering dimension.** The main goal of this section is to prove the Exhaustion-Covering Dimension Proposition 11.8 which allows us, in many cases, to obtain an upper bound on the covering dimension of a topological space in terms of covering dimensions of suitable subspaces. We start out with the following fairly straightforward lemma.

Lemma 11.5. (Closed Subspace Covering Dimension Lemma) Let X be a topological space and let $A \subset X$ be a subspace. If A is a closed subset, then $\operatorname{cdim}(A) \leq \operatorname{cdim}(X)$.

Proof. As we will see, the proof of the lemma is very similar to the proof of the Compact-Closed Lemma 1.21 (1) and of the Closed Subset-Paracompact Lemma 10.3. Indeed, let X be a topological space of covering dimension $d = \operatorname{cdim}(X)$ and let $A \subset X$ be a closed subset. If $d = \operatorname{cdim}(X) = \infty$, then the statement of the lemma is trivial. Thus we assume that $d = \operatorname{cdim}(X) < \infty$. We need to show that $\operatorname{cdim}(A) \leq d$. Let $\{U_i\}_{i\in I}$ be an open cover of A. By definition of the subspace topology there exists for each $i \in I$ an open subset V_i of X such that $U_i = V_i \cap A$. Since A is a closed subset of X see that $\{V_i\}_{i\in I}$ together with $X \setminus A$ is an open cover of X. Since $\operatorname{cdim}(X) = d$ there exists an open refinement $\{W_j\}_{j\in J}$ of this cover of X of order $\leq d+1$. Evidently $\{W_j \cap A\}_{j\in J}$ is an open refinement of our original cover of A of order $\leq d+1$. ■

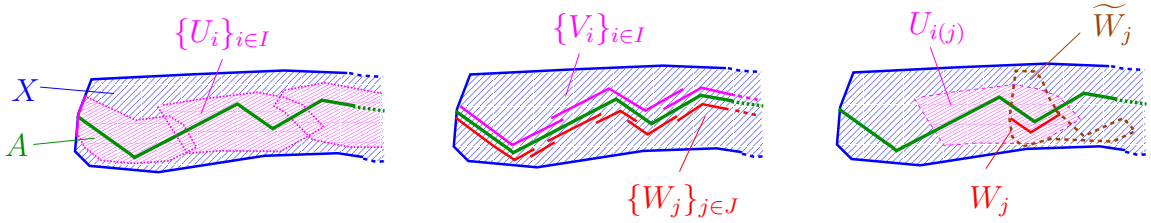
Proposition 11.6. (Finite Union-Covering Dimension Proposition) Let X be a topological space and let $A_1, A_2, \ldots, A_k$ be finitely many closed subsets of X. Then

$$\operatorname{cdim}(A_1 \cup \cdots \cup A_k) \;=\; \max\{\operatorname{cdim}(A_1), \ldots, \operatorname{cdim}(A_k)\} \;\in\; \mathbb{N}_0 \cup \{\infty\}.$$

Example. Let $n \in \mathbb{N}_0$. We can write S^n as the union of the upper and lower hemispheres $S^n_{\geq 0}$ and $S^n_{\leq 0}$. We obtain that

$$\underset{\text{by Proposition 11.6 since } S^n_{\geq 0} \text{ and } S^n_{\leq 0} \text{ are closed subsets of } S^n}{\operatorname{cdim}(S^n) \;=\; \max\{\operatorname{cdim}(S^n_{\geq 0}), \operatorname{cdim}(S^n_{\leq 0})\}} \;\underset{\text{by Lemma 11.1 since on page 152 we saw that both hemispheres are homeomorphic to } \overline{B}^n}{=}\; \operatorname{cdim}(\overline{B}^n) \;\underset{\text{Theorem 11.3}}{\leq}\; n.$$

The proof of the Finite Union-Covering Dimension Proposition 11.6 requires some preparations.



Definition. Let X be a topological space and let $A \subset X$ be a subset. We say that a family $\{U_i\}_{i\in I}$ of subsets of X has order $m \in \mathbb{N}_0 \cup \{\infty\}$ in A if the following two statements hold:[125]

(1) There exists a $J \subset I$ with $\#J = m$ such that $A \cap \bigcap_{j\in J} U_j \neq \varnothing$.

(2) For each $J \subset I$ with $\#J > m$ we have $A \cap \bigcap_{j\in J} U_j = \varnothing$.

Auxiliary Lemma 11.7. Let X be a topological space, let $d \in \mathbb{N}_0$ and let $A \subset X$ be a closed subset with $\operatorname{cdim}(A) \leq d$. If $\{U_i\}_{i\in I}$ is an open cover of X, then there exists an open refinement of $\{U_i\}_{i\in I}$ that has order at most $d+1$ in A.

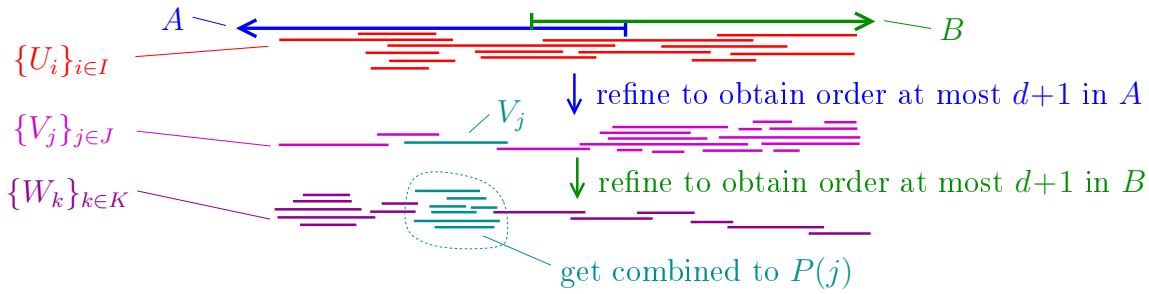
Proof of Lemma 11.7. For each $i \in I$ we set $V_i = U_i \cap A$. Since $\{V_i\}_{i\in I}$ is an open cover of A and since $\operatorname{cdim}(A) \leq d$ there exists an open refinement $\{W_j\}_{j\in J}$ of $\{V_i\}_{i\in I}$ of order $d+1$. For each $j \in J$ we can and will pick an $i(j) \in I$ with $W_j \subset V_{i(j)}$.

By definition of the subspace topology we can pick for each $j \in J$ an open subset $\widetilde{W}_j \subset X$ with $W_j = \widetilde{W}_j \cap A$. Since A is a closed subset we see that $\{\widetilde{W}_j \cap U_{i(j)}\}_{j\in J}$ together with the sets $\{U_i \setminus A\}_{i\in I}$ is an open cover of X that is a refinement of the original cover $\{U_i\}_{i\in I}$ and that has order at most $d+1$ in A. ∎

Proof of the Finite Union-Covering Dimension Proposition 11.6. An elementary induction argument shows that it suffices to prove the proposition for $k = 2$. Furthermore we can assume that the two subspaces cover the total topological space. In other words, we can assume that we are in the following setting. We are given a topological space X and two closed subsets $A, B \subset X$ such that $X = A \cup B$. We set

$$d \;:=\; \max\{\operatorname{cdim}(A), \operatorname{cdim}(B)\} \quad \in\; \mathbb{N}_0 \cup \{\infty\}.$$

We need to show that $\operatorname{cdim}(X) = d$. Since A and B are closed subsets we obtain from the Closed Subspace Covering Dimension Lemma 11.5 that $\operatorname{cdim}(X) \geq d$. Thus it remains to show that $\operatorname{cdim}(X) \leq d$.



[125] In other words, the family $\{U_i\}_{i\in I}$ of subsets of X has order m in A if and only if the family $\{U_i \cap A\}_{i\in I}$ of subsets of A has order m.

If $d = \infty$, then the statement is trivial. Thus we assume that $d \in \mathbb{N}_0$. Let $\{U_i\}_{i\in I}$ be an open cover of X. By Lemma 11.7 there exists an open refinement $\{V_j\}_{j\in J}$ of $\{U_i\}_{i\in I}$ that has order at most $d+1$ in A and there exists an open refinement $\{W_k\}_{k\in K}$ of $\{V_j\}_{j\in J}$ that has order at most $d+1$ in B.

For each $k \in K$ we pick $j(k) \in J$ with $W_k \subset V_{j(k)}$. Given $j \in J$ we set[126]

$$P(j) \ := \bigcup_{k \in K \text{ with } j(k) = j} W_k \qquad \subset \ V_j.$$

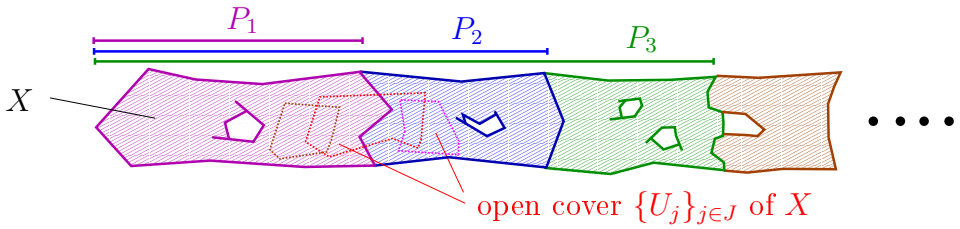
The following claim says that $\{P(j)\}_{j\in J}$ has all the desired properties.

Claim.

(1) $\{P(j)\}_{j\in J}$ is an open cover of X.
(2) $\{P(j)\}_{j\in J}$ is a refinement of the original cover $\{U_i\}_{i\in I}$ of X.
(3) The order of the open cover $\{P(j)\}_{j\in J}$ is at most $d+1$.

Proof.

(1) It is clear that each $P(j)$ is open. Furthermore, given $x \in X$ there exists a $k \in K$ with $x \in W_k$ but this implies that $x \in P(j(k))$.
(2) For every $j \in J$ we have $P(j) \subset V_j$. Since $\{V_j\}_{j\in J}$ was a refinement of $\{U_i\}_{i\in I}$ we see that $\{P(j)\}_{j\in J}$ is a refinement of $\{U_i\}_{i\in I}$.
(3) Suppose we have distinct $j_1, \ldots, j_e \in J$ such that $P(j_1) \cap \cdots \cap P(j_e)$ contains a point x. We need to show that $e \leq d+1$. For $l = 1, \ldots, e$ we can and will pick a $k_l \in K$ with $j(k_l) = j_l$ and with $x \in W_{k_l}$. Note that $k_1, \ldots, k_l$ are also distinct. Now we see that
$$x \ \in \ W_{k_1} \cap \cdots \cap W_{k_e} \ \subset \ V_{j_1} \cap \cdots \cap V_{j_e}.$$
Since $X = A \cup B$ we know that $x \in A$ or $x \in B$.
- If $x \in A$, then $e \leq d+1$ since $\{V_j\}_{j\in J}$ has order at most $d+1$ in A.
- If $x \in B$, then $e \leq d+1$ since $\{W_k\}_{k\in K}$ has order at most $d+1$ in B. ■



The following proposition can be viewed as a generalization of the Finite Union-Covering Dimension Proposition 11.6.

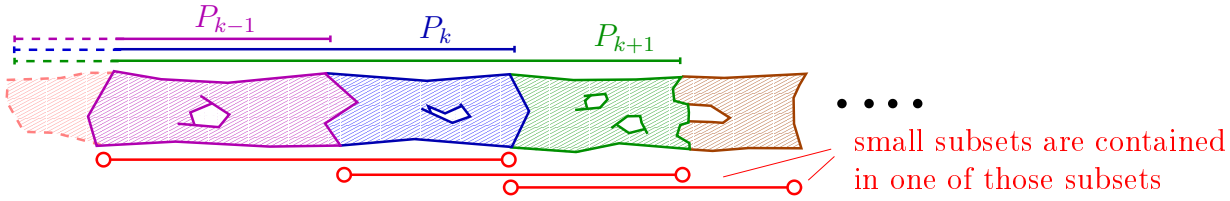
Proposition 11.8. (Exhaustion-Covering Dimension Proposition) Let X be a topological space, let $d \in \mathbb{N}_0$ and let $\{P_i\}_{i\in\mathbb{N}}$ be a sequence of closed subsets of X such that the following three conditions are satisfied:[127]

(1) We have $X = \bigcup_{i\in\mathbb{N}} P_i$.

[126] Here we use the same approach as in the proof of the Shrinking Lemma 10.10.

(2) For each $i \in \mathbb{N}$ we have $P_i \subset \mathring{P}_{i+1}$.
(3) For each $i \in \mathbb{N}$ we have $\operatorname{cdim}(P_{i+1} \setminus \mathring{P}_i) \leq d$.
Then $\operatorname{cdim}(X) \leq d$.

Remark. In many settings the combination of the Exhaustion-Covering Dimension Proposition 11.8, the Closed Subspace Covering Dimension Lemma 11.5 and the Finite Union-Covering Dimension Proposition 11.6 can be used to give an upper bound on the covering dimension of a non-compact space. For example in Proposition 11.11 we will use this trinity to show that the covering dimension of any subspace of $\mathbb{R}^n$ is $\leq n$. Furthermore in the Covering Dimension-of-Manifolds Proposition 27.7 we will use these three results to show that the covering dimension of any n-dimensional "topological manifold" is $\leq n$.



Proof. [128] Let X be a topological space, let $d \in \mathbb{N}_0$ and let $\{P_i\}_{i\in\mathbb{N}}$ be a sequence of closed subsets of X such that the following two conditions are satisfied:

(1) We have $X = \bigcup_{i\in\mathbb{N}} P_i$.
(2) For each $i \in \mathbb{N}$ we have $P_i \subset \mathring{P}_{i+1}$.

To be on the safe side we set $P_0 := \varnothing$. In the following we say that a subset $W \subset X$ is *small* if there exists a $j \in \mathbb{N}$ with $W \subset \mathring{P}_{j+1} \setminus P_{j-1}$.

Claim 1. Let $W \subset X$ be a small subset and let $k \in \mathbb{N}_0$.

(1) $\quad W \cap P_k \neq \varnothing \implies W \subset \mathring{P}_{k+1}$
(2) $\quad W \cap (X \setminus \mathring{P}_k) \neq \varnothing \implies W \cap \mathring{P}_{k-1} = \varnothing$.

[127] The first two conditions just say that $\{P_i\}_{i\in\mathbb{N}}$ is an exhaustion of X in the sense of the definition on page 338.
[128] As we mentioned above, the Exhaustion-Covering Dimension Proposition 11.8 can be viewed as a generalization of the Finite Union-Covering Dimension Proposition 11.6. In fact the proof of the Exhaustion-Covering Dimension Proposition 11.8 can be viewed as a refinement of the ideas of the proof of the Finite Union-Covering Dimension Proposition 11.6.

Proof. Note that Statement (2) is just the contrapositive of Statement (1). Thus it suffices to prove Statement (1). We assume that $W \cap P_k \neq \varnothing$. Since W is small there exists a $j \in \mathbb{N}$ with $W \subset \mathring{P}_{j+1} \setminus P_{j-1}$. Note that $W \cap P_{j-1} = \varnothing$. Since $W \cap P_k \neq \varnothing$ we see that $k \geq j$. But this implies that $W \subset \mathring{P}_{j+1} \subset \mathring{P}_{k+1}$. ⊞

Now we turn to the actual proof of the Exhaustion-Covering Dimension Proposition 11.8. Thus we make the following extra assumption:

(3) For each $i \in \mathbb{N}$ we have $\operatorname{cdim}(P_{i+1} \setminus \mathring{P}_i) \leq d$.

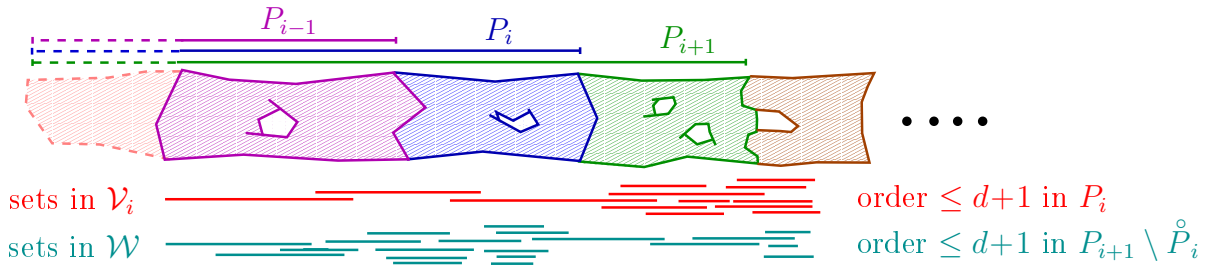
Recall that we need to show that $\operatorname{cdim}(X) \leq d$. Thus let $\mathcal{U} = \{U_j\}_{j \in J}$ be an open cover of X. It follows easily from (1) and (2) that the sets $\{\mathring{P}_{i+1} \setminus P_{i-1}\}_{i \in \mathbb{N}}$ form an open cover of X. Thus, after possibly replacing $\mathcal{U}$ by the open cover $\{U_j \cap (\mathring{P}_{i+1} \setminus P_{i-1})\}_{j \in J, i \in \mathbb{N}}$ we can assume that each set in the given open cover $\mathcal{U}$ is small in the above sense.

Claim 2. There exists a sequence $\mathcal{V}_i$, $i \in \mathbb{N}_0$ of families of subsets of X with the following properties:

(0) $\mathcal{V}_0 = \mathcal{U}$.
(1) Each $\mathcal{V}_i$ is an open cover of X.
(2) Each $\mathcal{V}_i$ with $i \geq 1$ is a refinement of $\mathcal{V}_{i-1}$.
(3) If $i \geq 1$ and $A \in \mathcal{V}_{i-1}$ is a set that is contained in $\mathring{P}_{i-2}$, then $A \in \mathcal{V}_i$.
(4) Each set in $\mathcal{V}_i$ is small in the above sense.
(5) Each $\mathcal{V}_i$ has order at most $d+1$ in P_i.

Proof. We set $\mathcal{V}_0 = \mathcal{U}$. By the discussion preceding the claim we know that (4) is satisfied. Otherwise there is nothing to show.

Now we suppose that we have already constructed $\mathcal{V}_0, \ldots, \mathcal{V}_i$ with the desired properties. By hypothesis P_{i+1} is a closed subset of X. It follows that $P_{i+1} \setminus \mathring{P}_i$ is also a closed subset of X. By hypothesis we know that $\operatorname{cdim}(P_{i+1} \setminus \mathring{P}_i) \leq d$. Thus it follows from Lemma 11.7 that there exists an open refinement $\mathcal{W}$ of $\mathcal{V}_i$ that has order at most $d+1$ in $P_{i+1} \setminus \mathring{P}_i$. Since $\mathcal{W}$ is a refinement of $\mathcal{V}_i$ we can and will pick for each $W \in \mathcal{W}$ a set $\Psi(W) \in \mathcal{V}_i$ with $W \subset \Psi(W)$. For $A \in \mathcal{V}_i$ we set



$$\Phi(A) \;:=\; (A \cap \mathring{P}_i) \cup \bigcup_{\substack{W \in \mathcal{W} \text{ with } \Psi(W) = A \\ \text{such that } W \cap P_i \neq \varnothing \\ \text{and such that } W \cap \mathring{P}_{i-1} = \varnothing}} W \;\subset A.$$

Note that for any $W \in \mathcal{W}$ with $W \cap P_i \neq \varnothing$ and with $W \cap \mathring{P}_{i-1} = \varnothing$ we have by definition $W \subset \Phi(\Psi(W))$. We define $\mathcal{V}_{i+1} \subset \mathcal{P}(X)$ to be the following two types of subsets of X:

(α) all $\Phi(A)$ for $A \in \mathcal{V}_i$,
(β) all $W \in \mathcal{W}$ such that $W \cap P_i = \varnothing$.

We need to verify that $\mathcal{V}_{i+1}$ has the desired properties:

(1) We want to show that $\mathcal{V}_{i+1}$ is an open cover of X. Evidently each set in $\mathcal{V}_{i+1}$ is open. Now let $x \in X$. We need to show that there exists a $U \in \mathcal{V}_{i+1}$ with $x \in U$.
   - First we suppose that $x \in \mathring{P}_i$. Since $\mathcal{V}_i$ is an open cover of X there exists an $A \in \mathcal{V}_i$ with $x \in A$. Since $x \in \mathring{P}_i$ we have $x \in A \cap \mathring{P}_i \subset \Phi(A)$. Thus we have shown that x is contained in a set of type (α).

- Now we suppose that $x \notin \mathring{P}_i$. Since $\mathcal{W}$ is an open cover of X we know that there exists a $W \in \mathcal{W}$ with $x \in W$. If $W \cap P_i = \varnothing$, then W is a set of type (β). Thus it remains to consider the case that $W \cap P_i \neq \varnothing$. Since $x \in W$ and $x \notin \mathring{P}_i$ we have $W \cap (X \setminus \mathring{P}_i) \neq \varnothing$, thus we obtain from Claim 1 (2), that $W \cap \mathring{P}_{i-1} = \varnothing$. This implies that $x \in W \subset \Phi(\Psi(W))$. We have thus shown that x is contained in a set of type (α).

(2) It is clear from the construction that $\mathcal{V}_{i+1}$ is a refinement of $\mathcal{V}_i$.

(3) Let $A \in \mathcal{V}_i$ be a set that is contained in $\mathring{P}_{i-1}$. By definition $\Phi(A) = A$. Thus we see that $A = \Phi(A) \in \mathcal{V}_i$.

(4) Since each set $\mathcal{V}_i$ is small and since $\mathcal{V}_{i+1}$ is a refinement of $\mathcal{V}_i$ we see that each set in $\mathcal{V}_{i+1}$ is also small.

(5) We need to show that $\mathcal{V}_{i+1}$ has order at most $d+1$ in P_{i+1}. Let $U_1, \ldots, U_k$ be distinct sets in $\mathcal{V}_{i+1}$ such that there exists an $x \in P_{i+1}$ with $x \in U_1 \cap \cdots \cap U_k$. We need to show that $k \leq d+1$.

- First we suppose that $x \in P_i$. In this case $U_1, \ldots, U_k$ are of type (α), i.e. there exist distinct $A_1, \ldots, A_k \in \mathcal{V}_i$ such that each U_j is given by $U_j = \Phi(A_j)$. By construction we have $\Phi(A_j) \subset A_j$. Thus we see that x is contained in each A_j. Since $\mathcal{V}_i$ has order at most $d+1$ in P_i we see that $k \leq d+1$.
- We suppose that $x \in P_{i+1} \setminus P_i$. After possibly reordering we can assume that $U_1, \ldots, U_l$ are of type (α) and $U_{l+1}, \ldots, U_k$ are of type (β). By definition of the two types of sets this implies the following:
  (a) There exist distinct $A_1, \ldots, A_l \in \mathcal{V}_i$ with $U_j = \Phi(A_j)$ for $j = 1, \ldots, l$. Note that by definition of the sets of type (α) and the fact that $x \notin \mathring{P}_i$ there exist $W_1, \ldots, W_l \in \mathcal{W}$ with $x \in W_j$ for $j = 1, \ldots, l$ and with $W_j \cap P_i \neq \varnothing$ for $j = 1, \ldots, l$. Since $\Psi(W_j) = A_j$ for $j = 1, \ldots, l$ are pairwise distinct we see that $W_1, \ldots, W_l$ are pairwise distinct.
  (b) We have $U_{l+1}, \ldots, U_k \in \mathcal{W}$ with $U_j \cap P_i = \varnothing$ for $j = l+1, \ldots, k$.
  It follows that $W_1, \ldots, W_l, U_{l+1}, \ldots, U_k$ are pairwise distinct sets in $\mathcal{W}$ and each contains x. Since $\mathcal{W}$ has order at most $d+1$ in $P_{i+1} \setminus \mathring{P}_i$ we see that $k \leq d+1$. ⊞

The following claim completes the proof of the proposition.

Claim 3. We consider

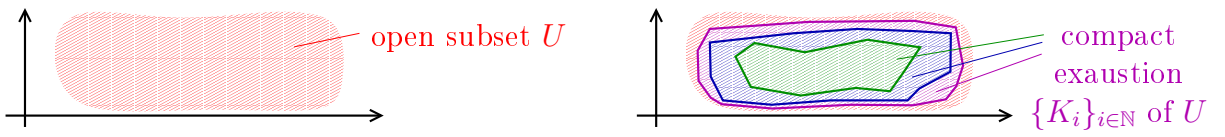
$$\mathcal{V} := \bigcup_{i \in \mathbb{N}} \{V \in \mathcal{V}_i \,|\, V \subset \mathring{P}_{i-1}\} \quad \subset \mathcal{P}(X).$$

We view $\mathcal{V}$ as a family of subsets. This family of subsets has the following properties:

(1) It is an open cover of X.
(2) It a refinement of $\mathcal{U}$.
(3) It has order at most $d+1$.

Proof.

(1) Let $x \in X$. Since $X = \bigcup_{i\in\mathbb{N}} P_i$ there exists an $i \in \mathbb{N}_{\geq 2}$ such that $x \in P_{i-2}$. Since $\mathcal{V}_i$ is an open cover of X there exists a $V \in \mathcal{V}_{i+2}$ with $x \in V$. By Claim 2 (4) we know that V is small. Therefore it follows from the fact that $V \cap P_{i-2} \neq \varnothing$ together with Claim 1 (1), that $V \subset \mathring{P}_{i-1}$, i.e. $V \in \mathcal{V}$. This shows that the sets in $\mathcal{V}$ form an open cover of X.
(2) By Claim 2 (2) each $\mathcal{V}_i$ is a refinement of $\mathcal{U}$, it follows immediately that $\mathcal{V}$ is a refinement of $\mathcal{U}$.
(3) Let $U_1, \ldots, U_k \in \mathcal{V}$ be distinct sets in $\mathcal{V}$ with $U_1 \cap \cdots \cap U_k \neq \varnothing$. We need to show that $k \leq d+1$.



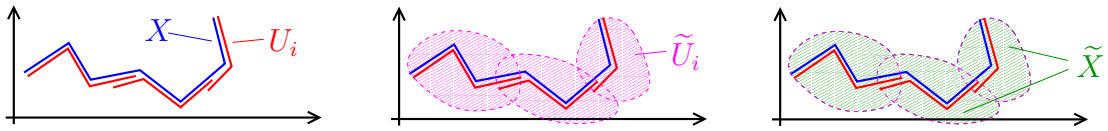
We pick $x \in U_1 \cap \cdots \cap U_k$ and we pick an $i_0 \in \mathbb{N}$ with $x \in P_{i_0}$. Next note that by definition of $\mathcal{V}$ there exists for each $j \in \{1, \ldots, k\}$ an $i_j \in \mathbb{N}$ with $U_j \in \mathcal{V}_{i_j}$ and with $U_j \subset \mathring{P}_{i_j-1}$. We set $i := \max\{i_0, i_1, \ldots, i_k\}$. It follows from Claim 2 (3), applied iteratively, that for each j we have $U_j \in \mathcal{V}_i$. By Claim 2 (5) we know that $\mathcal{V}_i$ has order at most $d+1$ in P_i. Since $x \in P_{i_0} \subset P_i$ we see that indeed $k \leq d+1$. ■

Corollary 11.9. For every open subset $U \subset \mathbb{R}^n$ we have $\operatorname{cdim}(U) \leq n$.

Proof. Let $U \subset \mathbb{R}^n$ be an open subset. By the Second Countability Lemma 9.1 we know that U is second-countable and by the discussion on page 178 we know that U is regionally compact. Evidently U is Hausdorff. It follows from the Compact Exhaustion Lemma 9.3 (1) that there exists a sequence of compact subsets $\{K_i\}_{i\in\mathbb{N}}$ of U such that the following two conditions are satisfied:

(1) for every $i \in \mathbb{N}$ we have $K_i \subset \mathring{K}_{i+1}$,
(2) we have $U = \bigcup_{i\in\mathbb{N}} K_i$.

Since $\mathbb{R}^n$ is Hausdorff we know by the Compact-Closed Lemma 1.21 that K_i is closed. Also note that each $K_{i+1} \setminus \mathring{K}_i$ is a closed subset of the compact subset K_{i+1}. In particular $K_{i+1} \setminus \mathring{K}_i$ is compact by the Compact-Closed Lemma 1.21. By Theorem 11.3 we know that for each $i \in \mathbb{N}$ we have $\operatorname{cdim}(K_{i+1} \setminus \mathring{K}_i) \leq n$. It follows from the Exhaustion-Covering Dimension Proposition 11.8 that $\operatorname{cdim}(U) \leq n$. ■



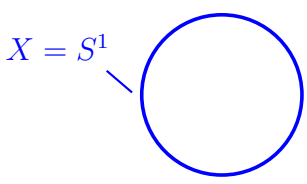
Question 11.10. Is the inequality from Corollary 11.9 always an equality? In other words, is it true that for every open subset $U \subset \mathbb{R}^n$ we have $\operatorname{cdim}(U) = n$?

We will answer the above question in Section 27.3. We conclude this discussion of the Finite Union-Covering Dimension Proposition 11.6 and its consequences with the following proposition. The statement of the proposition is perhaps not a surprise, but the proof is exceedingly neat.

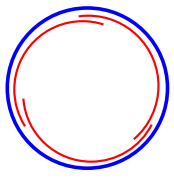
Proposition 11.11. For every subset $X \subset \mathbb{R}^n$ we have $\mathrm{cdim}(X) \leq n$.

Remark. Later, in Theorem 77.6 we will state a characterization of subsets X of $\mathbb{R}^n$ with $\mathrm{cdim}(X) = n$.

Proof. Let $\{U_i\}_{i\in I}$ be an open cover of X. By definition of the subspace topology we know that for each $i \in I$ there exists an open subset $\widetilde{U}_i$ of $\mathbb{R}^n$ with $U_i = X \cap \widetilde{U}_i$. We set $\widetilde{X} := \bigcup_{i\in I} \widetilde{U}_i$. Evidently $\widetilde{X}$ is an open subset of $\mathbb{R}^n$ and $\{\widetilde{U}_i\}_{i\in I}$ is an open cover of $\widetilde{X}$. By Corollary 11.9 we know that $\mathrm{cdim}(\widetilde{X}) \leq n$. This implies that there exists an open refinement $\{\widetilde{V}_j\}_{j\in J}$ of $\{\widetilde{U}_i\}_{i\in I}$ of order $\leq n+1$. But then $\{X \cap \widetilde{V}_j\}_{j\in J}$ is evidently an open refinement of $\{U_i\}_{i\in I}$ of order $\leq n+1$. ■

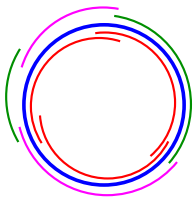


11.3. **The Covering Dimension Refinement Theorem.** The following theorem will play a crucial role in the proof of the Small Atlas Proposition 27.8 which says that every "smooth manifold" admits a "finite atlas". This result in turn is an essential ingredient in the proof of the Euclidean Embedding Theorem 27.1 that says that any "smooth manifold" admits a "smooth embedding" into some $\mathbb{R}^n$.



Theorem 11.12. (Covering Dimension Refinement Theorem) Let X be a Hausdorff space of covering dimension m and let $\{U_i\}_{i\in I}$ be an open cover of X.

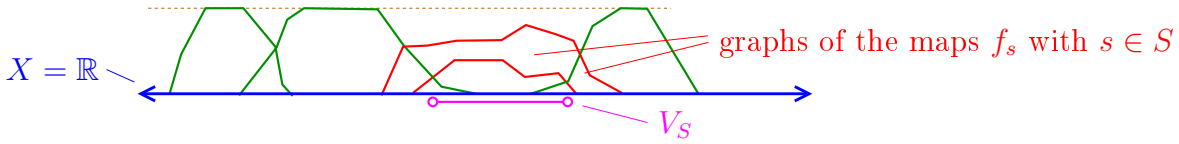
(1) If X is paracompact, then there exists a locally finite refinement $\{V_j\}_{j\in J}$ of $\{U_i\}_{i\in I}$ and subsets $J_1, \ldots, J_{m+1}$ of J such that $J = J_1 \sqcup \cdots \sqcup J_{m+1}$ and such that for any $n \in \{1, \ldots, m+1\}$ and any $r, s \in J_n$ we have $V_r \cap V_s = \varnothing$.



(2) If X is second-countable, then we can arrange that J is countable.

covering dimension = 1

open cover $\{U_i\}_{i\in I}$ of order 1



open cover $\{V_j\}_{j\in J}$ that splits into two families of disjoint sets

Proof. Let $\{U_i\}_{i\in I}$ be an open cover of X. Since X has covering dimension m we might as well assume that the open cover $\{U_i\}_{i\in I}$ has order $m+1$. If X is second-countable we can assume, by the Countable Covering Lemma 9.2, that I is countable. Since X is paracompact

and Hausdorff it follows from the Paracompact-Partition of Unity Theorem 10.9 that there exists a partition of unity $\{f_j\colon X \to [0,1]\}_{i\in I}$ such that for each $i \in I$ we have $\operatorname{supp}(f_i) \subset U_i$. Given a finite non-empty subset $S \subset I$ we set

$$V_S \;:=\; \{x \in X \,|\, f_s(x) > f_i(x) \text{ for all } s \in S \text{ and all } i \notin S\}.$$

Claim 1.

(a) Each V_S is open.
(b) Each $x \in X$ is contained in some V_S.
(c) If $i \in S$, then $V_S \subset U_i$. In particular if S is non-empty and finite, then V_S is contained in some U_i.
(d) Let S and T of I be two finite non-empty subsets of J. If $\#S = \#T$ and $S \neq T$, then $V_S \cap V_T = \varnothing$.

Proof. We basically proved this claim already in the proof of the Countable Cover Proposition 10.11. For the reader's convenience we recall the argument.

(a) Let $S \subset I$ be non-empty and finite. We need to show that V_S is open. By the JH-Lemma 1.7 it suffices to show that given any $x \in V_S$ there exists an open neighborhood U of $x \in X$ such that $V_S \cap U$ is open. Thus let $x \in V_S$. By definition of a partition of unity there exists a neighborhood U on which all but finitely many of the functions f_i vanish. We set $T := \{i \in I \setminus S \,|\, f_i(x) \neq 0\}$. We see that

$$V_S \cap U \;=\; \bigcap_{t\in T}\bigcap_{s\in S} \underbrace{\{x \in X \,|\, f_s(x) > f_t(x)\}}_{=(f_s-f_t)^{-1}((0,\infty))}.$$

This is the intersection of finitely many open sets, thus open.
(b) Let $x \in X$. By definition of a partition of unity the set $S = \{i \in I \,|\, f_i(x) > 0\}$ is finite and non-empty. Evidently we have $x \in V_S$.
(c) Let $S \subset I$ be a finite non-empty subset. Given any $i \in S$ we have $V_S \subset \operatorname{supp}(f_i) \subset U_i$.
(d) Let S and T of I be two different finite non-empty subsets of J with $\#S = \#T$. We can pick $s \in S \setminus T$ and we can pick $t \in T \setminus S$. If $x \in V_S$, then $f_s(x) > f_t(x)$ and if $x \in V_T$, then $f_t(x) > f_s(x)$. This implies that $V_S \cap V_T = \varnothing$. ⊞

Beyond this claim which is already familiar we also have the following new claim.

Claim 2. If $S \subset I$ is a finite subset with $\#S > m+1$, then $V_S = \varnothing$.

Proof. If $S \subset I$ is a finite subset with $\#S > m+1$, then

$$\underset{\text{by Claim (1c)}}{V_S \;\underset{\uparrow}{\subset}\; \bigcap_{j\in S} U_j \;\underset{\uparrow}{=}\; \varnothing.}$$

since $\#S > m+1$ and $\{U_i\}_{i\in I}$ has order $m+1$ ⊞

Given $n \in \mathbb{N}$ we set

$$J_n \;:=\; \{\text{all subsets of } I \text{ with precisely } n \text{ elements}\}$$

and we set $J := \bigsqcup_{n\in\mathbb{N}} J_n$. Now we can conclude the argument:

(1) It follows from Claim 1 (a)-(c) that $\{V_j\}_{j\in J}$ is an open refinement of the original cover $\{U_i\}_{i\in I}$. Furthermore it follows from Claim 2 that $J = J_1 \sqcup \cdots \sqcup J_{m+1}$. Finally it follows from Claim 1 (d) that for any $n \in \{1,\dots,m+1\}$ and any $S,T \in J_n$ with $S \neq T$ the sets V_S and V_T are disjoint.

(2) Finally, if X is second-countable then we already arranged that I is countable. It follows from the Countability Lemma 0.8 (3) and (6) that J is also countable. ■

11.4. **The Euclidean Embedding Theorem for Topological Spaces.** We conclude this discussion of covering dimensions with the following Embedding Theorem.

Theorem 11.13. (Euclidean Embedding Theorem for Topological Spaces) Let X be a topological space such that the covering dimension $d := \operatorname{cdim}(X)$ is finite. If X is second countable, Hausdorff and regionally compact, then there exists a closed embedding $X \to \mathbb{R}^{2d+1}$, in other words, X is homeomorphic to a closed subset of $\mathbb{R}^{2d+1}$.

Before we turn to the proof of the Euclidean Embedding Theorem 11.13 for Topological Spaces it is worth pointing out a little corollary.

Corollary 11.14. Let X be a topological space with $\operatorname{cdim}(X) < \infty$. If X is second countable, Hausdorff and regionally compact, then X is completely metrizable.[129][130]

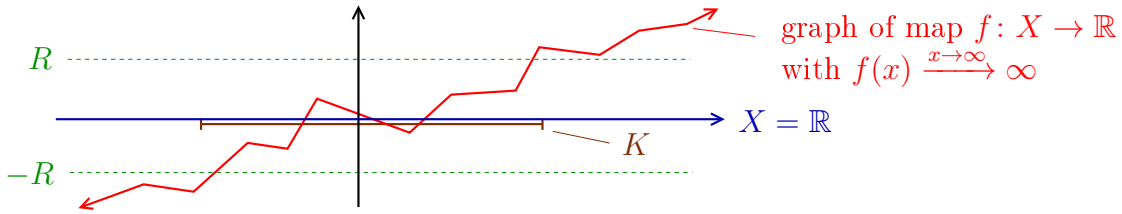
Proof. Let X be a topological space with $\operatorname{cdim}(X) < \infty$ that is second countable, Hausdorff and regionally compact. By the Euclidean Embedding Theorem 11.13 for Topological Spaces there exists an embedding $f\colon X \to \mathbb{R}^{2d+1}$ such that $f(X)$ is a closed subset. We equip $\mathbb{R}^{2d+1}$ with the usual Euclidean metric d. Since $f(X)$ is a closed subset we know by the Closed Subspace-Completeness Lemma 6.9 that $(f(X), d)$ is also complete and by Exercise 1.3 we know that the metric d on $f(X)$ gives the subspace topology.

Since $f\colon X \to f(X)$ is a homeomorphism we see that X admits a complete metric such that the metric topology agrees with the given topology. ■

The proof of the Euclidean Embedding Theorem 11.13 will require the remainder of this section. We start out with formulating a criterion for a map $f\colon X \to \mathbb{R}^N$ to be a closed embedding.

Definition. Let X be a topological space and let $f \in C(X,\mathbb{R}^N)$. We write

$$f(x) \xrightarrow{x\to\infty} \infty \quad :\Longleftrightarrow \quad \begin{array}{c}\text{for every } R>0 \text{ there exists a compact subset } K\subset X\\ \text{such that } \|f(x)\|_{\max} > R \text{ for all } x \in X\setminus K\end{array}$$



Lemma 11.15. Let X be a topological space and let $f\colon X \to \mathbb{R}^N$ be an injective map. If $f(x)\xrightarrow{x\to\infty}\infty$, then $f\colon X \to \mathbb{R}^N$ is a closed embedding.

---

[128] It is perhaps worth recalling that the Urysohn Metrization Theorem 9.4 implies that a second-countable Hausdorff space is metrizable. This shows that (1) and (2) have a significant overlap. Nonetheless the two statements are independent.

[129] Recall that on page 299 we said that a topological space X is *completely metrizable* if there exists a complete metric d on X such that the given topology agrees with the topology coming from d.

[130] Recall that by the Compact-Complete Proposition 6.10 we know that every *compact* metrizable space is already completely metrizable.

Proof. Let $f\colon X \to \mathbb{R}^N$ be a map which satisfies $f(x) \xrightarrow{x\to\infty} \infty$.

Claim. The map $f\colon X \to \mathbb{R}^N$ is proper.[131][132]

Proof. Let $L \subset \mathbb{R}^N$ be a compact subset. By Lemma 1.23 we know that L is closed and we know that it is bounded, i.e. there exists an $R \geq 0$, such that $L \subset \overline{B}_R^N(0)$. Since $f(x) \xrightarrow{x\to\infty} \infty$ there exists a compact subset $K \subset X$ with $f^{-1}(\overline{B}_R^N(0)) \subset K$. Now we see that

$$\begin{array}{rcll} f^{-1}(L) & = & f^{-1}\big(\overline{B}_R^N(0) \cap L\big) & = f^{-1}\big(\overline{B}_R^N(0)\big) \cap f^{-1}(L) \\ & \subset & K \cap f^{-1}(L) & = \text{compact subset} \cap \text{closed subset of } X \quad = \text{ compact.} \\ & & & \uparrow \text{since } L \text{ is closed} \qquad \uparrow \text{by the Compact-Closed Lemma 1.21 (1)} \end{array}$$

We have thus shown that $f\colon X \to \mathbb{R}^N$ is proper. ⊞

Now we assume that $f\colon X \to \mathbb{R}^N$ is furthermore injective. By the discussion on page 178 we know that $\mathbb{R}^N$ is regionally compact. Evidently $\mathbb{R}^N$ is also Hausdorff. Thus it follows from the Proper-Closed Proposition 2.43[133] that $f\colon X \to \mathbb{R}^N$ is in fact a closed embedding. ■

We proceed with introducing the following notation which we will use throughout the remainder of this chapter.

Notation. Let $N \in \mathbb{N}_0$.

(1) Given $x = (x_1, \ldots, x_N) \in \mathbb{R}^N$ we consider the maximum norm from page 102:

$$\|x\|_{\max} := \max\{|x_1|, \ldots, |x_N|\}.$$

(2) As in Lemma 6.11 we equip $\mathbb{R}^N$ with the metric that is given by

$$\rho(x, y) := \min\{1, \|x - y\|_{\max}\}.$$

It follows from the Equivalent Metric Lemma 1.2 and the Norm Equivalence Proposition 2.15 together with Lemma 6.11 that ρ induces the usual topology on $\mathbb{R}^N$. In particular $(\mathbb{R}^N, \rho)$ is also complete.

Let X be a topological space.

(3) We denote as usual by $C(X, \mathbb{R}^N)$ the set of continuous maps from X to $\mathbb{R}^N$.

---

[131] Recall that on page 180 we called a map $f\colon X \to Y$ between two topological spaces *proper* if the preimage of every compact subset of Y is a compact subset of X.

[132] Let $f\colon X \to \mathbb{R}^N$ be a map. The claim says that if $f(x) \xrightarrow{x\to\infty} \infty$, then f is proper. It is straightforward to show that the converse also holds. For our purpose though it is better work with the notion "$f(x) \xrightarrow{x\to\infty} \infty$" instead of the notion "proper".

[133] One can also deduce the statement from the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19.

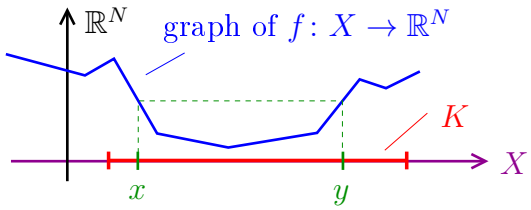
(4) If X is non-empty, then we equip $C(X,\mathbb{R}^N)$ with the metric

$$\rho(f,g) \;:=\; \sup\{\rho(f(x),g(x)) \,|\, x\in X\}.$$

Since $(\mathbb{R}^N,\rho)$ is complete we know by Proposition 6.12 that $(C(X,\mathbb{R}^N),\rho)$ is also complete.

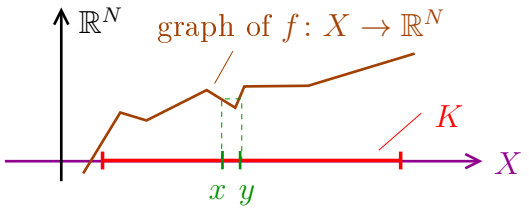
Lemma 11.16. Let X be a topological space. Furthermore let $f,g\in C(X,\mathbb{R}^N)$ such that $\rho(f,g)<1$. If $f(x)\xrightarrow{x\to\infty}\infty$, then also $g(x)\xrightarrow{x\to\infty}\infty$.

Proof. Let $R>0$. Since $f(x)\xrightarrow{x\to\infty}\infty$ there exists a compact subset $K\subset X$ such that $\|f(x)\|_{\max}>R+1$ for all $x\in X\setminus K$. For $x\in X\setminus K$ we now obtain that



$$\|g(x)\|_{\max} \underset{\text{triangle inequality}}{\geq} \|f(x)\|_{\max}-\|f(x)-g(x)\|_{\max} \underset{\substack{\text{since } \rho(f,g)<1 \text{ implies that } \rho(f(x),g(x))<1\\ \text{which implies that } \|f(x)-g(x)\|_{\max}<1}}{>} \|f(x)\|_{\max}-1 \underset{\text{choice of } K}{>} R+1-1 \;=\; R.$$

■



Definition. Let (X,d) be a metric space. Given $f\in C(X,\mathbb{R}^N)$ and given a non-empty compact subset $K\subset X$ we set

$$\Delta(f,K) \;:=\; \sup\{d(x,y)\,|\,x,y\in K \text{ with } f(x)=f(y)\}.$$

For safety, we extend this definition to $\Delta(f,\varnothing):=0$.

"large" $\Delta(f,K)$ means that $f\colon K\to\mathbb{R}^N$ is "far" from an injective map

"small" $\Delta(f,K)$ means that $f\colon K\to\mathbb{R}^N$ is "close" to an injective map

Lemma 11.17. Let (X,d) be a metric space. We equip $C(X,\mathbb{R}^N)$ with the metric ρ from above. Let $\epsilon>0$ and let $K\subset X$ be compact. Then

$$U_\epsilon(K) \;:=\; \{f\in C(X,\mathbb{R}^N)\,|\,\Delta(f,K)<\epsilon\}$$

is an open subset of $C(X,\mathbb{R}^N)$.

Proof. By definition of the topology in a metric space it suffices to show that for every $f\in U_\epsilon(K)$ there exists an $r>0$ with $B_r^\rho(f)\subset U_\epsilon(K)$. Thus let $f\in U_\epsilon(K)$. By definition of $U_\epsilon(K)$ we can pick a $b\in\mathbb{R}$ with $\Delta(f,K)<b<\epsilon$. We set

$$A \;:=\; \{(x,y)\in K\times K\,|\,d(x,y)\geq b\}.$$

In the Metric-is-Continuous Lemma 6.1 we showed that $d\colon K\times K\to\mathbb{R}$ is continuous. Thus it follows that A is a closed subset of the compact space $K\times K$. It follows from the Compact-Closed Lemma 1.21 that A itself is compact.

Claim 1. The map

$$\begin{array}{rcl} X\times X & \to & \mathbb{R} \\ (x,y) & \mapsto & \rho(f(x),f(y)) \end{array}$$

is strictly positive and continuous on A.

Proof. It follows from the Metric-is-Continuous Lemmas 6.1, Lemma 6.11 and the Product Topology-Basics Lemma 5.4 (3) that the map is continuous. Now let $(x, y) \in A \subset K \times K$. By definition of A we have $d(x, y) \geq b > \Delta(f, K)$. By definition of $\Delta(f, K)$ this implies that $f(x) \neq f(y)$. But this in turn implies that $d(f(x), f(y)) > 0$. ⊞

Since A is compact it follows from the claim and the Compact Image Lemma 2.13 that

$$r \;:=\; \tfrac{1}{2} \cdot \min\{\rho(f(x), f(y)) \,|\, (x, y) \in A\}$$

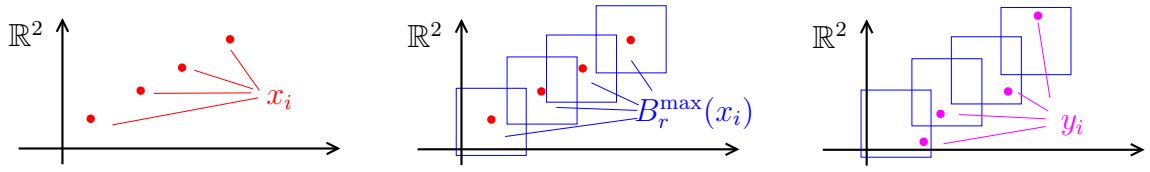
exists and that $r > 0$. It remains to prove the following claim.

Claim 2. We have $B_r^\rho(f) \subset U_\epsilon(K)$.

Proof. Let $g \in B_r^\rho(f)$, in other words, $\rho(f, g) < r$. We need to show that $g \in U_\epsilon(K)$. Since $b < \epsilon$ it suffices to show that for any $x, y \in K$ we have either $g(x) \neq g(y)$ or we have $d(x, y) \leq b$. Thus let $x, y \in K$. We distinguish two cases:

- Suppose that $(x, y) \in A$. In this case $\rho(f(x), f(y)) \geq 2r$. Note that we have the inequalities $\rho(f(x), g(x)) \leq \rho(f, g) < r$ and $\rho(f(y), g(y)) \leq \rho(f, g) < r$. In combination these show that $\rho(g(x), g(y)) > 0$, i.e. $g(x) \neq g(y)$.
- Suppose that $(x, y) \notin A$. In this case $d(x, y) < b$ by definition of A. ■

Definition.



(1) We say that points $P_0, \ldots, P_k \in \mathbb{R}^N$ are affinely independent if for every choice of $\lambda_0, \ldots, \lambda_k \in \mathbb{R}$ we have[134]

$$\sum_{i=0}^{k} \lambda_i \cdot P_i \;=\; 0 \quad \text{and} \quad \sum_{i=0}^{k} \lambda_i \;=\; 0 \qquad \Longrightarrow \qquad \lambda_0 = \cdots = \lambda_k = 0.$$

(2) We say that a subset $S \subset \mathbb{R}^N$ is in general position if every collection of $\leq N + 1$ distinct points in S is affinely independent.[135]

Lemma 11.18. Let $x_1, \ldots, x_n \in \mathbb{R}^N$ be distinct points and let $r > 0$. There exist distinct points $y_1, \ldots, y_n \in \mathbb{R}^N$ with the following properties:

(1) For all $i = 1, \ldots, n$ we have $\|x_i - y_i\|_{\max} < r$.
(2) The set $\{y_1, \ldots, y_n\}$ is in general position.

Proof. Given $x \in \mathbb{R}^N$ and $r \geq 0$ we denote by $B_r^{\max}(x) = \{y \in \mathbb{R}^N \,|\, \|x - y\|_{\max} < r\}$ the r-ball with respect to the maximum norm. With this notation we can formulate the following claim.

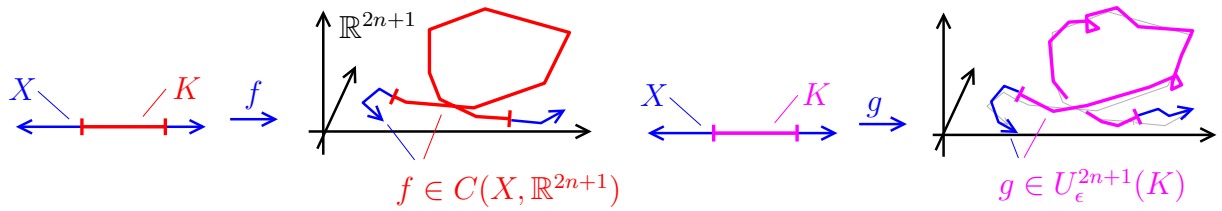
[134] In other words, $P_0, \ldots, P_k$ are affinely independent if the affine vector subspace of $\mathbb{R}^N$ spanned by these points is k-dimensional. Or put differently, $P_0, \ldots, P_k$ are affinely independent if $P_1 - P_0, \ldots, P_k - P_0$ are linearly independent.

[135] We leave it to the reader to verify that for $N = 3$ this is precisely the notion of being in general position that we introduced on page 323.

Claim. Let $V_1, \dots, V_k \subset \mathbb{R}^N$ be affine subspaces each of which has codimension ≥ 1. For each $x \in \mathbb{R}^N$ and $r > 0$ the set $B_r^{\max}(x) \setminus (V_1 \cup \dots \cup V_k)$ is non-empty.

Proof. Recall that by the Norm Equivalence Proposition 2.15 the maximum norm and the usual Euclidean norm define equivalent metrics on $\mathbb{R}^N$. Thus the desired statement follows immediately from the Baire Category Theorem 6.16 (1), the fact that the metric space $\mathbb{R}^N$ is complete and the fact that hyperplanes of codimension ≥ 1 are nowhere dense. ⊞

Let $x_1, \dots, x_n \in \mathbb{R}^N$ be distinct points and let $r > 0$. We construct the points $y_1, \dots, y_n$ iteratively. We set $y_1 := x_1$. Now suppose that points $y_1, \dots, y_k$ have already been found with the desired properties.



We denote by P the union of all affine subspaces of $\mathbb{R}^N$ that are generated by all subsets $A \subset \{y_1, \dots, y_k\}$ with $\#A \leq N$. Note that each such subspace in P has codimension $\geq N - \#A - 1 \geq 1$. By the above claim there exists a $y_{k+1} \in B_r^{\max}(x) \setminus P$. This point has the desired properties. ■

The following lemma is the key technical ingredient in the proof of the Euclidean Embedding Theorem 11.13 for Topological Spaces.

Lemma 11.19. Let (X, d) be a metric space that is second-countable and regionally compact such that $\operatorname{cdim}(X) \leq n$. If $K \subset X$ is a compact subspace, then for every $\epsilon > 0$ the set

$$U_\epsilon^{2n+1}(K) \;:=\; \{g \in C(X, \mathbb{R}^{2n+1}) \,|\, \Delta(g, K) < \epsilon\}$$

is dense in $C(X, \mathbb{R}^{2n+1})$ with respect to the metric ρ that we defined on page 383.

Proof. Let $f \in C(X, \mathbb{R}^{2n+1})$ and let $r \in (0, 1)$. We need to show that there exists a $g \in U_\epsilon^{2n+1}(K)$ such that $\rho(f, g) \leq r$.

Claim 1. There exist finitely many open non-empty subsets $U_1, \dots, U_m$ of K with the following properties:

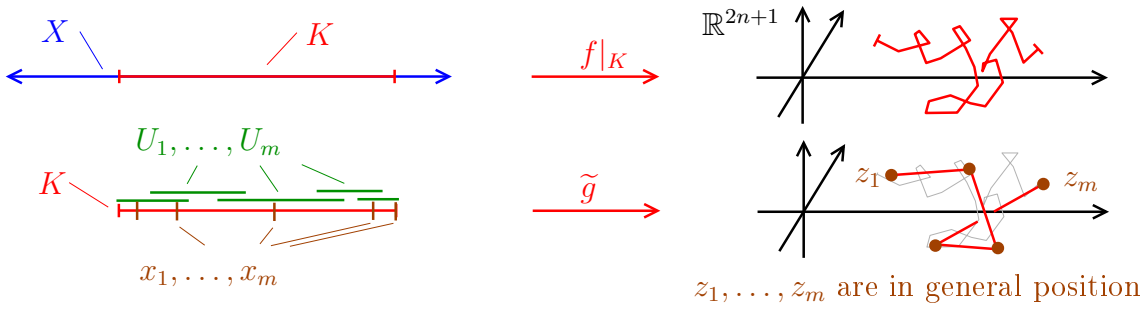
(1) the sets $U_1, \dots, U_m$ are an open cover of K,
(2) for all $i = 1, \dots, m$ we have $\operatorname{diam}(U_i) < \frac{\epsilon}{2}$,
(3) for all $i = 1, \dots, m$ we have $\operatorname{diam}(f(U_i)) < \frac{r}{2}$,
(4) the cover $\{U_1, \dots, U_m\}$ has order at most $n + 1$.

Proof. For each $x \in K$ we consider

$$V_x \;:=\; \underbrace{B_{\frac{\epsilon}{2}}^X(x)}_{\substack{\text{open ball of radius } \frac{\epsilon}{2} \\ \text{around } x \in X}} \;\cap\; f^{-1}\Big(\underbrace{B_{\frac{r}{2}}^{\mathbb{R}^{2n+1}}(f(x))}_{\substack{\text{open ball of radius } \frac{r}{2} \\ \text{around } f(x) \in \mathbb{R}^{2n+1}}} \Big) \cap K.$$

These sets form an open cover of K. By hypothesis we have $\operatorname{cdim}(X) \leq n$. Since $K \subset X$ is compact and since X is Hausdorff we know by the Compact-Closed Lemma 1.21 (2) that

$K \subset X$ is a closed subset. Thus it follows from the Closed Subspace Covering Dimension Lemma 11.5 that we also have $\operatorname{cdim}(K) \leq n$. Therefore there exists an open refinement $\{U_i\}_{i \in I}$ of the open cover $\{V_x\}_{x \in K}$ that has order at most $n+1$. Since K is compact we know that we can cover K by finitely many of the U_i. Finally, since each U_i is contained in some V_x we see that each of non-empty U_i has the desired properties (2) and (3). ⊞



Since X is regionally compact and second-countable and since metric spaces are Hausdorff we know by the Paracompact-Criterion Lemma 10.2 that X is paracompact. As we just mentioned, $K \subset X$ is a closed subset. Thus we obtain from the Closed Subset-Paracompact Lemma 10.3 that K itself is also paracompact. Thus it follows from the Paracompact-Partition of Unity Theorem 10.9 that there exists a partition of unity $\Phi_1, \ldots, \Phi_m$ on K such that for each $i \in \{1, \ldots, m\}$ we have $\operatorname{supp}(\Phi_i) \subset U_i$.

For each $i \in \{1, \ldots, m\}$ we pick a point $x_i \in U_i$. By Lemma 11.18 there exist distinct points $z_1, \ldots, z_m \in \mathbb{R}^{2n+1}$ with the following two properties:

(1) For each $i \in \{1, \ldots, m\}$ we have $\|z_i - f(x_i)\|_{\max} < \frac{r}{2}$,
(2) The set $\{z_1, \ldots, z_m\}$ is in general position.

Next we consider the map

$$\begin{array}{rccc} \widetilde{g}\colon & K & \to & \mathbb{R}^{2n+1} \\ & x & \mapsto & \sum_{i=1}^{m} \Phi_i(x) \cdot z_i. \end{array}$$

Claim 2. For all $x \in K$ we have $\|\widetilde{g}(x) - f(x)\|_{\max} < r$.

Proof. Given $x \in K$ we see that

$$\begin{aligned} \|\widetilde{g}(x) - f(x)\|_{\max} &\overset{\text{since } \Phi_1(x) + \cdots + \Phi_m(x) = 1}{=} \left\| \sum_{i=1}^{m} \Phi_i(x) \cdot (z_i - f(x_i)) \; + \; \sum_{i=1}^{m} \Phi_i(x) \cdot (f(x_i) - f(x)) \right\|_{\max} \\ &\leq \sum_{i=1}^{m} \underbrace{\Phi_i(x) \cdot \|z_i - f(x_i)\|_{\max}}_{< \frac{r}{2} \text{ by choice of } z_i} + \sum_{i=1}^{m} \Phi_i(x) \cdot \underbrace{\|f(x_i) - f(x)\|_{\max}}_{\substack{\text{if } \Phi_i(x) \neq 0, \text{ then } x \in U_i, \\ \text{since } \operatorname{diam}(f(U_i)) < \frac{r}{2} \text{ this} \\ \text{implies that this term } < \frac{r}{2}}} \\ &< \sum_{i=1}^{m} \Phi_i(x) \cdot \tfrac{r}{2} + \sum_{i=1}^{m} \Phi_i(x) \cdot \tfrac{r}{2} \;=\; r \cdot \underbrace{\sum_{i=1}^{m} \Phi_i(x)}_{=1} \;=\; r. \end{aligned}$$

⊞

Claim 3. If $x, y \in K$ satisfy $\widetilde{g}(x) = \widetilde{g}(y)$, then $d(x, y) < \frac{\epsilon}{2}$.

Proof. Let $x, y \in K$ with $\widetilde{g}(x) = \widetilde{g}(y)$. Since each $\operatorname{diam}(U_i) < \frac{\epsilon}{2}$ it suffices to show that there exists an $i \in \{1, \dots, m\}$ with $x, y \in U_i$. We set

$$A := \{i \in \{1, \dots, m\} \mid \Phi_i(x) \neq 0\} \qquad \text{and} \qquad B := \{i \in \{1, \dots, m\} \mid \Phi_i(y) \neq 0\}.$$

Recall that the cover $\{U_1, \dots, U_m\}$ has order $n+1$. Furthermore recall that by choice we know that each $\operatorname{supp}(\Phi_i)$ is contained in the corresponding U_i. Thus we see that $\#A \leq n+1$ and we see that $\#B \leq n+1$. Next note that

$$\sum_{i \in A \cup B} (\Phi_i(x) - \Phi_i(y)) \cdot z_i \underset{\substack{\uparrow \\ \text{since the } i \notin A \cup B \\ \text{do not contribute}}}{=} \widetilde{g}(x) - \widetilde{g}(y) \underset{\substack{\uparrow \\ \text{since } \widetilde{g}(x) = \widetilde{g}(y)}}{=} 0. \qquad \text{and} \qquad \sum_{i \in A \cup B} (\Phi_i(x) - \Phi_i(y)) \underset{\substack{\uparrow \\ \text{since the } \Phi_i \text{ are a partition of unity and} \\ \text{since the } i \notin A \cup B \text{ do not contribute}}}{=} 0$$

Since the points $z_1, \dots, z_m$ are distinct, since the set $\{z_1, \dots, z_m\} \subset \mathbb{R}^{2n+1}$ is in general position and since

$$\#\{z_i \mid i \in A \cup B\} = \#(A \cup B) \leq \#A + \#B = 2n+2$$

we see that $\Phi_i(x) - \Phi_i(y) = 0$ for each $i \in \{1, \dots, m\}$. Since $\sum_{i=1}^{m} \Phi_i(x) = 1$ we see that there exists an $i \in \{1, \dots, m\}$ with $\Phi_i(x) > 0$. By the above we have $\Phi_i(x) = \Phi_i(y) > 0$. This implies that $x, y \in \operatorname{supp}(\Phi_i) \subset U_i$. ⊞

In Claim 1 and 2 we constructed an interesting map $\widetilde{g} \colon K \to \mathbb{R}^{2n+1}$. It remains to extend this map in a satisfactory way to a map $g \colon X \to \mathbb{R}^{2n+1}$. To do so we consider the map

$$\begin{aligned} \Theta \colon K &\to \mathbb{R}^{2n+1} \\ x &\mapsto f(x) - \widetilde{g}(x). \end{aligned}$$

It follows from Claim 2 that this map takes values in $[-r, r]^{2n+1}$.

Since X is metric we know by the Metric Spaces-Normal Proposition 8.1 that X is normal. Furthermore, since K is compact and since X is Hausdorff we know by the Compact-Closed Lemma 1.21 that $K \subset X$ is a closed subset. This implies that we can apply the Tietze Extension Theorem 8.6 to obtain an extension of the above map $\Theta \colon K \to [-r, r]^{2n+1}$ to a continuous map $\widetilde{\Theta} \colon X \to [-r, r]^{2n+1}$. Finally we consider the map

$$\begin{aligned} g \colon X &\to \mathbb{R}^{2n+1} \\ x &\mapsto f(x) - \widetilde{\Theta}(x). \end{aligned}$$

By construction we have $g|_K = \widetilde{g}$. By Claim 3 we have $\Delta(g, K) \leq \frac{\epsilon}{2}$, which implies that $g \in U_\epsilon^{2n+1}(K)$. Furthermore, since Θ takes values in $[-r, r]^{2n+1}$ we see that $\rho(f, g) \leq r$. ■

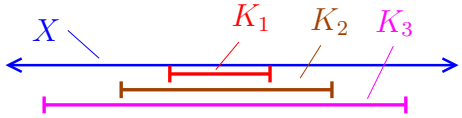
Now we turn to the actual proof of the Euclidean Embedding Theorem 11.13 for Topological Spaces.

Proof of the Euclidean Embedding Theorem 11.13. Let $n \in \mathbb{N}_0$ and let X be a topological space with $\operatorname{cdim}(X) \leq n$ that is second countable, Hausdorff and regionally compact. We need to show that X is homeomorphic to a closed subset of $\mathbb{R}^{2n+1}$. We make the following two preparations:

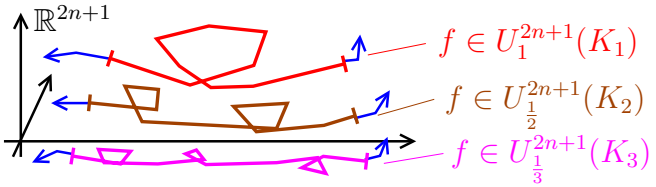
(1) Since X is second countable, Hausdorff and regionally compact we know by the Compact Exhaustion Lemma 9.3 (1) that there exists an exhaustion of X by compact subspaces. By the definition on page 338 this means that there exists a sequence

$\{K_i\}_{i\in\mathbb{N}}$ of compact subspaces of X such that the following two conditions are satisfied:

(a) We have $X = \bigcup\limits_{i\in\mathbb{N}} K_i$.



(b) For each $i \in \mathbb{N}$ we have $K_i \subset \mathring{K}_{i+1}$.



(2) Since X is second countable, Hausdorff and regionally compact we know by the Paracompact-Criterion Lemma 10.2 that X is paracompact, together with the Dieudonné Theorem 10.5 this implies that X is normal. It follows from the Urysohn Metrization Theorem 9.4 that X is metrizable. We pick a metric d on X such that the corresponding metric topology equals the given topology.

Claim 1. The set[136] $\bigcap\limits_{i=1}^{\infty} U^{2n+1}_{\frac{1}{i}}(K_i)$ is dense in $C(X,\mathbb{R}^{2n+1})$ with respect to the metric ρ that we defined on page 383.

Proof. It follows from our hypothesis that $\operatorname{cdim}(X) \leq n$, together with Lemmas 11.17 and 11.19, that each $U^{2n+1}_{\frac{1}{i}}(K_i)$ is open and dense in $C(X,\mathbb{R}^{2n+1})$. By Proposition 6.12 we know that the metric space $C(X,\mathbb{R}^{2n+1})$ is complete. The claim now follows from the Baire Category Theorem 6.16 (1) together with the Baire Space Characterization Lemma 6.17. ⊞

Claim 2. Every $f \in \bigcap\limits_{i=1}^{\infty} U^{2n+1}_{\frac{1}{i}}(K_i)$ is injective.

Proof. Let $x, y \in X$ such that $f(x) = f(y)$. There exists an $i \in \mathbb{N}$ such that for all $j \geq i$ we have $x, y \in K_j$. Now let $j \geq i$. By hypothesis $f \in U^{2n+1}_{\frac{1}{j}}(K_j)$. Thus it follows from $f(x) = f(y)$ that $d(x,y) \leq \frac{1}{j}$. Since this holds for all $j \geq i$ we see that $d(x,y) = 0$. ⊞

Since X is second countable, Hausdorff and regionally compact we know by the Exhaustion Function Lemma 10.7 that X admits an exhaustion function $\widetilde{f}\colon X \to \mathbb{R}_{\geq 0}$. Recall that according to the definition on page 358 this is a map $\widetilde{f}\colon X \to \mathbb{R}_{\geq 0}$ such that for every $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of X. We now consider the map

$$\begin{array}{rcl} f\colon X & \to & \mathbb{R}^{2n+1} \\ x & \mapsto & (\widetilde{f}(x), 0, \ldots, 0). \end{array}$$

By comparing definitions one sees that $f(x) \xrightarrow{x \to \infty} \infty$.

[136] Recall that in Lemma 11.17 we defined $U^{2n+1}_{\epsilon}(K) = \{f \in C(X,\mathbb{R}^N) \mid \Delta(f,K) < \epsilon\}$.

By Claim 1 the set $\bigcap_{i=1}^{\infty} U_{\frac{1}{i}}^{2n+1}(K_i)$ is dense in $(C(X,\mathbb{R}^{2n+1}),\rho)$. In particular we see that there exists a $\iota \in \bigcap_{i=1}^{\infty} U_{\frac{1}{i}}^{2n+1}(K_i)$ with $\rho(f,\iota) < 1$. The theorem now follows from the following observations:

(1) By Claim 2 we know that $\iota\colon X \to \mathbb{R}^N$ is injective.
(2) It follows from $\rho(f,\iota) < 1$ and Lemma 11.16 that $\iota(x) \xrightarrow{x \to \infty} \infty$.
(3) It follows from (1) and (2), together with Lemma 11.15, that $\iota\colon X \to \mathbb{R}^{2n+1}$ is a closed embedding. ■

Remark. There are many books that are completely dedicated to dimension theory, see e.g. [**HuW1948, Enge1978, Enge1995, Naga1983, Pear1975, Char2019**]. We refer the reader, whose appetite got whetted, to the above books for more results.

Exercises for Chapter 11.

Exercise 11.1. Give an example of a compact space X of covering dimension $\leq d$ and an open cover $\{U_i\}_{i\in I}$ such that there is no subset $J \subset I$ such that $\{U_j\}_{j\in J}$ is a cover of X of order $\leq d+1$.

Exercise 11.2. We consider the Topologist's Sine Curve

$$S \;:=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\} \cup \big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2.$$

Show that $\operatorname{cdim}(S) = 1$.

Exercise 11.3. Let X be a connected space with at least two points. Show that if X is T_1, in the sense of the definition on page 349, then $\operatorname{cdim}(X) \geq 1$.

Exercise 11.4. Let X be a topological space. Show that if $\operatorname{cdim}(X) = 0$, then X is normal.

Exercise 11.5. What is the covering dimension of $\mathbb{Q}$? Here we equip $\mathbb{Q} \subset \mathbb{R}$ as always with the subspace topology.

Exercise 11.6. Let C be the Cantor set as defined on page 130. What is the covering dimension of the topological space $X := (C\times[0,1]) \cup ([0,1]\times\{0\}) \subset \mathbb{R}^2$?

Exercise 11.7. Let $X = \{a,b,c,d\}$. We equip X with the topology that is generated by $\{a\},\{d\},\{b,d\}$ and $\{c,d\}$. What is $\operatorname{cdim}(X)$?

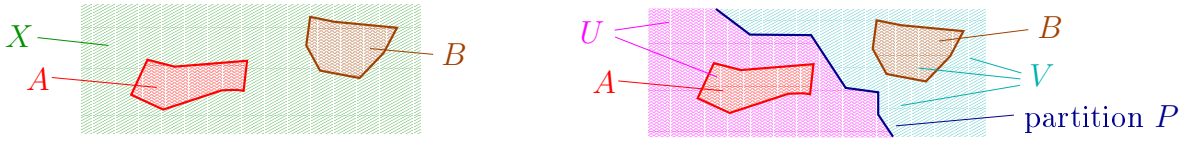
Exercise 11.8. Let X be a topological space and let $\{U_i\}_{i\in I}$ be an open cover of finite order. Is the open cover necessarily locally finite?

Exercise 11.9. Show that there exists a surjective map $f\colon X \to Y$ between topological spaces such that $\operatorname{cdim}(X) < \operatorname{cdim}(Y)$.
Remark. You could use the Cantor function from page 185.

Exercise 11.10. Let X be a topological space and let A and B be disjoint subsets of X. We say a subset $P \subset X$ is a *partition between A and B*, if there exist disjoint open subsets U and V of X with $A \subset U$, $B \subset V$ and $X \setminus P = U \cup V$.

Next we iteratively define classes $\mathcal{C}_{-1},\mathcal{C}_0,\mathcal{C}_1,\dots$ of topological spaces:

(1) We define $\mathcal{C}_{-1}$ to be the class consisting only of the empty topological space.



(2) Suppose that for some $n \in \mathbb{N}_0$ we have defined $\mathcal{C}_{-1}, \mathcal{C}_0, \ldots, \mathcal{C}_{n-1}$. Given a topological space X we say $X \in \mathcal{C}_n$ if for every $x \in X$ and every closed subset $B \subset X$ with $x \notin B$ there exists a partition P between $\{x\}$ and B with $P \in \mathcal{C}_{n-1}$.

We define $\mathcal{C}_\infty$ to be the class of all topological spaces. Note that $\mathcal{C}_{-1} \subset \mathcal{C}_0 \subset \mathcal{C}_1 \subset \ldots$. Given a topological space X we define the *small inductive dimension* $\operatorname{ind}(X)$ as follows:

$$\operatorname{ind}(X) \;:=\; \min\{n \in \mathbb{Z}_{\geq -1} \cup \{\infty\} \mid X \in \mathcal{C}_n\}.$$

Prove the following statements:

(a) If X is a non-empty discrete space, then $\operatorname{ind}(X) = 0$.
(b) The small inductive dimension of $\mathbb{R}$ equals 1.
(c) For every subspace A of a topological space X we have $\operatorname{ind}(A) \leq \operatorname{ind}(X)$.

Exercise 11.11. We iteratively define classes $\mathcal{D}_{-1}, \mathcal{D}_0, \mathcal{D}_1, \ldots$ of topological spaces:

(1) We define $\mathcal{D}_{-1}$ to be the class consisting only of the empty topological space.
(2) Suppose that for some $n \in \mathbb{N}_0$ we have defined $\mathcal{D}_{-1}, \mathcal{D}_0, \ldots, \mathcal{D}_{n-1}$. Given a topological space X we say $X \in \mathcal{D}_n$ if for any two closed disjoint subsets A and B of X there exists a partition P between A and B with $P \in \mathcal{D}_{n-1}$. (We refer to Exercise 11.10 for the definition of a partition.)

We define $\mathcal{D}_\infty$ to be the class of all topological spaces. Note that $\mathcal{D}_{-1} \subset \mathcal{D}_0 \subset \mathcal{D}_1 \subset \ldots$. Given a topological space X we define the *large inductive dimension* $\operatorname{ind}(X)$ as follows:

$$\operatorname{Ind}(X) \;:=\; \min\{n \in \mathbb{Z}_{\geq -1} \cup \{\infty\} \mid X \in \mathcal{D}_n\}.$$

Prove the following statements:

(a) The large inductive dimension of $[0,1]$ equals 1.
(b) For every closed subspace A of a topological space X we have $\operatorname{Ind}(A) \leq \operatorname{Ind}(X)$.

Exercise 11.12. Given a topological space X we denote by $\operatorname{ind}(X)$ the small inductive dimension that we defined in Exercise 11.10 and we denote by $\operatorname{Ind}(X)$ the large inductive dimension that we defined in Exercise 11.11.

(a) Let X be the Sierpiński space that we introduced on page 186, i.e. let $X = \{0,1\}$ with the topology $\mathcal{T} = \{\varnothing, X, \{0\}\}$. Show that $\operatorname{cdim}(X) = \operatorname{Ind}(X) = 0$ and show that $\operatorname{ind}(X) = \infty$.
(b) Let $X = \{1,2,3\}$ with the topology that is generated by the subsets $\{1,2\}$ and $\{2,3\}$. Show that $\operatorname{cdim}(X) = 1$ and show that $\operatorname{ind}(X) = \operatorname{Ind}(X) = \infty$.

Remark. This exercise shows that the covering dimension, the small inductive and the large inductive dimension are different "dimension functions".

Exercise 11.13. Let X be the topological space that is obtained from the open disk B^2 by removing three points. By Corollary 11.9 we know that $\operatorname{cdim}(X) \leq 2$. It follows from

the Euclidean Embedding Theorem 11.13 that there exists an embedding $f\colon X \to \mathbb{R}^5$ such that $f(X)$ is a closed subset. Determine

$$\min\{n \in \mathbb{N}_0 \,|\, \text{there exists an embedding } f\colon X \to \mathbb{R}^n \text{ such that } f(X) \text{ is a closed subset}\}.$$

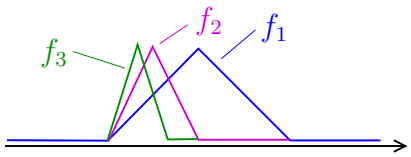
Exercise 11.14. Let $P_1, \ldots, P_5$ be five points in $\mathbb{R}^2$ that are in general position. Show that there exist four points among $P_1, \ldots, P_5$ that span a convex quadrilateral.
Remark. This result was proved by George Szekeres and Esther Klein in 1935. Paul Erdös called this statement the Happy Ending Theorem since it lead to the marriage of George Szekeres and Esther Klein who were married for 68 years.

12. The compact-open topology

Given two topological spaces X and Y we will introduce the compact-open topology on the set of all continuous maps $X \to Y$.
First, recall that we saw on page 124 that a topology on a given set X makes it possible to talk of the convergence of a sequence in X. From real analysis we know that it is not only interesting to think about convergence of sequences of points but also to talk of convergence of functions. In fact, in real analysis one often encounters two different types of convergence that we now recall.

Definition. Let $U \subset \mathbb{R}^n$ be a subset, let $\{f_n \colon U \to \mathbb{R}\}_{n\in\mathbb{N}}$ be a sequence of functions and let $f \colon U \to \mathbb{R}$ be a function. We define

$$(f_n)_{n\in\mathbb{N}} \text{ converges pointwise to } f \quad :\Longleftrightarrow \quad \underset{x\in U}{\forall} \; \underset{\epsilon>0}{\forall} \; \underset{N\in\mathbb{N}}{\exists} \; \underset{n\geq N}{\forall} \; |f_n(x) - f(x)| < \epsilon$$



and

$$(f_n)_{n\in\mathbb{N}} \text{ converges uniformly to } f \quad :\Longleftrightarrow \quad \underset{\epsilon>0}{\forall} \; \underset{N\in\mathbb{N}}{\exists} \; \underset{x\in U}{\forall} \; \underset{n\geq N}{\forall} \; |f_n(x) - f(x)| < \epsilon.$$

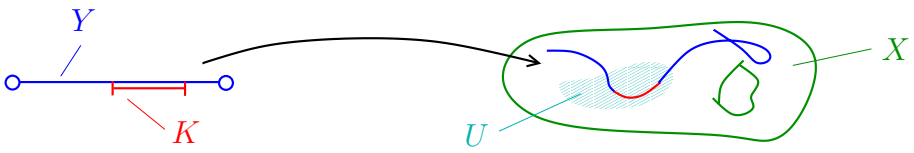
Example. We consider the sequence of functions

$$\begin{array}{rccl} f_n \colon \mathbb{R} & \to & \mathbb{R} & \\ & & \begin{cases} 0, & \text{if } t < 0 \text{ or } t > \frac{2}{n}, \\ n \cdot t, & \text{if } t \in [0, \frac{1}{n}], \\ 2 - n \cdot t, & \text{if } t \in (\frac{1}{n}, \frac{2}{n}]. \end{cases} \\ t & \mapsto & & \end{array}$$

One easily verifies that this sequence converges pointwise to the zero function but it does not converge uniformly to the zero function.

At times one also wants to study convergence of sequences of continuous[137] maps between general topological spaces. This leads us to the following definition.

Definition. Let X and Y be topological spaces.



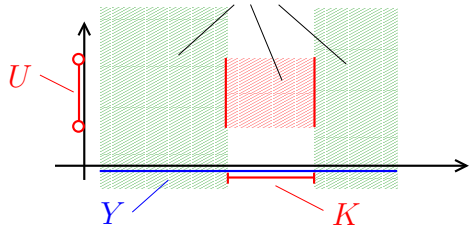
(1) We denote by $X^Y = C(Y, X)$ the set of all continuous maps from Y to X.
(2) The compact-open topology on X^Y is the topology generated, in the sense of the definition on page 135, by all the sets of the form

$$M(K, U) \;:=\; \{f \in X^Y \mid f(K) \subset U\}$$

where $K \subset Y$ is compact and where $U \subset X$ is open. This definition is illustrated in the figure below.

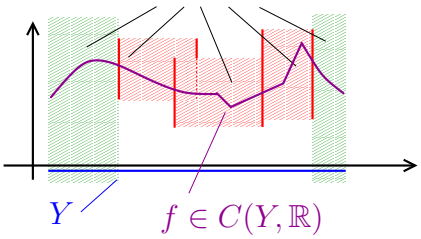
Examples.

[137] Here and in the following we sometimes talk explicitly about "continuous" maps, even though it is usually understood in these notes that all maps are continuous.



(1) Let $Y \subset \mathbb{R}$ be an interval. We want to consider the compact-open topology on $C(Y,\mathbb{R}) = \mathbb{R}^Y$. As usual we picture elements of $C(Y,\mathbb{R})$ by their graphs. In the figure below we show on the left an open set $M(K,U)$ as above and on the right we show the graph of some function $f \in C(Y,\mathbb{R})$ and an open neighborhood thereof.

Now let $f_n \in C(Y,\mathbb{R})$, $n \in \mathbb{N}$ be a sequence of functions and let $f \in C(Y,\mathbb{R})$. We leave it as an amusing, albeit somewhat lengthy, exercise to show that the following holds:



$$(f_n)_{n\in\mathbb{N}} \text{ converges}^{138} \text{ to } f \text{ with respect to the compact-open topology} \iff \text{for each compact subset } K \subset Y \text{ the sequence } (f_n|_K)_{n\in\mathbb{N}} \text{ converges uniformly to } f|_K$$

Alternatively a proof[139] for this statement is given in [**Will1970**, Theorem 43.7] or in [**Jos1983**, Theorem 15.1.2].

$M(K,U)$ are the continuous functions whose graph is contained in this set

open neighborhood of $f \in C(Y,\mathbb{R})$ with respect to the compact-open topology

(2) We consider $Y = \{1,\dots,n\}$ which we equip with the discrete topology. In Exercise 12.7 we will see that for any topological space X we have a homeomorphism $X^Y \cong X^n$.

The final example deserves its own lemma.

Lemma 12.1. Let $m,n \in \mathbb{N}$. We have the obvious inclusion

$$\begin{array}{ccc} \mathrm{M}(m\times n,\mathbb{R}) & \to & C(\mathbb{R}^n,\mathbb{R}^m) = (\mathbb{R}^m)^{\mathbb{R}^n} \\ A & \mapsto & \begin{pmatrix} \mathbb{R}^n & \to & \mathbb{R}^m \\ v & \mapsto & Av \end{pmatrix}. \end{array}$$

The compact-open topology on $C(\mathbb{R}^n,\mathbb{R}^m)$ induces the usual topology on $\mathrm{M}(m\times n,\mathbb{R})$ that we introduced on page 171.

Sketch of proof. This statement can be proved, with some effort, using the Subbasis Lemma 1.28. Alternatively the statement can also be deduced from [**Hat2002**, Proposition A.13] or [**Mun1975**, Theorem 5.1]. ■

[139] We refer to page 124 for the definition of convergence of a sequence in a topological space.

To get some practice with the compact-open topology we will prove the following two lemmas in Exercises 12.1 and 12.2.

Lemma 12.2. Let X and Y be topological spaces. If Y is Hausdorff, then X^Y is also Hausdorff.

Lemma 12.3. (Constant Map Lemma) If X and Y are non-empty topological spaces, then the map

$$\begin{array}{rcl} X & \to & X^Y \\ x & \mapsto & \text{constant map } y \mapsto x \end{array}$$

is continuous and it is an embedding.

We continue with a few technical statements on the compact-open topology. In most applications later on we will consider the case that $Y = [0,1]$. In particular the extra hypothesis in the subsequent propositions on the topological space Y will not be an issue in our future applications.

Proposition 12.4. (Evaluation Map Proposition) Let X and Y be topological spaces. If Y is regionally compact, then the following two statements hold:

(1) The evaluation map[140]

$$\begin{array}{rcl} e\colon X^Y \times Y & \to & X \\ ((f\colon Y \to X), y) & \mapsto & f(y) \end{array}$$

is continuous.

(2) For any $y \in Y$ the evaluation map

$$\begin{array}{rcl} e_y\colon X^Y & \to & X \\ (f\colon Y \to X) & \mapsto & f(y) \end{array}$$

is continuous.

Proof.

(1) Let U be an open subset of X. We need to show that $e^{-1}(U)$ is open. By the JH-Lemma 1.7 it suffices to show that given $(f,y) \in e^{-1}(U)$ there exists a neighborhood W of (f,y) with $W \subset e^{-1}(U)$. Thus let $f \in X^Y$ and $y \in Y$ with $e(f,y) = f(y) \in U$. Since f is continuous and since Y is regionally compact there exists a compact neighborhood K of y which is contained in the open neighborhood $f^{-1}(U)$ of y. In other words, we have found a compact neighborhood K of y with $f(K) \subset U$. Therefore we have $f \in M(K,U)$ and the map e sends $W := M(K,U) \times K$ into U. By the definition of the product topology the set $W = M(K,U) \times K$ is in fact a neighborhood of (f,y) in $X^Y \times Y$.

(2) This statement follows from (1) and the Product Topology-Basics Lemma 5.4 (2a). ∎

We continue with the following elementary but essential lemma.

[140] Here we equip $X^Y \times Y$ with the product topology from page 224.

Lemma 12.5. (Compact-Open Functoriality Lemma) Let X and Y be topological spaces.

(1) If $\varphi\colon X \to \widetilde{X}$ is a continuous map, then the induced map
$$\begin{array}{rcl} \varphi^*\colon X^Y & \to & \widetilde{X}^Y \\ (f\colon Y \to X) & \mapsto & (\varphi \circ f\colon Y \to \widetilde{X}) \end{array}$$
is continuous.

(2) If $\varphi\colon X \to \widetilde{X}$ is an embedding, then so is $\varphi^*\colon X^Y \to \widetilde{X}^Y$.

(3) Let $\varphi, \psi\colon X \to \widetilde{X}$ be continuous maps. If φ and ψ are homotopic[141], then so are $\varphi^*, \psi^*\colon X^Y \to \widetilde{X}^Y$.

(4) If $\widetilde{X}$ is a topological space that is homotopy equivalent to X, then $\widetilde{X}^Y$ is also homotopy equivalent to X^Y.

(5) If $\psi\colon Y \to \widetilde{Y}$ is a continuous map, then the induced map
$$\begin{array}{rcl} \psi_*\colon X^{\widetilde{Y}} & \to & X^Y \\ (f\colon \widetilde{Y} \to X) & \mapsto & (f \circ \psi\colon Y \to X) \end{array}$$
is continuous.

Remark. The Compact-Open Functoriality Lemma 12.5 (2) says in particular, that given topological spaces X and Y and a subset A of X, we can view A^Y as a subset of X^Y.

Proof. To clarify the statements we replace in this proof the notation $M(K,U)$ by the notation $M_{X^Y}(K,U)$, with the obvious interpretation thereof.

(1) We check continuity using the continuity criterion of the Subbasis-Continuity Proposition 2.9. Thus let $K \subset Y$ be a compact subset and let $U \subset \widetilde{X}$ be an open subset. We have
$$\begin{aligned} (\varphi^*)^{-1}(M_{\widetilde{X}^Y}(K,U)) &= \{f \in X^Y \mid \varphi^*(f) \in M_{\widetilde{X}^Y}(K,U)\} = \{f\colon Y \to X \mid \overbrace{(\varphi \circ f)(K)}^{=\varphi(f(K))} \subset U\} \\ &= \underset{\text{by Exercise 0.2}}{\uparrow} \{f\colon Y \to X \mid f(K) \subset \varphi^{-1}(U)\} \;=\; M_{X^Y}(K, \varphi^{-1}(U)). \end{aligned}$$
Since φ is continuous we see that $\varphi^{-1}(U)$ is an open subset of X. Since the sets $M(K,U)$ form by definition a basis for the topology of $\widetilde{X}^Y$ we deduce from the Subbasis-Continuity Proposition 2.9 that φ^* is indeed continuous.

(2) Since φ is an embedding we can identify X with its image in $\widetilde{X}$. Put differently, it suffices to consider the case of an inclusion $i\colon X \to \widetilde{X}$. By the Open -Injective Map Lemma 2.16 (1) together with Lemma 2.11 it suffices to show that for any compact subset $K \subset Y$ and any open subset $U \subset X$ the image $i_*(M_{X^Y}(K,U))$ is an open subset of $i_*(X^Y)$. Since $U \subset X$ is open there exists, by definition of the subspace

[141] We apologize to the reader for using the notion of being homotopic, even though it is only introduced on page 418. The reader who made it that far into this chapter will surely not be frightened by this inconvenience.

topology, an open subset $V \subset \widetilde{X}$ such that $U = V \cap X$. We have

$$\begin{array}{rcl} i_*(M_{X^Y}(K,U)) & = & \{i \circ f \colon Y \to \widetilde{X} \mid f \colon Y \to X \text{ and } f(K) \subset U\} \\ & = & \{f \colon Y \to X \mid f(K) \subset V\} \;=\; i_*(X^Y) \cap M_{\widetilde{X}^Y}(K,V). \end{array}$$

since $f(Y) \subset X$ implies for any $x \in X$ that $f(x) \in U$ if and only if $f(x) \in V$

By the definition of the subspace topology this is an open subset of $i_*(X^Y) \subset \widetilde{X}^Y$.

(3) Let $F \colon X \times [0,1] \to Y$ be a homotopy between $F_0 = \varphi$ and $F_1 = \psi$. Using the Subbasis-Continuity Proposition 2.9 and the JH-Lemma 1.7 it is not particularly challenging to show that the map

$$\begin{array}{rcl} X^Y \times [0,1] & \to & \widetilde{X}^Y \\ (g \colon Y \to X, t) & \mapsto & \begin{pmatrix} Y & \to & \widetilde{X} \\ y & \mapsto & F(g(x),t) \end{pmatrix} \end{array}$$

is continuous. This is the desired homotopy between φ^* and ψ^*.

(4) This statement follows almost immediately from (3).

(5) Let $K \subset Y$ be a compact subset and let $U \subset X$ be an open subset. We have

$$\begin{array}{rcl} (\psi_*)^{-1}(M_{X^Y}(K,U)) & = & \{f \in X^{\widetilde{Y}} \mid \psi_*(f) \in M_{X^Y}(K,U)\} \\ & = & \{f \colon \widetilde{Y} \to X \mid \underbrace{(f \circ \psi)(K)}_{=f(\psi(K))} \subset U\} \;=\; M_{X^{\widetilde{Y}}}(\psi(K),U). \end{array}$$

Since ψ is continuous we obtain from the Compact Image Lemma 2.13 that $\psi(K)$ is a compact subset of $\widetilde{Y}$. Thus we obtain again from the Subbasis-Continuity Proposition 2.9 that ψ_* is indeed continuous. ■

On many occasions we will also need the following rather technical proposition.

Proposition 12.6. (Compact-Open Exponential Proposition) Let Y be a topological space that is regionally compact. Furthermore let X and T be two topological spaces. Let $H \colon Y \times T \to X$ be a map. Given $t \in T$ we denote by $H_t \colon Y \to X$ the map defined by $H_t(y) := H(y,t)$. Then

$$H \colon Y \times T \to X \text{ is continuous} \iff \begin{array}{l} (1) \text{ each } H_t \colon Y \to X \text{ is continuous, and} \\ (2) \text{ the map}^{142} \; T \to X^Y \text{ given by } t \mapsto H_t \text{ is continuous.} \end{array}$$

In other words, the map

$$\begin{array}{rcl} X^{Y \times T} & \to & (X^Y)^T \\ (H \colon Y \times T \to X) & \mapsto & \begin{pmatrix} T & \to & X^Y \\ t & \mapsto & (y \mapsto H(y,t)) \end{pmatrix} \end{array}$$

is well-defined[143] and it is a bijection.

Proof. [144] Note that the "in other words" part of the proposition is indeed just a reformulation of the first part of the proposition. Thus it remains to prove the equivalence of the two statements in the beginning.

[142] Note that by (1) we know that $H_t \in X^Y$.

[143] Here "well-defined" means that the map $T \to X^Y$ actually defines an element in $(X^Y)^T$. More precisely, the map $T \to X^Y$ given by $z \mapsto (y \mapsto H(y,z))$ actually lies in $(X^Y)^T$.

[144] I strongly advise against reading the proof.

First we prove the "$\Leftarrow$"-direction. We point out that $H\colon Y\times T\to X$ is the composition of the two maps

$$\begin{array}{rcl} Y\times T & \to & X^Y\times Y \\ (y,t) & \mapsto & (H_t,y) \end{array} \qquad \text{and the evaluation map} \qquad \begin{array}{rcl} X^Y\times Y & \to & X \\ (f,y) & \mapsto & f(y). \end{array}$$

The first map is continuous by (2) and the Product Topology-Basics Lemma 5.4 (3). Furthermore, since Y is regionally compact we obtain from the Evaluation Map Proposition 12.4 that the second map is continuous. Thus H itself is continuous.

Now we turn to the "$\Rightarrow$"-direction. Thus we suppose that $H\colon Y\times T\to X$ is continuous.

(1) Let $t\in T$. The map H_t is the composition of the inclusion $Y\to Y\times T$, $y\mapsto(y,t)$ with the map H. The first map is continuous by the Product Topology-Basics Lemma 5.4 (2a) and the second map is continuous by our hypothesis. Hence H_t is also continuous. In particular we now know that H_t defines an element in X^Y.

(2) We need to show that the map $T\to X^Y$ given by $t\mapsto H_t$ is continuous. By the Subbasis-Continuity Proposition 2.9 and the JH-Lemma 1.7 it suffices to show that for any set of the form $M(K,U)\subset X^Y$ and any $t\in T$ with $H_t\in M(K,U)$ there exists a neighborhood W of $t\in T$ such that for all $t'\in W$ we have $H_{t'}\in M(K,U)$.

Thus let K be a compact subset of Y, let U be an open subset of X and let $t\in T$ with $H_t\in M(K,U)$. We start out with the following claim.

Claim. Given any $y\in K$ there exist open neighborhoods $V_y\subset Y$ of y and $W_y\subset T$ of t such that $H(V_y\times W_y)\subset U$.

Proof. By the continuity of $H\colon Y\times T\to X$ we know that $H^{-1}(U)$ is an open subset of $Y\times K$. Note that $H(y,t)=H_t(y)\in U$ since $H_t\in M(K,U)$ and $y\in K$. Thus $H^{-1}(U)$ is an open neighborhood of $(y,t)\in Y\times K$. The existence of V_y and W_y is now a consequence of the definition of the product topology of $Y\times T$. ⊞

It follows from the compactness of K and the Compact Subspace Covering Lemma 1.19 that there exist points $y_1,\dots,y_n\in K$ with $K\subset V_{y_1}\cup\dots\cup V_{y_n}$. Next we set $W:=W_{y_1}\cap\dots\cap W_{y_n}\subset T$. Note that this is an open neighborhood of t. Then

$$H(K\times W) \underset{\substack{\uparrow\\ \text{since } K\subset \bigcup_{i=1}^n V_{y_i}}}{\subset} H\Big(\bigcup_{i=1}^n V_{y_i}\times W\Big) \underset{\substack{\uparrow\\ \text{since } W\subset W_{y_i}}}{\subset} H\Big(\bigcup_{i=1}^n V_{y_i}\times W_{y_i}\Big) = \bigcup_{i=1}^n \underbrace{H(V_{y_i}\times W_{y_i})}_{\subset U} \subset U.$$

It follows from this observation and the definition of $H_{t'}$ and $M(K,U)$ that for any $t'\in W$ we have $H_{t'}\in M(K,U)$. ■

On one later occasion we will also need the following equally technical proposition.

Proposition 12.7. (Exponential Proposition) Let X,Y and Z be topological spaces. If Y and Z are both regionally compact and Hausdorff, then the map[145]

$$\begin{array}{rcl} X^{Y\times Z} & \to & (X^Y)^Z \\ (f\colon Y\times Z\to X) & \mapsto & \left(\begin{array}{rcl} Z & \to & X^Y \\ z & \mapsto & (y\mapsto f(y,z)) \end{array}\right) \end{array}$$

is a homeomorphism.

Remark. In fact a slightly stronger version of the Exponential Proposition 12.7 holds. By [**Dug1966**, Theorem XII.5.3] one only needs to assume that Y is regionally compact, with no further restrictions on X, Y or Z. We will not need this stronger statement.

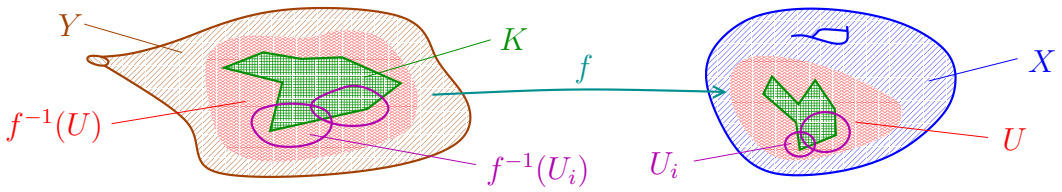
Once again no sane person will ever voluntarily read the proof. For those readers who are still around we first provide the proof of the following lemma.

Lemma 12.8. Let X and Y be topological spaces. Furthermore let $\mathcal{V}$ be a subbasis for X. We consider

$$\mathcal{C} \;=\; \big\{M(K,V) \in \mathcal{P}\big(X^Y\big) \;\big|\; K \text{ a compact subset of } Y \text{ and } V \in \mathcal{V}\big\}.$$

If Y is Hausdorff, then $\mathcal{C}$ is subbasis[146] for the topology of X^Y.

Proof. Let K be a compact subset of Y, let U be an open subset of X and let f be a point in $M(K,U)$, i.e. $f\colon Y \to X$ is a map with $K \subset f^{-1}(U)$. By the Basis Characterization Lemma 1.32 (2) we need to show that there exist finitely many $C_1, \ldots, C_m \in \mathcal{C}$ with $f \in \bigcap_{i=1}^{m} C_i \subset M(K,U)$.



Since $\mathcal{V}$ is a subbasis for the topology of X we can write $U = \bigcup_{i\in I} U_i$ where each U_i is of the form $U_i = \bigcap_{V\in P_i} V$ where P_i is a finite subset of $\mathcal{V}$. Since K is compact and since f is continuous it follows from the Compact Subspace Covering Lemma 1.19 that there exists a finite subset $J \subset I$ such that $K \subset \bigcup_{j\in J} f^{-1}(U_j)$.

Since K is compact and Hausdorff we obtain from the Shrinking Lemma 10.10, together with the Compact-Closed Lemma 1.21 (1) and the hypothesis that Y is Hausdorff, that there exist compact subsets $K_j \subset f^{-1}(U_j)$, $j \in J$, with $K \subset \bigcup_{j\in J} K_j$.

Thus we see that

$$\begin{array}{ccccccc} f & \in & \bigcap\limits_{j\in J} M(K_j,U_j) & = & \bigcap\limits_{j\in J} M\Big(K_j, \bigcap\limits_{V\in P_j} V\Big) & \overset{\text{since } M(K,A\cap B) = M(K,A)\cap M(K,B)}{=} & \bigcap\limits_{j\in J}\bigcap\limits_{V\in P_j} \underbrace{M(K_j,V)}_{\in\mathcal{C}} \;\subset\; M(K,U). \\ & & \uparrow & & \uparrow & & \uparrow \\ & & \text{since } K_j \subset f^{-1}(U_j) & & \text{definition of } P_j & & \text{since } K \subset \bigcup_{j\in J} K_j \text{ and since each } V \text{ lies in } U \end{array}$$

The finitely many sets $\{M(K_j,V)\}_{j\in J, V\in P_j}$ in $\mathcal{C}$ thus do the trick. ∎

Now we are finally ready to provide the proof of the Exponential Proposition 12.7.

[145] By the Compact-Open Exponential Proposition 12.6 we know that the map is well-defined and that it is a bijection.

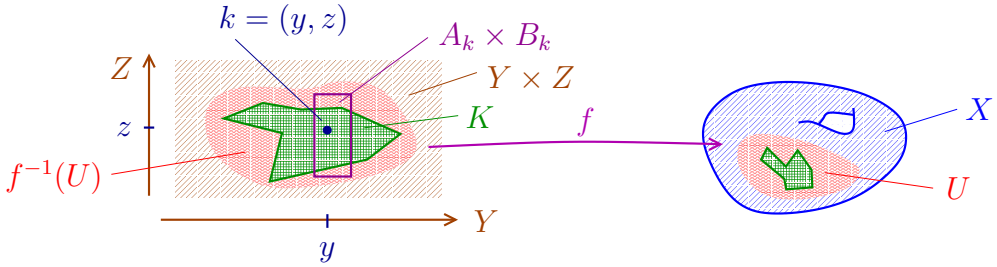
[146] We refer to page 135 for the definition of a subbasis of a topological space.

Proof of Proposition 12.7. Let X, Y and Z be topological spaces. We assume that Y and Z are both regionally compact and Hausdorff. We need to show that the map

$$\begin{array}{rcl} \Phi\colon X^{Y\times Z} & \to & (X^Y)^Z \\ (f\colon Y\times Z\to X) & \mapsto & \begin{pmatrix} Z & \to & X^Y \\ z & \mapsto & (y\mapsto f(y,z)) \end{pmatrix} \end{array}$$

is a homeomorphism.

Claim. The set



$$\mathcal{C} = \left\{ M(A\times B,U) \in \mathcal{P}\big(X^{Y\times Z}\big) \;\middle|\; \begin{array}{l} A \text{ a compact subset of } Y,\ B \text{ a compact subset of } Z \\ \text{and } U \text{ an open subset of } X \end{array} \right\}$$

is a subbasis for the topological space $X^{Y\times Z}$.

Proof. Let $K \subset Y \times Z$ be a compact subset, let U be an open subset of X and let f be a point in $M(K,U)$, i.e. $f\colon Y\times Z \to X$ is a map with $K \subset f^{-1}(U)$. By the Basis Characterization Lemma 1.32 (2) we need to show that there exist finitely many $C_1,\dots,C_m \in \mathcal{C}$ with $f \in \bigcap_{i=1}^m C_i \subset M(K,U)$.

Let $k \in K \subset Y\times Z$. We write $k=(y,z)$. Since $f^{-1}(U)$ is an open subset of $Y\times Z$ it follows from the definition of the product topology on $Y\times Z$ that there exist open neighborhoods $V_k \subset Y$ of y and $W_k \subset Z$ of z such that $k=(y,z) \in V_k \times W_k \subset f^{-1}(U)$. Since Y and Z are regionally compact we can find a compact neighborhood $A_k \subset Y$ of y and a compact neighborhood $B_k \subset Z$ of z such that $k \in A_k \times B_k \subset V_k \times W_k \subset f^{-1}(U)$. Since K is compact it follows from the Compact Subspace Covering Lemma 1.19 that there exist finitely many points $k_1,\dots,k_m \in K$ such that $K \subset \bigcup_{i=1}^m A_{k_i}\times B_{k_i}$. Now we see that

$$f \;\in\; \underset{\text{since } f(A_{k_i}\times B_{k_i})\subset U}{\uparrow} \bigcap_{i=1}^m \overbrace{M(A_{k_i}\times B_{k_I},U)}^{\in\mathcal{C}} \;\overset{\text{since } M(V\cup W,U)=M(V,U)\cap M(W,U)}{\underset{\downarrow}{=}}\; M\Big(\bigcup_{i=1}^m A_{k_i}\times B_{k_i},U\Big) \;\underset{\text{since } K\subset \bigcup_{i=1}^m A_{k_i}\times B_{k_i}}{\underset{\uparrow}{\subset}}\; M(K,U).$$

As we already remarked in the Compact-Open Exponential Proposition 12.6, the given map $\Phi\colon X^{Y\times Z} \to (X^Y)^Z$ is clearly a bijection. Furthermore under this bijection the sets $M(A\times B,U)$ are precisely the sets $M(B,M(A,U))$. By the claim the former sets form a subbasis for $X^{Y\times Z}$. Thus it suffices to show that the latter sets form a subbasis for $(X^Y)^Z$. But that is an immediate consequence of Lemma 12.8, applied twice, and our hypothesis that Y and Z are Hausdorff. ∎

The following proposition is also somewhat technical.

Proposition 12.9. (Compact-Open Composition Proposition) Let X, Y and Z be topological spaces. If Y is regionally compact, then the map

$$\begin{array}{rcl} \Phi\colon X^Y \times Y^Z & \to & X^Z \\ (f,g) & \mapsto & f \circ g \end{array}$$

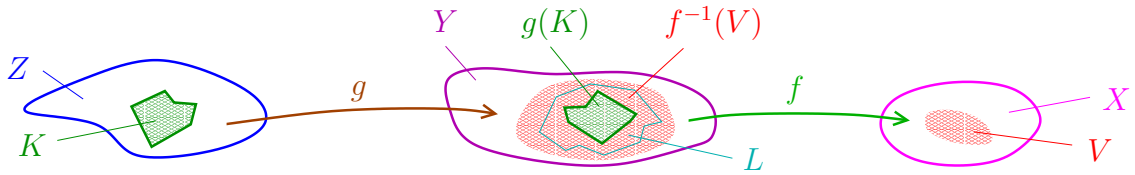
is continuous.

The proof of the Compact-Open Composition Proposition 12.9 rests on the following little lemma.

Lemma 12.10. Let Y be a topological space that is regionally compact. If K is a compact subset that is contained in an open subset U of Y, then there exists a compact subset L with $K \subset \mathring{L} \subset L \subset U$.

Proof. Let $x \in K$. Since Y is regionally compact there exists a compact neighborhood $L_x \subset U$ of x. Since K is compact there exist $x_1, \ldots, x_m \in K$ with $K \subset \mathring{L}_{x_1} \cup \cdots \cup \mathring{L}_{x_m}$. We set $L := L_{x_1} \cup \cdots \cup L_{x_m}$. By the Compact-Union-Intersection Lemma 1.20 (1) we know that L is compact. We have

$$K \subset \bigcup_{i=1}^m \mathring{L}_{x_i} \subset \underset{\text{Lemma 1.11 (1a)}}{\text{interior of}} \bigcup_{i=1}^m L_x = \mathring{L}_{x_i} \subset L \subset U.$$



■

Proof of the Compact-Open Composition Proposition 12.9. By the Subbasis-Continuity Proposition 2.9 and the JH-Lemma 1.7 and the definition of the product topology on $X^Y \times Y^Z$ it suffices to prove the following claim.

Claim. Let K be a compact subset of Z and let V be an open subset of X. If $f \in X^Y$ and $g \in Y^Z$ satisfy $f \circ g \in M(K,V)$, then there exists an open subset $U \subset Y$ and a compact subset $L \subset Y$ with

$$\Phi\big(\underbrace{M(L,V)}_{\subset X^Y} \times \underbrace{M(K,U)}_{\subset Y^Z}\big) \subset M(K,V).$$

Proof. First note that $g(K) \subset Y$ is compact by the Compact Image Lemma 2.13 and that $f^{-1}(V) \subset Y$ is open since f is evidently continuous. Since Y is regionally compact we obtain from Lemma 12.10 that there exists a compact subset L with $g(K) \subset \mathring{L} \subset L \subset f^{-1}(U)$. It is clear that $U = \mathring{L}$ and L have the desired properties. ■

The following corollary gives us a very long list of new examples of topological groups.

Corollary 12.11. Let X be a topological space. If X is compact and Hausdorff, then the group

$$\text{Homeo}(X) := \text{the set of all self-homeomorphisms of } X,$$

equipped with the subspace topology coming from X^X, is a topological group.

Remark. Let X be a topological space that is regionally compact and Hausdorff. In light of the Compact-Open Composition Proposition 12.9 one might expect that in this case

Homeo(X) forms a group. In [**Dij2005**] it is shown that this is in general *not* the case. On the other hand it is shown in [**Are1946**, Theorem 4] that if X is furthermore regionally connected, then Homeo(X) is in fact a topological group.

Proof. Let X be a topological space that is compact and Hausdorff. First note that by Lemma 2.41 we know that X is regionally compact. Thus it follows from the Compact-Open Composition Proposition 12.9 that the multiplication map $\mathrm{Homeo}(X)\times\mathrm{Homeo}(X) \to \mathrm{Homeo}(X)$ is continuous. Therefore it suffices to show that the map

$$\begin{array}{rccc} \Phi\colon & \mathrm{Homeo}(X) & \to & \mathrm{Homeo}(X) \\ & f & \mapsto & f^{-1} \end{array}$$

is continuous. The proof of continuity rests on the following simple claim.

Claim 1. If $K \subset X$ and $U \subset X$ are subsets, then $\Phi^{-1}(M(K,U)) = M(X \setminus U, X \setminus K)$.

Proof. Let $h \in \mathrm{Homeo}(X)$. We have

$$\begin{array}{lll} & \overset{\text{since } \Phi \text{ is a bijection and } \Phi(h) = h^{-1}}{\overset{\downarrow}{\iff}} & \overset{\text{since } h \text{ is a bijection}}{\overset{\downarrow}{\iff}} \\ h \in \Phi^{-1}(M(K,U)) & \iff h^{-1} \in M(K,U) & \iff h^{-1}(K) \subset U \iff K \subset h(U) \\ & \iff \underbrace{X \setminus h(U)}_{=h(X\setminus U)} \subset X \setminus K & \iff h \in M(X \setminus U, X \setminus K). \end{array}$$

⊞

By the Subbasis-Continuity Proposition 2.9 it now suffices to prove the following claim.

Claim 2. If $K \subset X$ is a compact subset and if $U \subset X$ is an open subset, then $\Phi^{-1}(M(K,U))$ is an open subset of X.

Proof. By Claim 1 we know that $\Phi^{-1}(M(K,U)) = M(X \setminus U, X \setminus K)$. Since U is open we know that $X \setminus U$ is closed. Since X is compact we obtain from the Compact-Closed Lemma 1.21 (1) that $X \setminus U$ is compact. Furthermore, since K is compact and since X is Hausdorff we obtain from the Compact-Closed Lemma 1.21 (2) that $X \setminus K$ is open. Thus we see that $M(X \setminus U, X \setminus K)$ is an open subset of X^X. ■

We conclude this section with a different source of topological groups.

Lemma 12.12. Let X be a topological space.

(1) Let $\widetilde{X}$ and Y be topological spaces. If Y is regionally compact, then the map

$$\begin{array}{rccc} \Psi\colon & X^Y \times \widetilde{X}^Y & \to & (X \times \widetilde{X})^Y \\ & (f, \widetilde{f}) & \mapsto & \left(\begin{array}{rcl} f \times \widetilde{f}\colon Y & \to & X \times \widetilde{X} \\ y & \mapsto & (f(y), \widetilde{f}(y)) \end{array} \right) \end{array}$$

is continuous.

(2) Let G be a topological group. If G is regionally compact, then the topological space G^X together with the multiplication

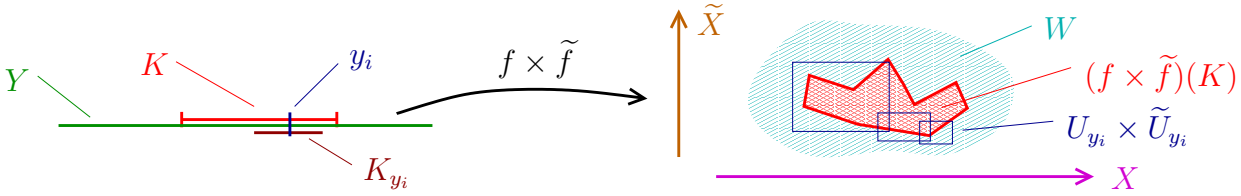
$$\begin{array}{rccc} & G^X \times G^X & \to & G^X \\ & (f,g) & \mapsto & \left(\begin{array}{rcl} X & \to & G \\ x & \mapsto & f(x) \cdot g(x) \end{array} \right) \end{array}$$

is a topological group.

Proof.

(1) By the Subbasis-Continuity Proposition 2.9 it suffices to show that for any compact subset $K \subset Y$ and any open subset $W \subset X \times \widetilde{X}$ the preimage $\Psi^{-1}\big(M_{(X\times\widetilde{X})^Y}(K,W)\big)$ is an open subset of $X^Y \times \widetilde{X}^Y$. We will do so by appealing to the JH-Lemma 1.7.

Thus let $(f,\widetilde{f}) \in \Psi^{-1}(M_{(X\times\widetilde{X})^Y}(K,W))$. Note that this means that we are given $f\colon Y \to X$ and $\widetilde{f}\colon Y \to \widetilde{X}$ with $(f\times\widetilde{f})(K) \subset W$. For each $y \in K$ we can and will pick open subsets U_y of X and $\widetilde{U}_y$ of $\widetilde{X}$ such that $(f\times\widetilde{f})(y) \in U_y \times \widetilde{U}_y \subset W$. By the Product Topology-Basics Lemma 5.4 (1b) we know that $(f\times\widetilde{f})^{-1}(U_y\times\widetilde{U}_y)$ is an open subset of Y. Since Y is regionally compact there exists a compact neighborhood K_y of y such that $y \in K_y \subset (f\times\widetilde{f})^{-1}(U_y\times\widetilde{U}_y)$.



Since K is compact we obtain from the Compact Subspace Covering Lemma 1.19 that there exist $y_1,\dots,y_m \in Y$ such that $K \subset K_{y_1}\cup\cdots\cup K_{y_m}$. Now we see that

$$(f,\widetilde{f}) \in \underset{\uparrow}{\bigcap_{i=1}^{m}} M_{X^Y}(K_{y_i},U_{y_i})\times M_{\widetilde{X}^Y}(K_{y_i},\widetilde{U}_{y_i}) \subset \underset{\uparrow}{\Psi^{-1}\big(M_{(X\times\widetilde{X})^Y}(K,W)\big)} \subset X^Y\times\widetilde{X}^Y.$$

since $(f\times\widetilde{f})(K_{y_i}) \subset U_{y_i}\times\widetilde{U}_{y_i}$ — since $U_{y_i}\times\widetilde{U}_{y_i} \subset W$ and since $K \subset \bigcup K_{y_i}$

It follows from the JH-Lemma 1.7 that $\Psi^{-1}(M_{(X\times\widetilde{X})^Y}(K,U))$ is indeed an open subset of $X^Y \times \widetilde{X}^Y$.

(2) At this stage there is not much left that needs to be done, we outsource the argument to Exercise 12.4. ■

Exercises for Chapter 12.

Exercise 12.1. Let X and Y be topological spaces. Suppose that Y is Hausdorff. Show that X^Y is also Hausdorff.

Exercise 12.2. Let X and Y be non-empty topological spaces. We consider the following map:

$$\begin{array}{rcl} \varphi\colon X & \to & X^Y \\ x & \mapsto & \text{constant map } y \mapsto x \end{array}$$

(a) Show that φ is continuous.
(b) Show that φ is an embedding.

Exercise 12.3. Let X be a topological space that is compact and Hausdorff. Show that the group $\mathrm{Homeo}(X)$ of self-homeomorphisms of X, equipped with the compact-open topology, is a topological group.

Exercise 12.4. Let $X, \widetilde{X}$ and Y be topological spaces. We suppose that Y is regionally compact and Hausdorff. Show that the map

$$\begin{array}{rcl} X^Y \times \widetilde{X}^Y & \to & (X \times \widetilde{X})^Y \\ (f,g) & \mapsto & \left(\begin{array}{ccc} Y & \to & X \times \widetilde{X} \\ y & \mapsto & (f(y), \widetilde{f}(y)) \end{array} \right) \end{array}$$

is a homeomorphism.

Remark. We refer to [**Enge1989**, Exercise 3.4B, p. 165] for a similar, and for the most part, much more general statement.

Exercise 12.5. Let X be a topological space and let G be a topological group. We suppose that G is regionally compact. Show that G^X with the multiplication

$$\begin{array}{rcl} G^X \times G^X & \to & G^X \\ (f,g) & \mapsto & \left(\begin{array}{ccc} X & \to & G \\ x & \mapsto & f(x) \cdot g(x) \end{array} \right) \end{array}$$

is a topological group.

Exercise 12.6. Let $n \in \mathbb{N}$. We consider the following map

$$\begin{array}{rcl} \Theta\colon \mathrm{SO}(n) & \to & \mathrm{Homeo}(S^{n-1}) := \text{self-homeomorphisms of } S^{n-1} \\ A & \mapsto & (P \mapsto A \cdot P). \end{array}$$

(a) Show that the map Θ is continuous.
(b) Show that the map Θ is an embedding.

Hint. Use Lemma 2.1 (4) and Lemma 12.1.

Exercise 12.7. Let $Y = \{1, \ldots, n\}$ be a finite discrete space with n elements and let X be a topological space. Show there exists a homeomorphism $X^Y \cong X^n$.

13. Mixing product and quotient topologies

In this, rather technical chapter, we will see that mixing product and quotient topologies can be quite delicate. In particular we will give rather disturbing examples of natural continuous bijections that are not homeomorphisms. Fortunately we will also give some criteria which let us circumvent these issues.

13.1. **Mixing product and quotient topologies: a disturbing example.** We start out with the following elementary lemma.

Lemma 13.1. Let X and Y be two topological spaces. Suppose we are given an equivalence relation $\sim$ on X. We denote by $\sim_\times$ the equivalence relation on $X \times Y$ that is generated by $(x, y) \sim_\times (x', y)$ whenever $x \sim x'$. The following map is a bijection and it is continuous:

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\!\sim_\times & \to & (X/\!\sim) \times Y \\ [(x, y)] & \mapsto & ([x], y). \end{array}$$

Proof. It follows basically immediately from the definition of $\sim_\times$ that the map φ is a bijection. We will walk cautiously through the continuity argument.

We denote by $p\colon X \times Y \to (X \times Y)/\!\sim_\times$ and $q\colon X \to X/\!\sim$ the two natural projections. We have the following commutative diagram

$$\begin{array}{ccc} & X \times Y & \\ {\scriptstyle p}\swarrow & & \searrow{\scriptstyle q\times \mathrm{id}_Y} \\ (X \times Y)/\!\sim_\times & \xrightarrow{\quad\varphi\quad} & (X/\!\sim) \times Y. \end{array}$$

Let $W \subset (X/\!\sim) \times Y$ be an open subset. We need to show that $\varphi^{-1}(W)$ is an open subset of $(X \times Y)/\!\sim_\times$. By definition of the quotient topology we need to show that $p^{-1}(\varphi^{-1}(W))$ is an open subset of $X \times Y$.

By the JH-Lemma 1.7 and the definition of the product topology it suffices to prove the following claim.

Claim. For each $(x, y) \in p^{-1}(\varphi^{-1}(W)) \subset X \times Y$ there exists an open neighborhood U_x of $x \in X$ and an open neighborhood V_y of $y \in Y$ such that $U_x \times V_y \subset p^{-1}(\varphi^{-1}(W))$.

Proof. Since $([x], y) \in W$ and since W is an open subset of $(X/\!\sim) \times Y$ we obtain, by definition of the product topology, an open neighborhood $\widetilde{U}_{[x]}$ of $[x] \in X/\!\sim$ and an open neighborhood V_y of $y \in Y$ with $\widetilde{U}_{[x]} \times V_y \subset W$. We set $U_x := q^{-1}(\widetilde{U}_{[x]})$. By definition of the quotient topology this is an open subset of X. Therefore it remains to show that $U_x \times V_y \subset p^{-1}(\varphi^{-1}(W))$. In other words, we need to show that $\varphi(p(U_x \times V_y)) \subset W$. This inclusion follows from the following short argument:

$$\varphi(p(U_x \times V_y)) = (\varphi \circ p)(U_x \times V_y) \underset{\substack{\uparrow \\ \text{by the above commutative triangle}}}{=} (q \times \mathrm{id}_Y)(U_x \times V_y) \underset{\substack{\uparrow \\ \text{since } U_x = q^{-1}(\widetilde{U}_{[x]})}}{=} q(q^{-1}(\widetilde{U}_{[x]})) \times V_y = \widetilde{U}_{[x]} \times V_y \subset W.$$

This concludes the proof of the claim and thus also of the lemma. ∎

One would expect that the map from Lemma 13.1 surely must be a homeomorphism. But perhaps rather shockingly, the next lemma shows that in general this is not the case:

Lemma 13.2. There exist topological spaces X and Y and an equivalence relation $\sim$ on X with the following property: If we denote by $\sim_\times$ the equivalence relation on $X \times Y$ generated by $(x, y) \sim_\times (x', y)$ whenever $x \sim x'$, then the map

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\!\sim_\times & \to & (X/\!\sim) \times Y \\ [(x, y)] & \mapsto & ([x], y) \end{array}$$

is a bijection and it is continuous, but it is *not* a homeomorphism.

Remark. We refer to [**Fab2005**, Theorem 1], [**BrownR2006**, p. 111] and [**Bou1998**, p. 128] for other examples which also show that mixing product and quotient topologies is in general a very dangerous idea.

Proof. We consider $X = \mathbb{R} \times \mathbb{N} = \{(x, n) \,|\, x \in \mathbb{R}, n \in \mathbb{N}\}$, equipped with the product topology. Let $\sim$ be the equivalence relation on X that is generated by $(0, m) \sim (0, n)$ for all $m, n \in \mathbb{N}$. We set $Y := \prod_{i \in \mathbb{N}} \mathbb{R}$, equipped with the product topology introduced on page 226. By Lemma 13.1 we know that the map

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\!\sim_\times & \to & (X/\!\sim) \times Y \\ [(x, y)] & \mapsto & ([x], y) \end{array}$$

is a bijection and that it is continuous. It remains to show that φ is not a homeomorphism. We will do so by exhibiting an open subset V of $(X \times Y)/\!\sim_\times$ such that the image $\varphi(V)$ is not an open subset of $(X/\!\sim) \times Y$.

Before we can proceed we need to introduce the following notation:

(1) We denote by $q\colon X \to X/\!\sim$ the natural projection.
(2) We write $f = q \times \mathrm{id}_Y\colon X \times Y \to (X/\!\sim) \times Y$.
(3) Given $n \in \mathbb{N}$ we set

$$U_n := \{((t, n), (y_1, y_2, y_3, \dots)) \in X \times Y \,|\, |t \cdot y_n| < 1\}.$$

and we set $U := \bigcup_{n \in \mathbb{N}} U_n$.

The key to proving the lemma is the following claim.

Claim 1. The set U has the following properties:
(1) U is an open subset of $X \times Y$,
(2) $f^{-1}(f(U)) = U$,
(3) $f(U)$ is not open in $(X/\!\sim) \times Y$.

Proof.

(1) We want to show that U is an open subset of $X \times Y$. It suffices to show that each U_n is open. First note that the map

$$\begin{array}{rcl} \gamma\colon X \times Y = \mathbb{R} \times \mathbb{N} \times \prod_{i \in \mathbb{N}} \mathbb{R} & \to & \mathbb{R} \\ (t, n, y_1, y_2, \dots) & \mapsto & t \cdot y_n \end{array}$$

is continuous by the Topological-Product Proposition 5.1. Furthermore note that $\{n\}$ is an open subset of $\mathbb{N}$. Now we see that

$$U_n = \gamma^{-1}((-1, 1)) \cap \underbrace{\mathbb{R} \times \{n\} \times \prod_{i \in \mathbb{N}} \mathbb{R}}_{\text{open by definition of the product topology}}$$

is the intersection of two open sets, thus it is open itself.

(2) We need to show $f^{-1}(f(U)) = U$. By the Image-Preimage Lemma 0.2 (1) it remains to show that $f^{-1}(f(U)) \subset U$. In other words, we need to show that if v is an element of $X \times Y$ with $f(v) \in f(U)$, then $v \in U$. But this statement follows from the following claim.

Subclaim. Let $v = ((s,m),(y_1,y_2,\dots))$ and $w = ((t,n),(z_1,z_2,\dots))$ be two elements in $X \times Y$. If $f(v) = f(w)$ and if $w \in U$, then we also have $v \in U$.

Proof. If $v = w$, then there is nothing to show. On the other hand, if $v \neq w$, then it follows from the definition of the map f and the equivalence relation $\sim$ that $s = t = 0$. But this implies that v and w lie in every U_n, in particular they both lie in U. ⊞

(3) We prove this statement by contradiction. Thus suppose that $f(U)$ is, contrary to our hopes, an open subset of $(X/\sim) \times Y$. Note that $((0,0),(0,0,\dots)) \in U$. This implies that $f((0,0),(0,0,\dots)) = ([(0,0)],(0,0,\dots))$ is contained in $f(U)$. By definition of the product topology of $(X/\sim) \times Y$ and of the product topology of $Y = \prod_{i\in\mathbb{N}} \mathbb{R}$ there exists an open subset $V \subset X/\sim$ and open subsets $W_i \subset \mathbb{R}$ with $([(0,0)],(0,0,\dots)) \in V \times \prod_{i\in\mathbb{N}} W_i \subset f(U)$ and such that all but finitely W_i are equal to $\mathbb{R}$. We pick an $N \in \mathbb{N}$ with $W_N = \mathbb{R}$. Since $[(0,0)] \in V$ we see that $q^{-1}(V)$ is an open subset of $X = \mathbb{R} \times \mathbb{N}$ that contains the subset $q^{-1}([(0,0)]) = \{0\} \times \mathbb{N}$. In particular $q^{-1}(V)$ contains some point (s,N) with $s \neq 0$. We pick a real number $y_N > \frac{1}{|s|}$ and we consider the point

$$P \;:=\; ((s,N),(0,\dots,0,\underset{\substack{\uparrow\\ N\text{-th entry}}}{y_N},0,\dots)) \;\in X \times Y.$$

Note that

$$P \underset{\substack{\uparrow\\ \text{since } (s,N)\in q^{-1}(V)\\ \text{and since } W_N=\mathbb{R}}}{\in} q^{-1}(V) \times \prod_{i\in\mathbb{N}} W_i \underset{\substack{\uparrow\\ \text{since } f = q\times \mathrm{id}_Y}}{=} f^{-1}\Big(V \times \prod_{i\in\mathbb{N}} W_i\Big) \underset{\substack{\uparrow\\ \text{see above}}}{\subset} f^{-1}(f(U)) \underset{\substack{\uparrow\\ \text{by (2)}}}{=} U = \bigcup_{n\in\mathbb{N}} U_n.$$

By definition of the U_n's we see that the only possibility is that $P \in U_N$. But we have $|s \cdot y_N| > 1$, i.e. P cannot possibly lie in U_N. We have obtained a contradiction. ⊞

It remains to prove the following claim.

Claim 2. We set $V := p(U)$.

(1) V is an open subset of $(X \times Y)/\sim_\times$,

(2) $\varphi(V)$ is not an open subset of $(X/\sim) \times Y$.

Proof. We denote by $p\colon X \times Y \to (X \times Y)/\sim_\times$ the natural projection. We have the following commutative diagram

$$\begin{array}{ccc} X \times Y & \xrightarrow{\quad f = q\times \mathrm{id}_Y \quad} & (X/\sim) \times Y \\ & {\scriptstyle p}\searrow \quad \nearrow{\scriptstyle \varphi} & \\ & (X \times Y)/\sim_\times . & \end{array}$$

Note that

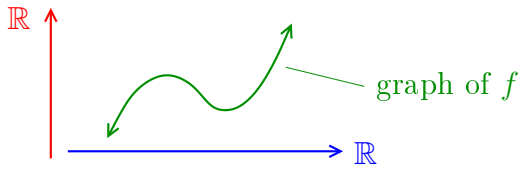
$$p^{-1}(V) \;=\; p^{-1}(p(U)) \;\underset{\uparrow}{=}\; f^{-1}(f(U)) \;\underset{\uparrow}{=}\; U \;\underset{\uparrow}{=}\; \text{an open subset of } X \times Y.$$

since $p = \varphi^{-1} \circ f$ and since φ is a bijection — by the previous claim

By the definition of the quotient topology on $(X \times Y)/\!\sim_\times$ this means that V is indeed an open subset of $(X \times Y)/\!\sim_\times$. Furthermore we have $\varphi(V) = \varphi(p(U)) = f(U)$. But by the previous claim we know that $f(U)$ is not an open subset of $(X/\!\sim) \times Y$. This concludes the proof of the claim and thus of the lemma. ■

The previous lemma leads us to the following cautionary remark:

Remark.



In general products and quotients of topological spaces do not mix well.

13.2. **Whitehead's Quotient Theorem.** In this section we will state Whitehead's Quotient Theorem. It allows us to prove the Product-Quotient Mixing Lemma 13.6 which shows that the disturbing situation of Lemma 13.1 cannot arise if Y is regionally compact. In many applications later on we will consider the case $Y = [0, 1]$ and the Product-Quotient Mixing Lemma 13.6 will ride to our rescue.

Definition. We say that a map $f\colon X \to Y$ between topological spaces is a quotient map if f is surjective and if a subset $U \subset Y$ is open in Y if and only if the preimage $f^{-1}(U)$ is open in X.

Examples.

(1) We consider the map $f\colon \mathbb{R} \to \mathbb{R}$ whose graph is shown in the figure below. This map is continuous, it is *not* an open map, but the reader is invited to verify that the map is in fact a quotient map.

(2) Let $X = \{0, 1\}$ be a set of two elements $0, 1$. Let $\mathcal{S} = \{\varnothing, X\}$ be the trivial topology and let $\mathcal{T} = \{\varnothing, X, \{0\}, \{1\}\}$ be the discrete topology. Evidently the identity map $(X, \mathcal{T}) \to (X, \mathcal{S})$ is a continuous bijection. But clearly it is not a quotient map.

The following lemma summarizes a few elementary properties of quotient maps.

Lemma 13.3. (Quotient Map Lemma)

(1) Let X be a topological space and let $\sim$ be an equivalence relation on X. The projection $X \to X/\!\sim$ is a quotient map.
(2) If $f\colon X \to Y$ is a quotient map, then it is also continuous.
(3) If $f\colon X \to Y$ is a bijection between topological spaces and if it is a quotient map, then f is a homeomorphism.

Proof.

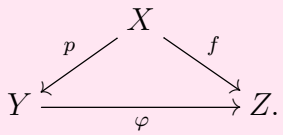
(1) This statement follows immediately from the definition of the quotient topology on the quotient $X/\!\sim$.

(2) Let $f\colon X \to Y$ be a quotient map. It follows immediately from the "only if" bit of the definition of a quotient map that f is continuous.
(3) This statement follows immediately from (2) and the Open -Injective Map Lemma 2.16 (2). ■

The following is the key technical theorem which in most reasonable situations will help us to navigate the choppy waters involving product and quotient maps.

Theorem 13.4. (Whitehead Quotient Theorem) Let $f\colon X \to Z$ be a map between topological spaces that is a quotient map. Furthermore let Y be a topological space. If Y is regionally compact (e.g. if $Y = [0,1]$), then the map

$$f \times \mathrm{id}_Y\colon X \times Y \ \to \ Z \times Y$$



is also a quotient map.

Remark. This theorem is sometimes just called the "Whitehead Theorem" since it was first proved by John Whitehead [**WhdJ1948**, Lemma 4] in 1948. For disambiguation purposes we refer to it as the Whitehead Quotient Theorem and we reserve the name "Whitehead Theorem" for Theorem 162.1.

We will provide the proof of the Whitehead Quotient Theorem 13.4 in the next section. In the following we first state and prove some useful consequences of the Whitehead Quotient Theorem 13.4. In fairness to the reader one should perhaps say that it is arguably best to move on to the next chapter. It is only advisable to read the remainder of this section once one really faces acute technical problems involving the mix of product and quotient maps.

The following little lemma is the key to many applications of the Whitehead Quotient Theorem 13.4.

Lemma 13.5. Suppose we are given a commutative diagram of maps between topological spaces:

The following two statements hold:
(1) If p and f are quotient maps, then φ is also a quotient map.
(2) If p is a quotient map and if f is continuous, then φ is continuous.

Proof.

(1) Suppose that p and f are quotient maps. Let $V \subset Z$ be an open subset. We have the following implications:

$$\begin{array}{ccccc} V \text{ is open} & \Leftrightarrow & f^{-1}(V) \text{ is open} & \Leftrightarrow & p^{-1}(\varphi^{-1}(V)) \text{ is open} \\ & \uparrow & & \uparrow & \\ & \text{since } f \text{ is a quotient map} & & \text{since } f = \varphi \circ p \text{ we have } f^{-1}(V) = p^{-1}(\varphi^{-1}(V)) & \end{array} \quad \begin{array}{ccc} \Leftrightarrow & \varphi^{-1}(V) \text{ is open.} \\ \uparrow & \\ \text{since } p \text{ is a quotient map and since } p(p^{-1}(\varphi^{-1}(V))) = \varphi^{-1}(V) & \end{array}$$

Furthermore, it follows from the fact that the diagram commutes and the fact that f is surjective, that φ is surjective. We have thus verified that φ is a quotient map.
(2) Now we suppose that p is a quotient map and that f is continuous. We need to show that given an open subset $V \subset Z$ the preimage $\varphi^{-1}(V)$ is open. The argument is

basically exactly the same as in (1), except that the first arrow is only a right arrow, since we only assume that f is continuous. ■

We have the following addendum to Lemma 13.1.

Lemma 13.6. (Product-Quotient Mixing Lemma) Let X and Y be two topological spaces. Suppose we are given an equivalence relation $\sim$ on X. We denote by $\sim_\times$ the equivalence relation on $X \times Y$ that is generated by $(x, y) \sim_\times (x', y)$ whenever $x \sim x'$. If Y is regionally compact, then the following map is a homeomorphism:

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\!\sim_\times & \to & (X/\!\sim) \times Y \\ [(x, y)] & \mapsto & ([x], y). \end{array}$$

Proof. As we pointed out in the proof of Lemma 13.1, it is basically clear that φ is a bijection. By the Quotient Map Lemma 13.3 it remains to show that φ is a quotient map. We denote by $p\colon X \times Y \to (X \times Y)/\!\sim_\times$ and $q\colon X \to X/\!\sim$ the two natural projections. We have the following commutative diagram

$$\begin{array}{ccc} & X \times Y & \\ {\scriptstyle p}\swarrow & & \searrow{\scriptstyle f=q\times \mathrm{id}_Y} \\ (X \times Y)/\!\sim_\times & \xrightarrow{\quad\varphi\quad} & (X/\!\sim) \times Y. \end{array}$$

By the Quotient Map Lemma 13.3 (1) we know that p and q are quotient maps. Since Y is regionally compact we obtain from the Whitehead Quotient Theorem 13.4 that $q \times \mathrm{id}_Y$ is a quotient map. It follows from Lemma 13.5 (1) that φ is also a quotient map. ■

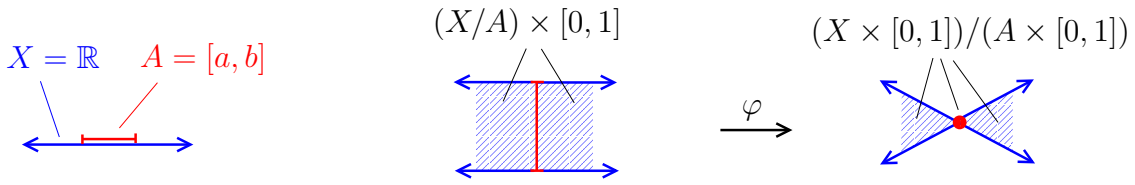
Later on we will use the following special case of the Product-Quotient Mixing Lemma 13.6.

Lemma 13.7. Let X and Y be two topological spaces, let $A \subset X$ be a subset and let $f\colon A \to Y$ be a map. Using the notation from page 262, we see that the map

$$\begin{array}{rcl} (X \times [0,1]) \cup_{f\times \mathrm{id}_{[0,1]}} (Y \times [0,1]) & \to & (X \cup_f Y) \times [0,1] \\ [(P, t)] & \mapsto & ([P], t) \end{array}$$

is a homeomorphism.

Proof. Once one unravels the definitions it is clear that this statement follows immediately from the Product-Quotient Mixing Lemma 13.6 together with the observation that $[0, 1]$ is regionally compact. ■



We conclude this list of applications of the Whitehead Quotient Theorem 13.4 with the following proposition that gives a fairly explicit illustration of how the Whitehead Quotient Theorem 13.4 can be used.

Proposition 13.8. Let X be a topological space, let A be a subset of X and let Y be a topological space that is regionally compact. Then the map

$$\begin{array}{rcl} \varphi\colon (X/A) \times Y & \to & (X \times Y)/(A \times Y) \\ ([x], y) & \mapsto & [(x, y)] \end{array}$$

is a quotient map, in particular it is continuous.

Example. In the figure below we illustrate the map studied in Proposition 13.8 in the case that $X = \mathbb{R}$, $A = [a, b]$ and $Y = [0, 1]$.

Proof. We denote by $p\colon X \times Y \to (X \times Y)/(A \times Y)$ and $q\colon X \to X/A$ the two natural projections. We have the following commutative diagram

$$\begin{array}{ccc} & X \times Y & \\ {\scriptstyle q\times \mathrm{id}_Y}\swarrow & & \searrow{\scriptstyle p} \\ (X/A) \times Y & \xrightarrow{\quad\varphi\quad} & (X \times Y)/(A \times Y). \end{array}$$

By the Quotient Map Lemma 13.3 the maps p and q are quotient maps. Since Y is regionally compact we obtain from the Whitehead Quotient Theorem 13.4 that $q \times \mathrm{id}_Y$ is a quotient map. It follows from Lemma 13.5 that φ is also a quotient map. By the Quotient Map Lemma 13.3 (2) this implies that φ is indeed continuous. ■

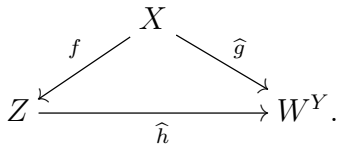
13.3. **Proof of the Whitehead Quotient Theorem 13.4.** Now that we procrastinated for as long as possible, we will finally run out of reasons not to turn to the proof of the Whitehead Quotient Theorem 13.4. In fact we provide two proofs.

The first proof of the Whitehead Quotient Theorem 13.4 cleverly reduces the proof to the Compact-Open Exponential Proposition 12.6. This approach pushes all the set-theoretic nastiness into the proof of the Compact-Open Exponential Proposition 12.6. The second proof of the Whitehead Quotient Theorem 13.4 is a bare-hands argument which can be read independently of the previous section on the compact-open topology.

Proof. First proof of Theorem 13.4, using the Compact-Open Exponential Proposition 12.6] We write $W = Z \times Y$ and we equip W with the topology that turns

$$\begin{array}{rcl} g\colon X \times Y & \to & W \\ (x, y) & \mapsto & (f(x), y) \end{array}$$

into a quotient map. In other words, as a set we have $W = Z \times Y$, but this time equipped with the topology that is defined by the condition that $U \subset W$ is open if and only if $g^{-1}(U)$ is open. Note that with this topology on W the map g is in particular continuous. Next we consider the following diagram



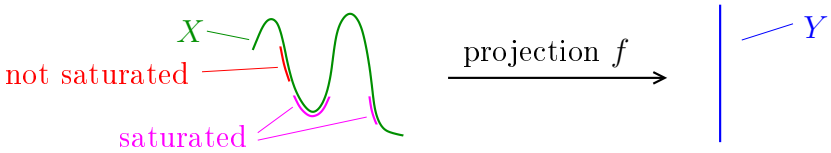
$$\begin{array}{ccc} X \times Y & \xrightarrow{\quad f\times \mathrm{id}_Y\quad} & Z \times Y \\ & {\scriptstyle g(x,y)=(f(x),y)}\searrow \quad \swarrow{\scriptstyle h(z,y)=(z,y)} & \\ & W & \end{array}$$

where $h\colon Z \times Y \to W$ is the identity. Since g is by definition a quotient map it remains to show that h is a homeomorphism. Evidently h is a bijection. Furthermore note that every open set in $Z \times Y$ is open in W since $f \times \mathrm{id}_Y$ is continuous. Thus it remains to show that h is continuous.

We consider the maps

$$\begin{array}{rcl} \widehat{g}\colon X & \to & W^Y \\ x & \mapsto & \begin{pmatrix} Y & \to & W \\ y & \mapsto & g(x,y) \end{pmatrix} \end{array} \quad \text{and} \quad \begin{array}{rcl} \widehat{h}\colon Z & \to & W^Y \\ z & \mapsto & \begin{pmatrix} Y & \to & W \\ y & \mapsto & h(z,y) \end{pmatrix} \end{array}$$

These maps fit into the following commutative diagram:



We make the following observations:

(1) Since $g\colon X \times Y \to W$ is continuous and since Y is by hypothesis regionally compact we obtain from the Compact-Open Exponential Proposition 12.6 that $\widehat{g}\colon X \to W^Y$ is continuous.
(2) By our hypothesis the map f is a quotient map.
(3) It follows from (1) and (2), together with Lemma 13.5 (2), that the map $\widehat{h}\colon Z \to W^Y$ is continuous.
(4) It follows from the Compact-Open Exponential Proposition 12.6 and (3) that h is indeed continuous. ■

Our second proof of the Whitehead Quotient Theorem 13.4 is independent of earlier results. But it does mean that we will have to get our hands somewhat dirty.

Definition. Let $f\colon X \to Y$ be a map between two sets. We say $U \subset X$ is saturated with respect to f if $U = f^{-1}(f(U))$. If f is understood, then we just say U is saturated.

Remark. Let $f\colon X \to Y$ be a map between two sets.

(1) Let $U \subset Y$ be a subset. By the Image-Preimage Lemma 0.2 (1) we know that $U \subset f^{-1}(f(U))$. Thus U is saturated if and only if $f^{-1}(f(U)) \subset U$.
(2) If f is an injection, then it follows from the Image-Preimage Lemma 0.2 (1) that every subset of X is saturated.

The following is, besides the Image-Preimage Lemma 0.2, the only purely set-theoretic lemma of these notes.

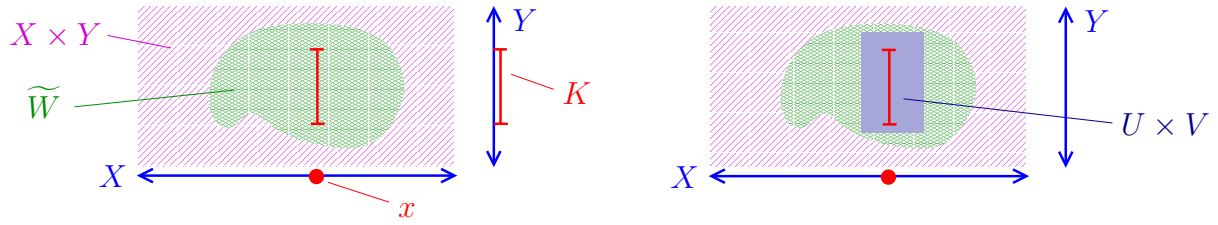
Lemma 13.9. Let $f\colon X \to Z$ be a map between two sets and let Y be another set. Let $\widetilde{W}$ be a subset of $X \times Y$ that is saturated with respect to the map $f \times \mathrm{id}_Y\colon X \times Y \to Z \times Y$. Let $K \subset Y$. We consider the set

$$U \;:=\; \{x' \in X \,|\, \{x'\} \times K \subset \widetilde{W}\}.$$

The set U is saturated with respect to f.

Proof. We write $h = f \times \mathrm{id}_Y$. By the above we need to show that $f^{-1}(f(U)) \subset U$. Thus let $x \in f^{-1}(f(U)) \subset X$. We have

$$h(\{x\}\times K) \underset{\substack{\uparrow\\ \text{definition of } h}}{=} (f\times \mathrm{id}_Y)(\{x\}\times K) = \{f(x)\}\times K \underset{\substack{\uparrow\\ \text{since } f(x)\in f(U) \text{ we know that}\\ f(x)=f(x') \text{ for some } x'\in U}}{=} \{f(x')\}\times K \underset{\substack{\uparrow\\ \text{definition of}\\ h = f\times \mathrm{id}_Y}}{=} h(\{x'\}\times K) \underset{\substack{\uparrow\\ \text{since } x'\in U}}{\subset} h(\widetilde{W}).$$



It follows that

$$\{x\}\times K \underset{\substack{\uparrow\\ \text{Image-Preimage Lemma 0.2 (1)}}}{\subset} h^{-1}(h(\{x\}\times K) \underset{\substack{\uparrow\\ \text{by the above argument}}}{\subset} h^{-1}(h(\widetilde{W})) \underset{\substack{\uparrow\\ \text{since } \widetilde{W} \text{ is saturated}}}{=} \widetilde{W}.$$

We have thus shown that $x \in U$. ∎

We will also need the following lemma which is again in the realm of topological spaces. It can be viewed as a minuscule generalization of the Tube Lemma from Exercise 5.9.

Lemma 13.10. Let X and Y be topological spaces, let $x \in X$ and let $K \subset Y$ be a compact subset. Let $\widetilde{W} \subset X \times Y$ be an open subset that contains $\{x\} \times K$. There exist open neighborhoods $U \subset X$ of x and $V \subset Y$ of K such that $\{x\} \times K \subset U \times V \subset \widetilde{W}$.

Proof of Lemma 13.10. Since $\widetilde{W} \subset X \times Y$ is open and since $\{x\} \times K \subset \widetilde{W}$ we can find for any $k \in K$ open neighborhoods A_k of $x \in X$ and B_k of $k \in Y$ such that $A_k \times B_k \subset \widetilde{W}$. Since K is compact there exist $k_1, \ldots, k_m \in K$ such that $K \subset V := B_{k_1} \cup \cdots \cup B_{k_m}$. We define $U := U_{k_1} \cap \cdots \cap U_{k_m}$. Since U is the intersection of finitely many open sets each of which contain x we see that U is an open neighborhood of x. Clearly we have the inclusions $\{x\} \times K \subset U \times V \subset \widetilde{W}$. ∎

For convenience we remind the reader of the following lemma.

Lemma 1.7. Let X be a topological space and let $U \subset X$ be a subset. If given any $x \in U$ there exists a neighborhood V of x that is contained in U, then U is open.

Now we can provide our alternative proof of the Whitehead Quotient Theorem 13.4.

Second proof of Theorem 13.4. Let $f\colon X \to Z$ be a map between topological spaces that is a quotient map. Furthermore let Y be a topological space that is regionally compact. We need to show that the map

$$f \times \mathrm{id}_Y\colon X \times Y \;\to\; Z \times Y$$

is also a quotient map.

Since f is a quotient map we know by the Quotient Map Lemma 13.3 (2) that f is continuous. Therefore it follows from the Product Topology-Basics Lemma 5.4 (3) that the map $f \times \mathrm{id}_Y$ is continuous. Therefore it now remains to show that if $W \subset Z \times Y$ is a subset

such that the preimage $\widetilde{W} := (f \times \mathrm{id}_Y)^{-1}(W)$ is an open subset of $X \times Y$, then W itself is open.

We intend to use the JH-Lemma 1.7 to show that W is open. Thus let $(z, y) \in W$. We pick $x_0 \in f^{-1}(z)$. We equip $\{x_0\} \times Y \subset X \times Y$ with the subspace topology. By the Product Topology-Basics Lemma 5.4 (2a) the map

$$\begin{array}{rccc} i\colon & Y & \to & \{x_0\} \times Y \\ & y & \mapsto & (x_0, y) \end{array}$$

is an embedding. In particular $Y_{x_0} := i^{-1}(\widetilde{W} \cap (\{x_0\} \times Y))$ is an open subset of Y. Note that $\{x_0\} \times Y_{x_0} \subset \widetilde{W}$. Since Y is regionally compact we can find a compact neighborhood K_{x_0} of x_0 that is contained in Y_{x_0}. By definition of a neighborhood there exists an open subset Y'_{x_0} of Y with $x_0 \in Y'_{x_0} \subset K_{x_0}$. We define

$$U_{x_0} \ := \ \{x \in X \,|\, \{x\} \times K_{x_0} \subset \widetilde{W}\}.$$

Claim 1. The set $f(U_{x_0})$ is an open subset of Z.

Proof. First we intend to use the JH-Lemma 1.7 to show that U_{x_0} is indeed an open subset of Y_{x_0}. Thus let $x \in U_{x_0}$. Since $\widetilde{W}$ is an open subset of $X \times Y$ and since K_{x_0} is compact it follows from Lemma 13.10 that there exist open subsets $A \subset X$ and $B \subset Y$ with $x \in A$ and $K_{x_0} \subset B$ such that $A \times B \subset \widetilde{W}$. Evidently this implies that $A \subset U_{x_0}$. Since $x \in A$ we have verified that the openness criterion of the JH-Lemma 1.7 is satisfied. We have thus shown that U_{x_0} is an open subset of Y_{x_0}.

Now we want to show that $V := f(U_{x_0})$ is an open subset of Z. By Lemma 13.9 we know that U_{x_0} is saturated with respect to f. In other words, we know that $U_{x_0} = f^{-1}(V)$. Now we use that by hypothesis $f\colon X \to Z$ is a quotient map. Since $f^{-1}(V) = U_{x_0}$ is open by (1) we obtain that V itself is open. But that is what we had wanted to show. ⊞

By definition of the product topology we obtain that $f(U_{x_0}) \times Y'_{x_0}$ is an open subset of $X \times Y$. Evidently we have $(x, y) \in f(U_{x_0}) \times Y'_{x_0}$. It remains to prove the following claim.

Claim 2. We have $f(U_{x_0}) \times Y'_{x_0} \subset W$.

Proof. The claim follows from the following equalities and inclusions:

$$f(U_{x_0}) \times Y'_{x_0} \ = \ (f \times \mathrm{id}_Y)(U_{x_0} \times Y'_{x_0}) \ \underset{\substack{\uparrow \\ \text{since } Y'_{x_0} \subset K_{x_0}}}{\subset} \ (f \times \mathrm{id}_Y)(U_{x_0} \times K_{x_0}) \ \overset{\substack{\text{definition of } U_{x_0} \\ \downarrow}}{\subset} \ (f \times \mathrm{id}_Y)(\widetilde{W}) \ \underset{\substack{\uparrow \\ \text{by the Image-Preimage Lemma 0.2 (2)} \\ \text{since by definition } \widetilde{W} = (f \times \mathrm{id}_Y)^{-1}(W)}}{=} \ W.$$

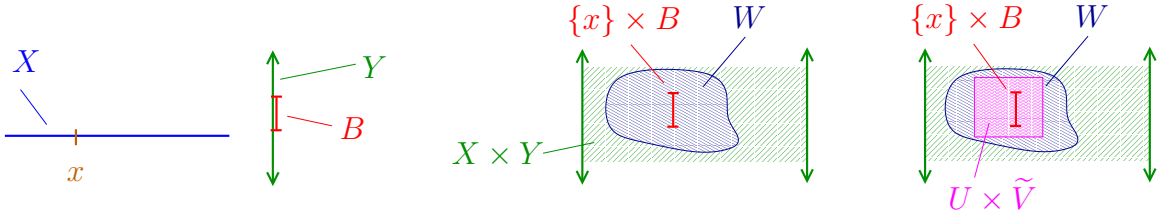
■

Remark. A different proof of the Whitehead Quotient Theorem 13.4, based on Propositions 12.4 and 12.6, is given in [**Hat2002**, Lemma A.17].

13.4. **Mixing product and quotient topologies II (∗).** In this section we prove a second statement regarding the interplay between product and quotient topologies. More precisely, we will prove the following proposition.

Proposition 13.11. Let X and Y be topological spaces. Let B be a subset of Y. We denote by $q\colon Y \to Y/B$ the projection. If B is a compact subset of Y and if Y is Hausdorff, then the map

$$\begin{array}{rccc} \mathrm{id}_X \times q\colon & X \times Y & \to & X \times (Y/B) \\ & (x,y) & \mapsto & (x,[y]) \end{array}$$



is a quotient map.

Remark.

(1) At first glance the statement of Proposition 13.11 might sound quite similar to the statement of the Whitehead Quotient Theorem 13.4. But in a way it is quite different, this time there are no conditions at all on the "unaffected" factor X, but we do put a condition on the projection $Y \to Y/B$.
(2) According to [**tD2008**, Chapter 2.2, Exercise 16] one does not need to assume that Y is Hausdorff.
(3) Finally we refer to [**BrownR2006**, Chapter 4.3] for more information on the interplay between product and quotient topologies.

In the proof of Proposition 13.11 we need the following fairly elementary lemma.

Auxiliary Lemma 13.12. Let X and Y be topological spaces and let B be a compact subset of Y. Let $x \in X$. If W is an open subset of $X \times Y$ that contains $\{x\} \times B$, then there exists an open subset U of X and an open subset $\widetilde{V} \subset Y$ with $\{x\} \times B \subset U \times \widetilde{V} \subset W$.

Proof. Let W be an open subset of $X \times Y$ that contains $\{x\} \times B$. By definition of the product topology we can find for each $b \in B$ an open neighborhood U_b of x in X and an open neighborhood V_b of b in Y such that $U_b \times V_b \subset W$. Since B is compact there exist $b_1, \ldots, b_m$ such that $B \subset V_{b_1} \cup \cdots \cup V_{b_m}$. One can easily verify that $U := U_{b_1} \cap \cdots \cap U_{b_m}$ and $\widetilde{V} := V_{b_1} \cup \cdots \cup V_{b_m}$ have the desired properties. ■

Proof of Proposition 13.11. Let X and Y be topological spaces and let B be a compact subset of Y. We assume that Y is Hausdorff. We denote by $q\colon Y \to Y/B$ the natural projection. Note that $p = \mathrm{id}_X \times q$. First note that it follows from the Topological-Quotient Proposition 5.15 (1b) and the Product Topology-Basics Lemma 5.4 (3) that p is continuous. This implies the "only if"-direction. It remains to show that "if"-direction. Thus let $W \subset X \times (Y/B)$ be a subset that has the property that $p^{-1}(W)$ is an open subset of $X \times Y$. We need to show that W is an open subset of $X \times (Y/B)$. By the JH-Lemma 1.7 and the definition of the product topology it suffices to prove the following claim.

Claim. For each $(x,[y]) \in W \subset X \times (Y/B)$ there exists an open neighborhood U_x of $x \in X$ and an open neighborhood $V_{[y]}$ of $[y] \in Y/B$ such that $U_x \times V_{[y]} \subset W$.

Proof. As in the proof of Proposition 13.8 we consider two cases separately. First we consider the case that $[y] = [B] \in Y/B$. It follows that $p^{-1}((x,[y])) = \{x\} \times B$. By hypothesis $p^{-1}(W)$ is an open subset of $X \times Y$ that contains $p^{-1}((x,[y])) = \{x\} \times B$. Therefore it follows from Lemma 13.12 there exists an open subset U_x of X and an open

subset $\widetilde{V}_y \subset Y$ with $\{x\} \times B \subset U_x \times \widetilde{V}_y \subset p^{-1}(W)$. We denote by $V_{[y]}$ the image of $\widetilde{V}_y$ under the projection $q\colon Y \to Y/B$. Note that $V_{[y]}$ is an open neighborhood of $[y] \in Y/B$.[147] Finally note that

$$U_x \times V_{[y]} \;=\; (\mathrm{id}_X \times q)(U_x \times \widetilde{V}_y) \;=\; p(U_x \times \widetilde{V}_y) \subset p(p^{-1}(W)) \;=\; W.$$

It remains to consider the case that $[y] \neq [B] \in Y/B$. We see that $(x, y) \in W$. Since B is compact and since Y is Hausdorff we know by the Compact-Closed Lemma 1.21 that B is a closed subset of Y, i.e. $Y \setminus B$ is open. It follows immediately from the definition of the product topology on $X \times B$, the fact that $Y \setminus B$ is open, the fact that $p^{-1}(W)$ is an open neighborhood of (x, y) and the fact that $y \notin B$ that there exists an open neighborhood U_x of x and an open neighborhood $\widetilde{V}_y$ of y with $\widetilde{V}_y \subset X \setminus B$ and with $U_x \times \widetilde{V}_y \subset p^{-1}(W)$. One easily verifies that U_x and $V_y = q(\widetilde{V}_y)$ have the desired properties. ■

[147] Indeed, since $B \subset \widetilde{V}_y$ we see that $q^{-1}(V_{[y]}) = q^{-1}(q(\widetilde{V}_y)) = \widetilde{V}_y \cup B = \widetilde{V}_y$, which is an open set. By the definition of the quotient topology on Y/B we see that $q^{-1}(V_{[y]})$ is indeed open.

Part II

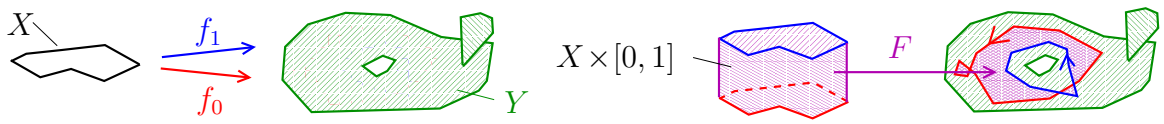
Basics of homotopy theory

14. Homotopies

Loosely speaking two maps $f, g\colon X \to Y$ are called homotopic if one can be deformed into the other. In the subsequent chapter we will use to this notion of homotopic maps to explain what it means for two topological spaces to be "homotopy equivalent".

14.1. **Homotopic maps.** In its most basic form a homotopy is a continuous deformation of maps between two topological spaces. To make this notion precise it is convenient to introduce the following notation.

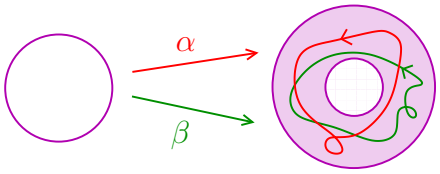
Notation. Let X and Y be two topological spaces and let $I \subset \mathbb{R}$ be a subset. Given a map $F\colon X \times I \to Y$[148] and given $t \in I$ we often denote by F_t the map[149]



$$\begin{array}{rccc} F_t\colon & X & \to & Y \\ & x & \mapsto & F(x,t). \end{array}$$

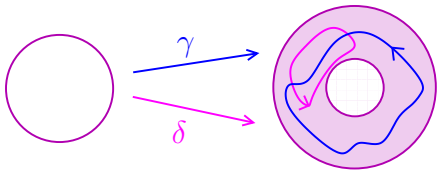
Now we move on to the actual definition we are interested in.

Definition. Let X and Y be two topological spaces.



(1) Let $f_0, f_1\colon X \to Y$ be two maps. A homotopy between the maps f_0 and f_1 is a map $F\colon X \times [0,1] \to Y$ with $F_0 = f_0$ and $F_1 = f_1$. If there exists a homotopy between the maps f_0 and f_1, then we say that f_0 and f_1 are homotopic and sometimes we write $f_0 \simeq f_1$.

(2) A map $f\colon X \to Y$ is called null-homotopic if it is homotopic to a constant map.

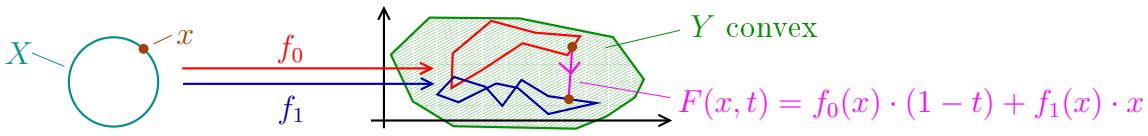


Examples.

(1) In the figure below we show four maps α, β, γ and δ from the circle S^1 to the annulus $Y = B_2(0) \setminus B_1(0)$. The maps α and β are homotopic whereas the maps γ and δ look as if they are not homotopic. But only much later, namely in Chapter 48, will we develop methods for showing that these maps are indeed not homotopic.

the maps α and β are homotopic

the maps γ and δ appear not to be homotopic



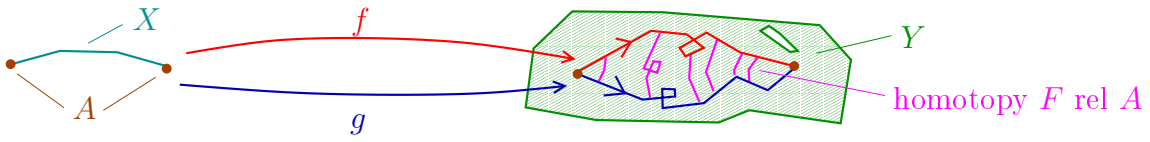
[148] Recall that all maps between topological spaces are understood to be continuous.

[149] Note that it follows from the Product Topology-Basics Lemma 5.4 (1a) together with Lemma 2.1 (1) that the map F_t is indeed continuous.

(2) Given an orthogonal matrix $A \in \mathrm{O}(n)$ we denote by $\rho(A)$ the map $f\colon S^{n-1} \to S^{n-1}$ that is given $x \mapsto A \cdot x$.
   (a) Let $\gamma\colon [0,1] \to \mathrm{SO}(n)$ be a path from some matrix A to some matrix B. The map[150]
   $$\begin{array}{rcl} S^{n-1} \times [0,1] & \to & S^{n-1} \\ (x,t) & \mapsto & \gamma(t) \cdot x \end{array}$$
   is a homotopy from $\rho(A)$ to $\rho(B)$.
   (b) Let $A \in \mathrm{O}(n)$. If $\det(A) = 1$, i.e. if $A \in \mathrm{SO}(n)$, then it follows from the Matrix Group Path-Component Proposition 2.37 (3) that there exists a path $\gamma\colon [0,1] \to \mathrm{SO}(n)$ with $\gamma(0) = A$ and $\gamma(1) = \mathrm{id}$. It follows from (a) that $\rho(A)$ is homotopic to the identity. Much later, on page 1686, we will see that if $\det(A) = -1$, then f is actually not homotopic to the identity.
   (c) It follows immediately from the definitions that a topological space X is path-connected if any two maps $\{*\} \to X$ are homotopic.

The next example of a homotopy is written down as a lemma.

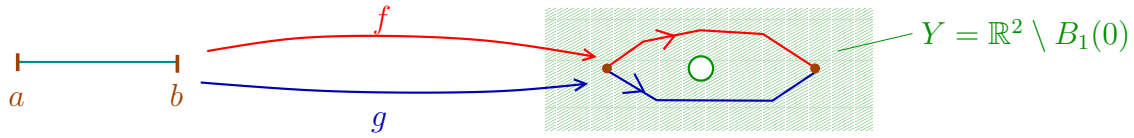
Lemma 14.1. (Convex Homotopy Lemma) Let X be a topological space and let $Y \subset \mathbb{R}^n$ be a subset. Furthermore let $f_0, f_1\colon X \to Y$ be two maps. If Y is convex, then
$$\begin{array}{rcl} F\colon X \times [0,1] & \to & Y \\ (x,t) & \mapsto & \underbrace{f_0(x) \cdot (1-t) + f_1(x) \cdot t}_{\in Y \text{ since } Y \text{ is convex}} \end{array}$$
is a homotopy between f_0 and f_1.



Proof. Basically by definition we have $F_0 = f_0$ and $F_1 = f_1$. But we are not done yet, the conscientious reader will not have failed to notice that we need to show that the map F is actually continuous. The map F can be written as the composition of the following two maps:
$$X \times [0,1] \xrightarrow{(x,t) \mapsto (f_0(x), f_1(x), t)} \mathbb{R}^n \times \mathbb{R}^n \times [0,1] \xrightarrow{(x,y,t) \mapsto (x \cdot (1-t) + y \cdot t)} \mathbb{R}^n.$$
The first map is continuous by the Product Topology-Basics Lemma 5.4 (2) and the Product Topology-Basics Lemma 5.4 (1) and the second map is continuous by Lemmas 2.3 and the Product Topology-Basics Lemma 5.4 (2a). ■

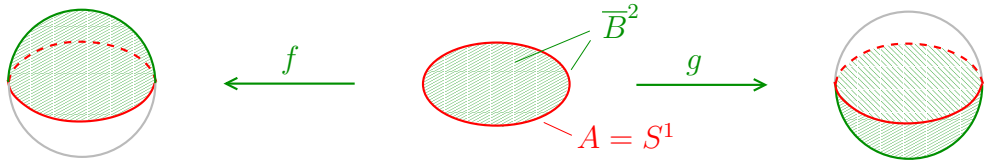
Often it is more interesting to consider homotopies that fix a given subset. This leads us to the following definition.

Definition. Let X and Y be topological spaces and let $A \subset X$ be a subset.
   (1) We say a map $F\colon X \times [0,1] \to Y$ is a homotopy rel A if for all $x \in A$ and $s, t \in [0,1]$ we have $F(x,s) = F(x,t)$.



[150] It follows from various standard results, see e.g. Lemma 2.3, the Product Metric Lemma 5.3 and the Product Topology-Basics Lemma 5.4 (4) that the map is continuous.

(2) We say that two maps $f, g\colon X \to Y$ with $f|_A = g|_A$ are homotopic rel A if there exists a homotopy F rel A with $F_0 = f$ and $F_1 = g$.



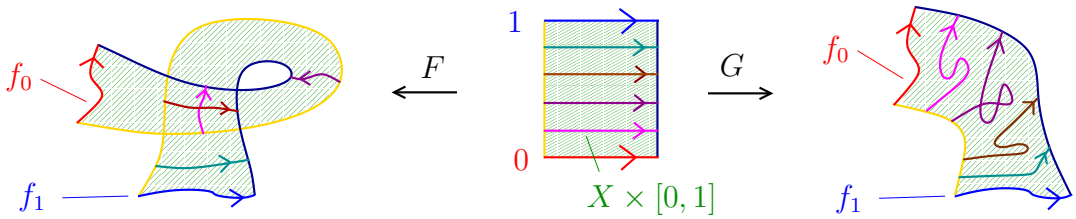
Examples.

(1) Let $f, g\colon [a,b] \to Y = \mathbb{R}^2 \setminus B_1(0)$ be the two maps from an interval to the topological space Y that are shown in the figure below. Note that $f(a) = g(a)$ and $f(b) = g(b)$. As we will see in Exercise 14.2, any two maps from an interval into a path-connected space are homotopic. On other hand it looks rather unlikely that the two maps are homotopic rel $\{a,b\}$, i.e. it does not look like we can deform f into g while keeping the endpoints of the interval fixed. Unfortunately we will have to wait till Chapter 48 to develop tools for showing that these two maps f and g are indeed not homotopic rel $\{a,b\}$.

(2) We consider the two maps $f, g\colon \overline{B}^2 \to S^2$ that are shown in the figure below. These maps agree on S^1. It is fairly easy to see that the two maps are homotopic but it seems rather unlikely that they are homotopic rel S^1. Unfortunately, as in (1), right now we lack the tools for showing the latter statement. Only much later, namely in Exercise 74.24, will we see that the two maps f and g are not homotopic rel S^1.

We continue with the next variation on the notion of homotopy.

Definition. Let X and Y be two topological spaces.



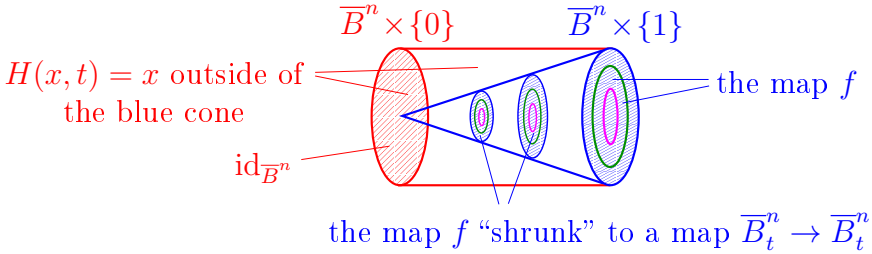
(1) (a) An isotopy is a homotopy $F\colon X \times [0,1] \to Y$ such that for each $t \in [0,1]$ the map $F_t\colon X \to Y$ is an embedding.

(b) A homeotopy is a homotopy $F\colon X \times [0,1] \to Y$ such that for each $t \in [0,1]$ the map $F_t\colon X \to Y$ is a homeomorphism.

(2) Let $f_0, f_1\colon X \to Y$ be two maps that are embeddings. We say f_0 and f_1 are isotopic if there exists an isotopy $F\colon X \times [0,1] \to Y$ with $F_0 = f_0$ and $F_1 = f_1$. Similarly we define homeotopic.

Examples.

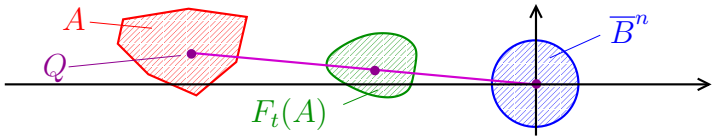
(1) In the figure below we show two maps $f_0, f_1\colon [0,1] \to \mathbb{R}^2$ that are embeddings. We also indicate two homotopies F and G between f_0 and f_1. The map F is an isotopy, the map G is not.



F is an isotopy $\qquad$ G is not an isotopy

(2) Let $n \in \mathbb{N}$. Let $f\colon \overline{B}^n \to \overline{B}^n$ be a homeomorphism. If $f|_{S^{n-1}} = \mathrm{id}_{S^{n-1}}$, then f is isotopic to $\mathrm{id}_{\overline{B}^n}$. Indeed, in Exercise 14.5 we will see that the map

$$\begin{array}{rcl} H\colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} t \cdot f(\frac{x}{t}), & \text{if } 0 \le \|x\| < t, \\ x, & \text{otherwise} \end{cases} \end{array}$$



is continuous and that each H_t is a homeomorphism. It is clear that $H_0 = \mathrm{id}$ and $H_1 = f$. Thus we see that H is the desired isotopy. The fact that f is isotopic to $\mathrm{id}_{\overline{B}^n}$ is often referred to as the *Alexander trick*.[151]

The next lemma is a refined version of the Convex-to-Ball Proposition 2.20 (2).

Lemma 14.2. Let A be a bounded closed convex subset of $\mathbb{R}^n$ with non-empty interior. Let Q be a point in the interior of A. There exists a canonical isotopy $F\colon A \times [0,1] \to \mathbb{R}^n$ with the following three properties:

(1) we have $F_0 = \mathrm{id}_A$,
(2) the map F_1 is a homeomorphism from A to $\overline{B}^n$ and this map restricts to a homeomorphism $\partial A \to S^{n-1}$,
(3) for any $t \in [0,1]$ we have $F(Q,t) = (1-t) \cdot Q$.[152]

Remark. If A is "diffeomorphic" to $\overline{B}^n$, then the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 gives a significant refinement of the conclusion of Lemma 14.2.

[151] The existence of such a homotopy was first observed by James Alexander in 1923, see [**Al1924a**].
[152] In particular, if Q is already the origin, then F is a homotopy rel the origin.

Proof. First consider the case that Q is the origin. As in the statement of the Convex-to-Ball Proposition 2.20 (2) we consider the map.

$$\begin{array}{rcl} \rho\colon A \setminus \{Q\} & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & \sup\big\{\|rx\| \,\big|\, r \in \mathbb{R}_{>0} \text{ and } r(x-Q)+Q \in A\big\}. \end{array}$$

In Lemma 2.21 (1) we showed that ρ is continuous. Similar to the discussion on page 160 we consider the map

$$\begin{array}{rcl} F\colon A \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} x \cdot \frac{1}{(1-t)+t\cdot\rho(x)}, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0. \end{cases} \end{array}$$

As in Lemma 2.21 (2) one can show that F is continuous. It is straightforward to verify that this map has all the desired properties.

We leave it to the reader to modify the above proof to deal with the case that Q is not the origin. ■

After these examples we return to developing the general theory of homotopies. On many occasions it will be useful to combine two homotopies or isotopies. This leads us to the following lemma.

Lemma 14.3. (Homotopy Stacking Lemma) Let X and Z be topological spaces.

(a) Let Y be a topological space and let $f\colon X \times Y \to Z$ be a map. Suppose we are given finitely many closed subsets $A_1, \ldots, A_m$ of Y with $\bigcup_{i=1}^{m} A_i = Y$. If each map $X \times A_i \to X \times Y \to Z$ is continuous, then f itself is continuous.

(b) Let $a < b < c$ be real numbers and let $f\colon X \times [a,c] \to Z$ be a map. If the restrictions of f to $X \times [a,b]$ and to $X \times [b,c]$ are continuous, then f itself is continuous.

Proof.

(1) By the Product Topology-Basics Lemma 5.4 (4) the identity

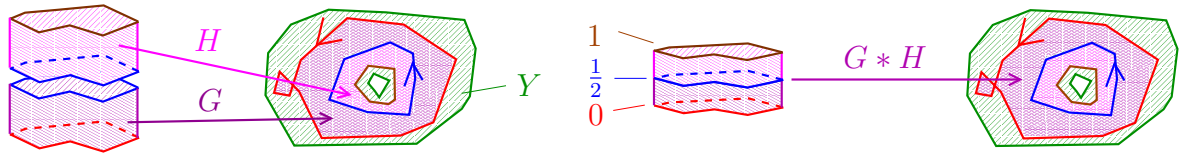
$$X \times \begin{array}{c} A_i \text{ equipped with the} \\ \text{subspace topology from } Y \end{array} \longrightarrow \begin{array}{c} X \times A_i \text{ equipped with the subspace} \\ \text{topology from } X \times Y \end{array}$$

is actually a homeomorphism. Together with our hypothesis this shows that for each $i \in \{1, \ldots, m\}$ the map

$$f|_{X\times A_i}\colon \underbrace{X \times A_i}_{\substack{\uparrow \\ \text{equipped with subspace topology from } X \times Y}} \longrightarrow Z$$

is continuous. By the Product-of-Subsets Lemma 5.5 (1) we know that $A_i \times Y$ is a closed subset of $X \times Y$. Now it follows from the Pasting Proposition 2.6 (2) that f is indeed continuous.

(2) This statement is just a frequently used special case of (1). ■



Now we can introduce the promised lemma that allows us to combine homotopies.

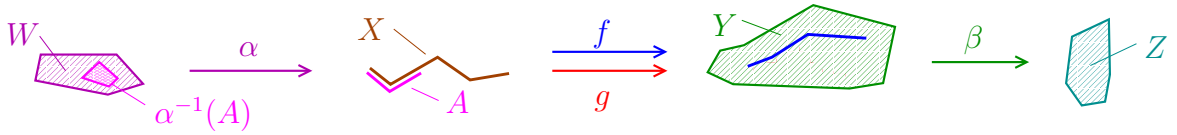
Lemma 14.4. (Homotopy Combination Lemma) Let X and Y be topological spaces and let $A \subset X$ be a (possibly empty) subset of X. Let $G, H\colon X \times [0,1] \to Y$ be two

homotopies rel A. If $G_1 = H_0$, then the map

$$\begin{array}{rcl} G * H \colon X \times [0,1] & \to & Y \\ (P,t) & \mapsto & \begin{cases} G(P,2t), & \text{if } t \in [0,\frac{1}{2}], \\ H(P,2t-1), & \text{if } t \in [\frac{1}{2},1]. \end{cases} \end{array}$$

is a homotopy rel A from G_0 to H_1. Furthermore, if G and H are isotopies (homotopies), then $G * H$ is also an isotopy (homeotopy). We refer to $G * H$ as the combination of G and H.

Proof. We only need to verify that $G * H$ is indeed continuous, but that is a consequence of the Homotopy Stacking Lemma 14.3 together with our hypothesis that $G_1 = H_0$. ■



The following lemma says in particular that being homotopic is an equivalence relation on the set of maps between two topological spaces.

Lemma 14.5.

(1) Let X be and Y topological spaces and let A be a (possibly empty) subset of X. Then "homotopy rel A of maps" forms an equivalence relation on the set of maps from X to Y. The same applies for "isotopy" and "homeotopy".

(2) Let $f, g \colon X \to Y$, let $\alpha \colon W \to X$ and $\beta \colon Y \to Z$ be maps between topological spaces. Furthermore let $A \subset X$ be a (possibly empty) subset. The following conclusion holds:

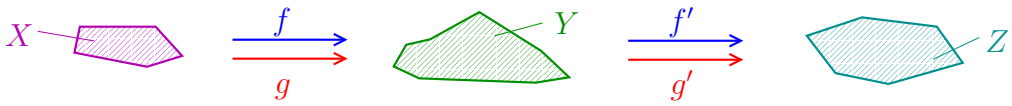
$$\begin{array}{rcl} f \text{ is homotopic to } g \text{ rel } A & \implies & f \circ \alpha \text{ is homotopic to } g \circ \alpha \text{ rel } \alpha^{-1}(A) \\ f \text{ is homotopic to } g \text{ rel } A & \implies & \beta \circ f \text{ is homotopic to } \beta \circ g \text{ rel } A \end{array}$$

Proof.

(1) We have to show that "homotopy rel A" satisfies the three properties of an equivalence relation. To simplify the notation we only deal with the case $A = \varnothing$. In the following let $f, g, h \colon X \to Y$ be three maps.

- The "constant homotopy" given by $F(x,t) := f(x)$ defines a homotopy between f and f.
- Let F be a homotopy from f to g. Then it is clear that the map F' that is defined by $F'(x,t) := F(x, 1-t)$ is a homotopy from g to f.
- Let F be a homotopy from f to g and let G be a homotopy from g to h. We consider the map

$$\begin{array}{rcl} X \times [0,1] & \to & Y \\ (x,t) & \mapsto & \begin{cases} F(x,2t), & \text{if } t \in \left[0,\frac{1}{2}\right], \\ G(x,2t-1), & \text{if } t \in \left(\frac{1}{2},1\right] \end{cases} \end{array}$$



It follows from the Homotopy Stacking Lemma 14.3 that this map is continuous. It is now clear that this map is a homotopy from f to h.

(2) This statement is basically obvious, we just need to precompose and postcompose a homotopy $H\colon X \times [0,1] \to Y$ between f and g by $\alpha \times \mathrm{id}_{[0,1]}\colon W \times [0,1] \to X \times [0,1]$ respectively by $\beta\colon Y \to Z$. ■

Lemma 14.6. Let X, Y and Z be topological spaces. Let $f, f'\colon X \to Y$ and $g, g'\colon Y \to Z$ be maps.

(1) If f and f' are homotopic and if g and g' are homotopic, then the map $g \circ f$ is homotopic to $g' \circ f'$.

(2) If there exists a subset A of X such that f and f' are homotopic rel A and if there exists a subset B of Y such that $f(A) = f'(A) \subset B$ and such that g and g' are homotopic rel B, then $g \circ f$ is homotopic to $g' \circ f'$ rel A.

Proof.

(1) Let $F\colon X \times [0,1] \to Y$ be a homotopy between f and f' and let $G\colon Y \times [0,1] \to Z$ be a homotopy between g and g'. We denote by $\pi\colon X \times [0,1] \to [0,1]$ the projection onto the second factor. We now consider the map

$$\begin{array}{rccc} H\colon X \times [0,1] & \xrightarrow{(F,\pi)} & Y \times [0,1] & \xrightarrow{G} Z \\ (x,t) & \mapsto & (F(x,t),t) & \\ & & (y,t) & \mapsto G(y,t). \end{array}$$

It follows from Lemma 2.1 (1) and the Product Topology-Basics Lemma 5.4 (1b) that the map $H(x,t) = G(F(x,t),t)$ is actually continuous. By plugging in $t = 0$ and $t = 1$ we see that $H\colon X \times [0,1] \to Z$ is a homotopy between $g \circ f$ and $g' \circ f'$.

(2) One can easily verify that the homotopy in (1) also does the trick for (2). ■

14.2. **Homotopies on quotients and pushouts.** In this section we collect several subtle lemmas which show that, under the right circumstances, homotopies descend to quotient spaces and that given a "gluing $X \cup_f Y$" we can also glue homotopies. This section is much less pleasant to read than the previous section and it is arguably best if the reader only takes a peek once the results are actually used.

Before we state these two technical statements, we point out that the proof of these two statements eventually boils down to the rather subtle and delicate Whitehead Quotient Theorem 13.4.

After this preamble, let us move to the key result of this section which shows that homotopies descend to quotients.

Theorem 14.7. (Homotopy Quotient Theorem) Let X and Y be topological spaces. Furthermore let $\sim_X$ be an equivalence relation on X and let $\sim_Y$ be an equivalence relation on Y. If $F\colon X \times [0,1] \to Y$ is a homotopy such that $F(x,t) \sim_Y F(x',t)$ whenever $x \sim_X x'$, then the map[153]

$$\begin{array}{rcl} \varphi\colon (X/\!\sim_X) \times [0,1] & \to & Y/\!\sim_Y \\ ([x],t) & \mapsto & [F(x,t)] \end{array}$$

is continuous.

Remark. We will deal with the important special case where the equivalence relation on X is given by a group action in Exercise 48.23.

Proof. We denote by $p\colon X \to X/\!\sim_X$ and $q\colon Y \to Y/\!\sim_Y$ the natural projections. We have the following commutative diagram

$$\begin{array}{ccc} & X \times [0,1] & \\ {\scriptstyle p\times \mathrm{id}_{[0,1]}}\swarrow & & \searrow{\scriptstyle q\circ F} \\ (X/\!\sim_X) \times [0,1] & \xrightarrow[([x],t)\mapsto [F(x,t)]]{\varphi} & Y/\!\sim . \end{array}$$

By the Quotient Map Lemma 13.3 (1) the map p is a quotient map. Since $[0,1]$ is regionally compact we obtain from the Whitehead Quotient Theorem 13.4 that $p \times \mathrm{id}_{[0,1]}$ is also a quotient map. Note that by the Topological-Quotient Proposition 5.15 (1a) and by hypothesis the map $q \circ F$ is continuous. Thus we obtain from Lemma 13.5 (1) that φ is continuous. ∎

For the reader who is wary of the Whitehead Quotient Theorem 13.4 we provide a second argument that works in many, but certainly not all cases.

Proof of Theorem 14.7 if X is compact and if $X/\!\sim_X$ is Hausdorff. On $X \times [0,1]$ we consider the equivalence relation $\sim$ given by $(x,t) \sim (x',t') \iff x \sim_X x'$. We denote by $h\colon X \times [0,1] \to (X \times [0,1])/\!\sim$ the natural projection. We consider the maps

$$\begin{array}{rcl} f\colon X \times [0,1] & \to & X/\!\sim_X \times [0,1] \\ (x,t) & \mapsto & ([x],t) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \pi\colon (X \times [0,1])/\!\sim & \to & X/\!\sim_X \times [0,1] \\ [(x,t)] & \mapsto & ([x],t). \end{array}$$

By the Topological-Quotient Proposition 5.15 (1a) the projection $p\colon X \to X/\!\sim_X$ is continuous. This shows that the map to the left is continuous. By the Topological-Quotient Proposition 5.15 (1b) this implies that the induced map π to the right is also continuous. One can easily verify that π is a bijection. By hypothesis X is compact. By the Product Topology Properties Proposition 5.6 (2) this implies that $X \times [0,1]$ is compact. It follows from Topological-Quotient Proposition 5.15 (1a) and the Compact Image Lemma 2.13 that $(X \times [0,1])/\!\sim$ is compact. Next recall that by hypothesis $X/\!\sim_X \times$ is Hausdorff. By the Product Topology Properties Proposition 5.6 (1) this implies that $X/\!\sim_X \times [0,1]$ is Hausdorff. In summary it follows from the Compact-Hausdorff Proposition 2.17 (3) that π is a homeomorphism.

Now we consider the following diagram:

$$\begin{array}{ccccc} X \times [0,1] & & \xrightarrow{\quad F \quad} & & Y \\ \downarrow{\scriptstyle f} & \searrow{\scriptstyle h} & & & \downarrow{\scriptstyle q} \\ & & (X \times [0,1])/\!\sim & & \\ & \swarrow{\scriptstyle \pi}_{\cong} & & \searrow{\scriptstyle g} & \\ (X/\!\sim_X) \times [0,1] & & \xrightarrow{\quad \varphi \quad} & & Y/\!\sim_Y . \end{array}$$

[153] It follows from our hypothesis on F that the map φ is well-defined.

We make the following clarifications and observations:

(1) Note that the map $q \circ F\colon X \times [0,1] \to Y$ factors by our hypothesis through the map $h\colon X \times [0,1] \to (X \times [0,1])/\sim$. It follows again from the Topological-Quotient Proposition 5.15 (1b) that the induced map $g\colon (X \times [0,1]) \sim \to Y/\sim_Y$ is continuous.
(2) We denote by $q\colon Y \to Y/\sim_Y$ the natural projection.
(3) The map $\varphi\colon (X/\sim_X) \times [0,1] \to Y/\sim_Y$ equals the map $q \circ \overline{F} \circ \pi^{-1}$. We just showed that each of these three maps is continuous. Thus φ is continuous. ■

Example. Let $n \in \mathbb{N}$ and let $\varphi\colon [0,1] \to \mathrm{GL}(n,\mathbb{R})$ be a map. It follows from the Homotopy Quotient Theorem 14.7 that the map

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^{n-1} \times [0,1] & \to & \mathbb{R}\mathrm{P}^{n-1} \\ ([P],t) & \mapsto & [\varphi(t) \cdot P] \end{array}$$

is continuous. The same conclusion also holds if we replace "$\mathbb{R}$" by "$\mathbb{C}$".

The following lemma is a hands-on special case of the Homotopy Quotient Theorem 14.7.

Lemma 14.8. Let X be a topological space. Furthermore let $A \subset B$ be two subsets of X. If $F\colon B \times [0,1] \to X$ is a homotopy with $F(A \times [0,1]) \subset A$, then the induced map[154]

$$\begin{array}{rcl} (X/A) \times [0,1] & \to & Y/B \\ ([x],t) & \mapsto & [F(x,t)] \end{array}$$

is continuous.

Example. Let $\gamma\colon [0,1] \to \mathrm{O}(n)$ be a continuous map. We consider the maps

$$\begin{array}{rcl} F\colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \gamma(t) \cdot x \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \overline{F}\colon (\overline{B}^n/S^{n-1}) \times [0,1] & \to & \overline{B}^n/S^{n-1} \\ ([x],t) & \mapsto & [\gamma(t) \cdot x]. \end{array}$$

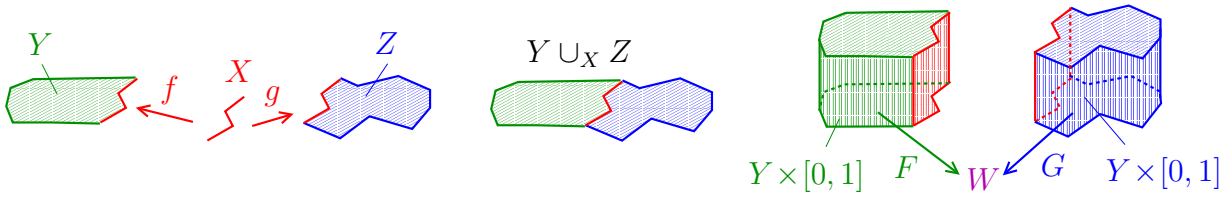
It follows from Lemma 2.3, the Product Metric Lemma 5.3 and the Product Topology-Basics Lemma 5.4 (4) that the map F to the left is continuous. We now obtain from Lemma 14.8 that the map $\overline{F}$ to the right is also continuous.

Proof. This statement follows immediately from the Homotopy Quotient Theorem 14.7 and the fact that quotients of topological spaces are defined via equivalence relations. ■

We conclude this section with the following lemma which shows how to define homotopies on pushouts.

Lemma 14.9. (Homotopy Pushout Lemma) Let $f\colon X \to Y$ and $g\colon X \to Z$ be maps between topological space. As on page 259 we define the pushout

$$Y \cup_X Z \;:=\; (Y \sqcup Z)/\sim \qquad \text{where } f(x) \sim g(x) \text{ for all } x \in X.$$



Furthermore let W be another topological space. Suppose that we are given two homotopies $G\colon Y \times [0,1] \to W$ and $H\colon Z \times [0,1] \to W$ such that for every $x \in X$ and every

[154] Since F is a homotopy rel A we see that the map is well-defined.

$t \in [0,1]$ we have $G(f(x),t) = H(g(x),t)$. Then the map

$$\begin{array}{rcl} F\colon (Y \cup_X Z) \times [0,1] & \to & W \\ ([P],t) & \mapsto & \begin{cases} G(P,t), & \text{if } P \in Y, \\ H(P,t), & \text{if } P \in Z \end{cases} \end{array}$$

is well-defined and it is continuous.

Proof. It follows from Exercise 5.3 that the map

$$\begin{array}{rcl} (Y \sqcup Z) \times [0,1] & \to & W \\ (P,t) & \mapsto & \begin{cases} G(P,t), & \text{if } P \in Y, \\ H(P,t), & \text{if } P \in Z \end{cases} \end{array}$$

is continuous. The statement now follows from the Homotopy Quotient Theorem 14.7 and the definition of the pushout as a quotient of $Y \sqcup Z$. ■

Exercises for Chapter 14.

Exercise 14.1. Let X be a topological space and let $f, g\colon X \to S^n$ be two maps such that for any $x \in X$ we have $\|f(x) - g(x)\| < 2$. Show that f and g are homotopic.

Exercise 14.2. Let Y be a path-connected space.

(a) Show that any two maps from an interval into Y are homotopic.

(b) Let $k \in \mathbb{N}_0$. Show that any two maps $\overline{B}^k \to Y$ are homotopic.

Exercise 14.3. Let X be a topological space and let $f, g\colon X \to S^1$ be maps. We assume that for any $x \in X$ we have $f(x) \neq -g(x) \in S^1$. Show that f and g are homotopic.
Hint. Consider the map $S^1 \to S^1$ that is given by $z \mapsto f(z) \cdot g(z)^{-1}$.

Exercise 14.4. Let X be a topological space and let $f\colon X \to \mathbb{R}^n \setminus \{0\}$ be a map. Show that f is homotopic to the map $X \to \mathbb{R}^n \setminus \{0\}$ given by $x \mapsto \frac{f(x)}{\|f(x)\|}$.

Exercise 14.5. Let $n \in \mathbb{N}$ and let $f\colon \overline{B}^n \to \overline{B}^n$ be a homeomorphism with $f|_{S^{n-1}} = \mathrm{id}_{S^{n-1}}$. We consider the map

$$\begin{array}{rcl} H\colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} t \cdot f(\frac{x}{t}), & \text{if } 0 \leq \|x\| < t, \\ x, & \text{otherwise.} \end{cases} \end{array}$$

(a) Show that H is continuous.

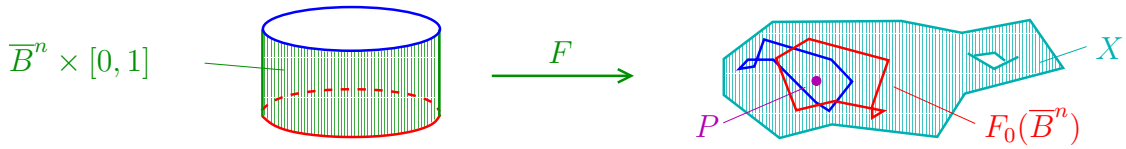
(b) Show that for each $t \in [0,1]$ the map $H_t\colon \overline{B}^n \to \overline{B}^n$ is a homeomorphism.

Remark. The fact that f is isotopic to $\mathrm{id}_{\overline{B}^n}$ is often referred to as the *Alexander trick*.

Exercise 14.6. Let X and Y be topological spaces and let $F\colon X \times [0,1] \to Y$ be a homotopy. Show that there exists a homotopy $G\colon X \times [0,1] \to Y$ with the following properties:

(1) $G_0 = F_0$ and $G_1 = F_1$,
(2) there exists an $\epsilon \in (0,1)$ such that for each $t \in [0,\epsilon]$ we have $G_t = G_0$ and such that for each $t \in [1-\epsilon, 1]$ we have $G_t = G_1$
(3) For each $s \in [0,1]$ there exists a $t \in [0,1]$ with $G_s = F_t$.

Exercise 14.7.



(a) Let $f\colon [0,1] \to [0,1]$ be a self-homeomorphism.
  (i) Show that f is monotonously increasing or monotonously decreasing.
  (ii) Suppose f is monotonously increasing. Show that f is isotopic to the map that is given by $g(x) = x$.
  (iii) Suppose f is monotonously decreasing. Show that f is isotopic to the map that is given by $g(x) = -x$.

(b) Show that any self-homeomorphism of S^1 is isotopic to the map $f(z) = z$ or to the map $g(z) = \overline{z}$.
Hint. Let $f\colon S^1 \to S^1$ be a self-homeomorphism. First consider the case that $f(1) = 1$.

Remark. We will provide a different, and arguably more satisfying, proof of Statement (a) in Exercise 48.24.

Exercise 14.8. Let X be a Hausdorff space, let $P \in X$ and let $F\colon \overline{B}^n \times [0,1] \to X$ be a map such that for every $t \in [0,1]$ the image $F_t(\overline{B}^n)$ is a neighborhood of P.

(a) Show that there exists a connected open neighborhood U of P such that for every $t \in [0,1]$ we have $F_t(S^{n-1}) \cap U = \varnothing$.
(b) Let U be as in (a). Show that for each $t \in [0,1]$ we have $U \subset F_t(B^n)$.

Exercise 14.9. Let h be a complex polynomial of degree ≥ 1. In Exercise 2.35 we showed that the map

$$\begin{array}{rcl} \Theta(h)\colon \mathbb{C} \cup \{\infty\} & \to & \mathbb{C} \cup \{\infty\} \\ z & \mapsto & \begin{cases} h(z), & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty \end{cases} \end{array}$$

is continuous. Now let f and g be two polynomials with complex coefficients of degree ≥ 1. Suppose that $\deg(f) = \deg(g)$. Show that the maps $\Theta(f)$ and $\Theta(g)$ are homotopic.
Remark. It is quite easy to write down a candidate for a homotopy. But why is the map you wrote down actually continuous?

Exercise 14.10. Using Lemma 2.18 we can make the identification $S^1 = \mathbb{R} \cup \{\infty\}$. Now let f be a polynomial with real coefficients of degree $n \geq 1$. In Exercise 2.35 we showed that the map

$$\begin{array}{rcl} F\colon S^1 = \mathbb{R}\cup\{\infty\} & \to & \mathbb{R}\cup\{\infty\} = S^1 \\ t & \mapsto & \begin{cases} f(t), & \text{if } t\in\mathbb{R}, \\ \infty, & \text{if } t=\infty \end{cases} \end{array}$$

is continuous. (See the figure on page 188 for an illustration.) Show that F is homotopic to one of the following three types of self-maps of S^1:

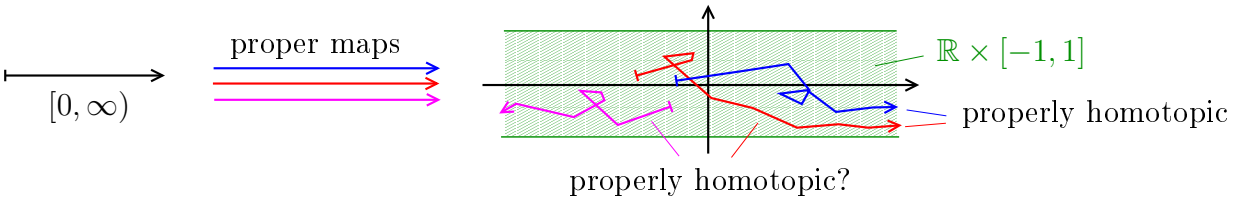
$$(1)\qquad a(z) = z \qquad\qquad (2)\qquad b(z) = \overline{z} \qquad\qquad (3)\qquad c(z) = 1.$$

Exercise 14.11. Let X be a topological space and let Y be a topological space that is regionally compact. Let $f_0, f_1\colon Y \to X$ be two maps. Show that the following holds:

$$f_0 \text{ and } f_1 \text{ are homotopic} \iff f_0 \text{ and } f_1 \text{ lie in the same path component of } Y^X.$$

Remark. Use the Compact-Open Exponential Proposition 12.6.

Exercise 14.12. We consider the two maps $f, g\colon [0,1] \to \mathbb{R}^3$ shown in the figure below. Note that $f(0) = g(0)$ and $f(1) = g(1)$.



(a) Show that the maps f and g are homotopic rel $\{0\}$.
(b) Are the two maps f and g homotopic rel $\{0,1\}$?

Exercise 14.13. Recall that according to the definition on page 180 a map $f\colon A \to B$ between topological spaces is called *proper*, if the preimage of each compact subset of B is a compact subset of A. Let X and Y be topological spaces. Provide an example of a homotopy $F\colon X\times[0,1] \to Y$ such that each $F_t\colon X \to Y$ is proper but such that the map $F\colon X\times[0,1] \to Y$ is not proper itself.
Hint. You can find examples with $X = Y = \mathbb{R}$ and $F_0 = F_1 = \mathrm{id}$.

Exercise 14.14. Recall that according to the definition on page 180 a map $f\colon A \to B$ between topological spaces is called *proper*, if the preimage of each compact subset of B is a compact subset of A. Let X and Y be topological spaces. We say that two maps $f, g\colon X \to Y$ are *properly homotopic* if there exists a *proper homotopy* $F\colon X\times[0,1] \to Y$ between f and g, i.e. F is a homotopy between f and g and the map $F\colon X\times[0,1] \to Y$ is also proper.

(a) Show that any two proper maps $[0,\infty) \to \mathbb{R}^2$ are properly homotopic.
(b) Show that there exist proper maps $f, g\colon [0,\infty) \to \mathbb{R}\times[-1,1]$ that are not properly homotopic.

15. Homotopy equivalences and homotopy equivalent topological spaces

This chapter is a direct continuation of the previous chapter. In the last chapter we defined what it means for *maps* between topological spaces to be *homotopic*. Now in this chapter we will use this notion to define what it means for *topological spaces* to be *homotopy equivalent*. This notion is rather subtle and - at least for this author - not entirely intuitive.

15.1. Homotopy equivalent topological spaces.

For the reader's convenience we recall the following definition from page 418.

Definition. Let X and Y be two topological spaces. We say that two maps $f_0, f_1 \colon X \to Y$ are homotopic, written $f_0 \simeq f_1$, if there exists map $F \colon X \times [0,1] \to Y$ with $F_0 = f_0$ and with $F_1 = f_1$.

The following definition is one of the key definitions in topology. Unfortunately it usually takes some time to fully digest it.

Definition. Let X be and Y topological spaces.

(1) A map $f \colon X \to Y$ is a homotopy equivalence between X and Y, if f admits a homotopy inverse, i.e. a map $g \colon Y \to X$ with $g \circ f \simeq \mathrm{id}_X$ and $f \circ g \simeq \mathrm{id}_Y$.
(2) If there exists a homotopy equivalence between X and Y, then we say that X and Y are homotopy equivalent.
(3) Given a topological space X we refer to the class of all topological spaces that are homotopy equivalent to X as the homotopy type of X.

Remark.

(1) Basically by definition a homeomorphism is a homotopy equivalence.
(2) In this chapter we study basic properties and basic examples of homotopy equivalences. Much much later we will state and prove the Whitehead Theorem 162.1 which in many cases gives a fairly practical criterion for showing that a given map is a homotopy equivalence.

The name "homotopy equivalence" already suggests that this is an equivalence relation on the class of topological spaces. This is indeed the case:

Lemma 15.1. (Homotopy-Equivalence Basics Lemma)

(1) Let $f \colon X \to Y$ and $g \colon Y \to Z$ be maps between topological spaces. If two out of the three maps f, g and $g \circ f$ are homotopy equivalences, then so is the third.
(2) The relation "homotopy equivalence" is an equivalence relation on the class of all topological spaces.[155]
(3) Let $f, g \colon X \to Y$ be two maps between topological spaces. If f is a homotopy equivalence and if g is homotopic to f, then g is also a homotopy equivalence.
(4) Let X, Y and Z be topological spaces.
   (a) Let $f \colon X \to Y$ and let $g_0, g_1 \colon Y \to Z$ be maps such that $g_0 \circ f \simeq g_1 \circ f$. If f is a homotopy equivalence, then $g_0 \simeq g_1$.
   (b) Let $f_0, f_1 \colon X \to Y$ and let $g \colon Y \to Z$ be maps such that $g \circ f_0 \simeq g \circ f_1$. If g is a homotopy equivalence, then $f_0 \simeq f_1$.

Proof.

(1) Let $f\colon X \to Y$ and $g\colon Y \to Z$ be maps between topological spaces. There are three slightly different statements that need to be proved.

(a) First suppose that the maps $f\colon X \to Y$ and $g\colon Y \to Z$ admit homotopy inverses $f'\colon Y \to X$ and $g'\colon Z \to Y$. Then we see that

$$(f' \circ g') \circ (g \circ f) \;=\; f' \circ (g' \circ g) \circ f \;\underset{\uparrow}{\simeq}\; f' \circ \mathrm{id}_Y \circ f \;=\; f' \circ f \;\simeq\; \mathrm{id}_X\,.$$

by Lemma 14.5 (2) since $g' \circ g \simeq \mathrm{id}_Y$

Similarly one shows that $(g \circ f) \circ (f' \circ g') \simeq \mathrm{id}_Z$. Thus we have shown that $g \circ f$ is a homotopy equivalence.

(b) Next suppose that $f\colon X \to Y$ and $g \circ f\colon X \to Z$ admit homotopy inverses $f'\colon Y \to X$ and $h'\colon Z \to X$. Then we see that

$$(f \circ h') \circ g \;\underset{\uparrow}{\simeq}\; f \circ h' \circ (g \circ f) \circ f' \;\underset{\uparrow}{\simeq}\; f \circ \mathrm{id}_X \circ f' \;\simeq\; \mathrm{id}_Y\,.$$

by Lemma 14.5 (2) since $f \circ f' \simeq \mathrm{id}_Y$ — since h' is a homotopy inverse of $g \circ f$

Similarly one shows that $g \circ (f \circ h') \simeq \mathrm{id}_Z$. Thus we have shown that g is a homotopy equivalence.

(c) A slight variation on the argument of (1b) shows that if g and $g \circ f$ are homotopy equivalence, then so is f.

(2) It is clear that the only property of an equivalence relation that requires any thought is transitivity. But this follows from (1).

(3) We leave the elementary verification of this statement to the reader.

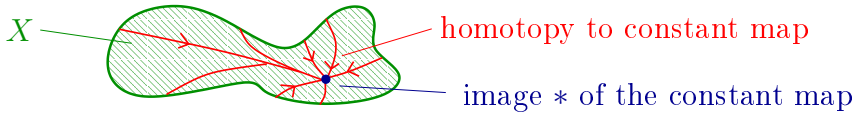
(4) The proof is very similar to the proof of (1). Again we leave the details to the reader. ■

Before we give examples of homotopy equivalent topological spaces we introduce the following definition.

Definition. Let X be a topological space. We say X is contractible, if X is homotopy equivalent to a topological space which consists of precisely one point.

Remark. Note that the empty topological space is *not* contractible.

The following elementary lemma gives a handy criterion for showing that a topological space is contractible.



[155]The perspicacious reader might notice that here things get logically a little dicey. More precisely, on page 89 we had recalled the notion of an equivalence relation. But we had only defined the notion of an "equivalence relation" on a set and "all topological spaces" do not form a set they "only" form a class. One can also define the notion of an "equivalence relation" on a class, see e.g. [**FPr1985**, Kapitel 2]. But we do not want to get into the discussion "what is a class?". As a cheap way out we interpret the second statement of the lemma as saying that reflexivity, symmetry and transitivity hold for "homotopy equivalence" with the obvious interpretation.

Lemma 15.2. (Contractibility Criterion Lemma) Let X be a topological space.

(1) X is contractible $\iff$ (2) there exists an $x_0 \in X$ such that the inclusion $\{x_0\} \to X$ is a homotopy equivalence

$\iff$ (3) there exists an $x_0 \in X$ such that the identity map id_X is homotopic to the constant map c_{x_0}.

Furthermore, if statement (2) or (3) of the Contractibility Criterion Lemma 15.2 hold for a single point, then the statements also hold for all points in X.

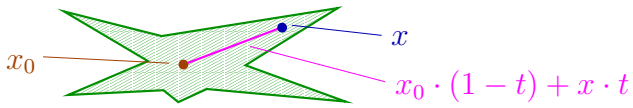
Proof.

(1)⇒(2) First suppose that X is contractible. Let $Y = \{*\}$ be the topological space consisting of a single element. Since X is contractible we know that there exists a map $g\colon \{*\} \to X$ that is a homotopy equivalence. We set $x_0 := g(*)$. Basically by definition the inclusion map $\{x_0\} \to X$ is also a homotopy equivalence.

(2)⇒(3) Let $x_0 \in X$ be a point such that the inclusion map $f\colon \{x_0\} \to X$ is a homotopy equivalence. Let $g\colon X \to \{x_0\}$ be the unique map. Since f is a homotopy equivalence we know that $f \circ g$ is homotopic to id_X. But $f \circ g = c_{x_0}$. Thus we have shown that id_X is homotopic to c_{x_0}.

(3)⇒(1) Finally we suppose that the identity map of X is homotopic to a constant map $f\colon X \to X$. Let $*$ be the unique point in the image of $*$. We set $Y := \{*\}$. Let $g\colon \{*\} \to X$ be the inclusion map. By hypothesis we have $g \circ f \simeq \mathrm{id}_X$. Furthermore we evidently have $f \circ g = \mathrm{id}_Y$. This shows that X is homotopic equivalent to $Y = \{*\}$. ■

Finally the "furthermore statement" is proved in Exercise 15.10.



We give two basic examples of homotopy equivalent topological spaces.

Examples.

(1) We say a subset X of $\mathbb{R}^n$ is star-shaped if there exists a point $x_0 \in X$ such that for any $x \in X$ the segment from x_0 to x lies in X. Basically by the same argument as in the Convex Homotopy Lemma 14.1 we see that the map

$$\begin{array}{rcl} f\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & x_0 \cdot (1-t) + x \cdot t \end{array}$$

is a homotopy from id_X to a constant map. By the Contractibility Criterion Lemma 15.2 this shows that X is contractible.

(2) It follows from the previous example together with the fact that being homotopy equivalence is transitive, see the Homotopy-Equivalence Basics Lemma 15.1 (2), that for any $n \in \mathbb{N}$ and any $k \in \mathbb{N}$ the topological spaces $\mathbb{R}^n$ and $\mathbb{R}^k$ are homotopy equivalent.

We recall the following definition from page 167.

Definition. Let X be a topological space. We denote by $\pi_0(X)$ the set of path-components of X.

Lemma 15.3. (π_0-Homotopy Equivalence Lemma)

(1) Let $f\colon X \to Y$ be a map between topological spaces. If f is a homotopy equivalence, then f induces a bijection[156] $f_*\colon \pi_0(X) \to \pi_0(Y)$.
(2) If X and Y are homotopy equivalent topological spaces, then X is path-connected if and only if Y is path-connected.
(3) If X is a contractible topological space, then it is path-connected.

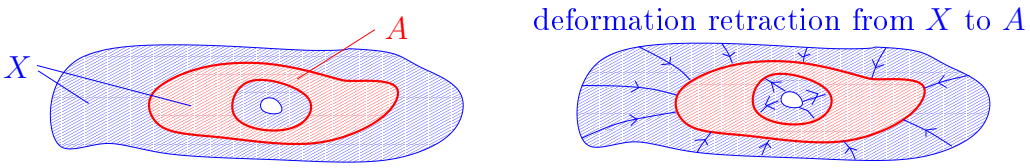
Proof. We leave the proof of the following lemma as an edifying exercise to the reader, see Exercise 15.12. ■

15.2. **Deformation retractions.** Before we give the definition of a deformation retraction let us give the definition of a retraction.

Definition. Let X be a topological space. We say a subset $A \subset X$ is a retract of X if there exists a retraction $r\colon X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$.

retraction r from X to A

We immediately move on to the related notion of a deformation retraction.

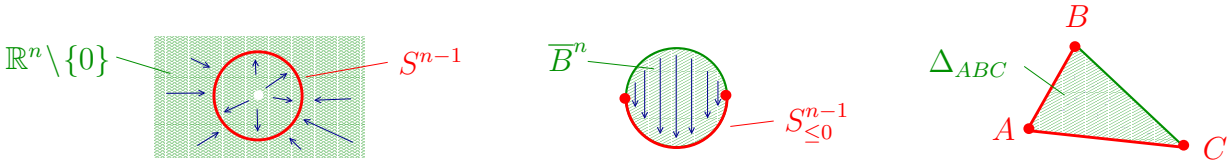


Definition. Let X be a topological space and let A be a subset.

(1) A homotopy $F\colon X \times [0,1] \to X$ is called a homotopy rel A, if $F(a,t) = a$ for all $a \in A$ and all $t \in [0,1]$.
(2) A deformation retraction from X to A is a homotopy $F\colon X \times [0,1] \to X$ which has the following three properties:[157]
   (a) $F_0 = \mathrm{id}_X$,
   (b) F is a homotopy rel A,
   (c) $F_1(X) \subset A$.
(3) We say A is a deformation retract of X if there exists a deformation retraction from X to A.[158]
(4) We say a retraction $r\colon X \to A$ is realized by a deformation retraction if there exists a deformation retraction F from X to A with $F_1 = r$.

We say a point $a \in X$ is a deformation retract of X if the subset $\{a\}$ if a deformation retract of X.

Examples.



[156] On page 200 we saw that $f\colon X \to Y$ induces a map $f_*\colon \pi_0(X) \to \pi_0(Y)$.
[157] Note that $F_1\colon X \to A$ is retraction from X to A.
[158] Unfortunately in the literature the term "deformation retract" is used differently by different authors. Our notion of a "deformation retract" agrees with the definition in [**Hat2002**, p. 2] and [**Mun1984**, p. 208]. What we call a "deformation retract" is called a "strong deformation retract" in [**Bre1993**, p. 45]

(1) For any topological space X, any interval $I \subset \mathbb{R}$ and any $a \in I$ the subspace $X \times \{a\}$ is a deformation retract of $X \times I$. In fact the deformation retraction is given[159] by

$$\begin{array}{rcl} (X \times I) \times [0,1] & \to & X \times I \\ ((x,s),t) & \mapsto & (x, s \cdot (1-t) + a \cdot s). \end{array}$$

(2) Let $n \in \mathbb{N}$. In Exercise 15.13 we will prove the following two statements:
   (a) The sphere S^{n-1} is a deformation retract of $\mathbb{R}^n \setminus \{0\}$.
   (b) The hemispheres $S^{n-1}_{\leq 0}$ is a deformation retract of $\overline{B}^n$.
   (c) Given any three non-collinear points $A, B, C \in \mathbb{R}^n$ the triangle Δ_{ABC} admits a deformation retraction to the union of any two sides of the triangle.

Lemma 15.4. (Iterated Deformation Retracts Lemma) Let X be a topological space and let $A \subset B \subset X$ be subspaces. If A is a deformation retract of B and if B is a deformation retract of X, then A is a deformation retract of X.

Proof. Let X be a topological space and let $A \subset B \subset X$ be subspaces. Furthermore let $F\colon B \times [0,1] \to B$ be a deformation retraction from B to A and let $G\colon X \times [0,1] \to X$ be a deformation retraction from X to B. We consider the map

$$\begin{array}{rcl} X \times [0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} G(x,2t), & \text{if } t \in [0,\frac{1}{2}], \\ F(G_1(x), 2t-1), & \text{if } t \in [\frac{1}{2},t]. \end{cases} \end{array}$$

It follows from the Homotopy Stacking Lemma 14.3 that this map is continuous. Once continuity is verified it is clear that this map is indeed a deformation retraction from X to A. ■

---

and [**Rot1988**, p. 209]. In these books this notion is used to distinguish it from the notation of a "weak deformation retract", which means that there exists a map $F\colon X \times [0,1] \to X$ such that

(1) for every $x \in X$ we have $F(x,0) = x$ and $F(x,1) \in A$,
(2) for every $a \in A$ we have $F(a,1) = a$.

It turns out that the two concepts are indeed different. For example, let Z be the infinite zigzag comb which is shown below the Point Deformation Retract Lemma 15.6. the Point Deformation Retract Lemma 15.6 (2) says that every one-point subset of Z is a weak deformation retract of Z but the Point Deformation Retract Lemma 15.6 (3) says no one-point subset of Z is a strong deformation retract of X.

[159] It follows from the discussion on page 142 and the Product Topology-Basics Lemma 5.4 (3) that this map is actually continuous.

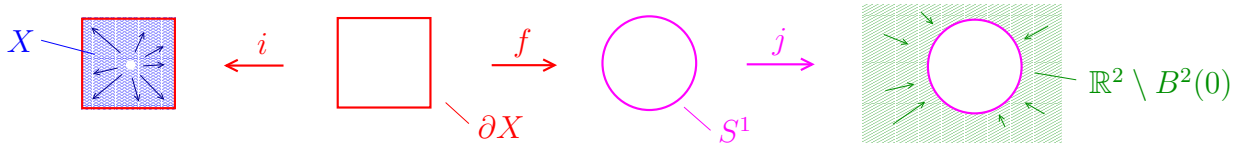
Lemma 15.5. (Deformation Retract-Homotopy Equivalence Lemma) Let A be a subset of a topological space X which admits a deformation retraction F from X to A. Then the inclusion map

$$\begin{array}{rcl} i\colon A & \to & X \\ a & \mapsto & a \end{array} \qquad \text{and the map} \qquad \begin{array}{rcl} r\colon X & \to & A \\ x & \mapsto & F(x,1) \end{array}$$

are homotopy inverses of one another. In particular both maps are homotopy equivalences and in particular the deformation retract A is homotopy equivalent to the total space X.

Proof. By definition of a deformation retraction the map $r \circ i = F_1 \circ i\colon A \to A$ is the identity. Thus it remains to show that $i \circ r\colon X \to X$ is homotopic to the identity. A homotopy between id and $i \circ r$ is given by F. ■

Example. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the previous example the sphere S^{n-1} and $\mathbb{R}^n \setminus \{0\}$ are homotopy equivalent.



Remark. We now have three methods for showing that topological spaces are homotopy equivalent:

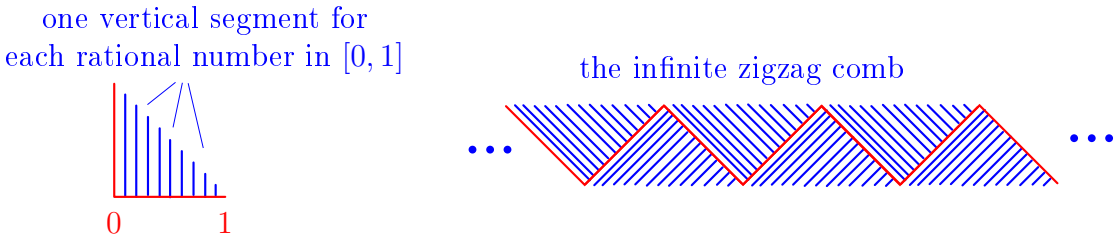
(1) Homeomorphisms are almost by definition homotopy equivalences.
(2) the Homotopy-Equivalence Basics Lemma 15.1 (2) says that being homotopy equivalent is an equivalence relation.
(3) the Deformation Retract-Homotopy Equivalence Lemma 15.5 says that if A is a deformation retract of some topological space X, then the inclusion $i\colon A \to X$ is a homotopy equivalence.

The combination of these three methods can be very powerful. For example let us consider $X = ([-1,1] \times [-1,1]) \setminus \{(0,0)\}$ and $Y = \mathbb{R} \setminus B^2(0)$. We consider the maps

$$X \xhookleftarrow{i} \partial X \xrightarrow[f]{x \mapsto \frac{x}{\|x\|}} S^1 \xhookrightarrow{j} \mathbb{R}^2 \setminus B^2(0).$$

As above one can easily show that ∂X is a deformation retract of X and that S^1 is a deformation retract of $\mathbb{R}^2 \setminus B^2(0)$. Furthermore f is a homeomorphism. It follows from the combination of (1), (2) and (3) that X is homotopy equivalent to $\mathbb{R}^2 \setminus B^2(0)$. In the Point

Deformation Retract Lemma 15.6 and much later in Exercise **??** we will see that it is in general not true that homotopy equivalent topological spaces admit deformation retracts that are homeomorphic. Nonetheless in Corollary 17.17 we will show that (1), (2) and (3) are in fact enough to characterize homotopy equivalence. More precisely we will show that given two topological X and Y the following two statements are equivalent:



- X and Y are homotopy equivalent.

- There exists a topological space W and closed embeddings $i\colon X \to W$ and $j\colon Y \to W$ such that $i(X)$ is a deformation retract of W and $j(Y)$ is a deformation retract of W.

The notions of a topological space being contractible and admitting a deformation retraction to a point sound quite similar. The following lemma gives the precise relationship between these two notions.

Lemma 15.6. (Point Deformation Retract Lemma)

(1) If a topological space X admits a deformation retraction to a point $x_0 \in X$, then X is homotopy equivalent to $\{x_0\}$, in particular X is contractible.
(2) If a topological space X is contractible, then given any point $x_0 \in X$ there exists a homotopy $H\colon X \times [0,1] \to X$ such that $H_0 = \mathrm{id}_X$ and $H_1(x) = x_0$ for all $x_0 \in X$.
(3) The "infinite zigzag comb" shown in the figure below is contractible, but it does not admit a deformation retraction to a point.

Proof.

(1) This statement follows immediately from the Deformation Retract-Homotopy Equivalence Lemma 15.5.
(2) Suppose X is a topological space that is contractible. By the Contractibility Criterion Lemma 15.2 we know that there exists a homotopy $G\colon X \times [0,1] \to X$ from id_X to a constant map. Let x_1 be the image of this constant map. Recall that we know from the π_0-Homotopy Equivalence Lemma 15.3 that X is path-connected. Thus there exists a path $\gamma\colon [0,1] \to X$ from x_1 to x_0. The desired homotopy is now given by the map[160]
$$\begin{array}{rcl} H\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} G(x, 2\cdot t), & \text{if } t \in [0, \frac{1}{2}], \\ \gamma(2\cdot t - 1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$
(3) This statement will be proved in Exercise 15.2. ■

We conclude this discussion of deformation retractions with an extremely useful example that gets formulated as a proposition.

Proposition 15.7. (Matrix Groups Deformation Retract Proposition) Let $n \in \mathbb{N}_0$ and let $k \in \{1, \ldots, n\}$. We write
$$\begin{array}{rcl} \mathrm{GL}(n,k) & = & \text{set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^n \\ \mathrm{O}(n,k) & = & \text{set of } k\text{-tuples of orthonormal vectors of } \mathbb{R}^n. \end{array}$$

[160] It follows from the Homotopy Stacking Lemma 14.3 that this map is continuous.

(Note that for $k = n$ we have $\mathrm{GL}(n,k) = \mathrm{GL}(n)$ and $\mathrm{O}(n,k) = \mathrm{O}(n)$.) We denote by $r\colon \mathrm{GL}(n,k) \to \mathrm{O}(n,k)$ the map given by the Gram-Schmidt Orthonormalization Process 2.38. The following statements hold:

(1) The above retraction $r\colon \mathrm{GL}(n,k) \to \mathrm{O}(n,k)$ is realized by a deformation retraction $R\colon \mathrm{GL}(n,k) \times [0,1] \to \mathrm{O}(n,k)$ which has the following extra property:
($*$) For every k-dimensional vector subspace V of $\mathbb{R}^n$ and every $t \in [0,1]$ we have

$$R_t(\text{basis of } V) \;=\; \text{basis of } V.$$

(2) The inclusion $\mathrm{O}(n,k) \to \mathrm{GL}(n,k)$ is a homotopy equivalence.

The analogous statements hold if we replace the pair $\mathrm{O}(n,k)$ and $\mathrm{GL}(n,k)$ by one of the following four pairs:

(a)	$\mathrm{GL}_+(n,\mathbb{R})$	and	$\mathrm{SO}(n)$
(b)	$\mathrm{SL}(n,\mathbb{R})$	and	$\mathrm{SO}(n)$
(c)	$\mathrm{GL}(n,\mathbb{C})$	and	$\mathrm{U}(n)$
(d)	$\mathrm{SL}(n,\mathbb{C})$	and	$\mathrm{SO}(n)$.

Remark. In Proposition 33.10 we will see that the deformation retraction can be chosen to be "smooth".

Proof.

(1) On page 173, in the proof of the Matrix Group Path-Component Proposition 2.37, we implicitly already showed that each of the $2k$ steps of the Gram-Schmidt Orthogonalization Process is realized by a deformation retraction that satisfies ($*$). It follows from the Iterated Deformation Retracts Lemma 15.4 that we can combine these $2k$ deformation retractions to obtain the desired deformation retraction

$$R\colon \mathrm{GL}(n,k) \times [0,1] \;\to\; \mathrm{GL}(n,k)$$

from $\mathrm{GL}(n,k)$ to $\mathrm{O}(n,k)$ such that R that satisfies ($*$). If $n = k$, then it follows from the Gram-Schmidt Orthonormalization Process 2.38 (2) and (3) that this deformation retraction R restricts to a deformation retraction from $\mathrm{GL}_+(n,\mathbb{R})$ to $\mathrm{SO}(n)$ and from $\mathrm{SL}(n,\mathbb{R})$ to $\mathrm{SO}(n)$.

Finally note that the complex cases are treated in a very similar fashion.

(2) This statement follows immediately from (1) and the Deformation Retract-Homotopy Equivalence Lemma 15.5. ■

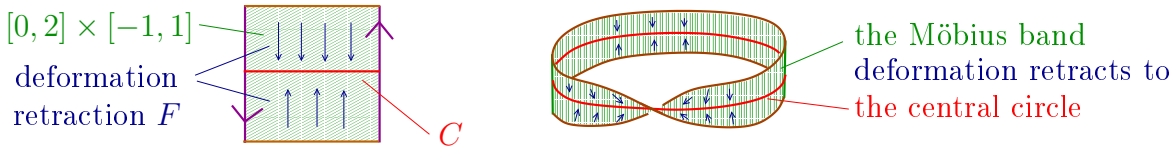
In the following we will see that deformation retractions descend to quotients under suitable hypotheses.

Theorem 15.8. (Deformation Retraction Quotient Theorem) Let X be a topological space and let $A \subset X$ be a subset. Furthermore let $F\colon X \times [0,1] \to X$ be a deformation retraction from X to A. Suppose that "$\sim$" is an equivalence relation on X which is compatible with the deformation retraction F in the sense that $F(x,t) \sim F(x',t)$ whenever $x \sim x'$. Then the map

$$\begin{array}{rcl} \overline{F}\colon (X/\sim) \times [0,1] & \to & X/\sim \\ ([x],t) & \mapsto & [F(x,t)] \end{array}$$

is a deformation retraction from $X/\sim$ to $A/\sim$.

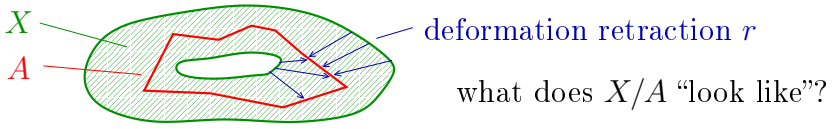
Proof. It follows from the Homotopy Quotient Theorem 14.7 that $\overline{F}$ is continuous. It is now clear that $\overline{F}$ is a deformation retraction from $X/\sim$ to $A/\sim$. ■



Example. We consider $X = [0,2] \times [-1,1]$ together with the equivalence relation "$\sim$" that is generated by

$$(0,y) \sim (1,-y) \quad \text{for all } y \in [-1,1].$$

Basically the same argument as on page 264 shows that we can view $X/\sim$ as the Möbius band. We consider the maps



$$\begin{array}{rcl} F\colon X \times [0,1] & \to & X \\ ((x,y),t) & \mapsto & (x, y \cdot (1-t)) \end{array} \quad \text{and} \quad \begin{array}{rcl} \overline{F}\colon (X/\sim) \times [0,1] & \to & X/\sim \\ ([(x,y)],t) & \mapsto & [(x, y \cdot (1-t))]. \end{array}$$

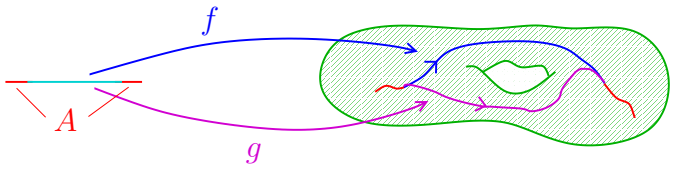
Note that F is a deformation retraction from X to $C := [0,2] \times \{0\}$. One can easily verify that F is compatible with the equivalence relation "$\sim$". Thus we obtain from the Deformation Retraction Quotient Theorem 15.8 that $\overline{H}$ is a deformation retraction from the Möbius band to $C/\sim$. Note that $C/\sim$ is homeomorphic to $[0,2]/0 \sim 2$ which is in turn homeomorphic to S^1. It follows from this discussion together with the Deformation Retract-Homotopy Equivalence Lemma 15.5 that the Möbius band is homotopy equivalent to S^1.

We conclude our discussion of deformation retracts with the following proposition which might sound innocuous, but whose proof relies eventually on the tricky Whitehead Quotient Theorem 13.4.

Proposition 15.9. (Quotient Deformation Retract Proposition) Let X be a topological space and let A be a subset of X. If A is a deformation retract of X, then the point A/A is a deformation retract of X/A. In particular X/A is contractible.

Proof. Let $r\colon X \times [0,1] \to X$ be a deformation retraction from X to A. We consider the equivalence relation "$\sim$" on X that is generated by the condition that all points in A are equivalent. Note that by definition of a deformation retraction the homotopy r is compatible with the equivalence relation "$\sim$". Therefore it follows from the Deformation Retraction Quotient Theorem 15.8 that the map

$$\begin{array}{rcl} (X/\sim) \times [0,1] & \to & X/\sim \\ ([x],t) & \mapsto & [r(x,t)]. \end{array}$$



is a deformation retraction from $X/\sim = X/A$ to $A/\sim = A/A$. ■

15.3. **Homotopies and homotopy equivalences for pairs of topological spaces.** On page 418 we defined what it means for two maps $f, g\colon X \to Y$ between topological spaces to be homotopic and on page 430 we defined what it means for two topological spaces to be homotopy equivalent.

On many occasions one would like to restrict the freedom of a homotopy by fixing some subset pointwise or setwise. This idea leads us to two relative versions of "homotopy". The first version we already saw on page 419. For the reader's convenience we recall the definition.

Definition. Let $f, g\colon X \to Y$ be two maps between topological spaces and let $A \subset X$ be a subset such that $f|_A = g|_A$.

(1) A homotopy between f and g rel A is a homotopy $H\colon X \times [0,1] \to Y$ between f and g such that $H(a,t) = f(a) = g(a)$ for all $t \in [0,1]$ and all $a \in A$.
(2) We say f and g are homotopic rel A, if such a homotopy rel A exists.

Before we continue it is convenient to introduce the following harmless definition which is an analogue of the category of pairs of sets that we had introduced on page 196.

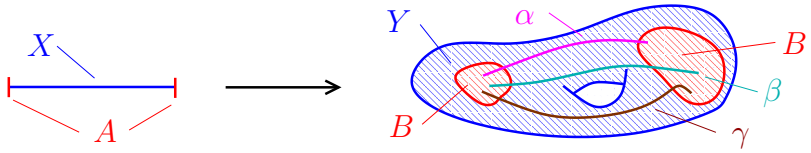
Definition.

(1) A pair of topological spaces is a pair (X, A), where X is a topological space and A is a subset of X.
(2) A map $f\colon (X, A) \to (Y, B)$ between pairs of topological spaces is a map $f\colon X \to Y$ of topological spaces with $f(A) \subset B$.
(3) We refer to the category $\mathcal{PairTop}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{PairTop}) &:= \text{all pairs of topological spaces,} \\ \mathrm{Mor}((X,A),(Y,B)) &:= \text{all continuous maps } f \text{ from } X \text{ to } Y \text{ with } f(A) \subset B \end{aligned}$$

with the usual composition of maps as the category of pairs of topological spaces.

We continue with another notion of a "relative homotopy".



Definition. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets. Let $f, g\colon (X, A) \to (Y, B)$ be two maps of pairs of topological spaces.

(1) A homotopy between f and g is a map[161]

$$H\colon X \times [0,1] \to Y,$$

such that the following two conditions are satisfied:
(a) $H_0 = f$ and $H_1 = g$, and
(b) $H(a,t) \in B$ for all $a \in A$ and all $t \in [0,1]$.
(2) If there exists a homotopy between f and g, then we say that f and g are homotopic and we write $f \simeq g$.

[161] For $A = B = \varnothing$ we get the usual notion of a homotopy between maps $f, g\colon X \to Y$.

$\alpha, \beta\colon (X, A) \to (Y, B)$ are homotopic but $\alpha, \gamma\colon (X, A) \to (Y, B)$ are not homotopic

For completeness we also mention the following definition which is the obvious relative analogue of the concepts that we introduced on page 430.

Definition. Let (X, A) and (Y, B) be two pairs of topological spaces.

(1) A map $f\colon (X, A) \to (Y, B)$ is a homotopy equivalence between (X, A) and (Y, B), if there exists a map $g\colon (Y, B) \to (X, A)$ such that the following hold:
   (a) $g \circ f$ and id_X are homotopic as maps of (X, A) to itself,
   (b) $f \circ g$ and id_Y are homotopic as maps of (Y, B) to itself.

(2) If there exists a homotopy equivalence between (X, A) and (Y, B), then we say that (X, A) and (Y, B) are homotopy equivalent.

Examples.

(1) The two pairs of topological spaces (X, A) and (Y, B) shown in the figure below are homotopy equivalent.

(2) Let X be a topological space and let $A \subset B$ be subsets of X. If A is a deformation retract of B, then the inclusion map $(X, A) \to (X, B)$ is easily seen to be a homotopy equivalence of pairs of topological spaces.

(3) Let $A \subset Y$ be subsets of X. If Y is a deformation retract of X, then the inclusion map $(Y, A) \to (X, A)$ is again easily seen to be a homotopy equivalence of pairs of topological spaces.

The above notions can be generalized even further. For example, one could define triples of topological spaces and there is an obvious definition of what it means for maps $f, g\colon (X, A, B) \to (Y, C, D)$ between triples of topological spaces to be homotopic. Similarly, given pairs of topological spaces (X, A) and (Y, B) and a subset Z of A there is an obvious definition for what it means for two maps $f, g\colon (X, A) \to (Y, B)$ to be homotopic rel Z. We will not spell out all the definitions. From the context it should always be clear what we mean.

15.4. **The set of homotopy classes of maps between topological spaces.** In this short section we study the set of homotopy classes of maps between topological spaces. This set will play a crucial much much later in Chapter 164. But at first reading one can still safely ignore this section.

Definition. Given two topological spaces X and Y we define

$$[X,Y] := \{\text{maps } X \to Y\}/\sim \quad \text{where } f \sim g \text{ if there exists a homotopy between } f \text{ and } g.$$

Sometimes, given a map $f\colon X \to Y$ we denote by $[f]$ the equivalence class it represents in $[X,Y]$.

Example. We write $I = [0,1]$. In Exercise 15.1 we will see that for any path-connected topological space X the set $[I,X]$ consists of a single element, i.e. all maps $I = [0,1] \to X$ are homotopic.

The following lemma is an immediate consequence of Lemma 14.6.

Lemma 15.10. Let X, Y and Z be topological spaces. The map

$$\begin{array}{rcl} [X,Y] \times [Y,Z] & \to & [X,Z] \\ ([f],[g]) & \mapsto & [g \circ f] \end{array}$$

is well-defined.

Lemma 15.10 leads us to the following definition.

Definition. We define the homotopy category $\mathcal{HomTop}$ of topological spaces by[162]

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{HomTop}) & := & \text{all topological spaces,} \\ \mathrm{Mor}(X,Y) & := & [X,Y] \end{array}$$

with the composition

$$\begin{array}{rcl} \mathrm{Mor}(X,Y) \times \mathrm{Mor}(Y,Z) & \to & \mathrm{Mor}(X,Z) \\ ([f],[g]) & \mapsto & [g \circ f]. \end{array}$$

We continue with the following harmless definition.

Definition. Let $f\colon X \to Y$ be a map between topological spaces. A map $g\colon Y \to X$ is called a homotopy left inverse of f if $g \circ f$ is homotopic to id_X. Furthermore, a map $h\colon Y \to X$ is called a homotopy right inverse of f if $f \circ h$ is homotopic to id_Y.

Taking the categorical view point now allows us to prove the following lemma by a completely approach.

Lemma 15.11. Let $f\colon X \to Y$ be a map between topological spaces. If f admits a homotopy left inverse g and a homotopy right inverse h, then f is in fact a homotopy equivalence and both g and h are homotopy inverses.

Proof. This lemma follows immediately from applying Lemma 3.3 to the homotopy category $\mathcal{HomTop}$. ∎

We conclude this section with the following elementary but useful lemma.

Lemma 15.12.

(1) Let $f\colon X \to Y$ be a map between topological spaces. The element $[f] \in \mathrm{Mor}(X,Y)$ is an isomorphism[163] in the category $\mathcal{HomTop}$ if and only if f is a homotopy equivalence.

[162] Note that in this category the morphisms are not maps but they are equivalence classes of maps.

(2) Let $f\colon X_1 \to X_2$ be a map between topological spaces and let A be a topological space. If f is a homotopy equivalence, then the induced maps

$$\begin{array}{rcl} [X_2, A] & \to & [X_1, A] \\ [g] & \mapsto & [g \circ f] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} [A, X_1] & \to & [A, X_2] \\ [g] & \mapsto & [f \circ g] \end{array}$$

are bijections.

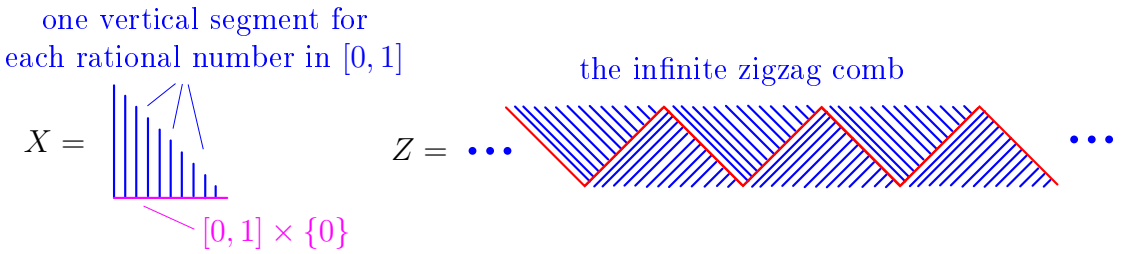
Proof.

(1) This statement is a tautology, it follows immediately from the definitions.
(2) This statement follows immediately from (1) together with Lemma 3.4. ■

Exercises for Chapter 15.

Exercise 15.1. Let X be a topological space and let Y be a contractible topological space.

(a) Show that all maps $X \to Y$ are homotopic.
(b) We suppose that X is path-connected. Show that all maps $Y \to X$ are homotopic.



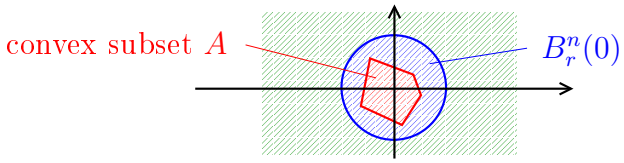
Exercise 15.2.

(a) We consider the topological space

$$X \;=\; \{(x,y) \,|\, x \in [0,1] \cap \mathbb{Q}, y \in [0, 1-x]\} \cup ([0,1] \times \{0\})$$

that is shown in the figure below to the left.
  (i) Show that given any point P in $[0,1] \times \{0\}$ there exists a deformation retraction from X to P.
  (ii) Show that for any point Q in X that does not lie on $[0,1] \times \{0\}$ there is no deformation retraction from X to Q.

(b) We consider the infinite zigzag comb Z that is shown in the figure below to the right.
  (i) Show that Z is contractible.
  (ii) Show that Z does not admit a deformation retraction to any point in Z.



Exercise 15.3. Let $X = \{0,1\}$ be the Sierpiński space, i.e. let X be the topological space with two elements 0 and 1 and where the open sets are precisely $\varnothing, \{0\}, X$.

(a) Is $\{0\}$ a deformation retract of X?
(b) Is $\{1\}$ a deformation retract of X?

Exercise 15.4. Let $0 < r < s$ be two real numbers. Show that the obvious inclusion map $B_r^n(0) \setminus \{0\} \to B_s^n(0) \setminus \{0\}$ is a homotopy equivalence.

[163] We refer to page 198 for the definition of an isomorphism in a category.

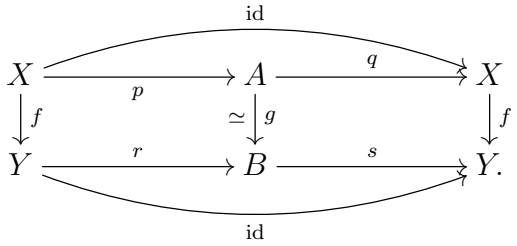
Exercise 15.5. Let A be a convex subset of $\mathbb{R}^n$ which contains the origin 0. Let $r > 0$ such that $A \subset B_r^n(0)$. Show that $\mathbb{R}^n \setminus B_r^n(0)$ is a deformation retract of $\mathbb{R}^n \setminus A$.
Remark. This exercise is a generalization of Exercise 15.4.

Exercise 15.6. Let $T = (V, E, i, t)$ be a tree in the sense of the definition on page 315. As on page 308 we consider the corresponding topological realization $|T|$. Show that the topological realization $|T|$ is contractible.
Remark. You could make use of Lemma 7.7. You should also explain carefully why the homotopies you write down are actually continuous.

Exercise 15.7. Let X be a topological space and let $H\colon X \times [0,1] \to X$ be a deformation retraction to a subset A. We consider

$$\begin{array}{rcl} \phi\colon X & \to & [0,1] \\ x & \mapsto & \inf\{t \in [0,1] \,|\, H(x,t) \in A\}. \end{array}$$

Is the map ϕ necessarily continuous?



Exercise 15.8. Show that the topological spaces

$$X = \{\tfrac{1}{n} \,|\, n \in \mathbb{N}\} \cup \{0\} \quad \text{and} \quad Y = \{\tfrac{1}{n} \,|\, n \in \mathbb{N}\} \cup \{-1\}$$

are not homotopy equivalent.

Exercise 15.9. Let $f\colon X \to Y$ and $g\colon A \to B$ be maps between topological spaces. We say *f is a retract of g* if there exists a commutative diagram of maps

such that $q \circ p = \mathrm{id}_X$ and $s \circ r = \mathrm{id}_Y$. Show that if g is a homotopy equivalence, then f is also a homotopy equivalence.
Hint. Use Lemma 15.11.

Exercise 15.10. Let X be a topological space.

(a) Suppose that there exists an $x_0 \in X$ such that the inclusion $\{x_0\} \to X$ is a homotopy equivalence. Show that for every $x_1 \in X$ the inclusion $\{x_1\} \to X$ is a homotopy equivalence.
(b) Suppose that there exists an $x_0 \in X$ such that the identity map id_X is homotopic to the constant map c_{x_0}. Show that for every $x_1 \in X$ the identity map id_X is homotopic to the constant map c_{x_1}.

Exercise 15.11. Does there exist a topological space with three elements that is homotopy equivalent to the topology space $X = \{*\}$ given by a single point?

Exercise 15.12. Let $f\colon X \to Y$ be a map between topological spaces. Show that if f is a homotopy equivalence, then f induces a bijection $\pi_0(X) \to \pi_0(Y)$.[164]

Exercise 15.13. Let $n \in \mathbb{N}$. Prove the following three statements:

(a) The sphere S^{n-1} is a deformation retract of $\mathbb{R}^n \setminus \{0\}$.
(b) The hemispheres $S^{n-1}_{\leq 0}$ is a deformation retract of $\overline{B}^n$.
(c) Given any three non-collinear points $A, B, C \in \mathbb{R}^n$ the triangle Δ_{ABC} admits a deformation retraction to the union of any two sides of the triangle.
Hint. You could first consider the case that $A = (0,0)$, $B = (0,1)$ and $C = (1,0)$.

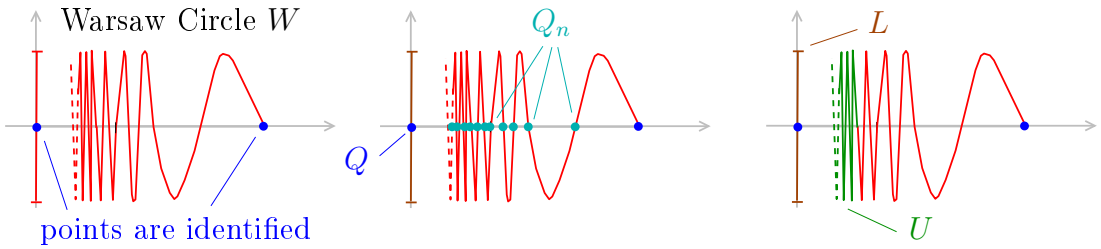
These three examples are illustrated in the figure on page 434.

Exercise 15.14. Let

$$S \;:=\; \big\{(0,y)\,\big|\,y \in [-1,1]\big\} \cup \big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x \in (0,\tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2.$$

be the "Topologist's Sine Curve" from page 164. As on page 276 we refer to the quotient space $W := S/(0,0) \sim (\frac{1}{\pi},0)$ as the *Warsaw Circle*. Our goal is to show that the circle is not contractible. To do so we introduce the following notation:

- We denote by $p\colon S \to W$ the projection .
- We set $Q = p(0,0)$ and given $n \in \mathbb{N}$ we set $Q_n = p((\frac{1}{\pi n},0))$.
- We set $L := \{p(0,y)\,|\,y \in [-1,1]\} \subset W$ and $U := \big\{p(x,\sin(\frac{1}{x}))\,\big|\,x \in (0,\frac{1}{2\pi}]\big\} \subset W$.



Now go through the following steps:

(a) Let $g\colon W \to W$ be a map. We suppose that there exists an $n \in \mathbb{N}$ such that for all $m \geq n$ we have $g(Q_n) \in U$. Show that $g(Q) \in L \cup U$.
(b) Let $F\colon W \times [0,1] \to W$ be a homotopy. Show that

$$T \;:=\; \left\{ t \in [0,1] \,\middle|\, \begin{array}{c} F_t(Q) \in L \text{ and there exists an } n \in \mathbb{N} \text{ such} \\ \text{that for all } m \geq n \text{ we have } F_t(Q_m) \in U \end{array} \right\} \;\subset\; [0,1]$$

is open and closed.
(c) Show that W is not contractible.
Hint. Suppose that W is contractible. By the Contractibility Criterion Lemma 15.2 this means that there exists a homotopy $F\colon W \times [0,1] \to W$ with $F_0 = \mathrm{id}$ and such that $F_1(w) = Q$ for all $w \in W$. Use (b) to show that such F cannot exist.

[164] Recall that given a topological space Z we denote by $\pi_0(Z)$ the set of path-components of Z.

Exercise 15.15. We consider $X = [-1,1]/-1 \sim 1$ and we denote by $p\colon [-1,1] \to X$ the projection . We consider the two subspaces $A = p((-1,1)) \subset X$ and $B = p(\{0\}) \subset X$. Are the two pairs (X,A) and (X,B) of topological spaces homotopy equivalent?

Exercise 15.16. Let $U \subset \mathbb{R}^n$ be a neighborhood of 0 and let $f\colon U \to \mathbb{R}^n$ be a map with $f^{-1}(0) = \{0\}$. Furthermore let $g\colon U \to \mathbb{R}^n$ be a map with $f(x) - g(x) = O(\|x\|^2)$, i.e. we assume that there exists a $C \geq 0$ and a $\delta > 0$ such that $\|f(x) - g(x)\| < C \cdot \|x\|^2$ for all $x \in \overline{B}^n_\delta$. Show that there exists an $s > 0$ such that the maps f and g are homotopic as maps of pairs $(\overline{B}^n_s, \overline{B}^n_s \setminus \{0\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$.

16. Joins, mapping cones, cylinders and tori

In this section we first introduce two systematic ways to construct new topological spaces out of a given topological space and we present three systematic ways to construct new topological spaces out of a map $f\colon X \to Y$ between given topological spaces. Initially it might not be entirely apparent why we should be interested, but all five examples will play an important role at various points.

For example we will associate to a map $f\colon X \to Y$ between topological spaces a topological space $\mathrm{Cyl}(f\colon X \to Y)$, called the *mapping cylinder of* $f\colon X \to Y$. The mapping cylinder translates questions about the map $f\colon X \to Y$ to questions about the topological space $\mathrm{Cyl}(f\colon X \to Y)$.

16.1. **The join of two topological spaces.** In this section we introduce the join of two topological spaces. This construction will be useful on a few occasions, but it is difficult to argue that at this stage this is an essential topic in these notes.

Loosely speaking the join $X * Y$ is obtained by connecting each point in X to each point in Y via an interval. The following definition makes this idea precise.

Definition. Let X and Y be two non-empty topological spaces. We define the join $X * Y$ to be the topological space obtained from $X \times [0,1] \times Y$, equipped with the product topology, by performing the following two types of identifications:

(1) for every $x \in X$ we identify all points in $\{x\} \times \{0\} \times Y$ to a single point and
(2) for every $y \in Y$ we identify all points in $X \times \{1\} \times \{y\}$ to a single point.

Furthermore, if one of X or Y is the empty topological space, then we define the join $X * Y$ to be the other topological space.

For completeness we state the following lemma.

Lemma 16.1. Let X_1, Y_1, X_2, Y_2 be four topological spaces and let $f\colon X_1 \to X_2$ and $g\colon Y_1 \to Y_2$ be maps. The corresponding map

$$\begin{array}{rcl} f * g\colon X_1 * Y_1 & \to & X_2 * Y_2 \\ [(x,t,y)] & \mapsto & [(f(x),t,g(y))] \end{array}$$

is well-defined and continuous.

Proof. It is straightforward to verify that the map $f * g$ is well-defined. It follows easily from the Topological-Quotient Proposition 5.15 (1b), the Topological-Quotient Proposition 5.15 (1a) and the Product Topology-Basics Lemma 5.4 (3) that the map $f * g$ is continuous. ∎

Before we deal with a few examples we give a criterion for showing that a map of the form $f\colon X * Y \to Z$ is a homeomorphism.

Lemma 16.2. If X and Y are compact spaces, then the following two statements hold:

(1) The join $X * Y$ is compact.
(2) Let $f\colon X \times [0,1] \times Y \to Z$ be a map to a topological space Z such that for any $x, x_1, x_2 \in X$ and $y, y_1, y_2 \in Y$ we have the equalities $f(x,0,y_1) = f(x,0,y_2)$ and $f(x_1,1,y) = f(x_2,1,y)$. If Z is Hausdorff and if the induced map[165]

$$\begin{array}{rcl} \Psi\colon X * Y & \to & Z \\ [(x,t,y)] & \mapsto & f(x,y,t) \end{array}$$

is a bijection, then the map Ψ is a homeomorphism.

Proof.

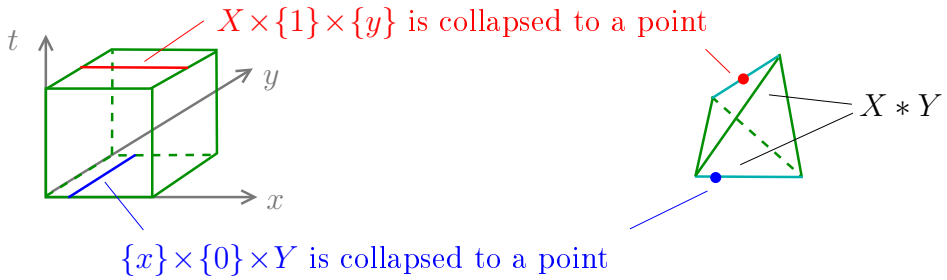
(1) It follows from our hypothesis and the Product Topology Properties Proposition 5.6 together with the Quotient-Compact Connected Lemma 5.16 (1) that the join $X*Y = (X \times [0,1] \times Y)/\sim$ is compact.
(2) The map $\Psi\colon X*Y \to Z$ is continuous by the Topological-Quotient Proposition 5.15 (1b). Thus we obtain from our hypotheses on Ψ and Z together with the Compact-Hausdorff Proposition 2.17 (3) that Ψ is indeed a homeomorphism. ■

The following, otherwise broadly irrelevant lemma, justifies somewhat the idea that the join $X*Y$ is obtained by connecting each point in X to each point in Y via an interval.

Lemma 16.3. Given $P, Q \in \mathbb{R}^n$ we denote by $\overline{PQ} = \{x\cdot(1-t)+y\cdot t \,|\, t\in[0,1]\}$ the Euclidean segment determined by P and Q. Let X and Y be two compact subsets of $\mathbb{R}^n$ which have the property that for any x, x' and y, y' the segments $\overline{xy}$ and $\overline{x'y'}$ intersect at most in the endpoints. Then the map

$$\begin{array}{rcl} \Theta\colon X*Y=(X\times[0,1]\times Y)/\sim & \to & \bigcup\limits_{x\in X, y\in Y}\overline{xy} \\ [(x,t,y)] & \mapsto & x\cdot(1-t)+y\cdot t \end{array}$$

is a homeomorphism.



Proof. It follows almost immediately from Lemma 16.2 and our hypothesis that the map Θ is a homeomorphism. ■

We continue with another example of joins.

Example. We consider the join of the two intervals $X=[0,1]$ and $Y=[0,1]$. The figure below suggests that the join $X*Y=[0,1]*[0,1]$ should be homeomorphic to a 3-dimensional pyramid. In fact let us consider the map

$$\begin{array}{rcl} \overbrace{([0,1]\times[0,1]\times[0,1])/\sim}^{=[0,1]*[0,1]} & \to & \Delta=\{(t_1,t_2,t_3)\in[0,1]^3 \,|\, t_1+t_2+t_3\le 1\} \\ [(x,t,y)] & \mapsto & \frac{1}{2}\cdot\big(x\cdot t, y\cdot(1-t), t\big). \end{array}$$

It follows easily from Lemma 16.2 (2) that this map is a homeomorphism.

We record the next example of joins as a lemma.

[165] It follows from our hypothesis on f that the map f descends to a map on $X*Y=(X\times[0,1]\times Y)/\sim$.

Lemma 16.4. (Join of Spheres Lemma) Given any $m, n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} S^m * S^n & \to & S^{m+n+1} \\ [(x,t,y)] & \mapsto & \underbrace{\left(x \cdot \cos\left(\frac{\pi t}{2}\right), y \cdot \sin\left(\frac{\pi t}{2}\right)\right)}_{\in \mathbb{R}^{m+1} \times \mathbb{R}^{n+1} = \mathbb{R}^{m+n+2}} \end{array}$$

is a homeomorphism.

Proof. Using Lemma 16.2 (2) one can fairly easily verify that the given map is a homeomorphism. ■

Convention. Let $m, n \in \mathbb{N}_0$. We use the homeomorphism from the Join of Spheres Lemma 16.4 to add the identification $S^m * S^n = S^{m+n+1}$ to our long list of avatars of the spheres.

For completeness we state the following fairly straightforward lemma.

Lemma 16.5. Let X and Y be topological spaces. If X and Y are both Hausdorff, then the join $X * Y$ is also Hausdorff.

Proof. The proof will be given in Exercise 16.2. ■

Finally we consider the delicate question whether the join is associative.

Proposition 16.6. (Join Associativity Proposition) Let X, Y and Z be non-empty topological spaces that are compact and Hausdorff. Then there exists a homeomorphism

$$(X * Y) * Z \xrightarrow{\cong} X * (Y * Z).$$

Remark.

(1) The join $X * Y$, viewed as a set, can be equipped with another reasonable topology, namely the "initial topology", see [**BrownR2006**, Chapter 5.7]. By [**BrownR2006**, Corollary 5.7.2] these two topologies agree if X and Y are compact and Hausdorff. When dealing with joins it seems that it is safest to stick to the case that X and Y are compact and Hausdorff. For example the Join Associativity Proposition 16.6 says that in this context the join is associative. But this statement is not true for all topological spaces. We refer to [**CoheD1957**], [**BrownR2006**, Chapter 5.7] and [**FF2016**, Chapter 2.4] for details.[166][167]

(2) Let $X_1, \ldots, X_k$ be finitely many topological spaces that are non-empty compact and Hausdorff. It follows from Join Associativity Proposition 16.6 and the discussion on page 98 that we can unambiguously define the join $X_1 * \cdots * X_k$.

Proof. We define the join $X * Y * Z$ as follows: we consider

$$\{(r,x,s,y,t,z) \in [0,1] \times X \times [0,1] \times Y \times [0,1] \times Z \,|\, r+s+t = 1\}/\sim$$

where "$\sim$" is generated by the following relations:

- $(0,x,s,y,t,z) \sim (0,x',s,y,t,z)$,
- $(r,x,0,y,t,z) \sim (r,x,0,y',t,z)$,
- $(r,x,s,y,0,z) \sim (r,x,s,y,0,z')$.

[166] As we will see in Lemma 13.2, products and quotients of topological spaces do not mix well. It is easy to write down "continuous looking" maps that are not continuous.

[167] In light of Lemma 13.2 it is perhaps not too shocking that the join is not associative.

In the following we will use "$\sim$" with several means, we leave it to the reader to figure out any given moment what is meant by this symbol.

Claim. The map

$$\begin{array}{rccc} \Theta\colon & \overbrace{(((X\times[0,1]\times Y)/\!\sim)\times[0,1]\times Z)/\!\sim}^{=(X*Y)*Z} & \to & \overbrace{(X\times[0,1]\times Y*[0,1]\times Z)/\!\sim}^{=X*Y*Z} \\ & [([(x,s,y)],t,z)] & \mapsto & [((1-t)\cdot(1-s),x,(1-t)s,y,t,z)] \end{array}$$

is a homeomorphism.

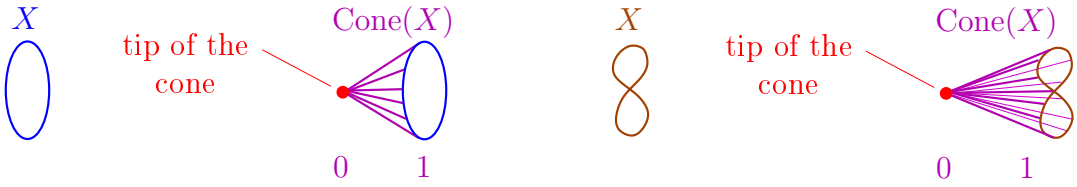
Proof. We consider the following diagram

$$\begin{array}{ccc} (X\times[0,1]\times Y)\times([0,1]\times Z) & \xrightarrow{\text{id}} & (X\times[0,1]\times Y)\times([0,1]\times Z) \\ \downarrow & & \downarrow \\ ((X\times[0,1]\times Y)\times([0,1]\times Z)/\!\sim & & \\ {\scriptstyle ([u],v)\mapsto[(u,v)]}\uparrow\varphi & \overset{\Phi}{\searrow} & \\ ((X\times[0,1]\times Y)/\!\sim\times([0,1]\times Z) & \xrightarrow{\Psi} & X*Y*Z. \\ \downarrow & \overset{\Theta}{\nearrow} & \\ (((X\times[0,1]\times Y)/\!\sim)\times[0,1]\times Z)/\!\sim & & \end{array}$$

We make the following clarifications and observations:

(1) All the maps are the obvious (projection) maps, except for φ which is the map given by Lemma 13.2. The diagram commutes basically by definition.
(2) It follows from the Twice Quotient Lemma 5.23 that Φ is continuous.
(3) Our hypothesis that Z is Hausdorff and compact implies by the Product Topology Properties Proposition 5.6 together with Lemma 2.41 that $[0,1]\times Z$ is regionally compact. Thus we obtain from the Product-Quotient Mixing Lemma 13.6 that φ is actually a homeomorphism.
(4) It follows from (2) and (3) that Ψ is continuous.
(5) It follows from (4) together with the Topological-Quotient Proposition 5.15 (1b) that Θ is continuous.
(6) It follows easily from the definitions that Θ is a bijection.
(7) By our hypotheses on X, Y and Z we obtain from the Product Topology Properties Proposition 5.6 and the Compact Image Lemma 2.13 that the domain $(X*Y)*Z$ of the map Θ is compact. Furthermore , by an argument as in Exercise 16.2 one sees that the target $X*Y*Z$ of the map Θ is Hausdorff.
(8) It follows from (5), (6) and (7) together with the Compact-Hausdorff Proposition 2.17 (3) that Θ is a homeomorphism. ⊞

Basically the same argument as in the above claim also shows that there exists a homeomorphism $X*(Y*Z)\to X*Y*Z$. In summary we see that there exists a homeomorphism $X*(Y*Z)\to(X*Y)*Z$. ■



16.2. **The cone and suspension of a topological space.** In this section we define the cone and suspension of a topological space. The cone of a topological space is a particularly easy construction.

Definition. Given a non-empty topological space X the cone on X is defined to be the topological space

$$\mathrm{Cone}(X) := (X \times [0,1])/(X \times \{0\}) = (X \times [0,1])/\sim \quad \text{where } (x,0) \sim (x',0) \text{ for all } x, x' \in X.$$

We refer to the point $X \times \{0\}$ as the tip of the cone $\mathrm{Cone}(X)$ or alternatively as the cone point. For completeness we define the cone of the empty topological space to be the one point topological space $\{*\}$. In this setting we refer to $*$ as the tip of the cone.

Remark. As a set $\mathrm{Cone}(X)$ consists of X, the tip of the cone, and for each $x \in x$ a segment from the tip of the cone to x.

Examples.

(1) Let $n \in \mathbb{N}_0$. It follows from the Topological-Quotient Proposition 5.15 (1b) that the map

$$\begin{array}{rcl} \mathrm{Cone}(S^n) & \to & \overline{B}^{n+1} \\ [(v,t)] & \mapsto & v \cdot t \end{array}$$

is continuous. One can easily verify that the map is a bijection. It follows immediately from the Quotient-Compact Connected Lemma 5.16 (1) and the Product Topology Properties Proposition 5.6 that $\mathrm{Cone}(S^n)$ is compact. Since $\overline{B}^{n+1}$ is Hausdorff we obtain from the Compact-Hausdorff Proposition 2.17 (3) that the given map is a homeomorphism. On a few occasions we will use this specific homeomorphism to make the identification $\mathrm{Cone}(S^n) = \overline{B}^{n+1}$.

(2) Let X be a subset of $\mathbb{R}^n$. We define its *physical cone* as

$$\widetilde{\mathrm{Cone}}(X) \;:=\; \text{union of all line segments from } \underbrace{(x,0)}_{\in \mathbb{R}^{n+1}} \text{ to } \underbrace{(0,1)}_{\in \mathbb{R}^{n+1}} \;\subset\; \mathbb{R}^{n+1}.$$

(a) We consider the map

$$\begin{array}{rcl} f_X\colon \mathrm{Cone}(X) & \to & \widetilde{\mathrm{Cone}}(X) \\ [(x,t)] & \mapsto & t \cdot (x,0) + (1-t) \cdot (0,1). \end{array}$$

In Exercise 16.3 we will see that this map is continuous. If X is a *compact* subset of $\mathbb{R}^n$, then it follows from the Compact-Hausdorff Proposition 2.17 that the map is a homeomorphism.

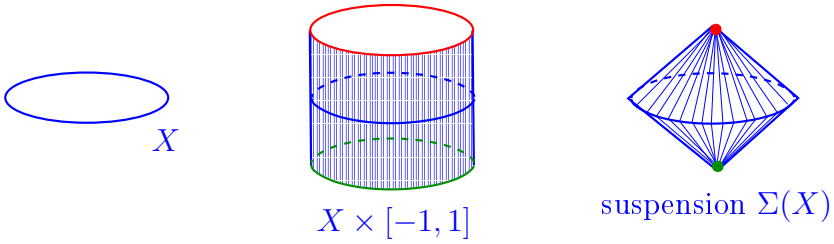
(b) After looking at the figure above and considering Examples (1) and (2a) one might walk away with the feeling that one has a pretty good understanding of the cone construction. But this optimism is potentially ill-founded. For example in Exercise 16.3 we see will see that for $X = (0,1) \subset \mathbb{R}$ the above map $f_X\colon \mathrm{Cone}(X) \to \widetilde{\mathrm{Cone}}(X)$ from (2a) is *not* a homeomorphism.

The definition of a cone does not seem to be particularly interesting, but we have one lemma whose proof is perhaps slightly more subtle than one might initially think.

Lemma 16.7. (Cone Contractibility Lemma) Let X be a topological space. The tip of the cone $\mathrm{Cone}(X)$ is a deformation retract of $\mathrm{Cone}(X)$.

Proof. The lemma follows easily from the Quotient Deformation Retract Proposition 15.9. For the reader's convenience we recall its statement: Let W be a topological space and let A be a subset of W. If A is a deformation retract of W, then the point A/A is a deformation retract of X/A. We return to our present setting. As we discussed on page 434, the map

$$\begin{array}{rcl} F\colon (X\times[0,1])\times[0,1] & \to & X\times[0,1] \\ ((x,s),t) & \mapsto & (x,s\cdot(1-t)) \end{array}$$



is a deformation retraction from $X\times[0,1]$ to $X\times\{0\}$. It follows from the Quotient Deformation Retract Proposition 15.9 that the tip of the cone, namely $(X\times\{0\})/(X\times\{0\})$ is a deformation retract of $\mathrm{Cone}(X)=(X\times[0,1])/(X\times\{0\})$. ■

We will state a few basic properties of the cone in the next lemma. But before we do so it is convenient to first introduce a close relative of the cone.

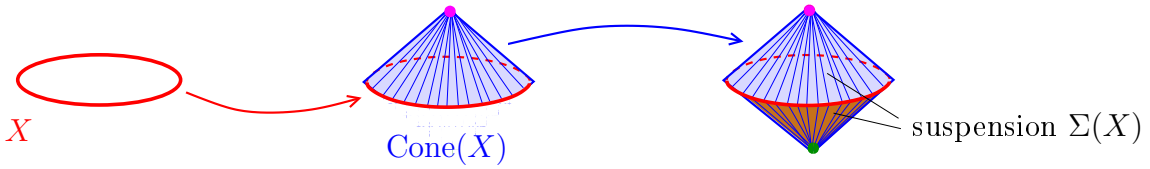
Definition. Let X be a non-empty topological space. We define the suspension of X to be the topological space

$$\Sigma(X) \;:=\; (X\times[-1,1])/\sim$$

where we identify all points in $X\times\{-1\}$ to a single point and we identify all points in $X\times\{1\}$ to a single point. Furthermore, we define the suspension of the empty topological space to be the topological space $S^0=\{\pm 1\}$, equipped with the discrete topology.

Before we give an example we state a basic lemma regarding cones and suspensions.

Lemma 16.8. (Cone-Suspension Basics Lemma) Let X be a topological space.



(0) Let X be a topological space.
  (a) The cone $\mathrm{Cone}(X)$ is naturally homeomorphic to the join $X*\{*\}$.
  (b) The suspension $\Sigma(X)$ is naturally homeomorphic to the join $X*S^0$.
(1) If X is compact, then $\mathrm{Cone}(X)$ and the suspension $\Sigma(X)$ are also compact.
(2) If X is Hausdorff, then $\mathrm{Cone}(X)$ and the suspension $\Sigma(X)$ are also Hausdorff.
(3) The maps

$$\begin{array}{rcl} X & \to & \mathrm{Cone}(X) \\ x & \mapsto & [(x,1)] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \mathrm{Cone}(X) & \to & \Sigma(X) \\ [(x,t)] & \mapsto & [(x,1-t)] \end{array}$$

are closed embeddings.

Sometimes we will use the embeddings in (3) to identify the domains with their images. For example we will use these maps to view X as a closed subset of $\mathrm{Cone}(X)$ and to view

$\mathrm{Cone}(X)$ as a closed subset of $\Sigma(X)$. In particular we can and will at times view X as a closed subset of $\Sigma(X)$.

Proof.

(0) We will prove this statement in Exercise 16.5.
(1) This statement follows from the Quotient-Compact Connected Lemma 5.16 (1) and the Product Topology Properties Proposition 5.6.
(2) In Exercise 16.7 we will show that if X is Hausdorff, then $\Sigma(X)$ is Hausdorff as well. The proof for $\mathrm{Cone}(X)$ is basically identical.
(3) We will prove this statement in Exercise 16.8. ■

Example. It is pretty clear from the figure on page 451 that the suspension of S^n is homeomorphic to S^{n+1}. In fact throughout the course we will use the following homeomorphism[168] to identify $\Sigma(S^n)$ with S^{n+1}:

$$\begin{array}{rcl} \Sigma(S^n) & \overset{\cong}{\to} & S^{n+1} \subset \mathbb{R}^{n+1} \times \mathbb{R} \\ [(P,t)] & \mapsto & \big(\underbrace{P \cdot \cos\left(\frac{\pi}{2}t\right)}_{\in \mathbb{R}^{n+1}}, \underbrace{\sin\left(\frac{\pi}{2}t\right)}_{\in \mathbb{R}}\big). \end{array}$$

Note that this homeomorphism sends the "North Pole" of $\Sigma(S^n)$ to the "North Pole" of S^{n+1}.

We conclude this discussion of suspensions with the fairly obvious notion of the suspension of a map.

Definition. Given a map $f\colon X \to Y$ between topological spaces we denote by

$$\begin{array}{rcl} \Sigma(f)\colon \Sigma(X) & \to & \Sigma(Y) \\ [(x,t)] & \mapsto & [(f(x),t)] \end{array}$$

the suspension of f.

Most of the statements of the following lemma will not come as a surprise.

Lemma 16.9. (Suspension Functor Lemma)

(1) If $f\colon X \to Y$ is a map between topological spaces, then $\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)$ is also continuous.
(2) If $f\colon X \to Y$ and $g\colon Y \to Z$ are maps between topological spaces, then the maps $\Sigma(g \circ f)$ and $\Sigma(g) \circ \Sigma(f)$ from $\Sigma(X)$ to $\Sigma(Z)$ agree.
(3) The maps

$$\begin{array}{rcl} X & \mapsto & \Sigma(X) \\ (f\colon X \to Y) & \mapsto & (\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)) \end{array}$$

[168] Using the Compact-Hausdorff Proposition 2.17 (3) and the Cone-Suspension Basics Lemma 16.8 (1) one easily verifies that this map is indeed a homeomorphism.

define a covariant functor from the category of topological spaces to the category of topological spaces. We refer to this functor as the suspension functor.

(4) Let $f, g\colon X \to Y$ be two maps between topological spaces. If f and g are homotopic rel a (possibly empty) subset A, then $\Sigma(f)$ and $\Sigma(g)$ are homotopic rel $\Sigma(A)$.

(5) If $f\colon X \to Y$ is a homotopy equivalence of topological spaces, then the suspension $\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)$ is also a homotopy equivalence.

Remark. We consider the topological space $X = [-1, 1]$, the subset $A = (-1, 1)$ and the inclusion map $i\colon A \to X$. In Exercise 16.14 we will prove the slightly scary statement that the induced map $\Sigma(i)\colon \Sigma(A) \to \Sigma(X)$ is *not* an embedding.

Proof.

(1) We consider the following commutative diagram

$$\begin{array}{ccc} X \times [-1,1] & \xrightarrow{f \times \mathrm{id}_{[-1,1]}} & Y \times [-1,1] \\ \downarrow & \nearrow & \downarrow \\ \Sigma(X) & \xrightarrow[\Sigma(f)]{} & \Sigma(Y). \end{array}$$

By the Product Topology-Basics Lemma 5.4 (3) we know that the top horizontal map is continuous. By the Topological-Quotient Proposition 5.15 (1a) the left and right vertical maps are continuous. It follows that the diagonal map is continuous. Finally we obtain from the Topological-Quotient Proposition 5.15 (1b) that the bottom horizontal map is continuous.

(2) This statement follows immediately from the definitions.

(3) This statement follows immediately from (1) and (2) and the definitions.

(4) Clearly it suffices to prove the following claim.

Claim. If $F\colon X \times [0, 1] \to Y$ is a map, then the map

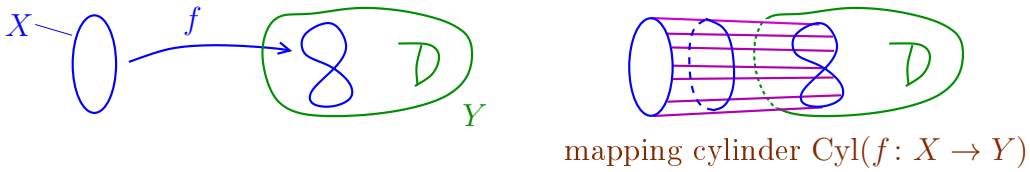
$$\begin{array}{rccc} G\colon & (\overbrace{(X \times [-1,1])/\!\sim}^{=\Sigma(X)}) \times [0,1] & \to & \overbrace{(Y \times [-1,1])/\!\sim}^{=\Sigma(Y)} \\ & ([(x,t)], s) & \mapsto & [(F(x,s),t)] \end{array}$$

is continuous.

Proof. Fortunately the claim follows immediately from the Homotopy Quotient Theorem 14.7. ⊞

(5) It suffices to show that if $f\colon X \to Y$ and $g\colon Y \to X$ are two maps such that $g \circ f \simeq \mathrm{id}_X$, then $\Sigma(g) \circ \Sigma(f) \simeq \mathrm{id}_{\Sigma(X)}$. Then we see that

$$\begin{array}{ccccccc} \Sigma(g) \circ \Sigma(f) & \underset{\text{by (3)}}{=} & \Sigma(g \circ f) & \underset{\text{by (4)}}{\simeq} & \Sigma(\mathrm{id}_X) & \underset{\text{by (3)}}{=} & \mathrm{id}_{\Sigma(X)}\,. \end{array}$$



■

16.3. **Mapping cylinder and mapping cone.** In this section we associate to a map $f\colon X \to Y$ between two topological spaces two different topological spaces. The main interest in these topological spaces is that these topological spaces encode some of the information contained in the actual map. On numerous occasions this will allow us to translate questions about maps between topological spaces into questions about topological spaces.

We start out with the definition of a mapping cylinder.

Definition. Let $f\colon X \to Y$ be a map between topological spaces. We define the corresponding mapping cylinder to be the topological space

$$\mathrm{Cyl}(f) := \mathrm{Cyl}(f\colon X \to Y) := ((X \times [0,1]) \sqcup Y)/\sim \text{ where } (x,1) \sim f(x) \text{ for all } x \in X.$$

mapping cylinder $\mathrm{Cyl}(f\colon X \to Y)$

Remark. In many, arguably most, textbooks on algebraic topology the mapping cylinder is defined by identifying $(x,0)$ with $f(x)$ instead of identifying $(x,1)$ with $f(x)$. The definitions are evidently equivalent, but as the author knows from experience, the usage of two different definitions can cause some confusion. The totally non-mathematical advantage of our definition is that it leads to "horizontal" pictures which take up less space.

Example. If X is a topological space and if $f\colon X \to \{y\}$ is the constant map to the topological space consisting of a single element y, then the mapping cylinder $\mathrm{Cyl}(f)$ is homeomorphic to $\mathrm{Cone}(X)$. This statement is almost, but not completely[169] evident. We invite the general-topology-aficionado to fill in the details.

Definition. Let $f\colon X \to Y$ be a map between two topological spaces. We refer to the maps

$$\begin{array}{ccc} X & \to & \mathrm{Cyl}(f\colon X \to Y) \\ x & \mapsto & [(x,0)] \end{array} \quad \text{and} \quad \begin{array}{ccc} Y & \to & \mathrm{Cyl}(f\colon X \to Y) \\ y & \mapsto & [y] \end{array}$$

as the natural inclusions. Sometimes we use these inclusions to identify X and Y with the corresponding subsets of the mapping cylinder.

The following lemma says that the natural inclusions are closed embeddings. This means that we can legitimately identify X and Y with their images in the mapping cylinder $\mathrm{Cyl}(f\colon X \to Y)$. On many occasions we will implicitly use the lemma without actually referring to it.

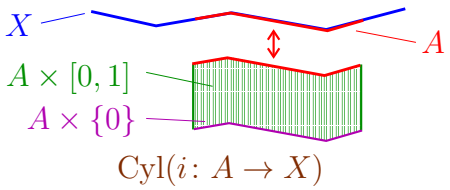
Lemma 16.10. (Mapping Cylinder Basics Lemma) Let $f\colon X \to Y$ be a map between topological spaces.

(1) If X and Y are compact, then $\mathrm{Cyl}(f)$ is also compact.
(2) If X and Y are Hausdorff, then $\mathrm{Cyl}(f)$ is also Hausdorff.
(3) The natural inclusions $X \to \mathrm{Cyl}(f)$ and $Y \to \mathrm{Cyl}(f)$ are embeddings, in particular they are continuous.
(4) The images of the natural inclusions $X \to \mathrm{Cyl}(f)$ and $Y \to \mathrm{Cyl}(f)$ are closed subsets.

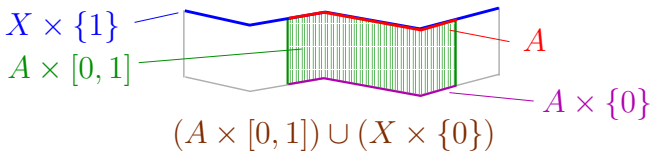
Proof.

(1) We suppose that X and Y are compact. It follows from the Product Topology Properties Proposition 5.6 (2) and the Pushout Properties Proposition 5.35 (1) that $\mathrm{Cyl}(f)$ is also compact.

[169] Note that the statement is *not* true for the empty topological space. This observation shows that the statement requires at least a little bit of thought.



(2) We suppose that X and Y are Hausdorff. We will prove Exercise 16.9 that in this case the mapping cylinder is Hausdorff.
(3) We will provide the proof of the third statement in Exercise 16.10.
(4) The preimage of $i(X)$ under the projection $(X \times [0,1]) \sqcup Y \to \mathrm{Cyl}(f)$ is $X \times \{0\}$. It follows from Lemma 5.12 and the Product-of-Subsets Lemma 5.5 that this is a closed subset. Therefore it follows from the Topological-Quotient Proposition 5.15 (0b) that $i(X)$ is indeed a closed subset of $\mathrm{Cyl}(f)$. The proof that the image of the natural inclusion $Y \to \mathrm{Cyl}(f)$ is closed is almost the same. ■



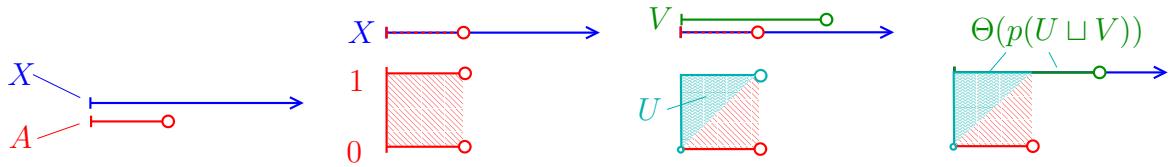
We continue with a (non-) example. We will not really make use of the following lemma, but it should warn the reader that the topology on a mapping cylinder is not necessarily what one might think it is.

Lemma 16.11. Let X be a topological space and let $A \subset X$ be a subset. We denote by $i\colon A \to X$ the inclusion map and we consider the map

$$\begin{array}{rcl} \Theta\colon \mathrm{Cyl}(i) = ((A \times [0,1]) \sqcup X)/(a,1) \sim i(a) & \to & \overbrace{(A \times [0,1]) \cup (X \times \{1\})}^{\text{equipped with the subspace topology coming from the product } X \times [0,1]} \\ [P] & \mapsto & \begin{cases} P, & \text{if } P \in A \times [0,1], \\ (P,1), & \text{if } P \in X. \end{cases} \end{array}$$

The following three statements hold:
(1) The map Θ is continuous and it is a bijection.
(2) If A is a closed subset of X, then Θ is a homeomorphism.
(3) There exist situations, e.g. $X = [0,\infty)$ and $A = [0,1)$, in which Θ is *not* a homeomorphism.

Proof.



(1) It follows easily from the Topological-Quotient Proposition 5.15 (1b) that the given map Θ is continuous. Furthermore it is basically clear that Θ is a bijection.
(2) Suppose that A is a closed subset of X. Note that $A \times \{1\}$ is a closed subset of $A \times [0,1]$. It follows basically from Lemma 5.36 that Θ is a homeomorphism.
(3) We consider the case $X = [0,\infty)$ and $A = [0,1)$. We denote by

$$p\colon (A \times [0,1)) \sqcup X \ \to \ \mathrm{Cyl}(i) = ((A \times [0,1)) \sqcup X)/\sim$$

the projection . We consider the open set $U := \{(x,t) \in [0,1) \times [0,1] \,|\, x > t\}$ of $A \times [0,1)$. Furthermore we consider the open subset $V := [0,2)$ of $X = [0,\infty)$. Note that $p^{-1}(p(U \sqcup V)) = U \sqcup V$. Thus it follows immediately from the definition of the quotient topology on $\mathrm{Cyl}(i) = ((A \times [0,1)) \sqcup X)/\sim$ that $p(U \sqcup V)$ is an open subset of $\mathrm{Cyl}(i)$. On the other hand we have

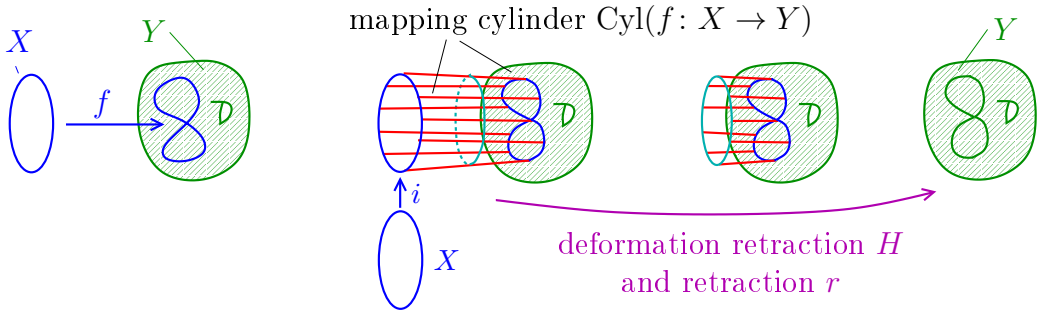
$$\Theta(p(U \sqcup V)) \ = \ U \cup \{(x,1) \,|\, x \in V\},$$

but considering the point $(1,1)$ one can easily verify that this is *not* an open subset of $(A \times [0,1]) \cup (X \times \{1\})$. ■

The following lemma summarizes some basic properties of the mapping cylinder.

Lemma 16.12. (Mapping Cylinder Basics Lemma II) Let $f\colon X \to Y$ be a map between topological spaces.

(1) The subspace Y is a deformation retract of $\mathrm{Cyl}(f\colon X \to Y)$, in fact an explicit deformation retraction is given by the following map



$$H\colon \mathrm{Cyl}(f\colon X \to Y) \times [0,1] \;\to\; \mathrm{Cyl}(f\colon X \to Y)$$
$$(P,t) \;\mapsto\; \begin{cases} P, & \text{if } P \in Y, \\ [(Q, s\cdot(1-t)+t)], & \text{if } P = [(Q,s)], \text{ where } Q \in X \text{ and } s \in [0,1]. \end{cases}$$

(2) We denote by $r = H_1$ the retraction $\mathrm{Cyl}(f\colon X \to Y) \to Y$ given by (1). If we denote by $i\colon X \to \mathrm{Cyl}(f)$ and $j\colon Y \to \mathrm{Cyl}(f)$ the natural inclusions, then the following statements hold:
   (a) The map $j\colon Y \to \mathrm{Cyl}(f\colon X \to Y)$ and $r\colon \mathrm{Cyl}(f\colon X \to Y) \to Y$ are homotopy equivalences.
   (b) The map $i\colon X \to \mathrm{Cyl}(f\colon X \to Y)$ is a homotopy equivalence if and only if the map $f\colon X \to Y$ is a homotopy equivalence.

Remark.

(1) On page 454 we saw that the mapping cylinder of a constant map $f\colon X \to \{y\}$ is homeomorphic to the cone on X. Thus we see that the Mapping Cylinder Basics Lemma 16.12 (1) can be viewed as a generalization of the Cone Contractibility Lemma 16.7.

(2) In Corollary 17.16 we will strengthen the statement of the Mapping Cylinder Basics Lemma 16.12 (2b), namely we will show that if $f\colon X \to Y$ is a homotopy equivalence, then $i(X)$ is in fact a deformation retract of $\mathrm{Cyl}(f\colon X \to Y)$.

Proof.

(1) We need to show that the map H is continuous. First note that the two maps

$$\begin{array}{rcl}(X\times[0,1])\times[0,1] & \to & \mathrm{Cyl}(f)\\ (Q,t) & \mapsto & [(Q,s\cdot(1-t)+t)]\end{array} \quad \text{and} \quad \begin{array}{rcl}Y\times[0,1] & \to & \mathrm{Cyl}(f)\\ (P,t) & \mapsto & P\end{array}$$

are continuous[170]. But this implies, by the somewhat delicate Homotopy Pushout Lemma 14.9, that

$$H\colon ((X\times[0,1])\cup_{(x,1)\mapsto f(x)} Y)\times[0,1] \to \mathrm{Cyl}(f)$$

itself is continuous. Once continuity is out of the way it is basically clear that H is a deformation retraction. Therefore it follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 that the inclusion $Y \to \mathrm{Cyl}(f\colon X\to Y)$ is a homotopy equivalence.

(2) (a) It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 that j and r are homotopy equivalences.

(b) We consider the map

$$\begin{array}{rcl}G\colon X\times[0,1] & \to & \mathrm{Cyl}(f\colon X\to Y)\\ (x,t) & \mapsto & [(x,t)].\end{array}$$

This map is continuous by the Topological-Quotient Proposition 5.15 (1b). We make the following observations:

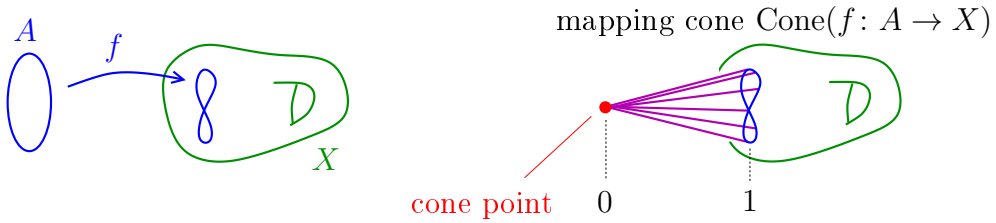
$$\begin{array}{ccccc}i=G_0\colon X\to\mathrm{Cyl}(f) \text{ is a homotopy equivalence} & \Leftrightarrow & i=G_1\colon X\to\mathrm{Cyl}(f) \text{ is a homotopy equivalence} & \Leftrightarrow & \overbrace{r\circ G_1}^{=f}\colon X\to Y \text{ is a homotopy equivalence}\\ \uparrow & & \uparrow & & \uparrow\\ \text{by the Homotopy-Equivalence Basics Lemma 15.1 (3), since } G_0 \text{ and } G_1 \text{ are homotopic} & & & & \text{by the Homotopy-Equivalence Basics Lemma 15.1 (1), since by (2a) we know that } r \text{ is a homotopy equivalence}\end{array}$$

We have thus shown that i is a homotopy equivalence if and only if $f = r\circ G_1$ is a homotopy equivalence. ∎

In the above discussion we associated to a map $f\colon X\to Y$ between topological spaces a new topological space, namely the mapping cylinder $\mathrm{Cyl}(f\colon X\to Y)$. But we see in the Mapping Cylinder Basics Lemma 16.12 (1) that the mapping cylinder, as a topological space, is in many ways the same as Y. Therefore we move on to the definition of the mapping cone which is a much more interesting construction.

Definition. Given a map $f\colon A\to X$ between topological spaces the corresponding mapping cone is defined as

$$\mathrm{Cone}(f\colon A\to X) \;:=\; (\mathrm{Cone}(A)\sqcup X)/\!\sim \text{ where } [(a,1)]\sim f(a) \text{ for all } a\in A.$$



We refer to the point $[A\times\{0\}]$ as the cone point of the mapping cone.

Remark. Let $f\colon A\to X$ be a map between topological spaces. If A is non-empty, then it follows almost immediately from the definitions that

$$\mathrm{Cone}(f\colon A\to X) \;=\; \mathrm{Cyl}(f\colon A\to X)/(A\times\{0\}).$$

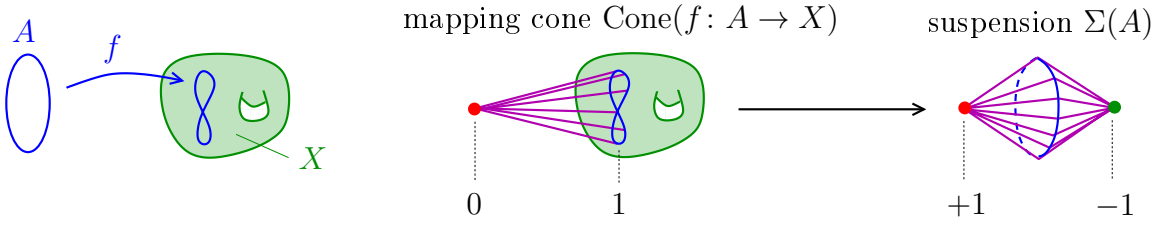
The following lemma summarizes some properties of mapping cones.

[170] For once this is basically obvious.

Lemma 16.13. (Mapping Cone Basics Lemma) Let $f\colon A \to X$ be a map between topological spaces.

(1) We denote by $i\colon A \to \mathrm{Cone}(A)$ the map that is given by $a \mapsto [(a,1)]$. The mapping cone $\mathrm{Cone}(f\colon A \to X)$ is the same[171] as the pushout of the maps $i\colon A \to \mathrm{Cone}(A)$ and $f\colon A \to X$, i.e. we have the pushout diagram

$$\begin{array}{ccc} A & \xrightarrow{\quad i \quad} & \mathrm{Cone}(A) \\ \downarrow{\scriptstyle f} & & \lrcorner \downarrow \\ X & \longrightarrow & \mathrm{Cone}(f\colon A \to X). \end{array}$$



(2) The natural inclusion
$$\begin{array}{ccc} X & \to & \mathrm{Cone}(f\colon A \to X) \\ x & \mapsto & [x] \end{array}$$
is a closed embedding. Often we will use these natural inclusions to identify X with its image in $\mathrm{Cone}(f\colon A \to X)$.

(3) If the map $f\colon A \to X$ is a (closed or open) embedding, then the natural map $\mathrm{Cone}(A) \to \mathrm{Cone}(f\colon A \to X)$ is a (closed or open) embedding.

(4) If A is non-empty, then the map
$$\begin{array}{ccc} \mathrm{Cone}(f\colon A \to X)/X & \to & \Sigma(A) \\ [(a,t)] & \mapsto & [(a,1-2t)] \end{array}$$
is a natural homeomorphism.

(5) The cone point $*$ defines a closed subset of $\mathrm{Cone}(f\colon A \to X)$.

(6) There exists a natural deformation retraction from $\mathrm{Cone}(f\colon A \to X) \setminus \{*\}$ to X. In particular the subset X is a deformation retract of the complement of the cone point.

Sketch of proof.

(1) This statement follows basically immediately from the definitions.

[171] At this point one can now argue whether they are the same on the nose or whether the obvious map is just a natural homeomorphism.

(2) This statement follows immediately from (1) together with the Topological Pushout-Maps Lemma 5.34 (3) and (4).
(3) This statement also follows immediately from (1) together with the Topological Pushout-Maps Lemma 5.34 (3) and (4).
(4) It is clear that the given map is a bijection. One can easily verify, without any extra wizardry, that the given map is indeed a homeomorphism.
(5) This statement follows quite easily from the definition of the topologies involved.
(6) The proof of this statement is basically identical to the proof of the Mapping Cylinder Basics Lemma 16.12 (1). ■

So what have we done so far? We have associated to a map $f\colon X \to Y$ between topological spaces the topological space $\mathrm{Cone}(f\colon X \to Y)$. This construction will allow us to turn questions about maps between topological spaces into questions about topological spaces. As always in algebraic topology, not only do we want a map

$$\text{set of maps between topological spaces} \;\to\; \text{set of topological spaces},$$

but we really want a functor. It is clear what the category should be on the right. It is a little less clear what the category should be on the left. Here it is.

Definition. We refer to the category *MapTop* with

$$\begin{aligned} \mathrm{Ob}(\mathit{MapTop}) &:= \text{all maps between topological spaces,} \\ \mathrm{Mor}(f\colon X \to Y, \widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) &:= \begin{array}{c}\text{all pairs of maps} \\ (\varphi\colon X \to \widetilde{X}, \psi\colon Y \to \widetilde{Y}) \\ \text{such that the diagram}\end{array} \quad \begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{Y} \end{array} \quad \text{commutes} \end{aligned}$$

with the (hopefully) obvious composition of morphisms as the category of maps between topological spaces.

The following lemma says that we can view "taking the mapping cone" and "taking the mapping cylinder" as covariant functors.

Lemma 16.14. (Mapping Cone Functor Lemma)

(1) The maps

$$(f\colon X \to Y) \mapsto \mathrm{Cyl}(f\colon X \to Y)$$

and

$$(\varphi\colon X \to \widetilde{X}, \psi\colon Y \to \widetilde{Y}) \mapsto \left(\begin{array}{l} \mathrm{Cyl}(f\colon X \to Y) \to \mathrm{Cyl}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) \\ \qquad [P] \mapsto \begin{cases} [(\varphi(x), t)], & \text{if } P = (x,t) \text{ with,} \\ & \quad x \in X,\, t \in [0,1] \\ [\psi(y)], & \text{if } P = y \text{ with } y \in Y \end{cases} \end{array} \right).$$

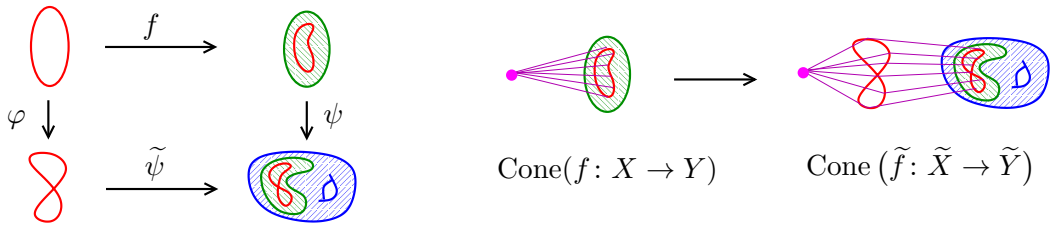
define a covariant functor from the category *MapTop* of maps between topological spaces to the category *Top* of topological spaces.
(2) If, in the setting of (1), the maps φ and ψ are embeddings, then the corresponding map $\mathrm{Cyl}(f\colon X \to Y) \to \mathrm{Cyl}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y})$ is also an embedding.
(3) The analogues of (1) and (2), with obvious modifications, hold if we replace mapping cylinders by mapping cones.

(4) Given a morphism[172]

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{Y} \end{array}$$

the map from (3) for mapping cones fits into the following commutative diagram:

$$\begin{array}{ccccc} Y & \hookrightarrow & \mathrm{Cone}(f\colon X \to Y) & \longrightarrow & \Sigma(X) \\ {\scriptstyle\psi}\downarrow & & \downarrow & & \downarrow{\scriptstyle\Sigma(\varphi)} \\ \widetilde{Y} & \hookrightarrow & \mathrm{Cone}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) & \longrightarrow & \Sigma(\widetilde{X}) \end{array}$$



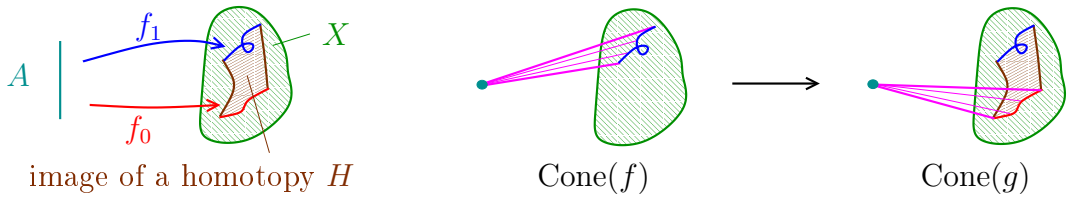
where the horizontal maps to the left are the inclusion maps that we introduced in the Mapping Cone Basics Lemma 16.13 (2) and where the horizontal maps to the right are given by the projection and the homeomorphism from the Mapping Cone Basics Lemma 16.13 (4).

Proof. One needs to convince oneself that the map between the mapping cylinders and the mapping cones is in fact continuous. For the mapping cylinders that is an immediate consequence of the Topological Pushout Proposition 5.33 (1b). For the mapping cones first note that the same argument as in the proof of the Suspension Functor Lemma 16.9 (1) shows that the map

$$\begin{array}{rcl} \mathrm{Cone}(X) & \to & \mathrm{Cone}(\widetilde{X}) \\ [(x,t)] & \mapsto & [(\varphi(x),t)] \end{array}$$

is continuous. The continuity of the map between the mapping cones now follows again from the Topological Pushout Proposition 5.33 (1b).

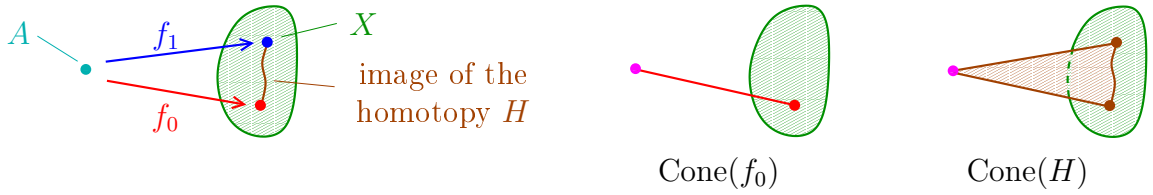
The second statement will be proved in Exercise 16.13 (3). Finally Statement (4) of the lemma follows basically from the definitions. ■



The following lemma shows in particular that homotopic maps give rise to homotopy equivalent mapping cones. In particular at times this lemma allows us to translate the question whether two maps are homotopic to the question whether two topological spaces are homotopy equivalent.

Proposition 16.15. (Mapping Cone Homotopy Equivalent Proposition) Let $f_0, f_1\colon A \to X$ be maps between topological spaces. If f_0, f_1 are homotopic, then there exists a homotopy equivalence $\mathrm{Cone}(f_0) \to \mathrm{Cone}(f_1)$ rel the union of X and the cone point.

It is not that difficult to write down explicit maps between the cones and to write down explicit homotopies. But we prefer to go take a more conceptual approach. Namely, instead



[172] In fancy speak this commutative diagram says that the inclusion maps into the mapping cone and the projection from the mapping cone to the suspension are natural transformations between suitable functors.

of proving the Mapping Cone Homotopy Equivalent Proposition 16.15 directly we will prove the following more technical lemma.

Lemma 16.16. (Mapping Cone Inclusion Lemma) Let $f_0, f_1 \colon A \to X$ be maps between topological spaces. Furthermore let $H \colon A \times [0,1] \to X$ be a homotopy between f_0 and f_1. Let $j \in \{0,1\}$. We denote by $i_j \colon A \to A \times \{j\}$ the obvious inclusion map.

(1) The inclusion map i_j induces by the Mapping Cone Functor Lemma 16.14 (3) a map $\mathrm{Cone}(f_j) \to \mathrm{Cone}(H)$. This map is an embedding.
(2) If we use the map from (1) to view $\mathrm{Cone}(f_j)$ as a subset of $\mathrm{Cone}(H)$, then it is a deformation retract of $\mathrm{Cone}(H)$.

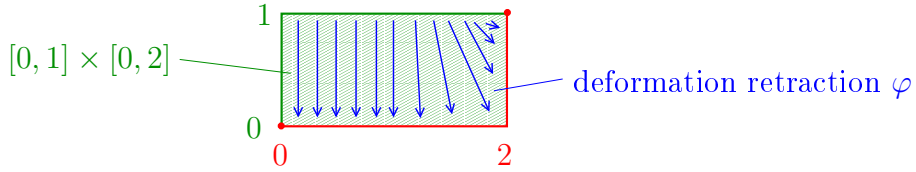
Proof of Proposition 16.15 assuming Lemma 16.16. Let H be a homotopy between f_0 and f_1. By the Mapping Cone Inclusion Lemma 16.16 we can view $\mathrm{Cone}(f_0)$ and $\mathrm{Cone}(f_1)$ as deformation retracts of $\mathrm{Cone}(H)$. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-Equivalence Basics Lemma 15.1 that $\mathrm{Cone}(f_0)$ and $\mathrm{Cone}(f_1)$ are homotopy equivalent. A quick inspection of the maps involved shows that the two cones are homotopy equivalent rel the union of X and the cone point. ■

Proof of the Mapping Cone Inclusion Lemma 16.16. Let $f_0, f_1 \colon A \to X$ be maps between topological spaces. Furthermore let $H \colon A \times [0,1] \to X$ be a homotopy between f_0 and f_1. For notational convenience we only deal with the case $j = 0$. We denote by $i \colon A \to A \times \{0\}$ the obvious inclusion map. We get a commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{f_0} & X \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle =} \\ A \times [0,1] & \xrightarrow{H} & X. \end{array}$$

Thus we get from the Mapping Cone Functor Lemma 16.14 (3) a map $\mathrm{Cone}(f_0) \to \mathrm{Cone}(H)$. It follows almost immediately from the Mapping Cone Functor Lemma 16.14 (3) that this map is an embedding.

Since this proof suffers from an abundance of intervals playing different roles we rescale two of the intervals:



(1) We use the interval $[0,1]$ for the homotopy H.

(2) We use the interval $[0,2]$ for the definition of the mapping cone.
(3) We use the interval $[0,3]$ for the definition of the desired deformation retraction.

With this convention out of the way we pick a deformation retraction

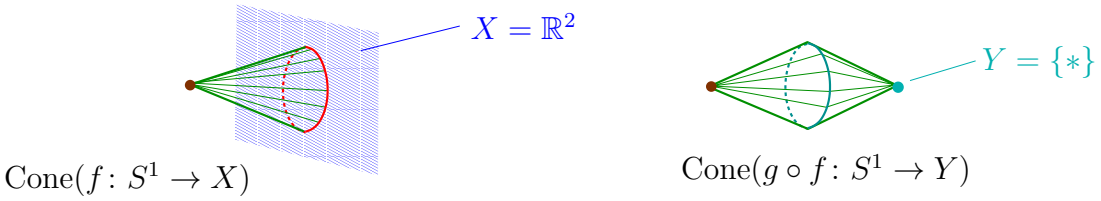
$$\varphi\colon ([0,1]\times[0,2])\times[0,3] \;\to\; [0,1]\times[0,2]$$

rel $([0,2]\times\{0\})\cup(\{2\}\times[0,1])$ such that $\varphi(r,s,t) = (r, \frac{1}{3}st)$ whenever $r \in [0,\frac{1}{2}]$. It is straightforward to see that such a deformation retraction exists. We refer to the figure below for an illustration.

Now we consider the map

$$G\colon \overbrace{(((A\times[0,1]\times[0,2])\sqcup X)/\!\sim)}^{=\mathrm{Cone}(H\colon A\times[0,1]\to X)}\times[0,3] \;\to\; \mathrm{Cone}(H)$$
$$([P],z) \;\mapsto\; \begin{cases} [(a,\varphi(x,y,z))], & \text{if } P=(a,x,y),\\ P, & \text{if } P\in X.\end{cases}$$

Using the Topological-Quotient Proposition 5.15 (1a) and the Homotopy Pushout Lemma 14.9 one can easily show that this map G is continuous. It is straightforward to verify that this map has the desired properties. ■



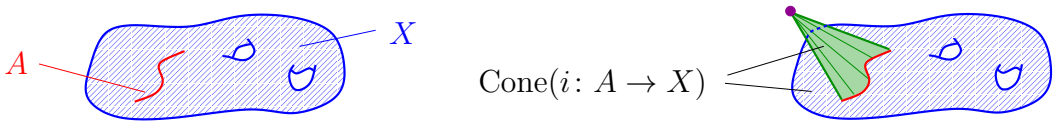
For completeness' sake we also state the following corollary.

Corollary 16.17. Let $f\colon A\to X$ be a map between topological spaces. Furthermore let $g\colon X\to Y$ be a homotopy equivalence. The map

$$\mathrm{Cyl}(f\colon A\to X) \;\to\; \mathrm{Cyl}(g\circ f\colon A\to Y)$$
$$[P] \;\mapsto\; \begin{cases} [(a,t)], & \text{if } P=(a,t)\in A\times[0,1],\\ [g(P)], & \text{if } P\in X\end{cases}$$

is a homotopy equivalence rel $A\times\{0\}$. The same way one sees that the mapping cones of f and $g\circ f$ are homotopy equivalent.

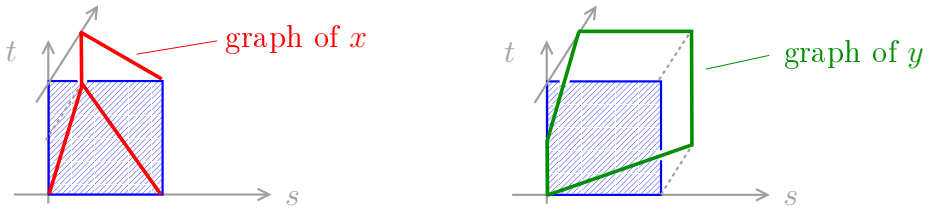
Example. Let $f\colon S^1\to\mathbb{R}^2$ be the inclusion and let $g\colon\mathbb{R}^2\to\{*\}$ be the retraction to the origin. In the figure below we show the corresponding mapping cones, which we now know are homotopy equivalent by Corollary 16.17.



Proof. The corollary is a straightforward consequence of the Mapping Cone Homotopy Equivalent Proposition 16.15. We leave it to the reader to fill in the details. ■

We conclude our discussion of mapping cones with the following proposition.

Proposition 16.18. Let X be a topological space and let A be a subset of X. We denote by $i\colon A \to X$ the inclusion map. We use the Mapping Cone Basics Lemma 16.13 (2) to view X as a subset of $\mathrm{Cone}(i\colon A \to X)$.



(1) If A is contractible, then given any $a_0 \in A$ there exists a deformation retraction G from $\mathrm{Cone}(i\colon A \to X)$ to X such that $G_1(\text{cone point } [A \times \{0\}]) = a_0$.
(2) If $a_0 \in A$ is a deformation retract of A, then there exists a deformation retraction G from $\mathrm{Cone}(i\colon A \to X)$ to X such that for any $t \in [0,1]$ we have $G_1([(a_0,t)]) = a_0$.

Proof. We first prove Statement (1). Thus let $a_0 \in A$. Since A is contractible it follows from the Point Deformation Retract Lemma 15.6 (2) that there exists a map $r\colon A \times [0,1] \to A$ such that $r_0 = \mathrm{id}$ and such that $r_1(a) = a_0$ for all $a \in A$. We pick continuous functions $x, y\colon [0,1] \times [0,1] \to [0,1]$ with the following properties:

(a) For any $t \in [0,1]$ we have $x(0,t) = 1$ or $y(0,t) = 0$.
(b) We have $x(s,0) = 0$ and $y(s,0) = s$ for all $s \in [0,1]$.
(c) We have $y(s,1) = 1$ for all $s \in [0,1]$.
(d) We have $x(1,t) = 0$ and $y(1,t) = 1$ for all $t \in [0,1]$.

We sketch graphs of such functions x and y in the figure below. Now we consider the map

$$F\colon \overbrace{((A \times [0,1])/(A \times \{0\}))}^{=\mathrm{Cone}(A)} \times [0,1] \to \overbrace{(A \times [0,1])/(A \times \{0\})}^{=\mathrm{Cone}(A)}$$
$$([(a,s)],t) \mapsto [(r(a,x(s,t)),y(s,t))].$$

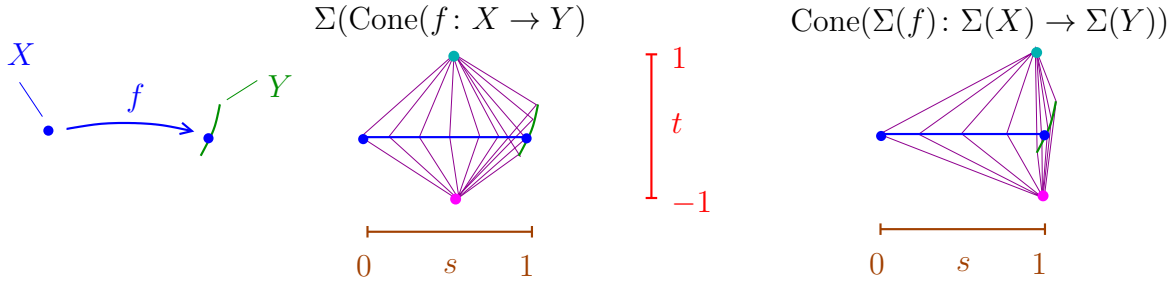
We make the following observations:

(0) Since x and y are continuous and since $[0,1]$ is regionally compact we obtain from the Topological-Quotient Proposition 5.15 (1b) and the Product-Quotient Mixing Lemma 13.6 that F is continuous.
(1) It follows from (a) that F is actually well-defined.
(2) It follows from (b) that $F_0 = \mathrm{id}$.
(3) It follows from (c) that F_1 takes values in $A \times \{1\}$.
(4) It follows from (d) that F is a homotopy rel $A \times \{1\}$.

In summary this shows that F is a deformation retraction from $\mathrm{Cone}(A)$ to $A \times \{1\}$. Now we consider the map

$$\begin{array}{rcl} G\colon \overbrace{(\mathrm{Cone}(A) \cup_{(a,1)=a} X)}^{=\mathrm{Cone}(i\colon A \to X)} \times [0,1] & \to & \mathrm{Cone}(i\colon A \to X) \\ ([P],t) & \mapsto & \begin{cases} [F(P,t)] & \text{if } P \in \mathrm{Cone}(A), \\ [P], & \text{if } P \in X. \end{cases} \end{array}$$

It follows from the Homotopy Pushout Lemma 14.9 that this map is continuous. Clearly G is a deformation retract from $\mathrm{Cone}(i\colon A \to X)$ to X. By construction it sends the cone point to a_0.



It remains to prove Statement (2). If we start out with a deformation retraction r from A to a_0, then the above homotopy F has the desired property. ■

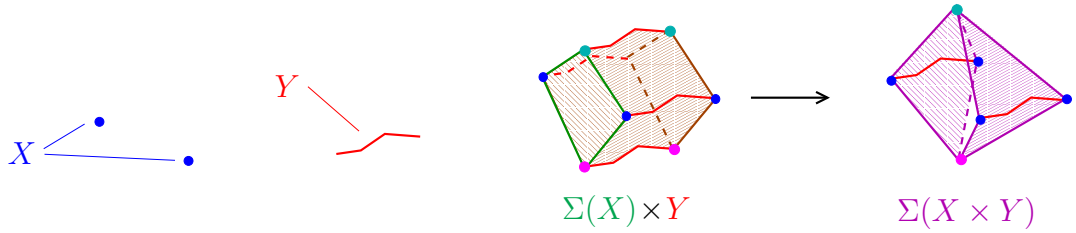
16.4. **The mapping cone of a suspension.** In this section we show that under favorable circumstances the operation of taking a mapping cone (or mapping cylinder) commutes with the operation of taking the suspension of a map. This technical proposition will play a useful role later on. The proposition is also a good way to test whether we really understand the various topologies involved in the definition of mapping cones, mapping cylinders and suspensions.

Proposition 16.19. (Mapping Cone-Suspension Proposition) If $f\colon X \to Y$ is a map between topological spaces, then the map[173]

$$\begin{array}{rcl} \Phi\colon \Sigma(\mathrm{Cone}(f\colon X \to Y)) & \to & \mathrm{Cone}(\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)) \\ P & \mapsto & \begin{cases} [([[(x,t)],s)], & \text{if } P = [([[(x,s)],t)] \text{ with } x \in X,\ t \in [-1,1] \\ & \quad \text{and with } s \in [0,1], \\ [([y],t)], & \text{if } P = [([y],t)] \text{ with } y \in Y \text{ and } t \in [-1,1]. \end{cases} \end{array}$$

is a homeomorphism.

In the proof of the Mapping Cone-Suspension Proposition 16.19 we will need the following lemma which is quite similar to Proposition 13.8.



[173] It takes a major effort to disentangle the notation. We write $[-]$ to indicate the equivalence class corresponding to a suspension and we write $[-]$ to indicate the equivalence class corresponding to the equivalence relation used to define mapping cones.

Lemma 16.20. (Suspension-Product Lemma) Let X be a topological space. If Y is a regionally compact space (e.g. if $Y = [0,1]$), then the map

$$\begin{array}{rccc} \varphi\colon & \Sigma(X) \times Y & \to & \Sigma(X \times Y) \\ & ([(x,t)], y) & \mapsto & [((x,y),t)] \end{array}$$

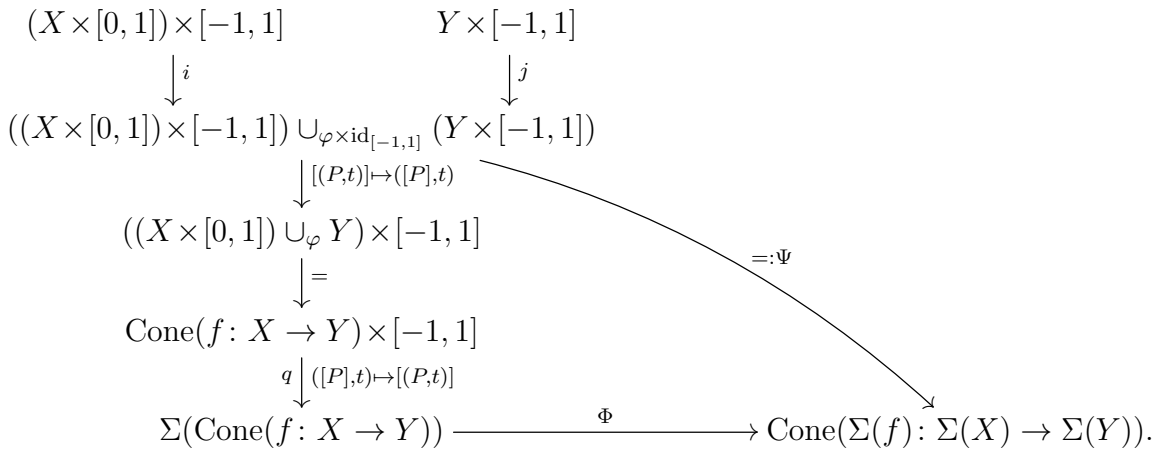
is continuous.

In the figure below we illustrate the Suspension-Product Lemma 16.20. This cute picture is not meant to hide the grim reality that for arbitrary topological spaces X it actually requires a non-trivial input to prove the Suspension-Product Lemma 16.20.

Proof. We denote by $p\colon (X \times Y) \times [-1,1] \to \Sigma(X \times Y)$ and $q\colon X \times [-1,1] \to \Sigma(X)$ the two natural projections. We have the following commutative diagram

$$\begin{array}{ccc} (X \times [-1,1]) \times Y & \xrightarrow[\cong]{(x,t,y)\mapsto(x,y,t)} & (X \times Y) \times [-1,1] \\ \downarrow{\scriptstyle q \times \mathrm{id}_Y} & & \downarrow{\scriptstyle p} \\ \Sigma(X) \times Y & \xrightarrow{\qquad\varphi\qquad} & \Sigma(X \times Y). \end{array}$$

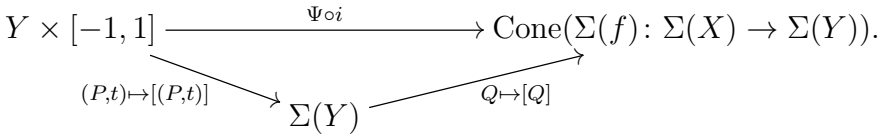
By the Product Topology-Basics Lemma 5.4 (2) the top horizontal map is a homeomorphism. By the Quotient Map Lemma 13.3 the maps p and q are quotient maps. Since Y is regionally compact we obtain from the Whitehead Quotient Theorem 13.4 that $q \times \mathrm{id}_Y$ is a quotient map. It follows from Lemma 13.5 that φ is also a quotient map. By the Quotient Map Lemma 13.3 (2) this implies that φ is indeed continuous. ■



Proof of the Mapping Cone-Suspension Proposition 16.19. Let $f\colon X \to Y$ be a map between topological spaces. One can easily verify that the given map Φ is a bijection. It remains to show that Φ and Φ^{-1} are continuous. We will do so in the following two claims. The domain and the target of Φ are both a scary mix of product and quotient topologies. Thus we need to tread super carefully.

Claim 1. The map Φ is continuous.

Proof. To prove the claim we introduce the following notation:



(a) We consider the map $\varphi\colon X \times \{1\} \to Y$ that is given by $\varphi(x,1) = f(x)$.
(b) We denote by $p\colon \mathrm{Cone}(f\colon X \to Y) \times [-1,1] \to \Sigma(\mathrm{Cone}(f\colon X \to Y))$ the projection
.

We consider the following diagram:

We make the following observations:

(1) By Lemma 13.7 we know that the vertical map between the second and the third row is a homeomorphism.
(2) It follows from (1) together with the Topological-Quotient Proposition 5.15 (1b), applied to the projection q, that Φ is continuous if Ψ is continuous.
(3) It follows from the Topological Pushout Proposition 5.33 (1b) that Ψ is continuous if $\Psi\circ i$ and $\Psi\circ j$ are continuous.
(4) We have the following commutative diagram:

The diagonal maps are continuous by the Topological-Quotient Proposition 5.15 (1a) and the Topological Pushout Proposition 5.33 (1b). Thus we see that $\Psi\circ i$ is continuous. The same argument shows that $\Psi\circ j$ is continuous.

The combination of (2), (3) and (4) shows that Φ is indeed continuous. ⊞

Claim 2. The map

$$\overbrace{\mathrm{Cone}(\Sigma(f)\colon\Sigma(X)\to\Sigma(Y))}^{=((\Sigma(X)\times[0,1])\sqcup\Sigma(Y))/\sim}\xrightarrow{\Phi^{-1}}\Sigma(\mathrm{Cone}(f\colon X\to Y))$$

$$P\mapsto\begin{cases}[([(x,s)],t)], & \text{if } P=[([(x,t)],s)] \text{ with } s\in[0,1] \text{ and}\\ & \text{with } [(x,t)]\in\Sigma(X), \text{ i.e. } x\in X,\ t\in[-1,1],\\ [([y],t)], & \text{if } P=[([y],t)] \text{ with } t\in Y,\ t\in[-1,1].\end{cases}$$

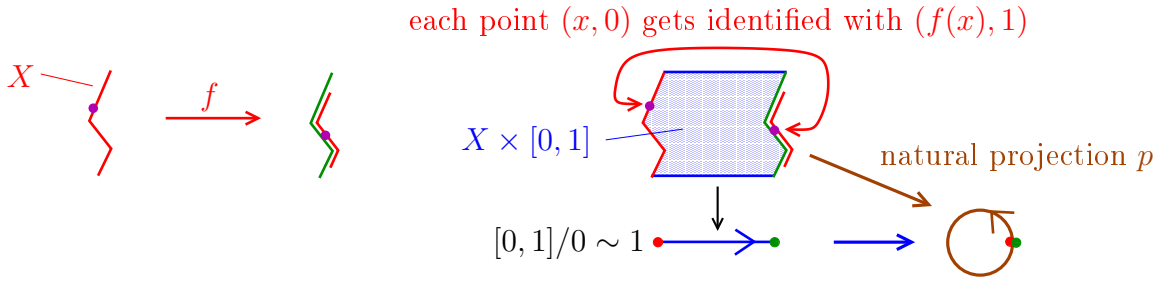
is continuous.

Proof. By the Topological Pushout Proposition 5.33 (1b) it suffices to show that the maps

$$\begin{array}{ccc}\Sigma(X)\times[0,1] & \to & \Sigma(\mathrm{Cone}(f\colon X\to Y))\\ ([(x,t)],s) & \mapsto & [([(x,s)],t)]\end{array}\quad\text{and}\quad\begin{array}{ccc}\Sigma(Y) & \to & \Sigma(\mathrm{Cone}(f\colon X\to Y))\\ [(y,t)] & \mapsto & [([y],t)]\end{array}$$

are continuous. The second map is continuous by the Suspension Functor Lemma 16.9 (1). Furthermore it follows from the combination of the Suspension-Product Lemma 16.20 with the Suspension Functor Lemma 16.9 (1) that the first map is continuous. ■

16.5. **The mapping torus.** In this last section we discuss the mapping torus. This construction gives rise to many interesting topological spaces. We will also see that determining the fundamental group of a mapping torus is somewhat challenging, but not impossible.



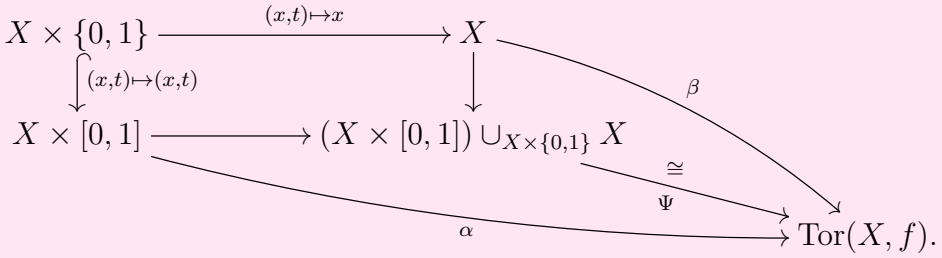
Definition. Let X be a topological space and let $f\colon X \to X$ be a map. We refer to

$$\mathrm{Tor}(X,f) \;:=\; (X\times[0,1])/\!\sim \qquad \text{where } (x,0)\sim(f(x),1) \text{ for all } x\in X,$$

as the mapping torus of (X,f). We refer to the map

$$\begin{array}{rcl}\mathrm{Tor}(X,f)=(X\times[0,1])/(x,0)\sim(f(x),1) & \to & S^1\\ [(x,t)] & \mapsto & \exp(2\pi\mathrm{i}t)\end{array}$$

as the natural projection onto S^1.



The following lemma shows that the mapping torus is a pushout. This is very useful since it allows us to use all the results from the Topological Pushout-Maps Lemma 5.34.

Lemma 16.21. Let X be a topological space and let $f\colon X\to X$ be a map. The natural maps

$$\begin{array}{rcl}\alpha\colon X\times[0,1] & \to & \mathrm{Tor}(X,f)\\ (x,t) & \mapsto & [(x,t)]\end{array} \qquad \text{and} \qquad \begin{array}{rcl}\beta\colon X & \to & \mathrm{Tor}(X,f)\\ x & \mapsto & [(x,0)]\end{array}$$

induce the following natural homeomorphism:

Proof. First note that it follows from the the Topological Pushout Proposition 5.33 (1b) that Ψ is continuous. Next we consider the natural map

$$\begin{array}{rcl}\Phi\colon (X\times[0,1])/\!\sim & \to & (X\times[0,1])\cup_{X\times\{0,1\}}X\\ [(x,t)] & \mapsto & [(x,t)].\end{array}$$

[173] It follows from the Topological-Quotient Proposition 5.15 (1b) that the natural projection is indeed continuous.

It follows from the the Topological Pushout Proposition 5.33 (1a) and the Topological-Quotient Proposition 5.15 (1b) that Φ is continuous. One can easily verify that Φ and Ψ are inverses of one another. Thus we have shown that both maps are homeomorphisms. ■

For completeness' sake we state the following almost self-evident lemma which gets used, often subconsciously, on numerous occasions.

Lemma 16.22. Let X be a topological space and let $f\colon X \to X$ be a map.

(1) The map

$$\begin{array}{rcl} \Theta\colon (X\times\mathbb{R})/(x,r) \overset{\text{with } x\in X \text{ and } r\in\mathbb{R}}{\sim} (f(x),r+1) & \to & \mathrm{Tor}(X,f) = (X\times[0,1])/(x,0)\sim(f(x),1) \\ [(x,t)] & \mapsto & [(x,t)] \end{array}$$

is a homeomorphism.

(2) For every interval $I \subset \mathbb{R}$ of length less than one, the map

$$\begin{array}{rcl} \varphi\colon X\times I & \to & (X\times\mathbb{R})/\sim \ \xrightarrow{\Theta}\ \mathrm{Tor}(X,f) \\ (x,t) & \mapsto & [(x,t)] \end{array}$$

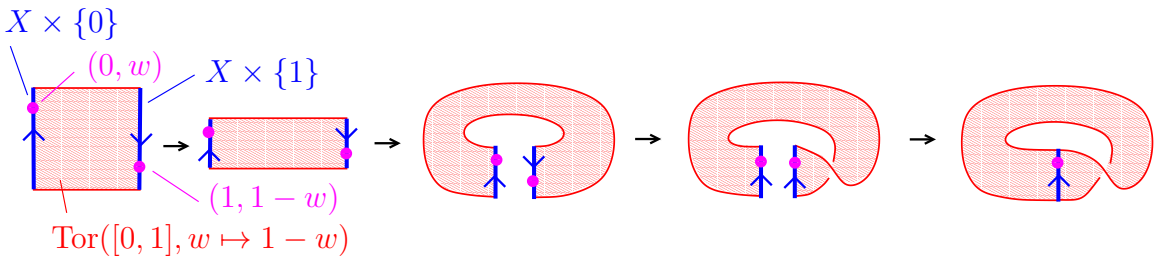
is an embedding. Furthermore, if I is closed respectively open, then φ is a closed respectively open embedding.

Proof. First note that it is straightforward to write down an inverse to Θ. The second statement follows from elementary arguments. We leave it to the reader to fill in the details. ■

The following lemma takes care of our two favorite properties of topological spaces, namely compactness and being Hausdorff.

Lemma 16.23. (Mapping Torus-Compact-Hausdorff Lemma) Let X be a topological space and let $f\colon X \to X$ be a homeomorphism.

(1) If X is Hausdorff, then the mapping torus $\mathrm{Tor}(X,f)$ is Hausdorff.
(2) If X is compact, then the mapping torus $\mathrm{Tor}(X,f)$ is compact.

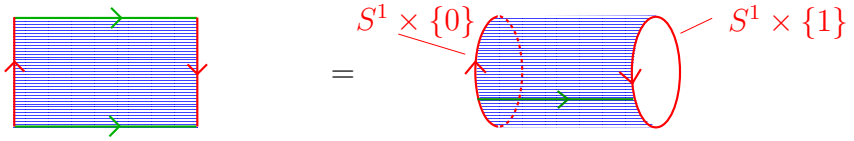


Proof.

(1) This statement will be proved in Exercise 16.16.
(2) This statement follows immediately from the Product Topology Properties Proposition 5.6 (2) and the Quotient-Compact Connected Lemma 5.16 (1). ■

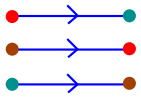
Next we will see that several well-established topological spaces are actually mapping tori.

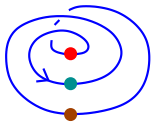
Examples.



(1) We consider the topological space $[0,1]$ and let $f\colon [0,1] \to [0,1]$ be the self-homeomorphism of $[0,1]$ that is given by $f(w) = 1 - w$. It follows immediately from the definitions that the corresponding mapping torus $\mathrm{Tor}([0,1],f)$ is precisely the Möbius band as defined on page 264.
(2) Let $X = S^1$ and let $f\colon X \to X$ be the homeomorphism that is given by $f(z) = \overline{z}$. It follows easily from the Compact-Hausdorff Proposition 2.17 (3) and the Mapping

Torus-Compact-Hausdorff Lemma 16.23 (1) that the map





$$\begin{array}{rcl} \overbrace{([0,1]\times[0,1])\,/\,(x,0)\sim(x,1),(0,y)\sim(1,1-y)}^{\text{Klein bottle}} & \to & \mathrm{Tor}(S^1,f) \\ [(x,y)] & \mapsto & [\exp(2\pi\,\mathrm{i}\,y),x)] \end{array}$$

is a homeomorphism from the Klein bottle to the mapping torus $\mathrm{Tor}(S^1, f)$.[174]

Klein bottle $[0,1]\times[0,1]/\sim$ mapping torus $\mathrm{Tor}(S^1, z \mapsto \overline{z})$

(3) As a final example we consider $X = \mathbb{Z}_3 = \{0,1,2\}$, equipped with the discrete topology. Let $f\colon X \to X$ be the homeomorphism that is given by $f(x) = x+1 \bmod 3$. As we illustrate in the figure below, the mapping torus $\mathrm{Tor}(X, f)$ is homeomorphic to S^1.

the mapping torus $\mathrm{Tor}(\mathbb{Z}_3, f(x) = x+1)$  is homeomorphic to 

We slow down a little to consider the case $\varphi = \mathrm{id}$ in more detail. On page 264 we already saw that $\mathrm{Tor}(S^1, \mathrm{id})$ is homeomorphic to the torus $S^1 \times S^1$. Thus the following lemma does not come as a surprise.

Lemma 16.24. (Mapping Torus-of-id Lemma) Given any topological space X the map

$$\begin{array}{rcl} \Phi\colon \mathrm{Tor}(X,\mathrm{id}) & \to & X \times S^1 \\ [(x,t)] & \mapsto & (x, \exp(2\pi\,\mathrm{i}\,t)) \end{array}$$

is a homeomorphism.

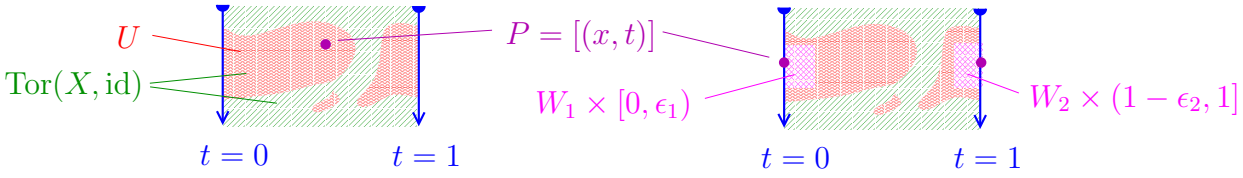
Convention. Let X be a topological space. We use the homeomorphism from the Mapping Torus-of-id Lemma 16.24 to make the identification $\mathrm{Tor}(X, \mathrm{id}) = X \times S^1$.

Proof. It is easy to verify that Φ is a bijection. Using Remark 5.17 (1) one can easily show that Φ is continuous. It still remains to show that Φ is actually a homeomorphism.

First we provide an argument based on Proposition 13.11. First note that it follows from the Compact-Hausdorff Proposition 2.17 (3) that the map $[0,1]/\{0,1\} \to S^1$ induced

[174] What does the mapping torus $\mathrm{Tor}(S^1, z \mapsto -z)$ look like?

by $[t] \mapsto \exp(2\pi \mathrm{i} t)$ is a homeomorphism. We use this homeomorphism to replace S^1 by $[0,1]/\{0,1\}$. Next we consider the following diagram:



$$\begin{array}{ccc} & X \times [0,1] & \\ {\scriptstyle (x,t)\mapsto(x,[t])} \swarrow^{p} & & \searrow^{q} {\scriptstyle (x,t)\mapsto[(x,t)]} \\ X \times ([0,1]/\{0,1\}) & \xrightarrow[(x,[t])\mapsto[(x,t)]]{\Phi^{-1}} & (X \times [0,1])/(x,0) \sim (x,1). \end{array}$$

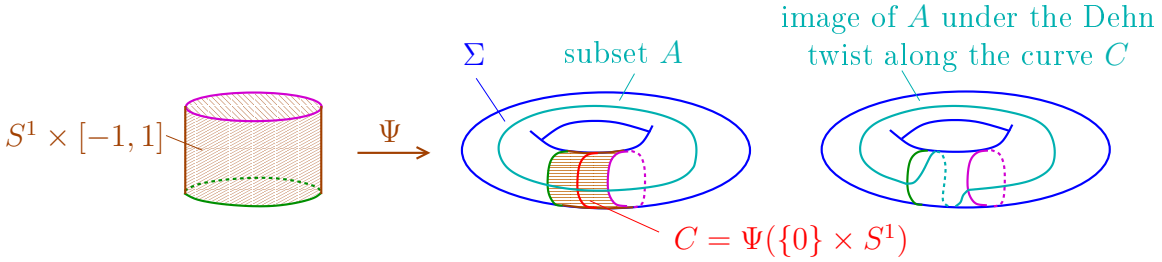
By Proposition 13.11, applied to $Y = [0,1]$ and the compact subset $B = \{0,1\}$ we know that p is a quotient map. By the Topological-Quotient Proposition 5.15 (1a) we know that q is continuous. Since the diagram commutes we obtain from Lemma 13.5 that Φ^{-1} is continuous. We have thus shown that Φ is a homeomorphism.

In the rather unlikely event that the reader skipped Proposition 13.11 we also give a more direct argument. By the Open -Injective Map Lemma 2.16 (2) it remains to show that Φ is an open map. So let U be an open subset of $\mathrm{Tor}(X, \mathrm{id}) = (X \times [0,1])/\!\sim$. Let $P := [(x,t)] \in U$ be a point. We can assume that $t \in [0,1)$. We need to show that $Q := \Phi([(x,t)])$ admits an open neighborhood Y that is contained in $V := \Phi(U)$. In the following we denote by $p\colon X \times [0,1] \to \mathrm{Tor}(X, \mathrm{id})$ the projection .

If $t \in (0,1)$, then by the definition of the topology on $\mathrm{Tor}(X, \mathrm{id})$ there exists an open subset $W \subset X$ and an open interval $(a,b) \subset (0,1)$ with $P \in W \times (a,b) \subset U$. We set $Y := \Phi(W \times (a,b)) = W \times \{\exp(2\pi \mathrm{i} t) \,|\, t \in (a,b)\}$. Note that $p^{-1}(Y) = Y$ is an open subset of $X \times [0,1]$. Thus Y has the desired property

Now suppose that $t = 0$. In $X \times [0,1]$ we pick an open neighborhood $W_1 \times [0, \epsilon_1)$ of the point $(x,0)$ that is contained in $p^{-1}(U)$. Similarly we pick an open neighborhood $W_2 \times (1-\epsilon_2, 1]$ of the point $(x,1)$ that is also contained in $p^{-1}(U)$. It is now straightforward to see that $Y := (W_1 \cap W_2) \times \{\exp(2\pi \mathrm{i} s) \,|\, s \in (-\epsilon_2, \epsilon_1)\}$ has the desired property. ■

Now we continue the discussion of mapping tori with a few more examples.



Examples.

(1) In [**Rolf1990**, Chapter 10.I.10] and [**BZH2014**, Section 5.C] it is shown that the complement of the trefoil and the complement of the figure-8 knot are homeomorphic to a mapping torus, where the fiber is given by removing a point from the torus.

(2) If one wants to construct new interesting topological spaces out of a given topological space we need to find "non-trivial" self-homeomorphisms. For example let Σ be a surface and let $\Psi\colon [-1,1] \times S^1 \to \Sigma$ be an embedding The map

$$\begin{array}{rcl} \Sigma & \to & \Sigma \\ P & \mapsto & \begin{cases} P, & \text{if } P \notin \Psi([-1,1] \times S^1), \\ \Psi(t, z \cdot \exp(\mathrm{i} \cdot ((t+1) \cdot \pi))) & \text{if } P = \Psi(t,z) \text{ for some } t \in [-1,1] \text{ and } z \in S^1, \end{cases} \end{array}$$

is called a *Dehn twist*[175] *twist along the curve* $C := \Psi(\{0\} \times S^1)$. We will discuss Dehn twists in greater detail on page 3126.

For completeness we also state the following lemma.

Lemma 16.25. (Manifold-Mapping Torus Lemma) Let M be an n-dimensional smooth manifold and let $f\colon M \to M$ be a diffeomorphism. The following statements hold:

(1) The mapping torus $\mathrm{Tor}(M,f)$ is naturally an $(n+1)$-dimensional smooth manifold such that the obvious inclusion map $M \times (0,1) \to \mathrm{Tor}(M,f)$ is a smooth map.
(2) The boundary $\partial\,\mathrm{Tor}(M,f)$ is given by the mapping torus $\mathrm{Tor}(\partial M, f|_{\partial M})$, in particular, if M is closed, then $\mathrm{Tor}(M,f)$ is also closed.
(3) If M is orientable and if f is orientation-preserving, then $\mathrm{Tor}(M,f)$ is also an orientable smooth manifold.

Proof. First consider the case that M has no boundary. By the Smooth Manifold Product Proposition 19.31 (4) we know that $M \times [0,1]$ is an $(n+1)$-dimensional smooth manifold with boundary given by $M \times \{0,1\}$. Note that we obtain the mapping torus $\mathrm{Tor}(M,f)$ from the smooth manifold $M \times [0,1]$ by identifying the boundary component $M \times \{0\}$ with $M \times \{1\}$. Thus the statements are an immediate consequence of the Gluing-Smooth Manifolds-Proposition **??**.

We will not make use of the Manifold-Mapping Torus Lemma 16.25 when M has non-empty boundary. Thus we leave it to the curious reader to modify the above argument to the general case. ■

The lemma says in particular that self-diffeomorphisms of surfaces give rise to 3-dimensional smooth manifolds. This construction is an important source of examples of 3-dimensional smooth manifolds.

Definition. Let X and Y be topological spaces. Two homeomorphisms $f,g\colon X \to Y$ are called isotopic, if there exists an isotopy from f to g, i.e. a map

$$\begin{array}{rcl} H\colon X \times [0,1] & \to & Y \\ (x,t) & \mapsto & H(x,t) \end{array}$$

such that the following hold:

(1) We have $H(x,0) = f(x)$ and $H(x,1) = g(x)$ for all $x \in X$,
(2) for each $t \in [0,1]$ the map $X \to Y$ given by $x \mapsto H(x,t)$ is a homeomorphism.

Examples.

[175] Max Dehn (1878-1952) was a German–Jewish mathematician. In 1939 he fled to Norway. After the German occupation of Norway he fled to America via Siberia and Japan. He died in 1952 in Black Mountain, North Carolina.

(1) We consider $X = [0,2]$ and the two self-homeomorphisms given by $f(x) = x$ and by $g(x) = \frac{1}{2} \cdot x^2$. Then[176]

$$\begin{array}{rcl} H\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & f(x) \cdot (1-t) + g(x) \cdot t \end{array}$$

is an isotopy from f to g.

(2) Lickorish [**Lic1962**] showed that any self-homeomorphism of a compact orientable 2-dimensional smooth manifold is isotopic to the concatenation of finitely many Dehn twists.

Lemma 16.26. Let X be a topological space. If $f, g\colon X \to X$ are two homeomorphisms that are isotopic, then the mapping tori $\mathrm{Tor}(X,f)$ and $\mathrm{Tor}(X,g)$ are homeomorphic.

Proof. The lemma will be proved in Exercise 16.17. ■

Example. We consider $X = S^1$ and the self-homeomorphism that is given by $g(z) = -z$. Note that the map $H(z,t) = \exp(\pi \mathrm{i} t) \cdot z$ defines an isotopy from $f = \mathrm{id}$ to g. It follows from Lemma 16.26 that the mapping torus $\mathrm{Tor}(S^1, g(z) = -z)$ is homeomorphic to the torus $\mathrm{Tor}(S^1, \mathrm{id}) = S^1 \times S^1$.

Now we can determine which surfaces are mapping tori.

Proposition 16.27. The annulus, the Möbius band, the torus and the Klein bottle are, up to homeomorphism, the only connected, compact 2-dimensional topological manifolds that can be written as a mapping torus $\mathrm{Tor}(X,f)$ of a connected 1-dimensional topological manifold X.

Proof. By the examples (1), (2) on page 468 and by the Mapping Torus-of-id Lemma 16.24 we know that there exist the following types of homeomorphisms:

$$\begin{array}{rcl} \text{annulus } S^1 \times [0,1] & \cong & \mathrm{Tor}([0,1], \mathrm{id}) \\ \text{Möbius band} & \cong & \mathrm{Tor}([0,1], x \mapsto 1-x) \end{array} \quad \text{and} \quad \begin{array}{rcl} \text{torus } S^1 \times S^1 & \cong & \mathrm{Tor}(S^1, \mathrm{id}) \\ \text{Klein bottle} & \cong & \mathrm{Tor}(S^1, z \mapsto \overline{z}). \end{array}$$

In particular all these four smooth manifolds are homeomorphic to mapping tori. It remains to show that these are the only connected, compact 2-dimensional topological manifolds that can be written as a mapping torus.

It follows from the Topological 1-Dimensional Manifold Classification Theorem 22.1 that any compact connected 1-dimensional topological manifold is homeomorphic to $[0,1]$ or to S^1. We know from Lemma 50.1 that any self-homeomorphism is isotopic to one of the self-homeomorphisms that we had written down above. But then it follows from Lemma 16.26 that any mapping torus is homeomorphic to one from the above list. ■

For proving statements about mapping tori the following lemma gives a useful alternative point of view.

Lemma 16.28. (Mapping Torus-of-Homeomorphism Lemma) Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. Then the following hold:

(1) The map[177]

$$\begin{array}{rcl} \mathbb{Z} \times (X \times \mathbb{R}) & \to & X \times \mathbb{R} \\ (n, (x,t)) & \mapsto & (f^n(x), t+n) \end{array}$$

defines a continuous, proper and discrete action[178] of the group $\mathbb{Z}$ on $X \times \mathbb{R}$.

[176] Let $t \in [0,1]$. Why is the map $[0,2] \to [0,2]$ given by $x \mapsto H(x,t)$ a homeomorphism?

(2) The map

$$\begin{array}{rcl} \mathrm{Tor}(X,f) = (X\times[0,1])/\!\sim & \to & (X\times\mathbb{R})/\mathbb{Z} \\ [(x,t)] & \mapsto & [(x,t)] \end{array}$$

is a homeomorphism.

Proof. We leave the task of providing the elementary proof to the reader. ■

In the following, given a topological space X and a homeomorphism $f\colon X\to X$ we denote the corresponding quotient space by $(X\times\mathbb{R})/\mathbb{Z}_f$ and we will identify the mapping torus $\mathrm{Tor}(X,f)$ with $(X\times\mathbb{R})/\mathbb{Z}_f$ using the homeomorphism of the Mapping Torus-of-Homeomorphism Lemma 16.28.

Remark. It follows from the Mapping Torus-of-Homeomorphism Lemma 16.28 together with the Manifold Quotient-by-Group Action Proposition 19.32 that if X is an n-dimensional topological (respectively) smooth manifold and f is a homeomorphism, then the corresponding mapping torus $\mathrm{Tor}(X,f) = (X\times\mathbb{R})/\mathbb{Z}_f$ is a $(n+1)$-dimensional topological (respectively smooth) manifold. Furthermore, if X is in fact an n-dimensional smooth manifold and $f\colon X\to X$ is a diffeomorphism, then almost the same argument shows that the mapping torus $\mathrm{Tor}(X,f) = (X\times\mathbb{R})/\mathbb{Z}_f$ is an $(n+1)$-dimensional smooth manifold.

Lemma 16.29. (Mapping Torus Covering Lemma) Let X be a topological space and let $f\colon X\to X$ be a homeomorphism. The map

$$\begin{array}{rcl} X\times\mathbb{R} & \to & (X\times\mathbb{R})/\mathbb{Z}_f = \mathrm{Tor}(X,f) \\ (x,t) & \mapsto & [(x,t)] \end{array}$$

is a covering of infinite degree. Furthermore for $k\in\mathbb{N}$ the map

$$\begin{array}{rcl} \mathrm{Tor}(X,f^k) = (X\times\mathbb{R})/\mathbb{Z}_{f^k} & \to & (X\times\mathbb{R})/\mathbb{Z}_f = \mathrm{Tor}(X,f) \\ [(x,t)] & \mapsto & [(x,k\cdot t)] \end{array}$$

is a k-fold covering.

Proof. Let X be a topological space and let $f\colon X\to X$ be a homeomorphism. The first statement is an immediate consequence of the Mapping Torus-of-Homeomorphism Lemma 16.28 and Proposition 48.10.

Now let $k\in\mathbb{N}$. We consider the following commutative diagram of maps:

$$\begin{array}{ccc} (X\times\mathbb{R})/\mathbb{Z}_{f^k} & \xrightarrow{[(x,t)]\mapsto[(x,k\cdot t)]} & (X\times\mathbb{R})/\mathbb{Z}_f. \\ & {\scriptstyle [(x,t)]\mapsto[(x,k\cdot t)]}\searrow \quad \nearrow{\scriptstyle [(x,t)]\mapsto[(x,t)]} & \\ & (X\times\mathbb{R})/(k\cdot\mathbb{Z})_f & \end{array}$$

The left diagonal map is easily seen to be well-defined and to be a homeomorphism. By Proposition 48.10 the right diagonal map is a k-fold covering. It follows that the top horizontal map is also a k-fold covering. ■

---

[177] Here for $n\geq 1$ we write $f^n(x) = (\overbrace{f\circ\cdots\circ f}^{n\text{-times}})(x)$, for $n=0$ we write $f^0(x)=x$ and for $n\leq -1$ we write $f^n(x) = (\underbrace{f^{-1}\circ\cdots\circ f^{-1}}_{|n|\text{-times}})(x)$.

[178] Why is it an action?

Examples.

(1) We apply Mapping Torus Covering Lemma 16.29 to $X = [0,1]$ and the homeomorphism that is given by $f(x) := 1 - x$. Note that for all x we have

$$f^2(x) \;=\; f(f(x)) \;=\; f(1-x) \;=\; 1-(1-x) \;=\; x.$$

This shows that $f^2 = \mathrm{id}$. Thus we recover the statement from page 1070 that the annulus $\mathrm{Tor}([0,1], \mathrm{id})$ is a 2-fold covering of the Möbius band $\mathrm{Tor}([0,1], f(x) = 1-x)$.

(2) We apply Mapping Torus Covering Lemma 16.29 to $X = S^1$ and the self-homeomorphism of $X = S^1$ that is given by $f(z) := \overline{z}$. As in the previous example we see that $f^2 = \mathrm{id}$. Thus we get, after the discussion on page 1078, a new proof that the torus $\mathrm{Tor}(S^1, \mathrm{id})$ is a 2-fold covering of the Klein bottle $\mathrm{Tor}(S^1, f(z) = \overline{z})$.

Exercises for Chapter 16.

Exercise 16.1. Let X and Y be topological spaces. Show that the join $X * Y$ is homeomorphic to the pushout of the maps

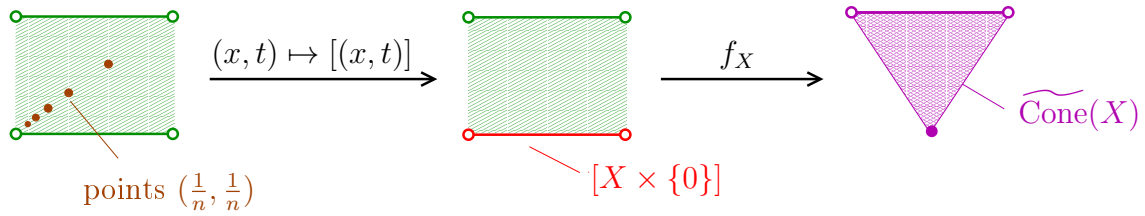
$$\begin{array}{ccc} X \times \{0,1\} \times Y & \longrightarrow & X \times [0,1] \times Y \\ \downarrow & & \\ X \sqcup Y & & \end{array}$$

where the horizontal map is the inclusion and the vertical map is defined by the two projections $X \times \{0\} \times Y \to X$ and $X \times \{1\} \times Y \to Y$.
Remark. This exercise explains in particular the initially slightly odd convention in the definition of the join for the special case that at least one of X or Y is the empty topological space.

Exercise 16.2. Let X and Y be topological spaces. Show that if X and Y are Hausdorff, then the join $X * Y$ is also Hausdorff.

Exercise 16.3. Given a subset X of $\mathbb{R}^n$ we define its *physical cone* as

$$\widetilde{\mathrm{Cone}}(X) \;:=\; \text{union of all line segments from } \underbrace{(x,1)}_{\in \mathbb{R}^{n+1}} \text{ to } \underbrace{(0,0)}_{\in \mathbb{R}^{n+1}} \;\subset\; \mathbb{R}^{n+1}$$



and we consider the map

$$\begin{array}{rccl} f_X \colon & \mathrm{Cone}(X) & \to & \widetilde{\mathrm{Cone}}(X) \\ & [(x,t)] & \mapsto & t \cdot (x,1) + (1-t) \cdot (0,1). \end{array}$$

(a) Let X be a compact subset of $\mathbb{R}^n$. Show that the map f_X is a homeomorphism.

(b) Let $X = (0,1) \subset \mathbb{R}$. Show that the map f_X is not a homeomorphism.
Remark. It is actually true that f_X is continuous and a bijection. To show that f_X is not a homeomorphism we need to show that there exists an open subset U of $\mathrm{Cone}(X)$ such that the image under f_X is not open. You could try your hand at

$$U \;:=\; \mathrm{Cone}(X) \setminus \{[(\tfrac{1}{n}, \tfrac{1}{n})] \,|\, n \in \mathbb{N}_{\geq 2}\}.$$

Exercise 16.4. Let X be a topological space. Show that $\mathrm{Cone}(X)$ respectively the suspension $\Sigma(X)$ are homeomorphic to the pushout of the diagram

$$\begin{array}{ccc} X & \xrightarrow{x\mapsto(x,1)} & X \times [0,1] \\ \downarrow & & \\ \{*\} & & \end{array} \qquad \text{respectively} \qquad \begin{array}{ccc} X & \xrightarrow{x\mapsto[(x,0)]} & \mathrm{Cone}(X) \\ {\scriptstyle x\mapsto[(x,0)]}\downarrow & & \\ \mathrm{Cone}(X) & & \end{array}$$

Remark. These descriptions of the cone and the suspension explain our definitions for the case that X is the empty topological space.

Exercise 16.5. Let X be a topological space.

(a) Show that the cone $\mathrm{Cone}(X)$ is naturally homeomorphic to the join $X * \{*\}$.
(b) Show that the suspension $\Sigma(X)$ is naturally homeomorphic to the join $X * S^0$.

Remark. We refer to page 446 for the definition of the join of two topological spaces.

Exercise 16.6. Let X be a topological space. Show that the suspension $\Sigma(X)$ is path-connected.

Exercise 16.7. Let X be a topological space. Show that if X is Hausdorff, then the suspension $\Sigma(X)$ is also Hausdorff.

Exercise 16.8. Let X be a topological space. Show that the injections

$$\begin{array}{ccc} X & \to & \mathrm{Cone}(X) \\ x & \mapsto & [(x,1)] \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{Cone}(X) & \to & \Sigma(X) \\ [(x,t)] & \mapsto & [(x,1-t)] \end{array}$$

are embeddings.

Exercise 16.9. Let $f\colon X \to Y$ be a map between topological spaces. Show that if X and Y are Hausdorff, then the mapping cylinder $\mathrm{Cyl}(f)$ is also Hausdorff.
Remark. This exercise is the content of the Mapping Cylinder Basics Lemma 16.10 (2).

Exercise 16.10. Let $f\colon X \to Y$ be a map between topological spaces. Show that the natural inclusions

$$\begin{array}{ccc} X & \to & \mathrm{Cyl}(f\colon X \to Y) \\ x & \mapsto & (x,0) \end{array} \quad \text{and} \quad \begin{array}{ccc} Y & \to & \mathrm{Cyl}(f\colon X \to Y) \\ y & \mapsto & [y] \end{array}$$

are embeddings.
Remark. This exercise is the content of the Mapping Cylinder Basics Lemma 16.10 (3).

Exercise 16.11. Let $f\colon X \to Y$ be a map between topological spaces and let Z be a topological space.

(a) Show that the map

$$\Theta\colon \mathrm{Cyl}(f\times \mathrm{id}\colon X\times Z\to Y\times Z) \to \mathrm{Cyl}(f\colon X\to Y)\times Z$$
$$P \mapsto \begin{cases} ([(Q,t)],s), & \text{if } P=[(Q,t,s)] \text{ with } Q\in X, t,s\in[0,1],\\ ([Q],s), & \text{if } P=[(Q,s)] \text{ with } Q\in Y, s\in[0,1]. \end{cases}$$

is continuous.

(b) Suppose that Z is regionally compact. Show that the map Θ from (a) is a homeomorphism.
Hint. Use the Product-Quotient Mixing Lemma 13.6.

Exercise 16.12. Let X be a topological space and let A be a subset of X.

(a) We denote by $i\colon A\to X$ the inclusion. Show that the map

$$\begin{array}{rcl} A\times[0,1] & \to & \mathrm{Cyl}(i) = ((A\times[0,1])\sqcup X)/\!\sim \\ (a,t) & \mapsto & [(a,t)] \end{array}$$

is an embedding.

(b) Let $f\colon A\to X$ be an embedding. Is the map $A\times[0,1]\to \mathrm{Cyl}(f)$ necessarily an embedding?

Exercise 16.13. Give a proof of the Mapping Cone Functor Lemma 16.14 (3).

Exercise 16.14. We consider the topological space $X=[-1,1]$, the subset $A=(-1,1)$ and the inclusion map $i\colon A\to X$. Show that the induced map $\Sigma(i)\colon \Sigma(A)\to\Sigma(X)$ is *not* an embedding.
Remark. It might help to have a look at the equally scary Exercise 16.3.

Exercise 16.15. Let X and Y be topological spaces. We consider the corresponding join $X*Y=(X\times[0,1]\times Y)/\!\sim$ as defined on page 446. Show that the map

$$\begin{array}{rcl} X*Y=(X\times[0,1]\times Y)/\!\sim & \cong & (\mathrm{Cone}(X)\times Y)\cup_{(X\times\{1\})\times Y = X\times(Y\times\{1\})} (X\times \mathrm{Cone}(Y)) \\ [(x,t,y)] & \mapsto & \begin{cases} (x,[(y,2t)]), & \text{if } t\in[0,\frac{1}{2}],\\ ([(x,2(t-1))],y), & \text{if } t\in[\frac{1}{2},1]. \end{cases} \end{array}$$

is a homeomorphism.
Remark. Evidently you need to verify that all the maps are actually continuous.

Exercise 16.16. Let X be a topological space and let $f\colon X\to X$ be a homeomorphism. We assume that X is Hausdorff. Show that the mapping torus $\mathrm{Tor}(X,f)$ is also Hausdorff.

Exercise 16.17. Let X be a topological space. Show that if $f,g\colon X\to X$ are two homeomorphisms that are isotopic, then the mapping tori $\mathrm{Tor}(X,f)$ and $\mathrm{Tor}(X,g)$ are homeomorphic.

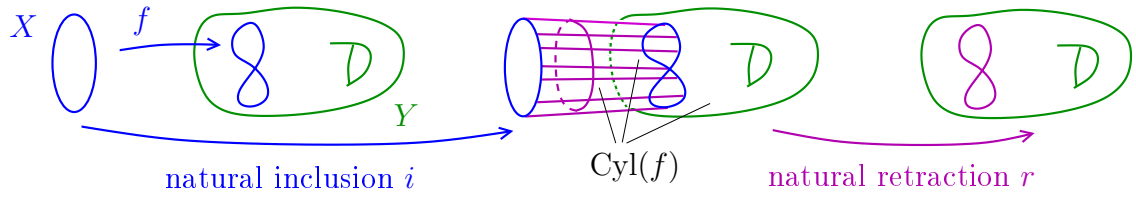
Exercise 16.18. Let $\varphi\colon \overline{B}^2\to\overline{B}^2$ be the map that is given by $(x,y)\mapsto(x,-y)$. Is the corresponding mapping torus $\mathrm{Tor}(\overline{B}^2,\varphi)$ homeomorphic to the solid torus?

Exercise 16.19. Let $f\colon X\to Y$ be a map between two topological spaces. Show that if X and Y are both locally contractible, then so is the mapping cylinder $\mathrm{Cyl}(f\colon X\to Y)$.

17. Cofibrations

Loosely speaking a map $i\colon A \to X$ between topological spaces is called a cofibration if it has the homotopy extension property, i.e. if a homotopy on A extends to a homotopy on X. As we will see many "reasonable" inclusion maps, e.g. the inclusion of a "submanifold" into a "smooth manifold", or of a "subcomplex" of a "CW-complex" into the CW-complex are cofibrations. The main technical achievement of this chapter is the daunting proof of the Homotopy Pushout Theorem 17.19 which will come in handy on several occasions throughout these notes.

Nonetheless, for the most part the results in this chapter are not essential for the understanding of the subsequent chapters, thus not much harm is done by initially skipping this chapter. It is best to return to it, when some of the results are actually needed.
Throughout this chapter we will on numerous occasions make use of the notion of a mapping cylinder and of a mapping cone. Thus we start out by recalling the definition of a mapping cylinder and a mapping cone that we had initially given on pages 454 and page 457.



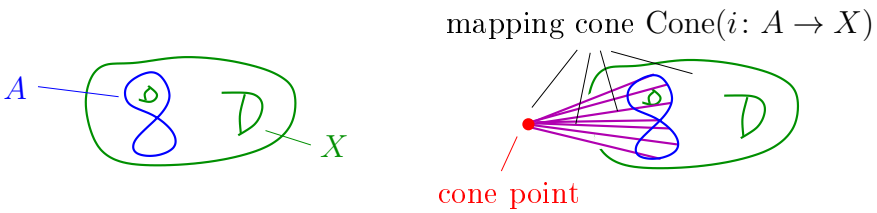
Definition. Let $f\colon X \to Y$ be a map between topological spaces. We define the corresponding mapping cylinder to be the topological space

$$\mathrm{Cyl}(f\colon X \to Y) \;:=\; ((X \times [0,1]) \sqcup Y)/\!\sim \quad \text{where } (x,1) \sim f(x) \text{ for all } x \in X.$$

We refer to the maps

$$\begin{array}{l} X \xrightarrow{i} \mathrm{Cyl}(f) \\ x \mapsto (x,0) \end{array} \quad \text{respectively} \quad \begin{array}{l} \mathrm{Cyl}(f) \xrightarrow{r} Y \\ P \mapsto \begin{cases} P, & \text{if } P \in Y, \\ f(Q), & \text{if } P = [(Q,t)] \text{ with } Q \in X, t \in [0,1]. \end{cases} \end{array}$$

as the natural inclusion respectively the natural retraction.[179]



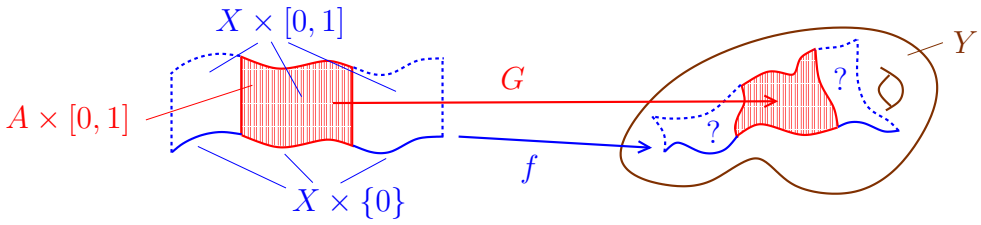
Definition. Given a map $f\colon A \to X$ between topological spaces the corresponding mapping cone is defined as

$$\mathrm{Cone}(f\colon A \to X) \;:=\; (A \times [0,1]) \sqcup X/\!\sim \qquad \text{where} \quad \begin{array}{l} (a,0) \sim (b,0) \text{ for all } a,b \in A \text{ and} \\ (a,1) \sim f(a) \text{ for all } a \in A. \end{array}$$

We refer to the point $[A \times \{0\}] \in \mathrm{Cone}(f)$ as the cone point. We illustrate the definition for an inclusion map $i\colon A \to X$ in the figure below.

17.1. **Cofibrations: definition and basic examples.** We immediately introduce the main player of this section.

[179] Note that by the Mapping Cylinder Basics Lemma 16.12 we know that there exists in fact a natural deformation retraction $R\colon \mathrm{Cyl}(f) \times [0,1] \to \mathrm{Cyl}(f)$ from $\mathrm{Cyl}(f)$ to Y, viewed as a subspace of $\mathrm{Cyl}(f)$, such that $R_1 = r$.



Definition.

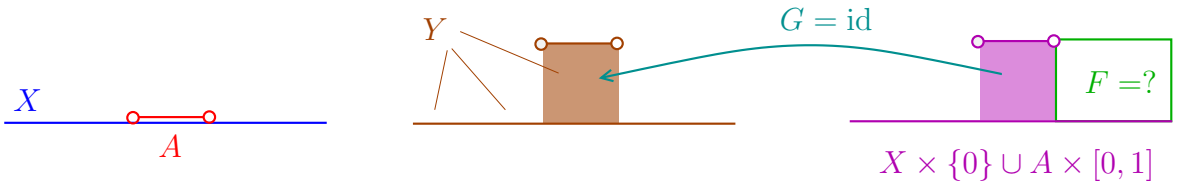
(1) A map $i\colon A \to X$ between topological spaces is called a cofibration if it has the homotopy extension property, i.e. if given any topological space Y and any two maps $f\colon X \times \{0\} \to Y$ and $G\colon A \times [0,1] \to Y$ with $f(i(a),0) = G(a,0)$ for all $a \in A$ there exists a map $F\colon X \times [0,1] \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} A \times \{0\} & \hookrightarrow & A \times [0,1] \\ \downarrow{\scriptstyle i} & \overset{f}{\nearrow} & \downarrow{\scriptstyle i\times \mathrm{id}} \\ X \times \{0\} & \hookrightarrow & X \times [0,1]. \end{array} \qquad Y,\ G,\ F$$

We illustrate the definition in the figure below.

(2) If $i\colon A \to X$ is a cofibration such that $i(A)$ is a closed subset of X, then we refer to i as a closed cofibration.

Remark.



(1) As we will see in the Cofibration-Closed Injective Lemma 17.6, in most cases of interest the map $i\colon A \to X$ is for all intents and purposes an inclusion. For such situations the definition of the homotopy extension property is illustrated in the figure above.

(2) In some books what we call a cofibration is called a "Hurewicz cofibration". Also, in some books, see e.g. [**Pic1992**], a cofibration is defined as what we call a closed cofibration.

Non-Example. Let us start out with a non-example. Namely let us consider $X = \mathbb{R}$ and the subspace $A = (0,1)$. We write $Y = \mathbb{R} \times \{0\} \cup (0,1) \times [0,1]$ and let $f\colon X \to Y$ be the obvious inclusion map and let $G\colon (0,1) \times [0,1] \to Y$ be the obvious inclusion map. (See the figure below for an illustration.) It is an amusing exercise to show that G cannot be extended to a homotopy on all of $\mathbb{R}$.[180] It is an equally amusing exercise to show that the

[180] Here is a hint: if there was an extension of G to a homotopy $F\colon X \times [0,1] \to Y$, what would/should $F(1,1)$ be?

homotopy can be extended if throughout we replace the open interval $A = (0,1)$ by the closed interval $A = [0,1]$.

We continue with the following fairly elementary lemma.

Lemma 17.1. (Cofibration Composition Lemma) If $f\colon X \to Y$ and $g\colon Y \to Z$ are two (closed) cofibrations, then the composition $g \circ f\colon X \to Z$ is also a (closed) cofibration.

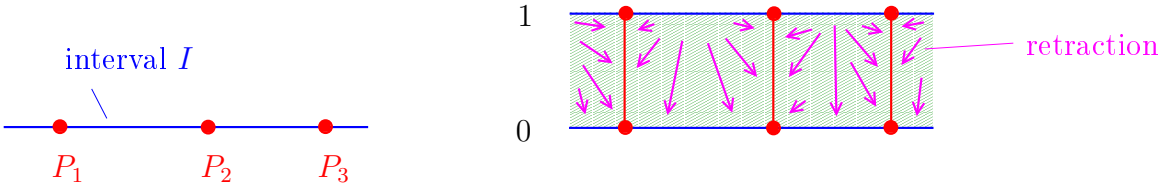
Proof. The lemma will be proved in Exercise 17.2. ■

Before we give examples of cofibrations it is convenient to add a characterization of cofibrations to our repertoire.

Lemma 17.2. (Cofibration Characterization Lemma) If $i\colon A \to X$ is a map between two topological spaces, then the following two statements are equivalent:

(1) The map $i\colon A \to X$ is a cofibration.

(2) The map[181]



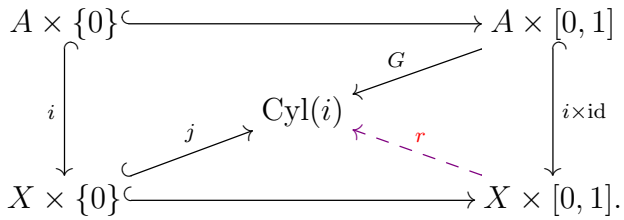
$$\begin{array}{rccl} s\colon & \mathrm{Cyl}(i) & \to & X \times [0,1] \\ & P & \mapsto & \begin{cases} (i(a), 1-t), & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1], \\ (P, 0), & \text{if } P \in X \end{cases} \end{array}$$

admits a left-inverse, in other words, there exists a map $r\colon X \times [0,1] \to \mathrm{Cyl}(i)$ such that $r \circ s = \mathrm{id}_{\mathrm{Cyl}(i)}$.

If A is a subset of X and if $i\colon A \to X$ is the inclusion map, then (1) and (2) are equivalent to

(3) The set $(X \times \{0\}) \cup (A \times [0,1])$ is a retract of $X \times [0,1]$.

Example. Let I be an interval in $\mathbb{R}$ and let $P_1, \ldots, P_k$ be finitely many distinct points in I. In the figure below we show a retraction from $I \times [0,1]$ to $(I \times \{0\}) \cup (\{P_1, \ldots, P_k\} \times [0,1])$. Together with the Cofibration Characterization Lemma 17.2 this shows that the inclusion $\{P_1, \ldots, P_k\} \to I$ is a cofibration.



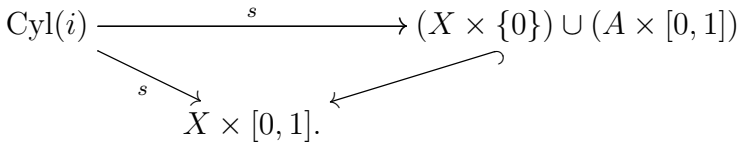
Proof. First we prove the "(1) ⇒ (2)"-direction. Thus we now suppose that the map $i\colon A \to X$ is a cofibration. We consider the inclusion map $j\colon X \times \{0\} \to \mathrm{Cyl}(i)$ which is

[181] It follows from the Topological Pushout Proposition 5.33 (1b) that this map is continuous.

given by $j(x,0) = x$ and we consider the map

$$\begin{array}{rcl} G\colon A \times [0,1] & \to & \mathrm{Cyl}(i) \\ (a,s) & \mapsto & [(a, 1-s)]. \end{array}$$

We obtain the following diagram:



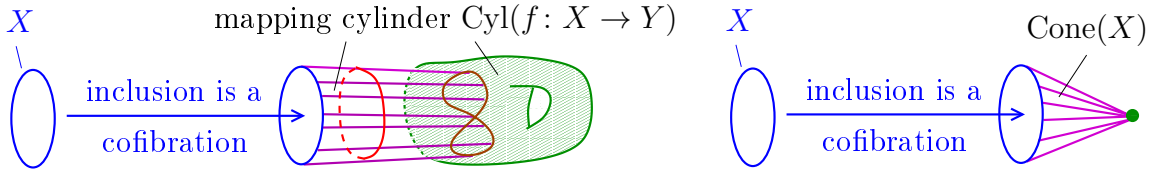
One easily verifies that the black diagram commutes. Since $i\colon A \to X$ is a cofibration we obtain a map $r\colon X \times [0,1] \to \mathrm{Cyl}(i)$ which makes the diagram commute. It is straightforward to verify that $r \circ s = \mathrm{id}_{\mathrm{Cyl}(i)}$.

The proof of the converse, i.e. the proof of the "(2) $\Rightarrow$ (1)"-direction is also quite straightforward. We will provide the proof in Exercise 17.3.

Now we assume that A is a subset of X and that $i\colon A \to X$ is the inclusion map. We need to provide the proof for the equivalence of (2) and (3). This turns out to be quite subtle.

(a) First we assume that A is a closed subset of X.[182] Note that the image of $\mathrm{Cyl}(i)$ in $X \times [0,1]$ under the map s is precisely $(X \times \{0\}) \cup (A \times [0,1])$. Thus we have the following commutative diagram

To show that (2) and (3) are equivalent it suffices to show that the top horizontal map is a homeomorphism. It is basically clear that the top horizontal map is a bijection. Furthermore it follows easily from the Topological Pushout Proposition 5.33 (1b) that the map is continuous. Finally it follows from our hypothesis that A is a *closed* subset, together with Lemma 16.11 (2), that the top horizontal map is indeed a homeomorphism.



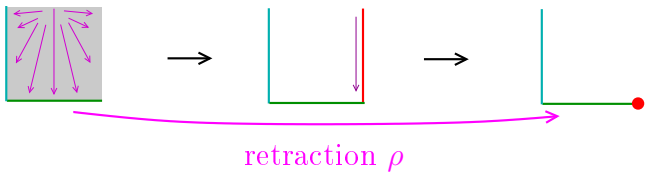
(b) The logic of (a) breaks down if A is not a closed subset. More precisely, in Lemma 16.11 (3) we saw that in general the top horizontal map is *not* a homeomorphism. Rather surprisingly it is nonetheless true that (2) and (3) are equivalent. This delicate argument is given in [**Strø1968**, Lemma 4] or alternatively in [**Hat2002**, Proposition A.18]. ■

The next proposition gives another rich source of examples of cofibrations.

Proposition 17.3. (Cone-Mapping Cylinder Inclusion Cofibration Proposition)

[182] This is also the only case we will ever need in practice.

(1) If $f\colon X \to Y$ is a map between two topological spaces, then the natural inclusion $i\colon X \to \mathrm{Cyl}(f)$ is a closed cofibration.
(2) Let X be a non-empty topological space. The natural inclusion $X \to \mathrm{Cone}(X)$ is a closed cofibration.



The proof of the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 relies on the following elementary lemma.

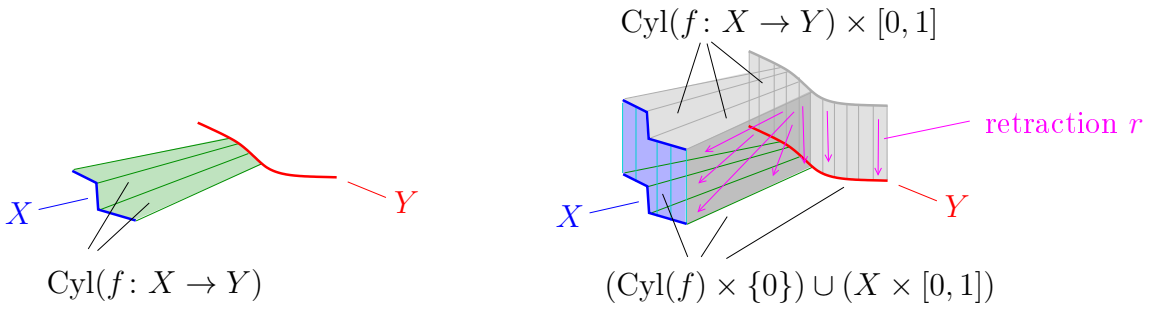
Lemma 17.4. There exists a retraction

$$\rho\colon [0,1]\times[0,1] \;\to\; (\{0\}\times[0,1]) \cup ([0,1]\times\{0\})$$

that has the property that $\rho(\{1\}\times[0,1]) = \{(1,0)\}$.

Proof. In the figure below we show how such a retraction ρ can be constructed, namely we first retract to the $\sqcup$-shaped set $(\{0,1\}\times[0,1]) \cup ([0,1]\times\{0\})$ and then we retract to $(\{0\}\times[0,1]) \cup ([0,1]\times\{0\})$ by collapsing $\{1\}\times[0,1]$ to the point $\{0,1\}$. ■

Proof of the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3. First note that if X is a non-empty topological space and if $f\colon X \to \{*\}$ is the constant map, then, as we pointed out on page 454, the mapping cylinder $\mathrm{Cyl}(f)$ is basically the cone of X. Thus we see that Statement (2) is a special case of Statement (1).



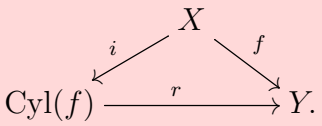
It remains to prove Statement (1). Let $f\colon X \to Y$ be a map between topological spaces. By the Mapping Cylinder Basics Lemma 16.10 (4) we know that the image of X in $\mathrm{Cyl}(f)$ is a closed subset. Thus it remains to show that $i\colon X \to \mathrm{Cyl}(f)$ is a cofibration. By the Mapping Cylinder Basics Lemma 16.10 (3) the map i is an embedding, thus we can identify X with its image in $\mathrm{Cyl}(f)$.

By the Cofibration Characterization Lemma 17.2 (3)⇒(1) it suffices to prove the following claim:

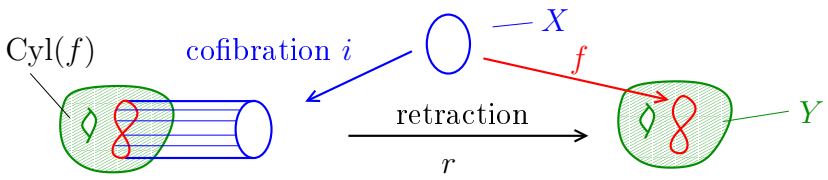
Claim. There is a retraction r from $\mathrm{Cyl}(f)\times[0,1]$ to its subset $(\mathrm{Cyl}(f)\times\{0\})\cup(X\times[0,1])$.

Proof. To construct the desired retraction r we recall that in Lemma 17.4 we saw that there exists a retraction

$$s\colon [0,1]\times[0,1] \;\to\; (\{0\}\times[0,1]) \cup ([0,1]\times\{0\})$$



that has the property that $s(\{1\} \times [0,1]) = \{(1,0)\}$. Now the desired retraction is given by the map[183]



$$r\colon \operatorname{Cyl}(f) \times [0,1] \to (\operatorname{Cyl}(f) \times \{0\}) \cup (X \times [0,1])$$
$$P \mapsto \begin{cases} [(x, s(t,u))], & \text{if } P = [(x,t,u)] \text{ with } x \in X \text{ and } t,u \in [0,1], \\ [(y,0)], & \text{if } P = [(y,u)] \text{ with } y \in Y \text{ and } u \in [0,1]. \end{cases}$$ ■

We conclude this section with a proposition which says that any map $f\colon X \to Y$ between topological spaces can be "replaced" by a cofibration $X \to \operatorname{Cyl}(f)$.

Proposition 17.5. (Replace-by-Cofibration Proposition) Let $f\colon X \to Y$ be a map between topological spaces. We denote by $i\colon X \to \operatorname{Cyl}(f)$ the natural inclusion. The natural retraction $r\colon \operatorname{Cyl}(f) \to Y$ is a homotopy equivalence and the following diagram commutes:

By the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 (1) we know that the left diagonal map $i\colon X \to \operatorname{Cyl}(f)$ is a cofibration.

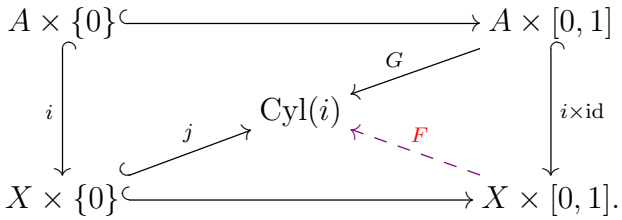
Proof. We showed in the Mapping Cylinder Basics Lemma 16.12 (2a) that the natural retraction $r\colon \operatorname{Cyl}(f) \to Y$ is a homotopy equivalence. It is clear that the given diagram commutes. Thus we are done by the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 (1). That was quick. ■

17.2. **Properties of cofibrations.** The following lemma summarizes a few key properties of cofibrations.

[183] This map is continuous by Pasting Proposition 2.6 (2).

Lemma 17.6. (Cofibration-Closed Injective Lemma) If $i\colon A \to X$ is a cofibration, then the following three statements hold:

(1) the map $i\colon A \to X$ is injective,
(2) the map $i\colon A \to X$ is an embedding,
(3) if X is Hausdorff, then $i(A)$ is a closed subset of X, i.e. i is a closed cofibration.



Remark. In Exercise 17.6 we will see that in the Cofibration-Closed Injective Lemma 17.6 (3) we cannot drop the hypothesis that X is Hausdorff.

Proof. Let $i\colon A \to X$ be a cofibration.

(1) Similar to the proof of the Cofibration Characterization Lemma 17.2 we consider the inclusion map $j\colon X \times \{0\} \to \mathrm{Cyl}(i)$ which is given by $j(x,0) = x$ and we consider the map

$$\begin{array}{rccl} G\colon & A \times [0,1] & \to & \mathrm{Cyl}(i) \\ & (a,s) & \mapsto & [(a,1-s)]. \end{array}$$

We obtain the following diagram:

One easily verifies that the black diagram commutes. Since i is a cofibration we obtain a map $F\colon X \times [0,1] \to \mathrm{Cyl}(i)$ which makes the diagram commute. Note that by design for any $t \in (0,1]$ the map $G\colon A \times \{t\} \to \mathrm{Cyl}(i)$ is injective. Since the diagram commutes this implies that $i \times \mathrm{id}_{\{t\}}\colon A \times \{t\} \to X \times \{t\}$ is also injective, i.e. $i\colon A \to X$ is injective.

(2) We continue with the argument and the notation in (1). Let $t \in (0,1]$. The map $G|_{A\times\{t\}}\colon A \times \{t\} \to A \times \{1-t\}$ is evidently a homeomorphism. Thus we see that

$$(G|_{A\times\{t\}})^{-1} \circ F|_{X\times\{t\}}\colon i(A) \times \{t\} \ \to \ A \times \{t\}$$

is an inverse to the map $i \times \mathrm{id}_{\{t\}}\colon A \times \{t\} \to X \times \{t\}$. This implies that the map $i \times \mathrm{id}_{\{t\}}\colon A \times \{t\} \to X \times \{t\}$ is an embedding, but this also implies that the map $i\colon A \to X$ is an embedding.

(3) Note that

$$\begin{array}{ccl} & & \text{for } x \in A \text{ we have } F(x,0) = G(x,0) = [(x,1)] = [x] \text{ by construction of } F, \text{ furthermore} \\ & & \text{for } x \notin A \text{ the point } [x] \text{ does not lie in } \mathrm{Cyl}(i), \text{ thus it does not lie in the image of } F \\ A & \overset{\downarrow}{=} & \{x \in X \mid F(x,0) = [x]\} \\ & = & \left\{ \begin{array}{l} \text{the points in } X \text{ on} \\ \text{which the maps} \end{array} \begin{array}{ccc} X & \to & \mathrm{Cyl}(i) \\ x & \mapsto & F(x,0) \end{array} \text{ and } \begin{array}{ccc} X & \to & \mathrm{Cyl}(i) \\ x & \mapsto & [x] \end{array} \text{ agree} \right\}. \end{array}$$

It follows from this description of A, our hypothesis that X is Hausdorff (which implies by (2) and the Mapping Cylinder Basics Lemma 16.10 (2) that $\mathrm{Cyl}(i)$ is also Hausdorff) and Exercise 2.33 that A is indeed a closed subset of X. ∎

The following lemma shows that inclusion maps that are cofibrations are particularly nicely behaved.

Lemma 17.7. (Cofibration-Quotient Lemma) Let X be a topological space and let $A \subset X$ be a non-empty subset. We denote by $i\colon A \to X$ the inclusion map. If i is a closed cofibration, then the following three statements hold:

(1) The map[184]

$$\begin{array}{rcl} \varphi\colon \mathrm{Cone}(i\colon A \to X) & \to & X/A \\ P & \mapsto & \begin{cases} [P], & \text{if } P \in X, \\ [A], & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1] \end{cases} \end{array}$$

is a homotopy equivalence.

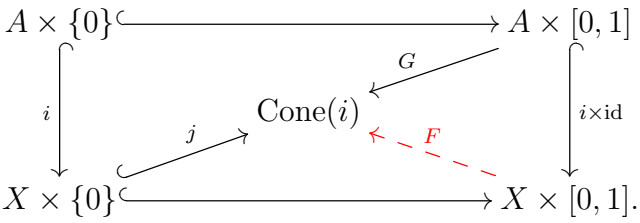
(2) If A is contractible, then the projection $X \to X/A$ is a homotopy equivalence.

(3) If $a_0 \in A$ is a point such that $\{a_0\}$ is a deformation retract of A, then the projection $X \to X/A$ is a homotopy equivalence between the pointed topological spaces (X, a_0) and $(X/A, [A])$.

Remark. The statement of the Cofibration-Quotient Lemma 17.7 (2) is related in spirit to the statement of Proposition 70.5.

Proof. Let X be a topological space and let $A \subset X$ be a closed subset such that the inclusion $i\colon A \to X$ is a cofibration.

(1) Similar to the proof of the Cofibration-Closed Injective Lemma 17.6 (1) we consider the following two maps:



(a) First of all we consider the obvious inclusion map $j\colon X \times \{0\} \to \mathrm{Cone}(i)$ which is given by $j(x,0) = x$.

(b) We consider the map

$$\begin{array}{rcl} G\colon A \times [0,1] & \to & \mathrm{Cone}(i) \\ (a,s) & \mapsto & [(a, 1-s)]. \end{array}$$

Note that G_1 sends all points in A to the cone point.

We obtain the following diagram:

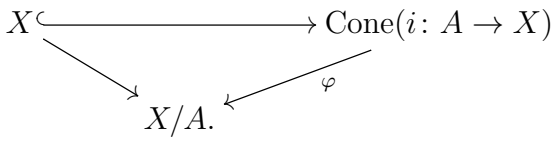
One easily verifies that the diagram commutes. Since i is a cofibration we obtain a map $F\colon X \times [0,1] \to \mathrm{Cone}(i)$ which makes the diagram commute. Note that the map $F_1\colon X \to \mathrm{Cone}(i)$ sends all points in A to the cone point. Thus F_1 descends to a map $\psi\colon X/A \to \mathrm{Cone}(i)$. It remains to prove the following claim.

Claim. The maps $\varphi\colon \mathrm{Cone}(i) \to X/A$ and $\psi\colon X/A \to \mathrm{Cone}(i)$ are homotopy inverses of one another.

[184]It follows from the ever popular Pasting Proposition 2.6 (2) and the fact that A is a closed subset of X that the map φ is continuous.

Proof. Note that $F(A \times [0,1]) = G(A \times [0,1]) \subset A$. Therefore it follows from Lemma 14.8 that the map

$$H\colon (X/A) \times [0,1] \xrightarrow{([x],t)\mapsto[(x,t)]} (X \times [0,1])/(A \times [0,1]) \xrightarrow{[(x,t)]\mapsto[F(x,t)]} X/A$$



is continuous. It follows immediately from the definitions that H is a homotopy between $\mathrm{id}_{X/A}$ and $\varphi \circ \psi$.

Conversely we consider the map

$$\begin{array}{rcl} H\colon \mathrm{Cone}(i) \times [0,1] & \to & \mathrm{Cone}(i) \\ (P,s) & \mapsto & \begin{cases} F(P,s), & \text{if } P \in X, \\ [a,(1-s)\cdot t], & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1]. \end{cases} \end{array}$$

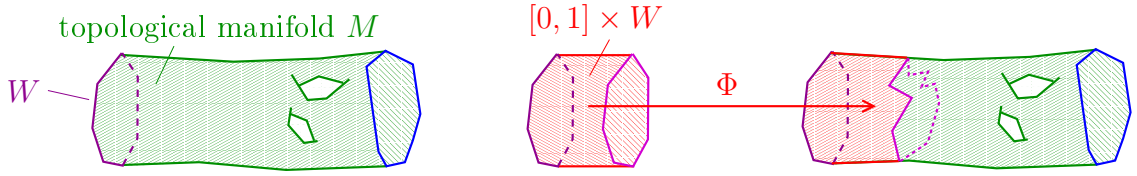
One easily verifies that this is a homotopy from $\mathrm{id}_{\mathrm{Cone}(i)}$ to $\psi \circ \varphi$. ⊞

(2) We consider the following diagram

It follows immediately from the definition of φ that this diagram commutes. Now suppose that A is contractible. By Proposition 16.18 (1) there exists a deformation retraction G from $\mathrm{Cone}(i\colon A \to X)$ to X. By Statement (1) we know that φ is a homotopy equivalence. Thus it follows from the Homotopy-Equivalence Basics Lemma 15.1 (1) that the map $X \to X/A$ is a homotopy equivalence.

(3) Now assume that $a_0 \in A$ is a point which has the property that $\{a_0\}$ is a deformation retract of A. By Proposition 16.18 (2) there exists a deformation retraction G from $\mathrm{Cone}(i\colon A \to X)$ to X such that for any $t \in [0,1]$ we have $G_1([(a_0,t)]) = a_0$. Next we point out that the homotopy equivalence H from (1) has the property that $H(a_0,t) = [(a_0,1-t)]$. If one combines these observations with the argument in (2) it is not difficult to see that the projection is in fact a homotopy equivalence of the pointed topological spaces (X,a_0) and $(X/A,[a_0])$. ■

17.3. **"Real-life" Examples of cofibration.** In future chapters we will discuss many interesting types of topological spaces, e.g. smooth and topological manifolds, CW-complexes and simplicial complexes. To make the search for results less confusing we now list several settings that give rise to cofibrations, even though we have not introduced the concepts yet.



On page 511 we will introduce the notion of a topological manifold M and its boundary ∂M and on page 543 we will introduce the notion of a smooth manifold M and its boundary ∂M. At this state we will not give the definitions, but in the figure below we show a cartoon version of a 2-dimensional topological manifold and of a 2-dimensional smooth manifold which hopefully gives the reader an idea of the concept.

Proposition 17.8. (Manifold Boundary-Cofibration Proposition) Let M be a topological manifold. For any union W of components of ∂M the inclusion $i\colon W \to M$ is a closed cofibration.

Proof. Let M be a topological manifold and let W be a union of components of ∂M. It follows from the Topological Collar Neighborhood Theorem 75.5[185] that there exists a map $\Phi\colon [0,1]\times W \to M$ with the following four properties:

(1) The map Φ is an embedding.
(2) The image of $[0,1)\times W$ is an open subset of M.
(3) For every $P\in W$ we have $\Phi(0,P)=P$.
(4) The image of $[0,1]\times W$ is a closed subset of M.

Recall that in Lemma 17.4 we saw that there exists a retraction

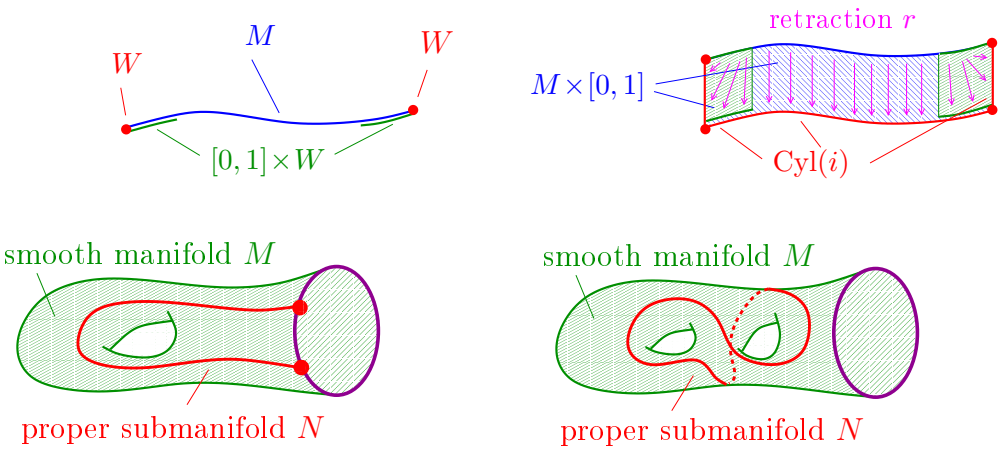
$$\varphi=(\varphi_1,\varphi_2)\colon [0,1]\times[0,1] \;\to\; (\{0\}\times[0,1])\cup([0,1]\times\{0\})$$

that has the property that $\varphi(\{1\}\times[0,1])=\{(1,0)\}$. We consider the map[186]

$$r\colon M\times[0,1] \;\to\; \mathrm{Cyl}(i)=((W\times[0,1])\sqcup M)/\!\sim \quad \text{where } (x,1)\sim x \text{ for } x\in W$$

$$(P,t) \;\mapsto\; \begin{cases} (\Phi(\underbrace{z\cdot\varphi_1(s,t),Q}_{\in\Phi([0,1]\times W)}),\varphi_2(s,t)), & \text{if } P=\Phi(s,Q) \text{ with } s\in[0,1] \text{ and } Q\in W,\\ P, & \text{if } P\in M\setminus\Phi([0,1)\times W). \end{cases}$$

(We refer to the figure below for an illustration of the map r.) One can easily verify that r is a left-inverse to the map $s\colon \mathrm{Cyl}(i)\to M\times[0,1]$ that we had considered in the Cofibration Characterization Lemma 17.2 (2). Thus it follows from the Cofibration Characterization Lemma 17.2 that $i\colon W\to M$ is a cofibration. Finally it follows from the Topological Manifold Boundary Proposition 75.2 (4a) that the union W of boundary components of the topological manifold M is a closed subset.[187] It follows that $i\colon W\to M$ is in fact a closed cofibration. ∎

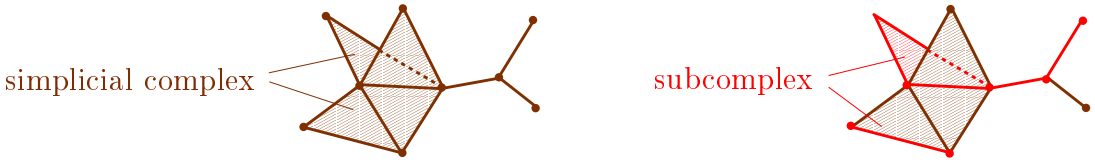


Next we turn to "proper submanifolds" of smooth manifolds. We will introduce this concept on page 550. In the figure below we again provide a cartoon to give the reader an idea what the concept of a "proper submanifold" is about.

---

[185] For smooth manifolds we could also use the Smooth Collar Neighborhood Theorem 28.3.

[186] Recall that by (2) and (4) the sets $\Phi([0,1]\times W)$ and $M\setminus\Phi([0,1)\times W)$ are actually closed subsets of M. It now follows from this observation together with the Basics-of-Collars Lemma 28.4 and Pasting Proposition 2.6 (2) that the map r is indeed continuous.

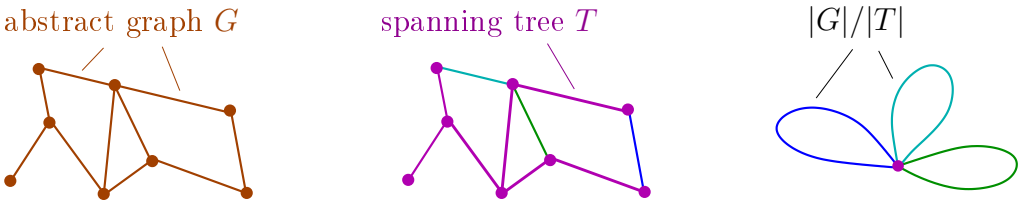


[187] See also the Smooth Manifold Boundary Proposition 19.26 (3a) for the corresponding statement for smooth manifolds which is much easier to prove.

Proposition ??. (Submanifold-Cofibration) Let M be a smooth manifold. For any compact proper submanifold N of M the inclusion $i\colon N \to M$ is a closed cofibration.

Proof. The proof of the Submanifold-Cofibration Proposition **??** relies on the General Tubular Neighborhood Theorem **??** which can be viewed as a submanifold analogue of the Topological Collar Neighborhood Theorem 75.5 and the Smooth Smooth Collar Neighborhood Theorem 28.3. Since the General Tubular Neighborhood Theorem **??** is more delicate to formulate we refrain from doing so right now and we refer to the impatient reader to the proof of the Submanifold-Cofibration Proposition **??** on page **??**. ■

Finally we turn to CW-complexes and simplicial complexes. We will define the notion of a CW-complex on page 1478 and we will define the notion of a simplicial complex on page 1994. As we will see on pages 1484 and 1995 there are also natural notions of subcomplexes. We will not give any of the definitions. But as an illustration we show in the figure below a simplicial complex together with a subcomplex.



We also point out that a topological graph, as defined on page 310, is essentially the same as a 1-dimensional CW-complex and that by the Simplicial-Implies-CW Lemma 93.24 every simplicial (sub-) complex is a CW- (sub-) complex.
The following theorem gives us one of the most important examples of a cofibration.

Theorem 17.9. (Subcomplex Cofibration Theorem) Let X be a CW-complex or a simplicial complex or a topological graph. Given any subcomplex A (or subgraph A) the corresponding inclusion map $i\colon A \to X$ is a closed cofibration.

Proof. By the Simplicial-Implies-CW Lemma 93.24 we only need to consider the case of a CW-complex. In this setting the desired statement is precisely the statement of the Homotopy Extension Theorem 70.1. The special case that X is the topological realization of a graph will also be dealt with in Exercise 17.4. ■

Proposition 17.10. (Graph-mod-Tree Proposition) Let $G = (V, E, i, t)$ be a finite connected non-empty abstract graph in the sense of the definition on page 307.

(1) There exists spanning tree T for G.
(2) The quotient $|G|/|T|$ is naturally homeomorphic to the topological realization of a finite abstract graph that has a single vertex.
(3) The projection $|G| \to |G|/|T|$ is a homotopy equivalence.

Remark. In Proposition 50.15 we will give a hands-on proof of the Graph-mod-Tree Proposition 17.10 that, for better or worse, does not use the language of cofibrations. In Proposition 70.4 we will generalize the Graph-mod-Tree Proposition 17.10 in a suitable sense to infinite graphs.

Proof. Let G be a finite connected non-empty abstract graph.

(1) By the Spanning Tree Existence Proposition 7.10 we know that G admits a spanning tree T and that T contains all vertices of G.
(2) As on page 321 we consider the corresponding quotient abstract graph G/T. Since T contains all vertices of G we see that G/T is an abstract graph with a single vertex. By the Quotient Abstract Graph Lemma 7.14 we know that $|G/T|$ is homeomorphic to $|G|/|T|$.
(3) In Exercise 15.6 we showed, using Lemma 7.7, that topological realizations of trees are contractible. Furthermore by the Subcomplex Cofibration Theorem 17.9, or alternatively by Exercise 17.4, we know that the inclusion map $i\colon |T| \to |G|$ is a closed cofibration. Thus it follows from the above together with the Cofibration-Quotient Lemma 17.7 that the projection $|G| \to |G|/|T|$ is a homotopy equivalence. ■

17.4. **Products and cofibrations.** In this and the following two sections we collect several technical useful results on cofibrations. As stand-alone sections these are arguably not much fun to read. Thus it is better to move on and to come back to these three sections when the results are needed.

Proposition 17.11. (Product-Cofibration Proposition)

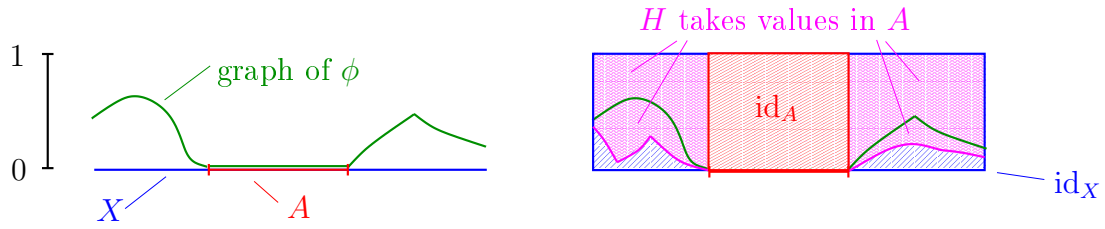
(1) If $f\colon A \to X$ and $g\colon B \to Y$ are two (closed) cofibrations, then the product map $f \times g\colon A \times B \to X \times Y$ is also a (closed) cofibration.
(2) If $f\colon A \to X$ is a (closed) cofibration and if Z is a topological space, then the resulting map $f \times \mathrm{id}_Z\colon A \times Z \to X \times Z$ is also a (closed) cofibration.

Example. Let I be an interval and let $P \in I$. On page 479 we saw that the inclusion $\{P\} \to I$ is a cofibration. It follows from the Product-Cofibration Proposition 17.11 that given any topological space Z the inclusion $\{P\} \times Z \to I \times Z$ is a cofibration.

Proof. It is clear that Statement (2) is an immediate consequence of Statement (1). Thus it remains to prove Statement (1). Now let $f\colon A \to X$ and $g\colon B \to Y$ be two cofibrations,

By the Cofibration-Closed Injective Lemma 17.6 we can assume that $f\colon A \to X$ and $g\colon B \to Y$ are both inclusions. We point out that by the Cofibration Characterization Lemma 17.2 (1) $\Rightarrow$ (3) there exist retractions $r\colon X \times [0,1] \to (X \times \{0\}) \cup (A \times [0,1])$ and $s\colon Y \times [0,1] \to (Y \times \{0\}) \cup (B \times [0,1])$. We denote by $r =: (r_X, r_{[0,1]})$ the coordinate functions of r viewed as a map with values in $X \times [0,1]$. Similarly we define $s =: (s_Y, s_{[0,1]})$. Next we consider the map

$$\begin{array}{rcl} (X \times Y) \times [0,1] & \to & ((X \times Y) \times \{0\}) \cup ((A \times B) \times [0,1]) \\ ((x,y),t) & \mapsto & \big(\underbrace{(r_X(x,t), s_Y(y,t))}_{\in X \times Y}, \underbrace{\tfrac{1}{2}(r_{[0,1]}(x,t) + s_{[0,1]}(y,t))}_{\in [0,1]}\big). \end{array}$$



One can easily verify that this map is a retraction. It follows from the Cofibration Characterization Lemma 17.2 (3) $\Rightarrow$ (1) that $f \times g\colon A \times B \to X \times Y$ is indeed a cofibration.

If f and g are in fact closed cofibrations, then it follows from the Product-of-Subsets Lemma 5.5 (1) and the above that $f \times g$ is also a closed cofibration. ∎

We continue with the following characterization of closed cofibrations that we initially proved in [**Strø1966, Strø1968**].

Theorem 17.12. (Strom's Cofibration Characterization Theorem) Let X be a topological space and let A be a closed subset. The following two statements are equivalent:

(1) The inclusion $i\colon A \to X$ is a cofibration.
(2) There exists a map $\phi\colon X \to [0,1]$ such that $A = \phi^{-1}(0)$ and there exists a homotopy $H\colon X \times [0,1] \to X$ rel A such that $H_0 = \mathrm{id}_X$ and such that $H(x,t) \in A$ whenever $t > \phi(x)$.

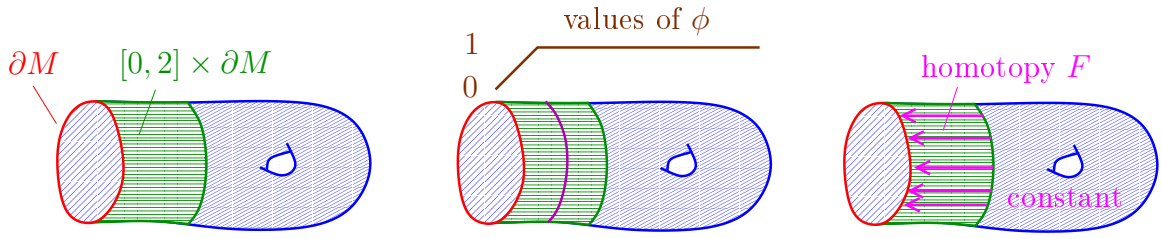
Remark.

(1) We continue with the notation of the above Strom's Cofibration Characterization Theorem 17.12. We consider the open subset $U := \phi^{-1}([0,1))$. The homotopy H restricts to a homotopy $K\colon U \times [0,1] \to X$ rel A with $K_0 = \mathrm{id}$ and with $K_1(U) \subset A$. This almost sounds like A is a deformation retract of U, but the given situation is somewhat looser, since K can take values outside of U.
(2) Sometimes a topological space X together with a closed subset A that admit H and ϕ as in Strom's Cofibration Characterization Theorem 17.12 (2) is called a *neighborhood deformation retract pair*, or short, *NDR-pair*.
(3) Let X be a topological space and let $x_0 \in X$. The pointed space (X, x_0) is called *well-pointed* if the inclusion $\{x_0\} \to X$ is a cofibration. If (X, x_0) is well-pointed, then in most practical situations the point $x_0 \in X$ is good in the sense of the definition

on page 1171. Nonetheless, as discussed in

https://mathoverflow.net/questions/87387/

it is not necessarily the case that x_0 is good.



Example. Let M be a topological manifold. As in the proof of the Manifold Boundary-Cofibration Proposition 17.8 we appeal to the Topological Collar Neighborhood Theorem 75.5 to obtain a collar neighborhood $[0,2] \times \partial M$ of ∂M. Next we consider the maps

$$\begin{array}{rcl} \phi\colon M & \to & [0,1] \\ P & \mapsto & \begin{cases} s, & \text{if } P=(Q,s) \text{ with } Q \in \partial M \text{ and } t \in [0,1], \\ 1, & \text{otherwise} \end{cases} \end{array}$$

and

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & M \\ (P,t) & \mapsto & \begin{cases} (Q, \frac{2(s-t)}{2-t}), & \text{if } P=(Q,s) \text{ with } Q \in \partial M \text{ and } s \in [t,2], \\ (Q,0), & \text{if } P=(Q,s) \text{ with } Q \in \partial M \text{ and } s \in [0,t], \\ P, & \text{otherwise.} \end{cases} \end{array}$$

One can easily verify that the conditions of Strom's Cofibration Characterization Theorem 17.12 are satisfied. This gives basically a new proof of the Manifold Boundary-Cofibration Proposition 17.8.

Proof. First we deal with the "(1)⇒(2)"-direction. Thus we suppose that $i\colon A \to X$ is a cofibration. Note that by the Cofibration Characterization Lemma 17.2 (1)⇒(3) we know that there exists a retraction $r\colon X \times [0,1] \to (X \times \{0\}) \cup (A \times [0,1])$. We denote the two coordinate functions of r, viewed as a map with values in $X \times [0,1]$, by $r_X\colon X \times [0,1] \to X$ and $r_{[0,1]}\colon X \times [0,1] \to [0,1]$. We consider the following two maps:

$$\begin{array}{rcl} \phi\colon X & \to & [0,1] \\ x & \mapsto & \max\limits_{t \in [0,1]} |t - r_{[0,1]}(x,t)| \end{array} \quad \text{and} \quad \begin{array}{rcl} H\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & r_X(x,t). \end{array}$$

Note that by definition of a retraction we have $H_0 = \mathrm{id}_X$.

Claim 1. The map ϕ is well-defined and continuous.

Proof. We consider the map $\theta\colon X \times [0,1] \to [0,1]$ that is given by $\theta(x,t) := |t - r_{[0,1]}(x,t)|$. Since $[0,1]$ is compact and since θ is continuous we obtain from the Compact Image Lemma 2.13 (2) that θ assumes a maximum, hence ϕ is well-defined.

It remains to show that $\phi\colon X \to [0,1]$ is continuous. Let V be an open subset of $[0,1]$. By the JH-Lemma 1.7 it suffices to show that given any $x_0 \in \phi^{-1}(V)$ there exists an open neighborhood U of x_0 with $U \subset \phi^{-1}(V)$. First we consider the case that $\phi(x_0) \in (0,1)$. This implies that we can pick $\epsilon > 0$ such that $(\phi(x_0) - \epsilon, \phi(x_0) + \epsilon) \subset V$. Note that by

definition of ϕ and θ we have $\theta(\{x_0\} \times [0,1]) \subset [0, \phi(x_0)]$. Since $[0,1]$ is compact and since $[0, \phi(x_0) + \epsilon)$ is an open subset of $[0,1]$ we obtain from Exercise 5.9 that there exists an open neighborhood U_1 of $x_0 \in X$ such that

$$\{x_0\} \times [0,1] \ \subset \ U_1 \times [0,1] \ \subset \ \theta^{-1}([0, \phi(x_0) + \epsilon)).$$

Hence, for every $x \in U_1$ we have $\phi(x) \leq \phi(x_0) + \epsilon$. Next suppose we are given $t_0 \in [0,1]$ such that $\theta(x_0, t_0) \in (\phi(x_0) - \epsilon, \phi(x_0) + \epsilon)$. By definition of the product topology there exists an open subset $U_2 \subset X$ such that

$$(x_0, t_0) \ \in \ U_2 \times \{t_0\} \ \subset \ \theta^{-1}((\phi(x_0) - \epsilon, \phi(x_0) + \epsilon)).$$

Note that this implies that for every $x \in U_2$ we have $\phi(x) \geq \phi(x_0) - \epsilon$. In particular we see that $U_1 \cap U_2 \subset \phi^{-1}((\phi(x_0) - \epsilon, \phi(x_0) + \epsilon)) \subset V$. Basically the same argument also works if $\phi(x_0) = 0$ or $\phi(x_0) = 1$. ⊞

Claim 2. We have $A = \phi^{-1}(0)$.

Proof. First let $x \in A$. Since r is a retraction we know that $r(x,t) = (x,t)$ for all $t \in [0,1]$. This means that $r_{[0,1]}(x,t) = t$ for all $t \in [0,1]$. Thus we see that $\phi(x) = 0$. Conversely, suppose that we have $x \in X$ with $\phi(x) = 0$. One easily verifies that this implies that for every $t > 0$ we have $r(x,t) \in A \times [0,1]$, in other words, we have $\{x\} \times (0,1] \subset r^{-1}(A \times [0,1])$. Since $A \times [0,1]$ is a closed subset of $X \times [0,1]$ we see that the closure of $\{x\} \times (0,1]$ is contained in $r^{-1}(A \times [0,1])$. But the closure is precisely $\{x\} \times [0,1]$. Thus we have shown that $\{x\} \times [0,1]$ also belongs to $r^{-1}(A \times [0,1])$. But this implies that $x \in A$. ⊞

It remains to prove the following claim.

Claim 3. Given $(x,t) \in X \times [0,1]$ with $t > \phi(x)$ we have $H(x,t) \in A$.

Proof. So suppose we are given $(x,t) \in X \times [0,1]$ with $t > \phi(x)$. Note that this implies that $t > \phi(x) \geq |t - r_{[0,1]}(x,t)|$. This is only possible if $r_{[0,1]}(x,t) > 0$. Thus we see that $r(x,t) \in A \times [0,1]$. This implies that $H(x,t) \in A$. This concludes the proof of the claim and thus completes the proof of the "(2)⇒(1)"-direction.

Finally we provide the proof for the "(1)⇒(2)"-direction. Given $\phi\colon X \to [0,1]$ and the homotopy $H\colon X \times [0,1] \to X$ we consider the map

$$\begin{array}{rcl} r\colon X \times [0,1] & \to & (X \times \{0\}) \cup (A \times [0,1]) \\ (x,t) & \mapsto & (H(x,t), \max\{t - \phi(x), 0\}). \end{array}$$

One can easily verify that this map is indeed a retraction. Thus it follows from the Cofibration Characterization Lemma 17.2 (3)⇒(1) that the inclusion $i\colon A \to X$ is a cofibration. ■

Proposition 17.13. Let $A \subset X$ and $B \subset Y$ be subsets of topological spaces. If the inclusion maps $i\colon A \to X$ and $j\colon B \to Y$ are closed cofibrations, then the inclusion map

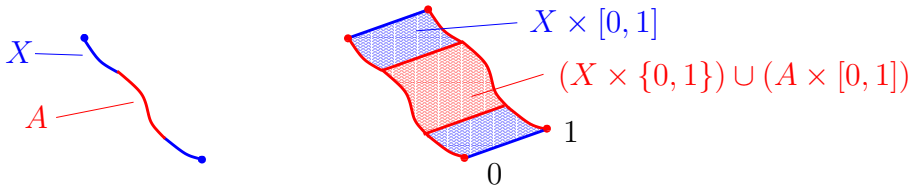
$$(A \times Y) \cup (X \times B) \ \to \ X \times Y$$

is also a closed cofibration.

Remark. In Exercise 17.7 we will see that the conclusion of Proposition 17.13 does not hold, if neither A nor B are closed subsets.

Proof. Since i and j are closed cofibrations we can pick maps $\phi\colon X \to [0,1]$, $\psi\colon Y \to [0,1]$ and homotopies $G\colon X \times [0,1] \to X$ and $H\colon Y \times [0,1] \to Y$ as in Strom's Cofibration Characterization Theorem 17.12. We consider the maps

$$\begin{array}{rcl} \gamma\colon X \times Y & \to & [0,1] \\ (x,y) & \mapsto & \min\{\phi(x), \psi(y)\} \end{array}$$



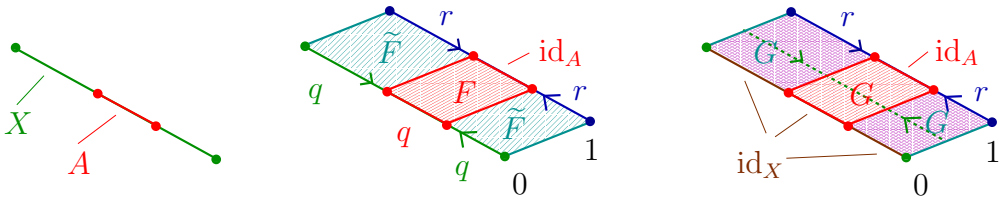
and

$$\begin{array}{rcl} K\colon (X \times Y) \times [0,1] & \to & X \times Y \\ ((x,y),t) & \mapsto & (G(x, \min\{t, \psi(y)\}), H(y, \min\{t, \phi(x)\})). \end{array}$$

It is easy to see that $\gamma^{-1}(0) = (X \times B) \cup (A \times Y)$. Next note that it is basically clear that $K_0 = \mathrm{id}$. Finally note that by construction we have $K((x,y),t) \in (A \times Y) \cup (X \times B)$, whenever $t > \gamma(x,y)$. Therefore it follows from Strom's Cofibration Characterization Theorem 17.12 that the inclusion map $(A \times X) \cup (X \times B) \to X \times Y$ is a closed cofibration. ■

Corollary 17.14. Let X be a topological space and let $A \subset X$ be a subset. If the inclusion $i\colon A \to X$ is a closed cofibration, then the inclusion $(X \times \{0,1\}) \cup (A \times [0,1]) \to X \times [0,1]$ is also a closed cofibration.

Proof. On page 479 we saw that the inclusion map $\{0,1\} \to [0,1]$ is a cofibration. It follows from this observation together with Proposition 17.13 that the given inclusion map is a closed cofibration. ■

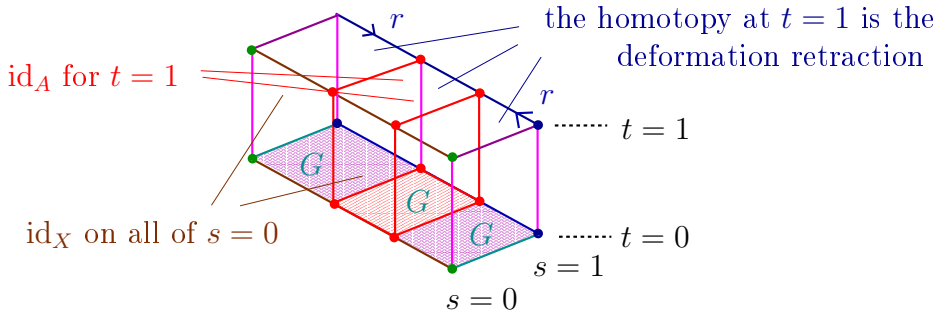


Proposition 17.15. (Homotopy Equivalence-Cofibration Proposition) Let $i\colon A \to X$ be a closed cofibration. If i is a homotopy equivalence, then $i(A)$ is a deformation retract of X.

Proof. Let $i\colon A \to X$ be a cofibration. By the Cofibration-Closed Injective Lemma 17.6 we can assume that A is a closed subset of X and that $i\colon A \to X$ is the inclusion. Let $q\colon X \to A$ be a homotopy inverse of i. Recall that this means that $q \circ i = q\colon A \to A$ is homotopic to id_A and $i \circ q$ is homotopic to id_X.

We pick a homotopy $F\colon A \times [0,1] \to A$ from $q \circ i = q\colon A \to A$ to id_A. Since $i\colon A \to X$ is a cofibration we can extend the map $q\colon X \to A$ on X and the homotopy $F\colon A \times [0,1] \to A$ to a homotopy $\widetilde{F}\colon X \times [0,1] \to A$. Note that $\widetilde{F}_1|_A = F_1|_A = \mathrm{id}_A$, in other words, $\widetilde{F}_1\colon X \to A$ is a retraction. We write $r := \widetilde{F}_1\colon X \to A \subset X$.

Note that $r\colon X \to X$ is homotopic to $q = i \circ q\colon X \to X$ which in turn is homotopic to id_X. Thus it follows from Lemma 14.5 (1) that there exists a homotopy G from id_X to r.

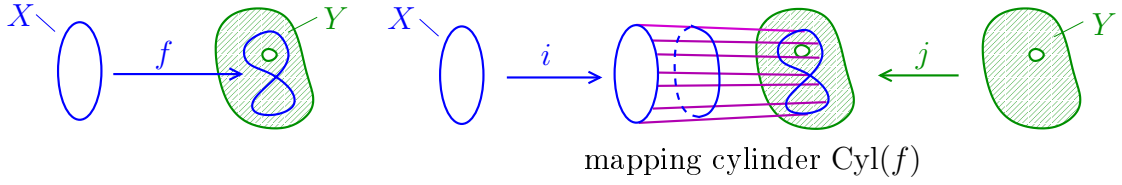


Now we consider the following map

$$\begin{array}{rcl} K\colon ((X\times\{0,1\})\cup(A\times[0,1]))\times[0,1] & \to & X \\ (x,s,t) & \mapsto & \begin{cases} x, & \text{if } s=0, \\ G(r(x),1-t), & \text{if } s=1, \\ G(x,(1-t)s), & \text{if } x\in A, \\ G(x,s), & \text{if } t=0. \end{cases} \end{array}$$

It follows easily from the hypothesis that A is a closed subset together with Pasting Proposition 2.6 (2) that the map is continuous.

By Corollary 17.14 we know that $(X\times\{0,1\})\cup(A\times[0,1])\to X\times[0,1]$ is a cofibration. Thus we can extend the homotopy K to a homotopy $\widetilde{K}\colon (X\times[0,1])\times[0,1]\to X$. The map $\widetilde{K}_1\colon X\times[0,1]\to X$ is now a homotopy rel A from id_X to the retraction r. We have thus shown that A is a deformation retract of X. ∎



The Homotopy Equivalence-Cofibration Proposition 17.15 admits two interesting corollaries. Since both involve mapping cylinders, let us recall the definition. Given a map $f\colon X\to Y$ between topological spaces we set

$$\mathrm{Cyl}(f) := ((X\times[0,1])\sqcup Y)/\!\sim \text{ where } (x,1)\sim f(x) \text{ for all } x\in X.$$

Furthermore we consider the natural inclusions

$$\begin{array}{rcl} i\colon X & \to & \mathrm{Cyl}(f) \\ x & \mapsto & [(x,0)] \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon Y & \to & \mathrm{Cyl}(f) \\ y & \mapsto & [y] \end{array}$$

The first corollary to the Homotopy Equivalence-Cofibration Proposition 17.15 is a strengthening of the Mapping Cylinder Basics Lemma 16.12 (2b).

Corollary 17.16. Let $f\colon X\to Y$ be a map between two topological spaces. The following two statements are equivalent:

(1) f is a homotopy equivalence,
(2) $i(X)$ is a deformation retract of $\mathrm{Cyl}(f)$.

Proof. By the Mapping Cylinder Basics Lemma 16.12 (2b) we know that the following two statements are equivalent:

(1) f is a homotopy equivalence,
(2′) $i\colon X \to \mathrm{Cyl}(f)$ is a homotopy equivalence.

Thus it remains to show that (2) and (2′) are equivalent. By the Deformation Retract-Homotopy Equivalence Lemma 15.5 we know that the "(2)⇒(2′)"-implication holds. It remains to prove the "(2′)⇒(2)"-direction. Thus we assume that $i\colon X \to \mathrm{Cyl}(f)$ is a homotopy equivalence. By the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 we know that the natural inclusion $i\colon X \to \mathrm{Cyl}(f)$ is a closed cofibration. But now it follows from the Homotopy Equivalence-Cofibration Proposition 17.15 that $i(X)$ is indeed a deformation retract of X. ■

Corollary 17.17. Let X and Y be two topological spaces. The following two statements are equivalent:

(1) X and Y are homotopy equivalent.
(2) There exists a topological space W and two closed embeddings $i\colon X \to W$ and $j\colon Y \to W$ such that $i(X)$ is a deformation retract of W and $j(Y)$ is a deformation retract of W.

Proof. The "(2)⇒(1)"-direction is just a consequence of the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the fact that being homotopy equivalent is an equivalence relation, see the Homotopy-Equivalence Basics Lemma 15.1 (2).

We turn to the proof of the "(1)⇒(2)"-direction. Thus we now assume that X and Y are homotopy equivalent. Let $f\colon X \to Y$ be a homotopy equivalence. We consider the corresponding mapping cylinder $\mathrm{Cyl}(f)$. By the Mapping Cylinder Basics Lemma 16.10 we know that the natural inclusions $i\colon X \to \mathrm{Cyl}(f)$ and $j\colon Y \to \mathrm{Cyl}(f)$ are closed embeddings. In the Mapping Cylinder Basics Lemma 16.12 we showed that $j(Y)$ is always, regardless of the choice of f, a deformation retract of $\mathrm{Cyl}(f)$. Finally, since $f\colon X \to Y$ is by hypothesis a homotopy equivalence we now know by Corollary 17.16 that $i(X)$ is a deformation retract of $\mathrm{Cyl}(f)$. ■

17.5. **Push-outs and cofibrations.** In this section we will consider the relationship between cofibrations and pushouts. We recall the following notation from page 1260.

Notation. Let $f\colon A \to X$ and $g\colon A \to Y$ be two maps between topological spaces. We write

$$X \cup_A Y \;:=\; (X \sqcup Y)/\!\sim \qquad \text{where } f(a) \sim g(a) \text{ for all } a \in A.$$

We refer to $X \cup_A Y$ as the pushout of f and g.

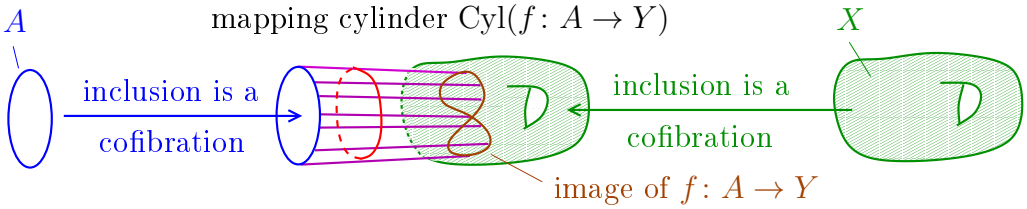
The next proposition continues a theme that we already encountered in the Pushout Lemma 4.8 and the Topological Pushout-Maps Lemma 5.34.

Proposition 17.18. (Opposite Map-Cofibration Proposition) Let $f\colon A \to X$ and $g\colon A \to Y$ be two maps between topological spaces. We consider the corresponding

pushout diagram

$$\begin{array}{ccc} A & \xrightarrow{f} & X \\ {\scriptstyle g}\downarrow & & \lrcorner\downarrow{\scriptstyle i} \\ Y & \xrightarrow{j} & X \cup_A Y. \end{array}$$

The following two statements hold:



(1) If f is a (closed) cofibration, then the "opposite map" $j\colon Y \to X \cup_A Y$ is also a (closed) cofibration.
(2) If f is a closed cofibration and if f is a homotopy equivalence, then the "opposite map" $j\colon Y \to X \cup_A Y$ is also a homotopy equivalence.

The same statements hold, by symmetry, for g and the "opposite map" i.

Example. Let $f\colon A \to Y$ be a map between topological spaces. We consider the pushout diagram

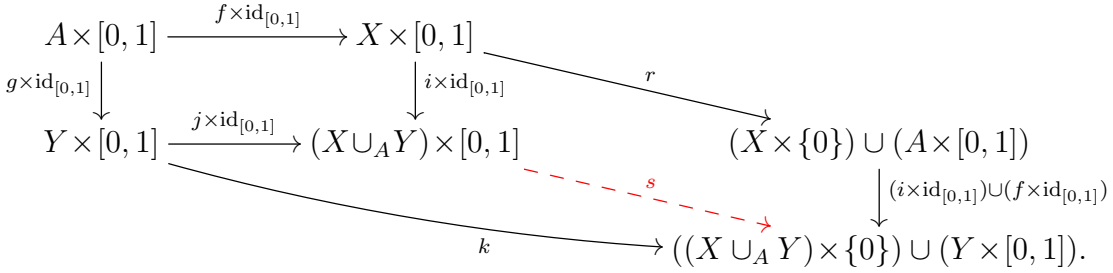
$$\begin{array}{ccc} A & \xrightarrow{a\mapsto(a,0)} & A \times [0,1] \\ {\scriptstyle f}\downarrow & & \lrcorner\downarrow{\scriptstyle i} \\ Y & \xrightarrow{j} & \underbrace{(A \times [0,1]) \cup_A Y}_{=\mathrm{Cyl}(f)}. \end{array}$$

By the discussion on page 488 we know that the top horizontal map is a cofibration. Thus it follows from the Opposite Map-Cofibration Proposition 17.18 that the natural inclusion $Y \to \mathrm{Cyl}(f\colon A \to Y)$ is a cofibration. Thus, together with the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 (1) we see that both the natural inclusions $A \to \mathrm{Cyl}(f\colon A \to Y)$ and $Y \to \mathrm{Cyl}(f\colon A \to Y)$ are cofibrations.

Proof. Throughout the proof we assume that $f\colon A \to X$ is a cofibration. By the Cofibration-Closed Injective Lemma 17.6 we can assume that A is a subspace of X and that $f\colon A \to X$ is the inclusion.

First we want to show that $j\colon Y \to X \cup_A Y$ is also a cofibration. Since f is a cofibration we know by the Cofibration Characterization Lemma 17.2 (1)⇒(3) that there exists a retraction

$$r\colon X \times [0,1] \;\to\; (X \times \{0\}) \cup (A \times [0,1]).$$



We introduce the following extra maps:

(1) We denote by $i\colon X \to X \cup_A Y$ and $j\colon Y \to X \cup_A Y$ the two natural maps.

(2) We consider the pushout diagram

$$\begin{array}{ccc} Y \times \{0\} & \longrightarrow & Y \times [0,1] \\ {\scriptstyle j\times \mathrm{id}}\downarrow & & \lrcorner \downarrow {\scriptstyle k} \\ ((X \cup_A Y) \times \{0\}) & \longrightarrow & ((X \cup_A Y) \times \{0\}) \cup (Y \times [0,1]). \end{array}$$

We denote by $k\colon Y \times [0,1] \to ((X \cup_A Y) \times \{0\}) \cup (Y \times [0,1])$ the natural map. Now we consider the following diagram:

We make the following observations:

(1) It follows immediately from the Topological Pushout-Maps Lemma 5.34 (3) that we can view $Y \times [0,1]$ as a subspace of $(X \cup_A Y) \times [0,1]$.

(2) The diagonal dashed map s comes from the fact, discussed on page 1264, that the pushout commutes with taking products with the regionally compact space $[0,1]$.

(3) It follows from (1) and (2) that we can view the map s as a retraction. Thus it follows from the Cofibration Characterization Lemma 17.2 that the map $Y \to X \cup_A Y$ is indeed a cofibration.

Finally note that if f is a closed cofibration, then it follows from the above together with the Topological Pushout-Maps Lemma 5.34 (4) that the map $Y \to X \cup_A Y$ is also a closed cofibration.

Now we assume that f is a closed cofibration and that it is a homotopy equivalence. We need to show that $j\colon Y \to X \cup_A Y$ is a homotopy equivalence. By the Topological Pushout-Maps Lemma 5.34 (3) we know that j is an embedding. By the Deformation Retract-Homotopy Equivalence Lemma 15.5 it now suffices to show that $j(Y)$ is a deformation retract of $X \cup_A Y$. By the Homotopy Equivalence-Cofibration Proposition 17.15 we know that there exists a deformation retraction $G\colon X \times [0,1] \to X$ from X to A. We consider the map

$$\begin{array}{rcl} H\colon (X \cup_A Y) \times [0,1] & \to & X \cup_A Y \\ ([P],t) & \mapsto & \begin{cases} i(G(Q),t), & \text{if } P = i(Q) \text{ with } Q \in X, \\ j(Q), & \text{if } P = j(Q) \text{ with } Q \in Y. \end{cases} \end{array}$$

It follows from the Homotopy Pushout Lemma 14.9 that this map is actually continuous. Now that we put our worries regarding continuity to rest it is clear that this map is a deformation retraction from $X \cup_A Y$ to $j(Y)$. ■

The following theorem is the main result of this chapter.

Theorem 17.19. (Homotopy Pushout Theorem) Suppose we are given the following commutative diagram of maps between topological spaces:

$$\begin{array}{ccccc} X & \xleftarrow{\ i\ } & A & \xrightarrow{\ f\ } & Y \\ \downarrow{\scriptstyle \varphi_X} & & \downarrow{\scriptstyle \varphi_A} & & \downarrow{\scriptstyle \varphi_Y} \\ X' & \xleftarrow{\ i'\ } & A' & \xrightarrow{\ f'\ } & Y'. \end{array}$$

If the vertical maps are homotopy equivalences and if the maps i and i' to the left are closed cofibrations, then the induced map

$$\begin{array}{rcl} X \cup_A Y & \to & X' \cup_{A'} Y' \\ [P] & \mapsto & \begin{cases} \varphi_X(P), & \text{if } P \in X, \\ \varphi_Y(P), & \text{if } P \in Y \end{cases} \end{array}$$

between the pushouts is a homotopy equivalence.

Remark. We outsource the proof, which follows quite closely the argument in [**Rap2016**], to the next section. Alternative proofs are given in [**BrownR1968**, p. 249], [**BrownR2006**, Proposition 7.5.7] and [**tD2008**, Proposition 5.3.4].

Proposition 17.20. Let $\varphi\colon Y \to Y'$ be a homotopy equivalence between two topological spaces. Furthermore let A be a topological space and let $f\colon A \to Y$ and $f'\colon A \to Y'$ be two maps such that $\varphi \circ f$ is homotopic to f'. Then there is a homotopy equivalence

$$\mathrm{Cone}(f\colon A \to Y) \ \to\ \mathrm{Cone}(f'\colon A \to Y')$$

Example. Let $f_0, f_1\colon A \to Y$ be two maps between topological spaces. If f_0 and f_1 are homotopic, then it follows immediately from Proposition 17.20, applied to the map $\varphi = \mathrm{id}\colon Y \to Y' = Y$, that the mapping cones $\mathrm{Cone}(f\colon A \to Y)$ and $\mathrm{Cone}(f'\colon A \to Y)$ are homotopy equivalent. Note that this recovers for the most part the statement of the Mapping Cone Homotopy Equivalent Proposition 16.15.

Proof. Let $F\colon A \times [0,1] \to Y'$ be a homotopy between $\varphi \circ f$ and f'. We consider the following commutative diagram

$$\begin{array}{ccccc} \mathrm{Cone}(A) & \xleftarrow{\quad} & A & \xrightarrow{\ f\ } & Y \\ \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \varphi} \\ \mathrm{Cone}(A) & \xleftarrow{\quad} & A & \xrightarrow{\ \varphi\circ f\ } & Y' \\ \downarrow{\scriptstyle x\mapsto(x,0)} & & \downarrow{\scriptstyle a\mapsto(a,0)} & & \downarrow{\scriptstyle y\mapsto(y,0)} \\ \mathrm{Cone}(A)\times[0,1] & \xleftarrow{\quad} & A\times[0,1] & \xrightarrow{\ (a,t)\mapsto(F(a,t),t)\ } & Y'\times[0,1] \\ \uparrow{\scriptstyle x\mapsto(x,1)} & & \uparrow{\scriptstyle a\mapsto(a,1)} & & \uparrow{\scriptstyle y\mapsto(y,1)} \\ \mathrm{Cone}(A) & \xleftarrow{\quad} & A & \xrightarrow{\ f'\ } & Y'. \end{array}$$

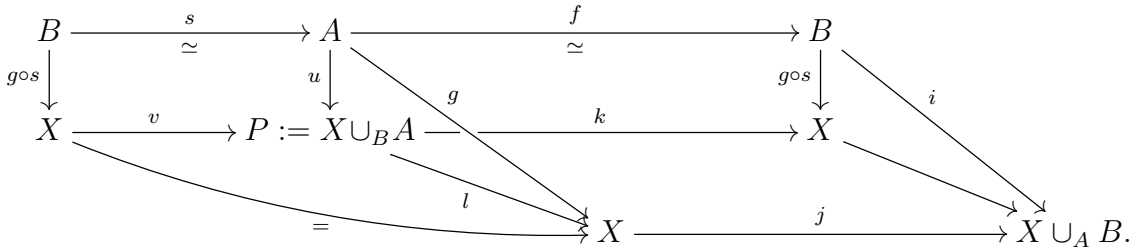
The vertical maps are evidently homotopy equivalences. Furthermore we know by the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 (2) and the Product-Cofibration Proposition 17.11 that the left horizontal maps are closed cofibrations. It follows from the Homotopy Pushout Theorem 17.19 together with the Homotopy-Equivalence Basics Lemma 15.1 (1) that the pushout on top is homotopy equivalence to the pushout at the

bottom. But the pushout on top is precisely $\mathrm{Cone}(f\colon A \to Y)$ and the pushout at the bottom is precisely $\mathrm{Cone}(f'\colon A \to Y')$. ■

Remark. Another typical application of the Homotopy Pushout Theorem 17.19 is given in the proof of the Handles-Cells Proposition 136.18 where we show that "handle attachments" and "cell attachments" lead to homotopy equivalent topological spaces.

17.6. **Proof of Theorem 17.19.** In this section we provide a proof of Theorem 17.19, following the argument of [**Rap2016**]. The least that can be said is that the proof is not for the faint of heart.

The following lemma is a key step towards the proof of Theorem 17.19.



Lemma 17.21. Let $f\colon A \to X$ and $g\colon A \to Y$ be two maps between topological spaces. We consider the corresponding pushout diagram

$$\begin{array}{ccc} A & \underset{f}{\overset{s}{\rightleftarrows}} & B \\ {\scriptstyle g}\downarrow & & \lrcorner\downarrow{\scriptstyle i} \\ X & \xrightarrow{\ j\ } & X \cup_A B. \end{array}$$

Let f be a homotopy equivalence. If g is a closed cofibration, and if there exists a map $s\colon B \to A$ with $f \circ s = \mathrm{id}_B$ and which is a closed cofibration, then the map "opposite to f", i.e. the map j is a homotopy equivalence.

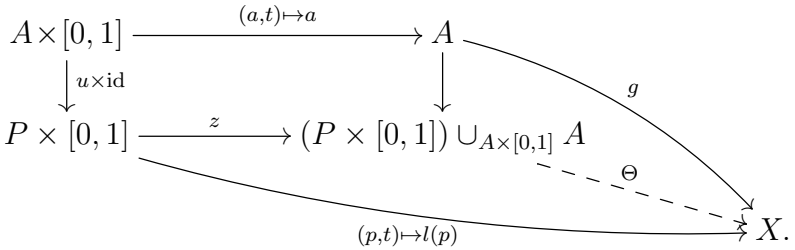
Remark. Sometimes it takes a while to spot the differences to earlier results. In the similar looking the Opposite Map-Cofibration Proposition 17.18 we had assumed that f is not only a homotopy equivalence but also a closed cofibration. Now we assume g is a closed cofibration and that we have the extra map s to play with.

Proof of Lemma 17.21. First note that it follows from the hypotheses that $f \circ s = \mathrm{id}_B$ and that f is a homotopy equivalence, together with the Homotopy-Equivalence Basics Lemma 15.1 (1), that s is also a homotopy equivalence. We consider the following diagram:

We make the following clarifications and observations:

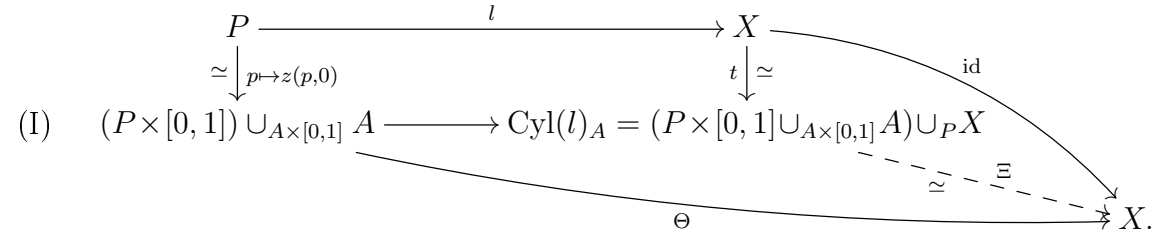
(1) To the top left we have a pushout square. In particular the maps $u\colon A \to X \cup_B A$ and $v\colon X \to X \cup_B A$ are the corresponding natural maps.
(2) The map $k\colon X \cup_B A \to X$ is defined via the identity on X and the map $g \circ s \circ f$ on A.

(3) It follows easily from the Pushout Lemma 4.8 (1) and (2)[188] that the square to the top right is a pushout diagram.
(4) The map $l\colon X \cup_B A \to X$ is defined via the identity on X and the map g on A.
(5) It follows easily from the definitions that the diagram commutes.
(6) Since s is a closed cofibration and a homotopy equivalence it follows from the Opposite Map-Cofibration Proposition 17.18 (2) that the map $v\colon X \to X \cup_B A$ is also a closed cofibration and a homotopy equivalence.
(7) Note that $k \circ v = \mathrm{id}_X$ and $l \circ v = \mathrm{id}_X$. Since v and id_X are homotopy equivalences we obtain from the Homotopy-Equivalence Basics Lemma 15.1 (1) that k and l are also homotopy equivalences.
(8) Since $g \circ s$ is a closed cofibration we obtain from the Opposite Map-Cofibration Proposition 17.18 (1) that the map u is also a closed cofibration.



Next we consider the following two pushout diagrams:

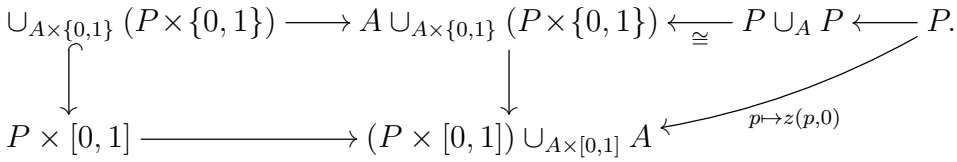
$$\begin{array}{ccc} P & \xrightarrow{l} & X \\ \downarrow{\scriptstyle p\mapsto(p,1)} & \simeq & \downarrow{\scriptstyle t} \\ (P\times[0,1]) \cup_{A\times[0,1]} A & \to & \underbrace{((P\times[0,1])\cup_{A\times[0,1]} A)\cup_P X}_{=:\mathrm{Cyl}(l)_A} \end{array} \quad \text{and} \quad \begin{array}{ccc} P = X\cup_B A & \xrightarrow{k} & X \\ \downarrow{\scriptstyle \varphi(p)=(p,1)} & \simeq & \downarrow{\scriptstyle m} \\ \mathrm{Cyl}(l)_A & \xrightarrow{w} & \mathrm{Cyl}(l)_A \cup_P X. \end{array}$$



Providing the proof of the following claim is the main difficulty in the proof of the lemma.

Claim. The map $w\colon \mathrm{Cyl}(l)_A \to \mathrm{Cyl}(l)_A \cup_P X$ is a homotopy equivalence.

Proof. To prove the claim we first consider the following pushout diagram:



We take the resulting map Θ and use it to produce the following even more confusing pushout diagram

[188]The Pushout Lemma 4.8 (2) implies that the natural map $X \cup_B B \to (X \cup_B \cup A) \cup_A \cup B$ is a homeomorphism and the Pushout Lemma 4.8 (1) implies that the natural map $X \to X \cup_B B$ is a homeomorphism. We will apply this type of argument on several occasions.

We continue with the following comments:

(9) We claim that the left-hand vertical map is a closed cofibration. To verify this statement we consider the following commutative diagram

We make a few comments:

(a) The left top horizontal map is induced by the projection $A \times [0,1] \to A$ and the identity on $P \times \{0,1\}$.

(b) The left vertical map is the "obvious" map. It is a closed cofibration by the combination of Corollary 17.14 with Lemma 5.36.

(c) The middle vertical map and the bottom horizontal map are the obvious maps.

(d) We leave it to the reader to verify that the square is in fact a pushout diagram.

(e) It follows from (b) and (d) together with the Opposite Map-Cofibration Proposition 17.18 that the middle vertical map is a closed cofibration.

(f) The map $P \cup_A P \to A \cup_{A\times\{0,1\}} (P \times \{0,1\})$ is given by sending the "left copy" of P to $P \times \{0\}$ and the "right copy" of P to $P \times \{1\}$. There is an obvious inverse which shows that this map is actually a homeomorphism.

(g) The map $P \to P \cup_A P$ is given by sending P to the "left copy" of P. Since $A \to P$ is a closed cofibration we obtain again from the Opposite Map-Cofibration Proposition 17.18 that the map $P \to P \cup_A P$ is a closed cofibration.

(h) It follows immediately from the definitions that the triangle to the right commutes. Thus we obtain from (e), (f) and (g) together with the Cofibration Composition Lemma 17.1 that the diagonal map is a closed cofibration. But that is precisely what we wanted to show.

(10) We claim that the left-hand vertical map $P \to (P \times [0,1]) \cup_{A\times[0,1]} A$ of (I) is a homotopy equivalence. This can be seen as follows. By (9) and the Cofibration-Closed Injective Lemma 17.6 we can identify P with its image under the inclusion. It follows from the Homotopy Pushout Lemma 14.9 that the obvious deformation retraction on $P\times[0,1]$ and the constant map on A give rise to a deformation retraction from $(P \times [0,1]) \cup_{A\times[0,1]} A$ to the image of P. Thus it follows from the elementary the Deformation Retract-Homotopy Equivalence Lemma 15.5 that the inclusion is indeed a homotopy equivalence.

(11) We consider the pushout square in (I). It follows from (9), (10) and the Opposite Map-Cofibration Proposition 17.18 (2) that the right-hand vertical map t in (I) is also closed cofibration and a homotopy equivalence.

(12) We deduce from (11) and the Homotopy-Equivalence Basics Lemma 15.1 (1) that Ξ is a homotopy equivalence.

Next we consider the following diagram:

(II)
$$\begin{array}{ccc} P = X \cup_B A & \xrightarrow[\simeq]{k} & X \\ {\scriptstyle\simeq}\downarrow{\scriptstyle \varphi(p)=(p,0)} & & \downarrow{\scriptstyle m} \\ \mathrm{Cyl}(l)_A & \xrightarrow{w} & \mathrm{Cyl}(l)_A \cup_P X \\ {\scriptstyle\simeq}\downarrow{\scriptstyle \Xi} & & \\ X. & & \end{array} \qquad (l : \mathrm{Cyl}(l)_A \to X)$$

We make the following clarifications and observations:

(13) $\mathrm{Cyl}(l)_A \cup_P X$ is the pushout of the pushout diagram to the to top.

(14) The composition $P \xrightarrow{\varphi} \mathrm{Cyl}(l)_A \xrightarrow{\Xi} X$ equals the map l.

(15) Since l is a homotopy equivalence and since we just saw that $\Xi\colon \mathrm{Cyl}(l)_A \to X$ is a homotopy equivalence we obtain again from the Homotopy-Equivalence Basics Lemma 15.1 (1) that $\varphi\colon P \to \mathrm{Cyl}(l)_A$ is a homotopy equivalence.

(16) We will now argue that the map $\varphi\colon P \to \mathrm{Cyl}(l)_A$ is a closed cofibration. To do so we consider the following diagram:

$$\begin{array}{ccc} & & P \\ & & \downarrow \\ (A \times [0,1]) \cup_{A\times\{0,1\}} (P \times \{0,1\}) & \longrightarrow & X \cup_A P \\ \downarrow & & \downarrow \\ P \times [0,1] & \longrightarrow & \mathrm{Cyl}(l)_A. \end{array} \qquad \varphi$$

We make the following observations:

(a) The top vertical map is a closed cofibration by the Opposite Map-Cofibration Proposition 17.18 and our hypothesis that $A \to X$ is a closed cofibration.

(b) The map $X \cup_A P \to \mathrm{Cyl}(l)_A$ is defined by t on X and by φ on P.

(c) The vertical map to the left is induced by the inclusions.

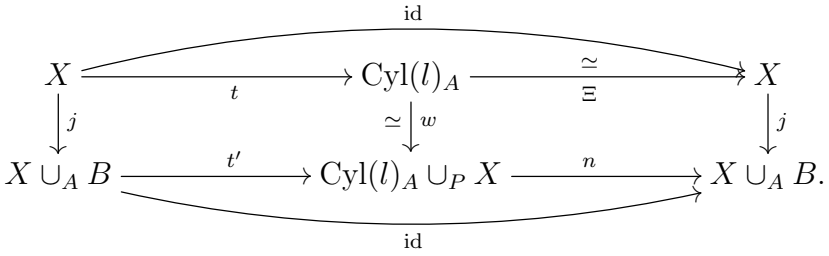
(d) The horizontal map on the top is induced by the projection $A \times [0,1] \to A$, the obvious identification $P \times \{0\} \to P$ and the map l on $P = P \times \{1\} \to X$.

(e) We consider the maps

$$(P \times [0,1]) \cup_{(A\times[0,1])\cup_{A\times\{0,1\}}(P\times\{0,1\})} (X \cup_A P) \;\leftrightarrow\; \underbrace{((P \times [0,1]) \cup_{A\times[0,1]} A) \cup_P X}_{=\mathrm{Cyl}(l)_A}$$

which are the obvious maps on $P \times [0,1]$, the obvious map on X and which going left-to-right is given by the obvious map $P \to P \times \{0\}$ and which right-to-left is given by the natural map $A \to X \cup_B A = P$. These maps are well-defined and inverses of one another, hence they are isomorphisms. These maps show that the square is a pushout diagram.

(f) It follows from Corollary 17.14 together with Lemma 5.36 that the left vertical map in the square is a closed cofibration.



(g) It follows (f) together with the Opposite Map-Cofibration Proposition 17.18 (1) that the right vertical map in the square is also a closed cofibration.

(h) By (a) and (g) the map of our desire is a composition of two closed cofibrations, hence it is itself a closed cofibration by the Cofibration Composition Lemma 17.1.

(17) It follows from (15) and (16) together with the Opposite Map-Cofibration Proposition 17.18 (2), applied the diagram (II), that the map $m\colon X \to \mathrm{Cyl}(l)_A \cup_P X$ is a homotopy equivalence.

(18) By (7), (15) and (17) we know that m, k, φ are homotopy equivalences. By the diagram (II) we have $w \circ \varphi = m \circ k$. Thus we obtain from the Homotopy-Equivalence Basics Lemma 15.1 (1) that w is also a homotopy equivalence. ⊞

Finally we consider the following diagram:

Here are the customary clarifications and observations:

(19) Recall that the map $t\colon X \to \mathrm{Cyl}(l)_A$ is the natural inclusion.

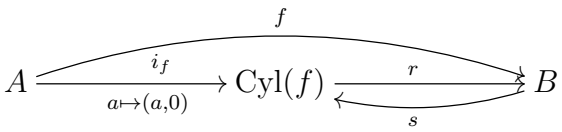
(20) By definition of t and Ξ we have $\Xi \circ t = \mathrm{id}_X$.

(21) The map $t'\colon X \cup_A B \to \mathrm{Cyl}(l)_A \cup_P X$ is defined by $w \circ t\colon X \to \mathrm{Cyl}(l)_A$ and it is defined by $m \circ g \circ s\colon B \to X$. Furthermore the map $n\colon \mathrm{Cyl}(l)_A \cup_P X \to X \cup_A B$ is defined by Ξ on $\mathrm{Cyl}(l)_A$ and by the natural map $j\colon X \to X \cup_A B$ on X.

(22) One can easily verify that $n \circ t' = \mathrm{id}_{X \cup_A B}$.

(23) It follows immediately from the definitions that the diagram commutes.

It follows from (20), (22) and (23) and the above commutative diagram that j is a retract of the map w, in the sense of the definition in Exercise 15.9. Since w is a homotopy equivalence we obtain from Exercise 15.9 that j is also a homotopy equivalence. We are done! ■

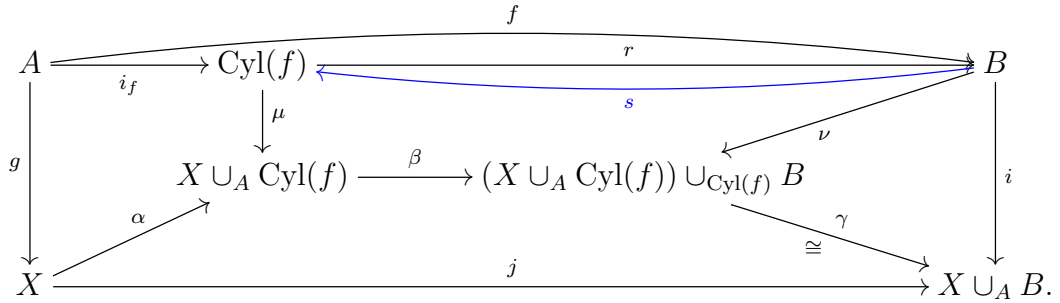


The next lemma is the same statement as Lemma 17.21 except that we can drop the hypothesis on the existence of s.

Lemma 17.22. (Opposite Map-Homotopy Equivalence Lemma) Let $f\colon A \to X$ and $g\colon A \to Y$ be two maps between topological spaces. We consider the corresponding pushout diagram

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle i} \\ X & \xrightarrow{j} & X \cup_A B. \end{array}$$

Let f be a homotopy equivalence. If g is a closed cofibration, then the map "opposite to f", i.e. the map j is a homotopy equivalence.



Proof of the Opposite Map-Homotopy Equivalence Lemma 17.22. We consider the maps

where $i_f\colon A \to \mathrm{Cyl}(f)$ and $s\colon B \to \mathrm{Cyl}(f)$ are the natural inclusions and $r\colon \mathrm{Cyl}(f) \to B$ is the natural retraction. We make the following observations:

(1) It follows from the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 and the discussion on page 495 that i_f and s are closed cofibrations.
(2) It follows immediately from the definitions that $f = r \circ i_f$ and $r \circ s = \mathrm{id}_B$.
(3) By the Mapping Cylinder Basics Lemma 16.10 (3) and the Mapping Cylinder Basics Lemma 16.12 we know that r is a homotopy equivalence.
(4) It follows from the hypothesis that f is a homotopy equivalence, together with (2) and (3) and together with the Homotopy-Equivalence Basics Lemma 15.1 (1), that i_f is a homotopy equivalence.

Next we consider the following diagram

We continue with the following clarifications and observations:

(5) The quadrilateral to the left is a pushout diagram. In particular α and μ are the natural maps of a pushout.
(6) The quadrilateral in the top center is also a pushout diagram. In particular β and ν are the natural maps of a pushout.
(7) The map γ is the natural homeomorphism given by the Pushout Lemma 4.8 (2).
(8) It follows immediately from the definitions that the diagram commutes.
(9) We consider the quadrilateral to the left.
   (a) By (1) and (4) we know that i_f is a homotopy equivalence and that it is a closed cofibration. Thus we obtain from (5) together with the Opposite Map-Cofibration Proposition 17.18 (2) that the opposite map $\alpha\colon X \to X \cup_A \mathrm{Cyl}(f)$ is a homotopy equivalence.
   (b) By hypothesis g is a closed cofibration, thus we obtain from (5) together with the Opposite Map-Cofibration Proposition 17.18 (1) that μ is also a closed cofibration.
(10) Next we obtain the quadrilateral in the top center. By (1), (3), (6) and (9b) we can apply Lemma 17.21 and we obtain that the map β is a homotopy equivalence.
(11) By (7), (9a) and (10) we know that α, β and γ are homotopy equivalences. Since the diagram commutes we see that the bottom map $j\colon X \to X \cup_A B$ is indeed a homotopy equivalence. ■

Proof of Theorem 17.19. We are given the following commutative diagram

$$\begin{array}{ccccc} X & \xleftarrow{\ i\ } & A & \xrightarrow{\ f\ } & Y \\ \downarrow{\scriptstyle \varphi_X} & & \downarrow{\scriptstyle \varphi_A} & & \downarrow{\scriptstyle \varphi_Y} \\ X' & \xleftarrow{\ i'\ } & A' & \xrightarrow{\ f'\ } & Y' \end{array}$$

where all of the vertical maps are homotopy equivalences and where the maps i and i' to the left are closed cofibrations. Recall that we need to show that the induced map

$$\Phi\colon X \cup_A Y \ \to\ X' \cup_{A'} Y'$$

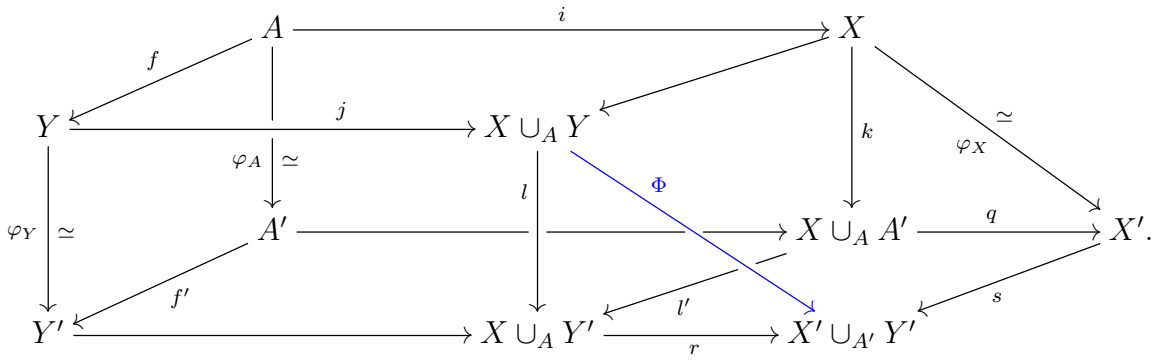
is a homotopy equivalence.

Case 1. First we assume that f and f' are homotopy equivalences. We consider the following commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{\ u\ } & X \cup_A Y \\ \simeq\downarrow{\scriptstyle \varphi_X} & & \downarrow{\scriptstyle \Phi} \\ X' & \xrightarrow{\ u'\ } & X' \cup_{A'} Y' \end{array} .$$

We make the following comments:

(1) The horizontal maps u and u' are the obvious natural maps coming from the following pushout diagrams

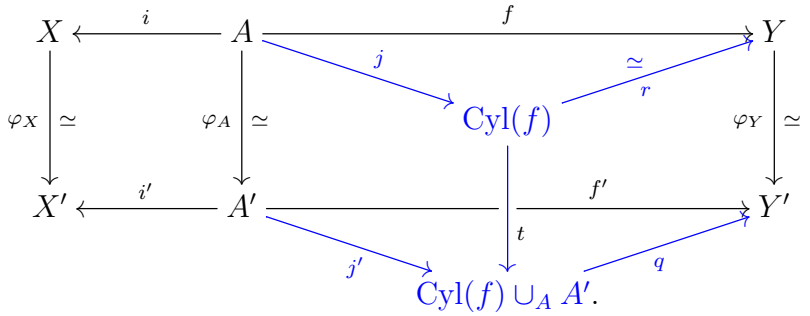


$$\begin{array}{ccc} A & \xrightarrow{\ f\ }_{\simeq} & Y \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle v} \\ X & \xrightarrow{\ u\ } & X \cup_A Y \end{array} \qquad \text{and} \qquad \begin{array}{ccc} A' & \xrightarrow{\ f'\ }_{\simeq} & Y' \\ {\scriptstyle i'}\downarrow & & \downarrow{\scriptstyle v'} \\ X' & \xrightarrow{\ u'\ } & X' \cup_{A'} Y'. \end{array}$$

Since f and f' are homotopy equivalences and since i and i' are closed cofibrations we obtain from the Opposite Map-Homotopy Equivalence Lemma 17.22, applied to these two pushout diagrams, that the horizontal maps u and u' are homotopy equivalences.

(2) The left vertical map of the diagram of the claim is a homotopy equivalence by hypothesis.

(3) It follows from (1) and (2), together with the Homotopy-Equivalence Basics Lemma 15.1 (1), that Φ is a homotopy equivalence.



Case 2. Next we assume that f and f' are cofibrations. We consider the following diagram:

We make the following observations and clarifications:

(1) The top square and bottom left square are the obvious pushout diagrams.
(2) The vertical map $l\colon X \cup_A Y \to X \cup_A Y'$ is the map induced by φ_Y. The square in the front is a pushout diagram by the Pushout Lemma 4.8 (2).
(3) The square in the back is defined to be a pushout diagram.
(4) Since i is a closed cofibration and φ_A is a homotopy equivalence it follows from the Opposite Map-Homotopy Equivalence Lemma 17.22, applied to the pushout diagram in the back, that k is a homotopy equivalence.
(5) Since $i\colon A \to X$ is a closed cofibration we obtain, by applying the Opposite Map-Cofibration Proposition 17.18 to the pushout diagram on the top, that the "opposite map" $j\colon Y \to X \cup_A Y$ is a closed cofibration.
(6) Since j is a cofibration and since φ_Y is homotopy equivalence we obtain again from the Opposite Map-Homotopy Equivalence Lemma 17.22, this time applied to the pushout diagram in front, that l is a homotopy equivalence.
(7) Since f' is a closed cofibration we obtain again from the Opposite Map-Cofibration Proposition 17.18 that the "opposite map" l' is a closed cofibration.
(8) We turn to the right part of the diagram. The map $q\colon X \cup_A A' \to X'$ is defined by φ_X on X and i' on A. Furthermore the map $r\colon X \cup_A Y' \to X' \cup_{A'} Y'$ is defined by φ_X on X' and id on Y'. Finally $s\colon X' \to X' \cup_{A'} Y'$ is the natural map. One can easily verify that the right hand part of the diagram commutes.
(9) Since φ_X and k are homotopy equivalences and since $q \circ k = \varphi_X$ we obtain from the Homotopy-Equivalence Basics Lemma 15.1 (1) that q is a homotopy equivalence.
(10) As we mentioned in (2), the bottom left square is a pushout square. Furthermore it follows immediately from the definitions that the big square formed by the two squares at the bottom is also a pushout square. It follows from a fairly elementary argument, see e.g. Exercise 4.12, that the bottom right square is also a pushout square.
(11) It follows from (7), (9) and (10) together with the hard-fought the Opposite Map-Homotopy Equivalence Lemma 17.22 that r is a homotopy equivalence.
(12) Since $\Phi = r \circ l$ we obtain from (6) and (11) that Φ is indeed a homotopy equivalence.

Case 3. Finally we deal with the case that f and f' are arbitrary maps. We consider the following diagram

We make the following clarifications and observations:

(1) The black part of the diagram is precisely the commutative diagram of our setup.
(2) The top triangle is given by the usual factorization of the map $f\colon A \to Y$ into the natural inclusion $j\colon X \to \mathrm{Cyl}(f)$ and the natural retraction $r\colon \mathrm{Cyl}(f) \to Y$. By the Cone-Mapping Cylinder Inclusion Cofibration Proposition 17.3 we know that j is a

closed cofibration. Furthermore, by the Mapping Cylinder Basics Lemma 16.12 (2a) we know that r is a homotopy equivalence.

(3) The left parallelogram is defined to be the pushout of the maps $j\colon A \to \mathrm{Cyl}(f)$ and $\varphi_A\colon A \to A'$.

(4) Since j is a closed cofibration we obtain from (3) and the Opposite Map-Cofibration Proposition 17.18 that the map $j'\colon A' \to \mathrm{Cyl}(f) \cup_A A'$ is also a closed cofibration.

(5) Since φ_A is a homotopy equivalence and since j is a closed cofibration we obtain from the Opposite Map-Homotopy Equivalence Lemma 17.22 that t is a homotopy equivalence.

(6) The map $q\colon \mathrm{Cyl}(f) \cup_A A' \to Y'$ is defined via t on $\mathrm{Cyl}(f)$ and f' on A'.

(7) It follows easily from the definitions that the right parallelogram commutes, i.e. we have $q \circ t = \varphi_Y \circ r$. Since r, φ_Y and t are homotopy equivalences and since $q \circ t = \varphi_Y \circ r$ we obtain from the Homotopy-Equivalence Basics Lemma 15.1 (1) that q is a homotopy equivalence.

Next we consider the commutative diagram

$$\begin{array}{ccccc} X & \xleftarrow{\ i\ } & A & \xrightarrow{\ j\ } & \mathrm{Cyl}(f) \\ \downarrow{\scriptstyle \varphi_X} & & \downarrow{\scriptstyle \varphi_A} & & \downarrow{\scriptstyle t} \\ X' & \xleftarrow{\ i'\ } & A' & \xrightarrow{\ j'\ } & \mathrm{Cyl}(f) \cup_A A' \end{array}$$

Here we just make a single observations:

(8) By (2) and (4) and by hypothesis we know that all horizontal maps are closed cofibrations. Furthermore by hypothesis and (5) we know that all vertical maps are homotopy equivalences. Thus we obtain from Case 2 that the induced map

$$\Xi\colon X \cup_A \mathrm{Cyl}(f) \ \to\ X' \cup_{A'} (\mathrm{Cyl}(f) \cup_A A')$$

is a homotopy equivalence.

We move on to consider the following diagram:

$$(*) \qquad \begin{array}{ccccc} X \cup_A \mathrm{Cyl}(f) & & \xleftarrow{\quad\alpha\quad} & & \mathrm{Cyl}(f) \xrightarrow[\simeq]{r} Y \\ \simeq\downarrow{\scriptstyle \nu} & \overset{\simeq}{\searrow}{\scriptstyle \Xi} & & & \simeq\downarrow{\scriptstyle t} \qquad \simeq\downarrow{\scriptstyle \varphi_Y} \\ X' \cup_A \mathrm{Cyl}(f) & \underset{\cong}{\swarrow}{\scriptstyle \mu} & X' \cup_{A'} (\mathrm{Cyl}(f) \cup_A A') & \overset{\beta}{\nwarrow} & \\ & & \xleftarrow[\gamma]{\quad} \mathrm{Cyl}(f) \cup_A A' & \xrightarrow[q]{\simeq} & Y'. \end{array}$$

We make the following clarifications and observations:

(9) The lower left diagonal map μ is the natural homeomorphism that is provided by the Pushout Lemma 4.8 (2).

(10) The horizontal map α at the top left and the diagonal map β are the natural maps coming from pushouts. The vertical map ν to the left is induced by φ_X and the horizontal map γ at the bottom left map is induced by i'. One can easily verify that the diagram commutes.

(11) Recall that by hypothesis $i\colon A \to X$ and $i'\colon A' \to X'$ are closed cofibrations. Thus we obtain from the Opposite Map-Cofibration Proposition 17.18, applied to the pushouts

$$\begin{array}{ccc} A & \xrightarrow{\ i\ } & X \\ \downarrow & & \downarrow \\ \mathrm{Cyl}(f) & \xrightarrow{\ \alpha\ } & X \cup_A \mathrm{Cyl}(f) \end{array} \qquad \text{and} \qquad \begin{array}{ccc} A' & \xrightarrow{\ i'\ } & X' \\ \downarrow & & \downarrow \\ \mathrm{Cyl}(f)\cup_A A' & \xrightarrow{\ \beta\ } & X'\cup_{A'}(\mathrm{Cyl}(f)\cup_A A') \end{array}$$

that the maps α and β are closed cofibrations. Since $\gamma = \mu \circ \beta$ and since μ is a homeomorphism we see that γ is also a closed cofibrations.

Finally we consider the following diagram:

$$\begin{array}{ccc} (X \cup_A \mathrm{Cyl}(f)) \cup_{\mathrm{Cyl}(f)} Y & \longrightarrow & (X' \cup_A \mathrm{Cyl}(f)) \cup_{\mathrm{Cyl}(f)\cup_A A'} Y' \\ \downarrow\cong & & \downarrow\cong \\ X \cup_A Y & \xrightarrow{\ \Phi\ } & X' \cup_{A'} Y'. \end{array}$$

As usual we cannot be refrained from making comments.

(12) The top horizontal map is induced by ν and φ_Y.

(13) By (5), (8), (9) and our hypothesis we know that all the vertical maps in the diagram $(*)$ are homotopy equivalences. Furthermore by (2) and (7) we know that the right horizontal maps of $(*)$ are homotopy equivalences. Thus we obtain from Case 1 that the top horizontal map in our present diagram is a homotopy equivalence.

(14) The vertical maps are the natural homeomorphism provided by the Pushout Lemma 4.8 (2).

(15) One can easily verify that the diagram commutes. Since the top horizontal map is a homotopy equivalence and since the vertical maps are homeomorphisms we see that the bottom horizontal map Φ is also a homotopy equivalence. And that had been our goal since page 497. ■

This concludes our discussion of closed cofibrations. More information on closed cofibrations can be found in [**tD2008**, Chapter 5], [**BrownR2006**, Chapter 7], [**May1999a**, Chapter 6] and [**Pic1992**, Chapter 2.3].

Exercises for Chapter 17.

Exercise 17.1. Solve the following problems "by hand", i.e. without making use of any of above results. For example you should not use the Cofibration-Closed Injective Lemma 17.6.

(a) Let $A = [a, b]$ be a compact interval and let $X = \mathbb{R}$. Show that the inclusion $i\colon A \to X$ is a cofibration.

(b) Let $A = \mathbb{R} \setminus \{0\}$ and $X = \mathbb{R}$. Show that the inclusion $i\colon A \to X$ is not a cofibration.

(c) Let $A = (-1, 1)$ and $X = \mathbb{R}$. Show that the inclusion $i\colon A \to X$ is not a cofibration.

Exercise 17.2. Let $f\colon X \to Y$ and $g\colon Y \to Z$ be two (closed) cofibrations. Show that $g \circ f\colon X \to Z$ is a (closed) cofibration.

Exercise 17.3. Prove the "(2) $\Rightarrow$ (1)"-direction of the Cofibration Characterization Lemma 17.2.

Exercise 17.4. Let $X = (V, E, i, t)$ be an abstract graph as defined on page 307 and let A be a subgraph as defined on page 317. We denote by $|X|$ and $|A|$ the topological realizations of X and A as defined on page 308. Show that the corresponding inclusion map $i\colon |A| \to |X|$ is a closed cofibration.
Remark. This is a special case of the Subcomplex Cofibration Theorem 17.9.

Exercise 17.5. Given an example of a topological space X and a non-empty subset A such that the map $\mathrm{Cone}(i\colon A \to X) \to X/A$ given in the Cofibration-Quotient Lemma 17.7 (1) is not a homotopy equivalence.

Exercise 17.6. Let $X = \{x, y\}$ be a set with two elements and the trivial topology furthermore let $A = \{x\}$. Show that the inclusion $A \to X$ is a cofibration.
Remark. This is an example of a cofibration that is not closed.

Exercise 17.7. Let $X = \{a, b\}$ be the topological space with two elements a and b and where the open sets are precisely $\varnothing, \{a\}, X$. We set $A := \{a\}$.

(a) Show that the inclusion $A \to X$ is a cofibration.
(b) Show that the inclusion $(X \times A) \cup (A \times X) \to X \times X$ is not a cofibration.

Remark. This exercise shows that the conclusion of Proposition 17.13 does not hold if neither A nor B are closed subsets.

Exercise 17.8. Let $i\colon A \to X$ be a closed cofibration. Show that the induced map $\mathrm{Cone}(A) \to \mathrm{Cone}(X)$ is also a cofibration.
Hint. Make sense of the following diagram and use it is as a guideline:

$$\begin{array}{ccccc}
A \times \{0\} & \longrightarrow & X \times \{0\} & \longrightarrow & \{*\} \\
\downarrow & & \downarrow & & \downarrow \\
A \times [0,1] & \longrightarrow & (X \times \{0\}) \cup_{A \times \{0\}} (A \times [0,1]) & \longrightarrow & \mathrm{cone}(A) = * \cup_{A \times \{0\}} (A \times [0,1]) \\
 & & \downarrow & & \downarrow \\
 & & X \times [0,1] & \longrightarrow & \mathrm{Cone}(X).
\end{array}$$

Part III

Topological and smooth manifolds

In this part of the lecture notes we introduce the concept of topological and smooth manifolds. We develop all the basic notions, like tangent spaces and orientations, and we will prove some of the foundational results like the Inverse Mapping Theorem 24.1, the Smooth Embedding Theorem 24.10, the Regular Value Theorem 26.4, the Euclidean Embedding Theorem 27.1 and Sard's Theorem 31.1. Throughout we will allow manifolds to have a boundary, which makes it technically more demanding to write down the correct statements and precise proofs.

18. Topological manifolds

In this chapter we introduce topological manifolds and study some basic properties. Afterwards, in the next chapter, we will introduce smooth manifolds, which for most applications are even more interesting.

18.1. **Topological manifolds: definition and examples.** Before we can give the definition of topological manifolds we need to introduce the following notation.

Notation. Given $n \in \mathbb{N}_0$ we write

$$\begin{aligned} \mathbb{H}^n &= \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_n \geq 0\} \\ \partial\,\mathbb{H}^n &= \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_n = 0\}. \end{aligned}$$

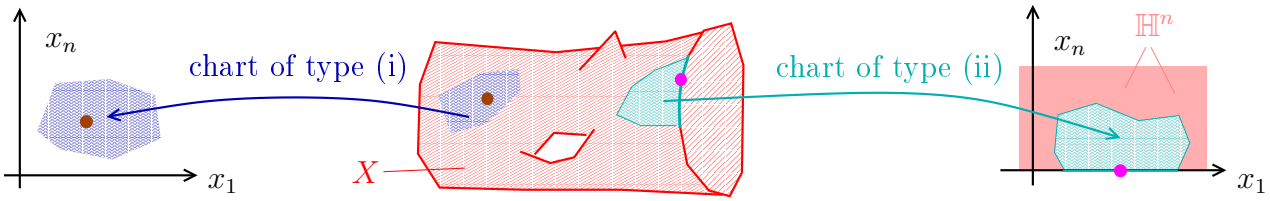
We refer to $\mathbb{H}^n$ as the upper half-space in $\mathbb{R}^n$. We equip both sets with the subspace topology coming from $\mathbb{R}^n$. One can easily verify that $\partial\,\mathbb{H}^n$ is indeed the boundary of $\mathbb{H}^n$ viewed as a subset of $\mathbb{R}^n$. Furthermore it is straightforward to show that the map $\mathbb{R}^{n-1} \to \partial\,\mathbb{H}^n$ given by $x \mapsto (x, 0)$ is a homeomorphism.

Now we can move on to the definition of a topological manifold.

Definition. Let X be a topological space.

(1) An n-dimensional chart for X at a point $x \in X$ is a homeomorphism $\Phi\colon U \to V$ where U is an open neighborhood of x and
   (i) V is an open subset of $\mathbb{R}^n$ or
   (ii) V is an open subset of the upper half-space $\mathbb{H}^n$ and $\Phi(x)$ lies in $\partial\,\mathbb{H}^n$.
   In the former case we say that Φ is a chart of type (i), in the latter case we say that Φ is a chart of type (ii).
(2) We say X is an n-dimensional topological manifold, if X is second-countable and Hausdorff, and if for every $x \in X$ there exists an n-dimensional chart $\Phi\colon U \to V$ at x.[189]
(3) An n-dimensional atlas for X is a collection of n-dimensional charts such that the domains of the charts cover all of X.

For topological manifolds we can furthermore define the notion of the boundary (points):



(4) We say that a point x on a topological manifold X is a boundary point if x does not admit a chart of type (i).[190] We denote by ∂X the set of all boundary points of X. We refer to ∂X as the boundary of X.
(5) We say a topological manifold X is closed if X is compact with $\partial X = \varnothing$.[191]

Remark.

[188] The definition of a (topological) manifold goes back to the work of Hermann Weyl [**Wey1913, Wey1964**, Chapter I.4].

[189] It might sound more natural to define a boundary point to be a point that admits a chart of type (ii). In fact we will see in the Topological Manifold Boundary Proposition 75.2 that a point on a topological manifold admits *either* a chart of type (i) or a chart of type (ii). But the proof of this statement is not trivial and as of now we cannot prove this statement. As we will see in the subsequent examples our definition works fairly well, even without making use of the Topological Manifold Boundary Proposition 75.2.

[190] The latter condition just means that all points in X admit a chart of type (i).

(1) In some references, see e.g. **[Hu1969, Aub2001]** and **[PoR2021]**, a topological manifold is defined as above, except that the condition that X is second-countable is replaced by the condition that X is paracompact. We will see in the Manifold-Partitions of Unity Existence Theorem 21.1 and Proposition 21.5 that these two definitions of topological manifolds are equivalent. Furthermore in **[Wall2016]** the condition of being second-countable is replaced by the condition that X is the union of countably many compact subsets. We will see in Lemmas 18.12 and 21.6 that these two definitions of topological manifolds are also equivalent.

(2) Note that only in the Topological Manifold-Dimension Proposition 75.4 will we show that the dimension of a non-empty topological manifold is uniquely determined.

In the following we will give several examples of topological manifolds. When it comes to verifying that a topological space is a topological manifold the main focus is usually on establishing that any point admits a chart. It is easy to forget that one also needs to verify that the topological space is second-countable and Hausdorff. In many cases this task is taken care of by the following lemma.

Lemma 18.1. Let $n \in \mathbb{N}$. Every subset of $\mathbb{R}^n$ is second-countable and Hausdorff.

Proof. Let A be a subset of $\mathbb{R}^n$. By the Second Countability Lemma 9.1 we know that A is second-countable. Furthermore, it follows from Proposition 1.13 and Lemma 1.14 that A is also Hausdorff. ■

For the record we also state the following elementary lemma.

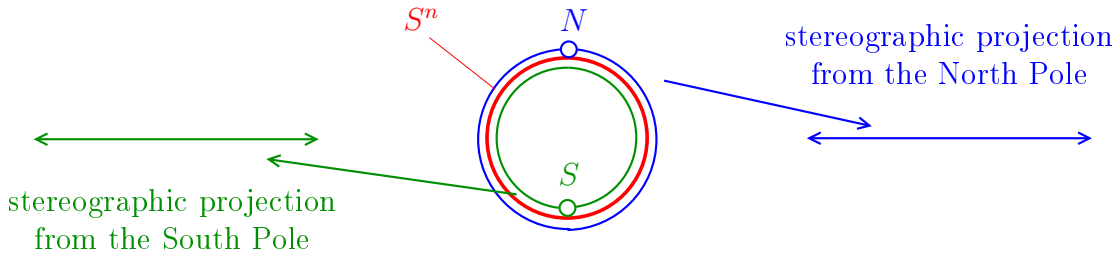
Lemma 18.2. Let X be a topological space.

(1) If X admits a countable atlas, then X is second-countable.
(2) If X is compact and if it admits an atlas, then X is second-countable.

Proof.

(1) Suppose X admits a countable atlas $\{\Phi_i \colon U_i \to V_i\}_{i \in I}$. By Lemma 18.1 we know that each V_i, and thus each U_i, is second-countable. It follows from the Second Countability Lemma 9.1 (4) that X itself is second-countable.

(2) The second statement in turn is an immediate consequence of the first statement since every compact space that admits an atlas also admits a finite atlas. ■

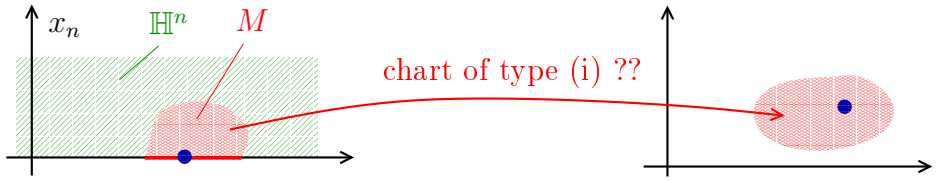


Now we turn to giving examples of topological manifolds.

Examples. Let $n \in \mathbb{N}$.

(1) We consider the sphere S^n. As usual we refer to $N := (0, \dots, 0, 1) \in S^n$ as the *North Pole* and similarly we refer to $S := (0, \dots, 0, -1) \in S^n$ as the *South Pole*. It follows quite easily from slight modifications of the arguments in the proof of Lemma 2.18 that the stereographic projection $S^n \setminus \{N\} \to \mathbb{R}^n$ from the North Pole together

with the stereographic projection $S^n \setminus \{S\} \to \mathbb{R}^n$ from the South Pole, as defined in Lemma 2.18, are two n-dimensional charts of type (i) that cover all of S^n. By Lemma 18.1 this shows that $S^n \subset \mathbb{R}^{n+1}$ is an n-dimensional topological manifold.



Note that both charts are of type (i), thus we see that the boundary of the topological manifold S^n is the empty set.[191] Finally note that S^n is compact, thus S^n is a closed n-dimensional topological manifold.

(2) Every open subset U of $\mathbb{R}^n$ is an n-dimensional topological manifold. This follows again from Lemma 18.1 and the observation that the identity map is a chart of type (i) for all points. In particular we see that the boundary of U is empty.

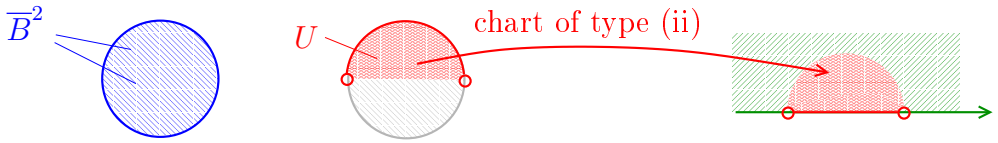
(3) Let M be an open subset of the upper half-space $\mathbb{H}^n = \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_n \geq 0\}$. Again, using Lemma 18.1, it is straightforward to see that M is an n-dimensional topological manifold:
   (a) Given any point $X = (x_1, \dots, x_n) \in M$ with $x_n > 0$ the identity map on the open subset $U := \{(y_1, \dots, y_n) \in M \,|\, y_n > 0\}$ is a chart of type (i) around x.
   (b) Given any point $(x_1, \dots, x_n) \in M$ with $x_n = 0$ the identity map $M \to M$ is a chart of type (ii) around x.

   In this example we run into a major, and rather painful, subtlety. Namely one would think that the boundary of M as a topological manifold should be precisely the points in M with $x_n = 0$. But at the moment we cannot draw this conclusion. After all, in principle, such points also might admit charts of type (i). Only after having introduced and studied homology groups we will see in the Topological Manifold Boundary Proposition 75.2 that no such charts of type (i) exist.

(4) Next we want to show that the closed n-ball $\overline{B}^n$ is an n-dimensional topological manifold. We provide the following charts:
   (a) We consider the chart of type (i) that is given by the identity on the open subset B^n of $\overline{B}^n$.

[191] The vigilant reader will have noticed that we have committed a major sin: we introduced an object called "boundary" twice, with quite different meanings:
   (a) On page 116 we introduced the boundary ∂A of a subset A of a topological space X.
   (b) On page 511 we introduced the boundary ∂M of a topological manifold M.

Usually it is clear from the context what we mean when we write ∂. This sorry state of affairs explain why some authors, e.g. [**Kel1975**], refer to the boundary of a subset of a topological space as the *frontier*.



(b) We set $U := \{(x_1, \ldots, x_n) \in \overline{B}^n \,|\, x_n > 0\}$ and we consider the map

$$\begin{array}{rcl} U & \to & \mathbb{H}^n \\ (x_1, \ldots, x_n) & \mapsto & (x_1, \ldots, x_{n-1}, \sqrt{1 - x_1^2 - \cdots - x_{n-1}^2} - x_n). \end{array}$$

This is a chart of type (ii) for all points in $\{(x_1, \ldots, x_n) \in S^{n-1} \,|\, x_n > 0\}$. We refer to the figure below for an illustration of this chart.

(c) We consider the obvious variations of the previous chart for $x_n < 0$ and for other coordinates.

These charts form an atlas for $\overline{B}^n$, together with Lemma 18.1 this shows that $\overline{B}^n$ is an n-dimensional topological manifold. We have found a chart of type (i) for each point in B^n and for the points on S^{n-1} we have found charts of type (ii). This shows that $\partial\overline{B}^n \subset S^{n-1}$. Furthermore we have the strong suspicion that $\partial\overline{B}^n = S^{n-1}$ but as in (3), as of right now we cannot confirm this. We will only be able to confirm our hunch by the time we have proved the Topological Manifold Boundary Proposition 75.2.

(5) Given $a < b$ in $\mathbb{R}$ the interval $[a, b]$ is easily seen to be a 1-dimensional topological manifold. Every point in (a, b) admits a chart of type (i). It follows from Lemma 7.11 together with the Topological Valence Determination Proposition 7.12 that the two points $a, b \in [a, b]$ do *not* admit charts of type (i).[192] Thus the boundary of $[a, b]$ consists, as expected, of the two points a and b. Similarly the boundary of the half-open interval $[a, b)$ equals $\{a\}$.

(6) In Exercise 18.1 we will see that a topological space X is a 0-dimensional topological manifold if and only if X is countable and X is equipped with the discrete topology. It follows from the Compact-Discrete Lemma 1.22 that a compact 0-dimensional topological manifold is precisely a finite set equipped with the discrete topology.

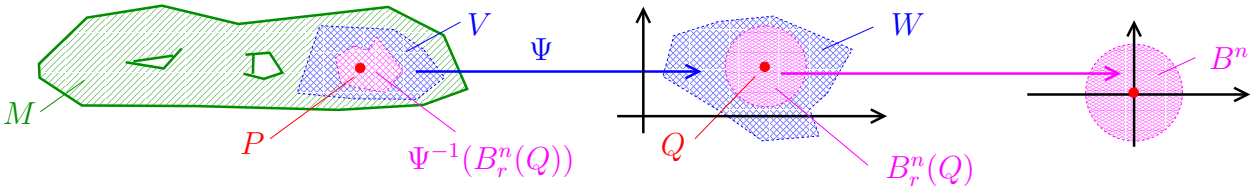
(7) We conclude this list of examples with the simplest of all examples: the empty set is a topological manifold of any dimension.

It is also worth looking at a few non-examples.

Non-Examples.

(1) In Exercise 18.2 we will verify that the line with two zeros admits a chart of type (i) for every point. It is also easy to see that the line with two zeros is second-countable. But since the line with two zeros is not Hausdorff we see that it is not a topological manifold.

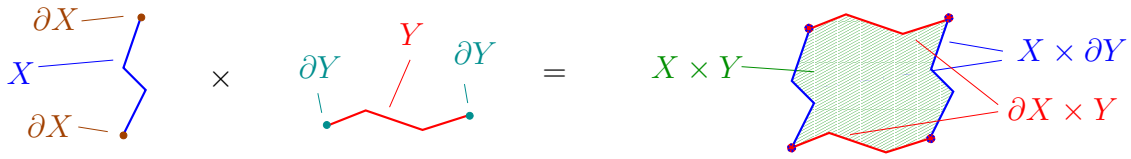
(2) We consider the topological space X that is given by the set $X = \mathbb{R}$ but for once we equip $X = \mathbb{R}$ with the discrete topology. Every point of X admits a 0-dimensional chart and X is obviously Hausdorff. But X is not second-countable, thus X is not a topological manifold.



[192] One could also prove this fact directly by hand, see Exercise 2.40.

(3) In Section 22.4 we will see that there exists a *connected* Hausdorff space which admits a 1-dimensional atlas, but which is not second-countable. In particular this topological space is not a topological manifold.

The following lemma will get used, at least implicitly, on numerous occasions.



Lemma 18.3. Let X be an n-dimensional topological manifold and let $P \in X$.
(1) If $P \in X \setminus \partial X$, then there exists a chart $\Phi\colon U \to B^n$ with $\Phi(P) = 0$.
(2) If $P \in \partial X$, then there exists a chart $\Phi\colon U \to B^n_{\geq 0}$ with $\Phi(P) = 0$.[193]

Proof.
(1) If $P \in X \setminus \partial X$, then by definition of ∂X there exists a chart $\Psi\colon V \to W$ for the point P of type (i). We write $Q = \Psi(P)$. Note that W is an open subset of $\mathbb{R}^n$. This implies that there exists an $r > 0$ with $B^n_r(Q) \subset W$. The desired chart is given by composing $\Psi\colon \Psi^{-1}(B^n_r(Q)) \to B^n_r(Q)$ with the obvious homeomorphism $B^n_r(Q) \to B^n$.
(2) The proof of this statement is basically identical to the proof of (1). ∎

The following proposition gives a useful method for constructing more topological manifolds.

Proposition 18.4. (Topological Manifold Product Proposition) Let X be an m-dimensional topological manifold and let Y be an n-dimensional topological manifold. Then the following hold:
(1) The product $X \times Y$ is an $(m+n)$-dimensional topological manifold.
(2) (a) Each point in $(X \times Y) \setminus ((\partial X \times Y) \cup (X \times \partial Y))$ admits a chart of type (i).
(b) Each point in $(\partial X \times Y) \cup (X \times \partial Y)$ admits a chart of type (ii).
(c) We have[194] $\partial(X \times Y) \subset (\partial X \times Y) \cup (X \times \partial Y)$.
(3) If X and Y are closed topological manifolds, then so is $X \times Y$.

Examples.
(1) It follows from the Topological Manifold Product Proposition 18.4 and the above discussion of S^1 that for any $m \in \mathbb{N}$ the m-dimensional torus $(S^1)^m$ is a closed m-dimensional topological manifold.

[193] Here we use the notation introduced on page 152, namely $B^n_{\geq 0} = \{(x_1, \ldots, x_{n+1}) \in B^n \mid x_{n+1} \geq 0\}$.
[194] Note that right now we can only prove the inclusion "$\subset$". Later on in the Topological Manifold Boundary Proposition 75.2 we will see that in fact we have an equality.

(2) It follows from the Topological Manifold Product Proposition 18.4 and the above examples that the annulus $S^1 \times [0,1]$ is a 2-dimensional topological manifold with $\partial(S^1 \times [0,1]) \subset S^1 \times \{0,1\}$.

(3) Let $X = \overline{B}^2$ and $Y = [0,1]$, then $X \times Y = \overline{B}^2 \times [0,1]$ is the solid cylinder which is a 3-dimensional topological manifold and the boundary satisfies

$$\partial\big(\overline{B}^2 \times [0,1]\big) \underset{\uparrow}{\subset} (\partial\overline{B}^2 \times [0,1]) \cup (\overline{B}^2 \times \partial([0,1])) \underset{\uparrow}{\subset} (S^1 \times [0,1]) \cup (\overline{B}^2 \times \{0,1\}).$$

in the Topological Manifold Boundary Proposition 75.2 we will see that equality holds

since $\partial\overline{B}^2 \subset S^1$

Proof.

(1) Let X be an m-dimensional topological manifold and let Y be an n-dimensional topological manifold. We consider the topological space $X \times Y$. In the Product Topology Properties Proposition 5.6 we remarked that the product of two Hausdorff spaces is again Hausdorff. Thus we see that $X \times Y$ is Hausdorff. Furthermore note that it follows from the Second Countability Lemma 9.1 (3) that $X \times Y$ is second-countable.

It remains to find charts for $X \times Y$. So let $(x,y) \in X \times Y$. We distinguish three cases:

(a) If $x \in X \setminus \partial X$ and $y \in Y \setminus \partial Y$ then by taking "product charts" it is straightforward to find a chart of type (i) for $(x,y) \in X \times Y$.

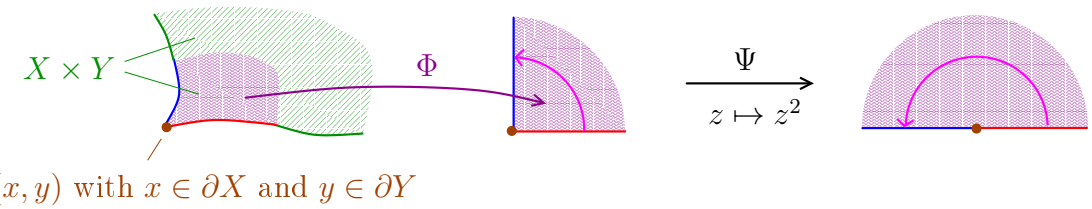
(b) If $x \in X \setminus \partial X$ and $y \in \partial Y$ or if $x \in \partial X$ and $y \in Y \setminus \partial Y$ then it is equally straightforward to find a product chart of type (ii) for $(x,y) \in X \times Y$.

(c) Finally suppose that $x \in \partial X$ and $y \in \partial Y$. Our goal is to find a chart of type (ii) for $(x,y) \in X \times Y$. First note that using a product chart it is pretty straightforward to see that there exists an open neighborhood U of $(x,y) \in X \times Y$ and a homeomorphism $\Phi\colon U \to \mathbb{R}^{m+n-2} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$. Next we consider the map

$$\begin{array}{rcl} \Psi\colon \mathbb{R}^{m+n-2} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} & \to & \mathbb{R}^{m+n-2} \times \mathbb{R} \times \mathbb{R}_{\geq 0} \\ (x_1, \dots, x_{m+n-2}, \underbrace{r\cos(\varphi), r\sin(\varphi)}_{=:z \in \mathbb{C}}) & \mapsto & (x_1, \dots, x_{m+n-2}, \underbrace{r^2 \cdot \cos(2\varphi), r^2 \cdot \sin(2\varphi)}_{=z^2}). \end{array}$$

Note that the map $\mathbb{C} \to \mathbb{C}$ that is given by $z = x + \mathrm{i}y \mapsto z^2 = (x^2 - y^2) + 2xy\mathrm{i}$ is continuous. It follows that Ψ is continuous. It is straightforward to show, say using the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19, that Ψ is indeed a homeomorphism.

One can now easily verify that $\Psi \circ \Phi$ is a chart of type (ii) around (x,y).



(2) We proved Statements (a) and (b) in (1). Furthermore Statement (c) is an immediate consequence of (b) and the definition of the boundary of a topological manifold.

(3) Now suppose that X and Y are closed. By (2) we know that $\partial(X \times Y) = \varnothing$ and from the Product Topology Properties Proposition 5.6 (2) we obtain that $X \times Y$ is compact. Thus we have shown that $X \times Y$ is a closed topological manifold. ■

We conclude this section with two technical lemmas.

Lemma 18.5. Let X and Y be two topological manifolds.

(1) If $f\colon X \to Y$ is a local homeomorphism, then $f(\partial X) = (\partial Y) \cap f(X)$.

(2) If $f\colon X \to Y$ is in fact a homeomorphism, then f restricts to a homeomorphism $\partial X \to \partial Y$.

Proof. The lemma follows from the elementary observation that the restriction of a chart for a point on a topological manifold has the same type as the original chart. We leave it to the reader to fill in the minuscule details. ■

The following lemma is slightly more interesting than the previous lemma.

Lemma 18.6. (Manifold Boundary-Closed Subset Lemma) Let X be a topological manifold.

(1) Any union of components of ∂X is a closed subset of X. In particular ∂X itself is a closed subset of X.
(2) If X is compact, then ∂X is also compact.
(3) $X \setminus \partial X$ is an open subset of X and if $\partial X \neq \varnothing$, then $X \setminus \partial X$ is non-compact.

Proof. Let X be a topological manifold.

(1) First note that, basically by definition, the set of points in X admitting a chart of type (i) is an open subset of X. It follows from the definition of ∂X that $X \setminus \partial X$ is an open subset. Thus the boundary ∂X is a closed subset of X. We denote by $\{Y_i\}_{i \in I}$ the components of ∂X. By the Components-are-Closed Lemma 2.34 each Y_i is an open subset of ∂X. Thus for any $i \in I$ there exists, by definition of the subspace topology, an open set $Z_i \subset X$ with $Z_i \cap \partial X = Y_i$. For any $J \subset I$ we have

$$X \setminus \Big(\bigcup_{j \in J} Y_j \Big) = \underbrace{(X \setminus \partial X)}_{\text{open in } X} \cup \underbrace{\bigcup_{j \notin J} Z_j}_{\text{open in } X}.$$

We have thus shown that the union of components of ∂X corresponding to J is indeed a closed subset of X.

(2) Now suppose that X is compact. Thus ∂X is a closed subset of the compact space X. We obtain from the Compact-Closed Lemma 1.21 (1) that ∂X itself is compact.

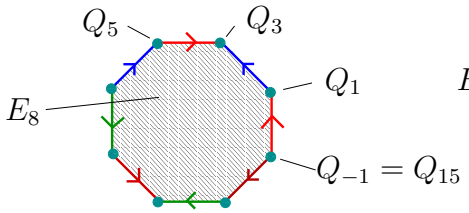
(3) It follows from (1) that $X \setminus \partial X$ is open. It remains to show that if $X \setminus \partial X$ is compact, $\partial X = \varnothing$. It follows from the elementary the Disjoint Union Topology-Properties Lemma 5.13 (2) that we only need to consider the case that X is connected. Thus assume that $Y := X \setminus \partial X$ is compact. Since X is Hausdorff we obtain from the Compact-Closed Lemma 1.21 that Y is closed. By (1) we know that ∂X is also closed. Since X is connected, since $X = Y \sqcup \partial X$ and since $Y \neq \varnothing$ we see that $\partial X = \varnothing$. ■

18.2. **Surfaces are topological manifolds.** On pages 265 and 266 we introduced the orientable surface of genus $g \in \mathbb{N}_0$ and the non-orientable surface of genus $g \in \mathbb{N}$. The

names already suggests that these should be 2-dimensional topological manifolds, and the following proposition confirms our hunch.

Proposition 18.7. (Surface-is-Topological Manifold Proposition)

(1) For every $g \in \mathbb{N}_0$ the surface Σ_g of genus g is a closed 2-dimensional topological manifold.



(2) For every $g \in \mathbb{N}$ the non-orientable surface N_g of genus g is a closed 2-dimensional topological manifold.

Proof. To simplify the discussion we will only prove Statement (1) of the proposition. We leave it to the reader to modify the argument to deal with the non-orientable case.

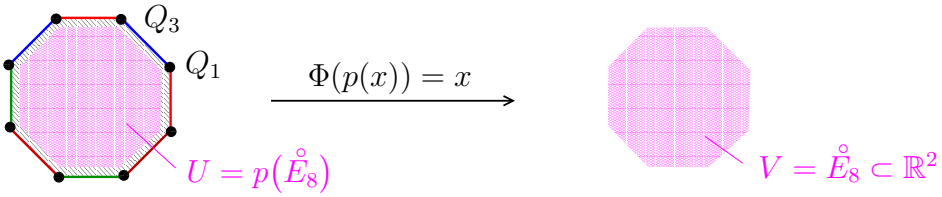
We start out this proof with the discussion of the two cases $g = 0$ and $g = 1$ that we had basically dealt with already. First recall that on page 513 we saw that any S^n is a closed n-dimensional topological manifold. The surface of genus 0 is by definition the sphere S^2, thus we are done by the above. Furthermore, the surface of genus 1 is by definition the torus $S^1 \times S^1$. The desired statement thus follows from the above and the Topological Manifold Product Proposition 18.4.

It remains to deal with the case $g \geq 2$. To simplify the notation we only deal with the case $g = 2$. The proof of the general case is totally analogous. Recall that the surface of genus 2 is defined as $E_8/\sim$ where E_8 is the octagon with the vertices $Q_k = \exp(2\pi \mathrm{i} k/16)$, $k = 1, 3, \ldots, 15$ and where "$\sim$" is the equivalence relation that we introduced on page 265.

$E_8/\sim$ is the surface of genus 2

Note that E_8 is compact by the Heine-Borel Theorem 1.24. Thus we obtain from the Quotient-Compact Connected Lemma 5.16 (1) that $E_8/\sim$ is also compact. In the following we will see that $E_8/\sim$ admits a finite atlas, by Lemma 18.2 this implies in particular that $E_8/\sim$ is second-countable.[195] Note that E_8 is compact by the Heine-Borel Theorem 1.24. Thus we obtain from the Compact Image Lemma 2.13 that $E_8/\sim$ is also compact. We leave it to the reader to verify that $E_8/\sim$ is Hausdorff.[196]

Thus, to show that $E_8/\sim$ is a closed 2-dimensional topological manifold it remains to give a finite atlas for $E_8/\sim$ that consists only of charts of type (i).

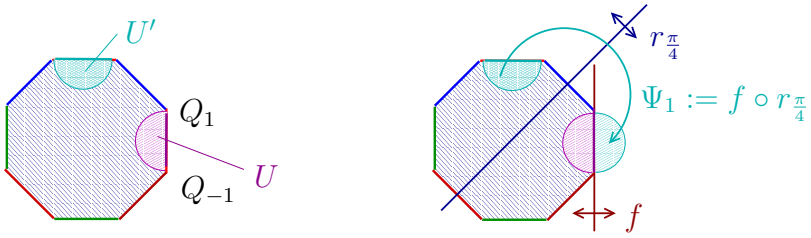


[195] It would also not be difficult to prove second-countability "by hand".

[196] This can either be done "by hand", or more elegantly but possibly with more work, by using the Quotient Hausdorff Lemma 5.21.

First we consider the map

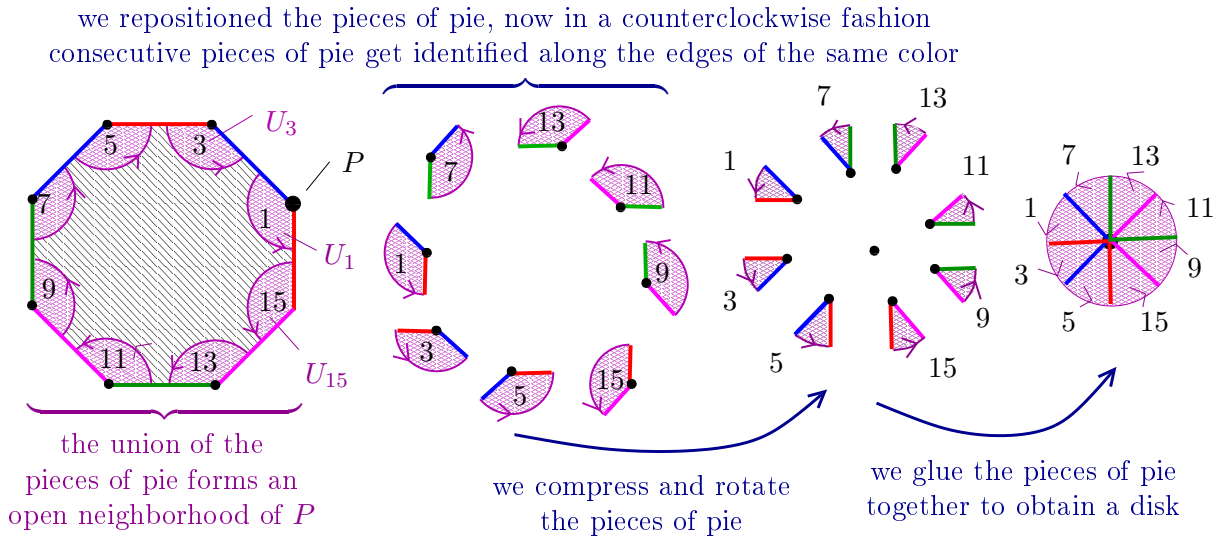
$$\begin{array}{rcl} \Phi\colon U := p\big(\mathring{E}_8\big) & \to & V = \mathring{E}_8 \subset \mathbb{R}^2 \\ p(x) & \mapsto & x. \end{array}$$



One can easily verify that this is a chart of type (i) for each point in the interior of E_8.

Next we introduce charts that cover the interiors of the edges. First we consider the edge given by Q_{-1} and Q_1. We denote by U and U' the half-disks that are illustrated in the figure below. (Note that it is understood that the line segment is included but that the circle is not included in U and U'.) Let $f\colon \mathbb{R}^2 \to \mathbb{R}^2$ be the reflection in the line that goes through Q_{-1} and Q_1. It is straightforward to verify that the map

$$\begin{array}{rcl} \Psi_1\colon p(U \cup U') & \to & \text{the open disk } U \cup f(r_{\frac{\pi}{4}}(U)) \subset \mathbb{R}^2 \\ p(x) & \mapsto & \begin{cases} x, & \text{if } x \in U \\ f(r_{\frac{\pi}{4}}(x)), & \text{if } x \in U' \end{cases} \end{array}$$



is well-defined. Furthermore, using Pasting Proposition 2.6 (2) one can show that Ψ_1 and its inverse are both continuous. Finally, it follows easily from the definitions that $p(U \cup U')$ is an open subset of $E_8/\!\sim$. Thus Ψ_1 is a chart of type (i) for all points in the interior of the edge from Q_{-1} to Q_1. Similarly we define charts Ψ_2, Ψ_3, Ψ_4 that take care of the other pairs of edges.

It remains to find a chart of type (i) that takes care of the point P in $E_8/\!\sim$ that is represented by the vertices. (It is a fun exercise to verify that all vertices get identified.) We pick an $\eta > 0$ such that the η-disks centered at $Q_1, \ldots, Q_{15}$ are disjoint. For $k = 1, 3, \ldots, 15$ we set $U_k := B_\eta(Q_k) \cap E_8$. The sets $U_1, U_3, \ldots, U_{15}$ are disjoint and one can easily verify that $p(U_1) \cup p(U_3) \cup \cdots \cup p(U_{15})$ is an open neighborhood of $p(Q_1) = p(Q_3) = \cdots = p(Q_{15})$.

Before we write down the chart rigorously it might help to visualize the situation. To the left of the figure below we see the sets $U_1, \ldots, U_{15}$. Next we arrange these "pieces of pie" as in the second second part of the above. Thus we see the "pieces of pie" with an angle of $\frac{3\pi}{4}$ where we show the various identifications of the edges. The map from the second to the third part is given by compressing the angle of the "pieces of pie" to a third and by rotating

the "pieces of pie". These eight "pieces of pie", each with an angle of $\frac{\pi}{4}$, can be combined to give a disk in $\mathbb{R}^2$.

Now we want to turn the above idea into formal mathematics. We consider the map

$$\Omega\colon p(U_1)\cup\cdots\cup p(U_{15}) \;\to\; B^2_\eta(0)$$

that is defined on each $p(U_k)$, $k\in\{1,3,\ldots,15\}$ to be the map

$$p\big(\underbrace{Q_k + r\cdot\exp(\mathrm{i}\alpha)}\big) \;\mapsto\; r\cdot\exp(\mathrm{i}(\tfrac{1}{3}(\alpha-\beta(k))+\gamma(k))).$$

where $r\in[0,\eta)$ and $\alpha\in[\beta(k),\beta(k)+\frac{3}{4}\pi]$

Here $\beta(k)$ and $\gamma(k)$ are given by the following table:

k	1	3	5	7	9	11	13	15
$\beta(k)$	$\frac{3}{4}\pi$	π	$\frac{5}{4}\pi$	$\frac{3}{2}\pi$	$\frac{7}{4}\pi$	0	$\frac{1}{4}\pi$	$\frac{1}{2}\pi$
$\gamma(k)$	$\frac{3}{4}\pi$	π	$\frac{5}{4}\pi$	$\frac{1}{2}\pi$	$\frac{7}{4}\pi$	0	$\frac{1}{4}\pi$	$\frac{3}{2}\pi$

It is straightforward, albeit slightly cumbersome, to verify that Ω is a bijection. Furthermore, using Exercise 5.33 together with Pasting Proposition 2.6 (2) one can show fairly easily that Ω is continuous and that its inverse is also continuous. In other words, the map Ω is a homeomorphism. As pointed out above, it is straightforward to verify that $p(U_1)\cup\cdots\cup p(U_{15})$ is an open subset of $E_8/\!\sim$. In summary, we have shown that Ω is a chart of type (i) for P.

The eight charts $\Phi, \Psi_1, \Psi_2, \Psi_3, \Psi_4$ and Ω are now charts of type (i) that cover all of $E_8/\!\sim$. We have thus found the desired atlas. ■

18.3. **Properties of topological manifolds.** Topological manifolds are particularly important and also particularly nice topological spaces. For example the next lemma shows in particular that when it comes to topological manifolds, we do not have to worry about the two different definitions of connectedness.

Lemma 18.8. (Topological Manifolds-Local Properties Lemma)

(1) Every n-dimensional topological manifold is locally homeomorphic to an open ball in $\mathbb{R}^n$ or an open half-ball in $\mathbb{H}^n$, in particular it is locally homeomorphic to a convex subset of $\mathbb{R}^n$ or $\mathbb{H}^n$.
(2) Every topological manifold is locally contractibleand in particular locally path-connected.
(3) (a) The components of a topological manifold M are precisely the path-components of M. In particular M is connected if and only if M is path-connected.
(b) The components of a topological manifold are open and closed subsets of M.
(4) Every topological manifold is regionally compact.
(5) Every topological manifold is locally precompact.

Remark. Throughout the lecture notes we will on many occasions make use of the Topological Manifolds-Local Properties Lemma 18.8 (3) without referring to it explicitly.

Proof. Let X be an n-dimensional topological manifold.

(1) Let X be an n-dimensional topological manifold and let $P \in X$. First assume that $P \notin \partial X$. This means that there exists a chart $\Phi\colon U \to V$ of type (i) from some open neighborhood U of x to some open subset V of $\mathbb{R}^n$. We set $Q = \Phi(P)$. Since V is open there exists an $r > 0$ such that $B_r^n(Q) \subset V$. Evidently $B_r^n(Q)$ is convex and we see that $\Phi^{-1}(B_r^n(Q))$ is an open neighborhood of P that is homeomorphic to a convex subset of $\mathbb{R}^n$. Basically the same argument also works if $P \in \partial X$.
(2) On page 432 we saw that convex sets are contractible. Thus it follows from (1) that topological manifolds are locally contractible. In particular we see that topological manifolds are locally path-connected.
(3) This statement is an immediate consequence of (2) and of the Locally Path-Connectedness Lemma 2.40.
(4) On page 178 we saw that open subsets of $\mathbb{R}^n$ are regionally compact. The same argument shows that open subsets of $\mathbb{H}^n$ are regionally compact. Using the Compact Image Lemma 2.13 it is now easy to see that topological manifolds are regionally compact.
(5) Since topological manifolds are by definition Hausdorff this statement follows immediately from (4) together with Lemma 2.42. ■

The humble Topological Manifolds-Local Properties Lemma 18.8, together with previous work, begets several interesting consequences.

Proposition 18.9. (Manifold Paracompact-Normal Proposition)
(1) Every topological manifold is paracompact.
(2) Every topological manifold X is normal, i.e. given any two disjoint closed subsets A and B of X there exist disjoint open neighborhoods U of A and V of B.

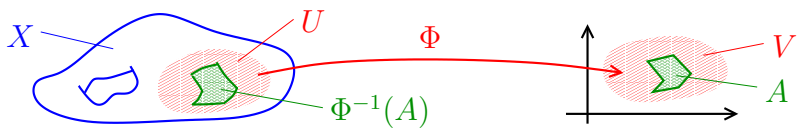
Proposition 18.10. (Manifold Metrization Proposition) Every topological manifold X is completely metrizable, i.e. there exists a complete metric d on X such that the given topology agrees with the topology coming from d.

Remark.

(1) In the Atlas Improvement Proposition 21.3 we will give an alternative proof that topological manifolds are paracompact.
(2) In the Manifold Metrization Proposition 27.4 we will give a different proof of the Manifold Metrization Proposition 18.10 which does not require the Urysohn Metrization Theorem 9.4.

Proof of the Manifold Paracompact-Normal Proposition 18.9. Let X be a topological manifold.

(1) By the Topological Manifolds-Local Properties Lemma 18.8 we know that X is regionally compact. By definition X is Hausdorff and second-countable. Thus it follows from the Paracompact-Criterion Lemma 10.2 that X is paracompact.
(2) By definition topological manifolds are Hausdorff. We just saw in (1) that topological manifolds are paracompact. Therefore it follows from Dieudonné's Theorem 10.5 that topological manifolds are also normal. ■



Proof of the Manifold Metrization Proposition 18.10. Let X be a topological manifold. By the Manifold Paracompact-Normal Proposition 18.9 (2) we know that X is normal. By definition X is second-countable and Hausdorff. The latter condition implies by the Points-in-Hausdorff Space Lemma 1.15 (1) that every one-point subset of X is closed. This shows that all the hypotheses of the Urysohn Metrization Theorem 9.4 are satisfied and we conclude that X is metrizable.

Furthermore, in the Topological Manifolds-Local Properties Lemma 18.8 we just saw that X is also regionally compact. Thus it follows from the Completely Metrizable Criterion Proposition 10.8 that we can upgrade "metrizable" to "completely metrizable". ■

On several occasions we will need the following, slightly technical lemma.

Lemma 18.11. Let X be a Hausdorff space (e.g. X could be a topological manifold), let U be an open subset of X and let $\Phi\colon U \to V$ be a homeomorphism (e.g. Φ could be a chart of type (i) or (ii).)

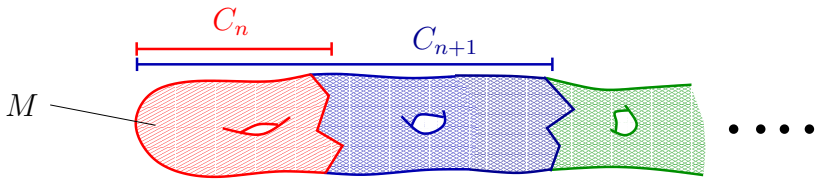
(1) If $A \subset V$ is a subset that is compact, then the corresponding subset $\Phi^{-1}(A)$ is a compact and in particular a closed subset of X.[197]
(2) If $B \subset V$ is a subset such that the closure of B is compact, then the closure of $\Phi^{-1}(B)$ is also compact.

Proof. Let X be a Hausdorff space, let U be an open subset of X and let $\Phi\colon U \to V$ be a homeomorphism. We denote by $\Psi = \Phi^{-1}\colon V \to U$ the inverse map.

(1) Let $A \subset V$ be a subset that is compact. It follows from the Compact Image Lemma 2.13 that $\Psi(A)$ is a compact subset of X. But by hypothesis X is Hausdorff.

[197] It does not suffice that A is a closed subset of the topological space V. Indeed, $A = V$ is a closed subset of V, but $U = \Phi^{-1}(V)$ is in general not a closed subset of X.

Hence it follows from the Compact-Closed Lemma 1.21 (2) that $\Psi(A) = \Phi^{-1}(A)$ is closed in X.



(2) Let $B \subset V$ be a subset such that the closure $A := \overline{B}$ is compact. By (1) we know that $\Phi^{-1}(A) = \Psi(A)$ is compact and closed. Since $\Phi^{-1}(B) \subset \Phi^{-1}(A)$ and the latter set is closed we see that the closure of $\Phi^{-1}(B)$ is contained in the compact set $\Phi^{-1}(A)$. But then it follows from the Compact-Closed Lemma 1.21 that the closure of $\Phi^{-1}(B)$ is also compact. ■

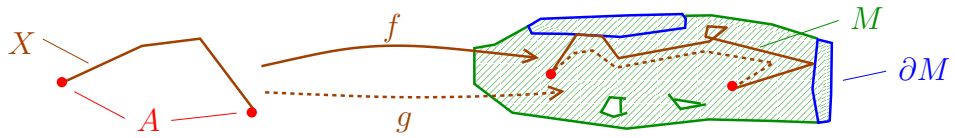
We continue with another technical lemma.

Lemma 18.12. (Topological Manifold Exhaustion Lemma) Let M be a topological manifold. There exists a compact exhaustion of M in the sense of the definition on page 338. More precisely, there exists a family of compact subsets $\{C_n\}_{n\in\mathbb{N}}$ of M such that the following two conditions are satisfied:

(1) we have $M = \bigcup_{n\in\mathbb{N}} C_n$,

(2) for every $n \in \mathbb{N}$ we have $\overset{\circ}{C}_n \subset C_{n+1}$.

Proof. The lemma follows immediately from the Compact Exhaustion Lemma 9.3 (1) together with the Topological Manifolds-Local Properties Lemma 18.8 (4). ■



Remark. We will prove a refinement of the Topological Manifold Exhaustion Lemma 18.12 in the Manifold Exhaustion Lemma 21.2. For smooth manifolds we will prove a further refinement in the Compact Submanifold Exhaustion Proposition 31.2.

We conclude this section with the following technical lemma.

Lemma 18.13. (Push Away From Boundary Lemma) Let M be a topological manifold.

(1) Let X be a compact space, let $A \subset X$ be closed and let $f\colon X \to M$ be a map. If $f(A) \subset M \setminus \partial M$, then f is homotopic rel A to a map $g\colon X \to M \setminus \partial M$.

(2) If M is path-connected, then $M \setminus \partial M$ is also path-connected.

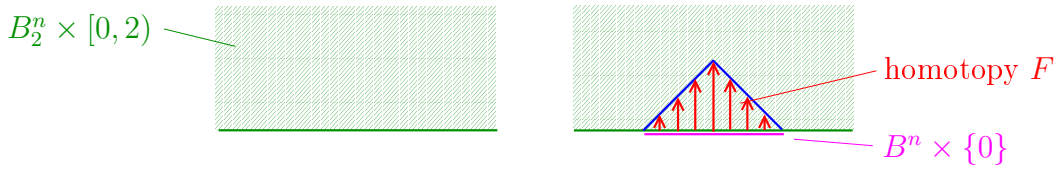
Remark. the Push Away From Boundary Lemma 18.13 foreshadows the Smooth Collar Neighborhood Theorems 28.3 and 75.5 that we will prove later. In Exercise 28.2 we will prove a "smooth" version of the Push Away From Boundary Lemma 18.13.

Proof.

(2) Let us first show how to deduce (2) from (1). This also serves as a good example for (1). So let us assume that M is path-connected. Let $P, Q \in M \setminus \partial M$. Since M is path-connected there exists a map $f\colon [0,1] \to M$ with $f(0) = P$ and $f(1) = Q$. We apply (1) to f and $A := \{0,1\} \subset X := [0,1]$ and we obtain a map $g\colon [0,1] \to M \setminus \partial M$ with $g(0) = f(0) = P$ and $g(1) = f(1) = Q$.

(1) Let X be a compact space, let $A \subset X$ be closed and let $f\colon X \to M$ be a map with $f(A) \subset M \setminus \partial M$. Since X is compact we know by the Compact Image Lemma 2.13 that $f(X)$ is compact. By the Manifold Boundary-Closed Subset Lemma 18.6 we know that ∂M is compact. It follows that $f(X) \cap \partial M$ is compact. As we pointed out on page 127, this implies that $f(X) \cap \partial M$ is also compact. It follows from the Compact Subspace Covering Lemma 1.19 and a variation on Lemma 18.3 that there exist charts $\Phi_i\colon U_i \to B_2^{n-1} \times [0,2)$, $i = 1, \dots, k$ of type (ii) such that

$$f(X) \cap \partial M \subset \bigcup_{i=1}^{k} \Phi_i^{-1}(B^{n-1} \times \{0\}) \quad \text{and such that} \quad A \subset M \setminus \bigcup_{i=1}^{k} \Phi_i^{-1}(B_2^{n-1} \times [0,2)).$$



Next we consider the homotopy

$$\begin{aligned} F\colon B^{n-1} \times [0,2) \times [0,1] &\to B^{n-1} \times [0,2) \\ ((x,s),t) &\mapsto \begin{cases} (x,s), & \text{if } \|x\| > 1 \text{ or } s \geq 1 - \|x\|, \\ (x, s\cdot(1-t) + (1-\|x\|)\cdot t), & \text{if } \|x\| \leq 1 \text{ and } s \leq 1 - \|x\| \end{cases} \end{aligned}$$

which is illustrated in the figure below. Using the charts $\Phi_1, \dots, \Phi_k$ we can "transplant" the homotopy F and we obtain homotopies $F_1, \dots, F_k\colon M \times [0,1] \to M$. Now we apply these homotopies one after another to obtain a homotopy $M \times [0,1] \to M$. More precisely, we consider the homotopy that is given by

$$\begin{aligned} M \times [0,1] &\to M \\ (x,t) &\mapsto F_1(\dots F_2(F_1(x,t),t),\dots,t). \end{aligned}$$

One can easily verify that F has all the desired properties. ∎

18.4. **Submanifolds.** In this section we want to specify what we mean by a submanifold of a topological manifold.

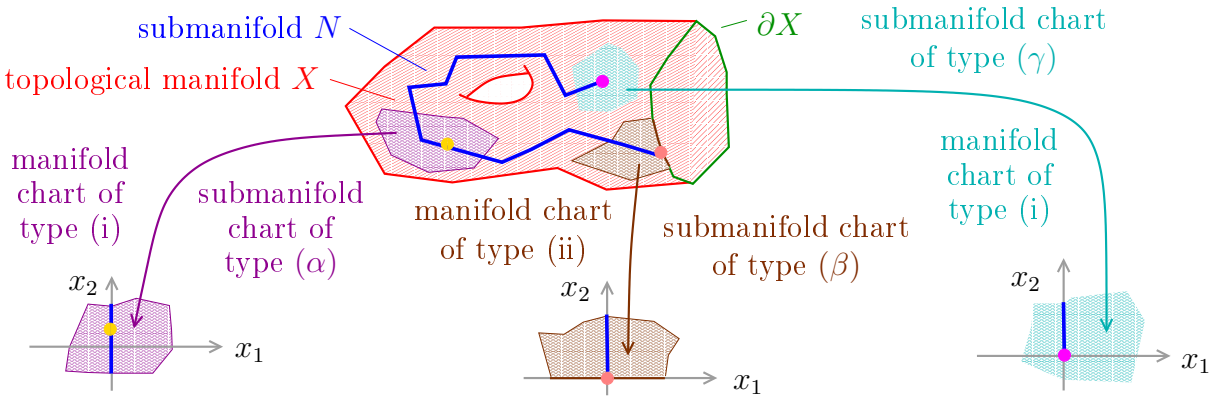
Definition. Let X be an n-dimensional topological manifold.

(1) We say a subset $N \subset X$ is a k-dimensional submanifold if given any $P \in N$ one of the following holds:

(α) there exists a chart $\Phi\colon U \to V$ of type (i) for X and P such that[198]

$$\Phi(U \cap N) \;=\; V \cap \{(0,\dots,0,x_1,\dots,x_k) \,|\, x_i \in \mathbb{R}\},$$

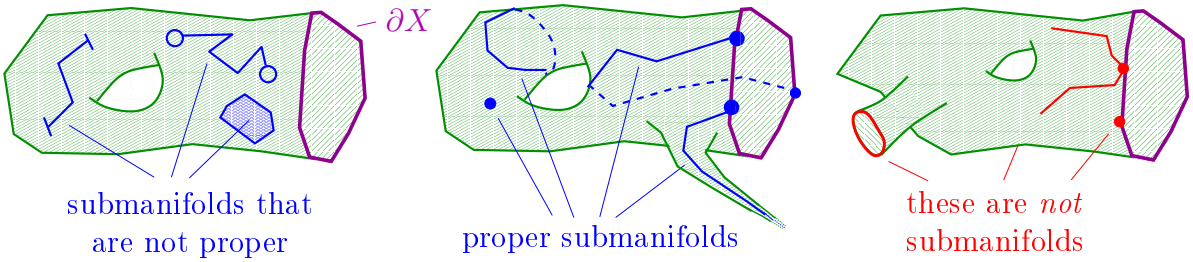
(β) or there exists a chart $\Phi\colon U \to V$ of type (ii) for X and P such that $\Phi(P)$ lies in $\partial\,\mathbb{H}^n$ and[199]



$$\Phi(U \cap N) \;=\; V \cap \{(0,\ldots,0,x_1,\ldots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\},$$

(γ) or there exists a chart $\Phi\colon U \to V$ of type (i) for X and P such that $\Phi(P)$ lies in $\partial\,\mathbb{H}^n$ and[200]

$$\Phi(U \cap N) \;=\; V \cap \{(0,\ldots,0,x_1,\ldots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\}.$$



We refer to such charts as submanifold charts of N.

(2) We say a submanifold N is proper if N is a closed subset of X and if for each $P \in N$ we can find submanifold charts of type (α) and (β).

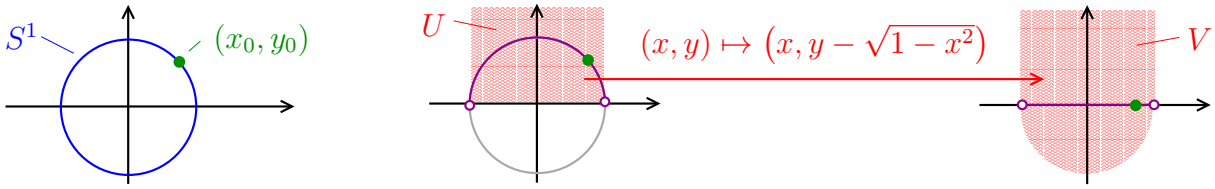
Examples.

(1) In the figure below we give typical examples of submanifolds, some of which are proper, some are not. We also show some subsets that are not submanifolds. In particular it is worth pointing out that a non-empty submanifold of X is never a subset of ∂X.[201]

(2) Let us show that S^1 is a proper 1-dimensional submanifold of $\mathbb{R}^2$. First we consider the case of a point $P = (x_0, y_0) \in S^1$ with $x_0 \in (-1, 1)$ and with $y_0 > 0$. We consider

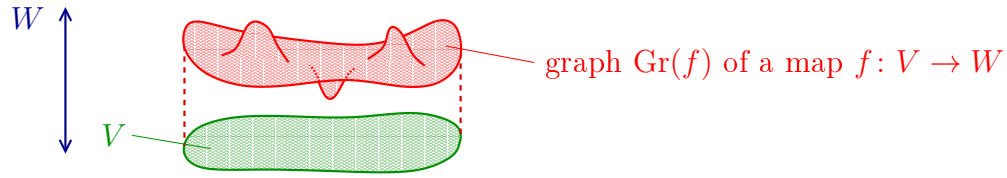
[198] Why are the zeros to the left and not to the right?

[199] For $k = 0$ we interpret $\{(0,\ldots,0,x_1,\ldots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\}$ as the empty set.



[200] See the previous footnote.

[201] Indeed, suppose that N is a non-empty submanifold of a topological manifold X. It follows immediately from the definitions of a submanifold that N contains a point P that is contained in a chart of type (i) for X. But by the definition of ∂X on page 511 this means that $P \notin \partial X$.



the map

$$\Phi\colon \overbrace{\{(x,y)\,|\,x\in(-1,1) \text{ and } y>0\}}^{=:U} \to \overbrace{\{(x,y)\,|\,x\in(-1,1) \text{ and } y>-\sqrt{1-x^2}\}}^{=:V}$$
$$(x,y) \mapsto \big(x, y-\sqrt{1-x^2}\big).$$

One can easily verify that this is a chart of type (α) for $P=(x_0,y_0)$. By precomposing Φ by a rotation one obtains a chart of type (α) for any other point on S^1. Since S^1 is a closed subset of $\mathbb{R}^2$ we see that S^1 is a 1-dimensional proper submanifold of $\mathbb{R}^2$. A very mild variation on this argument shows that S^n is a proper n-dimensional proper submanifold of $\mathbb{R}^{n+1}$.

(3) Let $f\colon V\to W$ be a map between two topological manifolds with $f(V)\subset W\setminus\partial W$. In Exercise 18.8 we will see that the graph $\mathrm{Gr}(f):=\{(x,f(x))\,|\,x\in V\}$ is a proper submanifold of the topological manifold $V\times W$. An especially intersection example

is given by the Cantor function $f\colon[0,1]\to\mathbb{R}$ that we introduced on page 185. The above discussion implies that the graph of the Cantor function is a proper 1-dimensional submanifold of $[0,1]\times\mathbb{R}$.

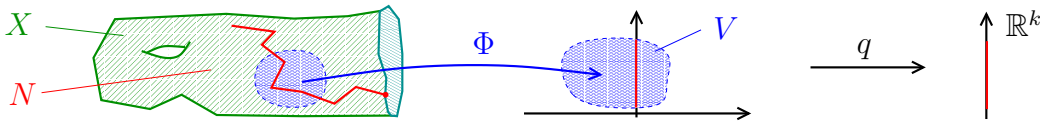
(4) Let X be a topological manifold. It follows easily from the definitions that a subset $N\subset X$ is a 0-dimensional submanifold of X if and only if N is a discrete subset of $X\setminus\partial X$.

(5) Let X be a topological manifold and let $U\subset X$ be an open subset. It follows almost immediately from the definitions that U is a codimension-zero submanifold of X. Furthermore, if we view U as a topological manifold in its own right, then it follows again basically immediately from the definitions, see also Lemma 18.5, that $\partial U = U\cap\partial X$.

Remark. The notion of a "submanifold" is used differently by different authors. Therefore, reading the literature it is a good idea to check what definition of a submanifold the authors use. In particular our definition of a "proper submanifold" is often used as the definition of a submanifold.

The following lemma shows that submanifolds are topological manifolds in their own right.

Lemma 18.14. (Submanifold-is-Manifold Lemma) Let X be a topological manifold. If $N\subset X$ is a k-dimensional submanifold, then N is a k-dimensional topological manifold.



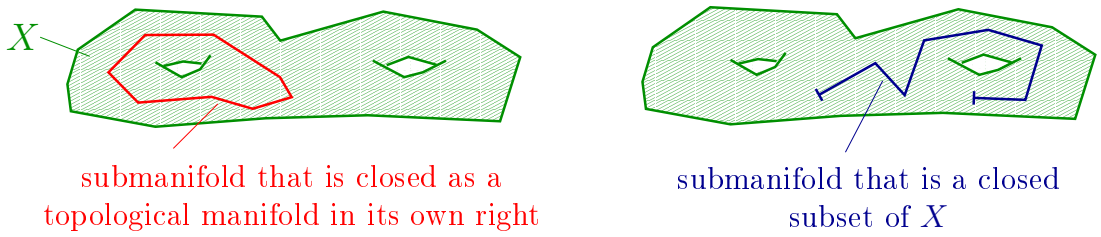
Remark. Let X be a topological manifold and let $N \subset X$ be a k-dimensional submanifold. In the Topological Manifold Boundary Proposition 75.2 we will see that N is a proper submanifold if and only if the following two conditions are satisfied:

(1) N is a closed subset of X.
(2) We have the equality $\partial N = (\partial X) \cap N$.[202] [203]

Proof. Let X be a topological manifold and let $N \subset X$ be a k-dimensional submanifold. It follows from Lemmas 1.14 and 9.1 that N is Hausdorff and second-countable. We denote by $q\colon \mathbb{R}^n \to \mathbb{R}^k$ the projection onto the last k coordinates. Let $P \in N$. We make the following slightly excessive observations:

(a) If P admits a submanifold chart $\Phi\colon U \to V$ of type (α), then this submanifold chart is a chart of type (i) for $P \in X$ and the map $q \circ \Phi|_{U \cap N}$ is a k-dimensional chart of type (i) for $P \in N$.
(b) If P admits a submanifold chart $\Phi\colon U \to V$ of type (β), then this submanifold chart is a chart of type (ii) for $P \in X$ and the map $q \circ \Phi|_{U \cap N}$ is a k-dimensional chart of type (ii) for $P \in N$.
(c) If P admits a submanifold chart $\Phi\colon U \to V$ of type (γ), then this submanifold chart is a chart of type (i) for $P \in X$ and the map $q \circ \Phi|_{U \cap N}$ is a k-dimensional chart of type (ii) for $P \in N$.

It follows from these observations that N is indeed a k-dimensional topological manifold. ■



Remark. Unfortunately, when it comes to submanifolds the double usage of the word "closed" can lead to confusion. More precisely, let X be a topological manifold and let N be a submanifold.

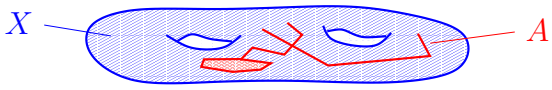
(1) If N, viewed as a topological manifold in its own right, is closed, then it is in particular compact, and it follows from the Compact-Closed Lemma 1.21 (2) that N is actually a closed subset of X.
(2) If N is a closed subset of X, then it does not follow that N is a closed topological manifold. For example take $X = \mathbb{R}^2$ and $N = \{0\} \times \mathbb{R}$. In this case N is a closed subset and it is actually even a proper submanifold. But N is evidently not compact, hence it is not a closed topological manifold.

---

[202] Here by ∂N we mean the boundary of N, viewed as a topological manifold in its own right.
[203] Note that if N is a proper submanifold, then as of right now we lack the means to show that $\partial N = (\partial X) \cap N$, in fact we even lack the means to show either of the "$\subset$" and "$\supset$" inclusions.

Exercises for Chapter 18.

Exercise 18.1. Let X be a topological space. Show that the following two statements are equivalent:

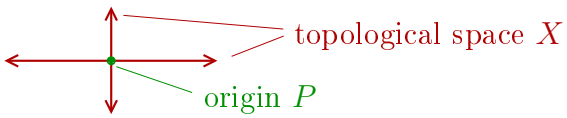


(1) X is a 0-dimensional topological manifold.
(2) The set X is countable and X is equipped with the discrete topology.

Exercise 18.2. Show that the line with two zeros admits a chart of type (i) for every point.

Exercise 18.3.

(a) Let $X = \mathbb{R} \cup \{*\}$ be the line with two zeros. Does there exist a map $f\colon X \to \mathbb{R}$ with $f(0) = 0$ and $f(*) = 1$.
(b) Let X be a topological manifold and let $P, Q \in X$ be two disjoint points. Show that there exists a map $f\colon X \to \mathbb{R}$ with $f(P) = 0$ and $f(Q) = 1$.

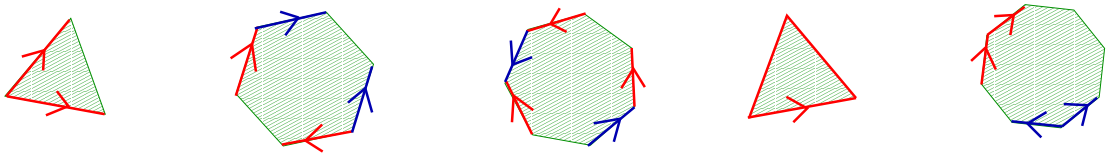


Exercise 18.4. Let X be a connected topological manifold and let $A \subset X$ be a non-empty closed subset with $A \neq X$. Show that $X \setminus A$ is not compact.

Exercise 18.5. Does there exist a compact space that satisfies all axioms of a closed 1-dimensional topological manifold except for the Hausdorff axiom?

Exercise 18.6. Let $f\colon X \to Y$ be a map between two topological manifolds. Show that given any $x \in X$ there exist neighborhoods U of x and V of $f(x)$ with $f(U) \subset V$ such that both U and V are homeomorphic to closed balls.

Exercise 18.7. We consider the topological space $X = \{(x, y) \in \mathbb{R}^2 \,|\, x \cdot y = 0\}$ shown in the figure below. Show that X is not a topological manifold.
Remark. It is clear that things go awry at the origin P. But it is somewhat tricky to nail down why there is no chart around that point.

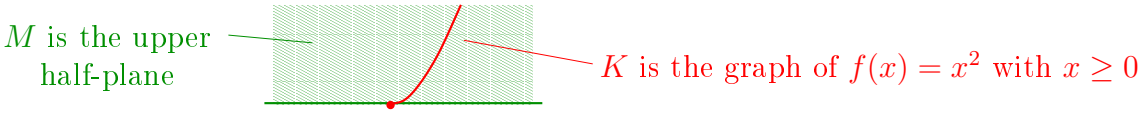


Exercise 18.8. Let $f\colon V \to W$ be a map between two topological manifolds such that $f(V) \subset W \setminus \partial W$. Show that the corresponding graph $\mathrm{Gr}(f) := \{(x, f(x)) \,|\, x \in V\}$ is a proper submanifold of the topological manifold $V \times W$.

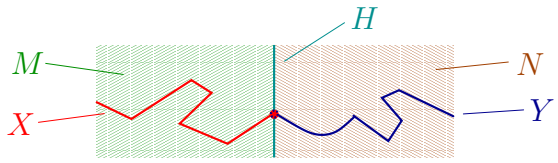
Exercise 18.9. Can you find an atlas for S^n that consists of a single chart?

Exercise 18.10. Let W be an n-gon with sides $F_1, \dots, F_n$. Suppose we identify some of the sides in an orientation-preserving or orientation-reversing way.

(a) Under what conditions on the identification scheme do we get a topological manifold?
(b) If we get a topological manifold, what is its boundary?
(c) If you have a sense of what an orientable topological manifold should be, under what conditions do we get an orientable topological manifold?



Remark. Strictly speaking we do not have the tools right now to rigorously prove the statements. So the exercise is to make an educated guess.



Exercise 18.11. In the figure below we show the topological manifold

$$X \;=\; \{(x,y) \in \mathbb{R}^2 \,|\, y \geq 0\}$$

together with the subset $K := \{(x, x^2) \,|\, x \geq 0\}$. Is K a submanifold of X?

Exercise 18.12. Let $M := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_1 \leq 0\}$, $N := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_1 \geq 0\}$ and $H := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_1 = 0\}$. Let $X \subset M$ be a k-dimensional topological submanifold with $\partial X = X \cap H$ and let $Y \subset N$ be a k-dimensional topological submanifold with $\partial Y = Y \cap H$. We suppose that $X \cap H = Y \cap H$. Show that $X \cup Y$ is a k-dimensional topological submanifold of $\mathbb{R}^n$.

Exercise 18.13. Let X be a topological manifold, let $P \in X$ and let $f\colon K \to X$ be a map from a compact space K to X. Show that if $P \notin f(K)$, then there exists an open neighborhood U of P with $f(K) \cap U = \varnothing$.

Exercise 18.14. Let X be a topological manifold, let K be a compact subset and let U be an open neighborhood of K. Show that there exists an open subset V of X with $K \subset V \subset U$ such that $\overline{V} \subset U$ and such that $\overline{V}$ is compact.

Exercise 18.15. Let $n \in \mathbb{N}$. Let $\Phi_+\colon S^n \to \mathbb{R}^n \cup \{\infty\}$ be the stereographic projection from the North Pole $(0, \dots, 0, 1)$ and let $\Phi_-\colon S^n \to \mathbb{R}^n \cup \{\infty\}$ be the stereographic projection from the South Pole $(0, \dots, 0, -1)$. Show that the map $\Phi_- \circ \Phi_+^{-1}\colon \mathbb{R}^n \setminus \{0\} \to \mathbb{R}^n \setminus \{0\}$ is given by $x \mapsto \frac{1}{\|x\|^2} \cdot x$.

Exercise 18.16. Let X be a connected topological manifold of dimension ≥ 2 and let $P_1, \ldots, P_k \in X$ be finitely many points. Show that $X \setminus \{P_1, \ldots, P_k\}$ is connected.
Remark. You could make use of the Union Connected Lemma 2.28.

Exercise 18.17. Let $g \in \mathbb{N}_0$.

(a) Show that the surface of genus g admits an atlas with two charts.
(b) Show that the surface of genus g admits an atlas consisting of three charts whose domains are diffeomorphic to 2-balls.

Exercise 18.18. Let X be a connected topological manifold.

(a) Suppose that X is compact. Show that there exists a surjective map $[0,1] \to X$.
(b) Suppose that X is non-compact. Show that there exists a surjective map $\mathbb{R} \to X$.

Hint. You might want to use the Space-Filling Curve Theorem 6.13.
Remark. Any surjective map from a connected one-dimensional topological manifold to a non-empty topological manifold of dimension ≥ 2 is called a *space-filling curve*.

Exercise 18.19. Let X be a topological manifold. Show that if X is connected, then $X \setminus \partial X$ is also connected.
Remark. Suppose that U and V are open disjoint subsets of $X \setminus \partial X$ with $X \setminus \partial X = U \cup V$. Show that there exists a decomposition $\partial M = A \sqcup B$ into open subsets such that $U \cup A$ and $V \cup B$ are open subsets of X.

Exercise 18.20. Let X be a topological manifold and let $A \subset X$ be a submanifold of codimension ≥ 2. Show that if X is path-connected, then so is $X \setminus A$.
Remark. You could try to modify the argument of the Push Away From Boundary Lemma 18.13.

Exercise 18.21. Given a subset $I \subset \mathbb{R}$ we define

$$H(I) \;:=\; \{(x,y) \in \mathbb{R}^2 \,|\, y > 0 \text{ or } x \in I \text{ and } y = 0\}.$$

In other words, $H(I)$ is the open upper half-plane of $\mathbb{R}^2$ together with the points on the x-axis corresponding to I.

(a) Let $I \subset \mathbb{R}$ be a subset. Show that $H(I)$ is a submanifold of $\mathbb{R}^2$ if and only if I is an open subset of $\mathbb{R}$.
(b) We consider

$$\begin{aligned} X &:= H((-\infty, 0) \cup (0, \infty)) \\ Y &:= H((-\infty, -1) \cup (1, \infty)). \end{aligned}$$

Are the two topological manifolds X and Y homeomorphic?

19. Smooth manifolds

In this chapter we introduce smooth structures on topological manifolds. A topological manifold equipped with a smooth structure will just be called a smooth manifold. In the literature the term "smooth manifold" can be used with quite different conventions and meanings. So we try to state clearly the various definitions used throughout these notes.

19.1. **Smooth functions on subsets of $\mathbb{R}^n$.** In the next section we want to define the notion of a "smooth structure" on a topological manifold. In this section we want to recall some basic definitions and facts regarding "classical" smooth maps.
Before we discuss properties of smooth maps we have to agree on what we mean by smooth maps on a subset of $\mathbb{R}^n$. The first definition is surely uncontroversial.

Definition. Let U be an open subset of $\mathbb{R}^n$.

(1) Let $f\colon U \to \mathbb{R}$ be a map, let $i \in \{1,\dots,n\}$ and let $P \in U$. We denote by e_i as usual the i-th vector of the standard basis of $\mathbb{R}^n$. We define the *i-th partial derivative of f at P* as follows:
$$\frac{\partial}{\partial x_i} f\big|_P := \lim_{h\to 0} \frac{f(P+h\cdot e_i)-f(P)}{h},$$
if the limit exists.[204]

(2) We say a map $f = (f_1,\dots,f_m)\colon U \to \mathbb{R}^m$ is *smooth*, if for every coordinate function f_i all iterated partial derivatives $\frac{\partial}{\partial x_{k_1}} \dots \frac{\partial}{\partial x_{k_d}} f_i$, of arbitrarily large degree, exist.

Example. One can easily verify that given any $n \in \mathbb{N}_0$ the following maps are smooth:
$$\begin{array}{ccc} \mathbb{R}\times\mathbb{R} & \to & \mathbb{R} \\ (x,y) & \mapsto & x\cdot y \end{array} \qquad \begin{array}{ccc} \mathbb{R}\setminus\{0\} & \to & \mathbb{R} \\ x & \mapsto & \frac{1}{x} \end{array} \qquad \text{and} \qquad \begin{array}{ccc} \mathbb{R}^n\times\mathbb{R}^n & \to & \mathbb{R} \\ (x,y) & \mapsto & x+y. \end{array}$$

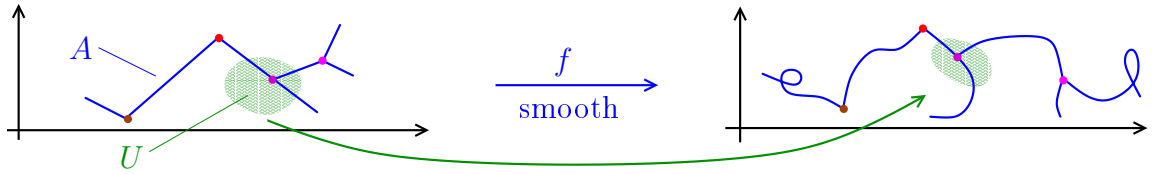
Remark. Since partial derivatives are just classical derivatives in a slightly different context we see that all the classical rules for derivatives hold. For example on several occasions we will use the Product Rule for partial derivatives which says that for an open subset $U \subset \mathbb{R}^n$ and two smooth functions $f, g\colon U \to \mathbb{R}$ and $P \in U$ and $i \in \{1,\dots,n\}$ we have
$$\frac{\partial(f\cdot g)}{\partial x_i}(P) = \frac{\partial f}{\partial x_i}(P)\cdot g(P) + f(P)\cdot \frac{\partial g}{\partial x_i}(P).$$

Theorem 19.1. (Schwarz Theorem) Let U be an open subset of $\mathbb{R}^n$ and let $f\colon U \to \mathbb{R}$ be a map. Furthermore let $i, j \in \{1,\dots,n\}$. For any $P \in U$ we have
$$\frac{\partial^2}{\partial x_i\,\partial x_j}(P) = \frac{\partial^2}{\partial x_i\,\partial x_j}(P).$$

Proof. This fundamental theorem is for example proved in [**RudiW1976**, Theorem 9.41]. ∎

On many occasions it will also be interesting to consider maps which are not defined on open subsets of $\mathbb{R}^n$. This leads us to the following more risqué definition.

[204] As usual the notation for partial derivatives can change slightly, depending on the circumstances, for example for $n = 1$ we might write $\frac{\partial}{\partial x}$ instead of $\frac{\partial}{\partial x_i}$.



Definition. Let A be any subset of $\mathbb{R}^n$. We say a map $f\colon A \to \mathbb{R}^m$ is smooth, if for every $a \in A$ there exists an open neighborhood U (in $\mathbb{R}^n$) of a, viewed as a point in $\mathbb{R}^n$, and a smooth map $\widetilde{f}\colon U \to \mathbb{R}^m$ (now "smooth" in the sense above) which coincides with f on $A \cap U$.[205]

Examples.

(1) Let $A = \{(x,y) \in \mathbb{R}^2 \,|\, x \cdot y = 0\} \subset \mathbb{R}$. The map $f\colon A \to \mathbb{R}$ given by $f(x,y) = x^2 - y^2$ is smooth, since it can be extended in an obvious way to a smooth map on all of $\mathbb{R}^2$.

(2) The map $f\colon [0,\infty) \to \mathbb{R}$ given by $f(x) = \sqrt{x}$ is not smooth, since it cannot be extended to a smooth function on any open interval (a,b) that contains 0.

(3) In the figure below we show a subset A of $\mathbb{R}^2$ and a smooth map $f\colon A \to \mathbb{R}^2$ which is more exotic than the lame example given in (1).

smooth map $\widetilde{f}$ on the open subset U that agrees with f on $A \cap U$

Definition. A subset of a topological space is called regular closed if $A = \overline{\mathring{A}}$, i.e. if it equals the closure of its interior.[206]

Example.

(1) By the discussion on page 118 every closed ball $\overline{B}_r(x)$ of radius > 0 is regular closed.

(2) One can easily show that every closed interval with non-empty interior is regular closed.

Lemma 19.2. Let $A \subset \mathbb{R}^n$ be a subset that is regular closed and let $f\colon A \to \mathbb{R}$ be a smooth map. Given any $i \in \{1,\dots,n\}$ there exists a unique continuous map $A \to \mathbb{R}$ that agrees with the partial derivatives $\frac{\partial f}{\partial x_i}$ on the open subset $\mathring{A}$.

Convention. Let $A \subset \mathbb{R}^n$ be a subset that is regular closed and let $f\colon A \to \mathbb{R}$ be a smooth map. Given $i \in \{1,\dots,n\}$ we refer to the map $A \to \mathbb{R}$ from Lemma 19.2 also as the partial derivative $\frac{\partial f}{\partial x_i}$.

Proof. Let $A \subset \mathbb{R}^n$ be a subset that is regular closed, let $f\colon A \to \mathbb{R}$ be a smooth map and let $i \in \{1,\dots,n\}$. By the above definition of a smooth map on A these partial derivatives extend locally to continuous maps on A. Since $\mathbb{R}$ is Hausdorff and since $\overline{\mathring{A}}$ we obtain from Exercise 2.33 that these extensions are unique. ■

The following proposition can be viewed as the smooth analogue of the Pasting Proposition 2.6 for continuous maps. It gives a convenient criterion for showing that a given map

[205] Note that if A is an open subset of $\mathbb{R}^n$, then this definition of a smooth map $A \to \mathbb{R}^n$ actually agrees with the previous definition.

[206] The name "regular closed" is for example used in [**SS1978**, p. 6].

is smooth. This proposition will be used throughout the lecture notes, mostly without referring to it explicitly.

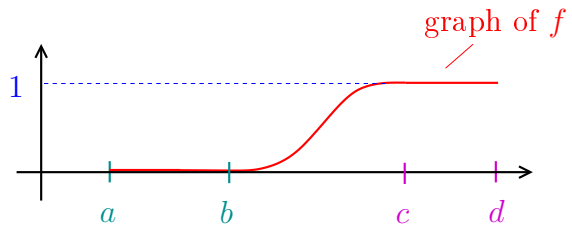
Proposition 19.3. (Smooth Pasting Proposition I) Let A be a subset of $\mathbb{R}^n$, let $f\colon A \to \mathbb{R}^m$ be a map and let $\{V_i\}_{i\in I}$ be an open cover of A. Then the following holds:

$$f\colon A \to \mathbb{R}^m \text{ is smooth} \iff \text{every restriction } f|_{V_i}\colon V_i \to \mathbb{R}^m \text{ is smooth.}$$

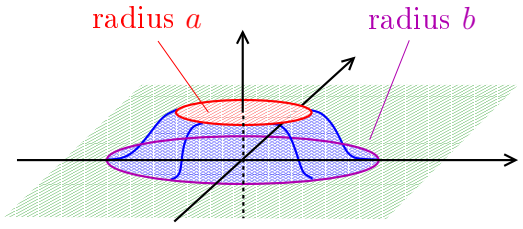
Proof. The lemma follows immediately from the definitions. ∎

Notation. Let $I \subset \mathbb{R}$ be an interval. Given a smooth map $f = (f_1, \dots, f_n)\colon I \to \mathbb{R}^n$ and given $x_0 \in \mathring{I}$ we set

$$f'(x_0) := \left(\frac{\partial}{\partial x}\Big|_{x_0} f_1, \dots, \frac{\partial}{\partial x}\Big|_{x_0} f_n \right) = \lim_{h\to 0} \frac{f(x_0+h)-f(x_0)}{h}.$$



If I is closed and if I has non-empty interior, then we see that I is regular closed. Thus, by the above discussion, we can unambiguously extend $f'\colon \mathring{I} \to \mathbb{R}^n$ to a continuous map $f'\colon I \to \mathbb{R}^n$.



The following lemma is one of the key tools for constructing interesting smooth functions.

Lemma 19.4. (Smooth Transition Function Lemma)

(1) Suppose that we are given real numbers $a \le b < c \le d$ and $\epsilon > 0$. There exists a smooth function $f\colon [a,d] \to [0,1]$ with the following properties:
   (a) $f|_{[a,b]} \equiv 0$ and $f|_{[c,d]} \equiv 1$.
   (b) f is strictly monotonously increasing on $[b,c]$.
   (c) Given any $t \in (a,d)$ we have $f'(t) < (1+\epsilon)\cdot \frac{1}{c-b}$.

(2) Let $a < b$ be two positive real numbers and let $n \in \mathbb{N}$. There exists a smooth function $f\colon \mathbb{R}^n \to [0,1]$ such that $f(x) = 1$ whenever $\|x\| \le a$ and such that $f(x) = 0$ whenever $\|x\| > b$.

Sketch of proof.

(1) We consider the map

$$\begin{aligned} \varphi\colon \mathbb{R} &\to \mathbb{R} \\ x &\mapsto \begin{cases} 0, & \text{if } x \le 0, \\ \exp(-\frac{1}{x^2}), & \text{if } x > 0. \end{cases} \end{aligned}$$

An induction argument, using l'Hopital's rule, shows that φ is in fact smooth, see [**Kön2004**, Chapter 9] for details. Next we consider the map

$$\begin{aligned} \Phi\colon \mathbb{R} &\to \mathbb{R} \\ x &\mapsto \int_{t=0}^{t=x} \varphi(t)\cdot\varphi(1-t)\,dt. \end{aligned}$$

Using a little bit of massaging this map Φ can be turned into the desired map f. We leave it to the reader to fill in the remaining details.

(2) By (1) there exists a smooth function $\varphi\colon [0,\infty) \to [0,1]$ such that $\varphi(x) = 0$ for $x \in [0,a]$ and such that $\varphi(x) = 1$ for $x \in [b,\infty)$. Now consider the map

$$\begin{array}{rccc} f\colon \mathbb{R}^n & \to & [0,1] \\ x & \mapsto & 1-\varphi(\|x\|). \end{array}$$

Since $x \mapsto \|x\|$ is smooth on $\mathbb{R}^n\backslash\{0\}$ we see that f is smooth on $\mathbb{R}^n\backslash\{0\}$. Furthermore, since f is constant on a neighborhood of the origin it follows from the Smooth Pasting Proposition 19.3 that f is in fact smooth on all of $\mathbb{R}^n$. ■

In the following we give characterizations of smooth maps on intervals and certain subsets of $\mathbb{R}^n$. To the best of our knowledge we do not make use of the characterizations, neither explicitly nor implicitly. Nonetheless, it is good to know that they exist.

Proposition 19.5. (Smooth Functions on Compact Interval Proposition) Let $a < b$ be two real numbers and let $f\colon [a,b] \to \mathbb{R}$ be a function. The following two statements are equivalent:

(1) The function $f\colon [a,b] \to \mathbb{R}$ is smooth in the above sense.
(2) All derivatives of $f\colon (a,b) \to \mathbb{R}$ are defined on the open interval (a,b) and they extend to continuous maps on the closed interval $[a,b]$.

Proof. The "(1)⇒(2)"-implication is basically clear. The "(2)⇒(1)"-implication is a consequence of Borel's Theorem, see [**Strg1981**, Theorem 4.32]. ■

In fact an even more general statement holds:

Theorem 19.6. (Whitney Extension Theorem) Let $a < b$ be two real numbers, let U be an open subset of $\mathbb{R}^{n-1} \times [a,b]$ and let $f\colon U \to \mathbb{R}^m$ be a function. The following statements are equivalent:

(1) The map $f\colon U \to \mathbb{R}^m$ is smooth in the sense of the definition on page 531.
(2) The map f is smooth on the open subset $U \cap (\mathbb{R}^{n-1} \times (a,b))$ and all its partial derivatives extend to continuous maps on $U \cap (\mathbb{R}^{n-1} \times \{a,b\})$.

If $U = \mathbb{R}^{n-1} \times [a,b]$, the two statements are also equivalent to:

(3) The map f can be extended to a smooth map on all of $\mathbb{R}^n$.

The above statements also hold for half-spaces $\mathbb{R}^{n-1} \times (-\infty,a]$ and $\mathbb{R}^{n-1} \times [a,\infty)$.

Remark. The theorem was first proved by Hassler Whitney [**Why1934**] in 1934.

Proof. The "(1)⇒(2)"-implication and the "(3)⇒(1)"-implication are basically clear. The "(2)⇒(3)"-implication is a consequence of a generalization of Borel's Theorem, see [**Hör1990a**, Theorem 2.3.6]. An outline of the argument is also given in [**KP2002**, Theorem 2.3.2]. Finally note that the "(1)⇒(3)"-implication also follows from the Tietze Extension Theorem 8.6 combined with the Smooth Approximation Proposition 21.10. ■

19.2. **Taylor's Theorem.** In this short section we formulate Taylor's Theorem, so that later on we can refer to it. Since the reader is most likely aware of its existence it is arguably best to move on to the next section.

Definition. Let $n \in \mathbb{N}_0$.

(1) Let $m \in \mathbb{N}_0$ and let $I = (i_1, \ldots, i_m)$ be a sequence of length m with values in the set $\{1, \ldots, n\}$.
   (a) We write $|I| = m$.
   (b) We write $\partial_I = \frac{\partial^m}{\partial x_{i_1} \cdots \partial x_{i_m}}$.
   (c) Given $x, a \in \mathbb{R}^n$ we write $(x-a)^I = (x_{i_1} - a_{i_1}) \cdot \cdots \cdot (x_{i_m} - a_{i_m})$ and similarly we define $|x-a|^I$.

(2) Let $U \subset \mathbb{R}^n$ be an open subset. Given a smooth map $f\colon U \to \mathbb{R}$, given $a \in U$ and given $k \in \mathbb{N}_0$ we define the k-th Taylor polynomial of f at a as follows:

$$p_k \;:=\; p(f,a)_k \;:=\; \sum_{m=0}^{k} \frac{1}{m!} \sum_{|I|=m} \partial_I f|_a \cdot (x-a)^I.$$

Furthermore, given any $x \in \mathbb{R}^m$ such that the segment $\{(1-t)\cdot a + t \cdot x \,|\, t \in [0,1]\}$ lies in A we define the k-th remainder term of f at a as follows:

$$r_k \;:=\; r(f,a)_k \;:=\; \frac{1}{k!} \sum_{|I|=k+1} (x-a)^I \cdot \int_{t=0}^{t=1} (1-t)^k \cdot \partial_I f|_{(1-t)\cdot a + t\cdot x}\, dt.$$

Theorem 19.7. (Taylor's Theorem) Let $U \subset \mathbb{R}^n$ be an open subset, let $f\colon U \to \mathbb{R}$ be a smooth map, let $a \in U$ and let $k \in \mathbb{N}_0$. If W is a convex neighborhood of a in U, then for every $x \in W$ we have

$$f(x) \;=\; p(f,a)_k(x) + r(f,a)_k(x).$$

Proof. Taylor's Theorem gets proved in basically every single book on multivariable analysis. We refer to [**Lee2002**, p. 648] for a short proof. ∎

Corollary 19.8. Let $U \subset \mathbb{R}^n$ be an open subset, let $f\colon U \to \mathbb{R}$ be a smooth map, let $a \in U$, let $k \in \mathbb{N}_0$ and let W be a convex neighborhood of a in U. Finally suppose that we are given $M \in \mathbb{R}$ such that

$$M \;\geq\; \text{absolute value of all } (k+1)\text{-st partial derivatives of } f \text{ on } W.$$

Then for every $x \in W$ we have

$$\big|f(x) - p(f,a)_k(x)\big| \;\leq\; \frac{n^{k+1}\cdot M}{(k+1)!} \cdot \|x-a\|^{k+1}.$$

Proof. The corollary follows easily from Taylor's Theorem 19.7, the definitions, the observation that for any I we have $|(x-a)^I| \leq \|x-a\|^{|I|}$ and some elementary estimates. ∎

19.3. **The differential of a smooth map.** We start out with the following definition that should also be familiar from a course in real analysis.

Definition. Let $U \subset \mathbb{R}^n$ be an open subset and let $f\colon U \to \mathbb{R}^m$ be a map. We say that f is differentiable in P if there exists a matrix $\mathrm{D}f_P$ such that

$$\lim_{v \to 0} \frac{\|f(P+v) - f(P) - \mathrm{D}f_P \cdot v\|}{\|v\|} \;=\; 0$$

We refer to the $(m \times n)$-matrix $\mathrm{D}f_P$ (which is easily shown to be unique) as the differential of f at P.

Intuitively speaking a map $f\colon U \to \mathbb{R}^m$ is differentiable in P if in a neighborhood of P the map f is "close" to the affine linear map $w \mapsto \mathrm{D}f_P(P - w) + f(P)$.

Example. If $A \in \mathrm{M}(m \times n, \mathbb{R})$ and $v \in \mathbb{R}^m$, then it follows almost immediately from the definitions that for every $P \in \mathbb{R}^n$ the affine map $x \mapsto A \cdot x + v$ is differentiable with differential $\mathrm{D}f_P = A$.

The following proposition is essential for showing differentiability and computing differentials. We will use it all the time without acknowledging it.

Proposition 19.9. (Differential-from-Partial Derivatives Proposition) Let $U \subset \mathbb{R}^n$ be an open subset and let $f = (f_1, \ldots, f_m)\colon U \to \mathbb{R}^m$ be a map. If f is smooth, then the map f is differentiable in every $P \in U$ and for every $P \in U$ we have

$$\mathrm{D}f_P \;:=\; \left(\frac{\partial f_i}{\partial x_j}\Big|_P \right)_{i=1,\ldots,m, j=1,\ldots,n}$$

Proof. This statement is contained in every book on multivariable real analysis, see e.g. [**Lee2002**, Proposition C.8] or [**Fors2008**, p. 70]. ∎

Example. Let $I \subset \mathbb{R}$ be an open subset, let $f = (f_1, \ldots, f_m)\colon I \to \mathbb{R}^m$ be a smooth map and let $P \in I$. It follows immediately from the definitions that

$$f'(P) \;=\; \mathrm{D}\, f_P \cdot \underbrace{1}_{\in \mathbb{R}} \;=\; \text{the unique column vector of } \mathrm{D}f_P \;\in\; \mathbb{R}^m.$$

Put differently, the vector $f'(P) \in \mathbb{R}^m$, viewed as an $(m \times 1)$-matrix in the obvious way, equals $\mathrm{D}f_P$.

We also recall the chain rule for differentials.

Proposition 19.10. (Chain Rule) Let $U \subset \mathbb{R}^k$ and $V \subset \mathbb{R}^l$ be open subsets and let $f\colon U \to \mathbb{R}^l$ and $g\colon V \to \mathbb{R}^m$ be two smooth maps such that $f(U) \subset V$. The composition $g \circ f\colon U \to \mathbb{R}^m$ is smooth and given any $P \in U$ we have

$$\underbrace{\mathrm{D}(g \circ f)_P}_{m \times k\text{-matrix}} \;=\; \underbrace{\mathrm{D}g_{f(P)}}_{m \times l\text{-matrix}} \cdot \underbrace{\mathrm{D}f_P}_{l \times k\text{-matrix}} \qquad \text{"Chain Rule".}$$

Proof. This proposition is proved in every book on multivariable real analysis, see e.g. [**Lee2002**, Proposition C.3]). ∎

Example. Let $U \subset \mathbb{R}^k$ be an open subset and let $f, g\colon U \to \mathbb{R}$ be smooth maps. It follows from Chain Rule 19.10 and the discussion on page 531 that the following maps are also smooth:[207]

$$\begin{array}{ccc} U & \to & \mathbb{R} \\ x & \mapsto & f(x) \cdot g(x) \end{array} \qquad \text{and} \qquad \begin{array}{ccc} U & \to & \mathbb{R} \\ x & \mapsto & f(x) + g(x). \end{array}$$

We move on to the following definition.

[207] This example is the smooth analogue of Lemma 2.3.

Definition. Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$.[208] We say that a map $f\colon U \to V$ is a diffeomorphism if f is smooth, if f is a bijection and if $f^{-1}\colon V \to U$ is also smooth. If such a diffeomorphism exists, then we say that U and V are diffeomorphic.

Examples.

(1) Let $n \in \mathbb{N}$ and $r, s > 0$ and $x, y \in \mathbb{R}^n$. It is straightforward to show that the open balls $B_r^n(x)$ and $B_s^n(y)$ are diffeomorphic.

(2) We consider the maps

$$\begin{array}{rcl} B^n & \to & \mathbb{R}^n \\ x & \mapsto & \dfrac{x}{\sqrt{1-\|x\|^2}} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \mathbb{R}^n & \to & B^n \\ x & \mapsto & \dfrac{x}{\sqrt{1+\|x\|^2}}. \end{array}$$

One can easily verify that they are smooth and that they are inverses of one another. This shows that both maps are diffeomorphisms. In particular we have shown that B^n is diffeomorphic to $\mathbb{R}^n$.[209]

Next we recall a proposition from the analysis courses. Since this proposition is one of the reasons why later on dealing with smooth manifolds is easier than dealing with topological manifolds we also provide the proof.

Proposition 19.11. (Smooth Invariance of Domain Proposition) Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open sets.

(1) If $f\colon U \to V$ is a diffeomorphism with inverse $f^{-1}\colon V \to U$, then for any $P \in U$ we have

$$\mathrm{D}(f^{-1})_{f(P)} \cdot \mathrm{D}f_P = \mathrm{id}_m \qquad \text{and} \qquad \mathrm{D}f_P \cdot \mathrm{D}(f^{-1})_{f(P)} = \mathrm{id}_n\,.$$

In particular the differential $\mathrm{D}f_P$ is an invertible matrix.

(2) If U and V are diffeomorphic and non-empty, then $m = n$.

Example. Suppose U is an open subset, let's say connected, of $\mathbb{R}^n$ and that $f\colon U \to \mathbb{R}^n$ is a smooth map such that $\mathrm{D}f_P$ is invertible for every $P \in U$. One might be tempted to think that $f\colon U \to f(U)$ is already a diffeomorphism itself. But this is not necessarily the case, a counterexample is for example given by

$$\begin{array}{rcl} f\colon \mathbb{C}\setminus\{0\} & \to & \mathbb{C}\setminus\{0\} \\ z & \mapsto & z^2. \end{array}$$

One can easily verify that $\mathrm{D}f_z$ is invertible for every $z \in \mathbb{C}\setminus\{0\}$. But f is evidently not injective.

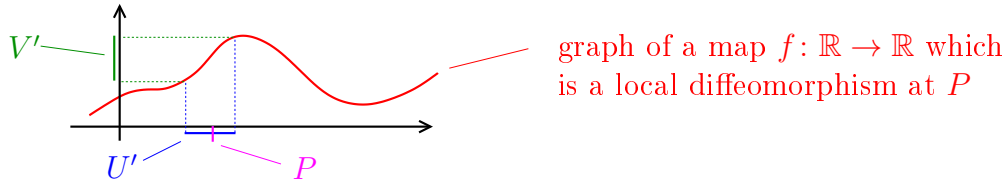
Proof.

(1) Let $f\colon U \to V$ be a diffeomorphism between open sets $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$. We denote by $f^{-1}\colon V \to U$ the inverse of f. Let $P \in U$. We see that

$$\mathrm{D}(f^{-1})_{f(P)} \cdot \mathrm{D}f_P \underset{\uparrow}{=} \mathrm{D}(f^{-1}\circ f)_P = \mathrm{D}(\mathrm{id}_U)_P = \mathrm{id}_m \in \mathrm{M}(m\times m, \mathbb{R}).$$

Chain Rule 19.10

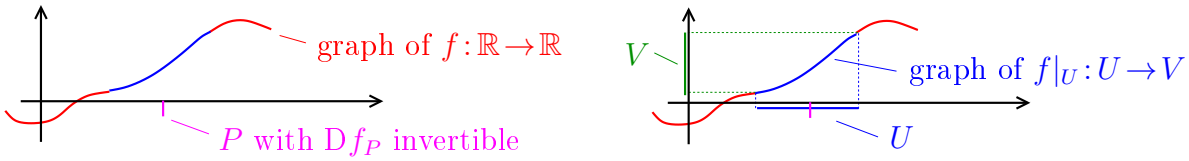
[208] Note that we do *not* demand that U and V are open subsets.



[209] In the Star Shaped-Diffeomorphism Type Theorem **??** we will prove a much more general statement, namely we will see that every open star-shaped subset of $\mathbb{R}^n$ is diffeomorphic to $\mathbb{R}^n$.

The same way one shows that $\mathrm{D}f_P \cdot \mathrm{D}(f^{-1})_{f(P)} = \mathrm{id}_n \in \mathrm{M}(n \times n, \mathbb{R})$. In other words, the matrices $\mathrm{D}f_P$ and $\mathrm{D}(f^{-1})_{f(P)}$ are inverses of one another. This implies that $\mathrm{D}f_P$ is invertible.

(2) Since U is non-empty we can find a $P \in U$. By (1) the $(m \times n)$–matrix $\mathrm{D}f_P$ is invertible, this means that the matrix is a square matrix, i.e. $m = n$. ■



Before we state the next theorem let us introduce the following harmless definition, which is in line with our definition of a local property of a map that we gave on page 179.

Definition. Let $f\colon U \to V$ be a smooth map between two open subsets of $\mathbb{R}^n$ and let $P \in U$. We say f is a local diffeomorphism at P if there exist open neighborhoods U' of P in U and V' of $f(P)$ in V such that $f|_{U'}\colon U' \to V'$ is a diffeomorphism.

Now we can formulate the following theorem which can be viewed as a partial inverse to the Smooth Invariance of Domain Proposition 19.11 (1).

Theorem 19.12. (Inverse Function Theorem) Let $U \subset \mathbb{R}^n$ be an open subset and let $f\colon U \to \mathbb{R}^n$ be a smooth map. Furthermore let $P \in U$ be a point. If $\mathrm{D}f_P$ is invertible, then f is a local diffeomorphism at P.

Proof. This theorem is proved in most courses on multivariable real analysis. A proof is for example given in [**Lee2002**, Corollary C.34]. ■

The Inverse Function Theorem 19.12 is one of the main results in real analysis. For example the proof of the following proposition rests heavily on the Inverse Function Theorem 19.12.

Theorem 19.13. (Smooth Invariance of Domain Theorem) Let $U \subset \mathbb{R}^n$ be an open set and let $f\colon U \to \mathbb{R}^n$ be a smooth map such that the differential $\mathrm{D}f_P$ is invertible at every point P in the open set U. Then the following two statements hold:

(1) The map f is open, i.e. given any open subset $V \subset U$ the image $f(V)$ is an open subset of $\mathbb{R}^n$.

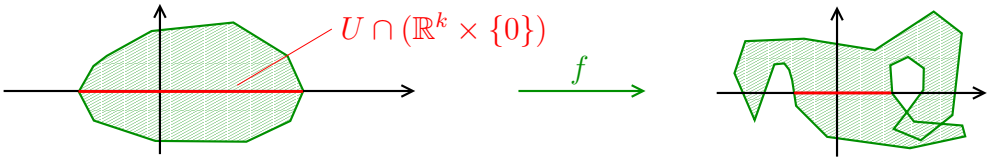
(2) If f is injective, then $f\colon U \to f(U)$ is a diffeomorphism.

Remark. In the Topological Invariance of Domain Theorem 82.7 we will see that the statement of the Smooth Invariance of Domain Theorem 19.13 (1) also holds if we only assume that f is continuous and injective.

Proof. Let $U \subset \mathbb{R}^n$ be an open set and let $f\colon U \to \mathbb{R}^n$ be a smooth map such that the differential $\mathrm{D}f_P$ is invertible at every point P in the open set U.

(1) Let $V \subset U$ be an open subset. We need to show that $f(V)$ is an open subset of $\mathbb{R}^n$. Let $Q \in f(V)$. We pick $P \in V$ with $f(P) = Q$. Since $\mathrm{D}f_P$ is invertible it follows from the Inverse Function Theorem 19.12, applied to the restriction $f\colon V \to \mathbb{R}^n$, that there exists an open neighborhood V' of P and an open neighborhood W' of $Q = f(P)$ such that $f\colon V' \to W'$ is a diffeomorphism. But this implies that $W' \subset f(V)$. It follows from this discussion, together with the elementary the JH-Lemma 1.7, that $f(V)$ is indeed an open subset of $\mathbb{R}^n$.

(2) We now suppose that $f\colon U \to \mathbb{R}^n$ is injective. By (1) we know that $f(U)$ is an open subset of $\mathbb{R}^n$. We consider the inverse $f^{-1}\colon f(U) \to U$. We need to show that $f^{-1}\colon f(U) \to U$ is smooth. Since f is a local diffeomorphism we see that f^{-1} is also a local diffeomorphism. This implies that f^{-1} is locally smooth which implies by the Smooth Pasting Proposition 19.3 that f^{-1} itself is smooth. ■



19.4. **Special topics in the theory of smooth functions.** In this short section we collect a ragtag of results on smooth functions, each of which will have its moment of glory later on. Nonetheless, in a first reading of this chapter, this section can be skipped.

The first proposition says that locally, up to translation, one can describe any smooth map as matrix multiplication, where the coefficients of the matrix are allowed to vary.

Proposition 19.14. (Map-as-Matrix Multiplication Proposition) Let $U \subset \mathbb{R}^n$ be some convex subset that contains the origin. Furthermore let $f\colon U \to \mathbb{R}^m$ be a smooth map with $f(0) = 0$.

(1) There exists a smooth map $A\colon U \to \mathrm{M}(m \times n, \mathbb{R})$ such that $A(0) = \mathrm{D}f_0$ and such that
$$f(x) \;=\; A(x) \cdot x \qquad \text{for all } x \in U.$$

(2) If there exist $k \in \{0, \ldots, n\}$ and $l \in \{0, \ldots, m\}$ with $f((\mathbb{R}^k \times \{0\}) \cap U) \subset \mathbb{R}^l \times \{0\}$, then we can arrange that for each $x \in (\mathbb{R}^k \times \{0\}) \cap U$ the corresponding matrix $A(x)$ is of the form $\begin{pmatrix} * & * \\ 0 & * \end{pmatrix}$, where the top left corner is an $l \times k$-matrix.

Proof. First we take care of Statement (1). By considering the coordinate functions of a given map $f = (f_1, \ldots, f_m)\colon U \to \mathbb{R}^m$ separately we see that it suffices to deal with the case $m = 1$. Thus let $f\colon U \to \mathbb{R}$ be a smooth map with $f(0) = 0$. Note that in this case we need to show that there exist smooth maps $a_1, \ldots, a_n\colon U \to \mathbb{R}$ such that $a_i(0) = \frac{\partial f}{\partial x_i}(0)$ and with

$$f(x) \;=\; \sum_{i=1}^{n} a_i(x_i) \cdot x_i \qquad \text{for all } x = (x_1, \ldots, x_n) \in U.$$

We observe that given any $x = (x_1, \dots, x_n) \in U$ we have

$$f(x) = f(x) - \underbrace{f(0)}_{=0} = \int_{t=0}^{t=1} \frac{d}{dt} f(\underbrace{t \cdot x}_{\in U})\, dt = \int_{t=0}^{t=1} \sum_{i=1}^{n} \frac{\partial f(t\cdot x)}{\partial x_i} \cdot x_i \, dt = \sum_{i=1}^{n} \underbrace{\int_{t=0}^{t=1} \frac{\partial f(tx)}{\partial x_i}\, dt}_{=:a_i(x)} \cdot x_i.$$

Fundamental Theorem of Calculus — Chain Rule 19.10

If U is open, then it follows from standard methods in analysis, e.g. the Leibniz Integral Rule [**PedS2015**, Theorem 9.2.11], that each a_i is smooth. If U is not open, then this fact can be shown with more effort by hand. Alternatively one can use the Smooth Extension Proposition 21.9 to reduce the problem to the open case.

Finally note that it follows from the above equality and the Product Rule that we have the equality $a_i(0) = \frac{\partial f}{\partial x_i}(0)$. This shows that we have indeed $A(0) = \mathrm{D}f_0$. This concludes the proof of Statement (1).

Now we turn to the proof of Statement (2). In fact it is straightforward to see that the map $A\colon U \to \mathrm{M}(m \times n, \mathbb{R})$ we constructed above has the desired property. Indeed, as above we only have to deal with the case $m = 1$ and $l = 1$. But if $f((\mathbb{R}^k \times \{0\}) \cap U) = \{0\}$, then it follows immediately from the construction of the matrix that for each $x \in (\mathbb{R}^k \times \{0\}) \cap U$ we obtain the zero matrix. ■

On very few occasions we will need the following proposition.

Proposition 19.15. Let $U \subset \mathbb{R}^n$ be an open subset, let $f\colon U \to \mathbb{R}^n$ be a smooth map and let $P \in U$. If $\mathrm{D}f_P$ is invertible, then there exists an $\epsilon > 0$ such that $f(B^n_\epsilon(P))$ is convex.

Proof. The proposition is proved in [**Pol2001**, Theorem 2.1]. ■

We conclude this section with a harmless lemma which is elementary, but which time and again puzzles the author.

Lemma 19.16. Let $U \subset \mathbb{R}^k$ and $V \subset \mathbb{R}^l$ be two open non-empty subsets and suppose we are given a map of the form

$$\begin{aligned} \Theta\colon U \times V &\to \mathbb{R}^k \times \mathbb{R}^l = \mathbb{R}^{k+l} \\ (x, y) &\mapsto (f(x, y), g(y)). \end{aligned}$$

that is a diffeomorphism onto its image. Then $g\colon V \to \mathbb{R}^l$ is also a diffeomorphism onto its image and the inverse of Θ is of the form

$$\begin{aligned} \Theta^{-1}\colon \Theta(U \times V) &\to U \times V \subset \mathbb{R}^k \times \mathbb{R}^l \\ (x, y) &\mapsto (\varphi(x, y), g^{-1}(y)) \end{aligned}$$

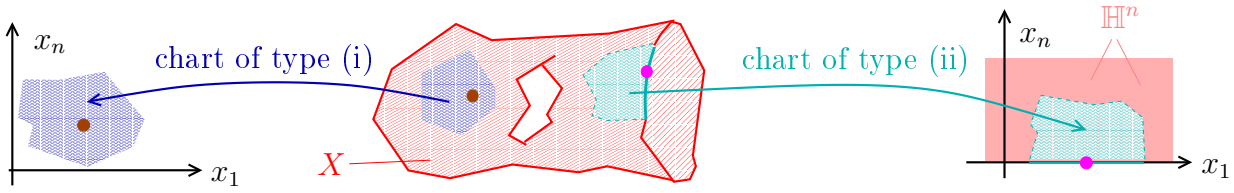
for some smooth map $\varphi\colon \Theta(U \times V) \to \mathbb{R}^k$.

Proof. We denote by $p\colon \mathbb{R}^k \times \mathbb{R}^l \to \mathbb{R}^k$ and $q\colon \mathbb{R}^k \times \mathbb{R}^l \to \mathbb{R}^l$ the obvious projections. We set $\varphi = p \circ \Theta^{-1}$ and $\psi = q \circ \Theta^{-1}$. Note that φ and ψ are compositions of smooth maps, hence smooth. Furthermore we have $\Theta^{-1} = (\varphi, \psi)$. Now let $x \in U$. We denote by $j_x\colon V \to U \times V$ the inclusion map that is given by $y \mapsto (x, y)$. Given any $y \in V$ we perform the following calculation:

$$\psi(x, g(y)) = (q \circ \Theta^{-1} \circ j_x \circ g)(y) = (q \circ \Theta^{-1} \circ j_x \circ q \circ \Theta \circ j_x)(y) = (q \circ \Theta^{-1} \circ \Theta \circ j_x)(y) = y.$$

by definition of ψ — definition of g — since $q \circ j_x = \mathrm{id}_{\mathbb{R}^l}$

This shows that $y \mapsto \psi(x,y)$ is an inverse to g. In particular g is a diffeomorphism and $\psi(x,y) = g^{-1}(y)$ for all $y \in V$. ■



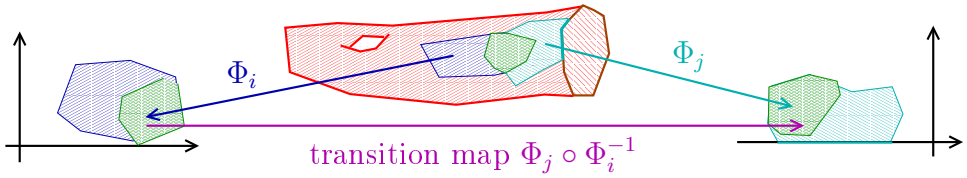
19.5. **Smooth manifolds.** In this section we will finally introduce one of the most important notions of these lecture notes, namely the concept of a "smooth manifold".
For the reader's convenience we first recall the notion of a topological manifold that we introduced on page 511.

Definition. Let X be a topological space.

(1) An *n-dimensional chart for X at a point $x \in X$* is a homeomorphism $\Phi\colon U \to V$ where U is an open neighborhood of x and
 (i) V is an open subset of $\mathbb{R}^n$ or
 (ii) V is an open subset of the upper half-space $\mathbb{H}^n$ and $\Phi(x)$ lies in $\partial\mathbb{H}^n$.
 In the former case we say that Φ is a chart of type (i), in the latter case we say that Φ is a chart of type (ii). We refer to the figure below for an illustration.

(2) We say X is an *n-dimensional topological manifold*, if X is second-countable and Hausdorff, and if for every $x \in X$ there exists an n-dimensional chart $\Phi\colon U \to V$ at x.

(3) An *n-dimensional atlas* for X is a collection of n-dimensional charts such that the domains of the charts cover all of X.

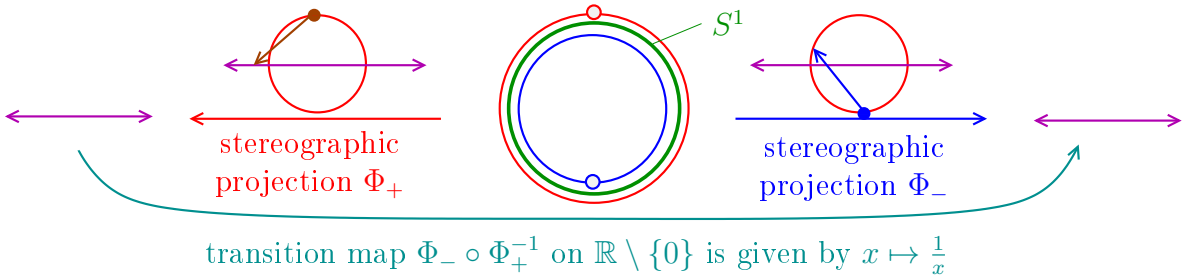


Definition. Let X be a topological manifold.

(1) We say that two n-dimensional charts $\Phi_1\colon U_1 \to V_1$ and $\Phi_2\colon U_2 \to V_2$ are *smoothly compatible* if the *transition map*[210]

$$\Phi_2 \circ \Phi_1^{-1}\colon \underbrace{\Phi_1(U_1 \cap U_2)}_{\text{open set in } \mathbb{R}^n \text{ or } \mathbb{H}^n} \to \underbrace{\Phi_2(U_1 \cap U_2)}_{\subset \mathbb{R}^n}$$

is a diffeomorphism.[211]



(2) An n-dimensional atlas of an topological manifold for X is called *smooth* if all charts in the atlas are smoothly compatible to one another.

[210] Once again we refer to page 532 for the definition of a smooth map $U \to \mathbb{R}^n$ where U is an open subset of $\mathbb{H}^n$. We also refer to the Whitney Extension Theorem 19.6 for an alternative characterization of smooth maps on $\mathbb{H}^n$.

[211] Note that this condition is indeed symmetric in i and j.

Example. Let $n \in \mathbb{N}$. We denote by $N := (0, \dots, 0, 1)$ the North Pole of S^n and we denote by $S := (0, \dots, 0, -1)$ the South Pole of S^n. Let $\Phi_+ \colon S^n \setminus \{N\} \to \mathbb{R}^n$ be the stereographic projection from the North Pole N and let $\Phi_- \colon S^n \setminus \{S\} \to \mathbb{R}^n$ be the stereographic projection from the South Pole S, as defined in Lemma 2.18. In Exercise 18.15 we saw that the maps $\Phi_- \circ \Phi_+^{-1} \colon \mathbb{R}^n \setminus \{0\} \to \mathbb{R}^n \setminus \{0\}$ is given by the diffeomorphism $x \mapsto \frac{1}{\|x\|^2} \cdot x$. This shows that Φ_+ and Φ_- are smoothly compatible. Thus the atlas for S^n given by Φ_+ and Φ_- is a smooth atlas.

Definition. Let M be a topological manifold and let $\mathcal{A}$ be a smooth atlas for M. We say $\mathcal{A}$ is maximal if every chart Ψ that is smoothly compatible with all the charts in the smooth atlas $\mathcal{A}$ is already contained in $\mathcal{A}$.

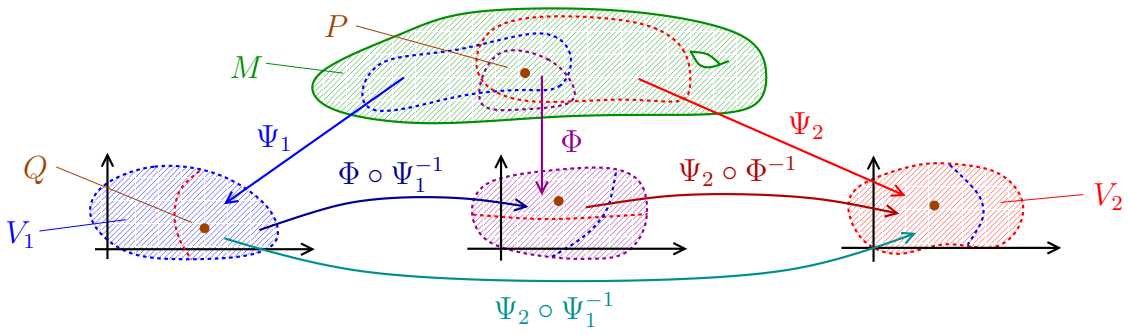
Proposition 19.17. (Maximal Atlas Existence Proposition) Let M be a topological manifold and let $\mathcal{A}$ be a smooth atlas for M.

(1) The smooth atlas is contained in a unique maximal smooth atlas for M.
(2) The unique maximal smooth atlas from (1) is given by the set of all charts of type (i) and (ii) from page 511 that are smoothly compatible with all charts in the given smooth atlas $\mathcal{A}$.

Proof. Let $\mathcal{A}$ be a smooth atlas for M. We denote by $\mathcal{B}$ the set of all charts of M that are smoothly compatible with respect to all charts in $\mathcal{A}$.

Claim 1. The charts in $\mathcal{B}$ form a smooth atlas.

Proof. Let $\Psi_1 \colon U_1 \to V_1$ and $\Psi_2 \colon U_2 \to V_2$ be two charts in $\mathcal{B}$. We need to show that Ψ_1 and Ψ_2 are smoothly compatible, i.e. we need to show that the transition map



$$\Psi_2 \circ \Psi_1^{-1} \colon \Psi_1(U_1 \cap U_2) \;\to\; \Psi_2(U_1 \cap U_2)$$

is smooth. By the Smooth Pasting Proposition 19.3 it suffices to show that the map is locally smooth. Thus let $Q \in \Psi_1(U_1 \cap U_j)$. We write $P := \Psi_1^{-1}(Q) \in M$. We pick a chart $\Phi \colon A \to B$ from our smooth atlas $\mathcal{A}$ with $P \in A$. Since Ψ_1 and Ψ_2 are smoothly compatible with all charts in $\mathcal{A}$ we know that the maps $\Phi \circ \Psi_1^{-1} \colon \Psi_1(U_1 \cap A) \to \Phi(U_1 \cap A)$ and $\Psi_2 \circ \Phi^{-1} \colon \Phi(U_2 \cap A) \to \Psi_2(U_2 \cap A)$ are smooth. Thus we see that the restriction of $\Psi_2 \circ \Psi_1^{-1}$ to the open neighborhood $\Psi_1(U_1 \cap U_2 \cap A)$ of P is smooth. ⊞

It remains to prove the following claim.

Claim 2. The smooth atlas $\mathcal{B}$ is maximal and it is the unique maximal smooth atlas that contains $\mathcal{A}$.

Proof. If Ψ is a chart that is smoothly compatible with all charts in $\mathcal{B}$, then it is also smoothly compatible with all charts in $\mathcal{A}$, thus Ψ is already contained in $\mathcal{B}$. This shows that $\mathcal{B}$ is maximal.

Now let $\mathcal{C}$ be a maximal smooth atlas that contains $\mathcal{A}$. We need to show that $\mathcal{B} = \mathcal{C}$. First let $\Phi \in \mathcal{C}$. By definition Φ is smoothly compatible with all charts $\mathcal{A}$, thus $\Phi \in \mathcal{B}$. Now let $\Phi \in \mathcal{B}$. The proof of Claim 1 shows that Φ is also smoothly compatible with any chart that is smoothly compatible with all charts in $\mathcal{A}$. Thus we see that $\Phi \in \mathcal{C}$. ■

Definition. Let X be a topological manifold.

(1) An n-dimensional smooth structure on X is a choice of a maximal n-dimensional smooth atlas for X.
(2) Let $\mathcal{A}$ be an n-dimensional smooth atlas for X. By the Maximal Atlas Existence Proposition 19.17 the smooth atlas $\mathcal{A}$ is contained in a unique maximal n-dimensional smooth atlas $\mathcal{M}$. We refer to $\mathcal{M}$ as the smooth structure defined by $\mathcal{A}$.[212]
(3) An n-dimensional smooth manifold is a pair $(X, \mathcal{M})$ consisting of a topological manifold X together with an n-dimensional smooth structure $\mathcal{M}$, i.e. together with a maximal smooth atlas $\mathcal{M}$ for X. (As with many other definitions we usually suppress the choice of a smooth atlas from the notation.) We refer to the topological space X as the underlying topological manifold of the smooth manifold $(X, \mathcal{A})$.

Remark.

(1) In the literature the term "manifold" gets used with wildly different meanings, in particular often it gets to mean "topological manifold" or "smooth manifold". To make matters worse, there are also other perfectly reasonable notions of a "manifold", namely on page 2093 we will introduce "PL-manifolds" and on page 2104 we will get to know "combinatorial manifolds". To prevent any misunderstanding we only rarely write "manifold" without any decorations. We only do so in informal discussions where the precise meaning is irrelevant.
(2) Since the underlying topological space of a smooth manifold is a topological manifold, many results on topological manifolds hold by fiat also for smooth manifolds. For example by the Topological Manifolds-Local Properties Lemma 18.8 we know that every topological manifold, and thus also every smooth manifold, is locally contractible.

[212] In practice we might be a little sloppy every now and then and we might not distinguish in our notation between a smooth atlas and the corresponding maximal smooth atlas, i.e. the corresponding smooth structure.

(3) The question which topological manifolds admit smooth atlases is subtle. Perhaps rather shockingly in 1960 Michel Kervaire [**Kerv1960**] showed that there exists a 10-dimensional topological manifold that does not admit a smooth atlas. We will discuss this question in greater detail in Section **??**.
(4) A map $f\colon U \to \mathbb{R}^m$ from an open subset of $\mathbb{R}^n$ to $\mathbb{R}^m$ is called a *C^k-map*, if all iterated k-fold partial derivatives exist and if they are continuous. Throughout the above discussion one could replace "smooth" by "C^k". This leads to the notion of a C^k-atlas, a C^k-structure and a C^k-manifold. In [**Hirs1976**, Theorem 2.9] it is shown that every C^1-structure gives rise to an essentially unique smooth structure.

The following proposition gives us interesting examples of smooth manifolds.

Proposition 19.18. The following topological manifolds admit a smooth atlas:
(1) open subsets of $\mathbb{R}^n$ and open subsets of $\mathbb{H}^n$,
(2) all closed balls $\overline{B}^n$,
(3) all spheres $S^n \subset \mathbb{R}^{n+1}$,
(4) the n-dimensional torus $(S^1)^n$,
(5) the surfaces of genus $g \in \mathbb{N}_0$, as defined on page 265,
(6) the non-orientable surfaces of genus $g \in \mathbb{N}$, as defined on page 266.

More precisely, the atlases that we provided in Section 18.1 and in the proof of the Surface-is-Topological Manifold Proposition 18.7 are smooth.

Proof. It is straightforward to verify that the atlases for examples (1) to (4) that we provided in Section 18.1 are smooth. For example on page 542, see also Exercise 18.15, we saw that the transition map for the atlas for S^n given by the stereographic projections from the Poles is smooth, which shows that the given atlas for S^n is smooth.

It remains to consider the (non-orientable) surfaces of genus $g \geq 2$. The atlas that we provided in the proof of the Surface-is-Topological Manifold Proposition 18.7 might initially look dubious. In fact all transition maps are compositions of (some of) the following types of maps:

(1) reflections in lines,
(2) translations,
(3) and for some $\eta > 0$ the map

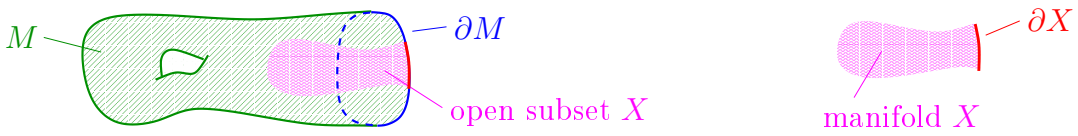
$$\begin{array}{rcl} \{r \cdot \exp(\mathrm{i}\alpha) \,|\, r \in (0,\eta), \alpha \in (0, \frac{\pi}{4})\} & \to & \{r \cdot \exp(\mathrm{i}\alpha) \,|\, r \in (0,\eta), \alpha \in (0, \frac{3\pi}{4})\} \\ z = r \cdot \exp(\mathrm{i}\varphi) & \mapsto & r \cdot \exp(3\mathrm{i}\varphi) = \frac{1}{|z|^2} \cdot z^3, \end{array}$$

(4) the inverse of (3).

It is clear that the first three types of maps are smooth. It follows from the Smooth Invariance of Domain Theorem 19.13 (2) that the fourth map is also smooth. Thus the transition maps in the atlas are smooth. ■

Convention. As we discussed in Proposition 19.18, the atlases that we provided in Section 18.1 and in the proof of the Surface-is-Topological Manifold Proposition 18.7, give smooth atlases for the following topological manifolds:
(1) open subsets of $\mathbb{R}^n$ and open subsets of $\mathbb{H}^n$,
(2) all closed balls $\overline{B}^n$,

(3) all spheres $S^n \subset \mathbb{R}^{n+1}$,
(4) the n-dimensional torus $(S^1)^n$,
(5) the surfaces of genus $g \in \mathbb{N}_0$, as defined on page 265,
(6) the non-orientable surfaces of genus $g \in \mathbb{N}$, as defined on page 266.



We will invariably work with the corresponding smooth structures, unless we say something different. We refer to these as the standard smooth structures on these topological manifolds.

For completeness we state the following lemma which is closely related to the discussion on page 526.

Lemma 19.19. (Open Subset-Submanifold Lemma) Let M be a smooth manifold and let X be an open subset of M. The restrictions of the charts of the smooth atlas of M to X define a smooth atlas for X.

Remark. In the Open Subset-Submanifold Lemma 19.19 we will prove an important addendum to Lemma 19.20.

Proof. The lemma follows easily from the definitions. ■

Convention. We will constantly use the Open Subset-Submanifold Lemma 19.19 to view open subsets of a smooth manifold as smooth manifolds in their own right.

On page 511 we defined the boundary of a topological manifold. We can now similarly define the notion of the boundary of a smooth manifold.

Definition. Let M be a smooth manifold.

(1) We say that a point $x \in M$ is a boundary point if x does not admit a chart of type (i) in the smooth structure. We denote by ∂M the set of all boundary points of M. We refer to ∂M as the boundary of M.
(2) We say a smooth manifold M is closed if M is compact with $\partial M = \varnothing$.

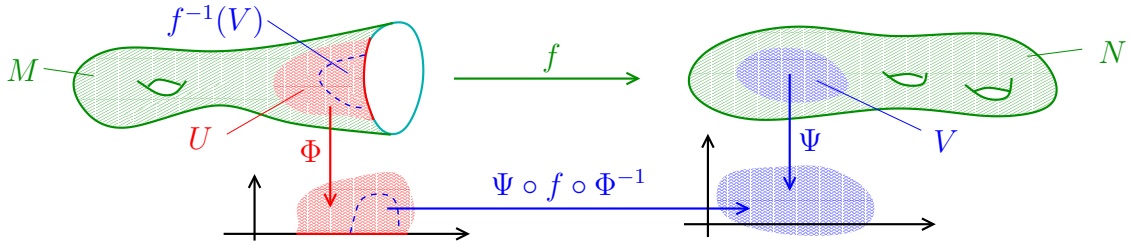
Remark. As we just mentioned, on page 511 we already defined the boundary of a topological manifolds. In the Topological Manifold Boundary Proposition 75.2 (2) we will see that the boundary of a smooth manifold in the above sense agrees with the boundary of a topological manifold.

The following lemma can be viewed as an addendum to the Open Subset-Submanifold Lemma 19.19.

Lemma 19.20. Let M be a smooth manifold and let X be an open subset of M. We use the Open Subset-Submanifold Lemma 19.19 to view X as a smooth manifold in its own right. The boundary ∂X of X viewed as a smooth manifold is given by $\partial X = X \cap \partial M$.

Proof. The lemma follows easily from the definitions. ■

19.6. **Smooth maps between smooth manifolds.** We give a few more standard definitions regarding smooth manifolds.



Definition. Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold.

(1) A map $f\colon M \to N$ is called smooth if for every chart $\Phi\colon U \to \widetilde{U}$ of M and every chart $\Psi\colon V \to \widetilde{V}$ of N, in the respective smooth structures, the concatenation

$$\Psi \circ f \circ \Phi^{-1}\colon \underbrace{\Phi(U \cap f^{-1}(V))}_{\text{open subset of } \mathbb{R}^m \text{ or } \mathbb{H}^m} \to \widetilde{V} \subset \mathbb{R}^n$$

is smooth, in the sense of our definition on page 532.

(2) We denote by $C^\infty(M,N)$ the set of all smooth maps from M to N.

Checking the condition in the definition of a smooth manifold for all charts in the smooth structure is evidently very very painful. Fortunately the following lemma simplifies the life of a working mathematician greatly.

Lemma 19.21. (Smooth-via-Atlas Lemma) Let $f\colon M \to N$ be some map between an m-dimensional smooth manifold M and an n-dimensional smooth manifold N. Furthermore let $\{\Phi_i\colon U_i \to \widetilde{U}_i\}_{i\in I}$ be charts in the smooth structure with $M = \bigcup_{i\in I} U_i$ and let $\{\Psi_j\colon V_j \to \widetilde{V}_j\}_{J\in J}$ be charts in the smooth structure $N = \bigcup_{j\in J} V_j$. If for all $i \in I$ and $j \in J$ the map

$$\Psi_j \circ f \circ \Phi_i^{-1}\colon \Phi(U_i \cap f^{-1}(V_j)) \to \widetilde{V}_j \subset \mathbb{R}^n$$

is smooth, then f is smooth.

Proof. The proof of the lemma is somewhat similar to the proof of Claim 1 in the proof of the Maximal Atlas Existence Proposition 19.17. Namely, the lemma follows easily from the Smooth Pasting Proposition 19.3 together with the fact, see Proposition 19.10, that the composition of smooth maps between open subsets of some $\mathbb{R}^n$'s is again smooth. We leave it to the reader to fill in the details. ■

Example.

(1) We consider maps $f\colon S^n \to \mathbb{R}^m$. As on page 542 we equip S^n with the smooth atlas that is given by the stereographic projections and we equip $\mathbb{R}^m$ with the smooth atlas given by the identity chart. An entertaining calculation shows that the inverses of

the stereographic projections $\Phi_\pm$ are given by

$$\begin{array}{rcl} \Phi_\pm^{-1}\colon \mathbb{R}^n & \to & \mathbb{R}^n \setminus \{(0,\dots,0,1)\} \\ (x_1,\dots,x_n) & \mapsto & \left(\frac{2x_1}{x_1^2+\cdots+x_n^2+1}, \dots, \frac{2x_1}{x_1^2+\cdots+x_n^2+1}, \pm 1 \mp \frac{2}{x_1^2+\cdots+x_n^2+1} \right) \end{array}$$

the Smooth-via-Atlas Lemma 19.21 implies that $f\colon S^n \to \mathbb{R}^m$ is smooth precisely if $f \circ \Phi_\pm{}^{-1}\colon \mathbb{R}^n \to \mathbb{R}^m$ are smooth. For example it follows immediately that the inclusion map $S^n \to \mathbb{R}^{n+1}$ is smooth.

(2) Let U be an open subset of $\mathbb{R}^n$ and let $f\colon U \to \mathbb{R}^m$ be a map. It follows easily from the definitions that the map f is smooth as a map between smooth manifolds if and only if it is smooth in the "classical" sense of page 531.

(3) Let $n \in \mathbb{Z}$. In Exercise 19.5 we will see that the following map is smooth:

$$\begin{array}{rcl} S^1 & \to & S^1 \\ z & \mapsto & z^n \end{array}$$

We continue with a very straightforward lemma which gets used implicitly all the time.

Lemma 19.22.

(1) Every smooth map between two smooth manifolds is continuous.

(2) The composition of two smooth maps between smooth manifolds is again smooth.

Proof.

(1) Let $f\colon M \to N$ be a smooth map between two smooth manifolds M and N. Let $\{\Phi_i\colon U_i \to \widetilde{U}_i\}_{i\in I}$ be the charts in the smooth structure of M. Furthermore let $\{\Psi_j\colon V_j \to \widetilde{V}_j\}_{J\in J}$ be the charts in the smooth atlas of N. By hypothesis all the maps

$$\Psi_j \circ f \circ \Phi_i^{-1}\colon \Phi(U_i \cap f^{-1}(V_j)) \to \widetilde{V}_j \subset \mathbb{R}^n$$

are smooth. In particular they are continuous. Since Φ_i and Ψ_j are by definition homeomorphisms we see that the restriction of f to each $U_i \cap f^{-1}(V_j)$ is continuous. Since these form an open cover of M we obtain from the Pasting Proposition 2.6 that f is indeed continuous.

(2) By the Chain Rule 19.10 this statement holds for smooth maps between open subsets of some $\mathbb{R}^n$'s. The statement for smooth maps between smooth manifolds follows fairly easily from this observation, together with the Smooth-via-Atlas Lemma 19.21 and the Smooth Pasting Proposition 19.3. We leave it to the reader to fill in the details. ∎

Definition.

(1) We say a map $f\colon M \to N$ between smooth manifolds is a diffeomorphism if f is smooth, if f is a bijection and if $f^{-1}\colon N \to M$ is also smooth. If such a diffeomorphism exists, then we say that M and N are diffeomorphic.

(2) Let $f\colon M \to N$ be a map between two smooth manifolds and let $P \in M$. We say f is a local diffeomorphism at P if there exist open neighborhoods U of P in M and V of $f(P)$ in N such that[213] $f|_U\colon U \to V$ is a diffeomorphism.

[213] By the Open Subset-Submanifold Lemma 19.19 we can and will view U and V as smooth manifolds in their own right.

Example.

(1) Let $A \in \mathrm{O}(n)$. It is true, but slightly nasty to verify directly from the definitions, that the map

$$\begin{array}{rcl} S^{n-1} & \to & S^{n-1} \\ v & \mapsto & A \cdot v \end{array}$$

is a diffeomorphism. We will give a satisfactory argument on page 554.

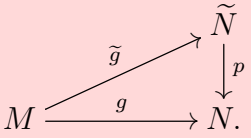
(2) Let $n \in \mathbb{N}$. In Exercise 19.6 we will see that the map

$$\begin{array}{rcl} \mathbb{R}^n & \to & (S^1)^n = S^1 \times \cdots \times S^1 \\ (t_1, \ldots, t_n) & \mapsto & (\exp(2\pi \mathrm{i} t_1), \ldots, \exp(2\pi \mathrm{i} t_n)) \end{array}$$

is a local diffeomorphism.

Remark. The Inverse Function Theorem 19.12 gives a tremendously convenient way for showing that a smooth map between open subsets of $\mathbb{R}^n$ is a local diffeomorphism. Later on, in the Inverse Mapping Theorem 24.1 we will state and prove a generalization of the Inverse Function Theorem 19.12 to the more general context of smooth maps between smooth manifolds.

The following harmless proposition contains two basic statements about smooth maps between smooth manifolds. The first statement can be viewed as a smooth analogue of the Pasting Proposition 2.6



Proposition 19.23. (Smooth Pasting Proposition II) Let $f\colon M \to N$ be a map between two smooth manifolds.

(1) (a) If there exists an open cover $\{U_i\}_{i \in I}$ of M such that for every $i \in I$ the restriction $f|_{U_i}\colon U_i \to N$ is smooth, then f itself is smooth.

(b) If there exists a smooth atlas $\{\Phi_i\colon U_i \to \widetilde{U}_i\}_{i \in I}$ for M and a smooth atlas $\{\Psi_i\colon V_j \to \widetilde{V}_j\}_{j \in J}$ for N such that $\bigcup_{i,j} (U_i \cap f^{-1}(V_j)) = M$ and such that each $\Psi_j \circ f \circ \Phi_i^{-1}\colon \Phi_i(U_i \cap f^{-1}(V_j)) \to V_j$ is smooth, then f is smooth.

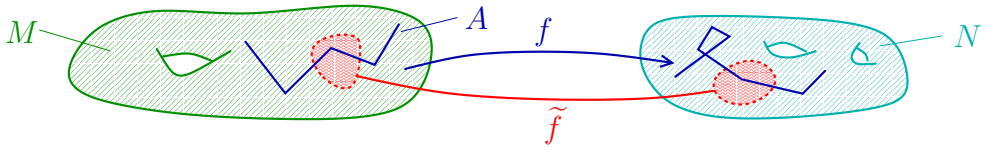
(2) If $f\colon M \to N$ is a bijection (e.g. if it is a homeomorphism) and if it is a local diffeomorphism, then it is in fact a diffeomorphism.

(3) Let $\widetilde{N}$ be a smooth manifold and let $p\colon \widetilde{N} \to N$ be a local diffeomorphism. Furthermore let $\widetilde{f}\colon M \to \widetilde{N}$ be a map such that the following diagram commutes:

Then $f\colon M \to N$ is smooth if and only if $\widetilde{f}\colon M \to \widetilde{N}$ is smooth.

Remark.

(1) In contrast to the Pasting Proposition 2.6 it does not suffice to check smoothness on finitely many *closed* subsets. For example, consider the map $\mathbb{R} \to \mathbb{R}$ that is given by $x \to |x|$. The restrictions to the closed subsets $(-\infty, 0]$ and $[0, \infty)$ are smooth, but the map is evidently not smooth on all of $\mathbb{R}$.



(2) In practice one can often control a map $f\colon M \to N$ on compact codimension-zero submanifolds instead of open subsets. As we just pointed out, one cannot conclude that f is smooth. But in Proposition **??** we will see that one can modify f slightly to turn f into a smooth map.

Proof.

(1) Both statements follow immediately from the Smooth Pasting Proposition 19.3.
(2) Let $f\colon M \to N$ be a local diffeomorphism that is a bijection. We need to show that $f^{-1}\colon N \to M$ is also smooth. But that follows immediately from (1) and our hypothesis that f is a local diffeomorphism.
(3) This statement follows immediately from (1a). ■

For completeness' sake we provide the following definition which is a just a generalization of the definition on page 532.

Definition. Let M and N be smooth manifolds. Furthermore let $A \subset M$ be some subset and let $f\colon A \to N$ be a map. We say that f is smooth if given any $a \in A$ there exists an open neighborhood U in M of a and a smooth map $\widetilde{f}\colon U \to N$[214] and which coincides with f on A..

Definition. Let M be a topological manifold. We say that two smooth structures $\mathcal{A}$ and $\mathcal{B}$ are equivalent if there exists a diffeomorphism between $(M, \mathcal{A})$ and $(M, \mathcal{B})$.

Remark.

(1) There exist topological manifolds that admits inequivalent smooth structures. For example, as we will see in Corollary **??**, John Milnor [**Miln1956a**] showed in 1956 that S^7 admits at least two inequivalent smooth structures.
(2) In Theorem **??** we will see that in dimensions $n \neq 4$ every closed topological manifold admits at most a finite number of inequivalent smooth structures. Amazingly, this statement is wrong in dimension 4. More precisely there is a plethora of closed 4-dimensional smooth manifolds that admit an infinite number of pairwise inequivalent smooth structures, see e.g. Theorem 135.13 for details.

19.7. **Submanifolds of smooth manifolds.** In Section 18.4 we introduced the notion of a submanifold of a topological manifold. The definition of a submanifold of a smooth manifold is basically the same, the only difference is that now we demand that the submanifold charts are smooth. For the reader's convenience we write down the detailed definition, even though there is a serious overlap with our previous definition.

[214] Let $U \subset M$ be an open subset and let $\widetilde{f}\colon U \to N$ be a map. We use the convention on page 545 to view U as a smooth manifold in its own right, and thus we have defined what it means for $\widetilde{f}$ to be smooth.

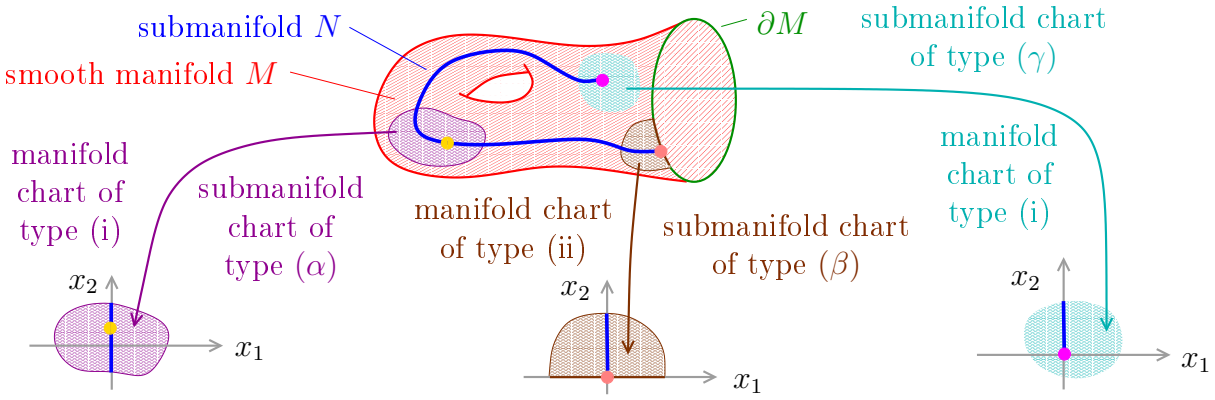
Definition. Let M be an n-dimensional smooth manifold.

(1) We say a subset $N \subset M$ is a k-dimensional submanifold if given any $P \in N$ one of the following holds:

(α) there exists a chart $\Phi\colon U \to V$ of type (i) in the smooth structure for M and P such that

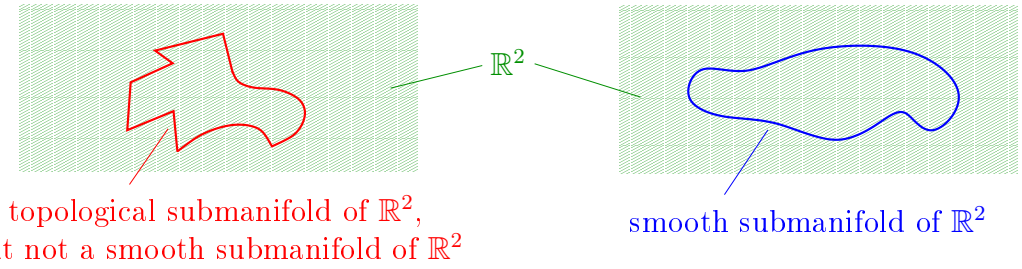
$$\Phi(U \cap N) \;=\; V \cap \{(0,\dots,0,x_1,\dots,x_k) \,|\, x_i \in \mathbb{R}\},$$

(β) or there exists a chart $\Phi\colon U \to V$ of type (ii) in the smooth structure for M and P such that $\Phi(P)$ lies in $\partial\mathbb{H}^n$ and[215]



$$\Phi(U \cap N) \;=\; V \cap \{(0,\dots,0,x_1,\dots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\},$$

(γ) or there exists a chart $\Phi\colon U \to V$ of type (i) in the smooth structure for M and P such that $\Phi(P)$ lies in $\partial\mathbb{H}^n$ and[216]

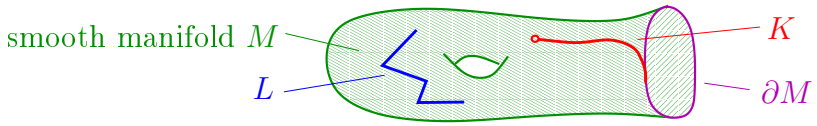


$$\Phi(U \cap N) \;=\; V \cap \{(0,\dots,0,x_1,\dots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\}.$$

We refer to such charts as submanifold charts of N. Any collection of submanifold charts of N that covers N is called a submanifold atlas.

(2) We say a submanifold N is proper if N is a closed subset of M and if for each $P \in N$ we can find submanifold charts of type (α) and (β).

Remark. Sometimes the above language can be ambiguous. For example, if we consider $M = \mathbb{R}^2$ it is not clear whether we view M as a topological manifold or as a smooth manifold. If from the context it is not clear what we mean, then we distinguish in our language between a *topological submanifold* and a *smooth submanifold*. This distinction is illustrated in the figure below.



[216] For $k = 0$ we interpret $\{(0,\dots,0,x_1,\dots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\}$ as the empty set.

Examples.

(1) We consider the topological manifold $M = \mathbb{R}^2$ with the smooth atlas $\mathcal{A}$ given by the identity $\Phi = \mathrm{id}_M$. Let $f\colon \mathbb{R} \to \mathbb{R}$ be a smooth function. We consider the subset $N = \{(x, f(x) \,|\, x \in \mathbb{R}\} \subset \mathbb{R}^2$. We cannot use the unique chart Φ in our atlas $\mathcal{A} = \{\Phi\}$ to show that N is indeed a submanifold of the smooth manifold $(\mathbb{R}^2, \mathcal{A})$. But the chart $\Psi\colon \mathbb{R}^2 \to \mathbb{R}^2$ given by $\Psi(x, y) = (x, y - f(x))$ lies in the smooth structure, i.e. in the maximal smooth atlas, defined by $(\mathbb{R}^2, \mathcal{A})$ and we can use it to verify that N is indeed a submanifold of the smooth manifold $(\mathbb{R}^2, \mathcal{A})$.

(2) In the figure below we show a smooth manifold M with boundary together with two subsets K and L. In Exercise 19.22 we will make the setting more precise and we will see that both K and L are submanifolds of the topological manifold M but that they are not submanifolds if we view M as a smooth manifold.

Remark. As we remarked on page 526, there are various subtly different definitions of a "submanifold" out in the literature. This is even more pronounced when it comes to submanifolds of smooth manifolds, especially if M and N are allowed to have boundary.

(1) Surely there is no textbook that would consider L in the above figure as a submanifold of the smooth manifold M. As we remarked above, if we follow our convention or the convention of [**Wall2016**, p. 31], then K is not a submanifold of M. On the other hand the definition used in [**Lee2002**, p. 98] or [**Hirs1976**, p. 30] views K as a smooth submanifold of the smooth manifold M.

(2) Also note that what we call a proper submanifold is called a neat submanifold in [**Hirs1976**, p. 30].

The following lemma is an analogue of the Submanifold-is-Manifold Lemma 18.14 .

Lemma 19.24. (Submanifold Smooth Structure Lemma) Let M be a smooth manifold and let N be a smooth submanifold of M. The collection of all submanifold charts of M gives naturally rise to a smooth atlas for N. The corresponding smooth structure has the following properties:

(1) The inclusion map $N \to M$ is a smooth map.
(2) If we start out with some submanifold atlas for M, then this gives rise to the same smooth structure on N.
(3) Let $f\colon W \to M$ be a smooth map. If $f(W) \subset N$, then $f\colon W \to N$ is also smooth.
(4) We assume that N is a submanifold of codimension-zero. Let $f\colon N \to W$ be a map to a smooth manifold. The following two statements are equivalent:
   (a) The map $f\colon N \to W$ is smooth as a map between smooth manifolds.
   (b) The map $f\colon N \to W$ is smooth in the sense of the definition on page 549, where we think of N as a subset of the smooth manifold M.

Convention. In the setting of the Submanifold Smooth Structure Lemma 19.24 we will refer to the smooth structure on the submanifold N, which we construct in the proof of the Submanifold Smooth Structure Lemma 19.24, as the standard smooth structure on N.[217]

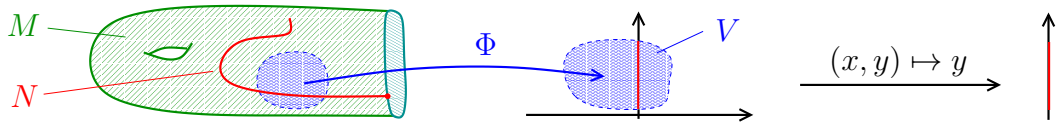
Proof. We start out with the following claim.

Claim. Let U and V be open subsets of $\mathbb{R}^n$ and let $f\colon U \to V$ be a smooth map.

(a) If for every $y \in \mathbb{R}^k$ we have $f(0,y) \in \{0\} \times \mathbb{R}^k$, then the map

$$\underbrace{\{y \in \mathbb{R}^k \,|\, (0,y) \in U\}}_{\text{open subset of } \mathbb{R}^k} \xrightarrow{f} V \cap (\{0\} \times \mathbb{R}^k) \xrightarrow{(0,y)\mapsto y} \underbrace{\{y \in \mathbb{R}^k \,|\, (0,y) \in V\}}_{\text{open subset of } \mathbb{R}^k}$$

is smooth.



(b) The analogue of (a) holds if we replace the $\mathbb{R}^k$ to the left by $\mathbb{H}^k$.

Proof. The claim follows from the observation that the map to the right is the restriction of the projection $\mathbb{R}^{n-k} \times \mathbb{R}^k \to \mathbb{R}^k$, which evidently is smooth, to a suitable subset. ⊞

Let M be an n-dimensional smooth manifold and let $N \subset M$ be a k-dimensional submanifold. It follows from Lemma 1.14 and the Second Countability Lemma 9.1 that N is Hausdorff and second-countable. Now let $\Phi\colon U \to V$ be a submanifold chart of type (α). As we pointed out in the proof of the Submanifold-is-Manifold Lemma 18.14 it is pretty straightforward to verify that the map

$$U \cap N \xrightarrow{\Phi} V \cap \{(0,x) \in \mathbb{R}^{n-k} \times \mathbb{R}^k\} \xrightarrow{(0,y)\mapsto y} \{x \in \mathbb{R}^k \,|\, (0,x) \in V\}$$

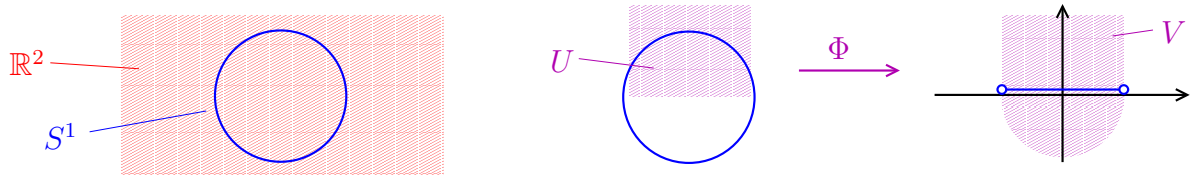
is a chart of type (i) for N. In the same fashion submanifold charts of type (β) and (γ) give rise to charts of type (ii) for N.

(1) It follows easily from the claim that the above charts define a smooth atlas on N.

(2) Again using the claim one can easily show that any submanifold atlas for N gives rise to the same smooth structure on N.

(3) Let $f\colon W \to M$ be a smooth map between smooth manifolds with $f(W) \subset N$. It follows easily from the fact that the projection $\mathbb{R}^n \xrightarrow{(x,y)\,\mapsto\, x} \mathbb{R}^k$ is smooth that the map $f\colon W \to N$ is also smooth.

(4) This statement follows easily, but not immediately, from the definitions. We leave it to the reader to fill in the details. ■



Examples.

[217] The reader might be worried that we equip certain topological manifolds with different "standard smooth structures". But, as we will see on page 553, for S^n this new standard smooth structure equals the standard smooth structure introduced earlier on.

(1) Let $n \in \mathbb{N}$. We consider the n-dimensional sphere $S^n \subset \mathbb{R}^{n+1}$. Similar to the discussion on page 513 we consider the map

$$\begin{array}{rcl} \Phi\colon U := B^n \times (0,\infty) & \to & V = \{(x,y) \in B^n \times \mathbb{R} \,|\, y > -\|x\|^2\} \\ (x,y) & \mapsto & (x, y - \|x\|^2). \end{array}$$

One can easily verify that this is a submanifold chart of type (α) from the smooth structure of $\mathbb{R}^{n+1}$. By changing the roles of the coordinates and changing signs we see that we can cover S^n by altogether $2(n+1)$ such submanifold charts which shows that S^n is an n-dimensional submanifold of the smooth manifold $\mathbb{R}^{n+1}$. In particular we obtain from the Submanifold Smooth Structure Lemma 19.24 a smooth atlas for S^n. We leave it to the reader to verify, using the Submanifold Smooth Structure Lemma 19.24 (2), that this smooth atlas is smoothly compatible to the smooth atlas that we gave on page 513. In particular both define the same smooth structure.

(2) Let M be a smooth manifold and let $U \subset M$ be an open subset. As on page 526 one sees easily that U is a codimension-zero submanifold of M. Furthermore, if we use the Submanifold Smooth Structure Lemma 19.24 to view U as a smooth manifold in its own right, then we obtain, basically by definition, the same smooth structure as we obtained in the Open Subset-Submanifold Lemma 19.19. Finally note that it follows again basically immediately from the definitions that $\partial U = U \cap \partial M$.

Remark. If one is mathematically very honest, then one realizes that it is actually a pain to work directly with the definition of the standard smooth structure on a submanifold. For example, just using the definition, it is not that easy to show that a given map $f\colon N \to W$ is smooth. Life will improve once we have proved the Smooth Embedding Theorem 24.10.

It is worth stressing the following special case of the Submanifold Smooth Structure Lemma 19.24.

Lemma 19.25. (Restrict-to-Submanifold-or-Boundary Lemma)

(1) Let M be a smooth submanifold of some $\mathbb{R}^n$ and let $f\colon M \to N$ be a map to some smooth manifold N. If there exists an open neighborhood U of $M \subset \mathbb{R}^n$ and a map $g\colon U \to N$ that is smooth in the sense of page 531 and which satisfies $g|_M = f$, then f itself is smooth.

(2) Let M be a smooth manifold and let N be a smooth submanifold of some $\mathbb{R}^n$. Let $f\colon M \to N$ be a map such that the composition $f\colon M \to N \to \mathbb{R}^n$ is smooth. Then f itself is smooth.

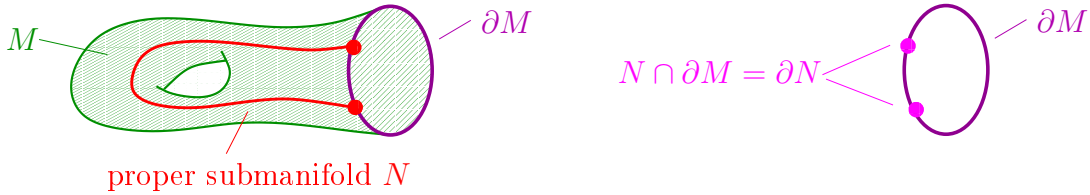
Proof.

(1) We denote by $i\colon M \to U$ the inclusion map. It follows from the Submanifold Smooth Structure Lemma 19.24 (1) and (2) that i is smooth. By the discussion on page 547 we know that $f\colon U \to N$ is smooth as a map between smooth manifolds. Finally it follows from Lemma 19.22 that $f \circ i\colon M \to N$ is also smooth.

(2) This statement is a special case of the Submanifold Smooth Structure Lemma 19.24 (3). ■

Example. Let $A \in \mathrm{O}(n)$. We consider again the map

$$\begin{array}{rcl} f\colon S^{n-1} & \to & S^{n-1} \\ v & \mapsto & A \cdot v. \end{array}$$



We denote by $g\colon \mathbb{R}^n \to \mathbb{R}^n$ the map that is also given by multiplication by A. By the discussion on page 536 we know that this defines a smooth map on $\mathbb{R}^n$. It follows from the Restrict-to-Submanifold-or-Boundary Lemma 19.25 (1) that the restriction $S^{n-1} \to \mathbb{R}^n$ is smooth. But this map takes values in S^{n-1}, so it follows from the Restrict-to-Submanifold-or-Boundary Lemma 19.25 (2) that the original map $f\colon S^{n-1} \to S^{n-1}$ is actually smooth. The same argument shows of course that f^{-1}, which is given by multiplication with A^{-1} is smooth. Thus we now have a convincing argument that for any $A \in \mathrm{O}(n)$ the map f is a diffeomorphism, solving the slight conundrum from page 548.

19.8. **Topological properties of smooth manifolds.** In this section we will employ several results from Section 19.1 to draw conclusions on smooth manifolds. The fact that real analysis provides us with such powerful tools, like the Inverse Function Theorem 19.12 and the resulting Smooth Invariance of Domain Theorem 19.13, is one of the reasons why dealing with smooth manifolds is much easier than dealing with topological manifolds.
We start out with the following, slightly subtle proposition.

Proposition 19.26. (Smooth Manifold Boundary Proposition) Let M be an n-dimensional smooth manifold. The following statements hold:

(1) Every point on M admits either a chart of type (i) in the smooth structure or it admits a chart of type (ii) in the smooth structure.
(2) The restrictions of all of the charts of the smooth atlas to the boundary ∂M give rise to a natural smooth atlas on ∂M and turn ∂M into a smooth $(n-1)$-dimensional smooth manifold with $\partial(\partial M) = \varnothing$. The corresponding natural smooth structure has the following properties:[218]
   (a) The inclusion map $\partial M \to M$ is a smooth map.
   (b) Restrictions of any set of charts of M that cover ∂M define the same smooth structure on ∂M.
   (c) Let $f\colon W \to M$ be a smooth map between smooth manifolds. If $f(W) \subset \partial M$, then $f\colon W \to \partial M$ is also smooth.
(3) (a) Any union of components of ∂M is a closed subset of M. In particular ∂M itself is a closed subset of M.
   (b) If M is compact, then ∂M is also compact.
(4) $M \setminus \partial M$ is an open subset of M, furthermore, if ∂M is non-empty, then $M \setminus \partial M$ is non-compact.
(5) Let N be a submanifold of M. The following two statements are equivalent:
   (a) N is a proper submanifold.
   (b) The following two conditions are satisfied:
      (i) N is a closed subset of M.
      (ii) We have the equality $\partial N = N \cap \partial M$.

(6) If N is a proper submanifold of M, then[219] $\partial N = N \cap \partial M$ is a proper submanifold of ∂M.

Convention. Let M be an n-dimensional smooth manifold. We refer to the smooth structure on ∂M that we obtain in the proof of the Smooth Manifold Boundary Proposition 19.26, by restricting charts from M, as the standard smooth structure on ∂M.

Remark.

(1) Let M be a smooth manifold. By the Smooth Manifold Boundary Proposition 19.26 (1) a point $x \in M$ is a boundary point if and only if x admits a chart of type (ii).
(2) Here again we would expect that a similar statement as in the Smooth Manifold Boundary Proposition 19.26 should hold for topological manifolds. But since for topological manifolds we have fewer tools, e.g. right now we are missing an analogue of the Smooth Invariance of Domain Theorem 19.13, we have to postpone a proof of the analogue of the Smooth Manifold Boundary Proposition 19.26 (1) for topological manifolds to the Topological Manifold Boundary Proposition 75.2.
(3) In practice the description of the smooth structure on ∂M can be a nuisance to work with. An alternative point of view is given in Exercise 24.12.

Example. Let $n \in \mathbb{N}$. On page 513 we constructed an explicit smooth atlas for $\overline{B}^n$ which gives charts of type (ii) precisely for the points in S^{n-1}. Thus it follows from the Smooth Manifold Boundary Proposition 19.26 that the boundary of the smooth manifold $\overline{B}^n$ is indeed given by S^{n-1}. We leave it to the reader to verify, the Smooth Manifold Boundary Proposition 19.26 (2b), that the smooth structure on $\partial\overline{B}^n = S^{n-1}$ agrees with the standard smooth structure on S^{n-1} that we introduced on page 544.

Proof. Let M be an n-dimensional topological manifold that is equipped with a smooth atlas $\{\Phi_i \colon U_i \to V_i\}_{i \in I}$.

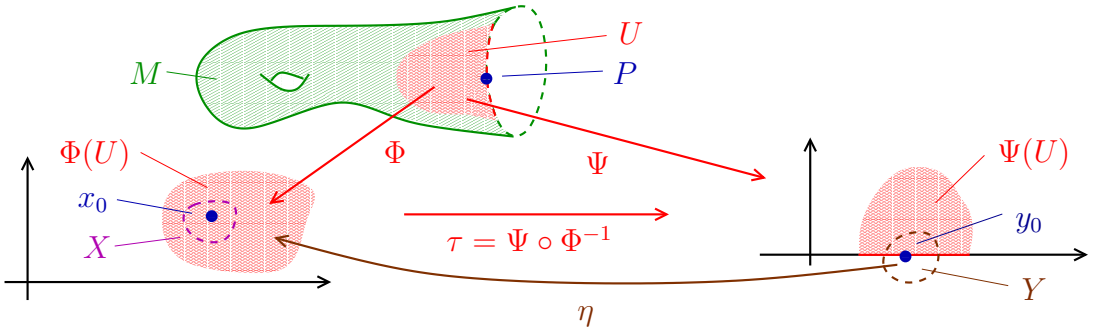
(1) Suppose there exists a point P that admits a chart Φ of type (i) and a chart Ψ of type (ii). By intersecting the two domains, which are both open neighborhoods of P, we can assume that the charts have a common domain U. We set $x_0 = \Phi(P)$ and $y_0 = \Psi(P)$.

We set $\tau := \Psi \circ \Phi^{-1}$. Since Φ and Ψ belong to a smooth atlas we see that τ and τ^{-1} are smooth. Note that by definition on page 532 of a smooth map on a (not necessarily open subset) of $\mathbb{R}^n$ there exists an open neighborhood Y of $y_0 \in \mathbb{R}^n$ and a smooth map $\eta \colon Y \to \mathbb{R}^n$ such that η agrees with τ^{-1} on $Y \cap \Psi(U)$.

[218] This statement is similar in nature to the statement of the Submanifold Smooth Structure Lemma 19.24.
[219] Here ∂N denotes the boundary of N, where we use the Submanifold Smooth Structure Lemma 19.24 to view N as a smooth manifold in its own right.

Claim. There exists an open subset $X \subset \mathbb{R}^n$ with $x_0 \in X \subset \tau^{-1}(Y) \cap \Phi(U)$.

Proof. Note that $\tau\colon \Phi(U) \to \Psi(U)$ is in particular continuous and that, by definition of the subspace topology, $Y \cap \Psi(U)$ is an open neighborhood of $y_0 \in \Psi(U)$. Thus we see that $\tau^{-1}(Y)$ is an open neighborhood of x_0. Thus $X := \tau^{-1}(Y) \cap \Phi(U)$ has the desired property. ⊞



We make the following observations:

(a) Let $x \in X$. Note that $\eta \circ \tau = \mathrm{id}_X$. Since X is an open subset of $\mathbb{R}^n$ we can take differentials at x of both sides. Since X is open and since Y is open we can apply the Chain Rule 19.10 to the left-hand side and we see that $\mathrm{D}\tau_x$ is invertible.

(b) It follows from (a) and the Smooth Invariance of Domain Theorem 19.13 that $\tau(X)$ is an open subset of $\mathbb{R}^n$.

(c) Since $X \subset \Phi(U)$ we have $\tau(X) \subset \tau(\Phi(U)) = \Psi(U) \subset \mathbb{H}^n$. Furthermore we know that $y_0 \in \Phi(U)$ and that $y_0 \in \partial\,\mathbb{H}^n$. In summary, we have that $\tau(X) \subset \mathbb{H}^n$ and that $\tau(X) \cap \partial\,\mathbb{H}^n \neq \varnothing$.

(d) Finally note that (b) and (c) are contradictory.

The remainder of the proof consists mostly of cleverly applying (1). In the unlikely case that the reader does not feel like reading more technical proofs it is a good moment to move on.

(2) First note that it follows from Lemma 1.14 and from the Second Countability Lemma 9.1 (2) that ∂M is Hausdorff and second-countable.

Next we want to show that the smooth atlas on M gives rise to a natural smooth atlas on ∂M. We start out with the following claim.

Claim. Let U and V be open subsets of $\mathbb{H}^n$ and let $f\colon U \to V$ be a smooth map. If for every $y \in \mathbb{R}^{n-1}$ we have $f(y,0) \in \mathbb{R}^{n-1} \times \{0\}$, then the map

$$\underbrace{\{x \in \mathbb{R}^k \,|\, (x,0) \in U\}}_{\text{open subset of } \mathbb{R}^{n-1}} \xrightarrow{f} V \cap (\mathbb{R}^{n-1} \times \{0\}) \xrightarrow{(x,0)\mapsto x} \underbrace{\{x \in \mathbb{R}^{n-1} \,|\, (x,0) \in V\}}_{\text{open subset of } \mathbb{R}^{n-1}}$$

is smooth.

Proof. This statement follows easily from the definition of a smooth map on open subsets of $\mathbb{H}^n$ and the fact that the composition of smooth maps is again smooth. ⊞

We continue with the following observation. Let $\Phi\colon U \to V$ be a chart of type (ii) for M. Note that it is a chart of type (i) precisely for the points in $\Phi^{-1}(\partial\,\mathbb{H}^n)$. It follows from (1) and the definition of ∂M that $\Phi^{-1}(\partial\,\mathbb{H}^n) = \partial M \cap U$.

Given $i \in I$ we now set $\widetilde{V}_i = V_i \cap \partial\,\mathbb{H}^n$, we set $\widetilde{U}_i := \Phi_i^{-1}(\widetilde{V}_i)$ and we set $\widetilde{\Phi}_i := \Phi_i|_{\widetilde{U}_i}$. Furthermore we denote by $p\colon \mathbb{R}^n \to \mathbb{R}^{n-1}$ the map given by the projection onto the first $n-1$ coordinates. It follows fairly easily from the above discussion and the claim that $\{p \circ \widetilde{\Phi}_i\colon \widetilde{U}_i \to p(\widetilde{V}_i)\}_{i\in I}$ is a smooth atlas for ∂M and that with respect to this atlas every point in ∂M admits a chart of type (i). In other words, $\partial(\partial M) = \varnothing$.

(a) It follows easily from the fact that the inclusion $\mathbb{R}^{n-1} \xrightarrow{x \mapsto (x,0)} \mathbb{R}^n$ is smooth that the inclusion $\partial M \to M$ is a smooth map.

(b) It follows easily from the claim that if we start out with some set of charts covering ∂M, that these define the same smooth structure on ∂M.

(c) Let $f\colon W \to M$ be a smooth map between smooth manifolds with $f(W) \subset \partial M$. It follows easily from the fact that the projection $\mathbb{H}^n \xrightarrow{(x,y) \mapsto x} \mathbb{R}^{n-1}$ is smooth that the map $f\colon W \to \partial M$ is also smooth.

(3) The proof of the third statement is basically identical to the proof of the Manifold Boundary-Closed Subset Lemma 18.6.[220]

(4) The proof of this statement is basically identical to the proof of the corresponding statement for topological manifolds, see the Manifold Boundary-Closed Subset Lemma 18.6 (3).

(5) Let $N \subset M$ be a k-dimensional submanifold. Recall that N is called *proper* if N is a closed subset of M and if every point in N admits a submanifold chart of type (α) or (β), as defined on page 524. As in the proof of the Submanifold-is-Manifold Lemma 18.14 we denote by $q\colon \mathbb{R}^n \to \mathbb{R}^k$ the projection onto the last k coordinates and we make the following observations:

- If P admits a submanifold chart of type (α), then this submanifold chart is a chart of type (i) for $P \in M$ and the map $q \circ \Phi|_{U\cap N}$ is a k-dimensional chart of type (i) for $P \in N$.
- If P admits a submanifold chart of type (β), then this submanifold chart is a chart of type (ii) for $P \in M$ and the map $q \circ \Phi|_{U\cap N}$ is a k-dimensional chart of type (ii) for $P \in N$.
- If P admits a submanifold chart of type (γ), then this submanifold chart is a chart of type (i) for $P \in M$ and the map $q \circ \Phi|_{U\cap N}$ is a k-dimensional chart of type (ii) for $P \in N$.

The equivalence of (a) and (b) now follows from these three observations together with (1).

(6) Let N be a proper submanifold of M. We want to show that ∂N is a proper submanifold of ∂M.

- As we saw in (5), a point $P \in \partial N$ admits a submanifold chart of type (β). But such a submanifold chart restricts to a submanifold chart of type (α) for ∂N viewed as a subset of ∂M.
- In (5) we just saw that $\partial N = M \cap \partial M$. Since N is a closed subset of M we obtain from the definition of the subspace topology that ∂N is a closed subset of ∂M.

[220] Note that this statement does not follow directly from the Manifold Boundary-Closed Subset Lemma 18.6 since our definition of the boundary of a smooth manifold, given on page 545, is a priori different from the definition of the boundary of a topological manifold. Only later in the Topological Manifold Boundary Proposition 75.2 (2) will we see that there is no difference.

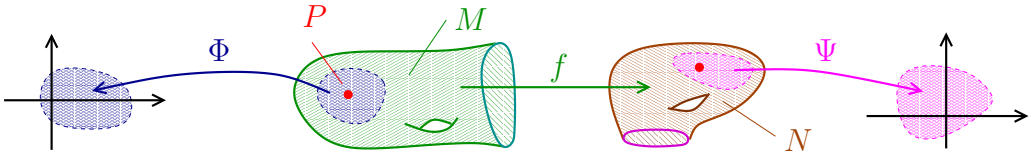
These two observations put together show that ∂N is indeed a proper submanifold of ∂M. ■

The following lemma is the obvious analogue of Lemma 18.5.

Lemma 19.27. Let M and N be two smooth manifolds.

(1) If $f\colon M \to N$ is a local diffeomorphism, then $f(\partial M) = (\partial N) \cap f(M)$.
(2) If $f\colon M \to N$ is in fact a diffeomorphism, then f restricts to a diffeomorphism $\partial M \to \partial N$, where we equip ∂M and ∂N with the above standard smooth structure.

Proof. As in the case of the sister Lemma 18.5, the statement follows easily from the definitions and is left to the reader. ■



The following proposition says that the dimension of a non-empty smooth manifold is well-defined. Eventually, using homology groups, we will show in the Topological Manifold-Dimension Proposition 75.4 that the analogous statements also holds for topological manifolds.

Proposition 19.28. (Smooth Manifold-Dimension Proposition) Let M be a non-empty m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. If M and N are diffeomorphic, then $m = n$.

Proof. Let M be a non-empty m-dimensional smooth manifold, let N be an n-dimensional smooth manifold and let $f\colon M \to N$ be a diffeomorphism.

It follows from the hypothesis that M is non-empty, together with the Smooth Manifold Boundary Proposition 19.26 (4), that $M \setminus \partial M$ is non-empty. This implies that the smooth manifold M admits a chart $\Phi\colon U \to \widetilde{U}$ of type (i), where $\widetilde{U}$ is an open subset of $\mathbb{R}^m$.

Since f is a diffeomorphism we see that $\Phi \circ f^{-1}\colon f(U) \to V$ is a chart of type (i) for N. In particular we see that $f(P) \in N$ admits a chart of type (i). Now let $\Psi\colon V \to \widetilde{V}$ be a chart of type (i) from the given smooth atlas of N for $f(P)$. Note that $\widetilde{V}$ is an open subset of $\mathbb{R}^n$.

By the Smooth Manifold Boundary Proposition 19.26 we know that Ψ also has to be a chart of type (i). Furthermore note that $U \cap f^{-1}(V)$ contains P, thus it is non-empty. In summary we see that

$$\Psi \circ f \circ \Phi^{-1}\colon \Phi(U \cap f^{-1}(V)) \;\to\; \Psi(f(U) \cap V)$$

is a diffeomorphism between an open non-empty subset of $\mathbb{R}^m$ and an open non-empty subset of $\mathbb{R}^n$. It follows from the Smooth Invariance of Domain Proposition 19.11 that $m = n$. ■

19.9. **The Smooth Path-Connectivity Proposition.** We continue with the following slightly proposition, which is somewhat technical, but which will have surprisingly many uses.

Proposition 19.29. (Smooth Path-Connectivity Proposition) Let M be a smooth manifold.

(1) Every map $\gamma\colon [a,b] \to M$ is homotopic rel the endpoints $\{a,b\}$ to a smooth map.
(2) If M is path-connected, then given any $P, Q \in M$ there exists a smooth path from P to Q.

The proof of the Smooth Path-Connectivity Proposition 19.29 requires the remainder of this section. The reader might be well advised to move on to the next section. For the reader who sticks around, we first formulate and prove the following useful lemma, which will be a key ingredient in the proof of the Smooth Path-Connectivity Proposition 19.29.

Lemma 19.30. Let M be a smooth manifold. Let $\alpha\colon [a,b] \to M$ and $\beta\colon [b,c] \to M$ be two smooth paths with $\alpha(b) = \beta(b)$. There exists a smooth map $\gamma\colon [a,c] \to M$ which is homotopic to the map $[a,c] \to M$ that is defined by α and β.

Proof of Lemma 19.30. To simplify the notation we assume that $a = 0$, $b = 1$ and $c = 2$. By the Smooth Transition Function Lemma 19.4 there exists a smooth map $\tau\colon [0,1] \to [0,1]$ such that $\tau(t) = 0$ for $t \in [0, \frac{1}{3}]$ and such that $\tau(t) = 1$ for $t \in [\frac{2}{3}, 1]$. We consider the map

$$\begin{array}{rcl} \gamma\colon [0,2] & \to & M \\ t & \mapsto & \begin{cases} \alpha(\tau(t)), & \text{if } t \in [0,1], \\ \beta(\tau(t-1)), & \text{if } t \in [1,2]. \end{cases} \end{array}$$

Note that γ is constant on the interval $[\frac{2}{3}, \frac{4}{3}]$. Thus it follows easily from the Smooth Pasting Proposition 19.23 that γ is smooth. Finally the desired homotopy is given by the map

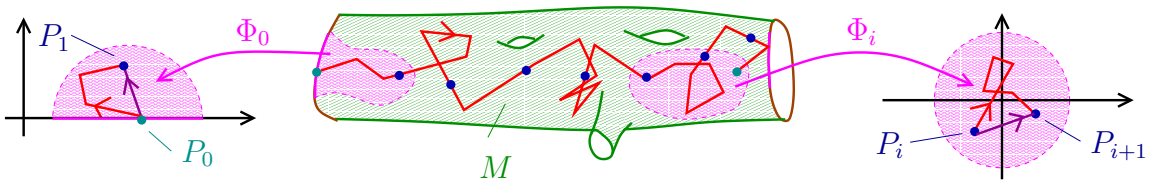
$$\begin{array}{rcl} [0,2] \times [0,1] & \to & M \\ (t,s) & \mapsto & \begin{cases} \alpha((1-s)\cdot t + s \cdot \tau(t)), & \text{if } t \in [0,1], \\ \beta((1-s)\cdot (t-1) + s \cdot \tau(t-1)), & \text{if } t \in [1,2]. \end{cases} \end{array}$$

■

Proof of the Smooth Path-Connectivity Proposition 19.29. Note that Statement (2) is an immediate consequence of Statement (1). Thus it suffices to prove Statement (1).

Let M be an n-dimensional smooth manifold. Let $\gamma\colon [a,b] \to M$ be a map. We need to show that γ is homotopic rel $\{a,b\}$ to a smooth map $\widetilde{\gamma}\colon [a,b] \to M$.

Since $\gamma([a,b])$ is compact it follows easily from Lemmas 1.19 and 18.3 that we can find points $a = t_0 < t_1 < \cdots < t_k = b$ and charts $\{\Phi_i\colon U_i \to V_i\}_{0=1,\ldots,k-1}$ with the following properties:



(a) For each $i \in \{0,\ldots,k-1\}$ we have $\gamma([t_i, t_{i+1}]) \subset U_i$.
(b) Each V_i is a convex open subset either of $\mathbb{R}^n$ or of $\mathbb{H}^n$.

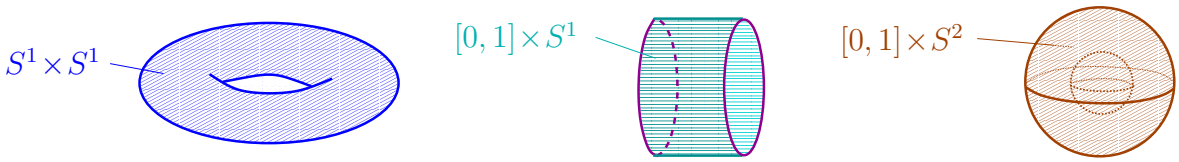
For $i = 0,\ldots,k-1$ we set $P_i = \Phi_i(\gamma(t_i))$ and for $i = 0,\ldots,k-1$ we consider the homotopy

$$\begin{array}{rcl} F_i\colon [t_i, t_{i+1}] \times [0,1] & \to & \mathbb{R}^n \\ (\lambda, s) & \mapsto & (1-s)\cdot \Phi_i(\gamma(\lambda)) + s \cdot \underbrace{\left(\frac{t_{i+1}-\lambda}{t_{i+1}-t_i} \cdot P_i + \frac{\lambda - t_i}{t_{i+1}-t_i} \cdot P_{i+1} \right)}_{\text{“straight path” from } P_i \text{ to } P_{i+1}}. \end{array}$$

Note that F_i is a homotopy rel $\{t_i, t_{i+1}\}$ from $\Phi_i \circ \gamma|_{[t_i,t_{i+1}]}$ to the “straight path” from P_i to P_{i+1}. Since V_i is a convex subset we see that this homotopy takes values in V_i. We now see that $\Phi_i^{-1} \circ F_i\colon [t_i, t_{i+1}] \times [0,1] \to M$ is a homotopy from $\gamma|_{[t_i,t_{i+1}]}$ rel $\{t_i, t_{i+1}\}$ to a smooth path $[t_i, t_{i+1}] \to M$.

Finally it follows from these results, together with Lemma 19.30, that there exists in fact a homotopy rel $\{a, b\}$ from $\gamma\colon [a, b] \to M$ to a smooth map $[a, b] \to M$. ■

19.10. **Products of smooth manifolds I.** In the Topological Manifold Product Proposition 18.4 we saw that the product of any two topological manifolds is again a topological manifold. The proof of the Topological Manifold Product Proposition 18.4 was mostly straightforward, except that if both topological manifolds have non-empty boundary, then we had to use a little ruse to find a chart. In the following proposition, where we will deal with smooth manifolds, we will sidestep this tricky business.



Proposition 19.31. (Smooth Manifold Product Proposition) Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. We assume that $\partial M = \varnothing$ or $\partial N = \varnothing$. We denote by

$$\begin{array}{rcl} p\colon M \times N & \to & M \\ (x, y) & \mapsto & x \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon M \times N & \to & N \\ (x, y) & \mapsto & y \end{array}$$

the two projections. The following statements hold:

(1) The product $M \times N$ is an $(m + n)$-dimensional topological manifold that admits a *unique* smooth manifold structure that satisfies the following two conditions:
   (a) The projections $p\colon M \times N \to M$ and $q\colon M \times N \to N$ are smooth.
   (b) For any smooth manifold W and any map $f\colon W \to M \times N$ the following holds: If the two maps $p \circ f\colon W \to M$ and $q \circ f\colon W \to N$ are smooth, then f itself is smooth.

(2) (a) If $\partial M = \varnothing$, then $\partial(M \times N) = M \times (\partial N)$.
   (b) If $\partial N = \varnothing$, then $\partial(M \times N) = (\partial M) \times N$.[221]

Remark. In Propositions 20.6 and **??** we will deal with the product of two smooth manifolds where both smooth manifolds are allowed to have non-empty boundary.

Proof. We first consider the case that $\partial M = \varnothing$. In the Topological Manifold Product Proposition 18.4 we already saw that $M \times N$ is an $(m+n)$-dimensional topological manifold.

Now we turn to the construction of a smooth atlas. Let $\{\Phi_i\colon U_i \to \widetilde{U}_i\}_{i \in I}$ be the smooth atlas of M and let $\{\Psi_j\colon V_j \to \widetilde{V}_j\}_{j \in J}$ be the smooth atlas of N. One can easily verify that

[221] Note that here, when we are dealing with smooth manifolds, we can determine the boundary. This is in contrast to the slightly unfortunate situation in the Topological Manifold Product Proposition 18.4.

the maps

$$\begin{array}{rcl} \Phi_i \times \Psi_j \colon U_i \times V_j & \to & \widetilde{U}_i \times \widetilde{V}_j \\ (x, y) & \mapsto & (\Phi_i(x), \Psi_j(y)) \end{array}$$

form a *smooth* atlas for $M \times N$. We equip $M \times N$ with this smooth atlas and with the corresponding smooth structure. We make the following observations:

- It follows easily from the definitions that this smooth atlas has the properties (1a) and (1b).
- Since $\partial M = \varnothing$ it is also clear that $\Phi_i \times \Psi_j$ is of type (ii) if and only if Ψ_j is of type (ii). It follows from this observation, together with the Smooth Manifold Boundary Proposition 19.26 (1), that $\partial(M \times N) = M \times (\partial N)$.

The fact that the smooth structure is uniquely determined by (1a) and (1b) follows from a very general, formal argument. Suppose that $M \times N$ is equipped with two smooth atlases $\mathcal{A}$ and $\mathcal{B}$ that satisfy (1a) and (1b). We need to show that the identity map $\mathrm{id} \colon (M \times N, \mathcal{A}) \to (M \times N, \mathcal{B})$ is smooth. Since $\mathcal{A}$ satisfies (1a) we know that $p \circ \mathrm{id}$ and $q \circ \mathrm{id}$ are smooth. But since $\mathcal{B}$ satisfies (1b) this implies that id is smooth.

Finally we consider the case that $\partial M \neq \varnothing$ and $\partial N = \varnothing$. Recall that a chart of type (ii) takes values in the upper half-space which is defined by restricting the *last* coordinate to ≥ 0. Thus we proceed as above, except that we consider the product charts $\Phi_i \times \Psi_j$ to make sure that the product of a chart of type (i) and a chart of type (ii) is in fact a chart of type (ii). ■

Convention. Let M and N be two smooth manifolds, where at most one has non-empty boundary. Unless we say explicitly something else we will always equip $M \times N$ with the smooth structure introduced in the Smooth Manifold Product Proposition 19.31. We will refer to this as the standard smooth structure on $M \times N$.

Example.

(1) We equip each $\mathbb{R}^k$ with the standard smooth structure that we introduced on page 544. In Exercise 19.27 we will see that the map

$$\begin{array}{rcl} \mathbb{R}^{m+n} & \to & \mathbb{R}^m \times \mathbb{R}^n \\ (x_1, \ldots, x_m, y_1, \ldots, y_n) & \mapsto & ((x_1, \ldots, x_m), (y_1, \ldots, y_n)) \end{array}$$

is a diffeomorphism. This observation can be viewed as a variation on the Product Metric Lemma 5.3.

(2) We now see that products of spheres are naturally smooth manifolds.

(3) Let M and N be two smooth manifolds, where at most one has non-empty boundary. Let $Q \in N$ and $P \in M$. It follows from the Smooth Manifold Product Proposition 19.31 (1b) that the two inclusion maps

$$\begin{array}{rcl} i_Q \colon M & \to & M \times N \\ x & \mapsto & (x, Q) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} j_P \colon N & \to & M \times N \\ y & \mapsto & (P, y) \end{array}$$

are smooth.

(4) Let $f\colon V \to W$ be a smooth map between two smooth manifolds with $\partial V = \varnothing$ and with $\partial W = \varnothing$. As on page 526 one sees that the graph $\mathrm{Gr}(f) := \{(x, f(x)) \,|\, x \in V\}$ is a proper submanifold of the smooth manifold $V \times W$.[222]

19.11. **Manifolds and group actions.** In this section we will see that group actions can be used to construct interesting new examples of smooth manifolds.

For the reader's convenience we recall some definitions from pages 248 and 253.

Definition. Let X be a set and let G be a group with trivial element e that acts on X.

(1) An action is called free, if $g \cdot x = x$ for some $x \in X$ implies that $g = e$.
(2) Suppose that X is a topological space.
   (a) We say that the action is continuous, if for every $g \in G$ the map $X \to X$ given by $x \mapsto g \cdot x$ is continuous.
   (b) We say the action is proper if for every two points x and y in X there exist open neighborhoods U of x and V of y such that the set $\{g \in G \,|\, gU \cap V \neq \varnothing\}$ is finite.

We add the following almost self-explanatory definition.

Definition. Let M be a smooth manifold which is equipped with an action by a group G. We say that the action is smooth if for every $g \in G$ the map $M \to M$ given by $x \mapsto g \cdot x$ is smooth.

The following proposition is the main result of this section.

Proposition 19.32. (Manifold Quotient-by-Group Action Proposition) If a group G acts freely, properly and continuously on an n-dimensional topological manifold M, then the following hold:

(1) The quotient space M/G is also an n-dimensional topological manifold and the projection $p\colon M \to M/G$ is a local homeomorphism.
(2) If M is a smooth manifold and if G acts smoothly, then there exists a unique smooth structure on M/G such that the projection $p\colon M \to M/G$ is a local diffeomorphism.

Furthermore, in both cases the following four statements hold:

(a) The G-action restricts to an action on ∂M and we have $\partial(M/G) = (\partial M)/G$.
(b) If M is compact, then M/G is compact.
(c) If M is closed, then M/G is closed.
(d) If $N \subset M$ is a (proper) submanifold such that the G-action restricts to an action on N, then N/G is a (proper) submanifold of M/G.

Convention. In the setting of the Manifold Quotient-by-Group Action Proposition 19.32 (2) we will refer to the smooth structure on M/G as the standard smooth structure on M/G.

Before we provide the proof of the Manifold Quotient-by-Group Action Proposition 19.32 let us first discuss some consequences and examples.

In the Topological-Quotient Proposition 5.15 (1b) we saw that the quotient topology has a universal property. The following proposition shows that the standard smooth structure on M/G also has a universal property:

[222] In the Local Graph Lemma 24.4 we will prove a partial converse to this statement.

Corollary 19.33. (Smooth Map-Descends-to-Quotient Corollary) Let G is a group that acts freely, properly and smoothly on an n-dimensional smooth manifold M. Furthermore let $f\colon M \to N$ be a smooth map such that for every $x \in X$ and every $g \in G$ we have $f(g \cdot x) = x$. The induced map

$$\begin{array}{rcl} \overline{f}\colon M/G & \to & N \\ [x] & \mapsto & f(x) \end{array}$$

is also smooth. If f is in fact a local diffeomorphism, then $\overline{f}$ is also a local diffeomorphism.

Proof. Let $[x] \in M/G$. Since the projection $p\colon M \to M/G$ is a local diffeomorphism there exists an open neighborhood U of x and an open neighborhood V of $[x]$ such that $p\colon U \to V$ is a diffeomorphism. Note that $\overline{f}|_V = f \circ p^{-1}\colon V \to N$ is smooth. It follows from the Smooth Pasting Proposition 19.23 that $\overline{f}$ is smooth. If f is a local diffeomorphism then a very mild modification of the above argument shows that $\overline{f}$ is also a local diffeomorphism. ■

We state our first example as a lemma.

Lemma 19.34. (Torus-as-Quotient Lemma)

(1) The action

$$\begin{array}{rcl} \mathbb{Z}^n \times \mathbb{R}^n & \to & \mathbb{R}^n \\ (z, v) & \mapsto & z + v \end{array}$$

from page 249 is free, proper and smooth.

(2) It follows from (1) and the Manifold Quotient-by-Group Action Proposition 19.32 that $\mathbb{R}^n/\mathbb{Z}^n$ has a standard smooth structure as an n-dimensional smooth manifold. We equip $(S^1)^n = S^1 \times \ldots S^1$ with the standard smooth structure coming from Proposition 19.18 and the Smooth Manifold Product Proposition 19.31. The map

$$\begin{array}{rcl} \mathbb{R}^n/\mathbb{Z}^n & \to & (S^1)^n = S^1 \times \cdots \times S^1 \\ [(t_1, \ldots, t_n)] & \mapsto & (\exp(2\pi \mathrm{i} t_1), \ldots, \exp(2\pi \mathrm{i} t_n)). \end{array}$$

is a diffeomorphism.

Proof. The proof of Statement (1) is elementary. Thus let us turn to the proof of Statement (2). As we mentioned on page 548, the map

$$\begin{array}{rcl} \mathbb{R}^n & \to & (S^1)^n = S^1 \times \cdots \times S^1 \\ (t_1, \ldots, t_n) & \mapsto & (\exp(2\pi \mathrm{i} t_1), \ldots \exp(2\pi \mathrm{i} t_n)) \end{array}$$

is a local diffeomorphism. By Lemma 5.25 the map

$$\begin{array}{rcl} f\colon \mathbb{R}^n/\mathbb{Z}^n & \to & (S^1)^n = S^1 \times \cdots \times S^1 \\ [(t_1, \ldots, t_n)] & \mapsto & (\exp(2\pi \mathrm{i} t_1), \ldots, \exp(2\pi \mathrm{i} t_n)) \end{array}$$

is a homeomorphism. By the Smooth Map-Descends-to-Quotient Corollary 19.33 (2) the map f is also a local diffeomorphism. Thus it follows from the Smooth Pasting Proposition 19.23 that the map f is in fact a diffeomorphism. ■

We continue with two more examples.

Examples.

(1) Using the action from page 251 of $G = \{\pm 1\}$ on $M = S^n$ we obtain that the real projective space $\mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\}$ admits a canonical structure of a closed n-dimensional

smooth manifold.[223] Now let $m \leq n$. We have the embedding

$$\begin{array}{rcl} \iota\colon \mathbb{R}\mathrm{P}^m & \to & \mathbb{R}\mathrm{P}^n \\ [x] & \mapsto & [(x,0)]. \end{array}$$

It follows from the Manifold Quotient-by-Group Action Proposition 19.32 (2d) that $\iota(\mathbb{R}\mathrm{P}^m)$ is in fact a submanifold of the smooth manifold $\mathbb{R}\mathrm{P}^n$. As on page 256 we will at times drop ι from the notation and we will view $\mathbb{R}\mathrm{P}^m$ as a subspace and submanifold of $\mathbb{R}\mathrm{P}^n$.

(2) We consider $M = \mathbb{R} \times [-1,1]$ which we endow with the obvious smooth structure. Using the action of $G = \mathbb{Z}$ on $M = \mathbb{R} \times [-1,1]$ from page 252 we obtain that the Möbius band $(\mathbb{R} \times [-1,1])/\mathbb{Z}$ has a canonical structure of a 2-dimensional smooth manifold. Furthermore, we have

$$\partial(\text{Möbius band}) \underset{\substack{\uparrow \\ \text{by the Manifold Quotient-by-Group} \\ \text{Action Proposition 19.32 (a)}}}{=} (\mathbb{R} \times \{-1,1\})/\mathbb{Z} \underset{\substack{\uparrow \\ \text{see Exercise 5.43}}}{\cong} S^1.$$

Convention. In line with the above convention we refer to the above smooth structures on $\mathbb{R}^m/\mathbb{Z}^m$, on $\mathbb{R}\mathrm{P}^n$ and on the Möbius band as the standard smooth structures on $\mathbb{R}^m/\mathbb{Z}^m$, on $\mathbb{R}\mathrm{P}^n$ and on the Möbius band.

Remark. On page 255 we made the identification

$$\begin{array}{rcl} (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) & \to & \mathbb{R}\mathrm{P}^n := S^n/\{\pm 1\} \\ [x] & \mapsto & \left[\frac{x}{\|x\|}\right]. \end{array}$$

Under this identification we obtain a standard smooth structure on $(\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\})$. Note that it follows from the Submanifold Smooth Structure Lemma 19.24 (3) that the map $\mathbb{R}^{n+1} \setminus \{0\} \to S^n$ given by $x \mapsto \frac{x}{\|x\|}$ is smooth. Thus it follows from the Manifold Quotient-by-Group Action Proposition 19.32 that the map $\mathbb{R}^{n+1} \setminus \{0\} \to (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\})$ is also smooth.

The proof of the Manifold Quotient-by-Group Action Proposition 19.32 relies on the following two somewhat technical lemmas.

Lemma 19.35. Let X be a topological space and let G be a group that acts freely, properly and continuously on X. If X is Hausdorff, then for every $x \in X$ there exists an open neighborhood U such that $gU \cap U = \varnothing$ for all $g \neq e$.

Proof of Lemma 19.35. Let X be a topological space that is Hausdorff. Furthermore let G be a group that acts freely, properly and continuously on X. Finally let $x \in X$. Since G acts freely we know that for every non-trivial $g \in G$ we have $gx \neq x$.

Since the action is proper and continuous we can apply Lemma 5.28 to $a = b = x$ and we obtain open neighborhoods A and B of x such that $gA \cap B = \varnothing$ for every non-trivial $g \in G$. Thus $U := A \cap B$ has the desired property. ∎

[223] We will give an explicit smooth atlas for $\mathbb{R}\mathrm{P}^n$ in Exercise 19.16.

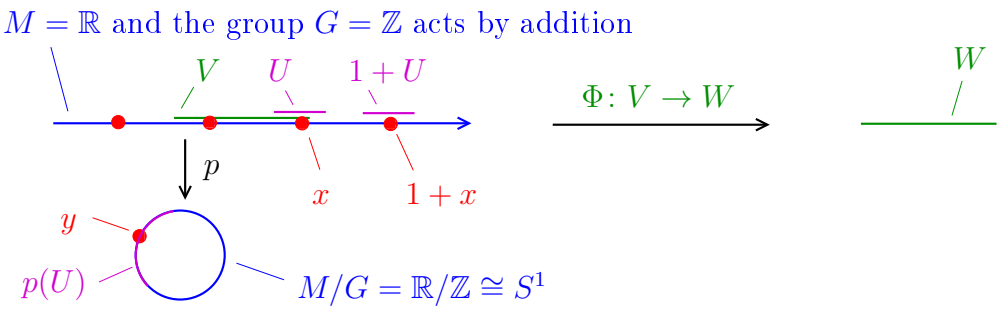
Lemma 19.36. Let X be a topological space that is Hausdorff. Furthermore let G be a group that acts continuously on X. We denote by $p\colon X \to X/G$ the projection. If $U \subset X$ is an open subset such that the map $p\colon U \to X/G$ is injective, then the map $p\colon U \to p(U)$ is a homeomorphism.

Proof of Lemma 19.36. By the Group-Action Projection Lemma 5.24 the projection $p\colon X \to X/G$ is continuous. Thus the restriction of p to U is also continuous. By our hypothesis the map $p\colon U \to p(U)$ is injective and evidently it is surjective. Thus the map is a bijection. It follows from Lemma 2.10 and the fact that U is open that $U \to X$ is an open map. Furthermore by the Group-Action Projection Lemma 5.24 (2a) the map $p\colon X \to X/G$ is also open. In summary we see that $p\colon U \to p(U)$ is open. It follows from the Open -Injective Map Lemma 2.16 (2) that the map $p\colon U \to p(U)$ is in fact a homeomorphism. ■

Now we are in a position to prove the Manifold Quotient-by-Group Action Proposition 19.32. For clarity we deal with topological manifolds and smooth manifolds separately.

Proof of Proposition 19.32 for topological manifolds. Let M be an n-dimensional topological manifold and let G be a group that acts on M. We suppose that the action is continuous, free and proper. We want to show that M/G is an n-dimensional topological manifold. Thus we need to prove the following claim.

Claim.
(1) M/G is second-countable,
(2) M/G is Hausdorff, and
(3) every point $y \in M/G$ admits an n-dimensional chart.



Proof. The first statement of the claim follows immediately from the Group-Action Projection Lemma 5.24 and 9.1 (5). The second statement follows from the Group Action-Hausdorff Quotient Proposition 5.27. Thus it remains to deal with the third statement. As usual we denote by $p\colon M \to M/G$ the projection. Let $y \in M/G$. We pick an $x \in M$ with $p(x) = y$. We make the following two observations:

- Since M is an n-dimensional topological manifold there exists an n-dimensional chart $\Phi\colon V \to W$ with $x \in V$.
- By Lemma 19.35 there exists an open neighborhood U of x such that $gU \cap U \neq \varnothing$ for every $g \neq e$. Note that this implies that the restriction of $p\colon M \to M/G$ to U is injective.

After possibly replacing U and V by $U \cap V$ we can assume that $U = V$. Note that by the Group-Action Projection Lemma 5.24 (2a) the projection $p(U)$ is an open neighborhood of x. Finally we consider the maps

$$p(U) \xrightarrow{p^{-1}} U \xrightarrow{\Phi} W.$$

The map Φ is by definition a homeomorphism. Furthermore it follows from Lemma 19.36 that the map $p\colon U \to p(U) \subset M/G$ is a homeomorphism as well. Thus the above map $\Phi \circ p^{-1}\colon p(U) \to W$ is a homeomorphism, in particular it is an n-dimensional chart for M/G that contains y. ⊞

We have now shown that M/G is an n-dimensional topological manifold. It remains to prove the following claim.

Claim.

($*$) The projection $p\colon M \to M/G$ is a local homeomorphism.
(a) The G-action on M restricts to an action on ∂M and we have $\partial(M/G) = (\partial M)/G$.
(b) If M is compact, then M/G is compact.
(c) If M is closed, then M/G is closed.
(d) If $N \subset M$ is a (proper) submanifold such that the G-action restricts to an action on N, then N/G is a (proper) submanifold of M/G.

Proof.

($*$) Implicitly we had already proved the first statement, indeed, given $x \in M$ we run through the above argument and we see, with the same notation, that $p(U)$ is an open subset of M/G and that $p\colon U \to p(U)$ is a homeomorphism.
(a) It follows from Lemma 18.5 (1) that the G-action on M restricts to an action on ∂M. Furthermore it follows easily from Lemma 18.5 (2) and the above statement ($*$) that $\partial(M/G) = (\partial M)/G$. We leave it to the reader to fill in the details.
(b) The third statement is of course just an immediate consequence of the Compact Image Lemma 2.13.
(c) This statement is an immediate consequence of statements (a) and (b).
(d) We now construct submanifold charts for $N/G \subset M/G$ from submanifold charts for $N \subset M$ the same way that we constructed manifold charts for M/G from manifold charts of M. Note that these submanifold charts for N/G have the same type as the submanifold charts for N.

Finally suppose that N is a proper submanifold. Recall that this means that N is a closed subset of M and that we only require submanifold charts of type (α) and (β). As we just mentioned, the type of the submanifold charts involved does not change. Finally it follows from the hypothesis that the G-action on M restricts to a G-action on N together withe Group-Action Projection Lemma 5.24 (2b) that N/G is a closed subset of M/G. ■

Proof of Proposition 19.32 for smooth manifolds. Let $(M, \mathcal{A})$ be an n-dimensional smooth manifold. Let G be a group that acts freely, properly and smoothly on M. We

need to show that M/G admits a smooth atlas such that the projection $p\colon M \to M/G$ is a local diffeomorphism.

(1) We run through the proof of the Manifold Quotient-by-Group Action Proposition 19.32 (1), but this time only using charts for M that lie in $\mathcal{A}$, and we obtain an atlas $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ for M/G. It is straightforward to see that any transition map $\Phi_j \circ \Phi_i^{-1}\colon \Phi_i(U_i \cap U_j) \to \Phi_j(U_i \cap U_j)$ can be written as the composition of (some) the following maps:
   - charts[224] and their inverses,
   - restrictions to open subsets,
   - the restriction of the action of $g \in G$ on M to some open subset.

   All these maps are smooth maps between smooth manifolds.[225] Thus the transition maps are smooth.

(2) Note that in the above proof of the Manifold Quotient-by-Group Action Proposition 19.32 (1) we already saw that the projection $p\colon M \to M/G$ is a local homeomorphism. It is straightforward to verify that, with our choice of a smooth atlas for M/G, the projection is in fact a local diffeomorphism.

The proof of the remaining statements (a), (b), (c) and (d) is basically identical to the above proof for topological manifolds.

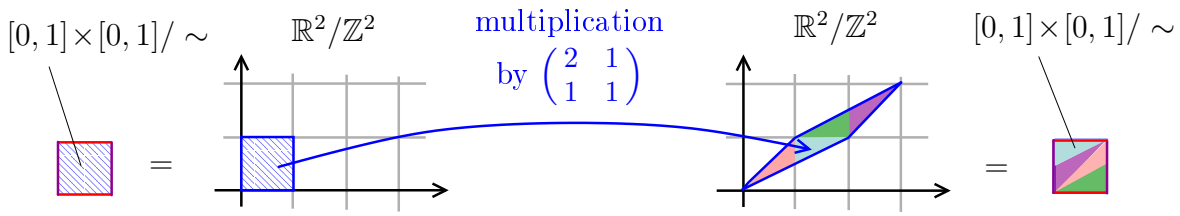
Finally, the statement that the smooth structure on M/G is uniquely determined by the smooth structure on M and the property that the projection $M \to M/G$ is a local diffeomorphism is a consequence of the Smooth Pasting Proposition 19.23 (1) and the fact that the action is proper. We leave it to the reader to fill in the details. ■

We conclude this section with the following amusing lemma. It gives an example of a diffeomorphism that will pop up on several occasions.

Lemma 19.37. (Maps-on-Torus Lemma) Let $n \in \mathbb{N}$. If $A \in \mathrm{GL}(n,\mathbb{Z})$ is a matrix, then the map

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^n/\mathbb{Z}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ [v] & \mapsto & [A\cdot v] \end{array}$$

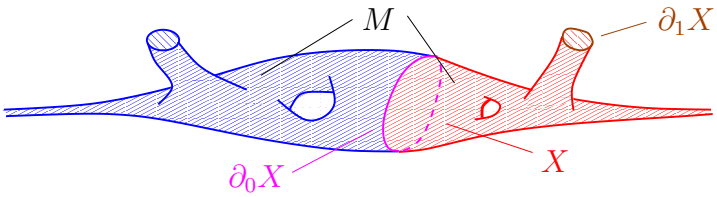
is a diffeomorphism. (In Exercise 25.8 we will see that this diffeomorphism is "orientation-preserving" if and only if $A \in \mathrm{SL}(n,\mathbb{Z})$.)



Proof. We will provide the proof in Exercise 19.14. ■

Example. We consider the matrix $A = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix} \in \mathrm{GL}(2,\mathbb{Z})$. The corresponding self-diffeomorphism $f(A)$ of $\mathbb{R}^2/\mathbb{Z}^2 = ([0,1]\times[0,1])/\!\sim$ is illustrated in the figure below.

19.12. **Codimension-Zero submanifolds and decompositions of smooth manifolds.** We start out by introducing the following notation.



[224] Recall that we view open subsets of $\mathbb{R}^n$ as smooth manifolds. With this convention charts are in fact diffeomorphisms between smooth manifolds.

[225] Here the smooth manifolds are open subsets of $\mathbb{R}^n$ or of M.

Notation. Let M be an n-dimensional smooth manifold and let X be a codimension-zero submanifold. We write[226]

$$\partial_0 X \;:=\; \partial X \setminus \partial M \quad \text{and} \quad \partial_1 X \;:=\; \partial X \cap \partial M.$$

The following proposition is used frequently, often without noticing it.

Proposition 19.38. (Codimension-Zero Submanifold Proposition) Let M be an n-dimensional smooth manifold and let X be a codimension-zero submanifold. The following statement holds:

(1) $\partial_0 X$ and $\partial_1 X$ are unions of components of ∂X.

In the remainder we assume that X is a closed subset of M (e.g. X could be a compact subset). Then the following statements hold:

(2) The boundary of X as a subset of M agrees with $\partial_0 X$.

(3) The interior $\mathring{X}$ of X as a subset of M agrees with $X \setminus \partial_0 X$.

We can furthermore make some statements about the complement $Y := M \setminus \mathring{X}$ of the interior:

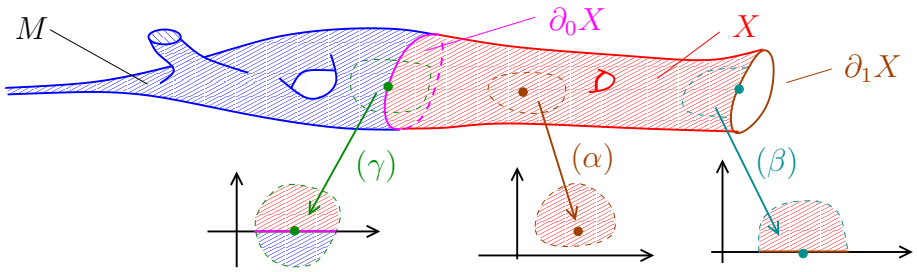
(4) $Y = M \setminus \mathring{X}$ is a codimension-zero submanifold with $\partial_0 Y = \partial_0 X$ and $\partial_1 Y = \partial M \setminus \partial_1 X$.

(5) Y is a closed subset of M and if M is compact, then $Y = M \setminus \mathring{X}$ is also compact.

(6) If M is connected and if $\partial_0 X$ is connected, then $Y = M \setminus \mathring{X}$ is also connected.

Remark. In Proposition 75.3 we will prove an analogue of the Codimension-Zero Submanifold Proposition 19.38 for topological manifolds.

Proof. Let X be a codimension-zero submanifold of M and let $P \in X$. By the Submanifold Smooth Structure Lemma 19.24 we can and will view the submanifold X as a smooth manifold in its own right. We start out with the following observation:



(α) A submanifold chart of type (α) for P is a manifold chart of type (i) for $P \in M$ and a manifold chart of type (i) for $P \in X$.

(β) A submanifold chart of type (β) for P is a manifold chart of type (ii) for $P \in M$ and a manifold of type (ii) for $P \in X$.

[226] Recall that by the Submanifold Smooth Structure Lemma 19.24 we can view the submanifold X as a smooth manifold in its own right. Here ∂X denotes the corresponding boundary of X viewed as a smooth manifold.

(γ) A submanifold chart of type (γ) for P is a manifold chart of type (i) for $P \in M$ and a manifold chart of type (ii) for $P \in X$.

Note that by the Smooth Manifold Boundary Proposition 19.26 (1) the chart type for a point is uniquely determined.

(1) From the above observations we see that the following hold:

$$\begin{aligned} \partial_0 X &= \text{the set of all } P \in X \text{ that admit a submanifold chart of type } (\gamma) \\ \partial_1 X &= \text{the set of all } P \in X \text{ that admit a submanifold chart of type } (\beta) \end{aligned}$$

It follows immediately that $\partial_0 X$ and $\partial_1 X$ are both open subsets of ∂X. Thus it follows from the Component Lemma 2.33 (4) that they are unions of components of ∂X.

Now we assume that X is a closed subset of M.

(2) Let $P \in M$. The desired statement follows from the following observations:

$$\begin{array}{l} \text{this follows from the hypothesis that } X \text{ is a closed subset and Lemma 1.10} \\ \downarrow \\ P \text{ lies in the boundary of } X \text{ as a subset of } M \iff P \text{ lies on } X \text{ and every open neighborhood of } P \text{ contains a point in } M \setminus X \\ \iff P \text{ admits a submanifold chart of type } (\gamma) \iff P \in \partial_0 X. \\ \uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\ \text{since } X \text{ is a submanifold of codimension zero} \qquad\qquad\qquad\qquad \text{see above} \end{array}$$

(3) This statement follows immediately from (2) together with the Interior-Closure Lemma 1.9 (6).

Now we turn to the proofs of the statements about $Y = M \setminus \mathring{X}$.

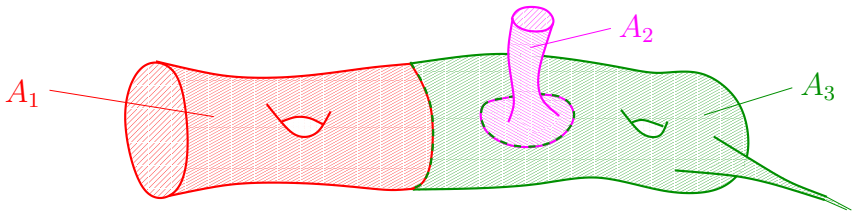
(4) By the Interior-Closure Lemma 1.9 (7) together with the above Statements (2) and (3) we know that $\mathring{Y} = Y \setminus \partial_0 X$. Now let $P \in Y$.
   (a) If $P \in \mathring{Y}$, then the charts for M, intersected with $\mathring{Y}$, give rise to codimension-zero submanifold charts of type (α) respectively (β) for $P \in Y$.
   (b) If $P \in \partial_0 X$, then by the above we know that there exists a submanifold chart of type (γ) for $P \in X$. But flipping the last coordinate we see that this gives rise to a submanifold chart of type (γ) for $P \in Y = M \setminus \mathring{X}$.

   It follows from this discussion that Y is indeed a codimension-zero submanifold of M. Furthermore, using the discussion in the beginning of the proof we see easily that $\partial_0 Y = \partial_0 X$ and $\partial_1 Y = \partial M \setminus \partial_1 X$.

(5) By the Interior-Closure Lemma 1.9 (1) we know that $\mathring{X}$ is an open subset of M. Thus we see that $Y = M \setminus \mathring{X}$ is a closed subset of M. If M is compact, then we obtain from the Compact-Closed Lemma 1.21 that $Y = M \setminus \mathring{Y}$ is also compact.

(6) This statement follows immediately from Statement (2) together with the Complement Connected Lemma 2.29. ■

the Codimension-Zero Submanifold Proposition 19.38 partially motivates the following definition.



Definition. Let M be an n-dimensional smooth manifold. We say M is decomposed into submanifolds $\{A_i\}_{i \in I}$ if the following conditions hold:

(1) We have $M = \bigcup_{i \in I} A_i$.

(2) Each A_i is a codimension-zero submanifold of M.

(3) Each A_i is a closed subset of M.

(4) For any $i, j \in I$ with $i \neq j$ the intersection $A_i \cap A_j$ is a union of boundary components of A_i and it is a union of boundary components of A_j.

On page 564 we equipped the real projective plane with a standard smooth structure. In Exercise 19.20 we will see that the Klein bottle $([0,1] \times [0,1])/\sim$ comes with a canonical smooth structure. The following cute lemma says that the Klein bottle and the real projective plane admit some interesting decompositions into submanifolds.

Lemma 19.39.

(1) We can decompose the Klein bottle into two submanifolds M and N where M and N are both diffeomorphic to the Möbius band.

(2) We can decompose the real projective plane into two submanifolds D and M where D is diffeomorphic to the disk $\overline{B}^2$ and M is diffeomorphic to the Möbius band.

Proof.

(1) The proof of the first statement is sketched in Figure A. In Figure B we attempt to sketch the equivalent statement that the Klein bottle is obtained from gluing two copies of the Möbius band along the common boundary.

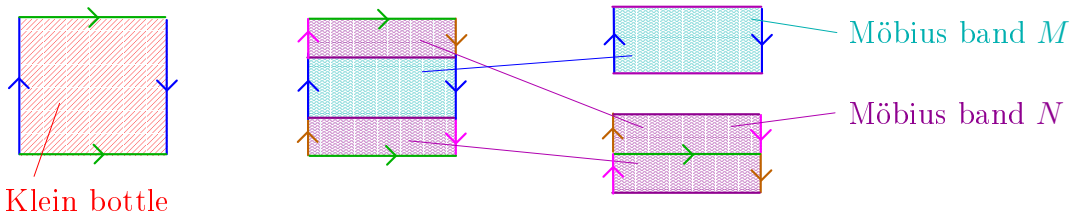


Figure A: Illustration of the proof of Lemma 19.39 (1).

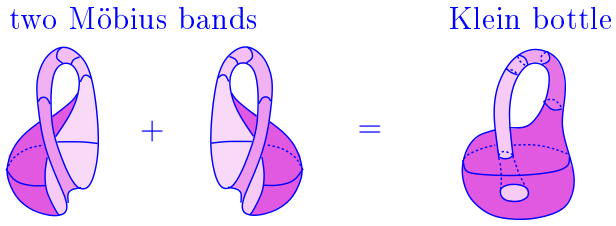

Figure B: Illustration of the proof of Lemma 19.39 (1).

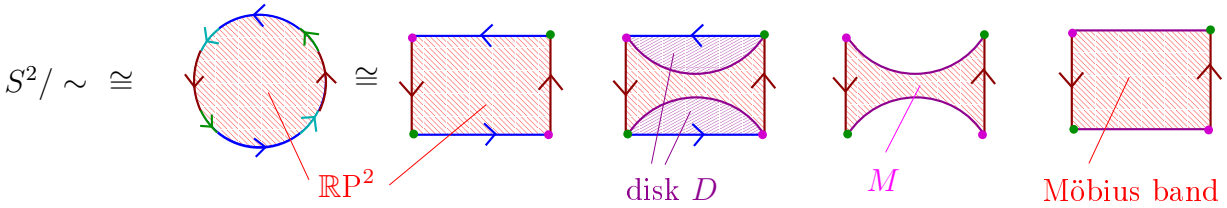
(2) Let $p\colon S^2 \to \mathbb{R}\mathrm{P}^2 = S^2/x \setminus -x$ be the projection. To simplify the notation we think in the following of $\overline{B}^2 \subset \mathbb{C}$ and $S^2 \subset \mathbb{C} \times \mathbb{R}$. We consider the following two subsets of S^2 which are illustrated in the figure below:

$$\widetilde{D} := \{(z,t) \in S^2 \,|\, t \geq \tfrac{1}{2}\} \qquad \text{and} \qquad \widetilde{M} := \{(z,t) \in S^2 \,|\, t \in [0, \tfrac{1}{2}]\}.$$

Furthermore we set $D := p(\widetilde{D})$ and $M := p(\widetilde{M})$. We consider the Möbius band

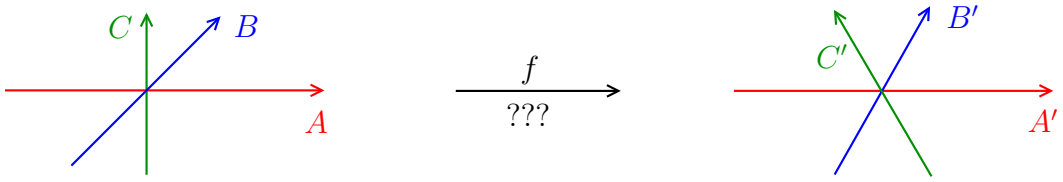


$\mathbb{R} \times [-1,1]/\!\sim$ as defined on page 252. We leave it to the reader to verify that the two maps

$$\begin{aligned} \overline{B}^2 &\to D \\ z &\mapsto p\Big(\tfrac{\sqrt{3}}{2}z, \sqrt{1 - \tfrac{3}{4}\cdot|z|^2}\Big) \end{aligned} \qquad \text{and} \qquad \begin{aligned} \mathbb{R} \times [-1,1]/\!\sim &\mapsto M \\ [(x,t)] &\mapsto p\Big(\sqrt{1 - \tfrac{1}{4}t^2}\cdot\exp(\pi\,\mathrm{i}x), \tfrac{1}{2}t\Big) \end{aligned}$$

are diffeomorphisms.[227] ■

Remark. If one is not bothered too much about smooth structures, then another decomposition of the real projective plane into a Möbius band and a real disk is sketched in the figure below. Here, for $\mathbb{R}\mathrm{P}^2$ we use the homeomorphism $\mathbb{R}\mathrm{P}^2 \cong \overline{B}^2/\!\sim$ that we gave in Lemma 5.32.



[227] This can clearly be done, but it not particularly pleasant. The work becomes easier if one uses the Smooth Embedding Theorem 24.10.

Exercises for Chapter 19.

Exercise 19.1. Show that there exists a diffeomorphism $[0,1) \to [0,\infty)$ such that $f(x) = x$ for all $x \in [0, \frac{1}{2})$.
Hint. Use the Smooth Transition Function Lemma 19.4 and some creativity.

Exercise 19.2. Let $M := A \sqcup B \sqcup C \subset \mathbb{R}^2$ be the subset shown in the figure below. Does there exist a smooth map $f\colon M \to \mathbb{R}^2$, as illustrated in the figure below? which restricts to diffeomorphisms $A \to A'$, $B \to B'$ and $C \to C'$?

Exercise 19.3. We consider the topological space $X = \mathbb{R}$ and the following three charts:

$$\begin{array}{rcl} \Phi_1\colon \mathbb{R} & \to & \mathbb{R} \\ x & \mapsto & x \end{array} \qquad \begin{array}{rcl} \Phi_2\colon \mathbb{R} & \to & \mathbb{R} \\ x & \mapsto & x^3 \end{array} \qquad \begin{array}{rcl} \Phi_1\colon \mathbb{R} & \to & (-\frac{\pi}{2}, \frac{\pi}{2}) \\ x & \mapsto & \arctan(x). \end{array}$$

(a) Is the atlas given by $\{\Phi_1\}$ a smooth atlas for $X = \mathbb{R}$?
(b) Is the atlas given by $\{\Phi_2\}$ a smooth atlas for $X = \mathbb{R}$?
(c) Is the atlas given by $\{\Phi_1, \Phi_2\}$ a smooth atlas for $X = \mathbb{R}$?
(d) Is the atlas given by $\{\Phi_1, \Phi_3\}$ a smooth atlas for $X = \mathbb{R}$?

Exercise 19.4. Let $x, y \in B^n$. Show that there exists a diffeomorphism $f\colon B^n \to B^n$ with $f(x) = y$.

Exercise 19.5. Let $n \in \mathbb{Z}$. We consider the following map:

$$\begin{array}{rcl} S^1 & \to & S^1 \\ z & \mapsto & z^n \end{array}$$

(a) Show, just using the definitions and the Smooth-via-Atlas Lemma 19.21, that f is smooth.
(b) Show that if $n \neq 0$, then f is a local diffeomorphism.

Exercise 19.6.

(a) Let $r \in \mathbb{R}$. Show that the map

$$\begin{array}{rcl} (r - \frac{1}{2}, r + \frac{1}{2}) & \to & S^1 \setminus \{-\exp(2\pi i \cdot r)\} \\ t & \mapsto & \exp(2\pi \mathrm{i} \cdot t) \end{array}$$

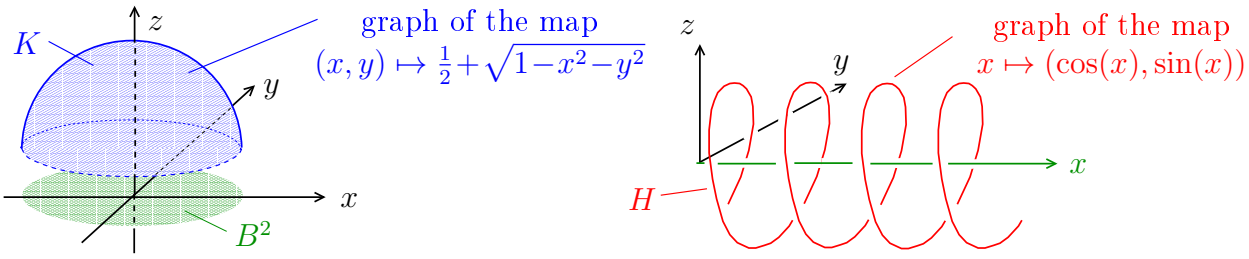
is a diffeomorphism.
(b) Let $n \in \mathbb{N}$. Show that the map

$$\begin{array}{rcl} \mathbb{R}^n & \to & (S^1)^n = S^1 \times \cdots \times S^1 \\ (t_1, \ldots, t_n) & \mapsto & (\exp(2\pi \mathrm{i} \cdot t_1) \ldots, \exp(2\pi \mathrm{i} \cdot t_n)) \end{array}$$

is a local diffeomorphism.

Remark. The point of this exercise is that one really needs to look up what are the standard smooth structures on the various smooth manifolds involved.

Exercise 19.7.



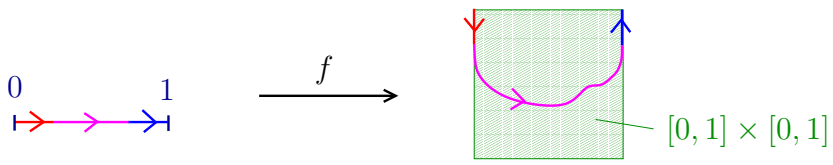
(1) Show that the topological space $X = \{(x, y) \in \mathbb{R}^2 \,|\, x \in [0, 1] \text{ and } y \in [0, x]\}$ is a topological manifold.
(2) Does the topological manifold X admit a smooth atlas?

Exercise 19.8. Give an example of two smooth atlases $\{\Phi_i\}_{i\in I}$ and $\{\Psi_j\}_{j\in J}$ for $X = \mathbb{R}$ such that for all $i \in I$ and $j \in J$ the map $\Psi_j \circ \Phi_i^{-1}$ is smooth, but such that the two atlases are not equivalent.

Exercise 19.9. Show that the following two statements are equivalent:

(1) S^n admits two inequivalent smooth structures.
(2) There exists a smooth manifold that is homeomorphic to S^n but not diffeomorphic to S^n, where we equip S^n with the standard smooth structure.

Exercise 19.10. Let V be some smooth manifold and let W be some smooth manifold with $\partial W = \varnothing$. Furthermore let $f\colon V \to W$ be a smooth map. Show that the corresponding graph $\mathrm{Gr}(f) := \{(x, f(x)) \,|\, x \in V\}$ is a proper submanifold of the smooth manifold $V \times W$.
Remark. This is the smooth analogue of Exercise 18.8.



Exercise 19.11. Let M be a smooth manifold and let W be a submanifold of M. We denote by ∂W the boundary of W viewed as a smooth manifold in its own right. Show that for every component C of ∂W we have either $C \subset \partial M$ or $C \subset M \setminus \partial M$.

Exercise 19.12. Show that there exists a smooth map $f = (f_1, f_2)\colon [0, 1] \to [0, 1] \times [0, 1]$ with the following properties:

(a) For $t \in [0, \frac{1}{4}]$ we have $f(t) = (0, 1 - t)$.
(b) For $t \in [\frac{3}{4}, 1]$ we have $f(t) = (1, t)$.
(c) The map $f_1\colon [0, 1] \to [0, 1]$ is monotonously increasing.
(d) For each $t \in [0, 1]$ we have $f'(t) \neq 0 \in \mathbb{R}^2$.
(e) For $t \neq \{0, 1\}$ we have $f_2(t) \in (0, 1)$.

Hint. Use the Smooth Transition Function Lemma 19.4.

Exercise 19.13. Let U be an open convex neighborhood of $0 \in \mathbb{R}^n$ and let $f\colon U \to \mathbb{R}$ be a smooth map with $f(0) = 0$. We assume that 0 is a critical point, i.e. we assume that the

differential $\mathrm{D}f_0$ is zero. Show that there exist smooth functions $h_{ij}\colon U \to \mathbb{R}$, $i, j = 1, \ldots, n$ such that $h_{ij} = h_{ji}$ and such that

$$f(x) \;=\; \sum_{i=1}^{n} \sum_{j=1}^{n} h_{ij}(x) \cdot x_i \cdot x_j \qquad \text{for all } x = (x_1, \ldots, x_n) \in U.$$

Hint. Make use of the Map-as-Matrix Multiplication Proposition 19.14.

Exercise 19.14. Let $n \in \mathbb{N}$ and let $A \in \mathrm{GL}(n, \mathbb{Z})$ be a matrix. Show that the map

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^n/\mathbb{Z}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ [v] & \mapsto & [A \cdot v] \end{array}$$

is a diffeomorphism.

Exercise 19.15. Let M be a smooth manifold and let $N \subset M$ be a smooth submanifold with $\dim(N) < \dim(M)$.

(a) Show that the interior of N in M is the empty set.
(b) Show that the closure of $M \setminus N$ in M equals M.

Exercise 19.16. Let $n \in \mathbb{N}_0$. As on page 255 we have the identification

$$\begin{array}{rcl} \Phi\colon \mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\} & \to & \mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \\ [x] & \mapsto & [x]. \end{array}$$

We use the description on the right to define a smooth structure on $\mathbb{R}\mathrm{P}^n$.

(a) Let $i \in \{0, \ldots, n\}$. Show that $V_i := \{[x_0 : \cdots : x_n] \in \mathbb{R}\mathrm{P}^n \,|\, x_i \neq 0\}$ is an open subset of $\mathbb{R}\mathrm{P}^n$.
(b) Show that the maps

$$\begin{array}{rcl} \Phi_i\colon \{[x_0 : \cdots : x_n] \in \mathbb{R}\mathrm{P}^n \,|\, x_i \neq 0\} & \to & \mathbb{R}^n \\ [x_0 : \cdots : x_n] & \mapsto & \big(\frac{x_0}{x_i}, \ldots, \frac{x_{i-1}}{x_i}, \frac{x_{i+1}}{x_i}, \ldots, \frac{x_n}{x_i}\big). \end{array}$$

form a smooth atlas for $\mathbb{R}\mathrm{P}^n$.
(c) Show that the smooth structure defined in (b) is equivalent to the standard smooth structure on $\mathbb{R}\mathrm{P}^n$ that we introduced on page 564.

Exercise 19.17. We consider the stereographic projection

$$\begin{array}{rcl} \Phi\colon S^2 & \to & \mathbb{R}^2 \cup \{\infty\} = \mathbb{C} \cup \{\infty\} \\ (x_1, x_2, x_3) & \mapsto & \begin{cases} \Big(\frac{x_1}{1-x_3}, \frac{x_2}{1-x_3}\Big), & \text{if } x_3 < 1, \\ \infty, & \text{if } x_3 = 1. \end{cases} \end{array}$$

Let $q(z)$ be a polynomial with complex coefficients. We denote by $N := (0, 0, 1)$ the North Pole. Show that the map

$$\begin{array}{rcl} f\colon S^2 & \to & S^2 \\ P & \mapsto & \begin{cases} \Phi^{-1}(q(\Phi(P))), & \text{if } P \neq N, \\ N, & \text{if } P = N \end{cases} \end{array}$$

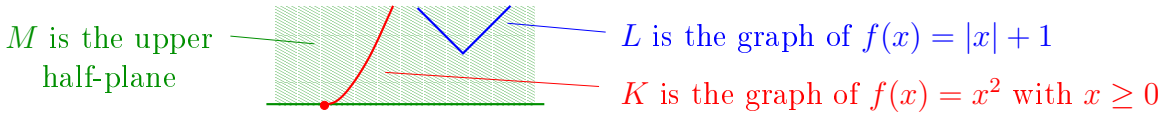
is smooth.
Hint. Use Exercise 18.15.

Exercise 19.18. Let M be a smooth manifold and let $U \subset M$ be an open subset. Furthermore let $f\colon U \to \mathbb{R}^k$ be a smooth map and let $P \in U$. Show that there exists an open neighborhood V of P and a smooth map $g\colon M \to \mathbb{R}^k$ such that f and g agree on V.
Hint. Use the Smooth Transition Function Lemma 19.4.

Exercise 19.19. Let M be a compact smooth manifold and let N be a proper codimension-zero submanifold of M. Show that if M is connected and if $N \neq \varnothing$, then $M = N$.

Exercise 19.20. We consider the square $X = [0,1] \times [0,1]$ with the equivalence relation that is generated by $(0,y) \sim (1,1-y)$ and $(x,0) \sim (x,1)$. On page 265 we defined the Klein bottle to be the quotient $X/\!\sim$.

(a) Show that X admits a smooth structure such that the projection $X \to X/\!\sim$ is smooth.
(b) Show that X is diffeomorphic to the non-orientable surface of genus one.



Remark. Note that part (b) is a refinement of Exercise 5.50. Also note that in Exercise 25.11 we will give an alternative, but equivalent, description of the smooth structure on the Klein bottle.

Exercise 19.21. Let $n \in \mathbb{N}_0$ and let $P, Q \in B^n = \overline{B}^n \setminus S^{n-1}$.

(a) Show that there exists a self-diffeomorphism φ of $\overline{B}^n$ with $\varphi(P) = Q$.
(b) Show that there exists a self-diffeomorphism φ of $\overline{B}^n$ with $\varphi(P) = Q$ and which is the identity in some neighborhood of S^{n-1}.

Exercise 19.22. In the figure below we show $M = \{(x,y) \in \mathbb{R}^2 \,|\, y \geq 0\}$ together with two subsets $K := \{(x,x^2) \,|\, x \geq 0\}$ and $L := \{(x,|x|+1) \,|\, x \in \mathbb{R}\}$.

(a) Show that both K and L are submanifolds of the topological manifold M.
Remark. You might have already shown in Exercise 18.11 that K is a submanifold.
(b) Show that K and L are not submanifolds if we view M as a smooth manifold.

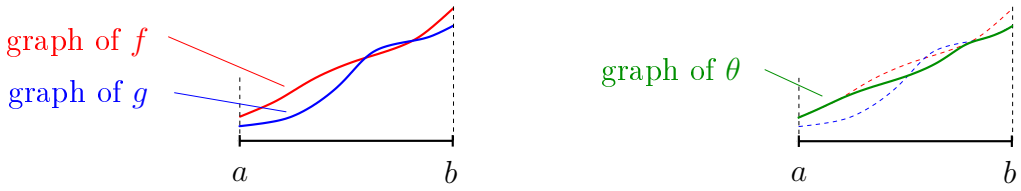
Exercise 19.23. Let M be a smooth manifold and let $f\colon M \to N$ be a map to some smooth manifold N. Furthermore let W be a smooth manifold and let $\varphi\colon W \to M$ be a smooth injective map. Show that if $f \circ \varphi\colon W \to N$ is smooth, then it is nonetheless in general not true that $f\colon M \to N$ is smooth[228] on the subset $\varphi(W) \subset M$.
Remark. In Exercise 19.24 we will see that in many important settings we can in fact deduce that f is smooth on the subset $\varphi(W) \subset M$.

Exercise 19.24. Let M be a smooth manifold and let $f\colon M \to N$ be a map to some smooth manifold N. Recall that given a subset $A \subset M$ we defined on page 549 what it means for f to be smooth on A.

(a) We use the Smooth Manifold Boundary Proposition 19.26 to view the boundary ∂M as a smooth manifold in its own right. We denote by $\iota\colon \partial M \to M$ the inclusion map. Show that $f \circ \iota\colon \partial M \to N$ is smooth if and only if f is smooth on ∂M.

[228] Recall that given a subset $A \subset M$ we defined on page 549 what it means for f to be smooth on A.

(b) Let W be a submanifold of M. We use the Submanifold Smooth Structure Lemma 19.24 to view W as a smooth manifold in its own right. We denote by $\iota\colon W \to M$ the inclusion map. Show that $f \circ \iota\colon W \to N$ is smooth if and only if f is smooth on W.



Remark. Exercise 19.23 shows that the results of this exercise cannot be generalized ad infinitum.

Exercise 19.25. Show that the Klein bottle can be decomposed into two submanifolds that are diffeomorphic to the annulus $[0,1] \times S^1$.

Exercise 19.26. Let $f\colon [a,b] \to \mathbb{R}$ and $g\colon [a,b] \to \mathbb{R}$ be smooth maps such that $f'(x) > 0$ and $g'(x) > 0$ for all $x \in [a,b]$. We assume that $g(b) > f(a)$. Show that there exists an $\eta > 0$ and a smooth map $\theta\colon [a,b] \to \mathbb{R}$ with the following properties:

(1) $\theta'(x) > 0$ for all $x \in [a,b]$,
(2) θ agrees with f on $[a, a+\eta]$,
(3) θ agrees with g on $[b-\eta, b]$.

Hint. You could use the Smooth Transition Function Lemma 19.4 and consider the derivatives of f and g.

Exercise 19.27. We equip each $\mathbb{R}^k$ with the standard smooth structure that we introduced on page 544 and we equip $\mathbb{R}^m \times \mathbb{R}^n$ with the product smooth structure introduced in the Smooth Manifold Product Proposition 19.31. Show that the map

$$\begin{array}{rcl} \mathbb{R}^{m+n} & \to & \mathbb{R}^m \times \mathbb{R}^n \\ (x_1, \dots, x_m, y_1, \dots, y_n) & \mapsto & ((x_1, \dots, x_m), (y_1, \dots, y_n)) \end{array}$$

is a diffeomorphism.

Exercise 19.28. Show that $N := \{(x,y) \in \mathbb{R}^2 \,|\, y \geq x^2\}$ is not a smooth submanifold of the smooth manifold $M = \{(x,y) \in \mathbb{R}^2 \,|\, y \geq 0\}$.

Exercise 19.29. Let M be an m-dimensional submanifold of $\mathbb{R}^n$. Show that

$$T \;:=\; \{(P,w) \,|\, P \in M, w \in \mathrm{T}_P M\} \;\subset\; \mathbb{R}^n \times \mathbb{R}^n$$

is an $2m$-dimensional smooth submanifold of $\mathbb{R}^n \times \mathbb{R}^n$.

Exercise 19.30. Let $A \subset \mathbb{R}^k$ and $B \subset \mathbb{R}^l$ be smooth submanifolds such that at most one has non-empty boundary. Show that $A \times B \subset \mathbb{R}^k \times \mathbb{R}^l = \mathbb{R}^{k+l}$ is a smooth submanifold of dimension $\dim(A) + \dim(B)$.

Exercise 19.31. Let M be a smooth manifold and let W be a (proper) submanifold.

(a) Show that $W \cap \partial M$ is a (proper) submanifold of ∂M.
(b) Let X be a (proper) submanifold of W. Show that X is also a (proper) submanifold of M.

Exercise 19.32. Let M be an n-dimensional smooth manifold with empty boundary. We consider the product $M \times M$.

(a) Show that the diagonal $\Delta := \{(x, x) \,|\, x \in M\}$ is an n-dimensional submanifold of $M \times M$.

(b) Show that the diagonal Δ is *diffeomorphic* to M.
Remark. There is an obvious bijection, but why is this bijection a diffeomorphism?

Exercise 19.33. Let X be a topological space and let M be a smooth manifold. Furthermore let $f\colon X \to M$ be a map. Now suppose that we are given two smooth structures $\mathcal{A}$ and $\mathcal{A}'$ on X such that $f\colon (X, \mathcal{A}) \to M$ and $f\colon (X, \mathcal{A}') \to M$ are local diffeomorphisms. Show that the two smooth structures on X are the same.
Hint. Use the Smooth Pasting Proposition 19.23.
Remark. This exercise can be viewed as the smooth manifold version of Exercise 2.3.

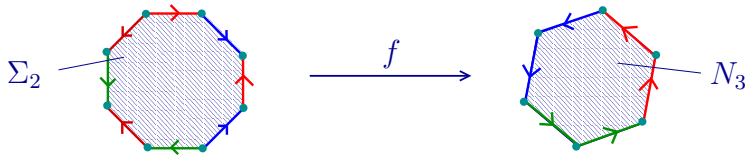
Exercise 19.34. Let $n \in \mathbb{N}$. A *lattice in* $\mathbb{R}^n$ is a subgroup of $(\mathbb{R}^n, +)$ that is a discrete subset of $\mathbb{R}^n$.

(a) Let $v_1, \ldots, v_k \in \mathbb{R}^n$ be linearly independent vectors. Show that $\Lambda = \mathbb{Z}\cdot v_1 + \cdots + \mathbb{Z}\cdot v_k$ is a lattice in $\mathbb{R}^n$. We refer to k as the rank of the lattice.

(b) Show that any lattice in $\mathbb{R}^n$ is of the form described in (a).

(c) Show that the obvious action of a lattice $\Lambda \subset \mathbb{R}^n$ on $\mathbb{R}^n$, i.e. the action that is given by addition, is proper.

If Λ is a lattice in $\mathbb{R}^n$, then it follows from (c) and the Manifold Quotient-by-Group Action Proposition 19.32 that $\mathbb{R}^n/\Lambda$ is naturally an n-dimensional smooth manifold.



(d) Show that if Λ and $\widetilde{\Lambda}$ are two lattices in $\mathbb{R}^n$ of the same rank, then $\mathbb{R}^n/\Lambda$ and $\mathbb{R}^n/\widetilde{\Lambda}$ are diffeomorphic.

Exercise 19.35. Let $g \in \mathbb{N}$. Let M be the smooth manifold that we obtain from removing a single point from the surface of genus g. Does there exist a smooth map $M \to S^2$ that is a local diffeomorphism?

Exercise 19.36. In the figure below we show to the left the usual way to depict the Möbius band M as submanifold in $\mathbb{R}^3$. Does there exist an embedding of the Möbius band in $\mathbb{R}^3$ such that the boundary is the curve K shown to the right?

Exercise 19.37. Given $g \in \mathbb{N}_0$ we denote by Σ_g the surface g as defined on page 266 and given $k \in \mathbb{N}$ we denote by N_k the non-orientable surface of genus k as defined on page 266. Show that given any $k \in \mathbb{N}$ there exists a smooth map $f\colon \Sigma_{k-1} \to N_k$ that is a local diffeomorphism and that has the property that for each $x \in N_k$ we have $\#f^{-1}(x) = 2$.

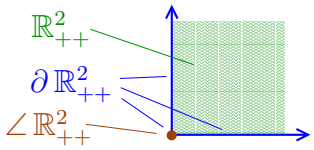
20. Smooth manifolds with corner

In this chapter we introduce smooth manifolds with corner. This might be viewed as a rather obscure topic, but it naturally arises in various situations, for example when one considers smooth homotopies of smooth manifolds with non-empty boundary.

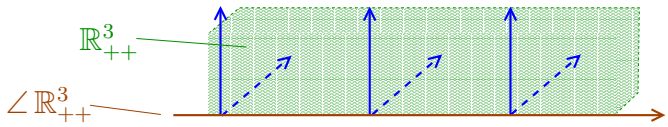
20.1. **Definition of smooth manifolds with corner.** In the Topological Manifold Product Proposition 18.4 we saw that the product of two topological manifolds X and Y is again a topological manifold. If both X and Y have non-empty boundary we had to make use of a delicate chart (see also the Corner Smooth Lemma 20.1 below.) It turns out that for smooth atlases this approach does not necessarily lead to a smooth atlas on $X \times Y$. This debacle requires us to introduce smooth manifolds with corner.

Notation. Given $n \in \mathbb{N}_{\geq 2}$ we refer to

$$\mathbb{R}^n_{++} := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_{n-1} \geq 0 \text{ and } x_n \geq 0\}$$



as the upper right quadrant of $\mathbb{R}^n$. We refer to

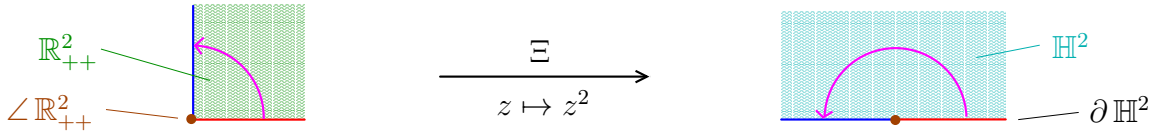


$$\partial\mathbb{R}^n_{++} := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_{n-1} = 0 \text{ or } x_n = 0\}$$

as the boundary of $\mathbb{R}^n_{++}$ and we refer to

$$\angle\mathbb{R}^n_{++} := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_{n-1} = 0 \text{ and } x_n = 0\}$$

as the corner of $\mathbb{R}^n_{++}$.



Lemma 20.1. (Corner Smooth Lemma) Let $n \in \mathbb{N}_{\geq 2}$.

(1) The map[229]

$$\begin{array}{rcl} \Xi\colon \mathbb{R}^n_{++} & \to & \mathbb{H}^n \\ (x_1, \dots, x_{n-2}, \underbrace{r \cdot \cos(\varphi), r \cdot \sin(\varphi)}_{=:z\in\mathbb{C}}) & \mapsto & (x_1, \dots, x_{n-2}, \underbrace{r^2 \cdot \cos(2\varphi), r^2 \cdot \sin(2\varphi)}_{=z^2}). \end{array}$$

is a homeomorphism which restricts to a homeomorphism $\partial\mathbb{R}^n_{++} \to \partial\mathbb{H}^n$.

(2) Let U be an open subset of $\mathbb{R}^n_{++}$ that contains a point of the corner $\angle\mathbb{R}^n_{++}$. There is no diffeomorphism $f\colon U \to V$ from U to some open subset $V \subset \mathbb{H}^n$ such that $f(\partial\mathbb{R}^n_{++} \cap U) \subset \partial\mathbb{H}^n$.

Proof.

[228] We first encountered this nice map on page 516.

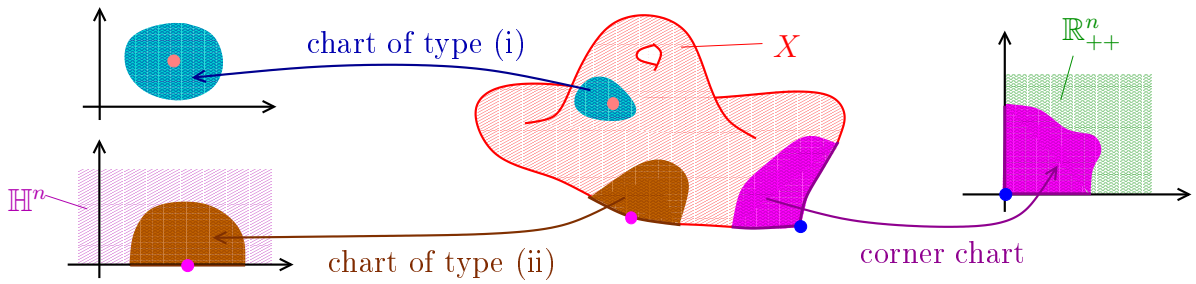
[229] Note that the definition of a diffeomorphism on page 537 also makes sense for subsets of $\mathbb{R}^n$ that are not open.

(1) The map $\mathbb{C} \to \mathbb{C}$ that is given by $z = x + \mathrm{i}y \mapsto z^2 = (x^2 - y^2) + 2xy\mathrm{i}$ is continuous. It follows that Ξ is continuous. It is straightforward to show, say using the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19, that Ξ is indeed a homeomorphism.

(2) The proof of this statement is similar to the proof of the Smooth Manifold Boundary Proposition 19.26 (1). We outsource the proof to Exercise 20.1. ■

In the following we recall the definition of charts of type (i) and (ii) from page 511 and we introduce the notion of a corner chart.

Definition. Let X be a topological space and let $x \in X$. An n-dimensional chart at the point $x \in X$ is a homeomorphism $\Phi\colon U \to V$ where U is an open neighborhood of x and



(i) V is an open subset of $\mathbb{R}^n$ or

(ii) V is an open subset of the upper half-space $\mathbb{H}^n$ and $\Phi(x)$ lies in $\partial\,\mathbb{H}^n$.

An n-dimensional corner chart at the point $x \in X$ is a homeomorphism $\Phi\colon U \to V$ where U is an open neighborhood of x and

(c) V is an open subset of $\mathbb{R}^n_{++}$ and $\Phi(x)$ lies in $\angle\,\mathbb{R}^n_{++}$.

To simplify the discussion we refer to these as charts of type (i), (ii) and (c). Sometimes we call a chart of type (c) also a corner chart.

It follows from the Corner Smooth Lemma 20.1 (1) that if a point $x \in X$ admits a corner chart, then it also admits a chart of type (ii). Thus if we are only interested in topological manifolds such charts do not add anything new and they are basically irrelevant. As the Corner Smooth Lemma 20.1 (2) indicates, smoothly the situation is different. This leads us to the following definition.

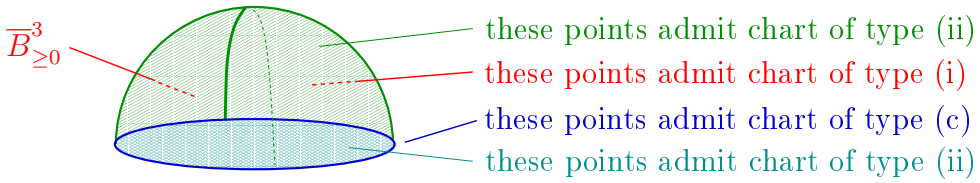
Definition. Let X be a topological space.

(1) An n-dimensional corner atlas for the topological space X is a collection of n-dimensional charts of type (i), (ii) and (c) such that the domains cover all of X.

(2) We say that two n-dimensional charts $\Phi_1\colon U_1 \to V_1$ and $\Phi_2\colon U_2 \to V_2$ for X are smoothly compatible if the transition map

$$\Phi_2 \circ \Phi_1^{-1}\colon \underbrace{\Phi_1(U_1 \cap U_2)}_{\substack{\text{open set in} \\ \mathbb{R}^n,\ \mathbb{H}^n \text{ or } \mathbb{R}^n_{++}}} \to \underbrace{\Phi_2(U_1 \cap U_2)}_{\subset \mathbb{R}^n}$$

is smooth, in the sense of our definition on page 532.



(3) A corner atlas $\mathcal{A}$ is called smooth if all charts in the corner atlas are smoothly compatible to one another.

(4) A smooth corner $\mathcal{A}$ for M is called maximal if every chart Ψ that is smoothly compatible with all the charts in the smooth atlas $\mathcal{A}$ is already contained in $\mathcal{A}$. The proof of the Maximal Atlas Existence Proposition 19.17 shows that every smooth corner atlas is contained in a unique maximal smooth corner atlas.
(5) An n-dimensional smooth manifold with corner is a pair $(X, \mathcal{A})$ consisting of a second-countable Hausdorff space together with a maximal n-dimensional smooth corner atlas $\mathcal{A}$ for X.

Example. Let $n \geq 2$. We consider the upper half-ball

$$\overline{B}^n_{\geq 0} \;=\; \{(x_1, \ldots, x_n) \in \overline{B}^n \,|\, x_n \geq 0\}.$$

In Exercise 20.2 we will see that $\overline{B}^n_{\geq 0}$ is a smooth manifold with corner, with charts as shown in the figure below.

The following lemma says, as we already hinted at, that as topological manifolds we did not introduce anything new.

Lemma 20.2. If $(X, \mathcal{A})$ is an n-dimensional smooth manifold with corner, then the underlying topological space X is an n-dimensional topological manifold.

Proof. This lemma follows, as will be clear to the reader, from the observation that the composition of a corner chart with the homeomorphism given in the Corner Smooth Lemma 20.1 is a chart of type (ii). ■

Definition. Many of the definitions for smooth manifolds extend in an obvious way to smooth manifolds with corner:

(1) As in Lemmas 19.19 and 19.20, and as in the convention on page 545, we can view an open subset of a smooth manifold with corner as a smooth manifold with corner.
(2) A smooth map between smooth manifolds with corner is defined as on page 546.

For completeness' sake we state the following generalization of Lemma 19.22.

Lemma 20.3.

(1) Every smooth map between two smooth manifolds with corner is continuous.
(2) The composition of two smooth maps between smooth manifolds with corner is again smooth.

Proof. The proof is basically identical to the rather trivial proof of Lemma 19.22. ■

The following proposition is a generalization of the Smooth Manifold Boundary Proposition 19.26 (1).

Proposition 20.4. (Unique Type of Chart Proposition) Let M be a smooth manifold with corner and let $x \in M$. Precisely one of the following three statements holds:

(1) The point x admits a chart of type (i) from the smooth structure.

(2) The point x admits a chart of type (ii) from the smooth structure.
(3) The point x admits a chart of type (c) from the smooth structure.

Proof. The fact that a point that admits charts of type (i) in the smooth structure cannot also admit a chart of type (ii) in the smooth structure is the content of the Smooth Manifold Boundary Proposition 19.26 (1). The same argument also shows that such a point cannot admit a chart of type (c) in the smooth structure.

The fact that charts of type (ii) and (c) in the smooth structure are mutually exclusive follows easily from the Corner Smooth Lemma 20.1 (2). We outsource the proof to Exercise 20.3. Alternatively see also [**Lee2002**, Proposition 16.20] for details. ■

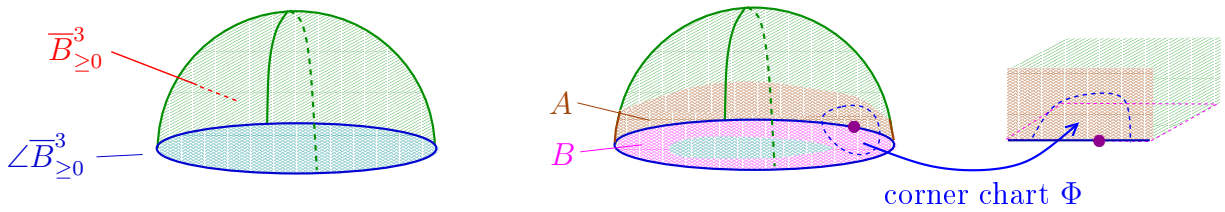
The Unique Type of Chart Proposition 20.4 leads us to the following analogue and generalization of the definitions on pages 511 and 545.

Definition. Let M be a smooth manifold with corner.

(1) We say that a point $x \in M$ is a boundary point if x admits a chart of type (ii) or (c) in the smooth structure. We denote by ∂M the set of all boundary points of M. We refer to ∂M as the boundary of M.
(2) We say that a point $x \in M$ is a corner point if x admits a chart of type (c) in the smooth structure. We denote by $\angle M$ the set of all corner points of M. We refer to $\angle M$ as the corner of M.

We conclude this section with the following proposition which is an analogue of the Smooth Manifold Boundary Proposition 19.26 (2) and (3).

Proposition 20.5. Let M be an n-dimensional smooth manifold with corner. The following statements hold:



(1) The corner $\angle M$ has a natural structure of an $(n-2)$-dimensional smooth manifold with $\partial(\angle M) = \varnothing$. Furthermore the inclusion map $\angle M \to M$ is a smooth map.
(2) Any union of components of ∂M is a closed subset of M.
(3) Any union of components of $\angle M$ is a closed subset of M.

Proof. The proof of these statements is very similar to the proof of the Smooth Manifold Boundary Proposition 19.26 (2) and (3). All we really have to do is to replace the Smooth Manifold Boundary Proposition 19.26 (1) by the Unique Type of Chart Proposition 20.4. We leave it to the reader to fill in the details. ■

Of course one could now develop the theory of smooth manifolds with corner in great detail. For example one could now introduce the notion of a submanifold of a smooth manifold with corner. We will spare the author and the reader to go through this discussion which would mostly be a case of "l'art pour l'art".
Instead, to pique the reader's interest we give a sneak preview of a later result. To formulate the result we will need the following definition.

Definition. Let M be an n-dimensional smooth manifold with corner. We say that the corner $\angle M$ is two-sided if there exist two disjoint open subsets A and B of ∂M such that the following conditions are satisfied:

(1) $A \cup \angle M \cup B$ is an open subset of ∂M,
(2) For every chart $\Phi\colon U \to V \subset \mathbb{R}^n_{++}$ of type (c) one of the following holds:
- $\Phi(A \cap U) \subset \{(x_1, \dots, x_n) \,|\, x_{n-1} = 0\}$ and $\Phi(B \cap U) \subset \{(x_1, \dots, x_n) \,|\, x_n = 0\}$, or
- $\Phi(B \cap U) \subset \{(x_1, \dots, x_n) \,|\, x_{n-1} = 0\}$ and $\Phi(A \cap U) \subset \{(x_1, \dots, x_n) \,|\, x_n = 0\}$.

The following proposition now says that smooth manifolds with corner can be turned into smooth manifolds without corner.

Proposition ?? (Simplified). Let M be a smooth manifold with corner $\angle M$. If $\angle M$ is two-sided, then any choice of a "bicollar" gives rise to a smooth atlas on M which consists only of charts of type (i) and (ii).

20.2. **Products of smooth manifolds II.** In the Topological Manifold Product Proposition 18.4 we saw that the product of two topological manifolds is again a topological manifold. The case that both topological manifolds have non-empty boundary was somewhat tricky.

Thus, when in Section 19.10 we started to look at the product of two smooth manifolds we sidestepped the issue by only considering the product of two smooth manifolds where at least one has empty boundary. We now turn to the product of two smooth manifolds where both are allowed to have non-empty boundary.

Proposition 20.6. (Smooth Manifold Product Proposition) Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. We denote by

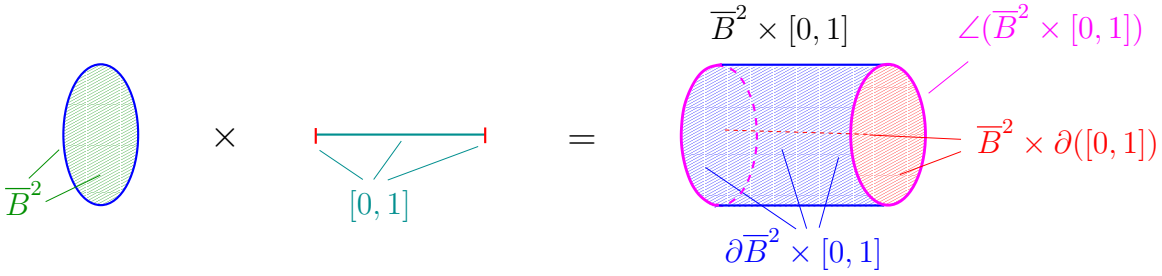
$$\begin{array}{rcl} p\colon M \times N & \to & M \\ (x,y) & \mapsto & x \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon M \times N & \to & N \\ (x,y) & \mapsto & y \end{array}$$

the two projections. The following statements hold:

(1) The product $M \times N$ is an $(m+n)$-dimensional topological manifold that admits a *unique* structure as a smooth manifold with corner that satisfies the following two conditions:
   (a) The projections $p\colon M \times N \to M$ and $q\colon M \times N \to N$ are smooth.
   (b) For every smooth manifold with corner W and every map $f\colon W \to M \times N$ the following holds: If the two maps $p \circ f\colon W \to M$ and $q \circ f\colon W \to N$ are smooth, then f itself is smooth.
(2) $\partial(M \times N) = (M \times \partial N) \cup (N \times \partial M)$.
(3) $\angle(M \times N) = \partial M \times \partial N$.

Proof. Similar to the proof of the Smooth Manifold Product Proposition 19.31 we obtain a corner atlas for $M \times N$ by taking products of charts of M and N. The proof of the

proposition is thus just a straightforward modification of the already very straightforward proof of the Smooth Manifold Product Proposition 19.31. The only real difference is that for the proofs of Statement (2) and (3) we need to replace the Smooth Manifold Boundary Proposition 19.26 (1) by the Unique Type of Chart Proposition 20.4. ■



Example.

(1) If $\partial M = \varnothing$ or $\partial N = \varnothing$, then the Smooth Manifold Product Proposition 20.6 is of course just a special case of the Smooth Manifold Product Proposition 19.31.

(2) Let $M = \overline{B}^2$ and $N = [0,1]$, then $M \times N = \overline{B}^2 \times [0,1]$ is the solid cylinder which is a 3-dimensional smooth manifold with corner such that

$$\begin{aligned} \text{boundary } \partial\big(\overline{B}^2 \times [0,1]\big) &= (S^1 \times [0,1]) \cup (\overline{B}^2 \times \{0,1\}) \\ \text{corner } \angle\big(\overline{B}^2 \times [0,1]\big) &= S^1 \times \{0,1\}. \end{aligned}$$

(3) Later, on page 811, given two smooth manifolds M and N and given smooth maps $f, g\colon M \to N$ we will introduce the notation of a smooth homotopy between f and g. This is just a smooth map $F\colon M \times [0,1] \to N$ with $F_0 = f$ and $F_1 = g$. At this point we will be very interested in products of the form $M \times [0,1]$.

We continue with the following lemma.

Lemma 20.7. Let $f\colon M \to \widetilde{M}$ and $g\colon N \to \widetilde{N}$ be smooth maps between smooth manifolds. The map

$$\begin{aligned} f \times g\colon M \times N &\to \widetilde{M} \times \widetilde{N} \\ (x,y) &\mapsto (f(x), g(y)) \end{aligned}$$

is a smooth map between smooth manifolds with corner.

Proof. The proof is formally similar to the proof of the Product Topology-Basics Lemma 5.4 (3). We encourage the reader to fill in the details. ■

By Proposition **??** we know that, upon the choice of a bicollar, we can usually dispose of corners. For products of smooth manifolds this leads to the following proposition.

Proposition ?? (Simplified). Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. The corner $\angle(M \times N)$ is two-sided and any choice of a "bicollar" gives rise to a smooth atlas on $M \times N$ which consists only of charts of type (i) and (ii).

If one keeps one's eyes open, smooth manifolds with corner occur naturally in many settings. Nonetheless, the theory of smooth manifolds with corner is an unloved (and some would say unlovable) topic which did not receive much treatment in the literature. We refer to

[**Lee2002**, Chapter 16] and [**Joy2012**] for more information on smooth manifolds with corner and the obvious generalization where one allows charts that take values in open subsets of $\mathbb{R}^k \times (\mathbb{R}_{\geq 0})^{n-k}$.

Exercises for Chapter 20.

Exercise 20.1. Let $n \in \mathbb{N}_{\geq 2}$. Let U be an open subset of $\mathbb{R}^n_{++}$ that contains a point of the corner $\angle \mathbb{R}^n_{++}$. Show that there is no diffeomorphism $f\colon U \to V$ from U to some open subset $V \subset \mathbb{H}^n$ such that $f(\partial \mathbb{R}^n_{++} \cap U) \subset \partial \mathbb{H}^n$.

Exercise 20.2. Let $n \geq 2$. Show that the upper half-ball

$$\overline{B}^n_{\geq 0} \;=\; \{(x_1, \ldots, x_n) \in \overline{B}^n \,|\, x_n \geq 0\}$$

admits the structure of a smooth manifold with corner such that

$$\angle \overline{B}^n_{\geq 0} \;=\; \{(x_1, \ldots, x_{n-1}, 0) \in \overline{B}^n \,|\, (x_1, \ldots, x_{n-1}) \in S^{n-2}\} \;=\; S^{n-2} \times \{0\}.$$

Exercise 20.3. Let M be an n-dimensional smooth manifold with corner and let $x \in M$. Show that x cannot admit both a chart of type (ii) and a chart of type (c).

Exercise 20.4. Give an example of a smooth manifold M with corner such that the corner $\angle M$ is not two-sided.

21. Partitions of unity on manifolds

In this short chapter we show in particular that (smooth) manifolds admit (smooth) partitions of unity and that they admit (smooth) exhaustion functions. For topological manifolds these results also follow from earlier results, like the Paracompact-Partition of Unity Theorem 10.9 which builds on Urysohn's Lemma 8.4. But for smooth manifolds the results of this chapter are new and for topological manifolds the arguments from this chapter are more elementary than the earlier ones.

The existence of (smooth) partitions of unity will be a key technical tool for constructing interesting (smooth) functions on (smooth) manifolds. In particular they will allow us to prove the Smooth Extension Proposition 21.9 and the Smooth Approximation Proposition 21.10.

21.1. Existence on partitions of unity on manifolds.

First we recall the following definitions from page 360.

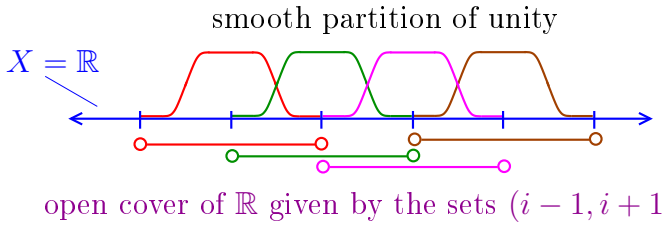
Definition. Let X be a topological space.

(1) The support of a function $f\colon X \to \mathbb{R}$ is defined as

$$\operatorname{supp}(f) \;:=\; \overline{\{x \in X \mid f(x) \neq 0\}}.$$

(2) A partition of unity on X is a family of maps $\{f_i\colon X \to [0,1]\}_{i\in I}$ with the following properties:

(a) For each $x \in X$ there exists an open neighborhood U of x such that f_i vanishes on U for all but finitely many i.[230]



(b) For every $x \in X$ we have $\sum_{i\in I} f_i(x) = 1$.

The following theorem guarantees the existence of many interesting (smooth) partitions of unity.

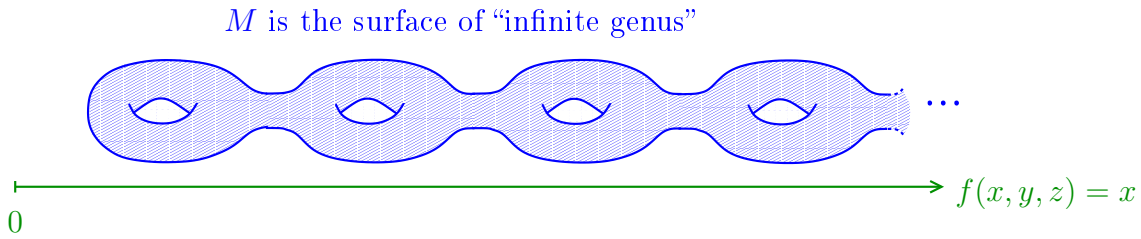
Theorem 21.1. (Manifold-Partitions of Unity Existence Theorem) Let X be a topological manifold.

(1) Given any open cover $\{U_i\}_{i\in I}$ there exists a partition of unity $\{f_i\}_{i\in I}$ such that for each $i \in I$ we have $\operatorname{supp}(f_i) \subset U_i$.

(2) If X is in fact a smooth manifold, then we can arrange that the maps f_i are smooth.

Remark.

[230] It follows from the elementary Closure-of-Locally Finite Cover Lemma 10.6 that Condition (1) is satisfied if and only if the supports $\{\operatorname{supp}(f_i)\}_{i\in I}$ form a locally finite family of subsets of X. In other words, Condition (1) is satisfied if and only if given any $x \in X$ there exists an open neighborhood U of x such that $U \cap \operatorname{supp}(f_i) = \varnothing$ for all but finitely many i.



(1) the Manifold-Partitions of Unity Existence Theorem 21.1 is a great tool for constructing (smooth) maps *out* of a topological or smooth manifold. For constructing maps *into* a smooth manifold a particularly useful tool is given by the Neighborhood Projection Theorem 28.1.
(2) In the Topological Manifolds-Local Properties Lemma 18.8 we saw that topological manifolds are regionally compact. Since topological manifolds are by definition Hausdorff and second-countable we deduce from the Paracompact-Criterion Lemma 10.2 that topological manifolds are paracompact. In the Paracompact-Partition of Unity Theorem 10.9 we used Urysohn's Lemma 8.4 to show that any paracompact space satisfies the conclusion of the Manifold-Partitions of Unity Existence Theorem 21.1 (1). Or, to cut a long story short, the above earlier results already provide a proof of the Manifold-Partitions of Unity Existence Theorem 21.1. In this chapter we give a different proof, that does not make use of Urysohn's Lemma 8.4, and that has the distinct advantage that it also provides a proof of the Manifold-Partitions of Unity Existence Theorem 21.1 (2).
(3) The combination of the Manifold-Partitions of Unity Existence Theorem 21.1 and the Paracompact-Partition of Unity Theorem 10.9 shows that topological manifolds are paracompact. This provides a new proof of the Manifold Paracompact-Normal Proposition 18.9 (1).

We postpone the proof of the Manifold-Partitions of Unity Existence Theorem 21.1 to the next section. In the following we provide a typical application of the existence of partitions of unity. To do so we recall the following definition from page 358.

Definition. Let X be a topological space. An exhaustion function is a map $f\colon X \to \mathbb{R}_{\geq 0}$ such that for every $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of X.[231]

Examples.

(1) Let $M = [0,1)$ be the half-open interval, viewed as a 1-dimensional smooth manifold. In this case the function defined by $f(x) = \frac{1}{1-x}$ is a smooth exhaustion function.
(2) We consider the surface of infinite genus illustrated in the figure below. In this case the function $f(x,y,z) = x$ is a smooth exhaustion function.

Lemma 21.2. (Manifold Exhaustion Lemma)
(1) Every topological manifold admits an exhaustion function.

[231] One can easily show that a map $X \to \mathbb{R}_{\geq 0}$ is an exhaustion function if and only if it is proper in the sense of the definition on page 180.

(2) Every smooth manifold admits a smooth exhaustion function.

Remark.

(1) In the Exhaustion Function Lemma 10.7 we used Urysohn's Lemma 8.4 to show that every topological space that is regionally compact, second-countable and Hausdorff admits an exhaustion function. Thus, as in the previous remark, we see that we already gave a proof of the Manifold Exhaustion Lemma 21.2 (1). The interest of the present proof is that it does not make use of Urysohn's Lemma 8.4 and that it gives a stronger conclusion for smooth manifolds.

(2) The Manifold Exhaustion Lemma 21.2 can be viewed as a refinement of the Topological Manifold Exhaustion Lemma 18.12.

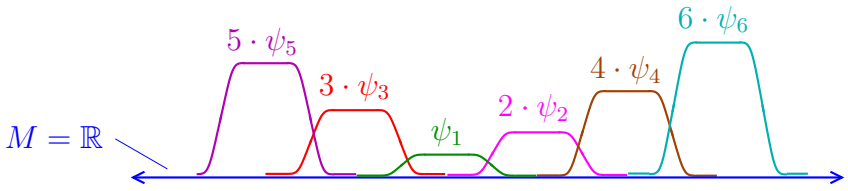
Proof. In the following we provide the proof for smooth manifolds. The proof for topological manifolds is almost verbatim the same.[232] Thus let M be a smooth manifold. By the Topological Manifolds-Local Properties Lemma 18.8 (5) we know that M is locally precompact, i.e. given any $x \in M$ there exists a neighborhood U of x such that the closure of U in M is compact. It follows from the observation that M is by definition second-countable, together with the Countable Covering Lemma 9.2, that there exists a countable cover $\{U_k\}_{k\in\mathbb{N}}$ of M by precompact sets. Furthermore by the Manifold-Partitions of Unity Existence Theorem 21.1 we now know that there exists a smooth partition of unity $\{\psi_k\}_{k\in\mathbb{N}}$ such that for each $k \in \mathbb{N}$ we have $\operatorname{supp}(\psi_k) \subset U_k$. We define

$$\begin{aligned} f\colon M &\to \mathbb{R}_{\geq 0} \\ x &\mapsto \sum_{k\in\mathbb{N}} k \cdot \psi_k(x). \end{aligned}$$

By definition of a partition of unity we know that locally this is a finite sum of smooth functions. It follows from the Smooth Pasting Proposition 19.23 that f is smooth. It remains to prove the following claim.

Claim. For every $c \in \mathbb{R}$ the preimage $f^{-1}([0,c])$ is compact.

Proof. Let $c \in \mathbb{R}$. We pick $N \in \mathbb{N}$ with $N \geq c$. We start out with the following observation: Given any point $x \notin \overline{U}_1 \cup \cdots \cup \overline{U}_N$ we have



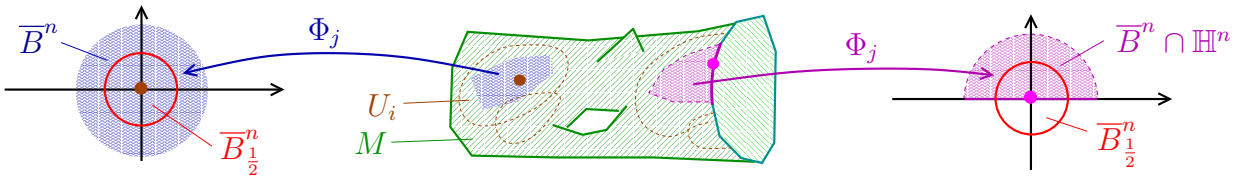
$$f(x) = \sum_{k=1}^{\infty} k \cdot \psi_k(x) \underset{\substack{\uparrow \\ \text{since } x \notin \overline{U}_1 \cup \cdots \cup \overline{U}_N \text{ and since } \operatorname{supp}\psi_k \subset U_k \subset \overline{U}_k}}{=} \sum_{k=N+1}^{\infty} k \cdot \psi_k(x) \geq \sum_{k=N+1}^{\infty} N \cdot \psi_k(x) \underset{\uparrow}{=} N \cdot \underbrace{\sum_{k=1}^{\infty} \psi_k(x)}_{=1} = N > c.$$

It follows from this observation that

$$f^{-1}([0,c]) = \underbrace{f^{-1}([0,c])}_{\text{closed}} \cap \big(\underbrace{\overline{U}_1 \cup \cdots \cup \overline{U}_N}_{\text{compact}}\big).$$

It follows from the Compact-Closed Lemma 1.21, see also Exercise 1.22, that $f^{-1}([0,c])$ is indeed compact. ∎

[232] Also, as we just mentioned in the remark above, the statement for topological manifolds is a special case of the Exhaustion Function Lemma 10.7. In fact our proof for smooth manifolds is almost identical to the proof of the Exhaustion Function Lemma 10.7, the biggest difference is that we need to replace the Paracompact-Criterion Lemma 10.2 and the Paracompact-Partition of Unity Theorem 10.9 by the Manifold-Partitions of Unity Existence Theorem 21.1.



21.2. **Proof of the Manifold-Partitions of Unity Existence Theorem 21.1.** In this section we now provide the long overdue proof of the Manifold-Partitions of Unity Existence Theorem 21.1. The key ingredient is the following proposition which sounds technical, but which is interesting in its own right.

Proposition 21.3. (Atlas Improvement Proposition) Given an n-dimensional topological manifold M and given an open cover $\{U_i\}_{i\in I}$ there exists an atlas $\{\Phi_j \colon V_j \to W_j\}_{j\in J}$ with the following properties:

(1) The index set J is countable. If M is compact, then J can be chosen to be finite.
(2) The open cover $\{V_j\}_{j\in J}$ is a refinement of the open cover $\{U_i\}_{i\in I}$. In other words, given any $j \in J$ there exists an $i \in I$ with $V_j \subset U_i$.
(3) Each W_j is either the open n-ball B^n or the open half-ball $B^n \cap \mathbb{H}^n$.
(4) The open cover $\{V_j\}_{j\in J}$ is locally finite, i.e. given any point $x \in M$ there exists an open neighborhood X of x which has the property that $X \cap V_j = \varnothing$ for all but finitely many $j \in J$.
(5) We have $M = \bigcup\limits_{j\in J} \Phi_j^{-1}(W_j \cap \overline{B}^n_{\frac{1}{2}})$.

If M is in fact a smooth manifold, then we can also arrange that the following extra condition is satisfied:

(6) The charts are smooth, i.e. they lie in the maximal atlas of M.

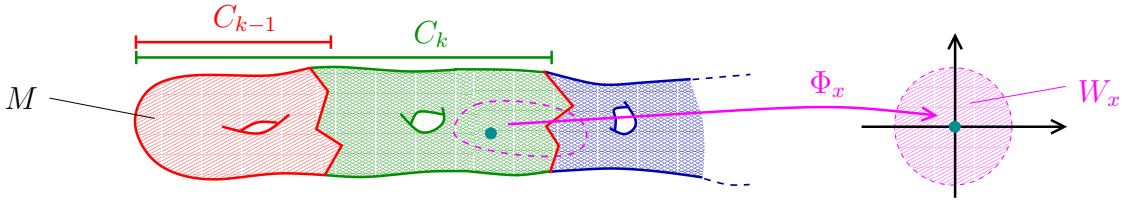
Remark.

(1) the Atlas Improvement Proposition 21.3 implies in particular that every topological manifold is paracompact. This provides a new proof of Manifold Paracompact-Normal Proposition 18.9 (1).
(2) the Atlas Improvement Proposition 21.3 implies in particular that every topological manifold admits a locally finite cover by compact subsets.
(3) In the Atlas Improvement Proposition 21.3 we showed in particular that an n-dimensional topological manifold M admits a locally finite atlas. In the Covering Dimension-of-Manifolds Proposition 27.7 we will see that the covering dimension of M is $\leq n$. In the Small Atlas Proposition 27.8 we will use this fact to refine some of the conclusions of the Atlas Improvement Proposition 21.3.

Now it is time to provide the proof of the Atlas Improvement Proposition 21.3.

Proof. To simplify the discussion we only treat the case that M is a topological manifold with empty boundary. The proof of all other cases can is basically the same and is left to the reader.

Thus let M be an n-dimensional topological manifold with empty boundary and let $\{U_i\}_{i\in I}$ be an open cover of M. By the Topological Manifold Exhaustion Lemma 18.12 there exists a family of compact subsets $\{C_k\}_{k\in\mathbb{N}}$ of M such that the following two conditions are satisfied:



(1) we have $M = \bigcup_{k\in\mathbb{N}} C_k$,

(2) for every $k \in \mathbb{N}$ we have $C_k \subset \mathring{C}_{k+1}$.

Note that it follows from the Compact-Closed Lemma 1.21 (2) that each $\mathring{C}_{k+1} \setminus C_{k-1}$ is an open subset of M. Furthermore, by design these open subsets cover all of M. Using this observation it is elementary to see that given any $x \in M$ there exists a chart $\Phi_x \colon V_x \to W_x$ with the following properties:

- V_x is an open neighborhood of x which is contained in some U_i,
- there exists a $k \in \mathbb{N}$ with $V_x \subset \mathring{C}_{k+1} \setminus C_{k-1}$,
- W_x is the open n-ball B^n of radius 1.

For each $x \in M$ we set $\widetilde{U}_x := \Phi_x^{-1}(B^n_{\frac{1}{2}})$. Evidently the $\widetilde{U}_x$ are open sets which cover all of M. It follows from the Compact Subspace Covering Lemma 1.19 that for each $k \in \mathbb{N}$ there exists a finite set $J_k \subset M$ such that $C_k \subset \bigcup_{x\in J_k} \widetilde{U}_x$. We set $J := \bigcup_{k\in\mathbb{N}} J_k$. We now claim that the atlas $\{\Phi_j \colon V_j \to W_j\}_{j\in J}$ has all the desired properties. In fact all statements basically hold by construction. Perhaps Property (4) is the least obvious one, so we provide the argument. Thus let $x \in M$. There exists a $k \in \mathbb{N}$ such that $x \in \mathring{C}_{k+1} \setminus C_{k-1}$. We set $X := \mathring{C}_{k+1} \setminus C_{k-1}$. By construction we have $X \cap V_j = \varnothing$ unless $j \in J_k \cup J_{k-1}$. ■

At this point it is convenient to recall the following definition from page 360.

Definition. Let $\{U_i\}_{i\in I}$ be an open cover of a topological space X. A partition of unity subordinate to the open cover is a partition of unity $\{f_j \colon X \to [0,1]\}_{j\in J}$ such that for each $j \in J$ there exists an $i \in I$ with $\operatorname{supp}(f_j) \subset U_i$.

With this definition we can now formulate the following lemma.

Lemma 21.4. Let X be a topological space (smooth manifold) and let $\{U_i\}_{i\in I}$ be an open cover of X. Suppose that there exists a (smooth) partition of unity $\{\varphi_j \colon X \to [0,1]\}_{j\in J}$ subordinate to the given open cover, then there exists in fact a (smooth) partition of unity $\{\psi_i \colon X \to [0,1]\}_{i\in I}$ such that for every $i \in I$ we have $\operatorname{supp}(\psi_i) \subset U_i$.

Remark. For topological spaces the statement of Lemma 21.4 is precisely the (2)⇒(3)-direction of the Paracompact-Partition of Unity Theorem 10.9. But even for topological spaces our proof of Lemma 21.4 is of interest, since it is a direct proof, whereas in the Paracompact-Partition of Unity Theorem 10.9 we took an indirect approach via Urysohn's Lemma 8.4.

Proof. Let $\{\varphi_j\colon X \to [0,1]\}_{j\in J}$ be a (smooth) partition of unity subordinate to the given open cover $\{U_i\}_{i\in I}$ of the topological space X (smooth manifold X). For each $j \in J$ there exists therefore an $i(j) \in I$ with $\operatorname{supp}(\varphi_j) \subset U_{i(j)}$. Given $i \in I$ we set

$$\begin{array}{rcl} \psi_i\colon X & \to & [0,1] \\ x & \mapsto & \displaystyle\sum_{j\in J \text{ with } i(j)=i} \varphi_j(x). \end{array}$$

Note that ψ_i is locally a finite sum of (smooth) maps, hence the map ψ_i is locally continuous (locally smooth), which implies by the Pasting Proposition 2.6 (respectively the Smooth Pasting Proposition 19.23) that ψ_i is continuous (respectively smooth). Evidently the maps ψ_i add up to 1. Thus it remains to prove the following claim.

Claim. For each $i \in I$ we have $\operatorname{supp}(\psi_i) \subset U_i$.

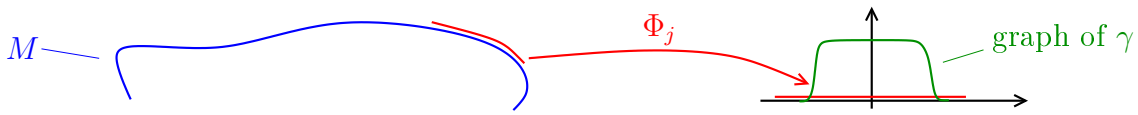
Proof. Let $i \in I$. The claim follows from the following slightly delicate steps:

(1) By the definition of a partition of unity, see page 360, we know that the family $\{\varphi_j^{-1}((0,1])\}_{j\in J}$ is locally finite.
(2) It follows easily from (1) and the Closure-of-Locally Finite Cover Lemma 10.6, that the family $\{\operatorname{supp}(\varphi_j)\}_{j\in J}$ is also locally finite.
(3) It follows from (2) and Lemma 1.11 (3b) that $\displaystyle\bigcup_{j\in J \text{ with } i(j)=i} \operatorname{supp}(\varphi_j)$ is a closed subset of X.
(4) By definition of ψ_i we know that $\psi_i^{-1}((0,1])$ is contained in $\displaystyle\bigcup_{j\in J \text{ with } i(j)=i} \operatorname{supp}(\varphi_j)$.

Now we obtain the following inclusions:

$$\operatorname{supp}(\psi_i) \;=\; \overline{\psi_i^{-1}((0,1])} \;\subset\; \bigcup_{j\in J \text{ with } i(j)=i} \underbrace{\operatorname{supp}(\varphi_j)}_{\subset U_{i(j)}=U_i} \;\subset\; U_i.$$

$\uparrow$ follows from (3) and (4)



■

Now we can finally provide the proof of the Manifold-Partitions of Unity Existence Theorem 21.1.

Proof of the Manifold-Partitions of Unity Existence Theorem 21.1. Let M be a topological or a smooth manifold with a given open cover $\{U_i\}_{i\in I}$ of M. We apply the Atlas Improvement Proposition 21.3 and we obtain a (smooth) atlas $\{\Phi_j\colon V_j \to W_j\}_{j\in J}$ with Properties (1)–(6). Note that according to the Smooth Transition Function Lemma 19.4 there exists a smooth function $\gamma\colon B^n \to [0,1]$ such that $\gamma(x) = 1$ whenever $\|x\| \leq \frac{1}{2}$ and such that $\gamma(x) = 0$ whenever $\|x\| > \frac{3}{4}$. For each $j \in J$ we consider the function

$$\begin{array}{rcl} g_j\colon M & \to & [0,1] \\ x & \mapsto & \begin{cases} \gamma(\Phi_j(x)), & \text{if } x \in V_j, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

We make the following observations:

(a) Let $j \in J$. Note that the restriction of g_j to the open sets V_j and $M \setminus \Phi_j^{-1}(\overline{B}^n_{\frac{3}{4}})$ is continuous, hence g_j is continuous by the Pasting Proposition 2.6 (2). Using Property (6) of the atlas and using the Smooth Pasting Proposition 19.23 (1) we also see that the g_j are smooth, if we start out with a smooth manifold.
(b) It follows from Property (4) of the atlas that given any $x \in M$ there exists an open neighborhood W of x such that $g_j(x) = 0$ for all but finitely many $j \in J$.
(c) It follows from Property (2) of the atlas that for each $j \in J$ there exists an $i \in I$ with $\operatorname{supp}(g_j) \subset U_i$.
(d) It follows from Property (5) of the atlas that for each $x \in M$ there exists a $j \in J$ with $g_j(x) \neq 0$.

It follows from (b) that it makes sense to consider the function $G\colon M \to \mathbb{R}_{\geq 0}$ that is given by $G(x) := \sum_{j \in J} g_j(x)$. By (d) we know that G is non-zero everywhere. Furthermore, in the setting of a smooth manifold this function is smooth. It is now clear that the functions $x \mapsto \varphi_j(x) := \frac{g_j(x)}{G(x)}$ are a (smooth) partition of unity subordinate to the given open cover.

It follows from this discussion together with Lemma 21.4 that there exists a (smooth) partition of unity $\{\psi_i\colon X \to [0,1]\}_{i \in I}$ such that for every $i \in I$ we have $\operatorname{supp}(\psi_i) \subset U_i$. ■

21.3. **Paracompactness and second-countability.** On page 511 we defined an n-dimensional topological manifold as a topological space that satisfies the following three conditions:

(a) X is Hausdorff,
(b) X is locally homeomorphic to an open subset of $\mathbb{R}^n$ or $\mathbb{H}^n$,
(c) X is second-countable.

We now consider also the following two properties of topological spaces:

(d) X is paracompact,
(e) X is the union of countably many compact subsets.

In some references, see e.g. [**Hu1969, Aub2001**] and [**PoR2021**], a topological manifold is defined as a topological space that satisfies (a), (b) and (d). Furthermore in [**Wall2016**] a topological manifold is defined as a topological space that satisfies (a), (b) and (e). Our goal in this section is to show that if a topological space already satisfies (a) and (b), and if X is connected, then (c) is equivalent to (d) and also to (e).

In fact in the Manifold Paracompact-Normal Proposition 18.9 (1) we just saw that every topological manifold is paracompact. Furthermore in in the Topological Manifold Exhaustion Lemma 18.12 we showed in particular that every topological manifold satisfies (e). The following two results show that a connected space that satisfies (a), (b) and (d) respectively (e), also satisfies (a), (b) and (c).

We will not really make use of these results, except that it allows us to quote results from other resources without inhibition and with complete easy of mind. First we have

the following proposition which can be viewed as a converse to the Manifold-Partitions of Unity Existence Theorem 21.1.

Proposition 21.5. Let $n \in \mathbb{N}$ and let X be a topological space that is Hausdorff, connected and that is locally homeomorphic to an open subset of $\mathbb{R}^n$ or to an open subset of $\mathbb{H}^n$. If X is paracompact, then it is also second-countable.

The proof of Proposition 21.5 rests on the following lemma, which can be viewed as the promised partial converse to the Topological Manifold Exhaustion Lemma 18.12.

Lemma 21.6. Let $n \in \mathbb{N}$ and let X be a topological space that is locally homeomorphic to an open subset of $\mathbb{R}^n$ or to an open subset of $\mathbb{H}^n$. If X can be written as a union of countably many compact subsets, then X is second-countable.

Proof of Lemma 21.6. Let $\{K_i\}_{i\in I}$ be a countable family of compact subsets of X that cover X.

Claim. Each K_i is contained in an open subset V_i that is second-countable.

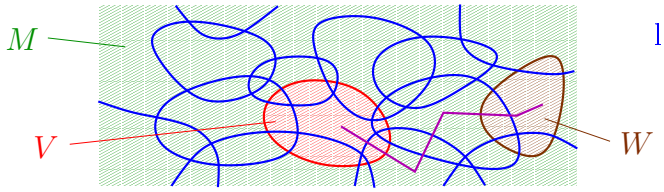
Proof. Let $i \in I$. Since K_i is compact and since X is locally homeomorphic to an open subset of $\mathbb{R}^n$ or to an open subset of $\mathbb{H}^n$ we see that K_i can be written as the union of finitely many sets $A_1, \ldots, A_n$ each of which is contained in an open subset U_i that is homeomorphic to a subset of $\mathbb{R}^n$ or $\mathbb{H}^n$. By the Second Countability Lemma 9.1 (1) and (2) we know that each U_i is second-countable and by the Second Countability Lemma 9.1 (4) we know that $V_i := U_1 \cup \cdots \cup U_n$ is second-countable. ⊞

It follows from the claim that X is the union of countably many second-countable open subsets. Thus we obtain from the Second Countability Lemma 9.1 (4) that X itself is second-countable. ■

Proof of Proposition 21.5. Let X be a topological space that is Hausdorff and connected and that is furthermore paracompact. To simplify the notation we only deal with the case that X is locally homeomorphic to an open subset of $\mathbb{R}^n$. The proof of the general case is almost identical. The goal is to show, using Lemma 21.6, that X is second-countable.

Claim 1. There exists a locally finite open cover $\mathcal{W}$ of X by subsets such that the closure of each $W \in \mathcal{W}$ is compact.

Proof. Note that by hypothesis for each $a \in X$ there exists an open neighborhood U_a and a homeomorphism $\Phi_a \colon U_a \to V_a$ where V_a is an open subset of $\mathbb{R}^n$. We pick an $r > 0$ such that $\overline{B}_r^n(\Phi_a(a)) \subset V_a$ and we set $W_a := \Phi_a^{-1}(B_r^n(a))$. These sets form an open cover of X. Note that it follows from our hypothesis that X is Hausdorff, from our choice of r, and from Lemma 18.11 that the closure of W_a is compact. Since X is paracompact there exists a locally finite refinement $\mathcal{W}$ of the open cover $\{W_a\}_{a\in X}$. This refinement has all the desired properties. ⊞



We pick a non-empty $V \in \mathcal{W}$.

Claim 2. Given any $W \in \mathcal{W}$ there exists a $k \in \mathbb{N}$ and sets $V = W_1, W_2, \ldots, W_k = W$ in $\mathcal{W}$ such that for each $i \in \{1, \ldots, k-1\}$ we have $W_i \cap W_{i+1} \neq \varnothing$.

Proof. We consider

$$U := \left\{ P \in M \,\middle|\, \begin{array}{c} \text{there exist sets } V = W_1, W_2, \ldots, W_k = W \text{ in } \mathcal{W} \text{ such} \\ \text{that each } W_i \cap W_{i+1} \neq \varnothing \text{ and such that } P \in W_k \end{array} \right\}.$$

Evidently $V \subset U$, thus U is non-empty. Since M is connected it remains to show that U is open and closed. First let $P \in U$. We pick a sequence $V = W_1, W_2, \ldots, W_k = W$ in $\mathcal{W}$ as in the definition of U. Evidently $P \in W_k \subset U$. This shows that U is open. Conversely, let $P \notin U$. We pick $W \in \mathcal{W}$ with $P \in W$. If $U \cap W$ was non-empty, it would follow basically immediately from the definition of U that we have $W \subset U$ and thus also $P \in U$, which is impossible. This shows that U is closed. ⊞

Given $W \in \mathcal{W}$ we define

$$\varphi(W) := \text{minimal } k \in \mathbb{N} \text{ such that there exists a sequence as in Claim 2}$$

and given $k \in \mathbb{N}$ we set

$$Z_k := \overline{\bigcup_{W \in \mathcal{W} \text{ with } \varphi(W) \leq k} W}.$$

Claim 3.
(1) For each $k \in \mathbb{N}$ there exists only finitely many $W \in \mathcal{W}$ with $\varphi(W) \leq k$.
(2) For each $k \in \mathbb{N}$ the set Z_k is compact.

Proof. First we make the following observation. If for some $k \in \mathbb{N}$ there exist only finitely many $W \in \mathcal{W}$ with $\varphi(W) \leq k$, then we obtain from Lemmas 1.20, 1.11 and 1.21 that Z_k is compact.

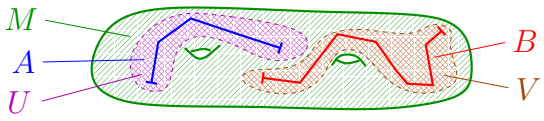
Thus it suffices to show Statement (1) of the claim. We prove this statement by induction. First let us deal with the case $k = 1$. Note that $\varphi(W) = 1$ if and only if $W = V$. Thus we see that $\varphi(1) = 1$. Now assume that the statement holds for some $k \in \mathbb{N}$.

Since $\mathcal{W}$ is locally finite there exists for each $z \in Z_k$ an open neighborhood U_z which has non-empty intersection with at most finitely many sets in $\mathcal{W}$. By our induction hypothesis and the above observation we know that Z_k is compact. Hence we can cover Z_k by finitely many of such U_z. But this implies that Z_k has non-empty intersection only with finitely many $W \in \mathcal{W}$. By definition we know that each $W \in \mathcal{W}$ with $\varphi(W) = k + 1$ satisfies $W \cap Z_k \neq \varnothing$. Thus we have shown that there are only finitely many $W \in \mathcal{W}$ with $\varphi(W) \leq k + 1$. ⊞

It follows from Claim 2 and Claim 3 that X is the union of countably many compact subsets. It follows from Lemma 21.6 that X is indeed second-countable. ■

21.4. **Smooth extensions and approximations.** In this section we will see that partitions of unity can be very helpful for constructing maps on manifolds. We start out with the following variation on Urysohn's Lemma 8.4 for topological and smooth manifolds.

Lemma 21.7. (Urysohn's Lemma for Manifolds) Let M be a smooth manifold and let A and B be two disjoint closed subsets of M.



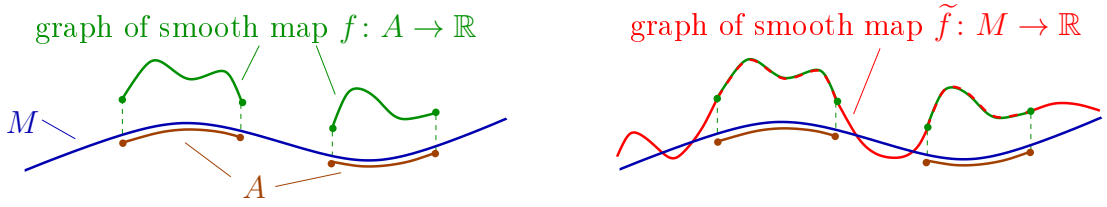
(1) There exists a map $f\colon M \to [0,1]$ with $f|_A \equiv 0$ and $f|_B \equiv 1$.
(2) If M is in fact a smooth manifold, then we can arrange in (1) that f is smooth.

Proof. Let M be a topological manifold. By the Manifold Paracompact-Normal Proposition 18.9 (2) we know that M is normal. Thus Statement (1) is an immediate consequence of Urysohn's Lemma 8.4.

Note that this approach to proving Statement (1) does not generalize to Statement (2). In the following we will therefore provide a different proof of Statement (1), which does not appeal to Urysohn's Lemma 8.4, and which generalizes to smooth manifolds.

Thus let M be a topological manifold and let A and B be two disjoint closed subsets of M. As we mentioned above, we know by the Manifold Paracompact-Normal Proposition 18.9 (2) that M is normal. By definition this means that there exist open neighborhoods U of A and V of B such that $U \cap V = \varnothing$.

Note that $M \backslash B, V$ is an open cover of M. By the Manifold-Partitions of Unity Existence Theorem 21.1 (1) there exists a corresponding partition of unity f, g with $\operatorname{supp}(f) \subset V$, $\operatorname{supp}(g) \subset M \setminus B$. It follows almost immediately from the various definitions that f has the desired properties.



Now assume that M is in fact a smooth manifold. We use the same argument as above. The only difference is that this time we use the Manifold-Partitions of Unity Existence Theorem 21.1 (2). ■

Proposition 21.8. (Continuous Extension Proposition) Let M be a topological manifold, let $A \subset M$ be a closed subset and let $f\colon A \to \mathbb{R}^n$ be a map. Given any open neighborhood U of A there exists a smooth map $\widetilde{f}\colon M \to \mathbb{R}^n$ such that $\widetilde{f}|_A = f$ and such that $\operatorname{supp}(\widetilde{f}) \subset U$.

Proof. The Continuous Extension Proposition 21.8 is an immediate consequence of the Manifold Paracompact-Normal Proposition 18.9 (2), Lemma 21.7 and the Tietze Extension Theorem 8.6. ■

In the remainder of this section we will use partitions of unity to construct useful smooth functions on smooth manifolds. First we have the smooth analogue of the Continuous Extension Proposition 21.8.

Proposition 21.9. (Smooth Extension Proposition) Let M be a smooth manifold, let $A \subset M$ be a closed subset and let $f\colon A \to \mathbb{R}^n$ be a smooth map. Given any open neighborhood U of A there exists a smooth map $\widetilde{f}\colon M \to \mathbb{R}^n$ such that $\widetilde{f}|_A = f$ and such that $\operatorname{supp}(\widetilde{f}) \subset U$.

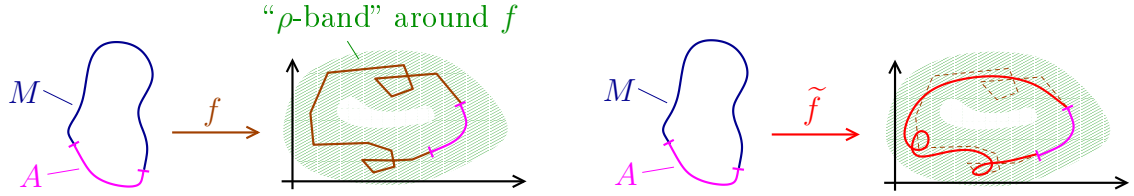
Proof. It follows almost immediately from the definition of a smooth map $f\colon A \to \mathbb{R}^n$ such that for each $P \in A$ there exists an open neighborhood $W_P \subset U$ and a smooth map $\widetilde{f}_P\colon W_P \to \mathbb{R}^n$ that agrees with f on $W_P \cap A$.

Since A is closed we see that the sets $\{W_P\}_{P\in A}$ and $M \setminus A$ form an *open* cover of M. By the Manifold-Partitions of Unity Existence Theorem 21.1 there exists a smooth partition of unity $\{\varphi_P\}_{P\in M}$ and ψ such that for each $P \in M$ we have $\operatorname{supp}(\varphi_P) \subset W_P$ and such that $\operatorname{supp}(\psi) \subset M \setminus A$. In particular we have $\psi|_A \equiv 0$.

Given $P \in M$ we set

$$\begin{array}{rcl} \Theta_P\colon M & \to & \mathbb{R}^n \\ x & \mapsto & \begin{cases} \varphi_P(x)\cdot \widetilde{f}(P), & \text{if } x \in W_P, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

It follows almost immediately from the Smooth Pasting Proposition 19.23 that Θ_P is smooth. We consider the map



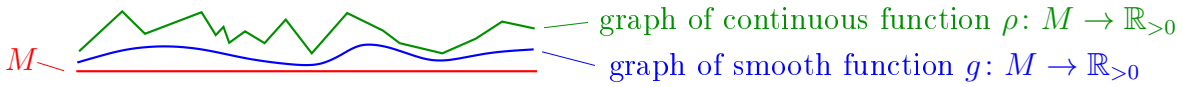
$$\begin{array}{rcl} \widetilde{f}\colon M & \to & \mathbb{R}^n \\ x & \mapsto & \displaystyle\sum_{P\in A} \Theta_P(x). \end{array}$$

It follows easily from $\psi|_A \equiv 0$ and the fact that we are dealing with a partition of unity that $\widetilde{f}$ agrees with f on A. Furthermore it follows easily from Lemma 1.11 that $\operatorname{supp}(\widetilde{f}) \subset U$. ■

Proposition 21.10. (Smooth Approximation Proposition) Let M be a smooth manifold and let $f\colon M \to \mathbb{R}^n$ be a map that is smooth on a (possibly empty) closed subset A. Given any map[233] $\rho\colon M \to \mathbb{R}_{\geq 0}$ with $\rho(x) > 0$ for all $x \notin A$ there exists a *smooth* map $\widetilde{f}\colon M \to \mathbb{R}^n$ with the following two properties:

(1) The maps f and $\widetilde{f}$ agree on A.

(2) For every $x \in M$ we have $\|f(x) - \widetilde{f}(x)\| \leq \rho(x)$.



[233] Evidently we demand, as always, that ρ is continuous.

Remark. In the Whitney Approximation Theorem 29.1 we will generalize the above proposition from the target $\mathbb{R}^n$ to any smooth manifold N.

Before we turn to the proof of the Smooth Approximation Proposition 21.10 let us formulate two useful corollary.

Corollary 21.11. (Replace-by-Smooth Non-Negative Function Corollary) Let M be a smooth manifold.

(1) For every map $\rho\colon M \to \mathbb{R}_{>0}$ there exists a smooth map $g\colon M \to \mathbb{R}_{>0}$ such that $g(x) \in (0, \rho(x)]$ for all $x \in M$.
(2) Let $f\colon M \to \mathbb{R}$ be a map (not necessarily continuous) with the property that for every $x \in M$ there exists an open neighborhood U_x of x and an $\epsilon_x > 0$ such that for each $y \in U_x$ we have $f(y) \geq \epsilon_x$. Then there exists a smooth map $g\colon M \to (0, \infty)$, such that for all $x \in M$ we have $g(x) \leq f(x)$.

Proof of the Replace-by-Smooth Non-Negative Function Corollary 21.11.

(1) This statement follows immediately from Smooth Approximation Proposition 21.10 applied to the zero function $f \equiv 0$, to $A = \varnothing$ and to the given map $\rho\colon M \to \mathbb{R}_{>0}$.
(2) In the Manifold Paracompact-Normal Proposition 18.9 (1) we saw that topological manifolds are paracompact. Thus Statement (2) follows immediately from Lemma 10.12 together with Statement (1). ■

Proof of the Smooth Approximation Proposition 21.10. By Proposition 21.9 there exists a smooth map $g\colon M \to \mathbb{R}^n$ that agrees with f on A. We consider the open[234] subset

$$V \;:=\; \{y \in M \,|\, |g(y) - f(y)| < \rho(y)\}.$$

Claim. There exists a countable set $I \subset M \setminus A$ together with an open neighborhood $U_P \subset M \setminus A$ for each $P \in I$ such that $\bigcup_{P \in I} U_P = M \setminus A$ and such that for every $y \in U_P$ we have

$$|f(y) - f(P)| \;<\; \rho(y).$$

Proof. Let $x \in M \setminus A$. Since $\rho(x) > 0$ we obtain from the continuity of ρ and f that there exists an open neighborhood U_x of x in the open set $M \setminus A$ such that for every $y \in U_x$ we have

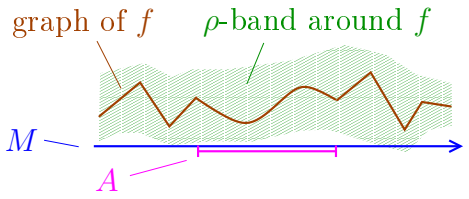
$$|\rho(y) - \rho(x)| \;\leq\; \tfrac{1}{2} \cdot \rho(x) \qquad \text{and} \qquad |f(y) - f(x)| \;<\; \tfrac{1}{2} \cdot \rho(x).$$

It follows from the triangle inequality that given any $y \in U_x$ we have $|f(y) - f(x)| < \rho(y)$. It follows from the Second Countability Lemma 9.1 (2) and the Countable Covering Lemma 9.2 that there exists a countable $I \subset M \setminus A$ such that $M \setminus A$ is covered by the U_P. ⊞

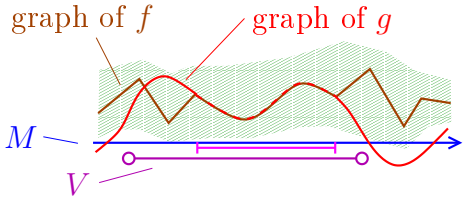
[234]Note that $|g(y) - f(y)| < \rho(y)$ if and only if $|g(y) - f(y)| - \rho(y) \in (-\infty, 0)$. Using this observation it is indeed clear that $V \subset M$ is open.

By the Manifold-Partitions of Unity Existence Theorem 21.1 there exists a smooth partition of unity $\{\varphi_P\}_{P\in I}, \psi$ such that for each $P \in I$ we have $\operatorname{supp}(\varphi_P) \subset U_P$ and such that $\operatorname{supp}(\psi) \subset V$. We consider the map

$$\begin{aligned} \widetilde{f}\colon M &\to \mathbb{R}^n \\ x &\mapsto \psi(x)\cdot g(x) + \sum_{P\in I} \varphi_P(x)\cdot f(P). \end{aligned}$$



Note that $\widetilde{f}$ is smooth and that $\widetilde{f}$ agrees with f on A. It remains to prove the following claim.



Claim. For every $x \in M$ we have $\|f(x) - \widetilde{f}(x)\| \le \rho(x)$.

Proof. Let $x \in M$. We perform the following calculation:

$$\begin{aligned} \|f(x) - \widetilde{f}(x)\| &\overset{\text{since } \psi+\sum\varphi_P\equiv 1}{=} \left\| \left(\psi(x) + \sum_{P\in I}\varphi_P(x)\right)\cdot f(x) - \left(\psi(x)\cdot g(x) + \sum_{P\in I}\varphi_P(x)\cdot f(P)\right)\right\| \\ &\le \psi(x)\cdot \underbrace{|f(x)-g(x)|}_{\le \rho(x) \text{ if } \psi(x)\neq 0} + \sum_{P\in I}\varphi_P(x)\cdot \underbrace{|f(x)-f(P)|}_{\le \rho(x) \text{ if } \varphi_P(x)\neq 0} \\ &\le \psi(x)\cdot\rho(x) + \sum_{P\in I}\varphi_P(x)\cdot\rho(x) \overset{\text{since } \psi+\sum\varphi_P\equiv 1}{=} \rho(x). \end{aligned}$$

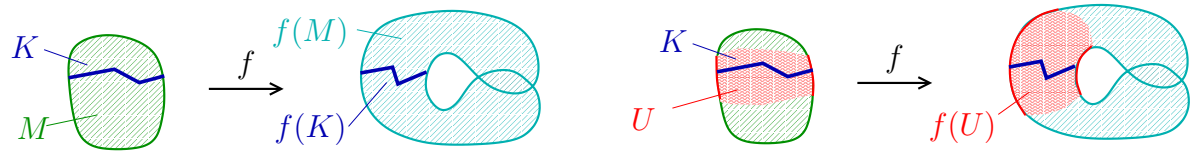
■

Let M be a smooth manifold. For any function $f\colon M \to \mathbb{R}_{\ge 0}$ the preimage $f^{-1}(0)$ is of course a closed set. Rather surprisingly the following proposition shows that every closed subset of M can be realized as the zero set of a smooth function.

Proposition 21.12. (Zero Set-Realization Proposition) Let M be a smooth manifold. Given any closed subset $C \subset M$ there exists a smooth function $f\colon M \to \mathbb{R}_{\ge 0}$ such that $C = f^{-1}(0)$.

Proof. Let M be a smooth manifold and let $C \subset M$ be a closed subset. Recall that by the Manifold Metrization Proposition 18.10 we know that M is metrizable, i.e. there exists a metric d such that the metric topology agrees with the given topology.

If C is the empty set, then we take f to be the constant function $= 1$. Now assume that C is non-empty. This allows us to consider the map



$$\begin{aligned} g\colon M &\to \mathbb{R}_{\ge 0} \\ x &\mapsto d(x,C) := \inf\{d(x,c) \mid b \in C\}. \end{aligned}$$

By the Distance-to-Subspace Lemma 6.2 we know that the map is continuous and, using that C is a closed subset, we know that $g(x) = 0$ if and only if $x \in C$.

Note that g is constant $= 0$ on C. In particular it is a smooth function on C. By the Smooth Approximation Proposition 21.10 we know that there exists a smooth map $f\colon M \to \mathbb{R}_{\geq 0}$ such that for any $x \in M$ we have $|f(x) - g(x)| \leq \frac{g(x)}{2}$. Clearly this map has the desired properties. ■

We conclude this chapter with the following useful theorem.

Theorem 21.13. (Neighborhood Smooth Embedding Theorem) Let $f\colon M \to N$ be a map between smooth manifolds. Furthermore let $K \subset M$ be a closed subset such that the map $f\colon K \to f(K)$ is a homeomorphism and such that $f(K)$ is a closed subset of N. If f is a local diffeomorphism at each $P \in K$, then there exists an open neighborhood U of K such that the restriction of f to U is a smooth embedding and such that $f(U)$ is an open subset of N.

Proof. By the Topological Manifolds-Local Properties Lemma 18.8 we know that M is regionally compact. Furthermore, by the Manifold Paracompact-Normal Proposition 18.9 (1) we know that N is paracompact. The proof of the Neighborhood Smooth Embedding Theorem 21.13 is now almost identical to the proof of the Neighborhood Embedding Theorem 10.13. All we have to do is to replace the Pasting Proposition 2.6 by the Smooth Pasting Proposition 19.23. ■

Exercises for Chapter 21.

Exercise 21.1. Provide an example of a connected space X that does not admit an exhaustion function $f\colon X \to \mathbb{R}_{\geq 0}$.

Exercise 21.2. Give an example of two topological manifolds M and N, a closed subset $A \subset M$ and a map $f\colon A \to N$ such that f cannot be extended to a map $\widetilde{f}\colon M \to N$.
Remark. This exercise shows that the Continuous Extension Proposition 21.8 cannot be extended from $N = \mathbb{R}^n$ to the completely general setting.

Exercise 21.3. Let $A \subset \mathbb{R}$ be a subset which is *not* closed.

(a) Show that there exists a smooth map $f\colon A \to \mathbb{R}$ which cannot be extended to a smooth map on all of $\mathbb{R}$.

(b) Show that there exists a continuous map $f\colon \mathbb{R} \to \mathbb{R}$ which is smooth on A but for which there does not exist a smooth map $\widetilde{f}\colon \mathbb{R} \to \mathbb{R}$ such that for all $x \in \mathbb{R}$ we have $|f(x) - \widetilde{f}(x)| \leq 1$.

Remark. This exercise shows that in the Smooth Extension Proposition 21.9 and the Smooth Approximation Proposition 21.10 the hypothesis that A is closed is absolutely essential.

22. 1-dimensional manifolds and the long line

This chapter can be seen as a short break from developing the general theory of smooth manifolds. In this chapter we will only consider "1-dimensional objects". More precisely, we will do the following:

(1) In the Classification Theorems 22.1 and 22.7 we will give the classification of connected 1-dimensional topological respectively smooth manifolds.
(2) We will construct the *long line*. As we will see in Theorem 22.13, this is a path-connected topological space that satisfies all properties of a 1-dimensional topological manifold, except that it is not second-countable.

We will at times use these classification Theorems 22.1 and 22.7. But the proofs are somewhat technical and do not make for particularly leisurely reading. Thus the reader might be best served by having a quick glance at the, not very surprising, classification theorems and by moving on to the next chapter.

22.1. The classification of 1-dimensional topological manifolds.

One of the goals of topology is to completely classify suitable classes of topological spaces up to homeomorphism. For example one could try to classify all connected topological and smooth manifolds of a given dimension. In this section we give a complete classification in the 1-dimensional setting.

In the following we first deal with 1-dimensional *topological* manifolds.

Example. Some of the main examples of 1-dimensional topological manifolds are S^1, $\mathbb{R}$, the closed interval $[0,1]$ and the half-open interval $[0,1)$.

(1) Note that for S^1 and $\mathbb{R}$ we found atlases consisting only of charts of type (i), i.e. the boundary of S^1 and of $\mathbb{R}$ is empty. On the other hand, as we pointed out on page 514, it follows easily from Lemma 7.11 together with the Topological Valence Determination Proposition 7.12 that the boundary of $[0,1]$ equals $\{0,1\}$ and that the boundary of $[0,1)$ equals $\{0\}$.
(2) By the Heine-Borel Theorem 1.24 we know that S^1 and $[0,1]$ are compact, whereas $\mathbb{R}$ and $[0,1)$ are non-compact.

This discussion shows in particular that S^1, $\mathbb{R}$, $[0,1]$ and $[0,1)$ are pairwise non-homeomorphic.

The following theorem shows that the above list of 1-dimensional topological manifolds is in a suitable sense complete.

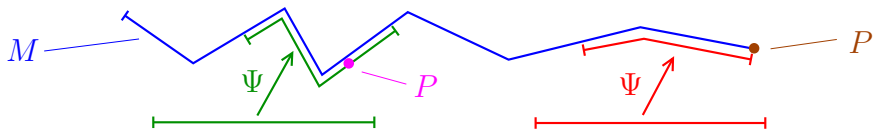
Theorem 22.1. (Topological 1-Dimensional Manifold Classification Theorem) Let M be a connected non-empty 1-dimensional topological manifold. Then the homeomorphism type of M is given by the following table

	without boundary	with non-empty boundary
compact	the circle S^1	the closed interval $[0,1]$
non-compact	the real line $\mathbb{R}$	the half-open interval $[0,1)$.

Remark. Note that the adjectives "Hausdorff" and "second-countable" in the definition of a topological manifold are both necessary:

(1) The line with two zeros, which we introduced on page 122, has all the properties of a 1-dimensional topological manifold except for the Hausdorff axiom.
(2) If one drops the condition that a topological manifold has to be second-countable, then there are two more examples of connected 1-dimensional topological manifolds, namely the "open long ray $\mathbb{L}^+$ and the "long line $\mathbb{L}$" which we will introduce on page 613.

Remark.



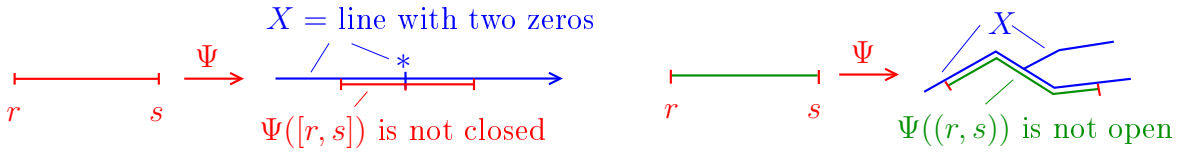
(1) Many proofs of the Topological 1-Dimensional Manifold Classification Theorem 22.1 exist in the literature, see e.g. [**Gal1987**], [**Lee2000**, Theorem 6.1] and [**FuR1984**, Sections 3.1.1.16-19].
(2) We will classify 2-dimensional topological manifolds in Theorem 55.4. On the other hand we will see in Theorem 60.4 that closed smooth manifolds of dimension ≥ 4 cannot be classified.

The proof of the Topological 1-Dimensional Manifold Classification Theorem 22.1 requires several preparations. We start out with the following definition.

Definition. Let M be a topological space.

(1) A c-parametrization for M is a homeomorphism $\Psi\colon [r,s] \to C$ from a compact interval $[r,s]$ with $r < s$ to a closed subset C of M such that $\Psi((r,s))$ is an open subset of M.
(2) A c-atlas is a family of c-parametrizations $\{\Psi_i\colon [r_i,s_i] \to C_i\}_{i\in I}$ of M such that the union of the C_i's equals M.

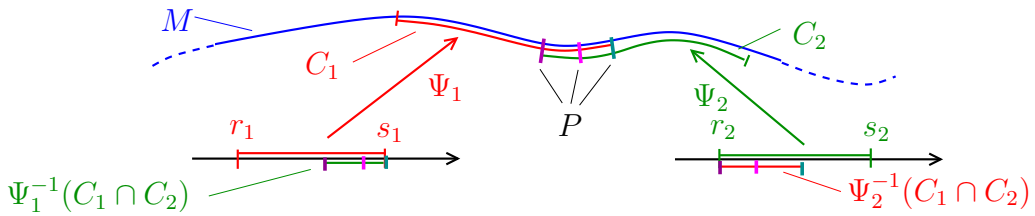
Lemma 22.2. Let M be a 1-dimensional topological manifold. Given any $P \in M$ and given any neighborhood W of P there exists a c-parametrization $\Psi\colon [r,s] \to C$ such that C is a neighborhood of P and such that $C \subset W$.



Proof. We distinguish the following cases.

- If $P \in M \setminus \partial M$, then we pick a chart $\Phi\colon U \to (-2,2)$ of type (i) with $\Phi(P) = 0$ and with $U \subset W$. We write $V = \Phi^{-1}((-1,1))$, $I = [-1,1]$ and $C = \Phi^{-1}([-1,1])$.
- If $P \in \partial M$, then we pick a chart $\Phi\colon U \to [0,2)$ of type (ii) with $\Phi(P) = 0$ and with $U \subset W$. We write $V = \Phi^{-1}([0,1))$, $I = [0,1]$ and $C = \Phi^{-1}([0,1])$.

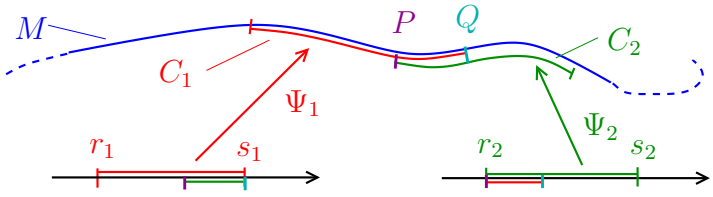
It follows from Lemma 18.11 that C is closed in M. (Note that here we use that topological manifolds are Hausdorff.) Also note that it follows from the Open -Closed Inclusion Lemma 2.10 that V is open in M and that V is a neighborhood of P. Thus the map $\Phi^{-1}\colon I \to C$ has all the desired properties. ∎



Example. In the figure below we also show two "non-examples" of c-parametrizations for wannabe 1-dimensional topological manifolds. In the situation to the left the image of the map $\Psi\colon [r,s] \to X$ is not closed whereas in the situation to the right $\Psi((r,s))$ is not an open subset of X.

In the following lemmas we study the "interaction" between two c-parametrizations whose images intersect.

Lemma 22.3. Let M be a topological space and let $\Psi_1\colon [r_1,s_1] \to C_1$ and $\Psi_2\colon [r_2,s_2] \to C_2$ be two c-parametrizations. Let $P \in C_1 \cap C_2$ and let $i \in \{1,2\}$. If $\Psi_i^{-1}(P)$ is not an endpoint of $[r_i,s_i]$, then one of the following happens:



(1) $P \in \Psi_i((r_i,s_i)) \cap \Psi_{3-i}((r_{3-i},s_{3-i}))$, or
(2) $\Psi_{3-i}^{-1}(P)$ is an endpoint of $[r_{3-i},s_{3-i}]$.

Proof. Let $P \in C_i \cap C_{3-i}$ with $\Psi_i^{-1}(P) \in (r_i,s_i)$. If $\Psi_{3-i}^{-1}(P)$ is an endpoint of $[r_{3-i},s_{3-i}]$, then we are done. Now suppose that $\Psi_{3-i}^{-1}(P)$ is not an endpoint of $[r_{3-i},s_{3-i}]$, i.e. we suppose that $\Psi_{3-i}^{-1}(P) \in (r_{3-i},s_{3-i})$. But this means that $P \in \Psi_i((r_i,s_i)) \cap \Psi_{3-i}((r_{3-i},s_{3-i}))$. ■

Lemma 22.4. Let M be a topological space and let $\Psi_1\colon [r_1,s_1] \to C_1$ and $\Psi_2\colon [r_2,s_2] \to C_2$ be two c-parametrizations.

(1) For every component X of $C_1 \cap C_2$ there exist points $P,Q \in X$ (where we allow $P=Q$) such that for $i=1,2$ the following two statements hold:
  (a) The preimage $\Psi_i^{-1}(X)$ is the closed interval with endpoints $\Psi_i^{-1}(P)$ and $\Psi_i^{-1}(Q)$.
  (b) If $\Psi_i^{-1}(P)$ is not an endpoint of $[r_i,s_i]$, then $\Psi_{3-i}^{-1}(P)$ is an endpoint of $[r_{3-i},s_{3-i}]$. The same statement also holds for Q.
(2) If X is a component of $C_1 \cap C_2$ such that $\Psi_i^{-1}(X)$ is contained in (r_i,s_i), then C_{3-i} is contained in C_i.
(3) $C_1 \cap C_2$ has at most two components.

Proof. Let X be a component of $C_1 \cap C_2$. By the Component Lemma 2.33 we know that X is connected. Furthermore, since C_1 and C_2 are closed in M we know that $C_1 \cap C_2$ is closed in M and by the Components-are-Closed Lemma 2.34 this implies that the component X is also a closed subset of M.

We consider $W_1 = \Psi_1^{-1}(X)$. By the above discussion we know that W_1 is a closed connected subset of the interval $[r_1, s_1]$. Since W_1 is a connected subset of the interval $[r_1, s_1]$ we obtain from Exercise 2.18 that W_1 is closed interval contained in $[r_1, s_1]$. In other words $W_1 = [a_1, b_1]$ for some $r_1 \leq a_1 \leq b_1 \leq s_1$.

Claim. The points $P := \Psi_1(a_1)$ and $Q := \Psi_1(b_1)$ have the desired properties stated in (1).

Proof. We write $a_2 = \Psi_2^{-1}(P)$ and $b_2 = \Psi_2^{-1}(Q)$ and we set $\Theta := \Psi_2^{-1} \circ \Psi_1$. Note that $\Theta(a_1) = a_2$ and $\Theta(b_1) = b_2$. It follows from an elementary argument, see Exercise 2.6, that Θ sends the interval $[a_1, b_1]$ homeomorphically to the interval with endpoints a_2 and b_2.

(1a) It follows from the above that (1a) is satisfied for $i = 1, 2$.

(1b) Suppose that $a_i = \Psi_i^{-1}(P)$ is not an endpoint of $[r_i, s_i]$. Since $a_i \notin (r_i, s_i)$ we see that $P = \Psi_i(a_i) \notin \Psi_i((r_i, s_i)) \cap \Psi_{3-i}((r_{3-i}, s_{3-i}))$. It follows from Lemma 22.3 that $a_{3-i} = \Psi_{3-i}^{-1}(P)$ is an endpoint of $[r_{3-i}, s_{3-i}]$. ⊞

It remains to prove the remaining two statements of the lemma.

(2) We continue with the above notation. If neither a_i nor b_i is an endpoint of $[r_i, s_i]$, then it follows from the above that a_{3-i} and b_{3-i} are both endpoints of $[r_{3-i}, s_{3-i}]$. But this means that the interval given by a_{3-i} and b_{3-i} equals $[r_{3-i}, s_{3-i}]$, which implies that $C_{3-i} \subset C_i$.

(3) By (1) we know that each component of $C_1 \cap C_2$ contains at least two endpoints of the intervals $[r_1, s_1]$ and $[r_2, s_2]$. Since there are only four endpoints we see that there is only enough room for at most two components. ■

Lemma 22.5. Let M be a 1-dimensional topological manifold.[235] Let $\Psi_1 \colon [r_1, s_1] \to C_1$ and $\Psi_2 \colon [r_2, s_2] \to C_2$ be two c-parametrizations. If $C_1 \cap C_2$ has one component, then there exist $\widetilde{r} \leq r_1 < s_1 \leq \widetilde{s}$ and a c-parametrization

$$\widetilde{\Psi} \colon [\widetilde{r}, \widetilde{s}] \ \to \ C_1 \cup C_2$$

such that $\widetilde{\Psi}|_{[r_1, s_1]} = \Psi_1$.

Proof of Lemma 22.5 if C_1 is not contained in C_2. First we deal with the case that C_1 is not contained in C_2. Since $C_1 \cap C_2$ consists of one component and since C_1 is not contained in C_2 we obtain from Lemma 22.4 that $\Psi_1^{-1}(C_1 \cap C_2)$ contains precisely one endpoint of $[r_1, s_1]$. We will now deal with the case that the endpoint is s_1. The other case is treated in essentially the same way.

Next note that Lemma 22.4 now says that there exists a $b \in [r_1, s_1]$ with the following properties:

(1) $\Psi_1^{-1}(C_1 \cap C_2) = [b, s_1]$,
(2) $\Psi_2^{-1}(\Psi_1(b))$ is an endpoint of $[r_2, s_2]$.

[235] Note that in contrast to the previous Lemma 22.4 we now actually assume that we are dealing with a 1-dimensional topological manifold.

Note that after possibly replacing $t \mapsto \Psi_2(t)$ by $t \mapsto \Psi_2(r_2 + s_2 - t)$ we can assume that $\Psi_2^{-1}(\Psi_1(b)) = r_2$. (Note that now we are conveniently enough in a setting which corresponds to the situation shown in the figure below.) Next note that Lemma 22.4 now also says that $\Psi_2^{-1}(\Psi_1([b, s_1])) = [r_2, c]$ for some $c \in [r_2, s_2]$.

We consider the map

$$\begin{array}{rcl} \widetilde{\Psi}\colon [r_1, s_1 + (s_2 - c)] & \to & C_1 \cup C_2 \\ x & \mapsto & \begin{cases} \Psi_1(x), & \text{if } x \in [r_1, s_1], \\ \Psi_2(x - s_1 + c), & \text{if } x \in [s_1, s_1 + (s_2 - c)]. \end{cases} \end{array}$$

By construction we have $\widetilde{\Psi}|_{[r_1,s_1]} = \Psi_1$. Thus it suffices to prove the following claim.

Claim. The map $\widetilde{\Psi}$ is a c-parametrization.

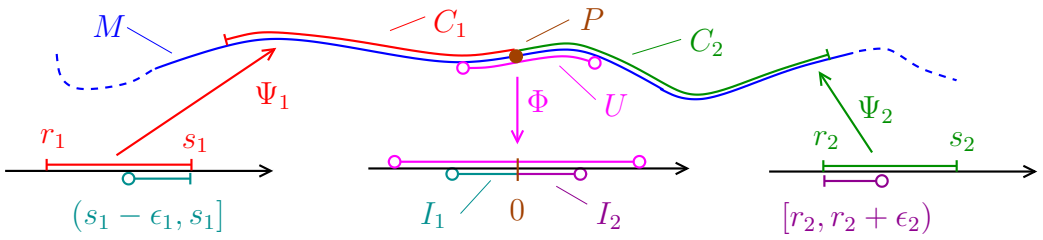
Proof. We set $\widetilde{r} = r_1$ and $\widetilde{s} = s_1 + (s_2 - c)$. It follows from the Pasting Proposition 2.6 that $\widetilde{\Psi}\colon [\widetilde{r}, \widetilde{s}] \to C_1 \cup C_2$ is continuous and one can easily verify that $\widetilde{\Psi}\colon [\widetilde{r}, \widetilde{s}] \to C_1 \cup C_2$ is a bijection. Since M is Hausdorff we obtain from the Compact-Hausdorff Proposition 2.17 (3) that $\widetilde{\Psi}\colon [\widetilde{r}, \widetilde{s}] \to C_1 \cup C_2$ is in fact a homeomorphism and that $C_1 \cup C_2$ is a closed subset of M.

It remains to prove that $\widetilde{\Psi}((\widetilde{r}, \widetilde{s}))$ is an open subset of M. We set $P := \Psi_1(s_1)$. Note that

$$\widetilde{\Psi}((\widetilde{r}, \widetilde{s})) \;=\; \underbrace{\Psi_1((r_1, s_1))}_{\substack{\text{open since } \Psi_1 \\ c\text{-parametrization}}} \;\cup\; \underbrace{\Psi_2((r_2, s_2))}_{\substack{\text{open since } \Psi_2 \\ c\text{-parametrization}}} \;\cup\; \{P\} \;\subset\; M.$$

If $P \in \Psi_2((r_2, s_2))$, then we are done. Therefore it remains to consider the slightly delicate case that $P \notin \Psi_2((r_2, s_2))$. Note that this means that $P = \Psi_2(r_2)$. In this case we still need to show that

$$\widetilde{\Psi}((\widetilde{r}, \widetilde{s})) \;=\; \Psi_1((r_1, s_1]) \cup \Psi_2([r_2, s_2))$$



is a neighborhood of P.

(i) First we assume that P admits a chart of type (i). This means that we can pick a chart $\Phi\colon U \to (-1, 1)$ of type (i) around P with $\Phi(P) = 0$.
- Since $\Psi_1^{-1}(U)$ is an open subset of $[r_1, s_1]$ that contains s_1 we see that there exists an $\epsilon_1 > 0$ such that $\Psi_1((s_1 - \epsilon_1, s_1]) \subset U$.
- Similarly we see that there exists an $\epsilon_2 > 0$ such that $\Psi_2([r_2, r_2 + \epsilon_2)) \subset U$.

Note that $I_1 = \Phi(\Psi_1((s_1 - \epsilon_1, s_1]))$ is a half-open interval in $(-1, 1)$ that contains 0 and that $I_2 = \Phi(\Psi_2([r_2, r_2 + \epsilon_2)))$ is a half-open interval in $(-1, 1)$ that contains 0. Furthermore note that $I_1 \cap I_2 = \{0\}$. It follows that $I_1 \cup I_2$ is an open neighborhood of 0. But that implies that $\Psi_1((s_1 - \epsilon_1, s_1]) \cup \Psi_2([r_2, r_2 + \epsilon_2))$ is a neighborhood of P. Note that this implies that $\widetilde{\Psi}((\widetilde{r}, \widetilde{s})) = \Psi_1((r_1, s_1]) \cup \Psi_2([r_2, s_2))$ is a neighborhood of P.

(ii) A slight modification of the above argument also shows that P actually cannot admit a chart of type (ii). ∎

Proof of Lemma 22.5. We now deal with the case that C_1 is contained in C_2. We split C_2 into two c-parametrizations C_2' and C_2'' such that C_1 is contained in neither C_2' nor C_2'' and apply the previous case twice. ∎

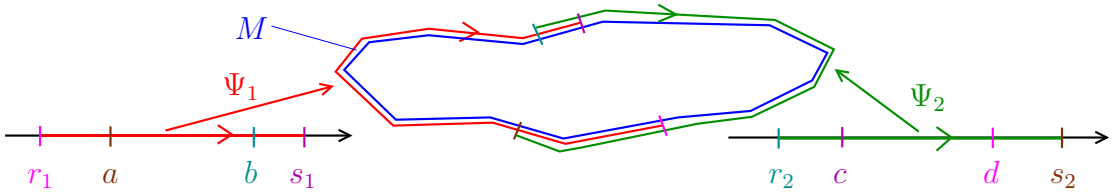
Lemma 22.6. Let M be a 1-dimensional topological manifold. Let $\Psi_1\colon [r_1, s_1] \to C_1$ and $\Psi_2\colon [r_2, s_2] \to C_2$ be two c-parametrizations. If $C_1 \cap C_2$ has two components, then there exists a homeomorphism

$$\Theta\colon S^1 \to C_1 \cup C_2$$

such that $\Theta(S^1) = C_1 \cup C_2$ is an open subset of M.

Proof. The proof is a variation on the proof of Lemma 22.5. Since $C_1 \cap C_2$ consists of two components we obtain from Lemma 22.4 that there exist $a, b \in \mathbb{R}$ with $r_1 \le a < b \le s_1$ such that the following hold:

(1) $\Psi_1^{-1}(C_1 \cap C_2) = [r_1, a] \cup [b, s_1]$,
(2) $\Psi_2^{-1}(\Psi_1(a))$ and $\Psi_2^{-1}(\Psi_1(b))$ are endpoints of $[r_2, s_2]$.



Note that after possibly replacing $t \mapsto \Psi_2(t)$ by $t \mapsto \Psi_2(r_2 + s_2 - t)$ we can assume that $\Psi_2(s_2) = \Psi_1(a)$ and $\Psi_2(r_2) = \Psi_1(b)$. Let $c \in [r_2, s_2]$ with $\Psi_2(c) = \Psi_1(s_1)$ and let $d \in [r_2, s_2]$ with $\Psi_2(d) = \Psi_1(r_1)$. Since C_2 is not contained in C_1 we see that $c < d$.

We consider the map

$$\begin{array}{rcl} \widetilde{\Psi}\colon [r_1, s_1 + (d-c)]/{\sim} & \to & C_1 \cup C_2 \\ & & \text{(we identify the two endpoints of the interval)} \\ [x] & \mapsto & \begin{cases} \Psi_1(x), & \text{if } x \in [r_1, s_1], \\ \Psi_2(x - s_1 + c), & \text{if } x \in [s_1, s_1 + (d-c)]. \end{cases} \end{array}$$

Note that $\widetilde{\Psi}$ is indeed well-defined.

As in the proof of Lemma 22.5 one can show fairly easily that $\widetilde{\Psi}$ is a homeomorphism, that the image is closed and that $C_1 \cup C_2$ is an open subset of M. Finally the desired homeomorphism $\Theta\colon S^1 \to C_1 \cup C_2$ is given by the observation, which we proved on page 244, that $[r_1, s_1 + (d-c)]/{\sim}$ is homeomorphic to S^1. ■

Now we can provide the proof of the Topological 1-Dimensional Manifold Classification Theorem 22.1. We break the proof into two parts. First we deal with the compact case, afterwards we will deal with the non-compact case.

Proof of Theorem 22.1 in the compact case. Let M be a compact connected 1-dimensional topological manifold. We start out with the following claim.

Claim. There exists a finite c-atlas for M.

Proof. Recall that by Lemma 22.2 we know that for each $P \in M$ there exists a c-parametrization $\Psi_P \colon I_P \to C_P$ such that C_P is a neighborhood of P, i.e. such that there exists an open subset V_P of M with $P \in V_P \subset C_P$. In particular $\{V_P\}_{P \in M}$ is an open cover of M. Since M is compact we see that there exist $P_1, \ldots, P_k \in M$ such that the corresponding open subsets cover M. The corresponding c-parametrizations form a finite c-atlas for M. ⊞

Claim. Either M is homeomorphic to S^1 or M is homeomorphic to $[0,1]$.

Proof. We prove the claim by induction on the number of elements of a finite c-atlas. If we have a c-atlas consisting of a single c-parametrization, then evidently M is homeomorphic to $[0,1]$. Now assume that we have $k \geq 2$ and that the statement holds whenever we have a c-atlas with $< k$ c-parametrizations. Let $\{\Psi_i \colon I_i \to C_i\}_{i=1,\ldots,k}$ be a c-atlas for M. Note that C_1 and $C_2 \cup \cdots \cup C_k$ are both non-empty closed subsets of M. Since M is connected we see that there exists a $j \in \{2, \ldots, k\}$ with $C_2 \cap C_j \neq \varnothing$. If $C_2 \subset C_j$ or $C_j \subset C_2$, then we can throw out of one of the c-parametrizations and we are done by induction.

Thus suppose that this is not the case. By Lemma 22.4 (3) we know that $C_2 \cap C_j$ consists of either one component or of two components. We deal with these two cases separately:

(1) If $C_2 \cap C_j$ consists of one component, then we know by Lemma 22.5 that there exists a c-parametrization $\widetilde{\Psi}$ with image $C_2 \cup C_j$. Thus $\{\Psi_i\}_{i \neq 2,j}$ together with $\widetilde{\Psi}$ is a c-parametrization of M with $k-1$ charts. Thus we are done by induction.

(2) Finally suppose that $C_2 \cap C_j$ consists of two components. By Lemma 22.6 we know that there exists a homeomorphism $\Theta \colon S^1 \to C_2 \cup C_j$ such that the image is a subset of M that is closed and open. Since M is connected we see that $C_2 \cup C_j = M$. ■

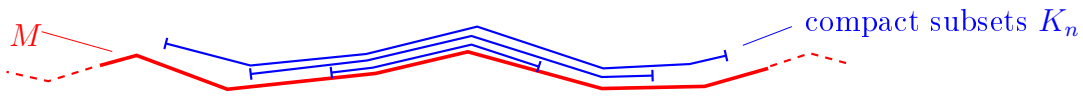
Now we turn to the classification of non-compact connected 1-dimensional topological manifolds.

Proof of Theorem 22.1 in the non-compact case. Let M be a non-compact connected 1-dimensional topological manifold. We start out with the following claim.

Claim. There exists a countable c-atlas $\{\Psi_i \colon [r_i, s_i] \to C_i\}_{i \in \mathbb{N}}$ and a family $\{V_i\}_{i \in \mathbb{N}}$ of open subsets of M with the following properties:

(1) The sets $\{C_i\}_{i \in \mathbb{N}}$ are a locally finite cover of M.[236]

(2) For each $i \in \mathbb{N}$ we have $V_i \subset C_i$ and the sets $\{V_i\}_{i \in \mathbb{N}}$ form an open cover of M.



Proof. By the Topological Manifold Exhaustion Lemma 18.12 there exists a family of compact subsets $\{K_n\}_{n \in \mathbb{N}}$ of M and a family of open subsets $\{W_{n+\frac{1}{2}}\}_{n \in \mathbb{N}}$ of M such that the following two conditions are satisfied:

(a) for every $n \in \mathbb{N}$ we have $K_n \subset \overset{\circ}{K}_{n+1}$,

(b) we have $M = \bigcup_{n \in \mathbb{N}} K_n$.

Note that it follows from the Compact-Closed Lemma 1.21 (2) that each $\overset{\circ}{K}_{n+1} \setminus K_{n-1}$ is an open subset of M. Furthermore, by design these open subsets cover all of M.

[236] Recall, that according to the definition on page 114 this means that each $x \in M$ admits an open neighborhood W such that $\{i \in \mathbb{N} \,|\, C_i \cap W \neq \varnothing\}$ is finite.

It follows from the previous observation together with Lemma 22.2 that for each $P \in M$ there exists a c-parametrization $\Psi_P \colon I_P \to C_P$ with the following properties:

(i) C_P is a neighborhood of P, i.e. this means that there exists an open subset V_P of M with $P \in V_P \subset C_P$,

(ii) there exists an $n \in \mathbb{N}$ with $V_P \subset \mathring{K}_{n+1} \setminus K_{n-1}$.

Let $n \in \mathbb{N}$. It follows from the compactness of K_n, the fact that the V_P are an open cover of M and the Compact Subspace Covering Lemma 1.19 that there exists a finite set $X_n \subset M$ such that $K_n \subset \bigcup_{P \in X_n} V_P$. We set $X := \bigcup_{n \in \mathbb{N}} X_n$. One can now easily verify that the c-atlas $\{\Phi_P^{-1} \colon I_P \to C_P\}_{P \in X}$ together with the sets $\{V_P\}_{P \in X}$ has all the desired properties. ⊞

We move on to the next claim.

Claim. Given any $k, l \in \mathbb{N}$ there exist $r_0, \dots, r_m \in \mathbb{N}$ with $k = r_0$ and $l = r_m$ such that for every $i \in \{0, \dots, m-1\}$ we have $C_{r_i} \cap C_{r_{i+1}} \neq \varnothing$.

Proof. Let $k \in \mathbb{N}$. Recall that by construction the V_i introduced in the first claim form an open cover of M. We set

$$L := \{l \in \mathbb{N} \,|\, \text{there exist } k = r_0, \dots, r_m = l \text{ with } V_{r_i} \cap V_{r_{i+1}} \neq \varnothing \text{ for } i = 0, \dots, m-1\}.$$

Note that $A := \bigcup_{l \in L} V_l$ and $B := \bigcup_{l \notin L} V_l$ are both open subsets of M with $A \cup B = M$. It follows easily from the definitions that $A \cap B = \varnothing$. Since $k \in L$ we know that A is non-empty. Since M is connected we see that $A = M$. It follows almost immediately from this observation that $L = \mathbb{N}$. ⊞

We define a map $\varphi \colon \mathbb{N} \to \mathbb{N}$ as follows. We set $\varphi(1) := 1$. By the above claim it makes sense to iteratively set

$$\varphi(n) := \min\big\{k \in \mathbb{N} \,\big|\, k \notin \{\varphi(1), \dots, \varphi(n-1)\} \text{ and } C_k \cap (C_{\varphi(1)} \cup \dots \cup C_{\varphi(n-1)}) \neq \varnothing\big\}.$$

Given $n \in \mathbb{N}$ we also set $D_n := C_{\varphi(1)} \cup \dots \cup C_{\varphi(n)}$. Note that it follows immediately from the claim that $\bigcup_{n \in \mathbb{N}} D_n = \bigcup_{n \in \mathbb{N}} C_{\varphi(n)} = M$.

Claim. There exists a monotonously decreasing sequence $\{a_n\}_{n \in \mathbb{N}}$ of real numbers, a monotonously increasing sequence $\{b_n\}_{n \in \mathbb{N}}$ of real numbers and a sequence of homeomorphisms $\Phi_n \colon D_n \to [a_n, b_n]$ such that for each $n \in \mathbb{N}$ we have $\Phi_n|_{D_{n-1}} = \Phi_{n-1}$.

Proof. We set $\Phi_1 = \Psi_1 \colon [r_1, s_1] \to C_1 = D_1$. We construct the sequences of real numbers and of homeomorphisms iteratively by applying Lemma 22.5. ⊞

Note that $I := \bigcup_{n \in \mathbb{N}} [a_n, b_n]$ is an interval in $\mathbb{R}$ and that the maps Φ_n define a bijection

$$\begin{aligned} \Phi \colon M &\to I \\ x &\mapsto \Phi_n(x) \quad \text{if } x \in D_n. \end{aligned}$$

By construction the restriction of Φ_n to each D_n is continuous. This implies also that the restriction of Φ_n to each C_n is continuous. Since the $\{C_n\}_{n \in \mathbb{N}}$ form a locally finite

cover of M of closed subsets we obtain from the Pasting Proposition 2.6 that Φ is actually continuous.

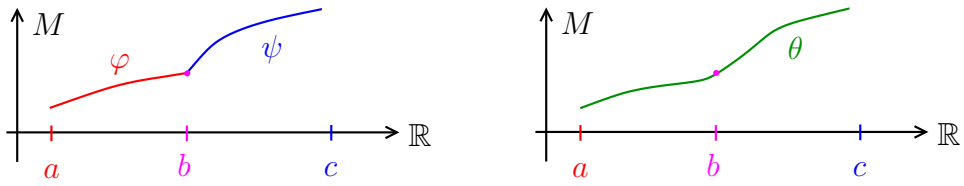
It remains to show that the inverse $\Phi^{-1}\colon I \to M$ is continuous. Since each D_n is compact we obtain from the Compact-Hausdorff Proposition 2.17 (3) that the restriction of Φ^{-1} to each $[a_n, b_n]$ is continuous. It follows from Exercise 2.14 that $\Phi^{-1}\colon I \to M$ is continuous.

Since every non-compact interval is homeomorphic to either $\mathbb{R}$ or $[0,1)$ we are finally done. ■

22.2. **The classification of 1-dimensional smooth manifolds.** If we consider smooth manifolds instead of topological manifolds and diffeomorphisms instead of homeomorphisms we get the same answer. More precisely the following proposition holds.

Theorem 22.7. (Smooth 1-Dimensional Manifold Classification Theorem) Let M be a connected non-empty 1-dimensional smooth manifold. Then the diffeomorphism type of M is given by the following table

	without boundary	with non-empty boundary
compact	the circle S^1	the closed interval $[0,1]$
non-compact	the real line $\mathbb{R}$	the half-open interval $[0,1)$.



Remark.

(1) Other references for this theorem are [**GP1974**, p. 212], [**Shas2011**, Theorem 5.4.1] and [**Miln1965a**, appendix].
(2) We will provide a different proof of the Smooth 1-Dimensional Manifold Classification Theorem 22.7 in Proposition 142.1 and Exercise 142.2.

The proof of the Smooth 1-Dimensional Manifold Classification Theorem 22.7 relies on the following lemma.

Lemma 22.8. Let M be a 1-dimensional smooth manifold and suppose we have two smooth maps $\varphi\colon [a,b] \to M$ and $\psi\colon [b,c] \to M$ which are diffeomorphisms onto their images and which satisfy $\varphi([a,b]) \cap \psi([b,c]) = \{\varphi(b)\} = \{\psi(b)\}$. Then there exists a smooth map $\theta\colon [a,c] \to M$ which is a diffeomorphism onto its image with the following properties:

(1) $\theta([a,b]) = \varphi([a,b])$, with $\theta([b,c]) = \psi([b,c])$, and
(2) there exists an $\epsilon > 0$ such that $\theta = \varphi$ on $[a, a+\epsilon]$ and $\theta = \psi$ on $[c-\epsilon, c]$.

Proof. If $a = b$ then we can take $\theta = \psi$ and if $b = c$, then we can take $\theta = \varphi$. So we only need to consider the case that $a < b < c$. By picking a chart from the smooth atlas around $\varphi(b) = \psi(b)$ we might as well assume that $M = \mathbb{R}$. After possibly applying the reflection $t \mapsto -t$ to $M = \mathbb{R}$ we can furthermore assume that φ and ψ are strictly monotonously increasing.

We consider the map
$$\begin{array}{rccl} \chi\colon [a,c] & \to & \mathbb{R} \\ x & \mapsto & x - b + \varphi(b). \end{array}$$
It remains to show that the following hold:

(1) There exists an $\eta_a > 0$ and a smooth map $\theta_a\colon [a,b] \to \mathbb{R}$ which agrees with φ on $[a, a+\eta_a]$ and which agrees with χ on $[b-\eta_a, b]$.
(2) There exists an $\eta_c > 0$ and a smooth map $\theta_c\colon [b,c] \to \mathbb{R}$ which agrees with χ on $[b, b+\eta_c]$ and which agrees with ψ on $[c-\eta_c, c]$.

The existence of both was proved in Exercise 19.26, which in turn relies on the Smooth Transition Function Lemma 19.4. ■

Proof of the Smooth 1-Dimensional Manifold Classification Theorem 22.7. Let M be a connected non-empty 1-dimensional smooth manifold. Evidently the idea is modify the proof of the Topological 1-Dimensional Manifold Classification Theorem 22.1. In the following we discuss the case that M is non-compact with empty boundary. All other cases are treated in a similar fashion.

In the proof of Lemma 22.2 we now use smooth charts to obtain smooth c-parametrizations for M. If we now go through the proof of the Topological 1-Dimensional Manifold Classification Theorem 22.1 we see that there exists a homeomorphism $f\colon \mathbb{R} \to M$ which is smooth outside of a (possibly infinite) discrete subset $D \subset \mathbb{R}$. By applying Lemma 22.8 to each $x \in D$ we can turn f into a diffeomorphism. ■

22.3. **Interlude: The order topology.** In the next section we will introduce the "long line", which is a topological space, that has all the properties of a connected 1-dimensional topological manifold, except that it is not second-countable. The construction of the "long line" makes use of the order topology which we will introduce in this section.

First we recall some definitions. At least this particular author invariably forgets the precise meanings of the different type of orders that exist.

Definition. A partial order on a set X is a relation $\leq$ that has the following properties:

(1) For every $x \in X$ we have $x \leq x$.
(2) Whenever $x \leq y$ and $y \leq x$, then we have $x = y$.
(3) Whenever $x \leq y$ and $y \leq z$, then we also have $x \leq z$.

A total order is a partial order that also satisfies the following condition:

(4) For every $x, y \in X$ we have $x \leq y$ or $y \leq x$.

Finally a well-order is a total order that satisfies the following condition:

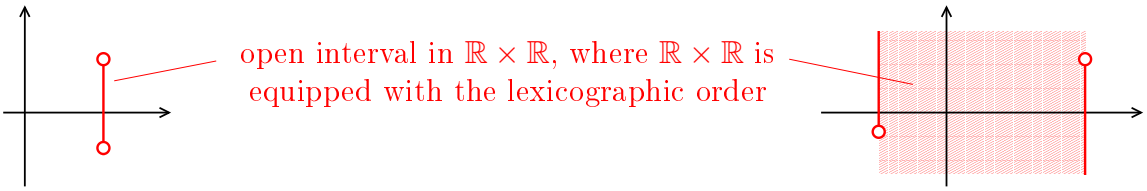
(5) Every non-empty subset has a minimal element.

Such a pair $(X, \leq)$ is called a partially ordered set, totally ordered set respectively well-ordered set.

Next we introduce some self-explanatory notation.

Notation. Let $(X, \leq)$ be a totally ordered set. As usual, given $x, y \in X$ we write $x < y$ if $x \leq y$ and $x \neq y$. Given $x, y \in X$ we write
$$\begin{array}{rclcrcl} (x,y) & := & \{a \in X \,|\, x < a < y\}, & & (x,y] & := & \{a \in X \,|\, x < a \leq y\} \\ [x,y) & := & \{a \in X \,|\, x \leq a < y\} & \text{and} & [x,y] & := & \{a \in X \,|\, x \leq a \leq y\}. \end{array}$$

We refer to these subsets in the obvious way as open intervals, half-open intervals and closed intervals.



Definition. Let $(X, \leq)$ be a totally ordered set on X. Let $\mathcal{B}$ be the subset of the power set $\mathcal{P}(X)$ given by the subsets of X of the following four types:

(1) All intervals (a, b) in X.
(2) If x_0 is a smallest element of $(X, \leq)$, then we also consider the intervals $[x_0, b)$.
(3) If x_1 is a largest element of $(X, \leq)$, then we also consider the intervals $(a, x_1]$.
(4) The total set X.

We leave it to the reader to verify that $\mathcal{B}$ has the basis property, as defined on page 132.[237] By the Topology-from-Basis Lemma 1.27 the basis $\mathcal{B}$ defines a topology on X. We refer to this topology as the order topology on X.

Examples.

(1) If we equip $X = \mathbb{R}$ with the usual total order $\leq$, then the resulting order topology equals, basically by definition, the usual topology on X.
(2) We equip $X = \mathbb{R} \times \mathbb{R}$ with the lexicographic order induced from the usual well-order on the two $\mathbb{R}$-factors. Now we equip X with the corresponding order topology. In the figure below we show some open intervals in $\mathbb{R} \times \mathbb{R}$. We will discuss this fun example in greater detail in Exercise 22.4.

(3) We equip $\mathbb{N}_0$ and the half-open interval $[0, 1)$ with the usual total orders and we equip $\mathbb{N}_0 \times [0, 1)$ with the lexicographic order. In Exercise 22.3 we will show that if we equip $\mathbb{N}_0 \times [0, 1)$ with the corresponding order topology, then $\mathbb{N}_0 \times [0, 1)$ is homeomorphic to $[0, \infty)$.

Convention. In this chapter, given a totally ordered set $(X, \leq)$ we equip X with the corresponding order topology. On numerous occasions we will use the obvious statement that if two totally ordered sets $(X_1, \leq_1)$ and $(X_2, \leq_2)$ are of the same order type, then the corresponding topological spaces are homeomorphic.

On several occasions we will use the following lemma, without explicitly referring to it.

Lemma 22.9. Let $(X, \leq)$ be a totally ordered set. Given any interval $I = (a, b)$, $[a, b)$, $(a, b]$ and $[a, b]$ in X the order topology on $(I, \leq)$ agrees with the subspace topology coming from X.

Proof. We will prove the lemma in Exercise 22.2. ∎

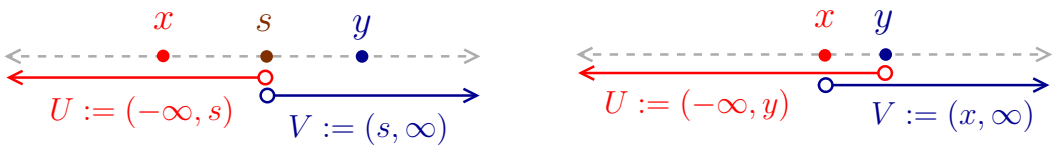
[237] At first glance it might look unnecessary to explicitly throw in X into the set $\mathcal{B}$. But if X should happen to consist of a single element, then the sets of type (1), (2) and (3) actually do not satisfy property B1.

Example. Later in this section the half-open interval $[0,1) \subset \mathbb{R}$, equipped with the usual total order $\leq$, will play an important role. It follows from Lemma 22.9 that the resulting order topology equals the usual topology on $X \subset \mathbb{R}$.

We conclude this section with the following fairly straightforward lemma.

Lemma 22.10. Let $(X, \leq)$ be a totally ordered set. The topological space X that is given by the order topology is Hausdorff.

Proof. Let $(X, \leq)$ be a totally ordered set. We start out with the following claim.



Claim. Given any $x \in X$ the sets

$$(-\infty, x) := \{a \in X \,|\, a < x\} \qquad \text{and} \qquad (x, \infty) := \{b \in X \,|\, x < b\}$$

are open subsets in the order topology.

Proof. If X has a minimal element x_0, then evidently we have $(-\infty, x) = [x_0, x)$. By definition this set is open. On the other hand, if X does not have a minimal element, then we have $(-\infty, x) = \bigcup_{a<x} (a, x)$ which is of course an open subset of X. Basically the same argument also shows that (x, ∞) is open. ⊞

Now let $x \neq y$ be two distinct points in X. Since $(X, \leq)$ is totally ordered we know that $x < y$ or $y < x$. Without loss of generality we can assume that $x < y$. If there exists an $s \in (x, y)$, then we set $U := (-\infty, s)$ and $V := (s, \infty)$. Otherwise we set $U := (-\infty, y)$ and $V := (x, \infty)$. By the claim U and V are open. It is now clear that these are disjoint open neighborhoods of x and y. ■

22.4. **The long line.** Let us start with the following dull definition.

Definition. Let $(X, \leq)$ be a partially ordered set. Given $x \in X$ we refer to

$$S_x := \{y \in X \,|\, y < x\}$$

as the x-section of $(X, \leq)$.

We consider the well-ordered set $(\mathbb{N}, \leq)$. Evidently the set is *countable*, but every section is actually *finite*. The following, quite remarkably, theorem says that the same type of mismatch between the cardinalities of all sections and the cardinality of the actual well-ordered set can also happen for other cardinalities.

Theorem 22.11.

(1) There exists an uncountable well-ordered set such that every section is countable.
(2) If X and Y are two well-ordered sets as in (1), then X and Y have the same order type.

We denote by ω_1 any well-ordered set as in (1).

Remark.

(1) The alert reader will have noticed that Statement (1) of Theorem 22.11 is precisely the content of Exercise 0.6.
(2) The order type of such a well-ordered set as in Theorem 22.11 is often called the *first uncountable ordinal*. We refer to [**Je2003**] and [**Dev1993**, Chapter 3] for an introduction into the concept of "ordinals".
(3) The construction of the well-ordered set ω_1 is a product of the ever-fertile mind of our friends the set-theorists. To the best of my knowledge there is no "down to earth" construction of ω_1.
(4) The set well-ordered set ω_1 is studied, in "everyday language", in [**Mun1975**, p. 67] and [**Gaul2014**, Chapter B.2].

Proof.

(1) By the Well-Ordering Theorem 0.7 there exists a well-order on any set. In particular there exists a well-order $\leq$ on the uncountable set $X = \mathbb{R}$. If every section of $(X, \leq)$ is countable, then we are done since $\mathbb{R}$ is uncountable. If not, then we consider the following non-empty subset

$$S := \{x \in X \mid \text{ the } x\text{-section is uncountable}\}.$$

Recall that by definition of a well-order we know that the non-empty subset S of X contains a minimal element z. Finally we consider the corresponding z-section $Y := S_z := \{x \in X \mid x < z\}$. Note that it follows from the construction of z that $Y = S_z$ is uncountable. Furthermore note that it follows immediately from the definition of z that every section of $Y = S_z$ is actually countable.
(2) We will not make use of this statement, thus we will not provide a proof. Instead we refer to [**Mun1975**, p. 73] or alternatively to [**Je2003**, Theorem I.2.12] for a proof. ■

Later on we will need the following simple lemma.

Lemma 22.12. The well-ordered set ω_1 does not have a maximal element.

Proof. Let $x \in \omega_1$. We need to show that x is not a maximal element. By one of the two defining properties of ω_1 we know that the section $S_x = \{y \in X \mid y < x\}$ is countable. It follows from the Countability Lemma 0.8 (4) that $\{y \in X \mid y \leq x\} = S_x \cup \{x\}$ is also countable. Since ω_1 is uncountable we see that x cannot be a maximal element. ■

Now we are finally ready to give the definition of the legendary long line.

Definition.

(1) We equip $[0, 1)$ with the usual well-order. Next we equip $\mathbb{L}_{\geq 0} := \omega_1 \times [0, 1)$ with the lexicographic order that we introduced on page 92 and we equip $\mathbb{L}_{\geq 0}$ with the corresponding order topology. We refer to this topological space $\mathbb{L}_{\geq 0}$ as the closed long ray.
(2) We denote by $* \in \omega_1$ the minimal element. We refer to $\mathbb{L}^+ := \mathbb{L}_{\geq 0} \backslash \{(*, 0)\}$, equipped with the subspace topology coming from $\mathbb{L}_{\geq 0}$, as the open long ray.

(3) We write $\mathbb{L}_{\leq 0} := \mathbb{L}_{\geq 0}$. We refer to the topological space $\mathbb{L} := \mathbb{L}_{\leq 0} \sqcup_{(*,0)=(*,0)} \mathbb{L}_{\geq 0}$ as the long line. (In the literature the long line is sometimes also called the Alexandroff line.)

Remark. In many references, see e.g. [**Mun1966a**, p. 158], [**SS1978**, p. 71] and [**Kra2009**, p. 66], the open long ray is called the long line.

The following proposition shows in particular that the open long ray $\mathbb{L}^+$ and the long line $\mathbb{L}$ both satisfy all properties of a 1-dimensional topological manifold, except that neither is second-countable.

Theorem 22.13. The open long ray $\mathbb{L}^+$ and the long line $\mathbb{L}$ both have the following properties:

(1) they are Hausdorff,
(2) they are locally homeomorphic to $\mathbb{R}$,
(3) they are path-connected and
(4) they are not second-countable.

Remark.

(1) The proof we give below is based on the sketch given in [**Mun1966a**, p. 158]. An alternative account of the proof is given in [**Gaul2014**, Chapter 1.2].
(2) The discovery of the long line $\mathbb{L}$ goes back to work of Georg Cantor [**Cant1883**] from 1883.
(3) A slightly less otherworldly example of a topological space that satisfies all properties of a path-connected topological manifold, except that it is not second-countable, is given in [**Bre1993**, Corollary 17.5] and [**Spr1957**, p. 56].

We will prove Theorem 22.13 in the next section. In the remainder of this section we will discuss the open long ray and long line in greater detail. First of all the following proposition lists several weird and surprising properties of the open long ray and the long line.

Proposition 22.14.

(1) Every map $f\colon \mathbb{L}^+ \to \mathbb{R}$ is eventually constant, i.e. there exists an $(x,s) \in \mathbb{L}^+$ such that $f((y,t)) = f(x,s)$ for every $(y,t) \geq (x,s)$.
(2) The topological space $\mathbb{L}^+$ is not paracompact.
(3) Every bounded map $f\colon \mathbb{L}^+ \to \mathbb{L}^+$ is homotopic to a constant map.
(4) Every unbounded map $f\colon \mathbb{L}^+ \to \mathbb{L}^+$ is homotopic to the identity map.
(5) An unbounded map $f\colon \mathbb{L}^+ \to \mathbb{L}^+$ is never homotopic to bounded map.
(6) The open long line $\mathbb{L}^+$ is not contractible.

Proof.

(1) It is a great exercise to try to prove this statement. If, inexplicably, the reader is not inclined to provide the arguments, then we refer to [**Gaul2014**, Proposition 1.17] for a proof.
(2) We need to show that $\mathbb{L}^+$ admits an open cover that does not admit a locally finite open refinement. In fact one can show that the open subsets $U_{(x,s)} := ((*,0),(x,s))$ of $\mathbb{L}^+$ is such an open cover. Since we will not make use of this statement we will

not show that this cover does not admit a locally finite open refinement. The statement can be proved using a slight variation on the argument given on [**Jos1983**, Theorem 15.3.2(vi)].

(3)-(5) These statements are proved in [**Gaul2014**, Proposition 1.12].

(6) This statement follows immediately from (5) and the Contractibility Criterion Lemma 15.2. ■

At this stage one might fear that now, when we no longer restrict ourselves to second-countable topological spaces, the genie is out of the bottle, and that thus any type of classification result is completely out of reach. Rather stunningly this is not the case.

The following theorem can now be viewed as a generalization of the Topological 1-Dimensional Manifold Classification Theorem 22.1.

Theorem 22.15. Let X be a topological space that is Hausdorff and path-connected.

(1) If X is locally homeomorphic to an open subset of $\mathbb{R}$, then X is homeomorphic to one of the following: S^1, $\mathbb{R}$, $\mathbb{L}^+$ and $\mathbb{L}$.

(2) If X is locally homeomorphic to an open subset of $\mathbb{R}_{\geq 0}$, then either X is homeomorphic to one of the above, or one of the following: $[0,1)$, $[0,1]$ and $\mathbb{L}_{\geq 0}$.

Proof.

(1) This statement is proved in [**KnesH1958**].

(2) This statement can be deduced easily from (1) by first removing the "boundary points". We leave it to the reader to provide the details. ■

By Theorem 22.13 we now know in particular that the long line $\mathbb{L}$ admits an atlas. In fact, as is shown in [**Gaul2014**, Proposition 7.9], there exists an atlas on $\mathbb{L}$ that is smooth, i.e. such that all transition maps are smooth. Much more impressively, it turns out that there are uncountable many mutually non-diffeomorphic smooth structures on $\mathbb{L}$. We refer to [**Gaul2014**, Theorem 7.14] and [**Nyi1992**] for a precise formulation and a proof of this assertion.

22.5. **Proof of Theorem 22.13.** In this section we finally provide the proof of Theorem 22.13. We start out with some general definitions and statements regarding well-ordered sets.

Definition. Let $(X, \leq)$ be a well-ordered set. A subset A of X is called inductive if for every $a \in X$ with $S_a \subset A$ we also have $a \in A$.

Examples.

(1) Let $X = \mathbb{R}_{\geq 0}$. The interval $A = [0,2)$ is not inductive whereas $A = [0,2]$ is inductive.

(2) One can easily show that the only inductive subset of $\mathbb{N}_0$ is $\mathbb{N}_0$.

The grandiose name of the following theorem is designed to impress friends and family.

Theorem 22.16. (Principle of Transfinite Induction) Let $(X, \leq)$ be a well-ordered set. If $A \subset X$ is an inductive subset of X, then $A = X$.

Proof. Let $A \subset X$ be an inductive subset. We suppose that $A \neq X$. Since X is well-ordered the set $X \setminus A$ has a minimal element y. Since y is the minimal element of $X \setminus A$

we see that for every $x < y$ we have $x \in A$. But this means that the y-section S_y is contained in A. But since A is inductive this implies that $y \in A$. We have thus obtained a contradiction. ■

In the proof of Theorem 22.13 we will need the following fairly straightforward lemma.

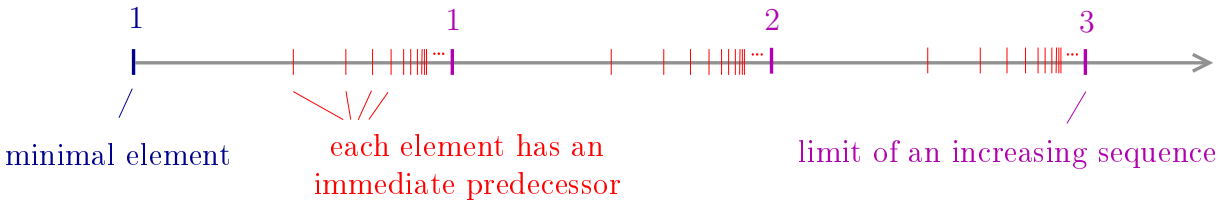
Definition. Let $(X, \leq)$ be a partially ordered set.

(1) Let $x \in X$. We say that $a \in X$ is an immediate predecessor of x if $a < x$ and if there is no $b \in X$ with $a < b < x$.
(2) Let $x \in X$. We say that $a \in X$ is an immediate successor of x if $x < a$ and if there is no $b \in X$ with $x < b < a$.
(3) Let $A \subset X$ be a subset. We say that $x \in X$ is an upper bound of A if for every $a \in A$ we have $a \leq x$.
(4) Let $A \subset X$ be a subset. We say that $x \in X$ is a supremum of A if x is an upper bound of A and if there is no upper bound of A that is less than x.
(5) Let $x_1 < x_2 < \dots$ be an increasing sequence of elements in X. If $b = \sup\{x_1, x_2, \dots\}$ then we say that b is a limit of the sequence.

Examples.

(1) Every element in $\mathbb{Z}$ has an immediate predecessor and an immediate successor.
(2) No element in $\mathbb{R}$ has an immediate predecessor and no element in $\mathbb{R}$ has an immediate successor.
(3) If $(X, \leq)$ is a well-ordered set, then it follows easily from the definitions that every proper subset $A \subsetneq X$ admits a unique supremum.

Lemma 22.17. Let $(X, \leq)$ be a well-ordered set and let $x \in X$ such that the corresponding section S_x is countable. Precisely one of the following three statements holds:



(1) x is the minimal element of X.
(2) There exists an immediate predecessor of x.
(3) x is the limit of an increasing sequence $x_0 < x_1 < x_2 <$ of elements of X.

Proof. Let $(X, \leq)$ be a well-ordered set and let $x \in X$ such that the corresponding section $S_x = \{w \in X \,|\, w < x\}$ is countable. We only need to consider the case that $x \in X$ is not the minimal element. This means that the section S_x is non-empty. If the section S_x is finite, then it admits a maximal element, which is clearly an immediate predecessor of x. Next we suppose that the section S_x is infinite. By hypothesis on x we know that S_x is also countable. Thus there exists a bijection $\varphi\colon \mathbb{N}_0 \to S_x$. Now given any $n \in \mathbb{N}_0$ we set $y_n := \max\{\varphi(0), \dots, \varphi(n)\}$. By construction we have $y_1 \leq y_2 \leq y_3 \leq \dots$. If the sequence $y_1, y_2, \dots$ is eventually constant, i.e. if there exists an N such that $y_n = Y_N$ for every $n \geq N$, then Y_N is easily seen to be an immediate predecessor of x. Otherwise there exists a subsequence $y_{s_1} < y_{s_2} < y_{s_3} < \dots$ which is strictly increasing. By construction x is the limit of this sequence.

Finally we leave it to the reader to verify that three possibilities are mutually exclusive. ■

Example. We consider the subset $X := \mathbb{N}_0 \cup \{n - \frac{1}{k} \,|\, n \in \mathbb{N}_0 \text{ and } k \in \mathbb{N}_{\geq 2}\}$ of $\mathbb{R}$, equipped with the usual partial order. One can easily verify that $(X, \leq)$ is actually well-ordered.

The number 0 is evidently the minimal element. Every x of the form $n-\frac{1}{k}$ with $n \in \mathbb{N}$ and $k \in \mathbb{N}_{\geq 2}$ has an immediate successor, namely $n-\frac{1}{k-1}$. Finally every $n \in \mathbb{N}$ is the limit of the increasing sequence $x_i = n - \frac{1}{1+i}$.

Lemma 22.18. Let $(X, \leq)$ be a totally ordered set.

(1) Let $a < b < c$ be three elements of X. The interval $\overbrace{[a,c)}^{\subset X}$ has the order type of $\overbrace{[0,1)}^{\subset \mathbb{R}}$ if and only if each of the two intervals $[a,b)$ and $[b,c)$ has the order type of $[0,1)$.

(2) Let $b \in X$ be the limit of an increasing sequence $x_0 < x_1 < \ldots$ of elements of X. If each $[x_n, x_{n+1})$ has the order type of $[0,1)$, then so does $[x_0, b)$.

Proof. Throughout the proof we will make use of the following simple observation: if $(A, \leq)$ and $(B, \leq)$ are two totally ordered sets, then they have the same order type if and only if there exists an order-preserving bijection $f\colon A \to B$. In other words, the fact that A and B are totally ordered implies that the inverse $f^{-1}\colon B \to A$ is automatically order-preserving. Now we turn to the proofs of the two statements.

(1) Let $a < b < c$ be three elements of X. First suppose that there exist order-preserving bijections $f\colon [a,b) \to [0,1)$ and $g\colon [b,c) \to [0,1)$. It is clear that the map

$$\begin{array}{rcl} [a,c) & \to & [0,1) \\ t & \mapsto & \begin{cases} \frac{1}{2} \cdot f(t), & \text{if } t \in [a,b), \\ \frac{1}{2} + \frac{1}{2} \cdot g(t), & \text{if } t \in [b,c) \end{cases} \end{array}$$

is an order-preserving bijection. Conversely suppose that there exists an order-preserving bijection $h\colon [a,c) \to [0,1)$. We point out that $h([a,b)) = [0, h(b))$ and $h([b,c)) = [h(b), 1)$. Evidently the intervals $[0,h(b))$ and $[h(b),1)$ have the order type of $[0,1)$. Thus we are done.

(2) Now let $b \in X$ be the limit of an increasing sequence $x_0 < x_1 < \ldots$ of elements of X. We suppose that for each $n \in \mathbb{N}_0$ there exists an order-preserving bijection $\varphi_n\colon [x_n, x_{n+1}) \to [0,1)$. One can now easily verify that the map

$$\begin{array}{ccccc} [x_0, b) & = & \bigsqcup_{n \in \mathbb{N}_0} [x_n, x_{n+1}) & \to & [0,1) \\ \uparrow & & & & \\ \text{since } b \text{ is the limit of the} & & t & \mapsto & \frac{1}{2^{n+1}} \cdot \varphi_n(t) + \sum_{i=0}^{n-1} \frac{1}{2^{i+1}} \quad \text{for } t \in [x_n, x_{n+1}) \\ \text{increasing sequence } x_0 < x_1 < \ldots & & & & \end{array}$$

is an order-preserving bijection. ∎

The next lemma contains the heart of the proof of Theorem 22.13.

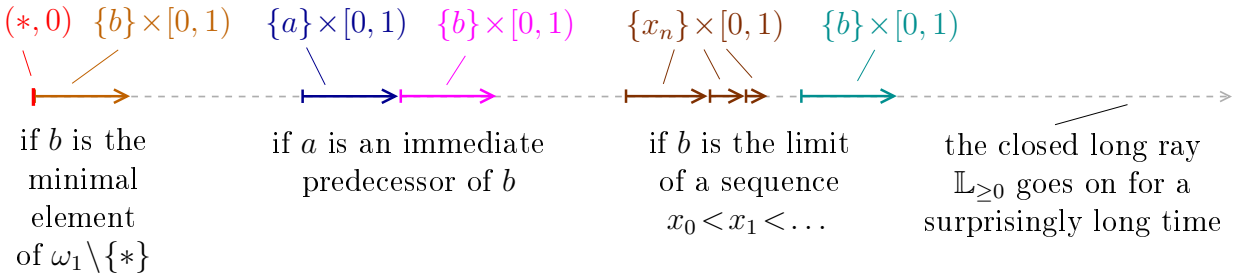
Lemma 22.19. As above we denote by $*$ the minimal element of ω_1 and let $x \in \omega_1 \setminus \{*\}$.

(1) The half-open interval $[(*,0),(x,0)) \subset \mathbb{L}_{\geq 0}$ has the order type of $[0,1)$.

(2) The open interval $((*,0),(x,0)) \subset \mathbb{L}_{\geq 0}$ has the order type of $(0,1)$.

Proof. We consider the set

$$B := \big\{ b \in \omega_1 \setminus \{*\} \,\big|\, \text{the set } [(*,0),(b,0)) \text{ has order type of } [0,1) \big\}.$$



We want to show that $B = \omega_1 \setminus \{*\}$. Note that it follows from the fact that ω_1 is well-ordered that the complement of the minimal element $*$, i.e. the set $\omega_1 \setminus \{*\}$, is again well-ordered. Thus it follows from Theorem 22.16, i.e. it follows from the Principle of Transfinite Induction, that it suffices to show that B is inductive.

Now let $b \in B$ such that $S_b \subset B$. By Lemma 22.17 we know that one of the following holds:

(1) b is the minimal element of B.
(2) b has an immediate predecessor a.
(3) b is the limit of an increasing sequence $x_0 < x_1 < \dots$ of elements of X.

We will now treat these three cases separately.

(1) Suppose that b is the minimal element of $\omega_1 \setminus \{*\}$. In this case we see easily that $[(*,0),(b,0)) = \{(*,t) \,|\, t \in [0,1)\}$, which evidently has the order type of $[0,1)$.
(2) Suppose that b has an immediate predecessor a. Since $S_b \subset B$ and $a < b$ we see that $a \in B$, i.e. we see that $[(*,0),(a,0))$ has order type $[0,1)$. Next note that the fact that a is an immediate predecessor of b implies that $[(a,0),(b,0)) = \{(a,x) \,|\, x \in [0,1)\}$. Thus we see that this interval also has order type $[0,1)$. It follows from Lemma 22.18 (1) that $[(*,0),(b,0))$ has order type $[0,1)$.
(3) Now suppose that b is the limit of an increasing sequence $x_0 < x_1 < \dots$ of elements of X. Since $S_b \subset B$ and since for each x_n we have $x_n < b$ we see as in (2) that each $[(*,0),(x_n,0))$ has order type $[0,1)$. It follows from Lemma 22.18 (1) that each interval $[(x_n,0),(x_{n+1},0))$ has order type $[0,1)$. Finally it follows from Lemma 22.18 (2) that the interval $[(*,0),(b,0))$ has order type $[0,1)$. ∎

Now we can finally provide the proof of Theorem 22.13.

Proof of Theorem 22.13. We will prove the desired statements only for the open long ray $\mathbb{L}^+$. We leave it to the reader to make the minor modifications need to show that the analogous statements also hold for the long line $\mathbb{L}$. Now recall that we need to show the following four statements regarding the open long ray $\mathbb{L}^+$.

(1) $\mathbb{L}^+$ is Hausdorff,
(2) $\mathbb{L}^+$ is locally homeomorphic to an open subset of $\mathbb{R}$,
(3) $\mathbb{L}^+$ is path-connected,
(4) $\mathbb{L}^+$ is not second-countable.

We turn to the proofs of these four statements.

(1) This statement conveniently enough follows immediately from Lemma 22.10.

(2) Let $(x,t) \in \mathbb{L}^+$. By Lemma 22.12 we can pick some $y > x$. Since $y > x$ we see that $U := ((*,0),(y,0))$ is an open neighborhood of (x,t). Note that by Lemma 22.19 we know that the interval $[(*,0),(y,0))$ has the order type of $[0,1)$. It follows that the open interval $U := ((*,0),(y,0))$ is homeomorphic to $(0,1)$.

(3) Let (x,s) and (y,t) be two points in $\mathbb{L}^+$. By Lemma 22.12 we can pick $z \in X$ with $z > x$ and $z > y$. As in (2) we obtain from Lemma 22.19 that the open interval $U := ((*,0),(z,0))$ is homeomorphic to $(0,1)$. Since the open interval contains the points (x,s) and (y,t) and since $(0,1)$ is path-connected we see that there exists a path $\gamma\colon [0,1] \to \mathbb{L}^+$ that connects (x,s) and (y,t).

(4) Let $\mathcal{B}$ be a basis for the topological space $\mathbb{L}^+$. We need to show that $\mathcal{B}$ is uncountable. For each $x \in \omega_1$ we consider the open interval $U_x := ((x,\frac{1}{4}),(x,\frac{3}{4}))$. It follows from the definition of a basis that given any $x \in X$ there exists a set $B_x \in \mathcal{B}$ with $(x,\frac{1}{2}) \in B_x \subset U_x$. Since the U_x are disjoint we see that the B_x are distinct. Since X is uncountable we obtain from the Countability Lemma 0.8 (1) that $\mathcal{B}$ is uncountable. ■

Exercises for Chapter 22.

Exercise 22.1. Let X be a 1-dimensional topological manifold. Show that X is homeomorphic to a proper submanifold of $\mathbb{H}_2$.
Remark. Since X is second-countable we know by Exercise 9.1 that X has only countably many components.

Exercise 22.2.

(a) Let $(X,\leq)$ be a totally ordered set. Show that given any interval $I = (a,b)$, $[a,b)$, $(a,b]$ and $[a,b]$ in X the order topology on $(I,\leq)$ agrees with the subspace topology coming from X.

(b) Let $(X,\leq)$ be a totally ordered set and let $A \subset X$ be a subset. Show that the order topology on $(A,\leq)$ does not necessarily agree with the subspace topology coming from X.

Exercise 22.3. We equip $\mathbb{N}_0$ and the half-open interval $[0,1)$ with the usual total orders and we equip $\mathbb{N}_0 \times [0,1)$ with the lexicographic order. Finally we equip $\mathbb{N}_0 \times [0,1)$ with the corresponding order topology. Show that $\mathbb{N}_0 \times [0,1)$ is homeomorphic to $[0,\infty)$.

Exercise 22.4. We consider $X := \mathbb{R} \times \mathbb{R}$, for once equipped with the order topology $\mathcal{O}$.

(a) Let $\mathcal{T}$ be the usual topology on $X = \mathbb{R} \times \mathbb{R} = \mathbb{R}^2$. Do we have an inclusion $\mathcal{O} \subset \mathcal{T}$? Do we have an inclusion $\mathcal{T} \subset \mathcal{O}$?

(b) Show that the topological space $(X,\mathcal{O})$ is Hausdorff.

(c) Is the topological space $(X,\mathcal{O})$ second-countable?

(d) Is $(X,\mathcal{O})$ locally homeomorphic to open subsets of $\mathbb{R}$?

(e) Is $(X,\mathcal{O})$ homeomorphic to the long line?

Exercise 22.5. Let ω_1 be the well-ordered set introduced in Theorem 22.11.

(a) Show that for every $x \in \omega_1$ the subset $\{y \in \omega_1 \,|\, x < y\}$ is uncountable.

(b) Let $X = \{x \in \omega_1 \,|\, x \text{ has no immediate successor}\}$. Show that X is uncountable.

Exercise 22.6.

(a) We consider the well-ordered set $\mathbb{L}^+ := \omega_1 \times [0,1)$. Show that every increasing sequence in $\mathbb{L}_{\geq 0}$ converges.

(b) A topological space that has the property that every sequence admits a convergent subsequence is called sequentially compact. Show that the closed long ray $\mathbb{L}^+$ is sequentially compact.

Exercise 22.7. Show that the open long ray $\mathbb{L}^+$ and the long line $\mathbb{L}$ are not homeomorphic. *Hint.* What happens if you remove a point?

Exercise 22.8.

(a) Let $(X, \leq)$ be a well-ordered set. Let $x \in X$. Show that either x is the largest element of X or that x has an immediate successor.

(b) Give an example of a partially ordered set $(X, \leq)$ that is not well-ordered but that nonetheless has the property that every $x \in X$ has an immediate successor.

Exercise 22.9. Let $(X, \leq)$ be a partially ordered set and let $x \in X$.

(1) We say x has *depth* -1 if x is a minimal element of X.

(2) We say x has *depth* 0 if x has an immediate predecessor.

Now we iteratively define what it means for $x \in X$ to have depth $k \in \mathbb{N}_{\geq 2}$.

(3) We say x has *depth* k if x is not of depth $k-1$ but if there exists an increasing sequence $x_1 < x_2 < \dots$ in X, such that each x_i has depth $< k$, and such that x is a limit of this sequence.

Show that there exists a countable well-ordered subset of $\mathbb{R}$ that admits elements of depth two.

Exercise 22.10. Does the long line $\mathbb{L}$ admit an embedding into $\mathbb{R}^2$?

Exercise 22.11. A topological space X is called homogeneous if given any $x, y \in X$ there exists a homeomorphism $f\colon X \to X$ with $f(x) = y$. Show that the long ling $\mathbb{L}$ is homogeneous.

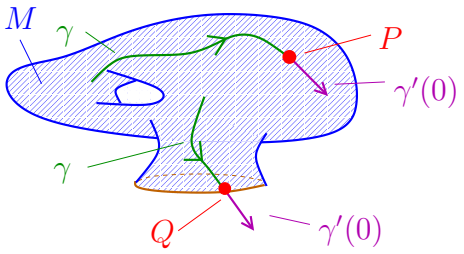
23. Tangent spaces of smooth manifolds

In this chapter we introduce the notion of tangent spaces of smooth manifolds. As a warm-up we first consider tangent spaces of smooth submanifolds of some $\mathbb{R}^k$. In this setting the notion of a tangent space can be motivated easily. The notion of a tangent space for a general "abstract" manifold takes more time to get used to and to appreciate.

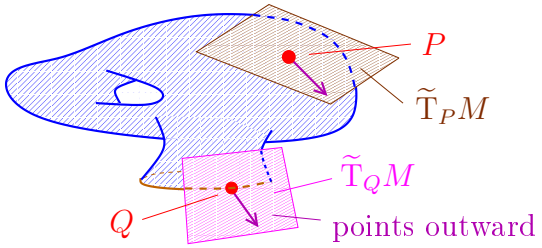
23.1. **Tangent spaces of smooth submanifolds of $\mathbb{R}^k$.** In this section we study smooth submanifolds of some $\mathbb{R}^k$, where, as always, we equip $\mathbb{R}^k$ with the standard smooth structure. Note that in the Submanifold Smooth Structure Lemma 19.24 we saw that every smooth submanifold of $\mathbb{R}^k$ inherits a standard smooth structure.

Definition. Let M be an n-dimensional smooth submanifold of $\mathbb{R}^k$ and let $P \in M$.

(1) A curve through P is a map $\gamma\colon I \to M$ where $I \subset \mathbb{R}$ is an open or half-open interval with $0 \in I$ and with $\gamma(0) = P$.



(2) Given a smooth curve $\gamma\colon I \to M$ through P we denote by $\gamma'(0) \in \mathbb{R}^k$ the derivative of γ viewed as a smooth map[238] $\gamma\colon I \to M \to \mathbb{R}^k$.



(3) We define the physical tangent space as the set of all derivatives of smooth curves on M through P, i.e. we define[239]

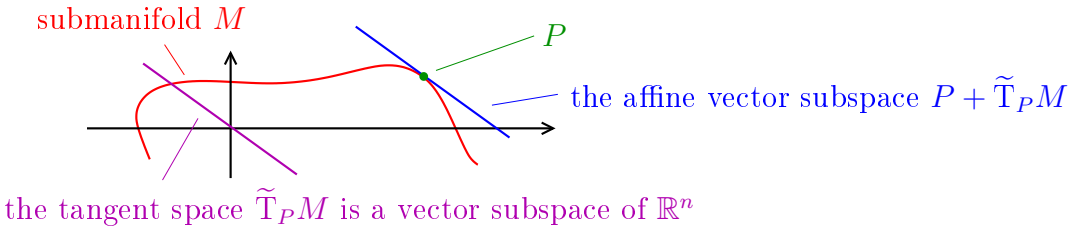
$$\widetilde{\mathrm{T}}_P M \;:=\; \{\gamma'(0)\,|\,\gamma\colon I \to M \text{ a smooth curve through } P\} \;\subset\; \mathbb{R}^k.$$

We refer to any vector in $\widetilde{\mathrm{T}}_P M$ as a tangent vector to M at P.

(4) Let $P \in \partial M$. We say a tangent vector $v \in \widetilde{\mathrm{T}}_P M$ points outward if $v = \gamma'(0)$ for some smooth map $\gamma\colon (-\epsilon, 0] \to M$ and if $v \notin \widetilde{\mathrm{T}}_P \partial M$. Similarly we also define the notion that v points inward.

Remark.

(1) Let M be an n-dimensional smooth submanifold of $\mathbb{R}^k$ and let $P \in M$. If $P \notin \partial M$, then using charts and using the definition of a smooth map on a half-open interval, see page 549, one can easily show that

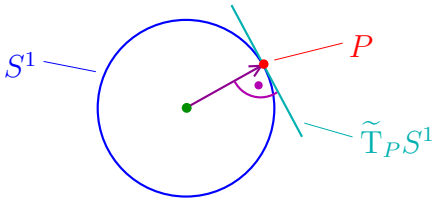


$$\widetilde{\mathrm{T}}_P M \;:=\; \text{all derivatives } \gamma'(0) \text{ of smooth maps } \gamma\colon (-\epsilon, \epsilon) \to M \text{ with } \gamma(0) = P.$$

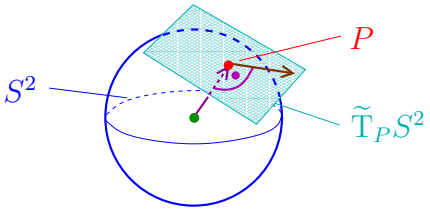
(2) Let M be an n-dimensional smooth submanifold of $\mathbb{R}^k$ and let $P \in M$. In the Physical Tangent Space-Functor Proposition 23.2 (0) we will see that $\widetilde{\mathrm{T}}_P M$ is an n-dimensional vector subspace of $\mathbb{R}^k$. In pictures we usually show, for clarity, the

[238] Note that according to the Submanifold Smooth Structure Lemma 19.24 the inclusion $M \to \mathbb{R}^k$ is smooth, so the composition of the smooth map $\gamma\colon I \to M$ with the inclusion $M \to \mathbb{R}^k$ is also smooth.

[239] Note that if 0 is an endpoint of the interval I, then we use the convention from page 533 to define the derivative of γ at 0.



affine vector subspace $P + \widetilde{T}_P M$. This affine vector space is the "best possible" approximation of M by an affine vector subspace.



We formulate our first examples as a lemma.

Lemma 23.1. Let $n \in \mathbb{N}_0$.

(1) Let M be an open subset of $\mathbb{R}^n$ or of the half-plane $\mathbb{H}^n$. For every $P \in M$ we have the equality $\widetilde{\mathrm{T}}_P M = \mathbb{R}^n$.
(2) If $W \subset \mathbb{R}^n$ is a k-dimensional vector space and $Q \in \mathbb{R}^n$, then the affine space $Q + W = \{Q + w \,|\, w \in W\}$ is a k-dimensional smooth submanifold of $\mathbb{R}^n$ and for any $P \in W$ we have $\widetilde{\mathrm{T}}_P W = W$.
(3) Given any $P \in S^n \subset \mathbb{R}^{n+1}$ we have the equality $\widetilde{\mathrm{T}}_P S^n = \{v \in \mathbb{R}^{n+1} \,|\, \langle v, P\rangle = 0\}$.

Proof.

(1) First let M be an open subset of $\mathbb{R}^n$ and let $P \in M$. Note that by definition we have $\widetilde{\mathrm{T}}_P M \subset \mathbb{R}^n$. Conversely let $v \in \mathbb{R}^n$. Since M is open there exists an $\epsilon > 0$ such that $\{P + t \cdot v \,|\, t \in [0, \epsilon]\} \subset U$. Thus we can consider the smooth map $\gamma\colon [0, \epsilon) \to M$ given by $\gamma(t) = P + t \cdot v$. Evidently $\gamma'(0) = v$, which shows that $v \in \widetilde{\mathrm{T}}_P M$. The proof of the case that M is an open subset of $\mathbb{H}^n$ is very similar, we just have to notice that for any $v \in \mathbb{R}^n$ we have $v \in \mathbb{H}^n$ or $-v \in \mathbb{H}^n$. We leave it to the reader to fill in the few remaining details.
(2) It follows from very elementary linear algebra that there exists an invertible matrix $A \in \mathrm{GL}(n, \mathbb{R})$ such that $A \cdot W = \{0\} \times \mathbb{R}^k$. The map

$$\begin{array}{rcl} Q + W & \to & \mathbb{R}^n \\ x & \mapsto & A \cdot (x - Q) \end{array}$$

is now a submanifold chart. Thus $Q + W$ is a k-dimensional smooth submanifold of $\mathbb{R}^n$. Using this chart one can also easily verify that for any $P \in W$ we indeed have $\widetilde{\mathrm{T}}_P W = W$. We leave it to the reader to fill in the details.

(3) Let $P \in S^n$. We need to show that $\widetilde{\mathrm{T}}_P M = \{v \in \mathbb{R}^{n+1} \mid \langle v, P\rangle = 0\}$. We prove the two inclusions separately.

($\subset$) Let I be a (half-) open interval with $0 \in I$ and let $\gamma\colon I \to S^n$ be a smooth map with $\gamma(0) = P$. For any $t \in I$ we have

$$0 \underset{\uparrow}{=} \frac{d}{dt}\|\gamma(t)\|^2 = \frac{d}{dt}\langle \gamma(t), \gamma(t)\rangle \underset{\uparrow}{=} 2 \cdot \langle \gamma'(t), \gamma(t)\rangle.$$

since $\|\gamma(t)\| \equiv 1$ follows from the Product Rule

In particular for $t = 0$ we see that $0 = \langle \gamma'(0), \gamma(0)\rangle = \langle \gamma'(0), P\rangle$.

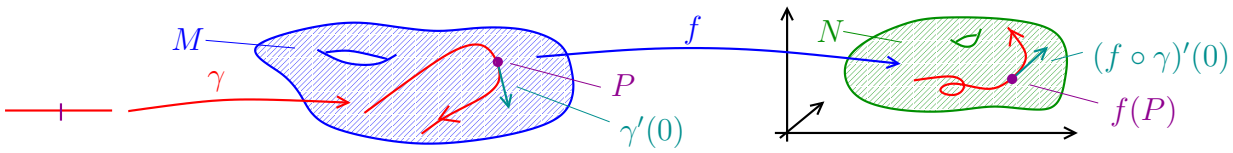
($\supset$) Suppose we are given $v \in \mathbb{R}^{n+1}$ with $\langle v, P\rangle = 0$. If $v = 0$, then v is the derivative of the constant curve through P. Now assume that $v \neq 0$. We consider the curve that is defined by $\gamma(t) := P \cdot \cos(t \cdot \|v\|) + \frac{v}{\|v\|} \cdot \sin(t \cdot \|v\|)$. Evidently we have $\gamma(0) = P$ and $\gamma'(0) = v$. Finally note that it follows from $\langle v, P\rangle = 0$ that γ defines a curve on S^n. Thus we have shown that $v \in \widetilde{\mathrm{T}}_P S^n$. ■

Proposition 23.2. (Physical Tangent Space-Functor Proposition)

(0) If M is a d-dimensional submanifold of $\mathbb{R}^n$, then for each $P \in M$ the physical tangent space $\widetilde{\mathrm{T}}_P M$ is a d-dimensional vector subspace of $\mathbb{R}^n$.

(1) Let $f\colon M \to N$ be a smooth map[240] between smooth submanifolds of $\mathbb{R}^m$ respectively $\mathbb{R}^n$. Given any $P \in M$ the map[241]

$$\begin{array}{rcl} \mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P M & \to & \widetilde{\mathrm{T}}_{f(P)} N \\ \gamma'(0) & \to & (f \circ \gamma)'(0) \end{array}$$



is well-defined and linear.

(2) The maps from (1) have the following two properties:[242]

(a) If $\mathrm{id}\colon M \to M$ is the identity map, then for any $P \in M$ the corresponding map $\mathrm{D}\,\mathrm{id}_P\colon \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_P M$ is also the identity.

(b) For any two smooth maps $f\colon L \to M$ and $g\colon M \to N$ between smooth submanifolds and any $P \in L$ we have

$$\mathrm{D}(g \circ f)_P = \mathrm{D}g_{f(P)} \circ \mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P L \to \widetilde{\mathrm{T}}_{g(f(P))} N.$$

[241] At the danger of repeating ourselves, we use the Submanifold Smooth Structure Lemma 19.24 to view M and N as smooth manifolds in their own right. Thus by a smooth map we mean a smooth map between these two smooth manifolds.

[242] By the Submanifold Smooth Structure Lemma 19.24 the inclusion map $N \to \mathbb{R}^n$ is smooth, thus $f \circ \gamma$ is indeed a smooth curve that takes values in $\mathbb{R}^n$, thus it makes sense to take its derivative.

Definition. Let $f\colon M \to N$ be a smooth map between smooth submanifolds of $\mathbb{R}^m$ respectively $\mathbb{R}^n$. Given any $P \in M$ we refer to the map

$$\begin{array}{rccc} \mathrm{D}f_P\colon & \widetilde{\mathrm{T}}_P M & \to & \widetilde{\mathrm{T}}_{f(P)} N \\ & \gamma'(0) & \to & (f\circ\gamma)'(0), \end{array}$$

that we introduced in the Physical Tangent Space-Functor Proposition 23.2 (2), as the differential of f at P.

Proof. We start with a preamble. In the proofs of (0) and (1) we will consider smooth maps $h\colon W \to \mathbb{R}^t$ where W is an open subset of some $\mathbb{R}^s$. For each $P \in W$ we denote by $\mathrm{D}h_P \in \mathrm{M}(t\times s, \mathbb{R})$ the differential as defined on page 536. Throughout the proofs of (0) and (1) we use this notation exclusively for such maps.

(0) Let M be a d-dimensional submanifold of $\mathbb{R}^m$ and let $P \in M$. First we consider the case that $P \in M \setminus \partial M$. Since M is a smooth submanifold of $\mathbb{R}^m$ we know that there exists a submanifold chart $\Phi\colon U \to V$ for $P \in M$. We write $Q := \Phi(P)$ and $\Psi := \Phi^{-1}\colon V \to U$. We write

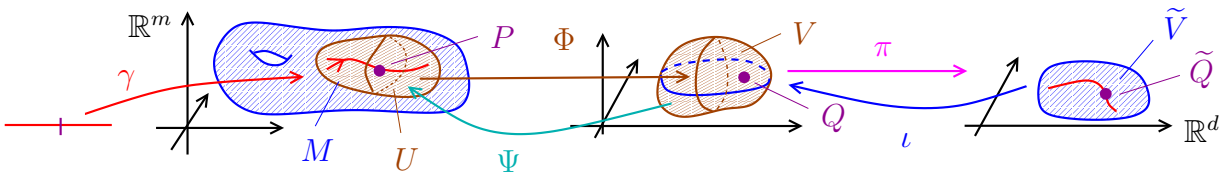
$$\widetilde{V} \;:=\; \{x \in \mathbb{R}^d \,|\, (x,0) \in V\}.$$

This is an open subset of $\mathbb{R}^d$. We denote by $\iota\colon \widetilde{V} \to V$ the injective map given by $x \mapsto (x,0)$. Note that $Q = \iota(\widetilde{Q})$ for some $\widetilde{Q} \in \widetilde{V}$.

Claim.
$$\widetilde{\mathrm{T}}_P M \;=\; \underbrace{\mathrm{D}(\Psi\circ\iota)_{\widetilde{Q}}\cdot\mathbb{R}^d}_{\uparrow} \;\subset\; \mathbb{R}^m.$$
note that $\Psi\circ\iota\colon \widetilde{V} \to \mathbb{R}^m$ is indeed defined on an open subset of $\mathbb{R}^d$, thus it makes sense to consider the "classical" differential

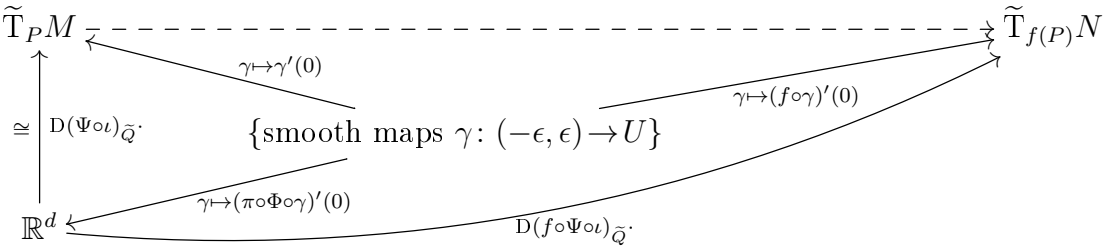
Proof. We show the two inclusions "$\supset$" and "$\subset$" separately.

($\subset$) Let $\gamma\colon (-\epsilon,\epsilon) \to M$ be a smooth map with $\gamma(0) = P$. We need to show that $\gamma'(0) \in \mathrm{D}(\Psi\circ\iota)_{\widetilde{Q}}(\mathbb{R}^d)$. Note that after possibly reducing ϵ we can assume that $\gamma((-\epsilon,\epsilon)) \subset U$. We denote by $\pi\colon \mathbb{R}^n = \mathbb{R}^d \times \mathbb{R}^{n-d} \to \mathbb{R}^d$ the projection that is given by $(x,y) \mapsto x$. We see that



$$\gamma'(0) \;=\; (\Psi\circ\iota\circ\pi\circ\Phi\circ\gamma)'(0) \underset{\uparrow}{=} \mathrm{D}(\Psi\circ\iota)_{\widetilde{Q}}\cdot\underbrace{(\pi\circ\Phi\circ\gamma)'(0)}_{\text{vector in } \mathbb{R}^d}.$$
Chain Rule 19.10 together with the remark on page 536

($\supset$) Let $v \in \mathbb{R}^d$. Since $\widetilde{V}$ is open we there exists an $\epsilon > 0$ such that the corresponding curve $\gamma\colon (-\epsilon,\epsilon) \to \mathbb{R}^d$ given by $t \mapsto \widetilde{Q} + t\cdot v$ takes values in $\widetilde{V}$. Then



$$\mathrm{D}(\Psi\circ\iota)_{\widetilde{Q}}\cdot v \;=\; \mathrm{D}(\Psi\circ\iota)_{\widetilde{Q}}\cdot\gamma'(0) \underset{\uparrow}{=} (\Psi\circ\iota\circ\gamma)'(0).$$
Chain Rule 19.10

Since $\Psi\circ\iota\circ\gamma\colon (-\epsilon,\epsilon) \to M$ is a smooth map which sends 0 to P we have shown the "$\supset$"-inclusion. ⊞

This concludes the proof of Statement (0) if $P \in M \setminus \partial M$. The case that $P \in \partial M$ is treated in a very similar fashion. We leave it to the reader to fill in the details.

(1) To simplify the notation a little bit we consider the case that $P \notin \partial M$. The case that $P \in \partial M$ is dealt with in essentially the same way. We continue with the notation and setup that we introduced in (0) for $M \subset \mathbb{R}^m$. We consider the following diagram

We make the following observations:

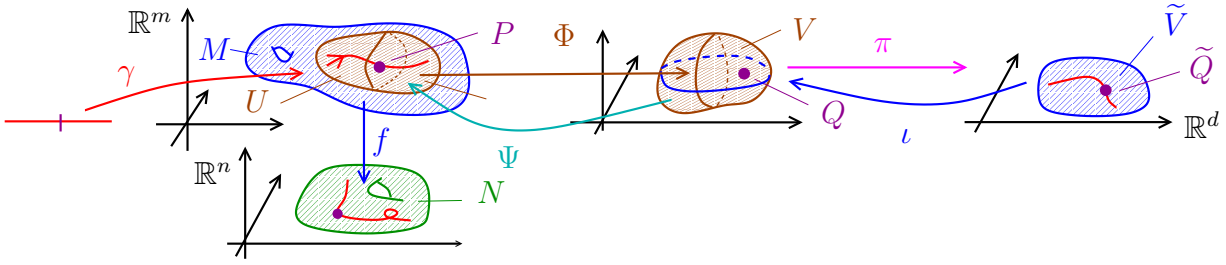
(a) In the proof of the "$\subset$"-statement in (0) we already showed that the triangle to the left commutes.

(b) In (0) we showed that the left vertical map is an epimorphism.

(c) By the Chain Rule 19.10 we have $\mathrm{D}(\Psi \circ \iota)_{\widetilde{Q}} = \mathrm{D}\Psi_Q \cdot \mathrm{D}\iota_{\widetilde{Q}}$.

(d) Recall that Ψ is a diffeomorphism. It follows from this fact together with the Smooth Invariance of Domain Proposition 19.11 that $\mathrm{D}\Psi_Q$ is an invertible matrix.

(e) Since the inclusion ι is a linear map we obtain from the discussion on page 536 that multiplication by the matrix $\mathrm{D}\iota_{\widetilde{Q}}$ equals the inclusion $\mathbb{R}^d \to \mathbb{R}^m$.



(f) It follows from (d) and (e) that the left vertical map is a monomorphism.

(g) The combination of (b) and (f) shows that the left vertical map is an isomorphism.

(h) It follows again from the Chain Rule 19.10 that the triangle to the bottom right commutes.

(i) Basically by definition of $\widetilde{\mathrm{T}}_P M$ the upper left diagonal map is a surjection.

The above observations imply that there is a unique horizontal map which makes the upper triangle commute. In other words, the map $\mathrm{D}f_P \colon \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_{f(P)} N$ given by $\gamma'(0) \to (f \circ \gamma)'(0)$ is well-defined. Furthermore, since the above diagram commutes and since the left vertical map is an isomorphism and since the right diagonal map is a homomorphism we see that the top horizontal map is indeed a homomorphism.

In the following proof of (2) we denote by D again the differential as defined on page 623.

(2) (a) This statement is obvious.
(b) Let $f\colon L \to M$ and $g\colon M \to N$ be smooth maps between smooth submanifolds, let $P \in L$ and let $v \in \widetilde{\mathrm{T}}_P L$. Let $\gamma\colon I \to L$ be a smooth curve through P with $\gamma'(0) = v$. We see that

$$\mathrm{D}(g \circ f)_P(v) \;=\; ((g \circ f) \circ \gamma)'(0) \;=\; (g \circ (f \circ \gamma))'(0) \underset{\substack{\uparrow \\ \text{since } (f\circ\gamma)'(0) = \mathrm{D}f_P(v)}}{=} \mathrm{D}g_{f(P)}(\mathrm{D}f_P(v)).$$

■

Proposition 23.3. (Physical Tangent Space-Inclusion Proposition) Let M be a smooth submanifold of $\mathbb{R}^m$.

(1) Let W be a submanifold of M (e.g. W could be an open subset of M) and let $P \in W$. We denote by $i\colon W \to M$ the inclusion.
   (a) We have $\widetilde{\mathrm{T}}_P W \subset \widetilde{\mathrm{T}}_P M$ and the differential $\mathrm{D}i_P\colon \widetilde{\mathrm{T}}_P W \to \widetilde{\mathrm{T}}_P M$ is the inclusion.
   (b) If W is of codimension-zero, then we have $\widetilde{\mathrm{T}}_P W = \widetilde{\mathrm{T}}_P M$.
(2) We denote by $i\colon \partial M \to M$ the inclusion. We have $\widetilde{\mathrm{T}}_P \partial M \subset \widetilde{\mathrm{T}}_P M$ and the differential $\mathrm{D}i_P\colon \widetilde{\mathrm{T}}_P \partial M \to \widetilde{\mathrm{T}}_P M$ is the inclusion.
(3) Let N be a smooth submanifold of some $\mathbb{R}^n$. If $f\colon M \to N$ is a local diffeomorphism, then for every $P \in M$ the differential $\mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_{f(P)} N$ is an isomorphism.

Proof.

(1) (a) By the Submanifold Smooth Structure Lemma 19.24 we know that the inclusion $i\colon W \to M$ is smooth. Any smooth curve in W is thus a smooth curve in M. With this observation Statement (1a) is now obvious.
   (b) If W is of codimension-zero, then we know by the Physical Tangent Space-Functor Proposition 23.2 (0) that the vector spaces $\widetilde{\mathrm{T}}_P W$ and $\widetilde{\mathrm{T}}_P M$ have the same dimension. Thus it follows from (1a) that the vector spaces are actually the same.
(2) As discussed in the Smooth Manifold Boundary Proposition 19.26, the inclusion map $\partial M \to M$ is smooth. Thus the statement is obvious.
(3) Let $f\colon M \to N$ be a local diffeomorphism and let $P \in M$. Since f is a local diffeomorphism there exists an open neighborhood U of P and an open neighborhood V of $Q = f(P)$ such that the restriction $\varphi = f|_U\colon U \to V$ is a diffeomorphism. We write $\psi = \varphi^{-1}\colon V \to U$. We denote by $i\colon U \to M$ and $j\colon V \to N$ the inclusions. We obtain the following diagram:

$$\begin{array}{ccc}
\widetilde{\mathrm{T}}_P M & \xrightarrow{\quad \mathrm{D}f_P \quad} & \widetilde{\mathrm{T}}_{f(P)} N \\
{\scriptstyle \mathrm{D}i_P}\uparrow = & & = \uparrow{\scriptstyle \mathrm{D}j_{f(P)}} \\
\widetilde{\mathrm{T}}_P U & \underset{\mathrm{D}\psi_{f(P)}}{\overset{\mathrm{D}\varphi_P}{\rightleftarrows}} & \widetilde{\mathrm{T}}_{f(P)} V.
\end{array}$$

We make the following three observations:
   (a) We have $f \circ i = j \circ \varphi$. Thus it follows from the Physical Tangent Space-Functor Proposition 23.2 (2b) that the diagram commutes.

(b) It follows from $\psi \circ \varphi = \mathrm{id}_U$ and $\varphi \circ \psi = \mathrm{id}_V$, together with the Physical Tangent Space-Functor Proposition 23.2 (2) that $\mathrm{D}\varphi_P = \mathrm{D}\psi^{-1}_{f(P)}$. In particular we see that the bottom horizontal map is an isomorphism.

(c) By (1) we know that the vertical maps are the identity.

It follows from the above three observations that the top horizontal map is also an isomorphism. ■

The last lemma of this section relates the two notions of differentials that we have introduced so far.

Lemma 23.4. (Differential-equals-Differential Lemma) Let $f\colon M \to N$ be a smooth map between an *open subset of* $\mathbb{R}^m$ and a *smooth submanifold of* $\mathbb{R}^n$. For every $P \in M$ the following statement holds:

$\underbrace{\mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P M = \mathbb{R}^m \to \widetilde{\mathrm{T}}_P N \subset \mathbb{R}^n}_{\text{differential as defined on page 623}}$ is given by multiplication by $\underbrace{\mathrm{D}f_P \in \mathrm{M}(n \times m, \mathbb{R}).}_{\text{the differential as defined on page 536}}$

Proof. Since $\mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P M = \mathbb{R}^m \to \widetilde{\mathrm{T}}_P N = \mathbb{R}^n$ is linear we only have to check this statement for the standard basis $e_1, \ldots, e_m$ of $\widetilde{\mathrm{T}}_P M = \mathbb{R}^m$. Let $i \in \{1, \ldots, m\}$. Since M is an open subset of $\mathbb{R}^m$ there exists an $\epsilon > 0$ such that the map $\gamma\colon (-\epsilon, \epsilon) \to \mathbb{R}^m$ given by $t \mapsto P + t \cdot e_i$ takes values in M. Now we see:

$$(\mathrm{D}f_P)(e_i) \;=\; (\mathrm{D}f_P)(\gamma'(0)) \;\underset{\text{see page 623}}{\overset{\uparrow}{=}}\; (f \circ \gamma)'(0) \;\underset{\text{Chain Rule 19.10}}{\overset{\uparrow}{=}}\; \mathrm{D}f_P \cdot (\gamma'(0)) \;=\; \mathrm{D}f_P \cdot e_i$$

■

23.2. **Smooth manifolds and functors.** Before we move on to tangent spaces of general smooth manifolds it is convenient to formulate some of the above results in the language of category theory.

Definition.

(1) We refer to the category $\mathcal{SmMfd}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{SmMfd}) &:= \text{all smooth manifolds,} \\ \mathrm{Mor}(X, Y) &:= \text{all smooth maps from } X \text{ to } Y, \end{aligned}$$

with the usual composition of maps as the category of smooth manifolds.

(2) We refer to the category $\mathcal{SmMfd}_{\mathbb{R}^n}$ with[244]

$$\begin{aligned} \mathrm{Ob}(\mathcal{SmMfd}_{\mathbb{R}^n}) &:= \text{all smooth submanifolds of } \mathbb{R}^n \text{ for an arbitrary } n \in \mathbb{N}_0, \\ \mathrm{Mor}(X, Y) &:= \text{all smooth maps from } X \text{ to } Y, \end{aligned}$$

with the usual composition of maps as the category of smooth submanifolds of some $\mathbb{R}^n$.

In our setting we need a slight variation on the above categories.

Definition.

[244] Here the dimension n is variable, thus the category contains as objects that are submanifolds of $\mathbb{R}^0$, $\mathbb{R}$, $\mathbb{R}^2$, $\mathbb{R}^3$, and so on.

(1) A pointed smooth manifold is a pair (M, x_0) where M is a smooth manifold and x_0 is a point in M.
(2) We refer to the category $\mathcal{PSmMfd}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{PSmMfd}) &:= \text{all pointed smooth manifolds,} \\ \mathrm{Mor}((M,x_0),(N,y_0)) &:= \text{all smooth maps } f \text{ from } M \text{ to } N \text{ with } f(x_0) = y_0 \end{aligned}$$

with the usual composition of maps as the category of pointed smooth manifolds.
(3) We define the category $\mathcal{PSmMfd}_{\mathbb{R}^n}$ of pointed smooth submanifolds of some $\mathbb{R}^n$ exactly the same way.

With these definitions we can rephrase (most of) the Physical Tangent Space-Functor Proposition 23.2 as follows.

Proposition 23.5. The maps

$$\begin{aligned} (M,P) &\mapsto \widetilde{\mathrm{T}}_P M \\ (f\colon (M,P) \to (N,Q)) &\mapsto (\mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_Q N) \end{aligned}$$

define a covariant functor from the category $\mathcal{PSmMfd}_{\mathbb{R}^n}$ of pointed smooth submanifolds of some $\mathbb{R}^n$ to the category $\mathcal{Vec}_{\mathbb{R}}$ of $\mathbb{R}$-vector spaces.

Note that $\mathcal{SmMfd}_{\mathbb{R}^n}$ is a full subcategory of $\mathcal{SmMfd}$ in the sense of the definition of a full subcategory on page 197. Similar $\mathcal{PSmMfd}_{\mathbb{R}^n}$ is a full subcategory of $\mathcal{PSmMfd}$. Thus the following question arises:

Question 23.6.

(1) Can we "extend" the covariant functor

$$\begin{aligned} \mathcal{PSmMfd}_{\mathbb{R}^n} &\to \mathcal{Vec}_{\mathbb{R}} \\ (M,P) &\mapsto \widetilde{\mathrm{T}}_P M \\ (f\colon (M,Q) \to (N,Q)) &\mapsto (\mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_Q N) \end{aligned}$$

to a covariant functor $\mathcal{PSmMfd} \to \mathcal{Vec}_{\mathbb{R}}$?

(2) If we can extend the covariant functor, is the extension "essentially unique"?

We will make Question 23.6 (1) more precise in the following section. There are many reasons why one should hope for a positive answer to Question 23.6 (1). For example, even if we only care about smooth submanifolds of some $\mathbb{R}^n$, very often it is convenient to work with "abstract" descriptions. For example in Torus-as-Quotient Lemma 19.34 we showed that the torus $S^1 \times S^1$ is diffeomorphic to $\mathbb{R}^2/\mathbb{Z}^2$. In many situations it is much more pleasant to work with the smooth manifold $\mathbb{R}^2/\mathbb{Z}^2$ instead of working directly with the torus $S^1 \times S^1$. The reader will thus be pleased to hear that we will give a positive answer in the Tangent Space-Isomorphism Proposition 23.16 (4).

Finally note that once we have proved the Euclidean Embedding Theorem 27.1 we will be able to provide an answer to Question 23.6 (2) in Exercise 27.1.

23.3. Tangent spaces of smooth manifolds.

In this section we introduce the notion of tangent spaces to points on general smooth manifolds. We jump right into the fray by giving the definition. We will then spend some time trying to explain why this, initially invariably confusing, definition is actually meaningful.

Definition. Let M be a smooth manifold and let $P \in M$.[245]

(1) A derivation at P is a linear map[246] $w\colon C^\infty(M,\mathbb{R}) \to \mathbb{R}$ such that for every choice of $f, g \in C^\infty(M,\mathbb{R})$ we have

$$w(f \cdot g) \;=\; f(P) \cdot w(g) + w(f) \cdot g(P) \qquad \text{“Leibniz rule”}.$$

(2) The set of all derivations at P is called the tangent space $\mathrm{T}_P M$ at P. We refer to elements of $\mathrm{T}_P M$, i.e. we refer to derivations at P, also as tangent vectors. Sometimes, especially when we also talk about the physical tangent space $\widetilde{\mathrm{T}}_P M$, we refer to $\mathrm{T}_P M$ also the abstract tangent space at P.

Lemma 23.7. Let M be a smooth manifold. For every $P \in M$ the tangent space $\mathrm{T}_P M$ is a vector subspace of the vector space of linear maps $C^\infty(M,\mathbb{R}) \to \mathbb{R}$.

Proof. Let v, w be two derivations at P. We need to show that $v + w$ is also a derivation at P. Thus let $f, g \in C^\infty(M,\mathbb{R})$. We perform the following calculation:

$$\begin{aligned}(v+w)(f\cdot g) \;=\; v(f\cdot g) + w(f\cdot g) \;&=\; f(P)\cdot v(g) + v(f)\cdot g(P) + f(P)\cdot w(g) + w(f)\cdot g(P)\\ &=\; f(P)\cdot(v(g)+w(g)) + (v(f)+w(f))\cdot g(P)\\ &=\; f(P)\cdot(v+w)(g) + (v+w)(f)\cdot g(P).\end{aligned}$$

An even easier argument shows that if $\lambda \in \mathbb{R}$, then $\lambda \cdot v$ is also a derivation at P. Finally note that evidently the zero homomorphism is a derivation. ∎

Lemma 23.8. Let M be a smooth manifold, let $P \in M$ and let $w \in \mathrm{T}_P M$.

(1) If $f\colon M \to \mathbb{R}$ is a constant map, then $w(f) = 0$.
(2) Let $f, g \in C^\infty(M,\mathbb{R})$. If $f(P) = g(P) = 0$, then $w(f \cdot g) = 0$.
(3) Let $f, g \in C^\infty(M,\mathbb{R})$. If there exists some open neighborhood U of P such that $f|_U = g|_U$, then $w(f) = w(g)$.

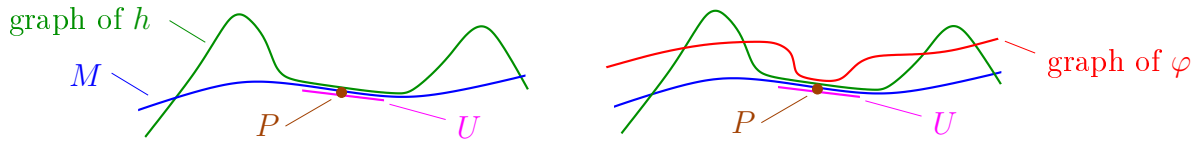
Proof.

(1) Let $f\colon M \to \mathbb{R}$ be a constant map. We denote by c the map that is $= 1$ everywhere. We perform the following calculation:

$$w(f) \underset{\substack{\uparrow\\ \text{follows from } f = f(P)\cdot c,\\ \text{since } w \text{ linear}}}{=} f(P)\cdot w(c) \underset{\substack{\uparrow\\ \text{since } c = c\cdot c}}{=} f(P)\cdot w(c\cdot c) \underset{\substack{\uparrow\\ \text{Leibniz rule}}}{=} f(P)\cdot\big(\underbrace{c(P)}_{=1}\cdot w(c) + w(c)\cdot\underbrace{c(P)}_{=1}\big) = f(P)\cdot 2\cdot w(c).$$

Comparing the second and the last term we see that those terms, and hence all terms, are zero.

(2) Let $f, g \in C^\infty(M,\mathbb{R})$. If $f(P) = g(P) = 0$, then



$$w(f\cdot g) \underset{\substack{\uparrow\\ \text{by definition of a derivation}}}{=} f(P)\cdot w(g) + w(f)\cdot g(P) \;=\; 0\cdot w(g) + w(f)\cdot 0 \;=\; 0.$$

[245] We should stress that we allow P to be in the boundary of M.
[246] Recall that according to the definition on page 546 we denote by $C^\infty(M,\mathbb{R})$ the vector space of all smooth maps $M \to \mathbb{R}$.

(3) Let $f, g \in C^\infty(M, \mathbb{R})$. We suppose that there exists some open neighborhood U of P such that $f|_U = g|_U$. We set $h := f - g$. Note that h vanishes on U. Using the Smooth Transition Function Lemma 19.4 one can easily show that there exists a smooth map $\varphi\colon M \to \mathbb{R}$ which is $\equiv 1$ on $M \setminus U$ and which satisfies $\varphi(P) = 0$. We see that

$$w(f) - w(g) \underset{\substack{\uparrow \\ \text{since } w \text{ linear}}}{=} w(h) \underset{\substack{\uparrow \\ \text{since } h = h\cdot\varphi}}{=} w(h \cdot \varphi) \underset{\substack{\uparrow \\ \text{by (2) since } h(P)=\varphi(P)=0}}{=} 0.$$

■

This definition of a tangent space might sound rather odd, but the following proposition should help in getting some intuition for the definition.

Proposition 23.9. Let M be an open subset of $\mathbb{R}^n$. For any $P \in M$ the map

$$\begin{aligned} \Xi_P\colon \mathbb{R}^n &\to \mathrm{T}_P M \\ v &\mapsto \Big(\begin{aligned} C^\infty(M,\mathbb{R}) &\to \mathbb{R} \\ f &\mapsto \underbrace{\tfrac{d}{dt}\big|_{t=0} f(P + t\cdot v))}_{= \mathrm{D}f_P \cdot v \text{ by the Chain Rule 19.10}} \end{aligned} \Big) \end{aligned}$$

is an isomorphism of vector spaces.

Proof. Let M be an open subset of $\mathbb{R}^n$ and let $P = (P_1, \ldots, P_n) \in M$. Our first claim implies that Ξ_P actually takes values in $\mathrm{T}_P M$.

Claim. For every $v \in \mathbb{R}^n$ the map

$$\begin{aligned} C^\infty(M,\mathbb{R}) &\to \mathbb{R} \\ f &\mapsto \mathrm{D}f_P \cdot v \end{aligned}$$

is a derivation.

Proof. It is clear that the map is linear in f. So it remains to show that it satisfies the Leibniz rule. Let $f, g \in C^\infty(M, \mathbb{R})$. Note that the map $f \cdot g$ equals the following composition of maps:

$$M \xrightarrow[=:d]{x \mapsto (x,y)} M \times M \xrightarrow{f \times g} \mathbb{R} \times \mathbb{R} = \mathbb{R}^2 \xrightarrow[=:m]{(x,y)\mapsto x\cdot y} \mathbb{R}.$$

We see that

$$\begin{aligned} \mathrm{D}(f\cdot g)_P \cdot v &= \mathrm{D}(m \circ (f \times g) \circ d)_P \cdot v \overset{\text{Chain Rule 19.10}}{=} \mathrm{D}m_{(f(P),g(P))} \cdot (\mathrm{D}(f \times g)_{P\times P} \cdot \mathrm{D}d_P) \cdot v \\ &= (g(P)\ f(P)) \begin{pmatrix} \mathrm{D}f_P & 0 \\ 0 & \mathrm{D}g_P \end{pmatrix} \cdot \begin{pmatrix} 1 \\ 1 \end{pmatrix} \cdot v = g(P)\cdot \mathrm{D}f_P \cdot v + f(P) \cdot \mathrm{D}g_P \cdot v. \end{aligned}$$

We have thus successfully verified that the Leibniz rule holds. ⊞

It is clear that the map $\Xi_P\colon \mathbb{R}^n \to \mathrm{T}_P M$ given by $v \mapsto \mathrm{D}f_P \cdot v$ is linear. Thus it remains to show that Ξ_P is injective and surjective. Before we continue we introduce one piece of notation, namely given $i \in \{1, \ldots, n\}$ we denote by $c_i\colon M \to \mathbb{R}$ the map given by $(x_1, \ldots, x_n) \mapsto x_i$.

Claim. The map $\Xi_P\colon \mathbb{R}^n \to \mathrm{T}_P M$ is injective.

Proof. Let $v = (v_1, \dots, v_n) \in \mathbb{R}^n$ with $\Xi_P(v) = 0$. Given any $i \in \{1, \dots, n\}$ we see that

$$0 \;=\; \Xi_P(v)(c_i) \;=\; \tfrac{d}{d}\big|_{t=0}\, c_i(P + t\cdot v) \;\underset{\text{definition of } c_i}{\overset{\uparrow}{=}}\; \tfrac{d}{dt}\big|_{t=0}\,(P_i + t\cdot v_i) \;=\; v_i.$$

We have now shown that $v = (0, \dots, 0) = 0 \in \mathbb{R}^n$. ⊞

Claim. The map $\Xi_P\colon \mathbb{R}^n \to \mathrm{T}_P M$ is surjective.

Proof. Let $w \in \mathrm{T}_P M$. We set $v_i := w(c_i) \in \mathbb{R}$ and we set $v := (v_1, \dots, v_n) \in \mathbb{R}^n$. We claim that $\Xi_P(v) = w$. Let $f \in C^\infty(M, \mathbb{R})$. By Taylor's Theorem 19.7 we have

$$f(x) \;=\; f(P) + \sum_{i=1}^{n} \frac{\partial f}{\partial x_i}\big|_P \cdot (c_i - P_i) + \underbrace{\sum_{i=1}^{n}\sum_{j=1}^{n} (c_i - P_i)(c_j - P_j)\cdot \int_0^1 (1-t)\frac{\partial^2}{\partial x_i \partial x_j}\big|_{P+t(x-P)} dt}_{\text{it follows from Lemma 23.8 (2) that } w(\dots) = 0}.$$

Finally we see that we have the following equalities:

$$w(f) \;\underset{\text{above observation}}{\overset{\uparrow}{=}}\; \overbrace{w(f(P))}^{=0 \text{ by Lemma 23.8}} + w\Big(\sum_{i=1}^{n} \frac{\partial f}{\partial x_i}\big|_P \cdot (c_i - P_i)\Big) \;\underset{\text{linearity of } w}{\overset{\uparrow}{=}}\; \sum_{i=1}^{n} \frac{\partial f}{\partial x_i}\big|_P \cdot (\underbrace{w(c_i)}_{=v_i} - \underbrace{w(P_i)}_{=0}) \;\underset{\text{Chain Rule 19.10}}{\overset{\uparrow}{=}}\; \Xi_P(v).$$

■

The following proposition summarizes some basic properties of the tangent space. It can be viewed as an analogue of the Physical Tangent Space-Functor Proposition 23.2 (1) and (2) and of Proposition 23.5.

Proposition 23.10. (Tangent Space-Functor Proposition) Let M and N be two smooth manifolds.

(1) If $f\colon M \to N$ is a smooth map, then for every $P \in M$ the map

$$\begin{array}{rcl} \mathrm{D}f_P\colon \mathrm{T}_P M & \to & \mathrm{T}_{f(P)} N \\ v & \mapsto & \left(\begin{array}{rcl} C^\infty(N, \mathbb{R}) & \to & \mathbb{R} \\ g & \mapsto & v(g \circ f) \end{array}\right) \end{array}$$

is well-defined and linear.

(2) The maps from (1) have the following two properties:

(a) If $\mathrm{id}\colon M \to M$ is the identity map, then for any $P \in M$ the differential $\mathrm{D}\,\mathrm{id}_P\colon \mathrm{T}_P M \to \mathrm{T}_P M$ is also the identity.

(b) For any two smooth maps $f\colon L \to M$ and $g\colon M \to N$ between smooth manifolds and any $P \in L$ we have

$$\mathrm{D}(g \circ f)_P \;=\; \mathrm{D}g_{f(P))} \circ \mathrm{D}f_P\colon \mathrm{T}_P L \;\to\; \mathrm{T}_{g(f(P)} N \qquad \text{“Chain Rule”}.$$

(3) The maps

$$\begin{array}{rcl} (M, P) & \mapsto & \mathrm{T}_P M \\ (f\colon (M, Q) \to (N, Q)) & \mapsto & (\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_Q N) \end{array}$$

define a covariant functor from the category $\mathcal{PSmMfd}$ of pointed smooth manifolds to the category $\mathcal{Vec}_{\mathbb{R}}$ of $\mathbb{R}$-vector spaces.

Definition. Given a smooth map $f\colon M \to N$ between two smooth manifolds and given $P \in M$ we refer to the map

$$\begin{array}{rccl} \mathrm{D}f_P\colon & \mathrm{T}_P M & \to & \mathrm{T}_{f(P)}N \\ & v & \mapsto & (g \mapsto v(g \circ f)) \end{array}$$

from the Tangent Space-Functor Proposition 23.10 (1) as the differential of f at P.

Proof.

(1) The only statement one needs to think about for a second is, why does $\mathrm{D}f_P$ take values in $\mathrm{T}_{f(P)}N$? Thus let $v \in \mathrm{T}_P M$. We need to show that $g \mapsto v(g \circ f)$ is indeed a derivation. Now let $g, h \in C^\infty(N, \mathbb{R})$. We perform the following little calculation:

$$v((g \cdot h) \circ f) \;=\; v((g \circ f) \cdot (h \circ f)) \;=\; (g \circ f)(P) \cdot v(h \circ f) + v(g \circ f) \cdot (h \circ f)(P).$$

We have thus verified that the Leibniz rule is satisfied.

(2) This statement follows follow almost immediately from the definitions.

(3) This statement just summarizes the contents of (1) and (2) and of Lemma 23.7. ■

Example. Let M and N be two smooth manifolds. If $f\colon M \to N$ is a constant map, then it follows from Lemma 23.8 that for each $P \in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is actually the zero homomorphism.

The following proposition is the analogue of the Physical Tangent Space-Functor Proposition 23.2 (0).

Proposition 23.11. (Tangent Space-Dimension Proposition) If M is an n-dimensional smooth manifold, then for every $P \in M$ the corresponding tangent space $\mathrm{T}_P M$ is an n-dimensional vector subspace of the vector space $\mathrm{Hom}(C^\infty(M, \mathbb{R}), \mathbb{R})$.

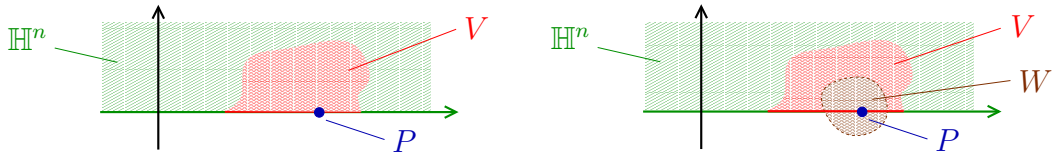
The proof of the Tangent Space-Dimension Proposition 23.11 relies on the following two lemmas.

Lemma 23.12. Let M be a smooth manifold and let $U \subset M$ be an open subset U. We denote by $\iota\colon U \to M$ the inclusion. For every $P \in U$ the map $\mathrm{D}\iota_P\colon \mathrm{T}_P U \to \mathrm{T}_P M$ is an isomorphism.

Proof. The lemma follows, with a little bit of thought, from Lemma 23.8 (3). We will fill in the details in Exercise 23.5. ■

Lemma 23.13. Let $n \in \mathbb{N}$ and let $V \subset \mathbb{H}^n$ be an open subset. We denote by $\iota\colon V \to \mathbb{R}^n$ the inclusion. For every $P \in \partial V$ the map $\mathrm{D}\iota_P\colon \mathrm{T}_P V \to \mathrm{T}_P \mathbb{R}^n$ is an isomorphism.

Proof. Let $P \in \partial V$. First we show that the map $\mathrm{D}\iota_P\colon \mathrm{T}_P V \to \mathrm{T}_P \mathbb{R}^n$ is injective. Thus let $w \in \mathrm{T}_P V$ with $\mathrm{D}\iota_P(w) = 0$. We need to show that $w(f) = 0$ for every smooth map $f\colon V \to \mathbb{R}$. Thus let $f\colon V \to \mathbb{R}$ be a smooth map. By definition of a smooth map on $\mathbb{H}^n$, seepage 532, there exists an open neighborhood $W \subset \mathbb{R}^n$ of P and a smooth map $g\colon W \to \mathbb{R}$ with $f|_{V \cap W} = g|_{V \cap W}$. By Exercise 19.18, applied to g, there exists furthermore an open neighborhood X of P and a smooth map $h\colon \mathbb{R}^n \to \mathbb{R}$ such that $h|_{W \cap X} = g|_{W \cap X}$.



We calculate

$$w(f) \underset{\substack{\uparrow\\ \text{by Lemma 23.8 (3), since}\\ f \text{ and } h|_W \text{ agree on } W\cap X}}{=} w(h|_W) = w(h\circ\iota) \underset{\substack{\uparrow\\ \text{by definition of } \mathrm{D}\iota_P(w)}}{=} (\mathrm{D}\iota_P(w))(h) = 0.$$

It remains to show that $\mathrm{D}\iota_P\colon \mathrm{T}_P W \to \mathrm{T}_P\mathbb{R}^n$ is surjective. For $i=1,\dots,n$ we write

$$\begin{aligned} C^\infty(W,\mathbb{R}) &\xrightarrow{v_i} \mathbb{R} \\ f &\mapsto \lim_{h\to 0^+} \tfrac{1}{h}\cdot(f(\underbrace{P+h\cdot e_i}_{\in W \text{ for small } h>0}) - f(P)) \end{aligned} \quad \& \quad \begin{aligned} C^\infty(\mathbb{R}^n,\mathbb{R}) &\xrightarrow{w_i} \mathbb{R} \\ f &\mapsto \underbrace{\lim_{h\to 0} \tfrac{1}{h}\cdot(f(P+h\cdot e_i) - f(P))}_{=\frac{\partial}{\partial x_i}|_P}. \end{aligned}$$

One can easily verify that $v_1,\dots,v_n$ are derivations. Evidently we have $(\mathrm{D}\iota_P)(v_i) = w_i$. By Proposition 23.9 we know that $w_1,\dots,w_n$ form a basis for $\mathrm{T}_P\mathbb{R}^n$. We have thus shown that $\mathrm{D}\iota_P$ is a surjection. ∎

Proof of the Tangent Space-Dimension Proposition 23.11. Let M be an n-dimensional smooth manifold. Furthermore let $P\in M$. First we consider the case that $P\notin \partial M$. Thus we can pick a chart $\Phi\colon U\to V$ of type (i) where V is an open subset of $\mathbb{R}^n$. We denote by $i\colon U\to M$ the inclusion map. We have the following isomorphisms:

$$\mathrm{T}_P M \xleftarrow[\substack{\uparrow\\ \text{isomorphism by}\\ \text{Lemma 23.12}}]{\mathrm{D}i_P} \mathrm{T}_P U \xrightarrow[\substack{\uparrow\\ \text{by the Tangent Space-Functor}\\ \text{Proposition 23.10 this is an isomorphism}\\ \text{with inverse given by } \mathrm{D}(\Phi^{-1})_{\Phi(P)}}]{\mathrm{D}\Phi_P} \mathrm{T}_{\Phi(P)}V \xrightarrow[\substack{\uparrow\\ \text{isomorphism given by}\\ \text{Proposition 23.9}}]{\cong} \mathbb{R}^n.$$

Now suppose that $P\in\partial M$. This means that there exists a chart $\Phi\colon U\to V$ of type (ii) where V is an open subset of $\mathbb{H}^n$ and $\Phi(P)\in\partial\mathbb{H}^n$. We denote by $j\colon V\to\mathbb{R}^n$ the inclusion map. In this setting we have the following isomorphisms:

$$\mathrm{T}_P M \xleftarrow[\substack{\uparrow\\ \text{isomorphism by}\\ \text{Lemma 23.12}}]{\mathrm{D}i_P} \mathrm{T}_P U \xrightarrow[\substack{\uparrow\\ \text{by the Tangent Space-Functor}\\ \text{Proposition 23.10 this is an}\\ \text{isomorphism with inverse given}\\ \text{by } \mathrm{D}(\Phi^{-1})_{\Phi(P)}}]{\mathrm{D}\Phi_P} \mathrm{T}_{\Phi(P)}V \xrightarrow[\substack{\uparrow\\ \text{isomorphism}\\ \text{given by}\\ \text{Lemma 23.13}}]{\mathrm{D}j_P} \mathrm{T}_{\Phi(P)}\mathbb{R}^n \xrightarrow[\substack{\uparrow\\ \text{isomorphism given by}\\ \text{Proposition 23.9}}]{\cong} \mathbb{R}^n.$$

∎

The following proposition is the analogue of the Physical Tangent Space-Inclusion Proposition 23.3.

Proposition 23.14. Let M be a smooth manifold.

(1) Let W be a submanifold of M (e.g. W could be an open subset of M) and let $P\in W$. We denote by $i\colon W\to N$ the inclusion.
   (a) The differential $\mathrm{D}i_P\colon \mathrm{T}_P W\to \mathrm{T}_P M$ is a monomorphism.

(b) If W is of codimension-zero, then the differential $\mathrm{D}i_P\colon \mathrm{T}_P W \to \mathrm{T}_P M$ is an isomorphism.

(2) We denote by $i\colon \partial M \to M$ the inclusion. The differential $\mathrm{D}i_P\colon \mathrm{T}_P \partial M \to \mathrm{T}_P M$ is a monomorphism.

(3) Let N be a smooth manifold. If $f\colon M \to N$ is a local diffeomorphism, then for every $P \in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ is an isomorphism.

Convention. Let M be a smooth manifold. Since it is notationally dreadful to carry around inessential information we will usually use the following two conventions.

(1) Let W be a submanifold of M. We denote by $i\colon W \to M$ the inclusion map. By the Physical Tangent Space-Inclusion Proposition 23.14 we know that the map $\mathrm{D}i_P\colon \mathrm{T}_P W \to \mathrm{T}_P M$ is a monomorphism. On many occasions we will just identify $\mathrm{T}_P W$ with its image under $\mathrm{D}i_P$ in $\mathrm{T}_P M$. In particular we will view $\mathrm{T}_P W$ as a vector subspace of $\mathrm{T}_P M$.

(2) Let $P \in \partial M$. By the same logic as in (1) we will view $\mathrm{T}_P \partial M$ as a vector subspace of $\mathrm{T}_P M$.

This convention brings us in line with corresponding situation for physical tangent spaces as described in the Physical Tangent Space-Inclusion Proposition 23.3 (1) and (2).

Proof. Let M be an n-dimensional smooth manifold.

(1) (a) Let W be a k-dimensional submanifold of M and let $P \in W$. In the following we deal with the case that P admits a submanifold chart of type (α) in the sense of the definition on page 550. Using Lemma 23.13 the other cases are treated in a similar fashion. Thus let $\Phi\colon U \to V$ be a submanifold chart of type (α). We write $H = \{0\} \times \mathbb{R}^k \subset \mathbb{R}^n$ and $Q = \Phi(P) \in H$. We denote by $\iota\colon H \to \mathbb{R}^n$ the inclusion and we denote by $\pi\colon \mathbb{R}^n \to H$ the projection that is given by $(x, y) \mapsto (0, y)$. We consider the following diagram:

$$\begin{array}{ccccccc}
\mathrm{T}_P W & \longleftarrow & \mathrm{T}_P(W \cap U) & \xrightarrow{\mathrm{D}(\Phi|_{W\cap U})_P} & \mathrm{T}_Q(V \cap H) & \longrightarrow & \mathrm{T}_Q H \\
\downarrow{\scriptstyle \mathrm{D}i_P} & & \downarrow & & \downarrow & & \downarrow{\scriptstyle \mathrm{D}\iota_Q} \quad \circlearrowleft\ {\scriptstyle \mathrm{D}\pi_Q} \\
\mathrm{T}_P M & \longleftarrow & \mathrm{T}_P U & \xrightarrow{\mathrm{D}\Phi_P} & \mathrm{T}_Q V & \longrightarrow & \mathrm{T}_Q \mathbb{R}^n.
\end{array}$$

We make the following clarifications and observations:

- All maps that are not given explicitly are the differentials of the obvious inclusion maps.
- It follows from the Tangent Space-Functor Proposition 23.10 (2) that the diagram commutes.
- It follows from Lemma 23.12 that the horizontal maps to the left and to the right are isomorphisms.
- Since Φ and also $\Phi|_{W\cap U}$ are diffeomorphisms we obtain from from the Tangent Space-Functor Proposition 23.10 that the middle horizontal maps are isomorphisms.
- Note that $\pi \circ \iota\colon H \to H$ is the identity. It follows from the Tangent Space-Functor Proposition 23.10 (2) that $\mathrm{D}\pi_Q \circ \mathrm{D}\iota_Q = \mathrm{D}(\pi \circ \iota)_Q = \mathrm{D}\,\mathrm{id}_Q = \mathrm{id}$. Thus we see that $\mathrm{D}\iota_Q$ is a monomorphism.

The combination of the above shows that in fact all vertical maps are monomorphisms.

(b) This statement follows immediately from (a) and the fact, which we just proved in the Tangent Space-Dimension Proposition 23.11, that $\mathrm{T}_P W$ and $\mathrm{T}_P M$ have the same dimension.

(2) The proof of this statement is very similar to the proof of Statement (1). We leave it to the reader to fill in the details.

(3) The proof of this statement is basically identical to the proof of the analogous statement in the Physical Tangent Space-Inclusion Proposition 23.3, all we have to is to replace the Physical Tangent Space-Functor Proposition 23.2 (2) by the Tangent Space-Functor Proposition 23.10 (2). Again we leave it to the reader to fill in the details. ■

We conclude this section with a short discussion of outward and inward pointing tangent vectors. These notions are the analogues of the notions we introduced on page 620.

Definition. Let M be a smooth manifold and let $P \in \partial M$. We say a tangent vector $w \in \mathrm{T}_P M$ points outward, if the following two conditions are satisfied:

(1) For every smooth map $f\colon M \to \mathbb{R}_{\geq 0}$ with $f|_{\partial M} \equiv 0$ we have $w(f) \geq 0$.

(2) There exists a smooth map $f\colon M \to \mathbb{R}_{\geq 0}$ with $f|_{\partial M} \equiv 0$ such that $w(f) > 0$.

By replacing "$\geq$" and "$>$" by "$\leq$" and "$<$" we obtain the notion of an inward pointing tangent vector.

The following lemma says that for a point $P \in \partial M$ there is a trichotomy for the tangent vectors in $\mathrm{T}_P M$.

Lemma 23.15. Let M be a smooth manifold, let $P \in \partial M$ and let $w \in \mathrm{T}_P M$. Precisely one of the following three statements holds:

(1) w points outward,

(2) w points inward,

(3) $w \in \mathrm{D}\iota_P(\mathrm{T}_P\, \partial M \to \mathrm{T}_P M)$, where $\iota\colon \partial M \to M$ is the inclusion map.

Proof. We will prove the lemma in Exercise 23.7. ■

23.4. **The relationship between the definitions of tangent spaces.** Given a k-dimensional smooth submanifold M of some $\mathbb{R}^m$ and given $P \in M$ we have now introduced two notions of tangent spaces. On page 620 we introduced the physical tangent space $\widetilde{\mathrm{T}}_P M$, which is a k-dimensional vector subspace of $\mathbb{R}^m$. Later, on page 628 we introduced the tangent space $\mathrm{T}_P M$ in a significantly more abstract way.

The next proposition elucidates the relationship between the physical tangent space $\widetilde{\mathrm{T}}_P M$ and the tangent space $\mathrm{T}_P M$.

Proposition 23.16. (Tangent Space-Isomorphism Proposition)

(1) Let M be a k-dimensional submanifold of $\mathbb{R}^m$ and let $P \in M$. The map

$$\begin{array}{rcl} \Theta_M \colon \widetilde{\mathrm{T}}_P M & \to & \mathrm{T}_P M \\ v & \mapsto & \left(\begin{array}{rcl} C^\infty(M,\mathbb{R}) & \to & \mathbb{R} \\ g & \mapsto & \underset{\uparrow}{\mathrm{D}g_P(v)} \end{array} \right) \end{array}$$

where $\mathrm{D}g_P \colon \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_{g(P)}\mathbb{R} = \mathbb{R}$

is well-defined and it is an isomorphism of vector spaces.

(2) Let M be a k-dimensional submanifold of $\mathbb{R}^m$. For $P \in \partial M$ the isomorphism Θ_M restricts to a bijection between outward tangent vectors in $\widetilde{\mathrm{T}}_P M$ (as defined on page 620) and outward tangent vectors in $\mathrm{T}_P M$ (as defined on page 634). The same statement also holds with "outward" replaced by "inward".

(3) If $f \colon M \to N$ is a smooth map between submanifolds of $\mathbb{R}^m$ respectively $\mathbb{R}^n$, then the following diagram commutes

$$\begin{array}{ccc} \widetilde{\mathrm{T}}_P M & \xrightarrow{\Theta_M} & \mathrm{T}_P M \\ {\scriptstyle \mathrm{D}f_P}\downarrow & & \downarrow{\scriptstyle \mathrm{D}f_P} \\ \widetilde{\mathrm{T}}_{f(P)} N & \xrightarrow{\Theta_N} & \mathrm{T}_{f(P)} N. \end{array}$$

Here to the left we consider the differential as defined on page page 623 and to the right we consider the differential as defined on page 631.

(4) The maps Θ_M defined in (1) give a natural isomorphism, in the sense of the definition on page 203, between the covariant functors

$$\begin{array}{rcl} \mathcal{PSmMfd}_{\mathbb{R}^n} & \to & \mathcal{Vec}_{\mathbb{R}} \\ (M,P) & \mapsto & \widetilde{\mathrm{T}}_P M \\ f & \mapsto & \mathrm{D}f_P \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \mathcal{PSmMfd}_{\mathbb{R}^n} & \to & \mathcal{Vec}_{\mathbb{R}} \\ (M,P) & \mapsto & \mathrm{T}_P M \\ f & \mapsto & \mathrm{D}f_P \end{array}$$

which we introduced in Propositions 23.5 and 23.10.

Remark.

(1) The Tangent Space-Isomorphism Proposition 23.16 (4) gives an affirmative answer to Question 23.6 (1).

(2) What matters in the end is that we managed to define a functor $(M,P) \to \mathrm{T}_P M$ that satisfies the Tangent Space-Isomorphism Proposition 23.16. The actual definition of $\mathrm{T}_P M$ is in the following utterly irrelevant. In fact in Section 23.5 we will sketch a different construction of such a functor, but at the end the actual definition of $\mathrm{T}_P M$ never gets used.

Proof. We prove the three statements in a different order than formulated.

(3) Let $f \colon M \to N$ be a smooth map between submanifolds of $\mathbb{R}^m$ respectively $\mathbb{R}^n$. Furthermore let $v \in \widetilde{\mathrm{T}}_P M$ and let $g \in C^\infty(N,\mathbb{R})$. We see that

$$(\mathrm{D}f_P \circ \Theta_M)(v)(g) \;=\; \mathrm{D}(g \circ f)_P(v) \;\underset{\uparrow}{=}\; (\mathrm{D}g_{f(P)} \circ \mathrm{D}f_P)(v) \;=\; (\Theta_N \circ \mathrm{D}f_P)(v)(g).$$

chain rule of the Physical Tangent Space-Functor Proposition 23.2 (2)

(1) As in the proof of Proposition 23.9 we see that Θ_M is well-defined in the sense that for any $v \in \widetilde{\mathrm{T}}_P M$ the map $C^\infty(M,\mathbb{R}) \to \mathbb{R}$ given by $g \mapsto \mathrm{D}g_P(v)$ is indeed a derivation.

It remains to show that the maps Θ_M are isomorphisms. Let M be a k-dimensional smooth submanifold of $\mathbb{R}^m$ and let $P \in M$. As always we use the Submanifold Smooth Structure Lemma 19.24 to view M as a smooth manifold in its own right. We pick a corresponding chart $\Phi\colon U \to V$ around P. We write $Q = \Phi(P)$. We denote by $i\colon U \to M$ and $j\colon V \to \mathbb{R}^k$ the inclusion maps. We consider the following diagram

$$\begin{array}{ccccccc}
\widetilde{\mathrm{T}}_P M & \xleftarrow{\mathrm{D}i_P} & \widetilde{\mathrm{T}}_P U & \xrightarrow{\mathrm{D}\Phi_P} & \widetilde{\mathrm{T}}_Q V & \xrightarrow{\mathrm{D}j_Q} & \widetilde{\mathrm{T}}_Q \mathbb{R}^k \\
\downarrow{\scriptstyle \Theta_M} & & \downarrow{\scriptstyle \Theta_U} & & \downarrow{\scriptstyle \Theta_V} & & \downarrow{\scriptstyle \Theta_{\mathbb{R}^k}} \\
\mathrm{T}_P M & \xleftarrow{\mathrm{D}i_P} & \mathrm{T}_P U & \xrightarrow{\mathrm{D}\Phi_P} & \mathrm{T}_Q V & \xrightarrow{\mathrm{D}j_Q} & \mathrm{T}_Q \mathbb{R}^k.
\end{array}$$

We make the following observations:

- It follows from (3) that the diagram commutes.
- It follows from Propositions 23.3 and 23.14 that the left and right horizontal maps are isomorphisms.
- Since Φ is a diffeomorphism we obtain from Propositions 23.2 and 23.10 that the middle horizontal maps are isomorphisms.
- By Proposition 23.9 we know that the right vertical map is an isomorphism.

The combination of the above shows that the left vertical map is indeed an isomorphism.

(2) Let M be a k-dimensional submanifold of $\mathbb{R}^m$ and let $P \in \partial M$. Let $v \in \mathrm{T}_P M$ be a vector that points outward. Recall that this means that $v = \gamma'(0)$ where $\gamma\colon (-\epsilon, 0] \to M$ is a smooth map with $\gamma(0) = P$ but with $\gamma'(0) \notin \widetilde{\mathrm{T}}_P(\partial M)$. Let $g\colon M \to \mathbb{R}_{\geq 0}$ be a smooth map with $g|_{\partial M} \equiv 0$. We obtain that

$$(\Theta_M)(v)(g) \;=\; \mathrm{D}g_P(v) \;=\; \mathrm{D}g_P(\gamma'(0)) \underset{\substack{\uparrow \\ \text{Chain Rule 23.2 (2)}}}{=} (g \circ \gamma)'(0) \underset{\substack{\uparrow \\ \text{since } (g\circ\gamma)(t)\geq 0 \text{ for } t\leq 0 \\ \text{and } (g\circ\gamma)(0) = 0}}{\leq} 0.$$

Furthermore, note that using charts it is not difficult to construct a smooth map $g\colon M \to \mathbb{R}_{\geq 0}$ with $g|_{\partial M} \equiv 0$ and with $(\Theta_M)(v)(g) > 0$. This shows that $\Theta_M(v)$ does indeed point outward. The converse can also be proved by considering charts. We leave it to the reader to fill in the details.

(4) This statement follows immediately from (1) and (3), and the definition of a natural isomorphism, see page 203. ■

the Tangent Space-Isomorphism Proposition 23.16 allows us to go back and forth between the two flavors of tangent spaces for a smooth submanifold of some $\mathbb{R}^k$. This leads us to the following convention.

Convention. Given a submanifold M of some $\mathbb{R}^k$ and $P \in M$ we will often, especially in the later chapters, use the natural isomorphism from the Tangent Space-Isomorphism Proposition 23.16 to make the identification $\widetilde{\mathrm{T}}_P M = \mathrm{T}_P M$.

As a special case we have the following convention.

Example. Let M be an open subset M of $\mathbb{R}^n$ or of $\mathbb{H}^n$ and let $P \in M$. The above convention says that at times we make the identification

$$\begin{array}{ccccc} \mathbb{R}^n & = & \widetilde{\mathrm{T}}_P M & = & \mathrm{T}_P M. \\ & \uparrow & & \uparrow & \\ & \text{Lemma 23.1} & & \text{identified via the natural isomorphism} & \\ & & & \text{provided by the Tangent Space-Isomorphism Proposition 23.16} & \end{array}$$

Going through the definitions one sees easily that this isomorphism $\mathbb{R}^n \to \mathrm{T}_P M$ is precisely the isomorphism provided by Proposition 23.9.

Definition. Let $I \subset \mathbb{R}$ be an open subset, let M be a smooth manifold and let $f\colon I \to M$ be a smooth map. Given any $t \in I$ we write

$$f'(t) \;:=\; \mathrm{D}f_t(\text{tangent vector } 1 \in \mathrm{T}_t\mathbb{R} = \widetilde{\mathrm{T}}_t\mathbb{R} = \mathbb{R}) \;\in\; \mathrm{T}_{f(t)}M.$$

Remark. If M is a smooth submanifold of some $\mathbb{R}^n$, then under above the identification $\widetilde{\mathrm{T}}_P M = \mathrm{T}_P M$ one sees that the above definition of $f'(t) \in \mathrm{T}_{f(t)}M = \widetilde{\mathrm{T}}_{f(t)}M \subset \mathbb{R}^n$ agrees with the definition on page 533.

23.5. **Alternative construction of tangent spaces.** In this short section we present an alternative approach to answering Question 23.6 (1). To simplify the discussion we will only work with smooth manifolds with empty boundary. Therefore we introduce the following notation.

Notation. We write:

$$\begin{array}{rcl} \mathcal{SmMfd}_{\partial=\varnothing} & := & \text{category of smooth manifolds without boundary,} \\ \mathcal{PSmMfd}_{\partial=\varnothing} & := & \text{category of pointed smooth manifolds without boundary.} \end{array}$$

Similarly we define the analogues where we only consider smooth submanifolds without boundary of some $\mathbb{R}^n$.

Definition.

(1) Let M be a smooth manifold and let $P \in M$. Let us consider

$$\widehat{\mathrm{T}}_P M \;:=\; \{\text{all smooth maps } \gamma\colon (-\epsilon,\epsilon) \to M \text{ with } \gamma(0) = P\}/\!\sim$$

where we define

$$\alpha \sim \beta \quad\Longleftrightarrow\quad \begin{array}{c} \text{there exists a chart } \Phi\colon U \to V \text{ and an } \eta > 0 \text{ with} \\ (\Phi \circ \alpha|_{(-\eta,\eta)})'(0) \;=\; (\Phi \circ \beta|_{(-\eta,\eta)})'(0) \;\in\; \mathbb{R}^n. \end{array}$$

(2) If $f\colon M \to N$ is a smooth map between two smooth manifolds without boundary, then for any $P \in M$ we define

$$\begin{array}{rcl} \mathrm{D}f_P\colon \widehat{\mathrm{T}}_P M & \to & \widehat{\mathrm{T}}_{f(P)} N \\ [\alpha] & \mapsto & [f \circ \alpha]. \end{array}$$

It is not that difficult to show that $\widehat{\mathrm{T}}_P M$ and $\mathrm{D}f_P$ have the same formal properties as the tangent spaces $\mathrm{T}_P M$ and the differentials $\mathrm{D}f_P$, in the sense that the fairly obvious analogues of Propositions 23.10, 23.11 and 23.14 hold. In particular we see that the maps

$$\begin{array}{rcl} (M, P) & \mapsto & \mathrm{T}_P M \\ (f\colon (M, Q) \to (N, Q)) & \mapsto & (\mathrm{D}f_P\colon \widehat{\mathrm{T}}_P M \to \widehat{\mathrm{T}}_Q N) \end{array}$$

define a covariant functor from the category $\mathcal{PSmMfd}_{\partial=\varnothing}$ of pointed smooth manifolds with empty boundary to the category $\mathcal{Vec}_{\mathbb{R}}$ of $\mathbb{R}$-vector spaces.

Furthermore, similar to the Tangent Space-Isomorphism Proposition 23.16 one can show that the maps

$$\begin{array}{rcl} \Theta_M \colon \widehat{\mathrm{T}}_P M & \to & \mathrm{T}_P M \\ [\gamma] & \mapsto & \left(\begin{array}{rcl} C^\infty(M,\mathbb{R}) & \to & \mathbb{R} \\ g & \mapsto & (g\circ\gamma)'(0) \end{array} \right) \end{array}$$

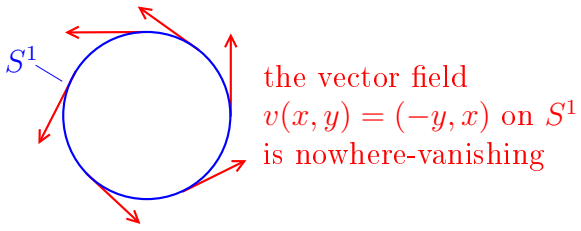
define a natural isomorphism.

Thus, at least in the absence of boundary, $\widehat{\mathrm{T}}_P M$ can be used as a replacement of $\mathrm{T}_P M$. One can also develop this theory for smooth manifolds with boundary, but as in the setting of the physical tangent space, this becomes rather messy. We refer to [**Jä93**, Chapter 3.3] and [**Nic2020**, Chapter 2] for details on $\widehat{\mathrm{T}}_P M$. We will not make use of this alternative point of view on tangent spaces of smooth manifolds. Another approach to defining the tangent space is given in [**Shah2016**, Chapter III.4.D].

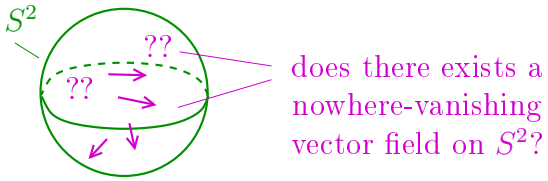
23.6. **Vector fields.** In this section we will study vector fields on smooth manifolds and we will see that often they give rise to self-maps of smooth manifolds. These notions will play a role on many occasions throughout these notes.

Definition. Let $M \subset \mathbb{R}^n$ be a submanifold.

(1) A vector field on M is a continuous map $v\colon M \to \mathbb{R}^n$ such that for every $P \in M$ we have $v(P) \in \widetilde{\mathrm{T}}_P M$.
(2) A vector field on M is called smooth, if the map $v\colon M \to \mathbb{R}^n$ is smooth.[247]
(3) Given a vector field v on M we say that $x \in M$ is a zero of v if $v(x) = 0$.



Example. Let $n \in \mathbb{N}$ and let P be a point on S^n. By Lemma 23.1 we have



$$\widetilde{\mathrm{T}}_P S^n \;=\; \{v \in \mathbb{R}^{n+1} \mid \langle P, v\rangle = 0\}.$$

For an odd-dimensional sphere S^{2k-1} a smooth vector field is given by[248]

$$\begin{array}{rcl} v\colon S^{2k-1} & \to & \mathbb{R}^{2k} \\ (x_1, x_2, \ldots, x_{2k-1}, x_{2k}) & \mapsto & (-x_2, x_1, \ldots, -x_{2k}, x_{2k-1}). \end{array}$$

This vector field has the property that it has no zeros. In the case of the 1-sphere S^1 this is just the vector field of constant length 1 that points in the "counterclockwise direction".

The following question arises:

[247] As always we view M as a smooth manifold in its own right and we use the definition of smoothness from page 546.

[248] Indeed, for any $P \in S^{2k-1}$ we have $\langle P, v(P)\rangle = 0$, i.e. $v(P)$ does indeed lie in the tangent space $\mathrm{T}_P S^{2k-1}$. It follows easily from the Restrict-to-Submanifold-or-Boundary Lemma 19.25 (1) that v is indeed smooth.

Question 23.17. Does there exist a nowhere-vanishing vector field on even-dimensional spheres?

We will answer this question with the Hairy Ball Theorem 38.12[249] or alternatively in the Euler Characteristic-Vector Field Theorem 97.15.

Now we define the notion of a vector field on any smooth manifold.

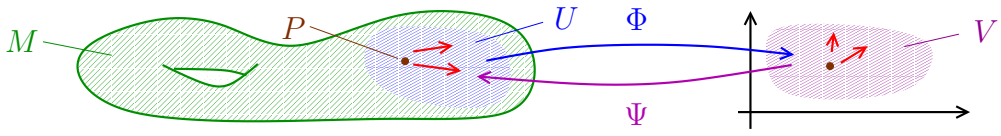
Definition. Let M be a k-dimensional smooth manifold.

(1) A vector field on M is a map

$$v\colon M \to \bigsqcup_{P\in M} \mathrm{T}_P M$$

such that for each $P \in M$ we have $v(P) \in \mathrm{T}_P M$ and such that the following continuity condition is satisfied: If $\Phi\colon U \to V$ is a chart[250] from an open set U of M to an open set V of $\mathbb{R}^k$ or of $\mathbb{H}^k$, then the following map is continuous:

$$\begin{aligned} V &\to \mathbb{R}^k \\ Q &\mapsto \big(\Theta_V^{-1} \circ \mathrm{D}\Phi_{\Psi(Q)} \circ \big(\underbrace{\mathrm{D}i_{\Psi(Q)}}_{\substack{\text{isomorphism}\\ \text{by Proposition 23.14}}} \big)^{-1} \big(\underbrace{v(\Psi(Q))}_{\in \mathrm{T}_{\Phi^{-1}(Q)}M} \big)\big) \in \widetilde{\mathrm{T}}_Q V = \mathbb{R}^k. \end{aligned}$$



Here we use the following notation:

- We denote by $\Psi := \Phi^{-1}\colon V \to U$ the inverse of Φ.
- We denote by $i\colon U \to M$ the inclusion map.
- We denote by $\Theta_V\colon \widetilde{\mathrm{T}}_P V \to \mathrm{T}_P M$ the natural isomorphism from the Tangent Space-Isomorphism Proposition 23.16.

(2) We say that the vector field v is smooth if in the definition of (1) the resulting map $V \to \mathbb{R}^k$ is always smooth.

(3) Given a vector field v on M we say that $x \in M$ is a zero of v if $v(x) = 0$.

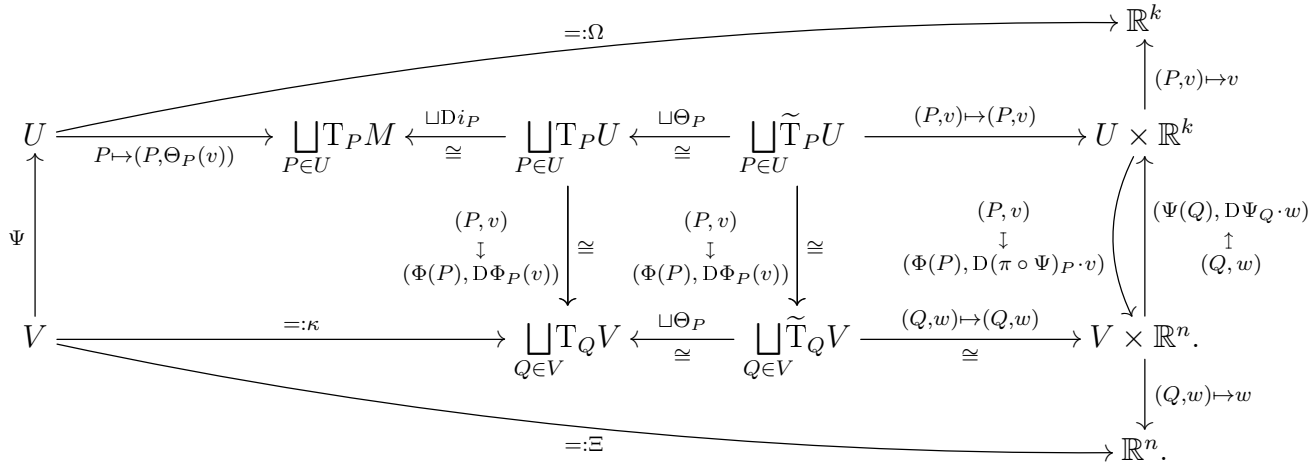
Remark. As in the Smooth-via-Atlas Lemma 19.21 one can show fairly easily that it suffices to check the condition in part (1) of the definition only for a smooth atlas and not for all charts.

On smooth submanifolds of $\mathbb{R}^n$ we now have a priori two different notions of (smooth) vector fields. The following lemma shows that these two notions are essentially the same.

Lemma 23.18. Let $M \subset \mathbb{R}^n$ be a smooth submanifold. Given $P \in M$ we denote by $\Theta_P\colon \widetilde{\mathrm{T}}_P M \to \mathrm{T}_P M$ the natural isomorphism from the Tangent Space-Isomorphism

[249] We give alternative proofs of the Hairy Ball Theorem on page 1689 and on page 2124.

[250] Recall that for a smooth manifold we mean by a "chart" a chart from the given smooth structure.



Proposition 23.16. Let $v\colon M \to \mathbb{R}^n$ be a map such that for each $P \in M$ we have $v(P) \in \widetilde{\mathrm{T}}_P M \subset \mathbb{R}^n$. The following statement holds:

(1) The map v is a vector field on M if and only if $P \mapsto \Theta_P(v)$ is a vector field on M.
(2) The map v is a smooth vector field on M if and only if $P \mapsto \Theta_P(v)$ is a smooth vector field on M.

Proof. Let $M \subset \mathbb{R}^n$ be a k-dimensional smooth submanifold. In the following we deal with (2), the proof for (1) follows exactly the same logic.

Let $\widetilde{\Phi}\colon \widetilde{U} \to \widetilde{V}$ be a submanifold chart for M. To simplify the notation we consider the case that Φ is a submanifold chart of type (α) in the sense of the definition on page 550. The other cases are treated the same way. We write $U := \widetilde{U} \cap M$ and $V := \{y \in \mathbb{R}^k \mid (0, y) \in \widetilde{V}\}$. We denote by $\iota\colon V \to \widetilde{V}$ the inclusion and we denote by $\pi\colon \mathbb{R}^k = \mathbb{R}^{n-k} \times \mathbb{R}^k \to \mathbb{R}^n$ the projection given by $(x, y) \mapsto y$. We denote by $\Phi\colon U \to V$ the diffeomorphism that is determined by the condition that $\iota \circ \Phi = \widetilde{\Phi}|_{\widetilde{U}}$.

We denote by $\Psi\colon V \to U$ the inverse of Φ and we denote by $i\colon U \to M$ the inclusion. We consider the following diagram:

We make the following clarifications and observations:

- The maps κ, Ω and Ξ are defined in such a way that the left square commutes and the top and bottom triangle commute.
- The middle square commutes by the naturality of the maps Θ.
- The right hand square commutes (in both possibilities) since $\Psi = \Phi^{-1}$ and by the chain rule.
- The two right vertical maps connecting the second and the third row are smooth since the maps $P \mapsto \mathrm{D}\Phi_P$, $P \mapsto \mathrm{D}(\pi \circ \Psi)_P$ and $Q \mapsto \mathrm{D}\Psi_Q$ are smooth.
- The question whether the vector field $P \mapsto \Theta_P(v)$ is smooth in the sense of the definition on page 639 boils down to the question whether $\Xi\colon V \to \mathbb{R}^n$ is smooth.
- Note that the naturality of the Θ maps implies that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{\mathrm{T}}_PU & \xrightarrow{\Theta} & \mathrm{T}_PU \\ {\scriptstyle \mathrm{D}i_P}\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle \mathrm{D}i_P} \\ \widetilde{\mathrm{T}}_PM & \xrightarrow{\Theta} & \mathrm{T}_PM. \end{array}$$

If one goes through the definitions, and one uses the above observation, then one sees that the map Ω is precisely the map $P \mapsto v(P)$. Thus the question whether v is smooth vector field on M in the sense of the definition on page 638 boils down to the question whether Θ is smooth.

- It follows easily from the above that Ξ is smooth if and only if Ω is smooth. ■

As a teaser we state the following question.

Question 23.19. Which closed connected 2-dimensional smooth manifolds admit a nowhere-vanishing vector field?

We will address the question in Exercise 23.11. For orientable 2-dimensional smooth manifolds we will prove an answer in Corollary 45.23 (2). Furthermore we will give a complete answer on page 2125. While we are throwing out questions, let us also pose the following more general, but rather vague question.

Question 23.20. How can we tell whether a closed smooth manifold admits a nowhere-vanishing vector field?

Rather surprisingly we will be able to give a complete and satisfactory answer to this question in the Euler Characteristic-Vector Field Theorem 97.15 and the Nowhere Vanishing Vector Field Existence Theorem 129.6.

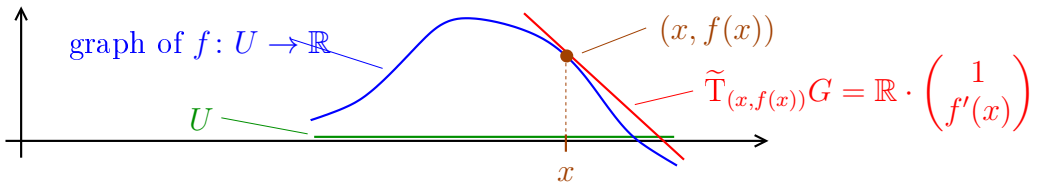
For completeness' sake we state the following basic lemma, which will get used on several occasions.

Lemma 23.21. (Vector Field-Pullback Lemma) Let $f\colon M \to N$ be a map between two smooth manifolds and let v be a (smooth) vector field on N. If f is a local diffeomorphism, then for each $x \in M$ we can define $(f^*v)(x) = (\mathrm{D}f_x)^{-1}(v(f(x)) \in \mathrm{T}_xM$. These vectors define a (smooth) vector field f^*v on M. We refer to f^*v as the pullback of v under f.

Example. Let $p\colon S^n \to \mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\}$ be the usual projection. Given any vector field v on $\mathbb{R}\mathrm{P}^n$ the pullback f^*v is a vector field on S^n. The number of zeros of f^*v equals twice the number of zeros of v.

Proof. The lemma follows easily from the definitions. We leave it to the reader to fill in the details. ■

We will return to the study of vector fields on numerous occasions. They are obviously interesting in their own right. Furthermore, as we will see in the Flow Theorem 35.1, they can also be used to construct interesting self-maps of smooth manifolds.

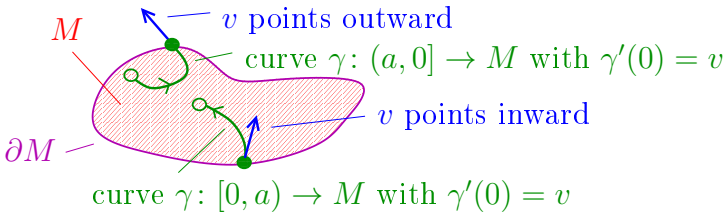


Exercises for Chapter 23.

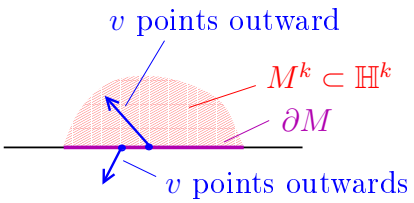
Exercise 23.1. Let $U \subset \mathbb{R}^n$ be an open subset and let $f\colon U \to \mathbb{R}^k$ be a smooth map. On page 562 we discussed that the graph

$$G \;:=\; \{(x, y) \in \mathbb{R}^n \times \mathbb{R}^k \,|\, x \in U\}$$

is an n-dimensional smooth submanifold of $\mathbb{R}^{n+k}$. Show that for every $x \in U$ we have



$$\widetilde{\mathrm{T}}_{(x,f(x))}G \;=\; \text{span of the columns of the } (n+k)\times n\text{-matrix } \begin{pmatrix} \mathrm{id}_n \\ \mathrm{D}f_x \end{pmatrix}.$$



Exercise 23.2. Let M be a k-dimensional smooth submanifold of $\mathbb{R}^n$, let $P \in \partial M$ and let $v \in \widetilde{\mathrm{T}}_P M$. Show that precisely one of the following statements holds:

(1) $v \in \widetilde{\mathrm{T}}_P \partial M$,
(2) v points inward,
(3) v points outward.

Hint. First deal with the case that M is an open subset of the upper half-space $\mathbb{H}^k$.

Exercise 23.3. Let M be a smooth manifold, let $P \in \partial M$ and let $v \in \mathrm{T}_P M$. We denote by $i\colon \partial M \to M$ be the inclusion map. Show that precisely one of the following statements holds:

(1) v lies in the image of $\mathrm{D}i_P\colon \mathrm{T}_P\partial M \to \mathrm{T}_P M$,
(2) v points inward,
(3) v points outward.

Exercise 23.4. Let $M \subset \mathbb{R}^m$ and $N \subset \mathbb{R}^n$ be two closed smooth submanifolds. Show that $M \times N \subset \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$ is a smooth submanifold and show that for any $x \in M$ and $y \in N$ we have

$$\widetilde{\mathrm{T}}_{(x,y)}(M \times N) \;=\; \widetilde{\mathrm{T}}_x M \;\times\; \widetilde{\mathrm{T}}_y N \;\subset\; \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}.$$

Exercise 23.5. Let M be a smooth manifold and let $U \subset M$ be an open subset. We denote by $\iota\colon U \to M$ the inclusion. Show that for every $P \in U$ the map $\mathrm{D}\iota_P\colon \mathrm{T}_P U \to \mathrm{T}_P M$ is an isomorphism.
Hint. Use Lemma 23.8 (3).

Exercise 23.6. Let $M \subset \mathbb{R}^n$ be a k-dimensional smooth submanifold and let $P \in M \setminus \partial M$.

(a) Show that there exists an $A \in \mathrm{O}(n)$ with $A \cdot \widetilde{\mathrm{T}}_P M = \{(0,y) \in \mathbb{R}^n \,|\, y \in \mathbb{R}^k\}$.

(b) Show that there exists a neighborhood U of $P \subset M$ such that the map

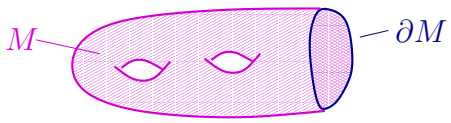
$$\begin{array}{ccccccc} U & \to & \widetilde{\mathrm{T}}_P M & \xrightarrow{x \mapsto A \cdot x} & \{(x,0) \,|\, x \in \mathbb{R}^k\} & \xrightarrow{(x,y) \mapsto x} & \mathbb{R}^k \\ x & \mapsto & \text{orthogonal projection} & & & & \\ & & \text{of } x - P \text{ onto } \widetilde{\mathrm{T}}_P M & & & & \end{array}$$

is a chart for M.

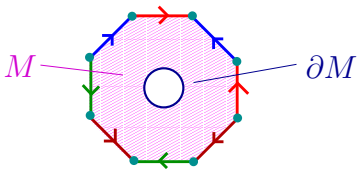
Exercise 23.7. Let M be a smooth manifold, let $P \in \partial M$ and let $w \in \mathrm{T}_P M$.

(a) Let N be a smooth manifold and let $f\colon M \to N$ be a local diffeomorphism with $f(P) \in \partial N$. Show that $w \in \mathrm{T}_P M$ points outward if and only if $\mathrm{D}f_P(w) \in \mathrm{T}_P N$ points outward.

(b) Show that precisely one of the following three statements holds:
(i) w points outward,
(ii) w points inward,
(iii) $w \in \mathrm{D}\iota_P(\mathrm{T}_P\, \partial M \to \mathrm{T}_P M)$, where $\iota\colon \partial M \to M$ is the inclusion map.
Hint. First show that it suffices to consider the case that M is an open subset of some $\mathbb{H}^n$.



Exercise 23.8. Let M be a smooth manifold, let $X \subset M$ be a proper submanifold, let $P \in \partial X$ and let $w \in \mathrm{T}_P X$. We denote by $\iota\colon X \to M$ the inclusion map. Show that $w \in \mathrm{T}_P X$ points outward if and only if $\mathrm{D}\iota_P(w)$ points outward.



Exercise 23.9. We consider the following submanifold of $\mathbb{R}^3$:

$$M \;:=\; \{(x, y, x^2 + y^2) \,|\, x, y \in \mathbb{R}\}.$$

Determine $\widetilde{\mathrm{T}}_{(1,2,5)} M \subset \mathbb{R}^3$.

Exercise 23.10. We consider the smooth manifold M shown in the figure below. Show that it admits a nowhere vanishing smooth vector field.

Exercise 23.11.

(a) For which closed connected 2-dimensional smooth manifolds can you find a nowhere-vanishing vector field?

(b) For which compact connected 2-dimensional smooth manifolds M can you find a nowhere-vanishing vector field v with the additional property that for each $P \in \partial M$ we have $v(P) \in \mathrm{T}_P(\partial M)$?

Remark. At this stage you cannot give a complete answer to these questions. The goal is to find the largest collection of examples where such vector fields exist.

Exercise 23.12.

(a) Can you find a vector field on S^2 with two zeros?

(b) Can you find a vector field on S^2 with one zero?

Exercise 23.13. Let $n \in \mathbb{N}$. We consider $M = \mathbb{R}^n \cup \{\infty\}$. We denote by 0 the origin of $\mathbb{R}^n$.

(a) We consider the maps $\Phi = \mathrm{id}\colon \mathbb{R}^n \to \mathbb{R}^n$ and

$$\begin{array}{rcl} \Psi\colon M \setminus \{0\} & \to & \mathbb{R}^n \\ x & \mapsto & \begin{cases} \frac{1}{\|x\|^2} \cdot x, & \text{if } x \neq \infty, \\ 0, & \text{if } x = \infty. \end{cases} \end{array}$$

Show that Φ and Ψ form a smooth atlas for M.

(b) We consider the map

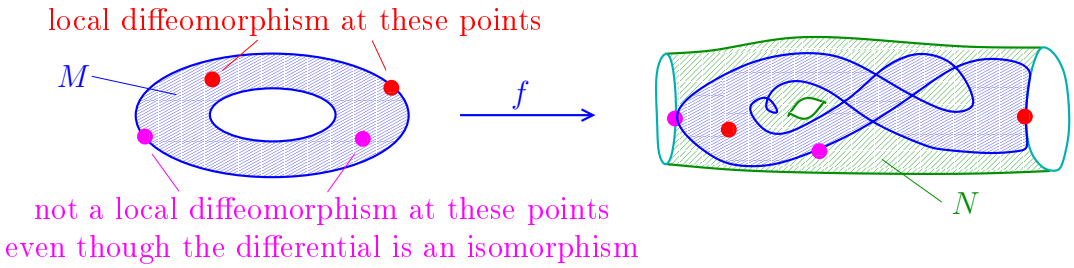
$$\begin{array}{rcl} f\colon M & \to & M \\ x & \mapsto & \begin{cases} 3x, & \text{if } x \neq \infty, \\ \infty, & \text{if } x = \infty \end{cases} \end{array}$$

Note that $f(0) = 0$ and $f(\infty) = \infty$.

(i) Show that f is smooth.

(ii) Show that $\mathrm{D}f_0 = 3 \cdot \mathrm{id}_{\mathrm{T}_0 M}$ and show that $\mathrm{D}f_\infty = \frac{1}{3} \cdot \mathrm{id}_{\mathrm{T}_\infty M}$.

24. The Inverse Mapping Theorem and the Smooth Embedding Theorem



24.1. **The Inverse Mapping Theorem.** By the Physical Tangent Space-Inclusion Proposition 23.14 we know that for a local diffeomorphism the differential at any point is an isomorphism. The following theorem gives the much more interesting converse. The theorem gives in particular a convenient criterion for showing that a map between smooth manifolds is a (local) diffeomorphism.

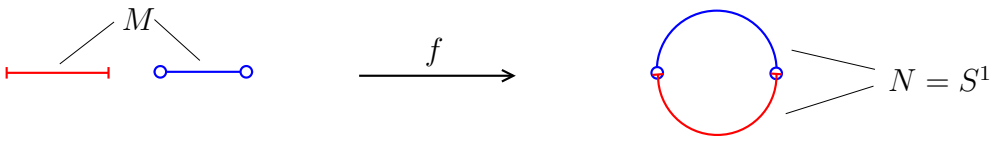
Theorem 24.1. (Inverse Mapping Theorem) Let $f\colon M \to N$ be a smooth map between two smooth manifolds.

(1) Let $P \in M$ such that $\mathrm{D}f_P$ is invertible.
   (a) If $P \notin \partial M$, then f is a local diffeomorphism at P.
   (b) If $P \in \partial M$ and if furthermore there exists an open neighborhood U of P such that $f(U \cap \partial M) \subset f(U) \cap \partial N$, then f is a local diffeomorphism at P.

(2) If $\mathrm{D}f_P$ is invertible for every $P \in M$, if f is a bijection and if $f(\partial M) = \partial N$, then f is a diffeomorphism.

Remark. In Exercise 24.1 we will consider the case $P \in \partial M$ and $f(P) \notin \partial N$.

Examples.



(1) The above figure indicates in particular a map $f\colon M \to N$ and two points $P \in \partial M$, such that $\mathrm{D}f_P$ is an isomorphism, but such f is not a local diffeomorphism at P. This shows that in general in the formulation of the Inverse Mapping Theorem 24.1 we do indeed have to put an extra condition on f if $P \in \partial M$.

(2) We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R}^n & \to & B^n \\ (x_1, \dots, x_n) & \mapsto & \frac{x_1^2+\dots+x_n^2}{1+x_1^2+\dots+x_n^2} \cdot (x_1, \dots, x_n). \end{array}$$

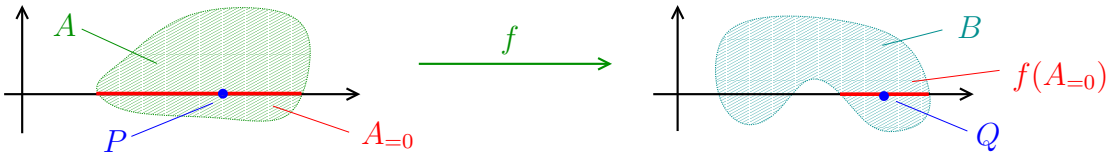
A slightly heroic calculation shows that f satisfies the conditions of the Inverse Mapping Theorem 24.1 (2), thus we see that f is a diffeomorphism. This is actually quite interesting since at first glance it is not totally apparent why $f^{-1}\colon B^n \to \mathbb{R}^n$ is smooth at the origin.

(3) We consider the smooth map $f\colon M \to N$ that is illustrated in the figure below. It is a bijection and for every $x \in M$ the differential $\mathrm{D}f_x\colon \mathrm{T}_xM \to \mathrm{T}_{f(x)}N$ is an isomorphism. But evidently f is not a diffeomorphism. This shows that we cannot drop the condition $f(\partial M) = \partial N$ in the statement of the Inverse Mapping Theorem 24.1 (2).

Evidently the proof of the Inverse Mapping Theorem 24.1 rests on the shoulders of the Inverse Function Theorem 19.12, which we now recall for the reader's convenience.

Theorem 19.12. (Inverse Function Theorem) Let $U \subset \mathbb{R}^n$ be an open subset, let $f\colon U \to \mathbb{R}^n$ be a smooth map and let $P \in U$ be a point. If $\mathrm{D}f_P \in \mathrm{M}(n\times n, \mathbb{R})$ is invertible, then f is a local diffeomorphism at P.

For the purpose of this section it is convenient to introduce the following notation that is modelled on the notation introduced on page 152.



Notation. Given a subset A of $\mathbb{R}^n$ we write

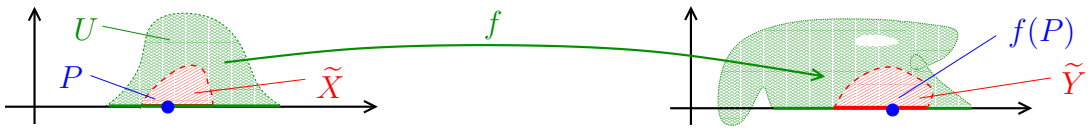
$$A_{>0} \;=\; A \cap \{(x_1, \ldots, x_n) \in \mathbb{R}^n \,|\, x_n > 0\}.$$

We define $A_{<0}$, $A_{=0}$ and $A_{\neq 0}$ in the analogous way.

The proof of the Inverse Mapping Theorem 24.1 for the case $P \in \partial M$ rests on the following lemma, which might actually be interesting in its own right.

Lemma 24.2. Let A and B be open subsets of $\mathbb{R}^n$ and let $f\colon A \to B$ be a diffeomorphism. If $f(A_{=0}) \subset B_{=0}$, then $f(A_{=0})$ is an open subset of $B_{=0}$

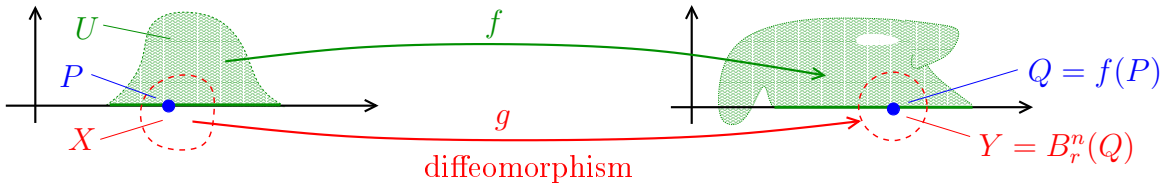
Proof. Let $Q \in f(A_{=0})$. We pick $P \in A_{=0}$ with $Q = f(P)$. We denote by $i\colon A_{=0} \to A$ the inclusion map and we denote by $j\colon B_{=0} \to B$ the inclusion map. Finally we denote by $f_{=0}\colon A_{=0} \to B_{=0}$ the restriction of f to $A_{=0}$. Note that $f \circ i = j \circ f_{=0}\colon A_{=0} \to B$. It follows from the chain rule that



$$\mathrm{D}f_P \circ \mathrm{D}i_P \;=\; \mathrm{D}j_Q \circ \mathrm{D}(f_{=0})_P\colon \widetilde{\mathrm{T}}_P A_{=0} \to \widetilde{\mathrm{T}}_Q B = \mathbb{R}^n.$$

Since f is a diffeomorphism we know that $\mathrm{D}f_P$ is an isomorphism. Clearly $\mathrm{D}i_P$ has rank $n-1$. It follows from the above that the map to the right also has rank $n-1$. But this is only possible if $\mathrm{D}(f_{=0})_P$ has rank $n-1$. This shows that $\mathrm{D}(f_{=0})_P\colon \widetilde{\mathrm{T}}_P A_{=0} \to \widetilde{\mathrm{T}}_Q B_{=0}$ is an isomorphism. It follows from the Inverse Function Theorem 19.12 that the image of $A_{=0}$ contains an open neighborhood of $Q \in B_{=0}$. It follows from the JH-Lemma 1.7 that $f(A_{=0})$ is an open subset of $B_{n=0}$. ■

Using Lemma 24.2 we can now prove the following variation on the Inverse Function Theorem 19.12.



Lemma 24.3. Let $U \subset \mathbb{H}^n$ be an open subset and let $f\colon U \to \mathbb{R}^n$ be a smooth map with $f(U \cap \partial\,\mathbb{H}^n) \subset \partial\,\mathbb{H}^n$. Furthermore let $P \in U \cap \partial\,\mathbb{H}^n$ be a point. If $\mathrm{D}f_P$ is an isomorphism and if $\mathrm{D}f_P(\mathbb{H}^n) \subset \mathbb{H}^n$, then f is a local diffeomorphism at P in the sense that there exists

an open neighborhood $\widetilde{X}$ of $P \in U$ and an open neighborhood $\widetilde{Y}$ of $f(P) \in \mathbb{H}^n$ such that the map $f\colon \widetilde{X} \to \widetilde{Y}$ is a diffeomorphism between the two smooth manifolds $\widetilde{X}$ and $\widetilde{Y}$.

Proof. Note that by definition of a smooth map on an open subset of $\mathbb{H}^n$, see page 532, there exists an open neighborhood X of $P \in \mathbb{R}^n$ and a smooth map $g\colon X \to \mathbb{R}^n$ which agrees with f on $U \cap X$.

We set $Q := f(P)$. It follows easily from the Inverse Function Theorem 19.12 that, after possibly replacing X by a smaller open neighborhood of P, we can assume that there exists an open ball $Y := B^n_r(Q) \subset \mathbb{R}^n$ such that $g\colon X \to Y = B^n_r(Q)$ is a diffeomorphism.

Next recall that given a subset A of $\mathbb{R}^n$ we write

$$A_{>0} \;=\; A \cap \{(x_1, \ldots, x_n) \in \mathbb{R}^n \,|\, x_n > 0\}.$$

and we define $A_{<0}$, $A_{=0}$ and $A_{\neq 0}$ in the analogous way. With this notation it remains to prove the following claim.

Claim. We have $f(X_{\geq 0}) = Y_{\geq 0}$ and the map $f = g\colon X_{\geq 0} \to Y_{\geq 0}$ is a diffeomorphism.

Proof. We already know that $g\colon X \to Y$ is a diffeomorphism. Thus it remains to prove that $g(X_{\geq 0}) = Y_{\geq 0}$.

First note that by hypothesis we have $g(X_{=0}) \subset Y_{=0}$. It follows from Lemma 24.2 that $g(X_{=0})$ is an open subset of $Y_{=0}$. Furthermore note $X_{=0}$ is a closed subset of X, thus $g(X_{=0})$ is a closed subset of Y. But since $g(X_{=0})$ is contained in $Y_{=0}$ it follows from the elementary the Neighborhood Openness Criterion 1.5 that $g(X_{=0})$ is a closed subset of $Y_{=0}$. In summary we see that $g(X_{=0})$ is a subset of $Y_{=0}$ that is open and closed. Since $Y_{=0} \cong B^{n-1}_r(Q)$ is connected and since $P \in X_{=0}$ we see that $g(X_{=0}) = Y_{=0}$.

Since $g\colon X \to Y$ is a homeomorphism and since $g(X_{=0}) = Y_{=0}$ we see that $g\colon X_{\neq 0} \to Y_{\neq 0}$ is also a homeomorphism. Note that $Y_{\neq 0}$ has precisely two components namely $Y_{>0}$ and $Y_{<0}$. Thus $X_{\neq 0}$ also has precisely two components. Since $X_{>0}$ and $X_{<0}$ are open, closed and non-empty it follows from the elementary the Component Lemma 2.33 that the two components of $X_{\neq 0}$ are precisely $X_{>0}$ and $X_{<0}$. It follows from the fact that g gives a bijection of the components and from our hypothesis $\mathrm{D}f_P(\mathbb{H}^n) \subset \mathbb{H}^n$ that $g^{-1}(Y_{<0}) \subset X_{<0}$ and $g^{-1}(Y_{>0}) \subset X_{>0}$. ∎

Proof of the Inverse Mapping Theorem 24.1.

(1) Let $f\colon M \to N$ be a smooth map between smooth manifolds. We set $m := \dim(M)$ and $n := \dim(N)$.

(a) Let $P \in M \setminus \partial M$ be a point. We write $Q := f(P)$. In the following we assume that $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_Q N$ is invertible. We pick a chart $\Phi\colon U \to \widetilde{U}$ of type (i) around P and we pick a chart $\Psi\colon V \to \widetilde{V}$ around $f(P)$.[251] We write $\widetilde{P} := \Phi(P)$ and $\widetilde{Q} := \Psi(Q)$.

After possibly replacing U by $U \cap f^{-1}(V)$ we can assume that $f(U) \subset V$. We consider the map $g := \Psi \circ f \circ \Phi^{-1}\colon \widetilde{U} \to \widetilde{V} \subset \mathbb{R}^n$.

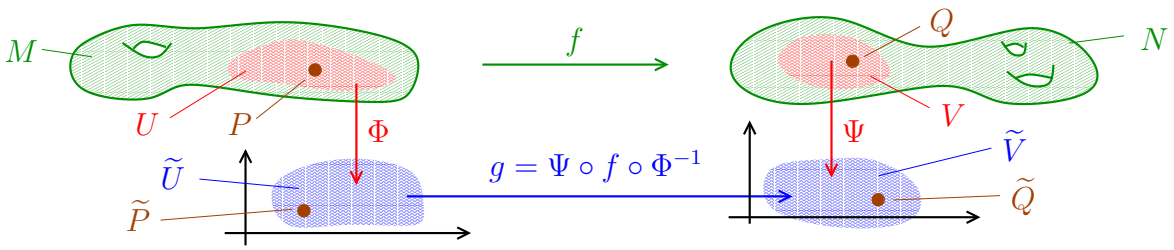
Claim. The differential $\mathrm{D}g_{\widetilde{P}} \in \mathrm{M}(m \times n, \mathbb{R})$ is an invertible matrix.

Proof. Let $i\colon U \to M$ and $j\colon V \to N$ be the inclusion maps. We consider the following diagram:

$$\begin{array}{ccccccccc}
\mathrm{T}_P M & \xleftarrow{\mathrm{D}i_P} & \mathrm{T}_P U & \xrightarrow{\mathrm{D}\Phi_P} & \mathrm{T}_{\widetilde{P}}\widetilde{U} & \xrightarrow{\Theta_{\widetilde{U}}} & \widetilde{\mathrm{T}}_{\widetilde{P}}\widetilde{U} & \xrightarrow{\mathrm{id}} & \mathbb{R}^m \\
\downarrow{\scriptstyle \mathrm{D}f_P} & & \downarrow{\scriptstyle \mathrm{D}f_P} & & \downarrow{\scriptstyle \mathrm{D}g_{\widetilde{P}}} & & \downarrow{\scriptstyle \mathrm{D}g_{\widetilde{P}}} & & \downarrow{\scriptstyle \mathrm{D}g_{\widetilde{P}}} \\
\mathrm{T}_Q N & \xleftarrow{\mathrm{D}j_P} & \mathrm{T}_Q V & \xrightarrow{\mathrm{D}\Psi_Q} & \mathrm{T}_{\widetilde{Q}}\widetilde{V} & \xrightarrow{\Theta_{\widetilde{V}}} & \widetilde{\mathrm{T}}_{\widetilde{Q}}\widetilde{V} & \xrightarrow{\mathrm{id}} & \mathbb{R}^n.
\end{array}$$

We make the following observations:

- It follows from Lemma 23.12 that the left horizontal maps are isomorphisms.
- Since Φ and Ψ are diffeomorphisms we obtain from the Tangent Space-Functor Proposition 23.10 that the center-left horizontal maps are invertible.
- It follows from the Tangent Space-Functor Proposition 23.10 that the two rectangles to the left commute.
- The horizontal maps $\Theta_{\widetilde{U}}$ and $\Theta_{\widetilde{V}}$ are the natural isomorphisms from the Tangent Space-Isomorphism Proposition 23.16. In particular the third rectangle commutes.
- By the Differential-equals-Differential Lemma 23.4 we know that the rectangle to the right commutes.

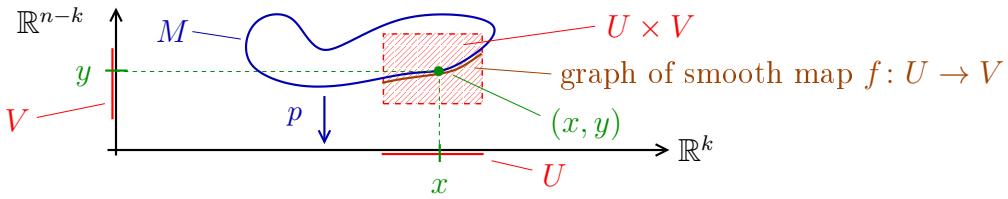


The combination of all of the above, together with our hypothesis that $\mathrm{D}f_P$ is invertible implies that $\mathrm{D}g_{\widetilde{P}}$ is indeed an invertible matrix. ⊞

It follows from the claim and the Inverse Function Theorem 19.12 that there exists an open neighborhood Y of $\widetilde{P} \in \widetilde{U}$ and an open neighborhood Z of $\widetilde{Q} \subset \widetilde{V}$ such that g restricts to a diffeomorphism $Y \to Z$. It follows that $f\colon \Phi^{-1}(Y) \to \Psi^{-1}(Z)$ is a diffeomorphism. We have thus shown that f is a local diffeomorphism at P.

(b) Now we assume that $P \in \partial M$ and we assume that there exists an open neighborhood U of P such that $f(U \cap \partial M) \subset f(U) \cap \partial N$, then f is a local diffeomorphism at P. The proof of this statement is almost identical to the proof of (a). We just need to replace the Inverse Function Theorem 19.12 by Lemma 24.3. (The condition that $\mathrm{D}g_P(\mathbb{H}^n) \subset \mathbb{H}^n$ is automatically satisfied since $g(P) \in \partial\mathbb{H}^n$ and $g(\widetilde{U}) \subset \mathbb{H}^n$.) We leave it to the reader to fill in the details.

(2) The second statement follows immediately from (1) and the Smooth Pasting Proposition 19.23 (2). ■



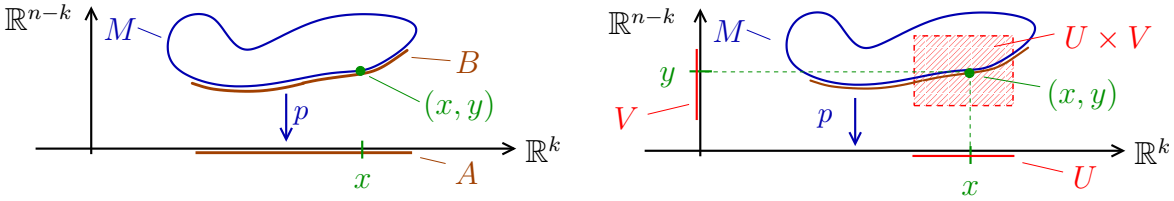
[251] Note that a priori we do not know yet whether $Q = f(P) \in \partial N$, so Ψ could be a chart of type (i) or of type (ii).

24.2. **The Local Graph Lemma.** On page 562 we saw that graphs of smooth maps between smooth manifolds give rise to submanifolds. Using the Inverse Mapping Theorem 24.1 we can now show that locally, after possibly a rotation, any submanifold of $\mathbb{R}^n$ without boundary is a graph.

Lemma 24.4. (Local Graph Lemma) Let $M \subset \mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^{n-k}$ be a k-dimensional smooth submanifold. We denote by $p\colon \mathbb{R}^n \to \mathbb{R}^k$ the projection onto the first k coordinates. Let $(x, y) \in M \setminus \partial M$ such that $\mathrm{D}p_{(x,y)}\colon \widetilde{\mathrm{T}}_{(x,y)}M \to \mathbb{R}^k$ is an isomorphism. There exists an open neighborhood U of $x \in \mathbb{R}^k$, an open neighborhood V of $y \in \mathbb{R}^{n-k}$ and a smooth map $f\colon U \to V$ such that

$$M \cap (U \times V) = \text{ Graph of } f\colon U \to V \ = \ \{(z, f(z)) \,|\, z \in U\}.$$

Remark.



(1) Let $M \subset \mathbb{R}^n$ be a k-dimensional smooth submanifold and let $z \in M \setminus \partial M$. By the Orthogonal Action Lemma 5.26 (5) there exists an orthogonal matrix $A \in \mathrm{SO}(n)$ with $A \cdot \widetilde{\mathrm{T}}_z M = \mathbb{R}^k \times \{0\}$. It follows that, after a rotation, one can arrange that the hypotheses of the Local Graph Lemma 24.4 holds. For readers who come back to this discussion from a future chapter we pointed out that in the Diffeotopies-via-Matrices Lemma 33.8 we will see that a rotation can be realized by a diffeotopy of $\mathbb{R}^n$.

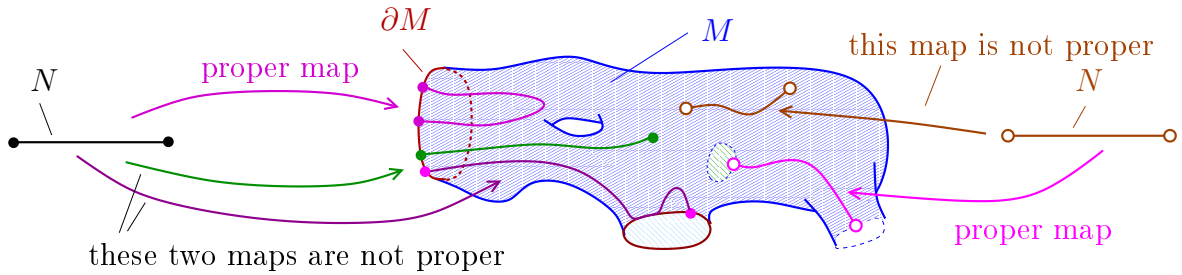
(2) In the Diffeomorphic-to-Euclidean Submanifold Corollary 27.2 we will see that every smooth manifold is diffeomorphic to a smooth submanifold of some $\mathbb{R}^d$. Thus we see that locally every smooth manifold without boundary is diffeomorphic to a graph.

Proof. We view M as a smooth manifold in its own right. By hypothesis the map $\mathrm{D}p_{(x,y)}\colon \widetilde{\mathrm{T}}_{(x,y)}M \to \widetilde{\mathrm{T}}_x\mathbb{R}^k = \mathbb{R}^k$ is an isomorphism. It follows from the Inverse Mapping Theorem 24.1 that there exists an open neighborhood A of $(x, y) \in M$ and an open neighborhood B of $x \in \mathbb{R}^k$ such that $p\colon A \to B$ is a diffeomorphism. Note that the inverse of $p\colon A \to B$ is necessarily of the form

$$\begin{array}{ccc} B & \to & A \\ z & \mapsto & (z, f(z)) \end{array}$$

where $f\colon B \to \mathbb{R}^{n-k}$ is a smooth map.

By the definition of the subspace topology on M and by the definition of the topology on $\mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^{n-k}$ there exists an open neighborhood U of x and an open neighborhood V of y such that $(U \times V) \cap M \subset A$. It is now clear that U, V and f have the desired properties. ■



24.3. **Immersions and smooth embeddings.** For the reader's convenience we recall the following definition from page 152.

Definition. We say a map $f\colon X \to Y$ between two topological spaces X and Y is an embedding if $f\colon X \to f(X)$ is a homeomorphism, where $f(X)$ is equipped with the subspace topology.

Next we state a new definition.

Definition. Let N and M be topological manifolds. A map $\varphi\colon N \to M$ is called proper if the following two conditions are satisfied:

(1) $\varphi^{-1}(\partial M) = \partial N$,
(2) $\varphi(N)$ is a closed subset of M.

For an *embedding* of topological manifolds the following, rather technical, lemma gives an alternative characterization of the second condition of a proper map between topological manifolds.

Lemma 24.5. Let M and N be topological manifolds and let $\varphi\colon N \to M$ be a map. If φ is in fact an embedding, then the following two conditions are equivalent:[252]

(1) $\varphi(N)$ is a closed subset of M.
(2) For every compact subset K of N the preimage $\varphi^{-1}(K)$ is compact.

[252]By the Topological Manifolds-Local Properties Lemma 18.8 we know that topological manifolds are regionally compact. Thus the content of Lemma 24.5 is closely related to the Proper-Closed Proposition 2.43.

Remark. On page 180 we introduced the definition that a map $f\colon X \to Y$ between topological spaces is called *proper* if the preimage of every compact subset of Y is a compact subset of X. Unfortunately we now have two notions of the adjective "proper".

Let us start with the good news. Let M and N be two topological manifolds and let $\varphi\colon N \to M$ be a map. If φ is an embedding, then Lemma 24.5 says that the following two statements are equivalent:

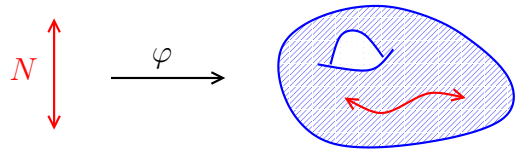
(1) φ satisfies the second condition of a proper map between topological manifolds.
(2) $\varphi\colon N \to M$ is a proper map of topological spaces.

We continue with the bad news. In general the two notions of being "proper" diverge:

(1) The constant map $\mathbb{R} \to \{*\}$ is a proper map of topological manifolds but it is not a proper map of topological spaces.
(2) The inclusion map $f\colon N = [-1,1] \to \mathbb{R} = M$ is a proper map of topological spaces but it is not a proper map of topological manifolds.

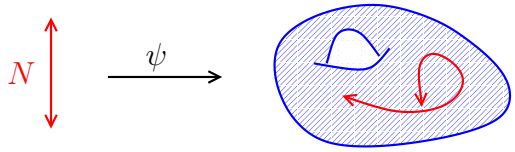
Since both definitions of "proper" are commonly used in the literature we will have to live with this very unfortunate ambiguity. We will strive to make sure that, given a map between two topological manifolds, it is clear which of the two definitions of "proper" we are working with.

Proof. First we prove the "(1)⇒(2)"-implication. Thus we assume that $\varphi(M)$ is a closed subset of N. Let K be a compact subset of N. Since $\varphi(M)$ is a closed subset of N we know by the Neighborhood Openness Criterion 1.5 that $\varphi(M) \cap K$ is a closed subset of K. Thus we obtain from the Compact-Closed Lemma 1.21 that $\varphi(M) \cap K$ is compact. But $\varphi\colon M \to N$ is an embedding, i.e. $\varphi\colon M \to \varphi(M)$ is a homeomorphism. We denote by $\psi\colon \varphi(M) \to M$ the inverse map, which is a homeomorphism. We now see that $\varphi^{-1}(K) = \varphi^{-1}(\varphi(M) \cap K) = \psi(K)$ is compact.



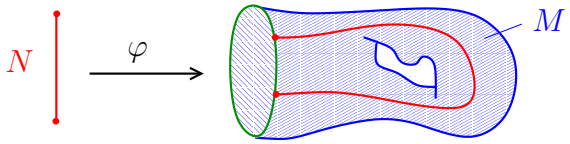
Now we prove the "(2)⇒(1)"-implication. We need to show that $\varphi(M)$ is a closed subset of N. By the Atlas Improvement Proposition 21.3 (which, even though it appears later is completely independent of the present discussion) there exists a locally finite cover $\{K_j\}_{j\in J}$ of N by compact subsets. Since N is Hausdorff we know that each K_j is also a closed subset of N. Thus by Lemma 1.8 it suffices to show that each $\varphi(M) \cap K_j$ is a closed subset of N. Now let $j \in J$. By hypothesis we know that $\varphi^{-1}(K_j)$ is compact. Note that $\varphi(M) \cap K_j = \varphi(\varphi^{-1}(K_j))$. It follows from this observation, together with the Compact Image Lemma 2.13 (1) and the Compact-Closed Lemma 1.21 (2) that $\varphi(M) \cap K_j$ is indeed closed. ■

We continue with the following definition that is specific to smooth manifolds.

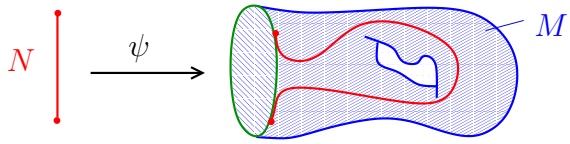


Definition. A map $\varphi\colon N \to M$ between two smooth manifolds is called an immersion if the following conditions are satisfied:

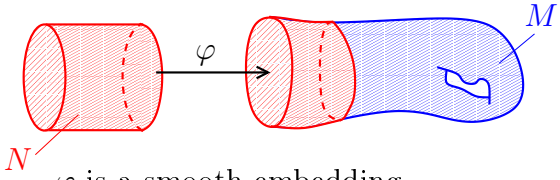
(1) The map φ is smooth.
(2) For each $P \in N$ the map $\mathrm{D}\varphi_P\colon \mathrm{T}_P N \to \mathrm{T}_{\varphi(P)} M$ is a monomorphism.
(3) If $\partial M \neq \varnothing$, then we require that also the following conditions are satisfied:
    (a) For each $P \in N \setminus \partial N$ we have $\varphi(P) \in M \setminus \partial M$.[253]
    (b) For each $P \in \partial N$ with $\varphi(P) \in \partial M$ the image $\mathrm{D}\varphi_P(\mathrm{T}_P N)$ is *not* contained in $\mathrm{T}_{\varphi(P)}(\partial M)$.[254][255]



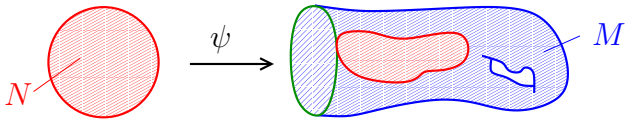
(c) For every component C of ∂N we have either $\varphi(C) \subset \partial M$ or $\varphi(C) \subset M \setminus \partial M$.[256]
An immersion that also satisfies the following extra condition
(5) $\varphi\colon N \to M$ is an embedding,[257]
is called a smooth embedding.



φ is a smooth embedding



ψ is not a smooth embedding since
$\varphi\colon N \to \varphi(N)$ is not a homeomorphism



φ is a smooth embedding

ψ is not a smooth embedding since
condition (3b) is not satisfied

φ is a smooth embedding

ψ is not a smooth embedding since
condition (3c) is not satisfied

Remark. Let M be a smooth manifold and let $\varphi\colon M \to \mathbb{H}^n$ be a smooth map. We denote by $p\colon \mathbb{H}^n \to [0,\infty)$ the projection onto the last coordinate. One can show easily that Condition (b) in the definition of an immersion is satisfied if and only if for each $P \in \partial N$ with $\varphi(P) \in \partial M$ the map $\mathrm{D}(q \circ \varphi)(P)\colon \mathrm{T}_P M \to \mathbb{R}$ is an epimorphism.

The following lemma gives an instructive example of immersions and smooth embeddings.

Lemma 24.6. Given $\lambda \in \mathbb{R}$ we consider the following map

$$\begin{array}{rcl} \varphi_\lambda\colon \mathbb{R} & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ t & \mapsto & [(t, \lambda \cdot t)]. \end{array}$$

---

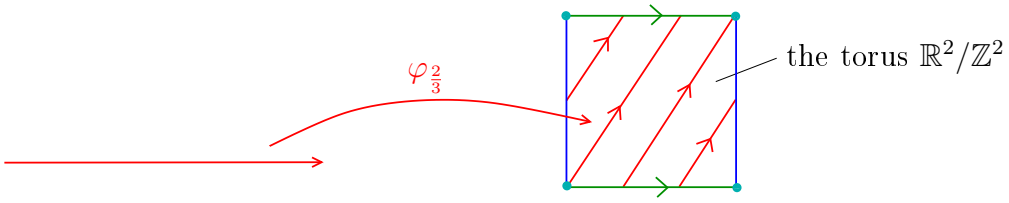
[253] Note that this condition is implied if $\varphi^{-1}(\partial M) = \partial N$, but the condition (3) is weaker than the condition that $\varphi^{-1}(\partial M) = \partial N$.

[254] Here we use the sanity preserving convention from page 633 which allows us to view $\mathrm{T}_{\varphi(P)}\partial M$ as a vector subspace of $\mathrm{T}_{\varphi(P)}M$.

[255] Another way of expressing this condition is that the map $\mathrm{T}_P N \to \mathrm{T}_{\varphi(P)}M/\mathrm{T}_{\varphi(P)}\partial M$ is an epimorphism.

[255] One can also state this condition as a local condition, namely using the fact that boundaries are closed subsets – see the Smooth Manifold Boundary Proposition 19.26 – one can easily show that this condition is equivalent to

(c') For every $P \in \partial N$ with $\varphi(P) \in \partial M$, there exists a neighborhood V of P such that $\varphi(P) \subset \partial M$.



[256] If N is compact, then it follows from the Compact-Hausdorff Proposition 2.17 (2) that it suffices to verify that φ is injective and continuous.

The following statements hold:

(1) The map φ_λ is an immersion.
(2) The map φ_λ is injective if and only if λ is irrational.
(3) If λ is irrational, then $\varphi_\lambda \colon \mathbb{R} \to \mathbb{R}^2/\mathbb{Z}^2$ is *not* an embedding, in particular φ_λ is not a smooth embedding.
(4) Suppose λ is rational. We write $\lambda = \frac{p}{q}$ with $p \in \mathbb{Z}$ and $q \in \mathbb{N}$ such that p and q are coprime. The map

$$\begin{array}{rcl} f_\lambda \colon S^1 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ \exp(2\pi \mathrm{i} t) & \mapsto & [(qt, \lambda \cdot qt)] \end{array}$$

is well-defined and it is a smooth embedding.

Proof. We write $\varphi = \varphi_\lambda$.

(1) We denote by $p \colon \mathbb{R}^2 \to \mathbb{R}^2/\mathbb{Z}^2$ the projection and we denote by $\Phi \colon \mathbb{R} \to \mathbb{R}^2$ the map that is given by $t \mapsto (t, \lambda \cdot t)$. Evidently we have $\varphi = p \circ \Phi$. Let $t \in \mathbb{R}$. We consider the following diagram:

$$\begin{array}{ccccc} \mathrm{T}_t\mathbb{R} & & \xrightarrow{\mathrm{D}\Phi_t} & & \mathrm{T}_{\Phi(t)}\mathbb{R}^2 \xrightarrow{\mathrm{D}p_{\Phi(t)}} \mathrm{T}_{\varphi(t)}(\mathbb{R}^2/\mathbb{Z}^2) \\ \Theta \uparrow \cong & & & & \cong \uparrow \Theta \\ \mathbb{R} = \widetilde{\mathrm{T}}_{\varphi(t)}\mathbb{R} & & \xrightarrow{\mathrm{D}\Phi_t} & & \widetilde{\mathrm{T}}_{\Phi(t)}\mathbb{R}^2 = \mathbb{R}^2 \end{array}$$

We make the following observations:
(a) It follows from $\varphi = p \circ \Phi$ and the functoriality of differentials that the top of the diagram commutes.
(b) By the Manifold Quotient-by-Group Action Proposition 19.32 we know that the map $p \colon \mathbb{R}^2 \to \mathbb{R}^2/\mathbb{Z}^2$ is a local diffeomorphism, hence the differential of p at any point is an isomorphism.
(c) The vertical maps are the natural isomorphisms provided by the Tangent Space-Isomorphism Proposition 23.16. In particular the square commutes.
(d) By the Differential-equals-Differential Lemma 23.4 the bottom horizontal map is given by multiplication by the matrix $\mathrm{D}\Phi_t = \begin{pmatrix} 1 \\ \lambda \end{pmatrix}$. In particular the bottom map is a monomorphism.

It follows from all of the above the $\mathrm{D}\varphi_t \colon \mathrm{T}_t\mathbb{R} \to \mathrm{T}_{\varphi(t)}(\mathbb{R}^2/\mathbb{Z}^2)$ is a monomorphism.

(2) This statement is an amusing exercise that is left to the reader.

(3) The proof of this statement requires the simple number theoretic fact that given any $\alpha \in \mathbb{R}$ and any $N \in \mathbb{N}$ there exist $n, m \in \mathbb{Z}$ with $1 \leq n \leq N$ and with $|n\alpha - m| < \frac{1}{N}$.[257] We leave it to the reader to fill in the remaining details.

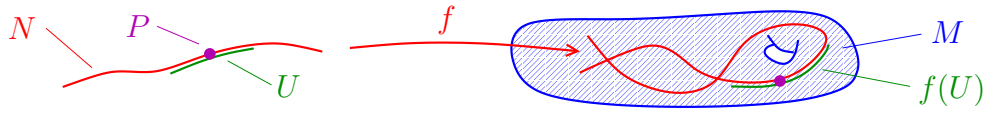
(4) Let λ be rational. We write $\lambda = \frac{p}{q}$ with $p \in \mathbb{Z}$ and $q \in \mathbb{N}$ such that p and q are coprime. We consider the following diagram

$$\begin{array}{ccccc} S^1 & \xrightarrow{\quad f_\lambda \quad} & \mathbb{R}^2/\mathbb{Z}^2 & & \\ \uparrow{\scriptstyle g([t])=\exp(2\pi i t)} & & \uparrow{\scriptstyle \varphi_\lambda} & & \\ \mathbb{R}/\mathbb{Z} & \xleftarrow[[t]\hookleftarrow t]{=:p} & \mathbb{R} & \xrightarrow[t\mapsto qt]{=:h} & \mathbb{R} \end{array} \quad \text{which gives rise to} \quad \begin{array}{ccccc} \mathrm{T}_{\exp(2\pi i t)}S^1 & \xrightarrow{\quad f_\lambda \quad} & \mathrm{T}_{\varphi(t)}\mathbb{R}^2/\mathbb{Z}^2 & & \\ \cong\uparrow{\scriptstyle g} & & \uparrow{\scriptstyle \varphi_\lambda} & & \\ \mathrm{T}_{[t]}\mathbb{R}/\mathbb{Z} & \xleftarrow[\cong]{\mathrm{D}p_t} & \mathrm{T}_t\mathbb{R} & \xrightarrow[\cong]{\mathrm{D}h_t} & \mathrm{T}_t\mathbb{R}. \end{array}$$

Considering the commutative diagram on the right we see that f_λ is indeed an immersion. Furthermore it is straightforward to see that $f_\lambda \colon S^1 \to \mathbb{R}^2/\mathbb{Z}^2$ is injective. Thus it follows from the Compact-Hausdorff Proposition 2.17 (3) that f_λ is a smooth embedding. ■

We continue our discussion of smooth embeddings with the following modest lemma.

Lemma 24.7. Let $\varphi \colon N \to M$ be a map between smooth manifolds.



(1) If φ is a smooth embedding, then $\varphi|_{\partial N} \colon \partial N \to M$ is also a smooth embedding.

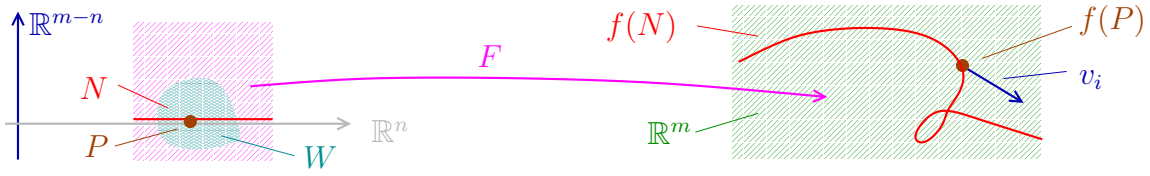
(2) If φ is a proper smooth embedding, then $\varphi|_{\partial N} \colon \partial N \to \partial M$ is also a proper smooth embedding.

Proof. The statement follows almost immediately from the Physical Tangent Space-Inclusion Proposition 23.14 (2) and the Smooth Manifold Boundary Proposition 19.26 (3a). ■

We conclude this section with the Local Smooth Embedding Theorem which can be viewed as a generalization of the Inverse Mapping Theorem 24.1.

Theorem 24.8. (Local Smooth Embedding Theorem) Let $f \colon N \to M$ be a smooth map between two smooth manifolds. Let $P \in N$ be a point with $f(P) \notin \partial M$. We suppose that $\mathrm{D}f_P \colon \mathrm{T}_P N \to \mathrm{T}_{f(P)} M$ is a monomorphism. Then there exists an open neighborhood U of P such that the restriction of f to a map $U \to M$ is a smooth embedding.

Proof. Since we were very meticulous in the proof of the Inverse Mapping Theorem 24.1, we feel that it is now OK to provide fewer details in the proof. Thus let $P \in N$ be a point such that $f(P) \notin \partial M$ and such that $\mathrm{D}f_P \colon \mathrm{T}_P N \to \mathrm{T}_{f(P)} M$ is a monomorphism.



First we consider the case $P \in N \setminus \partial N$. Since $P \notin \partial N$ and $f(P) \notin \partial M$ we see that, after applying charts, we might as well assume that N is an open subset of $\mathbb{R}^n$ and that M is an open subset of $\mathbb{R}^m$. Since $\mathrm{D}f_P \colon \mathrm{T}_P N \to \mathrm{T}_{f(P)} M$ is a monomorphism we can pick $v_1, \ldots, v_{m-n} \in \mathbb{R}^m$ such that the image of $\mathrm{D}f_P$ together with the vectors $v_1, \ldots, v_{m-n}$

[257] This statement is known as Dirichlet's Approximation Theorem, but it is actually elementary to prove, see e.g. [**Lee2002**, Lemma 4.21].

span $\mathbb{R}^m$. Now we consider the map

$$\begin{aligned} F\colon M \times \mathbb{R}^{m-n} &\to \mathbb{R}^m \\ (x, (\lambda_1, \dots, \lambda_{m-n})) &\mapsto f(x) + \sum_{i=1}^{m-n} \lambda_i \cdot v_i. \end{aligned}$$

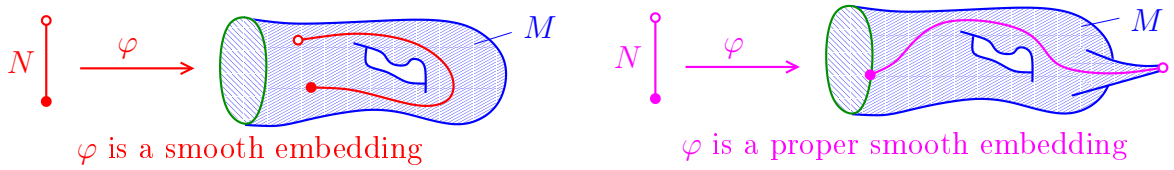
Basically by design the differential $\mathrm{D}F_{(P,0)}$ is an epimorphism, and thus an isomorphism. Therefore it follows from the Inverse Function Theorem 19.12 that there exists an open neighborhood U of $(P,0)$ such that $F|_W\colon W \to \Phi(W)$ is a diffeomorphism. It follows almost immediately that the restriction of f to $\{u \in N \,|\, (u,0) \in W\}$ has the desired property.

Finally we consider the case that $P \in \partial N$. After picking a chart we might as well assume that N is an open subset of $\mathbb{H}^n$. By definition of a smooth map on an open subset of $\mathbb{H}^n$, see pages 532 and 549, there exists an $r > 0$ such that $B^n_r(P) \cap \mathbb{H}^n \subset N$ and a smooth map $\widetilde{f}\colon B^n_r(P) \to M$ that agrees with f on $B^n_r(P) \cap \mathbb{H}^n$. Now that P lies in the interior of $B^n_r(P)$ it follows from the previous case that there exists an open neighborhood $\widetilde{U}$ of $P \in B^n_r(P)$ such that the restriction of $\widetilde{f}$ to a map $\widetilde{U} \to M$ is a smooth embedding. We now set $U := \widetilde{U} \cap \mathbb{H}^n$. Then the restriction of f to U is a smooth embedding. ■

24.4. **The Smooth Embedding Theorem.** We start out with a little lemma.

Lemma 24.9. Let M be a smooth manifold and let W be a (proper) submanifold. The inclusion $\iota\colon W \to M$ is a (proper) smooth embedding.

Proof.



(1) By the Submanifold Smooth Structure Lemma 19.24 the inclusion ι is smooth.
(2) It follows from the Physical Tangent Space-Inclusion Proposition 23.14 that each $\mathrm{D}\iota_P$ is a monomorphism.
(3) (a) Basically by definition we have $W \setminus \partial W \subset M \setminus \partial M$.
    (b) For $P \in \partial N$ with ∂M we have a submanifold chart of type (β) which implies that $\mathrm{T}_P N \not\subset \mathrm{T}_P \partial M$.
    (a) In Exercise 19.11 we showed that for every component C of ∂W we have either $C \subset \partial M$ or $C \subset M \setminus \partial M$.
(4) By definition of the subspace topology ι is an embedding.

If W is a proper submanifold, then it follows from an easy comparison of the definitions that ι is indeed a proper embedding. ■

The following theorem can be viewed as a converse to the simple-minded Lemma 24.9.

Theorem 24.10. (Smooth Embedding Theorem) Let N be an n-dimensional smooth manifold and let M be a smooth manifold.

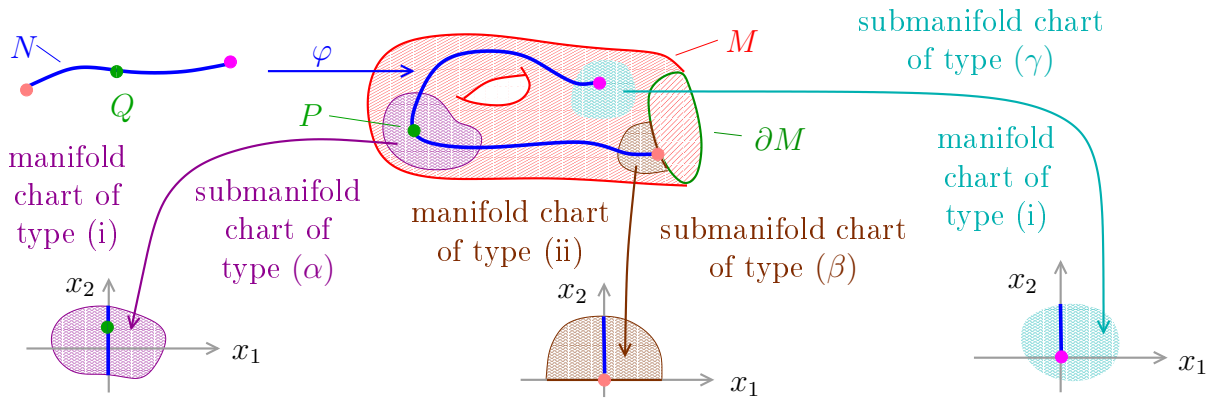
(1) If $\varphi\colon N \to M$ is a smooth embedding, then $\varphi(N)$ is an n-dimensional submanifold of M and the map $\varphi\colon N \to \varphi(N)$ is a diffeomorphism.[258]
(2) If $\varphi\colon N \to M$ is a proper smooth embedding, then $\varphi(N)$ is a proper n-dimensional submanifold of M and the map $\varphi\colon N \to \varphi(N)$ is a diffeomorphism.

Remark. Let M be a smooth manifold and let N be a smooth submanifold in the sense of the definition on page 550. The Smooth Embedding Theorem 24.10 implies that the standard smooth structure on N, which we introduced on page 552, is characterized by the property that it is the unique smooth structure that turns the inclusion $i\colon N \to M$ into a smooth embedding.

Proof. Let N be an n-dimensional smooth manifold and let M be an m-dimensional smooth manifold. Let $\varphi\colon N \to M$ be a smooth embedding. By definition this means that φ satisfies the following:

(1) The map φ is smooth.
(2) For each $P \in N$ the induced map $\mathrm{D}\varphi_P\colon \mathrm{T}_P N \to \mathrm{T}_{\varphi(P)} M$ is a monomorphism.
(3) If $\partial M \neq \varnothing$, then we require that also the following conditions are satisfied:
  (a) For each $P \in N \setminus \partial N$ we have $\varphi(P) \in M \setminus \partial M$.
  (b) For each $P \in \partial N$ with $\varphi(P) \in \partial M$ the image $\mathrm{D}\varphi_P(\mathrm{T}_P N)$ is *not* contained in $\mathrm{T}_{\varphi(P)}(\partial M)$.
  (c) For every component C of ∂N we have either $\varphi(C) \subset \partial M$ or $\varphi(C) \subset M \setminus \partial M$.
(4) $\varphi\colon N \to M$ is an embedding.

We need to show that $\varphi(N)$ is an n-dimensional submanifold of M and that the map $\varphi\colon N \to \varphi(N)$ is a diffeomorphism.



Claim. Let $Q \in N$. The following statements hold:

(α) $Q \notin \partial N$ and $\varphi(Q) \notin \partial M$ $\Rightarrow$ there exists a submanifold chart of type (α) for $\varphi(Q)$
(β) $Q \in \partial N$ and $\varphi(Q) \in \partial M$ $\Rightarrow$ there exists a submanifold chart of type (β) for $\varphi(Q)$
(γ) $Q \in \partial N$ and $\varphi(Q) \notin \partial M$ $\Rightarrow$ there exists a submanifold chart of type (γ) for $\varphi(Q)$.

We refer to page 550 for the definitions of the various submanifold charts. A cartoon version of the definitions is also given in the figure below.

Proof. Note that by hypothesis (3a) the above three cases are the only cases that can occur. Thus we see that the claim implies that $\varphi(N)$ is indeed a submanifold of M. Furthermore it follows from the Submanifold Smooth Structure Lemma 19.24 and the Smooth Pasting Proposition 19.23 that $N \to \varphi(N)$ is a diffeomorphism. Furthermore, if φ is proper in the sense of the definition on page 650, then $\varphi(N)$ is a closed subset of M and $\varphi^{-1}(\partial M) = \partial N$.

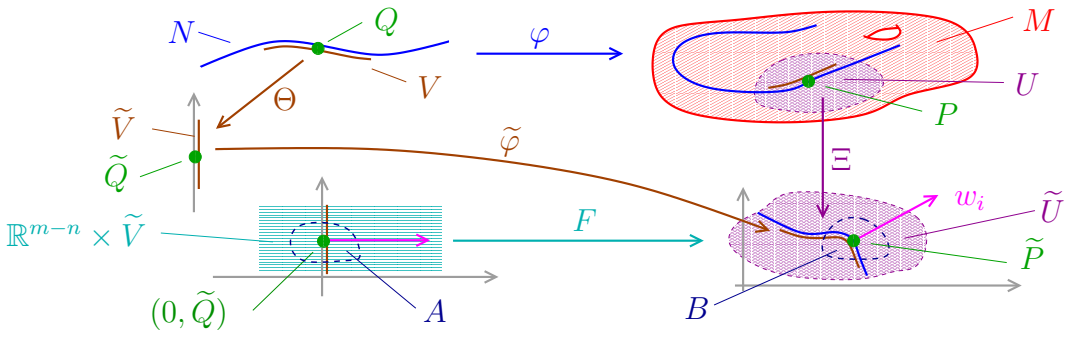
[258] Recall that a smooth submanifolds inherits by the Submanifold Smooth Structure Lemma 19.24 the structure of a smooth manifold. Thus it makes sense to say that $\varphi\colon N \to \varphi(N)$ is a diffeomorphism.

The latter fact implies, assuming the claim, that only submanifold charts of type (α) and (β) occur. Together with the fact that $\varphi(N)$ is closed we now know, by the definition on page 550, that $\varphi(N)$ is indeed proper submanifold. In other words, all that is left to do is to prove the claim.

So let us provide the proof of the claim. Let $Q \in N$. We treat the three cases separately.

(α) We assume that $Q \notin \partial M$ and we assume that $P := \varphi(Q) \notin \partial M$.

- Since $Q \notin \partial M$ we can pick a chart $\Theta\colon V \to \widetilde{V}$ of type (i) around Q.
- By hypothesis $\varphi\colon N \to M$ is an embedding which means that $\varphi\colon N \to \varphi(N)$ is a homeomorphism. This implies that $\varphi(V)$ is an open subset of $\varphi(N)$. By definition of the subspace topology this means that there exists an open subset $Z \subset M$ with $\varphi(V) = Z \cap \varphi(N)$.
- Since $P \notin \partial M$ we can pick a chart $\Xi\colon U \to \widetilde{U}$ of type (i) around P with $U \subset Z$.
- After possibly replacing V by $V \cap \varphi^{-1}(U)$ we can and will assume that $\varphi(U) \subset V$.



Since $\varphi(U) \subset V$ we can consider $\widetilde{\varphi} := \Xi \circ \varphi \circ \Theta^{-1}\colon \widetilde{V} \to \widetilde{U}$. Since φ is an immersion we know that $\mathrm{D}\varphi_Q\colon \mathrm{T}_Q N \to \mathrm{T}_P M$ is a monomorphism. It follows from the Tangent Space-Isomorphism Proposition 23.16 that the corresponding map $\mathrm{D}\widetilde{\varphi}_{\widetilde{Q}}\colon \mathbb{R}^n \to \mathbb{R}^m$ is a monomorphism. Thus there exist vectors $w_1, \ldots, w_{m-n} \in \mathbb{R}^m$ such that the image of $\mathrm{D}\varphi_Q$ together with these vectors span $\mathbb{R}^m$. We consider the map

$$\begin{array}{rcl} F\colon \mathbb{R}^{m-n} \times \widetilde{V} & \to & \mathbb{R}^m \\ ((t_1, \ldots, t_{m-n}), x) & \mapsto & \widetilde{\varphi}(x) + \sum_{i=1}^{m-n} t_i \cdot w_i. \end{array}$$

Note that

$$\mathrm{D}F_{(0,\widetilde{Q})} \;=\; \begin{pmatrix} w_1 & \ldots & w_{m-n} & \mathrm{D}\widetilde{\varphi}_{\widetilde{Q}} \end{pmatrix} \;\in\; \mathrm{M}(m \times m, \mathbb{R}).$$

Thus we see that $\mathrm{D}F_{(0,\widetilde{Q})}$ is invertible. It follows from the Inverse Function Theorem 19.12 that there exists an open neighborhood A of $(0, \widetilde{Q})$ and an open neighborhood B of $\widetilde{P} \in \widetilde{U}$ such that $F\colon A \to B$ is a diffeomorphism. It follows almost immediately from the construction that $(F|_B)^{-1} \circ \Xi\colon \Xi^{-1}(B) \to A$ is a submanifold chart of type (α) for P.

(β) The proof of this case is very similar to the proof of (α). We need to make only a few minor adjustments:

- This time we use charts of type (ii) for Q and for P. Our hypothesis (3c) implies that there exists an open neighborhood V of Q such that $\varphi(V \cap \partial N) \subset \partial M$.
- Our hypothesis (3b) implies that we can find $w_1, \ldots, w_{m-n} \in \mathbb{R}^{m-1} \times \{0\}$ such that the image of $\mathrm{D}\varphi_Q$ together with these vectors span $\mathbb{R}^m$.

Using these two observations one can now show easily that the approach taken in (α) leads to a submanifold chart of type (β). The only difference is that we need to use Lemma 24.3 instead of the Inverse Function Theorem 19.12.

(γ) The proof of this statement is again very similar to the proof of (α). We start out with a chart of type (ii) for Q and a chart of type (i) for P. We obtain a smooth map $\widetilde{\varphi}\colon \widetilde{V} \to V$ where $\widetilde{V}$ is an open subset of $\mathbb{H}^n$. By the definition of a smooth map on $\mathbb{H}^n$, see page 532, we can (after possibly first shrinking $\widetilde{V}$) extend this map to an open subset of $\mathbb{R}^n$. The rest of the argument is now basically identical to the proof of (α). ■

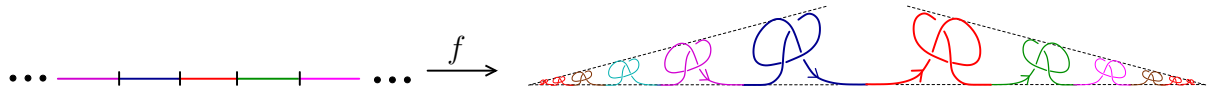
Examples.

(1) We consider the map

$$\begin{aligned} \Psi\colon \mathbb{R}^2 \times S^1 &\to \mathbb{R}^3 \\ ((x,y), \exp(\mathrm{i}\varphi)) &\mapsto \underbrace{\begin{pmatrix} \cos\varphi & -\sin\varphi & 0 \\ \sin\varphi & \cos\varphi & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{\text{rotation around } z\text{-axis}} \cdot \underbrace{\begin{pmatrix} 1+\frac{1}{2}x \\ 0 \\ -\frac{1}{2}y \end{pmatrix}}_{\substack{\text{describes circle} \\ \text{in } xz\text{-plane}}} \end{aligned}$$

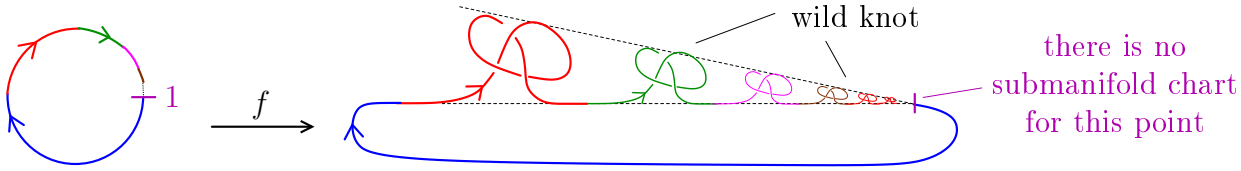
which we introduced in Lemma 5.7.

(a) Using the natural isomorphism from the Tangent Space-Isomorphism Proposition 23.16 one can show fairly easily that Θ restricts to a smooth embedding $\Psi\colon \overline{B}^2 \times S^1 \to \mathbb{R}^3$.



(b) It follows from (a) together with Lemma 24.7 that Ψ also restricts to a smooth embedding $\Psi\colon S^1 \times S^1 \to \mathbb{R}^3$.

By Theorem 24.10 this allows us to view $\overline{B}^2 \times S^1$ and $S^1 \times S^1$ as submanifolds of $\mathbb{R}^3$.

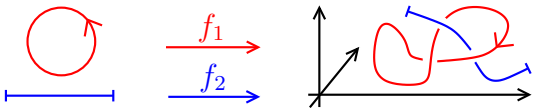


(2) Let $n \in \mathbb{N}_0$. In Lemma 2.18 we used the stereographic projection to give an explicit homeomorphism $\Phi\colon S^n \to \mathbb{R}^n \cup \{\infty\}$. We leave it to the reader to verify that the

map $\mathbb{R}^n \to \mathbb{R}^n \cup \{\infty\} \xrightarrow{\Phi^{-1}} S^n$ is a smooth embedding. We will use this embedding to view $\mathbb{R}^n$ as a submanifold of the smooth manifold S^n.

(3) We consider the map $f\colon \mathbb{R} \to \mathbb{R}^3$ that is shown in the figure below. The map f is a smooth embedding, hence its image is a smooth submanifold of $\mathbb{R}^3$.

(4) Note that in Theorem 24.10 it is essential that we are dealing with an immersion. For example consider the map $f\colon S^1 \to \mathbb{R}^3$ that is illustrated in the figure below. With a little bit of good will and effort one can arrange that f is smooth and that $\mathrm{D}f_P$ is a monomorphism at all points except for $P = 1$. Using the Compact-Hausdorff Proposition 2.17 (3) it is straightforward to show that this map is a homeomorphism onto its image, i.e. it is an embedding. But in Theorem 124.13 we will see that $f(S^1)$ is not even a topological submanifold of $\mathbb{R}^3$, more precisely we will see, that are no submanifold charts for the point $f(1) \in f(S^1)$.[259]



The following lemma is often used implicitly when dealing with smooth embeddings of disconnected manifolds.

Lemma 24.11. (Disjoint Union-Smooth Embedding Lemma) Let $M_1, \dots, M_k$ be compact smooth manifolds, let N be a smooth manifold and let $f_i\colon M_i \to N$ be smooth embeddings. If the images are disjoint, then the map

$$\bigsqcup_{i=1}^{k} f_i\colon \bigsqcup_{i=1}^{k} M_i \;\to\; N$$

is also a smooth embedding.

$f_1 \sqcup f_2\colon M_1 \sqcup M_2 \to \mathbb{R}^2$ is a smooth embedding

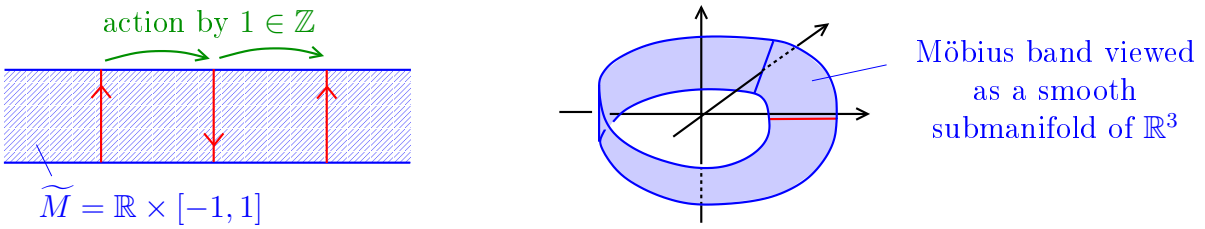
Proof. The only statement one really needs to verify is that the map is an embedding. This follows from Lemma 8.3 which we can apply by our hypothesis that $M_1, \dots, M_k$ are compact, the fact that N is by definition Hausdorff and the observation that by the Manifold Paracompact-Normal Proposition 18.9 we know that N is normal. ∎

We state our next example as a lemma.

[259] The image of an embedding $S^1 \to \mathbb{R}^3$ such that the image is not a topological submanifold is sometimes called a *wild knot*.

Lemma 24.12. (Möbius Smooth Embedding Lemma) As we discussed on pages 252 and 564 the map

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n,(x,y)) & \mapsto & (x+n, (-1)^n \cdot y) \end{array}$$



defines an action of $\mathbb{Z}$ on $\widetilde{M} := \mathbb{R} \times [-1,1]$ that is free and smooth. The quotient space $M := (\mathbb{R} \times [-1,1])/\mathbb{Z}$ is called the Möbius band. Given $\varphi, \psi \in \mathbb{R}$ and $r \in [-1,1]$ we set

$$A(\varphi) := \begin{pmatrix} \cos\varphi & -\sin\varphi & 0 \\ \sin\varphi & \cos\varphi & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad v(r,\psi) := \begin{pmatrix} 2 + r\sin\psi \\ 0 \\ r\cos\psi \end{pmatrix}.$$

The map

$$\begin{array}{rcl} \Psi\colon (\mathbb{R} \times [-1,1])/\mathbb{Z} & \to & \mathbb{R}^3 \\ [(\varphi, r)] & \mapsto & A(2\pi \cdot \varphi) \cdot v\big(r, \pi\varphi\big) \end{array}$$

is a smooth embedding. Thus the Smooth Embedding Theorem 24.10 allows us to view the Möbius band as a submanifold of $\mathbb{R}^3$.

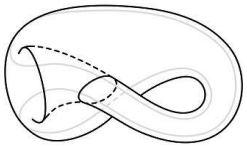
Proof. On page 252 we already mentioned that Ψ is an embedding. It remains to show that it is an immersion. We denote by $\Phi\colon \widetilde{M} = \mathbb{R} \times [-1,1] \to \mathbb{R}^3$ the map that is given by $\Phi(\varphi, r) = A(2\pi \cdot \varphi) \cdot v(r, \pi\varphi)$ and we denote by $p\colon \widetilde{M} = \mathbb{R} \times [-1,1] \to (\mathbb{R} \times [-1,1])/\mathbb{Z}$ the projection. Given any $(\varphi, r) \in \widetilde{M} = \mathbb{R} \times [-1,1]$ we consider the following diagram:

$$\begin{array}{ccccc} \widetilde{\mathrm{T}}_{(\varphi,r)}\widetilde{M} & & \xrightarrow{\Theta} & & \mathrm{T}_{(\varphi,r)}\widetilde{M} \xrightarrow{\mathrm{D}p_{(\varphi,r)}} \mathrm{T}_{(\varphi,r)}M \\ \big\downarrow{\scriptstyle \mathrm{D}\Phi_{(\varphi,r)}} & & & & \big\downarrow{\scriptstyle \mathrm{D}\Phi_{(\varphi,r)}} \quad \swarrow{\scriptstyle \mathrm{D}\Psi_{[\varphi,r]}} \\ \widetilde{\mathrm{T}}_{\Phi(\varphi,r)}\mathbb{R}^3 & & \xrightarrow{\Theta} & & \mathrm{T}_{\Phi(\varphi,r)}\mathbb{R}^3 \end{array}$$

We make the following observations and clarifications:

(1) The horizontal maps to the left are the natural isomorphisms provided by the Tangent Space-Isomorphism Proposition 23.16.
(2) A slightly heroic, but ultimately elementary calculation using the Differential-equals-Differential Lemma 23.4 shows that the vertical map to the left is a monomorphism.
(3) It follows from the Manifold Quotient-by-Group Action Proposition 19.32 that the horizontal to the top right is an isomorphism.
(4) The triangle commutes by the functoriality of differentials.

The combination of the above shows that the diagonal map is a monomorphism. ■



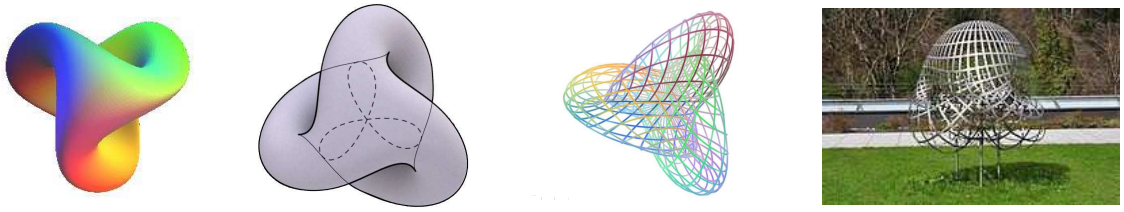
24.5. **Immersions and smooth embeddings of smooth manifolds into $\mathbb{R}^n$ I.** In Question 5.37 we had asked whether the projective space $\mathbb{R}\mathrm{P}^2$ or the Klein bottle can be viewed as subsets of $\mathbb{R}^3$. Now that we have more mathematical language at our disposal

we can turn this vague question into a precise question. In fact we can reinterpret this question in three different ways:

Question 24.13.
(1) Does $\mathbb{R}P^2$ (respectively the Klein bottle) admit an immersion into $\mathbb{R}^3$?
(2) Does $\mathbb{R}P^2$ (respectively the Klein bottle) admit a smooth embedding into $\mathbb{R}^3$?
(3) Does $\mathbb{R}P^2$ (respectively the Klein bottle) admit an embedding into $\mathbb{R}^3$?

We start out with Question 24.13 (1).

(a) We saw in the figure on page 265 that there exists an immersion of the Klein bottle K into $\mathbb{R}^3$. In the figure below we show the images of two other immersions of the Klein bottle into $\mathbb{R}^3$. This gives a non-rigorous positive answer to Question 24.13 (1) for the Klein bottle. In Exercise 24.17 we will give a rigorous positive answer to Question 24.13 (1) for the Klein bottle. Finally we point out that explicit immersions of the Klein bottle into $\mathbb{R}^3$ are discussed in detail in [**Frai2012**].



(b) The case of the real projective plane is much more interesting. In 1901 David Hilbert, arguably the greatest German mathematician of his generation, gave his PhD student Werner Boy [**Boy1903**][260] the task to prove that there is no immersion of $\mathbb{R}P^2$ into $\mathbb{R}^3$. To everyone's surprise Boy did the opposite, he showed that it was possible to immerse $\mathbb{R}P^2$ into $\mathbb{R}^3$. In the figure below we give several illustrations of the image of the immersion. A detailed description of the immersion is given in [**Kir2007, Ap1987**]. But perhaps it is more helpful to just watch the following video:

`https://www.youtube.com/watch?v=uiq-EcQz_uU`

A fun description of Boy's surface, and of many other concepts from topology, can also be found here:

`http://www.savoir-sans-frontieres.com/JPP/telechargeables/English/Topo_the_world_eng.pdf`

Boy's surface at Oberwolfach

As of right now we do not have the tools to answer Questions 24.13 (2) and (3). In Corollary 43.13 we will give an answer to Question 24.13 (2). Note that on pages 2705

[260] Werner Boy (1879-1914) was a German mathematician who died in the first weeks of World War I.

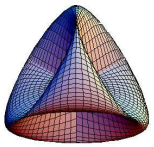
and 2705 we provide two different proofs of Corollary 43.13. Furthermore we will give an answer to Question 24.13 (3) in Corollary 124.6.
Since we cannot Question 24.13 (2) and (3), let us stick to statements we can actually prove. For example the next proposition says that any $\mathbb{R}\mathrm{P}^n$ can be smoothly embedded into some $\mathbb{R}^N$.

Proposition 24.14. (Real Projective Space-Smooth Embedding Proposition)
(1) The map

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^2 = S^2/\pm 1 & \to & \mathbb{R}^4 \\ [(x,y,z)] & \mapsto & (yz, xz, xy, x^2+2y^2+3z^2) \end{array}$$

is a smooth embedding.
(2) Let $n \in \mathbb{N}$. The map

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^n = S^n/\pm 1 & \to & \mathbb{R}^{\frac{n\cdot(n+1)}{2}+1} \\ [(x_1,\ldots,x_{n+1})] & \mapsto & \left((x_i\cdot x_j)_{i=1,\ldots,n+1, j=1,\ldots,i-1}, \sum_{k=1}^{n+1} k\cdot x_k^2\right) \end{array}$$



is a smooth embedding.

Proof. We will prove Statement (1) in Exercise 24.9. We leave the proof of Statement (2) to the intellectually intrepid reader. ■

Remark. We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R}\mathrm{P}^2 & \to & \mathbb{R}^3 \\ [(x,y,z)] & \mapsto & (yz, xz, xy). \end{array}$$

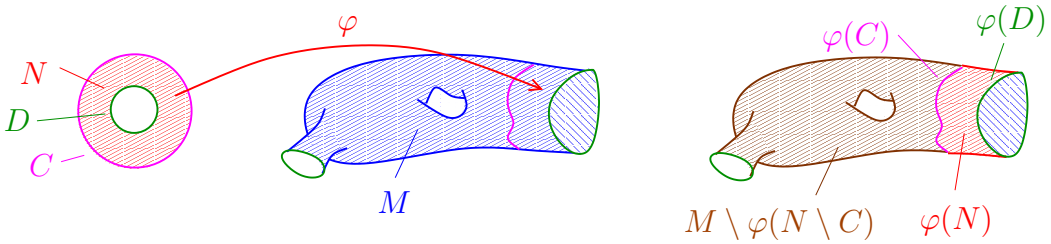
In other words, we consider the composition of the smooth embedding $\mathbb{R}\mathrm{P}^2 \to \mathbb{R}^3$ from the Real Projective Space-Smooth Embedding Proposition 24.14 with the projection $\mathbb{R}^4 \to \mathbb{R}^3$ onto the first three coordinates. In Exercise 24.10 we will see that there are precisely 6 points on $\mathbb{R}\mathrm{P}^2$ such that $\mathrm{D}f_P$ is not a monomorphism. By [**Ap1987**, p. 40] the image $f(\mathbb{R}\mathrm{P}^2) \subset \mathbb{R}^3$ is the so-called *Steiner surface* or *Roman surface*, which was first discovered by the Swiss mathematician Jacob Steiner in Rome in 1844.

Steiner surface in $\mathbb{R}^3$

As always in mathematics, a result generates new questions. For example, now that by the Real Projective Space-Smooth Embedding Proposition 24.14 we know that we can smoothly embed each $\mathbb{R}\mathrm{P}^n$ into $\mathbb{R}^{\frac{n\cdot(n+1)}{2}+1}$, the following question naturally arises:

Question 24.15. Given $n \in \mathbb{N}$, what is the minimal dimension $d(n)$ such that $\mathbb{R}\mathrm{P}^n$ admits a smooth embedding into $\mathbb{R}^{d(n)}$?

By the Real Projective Space-Smooth Embedding Proposition 24.14 we know that $d(n) \leq \frac{n\cdot(n+1)}{2} + 1$. In the Weak Whitney Embedding Theorem 30.7 we will show that $d(n) \leq 2n+1$ and in Corollary 43.13 we will see that $d(2) \geq 4$. Furthermore it follows from Proposition 123.11 that $d(n) \geq n+2$. Over the years there have been lots of partial



answers to Question 24.15, see e.g. [**Mah1962, MahM1968**]. Nonetheless it seems like Question 24.15 has not been fully answered yet. Some of the results are summarized in

`https://www.lehigh.edu/~dmd1/immtable`

24.6. **Immersions among smooth manifolds of the same dimension.** In the following proposition we consider immersions and smooth embeddings between smooth manifolds of the same dimension.

Proposition 24.16. (Codimension-Zero Smooth Embedding Proposition) Let M and N be smooth manifolds of the same dimension and let $\varphi\colon N \to M$ be an immersion. Recall that by the definition of an immersion on page 651 we know that for every component C of ∂N we have either $\varphi(C) \subset \partial M$ or $\varphi(C) \subset M \setminus \partial M$. We denote by C the union of all components of ∂N with $\varphi(C) \not\subset \partial M$ and we write $D := \partial N \setminus C$.

(1) The image $\varphi(N \setminus C)$ is an open subset of M.
(2) If $\varphi\colon N \to M$ is a smooth embedding and if $\varphi(N)$ is a closed subset of M, then the following five statements hold:
   (a) $\varphi(N)$ is a submanifold of M with[261] $\partial_0(\varphi(N)) = \varphi(C)$ and $\partial_1(\varphi(N)) = \varphi(D)$.
   (b) M is decomposed, in the sense of the definition on page 570, into the submanifolds $\varphi(N)$ and $X := M \setminus \varphi(N \setminus C)$.
   (c) The boundary of $M \setminus \varphi(N \setminus C)$ as a smooth manifold in its own right is given by $(\partial M \setminus \varphi(D)) \cup \varphi(C)$.
   (d) If ∂N is connected and if M is connected, then X is also connected.
   (e) If M is compact, then $M \setminus \varphi(N \setminus \partial N)$ is also compact.
   (We refer to the below for an illustration.)
(3) If $\varphi\colon N \to M$ is a smooth embedding, if N is closed and if M is connected, then φ is a diffeomorphism.

Example. It follows from the Codimension-Zero Smooth Embedding Proposition 24.16 (3) that it is impossible to smoothly embed a closed n-dimensional smooth manifold into $\mathbb{R}^n$.

Sketch of proof.

(1) This statement follows almost immediately from the Inverse Mapping Theorem 24.1.
(2) By the Smooth Embedding Theorem 24.10 we know that $\varphi(N)$ is a codimension-zero submanifold of N. The statement about $\partial_0(\varphi(N))$ and $\partial_1(\varphi(N))$ follows immediately from the definition on page 568.

   All the remaining statements follow from our hypothesis that $\varphi(N)$ is a closed subset of M together with the Codimension-Zero Submanifold Proposition 19.38.

[261] We refer to page 568 for the definition of ∂_0 and ∂_1 of a codimension-zero submanifold.

(3) We already know by Theorem 24.10 that $\varphi\colon N \to \varphi(N)$ is a diffeomorphism. Thus it suffices to show that $\varphi(N) = M$. First note that it follows from the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 (2) that $\varphi(N)$ is a closed subset of M. Furthermore, it follows easily from the Smooth Invariance of Domain Theorem 19.13 that $\varphi(N)$ is an open subset of M. Since M is connected we see that $M = \varphi(N)$. ■

Exercises for Chapter 24.

Exercise 24.1. Let $f\colon M \to N$ be a smooth map between two n-dimensional smooth manifolds such that $f(\partial M) \subset N \setminus \partial N$. Let $P \in \partial M$ be a point such that $\mathrm{D}f_P$ is invertible. Show that there exists a chart $\Phi\colon U \to B^n_{\geq 0}$ for M around P and a chart $\Psi\colon V \to B^n$ around $f(P)$ such that the map $\Psi \circ f \circ \Phi^{-1}\colon B^n_{\geq 0} \to B^n$ is the inclusion.

Exercise 24.2. At which points is the map

$$\begin{array}{rcl} f\colon S^2 & \to & S^2 \\ (x,y,z) & \mapsto & \frac{1}{x^4+y^4+z^4}(x^2,y^2,z^2) \end{array}$$

a local diffeomorphism?

Exercise 24.3. Let X and Y be two topological spaces and let $\varphi\colon X \to Y$ be an embedding. We consider the following two conditions on φ.

(I) $\varphi(X)$ is a closed subset of Y.
(II) For every compact subset K of Y the preimage $\varphi^{-1}(K)$ is compact.

In Lemma 24.5 we saw that the two conditions (I) and (II) are equivalent if we are dealing with a map between topological manifolds.

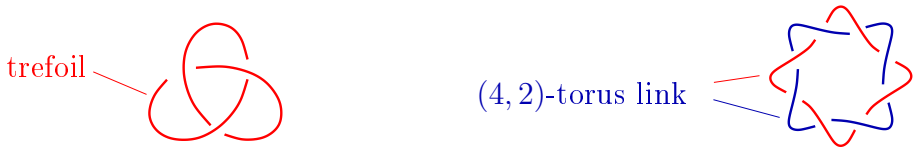
(a) Given an example of a map $\varphi\colon X \to Y$ between two topological spaces such that (I) is satisfied but (II) is not satisfied.
(b) Given an example of a map $\varphi\colon X \to Y$ between two topological spaces such that (II) is satisfied but (I) is not satisfied.

Exercise 24.4. Let M and N be smooth manifolds and let $f\colon M \to N$ be an immersion. We denote by $\Delta = \{(x,x) \in M \times M \,|\, x \in M\}$ the "diagonal" of $M \times M$.

(a) Show that there exists an open neighborhood U of the diagonal Δ such that for every $(x,y) \in U \setminus \Delta$ we have $f(x) \neq f(y)$.
(b) We suppose that M is compact. Show that f admits only finitely many double points, i.e. that there exist only finitely many distinct pairs $(x_1,y_1),\dots,(x_n,y_n)$ in $(M \times M) \setminus \Delta$ such that $f(x_i) = f(y_i)$ for $i = 1,\dots,n$.

Exercise 24.5.

(1) Show that a closed n-dimensional smooth manifold cannot admit an immersion into $\mathbb{R}^n$.
(2) Let $\varphi\colon \overline{B}^2 \to T := S^1 \times S^1$ be a smooth embedding.
   (a) Does there exist an immersion of $M := T \setminus \varphi(B^2)$ to $\mathbb{R}^2$?
   (b) Does there exist a smooth immersion of $M := T \setminus \varphi(B^2)$ to $\mathbb{R}^2$?



Exercise 24.6. Let $m, n \in \mathbb{N}_0$. Show that the smooth submanifold $S^m \times S^n$ is diffeomorphic to a smooth submanifold of $\mathbb{R}^{m+n+1}$.

Exercise 24.7. Let $A \in \mathrm{M}(m \times n, \mathbb{R})$ with rows $r_1, \dots, r_m$. Show that the map

$$\begin{array}{rcl} \mathbb{R}^n & \to & \mathbb{R}^m \\ v & \mapsto & A \cdot v \end{array}$$

is a monomorphism if and only if there exist $i_1, \dots, i_n \in \{1, \dots, m\}$ such that the determinant of the $n \times n$-matrix with rows $r_{i_1}, \dots, r_{i_n}$ has non-zero determinant.

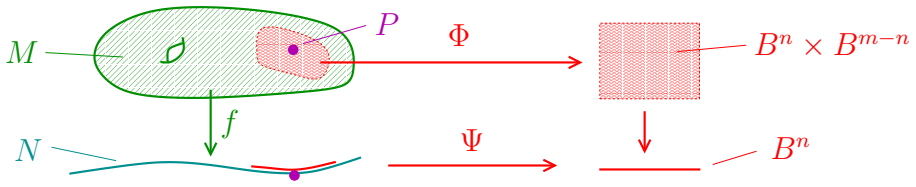
Exercise 24.8. Consider the subsets of $\mathbb{R}^3$ that are shown in the figure below. Show that they are smooth submanifolds of $\mathbb{R}^3$ by giving explicit smooth embeddings of S^1 and $S^1 \sqcup S^1$ into $\mathbb{R}^3$ such that the images equals the shown subsets.

Exercise 24.9. Show that the map

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^2 = S^2/\pm 1 & \to & \mathbb{R}^4 \\ [(x,y,z)] & \mapsto & (yz, xz, xy, x^2 + 2y^2 + 3z^2) \end{array}$$

is a smooth embedding.

Exercise 24.10. We consider the map



$$\begin{array}{rcl} f\colon \mathbb{R}\mathrm{P}^2 & \to & \mathbb{R}^3 \\ [(x,y,z)] & \mapsto & (yz, xz, xy). \end{array}$$

Show that there are precisely 6 points on $\mathbb{R}\mathrm{P}^2$ such that $\mathrm{D}f_P$ is not a monomorphism.

Exercise 24.11. Let $f\colon M \to N$ be a smooth map between two smooth manifolds M and N of dimensions m respectively n. Let $P \in M \setminus \partial M$ such that $f(P) \in N \setminus \partial N$. We suppose that the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ is an epimorphism.[262] Show that there exists a chart $\Phi\colon U \to B^n \times B^{m-n}$ around P and a chart $\Psi\colon V \to B^n$ around $f(P)$ with $f(U) \subset V$ such that the map $\Psi \circ f \circ \Phi^{-1}\colon B^n \times B^{m-n} \to B^n$ is just the projection onto the first factor.
Remark. This statement can be viewed as a weak version of the Submersion Theorem **??**.

Exercise 24.12. Let M be a smooth manifold. We equip ∂M with the smooth structure that we introduced on page 555. Let W be a smooth manifold and let $f\colon W \to M$ be a smooth map with $f(W) \subset \partial M$.

[262] Note that this hypothesis implies that $m \geq n$.

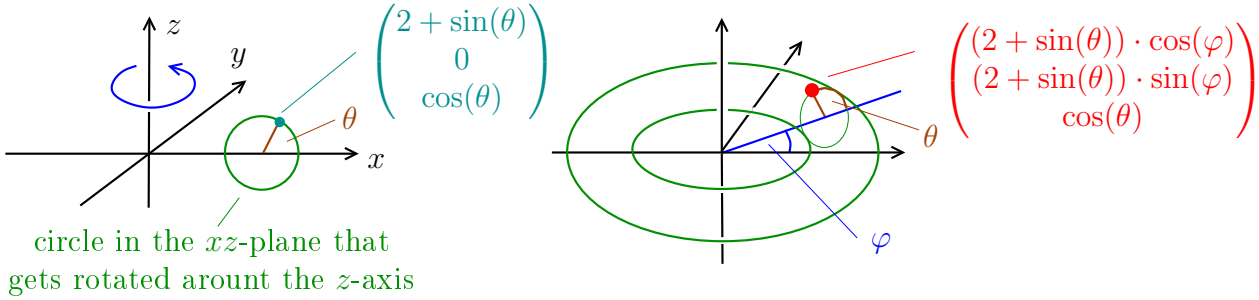
(a) Show that if $\mathrm{D}f_P\colon \mathrm{T}_P W \to \mathrm{T}_P M$ is a monomorphism for each P, then $f\colon W \to \partial M$ is an immersion.
(b) Show that if f is a bijection and if $\mathrm{D}f_P\colon \mathrm{T}_P W \to \mathrm{T}_P \partial M \subset \mathrm{T}_P M$ is an isomorphism for each P, then $f\colon W \to \partial M$ is a diffeomorphism.

Remark. This exercise can be viewed as a variation on the Smooth Embedding Theorem 24.10.

Exercise 24.13. Let M be an m-dimensional smooth manifold, let N be an n-dimensional smooth manifold and let $f\colon M \to N$ to be a smooth map.

(a) Let $P \in M$ such that $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ is a monomorphism. Show that there exists a chart $\Phi\colon U \to \widetilde{U}$ around P and a chart $\Psi\colon V \to \widetilde{V}$ around $f(P)$ such that the map
$$\Psi \circ f \circ \Phi^{-1}\colon \Phi(f^{-1}(V) \cap U) \;\to\; \mathbb{R}^n$$
is the map
$$(x_1, \ldots, x_m) \;\mapsto\; (x_1, \ldots, x_m, 0, \ldots, 0).$$

(b) We now assume that there exists a $k \in \mathbb{N}$ such that for any $P \in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ has rank k. Show that for each $P \in M$ there exists a chart $\Phi\colon U \to \widetilde{U}$ around P and a chart $\Psi\colon V \to \widetilde{V}$ around $f(P)$ such that the map
$$\Psi \circ f \circ \Phi^{-1}\colon \Phi(f^{-1}(V) \cap U) \;\to\; \mathbb{R}^n$$
is the map
$$(x_1, \ldots, x_m) \;\mapsto\; (x_1, \ldots, x_k, 0, \ldots, 0).$$



Remark. This statement is known as the *Constant Rank Theorem*.

Exercise 24.14. Let M be a connected m-dimensional smooth manifold and let $N \subsetneq M$ be a submanifold. Show that if there exists a smooth retraction $f\colon M \to N$, then $\dim(N) < \dim(M)$.
Hint. Show that if N is a smooth retract of M with $\dim(N) = \dim(M)$, then N is closed and open in M.

Exercise 24.15. Show that the map
$$\begin{array}{rcl} \mathbb{R}^2/(2\pi\mathbb{Z})^2 & \to & \mathbb{R}^3 \\ (\varphi, \theta) & \mapsto & \underbrace{\begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{\text{rotation around the } z\text{-axis}} \cdot \underbrace{\begin{pmatrix} 2+\sin(\theta) \\ 0 \\ \cos(\theta) \end{pmatrix}}_{\substack{\text{describes a circle} \\ \text{in the } xz\text{-plane}}} \end{array}$$

is a smooth embedding.

Remark. By Torus-as-Quotient Lemma 19.34 we know that the torus $S^1 \times S^1$ is diffeomorphic to $\mathbb{R}^2/(2\pi\mathbb{Z})^2$. This fact, together with the fact that f is a smooth embedding and the Smooth Embedding Theorem 24.10 proves, the hardly surprising fact, that the torus is diffeomorphic to a submanifold of $\mathbb{R}^3$.

Exercise 24.16. We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R}\times\mathbb{R}_{>0} & \to & \mathbb{R}^3 \\ (\varphi, r) & \mapsto & \begin{pmatrix} r\cdot\cos(\varphi) \\ r\cdot\sin(\varphi) \\ \varphi \end{pmatrix} \end{array}$$

(a) Sketch the image of f.
(b) Show that f is a smooth embedding.

Exercise 24.17. On page 265 we considered the Klein bottle

$$K \;:=\; ([0,1]\times[0,1])/\sim \qquad \text{where } (x,0)\sim(x,1) \text{ and } (y,0)\sim(1,1-y).$$

We now consider

$$\widetilde{K} \;:=\; \mathbb{R}^2/\sim \qquad \text{where } (u,v)\sim(u+2k\cdot\pi, (-1)^k\cdot v + 2l\pi) \text{ for all } k,l\in\mathbb{Z}.$$

(a) In the description of $\widetilde{K}$ we implicitly gave an action of $\mathbb{Z}^2$ on $\mathbb{R}^2$. This action is smooth. Show that this action is not free. Nonetheless show that $\widetilde{K}$ has a canonical smooth structure coming from $\mathbb{R}^2$.
(b) Show that K is diffeomorphic to $\widetilde{K}$.
(c) Show that the map

$$\begin{array}{rcl} \widetilde{K} & \to & \mathbb{R}^3 \\ [(u,v)] & \mapsto & \begin{pmatrix} \frac{\cos(2u)\cdot\sin(v)}{1-\frac{1}{\sqrt{2}}(\sin(u)\cdot\cos(u)+\sin(2u)\cdot\sin(v))} \\ \frac{\sin(2u)\cdot\sin(v)-\sin(u)\cdot\cos(v)}{\sqrt{2}(1-\frac{1}{\sqrt{2}}\sin(u)\cdot\cos(u)+\sin(2u)\cdot\sin(v))} \\ \frac{\cos(u)\cdot\cos(v)}{1-\frac{1}{2}(\sin(u)\cdot\cos(u)+\sin(2u)\cdot\sin(v))} \end{pmatrix} \end{array}$$

is an immersion.

25. Orientations of smooth manifolds

In this chapter we will introduce the notion of an orientation of a smooth manifold. This notion captures something very intuitive, even though the technical definition takes a little while to get used to.

25.1. **Orientations of real vector spaces I.** Before we can introduce and study orientations of smooth manifolds we need to introduce the notion of an orientation of a finite-dimensional real vector space. This section is pure linear algebra.

Definition. Let V be some finite-dimensional real vector space. If $X = (x_1, \dots, x_n)$ and $Y = (y_1, \dots, y_n)$ are bases[263] for V, then there exists a unique matrix $P_{X,Y} = (p_{ij})$ such that given any $i \in \{1, \dots, n\}$ we have $x_i = \sum_{j=1}^{n} p_{ji} \cdot y_j$. We refer to $P_{X,Y}$ as the transition matrix from X to Y.

The following lemma is taught in every proper linear algebra course.

Lemma 25.1. (Transition Matrix Lemma) Let V be a finite-dimensional real vector space.

(1) If X and Y are two bases of V, then $P_{Y,X} = P_{X,Y}^{-1}$.[264]
(2) If X, Y and Z are bases of V, then $P_{X,Z} = P_{Y,Z} \cdot P_{X,Y}$.

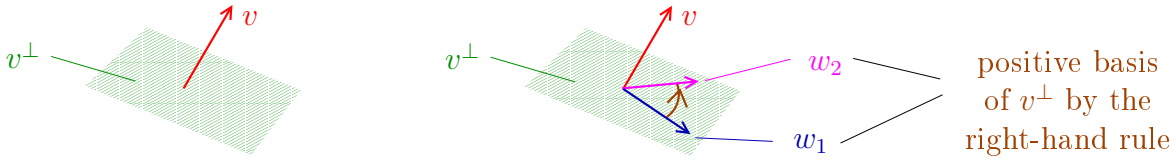
Definition. Let V be a finite-dimensional real vector space of dimension > 0.

(1) We say that two bases of V are equivalent[265] if the determinant of the corresponding transition matrix is positive.[266]
(2) An equivalence class of bases is called an orientation for V. An oriented vector space is a vector space together with an orientation.
(3) Let $\mathcal{O}$ be an orientation for V. We say a basis $(v_1, \dots, v_k)$ of V is a positive basis, if $(v_1, \dots, v_k)$ lies in $\mathcal{O}$, otherwise we say that it is a negative basis.

Examples. Let $n \in \mathbb{N}$.

(1) We refer to the orientation on the real vector space $\mathbb{R}^n$ that is given by the equivalence class of the canonical basis $(e_1, \dots, e_n)$ as the standard orientation of $\mathbb{R}^n$. It follows immediately from the definition that

$$(v_1, \dots, v_n) \text{ is a positive basis for } \mathbb{R}^n \iff \det \underbrace{(v_1 \ \dots \ v_n)}_{n \times n\text{-Matrix}} > 0.$$



Unless we say something else we always view the real vector space $\mathbb{R}^n$ as equipped with the standard orientation.

[263] Here and throughout the notes a basis of a finite-dimensional vector space is always understood to be an ordered basis.
[264] To avoid discussions we define the inverse of the empty matrix to be the empty matrix.
[265] It follows easily from the Transition Matrix Lemma 25.1 and the multiplicativity of the determinant that this notion of "equivalent" does indeed define an equivalence relation.
[266] If V is 0-dimensional, then it has only the empty basis, we use the convention that the determinant of the empty matrix is $+1$.

(2) Let $v \in \mathbb{R}^n$ be a non-zero vector. We consider the orthogonal complement of v, i.e. we consider the vector space $v^\perp = \{w \in \mathbb{R}^n \mid \langle v, w\rangle = 0\}$. In Exercise 25.1 we will show, using elementary linear algebra, that

$$(w_1, \dots, w_{n-1}) \text{ is a positive basis of } v^\perp \quad :\Longleftrightarrow \quad \det(v\ w_1\ \dots\ w_{n-1}) > 0$$

does indeed define an orientation on $v^\perp$. We say that this orientation is obtained by the *right-hand rule*.

(3) Let V be a real vector space of dimension ≥ 1. If $(v_1, v_2, \dots, v_n)$ is a basis of V, then the basis $(-v_1, v_2, \dots, v_n)$ is inequivalent to the original basis.

(4) In the Complex Vector Space-Orientation Lemma 32.22 we will see that every *complex* vector space of dimension $n \in \mathbb{N}$, viewed as a $2n$-dimensional real vector space, comes with a natural orientation. The algebraically inclined reader might want to figure out what this means and how this works.

It follows easily from the previous example that any finite-dimensional real vector space of dimension ≥ 1 admits precisely two orientations. For a surprisingly large number of situations it is actually very convenient to extend the notion of an orientation to 0-dimensional real vector spaces in such a way that there are also precisely two orientations. This leads us to the following definition.

Definition. An orientation of a 0-dimensional real vector space is defined as a choice of a number in $\{-1, +1\}$.

Definition. Let V be a finite-dimensional real vector space. Given an orientation $\mathcal{O}$ for such a vector space V we denote by $-\mathcal{O}$ the other orientation. Sometimes we refer to it as the opposite orientation.

Definition. Let V and W be finite-dimensional real vector spaces.

(1) Let $f\colon V \to W$ be an isomorphism. If $\dim(V) = \dim(W) > 0$, then basic linear algebra shows that f induces a bijection

$$\begin{array}{rcl} f\colon \text{orientations of } V & \to & \text{orientations of } W \\ [(v_1, \dots, v_n)] & \mapsto & [(f(v_1), \dots, f(v_n))]. \end{array}$$

If $\dim(V) = \dim(W) = 0$, then given an orientation $\epsilon \in \{-1, 1\}$ for V we refer to ϵ also as the image of orientation under the isomorphism $f\colon V \to W$.

(2) Now assume that V and W are oriented. We say an isomorphism $\Phi\colon V \to W$ is orientation-preserving if the image of the orientation of V under the map f described in (1) equals the orientation of W.[267] Otherwise we say that Φ is orientation-reversing.

For reference we state the following straightforward fact as a lemma.

[267] In other words, the map is orientation-preserving if the image of a positive basis of V is a positive basis of W.

Lemma 25.2. Let $\Phi\colon V \to W$ be an isomorphism between two oriented finite-dimensional real vector spaces with $\dim(V) = \dim(W) > 0$. Furthermore let X be a basis for V and let Y be a basis for W. We make either following hypothesis:

(1) either both bases are positive or
(2) both bases are negative,

then

$$\Phi \text{ is orientation-preserving} \quad \Longleftrightarrow \quad \det(P_{\Phi(X),Y}) > 0.$$

The following lemma often gets used subconsciously:

Lemma 25.3. (Orientation-Composition Lemma) Let $V_0, \dots, V_k$ be oriented vector spaces. Furthermore let $f_i\colon V_i \to V_{i+1}$, $i = 0, \dots, k-1$ be isomorphisms. Then

$$\begin{array}{c}\text{the map } f_{k-1} \circ \cdots \circ f_0\colon V_0 \to V_k \\ \text{is orientation-preserving}\end{array} \quad \Longleftrightarrow \quad \begin{array}{c}\text{the number of } f_i \text{ which are} \\ \text{orientation-reversing is even.}\end{array}$$

In particular the composition of orientation-preserving isomorphisms is again orientation-preserving.

Proof. If all vector spaces are 0-dimensional, then the statement is completely elementary. Otherwise the lemma follows easily from the Transition Matrix Lemma 25.1 and Lemma 25.2 together with the multiplicativity of the determinant. ■

Definition. A short exact sequence of real vector spaces is a sequence of homomorphisms

$$U \xrightarrow{\varphi} V \xrightarrow{\psi} W$$

between real vector spaces U, V and W such that the following conditions are satisfied:

(1) $\varphi\colon U \to V$ is a monomorphism,
(2) $\psi\colon V \to W$ is an epimorphism,
(3) $\operatorname{im}(\varphi) = \ker(\psi)$.

Example. Let V be a real vector space and let $U \subset V$ be a vector subspace. Then the maps $U \to V \to V/U$, given by the inclusion and the natural projection, form a short exact sequence of real vector spaces. In fact every short exact sequence is essentially of this form. More precisely, if $U \xrightarrow{\varphi} V \xrightarrow{\psi} W$ is a short exact sequence, then we obtain the following commutative diagram

$$\begin{array}{ccccc} U & \xhookrightarrow{\quad\varphi\quad} & V & \xrightarrow{\quad\psi\quad} & W \\ \downarrow{\scriptstyle \varphi} & & \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle w \mapsto [v] \text{ where } \psi(v) = w} \\ \varphi(U) & \xhookrightarrow{\quad\quad} & V & \xrightarrow{\quad\quad} & V/\varphi(U). \end{array}$$

where all vertical maps are isomorphisms.

Lemma 25.4. Let

$$U \xhookrightarrow{\quad\varphi\quad} V \xrightarrow{\quad\psi\quad} W$$

be a short exact sequence of finite-dimensional real vector spaces. We suppose that U and W are oriented and that $\dim(U) > 0$ and $\dim(W) > 0$.

(1) We pick a positive basis $(u_1, \dots, u_k)$ for U and a positive basis $(w_1, \dots, w_l)$ for W.

(2) We pick lifts $\widetilde{w}_1, \dots, \widetilde{w}_l \in V$ of $w_1, \dots, w_l \in W$.

Then $(u_1, \dots, u_k, \widetilde{w}_1, \dots, \widetilde{w}_l)$ is an ordered basis for V and the orientation it defines only depends on the orientations of U and W.

Sketch of proof. It is straightforward to verify that the given vectors define a basis for V. Furthermore note that any other choice of a positive basis for U, choice of positive basis for W and choice of lifts of $w_1, \dots, w_l \in W$ leads to a transition matrix of the form

$$\begin{pmatrix} A & X \\ 0 & B \end{pmatrix}$$

with $\det(A) > 0$ and $\det(B) > 0$. Thus the two sets of choices lead to equivalent bases for V. ■

Definition. Let

$$U \xrightarrow{\varphi} V \xrightarrow{\psi} W$$

be a short exact sequence of finite-dimensional real vector spaces. We suppose that U, V and W are oriented.

(1) If $\dim(U) > 0$ and $\dim(W) > 0$, then we say that the orientations are compatible if the orientations of U and W define, in the sense of Lemma 25.4, the orientation of V.
(2) Suppose that $\dim(U) = 0$.
   (a) If the orientation of U is $+1$, then we say that the orientations are compatible if the isomorphism $\psi\colon V \to W$ is orientation-preserving.
   (b) If the orientation of U is -1, then we say that the orientations are compatible if the isomorphism $\psi\colon V \to W$ is orientation-reversing.
(3) The analogue of (2) holds is $\dim(W) = 0$.

If the orientations are not compatible, then we say that they are incompatible.

Lemma 25.5. (Compatible Orientations Lemma) Let

$$U \xrightarrow{\varphi} V \xrightarrow{\psi} W$$

be a short exact sequence of real vector spaces.

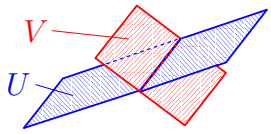
(1) If two out of U, V and W are oriented, then there exists a unique orientation on the third vector space such that the three orientations are compatible.
(2) Suppose U, V and W are oriented in a compatible way.
   (a) If we reverse an *even* number of the given three orientations, then the orientations are again *compatible*.
   (b) If we reverse an *odd* number of the given three orientations, then the orientations are *incompatible*.

Proof. The proof is straightforward and basically trivial. We will not bore the reader with details. ■

The Compatible Orientations Lemma 25.5 can be used to define various induced orientations.

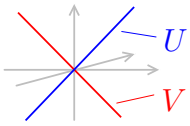
Definition. Let U and V be oriented finite-dimensional real vector spaces. We define the direct sum orientation on $U \oplus V$ to be the unique orientation[268] that makes the orientations

in the following short exact sequence of real vector spaces compatible:



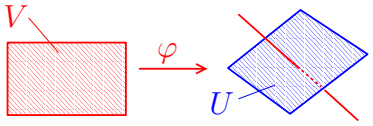
$$U \xrightarrow{u\mapsto(u,0)} U\oplus V \xrightarrow{u\oplus v\mapsto v} V.$$

Remark. If U and V are 0-dimensional real vector spaces with orientations $\mu\in\{-1,1\}$ and $\nu\in\{-1,1\}$, then our conventions imply that $U\oplus V$ has the orientation $\mu\cdot\nu\in\{-1,1\}$.



Definition. Let W be a real vector space and let U be a vector subspace of W.

(1) Let V be another vector subspace of W. We say U and V intersect transversally if $W=U+V$.



(2) Let V be a real vector space and let $\varphi\colon V\to W$ be a homomorphism. We say U and φ intersect transversally if $W=U+\varphi(V)$.

U and V intersect transversally in $W=\mathbb{R}^3$

U and V do not intersect transversally in $W=\mathbb{R}^3$

U and φ intersect transversally in $W=\mathbb{R}^3$

Remark. Let W be a real vector space and let U,V be oriented vector subspaces. We denote by $\iota\colon V\to W$ the inclusion map. It follows immediately from the definitions that U and V are transverse if and only if U and ι are transverse. On many occasions this little observation allows us to treat (1) as a special case of (2).

The following lemma is utterly elementary, but we use it so often that it is convenient to state it explicitly.

Lemma 25.6. Let W be a real vector space and let U be a vector subspace of W.

(1) Let V be another vector subspace of W. If U and V intersect transversally, then the map

$$\begin{array}{rcl} V/U\cap V & \to & W/U \\ [v]=v+U\cap V & \mapsto & [v]=v+U \end{array}$$

is an isomorphism.

(2) Let V be a real vector space and let $\varphi\colon V\to W$ be a homomorphism. If U and φ intersect transversally, then the map

$$\begin{array}{rcl} V/\varphi^{-1}(U) & \to & W/U \\ [v]=v+\varphi^{-1}(U) & \mapsto & [\varphi(v)]=\varphi(v)+U \end{array}$$

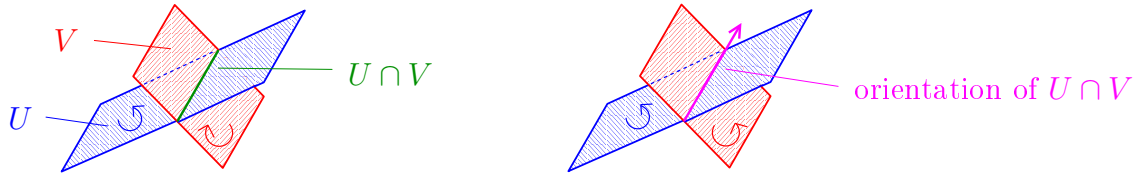
is an isomorphism.

Proof. As pointed out above, (1) is just a reader friendly special case of (2). Thus it remains to prove (2). It is clear that the map is a monomorphism. It follows almost immediately from the hypothesis that U and φ intersect transversally that the map is also an epimorphism. ■

[268] Here of course we use the Compatible Orientations Lemma 25.5.

Definition. Let W be an oriented real vector space and let U be an oriented vector subspace.

(1) Let V be another oriented vector subspace of W. We assume that U intersects V transversally. We consider the following diagram:



$$\begin{array}{ccccc} U & \hookrightarrow & W & \twoheadrightarrow & W/U \\ & & & & \cong\uparrow{\scriptstyle [v]\mapsto[v]} \\ U\cap V & \hookrightarrow & V & \twoheadrightarrow & V/(U\cap V). \end{array}$$

It follows from Lemma 25.6 that the right-hand vertical map is an isomorphism. Note that the horizontal sequences are short exact sequences. By the Compatible Orientations Lemma 25.5 the orientations on U and W induce an orientation on W/U and the isomorphism induces an orientation on $V/(U\cap V)$. Finally, again using the Compatible Orientations Lemma 25.5 we see that this orientation on $V/(U\cap V)$, together with the given orientation on V, induces an orientation on $U\cap V$. We refer to this as the intersection orientation on $U\cap V$.

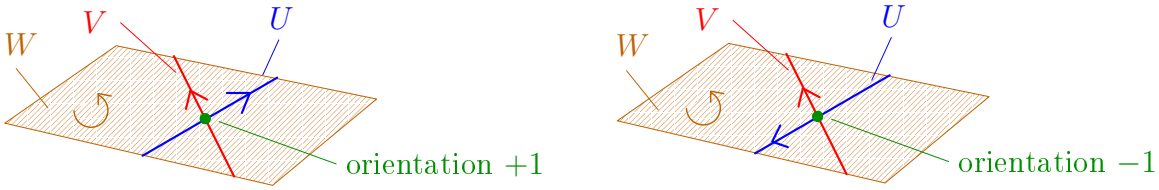
(2) Let V be another real vector space and let $\varphi\colon V\to W$ be a homomorphism. We assume that φ intersects U transversally. We consider the following diagram:

$$\begin{array}{ccccc} U & \hookrightarrow & W & \twoheadrightarrow & W/U \\ & & & & \cong\uparrow{\scriptstyle [v]\mapsto[\varphi(v)]} \\ \varphi^{-1}(U) & \hookrightarrow & V & \twoheadrightarrow & V/\varphi^{-1}(U). \end{array}$$

By the same logic as in (1) we see that we obtain an orientation on $\varphi^{-1}(U)$. We refer to this as the preimage orientation on $\varphi^{-1}(U)$.

Remark.

(1) A priori there are many reasonable ways to define the intersection orientation on $U\cap V$. Our convention agrees with the convention chosen in [**GP1974**, p. 100].



(2) Our convention of the intersection orientation is designed as follows: Let A, B and C be oriented real vector spaces. We set $W := A\oplus B\oplus C$ and we consider the vector subspaces $U = A\oplus B\oplus\{0\}$ and $V = \{0\}\oplus B\oplus C$. If we equip U, V, W with the obvious orientations, then the intersection orientation on $U\cap V = \{0\}\oplus B\oplus\{0\}$ is the obvious orientation.

(3) Let W be an oriented real vector space and let U, V be oriented vector subspaces. We denote by $\iota\colon V\to W$ the inclusion map. As we remarked above, it follows immediately from the definitions that U and V are transverse if and only if U and ι are transverse. Furthermore, if this is the case, then it follows again immediately from

the definitions that the intersection orientation on $U \cap V$ agrees with the preimage orientation on $\iota^{-1}(U) = U \cap V$.

Example. Let W be an oriented real vector space and let U and V be oriented vector subspaces with $W = U + V$ and with $U \cap V = 0$. We equip $U \oplus V$ with the direct sum orientation that we defined on page 672. It follows immediately from the definitions that the intersection-orientation of $U \cap V$ is given as follows:

$$\text{orientation of } U \cap V = \begin{cases} +1, & \text{if direct sum orientation of } U \oplus V \text{ equals orientation of } W, \\ -1, & \text{otherwise.} \end{cases}$$

We conclude this discussion of orientations on real vector spaces and of orientation-preserving and orientation-reversing isomorphisms with a short discussion of *automorphisms* of finite dimensional real vector spaces.

Definition. Let V be a finite dimensional real vector space and let $f\colon V \to V$ be an automorphism.

(1) If $\dim(V) > 0$, then we say that f is orientation-preserving if for one choice of a basis X for V we have $\det(P_{f(X),X}) > 0$. Otherwise we say that f is orientation-reversing.
(2) If $\dim(V) = 0$, then we always say that f is orientation-preserving.

We will use this notion at several occasions. At this point there is not much to say except that we have the following very elementary lemma which we will use many times, often without noticing.

Lemma 25.7. Let V be a finite dimensional real vector space.

(1) The composition of orientation-preserving automorphisms is again orientation-preserving.
(2) Let $\varphi\colon V \to W$ be an isomorphism and let $f\colon V \to V$ be an automorphism. Then the following two statements are equivalent:
   - $f\colon V \to V$ is orientation-preserving,
   - $\varphi \circ f \circ \varphi^{-1}\colon W \to W$ is orientation-preserving.

Proof. Both statements follow immediately from the Orientation-Composition Lemma 25.3. ■

25.2. **Orientations of smooth manifolds.** After the preparations from the last section we can now introduce the notion of an orientation on a smooth manifold.

[268] It follows immediately from the Transition Matrix Lemma 25.1 and the multiplicativity of the determinant that the sign of $\det(P_{f(X),X})$ does not depend on the choice of the basis X.

An orientation of a smooth manifold M is supposed to be an orientation for each tangent space $\mathrm{T}_P M$ which is "continuous". Turning the idea of "continuity" into a precise notion requires a little bit of thought.

Definition. Let M be a smooth manifold.

(1) An orientation for M is a map which assigns to every tangent space $\mathrm{T}_P M$, $P \in M$, an orientation such that the following continuity condition is satisfied:
   (∗) For every chart $\Phi\colon U \to V$ of the smooth structure of M and every component U' of U the map

$$\begin{array}{ccccccc} \mathrm{T}_P M & \xleftarrow[\uparrow]{\cong} & \mathrm{T}_P U & \xrightarrow[\cong]{\mathrm{D}\Phi_P} & \mathrm{T}_{\Phi(P)} V & \xrightarrow[\uparrow]{\Theta_V} & \widetilde{\mathrm{T}}_{\Phi(P)} V \quad = \quad \mathbb{R}^k \\ \text{isomorphism by} & & \text{by Proposition 23.14 (2)} & & \text{natural isomorphism} & & \text{Lemma 23.1} \\ & & & & \text{from Proposition 23.16} & & \end{array}$$

   is either orientation-preserving for all $P \in U'$ or it is orientation-reversing for all $P \in U'$.

(2) A smooth manifold together with an orientation is called an oriented smooth manifold.

(3) A smooth manifold that admits an orientation is called orientable, otherwise we say that the smooth manifold is non-orientable.

Remark. Let M be a 0-dimensional smooth manifold. For each $P \in M$ the tangent space $\mathrm{T}_P M$ is a 0-dimensional real vector space. By the definition on page 669 an orientation of $\mathrm{T}_P M$ is a choice of an element of $\{-1, 1\}$. By the discussion on page 514 we know that the 0-dimensional smooth manifold has the discrete topology. Thus we see that an orientation of 0-dimensional smooth manifold is the same as a map $M \to \{-1, 1\}$. Given a 0-dimensional smooth manifold M we equip it, unless we say something else, with the orientation given by assigning $+1$ to each point in M.

Convention. Given a picture of a 1-dimensional submanifold M of $\mathbb{R}^2$ or $\mathbb{R}^3$ we indicate an orientation by drawing a positive vector in $\mathrm{T}_P M = \widetilde{\mathrm{T}}_P M \subset \mathbb{R}^3$. (Note that in this case a non-zero vector is already a basis for the tangent space). On page 680 we will introduce two conventions for indicating orientations of 2-dimensional submanifolds of $\mathbb{R}^3$.

In practice the following lemma can be quite useful for verifying that orientations of tangent spaces actually define an orientation of a smooth manifold. In particular it says that instead of having to check the continuity condition for all charts, it suffices to consider charts that cover all of M.

Lemma 25.8. (Orientations-via-Atlas Lemma) Let M be a smooth manifold. Suppose that for each $P \in M$ we are given an orientation of $\mathrm{T}_P M$. The following statements are equivalent:

(1) The orientations of the tangent spaces define an orientation for M.

(2) Given any $x \in M$ there exists a chart $\Phi\colon U \to V$ in the given smooth structure of M which satisfies the above continuity condition, i.e. which has the property that for every component U' of U the map

$$\begin{array}{ccccccccc} \mathrm{T}_P M & \xleftarrow{\cong} & \mathrm{T}_P U & \xrightarrow[\cong]{\mathrm{D}\Phi_P} & \mathrm{T}_{\Phi(P)} V & \xrightarrow[\uparrow]{\Theta_V} & \widetilde{\mathrm{T}}_{\Phi(P)} V & = & \mathbb{R}^k \\ & & \uparrow & & & & \uparrow & & \uparrow \\ & & \text{isomorphism by} & & & & \text{natural isomorphism} & & \text{Lemma 23.1} \\ & & \text{by Proposition 23.14 (2)} & & & & \text{from Proposition 23.16} & & \end{array}$$

is either orientation-preserving for all $P \in U'$ or it is orientation-reversing for all $P \in U'$.

Proof. The implication (1) $\Rightarrow$ (2) is a tautology. Now let us turn to the proof of the reverse implication (2) $\Rightarrow$ (1).

Let M be a smooth manifold. The case $\dim(M) = 0$ is trivial. Therefore we now assume that $\dim(M) > 0$. Suppose that for each $P \in M$ we are given an orientation ω_P of $\mathrm{T}_P M$. We start out with introducing some notation.

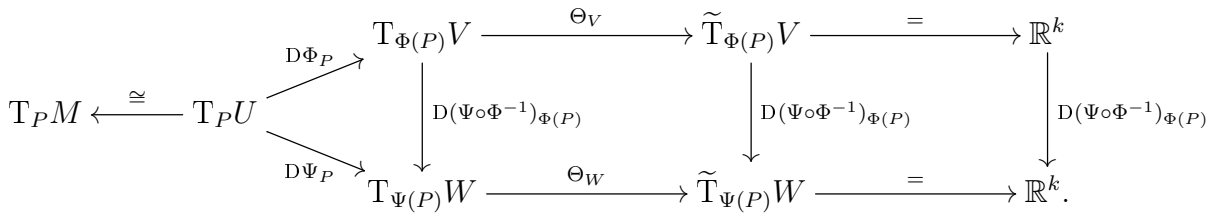
Given a chart $\Phi\colon U \to V$ from the smooth structure we consider the map

$$\begin{array}{rcl} \chi_\Phi\colon U & \to & \{\pm 1\} \\ P & \mapsto & \begin{cases} +1, & \text{if } (\Theta_V \circ \mathrm{D}\Phi_P)(\omega_P) \text{ equals the standard orientation of } \mathbb{R}^k, \\ -1, & \text{otherwise.} \end{cases} \end{array}$$

We equip $\{\pm 1\}$ with the discrete topology. We make the following observations:

(a) The continuity condition for Φ is by definition satisfied if and only if χ_Φ is constant on each component of U.

(b) By the Connected-to-Discrete Lemma 2.27 a map $U \to \{\pm 1\}$ is continuous if and only if it is constant on each component of U.



(c) By the Pasting Proposition 2.6 a map is continuous if and only if it is locally continuous.

(d) Let $\widetilde{U} \subset U$ be an open subset. We write $\widetilde{\Phi} := \Phi|_{\widetilde{U}}\colon \widetilde{U} \to \Phi(\widetilde{U})$. This is again a chart and one can easily verify that we have $\chi_\Phi|_{\widetilde{U}} = \chi_{\widetilde{\Phi}}$.

It is now straightforward to assemble a proof of the lemma from the above observations and the following claim.

Claim. Let $U \subset M$ be a connected subset and let $\Phi\colon U \to V$ and $\Psi\colon U \to W$ be two charts from the smooth atlas. Then $\chi_\Phi\colon U \to \{\pm 1\}$ is constant if and only if $\chi_\Psi\colon U \to \{\pm 1\}$ is constant.

Proof. Given $P \in U$ we consider the following diagram:

Here we also make a few observations:

(a) The diagram commutes by the functoriality of differentials and the naturality of the Θ maps.

(b) By the Differential-equals-Differential Lemma 23.4 the vertical map to the right is given by multiplication by the $(k \times k)$-matrix $\mathrm{D}(\Psi \circ \Phi^{-1})_{\Phi(P)}$.

(c) The map
$$\begin{array}{rcl} U & \to & \{\pm 1\} \\ P & \mapsto & \text{sign of } \det(\mathrm{D}(\Psi \circ \Phi^{-1})_{\Phi(P)}) \end{array}$$
is continuous. It follows from the connectedness of U and the Connected-to-Discrete Lemma 2.27 that this map is in fact constant.

The claim follows easily from combining all of the above. ■

As of right now there are not that many examples of oriented smooth manifolds that we can provide.

Example.

(1) Let $n \in \mathbb{N}$ and let U be an open subset of $\mathbb{R}^n$ or of the half-space $\mathbb{H}^n$. As always we equip U with the smooth structure given by the identity chart. We now use the Orientations-via-Atlas Lemma 25.8 in reverse to endow U with an orientation. More precisely, given any $P \in U$ we have the isomorphism
$$\begin{array}{ccccc} \mathbb{R}^n & = & \widetilde{\mathrm{T}}_P U & \xleftarrow{\Theta_U} & \mathrm{T}_P U. \\ & & \uparrow & & \uparrow \\ & & \text{Lemma 23.1} & & \text{natural isomorphism from Proposition 23.16} \end{array}$$
Now we use the standard orientation of the vector space $\mathbb{R}^n$ and the above isomorphism to equip $\mathrm{T}_P U$ with an orientation. It follows almost immediately from the Orientations-via-Atlas Lemma 25.8 that this defines an orientation on the smooth manifold U. We refer to this orientation on U as the standard orientation on U.

(2) We define the standard orientation on $\mathbb{R}^0 = \{0\}$ to be $+1$.

We will construct more examples of oriented smooth manifolds in the subsequent sections. But first let us conclude this section with the following definition.

Definition. Let M be an oriented smooth manifold. If for each tangent space we pick the opposite orientation then evidently we obtain again an orientation, which we refer to as the opposite orientation. We denote the resulting oriented smooth manifold by $-M$.

25.3. **Orientations of submanifolds of $\mathbb{R}^n$ and unit normal fields.** In this section we will consider "real-life" examples of smooth manifolds, namely we will consider submanifolds M of some $\mathbb{R}^n$. Throughout this section we will work with the physical tangent spaces $\widetilde{\mathrm{T}}_P M \subset \mathbb{R}^n$.

Observation 25.9. Let $M \subset \mathbb{R}^n$ be a smooth submanifold. Under the natural isomorphism $\widetilde{\mathrm{T}}_P M \to \mathrm{T}_P M$ from the Tangent Space-Isomorphism Proposition 23.16 we see that an orientation of M is the same as a map which assigns to every physical tangent space $\widetilde{\mathrm{T}}_P M$, $P \in M$, an orientation such that the following continuity condition is satisfied:

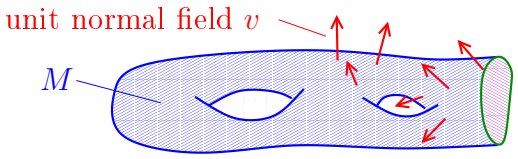
(∗) For every chart $\Phi\colon U \to V$ of the smooth structure of the smooth manifold M (with the smooth structure defined in the Submanifold Smooth Structure Lemma 19.24)

and every component U' of U the map

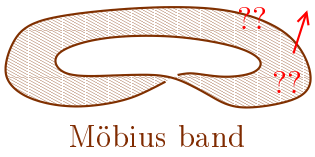
$$\widetilde{\mathrm{T}}_P M \xleftarrow[\uparrow]{=} \widetilde{\mathrm{T}}_P U \xrightarrow[\cong]{\mathrm{D}\Phi_P} \widetilde{\mathrm{T}}_{\Phi(P)} V \underset{\uparrow}{=} \mathbb{R}^k$$

Proposition 23.3 — Lemma 23.1

is either orientation-preserving for all $P \in U'$ or it is orientation-reversing for all $P \in U'$.



Furthermore, as in the Orientations-via-Atlas Lemma 25.8 the continuity condition only needs to be verified for charts in some smooth atlas of M.



Definition. Let M be a codimension-one smooth submanifold of $\mathbb{R}^{n+1}$. A unit normal field is a map[269]

$$v\colon M \to \mathbb{R}^{n+1}$$

such that the following conditions are satisfied:

(1) For each $P \in M$ we have $\|v(P)\| = 1$,
(2) for each $P \in M$ we have $v(P) \perp \widetilde{\mathrm{T}}_P M$.

Examples.

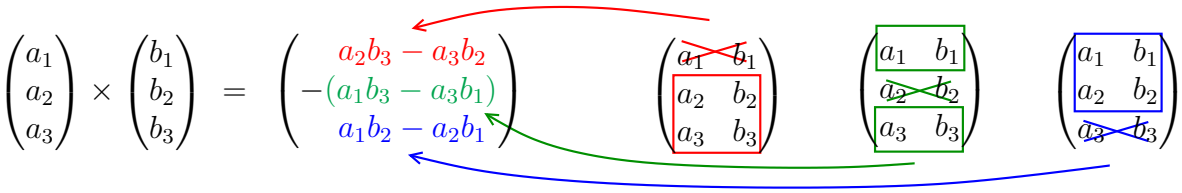
(1) Let $n \in \mathbb{N}$. It follows from Lemma 23.1 that the map

$$\begin{aligned} v\colon S^n &\to \mathbb{R}^{n+1} \\ P &\mapsto P \end{aligned}$$

is a unit normal field.

(2) In the Möbius Smooth Embedding Lemma 24.12 we saw that we can view the Möbius band as a smooth submanifold M of $\mathbb{R}^3$. Does M admit a unit normal field? This seems unlikely, but how do you show the non-existence of a unit normal field?

Our next goal is to show that for a codimension-one smooth submanifold of $\mathbb{R}^{n+1}$ there is a natural correspondence between orientations and unit normal fields. The key tool for doing so is the following definition from linear algebra.



Definition. Let $w_1, \dots, w_n \in \mathbb{R}^{n+1}$. As in [**Blo1979**, Chapter 5.14] we define the cross product[270]

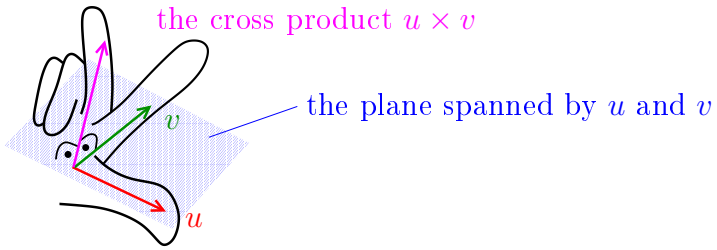
$$w_1 \times \cdots \times w_n := \sum_{k=1}^{n+1} (-1)^{k+1} \cdot e_k \cdot \det \begin{pmatrix} n \times n\text{-matrix obtained from} \\ \text{the } (n+1) \times n\text{-matrix } (w_1 \ \dots \ w_n) \\ \text{by crossing out the } k\text{-th row} \end{pmatrix}.$$

In the following lemma we summarize a few properties of the cross product.

[269] As always we expect maps to be continuous.

[270] By the convention on page 99 the determinant of a 0×0-matrix is $+1$. It follows that for $n = 1$ the cross product is always the vector $e_1 = 1 \in \mathbb{R}$.

Lemma 25.10. (Cross Product Lemma)



(1) The map

$$\begin{array}{rcl} \mathbb{R}^{n+1} \times \cdots \times \mathbb{R}^{n+1} & \to & \mathbb{R}^{n+1} \\ (v_1, \ldots, v_n) & \mapsto & \underbrace{v_1 \times \cdots \times v_n}_{\text{cross product}} \end{array}$$

is smooth.

(2) Let $v_1, \ldots, v_n \in \mathbb{R}^{n+1}$. The following statements hold:
   (a) $\det(v_1 \times \cdots \times v_n \; v_1 \; \ldots \; v_n) \geq 0$.
   (b) $v_1 \times \cdots \times v_n$ is orthogonal to each $v_1, \ldots, v_n$.
   (c) The cross product $v_1 \times \cdots \times v_n$ is non-zero if and only if the vectors $v_1, \ldots, v_n$ are linearly independent.[271]

(3) Suppose that $v_1, \ldots, v_n$ and $w_1, \ldots, w_n$ are both collections of linearly independent vectors in $\mathbb{R}^{n+1}$. The following statements hold:
   (a) $v_1 \times \cdots \times v_n$ and $w_1 \times \cdots \times w_n$ are linearly dependent if and only if we have $\text{Span}(v_1, \ldots, v_n) = \text{Span}(w_1, \ldots, w_n)$.
   (b) There exists a $\lambda > 0$ with $v_1 \times \cdots \times v_n = \lambda \cdot (w_1 \times \cdots \times w_n)$ if and only if the vectors span the same vector subspace of $\mathbb{R}^{n+1}$ and if $v_1, \ldots, v_n$ and $w_1, \ldots, w_n$ are equivalent bases.

Sketch of proof.

(1) This statement follows from the Leibniz formula for determinants.

(2) Let $v_1, \ldots, v_n \in \mathbb{R}^n$. For any $u \in \mathbb{R}^{n+1}$ it follows from the Leibniz expansion by the first row that

$$\det(u \; v_1 \; \ldots \; v_n) \; = \; \langle u, v_1 \times \cdots \times v_n \rangle.$$

   (a) Using the above equality we see that

$$\det(v_1 \times \cdots \times v_n \; v_1 \; \ldots \; v_n) \; = \; \langle v_1 \times \cdots \times v_n, v_1 \times \cdots \times v_n \rangle \; \geq \; 0.$$

[271] In the Cross Product Characterization Proposition **??** we will see that the length of the cross product $v_1 \times \cdots \times v_n$ equals the "n-dimensional volume" of the parallelotope spanned by $v_1, \ldots, v_n$.

(b) Let $i \in \{1, \dots, n\}$. We see that

$$\langle v_i, v_1 \times \cdots \times v_n \rangle \underset{\text{by the above equality}}{=} \det(v_i \ v_1 \ \dots \ v_n) \underset{\text{since two columns are the same}}{=} 0.$$

(c) This statement follows from the fact, proved in Exercise 24.7, that an $(n+1) \times n$-matrix has rank n if and only if there exist n rows that are linearly independent.

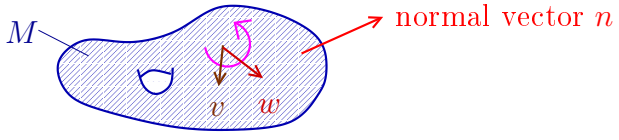
(3) (a) Statement (3a) follows from Statement (2b).

(b) It follows from (3a) that we only have to consider the case that $v_1, \dots, v_n$ and $w_1, \dots, w_n$ span the same vector space. Let A be the transition matrix. It follows easily from the definitions that $v_1 \times \cdots \times v_n = \det(A) \cdot (w_1 \times \cdots \times w_n)$ which implies the statement. ■

In the following proposition we will see that for a codimension-one smooth submanifold of $\mathbb{R}^{n+1}$ there is a natural bijection between orientations and unit normal fields.

Proposition 25.11. (Orientations-via-Normal Vector Fields Proposition) Let $n \in \mathbb{N}$ and let M be a codimension-one smooth submanifold of $\mathbb{R}^{n+1}$. The maps

$$\begin{array}{rcl} \{\text{unit normal fields on } M\} & \leftrightarrow & \{\text{orientations on } M\} \\ & & \text{given a point } P \in M \text{ we say that a} \\ v & \mapsto & \text{basis } w_1, \dots, w_n \text{ of } \widetilde{\mathrm{T}}_P M \text{ is positive} \\ & & \text{if } \det\left(v(P) \ w_1 \ \dots \ w_n\right) > 0 \\ \text{given a point } P \in M \text{ we pick a positive} & & \\ \text{basis } w_1, \dots, w_n \text{ for } \widetilde{\mathrm{T}}_P M \text{ and normalize} & \leftarrow\!\shortmid & \text{orientation on } M \\ \text{the vector } w_1 \times \cdots \times w_n \text{ to length one} & & \end{array}$$



are well-defined and inverses of one-another.

Convention. Given a picture of a 2-dimensional submanifold M of $\mathbb{R}^3$ we have two conventions for indicating an orientation:

(1) We draw a part of a little circle together with a directional arrow. This indicates that a positive basis is given by (v, w) where w is obtained by rotating v into the indicated direction by an angle in $(0, \pi)$.

(2) Alternatively we draw a normal vector n, in this case a basis (v, w) of the tangent space is positive if (n, v, w) is a positive basis for $\mathbb{R}^3$.

both conventions indicate the same orientation of M

Proof. We start out with the following claim.

Claim. For every unit normal field v the construction defines an orientation on M.

Proof. It follows from the discussion on page 669 that for each $P \in M$ the construction does indeed define an orientation on $\widetilde{\mathrm{T}}_P M$. It remains to show that the continuity condition holds.

Let $\Phi\colon U \to V \subset \mathbb{R}^{n+1}$ be a submanifold chart with U connected. Recall that Φ gives rise to a chart $\Psi\colon U \cap M \to \widetilde{V} \subset \mathbb{R}^n$ of M viewed as an n-dimensional smooth manifold. For $Q \in U$ we now denote by $f(Q)$ the $(n+1)$-st coordinate of $\mathrm{D}\Phi_Q(v(Q)) \in \mathbb{R}^{n+1}$. Note that $f\colon U \to \mathbb{R}$ is continuous and note that f is non-zero everywhere. Now let again $Q \in U$. For $i = 1, \dots, n$ we set $w_i := \mathrm{D}\Psi^{-1}_{\Psi(Q)}(e_i)$. We have

$$\underbrace{\det(v(Q)\, w_1 \,\dots\, w_n)}_{\substack{\text{by definition} > 0 \\ \text{if } w_1,\dots,w_n \text{ is a} \\ \text{positive basis}}} \;=\; \det(\mathrm{D}\Phi_Q)^{-1} \cdot \begin{pmatrix} * & e_1 & \dots & e_n \\ f(Q) & 0 & \dots & 0 \end{pmatrix} \;=\; \det(\mathrm{D}\Phi_Q)^{-1} \cdot f(Q) \cdot (-1)^{n+1}.$$

$\uparrow$ follows from the Chain Rule 19.10

This shows that the isomorphism $\mathrm{D}\Psi^{-1}_{\Psi(Q)}\colon \mathbb{R}^n \to \widetilde{\mathrm{T}}_Q M$ is orientation-preserving if and only if $\det(\mathrm{D}\Phi_Q)^{-1} \cdot f(Q) \cdot (-1)^{n+1} > 0$. But this function in Q is non-zero everywhere. Hence, since U is connected, we see that the sign of this expression is independent of $Q \in U$. ⊞

Claim. For every orientation on M the construction defines a unit normal field on M.

Proof. It follows from the Cross Product Lemma 25.10 that for each $P \in M$ the vector $w_1 \times \dots \times w_n$ is indeed normal to $\widetilde{\mathrm{T}}_P M$ and that it is independent of the choice of the positive basis $w_1, \dots, w_n$ of $\widetilde{\mathrm{T}}_P M$. It only remains to show that the resulting map $v\colon M \to \mathbb{R}^{n+1}$ is continuous. Thus let $P \in M$. We pick a chart $\Phi\colon U \to V$ around P such that U is connected. After possibly composing Φ with a reflection we can assume that for each $Q \in V$ the map

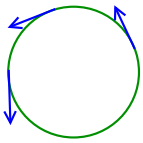
$$\mathrm{D}\Phi^{-1}_Q\colon \mathbb{R}^n \;\to\; \widetilde{\mathrm{T}}_{\Phi^{-1}(Q)} M$$

is orientation-preserving. It now follows that on U the map v is given by

$$\begin{array}{rcl} U & \to & \mathbb{R}^{n+1} \\ x & \mapsto & \mathrm{D}\Phi^{-1}_{\Phi(x)}(e_1) \times \dots \times \mathrm{D}\Phi^{-1}_{\Phi(x)}(e_1) \text{ normalized to length } = 1. \end{array}$$

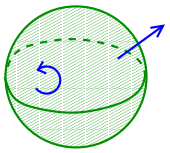
By the Cross Product Lemma 25.10 (1) we know that this map is continuous. This shows that v is locally continuous, hence it is continuous. ⊞

We have now shown that the maps given in the statement of current proposition are well-defined. It follows easily from the Cross Product Lemma 25.10 (2) that the two maps are also inverses of one another. ■



Example.

(1) Let $n \in \mathbb{N}$. As mentioned above it follows from Lemma 23.1 that the map



$$\begin{array}{rcl} v\colon S^n & \to & \mathbb{R}^{n+1} \\ P & \mapsto & P \end{array}$$

is a unit normal field. Given $P \in S^n$ we say that a basis $(v_1, \dots, v_n)$ of the tangent space $\widetilde{\mathrm{T}}_P S^n \subset \mathbb{R}^{n+1}$ is positive if $\det(P\, v_1 \,\dots\, v_n) > 0$. It follows from the Orientations-via-Normal Vector Fields Proposition 25.11 and Observation 25.9 that these orientations define an orientation of the smooth manifold S^n. We refer to this as the standard orientation of S^n. Unless we explicitly say something else we will always view S^n as an oriented smooth manifold with the above orientation.

(2) We equip the 0-dimensional sphere $S^0 = \{\pm 1\}$ with the obvious orientation given by $\pm 1 \mapsto \pm 1$.

orientation of S^1

orientation of S^2

25.4. **Orientation-preserving and reversing maps.** The next definition is basically self-explanatory.

Definition. Let $f\colon M \to N$ be a map smooth between two oriented smooth manifolds such that for every $P \in M$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is an isomorphism.[272]

(1) We say the map f is orientation-preserving if for every $P \in M$ the induced isomorphism $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is orientation-preserving.
(2) We say the map f is orientation-reversing if for every $P \in M$ the induced isomorphism $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is orientation-reversing.

Examples.

(1) The map

$$\begin{array}{rccl} \Xi\colon \mathbb{R} & \to & S^1 \subset \mathbb{C} = \mathbb{R}^2 \\ t & \mapsto & \exp(\mathrm{i}t) = \begin{pmatrix} \cos(t) \\ \sin(t) \end{pmatrix} \end{array}$$

is a local diffeomorphism. If we equip $\mathbb{R}$ and S^1 with the standard orientation, then Ξ is orientation-preserving. Indeed, for any $t \in \mathbb{R}$ we have

$$\mathrm{D}(\Xi_t)(1) = \underset{\substack{\uparrow \\ \text{positive basis of } \widetilde{\mathrm{T}}_t\mathbb{R}}}{\begin{pmatrix} -\sin(t) \\ \cos(t) \end{pmatrix}} \in \widetilde{\mathrm{T}}_{\begin{pmatrix} \cos(t) \\ \sin(t) \end{pmatrix}} S^1 \text{ which is positive since } \det \begin{pmatrix} \cos(t) & -\sin(t) \\ \sin(t) & \cos(t) \end{pmatrix} > 0.$$

(2) Let $A \in \mathrm{O}(n)$. In Exercise 25.5 we will see that the map $S^n \to S^n$ given by $x \mapsto A \cdot x$ is orientation-preserving if and only if $\det(A) = 1$.
(3) Let $f\colon M \to N$ be a local diffeomorphism between two oriented smooth manifolds. If M is non-empty and *connected*, then it follows from the Basics-of-Orientations Lemma 25.13 below that f is either orientation-preserving or orientation-reversing. On the other hand for disconnected M one can easily come up with maps that are neither orientation-preserving nor orientation-reversing.

The following lemma gives an easy criterion for showing that a diffeomorphism between two open subsets of $\mathbb{R}^n$ or of $\mathbb{H}^n$ is orientation-preserving.

Lemma 25.12. (Orientation Checking-via-Differentials Lemma) Let $n \in \mathbb{N}$ and let $f\colon X \to Y$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$ or $\mathbb{H}^n$. Recall that by the discussion on page 677 we equip X and Y with the standard orientations. Given $P \in X$

[272] In most applications f is a local diffeomorphism, but by the Physical Tangent Space-Inclusion Proposition 23.14 the inclusion of a codimension-zero submanifold into its "surrounding" smooth manifold also has this property.

we have[273]

$$\underset{\substack{\uparrow\\ \text{differential as defined on page 631}}}{\mathrm{D}f_P\colon \mathrm{T}_PX \to \mathrm{T}_{f(P)}Y} \text{ is orientation-preserving} \iff \det\Big(\underbrace{\text{differential } \mathrm{D}f_P}_{n\times n\text{-matrix}}\Big) > 0.$$

In particular we see

$$f\colon X \to Y \text{ is orientation-preserving} \iff \det(\mathrm{D}f_P) > 0 \text{ for all } P \in X.$$

Example. Let $U \subset \mathbb{R}^n$ be an open subset. Let $A \in \mathrm{GL}(n,\mathbb{R})$ with $\det(A) > 0$ and let $v \in \mathbb{R}^n$. It follows easily from the discussion on page 536 and the Orientation Checking-via-Differentials Lemma 25.12 that the map f given by $f(x) = x \mapsto A \cdot x + v$ defines an orientation-preserving diffeomorphism $U \to f(U)$.

Proof. By the Tangent Space-Isomorphism Proposition 23.16 we have the following commutative diagram

$$\begin{array}{ccc} \mathbb{R}^n = \widetilde{\mathrm{T}}_PX & \xrightarrow[\cong]{\Theta_X} & \mathrm{T}_PX \\ \downarrow{\scriptstyle \mathrm{D}f_P} & & \downarrow{\scriptstyle \mathrm{D}f_P} \\ \mathbb{R}^n = \widetilde{\mathrm{T}}_{f(P)}Y & \xrightarrow[\cong]{\Theta_Y} & \mathrm{T}_{f(P)}Y. \end{array}$$

The lemma follows from combining the following observations:

(1) As on page 668 we equip $\mathbb{R}^n$ with the standard orientation that is defined by the standard basis $(e_1,\dots,e_n)$ of $\mathbb{R}^n$.
(2) The horizontal maps are orientation-preserving by definition of the orientations of the oriented smooth manifolds X and Y.
(3) By the Differential-equals-Differential Lemma 23.4 the vertical map to the left is given by multiplication by the differential $\mathrm{D}f_P \in \mathrm{M}(n\times n,\mathbb{R})$. It follows from Lemma 25.2 that the vertical map to the left is orientation-preserving if and only if $\det(\mathrm{D}f_P) > 0$.
(4) It follows from the Orientation-Composition Lemma 25.3 that the left-hand vertical map is orientation-preserving if and only if the right-hand vertical map is orientation-preserving. ∎

The following lemma summarizes a few elementary properties of orientations and of orientation-preserving maps.

Lemma 25.13. (Basics-of-Orientations Lemma) Let $n \in \mathbb{N}_0$ and let M be an n-dimensional smooth manifold.

(1) If two orientations on M agree at a point and if M is path-connected, then the two orientations agree everywhere.
(2) If M is path-connected and non-empty, then M is either non-orientable or it admits precisely two orientations, which are opposites of one another.
(3) Let $f\colon M \to N$ be a diffeomorphism. If M is path-connected and if there exists a $P \in M$, such that $\mathrm{D}f_P\colon \mathrm{T}_PM \to \mathrm{T}_{f(P)}N$ is orientation-preserving, then f is orientation-preserving.[274]

[273] Unfortunately the symbol $\mathrm{D}f_P$ has several, subtly different meanings. To the left it stands for the induced map on tangent spaces. To the right it stands for the $n\times n$–matrix given by the partial derivatives of f.

(4) Suppose M is equipped with an orientation $\mathcal{O}$. Let $f\colon M \to M$ be a self-diffeomorphism. Then

$$\begin{array}{c} f \text{ is orientation-preserving} \\ \text{with respect to } \mathcal{O} \end{array} \iff \begin{array}{c} f \text{ is orientation-preserving} \\ \text{with respect to } -\mathcal{O}. \end{array}$$

(5) Let $M_0, \dots, M_k$ be oriented smooth manifolds. Suppose that for $i = 0, \dots, k-1$ we are given a smooth map $f_i\colon M_i \to M_{i+1}$ such that for every $P \in M_i$ the differential $\mathrm{D}(f_i)_P\colon \mathrm{T}_P M_i \to \mathrm{T}_{f_i(P)} M_{i+1}$ is an isomorphism. Then

$$\begin{array}{c} \text{the map } f_{k-1} \circ \cdots \circ f_0\colon M_0 \to M_k \\ \text{is orientation-preserving} \end{array} \iff \begin{array}{c} \text{the number of } f_i \text{ which are} \\ \text{orientation-reversing is even.} \end{array}$$

In particular the composition of orientation-preserving diffeomorphisms is again orientation-preserving.

(6) (a) Let N be a smooth manifold and let $f\colon N \to M$ be a smooth map that is a local diffeomorphism. If M is oriented, then there exists a unique orientation on N such that f is an orientation-preserving map.

(b) Let N be a submanifold of codimension zero. (In many applications N is just an open subset of M.) If M is oriented, then N admits a unique orientation such that the inclusion map $N \to M$ is orientation-preserving.

(7) If $M \setminus \partial M$ admits an orientation, then M admits a unique orientation such that the inclusion $M \setminus \partial M \to M$ is orientation-preserving.

Convention. Let M be an oriented smooth manifold and let N be a submanifold of codimension zero. We refer to the orientation on N that we introduced in the Basics-of-Orientations Lemma 25.13 (6b), i.e. the unique orientation on N such that the inclusion map $N \to M$ is orientation-preserving, as the standard orientation of a codimension-zero submanifold.

Example. It follows from the Basics-of-Orientations Lemma 25.13 that for each $n \in \mathbb{N}$ the closed ball $\overline{B}^n$ inherits an orientation from $\mathbb{R}^n$. We refer to this as the standard orientation on $\overline{B}^n$. Given $P \in \overline{B}^n$ it follows immediately from the definitions that the image of the standard basis $e_1, \dots, e_n$ of $\mathbb{R}^n$ under the natural isomorphism $\Theta\colon \widetilde{\mathrm{T}}_P \overline{B}^n \to \mathrm{T}_P \overline{B}^n$ defines a positive basis for $\mathrm{T}_P \overline{B}^n$.

Proof. The case $n = 0$ follows from trivial considerations. Thus we now assume that $n \geq 1$.

(1) Suppose we are given two orientations on M. It follows immediately from the definitions that for any chart $\Phi\colon U \to V$ the two orientations either agree on all of U or they disagree on all of U.

But this implies that the set of points A where the orientations agree is open and that the set of points B where the orientations disagree is also open. If the orientations agree at a point we see that $A \neq \varnothing$. It follows from the Topological Manifolds-Local Properties Lemma 18.8 (3) that $A = M$.

[274] By definition $f\colon M \to N$ is orientation-preserving if $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ is orientation-preserving for every $P \in M$. If M is path-connected, then by Statement (3) says that it suffices to verify this condition for a single point.

(2) This statement follows easily from (1).
(3) The proof of this statement is very similar to the proof of the first statement. We leave it to the reader to fill in the details.
(4) This statement follows immediately from the definitions and the Orientation-Composition Lemma 25.3.
(5) Note only does the lemma smell like the Orientation-Composition Lemma 25.3, it is also an immediate consequence thereof.
(6) (a) Given $Q \in N$ we equip the vector space $\mathrm{T}_Q N$ with the orientation that turns $\mathrm{D}f_Q \colon \mathrm{T}_Q N \to \mathrm{T}_{f(Q)} M$ into an orientation-preserving isomorphism. Since f is a local diffeomorphism we see that charts of M gives rise to charts of N. It now follows easily from the Orientations-via-Atlas Lemma 25.8 that these orientations of the tangent spaces of N do indeed define an orientation of N.
    (b) Let N be a codimension-zero submanifold. We denote by $\iota \colon N \to M$ the inclusion. Let $Q \in N$. By the Physical Tangent Space-Inclusion Proposition 23.14 we know that $\mathrm{D}\iota_Q \colon \mathrm{T}_Q N \to \mathrm{T}_Q M$ is an isomorphism. As in (a) we equip the vector space $\mathrm{T}_Q N$ with the orientation that turns $\mathrm{D}f_Q \colon \mathrm{T}_Q N \to \mathrm{T}_{f(Q)} M$ into an orientation-preserving isomorphism. The charts of N, viewed as a smooth manifold in its own right, are given by restricting charts of M. Therefore it follows again from the Orientations-via-Atlas Lemma 25.8 that these orientations of the tangent spaces of N do indeed define an orientation of N.
(7) Using charts it suffices to prove this statement for smooth manifolds that are open subsets of $\mathbb{H}^n$, but in this case the statement is clear. ■

Definition. Let M be an oriented smooth manifold. We say an atlas $\{\Phi_i \colon U_i \to \widetilde{U}_i\}_{i \in I}$ is orientation-preserving if each Φ_i is orientation-preserving. Hereby we work with the following orientations:

(1) Each open subset U_i is a codimension-zero submanifold of M, thus we can equip it with the above standard orientation.
(2) Each $\widetilde{U}_i$ is an open subset of $\mathbb{R}^n$ or $\mathbb{H}^n$. Therefore it also comes with a standard orientation.

Remark. Note that if $\dim(M) > 0$, then any chart $\Phi \colon U \to V$ with V can be turned into an orientation-preserving respectively orientation-reversing chart by possibly composing Φ, on components of V, with the reflection in a hyperplane. In particular we see that any oriented smooth manifold of dimension ≥ 1 admits an orientation-preserving atlas.

The following lemma gives a convenient criterion for showing that a given map is orientation-preserving.

Lemma 25.14. Let $f \colon M \to N$ be a smooth map between two oriented n-dimensional smooth manifolds such that for each $P \in M$ the differential $\mathrm{D}f_P \colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ is an isomorphism. Let $\{\Phi_i \colon U_i \to \widetilde{U}_i\}_{i \in I}$ be an orientation-preserving atlas for M and let $\{\Psi_j \colon V_j \to \widetilde{V}_j\}_{j \in J}$ be an orientation-preserving atlas for N. The following two statements are equivalent:

(1) f is orientation-preserving.

(2) For each $i \in I$ and $j \in J$ and each $P \in U_i \cap f^{-1}(V_j)$ we have

$$\det \Big(\underbrace{\mathrm{D}(\Psi_j \circ f \circ \Phi_i^{-1})_{\Phi_i(P)}}_{\text{invertible } n \times n\text{-matrix}} \Big) \; > \; 0.$$

The analogous statement also holds for "orientation-reversing" and "< 0".

Proof. This lemma can be deduced easily from the Orientation Checking-via-Differentials Lemma 25.12 and the Basics-of-Orientations Lemma 25.13 (5) and the fact, shown in the Differential-equals-Differential Lemma 23.4 and the Tangent Space-Isomorphism Proposition 23.16 that the various definitions of differential are compatible. We leave it to the reader to fill in the few remaining details. ■

We continue with a lemma which gives another approach to defining an orientation on a given smooth manifold.

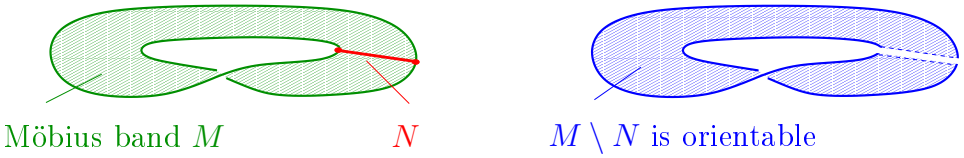
Lemma 25.15. (Define Orientations-via Transition Maps Lemma) Let $(M, \mathcal{A})$ be a smooth manifold of dimension ≥ 1. Suppose that all transition maps between charts in $\mathcal{A}$ are orientation-preserving. Given $P \in M$ we define

$$\text{orientation of } \mathrm{T}_P M \; := \; (\mathrm{D}\Phi_P)^{-1} \Big(\underbrace{\text{standard orientation of } \mathrm{T}_{\Phi(P)} V}_{\text{as defined on page 677}} \Big)$$

where $\Phi \colon U \to V$ is a chart around P from the given atlas. The following statements hold:

(1) The definition of the orientation of $\mathrm{T}_P M$ does not depend on the choice of the chart.
(2) The orientations of the tangent space $\mathrm{T}_P M$ define an orientation for M.
(3) With respect to this orientation the given atlas is orientation-preserving.

Sketch of proof. The first statement follows easily from the hypothesis that the transition maps are orientation-preserving together with the Orientation-Composition Lemma 25.3. The second statement is a consequence of the Orientations-via-Atlas Lemma 25.8. The third statement holds basically by definition. ■



Example. We consider the surface Σ of genus 2. In the Surface-is-Topological Manifold Proposition 18.7 we gave an explicit atlas for Σ. In Proposition 19.18 we saw that the transition maps are smooth. In Exercise 25.12 we will verify that all the transition maps are in fact orientation-preserving. Thus it follows from the Define Orientations-via Transition Maps Lemma 25.15 that Σ is orientable. Basically the same argument shows that all surfaces of genus $g \geq 3$ are also orientable. Note that, as the name suggests, the same approach does not work for the non-orientable surfaces of some genus $g \in \mathbb{N}$.

Lemma 25.16. (Complement-of-Boundary Orientation Lemma) Let M be a smooth manifold.

(1) Given any orientation on $M \setminus \partial M$ there exists a unique orientation on M such that the inclusion $M \setminus \partial M \to M$ is orientation-preserving.
(2) Let N be a submanifold of M of codimension ≥ 2. Given any orientation on $M \setminus N$ there exists a unique orientation on M such that the inclusion $M \setminus N \to M$ is orientation-preserving.

Non-Example. Let M be the Möbius band and let N be the proper 1-dimensional submanifold that is shown in the figure below. Then $M \setminus N$ is evidently orientable, whereas M is

not orientable. Thus we see that in the Complement-of-Boundary Orientation Lemma 25.16 the condition on the codimension is necessary.

Proof. The proof can be found in the long version of the lecture notes. ■

Proof. Let M be an n-dimensional smooth manifold. In the following we assume that $n \geq 2$. The case $n = 1$ can be dealt with by a similar argument or one can directly appeal to the Smooth 1-Dimensional Manifold Classification Theorem 22.7.

(1) We start out with a general claim.

Claim 1. Let $U \subset M$ be an open subset. We set $\widetilde{U} := U \cap (M \setminus \partial M)$.
(a) If U is connected, then so is $\widetilde{U}$.
(b) The closure of $\widetilde{U}$ in M contains U.

Proof.
(a) The first statement follows from the Topological Manifolds-Local Properties Lemma 18.8 and the Push Away From Boundary Lemma 18.13.
(b) This statement follows easily from Lemma 1.10. ⊞

Now let $\{\Phi_i \colon U_i \to V_i\}_{i \in I}$ be an atlas for M such that each U_i is connected. We equip the V_i, which are open subsets of $\mathbb{R}^n$ or $\mathbb{H}_n$, with the standard orientation. Given $i \in I$ we write $\widetilde{U}_i := U_i \cap (M \setminus \partial M)$, $\widetilde{V}_i := \Phi(\widetilde{U}_i)$ and we denote by $\widetilde{\Phi}_i$ the restriction of Φ_i to the diffeomorphism $\widetilde{\Phi}_i \colon \widetilde{U}_i \to \widetilde{V}_i$.

Now suppose that we are given an orientation for $M \setminus \partial M$. By Claim 1 (a) we know that each $\widetilde{U}_i$ is connected. Thus we know, say by the Basics-of-Orientations Lemma 25.13 (3), that $\widetilde{\Phi}_i \colon \widetilde{U}_i \to \widetilde{V}_i$ is orientation-preserving or orientation-preserving. In the first case we set $\rho_i := \mathrm{id}$ and in the second case let ρ_i be the reflection in the $(x_1 = 0)$-hyperplane.[275] Note that in either case the map $\rho_i \circ \widetilde{\Phi}_i \colon \widetilde{U}_i \to \rho_i(\widetilde{V}_i)$ is orientation-preserving.

Claim 2. All transition maps of the atlas $\{\rho_i \circ \Phi_i \colon U_i \to \rho_i(V_i)\}_{i \in I}$ for M are orientation-preserving.

Proof. Let $i, j \in I$. By the Orientation Checking-via-Differentials Lemma 25.12 it suffices to show that the image of

$$\begin{aligned} f \colon U_i \cap U_j &\to \mathbb{R} \\ x &\mapsto \det(\underbrace{\mathrm{D}((\rho_i \circ \Phi_i) \circ (\rho_j \circ \Phi_j)^{-1})_{\rho_j(\Phi_j(x))}}_{n \times n\text{-matrix}}) \end{aligned}$$

consists only of positive real numbers. Note that this map f is smooth and non-zero everywhere. Furthermore, since $\rho_i \circ \widetilde{\Phi}_i$ and $\rho_j \circ \widetilde{\Phi}_j$ are orientation-preserving we see,

[275] Here we use that $n \geq 2$, since for $n \geq 2$ the reflection in the $(x_1 = 0)$-hyperplane is an orientation-reversing diffeomorphism of $\mathbb{H}_n$.

say using the Orientation Checking-via-Differentials Lemma 25.12, that f is positive on $\widetilde{U}_i \cap \widetilde{U}_j$. Since $U_i \cap U_j$ is an open neighborhood of x we obtain from Claim 1 that x is contained in the closure of $\widetilde{U}_i \cap \widetilde{U}_j = (U_1 \cap U_2) \cap (M \setminus \partial M)$ in M. Thus it follows from the Closure-Interior Mapping Lemma 2.5 that $f(x) > 0$. ⊞

It follows from the claim together with the Define Orientations-via Transition Maps Lemma 25.15 that this atlas defines an orientation on M. It is clear that this orientation restricts to the given orientation on $M \setminus \partial M$.

(2) The argument is basically the same as in (1). In the proof of Claim 1 (a) we just need to replace the Push Away From Boundary Lemma 18.13 by Exercise 18.20. The remainder of the argument is identical. ■

25.5. **Boundary orientation.** In this section we will see that the boundary of an oriented smooth manifold inherits an orientation. Before we can formulate the lemma let us recall the following definition from page 634.

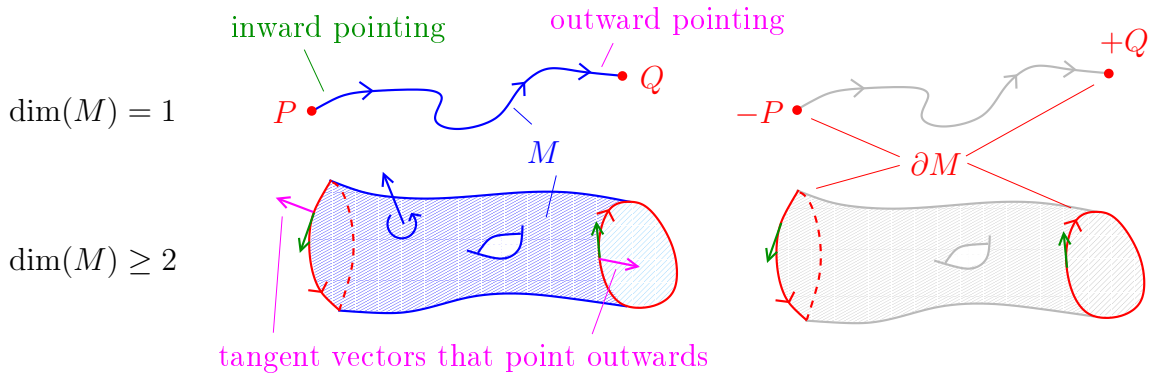
Definition. Let M be a smooth manifold, let $P \in \partial M$ and let $w \in \mathrm{T}_P M$. We say w points outward, if the following two conditions are satisfied:

(1) For every smooth map $f\colon M \to \mathbb{R}_{\geq 0}$ with $f|_{\partial M} \equiv 0$ we have $w(f) \geq 0$.
(2) There exists a smooth map $f\colon M \to \mathbb{R}_{\geq 0}$ with $f|_{\partial M} \equiv 0$ such that $w(f) > 0$.

Lemma 25.17. (Boundary Orientation Lemma) Let M be an oriented n-dimensional smooth manifold and let $P \in \partial M$.

(a) If $n = 1$, then we define the orientation of P as follows:

$$\text{orientation of } \mathrm{T}_P \partial M := \begin{cases} -1, & \text{if a positive tangent vector of } \mathrm{T}_P M \text{ points inward} \\ +1, & \text{if a positive tangent vector of } \mathrm{T}_P M \text{ points outward.} \end{cases}$$



(b) Now we assume that $n \geq 2$. We pick a tangent vector $w \in \mathrm{T}_P M$ that points outward in the sense of the definition on page 634. We say that a basis $(v_1, \ldots, v_{n-1})$ for $\mathrm{T}_P(\partial M)$ is a positive basis of $\mathrm{T}_P(\partial M)$ if $(w, v_1, \ldots, v_{n-1})$ is a positive basis of $\mathrm{T}_P M$.

The following five statements hold:

(0) If M is a smooth submanifold of some $\mathbb{R}^k$, then the orientation convention in (a) and (b) also makes sense for the physical tangent spaces and it is compatible with the Tangent Space-Isomorphism Proposition 23.16.
(1) For $n \geq 2$ the definition of a positive basis for $\mathrm{T}_P M$ does not depend on the choice of w.
(2) These orientations of the tangent spaces of ∂M define an orientation on ∂M.
(3) We have $\partial(-M) = -\partial M$.
(4) Let $f\colon M \to N$ be an orientation-preserving (orientation-reversing) local diffeomorphism between oriented n-dimensional smooth manifolds. We equip ∂M and ∂N with the orientations defined in (a) and (b). The restriction of f to a diffeomorphism $\partial M \to \partial N$ is also orientation-preserving (orientation-reversing).

Example. The boundary of the 1-dimensional smooth manifold $[a, b]$, which we equip with the standard orientation coming from $\mathbb{R}$, is easily seen to be given by $(-\{a\}) \cup \{b\}$.

Proof. The proof in the case that $\dim(M) = 1$ is basically trivial. Thus in the remainder of the proof we only consider the case that $n = \dim(M) \geq 2$.

(0) This statement follows easily from the definitions together with Tangent Space-Isomorphism Proposition 23.16 (2).

(1) Let $P \in \partial M$ and let $(v_1, \dots, v_{n-1})$ for $\mathrm{T}_P(\partial M)$ be a basis. We pick an orientation-preserving chart $\Phi\colon U \to V$ of type (ii) around P. We denote by $i\colon U \to M$ the inclusion map. We consider the isomorphisms

$$\mathrm{T}_P M \xleftarrow[\uparrow]{\mathrm{D}i_P} \mathrm{T}_P U \xrightarrow{\mathrm{D}\Phi_P} \mathrm{T}_P V \xrightarrow[\uparrow]{\Theta} \widetilde{\mathrm{T}}_P V \underset{\uparrow}{=} \mathbb{R}^n.$$

isomorphism by Proposition 23.14 — Proposition 23.16 — Lemma 23.1

We denote by $\Omega\colon \mathrm{T}_P M \to \mathbb{R}^n$ the resulting isomorphism. Furthermore we denote by $p\colon \mathbb{R}^n \to \mathbb{R}^{n-1}$ the projection onto the first $(n-1)$ coordinates and we denote by $q\colon \mathbb{R}^n \to \mathbb{R}$ the projection onto the last coordinate. We make the following two observations:

(a) It follows fairly easily from the Tangent Space-Isomorphism Proposition 23.16 (2) that a vector $w \in \mathrm{T}_P M$ points outward if and only if $q(\Omega(w))$ is negative.

(b) Given a vector $w \in \mathrm{T}_P M$ the following hold:

$$\begin{aligned} &(w, v_1, \dots, v_{n_1}) \text{ is a positive basis for } \mathrm{T}_P M \\ &\iff (\Omega(w), \Omega(v_1), \dots, \Omega(v_{n-1})) \text{ is a positive basis for } \mathbb{R}^n \\ &\iff \det(\Omega(w)\,\Omega(v_1)\,\dots\,\Omega(v_{n-1})) > 0 \\ &\iff (-1)^n \cdot q(\Omega(w)) \cdot \det(p(\Omega(v_1))\,\dots\,p(\Omega(v_{n-1}))) > 0. \end{aligned}$$

It follows that the definition of a positive basis is independent of the choice of the outward pointing vector w.

(2) Using the approach of (1) it is not difficult to verify this statement.

(3) This statement is basically obvious.

(4) This statement follows immediately from the observation that a local diffeomorphism sends outward pointing vectors to outward pointing vectors. ■

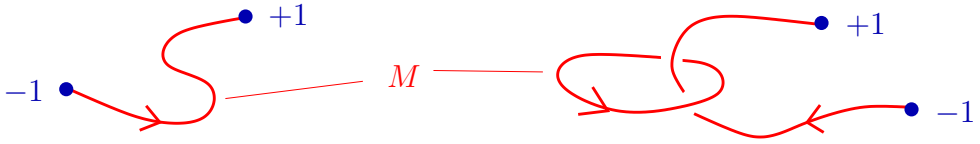
Convention. Let M be an oriented n-dimensional smooth manifold. Unless we say something else we always equip ∂M with the orientation given by the Boundary Orientation Lemma 25.17. We refer to this orientation of ∂M as the boundary orientation.

Example. Let $n \in \mathbb{N}$. As on page 684 we equip the smooth manifold $\overline{B}^{n+1}$ with the standard orientation coming from $\mathbb{R}^{n+1}$. It is not hard to see that the boundary orientation of $\partial\overline{B}^{n+1} = S^n$ agrees with the standard orientation of S^n that we introduced on page 681.

At this point it makes sense to introduce the following definition.

Definition. Given $n \in \mathbb{N}_0$ we refer to the category $\mathcal{OrSmMfd}_n$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{OrSmMfd}_n) &:= \text{all oriented } n\text{-dimensional smooth manifolds,} \\ \mathrm{Mor}(X,Y) &:= \text{all orientation-preserving diffeomorphisms from } X \text{ to } Y, \end{aligned}$$



with the usual composition of maps as the category of oriented n-dimensional smooth manifolds.

Remark. Note that the Boundary Orientation Lemma 25.17 says in particular that the map $M \mapsto \partial M$ defines a functor from the category $\mathcal{OrSmMfd}_n$ of oriented n-dimensional smooth manifolds to the category $\mathcal{OrSmMfd}_{n-1}$ of oriented n-dimensional smooth manifolds.

We conclude this discussion of the orientations of the boundary of 1-dimensional smooth manifolds with the following subtle consequence of the Smooth 1-Dimensional Manifold Classification Theorem 22.7.

Proposition 25.18. (Boundary-of-Compact Smooth 1-Manifold Proposition) Let M be a compact oriented 1-dimensional smooth manifold. We equip ∂M with the orientation defined on page 688. Then

$$\sum_{P \in \partial M} \underbrace{\text{orientation of } P}_{\in\{-1,1\}} \;=\; 0.$$

Proof. It suffices to prove the statement for a compact oriented connected 1-dimensional smooth manifold with non-empty boundary. By the Smooth 1-Dimensional Manifold Classification Theorem 22.7 we know that there exists a diffeomorphism $f\colon M \to [0,1]$. After possibly composing this diffeomorphism with the orientation-reversing map $[0,1] \to [0,1]$ given by $t \mapsto 1-t$ we can assume that f is in fact orientation-preserving. Now we see that

$$\sum_{P\in\partial M} \epsilon(P) \;\underset{\uparrow}{=}\; \sum_{P\in\partial([0,1])} \epsilon(P) \;\underset{\uparrow}{=}\; -1+1 \;=\; 0.$$

by the Boundary Orientation Lemma 25.17 see the example on page 688

■

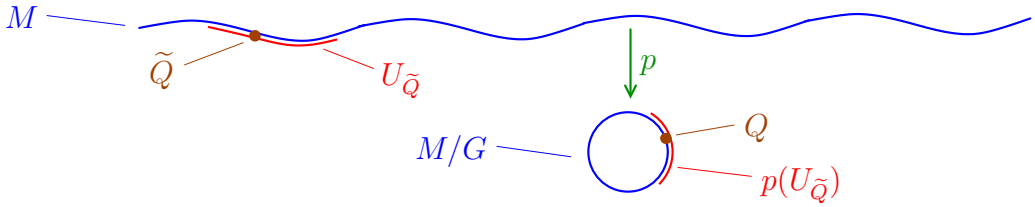
25.6. **Orientations and group actions.** We move on to considering the interplay between orientations and group actions.

Definition. Let M be an oriented smooth manifold that is equipped with a smooth action by a group G. We say that the action is orientation-preserving if for every $g \in G$ the diffeomorphism $M \to M$ given by $x \mapsto g \cdot x$ is orientation-preserving in the sense of the definition on page 682.

The first part of the following proposition can be viewed as a refinement of the Manifold Quotient-by-Group Action Proposition 19.32.

Proposition 25.19. (Orientation-Action Proposition) Let M be a smooth manifold. Furthermore let G be a group that acts freely properly and smoothly on M. By the Manifold Quotient-by-Group Action Proposition 19.32 the quotient M/G admits a standard smooth structure such that the quotient map $p\colon M \to M/G$ is a local diffeomorphism.

(1) If M is oriented and if the G-action is orientation-preserving, then the smooth manifold M/G admits an orientation such that the projection $p\colon M \to M/G$ is orientation-preserving.
(2) Conversely, if the smooth manifold M/G admits an orientation, then there exists a unique orientation on M such that the projection $p\colon M \to M/G$ is orientation-preserving. Furthermore this orientation has the property that the G-action on M is orientation-preserving.



Remark. In Exercise 25.10 we will prove a partial converse to the Orientation-Action Proposition 25.19 (2).

Proof. Both statements follow fairly easily from the definitions. But for completeness' sake let us sketch the argument.

(1) We assume that M is oriented and that for each $g \in G$ the map $M \to M$ given by $Q \mapsto g \cdot Q$ is orientation-preserving.

For each $Q \in M/G$ we pick some $\widetilde{Q} \in M$ with $p(\widetilde{Q}) = Q$ and we equip $\mathrm{T}_Q(M/G)$ with the orientation given by applying the isomorphism $\mathrm{D}p_{\widetilde{Q}}\colon \mathrm{T}_{\widetilde{Q}}M \to \mathrm{T}_Q(M/G)$ to the orientation of $\mathrm{T}_{\widetilde{Q}}M$. Since the G-action is orientation-preserving we see that this definition of the orientation is independent of the choice of $\widetilde{Q}$. We claim that these orientations of the tangent spaces of M/G form an orientation of the smooth manifold M/G.

For each $Q \in M/G$ we pick a chart $\Phi_{\widetilde{Q}}\colon U_{\widetilde{Q}} \to V_{\widetilde{Q}}$ around $\widetilde{Q}$ which has the property that the restriction of p to $U_{\widetilde{Q}}$ is a diffeomorphism onto its image. The maps $\Phi_{\widetilde{Q}} \circ (p|_{U_{\widetilde{Q}}})^{-1}\colon p(U_{\widetilde{Q}}) \to V_{\widetilde{Q}}$ form a smooth atlas for M/G. It follows almost immediately from the definitions that the orientations we just defined are continuous with respect to these charts. Since these charts form a smooth atlas for M/G we obtain from the Orientations-via-Atlas Lemma 25.8 that we have defined an orientation on M/G. By construction the map $p\colon M \to M/G$ is orientation-preserving.

(2) Now we assume that M/G is equipped with an orientation. For each $\widetilde{Q} \in M$ there exists an open neighborhood $U_{\widetilde{Q}}$ of $\widetilde{Q}$ such that the restriction of p to $p\colon U_{\widetilde{Q}} \to p(U_{\widetilde{Q}})$ is a diffeomorphism and such that there exists a smooth chart $\Phi_{\widetilde{Q}}\colon p(U_{\widetilde{Q}}) \to V_{\widetilde{Q}}$ for $p(\widetilde{Q}) \in M/G$.

We equip $\mathrm{T}_{\widetilde{Q}}M$ with the orientation that is obtained by applying the isomorphism $\mathrm{D}(p|_{U_{\widetilde{Q}}}^{-1})_{\widetilde{Q}}\colon \mathrm{T}_{p(\widetilde{Q})}(M/G) \to \mathrm{T}_{\widetilde{Q}}M$ to the given orientation of $\mathrm{T}_{p(\widetilde{Q})}(M/G)$.

Since the charts $\Phi_{\widetilde{Q}} \circ p\colon U_{\widetilde{Q}} \to V_{\widetilde{Q}}$ define a smooth atlas for M we see that these orientations do indeed define an orientation on M. Basically by construction these orientations are invariant under the G-action. ■

Example. Let $v \in \mathbb{R}^n$. We denote by $t\colon \mathbb{R}^n \to \mathbb{R}^n$ the translation by v. Note that given any $x \in \mathbb{R}^n$ the differential $\mathrm{D}t_x \in \mathrm{M}(n \times n, \mathbb{R})$, in the sense of the definition on page 536, is the identity matrix. Thus it follows from the Orientation Checking-via-Differentials Lemma 25.12 that the action of $\mathbb{Z}^n$ on $\mathbb{R}^n$ that is given by addition, is orientation-preserving. It follows from the Orientation-Action Proposition 25.19 that $\mathbb{R}^n/\mathbb{Z}^n$ is orientable.

We formulate the next examples as a lemma.

Lemma 25.20. (Surface Non-Orientability Lemma) The following smooth manifolds are non-orientable:

(1) the Möbius band,
(2) the projective plane $\mathbb{R}\mathrm{P}^2$,
(3) the Klein bottle, and
(4) any non-orientable surface of genus ≥ 1.

Remark. In Exercises 25.6 and 25.11 we will give different, arguably more satisfactory proofs that the projective plane $\mathbb{R}\mathrm{P}^2$ and the Klein bottle are non-orientable.

Proof. Let $X = \mathbb{R} \times [-1, 1]$ and $G = \mathbb{Z}$. As on page 252 we consider the action

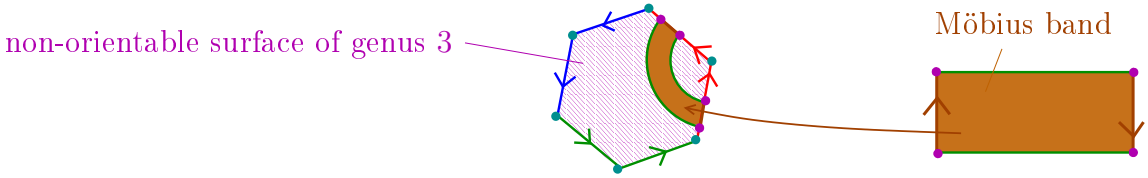
$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n, (x, y)) & \mapsto & (x + n, (-1)^n \cdot y). \end{array}$$

As we remarked on pages 252 and 564, this action is free, proper and smooth. By definition the quotient $(\mathbb{R} \times [-1, 1])/\mathbb{Z}$ is the Möbius band.

Claim. The Möbius band is non-orientable.

Proof. Suppose that the Möbius band $X/\mathbb{Z}$ admits an orientation. It follows from the Orientation-Action Proposition 25.19 that $X = \mathbb{R} \times [-1, 1]$ admits an orientation such that the $\mathbb{Z}$-action is orientation-preserving. It follows from the Basics-of-Orientations Lemma 25.13 (3) and (4) that this $\mathbb{Z}$-action preserves the standard orientation on $X = \mathbb{R} \times [-1, 1]$. Given $n \in \mathbb{Z}$ we consider the diffeomorphism of $X = \mathbb{R} \times [-1, 1]$ that is given by the action by n, i.e. we consider the diffeomorphism

$$\begin{array}{rcl} \Phi_n\colon \mathbb{R} \times [-1,1] & \to & \mathbb{R} \times [-1,1] \\ (x, y) & \mapsto & (x + n, (-1)^n \cdot y). \end{array}$$



Given any $(x, y) \in X$ the differential of Φ_n is given by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & (-1)^n \end{pmatrix}$. It follows from the Orientation Checking-via-Differentials Lemma 25.12 that for n odd the diffeomorphism Φ_n is not orientation-preserving. We have thus obtained a contradiction. ⊞

We turn to the proof that the three given closed smooth manifolds are non-orientable. By the Basics-of-Orientations Lemma 25.13 (6) it suffices to prove the following claim.

Claim. The open Möbius band is diffeomorphic to open subsets of the Möbius band, of the projective plane $\mathbb{R}\mathrm{P}^2$, of the Klein bottle and for any non-orientable surface of genus $g \geq 1$.

Proof. It is clear that the open Möbius band is an open subset of the Möbius band. The statements regarding the projective plane $\mathbb{R}\mathrm{P}^2$ and the Klein bottle follow immediately from Lemma 19.39.

Recall that by definition on page 266 the real projective plane is precisely the non-orientable surface of genus ≥ 1 and that by Exercise 5.50 the Klein bottle is diffeomorphic to the non-orientable surface of genus two. Thus it remains to deal with non-orientable surfaces of genus $g \geq 3$. In the figure below we indicate that for any $g \geq 3$ the non-orientable surface of genus g admits an open subset that is diffeomorphic to the open Möbius band. We leave it to the reader to upgrade this proof to the desired level of rigor. ■

Remark. For most people starting out with mathematics the definition of a submanifold M of some $\mathbb{R}^n$ and the definition of a tangent space to M as a vector subspace of $\mathbb{R}^n$ are quite natural and reasonable. But initially it is perhaps not clear why one should introduce "abstract" smooth manifolds. Furthermore the definition on page 628 of the tangent space $\mathrm{T}_P M$ to such a smooth manifold traditionally leads to a lot of head scratching.

The above proof of the Surface Non-Orientability Lemma 25.20 is a good example why it is useful to introduce these abstract notions. In principle it is possible to show that the Möbius band, viewed as a submanifold of $\mathbb{R}^3$, is non-orientable purely by working in the explicit 3-dimensional setting, see e.g. [**Frie2016a**, Lemma 9.16]. But this proof is rather messy and not very illuminating. In contrast, the fact that we can work with abstract smooth manifolds, in this case with $(\mathbb{R} \times [-1,1])/\mathbb{Z}$, and their tangent spaces liberates us from the constraints of the 3-dimensional setting and using Lemmas 25.12 and 25.13 we obtain a much clearer and much more elegant proof that the Möbius band is non-orientable.

We conclude this section with the following lemma which generalizes the Surface Non-Orientability Lemma 25.20 (3).

Lemma 25.21. (Real Projective Space Orientability Lemma) Let $n \in \mathbb{N}$. The real projective space $\mathbb{R}\mathrm{P}^n$ is orientable if and only if n is odd.

Proof. We outsource the proof to Exercise 25.6. ■

25.7. **Products of smooth manifolds and orientations.** In this section we will study products of oriented smooth manifolds. As discussed in Section 19.10 and Chapter 20, at this point it is natural to also study smooth manifolds with corner.
The following definition is copy-pasted from page 628.

Definition. Let M be a smooth manifold with *corner*. Given $P \in M$ we define the tangent space $\mathrm{T}_P M$ at P as the set of all derivations at P, i.e. $\mathrm{T}_P M$ is the vector space of all

linear maps $w\colon C^\infty(M,\mathbb{R}) \to \mathbb{R}$ such that for every choice of $f, g \in C^\infty(M,\mathbb{R})$ we have

$$w(f \cdot g) \;=\; f(P) \cdot w(g) + w(f) \cdot g(P) \qquad \text{“Leibniz rule”.}$$

Remark. The obvious generalizations of the results obtained in Section 23.3 hold with minor changes to the proofs. Furthermore one can also define, with almost the same definition as on page 675, the notion of an orientation on a smooth manifold with corner. Since every author's duty is to strive for brevity we will not go into detail.

For the reader's convenience we recall the Smooth Manifold Product Proposition 20.6.

Proposition 20.6. (Smooth Manifold Product Proposition) Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. We denote by

$$\begin{array}{rcl} p\colon M \times N & \to & M \\ (x,y) & \mapsto & x \end{array} \qquad \text{and} \qquad \begin{array}{rcl} q\colon M \times N & \to & N \\ (x,y) & \mapsto & y \end{array}$$

the two projections.

(1) The product $M \times N$ is an $(m+n)$-dimensional topological manifold that admits a *unique* structure as a smooth manifold with corner which that the following two conditions:
   (a) The projections $p\colon M \times N \to M$ and $q\colon M \times N \to N$ are smooth.
   (b) For any smooth manifold with corner W and any map $f\colon W \to M \times N$ the following holds: If the two maps $p \circ f\colon W \to M$ and $q \circ f\colon W \to N$ are smooth, then f itself is smooth.

(2) $\angle(M \times N) = \partial M \times \partial N$,[276]

(3) $\partial(M \times N) = (M \times \partial N) \cup (N \times \partial M)$.

We now have the following addendum to the Smooth Manifold Product Proposition 20.6.

Proposition 25.22. (Product Orientation Proposition) We continue with the notation of the Smooth Manifold Product Proposition 20.6. For the new statements we introduce the notation that given points $P \in M$ and $Q \in N$ we consider the inclusion maps

$$\begin{array}{rcl} i_Q\colon M & \to & M \times N \\ x & \mapsto & (x,Q) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} j_P\colon N & \to & M \times N \\ y & \mapsto & (P,y). \end{array}$$

The following statements hold:

(4) (a) All the inclusion maps i_P and j_Q are smooth.
   (b) Let $P \in M$ and $Q \in N$. The map

$$(\mathrm{D}i_Q)_P \oplus (\mathrm{D}i_P)_Q\colon \mathrm{T}_P M \oplus \mathrm{T}_Q N \;\to\; \mathrm{T}_{(P,Q)}(M \times N)$$

   is an isomorphism, the inverse is given by $\mathrm{D}p_{(P,Q)} \oplus \mathrm{D}q_{(P,Q)}$. (Sometimes we use this isomorphism to identify the vector spaces to the left and right.)
   (c) If M and N are oriented, then we equip the direct sum $\mathrm{T}_P M \oplus \mathrm{T}_Q N$ with the direct sum orientation that we defined on page 672. We use the isomorphism from (4b) to equip $\mathrm{T}_{(P,Q)}(M \times N)$ with the corresponding orientation. These orientations of tangent spaces define an orientation of $M \times N$.

[276] Recall that on page 582 we introduced the corner $\angle W$ of a smooth manifold with corner.

(d) If M and N are oriented, then

$$(-M) \times N \;=\; M \times (-N) \;=\; -(M \times N).$$

(5) We suppose that M and N are both oriented. If $\partial N = \varnothing$, then the above equality $\partial(M \times N) = (\partial M) \times N$ from (3) is in fact an equality of oriented smooth manifolds.[277]

Convention. Let M and N be two oriented smooth manifold. Unless we say something else we always equip the product $M \times N$ with the orientation given by the Product Orientation Proposition 25.22 (4). We refer to this orientation of $M \times N$ as the product orientation on $M \times N$.

Proof.

(4) (a) This statement follows from the Smooth Manifold Product Proposition 20.6 (1).
(b) This statement follows easily from the functoriality of the differentials.
(c) As so often, when it comes to verifying that orientations of tangent spaces define an orientation of the smooth manifold, we leave it to the reader to fill in the details.
(d) This statement follows from very elementary linear algebra.

(5) Let $P \in \partial M$ and $Q \in N$. Using Exercise 23.3 one can show that for an outward pointing vector $w \in \mathrm{T}_P M$ the image $\mathrm{D}(i_Q)_P(w) \in \mathrm{T}_{(P,Q)}(M \times N)$ is also outward pointing. We leave it to the reader to fill in the remaining details. ■

Remark. The definition of the product orientation is very slick, but it is perhaps worth spelling this out in more detail.

(1) If M and N are both of dimension ≥ 1, then it follows easily from the definitions that the orientation on $\mathrm{T}_{(P,Q)}(M \times N)$ is given by

$$\text{positive basis of } \mathrm{T}_{(P,Q)}(M \times N) \;:=\; \begin{matrix} (\mathrm{D}i_Q)_P(\text{positive basis of } \mathrm{T}_P M), \text{ followed by} \\ (\mathrm{D}j_P)_Q(\text{positive basis of } \mathrm{T}_Q N). \end{matrix}$$

(2) Let N be a smooth manifold and let $\{P\}$ be the 0-dimensional smooth manifold consisting of a single point P that is equipped with an orientation $\epsilon \in \{-1, 1\}$.
(a) If $\epsilon = 1$, then the product orientation on $\{P\} \times N$ is the orientation that turns the obvious map $N \to \{P\} \times N$ into an orientation-preserving diffeomorphism.
(b) If $\epsilon = -1$, then the production orientation $\{P\} \times N$ is the orientation that turns the obvious map $N \to \{P\} \times N$ into an orientation-reversing diffeomorphism.

(3) If $M = \{(P, \mu)\}$ and $N = \{(N, \nu)\}$ are two oriented 0-dimensional smooth manifolds, each consisting of a single point, then it follows from the above definition and the remark on page 672 that $M \times N = \{(P, Q)\}$ is equipped with the orientation $\mu \times \nu$.

Example.

(1) Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open subsets. We equip both with the standard orientation that we defined on page 677. It follows fairly easily from the definitions

[277] In Exercise 25.14 we will determine the relationship between the orientations of $\partial(M \times N)$ and $M \times \partial N$ if N is allowed to have non-empty boundary.

that the product orientation on $U \times V \subset \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$ equals the standard orientation of $U \times V$ viewed as an open subset of $\mathbb{R}^{m+n}$.

(2) If $N = \{P\}$ is the 0-dimensional smooth manifold consisting of a single point P, and if the orientation of that point is given by $+1$, then the product orientations on $N \times \{P\}$ and $\{P\} \times N$ are precisely the orientations that turn the maps

$$\begin{array}{ccc} M & \to & M \times \{P\} \\ x & \mapsto & (x, P) \end{array} \qquad \text{and} \qquad \begin{array}{ccc} M & \to & \{P\} \times M \\ x & \mapsto & (P, x) \end{array}$$

into orientation-preserving diffeomorphisms.

(3) Recall that on page 681 we equipped the 0-dimensional sphere $S^0 = \{\pm 1\}$ with the orientation given by $\pm 1 \mapsto \pm 1$. It follows immediately from the definitions that for any oriented smooth manifold M we have a natural orientation-preserving diffeomorphism $M \times S^0 \xrightarrow{\cong} (-M) \sqcup M$.

(4) Given any oriented smooth manifold N without boundary and given $a < b \in \mathbb{R}$ we have the equality

$$\partial([a,b] \times N) \underset{\substack{\uparrow \\ \text{Product Orientation} \\ \text{Proposition 25.22 (5)}}}{=} \partial([a,b]) \times N \underset{\substack{\uparrow \\ \text{see page 688}}}{=} (-\{a\} \cup \{b\}) \times N = (-\{a\} \times N) \cup (\{b\} \times N).$$

We have one last, rather unsurprising lemma.

Lemma 25.23. (Product Orientation Preserving Lemma) Let $f\colon M \to \widetilde{M}$ and $g\colon N \to \widetilde{N}$ be maps between oriented smooth manifolds. We consider the map

$$f \times g\colon M \times N \to \widetilde{M} \times \widetilde{N}.$$

Let $x \in M$ and $y \in N$ be points such that $\mathrm{D}f_x\colon \mathrm{T}_x M \to \mathrm{T}_{f(x)}\widetilde{M}$ is an isomorphism and such that $\mathrm{D}g_y\colon \mathrm{T}_y N \to \mathrm{T}_{g(y)}\widetilde{N}$ is an isomorphism.

(1) The map $\mathrm{D}(f \times g)_{(x,y)}\colon \mathrm{T}_{(x,y)}(M \times N) \to \widetilde{\mathrm{T}}_{(\widetilde{x},\widetilde{y})}(\widetilde{M} \times \widetilde{N})$ is an isomorphism.

(2) The map $f \times g$ is orientation-preserving at (x, y) if and only if both or none of f and g are orientation-preserving at x respectively y.

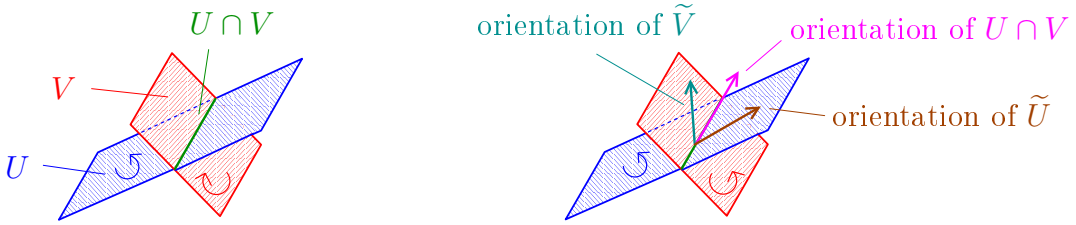
Proof. The lemma can be proved easily using product charts. We leave it to the reader to fill in the details. ■

This concludes our introduction to the notion of an orientation of smooth manifolds. Perhaps somewhat unintuitively there does also exist a perfectly fine notion of the orientation of a topological manifold. We will introduce this notion in Chapter 105. In the Smooth-Topological Orientation Proposition 105.11 we will see that this generalizes the present notion of an orientation. Furthermore in the Topological Manifold-Boundary Orientation Proposition 105.19 we will generalize the Boundary Orientation Lemma 25.17 to topological manifolds. Finally in Propositions 113.10 and 113.11 (see also page 2502) we will generalize the Product Orientation Proposition 25.22 to topological manifolds.

Exercises for Chapter 25.

Exercise 25.1. Let $v \in \mathbb{R}^n$ be a non-zero vector. We consider the orthogonal complement of v, i.e. we consider the vector space $v^\perp = \{w \in \mathbb{R}^n \mid \langle v, w\rangle = 0\}$. Show that

$$(w_1, \dots, w_{n-1}) \text{ is a positive basis of } v^\perp \quad :\Longleftrightarrow \quad \det(v\ w_1\ \dots\ w_{n-1}) > 0$$



defines an orientation on $v^\perp$.

Exercise 25.2. Let W be an oriented finite dimensional vector space and let U, V be oriented vector subspaces of W with $W = U + V$. What is the relationship between the intersection orientation of $U \cap V$ and the intersection orientation of $V \cap U$?

Exercise 25.3. Let W be an oriented real vector space and let U and V be oriented vector subspaces with $W = U + V$. We pick a vector subspace $\widetilde{U} \subset U$ such that $U = \widetilde{U} \oplus (U \cap V)$ and we pick a vector subspace $\widetilde{V} \subset V$ such that $V = (U \cap V) \oplus \widetilde{V}$.

(a) Show that there exist unique orientations on $U \cap V$, $\widetilde{U}$ and $\widetilde{V}$ such that the direct sum orientations of $U = \widetilde{U} \oplus (U \cap V)$, $V = (U \cap V) \oplus \widetilde{V}$ and $W = \widetilde{U} \oplus (U \cap V) \oplus \widetilde{V}$ are the given orientation.

(b) Show that the orientation of $U \cap V$ is precisely the intersection orientation.

Exercise 25.4. Let $\{v_1, v_2\}$ be a basis for $\mathbb{R}^2$ and let φ be the unique real number in $(-\pi, \pi)$ such that there exists a $\lambda > 0$ with

$$\begin{pmatrix} \cos\varphi & -\sin\varphi \\ \sin\varphi & \cos\varphi \end{pmatrix} v_1 \ = \ \lambda \cdot v_2.$$

Show that the basis (v_1, v_2) is a positive basis of $\mathbb{R}^2$ if and only if $\varphi \in (0, \pi)$.

Exercise 25.5. Let $A \in \mathrm{O}(n)$. Show that the map $S^n \to S^n$ given by $x \mapsto A \cdot x$ is orientation-preserving if and only if $\det(A) = 1$.

Exercise 25.6. Let $n \in \mathbb{N}$.

(a) Show that the action of $G = \{\pm 1\}$ on S^n is orientation-preserving if and only if n is odd.
Hint. Use the Tangent Space-Isomorphism Proposition 23.16 (2) and the Basics-of-Orientations Lemma 25.13 (3).

(b) Show that the real projective space $\mathbb{R}\mathrm{P}^n$ is orientable if and only if n is odd.
Hint. Use (a) together with the Basics-of-Orientations Lemma 25.13 and the Orientation-Action Proposition 25.19.

Exercise 25.7. Let M and N be two smooth manifolds of dimension ≥ 1. Show that $M \times N$ is orientable if and only if M and N are both orientable.

Exercise 25.8. Let $n \in \mathbb{N}$ and let $A \in \mathrm{GL}(n, \mathbb{Z})$ be a matrix. By the Maps-on-Torus Lemma 19.37 we know that the map

$$\begin{array}{rccc} f(A)\colon & \mathbb{R}^n/\mathbb{Z}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ & [v] & \mapsto & [A \cdot v] \end{array}$$

is a diffeomorphism. Show that this diffeomorphism is orientation-preserving if and only if $A \in \mathrm{SL}(n, \mathbb{Z})$, i.e. if and only if $\det(A) = 1$.

Exercise 25.9.

(a) Let $p\colon S^n \to \mathbb{R}^n \cup \{\infty\}$ be the stereographic projection from Lemma 2.18. It restricts to a diffeomorphism $\varphi\colon S^n \setminus \{(0, \dots, 0, 1)\} \to \mathbb{R}^n$. We equip both sides with the standard orientation. Show that φ is orientation-preserving if and only if n is odd.

(b) We consider the projection

$$\begin{array}{rccc} \psi\colon & S^n_{>0} = \{(x_1, \dots, x_{n+1}) \in S^n \mid x_{n+1} > 0\} & \mapsto & B^n \\ & (x_1, \dots, x_{n+1}) & \to & (x_1, \dots, x_n). \end{array}$$

We equip both sides with the standard orientation. Show that ψ is orientation-preserving if and only if n is even.

Exercise 25.10. Let G be a group that acts freely, properly and smoothly on an n-dimensional oriented smooth manifold M. Suppose that M/G is orientable.

(a) Suppose that M is path-connected. Show that every $g \in G$ acts on M in an orientation-preserving way.
Hint. Use the Orientation-Action Proposition 25.19 (2).

(b) Show that the conclusion of (a) does not hold if M is not path-connected.

Remark. This exercise can be viewed as a converse to the Orientation-Action Proposition 25.19 (1).

Exercise 25.11. We consider the following two self-diffeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rccc} A\colon & \mathbb{R}^2 & \to & \mathbb{R}^2 \\ & (x, y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rccc} B\colon & \mathbb{R}^2 & \to & \mathbb{R}^2 \\ & (x, y) & \mapsto & (x, y+1). \end{array}$$

We denote by G the subgroup of all diffeomorphisms of $\mathbb{R}^2$ that is generated by A and B. This means

$$G = \begin{array}{c} \text{all self-diffeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}. \end{array}$$

(a) For $n \in \mathbb{Z}$, what is $A^{-n}BA^n$?

(b) We write $C = A^2$. We denote by H the subgroup of all diffeomorphisms of $\mathbb{R}^2$ that is generated by C and B. Does A lie in H?
Hint. Consider which self-diffeomorphisms of $\mathbb{R}^2$ are orientation-preserving.

(c) Show that any element X of G lies in H or it is of the form $G = AY$ with $Y \in H$.

(d) Show that the group G acts freely and properly on $\mathbb{R}^2$.

(e) We consider the square $X = [0, 1] \times [0, 1]$ with the equivalence relation that is generated by $(0, y) \sim (1, 1-y)$ and $(x, 0) \sim (x, 1)$. Show that the map

$$\begin{array}{rccc} & X/\!\sim & \to & \mathbb{R}^2/G \\ & [(x, y)] & \mapsto & [(x, y)] \end{array}$$

is a diffeomorphism. (Recall that in Exercise 19.20 we equipped $X/\sim$ with a smooth structure.) This implies that $\mathbb{R}^2/G$ is diffeomorphic to the Klein bottle that we defined on page 265.

Remark. This discussion, together with the Orientation-Action Proposition 25.19, gives a new proof of the fact, already shown in the Surface Non-Orientability Lemma 25.20, that the Klein bottle is non-orientable.

Exercise 25.12. We consider the surface Σ of genus 2 and we consider the explicit atlas that we constructed in the proof of the Surface-is-Topological Manifold Proposition 18.7. Show that the transition maps are all orientation-preserving.

Exercise 25.13. Can a closed non-orientable connected smooth manifold be the boundary of a compact smooth manifold?

Exercise 25.14. Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. We equip the product smooth manifolds with corner $M \times N$ and $N \times M$ with the product orientations as defined in the Product Orientation Proposition 25.22.

(a) Show that the diffeomorphism

$$\begin{array}{rcl} M \times N & \to & N \times M \\ (x, y) & \mapsto & (y, x) \end{array}$$

is orientation-preserving if and only if $m \cdot n$ is even.

(b) We suppose that $\partial N = \varnothing$. We equip ∂M and $N \times M$ with the boundary orientation and we equip $N \times \partial M$ with the product orientation. Show that we have the following equality of *oriented* smooth manifolds:

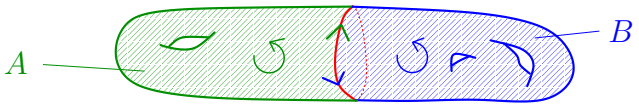
$$\partial(N \times M) \;=\; \begin{cases} N \times \partial M, & \text{if } n \text{ is even,} \\ -(N \times \partial M), & \text{if } n \text{ is odd.} \end{cases}$$

Exercise 25.15. Let M be an oriented smooth manifold without boundary. We denote by $-M$ the same smooth manifold with the opposite orientation. Show that the product orientations given by $M \times M$ and $(-M) \times (-M)$ are actually the same.

Exercise 25.16. Let M be a smooth codimension-one submanifold of $\mathbb{R}^n$, let $\gamma\colon [0,1] \to M$ be a curve and let $v \in (\widetilde{\mathrm{T}}_{\gamma(0)}M)^\perp$. Show that there exists a unique map $\widetilde{\gamma}\colon [0,1] \to \mathbb{R}^n$ such that $\widetilde{\gamma}(0) = \gamma(0) + v$ and such that for each $t \in [0,1]$ we have $\widetilde{\gamma}(t) - \gamma(t) \in (\widetilde{\mathrm{T}}_{\gamma(t)}M)^\perp$ with $\|\widetilde{\gamma}(t) - \gamma(t)\| = \|v\|$.

Remark. Evidently we want $\widetilde{\gamma}$ to be continuous. Note that we do not assume that M is orientable.

Exercise 25.17. We consider $\widetilde{M} := \mathbb{R} \times [-1,1]$ and the self-diffeomorphism



$$\begin{array}{rcl} g\colon \widetilde{M} = \mathbb{R} \times [-1,1] & \to & \widetilde{M} = \mathbb{R} \times [-1,1] \\ (r, s) & \mapsto & (r+1, -s). \end{array}$$

Recall that the Möbius band is defined as $M = \widetilde{M}/\sim$ where $P \sim g(P)$. We denote by $p\colon \mathbb{R}\times[-1,1] \to M$ the projection. We set $x := p(0,0)$. Show that there exists a diffeotopy $F\colon M \times [0,1] \to M$ with the following properties:

(1) $F_0 = \mathrm{id}$.
(2) $F_1(x) = x$.
(3) $\mathrm{D}(F_1)_x\colon \mathrm{T}_x M \to \mathrm{T}_x M$ is orientation-reversing.
(4) Bonus exercise: arrange that F is a diffeotopy rel ∂M.

Exercise 25.18. Let $f\colon \mathbb{R} \to \mathbb{R}$ be an orientation-preserving local diffeomorphism. Show that f is strictly monotonously increasing, i.e. show that for any real numbers $s > t$ we have $f(s) > f(t)$.

Exercise 25.19. Let M be an oriented smooth manifold and let A and B be codimension-zero submanifolds such that $A \cap B = \partial A = \partial B$. We equip the codimension-zero submanifolds A and B with the standard orientations defined on page 684 and we equip ∂A and ∂B with the orientations defined on page 689. Show that as oriented smooth manifolds we have $\partial A = -\partial B$.

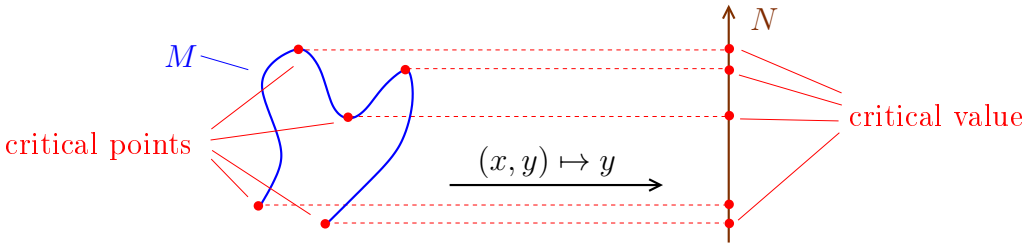
Exercise 25.20.

(a) Let M be a smooth manifold and let $k \in \mathbb{N}_0$. Show that if $M \times B^k$ is orientable, then so is M.
(b) Let M and N be non-empty smooth manifolds. Show that if $M \times N$ is orientable, then so are M and N.

Remark. This exercise can be viewed as a converse to the Product Orientation Proposition 25.22 (4c).

Exercise 25.21. Does there exist a connected oriented 1-dimensional smooth manifold that does not admit an orientation-reversing diffeomorphism?
Remark. In Exercise 43.16 we will study the 2-dimensional case.

26. The Regular Value Theorem



Let M be a smooth manifold, e.g. $M = \mathbb{R}^n$ or $M = \mathrm{M}(n \times n, \mathbb{R})$. In general it can be quite painful to show directly that a given subset, e.g. $\mathrm{O}(n) \subset \mathrm{M}(n \times n, \mathbb{R})$ is a smooth submanifold. Only the most enterprising reader will feel like writing down explicit submanifold charts for $\mathrm{O}(n) \subset \mathrm{M}(n \times n, \mathbb{R})$. In this chapter we will state and prove the Regular Value Theorem which can be used, among many other applications, to give an elegant proof that $\mathrm{O}(n)$ is a submanifold of $\mathrm{M}(n \times n, \mathbb{R})$.

26.1. **Regular values.** Not surprisingly the formulation of the Regular Value Theorem is preceded by the definition of a regular value. This notion might be familiar to the reader from an earlier course on real analysis.

Definition. Let M and N be smooth manifolds (possibly with boundary). Let $f\colon M \to N$ be a smooth map.

(1) Let $P \in M$.
   (a) If $P \in M \setminus \partial M$, then we say P is a regular point if $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)}N$ is an epimorphism.
   (b) If $P \in \partial M$, then we say P is a regular point if $\mathrm{D}f_P\colon \mathrm{T}_P(\partial M) \to \mathrm{T}_{f(P)}N$ is an epimorphism.[278]

   Otherwise we say that P is a critical point.
(2) We say $Q \in N$ is a regular value if all points in the preimage $f^{-1}(Q)$ are regular. Otherwise we call Q a critical value. In other words, the critical values are precisely the images of the critical points.

The following elementary observation will be used several times without explicitly mentioning it.

Observation. Let $f\colon M \to N$ be a smooth map between smooth manifolds.

(1) If $Q \in N$ is a point with $f^{-1}(Q) = \varnothing$, then Q is a regular value.
(2) If $\dim(M) < \dim(N)$, then the converse to (1) holds: it follows from the Tangent Space-Dimension Proposition 23.11 and elementary linear algebra that a point $Q \in N$ is a regular value if and only if we have $f^{-1}(Q) = \varnothing$.
(3) If $\varphi\colon X \to M$ is a local diffeomorphism, then it follows easily from the Chain Rule 19.10 that

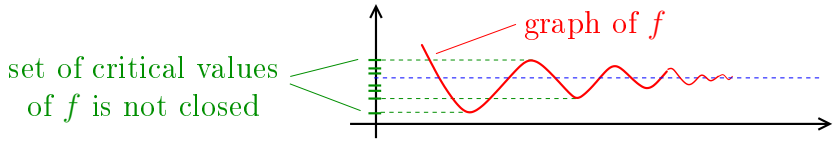
$$\text{set of critical points of } f \circ \varphi\colon X \to N \;=\; \varphi^{-1}(\text{set of critical points of } f\colon M \to N).$$

[278] Note that it follows from the Smooth Manifold Boundary Proposition 19.26 (2) that the restriction of a map on a smooth manifold to its boundary is also a smooth map.

From this observation together with the Image-Preimage Lemma 0.2 (2) it follows that

$$\text{set of critical values of } f\circ\varphi\colon X\to N \quad \underset{\substack{\uparrow\\ \text{equality holds if } \varphi \text{ is surjective}}}{\subset} \quad \text{set of critical values of } f\colon M\to N.$$

The following lemma is slightly less trivial than the above observation.



Lemma 26.1. (Regular Value-Open Subset Lemma) Let $f\colon M\to N$ be a smooth map between smooth manifolds.

(1) The set of regular points of f is an open subset of M.
(2) The set of critical points of f is a closed subset of M.

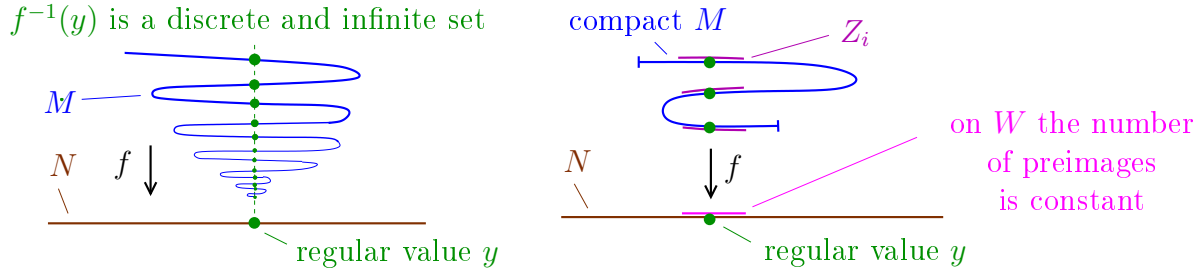
Example. We consider the smooth functions

$$\begin{array}{rcl} f\colon [1,\infty) & \to & \mathbb{R} \\ x & \mapsto & \frac{1}{x}\cdot\sin(x) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} f\colon \mathbb{R} & \to & \mathbb{R} \\ x & \mapsto & \begin{cases} e^{-\frac{1}{x^2}}\cdot\sin(\frac{1}{x}), & \text{if } x\neq 0, \\ 0, & \text{if } x=0. \end{cases} \end{array}$$

The first example shows that the set of critical values is not necessarily closed and the second example shows that the set of critical points is not necessarily discrete. For purely artistic reasons we show in the figure below the graph of some other smooth function $f\colon (a,b)\to\mathbb{R}$ for which the set of critical values is not closed.

Proof. The second statement is of course just a reader-friendly reformulation of the first statement. We write $m := \dim(M)$ and $n := \dim(N)$. Let P be a regular point of f. We pick a chart $\Phi\colon U\to V$ around P and we pick a chart $\Psi\colon W\to X$ around $f(P)$. We consider the map

$$\begin{array}{rcl} \Xi\colon \Phi(U\cap f^{-1}(W)) & \to & \mathrm{M}(n\times m,\mathbb{R}) \\ Q & \mapsto & \mathrm{D}(\Psi\circ f\circ\Phi^{-1})_Q. \end{array}$$



The lemma follows easily from the hypothesis that P is regular point and the following four observations:

(a) Since f is smooth we see that Ξ is continuous.
(b) A point $Q\in U\cap f^{-1}(W)$ is a regular point of f if and only if $\Xi(\Phi(Q))$ is a matrix of rank m.
(c) $U\cap f^{-1}(W)$ is an open neighborhood of P.
(d) By Lemma 42.8, see also Exercise 2.41, we know that the set of matrices of rank m is an open subset of $\mathrm{M}(n\times m,\mathbb{R})$. ■

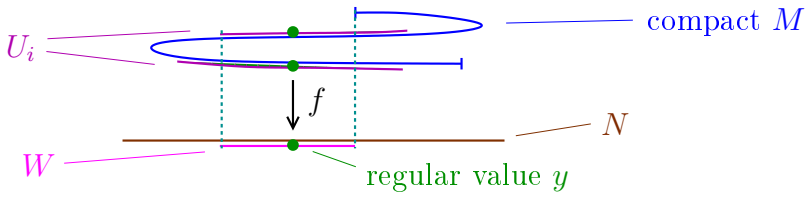
In the following lemma we summarize a few basic facts about regular points and values of smooth maps between smooth manifolds *of the same dimension*.

Lemma 26.2. (Stack of Records Lemma)[279] Let $f\colon M \to N$ be a smooth map between two smooth manifolds of the same dimension.

(1) For every regular point $x \in M \setminus \partial M$ the map f is a local diffeomorphism around x.
(2) Let $y \in N$ be a regular value.
   (a) The preimage $f^{-1}(y)$ is a discrete subset of M
   (b) If M is compact, then $f^{-1}(y)$ is finite subset of M.
   (c) If M is compact, then there exists an open neighborhood W of $y \in N$ with the following properties:
      (i) $f^{-1}(W)$ consists of disjoint open sets $Z_1, \dots, Z_k$ and the restriction of f to each Z_i defines a diffeomorphism $Z_i \to W$.
      (ii) Each $y' \in W$ is a regular value.
      (iii) For each $y' \in W$ we have the equality $\#f^{-1}(y) = \#f^{-1}(y')$.

Proof.

(1) Let $x \in M \setminus \partial M$ be a regular point of f. This means that $\mathrm{D}f_x\colon \mathrm{T}_{f(x)}M \to \mathrm{T}_{f(x)}N$ is an epimorphism. Since M and N have the same dimension this implies that $\mathrm{D}f_x$ is an isomorphism. It follows from the hypothesis that $x \in M \setminus \partial M$ together with the Inverse Mapping Theorem 24.1 that f is a local diffeomorphism around x.
(2) Let y be a regular value of f.
   (a) It follows immediately from (1) that for each $x \in f^{-1}(y)$ there exists an open neighborhood U of x such that $f\colon U \to f(U)$ is a diffeomorphism. This implies that $U \cap f^{-1}(y) = \{x\}$. We have thus shown that $f^{-1}(y)$ is a discrete subset of M.
   (b) By (a) we know that $f^{-1}(y)$ is a discrete subset of M. If M is compact, then it follows from the Compact-Discrete Lemma 1.22 that $f^{-1}(y)$ is actually a finite set.
   (c) We denote the points in $f^{-1}(y)$ by $x_1, \dots, x_k \in M$. Since $x_1, \dots, x_k$ are regular points we obtain from (a) open neighborhoods $U_1, \dots, U_k$ of $x_1, \dots, x_k$ and open neighborhoods $V_1, \dots, V_k$ of $f(x_1), \dots, f(x_k)$ such that for each i the map $f_i\colon U_i \to V_i := f(U_i)$ is a diffeomorphism. Since M is Hausdorff we can and will



[279] The idea behind the name is that W is a disk ("record") and "above it" lie k disks ("records"). The name might make more sense for the readers over 50.

arrange that the U_i are pairwise disjoint. We set

$$W := \underbrace{\Big(\bigcap_{i=1}^{k} V_i\Big)}_{\text{open subset}} \quad \setminus \quad \underbrace{f\Big(M \setminus \bigcup_{i=1}^{k} U_i\Big)}_{\substack{\text{since } M \text{ is compact we}\\ \text{obtain from Lemma 2.13 that}\\ \text{this is a closed subset of } N}}.$$

Note that W is open and that it contains y. Furthermore note that by construction we have $f^{-1}(W) \subset \bigcup_{i=1}^{k} U_i$. For $i = 1, \dots, k$ we set $Z_i := f^{-1}(W) \cap U_i$. Evidently these sets are still disjoint.

- For each $i \in \{1, \dots, k\}$ the map $f\colon Z_i \to W$ is a bijection and it is given by the restriction of a diffeomorphism to an open subset. Hence the map $f\colon Z_i \to W$ is actually a diffeomorphism.
- It follows from (i) that each point in $f^{-1}(W)$ is a regular point, thus every point in W is a regular value.
- By (i) the preimage of each $y' \in V$ consists of precisely k points, namely one x'_i in each U_i. In other words, we have shown that $\#f^{-1}(y) = k$ for all $y \in W$. ∎

26.2. **The Fundamental Theorem of Algebra ❀.** Perhaps rather surprisingly the straightforward Lemma 26.2 allows us to prove the Fundamental Theorem of Algebra.

Theorem 26.3. (Fundamental Theorem of Algebra) Every nonconstant polynomial with coefficients in $\mathbb{C}$ has a zero in $\mathbb{C}$.

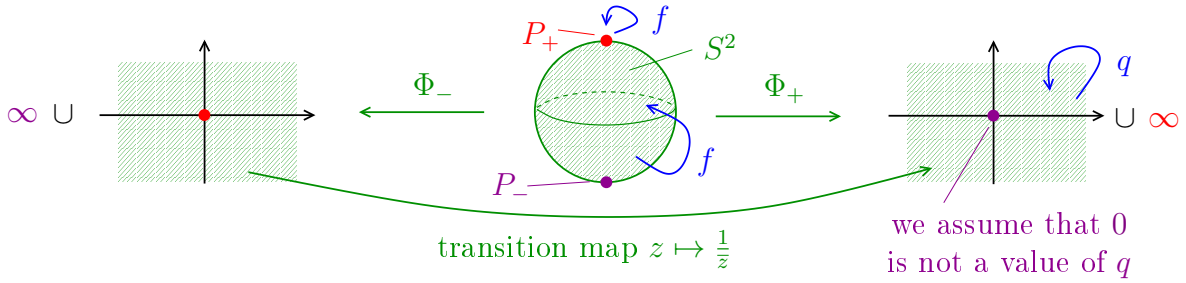
Remark. We will provide two other proofs of the Fundamental Theorem of Algebra 26.3 on page 1094 and on page 1700.

Proof. Let $q(z) = a_0 + a_1 z + \cdots + a_n z^n$ be a complex polynomial of degree $n \geq 1$ with complex coefficients. We will perform a proof by contradiction, so we now assume that $q(z)$ has no zeros. In our argument below we will use the following two inputs which we will not prove.

(i) Every complex polynomial of degree $d \geq 0$ has at most d zeros.
(ii) If p is a complex polynomial of degree ≥ 1, then the map $\mathbb{C} \to \mathbb{C}$ given by $z \mapsto p(z)$ takes on infinitely many values.

We make a few preparations for the proof:

(1) We write $P_+ = (0,0,+1)$. As in Lemma 2.18 we consider the stereographic projection from P_+ which is given as follows:



$$\begin{array}{rcl} \Phi_+ \colon S^2 & \to & \mathbb{R}^2 \cup \{\infty\} = \mathbb{C} \cup \{\infty\} \\ (x_1,x_2,x_3) & \mapsto & \begin{cases} \left(\frac{x_1}{1-x_3}, \frac{x_2}{1-x_3}\right), & \text{if } x_3 \neq +1, \\ \infty, & \text{if } x_3 = +1. \end{cases} \end{array}$$

Similarly we write $P_- = (0,0,-1)$ and we denote by $\Phi_- \colon S^2 \to \mathbb{C} \cup \{\infty\}$ the stereographic projection from P_-. Note that $\Phi_\pm(P_\pm) = \infty$ and $\Phi_\pm(P_\mp) = 0$.

(2) By Exercise 18.15 we know that the transition map between the two charts is given by

$$\begin{array}{rcl} \Phi_+ \circ \Phi_-^{-1} \colon \mathbb{C} \setminus \{0\} & \to & \mathbb{C} \setminus \{0\} \\ z & \mapsto & \frac{1}{|z|^2} \cdot z = \frac{1}{\bar{z}}. \end{array}$$

(3) As on page 513 and in Proposition 19.18 we equip S^2 with the usual smooth atlas given by Φ_+ and Φ_-.

Claim. The map

$$\begin{array}{rcl} f \colon S^2 & \to & S^2 \\ P & \mapsto & \begin{cases} \Phi_+^{-1}(q(\Phi_+(P))), & \text{if } P \neq P_+, \\ P_+, & \text{if } P = P_+ \end{cases} \end{array}$$

has the following two properties:

(1) the map f is smooth,
(2) the map f has at most $n+1$ critical points.

Proof.

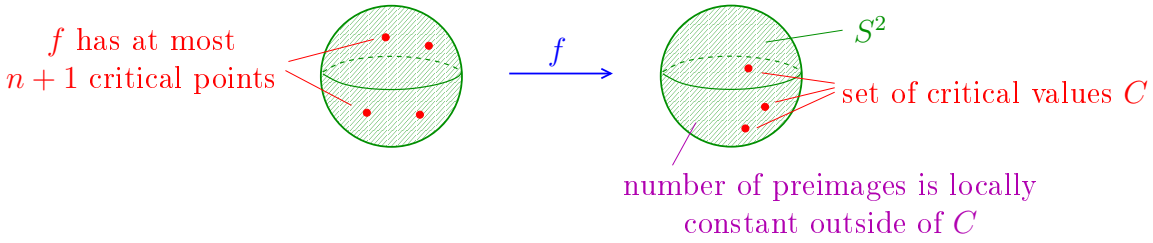
(1)
- The map $\Phi_+ \circ f \circ \Phi_+^{-1} \colon \mathbb{C} \to \mathbb{C}$ is given by $z \mapsto q(z)$, hence it is smooth.
- Note that our assumption that q has no zeros implies that P_- does not lie in the image of f. This in turn implies that ∞ does not lie in the image of $\Phi_- \circ f$. Thus we can consider the map

$$\Phi_- \circ f \circ \Phi_-^{-1} \colon \mathbb{C} \to \mathbb{C}.$$

It follows from the discussion of the transition map and the fact that $f(P_+) = P_+$ that this map is given by

$$z \mapsto \begin{cases} 0, & \text{if } z = 0, \\ \dfrac{1}{p(\frac{1}{\bar{z}})} = \dfrac{z^n}{\bar{a}_0 z^n + \bar{a}_1 z^{n-1} + \cdots + \bar{a}_n}, & \text{if } z \neq 0. \end{cases}$$

But since $a_n \neq 0$ we see that this map is smooth, even at zero.



It follows from the above together, with the Smooth Pasting Proposition 19.23, that f is smooth.

(2) Note that by standard results in complex analysis, see e.g. the Smooth-Complex Differentiability Proposition 32.3, we know that for a holomorphic function the derivative corresponds to the differential. It follows almost immediately from this observation together with input (i) that the map $\mathbb{C} \to \mathbb{C}$ given by $z \mapsto q(z)$ has at most n critical points. This implies that f has at most n critical points on $\Phi_+(\mathbb{C}) = S^2 \setminus \{P_+\}$. This implies that f has at most $n+1$ critical points. ⊞

Now we return to the main argument. First note that if $P_- = \Phi_+^{-1}(0)$ is a critical value of f, then this implies by the discussion on page 701 that 0 is a value of q, i.e. q has a zero. Now assume that $P_+ = \Phi_+^{-1}(0)$ is not a critical value of f. We denote by C the set of critical values of f. It follows from the claim that C is finite. Next we consider the map

$$\begin{array}{rcl} d\colon S^2 \setminus C & \to & \mathbb{N}_0 \\ P & \mapsto & \#f^{-1}(P). \end{array}$$

It follows from Lemma 26.2 that this map $d\colon S^2 \setminus C \to \mathbb{N}_0$ is locally constant, in particular it is continuous. Since C is finite we obtain from an elementary argument, see e.g. Exercise 18.16, that the left-hand side is connected. Since $\mathbb{N}_0$ is evidently discrete we obtain from the Connected-to-Discrete Lemma 2.27 that $d\colon S^2 \setminus C \to \mathbb{N}_0$ is actually a constant map.

Since q is not a constant polynomial it follows from input (ii) that the map $z \mapsto q(z)$, and thus also the map $f\colon S^2 \to S^2$, takes on infinitely many values. This implies that $d\colon S^2 \setminus C \to \mathbb{N}_0$ cannot be zero everywhere. But since this function is constant and since we assume that P_+ is a regular value we see that $d(P_+) = \#f^{-1}(P_+) = \#q^{-1}(0)$ is non-zero. But this implies that q has at least one zero. ■

26.3. **The Regular Value Theorem.** The following theorem is often a convenient way for showing that a given subset of a smooth manifold, e.g. a given subset of some $\mathbb{R}^n$ or some $\mathrm{M}(m \times n, \mathbb{R})$ is in fact a smooth submanifold.

Theorem 26.4. (Regular Value Theorem) Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold, let $f\colon M \to N$ be a smooth map and let $s \in N \setminus \partial N$ be a regular value of f. We denote by $f_\partial\colon \partial M \to N$ the restriction of f to ∂M.

(1) The preimage $X := f^{-1}(s)$ is a proper $(m-n)$-dimensional submanifold of M with $\partial f^{-1}(s) = (f_\partial)^{-1}(s)$.

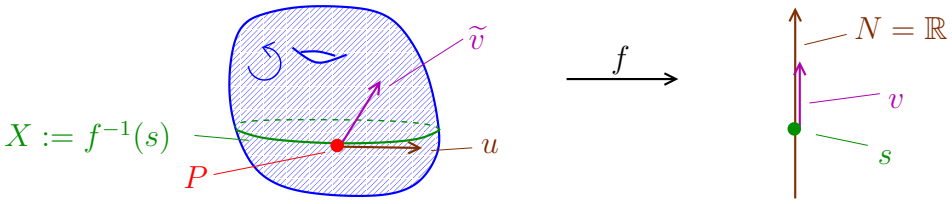
(2) We denote by $i\colon X \to M$ the inclusion. For every $P \in X$ we have

$$\operatorname{im}(\mathrm{D}i_P\colon \mathrm{T}_P X \to \mathrm{T}_P M) \;=\; \ker(\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathrm{T}_s N).$$

In particular, if M is a submanifold of some $\mathbb{R}^k$ and N is a submanifold of some $\mathbb{R}^l$, then

$$\widetilde{\mathrm{T}}_P X \;=\; \ker(\mathrm{D}f_P\colon \widetilde{\mathrm{T}}_P M \to \widetilde{\mathrm{T}}_s N).$$

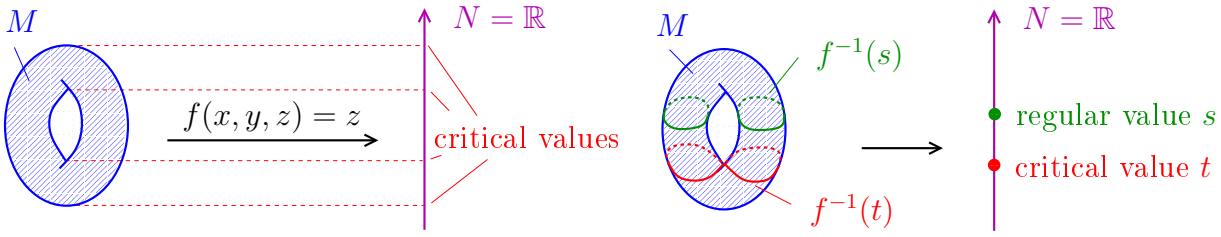
(3) Suppose we have an orientation on M and an orientation on $\mathrm{T}_s N$.
(a) Let $P \in X$. By (2) we have a short exact sequence[280]



$$\mathrm{T}_P X \xrightarrow{\mathrm{D}i_P} \mathrm{T}_P M \xrightarrow{\mathrm{D}f_P} \mathrm{T}_s N.$$

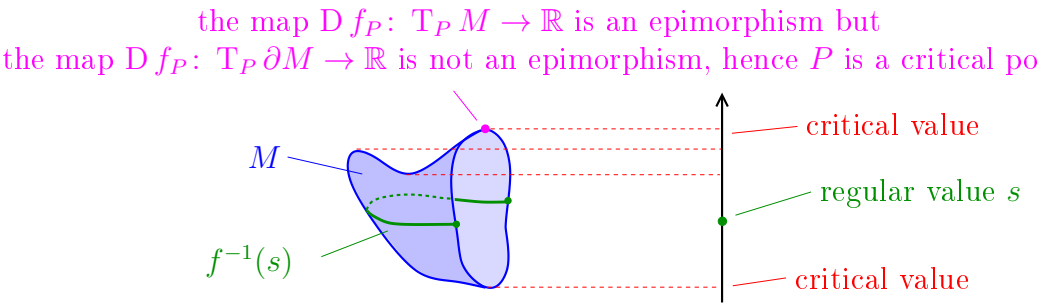
By our hypothesis the vector spaces in the middle and to the right are oriented. It follows from the Compatible Orientations Lemma 25.5 that there exists a unique orientation on $\mathrm{T}_P X$ such that the orientations are compatiblein the sense of the definition on page 671. These orientations on the tangent spaces $\mathrm{T}_P X$ define an orientation on the smooth manifold X.

(b) If we equip $\partial f^{-1}(s)$ with the boundary orientation, then the orientation agrees with the orientation on $(f_\partial)^{-1}(s)$ defined by the definition of (3a) applied to $f_\partial\colon \partial M \to N$.



(4) The intersection of X with any compact set of M is compact. In particular, if M is compact, then X is also compact.

Convention. Recall that the Submanifold Smooth Structure Lemma 19.24 says that a submanifold of a smooth manifold has a natural smooth structure. We will use this structure to view preimages of regular values as smooth manifolds in their own right.



Example.
