(2) Let $(x, \gamma) \in A$. As mentioned in Lemma 125.4 (3), this means that the four points $Q_1(x, \gamma)$, $Q_2(x, \gamma)$, $Q_3(x, \gamma)$ and $Q_4(x, \gamma)$ lie on a plane. But this immediately implies that for any $k \in \mathbb{Z}$ we have $\pi(x, \gamma) = \pi(x, i^k \cdot \gamma)$ which then gives us the equality $\psi(x, \gamma) = \psi(x, i^k \cdot \gamma)$.

(3) The final statement is a little more interesting. So let $x \in \partial D$ and let $\gamma \in S^1$. We assume that $(x, \gamma) \in A$. We write $a_i = a_i(x, \gamma)$, $i = 1, 2, 3, 4$.

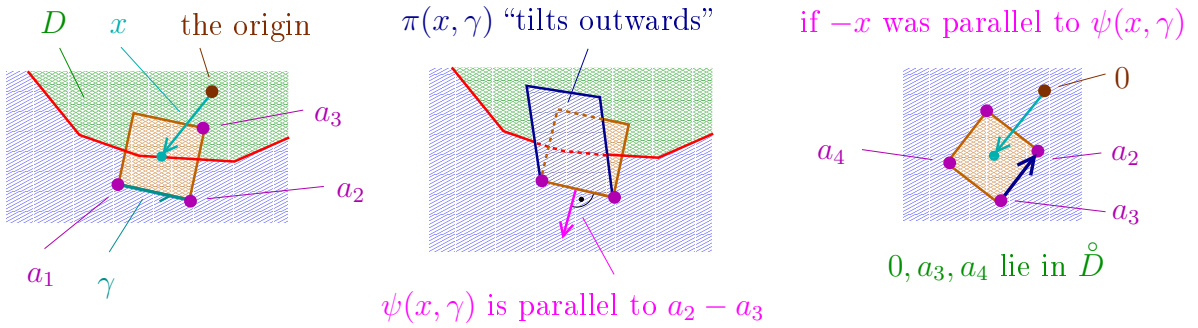
Claim. There exist two adjacent vertices which lie outside of $\mathring{D}$ and there are two adjacent vertices which have non-zero f-value.

Proof. We make the following observations:
(a) Since $(x, \gamma) \in A$ we have $f(a_1) + f(a_3) - f(a_2) - f(a_4) = 0$.
(b) By choice of f we know that all f-values are non-negative.
(c) By the preliminary remark (vi) on page 2731 we know that not all of the f-values are zero.
(d) Since x lies on ∂D and since D is convex we see that at most two f-values can be non-zero.[1518]

The claim follows easily from the above considerations and the elementary observation that every odd vertex is adjacent to every even vertex. ⊞

To simplify the notation let us now assume that the adjacent vertices a_1 and a_2 do *not* lie in the interior of D. Consequently $f(a_3) > 0$ and $f(a_4) > 0$. A straightforward

[1517] Since $a_3(x, \gamma) - a_2(x, \gamma)$ and $a_1(x, \gamma) - a_2(x, \gamma)$ are linearly independent we see that the two vectors in the cross product are linearly independent, in particular the cross product is indeed non-zero. Thus it makes sense to normalize the vector to length one.



[1518] Any vertex with non-zero f-value lies in the interior of D. So if three vertices have non-zero f, then the triangle spanned by these vertices lies in the interior, in particular x would lie in the interior of D.

calculation shows that

$$\psi(x,\gamma) \;=\; \begin{array}{c}\text{projection of}\\ \text{normalization of}\end{array} \begin{pmatrix} a_3 - a_2 \\ f(a_3)\end{pmatrix} \times \begin{pmatrix} a_1 - a_2 \\ 0\end{pmatrix} \text{ into the } xy\text{-plane} \;=\; \lambda\cdot(a_2 - a_3)$$

for some $\lambda > 0$.

Now suppose that $\psi(x,\gamma)$ is parallel to $-x$. This means, by the above calculation, that $a_3 - a_2 = -\mu \cdot x$ for some $\mu > 0$. It is now straightforward to verify that x lies in the interior of the convex hull of 0, a_3 and a_4. Since 0, a_3 and a_4 lie in the interior of D we see that x also lies in the interior of D. But that is a contradiction to our hypothesis that $x \in \partial D$. ∎

Lemma 125.6. We set

$$T \;:=\; (D \times S^1)/\!\sim \;\text{ where } (x,\gamma) \sim (x, i\cdot\gamma)$$

and we consider the following diagram

$$\begin{array}{ccc} D \times S^1 & \xrightarrow{\quad\psi\quad} & \mathbb{R}^2 \\ {\scriptstyle =:p}\big\downarrow{\scriptstyle (x,\gamma)\mapsto[(x,\gamma)]} & & \big\downarrow \\ T & \xrightarrow[{[(x,\gamma)]\mapsto \frac{1}{4}\sum_{k=0}^{3}\psi(x,i^k\gamma)}]{=:\psi'} & \mathbb{R}^2. \end{array}$$

The following statements hold:

(1) The map $p\colon D \times S^1 \to T$ is a 4-fold covering and the topological space T is homeomorphic to the solid torus $D^2 \times S^1$.
(2) The map ψ' is continuous.
(3) The restriction of the diagram to $A \subset D \times S^1$ is commutative.
(4) If we set
$$A' \;:=\; p(A) \quad \text{and} \quad B' \;:=\; \{[(x,\gamma)] \in T \,|\, \psi'([x,\gamma]) = 0\}$$
then we have $p(A \cap B) = A' \cap B'$.

Proof.

(1) For the experienced reader it should be clear that $p\colon D \times S^1 \to T = (D \times S^1)/\!\sim$ is a 4-fold covering and that $T \cong D \times (S^1/\!\sim) \cong D \times S^1$. On page 2731 we remarked that D is homeomorphic to $\overline{B}^2$, thus we see that T is indeed homeomorphic to the solid torus $\overline{B}^2 \times S^1$.

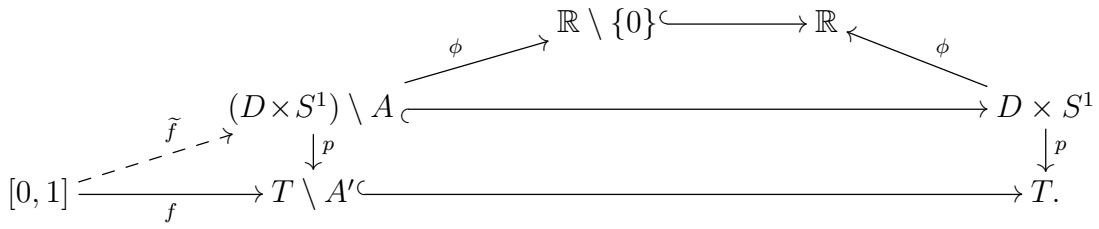
(2) The map $D^2 \times S^1 \to \mathbb{R}^2$ given by $(x, \gamma) \to \frac{1}{4}\sum_{k=0}^{3} \psi(x, i^k\gamma)$ is continuous. It descends to our map $\psi' \colon T = (D \times S^1)/\sim \to \mathbb{R}^2$. Thus it follows from the Topological-Quotient Proposition 5.15 (1b) that ψ' is continuous.
(3) It follows immediately from Lemma 125.5 (2) that for any $(x, \gamma) \in A$ we have the equality $\psi'([x, \gamma]) = \psi(x, \gamma)$.
(4) The equality $p(A \cap B) = A' \cap B'$ follows easily from (3). ■

From Lemma 125.6 (3) and Observation 125.3 we obtain the following observation.

Observation 125.7. To prove the Table Theorem 125.2 it suffices to show that $A' \cap B' \neq \varnothing$.

After spending so much time on preparations we can now finally apply the machinery from algebraic topology to tackle the problem. We introduce the following convention.

Convention. By Lemma 125.6 (1) we know that T is a solid torus. Given any $x_0 \in T$ we make an identification $\pi_1(T, x_0) = \mathbb{Z}$.[1519]



The following lemma turns our data into algebraic-topological information.

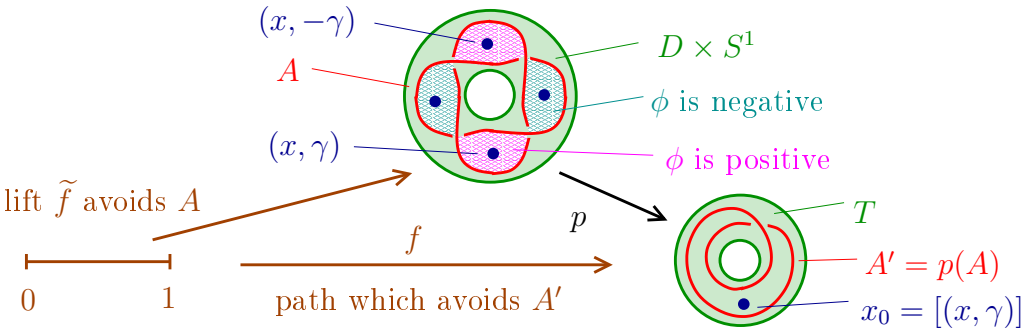
Lemma 125.8. We continue with the above notation. Let $x_0 \in T \setminus A'$. The image of $\pi_1(T \setminus A', x_0)$ in $\pi_1(T, x_0) = \mathbb{Z}$ is contained in the subgroup $2 \cdot \mathbb{Z}$.

Proof. Let $x_0 = [(x, \gamma)] \in T \setminus A'$. Note that by definition of A' we have $\phi(x, \gamma) \neq 0$.

(∗) Without loss of generality we can assume that $\phi(x, \gamma) > 0$.

Now let $[f] \in \pi_1(X \setminus A', x_0)$. In other words, $f \colon [0, 1] \to T \setminus A'$ is a loop in $x_0 = [(x, \gamma)]$. We need to show that $[f] \in 2 \cdot \mathbb{Z}$. By Proposition 48.11 we know that there exists a unique lift $\widetilde{f} \colon [0, 1] \to (D \times S^1) \setminus A$ with $\widetilde{f}(0) = (x, \gamma)$. We consider the following diagram:

We make the following observations:



(1) By definition of a lift we know that $\widetilde{f}(1)$ lies in the subset

$$p^{-1}(f(1)) = p^{-1}(f(0)) = p^{-1}(x_0) = \{(x, \gamma), (x, i \cdot \gamma), (x, -\gamma), (x, -i \cdot \gamma)\}.$$

(2) By Lemma 125.4 (2) and (∗) we know that $\phi(x, \gamma) = \phi(x, -\gamma) > 0$ and we know that $\phi(x, i \cdot \gamma) = \phi(x, -i \cdot \gamma) < 0$.
(3) Recall that by definition $A' = p(A)$. Therefore it follows from Lemma 125.4 (3) that $A = p^{-1}(A')$. In particular we have $(D \times S^1) \setminus A = p^{-1}(T \setminus A')$.
(4) It follows from (3) and the above diagram that the image of $\phi \circ \widetilde{f} \colon [0, 1] \to \mathbb{R}$ is contained in $\mathbb{R} \setminus \{0\}$.

[1519] In the following we do not care about the precise isomorphism, in particular we do not care about any sign ambiguity.

(5) Since $[0,1]$ is connected and since $\phi(\widetilde{f}(0)) = \phi(x,\gamma) > 0$ we obtain from (4) that $\phi(\widetilde{f}(1)) > 0$.
(6) It follows from (1), (2) and (5) that $\widetilde{f}(1) = (x,\gamma)$ or $\widetilde{f}(1) = (x,-\gamma)$.
(7) It follows easily[1520] from (6) that the loop $f * f$ lifts to a loop in $(D \times S^1, (x,\gamma))$.
(8) It follows from (7) and Lemma 48.15 (1) that $2 \cdot [f] = [f] \cdot [f] = [f * f]$ actually lies in the subgroup $p_*(\pi_1(D \times S^1, (x,\gamma)))$.
(9) Since $p\colon D \times S^1 \to T$ is a 4-fold connected covering we obtain from Lemma 48.15 (3) that $p_*(\pi_1(D \times S^1, (x,\gamma))) = 4 \cdot \mathbb{Z}$.
(10) The combination of (8) and (9) shows that $[f]$ lies in $2 \cdot \mathbb{Z}$. ■

The next convention is basically self-explanatory.

Convention. Any map denoted by i is given by an inclusion of the corresponding (pairs) of topological spaces.

The following lemma consists mostly of repackaging the result of Lemma 125.8.

Lemma 125.9. We continue with the above notation. Suppose that we are given a compact submanifold with corner $L \subset T$ such that $A' \subset \mathring{L} := L \setminus \partial_0 L$.[1521] The map

$$i_*\colon \mathrm{H}_2(L, L \cap \partial T; \mathbb{Z}_2) \to \mathrm{H}_2(T, \partial T; \mathbb{Z}_2)$$

is an epimorphism.

Proof. Let $L \subset T$ be a compact submanifold with corner such that $A' \subset \mathring{L} := L \setminus \partial_0 L$. If $L = T$ then there is nothing to show. So we assume that $L \neq T$. This implies in particular that $T \setminus \mathring{L} \neq \varnothing$.

We start out with the following claim which is basically a rewriting of Lemma 125.8.

Claim. For any homomorphism $\varphi\colon \mathrm{H}_1(T;\mathbb{Z}) \to \mathbb{Z}_2$ the composition

$$\mathrm{H}_1(T \setminus \mathring{L}; \mathbb{Z}) \xrightarrow{i_*} \mathrm{H}_1(T;\mathbb{Z}) \xrightarrow{\varphi} \mathbb{Z}_2$$

is the zero map.

[1520] How does this work?
[1521] Here we use the notation for submanifolds with corner that we introduced in Lemma 120.1.

Proof. It suffices to show the analogous statement for any path-component Y of $T \setminus \mathring{L}$. So let Y be a path-component of $T \setminus \mathring{L}$. We pick a point $x_0 \in Y$. We consider the following commutative diagram

$$\begin{array}{ccccccccc}
\pi_1(Y, x_0) & \longrightarrow & \pi_1(T \setminus \mathring{L}, x_0) & \longrightarrow & \pi_1(T \setminus A', x_0) & \overset{=0 \text{ by } (4)}{\longrightarrow} & \pi_1(T, x_0) & \overset{\eta}{\twoheadrightarrow} & \mathbb{Z}_2 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \cong & & \\
\mathrm{H}_1(Y; \mathbb{Z}) & \longrightarrow & \mathrm{H}_1(T \setminus \mathring{L}; \mathbb{Z}) & \longrightarrow & \mathrm{H}_1(T \setminus A'; \mathbb{Z}) & \longrightarrow & \mathrm{H}_1(T; \mathbb{Z}). & &
\end{array}$$

We make the following clarifications and observations:

(1) The map $\eta\colon \pi_1(T, x_0) \to \mathbb{Z}_2$ is the unique epimorphism.
(2) All the vertical maps are given by the corresponding Hurewicz homomorphism. The diagram commutes by the naturality of the Hurewicz homomorphisms.
(3) The Hurewicz homomorphism to the left is an epimorphism by the Hurewicz Theorem 84.5 since Y is path-connected. The Hurewicz homomorphism to the right is an isomorphism by the Hurewicz Theorem 84.5 since T is path-connected and since $\pi_1(T, x_0) \cong \mathbb{Z}$ is abelian.
(4) It follows from Lemma 125.8 that the map $\pi_1(T \setminus A', x_0) \to \pi_1(T, x_0) \xrightarrow{\eta} \mathbb{Z}_2$ is the trivial map.
(5) The claim follows immediately from combining (1) to (4). ⊞

Now we turn to the actual proof of the desired statement. We write $W := T \setminus \mathring{L}$. We consider the following diagram

$$\begin{array}{ccccccc}
\mathrm{Hom}(\mathrm{H}_1(W; \mathbb{Z}), \mathbb{Z}_2) & \overset{\text{ev}}{\underset{\cong}{\leftarrow}} & \mathrm{H}^1(W; \mathbb{Z}_2) & \overset{\cap[W]}{\underset{\cong}{\longrightarrow}} & \mathrm{H}_2(W, \partial W; \mathbb{Z}_2) & \overset{i_*}{\underset{\cong}{\longrightarrow}} & \mathrm{H}_2(T, \partial T \cup L; \mathbb{Z}_2) \\
\uparrow{\scriptstyle i^*} & & \uparrow{\scriptstyle i^*} & & & & \uparrow{\scriptstyle i_*} \\
\mathrm{Hom}(\mathrm{H}_1(T; \mathbb{Z}), \mathbb{Z}_2) & \overset{\text{ev}}{\underset{\cong}{\leftarrow}} & \mathrm{H}^1(T; \mathbb{Z}_2) & & \overset{\cap[T]}{\underset{\cong}{\longrightarrow}} & & \mathrm{H}_2(T, \partial T; \mathbb{Z}_2) \\
 & & & \nearrow{\scriptstyle i_*} & & & \uparrow{\scriptstyle i_*} \\
 & & & & \mathrm{H}_2(L, L \cap \partial T; \mathbb{Z}_2) & \overset{i_*}{\underset{\cong}{\longrightarrow}} & \mathrm{H}_2(\partial T \cup L, \partial T; \mathbb{Z}_2).
\end{array}$$

We make the following comments and clarifications:

(1) The vertical maps are induced by the various inclusions.
(2) The square to the left commutes by the naturality of the evaluation homomorphism. Furthermore, the horizontal maps to the left are isomorphisms by the First Cohomology Proposition 110.17.
(3) By Lemma 120.1 we know that W is a compact 3-dimensional smooth manifold. We equip it with the orientation coming from T.
(4) The horizontal maps "$\cap[W]$" and "$\cap[T]$" in the center are given by capping with the fundamental classes $[W]$ and $[T]$. These maps are isomorphisms by the Poincaré Duality Theorem 119.1.
(5) The horizontal map to the top right is an isomorphism by the Excision Theorem 120.2 (b).

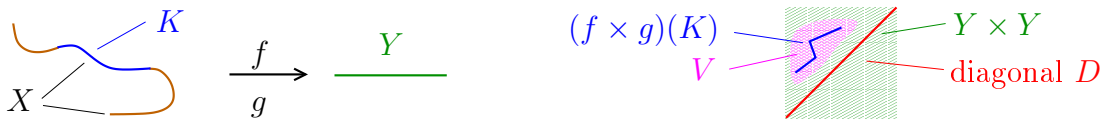
(6) The vertical maps to the right are a piece of the long exact sequence of the triple $(T, \partial T \cup L, \partial T)$, see the Topological LES-Proposition 74.13.
(7) The rectangle to the right commutes by Lemma 120.6, see in particular the example (a) on page 2653.
(8) By the above claim we know that the vertical map to the left is zero. Since all horizontal maps are isomorphisms and since the upper part of the diagram commutes we see that the vertical map to the top right is also the zero map.
(9) It follows from (6) and (8) that the vertical map to the bottom right is an epimorphism.
(10) The bottom triangle commutes since all maps are inclusion induced maps.
(11) The horizontal map at the very bottom is an isomorphism by the Excision Theorem 120.2 (c).
(12) Finally we note that it follows immediately from (9), (10) and (11) that the diagonal map $i_*\colon \mathrm{H}_2(L, L \cap \partial T; \mathbb{Z}_2) \to \mathrm{H}_2(T, \partial T; \mathbb{Z}_2)$ is an epimorphism. Fortunately that is precisely what we wanted to show. ■

Lemma 125.10. Let X be a topological space and let $f, g\colon X \to S^1$ be maps. If for every $x \in X$ we have $f(x) \neq -g(x) \in S^1$, then f and g are homotopic.

Sketch of proof. We consider the map

$$\begin{array}{ccccc} X & \xrightarrow{f \times g} & S^1 \times S^1 & \to & S^1 \\ & & (z, w) & \mapsto & z \cdot w. \end{array}$$

It follows from our hypothesis that this map takes values in $S^1 \setminus \{-1\} \cong (-\pi, \pi)$. Since $(-\pi, \pi)$ admits a deformation retraction to 0 one can now easily show that f and g are homotopic. We are fully confident that the reader did not fail to fill in all details when solving Exercise 14.3. ■



Lemma 125.11. Let $f, g\colon X \to Y$ be two maps between topological spaces. Suppose that there exists a compact subset $K \subset X$ such that $f(x) \neq g(x)$ for all $x \in K$. If Y is Hausdorff, then there exists an open neighborhood U of K such that $f(x) \neq g(x)$ for all $x \in U$.

Proof. We consider the map

$$\begin{array}{rccc} f \times g\colon X & \to & Y \times Y \\ x & \mapsto & (f(x), g(x)). \end{array}$$

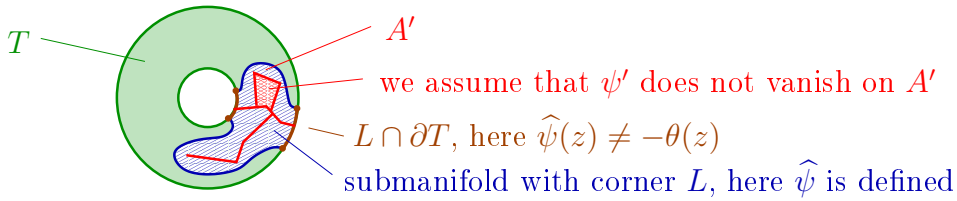
By the Topological-Product Proposition 5.1 (1b) we know that $f \times g$ is continuous. Since K is compact we obtain from the Compact Image Lemma 2.13 (1) that $(f \times g)(K)$ is a compact subset of $Y \times Y$. Let $D := \{(y, y) \mid y \in Y\}$ be the "diagonal" in $Y \times Y$. Since Y is Hausdorff we obtain from Exercise 5.23 that D is a closed subset of $Y \times Y$. Now, using our hypothesis that Y is Hausdorff we obtain from Exercise 1.31 (which is a variation on the Compact Hausdorff Spaces-Normal Lemma 1.16) an open neighborhood V of $(f \times g)(K)$ with $V \cap D = \varnothing$. We set $U := (f \times g)^{-1}(V)$. Since $f \times g$ is continuous we see that U is an open neighborhood of K. Evidently for any $x \in U$ we have $(f \times g)(x) \notin D$, i.e. we have $f(x) \neq g(x)$. ■

Now we head towards the denouement.

Proof of the Table Theorem 125.2. First recall that by Observation 125.7 it suffices to show that $A' \cap B' \neq \varnothing$. We do a proof by contradiction. So we make the following assumption:

(∗) We assume that $A' \cap B' = \varnothing$.

In other words, we assume that ψ' never vanishes on A'. Throughout the proof the following two maps will play a major role:



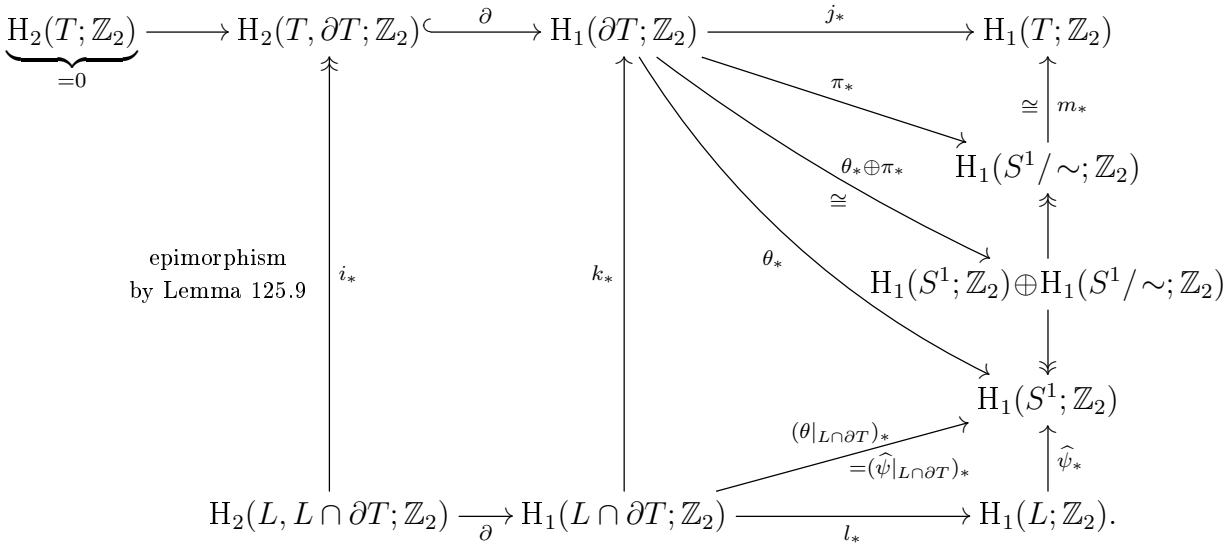
$$\widehat{\psi}\colon \{z \in T \,|\, \psi'(z) \neq 0\} \to S^1, \quad z \mapsto \tfrac{1}{\|\psi'(z)\|}\cdot\psi'(z) \qquad \text{and} \qquad \theta\colon \partial T = \partial D \times (S^1/\!\sim) \to \partial D \to S^1, \quad z \mapsto \tfrac{1}{\|z\|}\cdot z.$$

Note that A' has the following two properties:

(α) ψ' is non-zero on A' (in particular $\widehat{\psi}$ is defined on A'), and
(β) By Lemma 125.5 (3) we know that for any $z \in A' \cap \partial T$ we have $\widehat{\psi}(z) \neq -\theta(z)$.

The following claim says that we can enlarge A' to a submanifold with corner which still has properties (α) and (β). More precisely, we have the following claim.

Claim. The smooth manifold T admits a compact submanifold with corner L with the following properties:
(i) $A' \subset \mathring{L}$,
(ii) ψ' is non-zero on L (in particular $\widehat{\psi}$ is defined on L), and
(iii) for any $z \in L \cap \partial T$ we have $\widehat{\psi}(z) \neq -\theta(z)$.



Proof. Recall that T is a solid torus, in particular T is compact. Since A is a closed subset of $D \times S^1$ we obtain from the Compact-Closed Lemma 1.21 (1) and the Compact Image Lemma 2.13 that $A' = p(A)$ is compact.

(1) It follows from (α), the fact that A' is compact and Lemma 125.11 that there exists an open neighborhood U of A' such that ψ' vanishes nowhere on U.
(2) It follows from (β), Exercise 1.22 (which is an immediate consequence of the Compact-Closed Lemma 1.21 (1)) and Lemma 125.11 that there exists an open neighborhood V of $A' \cap \partial T$ such that $\widehat{\psi}(z) \neq -\theta(z)$ for all $z \in V$.

It follows from Lemma **??** (2) that there exists a submanifold L with corner of T such that $A' \subset \mathring{L} \subset L \subset U$ and such that $L \cap \partial T \subset V$. In particular we see that ψ' is non-zero on L and that for any $z \in L \cap \partial T$ we have $\widehat{\psi}(z) \neq -\theta(z)$. ⊞

We consider the following diagram:

We make the following comments, clarifications and observations:

(1) The horizontal maps at the top respectively the bottom are extracts of the long exact sequence in homology of the pair $(T,\partial T)$ respectively of the pair $(L,L\cap\partial T)$.

(2) The maps i,j,k,l indicate the obvious inclusion maps.

(3) We denote by $m\colon S^1/\!\sim \xrightarrow{\cong} \{0\}\times S^1/\!\sim \to D\times(S^1/\!\sim) = T$ the obvious map. Since D is convex we see that m is a homotopy equivalence, hence we obtain from the Homotopy Equivalence-H_*-Corollary 73.9 that m_* is an isomorphism.

(4) The map $\pi\colon \partial T = \partial D\times(S^1/\!\sim)\to S^1/\!\sim$ is the natural projection. It is elementary to show that the maps $m\circ\pi$ and j from ∂T to T are homotopic. Thus we obtain from the Homotopic Maps-and-Homology Proposition 73.6 that they induce the same map on homology. In other words, the triangle to the top right commutes.

(5) It follows from the naturality of the connecting homomorphism, see the Topological LES-Proposition 74.13, that the rectangle to the left commutes. All the remaining triangles to the right commute basically by definition or by the functoriality of homology groups.

(6) By the discussion on page 159 the map $\theta\colon \partial D\to S^1$ is a homeomorphism. It follows easily from this observation, together with the fact that $\partial T = \partial D\times(S^1/\!\sim)$, that the map $\theta_*\oplus\pi_*\colon \mathrm{H}_1(\partial T;\mathbb{Z}_2)\to \mathrm{H}_1(S^1;\mathbb{Z}_2)\oplus\mathrm{H}_1(S^1/\!\sim;\mathbb{Z}_2)$ is an isomorphism.

(7) It follows from (ii) and Lemma 125.10 that the restrictions of $\widehat{\psi}$ and θ to $L\cap\partial T$ are homotopic. We deduce from the Homotopic Maps-and-Homology Proposition 73.6 that the induced maps on homology are the same. Put differently, the two maps indicated at the upward-pointing diagonal arrow are actually the same.

(8) By Lemma 125.9 the left vertical map is an epimorphism. Since $\mathrm{H}_2(T,\partial T;\mathbb{Z}_2)\neq 0$ there exists a $\xi\in\mathrm{H}_1(L,L\cap\partial T;\mathbb{Z}_2)$ with $i_*(\xi)\neq 0$.

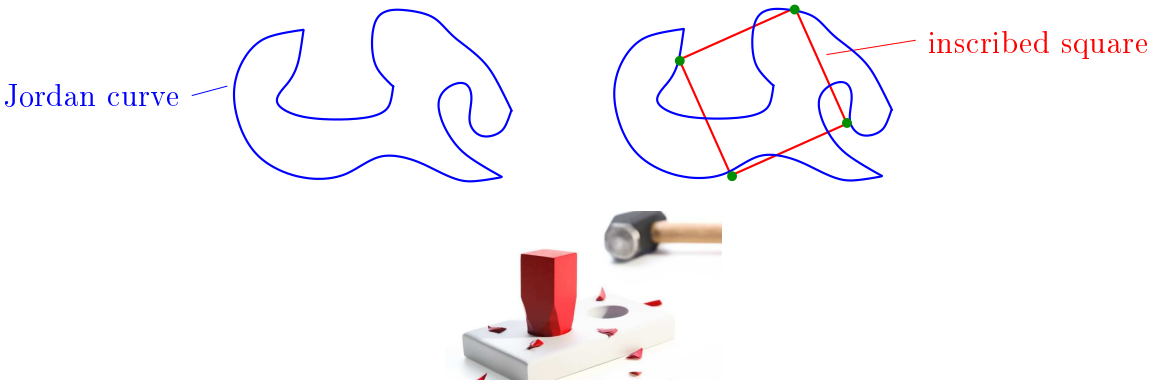
(9) It follows from the long exact sequence on top that $\partial i_*(\xi)\neq 0$ and that $j_*\partial i_*(\xi)=0$.

(10) It follows from (3), (4) and (9) that $\pi_*\partial i_*(\xi)=0$.

(11) By (6) we know that the map $\theta_*\oplus\pi_*$ is an isomorphism. Therefore we obtain from (8) and (10) that $\theta_*\partial i_*(\xi)\neq 0\in\mathrm{H}_1(S^1;\mathbb{Z}_2)$.

(12) Since the diagram commutes we obtain from (11) that $l_*\partial\xi \neq 0$ in $\mathrm{H}_1(L;\mathbb{Z}_2)$. But that is absurd, since the horizontal sequence at the bottom is exact. ■

125.2. **The square-peg problem ❀.** In this section we will give another amusing, but unfortunately even less practical application of cohomology theory. To introduce the topic we need the following definition.



Definition.

(1) The image of an injective map $S^1 \to \mathbb{R}^2$ is calleda Jordan curve.[1522]
(2) Given a Jordan curve C we say that a rectangle R is inscribed in C if all vertices of R lie on C.

The following question was asked by Otto Toeplitz [**Toep1911**] in 1911.[1523]

Question 125.12. Does every Jordan curve admit an inscribed square?

This question is known as the "inscribed square problem" or the "square-peg problem". Lev Schnirelmann [**Schni1944**][1524] gave a positive answer if the curve is smooth, in fact he gave a proof if the curve is C^2, i.e. if the map $S^1 \to \mathbb{R}^2$ is twice continuously differentiable. But the general case is still open.[1525] A detailed discussion of the question and its history is given in [**Matsc2014**].

In this section we will provide two partial answers to Question 125.12.

(1) We will use the Table Theorem 125.2 to deal with the case that the Jordan curve is the boundary of a compact convex obtuse subset of $\mathbb{R}^2$.
(2) We will show that we can inscribe a rectangle into every Jordan curve.

Let us start with the first result.

Proposition 125.13. Let J be a Jordan curve which is the boundary of a compact convex subset D. If D is obtuse, then J admits an inscribed square.

[1522]Note that this definition is slightly different from the definition we gave on page 795 where we defined a Jordan curve to be an injective map $S^1 \to \overline{\mathbb{C}} = S^2$.

[1523]Otto Toeplitz (1881-1940) was a Jewish German mathematician who was forced to emigrate in 1939. He is mainly known for his contributions to analysis.

[1524]We had already encountered Lev Schnirelmann in Theorem 40.1.

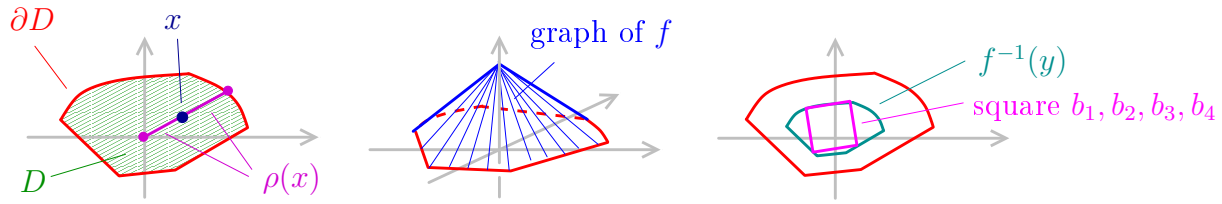
[1525]Recently the Fields medalist Terence Tao [**Tao2017**] wrote a long paper in which he outlined an approach to the square-peg problem. See also the following video:

https://www.youtube.com/watch?v=RGxnWgy5i80

Remark. This proposition also admits proofs that do not rely on topology, see for example **[Zi1921, Chr1950]**.

Proof. Let $D \subset \mathbb{R}^2$ be a compact convex obtuse subset. We need to show that there exist four points $a_1, a_2, a_3, a_4 \in \partial D$ which form a square. After a translation we can assume that the origin 0 is contained in the interior of D. Given $x \in D \setminus \{0\}$ we set

$$\rho(x) \;:=\; \sup\big\{\|rx\| \,\big|\, r \in \mathbb{R}_{>0} \text{ and } r \cdot x \in D\big\} \;\in \mathbb{R}_{>0}.$$



It follows almost immediately from Lemma 2.21[1526] that the map

$$\begin{array}{rcl} f\colon \mathbb{R}^2 & \to & [0,1] \\ x & \mapsto & \begin{cases} 1 - \|x\| \cdot \frac{1}{\rho(x)}, & \text{if } x \in D \setminus \{0\}, \\ 1, & \text{if } x = 0, \\ 0, & \text{if } x \notin D \end{cases} \end{array}$$

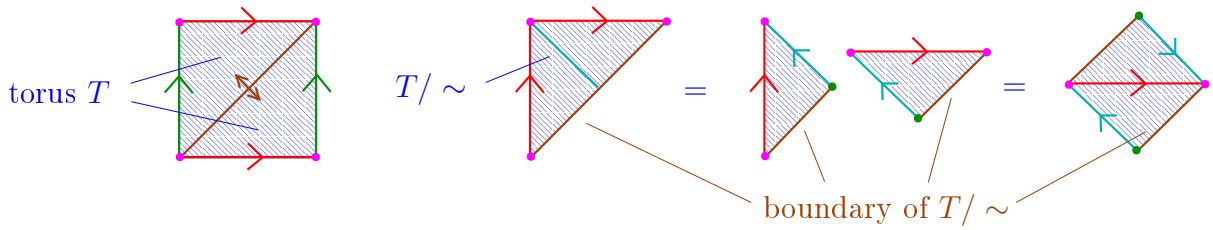
is continuous. Since D is obtuse we obtain from Lemma **??** that there exists a $d > 0$ such that D is d-non trivial. By the Table Theorem 125.2 there exist four points $b_1, b_2, b_3, b_4 \in \mathbb{R}^2$ with the following properties:

(1) the points form a square of side length d,
(2) the center of the square lies in D,
(3) we have $f(b_1) = f(b_2) = f(b_3) = f(b_4)$.

Since D is d-non trivial we see that at least one vertex lies inside of $\mathring{D}$. But since f is non-zero on $\mathring{D}$ we see that the common f-value, let's call it y, lies in the open interval $(0,1)$. It follows immediately from the definition of f that the four points b_1, b_2, b_3, b_4 lie on the subset $(1-y) \cdot \partial D$. In other words, if we multiply these four points by $\frac{1}{1-y}$, then we obtain the desired four points a_1, a_2, a_3, a_4 on ∂D. ∎

We conclude this chapter with the second contribution to the square-peg problem.

Proposition 125.14. Every Jordan curve admits an inscribed rectangle.



In **[Meye1982]** the subsequent ingenious proof of Proposition 125.14 is attributed to Herbert Vaughan. In preparation for the proof we need the following elementary lemma.

Lemma 125.15. Let $T = S^1 \times S^1$ be the torus. Let $\sim$ be the equivalence relation on T generated by $(z,w) \sim (w,z)$. The quotient space $T/\!\sim$ is homeomorphic to the Möbius band and

$$\partial(T/\!\sim) \;=\; \{[(z,z)] \,|\, z \in S^1\}.$$

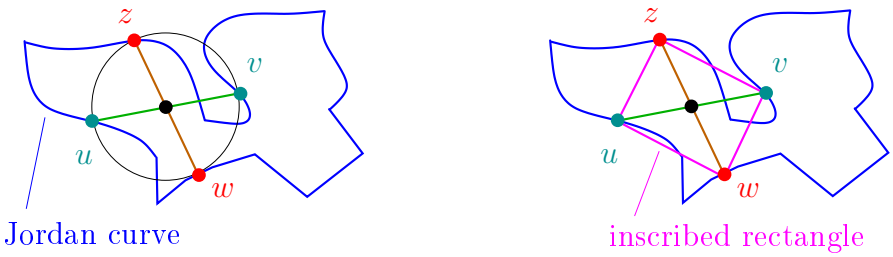
Proof. The homeomorphism is illustrated in the figure below. ∎

[1526] Well-trained eyes will not fail to spot that implicitly we also make use of the Interior-Closure Lemmas 1.9, the Pasting Proposition 2.6 and the Compact-Closed Lemma 1.21 to show that f is indeed continuous.

Now we are already ready to prove Proposition 125.14.

Proof of Proposition 125.14. Let $\gamma\colon S^1 \to \mathbb{R}^2$ be an injective map. We have to show that $\gamma(S^1)$ admits an inscribed rectangle. We consider the map

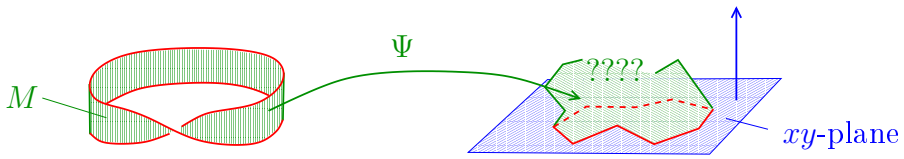
$$\begin{array}{rcl} \Phi\colon T := S^1 \times S^1 & \to & \mathbb{R}^2 \times \mathbb{R}_{\geq 0} \\ (z,w) & \mapsto & \Big(\frac{\gamma(z)+\gamma(w)}{2}, |\gamma(z)-\gamma(w)|\Big). \end{array}$$



Since for all $z, w \in S^1$ we have $\Phi(z,w) = \Phi(w,z)$ we see that Φ descends to a map

$$\begin{array}{rcl} \Psi\colon T/\sim & \to & \mathbb{R}^3 \end{array}$$

where $\sim$ denotes of course the equivalence relation generated by $(z,w) \sim (w,z)$.



Claim. The map $\Psi\colon T/\sim \to \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$ is not injective.

We first show that the claim implies the proposition. So now that we know that Ψ is not injective we know that there exist distinct pairs of points $\{z,w\}$ and $\{u,v\}$ with $\Phi(z,w) = \Phi(u,v)$. We consider the quadrilateral given by the points z,u,v,w. It follows from $\Phi(z,w) = \Phi(u,v)$ that the diagonals bisect each other and that the diagonals have the same length. But such a quadrilateral is necessarily a rectangle.[1527] We refer to the figure below for an illustration.

Proof. Let us assume that $\Psi\colon T/\sim \to H := \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$ is injective. By Lemma 125.15 the quotient $M := T/\sim$ is homeomorphic to the Möbius band and the boundary ∂M is given by $\{[(z,z)] \,|\, z \in S^1\}$. We see immediately from the definition of Ψ that for a point $[(z,w)] \in M = T/\sim$ we have $\Psi([(z,w)]) \in \partial H = \mathbb{R} \times \mathbb{R} \times \{0\}$ if and only if $[(z,w)] \in \partial M$. We denote by M_1 and M_2 two copies of M and we denote by $\mathrm{D}M = M_1 \cup_{\partial M_1 = \partial M_2} M_2$ the double of M. It follows from the proof of Lemma **??** (1) that $\mathrm{D}M$ is in fact homeomorphic to the Klein bottle, in particular $\mathrm{D}M$ is a closed, non-orientable 2-dimensional smooth manifold.

[1527] Hmm, why is that?

We denote by $\rho\colon \mathbb{R}^3 \to \mathbb{R}^3$ the reflection in the xy-plane, i.e. ρ is the map that is given by $\rho(x,y,z) = (x,y,-z)$. We consider the map

$$\begin{array}{rcll} \mathrm{D}M = M_1 \cup_{\partial M_1 = \partial M_2} M_2 & \to & \mathbb{R}^3 & \\ P & \mapsto & \Psi(P), & \text{if } P \in M_1, \\ P & \mapsto & \rho(\Psi(P)), & \text{if } P \in M_2. \end{array}$$

that is given by

It follows immediately from the above discussion that this map is well-defined and injective. Furthermore it follows from the Topological-Quotient Proposition 5.15 (1b) that the map is in fact continuous. But now we have constructed an injective map from the Klein bottle to $\mathbb{R}^3$. Since the Klein bottle is compact we obtain from the Compact-Hausdorff Proposition 2.17 that such a map is in fact an embedding. But we had just proved in the Topological Codimension-One Orientability Proposition 124.5 that such an embedding cannot exist. ■

Remark.

(1) The above proof of Proposition 125.14 is also explained in the following video:

`https://www.youtube.com/watch?v=AmgkSdhK4K8`

(2) There are many variations on Question 125.12. For example, given $r \neq 1$ one can ask whether every Jordan curve admits an inscribed rectangle with aspect ratio r. Even for smooth curves this had been an open problem for a long time. The first real progress since the work by Schnirelmann [**Schni1944**] happened in 2018 when Cole Hugelmeyer [**Hug2018**] showed that a deep result in knot theory, due to Josh Batson [**Bats2014**], implies that every smooth Jordan curve admits an inscribed rectangle of aspect ratio $\sqrt{3}$. The key idea of [**Hug2018**] is rather similar to the proof of Proposition 125.14. Even more impressively, an affirmative answer for smooth curves and any aspect ratio was given in 2020 by Josh Greene and Andrew Lobb [**GrL2020**].

Exercises for Chapter 125.

Exercise 125.1. Let $f\colon \mathbb{C} = \mathbb{R}^2 \to \mathbb{R}$ be a function, let $x \in \mathbb{C}$ and let $z \in \mathbb{C} \setminus \{0\}$. Show that there exists a $\theta \in [0, \frac{\pi}{2}]$ such that

$$f(x + e^{\mathrm{i}\theta} \cdot z) \;=\; f(x + e^{\mathrm{i}(\theta+\frac{\pi}{2})} \cdot z) \;=\; f(x + e^{\mathrm{i}(\theta+\pi)} \cdot z) \;=\; f(x + e^{\mathrm{i}(\theta+\frac{3\pi}{2})} \cdot z).$$

Exercise 125.2. Let X be a non-empty compact subset of $\mathbb{R}^2$ of diameter d. Does there exist a $P \in \mathbb{R}^2$ such that $X \subset \overline{B}^2_{\frac{d}{2}}(P)$?

Exercise 125.3. We consider the solid torus $T = \overline{B}^2 \times S^1$. Let $f\colon T \to \mathbb{R}$ be a map such that for any $(x, \gamma) \in T$ we have $f(x, -\gamma) = -f(x, \gamma)$. We write $A := \{(x, \gamma) \in T \mid f(x, \gamma) = 0\}$.

(a) Show that the inclusion induced map $\mathrm{H}_1(T \setminus A; \mathbb{Z}_2) \to \mathrm{H}_1(T; \mathbb{Z}_2)$ is the zero map.

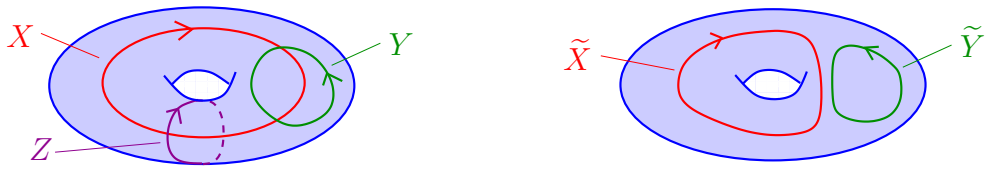
(b) Give an example of a map $f\colon T \to \mathbb{R}$ as above such that the inclusion induced map $\mathrm{H}_1(T \setminus A; \mathbb{Z}) \to \mathrm{H}_1(T; \mathbb{Z})$ is *not* the zero map.

126. The cup product and algebraic intersection numbers

In Chapter 43 we introduced the algebraic intersection number $X \cdot Y$ of two oriented submanifolds X and Y of complementary dimensions of a given oriented smooth manifold M. The main technical result that we proved back then is the Intersection Number Homotopy Invariance Theorem 43.5 which says that the algebraic intersection numbers is unchanged under smooth isotopies of $X \sqcup Y$.

In this chapter we first recall the definition of the algebraic intersection number. In the Intersection Number-via-Cup Product Theorem 126.5 we relate this algebraic intersection number to the cup product of suitable cohomology classes of M. The fact that algebraic intersection numbers correspond to the cup product can be used to compute cup products in a geometric and often entertaining way. Conversely this result can also be used to prove deep statements about intersections of submanifolds. For example we can give a new and very short proof of the Intersection Number Homotopy Invariance Theorem.

This chapter is written in a way such that it can be read independently of Chapter 43. In particular we will motivate some questions and results, even though we might have solved some of the issues already in Chapter 43.



126.1. **Algebraic intersection numbers of submanifolds.** Before we (re-) introduce the algebraic intersection number of submanifolds we want to recall a definition from page 817 and we want to give a motivating question.

Definition. Let M be a smooth manifold.

(1) We say that two oriented proper submanifolds Z_0 and Z_1 of M are properly smoothly isotopic if there exists a proper smooth isotopy between Z_0 and Z_1, i.e. if there exists a proper smooth isotopy $F\colon Z_0 \times [0,1] \to M$ with $F_0 = \mathrm{id}_{Z_0}$ and such that $F_1\colon Z_0 \to Z_1$ is an orientation-preserving diffeomorphism.

(2) Let X and Y be two oriented proper submanifolds of M. We say that X and Y can be made disjoint if there exist oriented proper disjoint submanifolds $\widetilde{X}$ and $\widetilde{Y}$ of M such that X and $\widetilde{X}$ and also Y and $\widetilde{Y}$ are properly smoothly isotopic.

Example. We consider the three submanifolds X, Y and Z of the torus that are illustrated in the figure below on the left. As is shown in the same figure on the right, one can make X and Y disjoint.

It does not look like we can make the submanifolds X and Z disjoint. But how can we prove it? We will record this question for later.

Question 126.1. Can we make the submanifolds X and Z, that are illustrated in the figure above, disjoint?

Our approach to addressing Question 126.1 is to introduce the "algebraic intersection number". Before we can introduce this notion we need to recall the following definition from page 968.

Definition. Let M be an m-dimensional smooth manifold. Let X and Y be proper submanifolds of M.

(1) Let $P \in X \cap Y$. We say P is a transverse intersection point if $P \notin \partial M$ and if X and Y intersect transversally in P, i.e. if the equality $\mathrm{T}_P X + \mathrm{T}_P Y = \mathrm{T}_P M$ holds.
(2) We say that X and Y intersect transversally if each intersection point is a transverse intersection point.

Lemma 126.2. Let M be an m-dimensional smooth manifold, let $X \subset M$ be a proper submanifold of dimension k and let $Y \subset M$ be a proper submanifold of the complementary dimension $m - k$. If X and Y intersect transversally and if X and Y are both compact, then the intersection $X \cap Y$ consists of finitely many points.

Proof. By the Submanifold Transversal Intersection Theorem 42.1 we know that $X \cap Y$ is a 0-dimensional submanifold of M. It follows easily from the definition of a 0-dimensional submanifold that $X \cap Y$ is a discrete subset of M. Since X and Y are compact we know by the Compact-Union-Intersection Lemma 1.20 (2) that $X \cap Y$ is also compact. It now follows from the Compact-Discrete Lemma 1.22 that $X \cap Y$ is finite. ■

Next we recall the following definition from page 989.

Definition. Let $m \in \mathbb{N}$ and let $k \in \{1, \ldots, m-1\}$. Furthermore let M be an m-dimensional oriented smooth manifold, let $X \subset M$ be a compact oriented proper submanifold of dimension k and let $Y \subset M$ be a compact oriented proper submanifold of the complementary dimension $m - k$. Suppose that X and Y intersect transversally.

(1) Let P be an intersection point of X and Y. We set $\operatorname{sign}(P) = 1$, if

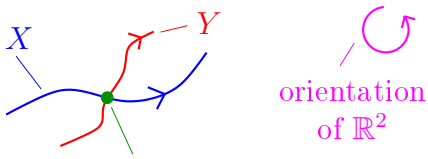
$$(\text{positive basis of } \mathrm{T}_P X, \text{positive basis of } \mathrm{T}_P Y) \;=\; \text{positive basis of } \mathrm{T}_P M.$$

Otherwise we set $\operatorname{sign}(P) = -1$.[1528]
(2) We define[1529]

$$\text{geometric intersection number of } X \text{ and } Y \;:=\; \#(X \cap Y)$$

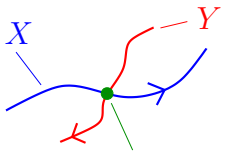
and

$$\text{algebraic intersection number of } X \text{ and } Y \;:=\; X \cdot Y \;:=\; \sum_{P \in X \cap Y} \operatorname{sign}(P) \in \mathbb{Z}.$$



If X and Y do not intersect, then the algebraic intersection number of X and Y is of course zero.

Remark. It follows from Lemma 43.1 that the above definition of the algebraic intersection number of two submanifolds agrees with the definition on page 989.



Examples.

(1) In the figure below we show pieces of oriented submanifolds of the oriented smooth manifold $\mathbb{R}^2$. On the left the sign of the intersection point is positive, on the right it is negative.

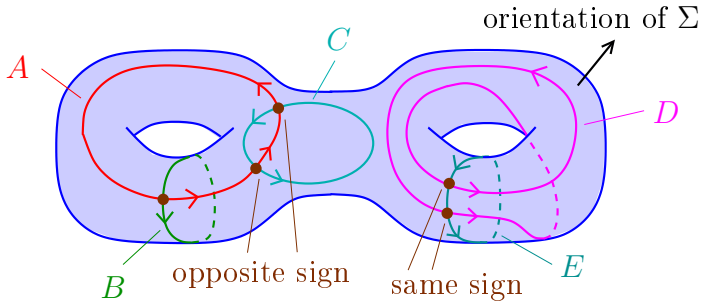
[1528] It is a straightforward exercise in linear algebra to show that the definition of $\operatorname{sign}(P)$ does not depend on the choice of the positive bases of $\mathrm{T}_P X$ and $\mathrm{T}_P Y$.
[1529] It follows from Lemma 126.2 that the geometric intersection number is finite and that the algebraic intersection number is given by a finite sum.

sign of the intersection point of the submanifolds X and Y in $\mathbb{R}^2$ equals $+1$

sign of the intersection point of the submanifolds X and Y in $\mathbb{R}^2$ equals -1

(2) We consider the surface of genus 2 with the orientation where the normal vector "sticks outward". Furthermore we consider the oriented submanifolds A, B, C, D and E that are illustrated in the figure below. For the submanifolds A and B we have

$$\begin{aligned} \text{geometric intersection number of } A \text{ and } B &= 1, \\ \text{the sign of the intersection point is negative, hence} & \\ \text{algebraic intersection number of } A \text{ and } B &= -1. \end{aligned}$$



For the submanifolds A and C we have

$$\begin{aligned} \text{geometric intersection number of } A \text{ and } C &= 2, \\ \text{the intersection points have opposite signs, therefore} & \\ \text{algebraic intersection number of } A \text{ and } C &= 0. \end{aligned}$$

Finally for the submanifolds D and E we have

$$\begin{aligned} \text{geometric intersection number of } D \text{ and } E &= 2, \\ \text{here both intersection points have negative sign, thus} & \\ \text{algebraic intersection number of } D \text{ and } E &= -2. \end{aligned}$$

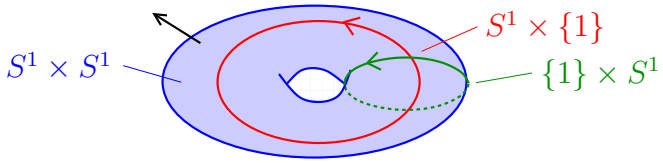
It is particularly instructive to consider the submanifolds A and C. They intersect geometrically in two points, but the signs are opposite. Note that these two intersection points also "vanish" if we "pull A and C apart" by a smooth isotopy.

(3) Now suppose that M and N are oriented smooth manifolds of dimensions m respectively n. We saw in Propositions 19.31 (1) and 20.6 that $M \times N$ is naturally[1530] an $(m+n)$-dimensional smooth manifold (possibly with corner). It is straightforward to show that for each $P \in M \setminus \partial M$ and $Q \in N \setminus \partial N$ the natural map[1531]

$$\mathrm{T}_P M \oplus \mathrm{T}_Q N \;\to\; \mathrm{T}_{(P,Q)}(M \times N)$$

[1530] What does he mean by "naturally"?

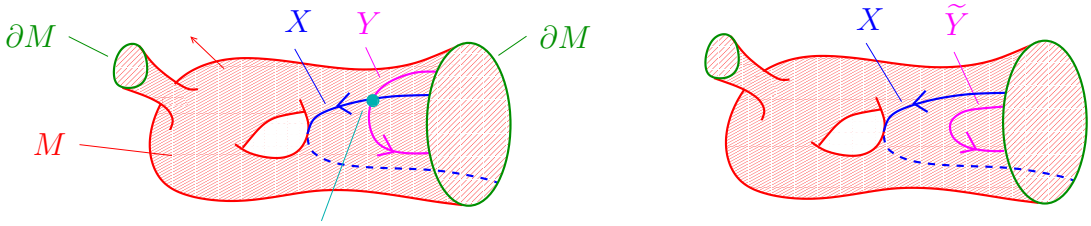
[1531] What is the natural map?



is an isomorphism. If $\{v_1, \ldots, v_m\}$ is a positive basis for $\mathrm{T}_P M$ and $\{w_1, \ldots, w_n\}$ is a positive basis for $\mathrm{T}_Q N$, then we endow $\mathrm{T}_{(P,Q)}(M \times N)$ with the orientation that makes the above isomorphism orientation-preserving.[1532]

Given $P \in M$ and $Q \in N$ it follows easily from the definitions that

$$\text{algebraic intersection number of } M \times \{Q\} \text{ and } \{P\} \times N \;=\; 1.$$



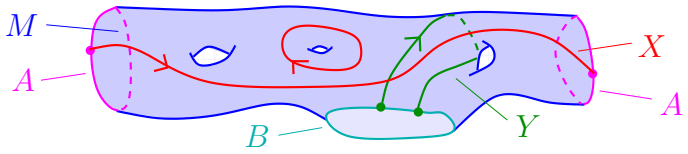
In the figure below we illustrate the statement that in the torus $S^1 \times S^1$ we have

$$\text{algebraic intersection number of } S^1 \times \{*\} \text{ and } \{*\} \times S^1 \;=\; 1.$$

(4) In Section 126.4 we will study the algebraic intersection number of complex submanifolds of a given complex manifold.

(5) The above example (2) suggests that if two submanifolds have non-zero algebraic intersection number, then they cannot be made disjoint. As we will see in the Intersection Number Homotopy Invariance Theorem 126.6, this hunch is basically correct. But if we deal with submanifolds with boundary one needs to think carefully about the correct setting. For example in the figure below we show on the left a smooth manifold M and we show two proper submanifolds X and Y such that the boundaries ∂X and ∂Y lie on the same component of ∂M. The algebraic intersection number is $+1$, but as we see in the figure below on the right, these two submanifolds can be made disjoint. Therefore in the following discussion we will always assume that the boundary components of X and Y lie in different boundary components of M.

the algebraic intersection number of X and Y equals $+1$



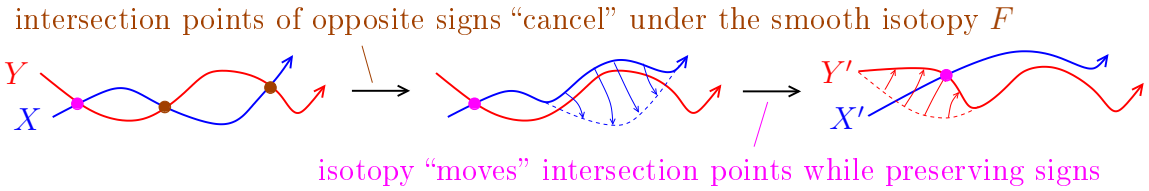
Before we continue, and in light of the last example, we introduce the following definition.

Definition. Let M be an oriented smooth manifold.

(1) A boundary decomposition for M is a decomposition $\partial M = A \cup B$ where A and B are unions of components of ∂M and $A \cap B = \varnothing$.

[1532] One can easily verify that these orientations on the tangent spaces of $M \times N$ define an orientation on $M \times N$. In fact it follows fairly easily from Proposition 113.11 that this definition of the product orientation agrees with the definition we gave on page 2502.

(2) Let X and Y be two submanifolds of M. We say X and Y are complementary if the following five conditions are satisfied:
   (a) X and Y are proper submanifolds,
   (b) there exists a boundary decomposition $\partial M = A \cup B$ with $\partial X \subset A$ and $\partial Y \subset B$,
   (c) both X and Y are oriented,
   (d) we have $\dim(X) + \dim(Y) = \dim(M)$ and we have $\dim(X), \dim(Y) \geq 1$,
   (e) the submanifolds X and Y intersect transversally.



We would be able to answer Question 126.1 if we could prove the following statement.

Statement 126.3. Let M be a compact oriented smooth manifold and let $\{X, Y\}$ and $\{X', Y'\}$ be two pairs of complementary submanifolds of M. Then the following holds:

$$\begin{array}{c} X, X' \text{ are properly smoothly isotopic and} \\ Y, Y' \text{ are properly smoothly isotopic} \end{array} \quad \Longrightarrow \quad X \cdot Y \;=\; X' \cdot Y'.$$

But how can we prove such a statement? In the figure below we sketch an idea: We break the smooth isotopies from X to X' and from Y to Y' into "smaller isotopies" such that each smaller isotopy either does not change the type of intersection points, or two intersection points of opposite sign get created or erased. Even though the idea is fairly convincing, it is very hard to turn this idea into a proper proof.

In the Intersection Number Homotopy Invariance Theorem 43.5 we gave a proof of the above statement, but if one goes through all the results that go into the proof of that theorem one sees that this approach is certainly not elementary.

We will provide a proof of the statement later in this section, once we have explained the relationship between algebraic intersection numbers and the cup product.

We conclude this introduction to algebraic intersection numbers with the following elementary lemma, which is basically the same as Lemma 43.2.

Lemma 126.4. Let M be a compact oriented smooth manifold. If X and Y are complementary submanifolds of M, then

$$Y \cdot X \;=\; (-1)^{\dim(X)\cdot\dim(Y)} \cdot X \cdot Y.$$

Sketch of proof. The statement follows easily from the definitions and the observation that the matrix that represents the linear homeomorphism that swaps the first k vectors with the last $(m-k)$ vectors of a basis of an m-dimensional vector space is represented by

the matrix $\begin{pmatrix} 0 & \mathrm{id}_k \\ \mathrm{id}_{m-k} & 0 \end{pmatrix}$. One easily verifies that the determinant of this matrix equals $(-1)^{k(m-k)}$. ■

126.2. **The cup product and algebraic intersection numbers.** We recall the following notation.

Notation.

(1) Given a compact oriented n-dimensional smooth manifold W we denote as usual by $[W] \in \mathrm{H}_n(W, \partial W)$ the fundamental class that we introduced on page 2199 or alternatively on page 2351. If W is a proper submanifold of some topological manifold M, then sometimes we denote by $[W] \in \mathrm{H}_n(M, \partial M)$ the image of $[W]$ under the inclusion induced map $\mathrm{H}_n(W, \partial W) \to \mathrm{H}_n(M, \partial M)$.

(2) Let M be a compact oriented n-dimensional smooth manifold and suppose that we are given a boundary decomposition $\partial M = A \cup B$. By the Poincaré Duality Theorem 119.1 we know that for each $k \in \mathbb{N}_0$ the map

$$\mathrm{H}^k(M, A) \xrightarrow{\cap [M]} \mathrm{H}_{n-k}(M, B)$$

is an isomorphism. We denote by

$$\mathrm{PD}_M \colon \mathrm{H}_{n-k}(M, B) \longrightarrow \mathrm{H}^k(M, A)$$

its inverse.[1533] If M is understood from the context then often we just write PD instead of PD_M.

The following theorem relates the cup product on a smooth manifold to algebraic intersection numbers. Or conversely, it expresses the algebraic intersection number of submanifolds as a cup product.

Theorem 126.5. (Intersection Number-via-Cup Product Theorem) Let M be a compact oriented m-dimensional smooth manifold together with a boundary decomposition $\partial M = A \cup B$. Let X and Y be a complementary pair of submanifolds of M with $\partial X \subset A$ and $\partial Y \subset B$. We write $k = \dim(X)$ and we denote by $i \colon X \to M$ and $j \colon Y \to M$ the obvious inclusion maps. Furthermore we denote by $[X] \in \mathrm{H}_k(X, \partial X)$ and $[Y] \in \mathrm{H}_{m-k}(Y, \partial Y)$ the fundamental classes of X and Y. Then

$$\underbrace{X \cdot Y}_{\substack{\text{defined} \\ \text{on page 2748}}} = \Big\langle \overbrace{\underbrace{\mathrm{PD}_M(\underbrace{i_*([X])}_{\in \mathrm{H}_k(M,A)})}_{\in \mathrm{H}^{m-k}(M,B)} \cup \underbrace{\mathrm{PD}_M(\underbrace{j_*([Y])}_{\in \mathrm{H}_{m-k}(M,B)})}_{\in \mathrm{H}^k(M,A)}}^{\in \mathrm{H}^m(M,\partial M)}, \overbrace{[M]}^{\in \mathrm{H}_m(M,\partial M)} \Big\rangle \in \mathbb{Z}.$$

In particular with the abbreviation $[X] = i_*([X])$ and $[Y] := j_*([Y])$ we have the slightly more readable equality

$$X \cdot Y = \langle \mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]), [M] \rangle.$$

Remark.

(1) As a reality check, note that a short moment's thought shows that the (anti-) commutativity of the algebraic intersection number of Lemma 126.4 does indeed correspond

[1533] If M is closed this statement is also contained in the Poincaré Duality Theorem 103.5.

precisely to the (anti-) commutativity of the cup product from the Cup Product-Commutativity Proposition 115.3.

(2) The following citation from [**Kir1989**, p. 21] encapsulates the roles of algebraic intersection numbers and cup products:

> "Think with [algebraic] intersection [numbers], prove with cup products."

More precisely, algebraic intersection numbers are very intuitive and often they can be used to guess a statement. But when it comes to proving statements, e.g. why does the intersection number only depend on the smooth isotopy type of a submanifold?, it is usually much easier to work with cup products.

(3) Alternative proofs of the Intersection Number-via-Cup Product Theorem 126.5 are given in [**GrH1981**, Proposition 31.7], [**Bre1993**, Theorem VI.11.9] and [**DaK2001**, Theorem 10.32]. Furthermore a quick outline of a proof is given in [**GoS1999**, Proposition 1.2.5].

(4) One could use the right-hand side of the Intersection Number-via-Cup Product Theorem 126.5 as the definition of the algebraic intersection number. We will discuss this idea in Exercise 126.3.

(5) If we drop the condition that M, X and Y are orientable, then we can still define an algebraic intersection number $X \cdot_{\mathbb{F}_2} Y$ and we can formulate Poincaré Duality with $\mathbb{F}_2$-coefficients. This allows us to formulate a variation on the Intersection Number-via-Cup Product Theorem 126.5. To save the trees we will not spell out the details at this point, instead we refer to the more general Theorem 127.15 for details.

Before we move on to the somewhat lengthy proof of the Intersection Number-via-Cup Product Theorem 126.5 we want to convince ourselves that proving the theorem is worth the effort.

One application of the Intersection Number-via-Cup Product Theorem 126.5 is that now we can provide a proof of a strengthened version of Statement 126.3. More precisely, we have the following theorem, which is basically the same as the earlier Intersection Number Homotopy Invariance Theorem .

Theorem 126.6. (Intersection Number Homotopy Invariance Theorem) Let M be a compact oriented smooth manifold.

(1) Let $\{X, Y\}$ and $\{X', Y'\}$ be pairs of complementary submanifolds of M. If X, X' are properly smoothly isotopic and if Y, Y' are also properly smoothly isotopic, then $X \cdot Y = X' \cdot Y'$.

(2) If X and Y are two complementary submanifolds of M that can be made disjoint, then $X \cdot Y = 0$.

Example. Now we can answer Question 126.1. It follows from the Intersection Number Homotopy Invariance Theorem 126.6 that the submanifolds X and Z, that are illustrated in the figure on page 2747, cannot be made disjoint since their algebraic intersection number is non-zero.

Proof. Let M be a compact oriented smooth manifold. We start out with the following claim.

Claim. Let Z and Z' be oriented proper s-dimensional submanifolds of M. If Z and Z' are properly smoothly isotopic, then $[Z] = [Z'] \in \mathrm{H}_s(M, \partial M)$.

Proof. We denote by $i\colon Z \to M$ and $i'\colon Z' \to M$ the inclusion maps. Since Z and Z' are properly smoothly isotopic there exists in particular an orientation-preserving diffeomorphism $f\colon Z \to Z'$ such that the maps $i, i' \circ f\colon (Z, \partial Z) \to (M, \partial M)$ are homotopic. We obtain that

$$[Z] \;=\; i_*([Z]) \;\underset{\text{Proposition 74.15}}{\uparrow}{=}\; (i' \circ f)_*([Z]) = \; i'_*(f_*([Z])) \;\underset{\substack{\text{by Proposition 107.2 since } f \text{ is an} \\ \text{orientation-preserving homeomorphism}}}{\uparrow}{=}\; i'_*([Z']) \;=\; [Z']$$

⊞

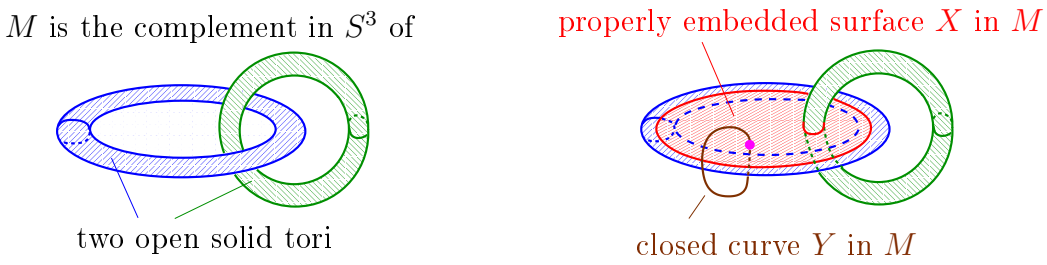
Now let $\{X, Y\}$ and $\{X', Y'\}$ be two pairs of complementary submanifolds of M. We assume that the submanifolds X, X' are properly smoothly isotopic and that the smooth manifolds Y, Y' are smoothly isotopic. We obtain that

$$X \cdot Y \;\underset{\text{Theorem 126.5}}{\uparrow}{=}\; \langle \mathrm{PD}_M([X]), \mathrm{PD}_M([Y]), [M] \rangle \;\underset{\text{by the claim}}{\uparrow}{=}\; \langle \mathrm{PD}_M([X']), \mathrm{PD}_M([Y']), [M] \rangle \;\underset{\text{Theorem 126.5}}{\uparrow}{=}\; X' \cdot Y'.$$

This concludes the proof of the first statement. The second statement is an immediate consequence of the first statement. ■

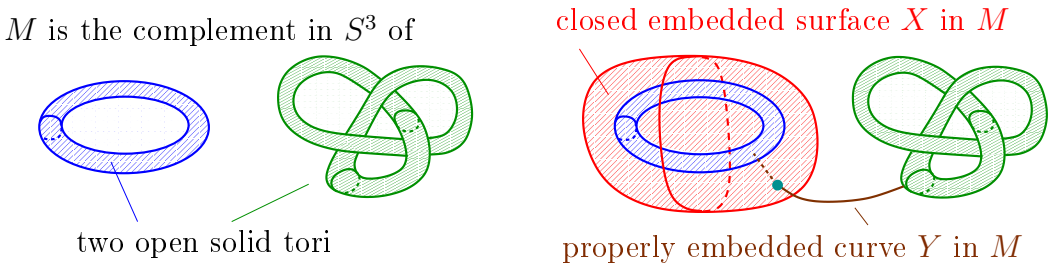
Now we will use the Intersection Number-via-Cup Product Theorem 126.5 "the other way", i.e. we will apply the theorem to use the algebraic intersection number to draw conclusions on (co-) homology classes and to determine cup products using our geometric understanding of submanifolds.

Corollary 126.7. Let M be a compact oriented connected m-dimensional smooth manifold together with a boundary decomposition $\partial M = A \cup B$. Let X be a k-dimensional proper submanifold of M with $\partial X \subset A$. If there exists a proper submanifold Y with $\partial Y \subset B$ such that X and Y form a complementary pair and if $X \cdot Y = \pm 1$, then we can write $\mathrm{H}_k(M, A) = \mathbb{Z} \cdot [X] \oplus K$ for some abelian group K. In particular we see that $[X]$ is a primitive element of $\mathrm{H}_k(M, A)$.



Proof. We consider the homomorphism

$$\begin{aligned} \Theta\colon \mathrm{H}_k(M, A) &\to \mathbb{Z} \\ \varphi &\mapsto \langle \mathrm{PD}_M(\varphi) \cup \mathrm{PD}_M([Y]), [M] \rangle. \end{aligned}$$



It follows from our hypothesis and the Intersection Number-via-Cup Product Theorem 126.5 that $\Theta([X]) = \pm 1$. The corollary now follows from the elementary discussion on page 1718. ■

Examples.

(1) Let M be the complement in S^3 of the two open 3-dimensional tori shown in the figure below on the left. On the right of that figure we show an annulus X that is properly embedded in M. On the right we also see a closed 1-dimensional submanifold Y of M. The two submanifolds X and Y are clearly transverse and they intersect in one point. So with whatever orientation, we have $X \cdot Y = \pm 1$. By Corollary 126.7 this implies in particular that $[X] \in \mathrm{H}_2(M, \partial M)$ is a primitive element.

(2) This time let M be the complement in S^3 of the two open 3-dimensional tori shown in the figure below on the left. Almost the same argument as in (1) shows that the surface X defines a primitive element in $\mathrm{H}_2(M)$.

In the next example we will show how to use the Intersection Number-via-Cup Product Theorem 126.5 to compute cup products.

Example. We consider the torus $T = S^1 \times S^1$ together with the submanifolds $X = S^1 \times \{*\}$ and $Y = \{*\} \times S^1$ which we endow with the usual orientations. By now we have many ways[1534] for showing that $\mathrm{PD}([X])$ and $\mathrm{PD}([Y])$ form a basis for $\mathrm{H}^1(T)$. Thus if we want to understand the cup product on the torus, it suffices to understand the cup products involving these two cohomology classes. We calculate that

$$-\langle \mathrm{PD}([Y]) \cup \mathrm{PD}([X]), [S^1 \times S^1] \rangle \underset{\uparrow}{=} \langle \mathrm{PD}([X]) \cup \mathrm{PD}([Y]), [S^1 \times S^1] \rangle \underset{\uparrow}{=} X \cdot Y \underset{\uparrow}{=} +1.$$

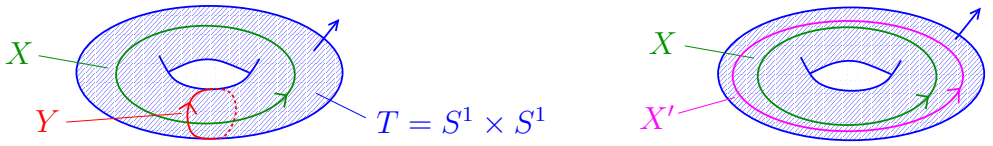
Cup Product-Commutativity Proposition 114.8 — Theorem 126.5 — see the figure on page 2756

Next we want to calculate the "square" $\mathrm{PD}([X]) \cup \mathrm{PD}([X])$. This requires a little trick since evidently X is not transverse to itself. To deal with this issue we consider a "parallel copy" of X, namely we consider $X' = S^1 \times \{z\}$ with $z \neq 1$. We calculate that

$$\langle \mathrm{PD}([X]) \cup \mathrm{PD}([X]), [S^1 \times S^1] \rangle \underset{\uparrow}{=} \langle \mathrm{PD}([X]) \cup \mathrm{PD}([X']), [S^1 \times S^1] \rangle \underset{\uparrow}{=} X \cdot X' \underset{\uparrow}{=} 0.$$

by the claim in the proof of the Intersection Number Homotopy Invariance Theorem 126.6 — by Theorem 126.5, since X and X' are disjoint, in particular transverse

and with the same argument we show that $\langle \mathrm{PD}([Y]) \cup \mathrm{PD}([Y]), [S^1 \times S^1] \rangle = 0$. We will now convince ourselves that these calculations match our previous calculations. To do so we denote by p_1 respectively p_2 the projection $S^1 \times S^1 \to S^1$ onto the first respectively the second factor and we denote by $\theta := \theta_{\mathbb{Z}} \in \mathrm{C}^1; \mathbb{Z})$ the singular 1-cocycle that we introduced



[1534] So, how many ways do you know?

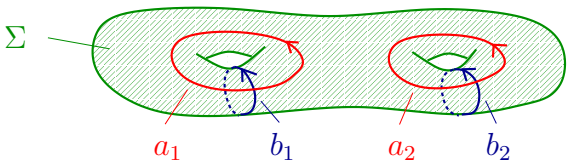
on page 2404. Now we see that

$$\begin{pmatrix} \mathrm{PD}([X])\cup\mathrm{PD}([X]) & \mathrm{PD}([X])\cup\mathrm{PD}([Y]) \\ \mathrm{PD}([Y])\cup\mathrm{PD}([X]) & \mathrm{PD}([Y])\cup\mathrm{PD}([Y]) \end{pmatrix} = \begin{pmatrix} [p_2^*\theta]\cup[p_2^*\theta] & -[p_2^*\theta]\cup[p_1^*\theta] \\ -[p_1^*\theta]\cup[p_2^*\theta] & [p_1^*\theta]\cup[p_1^*\theta] \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

on page 2555 we already showed that $[p_1^*\theta]\cap[T] = [1\times S^1] = [Y]$ and $[p_2^*\theta]\cap[T] = -[S^1\times 1] = -[X]$

see page 2555

Since this was so much fun, let us consider one more example.



Example. Let Σ be the surface of genus two. We consider the following bilinear pairing:[1535]

$$\begin{aligned} Q\colon \mathrm{H}_1(\Sigma)\times\mathrm{H}_1(\Sigma) &\to \mathbb{Z} \\ (\sigma,\tau) &\mapsto \langle \mathrm{PD}_\Sigma(\sigma)\cup\mathrm{PD}_\Sigma(\tau),[\Sigma]\rangle. \end{aligned}$$

Recall that by Proposition 80.10 we know that $\mathrm{H}_1(\Sigma)\cong\mathbb{Z}^4$. Next we consider the closed oriented curves a_1, b_1, a_2, b_2 that are shown in the figure below. It follows easily from the Intersection Number-via-Cup Product Theorem 126.5 that[1536]

$$\begin{pmatrix} Q([a_1],[a_1]) & Q([a_1],[b_1]) & Q([a_1],[a_2]) & Q([a_1],[b_2]) \\ Q([b_1],[a_1]) & Q([b_1],[b_1]) & Q([b_1],[a_2]) & Q([b_1],[b_2]) \\ Q([a_2],[a_1]) & Q([a_2],[b_1]) & Q([a_2],[a_2]) & Q([a_2],[b_2]) \\ Q([b_2],[a_1]) & Q([b_2],[b_1]) & Q([b_2],[a_2]) & Q([b_2],[b_2]) \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}.$$

Note that the determinant of the matrix to the right is one. Since Q is bilinear we obtain from Lemma 109.8 a new proof that $[a_1]$, $[b_1]$, $[a_2]$, $[b_2]$ is a basis for $H_1(\Sigma)$.[1537] By the Poincaré Duality Theorem 119.1 together with the Intersection Number-via-Cup Product Theorem 126.5 we have now also computed the cup product $\mathrm{H}^1(\Sigma;\mathbb{Z})\times\mathrm{H}^1(\Sigma;\mathbb{Z})\to\mathrm{H}^2(\Sigma;\mathbb{Z})$.

We will do one more calculation of the cup product right after the proof of the Intersection Number-via-Cup Product Theorem 126.5.

We conclude this lengthy discussion of the merits of the Intersection Number-via-Cup Product Theorem 126.5 with the following definition that generalizes the concept introduced on page

[1535] Later on, on page 2800 we will refer to this map as the *intersection form of* Σ and we will introduce the intersection form of any closed oriented even-dimensional topological manifold.

[1536] For the diagonal terms we use the "little trick" from the previous example, namely we use a "parallel copy" of the curves a_1, b_1, a_2, b_2.

[1537] We gave a different argument on page 1781.

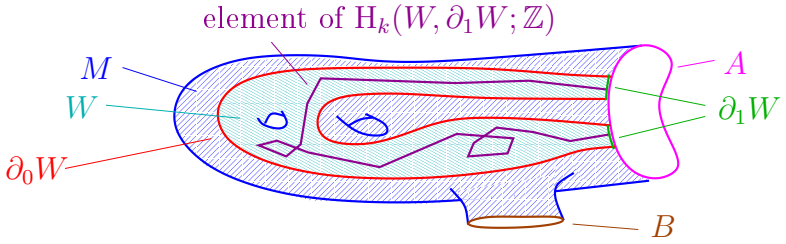
Definition. Let $m \in \mathbb{N}$ and let M be a compact oriented m-dimensional smooth manifold together with a boundary decomposition $\partial M = A \cup B$. Furthermore let $k \in \{1, \dots, m-1\}$, let X be a compact oriented proper k-dimensional submanifold of M with $\partial X \subset A$ and let Y be a compact oriented proper $(m-k)$-dimensional submanifold of M with $\partial Y \subset B$. We denote by $i\colon X \to M$ and $j\colon Y \to M$ the inclusion maps. Then we refer to

$$\Big\langle \overbrace{\mathrm{PD}_M(\underbrace{i_*([X])}_{\in \mathrm{H}_k(M,A)}) \cup \mathrm{PD}_M(\underbrace{j_*([Y])}_{\in \mathrm{H}_{m-k}(M,B)})}^{\in \mathrm{H}^m(M,\partial M)}, \overbrace{[M]}^{\in \mathrm{H}_m(M,\partial M)} \Big\rangle \in \mathbb{Z}$$

$\in \mathrm{H}^{m-k}(M,B)$ $\quad$ $\in \mathrm{H}^k(M,A)$

as the algebraic intersection number of X and Y. By the Intersection Number-via-Cup Product Theorem 126.5 this definition is consistent with the earlier definition on page 2748.

126.3. **Proof of the Intersection Number-via-Cup Product Theorem 126.5.** In this section we will prove the Intersection Number-via-Cup Product Theorem 126.5. Our proof of the Intersection Number-via-Cup Product Theorem 126.5 relies heavily on Lemmas 120.5 and 120.6 that relate Poincaré Duality in an oriented topological manifold M to Poincaré Duality in a compact codimension 0 submanifold W. For the reader's convenience we recall the Codimension-Zero Submanifold-PD Lemma 120.5. This lemma says that given a homology class in W we can apply Poincaré Duality in M or W and essentially we end up with the same result:



Lemma 120.5. (Codimension-Zero Submanifold-PD Lemma) Let M be a compact oriented m-dimensional topological manifold and let W be a compact m-dimensional submanifold with $\partial M \cap \partial W = \varnothing$. We write $\mathring{W} = W \setminus \partial W$. We fix the following notation:

(1) We denote by w the inclusion map $W \to M$ and also the inclusion map of the pairs $(W, \partial W) \to (M, M \setminus \mathring{W})$.

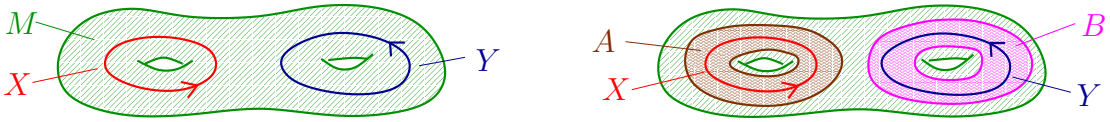
(2) We denote by $p\colon (M, \partial M) \to (M, M \setminus \mathring{W})$ the inclusion map of pairs.

For every $k \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}_k(W;\mathbb{Z}) & \xrightarrow{\mathrm{PD}_W} & \mathrm{H}^{m-k}(W,\partial W;\mathbb{Z}) & \xrightarrow[\cong]{(w^*)^{-1}} & \mathrm{H}^{m-k}(M, M\setminus \mathring{W};\mathbb{Z}) \\ \downarrow{\scriptstyle w_*} & & & & \downarrow{\scriptstyle p^*} \\ \mathrm{H}_k(M;\mathbb{Z}) & & \xrightarrow{\qquad\qquad \mathrm{PD}_M \qquad\qquad} & & \mathrm{H}^{m-k}(M,\partial M;\mathbb{Z}). \end{array}$$

We take a short rest from more technicalities and enjoy the fact that we can already prove the Intersection Number-via-Cup Product Theorem 126.5 in the special case that M is closed and that the submanifolds *do not intersect*.

Proof of Theorem 126.5 for disjoint submanifolds. Let M be a closed oriented m-dimensional smooth manifold and let X and Y be a complementary pair of *disjoint* submanifolds of M. Since the submanifolds are disjoint it suffices to show that the cup product of the Poincaré duals of $[X]$ and $[Y]$ is also zero.



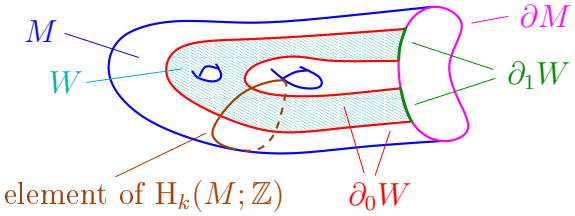
We write $k = \dim(X)$. We apply the General Tubular Neighborhood Theorem **??** to the submanifold $X \cup Y$ of M. We obtain disjoint tubular neighborhoods A for X and B for Y. We denote by $p\colon (M, \varnothing) \to (M, M \setminus \mathring{A})$ and $p\colon (M, \varnothing) \to (M, M \setminus \mathring{B})$ the obvious inclusion maps of pairs of topological spaces.

We apply the Codimension-Zero Submanifold-PD Lemma 120.5 to the codimension-zero submanifold A and the homology class $[X] \in \mathrm{H}_k(A;\mathbb{Z})$. We obtain an $\alpha \in \mathrm{H}^{m-k}(M, M \setminus \mathring{A};\mathbb{Z})$ with $p^*(\alpha) = \mathrm{PD}_M([X])$. Similarly we see that there exists a $\beta \in \mathrm{H}^k(M, M \setminus \mathring{B};\mathbb{Z})$ with $p^*(\beta) = \mathrm{PD}_M([Y])$.

We consider the following diagram

$$\begin{array}{ccc}
\mathrm{H}^{m-k}(M;\mathbb{Z}) \times \mathrm{H}^k(M;\mathbb{Z}) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^m(M;\mathbb{Z}) \\
\uparrow{\scriptstyle p^*\times p^*} \quad \begin{array}{c}(\mathrm{PD}_M([X]), \mathrm{PD}_M([Y])) \\ \updownarrow \\ (\alpha,\beta)\end{array} & & \uparrow \\
\mathrm{H}^{m-k}(M, M\setminus\mathring{A};\mathbb{Z}) \times \mathrm{H}^k(M, M\setminus\mathring{B};\mathbb{Z}) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^m(M, \underbrace{(M\setminus\mathring{A}) \cup (M\setminus\mathring{B})}_{=M};\mathbb{Z}).
\end{array}$$

The diagram commutes by the Cup Product-Naturality Proposition 115.4 (1). It follows from the fact that the lower right group is zero that the cup product of $\mathrm{PD}_M([X])$ and $\mathrm{PD}_M([Y])$ is zero. ∎



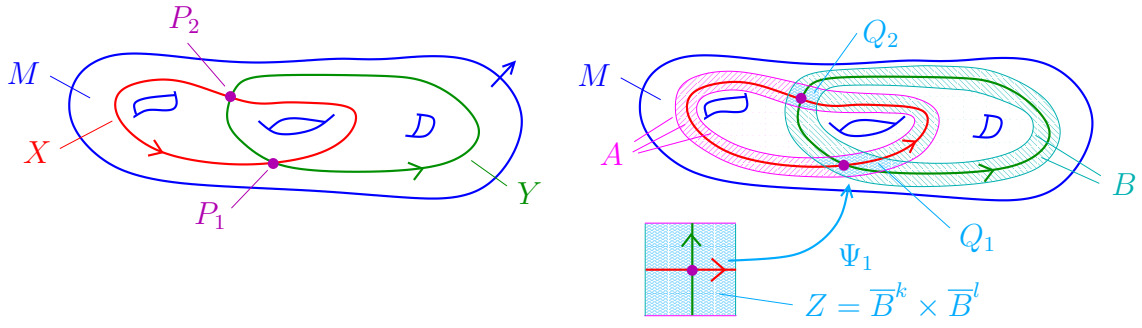
After this refreshing proof of the special case we continue with trying to prove the general case of the Intersection Number-via-Cup Product Theorem 126.5. We will need Lemma 120.6. Since the statement is rather technical, we recall the statement of the special case that is discussed in example (a) on page 2653.

Lemma 120.6. Let M be a compact oriented m-dimensional smooth manifold and let W be a compact m-dimensional submanifold with corner. We fix the following notation:

(1) We write $\partial_1 W = W \cap \partial M$ and $\partial_0 W = \overline{\partial W \setminus \partial_1 W}$,
(2) We write $\mathring{W} = W \setminus \partial_0 W$.
(3) The inclusion maps $(W, \partial_0 W) \to (M, M\setminus\mathring{W})$ and $(W, \partial_1 W) \to (M, \partial M)$ are denoted by w.
(4) Finally we denote by $p\colon (M, \varnothing) \to (M, M \setminus \mathring{W})$ the obvious map.

For every $k \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}_k(M;\mathbb{Z}) & & \xrightarrow{\quad\mathrm{PD}_M\quad} & & \mathrm{H}^{m-k}(M,\partial M;\mathbb{Z}) \\ \downarrow{\scriptstyle p_*} & & & & \downarrow{\scriptstyle w^*} \\ \mathrm{H}_k(M, M\setminus \mathring{W};\mathbb{Z}) & \xrightarrow[\cong]{(w_*)^{-1}} & \mathrm{H}_k(W,\partial_0 W;\mathbb{Z}) & \xrightarrow{\mathrm{PD}_W} & \mathrm{H}^{m-k}(W,\partial_1 W;\mathbb{Z}). \end{array}$$



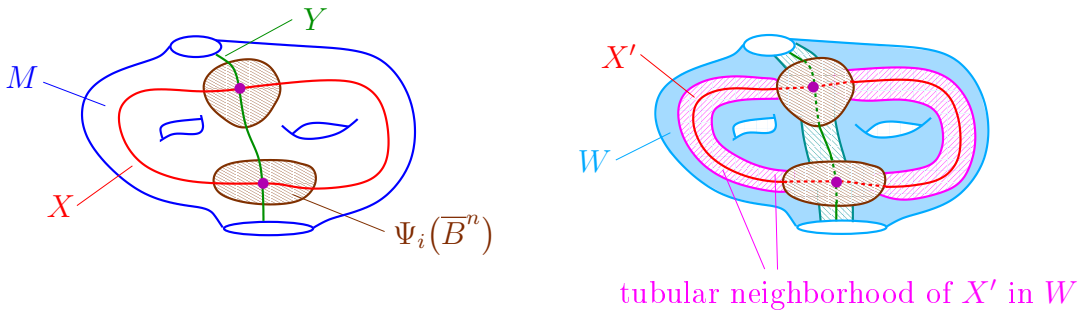
In the proof of the Intersection Number-via-Cup Product Theorem 126.5 we will also need the following proposition.

Proposition 126.8. Let M be a compact oriented smooth manifold and let X and Y be two complementary proper submanifolds of dimensions k and l. We denote by $P_1, \dots, P_s$ the intersection points of X and Y. Then there exist

(1) compact submanifolds with corner A and B such that A is a neighborhood for X and B is a neighborhood for Y, and
(2) injective maps $\Psi_i \colon \overline{B}^k \times \overline{B}^l \to M$, $i = 1, \dots, s$

such that the following statements hold:

(a) For each $i \in \{1, \dots, s\}$ we have $\Psi_i((0,0)) = P_i$.
(b) The images $Q_i := \Psi_i\big(\overline{B}^k \times \overline{B}^l\big)$, $i = 1, \dots, s$ are disjoint.
(c) We have $Q_1 \cup \dots \cup Q_s = A \cap B$.
(d) For each $i \in \{1, \dots, s\}$ the following statements hold:
  (d1) the restriction of Ψ_i to $B^k \times B^l$ is a diffeomorphism onto its image,
  (d2) we have $Q_i \cap X = \Psi_i(\overline{B}^k \times \{0\})$ and the map $\Psi_i \colon \overline{B}^k \times \{0\} \to X$ is an orientation-preserving smooth embedding,
  (d3) we have $Q_i \cap Y = \Psi_i(\{0\} \times \overline{B}^l)$ and the map $\Psi_i \colon \{0\} \times \overline{B}^l \to Y$ is an orientation-preserving smooth embedding.



Sketch of a proof. Let M be a compact oriented n-dimensional smooth manifold and let X and Y be two complementary proper submanifolds of dimensions k and l. We denote

by $P_1, \dots, P_s$ the intersection points of X and Y. For $i = 1, \dots, s$ we can and will pick smooth embeddings $\Psi_i \colon \overline{B}^n \to M \setminus \partial M$ such that the following conditions are satisfies:

(1) the images are disjoint,
(2) for each $i \in \{1, \dots, s\}$ the map Ψ_i restricts to orientation-preserving diffeomorphisms $B^k \times \{0\} \to \Psi_i(B^n) \cap X$ and $\{0\} \times B^l \to \Psi_i(B^n) \cap Y$.

We consider $W := M \setminus \bigcup_{i=1}^{s} \Psi_i(B^n)$. Note that $X' := W \cap X$ and $Y' := W \cap Y$ are proper submanifolds of the compact smooth manifold W. Thus we can apply the General Tubular Neighborhood Theorem **??** to obtain tubular neighborhoods for X' and Y'. Using the Connected Sum-Proposition **??** we can arrange the intersections of the tubular neighborhoods with $\Psi_i(S^{n-1})$ to be "standard $(n-1)$-dimensional balls". At this stage it is fairly straightforward to extend the tubular neighborhoods to the interiors of the $\Psi_i(B^n)$ and to obtain all the desired objects. We have faith in the unwavering enthusiasm of our readers for filling in the details. ■

Remark. An alternative approach to Proposition 126.8 would be to use tubular neighborhoods provided by Lemma **??**.

Given the situation of Proposition 126.8 we can make one more statement.

Lemma 126.9. We use the notation of Proposition 126.8. Let $i \in \{1, \dots, s\}$. We equip the topological manifold Q_i, which is a codimension-zero submanifold of M, with the induced orientation coming from the Topological Manifold-Induced Orientation Lemma 105.17. Furthermore we equip the topological manifold $\overline{B}^k \times \overline{B}^l$ with the orientation coming from the standard orientation of $\mathbb{R}^k \times \mathbb{R}^l = \mathbb{R}^{k+l}$. With these choices the following statement holds:

(f) If we denote by σ_i the sign of the intersection point P_i, then

$$\Psi_{i*}\big([\overline{B}^k \times \overline{B}^l]\big) \;=\; \sigma_i \cdot [Q_i].$$

Proof. Let $i \in \{1, \dots, s\}$. It follows from (d2) and (d3) that at the point $(0,0)$ the diffeomorphism $\Psi_i \colon B^k \times B^l \to \mathring{Q}_i$ is orientation-preserving if and only if $\sigma_i = 1$. Now the statement follows easily from the definition of σ_i, Proposition 107.2 and Lemma 105.12. ■

The last preparation we need before we can provide the actual proof of the Intersection Number-via-Cup Product Theorem 126.5 is the Poincaré Duality-Products Proposition 119.2, which for the reader's convenience we recall using our present notation.

Proposition 119.2. Let X be a compact oriented connected m-dimensional topological manifold and let Y be a compact oriented connected n-dimensional topological manifold. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the natural projections. We equip $X \times Y$ with the product orientation introduced in the Topological Product Orientation Proposition 113.10. Given any points $P \in X$ and $Q \in Y$ we have the following equality in $\mathrm{H}^{m+n}(X \times Y, \partial(X \times Y); \mathbb{Z})$:

$$\mathrm{PD}_{X\times Y}([X \times \{Q\}]) \cup \mathrm{PD}_{X\times Y}([\{P\} \times Y]) \;=\; [X \times Y]^*.$$

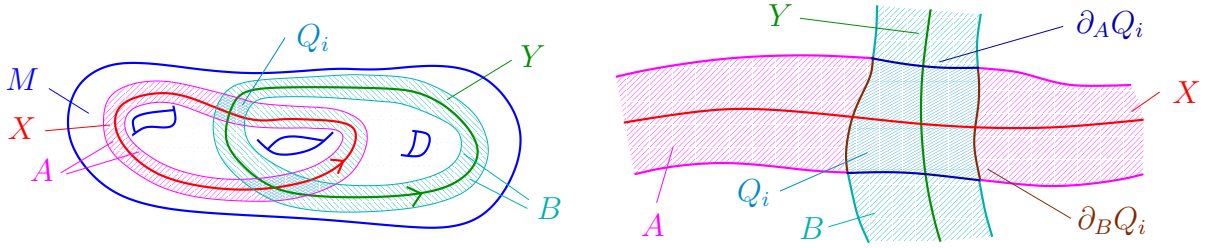
We turn to the actual proof of the Intersection Number-via-Cup Product Theorem 126.5.

Proof of the Intersection Number-via-Cup Product Theorem 126.5. Let M be a compact oriented connected m-dimensional smooth manifold. To simplify the notation we assume that M is closed. The case that M has boundary is proved in a rather similar fashion.[1538]

Let X and Y be a complementary pair of submanifolds of M. We introduce the following notation:

(1) We write $k = \dim(X)$ and $l = \dim(Y)$. Note that $l = m - k$.
(2) As usual we denote by $[X] \in \mathrm{H}_k(X)$ and $[Y] \in \mathrm{H}_l(Y)$ the fundamental classes of X and Y. By a slight abuse of notation we denote by $[X]$ respectively $[Y]$ also the images of these homology classes in any subset of M that contains X respectively Y.
(3) We denote the intersection points of X and Y by $P_1, \ldots, P_s$ and we denote the corresponding signs by $\sigma_1, \ldots, \sigma_s$.
(4) As usual, given a topological space X we denote by $\epsilon_X = \epsilon\colon \mathrm{H}_0(X) \to \mathbb{Z}$ the augmentation map.

With the notation that we just introduced, and keeping in mind the Cap Product-Kronecker Lemma 116.4 (1), the statement of the Intersection Number-via-Cup Product Theorem 126.5 can be reformulated as the following statement.



Statement.
$$\epsilon_M\big((\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y])) \cap [M]\big) \;=\; \sum_{i=1}^{s} \sigma_i.$$

We introduce many more objects, notations and conventions:

(5) We apply Proposition 126.8 to the submanifolds X and Y. In the remainder of the proof we use the notation that we introduced in that proposition. As a reminder, most of the relevant objects are illustrated in the figure on page 2759.
(6) We write $\mathring{A} = A \setminus \partial A$ and $\mathring{B} = B \setminus \partial B$.
(7) We denote all of the inclusion maps $(M, \varnothing) \to (M, M \setminus \mathring{A})$, $(M, \varnothing) \to (M, M \setminus \mathring{B})$ and $(M, \varnothing) \to (M, M \setminus (\mathring{A} \cap \mathring{B}))$ by p.
(8) We write $C = A \cap B = Q_1 \cup \cdots \cup Q_s$. Furthermore we write $\partial_A C = \partial A \cap B$ and $\partial_B C = A \cap \partial B$. Note that $\partial C = \partial_A C \cup \partial_B C$. Also note that $(M \setminus \mathring{A}) \cup (M \setminus \mathring{B}) = M \setminus \mathring{C}$.
(9) We denote by $c\colon C \to M$ the inclusion map and we denote by c also all the corresponding inclusion maps of pairs where the first terms are C and M.

[1538] Admittedly, the case that M has boundary also requires the generalization of the Codimension-Zero Submanifold-PD Lemma 120.5 to the case that W is a codimension-zero submanifold with corner. But that is not really a problem.

(10) Given $i \in \{1, \ldots, s\}$ we write $\partial_A Q_i = \partial_A C \cap Q_i$ and $\partial_B Q_i = \partial_B C \cap Q_i$. Note that $\partial Q_i = \partial_A Q_i \cup \partial_B Q_i$.
(11) Given $i \in \{1, \ldots, s\}$ we denote by $q_i \colon Q_i \to C$ the inclusion map and we denote by q_i also all the corresponding inclusion maps of pairs where the first terms are Q_i and C.
(12) Note that C and each Q_i are codimension-zero submanifolds of M. We equip these submanifolds with the corresponding orientation introduced in the Topological Manifold-Induced Orientation Lemma 105.17.

Now we consider the following diagram:[1539]

$$\begin{array}{ccccccc}
\mathrm{H}^l(M) \times \mathrm{H}^k(M) & \xrightarrow{\cup} & \mathrm{H}^m(M) & \xrightarrow{\cap[M]} & \mathrm{H}_0(M) & \xrightarrow{\epsilon_M} & \mathbb{Z} \\
\uparrow{\scriptstyle p^*\times p^*} & & \uparrow{\scriptstyle p^*} & & \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle =} \\
\mathrm{H}^l(M, M\setminus \mathring{A}) \times \mathrm{H}^k(M, M\setminus \mathring{B}) & \xrightarrow{\cup} & \mathrm{H}^m(M, M\setminus \mathring{C}) & \xrightarrow{\cap p_*([M])} & \mathrm{H}_0(M) & \xrightarrow{\epsilon_M} & \mathbb{Z} \\
\downarrow{\scriptstyle c^*\times c^*} & & \downarrow{\scriptstyle c^*} & & \uparrow{\scriptstyle c_*} & & \uparrow{\scriptstyle =} \\
\mathrm{H}^l(C, \partial_A C) \times \mathrm{H}^k(C, \partial_B C) & \xrightarrow{\cup} & \mathrm{H}^m(C, \partial C) & \xrightarrow{\cap[C]} & \mathrm{H}_0(C) & \xrightarrow{\epsilon_C} & \mathbb{Z} \\
\downarrow{\scriptstyle \bigoplus_{i=1}^s q_i^*\times q_i^*} & & \downarrow{\scriptstyle \bigoplus_{i=1}^s q_i^*} & & \uparrow{\scriptstyle \sum_{i=1}^s q_{i*}} & & \uparrow{\scriptstyle \mathrm{id}} \\
\bigoplus_{i=1}^s \mathrm{H}^l(Q_i, \partial_A Q_i) \times \mathrm{H}^k(Q_i, \partial_B Q_i) & \xrightarrow{\oplus\cup} & \bigoplus_{i=1}^s \mathrm{H}^m(Q_i, \partial Q_i) & \xrightarrow{\bigoplus_{i=1}^s \cap[Q_i]} & \bigoplus_{i=1}^s \mathrm{H}_0(Q_i) & \xrightarrow{\sum \epsilon_{Q_i}} & \mathbb{Z}.
\end{array}$$

Claim 1. The above diagram commutes.

Proof. In the following we deal with all of the nine squares of the diagram.

(a) The left squares in the first and second row commute by the Cup Product-Naturality Proposition 115.4 (1).
(b) The left square in the third row commutes by the Cup-Cap Disjoint Union Lemma 116.9 (1) together with the aforementioned the Cup Product-Naturality Proposition 115.4 (1).
(c) The middle square in the first row commutes by the Cap Product-Naturality Lemma 116.8 (1).
(d) It follows from our orientation conventions and the Codimension Zero-Fundamental Class Lemma 106.24 that $c_*([C]) = p_*([M])$. It follows from the Cap Product-Naturality Lemma 116.8 (1) that the middle square in the second row commutes.

[1539] Many of the vertical maps in the diagram are isomorphisms by excision, see page 2418 for details. But this is in fact irrelevant for our purpose.

(e) It follows from the remark on page 2351 that $\sum_{i=1}^{s} q_{i*}([Q_i]) = [C]$. Now we obtain from the Cap Product-Naturality Lemma 116.8 (1) and the Cup-Cap Disjoint Union Lemma 116.9 (2) that the middle square in the third row commutes.

(f) The squares that involve the augmentation maps commute by the discussion on page 1594. ⊞

We introduce a few last pieces of notation:

(13) We denote by $a\colon (A, \partial A) \to (M, M \setminus \mathring{A})$ and $b\colon (B, \partial B) \to (M, M \setminus \mathring{B})$ the inclusion maps, note that a and b induce isomorphisms on cohomology by excision, see page 2418 for details.

(14) We write

$$\alpha = (a^*)^{-1}(\underbrace{\mathrm{PD}_A([X])}_{\in \mathrm{H}^l(A,\partial A)}) \in \mathrm{H}^l(M, M\setminus\mathring{A}) \text{ and } \beta = (b^*)^{-1}(\underbrace{\mathrm{PD}_B([Y])}_{\in \mathrm{H}^k(B,\partial B)}) \in \mathrm{H}^k(M, M\setminus\mathring{B}).$$

(15) Given $i \in \{1, \ldots, s\}$ we write $X_i = X \cap Q_i$ and $Y_i = Y \cap Q_i$. It follows from Proposition 126.8 (e) and (f) that X_i and Y_i are codimension zero submanifolds of X and Y. Since X and Y are oriented we can view X_i and Y_i also as oriented topological manifolds. As usual we denote by $[X_i] \in \mathrm{H}_k(X_i, \partial X_i)$ and $[Y_i] \in \mathrm{H}_k(Y_i, \partial Y_i)$ the corresponding fundamental classes. With the same convention as before we denote by $[X_i]$ also the image under the inclusion induced map $\mathrm{H}_k(X_i, \partial X_i) \to \mathrm{H}_k(Q_i, \partial_B Q_i)$ and similarly we denote by $[Y_i]$ also the image under the inclusion induced map $\mathrm{H}_l(Y_i, \partial Y_i) \to \mathrm{H}_l(Q_i, \partial_A Q_i)$.

Claim 2. We have

(a) We have $p^*(\alpha) = \mathrm{PD}_M([X]) \in \mathrm{H}^l(M)$ and $p^*(\beta) = \mathrm{PD}_M([Y]) \in \mathrm{H}^k(M)$.

(b) For any $i \in \{1, \ldots, s\}$ we have

$$(q_i^* \circ c^*)(\alpha) = \mathrm{PD}_{Q_i}([X_i]) \in \mathrm{H}^l(Q_i, \partial_A Q_i) \text{ and } (q_i^* \circ c^*)(\beta) = \mathrm{PD}_{Q_i}([Y_i]) \in \mathrm{H}^k(Q_i, \partial_B Q_i).$$

(c) For any $i \in \{1, \ldots, s\}$ we have

$$\epsilon_{Q_i}\big((\,\mathrm{PD}_{Q_i}([X_i]) \cup \mathrm{PD}_{Q_i}([Y_i])) \cap [Q_i]\big) \;=\; \sigma_i.$$

Proof.

(a) By the Codimension-Zero Submanifold-PD Lemma 120.5 the following diagram commutes:

$$\begin{array}{ccccc}
\mathrm{H}_k(A) & & \xrightarrow{\quad [X]\mapsto\alpha \quad} & & \\
\big[\begin{smallmatrix}[X]\\ \downarrow \\ [X]\end{smallmatrix}\big] \Big\downarrow & \xrightarrow[\mathrm{PD}_A]{} & \mathrm{H}^l(A, \partial A) & \xrightarrow[(a^*)^{-1}]{\cong} & \mathrm{H}^l(M, M\setminus\mathring{A}) \Big\downarrow p^* \\
\mathrm{H}_k(M) & & \xrightarrow{\qquad\qquad \mathrm{PD}_M \qquad\qquad} & & \mathrm{H}^l(M).
\end{array}$$

We apply this commutative diagram to $[X] \in \mathrm{H}_k(A)$ and we obtain immediately that $p^*(\alpha) = \mathrm{PD}_M([X])$. The same way one shows that $p^*(\beta) = \mathrm{PD}_M([Y])$.

(b) Let $i \in \{1, \dots, s\}$. We denote by $r_i \colon Q_i \to A$ the inclusion map. We consider the following diagram:

$$\begin{array}{ccccc}
\mathrm{H}_k(A) & & \xrightarrow{\mathrm{PD}_A} & & \mathrm{H}^l(A, \partial A) \xleftarrow[\cong]{a^*} \mathrm{H}^l(M, M \setminus \mathring{A}) \\
\downarrow & & & & \downarrow r_i^* \quad \swarrow (q_i \circ c)^* \\
\mathrm{H}_k(A, A \setminus \mathring{Q}_i) & \xleftarrow[\cong]{r_{i*}} & \mathrm{H}_k(Q_i, \partial_B Q_i) & \xrightarrow{\mathrm{PD}_{Q_i}} & \mathrm{H}^l(Q_i, \partial_A Q_i).
\end{array}$$

We make the following observations:

(α) The triangle on the right commutes since $a \circ r_i = c \circ q_i \colon Q_i \to M$ are both the inclusion map.

(β) It follows from Lemma 120.6, applied to the codimension-zero submanifold Q_i of A, that the rectangle commutes.[1540]

(γ) By the Codimension Zero-Fundamental Class Lemma 106.24 we have $r_{i*}([X_i]) = [X] \in \mathrm{H}_k(A, A \setminus \mathring{Q}_i)$.

(δ) By the Excision Theorem 120.2 the map $r_{i*} \colon \mathrm{H}_k(Q_i, \partial_B Q_i) \to \mathrm{H}_k(A, A \setminus \mathring{Q}_i)$ is an isomorphism.

The desired equality $(q_i^* \circ c^*)(\alpha) = \mathrm{PD}_{Q_i}([X_i])$ follows from the above commutative diagram applied to $[X] \in \mathrm{H}_k(A)$. Exactly the same way we can also show that $(q_i^* \circ c^*)(\beta) = \mathrm{PD}_{Q_i}([Y_i])$.

(c) Let $i \in \{1, \dots, s\}$. We set $Z = \overline{B}^k \times \overline{B}^l$. We consider the following diagram:

$$\begin{array}{ccccccc}
\mathrm{H}^l(Q_i, \partial_A Q_i) \times \mathrm{H}^k(Q_i, \partial_B Q_i) & \xrightarrow{\cup} & \mathrm{H}^m(Q_i, \partial Q_i) & \xrightarrow{\cap [Q_i]} & \mathrm{H}_0(Q_i) & \xrightarrow{\epsilon_{Q_i}} & \mathbb{Z} \\
\downarrow \Psi_i^* \times \Psi_i^* & & \downarrow \Psi_i^* & & \uparrow \Psi_i^* & & \uparrow \mathrm{id} \\
\mathrm{H}^l(Z, \overline{B}^k \times \partial \overline{B}^l) \times \mathrm{H}^k(Z, \partial \overline{B}^k \times \overline{B}^l) & \xrightarrow{\cup} & \mathrm{H}^m(Z, \partial Z) & \xrightarrow{\cap \sigma_i \cdot [Z]} & \mathrm{H}_0(Z) & \xrightarrow{\epsilon_Z} & \mathbb{Z}.
\end{array}$$

As in the previous diagram, the squares to the left and right commute. The middle square is slightly more interesting. Lemma 126.9 says that $\Psi_{i*}([Q_i]) = \sigma_i \cdot [Z]$. Using this observation we obtain once again from the Cap Product-Naturality Lemma 116.8 (1) that the middle square commutes.

We calculate that

$$\begin{aligned}
\epsilon_{Q_i}\big((\mathrm{PD}_{Q_i}([X_i]) \cup \mathrm{PD}_{Q_i}([Y_i])) \cap [Q_i]\big) &\overset{\text{by the above commutative diagram}}{=} \sigma_i \cdot \epsilon_Z\big((\Psi_i^*(\mathrm{PD}_{Q_i}([X_i])) \cup \Psi_i^*(\mathrm{PD}_{Q_i}([Y_i]))) \cap [Z]\big) \\
&= \sigma_i \cdot \epsilon_Z\big((\mathrm{PD}_Z([\overline{B}^k \times \{0\}]) \cup \mathrm{PD}_Z([\{0\} \times \overline{B}^l])) \cap [Z]\big) \\
&\overset{\text{by Proposition 126.8 (d)}}{=} \sigma_i \cdot \epsilon_{\overline{B}^k \times \overline{B}^l}\big([\overline{B}^k \times \overline{B}^l]^* \cap [\overline{B}^k \times \overline{B}^l]\big) \overset{\text{definition of the dual fundamental class}}{=} \sigma_i.
\end{aligned}$$

the Poincaré Duality-Products Proposition 119.2

$\boxplus$

[1540] One can easily convince oneself that $\partial_A Q_i = \partial_1 Q_i$ and $\partial_B Q_i = \partial_0 Q_i$ for Q_i viewed as a submanifold with corner of A.

After all these preparations we can prove the desired equality:

$$\epsilon_M\big((\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y])) \cap [M]\big) \overset{\text{by the first row of the commutative diagram from Claim 1 and by Claim 2 (a)}}{\downarrow} = \epsilon_M\big((\alpha \cup \beta) \cap p_*([M])\big)$$
$$= \sum_{i=1}^{s} \epsilon_{Q_i}\big((\mathrm{PD}_{Q_i}([X_i]) \cup \mathrm{PD}_{Q_i}([Y_i])) \cap [Q_i]\big) \overset{\text{by Claim 2 (c)}}{=\!=\!\uparrow} \sum_{i=1}^{s} \sigma_i.$$
$$\uparrow \text{ by the second and third row of commutative diagram from Claim 1 and by Claim 2 (b)}$$

This concludes the proof of the theorem. ■

Remark. Towards the end of the proof of the theorem we marked in red color that we used the Poincaré Duality-Products Proposition 119.2. Most of the other statements that we used in the proof were fairly straightforward lemmas regarding cup and cap products. But arguably the key ingredient in the proof is the Poincaré Duality-Products Proposition 119.2 which was a variation on the Fundamental Class-Product Proposition 117.2 and which in turn was a fairly straightforward consequence of the Product Theorem 117.1.

126.4. **Algebraic intersection numbers of complex submanifolds.** In the following section we will apply the Intersection Number-via-Cup Product Theorem 126.5 to the study of the complex projective spaces $\mathbb{C}\mathrm{P}^n$. Before we do so it is convenient to study the algebraic intersection numbers of complex submanifolds of any complex manifold.
First let us recall the following definition that goes all the way back to pages 797.

Definition.

(1) An n-dimensional complex manifold is a $2n$-dimensional smooth manifold M without boundary together with a smooth atlas $\{\phi_j \colon U_j \to V_j\}_{j\in J}$ such that all transition maps are biholomorphisms.
(2) We define the maximal holomorphic atlas of a complex manifold the same way as we defined the maximal smooth atlas of a smooth manifold, see page 542.
(3) We say $W \subset M$ is a k-dimensional complex submanifold if for every point $P \in W$ there exists a chart $\phi_j \colon U_j \to V_j$ from the maximal holomorphic atlas with $P \in U_j$ and which satisfies that $\phi_j(U_j \cap W) \subset \mathbb{C}^k \times \{0\}$.

Remark.

(1) Let M be a complex manifold. It follows easily from the definitions that every complex submanifold of M is a complex manifold in its own right.
(2) Let V be an n-dimensional complex vector space. In the Complex Vector Space-Orientation Lemma 32.22 we showed that if $(v_1, \ldots, v_n)$ is a basis for V as a complex vector space, then the ordered basis $(v_1, \mathrm{i}v_1, \ldots, v_n, \mathrm{i}v_n)$ gives a well-defined orientation of the $2n$-dimension real vector space V, called the *natural orientation*.
(3) Let M be an n-dimensional complex manifold. In the Complex Manifold-Orientation Proposition 32.23 we showed that $\mathrm{T}_P M$ is canonically a complex vector space and we showed that the corresponding natural orientations define a natural orientation of M, viewed as a $2n$-dimensional smooth manifold.

Now we can formulate this elementary but rather useful lemma.

Lemma 126.10. Let M be a closed complex manifold and let X and Y be two closed complex submanifolds of M with $\dim(X) + \dim(Y) = \dim(M)$. Then the following hold:

(1) The sign at every transverse intersection point of X and Y is equal to $+1$.
(2) If X and Y intersect transversally, then the algebraic intersection number equals the geometric intersection number.

Proof.

(1) We write $k = \dim(X)$ and $l = \dim(Y)$. Suppose that P is a transverse intersection point of the submanifolds X and Y. We pick a basis $(v_1, \ldots, v_k)$ for the complex vector space $\mathrm{T}_P X$ and we pick a basis $(w_1, \ldots, w_l)$ for the complex vector space $\mathrm{T}_P Y$. Then $(v_1, \ldots, v_k, w_1, \ldots, w_l)$ is evidently a basis for the complex vector space $\mathrm{T}_P X \oplus \mathrm{T}_P Y = \mathrm{T}_P M$. We have
$$\underbrace{v_1, \mathrm{i}v_1, \ldots, v_k, \mathrm{i}v_k}_{\text{positive basis for } \mathrm{T}_P X}, \underbrace{w_1, \mathrm{i}w_1, \ldots, w_l, \mathrm{i}w_l}_{\text{positive basis for } \mathrm{T}_P Y} = \underbrace{v_1, \mathrm{i}v_1, \ldots, v_k, \mathrm{i}v_k, w_1, \mathrm{i}w_1, \ldots, w_l, \mathrm{i}w_l}_{\text{positive basis for } \mathrm{T}_P M}.$$
This shows that $\mathrm{sign}(P) = +1$. We have concluded the proof of the first statement.
(2) The second statement is an immediate consequence of the first statement. ∎

Example. We consider the complex projective space $\mathbb{C}\mathrm{P}^n$. In the Complex Projective Space-is-Complex Manifold Lemma 32.16 we saw that $\mathbb{C}\mathrm{P}^n$ is a complex manifold of complex dimension n. It follows easily from the definitions that for any $k \leq n$ the subset
$$X_k := \{[z_0 : \ldots : z_k : 0 : \ldots : 0] \mid (z_0, \ldots, z_k) \in \mathbb{C}^{k+1} \setminus \{0\}\}$$
is a k-dimensional complex submanifold. Similarly we see that for any $l \leq n$ the subset
$$Y_l := \{[0 : \ldots : 0 : z_{n-l} : \ldots : z_n] \mid (z_{n-l}, \ldots, z_n) \in \mathbb{C}^{l+1} \setminus \{0\}\}$$
is an l-dimensional complex submanifold. Evidently X_k and Y_l are biholomorphic to $\mathbb{C}\mathrm{P}^k$ respectively $\mathbb{C}\mathrm{P}^l$. Furthermore given any $k \leq n$ we have
$$X_k \cap Y_{n-k} = [0 : \ldots : 0 : \underset{\substack{\uparrow \\ (k+1)\text{-st entry}}}{1} : 0 : \ldots : 0]$$
consists of a single point P. We leave it as an illuminating exercise to verify that X_k and Y_{n-k} intersect transversally in P. It follows from Lemma 126.10 that $X_k \cdot Y_{n-k} = 1$. The same way we also see that $Y_k \cdot X_{n-k} = 1$.

126.5. **Applications to complex projective spaces.** In this section we will give two more applications of the Intersection Number-via-Cup Product Theorem 126.5.

Notation. Let $n \in \mathbb{N}$ and let $m \in \{0, \ldots, n\}$.

(1) We consider the inclusion map
$$\begin{aligned} i_{m,n} \colon \mathbb{C}\mathrm{P}^m &\to \mathbb{C}\mathrm{P}^n \\ [z_0 : \ldots : z_m] &\mapsto [z_0 : \ldots : z_m : 0 : \cdots : 0]. \end{aligned}$$
When m and n are understood we write i instead of $i_{m,n}$. Recall that in Lemma 121.6 we showed that for any $k \leq 2m$ the induced maps $i_* \colon \mathrm{H}_k(\mathbb{C}\mathrm{P}^m; \mathbb{Z}) \to \mathrm{H}_k(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$ and $i^* \colon \mathrm{H}^k(\mathbb{C}\mathrm{P}^n; \mathbb{Z}) \to \mathrm{H}^k(\mathbb{C}\mathrm{P}^m; \mathbb{Z})$ are isomorphisms.

(2) By a slight abuse of notation we abbreviate $(i_{m,n})_*([\mathbb{C}\mathrm{P}^m])$ to $[\mathbb{C}\mathrm{P}^m] \in \mathrm{H}_{2m}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$. Furthermore, again by a slight abuse of notation, we write $[\mathbb{C}\mathrm{P}^m]^* \in \mathrm{H}^{2m}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ for the unique element with $\langle [\mathbb{C}\mathrm{P}^m]^*, [\mathbb{C}\mathrm{P}^m]\rangle = 1$. Finally we write $x = [\mathbb{C}\mathrm{P}^1]^*$.

Now we can formulate the main result of this section.

Proposition 126.11. (Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition) Let $n \in \mathbb{N}$. For every $k \in \{0,\ldots,n\}$ we have

$$(\underbrace{[\mathbb{C}\mathrm{P}^1]^*}_{=x})^k \;=\; [\mathbb{C}\mathrm{P}^k]^* \;\in\; \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}).$$

Remark. In the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 we had used the Poincaré Duality Theorem 119.1 to show that for given $n \in \mathbb{N}$ and $k \in \{0,\ldots,n\}$ the k-th power $x^k \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ is a generator. In other words, we had proved that $x^k = \pm[\mathbb{C}\mathrm{P}^k]^*$. the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11 is a much better result since it allows us to nail down the cohomology class x^k. In particular we see that the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11 gives an affirmative answer to Question 121.8.

The key to the proof of the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11 is the following lemma.

Lemma 126.12. Let $n \in \mathbb{N}$. For any $k \in \{0,\ldots,n\}$ we have

$$\mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^k]) \cup \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^{n-k}]) \;=\; [\mathbb{C}\mathrm{P}^n]^* \;\in\; \mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}).$$

Proof. Let $n \in \mathbb{N}$. For $k \in \{0,\ldots,n\}$ we consider the inclusion map

$$\begin{array}{rcl} t_{k,n}\colon \mathbb{C}\mathrm{P}^k & \to & \mathbb{C}\mathrm{P}^n \\ [z_0 : \ldots : z_k] & \mapsto & [0 : \ldots : 0 : z_0 : \ldots : z_k]. \end{array}$$

We also consider the map[1541]

$$\begin{array}{rcl} \Phi\colon \mathbb{C}\mathrm{P}^k \times [0,1] & \to & \mathbb{C}\mathrm{P}^n \\ ([z],t) & \mapsto & \big[\underbrace{\big(z\cdot\cos^2\big(t\cdot\frac{\pi}{2}\big),0\big)}_{\in\mathbb{C}^{n+1}} + \underbrace{\big(0,z\cdot\sin^2\big(t\cdot\frac{\pi}{2}\big)\big)}_{\in\mathbb{C}^{n+1}}\big]. \end{array}$$

Then

$$\begin{array}{rcll} \langle \mathrm{PD}([\mathbb{C}\mathrm{P}^k]) \cup \mathrm{PD}([\mathbb{C}\mathrm{P}^{n-k}]), [\mathbb{C}\mathrm{P}^n]\rangle & = & \langle \mathrm{PD}(i_{k,n*}([\mathbb{C}\mathrm{P}^k])) \cup \mathrm{PD}(i_{n-k,n*}([\mathbb{C}\mathrm{P}^{n-k}])), [\mathbb{C}\mathrm{P}^n]\rangle & \\ & = & \langle \mathrm{PD}(t_{k,n*}([\mathbb{C}\mathrm{P}^k])) \cup \mathrm{PD}(i_{n-k,n*}([\mathbb{C}\mathrm{P}^{n-k}])), [\mathbb{C}\mathrm{P}^n]\rangle & \\ & & \uparrow & \\ & & \text{by the Homotopic Maps-and-Homology Proposition 73.6, since } \Phi \text{ is a homotopy from } i_{k,n} \text{ to } t_{k,n} & \\ & = & \langle \mathrm{PD}([t_{k,n}(\mathbb{C}\mathrm{P}^k)]) \cup \mathrm{PD}([i_{n-k,n}(\mathbb{C}\mathrm{P}^{n-k})]), [\mathbb{C}\mathrm{P}^n]\rangle & \\ & = & t_{k,n}(\mathbb{C}\mathrm{P}^k)\cdot i_{n-k,n}(\mathbb{C}\mathrm{P}^{n-k}) \;=\; 1. & \\ & & \uparrow \qquad\qquad\qquad\qquad \uparrow & \\ & & \text{by the Intersection Number-via-Cup Product Theorem 126.5 since submanifolds } t_{k,n}(\mathbb{C}\mathrm{P}^k) \text{ and } i_{n-k,n}(\mathbb{C}\mathrm{P}^{n-k}) \text{ are transverse} \quad \text{see page 2766 for details} & \end{array}$$

By definition of the dual fundamental class this implies the desired result. ∎

We record the following fairly immediate corollary.

[1541] It is quite straightforward to verify that this map is well-defined, i.e. it does not depend on the choice of the representative $z \in \mathbb{C}^{k+1}\setminus\{0\}$ and it does indeed take values in $\mathbb{C}\mathrm{P}^n$ since for any $t \in [0,1]$ we have $\big(z\cdot\cos^2\big(t\cdot\frac{\pi}{2}\big),0\big) + \big(0,z\cdot\sin^2\big(t\cdot\frac{\pi}{2}\big)\big) \neq 0$. Also note that it follows fairly easily from the Homotopy Quotient Theorem 14.7 that the map is continuous.

Corollary 126.13. Let $n \in \mathbb{N}$. For any $k \in \{0, \dots, n\}$ we have
$$\mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^k]) = [\mathbb{C}\mathrm{P}^{n-k}]^* \in \mathrm{H}^{2n-2k}(\mathbb{C}\mathrm{P}^n; \mathbb{Z}).$$

Proof. Let $n \in \mathbb{N}$ and let $k \in \{0, \dots, n\}$. Then

$$\begin{array}{rcl} \langle \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^k]), [\mathbb{C}\mathrm{P}^{n-k}] \rangle & \overset{\text{by definition of } \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^{n-k}])}{\downarrow =} & \langle \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^k]), \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^{n-k}]) \cap [\mathbb{C}\mathrm{P}^n] \rangle \\ & \underset{\text{by the Cup-Cap Lemma 116.7 and the Cup Product-Commutativity Proposition 114.8}}{\uparrow =} & \langle \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^k]) \cup \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^{n-k}]), [\mathbb{C}\mathrm{P}^n] \rangle \underset{\text{Lemma 126.12}}{\uparrow =} 1. \end{array}$$

By definition of the dual fundamental class this implies the desired result. ■

Proof of the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11. Recall that we need to show that for every $n \in \mathbb{N}$ and every $k \in \{0, \dots, n\}$ we have $([\mathbb{C}\mathrm{P}^1]^*)^k = [\mathbb{C}\mathrm{P}^k]^* \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$. We start out with the following observation that follows immediately from the discussion on page 2766 and the Cup Product-Naturality Lemma 114.10.

Observation. Let $m \in \mathbb{N}$ and let $k \in \{1, \dots, m\}$. If $([\mathbb{C}\mathrm{P}^1]^*)^k = [\mathbb{C}\mathrm{P}^k]^* \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^m; \mathbb{Z})$, then for any $n \geq m$ we also have $([\mathbb{C}\mathrm{P}^1]^*)^k = [\mathbb{C}\mathrm{P}^k]^* \in \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$

By the observation it suffices to prove the following claim.

Claim. For any $n \in \mathbb{N}$ we have $([\mathbb{C}\mathrm{P}^1]^*)^n = [\mathbb{C}\mathrm{P}^n]^* \in \mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$.

Proof. We prove the claim by induction on n. For $n = 1$ the statement holds by definition. So suppose that the statement holds for some $n-1$ with $n \geq 2$. Then the following equality holds in $\mathrm{H}^{2n}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$:

$$([\mathbb{C}\mathrm{P}^1]^*)^n = ([\mathbb{C}\mathrm{P}^1]^*)^{n-1} \cup [\mathbb{C}\mathrm{P}^1]^* \underset{\text{by induction and the observation}}{\uparrow =} [\mathbb{C}\mathrm{P}^{n-1}]^* \cup [\mathbb{C}\mathrm{P}^1]^* \underset{\text{Corollary 126.13}}{\uparrow =} \mathrm{PD}([\mathbb{C}\mathrm{P}^1]) \cup \mathrm{PD}([\mathbb{C}\mathrm{P}^{n-1}]) \underset{\text{Lemma 126.12}}{\uparrow =} [\mathbb{C}\mathrm{P}^n]^*.$$

This concludes the proof of the claim and thus of the proposition. ■

Now we can answer Question **??**.

Proposition 126.14. Every tubular neighborhood of $\mathbb{C}\mathrm{P}^1 = i_{1,2}(\mathbb{C}\mathrm{P}^1)$ in $\mathbb{C}\mathrm{P}^2$ is non-trivial.[1542]

In the figure on page 571 we had implicitly seen that the tubular neighborhood of $\mathbb{R}\mathrm{P}^1$ in $\mathbb{R}\mathrm{P}^2$ is a Möbius band, and thus non-trivial. The above proposition is thus an analogue of this simpler, and more visual, observation.

Proof. Suppose that $\mathbb{C}\mathrm{P}^1$ admits a trivial tubular neighborhood in $\mathbb{C}\mathrm{P}^2$. By definition this would mean that there exists a smooth embedding $\Phi\colon \mathbb{C}\mathrm{P}^1 \times \overline{B}^2 \to \mathbb{C}\mathrm{P}^2$ with $\Phi(P, 0) = P$ for all $P \in \mathbb{C}\mathrm{P}^1$. We denote by $i = i_{1,2}\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^2$ the usual inclusion map and we denote

[1542] We refer to page **??** for the definition of a trivial tubular neighborhood.

by $f\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^2$ the smooth embedding that is given by $P \mapsto \Phi(P,1)$. Then

$$\pm 1 \underset{\uparrow}{=} \langle \mathrm{PD}(i_*([\mathbb{C}\mathrm{P}^1]) \cup \mathrm{PD}(i_*([\mathbb{C}\mathrm{P}^1])), [\mathbb{C}\mathrm{P}^2]\rangle \underset{\uparrow}{=} \langle \mathrm{PD}(i_*([\mathbb{C}\mathrm{P}^1]) \cup \mathrm{PD}(f_*([\mathbb{C}\mathrm{P}^1])), [\mathbb{C}\mathrm{P}^2]\rangle$$

by the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11 or by the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7

by the Homotopic Maps-and-Homology Proposition 73.6 since $i, f\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^2$ are homotopic via the homotopy $(P,t) \mapsto \Phi(P,t)$

$$\underset{\uparrow}{=} i(\mathbb{C}\mathrm{P}^1) \cdot f(\mathbb{C}\mathrm{P}^1) \underset{\uparrow}{=} 0.$$

by Theorem 126.5 since $i(\mathbb{C}\mathrm{P}^1)$ and $f(\mathbb{C}\mathrm{P}^1)$ are disjoint

We have thus obtained a contradiction. ∎

126.6. **Higher dimensional analogue of Theorem 126.5.** Let M be a compact oriented m-dimensional smooth manifold, let $X \subset M$ be a closed oriented submanifold of dimension k and let Y be a compact oriented proper submanifold of the complementary dimension $m-k$. We suppose that X and Y are transverse. By assigning to each intersection point in $X \cap Y$ the sign introduced on page 2748 we can view $X \cap Y$ as a 0-dimensional oriented submanifold of M.[1543] With this convention we can reformulate the conclusion of the Intersection Number-via-Cup Product Theorem 126.5 as follows:

Theorem 126.15. With the above notation we have

$$\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]) \;=\; \mathrm{PD}_M([X \cap Y]) \;\in\; \mathrm{H}^m(M, \partial M; \mathbb{Z}).$$

Proof. Using the Cup-Cap Disjoint Union Lemma 116.9 one can easily verify that it suffices to prove the theorem for each connected component of M separately. Put differently, without loss of generality we can assume that M is connected. We denote by $P_1, \ldots, P_n$ the points in $X \cap Y$ and we denote by $\sigma_1, \ldots, \sigma_n \in \{\pm 1\}$ the corresponding signs. Now we calculate that

$$\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]) \underset{\uparrow}{=} (X \cdot Y) \cdot [M]^* = \sum_{i=1}^n \sigma_i \cdot [M]^* \underset{\uparrow}{=} \sum_{i=1}^n \mathrm{PD}_M(\sigma_i \cdot [\{P_i\}]) = \mathrm{PD}_M([X \cap Y]).$$

by Theorem 126.5 and since M is connected

see page 2619

∎

The formulation of Theorem 126.15 has the nice feature that with some effort one can also generalize it to submanifolds that are not of complementary dimensions. Before we can formulate this generalization we need to formulate the following lemma.

Lemma 126.16. Let M be an oriented m-dimensional smooth manifold, let $X \subset M$ be an oriented proper submanifold and let Y be an oriented proper submanifold. Suppose that X and Y intersect transversally. By the Submanifold Transversal Intersection Theorem 42.1 we know that $X \cap Y$ is a submanifold. Given $P \in X \cap Y$ we have a natural short exact sequence induced by the various inclusion maps:

$$0 \;\to\; \mathrm{T}_P(X \cap Y) \;\to\; \mathrm{T}_P X \oplus \mathrm{T}_P Y \;\xrightarrow{\rho}\; \mathrm{T}_P M \;\to\; 0.$$

We pick a set of vectors $\mathcal{C}$ in $\mathrm{T}_P X \oplus \mathrm{T}_P Y$ such that $\rho(\mathcal{C})$ is a positive basis for $\mathrm{T}_P M$. We say that a basis $\mathcal{B}$ for $\mathrm{T}_P(X \cap Y)$ is *positive* if the basis $\{\mathcal{B}, \mathcal{C}\}$ is a positive basis for $\mathrm{T}_P X \oplus \mathrm{T}_P Y$. This definition is independent of the choices and it turns $X \cap Y$ into an oriented submanifold of M.

[1543] Recall that on page 675 we remarked that the orientation of a 0-dimensional manifold M is the same as a map $M \to \{\pm 1\}$.

Proof. We leave the elementary proof to the reader. ■

Example. Let $n \in \mathbb{N}$ and let $0 \leq k \leq l \leq n$. We consider $\mathbb{C}\mathrm{P}^n$ with the complex submanifolds

$$\begin{aligned} A &= \{[z_0 : \cdots : z_l : 0 : \cdots : 0] \,|\, (z_0, \ldots, z_l) \in \mathbb{C}^{l+1} \setminus \{0\}\} \\ B &= \{[0 : \cdots : 0 : z_k : \cdots : z_n] \,|\, (z_k, \ldots, z_n) \in \mathbb{C}^{n+1-k} \setminus \{0\}\} \end{aligned}$$

and

$$C = \{[0 : \cdots : 0 : z_k : \cdots : z_l : 0 : \cdots : 0] \,|\, (z_k, \ldots, z_l) \in \mathbb{C}^{l+1-k} \setminus \{0\}\}.$$

As usual we equip $\mathbb{C}\mathrm{P}^n$ and A, B, C with the natural orientations coming from the Complex Manifold-Orientation Proposition 32.23. Then $A \cap B = C$ and one can easily show that the orientation of $A \cap B$ equals the orientation of C.

The following theorem is a generalization of Theorem 126.15 and thus also of the Intersection Number-via-Cup Product Theorem 126.5.

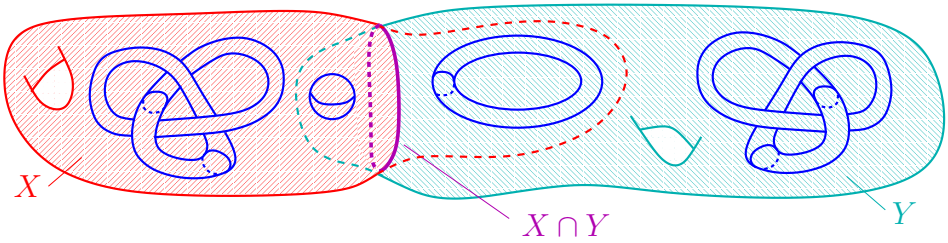
Theorem 126.17. Let M be a compact oriented m-dimensional smooth manifold. Furthermore let $X \subset M$ be a closed oriented submanifold of codimension k and let Y be a compact oriented proper submanifold of codimension l. Then[1544]

$$\underbrace{\mathrm{PD}_M([X])}_{\in \mathrm{H}^k(M,\partial M)} \cup \underbrace{\mathrm{PD}_M([Y])}_{\in \mathrm{H}^l(M)} = \mathrm{PD}_M([X \cap Y]) \in \mathrm{H}^{k+l}(M, \partial M; \mathbb{Z}).$$

Proof. A proof is given in [**Bre1993**, Theorem VI.11.9]. ■

Remark.

(1) Theorem 126.17 can be summarized as saying that cup products correspond to taking intersections of submanifolds. With this point of view, the symbol "$\cup$" for the cup product does not seem to be a great choice.
(2) It is conceivable that the conclusion of Theorem 126.17 also holds if we have a decomposition $\partial M = A \cup B$ of the boundary and we have proper submanifold X and Y with $\partial X \subset A$ and $\partial Y \subset B$. We leave the task of verifying such a generalization to other authors.



Examples.

(1) Let M be the smooth manifold that is the complement in S^3 of the three open solid tori and the open ball that are shown in the figure below. Furthermore let X and Y be the surfaces shown in that figure. Basically the same argument as on page 2755 shows that $[X]$ and $[Y]$ are non-trivial in $\mathrm{H}_2(M; \mathbb{Z})$. On the other hand the class $[X \cap Y] \in \mathrm{H}_1(M; \mathbb{Z})$ is clearly trivial. Therefore we deduce from Theorem 126.17 that $\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]) = 0$.
(2) Using Theorem 126.17 and using the example preceding that theorem one can fairly easily give a completely geometric calculation of the cup product of $\mathbb{C}\mathrm{P}^n$.

Remark. Using Theorem 126.17 one can easily modify the proof of Proposition 126.14 to show that given any $n \geq 2$ every tubular neighborhood of $\mathbb{C}\mathrm{P}^{n-1}$ in $\mathbb{C}\mathrm{P}^n$ is non-trivial.

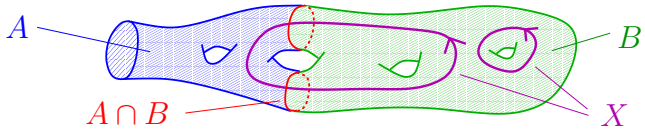
[1544]The sign should be taken with a slight grain of salt. It is conceivable that the sign depends on the various dimensions.

M is the complement in S^3 of three open solid tori and an open ball

Exercises for Chapter 126.

Exercise 126.1. Let M be a smooth manifold that admits two compact codimension-zero submanifolds A and B such that $A \cap B$ is a union of boundary components of A and a union of boundary components of B. By the Mayer–Vietoris Theorem 78.9 for Manifolds we obtain a long exact sequence

$$\cdots \to \mathrm{H}_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n(A) \oplus \mathrm{H}_n(B) \xrightarrow{i_A + i_B} \mathrm{H}_n(M) \xrightarrow{\partial_n} \mathrm{H}_{n-1}(A \cap B) \to \dots$$



Let X be a closed oriented n-dimensional submanifold of M that intersects $A \cap B$ transversally.

(a) Show that $X \cap (A \cap B)$ is a closed $(n-1)$-dimensional submanifold of $A \cap B$.

We equip $X \cap (A \cap B)$ with the orientation coming from $X \cap (A \cap B) = \partial(X \cap A)$. We view the fundamental class $[X]$ as an element in $\mathrm{H}_n(M)$ and we view the fundamental class $[X \cap (A \cap B)]$ as an element in $\mathrm{H}_{n-1}(A \cap B)$.

(b) Show that $\partial_n([X]) = \pm[X \cap (A \cap B)] \in \mathrm{H}_{n-1}(A \cap B)$.

(c) Determine the correct sign in (b).

Exercise 126.2. Let A, B be two 1-dimensional oriented submanifolds of S^2 with $A \cdot B = 0$. Sketch a proof for the claim that A and B can be made disjoint via isotopies of A and B.

Exercise 126.3. Let M be a compact oriented m-dimensional smooth manifold. Furthermore let $k \in \{1, \dots, m-1\}$, let X be a proper oriented k-dimensional submanifold of M and let Y be a proper oriented $(m-k)$-dimensional submanifold of M. We denote by $i\colon X \to M$ and $j\colon Y \to M$ the inclusion maps. We could define the algebraic intersection number of X and Y via the formula in the Intersection Number-via-Cup Product Theorem 126.5, i.e. we could define

$$X \cdot Y \;:=\; \langle \mathrm{PD}_M(i_*([X]) \cup \mathrm{PD}_M(j_*([Y])), [M] \rangle.$$

What, if any, conditions do you need to impose on the boundaries of X and Y for this definition to make any sense?

Remark. This exercise can be viewed as a continuation of the discussion on page 2750.

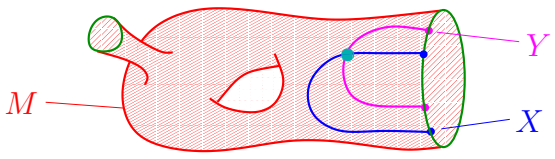
Exercise 126.4. Let M be a closed oriented connected m-dimensional smooth manifold. Furthermore let $p\colon \widetilde{M} \to M$ be a finite covering.

(a) Let X, Y be a complementary pair of submanifolds of M. We write $\widetilde{X} := p^{-1}(X)$ and $\widetilde{Y} := p^{-1}(Y)$. What is the relationship between $X \cdot Y$ and $\widetilde{X} \cdot \widetilde{Y}$? It suffices to give a short justification.

(b) Let X be a closed oriented submanifold of M. What is the relationship between $\mathrm{PD}_{\widetilde{M}}([\widetilde{X}])$ and $p^*(\mathrm{PD}_M([X])$?

(c) Reprove (a) using (b) and the Intersection Number-via-Cup Product Theorem 126.5.

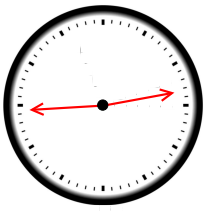
Exercise 126.5. Let M be an oriented m-dimensional smooth manifold, let X be a k-dimensional oriented proper submanifold and let Y be an $(m-k)$-dimensional oriented proper submanifold of M. We suppose that $X \cap Y \cap \partial M = \varnothing$. What is the relationship between the algebraic intersection number $X \cdot Y$ in M and $DX \cdot DY$ in $\mathrm{D}M$?
Here, as always, given a smooth manifold N we denote by $\mathrm{D}M = N \cup_{\partial N = \partial N'} N'$ the double of N. We view $\mathrm{D}M$ as an oriented smooth manifold where the orientation is chosen such that the orientation of $\mathrm{D}M$ agrees with the orientation on N.



Exercise 126.6. Let $n \in \mathbb{Z}$. In Exercise 32.12 we showed that

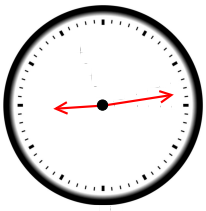
$$W_n \;:=\; \{[x:y:z] \in \mathbb{C}\mathrm{P}^2 \,|\, x^n + y^n + z^n = 0\}$$

is a closed 1-dimensional complex submanifold of the complex projective space $\mathbb{C}\mathrm{P}^2$. Show that $[W_n] = n \cdot [\mathbb{C}\mathrm{P}^1] \in \mathrm{H}_2(\mathbb{C}\mathrm{P}^2; \mathbb{Z})$.
Hint. Use Lemma 126.10.

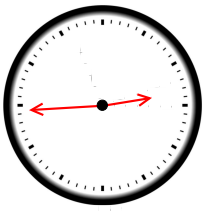


Exercise 126.7. Let $\Sigma \subset S^2 \times (-1,1)$ be a closed surface. Suppose that there exists a $P \in S^2$ such that Σ intersects $\{P\} \times [-1,1]$ in a single point. Show that if this intersection point is a transversal intersection point, then Σ intersects every path $\gamma\colon [0,1] \to S^2 \times [-1,1]$ from a point in $S^2 \times \{-1\}$ to a point in $S^2 \times \{1\}$.

Exercise 126.8. We consider the 2-dimensional smooth manifold M that is shown together with the two proper submanifolds X and Y that are shown in the figure below. Show that X and Y cannot be made disjoint by a smooth isotopy that keeps the boundaries of X and Y fixed.

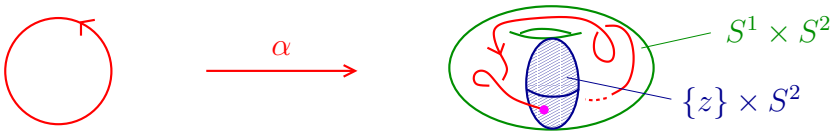


Exercise 126.9. By accident you ended up buying a clock where both hands have the same length, so you cannot distinguish the hand which shows the hour from the hand that indicates the minute. Fortunately, very often you can still tell the precise time. For example, in the configuration in the figure below it does not make sense for the hand that is indicating the hour to be just *before* 9 whereas the hand showing the minute is at 15.



Of course there will be some configurations when it is indeed impossible to tell which hand is which. How many such confusions moments will there be in a 12 hour period?
Hint. Consider a suitable map $\gamma\colon S^1 \to S^1 \times S^1$.

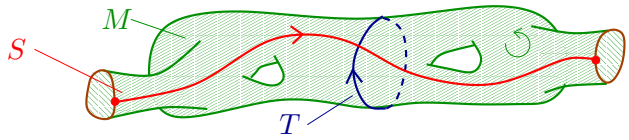
clock where both hands have the same length



this makes no sense

the time is 2:44

Exercise 126.10. Let C and D be closed curves in $\mathbb{R}^2$ that intersect transversally. Give a rigorous proof that the number of intersection points between C and D is an even number.



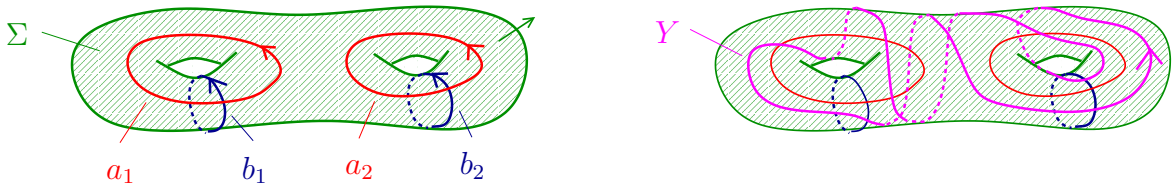
Exercise 126.11. Let $\alpha\colon S^1 \to S^1 \times S^2$ be a smooth embedding. We assume that there exists a $z \in S^1$ such that $\gamma(S^1)$ intersects the submanifold $\{z\} \times S^2$ in a single point P and we assume that the intersection point is transversal intersection point of sign $+1$. Show that $\alpha\colon S^1 \to S^1 \times S^2$ is smoothly isotopic to the embedding $\beta\colon S^1 \to S^1 \times S^2$ that is given by $t \mapsto (t, P)$.
Remark. This statement is sometimes referred to as the *light bulb trick*.

Exercise 126.12. Let M be a compact oriented 2-dimensional smooth manifold. We consider the following construction:

$$\begin{array}{rcl} \mathrm{H}_1(M, \partial M) \times \mathrm{H}_1(M, \partial M) & \to & \mathbb{Z} \\ (\sigma, \tau) & \mapsto & \text{algebraic intersection number } S \cdot T \text{ of proper transverse} \\ & & \text{submanifolds } S \text{ and } T \text{ of } M \text{ with } [S] = \sigma \text{ and } [T] = \tau. \end{array}$$

Does this give a well-defined map?

Exercise 126.13. We consider the surface Σ of genus 2 together with the four oriented curves a_1, b_1, a_2, b_2 that are shown in the figure below.



(a) Let X be a closed oriented 1-dimensional submanifold of Σ that intersects a_1, b_1, a_2, b_2 transversally. Show that

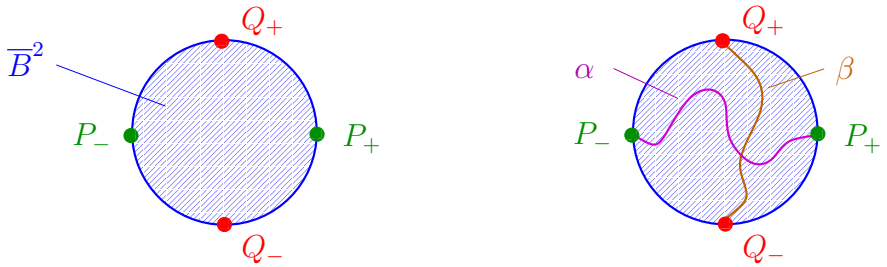
$$[X] \;=\; (X \underset{\uparrow}{\cdot} b_1) \cdot [a_1] \;-\; (X \underset{\uparrow}{\cdot} a_1) \cdot [b_1] \;+\; (Y \underset{\uparrow}{\cdot} b_2) \cdot [a_2] \;-\; (X \underset{\uparrow}{\cdot} a_2) \cdot [b_2] \;\in\; \mathrm{H}_1(\Sigma).$$

these are the algebraic intersection numbers of the given oriented curves

(b) Let X and Y be two closed oriented 1-dimensional submanifolds of Σ that are both transverse to a_1, a_2, b_1, b_2. Show that if X and Y have the same algebraic intersection numbers with a_1, a_2, b_1, b_2, then $[X] = [Y] \in \mathrm{H}_1(\Sigma)$.

Remark. The above gives a practical way, for Σ and similarly for many other smooth manifolds, to determine precisely the homology class represented by a submanifold. In particular it can be used to deal with the type of problems as in Exercise 80.16.

127. Intersections of cycles and the cup product



In this chapter we generalize some of the results from Chapter 126. In particular we will define the "algebraic intersection number" of two maps of topological manifolds into a given topological manifold, as long as the maps intersect "nicely". This notion generalizes the algebraic intersection number of two transverse submanifolds of a given smooth manifold that we introduced on page 2748.

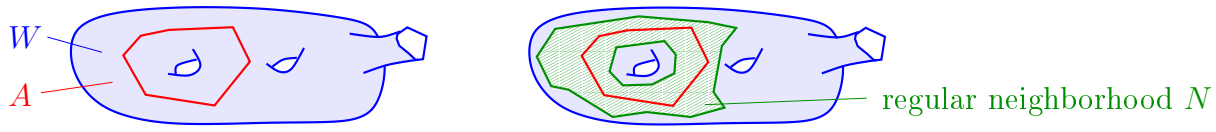
Furthermore we introduce the algebraic intersection number of two singular cycles that intersect "nicely". Afterwards we will see in Theorems 127.7 and 127.9 how these algebraic intersection numbers relate to the cup product. These theorems can be viewed as a generalization of the Intersection Number-via-Cup Product Theorem 126.5.

For many applications the results from Chapter 126 are good enough and for many readers it might make sense to move on to the next chapter. The main application of the results of this chapter will be the Lefschetz-Hopf Theorem 128.9 and the Poincaré-Hopf Theorem 129.7.

Since much of this chapter is quite technical we start out with the following motivating question.

Question 127.1. As shown in the figure below we consider the disk $\overline{B}^2$ together with the four points $P_\pm = (\pm 1, 0)$ and $Q_\pm = (0, \pm 1)$. Do there exist disjoint paths α and β such that α connects P_- to P_+ and β connects Q_- to Q_+?

It is pretty clear that the answer should be no. In fact once we have developed all the tools we will find it quite easy to answer Question 127.1 in the negative. We refer to Lemma 127.8 for the details.



127.1. The algebraic intersection number of maps of topological manifolds.

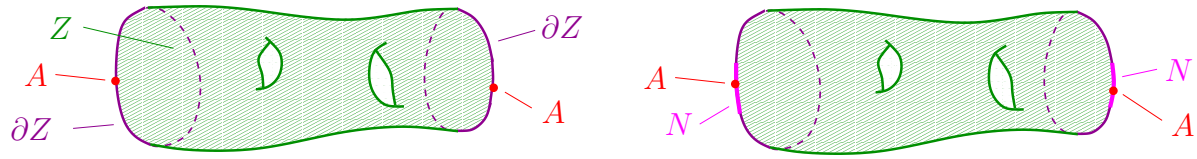
In this section we introduce the algebraic intersection number of two maps of topological manifolds into a given topological manifold. The precise setup and the definitions require some preparations. First we recall the following definition from page 2695.

Definition. Let W be a compact topological manifold and let $A \subset W \setminus \partial W$ be a subset. A regular neighborhood of A is a compact codimension-zero submanifold N of W with the following properties:

(1) N is contained in $W \setminus \partial W$ and A is contained in the interior of N.
(2) A is a deformation retract of N.
(3) ∂N is a deformation retract of $N \setminus A$.

The following proposition can be viewed as a variation on the Poincaré Duality Theorem 119.1.

Proposition 127.2. Let Z be a compact oriented m-dimensional topological manifold and let A be a closed submanifold of ∂Z.



(1) Let $N \subset \partial Z$ be a regular neighborhood of A. We denote by $j\colon A \to N$ the inclusion map. Given any $l \in \mathbb{N}_0$ the following two maps are isomorphisms:[1545]

$$\mathrm{H}^l(Z, \partial Z \setminus A) \xrightarrow[\cong]{\cap[Z]} \mathrm{H}_{m-l}(Z, N) \xleftarrow[\cong]{j_*} \mathrm{H}_{m-l}(Z, A).$$

(2) We make the following technical hypothesis:
(∗) Given any neighborhood U of $A \subset \partial Z$ there exists a regular neighborhood N of $A \subset \partial Z$ with $N \subset U$.
Under this hypothesis the isomorphism

$$\mathrm{PD}_Z\colon \mathrm{H}^l(Z, \partial Z \setminus A) \xrightarrow{\cong} \mathrm{H}_{m-l}(Z, A)$$

given in (1) does not depend on the choice of the regular neighborhood N. We denote the inverse of this map by PD_Z as well.

Proof.

(1) Let $N \subset \partial Z$ be a regular neighborhood of A. We denote by $i\colon \partial Z \setminus \mathring{N} \to \partial Z \setminus A$ and $j\colon A \to N$ the inclusion maps. We consider the following diagram:

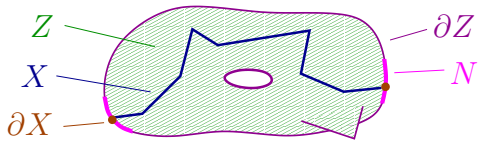
$$\begin{array}{ccccc} \mathrm{H}^l(Z, \partial Z \setminus A) & & \xrightarrow[\cong]{\cap[Z]} & & \mathrm{H}_{m-l}(Z, N) \xleftarrow[\cong]{j_*} \mathrm{H}_{m-l}(Z, A). \\ & \searrow^{i_*} & & \nearrow_{\cong}^{\cap[Z]} & \\ & & \mathrm{H}^l(Z, \partial Z \setminus \mathring{N}) & & \end{array}$$

We make the following observations:
(a) The diagonal cap product exists by Proposition 75.3 (4) together with the Excisive Triad-Proposition 109.12 (4).
(b) It follows from the Cap Product-Naturality Lemma 116.8 (1) that the triangle commutes.
(c) It follows from the hypothesis that N is a regular neighborhood, together with Lemma 123.1 (1), that the maps i and j are both homotopy equivalences. Thus

[1545] It follows from the Excisive Triad-Proposition 109.12 (3) that the cap product $\cap[Z]\colon \mathrm{H}^l(Z, \partial Z \setminus A) \to \mathrm{H}_{m-l}(Z, N)$ is actually defined. It is also worth pointing out that it is not possible to go directly from $\mathrm{H}^l(Z, \partial Z \setminus A)$ to $\mathrm{H}_{m-l}(Z, A)$ via capping with $[Z]$, since $(\partial Z, \partial Z \setminus A, A)$ is not an excisive triad.

we obtain from Corollary 74.16 and the Homotopic Maps-H*-Lemma 108.13 that the induced maps i^* and j_* are isomorphisms.

(d) It follows from the Poincaré Duality Theorem 119.1, which we can apply by Proposition 75.3 (4), that the right diagonal map is an isomorphism.



The above argument shows that the two horizontal maps are both isomorphisms.

(2) We need to show that the map in (1) does not depend on the choice of the regular neighborhood N. Thus let M and N be regular neighborhoods of $A \subset \partial Z$. It follows immediately from our hypothesis $(*)$ that it suffices to consider the case that $M \subset N$. We consider the following diagram:

$$\begin{array}{ccccc} & & \mathrm{H}_{m-l}(Z,M) & & \\ & \overset{\cap[Z]}{\nearrow}\cong & \downarrow & \overset{\cong}{\nwarrow} & \\ \mathrm{H}^l(Z,\partial Z\setminus A) & & & & \mathrm{H}_{m-l}(Z,A). \\ & \underset{\cap[Z]}{\searrow}\cong & \downarrow & \underset{\cong}{\swarrow} & \\ & & \mathrm{H}_{m-l}(Z,N) & & \end{array}$$

Here all unmarked maps are induced by inclusions. The triangle to the left commutes by the Cap Product-Naturality Lemma 116.8 and the triangle to the right commutes by the functoriality of cohomology groups. But this shows that the upper and the lower path from the left to the right give exactly the same map. ■

Definition. Let Z be a topological manifold. We say a proper submanifold X of Z is well-behaved if given any open neighborhood U of $\partial X \subset \partial Z$ the submanifold ∂X of ∂Z admits a regular neighborhood N with $N \subset U$.

Remark. Almost any proper submanifold X of some topological manifold Z that appears in nature is well-behaved. For example it follows from the Simplicial Regular Neighborhood Proposition 96.13 and Theorem 123.3 that X is well-behaved if ∂X is a PL-submanifold of ∂Z or if ∂X is a smooth submanifold of ∂Z.

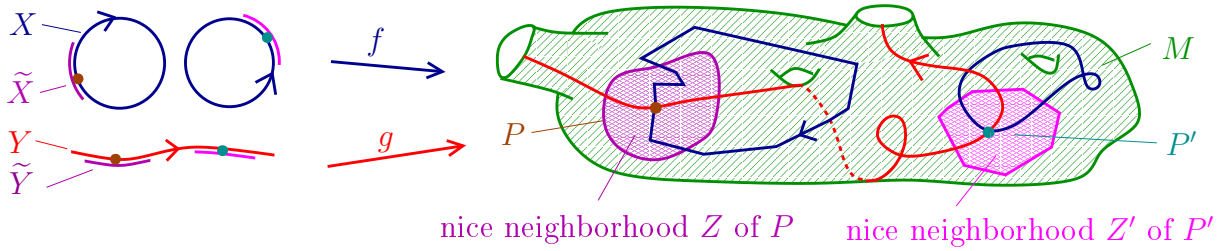
In the following we will study maps between topological manifolds. To simplify the discussion we use the following convention.

Convention. Let M be a topological manifold and let X be a submanifold of M. In our notation and our language often we do not distinguish between X as a submanifold and between the embedding $X \to M$.

Next we fix a convenient notation.

Notation. Given a map $f\colon Y \to X$ between topological spaces we write $|f| := f(Y)$.

Now we can give the first key definition of this chapter.



Definition. Let M be an m-dimensional topological manifold, let X be a k-dimensional topological manifold and let Y be an $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps.

(1) We say a point $P \in |f| \cap |g|$ is a nice intersection point of f and g if given any neighborhood U of P there exists a nice neighborhood Z, this means a submanifold $Z \subset M \setminus \partial M$ such that the following holds:
   (a) Z is homeomorphic to $\overline{B}^m$.
   (b) P is contained in[1546] $\mathring{Z} = Z \setminus \partial Z$ and Z is contained in U.
   (c) $|f| \cap |g| \cap Z = \{P\}$.

   Before we continue we set $\widetilde{X} := f^{-1}(|f| \cap Z)$ and we set $\widetilde{Y} := g^{-1}(|g| \cap Z)$. With this notation we also demand the following:
   (d) $\widetilde{X}$ is a compact codimension-zero submanifold of X and $\widetilde{Y}$ is a compact codimension-zero submanifold of Y.
   (e) The maps $f\colon \widetilde{X} \to Z$ and $g\colon \widetilde{Y} \to Z$ are both proper embeddings.
   (f) $f(\widetilde{X})$ and $g(\widetilde{Y})$ are both well-behaved submanifolds of Z.
   (g) $f(\widetilde{X})$ is homeomorphic to $\overline{B}^k$ and $g(\widetilde{Y})$ is homeomorphic to $\overline{B}^{m-k}$.

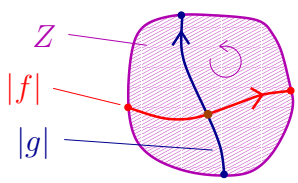
   In the figure below we illustrate the definition for two different nice intersection points.

(2) We say that f and g intersect nicely, if all points in $|f| \cap |g|$ are nice intersection points.

Remark. By the above convention we now also defined the notion of a nice intersection point of two submanifolds and we defined the notion that two submanifolds intersect nicely.

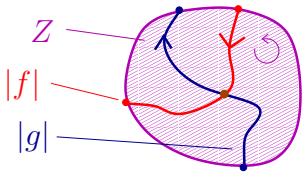
Convention. Let W be an oriented topological manifold. We equip any codimension-zero submanifold of W with the orientation coming from the Topological Manifold-Induced Orientation Lemma 105.17.

Now we are ready to give the second key definition of this chapter.



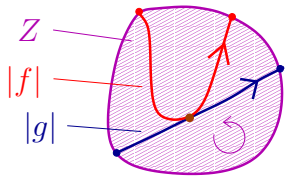
Definition. Let M be an oriented m-dimensional topological manifold, let X be an oriented k-dimensional topological manifold and let Y be an oriented $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps and let P be a nice intersection point of f and g. We pick a nice neighborhood Z of P. We define the

[1546] Note that by (a) we know that Z is a codimension-zero submanifold of M. Since $Z \subset M \setminus \partial M$ we know by Proposition 75.3 that the boundary of Z as a topological manifold agrees with the boundary of Z as a subset of M.



index of f and g at P as follows:[1547]

$$\operatorname{index}(f,g,P) \;=\; \Big\langle \overbrace{\underbrace{\mathrm{PD}_Z(\underbrace{f_*([\widetilde{X}])}_{\in \mathrm{H}_k(Z,\partial f(\widetilde{X}))})}_{\in \mathrm{H}^{m-k}(Z,\partial Z\setminus \partial f(\widetilde{X}))} \cup \underbrace{\mathrm{PD}_Z(\underbrace{g_*([\widetilde{Y}])}_{\in \mathrm{H}_{m-k}(Z,\partial(g(\widetilde{Y})))})}_{\in \mathrm{H}^{k}(Z,\partial Z\setminus \partial g(\widetilde{Y}))}}^{\in \mathrm{H}^m(Z,\partial Z)}, \overbrace{[Z]}^{\in \mathrm{H}_m(Z,\partial Z)} \Big\rangle \in \mathbb{Z}.$$



Example. In the figure below we show, in three cases, the indices of nice intersection points. The first two indices can be determined with some effort using the Poincaré Duality-Products Proposition 119.2 together with Proposition 113.11. Alternatively see Proposition 127.5 below. Finally we outsource the calculation of the third index to Exercise 127.2.

$\operatorname{index}(f,g,P) = +1$

$\operatorname{index}(f,g,P) = -1$

$\operatorname{index}(f,g,P) = 0$

Next we need to show that the index of a nice intersection point is well-defined.

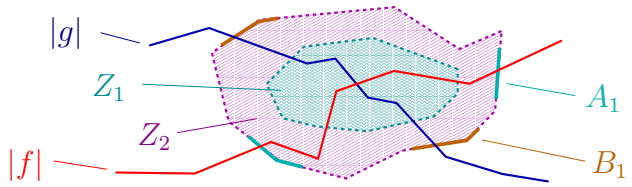
Lemma 127.3. Let M, $f\colon X \to M$ and $g\colon Y \to M$ as in the previous definition and let P be a nice intersection point of f and g. The corresponding index $\operatorname{index}(f,g,P)$ is well-defined, i.e. it is independent of the choice of the nice neighborhood Z of P.

Sketch of a proof. By the "given any neighborhood U of P" aspect of the definition of a nice intersection point it suffices to deal with nice neighborhoods Z_1 and Z_2 with $Z_1 \subset \mathring{Z}_2$. We define $\widetilde{X}_1$, $\widetilde{X}_2$, $\widetilde{Y}_1$ and $\widetilde{Y}_2$ in the obvious way. We pick regular neighborhoods A_1 of $\partial X_1 \subset \partial Z_1$ and B_1 of $\partial Y_1 \subset \partial Z_1$. Similarly we pick A_2 and B_2 with the obvious meaning.

Let $i \in \{1,2\}$. We write $C_i := \partial Z_i \setminus \mathring{A}_i$ and $D_i := \partial Z_i \setminus \mathring{B}_i$. Similar to the proof of the Excision Theorem for Topological Manifolds 75.10 we use the Topological Collar Neighborhood Theorem 75.5 to find open subsets $\widetilde{A}_i$, $\widetilde{B}_i$, $\widetilde{C}_i$ and $\widetilde{D}_i$ of ∂Z_i that admit deformation retractions to A_i, B_i, C_i respectively D_i. Now we consider the following maps

[1547] Here are a few clarifications:

(1) By hypothesis we know that Z, $\widetilde{X}$ and $\widetilde{Y}$ are compact codimension-zero submanifolds of M, X and Y. As we just remarked, by the Topological Manifold-Induced Orientation Lemma 105.17 they inherit an orientation from the given orientations on M, X and Y. As always we denote by $[Z]$, $[\widetilde{X}]$ and $[\widetilde{Y}]$ the corresponding fundamental classes.



(2) By hypothesis $f(\widetilde{X})$ and $g(\widetilde{Y})$ are well-behaved submanifolds of Z. Thus we obtain from Proposition 127.2 the corresponding maps PD_Z.

(3) By hypothesis $f(\widetilde{X})$ and $g(\widetilde{Y})$ are compact. It follows from the Topological Manifold Boundary Proposition 75.2 (4b) that $\partial f(\widetilde{X})$ and $\partial g(\widetilde{Y})$ are compact. By the Compact-Closed Lemma 1.21 (2) this implies that $\partial Z \setminus \partial f(\widetilde{X})$ and $\partial Z \setminus \partial g(\widetilde{Y})$ are open subsets of ∂Z. Since P is the only intersection point of f and g in Z we see that these two open subsets cover all of ∂Z. It now follows from the Excisive Triad-Proposition 109.12 (4) that the cup product is actually defined.

of triads of topological spaces:

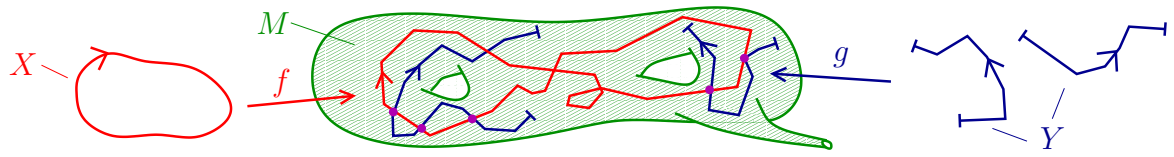
$$\begin{array}{ccccccccc} Z_1 & & Z_1 & & Z_2 & & Z_2 & & Z_2 \\ A_1 & \to & \widetilde{A}_1 & \to & \widetilde{A}_1 \cup ((\mathring{Z}_2 \setminus Z_1) \cup \widetilde{A}_2) & \leftarrow & \widetilde{A}_2 & \leftarrow & A_2 \\ \partial Z_1 \setminus A_1 & & \partial Z_1 \setminus A_1 & & (\partial Z_1 \setminus A_1) \cup (\mathring{Z}_2 \setminus Z_1) \cup (\partial Z_2 \setminus A_2) & & \partial Z_2 \setminus A_2 & & \partial Z_1 \setminus A_2. \end{array}$$

It follows from the Excisive Triad-Proposition 109.12 (4) that all these triads are excisive. Evidently the analogous statement also holds if we replace the A's by B's. Now the lemma can be deduced from the Cup Product-Naturality Proposition 115.4 and the Cap Product-Naturality Lemma 116.8 together with the Codimension Zero-Fundamental Class Lemma 106.24. We leave it to the reader to fill in the details. ■

The following lemma is a generalization of Lemma 126.2.

Lemma 127.4. Let M be an m-dimensional topological manifold, let X be a compact k-dimensional topological manifold and let Y be a compact $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps. If f and g intersect nicely, then $|f| \cap |g|$ is finite.

Proof. Let P be a nice intersection point of f and g. We pick a nice neighborhood Z for P. Note that this means in particular that Z is a codimension-zero submanifold of M with $Z \subset M \setminus \partial M$, $P \in Z \setminus \partial Z$ and with $|f| \cap |g| \cap Z = \{P\}$. By Proposition 75.3 (3) we know that $Z \setminus \partial Z$ is an open subset of M. We have thus shown that P is an isolated point, in the sense of the definition on page 235, of the subspace $|f| \cap |g|$. Since by hypothesis every intersection point is nice we see that $|f| \cap |g|$ is a discrete subset of M. Since X and Y are compact we know by the Compact Image Lemma 2.13 together with the Compact-Union-Intersection Lemma 1.20 (2) that $|f| \cap |g|$ is also compact. Thus we see that $|f| \cap |g|$ is a discrete compact space. By the Compact-Discrete Lemma 1.22 (1) this implies that $|f| \cap |g|$ is a finite set. ■



By Lemma 127.4 it now makes sense to introduce the following definition which can be viewed as an analogue of the definition on page 2748.

Definition. Let M be an oriented m-dimensional topological manifold. Let X be a compact oriented k-dimensional topological manifold and let Y be a compact oriented $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps. If f and g intersect nicely, then we define the algebraic intersection number of f and g to be

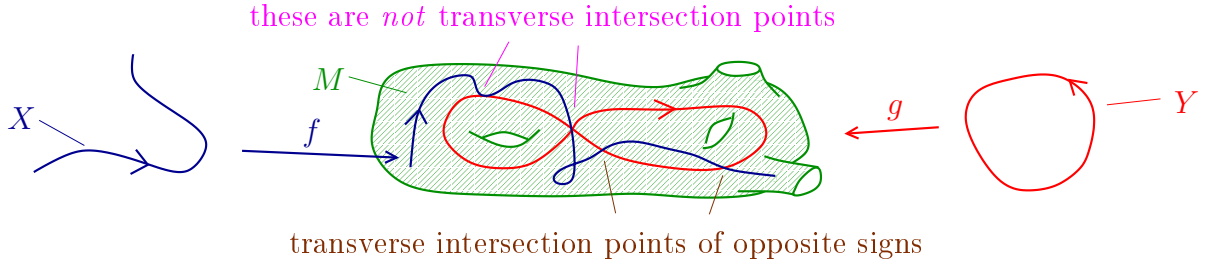
$$f \cdot g \;:=\; \sum_{P \in |f| \cap |g|} \operatorname{index}(f, g, P).$$

↑ finite sum by Lemma 127.4

Remark. Recall that by our convention on page 2777 we do not distinguish between a submanifold X of M and the actual embedding $X \to M$. In particular in the above definition

we also introduced the algebraic intersection number $X \cdot Y$ of two suitable submanifolds of M.

127.2. **Transverse intersection points of maps.** In this section we will see that the notion of a nice intersection points incorporates the notion of a transverse intersection point that we introduced on pages 2748. We will also see that the concept of the algebraic intersection number that we defined in the previous section is a generalization of the algebraic intersection number that we introduced on page 2748.
The following definition can be viewed as a generalization of the concepts we introduced on pages 968 and 2748.



Definition. Let M be an m-dimensional smooth manifold and let $k \in \{1, \dots, m-1\}$. Furthermore let X be a k-dimensional smooth manifold and let Y be an $(m-k)$-dimensional smooth manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be smooth maps.

(1) We say a point $P \in |f| \cap |g|$ is a transverse intersection point of f and g if $P \in M \setminus \partial M$, if $f^{-1}(P)$ contains a single point x_0, if $g^{-1}(P)$ contains a single point y_0, if $x_0 \in X \setminus \partial X$ and $y_0 \in Y \setminus \partial Y$, and if $f_*(\mathrm{T}_{x_0}X) + g_*(\mathrm{T}_{y_0}Y) = \mathrm{T}_P M$.

(2) Now we assume that M, X and Y are oriented. Let P be a transverse intersection point of f and g. We set $\operatorname{sign}(f, g, P) := +1$ if

$$(f_*(\text{positive basis of } \mathrm{T}_{x_0}X), g_*(\text{positive basis of } \mathrm{T}_{y_0}Y)) \;=\; \text{positive basis of } \mathrm{T}_P M,$$

and otherwise we set $\operatorname{sign}(f, g, P) := -1$.

Remark. If X and Y are compact proper submanifolds of M and if f and g are just the inclusion maps, then the above definitions are precisely the definitions provided on pages 968 and 2748.

Proposition 127.5. Let M be an m-dimensional smooth manifold and let $k \in \{1, \dots, m-1\}$. Furthermore let X be a k-dimensional smooth manifold and let Y be an $(m-k)$-dimensional smooth manifold. Finally let $f\colon X \to M$ and $g\colon Y \to M$ be smooth maps.

(1) Let $P \in |f| \cap |g|$. If P is a transverse intersection point of f and g, then P is a nice intersection point of f and g.

(2) If M, X and Y are oriented, then for any transverse intersection point P of f and g we have $\text{index}(f,g,P) = \text{sign}(f,g,P)$.

Proof. The alert reader will doubtlessly notice that the proof of the proposition mostly recycles ideas from the proof of Proposition 126.8 and Lemma 126.9.

Let U be an open neighborhood of P. It follows from the Local Smooth Embedding Theorem 24.8 that there exists an open neighborhood A of x_0 such that the restriction of f to $f\colon A \to M$ is a smooth embedding and such that $f(A) \subset U$. Furthermore, using the hypothesis that $f^{-1}(P) = \{x_0\}$ and using Exercise 18.13 we see that, after possibly shrinking A, we can assume that $f^{-1}(f(A)) = A$.

The same way we can evidently find an open neighborhood B of y_0 such that $g\colon B \to M$ is a smooth embedding, such that $g(B) \subset U$ and such that $g^{-1}(g(B)) = B$.

By the Smooth Embedding Theorem 24.10 we know that $f(A)$ and $g(B)$ are smooth submanifolds of M. By our hypothesis we know that P is a transverse intersection point of $f(A)$ and $g(B)$. It follows from the Submanifold Transversal Intersection Theorem 42.1 that there exists a chart $\Phi\colon V \to W$ for M around P with

$$\Phi(V \cap f(X)) \;=\; W \cap (\mathbb{R}^k \times \{0\}) \quad \text{and} \quad \Phi(V \cap g(Y)) \;=\; W \cap (\{0\} \times \mathbb{R}^{m-k}).$$

Next note that after possibly rescaling W we can assume that $\overline{B}^k \times \overline{B}^{m-k} \subset W$. We set $Z := \Phi^{-1}(\overline{B}^k \times \overline{B}^{m-k})$ and $\widetilde{X} := f^{-1}(Z)$ and $\widetilde{Y} := g^{-1}(Z)$. Note that by construction the maps $\Phi \circ f\colon \widetilde{X} \to \overline{B}^k \times \{0\}$ and $\Phi \circ g\colon \widetilde{Y} \to \{0\} \times \overline{B}^{m-k}$ are diffeomorphisms. It follows easily from the construction that Z has all the properties stated in the definition of a nice intersection point. This concludes the proof of Statement (1).

Now assume that M, X and Y are oriented. We set $\sigma := \text{sign}(f,g,P)$. We make the following preparations:

(1) We equip each $\overline{B}^n$ with the usual orientation coming from $\mathbb{R}^n$.

(2) After possibly composing $\Phi\colon Z \to \overline{B}^k \times \overline{B}^{m-k}$ with reflections in some $(x_i = 0)$-hyperplanes we can assume that the diffeomorphisms $\Phi \circ f\colon f^{-1}(Z) = \widetilde{X} \to \overline{B}^k \times \{0\}$ and $\Phi \circ g\colon g^{-1}(Z) = \widetilde{Y} \to \{0\} \times \overline{B}^{m-k}$ are both orientation-preserving.

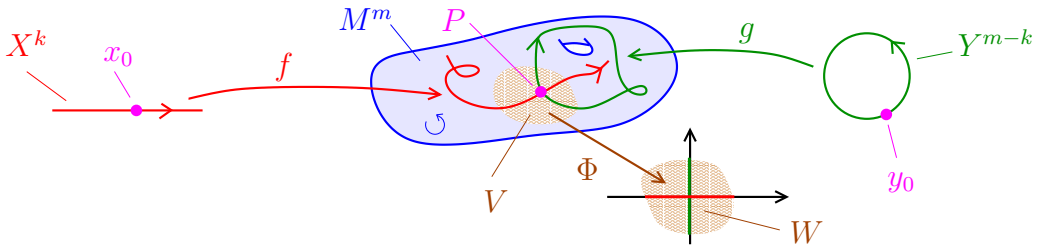
(3) We equip the topological manifold $\overline{B}^k \times \overline{B}^{m-k}$ with the product orientation as defined on page 2502. It follows from Proposition 113.11 that with this orientation the inclusion map $\overline{B}^k \times \overline{B}^{m-k} \to \mathbb{R}^m$ is orientation-preserving.

(4) Elementary linear algebra shows that (2) implies that $\Phi\colon Z \to \overline{B}^k \times \overline{B}^{m-k}$ is orientation-preserving if and only if $\sigma = +1$.

(5) It follows from Proposition 107.2 and Lemma 105.12 that $\Phi_*([Z]) = \sigma \cdot [\overline{B}^k \times \overline{B}^{m-k}]$.

Now we perform the following calculation:

$$\overbrace{\big\langle \text{PD}_Z(f_*[\widetilde{X}]) \cup \text{PD}_Z(g_*[\widetilde{Y}]), [Z] \big\rangle}^{=\text{index}(f,g,P),\ \text{by definition}} \overset{\text{by Lemma 109.6 (3) and the Cup Product-Naturality Lemma 114.10}}{\downarrow}$$



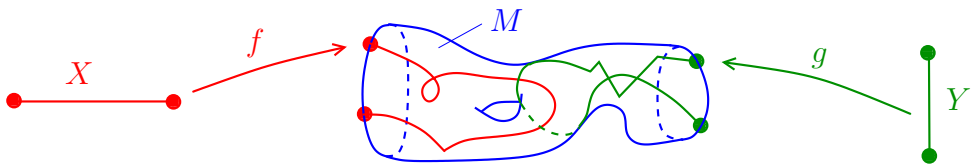
$$= \big\langle \Phi^*(\text{PD}_Z(f_*[\widetilde{X}])) \cup \Phi^*(\text{PD}_Z(g_*[\widetilde{Y}])), \Phi_*([Z]) \big\rangle$$

$$= \big\langle \sigma \cdot \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([\overline{B}^k \times 0]) \cup \sigma \cdot \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([0 \times \overline{B}^{m-k}])), \sigma \cdot [\overline{B}^k \times \overline{B}^{m-k}] \big\rangle$$

$$\overset{\text{by (4) and the pretty elementary Exercise 119.16}}{\uparrow}$$

$$= \sigma^3 \cdot \underbrace{\big\langle \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([\overline{B}^k \times 0]) \cup \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([0 \times \overline{B}^{m-k}])), [\overline{B}^k \times \overline{B}^{m-k}] \big\rangle}_{=1 \text{ by the Poincaré Duality-Products Proposition 119.2}} = \underbrace{\text{sign}(f,g,P)}_{=\sigma}.$$

■



The following is an immediate corollary to Proposition 127.5.

Corollary 127.6. Let M be an oriented m-dimensional smooth manifold, let X be an oriented k-dimensional submanifold and let Y be an oriented $(m-k)$-dimensional submanifold of M. We denote by $i\colon X \to M$ and $j\colon Y \to M$ the inclusion maps. If the submanifolds are transverse in the sense of the definition on page 968, then the maps $i\colon X \to M$ and $j\colon Y \to M$ are intersect nicely and the two definitions of the algebraic intersection given on pages 2748 and 2780 agree.

By Corollary 127.6 the following theorem is a generalization of the Intersection Number-via-Cup Product Theorem 126.5.

Theorem 127.7. Let M be a compact oriented connected m-dimensional topological manifold. Furthermore let A and B be two compact $(m-1)$-dimensional submanifolds of ∂M with $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Let X be a compact oriented k-dimensional topological manifold and let Y be a compact oriented $(m-k)$-dimensional topological manifold. Finally let $f\colon X \to M$ and $g\colon Y \to M$ be two proper maps with $f(\partial X) \subset A$ and $g(\partial Y) \subset B$. If f and g intersect nicely, then

$$f \cdot g = \Big\langle \overbrace{\underbrace{\mathrm{PD}_M(\underbrace{f_*([X])}_{\in \mathrm{H}_k(M,A)})}_{\in \mathrm{H}^{m-k}(M,B)} \cup \underbrace{\mathrm{PD}_M(\underbrace{g_*([Y])}_{\in \mathrm{H}_{m-k}(M,B)})}_{\in \mathrm{H}^{k}(M,A)}}^{\in \mathrm{H}^m(M,\partial M)}, \overbrace{[M]}^{\in \mathrm{H}_m(M,\partial M)} \Big\rangle \in \mathbb{Z}.$$

Remark. It follows immediately from Proposition 127.5 that Theorem 127.7 contains our earlier the Intersection Number-via-Cup Product Theorem 126.5 as a special case.

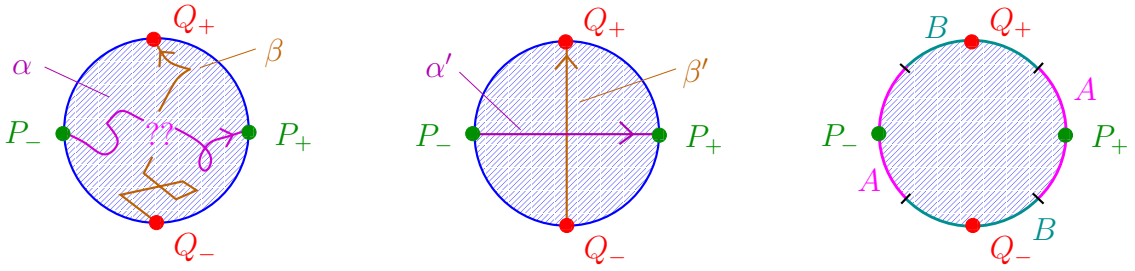
In Theorem 127.14 below we will give a result which takes more time to formulate and which implies the above Theorem 127.7. To keep at least the flow of the definitions and statements coherent we decided to formulate Theorem 127.14 in this section. But rather awkwardly this means that we now provide a proof of Theorem 127.7 that relies on the future Theorem 127.14.

Proof of Theorem 127.7 using Theorem 127.14. It follows easily from Lemma 127.12 that there exists a k-cycle $\sigma \in \mathrm{C}_k(M, A)$ and an $(m-k)$-cycle $\tau \in \mathrm{C}_{m-k}(M, B)$ with the following properties:

(1) we have $[\sigma] = f_*([X])$ and $[\tau] = g_*([Y])$,
(2) the cycles σ and τ are transverse,
(3) the equality $f \cdot g = \sigma \cdot \tau$ holds.

It follows that

$$f \cdot g \;=\; \sigma \cdot \tau \;\underset{\text{Theorem 127.14}}{\uparrow}{=}\; \langle \mathrm{PD}_M([\sigma]) \cup \mathrm{PD}_M([\tau]), [M] \rangle \;\underset{\text{since } [\sigma] = f_*([X]) \text{ and } [\tau] = g_*([Y])}{\uparrow}{=}\; \langle \mathrm{PD}_M(f_*[X]) \cup \mathrm{PD}_M(g_*[Y]), [M] \rangle.$$



■

As promised, we now find it quite easy to answer Question 127.1 in the negative.

Lemma 127.8. We consider the disk $\overline{B}^2$ together with the four points $P_\pm = (\pm 1, 0)$ and $Q_\pm(0, \pm 1)$. If $\alpha\colon [-1,1] \to \overline{B}^2$ is a proper map with $\alpha(\pm 1) = P_\pm$ and if $\beta\colon [-1,1] \to \overline{B}^2$ is a proper map with $\beta(\pm 1) = Q_\pm$, then α and β intersect in at least one point.

Proof. We write $I = [-1,1]$. Suppose that there exist proper maps $\alpha\colon I \to \overline{B}^2$ and $\beta\colon I \to \overline{B}^2$ with $\alpha(\pm 1) = P_\pm$ and with $\beta(\pm 1) = Q_\pm$ such that $|\alpha| \cap |\beta| = \varnothing$. We introduce the following notation:

(1) We consider the "straight paths" $\alpha'\colon I \to \overline{B}^2$ given by $\alpha'(t) = (t, 0)$ and $\beta'\colon I \to \overline{B}^2$ given by $\beta'(t) = (0, t)$.
(2) We write $A = \left\{ \exp(\mathrm{i}t) \,\middle|\, t \in \left[-\tfrac{\pi}{4}, \tfrac{\pi}{4}\right] \cup \left[\tfrac{3\pi}{4}, \tfrac{5\pi}{4}\right] \right\}$ and $B = \left\{ \exp(\mathrm{i}t) \,\middle|\, t \in \left[-\tfrac{3\pi}{4}, -\tfrac{\pi}{4}\right] \cup \left[\tfrac{\pi}{4}, \tfrac{3\pi}{4}\right] \right\}$.
(3) We denote by $\mathrm{PD}_{\overline{B}^2}$ the isomorphisms from the Poincaré Duality Theorem 119.1 corresponding to the decomposition $\partial \overline{B}^2 = A \cup B$.

We perform the following calculation:

$$\begin{array}{ccccccc} & \text{since } |\alpha| \cap |\beta| = \varnothing & & \text{Theorem 127.7} & & & \\ & \downarrow & & \downarrow & & & \\ 0 & = & \alpha \cdot \beta & = & \left\langle \mathrm{PD}_{\overline{B}^2}(\alpha_*([I])) \cup \mathrm{PD}_{\overline{B}^2}(\beta_*([I])), [\overline{B}^2] \right\rangle & & \\ & & & = & \left\langle \mathrm{PD}_{\overline{B}^2}(\alpha'_*([I])) \cup \mathrm{PD}_{\overline{B}^2}(\beta'_*([I])), [\overline{B}^2] \right\rangle & = & \alpha' \cdot \beta' \;=\; \pm 1. \\ & & & & \uparrow & & \uparrow \\ & & & & \text{Theorem 127.7} & & \alpha', \beta' \text{ intersect nicely in one point} \end{array}$$

$$\text{by considering the long exact sequences in homology of the pairs } (\overline{B}^2, A) \text{ and } (\overline{B}^2, B) \text{ we see that } \alpha_*([I]) = \alpha'_*([I]) \text{ and } \beta_*([I]) = \beta'_*([I])$$

We have thus obtained a contradiction. ■

127.3. **Intersections of cycles.** Now we turn to the study of singular chains in a topological manifold. To be on the safe side in our subsequent definitions we introduce the following convention.

Convention.

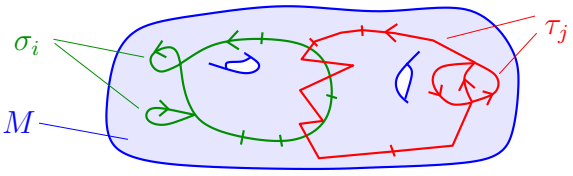
(1) Let X be a topological space. When we write "let $\sigma = a_1 \cdot \sigma_1 + \cdots + a_r \cdot \sigma_r$ be a singular m-chain in X" it is understood that the σ_i are pairwise different and that all the a_i are non-zero. We write $|\sigma| = |\sigma_1| \cup \cdots \cup |\sigma_r|$.

(2) Let M be an oriented m-dimensional topological manifold M and let $\sigma\colon \Delta^k \to M$ and $\tau\colon \Delta^{m-k} \to M$ be singular simplices. Since each Δ^n is in particular a topological manifold it makes sense to say that the singular simplices intersect nicely. Furthermore, throughout this chapter we equip the topological manifold Δ^n with the orientation given by the discussion on page 1581 together with the Smooth-Topological Orientation Proposition 105.11. In particular, if $\sigma\colon \Delta^k \to M$ and $\tau\colon \Delta^{m-k} \to M$ intersect nicely, then we obtain an algebraic intersection number $\sigma \cdot \tau$.

Definition. Let M be an m-dimensional topological manifold and let $\sigma = a_1 \cdot \sigma_1 + \cdots + a_r \cdot \sigma_r$ be a singular k-chain and let $\tau = b_1 \cdot \tau_1 + \cdots + b_s \cdot \tau_s$ be a singular $(m-k)$-chain in M. We say that σ and τ intersect nicely if the following two conditions are satisfied:

(1) For all $i \in \{1, \ldots, r\}$ and $j \in \{1, \ldots, s\}$ the maps $\sigma_i\colon \Delta^k \to M$ and $\tau_j\colon \Delta^{m-k} \to M$ intersect nicely.

(2) For all $(i, j) \neq (i', j') \in \{1, \ldots, r\} \times \{1, \ldots, s\}$ we have



$$(|\sigma_i| \cap |\tau_j|) \cap (|\sigma_{i'}| \cap |\tau_{j'}|) \;=\; \varnothing.$$

Put differently, any intersection point is the intersection point of a unique pair of singular simplices.

If this is the case and if M is oriented, then we define the algebraic intersection number of σ and τ to be

$$\sigma \cdot \tau \;:=\; \sum_{i,j} (a_i \cdot b_j) \cdot \underbrace{(\sigma_i \cdot \tau_j)}_{\uparrow}.$$

algebraic intersection number of $\sigma_i\colon \Delta^k \to M$ and $\tau_j\colon \Delta^{m-k} \to M$

Before we can state the main theorem of this chapter we recall the formulation of the Poincaré Duality theorem for (not necessarily compact) topological manifolds without boundary. Thus let W be an oriented m-dimensional topological manifold without boundary and let $K \subset W$ be a compact subset. By the Homology-Section Theorem 106.10 there exists a unique lift of the orientation classes of W to a class in $\mathrm{H}_m(W, W \setminus K)$. Given any $k \in \mathbb{N}_0$ we denote by

$$- \cap W\colon \mathrm{H}^k(W, W \setminus K) \;\to\; \mathrm{H}_{m-k}(W)$$

the map that is given by capping with this unique lift. Lemma 119.17 says that these maps define a well-defined map

$$- \cap W \colon \mathrm{H}^k_{\mathrm{c}}(W) \ \to \ \mathrm{H}_{m-k}(W).$$

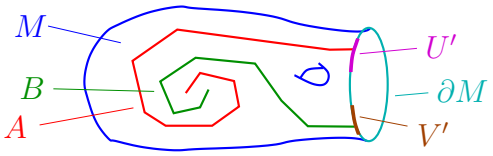
Furthermore the Poincaré Duality the Non-Compact PD Theorem 119.18 says that this map is an isomorphism. We denote by

$$\mathrm{PD}_W \colon \mathrm{H}_{m-k}(W) \ \to \ \mathrm{H}^k_{\mathrm{c}}(W)$$

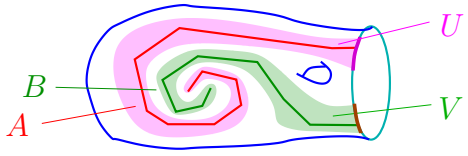
the inverse map. Finally we remind the reader that given a topological space X we denote by $\epsilon_X = \epsilon \colon \mathrm{H}_0(X) \to \mathbb{Z}$ the augmentation map.
Now we can formulate the main theorem of this chapter.

Theorem 127.9. Let M be an oriented m-dimensional topological manifold without boundary. Let $\sigma \in \mathrm{C}_k(M)$ and $\tau \in \mathrm{C}_{m-k}(M)$ be two cycles. If σ and τ intersect nicely, then[1548]

$$\sigma \cdot \tau \ = \ \epsilon_M\Big(\big(\overbrace{\mathrm{PD}_M([\sigma])}^{\in \mathrm{H}^{m-k}_{\mathrm{c}}(M)} \underbrace{\cup \overbrace{\mathrm{PD}_M([\tau])}^{\in \mathrm{H}^{k}_{\mathrm{c}}(M)}}_{\in \mathrm{H}^{m}_{\mathrm{c}}(M)}\big) \cap M\Big).$$



127.4. **Proof of Theorem 127.9.** Before we can provide the proof of Theorem 127.9 we need to recall some definitions and we need to prove several lemmas. First let us recall the following definition from page 123.



Definition. Let X be a topological space.

(1) Let A and B be disjoint subsets of X. We say U and V are separating open neighborhoods for A and B if U and V are disjoint, if U is an open neighborhood of A and if V is an open neighborhood of B.
(2) A topological space X is called normal if any two disjoint closed subsets A and B admit separating open neighborhoods.

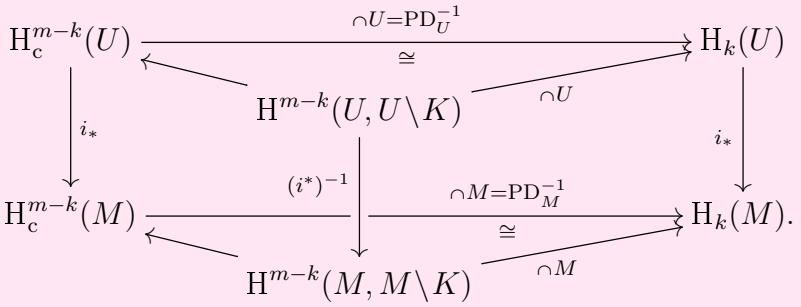
Proposition 127.10.

(1) Every topological manifold is normal.
(2) Let M be a topological manifold and let A and B be two closed disjoint subsets of M. If $U' \subset \partial M$ and $V' \subset \partial M$ are separating open neighborhoods for $A \cap \partial M$ and $B \cap \partial M$, then there exist separating open neighborhoods U and V of A and B such that $U \cap \partial M = U'$ and $V \cap \partial M = V'$.

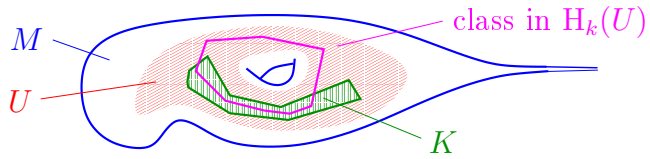
Sketch of proof.

(1) We had proved this statement in the Manifold Paracompact-Normal Proposition 18.9 (2).

[1548] We refer to page 2539 for the definition of the cup product on cohomology with compact support.



(2) Let M be a topological manifold and let A and B be two closed disjoint subsets of M. We pick a collar neighborhood $\partial M \times [0,1]$ as given by the Topological Collar Neighborhood Theorem 75.5.



Suppose that we are given separating neighborhoods $U' \subset \partial M$ and $V' \subset \partial M$ for $A \cap \partial M$ and $B \cap \partial M$. By the Topological Manifold Boundary Proposition 75.2 the complement $M \setminus \partial M$ is again a smooth manifold. By (1) it is normal. Thus there exist separating open neighborhoods $\widetilde{U}$ and $\widetilde{V}$ for the closed subsets $A \cap (M \setminus \partial M)$ and $B \cap (M \setminus \partial M)$. It follows from the Manifold Boundary-Closed Subset Lemma 18.6 (1) that $\widetilde{U}$ and $\widetilde{V}$ are open subsets of M. It is now straightforward to verify that $U := \widetilde{U} \cup ([0,1) \times U')$ and $V := \widetilde{V} \cup ([0,1) \times V')$ have all the desired properties. ■

Lemma 127.11. Let M be an oriented m-dimensional topological manifold with $\partial M = \varnothing$ and let $U \subset M$ be an open subset. Let $i\colon U \to M$ be the inclusion map. For any compact subset $K \subset U$ and any $k \in \mathbb{N}_0$ the map

$$i^*\colon \mathrm{H}^{m-k}(M, M \setminus K) \;\to\; \mathrm{H}^{m-k}(U, U \setminus K)$$

is an isomorphism and the following diagram commutes:

Proof. We make the following comments and observations:

(i) By excision, see page 2418, the map $i^*\colon \mathrm{H}^{m-k}(M, M \setminus K) \to \mathrm{H}^{m-k}(U, U \setminus K)$ is an isomorphism.

(iii) The triangles on the top and the bottom commute by definition of PD_U and PD_M, see Lemma 119.17.

(iv) The square to the left commutes by definition of the map $i_*\colon \mathrm{H}_{\mathrm{c}}^{m-k}(U) \to \mathrm{H}_{\mathrm{c}}^{m-k}(M)$, see page 2484.

(v) It follows from the Cap Product-Naturality Lemma 116.8 and Corollary 106.12 (2) that the square to the right commutes.

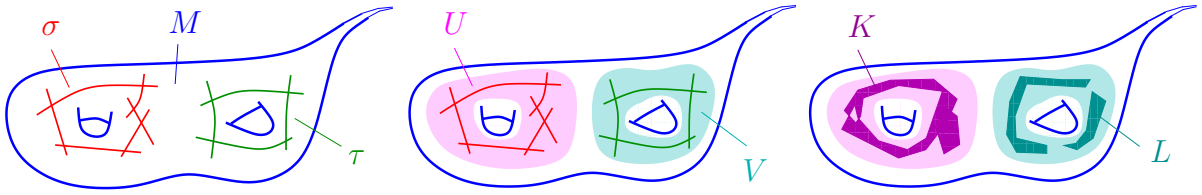
(vi) The rectangle in the back commutes by Lemma 119.24. ■

As in the case of the Intersection Number-via-Cup Product Theorem 126.5 it is perhaps instructive to first prove Theorem 127.9 in the special case that the cycles do not intersect.

Proof of Theorem 127.9 for disjoint cycles. Let M be an oriented m-dimensional topological manifold with $\partial M = \varnothing$. Let $\sigma \in \mathrm{C}_k(M)$ and $\tau \in \mathrm{C}_{m-k}(M)$ be two cycles such that $|\sigma| \cap |\tau| = \varnothing$. We have to show that $\mathrm{PD}_M([\sigma]) \cup \mathrm{PD}_M([\tau]) = 0$.

By Proposition 127.10 we can find separating open neighborhoods U and V for $|\sigma|$ and $|\tau|$. Given a compact subset J of M and given $i \in \mathbb{N}_0$ we denote by $\varphi_J \colon \mathrm{H}^i(M, M \setminus J) \to \mathrm{H}^i_{\mathrm{c}}(M)$ the natural map.

Claim.

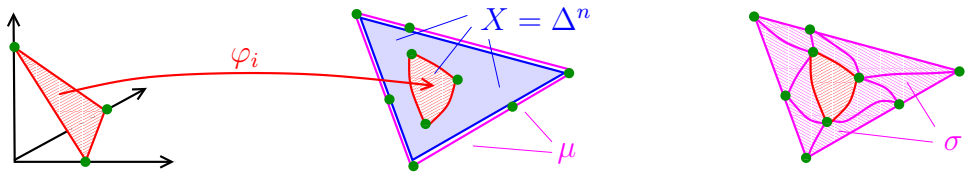


(1) There exists a compact subset $K \subset U$ and a cohomology class $\alpha \in \mathrm{H}^{m-k}(M, M \setminus K)$ such that $\varphi_K(\alpha) = \mathrm{PD}_M([\sigma])$.
(2) There exists a compact subset $L \subset V$ and a cohomology class $\beta \in \mathrm{H}^k(M, M \setminus L)$ such that $\varphi_L(\beta) = \mathrm{PD}_M([\tau])$.

Proof. We consider $\mathrm{PD}_U([\sigma]) \in \mathrm{H}^{m-k}_{\mathrm{c}}(U)$. By definition of cohomology with compact support there exists a compact subset K of U such that $\mathrm{PD}_U([\sigma])$ lies in the image of the natural map $\mathrm{H}^{m-k}(U, U \setminus K) \to \mathrm{H}^{m-k}_{\mathrm{c}}(U)$. The first statement of the claim now follows from Lemma 127.11. The proof of the second statement is evidently basically the same. ⊞

We consider the following diagram

$$\begin{array}{ccc}
\mathrm{H}^{m-k}_{\mathrm{c}}(M) \times \mathrm{H}^k_{\mathrm{c}}(M) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^m_{c}(M) \\
\Big\uparrow{\scriptstyle \varphi_K \times \varphi_L} \quad \Big\uparrow{\scriptstyle (\mathrm{PD}_M(\alpha), \mathrm{PD}_M(\beta)) \atop \updownarrow \atop (\alpha, \beta)} & & \Big\uparrow{\scriptstyle \varphi_M} \\
\mathrm{H}^{m-k}(M, M \setminus K) \times \mathrm{H}^k(M, M \setminus L) & \xrightarrow{\quad\cup\quad} & \mathrm{H}^m(M, \underbrace{(M \setminus K) \cup (M \setminus L)}_{=M}).
\end{array}$$



The diagram commutes by the definition of the cup product on cohomology with compact support, see page 2539. It follows from the observation that the lower right group is zero that the cup product of $\mathrm{PD}_M([\sigma])$ and $\mathrm{PD}_M([\tau])$ is zero. ■

Lemma 127.12. Let X be a compact oriented, n-dimensional topological manifold. Furthermore let $\varphi_i \colon \Delta^n \to X \setminus \partial X$, $i = 1, \ldots, r$, be orientation-preserving embeddings such that the images are disjoint. We write $W = X \setminus (\varphi_1(\mathring{\Delta}^n) \cup \cdots \cup \varphi_r(\mathring{\Delta}^n))$. Given any representative $\mu \in \mathrm{C}_{n-1}(\partial X)$ of the fundamental class of ∂X there exists a singular n-chain $\sigma \in \mathrm{C}_n(W)$ such that

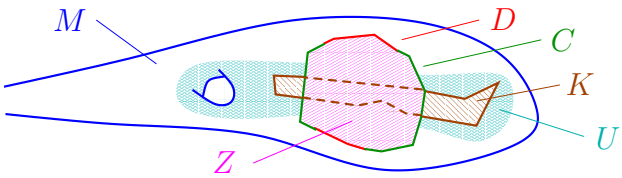
$$\partial(\sigma + \varphi_1 + \cdots + \varphi_r) = \mu \quad \text{and with} \quad [\sigma + \varphi_1 + \cdots + \varphi_r] \;=\; [X].$$

Example. In the proof below of Theorem 127.9 we will apply Lemma 127.12 to the case that $X = \Delta^n$ itself is the standard n-simplex. This particular situation is illustrated in the figure below.

Proof. By Proposition 75.3 we know that W is a compact n-dimensional topological manifold with $\partial W = \varphi_1(\partial\Delta^n) \cup \cdots \cup \varphi_r(\partial\Delta^n) \cup \partial X$. Since the φ_i are orientation-preserving we obtain from the Fundamental Class-of-Boundary Proposition 106.27 that $-\partial\varphi_1 - \cdots - \partial\varphi_r + \mu \in \mathrm{C}_{n-1}(\partial W)$ represents the fundamental class of ∂W. Again by the Fundamental Class-of-Boundary Proposition 106.27 we know that there exists a singular n-chain $\sigma \in \mathrm{C}_n(W)$ with $\partial\sigma = -\partial\varphi_1 - \cdots - \partial\varphi_r + \mu$. It follows from the Fundamental Class-Criterion Proposition 100.4 that $\sigma + \varphi_1 + \cdots + \varphi_r$ represents the fundamental class of X. ■

The formulation of the following, rather technical lemma, might initially be somewhat intimidating. We hope that the figure below helps somewhat with keeping track of the various objects. Also note that the lemma can be viewed as a cousin of first degree to the Codimension-Zero Submanifold-PD Lemma 120.5.

Lemma 127.13. Let M be an oriented m-dimensional topological manifold and let Z be a compact codimension-zero submanifold of M. Furthermore let C and D be two compact codimension-zero submanifolds of ∂Z with $C \cup D = \partial Z$ and with $\partial C = \partial D = C \cap D$.[1549] Let $U \subset M$ be an open subset with $U \cap \partial Z \subset C$ and let $K \subset U$ be a compact subset. We consider the three inclusion maps $p\colon (U, \varnothing) \to (U, U \setminus \mathring{Z})$, $g\colon (Z \cap U, C \cap U) \to (Z, C)$ and $z\colon (Z \cap U, C \cap U) \to (U, U \setminus \mathring{Z})$. We note that the induced map



$$z_*\colon \mathrm{H}_k(Z \cap U, C \cap U) \;\to\; \mathrm{H}_k(U, U \setminus \mathring{Z})$$

is an isomorphism by the Excision Theorem 75.10 for topological manifolds. With this preparation we can now formulate the conclusion of the lemma. Namely, the following diagram commutes:

$$\begin{array}{ccccc}
 & & \mathrm{H}_k(M) & \xleftarrow{\cap M} & \mathrm{H}^{m-k}(M, M\setminus K) \\
 & \nearrow & & \swarrow & \\
\mathrm{H}_k(U) & & \xleftarrow{\cap U} & & \mathrm{H}^{m-k}(U, U\setminus K) \\
\downarrow{\scriptstyle p_*} & & & & \\
\mathrm{H}_k(U, U\setminus\mathring{Z}) & \xrightarrow{(z_*)^{-1}} & \mathrm{H}_k(Z\cap U, C\cap U) & \xrightarrow{g_*} & \mathrm{H}_k(Z, C) \xleftarrow{\cap[Z]} \mathrm{H}^{m-k}(Z, D).
\end{array}$$

Here all the unmarked maps are induced by the obvious inclusion maps of (pairs) of topological spaces. Also note that the bottom cap product $\cap[Z]\colon \mathrm{H}^{m-k}(Z, D) \to \mathrm{H}_k(Z, C)$ is defined since our hypothesis on C and D together with the Excisive Triad-Proposition 109.12 (5) imply that (Z, C, D) is an excisive triad.

[1549] In fact in the proof we only need that we have a decomposition $\partial Z = C \cup D$ such that (Z, C, D) is an excisive triad.

Proof. We make the following preparations:

(a) We pick a representative $\nu_M \in \mathrm{H}_m(M, M \setminus K)$ for the lift of the orientation of M and similarly we pick $\nu_U \in \mathrm{H}_m(U, U \setminus K)$.

(b) We consider the two obvious inclusion maps $f\colon (Z, \partial Z) \to (Z, \overbrace{Z \setminus (\mathring{Z} \cap K)}^{=(Z\setminus K)\cup C})$ and $g\colon (Z \cap U, (Z \cap U) \setminus (\mathring{Z} \cap K)) \to (Z, Z \setminus (\mathring{Z} \cap K))$. It follows from the Excision Theorem 74.18 that the map $g_*\colon \mathrm{H}_m(Z \cap U, (Z \cap U) \setminus (\mathring{Z} \cap K)) \to \mathrm{H}_m(Z, Z \setminus (\mathring{Z} \cap K))$ is an isomorphism. We write $\nu_Z := g_*^{-1}(f_*([Z]))$.

Next we consider the following expanded version of the diagram shown in the lemma:

$$\begin{array}{ccccc}
 & & \mathrm{H}_k(M) & \xleftarrow{\cap \nu_M} & \mathrm{H}^{m-k}(M, M \setminus K) \\
 & \nearrow & & \swarrow & \\
\mathrm{H}_k(U) & \xleftarrow{\cap \nu_U} & \mathrm{H}^{m-k}(U, U \setminus K) & & \\
\downarrow & & \downarrow & & \\
\mathrm{H}_k(U, U \setminus \mathring{Z}) & \xrightarrow{(z_*)^{-1}} & \mathrm{H}_k(Z \cap U, C \cap U) & \xleftarrow{\cap \nu_Z} & \mathrm{H}^{m-k}(Z \cap U, (Z \cap U) \setminus K). \\
 & & & \searrow & \\
 & & \mathrm{H}_k(Z, C) & \xleftarrow[\cap f_*([Z])]{} & \mathrm{H}^{m-k}(Z, Z \setminus K) \\
 & & \downarrow = & & \downarrow \\
 & & \mathrm{H}_k(Z, C) & \xleftarrow[\cap [Z]]{} & \mathrm{H}^{m-k}(Z, D).
\end{array}$$

It suffices to show that all the five regions of the diagram commute:

(1) The parallelogram on the top of the diagram commutes by the Cap Product-Naturality Lemma 116.8 applied to the map $h\colon (U, U \setminus K, \varnothing) \to (M, M \setminus K, \varnothing)$, together with the observation that the Codimension Zero-Fundamental Class Lemma 106.24 implies that $h_*(\nu_U) = \nu_M$.

(2) The 4-gon on the right commutes since all maps are induced by inclusions.

(3) For the lower parallelogram we obtain commutativity from applying the Cap Product-Naturality Lemma 116.8 to the inclusion map[1550] $g\colon (Z \cap U, Z \cap U \setminus K, C \cap U) \to (Z, Z \setminus K, C)$.

(4) To show commutativity of the lower rectangle we apply the Cap Product-Naturality Lemma 116.8 to the inclusion map $f\colon (Z, D, C) \to (Z, Z \setminus K, C)$.

[1550]Here we use the symbol for this map of triples of topological spaces. We feel that recycling the name g is justified since this map of triples "contains" our original map $g\colon (Z \cap U, C \cap U) \to (Z, C)$ of pairs of topological spaces.

Finally we turn to the upper rectangle. We need to show that the following rectangle commutes:

$$\begin{array}{ccccc} \mathrm{H}_k(U) & \xleftarrow{\qquad\qquad\cap\nu_U\qquad\qquad} & & & \mathrm{H}^{m-k}(U, U\setminus K) \\ \downarrow{\scriptstyle p_*} & & & & \downarrow{\scriptstyle z^*} \\ \mathrm{H}_k(U, U\setminus \mathring{Z}) & \xleftarrow{z_*} & \mathrm{H}_k(Z\cap U, C\cap U) & \xleftarrow{\cap\nu_Z} & \mathrm{H}^{m-k}(Z\cap U, (Z\cap U)\setminus K). \end{array}$$

Now let $\beta \in \mathrm{H}^{m-k}(U, U\setminus K)$. We have the following equalities in $\mathrm{H}_k(U, U\setminus \mathring{Z})$:

$$\begin{array}{ccccc} p_*(\beta\cap\nu_U) & = & \beta\cap p_*(\nu_U) & & \\ & & \uparrow & & \\ & & \text{Cap Product-Naturality Lemma 116.8 applied to the map } p\colon (U, U\setminus K, \varnothing)\to(U, U\setminus K, U\setminus \mathring{Z}) & & \end{array}$$

$$\begin{array}{ccccc} & & \text{it follows from Lemma 106.31 that we have } p_*(\nu_U) = z_*(\nu_Z) \text{ in } \mathrm{H}_m(U, U\setminus K\cup U\setminus \mathring{Z}) & & \\ & & \downarrow & & \\ \beta\cap z_*(\nu_Z) & = & z_*(z^*(\beta)\cap\nu_Z). & & \\ \uparrow & & & & \\ \text{Cap Product-Naturality Lemma 116.8 applied to the map } z\colon (Z\cap U, Z\cap U\setminus K, C\cap U)\to(U, U\setminus K, U\setminus \mathring{Z}) & & & & \end{array}$$

We have thus shown that the diagram commutes. ■

After all these preparations we can finally attack Theorem 127.9.

Proof of Theorem 127.9. Let M be an oriented m-dimensional topological manifold with $\partial M = \varnothing$. Also let $\sigma = a_1\cdot\sigma_1 + \cdots + a_r\cdot\sigma_r \in \mathrm{C}_k(M)$ and $\tau = b_1\cdot\tau_1 + \cdots + b_s\cdot\tau_s \in \mathrm{C}_{m-k}(M)$ be two singular cycles that intersect nicely.

Claim 1. We can assume that we are in the following setting: There exists an $n\in\mathbb{N}_0$, there exist distinct points $P_1,\ldots,P_n\in M$ and there exist disjoint m-dimensional submanifolds $Z_1,\ldots,Z_n$ of M such that the following hold:

(1) For $i\neq j$ we have $|\sigma_i|\cap|\tau_j| = \varnothing$.
(2) For each $i\in\{1,\ldots,n\}$ we have $|\sigma_i|\cap|\tau_i| = \{P_i\}$.
(3) For $i = n+1,\ldots,\min\{r,s\}$ we have $|\sigma_i|\cap|\tau_i| = \varnothing$.
(4) For $i\in\{1,\ldots,n\}$ the following hold:[1551]
  (a) P_i is contained in $Z_i\setminus\partial Z_i$.
  (b) Z_i is homeomorphic to $\overline{B}^m$.
  (c) The map $\sigma_i\colon\Delta^k\to M$ is actually a proper embedding $\sigma_i\colon\Delta^k\to Z_i$ such that $X_i := \sigma_i(\Delta^k)$ is a well-behaved submanifold of Z_i. By the definition, see page 2777 this means that the submanifold $\partial X_i = \sigma_i(\partial\Delta^k)$ of ∂Z_i admits a regular neighborhood A_i.
  (d) Similarly to (c) the map $\tau_i\colon\Delta^{m-k}\to M$ is a proper embedding $\tau_i\colon\Delta^{m-k}\to Z_i$ such that $Y_i := \tau_i(\Delta^{m-k})$ is a well-behaved submanifold of Z_i. This means that the submanifold $\partial Y_i = \tau_i(\partial\Delta^k)$ of ∂Z_i admits a regular neighborhood B_i.
  (e) We have $A_i\cap B_i = \varnothing$.
  (f) For $j\neq i$ we have $|\sigma_j|\cap Z_i = \varnothing$ and $|\tau_j|\cap Z_i = \varnothing$.

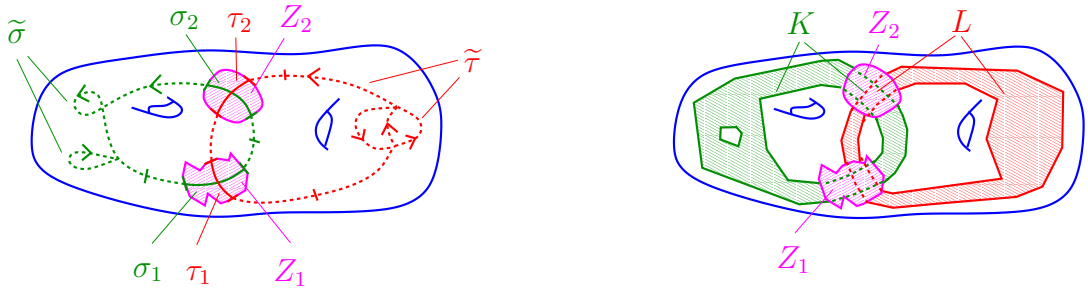
Proof. The proof of the claim is built out of the following ingredients:

(i) The fact, established in Exercise 18.13, that given any map $f\colon\Delta^l\to M$ and given any $P\in M\setminus f(\Delta^l)$ there exists an open neighborhood U of P with $f(\Delta^l)\cap U = \varnothing$.
(ii) The "given any neighborhood U" feature of the definition of a nice intersection point.

[1551] These statements imply in particular that P_i is a nice intersection point of σ_i and τ_i.

(iii) By the Standard Simplex Homeomorphism Lemma 72.1 we know that any Δ^l is homeomorphic to $\overline{B}^l$.

(iv) We use that it follows from (iii) and the definition of a nice intersection point that any $f(\widetilde{X})$ is homeomorphic to Δ^k and that any $g(\widetilde{Y})$ is homeomorphic to Δ^{m-k}. (Here we use the notation from the definition of a nice intersection point, i.e. $\widetilde{X}$ and $\widetilde{Y}$ are defined on page 2778.) We combine this piece of information with Lemma 127.12.



We leave it to the reader to work out the elementary albeit slightly messy details. ⊞

Next we introduce the following notation:

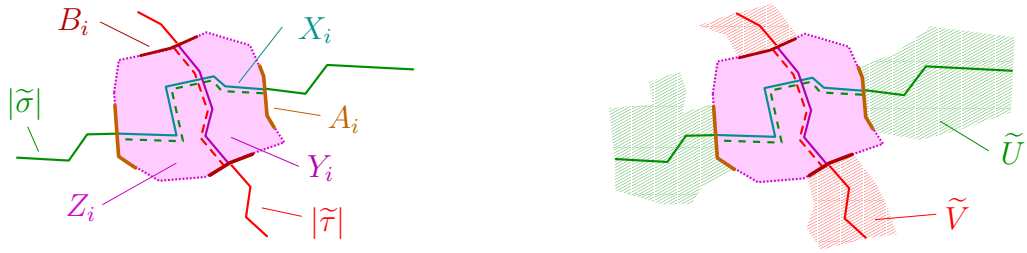
(5) We write $Z = Z_1 \cup \cdots \cup Z_n$.

(6) We write $\widetilde{\sigma} = a_{n+1} \cdot \sigma_{n+1} + \cdots + a_r \cdot \sigma_r$ and we denote by $|\widetilde{\sigma}|$ the union of the images of $\sigma_{n+1}, \ldots, \sigma_r$. Similarly we define $\widetilde{\tau}$ and $|\widetilde{\tau}|$.

We refer to the figure below on the left for an illustration.

Claim 2. There exist compact subsets K and L of M with the following properties:

(a) There exists a cohomology class $\varphi \in \mathrm{H}^{m-k}(M, M \setminus K)$ such that the image of φ in $\mathrm{H}^{m-k}_{\mathrm{c}}(M)$ equals $\mathrm{PD}_M([\sigma])$.



(b) There exists a cohomology class $\psi \in \mathrm{H}^k(M, M \setminus L)$ such that the image of ψ in $\mathrm{H}^k_{\mathrm{c}}(M)$ equals $\mathrm{PD}_M([\tau])$.

(c) We have $K \cap L \cap (M \setminus Z) = \varnothing$.

(d) For each $i \in \{1, \ldots, n\}$ we have $K \cap \partial Z_i \subset A_i$ and $L \cap \partial Z_i \subset B_i$.

We refer to the figure above on the right for an illustration.

Proof. By Proposition 75.3 we know that $W := M \setminus \mathring{Z}$ is an m-dimensional topological manifold. It follows from Proposition 127.10 (2) that there exist *disjoint* open neighborhoods $\widetilde{U} \subset W$ of $|\widetilde{\sigma}|$ and $\widetilde{V} \subset W$ of $|\widetilde{\tau}|$ such that for each $i \in \{1, \ldots, n\}$ we have $\widetilde{U} \cap \partial Z_i = \mathring{A}_i$ and $\widetilde{V} \cap \partial Z_i = \mathring{B}_i$. Next we write $U = \widetilde{U} \cup \bigcup_{i=1}^{n} \mathring{Z}_i$ and $V = \widetilde{V} \cup \bigcup_{i=1}^{n} \mathring{Z}_i$. Note that it follows from the elementary Lemma 1.8 (2) that U and V are open subsets of M. We refer to the figure below for an illustration.

We denote by $i\colon U \to M$ the inclusion map. Evidently we have $\sigma \in \mathrm{C}_k(U)$. Since U is an open subset of M we can thus consider $\mathrm{PD}_U([\sigma]) \in \mathrm{H}_{\mathrm{c}}^{m-k}(U)$. By Lemma 112.2 there exists a compact subset K of U and a cohomology class $\widetilde{\varphi} \in \mathrm{H}^{m-k}(U, U \setminus K)$ such that $\mathrm{PD}_U([\sigma])$ equals the image of $\widetilde{\varphi}$ under the natural map $\mathrm{H}^{m-k}(U, U \setminus K) \to \mathrm{H}_{\mathrm{c}}^{m-k}(U)$. By excision, see page 2418, the map $i^*\colon \mathrm{H}^{m-k}(M, M \setminus K) \to \mathrm{H}^{m-k}(U, U \setminus K)$ is an isomorphism. We set $\varphi := (i^*)^{-1}(\widetilde{\varphi})$. By Lemma 127.11 we know that the image of φ in $\mathrm{H}_{\mathrm{c}}^{m-k}(M)$ equals $\mathrm{PD}_M([\sigma])$.

By precisely the same argument we can also find a compact subset L of V and some cohomology class $\psi \in \mathrm{H}^k(M, M \setminus L)$ such that the image of ψ in $\mathrm{H}_{\mathrm{c}}^k(M)$ equals $\mathrm{PD}_M([\tau])$.

Finally note that by construction K and L, and also φ and ψ satisfy all the desired conditions set out in (a), (b), (c) and (d). ⊞

We continue with some more observations and notation.

(7) For $i = 1, \ldots, n$ we write $K_i = K \cap Z_i$ and $L_i = L \cap Z_i$. Note that by construction we have $K_i \cap L_i \subset \mathring{Z}_i = Z_i \setminus \partial Z_i$.

(8) Given any compact subset T of M we denote by $o\colon (M, \varnothing) \to (M, M \setminus T)$ the obvious map. Also we denote by $o^*\colon \mathrm{H}^*(M, M \setminus T) \to \mathrm{H}_{\mathrm{c}}^*(M)$ the obvious map.

(9) We denote by $z\colon Z \to M$ the inclusion map and we denote by z also all the inclusion maps of pairs of topological spaces where the total spaces are Z and M.

(10) Given $i \in \{1, \ldots, n\}$ we denote by $z_i\colon Z_i \to Z$ the inclusion map. We adopt the same convention as in (9) for pairs of topological spaces.

(11) We view Z as an m-dimensional submanifold of M and we equip Z with the orientation coming from the Topological Manifold-Induced Orientation Lemma 105.17. Given any subset $W \subset Z$ with $\partial Z \subset W$ we denote by $[Z]$ also the image of the fundamental class of Z under the map $\mathrm{H}_m(Z, \partial Z) \to \mathrm{H}_m(Z, W)$. We adopt the same convention for the $[Z_i]$.

(12) Recall that for each $i \in \{1, \ldots, n\}$ we have $K \cap \partial Z_i \subset A_i$ and $L \cap \partial Z_i \subset B_i$. This implies that we obtain the maps of pairs $(Z_i, \partial Z_i \setminus A_i) \to (Z_i, Z_i \setminus K_i)$ and $(Z_i, \partial Z_i \setminus B_i) \to (Z_i, Z_i \setminus L_i)$. We refer to each of these maps as the canonical map c.

(13) For each $i \in \{1, \ldots, n\}$ we have maps of pairs $d\colon (Z_i, \partial Z_i \setminus A_i) \to (Z_i, \partial Z_i \setminus \partial X_i)$ and $d\colon (Z_i, \partial Z_i \setminus B_i) \to (Z_i, \partial Z_i \setminus \partial Y_i)$. Since A_i is a regular neighborhood of ∂X_i and since B_i is a regular neighborhood of ∂Y_i we obtain from the Homotopic Maps-H*-Lemma 108.13 (4) that these maps induce isomorphisms of relative cohomology groups.

(14) By the Homology-Section Theorem 106.10 there exists a unique lift $\mu \in \mathrm{H}_m(M, M \setminus (K \cap L))$ of the orientation classes of M.

With the above definitions and observations it now makes sense to consider the following diagram:

$$
\begin{array}{ccccccc}
\mathrm{H}_{\mathrm{c}}^{m-k}(M)\times\mathrm{H}_{\mathrm{c}}^{k}(M) & \xrightarrow{\cup} & \mathrm{H}_{\mathrm{c}}^{m}(M) & \xrightarrow{\cap M} & \mathrm{H}_0(M) & \xrightarrow{\epsilon_M} & \mathbb{Z} \\
\uparrow{\scriptstyle o^*\times o^*} & & \uparrow{\scriptstyle o^*} & & \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \mathrm{id}} \\
\mathrm{H}^{m-k}(M,M\backslash K)\times\mathrm{H}^{k}(M,M\backslash L) & \xrightarrow{\cup} & \mathrm{H}^{m}(M,M\backslash(K\cap L)) & \xrightarrow{\cap\mu} & \mathrm{H}_0(M) & \xrightarrow{\epsilon_M} & \mathbb{Z} \\
\downarrow{\scriptstyle z^*\times z^*} & & \downarrow{\scriptstyle z^*} & & \uparrow{\scriptstyle z_*} & & \uparrow{\scriptstyle \mathrm{id}} \\
\mathrm{H}^{m-k}(Z,Z\backslash K)\times\mathrm{H}^{k}(Z,Z\backslash L) & \xrightarrow{\cup} & \mathrm{H}^{m}(Z,Z\backslash K\cap L) & \xrightarrow{\cap[Z]} & \mathrm{H}_0(Z) & \xrightarrow{\epsilon_Z} & \mathbb{Z} \\
\downarrow{\scriptstyle \bigoplus_{i=1}^{n} z_i^*\times z_i^*} & & \downarrow{\scriptstyle \bigoplus_{i=1}^{n} z_i^*} & & \uparrow{\scriptstyle \sum_{i=1}^{n} z_{i*}} & & \uparrow{\scriptstyle \mathrm{id}} \\
\bigoplus_{i=1}^{n}\mathrm{H}^{m-k}(Z_i,Z_i\backslash K_i)\times\mathrm{H}^{k}(Z_i,Z_i\backslash L_i) & \xrightarrow{\oplus\cup} & \bigoplus_{i=1}^{n}\mathrm{H}^{m}(Z_i,Z_i\backslash K_i\cap L_i) & \xrightarrow{\oplus\cap[Z_i]} & \bigoplus_{i=1}^{n}\mathrm{H}_0(Z_i) & \xrightarrow[\sum\epsilon_{Z_i}]{} & \mathbb{Z} \\
\downarrow{\scriptstyle \bigoplus_{i=1}^{n} c^*\times c^*} & & \downarrow{\scriptstyle \bigoplus_{i=1}^{n} c^*} & & \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle \mathrm{id}} \\
\bigoplus_{i=1}^{n}\mathrm{H}^{m-k}(Z_i,\partial Z_i\backslash \mathring{A}_i)\times\mathrm{H}^{k}(Z_i,\partial Z_i\backslash \mathring{B}_i) & \xrightarrow{\oplus\cup} & \bigoplus_{i=1}^{n}\mathrm{H}^{m}(Z_i,\partial Z_i) & \xrightarrow{\oplus\cap[Z_i]} & \bigoplus_{i=1}^{n}\mathrm{H}_0(Z_i) & \xrightarrow[\sum\epsilon_{Z_i}]{} & \mathbb{Z} \\
\cong\uparrow{\scriptstyle \bigoplus_{i=1}^{n} d^*\times d^*} & & \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle \mathrm{id}} \\
\bigoplus_{i=1}^{n}\mathrm{H}^{m-k}(Z_i,\partial Z_i\backslash \partial X_i)\times\mathrm{H}^{k}(Z_i,\partial Z_i\backslash \partial Y_i) & \xrightarrow{\oplus\cup} & \bigoplus_{i=1}^{n}\mathrm{H}^{m}(Z_i,\partial Z_i) & \xrightarrow{\oplus\cap[Z_i]} & \bigoplus_{i=1}^{n}\mathrm{H}_0(Z_i) & \xrightarrow[\sum\epsilon_{Z_i}]{} & \mathbb{Z}.
\end{array}
$$

Claim 3. The above diagram commutes.

Proof. In the following we deal with all of the fifteen squares of the diagram.

(a) The square on the top left commutes by definition of the cup product on cohomology with compact support, see page 2539.

(b) The left squares in the second row and also in the fourth row commute by the Cup Product-Naturality Proposition 115.4 (1).

(c) The left square in the third row commutes by the Cup-Cap Disjoint Union Lemma 116.9 (1) together with the aforementioned the Cup Product-Naturality Proposition 115.4 (1).

(d) The middle square in the first row commutes by definition of the map $\cap M$.

(e) It follows from Corollary 106.12 that $z_*([Z]) = \mu \in \mathrm{H}_m(M, M \setminus (K \cap L))$. Therefore we obtain from the Cap Product-Naturality Lemma 116.8 (1) that the middle square in the second row commutes.

(f) It follows from the remark on page 2351 that $\sum_{i=1}^{n} z_{i*}([Z_i]) = [Z]$. Now we obtain from the Cap Product-Naturality Lemma 116.8 (1) and the Cup-Cap Disjoint Union Lemma 116.9 (2) that the middle square in the third row commutes.

(g) The squares that involve the augmentation maps commute by the discussion on page 1594.

(h) It follows from the Cap Product-Naturality Lemma 116.8 (1) and our conventions regarding the meaning of $[Z_i]$ that the middle square in the fourth row commutes.

(i) It follows from the Cup Product-Naturality Proposition 115.4 that the bottom left square commutes.

(j) The remaining squares, that we did not discuss, commute for the trivial reason that the opposite maps in the square are actually on the nose the same map. ⊞

We introduce one last piece of notation:

(15) For each $i \in \{1, \dots, n\}$ we denote by $\mathrm{PD}_{Z_i} \colon \mathrm{H}_k(Z_i, \partial X_i) \to \mathrm{H}^{m-k}(Z_i, \partial Z_i \setminus \partial X_i)$ the isomorphism from Proposition 127.2.

Claim 4. Let $i \in \{1, \dots, n\}$.

(i) For the above $\varphi \in \mathrm{H}^{m-k}(M, M \setminus K)$ we have $(c^* \circ z_i^* \circ z^*)(\varphi) = a_i \cdot d^*(\mathrm{PD}_{Z_i}([X_i]))$.
(ii) For the above $\psi \in \mathrm{H}^k(M, M \setminus L)$ we have $(c^* \circ z_i^* \circ z^*)(\psi) = b_i \cdot d^*(\mathrm{PD}_{Z_i}([Y_i]))$.
(iii) We have
$$\epsilon_{Z_i}\big(\big((d^*(\mathrm{PD}_{Z_i}([X_i])) \cup d^*(\mathrm{PD}_{Z_i}([Y_i]))\big) \cap [Z_i]\big) \;=\; \mathrm{index}(\sigma_i, \tau_i, P_i).$$

Proof.

(i) We introduce the following notation:
(α) We set $U := (M \setminus Z) \cup \bigcup_{i=1}^n \mathring{Z}_i \cup \bigcup_{i=1}^n \mathring{A}_i = M \setminus \bigcup_{i=1}^n (\partial Z_i \setminus \mathring{A}_i)$. It is elementary to see that U is in fact an open subset of M.
(β) We write $C := A_i$ and $D := \partial Z_i \setminus \mathring{A}_i$. Note that it follows from Proposition 75.3 that C and D are compact codimension-zero submanifolds of ∂Z_i with $C \cup D = \partial Z_i$ and with $C \cap D = \partial C = \partial D$.
(γ) We denote by $p \colon (U, \varnothing) \to (U, U \setminus \mathring{Z}_i)$, $\widetilde{z} \colon (Z_i \cap U, C \cap U) \to (U, U \setminus \mathring{Z}_i)$ and $g \colon (Z_i \cap U, C \cap U) \to (Z_i, C)$ the obvious inclusion maps.
We perform the following calculation in $\mathrm{H}_k(Z_i, A_i)$:

$$\underbrace{(c^* \circ z_i^* \circ z^*)(\varphi)}_{\in \mathrm{H}^{m-k}(Z_i, \partial Z_i \setminus \mathring{A}_i)} \cap [Z_i] \;=\; g_*(\widetilde{z}_*^{-1}(p_*([\sigma]))) \;\overset{\text{since } \sigma = a_1 \cdot \sigma_1 + \cdots + a_r \cdot \sigma_r, \text{ since } p_*(\sigma_j) = 0 \text{ for } j \neq i \text{ and since } [\sigma_i] = [X_i]}{=}\; g_*(\widetilde{z}_*^{-1}(p_*(a_i \cdot [X_i]))) \;=\; a_i \cdot [X_i].$$

this follows from Lemma 127.13, applied to the above choices of C and D, and the observation that $\varphi \cap M = [\sigma]$ with $|\sigma| \subset U$, note that here we use that we have $U \cap \partial Z_i \subset C$ and $K \subset U$

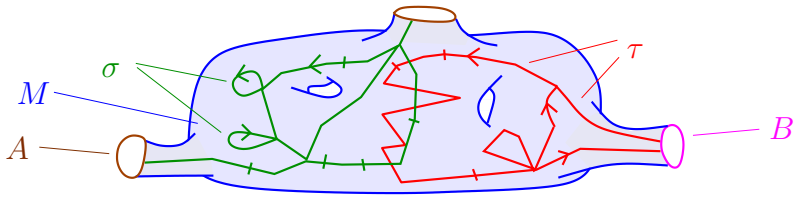
by the Codimension Zero-Fundamental Class Lemma 106.24

Now recall that in the proof of Proposition 127.2 we saw that the isomorphism PD_{Z_i} is given as follows:

$$\mathrm{H}^{m-k}(Z_i, \partial Z_i \setminus \partial X_i) \xrightarrow[\cong]{d^*} \mathrm{H}^{m-k}(Z_i, \partial Z_i \setminus \mathring{A}_i) \xrightarrow[\cong]{\cap [Z_i]} \mathrm{H}_k(Z_i, A_i) \xleftarrow[\cong]{j_*} \mathrm{H}_k(Z_i, \partial X_i).$$
$$\text{with } =: \mathrm{PD}_{Z_i} \text{ running from } \mathrm{H}_k(Z_i, \partial X_i) \text{ back to } \mathrm{H}^{m-k}(Z_i, \partial Z_i \setminus \partial X_i).$$

Since the inclusion induced map $j_* \colon \mathrm{H}_k(Z_i, \partial X_i) \to \mathrm{H}_k(Z_i, A_i)$ is an isomorphism we now see that $(c^* \circ z_i^* \circ z^*)(\varphi) = a_i \cdot d^*(\mathrm{PD}_{Z_i}([X_i]))$.
(ii) The proof of this statement is evidently the same as the proof of (2).
(iii) This statement follows immediately from the definitions together with the fact, obtained in Claim 3, that the bottom squares in the above diagram commute. ⊞

After all these preparations we can prove the desired equality:



$$\begin{aligned}
\epsilon_M\big((\mathrm{PD}_M([\sigma]) \cup \mathrm{PD}_M([\tau])) \cap M\big) &\overset{\text{by construction of } \varphi \text{ and } \psi \text{ in Claim 1 and the first row of the commutative diagram from Claim 2}}{=} \epsilon_M((\varphi \cup \psi) \cap \mu) \\
&\overset{\text{by the second, third and fourth row of the commutative diagram from Claim 2}}{=} \sum_{i=1}^{n} \epsilon_{Z_i}\big(\big((c^* \circ z_i^* \circ z^*)(\varphi) \cup (c^* \circ z_i^* \circ z^*)(\psi)\big) \cap [Z_i]\big) \\
&\overset{\text{by Claim 3}}{=} \sum_{i=1}^{n} a_i \cdot b_i \cdot \mathrm{index}(\sigma_i, \tau_i, P_i) \overset{\text{by the setting from page 2791}}{=} \sigma \cdot \tau.
\end{aligned}$$

This concludes the proof of the theorem. ■

We conclude this section with the following variation on Theorem 127.9.

Theorem 127.14. Let M be a compact orientable connected m-dimensional topological manifold. Furthermore let A and B be compact $(m-1)$-dimensional submanifolds of ∂M with $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Finally let $\sigma \in \mathrm{C}_k(M, A)$ and $\tau \in \mathrm{C}_{m-k}(M, B)$ be two cycles. If σ and τ intersect nicely, then

$$\sigma \cdot \tau = \big\langle \underbrace{\overbrace{\mathrm{PD}_M([\sigma])}^{\in \mathrm{H}^{m-k}(M,B)} \cup \overbrace{\mathrm{PD}_M([\tau])}^{\in \mathrm{H}^{k}(M,A)}}_{\in \mathrm{H}^{m}(M,\partial M)}, [M] \big\rangle.$$

Sketch of proof. The proof of the theorem follows along the lines of the proof of Theorem 127.9. The key difference is that we need to use Poincaré Duality for non-compact topological manifolds with boundary. More precisely, let U be an oriented m-dimensional topological manifold with boundary. By Theorem 106.30, given any compact set K of U the orientation defines a natural homology class μ_K in $\mathrm{H}_m(U, (U \setminus K) \cup \partial U)$. The same construction as in Lemma 119.17, this time using Lemma 106.31 instead of Corollary 106.12, shows that capping with these homology classes defines a well-defined map

$$\mathrm{PD}_U \colon \mathrm{H}^k_{\mathrm{c}}(U) \to \mathrm{H}_{m-k}(U, \partial U).$$

A moderately heroic effort shows that the proof of the Poincaré Duality Theorem 119.1, as provided in Section 119.4 can be modified to show that the above map PD_U is an isomorphism. Once this is out of the way it is fairly straightforward to modify the proof of Theorem 127.9 to obtain a proof of Theorem 127.14. ■

127.5. **The algebraic $\mathbb{F}_2$-intersection number** $(*)$**.** In this section we quickly discuss the "$\mathbb{F}_2$-analogue" of the results of the previous sections.

Definition. Let M be an m-dimensional topological manifold, let X be a k-dimensional topological manifold and let Y be an $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps. If f and g intersect nicely, then we define

$$\text{the algebraic } \mathbb{F}_2\text{-intersection number of } f \text{ and } g \;:=\; f \pitchfork_{\mathbb{F}_2} g \;:=\; \#(|f| \cap |g|) \bmod 2.$$

If X and Y are in fact submanifolds and f and g are the inclusion map, then we write $X \pitchfork_{\mathbb{F}_2} Y := f \pitchfork_{\mathbb{F}_2} g$.

We recall the following notation.

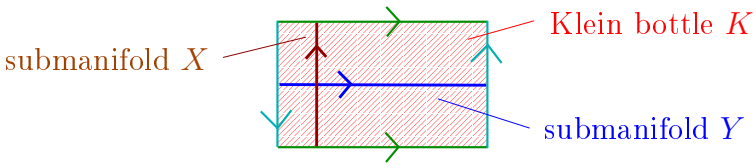
Notation.

(1) In the $\mathbb{F}_2$-Fundamental Class Corollary 106.5 we saw that any compact n-dimensional topological manifold W comes with its $\mathbb{F}_2$-fundamental class $[W]_{\mathbb{F}_2} \in \mathrm{H}_n(W, \partial W; \mathbb{F}_2)$. If W is in fact a proper submanifold of some other topological manifold M, then frequently we denote by $[W]_{\mathbb{F}_2} \in \mathrm{H}_n(M, \partial M; \mathbb{F}_2)$ the image of $[W]_{\mathbb{F}_2}$ under the inclusion induced map $\mathrm{H}_n(W, \partial W; \mathbb{F}_2) \to \mathrm{H}_n(M, \partial M; \mathbb{F}_2)$.

(2) In this section, given a compact topological manifold we denote by PD_M the Poincaré Duality isomorphisms with $\mathbb{F}_2$-coefficients provided by the Poincaré Duality Theorem 119.1.

Now we can formulate the following theorem, which is a variation on Theorem 127.7.

Theorem 127.15. Let M be a compact connected m-dimensional topological manifold. Furthermore let A and B be compact $(m-1)$-dimensional submanifolds of ∂M such that $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Let X be a compact k-dimensional topological manifold and let Y be a compact $(m-k)$-dimensional topological manifold. Finally let $f\colon X \to M$ and $g\colon Y \to M$ be two proper maps with $f(\partial X) \subset A$ and $g(\partial Y) \subset B$. If f and g intersect nicely, then



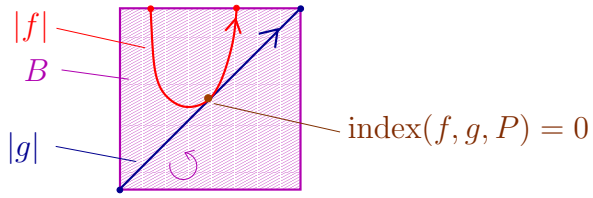
$$f \pitchfork_{\mathbb{F}_2} g \;=\; \Big\langle \overbrace{\mathrm{PD}_M\big(\underbrace{f_*([X]_{\mathbb{F}_2})}_{\in \mathrm{H}_k(M,A;\mathbb{F}_2)}\big)}^{\in \mathrm{H}^{m-k}(M,B;\mathbb{F}_2)} \cup \overbrace{\mathrm{PD}_M\big(\underbrace{g_*([Y]_{\mathbb{F}_2})}_{\in \mathrm{H}_{m-k}(M,B;\mathbb{F}_2)}\big)}^{\in \mathrm{H}^{k}(M,A;\mathbb{F}_2)}, \overbrace{[M]_{\mathbb{F}_2}}^{\in \mathrm{H}_m(M,\partial M;\mathbb{F}_2)} \Big\rangle \;\in\; \mathbb{F}_2^{\in \mathrm{H}^m(M,\partial M;\mathbb{F}_2)}.$$

In particular, if X and Y are already submanifolds of M, then

$$X \pitchfork_{\mathbb{F}_2} Y \;=\; \langle \mathrm{PD}_M([X]_{\mathbb{F}_2}) \cup \mathrm{PD}_M([Y]_{\mathbb{F}_2}), [M]_{\mathbb{F}_2} \rangle.$$

Proof. By the $\mathbb{F}_2$-Orientability Proposition 105.13 every topological manifold is $\mathbb{F}_2$-orientable. With this observation the proof of the theorem is a variation, and basically a simplification, of the proof of the Intersection Number-via-Cup Product Theorem 126.5. We leave it to the skeptical reader to fill in the details. ■

Example. Similar to the discussion on page 2754 we can use Theorem 127.15 to show that some homology classes are in fact non-zero. For example in the figure below we show the Klein bottle K together with two closed 1-dimensional submanifolds. These intersect in precisely one point, so their algebraic $\mathbb{F}_2$-intersection number is necessarily non-zero. Theorem 127.15 implies that $[X]_{\mathbb{F}_2}$ and $[Y]_{\mathbb{F}_2}$ are non-zero in $\mathrm{H}_1(K; \mathbb{F}_2)$.



Remark. A discussion of intersection numbers in topological manifolds is also given in [**Dol1980**, Chapter VIII.13].

Exercises for Chapter 127.

Exercise 127.1. Is every topological space that is Hausdorff also normal?

Exercise 127.2. We consider the manifold $M = Z = [0,1]^2$ and the two embeddings $f, g\colon [0,1] \to Z$ that are shown in the figure below. Note that $P = (0,0)$ is the unique intersection point of $|f|$ and $|g|$. Show that $\operatorname{index}(f,g,P) = 0$.

Exercise 127.3. Can one use the Generalized Alexander Duality Theorem 124.2 to answer Question 127.1? Or some other of the earlier theorems? If yes, how would you do it? You could also try to restrict yourselves to the case that the map α is injective.

Exercise 127.4. Let M be a compact oriented connected n-dimensional topological manifold and let $N \subset M$ be a compact oriented proper submanifold of codimension one. Finally let $\gamma\colon S^1 \to M$ be a map that intersects N nicely. Show that

$$\langle \mathrm{PD}_M([N]), \gamma_*([S^1]) \rangle \;=\; \gamma \cdot N.$$

Exercise 127.5. In the figure on page 2779 we saw that $-1, 0, 1$ can be indices of nice intersection points of oriented submanifolds. Can any other numbers occur as indices of nice intersection points?

Exercise 127.6. Let $n \in \mathbb{N}$. By the discussion on page 2423 we know that for any $k \in \mathbb{N}_0$ we have

$$\mathrm{H}^k(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2) \;\cong\; \begin{cases} \mathbb{F}_2, & \text{if } k = 0, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}$$

Use Theorem 127.15 to show that the obvious map

$$\mathbb{F}_2[x]/(x^{n+1}) \;\to\; (\mathrm{H}^*(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2), \cup)$$

is a ring isomorphism.

Remark. In the Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16 we used a rather different approach to calculating the cup product on $\mathrm{H}^*(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2)$.

128. The Lefschetz-Hopf Theorem

First we recall the following definition from page 2116.

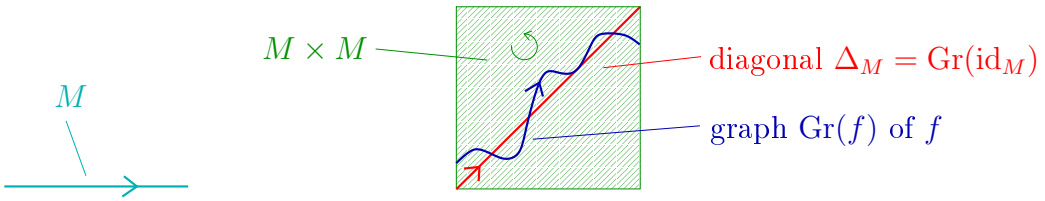
Definition. Let M be a compact topological manifold and let $f\colon M \to M$ be a map. We define the Lefschetz number of f to be

$$\Lambda(f) := \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \operatorname{tr}(f_*\colon \mathrm{H}_n(M;\mathbb{Z}) \to \mathrm{H}_n(M;\mathbb{Z})).$$

The following is one of our main results on the Lefschetz number.

. Theorems 97.10 and 104.12 (Lefschetz Fixed Point Theorem). Let M be a compact smooth or topological manifold and let $f\colon M \to M$ be a map. If the Lefschetz number $\Lambda(f)$ is non-zero, then f has a fixed point.

In this chapter we will prove the Lefschetz-Hopf Theorems 128.5 and 128.9. These allow us to compute the Lefschetz number $\Lambda(f)$ as the sum of "indices" of the fixed points of a given map $f\colon M \to M$. In particular, if there are no fixed points, then this sum is zero. Thus the Lefschetz-Hopf Theorems are generalizations of the above version of the Lefschetz Fixed Point Theorem.



Recall that in the Euler Characteristic-Vector Field Theorem 97.15 we used the Lefschetz Fixed Point Theorem 97.10 to show show that if a closed smooth manifold has non-zero Euler characteristic, then every vector field on M has at least one zero. In the following chapter we will use the Lefschetz-Hopf Theorems 128.5 and 128.9 to prove the Poincaré-Hopf Theorem 129.7 which is a significant generalization of the Euler Characteristic-Vector Field Theorem 97.15.

128.1. **The Lefschetz number as an intersection number.** We start out with recalling and introducing some notation. We will make use of this notation throughout this chapter.

Notation. Let M be an n-dimensional topological respectively smooth manifold.

(1) It follows from Propositions 18.4 and 20.6 that we can view $M \times M$ as an $2n$-dimensional topological respectively smooth manifold (possibly with corner).
(2) We denote by $p_1, p_2\colon M \times M \to M$ the projection onto the first respectively second factor.
(3) We write $\Delta_M := \{(x,x) \in M \times M \mid x \in M\}$.
(4) Let $f\colon M \to M$ be a map. We denote by $\mathrm{id} \times f\colon M \to M \times M$ the map that is given by $x \mapsto (x, f(x))$. We write $\operatorname{Gr}(f) := (\mathrm{id} \times f)(M)$. Note that $\operatorname{Gr}(\mathrm{id}) = \Delta_M$.
(5) The map $\mathrm{id} \times f\colon M \to M$ is easily seen to be a (smooth) proper embedding. Thus we can view $\operatorname{Gr}(f)$ as a proper n-dimensional submanifold of $M \times M$.
(6) Now assume that M is oriented.
    (a) We equip $M \times M$ with the product orientation that we defined on pages 695 and 2502.
    (b) We equip $\operatorname{Gr}(f)$ with the unique orientation that turns $\mathrm{id} \times f$ into an orientation-preserving map.
    (c) If M is furthermore closed, then we denote as usual by $[\operatorname{Gr}(f)] \in \mathrm{H}_n(\operatorname{Gr}(f);\mathbb{Z})$ the fundamental class of $\operatorname{Gr}(f)$. By the usual slight abuse of notation we denote

by $[\mathrm{Gr}(f)] \in \mathrm{H}_n(M \times M; \mathbb{Z})$ the homology class represented by this submanifold. Note that $[\mathrm{Gr}(f)] = (\mathrm{id} \times f)_*([M]) \in \mathrm{H}_n(M \times M; \mathbb{Z})$.

To formulate the main result of this section we will also need the following definition.

Definition.

(1) Given a finitely generated abelian group we write $\mathrm{F}H := H/\operatorname{Tor}(H)$, where $\operatorname{Tor}(H)$ denotes the torsion subgroup of H.

(2) Let W be a closed oriented $2n$-dimensional topological manifold. We refer to the map

$$\begin{array}{rccl} Q_W\colon & \mathrm{FH}_n(W;\mathbb{Z}) \times \mathrm{FH}_n(W;\mathbb{Z}) & \to & \mathbb{Z} \\ & (a,b) & \mapsto & \langle \mathrm{PD}_W(a) \cup \mathrm{PD}_W(b), [W] \rangle \end{array}$$

as the intersection form of W.

Remark. We will discuss the intersection form in great detail in Chapter 132.

Now we can formulate the following, potentially quite counterintuitive proposition.

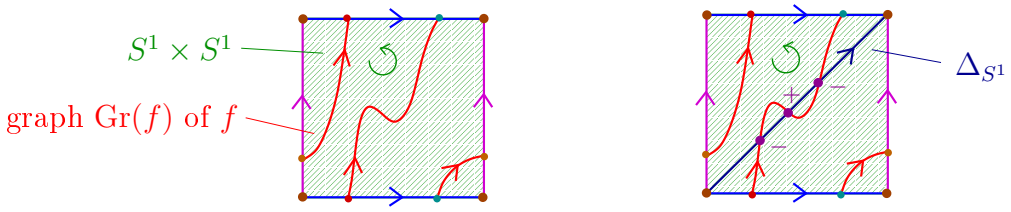
Proposition 128.1. Let M be a closed oriented connected n-dimensional topological manifold.

(1) We have $Q_{M\times M}([\Delta_M], [\Delta_M]) = \chi(M)$.

(2) Given any map $f\colon M \to M$ we have $Q_{M\times M}([\mathrm{Gr}(f)], [\Delta_M]) = \Lambda(f)$.

Remark. Sometimes in the literature, in line with the notation introduced on page 2781, the statement of Proposition 128.1 (1) gets shortened to the potentially ambiguous statement "$M \cdot M = \chi(M)$".

Examples.



(1) Suppose that in Proposition 128.1 we actually have a smooth manifold M and a smooth map $f\colon M \to M$. In this case we can view Δ_M and $\mathrm{Gr}(f)$ as oriented n-dimensional submanifolds of $M \times M$. If these two submanifold are transverse, then it follows from the Intersection Number-via-Cup Product Theorem 126.5 that we can calculate $Q_{M\times M}$ geometrically, more precisely, we have the following equality:

$$Q_{M\times M}([\mathrm{Gr}(f)], [\Delta_M]) \;=\; \begin{array}{c}\text{algebraic intersection number } \mathrm{Gr}(f)\cdot\Delta_M \text{ of the oriented} \\ \text{submanifolds } \Delta_M \text{ and } \mathrm{Gr}(f), \text{ as defined on page 2748.}\end{array}$$

For example, let us consider the map $f\colon S^1 \to S^1$ that is illustrated in the figure below. We see that

$$\mathrm{Gr}(f)\cdot\Delta_M \underset{\substack{\uparrow\\ \text{there are three intersection points}\\ \text{with signs } -1,\ +1 \text{ and } -1}}{=} -1+1-1 \;=\; -1 \underset{\substack{\uparrow\\ \text{since } \mathrm{tr}(f \circlearrowright \mathrm{H}_0(S^1;\mathbb{Z})) = 1\\ \text{and } \mathrm{tr}(f \circlearrowright \mathrm{H}_1(S^1;\mathbb{Z})) = 2}}{=} (-1)^0\cdot 1 + (-1)^1 \cdot 2 \;=\; \Lambda(f).$$

Fortunately this is consistent with Proposition 128.1 (2).

(2) Let $n \in \mathbb{N}$. We have

$$Q_{S^n \times S^n}([\Delta_{S^n}], [\Delta_{S^n}]) \underset{\uparrow}{=} \begin{pmatrix} 1 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ (-1)^{n^2} & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = 1 + (-1)^{n^2} = \chi(S^n).$$

see Lemma 117.3

Again this is consistent with Proposition 128.1 (1).

The proof of Proposition 128.1 requires some preparations. In particular we will need the following lemma.

Lemma 128.2. Let M be a closed oriented connected n-dimensional topological manifold, let $i \in \{0, \ldots, n\}$ and let $v_1, \ldots, v_m$ be a basis of $\mathrm{FH}^i(M; \mathbb{Z})$. There exists a basis $\widetilde{v}_1, \ldots, \widetilde{v}_m$ of $\mathrm{FH}^{n-i}(M; \mathbb{Z})$ such that for any $k, l \in \{1, \ldots, m\}$ we have $\langle v_k \cup \widetilde{v}_l, [M] \rangle = \delta_{kl}$.

Proof of Lemma 128.2. The statement of the lemma is precisely the content of Exercise 119.12. For the reader's convenience we nonetheless provide the proof. For $j = 1, \ldots, m$ we set $\sigma_j := v_j \cap [M] \in \mathrm{FH}_{n-i}(M; \mathbb{Z})$. By the Poincaré Duality Theorem 119.1 we know that $\sigma_1, \ldots, \sigma_m$ is a basis for $\mathrm{FH}_{n-i}(M; \mathbb{Z})$. Next note that it follows from the Universal Coefficient Theorem 110.12 for Cohomology Groups together with the Ext-Calculation Lemma 110.5 (5) and the Topological Manifolds-Invariants Proposition 104.14 (4) that the map

$$\begin{array}{ccc} \mathrm{FH}^{n-i}(M; \mathbb{Z}) & \to & \mathrm{Hom}(\mathrm{FH}_{n-i}(M; \mathbb{Z}), \mathbb{Z}) \\ \varphi & \mapsto & (\sigma \mapsto \langle \varphi, \sigma \rangle) \end{array}$$

is an isomorphism. We denote by $\widetilde{v}_1, \ldots, \widetilde{v}_m$ the cohomology classes with $\langle \widetilde{v}_k, \sigma_l \rangle = \delta_{kl}$. By the above $\widetilde{v}_1, \ldots, \widetilde{v}_m$ are a basis for $\mathrm{FH}^{n-i}(M; \mathbb{Z})$. Now we see that for any $k, l \in \{1, \ldots, m\}$ we have

■

Lemma 128.2 allows us to formulate our next lemma, which will be a key ingredient in the proof of Proposition 128.1.

Lemma 128.3. (Dual-of-Diagonal Lemma) Let M be a closed oriented connected n-dimensional topological manifold. For $i = 0, \ldots, n$ we pick a basis $v_1^i, \ldots, v_{m_i}^i$ of $\mathrm{FH}^i(M; \mathbb{Z})$. By Lemma 128.2 there exists a basis $\widetilde{v}_1^{n-i}, \ldots, \widetilde{v}_{m_i}^{n-i}$ of $\mathrm{FH}^{n-i}(M; \mathbb{Z})$ such that for any $k, l \in \{1, \ldots, m_i\}$ we have $\langle v_k^i \cup \widetilde{v}_l^{n-i}, [M] \rangle = \delta_{kl}$.

(1) We have the following equality in $\mathrm{H}^n(M \times M; \mathbb{Z})$:

$$\mathrm{PD}_{M \times M}([\Delta_M]) = \sum_{i=0}^{n} (-1)^{i \cdot (n-i-1)} \cdot \sum_{r=1}^{m_i} p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_r^i).$$

(2) Given any map $f\colon M \to M$ we have the following equality in $\mathrm{H}^n(M \times M; \mathbb{Z})$:

$$\mathrm{PD}_{M\times M}([\mathrm{Gr}(f)]) \;=\; \sum_{i=0}^{n} (-1)^{i\cdot(n-i-1)} \cdot \sum_{k=1}^{m_i}\sum_{l=1}^{m_i} \underbrace{\langle v_k^i \cup f^*(\widetilde{v}_l^{n-i}), [M]\rangle}_{\in\mathbb{Z}} \cdot p_1^*(\widetilde{v}_k^{n-i}) \cup p_2^*(v_l^i).$$

Proof of the Dual-of-Diagonal Lemma 128.3. First we show that Statement (1) follows almost immediately from Statement (2). Indeed, we have

$$\mathrm{PD}_{M\times M}(\overbrace{[\mathrm{Gr}(\mathrm{id}_M)]}^{=\Delta_M}) \;=\; \sum_{i=0}^{n} (-1)^{i\cdot(n-i-1)} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_i} \underbrace{\langle v_r^i \cup \widetilde{v}_s^{n-i}, [M]\rangle}_{=\delta_{rs}} \cdot p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_s^i).$$

$\uparrow$ Statement (2) applied to $f = \mathrm{id}_M$

Thus it remains to prove Statement (2) of the Dual-of-Diagonal Lemma 128.3. We start out the proof of Statement (2) with the following claim.

Claim. For $j \in \{0, \ldots, n\}$ and $r, s \in \{1, \ldots, m_j\}$ there exist a unique $a_{j,r,s} \in \mathbb{Z}$ such that

$$\mathrm{PD}_{M\times M}([\mathrm{Gr}(f)]) \;=\; \sum_{j=0}^{n}\sum_{r=1}^{m_j}\sum_{s=1}^{m_j} a_{j,r,s} \cdot p_1^*(\widetilde{v}_r^{n-j}) \cup p_2^*(v_s^j) \;\in\; \mathrm{H}^n(M \times M; \mathbb{Z}).$$

Proof. Recall that by the Topological Manifolds-Invariants Proposition 104.14 (4) we know that the homology groups of M are all finitely generated. Thus it follows from the Künneth Theorem 117.16 for Cohomology Groups that there exists a short exact sequence of the following form:

$$0 \to \bigoplus_{j=0}^{n} \mathrm{H}^{n-j}(M;\mathbb{Z}) \otimes \mathrm{H}^j(M;\mathbb{Z}) \to \mathrm{H}^n(M\times M;\mathbb{Z}) \to \bigoplus_{j=0}^{n+1} \overbrace{\mathrm{Tor}(\mathrm{H}^{n+1-j}(M;\mathbb{Z}), \mathrm{H}^j(M;\mathbb{Z}))}^{\substack{\text{torsion group by the}\\ \text{Tor-Properties Lemma 89.15 (8)}}} \to 0.$$

$$\varphi \otimes \psi \mapsto p_1^*(\varphi) \cup p_2^*(\psi)$$

The Künneth Theorem 117.16 also says that the short exact sequence splits. Since the group on the right is torsion it follows easily, using some of the elementary properties of tensor product that we listed in the Tensor Lemma 89.3, that the map

$$\bigoplus_{j=0}^{n} \underbrace{\mathrm{FH}^{n-j}(M;\mathbb{Z})}_{=\bigoplus_r \mathbb{Z}\cdot\widetilde{v}_r^{n-j}} \otimes \underbrace{\mathrm{FH}^j(M;\mathbb{Z})}_{=\bigoplus_s \mathbb{Z}\cdot v_s^j} \xrightarrow{\varphi\otimes\psi\mapsto p_1^*(\varphi)\cup p_2^*(\psi)} \mathrm{FH}^n(M\times M;\mathbb{Z})$$

is an isomorphism. The claim follows immediately from this fact. ⊞

First we remind the reader of a few facts on the cup, cap and cross product. To shorten the discussion we leave it to the reader to figure out what the various symbols stand for.

(a) Given $\varphi \in \mathrm{H}^i(M;\mathbb{Z})$ and $\sigma \in \mathrm{H}_i(M;\mathbb{Z})$ we have $\varphi \cap \sigma = \langle \varphi, \sigma\rangle \in \mathrm{H}_0(M;\mathbb{Z}) = \mathbb{Z}$.
(b) By the Cup-Cap Lemma 116.7 we have $(\psi \cup \varphi) \cap \sigma = \varphi \cap (\psi \cap \sigma)$.
(c) By the Cup Product-Commutativity Proposition 114.8 we have $\varphi \cup \psi = (-1)^{\deg(\varphi)\cdot\deg(\psi)} \cdot \psi \cup \varphi$.
(d) Given $g\colon X \to Y$ we know by Lemma 109.6 (3) we have $\langle g^*(\varphi), \sigma\rangle = \langle \varphi, g_*(\sigma)\rangle$.
(e) Given $g\colon X \to Y$ we know by the Cup Product-Naturality Lemma 114.10 that $g^*(\varphi) \cup g^*(\psi) = g^*(\varphi \cup \psi)$.

(f) By the Topological Product Orientation Proposition 113.10 we have $[M \times M] = [M] \times [M]$. Furthermore, by the Fundamental Class-Product Proposition 117.2 we have $p_1^*([M]^*) \cup p_2^*([M]^*) = [M \times M]^*$.

(g) By the Product Theorem 117.1 we have

$$\big(p_1^*(\alpha) \cup p_2^*(\beta)\big) \cap (\mu \times \nu) = (-1)^{\deg(\alpha)\cdot\deg(\beta)+\deg(\beta)\cdot\deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu).$$

(h) By Exercise 113.2 the cross product on H_0 corresponds to multiplication under the augmentation maps.

(i) Given any $k \in \mathbb{Z}$ we have $(-1)^k = (-1)^{k^2}$.

Given $i \in \{0, \dots, n\}$ and $k, l \in \{1, \dots, m_i\}$ we calculate that

$$\begin{aligned}
&\langle p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i}) \cup \mathrm{PD}_{M\times M}([\mathrm{Gr}(f)]), [M\times M]\rangle \\
&\quad = (-1)^n \cdot \langle p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i}), \mathrm{PD}_{M\times M}([\mathrm{Gr}(f)]) \cap [M\times M]\rangle && \text{by (a), (b), (c) and (i)} \\
&\quad = (-1)^n \cdot \langle p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i}), [\mathrm{Gr}(f)]\rangle && \text{by definition of } \mathrm{PD}_{M\times M} \\
&\quad = (-1)^n \cdot \langle p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i}), (\mathrm{id}\times f)_*([M])\rangle && \text{by definition of } [\mathrm{Gr}(f)] \\
&\quad = (-1)^n \cdot \langle (\mathrm{id}\times f)^*(p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i})), [M]\rangle && \text{by (d)} \\
&\quad = (-1)^n \cdot \langle (p_1\circ(\mathrm{id}\times f))^*(v_k^i) \cup (p_2\circ(\mathrm{id}\times f))^*(\widetilde{v}_l^{n-i}), [M]\rangle && \text{by (e)} \\
&\quad = (-1)^n \cdot \langle v_k^i \cup f^*(\widetilde{v}_l^{n-i}), [M]\rangle && \text{since } p_1\circ(\mathrm{id}\times f) = \mathrm{id} \\
&&& \text{and } p_2\circ(\mathrm{id}\times f) = f.
\end{aligned}$$

Next we perform an alternative calculation:

$$\begin{aligned}
&\langle p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i}) \cup \mathrm{PD}_{M\times M}([\mathrm{Gr}(f)]), [M\times M]\rangle \\
&\quad = \Big\langle (p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i})) \cup \sum_{j=0}^{n}\sum_{r=1}^{m_j}\sum_{s=1}^{m_j} a_{j,r,s}\cdot p_1^*(\widetilde{v}_r^{n-j}) \cup p_2^*(v_s^j), [M\times M]\Big\rangle && \text{by the claim} \\
&\quad = (-1)^{(n-i)(n-j)} \cdot \sum_{j=0}^{n}\sum_{r=1}^{m_j}\sum_{s=1}^{m_j} a_{j,r,s} \cdot \langle p_1^*(\overbrace{v_k^i \cup \widetilde{v}_r^{n-j}}^{\in \mathrm{H}^{i+n-j}(M)}) \cup p_2^*(\overbrace{\widetilde{v}_l^{n-i} \cup v_s^j}^{\in \mathrm{H}^{n-i+j}(M)}), [M\times M]\rangle && \text{by (c) and (e)} \\
&\qquad \underbrace{\qquad\qquad}_{=0, \text{ for } i+n-j>n} \quad \underbrace{\qquad\qquad}_{=0, \text{ for } n-i+j>n} \\
&\qquad \underbrace{\qquad\qquad\qquad\qquad\qquad\qquad}_{=0, \text{ for } i\neq j} \\
&\quad = (-1)^{n-i} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_i} a_{i,r,s} \cdot \langle p_1^*(v_k^i \cup \widetilde{v}_r^{n-i}) \cup p_2^*(\widetilde{v}_l^{n-i} \cup v_s^i), [M]\times[M]\rangle && \text{by (f) and (i)} \\
&\quad = (-1)^{n-i} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_i} a_{i,r,s} \cdot \langle v_k^i \cup \widetilde{v}_r^{n-i}, [M]\rangle \cdot \langle \widetilde{v}_l^{n-i} \cup v_s^i, [M]\rangle && \text{by (a), (g) and (h)} \\
&\quad = (-1)^{n-i} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_i} a_{i,r,s} \cdot (-1)^{i\cdot(n-i)} \cdot \underbrace{\langle v_k^i \cup \widetilde{v}_r^{n-i}, [M]\rangle}_{=\delta_{kr}} \cdot \underbrace{\langle v_s^i \cup \widetilde{v}_l^{n-i}, [M]\rangle}_{=\delta_{ls}} && \text{by (c)} \\
&\quad = (-1)^{n-i} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_i} a_{i,r,s} \cdot (-1)^{i\cdot(n-i)} \cdot \delta_{kr} \cdot \delta_{ls} = (-1)^{n-i+i\cdot(n-i)} \cdot a_{i,k,l}.
\end{aligned}$$

Comparing these two calculations of $\langle p_1^*(v_k^i) \cup p_2^*(\widetilde{v}_l^{n-i}) \cup \mathrm{PD}_{M\times M}([\mathrm{Gr}(f)]), [M\times M]\rangle$ we see that $(-1)^{i\cdot(n-i-1)} \cdot \langle v_k^i \cup f^*(\widetilde{v}_l^{n-i}), [M]\rangle = a_{i,k,l}$. But that is exactly what we needed to show. ∎

Now we are finally ready to provide the proof of Proposition 128.1 (1). Note, that as we pointed out in Lemma 97.6, we have $\Lambda(\mathrm{id}) = \chi(M)$. Thus we see that Proposition 128.1 (1) is just a special case of Proposition 128.1 (2). Nonetheless, to reduce the notational mess we first prove Proposition 128.1 (1) separately.

Proof of Proposition 128.1 (1). We start out with the following claim which gives us a description of $\mathrm{PD}_{M\times M}([\Delta_M])$ that differs slightly from the one provided by the Dual-of-Diagonal Lemma 128.3 (1).

Claim. $$\mathrm{PD}_{M\times M}([\Delta_M]) \;=\; \sum_{j=0}^{n} (-1)^j \cdot \sum_{s=1}^{m_j} p_1^*(v_s^j) \cup p_2^*(\widetilde{v}_s^{n-j}).$$

Proof. Let $j \in \{0,\dots,n\}$. Recall that we have $v_r^{n-j} \cup \widetilde{v}_s^j = \delta_{rs}$. From the Cup Product-Commutativity Proposition 114.8 we obtain that $\widetilde{v}_s^j \cup v_r^{n-j} = (-1)^{j\cdot(n-j)} \cdot \delta_{rs}$. In other words, we have $\widetilde{v}_s^j \cup (-1)^{j\cdot(n-j)} \cdot v_r^{n-j} = \delta_{rs}$. Now we see that

$$\mathrm{PD}_{M\times M}([\Delta_M]) \;\underset{\uparrow}{=}\; \sum_{j=0}^{n} \overbrace{(-1)^{j\cdot(n-j-1)} \cdot (-1)^{j\cdot(n-j)}}^{=(-1)^j} \cdot \sum_{s=1}^{m_j} p_1^*(v_s^j) \cup p_2^*(\widetilde{v}_s^{n-j}).$$

by the Dual-of-Diagonal Lemma 128.3 (1), applied to the bases $\{\widetilde{v}_r^j\}_{r=1,\dots,m_j}$ and the corresponding dual bases $\{(-1)^{j\cdot(n-j)} \cdot v_s^j\}_{s=1,\dots,m_j}$

⊞

Now we calculate that

$$\begin{aligned}
&\mathrm{PD}_{M\times M}([\Delta_M]) \cup \mathrm{PD}_{M\times M}([\Delta_M]) = \\
&\quad\underset{\uparrow}{=}\; \Big(\sum_{i=0}^{n} (-1)^{i\cdot(n-i-1)} \cdot \sum_{r=1}^{m_i} p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_r^i)\Big) \cup \Big(\sum_{j=0}^{n} (-1)^j \cdot \sum_{s=1}^{m_j} p_1^*(v_s^j) \cup p_2^*(\widetilde{v}_s^{n-j})\Big)\\
&\qquad \text{by the Dual-of-Diagonal Lemma 128.3 (1) and the claim}\\
&\quad= \sum_{i=0}^{n}\sum_{j=0}^{n} (-1)^{i\cdot(n-i-1)+j} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_j} p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_r^i) \cup p_1^*(v_s^j) \cup p_2^*(\widetilde{v}_s^{n-j})\\
&\quad\underset{\uparrow}{=}\; \sum_{i=0}^{n}\sum_{j=0}^{n} (-1)^{i\cdot(n-i-1)+j} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_j} (-1)^{i\cdot j + j\cdot(n-i)} \cdot \underbrace{p_1^*(\overbrace{v_s^j \cup \widetilde{v}_r^{n-i}}^{\in \mathrm{H}^{j+n-i}(M)}) \cup p_2^*(\overbrace{v_r^i \cup \widetilde{v}_s^{n-j}}^{\in \mathrm{H}^{i+n-j}(M)})}_{=0,\text{ for } i\neq j}\\
&\qquad \underbrace{\qquad\qquad}_{=0 \text{ if } j+n-i>n} \qquad\qquad \underbrace{\qquad\qquad}_{=0 \text{ if } i+n-j>n}\\
&\qquad \text{by the Cup Product-Commutativity Proposition 114.8 and the Cup Product-Naturality Lemma 114.10}\\
&\quad= \sum_{i=0}^{n} (-1)^{i\cdot(n-i-1)} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_i} (-1)^{i\cdot(n-i)} \cdot p_1^*(\underbrace{v_s^i \cup \widetilde{v}_r^{n-i}}_{=\delta_{sr}\cdot[M]^*}) \cup p_2^*(\underbrace{v_r^i \cup \widetilde{v}_s^{n-i}}_{=\delta_{rs}\cdot[M]^*})\\
&\quad\underset{\uparrow}{=}\; \sum_{i=0}^{n} (-1)^{i\cdot(n-i-1)} \cdot \sum_{r=1}^{m_i}\sum_{s=1}^{m_i} (-1)^{i\cdot(n-i)} \cdot p_1^*(\underbrace{v_s^i \cup \widetilde{v}_r^{n-i}}_{=\delta_{sr}\cdot[M]^*}) \cup p_2^*(\underbrace{v_r^i \cup \widetilde{v}_s^{n-i}}_{=\delta_{rs}\cdot[M]^*})\\
&\qquad \text{since } i+i^2 \text{ is even}\\
&\quad= \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} \underbrace{p_1^*([M]^*) \cup p_2^*([M]^*)}_{=[M\times M]^* \text{ by the Fundamental Class-Product Proposition 117.2}} \;=\; \chi(M)\cdot[M\times M]^*.
\end{aligned}$$

The desired statement now follows from the observation that by definition of $[M\times M]^*$ we have $\langle [M\times M]^*, [M\times M]\rangle = 1$. ■

Proof of Proposition 128.1 (2). The proof of Proposition 128.1 (2) is a generalization of the proof of Proposition 128.1 (1). It turns out that this argument is even less readable. In the following we quickly run through the argument and we only explain the steps that

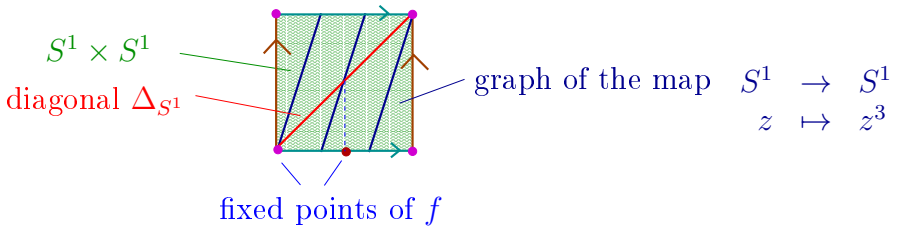
differ from the proof of Proposition 128.1 (2). We calculate that

$$\begin{aligned}
&\mathrm{PD}_{M\times M}([\mathrm{Gr}(f)]) \cup \mathrm{PD}_{M\times M}([\Delta_M]) = \\
&= \Big(\sum_{i=0}^{n} (-1)^{i\cdot(n-i-1)} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_i} \langle v_r^i \cup f^*(\widetilde{v}_s^{n-i}), [M]\rangle \cdot p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_s^i) \Big) \cup \Big(\sum_{j=0}^{n} (-1)^j \cdot \sum_{t=1}^{m_j} p_1^*(v_t^j) \cup p_2^*(\widetilde{v}_t^{n-j}) \Big) \\
&\quad \uparrow \text{ by the Dual-of-Diagonal Lemma 128.3 (2) and the rewriting procedure as in the claim in the proof of Proposition 128.1 (1)} \\
&= \sum_{i=0}^{n} \sum_{j=0}^{n} (-1)^{i\cdot(n-i-1)+j} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_i} \sum_{t=1}^{m_j} \langle v_r^i \cup f^*(\widetilde{v}_s^{n-i}), [M]\rangle \cdot p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_s^i) \cup p_1^*(v_t^j) \cup p_2^*(\widetilde{v}_t^{n-j}) \\
&= \sum_{i=0}^{n} \sum_{j=0}^{n} (-1)^{i\cdot(n-i-1)+j} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_i} \sum_{t=1}^{m_j} (-1)^{i\cdot j + j\cdot(n-i)} \cdot \langle v_r^i \cup f^*(\widetilde{v}_s^{n-i}), [M]\rangle \cdot \underbrace{p_1^*(v_t^j \cup \widetilde{v}_r^{n-i}) \cup p_2^*(v_s^i \cup \widetilde{v}_t^{n-j})}_{=0 \text{ unless } i=j} \\
&= \sum_{i=0}^{n} (-1)^{i\cdot(n-i-1)+i} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_i} \sum_{t=1}^{m_i} (-1)^{i\cdot i + i\cdot(n-i)} \cdot \langle v_r^i \cup f^*(\widetilde{v}_s^{n-i}), [M]\rangle \cdot p_1^*(\underbrace{v_t^i \cup \widetilde{v}_r^{n-i}}_{=\delta_{tr}\cdot[M]^*}) \cup p_2^*(\underbrace{v_s^i \cup \widetilde{v}_t^{n-i}}_{=\delta_{st}\cdot[M]^*}) \\
&= \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} \langle v_r^i \cup f^*(\widetilde{v}_r^{n-i}), [M]\rangle \cdot [M\times M]^* = \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} \Big\langle v_r^i \cup \sum_{s=1}^{m_i} a_{rs}^i \cdot \widetilde{v}_s^{n-i}, [M] \Big\rangle \cdot [M\times M]^* \\
&\quad \uparrow \text{ we define } a_{rs}^i \text{ in the obvious way such that this equality holds} \\
&= \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_i} a_{rs}^i \cdot \underbrace{\langle v_r^i \cup \widetilde{v}_s^{n-i}, [M]\rangle}_{=\delta_{rs}} \cdot [M\times M]^* = \sum_{i=0}^{n} (-1)^i \cdot \underbrace{\sum_{r=1}^{m_i} a_{rr}^i}_{=\mathrm{tr}(f^* \circlearrowleft \mathrm{H}^i(M;\mathbb{Z}))} \cdot [M\times M]^* = \underset{\uparrow}{\Lambda(f)} \cdot [M\times M]^*. \\
&\qquad\qquad \text{by Exercise 110.12}
\end{aligned}$$

As in the proof of Proposition 128.1 (1) we are now done. ■

128.2. **The Lefschetz-Hopf Theorem I.** In Proposition 128.1 we saw that we can express the Lefschetz number of a self-map of a manifold as an intersection number. Furthermore in the Intersection Number-via-Cup Product Theorem 126.5 and in the more fancy Theorem 127.9 we learned how to determine intersection numbers using signs and indices of intersection points. The combination of the results, together with some fairly standard arguments, allows to prove two versions of the Lefschetz-Hopf Theorem. In this section we will use the more elementary the Intersection Number-via-Cup Product Theorem 126.5 to prove the more basic version of the Lefschetz-Hopf Theorem.

Definition.



(1) Let M be a smooth manifold and let $f\colon M \to M$ be a smooth map.
   (a) Let $x \in M$ be a fixed point of f. Note that the differential $\mathrm{D}f_x$ is an endomorphism $\mathrm{D}f_x\colon \mathrm{T}_xM \to \mathrm{T}_xM$. We say that the fixed point x is non-degenerate if the endomorphism $\mathrm{id}_{\mathrm{T}_xM} - \mathrm{D}f_x$ of T_xM is invertible. Otherwise we say that the fixed point is degenerate.
   (b) Given a non-degenerate fixed point $x \in M$ we define

$$\mathrm{index}(f,x) \;:=\; \mathrm{sign}(\det(\mathrm{id} - \mathrm{D}f_x)) \;=\; \frac{\det(\mathrm{id} - \mathrm{D}f_x)}{\|\det(\mathrm{id} - \mathrm{D}f_x)\|}.$$

(2) Let X be a topological space and let $f\colon X \to X$ be a map. We say a fixed point x of f is isolated if there exists a neighborhood U of x which does not contain another fixed point.

Example. Let $n \in \mathbb{Z}$. We consider the map $f\colon S^1 \to S^1$ that is given by $f(z) = z^n$. An elementary calculation shows that for each fixed point $x \in S^1$ the differential $\mathrm{D}f_x$ is given by multiplication by n.

(1) If $n = 1$, then every point on S^1 is a fixed point of f, and each fixed point is degenerate.
(2) If $n \neq 1$, then the fixed points of f are $x_j = \exp(2\pi \mathrm{i} j/(n-1))$, $j = 1, \ldots, |n-1|$. If $n \geq 1$, then the index of every fixed point is $\operatorname{sign}(1-n) = -1$, and if $n \leq 0$, then the index of every fixed point is $\operatorname{sign}(1-n) = +1$.

Lemma 128.4.

(1) Let M be a smooth manifold and let $f\colon M \to M$ be a smooth map. Every non-degenerate fixed point is also an isolated fixed point.
(2) Let X be a topological space and let $f\colon X \to X$ be a map. We assume that X is compact and Hausdorff. In this setting every fixed point of f is isolated if and only if f has only finitely many fixed points.

Proof.

(1) Using charts we see that we only need to consider the case that M is an open subset of some $\mathbb{R}^n$ and we can assume that the fixed point is $x = 0$. We consider the map $g\colon M \to \mathbb{R}^n$ that is given by $x \mapsto x - f(x)$. By our hypothesis we know that $\mathrm{D}g_0 = \mathrm{id}_{\mathrm{T}_0 M} - \mathrm{D}f_0$ is invertible. It follows from the Inverse Function Theorem 19.12 that the map $x \mapsto g(x) = x - f(x)$ is a local diffeomorphism. In particular there exists an open neighborhood U of 0 such that the map $x \mapsto g(x) = x - f(x)$ is injective. But since $g(0) = 0$ this implies that U does not contain any other fixed point of f.
(2) This statement is the content of Exercise 5.20. For the reader's peace of mind we provide the proof. Thus let X be a topological space that is compact and Hausdorff. Furthermore let $f\colon X \to X$ be map. We denote by $F \subset X$ be the fixed point set of f.

If F is finite, then it follows easily from the hypothesis that X is Hausdorff that F is a discrete subset of X. Conversely, suppose that F is a discrete subset of X. Note that it follows from the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 together with the Product Topology Properties Proposition 5.6 that Δ_X and $\mathrm{Gr}(f)$ are closed subsets of $X \times X$. Thus $\Delta_X \cap \mathrm{Gr}(f)$ itself is a closed subset of $X \times X$, in particular it is a closed subset of Δ_X. We denote by $p\colon \Delta_X \to X$ the projection onto the first factor. Evidently this map is a homeomorphism and $F = p(\Delta_X \cap \mathrm{Gr}(f))$. Thus we have shown that F is a closed subset of X and by

hypothesis we know that F is discrete. Since X is compact we obtain from the Compact-Discrete Lemma 1.22 (1) that F is indeed finite. ■

Now we can formulate the first version of the Lefschetz-Hopf Theorem.

Theorem 128.5. (Lefschetz-Hopf Theorem I) Let M be a compact orientable smooth manifold and let $f\colon M \to M$ be a smooth map. If every fixed point of f is non-degenerate and if there is no fixed point on ∂M, then[1552]

$$\sum_{\substack{x \text{ a fixed} \\ \text{point of } f}} \operatorname{index}(f,x) \;=\; \Lambda(f).$$

Remark. If a smooth map has no fixed points, then the left hand side of the Lefschetz-Hopf Theorem 128.5 is evidently zero. Thus we see that the Lefschetz-Hopf Theorem 128.5 is a generalization of the Lefschetz Fixed Point Theorem 97.10, applied to the field $\mathbb{F} = \mathbb{Q}$.

Our first example hopefully puts any lingering worries about signs to rest.

Example. Let $n \in \mathbb{Z} \setminus \{1\}$. As on page 2806 we consider the map $f\colon S^1 \to S^1$ that is given by $f(z) = z^n$. We perform the following calculation:

$$\sum_{\substack{x \text{ a fixed} \\ \text{point of } f}} \operatorname{index}(f,x) \underset{\uparrow}{=} \sum_{j=1}^{|n-1|} \operatorname{index}(f, e^{2\pi \mathrm{i} j/(n-1)}) \underset{\uparrow}{=} \sum_{j=1}^{|n-1|} -\operatorname{sign}(n-1) \;=\; -(n-1).$$

both equalities follow from the discussion on page 2806

Fortunately this is consistent with the Lefschetz-Hopf Theorem 128.5 and the following calculation:

$$\Lambda(f) \;=\; \underbrace{\operatorname{tr}(f_*\colon \mathrm{H}_0(S^1;\mathbb{Z}) \to \mathrm{H}_0(S^1;\mathbb{Z}))}_{=1, \text{ see page 1594}} - \underbrace{\operatorname{tr}(f_*\colon \mathrm{H}_1(S^1;\mathbb{Z}) \to \mathrm{H}_1(S^1;\mathbb{Z}))}_{=n, \text{ by Lemma 76.10}} \;=\; 1-n.$$

Just for fun let us consider a second example.

Example. Let $n \in \mathbb{N}$. We consider $M = \mathbb{R}^n \cup \{\infty\}$. We denote by 0 the origin of $\mathbb{R}^n$. In Exercise 23.13 we showed that M is an n-dimensional smooth manifold with the atlas given by the obvious chart for $\mathbb{R}^n$ together with the chart

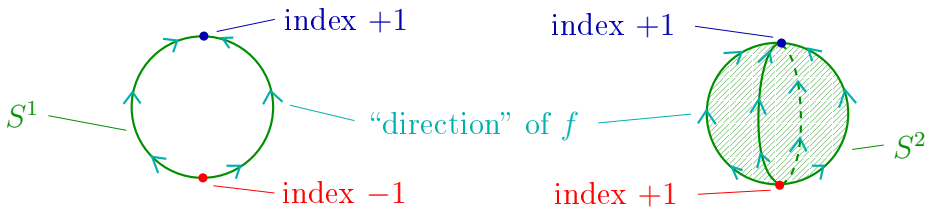
$$\begin{array}{rcl} M \setminus \{0\} & \to & \mathbb{R}^n \\ x & \mapsto & \begin{cases} \frac{1}{\|x\|^2} \cdot x, & \text{if } x \neq \infty, \\ 0, & \text{if } x = \infty. \end{cases} \end{array}$$

Furthermore we showed that the map

$$\begin{array}{rcl} f\colon M & \to & M \\ x & \mapsto & \begin{cases} 3x, & \text{if } x \neq \infty, \\ \infty, & \text{if } x = \infty \end{cases} \end{array}$$

is smooth, that it has two fixed points, namely the origin 0 and ∞, and that $\mathrm{D}f_0 = 3 \cdot \mathrm{id}$ and $\mathrm{D}f_\infty = \frac{1}{3} \cdot \mathrm{id}$. Thus we see

$$\sum_{\substack{x \text{ a fixed} \\ \text{point of } f}} \operatorname{index}(f,x) = \operatorname{index}(f,0) + \operatorname{index}(f,\infty) = \operatorname{sign}(\underbrace{(1-3)^n}_{\det(\mathrm{id} - \mathrm{D}f_0)}) + \operatorname{sign}(\underbrace{(1-\tfrac{1}{3})^n}_{\det(\mathrm{id} - \mathrm{D}f_\infty)}) = (-1)^n + 1.$$



Conveniently enough this is consistent with the Lefschetz-Hopf Theorem 128.5 and the following calculation:

$$\Lambda(f) \underset{\uparrow}{=} \Lambda(\mathrm{id}) \;=\; \chi(S^n) \;=\; 1 + (-1)^n.$$

follows from Lemma 97.7, since f is easily seen to be homotopic to id

[1552] Note that by Lemma 128.4 we know that the left-hand side is a finite sum.

In Lemma 2.18 we gave an explicit diffeomorphism between $\Phi\colon S^n \to M = \mathbb{R}^n \cup \{\infty\}$ that sends the South Pole to the origin and that sends the North Pole to ∞. For $n = 1$ and $n = 2$ we illustrate the map $\Phi^{-1} \circ f \circ \Phi\colon S^n \to S^n$ in the figure below.

Proof of the Lefschetz-Hopf Theorem 128.5. Let M be a compact orientable n-dimensional smooth manifold and let $f\colon M \to M$ be a smooth map such that every fixed point is non-degenerate. We pick an orientation. First we assume that M is closed.

We pick an orientation for M. We equip $\mathrm{Gr}(f) \subset M \times M$ and $\Delta_M \subset M \times M$ with the orientation which turns the projection onto the first factor into an orientation-preserving diffeomorphism.

Claim. Let x be a fixed point of f.[1553]

(1) The point (x, x) is a transverse intersection point of the submanifolds $\mathrm{Gr}(f)$ and Δ_M if and only if x is non-degenerate.

(2) If (x, x) is a transverse intersection point of $\mathrm{Gr}(f)$ and Δ_M, then the sign of the intersection point is given by $\mathrm{index}(f, x) = \frac{\det(\mathrm{id} - \mathrm{D}f_x)}{\|\det(\mathrm{id} - \mathrm{D}f_x)\|}$.

Proof. Note that we have a natural identification $\mathrm{T}_{(x,x)}(M \times M) = \mathrm{T}_x M \times \mathrm{T}_x M$. We pick a positive basis $v_1, \ldots, v_n$ for $\mathrm{T}_x M$. By the definition of the product orientation on $M \times M$, see page 695, we see that the basis $(v_1, 0), \ldots, (v_n, 0), (0, v_1), \ldots, (0, v_n)$ is a positive basis for $\mathrm{T}_{(x,x)}(M \times M)$. Next note that with respect to this basis we have

$$\underbrace{\begin{pmatrix} \mathrm{id}_n \\ \mathrm{D}f_x \end{pmatrix}}_{\substack{\text{positive basis} \\ \text{for } \mathrm{T}_{(x,x)}\mathrm{Gr}(f)}} \text{ followed by } \underbrace{\begin{pmatrix} \mathrm{id}_n \\ \mathrm{id}_n \end{pmatrix}}_{\substack{\text{positive basis} \\ \text{for } \mathrm{T}_{(x,x)}\Delta_M}} \text{ which gives us the matrix } \begin{pmatrix} \mathrm{id}_n & \mathrm{id}_n \\ \mathrm{D}f_x & \mathrm{id}_n \end{pmatrix} \text{ which has the same determinant as } \begin{pmatrix} \mathrm{id}_n & 0 \\ \mathrm{id}_n & \mathrm{id}_n - \mathrm{D}f_x \end{pmatrix}.$$

The desired statements follow immediately from this observation and the definitions. ⊞

Now we perform the following calculation:

$$\Lambda(f) \overset{\text{Proposition 128.1}}{=} \mathrm{Gr}(f) \cdot \Delta_M \overset{\substack{\text{by the Intersection Number-via-Cup Product} \\ \text{Theorem 126.5 and Claim (1)}}}{=} \sum_{\substack{(x,x) \text{ an intersection point} \\ \text{of } \mathrm{Gr}(f) \text{ and } \Delta_M}} \text{sign of } (x,x) \overset{\text{by Claim (2)}}{=} \sum_{\substack{x \text{ a fixed} \\ \text{point of } f}} \mathrm{index}(f, x).$$

We have thus proved the theorem in the special case that M is closed and orientable.

Now we allow that the smooth manifold M has non-empty boundary. As on page 1667 we consider the double $\mathrm{D}M := (M \times \{1\}) \sqcup_{\partial M \times \{1\} = \partial M \times \{2\}} (M \times \{2\})$. By the Doubling-Manifold Lemma 75.12 we know that $\mathrm{D}M$ is a closed orientable smooth manifold. We also

[1553] We refer to pages 2748 and 2748 for the definition of a transverse intersection point and the sign of a transverse intersection point.

consider the "double of f", i.e. we consider the map

$$\begin{array}{rcl} \psi\colon \mathrm{D}M & \to & \mathrm{D}M \\ [(P,\epsilon)] & \mapsto & [(f(P),\epsilon)]. \end{array}$$

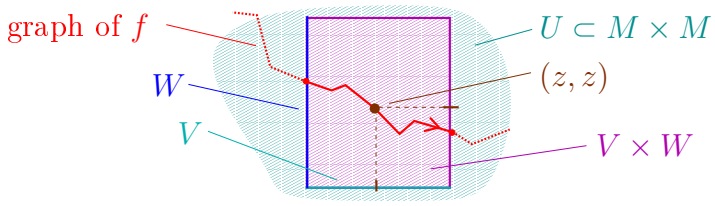
Let $x_1,\ldots,x_k$ be the fixed points of $f\colon M\to M$. Recall that we demand that no fixed point of f lies on ∂M. It follows immediately that the fixed points of ψ are precisely $(x_1,1),\ldots,(x_k,1)$, $(x_1,2),\ldots,(x_k,2)$. Now we see that

$$\begin{aligned} 2\cdot\sum_{i=1}^{k}\operatorname{index}(f,x_i) &\underset{\uparrow}{=} \sum_{i=1}^{k}\operatorname{index}(\psi,(x_i,1))+\sum_{i=1}^{k}\operatorname{index}(\psi,(x_i,2)) \underset{\uparrow}{=} \Lambda(\psi\colon \mathrm{D}M\to\mathrm{D}M) \\ &\underset{\uparrow}{=} 2\cdot\Lambda(f\colon M\to M)+\Lambda(f\colon \partial M\to\partial M) \underset{\uparrow}{=} 2\cdot\Lambda(f). \end{aligned}$$

it is elementary to see that $\operatorname{index}(f,x_i)=\operatorname{index}(\psi,(x_i,1))=\operatorname{index}(\psi,(x_i,2))$

by the above, since $\mathrm{D}M$ is a closed orientable smooth manifold

follows from Exercise 97.15



since there are no fixed points on ∂M and since ∂M is a closed orientable smooth manifold we know by the above that $\Lambda(f\colon \partial M\to\partial M)=0$

Dividing both sides by 2 gives us the desired equality. ■

128.3. **The Lefschetz-Hopf Theorem II.** In this section we will formulate and prove an advanced version of the Lefschetz-Hopf Theorem 128.5 which puts fewer restrictions on the fixed points. The down-side is that in general we need to work with a more tricky definition of the index of a fixed point.
We start out with the following not overly exciting lemma.

Lemma 128.6. Let M be an n-dimensional topological manifold and let $f\colon M\to M$ be a map. Let $z\in M\setminus\partial M$ be an isolated fixed point of $f\colon M\to M$. Given any neighborhood U of $(z,z)\in M\times M$ there exists a neighborhood V of $z\in M$ and a neighborhood W of $z\in M$ with the following properties:

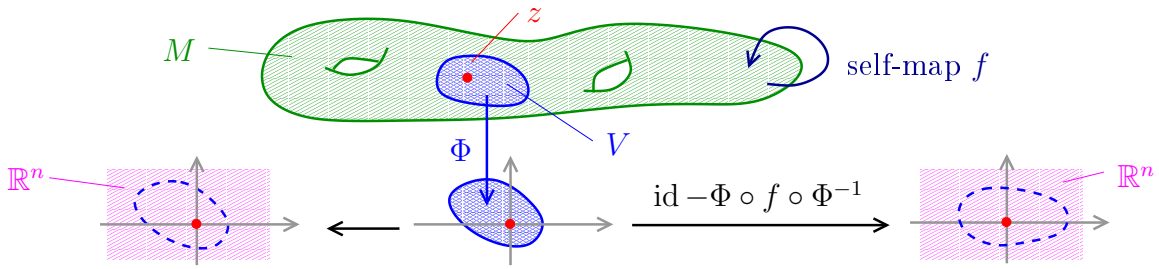
(1) We have $V\times W\subset U$.
(2) z is the only fixed point of f contained in V.
(3) V and W are both submanifolds of M and both are homeomorphic to $\overline{B}^n$.
(4) We have $V\subset\mathring{W}$ and $f(V)\subset\mathring{W}$.

Proof. This lemma follows fairly easily from Exercise 18.6. We leave it to the reader to fill in the details. ■

The lemma allows us to introduce the following definition.

Definition. Let M be an n-dimensional topological manifold and let $f\colon M\to M$ be a map. Furthermore let $z\in M\setminus\partial M$ be an isolated fixed point of f. We pick neighborhoods V and W of z that satisfy Properties (2) and (4) of Lemma 128.6. Furthermore we pick an embedding $\Phi\colon W\to\mathbb{R}^n$ with $\Phi(z)=0$. We define the index $\operatorname{index}(f,z)$ of the fixed

point z as the degree of the following homomorphism:



$\cong \mathbb{Z}$ by the Manifold-Local Homology Lemma 75.1 (2)

$$\overbrace{\mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})} \quad \xleftarrow[\uparrow]{\cong} \quad \mathrm{H}_n(\Phi(V), \Phi(V) \setminus \{0\}) \quad \xrightarrow[\uparrow]{\mathrm{id} - (\Phi \circ f \circ \Phi^{-1})_*} \quad \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}).$$

this map is induced by the inclusion $\Phi(V) \subset \mathbb{R}^n$, it is an isomorphism by the Excision Theorem 74.18, here we also use that we obtain from the Topological Invariance of Domain Theorem 82.7 that $\Phi(V)$ is a neighborhood of 0

map defined since $f(V) \subset W$ and since x is only fixed point of f contained in V

We illustrate this definition in the figure below.

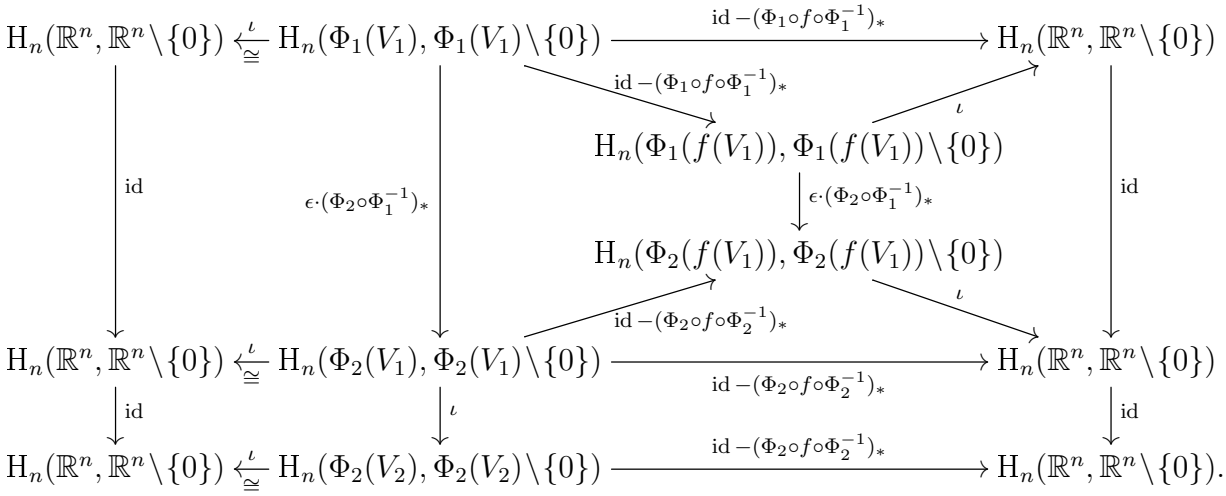
Example. Let $n \in \mathbb{N}$. We consider the map

$$\begin{aligned} f \colon \mathbb{R}^2 = \mathbb{C} &\to \mathbb{C} = \mathbb{R}^2 \\ z &\mapsto z + z^n. \end{aligned}$$

The point $z = 0$ is evidently an isolated fixed point. Note that $f'(z) = 1 + nz^{n-1}$. It follows that for $n \geq 2$ we have $\mathrm{id} - \mathrm{D}f_0 = \mathrm{id} - \mathrm{id} = 0$. Thus we we see that for $n \geq 2$ the fixed point 0 is degenerate. Since 0 is an isolated fixed point we can nonetheless define the index using the approach above. We set $V = \overline{B}^2$ and $W = \overline{B}^2_3$ and $\Phi = \mathrm{id}$. Since

$$\mathrm{id} - (\Phi \circ f \circ \Phi^{-1}) \;=\; \mathrm{id} - f \;=\; \mathrm{id} - (\mathrm{id} + (z \mapsto z^n)) \;=\; -(z \mapsto z^n)$$

we obtain easily from Lemma 76.10 that $\mathrm{index}(f, 0) = -n$.



The following lemma says that the above index is well-defined.

Lemma 128.7. Let M be an n-dimensional topological manifold and let $f \colon M \to M$ be a map. For an isolated fixed point $z \in M \setminus \partial M$ of f the above definition of $\mathrm{index}(f, z)$ does not depend on any choices.

Proof. Let V_1, W_1 and V_2, W_2 be neighborhoods of z that satisfy the properties stated in Lemma 128.6 (2) and (4). We pick embeddings $\Phi_1 \colon W_1 \to \mathbb{R}^n$ and $\Phi_2 \colon W_2 \to \mathbb{R}^n$ as in the definition of the index. We need to show that the choices lead to the same index.

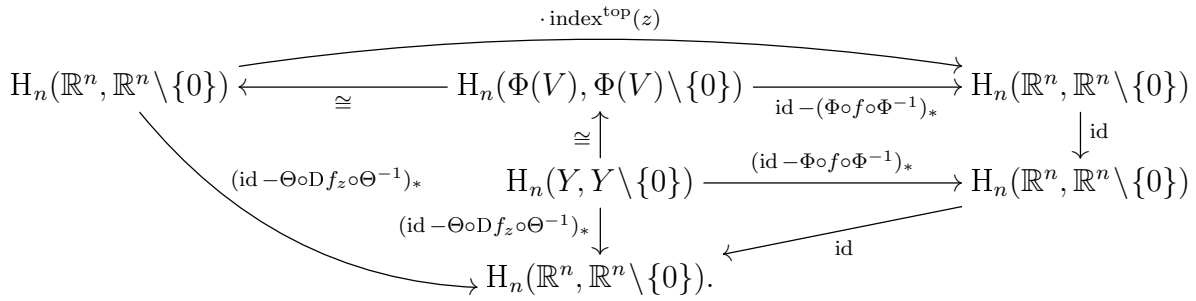
First note that by the "given any neighborhood" feature of Lemma 128.6 we can assume that $V_1 \times W_1 \subset V_2 \times W_2$. Next we set $\epsilon := +1$ if $\Phi_2 \circ \Phi_1^{-1}$ is orientation-preserving, otherwise

we set $\epsilon := -1$. Next we consider the following diagram:

We make the following clarifications and observations:

(1) The maps indicated by ι are the natural inclusion induced maps.
(2) Since $\Phi_1\colon W_1 \to \mathbb{R}^n$ is an embedding and since $V_1 \subset W_1$ we can consider the inverse $\Phi_1^{-1}\colon \Phi_1(V_1) \to V_1$. Furthermore, since $V_1 \subset V_2$ we can consider $\Phi_2(V_1)$ and we have $\Phi_2(V_1) \subset \Phi_2(V_2)$.
(3) It follows fairly immediately from the definition of ϵ that the diagram commutes.
(4) The left horizontal maps are isomorphisms by the Excision Theorem 74.18.

It follows from the above that the top and the bottom horizontal maps from left to right agree. But this means that we obtain the same degree. ■



The following lemma shows that the two notions of the index of a fixed point of a smooth map, introduced on pages 2805 and 2810 are consistent.

Lemma 128.8. Let M be a smooth manifold, let $f\colon M \to M$ be a smooth map and let $z \in M \setminus \partial M$ be a non-degenerate fixed point of f. The fixed point z is isolated, and the index of z, as defined on page 2805, agrees with the index of z as defined on page 2810.

Proof. Let M be a smooth manifold, let $f\colon M \to M$ be a smooth map and let $z \in M\setminus\partial M$ be a non-degenerate fixed point of f. For the purpose of this proof we denote by $\mathrm{index}^{\mathrm{sm}}(z)$ the index of z as defined on page 2805 and we denote by $\mathrm{index}^{\mathrm{top}}(z)$ the index of z as defined on page 2810.

First note that we already showed in Lemma 128.4 that z is an isolated fixed point. Thus it remains to show that $\mathrm{index}^{\mathrm{top}}(z) = \mathrm{index}^{\mathrm{sm}}(z)$. From our smooth atlas for M we pick a chart $\Phi\colon W \to \mathbb{R}^n$ around z with $\Phi(z) = 0$. It follows fairly easily from the hypothesis that z is a non-degenerate fixed point that there exists an open neighborhood V around z such that $V \subset W$, such that $\Phi(V) \subset W$, and such that V contains no other fixed point of f. We set $\Theta := \mathrm{D}\Phi_z\colon \mathrm{T}_z M \to \mathrm{T}_0\mathbb{R}^n = \mathbb{R}^n$.

Now we consider the following diagram:

We make the following clarifications and observations:

(1) By construction V and W satisfy the properties of Lemma 128.6 (2) and (4). This implies that the composition of the top two horizontal maps is given by multiplication by $\operatorname{index}^{\mathrm{top}}(z)$.
(2) It follows immediately from Lemma 76.15 that there exists an open neighborhood Y of 0, contained in $\Phi(V)$, such that the map $\mathrm{id} - \Phi \circ f \circ \Phi^{-1}$ is homotopic, as a map of pairs $(\Phi(V), \Phi(V) \setminus \{0\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$, to the map $\mathrm{D}(\mathrm{id} - \Phi \circ f \circ \Phi^{-1})_0$.
(3) By the Chain Rule 19.10 we have $\mathrm{D}(\mathrm{id} - \Phi \circ f \circ \Phi^{-1})_0 = \mathrm{id} - \Theta \circ \mathrm{D}f_z \circ \Theta^{-1}$.
(4) It follows from (2) together with Proposition 74.15 and some elementary considerations that the diagram commutes.
(5) It follows from the Excision Theorem 74.18 that the two maps decorated with "$\cong$" are indeed isomorphisms.

We see that

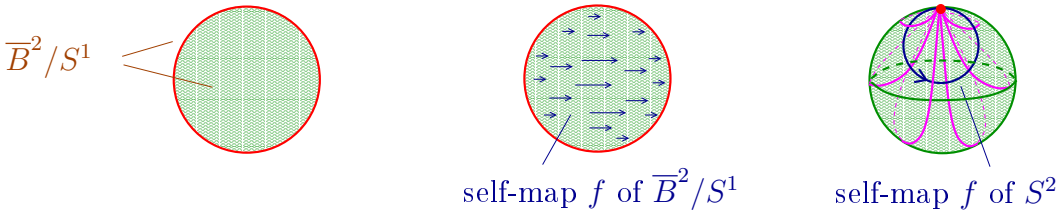
$$\begin{array}{ccc} & \overset{\text{by the above diagram and the above discussion}}{\downarrow} & \overset{\text{by Lemma 76.16}}{\downarrow} \\ \operatorname{index}^{\mathrm{top}}(z) & = \deg((\mathrm{id}_{\mathbb{R}^n} - \Theta \circ \mathrm{D}f_z \circ \Theta^{-1})_*) & = \operatorname{sign}(\det(\mathrm{id}_{\mathbb{R}^n} - \Theta \circ \mathrm{D}f_z \circ \Theta^{-1})) \\ & = \operatorname{sign}(\det(\mathrm{id}_{\mathrm{T}_z M} - \mathrm{D}f_z)) & = \operatorname{index}^{\mathrm{sm}}(z). \\ & \underset{\text{basic linear algebra}}{\uparrow} & \underset{\text{by the definition on page 2805}}{\uparrow} \end{array}$$

■

By Lemma 128.8 the following theorem is a generalization of our previous Lefschetz-Hopf Theorem 128.9.

Theorem 128.9. (Lefschetz-Hopf Theorem II) Let M be a compact orientable topological manifold and let $f\colon M \to M$ be a map which has no fixed points on ∂M. If f has finitely many fixed points, then

$$\sum_{\substack{x \text{ a fixed} \\ \text{point of } f}} \operatorname{index}(f, x) \;=\; \Lambda(f).$$



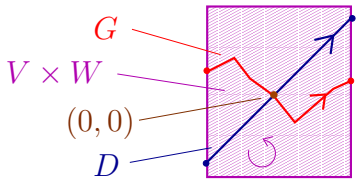
Remark.

(1) The Lefschetz-Hopf Theorem has its origin in the work of Heinz Hopf [**Hopf1929**, Section 8]. Various variations on the Lefschetz-Hopf Theorem 128.9 can be found in [**GD2003**, Chapter V.16] and [**JM2006**, Chapter 2.4].
(2) As on page 2807 we see that the Lefschetz-Hopf Theorem 128.9 is a generalization of the Lefschetz Fixed Point Theorem 104.12 for compact orientable topological manifolds.

Example. This time we consider S^2 with the avatar given by $\overline{B}^2/S^1$. We consider the map $f\colon \overline{B}^2/S^1 \to \overline{B}^2/S^1$ that is illustrated, to the best of the author's abilities, in the figure below.[1554] It has precisely one fixed point, namely $P := [S^1]$. We see that

$$\operatorname{index}(f,P) \underset{\text{Lefschetz-Hopf Theorem 128.9}}{\overset{\uparrow}{=}} \Lambda(f) \underset{\text{since } f \text{ is homotopic to id}}{\overset{\uparrow}{=}} \Lambda(\mathrm{id}) = \chi(S^2) = 2.$$

Note that with a little bit of care, say using the Smooth Transition Function Lemma 19.4, one can arrange that f is smooth. Also note that $\mathrm{D}f = \mathrm{id}$. Thus $P = [S^1]$ is a degenerate fixed point of f.[1555]



The proof of the Lefschetz-Hopf Theorem 128.9 rests heavily on the shoulders of the following two lemmas.

Lemma 128.10. Let $V \subset \mathbb{R}^n$ and $W \subset \mathbb{R}^n$ be two compact connected n-dimensional topological submanifolds of $\mathbb{R}^n$ that contain 0 in the interior. We assume that $V \subset \mathring{W}$. Let $f\colon V \to \mathbb{R}^n$ be a map with $f(V) \subset \mathring{W}$ and which has a unique fixed point, namely 0. We set $G := \{(v, f(v)) \,|\, v \in V\}$ and we set $D := \{(v,v) \,|\, v \in V\}$.

(1) G and D are well-behaved proper submanifolds of $V \times W$, in the sense of the definition on page 2777.

(2) The following equality holds:[1556] [1557]

$$\Big\langle \underbrace{\mathrm{PD}_{V\times W}([G])}_{\in \mathrm{H}^n((V\times W)\setminus \partial G)} \cup \underbrace{\mathrm{PD}_{V\times W}([D])}_{\in \mathrm{H}^n((V\times W)\setminus \partial D)}, [V\times W] \Big\rangle = \deg \begin{pmatrix} \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \\ \uparrow \cong \\ \mathrm{H}_n(V, V\setminus\{0\}) \\ \downarrow (\mathrm{id}-f)_* \\ \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \end{pmatrix}.$$

[1554] An alternative description of this map is given by considering $S^2 = \mathbb{R}^2 \cup \{\infty\}$. In this setting our map corresponds to the map $f\colon \mathbb{R}^2 \cup \{\infty\} \to \mathbb{R}^2 \cup \{\infty\}$ that is given by $f(x) = x + (1,0)$ for all $x \in \mathbb{R}^2$ and $f(\infty) = \infty$.

[1555] Incidentally this example gives an affirmative answer to the question asked in Exercise 2.12.

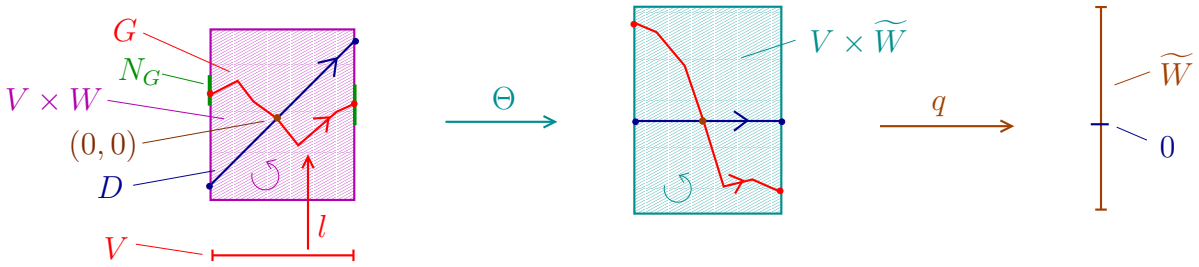
[1556] By (1) we know that G is a well-behaved proper submanifold of $V \times W$. Thus we can consider the isomorphism $\mathrm{PD}_{V\times W}\colon \mathrm{H}_n(V\times W, \partial G) \to \mathrm{H}^n(V\times W, (V\times W)\setminus \partial G)$ that we introduced in Proposition 127.2. Similarly we consider the isomorphism $\mathrm{PD}_{V\times W}$ with G replaced by D.

[1557] Since 0 is the only fixed point of f we see that $(\mathrm{id}-f)(V\setminus\{0\}) \subset \mathbb{R}^n \setminus \{0\}$.

Sketch of proof. First we prove Statement (1). More precisely, we will show that G is a well-behaved proper submanifold of $V \times W$. The proof that D is also a well-behaved submanifold is basically identical. Note that by Exercise 18.8 we know that G is a proper submanifold of $V \times W$. Next note by definition of a well-behaved submanifold we need to show that given any open neighborhood U of $\partial G \subset \partial(V \times W) = (\partial V \times W) \cup (V \times \partial W)$ the submanifold ∂G of $\partial(V \times W)$ admits a regular neighborhood N with $N \subset U$. Note that using the fact that ∂V is compact and using the hypothesis that $f(V) \subset \mathring{W}$ it is fairly elementary to see that there exists an $\epsilon > 0$ such that for every $x \in \partial G$ we have $\{x\} \times \overline{B}^n_\epsilon(f(x)) \subset U$. It is straightforward to verify that given any $\nu \in (0, \epsilon)$ the set

$$N_\nu \;:=\; \{(x,y) \in \partial V \times W \,|\, x \in \partial V \text{ and } y \in \overline{B}^n_\nu(f(x))\} \;\subset\; \partial(V \times W)$$

is a regular neighborhood of ∂G with $N_\nu \subset U$. This concludes the proof of Statement (1).



Next we turn to the proof of Statement (2). The key idea is to "tilt" the situation to turn the diagonal D into a "horizontal submanifold". Afterwards we can use the Poincaré Duality-Products Proposition 119.2 to perform the desired calculation.

Now we carry out the details. To do so we introduce the following objects:

(a) We pick a compact submanifold $\widetilde{W}$ of $\mathbb{R}^n$ with $W \subset \widetilde{W}$ and $(\mathrm{id} - f)(W) \subset \widetilde{W}$.
(b) We consider the maps

$$\begin{array}{rcl} l\colon V & \to & G \\ v & \mapsto & (v, f(v)) \end{array} \qquad \begin{array}{rcl} \Theta\colon V \times W & \to & V \times \widetilde{W} \\ (v,w) & \mapsto & (v, w - f(v)) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} q\colon V \times \widetilde{W} & \to & \widetilde{W} \\ (v,w) & \mapsto & w. \end{array}$$

(c) Note that by (1) we can pick a regular neighborhood N_G for $\partial G \subset \partial(V \times W)$ with $N_G \subset \partial V \times W$ and with $N_G \cap \partial D = \varnothing$.
(d) We denote by $\mu_{\widetilde{W},0} \in \mathrm{H}_n(\widetilde{W}, \widetilde{W} \setminus \{0\}) \cong \mathbb{Z}$ the standard generator, as defined on page 2328. Furthermore we denote by $\mu^*_{\widetilde{W},0} \in \mathrm{H}^n(\widetilde{W}, \widetilde{W} \setminus \{0\}; \mathbb{Z}) \cong \mathbb{Z}$ the corresponding dual.

Now we can perform the desired calculation:[1558]

$$\begin{array}{l}
\text{by Lemmas 116.4 and 116.7, under the natural identification } \mathrm{H}_0(V\times W)=\mathbb{Z} \\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \Big\downarrow \\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad =[G]\in \mathrm{H}_n(V\times W,N_G) \text{ by definition of } \mathrm{PD}_{V\times W} \\
\big\langle \mathrm{PD}_{V\times W}([G])\cup \mathrm{PD}_{V\times W}([D]),[V\times W]\big\rangle \;=\; \mathrm{PD}_{V\times W}([D])\cap\big(\overbrace{\mathrm{PD}_{V\times W}([G])\cap[V\times W]}\big) \\
\quad = \mathrm{PD}_{\Theta(V\times W)}(\Theta_*([D]))\cap\Theta_*([G]) \qquad\quad = \mathrm{PD}_{V\times\widetilde{W}}(\Theta_*([D]))\cap\Theta_*([G]) \\
\quad\uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\
\text{by the Cap Product-Naturality Lemma 116.8 and since the map } \Theta\colon V\times W\to\Theta(V\times W)\subset V\times\widetilde{W} \text{ is an } \textit{orientation-preserving} \text{ homeomorphism} \\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{follows from an argument similar to the one provided in the Codimension-Zero Submanifold-PD Lemma 120.5} \\
\quad = \mathrm{PD}_{V\times\widetilde{W}}([V\times\{0\}])\cap\Theta_*(l_*([V])) \quad = (-1)^n\cdot q^*(\mu^*_{\widetilde{W},0})\cap\Theta_*(l_*([V])) \\
\quad\uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\
\text{since } \Theta(D)=V\times\{0\} \text{ and } l(V)=G \text{ and since both maps are orientation-preserving} \qquad \text{this can be deduced fairly easily from the Poincaré Duality-Products Proposition 119.2} \\
\quad = (-1)^n\cdot\big\langle\mu^*_{\widetilde{W},0},q_*(\Theta_*(l_*([V])))\big\rangle \quad = \big\langle\mu^*_{\widetilde{W},0},(\mathrm{id}-f)_*([V])\big\rangle. \\
\quad\uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\
\text{by Lemmas 116.4 and 109.6 (3)} \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{since } q\circ\Theta\circ l=f-\mathrm{id}\colon V\to\widetilde{W} \text{ and since we know from Lemma 76.16 that } (f-\mathrm{id})_*=(-1)^n\cdot(\mathrm{id}-f)_* \\
\quad = \deg\big(\mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\})\xleftarrow{\cong}\mathrm{H}_n(V,V\setminus\{0\})\xrightarrow{(\mathrm{id}-f)_*}\mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\})\big). \\
\quad\uparrow \\
\text{this follows from the following commutative diagram}
\end{array}$$

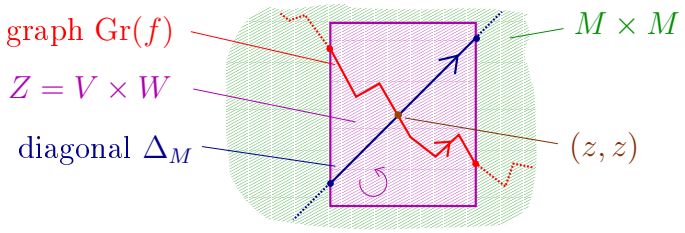
$$\begin{array}{ccccc}
\mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) & \xleftarrow{\cong} & \mathrm{H}_n(V,V\setminus\{0\}) & \xrightarrow{(\mathrm{id}-f)_*} & \mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) \\
 & & \uparrow & & \uparrow \\
 & & \mathrm{H}_n(V,\partial V) & \xrightarrow{(\mathrm{id}-f)_*} & \mathrm{H}_n(\widetilde{W},\widetilde{W}\setminus\{0\})
\end{array}$$

together with the fact that $[V]$ and $\mu_{\widetilde{W},0}$ are both mapped to the standard generator of $\mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\})$

Thus we have proved the desired equality. ∎

Lemma 128.11. Let M be a closed oriented n-dimensional topological manifold. Furthermore let $f\colon M\to M$ be a map. Finally let $z\in M$ be an isolated fixed point of f. We consider the two submanifolds $\mathrm{Gr}(f)$ and Δ_M of the $2n$-dimensional topological manifold $M\times M$. The following two statements hold:

(1) The point $(z,z)\in M\times M$ is a nice intersection point of the two submanifolds $\mathrm{Gr}(f)$ and Δ_M, in the sense of the definition on page 2778.
(2) We have the equality



$$\mathrm{index}(f,z) \;=\; \underbrace{\mathrm{index}(\mathrm{Gr}(f),\Delta_M,(z,z))}_{\substack{\text{index of the nice intersection point } (z,z),\\ \text{as defined on page 2779}}}.$$

Remark. On page 2813 we gave an example of a map $f\colon S^2\to S^2$ that has a unique fixed point P, which has index 2. It follows from Lemma 128.11 that (P,P) is a nice intersection point of the submanifolds $\mathrm{Gr}(f)$ and Δ_{S^2} of $S^2\times S^2$ of index 2. This gives an affirmative answer to the question posed in Exercise 127.5.

[1558] Careful reading of the equalities shows that it is in fact at times difficult to determine which relative (co-) homology groups the objects lie in. In particular on several occasions we implicitly use the Cap Product-Naturality Lemma 116.8 and Lemma 109.6 (3) to go from one relative homology group to another. Writing down the calculation in full detail would make the proof even more unreadable that it already is.

Proof.

(1) Let $z \in M$ be an isolated fixed point of $f\colon M \to M$. We need to show that the point $(z,z) \in M \times M$ is a nice intersection point of the two submanifolds $\mathrm{Gr}(f)$ and Δ_M. Thus let U be an open neighborhood of (z,z) in $M \times M$. By Lemma 128.6 there exists a neighborhood V of $z \in M$ and a neighborhood W of $z \in M$ with the following properties:
(i) We have $V \times W \subset U$.
(ii) z is the only fixed point of f contained in V.
(iii) V and W are both submanifolds of M and both are homeomorphic to $\overline{B}^n$.
(iv) We have $V \subset \mathring{W}$ and $f(V) \subset \mathring{W}$.
By (i) it remains to show that $Z := V \times W$ is a nice neighborhood of (z,z) in the sense of the definition on page 2778. Most of the conditions are easily verified. For example by (iii) we know that $V \times W$ is homeomorphic to $\overline{B}^{2n}$. Furthermore, by (ii) we know that $\mathrm{Gr}(f) \cap \Delta_M \cap (V \times W) = \{(z,z)\}$. Finally note that it follows almost immediately from Lemma 128.10 (1) that $\mathrm{Gr}(f)$ and Δ_M are both well-behaved proper submanifolds of $V \times W$.

(2) To simplify the notation we can and will assume that $V \subset \mathbb{R}^n$, $W \subset \mathbb{R}^n$, $z = 0$ and $\Phi = \mathrm{id}$. But now in this setting the desired equality is an immediate consequence of Lemma 128.10 (2). ■

Now that we have Lemma 128.11 under our belt the proof of the Lefschetz-Hopf Theorem 128.9 is formally very similar to the proof of the Lefschetz-Hopf Theorem 128.5.

Proof of the Lefschetz-Hopf Theorem 128.9. Let M be a compact orientable topological manifold and let $f\colon M \to M$ be a map which has only finitely many fixed points $z_1, \dots, z_k$, and all of them lie in $M \setminus \partial M$. We pick an orientation for M.

First we assume that M is actually closed. Now we easily obtain the desired equality:

$$\Lambda(f) \underset{\uparrow}{=} Q_{M\times M}([\mathrm{Gr}(f)],[\Delta_M]) \underset{\uparrow}{=} \mathrm{Gr}(f)\cdot\Delta_M \underset{\uparrow}{=} \sum_{i=1}^{k} \mathrm{index}(\mathrm{Gr}(f),\Delta_M,(z_i,z_i)) \underset{\uparrow}{=} \sum_{i=1}^{k} \mathrm{index}(f,z_i).$$

by Proposition 128.1 — by Lemma 128.11 (1) and Theorem 127.7 — by definition, see page 2780 — by Lemma 128.11 (2)

Now we assume that M has non-empty boundary. Once again we consider the double $\mathrm{D}M := (M \times \{1\}) \sqcup_{\partial M \times \{1\} = \partial M \times \{2\}} (M \times \{2\})$. By the Doubling-Manifold Lemma 75.12 we know that $\mathrm{D}M$ is a closed orientable topological manifold. We consider the map

$$\begin{array}{rcl} \psi\colon \mathrm{D}M & \to & \mathrm{D}M \\ [(P,\epsilon)] & \mapsto & [(f(P),\epsilon)]. \end{array}$$

Since all of the fixed points of f lie in $M \setminus \partial M$ we see that the fixed points of ψ are $(z_1, 1), \ldots, (z_k, 1), (z_1, 2), \ldots, (z_k, 2)$. Now we see that

$$2 \cdot \sum_{i=1}^{k} \operatorname{index}(f, z_i) \underset{\uparrow}{=} \sum_{i=1}^{k} \operatorname{index}(\psi, (z_i, 1)) + \sum_{i=1}^{k} \operatorname{index}(\psi, (z_i, 2)) \underset{\uparrow}{=} \Lambda(\psi \colon \mathrm{D}M \to \mathrm{D}M)$$

it follows immediately from the definitions that $\operatorname{index}(f, z_i) = \operatorname{index}(\psi, (z_i, 1)) = \operatorname{index}(\psi, (z_i, 2))$

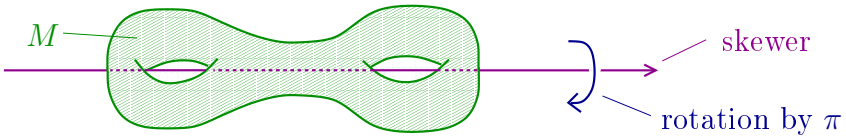
by the above, since $\mathrm{D}M$ is a closed orientable topological manifold

$$\underset{\uparrow}{=} 2 \cdot \Lambda(f \colon M \to M) + \Lambda(f \colon \partial M \to \partial M) \underset{\uparrow}{=} 2 \cdot \Lambda(f).$$

follows from Exercise 97.15

since there are no fixed points on ∂M and since ∂M is a closed orientable topological manifold we know by the above that $\Lambda(f \colon \partial M \to \partial M) = 0$

Dividing both sides by 2 yields the desired result. ■



Exercises for Chapter 128.

Exercise 128.1. We consider the surface $M \subset \mathbb{R}^3$ as shown in the figure below. Furthermore we consider the map $\varphi \colon M \to M$ which is given by "rotating M around the skewer by an angle of π".

(a) For $i = 0, 1, 2$ determine $\operatorname{tr}(\varphi_* \colon \mathrm{H}_i(M; \mathbb{Z}) \to \mathrm{H}_i(M; \mathbb{Z}))$.

(b) For each fixed point x of φ determine $\operatorname{index}(\varphi, x)$.

Remark. Evidently you should use the Lefschetz-Hopf Theorem 128.9 to check your calculations in (a) and (b) for consistency.

Exercise 128.2.

(a) Let $k, l \in \mathbb{Z}$. We consider the sphere $S^3 = \{(z, w) \in \mathbb{C}^2 \,|\, |z|^2 + |w^2| = 1\}$ and the self-map

$$\begin{array}{rcl} f \colon S^3 & \to & S^3 \\ (z, w) & \mapsto & (z^k, w^l). \end{array}$$

(b) We view S^2 as a subset of $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R}$. We consider the map

$$\begin{array}{rcl} g \colon S^2 & \to & S^2 \\ (z, t) & \mapsto & (z^2, t) \end{array}$$

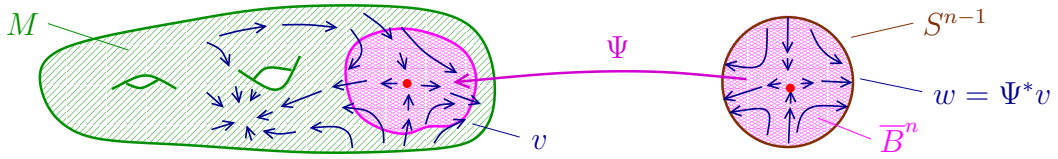
(c) Let $n \in \mathbb{N}$. We consider the maps

$$h \colon \mathbb{C} \cup \{\infty\} \to \mathbb{C} \cup \{\infty\}, \quad z \mapsto \begin{cases} z^n, & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty \end{cases} \qquad \text{and} \qquad k \colon \mathbb{C} \cup \{\infty\} \to \mathbb{C} \cup \{\infty\}, \quad z \mapsto \begin{cases} z + z^n, & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty. \end{cases}$$

In each case determine all fixed points, determine whether they are non-degenerate and determine the index of each fixed point.

129. The Poincaré-Hopf Theorem

Now we return to the study of vector fields on smooth manifolds.[1559] Recall that the Hairy Ball Theorem 38.12 says that there does not exist a nowhere-vanishing vector field on any even-dimensional sphere. Also recall that later on we proved a significant generalization of this result. Namely, using the Lefschetz Fixed Point Theorem 97.9 we proved the following proposition.

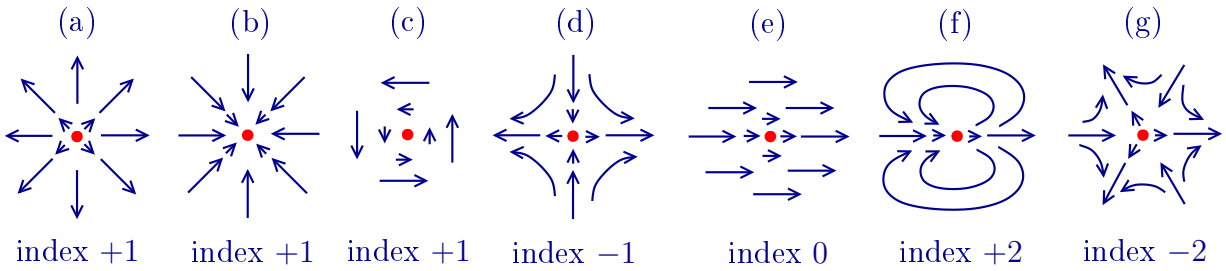


Theorem 97.15. Let M be a closed smooth manifold. If M admits a nowhere-vanishing vector field, then $\chi(M) = 0$.

In Chapter 127 we proved the Lefschetz-Hopf Theorem 128.9 which is a significant generalization of the Lefschetz Fixed Point Theorem 97.10 that we had just mentioned. In this chapter we will use this recently acquired theorems to prove the Poincaré-Hopf Theorem 129.7 which is a significant generalization of the above the Euler Characteristic-Vector Field Theorem 97.15.

129.1. **The index of a zero of a vector field.** In the following discussion it will be helpful to study zeros of vector fields in more detail. As we will, not all zeros are created equal but they actually come in different flavors. More precisely, we have the following definition.

Definition. Let M be an n-dimensional smooth manifold, let v be a vector field on M and let $x \in M \setminus \partial M$ be an isolated zero of v. We pick a smooth embedding $\Psi\colon \overline{B}^n \to M \setminus \partial M$ with $\Psi(0) = x$ and such that x is the only zero of v on $\Psi(\overline{B}^n)$. We denote by $w = \Psi^*(v)$ the pullback vector field on $\overline{B}^n$ as defined on page 641. In other words, given $y \in \overline{B}^n$ we write $w(y) := \mathrm{D}\Psi^{-1}_{\Psi(y)}(v(\Psi(y)))$. We define the index of v at x as follows:



$$\begin{array}{rcccc} \mathrm{index}(v,x) & := & \text{degree of the map} & \Theta_{\Psi,v}\colon S^{n-1} & \to & S^{n-1} \\ & & & y & \mapsto & \dfrac{w(y)}{\|w(y)\|}. \end{array}$$

Example. We consider the vector fields on $\mathbb{R}^2 = \mathbb{C}$ with isolated zero at the origin that are shown in the figure below. In the following we use the identity chart $\Psi = \mathrm{id}$ to determine the various indices. In fact, using Lemmas 76.10 and 76.11, we obtain the same table as on page 1022:

	(a)	(b)	(c)	(d)	(e)	(f)	(g)
vector field v at $(x,y)=z$	(x,y)	$(-x,-y)$	$(-y,x)$	$(x,-y)$	$(\lvert x\rvert+\lvert y\rvert,0)$	z^2	z^{-2}
degree of $\Theta_{\Psi,v}\colon S^1 \to S^1$	$+1$	$+1$	$+1$	-1	0	$+2$	-2.

[1559] We refer to page 639 for the definition of a vector field on a given smooth manifold M.

Lemma 129.1. Let M be an n-dimensional smooth manifold.

(1) Let v be a vector field on M. The definition of the index $\operatorname{index}(v,x)$ of an isolated zero $x \in M \setminus \partial M$ of a vector field v does not depend on the choice of the smooth embedding $\Psi\colon \overline{B}^n \to M$.
(2) If v and w are two vector fields on M that agree on an open subset $U \subset M$ and if z is an isolated zero of v in U, then $\operatorname{index}(v,z) = \operatorname{index}(w,z)$.

Proof. The second statement is a straightforward consequence of the first statement. Thus it remains to prove the first statement. Let $\Psi\colon \overline{B}^n \to M$ be a smooth embedding as in the definition of $\operatorname{index}(v,x)$. We need to show that any other such smooth embedding leads to the same index. The proof is performed in two stages.

(a) Let $A \in \mathrm{O}(n)$ be an orthogonal matrix. We denote by $\rho_A\colon \mathbb{R}^n \to \mathbb{R}^n$ the map that is given by multiplication by the matrix A. Next we consider the smooth embedding $\Psi \circ \rho_A\colon \overline{B}^n \to M$. A straightforward calculation using the Chain Rule 19.10, shows that $\Theta_{\Psi\circ\rho_A,v} = \rho_A^{-1} \circ \Theta_{\Psi,v} \circ \rho_A\colon S^{n-1} \to S^{n-1}$. It follows from the Sphere Degree Lemma 76.11 that $\deg(\Theta_{\Psi\circ\rho_A,v}) = \deg(\Theta_{\Psi,v})$.

(b) Now assume we are given some other smooth embedding $\Xi\colon \overline{B}^n \to M$. We consider

$$N := \underbrace{\{y \in M \mid v(y) \neq 0\}}_{\text{open subset by Exercise 97.16}} \cup \{x\}.$$

It follows from Exercise 97.16 and the fact that x is an isolated zero that N is an open subset of M. In particular we see that N is an n-dimensional submanifold of M. Since x is the only zero of v in $\Psi(\overline{B}^n)$ and $\Xi(\overline{B}^n)$ we see that $\Psi\colon \overline{B}^n \to M$ and $\Xi\colon \overline{B}^n \to M$ are tubular maps, in the sense of the definition on page **??**, for the 0-dimensional submanifold $\{x\}$ of N. By Proposition **??** there exists a diffeotopy $H\colon N \times [0,1] \to N$ rel $\{x\}$ and a matrix $A \in \mathrm{O}(n)$ such that $H_0 = \mathrm{id}$ and such that $H_1 \circ \Xi = \Psi \circ \rho_A\colon \overline{B}^n \to N$. Now we see that

$$\deg(\Theta_{\Xi,v}) = \deg(\Theta_{H_0\circ\Xi,v}) \underset{\uparrow}{=} \deg(\Theta_{H_1\circ\Xi,v}) = \deg(\Theta_{\Psi\circ\rho_A,v}) \underset{\uparrow}{=} \deg(\Theta_{\Psi,v}).$$

maps $\Theta_{H_t\circ\Xi,v}$ with $t \in [0,1]$ define a homotopy between $\Theta_{H_0\circ\Xi,v}$ and $\Theta_{H_1\circ\Xi,v}$, thus by the Sphere Degree Lemma 76.11 (3) the maps have the same degree

by (1)

■

The next example shows that any integer can occur as the index of an isolated zero of a vector field.

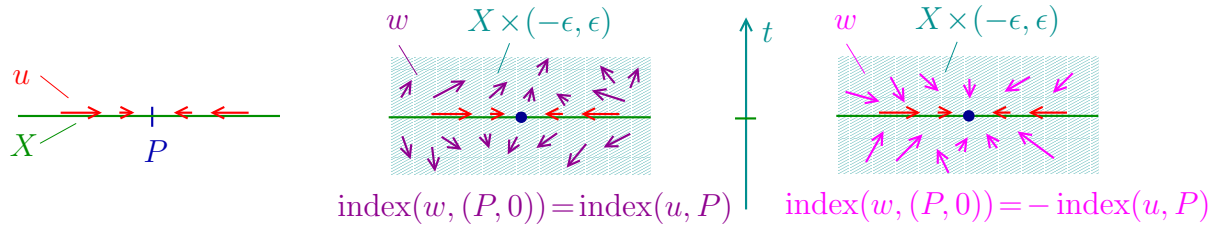
Example. Let $n \in \mathbb{N}_{\geq 2}$ and let $d \in \mathbb{Z}$. It follows from Lemma 76.10 and the Suspension-Degree Lemma 76.12 that there exists a self-map $\varphi\colon S^{n-1} \to S^{n-1}$ of degree d. Let $\lambda \in \mathbb{R}_{>0}$.

It is straightforward to verify that

$$\begin{array}{rcl} v(\varphi)\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ x & \mapsto & \begin{cases} 0, & \text{if } x = 0, \\ \lambda \cdot x \cdot \varphi(\frac{x}{\|x\|}), & \text{if } x \neq 0 \end{cases} \end{array}$$

is a continuous map, in particular it defines a vector field on $\mathbb{R}^n$. Evidently it has a single isolated zero at the origin and the corresponding index is precisely $d = \deg(\varphi)$.

The next lemma can be convenient for calculating the index of a zero of a vector field.

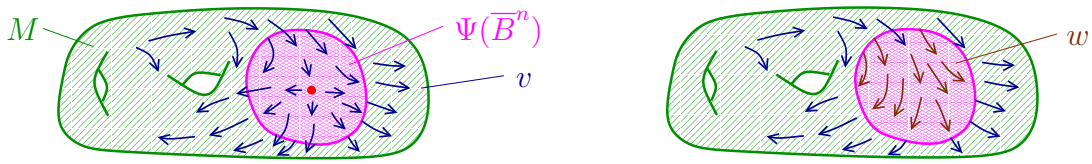


Lemma 129.2. Let $X \subset \mathbb{R}^n$ be an open subset and let $\epsilon > 0$. Furthermore suppose we are given a vector field $w = (u, v)\colon X \times (-\epsilon, \epsilon) \to \mathbb{R}^n \times \mathbb{R}$ with an isolated zero at $(P, 0)$.

(1) If $v(x,t) > 0$ whenever $t > 0$ and if $v(x,t) < 0$ whenever $t < 0$, then

$$\operatorname{index}(w, (P,0)) \;=\; \operatorname{index}(u, P).$$

(2) If $v(x,t) < 0$ whenever $t > 0$ and if $v(x,t) > 0$ whenever $t < 0$, then



$$\operatorname{index}(w, (P,0)) \;=\; -\operatorname{index}(u, P).$$

Proof. We leave it to the reader to verify that the two statements follow easily from the definitions together with Exercise 76.13. ■

The following lemma says that isolated zeros of a vector field of index 0 can be eliminated by adjusting the vector field in the neighborhood of the zero.

Lemma 129.3. Let M be an n-dimensional smooth manifold, let v be a vector field on M and let x be an isolated zero of v with $\operatorname{index}(v, x) = 0$. Let $\Psi\colon \overline{B}^n \to M \setminus \partial M$ be a smooth embedding with $\Psi(0) = x$ and such that x is the only zero of v in $\Psi(\overline{B}^n)$. There exists a vector field w on M that agrees with v on $M \setminus \Psi(B^n)$ and which has no zeros on $\Psi(\overline{B}^n)$.

Sketch of proof. By Corollary 85.6 we know that the map $\deg\colon \pi_{n-1}(S^{n-1}) \to \mathbb{Z}$ is an isomorphism. In particular this implies, using our hypothesis that $\operatorname{index}(v, x) = 0$, that there exists a homotopy $H\colon S^{n-1} \times [0,1] \to S^{n-1}$ from the map $\Theta_{\Psi,v}\colon S^{n-1} \to S^{n-1}$ to a

constant map. Using the homotopy H it is now straightforward to write down an explicit vector field w on M with the following properties:

(1) On $M \setminus \Psi(B^n)$ the vector field w equals v.
(2) On $\Psi(\overline{B}^n_{\frac{1}{2}})$ the vector field w is "constant" and non-zero.
(3) On $\Psi(\overline{B}^n \setminus B_{\frac{1}{2}})$ the vector field interpolates between (1) and (2).

We leave it to the reader to fill in the details. ■

We continue with the following refinement of the Non-Degenerate Vector Field Existence Proposition 45.15.

Proposition 129.4. (Non-Degenerate Vector Field Existence Proposition II) Every closed smooth manifold M admits a smooth vector field v such that all zeros are non-degenerate and such that

$$\sum_{x \text{ a zero of } v} \operatorname{index}(v, x) \;=\; \chi(M).$$

Remark. On page 2983 we will give an alternative proof of the Non-Degenerate Vector Field Existence Proposition 129.4.

Before we turn to the proof of the Non-Degenerate Vector Field Existence Proposition 129.4 let us first state and prove the following corollary.

Corollary 129.5. For every closed smooth manifold M the Euler characteristic $\chi(M)$ equals the smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$ of closed orientable smooth manifolds that we had introduced on page 1019.

Proof of Corollary 129.5. Let v be a smooth vector on M as in the Non-Degenerate Vector Field Existence Proposition 129.4. Then we see that

$$\chi(M) \;\underset{\substack{\uparrow\\ \text{choice of } v}}{=}\; \sum_{x \text{ a zero of } v} \operatorname{index}(v, x) \;\underset{\substack{\uparrow\\ \text{Smooth Poincaré–Hopf Theorem 45.17}}}{=}\; \chi^{\mathrm{smooth}}(M).$$

■

Proof of Proposition 129.4. Let M be a closed connected smooth manifold. First note that by the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a smooth simplicial structure $(K = (V, S), \Theta\colon |K| \to M)$. Inductively we can define a smooth vector field u on M with the following properties:

(1) The vector field u is defined to be the zero vector field on the vertices of the triangulation.
(2) Suppose the vector field u is defined on the k-skeleton of M, then on every $(k+1)$-simplex s we extend the vector field u in the following way:
   (a) the vector field vanishes on the barycenter $\underline{s}$ of s,
   (b) for all other points in the open simplex the vector field "points towards" the barycenter $\underline{s}$ of s.

   This can be done explicitly.[1560]

[1560]For the resilient reader we provide the gory details. Suppose we are given a vector field v on $\partial\Delta^{k+1}$. We denote by $b := (\frac{1}{k+1}, \ldots, \frac{1}{k+1})$ the barycenter of Δ^{k+1}. We denote by $r\colon \Delta^{k+1} \setminus \{b\} \to \partial\Delta^{k+1}$ the map that is given by sending x to the unique intersection point of the ray $b + \mathbb{R}_{\geq 0} \cdot (x - b)$ with $\partial\Delta^{k+1}$. Next

We sketch the construction of the vector field u in the figure below. Note that the zeros of the vector field u are precisely the barycenters of the original simplices. Furthermore, one can fairly easily verify that given a k-simplex s we have[1561] $\operatorname{index}(u, \underline{s}) = (-1)^k$. Thus we see that

$$\sum_{x \text{ a zero of } u} \operatorname{index}(u, x) = \sum_{s \text{ a } k\text{-simplex}} \operatorname{index}(u, \underline{s}) = \sum_{s \text{ a } k\text{-simplex}} (-1)^k \underset{\text{Corollary 93.25 (5)}}{=} \chi(M).$$

This argument is also sketched in [**Stee1951**, p. 202]. ■

We conclude this chapter with the following converse to the Smooth Euler Characteristic-Vector Field Theorem 45.22 and the Euler Characteristic-Vector Field Theorem 97.15.

Theorem 129.6. (Nowhere Vanishing Vector Field Existence Theorem) Let M be a closed connected smooth manifold. If $\chi(M) = 0$, then M admits a nowhere-vanishing smooth vector field.

Sketch of proof. Let M be a closed connected smooth manifold with $\chi(M) = 0$. We need to show that M admits a nowhere-vanishing smooth vector field. This statement is proved in [**Bre1993**, Corollary VII.14.5], [**Stee1951**, Corollary 39.8], [**Hirs1976**, Theorem 5.2.10] and alternatively also in [**Tur1990**, Lemma 6.3.4]. In the following we provide a terse sketch

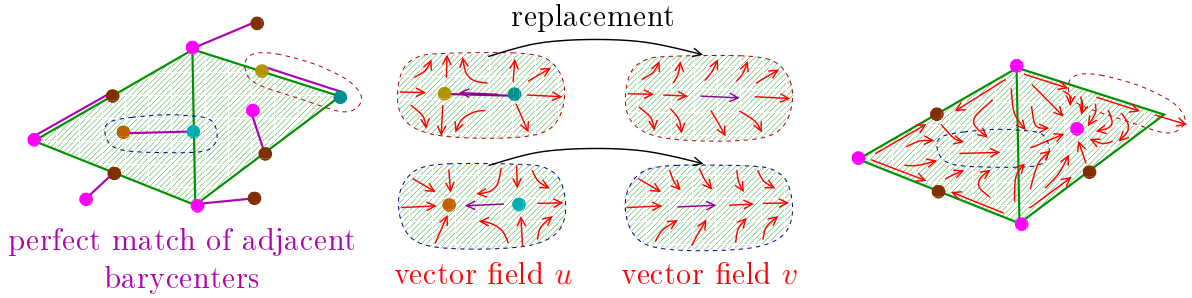
---

we consider the map

$$\begin{array}{rcl} \Delta^{k+1} & \to & \mathbb{R}^{k+2} \\ x & \mapsto & \begin{cases} \frac{\|x-b\|}{\|r(x)-b\|} \cdot (v(r(x)) + (b-x) \cdot \|x - r(x)\|), & \text{if } x \neq b, \\ 0, & \text{if } x = b. \end{cases} \end{array}$$

It is now fairly elementary to see that this vector field, transported back to M, has the desired properties. As always, with a little more care, using say the Smooth Transition Function Lemma 19.4, one can arrange that the vector field is actually smooth.

[1561]The fact that $\operatorname{index}(u, \underline{s}) = (-1)^k$ can be seen as follows. First note that the vector field u points in k directions towards $\underline{s}$ and in $(n-k)$ directions away from $\underline{s}$. Using a suitable embedding $\Psi\colon \overline{B}^m \to M$ with $\Psi(0) = \underline{s}$ we see that the corresponding map $\Theta_{\Psi,v}\colon S^{n-1} \to S^{n-1}$ is given by the diagonal matrix with k entries equal to -1 and $(n-k)$-entries equal to $+1$. Thus it follows from the Sphere Degree Lemma 76.11 that the degree of this map equals $(-1)^k$.



of the proof given in [**Tur1990**, Lemma 6.3.4]. We continue with the discussion of the above proof of Proposition 129.4 and we make the following observations and constructions.

(1) Some thought shows that it follows from our hypothesis that M is connected and that $\chi(M) = 0$ that we can find a perfect match between adjacent barycenters. More precisely, we can find a decomposition $S = \bigsqcup_{i \in I} \{s_i, t_i\}$ of the simplex set, such that each s_i is a codimension one face of t_i.

(2) Given each pair $\{s_i, t_i\}$ we consider a small suitable neighborhood of the 1-simplex $\{\underline{s_i}, \underline{t_i}\}$ of the barycentric subdivision. This neighborhood contains two critical points. As of right now, on this 1-simplex the vector field points from $\underline{s_i}$ to $\underline{t_i}$.

We can replace the vector field u on this neighborhood by a different vector field v that agrees with u on the boundary, which on the 1-simplex now points from $\underline{t_i}$ to $\underline{s_i}$ and which has no critical points. This replacement is illustrated in the figure below.

Hopefully this outline is convincing. Evidently filling in all details is a nightmarish task. Thankfully the details are provided in [**Tur1990**, Lemma 6.3.4]. ■

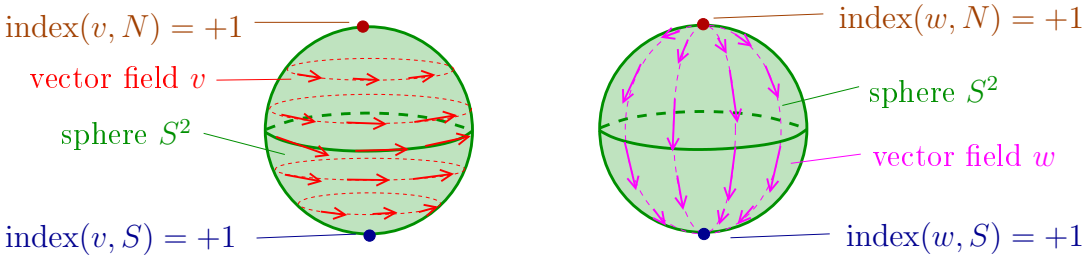
129.2. **The Poincaré-Hopf Theorem.** Now we can formulate the namesake of this chapter.

Theorem 129.7. (Poincaré-Hopf Theorem) Let M be compact smooth manifold. Let v be a vector field[1562] on M with finitely many zeros. If M has boundary, then we insist that along the boundary ∂M the vector field v is pointing outward. Then we have the formula

$$\sum_{x \text{ a zero of } v} \text{index}(v, x) \;=\; \chi(M).$$

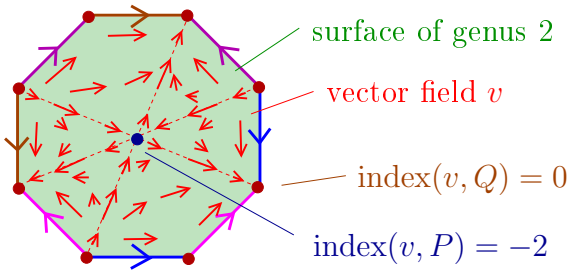
Remark.

(1) In the 2-dimensional setting the Poincaré-Hopf Theorem was first proved by Henri Poincaré [**Poi1885**] in the late 19th century. The generalization to the higher-dimensional case was first proved by Heinz Hopf [**Hopf1927b**] in 1927. There are many different proofs of the Poincaré-Hopf Theorem, sometimes with somewhat different hypotheses, in the literature, see e.g. [**BoT1982**, Theorem 11.25], [**Vic1994**, Theorem 7.27], [**Bre1993**, Theorem VI.12.13], [**Miln1965a**, p. 35], [**DFN1985**, Theorem 15.3.2], [**BaT2003**, Theorem 7.6.5] and [**MTo1997**, Theorem 12.1]. See



[1562]It is perhaps worth recalling that for us vector fields are assumed to be continuous. We do not make any assumptions on differentiability.

also the sketch in [**Bra2007**, p. 69]. The proof we provide is partly inspired by the proofs in [**DFN1985**] and [**Vic1994**].



(2) The proof of the Poincaré-Hopf Theorem 129.7 relies very much on the Lefschetz-Hopf Theorem 128.9. For readers who prefer to work with the weaker Lefschetz-Hopf Theorem 128.5 we leave it as a little challenge to deduce from it the conclusion of the Poincaré-Hopf Theorem 129.7 under the stronger hypotheses that the vector field is smooth and that the indices of the zeros are ± 1.

Examples.

(1) In the figure below we see two vector fields v and w on S^2. Each of these vector fields has precisely two zeros, namely the North Pole N and the South Pole S. Furthermore, considering the table on page 1022, it it pretty clear that for both vector fields both zeros have index $+1$. In particular we see that for both vector fields these two indices add up reassuringly to $\chi(S^2) = 2$.

(2) In the figure below we see a vector field on the surface Σ of genus two with two zeros P and Q. The table on page 1022 strongly suggests that $\text{index}(v, P) = -2$. By the discussion on page 1879 we also know that $\chi(\Sigma) = -2$. Thus it follows from the Poincaré-Hopf Theorem 129.7 that $\text{index}(v, Q) = 0$. By Lemma 129.3 this means that we can modify the vector field v to obtain a vector field which has no zero at Q. Thus we have found a vector field on Σ with a single zero, namely at P. This gives a belated solution to Exercise 97.12.

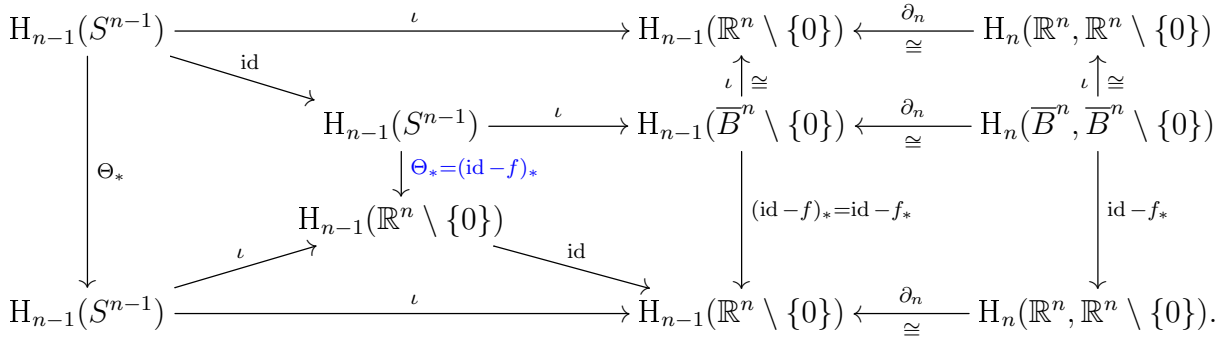
It is perhaps worth stating the following immediate corollary to the Poincaré-Hopf Theorem 129.7. Note that this corollary generalized the statement of the Euler Characteristic-Vector Field Theorem 97.15 to smooth manifolds with non-empty boundary.

Corollary 129.8. Let M be a compact smooth manifold. If M admits a nowhere-vanishing vector field v that either points outward along all of ∂M or that points inward along all of ∂M, then $\chi(M) = 0$.

Proof. First note that after possibly replacing the vector field v by $-v$ we can assume that v points outward along ∂M. If v has no zeros, then the sum over the indices of the zeros is also zero. Thus it follows from the Poincaré-Hopf Theorem 129.7 that $\chi(M) = 0$. ∎

In preparation for the proof of the Poincaré-Hopf Theorem 129.7 let us first let us make a little remark and prove a useful lemma.

Remark. Let M be a topological manifold. Furthermore let $U \subset M$ be an open subset and let $f\colon U \to M$ be map. If x is an isolated fixed point of f, then we can define $\operatorname{index}(f, x) \in \mathbb{Z}$ the same way as we did for the case $U = M$ on page 2810.



Lemma 129.9. Let U be an open neighborhood of the origin $0 \in \mathbb{R}^n$ which contains the closed ball $\overline{B}^n$. Furthermore let $v\colon U \to \mathbb{R}^n$ be a vector field on U which has a single zero, namely at 0. We consider the map

$$\begin{aligned} f\colon U &\to \mathbb{R}^n \\ x &\mapsto x - v(x). \end{aligned}$$

The point $x = 0$ is an isolated fixed point of f and we have the following equality:

$$\underbrace{\operatorname{index}(v, 0)}_{\substack{\text{index of a zero of a} \\ \text{vector field, see page 2818}}} = \underbrace{\operatorname{index}(f, 0).}_{\substack{\text{index of a fixed} \\ \text{point, see page 2810}}}$$

Proof. Since v has a single zero at $x = 0$ we see that $x = 0$ is the only fixed point of f, in particular it is an isolated fixed point. We consider the embedding $\Psi = \mathrm{id}\colon \overline{B}^n \to \mathbb{R}^n$ to compute the indices $\operatorname{index}(v, 0)$ and $\operatorname{index}(f, 0)$. We consider the map $\Theta\colon S^{n-1} \to S^{n-1}$ that is given by $x \mapsto \frac{v(x)}{\|v(x)\|}$. Furthermore we consider the following diagram:

We make the following observations and clarifications:

(1) The maps ι are the various inclusion induced maps.

(2) The map

$$\begin{aligned} H\colon S^{n-1} \times [0, 1] &\to \mathbb{R}^n \setminus \{0\} \\ (x, t) &\mapsto \frac{v(x)}{(1-t)\cdot\|v(x)\| + t} \end{aligned}$$

is a homotopy between $H_0 = \Theta$ and $H_1 = v = \mathrm{id} - f$. It follows from the existence of such a homotopy together with the Homotopic Maps-and-Homology Proposition 73.6 that we have the equality $\Theta_* = (\mathrm{id} - f)_*\colon \mathrm{H}_{n-1}(S^{n-1}) \to \mathrm{H}_{n-1}(\mathbb{R}^n \setminus \{0\})$.

(3) It follows from the naturality of the connecting homomorphisms, see the Topological LES-Corollary 74.14 that the squares to the right commute. All the remaining parts of the diagram commute by the functoriality of homology groups.

It follows from the above discussion that

$$\operatorname{index}(v,0) \;=\; \deg\begin{pmatrix} \mathrm{H}_{n-1}(S^{n-1}) \\ \downarrow \Theta_* \\ \mathrm{H}_{n-1}(S^{n-1}) \end{pmatrix} \;=\; \deg\begin{pmatrix} \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \\ {\scriptstyle \iota}\uparrow\cong \\ \mathrm{H}_n(\overline{B}^n, \overline{B}^n \setminus \{0\}) \\ \downarrow {\scriptstyle \mathrm{id} - f_*} \\ \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \end{pmatrix} \;=\; \operatorname{index}(f,0).$$

$\uparrow$ by the definition on page 2818 — $\uparrow$ by the above discussion — $\uparrow$ see definition on page 2810 ■

Now we can provide the proof of the Poincaré-Hopf Theorem 129.7. To simplify the discussion we first deal with the special case that the smooth manifold is closed and oriented. We will deal with the general case right afterwards.

Proof of the Poincaré-Hopf Theorem for closed orientable M. Let M be a closed orientable n-dimensional smooth manifold. Let v be a vector field on M with finitely many zeros $P_1, \ldots, P_k$. The idea now is similar to the idea behind the proof of the Euler Characteristic-Vector Field Theorem 97.15. Namely we intend to use the vector field v to produce a self-map f of M. We will then roll out the Lefschetz-Hopf Theorem 128.5 to obtain the desired result.

As the reader surely remembers, in Proposition 97.16 we gave two different constructions of a self-map f from a given vector field v. The first approach used more machinery whereas the second proof was much more hands-on. It is technically slightly tricky to adapt the first approach to our current needs. Thus in the following we present a slight refinement of the second construction of the self-map f. We refer to the proof of Proposition 97.16 for details.

(1) By Exercise 27.6, which is a variation on Theorem 27.1, we can assume the following:
   (a) M is a submanifold of some $\mathbb{R}^m$.
   (b) For each zero P_i there exists an open neighborhood U_i of P_i that is "flat", in the sense that there exists a $y_i \in \mathbb{R}^{m-n}$ such that $U_i \subset \mathbb{R}^n \times \{y_i\}$.

(2) We consider the map

$$\begin{array}{rcl} F\colon M \times \mathbb{R}_{\geq 0} & \to & \mathbb{R}^m \\ (P,t) & \mapsto & P - t \cdot v(P). \end{array}$$

(3) There exists an $\epsilon > 0$ such that $Z := \{P + w \,|\, P \in M \text{ and } w \in (\widetilde{\mathrm{T}}_P M)^\perp \text{ with } \|w\| \leq \epsilon\}$ is a neighborhood of M and such that the map

$$\begin{array}{rcll} q\colon Z & \to & M & \\ P + w & \mapsto & P & \text{where } P \in M \text{ and } w \in (\widetilde{\mathrm{T}}_P M)^\perp \text{ with } \|w\| \leq \epsilon \end{array}$$

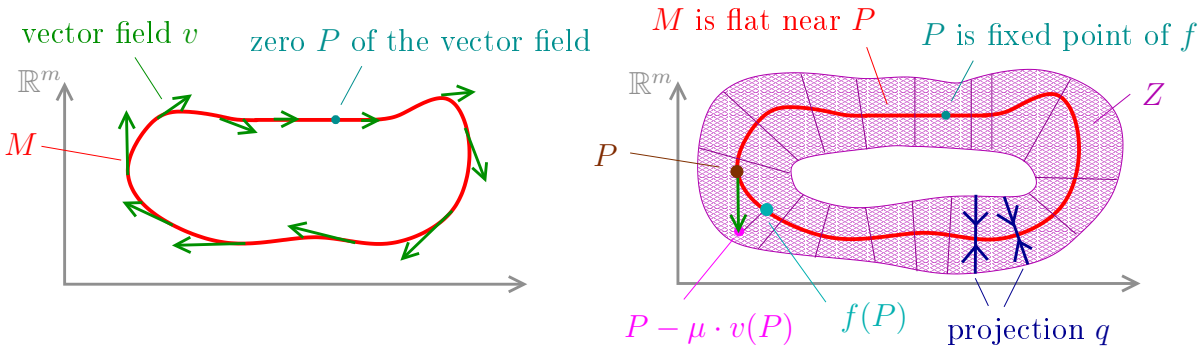
   is well-defined and continuous.

(4) There exists a $\mu > 0$ such that $F(M \times [0,\mu]) \subset Z$.

(5) We set $f := q \circ F_\mu\colon M \to M$.

(6) The map $q \circ F\colon M \times [0,\mu] \to M$ defines a homotopy between the identity and f.

Claim. Let $P \in M$.



(i) P is a zero of v if and only if P is a fixed point of f.

(ii) If P is a zero of v, then $\operatorname{index}(v, P) = \operatorname{index}(f, P)$.

Proof.

(i) Evidently if P is a zero of v, then it is a fixed point of f. Now suppose that P is not a zero of v. We can write $F_\mu(P) = P - \mu \cdot v(P) =: Q + w$ with $Q \in M$ and $w \in (\widetilde{\mathrm{T}}_Q M)^\perp$ with $\|w\| \leq \epsilon$. Since $\widetilde{\mathrm{T}}_P M \cap \widetilde{\mathrm{T}}_P M^\perp = \{0\}$ and since $v(P)$ is a non-zero vector in $\widetilde{\mathrm{T}}_P M$ we see that $P \neq Q$. By the definition in (5) we have $f(P) = Q$. Thus we have shown that $f(P) \neq P$.

(ii) It follows from (1b) and our explicit construction of f that we are essentially in the setting of Lemma 129.9, which then provides us with the desired equality. ⊞

Now we see that

$$\sum_{P \text{ a zero of } v} \operatorname{index}(v, P) \underset{\text{by the claim}}{=} \sum_{P \text{ a fixed point of } f} \operatorname{index}(f, P) \underset{\substack{\text{by the Lefschetz-Hopf Theorem 128.9} \\ \text{note that here we use that } M \text{ is orientable}}}{=} \Lambda(f) \overset{\text{follows from Lemma 97.7 and the fact, mentioned in (6), that } f \text{ is homotopic to id}}{=} \Lambda(\mathrm{id}) \underset{\text{see Lemma 97.6}}{=} \chi(M).$$

■

Next we drop the hypothesis that M needs to be closed.

Proof of the Poincaré-Hopf Theorem 129.7 for compact orientable M. In the following let M be a compact orientable n-dimensional smooth manifold and let v be a vector field on M that points outward on ∂M and that has only finitely many zeros $P_1, \ldots, P_k$.

We perform the following steps:

(1) By the Smooth Collar Neighborhood Theorem 28.3 we know that there exists a collar neighborhood $[-1, 0] \times \partial M$ for $\partial M = \{0\} \times \partial M$. Possibly after rescaling the collar neighborhood we can arrange that none of the points $P_1, \ldots, P_k$ lies in $[-1, 0] \times \partial M$.

(2) Given $(t, x) \in [-1, 0] \times \partial M$ we can use the isomorphism from the Smooth Manifold Product Proposition 19.31 (3) to make the identification $\mathrm{T}_{(t,x)}([-1, 0] \times \partial M) = (\mathrm{T}_t \mathbb{R}) \times \mathrm{T}_x \partial M = \mathbb{R} \times \mathrm{T}_x \partial M$. In particular on $[-1, 0] \times \partial M$ we can write the vector field v as $v(t, x) = (v_1(t, x), v_2(t, x))$ with $v_1(t, x) \in \mathbb{R}$ and $v_2(t, x) \in \mathrm{T}_x \partial M$.

(3) It follows easily from the hypothesis that v points outward, see page 634 for the definition of an outward pointing tangent vector, and the fact that ∂M is compact that there exists an $\epsilon \in [-1, 0)$ such that $v_1(t, x) > 0$ for every $x \in \partial M$ and every $t \in [\epsilon, 0]$.

(4) After further rescaling the collar neighborhood we might as well assume that $\epsilon = -1$.
(5) By the Non-Degenerate Vector Field Existence Proposition 129.4 we know that there exists a vector field u on ∂M with finitely many zeros $Q_1, \ldots, Q_l$ and such that the sum of the indices of the zeros of u equals precisely $\chi(\partial M)$.
(6) We consider the double $\mathrm{D}M := M \sqcup_{\partial M = \partial M'} M'$ where M' is a copy of M. By the Doubling-Manifold Lemma 75.12 we know that $\mathrm{D}M$ is a closed orientable n-dimensional smooth manifold.
(7) We denote by $\rho\colon \mathrm{D}M \to \mathrm{D}M$ the natural involution swapping the two copies of M.
(8) Our next goal is to construct a vector field w on M that equals v outside of the collar neighborhood, that equals u on ∂M and that interpolates between these vector fields on the collar neighborhood without creating new zeros. In fact the following vector field has precisely those properties:

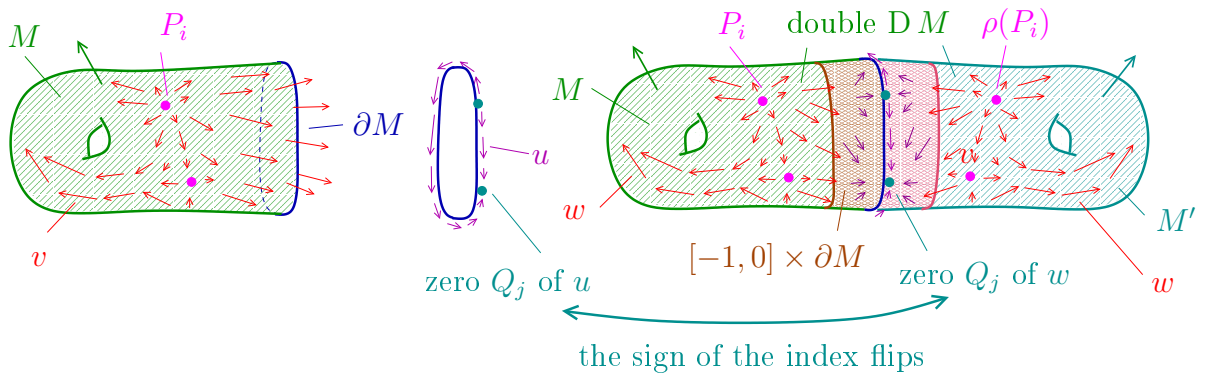
$$w(x) := \begin{cases} v(x), & \text{if } x \in M \setminus ([-1,0] \times \partial M), \\ (\underbrace{|t| \cdot v_1(y,t)}_{\in \mathbb{R}}, \underbrace{|t| \cdot v_2(y,t) + (1+t) \cdot u(y)}_{\in \mathrm{T}_y \partial M}), & \text{if } x = (t,y) \text{ with } t \in [-1,0] \ \&\ y \in \partial M. \end{cases}$$

We use the natural involution $\rho\colon \mathrm{D}M \to \mathrm{D}M$ to extend this vector field to $\mathrm{D}M$. More precisely, given $x' \in M'$ we set $w(x') = \mathrm{D}\rho_{\rho(x')}(w(\rho(x))$. Note that w is indeed a vector field on $\mathrm{D}M$, i.e. there are no continuity issues along $\partial M = \partial M'$.
(9) The zeros of w are $P_1, \ldots, P_k, \rho(P_1), \ldots, \rho(P_k)$ and $Q_1, \ldots, Q_l$. We make the following three observations:
  (a) We have $\mathrm{index}(w, P_i) = \mathrm{index}(v, P_i)$, since w equals v in a neighborhood of P_i.
  (b) We have $\mathrm{index}(w, \rho(P_i)) = \mathrm{index}(w, P_i)$, since ρ is a diffeomorphism.
  (c) It follows from our hypothesis that v points *outward* together with Lemma 129.2 that we have $\mathrm{index}(w, Q_j) = -\mathrm{index}(u, Q_j)$.

Now we have the following equality:

since $\mathrm{D}M$ is a *closed* orientable smooth manifold we already know from the above that the conclusion of the Poincaré-Hopf Theorem 129.7 holds for $\mathrm{D}M$

$$\sum_{i=1}^{k} \underbrace{\mathrm{index}(w, P_i)}_{\mathrm{index}(v,P_i) \text{ by (8a)}} + \sum_{i=1}^{k} \underbrace{\mathrm{index}(w, \rho(P_i))}_{= \mathrm{index}(v,P_i) \text{ by (8b) together with (8a)}} + \sum_{j=1}^{l} \underbrace{\mathrm{index}(w, Q_j)}_{= -\mathrm{index}(u,Q_j) \text{ by (8c)}} \overset{\downarrow}{=} \chi(\mathrm{D}M).$$



From this equality, together with (8a), (8b) and (8c) and the Euler Characteristic-Addition Lemma 87.5 we obtain the following equality:

$$2 \cdot \sum_{i=1}^{k} \mathrm{index}(v, P_i) - \underbrace{\sum_{j=1}^{l} \mathrm{index}(u, Q_j)}_{= \chi(\partial M) \text{ by (5)}} = \underbrace{2 \cdot \chi(M) - \chi(\partial M).}_{= \chi(\mathrm{D}M) \text{ by Lemma 87.5 and the Smooth Manifold-CW Structure Theorem 96.5}}$$

Cleaning up the bottom equality we obtain the desired equality. ∎

Finally we drop the hypothesis that M needs to be orientable.

Proof of the Poincaré-Hopf Theorem. Let M be a compact n-dimensional smooth manifold and let v be a vector field on M that points outward on ∂M and that has only finitely many zeros $P_1, \ldots, P_k$. Evidently we only need to consider the case that M is

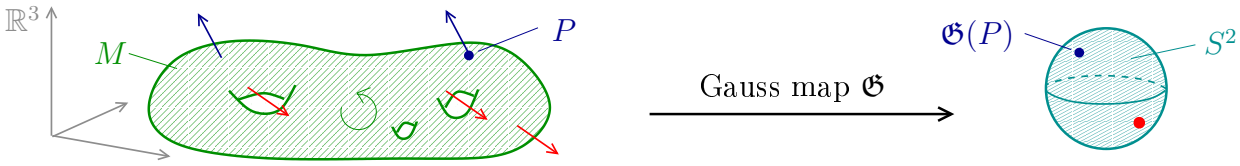
connected. Furthermore, by the previous discussions it remains to consider the case that M is non-orientable.

By the Orientation Covering-Proposition 49.5 there exists a 2-fold covering $p\colon \widetilde{M} \to M$ where $\widetilde{M}$ is a compact orientable smooth manifold and p is a local diffeomorphism. We equip $\widetilde{M}$ with the vector field p^*v that is the pullback of v under p, see the Vector Field-Pullback Lemma 23.21. In other words, p^*v is the unique vector field on $\widetilde{M}$ that satisfies $\mathrm{D}p_x(p^*v(x)) = v(p(x))$ for every $x \in \widetilde{M}$. We see that

$$2 \cdot \sum_{i=1}^{k} \operatorname{index}(v, P_i) \underset{\uparrow}{=} \sum_{i=1}^{k} \sum_{Q \in p^{-1}(P_i)} \operatorname{index}(p^*v, Q) \underset{\uparrow}{=} \chi(\widetilde{M}) \underset{\uparrow}{=} 2 \cdot \chi(M).$$

each P_i has two preimages and indices of the preimages agree with the index of P_i

by the above discussion, since $\widetilde{M}$ is orientable



by Proposition 69.4 and the Smooth Manifold-CW Structure Theorem 96.5 ■

129.3. **The Gauß map II.** In this section we return to the study of the Gauß map which we had introduced in Section 45.7. For the reader's convenience we recall the definition.

Definition. Let $n \in \mathbb{N}_0$ and let $M \subset \mathbb{R}^{n+1}$ be a closed oriented smooth submanifold of codimension one. We refer to the map

$$\begin{aligned} \mathfrak{G}\colon M &\to S^n \\ P &\mapsto \text{the unique } \mathfrak{G}(P) \in \mathbb{R}^{n+1} \text{ that has the following properties:} \\ &\quad (1)\ \mathfrak{G}(P) \text{ is normal to the physical tangent space } \widetilde{\mathrm{T}}_P M, \\ &\quad (2)\ \mathfrak{G}(P) \text{ has length one, i.e. } \mathfrak{G}(P) \in S^n, \\ &\quad (3)\ \mathfrak{G}(P) \text{ followed by a positive basis for } \widetilde{\mathrm{T}}_P M \text{ is a positive basis for } \mathbb{R}^{n+1} \end{aligned}$$

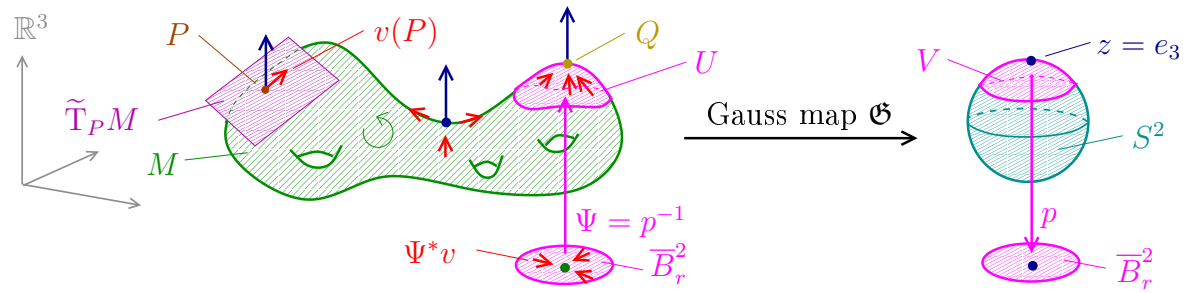
as the Gauß map of M.[1563] [1564]

Our goal now is to give another proof of the following theorem from Section 45.7.

[1563] A variation on the Gauß map appeared also in the definition of the rotation number of an immersion $S^1 \to \mathbb{R}^2$ on page 955.

[1564] As discussed in the Orientations-via-Normal Vector Fields Proposition 25.11, this map is smooth.

Theorem 45.24. (Gauß Map-Degree Theorem) Let $M \subset \mathbb{R}^{n+1}$ be a closed oriented connected smooth submanifold of codimension one. If n is even, then



$$\deg(\text{Gauß map } \mathfrak{G}\colon M \to S^n) \;=\; \tfrac{1}{2} \cdot \chi(M).$$

Remark. We refer to Section 45.7 for a discussion of consequences and alternative proofs of the Gauß Map-Degree Theorem 45.24.

Proof. Let $n \in \mathbb{N}_0$ and let $M \subset \mathbb{R}^{n+1}$ be a closed oriented connected smooth submanifold of codimension one. The proof we will now provide is a variation on the proof in Section 45.7. We refer to the earlier proof for details of the common aspects of the proofs. By Sard's Theorem 31.1 there exists some $z \in S^n$ such that z and $-z$ are both regular values of the Gauß map $\mathfrak{G}$. After a rotation, we can assume that $z = e_{n+1} = (0, \ldots, 0, 1) \in \mathbb{R}^{n+1}$. Next we consider the vector field

$$\begin{array}{rcl} v\colon M & \to & \mathbb{R}^{n+1} \\ Q & \mapsto & \underbrace{z - \langle z, \mathfrak{G}(Q)\rangle \cdot \mathfrak{G}(Q)}_{\text{orthogonal projection of } z \text{ to } \widetilde{\mathrm{T}}_Q M}. \end{array}$$

Clearly we have $v(Q) = 0$ if and only if $\mathfrak{G}(Q) = z$ or $\mathfrak{G}(Q) = -z$.

Let $Q \in M$ with $\mathfrak{G}(Q) = \pm z$. By design we know that Q is a regular value of $\mathfrak{G}$. By the Stack of Records Lemma 26.2 (1) we know that $\mathfrak{G}\colon M \to S^n$ is a local diffeomorphism at Q, thus, as on page 898, it makes sense to introduce the following definition:

$$\deg(\mathfrak{G}, Q) \;=\; \begin{cases} +1, & \text{if } \mathfrak{G} \text{ is orientation-preserving at } Q \\ -1, & \text{if } \mathfrak{G} \text{ is orientation-reversing at } Q. \end{cases}$$

Claim. Let $Q \in M$.
(1) If $\mathfrak{G}(Q) = z$, then $\operatorname{index}(v, Q) = (-1)^n \cdot \deg(\mathfrak{G}, Q)$.
(2) If $\mathfrak{G}(Q) = -z$, then $\operatorname{index}(v, Q) = \deg(\mathfrak{G}, Q)$.

Proof. First we consider the case that $\mathfrak{G}(Q) = z$. We make the following observations and preparations.

(a) We denote by $p\colon \mathbb{R}^{n+1} \to \mathbb{R}^n$ the projection onto the first n coordinates.
(b) It follows fairly easily from the Inverse Mapping Theorem 24.1 that there exists a neighborhood U of $Q \in M$, a neighborhood V of $z \in S^n$ and an $r \in \mathbb{R}_{>0}$ with the following properties:
 (i) U contains no other points x with $\mathfrak{G}(x) = z$.
 (ii) We have $\mathfrak{G}(U) \subset V$.

(iii) The restriction of the projection $p\colon \mathbb{R}^{n+1} \to \mathbb{R}^n$ to U and V defines diffeomorphisms $p\colon U \to \overline{B}^n_r$ and $p\colon V \to \overline{B}^n_r$. It follows immediately from the orientation conventions and some elementary linear algebra that both maps are orientation-preserving if n is even and both maps are orientation-reversing if n is odd.

(c) We set $\Psi := p^{-1}\colon \overline{B}^n_r \to U$.

(d) Recall that by definition we have $v(x) = z - \langle z, \mathfrak{G}(x)\rangle \cdot \mathfrak{G}(x)$. As we discussed on page 1038 one can easily show, using the Product Rule for partial differentials and using that $\mathfrak{G}(Q) = e$, that

$$\mathrm{D}(p \circ (x \mapsto -v(x)) \circ \Psi)_{p(Q)} \;=\; \mathrm{D}(p \circ \mathfrak{G} \circ \Psi)_{p(Q)}.$$

(e) We denote by $\rho\colon \overline{B}^n_r \to \overline{B}^n_r$ the map given by $\rho(x) = -x$.

We now see that

$$\begin{aligned}
\text{index}(v,Q) &\overset{\text{def. of index, see p. 2818, applied with our given } \Psi}{=} \deg\begin{pmatrix} S^{n-1}_r \to S^{n-1}_r \\ x \mapsto \frac{p(v(\Psi(x)))}{\|p(v(\Psi(x)))\|}\end{pmatrix} \overset{\text{by Exercises 14.4 and 76.4}}{=} \deg\big((p\circ v\circ\Psi)_* \circlearrowleft \mathrm{H}_n(\overline{B}^n_r, \overline{B}^n_r\setminus\{0\})\big) \overset{\text{by (d) together with the Local Diffeomorphism-Degree Proposition 76.14}}{=} \\
&= \deg\big((\rho\circ p\circ\mathfrak{G}\circ\Psi)_* \circlearrowleft \mathrm{H}_n(\overline{B}^n_r, \overline{B}^n_r\setminus\{0\})\big) \\
&\overset{\text{by Lemma 76.16}}{=} (-1)^n \cdot \deg\big((p\circ\mathfrak{G}\circ\Psi)_* \circlearrowleft \mathrm{H}_n(\overline{B}^n_r, \overline{B}^n_r\setminus\{0\})\big) \\
&= (-1)^n \cdot \deg(\mathfrak{G}, Q).
\end{aligned}$$

this follows from the definition of $\deg(\mathfrak{G}, Q)$ together with the Local Diffeomorphism-Degree Proposition 76.14 and the fact that we know that p and Ψ are either both orientation-preserving or they are both orientation-reversing

Now we consider the case that $\mathfrak{G}(Q) = -z$. The calculation is basically identical to the above. The only difference is that in this setting the map p is orientation-preserving if and only if n is odd, whereas before p was orientation-preserving if and only if n is even. On the other hand the behavior of the orientation of Ψ does not change, i.e. Ψ is orientation-preserving if and only if n is even. Thus we obtain the same result as above, except that by Lemma 76.16 we pick up a sign $(-1)^n$. ⊞

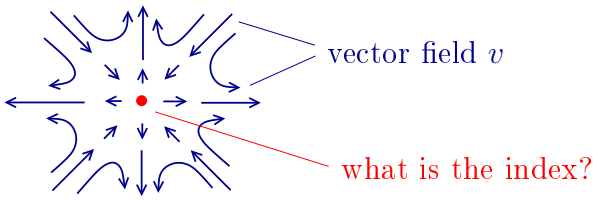
Now finally we assume that n is even. We perform the following calculation:

$$\begin{aligned}
2\cdot\deg(\text{Gauß map } \mathfrak{G}\colon M \to S^n) &\overset{\text{since } z \text{ and } -z \text{ are regular values we can apply the Local-Global Degree Proposition 101.6 to } z \text{ and to } -z}{=} \sum_{\substack{Q\in M \text{ with} \\ \mathfrak{G}(Q) = z}} \deg(\mathfrak{G}, Q) + \sum_{\substack{Q\in M \text{ with} \\ \mathfrak{G}(Q) = -z}} \deg(\mathfrak{G}, Q) \\
&= \sum_{\substack{Q\in M \text{ with} \\ v(Q) = 0}} \deg(\mathfrak{G}, Q) \qquad = \sum_{\substack{Q\in M \text{ with} \\ v(Q) = 0}} \text{index}(v, Q) = \chi(M).
\end{aligned}$$

since $v(Q)=0$ if and only if $\mathfrak{G}(Q)=-z$ or $\mathfrak{G}(Q)=z$ — by the claim and since n is even — by the Poincaré-Hopf Theorem 129 ■

Exercises for Chapter 129.

Exercise 129.1. We consider the two vector fields v and w that are shown in the figure below with a single zero at P. On page 1022 we already saw that $\text{index}(v, P) = +1$. What is $\text{index}(w, P)$?



Exercise 129.2.

(a) We consider the vector field v on $\mathbb{R}^2$ shown in the figure below. What is the index of v at the unique zero?

(b) Sketch a vector field v on $\mathbb{R}^2$ with a zero at some point P, such the corresponding index equals $+3$.

(c) Let $n \geq 2$. Show that for every $k \in \mathbb{Z}$ there exists a vector field v on $\mathbb{R}^n$ with a single zero at the origin 0 such that $\operatorname{index}(v, 0) = k$.

Exercise 129.3. Let M be a closed oriented n-dimensional smooth manifold. We consider the tangent bundle

$$\mathrm{T}M \;:=\; \bigsqcup_{x \in M} (\mathrm{T}_x M \times \{x\}).$$

(a) Show that $\mathrm{T}M$ is naturally an oriented $2n$-dimensional smooth manifold such that the map $\varphi\colon M \to \mathrm{T}M$ given by $x \mapsto (0, x) \in \mathrm{T}_x M \times \{x\}$ is a smooth embedding.

(b) Show that there exists a smooth embedding $\psi\colon M \to \mathrm{T}M$, that is homotopic to φ, such that the submanifolds $\varphi(M)$ and $\psi(M)$ of $\mathrm{T}M$ intersect transversally and such that $\varphi(M) \cdot \psi(M) = \chi(M)$. Here the left-hand side is the algebraic intersection number as defined on page 2748.
Hint. Use the Non-Degenerate Vector Field Existence Proposition 129.4.
Remark. In the literature the statement we just proved sometimes gets shortened to "$M \cdot M = \chi(M)$".

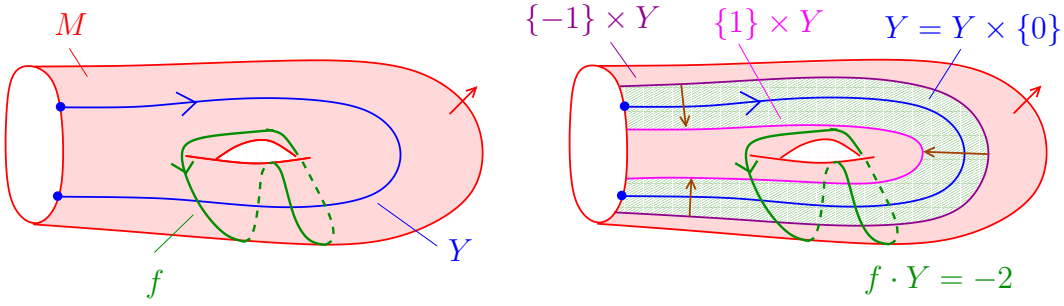
Exercise 129.4. We say that two vector fields v and w on a smooth manifold M are equivalent if there exists a diffeotopy $H\colon M \times [0,1] \to M$ with $H_0 = \mathrm{id}$ and such that $(H_1)_*(v) = w$, i.e. such that for every $x \in M$ we have $(\mathrm{D}H_1)_x(v(x)) = w_{H_1(x)}$. Are all nowhere-vanishing smooth vector fields on the torus $S^1 \times S^1$ equivalent?

130. Homology, cohomology and submanifolds

In this chapter, given an oriented, compact smooth manifold M we will relate the following objects:

(1) Codimension one submanifolds of M,
(2) cohomology classes in $\mathrm{H}^1(M;\mathbb{Z})$ of dimension one,
(3) homology classes in $\mathrm{H}_{n-1}(M,\partial M;\mathbb{Z})$ of codimension one,
(4) maps $M \to S^1$.

130.1. **Codimension one submanifolds.** Let M be a compact oriented connected n-dimensional topological manifold. Every compact oriented proper submanifold $Y \subset M$ of *codimension* k gives rise to a homomorphism



$$\begin{array}{rcl} \mathrm{H}_k(M;\mathbb{Z}) & \to & \mathbb{Z} \\ \sigma & \mapsto & \langle \underbrace{\mathrm{PD}_M([Y])}_{\in \mathrm{H}^k(M;\mathbb{Z})}, \sigma \rangle. \end{array}$$

In many circumstances the next proposition gives an explicit description of this homomorphism $\mathrm{H}_k(M;\mathbb{Z}) \to \mathbb{Z}$:

Proposition 130.1. Let M be a compact oriented connected n-dimensional topological manifold and let $Y \subset M$ be a compact oriented proper submanifold of *codimension* k. Let $f\colon X \to M$ be a map from a closed k-dimensional topological manifold X to M. If f is transverse to Y, then

$$\langle \underbrace{\mathrm{PD}_M([Y])}_{\in \mathrm{H}^k(M;\mathbb{Z})}, \underbrace{f_*([X])}_{\in \mathrm{H}_k(M;\mathbb{Z})} \rangle \;=\; f \cdot Y.$$

Remark. Let M be a compact oriented connected n-dimensional topological manifold and let $Y \subset M$ be a compact oriented proper submanifold of codimension one. In Proposition **??** we saw that Y admits a tubular neighborhood of the form $[-1,1]\times Y$ such that the product orientation of $[-1,1] \times Y$ matches the orientation of M. If $f\colon S^1 \to M$ is a map, then loosely speaking, the algebraic intersection number $f \cdot Y$ counts (with signs) how often f goes from $Y \times \{\mp 1\}$ to $Y \times \{\pm 1\}$.

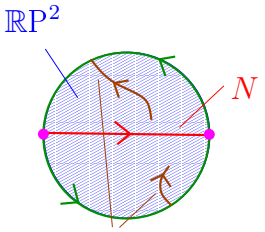
Proof. We have

$$f \cdot Y \underset{\text{by Theorem 127.7 since } f \text{ and } Y \text{ are transverse}}{=} \epsilon_M\big((\mathrm{PD}_M(f_*([X])) \cup \mathrm{PD}_M([Y])) \cap [M]\big) \underset{\text{by the Cup-Cap Lemma 116.7 and the discussion on page 2558}}{=} \epsilon_M\big(\mathrm{PD}_M([Y]) \cap (\mathrm{PD}_M(f_*([X]) \cap [M]))\big)$$

$$\underset{\text{definition of } \mathrm{PD}_M(f_*([X]))}{=} \epsilon_M(\mathrm{PD}_M([Y]) \cap f_*([X])) \qquad \underset{\text{Cap Product-Kronecker Lemma 116.4}}{=} \langle \mathrm{PD}_M([Y]), f_*([X]) \rangle.$$

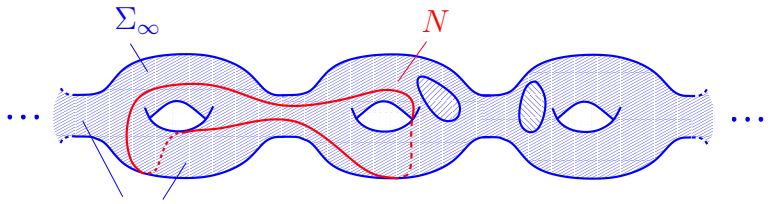
■

Now we can prove the following proposition which gives an easy criterion for showing that a codimension-one submanifold represents a non-trivial class in homology.



Proposition 130.2. (Non-Separating Codimension-One Submanifold Proposition) Let M be a compact oriented n-dimensional smooth manifold and let N be a compact orientable non-empty proper submanifold of codimension one. If the complement $M \setminus N$ is connected, then $[N] \in \mathrm{H}_{n-1}(M, \partial M; \mathbb{Z})$ is a primitive[1565] element of infinite order.

Example. The Non-Separating Codimension-One Submanifold Proposition 130.2 can in particular be seen as a generalization of the argument given on page 2754.

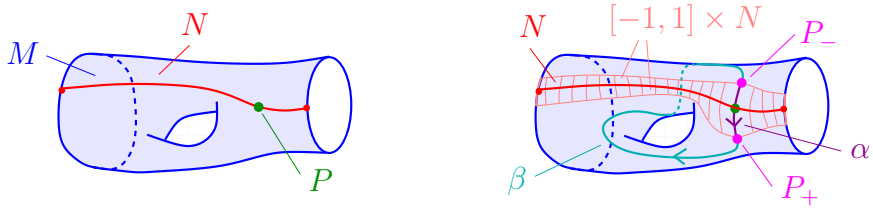


Remark. In any statement of a lemma, proposition or theorem it is always a good exercise to see whether the hypothesis stated are actually necessary. In the following we will discuss whether the conditions in the Non-Separating Codimension-One Submanifold Proposition 130.2 that M needs to be compact and oriented are necessary.

(1) We consider the real projective plane $\mathbb{R}\mathrm{P}^2$ and the 1-dimensional submanifold N that is illustrated in the figure below to the left. We see that $\mathbb{R}\mathrm{P}^2 \setminus N$ is connected, but since $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2; \mathbb{Z}) \cong \mathbb{F}_2$ we see that N cannot possibly represent an element of infinite order. On the other hand, an "$\mathbb{F}_2$-version" of the Non-Separating Codimension-One Submanifold Proposition 130.2, which by the $\mathbb{F}_2$-Orientability Proposition 105.13 also applies to non-orientable smooth manifolds, shows that N represents a non-trivial element in $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$.

(2) Let M be a non-compact oriented n-dimensional smooth manifold and let N be a compact orientable non-empty proper submanifold of codimension one. If ∂M is compact, then we will see in Exercise 130.1 using the Compact Submanifold Exhaustion Proposition 31.2 and 130.2, that the homology class $[N] \in \mathrm{H}_{n-1}(M; \mathbb{Z})$ is still an element of infinite order.

path in $\mathbb{R}\mathrm{P}^2 \setminus N$ shows that $\mathbb{R}\mathrm{P}^2 \setminus N$ is connected



$\Sigma_\infty \setminus N$ is connected

[1565] Recall that an element g of an additive abelian group G is called *primitive* if there does not exist an $h \in G$ and an $n \geq 2$ with $n \cdot h = g$.

Proof. Let M be a compact oriented n-dimensional smooth manifold and let N be a compact orientable proper submanifold of codimension one such that $M \setminus N$ is connected. By Proposition **??** we can find a trivial tubular neighborhood $[-1,1] \times N$ in M. By hypothesis $M \setminus N$ is connected. It follows from Proposition 123.4, Lemma 123.1 and the Topological Manifolds-Local Properties Lemma 18.8 (3) that $M \setminus (-1,1) \times N$ is path-connected.

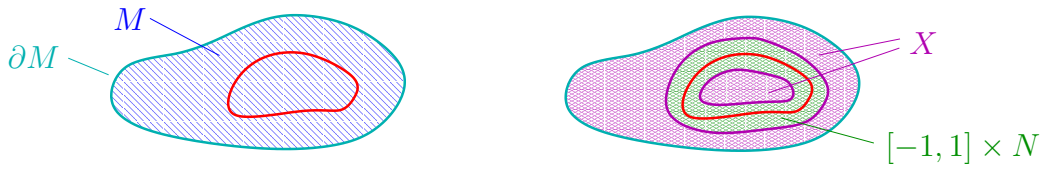
It follows from our hypothesis that N is non-empty, together with the Topological Manifold Boundary Proposition 75.2 (5), that we can pick a point $P \in N \setminus \partial N$. We write $P_\pm = P \times \{\pm 1\} \in [-1,1] \times N$. We denote by $\alpha\colon [0, \frac{1}{2}] \to [-1,1] \times N$ the "horizontal path" in $[-1,1] \times N$ from P_- to P_+. Since $M \setminus (-1,1) \times N$ is path-connected we can connect the two points P_+ to P_- via a path $\beta\colon [\frac{1}{2}, 1] \to M \setminus (-1,1) \times N$.

We consider the map $\gamma\colon S^1 = [0,1] \to M$ that is defined by α on $[0, \frac{1}{2}]$ and that is given by β on $[\frac{1}{2}, 1]$. We consider the following homomorphism

$$\begin{aligned} \Psi\colon \mathrm{H}_{n-1}(M, \partial M; \mathbb{Z}) &\to \mathbb{Z} \\ \sigma &\mapsto \langle \underbrace{\mathrm{PD}_M(\sigma)}_{\in \mathrm{H}^1(M;\mathbb{Z})}, \underbrace{\gamma_*([S^1])}_{\in \mathrm{H}_1(M;\mathbb{Z})} \rangle. \end{aligned}$$

We want to show that $[N] \in \mathrm{H}_{n-1}(M, \partial M; \mathbb{Z})$ is a primitive element of infinite order. It suffices to show that $\Psi([N]) = \pm 1 \in \mathbb{Z}$. In fact we have

$$\Psi([N]) \underset{\text{by definition}}{=} \langle \mathrm{PD}_M([N]), \gamma_*([S^1]) \rangle \underset{\substack{\text{by Proposition 130.1 since} \\ \gamma \text{ and } N \text{ are clearly transverse}}}{=} \gamma \cdot N \underset{\text{by construction of } \gamma}{=} \pm 1,$$



as desired. ∎

We conclude this section with the following lemma.

Lemma 130.3. Let M be a compact orientable n-dimensional smooth manifold with at most one boundary component and which furthermore satisfies $\mathrm{H}_1(M; \mathbb{Z}) = 0$. (For example we could take $M = \overline{B}^n$ or $M = S^n$). Then for every connected submanifold N of codimension one with $N \cap \partial M = \varnothing$ there exists a compact n-dimensional submanifold W of M with $\partial W = N$.

Proof. By Proposition **??** we can find a trivial tubular neighborhood $[-1,1] \times N$ in M. It follows from the argument of the proof of the Non-Separating Codimension-One Submanifold Proposition 130.2 and our assumption that M is orientable and the fact that M is compact that $X := M \setminus (-1,1) \times N$ is disconnected. Furthermore it follows from the Codimension-Zero Submanifold Proposition 19.38 that X is a submanifold of M with $\partial X = \partial M \cup (\{-1\} \times N) \cup (\{1\} \times N)$. Since ∂M consists of at most one component, since M is connected and since X is disconnected we see that there exists a component Y of X

with $\partial X = \{\epsilon\} \times N$ for some $\epsilon \in \{-1, 1\}$. By adding "half" of the tubular neighborhood to Y we obtain a submanifold with $\partial Y = M$. ■

130.2. **Representing homology classes by submanifolds II.** First we recall the following definition from page 2246.

Definition. Let M be a smooth manifold and let A be a union of components of ∂M.

(1) If N is a compact oriented k-dimensional submanifold of M with $\partial N \subset A$, then we denote by $[N]$ the image of the fundamental class $[N]$ in $\mathrm{H}_k(M, A; \mathbb{Z})$ under the inclusion induced map $\mathrm{H}_k(N, \partial N; \mathbb{Z}) \to \mathrm{H}_k(M, A; \mathbb{Z})$.
(2) We say that a homology class $z \in \mathrm{H}_k(M, A; \mathbb{Z})$ is represented by a submanifold if there exists a compact oriented proper k-dimensional submanifold N with $\partial N \subset A$ such that $[N] = z$.

Let M be an orientable, compact n-dimensional smooth manifold. We saw in the Intersection Number-via-Cup Product Theorem 126.5 that we can calculate the cup product of $\alpha \in \mathrm{H}^k(M, \partial M; \mathbb{Z})$ and $\beta \in \mathrm{H}^{n-k}(M; \mathbb{Z})$ if the Poincaré duals $\mathrm{PD}_M(\alpha) \in \mathrm{H}_{n-k}(M; \mathbb{Z})$ and $\mathrm{PD}_M(\beta) \in \mathrm{H}_k(M, \partial M; \mathbb{Z})$ are represented by transverse submanifolds. This rekindles our interest in the following question.

Question 102.11. Let M be an n-dimensional smooth manifold and let A be a union of components of ∂M. For which $k \in \mathbb{N}_0$ can homology classes in $\mathrm{H}_k(M, A; \mathbb{Z})$ be represented by submanifolds?

We already studied Question 102.11 in great detail in Section 102.4. For example in Corollary 102.14 and Corollary 102.17 we proved the following:

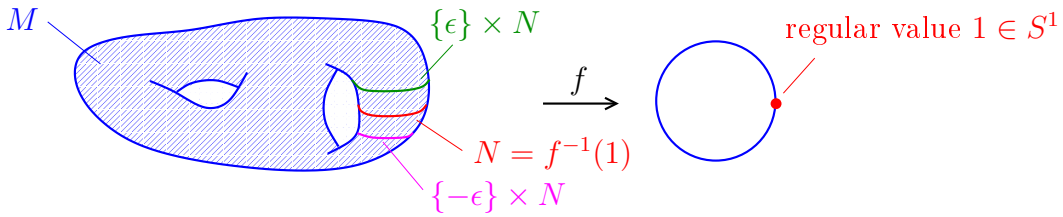
(1) If $n \geq 2$, then every class in $\mathrm{H}_1(M, A; \mathbb{Z})$ can be represented by a submanifold.
(2) If $n \geq 4$, then every class in $\mathrm{H}_2(M, A; \mathbb{Z})$ can be represented by a connected submanifold.

Instead of moving on to the next highest dimension, we now actually consider homology classes of *codimension one*. More precisely, we want to prove the following proposition.

Proposition 130.4. (Codimension-One Submanifold Existence Proposition) Let M be a compact orientable n-dimensional smooth manifold and let $A \subset \partial M$ be a union of boundary components. Every class in $\mathrm{H}_{n-1}(M, A; \mathbb{Z})$ can be represented by a submanifold.

Remark.

(1) In Proposition 130.6 we will prove a refinement of the Codimension-One Submanifold Existence Proposition 130.4.
(2) In Proposition **??** we will prove the codimension-two analogue of the Codimension-One Submanifold Existence Proposition 130.4. Furthermore in Proposition **??** we will prove an "$\mathbb{F}_2$-coefficient"-analogue of the Codimension-One Submanifold Existence Proposition 130.4.



Proof. Let M be a compact orientable n-dimensional smooth manifold. In the following we deal with the case that $A = \partial M$. The general case is proved in a similar fashion, but now one needs to use Exercise 118.5 (4) instead of the Maps-to-S^1 Proposition 118.13. We leave it to the reader to work out the details.

Now let $\sigma \in \mathrm{H}_{n-1}(M, \partial M; \mathbb{Z})$. We write $\phi = \mathrm{PD}_M(\sigma) \in \mathrm{H}^1(M; \mathbb{Z})$. By the Maps-to-$S^1$ Proposition 118.13 or alternatively by Proposition 163.20 there exists a smooth map $f\colon M \to S^1$ such that $\phi = f^*([S^1]^*)$ where $[S^1]^* \in \mathrm{H}^1(S^1; \mathbb{Z})$ is the dual fundamental class.

By Sard's Theorem 31.1 and the Full Measure-Density Proposition 30.3 (2) there exists a regular value $z \in S^1$. To simplify the notation we assume that in fact $z = 1$ is a regular value. We write $N := f^{-1}(1)$. By the Regular Value Theorem **??** (1), (2), (3) we know that N is a compact orientable $(n-1)$-dimensional smooth manifold. Furthermore we know from Theorem **??** (4) that there exists an $\epsilon \in (0, \pi)$ and a tubular neighborhood $[-\epsilon, \epsilon] \times N$ of N such that the following diagram commutes

$$\begin{array}{ccc} [-\epsilon, \epsilon] \times N & \hookrightarrow & M \\ \downarrow{\scriptstyle (s,x)\mapsto s} & & \downarrow{\scriptstyle f} \\ [-\epsilon, \epsilon] & \xrightarrow{s\mapsto \exp(2\pi \mathrm{i} s)} & S^1. \end{array}$$

We pick the orientation for N such that the inclusion map $[-\epsilon, \epsilon] \times N \to M$ is orientation-preserving. It remains to prove that $[N] = \sigma \in \mathrm{H}_{n-1}(M, \partial M; \mathbb{Z})$. Recall that $\phi = \mathrm{PD}_M(\sigma)$, i.e. $\sigma = \phi \cap [M]$. Therefore it suffices to show that $[N] = \phi \cap [M] \in \mathrm{H}_{n-1}(M, \partial M; \mathbb{Z})$.

We introduce the following notation:

(1) We write $I = [-\epsilon, \epsilon]$ and $\mathring{I} = (-\epsilon, \epsilon)$,
(2) we denote by $i\colon I \times N \to M$ the inclusion map and we denote by i also all maps of pairs where the first map is given by the inclusion map,
(3) we denote by q all maps of pairs of topological spaces where the first map is just the identity on M,
(4) finally we denote by $p\colon I \times N \to I$ the projection .

We consider the following diagram[1566]

$$\begin{array}{ccccc}
\mathrm{H}^1(M) & \times & \mathrm{H}_n(M,\partial M) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-1}(M,\partial M) \\
{\scriptstyle q^*}\uparrow & & \downarrow{\scriptstyle q_*} & & {\scriptstyle q_*}\downarrow{\scriptstyle =} \\
\mathrm{H}^1(M, M\setminus(\mathring{I}\times N)) & \times & \mathrm{H}_n(M, M\setminus(\mathring{I}\times N)\cup\partial M) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-1}(M,\partial M) \\
{\scriptstyle i^*}\downarrow{\scriptstyle \cong} & & \uparrow{\scriptstyle i_*} & & {\scriptstyle i_*}\uparrow \\
\mathrm{H}^1(I\times N,\partial I\times N) & \times & \mathrm{H}_n(I\times N,\partial(I\times N)) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_{n-1}(I\times N, I\times\partial N) \\
{\scriptstyle p^*}\uparrow & & \uparrow{\scriptstyle -\times[N]} & & {\scriptstyle -\times[N]}\uparrow \\
\mathrm{H}^1(I,\partial I) & \times & \mathrm{H}_1(I,\partial I) & \xrightarrow{\quad\cap\quad} & \mathrm{H}_0(I).
\end{array}$$

The proposition follows from the following claim.

Claim.

(1) The diagram commutes.[1567]
(2) The map $i^*\colon \mathrm{H}^1(M, M\setminus(\mathring{I}\times N)) \to \mathrm{H}^1(I\times N, \partial I\times N)$ is an isomorphism.
(3) We have $(q^*\circ i_*^{-1}\circ p^*)([I]^*) = \phi$.
(4) We have $i_*([I]\times[N]) = q_*([M])$.

Proof.

(1) The top two squares commute by the Cap Product-Naturality Lemma 116.8 applied to the two maps

$$\begin{aligned} q\colon (M,\varnothing,\partial M) &\to (M, M\setminus(\mathring{I}\times N),\partial M) \\ \text{and} \\ i\colon (I\times N,\partial I\times N, I\times\partial N) &\to (M, M\setminus(\mathring{I}\times N),\partial M). \end{aligned}$$

Finally regarding the bottom square, note that

$$p^*([I]^*)\cap([I]\times[N]) \underset{\text{Topological Product Orientation Proposition 113.10}}{=} p^*([I]^*)\cap([I\times N]) \underset{\text{Fundamental Class-Product Proposition 117.2 (2)}}{=} [\{0\}\times N] = (\overbrace{[I]^*\cap[I]}^{=[\{0\}]})\times[N].$$

Since $[I]^*\in\mathrm{H}^1(I,\partial I)$ and $[I]\in\mathrm{H}_1(I,\partial I)$ are generators it follows from this calculation that the bottom square commutes.

(2) It follows from excision for cohomology groups, see page 2418, that i^* is indeed an isomorphism. We leave it to the reader to verify the details.

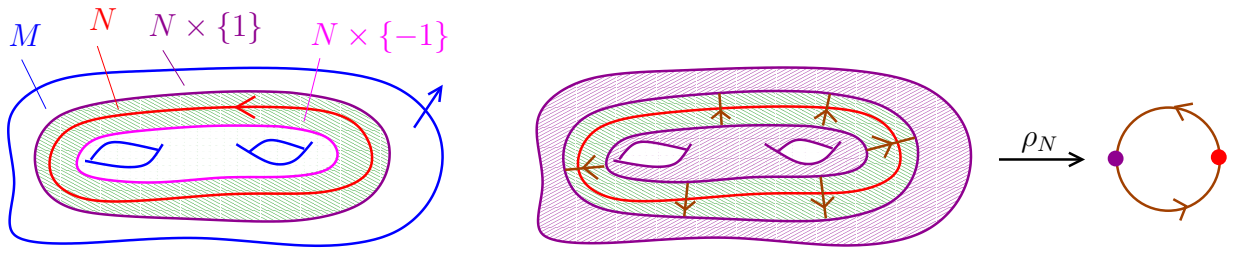
(3) We identify the interval I with its image in S^1 under the orientation-preserving map defined by $s\mapsto\exp(2\pi\mathrm{i}s)$. We denote by $j\colon I\to S^1$ and $j\colon (I,\partial I)\to(S^1, S^1\setminus\mathring{I})$ the inclusion maps. Furthermore we denote by $r\colon (S^1,\varnothing)\to(S^1, S^1\setminus\mathring{I})$ the obvious

[1566]For completeness' sake we recall that the relative cap product is only defined for excisive triads, see page 2536. So one should think for a second about why the second cap product is in fact defined.
[1567]Note that here for the first three rows we use the convention of page 2538 for what "commutativity" actually means.

map of pairs of topological spaces. We consider the following diagram

$$\begin{array}{ccc}
\mathrm{H}^1(S^1) & \xrightarrow{\quad f^* \quad} & \mathrm{H}^1(M) \\
{\scriptstyle r^*}\uparrow & & \uparrow{\scriptstyle q^*} \\
\mathrm{H}^1(S^1, S^1 \setminus \mathring{I}) & \xrightarrow{\quad f^* \quad} & \mathrm{H}^1(M, M \setminus (\mathring{I} \times N)) \\
{\scriptstyle \cong}\downarrow{\scriptstyle j^*} & & {\scriptstyle i^*}\downarrow{\scriptstyle \cong} \\
\mathrm{H}^1(I, \partial I) & \xrightarrow{\quad f^*=p^* \quad} & \mathrm{H}^1(I \times N, \partial I \times N).
\end{array}$$

Here the map j^* is an isomorphism by excision for cohomology groups. Also note that at the bottom horizontal map we have $f^* = p^*$ by the discussion on page 2837. Furthermore we note that by the functoriality of cohomology groups both squares commute. Finally we point out that it follows immediately from the Codimension Zero-Fundamental Class Lemma 106.24 that $r^*((j^*)^{-1}([I]^*)) = [S^1]^*$. The desired statement is a consequence of the observation that $\phi = f^*([S^1]^*)$.



(4) This statement follows immediately from the Codimension Zero-Fundamental Class Lemma 106.24. ■

130.3. **The basic Thom-Pontryagin Theory.** In the proof of the Codimension-One Submanifold Existence Proposition 130.4 we saw that a map from a smooth manifold N to S^1 gives rise to a codimension-one submanifold. In this section we will go in the opposite direction.

Definition. Let M be a compact oriented n-dimensional smooth manifold and let N be a proper oriented $(n-1)$-dimensional submanifold. By Proposition **??** there exists a trivial tubular neighborhood of the form $[-1,1]\times N$ such that the product orientation of $[-1,1]\times N$ matches the orientation of $[-1,1] \times N$, viewed as a codimension-zero submanifold of M. We refer to the map[1568]

$$\begin{array}{rccl}
\rho_N\colon & M & \to & S^1 \\
& P & \mapsto & \begin{cases} \exp(\pi i t), & \text{if } P = (t, Q) \in [-1,1] \times N, \\ -1, & \text{otherwise} \end{cases}
\end{array}$$

as the Thom-Pontryagin map.[1569] The definition of ρ_N is illustrated in the figure below.

[1568] It follows easily from the Codimension-Zero Smooth Embedding Proposition 24.16 and the Homotopy Stacking Lemma 14.3 that this map is indeed continuous.

[1569] Lev Pontryagin (1908-1988) was a Soviet topologist, he made many major contributions to topology, despite having lost his eyesight in an accident when he was 14.

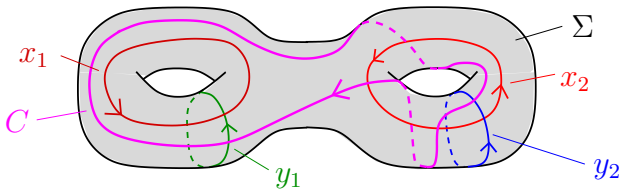
Remark. The Thom-Pontryagin map ρ_N that we had just constructed depends on the choice of a tubular neighborhood. But it follows from the uniqueness of tubular neighborhoods, see Proposition **??**, together with Lemma **??** (2) that any other choice of a tubular neighborhood $[-1,1] \times N$ leads to a map $M \to S^1$ that is homotopic to the original map.

Lemma 130.5. Let M be a compact oriented n-dimensional smooth manifold and let N be a proper oriented proper $(n-1)$-dimensional submanifold. We have

$$\rho_{N*} \;=\; \mathrm{PD}_M([N]) \;\in\; \mathrm{Hom}(\mathrm{H}_1(N;\mathbb{Z}),\mathbb{Z}) \;\underset{\uparrow}{=}\; \mathrm{H}^1(N;\mathbb{Z}).$$

identification from the First Cohomology Proposition 110.17

Proof. We had implicitly verified this lemma in the above proof of the Codimension-One Submanifold Existence Proposition 130.4. ■



Example. We return to the example that we had discussed on page 2607. More precisely, let Σ be the surface of genus 2. The closed curves x_1, y_1, x_2, y_2 shown in the figure below represent a basis for $\mathrm{H}_1(\Sigma;\mathbb{Z})$. We consider the epimorphism $\phi\colon \mathrm{H}_1(\Sigma) \to \mathbb{Z}$ that is given by $\phi(x_1) = 0$, $\phi(y_1) = 1$, $\phi(x_2) = -2$ and $\phi(y_2) = 1$. By the Maps-to-S^1 Proposition 118.13 we know that ϕ can be realized by some map $g\colon \Sigma \to S^1$. Now we will construct such a map explicitly.

We consider the closed curve C that is illustrated in the figure below. We claim that the corresponding map $\rho_C\colon \Sigma \to S^1$ has the desired property. Put differently, we claim that $\rho_{C*} = \phi \in \mathrm{Hom}(\mathrm{H}_1(N;\mathbb{Z}),\mathbb{Z})$. It suffices to show that the two homomorphisms agree on the basis $[x_1], [y_1], [x_2], [y_2]$ of $\mathrm{H}_1(\Sigma;\mathbb{Z})$. For example we have

$$\rho_{C*}([x_2]) \underset{\uparrow}{=} \langle \mathrm{PD}_M([C]), [x_2]\rangle \underset{\uparrow}{=} x_2 \cdot C \underset{\uparrow}{=} -2 \;=\; \phi(x_2).$$

Lemma 130.5 — Proposition 130.1 — see the figure below

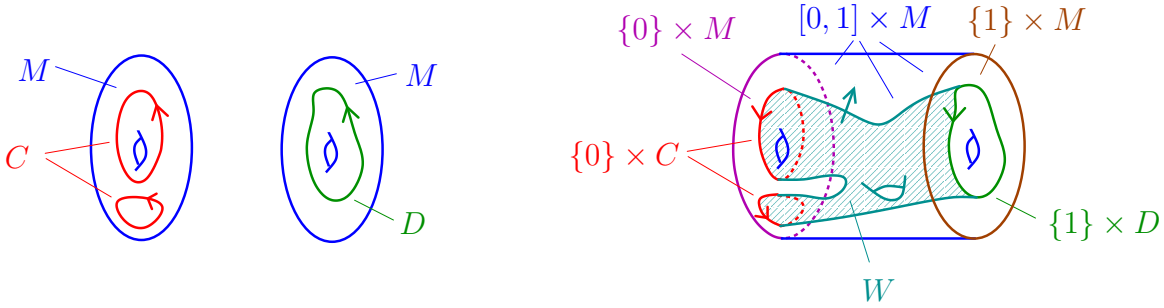
It is straightforward to verify that the same equalities hold for all the other basis elements.

Now we have the tools to prove the following refinement of Proposition 130.6.

Proposition 130.6. Let M be a compact orientable n-dimensional smooth manifold and let $\phi \in \mathrm{H}_{n-1}(M, \partial M;\mathbb{Z})$. Let $\partial\phi \in \mathrm{H}_{n-2}(\partial M)$ be the image of ϕ under the connecting homomorphism in the long exact sequence of the pair $(M, \partial M)$. If $F \subset \partial M$ is a submanifold that represents $\partial\phi \in \mathrm{H}_{n-2}(A)$, then ϕ can be represented by a submanifold N of M with $\partial N = F$.

Proof. Let M be a compact oriented n-dimensional smooth manifold. Suppose we are given a homology class $\phi \in \mathrm{H}_{n-1}(M, \partial M;\mathbb{Z})$ and a submanifold $F \subset \partial M$ that represents $\partial\phi \in \mathrm{H}_{n-2}(\partial M)$. As above we pick a trivial tubular neighborhood $[-1,1] \times F$ in ∂M such that the product orientation of $[-1,1] \times F$ matches the orientation of ∂M. Next we

consider the corresponding Thom-Pontryagin map



$$\begin{array}{rcl} \rho_F \colon \partial N & \to & S^1 \\ P & \mapsto & \begin{cases} \exp(\pi \mathrm{i} t), & \text{if } P = (t, Q) \in [-1,1] \times F, \\ -1, & \text{otherwise} \end{cases} \end{array}$$

Note that ρ_F is smooth on the closed subset $[-\frac{1}{2}, \frac{1}{2}] \times F$. It follows quite easily from the Whitney Approximation Theorem 29.1 (5) that ρ_F is homotopic rel $[-\frac{1}{2}, \frac{1}{2}] \times F$ to a smooth map $f \colon \partial N \to S^1$ which is "close to ρ_F" in the sense that it has the property that for $P \notin [-\frac{1}{2}, \frac{1}{2}] \times F$ we have $f(P) \notin \{\exp(\pi \mathrm{i}) \,|\, t \in [-\frac{1}{4}, \frac{1}{4}]\}$. Now note that it follows from Proposition 119.25 together with the Maps-to-S^1 Proposition 118.13 (3) that there exists a smooth map $g \colon M \to S^1$ that represents $\mathrm{PD}_M(\phi) \in \mathrm{H}^1(M, \partial M; \mathbb{Z})$ and that agrees with f on ∂M.

By Sard's Theorem 31.1 and the Full Measure-Density Proposition 30.3 (2) there exists an $s \in (-\frac{1}{4}, \frac{1}{4})$ such that $\exp(\pi \mathrm{i} s)$ is a regular value of g. We write $N := g^{-1}(z)$. By the proof of the Codimension-One Submanifold Existence Proposition 130.4 (1) we know that N is a smooth proper submanifold that represents ϕ. Note that by construction we have $\partial N = N \cap \partial M = \{s\} \times F$. Using a collar neighborhood of ∂M it is straightforward to find an isotopy that arranges that $\partial N = \{0\} \times F = F$. We leave it to the reader to fill in the few remaining details. ∎

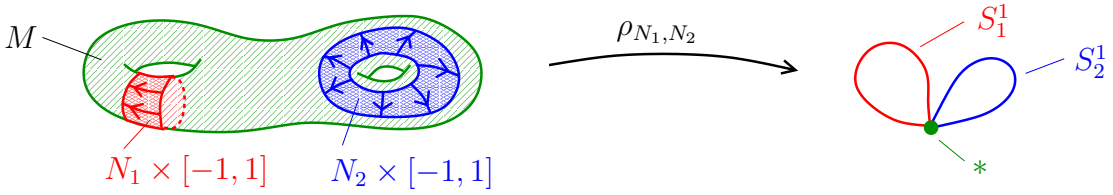
Later on we will make use of the following useful corollary.

Corollary 130.7. (Cobounding Submanifolds Corollary) Let M be a closed orientable n-dimensional smooth manifold and let C and D be two closed oriented $(n-1)$-dimensional submanifolds. If $[C] = [D] \in \mathrm{H}_n(M; \mathbb{Z})$, then there exists a compact oriented proper n-dimensional submanifold $W \subset [0,1] \times M$ such that $\partial W = (\{0\} \times C) \cup (\{1\} \times -D)$.

Proof. We consider the following diagram:

$$\begin{array}{ccccccccc} \ldots \longrightarrow & \mathrm{H}_n([0,1] \times M) & \xrightarrow{\partial} & \mathrm{H}_{n-1}((\{0\} \times M) \cup (\{1\} \times M)) & \xrightarrow{i_*} & \mathrm{H}_{n-1}([0,1] \times M) & \longrightarrow \ldots \\ & & & & & \downarrow{\scriptstyle p_*}\cong & \\ & & & & & \mathrm{H}_n(M) & \end{array}$$

Here the horizontal sequence is the long exact sequence in homology corresponding to the pair $([0,1] \times M, (\{0\} \times M) \cup (\{1\} \times M))$. Furthermore $p \colon [0,1] \times M \to M$ denotes the obvious projection. Our hypothesis that $[C] = [D] \in \mathrm{H}_n(M; \mathbb{Z})$ implies immediately that $p_*([\{0\} \times C]) = p_*([\{1\} \times D])$. Since p_* is an isomorphism and since the sequence is exact we see that there exists a homology class $\varphi \in \mathrm{H}_n([0,1] \times M)$ with $\partial \varphi = [\{0\} \times C] - [\{1\} \times D]$. Finally



note that it follows immediately from Proposition 130.6 that there exists in particular a compact oriented proper n-dimensional submanifold W of $[0,1] \times M$ with $[W] = \varphi$ and with $\partial W = (\{0\} \times C) \cup (\{1\} \times -D)$. ■

In the remainder of this chapter we study an amusing generalization of the above Thom-Pontryagin map.

Definition. Let M be a compact oriented n-dimensional smooth manifold. Furthermore let $N_1, \ldots, N_k$ be disjoint proper oriented $(n-1)$-dimensional submanifolds. As on page 2839 we pick a trivial tubular neighborhood of the form $[-1,1] \times (N_1 \cup \cdots \cup N_k)$. We consider the wedge $\bigvee_{j=1}^{k} S^1_j$ given by identifying the points $-1 \in S^1_j$ to a single point $*$. We again refer to the map

$$\begin{aligned} \rho_{N_1,\ldots,N_k} \colon M &\to \bigvee_{j=1}^{k} S^1_j \\ P &\mapsto \begin{cases} \exp(\pi i t) \in S^1_j, & \text{if } P = (t,Q) \in [-1,1] \times N_j, \\ *, & \text{otherwise} \end{cases} \end{aligned}$$

as the Thom-Pontryagin map.

Before we continue we recall that in the Fundamental Group-Wedge-of-Circles Lemma 52.4 we gave an identification

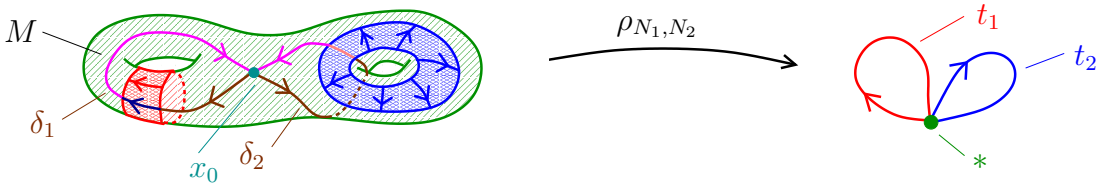
$$\langle t_1, \ldots, t_k \rangle \;=\; \pi_1\Big(\bigvee_{j=1}^{k} S^1_j, * \Big)$$

where each t_j is represented by a loop that goes once around the j-th circle S^1_j in a positive direction.

Proposition 130.8. (Epimorphism-onto-Free Group Proposition) Let M be a compact oriented connected n-dimensional smooth manifold and let $N_1, \ldots, N_k$ be disjoint proper oriented non-empty $(n-1)$-dimensional submanifolds. If $M \setminus (F_1 \cup \cdots \cup F_k)$ is connected, then for any $x_0 \in M$ the map

$$\rho_{N_1,\ldots,N_k} \colon \pi_1(M, x_0) \;\to\; \pi_1\Big(\bigvee_{j=1}^{k} S^1_j, * \Big) \;=\; \langle t_1, \ldots, t_k \rangle$$

is an epimorphism.

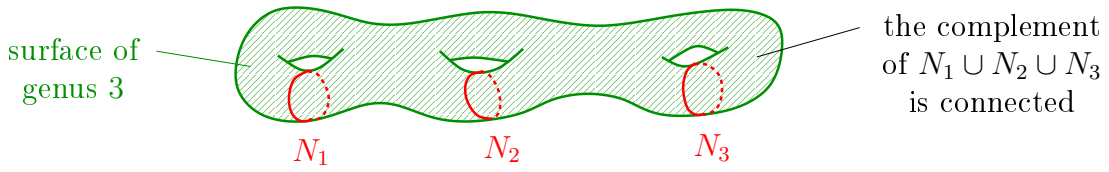


Proof. We write $N = N_1 \cup \cdots \cup N_k$ and $\rho = \rho_{N_1,\ldots,N_k}$. We pick a trivial tubular neighborhood of the form $[-1,1] \times N$. It follows from our hypothesis that $M \setminus N$ is connected, together with Proposition 123.4 and Lemma 123.1 that $M \setminus (-1,1) \times N$ is also connected. Since M is connected it follows from Proposition 47.20 that it suffices to consider a base point x_0 that lies in $M \setminus (-1,1) \times N$.

For $j = 1, \ldots, k$ we do the following:

(1) we pick a point $P_i \in N_i$,

(2) since $M \setminus (-1,1) \times N$ is connected we can pick a path α_j from x_0 to $(-1, P_j)$ and we can pick a path γ_j from $(1, P_j)$ to x_0,
(3) we denote by β_j the "horizontal" path in $[-1,1] \times \mathbb{N}_j$ from $(-1, P_j)$ to $(1, P_j)$,
(4) we write $\delta_j := \alpha_j * \beta_j * \gamma_j$.



It follows easily from the definitions that for $j = 1, \ldots, k$ we have $\rho_*([\delta_j]) = t_j$. We have thus shown that the generating set $\{t_1, \ldots, t_k\}$ lies in the image of ρ_*. In other words, ρ_* is indeed an epimorphism. ■

Example. Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g. As should be pretty clear from considering the figure below, the surface Σ_g contains g disjoint curves $N_1, \ldots, N_g$ such that the complement is connected. Thus it follows from the Epimorphism-onto-Free Group Proposition 130.8 that there exists an epimorphism

$$\pi_1(\Sigma_g) \ \to \ \langle x_1, \ldots, x_g \rangle.$$

In fact, as we will see in Exercise 130.2, it is not difficult to show the existence of such an epimorphism on a more algebraic level.

The previous example raises the following thought-provoking question.

Question 130.9. Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g.
(1) What is the maximal number $k = k(g) \in \mathbb{N}_0$ for which we can find k disjoint curves $F_1, \ldots, F_k$ on Σ_g such that $\Sigma_g \setminus (F_1 \cup \cdots \cup F_k)$ is connected?
(2) What is the maximal $l = l(g) \in \mathbb{N}_0$ for which there exists an epimorphism from $\pi_1(\Sigma_g)$ onto a free group of k generators?

In summary, as of right now we know the following:

$$g \ \underset{\text{by the above example}}{\overset{\leq}{\uparrow}} \ k(g) \ \underset{\text{Epimorphism-onto-Free Group Proposition 130.8}}{\overset{\leq}{\uparrow}} \ l(g) \ \underset{\text{Abelianization Proposition 53.20}}{\overset{\leq}{\uparrow}} \ 2g.$$

130.4. **Cyclic coverings of manifolds.** Our goal in this section is to give explicit constructions of cyclic coverings of manifolds. To simplify the language will use the following conventions throughout this section.

Convention.

(1) We will not distinguish between two coverings $p\colon X \to B$ and $q\colon T \to B$ that are equivalent in the sense of the definition on page 1368.
(2) We will use the Change-of-Base Point Proposition 47.10 as an excuse to suppress all base points from our notation.[1570]

The following proposition combines several results on coverings that we proved a while ago.

Proposition 130.10. Let M be a connected smooth manifold and let $\varphi\colon \pi_1(M) \to G$ be an epimorphism onto an abelian group. There exists a unique covering $p\colon \widetilde{M} \to M$ such that $p_*(\pi_1(\widetilde{M})) = \ker(\varphi)$. Furthermore this covering has the following properties:
(1) The covering is regular and the deck transformation group is isomorphic to G.
(2) The index of the covering is precisely $|G|$.

Proof. The proposition follows immediately from the Covering Existence Theorem 61.5 and Proposition 62.7 together with the Covering Uniqueness Theorem 61.9 and the Regular Covering-Characterization Corollary 62.8. ■

We sort-of introduced the following definition on page 1383.

Definition. We say a covering $p\colon X \to Y$ is (infinite) cyclic if p is a regular covering and if the deck transformation group is an (infinite) cyclic group.

Let M be a smooth manifold M. Given any primitive $\phi \in \mathrm{H}^1(M;\mathbb{Z}) = \mathrm{Hom}(\pi_1(M),\mathbb{Z})$ and given $n \in \mathbb{N}$ we know by Proposition 130.10 that there exist corresponding (infinite) cyclic covers of M. Our goal is to a very explicit constructions of these (infinite) cyclic covers for many smooth manifolds.
In the remainder of this section we will use the following notation:

Notation. Let M be a connected smooth manifold.
(1) We use the First Cohomology Proposition 110.17 to make the identification $\mathrm{H}^1(M;\mathbb{Z}) = \mathrm{Hom}(\pi_1(M),\mathbb{Z})$. It follows almost immediately from the definitions that under this identification the primitive elements in $\mathrm{H}^1(M;\mathbb{Z})$ correspond to the epimorphisms $\pi_1(M) \to \mathbb{Z}$.
(2) Let $\phi \in \mathrm{H}^1(M;\mathbb{Z})$ again be a primitive element. Furthermore let $n \in \mathbb{N}$. In the following we denote by $\phi_n\colon \pi_1(M) \to \mathbb{Z}_n$ the epimorphism that is given by the composition $\pi_1(M) \xrightarrow{\phi} \mathbb{Z} \to \mathbb{Z}_n$.

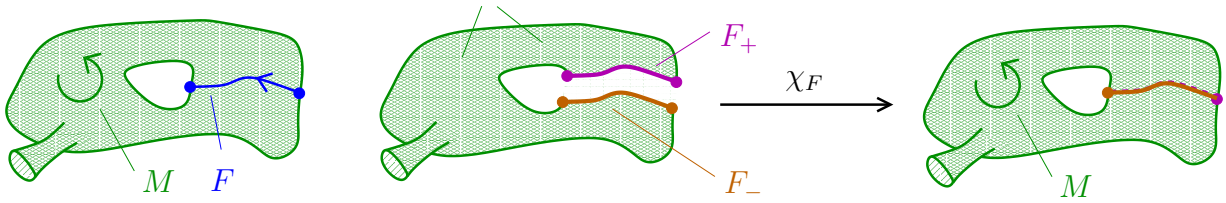
At this stage it is worth recalling the following definitions from page **??**.

Definition. Let M be an oriented smooth manifold and let $F \subset M$ be a compact oriented proper submanifold of codimension one. We pick an orientation-preserving tubular map $\Phi\colon [-1,1] \times F \to M$. We define

$$M \setminus\!\setminus F \;:=\; (M \setminus F) \sqcup (F \times \{\pm 0\})$$

[1570] More precisely, using the Change-of-Base Point Proposition 47.10 it is not difficult to show that for any topological space X, any abelian group G and any two paths $p, q\colon [0,1] \to X$ from a point x_0 to a point x_1 we have $p_* = q_*\colon \mathrm{Hom}(\pi_1(X,x_0),G) \to \mathrm{Hom}(\pi_1(X,x_1),G)$. In particular, given a path-connected topological space X and $x_0, x_1 \in X$ the groups $\mathrm{Hom}(\pi_1(X,x_0),G)$ and $\mathrm{Hom}(\pi_1(X,x_0),G)$ are canonically isomorphic.

with the topology that is generated by the following sets:



(1) the usual open subset of $M \setminus F$,
(2) the sets of the form $\Phi(U \times (0,\epsilon)) \cup (U \times \{+0\})$ where U is an open subset of F and where $\epsilon \in (0,1)$,
(3) the sets of the form $\Phi(U \times (-\epsilon,0)) \cup (U \times \{-0\})$ where U is an open subset of F and where $\epsilon \in (0,1)$.

We refer to $M \setminus\setminus F$ as M cut along F. This definition is illustrated in the figure below. We also introduce the following extra notation:

(4) We denote by $F_\pm$ the images of $F \times \{\pm 0\}$ in $M \setminus\setminus F$. Furthermore we denote by $i_\pm \colon F_\pm \to M \setminus\setminus F$ the obvious inclusion maps.
(5) We denote by $\sim_F$ the equivalence relation on the set $M \setminus\setminus F$ that is generated by $(P,+0) \sim (P,-0)$ for $P \in F$.
(6) We denote by χ_F the map

$$\begin{array}{rcl} \chi_F \colon M \setminus\setminus F & \to & M \\ P & \mapsto & \begin{cases} P, & \text{if } P \in M \setminus F, \\ Q, & \text{if } P = (Q, \pm 0). \end{cases} \end{array}$$

slightly incorrect picture of M cut along F

Now we can give the explicit construction of the cyclic coverings.

Proposition 130.11. (Cyclic-Covering Proposition) Let M be compact oriented connected smooth manifold. Furthermore let $\phi \in \mathrm{H}^1(M;\mathbb{Z}) = \mathrm{Hom}(\pi_1(M),\mathbb{Z})$ be a primitive element. Finally let $F \subset M$ be a compact oriented proper codimension-one submanifold[1571] that is dual to ϕ in the sense that $\mathrm{PD}_M([F]) = \phi$. We denote by $i_\pm \colon F \to F_\pm \subset M \setminus\setminus F$ the two obvious inclusion maps.

(1) We write

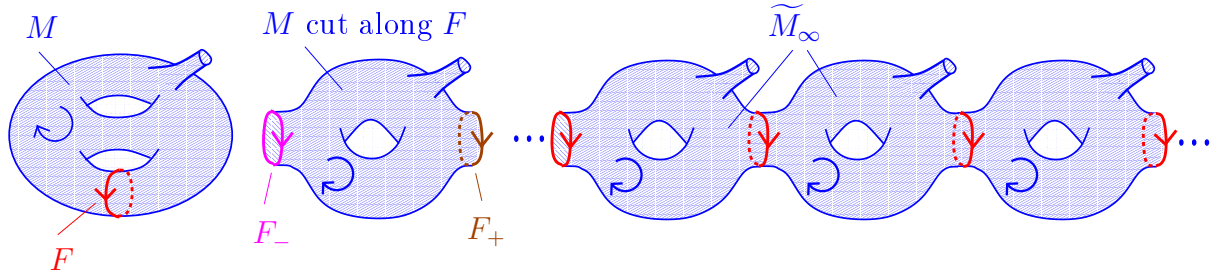
$$\widetilde{M}_\infty := \Big(\bigsqcup_{k \in \mathbb{Z}} (M \setminus\setminus F) \times \{k\} \Big) / \sim \qquad \begin{array}{c} \text{where } (i_-(P),k) \sim (i_+(P),k+1) \\ \text{for } P \in F \text{ and } k \in \mathbb{Z}. \end{array}$$

The map

$$\begin{array}{rcl} p \colon \widetilde{M}_\infty & \to & M \\ [(P,k)] & \mapsto & [\chi_F(P)] \end{array}$$

is the infinite cyclic covering corresponding to ϕ.

(2) Let $n \in \mathbb{N}$. We write



$$\widetilde{M}_n := \Big(\bigsqcup_{k \in \mathbb{Z}_n} (M \setminus\setminus F) \times \{k\} \Big) / \sim \qquad \begin{array}{c} \text{where } (i_-(P),k) \sim (i_+(P),k+1) \\ \text{for } P \in F \text{ and } k \in \mathbb{Z}_n. \end{array}$$

The map

$$\begin{array}{rcl} p \colon \widetilde{M}_n & \to & M \\ [(P,k)] & \mapsto & [\chi_F(P)] \end{array}$$

is the finite cyclic covering corresponding to ϕ_n.

Example. We consider the 2-dimensional smooth manifold M together with the submanifold F that are shown in the figure below. We illustrate the explicit construction of the infinite cyclic covering $\widetilde{M}_\infty$. The reader will not fail to spot the uncanny similarities with Lemma 56.12 and the figure on page 1272.

Proof.

(1) We pick a tubular map $\Phi\colon [-1,1]\times F \to M$ for F. It follows almost immediately from the definitions that the open sets $M \setminus F$ and $\Phi((-1,1)\times F)$ are uniformly covered in the sense of the definition on page 1067. Since these two open subsets cover all of M we see that $p\colon \widetilde{M}_\infty \to M$ is indeed a covering.

In the following we will show that $p\colon \widetilde{M}_\infty \to M$ is indeed the covering corresponding to $\ker(\phi)$.[1572] We consider the following map:

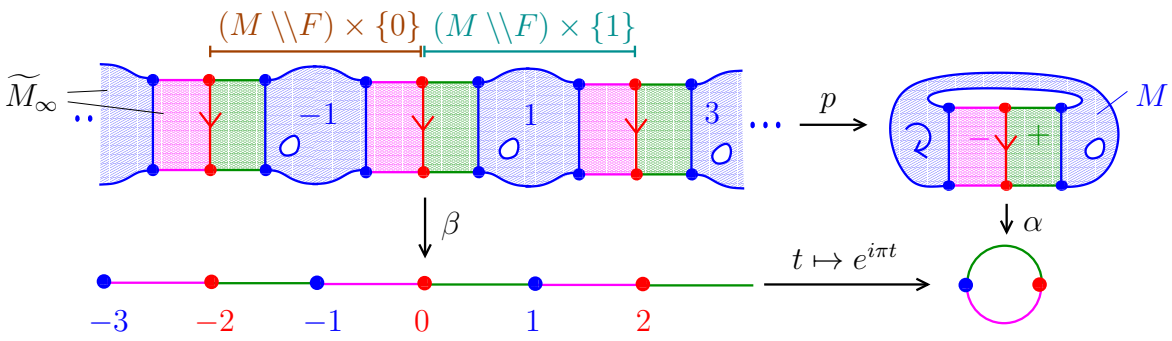
$$\begin{array}{rcl} \alpha\colon M & \to & S^1 \\ P & \mapsto & \begin{cases} \exp(\pi \mathrm{i} t), & \text{if } P = \Phi(t,Q) \text{ with } t \in [-1,1] \text{ and } Q \in F, \\ -1, & \text{otherwise} \end{cases} \end{array}$$

This is of course the Thom-Pontryagin map corresponding to the tubular map that we introduced on page 2839. Let $q\colon \mathbb{R} \to S^1$ be the universal covering that is given by $t \mapsto \exp(\pi \mathrm{i} t)$. Furthermore let

$$\begin{array}{rcl} r\colon \alpha^*\mathbb{R} = \{(P,t) \in M \times \mathbb{R} \mid \alpha(P) = p(t)\} & \to & M \\ (P,t) & \mapsto & P \end{array}$$

be the pullback of the covering q. Note that by the Topological-Pullback Lemma 56.16 (3) we know that $r\colon \alpha^*\mathbb{R} \to M$ is also a covering.

Claim. The covering $p\colon \widetilde{M}_\infty \to M$ is equivalent to the covering $r\colon \alpha^*\mathbb{R} \to M$.



Proof. The key to proving the claim is to consider the map

$$\begin{array}{rcl} \beta\colon \widetilde{M}_\infty & \to & \mathbb{R} \\ [P] & \mapsto & \begin{cases} 2i-1, & \text{if } P \in (M \setminus \Phi([-1,1]\times F)) \times \{i\}, \\ 2i+t, & \text{if } P \in \Phi(\{t\}\times F) \times \{i\} \text{ for some } t \in [-1,0), \\ 2i+t-2, & \text{if } P \in \Phi(\{t\}\times F) \times \{i\} \text{ for some } t \in (0,1], \\ 2i, & \text{if } P \in F_- \times \{i\} \text{ or } P \in F_+ \times \{i+1\}. \end{cases} \end{array}$$

Using Pasting Proposition 2.6 (2) one easily verify that this map is continuous. Next

[1571] Note that we do not assume that F is connected.

[1572] An alternative proof of this statement is given in [**Herr2019**, Lemma 1.31].

we consider the map

$$\begin{array}{rccc} \Theta\colon & \widetilde{M}_\infty & \to & \alpha^*\mathbb{R} \\ & P & \mapsto & (p(P), \beta(P)). \end{array}$$

It is straightforward to see that Θ is a bijection. We leave it to the reader to show that Θ is actually a homeomorphism. One can easily verify that $\Theta \circ r = p$. In summary we conclude that the two coverings q and r are indeed equivalent. ⊞

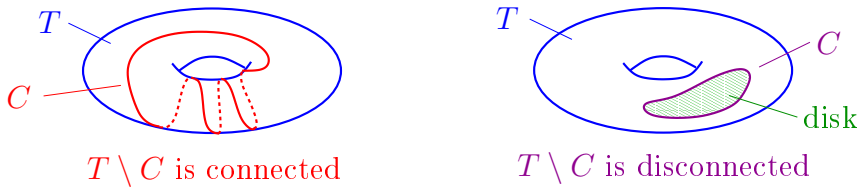
Now we see that

$$\begin{array}{ccccccccc} q_*(\pi_1(\widetilde{M}_\infty)) & = & r_*(\pi_1(\alpha^*\mathbb{R})) & \overset{\text{Topological-Pullback Lemma 56.16}}{=} & \alpha_*^{-1}(\pi_1(\mathbb{R})) & = & \ker(\alpha_*) & = & \ker(\phi). \\ & \uparrow & & & & \uparrow & & \uparrow & \\ & \text{since } q \text{ and } r \text{ are equivalent coverings} & & & & \text{since } \pi_1(\mathbb{R}) = 0 & & \text{Lemma 130.5} & \end{array}$$

We have thus shown that $q_*\colon \widetilde{M}_\infty \to M$ is indeed the covering corresponding to $\ker(\phi)$.

(2) The proof of this statement is very similar to the proof of (1). We just need to replace the covering $q\colon \mathbb{R} \to S^1$ by the covering $q\colon S^1 \to S^1$ given by $z \mapsto z^n$. We leave it to the reader to once again lessen the burden on the author by filling in the details. ■

130.5. **Curves on 2-dimensional smooth manifolds** (∗). We conclude this chapter with a discussion of curves on 2-dimensional smooth manifolds. The results of this section are nice-to-have, but they will not be used in the remainder of these notes. Thus it is safe to skip this section in the unlikely event that the reader is in a hurry.



Let us now recall the following definition from page 1123: A *closed oriented curve* C in a smooth manifold M is a closed oriented connected 1-dimensional submanifold of M or of ∂M. In this section we want to study curves on 2-dimensional smooth manifolds. Our main focus will be curves on the torus.

Before we state the results we recall that on page 1733 we saw that a closed oriented curve C in a smooth manifold M defines a homology class $[C] \in \mathrm{H}_1(M;\mathbb{Z})$. We start out with the following lemma.

Lemma 130.12. Let $T = S^1 \times S^1$ be the torus and let C be a closed oriented curve on T.

(1) If $T \setminus C$ is connected, then $[C]$ is a primitive element of $\mathrm{H}_1(T;\mathbb{Z})$.

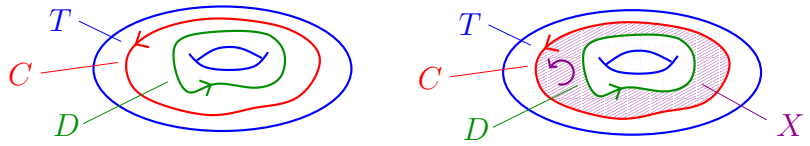
(2) If $T \setminus C$ is disconnected, then C is the boundary of an embedded disk.

Proof. If $T \setminus C$ is connected, then it follows from the Non-Separating Codimension-One Submanifold Proposition 130.2 that $[C]$ is a primitive element of $\mathrm{H}_1(T;\mathbb{Z})$. Now suppose that $T \setminus C$ is disconnected. By the Tubular Neighborhood Theorem **??** there exists a tubular neighborhood $[-1,1] \times C$. From Lemma 123.1 and Proposition 123.4 we obtain that $T \setminus (-1,1) \times C$ is also disconnected. Since C is connected this implies that $T \setminus (-1,1) \times C$ has two components A and B, one of which contains $\{-1\} \times C$ and one which contains $\{1\} \times C$.[1573] By the Codimension-Zero Submanifold Proposition 19.38 we know that A and B are compact 2-dimensional smooth manifolds, in particular they are finite CW-complexes. We have

$$\chi(A) + \chi(B) \;=\; \underbrace{\chi(T)}_{=0} + \underbrace{\chi(\{-1\} \times C)}_{=0} + \underbrace{\chi(\{1\} \times C)}_{=0} \;=\; 0.$$

Euler Characteristic-Addition Lemma 87.5

Since A and B have boundary it follows from the classification of compact 2-dimensional smooth manifolds and the calculation of Euler characteristics, see Lemma 87.6, that one of A or B is diffeomorphic to the disk $\overline{B}^2$. ■



Lemma 130.13. Let $T = S^1 \times S^1$ be the torus. Let C and D be two closed oriented curves on T. If C and D are disjoint and if $[C]$ and $[D]$ are both non-zero[1574] in $\mathrm{H}_1(T;\mathbb{Z})$, then $[C] = \pm[D]$.

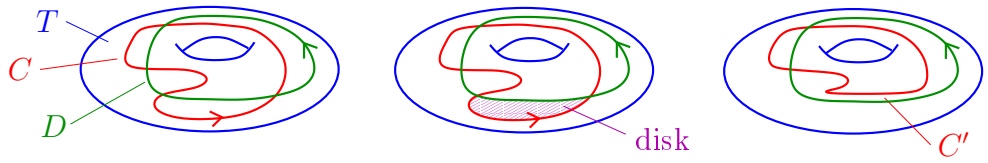
Proof. From the Intersection Number-via-Cup Product Theorem 126.5 together with our hypothesis that $C \cap D = \varnothing$ we obtain that $\mathrm{PD}_T([C]) \cup \mathrm{PD}_T([D]) = 0$. It follows easily from the calculation of the cup product of the torus, see Lemma 114.14, that $\mathrm{PD}_T([C]) = k \cdot \mathrm{PD}_T([D])$ for some $k \in \mathbb{Z}$. We obtain from Lemma 130.12 that $k \in \{-1, 1\}$. ■

Lemma 130.14. Let $T = S^1 \times S^1$ be the torus. Let C and D be two closed oriented curves on T. Suppose that $[C] = [D] \neq 0$, then the following hold:

(1) The two closed oriented curves are smoothly isotopic.
(2) If C and D are furthermore disjoint, then there exists an embedded annulus $X \subset T$ with $\partial X = C \cup -D$.

Furthermore, the same statements also hold if we replace the torus $T = S^1 \times S^1$ by the annulus $S^1 \times [-1,1]$.

[1573] Why is that?
[1574] Is this condition that $[C]$ and $[D]$ are both non-zero necessary?



Sketch of proof. We provide a sketch of a proof for the various statements:

(1) By the Transversality Theorem 42.4 (2) we can assume that C and D are already transverse. It follows from the calculation of the cup product of the torus and the Intersection Number-via-Cup Product Theorem 126.5 that the algebraic intersection number is 0. The argument is now similar to the argument of the proof of Theorem **??**, but this time we use Lemma 130.12 to find the desired embedded disks. We refer to the figure below for an illustration.

It is a good, and not entirely trivial, mental exercise to fill in the details. The argument is sketched in more detail in [**Rolf1990**, Lemma 5 of Chapter 2.C].

(2) The proof of this statement is similar to the proof of Lemma 130.12 (2). We leave it to the reader to fill in the details.

The proof in the case that $T = S^1 \times [-1, 1]$ is easier. We will discuss it in Exercise 131.1. ■

For completeness sake' we state the following proposition, even though we will not make use of it.

Proposition 130.15. Let F be a 2-dimensional smooth manifold and let C and D be two closed oriented curves on F.

(1) If C and D are homotopic, then C and D are smoothly isotopic.

(2) If C and D are furthermore disjoint and if they are not null-homotopic, then there exists an embedded annulus $X \subset F$ with $\partial X = C \cup -D$.

Proof.

(1) This statement is [**FaM2011**, Proposition 1.10]. (Closely related statements are also proved in [**Baer1928**], [**Eps1966**, Theorem 2.1].) Unfortunately all the references are somewhat cavalier when it comes to distinguishing continuous and smooth maps, but with some effort one can see that all the references provide smooth isotopies.

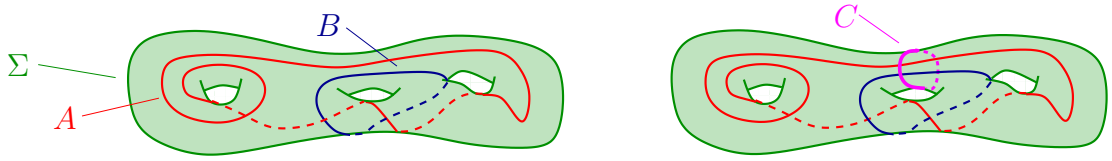
(2) If F is orientable, then we will provide the proof in Exercise 130.7. The proof of the non-orientable case is not much harder. ■

Exercises for Chapter 130.

Exercise 130.1. Let M be a *non-compact* oriented n-dimensional smooth manifold with compact boundary. Furthermore let N be a compact orientable non-empty proper submanifold of codimension-one such that $M \setminus N$ is connected. Show that $[N] \in \mathrm{H}_{n-1}(M; \mathbb{Z})$ is an element of infinite order.
Hint. Use Propositions 31.2 and 130.2.

Exercise 130.2. Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g. By the Fundamental Group-of-Surfaces Proposition 54.5 we know that there exists an isomorphism

$$\pi_1(\Sigma_g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \rangle.$$



Use this isomorphism to give a purely algebraic proof that $\pi_1(\Sigma_g)$ admits an epimorphism onto a free group on g generators.

Exercise 130.3. Here is one possible approach to answering Question 130.9 (1). Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g. Let $F_1, \dots, F_k$ be disjoint curves on Σ_g such that $\Sigma_g \setminus (F_1 \cup \dots \cup F_k)$ is connected. By the Tubular Neighborhood Theorem **??** we can pick a tubular neighborhood $\bigcup_{i=1}^{k} [-1,1] \times F_i$ for the submanifold $F_1 \cup \dots \cup F_k \subset \Sigma_g$. We consider the compact orientable 2-dimensional smooth manifold $X := \Sigma_g \setminus \bigcup_{i=1}^{k} (-1,1) \times F_i$. What can you say about the Euler characteristic of X? What does the classification of compact orientable 2-dimensional smooth manifolds tell you?

Exercise 130.4. Let Σ be a compact orientable connected 2-dimensional smooth manifold and let $A, B \subset \Sigma$ be two disjoint non-separating curves.

(a) Show that there exists a closed 1-dimensional smooth manifold $C \subset \Sigma$ that intersects each of A and B transversally in a single point.
Remark. Exercise 80.7 might come in handy.

(b) Can one also arrange that C is connected?

Exercise 130.5. Let M be a compact oriented connected smooth manifold and let F be a compact oriented proper submanifold. We use the notation from page 2845. In particular we denote by $i_\pm \colon F \to M \setminus\setminus F$ the two inclusion maps and we denote by $\chi_F \colon M \setminus\setminus F \to M$ the natural projection. Show that there exists a long exact sequence of the form

$$\dots \to \mathrm{H}_i(F) \xrightarrow{i_- - i_+} \mathrm{H}_i(M \setminus\setminus F) \xrightarrow{\chi_F} \mathrm{H}_i(M) \xrightarrow{\partial} \mathrm{H}_{i-1}(F) \to \dots$$

Exercise 130.6. Let (X, x_0) be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let $\phi \colon \pi_1(X, x_0) \to \langle t \rangle$ be an epimorphism. We denote by $p \colon \widetilde{X}_\infty \to X$ the covering corresponding to $\ker(\phi)$. By Proposition 62.7 we have an explicit identification of the group $\langle t \rangle$ with the deck transformation group of $p \colon \widetilde{X}_\infty \to X$. Given $\sigma \in \mathrm{C}_n(\widetilde{X}_\infty)$ and given $k \in \mathbb{Z}$ we write $t^k \cdot \sigma := (t^k)_*(\sigma)$.

(a) Let $n \in \mathbb{N}_0$ and let $\sigma, \mu \in \mathrm{C}_n(\widetilde{X}_\infty)$. Show that $p_*(\sigma) = p_*(\mu) \in \mathrm{C}_n(X)$ if and only if there exists a $k \in \mathbb{Z}$ with $\sigma = t^k \cdot \mu$.

(b) Let $n \in \mathbb{N}_0$. Show that the following sequence is exact:

$$0 \to \mathrm{C}_n(\widetilde{X}_\infty) \xrightarrow{t - \mathrm{id}} \mathrm{C}_n(\widetilde{X}_\infty) \xrightarrow{p_*} \mathrm{C}_n(X) \to 0.$$

Remark. By the LES Proposition 74.9 we obtain a corresponding long exact sequence

$$\dots \to \mathrm{H}_{n+1}(X) \xrightarrow{\partial} \mathrm{H}_n(\widetilde{X}_\infty) \xrightarrow{t - \mathrm{id}} \mathrm{H}_n(\widetilde{X}_\infty) \xrightarrow{p_*} \mathrm{H}_n(X) \xrightarrow{\partial} \mathrm{H}_{n-1}(\widetilde{X}_\infty) \to \dots.$$

(c) As a reality check, what does the long exact sequence in (b) look like for the covering $p \colon \mathbb{R} \to S^1$?

(d) Let $r \in \mathbb{N}$. We denote by $\widetilde{X}_r$ the covering of X corresponding to the epimorphism $\ker(\phi\colon \pi_1(X, x_0) \to \langle t \rangle = \mathbb{Z} \to \mathbb{Z}_r)$. Show that there exists an exact sequence relating the homology groups of $\widetilde{X}_\infty$ and $\widetilde{X}_r$.

Exercise 130.7. Let F be an oriented 2-dimensional smooth manifold and let C and D be two closed oriented *disjoint* curves on F that are not null-homotopic. Assume that C and D are homotopic. Show that there exists an embedded annulus $X \subset F$ with $\partial X = C \cup -D$.
Hint. Use Exercise 131.2. You might also want to use some of the ideas of the proof of Lemma 130.12.

Exercise 130.8. Let $T = S^1 \times S^1$ be the torus and let C and D be two closed oriented 1-dimensional submanifolds of T with $[C] = [D] \in \mathrm{H}_1(T; \mathbb{Z})$. Use the results from Section 130.5 to give a down-to-earth proof of the statement that there exists a compact oriented proper 2-dimensional submanifold Ω of $T \times [0, 1]$ such that

$$\partial\Omega \;=\; (\{0\}\times) \cup (\{1\} \times -D).$$

Remark. Evidently this is just a special case of the Cobounding Submanifolds Corollary 130.7. But it is fun to give a bare-hands proof in this special case.

Exercise 130.9. Let Σ be the surface of some genus $g \in \mathbb{N}_0$ and let $f\colon \Sigma \to \Sigma$ be some orientation-preserving self-diffeomorphism. We consider the corresponding mapping torus

$$\mathrm{Tor}(\Sigma, f) \;:=\; (\Sigma \times [0, 1])\,/\!\sim \qquad \text{where } (x, 0) \sim (f(x), 1) \text{ for all } x \in \Sigma.$$

Let F be a surface of some genus k. Suppose that there exists a map $\varphi\colon F \to \mathrm{Tor}(\Sigma, f)$ such that $\varphi_*([F]) = [\{0\} \times \Sigma] \in \mathrm{H}_2(\mathrm{Tor}(\Sigma, f))$. Show that $k \geq g$.
Hint. Make clever use of the Cyclic-Covering Proposition 130.11 and Exercise 102.3.

Exercise 130.10. Let M be a closed oriented n-dimensional smooth manifold. Furthermore let $\phi \in \mathrm{H}_{n-1}(M; \mathbb{Z})$, let $k \in \mathbb{N}$ and let F be a closed oriented $(n-1)$-dimensional submanifold that represents $k \cdot \phi$. Show that we can decompose $F = F_1 \sqcup \cdots \sqcup F_k$ where each F_i represents ϕ.
Hint. Consider the Thom-Pontryagin map $\rho = \rho_F\colon M \to S^1$ that we introduced on page 2839. Note that $\rho^{-1}(1) = F$. Let $p\colon S^1 \to S^1$ be the covering map given by $z \mapsto z^k$. Show that there exists a map $\widetilde{\rho}\colon M \to S^1$ such that $\rho = p \circ \widetilde{\rho}$.

Exercise 130.11. Given a closed oriented 2-dimensional smooth manifold S with components $S_1, \ldots, S_m$ we define

$$\chi_-(S) \;:=\; \sum_{i=1}^{m} \max\{-\chi(S_i), 0\}.$$

Let M be a closed oriented 3-dimensional smooth manifold. We consider the map

$$\begin{aligned} x_M\colon \mathrm{H}_2(M; \mathbb{Z}) &\to \mathbb{N}_0 \\ \sigma &\mapsto \min\left\{ \chi_-(S) \;\middle|\; \begin{array}{l} S \text{ is a closed oriented 2-dimensional} \\ \text{submanifold of } M \text{ with } [S] = \sigma \end{array} \right\}. \end{aligned}$$

Show that the map x_M is a seminorm, i.e. show that it has the following two properties:

(a) Given any $\sigma \in \mathrm{H}_2(M; \mathbb{Z})$ and $k \in \mathbb{Z}$ we have $x_M(k \cdot \sigma) = |k| \cdot x_M(\sigma)$.
Hint. Use Exercise 130.10.

(b) Given $\mu, \nu \in \mathrm{H}_2(M;\mathbb{Z})$ we have $x_M(\mu+\nu) \leq x_M(\mu) + x_N(\nu)$.
Hint. Use the Transversality Theorem 42.4 and Proposition 102.21.

(c) Show that there exists a unique seminorm $x_M \colon \mathrm{H}_2(M;\mathbb{R}) \to \mathbb{R}_{\geq 0}$ such that the map $\mathrm{H}_2(M;\mathbb{Z}) \xrightarrow{[\sigma] \mapsto [\sigma \otimes 1_{\mathbb{R}}]} \mathrm{H}_2(M;\mathbb{R}) \to \mathbb{R}_{\geq 0}$ agrees with the above map x_M.

Remark. This seminorm $x_M \colon \mathrm{H}_2(M;\mathbb{Z}) \to \mathbb{R}_{\geq 0}$ is usually called the *Thurston norm of* M. It was introduced by William Thurston [**Thu1986**] in 1976 and, as is shown in [**Thu1986**] and [**Gab1983**], it has many remarkable properties.

Exercise 130.12. We continue with the definitions introduced in Exercise 130.11. Let Σ be a closed connected 2-dimensional smooth manifold with $\chi(\Sigma) \leq 0$.

(1) Let $f \colon \Sigma \to \Sigma$ be a diffeomorphism. We consider the mapping torus $\mathrm{Tor}(\Sigma, f)$. Show that $x([\Sigma]) = \chi_-(\Sigma)$.
Hint. Let F be any closed oriented 2-dimensional submanifold of $\mathrm{Tor}(\Sigma, f)$ with $[F] = [\Sigma]$. Using the Cyclic-Covering Proposition 130.11 we obtain a map $F \to \Sigma \times \mathbb{R}$. Consider the map $F \to \Sigma \times \mathbb{R} \to \Sigma$ and use Exercise 101.4.

(2) We can to consider the Thurston norm of $N \times S^1$.
(a) Show that $x_{\Sigma^1 \times S^1}([\Sigma \times \{*\}] = \chi_-(\Sigma)$.
(b) Show that for any $\sigma \in \mathrm{H}_1(\Sigma)$ we have $x_{\Sigma^1 \times S^1}([S^1] \times \sigma) = 0$.
(c) Show that for any $\phi \in \mathrm{H}_2(\Sigma \times S^1;\mathbb{R})$ we have

$$x_{\Sigma \times S^1}(\phi) \;=\; \langle \underbrace{\mathrm{PD}_{\Sigma \times S^1}}_{\in \mathrm{H}^1(M;\mathbb{R})}, \underbrace{[\{*\} \times S^1]}_{\in \mathrm{H}_1(M;\mathbb{Z})} \rangle.$$

Hint. Either use Proposition 118.15 and (1). Alternatively use (2a) and (2b) together with Exercise 130.11 (b).

Exercise 130.13. Let M be a closed oriented n-dimensional smooth manifold. Given $\phi \in \mathrm{H}^1(M;\mathbb{Z})$ we define

$$x_M(\sigma) \;=\; \inf\{\|N\|_{\mathbb{R}} \mid N \text{ is a closed oriented submanifold of } M \text{ with } \mathrm{PD}_M([N]) = \phi\}.$$

($\|N\|_{\mathbb{R}}$: simplicial volume as defined in Exercise 101.9)

Let N be a closed oriented connected $(n-1)$-dimensional smooth manifold. Given any cohomology class $\phi \in \mathrm{H}^1(N \times S^1)$ determine $x_{N \times S^1}(\phi)$ in terms of $\|N\|_{\mathbb{R}}$ and $\phi(\{*\} \times S^1)$.
Hint. Use Proposition 118.15 and (a).

131. Applications to knot theory

After so much theory we want to practice what we have learned by applying our recent results to knot theory.

131.1. **The longitude of a knot.** We start out our discussion of knots with the following definition.

Definition. Let $K \subset S^3$ be an oriented knot.

(1) A thickening of K is an orientation-preserving smooth embedding[1575] $F\colon \overline{B}^2 \times K \to S^3$ such that $F(0,P) = P$ for all $P \in K$.

(2) Given a thickening F of K we refer to $X_K := S^3 \setminus F(B^2 \times K)$ as the knot exterior. We equip the codimension-zero submanifold X_K of S^3. with the corresponding standard orientation that we introduced on page 684.

(3) Given a thickening F of K and given $* \in K$ we refer to the oriented submanifold $\mu_K := F(S^1 \times \{*\})$ of $S^3 \setminus K$ as the meridian of K.

(4) By Lemma 100.16 (5) the inclusion induced map $\mathrm{H}_1(X_K;\mathbb{Z}) \xrightarrow{\cong} \mathrm{H}_1(S^3 \setminus K;\mathbb{Z})$ is an isomorphism and we have $\mathrm{H}_1(X_K;\mathbb{Z}) = \mathbb{Z} \cdot [\mu_K]$. We denote by ϕ_K the isomorphism

$$\begin{array}{rccc} \phi_K\colon \mathrm{H}_1(S^3 \setminus K;\mathbb{Z}) & \xleftarrow{\cong} & \mathrm{H}_1(X_K;\mathbb{Z}) & \xrightarrow{\cong} \mathbb{Z} \\ & & [\mu_K] & \to 1. \end{array}$$

(5) Given a thickening $F\colon \overline{B}^2 \times K \to S^3$ we define

$$\text{self-linking number of } F \;:=\; \phi_K(\underbrace{F_*([\{*\} \times K])}_{\in \mathrm{H}_1(X_K;\mathbb{Z})}),$$

where $* \in \overline{B}^2$ is a random point.

Remark. It follows from the uniqueness of tubular neighborhoods, see Proposition **??**, that the exterior X_K and the meridian μ_K are, in an appropriate sense, independent of the choice of the thickening. Therefore often we just say "the exterior" and "the meridian".

Lemma 131.1. (Knot Thickening Lemma) Let K be an oriented knot in S^3.

(1) Let $F\colon \overline{B}^2 \times K \to S^3$ be a thickening of K and let $s \in \mathbb{Z}$. Let $\gamma\colon S^1 \to K$ be an orientation-preserving diffeomorphism. Similar to Lemma **??** we consider the diffeomorphism

$$\begin{array}{rccc} \Psi\colon \overline{B}^2 \times K & \to & \overline{B}^2 \times K \\ (w, \gamma(z)) & \mapsto & (\underbrace{w \cdot_{\mathbb{C}} z^s}_{\substack{\text{multiplication in } \mathbb{C}, \text{ where} \\ w \in \overline{B}^2 \subset \mathbb{C} \text{ and } z^s \in \mathbb{C}}}, \gamma(z)). \\ \uparrow & & \\ \text{where } z \in S^1 & & \end{array}$$

The map $F \circ \Psi$ is a thickening with

$$\text{self-linking number of } F \circ \Psi \;=\; \text{self-linking number of } F + s.$$

(2) Given any $n \in \mathbb{Z}$ there exists a thickening of K with self-linking number n.

[1575] We equip S^3 and $\overline{B}^2 \times S^1$ with the standard orientation that we introduced on page 681 and on page 2502.

(3) If $F, F' \colon \overline{B}^2 \times K \to S^3$ are two thickenings of K with self-linking number n, then there exists a diffeotopy $H \colon S^3 \times [0,1] \to S^3$ rel K with $H_0 = \mathrm{id}$ and $H_1 \circ F = F'$.

Given $K \subset \mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ the analogous statements hold if we consider thickenings that are contained in $\mathbb{R}^3$. Furthermore, in this setting the diffeotopy in (3) of $\mathbb{R}^3$ can be assumed to have compact support.

Remark. Given an oriented knot K and $n \in \mathbb{Z}$ sometimes we use the uniqueness statement of the Knot Thickening Lemma 131.1 to talk about *the thickening of K with self-linking number n*. Sometimes we shorten this cumbersome expression to *the n-thickening of K*.

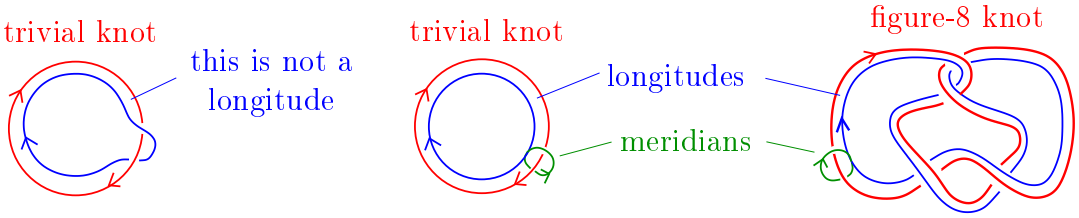
Proof.

(1) We denote by m the self-linking number of F. We write $\lambda := F(\{1\} \times K)$ and $\mu := F(S^1 \times \{1\})$ and we view λ and μ as oriented 1-dimensional submanifolds with the orientations given by K and S^1. We calculate that

$$\text{self-linking number of } F \circ \Psi = \phi_K(F_*(\Psi_*([\{1\} \times K]))) \underset{\uparrow}{=} \phi_K(s \cdot [\mu] + [\lambda]) \underset{\uparrow}{=} s + m.$$

follows from the Action-on-Torus Homology Lemma 84.7 (2) — since $\phi_K(\mu) = 1$ and by definition of m

(2) From the Tubular Neighborhood Theorem **??** we know that there exists a thickening $F \colon \overline{B}^2 \times K \to S^3$. We denote by m the self-linking number of F. The desired statement now follows from (1) applied to $n - m$.

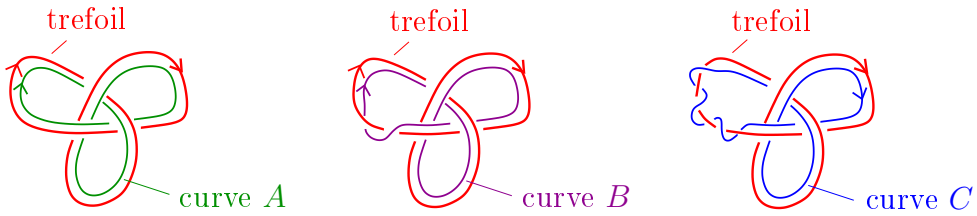


(3) The uniqueness statement is an immediate consequence of (1) together with Proposition **??** and Lemma **??** (3).

The same arguments as above also apply if we replace S^3 by $\mathbb{R}^3$. ■

Definition. Let $K \subset S^3$ be an oriented knot. We pick a thickening $F \colon \overline{B}^2 \times K \to S^3$ of self-linking number zero. We refer to any $\lambda_K := F(\{*\} \times K)$ as a longitude of K.[1576]

Examples.



(1) In the figure below we show the longitude and the meridian for the trivial knot and the figure-8 knot.

(2) In the figure below we show the trefoil knot with three wannabe longitudes. It is not entirely clear which one is the right longitude. We will soon develop a tool with which it will be straightforward to settle this issue.

On several occasions the following lemma comes in handy.

[1576] It follows from the Knot Thickening Lemma 131.1 (3) that the longitude is in an appropriate way uniquely determined.

Lemma 131.2. (Longitude-Meridian Lemma) Let K be an oriented knot and let $F\colon \overline{B}^2 \times K \to S^3$ be a thickening with self-linking number zero. We denote by $X_K = S^3 \setminus F(B^2 \times K)$ the corresponding knot exterior. Furthermore we denote as usual by $\mu_K = F(S^1 \times \{*\})$ and $\lambda_K = F(\{*\} \times K)$ the corresponding meridian and longitude.

(1) The classes $[\mu_K]$ and $[\lambda_K]$ form a basis for $\mathrm{H}_1(\partial X_K;\mathbb{Z})$.

(2) There exists a short exact sequence of the following form

$$\begin{array}{ccccccccc} 0 & \to & \mathrm{H}_2(X_K,\partial X_K;\mathbb{Z}) & \to & \overbrace{\mathrm{H}_1(\partial X_K;\mathbb{Z})}^{=\mathbb{Z}\cdot[\mu_K]\oplus\mathbb{Z}\cdot[\lambda_K]} & \to & \overbrace{\mathrm{H}_1(X_K;\mathbb{Z})}^{=\mathbb{Z}\cdot[\mu_K]} & \to & 0 \\ & & & & [\mu_K] & \mapsto & [\mu_K] & & \\ & & & & [\lambda_K] & \mapsto & 0. & & \end{array}$$

(3) The longitude λ_K is the unique, up to smooth isotopy, closed oriented curve on the torus $F(S^1 \times K)$ that is homologous to $K = \{0\} \times K$ in $F(\overline{B}^2 \times K)$ and that is null-homologous in X_K.

(4) If we view μ_K and λ_K as closed oriented curves on the oriented torus $F(S^1 \times K)$, then the algebraic intersection number equals $\mu_K \cdot \lambda_K = +1$.

(5) If denote by $i\colon \mu_K \to \partial X_K$ the inclusion map, then[15771578]

$$i^*([\mu_K]^*) \cap [\partial X_K] \;=\; -[\lambda_K] \;\in\; \mathrm{H}_1(\partial X_K;\mathbb{Z}).$$

(6) Recall that given an oriented curve C we denote by $-C$ the curve with the opposite orientation. With this notation we have $\mu_{-K} = -\mu_K$ and $\lambda_{-K} = -\lambda_K$.

Proof.

(1) This statement follows from Lemma 78.11 (2).

(2) We consider the long exact sequence of homology groups of the pair $(X_K, \partial X_K)$:

$$\underbrace{\mathrm{H}_2(X_K;\mathbb{Z})}_{=0 \text{ by Lemma 100.16 (4)}} \to \mathrm{H}_2(X_K,\partial X_K;\mathbb{Z}) \to \mathrm{H}_1(\partial X_K;\mathbb{Z}) \xrightarrow{\phi} \mathrm{H}_1(X_K;\mathbb{Z}).$$

By definition we have $\phi([\lambda_K]) = 0$. Furthermore we know from Lemma 100.16 that the right-hand map is an epimorphism. The statement follows immediately from these observations.

(3) It follows from (1) that the kernel of $\mathrm{H}_1(\partial X_K;\mathbb{Z}) \to \mathrm{H}_1(X_K;\mathbb{Z})$ equals $\mathbb{Z}\cdot[\lambda_K]$. Since $\mathrm{H}_1(F(\overline{B}^2 \times K);\mathbb{Z}) = \mathbb{Z}\cdot[K] = \mathbb{Z}\cdot[\lambda_K]$ we see that there exists a unique homology

[1577] We denote by $[\mu_K]^* \in \mathrm{H}^1(\mu_K;\mathbb{Z})$ the dual fundamental class as defined on page 2451, i.e. the unique cohomology class with $\langle [\mu_K]^*, [\mu_K] \rangle = 1$.

[1578] As we mentioned above, we equip X_K with a standard orientation. We equip ∂X_K with the corresponding boundary orientation as defined on page 689.

class that has the properties we are interested in. The desired statement now follows from Lemma 130.14 (1).

(4) This statement follows from the definitions and the easy observation that the oriented submanifolds $S^1 \times \{*\}$ and $\{*\} \times S^1$ of the oriented smooth manifold $S^1 \times S^1$ have algebraic intersection number one.

(5) We calculate that

$$\begin{array}{lll} i^*([\mu_K]^*) \cap [\partial X_K] & = i^*([\mu_K]^*) \cap F_*(-[S^1 \times K]) & = F_*\big([S^1 \times \{*\}]^* \cap (-[S^1 \times K])\big) \\ & \uparrow & \uparrow \\ & \text{using that } F \text{ is orientation-preserving} & \text{Cap Product-Naturality Lemma 116.8} \\ & \text{and using Exercise 25.19 we see} & \\ & \text{that } F_*([S^1 \times S^1]) = [\partial F(\overline{B}^2 \times K)] = -[\partial X_K] & \\ & = -F_*([\{*\} \times K]) & = -[\lambda_K]. \\ & \uparrow & \uparrow \\ & \text{see page 2555} & \text{by definition of } \lambda_K \end{array}$$

(6) This statement follows easily from the definitions. We leave it to the reader to provide the details. ■

131.2. **Detecting non-invertible and chiral knots.** Now that we have the notion of the self-linking number of thickening a knot we can also outline how to answer several questions on symmetries of knots we had asked a long time ago.

We start out with the following definition.

Definition. Let K be an oriented knot.

(1) The mirror K^{mir} is defined as the reflection of K in any hyperplane of $\mathbb{R}^4$.[1579] We give the mirror K^{mir} the orientation that turns the reflection into an orientation-preserving diffeomorphism $K \to K^{\text{mir}}$.

(2) The reverse K^{rev} is defined as the knot K with the reverse orientation.

(3) The inverse K^{inv} is defined as the mirror of the reverse of K.

Remark. The names "reverse" and "inverse" at times also get used with different meanings. We follow [**Conw1970**, p. 336] for our naming convention.

knot K | the mirror K^{mir} | the reverse K^{rev} | the inverse K^{inv}

Now the question arises whether an oriented knot is smoothly isotopic to any of its doppelganger. This leads us to the following definition.

Definition. Let K be an oriented knot.

(1) We say that K is amphichiral if it is smoothly isotopic to its mirror image. Otherwise we call the knot K chiral.[1581]

[1579] Note that it follows from Exercise 59.1 that, up to a smooth isotopy, the definition of K^{mir} does not depend on the choice of the hyperplane.

[1580] Note that on page 2387 we introduced the mirror of an unoriented knot. For the purpose of this section it is better to work with oriented knots.

(2) We say K is reversible if it is smoothly isotopic to its reverse.
(3) We say K is invertible if it is smoothly isotopic to its inverse.

Example. As we saw in the figure on page 1303, it is basically clear that the trivial knot is amphichiral and reversible. Furthermore, in the figure on page 1316 we showed that the figure-8 knot J is amphichiral. Also note that in Exercise 34.7 we showed that the trefoil and the figure-8 knot are reversible.

This lead us to the following two questions.

Question 58.2. Is every knot reversible?

Question 59.9. Is the trefoil chiral?

Before we show how to answer both questions let us introduce the following simple-minded definition.

Definition.

(1) A group system is a system (G, g_1, g_2) consisting of a group G together with two elements $g_1, g_2 \in G$.
(2) A isomorphism between group systems (G, g_1, g_2) and (H, h_1, h_2) is a group isomorphism $\varphi\colon G \to H$ with $\varphi(g_1) = h_1$ and $\varphi(g_2) = h_2$.

The following proposition explains why we care about group systems.

Proposition 131.3. (Knot-Group System Proposition)

(1) Let $K \subset S^3$ be an oriented knot. We pick a thickening $F\colon \overline{B}^2 \times K \to S^3$ of K with self-linking number zero.[1582] Furthermore we pick an orientation-preserving diffeomorphism $\gamma\colon S^1 \to K$. We write

$$x_{K,F} := F(1, \gamma(1)), \quad \mu_{K,F}\colon \begin{array}{ccc} S^1 & \to & S^3 \setminus K \\ z & \mapsto & F(z, \gamma(1)), \end{array} \quad \lambda_{K,F,\gamma}\colon \begin{array}{ccc} S^1 & \to & S^3 \setminus K \\ z & \mapsto & F(1, \gamma(z)). \end{array}$$

The isomorphism type of the group system

$$(\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}], [\lambda_{K,F,\gamma}])$$

depends only on the choice of the oriented knot K. Any group system that is isomorphic to the above group system is called a *group system for* K.
(2) Let K and J be two oriented knots. If K and J are smoothly isotopic, then the corresponding group systems are isomorphic.
(3) Given an oriented knot K with a group system $(\pi_K, \mu_K, \lambda_K)$ the following hold:
   (a) a group system for the mirror K^{mir} is given by $(\pi_K, \mu_K^{-1}, \lambda_K)$
   (b) a group system for the reverse K^{rev} is given by $(\pi_K, \mu_K^{-1}, \lambda_K^{-1})$
   (c) a group system for the inverse K^{inv} is given by $(\pi_K, \mu_K\ , \lambda_K^{-1})$.

Remark. Friedhelm Waldhausen [**Wald1968b**, Corollary 6.5] (see also [**BZH2014**, Theorem 3.16]) showed in 1968 that the converse to the Knot-Group System Proposition 131.3 (2) holds. Thus we are certainly on the right track.

Proof.

[1581] On page 1316 we introduced these notions of unoriented knots.
[1582] We know by the Knot Thickening Lemma 131.1 (2) that such a thickening always exists.

(1) This statement follows easily from the Knot Thickening Lemma 131.1 (3).
(2) This statement follows equally easily from the Isotopy Extension Theorem 36.1.
(3) Let $F\colon \overline{B}^2 \times K \to S^3$ be a thickening of K with self-linking number zero and let $\gamma\colon S^1 \to K$ be an orientation-preserving diffeomorphism. Throughout the proof of (3) we work with the group system $(\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}], [\lambda_{K,F,\gamma}])$ for K.

In the following we denote by ρ the reflection in a hyperplane of $\mathbb{R}^4$ and we set $K^{\text{mir}} = \rho(K)$. Finally we denote by $\varphi\colon S^1 \to S^1$ and $\psi\colon \overline{B}^2 \to \overline{B}^2$ the maps given by complex conjugation.

(a) First note that the map[1583]

$$\begin{aligned} F^{\text{mir}}\colon \overline{B}^2 \times K^{\text{mir}} &\to S^3 \\ (x,y) &\mapsto \rho(F(\psi(x), \rho(y))) \end{aligned}$$

is a thickening of K^{mir} with self-linking number zero. Furthermore note that $\gamma^{\text{mir}} := \rho \circ \gamma\colon S^1 \to K^{\text{mir}}$ is orientation-preserving. Thus we see that ρ_* induces an isomorphism between the group system $(\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}]^{-1}, [\lambda_{K,F,\gamma}])$ and the group system $(\pi_1(S^3 \setminus K^{\text{mir}}), x_{K^{\text{mir}},F^{\text{mir}}}, [\mu_{K^{\text{mir}},F^{\text{mir}}}], [\lambda_{K^{\text{mir}},F^{\text{mir}},\gamma^{\text{mir}}}])$.

(b) First note that the map

$$\begin{aligned} F^{\text{rev}}\colon \overline{B}^2 \times K^{\text{rev}} &\to S^3 \\ (x,y) &\mapsto F(\psi(x), y) \end{aligned}$$

is a thickening of K^{rev} with self-linking number zero. Furthermore note that $\gamma^{\text{rev}} := \gamma \circ \varphi\colon S^1 \to K^{\text{rev}}$ is orientation-preserving. Finally note that the group system $(\pi_1(S^3 \setminus K^{\text{rev}}, x_{K^{\text{rev}},F^{\text{rev}}}), [\mu_{K^{\text{rev}},F^{\text{rev}}}], [\lambda_{K^{\text{rev}},F^{\text{rev}},\gamma^{\text{rev}}}])$ equals the group system $(\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}^{-1}], [\lambda_{K,F,\gamma}^{-1}])$.

(c) This statement follows immediately from (a) and (b). ■

On page 1334 we saw that looking at finite quotients of groups can be a convenient tool for distinguishing groups. We now apply the same idea to group systems. There are various ways of making this idea precise. We will work with the following approach.

Definition. Let G be a *finite* group and let $x \in G$.

(1) Given a group system (π, g_1, g_2) where π is a finitely generated group we define

$$P_G^x(\pi, g_1, g_2) \;:=\; \overset{\text{finite sum by Exercise 53.3}}{\overset{\downarrow}{\sum_{\{\varphi \in \text{Hom}(\pi,G)\,|\,\varphi(g_1)=x\}}}} \varphi(g_2) \;\in\; \overset{\text{group ring as defined on page 1872}}{\overset{\downarrow}{\mathbb{Z}[G]}}.$$

It is clear that isomorphic group systems give the same element in $\mathbb{Z}[G]$.

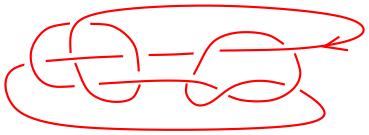
(2) Let K be a knot. Following [**Eis2007**, Definition 1.2] we refer to

$$P_G^x(K) \;:=\; P_G^x(\text{group system of } K) \;\in\; \mathbb{Z}[G],$$

as the (G,x)-coloring polynomial of K.

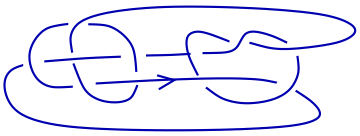
The art now is to find, given a knot, a finite group G and element $x \in G$ such that the (G,x)-coloring polynomial has content.

[1583] In particular note that the "extra ψ" ensures this map F^{mir} is indeed orientation-preserving.



Example. We consider the Kinoshita-Terasaka knot and the Conway knot that are shown in the figure below. This pair of knots is notoriously hard to distinguish. Now let G be the Mathieu group M_{11}, this is the unique simple group of order $7920 = 2^4 \cdot 3^2 \cdot 5 \cdot 11$ and the smallest of the sporadic simple groups, see [**CCNPW1985**] for details. As is explained in [**Eis2007**, p. 315], one way of describing $G = M_{11}$ is to note that it is the subgroup of the alternating group A_{11} that is generated by

$$x = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\ 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 1 \end{pmatrix} \quad \text{and} \quad y = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\ 2 & 3 & 5 & 7 & 10 & 1 & 8 & 6 & 11 & 9 & 4 \end{pmatrix}.$$



Note that x has order 11 in A_{11} and thus also in $G = M_{11}$. By [**Eis2007**, p. 317] we have the following table:

$$\begin{array}{lcllcl} P^x_G(K) & = & 1 + 11x^3 + 11x^7, & P^x_G(C) & = & 1 + 11x^3 + 11x^7, \\ P^x_G(K^{\mathrm{mir}}) & = & 1 + 11x^4 + 11x^8, & P^x_G(C^{\mathrm{mir}}) & = & 1 + 11x^4 + 11x^8, \\ P^x_G(K^{\mathrm{rev}}) & = & 1 + 11x^4 + 22x^8, & P^x_G(C^{\mathrm{rev}}) & = & 1 + 11x^4 + 11x^6 + 11x^8, \\ P^x_G(K^{\mathrm{inv}}) & = & 1 + 22x^3 + 11x^7, & P^x_G(C^{\mathrm{inv}}) & = & 1 + 11x^3 + 11x^5 + 11x^7. \end{array}$$

Since x has order 11 in G we see that all these elements of $\mathbb{Z}[G]$ are different. This shows that these eight oriented knots are pairwise non-smoothly isotopic. In particular this shows that the Kinoshita-Terasaka knot and the Conway knot are neither amphichiral, nor reversible nor invertible.

Kinoshita-Terasaka knot

Conway knot

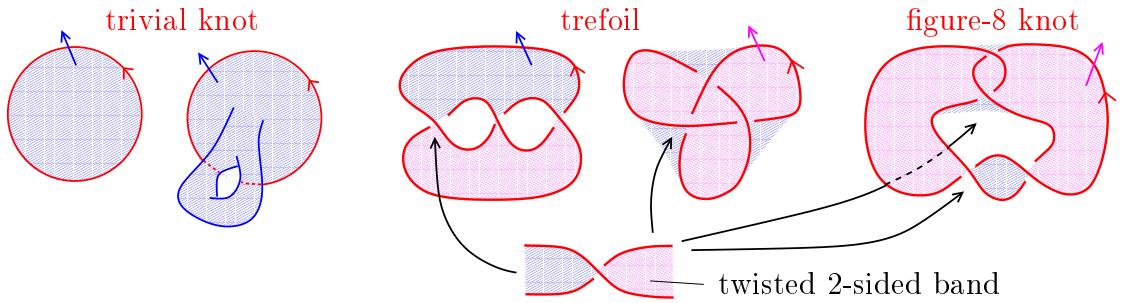
For the record let us formulate the following proposition.

Proposition 131.4. There exists an oriented knot that is neither amphichiral, nor reversible nor invertible.

We can now finally answer Question 59.9 in the affirmative.

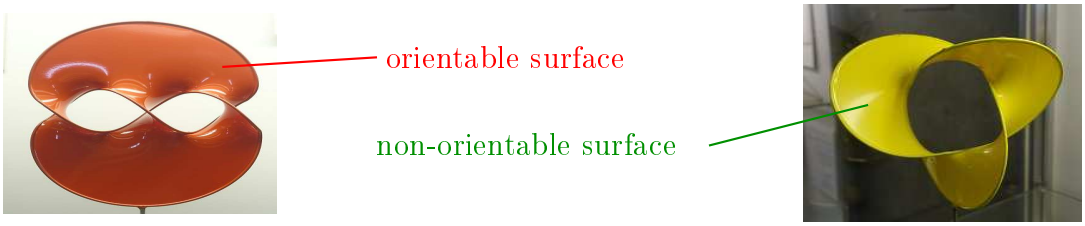
Proposition 131.5. The trefoil is chiral.

Proof. We equip the trefoil K with either orientation. In Proposition 59.6 we showed that there exists an epimorphism $\pi_1(S^3 \setminus K) \to S_3$. For a suitable choice of $x \in S_3$ one sees, using the Knot-Group System Proposition 131.3 and using the knot coloring polynomial $P^x_{S_3}$ that K is neither smoothly isotopic to it mirror nor to its inverse. Thus the unoriented trefoil is chiral. We will work out the details in Exercise 131.4. ∎



131.3. **Seifert surfaces.** The following is the key object in this section.

Definition. Let $K \subset S^3$ be a knot. A Seifert surface[1590] for K is a compact orientable connected 2-dimensional submanifold F of S^3 such that $\partial F = K$. If K itself is oriented, then we equip a Seifert surface F with the orientation such that $\partial F = K$ as oriented smooth manifolds.



[1590] Seifert surfaces are named after Herbert Seifert (1907-1996) whom we had already encountered at the Mayer–Vietoris Theorem 52.2.

Examples.

(1) In the figure below we show Seifert surfaces for the trivial knot, the trefoil and the figure-8 knot.

(2) In the figure below we see two surfaces of minimal surface area that bound the trefoil, both were manufactured by Jürgen Neukirch. The one on the left is orientable, thus it is a Seifert surface. The one on the right is diffeomorphic to the Möbius band, thus it is not a Seifert surface.

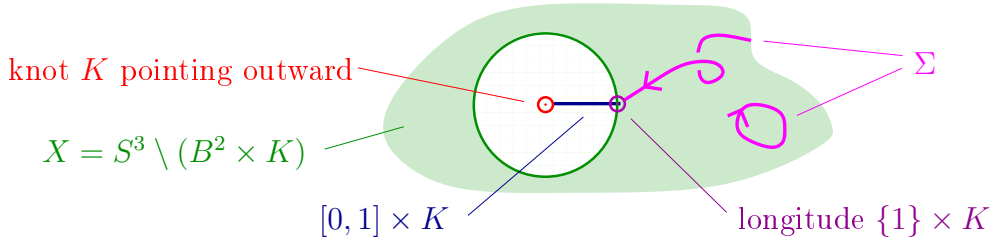
The following proposition is arguably one of the most useful results in knot theory.

Proposition 131.6. (Seifert Surface-Existence Proposition) Every knot $K \subset S^3$ admits a Seifert surface.

Remark.

(1) The proposition was first proved in 1930 by F. Frankl and Lev Pontryagin [**FPo1930**] in 1930. Shortly afterwards Herbert Seifert [**Sei1934**] gave a different proof. More precisely Seifert found an algorithm that given a diagram for a knot produces an explicit Seifert surface for the knot. Seifert's algorithm is also described in most books on knot theory, see e.g. [**Rolf1990**, p. 120] or [**Lic1997a**, Theorem 2.2].

(2) A slight generalization of the argument we give proves the following stronger statement: given any closed orientable n-dimensional smooth manifold $V \subset S^{n+2}$ there exists a compact orientable $(n+1)$-dimensional submanifold $W \subset S^{n+2}$ such that $\partial W = V$. We refer to [**Bre1993**, Theorem VII.14.7], [**Er1969**, Lemma 2.2] and [**BDR2017**] for details. The proof in these two references is close to the approach taken in the proof of the Seifert Surface-Existence Proposition 131.6, but it circumvents the use of the Codimension-One Submanifold Existence Proposition 130.4 by a more formal argument.



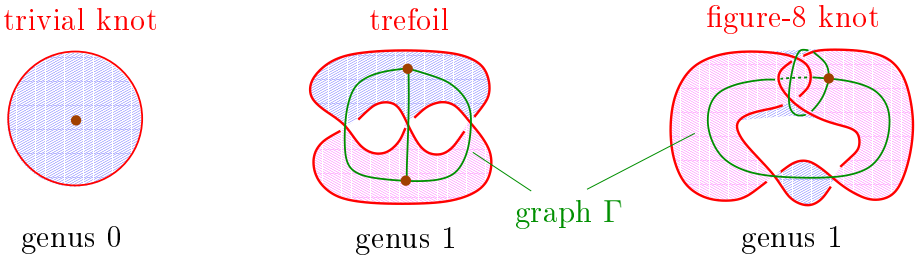
Proof. Let K be a knot. We need to show that there exists a compact orientable connected 2-dimensional submanifold F of S^3 such that $\partial F = K$.

First note that by the Knot Thickening Lemma 131.1 (2) we can pick a thickening $\overline{B}^2 \times K$ of the knot K with self-linking number zero. We denote by $X := S^3 \setminus (B^2 \times K)$ the knot

exterior. Note that by the Longitude-Meridian Lemma 131.2 (2) we know that there exists a unique homology class $\sigma \in \mathrm{H}_2(X, \partial X; \mathbb{Z})$ such that $\partial\sigma = [\{*\} \times K] \in \mathrm{H}_1(\partial X; \mathbb{Z})$. It follows from Proposition 130.6 that there exists a compact oriented proper 2-dimensional submanifold Σ of X such that $[\Sigma] = \sigma$ and such that $\partial\Sigma = \{*\} \times K$. We apply Proposition **??** to

$$([0,1] \times K) \cup \Sigma \ \subset \ (\overline{B}^2 \times K) \cup X \ = \ S^3$$

and we obtain a compact orientable 2-dimensional submanifold Z whose boundary equals K. This submanifold might not be connected, but the component of Z that contains K is the desired Seifert surface. ■

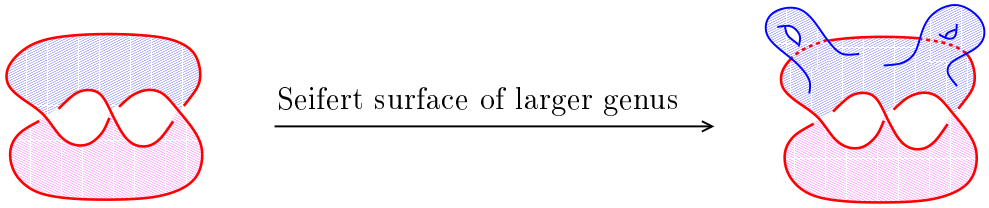


Definition. Let F be a compact orientable connected 2-dimensional smooth manifold with m boundary components. By the Surface Classification Theorem 55.4 there exists a unique $g \in \mathbb{N}_0$ such that F is homeomorphic to the surface of genus g minus m open disks. We refer to g as the genus of F.

Given a Seifert surface it is sometimes not entirely obvious how to determine the genus. The following lemma gives an easy criterion to determine the genus of a Seifert surface.

Lemma 131.7. Let F be a compact orientable connected 2-dimensional submanifold with one boundary component. If $\Gamma \subset F$ is a topological graph that is a deformation retract of F, then

$$\text{genus of } F \ = \ \tfrac{1}{2} \cdot (1 - \chi(F)) \ = \ \tfrac{1}{2} \cdot (1 - \#\text{vertices of } \Gamma + \#\text{edges of } \Gamma).$$



Proof. We calculate

$$\text{genus of } F \ \underset{\text{by Proposition 80.10 we have } \chi(F) = 1-2g}{=} \ \tfrac{1}{2}(1 - \chi(F)) \ \underset{\text{by Corollary 87.2 since } \Gamma \text{ is a deformation retract of } F}{=} \ \tfrac{1}{2} \cdot (1 - \chi(\Gamma)).$$

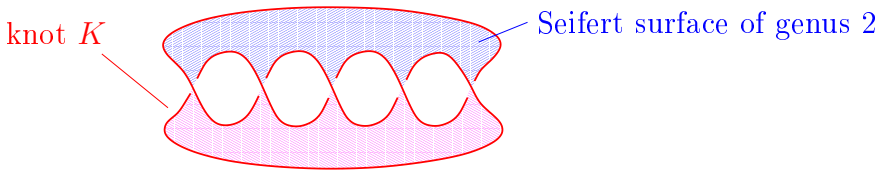
■

If a knot K bounds a Seifert surface of genus g, then the construction sketched in the figure below shows pretty convincingly that K also bounds Seifert surfaces of any genus $h \geq g$. So the interesting question is, what is the minimal genus of a Seifert surface for a given knot? This leads us to the following definition.

Definition. Given a knot $K \subset S^3$ we define

$$\text{genus}(K) := \text{minimal genus of a Seifert surface of } K.$$

Examples.



(1) As we have seen in the figure on page 2861, the trivial knot has genus 0. More interestingly, we showed in the Genus-Zero Knots Proposition 58.8 that if a knot has genus 0, then it is smoothly isotopic to the trivial knot.

(2) We had also just seen that the trefoil admits a Seifert surface of genus 1. Furthermore in Proposition 59.6 (2) we saw that the trefoil is not equivalent to the trivial knot. It follows from (1) that

$$\text{genus(trefoil)} \;=\; 1.$$

We conclude this section with the following question.

Question 131.8. We consider the knot K in the figure below. It admits a Seifert surface of genus two. Does it also admit a Seifert surface of genus one?

131.4. **Linking numbers.** We recall the following definition from page 2700.

Definition. An m-component link is a closed 1-dimensional submanifold of S^3.

Remark. It follows from the Smooth 1-Dimensional Manifold Classification Theorem 22.7 that a link is the same as a 1-dimensional submanifold of S^3 that is diffeomorphic to the disjoint union of finitely many copies of S^1.

Convention. When we write, "let $L = L_1 \sqcup \cdots \sqcup L_m$ be an m-component link", then it is understood that each L_i is non-empty. In particular each L_i is a knot in its own right.

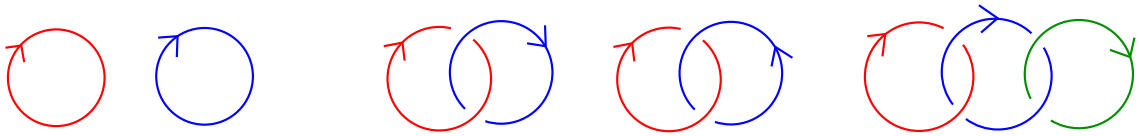
The following definition is the obvious generalization of the definition on page 1302.

Definition. We say that two m-component links $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ are smoothly isotopic if there exists a smooth map

$$\begin{array}{rccc} F\colon (S^1_1 \sqcup \cdots \sqcup S^1_m) \times [0,1] & \to & S^3 \\ (z,t) & \mapsto & F(z,t) \end{array}$$

such that the following hold:

(1) for each $i \in \{1, \dots, m\}$ we have $F(S^1_i \times \{0\}) = K_i$ and $F(S^1_i \times \{1\}) = J_i$, and
(2) for each $t \in [0,1]$ the map $F_t \colon S^1 \sqcup \cdots \sqcup S^1 \to S^3$ is a smooth embedding.



If L and J are oriented links, then we also demand that the isotopy is orientation-preserving, i.e. the map $F_1 \circ F_0^{-1} \colon K \to J$ is orientation-preserving

Examples.

(1) We say an m-component link $L \subset S^3$ is a *trivial link* if it bounds m disjoint disks in S^3. It follows immediately from the Lower-Dimensional Smooth Ball Embedding Theorem 37.10 that all m-component trivial links are in fact smoothly isotopic.
(2) In the figure below we show four examples of oriented links: the 2-component trivial link, two versions $\mathrm{H}^{\pm}$ of the Hopf link and one further link. The Hopf link is in fact related to the Hopf map

$$\begin{aligned} H \colon S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} &\to S^2 = \mathbb{C}\mathrm{P}^1 \\ (z_1, z_2) &\mapsto [z_1 : z_2] \end{aligned}$$

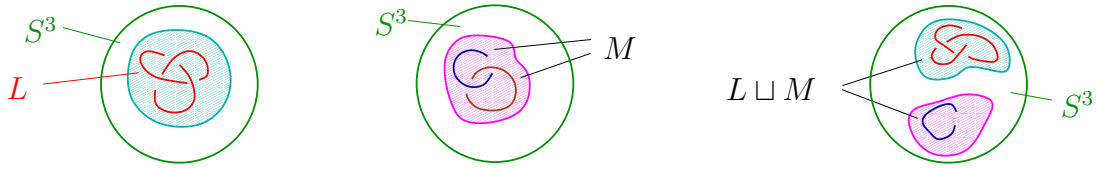
from page 1576. More precisely, if P, Q are two distinct points in S^2, then the preimage $\mathrm{H}^{-1}(\{P, Q\})$ is a 2-component link that is smoothly isotopic to the Hopf links without orientation. This can be seen as follows: for $P = [1:0]$ and $Q = [0:1]$ one can verify "by hand" that the preimage is smoothly isotopic to a Hopf link. Given any two other distinct points P' and Q' in S^2 we can find disjoint smooth paths from P to P' and Q to Q', the preimages of these paths give rise to a smooth isotopy of links.

2-component trivial link H^- Hopf links H^+ chain link

Our goal now is to distinguish links that are not smoothly isotopic. It follows immediately from the definition that if two links $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ are smoothly isotopic, then the components are smoothly isotopic knots. Therefore we are mostly interested in distinguishing links for which the components are smoothly isotopic. The following proposition generalizes Proposition 58.4. The proof is verbatim the same.

Proposition 131.9. Let $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ be two m-component links. If the links are smoothly isotopic, then the following two statements hold:

(1) There exists an orientation-preserving diffeomorphism $\Phi \colon S^3 \to S^3$ with $\Phi(L_i) = J_i$ for $i = 1, \dots, m$. If L and J are oriented, then there exists such a diffeomorphism Φ which for each $i \in \{1, \dots, m\}$ restricts to an orientation-preserving diffeomorphism $L_i \to J_i$.
(2) The link complements $S^3 \setminus L$ and $S^3 \setminus J$ are diffeomorphic, in particular homeomorphic.



Remark. By the Gordon-Luecke Theorem 58.7 we pointed out that for knots the converse to Proposition 58.4 (2) holds. More precisely, if K and J are two knots such that there

exists an orientation-preserving diffeomorphism between the knot complements $S^3 \setminus K$ and $S^3 \setminus J$, then K and J are smoothly isotopic. The analogous statement is no longer true for links. In the figure below we show two links $L = K \sqcup J$ and $L' = K' \sqcup J'$. In Exercise 131.7 we will see that $S^3 \setminus L$ and $S^3 \setminus L'$ are diffeomorphic. Even though we cannot prove it at the moment, it should be fairly clear that L and L' are not smoothly isotopic. This shows in particular that the problem of classifying links cannot be reduced to the problem of classifying the complements of links.

The following lemma gives a general construction of new links out of given ones.

Lemma 131.10. Let L and M be two links in S^3. We pick an orientation-preserving embedding $\varphi\colon \overline{B}^3 \to S^3$ with $L \subset \varphi(B^3)$ and we pick an orientation-preserving embedding $\psi\colon \overline{B}^3 \to S^3$ with $M \subset \psi(B^3)$. Finally we pick two orientation-preserving embeddings $\alpha, \beta\colon \overline{B}^3 \to S^3$ with disjoint images. The smooth isotopy type of $\alpha(\varphi^{-1}(L)) \cup \beta(\psi^{-1}(M))$ is well-defined and we refer to it as the split union $L \sqcup M$ of the links L and M.

Proof. We start out with the following statement which might actually be of independent interest.

Claim. Let X be a compact subset of an n-dimensional smooth manifold M and let $\varphi, \widetilde{\phi}\colon \overline{B}^n \to M$ be two smooth embeddings with $X \subset \varphi(B^n)$ and $X \subset \widetilde{\varphi}(B^n)$. There exists a smooth isotopy $\Theta\colon \overline{B}^n \times [0,1] \to M$ such that $\Theta_0 = \varphi$, $\Theta_1 = \widetilde{\varphi}$ and such that for each $t \in [0,1]$ we have $X \subset \Theta_t(B^n)$.

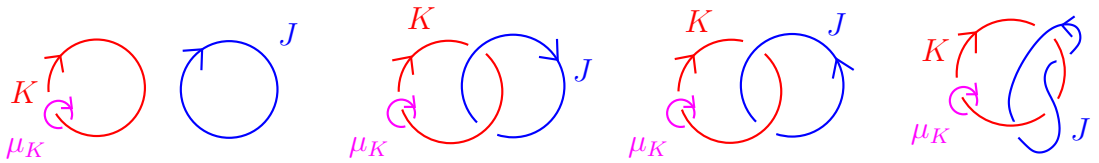
Proof. If X is empty, then there is nothing to show. So now assume that X is non-empty. We pick $P \in X$. It follows from the Smooth Isotopy Transitivity Proposition 33.3 and Proposition 36.4 that we can assume without loss of generality that $\varphi(0) = \widetilde{\varphi}(0) = P$. Note that this means that we can view φ and $\widetilde{\varphi}$ as tubular maps for the 0-dimensional submanifold $\{P\} \subset M$. It follows from Proposition **??** that there exists a smooth isotopy $\Theta\colon \overline{B}^n \times [0,1] \to M$ such that $\Theta_0 = \varphi$, $\Theta_1 = \widetilde{\varphi}$ and such that for each $t \in [0,1]$ we have $\Theta_t(0) = P$.

It follows from Exercise 14.8 that there exists an open neighborhood U of P such that for each $t \in [0,1]$ we have $U \subset \Theta_t(B^n)$. If $X \subset U$, then we are done. Otherwise we use Exercise 33.2 and the fact that X is by hypothesis compact, together with the Smooth Isotopy Transitivity Proposition 33.3, to reduce the general case to the case that $X \subset U$. ⊞

Now we go back the actual statement of the lemma. First note that it follows from the claim and Exercise 33.3 that the smooth isotopy type of $\alpha(\varphi^{-1}(L)) \cup \beta(\psi^{-1}(M))$ does not depend on the choice of φ and ψ. Finally note that it follows from the Smooth Ball Embedding Theorem 37.8 that the smooth isotopy type of $\alpha(\varphi^{-1}(L)) \cup \beta(\psi^{-1}(M))$ does not depend on the choice of α and β. ■

To distinguish links with components that are smoothly isotopic we will now introduce an invariant of oriented links.

Definition. Let $K \subset S^3$ be an oriented knot.



(1) As before we denote by μ_K the meridian as defined on page 1305 and as above we denote by ϕ_K the epimorphism $\phi_K \colon \mathrm{H}_1(S^3 \setminus K; \mathbb{Z}) \to \mathbb{Z}$ that is given by $\phi_K([\mu_K]) = 1$.
(2) We denote by $[\mu_K]^* \in \mathrm{H}^1(S^3 \setminus K; \mathbb{Z})$ the unique generator with $\langle [\mu_K]^*, [\mu_K] \rangle = 1$.
(3) If $J \subset S^3$ is an oriented knot that is disjoint from K, then we define the linking number of K and J to be

$$\mathrm{lk}(K, J) \;:=\; \phi_K([J]) \;\underset{\uparrow}{=}\; \langle [\mu_K]^*, [J] \rangle$$

equality holds by the above definitions

where $[J] \in \mathrm{H}_1(S^3 \setminus K; \mathbb{Z})$ denotes the image of the fundamental class of the oriented smooth manifold J under the inclusion $J \to S^3 \setminus K$.

Example. If K is the trivial knot, then we saw in Proposition 59.4 that $S^3 \setminus K$ is diffeomorphic to the open solid torus $B^2 \times S^1$ and it is fairly straightforward to determine $\phi_K \colon \mathrm{H}_1(S^3 \setminus K; \mathbb{Z}) \to \mathbb{Z}$ applied to a given curve. This allows us to determine the linking numbers of the oriented links shown in the figure below.

$\mathrm{lk}(K, J) = 0$ $\mathrm{lk}(K, J) = -1$ $\mathrm{lk}(K, J) = 1$ $\mathrm{lk}(K, J) = 2$

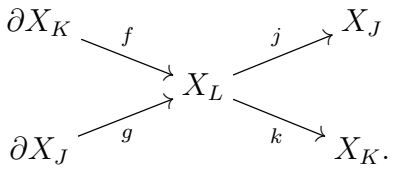
Proposition 131.11.

(1) Let $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ be two m-component oriented links. If the links L and J are smoothly isotopic, then for all $r, s \in \{1, \ldots, m\}$ we have

$$\mathrm{lk}(L_r, L_s) \;=\; \mathrm{lk}(J_r, J_s).$$

(2) Let $K \sqcup J$ be an oriented 2-component link. If we change the orientation of one of the components of the link, then the sign of the linking number flips.

Proof. The first statement is an immediate consequence of Proposition 131.9 (1). The second statement follows easily from the definitions. ■



Example. It follows from Proposition 131.11 together with the calculation of the linking numbers in the figure on page 2865 that the two Hopf links H^- and H^+ are not smoothly isotopic.

The following proposition says that the linking number $\mathrm{lk}(K,J)$ is symmetric in the oriented knots K and J.

Proposition 131.12. (Linking Number-Symmetry Proposition) For any oriented 2-component link $J \sqcup K$ we have

$$\mathrm{lk}(J,K) \;=\; \mathrm{lk}(K,J).$$

Proof. We pick a thickening for the link $L = J \sqcup K$ and use it to define the exteriors X_L, X_K and X_J. Throughout the proof we consider the following inclusion maps

Furthermore, throughout the proof we use the isomorphisms from the H_0-Proposition 72.5 and page 1594 to make the identifications $\mathrm{H}_0(\partial X_J;\mathbb{Z}) = \mathrm{H}_0(X_L;\mathbb{Z}) = \mathrm{H}_0(X_J;\mathbb{Z}) = \mathbb{Z}$. We start out with the following claim.

Claim. We have

$$\mathrm{lk}(K,J) \;=\; \big(\underbrace{k^*([\mu_K]^*)}_{\in \mathrm{H}^1(X_L;\mathbb{Z})} \cup \underbrace{j^*([\mu_J]^*)}_{\in \mathrm{H}^1(X_L;\mathbb{Z})}\big) \cap \underbrace{g_*([\partial X_J])}_{\in \mathrm{H}_2(X_L;\mathbb{Z})}.$$

Proof. We denote by $[J] \in \mathrm{H}_1(J;\mathbb{Z})$ the fundamental class. We have the following equalities:

$$\begin{array}{ccccc}
 & & & & \text{Cup Product-Commutativity Proposition 115.3} \\
 & & & & \downarrow \\
(k^*([\mu_K]^*) \cup j^*([\mu_J]^*)) \cap g_*([\partial X_J]) & & = & & -(j^*([\mu_J]^*) \cup k^*([\mu_K]^*)) \cap g_*([\partial X_J]) \\
= & & & & = \\
\uparrow & & & & \uparrow \\
-k^*([\mu_K]^*) \cap (j^*([\mu_J]^*) \cap g_*([\partial X_J])) & & = & & -k^*([\mu_K]^*) \cap g_*(g^*j^*[\mu_J]^* \cap [\partial X_J]) \\
\text{Cup-Cap Lemma 116.7} & & & & \text{Cup Product-Naturality Lemma 114.10 applied to } g \\
= & & = & & = \\
\uparrow & & \uparrow & & \uparrow \\
k^*([\mu_K]^*) \cap g_*([\lambda_J]) & & \langle [\mu_K]^*, k_*g_*([\lambda_J])\rangle & & \langle [\mu_K]^*, [J]\rangle \\
\text{Longitude-Meridian Lemma 131.2 (5)} & & \text{Lemmas 109.6 (3) and 116.4} & & \text{since } [\lambda_J] = [J] \in \mathrm{H}_1(X_K)
\end{array} \quad = \quad \mathrm{lk}(K,J).$$

see page 2865

⊞

Now we conclude that

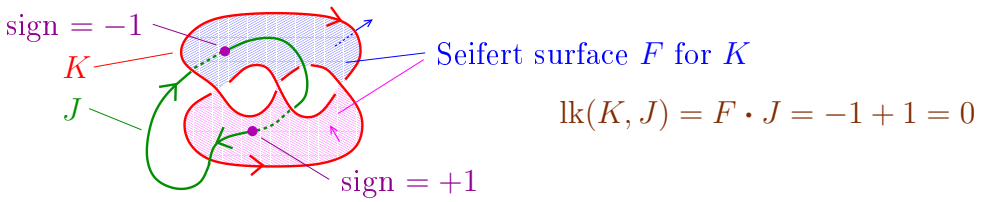
$$\begin{array}{ccccc}
\mathrm{lk}(K,J) & = & (j^*([\mu_J]^*) \cup k^*([\mu_K]^*)) \cap g_*([\partial X_J]) & = & (-k^*([\mu_K]^*) \cup j^*([\mu_J]^*)) \cap (-f_*([\partial X_K])) \\
 & \uparrow & & \uparrow & \\
 & \text{by the claim} & \text{by the Cup Product-Commutativity Proposition 115.3 and since by Corollary 106.28 we have } g_*([\partial X_J]) + f_*([\partial X_K]) = 0 \in \mathrm{H}_2(X_L;\mathbb{Z}) & &
\end{array}$$

$$= \mathrm{lk}(J,K).$$

$$\uparrow$$

by the claim

■



To determine the linking number in more complicated cases it is helpful to have different ways to calculate the linking number.

Proposition 131.13. (Linking Numbers-via-Intersection Numbers Proposition) Let $K \sqcup J$ be an oriented 2-component link. If F is a Seifert surface for K that is transverse to J, then

$$\mathrm{lk}(K,J) \;=\; F \cdot J$$

where $F \cdot J$ denotes the algebraic intersection number of F and J.

Example. In the figure below we show an oriented link $K \sqcup J$ and a Seifert surface F for K. Clearly we have $F \cdot J = 0$, thus it follows from the Linking Numbers-via-Intersection Numbers Proposition 131.13 that $\mathrm{lk}(K, J) = 0$.

Remark. The combination of the Linking Numbers-as-Intersection Numbers Proposition **??** and the Intersection Number-via-Cup Product Theorem 126.5, and some mild massaging, generalizes the statement of the Linking Numbers-via-Intersection Numbers Proposition 131.13 to the higher-dimensional setting and it gives an alternative proof of Proposition 131.13.

Proof. Let $K \sqcup J$ be an oriented 2-component link. We pick a tubular neighborhood $\overline{B}^2 \times K$ for K. After possibly shrinking the tubular neighborhood we can and will assume that $S^1 \times K$ intersects F transversally in a single curve[1591] and that $\overline{B}^2 \times K$ does not intersect J. We write $X := S^3 \setminus (B^2 \times K)$ and we write $F' := F \cap X$. It follows from our choice of tubular neighborhood and from the Submanifold Transversal Intersection Theorem 42.1 that F' is a compact proper submanifold of F.

We start out with the following claim.

Claim. We have $\mathrm{PD}_X([F']) = [\mu_K]^* \in \mathrm{H}^1(X; \mathbb{Z})$.

Proof. By definition of the Poincaré Duality isomorphism PD_X the claim is equivalent to showing that $[\mu_K]^* \cap [X] = [F']$. From the Longitude-Meridian Lemma 131.2 (2) we know that the connecting homomorphism $\partial\colon \mathrm{H}_2(X, \partial X; \mathbb{Z}) \to \mathrm{H}_1(\partial X; \mathbb{Z})$ is a monomorphism. Therefore it suffices to show that $\partial([\mu_K]^* \cap [X]) = \partial[F']$. We denote by $i\colon \partial X \to X$ the inclusion map. We calculate that

$$\partial([\mu_K]^* \cap [X]) \underset{\text{Proposition 119.25}}{=} -i^*([\mu_K]^*) \cap [\partial X] \overset{\text{Longitude-Meridian Lemma 131.2 (5) and (4)}}{=} [\lambda_K] \overset{\text{Longitude-Meridian Lemma 131.2 (5) and (4)}}{=} [\partial F'] \underset{\text{Fundamental Class-of-Boundary Proposition 106.27}}{=} \partial([F']).$$

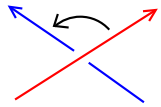
∎

Now we calculate that

$$\begin{array}{lllllll} F \cdot J & \overset{\text{Lemma 126.4}}{=} & J \cdot F & \overset{\text{since } J \subset X}{=} & J \cdot F' & \overset{\text{Intersection Number-via-Cup Product Theorem 126.5}}{=} & (\mathrm{PD}_X([J]) \cup \mathrm{PD}_X([F'])) \cap [X] \\ & & & & & = & [\mu_K]^* \cap [J] \\ & & & & & & \text{by the claim we have } \mathrm{PD}_X([F']) = [\mu_K]^* \text{ and} \\ & & & & & & \text{by definition we have } \mathrm{PD}_X([J]) \cap [X] = [J] \end{array}$$

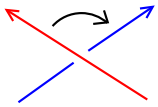
$$\begin{array}{lll} \overset{\text{Cup-Cap Lemma 116.7}}{=} & \mathrm{PD}_X([F']) \cap (\mathrm{PD}_X([J]) \cap [X]) \\ = & \langle [\mu_K]^*, [J] \rangle \\ & \text{see page 2865} \end{array} = \mathrm{lk}(K, J).$$

We have thus proved the desired equality. ∎



[1591] This last statement requires a little bit of thought. We leave the technical details to the reader.

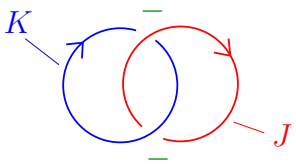
Next we will formulate a proposition that in many "real-life" situations is often the most efficient way to compute linking numbers. Before we formulate the proposition, recall that on page 1322 we introduced the notion of a knot diagram and the notion of an over- and undercrossing. These notion can be generalized in a pretty obvious way to the notion of a link diagram.
To enhance readability we will formulate the next proposition in a slightly informal way.



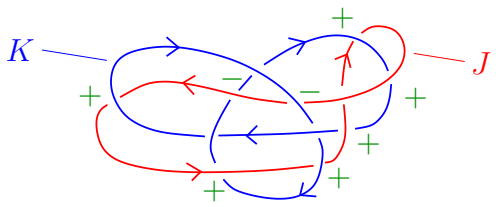
Proposition 131.14. (Linking Number-via-Signed Crossings Proposition) Let $K \sqcup J \subset S^3$ be an oriented 2-component link that is given by a diagram in the xy-plane. Then

$$\mathrm{lk}(K,J) \;=\; \begin{array}{l} \frac{1}{2} \cdot \text{number of positive crossings between } K \text{ and } J \\ - \;\; \frac{1}{2} \cdot \text{number of negative crossings between } K \text{ and } J \end{array}$$

where a crossing P is called a positive (respectively negative) crossing if the direction of the upper strand together with the direction of the lower strand give a positive (respectively negative) basis for $\mathbb{R}^2$.



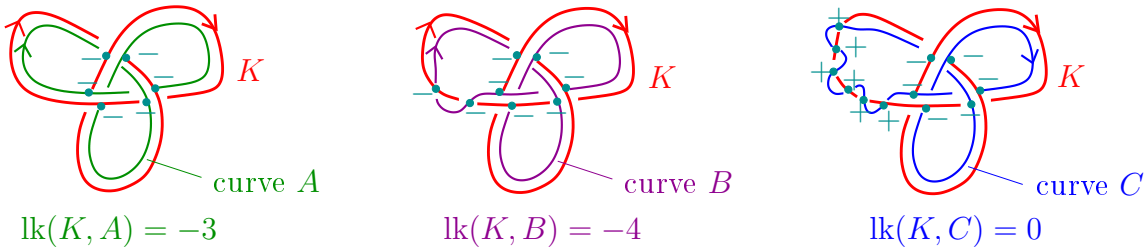
positive crossing



negative crossing

Examples.

(1) In the figure below we show two oriented links and we compute the linking number using Linking Number-via-Signed Crossings Proposition 131.14 by considering the signs of the crossings between K and J. As a reality check, on the left we consider the Hopf link that we had already considered in the figure on page 2865. In both cases we obtain that the linking number equals -1.



linking number $= -1$

linking number $= 2$

(2) Now we can settle the question from page 2854, which of the three closed curves shown in the figure on page 2869 is actually the longitude of the trefoil. More precisely, by definition the longitude λ_K satisfies $\phi_K([\lambda_K]) = 0$, but again by definition this means that $\mathrm{lk}(K, \lambda_K) = 0$. Conversely, loosely speaking any curve that runs "parallel to K" and that has linking number zero with K, is a longitude. Using Linking Number-via-Signed Crossings Proposition 131.14 we calculate the linking numbers of the oriented knot K with the oriented curves A, B and C. We obtain that C is the only curve with linking number zero. Thus C is the longitude.

Remark. Let $K \sqcup J \subset S^3$ be an oriented 2-component link that is given by a diagram in the xy-plane. An amusing exercise shows that

$$\mathrm{lk}(K,J) \;=\; \begin{array}{l} \text{number of positive crossings where } K \text{ crosses over } J \\ - \;\text{number of negative crossings where } K \text{ crosses over } J. \end{array}$$

Sketch of proof. [1592] We introduce the following notation:

(1) Given $t \in \mathbb{R}$ we consider the map

$$\begin{array}{rcl} \lambda_t \colon \mathbb{R}^3 & \to & \mathbb{R}^3 \\ (x,y,z) & \mapsto & (x,y,z+t). \end{array}$$

We extend this definition to a homeomorphism of S^3 by setting $\lambda_t(\infty) = \infty$.[1593]

(2) By the Seifert Surface-Existence Proposition 131.6 the knot J admits a Seifert surface F.

(3) We pick $r \in \mathbb{R}$ such that the minimal z-coordinate of any point on $\lambda_r(F)$ is greater than the maximal z-coordinate of any point in K.

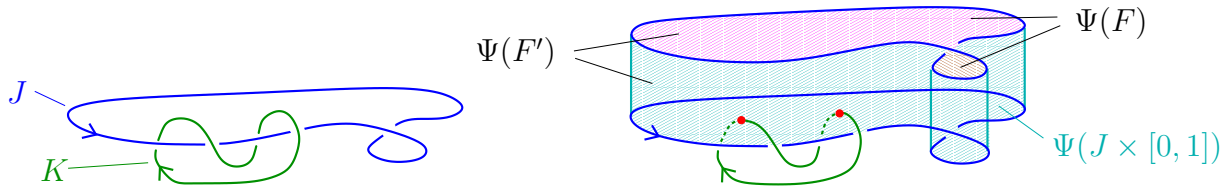
(4) We write $F' = ((J \times [0,1]) \cup F)/\!\sim$ where we identify any point in $J \subset F$ with the corresponding point in $J \times \{1\}$. Note that F' is a compact 2-dimensional smooth manifold that inherits an orientation from F.

(5) We consider the map[1594]

$$\begin{array}{rcl} \Psi \colon F' = ((J \times [0,1]) \cup F)/\!\sim & \to & \mathbb{R}^3 \\ Q & \mapsto & \begin{cases} \lambda_{t\cdot r}(P) & \text{if } Q = (P,t) \in J \times [0,1], \\ \lambda_r(Q), & \text{if } Q \in F. \end{cases} \end{array}$$

Then

$$\mathrm{lk}(K,J) \underset{\substack{\uparrow \\ \text{by the same argument} \\ \text{as in Proposition 131.13}}}{=} K \cdot \Psi \underset{\substack{\uparrow \\ \text{by choice of } r \text{ we have} \\ K \cap \Psi(F) = \varnothing}}{=} K \cdot \Psi|_{J \times [0,1]}.$$



The right-hand side can be computed easily, in fact the points in $K \cap \Psi(J \times [0,1])$ correspond precisely to the crossings of the diagrams where K crosses over J and one can easily convince oneself that the signs agree. The proposition now follows from the reformulation of the linking number in the remark preceding the proof. ∎

In the following lemma we give a 4-dimensional interpretation of the linking number.

[1592] A proof can evidently only be as precise as the input. Since we did not bother to completely rigorously formulate the statement we can also not expect a completely rigorous proof. But with some effort one can formulate both the statement and the proof rigorously.

[1593] Why is this map continuous?

[1594] Note that the map $\Psi \colon F' \to S^3$ is not necessarily injective. In particular the image is not necessarily a Seifert surface for J.

Lemma 131.15. Let K, K' be two disjoint oriented knots.

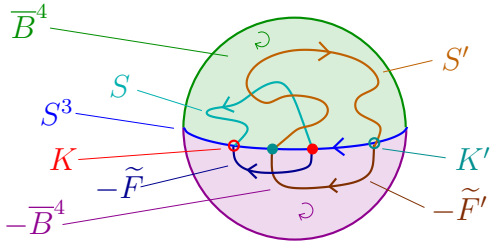
(1) There exist oriented proper 2-dimensional submanifolds S and S' of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$ such that S and S' are transverse.
(2) Let S, S' be two oriented proper 2-dimensional submanifolds of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$. If S and S' are transverse, then

$$\mathrm{lk}(K, K') \;=\; S \cdot_{\overline{B}^4} S'.$$

Remark. The combination of the Linking Numbers-as-Intersection Numbers Proposition **??** and the Intersection Number-via-Cup Product Theorem 126.5 generalizes the statement of Lemma 131.15 to the higher-dimensional setting and it gives an arguably mathematically purer proof of Lemma 131.15.

Sketch of proof. Let K, K' be two disjoint oriented knots.

(1) By the Seifert Surface-Existence Proposition 131.6 and the Transversality Theorem 42.4 (2) there exists a Seifert surface F for K that is transverse to K'. Furthermore let F' be a Seifert surface for K'. We pick a collar neighborhood $[0,2] \times S^3$ for $S^3 = \partial \overline{B}^4$. We use the collar neighborhood $[0,1] \times S^3$ to define the push-in[1595] $\widetilde{F}$ of F and we use the collar neighborhood $[0,2] \times S^3$ to define the push-in $\widetilde{F}'$ of F'. It follows easily from Lemma **??** that $\widetilde{F}$ and $\widetilde{F}'$ have the desired properties.
(2) First we note that



$$\mathrm{lk}(K, K') \underset{\text{Proposition 131.13}}{=} F \cdot_{S^3} K' \underset{\text{by inspection of the intersection points}}{=} \widetilde{F} \cdot_{\overline{B}^4} \widetilde{F}' \underset{\text{follows easily from the definitions}}{=} -(-\widetilde{F}) \cdot_{-\overline{B}^4} (-\widetilde{F}').$$

Now let S, S' be two oriented proper 2-dimensional submanifolds of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$. We think of $S^4 = \overline{B}^4 \cup (-\overline{B}^4)$ as the union of two copies of $\overline{B}^4$ with opposite orientations, the first copy contains S, S' and the second contains $-\widetilde{F}, -\widetilde{F}'$. (See the figure below for an illustration.) It follows fairly easily from the Smooth Collar Neighborhood Theorem **??** that $S \cup -\widetilde{F}$ and $S' \cup -\widetilde{F}'$ are oriented submanifolds of S^4.[1596] We calculate that

$$S \cdot_{\overline{B}^4} S' - \mathrm{lk}(K, K') \underset{\text{by the above}}{=} S \cdot_{\overline{B}^4} S' + (-\widetilde{F}) \cdot_{-\overline{B}^4} (-\widetilde{F}') \underset{\text{since } S \cap \widetilde{F}' = S' \cap \widetilde{F} = \varnothing}{=} (S \cup -\widetilde{F}) \cdot_{S^4} (S' \cup -\widetilde{F}') \underset{\text{by Theorem 127.7 and since } \mathrm{H}^2(S^4; \mathbb{Z}) = 0}{=} 0.$$

[1595] We refer to page **??** for the definition of push-ins.
[1596] The word "submanifold of S^4" is used in a slightly ambiguous way since it depends on whether we view S^4 as a topological manifold or a smooth manifold. In this case we view S^4 only as a topological manifold.

We have thus shown the desired equality $S \cdot_{\overline{B}^4} S' = \mathrm{lk}(K, K')$. ■

Given two disjoint knots K and J in $\mathbb{R}^3$ we now have different ways to define and think about the linking number. The following proposition, which mirrors [**Rolf1990**, Theorem 5.D.5], shows that they are all the same.

Proposition 131.16. (Linking Number Reformulation Proposition) Let $K \sqcup J$ be an oriented 2-component link in $\mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ and let F be a Seifert surface for J that intersects K transversally. The following numbers are all equal:[1597]

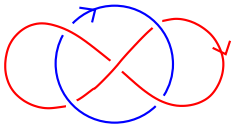
(1) $\phi_K([J])$ (definition of $\mathrm{lk}(K, J)$ page 2865)

(2) $K \cdot F$

(3) the signed count of crossings as in Proposition 131.14

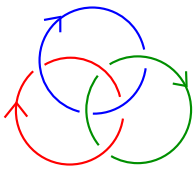
(4) $-\deg \begin{pmatrix} K \times J & \to & S^2 \\ (x, y) & \mapsto & \frac{x-y}{\|x-y\|} \end{pmatrix}$ (definition of $\mathrm{lk}(K, J)$ on page 1007)

(5) $\frac{1}{4\pi} \int_{s=0}^{s=2\pi} \int_{t=0}^{t=2\pi} \frac{\det \overbrace{\begin{pmatrix} (f(s) - g(t)) & f'(s) & g'(t) \end{pmatrix}}^{3 \times 3\text{–matrix}}}{\|f(s) - g(t)\|^3} \, dt \, ds$



Proof. The equality (1)=(2) is the content of the above Linking Numbers-via-Intersection Numbers Proposition 131.13 and the equality (1)=(3) is the content of the above Linking Number-via-Signed Crossings Proposition 131.14. The equality (3)=(4) was shown, with slightly different language, in Proposition 44.1. We proved (2)=(4) in the Linking Numbers-via-Intersection Numbers Proposition 44.3 The equality (4)=(5) was proved in the Gauß Linking Number Theorem **??**. ■

Example. Given any topological invariant the question that arises is, how good is it at distinguishing objects. It is quite easy to find examples of links which show that the linking number is far from being a complete invariant. In the figure below we show the Whitehead link and the Borromean rings. Both are links with zero linking numbers and unknotted components but which are appear to be non-trivial. The Whitehead link is named after John Henry Constantine Whitehead who also introduced the concept of CW-complexes. The Borromean rings are named after the Borromeo family that carries the Borromean rings in its coat of arms since medieval days.



We record the following question for later on.

Question 131.17. How can we show that neither the Whitehead link nor the Borromean rings are smoothly isotopic to the trivial link?

[1597] Here we use the notion of "degree" that we introduced on page 899 or on page **??**, which in turn equals the degree defined on page 2379 or alternatively on pages 2222.

Whitehead link

Borromean rings

coat of arms of the Borromeo family

Remark. We can of course try to determine the fundamental groups of the complements of the trivial links and the Whitehead link and the Borromean rings. But then the question arises, how can we distinguish these groups?

131.5. **Alexander duality and linking numbers** (∗). Let Y be a compact non-empty subset of S^3 that admits a regular neighborhood. (For example, by Propositions 123.5, **??** and 123.4 the subset Y could be a link or a spatial graph.) We can compute the isomorphism types of the first homology group of the complement $S^3 \setminus Y$ as follows:

$$\begin{array}{ccccccc} \mathrm{H}_1(S^3 \setminus Y;\mathbb{Z}) & \overset{\cong}{\to} & \mathrm{H}^1(Y;\mathbb{Z}) & \overset{\cong}{\to} & \mathrm{Hom}(\mathrm{H}_1(Y;\mathbb{Z}),\mathbb{Z}) & \cong & \mathrm{H}_1(Y;\mathbb{Z})/\text{torsion}. \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \text{Alexander Duality} & & \text{Universal Coefficient} & & & & \text{non-natural isomorphism} \\ \text{Theorem 123.6} & & \text{Theorem 110.12} & & & & \end{array}$$

The catch with the Alexander Duality Theorem 123.6 is that it is quite hard to "see" the isomorphism. For example, suppose we are given a basis for $\mathrm{H}_1(Y;\mathbb{Z})/\text{torsion}$, how do we get a basis for $\mathrm{H}_1(S^3 \setminus Y;\mathbb{Z})$? In many situations the following lemma resolves that issue.

Lemma 131.18. Let Y be a compact non-empty subset of S^3 that admits a regular neighborhood $N(Y)$. We suppose that $\mathrm{H}_1(Y;\mathbb{Z})$ is a free abelian group[1598] of rank k. Let $v(x), C_n$ be oriented curves in $N(Y)$ and let $D_1,\dots,D_k$ be oriented curves in $S^3 \setminus N(Y)$. If

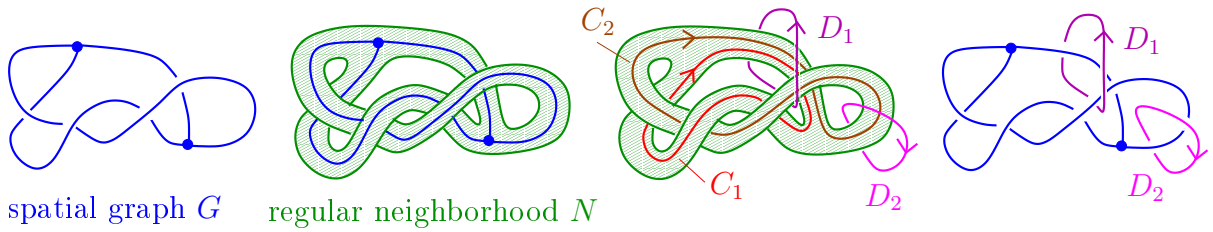
$$\det\Big(\underbrace{(\mathrm{lk}(C_i,D_j)_{i,j=1,\dots,k})}_{k\times k\text{–matrix}}\Big) \;=\; \pm 1,$$

then $[D_1],\dots,[D_k]$ form a basis of $\mathrm{H}_1(S^3 \setminus Y;\mathbb{Z})$.

Proof. Let Y be a compact non-empty subset of S^3 that admits a regular neighborhood $N = N(Y)$. We denote by $\mathring{N}$ the interior of N. We consider the homomorphisms

$$\begin{array}{rcl} \Omega\colon \mathbb{Z}^k & \to & \mathrm{H}_1(S^3\setminus\mathring{N};\mathbb{Z}) \\ (a_1,\dots,a_k) & \mapsto & \sum_{i=1}^{k} a_i\cdot[D_i] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \Theta\colon \mathrm{H}_1(S^3\setminus\mathring{N};\mathbb{Z}) & \to & \mathbb{Z}^k \\ \sigma & \mapsto & (\phi_{C_1}(\sigma),\dots,\phi_{C_k}(\sigma)). \end{array}$$

It follows from our hypothesis and the definition of linking numbers that $\Theta\circ\Omega$ is an epimorphism. Furthermore we know from the Alexander Duality Theorem 123.6 and the Universal Coefficient Theorem 110.12 that $\mathrm{H}_1(S^3 \setminus \mathring{N};\mathbb{Z})$ is also isomorphic to $\mathbb{Z}^k$. But by Lemma 51.9 (5) an epimorphism between two free abelian groups of the same rank is an isomorphism. Thus we see that Θ and Ω are isomorphisms.



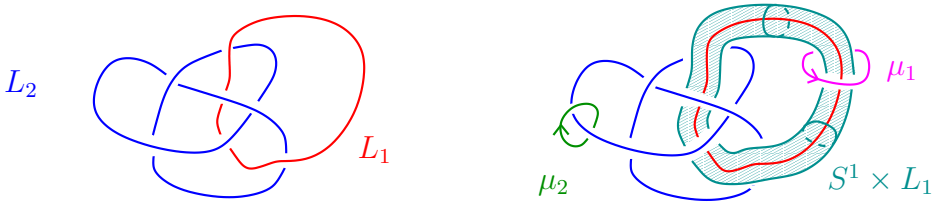
[1598] Is it possible that $\mathrm{H}_1(Y;\mathbb{Z})$ is not a free abelian group?

Since $\{[D_1], \dots, [D_k]\}$ is the image under Ω of the standard basis of $\mathbb{Z}^k$ we see that $[D_1], \dots, [D_k]$ form a basis for $\mathrm{H}_1(S^3 \setminus \mathring{N}; \mathbb{Z})$. But by Lemma 123.1 the inclusion induced map $\mathrm{H}_1(S^3 \setminus Y; \mathbb{Z}) \to \mathrm{H}_1(S^3 \setminus \mathring{N}; \mathbb{Z})$ is an isomorphism. Thus we see that $[D_1], \dots, [D_k]$ form a basis of $\mathrm{H}_1(S^3 \setminus Y; \mathbb{Z})$.[1599] ■

Example. In the figure below we consider a spatial graph G together with a regular neighborhood N. By Lemma 87.12 we know that $\mathrm{H}_1(G; \mathbb{Z}) \cong \mathbb{Z}^2$. In the figure below we also see two oriented curves C_1 and C_2 in N and two oriented curves D_1 and D_2 in $S^3 \setminus \mathring{N}$. Using Linking Number-via-Signed Crossings Proposition 131.14 one can easily calculate that

$$\begin{pmatrix} \mathrm{lk}(C_1, D_1) & \mathrm{lk}(C_1, D_2) \\ \mathrm{lk}(C_2, D_1) & \mathrm{lk}(C_2, D_2) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}.$$

It follows from Lemma 131.18 that $[D_1], [D_2]$ form a basis for $\mathrm{H}_1(S^3 \setminus G; \mathbb{Z})$.



In Lemma 123.8 we computed the homology groups of the complement of a link, but we could not determine explicit generators. The following lemma now solves that problem. In particular it gives an answer to Question 123.9.

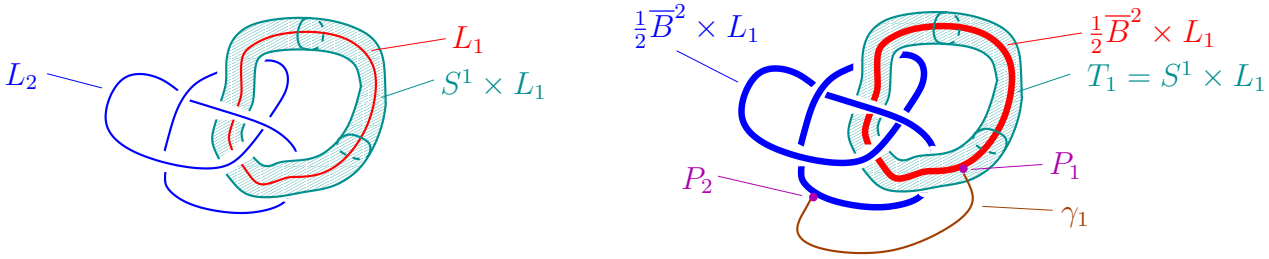
Lemma 131.19. Let $L = L_1 \sqcup \cdots \sqcup L_m$ be an m-component link. We pick a thickening $\overline{B}^2 \times L$ for L.

(1) A basis for $\mathrm{H}_1(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^m$ is given by the homology classes that are represented by the meridians $\mu_1, \dots, \mu_m$.

(2) A basis for $\mathrm{H}_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1}$ is given by considering the fundamental classes of all but one of the tori $S^1 \times L$, $i \in \{1, \dots, m\}$. More precisely, for any $j \in \{1, \dots, m\}$ a basis for $\mathrm{H}_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1}$ is given by

$$[S^1 \times L_1], \dots, [S^1 \times L_{i-1}], [S^1 \times L_{i+1}], \dots, [S^1 \times L_m].$$

Sketch of proof. Let $L = L_1 \sqcup \cdots \sqcup L_m$ be an m-component link. We know from Lemma 123.8 that $\mathrm{H}_1(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^m$ and that $\mathrm{H}_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1}$. We pick a thickening $\overline{B}^2 \times L$ for L. By the Smooth Collar Neighborhood Theorem 28.3 we can extend this thickening to a thickening $2\overline{B}^2 \times L$.



[1599] The alert reader will have noticed that the proof resembles the argument given in the Kronecker-Basis Lemma 109.7.

(1) The first statement follows from Lemma 131.18 applied to $\mathrm{C}_i = \{0\} \times L_i$, $i = 1, \ldots, m$ and $D_i := \mu_i$, $i = 1, \ldots, m$.

(2) To simplify the notation we consider the case $j = m$. We write $X' := S^3 \setminus \frac{1}{2}B^2 \times L$. For $i = 1, \ldots, m$ we write $T_i := S^1 \times L_i$. For $i = 1, \ldots, m$ we pick a point P_i on $\frac{1}{2}S^1 \times L_i \subset \partial X'$. Since $S^3 \setminus (2B^2 \times L)$ is path-connected we can pick for each $i \in \{1, \ldots, m-1\}$ a path γ_i from P_i to P_m that intersects T_i transversally in a single point and that does not intersect any of the T_j with $j \neq i, m$. Now we consider the map

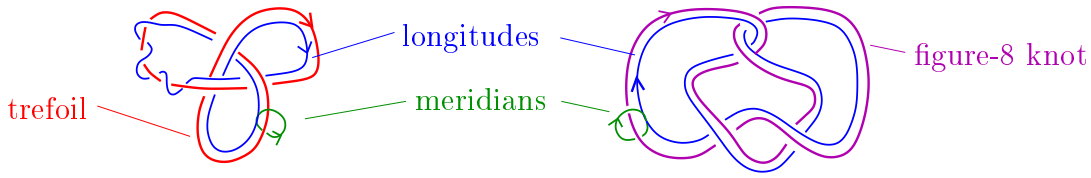
$$\begin{aligned} \Psi \colon \mathrm{H}_1(X', \partial X'; \mathbb{Z}) \times \mathrm{H}_2(X'; \mathbb{Z}) &\to \mathbb{Z} \\ (\sigma, \tau) &\mapsto \langle \mathrm{PD}_{X'}(\sigma) \cup \mathrm{PD}_{X'}(\tau), [X'] \rangle. \end{aligned}$$

It follows easily from Theorem 127.7 that for $i, j \in \{1, \ldots, m-1\}$ we have the equality $\Psi([\gamma_i], [T_j]) = \delta_{ij}$. By Lemma 109.8 this implies that $[T_1], \ldots, [T_{m-1}]$ do indeed form a basis of $\mathrm{H}_2(X'; \mathbb{Z})$. ■

Exercises for Chapter 131.

Exercise 131.1. Let $A = S^1 \times [-1, 1]$ be the annulus. Let C and D be two closed oriented curves on A. Suppose that $[C] = [D] \neq 0$. Show that the following two statements hold:

(a) the two closed oriented curves are smoothly isotopic,



(b) if C and D are furthermore disjoint, then there exists an embedded annulus $X \subset A$ with $\partial A = C \cup -D$.

Hint. Using the fact that A is an annulus you can find a smooth isotopy that makes the curves disjoint. At that point it is perhaps better to first prove (2).

Exercise 131.2. Let F be an oriented connected 2-dimensional smooth manifold and let C and D be distinct boundary curves. Suppose that C and D are homotopic. Show that F is diffeomorphic to the annulus $S^1 \times [-1, 1]$.

Exercise 131.3. Let K be a knot together with a diagram. In Section 59.6 we gave an explicit algorithm that determines the Wirtinger presentation for $\pi_1(S^3 \setminus K)$. Explain what element in this presentation corresponds to the longitude. Alternatively, for readers who like more explicit questions, determine the group system for the trefoil and the figure-8 knot.

Exercise 131.4. Show that the trefoil K is chiral.
Hint. In Proposition 59.6 we showed that there exists an epimorphism $\pi_1(S^3 \setminus K) \to S_3$.

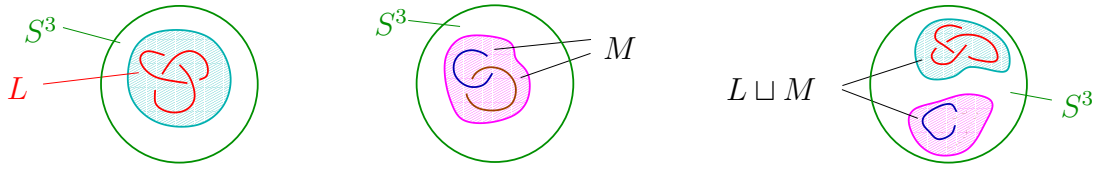
Exercise 131.5. Find explicit Seifert surfaces for the knots K_1 and K_2 shown in the figure below.
Remark. The answer to a question can only be as rigorous as the input. Since the input is a picture it suffices here of course to draw a convincing picture of a Seifert surface.

Exercise 131.6. Let $\varphi\colon \overline{B}^3 \to S^3$ and $\psi\colon \overline{B}^3 \to S^3$ be two smooth embeddings with disjoint images. Let $K \subset \varphi(\overline{B}^3)$ and $J \subset \psi(\overline{B}^3)$ be oriented knots. Show that $\operatorname{lk}(K, J) = 0$.

Exercise 131.7. We consider the two links shown in the figure below. Show that the link complements are diffeomorphic.

Exercise 131.8. Is every knot $K \subset S^3$ the boundary of a *non-orientable* compact surface that is smoothly embedded in S^3?

Exercise 131.9. The Borromean rings, shown in the figure on page 2872, have the property that if you remove one component, then the remaining two knots form a trivial link. Does there exist a four component link with the property that if you remove any of the four components, then you get a three component trivial link?

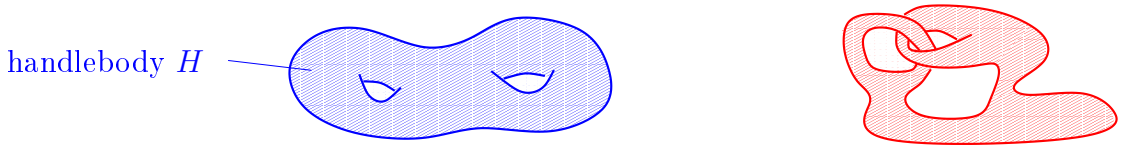


Exercise 131.10. Let $L = K \sqcup J$ and $L' = K' \sqcup J'$ be two oriented links such that the complements are diffeomorphic. Does it follow that $\operatorname{lk}(K, J) = \pm \operatorname{lk}(K', J')$?

Exercise 131.11. An m-component link $L = L_1 \sqcup \cdots \sqcup L_m \subset S^3$ is called *split link* if there exist disjoint closed smoothly embedded balls $B_1, \ldots, B_m \subset S^3$ such that each L_i is contained in B_i. Furthermore L is called a *boundary link* if there exist m disjoint Seifert surfaces $F_1, \ldots, F_m$.

(a) A split link is easily seen to be a boundary link. Do there exist boundary links that are not split?

(b) Show that if $L = L_1 \sqcup \cdots \sqcup L_m$ is a boundary link, then there exists an epimorphism from $\pi_1(S^3 \setminus L)$ onto a free group of rank m.
Hint. You could try to find an interesting map from $S^3 \setminus L$ onto the wedge of m circles.



Exercise 131.12. Let L and M be two links in S^3. We pick an orientation-preserving embedding $\varphi\colon \overline{B}^3 \to S^3$ with $L \subset \varphi(B^3)$ and we pick an orientation-preserving embedding $\psi\colon \overline{B}^3 \to S^3$ with $M \subset \psi(B^3)$. Finally we pick two orientation-preserving embeddings $\alpha, \beta\colon \overline{B}^3 \to S^3$ with disjoint images. We refer to $\alpha(\varphi^{-1}(L)) \cup \beta(\psi^{-1}(M))$ as the *split union* $L \sqcup M$ *of the links* L *and* M. The goal of this exercise is to show that the smooth isotopy class of the split union $L \sqcup M$ is independent of all the choices, in other words, show that the smooth isotopy class of the split union only depends on the smooth isotopy type of L and M.
Remark. Use Exercise **??**.

Exercise 131.13. Let $K \sqcup J$ be an oriented link in $\mathbb{R}^3$ and let $K^* \sqcup J^*$ be a mirror image as defined on page 1315. As usual we view $\mathbb{R}^3$ as a subset of $\mathbb{R}^3 \cup \{\infty\} = S^3$. Determine the relationship between $\mathrm{lk}(K, J)$ and $\mathrm{lk}(K^*, J^*)$.

Exercise 131.14. Let $n \geq 4$ and let $K \subset S^n$ be a closed orientable smooth submanifold of codimension 2. Show that there exists a compact orientable submanifold W of S^n with $\partial W = K$.
Remark. Note that in general the analogous statement is not true if we do not impose any conditions on the codimension. For example by the Euclidean Embedding Theorem 27.1 and the Smooth Embedding Theorem 24.10 we can view $\mathbb{C}\mathrm{P}^2$ as a smooth submanifold of some $S^n = \mathbb{R}^n \cup \{\infty\}$. But by the proof of Corollary 144.7 we know that $\mathbb{C}\mathrm{P}^2$ is not the boundary of any compact orientable smooth manifold, let alone one which is embedded in S^n.

Exercise 131.15. In the figure below we show two smooth embeddings of the genus two handlebody into $\mathbb{R}^3$. Are these two embeddings smoothly isotopic?

132. The intersection form I: Definition and calculations

In this chapter we will introduce and study the intersection form of compact oriented even-dimensional topological manifolds. Before we do so it is convenient to remind ourselves of a few basic notions and results in algebra.

132.1. **Pairings and forms.** On page 2656 we introduced the notion of a pairing over a commutative ring R. We recall the definition and we introduce some new notions.

Definition. Let R be a commutative ring.

(1) A pairing on $V \times W$ is a map
$$\varphi\colon V \times W \ \to \ S$$
such that for all $v, v' \in V$ and $W, w' \in W$ we have $\varphi(v+v', w) = \varphi(v,w) + \varphi(v',w)$ and $\varphi(v, w+w') = \varphi(v,w) + \varphi(v,w')$.[1600]

(2) A pairing is called R-bilinear if it is R-linear in V and if it is R-linear in W.

(3) We say that an R-bilinear pairing $\varphi\colon V \times V \to S$ is symmetric if $\varphi(v,w) = \varphi(w,v)$ for all $v, w \in V$. Furthermore we call the pairing anti-symmetric if $\varphi(v,w) = -\varphi(w,v)$ for all $v, w \in V$.

(4) We say that two R-bilinear pairings (V, φ) and (W, ψ) are isometric, written as $(V,\varphi) \cong (W,\psi)$, if there exists an isometry, i.e. an isomorphism $f\colon V \to W$ of R-modules such that $\varphi(v_1, v_2) = \psi(f(v_1), f(v_2))$ for all $v_1, v_2 \in V$.

(5) Given an R-bilinear pairing $\varphi\colon V \times V \to S$ we denote by $-\varphi$ the R-bilinear pairing that is given by $(-\varphi)(v,w) := -\varphi(v,w)$ for all $v, w \in V$.

(6) Given two R-bilinear pairings $\varphi\colon V \times V \to S$ and $\psi\colon W \times W \to S$ we define the direct sum of φ and ψ to be the R-bilinear pairing
$$\begin{array}{rcl} \varphi \oplus \psi\colon (V \oplus W) \times (V \oplus W) & \to & S \\ (v \oplus w, v' \oplus w') & \mapsto & \varphi(v,v') + \psi(w,w'). \end{array}$$

(7) Given an R-bilinear pairing (V,φ) and $n \in \mathbb{Z}$ we define
$$n \cdot (V,\varphi) \ := \ \begin{cases} \overbrace{(V,\varphi) \oplus \cdots \oplus (V,\varphi)}^{n\text{-summands}}, & \text{if } n \geq 0, \\ \underbrace{(V,-\varphi) \oplus \cdots \oplus (V,-\varphi)}_{|n|\text{-summands}}, & \text{if } n \leq 0. \end{cases}$$

(8) Given an R-bilinear pairing $(V, \varphi\colon V \times V \to S)$ and a submodule W of V we denote by $\varphi|_W$ the R-bilinear pairing that is given by restricting the map $\varphi\colon V \times V \to S$ to $W \times W \to S$.

In this chapter we will mostly be interested in the following special type of an R-bilinear pairing.

Definition. Let R be a commutative ring. A form[1601] is a finitely generated free R-module V together with an R-bilinear pairing $\varphi\colon V \times V \to R$ which is either symmetric or anti-symmetric. We refer to the rank of V also as the rank of the form.[1602]

For the reader's convenience we recall the following definition from page 2656.

Definition. Let R be a commutative ring. A form $\varphi\colon V \times V \to R$ is called non-singular if the map

$$\begin{array}{ccc} V & \to & \mathrm{Hom}_R(V,R) \\ v & \mapsto & \left(\begin{array}{ccc} V & \to & R \\ w & \mapsto & \varphi(v,w) \end{array} \right) \end{array}$$

is an isomorphisms.[1602]

In many situations it is convenient to represent a form by a matrix. We recall the relevant definition from the linear algebra courses.

Definition. Let R be a commutative ring and let $\varphi\colon V \times V \to R$ be a form. Given any basis $\{v_1, \ldots, v_k\}$ of the free R-module V we refer to the $(k \times k)$–matrix

$$(\varphi(v_i, v_j))_{i,j=1,\ldots,k} \ \in \ \mathrm{M}(k \times k, R)$$

as a matrix representing the form φ. Note that by the Non-Singularity Lemma 121.1 the form is non-singular if and only if the matrix representing the form is invertible.

The following elementary lemma is usually proved in a standard course on linear algebra. It is also straightforward to verify it using only the relevant definitions.[1603]

Lemma 132.1. Let R be a commutative ring and let $\varphi\colon V \times V \to R$ be a form. Let $\{v_1, \ldots, v_k\}$ and $\{w_1, \ldots, w_k\}$ be bases of the free R-module V. We write

$$A \ := \ (\varphi(v_i, v_j))_{i,j=1,\ldots,k} \quad \text{and} \quad B \ := \ (\varphi(w_i, w_j))_{i,j=1,\ldots,k}.$$

If $P = (p_{ij})_{i,j=1,\ldots,k} \in \mathrm{GL}(k, R)$ denotes the transition matrix that is uniquely defined by the property that $v_i = \sum_{j=1}^{k} p_{ij} w_j$ for $i = 1, \ldots, k$, then

$$A \ = \ P^T B P.$$

The following lemma is even more elementary, it follows basically immediately from the definitions.

Lemma 132.2.

(1) Let $\varphi\colon V \times V \to R$ be a form. If A is a matrix that represents φ, then the matrix $-A$ represents the form $-\varphi$.

[1600] The various definitions of "form" in the literature vary wildly. It is always a good idea, reading a paper or a book, to look up the precise definition of "form" that is used by the author.

[1601] The rank of a finitely generated free module over a commutative ring is well-defined, see e.g. [**Lam1999**, p. 4]. Note though that the rank of a finitely generated free module over a non-commutative ring is not necessarily well-defined. More precisely, there exists a non-commutative ring R and $m \neq n \in \mathbb{N}$ such that R^m is isomorphic to R^n. We refer to [**Lam1999**, p. 4] for such examples. WE will discuss this issue in Section **??**.

[1602] Note that a form is by definition (anti-) symmetric. It follows from this fact that the given condition is satisfied if and only if the condition with the two entries of φ swapped is satisfied. Thus the definition we give here is indeed consistent with the definition from page 2656.

[1603] It is easy though to get confused.

(2) Let $\varphi\colon V\times V\to R$ and $\psi\colon W\times W\to R$ be two forms. If A is a matrix that represents φ and if B is a matrix that represents ψ, then the matrix $A\oplus B := \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$ represents the form $\varphi\oplus\psi$.
(3) Let $\varphi\colon V\times V\to R$ be a form and let $n\in\mathbb{N}_0$. If A is a matrix that represents φ, then the matrix $n\cdot A := \underbrace{A\oplus\cdots\oplus A}_{n\text{-times}}$ represents the form $n\cdot\varphi$.

Before we can turn to topology we need to recall the following definition from page 2114.

Definition. Given a finitely generated abelian group H we refer to

$$\mathrm{F}H \;:=\; H/\operatorname{Tor}(H) \quad \text{where } \operatorname{Tor}(H) \text{ denotes the torsion subgroup of } H$$

as the maximal torsion-free quotient of H.

The following lemma summarizes everything we need to know about maximal torsion-free quotients.

Lemma 132.3.

(1) The maps

$$H \;\mapsto\; \mathrm{F}H \qquad \text{and} \qquad (\alpha\colon G\to H) \;\mapsto\; \begin{pmatrix} \alpha\colon \mathrm{F}G & \to & \mathrm{F}H \\ [g] & \mapsto & [\alpha(g)] \end{pmatrix}$$

define a covariant functor from the category of finitely generated abelian groups to the category of finitely generated free abelian groups.
(2) For every homomorphism $\alpha\colon A\to B$ between two finitely generated abelian groups the following diagram commutes:[1604]

$$\begin{array}{ccc} A & \xrightarrow{\alpha} & B \\ {\scriptstyle a\mapsto[a]}\downarrow & & \downarrow{\scriptstyle b\mapsto[b]} \\ \mathrm{F}A & \xrightarrow{\alpha} & \mathrm{F}B. \end{array}$$

(3) Any (anti-) symmetric pairing

$$\varphi\colon H\times H \;\to\; \mathbb{Z}$$

over a finitely generated abelian group descends to a well-defined form

$$\begin{aligned} \mathrm{F}H\times\mathrm{F}H &\to \mathbb{Z} \\ ([g],[h]) &\mapsto \varphi(g,h). \end{aligned}$$

Proof. In Lemma 97.4 we already showed that if H is a finitely generated abelian group, then $\mathrm{F}H$ is a finitely generated free abelian group. The remaining statements of the lemma are basically elementary. ∎

Convention. On many occasions we do not distinguish in the notation between an element in an abelian group H and the element it represents in the maximal torsion-free quotient $\mathrm{F}H$. Furthermore, given a homomorphism $\alpha\colon A\to B$ between two finitely generated abelian groups we often denote the induced map $\mathrm{F}A\to\mathrm{F}B$ by α as well.

[1604] In fancy speak this means that the projections $H\to\mathrm{F}H$ define a natural transformation from the identity functor to the functor $H\mapsto\mathrm{F}H$.

132.2. **The definition of the intersection form of topological manifolds.** Let M be a compact oriented m-dimensional topological manifold and let A and B be compact $(m-1)$-dimensional submanifolds of ∂M with $A \cup B = \partial M$ and with $A \cap B = \partial A = \partial B$. Recall that by the Poincaré Duality Theorem 119.1 we know that for any $k \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{H}^{m-k}(M, A; \mathbb{Z}) & \to & \mathrm{H}_k(M, B; \mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [M] \end{array}$$

is an isomorphism. As on page 2618 we denote by

$$\mathrm{PD}_M \colon \mathrm{H}_k(M, A; \mathbb{Z}) \to \mathrm{H}^{m-k}(M, B; \mathbb{Z})$$

the inverse of this isomorphism. This leads us to the following definition.

Definition. Let M be a compact oriented topological manifold of the even dimension $2n$. We refer to the map[1605][1606]

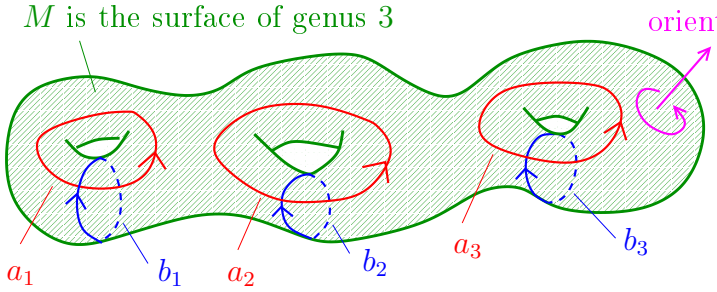
$$\begin{array}{rcl} Q_M \colon \mathrm{FH}_n(M; \mathbb{Z}) \times \mathrm{FH}_n(M; \mathbb{Z}) & \to & \mathbb{Z} \\ (a, b) & \mapsto & \big\langle \underbrace{\underbrace{\mathrm{PD}_M(a)}_{\in \mathrm{FH}^n(M, \partial M; \mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(b)}_{\in \mathrm{FH}^n(M, \partial M; \mathbb{Z})}}_{\in \mathrm{FH}^{2n}(M, \partial M; \mathbb{Z})}, [M] \big\rangle \end{array}$$

as the intersection form of M.

Remark. Since $\mathrm{PD}_M \colon \mathrm{H}_n(M; \mathbb{Z}) \to \mathrm{H}^n(M, \partial M; \mathbb{Z})$ is an isomorphism it is clear that the intersection form is basically just a reformulation of the cup product pairing

$$\begin{array}{rcl} \mathrm{H}^n(M, \partial M; \mathbb{Z}) \times \mathrm{H}^n(M, \partial M; \mathbb{Z}) & \to & \mathrm{H}^{2n}(M, \partial M; \mathbb{Z}) \\ (\alpha, \beta) & \mapsto & \alpha \cup \beta \end{array}$$

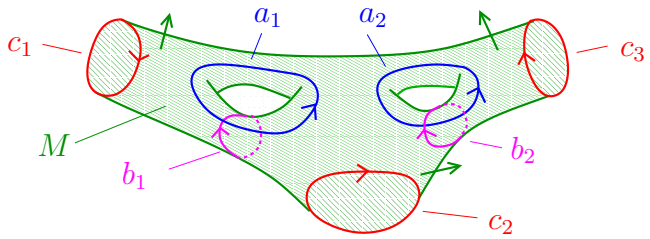
on cohomology groups in the middle dimension that we introduced in the Manifold-Non Singularity Proposition 121.2. The big psychological advantage of homology is that very often one can "see homology classes". For example, in many cases homology classes are represented by submanifolds and we can then use the Intersection Number-via-Cup Product Theorem 126.5 to compute the intersection form of a smooth manifold. Sometimes we can also represent homology classes by explicit cycles and we can use Theorem 127.9 to compute the intersection form.



Examples.

(1) First we consider the surface M of genus 3. In principle we could obtain the intersection form from the calculation of the cup product that we had performed in Lemma 114.16. But it is much more fun and instructive to use the Intersection Number-via-Cup Product Theorem 126.5 instead. More precisely, we consider the surface M that is illustrated in the figure below. We give it the usual orientation. We already saw in the discussion on page 1781 that the closed oriented curves $a_1, b_1, a_2, b_2, a_3, b_3$ illustrated in the figure below represent a basis for $\mathrm{H}_1(M; \mathbb{Z})$. It follows easily from the Intersection Number-via-Cup Product Theorem 126.5 that

[1605] Note that the homology group $\mathrm{H}_n(M; \mathbb{Z})$ in the middle dimension is not necessarily torsion-free. For example $M = S^1 \times \mathbb{R}\mathrm{P}^3$ is orientable, but it follows easily from the Künneth Formula 90.8 and the calculation of the homology groups of $\mathbb{R}\mathrm{P}^3$ in Proposition 80.11 that $\mathrm{H}_2(S^1 \times \mathbb{R}\mathrm{P}^3; \mathbb{Z}) \cong \mathbb{Z}_2$.



[1606] As mentioned above, in the notation usually we do not distinguish between an element in $\mathrm{H}_n(M; \mathbb{Z})$ and the element it represents in $\mathrm{FH}_n(M; \mathbb{Z})$.

with respect to this basis the intersection form is represented by the matrix shown in the figure below. An analogous statement holds of course for any surface of genus $g \geq 1$.[1607]

$$Q_M = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}$$

(2) Next we let M be the surface of genus two with three disks removed that is shown in the figure below. By the discussion on page 1784 we know that a basis for $\mathrm{H}_1(M;\mathbb{Z})$ is represented by the curves a_1, b_1, a_2, b_2 together with two out of the three boundary curves c_1, c_2, c_3. It follows from the Intersection Number-via-Cup Product Theorem 126.5 that with respect to the basis $[a_1], [b_1], [a_2], [b_2], [c_1], [c_2]$ the intersection form is represented by the matrix given in the figure below.

$$Q_M = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

(3) Next let us consider the $2n$-dimensional torus $M = S^n \times S^n$. By the Künneth Formula 90.8 we know that a basis for $\mathrm{H}_n(S^n \times S^n;\mathbb{Z})$ is given by $a = [S^n \times \{*\}]$ and $b = [\{*\} \times S^n]$. We have two approaches for determining the intersection with respect to this basis:

(a) We can use the Product Theorem 117.1 and its corollaries. More precisely, we first determine the Poincaré duals of $[S^n \times \{0\}]$ and $[\{0\} \times S^n]$ as in the Fundamental Class-Product Proposition 117.2 (2) and then we can apply Lemma 117.3.

(b) As on page 2755 we can use algebraic intersection numbers and the Intersection Number-via-Cup Product Theorem 126.5 to determine the intersection form.

In both cases we see that with respect to this basis the intersection form of $S^n \times S^n$ is represented by the matrix

$$\begin{pmatrix} Q_M(a,a) & Q_M(a,b) \\ Q_M(b,a) & Q_M(b,b) \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ (-1)^n & 0 \end{pmatrix}.$$

(4) We consider the complex manifold $\mathbb{C}\mathrm{P}^2$. As always we equip $\mathbb{C}\mathrm{P}^2$ with the natural orientation coming from the Complex Manifold-Orientation Proposition 32.23. It

[1607] What do the curves a_i and b_i look like in the more precise description of the surface of genus 3 as a dodecagon with identified sides?

follows from the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11 that the intersection form

$$Q_{\mathbb{C}\mathrm{P}^2}\colon \mathrm{H}_2(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \times \mathrm{H}_2(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \;\to\; \mathbb{Z}$$

is represented by the 1×1–matrix (1).

(5) Let M be a closed oriented $2n$-dimensional topological manifold. As usual we denote by $-M$ the same topological manifold with the opposite orientation. It follows immediately from the definitions together with Proposition 107.2 that $Q_{-M} = -Q_M$.

(6) For the complex projective space $\mathbb{C}\mathrm{P}^2$ we use the common notation that we write $\overline{\mathbb{C}\mathrm{P}}^2$ instead of $-\mathbb{C}\mathrm{P}^2$. With this notation it follows from (4) and (5) that the intersection form

$$Q_{\overline{\mathbb{C}\mathrm{P}}^2}\colon \mathrm{H}_2(\overline{\mathbb{C}\mathrm{P}}^2;\mathbb{Z}) \times \mathrm{H}_2(\overline{\mathbb{C}\mathrm{P}}^2;\mathbb{Z}) \;\to\; \mathbb{Z}$$

is represented by the 1×1–matrix (-1).

132.3. **Properties of the intersection form.** In the following proposition we summarize some of the key properties of the intersection form. The proposition shows in particular that the intersection form is a form in the sense of the definition on page 2877.

Proposition 132.4. (Intersection Form Proposition) Let M be a compact oriented $2n$-dimensional topological manifold. Then the following hold:

(1) The group $\mathrm{H}_n(M;\mathbb{Z})$ is finitely generated and $\mathrm{FH}_n(M;\mathbb{Z})$ is a finitely generated free abelian group.

(2) If n is even, then the intersection form Q_M is symmetric, otherwise it is anti-symmetric.

(3) If M is closed, then the intersection form is non-singular.

The proof of the Intersection Form Proposition 132.4 (3) relies on the following reformulation of the intersection form, which will also be useful later, on a separate occasion.

Lemma 132.5. Let M be a compact oriented connected $2n$-dimensional topological manifold. We denote by $i\colon (M,\varnothing) \to (M,\partial M)$ the inclusion map. We write

$$\begin{array}{rccccccc} \Phi\colon \mathrm{H}_n(M;\mathbb{Z}) & \xrightarrow{i_*} & \mathrm{H}_n(M,\partial M;\mathbb{Z}) & \xrightarrow{\mathrm{PD}_M} & \mathrm{H}^n(M;\mathbb{Z}) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(\mathrm{FH}_n(M;\mathbb{Z}),\mathbb{Z}). \\ & & & & \gamma & \mapsto & (a \mapsto \langle \gamma, a)\end{array}$$

For any $a, b \in \mathrm{FH}_n(M;\mathbb{Z})$ we have

$$Q_M(a,b) \;=\; \Phi(b)(a).$$

Proof of Lemma 132.5. First we consider the following diagram:

$$\begin{array}{ccc} \mathrm{H}_n(M;\mathbb{Z}) \times \mathrm{H}_n(M;\mathbb{Z}) & \xrightarrow{\mathrm{id}\times i_*} & \mathrm{H}_n(M;\mathbb{Z}) \times \mathrm{H}_n(M,\partial M;\mathbb{Z}) \\ \downarrow{\scriptstyle \mathrm{PD}_M\times\mathrm{PD}_M} & & \downarrow{\scriptstyle \mathrm{PD}_M\times\mathrm{PD}_M} \\ \mathrm{H}^n(M,\partial M;\mathbb{Z}) \times \mathrm{H}^n(M,\partial M;\mathbb{Z}) & \xrightarrow{\mathrm{id}\times i^*} & \mathrm{H}^n(M,\partial M;\mathbb{Z}) \times \mathrm{H}^n(M;\mathbb{Z}) \\ \downarrow{\scriptstyle \cup} & & \downarrow{\scriptstyle \cup} \\ \mathrm{H}^{2n}(M,\partial M;\mathbb{Z}) & \xrightarrow{\mathrm{id}} & \mathrm{H}^{2n}(M,\partial M;\mathbb{Z}). \end{array}$$

By Proposition 119.25 we know that the upper square commutes. We obtain from the Cup Product-Naturality Proposition 115.4, applied to the inclusion map $f\colon (M,\varnothing,\partial M) \to (M,\partial M,\partial M)$, that the lower square also commutes.

Now let $a, b \in \mathrm{FH}_n(M;\mathbb{Z})$. We calculate that

$$\begin{array}{lll}
 & \overset{\text{definition of } Q_M}{\downarrow} & \overset{\text{Cap Product-Kronecker Lemma 116.4 (1)}}{\downarrow} \\
Q_M(b,a) & = \langle \mathrm{PD}_M(b) \cup \mathrm{PD}_M(a), [M] \rangle & = (\mathrm{PD}_M(b) \cup \mathrm{PD}_M(a)) \cap [M] \\
 & = (\mathrm{PD}_M(b) \cup \mathrm{PD}_M(i_*(a))) \cap [M] & = (\mathrm{PD}_M(i_*(a)) \cap (\mathrm{PD}_M(b) \cap [M]) \\
 & \overset{\text{by the above commutative diagram}}{\uparrow} & \overset{\text{Cup-Cap Lemma 116.7}}{\uparrow} \\
 & = \mathrm{PD}_M(i_*(a)) \cap b & = \langle \mathrm{PD}_M(i_*(a)), b \rangle \quad = \Phi(a)(b). \\
 & \overset{\text{definition of } \mathrm{PD}_M(b)}{\uparrow} & \overset{\text{Cap Product-Kronecker Lemma 116.4 (1)}}{\uparrow} \qquad \overset{\text{definition of } \Phi \text{ and ev}}{\uparrow}
\end{array}$$

■

Proof of the Intersection Form Proposition 132.4.

(1) We proved this statement in the Topological Manifolds-Invariants Proposition 104.14.

(2) Given $v, w \in \mathrm{FH}_n(M;\mathbb{Z})$ we have the following equality:

$$\overbrace{\langle \underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{H}^n(M,\partial M;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{H}^n(M,\partial M;\mathbb{Z})}, [M] \rangle}^{=Q_M(v,w)} = (-1)^{n\cdot n} \cdot \overbrace{\langle \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{H}^n(M,\partial M;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{H}^n(M,\partial M;\mathbb{Z})}, [M] \rangle}^{=Q_M(w,v)}.$$

$$\uparrow$$

Cup Product-Commutativity Proposition 115.3

The statement follows from the observation that $(-1)^{n\cdot n} = (-1)^n$.

(3) Now suppose that M is closed. We consider the following diagram:

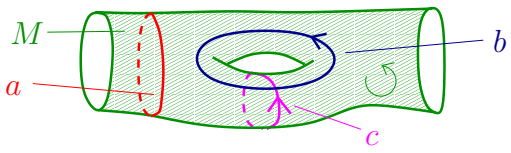
$$\begin{array}{ccc}
\mathrm{FH}_n(M;\mathbb{Z}) & \xrightarrow{b \mapsto (a \mapsto Q_M(b,a))} & \mathrm{Hom}(\mathrm{FH}_n(M;\mathbb{Z}),\mathbb{Z}). \\
 & \overset{\cong}{\searrow}^{\mathrm{PD}_M} \quad \overset{\mathrm{ev}}{\nearrow}_{\mathrm{ev}} & \\
 & \mathrm{FH}^n(M;\mathbb{Z}) &
\end{array}$$

We make the following observations:

(a) Since M is closed the map PD_M does indeed take values in the cohomology of M. Furthermore, by the Poincaré Duality Theorem 119.1 the map PD_M is an isomorphism.

(b) It follows from the Universal Coefficient Theorem 110.12 for Cohomology Groups together with the Ext-Calculation Lemma 110.5 (5) and the Topological Manifolds-Invariants Proposition 104.14 (4) that the evaluation map

$$\mathrm{ev}\colon\ \mathrm{FH}^n(M;\mathbb{Z}) \ \to\ \mathrm{Hom}(\mathrm{FH}_n(M;\mathbb{Z}),\mathbb{Z})$$



is an isomorphism.

(c) The diagram commutes by Lemma 132.5.

(d) We had just seen that the two diagonal maps are isomorphisms and that the diagram commutes. Thus we obtain that the top map is an isomorphism. By the definition on page 2878 this means precisely that the intersection form is non-singular. ■

Remark. Let M be a compact oriented $2n$-dimensional topological manifold. In the Intersection Form Proposition 132.4 we just saw that if M is closed, then the intersection form is non-singular. If M is not closed, then this conclusion does not necessarily hold. For example in the figure below we let M be the torus minus two open disks. We show a basis $\{a, b, c\}$ for $\mathrm{H}_1(M;\mathbb{Z})$. Using the Intersection Number-via-Cup Product Theorem 126.5 one can easily

see that the intersection form of M with respect to the given basis is represented by the matrix given in the figure. We see that the intersection form is anything but non-singular, in fact it is not even non-degenerate.[1608] Note though that in the Asymmetric Intersection

$$Q_M = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}$$

Pairing Proposition 132.15 and the Reduced Intersection Form Proposition 132.21 we will see that even to a topological manifold that is not closed we can associate two pairings that are non-singular or at least non-degenerate.

In the next lemma we want to see to what degree the isometry type of the intersection form is an invariant of the homeomorphism type of the topological manifold.

Lemma 132.6. Let M and N be compact oriented connected $2n$-dimensional topological manifolds. Let $f\colon (M,\partial M) \to (N,\partial N)$ be a homotopy equivalence of pairs of topological spaces.[1609]

(1) If $f_*([M]) = \quad [N]$, then f induces an isometry $Q_M \cong \quad Q_N$.
(2) If $f_*([M]) = -[N]$, then f induces an isometry $Q_M \cong -Q_N$.

Note that if f is a homeomorphism, then it follows from Proposition 107.2 that the first case occurs precisely when f is orientation-preserving and the second case occurs precisely when f is orientation-reversing.

Proof. [1610] Let $f\colon (M,\partial M) \to (N,\partial N)$ be a homotopy equivalence of pairs of topological spaces. It follows from Corollary 74.16 together with the Fundamental Class-Corollary 106.4 (3) that there exists an $\varepsilon \in \{-1,1\}$ which satisfies $f_*([M]) = \varepsilon \cdot [N]$.

Claim. For any $c \in \mathrm{H}_n(M;\mathbb{Z})$ we have $\mathrm{PD}_N(f_*(c)) = \varepsilon \cdot (f^{-1})^*(\mathrm{PD}_M(c)) \in \mathrm{H}^n(N,\partial N;\mathbb{Z})$.

Proof. So let $c \in \mathrm{H}_n(M;\mathbb{Z})$. We have

$$(f^{-1})^*(\mathrm{PD}_M(c)) \cap [N] \underset{\text{by the definition of } \varepsilon}{=} (f^{-1})^*(\mathrm{PD}_M(c)) \cap \varepsilon \cdot f_*([M]) \underset{\text{Cap Product-Naturality Lemma 116.8}}{=} \varepsilon \cdot f_*(\mathrm{PD}_M(c) \cap [M]) \underset{\text{definition of } \mathrm{PD}_M}{=} \varepsilon \cdot f_*(c).$$

It follows from the definition of PD_N that we get the desired equality. ⊞

[1608] In fact the annulus $[0,1] \times S^1$ also works as an example, but it is less fun.
[1609] Note that by Corollary 74.16 we know that the induced map $f_*\colon \mathrm{H}_{2n}(M,\partial M;\mathbb{Z}) \to \mathrm{H}_{2n}(N,\partial N;\mathbb{Z})$ is an isomorphism. By the Fundamental Class-Corollary 106.4 the fundamental classes are generators of the homology groups. Thus one of the two cases has to occur.
[1610] The proof is perhaps slightly longer than one might expect. In a sense the statement of the lemma is basically trivial, but we have to pay a price for using the slightly awkward Poincaré Duality isomorphism $\mathrm{PD}_M\colon \mathrm{H}_n(M;\mathbb{Z}) \to \mathrm{H}^{2n-n}(M,\partial M;\mathbb{Z})$.

Now let $a, b \in \mathrm{FH}_n(M;\mathbb{Z})$. Then

$$\begin{array}{lll} & \overset{\text{by definition of } Q_N}{\downarrow} & \overset{\text{by the claim}}{\downarrow} \\ Q_N(f_*(a), f_*(b)) & = \langle \mathrm{PD}_N(f_*(a)) \cup \mathrm{PD}_N(f_*(b)), [N]\rangle & = \\ & = \langle \varepsilon \cdot (f^{-1})^*(\mathrm{PD}_M(a)) \cup \varepsilon \cdot (f^{-1})^*(\mathrm{PD}_M(b)), \varepsilon \cdot f_*([M])\rangle & \\ & = \varepsilon \cdot \langle (f^{-1})^*(\mathrm{PD}_M(a) \cup \mathrm{PD}_M(b)), f_*([M])\rangle & = \varepsilon \cdot Q_M(a,b). \\ & \uparrow & \uparrow \\ & \text{by Proposition 115.4 (1) and since } \varepsilon^3 = \varepsilon & \text{by Lemma 109.6 (3) and the definition of } Q_M \end{array}$$

The lemma now follows from the observation that it follows from the hypothesis that f is a homotopy equivalence together with the Homotopy Equivalence-H_*-Corollary 73.9 that $f_*\colon \mathrm{FH}_n(M;\mathbb{Z}) \to \mathrm{FH}_n(N;\mathbb{Z})$ is an isomorphism. ■

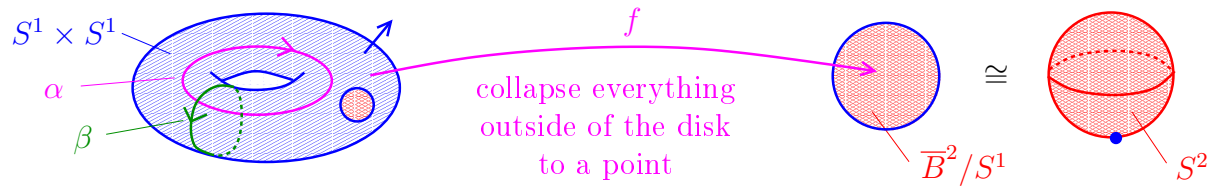
132.4. **The intersection form and degree-one maps.** As we remarked on page 2880, the intersection form of a compact oriented $2n$-dimensional topological manifold contains basically the same information as the cup product pairing

$$\begin{array}{rcl} \mathrm{H}^n(M, \partial M;\mathbb{Z}) \times \mathrm{H}^n(M, \partial M;\mathbb{Z}) & \to & \mathrm{H}^{2n}(M, \partial M;\mathbb{Z}) \\ (\alpha, \beta) & \mapsto & \alpha \cup \beta. \end{array}$$

Given a map $f\colon X \to Y$ between topological spaces it follows from the Cup Product-Naturality Lemma 114.10 that the cup product behaves well under the induced maps f^* on cohomology groups. It stands to reason that the intersection form should also behave well with respect to induced maps on homology.

So suppose we are given a degree-one map $f\colon X \to Y$ between closed oriented connected $2n$-dimensional topological manifolds. By the aforementioned the Cup Product-Naturality Lemma 114.10 we know that for any $\alpha \in \mathrm{FH}^i(Y;\mathbb{Z})$ and $\beta \in \mathrm{FH}^j(Y;\mathbb{Z})$ we have $f^*\alpha \cup f^*\beta = f^*(\alpha \cup \beta)$. It seems reasonable to expect that given $\alpha \in \mathrm{H}_n(X;\mathbb{Z})$ and $\beta \in \mathrm{H}_n(X;\mathbb{Z})$ the following equality holds:

$$(*) \qquad Q_X(\alpha, \beta) \;=\; Q_Y(f_*(\alpha), f_*(\beta)).$$



In fact here is a diagram that looks awfully relevant:

$$\begin{array}{ccccccc} \mathrm{H}_n(X;\mathbb{Z}) \times \mathrm{H}_n(X;\mathbb{Z}) & \xrightarrow[\cong]{\mathrm{PD}\times\mathrm{PD}} & \mathrm{H}^n(X;\mathbb{Z}) \times \mathrm{H}^n(X;\mathbb{Z}) & \xrightarrow{\cup} & \mathrm{H}^{2n}(X;\mathbb{Z}) & \xrightarrow{\langle -,[X]\rangle} & \mathbb{Z} \\ \downarrow{\scriptstyle f_*\times f_*} & & {\scriptstyle f^*\times f^*}\uparrow & & {\scriptstyle f^*}\uparrow{\scriptstyle \cong} & & \mathrm{id}\downarrow \\ \mathrm{H}_n(Y;\mathbb{Z}) \times \mathrm{H}_n(Y;\mathbb{Z}) & \xrightarrow[\cong]{\mathrm{PD}\times\mathrm{PD}} & \mathrm{H}^n(Y;\mathbb{Z}) \times \mathrm{H}^n(Y;\mathbb{Z}) & \xrightarrow{\cup} & \mathrm{H}^{2n}(Y;\mathbb{Z}) & \xrightarrow{\langle -,[Y]\rangle} & \mathbb{Z}. \end{array}$$

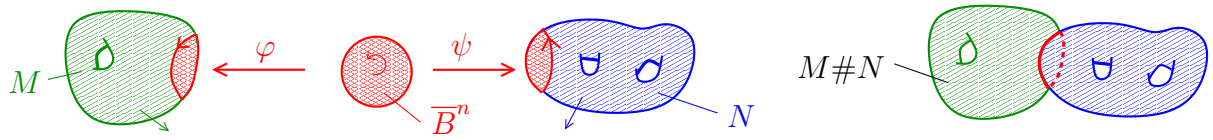
If this diagram did commute, then $(*)$ would hold. One could now waste a lot of time trying to convince oneself that the diagram commutes. Or alternatively one might notice, as we do in the following example, that $(*)$ just does not hold in general.

Example. We consider the map $f\colon S^1 \times S^1 \to S^2$ that is illustrated in the figure below. It follows easily from Lemma 107.3 that this is a degree-one map. We consider the two homology classes α and β on the torus that are sketched in the figure below. Note that it follows easily from the Intersection Number-via-Cup Product Theorem 126.5 that $Q_{S^1\times S^1}(\alpha, \beta) = +1$. On the other hand note that we have $f_*(\alpha) = f_*(\beta) = 0 \in \mathrm{H}_1(S^2;\mathbb{Z})$, which evidently implies that $Q_{S^2}(f_*(\alpha), f_*(\beta)) = 0$. Thus in this case the equality $(*)$ does not hold.[1611]

[1611] This still begs the question, in the above diagram, which of the squares does not commute?

Remark. With this discussion we also learned an interesting lesson:

Not every diagram commutes, not even up to sign.



132.5. **The connected sum of topological manifolds.** To get more examples of interesting intersection forms we want to study the intersection forms of the connected sum of smooth and topological manifolds. Recall that on page **??** we introduced the connected sum of two *smooth* manifolds. In this section we will now also define the connected sum of topological manifolds. The reader who is not that interested in topological manifolds can safely move on to the next section.

For those who are staying, let us recall the definition of the connected sum of two *oriented* smooth manifolds.

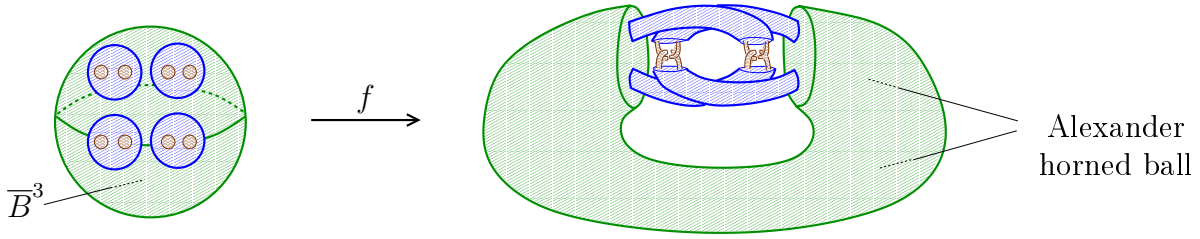
Definition. Let $n \in \mathbb{N}$ and let M and N be two connected oriented non-empty n-dimensional smooth manifolds. Furthermore let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\psi\colon \overline{B}^n \to N \setminus \partial N$ be smooth embeddings such that φ is orientation-preserving and such that ψ is orientation-reversing. We define the connected sum of the oriented smooth manifolds M and N as

$$M\#N := \big(M \setminus \varphi(B^n)\big) \sqcup \big(N \setminus \psi(B^n)\big)/\!\sim \text{ where } \varphi(P) \sim \psi(P) \text{ for all } P \in S^{n-1}.$$

In the Connected Sum-Proposition **??** we showed that the connected sum of two oriented smooth manifolds is again a smooth manifold.

Now we intend to generalize this notion to the setting of topological manifolds. The idea is to suitably adapt the concepts used in the above definition. Browsing through earlier chapters we see the following:

(1) On page 152 we defined an embedding to be a map $f\colon X \to Y$ between two topological spaces that is a homeomorphism onto its image.
(2) On page 2335 we introduced the notion of an orientation of a topological manifold and of an orientation-preserving map.



So are we done? Can we just copy-paste the above definition?

As we had just mentioned, in the Connected Sum-Proposition **??** we showed that the connected sum of two oriented smooth manifolds is again a smooth manifold. Recall that the proof of the Connected Sum-Proposition **??** relied heavily on the Smooth Embedding Theorem 24.10 which says that the image of a smooth embedding $f\colon X \to Y \setminus \partial Y$ is a smooth submanifold of the smooth manifold Y.

The question arises, whether the analogous statement holds for topological manifolds. In other words, we have the following question.

Question 132.7. Let X be an n-dimensional topological manifold. Is the image of an embedding $f\colon \overline{B}^n \to X \setminus \partial X$ necessarily a topological submanifold of X?

For better or worse the answer to Question 132.7 is no.[1612] Namely consider the embedding $f\colon \overline{B}^3 \to \mathbb{R}^3$ that is illustrated in the figure below. We refer to the image $f(\overline{B}^3)$ as the *Alexander horned ball*.[1613] It is clear that this is a weird embedding. We leave it to the reader to make the embedding precise and to show that $f(\overline{B}^3)$ is not a topological submanifold of $\mathbb{R}^3$. But even without filling in all details this map should shatter the reader's confidence that Question 132.7 has a positive answer.

This stupefying example leads us to the following definition.

Definition. Let X and Y be topological manifolds. We say an embedding $f\colon X \to Y$ is locally flat if $f(X)$ is a submanifold of Y.

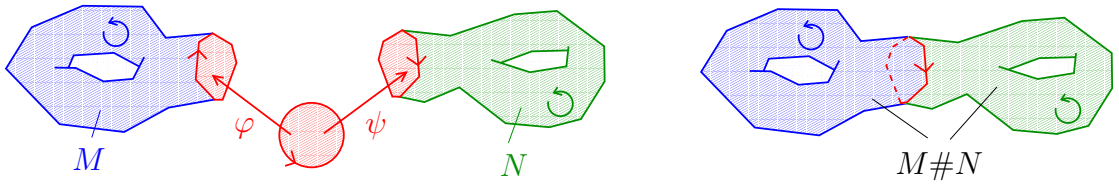
Remark. Let X and Y be a smooth manifolds. It follows from the Smooth Embedding Theorem 24.10 that every smooth embedding $X \to Y$ is actually a locally flat embedding.

With this definition we can now finally give a reasonable definition of the connected sum of two *topological* manifolds. For completeness' sake we now also define the connected sum if one or both topological manifolds involved are non-orientable.

Definition. Let $n \in \mathbb{N}$. Let M and N be two connected non-empty n-dimensional topological manifolds.

(1) Suppose that at least one of M or N is non-orientable. We pick two locally flat embeddings $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\psi\colon \overline{B}^n \to N \setminus \partial N$ and we define the connected sum of M and N as

$$M\#N := \big(M \setminus \varphi(B^n)\big) \sqcup \big(N \setminus \psi(B^n)\big)/\!\sim \text{ where } \varphi(P) \sim \psi(P) \text{ for all } P \in S^{n-1}.$$



(2) If both M and N are orientable, then we pick orientations for M and N. Let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\psi\colon \overline{B}^n \to N \setminus \partial N$ be locally flat embeddings such that φ is orientation-preserving and such that ψ is orientation-reversing. As before we define the connected sum of the oriented topological manifolds M and N as

$$M\#N := \big(M \setminus \varphi(B^n)\big) \sqcup \big(N \setminus \psi(B^n)\big)/\!\sim \text{ where } \varphi(P) \sim \psi(P) \text{ for all } P \in S^{n-1}.$$

[1612] That is not really a surprise, on page 659 we already saw wild knots in $\mathbb{R}^3$ and on page 1814 we saw the Alexander horned sphere. Both give examples of embeddings of topological manifolds such that the image is not a submanifold.

[1613] On page 1814 we referred to $f(S^2)$ as the Alexander horned sphere.

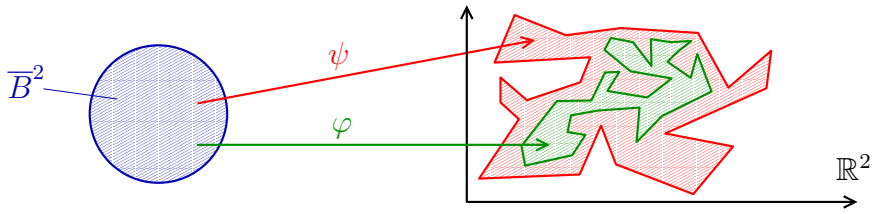
We refer to the figure below for an illustration. For completeness we define the connected sum of an empty manifold with another connected topological manifold M to be M, i.e. we set $\varnothing \# M := M \# \varnothing := M$.

The following proposition is the analogue of the Connected Sum-Proposition **??** that we formulated in the context of smooth manifolds.

Proposition 132.8. (Connected Sum-Proposition) Let $n \in \mathbb{N}$. Let M and N be two connected n-dimensional topological manifolds. (If both M and N are orientable, then we demand that M and N are oriented.) Let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\psi\colon \overline{B}^n \to N \setminus \partial N$ be two locally flat embeddings. (If M and N are orientable, then we demand that φ is orientation-preserving and that ψ is orientation-reversing.) The following five statements hold:

(1) The resulting connected sum $M \# N$ is an n-dimensional topological manifold such that $M \setminus \varphi(B^n)$ and $N \setminus \psi(B^n)$ are submanifolds.
(2) If M and N are closed, then $M \# N$ is also a closed topological manifold.
(3) If $n \geq 2$ or if at least one of M or N is closed, then $M \# N$ is also connected.
(4) The homeomorphism type of $M \# N$ does not depend on the choice of φ and ψ.
(5) If M and N are both oriented, then the topological manifold $M \# N$ admits a unique orientation that coincides with the orientations of the submanifolds $M \setminus \varphi(B^n)$ and $N \setminus \psi(B^n)$.

Convention. We always equip the connected sum of two oriented connected n-dimensional topological manifolds with the orientation from the Connected Sum-Proposition 132.8 (5).



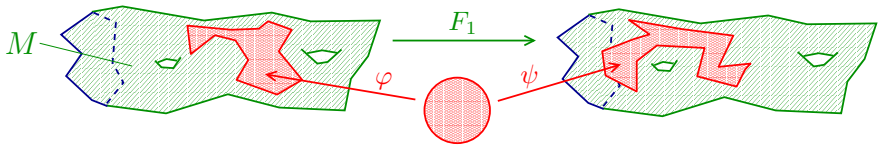
Most of the statements of the Connected Sum-Proposition 132.8 are easy to prove.

Proof of the Connected Sum-Proposition 132.8 (1), (2), (3) and (5). The proof is basically identical to the proofs of the corresponding statements in the smooth setting that we proved in the Connected Sum-Proposition **??**. There are just a few minor modifications that we need to make:

(1) We used the Codimension-Zero Smooth Embedding Proposition 24.16 to show that the image of a smooth embedding is a submanifold. This feature is now built into the definition of a locally flat embedding.
(2) We need to replace Propositions 24.16 and **??** by Propositions 75.3 and 75.8. ■

The fact that the connected sum operation does not really depend on the choice of the locally flat topological embeddings is much more difficult to prove. The key to doing so is the following difficult theorem.

Theorem 132.9. (Annulus Theorem) Let $n \in \mathbb{N}$ and let $\varphi, \psi\colon \overline{B}^n \to \mathbb{R}^n$ be two locally flat embeddings. If $\varphi(\overline{B}^n) \subset \psi(B^n)$, then $\psi(\overline{B}^n) \setminus \varphi(B^n)$ is homeomorphic to $[0,1] \times S^{n-1}$.



Proof. The case $n = 1$ is trivial. For $n = 2$ and $n = 3$ the Annulus Theorem follows from the work of Tibor Radó [**Rad1926**] and Edwin Moise [**Moi1952, Moi1977**]. The Annulus Theorem was proved for dimensions $n \geq 5$ by Rob Kirby [**Kir1969**] and in dimension 4 by Frank Quinn [**Qu1982**, p. 506]. We also refer to [**Edw1984**, p. 247] for more information. ■

Using the Annulus Theorem 132.9 one can now prove the following theorem which can be viewed as the topological analogue of the Smooth Ball Embedding Theorem 37.8.

Theorem 132.10. (Topological Ball Embedding Theorem) Let M be an n-dimensional topological manifold. (If M is orientable, then we pick an orientation for M.) In the following let $\varphi_1, \dots, \varphi_m \colon \overline{B}^n \to M \setminus \partial M$ and $\psi_1, \dots, \psi_m \colon \overline{B}^n \to M \setminus \partial M$ be two sets of m locally flat embeddings of $\overline{B}^n$ with disjoint images. (If M is orientable, then we demand that all φ_i and ψ_i are orientation-preserving or that all are orientation-reversing.) If $n \geq 2$ or if $m = 1$, then there exists a homeotopy

$$F \colon M \times [0,1] \;\to\; M$$

rel some neighborhood of ∂M from the identity $F_0 = \mathrm{id}_M$ to a homeomorphism $F_1 \colon M \to M$ such that for each $i \in \{1, \dots, m\}$ we have $F_1 \circ \varphi_i = \psi_i$. (Note that if M is orientable, then the homeomorphism F_1 is in fact orientation-preserving by Exercise 105.3).

Remark. We consider $\overline{B}^3$ as a submanifold of $\mathbb{R}^3$. Since the image of the embedding $\varphi \colon \overline{B}^3 \to \mathbb{R}^3$ that is given by the Alexander horned ball is not a submanifold of the topological manifold we see that there is no homeotopy $F \colon \mathbb{R}^3 \times [0,1] \to \mathbb{R}^3$ with $F_1 \circ \varphi = \mathrm{id}$. In particular we see that in the formulation of Theorem 132.10 we cannot drop the hypothesis that the embeddings are locally flat.

Proof of Theorem 132.10. This theorem follows from the Annulus Theorem 132.9 together with reasonably elementary arguments. The details are worked out in [**FNOP2019**, Proof of Theorem 5.11]. Alternatively the reader is encouraged to assemble the argument by using the obvious analogues Exercise 49.7 and Exercise **??**, which were both formulated in the setting of smooth manifolds, in the setting of topological manifolds. ■

Proof of the Connected Sum-Proposition 132.8 (4). Thanks to our preparations the proof is basically identical to the proof of the corresponding statement in the smooth setting that we proved in the Connected Sum-Proposition **??**. All we need to is to replace the Smooth Ball Embedding Theorem 37.8 by Theorem 132.10. ■

132.6. **The intersection form and the connected sum operation.** First let use see how the homology groups and fundamental groups behave under the connected sum operation.

Proposition 132.11. (Connected Sum-Invariants Proposition) Let $n \in \mathbb{N}$ and let M and N be two closed oriented connected n-dimensional topological manifolds. Furthermore let $\varphi\colon \overline{B}^n \to M$ be an orientation-preserving locally flat embedding and let $\psi\colon \overline{B}^n \to N$ be an orientation-reversing locally flat embedding. Then $\mathrm{H}_0(M\#N;R) \cong \mathrm{H}_n(M\#N;R) \cong R$. Furthermore, for any $i \neq 0, n$ and any commutative ring R the following inclusion induced maps are isomorphisms

$$\mathrm{H}_i(M\#N;R) \xleftarrow{\cong} \mathrm{H}_i(M\backslash\varphi(B^n);R) \oplus \mathrm{H}_i(N\backslash\psi(B^n);R) \xrightarrow{\cong} \mathrm{H}_i(M;R) \oplus \mathrm{H}_i(N;R).$$

Furthermore if $n \geq 3$, then the following inclusion induced maps are isomorphisms

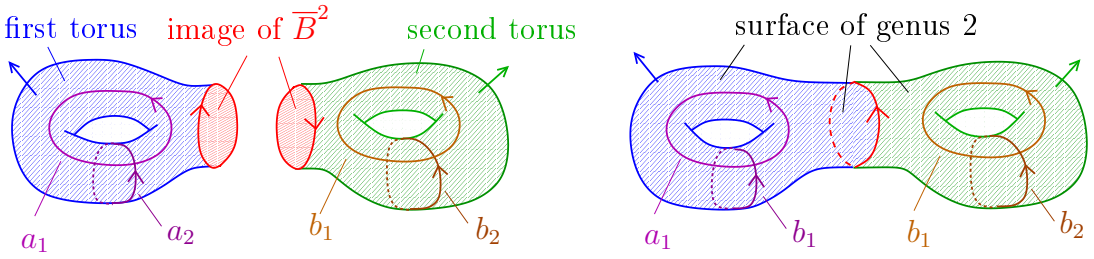
$$\pi_1(M\#N) \xleftarrow{\cong} \pi_1(M \setminus \varphi(B^n)) \ * \ \pi_1(N \setminus \psi(B^n)) \xrightarrow{\cong} \pi_1(M) * \pi_1(N).$$

Proof. We proved the statements in the Connected Sum-π_1-Proposition 52.12 and the Connected Sum-H_*-Proposition 100.13 for smooth manifolds. The proof for topological manifolds is very similar, we just need to note that it follows from by the Excisive Triad-Proposition 109.12 (5) and the Mayer–Vietoris Theorem 109.14 that the Mayer–Vietoris argument in the proof of Lemma 100.14 works for topological manifolds. ■

The next proposition says that the isomorphism of homology groups from the Connected Sum-Invariants Proposition 132.11 induces an isometry of intersection forms.

Proposition 132.12. (Intersection Form-Additivity Proposition) Let $n \geq 1$ and let M and N be compact oriented $2n$-dimensional topological manifolds. Furthermore let $\varphi\colon \overline{B}^n \to M$ be an orientation-preserving locally flat embedding and let $\psi\colon \overline{B}^n \to N$ be an orientation-reversing locally flat embedding. The isomorphism $\mathrm{H}_n(M\#N;\mathbb{Z}) \xrightarrow{\cong} \mathrm{H}_n(M;\mathbb{Z}) \oplus \mathrm{H}_n(N;\mathbb{Z})$ from the Connected Sum-Invariants Proposition 132.11 induces an isometry

$$Q_{M\#N} \xrightarrow{\cong} Q_M \oplus Q_N$$



of forms.

Example. We consider the surface Σ of genus two. In the figure below we recall that we can view Σ as the connected sum of two tori. It thus follows from the Intersection Form-Additivity Proposition 132.12, the discussion on page 2881 and Lemma 132.2 (2) that the intersection form on $\mathrm{H}_1(\Sigma;\mathbb{Z}) \cong \mathbb{Z}^4$ is represented by the matrix

$$\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \oplus \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}.$$

Not surprisingly this recovers the result from page 2881.

Remark. Let $n \geq 1$ and let M and N be closed oriented $2n$-dimensional topological manifolds. Furthermore let $\varphi\colon \overline{B}^n \to M$ be an orientation-preserving locally flat embedding and

let $\psi\colon \overline{B}^n \to N$ be an orientation-reversing locally flat embedding. the figure above suggests the following approach to proving the Intersection Form-Additivity Proposition 132.12:

(1) First we pick n-dimensional cycles $a_1, \dots, a_k$ in $M \setminus \varphi(\overline{B}^{2n})$ such that $[a_1], \dots, [a_k]$ form a basis of $\mathrm{FH}_n(M;\mathbb{Z})$ and which intersect nicely, in the sense of the definition on page 2785.

(2) Similarly we pick transverse n-dimensional cycles $b_1, \dots, b_l$ in $N \setminus \psi(\overline{B}^{2n})$ such that $[b_1], \dots, [b_l]$ form a basis of $\mathrm{FH}_n(N;\mathbb{Z})$ and which intersect nicely.

(3) It follows immediately from the Connected Sum-Invariants Proposition 132.11 that $[a_1], \dots, [a_k], [b_1], \dots, [b_l]$ form a basis for $\mathrm{FH}_n(M\#N;\mathbb{Z})$.

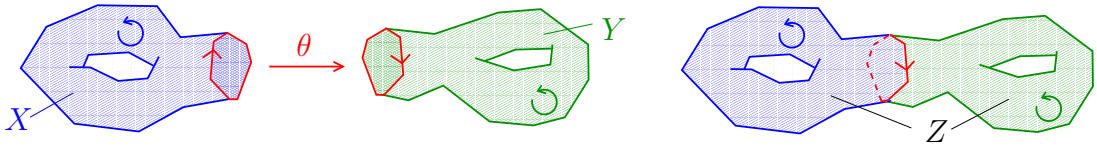
(4) In Theorem 127.9 we saw that the intersection form of cycles that intersect nicely in terms of the algebraic intersection number that we introduced on page 2785. We use this fact together with the basis from (3) to determine the intersection form of $M\#N$. Here we make the following observations:
   (a) By the orientation conventions from the Connected Sum-Proposition 132.8 (3) the algebraic intersection numbers of the a_i in M are the same as in $M\#N$.
   (b) Similarly the algebraic intersection numbers of the b_i in N are the same as in $M\#N$,
   (c) Since the a_i do not intersect the b_j we see that the algebraic intersection number $a_i \cdot b_j = 0$ for any i, j.

   Summarizing we obtain immediately from Theorem 127.9 that $Q_M \oplus Q_N \cong Q_{M\#N}$.

The above argument sounds very convincing. But there is a major catch: how can we find such $a_1, \dots, a_k$ and $b_1, \dots, b_l$? The problem is not that we need to avoid $\varphi(\overline{B}^{2n})$ and $\psi(\overline{B}^{2n})$.[1614] The problem is to find such cycles that are transverse. Even though we have some tools, e.g. we have Theorem **??** and the Transversality Theorem 42.4, it is very hard to turn the above approach into a rigorous proof. Furthermore, any attempt to make this approach work would inevitably end up with an unreadable mess.

After the discussion in the previous remark we recall the advice from Rob Kirby [**Kir1989**, p. 21], see page 2753:

> "Think with [algebraic] intersection [numbers], prove with cup products."



Thus we will use cup products to prove the Intersection Form-Additivity Proposition 132.12.

Proof of the Intersection Form-Additivity Proposition 132.12. Throughout the proof let $n \geq 1$. In the following we consider the case that the topological manifolds M and N

[1614] Why is this not a problem?

are closed. We leave it to the reader to make the slight adjustments needed to deal with the case that M and N are compact with possibly non-empty boundary.

We start out with a lengthy preparation. Thus let X and Y be two oriented connected $2n$-dimensional topological manifolds such that ∂X and ∂Y are both homeomorphic to S^{2n-1}. We equip ∂X and ∂Y with the orientation coming from the Topological Manifold-Boundary Orientation Proposition 105.19. Let $\theta\colon \partial X \to \partial Y$ be an orientation-reversing homeomorphism. We write $Z = X \cup_\theta Y$. In the following we view X and Y as subsets of Z. By the Gluing-Topological Manifolds-Proposition 75.8 we know that X and Y are in fact codimension-zero submanifolds of Z and that we can equip Z with an orientation such that the induced orientations on X and Y are the given orientations.

Claim. The inclusions $i\colon X \to Z$ and $j\colon Y \to Z$ induce an isometry

$$Q_X \oplus Q_Y \xrightarrow{\cong} Q_Z.$$

Proof. As in the Intersection Form-Additivity Proposition 132.12 we see that the two inclusion maps i and j induce an isomorphism $\mathrm{H}_n(X;\mathbb{Z}) \oplus \mathrm{H}_n(Y;\mathbb{Z}) \to \mathrm{H}_n(Z;\mathbb{Z})$. Evidently this isomorphism descends to an isomorphism $\mathrm{FH}_n(X;\mathbb{Z}) \oplus \mathrm{FH}_n(Y;\mathbb{Z}) \to \mathrm{FH}_n(Z;\mathbb{Z})$. Therefore it suffices to prove the following three statements.

(1) for $a, b \in \mathrm{FH}_n(X;\mathbb{Z})$ we have $Q_X(a,b) = Q_Z(i_*(a), i_*(b))$,
(2) for $a, b \in \mathrm{FH}_n(Y;\mathbb{Z})$ we have $Q_Y(a,b) = Q_Z(j_*(a), j_*(b))$,
(3) for $a \in \mathrm{FH}_n(X;\mathbb{Z})$ and $b \in \mathrm{FH}_n(Y;\mathbb{Z})$ we have $Q_Z(i_*(a), j_*(b)) = 0$.

We start out with the proof of the first statement. Thus let $a, b \in \mathrm{FH}_n(X;\mathbb{Z})$. We write $\mathring{X} = X \setminus \partial X$. We denote by $p\colon (Z, \varnothing) \to (Z, Z \setminus \mathring{X})$ and $i\colon (X, \partial X) \to (Z, Z \setminus \mathring{X})$ the two obvious inclusion maps of pairs of topological spaces. It is a consequence of the Excision Theorem 74.18 for Topological Manifolds that $i_*\colon \mathrm{FH}_k(X, \partial X;\mathbb{Z}) \to \mathrm{FH}_k(Z, Z \setminus \mathring{X};\mathbb{Z})$ is an isomorphism for every $k \in \mathbb{N}_0$. Then

$$\begin{aligned} Q_X(a,b) &\underset{\uparrow}{=} \langle \mathrm{PD}_X(a) \cup \mathrm{PD}_X(b), [X] \rangle \\ &\quad \text{by definition of } Q_X \\ &\underset{\uparrow}{=} \big\langle (i^*)^{-1}(\mathrm{PD}_X(a)) \cup (i^*)^{-1}(\mathrm{PD}_X(b)), i_*([X]) \big\rangle \\ &\quad \text{Lemma 109.6 (3) applied to } i\colon (X,\partial X) \to (Z, Z \setminus \mathring{X}), \\ &\quad \text{together with the Cup Product-Naturality Proposition 115.4 (1)} \\ &\underset{\uparrow}{=} \big\langle p^*((i^*)^{-1}(\mathrm{PD}_X(a))) \cup p^*((i^*)^{-1}(\mathrm{PD}_X(b))), [Z] \big\rangle \\ &\quad \text{first note that by the Codimension Zero-Fundamental Class Lemma 106.24 we have, } i_*([X]) = p_*([Z]), \text{ next} \\ &\quad \text{apply Lemma 109.6 (3) to } p, \text{ finally apply the Cup Product-Naturality Proposition 115.4 (1) to } p \\ &\underset{\uparrow}{=} \big\langle \mathrm{PD}_Z(i_*(a)) \cup \mathrm{PD}_Z(i_*(b)), [Z] \big\rangle \underset{\uparrow}{=} Q_Z(i_*(a), i_*(b)). \\ &\quad \text{by the Codimension-Zero Submanifold-PD} \quad \text{definition of } Q_Z \\ &\quad \text{Lemma 120.5 we know} \\ &\quad \text{that } p^*(i^*)^{-1}(\mathrm{PD}_X(c)) = \mathrm{PD}_Z(i_*(c)) \end{aligned}$$

The second statement is of course proved the same way. We turn to the proof of the third statement. So let $a \in \mathrm{FH}_n(X;\mathbb{Z})$ and $b \in \mathrm{FH}_n(Y;\mathbb{Z})$. The above argument shows that we can compute $Q_Z(i_*(a), j_*(b))$ in terms of the cup product in Z of an element in the image

$\mathrm{H}^n(Z, Z \setminus \mathring{X}) \to \mathrm{H}^n(Z)$ and an element in the image of $\mathrm{H}^n(Z, Z \setminus \mathring{Y}; \mathbb{Z}) \to \mathrm{H}^n(Z; \mathbb{Z})$. But $(Z \setminus \mathring{X}) \cup (Z \setminus \mathring{Y}) = Z$. So it follows from the Cup Product-Naturality Proposition 115.4 (1) that this cup product is zero. ⊞

After these preparations it is very easy to prove the actual statement of the proposition. Thus let M and N be closed oriented $2n$-dimensional topological manifolds and let $\varphi\colon \overline{B}^{2n} \to M$ be an orientation-preserving locally flat embedding and let $\psi\colon \overline{B}^{2n} \to N$ be an orientation-reversing locally flat embedding. We write $X = M \setminus \varphi(B^{2n})$ and $Y = N \setminus \psi(B^{2n})$. It follows from the definition of a locally flat embedding together with Proposition 75.3 that X and Y are compact topological manifolds. With this notation we can write $M = X \cup \overline{B}^{2n}$ and $N = Y \cup \overline{B}^{2n}$. It follows from the claim and the fact that $\mathrm{H}_n(\overline{B}^{2n}; \mathbb{Z}) = 0$ that the inclusions induce isometries

$$Q_{M\#N} \xleftarrow{\cong} Q_X \oplus Q_Y \xrightarrow{\cong} Q_M \oplus Q_N.$$

We have thus proved the desired statement. ■

We recall the following question.

Question 100.15. Are the topological spaces $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$, $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ and $S^2 \times S^2$ homeomorphic?

These topological spaces are hard to distinguish since we saw that they are simply connected and that their (co-) homology groups agree. Now we want to look at the intersection forms to see whether they can help us in distinguishing these three smooth manifolds.

Example. On page 2882 we saw that the intersection form of $\mathbb{C}\mathrm{P}^2$ is represented by the 1×1–matrix (1) and we saw that the intersection form of $\overline{\mathbb{C}\mathrm{P}}^2$ is represented by the 1×1–matrix (-1). From the Intersection Form-Additivity Proposition 132.12 we thus obtain:

(1) the intersection form of $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$ is represented by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, whereas

(2) the intersection form of $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ is represented by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$.

Finally we recall that on page 2881 we showed that

(3) the intersection form of $S^2 \times S^2$ is represented by the matrix $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

Motivated by Question 100.15 and Lemma 132.6 the following question arises.

Question 132.13. Are the forms over $\mathbb{Z}^2$ represented by the matrices

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

isometric (possibly up to a sign reversal)?

In Chapter 133 we will develop the theory of non-singular forms to answer Question 132.13.

132.7. **The asymmetric intersection pairings.** On page 2883 we saw that the intersection form of a topological manifold with non-empty boundary can be degenerate. In this and the following section we will associate to a compact oriented topological manifold the asymmetric intersection pairings which are non-singular and the reduced intersection form which is at least non-degenerate.

Before we provide the definitions let us recall and introduce a new definition.

Definition. Let R be a commutative ring and let V, W and S be R-modules. Recall that according to the definition on page 2656 we say that an R-bilinear pairing $\langle\ ,\ \rangle\colon V\times W\to R$ is non-singular if the induced maps

$$\begin{array}{ccc} V & \to & \mathrm{Hom}_R(W,S) \\ v & \mapsto & \left(\begin{array}{ccc} W & \to & S \\ w & \mapsto & \langle v,w\rangle \end{array}\right) \end{array} \quad \text{and} \quad \begin{array}{ccc} W & \to & \mathrm{Hom}_R(V,S) \\ w & \mapsto & \left(\begin{array}{ccc} V & \to & S \\ v & \mapsto & \langle v,w\rangle \end{array}\right) \end{array}$$

are isomorphisms. We now say that the R-bilinear pairing is non-degenerate if the above two maps are both monomorphisms. Otherwise we say that the R-bilinear pairing is degenerate.

Example. Let R be a commutative domain and let $A\in \mathrm{M}(n\times n;R)$. Elementary algebra, similar to the proof of the Non-Singularity Lemma 121.1, shows that the form

$$\begin{array}{ccc} R^n\times R^n & \to & R \\ (v,w) & \mapsto & v^TAw \end{array}$$

is non-singular if and only if $\det(A)$ is a unit in R and it is non-singular if and only if $\det(A)$ is non-zero.

For the record let us state the following lemma that follows almost immediately from the definitions.

Lemma 132.14. Let R be a commutative domain. Let V, W and S be R-modules and let

$$\langle\ ,\ \rangle\colon V\times W\to S$$

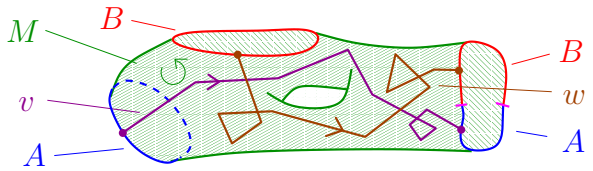
be an R-bilinear pairing. The following two statements are equivalent:

(1) The R-bilinear pairing is non-degenerate.
(2) For every $v\in V$ there exists a $w\in W$ with $\langle v,w\rangle\neq 0$ and for every $w\in W$ there exists a $v\in V$ with $\langle v,w\rangle\neq 0$.

In the Intersection Form Proposition 132.4 we saw that if we are given a *closed* oriented $2n$-dimensional topological manifold M, then the intersection form

$$\begin{array}{rccl} Q_M\colon & \mathrm{FH}_n(M;\mathbb{Z})\times \mathrm{FH}_n(M;\mathbb{Z}) & \to & \mathbb{Z} \\ & (a,b) & \mapsto & \Big\langle \underbrace{\underbrace{\mathrm{PD}_M(a)}_{\in \mathrm{FH}^n(M,\partial M;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(b)}_{\in \mathrm{FH}^n(M,\partial M;\mathbb{Z})}}_{\in \mathrm{FH}^{2n}(M,\partial M;\mathbb{Z})}, [M] \Big\rangle. \end{array}$$

is non-singular. On page 2883 we saw that if M is *not closed*, then this conclusion does not necessarily hold. More precisely we gave an explicit example of a compact orientable smooth manifold, namely the torus minus two open disks, such that the intersection form is degenerate, in particular it is singular.



We move on to the definition of asymmetric intersection pairings on topological manifolds.

Definition. Let M be a compact oriented n-dimensional topological manifold and suppose that we are given two compact $(n-1)$-dimensional submanifolds A and B of ∂M. We suppose that $A\cap B=\partial A=\partial B$. We write $X:=\partial M\setminus \mathring{A}$ and $Y:=\partial M\setminus \mathring{B}$. For each

$k \in \mathbb{N}_0$ we refer to the pairing[1615]

$$\begin{aligned} Q^{\text{as}}_{M,A,B}\colon \operatorname{FH}_k(M,A;\mathbb{Z}) \times \operatorname{FH}_{n-k}(M,B;\mathbb{Z}) &\to \mathbb{Z} \\ (v,w) &\mapsto \Big\langle \underbrace{\underbrace{\operatorname{PD}_M(v)}_{\in \operatorname{H}^{n-k}(M,X;\mathbb{Z})} \cup \underbrace{\operatorname{PD}_M(w)}_{\in \operatorname{H}^{k}(M,Y;\mathbb{Z})}}_{\in \operatorname{H}^{n}(M,\partial M;\mathbb{Z})}, [M] \Big\rangle \end{aligned}$$

as an asymmetric intersection pairing of M. When A and B are clear from the context we write Q^{as}_M instead of the cumbersome $Q^{\text{as}}_{M,A,B}$.

$$Q^{\text{as}}_{M,A,B}(v,w) = +1 - 1 = 0$$

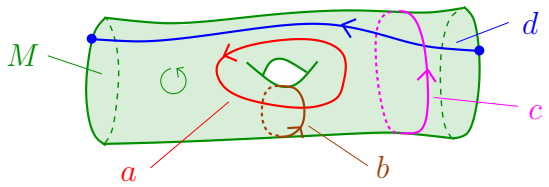
Remark. In the previous definition, if we take $A = B = \varnothing$, then we obtain precisely the intersection form as introduced on page 2800, in other words, $Q^{\text{as}}_{M,\varnothing,\varnothing} = Q_M$.

Example. Let M be the torus minus two open balls. We are interested in the (asymmetric) intersection pairings

$$Q_M\colon \operatorname{H}_1(M;\mathbb{Z}) \times \operatorname{H}_1(M;\mathbb{Z}) \to \mathbb{Z} \quad \text{and} \quad Q^{\text{as}}_{M,\varnothing,\partial M}\colon \operatorname{H}_1(M;\mathbb{Z}) \times \operatorname{H}_1(M,\partial M;\mathbb{Z}).$$

We consider the four curves a, b, c, d on M that are shown in the figure below. Note that the curves a, b, c represent a basis for $\operatorname{H}_1(M;\mathbb{Z})$, whereas the curves a, b, d represent a basis for $\operatorname{H}_1(M,\partial M;\mathbb{Z})$.[1616] Using these bases and using the Intersection Number-via-Cup Product Theorem 126.5 we see that

Q_M is represented by $\begin{array}{c} \\ a \\ b \\ c \end{array}\!\!\begin{array}{c} \begin{array}{ccc} a & b & c \end{array} \\ \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \end{array}$ and $Q^{\text{as}}_{M,\varnothing,\partial M}$ is represented by $\begin{array}{c} \\ a \\ b \\ c \end{array}\!\!\begin{array}{c} \begin{array}{ccc} a & b & d \end{array} \\ \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \end{array}$.



Note that the former matrix has determinant zero whereas the latter matrix has determinant 1. This calculation, together with the Non-Singularity Lemma 121.1 shows that the former pairing is degenerate whereas the latter pairing is non-singular.[1617] As we will see in the next proposition, it is not a coincidence that in this particular example the asymmetric intersection pairing is non-singular.

[1614] In most cases we will have $A \cup B = \partial M$. But the case $A = B = \varnothing$ can also be interesting.

[1615] Note that by Proposition 75.3 we know that X and Y are also compact submanifolds of ∂M with $\partial X = \partial A = A \cap X$ and $\partial Y = \partial B = B \cap Y$. Furthermore note that it follows from $A \cap B = \partial A = \partial B$ that $\partial M = X \cup Y$ and that $\partial M = (X \setminus \partial X) \cup (Y \setminus \partial Y) \cup C$ where each component of C is a component of ∂X and a component of ∂Y. Thus it follows from a slight generalization of the Excisive Triad-Proposition 109.12 (5), see also Exercise 109.5, that (M, X, Y) is an excisive triad. In particular it follows, see the definition on page 2536, that the cup product is actually defined.

[1616] Why is that?

[1617] In fact, using this observation and Exercise 121.2 (c) one can easily answer the previous footnote.

Proposition 132.15. (Asymmetric Intersection Pairing Proposition) Let M be a compact oriented n-dimensional topological manifold. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$.

(1) Given any $k \in \mathbb{N}_0$ the following pairing is non-singular:[1618]

$$Q^{\text{as}}_{M,A,B} \colon \mathrm{FH}_k(M, A; \mathbb{Z}) \times \mathrm{FH}_{n-k}(M, B; \mathbb{Z}) \to \mathbb{Z}.$$

For the remaining two statements of the proposition we assume that $n = 2k$ is even. We denote by $p_* \colon \mathrm{H}_k(M; \mathbb{Z}) \to \mathrm{H}_k(M, \partial M; \mathbb{Z})$ the obvious map.

(2) The following diagram commutes:

$$\begin{array}{ccc} \mathrm{FH}_k(M;\mathbb{Z}) \times \mathrm{FH}_k(M;\mathbb{Z}) & \xrightarrow{Q_M} & \mathbb{Z} \\ \downarrow{\scriptstyle \mathrm{id} \times p_*} & & \downarrow{\scriptstyle \mathrm{id}} \\ \mathrm{FH}_k(M;\mathbb{Z}) \times \mathrm{FH}_k(M, \partial M;\mathbb{Z}) & \xrightarrow{Q^{\text{as}}_{M,\varnothing,\partial M}} & \mathbb{Z}. \end{array}$$

(3) Let $v_1, \ldots, v_m$ be a basis of the free abelian group $\mathrm{FH}_k(M; \mathbb{Z})$. By (1) together with Exercise 121.2 (a) there exists a unique "dual" basis $v_1^*, \ldots, v_m^*$ of the free abelian group $\mathrm{FH}_k(M, \partial M; \mathbb{Z})$ with $Q^{\text{as}}_{M,\varnothing,\partial M}(v_i, v_j^*) = \delta_{ij}$ for all $i, j \in \{1, \ldots, m\}$. With this notation the following diagram commutes:

$$\begin{array}{ccc} \mathrm{FH}_k(M;\mathbb{Z}) & \xrightarrow{p_*} & \mathrm{FH}_k(M, \partial M;\mathbb{Z}) \\ \cong \uparrow{\scriptstyle e_i \mapsto v_i} & & {\scriptstyle e_i \mapsto v_i^*} \uparrow \cong \\ \mathbb{Z}^m & \xrightarrow[\text{matrix } (Q_M(v_i, v_j))_{i,j=1,\ldots,m}]{\text{multiplication by}} & \mathbb{Z}^m. \end{array}$$

Put differently, let $(Q_M(v_i, v_j))_{i,j=1,\ldots,m}$ be the $(m \times m)$–matrix that represents the intersection form Q_M with respect to the basis $v_1, \ldots, v_m$. This matrix represents the map $p_* \colon \mathrm{FH}_k(M; \mathbb{Z}) \to \mathrm{FH}_k(M, \partial M; \mathbb{Z})$ with respect to the bases $v_1, \ldots, v_m$ and $v_1^*, \ldots, v_m^*$.

Proof.

(1) We consider the map

$$\Psi \colon \mathrm{FH}_k(M, A; \mathbb{Z}) \xrightarrow{\mathrm{PD}_M} \mathrm{FH}^{n-k}(M, B; \mathbb{Z}) \xrightarrow{\mathrm{ev}} \mathrm{Hom}(\mathrm{FH}_{n-k}(M, B; \mathbb{Z}), \mathbb{Z}).$$

First note that almost the same argument as in the proof of Lemma 132.5 shows that for every $a \in \mathrm{FH}_k(M, A; \mathbb{Z})$ and every $b \in \mathrm{FH}_{n-k}(M, B; \mathbb{Z})$ we have $Q^{\text{as}}_{M,A,B}(a, b) = \Psi(b)(a)$. Furthermore note that as in the proof of the Intersection Form Proposition 132.4 (3) we see that the two maps PD_M and $\mathrm{ev} \colon \mathrm{FH}^{n-k}(M, B; \mathbb{Z}) \to \mathrm{Hom}(\mathrm{FH}_{n-k}(M, B; \mathbb{Z}), \mathbb{Z})$

[1618] This statement is a generalization of the Intersection Form Proposition 132.4 (3).

are isomorphisms. In particular $\Psi = \mathrm{ev} \circ \mathrm{PD}$ is an isomorphism. Together with the remark on page 2657 this discussion implies that $Q^{\mathrm{as}}_{M,A,B}$ is non-singular.

(2) This statement follows easily from the definitions together with the Cap Product-Naturality Lemma 116.8 and the Cup Product-Naturality Proposition 115.4. In fact we will work out the details in the proof of Lemma 132.16 (2).

(3) Let $i \in \{1, \ldots, m\}$. We write $p_*(v_i) = \sum_{j=1}^{m} b_{ji} \cdot v_j^*$. Let $j \in \{1, \ldots, m\}$. We see that

$$b_{ji} \underset{\substack{\uparrow \\ \text{since } Q^{\mathrm{as}}_{M,\varnothing,\partial M}(v_j, v_k^*) = \delta_{jk}}}{=} Q^{\mathrm{as}}_{M,\varnothing,\partial M}\Big(v_j, \sum_{k=1}^{m} b_{ki} \cdot v_k^*\Big) = Q^{\mathrm{as}}_{M,\varnothing,\partial M}(v_j, p_*(v_i)) \underset{\substack{\uparrow \\ \text{follows from (2)}}}{=} Q_M(v_j, v_i).$$

Since by definition the matrix (b_{ij}) represents the map p_* with respect to the given bases we obtain the desired result. ∎

In the remainder of this section we prove several properties of the asymmetric intersection pairings.

Lemma 132.16. Let M be a compact oriented connected n-dimensional topological manifold and suppose that we are given two compact $(n-1)$-dimensional submanifolds A and B of ∂M with $A \cap B = \partial A = \partial B$. The following two statements hold.

(1) If we are given $v \in \mathrm{H}_k(M, A; \mathbb{Z})$ and $w \in \mathrm{H}_{n-k}(M; \mathbb{Z})$, then

$$Q^{\mathrm{as}}_{M,A,B}(v, w) = (-1)^{k\cdot(n-k)} \cdot Q^{\mathrm{as}}_{M,B,A}(w, v).$$

(2) Suppose we are given two compact $(n-1)$-dimensional submanifolds A' and B' of ∂M that also satisfy (i) or (ii) and that furthermore satisfy $A \subset A'$ and $B \subset B'$. We denote by $p\colon (M, A) \to (M, A')$ and $q\colon (M, B) \to (M, B')$ the obvious maps. For any $v \in \mathrm{H}_k(M, A'; \mathbb{Z})$ and $w \in \mathrm{H}_{n-k}(M, B'; \mathbb{Z})$ we have the following equality:

$$Q^{\mathrm{as}}_{M,A',B'}(p_*(v), q_*(w)) = Q^{\mathrm{as}}_{M,A,B}(v, w).$$

Proof. We write $X = \partial M \setminus \mathring{A}$ and $Y = \partial M \setminus \mathring{B}$.

(1) Given $v \in \mathrm{H}_k(M, A; \mathbb{Z})$ and $w \in \mathrm{H}_{n-k}(M, B; \mathbb{Z})$ we have the following equality:

$$\overbrace{\Big\langle \underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{H}^{n-k}(M,X;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{H}^{k}(M,Y;\mathbb{Z})}, [M] \Big\rangle}^{= Q^{\mathrm{as}}_{M,A,B}(v,w)} \underset{\substack{\uparrow \\ \text{by the Cup Product-Commutativity Proposition 115.3}}}{=} (-1)^{(n-k)\cdot k} \cdot \overbrace{\Big\langle \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{H}^{k}(M,Y;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{H}^{n-k}(M,X;\mathbb{Z})}, [M] \Big\rangle}^{= Q^{\mathrm{as}}_{M,B,A}(w,v)}.$$

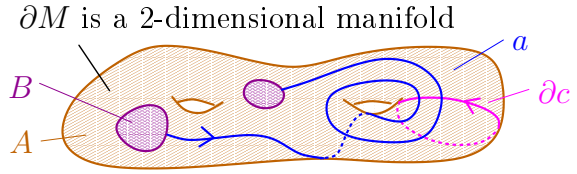
(2) Not surprisingly we write $X' = \partial M \setminus \mathring{A}'$ and $Y' = \partial M \setminus \mathring{B}'$. Note that by hypothesis we have $X' \subset X$ and $Y' \subset Y$. Let $f\colon (M, X') \to (M, X)$ and $g\colon (M, Y') \to (M, Y)$ be the obvious maps. Given $v \in \mathrm{H}_k(M, A'; \mathbb{Z})$ and $w \in \mathrm{H}_{n-k}(M, B'; \mathbb{Z})$ we have the

following equality:

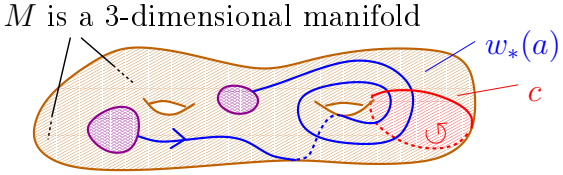
$$\overbrace{\Big\langle \underbrace{\mathrm{PD}_M(p_*(v))}_{\in \mathrm{H}^{n-k}(M,X';\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(q_*(w))}_{\in \mathrm{H}^{k}(M,Y';\mathbb{Z})}, [M] \Big\rangle}^{=Q^{\mathrm{as}}_{M,A',B'}(p_*(v),q_*(w))} \quad \begin{array}{l}\text{follows from the Cap Product-Naturality Lemma 116.8}\\ \downarrow \\ = \Big\langle \underbrace{f^*(\mathrm{PD}_M(v))}_{\in \mathrm{H}^{n-k}(M,X';\mathbb{Z})} \cup \underbrace{g^*(\mathrm{PD}_M(w))}_{\in \mathrm{H}^{k}(M,Y';\mathbb{Z})}, [M] \Big\rangle\end{array}$$

$$\begin{array}{l}\text{Cup Product-Naturality Proposition 115.4}\\ \downarrow \\ = \Big\langle \underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{H}^{n-k}(M,X;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{H}^{k}(M,Y;\mathbb{Z})}, [M] \Big\rangle \end{array} \quad = \quad Q^{\mathrm{as}}_{M,A,B}(v,w).$$

■



Our next result on asymmetric intersection pairing deals with the interplay between the asymmetric intersection pairing on a topological manifold and the asymmetric intersection pairings on its boundary.



Proposition 132.17. (Interaction Pairing-Boundary Proposition) Let M be a compact oriented n-dimensional topological manifold. Suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Let $a \in \mathrm{H}_k(A, \partial A; \mathbb{Z})$ and let $c \in \mathrm{H}_{n-k+1}(M, A; \mathbb{Z})$. We denote by $w\colon (A, \partial A) \to (M, B)$ the obvious map and we denote by $\partial\colon \mathrm{H}_{n-k+1}(M, A; \mathbb{Z}) \to \mathrm{H}_{n-k}(A; \mathbb{Z})$ the connecting homomorphism of the long exact sequence in homology of the pair (M, A). In this setting the following equality holds:

$$Q^{\mathrm{as}}_{A,\varnothing,\partial A}(\partial c, a) \;=\; Q^{\mathrm{as}}_{M,A,B}(c, w_*(a)).$$

In other words, the following diagram commutes in a suitable sense:

$$\begin{array}{ccc} \mathrm{H}_{n-k+1}(M, A; \mathbb{Z}) \times \mathrm{H}_k(M, B; \mathbb{Z}) & & \\ \Big\downarrow \partial \qquad \Big\uparrow w_* & \xrightarrow{\;Q^{\mathrm{as}}_{M,A,B}\;} & \mathbb{Z}. \\ \mathrm{H}_{n-k}(A; \mathbb{Z}) \times \mathrm{H}_k(A, \partial A; \mathbb{Z}) & \xrightarrow[\;Q^{\mathrm{as}}_{A,\varnothing,\partial A}\;]{} & \end{array}$$

In the proof of the Interaction Pairing-Boundary Proposition 132.17 we will need the following generalization of the Cup Product-Connecting Homomorphism Lemma 115.6.

Lemma 132.18. Let (X, A, B) be an excisive triad of topological spaces and let R be a commutative ring. We denote by $i\colon (A, A \cap B) \to (X, B)$ and $j\colon (A, A \cap B) \to (A \cup B, B)$ the inclusion maps and we denote by δ the connecting homomorphisms in the long exact sequence in cohomology corresponding to the pair (X, A) and the triple $(X, A \cup B, B)$. Note that it follows from the Excisive Characterization Lemma 109.13 (b) that $j^*\colon \mathrm{H}^{p+q}(A \cup$

$B, B; R) \to \mathrm{H}^{p+q}(A, A \cap B; R)$ is an isomorphism. The following diagram commutes

$$\begin{array}{ccc}
\mathrm{H}^p(A, A\cap B; R) \times \mathrm{H}^q(A; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(A, A\cap B; R) \\
\uparrow{\scriptstyle i^*} & & \cong\downarrow{\scriptstyle (j^*)^{-1}} \\
 & \downarrow{\scriptstyle \delta} & \mathrm{H}^{p+q}(A\cup B, B; R) \\
 & & \downarrow{\scriptstyle \delta} \\
\mathrm{H}^p(X, B; R) \times \mathrm{H}^{q+1}(X, A; R) & \xrightarrow{\cup} & \mathrm{H}^{p+q+1}(X, A\cup B; R)
\end{array}$$

up to the sign $(-1)^p$. Recall that according to the convention on page 2538 "commutes" means that if we start with an element in $\mathrm{H}^p(X, B; R)$ and an element in $\mathrm{H}^q(A; R)$, then the two routes to $\mathrm{H}^{p+q+1}(X, A \cup B; \mathbb{Z})$ lead to the same element up to multiplication by $(-1)^p$.

Proof of Lemma 132.18. We leave it to the long-suffering reader to go through the slightly painful task of modifying the proof of the Cup Product-Connecting Homomorphism Lemma 115.6 to get the desired result. ■

Proof of the Interaction Pairing-Boundary Proposition 132.17. We consider the following diagram of maps

$$\begin{array}{ccccc}
\mathrm{H}^k(A, \partial A; \mathbb{Z}) \times \mathrm{H}^{n-k}(A; \mathbb{Z}) & \xrightarrow{\cup} & \mathrm{H}^n(A, \partial A; \mathbb{Z}) & \xrightarrow{\langle -, [A]\rangle} & \\
\uparrow{\scriptstyle w^*} & & \cong\downarrow{\scriptstyle (u^*)^{-1}} & & \\
 & \downarrow{\scriptstyle \delta} & \mathrm{H}^n(\partial M, B; \mathbb{Z}) & \xrightarrow{\langle -, p_*([\partial M])\rangle} & \mathbb{Z}. \\
 & & \downarrow{\scriptstyle \delta} & & \\
\mathrm{H}^k(M, B; \mathbb{Z}) \times \mathrm{H}^{n-k+1}(M, A; \mathbb{Z}) & \xrightarrow{\cup} & \mathrm{H}^{n+1}(M, \partial M) & \xrightarrow{\langle -, [M]\rangle} &
\end{array}$$

We make the following clarifications and observations:

(1) By the Excisive Triad-Proposition 109.12 we know that (M, A, B) is an excisive triad.
(2) We denote by $u\colon (A, \partial A) \to (\partial M, B)$ the inclusion map. It follows from (1) and the Excisive Characterization Lemma 109.13 (b) that the map u induces an isomorphism on cohomology groups.
(3) We denote by $\delta\colon \mathrm{H}^n(A; \mathbb{Z}) \to \mathrm{H}^{n+1}(M, A; \mathbb{Z})$ and $\delta\colon \mathrm{H}^n(\partial M, B; \mathbb{Z}) \to \mathrm{H}^{n+1}(M, \partial M; \mathbb{Z})$ the connecting homomorphisms in cohomology of the pair (M, A) and of the triple $(M, \partial M, B)$.
(4) It follows from (1) and Lemma 132.18 that the left part of the diagram commutes up to the sign $(-1)^k$.
(5) We denote by $p\colon (\partial M, \varnothing) \to (\partial M, B)$ the obvious map. By the Codimension Zero-Fundamental Class Lemma 106.24 we have $p_*([\partial M]) = u_*([A]) \in \mathrm{H}_n(\partial M, B; \mathbb{Z})$. Together with Lemma 109.6 (3) it follows that the top right triangle commutes.
(6) Note that by the Fundamental Class-of-Boundary Proposition 106.27 we know that $\partial([M]) = [\partial M] \in \mathrm{H}_n(\partial M; \mathbb{Z})$. Together with the Cap Product-Connecting Homomorphism Lemma 116.10 this implies that the bottom right triangle commutes.

Next we consider the following two diagrams:

$$\begin{array}{ccc} \mathrm{H}_k(M,A;\mathbb{Z}) & \xrightarrow{\partial} & \mathrm{H}_k(A;\mathbb{Z}) \\ {\scriptstyle \mathrm{PD}_M}\downarrow & & \downarrow{\scriptstyle \mathrm{PD}_A} \\ \mathrm{H}^{n-k}(M,B;\mathbb{Z}) & \xrightarrow{w^*} & \mathrm{H}^{n+1-k}(A,\partial A;\mathbb{Z}) \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{H}_k(A,\partial A;\mathbb{Z}) & \xrightarrow{w_*} & \mathrm{H}_k(M,B;\mathbb{Z}) \\ {\scriptstyle \mathrm{PD}_A}\downarrow & & \downarrow{\scriptstyle \mathrm{PD}_M} \\ \mathrm{H}^{n-k}(A;\mathbb{Z}) & \xrightarrow{\delta} & \mathrm{H}^{n-k+1}(M,A;\mathbb{Z}). \end{array}$$

By Proposition 119.26 we know that the diagram to the left commutes up to the factor $(-1)^k$ whereas the diagram to the right commutes as it is. With all these preparations we can now easily carry out the desired calculation:

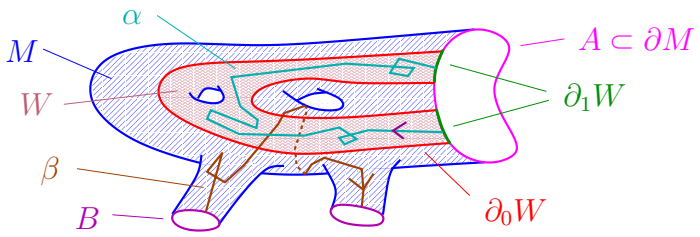
$$\begin{aligned} Q_{A,\varnothing,\partial A}(\partial c, a) &\overset{\text{by definition of } Q_A}{\downarrow} \\ &= \langle \mathrm{PD}_A(\partial c) \cup \mathrm{PD}_A(a), [A] \rangle \\ &= \langle \mathrm{PD}_M(c) \cup \delta(\mathrm{PD}_A(a)), [M] \rangle \\ &\overset{\text{since the first diagram commutes up to multiplication by } (-1)^k}{\uparrow} \\ &= Q^{\mathrm{as}}_{M,A,B}(c, w_*(a)). \end{aligned} \qquad \begin{aligned} &\overset{\text{since the second diagram commutes up to multiplication by } (-1)^k}{\downarrow} \\ &= (-1)^k \cdot \langle w^*(\mathrm{PD}_M(c)) \cup \mathrm{PD}_A(a), [A] \rangle \\ &= \langle \mathrm{PD}_M(c) \cup \mathrm{PD}_M(w_*(a)), [M] \rangle \\ &\overset{\text{since the third diagram commutes}}{\uparrow} \end{aligned}$$

■

The following proposition relates the asymmetric intersection pairing on a topological manifold to the asymmetric intersection pairing on a codimension-zero submanifold.

Proposition 132.19. (Intersection Form-Submanifold Proposition) Let M be a compact oriented m-dimensional topological manifold and let $W \subset M$ be a compact codimension-zero submanifold with corner.[1619] Let A and B be disjoint unions of components of ∂M with $\partial_1 W \subset A$. We denote by $i\colon (W, \partial_1 W) \to (M, A)$, $w\colon (W, \partial_0 W) \to (M, M \setminus \mathring{W})$ and $p\colon (M, B) \to (M, M \setminus \mathring{W})$ the obvious maps. For every $\alpha \in \mathrm{H}_k(W, \partial_1 W)$ and $\beta \in \mathrm{H}_{n-k}(M, B)$ we have the following equality:[1620]

$$Q^{\mathrm{as}}_{W,\partial_1 W,\partial_0 W}(\alpha, (w_*)^{-1}(p_*(\beta))) \;=\; Q^{\mathrm{as}}_{M,A,B}(i_*(\alpha), \beta).$$



In other words, the following diagram commutes in a suitable sense:

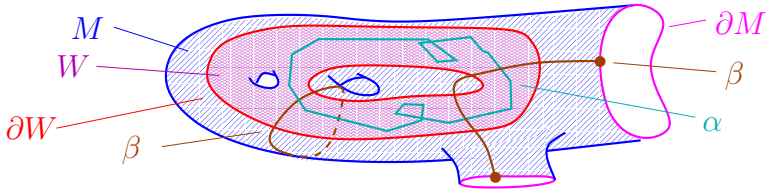
$$\begin{array}{ccc} \mathrm{H}_k(W,\partial_1 W;\mathbb{Z}) \times \mathrm{H}_{n-k}(W,\partial_0 W;\mathbb{Z}) & & \\ \Big\downarrow{\scriptstyle i_*} & {\scriptstyle w_*}\downarrow\cong & \searrow^{Q^{\mathrm{as}}_{W,\partial_1 W,\partial_0 W}} \\ & \mathrm{H}_{n+k}(M, M \setminus \mathring{W};\mathbb{Z}) & \to \mathbb{Z}. \\ & {\scriptstyle p_*}\uparrow & \nearrow_{Q^{\mathrm{as}}_{M,A,B}} \\ \mathrm{H}_k(M,A;\mathbb{Z}) \times \mathrm{H}_{n-k}(M,B;\mathbb{Z}) & & \end{array}$$

The analogous statement also holds with the roles of the first and the second entry swapped.

[1619] We refer to Lemma 120.1 for the definition of $\partial_0 W$ and $\partial_1 W$.

[1620] Here we use that we know by the Excision Theorem 120.2 that the map $w\colon (W, \partial W) \to (M, M \setminus \mathring{W})$ induces an isomorphism on homology groups.

Proof. We perform the following calculation:



$$\begin{aligned}
Q^{\mathrm{as}}_{W,\partial_1 W,\partial_0 W}(\alpha,(w_*)^{-1}(p_*(\beta))) &= \langle \mathrm{PD}_W(\alpha)\cup \mathrm{PD}_W((w_*)^{-1}(p_*(\beta))),[W]\rangle \\
&= \langle w^*((w^*)^{-1}(\mathrm{PD}_W(\alpha))\cup w^*(\mathrm{PD}_M(\beta)),[W]\rangle \underset{\uparrow}{=} \langle (w^*)^{-1}(\mathrm{PD}_W(\alpha))\cup \mathrm{PD}_M(\beta), w_*([W])\rangle \\
&\quad \uparrow \text{ by Lemma 120.6} \qquad\qquad \uparrow \text{ by Lemma 109.6 (3)} \\
&= \langle (w^*)^{-1}(\mathrm{PD}_W(\alpha))\cup \mathrm{PD}_M(\beta), p_*([M])\rangle \underset{\uparrow}{=} \langle p^*((w^*)^{-1}(\mathrm{PD}_W(\alpha)))\cup p^*(\mathrm{PD}_M(\beta)),[M]\rangle \\
&\quad \uparrow \text{ by the Codimension Zero-Fundamental Class Lemma 106.24 we have } w_*([W])=p_*([M]) \qquad \uparrow \text{ Lemma 109.6 (3)} \\
&= \langle \mathrm{PD}_M(i_*(\alpha)),\mathrm{PD}_M(\beta),[M]\rangle \;=\; Q^{\mathrm{as}}_{M,A,B}(i_*(\alpha),\beta). \\
&\quad \uparrow \text{ by the Codimension-Zero Submanifold-PD Lemma 120.5}
\end{aligned}$$

■

The case we will use most often is the special case that $\partial_0 W = \partial W$, $\partial_1 W = \varnothing$, $A = \varnothing$ and $B = \partial M$. In this case Proposition 132.20 specializes to the following slightly more readable proposition.

Proposition 132.20. Let M be a compact oriented m-dimensional topological manifold and let $W \subset M\backslash\partial M$ be a compact m-dimensional submanifold. We denote by $i\colon W \to M$, $w\colon (W,\partial W) \to (M, M\setminus \mathring{W})$ and $p\colon (M,\partial M) \to (M, M\setminus \mathring{W})$ the obvious maps. For every $\alpha \in \mathrm{H}_k(W)$ and $\beta \in \mathrm{H}_{n-k}(M,\partial M)$ we have the following equality:

$$Q^{\mathrm{as}}_{W,\varnothing,\partial W}(\alpha,(w_*)^{-1}(p_*(\beta))) \;=\; Q^{\mathrm{as}}_{M,\varnothing,\partial M}(i_*(\alpha),\beta).$$

132.8. **The reduced intersection form.** After the exhaustive and exhausting discussion of the asymmetric intersection pairings in the previous section, let us now move on to our second variation on the intersection form.

Proposition 132.21. (Reduced Intersection Form Proposition) Let M be a compact oriented $2n$-dimensional topological manifold. We denote by $i\colon \partial M \to M$ the inclusion map.

(1) Let $\alpha \in \mathrm{FH}_n(M;\mathbb{Z})$. The following two statements are equivalent:
   (a) $\alpha \in \mathrm{im}(i_*\colon \mathrm{FH}_n(\partial M;\mathbb{Z}) \to \mathrm{FH}_n(M;\mathbb{Z}))$.
   (b) For every $\beta \in \mathrm{FH}_n(M;\mathbb{Z})$ we have $Q_M(\alpha,\beta) = 0$.

(2) We write $\widehat{\mathrm{H}}_n(M;\mathbb{Z}) := \operatorname{coker}(i_*\colon \mathrm{H}_n(\partial M;\mathbb{Z}) \to \mathrm{H}_n(M;\mathbb{Z}))$. The form

$$\begin{array}{rccc} Q_M^{\mathrm{red}}\colon & \mathrm{F}\widehat{\mathrm{H}}_n(M;\mathbb{Z}) \times \mathrm{F}\widehat{\mathrm{H}}_n(M;\mathbb{Z}) & \to & \mathbb{Z} \\ & ([\varphi],[\psi]) & \mapsto & Q_M(\varphi,\psi) \end{array}$$

is well-defined and non-degenerate. We refer to this form as the reduced intersection form of M.

(3) If the intersection form Q_M is non-degenerate, then the obvious map $\mathrm{FH}_n(M;\mathbb{Z}) \to \mathrm{FH}_n(M;\mathbb{Z})$ is an isomorphism and it induces an isometry $Q_M \to Q_M^{\mathrm{red}}$.

Proof. We denote by $i\colon \partial M \to M$ and $j\colon (M,\varnothing) \to (M,\partial M)$ the obvious maps. Before we do anything else we recall that we have a long exact sequence

$$\ldots \to \mathrm{H}_n(\partial M;\mathbb{Z}) \xrightarrow{i_*} \mathrm{H}_n(M;\mathbb{Z}) \xrightarrow{j_*} \mathrm{H}_n(M,\partial M;\mathbb{Z}) \xrightarrow{\partial} \mathrm{H}_{n-1}(\partial M) \to \ldots$$

Now we turn to the actual proofs of the statements.

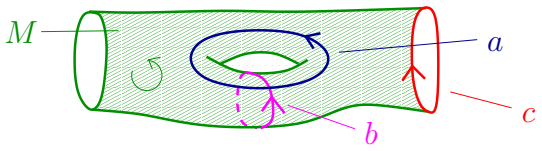
(1) Let $\alpha \in \mathrm{H}_n(M;\mathbb{Z})$. First we prove "(a)⇒(b)". Thus we assume that $\alpha = i_*(\gamma)$ for some $\gamma \in \mathrm{H}_n(\partial M;\mathbb{Z})$. Let $\beta \in \mathrm{H}_n(M;\mathbb{Z})$. We perform the following calculation:

$$\begin{aligned} Q_M(\alpha,\beta) &\underset{\text{by definition of } Q_M}{=} \langle \mathrm{PD}(i_*(\gamma)) \cup \mathrm{PD}(\beta), [M]\rangle \underset{\text{Cup-Cap Lemma 116.7 (3)}}{=} \langle \mathrm{PD}(\beta), j_*(\underbrace{\mathrm{PD}(i_*(\gamma)) \cap [M]}_{= i_*(\gamma) \text{ by definition of PD}})\rangle \\ &= \langle \mathrm{PD}(\beta), j_*(i_*(\gamma))\rangle \underset{\text{since } j_* \circ i_* = 0}{=} 0. \end{aligned}$$

Now we prove "(b)⇒(a)". Thus we assume that $Q_M(\alpha,\beta) = 0$ for all $\beta \in \mathrm{FH}_n(M;\mathbb{Z})$. This implies for any $\beta \in \mathrm{FH}_n(M;\mathbb{Z})$ we have the following equalities:

$$Q^{\mathrm{as}}_{M,\partial M,\varnothing}(j_*(\alpha),\beta) \underset{\substack{\text{by the Asymmetric Intersection} \\ \text{Pairing Proposition 132.15 (2)}}}{=} Q_M(\alpha,\beta\rangle \underset{\text{by assumption}}{=} 0.$$

By the Asymmetric Intersection Pairing Proposition 132.15 (1) we know that the pairing $Q^{\mathrm{as}}_{M,\partial M,\varnothing}$ is non-singular, in particular it is non-degenerate. Thus it follows from the above, together with Lemma 132.14, that $j_*(\alpha) = 0 \in \mathrm{FH}_n(M;\mathbb{Z})$. It follows from the above long exact sequence, together with Exercise 89.2, that $\operatorname{im}(i_*\colon \mathrm{FH}_n(\partial M;\mathbb{Z}) \to \mathrm{FH}_n(M;\mathbb{Z}))$.



(2) It follows immediately from (1) "(a)⇒(b)" that the form Q_M^{red} is well-defined. Furthermore it follows from (1) "(b)⇒(a)" and Lemma 132.14 that Q_M^{red} is non-degenerate.

(3) This statement follows immediately from (1) and Lemma 132.14. ∎

Examples.

(1) One last time we consider again our favorite example M, namely the torus minus two open disks. We use the notation from the figure on page 2903. A basis for $\mathrm{H}_1(M;\mathbb{Z})$ is given by a,b,c and the image of $\mathrm{H}_1(\partial M;\mathbb{Z}) \to \mathrm{H}_1(M;\mathbb{Z})$ is given by $\mathbb{Z}\cdot c$. With respect to these bases we see that

$$Q_M \text{ is represented by } \begin{array}{c} \\ a \\ b \\ c \end{array}\!\!\begin{array}{c} \begin{array}{ccc} a & b & c \end{array} \\ \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \end{array} \text{ and } Q_M^{\mathrm{red}} \text{ is represented by } \begin{array}{c} \\ a \\ b \end{array}\!\!\begin{array}{c} \begin{array}{cc} a & b \end{array} \\ \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \end{array}.$$

(2) In Exercise 132.7 we will provide an example of a compact orientable 4-dimensional smooth manifold M for which the reduced intersection form is not non-singular. We will obtain many more such examples later on in Proposition **??**.

Exercises for Chapter 132.

Exercise 132.1. We equip $\mathrm{H}_1(S^1 \times S^1; \mathbb{Z})$ with the standard basis $\mu = [S^1 \times \{*\}]$ and $\lambda = [\{*\} \times S^1]$. Show that

$$Q_{S^1 \times S^1}(a \cdot \mu + b \cdot \lambda, c \cdot \mu + d \cdot \lambda) \;=\; \det \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

Remark. The exercise is really quite easy, but it does produce a neat formula.

Exercise 132.2. Let M be a compact oriented topological manifold. Recall that we say that M is *amphichiral* if M admits an orientation-reversing self-homeomorphism, otherwise we say that M is *chiral*. For which $k, l \in \mathbb{N}_0$ is the connected sum $k \cdot \mathbb{CP}^2 \# l \cdot \overline{\mathbb{CP}}^2$ chiral? More precisely:

(a) for the values that you exclude, show that $k \cdot \mathbb{CP}^2 \# l \cdot \overline{\mathbb{CP}}^2$ is not chiral,
(b) for all the other values show explicitly that $k \cdot \mathbb{CP}^2 \# l \cdot \overline{\mathbb{CP}}^2$ is chiral.

Exercise 132.3. Let $n \in \mathbb{N}$ and let M and M' be two closed oriented connected non-empty n-dimensional topological manifolds. Let $X \subset M$ and $X' \subset M'$ be submanifolds that are homeomorphic to $\overline{B}^n$ and let $\varphi\colon \partial X \to \partial X'$ be an orientation-reserving homeomorphism. Show that $(M \setminus \mathring{X}) \cup_{\varphi\colon \partial X \to \partial X'} (M \setminus \mathring{X}')$ is homeomorphic to the connected sum $M \# N$.
Hint. Use the Alexander trick from Exercise 5.35.
Remark. Initially it might sound like this statement holds "by definition". But in fact in Exercise **??** we will see that the obvious analogue in the setting of smooth manifolds does *not* hold.

Exercise 132.4. Let R be a field and let $\varphi\colon V \times V \to R$ be a form. The vector subspace $R := \{v \in V \,|\, \varphi(v, w) = 0 \text{ for all } w \in V\}$ is called the *radical* of the form φ.

(a) Show that the map

$$\begin{array}{rcl} \overline{\varphi}\colon V/R \times V/R & \to & R \\ ([v], [w]) & \mapsto & \varphi(v, w) \end{array}$$

is well-defined and non-singular.
(b) Let S be a vector subspace of V with $V = R \oplus S$. Show that $(V/R, \overline{\varphi})$ is isometric to $(S, \varphi|_S)$.
(c) Show that (V, φ) is isometric to $(R, 0) \oplus (V/R, \overline{\varphi})$.

Remark. Recall that by our definition on page 2877 a form (V, φ) is definition symmetric or anti-symmetric and V is a finite-dimensional free module over the ring R.

Exercise 132.5. Let H be a finite-dimensional real vector space and let $\lambda\colon H \times H \to \mathbb{R}$ be a non-singular form. Furthermore let $A_1, A_2 \subset H$ be two vector subspaces with $A_1^\perp = A_2$ and $A_2^\perp = A_1$. Show that $(A_1 \cap A_2)^\perp = A_1 + A_2$.

Exercise 132.6. Let M be a compact oriented 4-dimensional topological manifold and let $i\colon \partial M \to M$ be the inclusion map.

(a) Show that if $i_*\colon \mathrm{H}_1(\partial M;\mathbb{Z}) \to \mathrm{H}_1(M;\mathbb{Z})$ is a monomorphism, then the intersection form Q_M is non-singular.

(b) Show that if $i_*\colon \mathrm{H}_1(\partial M;\mathbb{Q}) \to \mathrm{H}_1(M;\mathbb{Q})$ is a monomorphism, then the intersection form Q_M is non-degenerate.

Exercise 132.7. Let $n \in \mathbb{N}$. We consider the map

$$\begin{array}{rcl} \varphi\colon \overline{B}^2 \times S^1 & \to & \overline{B}^2 \times S^1 \subset \partial(\overline{B}^2 \times \overline{B}^2) \\ (z,w) & \mapsto & (z, w \cdot z^n). \end{array}$$

Furthermore we consider [1621]

$$M := (\overline{B}^2 \times \overline{B}^2) \underset{\substack{\overline{B}^2 \times S^1 \to \partial(\overline{B}^2 \times \overline{B}^2) \\ (z,w) \mapsto \varphi(z,w)}}{} (\overline{B}^2 \times \overline{B}^2).$$

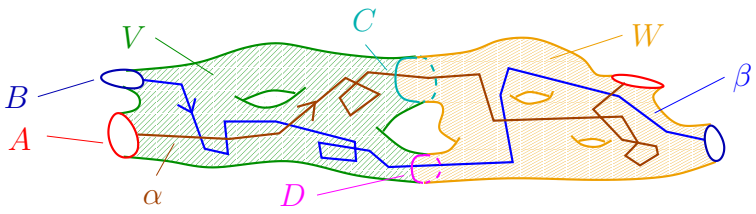
One can show by hand that M is a compact orientable 4-dimensional smooth manifold.[1622]

(a) Show that $\pi_1(M) = 0$, $\mathrm{H}_2(M;\mathbb{Z}) \cong \mathbb{Z}$ and $\mathrm{H}_2(M, \partial M;\mathbb{Z}) \cong \mathbb{Z}$.

(b) Show that $\mathrm{H}_1(\partial M;\mathbb{Z}) \cong \mathbb{Z}_n$ and $\mathrm{H}_2(\partial M;\mathbb{Z}) = 0$. (In fact very well-trained eyes will spot that ∂M is diffeomorphic to the lens space $L(n,1)$.)

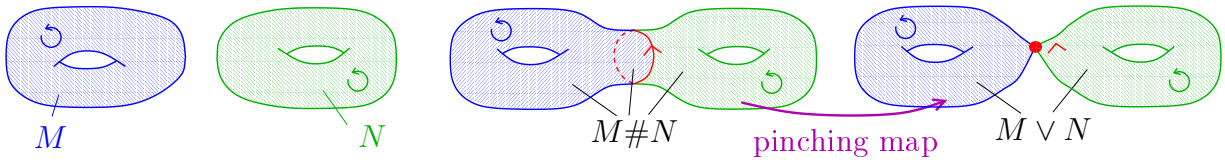
(c) Show that if $n \geq 2$, then the intersection form Q_M is represented by one of the two 1×1-matrices $(-n)$ or (n).
Hint. Use the Asymmetric Intersection Pairing Proposition 132.15 (3).
Remark. Note that it follows from (b) that the intersection form equals the reduced intersection form. Thus we have shown, as promised on page 2903, that there exists a compact orientable 4-dimensional smooth manifold M for which the reduced intersection form is not non-singular.

Exercise 132.8. Let M be a compact oriented n-dimensional topological manifold and let A, B be disjoint unions of components of ∂M. Furthermore let V and W be compact codimension-zero submanifolds of M as in the figure below and let $\alpha \in \mathrm{H}_k(M, A)$ and $\beta \in \mathrm{H}_{n-k}(X, B)$.



(a) Inspired by the figure below state a formula which computes $Q_M(\alpha, \beta)$ in terms of suitable intersection numbers of V and W.
Hint. What is the role of C and D in the figure below?

(b) Prove (a).



Exercise 132.9. Let $n \in \mathbb{N}$ and let M and N be two compact oriented connected non-empty n-dimensional smooth manifolds. In Exercise 100.16 we introduced the pinching map $p\colon M \# N \to M \vee N$ and studied the induced map on homology groups. Use the pinching

[1621] Later on page 2953 we will say that M is obtained from the 4-ball $\overline{B}^2 \times \overline{B}^2$ by attaching a 2-handle.

[1622] We will carry out the details in the Handle Attachment Proposition 136.1, but this is irrelevant for the present exercise.

map and the Wedge-Cup Product Lemma 115.8 to give a new proof of the Intersection Form-Additivity Proposition 132.12 for smooth manifolds. In other words, show that the intersection form $Q_{M\#N}$ is isometric to $Q_M \# Q_N$.

133. The intersection form II: Algebra and some topology

In Chapter 132 we introduced the intersection form of compact oriented even-dimensional topological manifolds. On page 2893 we considered the intersection forms of $S^2 \times S^2$, $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$. At that point it became clear that we have to invest some time to study (anti-) symmetric forms as purely algebraic objects.
We start out with the following lemma that summarizes all the basic facts about the interplay between forms and matrices that we will need in this chapter.

Lemma 133.1. (Forms-Matrices Lemma) Let R be a commutative ring.

(1) Let A be a (anti-) symmetric[1623] $n \times n$–matrix over R. We consider the map

$$\begin{array}{rccc} \varphi(A)\colon & R^n \times R^n & \to & R \\ & (v,w) & \mapsto & v^T A w. \end{array}$$

The following statements hold:
(a) $\varphi(A)$ is an (anti-) symmetric form over R.
(b) The form $\varphi(A)$ is non-singular, in the sense of the definition on page 2878, if and only if A is invertible, i.e. if $\det(A)$ is a unit in R
(c) If $P \in \mathrm{GL}(n,R)$ is an invertible matrix, then the forms $\varphi(P^T A P)$ and $\varphi(A)$ are isometric.
(d) If B is a (anti-) symmetric $n \times n$-matrix over R such that $\varphi(A)$ and $\varphi(B)$ are isometric, then there exists a $P \in \mathrm{GL}(n,R)$ with $B = P^T A P$.

(2) Let (V,ψ) be an (anti-) symmetric form over R of rank n. If A is a matrix that represents ψ, then $(V,\psi) \cong (R^n, \varphi(A))$. In particular every (anti-) symmetric form over R is isometric to $\varphi(A)$ for some (anti-) symmetric $n \times n$–matrix A over R.

Convention. The Forms-Matrices Lemma 133.1 allows us to go back and forth between (anti-) symmetric forms and (anti-) symmetric matrices. Thus in the following discussion we will blur the distinction between these two concepts. For example, given a (anti-) symmetric matrix A over a commutative ring we will often just refer to the (anti-) symmetric form $\varphi(A)$ as the form A.

Proof.

(1) (a) This statement follows almost immediately from the definitions and the observation that for any $v, w \in R^n$ we have

$$\varphi(A)(w,v) \;=\; w^T A v \;\underset{\uparrow}{=}\; (w^T A^T v)^T \;=\; v^T A^T w \;=\; \varphi(A^T)(v,w).$$

for a (1×1)–matrix (x) we have $(x)^T = (x)$

(b) The proof of this statement is an instructive exercise in linear algebra. We will not rob the reader of the joy of doing this exercise.

(c) We claim that the isomorphism $v \mapsto Pv$ defines an isometry from the form $(R^n, \varphi(P^T A P))$ to the form $(R^n, \varphi(A))$. Indeed, for any $v, w \in R^n$ we have

$$\varphi(A)(Pv, Pw) \;=\; (Pv)^T A P w \;=\; v^T (P^T A P) w \;=\; \varphi(P^T A P)(v,w).$$

(d) Let B be a (anti-) symmetric $n \times n$-matrix over R and let $f\colon R^n \to R^n$ be an isometry between $\varphi(A)$ and $\varphi(B)$, i.e. let f be an isomorphism such that for all

[1623] Recall that a matrix A is called *anti-symmetric* if $A^T = -A$.

$v, w \in R^n$ we have $v^T A w = \varphi(A)(v,w) = \varphi(B)(f(v), f(w)) = f(v)^T A f(w)$. Let P be the matrix representing f with respect to the standard basis of R^n. Since f is an isomorphism we know that $P \in \mathrm{GL}(n,R)$. Finally a straightforward calculation shows that $B = P^T A P$.

(2) Let $\psi\colon V \times V \to R$ be an (anti-) symmetric form over R. Let $v_1, \dots, v_n$ be a basis of V. We denote by $A = (\psi(v_i, v_j))_{i,j=1,\dots,n}$ the corresponding matrix representing the form ψ. We consider the isomorphism

$$\begin{array}{rcl} \Theta\colon R^k & \to & V \\ (\lambda_1, \dots, \lambda_n) & \mapsto & \lambda_1 v_1 + \cdots + \lambda_n v_n. \end{array}$$

We claim that Θ is an isometry from the form $(R^n, \varphi(A))$ to the form (V, ψ). Indeed, if we denote by $e_1, \dots, e_n$ the standard basis for R^n, then for any $i, j \in \{1, \dots, n\}$ we have

$$\psi(\Theta(e_i), \Theta(e_j)) \;=\; \psi(v_i, v_j) \;=\; ij\text{-entry of } A \;=\; e_i^T A e_j \;=\; \varphi(A)(e_i, e_j).$$

By bilinearity of forms we obtain the corresponding statement for all pairs of elements in R^n. ■

The Forms-Matrices Lemma 133.1 (1b), (1d) and (2) shows that the following definition makes sense.

Definition. Let R be a commutative ring. We denote by R^* the multiplicative units of R. Let (V, ψ) be a non-singular (anti-) symmetric form over R of rank n. We pick a basis $v_1, \dots, v_n$ of V. We refer to

$$\det(\psi) \;:=\; \det(\psi(v_i, v_j)_{i,j=1,\dots,n}) \;\in\; R^*/\{a^2 \mid a \in R^*\}$$

as the determinant of the form (V, ψ). Note that for $R = \mathbb{Z}$ the determinant is a well-defined element of $\{\pm 1\}$.

Example.

(1) For a matrix $A \in \mathrm{GL}(n,R)$ we have of course $\det(\varphi(A)) = \det(A) \in R^*/\{a^2 \mid a \in R^*\}$.

(2) We work with $R = \mathbb{Z}$. We set $A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Since $\det(A) = 1$ and $\det(A) = -1$ we see that $\varphi(A)$ and $\varphi(B)$ are non-isometric forms over $\mathbb{Z}^2$.

133.1. **Non-singular anti-symmetric forms.** In this section we will completely classify non-singular anti-symmetric forms over the real numbers and over the integers.
First we consider the matrix

$$S \;:=\; \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

It is anti-symmetric and it has determinant 1. From the Forms-Matrices Lemma 133.1 we obtain an anti-symmetric form $\varphi(S)$. The following proposition shows that $\varphi(S)$ is in some sense the only example of a non-singular anti-symmetric form over the real numbers or over the integers.

Proposition 133.2. (Anti-Symmetric Forms Proposition) If (V, φ) is a non-singular anti-symmetric form over $\mathbb{R}$ or over $\mathbb{Z}$, then there exists a $k \in \mathbb{N}_0$ such that[1624] $(V, \varphi) \cong$

$k \cdot \varphi(S)$, i.e. φ is represented by the $2k \times 2k$–matrix

$$\underbrace{\begin{pmatrix} 0 & 1 & \dots & 0 & 0 \\ -1 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & 1 \\ 0 & 0 & \dots & -1 & 0 \end{pmatrix}}_{k \text{ diagonal blocks of } 2 \times 2\text{-matrices}}.$$

In particular the rank of V is even.

Remark. Propositions 132.4 and 133.2 imply in particular that the isometry type of the intersection of a surface of genus g is determined by the formal properties of an intersection form. In particular we did not need to go through the discussion on page 2881 if we just need to know the *isometry type* of the intersection form.

Sketch of proof. First we remark that throughout the proof on many occasions we use the Forms-Matrices Lemma 133.1 without saying so explicitly.

After this preamble, let (V, φ) be a non-singular anti-symmetric form over $\mathbb{R}$ of rank n. We pick an $(n \times n)$–matrix A that represents φ. Since φ is anti-symmetric we see that all terms of A on the diagonal are zero. In the following we consider the usual three types of elementary matrices:

$$D_\lambda := \begin{pmatrix} \mathrm{id} & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \mathrm{id} \end{pmatrix}, \lambda \neq 0, \quad P := \begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix} \quad \text{and} \quad Q_\lambda := \begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & \lambda & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}.$$

We make the following elementary observations:

(i) Replacing a matrix B by $D_\lambda^T B D_\lambda$ means that first we multiply a column by λ, and then we multiply the corresponding row by λ.

(ii) Replacing a matrix B by $P^T B P$ means that first we exchange two columns, and then we exchange the corresponding two rows.

(iii) Replacing a matrix B by $Q_\lambda^T B Q_\lambda$ means that first we add λ-times one column to another column, and then we do the same operation for the corresponding rows.

Now we can perform the following sequence of operations to A:

$$A \overset{(1)}{=} \begin{pmatrix} 0 & * & * & \dots & * \\ * & 0 & * & \dots & * \\ * & * & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ * & * & * & * & 0 \end{pmatrix} \overset{(2)}{\to} \begin{pmatrix} 0 & 1 & * & \dots & * \\ -1 & 0 & * & \dots & * \\ * & * & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ * & * & * & * & 0 \end{pmatrix} \overset{(3)}{\to} \begin{pmatrix} 0 & 1 & 0 & \dots & 0 \\ -1 & 0 & * & \dots & * \\ 0 & * & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ 0 & * & * & * & 0 \end{pmatrix} \overset{(4)}{\to} \begin{pmatrix} 0 & 1 & 0 & \dots & 0 \\ -1 & 0 & 0 & \dots & 0 \\ 0 & 0 & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ 0 & 0 & * & * & 0 \end{pmatrix}$$

where we perform the following steps:

(1) We write out A, here and throughout the steps we use the convention that $*$ can mean any real number, the only condition being that all matrices are anti-symmetric.

(2) Since $\det(A) \neq 0$ there exists at least one entry on the first row which is non-zero. After operations of type (ii) and (i) we can arrange that the $(1,2)$-entry equals 1. By the anti-symmetry we see that the $(2,1)$-entry now equals -1.

[1624] Here, when we write $k \cdot \varphi(S)$ we use the definition from page 2877.

(3) Using operations of type (iii) we can "clean up" the remaining terms on the first row and column.
(4) Similarly, we can use operations of type (iii) to "clean up" the remaining terms on the second row and column.

At this stage we can continue with the same process, applied to the $(n-2)\times(n-2)$–matrix at the right bottom. Eventually we will have turned A into a matrix of the promised type.

Now suppose that (V,φ) is a non-singular anti-symmetric form over $\mathbb{Z}$. In Exercise 133.7 we will modify the above proof to deal with this new situation. ■

In a sense the Anti-Symmetric Forms Proposition 133.2 is rather disappointing. We had hoped that intersection forms will give us new meaningful invariants. But the Anti-Symmetric Forms Proposition 133.2 together with the Intersection Form Proposition 132.4 shows that intersection forms of closed even-dimensional topological manifolds do not give us any extra information that would allow us to distinguish. manifolds.

Nonetheless, the Anti-Symmetric Forms Proposition 133.2 has just enough content to answer Question 119.8 where we had asked which integers appear as Euler characteristics of closed orientable connected even-dimensional topological manifolds.[1625] Now we can provide a complete answer to this question.

Proposition 133.3.

(1) Let $k \in \mathbb{N}$. Given any $n \in \mathbb{Z}$ there exists a closed orientable connected $4k$-dimensional smooth manifold with Euler characteristic n.
(2) (a) The Euler characteristic of any closed orientable connected topological manifold of dimension 2 is even and ≤ 2. Conversely, any even number ≤ 2 is the Euler characteristic of such a smooth manifold.
(b) Let $k \in \mathbb{N}$. The Euler characteristic of any closed orientable connected topological manifold of dimension $4k+2$ is even. Conversely, any even number is the Euler characteristic of such a smooth manifold.

Remark. In Exercise 140.2 we will deal with the possible Euler characteristics of smooth manifolds with possibly non-empty boundary.

Proof. We start out with two claims that give us the stated restrictions on Euler characteristics of closed orientable topological manifolds.

Claim. Let $k \in \mathbb{N}_0$. The Euler characteristic of every closed orientable topological manifold M of dimension $4k+2$ is even.

Proof. We have

$$\chi(M) \underset{\uparrow}{=} \sum_{i=0}^{4k+2}(-1)^i\cdot\dim_{\mathbb{R}}(\mathrm{H}_i(M;\mathbb{R})) \underset{\uparrow}{=} \dim_{\mathbb{R}}(\mathrm{H}_{2k+1}(M;\mathbb{R})) + \sum_{i=0}^{2k}(-1)^i\cdot\overbrace{2\cdot\dim_{\mathbb{R}}(\mathrm{H}_i(M;\mathbb{R}))}^{\text{even}}$$

Manifold-χ-Proposition 104.36 (4); by the Co-Homology Symmetry Theorem Theorem 119.6 we have $\dim_{\mathbb{R}}(\mathrm{H}_i(M;\mathbb{R})) = \dim_{\mathbb{R}}(\mathrm{H}_{4k+2-i}(M;\mathbb{R}))$

$$\underset{\uparrow}{\equiv} 0 \mod 2.$$

by the Intersection Form Proposition 132.4 and the facts that M is closed and that $2k+1$ is odd we know that the intersection form on $\mathrm{H}_{2k+1}(M;\mathbb{R})$ is anti-symmetric and non-singular, by the Anti-Symmetric Forms Proposition 133.2 we thus know that $\dim_{\mathbb{R}}(\mathrm{H}_{2k+1}(M;\mathbb{R}))$ is even

[1625] This question arose from the fact, shown in the Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7, that the Euler characteristic of every closed odd-dimensional topological manifold is necessarily zero. So it was natural to wonder what is happening for closed even-dimensional topological manifolds.

⊞

Claim. The Euler characteristic of every every closed orientable connected 2-dimensional topological manifold M is ≤ 2.

Proof. Of course this statement follows from the Surface Classification Theorem 55.4 together with the calculation of the Euler characteristics on page 1879. But one can prove the claim directly. First the case that M is empty is trivial. Now assume that M is non-empty. In this case we have the following (in-) equalities:

$$\chi(M) \underset{\substack{\uparrow \\ \text{by the Euler Characteristic-H}_* \\ \text{Proposition 87.1}}}{=} \sum_{i\in\mathbb{N}_0} (-1)^i \cdot \operatorname{rank}(\mathrm{H}_i(M)) \underset{\substack{\uparrow \\ \text{by the Top-Homology Theorem 106.3}}}{=} \overbrace{\operatorname{rank}(\mathrm{H}_0(M))}^{=1 \text{ by the H}_0\text{-Proposition 72.5}} - \operatorname{rank}(\mathrm{H}_1(M)) + \overbrace{\operatorname{rank}(\mathrm{H}_2(M))}^{=1 \text{ by the Orientation-Top Homology Theorem 106.1}} \leq 2.$$

⊞

It remains to show that besides these two restrictions on the possible values of Euler characteristics, all other values can be realized. Our arguments in all of the three cases rely on the following observation.

Observation.

(i) On page 1879 we saw that for every $m \in \mathbb{N}_0$ we have $\chi(\mathbb{C}\mathrm{P}^m) = m+1$.

(ii) the Connected Sum-χ-Lemma 87.7 says that if M and N are two compact oriented connected *even-dimensional* smooth manifolds, then $\chi(M\#N) = \chi(M)+\chi(N)-2$.

(iii) There is any number of reasons, e.g. we could use the Product-χ-Lemma 87.8, why given any $m \in \mathbb{N}$ the Euler characteristic of the m-dimensional torus $(S^1)^m$ is zero.

Proof.

(1) Let $k \in \mathbb{N}$ and let $n \in \mathbb{Z}$. Note that $\chi(\mathbb{C}\mathrm{P}^k) = 2k+1$ is odd and ≥ 3. From the above observations it follows that

$$\chi(n \cdot \mathbb{C}\mathrm{P}^{2k} \# nk \cdot (S^1)^{4k}) \;=\; n\cdot(2k+1) - nk\cdot 2 \;=\; n.$$

(2) (a) Evidently we have $\chi(S^2) = 2$. Note let $n = 2m$ be an even integer with $n \leq 0$. It follows from the above observations that

$$\chi((m+1)\cdot(S^1\times S^1)) \;=\; (m+1-1)\cdot 2 \;=\; n.$$

(b) Let $k \in \mathbb{N}$ and let n be an even integer. From the above observations it follows that

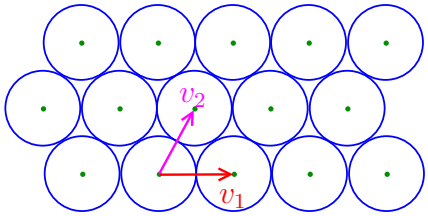
$$\chi\big(n \cdot \mathbb{C}\mathrm{P}^{2k+1} \# \tfrac{n}{2}(2k+1)\cdot(S^1)^{4k+2}\big) \;=\; n\cdot(2k+2) - \tfrac{n}{2}(2k+1)\cdot 2 \;=\; n. \qquad \blacksquare$$

133.2. **Interlude: Sphere-packing.** In this short section we want to consider sphere packings. The relationship with our actual goal of dealing with symmetric forms is arguably tenuous but nonetheless fascinating.

Definition. Let $v_1, \ldots, v_n$ be linearly independent vectors in $\mathbb{R}^n$. We refer to the group

$$\mathbb{Z}\cdot v_1 + \cdots + \mathbb{Z}\cdot v_n \;=\; \left\{ \sum_{i=1}^n a_i \cdot v_i \,\middle|\, a_1, \ldots, a_n \in \mathbb{Z} \right\}$$

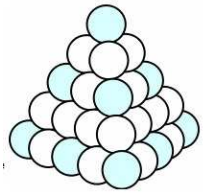
as the lattice spanned by $v_1, \ldots, v_n$.[1626]



We start out with the following theorem. The fact that strictly speaking we did not define all the terms will not bother us.

Theorem 133.4.

(1) A densest packing of disks of radius $\frac{1}{2}$ in $\mathbb{R}^2$ is given by setting the centers on the "hexagonal" lattice spanned by $v_1 = (1,0)$ and $v_2 = (\frac{1}{2}, \frac{\sqrt{3}}{2})$ shown in the figure below on the left. The density equals $\frac{\pi}{\sqrt{12}}$.



(2) No packing of balls of the same radius in $\mathbb{R}^3$ has density greater than that of the "face-centered cubic packing" shown in the figure below in the middle and on the right. The density equals $\frac{\pi}{\sqrt{18}}$.

Proof. The first statement was proved by L. Fejes Tóth [**FT1943, FT1972**] in 1943. It is much harder to prove the second statement. This statement had been conjectured by Kepler in 1613 and it was finally proved by Thomas Hales [**Hale20000, Hale2005, Hale2017**] in 2005. ■

densest disk packing

ball packings of highest density

For a mathematician it is natural to wonder what are the highest densities of packings in higher dimensions. Not surprisingly this is a very hard problem. Astonishingly the next case that was dealt with is the 8-dimensional setting. More precisely, the following theorem was proved by Maryna Viazovska [**Via2017**] in 2016.

Theorem 133.5. We consider the following matrix

$$E_8 := \begin{pmatrix} 2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 2 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 2 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 2 \end{pmatrix}.$$

No packing of unit balls in $\mathbb{R}^8$ has density greater than that given by the lattice spanned by the eight column vectors of the E_8–matrix. Furthermore, this packing has density $\frac{\pi^4}{384}$.

Remark. We also refer to [**Baez2018**] for other interesting appearances of the E_8–matrix, for example its relationship to the regular icosahedron

[1626] This is perhaps not the standard definition of a lattice, but who cares?

Shortly afterwards the 24-dimensional case was settled in [**CKMRV2017**], in this case a densest packing is given by the "Leech lattice". OK, that was fun, but now let us return to our actual problem, and let us see whether this section was of any use.

133.3. **Non-singular symmetric forms over the real numbers.** In an earlier section we saw that non-singular *anti-symmetric* forms are almost depressingly boring mathematical objects. In this and the next section we will consider non-singular *symmetric* forms. These will, fortunately, turn out to be much more interesting.

Examples. We list some symmetric integral matrices with determinant equal to ± 1. By the Forms-Matrices Lemma 133.1 these define in particular non-singular forms over $\mathbb{R}$ and also over $\mathbb{Z}$.

(1) The 1×1-matrices $(+1)$ and (-1).
(2) The slightly mysterious 8×8–matrix E_8 from the previous section.[1627]
(3) The matrix
$$H := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$
is symmetric and it has determinant -1.

It is natural to ask whether there is some type of analogue of the Anti-Symmetric Forms Proposition 133.2 for symmetric forms. In fact using the methods of the proof of the Anti-Symmetric Forms Proposition 133.2 one can prove the following statement.

Proposition 133.6. (Symmetric Forms-over-$\mathbb{R}$-Proposition) Let (V, φ) be a symmetric form over $\mathbb{R}$ of rank n.

(1) There exist $k_+, k_- \in \mathbb{N}_0$ such that $(V, \varphi) \cong k_+ \cdot (+1) \oplus k_- \cdot (-1) \oplus (n - k_- - k_+) \cdot (0)$.
(2) If the symmetric form (V, φ) is nonsingular, then there exists a $k \in \mathbb{N}_0$ such that $(V, \varphi) \cong k \cdot (+1) \oplus (n - k) \cdot (-1)$.

Remark. Recall that the Anti-Symmetric Forms Proposition 133.2 dealt with anti-symmetric forms over $\mathbb{R}$ and also with anti-symmetric forms over $\mathbb{Z}$. In contrast the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 only deals with symmetric forms over $\mathbb{R}$. It is a very instructive exercise to run through the proof of the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 and to determine where it breaks down if we work over $\mathbb{Z}$.

Sketch of proof. First let (V, φ) be a non-singular symmetric form over $\mathbb{R}$ of rank n. In the subsequent arguments below we use the conventions and notions we introduced in the Anti-Symmetric Forms Proposition 133.2. In particular we will also use the operations of type (i), (ii) and (iii) that we introduced in the proof of the Anti-Symmetric Forms Proposition 133.2.

We pick an $(n \times n)$–matrix A that represents φ. Now we can perform the following sequence of operations to A:

$$A \overset{(1)}{=} \begin{pmatrix} * & * & \dots & * \\ * & * & \dots & * \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \dots & * \end{pmatrix} \overset{(2)}{\longrightarrow} \begin{pmatrix} \epsilon_1 & * & \dots & * \\ * & * & \dots & * \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \dots & * \end{pmatrix} \overset{(3)}{\longrightarrow} \begin{pmatrix} \epsilon_1 & 0 & \dots & 0 \\ 0 & * & \dots & * \\ \vdots & \vdots & \ddots & \vdots \\ 0 & * & \dots & * \end{pmatrix}$$

[1627] A miracle! The matrix E_8 actually has determinant one.

where we perform the following steps:

(1) We write out A. Here and throughout the steps we use the convention that $*$ can mean anything, the only condition being that all matrices are symmetric.
(2) If Since $\det(A) \neq 0$ there exists at least one entry on the first row which is non-zero. After operations of type (iii) and (i) we can arrange that the $(1,1)$-entry equals some $\epsilon_1 \in \{-1, 1\}$.
(3) Using operations of type (iii) we can "clean up" the remaining terms on the first row and column.

At this stage we can continue with the same process, applied to the $(n-1)\times(n-1)$–matrix at the right bottom. Eventually we will have turned A into a diagonal matrix where all entries lie in $\{-1, 0, 1\}$. After operations of type (ii) we can arrange that the first diagonal entries are equal to $+1$ and the final ones are equal to -1.

Now suppose that (V, φ) is any symmetric form over $\mathbb{R}$. As in Exercise 132.4 we consider the radical

$$R \ := \ \{v \in V \,|\, \varphi(v, w) = 0 \text{ for all } w \in V\}.$$

Note that R is a vector subspace of V. We pick a vector subspace S of V with $R \oplus S = V$. As in Exercise 132.4 we see that (V, φ) is isometric to $(R, 0) \oplus (S, \varphi)$, and $(S, \varphi|_S)$ is non-singular. Thus the desired statement now follows from the above discussion of non-singular symmetric forms. ■

Let $n \in \mathbb{N}_0$. the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 raises the question whether or not the symmetric forms defined by $k \cdot (+1) \oplus (n-k) \cdot (-1)$ are isometric for different values of $k \in \{0, \ldots, n\}$. To answer this question it is helpful to introduce the following definition.

Definition. Let (V, φ) be a symmetric form over the real numbers.

(1) We say φ is positive-definite if $\varphi(v, v) > 0$ for all $v \neq 0$.
(2) We say φ is negative-definite if $\varphi(v, v) < 0$ for all $v \neq 0$.
(3) We say φ is indefinite if φ is neither positive-definite nor negative-definite.

Examples.

(1) The form $(+1)$ is positive-definite and the form (-1) is negative-definite.
(2) The form E_8 is positive-definite. Evidently one can show this by a brute force calculation. A more conceptual proof is given in [**HGK2010**, Theorem 1.16.14].
(3) The form H is indefinite, indeed, we have

$$\varphi(H)\left(\begin{pmatrix}1\\1\end{pmatrix}, \begin{pmatrix}1\\1\end{pmatrix}\right) \ = \ (1 \ \ 1)\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\begin{pmatrix}1\\1\end{pmatrix} \ = \ 2$$

and

$$\varphi(H)\left(\begin{pmatrix}1\\-1\end{pmatrix}, \begin{pmatrix}1\\-1\end{pmatrix}\right) \ = \ (1 \ \ -1)\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\begin{pmatrix}1\\-1\end{pmatrix} \ = \ -2.$$

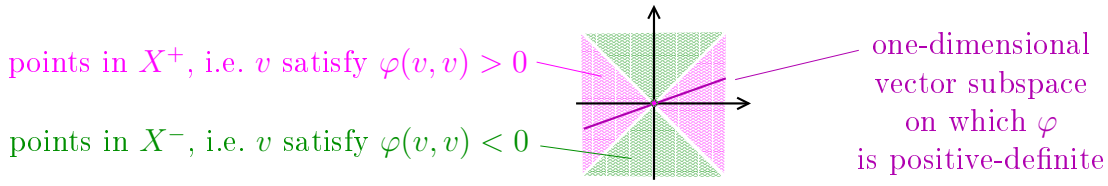
To distinguish non-isometric forms we need to introduce some invariants of forms.

Definition. Let (V, φ) be a symmetric form over the real numbers. We define

$b^+(\varphi) :=$ maximal dimension of a vector subspace U of V s. th. $\varphi|_U$ is positive-definite,
$b^-(\varphi) :=$ maximal dimension of a vector subspace U of V s. th. $\varphi|_U$ is negative-definite.

Furthermore we define the signature $\operatorname{sign}(\varphi)$ as

$$\operatorname{sign}(\varphi) \;:=\; b^+(\varphi) - b^-(\varphi).$$



Example. We consider the symmetric form

$$\begin{array}{rcl} \varphi\colon \mathbb{R}^2 \times \mathbb{R}^2 & \to & \mathbb{R} \\ \left(\begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}\right) & \mapsto & (v_1 \;\; v_2)\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\begin{pmatrix} v_1 \\ v_2 \end{pmatrix}. \end{array}$$

In the figure below we show the subsets

$$X^+ := \{v \in V \,|\, \varphi(v,v) > 0\} \cup \{0\} \quad \text{and} \quad X^- := \{v \in V \,|\, \varphi(v,v) < 0\} \cup \{0\}.$$

These subsets are evidently *not* vector subspaces of $V = \mathbb{R}^2$. The maximal dimension of a vector subspace contained in X^+ and X^- is in both cases equal to one. Thus we see that $b^+(\varphi) = b^-(\varphi) = 1$. In particular we see that $\operatorname{sign}(\varphi) = 0$.

The following lemma is an immediate consequence of the definitions.

Lemma 133.7. Let (V,φ) and (W,ψ) be two symmetric forms over $\mathbb{R}$. If (V,φ) and (W,ψ) are isometric, then

$$\dim_{\mathbb{R}}(V) = \dim_{\mathbb{R}}(W), \quad b^{\pm}(\varphi) = b^{\pm}(\psi) \quad \text{and} \quad \operatorname{sign}(\varphi) = \operatorname{sign}(\psi).$$

In the following proposition we determine $b^{\pm}$ and the signature for a non-singular form that is given by a diagonal matrix.

Proposition 133.8. (Signature-Eigenvalues Proposition) If D is a diagonal $(n \times n)$–matrix where the diagonal entries $d_1, \ldots, d_n$ are non-zero real numbers, then

$$b^+(\varphi(D)) \;=\; \text{number of positive } d_i\text{'s} \quad \text{and} \quad b^-(\varphi(D)) \;=\; \text{number of negative } d_i\text{'s}.$$

In particular

$$\operatorname{sign}(\varphi(D)) \;=\; \text{number of positive } d_i\text{'s} \;-\; \text{number of negative } d_i\text{'s}.$$

Proof. After reordering the diagonal entries we can assume that the first k entries of D are positive and that the remaining $(n-k)$ entries are negative. We write

$$\begin{array}{rcll} V^+ & := & \{(x_1, \ldots, x_k, 0, \ldots, 0) \in \mathbb{R}^n \,|\, x_1, \ldots, x_k \in \mathbb{R}\} & \text{and} \\ V^- & := & \{(0, \ldots, 0, y_1, \ldots, y_{n-k}) \in \mathbb{R}^n \,|\, y_1, \ldots, y_{n-k} \in \mathbb{R}\} & \end{array}$$

It is clear that $\varphi(D)|_{V^+}$ is positive-definite and that $\varphi(D)|_{V^-}$ is negative-definite. Thus $b^+(\varphi(D)) \geq k$ and $b^-(\varphi(D)) \geq n-k$. If remains to prove the following claim.

Claim. For any symmetric form (W,ψ) over $\mathbb{R}$ we have $b^+(\psi) + b^-(\psi) \leq \dim_{\mathbb{R}}(W)$.

Proof. Thus let W^+ be a positive-definite subspace of W and let W^- be a negative-definite subspace of W. The intersection $W^+ \cap W^-$ is a subspace that is positive-definite and negative-definite. So for any non-zero vector $v \in W^+ \cap W^-$ we have $\psi(v,v) > 0$ and

$\psi(v,v) < 0$. This is only possible if no such v exists, i.e. we have shown that the intersection $W^+ \cap W^- = \{0\}$. Now we see that

$$\dim(W^+) + \dim(W^-) \underset{\text{linear algebra}}{\overset{\uparrow}{=}} \dim(W^+ + W^-) + \dim(W^+ \cap W^-) \underset{W^+\cap W^- = \{0\}}{\overset{\uparrow}{=}} \dim(W^+ + W^-) \underset{\text{since } W^+ + W^- \subset W}{\overset{\uparrow}{\leq}} \dim(W). \qquad \blacksquare$$

Corollary 133.9.

(1) Let (V,φ) be a symmetric form over $\mathbb{R}$. We write $n = \dim_{\mathbb{R}}(V)$. The following statements hold:
   (a) We have $b^{\pm}(-\varphi) = b^{\mp}(\varphi)$, in particular we have $\operatorname{sign}(-\varphi) = -\operatorname{sign}(\varphi)$.
   (b) If (V,φ) is non-singular, then we have $b^+(\varphi) + b^-(\varphi) = \dim_{\mathbb{R}}(V)$.
   (c) If (V,φ) is non-singular, then we have $b^+(\varphi) = \frac{1}{2}(n + \operatorname{sign}(\varphi))$.
   (d) If we write $k_{\pm} = b^{\pm}(\varphi)$, then the given form (V,φ) is isometric to the form $k_+ \cdot (+1) \oplus k_- \cdot (-1) \oplus (n - k_- - k_+) \cdot (-1)$.
   (e) If (V,φ) is non-singular, then we have $\operatorname{sign}(\varphi) \equiv n \bmod 2$.

(2) If (V,φ) and (W,ψ) are two symmetric forms over $\mathbb{R}$, then

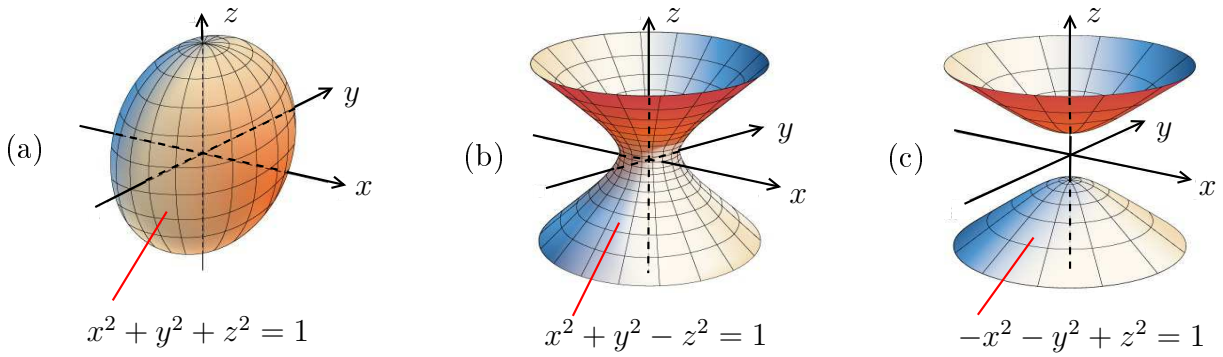
$$\operatorname{sign}(\varphi \oplus \psi) \;=\; \operatorname{sign}(\varphi) + \operatorname{sign}(\psi).$$

Proof.

(1) (a) This statement follows immediately from the definitions.
   (b) By the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 and Lemma 133.7 it suffices to prove the statement for non-singular symmetric forms that are represented by diagonal matrices. But for those forms the statement follows immediately from the Signature-Eigenvalues Proposition 133.8.
   (c) This statement is an immediate consequence of (b) and the definition of the signature.
   (d) This statement follows from the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6, Lemma 133.7 and the Signature-Eigenvalues Proposition 133.8.
   (e) We have $\operatorname{sign}(\varphi) = b^+(\varphi) - b^-(\varphi) \equiv b^+(\varphi) + b^-(\varphi) = n \bmod 2$.

(2) This statement follows immediately from Statement (1d), the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 applied to φ and ψ and the Signature-Eigenvalues Proposition 133.8. $\blacksquare$

Example. Given a non-singular symmetric form φ on $\mathbb{R}^3$ one can visualize it by considering the "unit-sphere"



$$S(\varphi) \;:=\; \{v \in \mathbb{R}^3 \,|\, \varphi(v,v) = 1\}.$$

Corollary 133.9 (3) implies in particular that every non-singular symmetric form on $\mathbb{R}^3$ is isometric to one of the following four forms

(a) $3 \cdot (1)$, (b) $2 \cdot (1) \oplus (-1)$
(c) $2 \cdot (-1) \oplus (1)$ (d) $3 \cdot (-1)$.

In the last case the unit-sphere is the empty set. In the other cases the unit-spheres are sketched in the figure below.

The following theorem says that the dimension and the signature are a complete invariant for isometry types of non-singular symmetric forms over $\mathbb{R}$.

Theorem 133.10. (Sylvester's Theorem a. k. a. Sylvester's law of inertia) Let (V, φ) and (W, ψ) be two non-singular symmetric forms over $\mathbb{R}$. Then

$$(V,\varphi) \text{ and } (W,\psi) \text{ are isometric} \iff \dim_{\mathbb{R}}(V) = \dim_{\mathbb{R}}(W) \text{ and } \operatorname{sign}(\varphi) = \operatorname{sign}(\psi).$$

Proof. The "$\Rightarrow$"-direction is precisely Lemma 133.7. It remains to prove the "$\Leftarrow$"-direction. So suppose we are given two non-singular symmetric forms (V, φ) and (W, ψ) over $\mathbb{R}$ with same dimension and same signature. It follows from our hypothesis together with Corollary 133.9 (c) and (d) that there exist $n, k \in \mathbb{N}_0$ such that (V, φ) and (W, ψ) are both isometric to $k \cdot (+1) \oplus (n-k) \cdot (-1)$. But this implies that (V, φ) and (W, ψ) are themselves isometric. ■

Remark. It is also very easy to classify symmetric forms over $\mathbb{R}$ that are not necessarily non-singular. More precisely, given a symmetric form (V, φ) over $\mathbb{R}$ we define the *nullity* $\sigma(\varphi)$ as

$$\nu(\varphi) \ := \ \text{maximal dimension of a subspace } W \text{ of } V \text{ such that } \varphi|_W \text{ is the zero form.}$$

It is an amusing little exercise to modify the proof of Sylvester's Theorem 133.10 to show that two symmetric forms over $\mathbb{R}$ are isometric if and only if their dimensions, signatures and nullities agree.

Now it is time to apply our recently acquired knowledge to topology.

Definition.

(1) If (V, φ) is a symmetric form over the integers, then we define

$$\begin{array}{rccl} g \otimes \mathbb{R} \colon & V \otimes \mathbb{R} \times V \otimes \mathbb{R} & \to & \mathbb{R} \\ & (v \otimes r, w \otimes s) & \mapsto & r \cdot \varphi(v,w) \cdot s. \end{array}$$

Furthermore we define

$$\operatorname{sign}(\varphi) \ := \ \operatorname{sign}(\varphi \otimes \mathbb{R}).$$

(2) Let $k \geq 1$ and let M be a compact oriented $4k$-dimensional topological manifold. We define the signature of M to be[1628]

$$\operatorname{sign}(M) \ := \ \operatorname{sign}(Q_M).$$

For convenience we define the signature of the empty topological manifold to be zero.

Remark. The signature of a manifold was first introduced in 1923 by Hermann Weyl [**Wey1923**, p. 432] in a little known paper written in Spanish. As is explained in [**Eckm2006**], Hermann Weyl deliberately chose this obscurity since at this point, according to Hermann Weyl, algebraic topology was not considered "a respectable field of mathematics".

Lemma 133.11. (Manifold-Signature Lemma) Let $k \in \mathbb{N}$.

(1) Let M be a compact oriented $4k$-dimensional topological manifold. The form $Q_M \otimes \mathbb{R}$ is isometric to the form

$$\begin{array}{rcl} \mathrm{H}^{2k}(M, \partial M; \mathbb{R}) \times \mathrm{H}^{2k}(M, \partial M; \mathbb{R}) & \to & \mathbb{R} \\ (\varphi, \psi) & \mapsto & \langle \varphi \cup \psi, [M] \rangle. \end{array}$$

(2) The signature is additive under the connected sum operation and under disjoint union.

(3) For every compact oriented $4k$-dimensional topological manifold we have

$$\operatorname{sign}(-M) \;=\; -\operatorname{sign}(M).$$

(4) Let M and N be two compact oriented $4k$-dimensional topological manifolds.
   (a) If M and N are homeomorphic, then $\operatorname{sign}(M) = \pm \operatorname{sign}(N)$.
   (b) If the pairs $(M, \partial M)$ and $(N, \partial N)$ are homotopy equivalent, then we have the equality $\operatorname{sign}(M) = \pm \operatorname{sign}(N)$.

Proof.

(1) This statement follows easily from the various definitions and Corollary 89.19.

(2) It follows easily from the Cup-Cap Disjoint Union Lemma 116.9 that the signature is additive under disjoint union. If we are given compact topological manifolds, then it follows immediately from the Intersection Form-Additivity Proposition 132.12 and Corollary 133.9 that the signature is additive under the connected sum operation.

(3) The third statement is an immediate consequence of Lemma 132.6 and Corollary 133.9.

(4) The last statement is also an immediate consequence of Lemma 132.6 and Corollary 133.9. ■

Examples. We have

$$\begin{array}{ccccccccccc} \operatorname{sign}(\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2) & = & \operatorname{sign}(\mathbb{C}\mathrm{P}^2) + \operatorname{sign}(\mathbb{C}\mathrm{P}^2) & = & \operatorname{sign}(1) + \operatorname{sign}(1) & = & 1+1 & = & 2 \\ & & \uparrow & & \uparrow & & & & \\ & & \text{Manifold-Signature Lemma 133.11 (2) and (3)} & & \text{see page 2882} & & & & \\ & & \downarrow & & \downarrow & & & & \\ \operatorname{sign}(\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2) & = & \operatorname{sign}(\mathbb{C}\mathrm{P}^2) - \operatorname{sign}(\mathbb{C}\mathrm{P}^2) & = & \operatorname{sign}(1) - \operatorname{sign}(1) & = & 1-1 & = & 0. \end{array}$$

Furthermore we have

$$\operatorname{sign}(S^2 \times S^2) \underset{\text{see page 2881}}{\overset{\uparrow}{=}} \operatorname{sign} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \underset{\text{Forms-Matrices Lemma 133.1}}{\overset{\uparrow}{=}} \operatorname{sign} \left(\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \cdot \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \right) = \operatorname{sign} \begin{pmatrix} 2 & 0 \\ 0 & -2 \end{pmatrix} \underset{\text{Signature-Eigenvalues Proposition 133.8}}{\overset{\uparrow}{=}} 0.$$

The above examples, together with Lemmas 132.6 and 133.11 (4) now allow us to give a partial answer to Question 100.15.

[1628] Recall that on page 2800 we introduced the intersection form $Q_M \colon \mathrm{FH}_{2k}(M; \mathbb{Z}) \times \mathrm{FH}_{2k}(M; \mathbb{Z}) \to \mathbb{Z}$. Furthermore, recall that by the Intersection Form Proposition 132.4 the intersection form Q_M is indeed symmetric, so it makes sense to consider its signature.

Corollary 133.12. The topological space $\mathbb{C}\mathrm{P}^2\#\mathbb{C}\mathrm{P}^2$ is neither homotopy equivalent (in particular it is not homeomorphic) to $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$ nor to $S^2 \times S^2$.

Remark. Corollary 133.12 shows in particular that in the definition of the connected sum of two orientable (topological) smooth manifolds we needed to work with *oriented* (topological) smooth manifolds.

Unfortunately we are not yet able to distinguish the two smooth manifolds $S^2 \times S^2$ and $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$. In fact Sylvester's Theorem 133.10 might suggest that we are again at a dead end. But this is not the case since Sylvester's Theorem is a statement about *real* symmetric forms, but we are really dealing with symmetric forms defined over the integers. We will exploit this extra piece of information in the next section.

133.4. **Non-singular symmetric forms over the integers.** We consider the matrices

$$H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and } D = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

It follows from Sylvester's Theorem 133.10 that the matrices give rise to *isometric forms over the real numbers*. The question arises, whether the forms on $\mathbb{Z}^2$ defined by these matrices are isometric. To get an idea let us consider what we can say about the "squares $\varphi(v, v)$" defined by these forms. Note that given any $v = \begin{pmatrix} a \\ b \end{pmatrix} \in \mathbb{R}^2$ we have

$$\varphi(H)(v,v) = \begin{pmatrix} a & b \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} a \\ b \end{pmatrix} = 2ab \quad \text{and} \quad \varphi(H)(v,v) = \begin{pmatrix} a & b \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\begin{pmatrix} a \\ b \end{pmatrix} = a^2 - b^2.$$

We see that for the form to the left we only get even integers whereas to the right any integer can occur. This already shows that the two forms are not isometric over the integers. It follows immediately from this discussion and the earlier calculations of the intersection forms that the intersection forms of $S^2 \times S^2$ and $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$ are not isometric, not even up to sign. This allows us to settle the remaining case of Question 100.15. More precisely, by Lemma 132.6 we have the following proposition.

Proposition 133.13. The topological space $S^2 \times S^2$ is not homotopy equivalent (in particular it is not homeomorphic) to $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$.

This encouraging discussion leads us to the following definition.

Definition. A symmetric form (V, φ) over the integers is called even if

$$\varphi(v, v) \equiv 0 \mod 2 \quad \text{for all } v \in V,$$

otherwise the intersection form is called odd. We refer to the property of φ being even or odd as the parity of the form.

The following lemma summarizes some basic facts about the parity of symmetric forms.

Lemma 133.14. (Parity Lemma)

(1) Isometric forms have the same parity.
(2) For a symmetric form φ the parities of φ and $-\varphi$ agree.
(3) The direct sum of an odd form with any other form is also odd.

(4) If A is a symmetric square matrix over the integers, then

$$\varphi(A) \text{ is even} \iff \text{all diagonal entries of } A \text{ are even.}$$

Examples. It follows from the Parity Lemma 133.14 that the forms $(+1)$, (-1) and $\begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix}$ are odd and that the forms E_8 and $H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ are even.

Proof. The only statement which requires a little thought is the fact that if $A = (a_{ij})$ is a symmetric $(n \times n)$–matrix with even diagonal entries, then $\varphi(A)$ is even. Thus let $v = (v_1, \dots, v_n) \in \mathbb{Z}^n$. We calculate that

$$\varphi(A)(v,v) = v^T A v = \sum_{i=1}^{n}\sum_{j=1}^{n} v_i v_j \cdot a_{ij} \underset{\text{since } A \text{ is symmetric}}{\overset{\uparrow}{=}} 2\sum_{i=1}^{n}\sum_{j=1}^{i-1} v_i v_j \cdot a_{ij} + \sum_{i=1}^{n} v_i^2 a_{ii} \underset{\text{since the } a_{ii} \text{ are even}}{\overset{\uparrow}{\equiv}} 0 \bmod 2.$$

■

We just saw that the two matrices

$$H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and } D = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

give rise to *isometric forms over the real numbers* and that the two matrices give rise to *non-isometric forms over the integers*. The question arises, how much more complicated is the classification of non-singular symmetric forms over the integers than the classification of non-singular forms over the real numbers. In particular the following question arises.

Question 133.15. Can we classify non-singular symmetric forms over the integers?

The following is the key theorem in the classification of non-singular *indefinite* symmetric forms over $\mathbb{Z}$.

Theorem 133.16. (Indefinite Forms Proposition) If φ_1 and φ_2 are two non-singular *indefinite* symmetric forms over the integers, then the following holds:

$$\varphi_1 \text{ and } \varphi_2 \text{ are isometric} \iff \varphi_1 \text{ and } \varphi_2 \text{ have the same rank, signature and parity.}$$

Example. Using the parity we had just seen that the intersection forms of the closed oriented 4-dimensional smooth manifolds $M = S^2 \times S^2$ and $N = \mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ are not isometric, even up to sign. Now we consider the closed oriented 4-dimensional smooth manifolds that we obtain from M and N by performing the connected sum with $\mathbb{C}\mathrm{P}^2$. In other words, we are considering $M \# \mathbb{C}\mathrm{P}^2 = (S^2 \times S^2) \# \mathbb{C}\mathrm{P}^2$ and $N \# \mathbb{C}\mathrm{P}^2 = \mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2 \# \mathbb{C}\mathrm{P}^2$. It follows from the Intersection Form-Additivity Proposition 132.12 that the intersection forms of these two smooth manifolds are represented by the matrices

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Both forms are non-singular indefinite and odd. Thus it follows from the Indefinite Forms Theorem 133.16, or alternatively from Exercise 133.12, that the intersection forms are isometric. Thus we cannot distinguish $M \# \mathbb{C}\mathrm{P}^2 = (S^2 \times S^2) \# \mathbb{C}\mathrm{P}^2$ and $N \# \mathbb{C}\mathrm{P}^2 = \mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2 \# \mathbb{C}\mathrm{P}^2$ using their intersection forms. In fact, it turns out that there is a good reason why we have

a hard time distinguishing them: as is shown in [**GoS1999**, p. 151] the two smooth manifolds $(S^2 \times S^2)\#\mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2\#\mathbb{C}\mathrm{P}^2$ are in fact diffeomorphic, in fact with good eyes one can write down an explicit diffeomorphism.

Proof. The proof of the theorem is provided in [**MH1973**, Theorem II.5.3] (see also [**GoS1999**, Theorem 1.2.14] for an outline of the proof). The proof relies crucially on a significant input from algebraic number theory, namely the Hasse-Minkowski theorem. This theorem says that given $a_1, \ldots, a_n \in \mathbb{Q} \setminus \{0\}$ the equation

$$x_1^2 \cdot a_1 + \cdots + x_n^2 \cdot a_n \;=\; 0$$

has a non-trivial integral solution if and only if it has a non-trivial real solution and if for each prime p the equation has also has a non-trivial solution over the p-adic numbers $\mathbb{Q}_p$. A proof of the Hasse-Minkowski theorem is given in [**Ser1973**, Chapter IV Theorem 8], [**BSh1966**, Section 7.1] or [**Neuk1999**, p. 385]. ■

As an immediate corollary to the Indefinite Forms Theorem 133.16 we obtain the classification of non-singular *indefinite odd* forms. More precisely, we have the following corollary.

Corollary 133.17. (Indefinite Odd Forms Lemma) If φ is a non-singular *indefinite* odd symmetric form over the integers, then

$$\varphi \;\cong\; b^+(\varphi) \cdot (1) \,\oplus\, b^-(\varphi) \cdot (-1).$$

Proof. Let φ be a non-singular indefinite odd symmetric form. It follows from the Signature-Eigenvalues Proposition 133.8 that the rank, signature and parity of the two non-singular indefinite odd forms in the statement of the corollary agree. So these two forms are isometric by the Indefinite Forms Theorem 133.16. ■

Now we turn to the study of even forms. We have the following, perhaps somewhat surprising proposition.

Proposition 133.18. (Even Forms Proposition) Let φ be a non-singular symmetric form over the integers. If φ is even, then $\mathrm{sign}(\varphi) \equiv 0 \bmod 8$.

Example. As a reality check, the two even non-singular symmetric forms that we are acquainted with are $H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and E_8. These forms a non-singular even forms and the signatures are 0 and 8, so that matches the Even Forms Proposition 133.18.

Proof. Given a non-singular symmetric form (W, ψ) over $\mathbb{Z}$ we say that an element $v \in W$ is *characteristic* if for all $w \in W$ we have

$$\varphi(v, w) \;\equiv\; \varphi(w, w) \mod 2.$$

We make the following observations:

(1) It follows immediately from the definitions that (W, ψ) is even if and only if 0 is a characteristic element.

(2) If $W = k \cdot (1) \oplus l \cdot (-1)$, then it follows from a straightforward calculation as in the proof of the Parity Lemma 133.14 that an element $u \in \mathbb{Z}^{k+l}$ is characteristic if and only if all its entries are odd.

It follows from Observation (1) that the following claim implies in particular the desired statement of the Even Forms Proposition 133.18.

Claim. Let (V, φ) be a non-singular symmetric form over $\mathbb{Z}$. If $v \in V$ is a characteristic element, then
$$\varphi(v, v) \equiv \operatorname{sign}(\varphi) \mod 8.$$

Proof. Let $v \in V$ be a characteristic element of (V, φ). It is straightforward to verify that $v + e_- + e_+$ is a characteristic element in $(V \oplus \mathbb{Z} \oplus \mathbb{Z}, \varphi \oplus (1) \oplus (-1))$, where e_- and e_+ are generators of the first respectively the second $\mathbb{Z}$-summand. Note that, regardless of φ, the form $\varphi \oplus (1) \oplus (-1))$ is indefinite and odd. Thus by the Indefinite Odd Forms Corollary 133.17 there exists an isometry[1629]
$$\Phi\colon \varphi \oplus (1) \oplus (-1) \xrightarrow{\cong} (b^+(\varphi) + 1) \cdot (1) \oplus (b^-(\varphi) + 1) \cdot (-1).$$
We write $u := \Phi(v + e_- + e_+)$. It is clear that u is a characteristic element for the form on the right-hand side. The above Observation (2) tells us that each entry of u is an odd integer. Now we calculate that

$$\begin{aligned}
\varphi(v,v) &\overset{\text{straightforward calculation}}{=} (\varphi \oplus (1) \oplus (-1))(v + e_- + e_+, v + e_- + e_+) \overset{\text{since } \Phi \text{ is an isometry}}{=} \\
&= ((b^+(\varphi) + 1) \cdot (1) \oplus (b^-(\varphi) + 1) \cdot (-1))(u, u) \\
&= \sum_{i=1}^{b^+(\varphi)+1} (\underbrace{i\text{-th entry of } u}_{\text{odd integer}})^2 + \sum_{i=b^+(\varphi)+2}^{b^+(\varphi)+b^-(\varphi)+2} (-1) \cdot (\underbrace{i\text{-th entry of } u}_{\text{odd integer}})^2 \\
&\equiv \sum_{i=1}^{b^+(\varphi)+1} 1 + \sum_{i=b^+(\varphi)+2}^{b^+(\varphi)+b^-(\varphi)+2} (-1) = (b^+(\varphi) + 1) - (b^-(\varphi) + 1) = \operatorname{sign}(\varphi) \bmod 8.
\end{aligned}$$
$\uparrow$ since for each odd number k we have $k^2 \equiv 1 \bmod 8$[1630]

■

Now we can provide the classification of non-singular indefinite *even* symmetric forms.

Corollary 133.19. (Indefinite Even Forms Corollary) If φ is a non-singular *indefinite* even symmetric form over the integers, then
$$\varphi \cong \tfrac{\operatorname{sign}(\varphi)}{8} \cdot E_8 \oplus \tfrac{\operatorname{rank}(\varphi) - |\operatorname{sign}(\varphi)|}{2} \cdot H.$$

Proof. First let φ be a non-singular even symmetric form over the integers. Note that it follows from the Even Forms Proposition 133.18 that $\operatorname{sign}(\varphi)$ is indeed divisible by 8. Furthermore it follows from $\operatorname{rank}(\varphi) = b^+(\varphi) + b^-(\varphi)$ and $\operatorname{sign}(\varphi) = b^+(\varphi) - b^-(\varphi)$ that $\operatorname{rank}(\varphi) - |\operatorname{sign}(\varphi)|$ is divisible by 2. So it makes sense to write down the right-hand side.

Next we recall that the two non-singular symmetric forms E_8 and H are even, that $\operatorname{rank}(E_8) = \operatorname{sign}(E_8) = 8$ and that $\operatorname{rank}(H) = 2$ and $\operatorname{sign}(H) = 0$. Now assume that φ is furthermore indefinite. It follows from the above observation regarding E_8 and H that the rank, signature and parity of the two non-singular indefinite even forms in the statement of the corollary agree. So these two forms are isometric by the Indefinite Forms Theorem 133.16. ■

[1629] Note that both sides are non-singular odd indefinite forms, regardless of what non-singular symmetric form φ we actually consider.

[1630] Why is it true that for each odd number k we have $k^2 \equiv 1 \bmod 8$?

Now we turn to the study of non-singular *definite* symmetric forms over the integers. We start out with some more examples of such forms. The following lemma is proved in [**MH1973**, Lemmas 6.1 and 6.2] and [**Ser1973**, p. 51].

Lemma 133.20. We denote by $e_1, \dots, e_{4m}$ the standard basis for $\mathbb{Z}^{4m}$. We denote by Γ_{4m} the submodule of $\mathbb{Z}^{4m}$ spanned by the vectors $\{e_i + e_j\}_{i,j=1,\dots,4m}$ and $\frac{1}{2}(e_1 + \dots + e_{4m})$.

(1) The restriction of the usual form $\langle\ ,\ \rangle$ on $\mathbb{Z}^{4m}$ to Γ_{4m} is a non-singular positive-definite symmetric form.
(2) The form Γ_{4m} is odd if and only if m is odd.
(3) The form Γ_8 is isometric to E_8.
(4) The form Γ_{16} is not isometric to $E_8 \oplus E_8$.

It turns out that there are many more *definite* symmetric forms than indefinite symmetric forms and that there is no known classification of such forms. For example, by [**MH1973**, p. 28] and [**Ser1973**, p. 55] we have the following table

dimension	8	16	24	32	40
number of isometry types of non-singular positive-definite *even* symmetric forms	1	2	24	$\geq 10^7$	$\geq 10^{51}$

Here in dimension 8, up to isometry, the unique example is $\Gamma_8 = E_8$ whereas in dimension 16 the unique examples are $\Gamma_8 \oplus \Gamma_8 = E_8 \oplus E_8$ and Γ_{16}.
Similar results are also known for the number of isometry classes of non-singular positive-definite *odd* symmetric forms of a given rank. We refer to [**CSl1999**, p. 416] and [**Kin2003**, Table 2] for details.

133.5. **Forms over $\mathbb{F}_2$.** Considering the power of the intersection form of a closed *oriented* even-dimensional topological manifold it is natural to ask, whether one can obtain similar results for closed (possibly) *non-orientable* even-dimensional topological manifolds. In fact we have the following definition.

Definition. Let M be a closed $2n$-dimensional topological manifold M (not necessarily orientable). We denote by $[M]_{\mathbb{F}_2} \in \mathrm{H}_{2n}(M;\mathbb{F}_2)$ the $\mathbb{F}_2$-fundamental class given by the $\mathbb{F}_2$-Fundamental Class Corollary 106.5. Given $k \in \mathbb{N}_0$ we denote by

$$\mathrm{PD}_M^{\mathbb{F}_2} \colon \mathrm{H}_k(M;\mathbb{F}_2) \ \to\ \mathrm{H}^{2n-k}(M;\mathbb{F}_2)$$

the inverse of the isomorphism given by the Poincaré Duality Theorem 119.1. We can now define the $\mathbb{F}_2$-valued intersection form as follows:

$$\begin{aligned} Q_M^{\mathbb{F}_2} \colon \mathrm{H}_n(M;\mathbb{F}_2) \times \mathrm{H}_n(M;\mathbb{F}_2) &\to \mathbb{F}_2 \\ (a,b) &\mapsto \left\langle \mathrm{PD}_M^{\mathbb{F}_2}(a) \cup \mathrm{PD}_M^{\mathbb{F}_2}(b), [M]_{\mathbb{F}_2} \right\rangle. \end{aligned}$$

The above definition is completely analogous to the definition of the $\mathbb{Z}$-valued intersection form on page 2800. Not surprisingly the $\mathbb{F}_2$-valued intersection forms shares many properties of the $\mathbb{Z}$-valued intersection form.

Proposition 133.21. ($\mathbb{F}_2$-Intersection Form Proposition)

(1) The $\mathbb{F}_2$-valued intersection form $Q_M^{\mathbb{F}_2}$ on a closed $2n$-dimensional topological manifold M is symmetric and non-singular.

(2) The $\mathbb{F}_2$-valued intersection forms of homeomorphic closed topological manifolds are isometric.

Proof. The proof is a very mild variation on the proofs of the Intersection Form Proposition 132.4 and Lemma 132.6. ■

Examples.

(1) Similar to the discussion on page 2881 one can show that the $\mathbb{F}_2$-valued intersection form of the torus $S^1 \times S^1$ is represented by the matrx $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

(2) The Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16, together with the obvious analogue of the Intersection Form-Additivity Proposition 132.12, implies that the $\mathbb{F}_2$-valued intersection form of $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is represented by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$.

The question arises, whether we can classify non-singular symmetric forms over $\mathbb{F}_2$. For better or worse it turns out that there is a straightforward classification. To state the classification we need the following definition which is inspired by our definition on page 2918.

Definition. Let V be a finite-dimensional $\mathbb{F}_2$-vector space. We say a form $\lambda\colon V \times V \to \mathbb{F}_2$ is even if $\lambda(v, v) = 0 \in \mathbb{F}_2$ for all $v \in V$. Otherwise we say that the symmetric form is odd. We call the property of a form to be even or odd to be the parity of the form.

Example. As we had just seen, the $\mathbb{F}_2$-valued intersection form of the torus $S^1 \times S^1$ is even whereas the $\mathbb{F}_2$-valued intersection form of the torus $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is odd. Thus we have found a new, and particularly complicated, proof that these two 2-dimensional smooth manifolds are not homeomorphic.

The following proposition gives a complete classification of non-singular symmetric forms over $\mathbb{F}_2$ up to isometry.

Proposition 133.22. (Non-Singular Forms-over-$\mathbb{F}_2$-Proposition) Two non-singular symmetric forms (V, κ) and (W, λ) over $\mathbb{F}_2$ are isometric if and only if $\dim(V) = \dim(W)$ and if κ and λ have the same parity.

Proof. We will prove the Non-Singular Forms-over-$\mathbb{F}_2$-Proposition 133.22 in Exercise 133.14. For peace of mind we point out that the proposition is proved in [**Hopk2015**, Theorem 2.7]. It can also be deduced from [**Szy1997**, Corollary 6.3.1]. ■

The proposition shows that, unfortunately, we extract only very little information from the $\mathbb{F}_2$-valued intersection form.

Remark. Let V be a finite-dimensional vector space over $\mathbb{F}_2$ and let $\langle\ ,\ \rangle\colon V \times V \to \mathbb{F}_2$ be an even form. It follows from the Non-Singular Forms-over-$\mathbb{F}_2$-Proposition 133.22 that V admits a *symplectic basis*, i.e. there exists a basis $a_1, \dots, a_k, b_1, \dots, b_k$ for V such that the following conditions are satisfied:

(1) For every $i, j \in \{1, \dots, k\}$ we have $\langle a_i, a_j \rangle = \langle b_i, b_j \rangle = 0$.
(2) For every $i, j \in \{1, \dots, k\}$ we have $\langle a_i, a_j \rangle = \delta_{ij}$.

This observation will come in handy later on.

Exercises for Chapter 133.

Exercise 133.1. Let φ be a symmetric form on a finite-dimensional real vector space V. Prove the following statement: If φ is positive-definite, then φ is non-singular.

Exercise 133.2. Let (V, g) be a non-singular symmetric form over the reals. We suppose that there exists a subspace W with $g|_W = 0$ and with $\dim(W) = \frac{1}{2}\dim(V)$. Show that $\operatorname{sign}(g) = 0$.

Exercise 133.3. Let R be a commutative ring. In this exercise we will see that non-singular symmetric forms over R give rise to a group. (We refer to page 2877 for the definition of a non-singular symmetric form.) Note that the set of symmetric non-singular forms $\varphi\colon R^k \times R^k \to R$ with the direct sum operation is a monoid.

We say a symmetric form φ is *hyperbolic* if it is isometric to a form of the form

$$\begin{array}{rcl} \psi\colon (V \oplus V) \times (V \oplus V) & \to & \mathbb{R} \\ (v_1 \oplus v_2), (w_1 \oplus w_2) & \mapsto & (v_1^T\, v_2^T) \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}. \end{array}$$

(a) Show that the monoid of symmetric non-singular forms $\varphi\colon R^k \times R^k \to R$ modulo the submonoid generated by hyperbolic forms is an abelian group. We refer to this group as the *Witt group* $W(R)$.

(b) Show that the maps

$$\begin{array}{rcl} W(\mathbb{R}) & \to & \mathbb{Z} \\ \varphi & \mapsto & \operatorname{sign}(\varphi) \end{array} \quad \text{and} \quad \begin{array}{rcl} W(\mathbb{Z}) & \to & \mathbb{Z} \\ \varphi & \mapsto & \operatorname{sign}(\varphi \otimes \mathbb{R}) \end{array}$$

are isomorphisms.

(c) Show that $W(\mathbb{Q})$ admits an epimorphism onto $\mathbb{Z} \oplus (\mathbb{Z}_2)^\infty$.
Hint. Consider determinants of matrices representing a given form.
Remark. The group $W(\mathbb{Q})$ is computed in [**MH1973**, Chapter IV.2] or alternatively in [**Lam2005**, Chapter VI.4].

Exercise 133.4. Let M be a closed oriented 3-dimensional smooth manifold. Show that $\operatorname{sign}(M \times [0,1]) = 0$.

Exercise 133.5.

(a) Let M be a closed oriented connected $4k$-dimensional topological manifold and let N be a closed oriented $4l$-dimensional topological manifold. Show that

$$\operatorname{sign}(M \times N) \;=\; \operatorname{sign}(M) \cdot \operatorname{sign}(N).$$

(b) We extend the definition of the signature from page 2916 by defining $\operatorname{sign}(M) = 0$ for any closed oriented connected topological manifold whenever $\dim(M) \not\equiv 0 \bmod 4$. Show that the conclusion of (a) holds without any restrictions on the dimensions of M and N.

Remark. This exercise is carried out in [**Brun2005**, Lemma 2.6].

Exercise 133.6. Let M be a closed non-orientable $4k$-dimensional smooth manifold. Let $p\colon \widetilde{M} \to M$ be the orientation covering that we introduced on page 1109. Show that $\operatorname{sign}(\widetilde{M}) = 0$.

Exercise 133.7.

(a) Explain how to modify the proof of the Anti-Symmetric Forms Proposition 133.2 so that it also holds for the integers.

(b) Explain why the proof of the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 cannot be generalized to the integers.

Exercise 133.8. Let A and C be invertible real $k \times k$-matrices. We assume that C is symmetric.

(a) Show that the signature of the matrix $\begin{pmatrix} 0 & A \\ A^T & C \end{pmatrix}$ is zero.

(b) Does the conclusion of (a) still hold if A and C are not invertible?

Exercise 133.9. For which $k \in \mathbb{Z}$ does there exist a closed oriented 3-dimensional smooth manifold N with $\operatorname{sign}(S^1 \times N) = k$?

Exercise 133.10. Let $A \in \mathrm{GL}(n, \mathbb{R})$. Show that

$$b^+(\varphi(A)) \;=\; \max\left\{ k \in \mathbb{N}_0 \;\middle|\; \begin{array}{l} \text{there exists a } k\text{-dimensional subspace } V \\ \text{of } \mathbb{R}^n \text{ with } v^T A v > 0 \text{ for all } v \in V \cap S^{n-1} \end{array} \right\}.$$

Exercise 133.11. Show that the map

$$\begin{array}{rcl} \{A \in \mathrm{GL}(n, \mathbb{R}) \,|\, A = A^T\} & \to & \mathbb{Z} \\ A & \mapsto & \operatorname{sign}(A) \end{array}$$

is continuous.

Hint. You can work either with the definition of the signature (or better, with the reformulation given in Exercise 133.10) or you could use Proposition 5.42.

Exercise 133.12. Show "by hand" that the forms on $\mathbb{Z}^3$ defined by the matrices

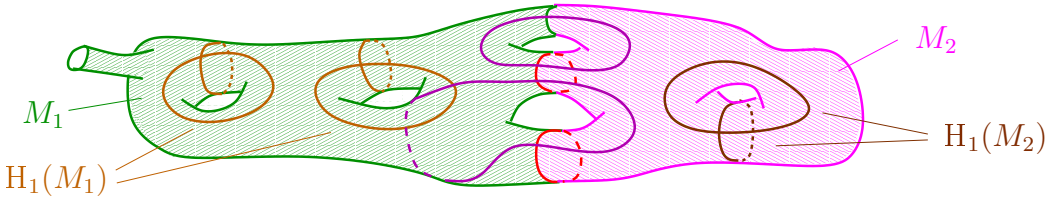
$$A \;=\; \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad B \;=\; \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

are isometric.

Exercise 133.13. Let $\varphi\colon V \times V \to \mathbb{Z}$ be a form over $\mathbb{Z}$. Show that there exists a non-degenerate form $\psi\colon W \times W \to \mathbb{Z}$ such that φ is isometric to the orthogonal sum of ψ with a form that is identically zero.

Exercise 133.14. Show that two non-singular symmetric forms (V, κ) and (W, λ) over $\mathbb{F}_2$ are isometric if and only if $\dim(V) = \dim(W)$ and if κ and λ have the same parity.

134. The Intersection Form III: The Novikov Additivity Theorem

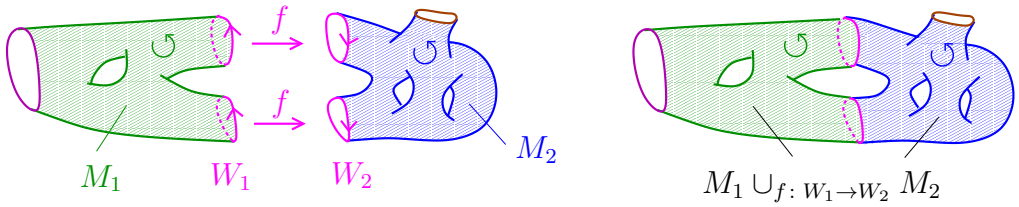


134.1. **Statement of the Novikov Additivity Theorem.** Let M be a compact oriented $4k$-dimensional topological manifold M. On page 2800 we introduced the intersection form

$$\begin{array}{rcl} Q_M\colon \mathrm{H}_{2k}(M)\times \mathrm{H}_{2k}(M) & \to & \mathbb{Z}. \\ (\varphi,\psi) & \mapsto & \langle \mathrm{PD}(\varphi)\cup \mathrm{PD}(\psi),[M]\rangle. \end{array}$$

On page 2916 we defined the signature $\mathrm{sign}(M)$ of a M as the signature of the intersection form Q_M.

In the Intersection Form-Additivity Proposition 132.12 we saw that the intersection form is additive under the connected sum operation. In the Manifold-Signature Lemma 133.11 we pointed out that this implies that the signature is additive under the connected sum operation.



In general, as we can see in the example below, if we glue two compact oriented $4k$-dimensional topological manifolds M_1 and M_2 along arbitrary boundary components, then the middle homology is in general not additive. In particular the intersection form is certainly in no way additive.

Rather surprisingly, the following theorem, which was first stated by Sergej Novikov [**Nov1970**, p. 154] in the mid 1960s, shows that the signature is additive under gluing along boundary components.

Theorem 134.1. (Novikov Additivity Theorem) Let M_1 and M_2 be two compact oriented $4k$-dimensional topological manifolds, let W_1 be a union of components of ∂M_1 and let W_2 be a union of components of ∂M_2. Finally let $f\colon W_1\to W_2$ be an orientation-reversing homeomorphism. Then

$$\mathrm{sign}\Big(\underbrace{M_1\cup_{f\colon W_1\to W_2} M_2}_{\substack{\text{by the Gluing-Topological}\\ \text{Manifolds-Proposition 75.8 this is an}\\ \text{oriented topological manifold}}}\Big) = \mathrm{sign}(M_1)+\mathrm{sign}(M_2).$$

Example.

(1) In Exercise 134.1 we will use the Novikov Additivity Theorem 134.1 to give a new proof that the signature is additive under the connected sum operation. This gives an alternative proof of the Manifold-Signature Lemma 133.11 (2).

(2) In Exercise 134.2 we will use the Novikov Additivity Theorem 134.1 to show that the signature of the double of a compact oriented $4k$-dimensional topological manifold is necessarily zero.

Remark.

(1) If one glues two $4k$-manifolds along submanifolds of the boundary that are not union of components, then in general the conclusion of the Novikov Additivity Theorem 134.1 no longer holds.

For example, by the discussion on page 2882 we know that $\text{sign}(\mathbb{C}\text{P}^2) = 1$. On the other hand the Handle Decomposition Theorem 138.5 says that every closed smooth manifold, in particular $\mathbb{C}\text{P}^2$, can be obtained iteratively by handle attachments.[1631] Each handle has vanishing homology, in particular vanishing intersection form and thus signature zero.

(2) In this more general setting, where we glue smooth manifolds along submanifolds of the boundary, C. T. C. Wall [**Wall1969**] proved a refinement of the Novikov Additivity Theorem 134.1. This refinement is usually referred to as the Wall Non-Additivity Theorem. A detailed discussion is given in [**Brun2005**, Chapter 5].

Before we move on to the long and exhausting proof of the Novikov Additivity Theorem 134.1 let us state the general theorem for general culture. It says that the signature is essentially the only invariant of compact oriented smooth manifolds that has the additivity property stated in the Novikov Additivity Theorem 134.1.

Theorem 134.2. (Jänich Theorem) Let $k \in \mathbb{N}$. If φ is a real valued orientation-preserving diffeomorphism[1632] invariant for compact oriented $4k$-dimensional smooth manifolds that satisfies the additivity property stated in the Novikov Additivity Theorem 134.1, then there exists a $C \in \mathbb{R}$ such that for every closed oriented k-dimensional smooth manifold we have $\varphi(M) = C \cdot \text{sign}(M)$.

Proof. The theorem was proved by Klaus Jänich [**Jä1968, Jä1969**] in 1968. ■

The remainder of this chapter is dedicated to the proof of the Novikov Additivity Theorem 134.1. Except for readers who have an insatiable appetite for technical proofs it is perhaps best to just move on to the next chapter, which makes for much more pleasant reading.

134.2. **Proof of the Novikov Additivity Theorem I.** We start out with the following blanket convention that applies to the whole chapter.

Convention. Throughout the remainder of this chapter we will work for (co-) homology groups with real coefficients. To simplify the notation we drop the "; $\mathbb{R}$" throughout.

By definition, and if you want by the Cup Product-Naturality Proposition 115.4, the signature of an oriented 4-dimensional topological manifold Z is defined in terms of the intersection form

$$Q_Z \colon \text{H}_{2k}(Z) \times \text{H}_{2k}(Z) \ \to \ \mathbb{R}.$$

[1631] It follows from Exercise 137.3 that $\mathbb{C}\text{P}^2$ has a handle decomposition consisting of a single 0-handle, a single 2-handle and a single 4-handle.

[1632] It is not clear to me whether the analogous statement also holds for topological manifolds.

For our purpose it is more useful to completely bypass homology, despite our emotional attachment to it, and to work with cohomology throughout. This leads us to the following definition.

Definition. Given a compact oriented $4k$-dimensional topological manifold Z we consider the form

$$\begin{aligned} I_Z\colon \mathrm{H}^{2k}(Z,\partial Z)\times \mathrm{H}^{2k}(Z,\partial Z) &\to \mathbb{R}\\ (\varphi,\psi) &\mapsto \langle \varphi\cup\psi,[Z]\rangle. \end{aligned}$$

Note that by the Cup Product-Commutativity Proposition 115.3 we know that this form is symmetric.

Next recall that in the Reduced Intersection Form Proposition 132.21 we introduced the reduced intersection form and we showed that it is non-singular. The following proposition gives us the cohomological analogue of the reduced intersection form.

Proposition 134.3. Let Z be a compact oriented $4k$-dimensional topological manifold. We denote by $\delta\colon \mathrm{H}^{2k-1}(\partial Z)\to \mathrm{H}^{2k}(Z,\partial Z)$ the connecting homomorphism of the long exact sequence of the pair $(Z,\partial Z)$.

(1) The following equality of vector subspaces holds:[1633]

$$\mathrm{im}(\delta\colon \mathrm{H}^{2k-1}(\partial Z)\to \mathrm{H}^{2k}(Z,\partial Z)) \;=\; \mathrm{H}^{2k}(Z,\partial Z)^{\perp},$$

where we take "$\perp$" with respect to the pairing I_Z

(2) We write $\widehat{\mathrm{H}}^{2k}(Z,\partial Z) := \mathrm{coker}(\delta\colon \mathrm{H}^{2k-1}(\partial Z)\to \mathrm{H}^{2k}(Z,\partial Z))$. The form

$$\begin{aligned} I_Z^{\mathrm{red}}\colon \widehat{\mathrm{H}}^{2k}(Z,\partial Z)\times \widehat{\mathrm{H}}^{2k}(Z,\partial Z) &\to \mathbb{R}\\ ([\varphi],[\psi]) &\mapsto \langle \varphi\cup\psi,[Z]\rangle \end{aligned}$$

is well-defined and non-singular.

(3) We have $\mathrm{sign}(Z)=\mathrm{sign}(I_Z)=\mathrm{sign}(I_Z^{\mathrm{red}})$.

The proof of Proposition 134.3 will require the remainder of this section. In the proof of Proposition 134.3, and also later on in this chapter, we will need to make use of the Cup Product-Naturality Proposition 115.4. To facilitate reading the coming proofs it is perhaps convenient to have the statement of the Cup Product-Naturality Proposition 115.4 at hand:

Proposition 115.4. (Cup Product-Naturality Proposition) Let (X,A,B) and (Y,C,D) be two excisive triads of topological spaces. Let $f\colon (X,A,B)\to(Y,C,D)$ be a map. For all $p,q\in\mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^p(Y,C)\times \mathrm{H}^q(Y,D) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(Y,C\cup D)\\ \downarrow{\scriptstyle f^*\times f^*} & & \downarrow{\scriptstyle f^*}\\ \mathrm{H}^p(X,A)\times \mathrm{H}^q(X,B) & \xrightarrow{\cup} & \mathrm{H}^{p+q}(X,A\cup B). \end{array}$$

Next we introduce some notation which we will use throughout this chapter.

Notation.

(1) Given a real vector space V we denote by $\overline{V}=\mathrm{Hom}_{\mathbb{R}}(V,\mathbb{R})$ the dual vector space.

[1633] In the words of the definition in Exercise 132.4 this means that $\mathrm{im}(\delta\colon \mathrm{H}^{2k-1}(\partial Z)\to \mathrm{H}^{2k}(Z,\partial Z))$ is the radical of the form I_Z.

(2) Given a homomorphism $f\colon V \to W$ between two real vector spaces we denote by $\overline{f}\colon \overline{W} \to \overline{V}$ the dual homomorphism.
(3) Given a compact oriented m-dimensional topological manifold Z we consider the maps

$$\begin{array}{rcl} \mathrm{D}\colon \mathrm{H}^r(Z) & \to & \overline{\mathrm{H}^{m-r}(Z,\partial Z)} \\ \varphi & \mapsto & (\psi \mapsto \langle \varphi \cup \psi, [Z]\rangle) \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{D}\colon \mathrm{H}^r(Z,\partial Z) & \to & \overline{\mathrm{H}^{m-r}(Z)} \\ \varphi & \mapsto & (\psi \mapsto \langle \varphi \cup \psi, [Z]\rangle). \end{array}$$

It follows from the Manifold-Non Singularity Proposition 121.2, which is a consequence of the Poincaré Duality Theorem 119.1, that these two maps are isomorphisms.[1634]
(4) Given a compact oriented m-dimensional topological manifold Z we also consider the maps

$$\begin{array}{rcl} \widetilde{\mathrm{D}}\colon \mathrm{H}^r(Z,\partial Z) & \to & \overline{\mathrm{H}^{m-r}(Z,\partial Z)} \\ \varphi & \mapsto & (\psi \mapsto \langle \varphi \cup \psi, [Z]\rangle = I_Z(\varphi,\psi) \end{array}.$$

(5) We denote by

$$\begin{array}{rcl} i\colon \partial Z & \to & Z \\ j\colon (Z,\varnothing) & \to & (Z,\partial Z) \end{array}$$

the obvious maps.

The following lemma is closely related to Proposition 119.25.

Lemma 134.4. Let Z be a compact oriented m-dimensional topological manifold. For any $r \in \mathbb{N}_0$ we consider the following diagram:

$$\begin{array}{ccccccccc} \ldots & \longrightarrow & \mathrm{H}^{r-1}(\partial Z) & \xrightarrow{\delta} & \mathrm{H}^r(Z,\partial Z) & \xrightarrow{j^*} & \mathrm{H}^r(Z) & \xrightarrow{i^*} & \ldots \\ & & \cong\downarrow \mathrm{D} & & \cong\downarrow \mathrm{D} & \overset{\widetilde{\mathrm{D}}}{\searrow} & \cong\downarrow \mathrm{D} & & \\ \ldots & \longrightarrow & \overline{\mathrm{H}^{m-r}(\partial Z)} & \xrightarrow{\overline{i^*}} & \overline{\mathrm{H}^{m-r}(Z)} & \xrightarrow[\overline{j^*}]{} & \overline{\mathrm{H}^{m-r}(Z,\partial Z)} & \xrightarrow{\overline{\delta}} & \ldots \end{array}$$

The following statements hold:
(1) The top and bottom horizontal sequences are exact.
(2) The diagram commutes.

Proof. The top horizontal sequence is just the long exact sequence in cohomology of the pair $(Z,\partial Z)$, hence it is exact. It follows by the same argument as in Lemma 108.4 that applying the $\mathrm{Hom}_{\mathbb{R}}(-,\mathbb{R})$ functor preserves exactness. This shows that the bottom horizontal sequence is also exact.

We turn to the proof that the diagram commutes. First we show that the square to the left commutes. Recall that given a topological space X we denote by $\epsilon_X\colon \mathrm{H}_0(X) \to \mathbb{R}$ the augmentation map that we introduced on pages 1590 and 1914. Let $\alpha \in \mathrm{H}^{r-1}(\partial Z)$ and let

[1634] Note that this statement only holds since we work with $\mathbb{R}$-coefficients.

$\beta \in \mathrm{H}^{m-r}(Z)$. Then

$$\begin{array}{lllll}
(\mathrm{D}\circ\delta)(\alpha)(\beta) & \overset{\text{by definition}}{=} \langle \delta(\alpha)\cup\beta, [Z]\rangle & \overset{\text{Cap Product-Kronecker Lemma 116.4}}{=} \epsilon_Z((\delta(\alpha)\cup\beta)\cap[Z]) & & \\
& = \epsilon_Z(\beta\cap(\delta(\alpha)\cap[Z])) & = \epsilon_Z(\beta\cap i_*(\alpha\cap[\partial Z])) & & \\
& \overset{\text{Cup-Cap Lemma 116.7}}{=} \epsilon_{\partial Z}(i^*(\beta)\cap(\alpha\cap[\partial Z])) & \overset{\text{by the Cap Product-Connecting Homomorphism Lemma 116.10 and the Fundamental Class-of-Boundary Proposition 106.27}}{=} \langle \alpha\cup i^*(\beta), [\partial Z]\rangle & \overset{\text{by definition}}{=} (\overline{i^*}\circ\mathrm{D})(\alpha)(\beta).\\
& \overset{\text{Cap Product-Naturality Lemma 116.8 and the discussion on page 1594}}{=} & \overset{\text{by the above arguments run backwards}}{=} & &
\end{array}$$

We turn to the two triangles on the right. Let $\alpha \in \mathrm{H}^r(Z, \partial Z)$ and let $\beta \in \mathrm{H}^{m-r}(Z, \partial Z)$. We perform the following calculation:

$$(\mathrm{D}\circ j^*)(\alpha)(\beta) \overset{\text{by definition of D}}{=} \langle j^*(\alpha)\cup\beta, [Z]\rangle = \overbrace{\langle \alpha\cup\beta, [Z]\rangle}^{=\widetilde{\mathrm{D}}(\alpha)(\beta)} = \langle \alpha\cup j^*(\beta), [Z]\rangle \overset{\text{by definition of D}}{=} (\overline{j^*}\circ\mathrm{D})(\alpha)(\beta).$$

Cup Product-Naturality Proposition 115.4 applied to the map $(Z, \varnothing, \partial Z) \to (Z, \partial Z, \partial Z)$ and map $(Z, \partial Z, \varnothing) \to (Z, \partial Z, \partial Z)$

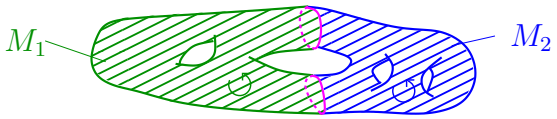
Conveniently enough this calculation takes care of both triangles. ■

Proof. Proof of Proposition 134.3] The lemma can be deduced, with a little bit of jiu-jitsu from the Reduced Intersection Form Proposition 132.21. But esthetically it is more appealing to give a direct proof. So let us do so.

(1) We have the equalities

$$\begin{array}{lll}
\mathrm{im}(\delta\colon \mathrm{H}^{2k-1}(\partial Z) \to \mathrm{H}^{2k}(Z, \partial Z)) & \overset{\text{by Lemma 134.4}}{=} & \ker\left(\mathrm{D}\circ\overline{j^*}\colon \mathrm{H}^{2k}(Z,\partial Z) \to \overline{\mathrm{H}^{2k}(Z,\partial Z)}\right)\\
& = \ker\left(\widetilde{\mathrm{D}}\colon \mathrm{H}^{2k}(Z,\partial Z) \to \overline{\mathrm{H}^{2k}(Z,\partial Z)}\right) & = \mathrm{H}^{2k}(Z,\partial Z)^{\perp}.\\
& \overset{\text{by Lemma 134.4 we have } \mathrm{D}\circ\overline{j^*} = \widetilde{\mathrm{D}}}{=} & \overset{\text{by definition of D and } I_Z}{=}
\end{array}$$

(2) It follows immediately from (1) "$\subset$", together with the symmetry of the cup product, that the form I_Z^{red} is well-defined. Furthermore it follows from (1) (b)"$\supset$" and some elementary algebra, see Exercise 132.4, that I_Z^{red} is non-singular.



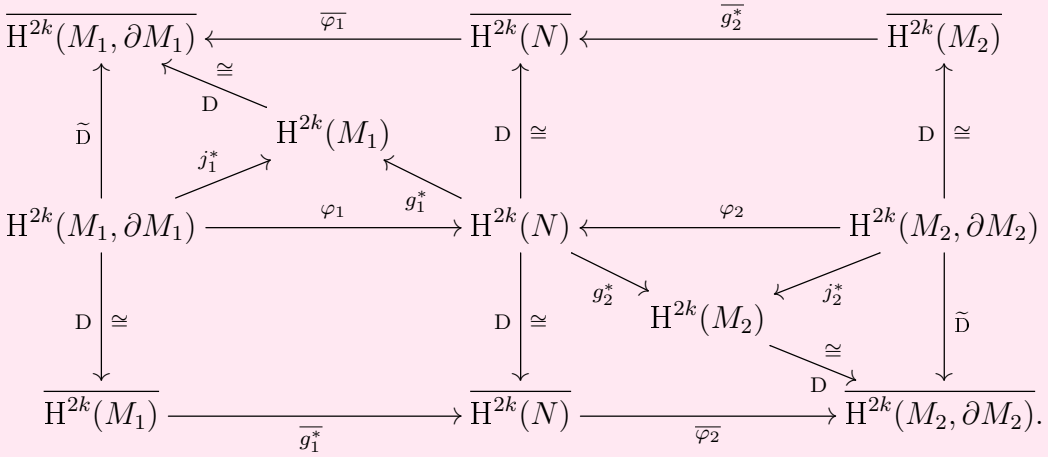
(3) Note that

$$\mathrm{sign}(Z) \overset{\text{Manifold-Signature Lemma 133.11}}{=} \mathrm{sign}(I_Z) \overset{\text{by Exercise 132.4}}{=} \mathrm{sign}\begin{pmatrix} 0 & 0\\ 0 & I_Z^{\mathrm{red}}\end{pmatrix} \overset{\text{Corollary 133.9}}{=} \mathrm{sign}(I_Z^{\mathrm{red}}).$$

■

134.3. **Proof of the Novikov Additivity Theorem II.** In this section we deal with the Novikov Additivity Theorem 134.1 in the special case that we glue the whole boundary of M_1 to the whole boundary of M_2.

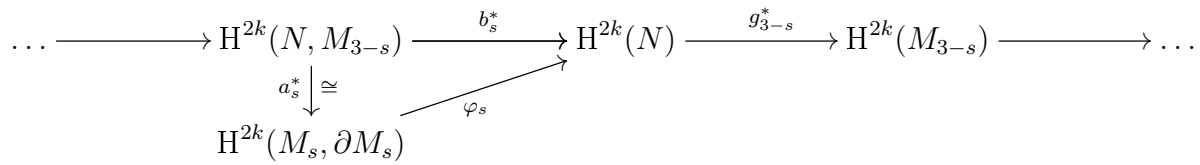
Proof of Theorem 134.1 if $W_1 = \partial M_1$ and $W_2 = \partial M_2$. Let M_1 and M_2 be two compact oriented $4k$-dimensional topological manifolds and let $f\colon \partial M_1 \to \partial M_2$ be an orientation-reversing homeomorphism. We set $N := M_1 \cup_{f\colon \partial M_1 \to \partial M_2} M_2$. We will use the Gluing-Topological Manifolds-Proposition 75.8 to view M_1 and M_2 as codimension-zero submanifolds of N. We need to show that $\mathrm{sign}(N) = \mathrm{sign}(M_1) + \mathrm{sign}(M_2)$.
For $s = 1, 2$ we denote by



$$\begin{aligned} a_s\colon (M_s, \partial M_s) &\to (N, M_{3-s}),\\ b_s\colon (N, \varnothing) &\to (N, M_{3-s}),\\ j_s\colon (M_s, \varnothing) &\to (M_s, \partial M_s)\\ g_s\colon M_s &\to N \end{aligned}$$

the obvious maps. Note that the induced map $a_s^*\colon \mathrm{H}^{2k}(N, M_{3-s}) \to \mathrm{H}^{2k}(M_s, \partial M_s)$ is an isomorphism by the Excision Theorem 109.1. Therefore we can define

$$\varphi_s := b_s^* \circ (a_s^*)^{-1}\colon \mathrm{H}^{2k}(M_s, \partial M_s) \to \mathrm{H}^{2k}(N).$$



Claim 1. We consider the following diagram:

This diagram has the following two properties:

(1) The top and bottom horizontal sequences are exact.
(2) The diagram commutes.

Proof. First we show that the top and bottom horizontal sequences are exact. For $s \in \{1, 2\}$ we consider the following diagram

The top horizontal sequence is just a segment of the long exact sequence in cohomology of the pair (N, M_{3-s}). As discussed above, the vertical map is an isomorphism by the Excision Theorem 109.1. By definition of φ_s the diagram commutes. It follows that the sequence with the $\mathrm{H}^{2k}(M_s, \partial M_s)$-term is also exact. It follows by the same argument as in Lemma 108.4 that applying the $\mathrm{Hom}_{\mathbb{R}}(-, \mathbb{R})$ functor preserves exactness. This concludes the proof that the top and bottom horizontal sequences in the big diagram are exact.

We turn to the proof of the commutativity of the diagram. By symmetry it suffices to show that the left-hand side commutes.

(a) First we consider the big triangle. The argument that this triangle commutes is quite similar to the proof of the Codimension-Zero Submanifold-PD Lemma 120.5. But for completeness' sake we carry out the details. Thus we now let $\alpha \in \mathrm{H}^{2k}(N)$ and we let $\beta \in \mathrm{H}^{2k}(M_1, \partial M_1)$. Next we set $\gamma := (a_1^*)^{-1}(\beta) \in \mathrm{H}^{2k}(N, M_2)$. We perform the following calculation:

$$\begin{array}{lll}
\overbrace{\langle g_1^*(\alpha) \cup \beta, [M_1]\rangle}^{=(D \circ g_1^*)(\alpha)(\beta)} & & \\
= \langle g_1^*(\alpha) \cup a_1^*(\gamma), [M_1]\rangle & \overset{\text{Cup Product-Naturality Proposition 115.4 applied to the map } (M_1, \varnothing, \partial M_1) \to (N, \varnothing, M_2)}{=} \langle g_1^*(\alpha \cup \gamma), [M_1]\rangle & \overset{\text{Lemma 109.6 (3)}}{=} \langle \alpha \cup \gamma, a_{1*}([M_1])\rangle \\
= \langle \alpha \cup \gamma, b_{1*}([N])\rangle & = \langle b_1^*(\alpha \cup \gamma), [N]\rangle & \\
\overset{\text{Codimension Zero-Fundamental Class Lemma 106.24}}{=} \langle \alpha \cup b_1^*(\gamma), [N]\rangle = \langle \alpha \cup (b_1 \circ (a_1^*)^{-1})(\beta), [N]\rangle = \underbrace{\langle \alpha \cup \varphi_1(\beta), [N]\rangle}_{=(\overline{\varphi_1} \circ D)(\alpha)(\beta)}. & & \\
\text{Cup Product-Naturality Proposition 115.4 applied to the map } (N, M_1, \varnothing) \to (N, M_1, M_1) & &
\end{array}$$

(b) We showed in Lemma 134.4 that the small triangle to the left commutes.

(c) We turn to the small triangle for which $\mathrm{H}^{2k}(N)$ is a vertex. First note that it follows immediately from the definitions that $b_1 \circ g_1 = a_1 \circ j_1 \colon (M_1, \varnothing) \to (N, M_2)$. This implies that $g_1^* \circ b_1^* = j_1^* \circ a_1^*$. Since $\varphi_1 = b_1^* \circ (a_s^*)^{-1}$ we see that $g_1^* \circ \varphi_1 = j_1^*$.

(d) Finally we consider the square at the bottom left. In (a) we just showed that

$$D \circ g_1^* = \overline{\varphi_1} \circ D \colon \mathrm{H}^{2k}(N) \ \to \ \overline{\mathrm{H}^{2k}(M_1, \partial M_1)}.$$

We take the $\mathrm{Hom}(-, \mathbb{R})$ dual of this statement. Using the symmetry of the cup product, see the Cup Product-Commutativity Proposition 115.3, we see that $\overline{\mathrm{D}} = \mathrm{D}$. Thus we obtain, as desired, that

$$\overline{g_1^*} \circ D = D \circ \varphi_1 \colon \mathrm{H}^{2k}(M_1, \partial M_1) \ \to \ \overline{\mathrm{H}^{2k}(N)}. \qquad \boxplus$$

Claim 2. For $s = 1, 2$ we set

$$A_s \ := \ \mathrm{im}(\varphi_s \colon \mathrm{H}^{2k}(M_s, \partial M_s) \to \mathrm{H}^{2k}(N)).$$

With respect to the form $I_N \colon \mathrm{H}^{2k}(N) \times \mathrm{H}^{2k}(N) \to \mathbb{R}$ we have the following equalities:

$$(1) \quad A_s^\perp \ = \ A_{3-s} \qquad \text{and} \qquad (2) \quad (A_1 \cap A_2)^\perp \ = \ A_1 + A_2.$$

Proof. First we prove Equality (1). This equality follows immediately from the commutative diagram in Claim 1, the fact that the bottom sequence is exact and one minute's worth of concentration. More precisely, we consider the following diagram, which is just given by a slight reorganization of the bottom part of the commutative diagram in Claim 1:

$$\begin{array}{ccccc}
\mathrm{H}^{2k}(M_1, \partial M_1) & \xrightarrow{\varphi_1} & \mathrm{H}^{2k}(N) & \xrightarrow{g_2^*} & \mathrm{H}^{2k}(M_2) \\
\mathrm{D} \downarrow \cong & & \mathrm{D} \downarrow \cong & & \mathrm{D} \downarrow \cong \\
\overline{\mathrm{H}^{2k}(M_1)} & \xrightarrow{\overline{g_1^*}} & \overline{\mathrm{H}^{2k}(N)} & \xrightarrow{\overline{\varphi_2}} & \overline{\mathrm{H}^{2k}(M_2, \partial M_2)}.
\end{array}$$

Since the diagram commutes, since the bottom sequence is exact and since the vertical maps are isomorphisms we see that

$$\underbrace{\operatorname{im}\left(\varphi_1\colon \mathrm{H}^{2k}(M_1,\partial M_1)\to \mathrm{H}^{2k}(N)\right)}_{=A_1} \;=\; \underbrace{\ker\left(\overline{\varphi_2}\circ \mathrm{D}\colon \mathrm{H}^{2k}(N)\to \overline{\mathrm{H}^{2k}(M_2,\partial M_2)}\right)}_{=A_2^\perp}.$$

Thus we have shown that $A_1 = A_2^\perp$. The same argument shows that $A_2 = A_1^\perp$. This concludes the proof of Equality (1).

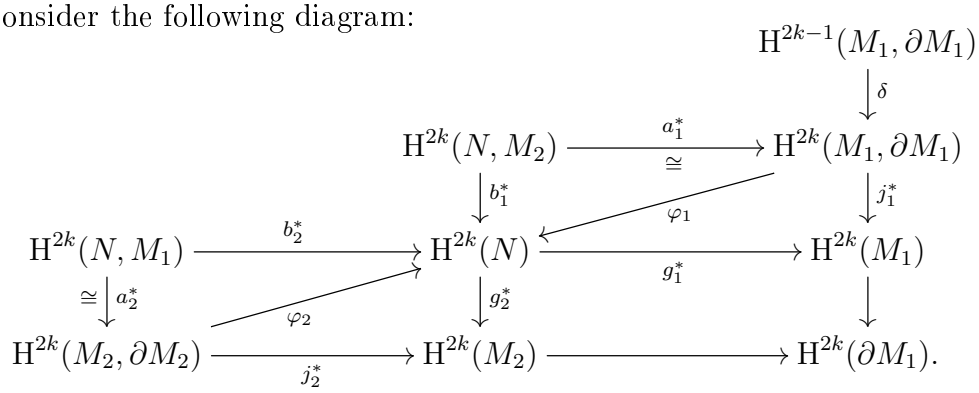
Next note that Equality (2) follows from Equality (1) together with some elementary algebra, see Exercise 132.5. For the reader's convenience we provide the argument. First note that it follows immediately from (1) that $A_1 + A_2 \subset (A_1 \cap A_2)^\perp$. To show equality it suffices to show that both vector subspaces have the same dimension. As the following calculation shows, this is indeed the case:

since N is closed we know by the Manifold-Non Singularity Proposition 121.2 that I_N is non-singular, hence for any vector subspace $B \subset \mathrm{H}^{2k}(N)$ we have $\dim(B^\perp) = \dim(\mathrm{H}^{2k}(N)) - \dim(B)$

$$\begin{array}{ccc} \dim((A_1\cap A_2)^\perp) & \overset{\downarrow}{=} & \dim(\mathrm{H}^{2k}(N))-\dim(A_1\cap A_2) \\ & = & \dim(A_1)+\dim(A_2)-\dim(A_1\cap A_2) \\ & \overset{\uparrow}{=} & \text{by (1)} \end{array} \qquad \begin{array}{ccc} & \overset{\downarrow}{=} & \dim(A_1)+\dim(A_1^\perp)-\dim(A_1\cap A_2) \\ & = & \dim(A_1+A_2). \\ & \overset{\uparrow}{=} & \text{since } 0\to A_1\cap A_2\to A_1\oplus A_2\to A_1+A_2\to 0 \text{ is exact} \end{array}$$ ⊞

Claim 3. Let $s \in \{1,2\}$. As in Proposition 134.3 we write

$$\widehat{\mathrm{H}}^{2k}(M_s,\partial M_s) \;:=\; \operatorname{coker}(\delta\colon \mathrm{H}^{2k-1}(\partial M_s)\to \mathrm{H}^{2k}(M_s,\partial M_s)).$$



The map

$$\varphi_s\colon \mathrm{H}^{2k}(M_s,\partial M_s) \;\to\; \mathrm{H}^{2k}(N)$$

induces an isomorphism

$$\begin{array}{rcl} \widehat{\varphi}_s\colon \widehat{\mathrm{H}}^{2k}(M_s,\partial M_s) & \to & A_s/(A_1\cap A_2) \\ [\sigma] & \mapsto & [\varphi_s(\sigma)]. \end{array}$$

Proof. We consider the following diagram:

We make the following clarifications and observations:

- All undecorated maps are induced by the obvious maps.
- The vertical sequences and the horizontal sequences are long exact sequences of pairs.
- All parts of the diagram commute. This basically follows from the definition of φ_s and φ_{3-s} and the fact that all the remaining maps are induced by maps of pairs of topological spaces. Note that the fact that the triangles involving φ_s, j_s^* and g_s^* commute was already discussed in Claim 1.

A little diagram chase now shows that each map $\widehat{\varphi}_s\colon \widehat{\mathrm{H}}^{2k}(M_s, \partial M_s) \to A_s/(A_1 \cap A_2)$, that is given by $[\sigma] \mapsto [\varphi_s(\sigma)]$, is well-defined and an isomorphism. ⊞

Claim 4. We consider the projections

$$p_s\colon \mathrm{H}^{2k}(M_s, \partial M_s) \to \widehat{\mathrm{H}}^{2k}(M_s, \partial M_s) \quad \text{and} \quad q\colon \mathrm{H}^{2k}(N) \to \mathrm{H}^{2k}(N)/(A_1 + A_2)$$

and we pick corresponding left-inverses

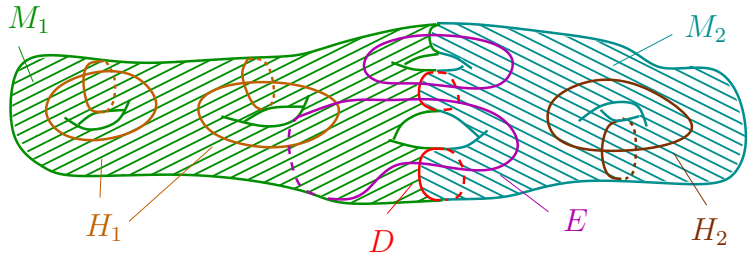
$$t_s\colon \widehat{\mathrm{H}}^{2k}(M_s, \partial M_s) \to \mathrm{H}^{2k}(M_s, \partial M_s) \quad \text{and} \quad u\colon \mathrm{H}^{2k}(N)/(A_1 + A_2) \to \mathrm{H}^{2k}(N).$$

Next we consider the following vector subspaces of $\mathrm{H}^{2k}(N)$:

$$\begin{aligned} H_1 &:= \operatorname{im}(\varphi_1 \circ t_1\colon \widehat{\mathrm{H}}^{2k}(M_1, \partial M_1) \to \mathrm{H}^{2k}(N)) \\ H_2 &:= \operatorname{im}(\varphi_2 \circ t_2\colon \widehat{\mathrm{H}}^{2k}(M_2, \partial M_2) \to \mathrm{H}^{2k}(N)) \\ D &:= A_1 \cap A_2 \\ E &:= \operatorname{im}(u\colon \mathrm{H}^{2k}(N)/(A_1 + A_2) \to \mathrm{H}^{2k}(N)). \end{aligned}$$

The following two statements hold:

(1) We have $\dim(D) = \dim(E)$.



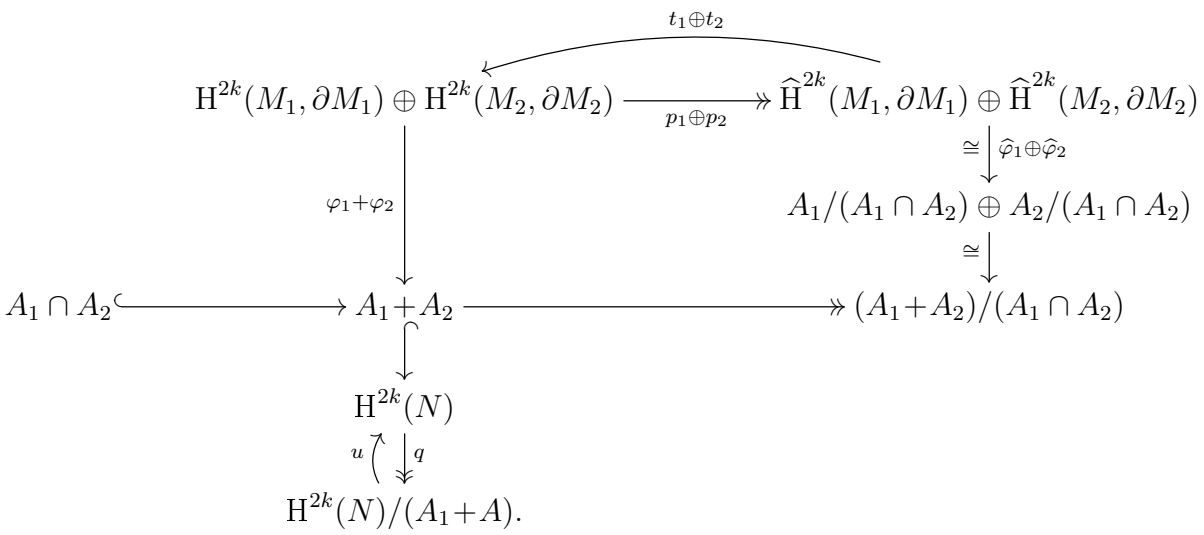
(2) The various inclusions induce an isomorphism

$$H_1 \oplus H_2 \oplus D \oplus E \xrightarrow{\cong} \mathrm{H}^{2k}(N).$$

(3) With respect to this decomposition of $\mathrm{H}^{2k}(N)$ given in (1) the form I_N can be written as follows:

$$I_N = \begin{array}{c} \\ H_1 \\ H_2 \\ D \\ E \end{array} \begin{array}{c} \begin{array}{cccc} H_1 & H_2 & D & E \end{array} \\ \begin{pmatrix} I^{\mathrm{red}}_{M_1} & 0 & 0 & * \\ 0 & I^{\mathrm{red}}_{M_2} & 0 & * \\ 0 & 0 & 0 & X \\ * & * & X^T & * \end{pmatrix} \end{array}$$

where X is represented by an invertible square matrix.

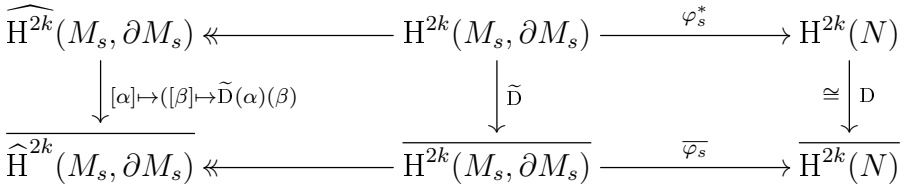


in each case the cohomology classes are the Poincaré duals of the homology classes

Proof.

(1) Recall that in the proof of Claim 2 (2) we already showed that we have the equality $\dim(A_1 \cap A_2) = \dim(N) - \dim(A_1 + A_2)$. But this means precisely that we have the promised equality $\dim(D) = \dim(E)$.

(2) We consider the following diagram:



The desired statement follows easily from the following observations:

- The central horizontal sequence is exact and the vertical sequence starting with $A_1 + A_2$ are exact.
- One can easily verify that the diagram commutes.

(3) The statement follows from the following three bullet points:

- The three zeros in the "D-column" and the "D-row" follow immediately from the fact, shown in Claim 3, that $(A_1 \cap A_2)^\perp = A_1 + A_2$.
- We consider the following diagram:

The square to the left commutes by definition and the square to the right commutes since it equals the upper left respectively the lower right quadrant of the diagram in Claim 1. But this means precisely that the "H_s-diagonal term" is given by $I^{\mathrm{red}}_{M_s}$.

- By (1) we know that X is a square matrix. The fact that X is invertible now follows from the fact, shown in the Manifold-Non Singularity Proposition 121.2, that I_N is non-singular. ⊞

Now we see that

$$\operatorname{sign}(N) = \operatorname{sign}(I_N) = \operatorname{sign}\begin{pmatrix} I^{\mathrm{red}}_{M_1} & 0 & 0 & * \\ 0 & I^{\mathrm{red}}_{M_2} & 0 & * \\ 0 & 0 & 0 & X \\ * & * & X^T & * \end{pmatrix} = \operatorname{sign}\begin{pmatrix} I^{\mathrm{red}}_{M_1} & 0 & 0 & 0 \\ 0 & I^{\mathrm{red}}_{M_2} & 0 & 0 \\ 0 & 0 & 0 & X \\ 0 & 0 & X^T & * \end{pmatrix}$$
$$= \operatorname{sign}(I^{\mathrm{red}}_{M_2}) + \operatorname{sign}(I^{\mathrm{red}}_{M_2}) + \underbrace{\operatorname{sign}\begin{pmatrix} 0 & X \\ X^T & * \end{pmatrix}}_{=0 \text{ by Exercise 133.2, (or Lemma 144.8), since } X \text{ is invertible}} = \operatorname{sign}(M_1) + \operatorname{sign}(M_2).$$

Proposition 134.3 (3) — since X is invertible there exists an isometry between the two forms — by Corollary 133.9 (2) — Proposition 134.3 (3)

■

134.4. **Proof of the Novikov Additivity Theorem III.** Before we formulate the next special case of Theorem 134.1 we introduce some definitions.

Definition.

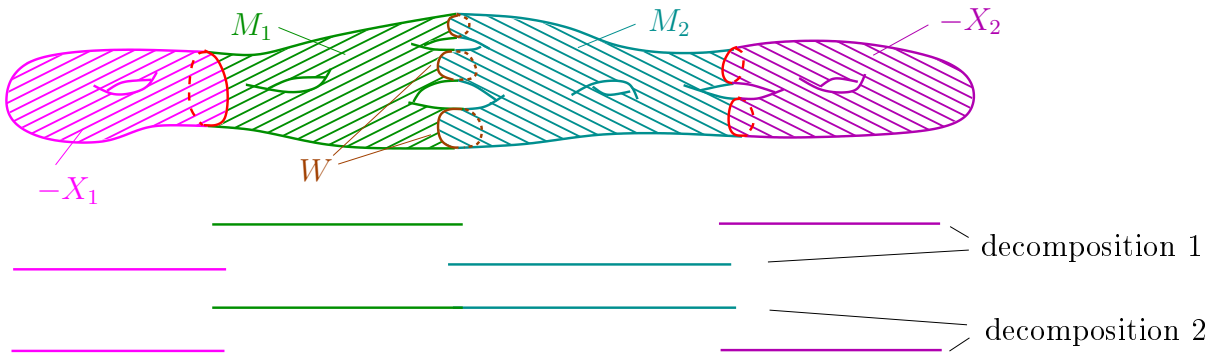
(1) We say that a closed oriented n-dimensional topological manifold S is nullbordant if there exists a compact oriented $(n+1)$-dimensional topological manifold T such that $\partial T = S$ as oriented topological manifolds. Such a T is called a nullbordism for S.

(2) In the setting of the Novikov Additivity Theorem 134.1 we refer to each of $\partial M_1 \setminus W_1$ and $\partial M_2 \setminus W_2$ as the unglued boundary

With this definition we can formulate the next special case of the Novikov Additivity Theorem 134.1 that we can deal with.

Proof of Theorem 134.1 if the unglued boundaries are nullbordant. We assume that the unglued boundary $\partial M_1 \setminus W_1$ and $\partial M_2 \setminus W_2$ are nullbordant. By the above definition this means that there exist compact oriented $4k$-dimensional topological X_1 and X_2 with $\partial X_s = \partial M_s \setminus W_s$ as oriented topological manifolds. Using the homeomorphism $f\colon W_1 \to W_2$ we can write $W := W_1 = W_2$. We perform the following calculation:

$$\operatorname{sign}(-X_1 \cup_{\partial M_1 \setminus W_1} M_1 \cup_W M_2 \cup_{\partial M_2 \setminus W_2} -X_2) \overset{\text{special case applied to } M_1 \sqcup -X_2 \text{ glued to } M_2 \sqcup -X_1 \text{ glued along the common boundary}}{=} \operatorname{sign}(M_1 \sqcup -X_2) + \operatorname{sign}(M_2 \sqcup -X_1)$$
$$= \operatorname{sign}(M_1) + \operatorname{sign}(M_2) - \operatorname{sign}(X_1) - \operatorname{sign}(X_2).$$



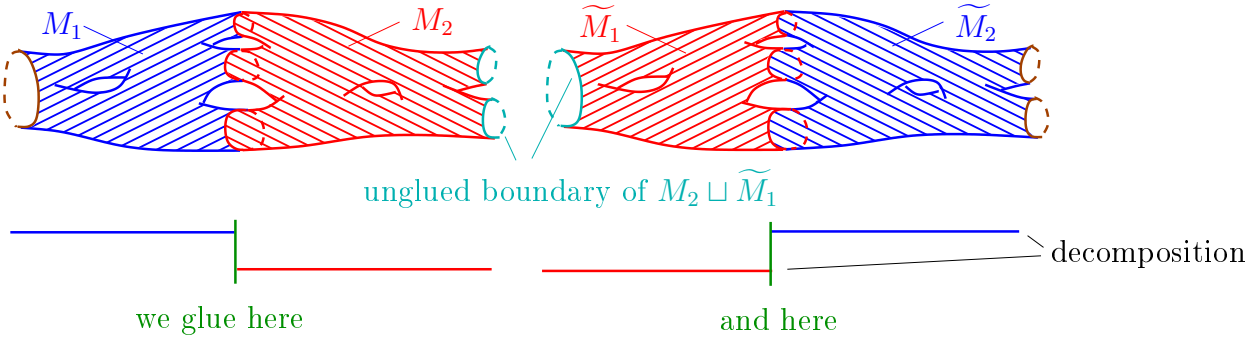
by the Manifold-Signature Lemma 133.11 we have $\operatorname{sign}(A \sqcup B) = \operatorname{sign}(A) + \operatorname{sign}(B)$ and we have $\operatorname{sign}(-A) = -\operatorname{sign}(A)$

Since this was so much fun we compute the signature of the glued manifold once again with a different decomposition:

$$\operatorname{sign}(-X_1 \cup_{\partial M_1 \setminus W_1} M_1 \cup_W M_2 \cup_{\partial M_2 \setminus W_2} -X_2) \overset{\text{special case applied to } M_1 \cup_W M_2 \text{ glued to } -X_2 \sqcup -X_1 \text{ glued along the common boundary}}{=} \operatorname{sign}(M_1 \cup_W M_2) + \operatorname{sign}(-X_1 \sqcup -X_2)$$
$$= \operatorname{sign}(M_1 \cup_W M_2) - \operatorname{sign}(X_1) - \operatorname{sign}(X_2).$$

Comparing these two calculations we obtain the desired result. ■

Now we can finally turn to the proof of the general case of the Novikov Additivity Theorem 134.1.



Proof of the Novikov Additivity Theorem 134.1. Let $\widetilde{M}_1$ and $\widetilde{M}_2$ be copies of M_1 and M_2. Furthermore we denote by $\widetilde{W} = \widetilde{W}_1 = \widetilde{W}_2$ a copy of $W = W_1 = W_2$. We perform the following calculation:

$$\begin{aligned} 2 \cdot \operatorname{sign}(M_1 \cup_W M_2) &= \operatorname{sign}\big((M_1 \cup_W M_2) \sqcup (\widetilde{M}_1 \cup_{\widetilde{W}} \widetilde{M}_2)\big) \\ &= \operatorname{sign}\big((M_1 \sqcup \widetilde{M}_2)_{W \sqcup \widetilde{W}} (\widetilde{M}_1 \sqcup M_2)\big) \\ &= \operatorname{sign}\big(M_1 \sqcup \widetilde{M}_2\big) + \operatorname{sign}\big(\widetilde{M}_1 \sqcup M_2\big) \;=\; 2 \cdot (\operatorname{sign}(M_1) + \operatorname{sign}(M_2)). \end{aligned}$$

follows from the previous special case, which we can apply for the following reason:
unglued boundary of $M_1 \sqcup \widetilde{M}_2$ is the boundary of $\widetilde{M}_1 \cup_{\widetilde{W}_1 = W_2} M_2$, in particular it is nullbordant,
unglued boundary of $\widetilde{M}_1 \sqcup M_2$ is the boundary of $M_1 \cup_{W_1 = \widetilde{W}_2} \widetilde{M}_2$, in particular it is nullbordant

the Manifold-Signature Lemma 133.11

Dividing both sides by 2 gives us the desired result. ∎

Exercises for Chapter 134.

Exercise 134.1. Use the Novikov Additivity Theorem 134.1 to show that the signature is additive under the connected sum operation.
Remark. This gives a new proof of the Manifold-Signature Lemma 133.11 (2).

Exercise 134.2. Let M be a compact oriented $4k$-dimensional topological manifold and let W be the union of some components of ∂M. As on page 1667 we refer to

$$\mathrm{D}_W M \;:=\; (M \times \{1\}) \cup_{W \times \{1\} = W \times \{2\}} (M \times \{2\})$$

as the *double of M along W*. By Lemmas 75.12 and 105.18 we know that $\mathrm{D}_W M$ is a compact orientable topological manifold. Show that the signature of $\mathrm{D}_W M$ is zero.

Exercise 134.3. Let $k \in \mathbb{N}$. Give an example of two compact oriented 4-dimensional topological manifolds M_1 and M_2 together with a homeomorphism $f\colon \partial M_1 \to \partial M_2$ such that the following statements are satisfied:

(a) $b_2(M_1) = k$ and $b_2(M_2) = k$.
(b) The inclusion induced maps $\mathrm{H}_2(M_1) \to \mathrm{H}_2(M_1 \cup_f M_2)$ and $\mathrm{H}_2(M_2) \to \mathrm{H}_2(M_1 \cup_f M_2)$ are both the zero map.

135. The intersection form IV: 4-dimensional manifolds

We have now introduced lots of invariants of topological spaces, namely the fundamental group, higher homotopy groups, homology groups and the cohomology groups together with the cup product. The question arises, whether we are done at some point, or whether this list of ever new invariants continues forever.
In an attempt to respond to this question we want to consider closed oriented simply connected 4-dimensional (topological) smooth manifolds and their intersection forms. What follows is a long survey on some amazing results. Unfortunately the proofs of any of these statements goes well beyond what we can cover in these introductory notes.
The following question will guide us through the chapter.

Question 135.1.

(1) Is the intersection form a complete invariant of closed oriented simply connected 4-dimensional (topological) smooth manifolds?[1635]
(2) Which isometry types of non-singular symmetric forms are realized by closed oriented simply connected 4-dimensional (topological) smooth manifolds?

135.1. **The K3-surface and Rokhlin's Theorem.** In the following we will give a mostly chronological account of the developments regarding the two (or possibly four?) questions posed in Question 135.1.
On page 2911 we introduced the initially rather unexpected form E_8. One might wonder whether a form as strange as E_8 can ever appear "in nature". As we will now see, somewhat surprisingly this is indeed the case.

Definition. We refer to

$$\mathrm{K3} := \left\{[z_0 : z_1 : z_2 : z_3] \in \mathbb{C}\mathrm{P}^3 \,\middle|\, z_0^4 + z_1^4 + z_2^4 + z_3^4 = 0\right\}$$

as the K3-surface. Sometimes the K3-surface is also called the Kummer surface.

Remark. The odd name "K3-surface" comes about as follows.

(1) First of all, as we will see in Proposition 135.2, K3 is a *2-dimensional* complex manifold, i.e. it is a complex *surface*.
(2) According to [**OTL2016**] the definition of the K3-surface is already implicit in the work of Srinivasa Ramanujan in the 1910s. The K3-surface was (re-) discovered by André Weil [**Weil1958**] who named it in honor of three algebraic geometers, Kummer, Kähler and Kodaira, and also the mountain K2 in Pakistan which is the second highest mountain on earth. More precisely, André Weil wrote: "Dans la seconde partie de mon rapport, il s'agit des varietés kählériennes dites K3, ainsi nommées en l'honneur de Kummer, Kähler, Kodaira et de la belle montagne K2 au Cachemire".

The following proposition summarizes some of the key aspects of the K3-surface.

[1635]Note that for a simply connected 4-dimensional topological manifold M we have $\mathrm{H}_1(M;\mathbb{Z}) = 0$ by the Hurewicz Theorem 84.5. If M is closed and orientable, then we have $\mathrm{H}_3(M;\mathbb{Z}) = 0$ by the Poincaré Duality Theorem 119.1. Thus we see that for closed oriented simply connected 4-dimensional topological manifolds the intersection form contains all the (co-) homological data we could ask for.

the mountain K2, almost as pretty as the K3-surface

Proposition 135.2. (K3-Intersection Form Proposition) The K3-surface is a closed simply connected complex manifold of complex dimension 2 or equivalently of real dimension 4. Furthermore we have

$$\text{intersection form of the K3-surface} \;\cong\; 2 \cdot E_8 \oplus 3 \cdot H.$$

Proof. All the statements are proved in [**GoS1999**, Theorem 1.3.8] or alternatively [**McS2016**, p. 176]. The intersection form is also calculated in [**Huy2016**, Proposition 3.5]. The calculation of the intersection form, perhaps somewhat disappointingly, makes use of the Indefinite Even Forms Corollary 133.19. ■

Remark. The K3-surface, albeit with a somewhat different definition as ours, plays a big role in (algebraic) geometry, as is indicated by the fact that a whole book [**Huy2005**] is dedicated to the study of the K3-surface(s). Note that it follows from [**Huy2016**, Theorem 2.4.2 and 7.1.1] that the K3-surface as defined above, viewed as a smooth manifold, admits many non-biholomorphic complex structures.[1636]

In the following we want to discuss one particular aspect of the K3-surface. Namely, the calculation of the intersection form of the K3-surface, of the intersection form of $S^2 \times S^2$ and the Intersection Form-Additivity Proposition 132.12 raises the question whether one can split off copies of $S^2 \times S^2$ form the K3-surface. More precisely the following question arose almost immediately after the introduction of the K3-surface.

Question 135.3.

(1) Does there exist a closed oriented 4-dimensional topological manifold M such that the K3-surface is homeomorphic to $M \# S^2 \times S^2$?

(2) Does there exist a closed oriented 4-dimensional smooth manifold M such that the K3-surface is diffeomorphic to $M \# S^2 \times S^2$?

We will return to the question shortly. But before we do so, we continue with our chronological discussion. Next in line is a result proved by Vladimir Rokhlin in 1952. To formulate Rokhlin's Theorem we need the notion of a "spin structure". The definition of a "spin structure" is for example given in [**GoS1999**, Chapter 1.4.2], but the precise definition is of no concern to us and we will use this notion as a black box. We just note that in the following we say that a smooth manifold is *spin*, if it admits a spin structure. We now state the key result on the existence of spin structures in our context.

Proposition 135.4. Let X be a closed oriented 4-dimensional smooth manifold.

(1) If X is spin, then the intersection form Q_X is even.

[1636] We had seen already in Corollary 63.2 that there exist complex manifolds that are diffeomorphic but not biholomorphic.

(2) If the intersection form Q_X is even and if $\mathrm{H}_1(X;\mathbb{Z})$ has no 2-torsion, then the smooth manifold X is spin.

Proof. The proposition is the content of [**GoS1999**, Corollary 5.7.6], which in turn is proved using the "Wu formula". The proposition is also discussed in [**Scor2005**, p. 163]. ■

Now let us state Rokhlin's celebrated theorem.

Theorem 135.5. (Rokhlin 1952) Let X be a closed oriented 4-dimensional smooth manifold. If X is spin, then $\mathrm{sign}(X)$ is divisible by 16.

Proof. This theorem was proved by Vladimir Rokhlin [**Rok1952**][**Rok1986a**, p. 21] in 1952. More modern proofs of Rokhlin's Theorem are given in [**FK1978**], [**LaM1989**, Theorem II.2.13 and Corollary IV.1.2] and [**Sav2002**, Theorem 2.1]. ■

Remark. We will now see that the converse to neither of the two statements in Proposition 135.4 holds.

(1) We consider the *Enriques surfaces*

$$X := \underbrace{\left\{[z_0:z_1:z_2:z_3] \in \mathbb{C}\mathrm{P}^3 \;\middle|\; z_0^4+z_1^4+z_2^4+z_3^4=0\right\}}_{=\text{K3-surface}} \Big/ (z_0,z_1,z_2,z_3) \sim (\overline{z}_1,-\overline{z}_0,\overline{z}_3,-\overline{z}_2).$$

We make the following observations:

(a) It is elementary to show that the equivalence relation $\sim$ on K3 defines a smooth free orientation-preserving action by the group $\mathbb{Z}_2$.

(b) It follows from (a) and Propositions 19.32 and 25.19 that the Enriques surface is a closed oriented connected 4-dimensional smooth manifold.

(c) Since the K3-surface is simply connected it follows from (a), together with Lemma 48.5, the Actions-Covering Proposition 48.9 and the Fundamental Group-via-Actions Theorem 48.16, that $\pi_1(X) \cong \mathbb{Z}_2$. In particular we obtain from the Hurewicz Theorem 84.5 that $\mathrm{H}_1(X;\mathbb{Z})$ has 2-torsion.

(d) As is shown in [**Hab1982**], the intersection form Q_X is isometric to $E_8 \oplus H$, in particular Q_X is even and $\mathrm{sign}(X) = 8$.

Note that it follows from (d) together with Rokhlin's Theorem 135.5 that X cannot be spin. In particular we see that the converse to Proposition 135.4 (1) does not hold. We refer to [**Hab1982**], [**FS1984**], [**GoS1999**, p. 93] and [**LaM1989**, p. 90] for more details on the Enriques surface.

(2) We consider the smooth manifold $S^1 \times \mathbb{R}\mathrm{P}^3$. It follows from the discussion on page 3066 that $S^1 \times \mathbb{R}\mathrm{P}^3$ is parallelizable, i.e. its tangent bundle is a trivial bundle. This implies that $S^1 \times \mathbb{R}\mathrm{P}^3$ admits a spin structure. Since $\mathrm{H}_2(S^1 \times \mathbb{R}\mathrm{P}^3;\mathbb{Z}) = 0$ we see that its intersection form is even. But $\mathrm{H}_1(S^1 \times \mathbb{R}\mathrm{P}^3) \cong \mathbb{Z} \oplus \mathbb{Z}_2$ has 2-torsion. Thus we see that the converse to Proposition 135.4 (2) does not hold.

The combination of Proposition 135.4 and Rokhlin's Theorem 135.5 gives us the following variation on Rokhlin's Theorem. This was historically the first result to address Question 135.1 (2).

Theorem 135.6. (Rokhlin 1952) Let X be a closed oriented 4-dimensional smooth manifold. If the intersection form Q_X is even and if $\mathrm{H}_1(X;\mathbb{Z})$ has no 2-torsion (e.g. if X is simply connected), then $\mathrm{sign}(X)$ is divisible by 16.[1637]

In a different direction the following theorem was the first noteworthy result towards an affirmative answer to Question 135.1 (1).

Theorem 135.7. (Milnor 1958) Let X and Y be two closed oriented simply connected 4-dimensional topological manifolds. Then

$$X \text{ and } Y \text{ are homotopy equivalent} \iff Q_X \text{ is isometric to } \pm Q_Y.$$

Proof. This theorem was proved for smooth manifolds by John Milnor [**Miln1958b**, Theorem 3] in 1958, building on work of John Whitehead [**WhdJ1949a**]. Furthermore [**GoS1999**, Theorem 1.2.25] and [**Kir1989**, Theorem 2.1] sketch a proof that also works for topological manifolds. ■

135.2. **The work of Michael Freedman and Simon Donaldson.** After the somewhat preliminary results by Vladimir Rokhlin and John Milnor the early 1980s saw two major breakthroughs by Michael Freedman and Simon Donaldson.
First, in 1981 Michael Freedman [**Fre1982**] gave a complete answer to Question 135.1 in the category of topological manifolds.[1638] More precisely, Michael Freedman [**Fre1982**] proved the following theorem.

Theorem 135.8. (Freedman 1981) Let Q be a nonsingular symmetric form over the integers.

(1) If Q is even, then up to an orientation-preserving homeomorphism, there exists a unique closed oriented simply connected topological manifold whose intersection form is isometric to Q.
(2) If Q is odd, then up to orientation-preserving homeomorphisms, there exist precisely two closed oriented simply connected topological manifolds whose intersection forms are isometric to Q. These two topological manifolds are distinguished by the Kirby-Siebenmann invariant which is discussed in the subsequent remark.

Remark.

(1) Let X be a simply connected closed topological manifold. By the Hurewicz Theorem 85.5 we know that the Hurewicz homomorphism $\pi_2(X) \to \mathrm{H}_2(X;\mathbb{Z})$ is an isomorphism. In particular, if $\pi_2(X)$ vanishes, then $\mathrm{H}_2(X;\mathbb{Z}) = 0$. This fact shows that Theorem 135.8, applied to the form on the trivial group $\{0\}$, implies that every homotopy 4-sphere is homeomorphic to S^4. We will discuss this in greater detail in Chapter **??**.
(2) The two homeomorphism types of Theorem 135.8 are distinguished by the Kirby-Siebenmann invariant[1639] $\mathrm{ks}(M) \in \mathrm{H}^4(M;\mathbb{Z}_2) = \mathbb{Z}_2$ of a closed connected non-empty 4-dimensional topological manifold M. This invariant is defined in [**KSi1977**, p. 318]

[1637] Recall that from the Even Forms Proposition 133.18 we know, for purely algebraic reasons, that the signature of a non-singular even symmetric form is divisible by 8.
[1638] Michael Freedman (*1951) is an American mathematician, in 1986 he was awarded the Fields medal for the proof of Theorem 135.8.
[1639] Here it is worth recalling that the Top-Cohomology Proposition 110.14 (3) says that for a closed connected non-empty 4-dimensional topological manifold we have $\mathrm{H}^4(X;\mathbb{Z}_2) \cong \mathbb{Z}_2$.

or alternatively in [**FQ1990**, Section 10.2B] and [**Rudy2016**, Chapter 3.4]. The Kirby-Siebenmann invariant has the following properties:

(a) By [**Rudy2016**, Theorem 3.4.3] this invariant vanishes if X admits a PL-structure.[1640] Recall that in Theorem 96.15 we saw that every smooth manifold admits a PL-structure. In particular we see that the Kirby-Siebenmann invariant vanishes for smooth manifolds. We refer to [**Cer1968**, p. IX] and [**Scor2005**, p. 220] for more details.

(b) By [**FNOP2019**, Theorem 7.3] the Kirby-Siebenmann invariant is additive under the connected sum operation.

(3) Freedman's Theorem also answers Question 135.3 (1) in the affirmative. More precisely, by the existence statement of Theorem 135.8 (1) there exists a closed oriented simply connected 4-dimensional topological manifold X with $Q_X \cong E_8$. It follows from Propositions 132.11 and 132.12, together with the uniqueness statement of Theorem 135.8 (1), there exists an orientation-preserving homeomorphism of the K3-surface to $X\#X\#3\cdot(S^2\times S^2)$.

(4) We conclude this remark with a quick foray into the high-dimensional world. For $n\geq 3$ Wall [**Wall1962**] (see also [**Ran2002**, p. 269]) classified diffeomorphism classes of pairs $(M,\partial M)$ where M is an orientable $(n-1)$-connected $2n$-dimensional smooth manifold and where the boundary ∂M is a homotopy sphere.[1641] The classification goes via the intersection form and one extra invariant which lies in the homotopy group $\pi_{n-1}(\mathrm{SO}(n))$.

Example. On page 2882 we saw that the intersection form of $\mathbb{C}\mathrm{P}^2$ is represented by the (1×1)–matrix (1). By (2b) we know that the Kirby-Siebenmann invariant of $\mathbb{C}\mathrm{P}^2$ vanishes. Theorem 135.8 (2) together with Remark (2) says that there exists a closed oriented simply connected 4-dimensional topological manifold, which usually is denoted by $*\mathbb{C}\mathrm{P}^2$, with the same intersection form as $\mathbb{C}\mathrm{P}^2$ but with non-zero Kirby-Siebenmann invariant. Theorem 135.8 (2) also says that $*\mathbb{C}\mathrm{P}^2$ is unique up to an orientation-preserving homeomorphism. The topological manifolds $\mathbb{C}\mathrm{P}^2$ and $*\mathbb{C}\mathrm{P}^2$ are not homeomorphic since the Kirby-Siebenmann invariants differ. But note that by Theorem 135.7 the topological manifolds $\mathbb{C}\mathrm{P}^2$ and $*\mathbb{C}\mathrm{P}^2$ are homotopy equivalent.

Among many other consequences we obtain the following rather surprising result.

Theorem 135.9. There exist closed orientable 4-dimensional topological manifolds that do not admit a smooth structure.

Proof. At this point we can combine the above results to give two types of examples of such smooth manifolds:

(1) It follows from Theorem 135.8 (2) and the above Remark (3) that given any non-singular odd symmetric form Q there exists a closed oriented 4-dimensional topological manifold X with $Q_X\cong Q$ and non-trivial Kirby-Siebenmann invariant. As we pointed out above in Remark (2a), this topological manifold does not admit a smooth structure.

[1640] We refer to page 2093 for the definition of a PL-structure.

[1641] See page 2625 for the definition of a homotopy sphere

(2) If we apply Freedman's Theorem 135.8 (1) to the non-singular positive-definite even form E_8 we obtain a certain closed oriented simply connected 4-dimensional topological manifold which, by Rokhlin's Theorem 135.6, cannot admit a smooth structure. ■

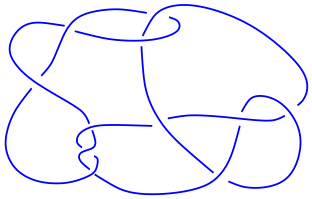
In a remarkable twist, shortly after Freedman proved his results on the intersection forms of 4-dimensional topological manifolds, Simon Donaldson[1642] "In 1982, when he was a second-year graduate student, Simon Donaldson proved a result that stunned the mathematical world." Simon Donaldson was awarded the Fields medal in 1986. , see [**Don1983**, Theorem A] and [**Don1987a**, Theorem 1], proved the following result regarding intersection forms of 4-dimensional smooth manifolds.[1643]

Theorem 135.10. (Donaldson 1982) Let X be a closed oriented connected 4-dimensional smooth manifold. If Q_X is positive-definite, then Q_X is represented by the identity matrix.

Example. We consider the positive-definite symmetric form $E_8 \oplus E_8$. It has signature 16, hence Rokhlin's Theorem 135.6 has no objections. But Donaldson's Theorem 135.10 implies that this form cannot be the intersection form of a closed oriented connected 4-dimensional smooth manifold.

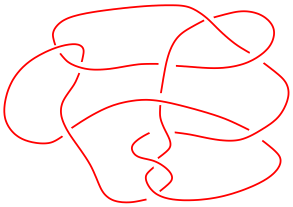
To understand the significance of Donaldson's Theorem, often referred to as *Donaldson's Theorem A*, recall that on page 2922 we saw that there are more than 10^{51} isometry classes of non-singular positive-definite symmetric forms of rank 40. By Freedman's Theorem 135.8 all of them arise as intersection forms of closed oriented connected 4-dimensional topological manifolds. By Donaldson's Theorem 135.10 the only one which appears as the intersection form of a closed oriented connected 4-dimensional smooth manifold is the one represented by the identity matrix.[1644]

Remark. It is difficult to exaggerate the importance of Donaldson's Theorem in mathematics.[1645] For example it is at the heart of the proof of Theorem **??** which says that $\mathbb{R}^4$ admits uncountably many smooth structures. But Donaldson's Theorem can also appear in totally unexpected situations. For example in 2017 Duncan McCoy [**McCoy2017**] used



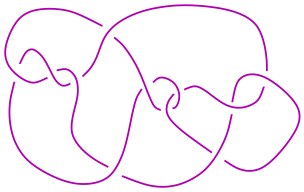
[1642]Simon Donaldson (*1957) is an English mathematician. He proved Theorem 135.10 when he was a second year PhD student. The Fields medalist Michael Atiyah described in [**At1987**] the work of Simon Donaldson as follows:

[1643]An exposition of the proof is also given in [**Law1985**] and a different proof, using Seiberg-Witten invariants is given in [**Nic2000**, Theorem 2.4.18] and a proof using Heegaard Floer homology is given in [**OS2003**, Theorem 9.1].



[1644]The identity matrix represents, by the Intersection Form-Additivity Proposition 132.12 and the discussion on page 2882, the intersection form of the connected sum of 40 copies of $\mathbb{C}P^2$.

[1645]Admittedly it is also hard to underestimate the role of Donaldson's Theorem outside of mathematics.



Donaldson's Theorem, and many other ingredients, to show that if K is an alternating knot with unknotting number one[1646], then such a crossing change can already be performed in an alternating diagram. For example, according to **[LiM]** the three alternating knots shown in the figure below have unknotting number one. By the aforementioned result we now know that we can turn these three knots into the trivial knot by changing a crossing in the alternating diagrams shown. Which crossings do you need to change?

the knot $11a_{12}$

the knot $11a_{41}$

the knot $11a_{56}$

Now that we have digested Donaldson's Theorem 135.10, the question arises, what can we say about *indefinite* intersection forms of closed oriented 4-dimensional smooth manifolds? First recall that in the Indefinite Odd Forms Corollary 133.17 we saw that every non-singular indefinite odd symmetric form is isometric to $m \cdot (1) \oplus n \cdot (-1)$ for some $m, n \in \mathbb{N}$. Next note that according to the Intersection Form-Additivity Proposition 132.12 and the discussion on page 2882 every such form is realized by the smooth manifold $m \cdot \mathbb{C}\mathrm{P}^2 \# n \cdot \overline{\mathbb{C}\mathrm{P}}^2$. Therefore, in the following we only need to discuss the realizability of non-singular indefinite *even* symmetric forms. Recall that in the Indefinite Even Forms Corollary 133.19 we showed that every non-singular even indefinite symmetric form is isometric to $m \cdot H \oplus n \cdot E_8$ for some $m \in \mathbb{N}_0$ and $n \in \mathbb{Z} \setminus \{0\}$. The following theorem, proved by Mikio Furuta **[Furu2001]** in 2001 gives some restrictions on the possible values of m and n.

Theorem 135.11. (Furuta's 10/8-Theorem) If M is a closed oriented connected 4-dimensional smooth manifold with *indefinite* even intersection form, then

$$b_2(M) \;\geq\; \tfrac{10}{8} \cdot \mathrm{sign}(M) + 2.$$

In particular[1647] $Q_M \cong m \cdot H \oplus n \cdot E_8$ with $m \geq |n| + 1$.

Remark. Furuta's 10/8-Theorem allows us to answer Question 135.3 (2) in the negative. More precisely, suppose that we have a decomposition of the K3-surface as a connected sum $M \# N$. We make the following four observations:

(1) Without loss of generality we have $\mathrm{sign}(M) \geq \mathrm{sign}(N)$.
(2) It follows from Proposition 135.2, the Parity Lemma 133.14 (3) and the Intersection Form-Additivity Proposition 132.12 that Q_M and Q_N are even.
(3) From the Manifold-Signature Lemma 133.11 (2) and Proposition 135.2 we obtain that $\mathrm{sign}(M) + \mathrm{sign}(N) = 16$.

[1646] We refer to page 1343 for the definition of the unknotting number of a knot. A knot is called *alternating* if it admits a diagram that is alternating, i.e. which has the property that each undercrossing is followed by an overcrossing and vice versa.

[1647] This second statement follows from the first statement together with the Indefinite Even Forms Corollary 133.19 and the calculation of the rank and signature of H and E_8.

(4) By Proposition 135.2 and the Connected Sum-Invariants Proposition 132.11 we know that $b_2(M) + b_2(N) = 22$.

If we combine these facts with Rokhlin's Theorem 135.6 we obtain easily that we have $\text{sign}(M) = 16$. Furthermore, it follows from Donaldson's Theorem 135.10 that Q_M is indefinite. Now Furuta's 10/8-Theorem implies that $b_2(M) \geq \frac{10}{8} \cdot 16 + 2 = 22$, but by Proposition 135.2 this equals $b_2(\text{K3})$. Thus we obtain from the Connected Sum-Invariants Proposition 132.11 that $b_2(N) = 0$.[1648] We can conclude that we cannot split off a copy of $S^2 \times S^2$ from K3. This answers Question 135.3 (2) in the negative.

Furuta's 10/8 Theorem is not yet optimal since it does not quite close the gap between the forms which we can realize by smooth manifolds and the forms which we can exclude. More precisely it follows from the Intersection Form-Additivity Proposition 132.12, the calculation of the intersection forms of the K3-surface, see Proposition 135.2, and of the intersection form of $S^2 \times S^2$ that for any $m \in \mathbb{Z} \setminus \{0\}$ and any $n \geq 3|m|$ there exists a closed oriented simply connected 4-dimensional smooth manifold with intersection form isometric to $m \cdot E_8 \oplus n \cdot H$. More precisely, we have

$$\text{intersection form of } m \cdot \text{K3} \,\#\, (n - 3|m|) \cdot (S^2 \times S^2) \;\cong\; m \cdot E_8 \oplus n \cdot H.$$

The following conjecture predicts that this result is optimal.

Conjecture 135.12. (11/8-Conjecture) If M is a closed oriented 4-dimensional smooth manifold with indefinite even intersection form, then

$$b_2(M) \;\geq\; \tfrac{11}{8} \cdot \text{sign}(M).$$

Equivalently, if $Q_M \cong m \cdot H \oplus n \cdot E_8$ with $n \neq 0$, then $m \geq \frac{3}{2}|n|$.[1649]

Remark.

(1) A proof of the 11/8-Conjecture would imply, by Freedman's Theorem 135.8, that any closed oriented simply connected 4-dimensional smooth manifold is *homeomorphic* to either a connected sum of the form $m \cdot \mathbb{C}\text{P}^2 \# n \cdot \overline{\mathbb{C}\text{P}}^2$ or alternatively to a connected sum of the form $m \cdot \text{K3} \# n \cdot (S^2 \times S^2)$.

(2) For simply connected smooth manifolds currently the best result is [**HLSX2018**, Corollary 1.13] which says that if M is a closed oriented simply connected 4-dimensional smooth manifold that is not homeomorphic to S^4, $S^2 \times S^2$ or the K3-surface and whose intersection form is indefinite and even, then $b_2(M) \geq \frac{10}{8} \cdot |\,\text{sign}(M)| + 4$.

The other question which arises in this context is whether closed orientable 4-dimensional smooth manifolds that are homeomorphic are also necessarily diffeomorphic. It turns out that in many cases the answer is very much no. For example the following theorem was proved in 1998 by Ron Fintushel and Ron Stern [**FS1998**].

[1648] By the Connected Sum-Invariants Proposition 132.11 and Proposition 135.2 we also know that $\pi_1(N) = 0$. Recall that by the Hurewicz Theorem 85.5 we know that if $\pi_1(N) = 0$ and $\text{H}_2(N; \mathbb{Z}) = 0$, then $\pi_2(N) = 0$. Thus it follows from Theorem **??** that N is homeomorphic to S^4. Since Question **??** is still open, we do not know whether N is diffeomorphic to S^4.

[1649] As before, the fact that these two statements are equivalent follows from the Indefinite Even Forms Corollary 133.19 and the calculation of the rank and signature of H and E_8.

Theorem 135.13. There exist closed orientable 4-dimensional smooth manifolds X_s, $s \in \mathbb{N}$ such that each X_s is homeomorphic to the K3-surface, but such that the X_s are pairwise non-diffeomorphic.

Similar results have been obtained for many other 4-dimensional smooth manifolds, e.g. for $\mathbb{C}\mathrm{P}^2 \# k\overline{\mathbb{C}\mathrm{P}}^2$ with $k = 9$ by Simon Donaldson [**Don1987a**] in 1987, $k = 8$ by Dieter Kotschick [**Kot1989**] in 1989 and $k = 7$ by Jongil Park [**Park2005**] in 2005, and since then also for $k = 6, 5, 4, 3, 2$, see e.g. [**AP2008, AP2010**] for more details on the history of this problem.

The following question is surely one of the most interesting problem in the theory of 4-dimensional smooth manifolds.

Question 135.14. Does every closed oriented connected 4-dimensional smooth manifold M admit infinitely many pairwise non-diffeomorphic smooth structures? Put differently, given any such M, do there always exist infinitely many smooth manifolds M_s, $s \in \mathbb{N}$ which are homeomorphic to M but which are pairwise non-diffeomorphic?

Note that an affirmative answer to Question 135.14 would also give a positive answer to Question **??**.

The following theorem shows that smooth manifolds that are homeomorphic are in fact "stably diffeomorphic".

Theorem 135.15. (Stable Diffeomorphism Theorem) Let M and N be two compact 4-dimensional smooth manifolds that are homeomorphic.[1650]

(1) If M and N are orientable, then there exists a $k \in \mathbb{N}$ such that $M \# k \cdot (S^2 \times S^2)$ and $N \# k \cdot (S^2 \times S^2)$ are diffeomorphic.
(2) If M and N are non-orientable, then there exists a $k \in \mathbb{N}$ such that $M \# k \cdot (S^2 \widetilde{\times} S^2)$ and $N \# k \cdot (S^2 \widetilde{\times} S^2)$ are diffeomorphic.[1651]

Proof.

(1) The theorem was first proved by Robert Gompf [**Gom1984**, p. 116] in 1984. An alternative proof, using Matthias Kreck's modified surgery [**Kre1999**] is given in [**Tei1992**, Theorem 5.1.1] and [**FNOP2019**, Theorem 12.2].
(2) The case that the smooth manifolds are closed and simply connected was first proved by C. T. C. Wall [**Wall1964**, Theorem 3] in 1964 (see also [**Scor2005**, p. 149] and [**Qu1983**, Theorem 1.1]). ■

This raises the question, whether in the above theorem $k = 1$ suffices. More precisely the following question is still open.

Question 135.16. Let M and N be two closed oriented simply connected 4-dimensional topological manifolds that homeomorphic. Is $M \# (S^2 \times S^2)$ diffeomorphic to $N \# (S^2 \times S^2)$?

There are some indications, see [**JZ2018**], that the answer to the above question should be no.

[1650] By the Smooth-Topological Orientation Proposition 105.11 we know that being orientable is a homeomorphism invariant.

[1651] Here $S^2 \widetilde{\times} S^2$ denotes the total space of the non-trivial S^2-bundle over S^2 that we introduced on page **??**.

Exercises for Chapter 135.

Exercise 135.1. As we discussed on 2943, it follows from Theorem 135.8 that there exists a closed orientable simply connected 4-dimensional topological manifold $*\mathbb{C}\mathrm{P}^2$ whose intersection form is represented by the (1×1)-matrix (1) and with $\mathrm{ks}(*\mathbb{C}\mathrm{P}^2)=1$.

Let M and N be two closed oriented simply connected 4-dimensional topological manifolds. Show that there exist $m,m',n,n'\in\mathbb{N}_0$ and $\epsilon\in\{0,1\}$ such that the topological manifolds $M\# m\cdot\mathbb{C}\mathrm{P}^2\# m'\cdot\overline{\mathbb{C}\mathrm{P}^2}\#\epsilon\cdot *\mathbb{C}\mathrm{P}^2$ and $N\# n\cdot\mathbb{C}\mathrm{P}^2\# n'\cdot\overline{\mathbb{C}\mathrm{P}^2}$ are homeomorphic.
Hint. Make use of the properties of the Kirby-Siebenmann invariant discussed on page 2943. Furthermore it is strongly advisable to use the Indefinite Forms Theorem 133.16.

Exercise 135.2. Let M and N be two closed oriented simply connected 4-dimensional smooth manifolds. Show that there exist $m,m',n,n'\in\mathbb{N}_0$ such that $M\# m\cdot\mathbb{C}\mathrm{P}^2\# m'\cdot\overline{\mathbb{C}\mathrm{P}^2}$ is diffeomorphic to $N\# n\cdot\mathbb{C}\mathrm{P}^2\# n'\cdot\overline{\mathbb{C}\mathrm{P}^2}$.
Remark. Make use of Exercise 135.1 and use the fact from page 2920 that the two smooth manifolds $(S^2\times S^2)\#\mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2\#\mathbb{C}\mathrm{P}^2$ are diffeomorphic.

Part XIV

Handle Structures and Morse Theory

136. Handle decompositions of smooth manifolds

As we have seen, CW-complexes and simplicial complexes have turned out to be useful tools in topology since often they make it possible to break a given topological space into smaller, more manageable pieces. In Theorems 96.2 and 96.5 we saw that every smooth manifold admits a simplicial structure, in particular it admits a CW-structure. Thus in principle we can study a smooth manifold by starting with a 0-dimensional CW-complex and attaching cells of dimensions $1, 2, \ldots$. The catch is that the inbetween objects are usually not smooth manifolds.

In this chapter we will introduce handle decompositions of smooth manifolds. These are in many ways quite similar to CW-structures, except that now all intermediate objects are smooth manifolds. In Chapter 138 we will use Morse theory to show that every compact smooth manifold admits a handle decomposition.

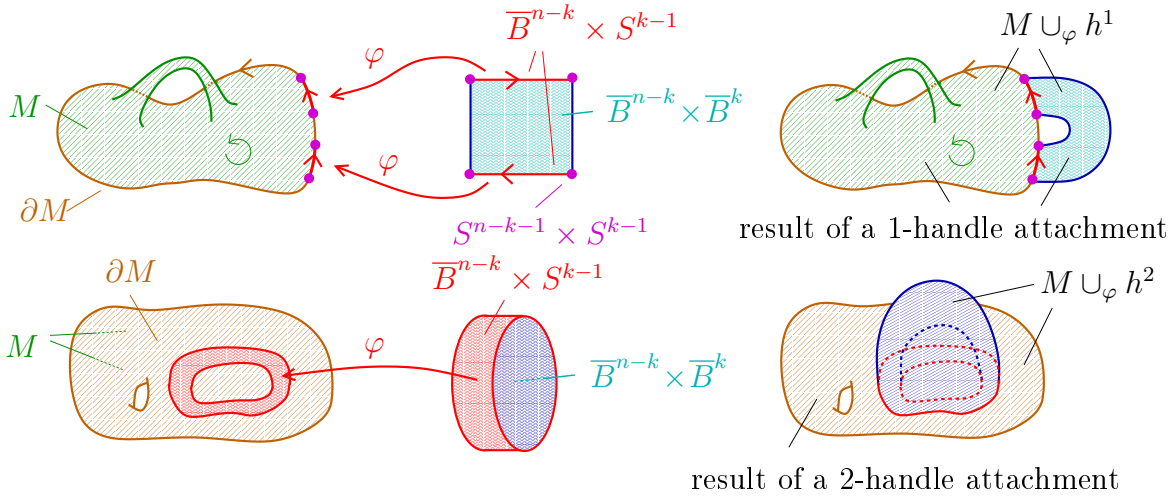
136.1. **Handle attachments.** The following definition is inspired by the definition of a thickened knot that we gave on page 2853.

Definition. Let W be an m-dimensional smooth manifold. A thickened l-sphere is a smooth embedding $\overline{B}^{m-l} \times S^l \to W$.

Our first proposition introduces the notion of a handle attachment and it summarizes some of the key properties.

Proposition 136.1. (Handle Attachment Proposition) Let M be a compact n-dimensional smooth manifold. Furthermore suppose that we are given a thickened $(k-1)$-sphere in the boundary ∂M, i.e. suppose we are given a smooth embedding $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$. We refer to[16521653]

$$M \cup_\varphi h^k \;:=\; M \cup_{\partial M \xleftarrow{\varphi} \overline{B}^{n-k} \times S^{k-1}} \left(\overline{B}^{n-k} \times \overline{B}^k\right)$$



as the result of a k-handle attachment to M. The following statements hold:

(1) (a) The topological space $M \cup_\varphi h^k$ is an n-dimensional topological manifold.
(b) Every choice of a collar[1654] $\Theta\colon [0,1] \times \partial M \to M$ equips $M \cup_\varphi h^k$ canonically with the structure of an n-dimensional smooth manifold. This smooth structure has the property that M and $\overline{B}^{n-k} \times \overline{B}^k$ are both submanifolds with corner, where the corner set in both cases is given by $\varphi(S^{n-k-1} \times S^{k-1})$.
(c) Let Θ and Ξ be two collars. By (1b) these two collars give rise to two smooth structures $\mathcal{A}_\Theta$ and $\mathcal{A}_\Xi$ on the topological manifold $M \cup_\varphi h^k$. Given any neighborhood U of the image of $\varphi(\overline{B}^{n-k} \times S^{k-1})$ in $M \cup_\varphi h^k$ there exists a homeotopy $H\colon (M \cup_\varphi h^k) \times [0,1] \to M \cup_\varphi h^k$ with the following four properties:
(i) $H_0 = \mathrm{id}$.
(ii) $H_1\colon (M \cup_\varphi h^k, \mathcal{A}_\Theta) \to (M \cup_\varphi h^k, \mathcal{A}_\Xi)$ is a diffeomorphism.
(iii) For each $t \in [0,1]$ the map h_t restricts to a diffeomorphism of M and it restricts to a diffeomorphism of $\overline{B}^{n-k} \times \overline{B}^k$.
(iv) $H(x,t) = x$ for all $x \notin U$ and all $t \in [0,1]$.
(d) Any two choices of collar neighborhoods give rise to diffeomorphic smooth structures on M.

(2) $M \cup_\varphi h^k$ is compact.
(3) The boundary of the smooth manifold $M \cup_\varphi h^k$ is given by

$$\partial(M \cup_\varphi h^k) \;=\; (\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup_{\varphi|_{S^{n-k-1}\times S^{k-1}}} (S^{n-k-1} \times \overline{B}^k).$$

(4) If $\varphi, \psi \colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ are two smooth embeddings that are smoothly isotopic, then $M \cup_\varphi h^k$ and $M \cup_\psi h^k$ are diffeomorphic. Furthermore, given any neighborhood U of ∂M one can find a diffeomorphism that is the identity on the common subset $M \setminus U$.

Remark.

(1) The fact that the precise smooth structure on $M \cup_\varphi h^k$ depends on a choice of a collar is a nuisance. Usually we use (1c) as an excuse to ignore this issue, albeit with a slightly bad conscience.
(2) The modification of the boundary that we saw in the Handle Attachment Proposition 136.1 (5) is called a *surgery along* $\varphi(\{0\} \times S^{k-1}) \subset \partial M$. We will study surgeries in greater detail in Chapter **??**.
(3) We deal with the question of whether $M \cup_\varphi h^k$ is orientable respectively connected in the Handle-Connected Lemma 136.8 and the Handles-Orientability Proposition 136.9.

Sketch of proof.

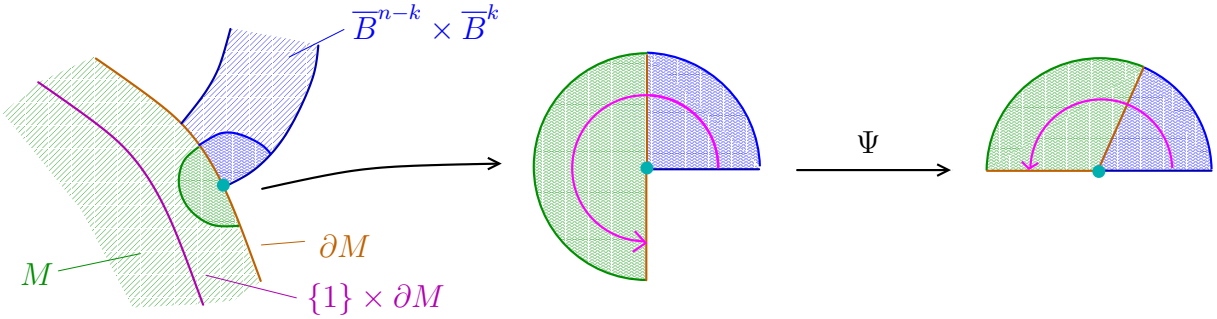
(1) The proof of Statement (1) is quite similar to the proof of the Gluing-Smooth Manifolds-Proposition **??** (1).
   (a) Let $\Theta \colon [0,1] \times \partial M \to M$ be a collar. We use this collar and the standard product neighborhood $[0,1] \times \overline{B}^{n-k} \times S^{k-1} \subset \overline{B}^{n-k} \times \overline{B}^k$ together with the argument from the proof of the Gluing-Smooth Manifolds-Proposition **??** (1) to find suitable

[1652] Recall that by the definition on page 262 this means that

$$M \cup_\varphi h^k \;:=\; \big(M \sqcup (\overline{B}^{n-k} \times \overline{B}^k)\big)/\!\sim \quad \text{where } \varphi(P) \sim P \text{ for } P \in \overline{B}^{n-k} \times S^{k-1}.$$

[1653] The fact that in the notation the map φ now goes from right to left is a little awkward, but all other conventions lead sooner or later also to slightly unnatural results.
[1654] Recall that by the Smooth Collar Neighborhood Theorem 28.3 a collar $[0,1] \times \partial M \to M$ always exists.

canonical charts for all points that do not lie on $\varphi(S^{n-k-1} \times S^{k-1})$. Furthermore, for points on $\varphi(S^{n-k-1} \times S^{k-1})$ one can easily find "charts" such that the image equals $\{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_{n-1} \leq 0 \text{ or } x_n \geq 0\}$. Similar to the proof of Proposition **??** we compose those charts with the map



$$\begin{array}{rcl} \Psi : \mathbb{R}^{n-2} \times \{(x,y) \in \mathbb{R}^2 \,|\, x \leq 0 \text{ or } y \geq 0\} & \to & \mathbb{R}^{n-2} \times \mathbb{R} \times \mathbb{R}_{\geq 0} \\ (x_1, \dots, x_{n-2}, \underbrace{r\cos(\varphi), r\sin(\varphi)}_{r \in \mathbb{R}_{\geq 0} \text{ and } \varphi \in [0, \frac{3}{2}\pi]}) & \mapsto & (x_1, \dots, x_{n-2}, r\cos(\tfrac{2}{3}\varphi), r\sin(\tfrac{2}{3}\varphi)). \end{array}$$

If one interprets the above discussion with good will, then one can see that this defines a smooth atlas on $M \cup_\varphi h^k$ which has all the desired properties.

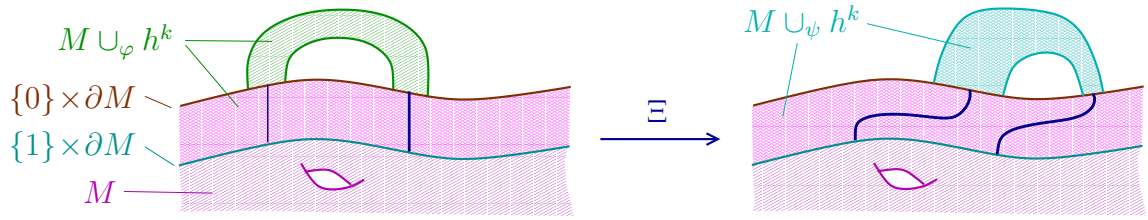
(b) We proved this statement already in (a).

(c) As in the proof of the Gluing-Smooth Manifolds-Proposition **??** (1c) this statement follows without too much effort from the uniqueness statement for collars, see the Uniqueness of Collar-Proposition **??**.

(d) This statement is an immediate consequence of (c).

(2) It follows from the compactness of M and $\overline{B}^{n-k} \times \overline{B}^k$ together with the Quotient-Compact Connected Lemma 5.16 (1) that $M \cup_\varphi h^k$ is compact.

(3) Similar to the proof of the Gluing-Smooth Manifolds-Proposition **??** (4) one can prove the statement about the description of $\partial(M \cup_\varphi h^k)$ quite easily using the Smooth Manifold Boundary Proposition 19.26.



(4) It follows from (1c) that throughout the proof of (4) we can work with the same collar neighborhood $[0,1] \times \partial M$. Now let $\varphi, \psi \colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be two smooth embeddings. We suppose that they are smoothly isotopic. Let $F \colon \overline{B}^{n-k} \times S^{k-1} \times [0,1] \to \partial M$ be a smooth homotopy with $F_0 = \varphi$ and $F_1 = \psi$. By the Isotopy Extension Theorem 36.1 together with the Trivial-Near-The-Ends-Lemma 33.4 there exists a diffeotopy $G \colon \partial M \times [0,1] \to \partial M$ with $G_t = \mathrm{id}$ for $t \in [0, \frac{1}{4}]$ and with $G_t \circ \varphi = \psi$ for all $t \in [\frac{3}{4}, 1]$. One can now easily verify that the map

$$\begin{array}{rcl} \Xi \colon M \cup_\varphi h^k & \to & M \cup_\psi h^k \\ [x] & \mapsto & \begin{cases} [x], & \text{if } x \in M \setminus ([0,1] \times \partial M), \\ [(t, G(1-t, y))], & \text{if } x = (t,y) \in [0,1] \times \partial M, \\ [x], & \text{if } x \in \overline{B}^{n-k} \times \overline{B}^k \end{cases} \end{array}$$

is a diffeomorphism. Finally suppose that we are given a neighborhood U of ∂M. Evidently we can pick a collar neighborhood $[0,1] \times \partial M$ that is contained in $M \setminus U$.

The diffeomorphism that we just constructed is now the identity on the common subset $M \setminus U$.

As on so many other occasions we leave it to the reader to fill in the annoying details. ■

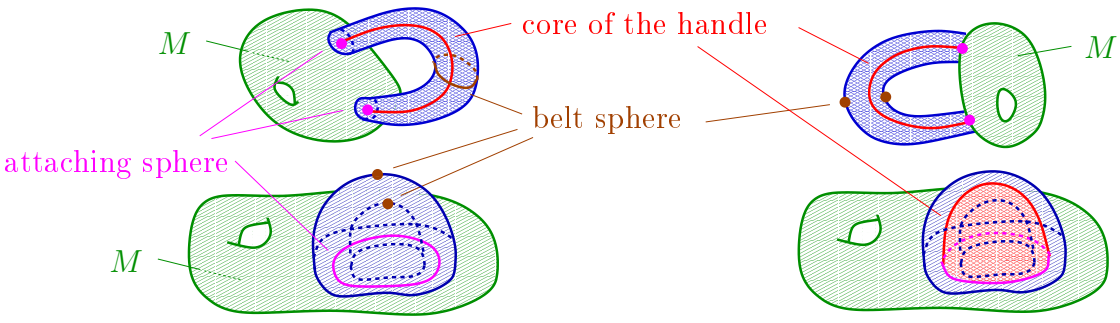
Remark. The approach in the proof of the Handle Attachment Proposition 136.1 for defining charts for $M \cup_\varphi h^k$ at the points in $\varphi(S^{n-k-1} \times S^{k-1})$ is sometimes called *rounding corners* or *smoothing corners*.

The Handle Attachment Proposition 136.1 motivates the following definition.

Definition. Let M be a compact n-dimensional smooth manifold. Suppose we are given a thickened $(k-1)$-sphere $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$.

(1) We say

$$M \cup_\varphi h^k \;:=\; M \cup_{\partial M \overset{\varphi}{\leftarrow} \overline{B}^{n-k} \times S^{k-1}} \left(\overline{B}^{n-k} \times \overline{B}^k\right)$$



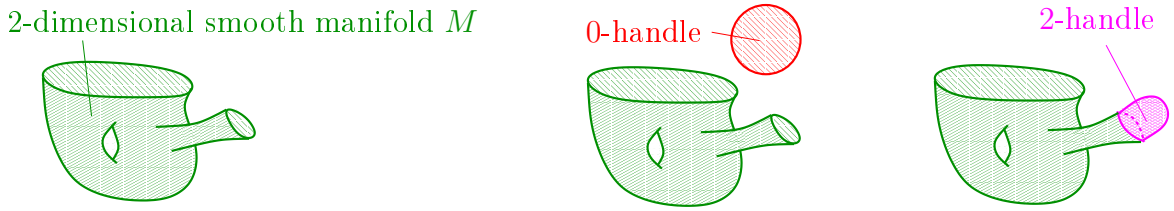
is obtained from M by attaching the k-handle $\overline{B}^{n-k} \times \overline{B}^k$ along φ. In particular we refer to the image of $\overline{B}^{n-k} \times \overline{B}^k$ in $M \cup_\varphi h^k$ as a k-handle or as a handle of index k.

(2) (a) We refer to the image of $\{0\} \times S^{k-1}$ in ∂M as the attaching sphere of the handle.
(b) We refer to the image of $\{0\} \times \overline{B}^k$ in $M \cup_\varphi h^k$ as the core of the handle.
(c) We refer to the image of $S^{n-k} \times \{0\}$ in $\partial(M \cup_\varphi h^k)$ as the belt sphere of the handle.

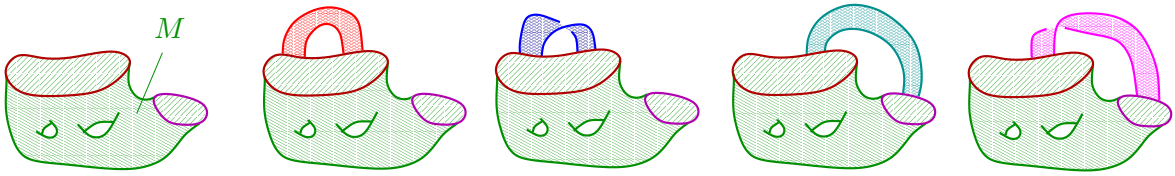
We refer to the figure below for an illustration of these definitions.

attachment of 1-handle to 3-dimensional smooth manifold

attachment of 1-handle to 2-dimensional smooth manifold



attachment of 2-handle to 3-dimensional smooth manifold



Example. Let M be a compact n-dimensional smooth manifold.

(1) Let us consider the extreme cases of attaching a 0-handle and attaching an n-handle.
   (a) It follows basically from the definitions that attaching a 0-handle is the same as taking the disjoint union with $\overline{B}^n$.
   (b) It follows immediately from the Codimension-Zero Smooth Embedding Proposition 24.16 (3) that any smooth embedding $\varphi\colon \overline{B}^0 \times S^{n-1} \to \partial M$ is a diffeomorphism onto a component of ∂M. Thus an n-handle attachment is the same as gluing an n-ball to a boundary component that is diffeomorphic to S^{n-1} via the diffeomorphism φ. Note that in Proposition **??** we will see that in general the result depends on the choice of φ.

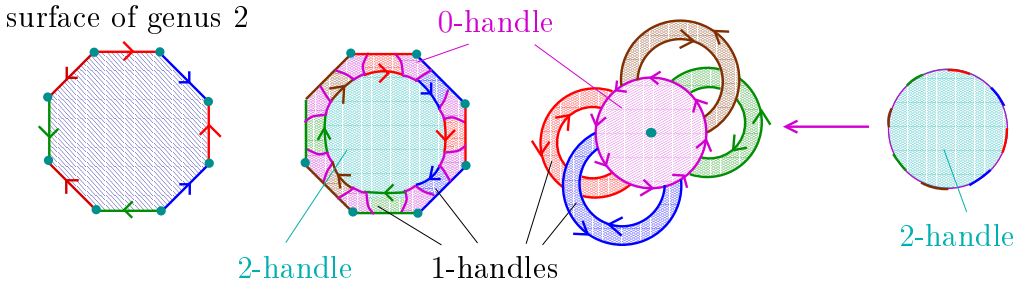
   We illustrate these two examples in the figure below.

(2) Next we turn to attachments of 1-handles. As is shown in the figure below, the effect of attaching a 1-handle depends on the choice of the attaching map $\varphi\colon \overline{B}^{n-1} \times S^0 \to \partial M$. In the 1-Handle Attachment Lemma 136.10 we will see that the four examples of 1-handle attachments that we see in the figure below exhaust in a suitable sense all possibilities for 1-handle attachments.

four types of 1-handle attachments

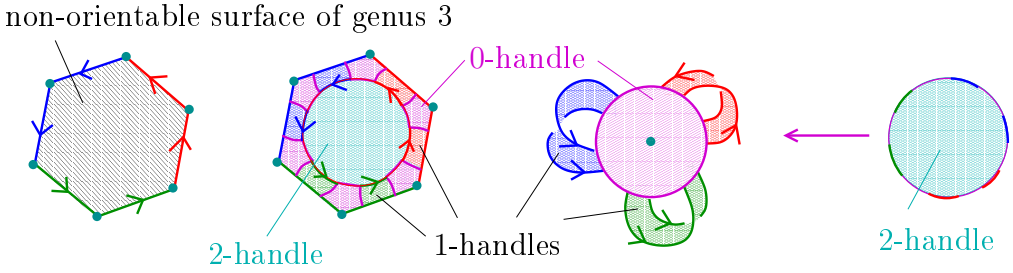
(3) For handle attachments that are not of index 0, 1 and $\dim(M)$ there is no straightforward classification of all possibilities. For example we consider the smooth manifold $M = \overline{B}^4$. Let $\gamma\colon S^1 \to S^3$ be a smooth embedding. Note that $K = \gamma(S^1)$ is a knot. In the Knot Thickening Lemma 131.1 we saw that for each $d \in \mathbb{Z}$ there exists an essentially unique tubular map $\overline{B}^2 \times K \to S^3$ of self-linking number d. Any such tubular map describes a 2-handle attachment to $\overline{B}^4$. There is no reason to believe that all these 2-handle attachments can be classified easily.

136.2. **Handle decompositions.** The following is a good example of a self-explanatory definition.



Definition. Let M be a compact n-dimensional smooth manifold. A handle decomposition for M is a diffeomorphism

$$\Theta\colon M \xrightarrow{\cong} \varnothing \cup_{\varphi_1} h^{k_1} \cup \cdots \cup_{\varphi_m} h^{k_m}$$



where for every $i = 1, \ldots, m$ the map φ_i is a thickened $(k_i - 1)$-sphere in the boundary of the smooth manifold $\varnothing \cup_{\varphi_1} h^{k_1} \cup \cdots \cup_{\varphi_{i-1}} h^{k_{i-1}}$. Usually we suppress the name of the diffeomorphism, in this case Θ, from the notation.

Examples.

(1) In the figure below we show a handle decomposition for the surface of genus $g = 2$. This handle decomposition consists of one 0-handle, $2g$ 1-handles and one 2-handle.

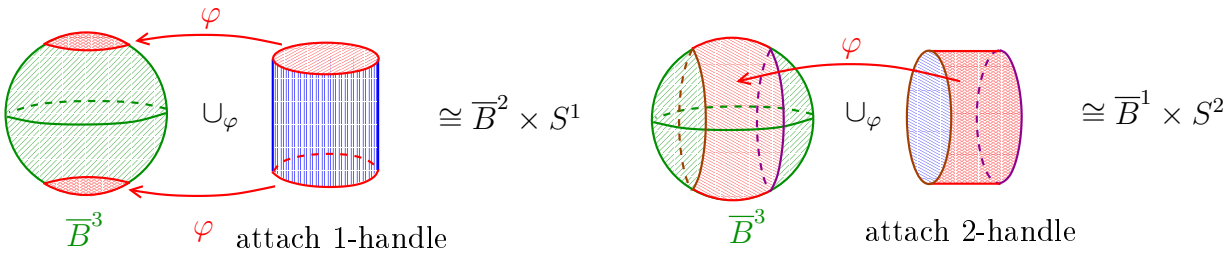
(2) In the figure below we show a handle decomposition for the non-orientable surface of genus $k = 3$. This handle decomposition consists of one 0-handle, k 1-handles and one 2-handle.

We formulate the next two types of examples as a lemma.

Lemma 136.2. (Handle Example Lemma)

(1) Let $n \in \mathbb{N}$. We consider the thickened $(n-1)$-sphere that is given by the identity

$$\mathrm{id}\colon \overline{B}^0 \to S^{n-1} \;\to\; \partial(\overline{B}^n).$$



If we attach an n-handle to $\overline{B}^n$ along id we obtain a smooth manifold that is diffeomorphic to S^n. In particular we see that S^n admits a handle decomposition with a single 0-handle and a single n-handle.

(2) Let $m, k \in \mathbb{N}$. We consider the thickened $(k-1)$-sphere

$$\begin{aligned} \varphi\colon \overline{B}^m \times S^{k-1} &\to S^{m+k-1} = \partial(\overline{B}^{m+k}) \\ (x, y) &\mapsto \frac{(\frac{1}{2} \cdot x, y)}{\|(\frac{1}{2} \cdot x, y)\|} \\ &\uparrow \\ &\text{with } (x, y) \in \overline{B}^m \times S^{k-1} \subset \mathbb{R}^m \times \mathbb{R}^k = \mathbb{R}^{m+k} \end{aligned}$$

If we attach a k-handle to the 0-handle $\overline{B}^{m+k}$ along the thickened $(k-1)$-sphere φ, then we obtain a smooth manifold that is diffeomorphic to $\overline{B}^m \times S^k$. In particular

we see that $\overline{B}^m \times S^k$ admits a handle decomposition with a single 0-handle and a single k-handle.

Proof.

(1) Let $n \in \mathbb{N}$. As on page 261 we consider the maps

$$\begin{aligned} g_\pm\colon \overline{B}^n = \overline{B}^n_\pm &\to S^n \\ (x_1, \dots, x_n) &\mapsto \big((-1)^n \cdot x_1, \dots, x_n, \pm\sqrt{1 - x_1^2 - \cdots - x_n^2}\big). \end{aligned}$$

We leave it to the reader to verify that the map[1655]

$$\begin{aligned} \overline{B}^n_+ \cup_{S^{n-1} \xleftarrow{\mathrm{id}} S^{n-1}} \overline{B}^n_- &\to S^n \\ [P] &\mapsto \begin{cases} g_+(P), & \text{if } P \in \overline{B}^n_+, \\ g_-(P), & \text{if } P \in \overline{B}^n_- \end{cases} \end{aligned}$$

is an orientation-preserving diffeomorphism.

(2) We will prove this statement in Exercise 136.2. ■

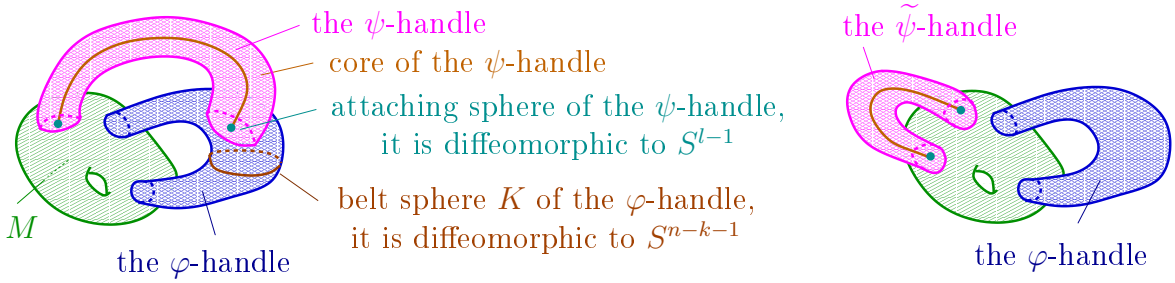
In the above we have now seen that some of our favorite smooth manifolds admit a handle decomposition. In Chapter 138 we will prove the Handle Decomposition Theorem 138.5 which states that in fact every compact smooth manifold admits a handle decomposition. In the remainder of this chapter we perform the less exciting task of proving several basic facts about handle attachments and handle decompositions.

136.3. **Handle rearrangements.** The following proposition shows that when we attach several handles, then we can rearrange the handle attachments so that they are done with increasing indices.

Proposition 136.3. (Handle Swapping Proposition) Let M be a compact n-dimensional smooth manifold. Suppose that for $i = 1, \dots, m$ we are given smooth embeddings

$$\varphi_i\colon \overline{B}^{n-k_i} \times S^{k_i-1} \to \partial(M \cup_{\varphi_1} h^{k_1} \cdots \cup_{\varphi_{i-1}} h^{k_i}).$$

Furthermore let



$$\psi\colon \overline{B}^{n-l} \times S^{l-1} \to \partial(M \cup_{\varphi_1} h_1^{k_1} \cdots \cup_{\varphi_m} h_m^{k_m})$$

[1655] As we mentioned in the formulation of the Handle Attachment Proposition 136.1, the precise smooth structure on $\overline{B}^n_+ \cup_{S^{n-1} \xleftarrow{\mathrm{id}} S^{n-1}} \overline{B}^n_-$ depends on the choice of a collar. We follow the convention from page 737, namely we consider $\overline{B}^n_\pm$ with the standard collar that we introduced on page 737. With this convention the given map is indeed an honest-to-God diffeomorphism.

be a smooth embedding. If for $i = 1, \dots, m$ we have $l \leq k_i$, then there exists a smooth embedding

$$\widetilde{\psi} \colon \overline{B}^{n-l} \times S^{l-1} \;\to\; \text{interior of } (\partial M \cap \partial(M \cup_{\varphi_1} h_1^{k_1} \cdots \cup_{\varphi_m} h_m^{k_m})) \text{ in } \partial M$$

such that $M \cup_{\varphi_1} h_1^{k_1} \cdots \cup_{\varphi_m} h_m^{k_m} \cup_{\psi} h^l$ is diffeomorphic to[1656] $M \cup_{\widetilde{\psi}} h^l \cup_{\varphi_1} h_1^{k_1} \cdots \cup_{\varphi_m} h_m^{k_m}$. Furthermore, given any neighborhood U of ∂M one can find a diffeomorphism that is the identity on the common subset $M \setminus U$.

Remark. Colloquially replacing the ψ-handle by the $\widetilde{\psi}$-handle in (the proof of) the Handle Swapping Proposition 136.3 is called a *handle slide*

Proof. To simplify the notation we prove the proposition for the special case $m = 1$. The proof of the general case is not much harder and we leave it to the reader to fill in the details.

Thus suppose that we are given a smooth embedding $\varphi \colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ and suppose that we are given a smooth embedding $\psi \colon \overline{B}^{n-l} \times S^{l-1} \to \partial(M \cup_{\varphi} h^k)$ with $l \leq k$. To simplify the notation we make the obvious identification $S^{l-1} = \{0\} \times S^{l-1} \subset \overline{B}^{n-l} \times S^{l-1}$. We write $f := \psi|_{S^{l-1}}$. Note that $f(S^{l-1})$ is precisely the attaching sphere of the ψ-handle. We denote by $K = S^{n-k-1} \times \{0\} \subset \partial(M \cup_{\varphi} h^k)$ the belt sphere of the φ-handle.

Claim 1. There exists a smooth homotopy $F \colon S^{l-1} \times [0,1] \to \partial(M \cup_{\varphi} h^k)$ such that $F_0 = f$ and $F_1(S^{l-1}) \subset \partial(M \cup_{\varphi} h^k) \setminus K$.

Proof. Note that we know by the Smooth Embedding Theorem 24.10 and the Handle Attachment Proposition 136.1 (1) that $f(S^{l-1})$ and K are both submanifolds of $\partial(M \cup_{\varphi} h^k)$. By the Transversality Theorem 42.4 there exists a smooth homotopy $F \colon S^{l-1} \times [0,1] \to \partial(M \cup_{\varphi} h^k)$ with $F_0 = f$ such that $F_1(S^{l-1})$ is transverse to the belt sphere K. Note that

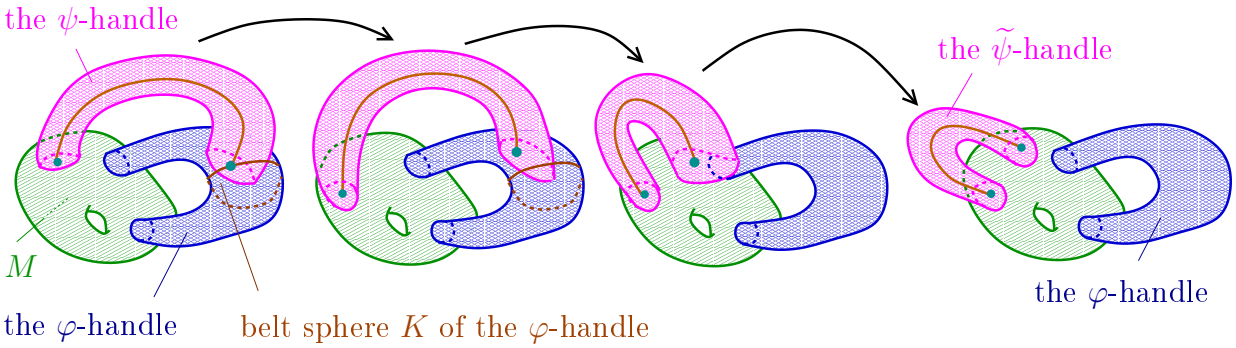
$$\dim(F_1(S^{l-1})) + \dim(K) \;=\; l - 1 + n - k - 1 \;\underset{\uparrow}{\leq}\; n - 2 \;<\; n - 1 \;=\; \dim(\partial(M \cup_{\varphi} h^k)).$$

by hypothesis we have $l \leq k$

It follows immediately from the definition of transverse intersection and this inequality of dimensions that $F_1(S^{l-1})$ is actually disjoint from the belt sphere K. ⊞

We continue with the following technical enhancement of the previous claim.

Claim 2. There exists a smooth homotopy $\Psi \colon (\overline{B}^{n-l} \times S^{l-1}) \times [0,1] \to \partial(M \cup_{\varphi} h^k)$ with $\Psi_0 = \psi$ and such that $\Psi_1(\overline{B}^{n-l} \times S^{l-1}) \subset \partial M \setminus \varphi(\overline{B}^{n-k} \times S^{k-1})$.



[1656] Note that it follows from the fact that ψ takes values in the interior of $\partial M \cap \partial(M \cup_{\varphi_1} h_1^{k_1} \cdots \cup_{\varphi_m} h_m^{k_m}))$ in ∂M that the maps $\varphi_1, \dots, \varphi_m$ can also be used to attach successively handles to $M \cup_{\widetilde{\psi}} h^l$.

Proof. It follows from the Handle Attachment Proposition 136.1 (1) that $\varphi(S^{n-k-1} \times \overline{B}^k)$ is a tubular neighborhood for the belt sphere $K = S^{n-k-1} \times \{0\} \subset \partial(M \cup_\varphi h^k)$. We obtain from the previous claim together with Exercise **??** and the Smooth Isotopy Transitivity Proposition 33.3 a smooth homotopy $G\colon f(S^{l-1}) \times [0,1] \to \partial(M \cup_\varphi h^k)$ such that $G_0 = \mathrm{id}$ and such that $G_1(f(S^{l-1})) \subset \partial(M \cup_\varphi h^k) \setminus \varphi(\overline{B}^{n-k} \times S^{k-1})$. Next note that using the Isotopy Extension Theorem 36.1 we can extend G to a smooth homotopy $G\colon (\psi(\overline{B}^{n-l} \times S^{l-1})) \times [0,1] \to \partial(M \cup_\varphi h^k)$. Unfortunately a priori we do not know that $G_1(\psi(\overline{B}^{n-l} \times S^{l-1})) \subset \partial M \setminus \varphi(\overline{B}^{n-k} \times S^{k-1})$. But it follows immediately from the "Tube Lemma", see Exercise (a), that there exists an $\epsilon > 0$ such that the map

$$\begin{array}{rcl} \Psi\colon (\overline{B}^{n-l} \times S^{l-1}) \times [0,1] & \to & \partial(M \cup_\varphi h^k) \\ ((v,P),t) & \mapsto & G(\psi(\underbrace{((1-t)+\epsilon \cdot t) \cdot v, P)}_{\in \overline{B}^{n-l} \times S^{l-1}}, t) \end{array}$$

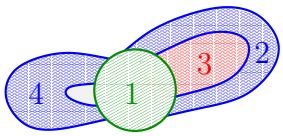
has all the desired properties. ⊞

It follows easily from the Handle Attachment Proposition 136.1 (5) that $\widetilde{\psi} := \Psi_1$ has all the desired properties. ■

The Handle Swapping Proposition 136.3 leads us to the following definition.

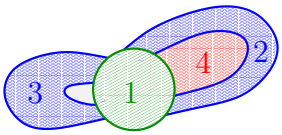
Definition. Let M be a compact n-dimensional smooth manifold. Suppose we are given a handle decomposition where the handles are attached with non-decreasing indices, i.e. we have a handle decomposition of the following form:

$$M = \varnothing \underbrace{\cup_{\varphi_{0,1}} h^0 \cdots \cup_{\varphi_{0,r_0}} h^0}_{0\text{-handles}} \cup \ldots \underbrace{\cup_{\varphi_{n,1}} h^n \cdots \cup_{\varphi_{n,r_n}} h^n}_{n\text{-handles}}.$$



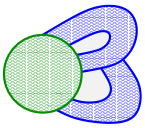
We introduce the following two concepts:

(1) Given $i \in \{0,\ldots,n\}$ we refer to



$$M^i := \varnothing \underbrace{\cup_{\varphi_{0,1}} h^0 \cdots \cup_{\varphi_{0,r_0}} h^0}_{0\text{-handles}} \cup \ldots \underbrace{\cup_{\varphi_{i,1}} h^i \cdots \cup_{\varphi_{i,r_i}} h^i}_{i\text{-handles}}.$$

as the i-skeleton of the handle decomposition.



(2) We say that a handle decomposition is standard if it is of the above form and if for each $i \in \{0,\ldots,n\}$ the attaching maps $\varphi_{i,1},\ldots,\varphi_{i,r_i}$ take values in ∂M^{i-1}.

non-standard
handle decomposition

standard
handle decomposition

non-standard
handle decomposition

Corollary 136.4. (Standard Handle Decomposition Corollary) Let M be a compact n-dimensional smooth manifold. If M admits a handle decomposition, then it also admits a handle decomposition with the same number of handles of each index, but which is now standard.

Proof. This follows immediately from iteratively applying the Handle Swapping Proposition 136.3 to reorder the handles. ■

Remark. In Chapter ?? we will see several other ways for modifying a given handle decomposition. But for the time being the above rearranging of handle attachments is good enough.

136.4. **Dual handle decomposition.** In this section we will see that we can associate to each handle decomposition a "dual" handle decomposition. More precisely, we have the following proposition.

Proposition 136.5. (Dual Handle Proposition) Let M be a closed n-dimensional smooth manifold together with a handle decomposition

$$M = \varnothing \cup_{\varphi_0} \underbrace{h^{k_0}}_{\text{0-th handle}} \cup \cdots \cup_{\varphi_m} \underbrace{h^{k_m}}_{m\text{-th handle}}.$$

There exists canonical handle decomposition

$$M = \varnothing \cup_{\psi_m} \underbrace{\widetilde{h}^{n-k_m}}_{\text{0-th dual handle}} \cup \cdots \cup_{\psi_0} \underbrace{\widetilde{h}^{n-k_0}}_{m\text{-th dual handle}},$$

called dual handle decomposition, with the following properties:

(1) For each $i \in \{0, \ldots, m\}$ the following statements hold:
   (a) The i-th handle of the dual handle decomposition equals, as a subset of M, the $(m-i)$-th handle of the original handle decomposition.
   (b) The indices of the handles are reversed, in the sense that

$$\begin{array}{c}\text{index of the } i\text{-th handle of}\\ \text{the dual handle decomposition}\end{array} = n - \begin{array}{c}\text{index of the } (m-i)\text{-th handle of}\\ \text{the original handle decomposition.}\end{array}$$

   In particular the number i-handles in the dual handle decomposition equals the number of $(n-i)$-handles in the original decomposition.
   (c) The roles of attaching spheres and belt spheres is reversed in the sense that

$$\begin{array}{c}\text{belt sphere of the } i\text{-th handle of}\\ \text{the dual handle decomposition}\end{array} = \begin{array}{c}\text{attaching sphere of the } (m-i)\text{-th handle}\\ \text{of the original handle decomposition.}\end{array}$$

   Furthermore the same statement, with the roles of attaching and belt spheres reversed, also holds.

(2) If the original handle decomposition is standard, then so is the dual handle decomposition.
(3) The dual of the dual handle decomposition is the original handle decomposition.

Example. In the figure below we show to the left a handle decomposition of S^2. But as we see, the decomposition of the sphere into subsets can also be read the other way and we obtain the dual handle decomposition.

Remark.

(1) It follows immediately from the Dual Handle Proposition 136.5 that every handle decomposition of a closed connected non-empty n-dimensional smooth manifold admits at least one n-handle. This gives in particular a solution to Exercise 136.3 (a).
(2) The handle decomposition that we construct in the proof of the Dual Handle Proposition 136.5 is sometimes called the *dual handle decomposition*.

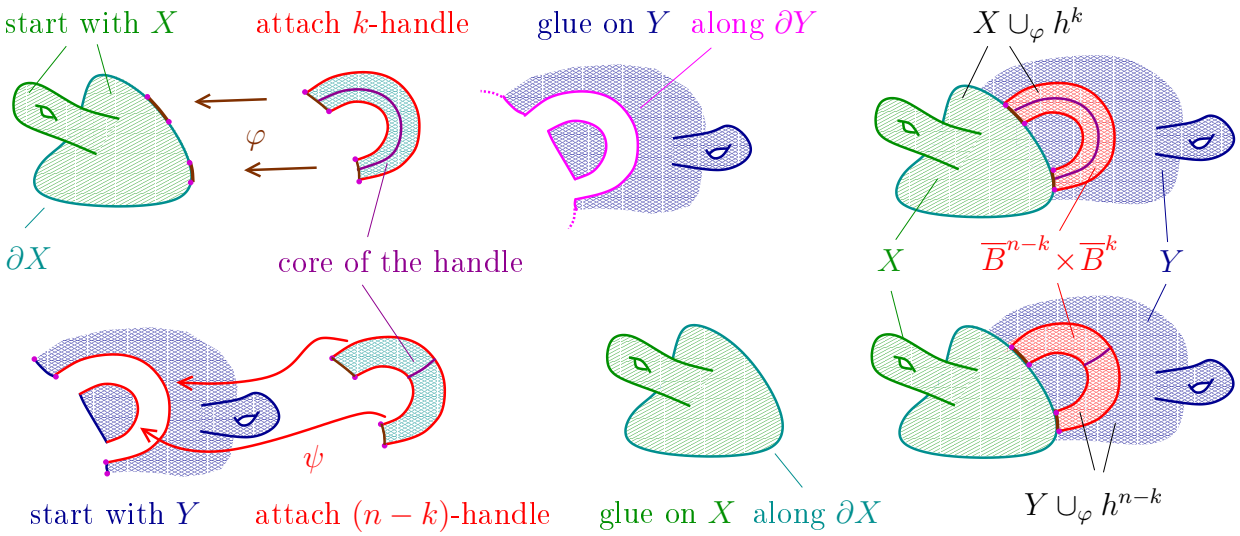
The following lemma is the key ingredient in the proof of the Dual Handle Proposition 136.5.

Lemma 136.6. Let X be an n-dimensional smooth manifold and let $\varphi\colon \overline{B}^{n-k}\times S^{k-1}\to\partial X$ be a smooth embedding. Let $X\cup_\varphi h^k := X\cup_{\partial X\overset{\varphi}{\leftarrow}\overline{B}^{n-k}\times S^{k-1}} (\overline{B}^{n-k}\times\overline{B}^k)$ be the result of attaching the corresponding k-handle to X. Furthermore let Y be an n-dimensional smooth manifold and let $\gamma\colon \partial Y\to\partial(X\cup_\varphi h^k)$ be a diffeomorphism. We consider the maps

$$\psi\colon \overline{B}^k\times S^{n-k-1}\to\partial Y,\quad (x,y)\mapsto\gamma^{-1}(y,x) \qquad \text{and} \qquad \delta\colon \partial X\to\partial(Y\cup_\psi h^k),\quad P\mapsto\begin{cases}\gamma^{-1}(P), & \text{if } P\in\partial X\setminus\varphi(B^{n-k}\times S^{k-1}),\\ \varphi^{-1}(P), & \text{if } P\in\varphi(B^{n-k}\times S^{k-1}).\end{cases}$$

The obvious map from

$$\underbrace{\big(X\cup_{\partial X\overset{\varphi}{\leftarrow}\overline{B}^{n-k}\times S^{k-1}}(\overline{B}^{n-k}\times\overline{B}^k)\big)}_{=X\cup_\varphi h^k}\cup_{\partial(X\cup_\varphi h^k)\overset{\gamma}{\leftarrow}\partial Y} Y$$



to

$$\underbrace{\big(Y\cup_{\partial Y\overset{\psi}{\leftarrow}\overline{B}^{k}\times S^{n-k-1}}(\overline{B}^{n-k}\times\overline{B}^k)\big)}_{=Y\cup_\psi h^k}\cup_{\partial(Y\cup_\psi h^k)\overset{\delta}{\leftarrow}\partial X} X$$

is a diffeomorphism.

Lemma 136.6 can be summarized as follows: If a smooth manifold W is obtained from X by attaching a k-handle and then gluing on Y, then we can also obtain W from Y by attaching an $(n-k)$-handle and gluing on X.

Sketch of proof of Lemma 136.6. Once one has digested the statement of the lemma, one realizes, that the lemma comes close to being a tautology. One can easily verify that the "obvious" maps in both directions are well-defined and inverses of one another.

Furthermore using the Topological Pushout Proposition 5.33 (1b) it is straightforward to verify that these maps are continuous, thus both maps are homeomorphisms. One still needs to show that both maps are in fact smooth. This joyless task is best left to the reader's office mate. ■

Proof of the Dual Handle Proposition 136.5. Let $M = \varnothing \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_m} h^{k_m}$ be a handle decomposition. Given $i = 0, \ldots, m$ we write $X_i := \varnothing \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_{i-1}} h^{k_{i-1}}$, $M_i := X_i \cup_{\varphi_i} h^{k_i}$ and $Y_i := M \setminus \mathring{M}_i$. Note that Y_i is an n-dimensional smooth manifold by the Codimension-Zero Submanifold Proposition 19.38. Therefore note that $Y_m = M \setminus M = \varnothing$. Since M is closed we can apply Lemma 136.6 iteratively altogether $(m+1)$ times. We see that $M = \varnothing \cup_{\psi_m} h^{n-k_m} \cup \cdots \cup_{\psi_0} h^{n-k_0}$ where for $i = 0, \ldots, m$ the map ψ_i is given by

$$\begin{array}{rcl} \psi_i \colon \overline{B}^{k_i} \times S^{n-k_i-1} & \to & \partial(\varnothing \cup_{\psi_m} h^{n-k_m} \cup \cdots \cup_{\psi_{i+1}} h^{n-k_{i+1}}) \\ (x, y) & \mapsto & [(y, x)]. \end{array}$$

It is straightforward to verify that this dual handle decomposition has all the properties stated in the proposition. ■

We conclude this section with the following perhaps slightly surprising corollary.

Corollary 136.7. Let M be a *closed* connected non-empty n-dimensional smooth manifold. For every handle decomposition of M we have the inequality:

$$1 + \#(n-1)\text{-handles} - \#n\text{-handles} \;\geq\; \text{minimal size of a generating set of } \pi_1(M).$$

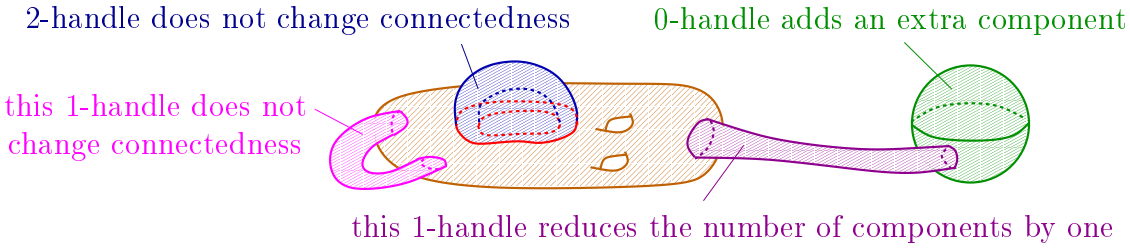
Proof. Let M be a closed connected non-empty n-dimensional smooth manifold that is equipped with a handle decomposition of M. We have the following (in-) equalities:

$$\overbrace{\begin{array}{l} 1 + \#(n-1)\text{-handles} \\ \quad - \#n\text{-handles} \end{array}}^{\text{original handle decomposition}} \underset{\uparrow}{=} \overbrace{\begin{array}{l} 1 + \#1\text{-handles} \\ \quad - \#0\text{-handles} \end{array}}^{\text{dual handle decomposition}} \underset{\uparrow}{\geq} \begin{array}{l} \text{minimal size of a} \\ \text{generating set of } \pi_1(M). \end{array}$$

Dual Handle Proposition 136.5 Corollary 136.12

■

136.5. **Handle attachments: Connectedness and orientability.** In this section we will see how handle attachments affect connectedness and orientability. In the subsequent section we will see how handle attachments affect various algebraic invariants. First let us deal with the basic concept of connectedness.



Lemma 136.8. (Handle-Connected Lemma) Let M be a compact n-dimensional smooth manifold. Suppose that we are given a thickened $(k-1)$-sphere in the boundary ∂M, i.e. suppose we are given a smooth embedding $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$. The following statements hold:

($k>1$) The inclusion induced map $\pi_0(M) \to \pi_0(M \cup_\varphi h^k)$ is a bijection.

($k=1$) (a) If the attaching map $\varphi\colon \overline{B}^{n-1} \times S^0 \to \partial M$ takes values in a single component of ∂M, then the inclusion induced map $\pi_0(M) \to \pi_0(M \cup_\varphi h^k)$ is a bijection.

(b) If the attaching map $\varphi\colon \overline{B}^{n-1} \times S^0 \to \partial M$ takes values in two components of ∂M, then the number of components goes down by one.

($k=0$) $M \cup_\varphi h^0$ has one extra component, namely the 0-handle.

Proof. The statements for $k > 1$ and $k = 1$ follow easily from the Union Connected Lemma 2.28. The statement for $k = 0$ follows from the fact that adding a 0-handle is just taking the disjoint union with the 0-handle. ■

Next we study the slightly subtle question how attaching a handle affects orientability.

Proposition 136.9. (Handles-Orientability Proposition) Let M be a compact oriented n-dimensional smooth manifold. Suppose that we are given a thickened $(k-1)$-sphere in the boundary ∂M, i.e. suppose we are given a smooth embedding $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$. The following statements hold:

(i) Let $\tau\colon S^{k-1} \to S^{k-1}$ be a reflection in some hyperplane of $\mathbb{R}^k$. The corresponding map $\varphi \circ (\mathrm{id}_{\overline{B}^{n-k}} \times \tau)\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ is also a thickened $(k-1)$-sphere and the smooth manifold $M \cup_{\varphi\circ(\mathrm{id}\times\tau)} h^k$ is diffeomorphic to $M \cup_\varphi h^k$.

(ii) If $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ is orientation-reversing, then there exists an orientation-reversing smooth embedding $\psi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ such that $M \cup_\psi h^k$ is diffeomorphic to $M \cup_\varphi h^k$.

Now we consider the various dimensions separately:

($k\geq 2$) $M \cup_\varphi h^k$ admits an orientation which agrees with the given orientation on $M \setminus \partial M$.

($k=1$) (a) If[1657] $\varphi\colon \overline{B}^{n-1} \times S^0 \to \partial M$ is orientation-preserving or orientation-reversing, then $M \cup_\varphi h^k$ admits an orientation that agrees with the given orientation on $M \setminus \partial M$.

(b) We suppose that the image of φ lies in a single component of M. If (a) is not satisfied, then $M \cup_\varphi h^k$ is non-orientable.

($k=0$) $M \cup_\varphi h^0 = M \sqcup \overline{B}^n$ is again orientable.

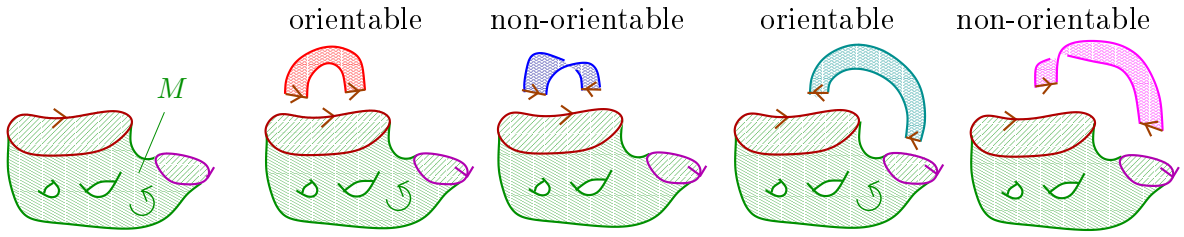
Proof.

(i) The reflection $\tau\colon S^{k-1} \to S^{k-1}$ extends in an obvious way to a diffeomorphism $\tau\colon \overline{B}^k \to \overline{B}^k$. The diffeomorphism from $M \cup_{\varphi\circ(\mathrm{id}\times\tau)} h^k$ to $M \cup_\varphi h^k$ is given by the identity on M and by $\mathrm{id}_{\overline{B}^{n-k}} \times \tau$ on $\overline{B}^{n-k} \times \overline{B}^k$.

(ii) This statement follows immediately from (1).

After these preparations we turn to the proofs of the main statements of the proposition.

($k \geq 2$) This statement follows immediately from (ii) together with the Gluing-Smooth Manifolds-Proposition **??** (6).



($k=1$) (a) This statement follows immediately from (ii) together with the Gluing-Smooth Manifolds-Proposition **??** (6).

(b) This statement is basically a special case of Exercise **??**.

($k=0$) This case is trivial. ■

The Handles-Orientability Proposition 136.9 (3) motivates the following definition.

Definition. Let M be a compact oriented n-dimensional smooth manifold. We say a thickened 0-sphere $\varphi\colon \overline{B}^n \times S^0 \to \partial M$ is orientable if φ is orientation-preserving or if it is orientation-reversing. Otherwise we say that the thickened 0-sphere is non-orientable.

The following lemma basically shows that there are not that many different possibilities for attaching 1-handles.

Lemma 136.10. (1-Handle Attachment Lemma) Let M be a compact oriented n-dimensional smooth manifold, let F be a component of ∂M and let $\varphi, \psi\colon \overline{B}^{n-1} \times S^0 \to F$ be two thickened 0-spheres. If φ and ψ are both orientable or if they are both non-orientable, then $M \cup_\varphi h^1$ and $M \cup_\psi h^1$ are diffeomorphic.

Proof. Let $\varphi, \psi\colon \overline{B}^{n-1} \times S^0 \to F$ be two thickened 0-spheres. First assume that $n \geq 3$. As in the Handles-Orientability Proposition 136.9 (1) let $\tau\colon S^0 \to S^0$ be the map that swaps

[1657] Recall that the orientation on S^0 is given by $-\{-1\} \cup +\{1\}$. By definition of the product orientation, see page 695, $\overline{B}^{n-1} \times S^0 \to -\overline{B}^{n-1} \sqcup \overline{B}^{n-1}$.

the two points ± 1. By the Handles-Orientability Proposition 136.9 we can, if convenient, replace φ by $\varphi \circ (\mathrm{id} \times \tau)$ and we can replace ψ by $\psi \circ (\mathrm{id} \times \tau)$. It follows from this observation that we can arrange that the maps $\varphi\colon \overline{B}^{n-1} \times \{1\} \to \partial M$ and $\psi\colon \overline{B}^{n-1} \times \{1\} \to \partial M$ are both orientation-preserving. It follows from our orientation hypothesis on φ and ψ that $\varphi\colon \overline{B}^{n-1} \times \{-1\} \to \partial M$ and $\psi\colon \overline{B}^{n-1} \times \{-1\} \to \partial M$ are both orientation-preserving or they are both orientation-reversing.

Since $n = \dim(M) \geq 3$ we have $\dim(\partial M) \geq 2$. Thus we can apply the Smooth Ball Embedding Theorem 37.8 which implies that the two maps φ and ψ are smoothly isotopic. Thus it follows from the Handle Attachment Proposition 136.1 that $M \cup_\varphi h^1$ and $M \cup_\psi h^1$ are diffeomorphic.

It remains to deal with the cases $n = 1$ and $n = 2$. The case $n = 1$ is basically trivial. Finally we will deal with the case $n = 2$ in Exercise 136.1. ■

136.6. **Handle attachments: Algebraic invariants.** In this section we will discuss how a handle attachment alters some of our favorite algebraic invariants of topological spaces, namely the fundamental group and the homology groups. The statements below are basically the same as for cell attachments that we gave in Propositions 69.11 and the Cell Attachment-H_*-Lemma 78.18. First we have the following analogue of the Cell Attachment-π_1-Proposition 69.11.

Proposition 136.11. (Handle Attachment-π_1-Proposition) Let M be a compact n-dimensional smooth manifold, let $k \in \mathbb{N}$ and let $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere. We pick $(x_0, y_0) \in S^{n-k-1} \times S^{k-1}$ and we set $P := \varphi(x_0, y_0) \in \partial M$. The following statements hold:

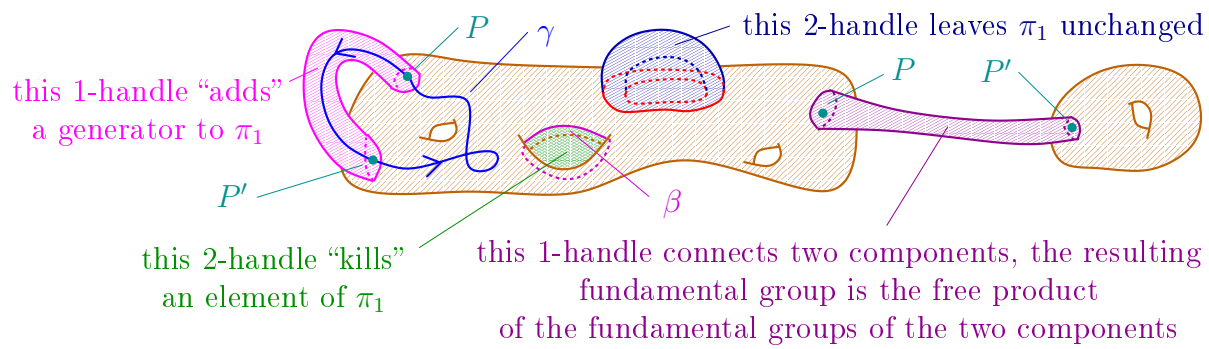
($k>2$) The inclusion induced map $\pi_1(M, P) \to \pi_1(M \cup_\varphi h^k, P)$ is an isomorphism.

($k=2$) Let $\beta\colon S^1 \to M$ be the loop that is given by $z \mapsto \varphi(x_0, z)$. The inclusion induced map $\pi_1(M, P) \to \pi_1(M \cup_\varphi h^2, P)$ descends to an isomorphism

$$\pi_1(M, P)/\langle\langle [\beta] \rangle\rangle \xrightarrow{\cong} \pi_1(M \cup_\varphi h^2, P).$$

($k=1$) We set $P' := \varphi(x_0, -y_0) \in \partial M$.

(a) Suppose that P and P' lie in the same component of M. Let γ be a loop in $M \cup_\varphi h^1$ that is given by the concatenation of the obvious path in the 1-handle from P to P' and some path in M from P' to P. With this notation the map



$$\pi_1(M, P) * \langle t \rangle \to \pi_1(M \cup_\varphi h^1, P)$$

that is given by the inclusion induced map $\pi_1(M, P) \to \pi_1(M \cup_\varphi h^1, P)$ and given by $t \mapsto [\gamma]$ is an isomorphism.

(b) Suppose that P and P' lie in two different components of M. Then we get an isomorphism

$$\pi_1(M, P) * \pi_1(M, P') \to \pi_1(M \cup_\varphi h^1, P).$$

Proof. The statements follow fairly easily from a slight generalization of the Seifert–van Kampen Theorem 54.4 and the HNN-Seifert–van Kampen Theorem 57.3 (b). Overall the proof is very similar to the proof of the Cell Attachment-π_1-Proposition 69.11 and we leave it to the reader to make the obvious alterations to obtain a proof for the present proposition. ■

Corollary 136.12. Let M be a compact connected non-empty smooth manifold. For every handle decomposition of M we have the inequality:

$$1 + \#\text{1-handles} - \#\text{0-handles} \;\geq\; \text{minimal size of a generating set of } \pi_1(M).$$

Proof. Let M be a compact connected non-empty smooth manifold that is equipped with a handle decomposition. We denote by r the number of 0-handles and we denote by s the number of 1-handles. First note, that by the Standard Handle Decomposition Corollary 136.4 we can assume that the handle decomposition is standard. We pick a base point P in one of the 0-handles. By the definition of a generating set, see page 1159, it suffices to prove the following claim.

Claim. There exists an epimorphism from a group of rank $1 + s - r$ onto $\pi_1(M, P)$.

Proof. Given $k \in \mathbb{N}_0$ we denote by M^k the k-skeleton of M. It follows fairly easily from our hypothesis that M is connected, together with the Handle-Connected Lemma 136.8 and the Handle Attachment-π_1-Proposition 136.11, that $\pi_1(M^1, P)$ is a free group on $1 + s - r$ generators. Next note that it follows from the Handle Attachment-π_1-Proposition 136.11 that the inclusion induced map $\pi_1(M^1, P) \to \pi_1(M, P)$ is an epimorphism. Thus we have shown, as desired, that there exists an epimorphism from a group of rank $1 + s - r$ onto $\pi_1(M, P)$. ∎

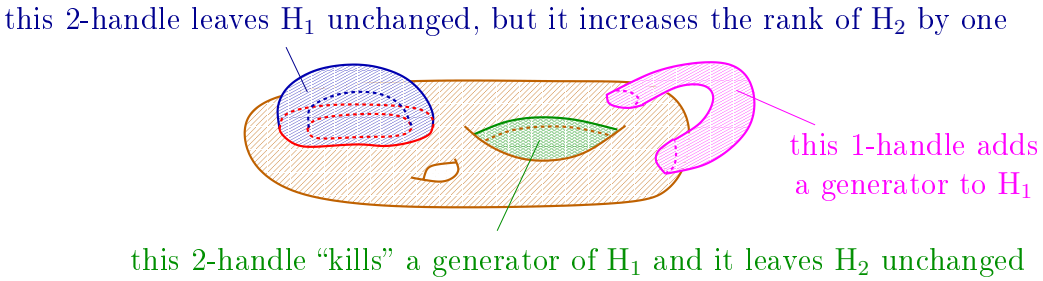
Next we study the effect of a handle attachment to homology groups. The following lemma is an analogue of the Cell Attachment-H_*-Lemma 78.18.

Lemma 136.13. (Handle Attachment-H_*-Lemma) Let M be a compact n-dimensional smooth manifold, let $k \in \mathbb{N}_0$, let $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere and let $x \in \overline{B}^{n-k}$. We denote by $i\colon M \to M \cup_\varphi h^k$ the inclusion map. There exists a natural exact sequence of the form[1658]

$$0 \to \mathrm{H}_k(M) \xrightarrow{i_*} \mathrm{H}_k(M \cup_\varphi h^k) \to \underbrace{\widetilde{\mathrm{H}}_{k-1}(S^{k-1})}_{\cong \mathbb{Z}} \xrightarrow[\text{induced by the map } y \mapsto \varphi(x,y)]{} \mathrm{H}_{k-1}(M) \xrightarrow{i_*} \mathrm{H}_{k-1}(M \cup_\varphi h^k) \to 0.$$

Furthermore, for any $l \neq k-1, n$ the inclusion induced map

$$i_*\colon \mathrm{H}_l(M) \xrightarrow{\cong} \mathrm{H}_l(M \cup_\varphi h^k)$$



is an isomorphism.

Remark. By considering the 0-th homology groups one can deduced the Handle-Connected Lemma 136.8 from the Handle Attachment-H_*-Lemma 136.13.

Proof. We consider the following diagram:

$$\mathrm{H}_j(M\cup_\varphi h^k) \xrightarrow{\partial} \widetilde{\mathrm{H}}_{j-1}(\varphi(\overline{B}^{n-k}\times S^{k-1})) \to \mathrm{H}_{j-1}(M)\oplus \overbrace{\widetilde{\mathrm{H}}_{j-1}(\varphi(\overline{B}^{n-k}\times \overline{B}^{k}))}^{=0} \to \mathrm{H}_{j-1}(M\cup_\varphi h^k) \to$$
$$\cong\uparrow \qquad\qquad \nearrow$$
$$\widetilde{\mathrm{H}}_{j-1}(S^{k-1})$$

Here the upper sequence is the long exact sequence coming from a slight generalization of the Mayer-Vietoris Theorem 78.9 for Smooth Manifolds. The maps emanating from below are the obvious maps. The statements of the lemma follow from staring at this diagram for a few short minutes. ■

136.7. **Handle attachments: Invariants of the boundary.** In this section, given a handle attachment $M\cup_\varphi h^k$ we will study the interaction between algebraic invariants of $M\cup_\varphi h^k$ and its boundary $\partial(M\cup_\varphi h^k)$. Again we first consider fundamental groups.

Lemma 136.14. Let M be a connected n-dimensional smooth manifold such that ∂M is also connected. Let $\varphi\colon \overline{B}^{n-k}\times S^{k-1}\to \partial M$ be a thickened $(k-1)$-sphere. The following statements hold:

(1) If $1\le k<n-1$, then the boundary $\partial(M\cup_\varphi h^k)$ is connected and non-empty.
(2) (a) If $1\le k\le n-3$ and if $\pi_1(\partial M)\to\pi_1(M)$ is an isomorphism, then the induced map $\pi_1(\partial(M\cup_\varphi h^k))\to\pi_1(M\cup_\varphi h^k)$ is also an isomorphism.
(b) If $1\le k\le n-2$ and if $\pi_1(\partial M)\to\pi_1(M)$ is an epimorphism, then the induced map $\pi_1(\partial(M\cup_\varphi h^k))\to\pi_1(M\cup_\varphi h^k)$ is also an epimorphism.

Proof. First we prove Statement (1). By the Handle Attachment Proposition 136.1 we have

$$\partial(M\cup_\varphi h^k) \;=\; \underbrace{(\partial M\setminus\varphi(B^{n-k}\times S^{k-1}))}_{\substack{\text{connected by the Complement}\\ \text{Connected Lemma 2.29,}\\ \text{since } \partial M \text{ is connected}}} \cup_{\varphi|\underbrace{S^{n-k-1}\times S^{k-1}}_{\neq\varnothing \text{ since } 1\le k<n-1}} \underbrace{(S^{n-k-1}\times \overline{B}^{k})}_{\substack{\text{connected since}\\ k<n-1}}.$$

It follows from the Complement Connected Lemma 2.29 that $\partial(M\cup_\varphi h^k)$ is indeed connected. Since $n-k-1\ge 0$ we see that the boundary is furthermore non-empty.

[1658] Note that this statement also holds for $k=0$, we just need to remember that by the Reduced Homology Lemma 74.1 we have $\widetilde{\mathrm{H}}_{-1}(\varnothing)=\mathbb{Z}$.

We turn to the proof of Statement (2). We pick and immediately ignore a base point in $\varphi(S^{n-k-1} \times S^{k-1}$. We consider the following diagram:

$$\begin{array}{ccc} \pi_1\big(\overbrace{(\partial M \backslash \varphi(B^{n-k} \times S^{k-1})) \underset{S^{n-k-1}\times S^{k-1}}{\cup} (S^{n-k-1} \times \overline{B}^k)}^{=\partial(M \cup_\varphi h^k)}\big) & \longrightarrow & \pi_1\big(\overbrace{M \underset{\overline{B}^{n-k}\times S^{k-1}}{\cup} (\overline{B}^{n-k} \times \overline{B}^k)}^{=M \cup_\varphi h^k}\big) \\ & \searrow & \uparrow \\ & & \pi_1\big(\partial M \underset{S^{n-k-1}\times S^{k-1}}{\cup} (S^{n-k-1} \times \overline{B}^k)\big). \end{array}$$

All the maps are induced by inclusions, hence the diagram commutes. First we consider the case that $1 \leq k \leq n-3$. In this setting we need to show that the top map is an isomorphism. This statement is a consequence of the following two observations:

(i) Note that it follows from Lemma 54.13 (1) and our hypothesis that $k \leq n-3$ that the map $\pi_1(\partial M \backslash \varphi(B^{n-k} \times S^{k-1})) \to \pi_1(\partial M)$ is an isomorphism. Next note that it follows from this observation together with the Seifert–van Kampen Theorem 54.4 and the Amalgamated Product Lemma 53.22 (1) that the diagonal map is an isomorphism.

(ii) By hypothesis we know that $\pi_1(\partial M) \to \pi_1(M)$ is an isomorphism. It follows from this observation together with the Seifert–van Kampen Theorem 54.4 and the Amalgamated Product Lemma 53.22 (1) that the vertical map is an isomorphism.

Finally we consider the case that $k \leq n-2$. In this setting we perform the same argument as above, except that need to replace Lemma 54.13 (1) by Lemma 54.13 (2) and that we need to replace the Amalgamated Product Lemma 53.22 (1) by the Amalgamated Product Lemma 53.22 (2). ■

Corollary 136.15. Let $n \in \mathbb{N}$ with $n \geq 4$. Let M be a compact connected non-empty n-dimensional smooth manifold that is equipped with a handle decomposition.

(1) If all handles have index $\leq n-3$, then the boundary ∂M is connected and the inclusion induced map $\pi_1(\partial M) \to \pi_1(M)$ is an isomorphism.

(2) If all handles have index $\leq n-2$, then the boundary ∂M is connected and the inclusion induced map $\pi_1(\partial M) \to \pi_1(M)$ is an epimorphism.

Proof. Let M be a compact connected non-empty n-dimensional smooth manifold that is equipped with a handle decomposition. If M has a single 0-handle, then the statement follows immediately from Lemma 136.14.

Now suppose that M has in fact more than one 0-handle. In Corollary **??** we will see that we can arrange that the handle decomposition has a single 0-handle. Alternatively we can argue directly as follows. Let $A_1, \ldots, A_k$ be the 0-handles. It follows easily from the hypothesis that M is connected that there exist 1-handles $B_1, \ldots, B_{k-1}$ such that $W := (A_1 \cup \cdots \cup A_k) \cup (B_1 \cup \cdots \cup B_{k-1})$ is connected. It is straightforward to verify that $\pi_1(W)$ is trivial and that ∂W is connected. We obtain M from W by attaching handles of index ≥ 1. Thus the desired statement again follows from Lemma 136.14. ■

We continue with the "homological analogue" of Lemma 136.14.

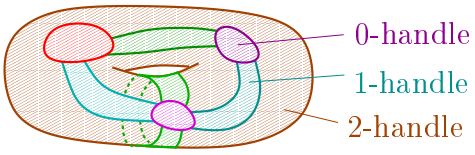
Lemma 136.16. Let M be an n-dimensional smooth manifold. Suppose we are given a thickened $(k-1)$-sphere $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$. Let $j \in \mathbb{N}_0$. The following statements hold:

(1) If $j \leq n-k-2$ and if $\mathrm{H}_i(\partial M) \to \mathrm{H}_i(M)$ is an isomorphism for $i = 0, \ldots, j$, then $\mathrm{H}_j(\partial(M \cup_\varphi h^k)) \to \mathrm{H}_j(M \cup_\varphi h^k)$ is also an isomorphism for $i = 0, \ldots, j$.

(2) If $j \leq n-k-1$ and if $\mathrm{H}_i(\partial M) \to \mathrm{H}_i(M)$ is an isomorphism for $i = 0, \ldots, j-1$ and if it is an epimorphism for $i = j$, then the analogous statements hold for the maps $\mathrm{H}_j(\partial(M \cup_\varphi h^k)) \to \mathrm{H}_j(M \cup_\varphi h^k)$.

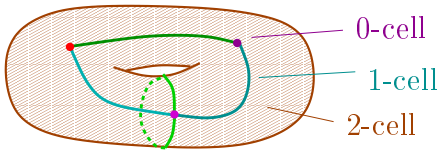
Proof. The lemma follows from applying the Mayer-Vietoris Theorem 78.9 to the decomposition $\partial M = (\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup (\overline{B}^{n-k} \times S^{k-1})$, to $M \cup_\varphi h^k$ and finally to $\partial(M \cup_\varphi h^k) = (\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup (S^{n-k-1} \times \overline{B}^k)$. Since we will not make use of the lemma we leave the pleasure of filling in the details to the reader. ■

The following is an immediate corollary to Lemma 136.16.



Corollary 136.17. Let M be a compact non-empty n-dimensional smooth manifold that is equipped with a handle decomposition and let $j \in \mathbb{N}_0$.

(1) If all handles have index $\leq n-j-2$, then for $i = 0, \ldots, j$ the inclusion induced map $\mathrm{H}_j(\partial M) \to \mathrm{H}_j(M)$ is an isomorphism.



(2) If all handles have index $\leq n-j-1$, then for $i = 0, \ldots, j-1$ the inclusion induced map $\mathrm{H}_i(\partial M) \to \mathrm{H}_i(M)$ is an isomorphism and the inclusion induced map $\mathrm{H}_j(\partial M) \to \mathrm{H}_j(M)$ is an epimorphism.

136.8. **Handle decompositions and CW-structures.** We conclude this chapter with a proposition that shows that a handle decomposition of a smooth manifold M gives rise to a CW-complex that is *homotopy equivalent* to the smooth manifold M. We will not really make use of this result, but it is good to know it exists, and in principle it can be used to deduce some results on handle decompositions from our long experience with CW-structures.

Proposition 136.18. (Handles-Cells Proposition) Every compact smooth manifold M that is equipped with a handle decomposition is homotopy equivalent to a CW-complex X such that for each $k \in \mathbb{N}_0$ the number of k-handles of M equals the number of k-cells of X.

handle decomposition of the torus

CW-complex

Remark. We will prove the Handles-Cells Proposition 136.18 using the Homotopy Pushout Theorem 17.19, which comes with a rather intimidating proof. A slightly more direct proof for the Handles-Cells Proposition 136.18 is given in [**Miln1963a**, Theorem 3.4].

As we mentioned in the remark, the key to proving the Handles-Cells Proposition 136.18 is the following theorem whose easy formulation belies the difficulty of the proof.

Theorem 17.19. (Homotopy Pushout Theorem) Suppose we are given the following commutative diagram of maps between topological spaces:

$$\begin{array}{ccccc} Y & \xleftarrow{f} & A & \xhookrightarrow{i} & X \\ {\scriptstyle\varphi_Y}\downarrow & & \downarrow{\scriptstyle\varphi_A} & & \downarrow{\scriptstyle\varphi_X} \\ Y' & \xleftarrow{f'} & A' & \xhookrightarrow{i'} & X'. \end{array}$$

If the vertical maps are homotopy equivalences and if the maps i and i' to the right are closed cofibrations[1659], then the induced map

$$Y \cup_A X \;\to\; Y' \cup_{A'} X'$$

between the pushouts is a homotopy equivalence.

Proof of the Handles-Cells Proposition 136.18. Let M be a compact smooth manifold with a given handle decomposition. By the Standard Handle Decomposition Corollary 136.4 we can arrange, without changing the number of handles of any index, that the handle decomposition is standard.

Given $k \in \mathbb{N}_0$ we denote, as on page 2958, by M^k the k-skeleton of the handle decomposition. In other words, M^k is the union of all handles of dimension $\leq k$. Furthermore, given any CW-complex X we denote by X^k its k-skeleton, i.e. X^k is the union of cells of dimension $\leq k$. We will prove the following slight refinement of the original statement of the Handles-Cells Proposition 136.18.

Statement. There exists a CW-complex X and a homotopy equivalence $g\colon M \to X$ with the following two properties:

(1) for each $k \in \mathbb{N}_0$ we have $g(M^k) \subset X^k$,
(2) for each $k \in \mathbb{N}_0$ the number of k-cells of X equals the number of k-handles of M.

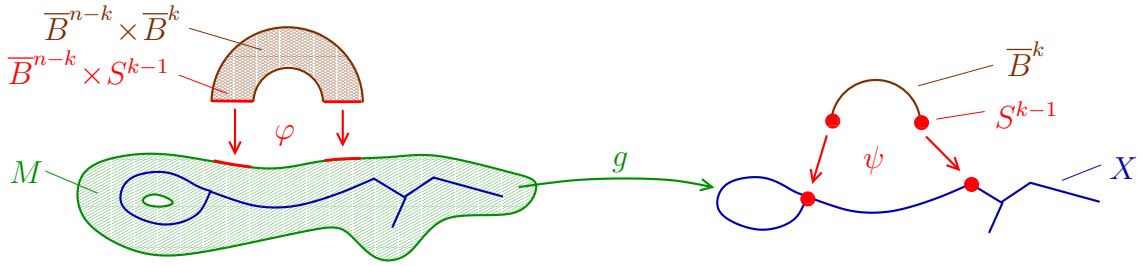
By an elementary induction argument it suffices to prove the following claim.

Claim. Let N be a compact n-dimensional smooth manifold that is equipped with a standard handle decomposition. We suppose that there exists a homotopy equivalence $f\colon N \to X$ to some CW-complex X such that for every $k \in \mathbb{N}_0$ we have $f(N^k) \subset X^k$. Let $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial N$ be a smooth embedding. There exists a cellular map[1660] $\psi\colon S^{k-1} \to X$ and a homotopy equivalence[1661]

$$g\colon \underbrace{\big(N \sqcup \big(\overline{B}^{n-k} \times \overline{B}^{k}\big)\big)/\!\sim}_{=N\cup_\varphi h^k} \;\to\; \underbrace{\big(X \sqcup \overline{B}^{k}\big)/\!\sim}_{\psi(x)\sim x \text{ for all } x\in S^{k-1}}.$$

Proof. We consider the map $\eta\colon S^{k-1} \to X$ that is given by $\eta(x) := (f \circ \varphi)(0, x)$. By the Cellular Approximation Theorem 70.15 there exists a homotopy $F\colon S^{k-1} \times [0,1] \to X$ from $F_0 = \eta\colon S^{k-1} \to X$ to a cellular map $F_1 = \psi\colon S^{k-1} \to X$. We obtain the following

[1659] We refer to page 478 for the definition of a closed cofibration. To get the hang of the argument it is not that important though to recall the definition of a closed cofibration.
[1660] We equip S^{k-1} with the canonical CW-structure that we introduced on page 1472.
[1661] Note that it follows from the CW-Complex Construction Lemma 68.32 and the fact that ψ is cellular that $(X \sqcup \overline{B}^k)/\!\sim$ is a CW-complex with one extra k-cell.



commutative diagram:

$$
\begin{array}{ccccc}
N & \hookleftarrow & \partial N & \xleftarrow{\varphi} & \overline{B}^{n-k} \times S^{k-1} \hookrightarrow \overline{B}^{n-k} \times \overline{B}^{k} \\
{\scriptstyle \mathrm{id}}\uparrow & & & & \uparrow{\scriptstyle x \mapsto (0,x)} \\
N & \xleftarrow{x \mapsto \varphi(0,x)} & & & S^{k-1} \hookrightarrow \overline{B}^{k} \\
{\scriptstyle f}\downarrow & & & & \downarrow \\
X & \xleftarrow{\eta} & & & S^{k-1} \hookrightarrow \overline{B}^{k} \\
{\scriptstyle \mathrm{id}}\downarrow & & & & \downarrow{\scriptstyle x \mapsto (x,0)} \\
X & \xleftarrow{F} & & & S^{k-1} \times [0,1] \hookrightarrow \overline{B}^{k} \times [0,1] \\
{\scriptstyle \mathrm{id}}\uparrow & & & & \uparrow{\scriptstyle x \mapsto (x,1)} \\
X & \xleftarrow{\psi} & & & S^{k-1} \hookrightarrow \overline{B}^{k}.
\end{array}
$$

It is clear that all of the vertical maps are homotopy equivalences. Furthermore note that it follows immediately from the Manifold Boundary-Cofibration Proposition 17.8 and the Product-Cofibration Proposition 17.11 that all of the right horizontal maps are closed cofibrations. Thus it follows from the Homotopy Pushout Theorem 17.19, applied altogether four times, that the induced maps between the various pushouts have homotopy inverses. Combining these four homotopy equivalences, respectively their homotopy inverses, we obtain the promised homotopy equivalence

$$
\underbrace{N \cup_{\overline{B}^{n-k} \times S^{k-1}} (\overline{B}^{n-k} \times \overline{B}^{k})}_{= (N \sqcup (\overline{B}^{n-k} \times \overline{B}^{k}))/\sim} \quad \to \quad \underbrace{X \cup_{S^{k-1}} \overline{B}^{k}}_{= (X \sqcup \overline{B}^{k})/\sim}.
$$

■

Exercises for Chapter 136.

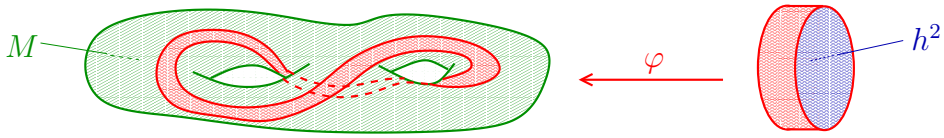
Exercise 136.1. Let M be a compact oriented 2-dimensional smooth manifold and let F be a component of ∂M. Show that any two orientation-preserving 1-handle attachments to F lead to diffeomorphic smooth manifolds.

Exercise 136.2. Let $m, k \in \mathbb{N}$. We consider the thickened $(k-1)$-sphere

$$
\begin{array}{rcl}
\varphi \colon \overline{B}^{m} \times S^{k-1} & \to & S^{m+k-1} = \partial(\overline{B}^{m+k}) \\
(x, y) & \mapsto & \frac{(\frac{1}{2} \cdot x, y)}{\|(\frac{1}{2} \cdot x, y)\|}.
\end{array}
$$

(a) Show that $\overline{B}^{m+k} \cup_{\varphi} h^{k}$ is homeomorphic to $\overline{B}^{m} \times S^{k}$.

(b) Show that $\overline{B}^{m+k} \cup_\varphi h^k$ is diffeomorphic to $\overline{B}^m \times S^k$.
Remark. This exercise is meant only for the heroically inclined reader.
Remark. The full details for a very similar statement are provided in [**Wall2016**, Lemma 5.4.2].



Exercise 136.3. Let M be a closed connected non-empty n-dimensional smooth manifold.
(a) Show that every handle decomposition of M admits at least one n-handle.
(b) Suppose we are given a handle decomposition of M with a unique n-handle. Show that this n-handle has non-empty intersection with every other handle.

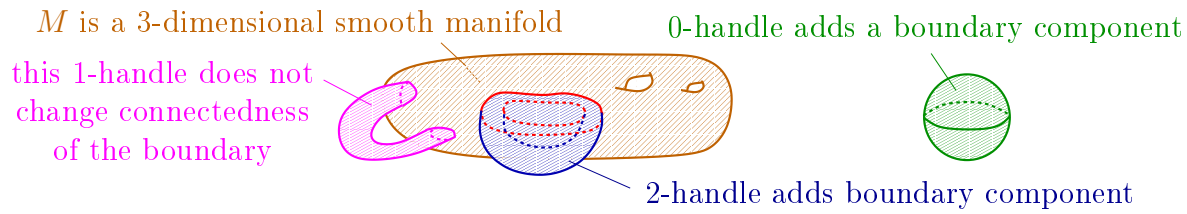
Exercise 136.4. On page 2955 we saw that the surface of genus 2 admits a handle decomposition with four 1-handles. Does it also admit a handle decomposition with less than four 1-handles?

Exercise 136.5. Let M be a compact oriented n-dimensional smooth manifold and let $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere. Show that if $k \geq 2$ and $n \geq k+3$, then there exists an epimorphism $\pi_1(\partial M) \to \pi_1(\partial(M \cup_\varphi h^k))$.

Exercise 136.6. Let $K \subset S^3$ be a knot. We pick a tubular neighborhood $\overline{B}^2 \times K$ and as on page 2213 we consider the knot exterior $X_K := S^3 \setminus (B^2 \times K)$. Can we add handles to X_K to obtain a smooth manifold that is diffeomorphic to S^3?

Exercise 136.7. We consider the 3-dimensional smooth manifold M shown in the figure below. Furthermore we consider the thickened 1-sphere $\varphi\colon \overline{B}^1 \times S^1 \to \partial M$ shown in the figure below. Can you recognize the diffeomorphism type of $M \cup_\varphi h^2$? Can you prove that it is what you think it is?

Exercise 136.8. Let M be a connected n-dimensional smooth manifold. Furthermore let $\varphi\colon \overline{B}^{n-1} \times S^0 \to \partial M$ be a thickened 0-sphere in ∂M. Let $\tau\colon \overline{B}^{n-1} \to \overline{B}^{n-1}$ be the reflection in a hyperplane. We consider the thickened 0-sphere



$$\begin{array}{rcl} \overline{B}^n \times S^0 & \to & \partial M \\ (P,\epsilon) & \mapsto & \begin{cases} \varphi(\tau(P),-1), & \text{if } \epsilon = -1, \\ \varphi(P,1), & \text{if } \epsilon = 1. \end{cases} \end{array}$$

Is it possible that $M \cup_\varphi h^1$ and $M \cup_\psi h^1$ are diffeomorphic?

Exercise 136.9. Let M be a compact n-dimensional smooth manifold such that ∂M is connected. Let $k \in \mathbb{N}_0$ and let $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere. Show that if $\in \{1, \ldots, n-1\}$, then $\partial(M \cup_\varphi h^k)$ is also connected.

Exercise 136.10. Let M be a compact n-dimensional smooth manifold.
(a) Let $k \in \mathbb{N}_0$ and let $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere. Prove that

$$\chi(M \cup_\varphi h^k) \;=\; \chi(M) + (-1)^k.$$

(b) Show that given any handle decomposition for M the following equality holds:

$$\sum_{k\in\mathbb{N}_0} (-1)^k \cdot \text{number of } k\text{-handles} \;=\; \chi(M).$$

Exercise 136.11. Let $k \in \mathbb{N}$ and let M be a compact orientable $2k$-dimensional smooth manifold which admits a handle decomposition such that all handles have index $\leq k$. Is the inclusion induced map $\mathrm{H}_k(\partial M) \to \mathrm{H}_k(M)$ necessarily an epimorphism?

Exercise 136.12. Let M be a compact smooth that is equipped with a standard handle decomposition. Given $k \in \mathbb{N}_0$ we denote by M^k the k-skeleton of the handle decomposition, i.e. M^k is the union of all handles up to dimension $\leq k$. Let P be a point in the 0-skeleton and let $i \in \mathbb{N}$.

(a) Show that for any $k > i$ the inclusion induced map $\pi_i(M^k, P) \to \pi_i(M, P)$ is an isomorphism.

(b) Show that the inclusion induced map $\pi_k(M^k, P) \to \pi_k(M, P)$ is an epimorphism.

Hint. Use the Whitney Approximation Theorem 29.1, the Replace-by-Smooth Homotopy Proposition 29.5 and Transversality Theorem 42.4 applied to a suitable choice of proper submanifolds.

Remark. This exercise can be viewed as a handle analogue of the corresponding statement for CW-complexes that we proved in the CW-Skeleton-π_n-Proposition 71.9.

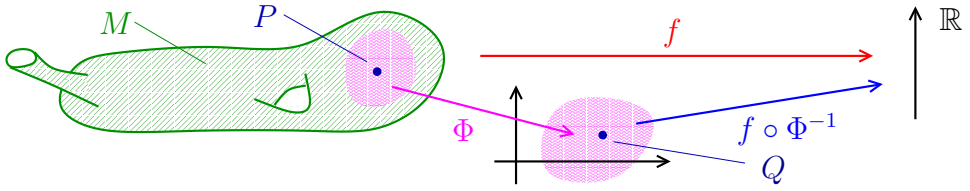
Exercise 136.13. Let M be a compact oriented n-dimensional smooth manifold, let F be a component of ∂M and let $\varphi, \psi\colon \overline{B}^{n-1} \times S^0 \to F$ be two thickened 0-spheres. Show that if F is non-orientable, then then $M \cup_\varphi h^1$ and $M \cup_\psi h^1$ are diffeomorphic.

Remark. This exercise is a variation on the 1-Handle Attachment Lemma 136.10.

137. Morse functions

In the last chapter we introduced handle decompositions and showed explicitly that some of our favorite compact smooth manifolds admit handle decompositions. Our next goal is to show that every compact smooth manifold admits a handle decomposition. We will do so via Morse theory, which builds on the fairly straightforward concept of a Morse function. In this chapter we will introduce Morse functions, we will show that they always exist and we will study their gradient vector fields.

137.1. **Non-degenerate critical points.** The following definition is just a special case of the definition on page 701.



Definition. Let M be a smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. We say $P \in M$ is a regular point if $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathbb{R}$ is non-zero, otherwise we say P is a critical point.

In our previous discussions we were trying hard to avoid critical points. In the following we will see that the study of critical points can actually be quite fruitful. In particular, as we will see shortly, critical points come in different flavors which have a great influence on the topology of the smooth manifold.

Lemma 137.1. Let M be an n-dimensional smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. Let $P \in M \setminus \partial M$ be a critical point. We pick a chart $\Phi\colon U \to V$ for P. We write $Q := \Phi(P)$. The congruence[1662] class of the Hessian matrix[1663]

$$\mathrm{Hess}(f\circ\Phi^{-1})_Q \;:=\; \left(\frac{\partial^2}{\partial x_i \partial x_j}\Big|_Q f\circ\Phi^{-1}\right)_{i,j=1,\dots,n} \;\in\; \mathrm{M}(n\times n,\mathbb{R})$$

is independent of the choice of the chart.

Proof. There are two approaches to proving the lem:

(1) Let $\Psi\colon X \to Y$ be some other chart around P. We set $R := \Psi(Q)$ and we set $Z := \mathrm{D}(\Psi\circ\Phi^{-1})_P$. A slightly heroic calculation, see [**Gaul1982**, p. 51], shows that $Z^T \cdot \mathrm{Hess}(f\circ\Psi^{-1})_R \cdot Z = \mathrm{Hess}(f\circ\Phi^{-1})_P$.

(2) The statement can also be proved more elegantly by defining intrinsically a symmetric form $\mathrm{H}_P f\colon \mathrm{T}_P M \times \mathrm{T}_P M \to \mathbb{R}$ which now happens to be represented by the matrix $\mathrm{Hess}(f\circ\Phi^{-1})_P$. At this point the lemma is a consequence of the purely algebraic the Forms-Matrices Lemma 133.1. This approach is taken in [**Miln1963a**, p. 4] and [**Nic2011**, p. 6]. ∎

[1662] Here recall that two real $n\times n$-matrices G and H are called *congruent* if there exists a matrix $Z \in \mathrm{GL}(n,\mathbb{R})$ such that $Z^T G Z = H$.

[1663] Implicitly we use throughout that the Hessian matrix is symmetric. The fact that given a smooth function the partial derivatives commute is variously known (depending on the geographic location of the author) as the Schwarz Theorem, the Young Theorem or the Clairaut Theorem.

It follows from Lemma 137.1, common sense and the combination of the Forms-Matrices Lemma 133.1 (1c) and the Signature-Eigenvalues Proposition 133.8 that the following definition is independent of any choices.

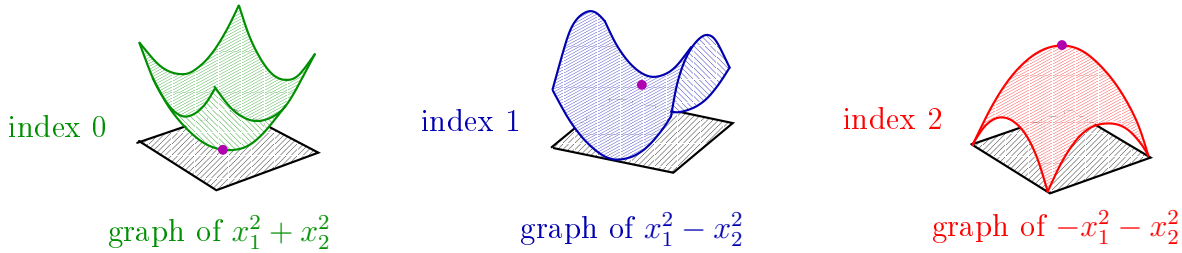
Definition. Let M be an n-dimensional smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. Let $P \in M \setminus \partial M$ be a critical point. We pick a chart $\Phi\colon U \to V$ for P and we write $Q := \Phi(P)$.

(1) We say the critical point P is non-degenerate if $\det(\mathrm{Hess}(f \circ \Phi^{-1})_Q) \neq 0$. Otherwise we call the critical point degenerate.

(2) We refer to[1664]

$$\mathrm{index}(f, P) \;:=\; \text{number of negative eigenvalues of } \mathrm{Hess}(f \circ \Phi^{-1})_Q$$

as the index of the critical point P.



Examples.

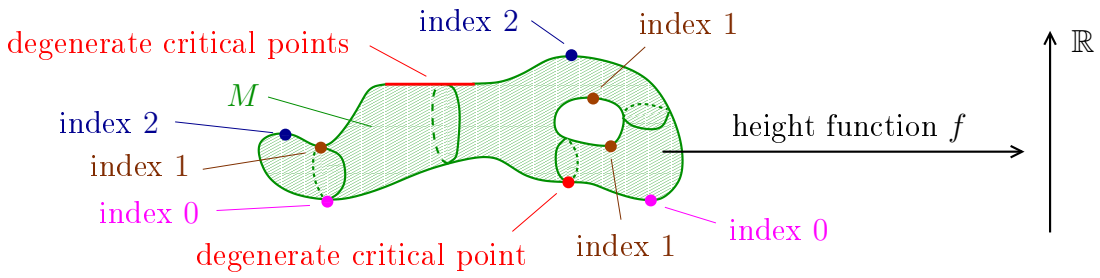
(1) The "mother of all examples" are the functions

$$\begin{array}{ccc} \mathbb{R}^n & \to & \mathbb{R} \\ (x_1, \ldots, x_n) & \mapsto & c + \sum_{i=1}^{n} a_i x_i^2 \end{array}$$

with $c, a_1, \ldots, a_n \in \mathbb{R}$. Evidently the origin 0 is a critical point. With respect to the identity chart the Hessian $\mathrm{Hess}(f)_0$ is the diagonal matrix with diagonal entries $a_1, \ldots, a_n$. Thus the origin is a non-degenerate critical point if and only if all a_i are non-zero. Finally, we have the following equality:

$$\mathrm{index}(f, 0) \;=\; \text{number of negative } a_i.$$

graph of $x_1^2 + x_2^2$ graph of $x_1^2 - x_2^2$ graph of $-x_1^2 - x_2^2$

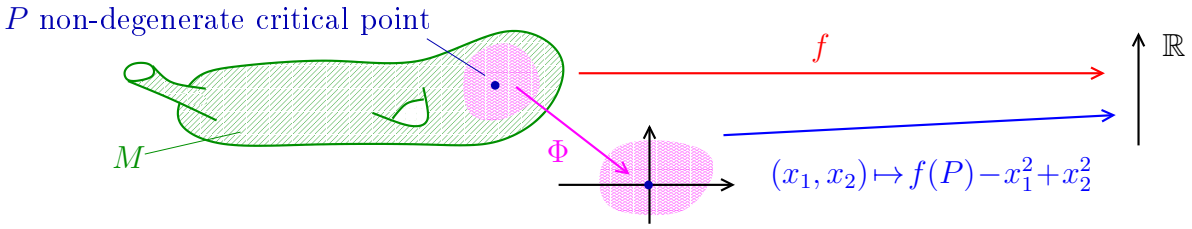


(2) We consider the smooth manifold $M \subset \mathbb{R}^3$ that is shown in the figure below together with the "height function" $f\colon M \to \mathbb{R}$ that is defined by $f(x, y, z) = z$. In the figure below we indicate all critical points of f and we show their indices.

The following result says that, up to taking an appropriate chart, the above mother of all examples is the only example of a non-degenerate critical point. The result was first proved by Marston Morse [**MorsM1934**] in 1934.

[1664] Alternatively one could use the Signature-Eigenvalues Proposition 133.8 to define

$$\mathrm{index}(f, P) \;:=\; b^-(\mathrm{H}_P f\colon \mathrm{T}_P M \times \mathrm{T}_P M \to \mathbb{R})$$



where $\mathrm{H}_P f$ is the intrinsic Hessian mentioned above and where $b^-(\varphi)$ of a symmetric form $\varphi\colon V \times V \to \mathbb{R}$ is defined, see page 2913, as the maximal dimension of a vector subspace W of V for which the symmetric form $\varphi|_W$ is negative-definite.

Theorem 137.2. (Morse Lemma) Let M be an n-dimensional smooth manifold. Furthermore let $f\colon M \to \mathbb{R}$ be a smooth function and let $P \in M \setminus \partial M$ be a critical point. If P is non-degenerate, then there exists a chart $\Phi\colon U \to V$ around P with $U \subset M \setminus \partial M$ and with $\Phi(P) = 0$ such that for every $(x_1, \ldots, x_n) \in V$ we have

$$(f \circ \Phi^{-1})(x_1, \ldots, x_n) \;=\; f(P) - x_1^2 - \cdots - x_k^2 + x_{k+1}^2 + \cdots + x_n^2$$

where $k = \operatorname{index}(f, P)$.

Remark.

(1) Recall that the Inverse Mapping Theorem 24.1 says that if the differential $\mathrm{D}f_P$ of a given map $f\colon M \to N$ between two smooth manifolds at a point $P \in M \setminus \partial M$ is invertible, then the map is locally a diffeomorphism. The Morse lemma is a similar statement: at a non-degenerate critical point the local behavior of a smooth map $f\colon M \to \mathbb{R}$ is determined by the second partial derivatives.

(2) Our proof of the Morse Lemma 137.2 is basically the same proof as in [**Miln1963a**, Lemma 2.2]. Somewhat different proofs are given in [**Nic2011**, Theorem 1.12] and [**Lau2011**, Section 3.3.2].

(3) Let M be an n-dimensional smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. Furthermore let $P \in M \setminus \partial M$ be a non-degenerate critical point. It follows easily from the Morse Lemma 137.2 that
   (a) P is a local maximum if and only if $\operatorname{index}(f, P) = n$.
   (b) P is a local minimum if and only if $\operatorname{index}(f, P) = 0$.

One of the key ingredients to the proof of the Morse Lemma 137.2 is the following proposition.

Proposition 19.14 (Map-as-Matrix Multiplication Proposition). Let $U \subset \mathbb{R}^n$ be an open convex subset that contains the origin and let $f\colon U \to \mathbb{R}$ be a smooth function with $f(0) = 0$. There exist smooth maps $a_1, \ldots, a_n\colon U \to \mathbb{R}$ such that for $i = 1, \ldots, n$ we

have $a_i(0) = \frac{\partial f}{\partial x_i}(0)$ and such that

$$f(x_1, \dots, x_n) \;=\; \sum_{i=1}^{n} a_i(x_1, \dots, x_n) \cdot x_i \quad \text{for all } x = (x_1, \dots, x_n) \in U.$$

This proposition gives us the following corollary, which is actually the content of Exercise 19.13.

Corollary 137.3. (Function-near-Critical Point Corollary) Let $U \subset \mathbb{R}^n$ be an open convex subset that contains the origin and let $f\colon U \to \mathbb{R}$ be a smooth function with $f(0) = 0$. If 0 is a critical point of f, then there exist smooth functions $h_{ij}\colon U \to \mathbb{R}$, $i, j = 1, \dots, n$ such that $h_{ij} = h_{ji}$ and such that

$$f(x) \;=\; \sum_{i=1}^{n} \sum_{j=1}^{n} h_{ij}(x) \cdot x_i \cdot x_j \quad \text{for all } x \in U.$$

Proof of Corollary 137.3. First note that by the Map-as-matrix multiplication Proposition 19.14 there exist smooth maps $a_1, \dots, a_n\colon U \to \mathbb{R}$ such that for $i = 1, \dots, n$ we have $a_i(0) = \frac{\partial f}{\partial x_i}(0) = 0$ and such that

$$f(x) \;=\; \sum_{i=1}^{n} a_i(x) \cdot x_i \quad \text{for all } x = (x_1, \dots, x_n) \in U.$$

Since 0 is a critical point we know that $a_1(0) = \cdots = a_n(0) = 0$. Thus, given $i \in \{1, \dots, n\}$ we can once again apply the ever-useful the Map-as-matrix multiplication Proposition 19.14 to the smooth map a_i and we obtain smooth maps $b_{i1}, \dots, b_{in}\colon U \to \mathbb{R}$ with $b_{ij}(0) = (\frac{\partial}{\partial x_j} a_i)(0) = (\frac{\partial}{\partial x_j} \frac{\partial}{\partial x_i} f)(0)$ and such that

$$a_i(x) \;=\; \sum_{j=1}^{n} b_{ij}(x) \cdot x_j \quad \text{for all } x \in U.$$

It now clear that the maps $h_{ij} := \frac{1}{2}(b_{ij} + b_{ji})$ have the desired properties. ■

Proof of the Morse Lemma 137.2. We make a few preparations.

(1) We can assume that M is an open convex neighborhood U of $0 \in \mathbb{R}^n$, that $P = 0$ is the non-degenerate critical point of $f\colon U = M \to \mathbb{R}$ and that $f(0) = 0$.
(2) Throughout the proof we use the usual notation that given $x \in \mathbb{R}^n$ we denote its coordinates by $x_1, \dots, x_n$.
(3) Let V and W be open neighborhoods of $0 \in \mathbb{R}^n$. We say two smooth maps $g\colon V \to \mathbb{R}$ and $h\colon W \to \mathbb{R}$ are *equivalent*, if there exist open sets $0 \in V' \subset V$ and $0 \in W' \subset W$ and a diffeomorphism $\Psi\colon V' \to W'$ with $\Psi(0) = 0$ such that $(g \circ \Psi^{-1})(y) = h(y)$ for all $y \in W'$. Note that this is indeed an equivalence relation.

With these preparations we can reformulate our goal as follows.

Goal. We want to show that $f\colon U \to \mathbb{R}$ is equivalent to a map that is of the form

$$(x_1, \dots, x_n) \;\mapsto\; \epsilon_1 \cdot x_1^2 + \cdots + \epsilon_n \cdot x_n^2$$

for some $\epsilon_1, \dots, \epsilon_n \in \{-1, 1\}$.

Note that once we have proved this goal we are done, since it follows from Lemma 137.1 that the number of negative ϵ_i's in a map as above equals precisely $\operatorname{index}(f, P)$.

Now let us turn to the task of achieving this goal. First note that by the Function-near-Critical Point Corollary 137.3 we know that there exist smooth functions $h_{ij}\colon U \to \mathbb{R}$,

$i, j = 1, \ldots, n$ such that $h_{ij} = h_{ji}$ and such that f is given by

$$(x_1, \ldots, x_n) \;\mapsto\; \sum_{i=1}^{n} \sum_{j=1}^{n} h_{ij}(x) \cdot x_i \cdot x_j.$$

The idea now is to "diagonalize" the matrices $(h_{ij}(x))_{i,j=1,\ldots,n}$. At this point it is worth recalling that in the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 we gave a constructive proof of the fact that given any real symmetric $(n \times n)$-matrix $A = (a_{ij})$ with $\det(A) \neq 0$ there exists a matrix $P \in \mathrm{GL}(n, \mathbb{R})$ and $\epsilon_1, \ldots, \epsilon_n \in \{-1, 1\}$ such that $P^T A P$ is the diagonal matrix with entries $\epsilon_1, \ldots, \epsilon_n$. The idea now is to imitate the proof of the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6. As in the proof of the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6 we proceed iteratively. This leads us to the following claim.

Claim. Given any $s \in \{0, \ldots, n\}$ the map $f \colon U \to \mathbb{R}$ is equivalent to a map of the form

$$(x_1, \ldots, x_n) \;\mapsto\; \sum_{i=1}^{s} \sum_{j=1}^{s} \mu_{ij}(x) \cdot x_i \cdot x_j \;+\; \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2,$$

where the μ_{ij} are smooth functions with $\mu_{ij} = \mu_{ji}$ and with $\epsilon_i \in \{\pm 1\}$.

Proof. Recall that our goal was precisely to prove the claim for $s = 0$. As we remarked above, for $s = n$ there is nothing left to show, since we already saw that it follows from the Function-near-Critical Point Corollary 137.3 that f is of the required form. Next suppose that the statement holds for some $s \in \{1, \ldots, n\}$. We need to show that the statement also holds for $s - 1$. We might as well assume that f itself is already of the form

$$(x_1, \ldots, x_n) \;\mapsto\; \sum_{i=1}^{s} \sum_{j=1}^{s} \mu_{ij}(x) \cdot x_i \cdot x_j \;+\; \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2 \qquad \text{with } \mu_{ij} = \mu_{ji}.$$

Since 0 is a non-degenerate critical point we know that the matrix $(\mu_{ij}(0))_{i,j=1,\ldots,s}$ is invertible. As we saw in the proof of the Symmetric Forms-over-$\mathbb{R}$-Proposition 133.6, it is an elementary linear algebra fact that there exists a matrix $A \in \mathrm{GL}(s, \mathbb{R})$ such that the ss-entry of $A^T \cdot (\mu_{ij}(0))_{i,j=1,\ldots,s} \cdot A$ is non-zero. By applying the diffeomorphism Φ that is given by the invertible matrix $\begin{pmatrix} A & 0 \\ 0 & \mathrm{id}_{n-s} \end{pmatrix}$ we see that we might as well assume that $\mu_{ss}(0) \neq 0$. After possibly shrinking U we can assume that $\mu_{ss}(x) \neq 0$ for all $x \in U$. Now we consider the map

$$\begin{aligned} \Phi \colon U &\to \mathbb{R}^n \\ x = (x_1, \ldots, x_n) &\mapsto \Big(x_1, \ldots, x_{s-1}, \sqrt{|\mu_{ss}(x)|} \cdot \Big(x_s + \sum_{i=1}^{s-1} \tfrac{\mu_{is}(x)}{|\mu_{ss}(x)|} \cdot x_i\Big), x_{s+1}, \ldots, x_n\Big). \end{aligned}$$

Evidently $\Phi(0) = 0$. A straightforward calculation shows that $\det(\mathrm{D}\Phi_0) = \sqrt{|\mu_{ss}(0)} \neq 0$. It follows from the Inverse Function Theorem 19.12 that, possibly after shrinking U even further, the map $\Phi \colon U \to \mathbb{R}^n$ is a diffeomorphism onto its image. It remains to show that $f \circ \Phi^{-1}$ is of the form

$$y = (y_1, \ldots, y_n) \;\mapsto\; \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \nu_{ij}(y) \cdot y_i \cdot y_j \;+\; \sum_{i=s}^{n} \epsilon_i \cdot y_i^2 \qquad \text{with } \nu_{ij} = \nu_{ji}.$$

Thus let $y = (y_1, \dots, y_n) \in \Phi(U)$. We write $(x_1, \dots, x_n) = x := \Phi^{-1}(y)$. Note that by definition of Φ we have

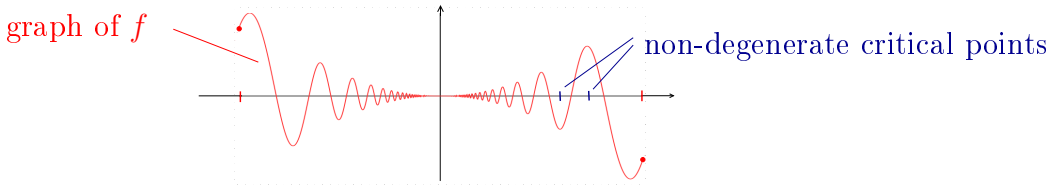
$$(y_1, \dots, y_n) \;=\; \Big(x_1, \dots, x_{s-1}, \sqrt{|\mu_{ss}(x)|} \cdot \Big(x_s + \sum_{i=1}^{s-1} \frac{\mu_{is}(x)}{|\mu_{ss}(x)|} \cdot x_i\Big), x_{s+1}, \dots, x_n\Big).$$

We perform the following little calculation:

$$\begin{aligned} y_s^2 \;&=\; |\mu_{ss}(x)| \cdot \Big(x_s + \sum_{i=1}^{s-1} \frac{\mu_{is}(x)}{|\mu_{ss}(x)|} \cdot x_i\Big) \cdot \Big(x_s + \sum_{j=1}^{s-1} \frac{\mu_{js}(x)}{|\mu_{ss}(x)|} \cdot x_j\Big) \\ &=\; |\mu_{ss}(x)| \cdot \Big(x_{ss}^2 + \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \frac{\mu_{is}(x) \cdot \mu_{js}(x)}{|\mu_{ss}(x)|^2} \cdot x_i \cdot x_j + 2 \cdot \sum_{i=1}^{s-1} \frac{\mu_{is}(x)}{|\mu_{ss}(x)|} \cdot x_i \cdot x_s\Big). \end{aligned}$$

Finally note that

$$\begin{aligned} (f \circ \Phi^{-1})(y) \;=\; f(x) \;&\overset{\text{follows from the above description of } f}{=}\; \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \mu_{ij}(x) \cdot x_i \cdot x_j \;+\; 2 \cdot \sum_{i=1}^{s} \mu_{is} \cdot x_i \cdot s_s \;+\; \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2 \;\overset{\text{follows immediately from the above calculation of } y_s^2}{=} \\ &=\; \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \underbrace{\Big(\mu_{ij}(x) - \frac{\mu_{is}(x) \cdot \mu_{js}(x)}{\mu_{ss}(x)}\Big)}_{=:\widetilde{\mu}_{ij}(x)} \cdot x_i \cdot x_j + \frac{\mu_{ss}(x)}{|\mu_{ss}(x)|} \cdot y_s^2 + \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2 \\ &=\; -\sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \widetilde{\mu}_{ij}(\Phi^{-1}(y)) \cdot y_i \cdot y_j \;+\; \underbrace{\frac{\mu_{ss}(0)}{|\mu_{ss}(0)|}}_{\in\{-1,1\}} \cdot y_s^2 + \sum_{i=s+1}^{n} \epsilon_i \cdot y_i^2. \end{aligned}$$



(the last step follows from $x_i = y_i$ for $i \neq s$, from $x = \Phi^{-1}(y)$ and from the fact that the sign of $\mu_{ss}(x)$ is constant on U)

This concludes the induction step. ∎

Corollary 137.4. Let M be a smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function such that no critical point is contained in ∂M.

(1) The set of non-degenerate critical points of f is a discrete subset of M.
(2) If M is compact and if all critical points are non-degenerate, then there exist only finitely many non-degenerate critical points of f.

Remark. As shown in the figure below, the set of non-degenerate critical points of a smooth function is not necessarily a closed subset. This shows in particular that in Corollary 137.4 (2) we really need to assume that all critical points are non-degenerate.

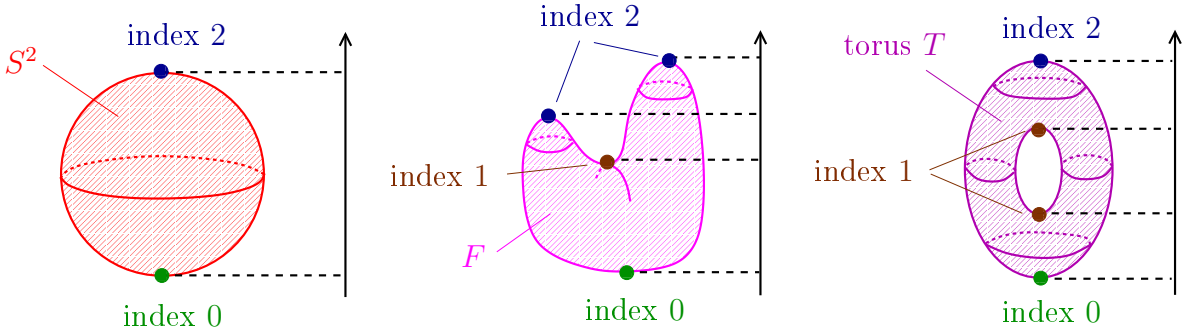
Proof.

(1) It follows immediately from the Morse Lemma 137.2 that every non-degenerate critical point admits an open neighborhood which contains no other critical point. But this means, by definition, that the non-degenerate critical points of f form a discrete subset of M.

(2) In the Regular Value-Open Subset Lemma 26.1 we showed that the set of critical points of f is a closed subset of M. Since we assume that all critical points are non-degenerate we see that the set of non-degenerate critical points is closed. By (1) we also know that this set is discrete. It follows from the hypothesis that M is compact, together with the Compact-Discrete Lemma 1.22 (2), that the set of non-degenerate critical points is indeed finite. ■

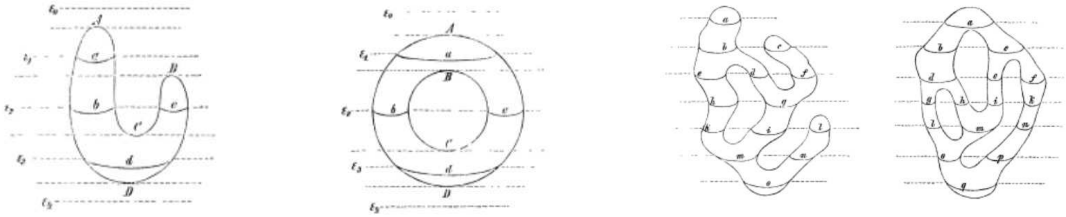
137.2. **Existence of Morse functions.** The following definition introduces the key character of the reminder of this chapter.

Definition. Let M be a smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. We say f is a Morse function if all critical points are non-degenerate and if no critical point lies on ∂M.



Before we discuss the general existence of Morse functions on smooth manifolds let us consider some explicit examples of Morse functions.

Examples.



(1) In the figure below we show three surfaces S^2, F and T in $\mathbb{R}^3$. In each case the "height function"

$$\begin{array}{rcl} h\colon \mathbb{R}^3 & \to & \mathbb{R} \\ (x,y,z) & \mapsto & z \end{array}$$

is a Morse function. Evidently S^2 and F are diffeomorphic, but the numbers of critical points differ. Just for fun we point out that August Möbius [**Möb1863**] in

1863 drew basically the same pictures, see the figure below.

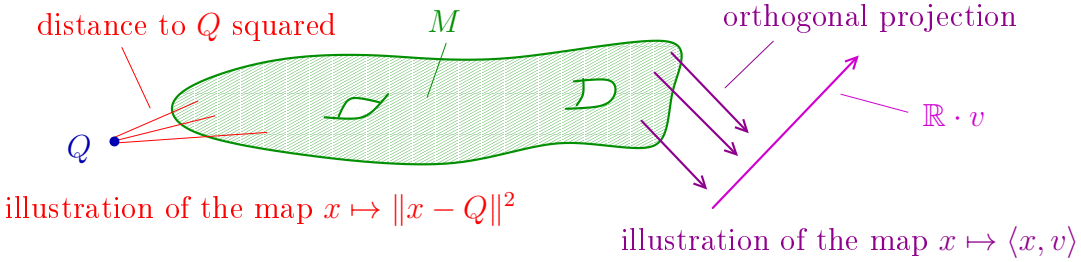
(2) Let $n \in \mathbb{N}_0$. We pick real numbers $c_0 < c_1 < \cdots < c_n$. We consider the following functions on $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$:

$$\begin{array}{rcl} f\colon \mathbb{R}\mathrm{P}^n & \to & \mathbb{R} \\ [x_0 : \cdots : x_n] & \mapsto & \dfrac{\sum_{j=0}^{n} c_j \cdot x_j^2}{x_0^2 + \cdots + x_n^2} \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{C}\mathrm{P}^n & \to & \mathbb{R} \\ [z_0 : \cdots : z_n] & \mapsto & \dfrac{\sum_{j=0}^{n} c_j \cdot |z_j|^2}{|z_0|^2 + \cdots + |z_n|^2}. \end{array}$$

Using the explicit charts given in Exercise 19.16 and the Complex Projective Space-is-Complex Manifold Lemma 32.16 we will verify in Exercise 137.3 that both maps are Morse functions, that both maps have precisely $n+1$ critical points and that these are of index $0, 1, \ldots, n$ respectively $0, 2, \ldots, 2n$.

(3) Let $n \in \mathbb{N}$. In the matrix Group-Smooth Manifold Proposition 26.7 we showed that $\mathrm{SO}(n)$ is a closed smooth manifold of dimension $\frac{1}{2}(n-1)$. Let $1 < c_1 < \cdots < c_n$ be real numbers. In [**Mata2002**, Lemma 3.12] it is shown that the map

$$\begin{array}{rcl} \mathrm{SO}(n) & \to & \mathbb{R} \\ A = (a_{ij}) & \mapsto & \sum_{j=1}^{n} c_j \cdot a_{jj} \end{array}$$



is a Morse function. Furthermore it is shown that the critical points are precisely the diagonal matrices in $\mathrm{SO}(n)$. With very similar ideas one can also obtain explicit Morse functions on the smooth manifolds $\mathrm{U}(n)$ and $\mathrm{SU}(n)$. We refer to [**Mata2002**, Examples 3.13 and 3.14] for details.

The following proposition provides a rich source of Morse functions.

Proposition 137.5. (Morse Function Existence Proposition) Let M be a closed smooth submanifold of some $\mathbb{R}^n$.

(1) The set of $Q \in \mathbb{R}^n$ for which the map $M \to \mathbb{R}$ given by $x \mapsto \|x - Q\|^2$ is a Morse function is a set of full measure.[1665]

(2) The set of $v \in \mathbb{R}^n$ for which the map $M \to \mathbb{R}$ given by $x \mapsto \langle x, v \rangle$ is a Morse function is a set of full measure.

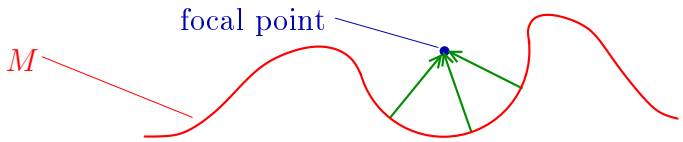
Sketch of proof. Let M be a closed smooth submanifold of some $\mathbb{R}^n$.

(1) Given $Q \in \mathbb{R}^n$ we consider the map

$$\begin{array}{rcl} f_Q \colon M & \to & \mathbb{R} \\ x & \mapsto & \|x - Q\|^2. \end{array}$$

Furthermore we consider

$$N := \{(p, w) \in \mathbb{R}^n \times \mathbb{R}^n \,|\, p \in M \text{ and } w \in (\widetilde{\mathrm{T}}_P M)^{\perp}\}.$$



It is not particularly difficult to show that N is an n-dimensional submanifold of $\mathbb{R}^{2n}$. Next we consider the "endpoint map"

$$\begin{array}{rcl} E \colon N & \to & \mathbb{R}^n \\ (p, w) & \mapsto & p + w \end{array}$$

[1665] We refer to page 762 for the definition of a subset of full measure.

which is evidently smooth. We say $Q \in \mathbb{R}^n$ is a *focal point* if Q is a critical value of E. A slightly heroic calculation, see [**Miln1963a**, Lemma 6.5], shows that Q is a focal point if and only if the map $f_Q \colon M \to \mathbb{R}$ has non-degenerate critical points. The desired statement now follows from the above discussion together with Sard's Theorem 31.1 which tells us that the set of critical values of E is of measure zero in $\mathbb{R}^n$.

(2) This statement is proved in [**Nic2011**, Corollary 1.25]. ■

Proposition 137.6. (Morse Function-Existence Proposition) Every closed smooth manifold admits a Morse function.

Remark.

(1) There are many refinements of the Morse Function-Existence Proposition 137.6 in the literature. For example, by [**Mata2002**, Theorem 2.20] every smooth function on a closed smooth manifold can be approximated by Morse functions.

(2) Using a doubling argument and collar neighborhoods it is a routine exercise to show, using the Morse Function-Existence Proposition 137.6, that also every compact smooth manifold admits a Morse function. But as we will see in Chapter 139, for compact smooth manifolds it is much more convenient to work with Morse functions that "respect the boundary". In the Morse Function-Existence Proposition 139.4 we will provide such a refinement of the Morse Function-Existence Proposition 137.6 for smooth manifolds with boundary.

(3) In Proposition 139.10 we will see that one can always find "self-indexing" Morse functions.

Proof. Let M be a closed smooth manifold. It follows from the Euclidean Embedding Theorem 27.1 together with the Smooth Embedding Theorem 24.10 that we can assume that M is a submanifold of some $\mathbb{R}^n$. It now follows from the Morse Function Existence Proposition 137.5 that M admits a Morse function. ■

137.3. **The gradient vector field.** In this section we will study the gradient vector field ∇f of a smooth function $f \colon M \to \mathbb{R}$ on a smooth submanifold $M \subset \mathbb{R}^n$. We will see that the gradient vector field of a Morse function has particularly nice properties. In particular we will obtain a new proof of the existence of non-degenerate vector fields on smooth manifolds.

Before we can introduce the gradient vector field we need to recall the following definition from page 2656.

Definition. Let V be a real vector space and let $\varphi\colon V \times V \to \mathbb{R}$ be a symmetric $\mathbb{R}$-bilinear pairing. We say φ is non-singular if the induced map

$$\begin{array}{rcl} V & \to & \mathrm{Hom}_{\mathbb{R}}(V, \mathbb{R}) \\ v & \mapsto & (w \mapsto \varphi(v, w)) \end{array}$$

is an isomorphism.

The one example we care about is provided by the following lemma.

Lemma 137.7. Let $\langle -, - \rangle\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ be the usual Euclidean pairing and let $V \subset \mathbb{R}^n$ be a vector subspace. The restriction of $\langle -, - \rangle\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ to $V \times V \to \mathbb{R}$ is non-singular.

Proof. Since V is finite-dimensional it suffices to show that $V \to \mathrm{Hom}_{\mathbb{R}}(V, \mathbb{R})$ is a monomorphism. Thus let $v \in V$ be non-zero. Then $\langle v, v \rangle \neq 0$, which shows that the homomorphism $w \mapsto \langle v, w \rangle$ is not the zero homomorphism. ■

Definition. Let M be a smooth submanifold of some $\mathbb{R}^n$ and let $f\colon M \to \mathbb{R}$ be a smooth function. We refer to the vector field

$$\begin{array}{rcl} \nabla f\colon M & \to & \mathbb{R}^n \\ P & \mapsto & \text{the unique vector}^{1666}\ \nabla f(P) \in \widetilde{\mathrm{T}}_P M \text{ such that for} \\ & & \text{all } w \in \widetilde{\mathrm{T}}_P M \text{ we have } \langle \nabla f(P), w \rangle = \mathrm{D}f_P(w). \end{array}$$

as the gradient vector field of f.

Before we discuss gradient vector fields in detail it is worth recalling the following definition from page 1021.

Definition. Let M be a smooth manifold and let v be a smooth vector field on M. Let $P \in M \setminus \partial M$ be a zero of v. We pick a chart $\Phi\colon U \to V$ with $\Phi(P) = 0$. We write $\Psi := \Phi^{-1}$. We consider the map

$$\begin{array}{rcl} \Psi^* v\colon V & \to & \mathbb{R}^n \\ x & \mapsto & (\Psi^* v)(x) = \mathrm{D}\Phi_{\Psi(x)} v(\Psi(x)). \end{array}$$

(1) If $\mathrm{D}(\Psi^* v)_0$ is an invertible matrix, then we say that the zero is non-degenerate. Otherwise we call the zero degenerate.
(2) If the zero is non-degenerate, then we define

$$\mathrm{index}(v, x) := \begin{cases} +1, & \text{if } \det(\mathrm{D}(\Psi^* v)_0) > 0, \\ -1, & \text{if } \det(\mathrm{D}(\Psi^* v)_0) < 0. \end{cases}$$

In Lemma 45.6 we showed that these notions do not depend on the choice of the chart Φ.

Proposition 137.8. (Gradient Vector Field Proposition) Let M be a smooth submanifold of some $\mathbb{R}^n$ and let $f\colon M \to \mathbb{R}$ be a smooth function. The gradient vector field ∇f is smooth and given any $P \in M$ the following statements hold:

(1) P is a critical point of f if and only if P is a zero of ∇f.
(2) If P is a critical point of f, then P is a non-degenerate critical point of f if and only if P is a non-degenerate zero of ∇f.
(3) If P is a non-degenerate critical point of f, then $\mathrm{index}(\nabla f, P) = (-1)^{\mathrm{index}(f,P)}$.

[1666] The existence and uniqueness of $v(P)$ is of course guaranteed by Lemma 137.7.

Before we get to the slightly messy proof of the Gradient Vector Field Proposition 137.8 let us first point out that we can now give a new proof of the Non-Degenerate Vector Field Existence Proposition 45.15.

Proposition 129.4. (Non-Degenerate Vector Field Existence Proposition) Every closed smooth manifold M admits a smooth vector field v such that all zeros are non-degenerate.

Proof of the Non-Degenerate Vector Field Existence Proposition 129.4. Let M be a closed smooth manifold. By the Euclidean Embedding Theorem 27.1 we can assume that M is a smooth submanifold of some $\mathbb{R}^n$. By the Morse Function Existence Proposition 137.5 we know that M admits a Morse function $f\colon M \to \mathbb{R}$. It follows from the Gradient Vector Field Proposition 137.8 that the gradient vector field ∇f is a vector field such that all zeros are non-degenerate. ■

The proof of the Gradient Vector Field Proposition 137.8 rests on the following two purely algebraic lemmas.

Auxiliary Lemma 137.9. Let T be a k-dimensional real vector space and let $\alpha\colon T\times T \to \mathbb{R}$ be a symmetric $\mathbb{R}$-bilinear pairing. Furthermore let $t_1,\dots,t_k$ be a basis for T. We set $\Theta := (\alpha(t_i,t_j))_{i,j=1,\dots,k} \in \mathrm{M}(k\times k,\mathbb{R})$.

(1) If α is non-singular, then $\det(\Theta)\neq 0$.
(2) If α is positive-definite, then $\det(\Theta) > 0$.

Proof. The first Statement follows from the Forms-Matrices Lemma 133.1 (1b) and the second statement follows from the Signature-Eigenvalues Proposition 133.8 and the fact, that very symmetric real matrix is diagonalizable. ■

Auxiliary Lemma 137.10. Let $\Psi\colon \mathbb{R}^k \to T$ be an isomorphism between real vector spaces. We suppose that T is equipped with a non-singular symmetric $\mathbb{R}$-bilinear pairing α. Let $f\colon T\to\mathbb{R}$ be a linear map. Given $i,j\in\{1,\dots,k\}$ we set $\theta_{ij} := \alpha(\Psi(e_i),\Psi(e_j))$ and we set $\Theta := (\theta_{ij})_{i,j=1,\dots,k} \in \mathrm{M}(k\times k,\mathbb{R})$. If $\widetilde{v}\in\mathbb{R}^k$ satisfies $\langle \widetilde{v}, v\rangle = (f\circ\Psi)(v)$ for all $v\in\mathbb{R}^k$, then[1667]

$$\widetilde{t} \;:=\; \sum_{j=1}^{k}\sum_{i=1}^{k} (\Theta^{-1})_{ij}\cdot\langle\widetilde{v},e_i\rangle\cdot\Psi(e_j)$$

has the property that

$$\alpha(\widetilde{t},t) \;=\; f(t) \qquad\qquad \text{for all } t\in T.$$

Proof of Lemma 137.10. It suffices to show that $\widetilde{t}$ satisfies the condition for the basis vectors $t=\Psi(e_r)$. For $r\in\{1,\dots,k\}$ we calculate

$$\begin{aligned}\alpha(\widetilde{u},\Psi(e_r)) &\overset{\text{definition of } \widetilde{t} \text{ and bilinearity of } \alpha}{\downarrow} \sum_{j=1}^{k}\sum_{i=1}^{k}(\Theta^{-1})_{ij}\cdot\langle\widetilde{v},e_i\rangle\cdot\underbrace{\alpha(\Psi(e_j),\Psi(e_r))}_{=\theta_{jr}} \;=\; \sum_{i=1}^{k}\underbrace{\sum_{j=1}^{k}(\Theta^{-1})_{ij}\cdot\theta_{jr}}_{=\delta_{ir}\text{ by definition of }\Theta^{-1}}\cdot\langle\widetilde{v},e_i\rangle \\ &= \langle\widetilde{v},e_r\rangle \underset{\text{by the defining property of } \widetilde{v}}{\uparrow} (f\circ\Psi)(e_r) \;=\; f(\Psi(e_r)).\end{aligned}$$

■

[1667] By Lemma 137.9 we know that Θ is invertible.

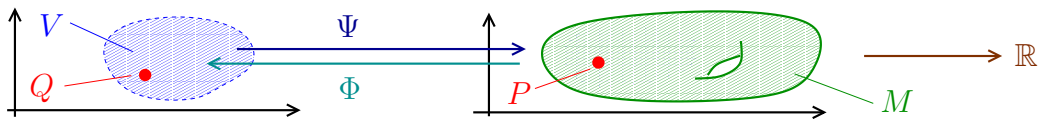
Auxiliary Lemma 137.11. Let $V \subset \mathbb{R}^k$ be an open subset and let $\Xi\colon V \to \mathrm{M}(k \times k, \mathbb{R})$ and $u\colon A \to \mathbb{R}^k$ be smooth maps. Let $Q \in A$. If $u(Q) = 0$, then

$$\mathrm{D}(\underbrace{x \mapsto \Xi(x) \cdot u(x)}_{\text{map } A \to \mathbb{R}^n})_S \;=\; \Xi(S) \cdot \mathrm{D}u_S \quad \in \mathrm{M}(n \times m, \mathbb{R}).$$

Proof of Lemma 137.11. The lemma follows immediately from the Product Rule applied to each entry and the fact that $u(Q) = 0$. ■

Proof of the Gradient Vector Field Proposition 137.8. We start out with a proof of a special case.

Claim 1. Let V be an open subset of some $\mathbb{R}^k$ or of some $\mathbb{H}^k$ and let $g\colon V \to \mathbb{R}$ be a smooth function. For any $Q \in V$ we have



$$\nabla g(Q) \;=\; \begin{pmatrix} \frac{\partial g}{\partial x_1}(Q) \\ \vdots \\ \frac{\partial g}{\partial x_k}(Q) \end{pmatrix}$$

Proof. By the differential-from-Partial Derivatives Proposition 19.9 we know that for each $Q \in V$ we have $\mathrm{D}g_Q = (\frac{\partial g}{\partial x_1}(Q) \dots \frac{\partial g}{\partial x_k}(Q)) \in \mathrm{M}(1 \times k, \mathbb{R})$. It follows easily from this observation and the definitions that the gradient vector field ∇g is indeed given by the map

$$\begin{array}{rcl} \nabla g\colon V & \to & \mathbb{R}^k \\ Q & \mapsto & \begin{pmatrix} \frac{\partial g}{\partial x_1}(Q) \\ \vdots \\ \frac{\partial g}{\partial x_k}(Q) \end{pmatrix}. \end{array}$$

Note that it follows from this description that the gradient vector field is smooth. Furthermore note that for any $Q \in V$ we have $\mathrm{D}(\nabla g)_Q = \mathrm{Hess}(g)_Q$. Thus it follows immediately from the definition of non-degenerate zeros and the index of a non-degenerate zero, using the identity chart, that the gradient vector field satisfies Statements (1)–(3). The case that V is an open subset of $\mathbb{H}^k$ is dealt with in the same way. ⊞

Now let M be a k-dimensional smooth submanifold of some $\mathbb{R}^n$ and let $f\colon M \to \mathbb{R}$ be a smooth function. The statements of the proposition are all local. Thus, after possibly restricting ourselves to the domain of a chart, we can assume that there exists a diffeomorphism $\Phi\colon M \to V$ where V is an open subset of $\mathbb{R}^k$ or $\mathbb{H}^k$. We write $\Psi := \Phi^{-1}\colon V \to M$. Given $i, j \in \{1, \dots, k\}$ and given $Q \in V$ we set $\theta_{ij}(Q) := \langle \mathrm{D}\Psi_Q(e_i), \mathrm{D}\Psi_Q(e_j) \rangle$. Furthermore we write $\Theta(Q) := (\theta_{ij}(Q))_{i,j=1,\dots,k} \in \mathrm{M}(k \times k, \mathbb{R})$. The following claim now gives a calculation of Δf.

Claim 2.

(1) Let $P \in M$. We set $Q := \Phi(P)$. Then

$$\nabla f(P) \;:=\; \sum_{j=1}^{k}\sum_{i=1}^{k} \underbrace{(\Theta(Q)^{-1})_{ij} \cdot \frac{\partial(f\circ\Psi)}{\partial x_i}(Q)}_{\in\mathbb{R}} \cdot \underbrace{\mathrm{D}\Psi_Q(e_j)}_{\in\widetilde{\mathrm{T}}_P M} \quad \in \widetilde{\mathrm{T}}_P M.$$

(2) For any $Q \in V$ we have

$$(\Psi^*(\nabla f))(Q) \;=\; (\Theta(Q)^{-1})^T \cdot (\nabla(f\circ\Psi))(Q) \quad \in \mathbb{R}^k.$$

Proof.

(1) This statement follows immediately from Claim 1, applied to the smooth function $g = f \circ \Psi \colon V \to \mathbb{R}$, and Lemma 137.10, applied to the isomorphism $\mathrm{D}\Psi_Q \colon \mathbb{R}^k \to \widetilde{\mathrm{T}}_P M$.

(2) For any any $Q \in V$ we have

$$\begin{aligned}
(\Psi^*(\nabla f))(Q) &\overset{\text{by definition of } \Psi^*}{=} \mathrm{D}\Phi_{\Psi(Q)}((\nabla f)(\Psi(Q))) \\
&= (\Theta(Q)^{-1})^T \cdot \begin{pmatrix} \frac{\partial(f\circ\Psi)}{\partial x_1}(Q) \\ \vdots \\ \frac{\partial(f\circ\Psi)}{\partial x_k}(Q) \end{pmatrix} \\
&\overset{\text{follows from Statement (1), the linearity of } \mathrm{D}\Phi_{\Psi(Q)} \text{ and fact that } \mathrm{D}\Phi_{\Psi(Q)}(\mathrm{D}\Psi_Q(e_j)) = e_j}{=} \sum_{j=1}^{k}\sum_{i=1}^{k} (\Theta(Q)^{-1})_{ij} \cdot \frac{\partial(f\circ\Psi)}{\partial x_i}(Q) \cdot e_j \\
&= (\Theta(Q)^{-1})^T \cdot (\nabla(f\circ\Psi))(Q). \qquad \text{by Claim 1}
\end{aligned}$$

⊞

It follows immediately from Claim 2 (a) that $\nabla f \colon M \to \mathbb{R}^n$ is smooth. It remains to prove Statements (1), (2) and (3). Since the various notions are defined via charts it suffices to prove the following claim.

Claim 3. Given any $Q \in V$ the following statements hold:

(1) Q is a critical point of the smooth map $f \circ \Psi \colon V \to \mathbb{R}$ if and only if Q is a zero of the vector field $\Psi^*(\nabla f)$ on V.

(2) If Q is a critical point of $f \circ \Psi$, then Q is a non-degenerate critical point of the map $f \circ \Psi \colon V \to \mathbb{R}$ if and only if Q is a non-degenerate zero of the vector field $\Psi^*(\nabla f)$ on V.

(3) If Q is a non-degenerate critical point of the smooth map $f \circ \Psi \colon V \to \mathbb{R}$, then $\mathrm{index}(\Psi^*(\nabla f), Q) = (-1)^{\mathrm{index}(f\circ\Psi, Q)}$.

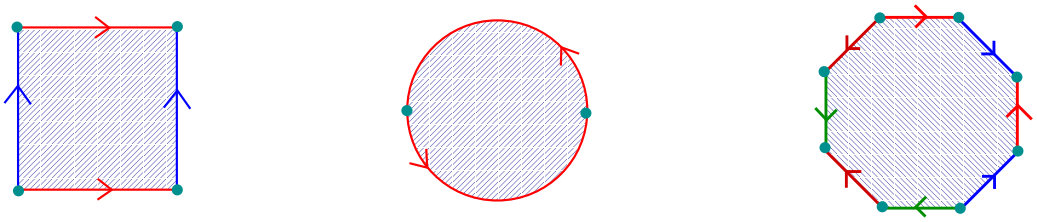
Proof. Let $\Theta \in V$. We start out with the following two observations:

(a) By Lemma 137.9 we know that $\det(\Theta(Q)) > 0$, which implies also that $\det((\Theta^{-1})^T) > 0$.

(b) Let Q be a critical point of $f \circ \Psi$. Then

$$\begin{aligned}
\mathrm{D}(x \mapsto (\Theta(x)^{-1})^T \cdot (\nabla(f\circ\Psi))(x))_Q &\overset{\text{by Lemma 137.11, since } \nabla(f\circ\Psi)(Q) = 0}{=} (\Theta(Q)^{-1})^T \cdot \mathrm{D}_Q(\nabla(f\circ\Psi)) \\
&= (\Theta(Q)^{-1})^T \cdot \mathrm{Hess}_Q(f\circ\Psi) \;\in\; \mathrm{M}(k\times k, \mathbb{R}). \\
&\qquad \text{follows immediately from Claim 1 and the definitions}
\end{aligned}$$

(c) Let $H \in \mathrm{M}(k \times k, \mathbb{R})$ be a symmetric matrix with non-zero determinant. Since the determinant of H is the product of the eigenvalues of H we see that



$$(-1)^{\text{number of negative eigenvalues of } H} = \begin{cases} -1, & \text{if } \det(H) < 0, \\ 1, & \text{if } \det(H) > 0. \end{cases}$$

All three desired statements follow almost immediately from Claim 2 (b) together with (a), (b) and (c). ■

Exercises for Chapter 137.

Exercise 137.1. Show that every Morse function is a height function. More precisely, let M be a smooth manifold and let $f\colon M \to \mathbb{R}$ be a Morse function. Show that there exists a smooth embedding $\varphi\colon M \to \mathbb{R}^n$ such that $f = h \circ \varphi$ where $h\colon \mathbb{R}^n \to \mathbb{R}$ is the map given by $(x_1, \ldots, x_n) \mapsto x_n$.

Exercise 137.2. Sketch Morse functions on the torus $T = [0,1]^2/\!\sim$, the real projective plane $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/x \sim -x$ and the surface of genus two $E_8/\!\sim$ such that each Morse function has a single local maximum and a single local minimum.

Exercise 137.3. Let $n \in \mathbb{N}_0$. We pick real numbers $c_0 < c_1 < \cdots < c_n$. We consider the following functions on $\mathbb{R}\mathrm{P}^n = S^n/\{\pm \mathrm{id}\}$ and $\mathbb{C}\mathrm{P}^n = S^{2n+1}/S^1$:

$$\begin{array}{rcl} f\colon \mathbb{R}\mathrm{P}^n & \to & \mathbb{R} \\ [x_0 : \cdots : x_n] & \mapsto & \sum_{j=0}^{n} c_j \cdot x_j^2 \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{C}\mathrm{P}^n & \to & \mathbb{R} \\ [z_0 : \cdots : z_n] & \mapsto & \sum_{j=0}^{n} c_j \cdot |z_j|^2. \end{array}$$

(a) Show that f is a Morse function, that f has precisely $n+1$ critical points and that these are of index $0, 1, \ldots, n$.

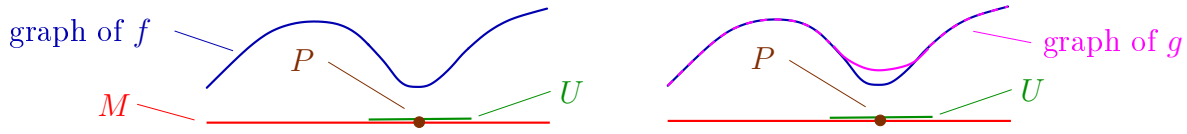
(b) Show that g is a Morse function, that g has precisely $n+1$ critical points and that these are of index $0, 2, \ldots, 2n$.

Remark. You might want to use the explicit charts given in Exercise 19.16 and the Complex Projective Space-is-Complex Manifold Lemma 32.16.
Remark. This exercise is basically a reformulation of Exercise 45.5.

Exercise 137.4. Let M be a smooth manifold and let $f\colon M \to \mathbb{R}$ be a Morse function. Furthermore let $\lambda\colon M \to \mathbb{R}$ be a smooth function such that $\mathrm{D}\lambda_P \neq 0$ for every $P \in M$. Show that $\lambda \cdot f\colon M \to \mathbb{R}$ is also a Morse function and that the critical points, and the corresponding indices, of $\lambda \cdot f$ agree with the critical points, and the corresponding indices, of λ.

Exercise 137.5. Let M be a nd N be two closed smooth manifolds and let $f\colon M \to \mathbb{R}$ and $g\colon N \to \mathbb{R}$ be Morse functions.

(a) Let $a, b \in \mathbb{R}$ with $a > \max(|f|)$ and $b > \max(|g|)$. Show that the map



$$\begin{array}{rccc} f \cdot g\colon & M \times N & \to & \mathbb{R} \\ & (x, y) & \mapsto & (a + f(x)) \cdot (b + g(y)) \end{array}$$

is a Morse function.

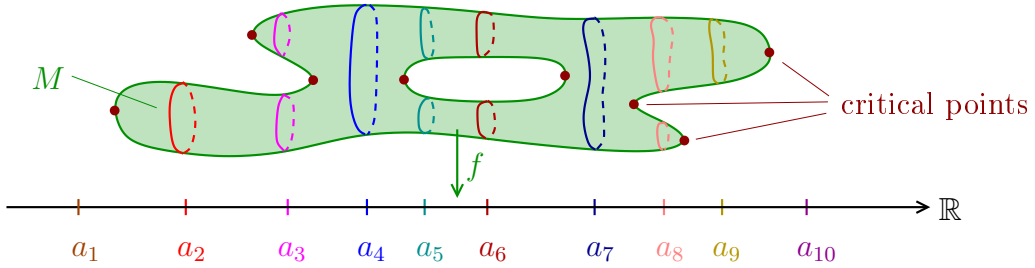
(b) Determine the critical points, and their indices, of the Morse function of $f \cdot g$ in terms of the critical points, and their indices, of f and g.

Exercise 137.6. Let M be a smooth manifold, let $f\colon M \to \mathbb{R}$ be a smooth function and let $P \in M \setminus \partial M$ be a non-degenerate critical point of f. Let U be a compact neighborhood of $P \in M \setminus \partial M$ which contains no other critical point. Show that there exists an $\epsilon > 0$ such that for every $\mu \in [0, \epsilon]$ there exists a smooth function $g\colon M \to \mathbb{R}$ with the following four properties:

(1) The function g agrees with f outside of U.
(2) P is a critical point of g with $\operatorname{index}(g, P) = \operatorname{index}(f, P)$.
(3) $g(P) = f(P) + \mu$.
(4) P is the only critical point of g in U.

138. Morse theory I: Closed smooth manifolds

In the last chapter we showed that every compact smooth manifolds admits Morse functions. In this chapter we will put Morse functions to good use, namely we will use them to show that every compact smooth manifold admits a handle decomposition.



138.1. **The Smooth Manifold-Product Theorem.** In this section and the following section we will see that there is a close relationship between the topology of a smooth manifold and the non-degenerate critical points of a Morse function.

Notation. Let M be a smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. Given $a \in \mathbb{R}$ we write

$$M_a := f^{-1}((-\infty, a]) = \{x \in M \mid f(x) \leq a\}.$$

Note that if a is a regular value and if $\partial M \cap f^{-1}(a) = \varnothing$, then it follows from the Regular Value Theorem 26.4 that $f^{-1}(a)$ is a closed submanifold of M and it follows from Exercise 26.6 that M_a is a submanifold of M with boundary $f^{-1}(a) \cup (\partial M \cap f^{-1}((-\infty, a]))$.

Example. In the figure below we show a smooth manifold M together with the "length" function $f\colon M \to \mathbb{R}$ given by $(x, y, z) \mapsto x$. For various $a_i \in \mathbb{R}$ we show the corresponding preimage $f^{-1}(a_i)$. The submanifold M_{a_i} is of course everything "to the $\leq$-left" of $f^{-1}(a_i)$.

Theorem 138.1. (No Critical Point-Diffeomorphism Theorem) Let M be a compact smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. Let $a < b \in \mathbb{R}$ such that $f^{-1}([a, b])$ does not contain a critical point of f. If $f^{-1}([a, b]) \cap \partial M = \varnothing$, then there exists a diffeomorphism $M_a \to M_b$. Furthermore, given any $\epsilon > 0$ one can find diffeomorphism $M_a \to M_b$ that is the identity on the common subset $M_{a-\epsilon}$.

Example. In the figure above there is no critical point in $f^{-1}([a_5, a_6])$. Thus we obtain from the No Critical Point-Diffeomorphism Theorem 138.1 that the smooth manifolds M_{a_5} and M_{a_6} are diffeomorphic. Furthermore, we can find a diffeomorphism that is the identity on "most of M_{a_5}".

Our proof of the No Critical Point-Diffeomorphism Theorem 138.1 rests on the following result, that will turn out to be of independent interest later on.

Theorem 138.2. (Smooth Manifold-Product Theorem) Let M be a compact smooth manifold, let $f\colon M \to \mathbb{R}$ be a smooth function and let $a < b \in \mathbb{R}$. We suppose that for every $P \in f^{-1}([a, b])$ the differential $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathbb{R}$ is non-zero.[1668] Furthermore we suppose that the following conditions are satisfied:

(1) $f^{-1}(a)$ is a closed submanifold of M or it is a union of components of ∂M.
(2) $f^{-1}(b)$ is a closed submanifold of M or it is a union of components of ∂M.

Then $f^{-1}([a,b])$ is diffeomorphic to $[a,b] \times f^{-1}(a)$.[1669]

Sketch of a proof of Theorem 138.2. Note that using the Euclidean Embedding Theorem 27.1 and the Smooth Embedding Theorem 24.10 we can assume that M is a submanifold of some $\mathbb{R}^n$. Given $P \in M$ we denote by[1670] $\operatorname{grad} f_P \in \widetilde{\mathrm{T}}_P M$ the gradient of f at P.[1671] Note that our hypothesis on f just says that given any $P \in f^{-1}([a,b])$ the gradient is non-zero. Thus given any $P \in f^{-1}([a,b])$ we can define

$$v(P) := \frac{\operatorname{grad} f_P}{\|\operatorname{grad} f_P\|^2} \in \widetilde{\mathrm{T}}_P M.$$

Claim 1. If $\gamma\colon [0,\epsilon] \to f^{-1}([a,b])$ is a solution to the differential equation $\gamma'(t) = v(\gamma(t))$, then $(f \circ \gamma)'(t) \equiv 1$.

Proof. We perform the following calculation:

$$\begin{array}{rcccccl} & & \text{Chain Rule 19.10} & & \text{definition of gradient, here we set } P{:=}\gamma(t) & & \\ (f\circ\gamma)'(t) & = & \mathrm{D}(f\circ\gamma)_t & \overset{\downarrow}{=} & \mathrm{D}f_{\gamma(t)}(\gamma'(t)) & \overset{\downarrow}{=} & \langle \gamma'(t), \operatorname{grad} f_P\rangle \\ & & & = & \langle v(\gamma(t)), \operatorname{grad} f_P\rangle & = & \left\langle \frac{1}{\|\operatorname{grad} f_P\|^2}\cdot \operatorname{grad} f_P, \operatorname{grad} f_P\right\rangle = 1. \\ & & & \overset{\uparrow}{} & & \overset{\uparrow}{} & \end{array}$$

by hypothesis we have $\gamma'(t) = v(\gamma(t))$ since $P = \gamma(t)$ and by definition of v ⊞

We set $W := f^{-1}(a)$. It remains to prove the following claim.

Claim 2.

(1) Given any $P \in W$ there exists a unique smooth map $\gamma_P\colon [a,b] \to f^{-1}([a,b])$ such that $\gamma_P(a) = P$ and such that for each $t \in [a,b]$ we have $\gamma_P'(t) = v(\gamma_P(t))$.

(2) The map

$$\begin{array}{rccc} \Theta\colon & [a,b]\times W & \to & M \\ & (t,P) & \mapsto & \gamma_P(t) \end{array}$$

is a smooth embedding with image $f^{-1}([a,b])$.

[1668] Let $P \in M$. We recall the following definition from page 701:

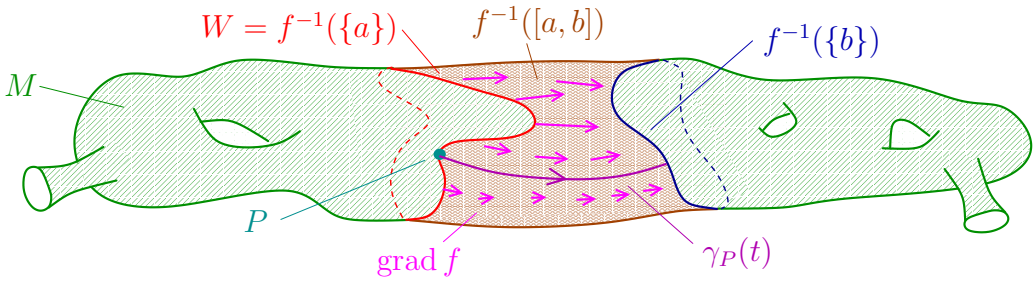
(1) If $P \notin M \setminus \partial M$, then P is a regular point if $\mathrm{D}f_P\colon \mathrm{T}_P M \to \mathbb{R}$ is non-zero.
(2) If $P \in \partial M$, then P is a regular point if the map $\mathrm{D}f_P\colon \mathrm{T}_P \partial M \to \mathbb{R}$ is non-zero.

Thus we see that for points in $M \setminus \partial M$ our condition just says that we demand that P is a regular point. For points on the boundary our condition is more relaxed.

[1669] To make sense of the proposition we need to make the following two observations:

(i) Our hypotheses (1) and (2), together with Exercise 26.6, imply that the Submanifold Smooth Structure Lemma 19.24 that $f^{-1}([a,b])$ is naturally a smooth manifold.
(ii) Our hypothesis (1), together with the combination of the Submanifold Smooth Structure Lemma 19.24 and the Smooth Manifold Boundary Proposition 19.26 shows that $f^{-1}(a)$ is a closed smooth manifold in it own right. It follows from the Smooth Manifold product Proposition 19.31 that the product $[a,b] \times f^{-1}(a)$ is naturally a smooth manifold.

Thus it actually does make sense to say that $f^{-1}([a,b])$ is diffeomorphic to $[a,b] \times f^{-1}(a)$.



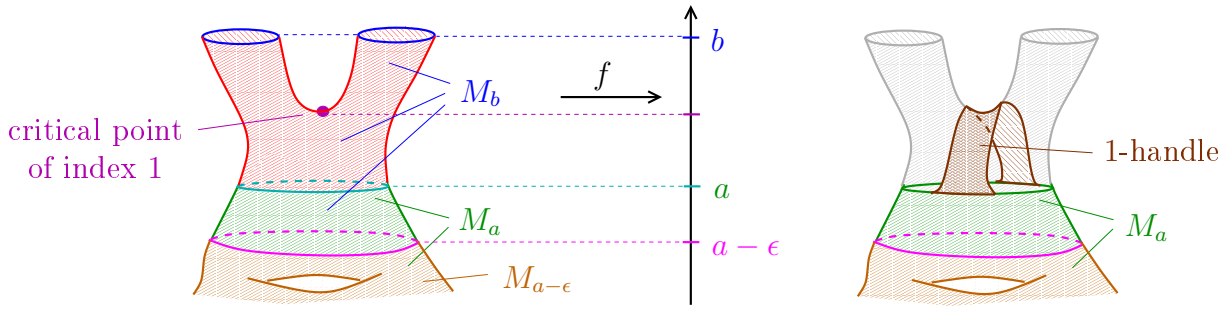
[1670] Recall that on page 620 we introduced the physical tangent space $\widetilde{\mathrm{T}}_P M$ which, by the Tangent Space-Natural isomorphism Proposition 23.16, is naturally isomorphic to $\mathrm{T}_P M$.

[1671] The gradient $\operatorname{grad} f_P \in \widetilde{\mathrm{T}}_P M$ of f at $P \in M$ is defined as the unique vector in $\widetilde{\mathrm{T}}_P M$ which satisfies $\langle w, \operatorname{grad} f_P\rangle = \mathrm{D}f_P(w) \in \mathbb{R}$ for all $w \in \widetilde{\mathrm{T}}_P M$. It is fairly elementary to show that $P \mapsto \operatorname{grad} f_P$ is a smooth map $M \to \mathbb{R}^n$.

Proof.

(1) This statement follows from the previous claim and standard theory of differential equations.
(2) It follows from (1) that the map $\Theta\colon [a,b]\times W\to M$ is well-defined. Furthermore it follows again from standard theory of differential equations that the map is smooth and that for each $t\in[a,b]$ the map $W\to M$ given by $P\mapsto\gamma_P(t)$ is a smooth embedding with image $f^{-1}(t)$. It follows easily from this observation and the previous claim that the map $\Theta\colon [a,b]\times W\to M$ is actually a smooth embedding with image $f^{-1}([a,b])$. ⊞

We leave it to the reader to dig out their favorite books on differential equations to fill in the details. Very similar statements are also proved in [**Miln1963a**, p. 10] and [**Lee2002**, Theorem 9.12, Corollary 9.17]. ■

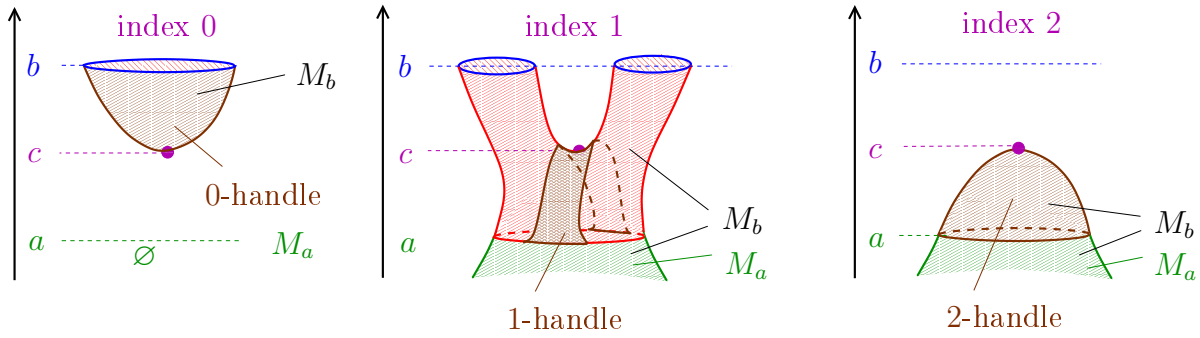


Now we have no troubles with providing the desired proof of the No Critical Point-Diffeomorphism Theorem 138.1.

Proof of the No Critical Point-Diffeomorphism Theorem 138.1. Let M be a compact smooth manifold and let $f\colon M\to\mathbb{R}$ be a smooth function. Let $a<b\in\mathbb{R}$ such that $f^{-1}([a,b])$ does not contain a critical point of f. We suppose that $f^{-1}([a,b])\cap\partial M=\varnothing$. By the Regular Value Theorem 26.4 we know that $W:=f^{-1}(a)$ is a closed smooth submanifold of M. By Theorem 138.2 we know that $f^{-1}([a,b])$ is diffeomorphic to $[a,b]\times W=[a,b]\times f^{-1}(a)$. It now follows from Exercise **??** (or alternatively from Lemma 139.2) that $M_b=M_a\cup f^{-1}([a,b])$ is diffeomorphic to M_a. Furthermore, if we are given some $\epsilon>0$, then it follows from Exercise **??** that we can find a diffeomorphism that is the identity on $M_{a-\epsilon}$. ■

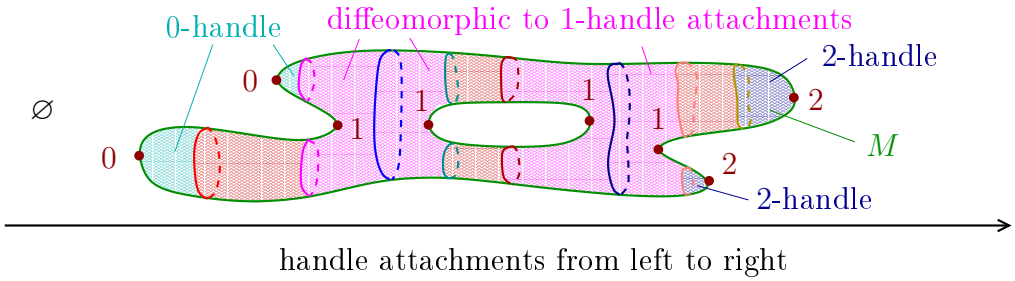
138.2. **The Handle Addition Theorem.** Let M be a compact smooth manifold and let $f\colon M\to\mathbb{R}$ be a smooth function. Furthermore let $a<b\in\mathbb{R}$ such that a and b are regular values and such that $f^{-1}([a,b])\cap\partial M=\varnothing$. Note that the Regular Value Theorem 26.4 implies that $f^{-1}(a)$ and $f^{-1}(b)$ are closed submanifolds of M. Note that if the stronger condition holds that $f^{-1}([a,b])$ does not contain a critical point of f, then the Smooth Manifold-Product Theorem 138.2 says that M_b is diffeomorphic to M_a. But what happens if $f^{-1}((a,b))$ contains a critical point?
On the left of the figure below we show a 2-dimensional smooth manifold M together with a smooth function $f\colon M\to\mathbb{R}$ such that there exists a unique critical point of index $k=1$ in $f^{-1}((a,b))$. On the left of the figure below we show the result of attaching a handle of index $k=1$ to M_a. Some goodwill shows that M_b is diffeomorphic to the result of attaching

this handle of index $k = 1$ to M_a. In fact given any $\epsilon > 0$ one can find a diffeomorphism that is the identity on the common subset $M_{a-\epsilon}$.



The following all-important theorem shows that a suitable generalization of the above observation holds in all reasonable settings.

Theorem 138.3. (Handle Addition Theorem) Let M be a compact smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth function. Furthermore let $a < b \in \mathbb{R}$ such that a and b are regular values and such that $f^{-1}([a,b]) \cap \partial M = \varnothing$.



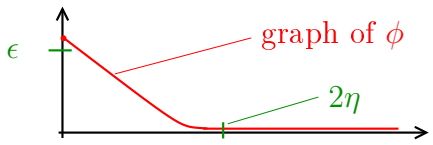
(1) Suppose there exists a single critical point $P \in f^{-1}([a,b])$. We set $k := \text{index}(f,P)$. If P is non-degenerate, then M_b is diffeomorphic to the result of attaching a k-handle to M_a.

(2) Suppose there exists a single critical value $c \in [a,b]$. Let $P_1, \ldots, P_m$ be the preimages of c. We suppose that $P_1, \ldots, P_m$ are non-degenerate critical points. Let $k_1, \ldots, k_m$ be the indices of the critical points. Then M_b is diffeomorphic to the result of attaching m handles of index k_i, $i = 1, \ldots, m$ to M_a along thickened spheres with disjoint images.

Furthermore, in both settings, given any $\epsilon > 0$ there exists an diffeomorphism as above which is the identity on the common subset $M_{a-\epsilon}$.

Example. In the figure below we return to the setting of the figure on page 2988. We show all the critical points and we indicate the indices. Furthermore, reading from left to right we show how M gets built out of the empty manifold by various handle attachments. To simplify our pictures we do not distinguish between a smooth manifold that is the result of attaching a k-handle and a smooth manifold that is diffeomorphic to the result of attaching a k-handle.

Remark. We provide an almost complete proof of Theorem 138.3. Only at the very end of the proof, on page 2995, when we need to prove that a certain map is a diffeomorphism, we not feel like dealing with the technical challenge of verifying that a given homeomorphism is in fact a diffeomorphism. We refer to our usual sources, namely [**Nic2011**, Theorem 2.7 and Remark 2.9], [**Miln1963a**, Theorem 3.2, Remark on p. 17, Remark 3.3] and [**Kos1993**, Chapter VII.2] for more details.



Proof. Let M be a compact smooth manifold, let $f\colon M \to \mathbb{R}$ be a smooth function and let $a < b \in \mathbb{R}$ be regular values such that $f^{-1}([a,b]) \cap \partial M = \varnothing$. In the following we will only prove Statement (1). Statement (2) can be proved either by generalizing the proof of Statement (1) or by using Exercise 137.6. We leave it to the reader to fill in the details for the proof of Statement (2).

Thus we suppose there exists a single critical point $P \in f^{-1}([a,b])$ and we suppose that P is non-degenerate. We set $c := f(P)$ and we set $k := \operatorname{index}(f,P)$. We need to show that M_b is diffeomorphic to the result of attaching a k-handle to M_a.

We make the following preparations:

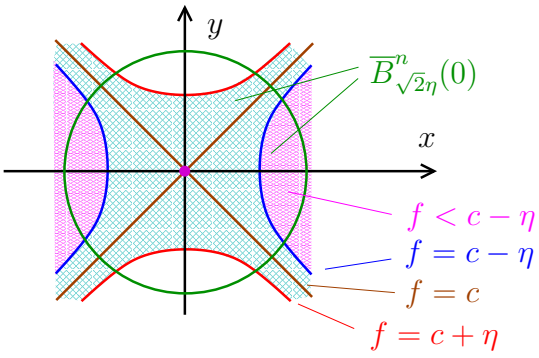
(1) We set $l := n - k$.
(2) We make the identification $\mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^l$. Given $x = (x_1, \ldots, x_k) \in \mathbb{R}^k$ we write $x^2 = x_1^2 + \cdots + x_k^2$ and similarly given $y = (y_1, \ldots, y_l) \in \mathbb{R}^l$ we write $y^2 = y_1^2 + \cdots + y_l^2$.
(3) By the Morse Lemma 137.2 we can identify a neighborhood of P in $M \setminus \partial M$ with a neighborhood V of $(0,0) \in \mathbb{R}^k \times \mathbb{R}^l$ such that $P = (0,0)$ and such that for every $(x,y) \in V$ we have $f(x,y) = c - x^2 + y^2$.
(4) Since a and b are regular values we know that $c \in (a,b)$. Thus we can pick an $\eta > 0$ such that $a \leq c - \eta < c + \eta \leq b$ and such that $\overline{B}^n_{\sqrt{2}\eta}(0) \subset V$. Note that by our hypothesis there are no critical points in $f^{-1}([a, c-\eta])$ and there are no critical points in $f^{-1}([c+\eta, b])$. Thus it follows from the No Critical Point-Diffeomorphism Theorem 138.1 that it suffices to show that $M_{c+\eta}$ is diffeomorphic to the result of attaching a k-handle to $M_{c-\eta}$.

Note that only in the neighborhood V do we have completely control over f. Unfortunately a priori the difference $M_b \setminus \mathring{M}_a$ is not contained in the neighborhood V. To deal with this issue we introduce an auxiliary function. First note that by the Smooth Transition Function Lemma 19.4 there exists a smooth map $\phi\colon [0,\infty) \to \mathbb{R}_{\geq 0}$ with $\phi(0) > \eta$, $\phi(t) = 0$ for $t \geq 2\eta$ and such that $\phi'(t) \in (-1, 0]$ for all $t \in [0,\infty)$. We refer to the figure below for an illustration.

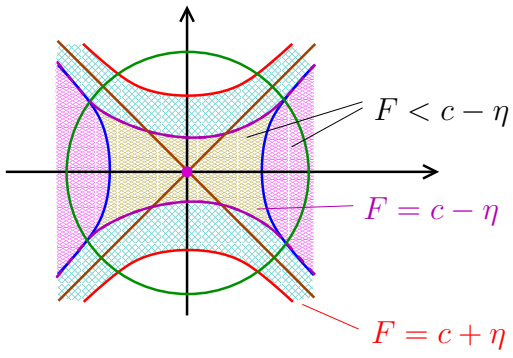
Next we consider the map

$$F\colon M \to \mathbb{R}$$
$$P \mapsto \begin{cases} f(x,y) - \phi(x^2+2y^2) = c - x^2 + y^2 - \phi(x^2+2y^2), & \text{if } P=(x,y) \in \overline{B}^n_{\sqrt{2}\eta}(0), \\ f(P), & \text{otherwise.} \end{cases}$$

The following claim summarizes some of the key properties of F.



Claim 1.



(1) The map F is smooth.
(2) The critical points of F are precisely the critical points of f.
(3) Given any $r \in \mathbb{R}$ we have $f^{-1}((-\infty, r]) \subset F^{-1}((-\infty, r])\}$.
(4) We consider the ellipsoid $E := \{(x,y) \in \mathbb{R}^2 \,|\, x^2 + 2y^2 \leq 2\eta\}$. Given any $r \in \mathbb{R}$ we have $F^{-1}((-\infty, r]) \setminus f^{-1}((-\infty, r]) \subset E \subset \overline{B}^n_{\sqrt{2}\eta}(0)$.
(5) The smooth manifold $F^{-1}((-\infty, c-\eta])$ is diffeomorphic to $F^{-1}((-\infty, c+\eta])$.
(6) We have $F^{-1}((-\infty, c+\eta]) = f^{-1}((-\infty, c+\eta])$.

In particular we have

$$M_{c-\eta} = f^{-1}((-\infty, c-\eta]) \overset{(3)}{\subseteq} F^{-1}((-\infty, c-\eta]) \cong F^{-1}((-\infty, c+\eta]) \overset{(6)}{=} f^{-1}((-\infty, c+\eta]) = M_{c+\eta}.$$

by (4) the difference is contained in $E \subset \overline{B}^n_{\sqrt{2}\eta}(0)$ — diffeomorphic by (5)

Proof. We prove the statements in a somewhat different order.

(1) Note that ϕ is zero outside of $\overline{B}^n_{\sqrt{2}\eta}(0)$. It follows from this observation together with the fact $\overline{B}^n_{\sqrt{2}\eta}(0)$ is contained in V that F is smooth.
(2) It is clear that we only need to consider the points (x,y) with $x^2 + 2y^2 \leq 2\eta$. For those points we compute, using the Chain Rule 19.10 that

$$\mathrm{D}f_{(x,y)} = (2x, 2y) \text{ and } \mathrm{D}F_{(x,y)} = (2x \cdot \overbrace{(-1 - \underbrace{\phi'(x^2+2y^2)}_{>-1 \text{ since } \phi'(t)\in(-1,0]})}^{<0}, 2y \cdot \overbrace{(1 - 2\cdot\underbrace{\phi'(x^2+2y^2)}_{\leq 0 \text{ since } \phi'(t)\in(-1,0]})}^{\geq 1}).$$

We see that $\mathrm{D}f_{(x,y)} = (0,0)$ if and only if $\mathrm{D}F_{(x,y)} = (0,0)$.

(3) Since $\phi(x,y) \geq 0$ for all $(x,y) \in \overline{B}^n_{\sqrt{2}\eta}(0)$ we see that $F(P) \leq f(P)$ for all $P \in M$. But this implies that for any $r \in \mathbb{R}$ we have $f^{-1}((-\infty, r]) \subset F^{-1}((-\infty, r])$.

(4) Note that the two maps $f\colon M \to \mathbb{R}$ and $F\colon M \to \mathbb{R}$ agree outside of $E \subset \overline{B}^n_{\sqrt{2}\eta}(0)$. The desired statement is an immediate consequence of this observation.

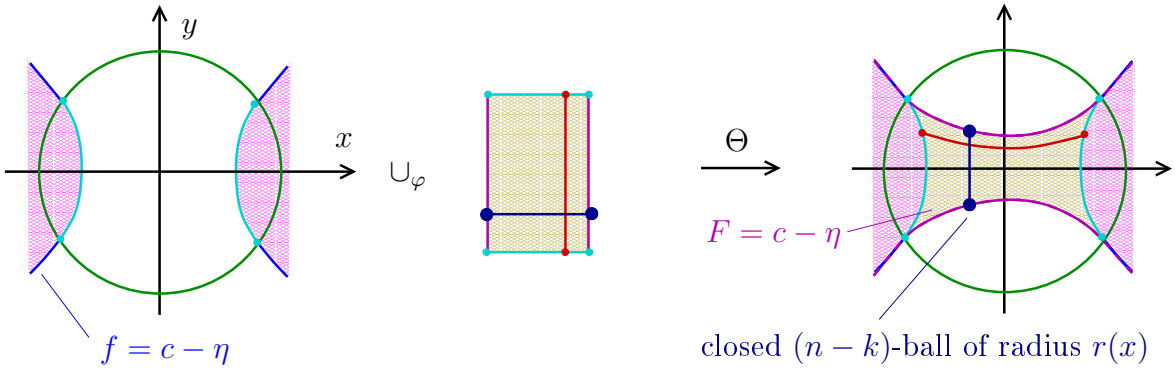
(6) Note that given any $(x,y) \in E$ we have

$$\begin{array}{ccccccc} F(x,y) & \underset{\uparrow}{\leq} & f(x,y) & \underset{\uparrow}{=} & c - x^2 + y^2 & \leq & c + \frac{1}{2}x^2 + y^2 \quad \underset{\uparrow}{\leq} \quad c + \eta. \\ \text{since } \phi(x,y) \geq 0 & & \text{since } E \subset \overline{B}^n_{\sqrt{2}\eta}(0) \subset V & & & & \text{since } (x,y) \in E = \{(x,y) \mid x^2 + 2y^2 \leq 2\eta\} \end{array}$$

The desired equality follows from this observation together with (4).

(5) We need to show that the smooth manifold $F^{-1}((-\infty, c-\eta])$ is diffeomorphic to $F^{-1}((-\infty, c-\eta])$. By the No Critical Point-Diffeomorphism Theorem 138.1 together with (2) it suffices to prove that the preimage $F^{-1}([c-\eta, c+\eta])$ does not contain a critical point of f. This statement follows from the following inclusions and statements:

$$\overbrace{F^{-1}([c-\eta, c+\eta])}^{\substack{\text{by construction we have } \phi(0) > \eta \\ \text{thus } F(0,0) = c - \phi(0) < c - \eta \\ \text{thus this set does not contain } (0,0)}} = F^{-1}((-\infty, c+\eta]) \setminus F^{-1}((-\infty, c-\eta))$$
$$\subset f^{-1}((-\infty, c+\eta]) \setminus f^{-1}((-\infty, c-\eta)) = \underbrace{f^{-1}([c-\eta, c+\eta])}_{\substack{\text{by hypothesis this contains} \\ \text{a single critical point of } f, \\ \text{namely } (0,0)}}.$$
$$\uparrow$$
follows from (3) and (6)



⊞

By Claim 1 it suffices to prove that the smooth manifold $F^{-1}((-\infty, c-\eta])$ is diffeomorphic to the result of attaching a k-handle to $M_{c-\eta} = f^{-1}((-\infty, c-\eta])$. This step is performed in the following claim.

Claim 2. We consider the thickened $(k-1)$-sphere

$$\begin{array}{rcl} \varphi\colon \overline{B}^{n-k} \times S^{k-1} & \to & f^{-1}(c-\eta) \subset \partial M_{c-\eta} \\ (x,y) & \mapsto & \left(\sqrt{2 \cdot \eta \cdot x^2 + \eta} \cdot y, \sqrt{2\eta} \cdot x\right). \end{array}$$

The smooth manifold $M_{c-\varphi} \cup_\varphi h^k = f^{-1}((-\infty, c-\eta]) \cup_\varphi h^k$ is diffeomorphic to the smooth manifold $F^{-1}((-\infty, c-\eta])$.

Proof. We only provide a sketch of the proof of Claim 2. As so often trying to show that a given map is really a diffeomorphism quickly leads to unreadable arguments. The full details for the proof are provided in [**Kos1993**, p. 129]. First note that a fairly straightforward argument shows that for any $x \in \overline{B}^k_{\sqrt{\eta}}(0)$ there exists an $r(x) \in \mathbb{R}_{>0}$ such that

$$\{y \in \overline{B}^l \mid F(x,y) \leq c + \eta\} \;=\; \overline{B}^{n-k}_{r(x)}(0).$$

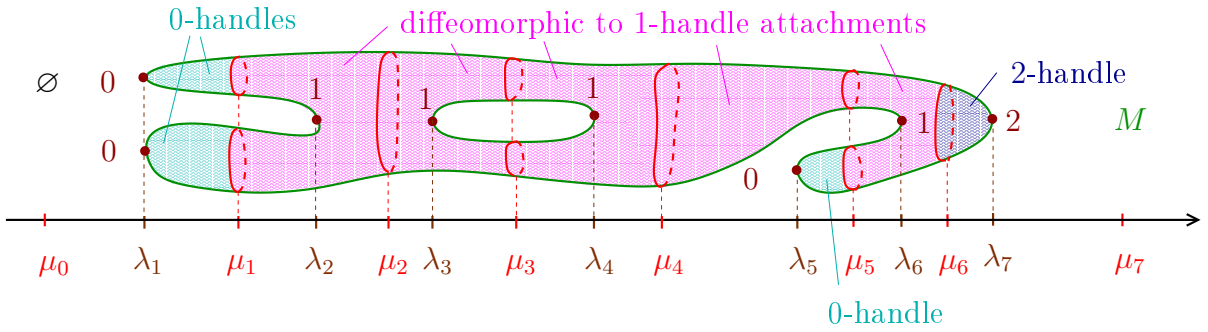
Now the desired diffeomorphism is given by

$$\begin{aligned} f^{-1}((-\infty, c-\eta]) \cup_\varphi (\overline{B}^l \times \overline{B}^k) &\to F^{-1}((-\infty, c-\eta]) \\ P &\mapsto \begin{cases} P, & \text{if } P \in f^{-1}((-\infty, c-\eta]), \\ \left(\sqrt{2\eta x^2 + \eta}\cdot y, x \cdot r(\sqrt{2\eta x^2 + \eta})\right), & \text{if } P = (x,y) \in \overline{B}^l \times \overline{B}^k. \end{cases} \end{aligned}$$

This completes the sketch of the proof of the claim. ⊞

Finally suppose we are given an $\epsilon > 0$. We need to show that there exists an diffeomorphism as above which is the identity on the common subset $M_{a-\epsilon}$. As the reader will surely have noticed, this is an immediate consequence of our construction together with the "furthermore" statement of the No Critical Point-Diffeomorphism Theorem 138.1. ■

138.3. **The Handle Decomposition Theorem.** With the results from the previous section it is now pretty straightforward to prove the following result.



Proposition 138.4. (Morse Function-Handle Decomposition Proposition) Let M be a closed smooth manifold. If $f\colon M \to \mathbb{R}$ is a Morse function, then there exists a standard handle decomposition of M such that for each $k \in \mathbb{N}_0$ the number of k-handles equals the number of critical points of f of index k.

Proof. Let M be a closed smooth manifold and furthermore let $f\colon M \to \mathbb{R}$ be a Morse function. Recall that by Corollary 137.4 (2) we know that f has only finitely many critical points. We order the corresponding critical values by $\lambda_1 < \cdots < \lambda_s$. Next we pick real numbers $\mu_0 < \lambda_1 < \mu_1 < \lambda_2 < \mu_2 < \cdots < \mu_{s-1} < \lambda_s$ and furthermore we pick some $\mu_s \geq \max(f\colon M \to \mathbb{R})$. Note that $M_{\mu_0} = \varnothing$ and $M_{\mu_s} = M$. It follows from Theorem 138.3 that each M_{μ_i} is diffeomorphic to the result of attaching finitely many handles to $M_{\mu_{i-1}}$.[1672] In fact Theorem 138.3 says that we can arrange that the handles are in one-to-one correspondence to the critical points with critical value λ_i and that the indices of the handles correspond precisely to the indices of the critical points. This shows that $M = M_{\mu_s}$ admits a handle decomposition with the predicted number of handles. Finally we apply the Standard Handle Decomposition Corollary 136.4 to conclude that M actually admits a standard handle decomposition with the same number of handles with the same indices. ■

Remark.

(1) In the Handles-to-Morse Function Proposition 139.9 we will prove a converse to the Morse Function-Handle Decomposition Proposition 138.4, namely we will see that handle decompositions give rise to Morse functions.

[1672]Note that implicitly we use our hypothesis that M is closed, since to apply Theorem 138.3 we need to ensure that $f^{-1}([\mu_{i-1}, \mu_i]) \cap \partial M = \varnothing$.

(2) Let M be a closed smooth manifold and let $f\colon M \to \mathbb{R}$ is a Morse function. In the proof of the Morse Function-Handle Decomposition Proposition 138.4 we just saw that f gives rise to a handle decomposition of M. Evidently $-f\colon M \to \mathbb{R}$ is also a Morse function. The corresponding handle decomposition is for all intents and purposes the same as the dual handle decomposition that we introduced in the Morse Function-Handle Decomposition Proposition 138.4. Since we will not make use of this statement we will also not bother with providing a proof.

Now we can easily prove the main theorem of this chapter.

Theorem 138.5. (Handle Decomposition Theorem) Every closed smooth manifold admits a standard handle decomposition.

Remark.

(1) In the literature the Handle Decomposition Theorem is often called the Handle Presentation Theorem.
(2) We will deal with compact smooth manifolds with non-empty boundary in the following chapter. In particular we will prove the Relative Handle Decomposition Theorem 139.6 that says that every compact smooth manifold admits a handle structure rel a given union of boundary components. As we point out in Theorem 139.7, this implies in particular that every compact smooth manifold admits a standard handle decomposition.

Proof. Let M be a closed smooth manifold. By the Morse Function-Existence Proposition 137.6 we know that there exists a Morse function $f\colon M \to \mathbb{R}$. It follows from the Morse Function-Handle Decomposition Proposition 138.4 that M admits a standard handle decomposition. ■

We can now give a new proof for some of the statements of the Smooth Manifolds-Invariants Proposition 96.6.

Proposition 96.6. (Smooth Manifolds-Invariants Proposition) Let M be a closed n-dimensional smooth manifold.

(1) For every $k > n$ we have $\mathrm{H}_k(M;\mathbb{Z}) = 0$.
(3) Given any $P \in M$ the fundamental group $\pi_1(M,P)$ is finitely presented.
(4) All homology groups of M are finitely generated abelian groups.

Remark.

(1) Morse theory can also be used to prove the above formulation of the Smooth Manifolds-Invariants Proposition 96.6 for compact smooth manifolds with non-empty boundary. In fact there are at least two approaches to achieving this goal:
   (a) Either one applies the above result to the double DM of a compact smooth manifold with boundary and one applies a little bit of algebra, e.g. the Finite Presentation-Retract Lemma 53.16 .
   (b) Alternatively one can wait for Theorem 139.7 where we prove the generalization of the Handle Decomposition Theorem 138.5 to compact smooth manifolds with non-empty boundary.
(2) As we saw in the proof of Proposition 96.7, one can use the Smooth Manifolds-Invariants Proposition 96.6 to show that homology groups and fundamental groups of arbitrary, not necessarily compact, smooth manifolds are countable.
(3) In the Morse Inequalities Theorem 140.12 and Proposition 140.11 we will give explicit upper bounds on the "size" of the homology groups of a closed smooth manifold in terms of the number of critical points of a Morse function respectively the number of handles in a handle decomposition.

Sketch of proof. Let M be a closed n-dimensional smooth manifold. By the Handle Decomposition Theorem 138.5 we know that M admits a handle decomposition. It follows easily from a straightforward induction argument using the Handle Attachment-π_1-Proposition 136.11 that for any $P \in M$ the fundamental group $\pi_1(M, P)$ is finitely presented. Similarly it follows from a straightforward induction argument using the Handle Attachment-H_*-Lemma 136.13 that for every $k > n$ we have $\mathrm{H}_k(M; \mathbb{Z}) = 0$ and, using the elementary group-theoretic the Rank Additivity Lemma 51.7 (1), we see that all homology groups of M are finitely generated abelian groups. ■

The next proposition is also a straightforward consequence of our results.

Proposition 138.6. (Morse Functions-Cells Proposition) Let M be a closed smooth manifold.

(1) If f is a Morse function for M, then M is homotopy equivalent to a CW-complex where the number of k-cells equals precisely the number of critical points of index k.
(2) The smooth manifold is homotopy equivalent to a finite CW-complex.

Example. Let $n \in \mathbb{N}_0$. Recall that on page 2979 we showed that there exists a Morse function $f\colon \mathbb{R}\mathrm{P}^n \to \mathbb{R}$ with precisely one critical point for each index $0, \ldots, n$. It follows from the Morse Functions-Cells Proposition 138.6 that $\mathbb{R}\mathrm{P}^n$ is homotopy equivalent to a CW-complex with precisely one cell of dimension $0, \ldots, n$ and no other cells. In the same vein the above results show that $\mathbb{C}\mathrm{P}^n$ is homotopy equivalent to a CW-structure with precisely one cell of degree $0, 2, \ldots, 2n$ and no other cells. This discussion almost recovers the result of Lemma 68.1.

Proof.

(1) This statement follows immediately from Corollary 137.4 (2), Theorem 138.3 and the Handles-Cells Proposition 136.18.
(2) This statement is a consequence of (1) and the Morse Function-Existence Proposition 137.6. Put differently, it is a consequence of the Handle Decomposition Theorem 138.5 and the Handles-Cells Proposition 136.18. ■

Remark.

(1) There are various other proofs that Morse functions give rise to CW-complexes that are homotopy equivalent to M, see e.g. [**BaH2004**, Theorem 3.28], [**Miln1965b**, Chapter 3] and [**Mata2002**, Theorem 4.18]. Terse argument are also given in [**Nic2011**, Theorem 2.10] and [**Wall2016**, Proposition 5.3.1]. Furthermore an even terser argument is given in [**Hirs1976**, Theorem 6.4.1].

(2) Given a closed smooth manifold there is a notion of a more refined version of a Morse function, namely of a Morse-Smale function. We will not provide the definition, instead we refer to [**BaH2004**, p. 7] for the definition. But we try to pique the reader's interest with the following two statements:
   (a) The Kupka-Smale Theorem, proved independently by Ivan Kupka [**Kupk1963**] and Steven Smale [**Sma1963**], says that every closed smooth manifold admits a Morse-Smale function. Alternatively see [**BaH2004**, Theorem 6.6] for a proof.
   (b) In [**Lau1992**, p. 222] (see also [**BaH2004**, p. 179]) it is shown that a Morse-Smale function gives rise to a CW-complex that is actually *homeomorphic* to M and such that for each $k \in \mathbb{N}_0$ the critical points of index k are in one-to-one correspondence to the k-cells.

(3) The Morse Functions-Cells Proposition 138.6 (2) is related to several earlier results:
   (a) In Theorems 96.2 we showed that every compact smooth manifold M admits a finite simplicial structure. By the Smooth Manifold-CW Structure Theorem 96.5 this implies in particular that M admits a finite CW-structure.
   (b) In Corollary 95.37 we used the Nerve Theorem 95.32 to show that every compact smooth manifold is weakly homotopy equivalent to a finite CW-complex.
   (c) Finally in Corollary 104.20 we used Borsuk's Theorem 104.3 to show that every topological manifold is homotopy equivalent to a CW-complex.

138.4. **Reeb's Theorem.** Theorem 138.3 also allows us to prove the following theorem which was first proved by Georges Reeb [**Reeb1946**] in 1946.

Theorem 138.7. (Reeb's Theorem) Let M be a closed n-dimensional smooth manifold. If M admits a smooth function $f\colon M \to \mathbb{R}$ with precisely two critical points which are both non-degenerate, then M is *homeomorphic* to S^n.

Remark. For the record we mention that by [**Miln1964b**, Theorem 1'] the conclusion of Theorem 138.7 also holds if the critical points are degenerate.

Reeb's Theorem 138.7 is an immediate consequence of Theorem 138.3 together with the following proposition.

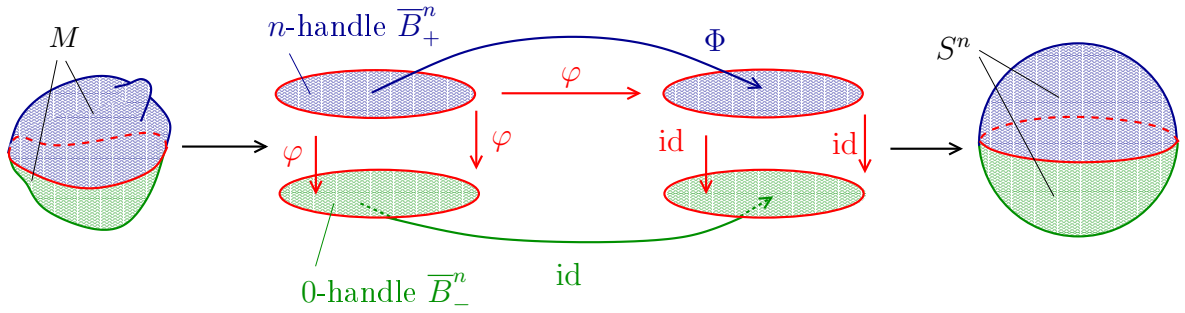
Proposition 138.8. Let $n \in \mathbb{N}$.

(1) If $\varphi\colon S^{n-1} \to S^{n-1}$ is a homeomorphism, then $\overline{B}^n \cup_\varphi \overline{B}^n$ is homeomorphic to S^n.

(2) Let M be a closed n-dimensional smooth manifold. If M admits a handle decomposition consisting of a single 0-handle and a single n-handle, then M is *homeomorphic* to S^n.

Proof.

(1) Let $\varphi\colon S^{n-1} \to S^{n-1}$ be a homeomorphism. We apply the Alexander trick to get an extension of $\varphi\colon S^{n-1} \to S^{n-1}$ to the ball $\overline{B}^n$. More precisely we consider the following



map:

$$\begin{array}{rcl} \Phi\colon \overline{B}^n & \to & \overline{B}^n \\ x & \mapsto & \begin{cases} \|x\| \cdot \varphi(\frac{x}{\|x\|}), & \text{if } x \neq 0, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

By Exercise 5.35 we know that this map Φ is a homeomorphism. Finally we consider the following sequence of homeomorphisms:

$$\begin{array}{rcl} \overline{B}^n_+ \cup_{\varphi\colon S^{n-1}\to S^{n-1}} \overline{B}^n_- & \overset{\cong}{\to} & \overline{B}^n_+ \cup_{\mathrm{id}\colon S^{n-1}\to S^{n-1}} \overline{B}^n_- \xrightarrow[\text{from page 261}]{\text{homeomorphism}} S^n. \\ [P] & \mapsto & \begin{cases} [\Phi(P)], & \text{if } P \in \overline{B}^n_+, \\ [P], & \text{if } P \in \overline{B}^n_-. \end{cases} \end{array}$$

(2) Let M be a closed n-dimensional smooth manifold that M admits a handle decomposition consisting of a single 0-handle and a single n-handle. This means that there exists a diffeomorphism $\varphi\colon S^{n-1} \to S^{n-1}$ such that M is diffeomorphic to[1673] $\overline{B}^n \cup_\varphi \overline{B}^n$. It now follows from (1) that M is homeomorphic to S^n. ■

Reeb's Theorem 138.7 and Proposition 138.8 raise several fantastic questions. First of all, it is natural to ask whether the analogue of Proposition 138.8 (1) holds if we replace "homeomorphism" by "diffeomorphism". Put differently, we have the following question.

Question 138.9. Let $\varphi\colon S^{n-1} \to S^{n-1}$ be a diffeomorphism. Is the smooth manifold $\overline{B}^n \cup_\varphi \overline{B}^n$ *diffeomorphic* to S^n?

Next let us reflect whether we can upgrade the composition of maps towards the end of the proof Proposition 138.8 into a diffeomorphism. The good news is that, by Exercise **??**, we can replace the map on the right-hand side by a diffeomorphism. The bad news is that, as we saw in Exercise 5.35, the map $\Phi\colon B^n \to \overline{B}^n$ given by the Alexander trick is not smooth at the origin, in particular Φ is not diffeomorphism. But perhaps we can pick Φ more cleverly? This leads us to our second question.

Question 138.10. Let $n \in \mathbb{N}$. Does every diffeomorphism $\varphi\colon S^n \to S^n$ extend to a diffeomorphism of $\overline{B}^{n+1}$?

In Propositions **??** and **??** we will provide answers to Questions 138.10 and 138.9.

[1673] Note that by the Gluing-Smooth Manifolds-Proposition **??** we can equip $\overline{B}^n \cup_\varphi \overline{B}^n$ with a canonical smooth structure.

Exercises for Chapter 138.

Exercise 138.1. Let M be a nd N be two closed n-dimensional smooth manifolds and let $f\colon M \to \mathbb{R}$ and $g\colon N \to \mathbb{R}$ be Morse functions with unique critical points of index 0 and n. Show that the connected sum $M\#N$ admits a Morse function φ with unique critical points of index 0 and n and such that for $k \in \{1, \dots, n-1\}$ we have

$$\begin{aligned}\text{number of critical points of } \varphi\colon M\#N \to \mathbb{R} = \quad & \text{number of critical points of } f\colon M \to \mathbb{R} \\ & + \text{number of critical points of } g\colon N \to \mathbb{R}.\end{aligned}$$

Exercise 138.2. Use handle decomposition to show that every closed n-dimensional smooth manifold admits an atlas with $n+1$ charts.
Remark. This exercise gives a new proof for some of the statements of Proposition 27.8.

139. Morse theory II: The Relative Handle Decomposition Theorem

In the Morse Function-Existence Proposition 137.6 we showed that every *closed* smooth manifold admits a Morse function. Using Theorem 138.3 this allowed us to prove the Handle Decomposition Theorem 138.5 which says that every *closed* smooth manifold admits a handle decomposition.

As we remarked on page 2981, it is not difficult to prove, using the Morse Function-Existence Proposition 137.6, that in fact every *compact* smooth manifold M admits a Morse function $f\colon M \to \mathbb{R}$. But this is not enough to prove the Handle Decomposition Theorem 138.5 for compact smooth manifolds with *non-empty boundary* since Theorem 138.3 has the hypothesis that $f^{-1}([a,b]) \cap \partial M = \varnothing$.

In this chapter we will see that compact smooth manifolds have in fact a handle decomposition. In fact we will do more, namely we will develop the theory of relative handle decompositions and we will study more refined versions of Morse functions. As we will see on several occasions, this extra effort for smooth manifolds with boundary will also come in handy in the study of *closed* smooth manifolds.

139.1. **Relative Handle Decompositions.** For smooth manifolds with non-empty boundary it will be convenient to study relative handle decompositions. This concept generalizes the notion of a handle decomposition that we introduced on page 2954.

Definition. Let M be a compact n-dimensional smooth manifold and let A be a (possibly empty) union of components of ∂M.

(1) A handle decomposition for M rel A is a diffeomorphism

$$\Theta\colon M \xrightarrow{\cong} ([0,1] \times A) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_m} h^{k_m}$$

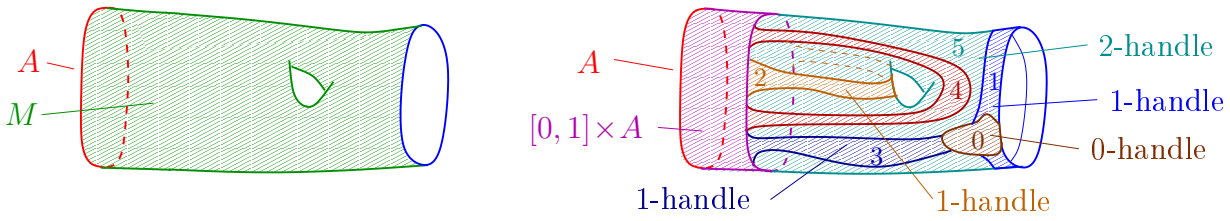
such that for $i = 0, \ldots, m$ the map φ_i is a thickened $(k_i - 1)$-sphere that takes values in

$$\partial\big(([0,1] \times A) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_{i-1}} h^{k_{i-1}}\big) \setminus (\{0\} \times A)$$

and such that for each $P \in A$ we have $\Theta(P) = (0, P)$.[1674]

In the following we will mostly suppress Θ from the notation. With this convention we introduce the following definitions:

(2) Given $i \in \{0, \ldots, n\}$ we refer to



$$M^i := ([0,1] \times A) \underbrace{\cup_{\varphi_{0,1}} h^0 \cdots \cup_{\varphi_{0,r_0}} h^0}_{0\text{-handles}} \cup \ldots \underbrace{\cup_{\varphi_{i,1}} h^i \cdots \cup_{\varphi_{i,r_i}} h^i}_{i\text{-handles}}.$$

as the i-skeleton of the relative handle decomposition.

(3) We say that a relative handle decomposition is standard if it is of the above form and if for each $i \in \{0, \ldots, n\}$ the attaching maps $\varphi_{i,1}, \ldots, \varphi_{i,r_i}$ take values in ∂M^{i-1}.

The following proposition is basically a generalization of the Dual Handle Proposition 136.5.

Proposition 139.1. (Relative Dual Handle Proposition) Let M be a compact n-dimensional smooth manifold. Furthermore let $\partial M = A \sqcup B$ be a decomposition of ∂M into two disjoint unions of components A and B. Finally let

standard handle decomposition of M rel A

$$M \;=\; ([0,1]\times A)\cup_{\varphi_0} \underbrace{h^{k_0}}_{\text{0-th handle}} \cup\cdots\cup_{\varphi_m} \underbrace{h^{k_m}}_{m\text{-th handle}}$$

be a handle decomposition of M rel A. We consider

$$M' \;:=\; (M\setminus([0,1)\times A))\cup_{B=B\times\{0\}} ([0,1]\times B)$$

and we set $A' := \{1\}\times A \subset M'$ and $B' := \{1\}\times B \subset M'$.

(0) There exists a diffeomorphism from M to M' that restricts to the obvious diffeomorphism $A \to A'$ and $B \to B'$.

There exists canonical handle decomposition

$$M' \;=\; ([0,1]\times B')\cup_{\psi_m} \underbrace{\widetilde{h}^{n-k_m}}_{\text{0-th dual handle}} \cup\cdots\cup_{\psi_0} \underbrace{\widetilde{h}^{n-k_0}}_{m\text{-th dual handle}},$$

of M' rel B' called dual handle decomposition, with the following properties:

(1) For each $i \in \{0,\dots,m\}$ the following statements hold:

(a) The i-th handle of the dual handle decomposition equals, as a subset of M', the $(m-i)$-th handle of the original handle decomposition.

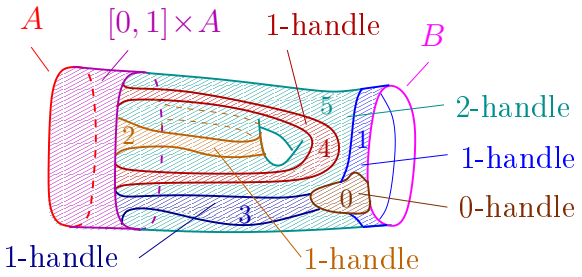
(b) The indices of the handles are reversed, in the sense that

$$\begin{array}{c}\text{index of the } i\text{-th handle of}\\ \text{the dual handle decomposition}\end{array} \;=\; n - \begin{array}{c}\text{index of the } (m-i)\text{-th handle of}\\ \text{the original handle decomposition.}\end{array}$$

In particular the number of i-handles in the dual handle decomposition equals the number of $(n-i)$-handles in the original decomposition.

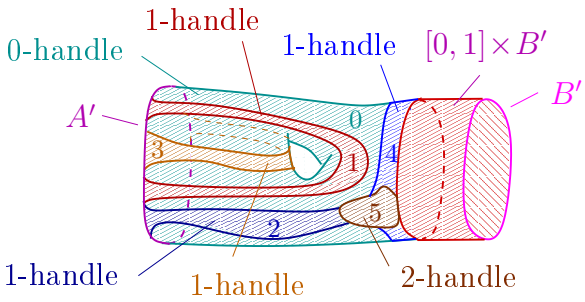
(c) The roles of attaching spheres and belt spheres is reversed in the sense that

$$\begin{array}{c}\text{belt sphere of the } i\text{-th handle of}\\ \text{the dual handle decomposition}\end{array} \;=\; \begin{array}{c}\text{attaching sphere of the } (m-i)\text{-th handle}\\ \text{of the original handle decomposition.}\end{array}$$



Furthermore the same statement, with the roles of attaching and belt spheres reversed, also holds.

(2) If the original handle decomposition is standard, then so is the dual handle decomposition.

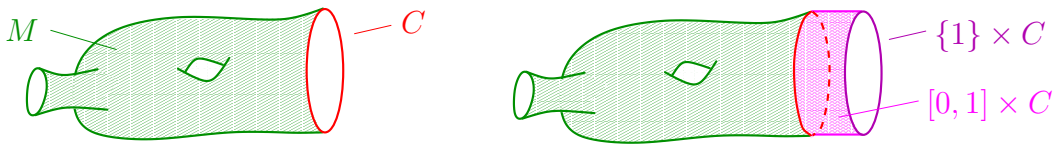


(3) The dual of the dual handle decomposition is the original handle decomposition.

Example. In the figure below we show again M, the torus minus two open disks, with two boundary components A and B. To the left we show the above handle decomposition of M rel A. To the right we see the corresponding dual handle decomposition of M' rel B'.

In the proof of the Relative Dual Handle Proposition 139.1 we will make use of the following lemma, which also doubles as Exercise **??**.

standard handle decomposition of M rel A



dual handle decomposition of M' rel B'

Lemma 139.2. Let M be a compact smooth manifold and let C be a union of components of ∂M. Let $\varphi\colon C \to C$ be a diffeomorphism. Given any neighborhood U of $C \subset M$ there exists a diffeomorphism

$$M \;\to\; \underbrace{(M \sqcup ([0,1]\times C))/\!\sim}_{\substack{\text{smooth manifold by the}\\ \text{Gluing-Smooth Manifolds-Proposition ??}}} \qquad \text{where } x \sim \varphi(x,0) \text{ for } x \in C$$

that is the identity on the common subset $M \setminus U$ and that restricts to the obvious diffeomorphism from C to $\{1\}\times C$.

Remark. In the setting of Lemma 139.2, we sometimes refer to $[0,1]\times C$ as an *external collar*.

Proof of Lemma 139.2. As is explained in the Gluing-Smooth Manifolds-Proposition **??** (1), to say that the topological space $(M \sqcup ([0,1]\times C))/\!\sim$ is a smooth manifold we actually need to pick a collar $[-1,0]\times C$ with $C = \{0\}\times C$ to define the actual smooth atlas. Since U is a neighborhood of C and since C is compact there exists an $\epsilon > 0$ such that $[-\epsilon, 0]\times C \subset U$. Using the Smooth Transition Function Lemma 19.4 one can easily show that there exists a smooth function $\eta\colon [-\epsilon,0] \to [-\epsilon,1]$ with $\eta(t) = t$ for $t \in [-\epsilon, -\frac{\epsilon}{2}]$, $\eta(0) = 1$ and such that $\eta'(t) > 0$ for all t. The desired diffeomorphism is now given by the identity on $M \setminus ([-\epsilon,0]\times C)$ and by stretching $[-\epsilon,0]\times C$ to $[-\epsilon,1]\times C$ via the map $(t,P) \mapsto (\eta(t),P)$. ∎

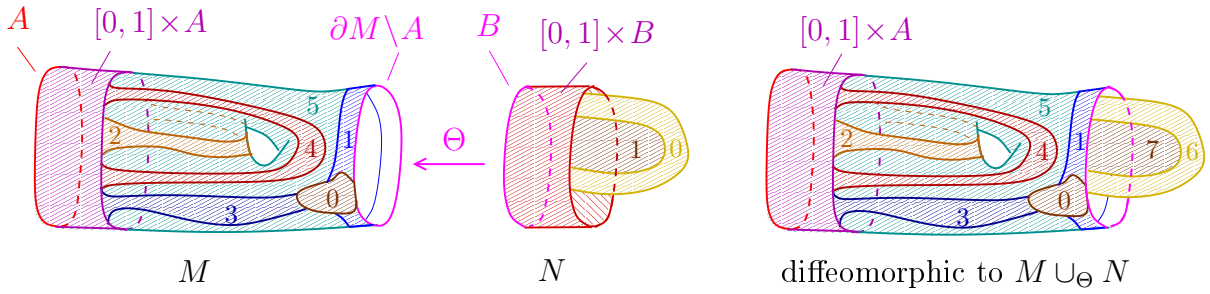
Proof of the Relative Dual Handle Proposition 139.1.

(0) It follows from the Codimension-Zero Smooth Embedding Proposition 24.16 that $W := M \setminus ([0,1)\times A)$ is a smooth manifold. It follows from Lemma 139.2 that both $M = ([0,1]\times A)\cup W$ and $M' = W \cup ([0,1]\times B)$ are diffeomorphic to W.

(1)-(3) The proof of the remaining statements is basically identical to the proof of the Dual Handle Proposition 136.5. We only need a minuscule generalization of Lemma 136.6, namely instead of considering diffeomorphisms $\gamma\colon \partial Y \to \partial(X \cup_\varphi h^k)$ we also need to allow diffeomorphisms $\gamma\colon C \to D$ where C is a component of ∂Y

and D is a component of $\partial(X \cup_\varphi h^k)$ that contains $h^k \cap \partial(X \cup_\varphi h^k)$. We leave it to the reader to fill in the details. ■

The following proposition says that we can "stack" relative handle decompositions.



Proposition 139.3. (Stacking Proposition) Let M be a compact n-dimensional smooth manifold and let N be a compact n-dimensional smooth manifold. Furthermore let A be a union of boundary components of M and let B be a union of boundary components of N. Next let

$$\begin{aligned} M &= ([0,1]\times A)\cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r} \\ \text{and} \qquad N &= ([0,1]\times B)\cup_{\psi_0} h^{l_0} \cup \cdots \cup_{\psi_s} h^{l_s} \end{aligned}$$

be handle decompositions rel A respectively rel B. Finally let $\Theta\colon B \to \partial M \setminus A$ be a diffeomorphism. We consider the smooth manifold $M \cup_\Theta N$. There exists a handle decomposition of the form

$$M \cup_\Theta N \xrightarrow{\cong} ([0,1]\times A)\cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r} \cup_{\widetilde{\psi}_0} h^{l_0} \cup \cdots \cup_{\widetilde{\psi}_s} h^{l_s}$$

rel A, where the attaching maps $\widetilde{\psi}_0, \ldots, \widetilde{\psi}_s$ are obtained in a hopefully obvious way from the attaching maps $\psi_0, \ldots, \psi_s$.

Proof. We have the following diffeomorphisms:

$$\begin{aligned} M \cup_\Theta N &= M \cup_\Theta (([0,1]\times B)\cup_{\psi_0} h^{l_0} \cup \cdots \cup_{\psi_s} h^{l_s}) = (M \cup_\Theta ([0,1]\times B))\cup_{\psi_0} h^{l_0} \cup \cdots \cup_{\psi_s} h^{l_s} \\ &\cong M\cup_{\widetilde{\psi}_0} h^{l_0} \cup \cdots \cup_{\widetilde{\psi}_s} h^{l_s} = ((([0,1]\times A)\cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r}) \cup_{\widetilde{\psi}_0} h^{l_0} \cup \cdots \cup_{\widetilde{\psi}_s} h^{l_s}. \end{aligned}$$

$\uparrow$ Lemma 139.2

■

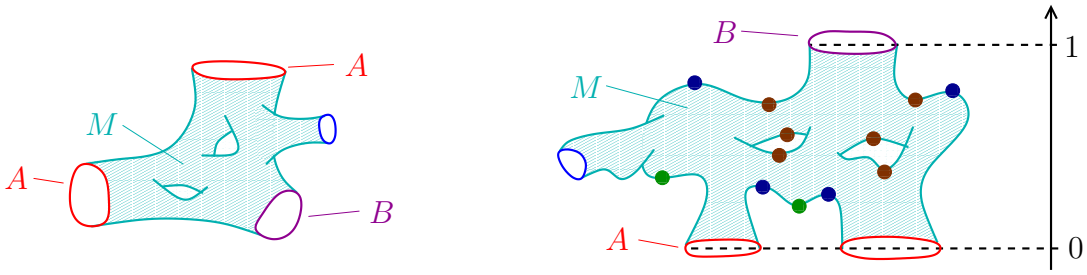
Examples.

(1) Let M be a compact smooth manifold with a handle decomposition

$$M = \varnothing \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r}.$$

We can view this as a handle decomposition rel $\varnothing$. By the Relative Dual Handle Proposition 139.1 we can equip M with the dual handle decomposition, which is de facto a handle decomposition rel ∂M. If we glue two copies of M along the common boundary, i.e. if we consider the double $\mathrm{D}M$, then it follows from the Stacking Proposition 139.3 that we can stack the original handle decomposition and the dual decompositions. In summary we obtain a handle decomposition for the double $\mathrm{D}M$ of the form

$$\mathrm{D}M = \varnothing \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r} \cup_{\widetilde{\psi}_r} h^{n-k_r} \cup \cdots \cup_{\widetilde{\psi}_0} h^{n-k_0}.$$



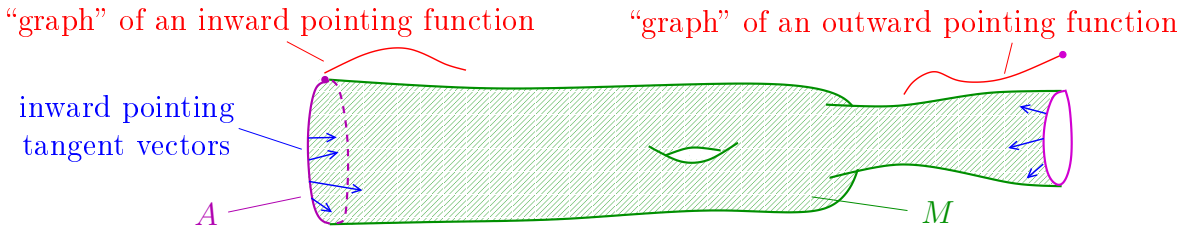
(2) First let $k, l \in \mathbb{N}$.
   (a) In Exercise 136.2 we showed that $\overline{B}^k \times S^l$ admits a handle decomposition rel $\varnothing$ consisting of one 0-handle and one l-handle.
   (b) By (a) together with the Relative Dual Handle Proposition 139.1 we see that $\overline{B}^k \times S^l$ admits a handle decomposition rel $\partial(\overline{B}^k \times S^l)$ consisting of one $(k+l)$-handle and one k-handle.

Now let $m, n \in \mathbb{N}$. In Lemma 59.1 we showed that S^{m+n-1} is diffeomorphic to $(S^{m-1} \times \overline{B}^n) \cup_{S^{m-1}\times S^{n-1}} (\overline{B}^m \times S^{n-1})$. Note that by the Stacking Proposition 139.3 we can stack the handle decomposition of $S^{m-1} \times \overline{B}^n$ rel $\varnothing$ with the handle decomposition of $\overline{B}^m \times S^{n-1}$ rel $\partial(\overline{B}^m \times S^{n-1})$. Thus we see that S^{m+n-1} admits a handle decomposition consisting of four handles of index 0, $m-1$, m and $m+n-1$.

139.2. **Morse functions for smooth manifolds with boundary.** Our goal will be to show the existence of suitable relative handle decompositions. The key tool to doing so is the following generalization of the Morse Function-Existence Proposition 137.6.

Proposition 139.4. (Morse Function-Existence Proposition) Let M be a compact smooth manifold and let A and B be two disjoint unions of components of ∂M. There exists a Morse function $f\colon M \to [0,1]$ such that $A = f^{-1}(0)$ and such that $B = f^{-1}(1)$.

Example. In the figure below we show a surface M with A and B as in the Morse Function-Existence Proposition 139.4. We also show a different embedding of M into $\mathbb{R}^3$ such that the height function $(x, y, z) \mapsto z$ has the desired properties.



The proof of the Morse Function-Existence Proposition 139.4 requires some technical preparations. First let us introduce the following definition.

Definition. Let M be a smooth manifold, let $f\colon M \to \mathbb{R}$ be a smooth function and let A be a union of components of ∂M. We say f is pointing inward on A if for every $P \in A$ and every inward pointing tangent vector[1675] $P \in \mathrm{T}_P M$ we have $\mathrm{D}f_P(v) > 0$. Similarly we are defining that f is pointing outward on A.

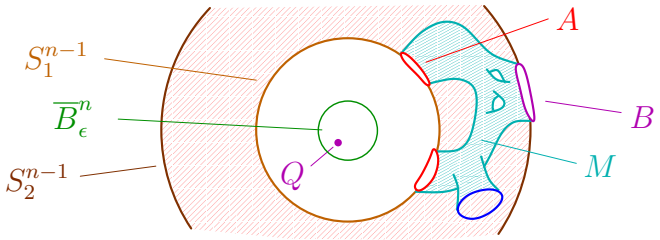
Lemma 139.5. Let N be a closed smooth manifold and let $f\colon [0,1] \times N \to \mathbb{R}$ be a smooth function that is pointing inward on $\{0\} \times N$ and that has no critical points. There exists a smooth function $g\colon [0,1] \times N \to \mathbb{R}$ with the following properties:
(1) The map g agrees with f on $[\frac{1}{2}, 1] \times N$.
(2) The map g has no critical points and it is pointing inward on $\{0\} \times N$.

[1675] We refer to page 634 for the definition of an inward pointing tangent vector.

(3) The map g is constant on $\{0\} \times N$ and the value on $\{0\} \times N$ equals the minimum of g on $[0,1] \times N$.

Sketch of a proof of Lemma 139.5. We pick some $s \in \mathbb{R}$ that is less than the minimum of f on $[0,1] \times N$. Using the Smooth Transition Function Lemma 19.4 it is pretty straightforward to see that there exist smooth maps $\alpha, \beta\colon [0,1] \to \mathbb{R}$ with $\alpha + \beta \equiv 1$, $\alpha(t) = 1$ for sufficiently small t and $\beta(t) = 1$ for $t \in [\frac{1}{2}, 1]$ such that the map

$$\begin{array}{rcl} g\colon [0,1] \times N & \to & \mathbb{R} \\ (t, P) & \mapsto & \alpha(t) \cdot (s+t) + \beta(t) \cdot f(P,t) \end{array}$$



has all the desired properties. We leave it to the reader to fill in the dull technical details. ■

Sketch of a proof of the Morse Function-Existence Proposition 139.4. Let M be a compact smooth manifold and let A and B be two disjoint unions of components of ∂M. A slight refinement of the Euclidean Embedding Theorem 27.1, similar to Exercise 27.3, shows, together with the Smooth Embedding Theorem 24.10, that we can view M as a submanifold of $\{x \in \mathbb{R}^n \mid \|x\| \in [1,2]\}$ such that $\varphi(A) \subset S_1^{n-1}$ and such that $\varphi(B) \subset S_2^{n-1}$. Using the Smooth Collar Neighborhood Theorem 28.3 we obtain collar neighborhoods $[0,1] \times A$ and $[0,1] \times B$.

As in the proof of the Morse Function Existence Proposition 137.5 one can show that given any $\epsilon > 0$ there exists a $Q \in \overline{B}_\epsilon^n$ such that

$$\begin{array}{rcl} f_Q\colon M & \to & \mathbb{R} \\ x & \mapsto & \|x - Q\|^2 \end{array}$$

is a Morse function. It is straightforward to see that by picking a sufficiently small $\epsilon > 0$ we can arrange that $f_Q\colon M \to \mathbb{R}$ is pointing inward on A and that it is pointing outward on B. Thus, Using Lemma 139.5, applied to $[0,1] \times A$ and $[0,1] \times B$ we can modify f_Q to obtain a Morse function on M that is constant on A and that is constant on B and such that all other values lie between the values on A and B. After rescaling we have obtained the desired Morse function.

A more detailed and authoritative proof of the Morse Function-Existence Proposition 139.4 is given in [**Miln1965b**, Theorem 2.5]. ■

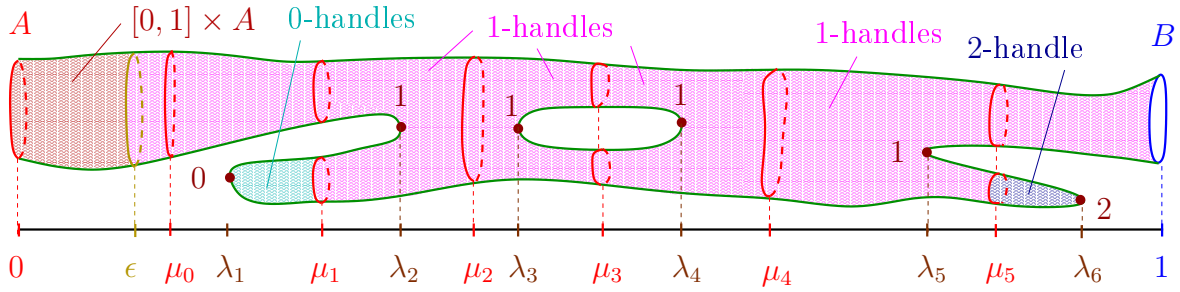
139.3. **The Relative Handle Decomposition Theorem.** Our goal in this section is to prove the following refinement of the Handle Decomposition Theorem 138.5.

Theorem 139.6. (Relative Handle Decomposition Theorem) Let M be a compact n-dimensional smooth manifold. Given any union A of components of ∂M there exists a standard handle decomposition of M rel A.

If we apply the Relative Handle Decomposition Theorem 139.6 to $A = \varnothing$ we obtain for free the following generalization of the Handle Decomposition Theorem 138.5.

Theorem 139.7. (Handle Decomposition Theorem) Every compact smooth manifold admits a standard handle decomposition.

Proof of the Relative Handle Decomposition Theorem 139.6. Let M be a compact smooth manifold and let A be a union of components of ∂M. We denote by B the union of the remaining components of ∂M. By the Morse Function-Existence Proposition 139.4 there exists a Morse function $f\colon M \to [0,1]$ such that $A = f^{-1}(0)$ and such that $B = f^{-1}(1)$. We make the following two observations:



(a) Since $\partial M = A \cup B$ we have $f^{-1}((0,1)) \cap \partial M = \varnothing$.
(b) Note that $A \cup B = \partial M$. Thus, by definition of a Morse function, A and B do not contain critical points, in other words, 0 is not a critical value and 1 is not a critical value.

By Corollary 137.4 (2) the Morse function has only finitely many critical points. We order the critical values by $0 < \lambda_1 < \cdots < \lambda_s < 1$. (Note that by (b) we know that $0 < \lambda_1$ and $\lambda_s < 1$.) We pick real numbers $0 < \epsilon < \mu_0 < \lambda_1 < \mu_1 < \lambda_2 < \mu_2 < \cdots < \mu_{s-1} < \lambda_s < 1 = \mu_s$.

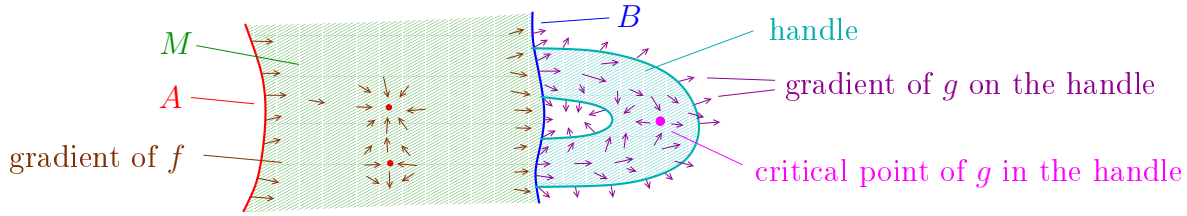
Note that it follows from (a) and the Regular Value Theorem 26.4 that $f^{-1}(\epsilon)$ is a closed submanifold of M. Thus it follows from the Smooth Manifold-Product Theorem 138.2 that $M_\epsilon = f^{-1}([0,\epsilon])$ is diffeomorphic to $[0,1] \times A$.

Next note that it follows from Theorem 138.3 and (a) that for each $i \in \{1,\dots,s\}$ there exists a diffeomorphism from M_{μ_i} to the result of attaching finitely many handles to $M_{\mu_{i-1}}$. Furthermore, Theorem 138.3 says that we can find such a diffeomorphism that is the identity on the common subset M_ϵ. This shows that $M = M_{\mu_s}$ admits a handle decomposition rel A.

Finally note that it follows immediately from iteratively applying the Handle Swapping Proposition 136.3 that we can rearrange our handle attachments to obtain a standard handle decomposition of M rel A. ∎

We conclude this section with the following generalization of Proposition 138.6.

Proposition 139.8. (Smooth Manifold-CW-Homotopy Type Proposition) Every compact smooth manifold is homotopy equivalent to a finite CW-complex.



Proof. This statement follows immediately from the Handle Decomposition Theorem 139.7 together with the Handles-Cells Proposition 136.18. ■

139.4. **Constructing Morse functions from handle decompositions.** By the Handle Addition Theorem 138.3 we know that Morse functions give rise to handle decompositions. In this section we will see that we can also go backwards. For example we have the following converse to Theorem 138.3.

Proposition 139.9. (Handles-to-Morse Function Proposition) Let M be a compact smooth manifold and suppose we are given a decomposition $\partial M = A \sqcup B$ where A and B are unions of components of ∂M.

(1) Let $\varphi\colon \overline{B}^{n-k} \times S^{k-1} \to B$ be a thickened $(k-1)$-sphere and let $f\colon M \to \mathbb{R}$ be a map that points inward on A and that points outward on B. Then there exists a smooth map $g\colon M \cup_\varphi h^k \to \mathbb{R}$ with the following properties:
   (a) The restriction of g to M equals f.
   (b) g points outward on $\partial(M \cup_\varphi h^k) \setminus A$.
   (c) In the handle $\overline{B}^{n-k} \times \overline{B}^k$ the map g has precisely one critical point, and this critical point has index k.

(2) If M is equipped with a handle decomposition $M \cong ([0,1] \times A) \cup_{\varphi_1} h^{k_1} \cup \cdots \cup_{\varphi_m} h^{m_k}$ rel A, then there exists a smooth map $g\colon M \to \mathbb{R}$ with the following properties:
   (a) On $[0,1] \times A$ the map g equals the projection onto $[0,1]$,
   (b) The map g has precisely m critical points $P_1, \ldots, P_m$, each of which is non-degenerate and such that for $i = 1, \ldots, m$ the index of the critical point P_i equals the index of the handle φ_i.

Proof.

(1) This statement is proved by running the proof of Theorem 138.3 "backwards". In particular the idea is, to define g on the k-handle to be a suitable modification of the function

$$\begin{array}{rcl} \overline{B}^k \times \overline{B}^{n-k} & \to & \mathbb{R} \\ (x_1, \ldots, x_k, y_1, \ldots, y_{n-k}) & \mapsto & -x_1^2 - \cdots - x_k^2 + y_1^2 + \cdots + y_{n-k}^2. \end{array}$$

   We refer to [**Kos1993**, p. 130] for the details.

(2) This statement follows immediately from applying (1) altogether m times. ■

We conclude this section with a neat refinement of the Morse Function-Existence Proposition 137.6. To formulate the result we introduce the following definition.

Definition. Let M be a compact n-dimensional smooth manifold and suppose we are given a decomposition $\partial M = A \sqcup B$ where A and B are unions of components of ∂M. A Morse function $f\colon M \to \mathbb{R}$ is called self-indexing with respect to A and B, if the following conditions are satisfied.

(1) We have $f|_A \equiv -\frac{1}{2}$ and $f|_B \equiv n + \frac{1}{2}$.
(2) If P is a critical point of f, then $f(P) = \operatorname{index}(f, P)$.

Proposition 139.10. Let M be a compact n-dimensional smooth manifold and suppose we are given a decomposition $\partial M = A \sqcup B$ where A and B are unions of components of ∂M. There exists a self-indexing Morse function $f\colon M \to \mathbb{R}$ with respect to A and B.

Sketch of proof. Let M be a compact n-dimensional smooth manifold and suppose we are given a decomposition $\partial M = A \sqcup B$ where A and B are unions of components of ∂M. By the Handle Decomposition Theorem 138.5 there exists a standard handle decomposition

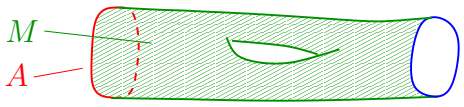
$$M \;=\; ([0,1] \times A) \underbrace{\cup_{\varphi_{0,1}} h^0 \cdots \cup_{\varphi_{0,r_0}} h^0}_{0\text{-handles}} \cup \ldots \underbrace{\cup_{\varphi_{n,1}} h^n \cdots \cup_{\varphi_{n,r_n}} h^n}_{n\text{-handles}}$$

rel A. Given $i \in \{-1, \ldots, n\}$ we denote by M^i the i-skeleton of the relative handle decomposition and we set $B_i := \partial M^i \setminus A$. It suffices to prove the following claim.

Claim. For $i = -1, \ldots, n$ there exists a Morse function f_i on M^i with the following properties:

(1) We have $f|_A \equiv -\frac{1}{2}$ and $f|_{B_i} \equiv i + \frac{1}{2}$.
(2) If P is a critical point of f_i, then $f_i(P) = \operatorname{index}(f_i, P)$.

Proof. For $i = -1$ we have $M^i = [0,1] \times A$ and we choose the map that is given by $(t, a) \mapsto t - \frac{1}{2}$. Now suppose the claim holds for some $i \in \{-1, \ldots, n-1\}$. By the Handles-to-Morse Function Proposition 139.9 we can extend the map $f_i\colon M^i \to \mathbb{R}$ to a Morse function on $g\colon M^{i+1} \to \mathbb{R}$ such that g has precisely r_{i+1} extra critical points, and each of these critical points has index $i+1$. Note that the value of g on these critical points is necessarily greater than $i + \frac{1}{2}$ and that the value of g on each $S^{n-k-1} \times B^k$ is greater than $i + \frac{1}{2}$. By rescaling, see Exercise 137.4, we can arrange that the value of g at each of these critical points is precisely $i + 1$ and we can arrange that the value of g on each $S^{n-k-1} \times B^k$ is greater than $i + \frac{1}{2}$. The values of g on B_i now lie in $[i + \frac{1}{2}, i + \frac{3}{2})$ and g points outward on B_i. Using a collar neighborhood for B_i together with Lemma 139.5 it is now fairly straightforward to arrange that the map g actually equals $i + \frac{3}{2}$ on B_i. As always, the adventurous reader is warmly invited to fill in the details. ⊞



For full details we refer to the original proof by Stephen Smale [**Sma1961b**, Theorem C]. Alternatively the statement is also proved in [**Miln1965b**, p. 45] and [**Nic2011**, Chapter 2.4]. ■

139.5. **Handle decompositions of topological manifolds.** The notion of a handle decomposition also makes sense, with a few suitable modifications in the definition, for compact topological manifolds. So the question arises, does every compact topological manifold admit a handle decomposition? It turns out that this is a subtle question.

(1) By Theorem **??** every compact topological manifold of dimension ≤ 3 admits a smooth structure. Thus it follows from Theorem 139.7 that every such topological manifold admits a handle decomposition.
(2) Rob Kirby and Larry Siebenmann [**KSi1977**, Essay III.2, Theorem 2.1] (see also [**Kupe2017b**, Theorem 1.22]) showed that every compact topological manifold of dimension ≥ 6 admits a topological handle decomposition. Later Frank Quinn [**Qu1982**, Theorem 2.3.1] extended this result to the 5-dimensional setting.
(3) It follows from Proposition **??** that every closed 4-dimensional topological manifold that admits a topological handle decomposition also admits a smooth structure. But in Theorem 135.9 we saw that there exist closed 4-dimensional topological manifolds that do not admit a smooth structure. In particular there exist closed 4-dimensional topological manifolds that do not admit a handle decomposition.

Exercises for Chapter 139.

Exercise 139.1. In the figure below we show once again M, the torus with two disks removed. Let A be one of the two boundary components. In the figure below we showed that M admits a handle decomposition rel A with one 0-handle, three 1-handles and one 2-handle. Does there exist a handle decomposition of M rel A with fewer handles?

Exercise 139.2. Let M be a compact connected non-empty smooth manifold that is equipped with a handle decomposition. On page 3004 we saw that the double $\mathrm{D}M$ comes with a canonical handle decomposition. For which dimensions of M can you use this fact to argue that the inclusion induced map $\pi_1(M) \to \pi_1(\mathrm{D}M)$ is an isomorphism?

Exercise 139.3. Give an explicit self-indexing Morse function for the torus $S^1 \times S^1$ and the Klein bottle.

140. Handle homology and the Morse inequalities

In this chapter we will see that a handle decomposition of a compact smooth manifold gives rise to a chain complex, namely the handle chain complex. This chain complex can be viewed as an analogue of the cellular chain complex of a CW-complex. We will see that the corresponding homology groups, called handle homology groups, are naturally isomorphic to the usual singular homology groups. We will use this isomorphism to prove the Morse inequalities, which show that the "size" of singular homology groups gives a lower bound on the number of singularities of a Morse function on a given smooth manifold.

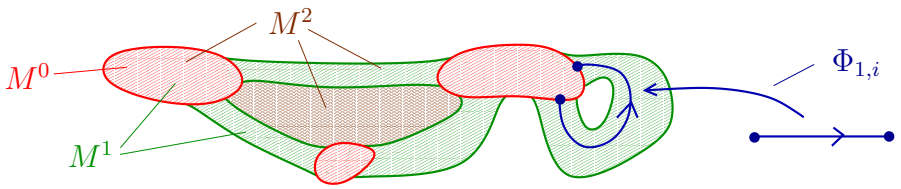
140.1. **Handle homology.** In Chapter 80 we introduced the cellular chain complex of a CW-complex X. Recall that this chain complex has the following two features:

(1) The chain groups are defined to be $\mathrm{C}_k^{\mathrm{CW}}(X) := \mathrm{H}_k(X^k, X^{k-1})$. By the Skeleton-Homology Lemma 80.1 this chain group can be viewed as the free abelian groups on the set of k-cells.
(2) The corresponding cellular homology groups are naturally isomorphic to the singular homology groups.

In this section we will outline how one can perform something very similar in the setting of smooth manifolds with a given handle decomposition. The following lemma is an analogue of the Skeleton-Homology Lemma 80.1.

Lemma 140.1. (Handle Skeleton-Homology Lemma) Let M be a compact n-dimensional smooth manifold together with a standard handle decomposition

$$M \cong \varnothing \underbrace{\cup_{\varphi_{0,1}} h^0 \cdots \cup_{\varphi_{0,r_0}} h^0}_{0\text{-handles}} \cup \ldots \underbrace{\cup_{\varphi_{n,1}} h^n \cdots \cup_{\varphi_{n,r_n}} h^n}_{n\text{-handles}}.$$



Let $k \in \mathbb{N}_0$. As on page 2958 we denote by M^k the k-skeleton of the handle decomposition, i.e. M^k is union of all handles of index $\leq k$.[1676]

(1) Let $k \in \{0, \ldots, n\}$. Given $i \in \{1, \ldots, r_i\}$ we denote by $\Phi_{k,i} \colon \overline{B}_i^k \to \{0\} \times \overline{B}_i^k \to M^k$ the map that is given by the inclusion map of the core of the i-th k-handle. For every $k, j \in \mathbb{N}_0$ the following map is an isomorphism:[1677]

$$\bigoplus_{i=1}^{r_i} \Phi_{k,i*} \colon \bigoplus_{i=1}^{r_i} \mathrm{H}_j(\overline{B}_i^k, \partial \overline{B}_i^k) \longrightarrow \mathrm{H}_j(M^k, M^{k-1}).$$

In particular the following holds:
   (a) For $i \neq k$ we have $\mathrm{H}_i(M^k, M^{k-1}) = 0$.
   (b) The group $\mathrm{H}_k(M^k, M^{k-1})$ is a free abelian group where the rank equals the number of k-handles.
(2) For $i > k$ we have $\mathrm{H}_i(M^k) = 0$.
(3) For $i < k$ the inclusion $j \colon M^k \to M$ induces an isomorphism $j_* \colon \mathrm{H}_i(M^k) \xrightarrow{\cong} \mathrm{H}_i(M)$.
(4) The inclusion $j \colon M^k \to M$ induces an epimorphism $j_* \colon \mathrm{H}_k(M^k) \twoheadrightarrow \mathrm{H}_k(M)$.

[1676] Note that this definition makes sense since the handle decomposition is standard.
[1677] Note that by definition of a standard handle decomposition, see page 2958, the restriction of $\Phi_{k,i}$ to $\partial \overline{B}_i^k$ does indeed take values in M^{k-1}.

Remark. The statement of the Handle Skeleton-Homology Lemma 140.1 (3) and (4) is very similar in spirit to the content of Exercise 136.12.

Proof. Not surprisingly the proof of the lemma is very similar to the proof of the Skeleton-Homology Lemma 80.1. But completeness sake let us go through the motions.

(1) We consider the following diagram

$$\begin{array}{ccc} \bigoplus_{i=1}^{r_i} \mathrm{H}_k(\overline{B}_i^k, \partial \overline{B}_i^k) & \xrightarrow{\oplus \Phi_{k,i*}} & \mathrm{H}_k(M^k, M^{k-1}) \\ \downarrow & & \uparrow \\ \bigoplus_{i=1}^{r_i} \mathrm{H}_k(\overline{B}^{n-k} \times \overline{B}_i^k, \overline{B}^{n-k} \times \partial \overline{B}_i^k) & \xrightarrow{\oplus \Phi_{k,i*}} & \bigoplus_{i=1}^{r_i} \mathrm{H}_k(\Phi_{k,i}(\overline{B}^{n-k} \times \overline{B}_i^k), \Phi_{k,i}(\overline{B}^{n-k} \times \partial \overline{B}_i^k)). \end{array}$$

The left vertical map is induced by the inclusions $x \mapsto (0, x)$. It is an isomorphism by Corollary 74.16. The bottom horizontal map is induced by homeomorphisms, thus it is also an isomorphism. Next note that the right vertical map is induced by the obvious inclusions. It follows almost immediately from the Excision Theorem 120.2 that the right vertical map is an isomorphism. Clearly he diagram clearly commutes. Hence we get that the top horizontal map is indeed an isomorphism. Finally the "in particular" statements now follow immediately from Lemma 76.1.

(2) We fix $i \in \mathbb{N}$. We want to show that $\mathrm{H}_i(M^k) = 0$ for $k = 0, \ldots, i-1$. First of all we have $\mathrm{H}_i(M^0) = 0$ since M^0 is diffeomorphic to a disjoint union of n-balls. Now assume that we already know that $\mathrm{H}_i(M^k) = 0$ for some $k < i-1$. We want to show that $\mathrm{H}_i(M^{k+1}) = 0$. We consider the long exact sequence of the pair (M^{k+1}, M^k):

$$\ldots \to \mathrm{H}_{i+1}(M^{k+1}, M^k) \to \underbrace{\mathrm{H}_i(M^k)}_{=0} \to \mathrm{H}_i(M^{k+1}) \to \underbrace{\mathrm{H}_i(M^{k+1}, M^k)}_{=0 \text{ by (1) since } i>k+1} \to \ldots$$

Thus we obtain that indeed $\mathrm{H}_i(M^{k+1}) = 0$.

(3) We fix $i \in \mathbb{N}_0$. Let $m > i$. This time we consider the following excerpt from the long exact sequence of the pair (M^{m+1}, M^m):

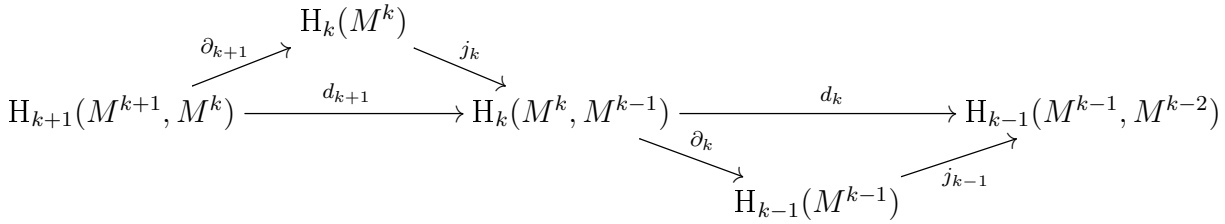
$$\ldots \to \underbrace{\mathrm{H}_{i+1}(M^{m+1}, M^m)}_{=0 \text{ by (1) since } i<m} \to \mathrm{H}_i(M^m) \to \mathrm{H}_i(M^{m+1}) \to \underbrace{\mathrm{H}_i(M^{m+1}, M^m)}_{=0 \text{ by (1) since } i<m} \to \ldots$$

This discussion implies in particular that we have inclusion induced isomorphisms $\mathrm{H}_i(M^k) \xrightarrow{\cong} \mathrm{H}_i(M^{k+1}) \xrightarrow{\cong} \ldots \xrightarrow{\cong} \mathrm{H}_i(M^n) = \mathrm{H}_i(M)$.

(4) In (3) we showed that the inclusion induced map $\mathrm{H}_k(M^{k+1}) \to \mathrm{H}_k(M)$ is an isomorphism. Thus it suffices to show that the inclusion induced map $\mathrm{H}_k(M^k) \to \mathrm{H}_k(M^{k+1})$ is an epimorphism. To show this we consider the following excerpt from long exact

sequence of the pair (M^{k+1}, M^k):

$$\ldots \to \mathrm{H}_{k+1}(M^{k+1}, M^k) \to \mathrm{H}_k(M^k) \to \mathrm{H}_k(M^{k+1}) \to \underbrace{\mathrm{H}_k(M^{k+1}, M^k)}_{=0 \text{ by (1)}} \to \ldots$$



We see that the inclusion induced map $\mathrm{H}_k(M^k) \to \mathrm{H}_k(M^{k+1})$ is indeed an epimorphism. ■

Lemma 140.2. Let M be compact smooth manifold together with a standard handle decomposition. Given $k \in \mathbb{N}_0$ we denote by $d = d_k$ the map

$$\mathrm{H}_k(M^k, M^{k-1}) \xrightarrow{\partial_k} \mathrm{H}_{k-1}(M^{k-1}) \xrightarrow{j_{k-1}} \mathrm{H}_{k-1}(M^{k-1}, M^{k-2})$$
$$\underbrace{\qquad\qquad\qquad\qquad\qquad\qquad}_{=:d=d_k}$$

where ∂_k is the connecting map in the long exact sequence of the pair (M^k, M^{k-1}) and where j_{k-1} is the map induced by the projection $\mathrm{C}_{k-1}(M^{k-1}) \to \mathrm{C}_{k-1}(M^{k-1}, M^{k-2})$. These maps have the property that for every $k \in \mathbb{N}_0$ we have $d_k \circ d_{k+1} = 0$.

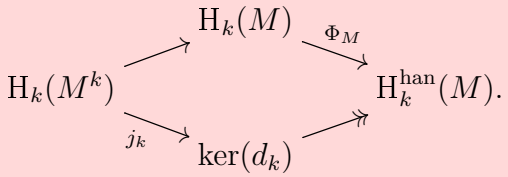
Proof. This proof is easy. We just need to copy-paste the proof of Lemma 80.2. Thus we consider the following commutative diagram of maps

The map $\partial_k \circ j_k \colon \mathrm{H}_k(M^k) \to \mathrm{H}_{k-1}(M^{k-1})$ is the composition of two successive maps in the long exact sequence of the pair (M^k, M^{k-1}), i.e. the map $\partial_k \circ j_k$ is the zero map. Since the diagram commutes we obtain that $d_k \circ d_{k+1} = 0$. ■

Definition. Let M be compact smooth manifold together with a standard handle decomposition.

(1) We refer to the map d_k from Lemma 140.2 as the handle boundary map.
(2) We write $\mathrm{C}_k^{\mathrm{han}}(M) := \mathrm{H}_k(M^k, M^{k-1})$ and we refer to $(\mathrm{C}_*^{\mathrm{han}}(M), d_*)$ as the handle chain complex.[1678]
(3) We denote the homology groups of the handle chain complex by $\mathrm{H}_k^{\mathrm{han}}(M)$ and we refer to these groups as the handle homology groups of the smooth manifold M with the given handle decomposition.

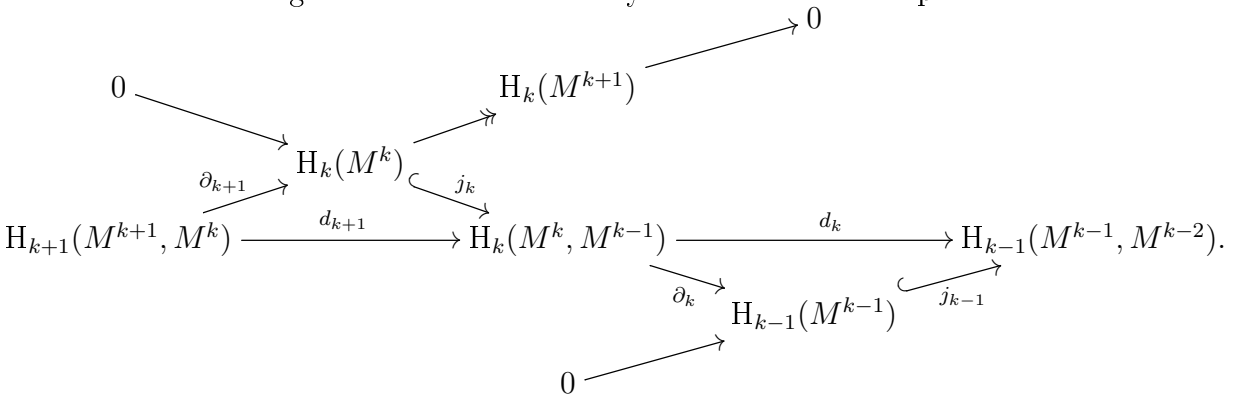
In the Singular-Cellular H_*-Isomorphism Proposition 80.4 we showed that for a CW-complex the singular and cellular homology groups are naturally isomorphic. The following proposition proves the analogous statement in our present setting.



Proposition 140.3. (Singular-Handle H_*-Isomorphism Proposition) Let M be compact smooth manifold together with a standard handle decomposition. Given any

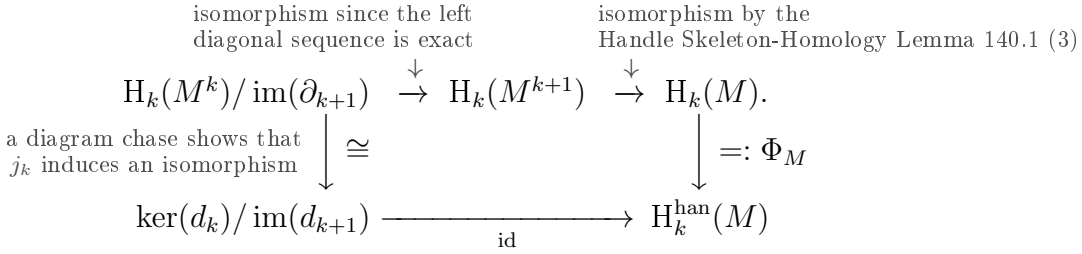
[1678] It follows from Lemma 140.2 that $(\mathrm{H}_k(M^k, M^{k-1}), d_k)_{k \in \mathbb{N}_0}$ is indeed a chain complex.

$k \in \mathbb{N}_0$ there exists a uniquely determined natural[1679] isomorphism



$$\Phi_M \colon \mathrm{H}_k(M) \xrightarrow{\cong} \mathrm{H}_k^{\mathrm{han}}(M)$$

with the property that the following diagram commutes:[1680]



In particular, in light of the above and the Homotopy Equivalence-H_*-Corollary 73.9, the isomorphism type of the handle homology groups depends only on the homotopy type of M.

Proof of the Singular-Handle H_*-Isomorphism Proposition 140.3. The proof of the Singular-Handle H_*-Isomorphism Proposition 140.3 is almost embarrassingly similar to the proof of the Singular-Cellular H_*-Isomorphism Proposition 80.4 (1). For the reader's convenience we nonetheless provide an abbreviated version of the argument. As in the proof of the Singular-Cellular H_*-Isomorphism Proposition 80.4 (1) we add a couple of maps to the commutative diagram that we had already encountered in the proof of Lemma 140.2:

Recall that by the Handle Skeleton-Homology Lemma 140.1 (1) and (2) we know that $\mathrm{H}_k(M^{k+1}, M^k) = 0$, $\mathrm{H}_k(M^{k-1}) = 0$ and $\mathrm{H}_{k-1}(M^{k-2}) = 0$. It follows almost immediately from these facts that the diagonal sequences in the above diagram are exact. Next we consider the diagram:

[1679] We leave it to the reader to figure out what "natural" should mean in this context.

[1680] Here we again denote by $j_k \colon \mathrm{H}_k(M^k) \to \mathrm{H}_k(M^k, M^{k-1})$ the obvious map. In the long exact sequence of the pair (M^k, M^{k-1}) we see that the image of $\mathrm{H}_k(M^n)$ in $\mathrm{H}_k(M^k, M^{k-1})$ lies in the kernel of the connecting homomorphism ∂_k. This implies that the map $j_k \colon \mathrm{H}_k(M^k) \to \mathrm{H}_k(M^k, M^{k-1})$ takes values in $\ker(d_k)$.

Next note that by construction the isomorphism Φ_M has the property that the following diagram commutes:

$$\begin{array}{ccccc} & & \mathrm{H}_k(M) & & \\ & \nearrow\!\!\!\!\!\rightarrow & & \searrow^{\Phi_M} & \\ \mathrm{H}_k(M^k) & & & & \mathrm{H}_k^{\mathrm{han}}(M). \\ & \searrow_{j_k} & & \nearrow\!\!\!\!\!\rightarrow & \\ & & \ker(d_k) & & \end{array}$$

Note that the top-left diagonal map is an epimorphism by the Handle Skeleton-Homology Lemma 140.1 (4). This implies immediately that Φ_M is uniquely determined.

Finally we leave it to the reader who figured out what it means for the isomorphism to be "natural" to actually show that it is natural. ■

In the next section we will discuss a practical approach to calculating the boundary maps in the handle chain complex. But even without this knowledge we can already obtain interesting consequences of the Singular-Handle H_*-Isomorphism Proposition 140.3. For example we can prove the following corollary.[1681]

Corollary 140.4. (Handles-Euler Characteristic Corollary) Let M be a compact smooth manifold. Given any handle decomposition for M the following equality holds:

$$\sum_{k\in\mathbb{N}_0} (-1)^k \cdot \text{number of } k\text{-handles} \;=\; \chi(M).$$

Proof. Let M be a compact smooth manifold together with a handle decomposition. Given $k \in \mathbb{N}_0$ we denote by c_k the number of k-handles. By the Standard Handle Decomposition Corollary 136.4 we can find a *standard* handle structure on M such that for every $k \in \mathbb{N}_0$ the number of k-handles also equals c_k. Using this new handle decomposition we perform the following calculation:

$$\begin{array}{rcccl} & \text{see definition on page 1882} & & \text{Singular-Handle } \mathrm{H}_*\text{-Isomorphism Proposition 140.3} & \\ \chi(M) & \overset{\downarrow}{=} & \displaystyle\sum_{k\in\mathbb{N}_0} (-1)^k \cdot \mathrm{rk}(\mathrm{H}_k(M)) & \overset{\downarrow}{=} & \displaystyle\sum_{k\in\mathbb{N}_0} (-1)^k \cdot \mathrm{rk}(\mathrm{H}_k^{\mathrm{han}}(M)) \\ & \overset{\uparrow}{=} & \displaystyle\sum_{k\in\mathbb{N}_0} (-1)^k \cdot \mathrm{rk}(\mathrm{C}_k^{\mathrm{han}}(M)) & \overset{\uparrow}{=} & \displaystyle\sum_{k\in\mathbb{N}_0} (-1)^k \cdot c_k. \\ & \text{Lemma 87.3} & & \text{Handle Skeleton-Homology Lemma 140.1} & \end{array}$$

■

Next we obtain the following corollary.

Corollary 140.5. (Odd-Dimensional Manifold-Euler Characteristic Corollary) The Euler characteristic of every closed odd-dimensional smooth manifold is zero.

Remark.

(1) In the Odd-Dimensional Manifold-Euler Characteristic Lemma 45.4 we showed that the smooth Euler characteristic of a closed orientable odd-dimensional smooth manifold is zero.
(2) In the Odd-Dimensional Manifold-Euler Characteristic Proposition 119.7 we used Poincaré Duality to prove a generalization of the Odd-Dimensional Manifold-Euler Characteristic Corollary 140.5 to compact odd-dimensional topological manifolds.

[1681] Admittedly we could already have proved that particular corollary earlier on, namely using the Handle Attachment-H_*-Lemma 136.13. This was precisely the content of Exercise 136.10.

Proof. Let M be a closed $(2n+1)$-dimensional smooth manifold. By the Handle Decomposition Theorem 138.5 we can equip M with a handle decomposition. By the Dual Handle Proposition 136.5 we can also consider the corresponding dual handle decomposition. Now we see that

$$\begin{aligned}\chi(M) &\overset{\text{Handles-Euler Characteristic Corollary 140.4}}{\downarrow} \sum_{k=0}^{2n+1}(-1)^k \cdot \begin{array}{c}\text{number of } k\text{-handles in}\\ \text{the handle decomposition}\end{array} \overset{\text{by definition of the dual handle decomposition}}{\downarrow} \sum_{k=0}^{2n+1}(-1)^k \cdot \begin{array}{c}\text{number of } (2n+1-k)\text{-handles in}\\ \text{the dual handle decomposition}\end{array}\\ &= \underset{\text{substitution } m=2n+1-k}{\uparrow} -\sum_{m=0}^{2n+1}(-1)^m \cdot \begin{array}{c}\text{number of } m\text{-handles in the}\\ \text{dual handle decomposition}\end{array} = \underset{\text{Handles-Euler Characteristic Corollary 140.4}}{\uparrow} -\chi(M).\end{aligned}$$

Thus we see that $\chi(M) = 0$. ■

We continue with an even more pleasing corollary.

Corollary 140.6. (Euler Characteristic-via-Critical Points Corollary) Let M be a closed smooth manifold. For any Morse function $f\colon M \to \mathbb{R}$ we have

$$\sum_{k\in\mathbb{N}_0}(-1)^k \cdot \#\text{critical points of } f \text{ of index } k \;=\; \chi(M).$$

Remark.

(1) For $M = S^2$ the statement of the Euler Characteristic-via-Critical Points Corollary 140.6 implicitly appears already in a paper written by Clerk Maxwell [**Max1870**] in 1870 with the beautiful title "on hills and dales".
(2) In Exercise 140.13 we will see that the Euler Characteristic-via-Critical Points Corollary 140.6 can also be deduced from the Poincaré-Hopf Theorem 129.7.

Proof. Let $f\colon M \to \mathbb{R}$ be a Morse function on a closed smooth manifold. It follows from the Morse Function-Handle Decomposition Proposition 138.4 that M admits a handle decomposition such that for each $k \in \mathbb{N}_0$ the number of k-handles equals the number of critical points of index k. The desired equality now follows immediately from the Handles-Euler Characteristic Corollary 140.4. ■

Corollary 129.5. For every closed smooth manifold M the Euler characteristic $\chi(M)$ equals the smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$ of closed orientable smooth manifolds that we had introduced on page 1019.

Proof. Let M be a closed smooth manifold. In the following we first recall the proof of the Non-Degenerate Vector Field Existence Proposition 129.4 that we gave on page 2983. By the Euclidean Embedding Theorem 27.1 we can assume that M is a smooth submanifold of some $\mathbb{R}^n$. By the Morse Function Existence Proposition 137.5 we know that M admits a Morse function $f\colon M \to \mathbb{R}$. It follows from the Gradient Vector Field Proposition 137.8 that the gradient vector field ∇f, that we defined on page 2982, is a vector field such that all zeros are non-degenerate.[1682]

[1682] We refer to page 2982 for the definition of a non-degenerate zero of a vector field and of the index of a non-degenerate zero of a vector field.

Now that we have repeated the argument on page 2983 we can easily prove the corollary, namely we see that

$$\begin{array}{ccccccc} \chi^{\mathrm{sm}}(M) & = & \sum\limits_{x \text{ a zero of } \nabla f} \operatorname{index}(\nabla f, x) & = & \sum\limits_{\substack{x \text{ a critical} \\ \text{point of } f}} \operatorname{index}(f, x) & = & \chi(M). \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \text{Smooth Poincaré–Hopf} & & \text{Gradient Vector Field} & & \text{Euler Characteristic-via-Critical} & & \\ \text{Theorem 45.17} & & \text{Proposition 137.8} & & \text{Points Corollary 140.6} & & \end{array}$$

∎

Recall that we had formulated the Smooth Poincaré–Hopf Theorem 45.17 in terms of the smooth Euler characteristic. We can now formulate it in terms of the usual Euler characteristic:

Theorem 140.7. (Smooth Poincaré–Hopf Theorem) Let M be a closed orientable smooth manifold and let v be a smooth vector field on M such that all zeros of v are non-degenerate. Then we have the equality

$$\sum_{x \text{ a zero of } v} \operatorname{index}(v, x) \;=\; \chi(M).$$

Proof. As we just mentioned in the proof of Corollary 129.5, the Smooth Poincaré–Hopf Theorem 45.17 contains precisely the desired statement, except that it is formulated with the smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$. Fortunately, thanks to Corollary 129.5 we now know that the smooth Euler characteristic $\chi^{\mathrm{sm}}(M)$ equals the usual Euler characteristic $\chi(M)$. ∎

140.2. **The boundary maps in the handle chain complex.** The following proposition is a useful tool for calculating the boundary maps in a given handle chain complex.

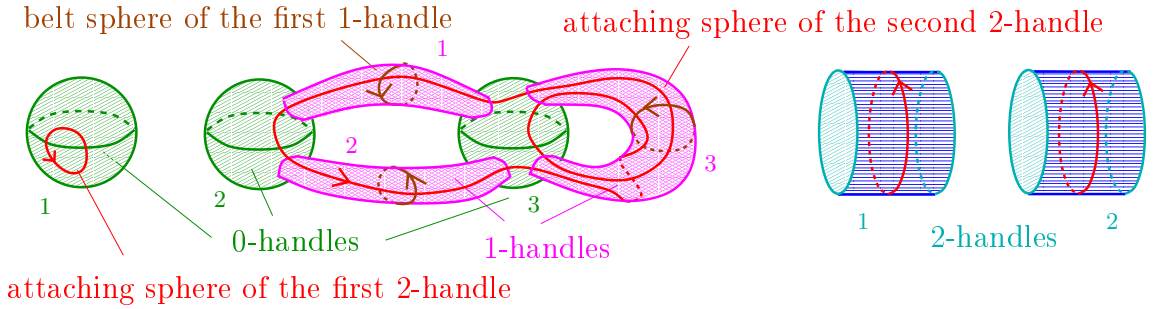
Proposition 140.8. (Handle Chain Complex-Boundary Map Proposition) Let M be an oriented n-dimensional smooth manifold together with a standard handle decomposition

$$M \cong \varnothing \underbrace{\cup_{\varphi_{0,1}} h^0 \cdots \cup_{\varphi_{0,r_0}} h^0}_{0\text{-handles}} \cup \ldots \underbrace{\cup_{\varphi_{n,1}} h^n \cdots \cup_{\varphi_{n,r_n}} h^n}_{n\text{-handles}}.$$

We assume that the inclusion maps of all the handles are orientation-preserving. Given $k \in \mathbb{N}_0$ and given $i \in \{1, \ldots, r_i\}$ we denote by $\Phi_{k,i} \colon \{0\} \times \overline{B}^k_i \to M^k$ the map that is given by the inclusion map of the core of the handle. By the Handle Skeleton-Homology Lemma 140.1 we know that

$$\mathcal{B}_k \;:=\; \{\Phi_{k,1*}([\{0\} \times \overline{B}^k]), \ldots, \Phi_{k,r_k*}([\{0\} \times \overline{B}^k])\}$$

is a basis of $\mathrm{H}^{\mathrm{han}}_k(M) := \mathrm{H}_k(M^k, M^{k-1})$. Given $j \in \{1, \ldots, r_{k+1}\}$ and $i \in \{1, \ldots, r_k\}$ we have the following equality:[1683]



$$\begin{array}{ccc} (i,j)\text{-entry of the matrix representing} \\ d_{k+1} \colon \mathrm{H}^{\mathrm{han}}_{k+1}(M) \to \mathrm{H}^{\mathrm{han}}_k(M) \\ \text{with respect to the bases } \mathcal{B}_{k+1} \text{ and } \mathcal{B}_k \end{array} \quad = \quad \begin{array}{c} \text{algebraic intersection number in } \partial M^k \text{ of} \\ \text{the attaching sphere of the } (k+1,j)\text{-handle} \\ \text{with the belt sphere of the } (k,i)\text{-handle.} \end{array}$$

[1683] For the right-hand side note that ∂M^k is a compact oriented $(n-1)$-dimensional smooth manifold, the attaching sphere of the $(k+1,j)$-handle is an oriented k-dimensional sphere in ∂M^k and the belt sphere of the (k,i)-handle is an oriented $(n-k-1)$-dimensional sphere in ∂M^k. So, according to the definition on page 2757, it makes sense to consider in ∂M^k the algebraic intersection number of the two spheres.

Example. We consider the 3-dimensional smooth manifold M which is shown in the figure below. It has three 0-handles, three 1-handles and two 2-handles. Using the Handle Chain Complex-Boundary Map Proposition 140.8 one sees that the corresponding handle chain complex is isomorphic to the following chain complex:

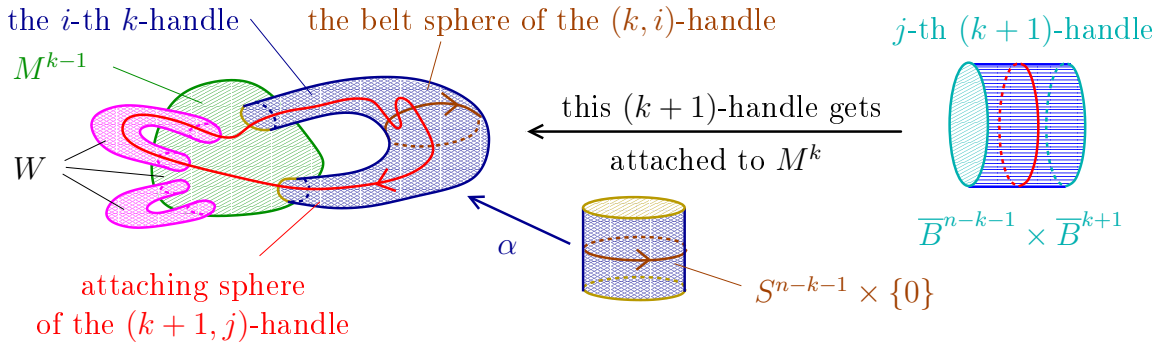
$$0 \to \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \xrightarrow{\begin{pmatrix}0 & -1\\ 0 & 1\\ 0 & 2\end{pmatrix}} \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\\ \mathbb{Z}\end{matrix} \xrightarrow{\begin{pmatrix}0 & 0 & 0\\ -1 & 1 & 0\\ 1 & -1 & 0\end{pmatrix}} \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\\ \mathbb{Z}\end{matrix} \to 0. \qquad \text{Thus we obtain that} \qquad \mathrm{H}_k^{\mathrm{han}}(M) \cong \begin{cases} 0, & \text{if } k \geq 3, \\ \mathbb{Z}, & \text{if } k = 2, \\ \mathbb{Z}, & \text{if } k = 1, \\ \mathbb{Z}^2, & \text{if } k = 0. \end{cases}$$

By the Handle Example Lemma 136.2 (2) we know that the component of M that is given by gluing the first 2-handle to the first 0-handle is diffeomorphic to $\overline{B}^1 \times S^2$. But what we can say about the other component of M? We will answer this question on page **??**.

Remark. Let M be an oriented smooth manifold that is equipped with a standard handle decomposition.

(1) If the various attaching spheres and the belt spheres intersect transversally, then we know by the Intersection Number-via-Cup Product Theorem 126.5 that the algebraic intersection number of the attaching spheres and the belt spheres can be determined in a pleasingly geometric way. If they do not intersect transversally, do no despair, since we can iteratively apply the Transversality Theorem 42.4 to find an isotopy of the attaching spheres so that the resulting attaching spheres intersect the belt spheres transversally. By the Handle Chain Complex-Boundary Map Proposition 140.8 (4) these isotopies do not change the diffeomorphism type of the smooth manifold. Put differently, after possibly fiddling a little bit with the handle decomposition we can compute the handle homology groups using intersection numbers of transverse spheres.

(2) In (1) we just argued that the boundary maps in the handle chain complex can be determined geometrically. In [**DGK2019**] this approach is used to define handle homology without referring to singular homology. Furthermore in [**DGK2019**] it is shown using the Cerf Theorem **??**, but again without making use of singular homology groups, that the isomorphism types of these geometrically defined handle homology groups only depend on the diffeomorphism type of the underlying smooth manifold. An outline of the argument is also given in [**GoS1999**, Chapter 4.2].



In fact this approach, together with Lemma 136.6, can be used to give an alternative proof of some of the statements of the Poincaré Duality Theorem 119.1. We refer to [**Kos1993**, Theorem VII.5.1] and [**DGK2019**] for details.

Proof. Let M be an oriented n-dimensional smooth manifold together with a standard handle decomposition

$$M \cong \varnothing \underbrace{\cup_{\varphi_{0,1}} h^0 \cdots \cup_{\varphi_{0,r_0}} h^0}_{0\text{-handles}} \cup \ldots \underbrace{\cup_{\varphi_{n,1}} h^n \cdots \cup_{\varphi_{n,r_n}} h^n}_{n\text{-handles}}$$

which has the property that the inclusion maps of all the handles are orientation-preserving. Let $k \in \mathbb{N}_0$, let $j \in \{1, \ldots, r_{k+1}\}$ and let $i \in \{1, \ldots, r_k\}$. We introduce the following notation:

(1) We denote by W the result of attaching to M^{k-1} all k-handles *except* for the i-th k-handle.
(2) We denote by $\alpha\colon \overline{B}^{n-k} \times \overline{B}^k \to M^k$ the embedding corresponding to the (k,i)-handle. Since the handle decomposition is standard we see that $\alpha(\overline{B}^{n-k} \times S^{k-1}) \subset M^{k-1} \subset W$. Furthermore note that $\alpha(S^{n-k-1} \times \{0\})$ is the belt sphere of the (k,i)-handle.
(3) Let $\beta\colon \overline{B}^{n-k-1} \times \overline{B}^{k+1} \to M^{k+1}$ be the embedding corresponding to the $(k+1,j)$-handle. Note that $\beta(\{0\} \times S^k)$ is the attaching sphere of the $(k+1,j)$-handle. Since we are dealing with a standard handle decomposition we see that $\beta(\{0\} \times S^k) \subset \partial M^k$.

Next we consider the following diagram:

$$\begin{array}{ccccc}
\mathrm{H}_{k+1}(\{0\}\times\overline{B}^{k+1}, \{0\}\times S^k) & \xrightarrow{\beta_*} & \mathrm{H}_{k+1}(M^{k+1}, M^k) & \xrightarrow{\partial_{k+1}} & \mathrm{H}_k(M^k) \\
\downarrow{\scriptstyle \partial_{k+1}} & & & & \downarrow \\
\mathrm{H}_k(\{0\}\times S^k) & \xrightarrow{\beta_*} & \mathrm{H}_k(M^k, W) & \longleftarrow & \mathrm{H}_k(M^k, M^{k-1}) \\
\downarrow{\scriptstyle \beta_*} & \nearrow & \uparrow{\scriptstyle h_*}\ \cong\ \downarrow{\scriptstyle h_*^{-1}} & & \\
\mathrm{H}_k(\partial M^k, \partial M^k \setminus \alpha(S^{k-1}\times B^{n-k})) & & & & \\
\uparrow{\scriptstyle h_*}\ \cong & & & & \\
\mathrm{H}_k(\alpha(S^{n-k-1}\times\overline{B}^k), \alpha(S^{n-k-1}\times S^{k-1})) & \longrightarrow & \mathrm{H}_k(\alpha(\overline{B}^{n-k}\times\overline{B}^k), \alpha(\overline{B}^{n-k}\times S^{k-1})) & & \\
\uparrow{\scriptstyle \alpha_*}\ \cong & & \downarrow{\scriptstyle \alpha_*^{-1}} & & \\
\mathrm{H}_k(S^{n-k-1}\times\overline{B}^k, S^{n-k-1}\times S^{k-1}) & \longrightarrow & \mathrm{H}_k(\overline{B}^{n-k}\times\overline{B}^k, \overline{B}^{n-k}\times S^{k-1}) & & \\
\downarrow{\scriptstyle \sigma\mapsto Q([S^{n-k-1}\times\{0\}],\sigma)} & & \downarrow{\scriptstyle \sigma\mapsto \widetilde{Q}([\overline{B}^{n-k}\times\{0\}],\sigma)} & \searrow{\scriptstyle n\cdot[\{0\}\times\overline{B}^k]\mapsto n} & \\
\mathbb{Z} & \xrightarrow[\mathrm{id}]{} & \mathbb{Z} & \xrightarrow[\mathrm{id}]{} & \mathbb{Z}.
\end{array}$$

We make the following clarifications and observations:

(1) By a slight abuse of notation we denote all of the following inclusion maps by h:

$$\begin{aligned} h\colon \alpha(\overline{B}^{n-k}\times\overline{B}^{k}) &\to M^k \\ h\colon (\alpha(\overline{B}^{n-k}\times\overline{B}^{k}),\alpha(\overline{B}^{n-k}\times S^{k-1})) &\to (M^k,W) \\ h\colon (\alpha(S^{n-k-1}\times\overline{B}^{k}),\alpha(S^{n-k-1}\times S^{k-1})) &\to (\partial M^k,\partial M^k\setminus\alpha(S^{k-1}\times B^{n-k})). \end{aligned}$$

(2) It follows from the Excision Theorem 120.2 that the maps

$$\begin{aligned} h_*\colon \mathrm{H}_k(\alpha(\overline{B}^{n-k}\times\overline{B}^{k}),\alpha(\overline{B}^{n-k}\times S^{k-1})) &\to \mathrm{H}_k(M^k,W) \quad \text{and} \\ h_*\colon \mathrm{H}_k(\alpha(S^{n-k-1}\times\overline{B}^{k}),\alpha(S^{n-k-1}\times S^{k-1})) &\to \mathrm{H}_k(\partial M^k,\partial M^k\setminus\alpha(S^{k-1}\times B^{n-k})) \end{aligned}$$

are isomorphisms.

(3) We consider the two asymmetric intersection pairings

$$\begin{aligned} Q\colon \mathrm{FH}_{n-k-1}(S^{n-k-1}\times\overline{B}^{k})\times\mathrm{FH}_k(S^{n-k-1}\times\overline{B}^{k},S^{n-k-1}\times S^{k-1}) &\to \mathbb{Z} \\ \widetilde{Q}\colon \mathrm{FH}_{n-k}(\overline{B}^{n-k}\times\overline{B}^{k},S^{n-k-1}\times\overline{B}^{k})\times\mathrm{FH}_k(\overline{B}^{n-k}\times\overline{B}^{k},\overline{B}^{n-k}\times S^{k-1}) &\to \mathbb{Z} \end{aligned}$$

as defined on page 2895.

(4) The undecorated maps are the obvious maps induced by inclusions.

(5) It follows from the naturality of the connecting homomorphism that the top rectangle in the diagram commutes.

(6) The regions between the second and the fifth row commute by the functoriality of relative homology groups.

(7) It follows from the Interaction Pairing-Boundary Proposition 132.17 that the bottom left square commutes.

(8) Finally note that it follows from the Poincaré Duality-Products Proposition 119.2 that $Q([\overline{B}^{n-k}\times\{0\}],[\{0\}\times\overline{B}^{k}])=1$. It follows from this observation that the bottom right triangle commutes.

We denote by $\Xi\colon \mathrm{H}_{k+1}(\{0\}\times\overline{B}^{k+1},\{0\}\times S^k)\to\mathbb{Z}$ the composition of the blue maps, i.e. the composition of the maps on right-hand path. We can now prove the desired equality:

$$\begin{array}{ll} & \text{this equality holds basically by definition} \\ (i,j)\text{-entry of the matrix representing } d_{k+1} & \downarrow = \Xi([\{0\}\times\overline{B}^{k+1}]) \\ \text{intersection form of } S^{n-k-1}\times\overline{B}^{k} & \text{intersection form of } \alpha(S^{n-k-1}\times\overline{B}^{k}) \\ \downarrow = Q([S^{n-k-1}\times\{0\}],\alpha_*^{-1}(h_*^{-1}([\beta(\{0\}\times S^k)]))) & \downarrow = Q([\alpha(S^{n-k-1}\times\{0\})],h_*^{-1}([\beta(\{0\}\times S^k)])) \\ \uparrow & \uparrow \\ \text{by the commutative diagram and since by the Fundamental Class-of-Boundary Proposition 106.27 we have } \partial([\{0\}\times\overline{B}^{k+1}])=[\{0\}\times S^k] & \text{since } \alpha \text{ is an orientation-preserving embedding} \\ = Q_{\partial M^k}([\underbrace{\alpha(S^{n-k-1}\times\{0\})}_{\text{belt sphere}}],[\underbrace{\beta(\{0\}\times S^k)}_{\text{attaching sphere}}]). & \\ \uparrow & \\ \text{by the Intersection Form-Submanifold Proposition 132.19} & \end{array}$$

This is precisely the equality that we had intended to show. ■

140.3. **The Morse inequalities.** Given a topological space X or a smooth manifold M we show in this section that the "size" of homology groups gives rise to lower bounds on the number of cells of a CW-structure for X or number of handles in a handle decomposition of M. Furthermore we will see that the homology groups give lower bounds on the number of non-degenerate critical points of a Morse function on M.
The key to proving these results is some charming algebra. To formulate the main algebraic statement we need to introduce the following notation.

Notation. Given a chain complex C_* and given $j \in \mathbb{N}_0$ we denote by $b_j(C) \in \mathbb{N}_0 \cup \{\infty\}$ the rank of $\mathrm{H}_j(C)$ and we denote by $q_j(C) \in \mathbb{N}_0 \cup \{\infty\}$ the minimal number of generators of the torsion subgroup $\operatorname{Tor}\mathrm{H}_j(C)$.

Proposition 140.9. Let C_* be a chain complex[1684] of finitely generated free abelian groups.

(a) Given any $k \in \mathbb{N}_0$ we have the inequality

$$\sum_{j=0}^{k}(-1)^j \cdot \operatorname{rank}(\mathrm{C}_{k-j}) \;\geq\; q_k(C) + \sum_{j=0}^{k}(-1)^j \cdot b_{k-j}(C).$$

(b) Given any $k \in \mathbb{N}_0$ we have the inequality

$$\operatorname{rank}(\mathrm{C}_k) \;\geq\; q_k(C) + q_{k-1}(C) + b_k(C).$$

Remark.

(α) (a) Let $k \in \mathbb{N}_0$. If we add Inequality (a) for k and $k-1$, then we obtain precisely Inequality (b). In other words, Proposition 140.9 (b) is a consequence of Proposition 140.9 (a). In Exercise 140.3 we will see that the converse is not true. Put differently, in general the inequalities one obtains from (a) are stronger than the inequalities from (b).

(b) By adding and subtracting equations one can also show easily that the following two statements are equivalent:

(i) For every $k \in \mathbb{N}_0$ the inequality in (a) is an equality.

(ii) For every $k \in \mathbb{N}_0$ the inequality in (b) is an equality.

(β) We refer to [**Far2004**, Chapter 1] for an alternative proof of Proposition 140.9 and for a generalization to chain complexes over more general rings.

The proof of Proposition 140.9 relies on the following elementary lemma.

Lemma 140.10. If $F \xrightarrow{\varphi} G \to H \to 0$ is an exact sequence where F and G are finitely generated free abelian groups, then

$$\operatorname{rank}(F) \;\geq\; \text{minimal number of generators of the torsion subgroup of } H.$$

Proof of Lemma 140.10. We write $m = \operatorname{rank}(F)$ and $n = \operatorname{rank}(G)$. Furthermore we set $k := \min\{m, n\}$. It follows from the Smith Normal form Theorem 51.5 that we can find bases for F and G such that the only entries of the corresponding $(n \times m)$-matrix A representing φ are on the diagonal. We denote by $a_1, \ldots, a_k$ these diagonal entries. Then

[1684] Note that according to our convention on page 1591 a chain complex "starts" at degree 0.

we see that

$$\text{torsion subgroup of } H \;\cong\; \text{torsion subgroup of } \mathbb{Z}^n/A\mathbb{Z}^m \;\cong\; \bigoplus_{a_i\neq 0}\mathbb{Z}_{a_i}.$$

Thus we see that the torsion subgroup of H admits a generating set with at most k elements. Since $k \leq m$ we see that the minimal number of generators of the torsion subgroup of H is $\leq \operatorname{rank}(F)$. ■

Proof of Proposition 140.9.

(a) Let (C_*, ∂_*) be a chain complex of finitely generated free abelian groups. For each $k \in \mathbb{N}_0$ we write $Z_k := \ker(\partial_k \colon C_k \to C_{k-1})$, $B_k := \operatorname{im}(\partial_{k+1} \colon C_{k+1} \to C_k)$ and $H_k = Z_k/B_k = \mathrm{H}_k(C_*)$. Basically by definition we have for each $k \in \mathbb{N}_0$ the short exact sequences

$$\text{(a)}\quad 0 \to B_k \to Z_k \to H_k \to 0 \qquad \text{and} \qquad \text{(b)}\quad 0 \to Z_k \to \mathrm{C}_k \xrightarrow{\partial} B_{k-1} \to 0.$$

Given $k \in \mathbb{N}_0$ we perform the following calculation:

$$\begin{aligned}\sum_{j=0}^{k}(-1)^j\cdot\operatorname{rank}(\mathrm{C}_{k-j}) &\overset{\text{follows from the Rank Additivity Lemma 51.7 (2) applied to the above two short exact sequences}}{=} \sum_{j=0}^{k}(-1)^j\cdot(\operatorname{rank}(H_{k-j})+\operatorname{rank}(B_{k-j})+\operatorname{rank}(B_{k-j-1}))\\ &\underset{\text{all the other terms cancel}}{=} \operatorname{rank}(B_k)+\sum_{j=0}^{k}(-1)^j\cdot\operatorname{rank}(H_{k-j}) \underset{\text{by Lemma 140.10 applied to the exact sequence (a)}}{\geq} q_k(C)+\sum_{j=0}^{k}(-1)^j\cdot\overbrace{\operatorname{rank}(H_{k-j})}^{=b_{k-j}(C)}.\end{aligned}$$

(b) As mentioned above, this inequality follows immediately from adding the inequality (a) for k and $k-1$. Indeed, one sees that almost all of the terms cancel and thus one obtains the promised inequality. ■

Evidently the idea now is to apply Proposition 140.9 to topology. To do so it is convenient to introduce the following definition.

Notation. Given a topological space X and given $j \in \mathbb{N}_0$ we write[1685]

$$b_j(X) := b_j(\mathrm{C}_*(X)) = \operatorname{rank}(\mathrm{H}_j(X)) \qquad \text{and} \qquad q_j(X) := q_j(\mathrm{C}_*(X)).$$

In other words, $q_j(X)$ is the minimal number of generators of the torsion subgroup $\operatorname{Tor}\mathrm{H}_j(X)$.

Proposition 140.11.

(1) Let M be a compact smooth manifold that is equipped with a handle decomposition. Given $k \in \mathbb{N}_0$ we denote by d_k the number of k-handles in the handle decomposition.

(a) Given any $k \in \mathbb{N}_0$ we have the inequality

$$\sum_{j=0}^{k}(-1)^j\cdot d_{k-j} \;\geq\; q_k(M)+\sum_{j=0}^{k}(-1)^j\cdot b_{k-j}(M).$$

(b) Given any $k \in \mathbb{N}_0$ we have the inequality

$$d_k \;\geq\; q_k(M)+q_{k-1}(M)+b_k(M).$$

[1685] On page 1882 we called $b_j(X)$ the j-th Betti number of X.

(2) Let X be a CW-complex with finitely many cells in each dimension. Given $k \in \mathbb{N}_0$ we denote by d_k the number of k-cells. The same inequalities as in (1) hold.

Example. Let $n \in \mathbb{N}_0$. By Proposition 80.11 we know that given any $j \in \mathbb{N}_0$ we have

$$\mathrm{H}_j(\mathbb{R}\mathrm{P}^n) \cong \begin{cases} \mathbb{Z}, & \text{if } j = 0 \text{ or if } j = n \text{ and } n \text{ is odd,} \\ \mathbb{Z}_2, & \text{if } j \text{ is odd and } j < n, \\ 0, & \text{if } j \text{ is even and } 0 < j \neq 0 \text{ or if } j > n. \end{cases}$$

It follows almost immediately from this calculation that for any $j \in \{0, \dots, n\}$ we have $q_j(\mathbb{R}\mathrm{P}^n) + q_{j-1}(\mathbb{R}\mathrm{P}^n) + q_{j-1}(\mathbb{R}\mathrm{P}^n) = 1$. By Proposition 140.11 (1b) this implies that any handle decomposition of $\mathbb{R}\mathrm{P}^n$ has at least one handle of each index $0, \dots, n$. Furthermore by Proposition 140.11 (2b) this calculation implies that any CW-decomposition of $\mathbb{R}\mathrm{P}^n$ has at least one cell of each index $0, \dots, n$. In particular this shows that the CW-structure of $\mathbb{R}\mathrm{P}^n$ that we introduced in Lemma 68.1 is "minimal". This observation also gives a solution to Exercise 80.9.

Proof.

(1) Let M be a compact smooth manifold that is equipped with a handle decomposition. Given $k \in \mathbb{N}_0$ we denote by d_k the number of k-handles in the handle decomposition. It follows from the Standard Handle Decomposition Corollary 136.4 that without loss of generality we can assume that the handle decomposition is standard. This allows us to consider the handle chain complex $\mathrm{C}_*^{\mathrm{han}}(M)$. Now we can prove Inequality (a):

$$\sum_{j=0}^{k} (-1)^j \cdot d_{k-j} \overset{\text{by the Handle Skeleton-Homology Lemma 140.1 we have } d_i = \mathrm{rank}(\mathrm{C}_i^{\mathrm{han}}(M))}{\downarrow} = \sum_{j=0}^{k} (-1)^j \cdot \mathrm{rank}(\mathrm{C}_{k-j}^{\mathrm{han}}(M)) \overset{\text{Proposition 140.11}}{\downarrow} \geq q_k(\mathrm{C}_*^{\mathrm{han}}(M)) + \sum_{j=0}^{k} (-1)^j \cdot b_{k-j}(\mathrm{C}_{k-j}^{\mathrm{han}}(M))$$
$$= q_k(M) + \sum_{j=0}^{k} (-1)^j \cdot b_{k-j}(M).$$
$$\uparrow$$
by the Singular-Handle H_*-Isomorphism Proposition 140.3 we know that $\mathrm{H}_j(\mathrm{C}_*^{\mathrm{han}}(M)) \cong \mathrm{H}_j(M)$

Finally, as we pointed out above, Inequality (b) is an immediate consequence of Inequality (a).

(2) Let X be a CW-complex with finitely many cells in each dimension. The proof in this setting is almost identical to the proof in (1), we just need to work with the cellular chain complex $\mathrm{C}_*^{\mathrm{CW}}(X)$ and we make use of the fact that by the Skeleton-Homology Lemma 80.1 we know that $d_i = \mathrm{rank}(\mathrm{C}_i^{\mathrm{CW}}(X))$ and we use that by the Singular-Cellular H_*-Isomorphism Proposition 80.4 we know that $\mathrm{H}_j(\mathrm{C}_*^{\mathrm{CW}}(X)) \cong \mathrm{H}_j(X)$. ■

Now we can formulate what is arguably the most interesting result of this section, since it connects two initially rather disparate objects.

Theorem 140.12. (Morse Inequalities Theorem) Let M be a closed smooth manifold together with a Morse function $f\colon M \to \mathbb{R}$. Given $k \in \mathbb{N}_0$ we write

$$d_k := \text{number of critical points of index } k.$$

The following two inequalities hold:

(a) Given any $k \in \mathbb{N}_0$ we have the inequality

$$\sum_{j=0}^{k}(-1)^j \cdot d_{k-j} \;\geq\; q_k(M) + \sum_{j=0}^{k}(-1)^j \cdot b_{k-j}(M).$$

(b) Given any $k \in \mathbb{N}_0$ we have the inequality

$$d_k \;\geq\; q_k(M) + q_{k-1}(M) + b_k(M).$$

Examples. Let $n \in \mathbb{N}_0$.

(1) Recall that on page 3023 we just showed that for every $j \in \{0, \ldots, n\}$ we have $q_j(\mathbb{R}\mathrm{P}^n) + q_{j-1}(\mathbb{R}\mathrm{P}^n) + q_{j-1}(\mathbb{R}\mathrm{P}^n) = 1$. By the Morse Inequalities Theorem 140.12 (b) this implies that any Morse function on $\mathbb{R}\mathrm{P}^n$ has at least one critical point of each index $0, \ldots, n$. In particular the Morse function on $\mathbb{R}\mathrm{P}^n$ that we gave on page 2979 has the minimal number of critical points.

(2) On page 1772 we showed that given any $j \in \mathbb{N}_0$ we have

$$\mathrm{H}_j(\mathbb{C}\mathrm{P}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } j = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

As in (1) it follows that the Morse function on $\mathbb{C}\mathrm{P}^n$ that we gave on page 2979 has the minimal number of critical points.

(3) Let M be a closed connected non-empty n-dimensional smooth manifold. By the Smooth Manifold-Top Homology Theorem 98.6, or alternatively by the Orientation-Top Homology Theorem 106.1 and Proposition 106.22 we know the following:
(a) If M is orientable, then $\mathrm{H}_n(M) \cong \mathbb{Z}$ and $\mathrm{Tor}(\mathrm{H}_{n-1}(M)) = 0$.
(b) If M is non-orientable, then $\mathrm{H}_n(M) \cong \mathbb{Z}$ and $\mathrm{Tor}(\mathrm{H}_{n-1}(M)) \cong \mathbb{Z}_2$.
Rather charmingly, in either case we see that $q_n(M) + q_{n-1}(M) + b_n(M) = 1$, which matches the fact that any Morse function has to have at least one global maximum, i.e. one critical point of index n.

Proof of Theorem 140.12. Let M be a closed smooth manifold together with a Morse function $f\colon M \to \mathbb{R}$. By the Morse Function-Handle Decomposition Proposition 138.4 we know that M admits a standard handle decomposition of M such that for each $k \in \mathbb{N}_0$ the number of k-handles equals the number of critical points of f of index k. The inequalities now follow from the inequalities of Proposition 140.11 (1). ■

Remark. Let M be a closed smooth manifold and let $f\colon M \to \mathbb{R}$ be a Morse function. Given $j \in \mathbb{N}_0$ we denote by d_j the number of critical points of f of index j. It follows from the Morse Inequalities Theorem 140.12, together with the de Rham Theorem 118.9 and Corollary 110.19 (2), that for every $k \in \mathbb{N}_0$ we have the inequality

$$\sum_{j=0}^{k}(-1)^j \cdot d_{k-j} \;\geq\; \sum_{j=0}^{k}(-1)^j \cdot \dim_{\mathbb{R}}(\underbrace{\mathrm{H}_{\mathrm{dR}}^{k-j}(M)}_{\uparrow}).$$

de Rham cohomology groups of M

This inequality can also proved directly using purely analytic methods, we refer to [**Chan1993**, Appendix] and [**Wit1982**] for details.

The question arises how "sharp" the Morse inequalities are. This leads us to the following definition.

Definition. Let M be a closed smooth manifold.

(1) A Morse function $f\colon M \to \mathbb{R}$ is called perfect if for every $k \in \mathbb{N}_0$ we have

$$\text{number of critical points of index } k \;=\; q_k(M) + q_{k-1}(M) + b_k(M).$$

(2) A handle decomposition is called minimal if for every $k \in \mathbb{N}_0$ we have

$$\text{number of handles of index } k \;=\; q_k(M) + q_{k-1}(M) + b_k(M).$$

Remark. Let M be a closed smooth manifold.

(1) Recall that by Propositions 138.4 and 139.9 we can go back and forth between Morse functions and handle decompositions. In particular we see that M admits a perfect Morse function if and only if M admits a minimal handle decomposition.
(2) Note that by the remark on page 3021 we know that if a Morse function is perfect, then the inequalities stated in the Morse Inequalities Theorem 140.12 (a) are also equalities. The same logic applies to the inequalities on the number of handles stated in Proposition 140.11 (1a).

It is now natural to ask which closed smooth manifolds admit perfect Morse functions. It follows from Corollaries 136.12 and 136.7 that the fundamental group gives additional lower bounds on the number of critical points of a Morse function. Thus in the following discussion we restrict ourselves to the case of simply connected smooth manifolds. So now we have a reasonable question:

Question 140.13. Does every closed simply connected smooth manifold admit a perfect Morse function?

In fact in 1962 Steven Smale [**Sma1962**, Theorem 6.1] proved the following theorem which gives an affirmative answer to Question 140.13 for high-dimensional smooth manifolds.[1686]

Theorem 140.14. Let M be a closed smooth manifold. If M is simply connected and if $\dim(M) \geq 6$, then f admits a perfect Morse function.

Remark. In [**Shark1993**, Chapter VII] Theorem 140.14 gets generalized, in a suitable sense, to certain closed non-simply connected smooth manifolds.

Thus let us turn our gaze towards the low-dimensional case. It follows from the classification of 2-dimensional smooth manifolds, see Theorem 55.4, and the resolution of the Poincaré Conjecture in dimension 3, see Theorem **??**, that Question 140.13 has an affirmative answer in dimensions 2 and 3 for the silly reason that the spheres are the only closed simply connected smooth manifolds in those dimensions. Furthermore for 5-dimensional smooth manifolds it follows from the classification of closed simply connected 5-dimensional smooth manifolds given by Denis Barden in 1965, see [**Bard1965**, Corollary 2.2.2], that Question 140.13 has an affirmative answer.
Finally we turn to the 4-dimensional setting. Since low-dimensional topologists usually prefer to think about handles we switch from Morse functions to handles.

[1686] We will sketch a proof in Exercise **??**.

Lemma 140.15. Let M be a closed orientable simply connected 4-dimensional smooth manifold. A handle decomposition is minimal if and only if it has no 1-handles and no 3-handles.

Proof. Let M be a closed orientable simply connected 4-dimensional smooth manifold. Note that in Exercise 119.19 we saw that it follows easily from the Hurewicz Theorem 84.5, the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 49.8, the Poincaré Duality Theorem 119.1 and the Universal Coefficient Theorem 110.12 for Cohomology Groups that $\mathrm{H}_1(M) = 0$, $\mathrm{H}_3(M) = 0$ and that $\mathrm{H}_2(M)$ is torsion-free. In particular we see that $q_k(M) + q_{k-1}(M) + b_k(M) = 0$ for $k = 1$ and $k = 3$.

Now we turn to the actual proof of the lemma. First note that the above calculation shows that a minimal handle decomposition has no 1-handles and no 3-handles. Conversely, suppose that we have a handle decomposition with no 1-handles and no 3-handles. It follows easily from the Handle-Connected Lemma 136.8 that the handle decomposition contains precisely one 0-handle and, say by considering the dual handle decomposition, we see that the handle decomposition contains precisely one 4-handle. Finally note that

$$\#\text{2-handles} \underset{\substack{\uparrow\\ \text{by the Handles-Euler}\\ \text{Characteristic Corollary 140.4}}}{=} \chi(M) - 2 \underset{\substack{\uparrow\\ \text{since } \mathrm{H}_1(M)=\mathrm{H}_3(M)=0\\ \text{and since } \mathrm{H}_0(M)=\mathrm{H}_4(M)\cong\mathbb{Z}}}{=} b_2(M) \underset{\substack{\uparrow\\ \text{since } q_1(M)=q_2(M)=0}}{=} q_2(M) + q_1(M) + b_2(M).$$

We have thus shown that the handle decomposition is minimal. ■

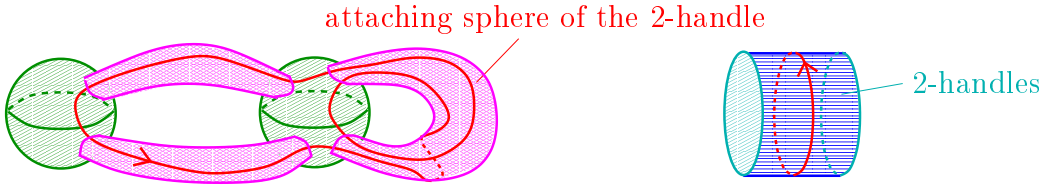
This leads us to following open problem, see [**Kir1997**, Propblem 4.18].

Question 140.16.

(1) Does every M closed simply connected 4-dimensional smooth manifold admit a handle decomposition without 1-handles?
(2) Does every M closed simply connected 4-dimensional smooth manifold admit a handle decomposition without 1- and 3-handles?

Note that a positive answer to Question 140.16 (2) would imply, by Reeb's Theorem 138.7 that every closed simply connected 4-dimensional smooth manifold M with $\mathrm{H}_2(M) = 0$ is homeomorphic to S^4. By Freedman's Theorem **??** this statement is correct. But this indicates that in all likelihood it will be very difficult to show that Question 140.16 (2) has a positive answer.

Remark. Chapters 138, 139 and 140 contain almost everything that we want to say about Morse theory. More detailed accounts of Morse theory are given in [**Miln1963a, Nic2011, Mata2002, Lau2011, Kos1993, Knu2015**]. There are also many variations on standard Morse theory. We want to mention two of them:



(1) Instead of smooth maps $M \to \mathbb{R}$ one can also consider smooth maps $M \to S^1$. The notion of a Morse function also makes sense, with basically the same definition, in this setting. The corresponding theory is developed in [**Nov1981, Nov1982, Paj2006, Far2004**]. In particular one can use "twisted homology" groups to give lower bounds on the number of critical points of a Morse function $f\colon M \to S^1$. We refer to [**Far2004**, Corollary 3.3] and [**Nov1981, Nov1982**] for details.
(2) Given a CW-complex or an (abstract) simplicial complex Robin Forman [**Form1995, Form1998**] developed the, initially surely counterintuitive, notion of "discrete Morse

theory". We refer to [**Form02, Knu2015, Scov2019**] and [**Koz2008**, Chapter 11] for details.

Exercises for Chapter 140.

Exercise 140.1. Consider the 3-dimensional smooth manifold that is sketched in the figure below.

(a) Determine $\pi_1(M)$.
(b) Make an educated guess what well-known smooth manifold M is diffeomorphic to.

Exercise 140.2.

(a) Let M be a compact orientable connected 2-dimensional topological manifold. Show that $\chi(M) \leq 2$.
Remark. Evidently this follows from the Surface Classification Theorem 55.4. But it would be more elegant to have a proof that does not rely on this result.
(b) Show that given any $k \in \mathbb{Z}_{\leq -2}$ there exists a compact orientable connected 2-dimensional smooth manifold M with $\chi(M) = k$.
(c) Let $n \in \mathbb{N}_{\geq 3}$. Show that given any $k \in \mathbb{Z}$ there exists a compact orientable connected n-dimensional smooth manifold M with $\chi(M) = k$.

Exercise 140.3. Give an example of a chain complex of finitely generated free abelian groups where the inequality of Proposition 140.9 (b) holds for all $k \in \mathbb{N}_0$, but such that the inequality of Proposition 140.9 (a) does not hold for all $k \in \mathbb{N}_0$.

Exercise 140.4. Given a closed connected non-empty smooth manifold M and given a Morse function $f\colon M \to \mathbb{R}$ we denote by $d_k(M, f)$ the number of critical points of f of index k. From the Morse Inequalities Theorem 140.12 and from Corollaries 136.12 and 136.7 we obtain lower bounds on the number of critical points $d_k(M, f)$ of a Morse function f in terms of the homology groups and the fundamental group of M. Show that these lower bounds are not optimal, i.e. show that there exists a closed connected non-empty smooth manifold M that does not admit a Morse function $f\colon M \to \mathbb{R}$ such that these lower bounds are equalities.
Hint. Apply the Morse Inequalities Theorem 140.12 to finite covers of a suitable M. For example you could take M to be the mapping torus $\mathrm{Tor}((S^1)^m, \varphi)$ for a suitable diffeomorphism of a high-dimensional torus $(S^1)^m$.

Exercise 140.5. Let M be a smooth homology 3-sphere, i.e. let M be a 3-dimensional smooth manifold such that for every $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(M; \mathbb{Z}) \cong \mathrm{H}_k(S^3; \mathbb{Z})$. Show that if $\pi_1(M)$ is non-trivial, then every Morse function on M has at least six critical points.
Remark. In Proposition 98.12 we saw that the Poincaré Homology Sphere is an example of such M.

Exercise 140.6. Let M be a closed smooth homology 5-sphere, i.e. let M be a 5-dimensional smooth manifold such that for ever $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(M;\mathbb{Z}) \cong \mathrm{H}_k(S^5;\mathbb{Z})$. Show that if $\pi_1(M)$ is non-trivial, then every Morse function on M has at least ten critical points.
Remark. In Exercise 140.5 we dealt with the case of smooth homology 3-spheres. Furthermore note that in Exercise 98.13 and in Proposition 141.5 we give examples of such M.

Exercise 140.7. Let $p \in \mathbb{N}$ and let $q \in \mathbb{Z}$ be coprime to p. We pick $r, s \in \mathbb{Z}$ such that $qr - ps = -1$. We write

$$A = \begin{pmatrix} q & p \\ s & r \end{pmatrix} \qquad \text{and we consider the orientation-reversing diffeomorphism} \qquad \begin{array}{rcl} \varphi\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [Av]. \end{array}$$

Let $\theta\colon \mathbb{R}^2/\mathbb{Z}^2 \to (S^1)^2$ be the usual diffeomorphism that is given by $[(x,y)] \mapsto (e^{2\pi \mathrm{i} x}, e^{2\pi \mathrm{i} y})$. We set

$$M := ((\overline{B}^2 \times S^1) \sqcup (\overline{B}^2 \times S^1))/\sim \qquad \text{where } (x,y) \sim (\theta \circ \varphi \circ \theta^{-1})(x,y) \text{ for } x, y \in S^1 \times S^1.$$

By the Gluing-Smooth Manifolds-Proposition **??** we know that M is a closed 3-dimensional smooth manifold.

(a) Show that M admits a handle decomposition with a unique handle in dimensions 0,1,2 and 3.
(b) Show that for every $n \in \mathbb{N}_0$ we have

$$\mathrm{H}_n^{\mathrm{hand}}(M) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 3, \\ 0, & \text{if } n = 2 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases}$$

Remark. In the Lens Space-Splitting Lemma 146.2 we will see that M is diffeomorphic to the lens space $L(p,q)$. Thus this exercise together with the Singular-Handle H_*-Isomorphism Proposition 140.3 gives us a new calculation of the singular homology groups of lens spaces.

Exercise 140.8. Let $g, n \in \mathbb{N}_0$. As usual we denote by $\Sigma_{g,n}$ the surface of genus g minus n open disks. What is the minimal number of handles in a handle decomposition of $\Sigma_{g,n}$?

Exercise 140.9. Let $n \in \mathbb{N}$. What is the minimal number k of critical points of a Morse function on the n-dimensional torus $(S^1)^n$? You need to show that there exists a Morse function such that the number of critical points equals k and you need to show that every Morse function has at least k critical points.

Exercise 140.10. Let M be a compact smooth manifold and let A be a union of components of ∂M. Suppose we are given a handle decomposition of M rel A. Define a relative handle chain complex $\mathrm{C}_*^{\mathrm{han}}(M,A)$ such that the corresponding homology groups $\mathrm{H}_*^{\mathrm{han}}(M,A)$ are isomorphic to the relative singular homology groups of (M,A).

Exercise 140.11. Let M be a compact smooth manifold and let A be two a union of components of ∂M. Furthermore let $f\colon M \to [0,1]$ be a Morse function such that $A = f^{-1}(0)$ and such that $\partial M = f^{-1}(1)$. formulate a result that gives a lower bound on the number of critical points of such f in terms of the relative homology groups $\mathrm{H}_*(M,A)$.
Remark. In the Morse Function-Existence Proposition 139.4 we saw that such a Morse function always exists.
Hint. Make use of Exercise 140.10.

Exercise 140.12. Let M be a closed smooth manifold and let $f\colon M \to \mathbb{R}$ be a Morse function. Given $k \in \mathbb{N}_0$ we denote by d_k the number of critical points of index k. The Morse function is called *lacunary* if for every $k \in \mathbb{N}_0$ at least one of d_k and d_{k+1} is zero. Show that every lacunary Morse function is perfect.
Remark. This statement is sometimes called the *Morse lacunary principle*.

Exercise 140.13. Let M be a closed smooth manifold and let $f\colon M \to \mathbb{R}$ be a smooth map. Furthermore let g be a Riemannian structure on M, as defined on page 1426. Given $P \in M$ we define the *gradient of f at P* to be the unique vector $\operatorname{grad} f_P \in \mathrm{T}_P M$ that satisfies

$$g_P(\operatorname{grad} f_P, w) \;=\; \mathrm{D}f_P(w) \;\in\; \mathrm{T}_{f(P)}\mathbb{R} = \mathbb{R} \qquad \text{for all } w \in \mathrm{T}_P M.$$

One can easily show that $P \mapsto \operatorname{grad} f_P$ defines a vector field on M in the sense of the definition on page 638.

(a) We suppose that f is a Morse function. Show that every zero of the vector field $\operatorname{grad} f$ is isolated.
(b) Let P be a critical point of f. Show that

$$\underbrace{\operatorname{index}(\operatorname{grad} f, P)}_{\text{see page 2818 for the definition}} \;=\; (-1)^{\operatorname{index}(f,P)}.$$

Remark. This exercise shows that the Euler Characteristic-via-Critical Points Corollary 140.6 can also be deduced from the Poincaré-Hopf Theorem 129.7.

141. Constructing smooth manifolds using handles

In this chapter we will do the following:

(1) We will use handles to construct interesting compact and closed smooth manifolds out of finite presentations of groups.
(2) We will show that every finite CW-complex is homotopy equivalent to a compact smooth manifold.

141.1. Finite presentations of groups and handle decompositions.

Proposition 141.1. Let $\pi = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle$ be a finite presentation. Given any $n \geq 4$ there exists a compact orientable connected non-empty n-dimensional smooth manifold with the following properties:

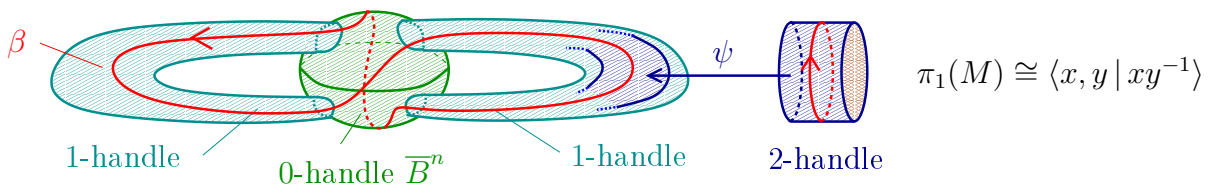
(1) $\pi_1(M) \cong \pi$.
(2) M admits a standard handle decomposition with precisely one 0-handle, k 1-handles, l 2-handles and no handles of index > 2.

Proof. Let $\pi = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle$ be a finite presentation and let $n \geq 4$. We start with the 0-handle $\overline{B}^n$. Since $n \geq 2$ we can pick k *orientation-preserving* thickened 0-spheres $\varphi_1, \dots, \varphi_k \colon \overline{B}^{n-1} \times S^0 \to \partial(\overline{B}^n)$ with disjoint images and we denote by W the result of attaching the corresponding k 1-handles to the 0-handle $\overline{B}^n$. Note that W, and thus also ∂W, is orientable by the Handles-Orientability Proposition 136.9.

We pick a base point $P \in \partial W$. It follows from the Handle Attachment-π_1-Proposition 136.11 that we can make an identification $\pi_1(W, P) = \langle g_1, \dots, g_k \rangle$. Since $n \geq 3$ we know by Lemma 136.14 that the inclusion induced map $\pi_1(\partial W, P) \to \pi_f 1(W, P)$ is an epimorphism. Therefore we can pick loops $\alpha_1, \dots, \alpha_l \colon (S^1, *) \to (\partial W, P)$ that represent $r_1, \dots, r_l \in \pi_1(W, P) = \langle g_1, \dots, g_k \rangle$.

By hypothesis we have $\dim(\partial W) = n - 1 \geq 3$. Thus we can apply Theorem **??** and we obtain that the map $\alpha_1 \sqcup \dots \sqcup \alpha_l \colon S^1 \sqcup \dots \sqcup S^1 \to \partial W$ is in fact homotopic to a smooth embedding $\beta_1 \sqcup \dots \sqcup \beta_l \colon S^1 \sqcup \dots \sqcup S^1 \to \partial W$. It follows from the Smooth Embedding Theorem 24.10 and the Tubular Neighborhood Theorem **??**[1687] that we can find smooth embeddings $\psi_1, \dots, \psi_l \colon \overline{B}^{n-2} \times S^1 \to \partial W$ with disjoint images such that for each $i \in \{1, \dots, l\}$ and each $x \in S^1$ we have $\psi_i((0, x)) = \beta_i(x)$. Finally we consider

$$M \;:=\; W \cup_{\psi_1} h^2 \cdots \cup_{\psi_l} h^2 \;=\; \varnothing \cup \overline{B}^n \cup_{\varphi_1} h^1 \cup \cdots \cup_{\varphi_k} h^1 \cup_{\psi_1} h^2 \cdots \cup_{\psi_l} h^2.$$



The proposition follows from the following calculation:

$$\begin{array}{ccccc} & & & & \\ \pi_1(M, P) & \overset{\text{by the Handle Attachment-}\pi_1\text{-Proposition 136.11, note that the } x_i \text{ are necessary since we lost track of the base points}}{\cong} & \langle g_1, \dots, g_k \rangle / \langle\langle x_1 r_1 x_1^{-1}, \dots, x_l r_l x_l^{-1} \rangle\rangle & & \\ & \overset{\text{by Lemma 53.2 (5)}}{\cong} & \langle g_1, \dots, g_k \rangle / \langle\langle r_1, \dots, r_l \rangle\rangle & \overset{\text{by definition}}{=} & \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle. \end{array}$$

■

Now we can provide a new proof of the following proposition.

[1687] Note that we can apply the Tubular Neighborhood Theorem **??** since ∂W is orientable.

Proposition 54.12. (Fundamental Group-Manifold Realization Proposition) Let $\pi = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle$ be a finite presentation. Given any $n \geq 4$ there exists a closed orientable connected non-empty n-dimensional smooth manifold W with $\pi_1(W) \cong \pi$.

Remark. The Fundamental Group-Manifold Realization Proposition 54.12 is a key ingredient of the proof of the fact, stated in Theorem 60.4, that closed smooth manifolds of a fixed dimension ≥ 4 cannot be classified.

Proof. Let $\pi = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle$ be a finite presentation and let $n \geq 4$. By Proposition 141.1 there exists a compact orientable connected non-empty n-dimensional smooth manifold with the following properties:

(1) $\pi_1(M) \cong \pi$.
(2) M admits a handle decomposition $M = \varnothing \cup h^0 \cup_{\varphi_1} h^1 \cdots \cup_{\varphi_k} h^1 \cup_{\psi_1} h^2 \cdots \cup_{\psi_l} h^2$.

By the Doubling-Manifold Lemma 75.12 the double $W := \mathrm{D}M$ is a closed orientable connected non-empty n-dimensional smooth manifold. Thus it suffices to prove the following claim.

Claim. There exists an isomorphism $\pi_1(\mathrm{D}M) \cong \pi$.

Proof. For fun we provide two different proofs.

(1) Note that by Corollary 136.15 we know that the boundary ∂M is connected. Therefore it follows from the Seifert-van Kampen Theorem 54.4 we have an isomorphism $\pi_1(\mathrm{D}M) \cong \pi_1(M) *_{\pi_1(\partial M)} \pi_1(M)$. Since $n \geq 4$ and since M has only handles of index ≤ 2 we obtain from Corollary 136.15 that the inclusion induced map $\pi_1(\partial M) \to \pi_1(M)$ is an epimorphism. It follows from the group-theoretic Lemma 75.15 that the map $\pi_1(M) \to \pi_1(\mathrm{D}M)$ is actually an isomorphism.
(2) On page 3004 we pointed out that it is a consequence of Propositions 139.1 and 139.3 that the double admits a handlebody presentation of the following form:

$$\mathrm{D}M = \underbrace{\varnothing \cup h^0 \cup_{\varphi_1} h^1 \cdots \cup_{\varphi_k} h^1 \cup_{\psi_1} h^2 \cdots \cup_{\psi_l} h^2}_{=M} \cup_{\alpha_l} h^{n-2} \cdots \cup_{\alpha_1} h^{n-2} \cup_{\beta_k} h^{n-1} \cdots \cup_{\beta_1} h^{n-1} \cup h^n,$$

where the $(n-2)$-handles corresponding to $\alpha_l, \dots, \alpha_1$ are dual to the 2-handles given by $\psi_l, \dots, \psi_1$ and the $(n-1)$-handles corresponding to $\beta_k, \dots, \beta_1$ are dual to the 1-handles given by $\varphi_k, \dots, \varphi_1$.
(a) First let us deal with the case that $n \geq 5$. In this case $\mathrm{D}M$ is obtained from M by attaching handles of index ≥ 3. But by the Handle Attachment-π_1-Proposition 136.11 we know that handle attachments of index ≥ 3 do not affect the fundamental group. Thus we see that $\pi_1(\mathrm{D}M) \cong \pi_1(M) \cong \pi$.

(b) The case $n = 4$ is a little bit more interesting. We have

$$\begin{array}{rcl} & & \text{by the Handle Attachment-}\pi_1\text{-Proposition 136.11} \\ & & \downarrow \\ \pi_1(\mathrm{D}M) & = & \pi_1(M)/\langle\langle \text{attaching circles of the dual 2-handles } \alpha_l, \dots, \alpha_1 \rangle\rangle \\ & = & \pi_1(M)/\langle\langle \text{belt circles of the 2-handles } \psi_l, \dots, \psi_1 \rangle\rangle \quad \cong \quad \pi_1(M) \cong \pi. \\ & & \uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\ & & \text{Relative Dual Handle Proposition 139.1 (1c)} \qquad \text{since belt circles are zero-homotopic} \end{array}$$ ■

This is a good moment to reminder the reader of the following question.

Question 54.15. Is every finitely presented group the fundamental group of a closed (or at least compact) orientable connected 3-dimensional smooth manifold?

We will answer Question 54.15 in Theorem 146.5.

141.2. **Integral homology spheres and homotopy spheres.** We remind the reader of the following definitions from page 2159 and page 2625.

Definition. Let M be an n-dimensional smooth manifold M.

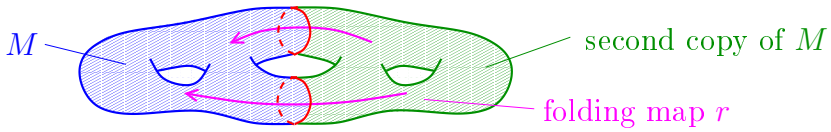
(1) If for every $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(M) \cong \mathrm{H}_k(S^n)$, then we refer to M as a smooth homology n-sphere.
(2) If M is a homology sphere and if M is simply connected, then we refer to M as a smooth homotopy n-sphere.

Our goal in this section is to apply the construction used in the Fundamental Group-Manifold Realization Proposition 54.12 to construct smooth homology and potentially interesting smooth homotopy spheres.

We start out with the following proposition, which the reader might recognize as Exercise 119.21.

Proposition 141.2. (Homology-of-Double Proposition) Let M be a compact orientable n-dimensional topological manifold. For every $j \in \mathbb{N}_0$ there exists an isomorphism

$$\mathrm{H}_j(\mathrm{D}M) \cong \mathrm{H}_j(M) \oplus \mathrm{Hom}(\mathrm{H}_{n-j}(M), \mathbb{Z}) \oplus \mathrm{Tor}(\mathrm{H}_{n-j-1}(M)).$$



Proof. Let $i\colon M \to \mathrm{D}M$ be the natural inclusion and let $r\colon \mathrm{D}M \to M$ be the folding map that we introduced on page 1668. Note that by definition we have $r \circ i = \mathrm{id}_M$. We consider the long exact sequence in homology of the pair $(\mathrm{D}M, M)$:

$$\dots \to \mathrm{H}_j(M) \xrightarrow{i_*} \mathrm{H}_j(\mathrm{D}M) \to \mathrm{H}_j(\mathrm{D}M, M) \to \dots$$

Now we see that we have the following isomorphisms:

$$\begin{array}{ccccc} & & & & \text{Excision Theorem 75.10, here the blue } M \text{ stands for the second copy of } M \text{ in the double } \mathrm{D}M \\ & & & & \downarrow \\ \mathrm{H}_j(\mathrm{D}M) & \cong & \mathrm{H}_j(M) \oplus \mathrm{H}_j(\mathrm{D}M, M) & \cong & \mathrm{H}_j(M) \oplus \mathrm{H}_j(M, \partial M) \\ & & \uparrow & & \\ & & \text{since } r \circ i = \mathrm{id}_M \text{ we see that the above long exact sequence breaks up into short exact sequences,} & & \\ & & \text{furthermore it follows from Lemma 78.2 that each short exact sequence splits and} & & \\ & & \text{that the middle term is isomorphic to the direct sum of the two other terms} & & \\ & \cong & \mathrm{H}_j(M) \oplus \mathrm{H}^{n-j}(M) & \cong & \mathrm{H}_j(M) \oplus \mathrm{Hom}(\mathrm{H}_{n-j}(M), \mathbb{Z}) \oplus \mathrm{Tor}(\mathrm{H}_{n-j-1}(M)). \\ & & \uparrow & & \uparrow \\ & & \text{Poincaré Duality Theorem 119.1} & & \text{Universal Coefficient Theorem 110.12} \end{array}$$ ■

Now we can prove the following refinement of the Fundamental Group-Manifold Realization Proposition 54.12.

Corollary 141.3. Let $\pi = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle$ be a finite presentation.

(1) Given any $n \geq 5$ there exists a closed orientable connected non-empty n-dimensional smooth manifold W with $\pi_1(W) \cong \pi$ and such that[1688]

$$\mathrm{H}_i(W) \;\cong\; \begin{cases} \pi_{\mathrm{ab}}, & \text{if } i = 1, \\ \mathbb{Z}^{l-k+\mathrm{rk}(\pi_{\mathrm{ab}})}, & \text{if } i = 2, \\ \mathbb{Z}^{l-k+\mathrm{rk}(\pi_{\mathrm{ab}})} \oplus \mathrm{Tor}(\pi_{\mathrm{ab}}), & \text{if } i = n-2, \\ \mathbb{Z}^{\mathrm{rk}(\pi_{\mathrm{ab}})}, & \text{if } i = n-1, \\ \mathbb{Z}, & \text{if } i = 0 \text{ or if } i = n, \\ 0, & \text{else.} \end{cases}$$

(2) There exists a closed orientable connected non-empty smooth manifold W of dimension $n = 4$ with $\pi_1(W) \cong \pi$ and such that the homology groups are as in (1), except that for $i = 2$ we take the direct sum of the terms that we wrote down for $i = 2$ and $i = n - 2$.

Proof. As in the proof of the Fundamental Group-Manifold Realization Proposition 54.12 that we just gave on page 3031 we use Proposition 141.1 to obtain a compact orientable connected non-empty n-dimensional smooth manifold with the following properties:

(1) $\pi_1(M) \cong \pi$.
(2) M admits a handle decomposition with precisely one 0-handle, k 1-handles, l 2-handles and no handles of index > 2.

In the above proof of the Fundamental Group-Manifold Realization Proposition 54.12 we saw that the fundamental group of $W := \mathrm{D}M$ is isomorphic to π and that W is a closed orientable connected non-empty n-dimensional smooth manifold. It remains to show that the homology groups of $W = \mathrm{D}M$ are as stated. In fact it follows from the Homology-of-Double Proposition 141.2 that it suffices to prove the following claim.

Claim.

$$\mathrm{H}_0(M) \cong \mathbb{Z}, \quad \mathrm{H}_1(M) \cong \pi_{\mathrm{ab}}, \quad \mathrm{H}_2(M) \cong \mathbb{Z}^{l-k+\mathrm{rk}(\pi_{\mathrm{ab}})} \quad \text{and} \quad \mathrm{H}_i(M) = 0 \text{ for } i \geq 3.$$

Proof. First note that the statements for $\mathrm{H}_0(M)$ and $\mathrm{H}_1(M)$ follow immediately from the H_0-Proposition 72.5 and the Hurewicz Theorem 84.5. Next note that

$$\mathrm{H}_i(M) \;\underset{\text{Singular-Handle } \mathrm{H}_*\text{-Isomorphism Proposition 140.3}}{\overset{\uparrow}{\cong}}\; \mathrm{H}_i^{\mathrm{han}}(M) \;\underset{\text{since } M \text{ has no handles of index} \geq 3}{\overset{\uparrow}{=}}\; \begin{cases} 0, & \text{if } i > 2, \\ \ker(\mathrm{C}_2^{han}(M) \to \mathrm{C}_1^{\mathrm{han}}(M)), & \text{if } i = 2. \end{cases}$$

[1688] We denote by π_{ab} the abelianization of π, as defined on page 1203.

Note that this observation for $i = 2$, together with Lemma 51.9, shows that $\mathrm{H}_2(M)$ is a free abelian group. Finally note that

$$\mathrm{rk}(\mathrm{H}_2(M)) \underset{\text{by definition of } \chi(M)}{\uparrow} \chi(M) + \sum_{i\neq 2} (-1)^{i+1} \cdot \mathrm{rk}(\mathrm{H}_i(M)) \underset{\text{by the Handles-Euler Characteristic Corollary 140.4 and above calculations}}{\uparrow} (1-k+l) - 1 + \mathrm{rk}(\pi_{\mathrm{ab}}) = l - k + \mathrm{rk}(\pi_{\mathrm{ab}}).$$

■

As we mentioned, our goal is to construct smooth homology spheres and smooth homotopy spheres. Corollary 141.3 leads us to the following group theoretic definitions.

Definition.

(1) The deficiency of a finite presentation $\langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle$ is defined to be $k - l$.
(2) A finite presentation is called balanced, if its deficiency equals zero.
(3) A group π is called perfect if its abelianization π_{ab} is trivial.

The following proposition gives us some interesting examples of (presentations of) groups.

Proposition 141.4.

(1) For every closed connected non-empty 3-dimensional smooth manifold M the fundamental group $\pi_1(M)$ admits a balanced presentation.
(2) The binary icosahedral group, that we introduced on page 2160, is a perfect group of order 120 that admits a balanced presentation.
(3) For every odd prime p the group $\mathrm{SL}(2, \mathbb{F}_p)$ is perfect and it admits a balanced presentation.

Proof.

(1) We will prove this statement in Exercise 141.2. Alternatively the statement is proved in Theorem 146.5.
(2) Let π be the binary icosahedral group. In Proposition 98.12 we showed that π is a perfect group of order 120. It remains to show that π admits a balanced presentation. There are two possible approaches:
   (a) In [**KSc1979**, Chapter II] it is shown that the binary icosahedral group is isomorphic to $\langle x, y \,|\, x^3 = y^5, x^3 = (xy)^2 \rangle$.
   (b) Recall that by definition $\pi \subset \mathrm{SU}(2)$. Thus it makes sense to consider the quotient $M := S^3/\pi$, which we called the Poincaré Homology Sphere. In Proposition 98.12 we showed that M is a closed orientable 3-dimensional smooth manifold. Thus it follows from (1) that $\pi \cong \pi_1(M)$ admits a balanced presentation.
(3) In Exercise 141.3 we will see that $\mathrm{SL}(2, \mathbb{F}_p)$ is perfect. The much more subtle fact that $\mathrm{SL}(2, \mathbb{F}_p)$ admits a balanced presentation is shown in [**CR1980**]. ■

In Proposition 98.11 we showed that there exist smooth homology 3-spheres. The combination of Corollary 141.3 and Proposition 141.4 gives us the high-dimensional analogue.

Proposition 141.5. Given any $n \geq 4$ there exists a smooth homology n-sphere with non-trivial fundamental group.

Remark.

(1) In Exercise 98.13 we used a different construction to obtain high-dimensional smooth homology spheres.

(2) Michel Kervaire [**Kerv1969**, Theorem 1] completely determined which finitely presented groups can occur as fundamental groups of smooth homology n-spheres for $n \geq 4$.

The construction that we used in the proof of Proposition 141.1 and that we used in the above proof of Propositions 54.12 is a never-ending source of joy, since even for presentations of the trivial group one obtains interesting examples of smooth manifolds:

Example. Let $k \in \mathbb{Z}$. We consider the presentation

$$\langle x, y \,|\, \underbrace{xyx = yxy}_{=(1)}, \underbrace{x^{k+1} = y^k}_{=(2)} \rangle.$$

We will now see that this is a presentation of the trivial group. Indeed, we have

(a) $y = x^{-1}y^{-1}yxy = (yx)^{-1}yxy \underset{\text{by (1)}}{=} (yx)^{-1}x(yx)$

(b) $y^{k+1} \underset{\substack{\text{follows from taking} \\ (k+1)\text{-st power of (a)}}}{=} (yx)^{-1}x^{k+1}(yx) \underset{\text{by (2)}}{=} (yx)^{-1}y^k(yx) = x^{-1}y^kx \underset{\text{by (2)}}{=} x^{-1}x^{k+1}x = x^{k+1} \underset{\text{by (2)}}{=} y^k.$

Thus $y^{k+1} = y^k$ which implies that $y = 1$. From (1) it follows that also $x = 1$. We have thus shown that this is indeed a presentation of the trivial group.

Let $n \geq 4$. We apply the construction of the proof of Propositions 54.12 and 141.1 to the above balanced presentation of the trivial group. By Corollary 141.3 we obtain a smooth homotopy n-sphere.

The following question arises:

Question 141.6. Are the smooth homotopy n-spheres that we just constructed[1689] diffeomorphic to S^n?

For $n = 4$ and some special cases Question 141.6 was answered in the affirmative [**Gom1991**]. In general though, at least for $n = 4$ Question 141.6 seems to be wide open. We refer to [**GoS1999**, p. 149] and [**Kir1989**, p. 18] for more information.

We have now seen that finite presentations of groups give rise to interesting smooth manifolds. The question arises, to what degree different presentations give rise to different smooth manifolds. It is worth recalling the following theorem.

Theorem 53.7. (Tietze Theorem) Any two finite presentations for some given group are related by a finite sequence of Tietze transformations, i.e. by a sequence of the following two transformations:

(a) $\langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle \quad \leftrightsquigarrow \quad \langle x_1, \dots, x_k \,|\, r_1, \dots, r_l, s \rangle$

where s is a word in in $r_1, \dots, r_l$, and

(b) $\langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle \quad \leftrightsquigarrow \quad \langle x_1, \dots, x_k, x \,|\, r_1, \dots, r_l, s \cdot x \cdot t \rangle$

where $x \neq x_1, \dots, x_k$ and where s, t are words in $x_1, \dots, x_k$.

In our context, where we study balanced presentations of the trivial group, we could like to go from one presentation to another while keeping the deficiency fixed. This leads us to the following definition.

[1689] Evidently there are various choices involved in these constructions.

Definition. Let $\langle x_1, \dots, x_k \mid r_1, \dots, r_l \rangle$ be a presentation. An Andrews-Curtis transformation is one of the following ways to obtain a new presentation:

(a) $\langle x_1, \dots, x_k \mid r_1, \dots, r_i, \dots, r_l \rangle \leftrightsquigarrow \langle x_1, \dots, x_k \mid r_1, \dots, x_j^{-\epsilon} \cdot r_i \cdot x_j^{\epsilon}, \dots r_l \rangle$
where $j \in \{1, \dots, k\}$ and $\epsilon \in \{\pm 1\}$

(b) $\langle x_1, \dots, x_k \mid r_1, \dots, r_i, \dots, r_l \rangle \leftrightsquigarrow \langle x_1, \dots, x_k, \mid r_1, \dots, r_i \cdot r_j, \dots, r_l \rangle$
where $i \neq j \in \{1, \dots, l\}$

(c) $\langle x_1, \dots, x_k \mid r_1, \dots, r_l \rangle \leftrightsquigarrow \langle x_1, \dots, x_k, x \mid r_1, \dots, r_l, x \rangle$
where $x \neq x_1, \dots, x_k$.

The following is now a slight reformulation of the Andrews-Curtis Conjecture which we first encountered in Section 53.4.

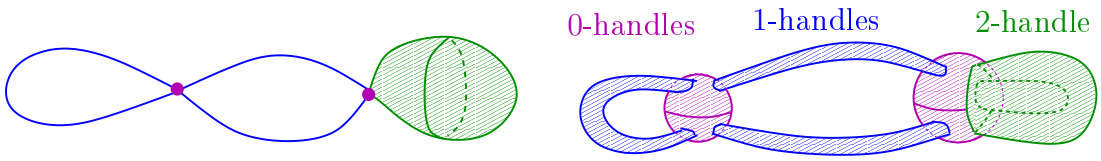
Conjecture 53.18. (Andrews-Curtis Conjecture) Any balanced presentation of the trivial group can be turned into the empty presentation by a finite sequence of Andrews-Curtis transformations.

In the Handle Cancellation Theorem **??** and the Handle Addition Theorem **??** we will see that the Andrews-Curtis transformations have analogues for handle decompositions. In particular, as is argued on [**GoS1999**, p. 149], an affirmative answer to the Andrews-Curtis Conjecture 53.18 would imply that Question 141.6 has a positive answer.

For better or worse the evidence towards the Andrews-Curtis Conjecture 53.18 is rather shaky. For example, let $k \in \mathbb{Z}$. As above we consider the following balanced presentation of the trivial group:

$$\langle x, y \mid xyx = yxy, x^{k+1} = y^k \rangle.$$

For most k it is unknown whether the presentation can be turned into the empty presentation by a finite sequence of Andrews-Curtis transformations. In fact the consensus seems to be that the Andrews-Curtis Conjecture 53.18 is most likely false.



Remark.

(1) More information and some partial results regarding the Andrews-Curtis Conjecture 53.18 can be found in [**Barm2011**, Chapter 11].
(2) Sergey Matveev [**Matv1987**, p. 917] (see also [**Kupe2017a**, Proposition 4.2] and [**Barm2011**, Chapter 11]) showed that the Andrews-Curtis Conjecture 53.18 is equivalent to a special case of the Zeeman Conjecture 162.15.

141.3. **Handle decompositions and CW-structures.** In the Handles-Cells Proposition 136.18 we saw that every compact smooth manifold M that is equipped with a handle decomposition is homotopy equivalent to a CW-complex X such that for each $k \in \mathbb{N}_0$ the number of k-handles of M equals the number of k-cells of X. In this section we will prove the following converse to this statement.

Proposition 141.7. (Manifold Construction Proposition) Given any finite CW-complex X there exists a compact orientable smooth manifold M that is homotopy equivalent to X and which admits a handle decomposition such that for each $k \in \mathbb{N}_0$ the number of k-cells of X equals the number of k-handles of M.

Remark.

CW-complex X thickening M of X

(1) In the Manifold Construction Proposition 141.7 we do not make any claims about the dimension of M. We leave it to the reader to figure out what is the lowest dimension for M that one can achieve with our proof.
(2) Let X be a finite CW-complex. Any compact smooth manifold M that is homotopy equivalent to X is called a *thickening of* X. the Manifold Construction Proposition 141.7 thus says in particular that every finite CW-complex admits a thickening.
(3) The theory of thickenings of finite CW-complexes is developed in detail in [**Maz1963**] and [**Wall1966b**]. In particular given a finite k-dimensional CW-complex it follows from [**Wall1966b**, p. 76] (see also [**BCFHLN2019**, Theorem 4.1] that the following statements hold:
   (a) Given any $n \geq 2k$ there exists an n-dimensional thickening of X.
   (b) If $n \geq 2k+1$ and if $n \geq 6$, then any two n-dimensional thickenings of X are actually diffeomorphic.

   We refer to [**BCFHLN2019**, Chapter 4] for more information on thickenings.
(4) The topic of finding smooth manifolds that "look" like a given topological space is also discussed in [**BuS2010**, Chapter 2].

The proof of the Manifold Construction Proposition 141.7 rests on the following lemma.

Lemma 141.8. If $N \geq 2r+2$, then for every smooth embedding $\varphi\colon S^r \to \mathbb{R}^N$ there exists an orientation-preserving smooth embedding $\Phi\colon \overline{B}^{N-r} \times S^r \to \mathbb{R}^N$ such that $\Phi(0,P) = \varphi(P)$ for all $P \in S^r$.

Proof. The statement of the lemma is basically the content of the Tubular Neighborhood Theorem **??** (5). For the reader's convenience we recall the proof. First we consider the standard smooth embedding $\theta\colon S^r \to \mathbb{R}^{r+1} \times \mathbb{R}^{N-r-1} = \mathbb{R}^N$ which is given by $x \mapsto (x,0)$. This smooth embedding can be "thickened" up. For example we could consider the smooth embedding

$$\begin{array}{rcl} \Theta\colon \overline{B}^{N-r} \times S^r & \to & \mathbb{R}^{r+1} \times \mathbb{R}^{N-r-1} = \mathbb{R}^N \\ (\underbrace{(x,y)}_{\substack{\uparrow \\ \text{with } x \in \mathbb{R} \text{ and } y \in \mathbb{R}^{N-r-1}}}, P) & \mapsto & ((1+\frac{x}{2}) \cdot P, y). \end{array}$$

After possibly composing Θ with a reflection in the last coordinate we see that Θ is orientation-preserving. By hypothesis we have $N \geq 2r+2$. Thus we obtain from Proposition **??** that there exists a smooth homotopy $F\colon S^r \times [0,1] \to \mathbb{R}^N$ with $F_0 = \theta$ and $F_1 = \varphi$. By the Isotopy Extension Theorem 36.1 there exists a diffeotopy $G\colon \mathbb{R}^N \times [0,1] \to \mathbb{R}^N$ with $G_1 \circ \theta = \varphi$. The map $\Phi := G_1 \circ \Theta\colon \overline{B}^{N-r} \times S^r \to \mathbb{R}^N$ has all the desired properties. ∎

The heart of the proof of the Manifold Construction Proposition 141.7 is contained in the following lemma.

Lemma 141.9. Let X be a finite CW-complex and let $\alpha\colon S^{k-1} \to X$ be a map. If X is homotopy equivalent to a compact orientable smooth manifold M, then there exists a compact orientable smooth manifold N and an orientation-preserving thickened $(k-1)$-sphere $\varphi\colon \overline{B}^{\dim(N)-k} \times S^{k-1} \to \partial N$ such that the following are satisfied:

(1) N is also homotopy equivalent to X.
(2) $N \cup_\varphi h^k$ is homotopy equivalent to $X \cup_\alpha \overline{B}^k$.
(3) If M is equipped with a handle decomposition, then we can equip N with a handle decomposition such that for each $k \in \mathbb{N}_0$ the number of k-handles of M equals the number of k-handles of N.

Proof of the Manifold Construction Proposition 141.7. Note that in the setting of Lemma 141.9 we know by Propositions 136.1 and 136.9 that $N \cup_\varphi h^k$ is again a compact orientable smooth manifold with one extra k-handle. Thus we see that the Manifold Construction Proposition 141.7 follows immediately from Lemma 141.9 and an elementary induction argument. ■

Proof of Lemma 141.9. Let $f\colon X \to M$ be a homotopy equivalence between a finite CW-complex X and a compact orientable m-dimensional smooth manifold M. Furthermore let $\alpha\colon S^{k-1} \to X$ be a map.

We pick some $r \geq \max\{k, 2k - \dim(M)\}$. We write $\widetilde{M} := M \times \overline{B}^r$ and we equip the product $\widetilde{M}$ with the smooth atlas provided by Proposition **??**. Note that the map $i\colon M \to \widetilde{M}$ given by $x \mapsto (x, 0)$ is a homotopy equivalence.

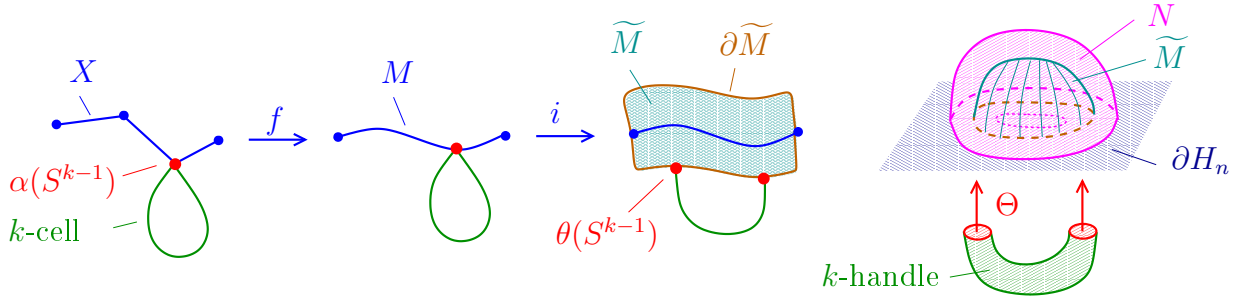
Claim. We write $\widetilde{f} := i \circ f\colon X \to \widetilde{M}$. There exists a homotopy $F\colon S^{k-1} \times [0,1] \to \widetilde{M}$ from the map $\widetilde{f} \circ \alpha\colon S^{k-1} \to \widetilde{M} = M \times \overline{B}^r$ to a smooth embedding $\theta\colon S^{k-1} \to \partial\widetilde{M}$.

Proof. By the combination of the Whitney Approximation Theorem 29.1 and the Transversality Theorem 42.4 we know that the map $\widetilde{f} \circ \alpha\colon S^{k-1} \to \widetilde{M}$ is homotopic to a smooth map that is transverse to the proper submanifold $M \times \{0\}$ of $\widetilde{M} = M \times \overline{B}^r$. Note that

$$\dim(S^{k-1}) + \dim(M \times \{0\}) \;=\; k - 1 + \dim(M) \underset{\substack{\uparrow \\ \text{since } r \geq k}}{<} r + \dim(M) \;=\; \dim(M \times \overline{B}^r).$$

Thus the image of a map $S^{k-1} \to \widetilde{M}$, which is transverse to $M \times \{0\}$, actually misses $M \times \{0\}$. Therefore we now know that $\widetilde{f} \circ \alpha\colon S^{k-1} \to \widetilde{M}$ is homotopic to a map that misses $M \times \{0\}$. Next, using the deformation retraction from $\overline{B}^k \setminus \{0\}$ to S^{k-1} we see that $\widetilde{f} \circ \alpha\colon S^{k-1} \to \widetilde{M}$ is actually homotopic to a map $\varphi\colon S^{k-1} \to M \times S^{k-1} \subset \partial\widetilde{M}$. Finally, since

$$2(k-1) \underset{\substack{\uparrow \\ \text{since } r \geq 2k - \dim(M)}}{<} \dim(M) + r - 1 \;=\; \dim(\partial\widetilde{M})$$



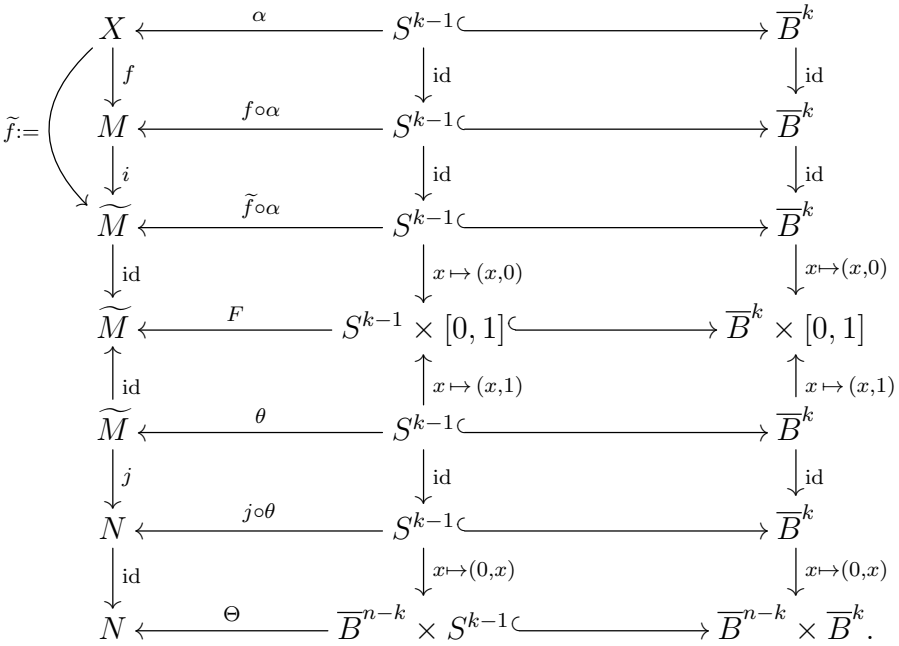
we obtain from the Whitney Approximation Theorem 29.1 together with Theorem **??** (1) that $\varphi\colon S^{k-1} \to \partial\widetilde{M}$ is homotopic to a smooth embedding $\theta\colon S^{k-1} \to \partial\widetilde{M}$. ⊞

By the Euclidean Embedding Theorem 27.1 there exists an $n \geq 2k+1$ such that there exists a proper smooth embedding $\widetilde{M} \to \mathbb{H}^n := \{(x_1, \ldots, x_n) \in \mathbb{R}^n \,|\, x_n \geq 0\}$. In particular,

by the Smooth Embedding Theorem 24.10 we can assume that $\widetilde{M}$ is a proper smooth submanifold of $\mathbb{H}^n$ for some $n \geq 2k$.

By the General Tubular Neighborhood Theorem **??** the proper submanifold $\widetilde{M}$ of $\mathbb{H}^n$ admits a tubular neighborhood $N \subset H_n$. By definition of a tubular neighborhood, see page **??**, we know that N is a compact codimension-zero submanifold of $\mathbb{H}^n$ with corner. Furthermore, by Proposition 123.4 we know that the inclusion $j\colon \widetilde{M} \to N$ is a homotopy equivalence. As we mentioned in Lemma 120.1, by rounding corners as in the proof of Proposition **??** we can view N as an n-dimensional smooth manifold.

The map $j \circ \theta\colon S^{k-1} \to \partial\widetilde{M} \subset \partial N$ takes values in $\partial\,\mathbb{H}^n$. Since $N \cap \partial\,\mathbb{H}^n$ is a codimension-zero submanifold of $\partial\,\mathbb{H}^n$ we see that there exists an open neighborhood U of $\theta(S^{k-1})$ in $\partial\,\mathbb{H}^n$ that is contained in N. Since $\partial\,\mathbb{H}^n$ is diffeomorphic to $\mathbb{R}^{n-1}$ and since, by our choice of n, we have $n-1 \geq 2(k-1)+2$, we obtain from Lemma 141.8 that there exists an orientation-preserving smooth embedding $\Theta\colon \overline{B}^{n-k} \times S^{k-1} \to \partial\,\mathbb{H}^n$ such that $\Theta(0,P) = \theta(P)$ for all $P \in S^{k-1}$. After possibly "shrinking" the balls we can arrange that the image of Θ actually lies in $U \subset N \cap \partial\,\mathbb{H}^n$.



Statement (2) of the lemma is a consequence of the following claim.

Claim. The topological space $X \cup_\alpha \overline{B}^k$ is homotopy equivalent to the smooth manifold $N \cup_\Theta h^k$.

Proof. The experienced reader will doubtlessly spot that this is the right moment to roll out the Homotopy Pushout Theorem 17.19. To apply this great theorem let us consider

the following commutative diagram:

All of the vertical maps are clearly homotopy equivalences. Furthermore note that it follows immediately from the Manifold Boundary-Cofibration Proposition 17.8 and the Product-Cofibration Proposition 17.11 that all of the right horizontal maps are closed cofibrations. Thus it follows from the Homotopy Pushout Theorem 17.19, applied altogether six times, that the induced maps between the various pushouts have homotopy inverses. Combining these six homotopy equivalences, respectively their homotopy inverses, we obtain the promised homotopy equivalence from $X \cup_\alpha \overline{B}^k$ to $N \cup_\Theta h^k$. ⊞

Finally assume that M is equipped with a handle decomposition. We sketch the proof how we can find a handle decomposition for N with the same number of handles. First, except for a slight sense of uneasy about rounding corners, it is pretty clear that we can equip $\widetilde{M} = M \times \overline{B}^r$ with a handle decomposition that is given by taking the product of each handle of M with $\overline{B}^r$. Now we consider the actual smooth manifold N which we are interested in. Note that N is by definition of a tubular neighborhood the total space of a linear $\overline{B}^s$-bundle $p\colon N \to \widetilde{M}$. This bundle might well be non-trivial, thus there is no reason to assume that N is actually a product $\widetilde{M} \times \overline{B}^s$. But, it follows from the same argument as in the Vector Bundles-Homotopies Proposition 143.13 and the fact that each handle is contractible that the restriction of p to each handle is actually a trivial linear $\overline{B}^s$-bundle. Thus we see that the handle structure on $\widetilde{M}$ does give rise to a handle structure on N with exactly the same number of handles of each index. ■

The next proposition explains what type of closed smooth manifolds one can obtain by the ever-popular doubling procedure to the smooth manifolds constructed in the proof of the Manifold Construction Proposition 141.7.

Proposition 141.10. Let X be a finite k-dimensional CW-complex. There exists an $N \geq 2k+1$ such that for every $n \geq N$ there exists a closed orientable n-dimensional

smooth manifold M which admits a standard handle decomposition and which admits a homotopy equivalence

$$\varphi\colon X \to M^{n-k-1}$$

from X to the $(n-k-1)$-skeleton of M.

Remark. Note that in the setting of Proposition 141.10 we obtain from Exercise 136.12 and the Handle Skeleton-Homology Lemma 140.1 (3) and (4), together with the Homotopy-π_n-Proposition 71.7 and the Homotopy Equivalence-H_*-Corollary 73.9, that the map $X \to M^{n-k-1} \to M$ induces an isomorphism of homotopy groups and homology groups up to dimension $n-k-2$.

Proof. Let X be a finite k-dimensional CW-complex. By the Manifold Construction Proposition 141.7 there exists a homotopy equivalence $\psi\colon X \to V$ from X to a compact smooth manifold V which has the nice property that it admits a handle decomposition such that all handles are of index $\leq k$. By the Standard Handle Decomposition Corollary 136.4 we can arrange that this handle decomposition is standard. After possibly replacing V by some $\overline{B}^s \times V$ we can arrange that $\dim(V) \geq 2k+1$. We set $N := \dim(V)$. Now let $n \geq N$. We set $W := \overline{B}^{n-N} \times V$ and we set $M := \mathrm{D}W$. We equip the double $M = \mathrm{D}W$ with the handle decomposition that we described on page 3004, namely which is given by the handle decomposition on M and the dual handle decomposition on the second copy of M. In particular we see that we can equip M with a handle decomposition such that the $(n-k-1)$-skeleton equals W. The map $\varphi\colon X \to M^{n-k-1} = V \times \overline{B}^{n-N}$ given by $P \mapsto (\psi(P), 0)$ is now the promised homotopy equivalence from X to the $(n-k-1)$-skeleton of M. ■

In the Manifold Construction Proposition 141.7 we just showed that every finite CW-complex X is homotopy equivalent to a compact smooth manifold X. The following question, which implicitly we had already asked on page 2643, arises.

Question 141.11. Given a finite CW-complex X, what extra conditions do we need to impose on X to ensure that X is homotopy equivalent to a *closed* smooth or topological manifold?

We make a couple of initial observations. Let X be a CW-complex.

(1) If X is homotopy equivalent to a closed orientable n-dimensional topological manifold, then it follows from the Poincaré Duality Theorem 119.1, together with the Homotopic Maps-and-Homology Proposition 73.6, Lemmas 108.13 and 116.8, that there exists a class $\sigma \in \mathrm{H}_n(X;\mathbb{Z})$ such that for each $k \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \cap\sigma\colon \mathrm{H}^{n-k}(X;\mathbb{Z}) & \to & \mathrm{H}_k(X;\mathbb{Z}) \\ \psi & \mapsto & \psi \cap \sigma \end{array}$$

is an isomorphism.

(2) If X is homotopy equivalent to a closed *non-orientable* topological manifold, then it follows from the Orientation Covering-Proposition 105.15 that X admits a 2-fold covering $\widetilde{X}$ which is homotopy equivalent to a closed orientable topological manifold.

(3) If X is homotopy equivalent to a closed (orientable) n-dimensional topological manifold, then every finite covering of X is also homotopy equivalent to a closed (orientable) n-dimensional topological manifold. In particular given any finite covering $\widetilde{X}$ the properties stated in (1) and (2) need to hold.

(4) These observations in (1), (2) and (3) already give lots of restrictions. We will generalize these conditions on page **??**. There we will show that any CW-complex X which is homotopy equivalent to a closed orientable n-dimensional topological manifold, is in fact a "Poincaré Duality space".

The extra conditions stated in (2), (3) and (4) vanish, if X is a simply connected CW-complex. Thus we have arrived at the following subtle variation on Question 141.11

Question 141.12. Let X be a finite simply connected CW-complex X which admits a class $\sigma \in \mathrm{H}_n(X;\mathbb{Z})$ as in (1). Is X homotopy equivalent to a closed n-dimensional smooth or topological manifold?

It turns out that the answer to Question 141.12 is no. Namely, there are other, more subtle bundle-theoretic obstructions to being homotopy equivalent to a closed smooth or topological manifold. Slightly more precisely, the obstruction is given by showing that the "Spivak Normal Fibration" of a given finite CW-complex has the structure of a vector bundle. In fact in [**DaP2015**, p. 21] (see also [**MadM1979**, p. 32]) it is shown that there exists a finite simply connected 5-dimensional CW-complex X such that the cohomology ring is isomorphic to the cohomology ring of $S^2 \times S^3$ but such that X is not homotopy equivalent to a closed topological manifold. Similar examples of such simply connected CW-complexes are given in [**GiS1965**, Theorem 5.2]. We also refer to [**CLM2021**, Chapter 5.5] and to [**CW2021**, Chapter 1.1.2] for details.

Exercises for Chapter 141.

Exercise 141.1. In the proof of the Fundamental Group-Manifold Realization Proposition 54.12 that we gave on page 3031 we used the following statement. Let M be a compact connected non-empty smooth manifold that admits a handle decomposition such that all handles have index ≤ 2. If $\dim(M) \geq 4$, then the inclusion induced map $\pi_1(M) \to \pi_1(\mathrm{D}M)$ is an isomorphism. Does this statement also hold if $\dim(M) = 3$?

Exercise 141.2. Let M be a closed connected 3-dimensional smooth manifold. Show that $\pi_1(M)$ admits a balanced presentation.
Hint. By the Handle Decomposition Theorem 138.5 we know that M admits a handle decomposition. By the Handle-Euler Characteristic Corollary 140.4 and the Odd-Dimensional Manifold-Euler Characteristic 140.5 we know that

$$\sum_{k=0}^{3}(-1)^k \cdot \text{number of } k\text{-handles} \;=\; 0.$$

You could first consider the case that the handle decomposition contains precisely one 0-handle and one 3-handle. Afterwards try to tackle the general case.

Exercise 141.3. Let k be a field with at least three elements. Show that $\mathrm{SL}(2,k)$ is perfect, i.e. show that the abelianization is the trivial group.
Hint. Use that for any non-zero $d \in k$ and $a \in k$ we have

$$\begin{pmatrix} d & 0 \\ 0 & d^{-1} \end{pmatrix}\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix}\begin{pmatrix} d^{-1} & 0 \\ 0 & d \end{pmatrix} \;=\; \begin{pmatrix} 1 & (d^2-1)a \\ 0 & 1 \end{pmatrix}.$$

Exercise 141.4. Give an example of a finite CW-complex X which is not homotopy equivalent to a closed topological manifold but which admits a class $\sigma \in \mathrm{H}_n(X;\mathbb{Z})$ such that for each $k \in \mathbb{N}_0$ the map

$$\begin{array}{rccc} \cap\sigma\colon \mathrm{H}^{n-k}(X;\mathbb{Z}) & \to & \mathrm{H}_k(X;\mathbb{Z}) \\ \psi & \mapsto & \psi \cap \sigma \end{array}$$

is an isomorphism.

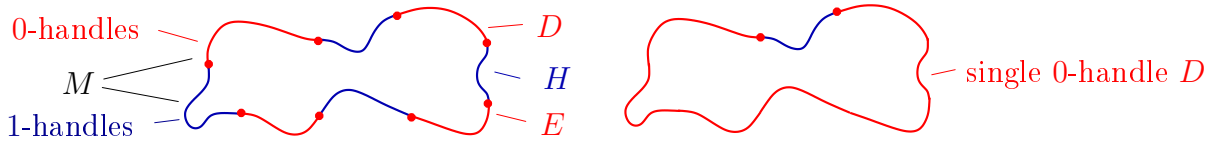
Hint. You could consider the wedge of a sphere with a suitable CW-complex with non-trivial fundamental group.

142. The classification of compact 2-dimensional smooth manifolds II

In this fairly short chapter we will finally complete the proof of the classification of compact 2-dimensional smooth manifolds. But first, as a warm-up, let us go one dimension lower, namely let us give a proof for half of the content of the Smooth 1-dimensional Manifold Classification Theorem 22.7.

Proposition 142.1. Every compact connected non-empty 1-dimensional smooth manifold is diffeomorphic either to S^1 or to $[0,1]$.

Remark. In Exercise 142.2 the reader is invited to show, using Propositions 31.2 and 142.1, that every non-compact connected 1-dimensional smooth manifold is diffeomorphic either to $[0,1)$ or to $\mathbb{R}$. This then completes the reproof of the Smooth 1-dimensional Manifold Classification Theorem 22.7.



Proof. Let M be a compact connected non-empty 1-dimensional smooth manifold. By the Handle Decomposition Theorem 138.5 we can equip M with a standard handle decomposition.

Claim. There exists a standard handle decomposition for M with a single 0-handle.

Proof. Since M is non-empty we know that M has at least one 0-handle. Now suppose that our handle decomposition has more than one 0-handle. Since M is connected and since the handle decomposition is standard it follows from the Handle-Connected Lemma 136.8 that there exists a 1-handle H that gets glued to two different 0-handles D and E. It is elementary to see that $D \cup E \cup H$ is diffeomorphic to $[-1,1]$. Thus we can combine $D \cup E \cup H$ to a single 0-handle. Note that the resulting handle decomposition is still standard. We now proceed iteratively. ⊞

We now fix a handle decomposition for M with a single 0-handle D. If the handle decomposition does not contain a 1-handle, then $M = D$, in particular M is diffeomorphic to $[0,1]$.

Now suppose that the handle decomposition contains at least one 1-handle. Since the handle decomposition is standard we know that all attaching maps of the 1-handles take values in $\partial M^1 = \partial D$. Now let $\varphi\colon \{0\} \times S^0 \to \partial D$ be an attaching map of a 1-handle. Note that the map is injective. Since both sets consist of precisely two elements we see that the attaching map is a bijection. In particular we see that $D \cup_\varphi (\{0\} \times \overline{B}^1)$ is a closed 1-dimensional smooth manifold. It is elementary to see that this smooth manifold is diffeomorphic to S^1. Since this smooth manifold is closed we see that there are no other 1-handles. Thus we have shown that M is diffeomorphic to S^1. ■

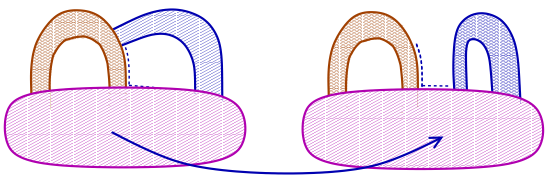
142.1. **Handle decompositions of 2-dimensional smooth manifolds.** In this section we will study handle decompositions of some of our favorite 2-dimensional smooth manifolds. We will also learn how to modify handle decompositions of 2-dimensional smooth manifolds. In the next section we will use the results from this section to give a surprisingly short proof of the statement that any compact connected non-empty 2-dimensional smooth

manifold is diffeomorphic to one of the standard examples.

We start out with the following lemma which is very specific to the 2-dimensional setting.

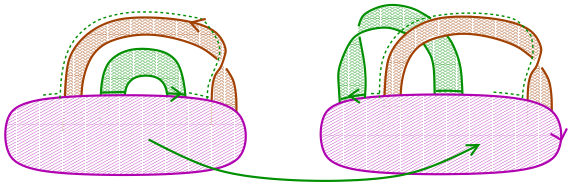
Lemma 142.2. Let M be a 2-dimensional smooth manifold, let C be a boundary component and let $\varphi\colon S^1 \to C$ be a diffeomorphism. The diffeomorphism type of $M \cup_\varphi h^2$ does not depend on the choice of φ.

Remark. The proof of Lemma 142.2 rests on the fact, proved in the diffeomorphisms-of-S^1-Extension Corollary 34.6, that for $n = 2$ every diffeomorphism of S^{n-1} extends to a diffeomorphism of $\overline{B}^n$. Note that by Theorem 146.7 and the Cerf Theorem 58.5 the analogous statement also holds for $n = 3$ and $n = 4$. In particular the obvious analogue of Lemma 142.2 also holds in those dimensions. But we will see in Proposition **??** that the analogue of Lemma 142.2 does *not* hold for $n = 7$.



Proof. Let M be a 2-dimensional smooth manifold, let C be a boundary component of M and let $\varphi, \psi\colon S^1 \to C$ be two diffeomorphisms. We consider the self-diffeomorphism $f := \varphi \circ \psi^{-1}\colon S^1 \to S^1$. By the diffeomorphisms-of-S^1-Extension Corollary 34.6 the self-diffeomorphism f of S^1 extends to a self-diffeomorphism F of the disk $\overline{B}^2$. Now we obtain from the Gluing-Smooth Manifolds-Proposition **??** (7) that $M \cup_\varphi h^2 = M \cup_{C \overset{\varphi}{\leftarrow} S^1} \overline{B}^2$ is diffeomorphic to $M \cup_\psi h^2 = M \cup_{C \overset{\psi}{\leftarrow} S^1} \overline{B}^2$. ■

In the following we will state and prove a few results which are not germane to the 2-dimensional setting, but which also have analogues in the higher-dimensional setting, which we will eventually discuss in Chapter **??**. In this and the following section we will use slightly informal language and we will partially work with figures. Nonetheless the mathematically mature reader should have no troubles with making the whole discussion completely and utterly rigorous.



First we formulate the following special case of the Handle Attachment Proposition 136.1 (4).

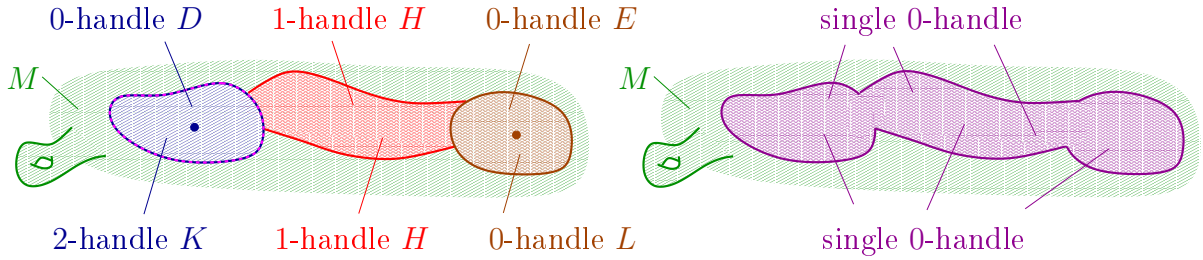
Lemma 142.3. Let M be a 2-dimensional smooth manifold. Given any smooth homotopy $F\colon (\overline{B}^1 \times S^0) \times [0,1] \to \partial M$ there exists a diffeomorphism $M \cup_{F_0} h^1 \to M \cup_{F_1} h^1$. Any such replacement of the 1-handle given by F_0 by the 1-handle given by F_1 is called a *handle slide*.

Example. For what follows it will be very helpful to get a little experience with what handle slides can do.

sliding the blue handle
off the brown handle

sliding the green handle
over the brown handle

Lemma 142.4. Every closed connected non-empty 2-dimensional smooth manifold admits a handle decomposition with the following properties:



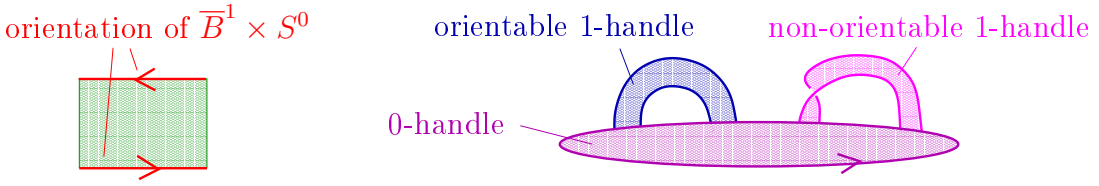
(1) There exists a single 0-handle.
(2) The attaching maps of all of the 1-handles take values in the boundary of the 0-handle.[1690]
(3) There exists a single 2-handle.

Remark. In Corollary **??** we will see that the conclusion of Lemma 142.4 in fact holds in all dimensions.

Sketch of proof. By the Handle Decomposition Theorem 138.5 we can equip M with a standard handle decomposition. Since M is non-empty we know that there exists at least one 0-handle. Suppose that M has more than one 0-handle. Since M is connected it follows from the fact that the handle decomposition is standard together with the Handle-Connected Lemma 136.8 that there exists a 1-handle H that gets glued to two different 0-handles D and E. In Exercise 142.3 we will see that $D \cup E \cup H$ is again diffeomorphic to a disk. Thus we can combine $D \cup E \cup H$ to a single 0-handle. It is straightforward to verify that the new handle decomposition is again standard and that the number of 2-handles is unaffected. We now proceed iteratively till we get down to a single 0-handle.

Next we apply the above procedure to the dual handle decomposition and we can arrange that the dual handle decomposition has a single 0-handle. Furthermore, as mentioned above, we can do this without changing the fact that the dual handle decomposition is standard and without changing the fact that the dual handle decomposition has a single 2-handle.

In summary, we have found a standard handle decomposition with a single 0-handle and a single 2-handle. ■



Definition.

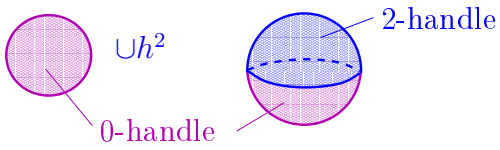
(1) We say a handle decomposition of 2-dimensional smooth manifold is completely standard, if it is of the form described in Lemma 142.4.
(2) Let M be a 2-dimensional smooth manifold that is equipped with a completely standard handle decomposition. We equip $\overline{B}^1 \times \overline{B}^1$ with the product orientation and we equip $\overline{B}^1 \times S^0 = \overline{B}^1 \times \partial\overline{B}^1 \subset \overline{B}^1 \times \overline{B}^1$ with the boundary orientation. As on page 2963 we say that a 1-handle with attaching map $\varphi\colon \overline{B}^1 \times S^0 \to \partial\overline{B}^2$ is orientable if the attaching map is either orientation-preserving on both components

[1690] In fact this statement is in this context equivalent to saying that the handle decomposition is standard in the sense of the definition on page 2958.

of $\overline{B}^1 \times S^0$ or if it is orientation-reversing on both components of $\overline{B}^1 \times S^0$. Otherwise we say that the 1-handle is non-orientable.

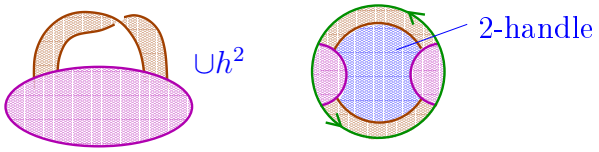
Lemma 142.5. Let M be a 2-dimensional smooth manifold M with a completely standard handle decomposition. The following two statements are equivalent:

(1) M is orientable.
(2) All 1-handles are orientable.



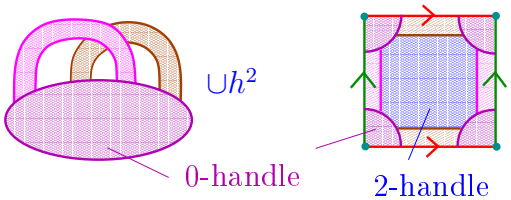
Proof. In the Gluing-Smooth Manifolds-Proposition **??** (6) we dealt with the orientability of smooth manifolds that are given by gluing oriented smooth manifolds along unions of boundary components. In our setting we only glue along codimension-zero submanifolds of the boundary. But the same statements hold and we see that our lemma is basically a special case of the Gluing-Smooth Manifolds-Proposition **??** (6). ■

Convention.

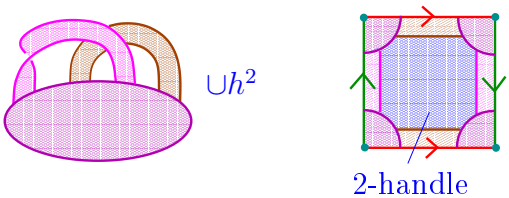


(1) Let M be a 2-dimensional smooth manifold M with a single 0-handle $\overline{B}^2$. If M is orientable, then we equip M with the orientation such that the natural map $\overline{B}^2 \to M$ given by the 0-handle is orientation-preserving.
(2) Let M be a closed 2-dimensional smooth manifold. If we are given a handle decomposition for M with a single 2-handle, then in the figures we show the 0-handles and the 1-handle attachments and we indicate with a discrete $\cup h^2$ the 2-handle. Note that by Lemma 142.2 the 2-handle attachment is basically unambiguous.

Examples.

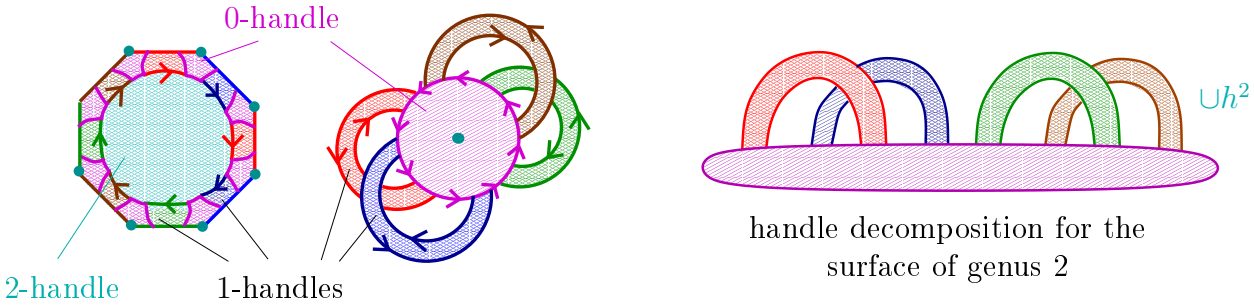


(1) In the figure below we show several completely standard handle decompositions for several of our favorite surfaces.

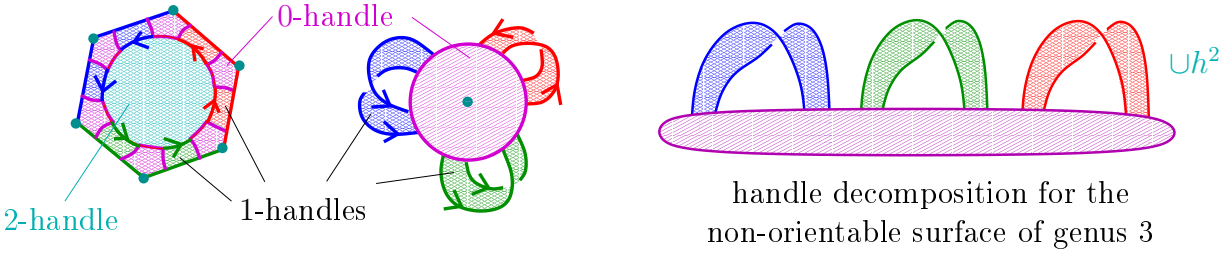


handle decomposition for the sphere

handle decomposition for $\mathbb{R}\mathrm{P}^2$

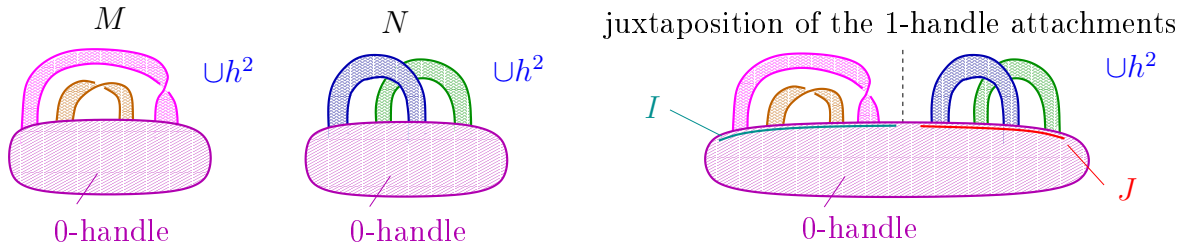


handle decomposition for the torus



handle decomposition for the Klein bottle

(2) (a) In the figure below we show a completely standard handle decomposition for the surface of genus two. This handle decomposition has an obvious generalizations to higher genera.



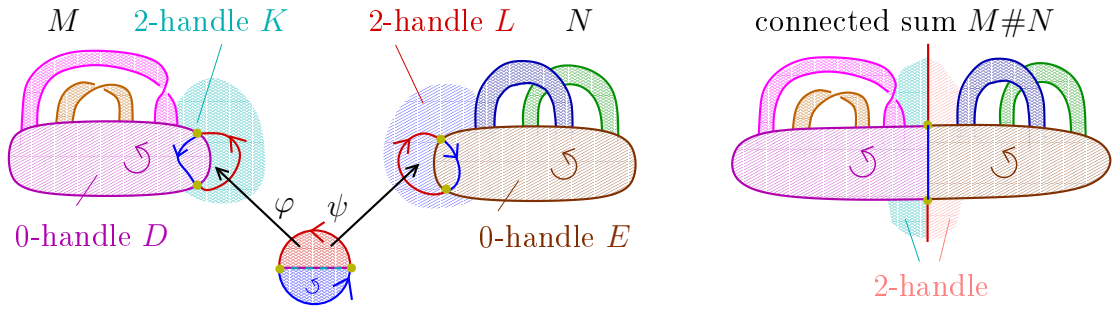
handle decomposition for the surface of genus 2

(b) In the figure below we show a completely standard handle decomposition for the non-orientable surface of genus 3, as defined on page 266. Again this example has obvious generalizations to higher genera.

handle decomposition for the non-orientable surface of genus 3

Lemma 142.6. Let M be a nd N be two closed 2-dimensional smooth manifolds. We assume that both are equipped with a completely standard handle decomposition. Then $M\#N$ has a completely standard handle decomposition such that the 1-handles are given by "juxtaposing" the 1-handle attachments for M and the 1-handle attachments for N. We will not give a formal definition of "juxtaposing", instead we refer to the figure below for a hopefully unambiguous "definition by illustration".

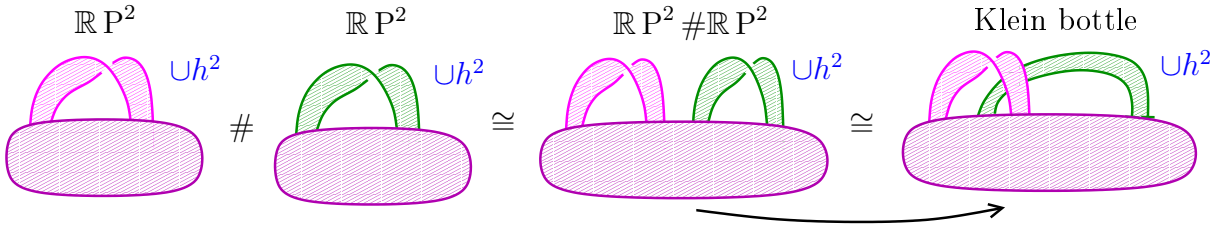
handle decomposition for $M\#N$



Proof. We denote by $D = \overline{B}^2$ the unique 0-handle of M and we denote by K the unique 2-handle of M. Furthermore we denote by $E = \overline{B}^2$ the unique 0-handle of N and we denote by L the unique 2-handle of N. It follows almost immediately from Exercise 136.3 that we can pick a smooth embedding $\varphi\colon \overline{B}^2 \to M$ such that $\varphi(\overline{B}^2_{\leq 0})$ is contained in the 0-handle D, such that $\varphi\colon \overline{B}^2_{\leq 0} \to D = \overline{B}^2$ is orientation-preserving and such that $\varphi(\overline{B}^2_{\geq 0})$ is contained in the 2-handle K. Similarly we pick a smooth embedding $\varphi\colon \overline{B}^2 \to N$, with the only real difference being, that we demand that the map $\psi\colon \overline{B}^2_{\leq 0} \to E$ is orientation-reversing. Now

we have

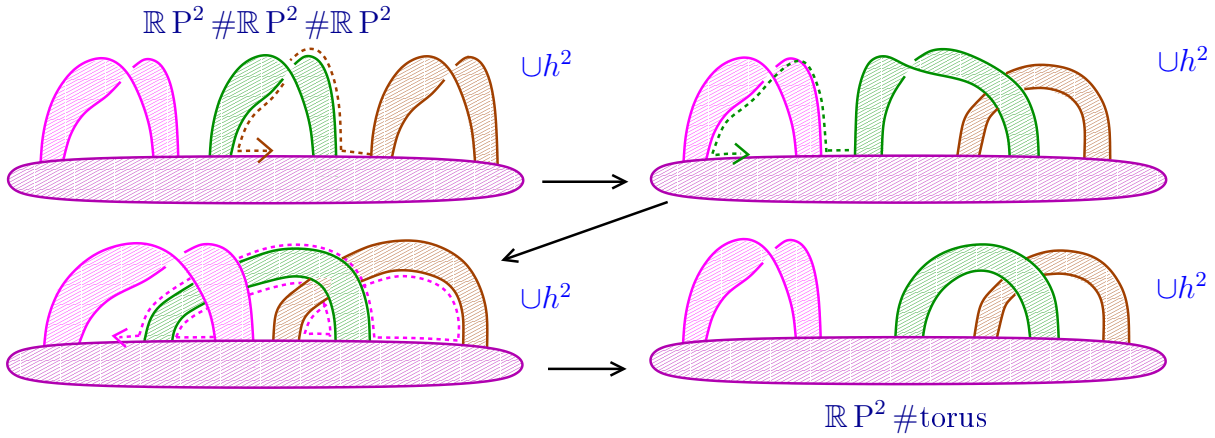
$$M\#N \overset{\text{by definition of the connected sum, note that if } M \text{ and } N \text{ are oriented, then the orientation conventions work out}}{\overset{\downarrow}{=}} (M \setminus \varphi(B^2)) \sqcup (N \setminus \psi(B^2))/\varphi(x) \sim \psi(x) \text{ for } x \in S^1$$



$$= \overbrace{(D \setminus \varphi(B^2_{\leq 0})) \cup (E \setminus \psi(B^2_{\leq 0}))}^{\text{diffeomorphic to } \overline{B}^2} \cup \text{ 1-handles of } M \cup \text{ 1-handles of } N \cup \underbrace{(K \setminus \varphi(B^2_{\geq 0})) \cup (L \setminus \psi(B^2_{\geq 0}))}_{\text{diffeomorphic to } \overline{B}^2}.$$

Thus we have obtained a handle decomposition for $M\#N$ with a single 0-handle, a single 2-handle, and such that the handles of M and N get attached to disjoint semicircles in the boundary of the 0-handle. In other words, the 1-handle attachments are juxtaposed. ■

Examples.



(1) In the figure below we use Lemma 142.6 to give a handle decomposition of the connected sum $\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2$ of two copies of the real projective plane $\mathbb{R}\mathrm{P}^2$. Furthermore we show a handle slide that results in the handle decomposition of the Klein bottle that we already saw in the figure on page 3047. This argument shows in particular that $\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2$ is diffeomorphic to Klein bottle. Thus we have obtained a new proof of Lemma **??**.

(2) (a) In the figure below we show, using altogether three handle slides, that the connected sum $\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2$ is diffeomorphic to the connected sum of $\mathbb{R}\mathrm{P}^2$ with the torus.

(b) Now let $g \in \mathbb{N}_0$. We consider the connected sum of $2g+1$ copies of $\mathbb{R}\mathrm{P}^2$ as given by attaching $2g+1$ non-orientable 1-handles to a single 0-handle. We iteratively apply the procedure in the figure below to the three right-most non-orientable 1-handles. We turn the two right-most non-orientable 1-handles into a pair of

interlocking orientable 1-handles. Eventually we see that the connected sum of $2g+1$ copies of $\mathbb{R}\mathrm{P}^2$ is diffeomorphic to the connected sum of $\mathbb{R}\mathrm{P}^2$ with the surface of genus g.

142.2. **The classification of compact 2-dimensional smooth manifolds.** We recall the following notation that we introduced on page 1234.

Notation. Given $g, n \in \mathbb{N}_0$ we write[1691]

$$\Sigma_{g,n} := \text{the surface of genus } g \text{ minus } n \text{ open disks.}$$

Furthermore for $g \in \mathbb{N}$ and $n \in \mathbb{N}_0$ we write

$$N_{g,n} := \text{the non-orientable surface of genug } g \text{ minus } n \text{ open disks.}$$

In the Surfaces-Non Homeomorphic Theorem 55.6 we showed that the above surfaces are pairwise non-homeomorphic, in particular we showed they are pairwise non-diffeomorphic.[1692] In this section we prove that any compact connected 2-dimensional smooth manifold is diffeomorphic to one of the above surfaces. This finally completes the classification of compact surfaces that we started in Chapter 55.

Here is the precise theorem we intend to prove.

Theorem 142.7. (Diffeomorphism-to-Standard Surfaces Theorem) Let Σ be a compact connected non-empty 2-dimensional smooth manifold.

(1) If Σ is orientable, then Σ is diffeomorphic to the surface $\Sigma_{g,n}$ for some $g, n \in \mathbb{N}_0$.
(2) If Σ is non-orientable, then Σ is diffeomorphic to the surface $N_{k,n}$ for some $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$.

Remark.

(1) Our proof of the Diffeomorphism-to-Standard Surfaces Theorem 142.7 is inspired by the ambitious [**GoS1999**, Exercise 4.2.4]. The key idea was communicated to us by Robert Gompf. The proof we provide is also outlined in [**Mart2016**, Theorem 6.1.6].
(2) In Exercise **??** we will also sketch an alternative approach to proving the Diffeomorphism-to-Standard Surfaces Theorem 142.7.

[1691] We refer to page 1233 for the definition of "minus n open disks".
[1692] In the Surfaces-Non diffeomorphic Corollary 45.21 we proved state the surfaces Σ_g are pairwise non-diffeomorphic.

(3) One can prove the Diffeomorphism-to-Standard Surfaces Theorem 142.7 through Morse theory, without using handles. This approach is taken in [**Mata2002**, Chapter 5.2] and [**Hirs1976**, Chapter 3].
(4) On page 1240 we discuss several other approaches to proving the analogue of the Diffeomorphism-to-Standard Surfaces Theorem 142.7 in the setting of topological manifolds.

To increase readability we split the proof of the Diffeomorphism-to-Standard Surfaces Theorem 142.7 into two parts. First we treat closed manifolds, afterwards we will prove the general case.

Proof of Theorem 142.7 for closed manifolds. By the Handle Decomposition Theorem 138.5 together with Lemma 142.4 it suffices to prove the proposition for a closed 2-dimensional smooth manifold that is equipped with a completely standard handle decomposition, i.e. that is equipped with a handle decomposition with the following properties:

(1) There exists a single 0-handle D.
(2) The attaching maps of all of the 1-handles take values in the boundary of the 0-handle.
(3) There exists a single 2-handle.

We prove this statement by induction on the number of 1-handles. If we have zero 1-handles, then M is given by gluing a 2-handle to a 0-handle via some attaching map $\varphi\colon S^1 \to S^1$. Now we see that we have the following diffeomorphisms:

$$M = \overline{B}^2 \cup_\varphi h^2 = \overline{B}^2 \cup_{S^1 \xleftarrow{\varphi} S^1} \overline{B}^2 \underset{\uparrow}{\cong} \overline{B}^2 \cup_{S^1 \xleftarrow{\mathrm{id}} S^1} \overline{B}^2 \underset{\uparrow}{\cong} S^2.$$

by Lemma 142.2 all attaching maps give same diffeomorphism type

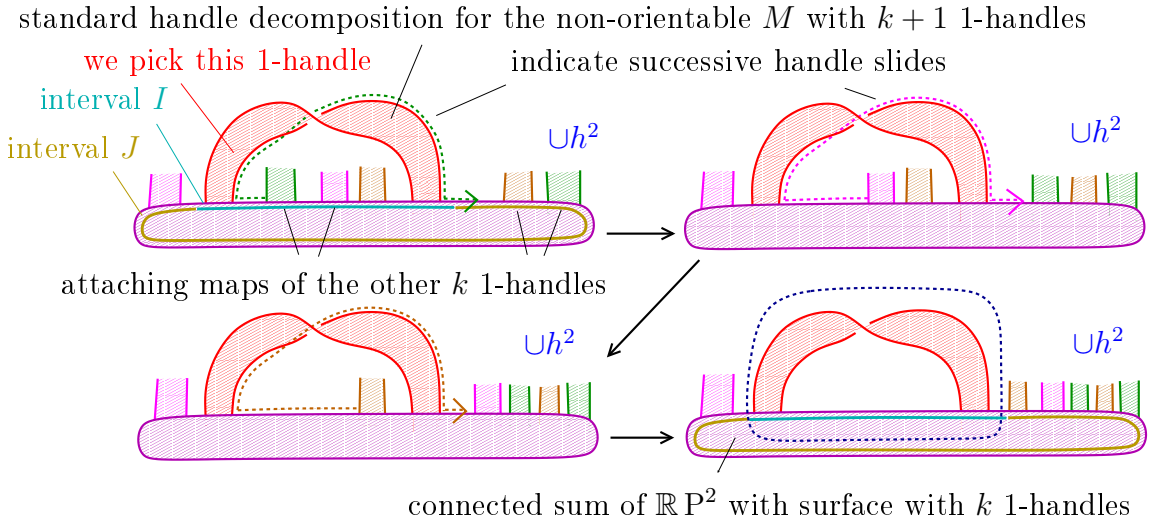
Handle Example Lemma 136.2

Next suppose that the claim holds whenever the number of 1-handles is $\leq k$. Thus let M be a smooth manifold as above with $k+1$ 1-handles.

Perhaps slightly surprisingly the case that the smooth manifold is non-orientable is slightly easier. So let us deal with this case initially. Since M is now assumed to be non-orientable we obtain from Lemma 142.5 that there exists a non-orientable 1-handle. We denote the corresponding attaching map by α. We denote by $\psi_1, \ldots, \psi_k$ the attaching maps of the remaining 1-handles. Let $I \subset \partial D$ be a compact interval that contains the image of the attaching map of the chosen 1-handle and let $J \subset \partial D$ be the compact interval with $\partial D = I \cup J$ and $I \cap J = \partial I = \partial J$. Here comes the key observation: *Since the 1-handle is non-orientable we see that $\partial(\overline{B}^2 \cup_\alpha h^1)$ is connected. Thus we can iteratively slide all handle attachments $\psi_1, \ldots, \psi_k$ that end up on I across the chosen 1-handle so that they take values in the interval J.* (We refer to the figure below for an illustration.) We denote the new handle attachment maps by $\widetilde{\psi}_1, \ldots, \widetilde{\psi}_k$.
We now see that

follows from Lemmas 142.2 and 142.3

$$M \cong \overline{B}^2 \cup_\alpha h^1 \cup_{\psi_1} h^1 \cdots \cup_{\psi_k} h^1 \cup h^2 \cong \overline{B}^2 \cup_\alpha h^1 \cup_{\widetilde{\psi}_1} h^1 \cdots \cup_{\widetilde{\psi}_k} h^1 \cup h^2$$



$$\cong \underbrace{(\overline{B}^2 \cup_\alpha h^1 \cup h^2)}_{\cong \mathbb{R}\mathrm{P}^2, \text{ see the figure below}} \# \underbrace{(\overline{B}^2 \cup_{\widetilde{\psi}_1} h^1 \ldots \cup_{\widetilde{\psi}_k} h^1 \cup h^2)}_{\text{by induction } \cong k \cdot \mathbb{R}\mathrm{P}^2 \text{ or } \cong \Sigma_{\frac{k}{2}}} \cong (k+1)\cdot\mathbb{R}\mathrm{P}^2 \cong \text{non-orientable surface of genus } k+1.$$

by Lemma 142.6

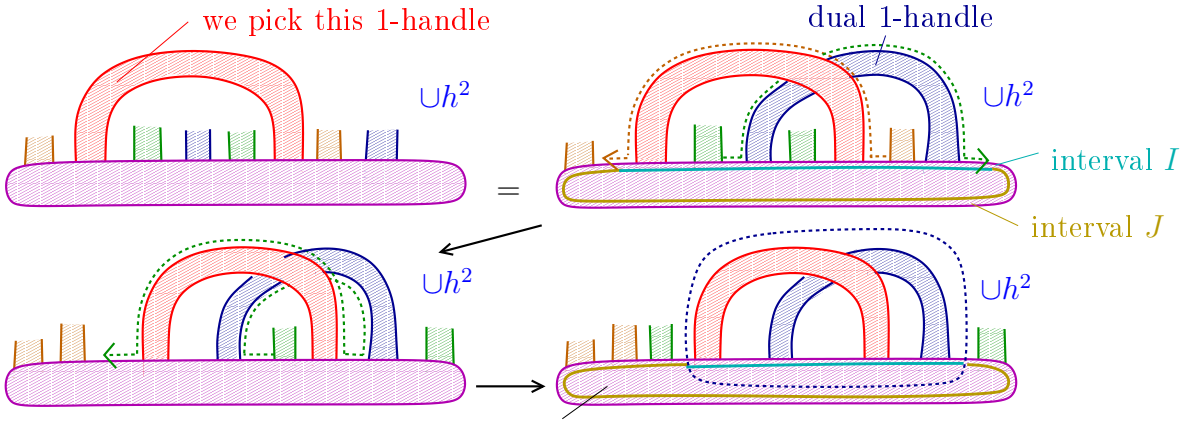
see the figure below where we see that $\mathbb{R}\mathrm{P}^2 \# \Sigma_l \cong (2l+1)\cdot\mathbb{R}\mathrm{P}^2$

by Lemma ?? (2)

We have thus proved the induction step if M is non-orientable.

Now we turn to the case that M is orientable. We pick any 1-handle. Since M is orientable the chosen 1-handle is orientable. Note that this implies that the boundary of $\overline{B}^2 \cup_\alpha h^1$ is disconnected. But since we work with a completely standard handle decomposition we know that, once we attached all 1-handles, the boundary is connected. This implies that there exists at least one other 1-handle that connects the two components of the boundary of $\overline{B}^2 \cup_\alpha h^1$. We pick such a 1-handle and we call it the *dual handle*. We denote its attaching map by β. We denote by $\psi_1, \ldots, \psi_{k-1}$ the attaching maps of the remaining 1-handles. Let $I \subset \partial D$ be a compact interval that contains the image of the attaching maps α and β and let $J \subset \partial D$ be the compact interval with $\partial D = I \cup J$ and $I \cap J = \partial I = \partial J$. Here comes the key observation: *It is straightforward to see that* $\partial(\overline{B}^2 \cup_\alpha h^1 \cup_\beta h^1)$ *is connected. Thus we can iteratively slide all handle attachments* $\psi_1, \ldots, \psi_k$ *that end up on* I *across the two 1-handles so that they take values in the interval* J. (We refer to the figure below for an illustration.) We denote the new handle attachment maps by $\widetilde{\psi}_1, \ldots, \widetilde{\psi}_{k-1}$.

We now see that



$$M \cong \overline{B}^2 \cup_\alpha h^1 \cup_\beta h^1 \cup_{\psi_1} h^1 \cdots \cup_{\psi_{k-1}} h^1 \cup h^2 \overset{\text{follows from Lemmas 142.2 and 142.3}}{\cong} \overline{B}^2 \cup_\alpha h^1 \cup_\beta h^1 \cup_{\widetilde{\psi}_1} h^1 \cdots \cup_{\widetilde{\psi}_{k-1}} h^1 \cup h^2$$

$$\cong \underbrace{(\overline{B}^2 \cup_\alpha h^1 \cup_\beta h^1 \cup h^2)}_{\cong \text{ torus, see the figure on page 3047}} \# \underbrace{(\overline{B}^2 \cup_{\widetilde{\psi}_1} h^1 \ldots \cup_{\widetilde{\psi}_{k-1}} h^1 \cup h^2)}_{\text{since all bands are orientable we know that this is an orientable surface, thus by induction we know that it is diffeomorphic to } \Sigma_{\frac{k-1}{2}}} \overset{\text{follows from Lemma ?? (1) or alternatively the discussion on page 3049}}{\cong} \text{surface of genus } \tfrac{k+1}{2}.$$

by Lemma 142.6

We have thus now proved the induction step also in the case that M is orientable. ∎

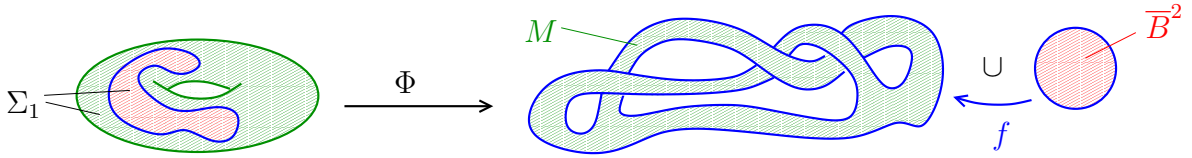
standard handle decomposition for the orientable M with $k+1$ 1-handles

connected sum of torus with surface with $k-1$ orientable 1-handles

In the following we will finally deal with 2-dimensional smooth manifolds with non-empty boundary.

Proof of Theorem 142.7 for all manifolds. Let M be a compact connected non-empty 2-dimensional smooth manifold. By the Smooth Manifold Boundary Proposition 19.26 the boundary ∂M is a closed 1-dimensional smooth manifold. Since ∂M is compact it has finitely many components that we denote by $C_1, \ldots, C_n$. (Note that we allow the case that $n = 0$.) Each component C_i is compact and has no boundary. Thus it follows from Proposition 142.1 that for each $i = 1, \ldots, n$ there exists a diffeomorphism $f_i \colon S^1 \to C_i$.

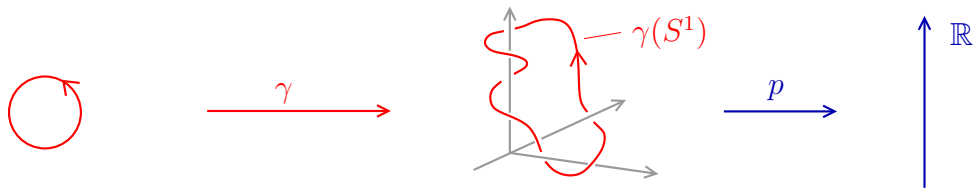
We denote by $\widehat{M}$ the result of gluing a disk to each boundary component. More precisely, we consider



$$\widehat{M} := \left(M \sqcup \bigsqcup_{i=1}^{n} (\overline{B}^2 \times \{i\}) \right) / \sim \quad \text{where } f_i(P) \sim (P, i) \text{ for } P \in S^1 \text{ and } i \in \{1, \ldots, n\}.$$

By the Gluing-Smooth Manifolds-Proposition **??** we know that $\widehat{M}$ is a closed connected non-empty 2-dimensional smooth manifold that contains M as a smooth submanifold and which has the property that the obvious maps $\overline{B}^2 \times \{i\} \to \widehat{M}$ are all smooth embeddings. Furthermore it follows from the Gluing-Smooth Manifolds-Proposition **??** (6) and the observation that $\overline{B}^2$ admits an orientation-reversing diffeomorphism, that M is orientable if and only if $\widehat{M}$ is orientable.

Now suppose that M is orientable. By the above $\widehat{M}$ is also orientable. Since $\widehat{M}$ is closed orientable connected and non-empty we know by the above that there exists a diffeomorphism $\Phi\colon \Sigma_g \to \widehat{M}$ from the surface of some genus g to $\widehat{M}$. Then Φ restricts to a diffeomorphism

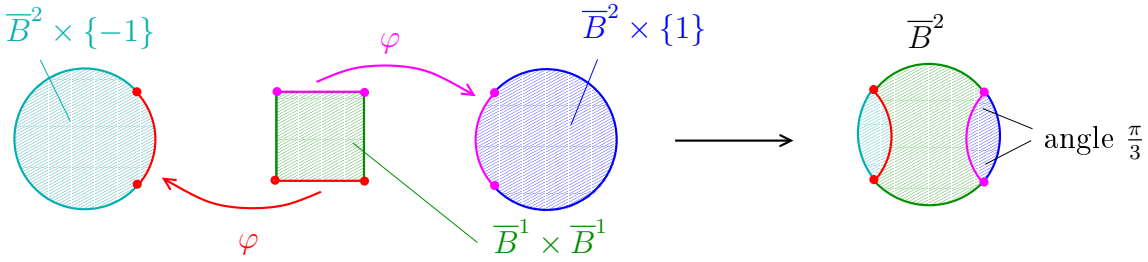


$$\Phi\colon \underbrace{\Sigma_g \setminus \bigcup_{i=1}^{n} \Phi^{-1}\big(B^2 \times \{i\}\big)}_{= \Sigma_{g,n} \text{ since the maps } \overline{B}\times\{i\}\to\Sigma_g \text{ are all smooth embeddings}} \to \; M.$$

If M is non-orientable, then $\widehat{M}$ is closed connected non-orientable and non-empty, thus we know that it is diffeomorphic to the non-orientable surface N_g for some g. As above we see that M is diffeomorphic to $N_{g,n}$. ■

Exercises for Chapter 142.

Exercise 142.1. We denote by $p\colon \mathbb{R}^3 \to \mathbb{R}$ the projection onto the third coordinate. Let $\gamma\colon S^1 \to \mathbb{R}^3$ be a smooth embedding such that the map $p \circ \gamma\colon S^1 \to \mathbb{R}$ has precisely two critical points. Show that $\gamma(S^1)$, viewed as a submanifold of $\mathbb{R}^3 \cup \{\infty\} = S^3$ is smoothly isotopic to the trivial knot.



Exercise 142.2. Show that every non-compact connected 1-dimensional smooth manifold is diffeomorphic either to $[0,1)$ or to $\mathbb{R}$.
Hint. Use Propositions 31.2 and 142.1.

Exercise 142.3. We consider the attaching map

$$\begin{aligned} \varphi\colon \overline{B}^1 \times S^0 &\to \overline{B}^2 \times \{\pm 1\} \\ (y,\epsilon) &\mapsto \Big(\big(\epsilon \cdot \sqrt{1-\tfrac{y^2}{4}}, \tfrac{y}{2}\big), \epsilon\Big). \end{aligned}$$

Show that $(\overline{B}^1 \times \overline{B}^1) \cup_{\varphi\colon \overline{B}^1\times S^0 \to S^1 \times \{\pm 1\}} (\overline{B}^2 \times \{\pm 1\})$ is diffeomorphic to $\overline{B}^2$.
Remark.

(1) It follows easily from this exercise together with the Smooth Ball Embedding Theorem 37.8 that any attaching of a 1-handle to two disks is diffeomorphic to $\overline{B}^2$.
(2) By "rotating around the x-axis" one sees that a similar statement also holds in the higher-dimensional setting.

$\overline{B}^2 \times \{-1\}$

Part XV

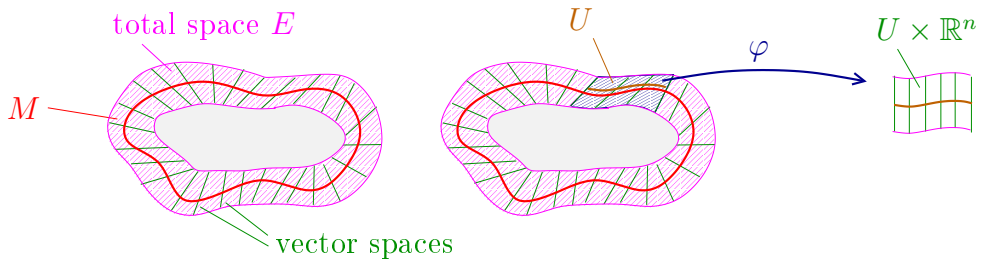
Bundles

143. Vector Bundles

In this chapter we introduce vector bundles and in the following chapter we will introduce their Pontryagin classes. Both chapters are only intended as a quick introduction. Therefore on many occasions we will only provide sketches of proofs or we will refer to the literature for the proofs. Furthermore we will be less worried about why maps are actually continuous. The best reference for these two chapters is the classic book by Milnor-Stasheff [**MiS1974**] on characteristic classes. Other references are [**Miln1957a, Hat2**] and [**Hus1993**].

143.1. **Vector bundles.** In this section we introduce vector bundles and we give several constructions and examples. The definition of a vector bundle is fairly similar to the definition of a smooth $\overline{B}^m$-bundle that we gave on page **??** and the definition of a linear $\overline{B}^m$-bundle that we gave on page **??**.
Loosely speaking, a vector bundle over a topological space X consists of a vector space for each $x \in X$, where the "vector spaces vary continuously with x". The following definition makes this idea precise.

Definition. An n-dimensional real vector bundle over a topological space X is a topological space E together with a map $p\colon E \to X$ and a real vector space structure on each $p^{-1}(x)$, $x \in X$ such that for each $x \in X$ there exists an open neighborhood U of x and a homeomorphism $\varphi\colon p^{-1}(U) \to U \times \mathbb{R}^n$ such that the following two conditions are satisfied:



(1) The following diagram commutes

$$\begin{array}{ccc} p^{-1}(U) & \xrightarrow{\varphi} & U \times \mathbb{R}^n \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle (y,v)\mapsto y} & \\ & U. & \end{array}$$

(2) For each $y \in U$ the map $\varphi\colon p^{-1}(y) \to \{y\} \times \mathbb{R}^n = \mathbb{R}^n$ is an isomorphism of vector spaces.

(The definition is illustrated in the figure below.) Exactly the same way we also define the notion of an n-dimensional complex vector bundle. When we are agnostic about whether we consider real or complex vector bundles, then sometimes we just say vector bundle. We introduce the following notation and language:

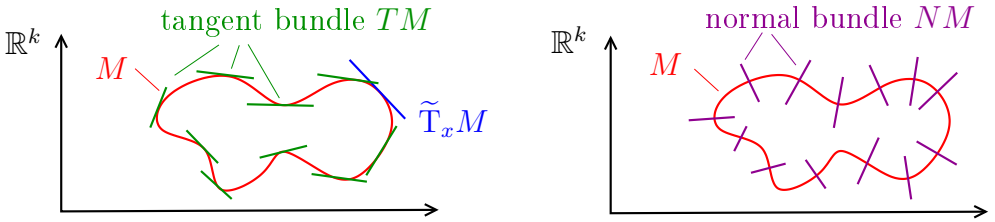
(a) We refer to the topological space E as the total space of the vector bundle and we refer to X as the base space of the vector bundle. Furthermore we refer to the map $p\colon E \to X$ as the projection.
(b) A 1-dimensional real (respectively complex) vector bundle is often called a real (respectively complex) line bundle.
(c) Given a vector bundle $p\colon E \to X$ and given $x \in X$ we write $E_x := p^{-1}(x)$. Sometimes we refer to E_x as the fiber of E over x.
(d) We refer to a homeomorphism $\varphi\colon p^{-1}(U) \to U \times \mathbb{R}^n$ which satisfies the above conditions (1) and (2) as a trivialization of the vector bundle.

Examples. In each of the following examples it is fairly elementary to verify that these are indeed vector bundles. For the sake of brevity[1693] we do not give all the details.

(1) For each topological space X the product $X \times \mathbb{R}^n$ together with the projection $p\colon X \times \mathbb{R}^n \to X$ is an n-dimensional vector bundle over X. We refer to this vector bundle as the *trivial n-dimensional real vector bundle over X*. The same way we also define the *trivial n-dimensional complex vector bundle over X*.

(2) Let M be an m-dimensional submanifold of $\mathbb{R}^k$.

(a) The map[1694]



$$\begin{array}{rcl} \mathrm{T}M := \{(x,v) \in M \times \mathbb{R}^k \,|\, x \in M \text{ and } v \in \widetilde{\mathrm{T}}_x M\} & \to & M \\ (x,v) & \mapsto & x \end{array}$$

is an m-dimensional real vector bundle over M. We refer to it as the *tangent bundle* of the submanifold M.

(b) The map

$$\begin{array}{rcl} NM := \{(x,v) \in M \times \mathbb{R}^k \,|\, x \in M \text{ and } v \in \mathbb{R}^k \text{ with } v \perp \widetilde{\mathrm{T}}_x M\} & \to & M \\ (x,v) & \mapsto & x \end{array}$$

is a $(k-m)$-dimensional real vector bundle over M. We call it the *normal bundle* of M in $\mathbb{R}^k$.

(3) Given any vector bundle $p\colon E \to X$ and given any subset $W \subset X$ the map $p\colon p^{-1}(W) \to W$ is evidently also a vector bundle. We refer to it as the restriction of p to W.

(4) Recall that given $n \in \mathbb{N}_0$ we defined on page 251 the real projective space to be

$$\mathbb{R}\mathrm{P}^n \;:=\; (\mathbb{R}^{n+1} \setminus \{0\})/\!\sim$$

[1693] No snickering please.

[1694] We refer to page 620 for the definition of the "physical tangent spaces" $\widetilde{\mathrm{T}}_x M \subset \mathbb{R}^k$ of a submanifold $M \subset \mathbb{R}^k$.

where $\sim$ denotes the equivalence relation on $\mathbb{R}^{n+1} \setminus \{0\}$ given by multiplication by an element in $\mathbb{R} \setminus \{0\}$. The map

$$\begin{array}{rcl} X = \{([v], \lambda v) \in \mathbb{R}\mathrm{P}^n \times \mathbb{R}^{n+1} \,|\, [v] \in \mathbb{R}\mathrm{P}^n, \lambda \in \mathbb{R}\} & \to & \mathbb{R}\mathrm{P}^n \\ ([v], w) & \mapsto & [v] \end{array}$$

defines a one-dimensional vector bundle over $\mathbb{R}\mathrm{P}^n$. We refer to it as the tautological real line bundle over $\mathbb{R}\mathrm{P}^n$. The same way we also define the tautological complex line bundle over $\mathbb{C}\mathrm{P}^n$ and the same way we also define the tautological line bundles over $\mathbb{R}\mathrm{P}^\infty$ and $\mathbb{C}\mathrm{P}^\infty$.

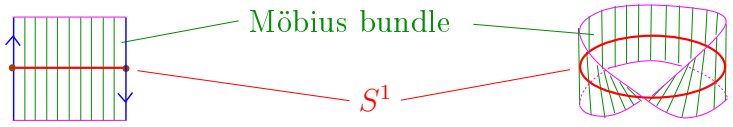
Before we introduce more examples we give the following, basically self-evident definition.

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Let $p\colon E \to X$ and $q\colon F \to X$ be two $\mathbb{K}$-vector bundles over a topological space X. An isomorphism of the $\mathbb{K}$-vector bundles over X is a map $\Phi\colon E \to F$ that satisfies the following two conditions:

(1) The following diagram commutes:

$$\begin{array}{ccc} E & \xrightarrow{\Phi} & F \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle q} & \\ & X. & \end{array}$$

(2) For each $x \in X$ the map $\Phi|_{E_x}\colon E_x \to F_x$ is an isomorphism of $\mathbb{K}$-vector spaces.



We continue with a few more examples of real bundles.

Examples.

(1) The map

$$\begin{array}{rcl} ([0,1] \times \mathbb{R})/(0,v) \sim (1,-v) & \to & S^1 \\ [(t,v)] & \mapsto & \exp(2\pi\,\mathrm{i}t) \end{array}$$

is a line bundle over S^1. The discussion on page 264 shows that the total space is homeomorphic to the open Möbius band. Therefore we refer to this bundle as the *Möbius bundle*. This bundle, and a bundle that is isomorphic to it, are illustrated in the figure below.

(2) Let M be an n-dimensional smooth manifold. (Note that in contrast to the discussion on page 3059 we do not assume that M is a submanifold of some $\mathbb{R}^k$.) We consider the map

$$\begin{array}{rcl} p\colon \mathrm{T}M := \{(x,v) \,|\, x \in M \text{ and } v \in \mathrm{T}_x M\} & \to & M \\ (x,v) & \mapsto & x. \end{array}$$

We would like to show that $p\colon \mathrm{T}M \to M$ is an n-dimensional real vector bundle. For each $x \in M$ the preimage $p^{-1}(x) = \{x\} \times \mathrm{T}_x M$ admits an obvious real vector space structure. Our next goal is to equip $\mathrm{T}M$ with a reasonable topology. For this we

note that any chart $\Phi\colon U \to V$ for M induces a bijection

$$\begin{array}{rcl} \widetilde{\Phi}\colon p^{-1}(U) & \to & V \times \mathbb{R}^n \\ (x, v) & \mapsto & (\Phi(x), \underbrace{\mathrm{D}\Phi_x(v)}_{\in \mathrm{T}_{\Phi(x)}V = \mathbb{R}^n}). \end{array}$$

We say that a subset $W \subset \mathrm{T}M$ is *open* if for every chart $\Phi\colon U \to V$ for M the image $\widetilde{\Phi}(W) \subset V \times \mathbb{R}^n$ is open. With this definition it is now reasonably easy to show that $p\colon \mathrm{T}M \to M$ is an n-dimensional real vector bundle over M. We refer to it as the *tangent bundle of* M.[1695]

If M is an n-dimensional submanifold of $\mathbb{R}^k$, then using the usual isomorphism $\widetilde{\mathrm{T}}_P M \cong \mathrm{T}_P M$ from the Tangent Space-Isomorphism Proposition 23.16 one can show fairly easily that the two tangent bundles that we defined above are isomorphic. In practice we will not distinguish between these two notions.

(3) Let M be an n-dimensional *complex* manifold. Since M is also a $2n$-dimensional smooth manifold we can consider the tangent bundle $p\colon \mathrm{T}M \to M$ as in (2). Using charts from the holomorphic atlas one can endow each tangent space $\mathrm{T}_x M$ with the structure of an n-dimensional complex vector space. This shows that the tangent bundle $\mathrm{T}M \to M$ can be viewed as a $\mathbb{C}$-vector bundle where the complex structure varies "smoothly". A "smooth" $\mathbb{C}$-vector bundle structure on the tangent space $\mathrm{T}M$ of a $2n$-dimensional smooth manifold is called an *almost complex structure*. The Newlander–Nirenberg Theorem, see [**NN1957**] and [**Hör1990b**, Section 5.7], gives a complete criterion for whether or not an almost complex structure on $\mathrm{T}M$ arises from a complex structure on M.

Proposition 143.1. (Vector Bundles-from-Representation) Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Let M be a connected locally contractible topological space, let $x_0 \in M$ be a point and furthermore let $\varphi\colon \pi_1(M, x_0) \to \mathrm{GL}(n, \mathbb{K})$ be a representation. We denote by $p\colon \widetilde{M}_{x_0} \to M$ the explicit universal covering that we constructed in the proof of the Covering Existence Theorem 61.5. The group $\pi_1(M, x_0)$ acts on $\widetilde{M}_{x_0}$ via the action provided by Proposition 61.14. We consider[1696]

$$\mathbb{K}^n \times_{\pi_1(M,x_0)} \widetilde{M}_{x_0} \ := \ (\mathbb{K}^n \times \widetilde{M}_{x_0})/\sim \qquad \text{where } (\varphi(g^{-1}) \cdot v, p) \sim (v, g \cdot p).$$

We equip $\mathbb{K}^n \times \widetilde{M}_{x_0}$ with the product topology and we equip $(\overline{M} \times \widetilde{M}_{x_0})/\sim$ with the quotient topology.

(1) The map

$$\begin{array}{rcl} q\colon \mathbb{K}^n \times_{\pi_1(M,x_0)} \widetilde{M}_{x_0} & \to & M \\ [(m, x)] & \mapsto & p(x) \end{array}$$

is continuous.

[1695] It does not take too much effort to show that the total space $\mathrm{T}M$ of the tangent bundle is naturally a $2n$-dimensional smooth manifold. (A related statement for physical tangent spaces of smooth submanifolds of $\mathbb{R}^n$ is proved in Exercise 19.29.) We will not make use of this neat fact.

(2) Let $x \in M$. We have $q^{-1}(x) = M \times_{\pi_1(M,x_0)} p^{-1}(x)$. We pick a path $\mu\colon [0,1] \to M$ from x to x_0. The map

$$\begin{array}{rcl} q^{-1}(x) = \mathbb{K}^n \times_{\pi_1(M,x_0)} p^{-1}(x) & \to & \mathbb{K}^n \\ [(m,\alpha)] & \mapsto & \varphi([\mu * \overline{\alpha}])(m) \end{array}$$

α is a path from x_0 to x

is well-defined.

(3) The map from (2) is a bijection.

(4) We use the $\mathbb{K}$-vector space structure on $\mathbb{K}^n$ and the bijection from (3) to define a group structure on $q^{-1}(x)$. This $\mathbb{K}$-vector space structure does not depend on the choice of μ.

All this data combined defines an n-dimensional $\mathbb{K}$-vector bundle over M.

Proof. Let $\varphi\colon \pi_1(M,x_0) \to \mathrm{GL}(n,\mathbb{K})$ be a representation.

(1) It follows immediately from the Topological-Product Proposition 5.1 (1a) and the Topological-Quotient Proposition 5.15 (1b) that the given map $q\colon \mathbb{K}^n \times_{\pi_1(M,x_0)} \widetilde{M}_{x_0} \to M$ is continuous.

(2) Let $x \in M$. Evidently we have $q^{-1}(x) = \mathbb{K}^n \times_{\pi_1(M,x_0)} p^{-1}(x)$. We pick a path $\mu\colon [0,1] \to M$ from x to x_0. We consider the map

$$\begin{array}{rcl} F\colon q^{-1}(x) = \mathbb{K}^n \times_{\pi_1(M,x_0)} p^{-1}(x) & \to & \mathbb{K}^n \\ [(m,\alpha)] & \mapsto & \varphi([\mu * \overline{\alpha}])(m) \end{array}$$

We need to show that the map is well-defined. Thus let $[\gamma] \in \pi_1(X,x_0)$. Then

$$\begin{array}{rcl} F(\varphi([\gamma]^{-1}) \cdot v, [\alpha]) & = & \varphi(\mu * \overline{\alpha}) \cdot \varphi([\gamma]^{-1}) \cdot v \\ & = & \varphi(\mu * \overline{\gamma * \alpha}) \cdot v \end{array} \begin{array}{rcl} & = & \varphi(\mu * \overline{\alpha} * \overline{\gamma}) \cdot v \\ & = & F([(v, [\gamma * \alpha])]) \end{array} = F([(v, [\gamma] \cdot [\alpha])]).$$

(3) By the Regular Covering-Characterization Corollary 62.8 and the Deck Group-Free Action Lemma 62.2 we know that the action of $\pi_1(M,x_0)$ on $p^{-1}(x)$ is free and transitive. It follows easily that the above map is a bijection.

(4) We need to show that the resulting $\mathbb{K}$-vector space structure on $q^{-1}(x)$ does not depend on the choice of μ. Thus let $\nu\colon [0,1] \to M$ be another path from x to x_0. We see that

$$\varphi([\nu * \overline{\alpha}])(m) \;=\; \varphi([\nu * \overline{\mu} * \mu * \overline{\alpha}])(m) \;=\; \varphi([\nu * \overline{\mu}]) \cdot \varphi([\mu * \overline{\alpha}])(m).$$

Thus we see that the maps $[(m,\alpha)] \mapsto \varphi([\nu * \overline{\alpha}])(m)$ and $[(m,\alpha)] \mapsto \varphi([\mu * \overline{\alpha}])(m)$ differ by multiplication by the invertible matrix $\varphi([\nu * \overline{\mu}])$. Thus both induce the same $\mathbb{K}$-vector space structure on $q^{-1}(x)$.

It remains to show that the above data defines an n-dimensional $\mathbb{K}$-vector bundle over M. Thus let $x \in M$. We pick an open neighborhood U of x such that $p^{-1}(U)$ is uniformly covered in the sense of the definition on page 1067. Furthermore we pick a path $\mu\colon [0,1] \to$

[1696] The perhaps slightly odd way of defining $\mathbb{K}^n \times_{\pi_1(M,x_0)} \widetilde{M}_{x_0}$ has, for the author, the origin from the analogous situation when in Proposition 174.4 we introduce local coefficient systems corresponding to representations.

M from x_0 to x. Similar to the above we consider the map

$$\begin{aligned} F\colon q^{-1}(U) = \mathbb{K}^n \times_{\pi_1(M,x_0)} p^{-1}(U) &\to \mathbb{K}^n \times U \\ [(v,[\alpha])] &\mapsto (\varphi(\mu * \overline{\alpha}) \cdot v, [\alpha]). \end{aligned}$$

Using our discussion above one can easily verify that this map is a trivialization. ■

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, let M be a connected locally contractible topological space, let $x_0 \in M$ be a point and let $\varphi\colon \pi_1(M, x_0) \to \mathrm{GL}(n, \mathbb{K})$ be a representation. We refer to the vector bundle that we defined in the Vector Bundles-from-Representation 143.1 as the $\mathbb{K}$-vector bundle defined by φ.

Example. It is fairly straightforward to show that the real vector bundle over S^1 corresponding to the representation $\pi_1(S^1, 1) \to \mathrm{GL}(1, \mathbb{R})$ given by sending the standard generator of $\pi_1(S^1, 1)$ to (-1) is isomorphic to the Möbius bundle.

The following definition is basically self-explanatory.

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ and let $p\colon E \to X$ be an n-dimensional $\mathbb{K}$-vector bundle.

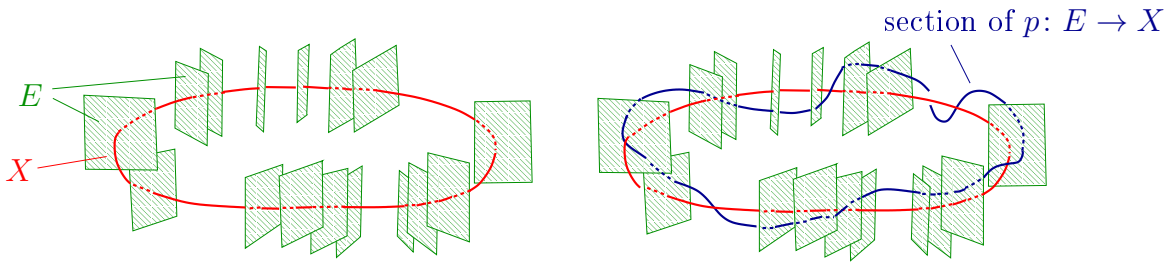
(1) We say p is trivializable if p is isomorphic to the trivial n-dimensional $\mathbb{K}$-vector bundle $X \times \mathbb{K}^n \to X$.
(2) Any choice of an isomorphism $E \to X \times \mathbb{K}^n$ is called a trivialization of the vector bundle p.

The following lemma is basically trivial, but it simplifies discussions later on.

Lemma 143.2. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ and let $p\colon E \to X$ be an n-dimensional $\mathbb{K}$-vector bundle.

(1) The $\mathbb{K}$-vector bundle is trivializable if and only if there exists a map $\varphi\colon E \to \mathbb{K}^n$ such that $p \times \varphi$ is a trivialization.
(2) If p is trivializable, then for any subset $W \subset X$ the restriction of p to W is also trivializable.
(3) If W is a subset of X such that the restriction of p to each component of W is trivializable, then the restriction of p to W is also trivial. ■

Proof. We leave it to the reader to provide the elementary proofs of the statements of the lemma. ■



Now we move on to two more definitions.

Definition.

(1) We say that a smooth manifold M is parallelizable if its tangent bundle $\mathrm{T}M$ is trivializable.
(2) A section of a vector bundle $p\colon E \to X$ is a continuous map $s\colon X \to E$ such that $p \circ s = \mathrm{id}_X$. We say a section is non-vanishing if $s(x) \neq 0$ for all $x \in X$.

Lemma 143.3. Let $p\colon E \to X$ be a vector bundle.

(1) The map $X \to E$ that sends each $x \in X$ to the unique zero element of $p^{-1}(x)$ is a section.
(2) If $s, t\colon X \to E$ are two sections, then the map $x \mapsto s(x) + t(x)$ is also a section.
(3) If $s\colon X \to E$ is a section and $\lambda \in \mathbb{R}$, then the map $x \mapsto \lambda \cdot s(x)$ is also a section.

Proof. We need to show that the given maps $X \to E$ are continuous. By the Pasting Proposition 2.6 we have to verify continuity only locally. But locally the statement follows easily from the definition of a vector bundle. ■

Examples.

(1) Given a vector bundle $p\colon E \to X$ a section $s\colon X \to E$ is given by sending each $y \in E$ to the zero-element of the vector space $p^{-1}(y)$.[1697] This section is usually called the zero-section of p.

(2) Let M be a smooth manifold. A section of the tangent bundle is usually called a vector field on M. A little bit of thought shows that this is is precisely the notion that we introduced on page 639 and that, given a submanifold M of $\mathbb{R}^n$, this definition of a vector field corresponds in a natural way to the notion that we introduced on page 638.

Lemma 143.4. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$.

(1) Given any n-dimensional $\mathbb{K}$-vector bundle $p\colon E \to X$ the following two statements are equivalent:
   (a) The $\mathbb{K}$-vector bundle is trivializable.
   (b) There exist n sections $s_1, \dots, s_n$ such that for every point $x \in X$ the vectors $s_1(x), \dots, s_n(x) \in E_x := p^{-1}(x)$ form a basis of the $\mathbb{K}$-vector space $E_x = p^{-1}(x)$.

(2) A line bundle is trivializable if and only if it admits a non-vanishing section.

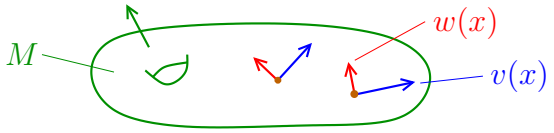
(3) If M is an orientable 2-dimensional smooth manifold, then its tangent bundle is trivializable if and only if it admits a non-vanishing vector field.

Sketch of proof.

(1) Let $p\colon E \to X$ be an n-dimensional $\mathbb{K}$-vector bundle. Suppose that there exists an isomorphism $\varphi\colon X \times \mathbb{K}^n \to E$ of $\mathbb{K}$-vector bundles over X. It is clear that in this case the maps $s_i\colon x \mapsto \varphi(x, e_i)$, $i = 1, \dots, n$, define sections such that for each $x \in X$ the vectors $s_1(x), \dots, s_n(x) \in E_x = p^{-1}(x)$ form a basis of $E_x = p^{-1}(x)$. Conversely, if we are given such sections, then the map

$$\begin{array}{rcl} X \times \mathbb{K}^n & \to & E \\ (x, (\lambda_1, \dots, \lambda_n)) & \mapsto & \sum_{i=1}^{n} s_i(x) \cdot \lambda_i \end{array}$$

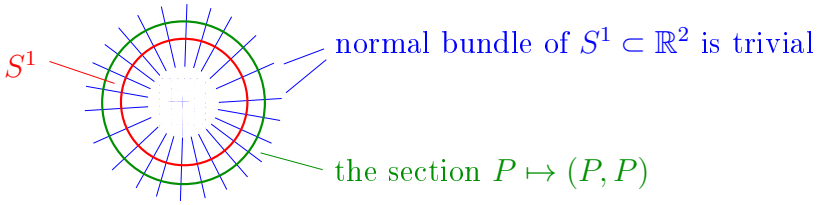
   is easily seen to be an isomorphism of $\mathbb{K}$-vector bundles over X.



(2) This statement is an immediate consequence of (1).

[1697] It is a good exercise in practicing the definitions to convince oneself that this map $s\colon X \to E$ is indeed continuous.

(3) Let M be an orientable 2-dimensional smooth manifold. By (1) we only have to show the following statement: if M admits a non-vanishing vector field v, then the tangent bundle is trivializable. So suppose that v is a non-vanishing vector field on M. We pick an orientation for M. By [**Lee2000**, Proposition 13.3] the smooth manifold M admits a Riemannian structure g.[1698] Since M is 2-dimensional and oriented we can now define

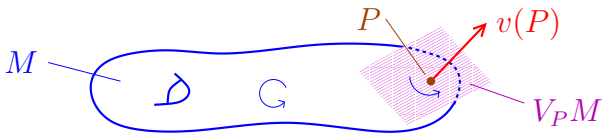


$$\begin{array}{rcl} w\colon M & \to & \mathrm{T}M \\ x & \mapsto & \begin{array}{l}\text{unique vector } w(x) \in \mathrm{T}_x M \text{ that has the following three properties:} \\ \text{(a)} \quad g(v(x), w(x)) = 0, \text{ i.e. } v(x) \text{ and } w(x) \text{ are orthogonal,} \\ \text{(b)} \quad g(w(x), w(x)) = 1, \text{ i.e. } w(x) \text{ has length one,} \\ \text{(c)} \quad \text{the vectors } v(x) \text{ and } w(x) \text{ form a positive basis for } \mathrm{T}_x M\end{array} \end{array}$$

(We refer to the figure below for an illustration of the definition of $w(x)$.) It is fairly easy to see that this is a section of the tangent bundle. It has the property that for each $x \in M$ the vectors $v(x)$ and $w(x)$ form a basis for $\mathrm{T}_x M$. Thus it follows from (1) that $\mathrm{T}M$ is a trivial bundle. ■

Examples.

(1) By Lemma 143.4 (2) the normal bundle of $S^n \subset \mathbb{R}^{n+1}$ is trivializable since it admits the non-vanishing section $P \mapsto (P, P)$. We illustrate this statement for $n = 1$ in the figure below.



(2) We can easily generalize the previous example. More precisely, let $n \in \mathbb{N}$ and let M be a closed oriented submanifold of $\mathbb{R}^n$ of codimension one. The map

$$\begin{array}{rcl} v\colon M & \to & NM \\ P & \mapsto & \begin{array}{c}\text{the unique vector } v(P) \in \mathbb{R}^n \text{ of length one that is normal to } \widetilde{\mathrm{T}}_P M \\ \text{and which, followed by a positive basis for } \widetilde{\mathrm{T}}_P M, \\ \text{forms a positive basis for } \mathbb{R}^n\end{array} \end{array}$$

is easily seen to be a section of the normal bundle. Since the normal bundle is one-dimensional we obtain from Lemma 143.4 (2) that the normal bundle of $M \subset \mathbb{R}^n$ is trivializable. We refer to the figure below for an illustration.

(3) In Exercise 143.6 we will show that the Möbius bundle does not admit a non-vanishing section. It follows from Lemma 143.4 (2) that the Möbius bundle is non-trivial.

[1698] We refer to page 1426 for the definition of a Riemannian structure.

(4) It follows from the Hairy Ball Theorem 38.12 and Lemma 143.4 (1) that even-dimensional spheres are not parallelizable.
(5) For any $n \in \mathbb{N}$ the n-dimensional torus $(S^1)^n = \mathbb{R}^n/\mathbb{Z}^n$ is parallelizable, in fact if we denote by $q\colon \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ the projection , then an isomorphism of vector bundles over $\mathbb{R}^n/\mathbb{Z}^n$ is given by

$$\begin{aligned} \varphi\colon (\mathbb{R}^n/\mathbb{Z}^n) \times \mathbb{R}^n &\to \mathrm{T}(\mathbb{R}^n/\mathbb{Z}^n) \\ (q(x), v) &\mapsto (q(x), \underset{\uparrow}{\mathrm{D}q_x}(v)) \end{aligned}$$

$$\mathrm{D}q_x\colon \mathbb{R}^n = \mathrm{T}_x\mathbb{R}^n \to \mathrm{T}_{q(x)}(\mathbb{R}^n/\mathbb{Z}^n)$$

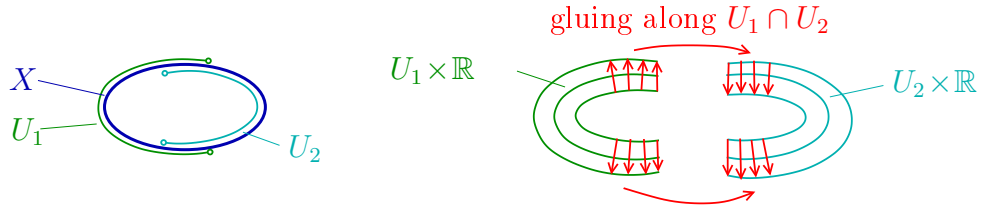
(6) Let $g \in \mathbb{N}_0$. On page 1879 we calculated that the Euler characteristic of the surface of genus g equals $\chi(\Sigma_g) = 2 - 2g$. Thus if $g \neq 1$ we obtain from the Euler Characteristic-Vector Field Theorem 97.15, which is a generalization of the Hairy Ball Theorem 38.12, together with Lemma 143.4 (1) that the surface of genus g is not parallelizable.
(7) If a smooth manifold is parallelizable, then evidently it is also orientable in the sense of Section 25.2. Put differently, a non-orientable smooth manifold is not parallelizable.
(8) Every closed orientable 3-manifold is parallelizable. This was first proved by Eduard Stiefel [**Stie1935**] in 1935. An elementary proof for this statement is given in [**BeL18**]. Alternative proofs can be found in [**DGGK2020**] and [**Kir1989**, p. 46].
(9) Let M and N be closed smooth manifolds. If M and N are parallelizable, then one can easily show that $M \times N$ is also parallelizable.

143.2. **Constructing vector bundles via transition maps.** The starting point of this section is the following lemma which says that we can construct vector bundles by specifying "transition maps".

Lemma 143.5. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, let X be a topological space and let $\{U_i\}_{i\in I}$ be family of subsets of X such that $\bigcup_{i\in I} \mathring{U}_i = X$. Furthermore let $n \in \mathbb{N}_0$. Suppose that for every $i, j \in I$ we have a map $\varphi_{ij}\colon U_i \cap U_j \to \mathrm{GL}(n, \mathbb{K})$ such that the following conditions are satisfied:

(1) For every $i, j, k \in I$ we have $\varphi_{jk} \circ \varphi_{ij} = \varphi_{ik}\colon U_i \cap U_j \cap U_k \to \mathrm{GL}(n, \mathbb{K})$.
(2) For every $i, j \in I$ and any $x \in U_i \cap U_j$ we have $\varphi_{ij}(x) = \varphi_{ji}(x)^{-1}$.

The map



$$\begin{aligned} p\colon \Big(\bigsqcup_{i\in I}(U_i \times \mathbb{K}^n)\Big)\Big/\underset{\downarrow}{(x, v) \sim (x, \varphi_{ij}(x)\cdot v)} &\to X \\ [(x, v)] &\mapsto x, \end{aligned}$$

$$\text{where } x \in U_i \cap U_j$$

together with the obvious $\mathbb{K}$-vector space structure on each $p^{-1}(x)$, is an n-dimensional $\mathbb{K}$-vector bundle over X.

Example. We consider $X = S^1$ and two open overlapping intervals $U_1, U_2 \subset X = S^1$. Let $\varphi\colon U_1 \cap U_2 \to \mathrm{GL}(1, \mathbb{R})$ be the map that equals (1) on one component of $U_1 \cap U_2$ and that

equals (-1) on the other component of $U_1 \cap U_2$. It is fairly straightforward to see that the resulting real vector bundle is isomorphic to the Möbius bundle. We refer to the figure below for an illustration.

Proof. Let $i \in I$. It follows fairly easily from (1) and (2) that the map

$$\begin{array}{ccc} U_i \times \mathbb{K}^n & \xrightarrow{(x,v)\mapsto[(x,v)]} & p^{-1}(U_i) \\ & {\scriptstyle (x,v)\mapsto x} \searrow \quad \swarrow {\scriptstyle p} & \\ & U_i & \end{array}$$

is a well-defined isomorphism of $\mathbb{K}$-vector bundles over U_i. Since the interiors of the U_i cover all of X we see that p is indeed an n-dimensional $\mathbb{K}$-vector bundle over X. ∎

We also have the following converse to Lemma 143.5.

Lemma 143.6. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Every $\mathbb{K}$-vector bundle $p\colon E \to X$ admits an isomorphism to a $\mathbb{K}$-vector bundle of the type constructed in Lemma 143.5.

Proof. Let $p\colon E \to X$ be an n-dimensional $\mathbb{K}$-vector bundle. Note that by definition of a vector bundle we know that there exists an open cover $\{U_i\}_{i\in I}$ such that the restriction of $p\colon E \to X$ to each U_i is trivializable. It follows from Lemma 143.2 that given any $i \in I$ there exists a map $\Theta_i\colon p^{-1}(U_i) \to \mathbb{K}^n$ such that $p \times \Theta_i\colon p^{-1}(U_i) \to U_i \times \mathbb{K}^n$ is a trivialization. Given $x \in U_i$ we write $\Theta_{i,x} := \Theta_i|_{E_x}$. Next, given $i, j \in I$ we consider the map

$$\begin{array}{rcl} \varphi_{ij}\colon U_i \cap U_j & \to & \mathrm{GL}(n,\mathbb{K}) = \mathrm{Aut}(\mathbb{K}^n) \\ x & \mapsto & \Theta_{i,x} \circ \Theta_{j,x}^{-1} = \left(\mathbb{K}^n \xrightarrow{\Theta_{j,x}^{-1}} E_x \xrightarrow{\Theta_{i,x}} \mathbb{K}^n\right) \end{array}$$

One can now easily verify that the map

$$\begin{array}{rcll} p\colon \left(\bigsqcup_{i\in I}(U_i \times \mathbb{K}^n)\right)/(x,v) \sim (x, \varphi_{ij}(x)\cdot v) & \to & E & \\ [(x,v)] & \mapsto & (p \times \Theta_i)^{-1}(x,v) & \text{if } x \in U_i \end{array}$$

is an isomorphism of $\mathbb{K}$-bundles over X. ∎

Corollary 143.7. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, let $n \in \mathbb{N}_0$ and let X be a topological space. The isomorphism classes of n-dimensional $\mathbb{K}$-vector bundles over X form a set.

Proof. This statement follows immediately from Lemma 143.6, modulo the minor nuisance that we never said what a set is. The less this particular author says about set theory, the better. ∎

Corollary 143.7 leads us to the following notation.

Notation. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ and let X be a topological space. Given $n \in \mathbb{N}_0$ we denote by $\mathrm{Vect}^n_{\mathbb{K}}(X)$ the set of isomorphism classes of n-dimensional $\mathbb{K}$-vector bundles over X.

143.3. **The pullback of vector bundles.** In this section and the coming sections we will introduce several constructions for obtaining new vector bundles out of given vector bundles. Before we head to the constructions it is helpful to introduce the following definition.

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. A bundle map between $\mathbb{K}$-vector bundles $p\colon E \to X$ and $q\colon F \to Y$ is a pair of maps $\Phi\colon E \to F$ and $\varphi\colon X \to Y$ such that the following two conditions are satisfied:

(1) The following diagram commutes:

$$\begin{array}{ccc} E & \xrightarrow{\Phi} & F \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{\varphi} & Y. \end{array}$$

(2) For each $x \in X$ the map $\Phi|_{E_x}\colon E_x \to F_{\varphi(x)}$ is a homomorphism of $\mathbb{K}$-vector spaces.

One can easily verify that the class of $\mathbb{K}$-vector bundles together with the above notion of morphisms and the obvious composition of bundle maps form a category. We refer to it as the category $\mathcal{VectBund}_{\mathbb{K}}$ of $\mathbb{K}$-vector bundles.

Remark. The author now faces a dilemma: given two vector bundles $p\colon E \to X$ and $q\colon E \to X$ over the same topological space X we now have two conflicting definitions for p and q to be "isomorphic". We have the definition on page 3060 which agrees with the above definition as long as $\varphi = \mathrm{id}_X$. In the discussion below we will almost invariably work with the former definition. Hopefully it is always clear from the context what is meant.

The following lemma, which is just a special case of Lemma **??** introduces the pullback of vector bundles.

Lemma 143.8. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, let $g\colon X \to Y$ be a map between topological spaces and let $q\colon F \to Y$ be an n-dimensional $\mathbb{K}$-vector bundle. As in the Topological-Pullback Lemma 56.16 (1) we consider the pullback

$$g^*F \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(g(x))\} \;\subset\; X \times F,$$

which is equipped with the subspace topology.

(1) The map
$$\begin{array}{rcl} p\colon g^*F \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(g(x))\} & \to & X \\ (x,v) & \mapsto & x \end{array}$$
is also an n-dimensional $\mathbb{K}$-vector bundle where for each $x \in X$ the $\mathbb{K}$-vector space structure on $p^{-1}(x) = \{x\} \times q^{-1}(g(x)) \subset X \times F$ is the obvious $\mathbb{K}$-vector space structure coming from $\{x\} \times q^{-1}(g(x)) = q^{-1}(g(x))$.

(2) The following diagram commutes
$$\begin{array}{ccc} g^*F & \xrightarrow{(x,v)\mapsto v} & F \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{g} & Y, \end{array}$$
in other words, the horizontal maps define a bundle map.

(3) If we are given a bundle map

$$\begin{array}{ccc} E & \xrightarrow{\Phi} & F \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{\varphi} & Y \end{array}$$

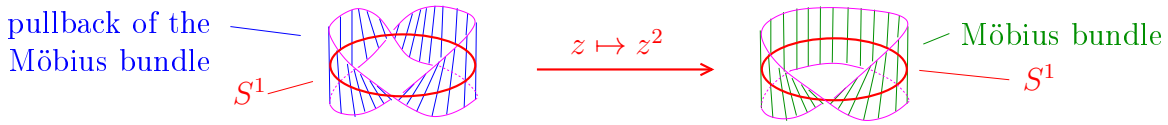
such that for each $x \in X$ the map $\Phi|_{E_x} \colon E_x \to F_{\varphi(x)}$ is an isomorphism, then the $\mathbb{K}$-vector bundle $E \to X$ is naturally isomorphic to the pullback $\varphi^* F \to X$.

Proof.

(1) Let $x \in X$. By Lemma 143.2 there exists a neighborhood $V \subset Y$ of $g(x)$ and a map $\varphi \colon q^{-1}(V) \to \mathbb{K}^n$ such that $q \times \varphi \colon q^{-1}(V) \to V \times \mathbb{K}^n$ is a trivialization. We consider the open neighborhood $U := g^{-1}(V) \subset X$ of x. It is now straightforward to verify that the map

$$\begin{array}{rcl} \psi \colon p^{-1}(U) & \to & U \times \mathbb{K}^n \\ (z, v) & \mapsto & (p(z), \varphi(v)) \end{array}$$

note that $v \in q^{-1}(g(z))$ and that $g(z) \in g(U) = V$



is a trivialization of the restriction of p to U.

(2) It is straightforward to verify that the diagram commutes.

(3) We consider the map $E \to g^* F$ given by $e \mapsto (\Phi(e), \varphi(p(e)))$. We leave it to the reader to verify that this map is a bundle isomorphism. ∎

Definition. Using the notation from Lemma 143.8 we refer to $g^* F \to X$ as the pullback of the $\mathbb{K}$-vector bundle $q \colon F \to Y$ under the map $g \colon X \to Y$.

Example. Let $p \colon M \to S^1$ be the Möbius bundle. We denote by $g \colon S^1 \to S^1$ the map that is given by $g(z) = z^2$. In Exercise 143.9 we will see that the pullback of the Möbius bundle under g is a trivial bundle. We refer to the figure below for an illustration of the pullback of the Möbius bundle.[1699]

The following lemma, which is basically just a slight variation on Lemma **??**, summarizes a few properties of the pullback of vector bundles.

Lemma 143.9. (Vector Bundle Pullback Lemma) Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$.

(1) Let $g \colon X \to Y$ be a map between two topological spaces and let $E \to Y$ and $F \to Y$ be two $\mathbb{K}$-vector bundles on Y. If E and F are isomorphic, then so are $g^* E$ and $g^* F$.

(2) The pullback of a trivializable $\mathbb{K}$-vector bundle is again a trivializable $\mathbb{K}$-vector bundle.

(3) If $q \colon F \to Y$ is a $\mathbb{K}$-vector bundle and if X is a subset of Y with inclusion map $i \colon X \to Y$, then

[1699] The reader who is blessed with a good memory might recognize that this statement is quite similar to the discussion on page 1070 where we saw that the annulus is a 2-fold covering of the Möbius band.

$$\begin{array}{rcl} i^*F & \to & q^{-1}(X) \\ (x,v) & \mapsto & v \end{array}$$

is a natural isomorphism from the $\mathbb{K}$-vector bundle $i^*F \to X$ to the restriction of F to the $\mathbb{K}$-vector bundle $q^{-1}(X) \to X$.

Proof. The proof of this lemma is basically identical to the not very substantial proof of Lemma **??**. We just need to replace Lemma **??** (3) by Lemma 143.8 (3). ■

The following lemma, which is basically just a slight variation on Lemma **??**, shows that the pullback of vector bundles is covariantly functorial in a suitable sense.

Lemma 143.10. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$.

(1) Let $q\colon F \to Z$ be a $\mathbb{K}$-vector bundle. Then

$$\begin{array}{rcl} \mathrm{id}_Z^* F & \to & F \\ (x,v) & \mapsto & v \end{array}$$

is a natural isomorphism from the pullback $\mathbb{K}$-vector bundle $\mathrm{id}_Z^* F \to Z$ to the original $\mathbb{K}$-vector bundle $q\colon F \to Z$.

(2) Let $q\colon F \to Z$ be a $\mathbb{K}$-vector bundle. If $f\colon X \to Y$ and $g\colon Y \to Z$ are maps between topological spaces, then

$$\begin{array}{rcl} f^*(g^*F) & \to & (g \circ f)^*F \\ (x,(y,v)) & \mapsto & (x,v) \end{array}$$

is a natural isomorphism from the double pullback $\mathbb{K}$-vector bundle $f^*(g^*F) \to X$ to the pullback $\mathbb{K}$-vector bundle $(g \circ f)^*F \to X$.

Proof. The proof of this lemma is basically identical to the not very substantial proof of Lemma **??**. Again we just need to replace Lemma **??** (3) by Lemma 143.8 (3). ■

Corollary 143.11. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$.

(1) Given any map $g\colon X \to Y$ between two topological spaces the pullback of $\mathbb{K}$-vector bundles induces a well-defined map

$$\begin{array}{rcl} f^*\colon \mathrm{Vect}_{\mathbb{K}}^n(Y) & \to & \mathrm{Vect}_{\mathbb{K}}^n(X) \\ [q\colon F \to Y] & \mapsto & [g^*F \to X]. \end{array}$$

(2) The maps

$$\begin{array}{rcl} X & \to & \mathrm{Vect}_{\mathbb{K}}^n(X) \\ (g\colon X \to Y) & \to & (g^*\colon \mathrm{Vect}_{\mathbb{K}}^n(Y) \to \mathrm{Vect}_{\mathbb{K}}^n(X)) \end{array}$$

define a contravariant functor from the category $\mathcal{T}op$ of topological spaces to the category of sets $\mathcal{S}et$.

Remark. By using "linear algebra of vector bundles", we will see that $\bigcup_{n \in \mathbb{N}_0} \mathrm{Vect}_{\mathbb{K}}^n(X)$ is "more than a set", namely that we can endow it with two monoid structures corresponding to the direct sum and tensor product. Thus we will upgrade Corollary 143.11 to a functor from the category of topological spaces to an algebraic category.

Proof. The first statement is an immediate consequence of the Vector Bundle Pullback Lemma 143.9 (0), whereas The first statement is an immediate consequence of the Vector Bundle Pullback Lemma 143.9 (3) and (4). ■

Later on we will need the following lemma.

Lemma 143.12.

(1) If $f\colon M \to N$ is a local diffeomorphism between smooth manifolds, then the map

$$\begin{array}{ccc} \mathrm{T}M & \to & f^*\mathrm{T}N \\ (x,v) & \mapsto & (x, \underbrace{(f(x), \mathrm{D}f_x(v))}_{\in \mathrm{T}N}) \end{array}$$

is a natural isomorphism of real vector bundles.

(2) If $p\colon \widetilde{M} \to M$ is a covering of a smooth manifold, then $p^*\mathrm{T}M$ is naturally isomorphic to $T\widetilde{M}$.

Proof. We rely on the never-ending energy of the reader to provide the proof of the first statement. The second statement is an immediate consequence of the first statement. ■

In the remainder of this chapter we will use on several occasions the notion of a "paracompact" topological space that we introduced on page 354. We will use the explicit definition only in the proof of the Vector Bundles-Homotopies Proposition 143.13. Otherwise it is enough to know that most topological spaces that we are interested in are paracompact. For example we established in the Manifold Paracompact-Normal Proposition 18.9 (1) and the CW-Complex Paracompactness Proposition 68.13 that all topological manifolds and all CW-complexes are paracompact.

Remark. Some books, see e.g. [**Hat2**, p. 77], make at some point the blanket assumption that all base spaces of vector bundles are paracompact.

The following proposition is one of the key statements in the theory of vector bundles.

Proposition 143.13. (Vector Bundles-Homotopies Proposition) Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$.

(1) Let $q\colon F \to Y$ be a $\mathbb{K}$-vector bundle, let X be a topological space and finally let $f_0, f_1\colon X \to Y$ be two maps. If f_0 and f_1 are homotopic and if X is paracompact, then the $\mathbb{K}$-vector bundles $f_0^*F \to X$ and $f_1^*F \to X$ are isomorphic. In fact any choice of a homotopy induces naturally an isomorphism between the two $\mathbb{K}$-vector bundles.

(2) Let X and Y be two paracompact spaces. If $f\colon X \to Y$ is a homotopy equivalence, then the map

$$f^*\colon \mathrm{Vect}^n_{\mathbb{K}}(Y) \to \mathrm{Vect}^n_{\mathbb{K}}(X),$$

that we introduced in Corollary 143.11, is a bijection.

(3) Let X be a topological space. If X is contractible and if X is paracompact (e.g. if X compact), then every $\mathbb{K}$-vector bundle over X is trivializable.

Example. It follows immediately from the aforementioned fact that topological manifolds are paracompact, see the Manifold Paracompact-Normal Proposition 18.9 (1), together with the Vector Bundles-Homotopies Proposition 143.13 (3) that every $\mathbb{K}$-vector bundle over the topological spaces $\overline{B}^n, B^n$ and $\mathbb{R}^n$ is trivializable.

The key to proving the Vector Bundles-Homotopies Proposition 143.13 is the following lemma.

Lemma 143.14. Let X be a paracompact space and let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. We denote by $i_0 \colon X \xrightarrow{x \mapsto (x,0)} X \times [0,1]$ and $i_1 \colon X \xrightarrow{x \mapsto (x,1)} X \times [0,1]$ the obvious embeddings. Given any $\mathbb{K}$-vector bundle $p \colon E \to X \times [0,1]$ the pullbacks $i_0^* E$ and $i_1^* E$ are isomorphic.

Remark. Note that Lemma 143.14 does not say that the $i_0^* E$ and $i_1^* E$ are *naturally* isomorphic. In fact, as we will see in Exercise 143.15, the isomorphism we provide depends on choices.

Before we provide the proof of Lemma 143.14 let us first show that the Vector Bundles-Homotopies Proposition 143.13 is a pretty straightforward consequence of Lemma 143.14.

Proof of the Vector Bundles-Homotopies Proposition 143.13 assuming Lemma 143.14.

(1) Let $q \colon F \to Y$ be a $\mathbb{K}$-vector bundle, let X be a topological space that is paracompact and let $H \colon X \times [0,1] \to Y$ be a homotopy between two maps $f_0, f_1 \colon X \to Y$. We denote by $i_0, i_1 \colon X \to X \times [0,1]$ the two obvious inclusions. Now we see that

$$\begin{array}{ccccccccc} f_0^* F & = & (H \circ i_0)^* F & \overset{\text{by the Vector Bundle Pullback Lemma 143.9}}{\cong} & \mathrm{H}^*(i_0^* F) & \underset{\text{Lemma 143.14}}{\cong} & \mathrm{H}^*(i_1^* F) & \overset{\text{by the Vector Bundle Pullback Lemma 143.9}}{\cong} & (H \circ i_1)^* F & = & f_1^* F. \\ & \uparrow & & & & & & & & \uparrow & \\ & \text{since } f_0 = H \circ i_0 & & & & & & & & \text{since } f_1 = H \circ i_1 & \end{array}$$

(2) Let $g \colon Y \to X$ be a homotopy inverse to f. Recall that this means that $f \circ g$ is homotopic to id_Y and that $g \circ f$ is homotopic to id_X. We consider the induced maps $f^* \colon \mathrm{Vect}_{\mathbb{K}}^n(Y) \to \mathrm{Vect}_{\mathbb{K}}^n(X)$. We have

$$\begin{array}{ccccc} g^* \circ f^* & = & (f \circ g)^* & = & \mathrm{id}_Y^* & = & \mathrm{id}_{\mathrm{Vect}_{\mathbb{K}}^n(Y)}. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Corollary 143.11 (2)} & & \underset{\text{since } f \circ g \simeq \mathrm{id}_Y}{\text{by Statement (1)}} & & \text{Corollary 143.11 (2)} & \end{array}$$

Similarly we see that $f^* \circ g^* = \mathrm{id}_{\mathrm{Vect}_{\mathbb{K}}^n(X)}$.

(3) Let $F \to X$ be a $\mathbb{K}$-vector bundle over a topological space that is paracompact and contractible. By definition of being contractible there exists a homotopy equivalence from the topological space X to the topological space $\{*\}$ consisting of a single point. Since every $\mathbb{K}$-vector bundle over $\{*\}$ is trivializable it follows from (2) and the Vector Bundle Pullback Lemma 143.9 (1) that every $\mathbb{K}$-vector bundle over X is trivializable. ∎

We conclude this section with the proof of Lemma 143.14.

Proof of Lemma 143.14. [1700] Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$.

Claim 1. Let $p \colon F \to Y \times [a,c]$ be an n-dimensional $\mathbb{K}$-vector bundle and let $b \in [a,c]$. If the restrictions of p to $Y \times [a,b]$ and to $Y \times [b,c]$ are both trivializable, then so is the restriction to $Y \times [a,c]$.

Proof. Since the restrictions of p to $Y \times [a,b]$ and to $Y \times [b,c]$ are both trivializable we can pick trivializations $\Phi \colon p^{-1}(Y \times [a,b]) \to \mathbb{K}^n \times Y \times [a,b]$ and $\Psi \colon p^{-1}(Y \times [b,c]) \to \mathbb{K}^n \times Y \times [b,c]$. We denote by $q \colon \mathbb{K}^n \times Y \times [a,c] \to \mathbb{K}^n$ the projection. It follows almost immediately from Proposition 143.18 that there exists a continuous map $\Theta \colon Y \times \{b\} \to \mathrm{GL}(\mathbb{K}, n)$ such that

[1700] The structure of the proof is somewhat similar to the idea behind the proof of the Topological Collar Neighborhood Theorem 75.5.

for all $v \in p^{-1}(Y \times \{b\})$ we have $q(\Phi(v)) = \Theta(p(v)) \cdot q(\Psi(v)) \in \mathbb{K}^n$. It is straightforward to verify that

$$\begin{array}{rcl} p^{-1}(Y \times [a,c]) & \to & \mathbb{K}^n \times Y \times [a,c] \\ v & \mapsto & \begin{cases} \Phi(v), & \text{if } p(v) \in Y \times [a,b], \\ (p(v), \Theta(p(y,b)) \cdot q(\Psi(v))), & \text{if } p(v) = (y,t) \in Y \times [b,c] \end{cases} \end{array}$$

is an isomorphism of $\mathbb{K}^n$-vector bundles. ⊞

Now let X be a paracompact space and $p\colon E \to X \times [0,1]$ be an n-dimensional $\mathbb{K}$-vector bundle.

Claim 2. There exists an open cover $\{U_i\}_{i \in I}$ of X such that the restriction of the $\mathbb{K}$-vector bundle $p\colon E \to X \times [0,1]$ to each $U_i \times [0,1]$ is trivializable.

Proof. Let $x \in X$. By definition of a vector bundle and by compactness of $[0,1]$ there exist neighborhoods $V_1, \dots, V_m$ of x and $0 = t_0 < \cdots < t_m = 1$ such that the restriction of $p\colon E \to X \times [0,1]$ to each $V_i \times [t_{i-1}, t_i]$ is trivial. It follows from Claim 1 and Lemma 143.2 (2) that the restriction of p to $(V_1 \cap \cdots \cap V_m) \times [0,1]$ is also trivial. Now we set $U_x := V_1 \cap \cdots \cap V_m$. The resulting sets $\{U_x\}_{x \in X}$ have the desired properties. ⊞

By Claim 2 there exists an open cover $\{U_i\}_{i \in I}$ of X such that the restriction of p to any $U_i \times [0,1]$ is trivializable. By the Countable Cover Proposition 10.11 there exists a *countable* locally finite open cover $\{V_k\}_{k \in \mathbb{N}_0}$ such that each component of any V_k is contained in some U_i. Note that it follows from Lemma 143.2 that the restriction of p to any $V_k \times [0,1]$ is also trivial and that for each $k \in \mathbb{N}_0$ there exists a map $\Phi_k\colon p^{-1}(V_k \times [0,1]) \to \mathbb{K}^n$ such that $p \times \Phi_k$ is a trivialization of the vector bundle over V_k.

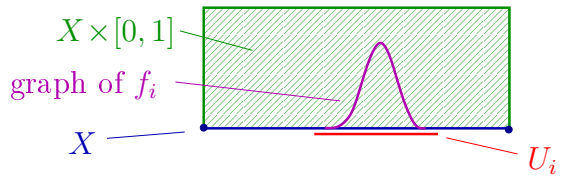
Next note that it follows from the Paracompact-Partition of Unity Theorem 10.9 that there exists a countable partition of unity $\{f_k\colon X \to [0,1]\}_{k \in \mathbb{N}_0}$ such that for each $k \in \mathbb{N}_0$ we have $\operatorname{supp}(f_k) \subset V_k$. Given $i \in \mathbb{N}_0$ we set $g_i := f_0 + \cdots + f_{i-1}$ and we set

$$X_i \;:=\; \text{graph of } g_i\colon X \to [0,1] \;:=\; \{(x, g_i(x)) \,|\, x \in X\} \;\subset\; X \times [0,1].$$

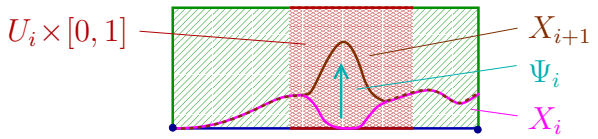
Note that $X_0 = X \times \{0\}$. We also set $X_\infty = X \times \{1\}$. Given $i \in \mathbb{N}_0 \cup \{\infty\}$ we write $E_i := p^{-1}(X_i)$. Next we consider the map

$$\begin{array}{rcl} \Psi_i\colon E_i & \to & E_{i+1} \\ v & \mapsto & \begin{cases} v, & \text{if } p(v) \notin U_i \times [0,1], \\ (p \times \Phi_i)^{-1}\underbrace{(x, g_{i+1}(x), \Phi_i(v))}_{\in U_i \times [0,1] \times \mathbb{K}^n}, & \text{if } p(v) = (x, g_i(x)) \in U_i \times [0,1]. \end{cases} \end{array}$$

We combine these maps to obtain the map



$$\begin{array}{rcll} \Theta\colon E_0 & \to & E_\infty & \\ x & \mapsto & \Psi_k(\dots(\Psi_0(x))) & \text{if } k \in \mathbb{N}_0 \text{ with } g_k(x) = 1. \end{array}$$



It follows immediately from the definitions that this map is well-defined, i.e. it does not depend on the choice of $k \in \mathbb{N}_0$ for a given x. Using this observation it is straightforward to verify that Ψ is continuous. Finally note that, basically by construction, the following

diagram commutes and that it defines an isomorphism of $\mathbb{K}$-vector bundles.

$$\begin{array}{ccc} E_0 = p^{-1}(X\times\{0\}) & \xrightarrow{\quad\Theta\quad} & E_\infty = p^{-1}(X\times\{1\}) \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X\times\{0\} & \xrightarrow{\quad(x,0)\mapsto(x,1)\quad} & X\times\{1\}. \end{array}$$

Together with the Vector Bundle Pullback Lemma 143.9 (2) this implies that the pullbacks i_0^*E and i_1^*E are isomorphic. ■

143.4. **The Grassmannian manifolds.** Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. On page 3060 we saw that the projective spaces $\mathbb{K}\mathrm{P}^n$ come with a tautological line bundle. The projective space $\mathbb{K}\mathrm{P}^n$ admits an obvious bijection with the set of all 1-dimensional subspaces of $\mathbb{K}^{n+1}$. With this view point the fiber of each point in $\mathbb{K}\mathrm{P}^n$ is precisely this 1-dimensional subspace. In the following we generalize this construction to higher-dimensional subspaces to obtain interesting higher-dimensional vector bundles.

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Given natural numbers $n, k \in \mathbb{N}$ we consider

$$G(n,k,\mathbb{K}) \;:=\; \text{the set of all } n\text{-dimensional linear subspaces of } \mathbb{K}^{n+k}.$$

To equip the set $G(n,k,\mathbb{K})$ with a topology we first note that we have a surjection[1701]

$$\begin{array}{rcl} \overbrace{\left\{\begin{array}{c}\text{all } n\text{-tuples } (v_1,\dots,v_n) \text{ of vectors in } \mathbb{K}^{n+k} \\ \text{that are linearly independent}\end{array}\right\}}^{\text{open subset of } \mathbb{K}^{n(n+k)}} & \to & G(n,k,\mathbb{K}) \\ (v_1,\dots,v_n) & \mapsto & \begin{array}{c}\text{subspace of } \mathbb{K}^{n+k} \\ \text{spanned by } v_1,\dots,v_n.\end{array} \end{array}$$

We equip $G(n,k,\mathbb{K})$ with the quotient topology. We refer to $G(n,k,\mathbb{K})$ as a real Grassmannian respectively complex Grassmannian.[1702] Next note that by definition we have $G(1,n,\mathbb{K}) = \mathbb{K}\mathrm{P}^n$. With some modest effort one can show that

$$\begin{array}{rcl} T := \overbrace{\{(V,w)\,|\,V\in G(n,k,\mathbb{K}) \text{ and } w\in V\}}^{\subset G(n,k,\mathbb{K})\times\mathbb{K}^n} & \to & G(n,k,\mathbb{K}) \\ (V,w) & \mapsto & V \end{array}$$

is an n-dimensional $\mathbb{K}$-vector bundle. With a little bit of thought one can show that the maps $\mathbb{K}^{n+k} \xrightarrow{v\mapsto(v,0)} \mathbb{K}^{n+k}\times\{0\} \subset \mathbb{K}^{n+k+1}$ induce embeddings $G(n,k,\mathbb{K}) \to G(n,k+1,\mathbb{K})$ and we refer to the direct limit as infinite real (respectively complex) Grassmannian $G(n,\mathbb{K})$. The n-dimensional $\mathbb{K}$-vector bundles over $G(n,k,\mathbb{K})$ give rise to an n-dimensional $\mathbb{K}$-vector bundle over $G(n,\mathbb{K})$. We refer to this $\mathbb{K}$-vector bundle as the tautological $\mathbb{K}$-vector bundle over the $\mathbb{K}$-Grassmannian.

Remark.

(1) A little bit of thought shows that we can identify $G(n, \mathbb{K})$ with the set of n-dimensional linear subspaces of $\mathbb{K}^\infty$.
(2) It is shown in [**MiS1974**, p. 56] (see also [**Wel2008**, Example 1.8] and [**Hat2**, p. 28 and 34]) that one can equip $G(n, k, \mathbb{K})$ with a smooth atlas such that $G(n, k, \mathbb{K})$ becomes a closed orientable nk-dimensional smooth (complex) manifold. We will not make use of this pretty fact.

Initially these tautological vector bundles might appear only mildly interesting. But rather stunningly they can be viewed as the "mother of all vector bundles". More precisely, the following proposition says that every n-dimensional $\mathbb{K}$-vector bundle is the pullback of the tautological bundle over the infinite Grassmannian $G(n, \mathbb{K})$ in an "essentially unique way".

Proposition 143.15. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. We denote by $T \to G(n, \mathbb{K})$ the tautological n-dimensional $\mathbb{K}$-vector bundle over the infinite Grassmannian $G(n, \mathbb{K})$ that we introduced on page 3074. Let X be a paracompact space. The following two statements hold:

(1) Given any n-dimensional $\mathbb{K}$-vector bundle $p\colon E \to X$ over X there exists a map $g\colon X \to G(n, \mathbb{K})$ such that g^*T is isomorphic to E.
(2) If $g_0, g_1\colon X \to G(n, \mathbb{K})$ are maps such that the $\mathbb{K}$-vector bundles g_0^*T and g_1^*T over X are isomorphic, then g_0 and g_1 are homotopic.

Before we turn to the proof of Proposition 143.15 let us formulate the following almost immediate corollary.

Corollary 143.16. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ and let X be a topological space that is paracompact. Given any $n \in \mathbb{N}_0$ we have a bijection

$$\begin{array}{rcl} [X, G(n, \mathbb{K})] & \to & \text{isomorphism classes of } n\text{-dimensional} \\ & & \mathbb{K}\text{-vector bundles over } X \\ [f\colon X \to G(n, \mathbb{K})] & \mapsto & f^*(\text{tautological vector bundle over } G(n, \mathbb{K})). \end{array}$$

Proof. This corollary is an immediate consequence of the Vector Bundles-Homotopies Proposition 143.13 (1) together with Proposition 143.15. ∎

In the following we will sketch the proof of Proposition 143.15. Full details for the proof are given in [**MiS1974**, Theorems 5.6 and 5.7]. For better readability we break the proof into two parts.

Sketch of proof of Proposition 143.15 (1). Let $p\colon E \to X$ be an n-dimensional $\mathbb{K}$-vector bundle over a paracompact space X.

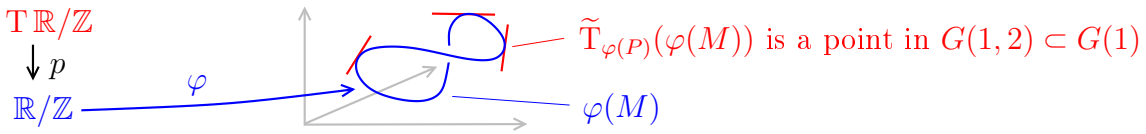
Claim. There exists a map $\Theta\colon E \to \mathbb{K}^\infty$ such that for any $x \in X$ the restriction to the fiber E_x is a monomorphism of $\mathbb{K}$-vector spaces.

Suppose for a second that we have proved the claim. In this case we consider the map

$$\begin{array}{rcl} g\colon X & \to & G(n, \mathbb{K}) \\ x & \mapsto & [\ \underbrace{\Theta(E_x)}_{n\text{-dimensional subspace of } \mathbb{K}^\infty}\ ]. \end{array}$$

[1701] The left-hand side is in fact an open subset of $\mathbb{K}^{n(n+k)}$. Why is that?
[1702] These objects are named after the German mathematician Hermann Grassmann (1809-1877).

Note that we have the following bundle map:



$$\begin{array}{ccc} E & \xrightarrow{v\mapsto(g(p(v)),\Theta(v))} & T \\ \downarrow{\scriptstyle p} & & \downarrow \\ X & \xrightarrow{g} & G(n,\mathbb{K}) \end{array}$$

Note that it follows easily from Lemma 143.8 (3) that the $\mathbb{K}$-vector bundles g^*T and E over X are isomorphic.

Proof.

(1) First, just for fun, we consider the important special case that we are dealing with the tangent bundle $p\colon \mathrm{T}M \to M$ over some closed n-dimensional smooth manifold M. By the Euclidean Embedding Theorem 27.1 we know that there exists a $k \in \mathbb{N}$ and a smooth embedding $\varphi\colon M \to \mathbb{R}^{n+k}$.[1703] The following map has the desired properties:

$$\begin{array}{rcl} g\colon M & \to & G(n,n+k,\mathbb{K}) \subset G(n,\mathbb{K}) \\ P & \mapsto & \underbrace{V_{\varphi(P)}(\varphi(M))}_{\substack{\text{physical tangent space of} \\ \text{the submanifold } \varphi(M)}}. \end{array}$$

(2) Now we consider the general case, i.e. let $p\colon E \to X$ be any n-dimensional $\mathbb{K}$-vector bundle over a paracompact space X. By definition of a vector bundle there exists an open cover $\{U_i\}_{i\in I}$ of X such that the restriction of p to each U_i is trivializable. Since X is paracompact we know by the Countable Cover Proposition 10.11 that there exists a *countable* open cover $\{V_j\}_{j\in\mathbb{N}}$ of X such that each component of any V_j is contained in some U_i. It follows from Lemma 143.2 that the restriction of p to each V_j is also trivial. By Lemma 143.2 this means that for each $j \in \mathbb{N}$ there exists a map $\Phi_j\colon p^{-1}(V_j) \to \mathbb{K}^n$ such that $p \times \Phi_j$ is a trivialization. Next, since X is paracompact we know by the Paracompact-Partition of Unity Theorem 10.9 that there exists a family of maps $\{f_j\colon X \to [0,1]\}_{j\in\mathbb{N}}$ with the following properties:

(a) For each $x \in X$ there exists an open neighborhood W of x such that f_j vanishes on W for all but finitely many j.

(b) For every $x \in X$ we have $\sum_{j\in\mathbb{N}} f_j(x) = 1$.

(c) For each $j \in \mathbb{N}$ we have $\mathrm{supp}(f_j) \subset V_j$.

Now we consider the map

$$\begin{array}{rcl} E & \to & \mathbb{K}^\infty = (\mathbb{K}^n)^\infty \\ v & \mapsto & \displaystyle\sum_{j\in J \text{ with } f_j(p(v))\neq 0} f_j(p(v)) \cdot \underbrace{\Phi_j(v)}_{\substack{\uparrow \\ \text{viewed as a vector in the } j\text{-th copy of } \mathbb{K}^n \text{ in } \mathbb{K}^\infty}} \end{array}$$

[1703] Note that in the proof of that proposition we used implicitly that smooth manifolds are paracompact.

We leave it to the reader to verify that this map has the desired properties. ■

Sketch of proof of Proposition 143.15 (2). Let $g_0, g_1 \colon X \to G(n, \mathbb{K})$ be two maps such that the $\mathbb{K}$-vector bundles g_0^*T and g_1^*T over X are isomorphic. This means that there exists a continuous map of the form

$$\begin{array}{ccc} g_0^*T & \to & g_1^*T \\ (x, v) & \mapsto & (x, \Phi_x(v)) \end{array}$$

where for each $x \in X$ the map $\Phi_x \colon g_0(x) \to g_1(x)$ is an isomorphism of $\mathbb{K}$-vector spaces. We need to show g_0 and g_1 are homotopic.

First suppose that for any $(x, v) \in g_0^*T$ and any $\lambda \in \mathbb{R}_{<0}$ we have $\Phi_x(v) \neq \lambda v$. In this case we consider the map

$$\begin{array}{rcl} H \colon X \times [0,1] & \to & G(n, \mathbb{K}) \\ (x, t) & \mapsto & \underbrace{\{(1-t) \cdot v + t \cdot \Phi_x(v) \mid v \in g_0(x)\}}_{\substack{n\text{-dimensional linear subspace of } \mathbb{K}^\infty \text{ since for} \\ \text{any } v \in g_0(x) \text{ and any } \lambda \in \mathbb{R}_{<0} \text{ we have } \Phi_x(v) \neq \lambda v}} \end{array} .$$

On [**MiS1974**, p. 68] it is shown that this map H is indeed continuous. Once continuity is out of the way it is clear that H is a homotopy between g_0 and g_1.

The general case can be reduced easily to the above special case. We consider the maps

$$\begin{array}{rcl} h_{\text{even}} \colon \mathbb{K}^\infty & \to & \mathbb{K}^\infty \\ (t_1, t_2, \dots) & \mapsto & (0, t_1, 0, t_2, 0, \dots) \end{array} \quad \text{and} \quad \begin{array}{rcl} h_{\text{odd}} \colon \mathbb{K}^\infty & \to & \mathbb{K}^\infty \\ (t_1, t_2, \dots) & \mapsto & (t_1, 0, t_2, 0, \dots) \end{array}$$

Note that both maps are homotopic to the identity.[1704] Now see that

$$g_0 \underset{\uparrow}{\sim} h_{\text{even}} \circ g_0 \overset{\downarrow}{\sim} h_{\text{odd}} \circ g_1 \underset{\uparrow}{\sim} g_1.$$

(now the previous special case applies; since h_{even} and h_{odd} are homotopic to the identity)

This shows that g_0 is homotopic to g_1. ■

143.5. **Trivializations of a vector bundle.** We recall the following definition from page 3063.

Definition. A trivialization of an n-dimensional $\mathbb{K}$-vector bundle $p \colon E \to X$ is an isomorphism $\Phi \colon E \to X \times \mathbb{K}^n$ of vector bundles.

Lemma 143.17. trivializations naturally give rise to orientations

trivializations correspond to choice of linearly independent sections

Proposition 143.18. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, let $p \colon E \to X$ be an n-dimensional $\mathbb{K}$-vector bundle $p \colon E \to X$ over a topological space X and let $\Phi \colon E \to X \times \mathbb{K}^n$ be a trivialization.

[1704] For h_{even} the homotopy to the identity map is given by the map $\mathbb{K}^\infty \times [0,1] \to \mathbb{K}^\infty$ which is given by $(x, t) \mapsto h_{\text{even}}(x) \cdot (1-t) + x \cdot t$. Using the Direct Limits-and-Products Lemma 56.4 one can show that this map is actually continuous.

We denote by $q\colon X \times \mathbb{K}^n \to \mathbb{K}^n$ the projection. We equip $\mathrm{GL}(n,\mathbb{K}) \subset \mathrm{M}(n\times n,\mathbb{K}) = \mathbb{K}^{n^2}$ with the usual topology that we introduced on page 171.

(1) If $f\colon E \to \mathrm{GL}(n,\mathbb{K})$ is a continuous map, then the map

$$\begin{array}{rcl} E & \to & X \times \mathbb{K}^n \\ e & \mapsto & (p(e), \underbrace{f(p(e))}_{\in \mathrm{GL}(n,\mathbb{K})} \cdot \underbrace{q(\Phi(e))}_{\in \mathbb{K}^n}) \end{array}$$

is also a trivialization.

(2) Every trivialization of $p\colon E \to X$ is of the form described in (1).

Proof. The first statement is basically clear. For the second statement we just need to consider self-automorphisms of the trivial bundle $X \times \mathbb{K}^n$. If $\Phi\colon X \times \mathbb{K}^n \to X \times \mathbb{K}^n$ is a self-automorphism, then we define

$$\begin{array}{rcl} f\colon X & \to & \mathrm{GL}(n,\mathbb{K}) \\ x & \mapsto & \text{the unique matrix } A(x) \in \mathrm{GL}(n,\mathbb{K}) \text{ such that on the fiber } \{x\}\times\mathbb{K}^n \text{ the} \\ & & \text{endomorphism } f\colon x \times \mathbb{K}^n \to \{x\} \times \mathbb{K}^n \text{ is given by multiplication by } A(x). \end{array}$$

We leave it to the reader to verify that this map is continuous. ■

Lemma 143.19. Let $n \in \mathbb{N}$ and let $p\colon E \to \overline{B}^1$ be an oriented trivializable n-dimensional $\mathbb{K}$-vector bundle. Suppose we are given linearly independent vectors $v_1,\dots,v_n \in p^{-1}(-1)$ and $w_1,\dots,w_n \in p^{-1}(-1)$. The following two statements are equivalent:

(1) There exists a trivialization of E that restricts to the given trivializations on the endpoints.

(2) $v_1,\dots,v_n \in p^{-1}(-1)$ and $w_1,\dots,w_n \in p^{-1}(-1)$ are either both positive or both negative bases.

Proof. First note that the (1) $\Rightarrow$ (2)-implication is an immediate consequence of Lemma 143.17 and **??**.

Now we turn to the proof of the (2) $\Rightarrow$ (1)-implication. Without loss of generality we can assume that both $v_1,\dots,v_n \in p^{-1}(-1)$ and $w_1,\dots,w_n \in p^{-1}(-1)$ are positive. Since p is trivializable we know that $p\colon E \to \overline{B}^1$ admits a trivialization. It follows from Proposition 143.18 that the two trivializations on the endpoints differ by a map $\varphi\colon \{\pm 1\} \to \mathrm{GL}(n,\mathbb{R})$. It follows from Lemma **??** that $\det(\varphi(-1)) = \det(\varphi(1))$. By the Matrix Group Path-Component Proposition 2.37 this implies that there exists a map $\varphi[-1,1] \to \mathrm{GL}(n,\mathbb{R})$ that extends φ. But then φ times the trivialization has the desired property. ■

143.6. **Classifying space.** Given a topological group (perhaps with CW-structure) G need to construct classifying space BG. Get a fiber bundle $G \to EG \to BG$. Since EG is contractible we see that $\pi_i(BG) \cong \pi_{i-1}(G)$.

In Proposition 156.20 we calculated $\pi_i(\mathrm{O})$ etc. Note that for $[f\colon S^k \to \mathrm{BO}] \in \pi_k(\mathrm{BO})$ we get a vector bundle (well-defined up to stabilization), thus we can define $w_0([f]) \in \mathbb{Z}_2$, $w_1([f]) \in \mathbb{Z}_2$ and $p_1([f]) \in \mathbb{Z}$. According to PT these give you the isomorphisms in Proposition 156.20.

Also get map $\pi_i(\mathrm{BO}) \to \pi_i(\mathrm{BG})$ (which is more or less stable homotopy groups of spheres), which is called the J-homomorphism. For $i = 1, 2$ this is an isomorphism from $\mathbb{Z}_2 \to \mathbb{Z}_2$.

talk about $BTop/BG$, $BPl/BTop$ and BO/BPl. Some of these are Eilenberg-Maclane spaces, see Fnop?

143.7. **The Whitney sum of vector bundles.** In this section we will generalize the notion of the direct sum of two vector spaces to the notion of the direct sum of two vector bundles over a given topological space.

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Let $p\colon E \to X$ be an m-dimensional $\mathbb{K}$-vector bundle and let $q\colon F \to X$ be an n-dimensional $\mathbb{K}$-vector bundle over a topological space X. The map

$$\begin{array}{rcl} E \oplus F := \{(v,w) \in E \times F \,|\, p(v) = q(w)\} & \to & X \\ (v,w) & \mapsto & p(v) \end{array}$$

is easily seen to be an $(m+n)$-dimensional $\mathbb{K}$-vector bundle. It is called the direct sum of the $\mathbb{K}$-vector bundles E and F.[1705]

Examples.

(1) Let $M \subset \mathbb{R}^n$ be a submanifold. Then for any point $P \in M$ we evidently have $\widetilde{\mathrm{T}}_P M \oplus (\widetilde{\mathrm{T}}_P M)^\perp = \mathbb{R}^n$. With this observation it follows that the map

$$\begin{array}{rcl} \mathrm{T}M \oplus NM & \to & M \times \mathbb{R}^n \\ ((P,v),(P,w)) & \mapsto & (P, v+w) \end{array}$$

is an isomorphism of real vector bundles. Put differently, the direct sum of the tangent bundle and the normal bundle is a trivial real bundle.

(2) We consider the sphere $S^2 \subset \mathbb{R}^3$. On page 3066 we saw that the tangent bundle $\mathrm{T}M$ is non-trivial and on page 3065 we saw that the normal bundle is trivializable. Thus we see that the direct sum of a non-trivial real vector bundle with a trivial real vector bundle can be trivial.

We state the last example as a lemma.

Lemma 143.20. Let M be an m-dimensional smooth manifold and let N be an n-dimensional smooth manifold. We denote by $p\colon M \times N \to M$ and $q\colon M \times N \to N$ the natural projections. The map[1706]

$$\begin{array}{rcl} \mathrm{T}(N \times N) & \to & p^*(\mathrm{T}M) \oplus q^*(\mathrm{T}N) \\ ((x,y),v) & \mapsto & \big(((x,y),(x,p_*(v))),\, ((x,y),(y,q_*(v)))\big) \end{array}$$

is an isomorphism of $(m+n)$-dimensional real vector bundles over $M \times N$.

Proof. The lemma is fairly elementary, a detailed proof is given in [**Tu2011**, p. 371]. ■

143.8. **Linear algebra on vector bundles.** In this section we will see that the same way that we could obtain new vector spaces out of given vector spaces we can also obtain new vector bundles out of given vector bundles. We had seen one instance already in the last section, namely the "bundle-fication" of the direct sum of vector spaces. In this section we will see several other constructions. These construction will not play a big role in this

[1705] The direct sum of two $\mathbb{K}$-vector bundles is often also called the Whitney sum.

[1706] The map might appear slightly intimidating, but it is "the obvious" map. It looks somewhat complicated since the pullback vector bundles $p^*(\mathrm{T}M)$ and $q^*(\mathrm{T}M)$ are both defined to be pairs, where the first entry is a point in $M \times N$ and the second entry is also a pair.

chapter, but, surprisingly, they will play a very useful role later on when compute homotopy groups of spheres. First we give (or recall) the definition of the tensor product of two vector spaces. The definition is a slight variation on the definition of the tensor products of two abelian groups that we gave in Section 89.1.

Definition. Let $\mathbb{K}$ be a field and let V and W be two $\mathbb{K}$-vector spaces. We define the tensor product $V \otimes_{\mathbb{K}} W$ to be the following $\mathbb{K}$-vector space:

$$V \otimes_{\mathbb{K}} W := \left\{ \begin{array}{l} \mathbb{K}\text{-vector spaces which is generated by all} \\ \text{symbols of the form } v \otimes w \text{ with } v \in V,\ w \in W \end{array} \right\} \Big/ N(V,W)$$

where $N(V,W)$ is the linear subspace generated by the elements of the form

$$(\mu v + \mu' v') \otimes \nu w - (\mu v \otimes \nu w + \mu' v' \otimes \nu w) \quad \text{and} \quad \mu v \otimes (\nu w + \nu' w') - (\mu v \otimes \nu w + \mu v \otimes \nu' w')$$

with $v, v' \in V$, $w, w' \in W$ and with $\mu, \mu', \nu, \nu' \in \mathbb{K}$. For $v \in V$ and $w \in W$ we denote, by a slight abuse of notation, the image of $v \otimes w$ in $V \otimes W$ again by $v \otimes w$.

Example. Let $\mathbb{K}$ be a field, let V be a $\mathbb{K}$-vector space with basis $v_1, \ldots, v_m$ and let W be a $\mathbb{K}$-vector space with basis $w_1, \ldots, w_n$. We leave it to the reader to verify that the tensor product $V \otimes_{\mathbb{K}} W$ is a $\mathbb{K}$-vector space with basis $\{v_i \otimes w_j\}_{i=1,\ldots,m, j=1,\ldots,n}$.

Note that the tensor product of vector spaces satisfies the obvious analogues of the tensor product of abelian groups, see Lemma 89.1, 89.2 and 89.3. Surely there is no need to spell these statements out in detail.
Next we define the tensor product of vector bundles.

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Let $p\colon E \to X$ be an m-dimensional $\mathbb{K}$-vector bundle and let $q\colon F \to X$ be an n-dimensional $\mathbb{K}$-vector bundle with the same base space X. We consider the set

$$E \otimes_{\mathbb{K}} F := \bigsqcup_{x \in X} \underbrace{E_x \otimes_{\mathbb{K}} F_x}_{\mathbb{K}\text{-vector space}} \qquad \text{with the obvious map } r\colon E \otimes_{\mathbb{K}} F \to X.$$

We equip $E \otimes_{\mathbb{K}} F$ with the smallest topology that has the property that for any open subset $U \subset X$ and any bundle isomorphisms $\phi\colon p^{-1}(U) \to U \times \mathbb{K}^m$ and $\psi\colon q^{-1}(U) \to U \times \mathbb{K}^n$ the map

$$\begin{array}{ccc} r^{-1}(U) & \to & U \times \overbrace{(\mathbb{K}^m \otimes_{\mathbb{K}} \mathbb{K}^n)}^{\text{topology is defined on page 153}} \\ v_x \otimes w_x & \mapsto & (x, \phi_x(v_x) \otimes \psi_x(w_x)) \end{array}$$

is a homeomorphism. One can now easily show that $r\colon E \otimes_{\mathbb{K}} F \to X$ is an $m \cdot n$-dimensional $\mathbb{K}$-vector bundle. It is called the tensor product of the $\mathbb{K}$-vector bundles E and F.

The tensor product gives us a functorial way to turn real vector spaces and bundles into complex vector spaces and bundles. We summarize this construction in the following lemma.

Lemma 143.21.

(1) Let V be a real vector space. The tensor product $V \otimes_{\mathbb{R}} \mathbb{C}$ with the complex multiplication induced by $z \cdot (v \otimes w) := v \otimes (z \cdot w)$ is a complex vector space with $\dim_{\mathbb{C}}(V \otimes_{\mathbb{R}} \mathbb{C}) = \dim_{\mathbb{R}}(V)$.

(2) Let $p\colon E \to X$ be a real vector bundle. We denote by $q\colon X \times \mathbb{C} \to X$ the trivializable 1-dimensional complex vector bundle. The vector bundle $E \otimes_{\mathbb{R}} \mathbb{C} := E \otimes_{\mathbb{R}} (X \times \mathbb{C})$, with the complex vector space structure on each fiber defined as in (1), is a complex vector bundle.
(3) The map $V \mapsto V \otimes_{\mathbb{R}} \mathbb{C}$ defines a covariant functor from the category $\mathcal{V}ec_{\mathbb{R}}$ to the category $\mathcal{V}ec_{\mathbb{C}}$ and the map $E \mapsto E \otimes_{\mathbb{R}} \mathbb{C}$ defines a covariant functor from $\mathcal{V}ect\mathcal{B}und_{\mathbb{R}}$ to $\mathcal{V}ect\mathcal{B}und_{\mathbb{C}}$.

Proof. We leave it to the reader to make the statements more precise and to prove them. ■

We can extend several other constructions for vector spaces to the setting of vector bundles.

Definition. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ and let $p\colon E \to X$ be an m-dimensional $\mathbb{K}$-vector bundle. We denote by $E^* \to X$ the $\mathbb{K}$-vector bundle where for each $x \in X$ the corresponding fiber is given by the dual vector space $\mathrm{Hom}_{\mathbb{K}}(E_x, \mathbb{K})$. It should be clear how to fill in the precise details for the definitions. We refer to $E^* \to X$ as the dual vector bundle of $p\colon E \to X$.

The next lemma brings together the tensor product of two vector bundles and the dual of a vector bundle in an elegant way.

Lemma 143.22. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$ and let $p\colon E \to X$ be an n-dimensional $\mathbb{K}$-vector bundle. There is a unique map

$$\Theta\colon E \otimes E^* \ \to \ X \times \mathrm{M}(n \times n, \mathbb{K})$$

of $\mathbb{K}$-vector bundles with the property that for any $x \in X$ and any basis $v_1, \ldots, v_n$ of the fiber $E_x = p^{-1}(x)$ with corresponding dual basis $v_1^*, \ldots, v_n^*$ of the dual vector space E_x^* we have $\Theta(v_i \otimes v_j^*) = (x, e_{ij})$ for any choice of $i, j \in \{1, \ldots, n\}$. Furthermore this map is in fact an isomorphism of $\mathbb{K}$-vector bundles over X.

Sketch of proof. In Exercise 143.10 we will see that the map on each fiber does not depend on the choice of the basis $v_1, \ldots, v_n$. With this observation it is then fairly easy to see that the map is an isomorphism of $\mathbb{K}$-vector bundles. We leave all further details to the reader. Over all this lemma is a good example of the magic of clever definitions. ■

It turns out that out of the blue we now have a new, and potentially interesting, invariant for CW-complexes. More precisely, we have the following proposition.

Proposition 143.23. Let $\mathbb{K} = \mathbb{R}$ or let $\mathbb{K} = \mathbb{C}$. The maps

$$\begin{array}{rcl} X & \mapsto & (\mathrm{Vect}^1_{\mathbb{K}}(X), \otimes) \\ (f\colon X \to Y) & \mapsto & \left(\begin{array}{rcl} f^*\colon \mathrm{Vect}^1_{\mathbb{K}}(Y) & \to & \mathrm{Vect}^1_{\mathbb{K}}(X) \\ E & \mapsto & f^*E \end{array} \right) \end{array}$$

define a contravariant functor from the category $\mathcal{T}op$ of topological space to the category $\mathcal{A}b\mathcal{G}roup$ of abelian groups. Here, in the group $(\mathrm{Vect}^1_{\mathbb{K}}(X), \otimes)$ the neutral element is given by the trivial 1-dimensional $\mathbb{K}$-vector bundle and the inverse of $[E \to X]$ is given by $[E^* \to X]$.

Sketch of proof. Let X be a topological space. First of all, note that by Corollary 143.7 we know that $\mathrm{Vect}^1_{\mathbb{K}}(X)$ is a set. Next, it is straightforward to show that "$\otimes$" defines an associative and commutative product on $\mathrm{Vect}^1_{\mathbb{K}}(X)$ with neutral element given by the 1-dimensional trivial bundle. Finally note that given a 1-dimensional $\mathbb{K}$-vector bundle

$E \to X$ we have

$$[E \to X] \otimes [E^* \to X] \;=\; [E \otimes E^* \to X] \underset{\uparrow}{=} [X \times \mathrm{M}(1 \times 1, \mathbb{K})] \;=\; [\mathbb{K} \times X].$$

Lemma 143.22

This shows that $\mathrm{Vect}^1_{\mathbb{K}}(X)$ is indeed an abelian group. The remaining statements of the proposition follow easily from the definitions and are left to the reader. ■

The proposition raises the following question.

Question 143.24. Is the contravariant functor $X \mapsto \mathrm{Vect}^1_{\mathbb{K}}(X)$ a "new" contravariant functor or is it a well-known functor in slight disguise?

We will give a complete answer to Question 143.24 in Theorem **??**. Now we provide two more definitions.

Definition. Let $p\colon E \to X$ be a real vector bundle.

(1) An orientation of $E \to X$ is a choice of an orientation for each E_x which is compatible with all trivializations.
(2) Given $k \in \mathbb{N}_0$ we denote by $\wedge^k E \to X$ the real vector bundle where for each $x \in X$ the fiber is given by the vector space $\wedge^k E_x^*$ that we introduced on page **??**.

We have enough faith in the reader to be confident that the reader can turn these slogans into proper rigorous definitions.

Examples.

(1) For any smooth manifold M an orientation of M is, almost by definition, the same as an orientation of the tangent bundle $\mathrm{T}M$.
(2) Similar to the proof of the Complex Manifold-Orientation Proposition 32.23 one can show that every k-dimensional complex vector bundle is an orientable $2k$-dimensional real vector bundle. In Exercise 143.12 we will prove a partial converse to this statement.
(3) Given a smooth manifold M a section of the bundle $\wedge^k \mathrm{T}M \to M$ is basically the same as a continuous k-form on M as defined on page **??**.

We conclude this section with the following lemma.

Lemma 143.25. Let M be an n-dimensional smooth manifold. The smooth manifold M is orientable if and only if the vector bundle $\wedge^n \mathrm{T}M^*$ is a trivial line bundle.[1707]

Proof. The bored reader will surely be pleased to hear that the proof is outsourced as Exercise 143.11. ■

Lemma 143.25 motivates the following definition which will come in handy later on.

Definition. Given an n-dimensional smooth manifold M we refer to the vector bundle $\wedge^n \mathrm{T}M^*$ as the orientation bundle.

143.9. **Vector bundles over spheres.** We conclude this chapter with a discussion of vector bundles over spheres.

[1707] Note that we know by the Alternating Forms-Basis Proposition **??** that $\wedge^n \mathrm{T}M^*$ is a line bundle.

Lemma 143.26. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, let $k \in \mathbb{N}$ and let $n \in \mathbb{N}$.

(1) Let $\varphi\colon S^{k-1} \to \mathrm{GL}(n,\mathbb{K})$ be a map. The map

$$\begin{array}{rcl} \Theta(\varphi)\colon ((S^k_{\geq 0} \times \mathbb{K}^n) \sqcup (S^k_{\leq 0} \times \mathbb{K}^n))/(x,v) \sim (x, \varphi(x)\cdot v) & \to & S^k \\ [(x,v)] & \mapsto & x \end{array}$$

is an n-dimensional $\mathbb{K}$-vector bundle over S^k. (The map $\varphi\colon S^{k-1} \to \mathrm{GL}(n,\mathbb{K})$ is called the clutching map and this construction of $\mathbb{K}$-vector bundles is called the clutching construction.)

(2) The map

$$\begin{array}{rcl} \overbrace{[S^{k-1}, \mathrm{GL}(n,\mathbb{K})]}^{\text{set of homotopy classes of maps } S^{k-1} \to \mathrm{GL}(n,\mathbb{K})} & \to & \mathrm{Vect}^n_{\mathbb{K}}(S^k) \\ [\varphi] & \mapsto & [\Theta(\varphi)] \end{array}$$

is well-defined.

Example. Let $k = 1$. We consider the map $\varphi\colon S^0 \to \mathrm{GL}(1,\mathbb{R})$ which is conveniently given by $\pm 1 \to (\pm 1)$. It is not difficult to see that the resulting real 1-dimensional vector bundle over S^1 is isomorphic to the Möbius bundle.

Sketch of proof. For Statement (1) we just note that, using collar neighborhoods of S^{k-1} in $S^k_{\geq 0}$ and $S^k_{\leq 0}$ it is straightforward to verify by hand that the clutching construction gives rise to a $\mathbb{K}$-vector bundle. We leave the details to the reader.

We turn to the proof of Statement (2). Let $f_0, f_1\colon S^{k-1} \to \mathrm{GL}(n,\mathbb{K})$ be two maps that are homotopic. This implies that there exists a homotopy $F\colon S^{k-1} \times [0,1] \to \mathrm{GL}(n,\mathbb{K})$ with $F_0(x) = f_1(x) \cdot f_0^{-1}(x)$ and $F_1 = \mathrm{id}$. By picking a suitable collar neighborhood of $S^{k-1} = \partial S^k_{\geq 0}$ we obtain an identification $S^k_{\geq 0} = (S^{k-1} \times [0,1]) \cup S^k_{\geq \frac{1}{2}}$. One can now easily verify that the following map is an isomorphism of $\mathbb{K}$-vector bundles over S^k:

$$\begin{array}{rcl} (S^k_{\geq 0} \times \mathbb{K}^n \sqcup S^k_{\leq 0} \times \mathbb{K}^n)/(x,v) \sim (x, f_0(x)\cdot v) & \to & (S^k_{\geq 0} \times \mathbb{K}^n \sqcup S^k_{\leq 0} \times \mathbb{K}^n)/(x,v) \sim (x, f_1(x)\cdot v) \\ (x,v) & \mapsto & \begin{cases} (x,v), & \text{if } x \in S^k_{\leq 0} \text{ or if } x \in S^k_{\geq \frac{1}{2}}, \\ (x, F(y,t)\cdot v), & \text{if } x = (y,t) \in S^{k-1} \times [0,1]. \end{cases} \end{array}$$

This concludes the proof of Statement (2). ∎

The following proposition gives a convenient description of $\mathrm{Vect}^n_{\mathbb{C}}(S^k)$.

Proposition 143.27. The map

$$\begin{array}{rcl} \Theta\colon [S^{k-1}, \mathrm{GL}(n,\mathbb{C})] & \to & \mathrm{Vect}^n_{\mathbb{C}}(S^k) \\ [\varphi] & \mapsto & [\Theta(\varphi)] \end{array}$$

is a well-defined bijection.

Proof. Let $\overline{B}^k_{\pm}$ be two copies of $\overline{B}^k$. In the following we make the hopefully obvious identification $S^k = S^k_{\geq 0} \cup_{S^{k-1}} S^k_{\leq 0} = \overline{B}^k_+ \cup_{S^{k-1}} \overline{B}^k_-$ and henceforth we work with the topological space to the right.

Now let $p\colon E \to S^k = \overline{B}^k_+ \cup_{S^{k-1}} \overline{B}^k_-$ be an n-dimensional complex vector bundle. We write $E^{\pm} := p^{-1}(\overline{B}^k_{\pm})$. Since $\overline{B}^k_+$ and $\overline{B}^k_-$ are compact and contractible we know by the Vector Bundles-Homotopies Proposition 143.13 that the bundles $E^{\pm} \to \overline{B}^k_{\pm}$ are trivial. By

Lemma 143.2 this means that there exist maps $\Phi^{\pm}\colon E^{\pm} \to \mathbb{C}^n$ such that $p \times \Phi^{\pm}\colon E^{\pm} \to \overline{B}^k_{\pm} \times \mathbb{C}^n$ are trivializations of $E^{\pm} \to \overline{B}^k_{\pm}$. Given $x \in \overline{B}^n_{\pm}$ we write $\Phi^{\pm}_x := \Phi^{\pm}|_{E_x}\colon E_x \xrightarrow{\cong} \mathbb{C}^n$. Similar to the proof of Lemma 143.6 we consider the map

$$\begin{aligned} \Omega(E)\colon S^{k-1} &\to \mathrm{GL}(n,\mathbb{C}) = \mathrm{Aut}(\mathbb{C}^n) \\ x &\mapsto \Phi^-_x \circ (\Phi^+_x)^{-1} = \left(\mathbb{C}^n \xrightarrow{(\Phi^+_x)^{-1}} E_x \xrightarrow{\Phi^-_x} \mathbb{C}^n\right) \end{aligned}$$

Claim. The homotopy class $[\Omega(E)] \in [S^{k-1}, \mathrm{GL}(n,\mathbb{C})]$ does not depend on the choice of trivializations $\Phi^{\pm}$.

Proof. Suppose we are given two other maps $\Psi^{\pm}\colon E^{\pm} \to \mathbb{C}^n$ such that $p \times \Psi^{\pm}\colon E^{\pm} \to \overline{B}^k_{\pm} \times \mathbb{C}^n$ are trivializations of $E^{\pm} \to \overline{B}^k_{\pm}$. By the Matrix Group Path-Component Proposition 2.37 we know that $\mathrm{GL}(n,\mathbb{C})$ is path-connected. This implies that there exists a path $\gamma\colon [1,2] \to \mathrm{GL}(n,\mathbb{C})$ with $\gamma(1) = \Phi^-_0 \circ (\Phi^+_0)^{-1}$ and $\gamma(2) = \Psi^-_0 \circ (\Psi^+_0)^{-1}$. The map

$$\begin{aligned} S^{k-1} \times [0,3] &\to \mathrm{GL}(n,\mathbb{C}) \\ (x,t) &\mapsto \begin{cases} \Phi^-_{x\cdot(1-t)} \circ (\Phi^+_{x\cdot(1-t)})^{-1}, & \text{if } t \in [0,1], \\ \gamma(t), & \text{if } t \in [1,2], \\ \Psi^-_{x\cdot(t-2)} \circ (\Psi^+_{x\cdot(t-2)})^{-1}, & \text{if } t \in [2,3] \end{cases} \end{aligned}$$

is now the desired homotopy. ⊞

We leave it to the reader to verify that the maps $\Theta\colon [S^{k-1}, \mathrm{GL}(n,\mathbb{C})] \to \mathrm{Vect}^n_{\mathbb{C}}(S^k)$ and $\Omega\colon \mathrm{Vect}^n_{\mathbb{C}}(S^k) \to [S^{k-1}, \mathrm{GL}(n,\mathbb{C})]$ are actually inverses of one-another. ■

Note that the group structure on $\mathrm{GL}(n,\mathbb{C})$ endows $[S^{k-1}, \mathrm{GL}(n,\mathbb{C})]$ with a group structure. Furthermore note that by Proposition 143.23 we know that $\mathrm{Vect}^1_{\mathbb{C}}(S^k)$ comes with a group structure. The following lemma relates these two group structures.

Lemma 143.28. Let $k \in \mathbb{N}$. The map

$$\begin{aligned} \Theta\colon [S^{k-1}, \mathrm{GL}(1,\mathbb{C})] &\to \mathrm{Vect}^1_{\mathbb{C}}(S^k) \\ [\varphi] &\mapsto [\Theta(\varphi)] \end{aligned}$$

is a group homomorphism, in other words, given $\varphi, \psi\colon S^{k-1} \to \mathrm{GL}(1,\mathbb{C})$ we have the equality $[\Theta(\varphi \cdot \psi)] = [\Theta(\varphi)] \otimes [\Theta(\psi)]$.

Sketch of proof. At the end of the day the proof boils down to the following observation. Given $a, b \in \mathbb{C} \setminus \{0\}$ the following diagram commutes:

$$\begin{array}{ccc} \mathbb{C} \otimes_{\mathbb{C}} \mathbb{C} & \xrightarrow{x\otimes y \mapsto x\cdot y} & \mathbb{C} \\ {\scriptstyle (x\mapsto a\cdot x)\otimes(y\mapsto b\cdot y)}\downarrow & & \downarrow{\scriptstyle z \mapsto a\cdot b\cdot z} \\ \mathbb{C} \otimes_{\mathbb{C}} \mathbb{C} & \xrightarrow{x\otimes y \mapsto x\cdot y} & \mathbb{C}. \end{array}$$

We leave it to the reader to assemble a proof out of this observation. ■

Remark. We consider 1-dimensional complex vector bundles over S^2. We have the following isomorphisms of abelian groups:

$$\mathrm{Vect}^1_{\mathbb{C}}(S^2) \xleftarrow[\uparrow]{\cong} [S^1, \mathrm{GL}(1,\mathbb{C})] \xleftarrow[\uparrow]{\cong} [S^1, U(2)] = [S^1, S^1] \xrightarrow[\uparrow]{[f]\mapsto \deg(f)} \mathbb{Z}.$$

group isomorphism by Proposition 143.27 — group isomorphism by Lemmas ?? and 15.12 (2) — group isomorphism by the Degree Isomorphism Proposition 86.8

We have thus completely classified the group of complex line bundles over S^2. Later on, in Theorem **??** we will generalize this calculation to give a complete calculation of $\mathrm{Vect}^1_{\mathbb{C}}(X)$ for any CW-complex X.

The reader might wonder why we formulated Proposition 143.27 for complex vector bundles instead of real vector bundles. The reason is that in the proof of Proposition 143.27 we used that $\mathrm{GL}(n,\mathbb{C})$ is path-connected. In the Matrix Group Path-Component Proposition 2.37 we saw that in contrast $\mathrm{GL}(n,\mathbb{R})$ has two path-components, one of which is $\mathrm{GL}_+(n,\mathbb{R}) = \{A \in \mathrm{GL}(n,\mathbb{R}) \mid \det(A) > 0\}$. For formulate a "real" analogue of Proposition 143.27 it is best to introduce the following notation.

Notation. Let X be a topological space.

(1) We say two oriented vector bundles $p\colon E \to X$ and $q\colon F \to X$ are isomorphic if there exists an isomorphism $\Phi\colon E \to F$ of vector bundles as defined on page 3060, such that for each $x \in X$ the map $E_x \to F_x$ is an orientation-preserving isomorphism.

(2) Let $n \in \mathbb{N}_0$. We denote by $\mathrm{Vect}^{n,+}_{\mathbb{R}}(X)$ the set of isomorphism classes of n-dimensional oriented $\mathbb{R}$-vector bundles over X.

Now we can formulate the following analogue of Proposition 143.27.

Proposition 143.29. The map

$$\begin{array}{rcl} \Theta\colon [S^{k-1}, \mathrm{GL}_+(n,\mathbb{R})] & \to & \mathrm{Vect}^{n,+}_{\mathbb{R}}(S^k) \\ [\varphi] & \mapsto & [\Theta(\varphi)] \end{array}$$

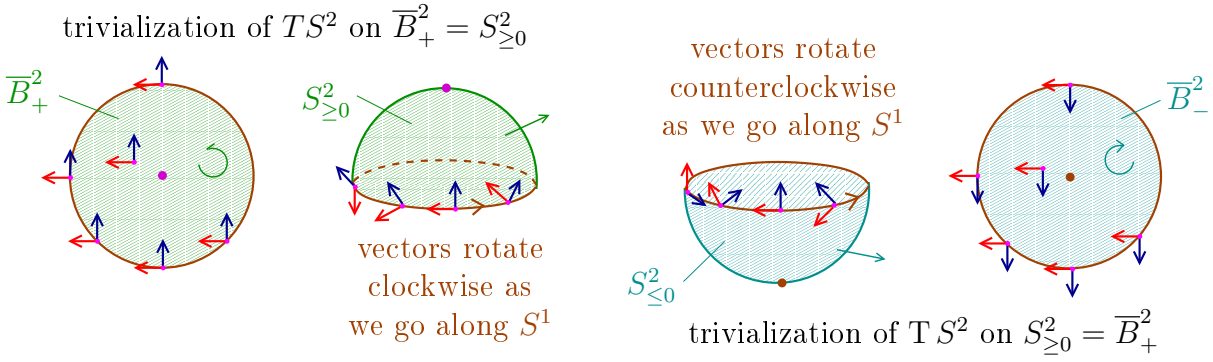
is a well-defined bijection.

Proof. The proof if is quite similar to the proof of Proposition 143.27. We leave it to the reader to verify that the statement regarding the orientations works out. ∎

Remark. Similar to the above we have the following bijections:

$$\mathrm{Vect}^{2,+}_{\mathbb{R}}(S^2) \xleftarrow[\uparrow]{\cong} [S^1, \mathrm{GL}_+(2,\mathbb{R})] \xleftarrow[\uparrow]{\cong} [S^1, O(2)] = [S^1, S^1] \xrightarrow[\uparrow]{[f]\mapsto \deg(f)} \mathbb{Z}.$$

bijection given by Proposition 143.29



group isomorphism by Proposition 15.7 and Lemma 15.12 (2)

group isomorphism by the

Given an oriented 2-dimensional real vector bundle $p\colon E \to S^2$ we refer to the corresponding integer on the right as the *Euler number of the vector bundle* $p\colon E \to S^2$.

Example. We just introduced the Euler number of an oriented 2-dimensional real vector bundle over S^2. In this final example we will try to understand the Euler number of the tangent bundle $\mathrm{T}S^2$ of S^2. In the figure below we try our best to illustrate the situation. We show two trivializations of the $\mathrm{T}S^2$ over $\overline{B}^2_+ = S^2_{\geq 0}$ and $S^2_{\leq 0} = \overline{B}^2_-$. We can restrict the two trivializations of $\mathrm{T}S^2$ to S^1.[1708] As we go along S^1 we see that at $z \in S^1$ we have to rotate the trivialization coming from $S^2_{\geq 0}$ by z^2 to obtain the trivialization coming from $S^2_{\leq 0}$. This implies that the Euler number of $\mathrm{T}S^2$ equals $+2$. The author is full aware that the figure below is only mildly helpful and we encourage the readers to draw pictures themselves.

[1708] Perhaps it is worth stressing, we consider the restriction of $\mathrm{T}S^2$ to S^1, we do not consider $\mathrm{T}S^1$.

Remark. Propositions 143.27 and 143.29, together with the discussion in Section 70.3, tell us that the key to understanding vector bundles over spheres lies in the understanding of the homotopy groups of $\mathrm{GL}(n,\mathbb{C})$ and $\mathrm{GL}_+(n,\mathbb{R})$. It turns out that this is a difficult problem. We will obtain some partial calculations in Chapter 156.

Exercises for Chapter 143.

Exercise 143.1. Let $p\colon E \to X$ be a vector bundle and let $s\colon X \to E$ be a section. Show that the zero set $\{x \in X \,|\, s(x) = 0\}$ is a closed subset of X.
Hint. Use Lemma 1.8 (2b).

Exercise 143.2. Does there exist a smooth vector field on S^2 with a single zero?

Exercise 143.3. Let W be a smooth manifold and let M be a submanifold of W. We denote by $i\colon M \to W$ the inclusion map. Show that there exists a vector bundle $E \to M$ such that $\mathrm{T}M \oplus E$ is isomorphic to $i^*(\mathrm{T}M)$.

Exercise 143.4. Show that S^3 and S^7 are parallelizable.

Exercise 143.5. Let $z \in \mathbb{R} \setminus \{0\}$. We denote by $\rho_z\colon \pi_1(S^1,1) \to \mathrm{GL}(1,\mathbb{R})$ the representation that sends the standard generator of $\pi_1(S^1,1) \cong \mathbb{Z}$ to the matrix (z). We denote by $E_z \to S^1$ the line bundle corresponding to this representation, see the definition on page 3063. For which z is this line bundle isomorphic to the trivial bundle and for which z is it isomorphic to the Möbius bundle?

Exercise 143.6. Show by hand that the Möbius bundle, as defined on page 3060, does not admit a section which is nowhere-vanishing.

Exercise 143.7. By Exercise 5.25 we can identify $\mathbb{R}\mathrm{P}^1$ with S^1. Let $p\colon E \to \mathbb{R}\mathrm{P}^1 = S^1$ be the tautological line bundle over $\mathbb{R}\mathrm{P}^1 = S^1$ from page 3060. Is this line bundle trivial? Is it isomorphic to the Möbius bundle?

Exercise 143.8. Let $g \geq 1$ and let Σ be the surface of genus g. Show that Σ admits a non-trivial real line bundle.

Exercise 143.9. Let $p\colon M \to S^1$ be the Möbius bundle and let $g\colon S^1 \to S^1$ be the map that is given by $g(z) = z^2$. Show that the pullback of the Möbius bundle under g is a trivial bundle.

Exercise 143.10. Let $\mathbb{K}$ be a field and let V be an n-dimensional $\mathbb{K}$-vector space. We write $V^* = \mathrm{Hom}_{\mathbb{K}}(V, \mathbb{K})$. Let $v_1, \ldots, v_n$ be a basis of V. We denote by $v_1^*, \ldots, v_n^*$ the corresponding dual basis of V^*. We consider the $\mathbb{K}$-homomorphism

$$\begin{array}{rcl} V \otimes V^* & \to & \mathrm{M}(n \times n, \mathbb{K}) \\ v_i \otimes v_j^* & \mapsto & e_{ij} := \begin{array}{c}(n \times n)\text{-matrix with a single non-zero entry,} \\ \text{namely } 1 \in \mathbb{K} \text{ in the } (i,j)\text{-entry.}\end{array} \end{array}$$

Show that this homomorphism does not depend on the choice of the basis $v_1, \ldots, v_n$.

Exercise 143.11. Let M be an n-dimensional smooth manifold. Show that M is orientable if and only if the orientation bundle $\wedge^n \mathrm{T}M^*$ is a trivial bundle.

Exercise 143.12. Let $p\colon E \to X$ be an oriented 2-dimensional real vector bundle over a paracompact space X. We want to show that E can be equipped with the structure of a 1-dimensional complex vector bundle.

(a) Show that given any $x \in X$ we can find a non-singular positive symmetric form $\langle\, , \,\rangle_x$ on E_x, such that the form varies "continuously with x". (Here you need that X is paracompact.)

(b) Given $x \in X$ we consider the map

$$\begin{array}{rcl} J\colon E_x \setminus \{0\} & \to & E_x \setminus \{0\} \\ v & \mapsto & \begin{array}{c}\text{the unique vector } w \in E_x \text{ with } \langle v, w\rangle_x = 0 \\ \text{and such that } v, w \text{ is a positive basis for } E_x.\end{array} \end{array}$$

Show that $J^2 = -\mathrm{id}_{E_x}$.

(c) Show that E can be equipped with the structure of a 1-dimensional complex vector bundle.

Exercise 143.13. Let M be the Möbius band. Show that there is no immersion $f\colon M \to \mathbb{R}^2$.

Hint. Suppose there was an immersion $f\colon M \to \mathbb{R}^2$. What can you say about the pull back of the tangent bundle of $\mathbb{R}^2$?

Exercise 143.14. Let $0 \to A \to B \to C \to 0$ be a short exact sequence of vector bundles over a topological space X. Show that the vector bundle $B \to X$ is isomorphic to the vector bundle $A \oplus C \to X$.

Exercise 143.15. Let X be a paracompact space and let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. We denote by $i_0\colon X \xrightarrow{x \mapsto (x,0)} X \times [0,1]$ and $i_1\colon X \xrightarrow{x \mapsto (x,1)} X \times [0,1]$ the obvious embeddings. In Lemma 143.14 we showed that given any $\mathbb{K}$-vector bundle $p\colon E \to X \times [0,1]$ the pullbacks i_0^*E and i_1^*E are isomorphic. Show in an example that the isomorphism that we constructed in the proof of Lemma 143.14 depends in general on the choices we make in the proof.

144. Cobordisms

One could ask whether every closed smooth manifold is the boundary of a compact smooth manifold. In fact in Corollary 119.9 we already saw that the answer is very much no. In this chapter we will "quantify" to what degree the answer is no by introducing the "cobordism group", which is an interesting object in its own right.

144.1. **The cobordism rings.** Given two closed n-dimensional smooth manifolds M and N we obtain a new closed n-dimensional smooth manifold by taking the disjoint union $M \sqcup N$. This operation has a neutral element, given by the empty smooth manifold, and it looks abelian and associative.[1709] Thus it looks that all closed n-dimensional smooth manifolds together with the operation "$\sqcup$" form a monoid.
For the reader's convenience we recall the definition of a monoid.

Definition. A monoid is a set S together with a map

$$\begin{array}{ccc} S \times S & \to & S \\ (x,y) & \mapsto & x \cdot y \end{array}$$

such that the following two conditions are satisfied:[1710]

(1) there exists a neutral element $e \in S$, i.e. an element which satisfies $e \cdot x = x \cdot e = x$ for all $x \in S$,
(2) the operation "$\cdot$" is associative, i.e. for all $x, y, z \in S$ we have $(x \cdot y) \cdot z = x \cdot (y \cdot z)$.

Careful comparison between the definition of a monoid and the discussion of smooth manifolds above reveals a subtle problem: "all closed n-dimensional smooth manifolds" do not form a set. As most mathematicians I have no intention of getting into the debate about what is a set. Instead we refer to [**FPr1985**] and [**Halm1960**] for details. Also, at this stage reading "Logicomix" [**DoP2009**], see the figure below, is almost a must.
Fortunately, we are saved by the following lemma.

Lemma 144.1. Let $n \in \mathbb{N}_0$.

(1) The homeomorphism classes of n-dimensional topological manifolds form a set.
(2) The diffeomorphism classes of n-dimensional smooth manifolds form a set.

Remark. Note that here it is essential that smooth manifolds are assumed to be second-countable. If we did not make this assumption, then any set with the discrete topology would be a 0-dimensional smooth manifold, but the bijection classes of sets do not form a set.

Sketchy proof.

(1) It follows from the Euclidean Embedding Theorem 27.1 (1) that every n-dimensional topological manifold is homeomorphic to a subspace of some $\mathbb{R}^k$. Thus we can identify "homeomorphism classes of n-dimensional topological manifolds" with a subset of the power set of $\mathbb{R}^\infty$, which is a set.

[1709] Very well-trained eyes will spot that purely set theoretically, $M \sqcup N$ and $N \sqcup M$ are not exactly the same, see the definition on page 88.
[1710] A *semi-group* is defined similarly, except that we do not demand the existence of a neutral element.

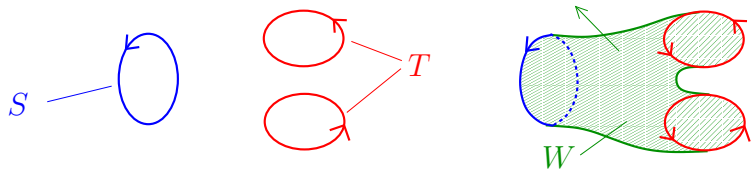
(2) As in (1) we see, using the Euclidean Embedding Theorem 27.1 (2) and using the Smooth Embedding Theorem 24.10 we see that it suffices to show that the diffeomorphism classes of n-dimensional manifolds, where the underlying topological space is a subset of some $\mathbb{R}^k$, form a set. But this follows from the fact that given a subset of some $\mathbb{R}^k$ the possible atlases form a set.

We leave it to our friends the logicians to turn the above sloppy argument into a proper proof. ■

Next we introduce a notation and we recall a definition from page **??**.

Definition.

(1) Given $n \in \mathbb{N}_0$ we denote by $\mathcal{M}_n$ the set of all diffeomorphism classes of closed oriented n-dimensional smooth manifolds.[17111712]



(2) Given $S, T \in \mathcal{M}_n$ we say that S and T are cobordant if there exists a cobordism between S and T, i.e. a compact oriented $(n+1)$-dimensional smooth manifold W such that[1713] ∂W admits an orientation-preserving diffeomorphism to $S \sqcup -T$. If S and T are cobordant, then we write $S \sim T$.

(3) We say $S \in \mathcal{M}_n$ is nullbordant if S is cobordant to the empty n-dimensional manifold, in other words, S is nullbordant if there exists a compact oriented $(n+1)$-dimensional smooth manifold W such that ∂W admits an orientation-preserving diffeomorphism to S.

[1711] Recall that the empty set is a closed oriented n-dimensional smooth manifold.

[1712] Also recall that an orientation for a 0-dimensional smooth manifold M consists of a choice of a sign in $\{\pm 1\}$ for each point in M, see the remark on page 675.

[1713] Recall that each component of ∂W inherits an orientation from the orientation of W.

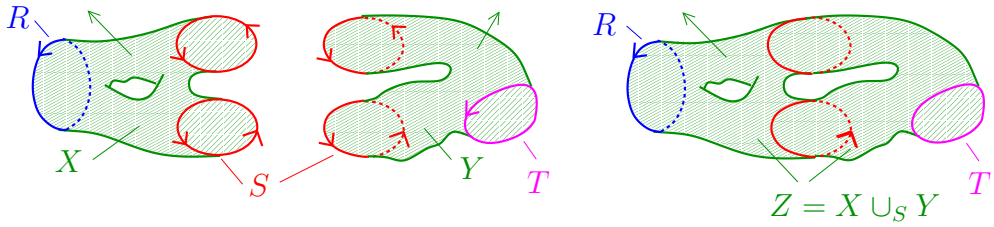
Convention. In the following we will often be slightly sloppy in our notation, meaning that we will not distinguish between a smooth manifold and its diffeomorphism class. For example, given oriented smooth manifolds W, S and T we often write $\partial M = S \sqcup T$, even though strictly speaking we have $\partial M = S' \sqcup T'$ where S' and T' are oriented smooth manifolds that admit an orientation-preserving diffeomorphism to S respectively T.

Remark. Let $n \in \mathbb{N}_{\geq 2}$ and let $S, T \in \mathcal{M}_n$. We suppose that S and T are cobordant. Using the connected sum operation, in particular using the Connected Sum-Proposition **??**, one can easily show that there exists a connected cobordism between S and T.

Lemma 144.2. Let $n \in \mathbb{N}_0$.

(1) The relation $\sim$ on $\mathcal{M}_n$ is an equivalence relation.

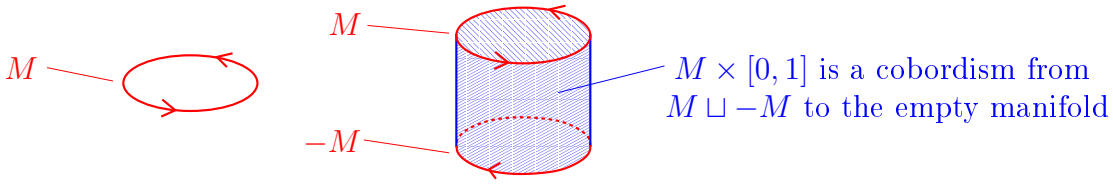
(2) The map
$$\begin{array}{rcl} \mathcal{M}_n \times \mathcal{M}_n & \to & \mathcal{M}_n \\ ([S],[T]) & \mapsto & [S \sqcup T] \end{array}$$
is well-defined and it descends to an abelian group structure on the set $\mathcal{M}_n/\sim$[1714] where the neutral element is given by the empty smooth manifold.



Proof.

(1) We first show that the relation $\sim$ on $\mathcal{M}_n$ is an equivalence relation.

(a) Given $M \in \mathcal{M}_n$ we have $M \sim M$ since, by the discussion on page 696, we have $\partial([0,1] \times M) = \{0\} \times (-M) \cup \{1\} \times M$.



(b) Suppose that $S \sim T$, i.e. there exists a compact oriented $(n+1)$-dimensional smooth manifold W with $\partial W = S \sqcup -T$. Then $\partial(-W) = -S \sqcup T = T \sqcup (-S)$ which shows that $T \sim S$.

(c) Finally suppose that we have $R, S, T \in \mathcal{M}_n$ with $R \sim S$ and $S \sim T$. We showed already in Lemma 144.2 that R is also cobordant to T. But there is no harm done in repeating the simple argument. This means that there exist compact oriented $(n+1)$-dimensional smooth manifolds X and Y with $\partial X = R \sqcup -S$ and $\partial Y = S \sqcup -T$. We set $Z := X \cup_S Y$. It follows from the Gluing-Smooth Manifolds-Proposition **??** that Z is a compact orientable $(n+1)$-dimensional smooth manifold with $\partial Z = R \sqcup -T$. We refer to the figure below for an illustration.

[1714] By Lemma 144.1 we know that $\mathcal{M}_n$ and thus also $\mathcal{M}_n/\sim$ are a set.

(2) This statement follows from the following five observations:
   (a) One can easily verify that the definition does not depend on the choice of the representatives in $\mathcal{M}_n$.
   (b) It is clear that the empty smooth manifold is a neutral element for the above operation.
   (c) We need to show that any $[M] \in \mathcal{M}_n$ has an inverse element. In fact this is represented by the oriented smooth manifold $-M$, since by the discussion on page 696, we have $\partial([0,1] \times M) = \{0\} \times (-M) \cup \{1\} \times M$, i.e. the smooth manifold $[0,1] \times M$ defines a cobordism from $M \sqcup -M$ to the empty smooth manifold. We refer to the figure below for an illustration.

   (d) The product structure is commutative since $A \sqcup B$ and $B \sqcup A$ are evidently naturally diffeomorphic.
   (e) The product structure is associative since $(A \sqcup B) \sqcup C$ and $A \sqcup (B \sqcup C)$ are evidently naturally diffeomorphic. ∎

Definition. Let $n \in \mathbb{N}_0$. We refer to

$$\Omega_n \ := \ (\mathcal{M}_n/\sim, \sqcup)$$

as the n-th cobordism group.

We have another natural operation on oriented connected smooth manifolds, namely the connected sum operation. The following lemma says that up to cobordisms the connected sum operation is the same as the disjoint union.

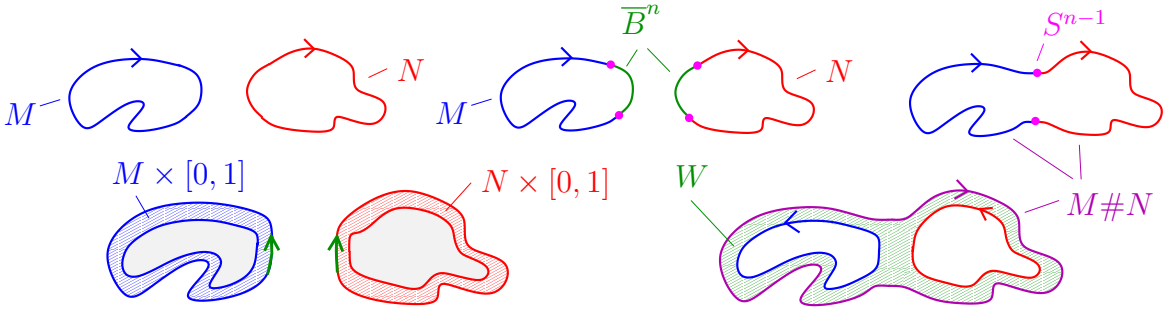
Lemma 144.3. Let $n \in \mathbb{N}$ and let M and N be two closed oriented connected n-dimensional smooth manifolds, then

$$M \# N \ = \ M \sqcup N \ \in \ \Omega_n.$$

Sketch of proof. A proof of this lemma is provided by the combination of Lemma ?? and of the Trace-of-Surgery Proposition ??. For the reader's convenience we also provide a direct proof.

Thus let M and N be two closed oriented connected n-dimensional smooth manifolds. Let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\psi\colon \overline{B}^n \to N \setminus \partial N$ be smooth embeddings such that φ is orientation-preserving and such that ψ is orientation-reversing.

We consider $[0,1] \times M$ and $[0,1] \times N$. Note that by the discussion on page 696, we have $\partial([0,1] \times M) = (\{0\} \times (-M)) \cup (\{1\} \times M)$ and $\partial([0,1] \times N) = (\{0\} \times (-N)) \cup (\{1\} \times N)$. By a slight abuse of notation we denote by φ and ψ the obvious smooth embeddings of $\overline{B}^n$ into $\{1\} \times M$ and $\{1\} \times N$. We use these two smooth embeddings to form the boundary connected sum



$$W \ := \ ([0,1] \times M) \#_b ([0,1] \times N) \ := \ ([0,1] \times M) \sqcup ([0,1] \times N) / \varphi(x) = \psi(x) \text{ for } x \in S^{n-1}$$

that we introduced on page ??.

By Proposition ?? we know that W admits the structure of an $(n+1)$-dimensional orientable smooth manifold such that

$$\partial W \;=\; \underbrace{(\{1\}\times M)\#(\{1\}\times N)}_{=M\#N} \sqcup \underbrace{(-\{0\}\times M)}_{=-M} \sqcup \underbrace{(-\{0\}\times N)}_{=-N}.$$

We have thus found the desired cobordism. ■

Definition. If we use exactly the same definitions as before except that we drop the condition that the smooth manifolds are orientable and we drop the condition that the cobordisms are orientable, then given $n\in\mathbb{N}_0$ we obtain the unoriented cobordism group

$$\mathcal{N}_n \;:=\; \{\text{closed } n\text{-dimensional smooth manifolds}\}/\text{unoriented cobordisms}.$$

The following lemma summarizes a few basic facts about unoriented cobordism groups.

Lemma 144.4.

(1) Let $n\in\mathbb{N}_0$. Every non-trivial element in $\mathcal{N}_n$ is of order two, i.e. given any $M\in\mathcal{N}_n$ we have $M\sqcup M=0\in\mathcal{N}_n$.

(2) Let $n\in\mathbb{N}$. Let M and N be two closed connected n-dimensional smooth manifolds.[1715] Then

$$M\#N \;=\; M\sqcup N \;\in\; \mathcal{N}_n.$$

Proof. Let $n\in\mathbb{N}_0$.

(1) Let $M\in\mathcal{N}_n$. We have

$$2\cdot M \;=\; M\sqcup M \;=\; (\{0\}\times M)\sqcup(\{1\}\times M) \;\underset{\uparrow}{=}\; \partial([0,1]\times M).$$

by the Smooth Manifold Product Proposition 19.31 we have this equality of unoriented smooth manifolds

(2) The proof of this statement is verbatim the same as in Lemma 144.3. ■

In the following proposition we collect the computations of the low-dimensional (unoriented) cobordism groups.

[1715] If M and N are orientable, then the connected sum $M\#N$ is only well-defined once we pick an orientation for M and N. If M and N are orientable, then the equality is understood as holding for the definition of the connected sum for any choice of orientation for M and N.

Proposition 144.5. We have the following table of isomorphism types of the (unoriented) cobordism groups for $n = 0, 1, 2, 3$:

	$n=0$	$n=1$	$n=2$	$n=3$
Ω_n	$\mathbb{Z}$	0	0	0
$\mathcal{N}_n$	$\mathbb{Z}_2$	0	$\mathbb{Z}_2 \cdot [\mathbb{R}\mathrm{P}^2]$	0

Proof.

($n=0$) Using the Smooth 1-Dimensional Manifold Classification Theorem 22.7 one can easily see that the maps

$$\begin{array}{rcl} \Omega_0 & \to & \mathbb{Z} \\ \bigsqcup_{i=1}^{k} \{(P_i, \epsilon_i)\} & \mapsto & \sum_{i=1}^{k} \epsilon_i \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \mathcal{N}_0 & \to & \mathbb{Z}_2 \\ \bigsqcup_{i=1}^{k} \{P_i\} & \mapsto & k \bmod 2 \end{array}$$

are isomorphisms.

($n=1$) In the Smooth 1-Dimensional Manifold Classification Theorem 22.7 we saw that every closed connected 1-dimensional smooth manifold is diffeomorphic to S^1. Evidently $S^1 = \partial \overline{B}^{2}$[1716], hence every generator, i.e. every (oriented) compact 1-dimensional smooth manifold represents the trivial element in Ω_1 and in $\mathcal{N}_1$. Therefore we see that $\Omega_1 = 0$ and $\mathcal{N}_1 = 0$.

($n=2$) In the Surface Classification Theorem 55.4 we saw that every closed orientable 2-dimensional smooth manifold is diffeomorphic to the surface of genus g for some g. By Proposition **??** (3) the surface of genus g is the boundary of the genus g handlebody. Thus we see that $\Omega_2 = 0$.

We turn to the calculation of $\mathcal{N}_2$. We want to prove the following claim.

Claim. The map

$$\begin{array}{rcl} \varphi\colon \mathbb{Z}_2 & \to & \mathcal{N}_2 \\ n & \mapsto & n \cdot \mathbb{R}\mathrm{P}^2 \end{array}$$

is an isomorphism.

Proof. We prove the claim in several steps:

(a) First we show that φ is a homomorphism. We denote by $\psi\colon \mathbb{Z} \to \mathcal{N}_2$ the map that is given by $n \mapsto n \cdot \mathbb{R}\mathrm{P}^2$. Since $\mathbb{Z}$ is a free group this is well-defined homomorphism. It remains to show that ψ in fact factors through the projection $\mathbb{Z} \to \mathbb{Z}_2 = \mathbb{Z}/2\mathbb{Z}$. But that is an immediate consequence of Lemma 144.4 (1).

(b) Next we show that $\varphi\colon \mathbb{Z}_2 \to \mathcal{N}_2$ is a monomorphism. We only need to show that $\varphi(1) = \mathbb{R}\mathrm{P}^2$ represents a non-trivial element in $\mathcal{N}_2$. In Corollary 119.9 we already saw, using the Euler characteristic and Poincaré Duality, that there is no compact 3-dimensional smooth manifold whose boundary is homeomorphic to $\mathbb{R}\mathrm{P}^2$. Put differently, $\mathbb{R}\mathrm{P}^2$ represents a non-trivial element in $\mathcal{N}_2$.

(c) It remains to show that φ is an epimorphism. So let M be a compact 2-dimensional smooth manifold representing an element in $\mathcal{N}_2$. Lemma 144.4 (2) shows that without loss of generality we can assume that M is connected. If M is orientable, then we already saw above that M is the boundary of a compact 3-dimensional smooth manifold, hence $[M] = 0 \in \mathcal{N}_2$.

[1716] This is an equality of oriented smooth manifolds if we equip S^1 and $\overline{B}^2$ with the usual orientation and also if we equip both smooth manifolds with the opposite orientation.

Finally we consider the case that M is non-orientable. We have

$$[M] \underset{\uparrow}{=} [\text{connected sum of } n \text{ copies of } \mathbb{R}\mathrm{P}^2] \underset{\uparrow}{=} n\cdot[\mathbb{R}\mathrm{P}^2] \underset{\uparrow}{=} (n \bmod 2)\cdot[\mathbb{R}\mathrm{P}^2].$$

by Theorem 55.4 that there exists an $n \in \mathbb{N}_0$ such that M is diffeomorphic to the connected sum of n copies of $\mathbb{R}\mathrm{P}^2$ — Lemma 144.4 (2) — Lemma 144.4 (1)

This completes the proof that φ is an epimorphism.

($n=3$) In the 3-Manifolds Bound Theorem 147.3 we already proved that $\Omega_3 = 0$. The fact that $\mathcal{N}_3 = 0$ was first shown by Albrecht Dold [**Dol1956**] in 1956. An alternative proof is given in [**Lic1963**, Thoerem 4.]. ■

We have thus shown that the (unoriented) cobordism groups for $n = 0, 1, 2, 3$ are not particularly exciting. Our next goal is to study Ω_4. By the discussion on page 1879 we know that $\chi(\mathbb{C}\mathrm{P}^2) = 3$. Thus the argument of Corollary 119.9 shows that $\mathbb{C}\mathrm{P}^2$ is a non-trivial element[1717] in Ω_4, but from Corollary 119.9 we cannot conclude whether or not $\mathbb{C}\mathrm{P}^2$ is an element of infinite order in Ω_4.

The following proposition is the key to showing that $\mathbb{C}\mathrm{P}^2$ is in fact an element of infinite order in Ω_4.

Proposition 144.6. (Boundary-Signature Theorem) Let M be a closed oriented $4k$-dimensional topological manifold with $k \geq 0$.[1718] If there exists a compact orientable topological manifold X with $\partial X = M$, then $\operatorname{sign}(M) = 0$.[1719]

It will take us a while to prove the Boundary-Signature Theorem 144.6, therefore we first provide the following corollary.

Corollary 144.7. For any $k \in \mathbb{N}$ the map

$$\begin{array}{rcl} \operatorname{sign}\colon \Omega_{4k} & \to & \mathbb{Z} \\ [M] & \mapsto & \operatorname{sign}(M) \end{array}$$

is an epimorphism.

Proof of Corollary 144.7. First we need to show that the map is well-defined. Thus suppose we are given closed oriented $4k$-dimensional smooth manifolds M and N with $[M] = [N] \in \Omega_{4k}$. By definition there exists a compact oriented smooth manifold X with $\partial X = M \sqcup -N$. We have

$$0 \underset{\uparrow}{=} \operatorname{sign}(\partial X) = \operatorname{sign}(M \sqcup (-N)) \underset{\uparrow}{=} \operatorname{sign}(M) + \operatorname{sign}(-N) \underset{\uparrow}{=} \operatorname{sign}(M) - \operatorname{sign}(N).$$

Boundary-Signature Theorem 144.6 — Manifold-Signature Lemma 133.11 (2) and (3)

This shows that $\operatorname{sign}\colon \Omega_{4k} \to \mathbb{Z}$ is well-defined. It follows from the Manifold-Signature Lemma 133.11 (2) that this map is a homomorphism. Finally it follows immediately from the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 that $\operatorname{sign}(\mathbb{C}\mathrm{P}^{2k}) = \pm 1$,[1720] which shows that $\operatorname{sign}\colon \Omega_{4k} \to \mathbb{Z}$ is an epimorphism. ■

The proof of the Boundary-Signature Theorem 144.6 will rely on a purely algebraic lemma. Before we can formulate that lemma we have to introduce one more definition.

[1717] In fact Corollary 119.9 also implies that $\mathbb{C}\mathrm{P}^2$ is a non-trivial element in $\mathcal{N}_4$.

[1718] Does the statement also hold for 0-dimensional smooth manifolds?

[1719] We refer to page 2916 for the definition of the signature of M.

[1720] In fact the more fancy Lemma 126.12 says that $\operatorname{sign}(\mathbb{C}\mathrm{P}^{2k}) = +1$, but this is irrelevant for the proof.

Definition. Given a form (V, g) and a subset $W \subset V$ we write

$$W^{\perp} := \{v \in V \mid g(v, w) = 0 \text{ for all } w \in W\}.$$

Example. We consider the form on $\mathbb{R}^2$ that is defined by the symmetric matrix

$$P := \begin{pmatrix} 0 & 1 \\ 1 & 2 \end{pmatrix}.$$

In this case for $H = \mathbb{R} \cdot (1, 0)$ we have $\mathrm{H}^{\perp} = H$.

The following lemma gives the solution to Exercise 133.2.

Lemma 144.8. Let (V, g) be a non-singular symmetric form over the reals. If there exists a subspace W with $g|_W = 0$ and with $\dim(W) = \frac{1}{2}\dim(V)$, then $\mathrm{sign}(g) = 0$.

Proof of Lemma 144.8. It follows from our hypothesis that $\dim(W) = \frac{1}{2}\dim(V)$ that we can find a basis $\{a_1, \ldots, a_k, b_1, \ldots, b_k\}$ for V such that $\{a_1, \ldots, a_k\}$ is a basis for W. Since $g|_W = 0$ and since g is symmetric we see that with respect to this basis the form g is given by a matrix of the form

$$\begin{pmatrix} 0 & P \\ P^T & Q \end{pmatrix}$$

where Q is a symmetric matrix. It follows from the hypothesis that g is non-singular that $\det(P) \neq 0$, see e.g. the Non-Singularity Lemma 121.1. Now we consider the following three transformations

$$\begin{pmatrix} P^{-1} & 0 \\ 0 & \mathrm{id} \end{pmatrix} \begin{pmatrix} 0 & P \\ P^T & Q \end{pmatrix} \begin{pmatrix} (P^T)^{-1} & 0 \\ 0 & \mathrm{id} \end{pmatrix} = \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & Q \end{pmatrix},$$

$$\begin{pmatrix} \mathrm{id} & 0 \\ -\frac{1}{2}Q & \mathrm{id} \end{pmatrix} \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & Q \end{pmatrix} \begin{pmatrix} \mathrm{id} & -\frac{1}{2}Q \\ 0 & \mathrm{id} \end{pmatrix} = \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix}$$

and

$$\begin{pmatrix} \mathrm{id} & \mathrm{id} \\ \mathrm{id} & -\mathrm{id} \end{pmatrix} \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix} \begin{pmatrix} \mathrm{id} & \mathrm{id} \\ \mathrm{id} & -\mathrm{id} \end{pmatrix} = \begin{pmatrix} 2\,\mathrm{id} & 0 \\ 0 & -2\,\mathrm{id} \end{pmatrix}.$$

It follows from the Forms-Matrices Lemma 133.1 (1) that the three matrices to the right all define isometric forms. Considering the last matrix we obtain from the Signature-Eigenvalues Proposition 133.8 that the signature is zero. ∎

The next result is the key ingredient in the proof of. As the name suggests, it is interesting in its own right.

Theorem 144.9. (Half-Live Half-Die Theorem) Let X be a compact orientable topological manifold of dimension $2n + 1$. We denote by $i\colon \partial X \to X$ the inclusion map.

(1) For any field $\mathbb{F}$ we have the following equalities:

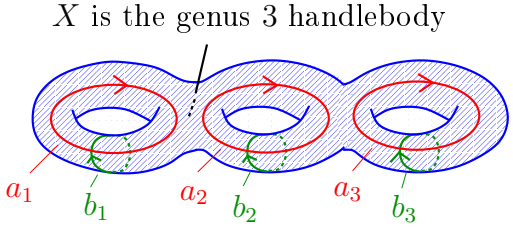
(a) $$\dim\left(\ker(i_*\colon \mathrm{H}_n(\partial X; \mathbb{F}) \to \mathrm{H}_n(X; \mathbb{F}))\right) = \frac{1}{2}\dim(\mathrm{H}_n(\partial X; \mathbb{F}))$$

and

(b) $$\dim\left(\mathrm{im}(i^*\colon \mathrm{H}^n(X; \mathbb{F}) \to \mathrm{H}^n(\partial X; \mathbb{F}))\right) = \frac{1}{2}\dim(\mathrm{H}^n(\partial X; \mathbb{F})).$$

The same statement also holds, regardless of whether or not X is orientable, if we restrict ourselves to $\mathbb{F}_2$-coefficients.

(2) We suppose that $n \geq 1$. For any $a, b \in \ker(i_*\colon \mathrm{H}_n(\partial X;\mathbb{Z}) \to \mathrm{H}_n(X;\mathbb{Z}))$ we have $Q_{\partial X}(a,b) = 0$.[1721] The same statement also holds, regardless of whether or not X is orientable, if we work with $\mathbb{F}_2$-coefficients and the $\mathbb{F}_2$-valued intersection form $Q^{\mathbb{F}_2}_{\partial X}$.



Remark. Given any homomorphism $\varphi\colon V \to W$ between finite-dimensional vector spaces the equality $\dim(\ker(\varphi))+\dim(\mathrm{im}(\varphi)) = \dim(V)$ holds. Thus statement (1a) of the theorem can be reformulated as saying that

$$\dim\big(\ker(i_*\colon \mathrm{H}_n(\partial X;\mathbb{F}) \to \mathrm{H}_n(X;\mathbb{F}))\big) \;=\; \dim\big(\mathrm{im}(i_*\colon \mathrm{H}_n(\partial X;\mathbb{F}) \to \mathrm{H}_n(X;\mathbb{F}))\big).$$

This explains why the theorem is called the "Half-Live Half-Die Theorem".

Examples.

(1) We consider the genus 3 handlebody X. In the figure below we show the usual basis $a_1, a_2, a_3, b_1, b_2, b_3$ for $\mathrm{H}_1(\partial X;\mathbb{R})$. In this case the kernel of the inclusion induced map $\mathrm{H}_1(\partial X;\mathbb{R}) \to \mathrm{H}_1(X;\mathbb{R})$ is the three dimensional subspace generated by b_1, b_2 and b_3.

(2) Let $K \subset S^3$ be a knot, we denote by X_K the knot exterior, see page 2213. The boundary of X_K is a torus. By the Longitude-Meridian Lemma 131.2 (1) the meridian μ and the longitude λ form a basis for $\mathrm{H}_1(X_K;\mathbb{R})$. have

$$\dim\Big(\underbrace{\ker(\mathrm{H}_1(\partial X_K;\mathbb{R}) \to \mathrm{H}_1(X_K;\mathbb{R}))}_{=\mathbb{R}\cdot\lambda \text{ by the Longitude-Meridian Lemma 131.2 (1)}}\Big) = 1 \;=\; \tfrac{1}{2}\cdot 2 \;=\; \tfrac{1}{2}\cdot\dim(\mathrm{H}_1(\partial X_K;\mathbb{R})).$$

For clarity we prove the two parts of the Half-Live Half-Die Theorem 144.9 separately.

Proof of the Half-Live Half-Die Theorem 144.9 (1). Let X be a compact oriented $(2n+1)$-dimensional topological manifold. We denote by $i\colon \partial X \to X$ the inclusion map and we write $M = \partial X$. Let $\mathbb{F}$ be any field. We first prove the first equality. Until further notice, we henceforth work with $\mathbb{F}$-coefficients for all (co-) homology groups. For space reasons we do not mention the $\mathbb{F}$-coefficients explicitly. We consider the long exact sequence in homology of the pair (X, M):

$$\to \mathrm{H}_{n+1}M \to \mathrm{H}_{n+1}X \to \mathrm{H}_{n+1}(X,M) \xrightarrow{\partial} \mathrm{H}_nM \xrightarrow{i_*} \mathrm{H}_nX \to \mathrm{H}_n(X,M) \to \mathrm{H}_{n-1}M \to$$

The key observation is that this long exact sequence is "symmetric" around $\mathrm{H}_n(M;\mathbb{F})$. More precisely, by the Co-Homology Symmetry Theorem Theorem 119.6 (2)[1722] we have

[1721] Here $Q_{\partial X}$ denotes the $\mathbb{Z}$-valued intersection form that we introduced on page 2800. Also recall that on page 2922 we introduced the $\mathbb{F}_2$-valued intersection form.

[1722] Even though it is irrelevant we would like to stress that the isomorphisms $\mathrm{H}_k(M;\mathbb{F}) \cong \mathrm{H}_{2n-k}(M;\mathbb{F})$, $\mathrm{H}_k(X;\mathbb{F}) \cong \mathrm{H}_{2n+1-k}(X,M;\mathbb{F})$ and $\mathrm{H}_k(X,M;\mathbb{F}) \cong \mathrm{H}_{2n+1-k}(X;\mathbb{F})$ are not natural.

the following isomorphisms:

$$\to \overbrace{\mathrm{H}_{n+1}M}^{\cong \mathrm{H}_{n-1}M} \to \overbrace{\mathrm{H}_{n+1}X}^{\cong \mathrm{H}_n(X,M)} \to \overbrace{\mathrm{H}_{n+1}(X,M)}^{\cong \mathrm{H}_nX} \xrightarrow{\partial} \mathrm{H}_nM \xrightarrow{i_*} \mathrm{H}_nX \to \mathrm{H}_n(X,M) \to \mathrm{H}_{n-1}M \to$$

Therefore it suffices to prove the following purely algebraic claim.

Claim. If

$$0 \to A_k \xrightarrow{\beta_k} A_{k-1} \to \cdots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \cdots \to A_{k-1} \xrightarrow{\alpha_k} A_k \to 0$$

is an exact sequence of finite-dimensional real vector spaces,[1723] then

$$\dim(\ker(\gamma\colon B \to A_1)) \;=\; \tfrac{1}{2} \cdot \dim B.$$

Proof. We prove the claim by induction on k. The case $k = 0$ is clear, since in this case $B = 0$. Now consider a symmetric sequence

$$0 \to A_k \xrightarrow{\beta_k} A_{k-1} \to \cdots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \cdots \to A_{k-1} \xrightarrow{\alpha_k} A_k \to 0.$$

as above. It follows from the Break-into-SES Lemma 78.4 that the following sequence is also exact

$$0 \to A_{k-1}/\beta_k(A_k) \to \cdots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \cdots \to \ker(A_{k-1} \xrightarrow{\alpha_k} A_k) \to 0.$$

But we have

$$\dim(A_{k-1}/\beta_k(A_k)) \underset{\substack{\uparrow \\ \text{since } \beta_k \text{ is injective}}}{=} \dim(A_{k-1}) - \dim(A_k) \underset{\substack{\uparrow \\ \text{since } \alpha_k \text{ is surjective}}}{=} \dim(\ker(A_{k-1} \xrightarrow{\alpha_k} A_k)).$$

So the new shorter sequence is also symmetric. So we can apply the induction hypothesis to get the desired equality. This concludes the proof of the claim and thus of the first equality of the lemma.

The proof of the second equality of the lemma is almost identical to the proof of the first equality. This concludes the proof of the lemma regarding $\mathbb{F}$-valued (co-) homology groups.

Now let X be any compact $(2n+1)$-dimensional topological manifold, without any assumptions on orientability. In this case verbatim the same argument as above works, we just need to replace $\mathbb{F}$-coefficients by $\mathbb{F}_2$-coefficients and we need to replace the Co-Homology Symmetry Theorem Theorem 119.6 (2) by the Co-Homology Symmetry Theorem Theorem 119.6 (1). ∎

Proof of the Half-Live Half-Die Theorem 144.9 (2). In the following we will only prove the statement regarding $\mathbb{Z}$-coefficients. The reader will have no troubles with making the straightforward adjustments needed to obtain a proof for $\mathbb{F}_2$-coefficients. Now let $a, b \in \ker(\mathrm{H}_n(M;\mathbb{Z}) \to \mathrm{H}_n(X;\mathbb{Z}))$.

Claim. There exist cohomology classes $\varphi, \psi \in \mathrm{H}^n(X;\mathbb{Z})$ such that $\mathrm{PD}_M(a) = i^*(\varphi)$ and $\mathrm{PD}_M(b) = i^*(\psi)$.

[1723] Recall that by the Topological Manifolds-Invariants Proposition 104.14 (4) together with Lemma 96.8 (1) we know that the real homology groups of X, M and (X, M) are finite-dimensional vector spaces.

Proof. We consider the following diagram

$$\begin{array}{ccccccccc}
\ldots \longrightarrow & \mathrm{H}^n(X,M;\mathbb{Z}) & \longrightarrow & \mathrm{H}^n(X;\mathbb{Z}) & \xrightarrow{i^*} & \mathrm{H}^n(M;\mathbb{Z}) & \xrightarrow{\delta} & \mathrm{H}^{n+1}(X,M;\mathbb{Z}) & \longrightarrow \ldots \\
& \cong\downarrow{\scriptstyle -\cap[X]} & & \cong\downarrow{\scriptstyle -\cap[X]} & & \cong\downarrow{\scriptstyle -\cap[M]} & & \cong\downarrow{\scriptstyle -\cap[X]} & \\
\ldots \longrightarrow & \mathrm{H}_{n+1}(X;\mathbb{Z}) & \longrightarrow & \mathrm{H}_{n+1}(X,M;\mathbb{Z}) & \longrightarrow & \mathrm{H}_n(M;\mathbb{Z}) & \xrightarrow{i_*} & \mathrm{H}_n(X;\mathbb{Z}) & \xrightarrow{\partial} \ldots
\end{array}$$

where the horizontal sequences of the pair (X,M). By Theorem 119.1 and Proposition 119.25 we know that the vertical maps are isomorphisms and we know that the diagram commutes up signs. The claim follows almost immediately from the above discussion. ⊞

Now we calculate that

$$\begin{array}{rcccccl}
Q_M(a,b) & = & \langle \mathrm{PD}_M(a) \cup \mathrm{PD}_M(b), [M]\rangle & = & \langle i^*(\varphi)\cup i^*(\psi), [M]\rangle_M & & \\
& = & \langle i^*(\varphi\cup\psi), [M]\rangle_M & = & \langle \varphi\cup\psi, i_*([M])\rangle_X & = & \langle \varphi\cup\psi, 0\rangle_X \;=\; 0. \\
& \uparrow & & \uparrow & & \uparrow & \\
& \text{Cup Product-Naturality Lemma 114.10} & & \text{Lemma 109.6 (3)} & & \text{Corollary 106.28} &
\end{array}$$

■

Finally we can turn to the actual proof of the Boundary-Signature Theorem 144.6.

Proof of the Boundary-Signature Theorem 144.6. Let X be a compact oriented $(4k+1)$-dimensional topological manifold with $k \geq 1$. We write $M = \partial X$. We want to show that $\mathrm{sign}(M) = 0$. If $M = \varnothing$, then there is nothing to show. So suppose that $M \neq \varnothing$.

Recall that it follows from the Intersection Form Proposition 132.4 that $Q_M \colon \mathrm{FH}_n(M;\mathbb{Z}) \times \mathrm{FH}_n(M;\mathbb{Z}) \to \mathbb{Z}$ is symmetric and non-singular. It follows easily that the form $Q_M \otimes \mathbb{R}$ is also symmetric and non-singular. Furthermore note that it follows almost immediately from the Half-Live Half-Die Theorem 144.9 (2) and Corollary 89.19 that $Q_M \otimes \mathbb{R}$ vanishes on $P := \ker(\mathrm{H}_{2k}(M;\mathbb{R}) \to \mathrm{H}_{2k}(X;\mathbb{R}))$.

Next we point out that by Half-Live Half-Die Theorem 144.9 (1b) together with Corollary 89.19 we know that $\dim(P) = \frac{1}{2}\dim(\mathrm{H}_{2k}(M;\mathbb{R}))$. Since, as we discussed, $Q_M \otimes \mathbb{R}$ is non-singular and symmetric and since it vanishes on the half-dimensional subspace P we now finally obtain from Lemma 144.8 that $\mathrm{sign}(M) = \mathrm{sign}(Q_M \otimes \mathbb{R}) = 0$. ■

Before we continue with the determination of cobordism groups we prove the following elementary lemma.

Lemma 144.10. For any $m, n \in \mathbb{N}_0$ the maps

$$\begin{array}{ccc} \Omega_m \times \Omega_n & \to & \Omega_{m+n} \\ ([M],[N]) & \mapsto & [M\times N] \end{array} \qquad \text{and} \qquad \begin{array}{ccc} \mathcal{N}_m \times \mathcal{N}_n & \to & \mathcal{N}_{m+n} \\ ([M],[N]) & \mapsto & [M\times N] \end{array}$$

are well-defined.

Proof. We prove the statement regarding the Ω_k's, the proof for the $\mathcal{N}_k$'s is verbatim the same. So suppose that we have $[M] = [M'] \in \Omega_m$ and $[N] \in \Omega_n$. This means that there exists a compact oriented $(m+1)$-dimensional smooth manifold W with $\partial W = M \sqcup (-M')$. But then we also have

$$\begin{array}{rcccl} \partial(W\times N) & = & \partial W \times N \;=\; (M \sqcup (-M')) \times N & = & (M\times N) \sqcup -(M'\times N). \\ & \uparrow & & \uparrow & \\ & \text{by the Smooth Manifold Product Proposition 19.31 (3) since } N \text{ is closed} & & \text{since } (-M')\times N = -(M'\times N) & \end{array}$$

This shows that $[M\times N] = [M'\times N]$. The same argument shows that the map does not depend on the representative of $[N] \in \Omega_n$. ■

Definition. We define

$$\Omega_* := \bigoplus_{n\in\mathbb{N}_0} \Omega_n \quad \text{and} \quad \mathcal{N}_* := \bigoplus_{n\in\mathbb{N}_0} \mathcal{N}_n.$$

Together with the maps defined in Lemma 144.10 we can view these groups as commutative rings. We refer to Ω_* as the cobordism ring and we refer to $\mathcal{N}_*$ as the unoriented cobordism ring.

The following theorem summarizes some of the most important results on the cobordism ring Ω_*.

Theorem 144.11. (Thom Cobordism Theorem)

(1) The ring homomorphism[1724][1725][1726]

$$\begin{aligned} \mathbb{Q}[\{x_m\}_{m\in\mathbb{N}}] &\to \Omega_* \otimes \mathbb{Q} \\ x_m &\mapsto \mathbb{C}\mathrm{P}^{2m} \end{aligned}$$

that is determined by

is an isomorphism.

(2) For small n the isomorphism types of Ω_n are given by

n	0	1	2	3	4	5	6	7	8	9	10	11
Ω_n	$\mathbb{Z}$	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	0	0	$\mathbb{Z}\oplus\mathbb{Z}$	$\mathbb{Z}_2\oplus\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_2$

Hereby a generator for $\Omega_4 \cong \mathbb{Z}$ is given by $\mathbb{C}\mathrm{P}^2$ and a basis for $\Omega_8 \cong \mathbb{Z}^2$ is given by $\{\mathbb{C}\mathrm{P}^4, \mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2\}$.[1727]

(3) The group Ω_n is non-trivial for every $n \geq 8$.

(4) Every torsion element in Ω_n has order 2.

Proof.

(1) The first statement was proved by René Thom [**Tho2007**, Chapter IV], see also [**Stong1968**, p. 177]. An outline of the proof is presented in [**Kupe2017c**].

(2) The calculation of the cobordism groups $\Omega_0, \ldots, \Omega_3$ was given in Proposition 144.5, the values $\Omega_4, \ldots, \Omega_7$ are given by René Thom in [**Tho2007**, Theorem IV.13]. For $\Omega_8, \ldots, \Omega_{11}$ we refer to [**MiS1974**, p. 203].

(3) This statement is proved in [**Dol1956**, p. 34].

(4) The last statement was proved by Terrence Wall [**Wall1960**], see also [**Stong1968**, p. 182]. ■

The following theorem, which is due to [**Tho2007**, Theorem IV.12] and [**Dol1956**, p. 32], gives the complete calculation of the unoriented cobordism ring $\mathcal{N}_*$.

[1724] On the left-hand side $\mathbb{Q}[\{x_m\}_{m\in\mathbb{N}}]$ denotes the polynomial ring over $\mathbb{Q}$ with variables $\{x_m\}_{m\in\mathbb{N}}$.

[1725] Note that the tensor product of two commutative rings is again a commutative ring with the "naive multiplication". In particular the right-hand side $\Omega_* \otimes \mathbb{Q}$ is a commutative ring.

[1726] If we give each variable x_m the grading $4m$, and if we equip $\Omega_* \otimes \mathbb{Q}$ with the obvious grading, then this is an isomorphism of graded rings.

[1727] Note that in the ring homomorphism from (1) we have $x_1 \mapsto [\mathbb{C}\mathrm{P}^2]$ and $x_1^2 \mapsto [\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2]$ and also $x_2 \mapsto [\mathbb{C}\mathrm{P}^4]$.

Theorem 144.12. (Thom-Dold Cobordism Theorem) We let $I = \{n \in \mathbb{N} \,|\, n \neq 2^i - 1\} = \{2, 4, 5, 6, 8, 9, \dots\}$. There exists a ring isomorphism

$$\mathbb{Z}_2[\{x_i\}_{i \in I}] \;\to\; \mathcal{N}_*$$

which is given by sending x_{2k} to $\mathbb{R}\mathrm{P}^k$ and given by sending x_i for odd i to an appropriate i-dimensional Dold smooth manifold. Here a Dold smooth manifold is a smooth manifold of the form[1728]

$$P(m,n) \;:=\; (S^m \times \mathbb{C}\mathrm{P}^n)/(x,z) \sim (-x,\overline{z}) \quad \text{for } x \in S^m \text{ and } z \in \mathbb{C}\mathrm{P}^n$$

for some $n, m \in \mathbb{N}_0$.

Exercises for Chapter 144.

Exercise 144.1. We consider the Klein bottle

$$K \;=\; (S^1 \times [0,1])/\!\sim \quad \text{where } (z,0) \;\sim\; (\overline{z},1) \text{ for all } z \in S^1.$$

In Lemma **??** (1) we showed that K is diffeomorphic to $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$. Thus it follows from Lemma 144.4 that $[K] = [\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2] = [\mathbb{R}\mathrm{P}^2 \sqcup \mathbb{R}\mathrm{P}^2] = 2 \cdot [\mathbb{R}\mathrm{P}^2] = 0 \in \mathcal{N}_2$. Write down an explicit compact 3-dimensional smooth manifold M with $\partial M = K$.

Exercise 144.2. Provide a proof for Lemma 144.8 that does not uses bases.[1729] Let us elaborate. Let (V, g) be a non-singular symmetric form over $\mathbb{R}$ and suppose that there exists a subspace W of V with $g|_W = 0$ and with $\dim(W) = \frac{1}{2}\dim(V)$. Show that given any subspace A of V such that $g|_A$ is positive (respectively negative) definite there exists a subspace B of V such that $g|_B$ is negative (respectively positive) definite and which satisfies $\dim(A) = \dim(B)$. A proof of this statement implies that $\mathrm{sign}(g) = 0$.

Exercise 144.3. Let $L = L_1 \cup \dots \cup L_m$ be an m-component link in S^3. We denote by X_L its exterior which is defined the same way as we defined the exterior of a knot on page 2213. The boundary of X_L consists of m tori $T_1, \dots, T_m$. Let $k \in \{1, \dots, m\}$. We denote by $i\colon T_k \to X_L$ the inclusion map.

(a) Show that $\dim(\mathrm{im}(i_*\colon \mathrm{H}_1(T_k;\mathbb{R}) \to \mathrm{H}_1(X_L;\mathbb{R}))) \geq 1$.

(b) Do we necessarily have $\dim(\mathrm{im}(i_*\colon \mathrm{H}_1(T_k;\mathbb{R}) \to \mathrm{H}_1(X_L;\mathbb{R}))) = 1$?

Exercise 144.4. Provide a proof for Lemma 150.1.

Exercise 144.5.

(a) Let M be an orientable n-dimensional smooth manifold with $n \geq 4$ and let $C \cong S^1$ be a closed connected one-dimensional submanifold. By the Tubular Neighborhood Theorem **??** there exists a tubular neighborhood $\overline{B}^{n-1} \times C = \overline{B}^{n-1} \times S^1$. By Propositions 24.16 and **??**

$$W \;:=\; (M \setminus (C \times B^{n-1})) \cup_{C \times S^{n-2} = S^1 \times S^{n-2}} (\overline{B}^2 \times S^{n-2})$$

is an n-dimensional smooth manifold. Compute $\pi_1(W)$ in terms of $\pi_1(M)$ and C. (This approach to modifying the smooth manifold M is sometimes called a *surgery*.)

[1728] It follows from the Manifold Quotient-by-Group Action Proposition 19.32 that each $P(m,n)$ is in fact a closed smooth manifold.

[1729] As the reader surely knows, introducing bases is morally wrong and should be avoided at all costs.

(b) Let $n \geq 3$ and let X be a closed n-dimensional smooth manifold. Suppose that there exists a compact orientable $(n+1)$-dimensional M with $\partial M = X$. Show that there exists also a compact orientable *simply connected* $(n+1)$-dimensional smooth manifold N with $\partial N = X$.
(c) Does (b) also hold for $n = 2$?

Exercise 144.6. Let V be an $\mathbb{F}_2$-vector space of dimension $2k$ and let $\langle\ ,\ \rangle\colon V \times V \to \mathbb{F}_2$ be a symmetric non-singular form. Suppose we are given vectors $a_1, \ldots, a_k \in V$ such that $\langle a_i, a_j \rangle = 0$ for all $i, j \in \{1, \ldots, k\}$. Show that there exist vectors $b_1, \ldots, b_k \in V$ such that the following conditions are satisfied:

(1) The vectors $a_1, \ldots, a_k, b_1, \ldots, b_k$ are a basis for V.
(2) For each $i, j \in \{1, \ldots, k\}$ we have $\langle a_i, b_j \rangle = \delta_{ij}$.
(3) For each $i, j \in \{1, \ldots, k\}$ we have $\langle b_i, b_j \rangle = 0$.

Remark. Such a basis for V is often called a *symplectic basis*.

145. Pontryagin classes and the Hirzebruch Signature Theorem

In this chapter we will introduce the Pontryagin classes of vector bundles. Afterwards we will formulate the Hirzebruch Signature Theorem, which amazingly, shows that the Pontryagin classes of the tangent bundle of a smooth manifold determine the signature.

145.1. **Pontryagin classes.** Given a topological space X and $i \in \mathbb{N}_0$ we define

$$\overline{\mathrm{H}}^i(X;\mathbb{Z}) \ := \ \mathrm{H}^i(X;\mathbb{Z})/\{a \in \mathrm{H}^i(X;\mathbb{Z}) \,|\, 2a = 0\}.$$

It should be clear that these cohomology groups $\overline{H}$ are also contravariantly functorial and that all the results on usual cohomology groups have obvious analogues.
The following result is one of the key theorems of this chapter. It was proved initially in about 1940 by Lev Pontryagin.

Theorem 145.1. For each $i \in \mathbb{N}_0$ we can assign to every vector bundle $p\colon E \to X$ over a paracompact space a cohomology class $p_i(E) \in \overline{\mathrm{H}}^{4i}(X;\mathbb{Z})$, called *$i$-th Pontryagin class*, such that the following conditions are satisfied:

(1) The 0-th Pontryagin class of any vector bundle over a topological space X is the unit element in $\overline{\mathrm{H}}^0(X;\mathbb{Z})$.
(2) For any trivial vector bundle all Pontryagin classes p_i with $i \geq 1$ are zero.
(3) The Pontryagin class behaves well under pullbacks, i.e. if we are given a vector bundle $q\colon F \to Y$ and a map $g\colon X \to Y$ of topological spaces, then for any $i \in \mathbb{N}_0$ we have
$$p_i(g^*F) \ = \ g^*(p_i(F)) \ \in \ \overline{\mathrm{H}}^{4i}(X;\mathbb{Z}).$$
(4) If $p\colon E \to X$ is an n-dimensional vector bundle, then $p_i(E) = 0$ for $i > \frac{n}{2}$.
(5) We denote by $x \in \overline{\mathrm{H}}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ the standard generator as introduced on page 2662 and in the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11. Then for $i = 0, \ldots, n+1$ we have[1730]
$$p_i(T\mathbb{C}\mathrm{P}^n) \ = \ \binom{n+1}{i} \cdot x^{2i} \ \in \ \overline{\mathrm{H}}^{4i}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \ = \ \mathbb{Z}[x]/(x^{n+1})$$
and all other Pontryagin classes are zero.

Given a vector bundle $p\colon E \to X$ we refer to
$$p(E) \ := \ \underbrace{\bigoplus_{i=0}^{\infty} p_i(E)}_{\text{finite sum by Theorem 145.1 (4)}} \ \in \ \overline{\mathrm{H}}^*(X;\mathbb{Z}) \ = \ \bigoplus_{i=0}^{\infty} \overline{\mathrm{H}}^i(X;\mathbb{Z})$$
as the *total Pontryagin class*. With this definition we can state the last property of Pontryagin classes:

(6) The total Pontryagin class is multiplicative with respect to the direct sum of vector bundles *up to 2-torsion*. More precisely, if $e\colon E \to X$ and $f\colon F \to X$ are two vector bundles, then
$$p(E \oplus F) \ = \ p(E) \cup p(F) \ \in \ \overline{\mathrm{H}}^*(X;\mathbb{Z}).$$

[1730] Note that for $i > \lfloor \frac{n}{2} \rfloor$ we have $x^{2i} = 0 \in \mathrm{H}^{4i}(\mathbb{C}\mathrm{P}^n) = 0$. Nonetheless, for later it is convenient to write down this expression for all i up to n.

Remark.

(1) The above introduction to Pontryagin classes differs somewhat from the usual approach taken in [**MiS1974, Hat2**]. In particular Pontryagin classes are usually defined as elements in the usual cohomology groups.
(2) It is not entirely clear whether classes $p_i(E)$ are uniquely defined by the properties stated in Theorem 145.1. Similar uniqueness statements hold for "Stiefel-Whitney classes" and "Chern classes", see [**Hat2**, Theorems 3.1 and 3.2], but it is nonetheless not clear to me how to prove uniqueness for Pontryagin classes. Fortunately that is of no concern to us.

For category aficionados we make the following remark.

Remark. We can squeeze some of the statements of Theorem 145.1 into the language of category theory:

(1) Let $\mathcal{Top}$ be the category of topological spaces and let $\mathcal{Set}$ be the category of sets, i.e. the objects are sets and the morphisms are just maps.
(2) As on page 3067 we denote by $\mathrm{Vect}^n_{\mathbb{R}}(X)$ the set of isomorphism classes of n-dimensional real vector bundles over X. We write $\mathrm{Vect}_{\mathbb{R}}(X) = \bigcup_{n\in\mathbb{N}} \mathrm{Vect}^n_{\mathbb{R}}(X)$.
(3) For each $i \in \mathbb{N}_0$ we consider the following two contravariant functors:

$$\begin{array}{c} \mathcal{Top} \to \mathcal{Set} \\ X \mapsto \mathrm{H}^{4i}(X;\mathbb{Z}) \\ \big(X \xrightarrow{f} Y\big) \mapsto \big(\overline{\mathrm{H}}^{4i}(Y) \xrightarrow{f^*} \overline{\mathrm{H}}^{4i}(X)\big) \end{array} \quad \& \quad \begin{array}{c} \mathcal{Top} \to \mathcal{Set} \\ X \mapsto \mathrm{Vect}_{\mathbb{R}}(X) \\ \big(X \xrightarrow{f} Y\big) \mapsto \begin{pmatrix} \mathrm{Vect}_{\mathbb{R}}(Y) \to \mathrm{Vect}_{\mathbb{R}}(X) \\ [G \xrightarrow{p} Y] \mapsto [f^*G \to X] \end{pmatrix}. \end{array}$$

(4) In this language we can say that Pontryagin classes are a natural transformation between these two contravariant functors. This sentence now models property (3) of Pontryagin classes.

Sketchy sketch of a proof. Given $n \in \mathbb{N}$ we denote by $G(n)$ the infinite Grassmannian that we introduced on page 3074. In [**Hat2**, Proposition 3.16] it is shown that[1731][1732]

$$(\overline{\mathrm{H}}^*(G(n);\mathbb{Z}), \cup) \;\cong\; \mathbb{Z}[q_1, \ldots, q_k] \text{ for } n = 2k \text{ or } n = 2k+1$$

where each q_i has degree $4i$. Now let $p\colon E \to X$ be an n-dimensional vector bundle. We denote by $F \to G(n)$ the n-dimensional vector bundle over the infinite Grassmannian $G(n)$ that we introduced on page 3074. By Proposition 143.15 there exists a map $g\colon X \to G(n)$ such that g^*F is isomorphic to E. We define $p_i(E) := g^*(q_i) \in \overline{\mathrm{H}}^{4i}(X;\mathbb{Z})$. It follows from Proposition 143.15 that this definition does not depend on the choice of the map g.

The proof that the Pontryagin classes have all the stated properties is given in [**MiS1974**, Chapter 15]. ■

[1731] The fact that the cohomology ring $(\overline{\mathrm{H}}^*(G(n);\mathbb{Z}), \cup)$ is a polynomial algebra should ring a bell: When we introduced the (infinite) Grassmannian $G(n)$ we were saying that it should be viewed as a generalization of the (infinite) real projective spaces. Thus the calculation of the cup product mirrors our calculation that $(\mathrm{H}^*(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}), \cup) \cong \mathbb{Z}[x]$, see the Cup Product-$\mathbb{C}\mathrm{P}^\infty$-Proposition 121.12, and our calculation that $(\mathrm{H}^*(\mathbb{R}\mathrm{P}^\infty;\mathbb{F}_2), \cup) \cong \mathbb{F}_2[x]$, see the Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16 (3).

[1732] The calculation of the cohomology ring over the usual cohomology groups $\mathrm{H}^*(G(n);\mathbb{Z})$ is somewhat more involved, see [**Hat2**, Theorem 3.9] for more information.

Example. Let $n \in \mathbb{N}$. Let M be a closed orientable submanifold of $\mathbb{R}^n$ of codimension one. For example we could take $M = S^{n-1} \subset \mathbb{R}^n$ or M could be the surface of some genus g which, by the discussion on page 708, we can view as a submanifold of $\mathbb{R}^3$.[1733] We want to determine the total Pontryagin class of the tangent bundle $\mathrm{T}M$. As before we denote by NM the normal bundle of $M \subset \mathbb{R}^n$. Then

$$p(\mathrm{T}M) \underset{\uparrow}{=} p(\mathrm{T}M) \cup p(NM) \underset{\uparrow}{=} p(\mathrm{T}M \oplus NM) \underset{\uparrow}{=} p(\text{trivial bundle } M \times \mathbb{R}^n) \underset{\uparrow}{=} 1.$$

by Theorem 145.1 (1) and (2) since the vector bundle NM is trivial, see page 3065 — by Theorem 145.1 (6) — see page 3079 — Theorem 145.1 (2)

In the remainder of this chapter we are mostly interested in tangent bundles of smooth manifolds, which leads us to the following definition.

Definition. Given a smooth manifold M we define its Pontryagin classes as the Pontryagin classes of its tangent bundle, i.e. for $i \in \mathbb{N}_0$ we write $p_i(M) := p_i(\mathrm{T}M) \in \overline{\mathrm{H}}^{4i}(M;\mathbb{Z})$.

Example. With these definitions the statement of Theorem 145.1 (5) is equivalent to

$$p(\mathbb{C}\mathrm{P}^n) \underset{\uparrow}{=} \sum_{i=0}^{n} \binom{n+1}{i} \cdot x^{2i} \underset{\uparrow}{=} \overbrace{(1+x^2)^{n+1}}^{\text{higher terms are zero in the ring}} \in \overline{\mathrm{H}}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \underset{\uparrow}{=} \mathbb{Z}[x]/(x^{n+1}).$$

by Theorem 145.1 (2) and (5) since $T\mathbb{C}\mathrm{P}^n$ is $2n$-dimensional — general binomial formula, together with the fact that $x^j = 0$ for $j \geq n+1$ — Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 126.11

For example we have

$$p(\mathbb{C}\mathrm{P}^1) = 1, \quad p(\mathbb{C}\mathrm{P}^2) = 1 + 3x^2, \quad p(\mathbb{C}\mathrm{P}^3) = 1 + 4x^2, \quad p(\mathbb{C}\mathrm{P}^4) = 1 + 5x^2 + 10x^4.$$

145.2. **Pontryagin classes as invariants of smooth manifolds.** So far, throughout these lectures we have basically only studied invariants of topological spaces. Even the de Rham cohomology groups that we introduced in Section **??** were shown in Proposition 118.6 to be topological invariants, i.e. their isomorphism types depend only on the homeomorphism type of the underlying topological space.
The Pontryagin classes of a smooth manifold M turn out to be more subtle invariants: they are defined using the tangent bundle of M. The definition of the tangent bundle in turn relies on the choice of the smooth structure. Put differently, a priori the Pontryagin classes $p_i(M) \in \overline{\mathrm{H}}^{4i}(M;\mathbb{Z})$ depend on the smooth structure of the smooth manifold.
The following lemma shows how diffeomorphisms interact with Pontryagin classes.

Lemma 145.2. If $f\colon M \to N$ is a local diffeomorphism between two smooth manifolds, then for any $i \in \mathbb{N}_0$ we have

$$p_i(\mathrm{T}M) = f^*(p_i(\mathrm{T}N)) \in \overline{\mathrm{H}}^{4i}(M;\mathbb{Z}).$$

Proof. The lemma is an immediate consequence of Lemma 143.12 (1) and Theorem 145.1 (3). ∎

[1733] The Pontryagin classes for surfaces are zero for the stupid reason that they live in dimensions $4i$, but that is besides the point for this example.

In [**Sharm1985**, Theorem 1.6] it is shown that the first Pontryagin class cannot detect the difference between different smooth structures. But the following theorem demonstrates that the higher Pontryagin classes contain information on smooth structures of smooth manifolds.

Theorem 145.3. For any $n \geq 2$ there exist two closed smooth manifolds M and M' with the following properties:

(1) the smooth manifolds M and M' are homeomorphic,
(2) the n-th Pontryagin class of M is trivial, whereas
(3) the n-th Pontryagin class of M' is non-zero.

In particular it follows from Lemma 145.2 that the smooth manifolds M and M' are not diffeomorphic.

Proof. This theorem is proved in [**KrL2005**, Theorem 4.8], see also [**KrL2005**, Proof of Proposition 4.7]. Examples of non-compact smooth manifolds M and M' with the same properties (1), (2) and (3) were given before by John Milnor [**Miln1964a**, p. 78] in 1964, see also [**Rudy2016**, p. 87]. Furthermore, similar ideas had already been used before by John Milnor [**Miln1956a**] in the proof of Theorem **??** where he showed that there exists a smooth manifold that is homeomorphic but not diffeomorphic to S^7. ■

In fact the non-zero Pontryagin classes of the smooth manifold M' in [**Miln1964a**, p. 78] and [**KrL2005**, Theorem 4.8] happen to be torsion elements, so the Pontryagin classes of M and M' differ by some torsion element in cohomology. This leads us to the definition of the *rational Pontryagin* classes of a smooth manifold.

Definition. Given a smooth manifold M and $i \in \mathbb{N}_0$ we define the i-th rational Pontryagin class $p_i(M;\mathbb{Q})$ of M to be the image of $p_i(M)$ under the map $\overline{\mathrm{H}}^{4i}(M;\mathbb{Z}) \to \mathrm{H}^{4i}(M;\mathbb{Q})$.

The following theorem says that rational classes can *not* be used to find examples of smooth manifolds that are homeomorphic but non-diffeomorphic. The theorem was proved by Sergei Novikov [**Nov1965**] in 1965.[1734]

Theorem 145.4. Let $f\colon M \to M'$ be a homeomorphism between closed smooth manifolds. We denote by $f^*\colon \mathrm{H}^*(M';\mathbb{Q}) \to \mathrm{H}^*(M;\mathbb{Q})$ the induced map on rational cohomology. Then for any $i \in \mathbb{N}_0$ we have

$$p_i(M;\mathbb{Q}) \;=\; f^*(p_i(M';\mathbb{Q})).$$

145.3. **Pontryagin numbers and the signature.** We start out with the definition of the Pontryagin numbers of a smooth manifold.

Definition.

(1) Let $n \in \mathbb{N}_0$. A partition of n is a set $I = \{i_1, \ldots, i_r\}$ of numbers in $\mathbb{N}$ such that $n = i_1 + \cdots + i_r$. Often we just write, $I = i_1 + \cdots + i_r$ is a partition of n.[1735]

[1734] Sergei Novikov (*1938) is a Russian mathematician who obtained a Fields medal in 1970.

(2) Let $n \in \mathbb{N}_0$ and let $I = i_1 + i_2 + \cdots + i_r$ be a partition of n. Given a closed oriented $4n$-dimensional smooth manifold we define its I-Pontryagin class as

$$p_I(M) \;:=\; p_{i_1}(M) \cup \cdots \cup p_{i_r}(M) \;\in\; \overline{\mathrm{H}}^{4n}(M;\mathbb{Z})$$

and we define the corresponding I-Pontryagin number as

$$\widetilde{p}_I(M) \;:=\; \langle p_I(M), [M]\rangle \;\in\; \mathbb{Z}.$$

Remark. Let M and M' be two closed oriented $4n$-dimensional smooth manifolds. If there exists an orientation-preserving diffeomorphism from M to M', then it follows easily from Lemma 145.2 that all of the Pontryagin numbers of M and M' agree.

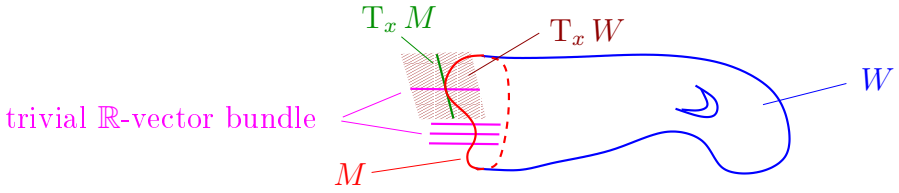
The following proposition relates Pontryagin classes to Chapter 144 which dealt with cobordisms. The proposition was first proved by Pontryagin.

Proposition 145.5. Let $n \in \mathbb{N}_0$ and let $I = i_1 + i_2 + \cdots + i_r$ be a partition of n.

(1) Let M be a closed oriented $4n$-dimensional smooth manifold. If M is the boundary of a compact orientable smooth manifold W, then $\widetilde{p}_I(M) = 0$.

(2) The map

$$\begin{array}{rccc} \widetilde{p}_I\colon & \Omega_{4n} & \to & \mathbb{Z} \\ & M & \mapsto & \widetilde{p}_I(M) \end{array}$$



is a well-defined homomorphism.

Proof. Let W be a compact oriented $(4n+1)$-dimensional smooth manifold. We set $M = \partial W$ and we denote by $i\colon M \to W$ the inclusion map. The subsequent calculation relies on the following claim.

Claim. If we denote by $\mathrm{T}M \oplus \mathbb{R}$ the direct sum of $\mathrm{T}M$ and the one-dimensional trivial bundle over M, then $i^*(\mathrm{T}(M) \cong \mathrm{T}M \oplus \mathbb{R}$.

Proof. By the Smooth Collar Neighborhood Theorem 28.3 we can find a neighborhood $[0,1] \times M \subset W$ for $M = \{0\} \times M$. We have

$$\begin{array}{ccccc} i^*(\mathrm{T}(M) & \cong & i^*(\mathrm{T}N \times [0,1])) & \cong & \mathrm{T}M \oplus i^*(T[0,1]) \;\cong\; \mathrm{T}M \oplus \mathbb{R}. \\ \uparrow & & \uparrow & & \uparrow \\ \text{Lemma 143.12 (1)} & & \text{Lemma 143.20} & & \text{Vector Bundle Pullback Lemma 143.9 (1)} \end{array}$$ ⊞

Let $I = i_1 + i_2 + \cdots + i_r$ be a partition of n. We turn to the proof of the first statement. We calculate that

$$\begin{array}{ccccccc} \widetilde{p}_I(M) & = & \langle p_I(\mathrm{T}M), [M]\rangle & = & \langle p_I(\mathrm{T}M \oplus \mathbb{R}), [M]\rangle & = & \langle p_I(i^*\mathrm{T}(M), [M]\rangle \\ & & & & \uparrow & & \uparrow \\ & & & & \text{Theorem 145.1 (2) and (6)} & & \text{by the claim} \\ & = & \langle i^* p_I(\mathrm{T}(M), [M]\rangle & = & \langle p_I(\mathrm{T}(M), i_*([M])\rangle & = & 0. \\ & & \uparrow & & \uparrow & & \uparrow \\ & & \text{Theorem 145.1 (3)} & & \text{Lemma 109.6 (3)} & & \text{Corollary 106.28} \end{array}$$

[1735] Note that a partition is unordered, hence we view $4 = 3+1$ and $4 = 1+3$ as the same partition.

Finally the second statement is an immediate consequence of the first statement and the trivial[1736] observation that for two closed oriented $4n$-dimensional smooth manifolds M and N we have

$$\widetilde{p}_I(M \sqcup N) \;=\; \widetilde{p}_I(M) + \widetilde{p}_I(N). \qquad \blacksquare$$

The following theorem gives the converse to Proposition 145.5.

Theorem 145.6. Let $n \in \mathbb{N}_0$. We denote by $\mathcal{I}$ the set of all partitions of n.

(1) The map

$$\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I \colon \Omega_{4n} \otimes \mathbb{Q} \;\to\; \bigoplus_{i\in\mathcal{I}} \mathbb{Q} \cdot i$$

is an isomorphism.

(2) Let M be a closed oriented $4n$-dimensional smooth manifold. If all Pontryagin numbers of M vanish, then $[M] = 0 \in \Omega_{4n}/\text{torsion}$.

Sketch of proof. We consider the following diagram of homomorphisms:

$$\begin{array}{ccc}
\Omega_{4n}/\text{torsion} & \xrightarrow{\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I} & \bigoplus_{i\in\mathcal{I}} \mathbb{Z} \cdot i \\
\downarrow & & \downarrow \\
\Omega_{4n} \otimes \mathbb{Q} & \xrightarrow{\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I} & \bigoplus_{i\in\mathcal{I}} \mathbb{Q} \cdot i. \\
= \uparrow & \nearrow_{\Psi} & \\
\bigoplus_{i_1+\cdots+i_r=n\in\mathcal{I}} \mathbb{Q} \cdot (\mathbb{C}\mathrm{P}^{2i_1} \times \ldots \times \mathbb{C}\mathrm{P}^{2i_r}) & &
\end{array}$$

The left upper vertical map is a monomorphism by the discussion on page 1910. The right upper vertical map is evidently a monomorphism. It is clear that the diagram commutes. Thus we see that Statement (2) of the theorem is an immediate consequence of Statement (1).

Put differently, it remains to show that the bottom horizontal map is an isomorphism. Note that the lower vertical map is the identity by the Thom Cobordism Theorem 144.11. Thus it suffices to show that the diagonal map is an isomorphism. As a reality check, note that the dimensions agree, in both cases the dimension is just given by the cardinality of $\mathcal{I}$.

In the following claim we carry out the arguments for $n = 1$ and $n = 2$ "by hand". The general case needs more clever arguments, for which we refer to [**Tho2007**, Corollary IV.16].

Claim.

(1) Let $n = 1$. With respect to the bases $\{\mathbb{C}\mathrm{P}^2\}$ and $\{p_1\}$ the diagonal map Ψ is represented by the matrix (3).

(2) Let $n = 2$. With respect to the bases $\{\mathbb{C}\mathrm{P}^4, \mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2\}$ and $\{p_2, p_{1+1}\}$ the diagonal map Ψ is represented by the matrix $\begin{pmatrix} 10 & 9 \\ 25 & 18 \end{pmatrix}$.

In particular in both cases the matrix is invertible.

[1736] Why is this "trivial"? How can one prove this "obvious" equality?

Proof. The case $n = 1$ is easy: We make the usual identification $p\mathrm{H}^*(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) = \mathbb{Z}[x]/(x^3)$, and we calculate that

$$\widetilde{p}_1(\mathbb{C}\mathrm{P}^2) \quad = \quad \langle p_1(\mathbb{C}\mathrm{P}^2), [\mathbb{C}\mathrm{P}^2]\rangle \quad \underset{\text{Theorem 145.1 (5)}}{=} \quad \langle 3x^2, [\mathbb{C}\mathrm{P}^2]\rangle \quad \underset{\text{Cup Product-}\mathbb{C}\mathrm{P}^n\text{-Proposition 126.11}}{=} \quad 3.$$

The case $n = 2$ is slightly more involved. First note that by Theorem 145.1 (5) we have $p(\mathbb{C}\mathrm{P}^4) = 1 + 5x^2 + 10x^4 \in \mathrm{H}^*(\mathbb{C}\mathrm{P}^4;\mathbb{Z}) = \mathbb{Z}[x]/(x^5)$. Thus as above we see that $\widetilde{p}_2(\mathbb{C}\mathrm{P}^4) = 10$. Furthermore, with similar arguments as above we have

$$\widetilde{p}_{1+1}(\mathbb{C}\mathrm{P}^4) \;=\; \langle p_1(\mathbb{C}\mathrm{P}^4) \cup p_1(\mathbb{C}\mathrm{P}^4), [\mathbb{C}\mathrm{P}^4]\rangle \;=\; \langle 5x^2 \cdot 5x^2, [\mathbb{C}\mathrm{P}^4]\rangle \;=\; 25.$$

This concludes the calculation of the first column of the matrix.

It remains to consider $\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2$. By the Cohomology Ring-of-Product Proposition 117.21 we can make the identification $\mathrm{H}^*(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2;\mathbb{Z}) = \mathbb{Z}[x,y]/(x^3,y^3)$ where x and y are the pullbacks of the standard generator of $\mathrm{H}^2(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ under the two natural projections. Using Lemma 143.20 and Theorem 145.1 (3), (5), (6) we see that $p(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = (1+3x^2)\cdot(1+3y^2)$. In particular $p_1(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = 3x^2 + 3y^2$ and $p_2(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = 9x^2y^2$. Furthermore note that this implies that $p_{1+1}(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = (3x^2+3y^2)^2 = 18x^2y^2$. The claim for $n = 2$ now follows from the observation that the Fundamental Class-Product Proposition 117.2 tells us that $\langle x^2 \cdot y^2, [\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2]\rangle = 1$. ∎

Our next goal is to use Theorem 145.6 to prove the following proposition. It says that the signature of a closed oriented smooth manifold can be determined from its Pontryagin numbers.

Proposition 145.7. Let $n \in \mathbb{N}_0$. We denote by $\mathcal{I}$ the set of all partitions of n. For each $I \in \mathcal{I}$ there exists $a_I \in \mathbb{Q}$ such that for any closed oriented $4n$-dimensional smooth manifold M we have

$$\mathrm{sign}(M) \;=\; \sum_{I\in\mathcal{I}} a_I \cdot \widetilde{p}_I(M).$$

Proof. Let $n \in \mathbb{N}_0$. We denote by $\mathcal{I}$ the set of all partitions of n. We consider the following diagram

$$\begin{array}{ccccc}
\Omega_{4n} & \xrightarrow{[M]\mapsto[M]\otimes 1} & \Omega_{4n}\otimes\mathbb{Q} & \xrightarrow[\cong]{\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I} & \bigoplus_{i\in\mathcal{I}}\mathbb{Q}\cdot i \\
\Big\downarrow{\scriptstyle \mathrm{sign}} & & \Big\downarrow & \swarrow{\scriptstyle \Phi} & \\
\mathbb{Z} & \hookrightarrow & \mathbb{Q} & &
\end{array}$$

$$[M]\otimes r \;\mapsto\; \mathrm{sign}(M)\cdot r$$

Here the left-hand map is a homomorphism by Corollary 144.7. By Proposition 145.5 we know that the top right map is an isomorphism. Therefore there exists a diagonal homomorphism Φ that makes the diagram commute. Given $i \in I$ we set $a_i \in \mathbb{Q}$ to be the value of Φ at $1 = 1\cdot i \in \mathbb{Q}\cdot i \subset \bigoplus_{i\in I}\mathbb{Q}\cdot i$. In other words, the map

$$\begin{array}{rcl}
\bigoplus_{i\in\mathcal{I}}\mathbb{Q}\cdot i & \to & \mathbb{Q} \\
\bigoplus_{i\in\mathcal{I}} x_i\cdot i & \mapsto & \sum_{i\in\mathcal{I}} x_i\cdot a_i.
\end{array}$$

is given by

The desired equality $\operatorname{sign}(M) = \sum_{j=1}^{r} a_j \cdot \widetilde{p}_{I_j}(M)$ now follows immediately from the commutativity of the previous diagram. ■

The coefficients in Proposition 145.7 had been completely determined by Friedrich Hirzebruch [**Hirz1953**]. The low-dimensional terms are given in the following theorem.

Theorem 145.8. (Hirzebruch Signature Theorem) Let $n \in \{1,2,3,4\}$ and let M be a closed oriented $4n$-dimensional smooth manifold. Given $i \in \mathbb{N}_0$ we write $p_i := p_i(M) \in \overline{\mathrm{H}}^{4i}(M;\mathbb{Z})$. The signature of M can be determined as follows:

n	$\operatorname{sign}(M)$ equals the Kronecker pairing of $[M]$ with the cohomology class
1	$\frac{1}{3}p_1$
2	$\frac{1}{45}(7p_2 - p_1^2)$
3	$\frac{1}{945}(62p_3 - 13p_2 \cup p_1 + 2p_1^3)$
4	$\frac{1}{14175}(381p_4 - 71p_3 \cup p_1 - 19p_2^2 + 22p_2 \cup p_1^2 - 3p_1^4)$.

Proof. We carry out the case $n = 2$. We adopt the notation from the proof of Proposition 145.7. By the Thom Cobordism Theorem 144.11 we have $\Omega_8 \otimes \mathbb{Q} = \mathbb{Q} \cdot [\mathbb{C}\mathrm{P}^4] \oplus \mathbb{Q} \cdot [\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2]$. Now let M be a closed oriented 8-dimensional smooth manifold. By the proof of Proposition 145.7 we have $\operatorname{sign}(M) = a_2 \cdot \widetilde{p}_2(M) + a_{1+1} \cdot \widetilde{p}_{1+1}(M)$ where

$$\begin{pmatrix} a_2 \\ a_{1+1} \end{pmatrix} = \begin{array}{c}\text{matrix of sign applied to}\\ \text{the basis } \mathbb{C}\mathrm{P}^4 \text{ and } \mathbb{C}\mathrm{P}^2\times\mathbb{C}\mathrm{P}^2\end{array} \cdot \begin{array}{c}\text{inverse of the matrix that expresses } p_2, p_{1+1}\\ \text{for the smooth manifolds } \mathbb{C}\mathrm{P}^4 \text{ and } \mathbb{C}\mathrm{P}^2\times\mathbb{C}\mathrm{P}^2\end{array}$$

$$= \underset{\uparrow}{} \begin{pmatrix} 1 & 1 \end{pmatrix} \begin{pmatrix} 10 & 9 \\ 25 & 18 \end{pmatrix}^{-1} = \tfrac{-1}{45} \begin{pmatrix} 1 & 1 \end{pmatrix} \begin{pmatrix} 18 & -9 \\ -25 & 10 \end{pmatrix} = \tfrac{1}{45} \begin{pmatrix} 7 \\ -1 \end{pmatrix}.$$

by Lemma 126.12 and Exercise 133.5 we know that the signatures of these two smooth manifolds are $+1$ for the second matrix we use the calculation from the proof of Theorem 145.6

This gives precisely the desired result for $n = 2$. The case $n = 1$ is evidently even easier.

The higher-dimensional cases are dealt with, more cleverly, in [**Hirz1953**] or alternatively in [**MiS1974**, p. 224]. These references also contain a precise formula for all $n \in \mathbb{N}_0$. ■

Remark.

(1) The expressions in Theorem 145.8 might seem random, but they do arise in a cogent way from the coefficients of the power series $\frac{\sqrt{t}}{\tanh(t)}$. This connection is explained in [**MiS1974**, Chapter 19].

(2) The signature of a smooth manifold is of course an integer. Thus we obtain from Theorem 145.8 the slightly mysterious statement that for any closed oriented 4-dimensional smooth manifold the integer $\langle p_1(M), [M] \rangle$ is divisible by 3.

The Hirzebruch Signature Theorem 145.8 has many fascinating consequences. Let us start out with the following.

Proposition 145.9. Let M be a closed orientable 12-dimensional smooth manifold. If $b_4(M) = 0$, then $b_6(M)$ is even.

Proof. Let M be a closed orientable 12-dimensional smooth manifold with $b_4(M) = 0$. It follows from the Universal Coefficient Theorem 110.12 that $\mathrm{H}^4(M;\mathbb{Z})$ is torsion. Thus we

see that modulo 2 we have the following equalities:

$$b_6(M) \underset{\uparrow}{\overset{\downarrow}{\equiv}} \operatorname{sign}(M) \underset{\uparrow}{=} \frac{1}{945}(62p_3(M) - 13p_2(M) \cup p_1(M) + 2p_1(M)^3) \underset{\uparrow}{=} 2 \cdot \frac{31}{945} \cdot p_3(M).$$

Intersection Form Proposition 132.4 and Corollary 133.9

by the Hirzebruch Signature Theorem 145.8

since $b_4(M) = 0$ we know by the Universal Coefficient Theorem 110.12 that $\mathrm{H}^4(M;\mathbb{Z})$ is torsion, hence we have $p_1^3(M) = p_2(M) \cup p_1(M) = 0$

Since $b_6(M)$ and $p_3(M)$ are integers we obtain from the equality $b_6(M) = 2 \cdot \frac{31}{945} \cdot p_3(M)$ that $b_6(M)$ is necessarily even. ■

In Proposition 69.4 we saw that the Euler characteristic of a finite CW-complex is multiplicative under finite covers. In fact we saw that this statement follows almost immediately from the definition of a CW-complex. The following theorem gives the analogous statement that the signature of a closed oriented $4n$-dimensional smooth manifold is multiplicative under finite covers.

Theorem 145.10. (Signature-Multiplicativity Theorem) Let $n \in \mathbb{N}_0$. Let M be a closed oriented $4n$-dimensional smooth manifold and let $\widetilde{M} \to M$ be a finite covering. Then

$$\operatorname{sign}\left(\widetilde{M}\right) = \left[\widetilde{M} : M\right] \cdot \operatorname{sign}(M).$$

Remark.

(1) Perhaps it is initially difficult to appreciate the significance of the Signature-Multiplicativity Theorem 145.10. If we only consider (co-) homological invariants, then there are basically only two statements that relate the invariants of a (reasonable) topological space X and an n-fold covering $p\colon \widetilde{X} \to X$ thereof:
   (a) as pointed out above, if X is a finite CW-complex, then $\chi(\widetilde{X}) = n \cdot \chi(X)$,
   (b) the Transfer Map Proposition 91.1 shows that $p_*\colon \mathrm{H}_*(\widetilde{X};\mathbb{Q}) \to \mathrm{H}_*(X;\mathbb{Q})$ is an epimorphism.

   Besides these observations, (co-) homological invariants behave fairly erratically under finite covers. One example of such "random" behavior is given in Exercise 145.2.

(2) One might think that one should be able to prove the Signature-Multiplicativity Theorem 145.10 in a naive way. But this is not the case. This can be seen from the fact that our sketch of the proof of the Signature-Multiplicativity Theorem 145.10 works only for smooth manifolds, the proof that we will sketch does not apply to topological manifolds.

(3) The statement of the Signature-Multiplicativity Theorem 145.10 does in fact hold for topological manifolds, but the proof is even harder, see e.g. [**SchafJ1970**, Theorem 8].

(4) The fact that there is no proof of the Signature-Multiplicativity Theorem 145.10 that does not in an essential way make use of the fact that M is a (topological) smooth manifold is highlighted by [**Wall1967**, Corollary 5.4.1].

(5) For compact $4n$-dimensional smooth manifolds with non-empty boundary the signature is in general *not* multiplicative under finite covers. We refer to [**APS1975**] for details.

Proof. Let $n \in \mathbb{N}_0$. By Proposition 145.7 there exist partitions $I_1, \ldots, I_r$ of $4n$ and rational numbers $a_1, \ldots, a_r$ such that for any closed oriented $4n$-dimensional smooth manifold X the following equality holds:

$$(*) \qquad \operatorname{sign}(X) \;=\; \sum_{j=1}^{r} a_j \cdot \langle p_{I_j}(X), [X] \rangle_X .$$

Now let M be a closed oriented $4n$-dimensional smooth manifold and let $q\colon \widetilde{M} \to M$ be a finite covering. We have

$$\operatorname{sign}\big(\widetilde{M}\big) \underset{\text{by } (*)}{=} \sum_{j=1}^{r} a_j \cdot \big\langle p_{I_j}\big(\widetilde{M}\big), \big[\widetilde{M}\big] \big\rangle_{\widetilde{M}} \underset{\substack{\text{by Theorem 145.1 (3), the Cup Product-Naturality Lemma 114.10 and} \\ \text{since } q^*\mathrm{T}M = T\widetilde{M}, \text{ see Lemma 143.12 (2)}}}{=} \sum_{j=1}^{r} a_j \cdot \big\langle q^*\big(p_{I_j}(M)\big), \big[\widetilde{M}\big] \big\rangle_{\widetilde{M}}$$

$$\underset{\text{Lemma 109.6 (3)}}{=} \sum_{j=1}^{r} a_j \cdot \big\langle p_{I_j}(M), q_*\big[\widetilde{M}\big] \big\rangle_M \underset{\text{Fundamental Class-Covering Proposition 106.25}}{=} \big[\widetilde{M}{:}M\big] \cdot \sum_{j=1}^{r} a_j \cdot \langle p_{I_j}(M), [M] \rangle_M \underset{\text{by } (*)}{=} \big[\widetilde{M}{:}M\big] \cdot \operatorname{sign}(M).$$

■

We conclude this chapter with a short discussion of other characteristic classes.

(1) Loosely speaking, a *characteristic class* is a map that associates to a vector bundle a cohomology class in the base space. We had just discussed the Pontryagin classes in some detail. There are several other characteristic classes:
   (a) To a vector bundle $p\colon E \to X$ one can also associate the *Stiefel-Whitney classes* $w_i(E) \in \overline{\mathrm{H}}^i(X; \mathbb{F}_2)$, $i \in \mathbb{N}_0$.
   (b) If $p\colon E \to X$ is an "oriented" n-dimensional vector bundle, then there exists the *Euler class* $e(E) \in \overline{\mathrm{H}}^n(X; \mathbb{Z})$.
   (c) Finally, if $p\colon E \to X$ is a complex vector bundle, then the corresponding *Chern classes* $c_i(E) \in \overline{\mathrm{H}}^{2i}(X; \mathbb{Z})$, $i \in \mathbb{N}_0$ are defined.

   The properties of Stiefel-Whitney classes and Chern classes are very similar to the properties stated in Theorem 145.1, in fact these characteristic classes are completely determined by the corresponding properties. Finally note that there are some relations between the various characteristic classes, for example given a vector bundle $p\colon E \to X$ the i-th Pontryagin class equals[1737]

$$p_i(E) \;:=\; c_{2i}(\text{the "complexification" } E \otimes \mathbb{C}) \;\in\; \overline{\mathrm{H}}^{4i}(X; \mathbb{Z}).$$

   We refer to **[MiS1974]** and **[Hat2]** for more details on these characteristic classes.
(2) For complex vector bundles over a smooth manifold M the images of the Chern classes in $\overline{\mathrm{H}}^{2i}(M; \mathbb{R})$ can also be defined in the context of de Rham cohomology. Since Pontryagin classes are defined via Chern classes this shows in particular that the images of the Pontryagin classes in real cohomology can be defined via de Rham cohomology. We refer to **[Che1979, MiS1974]** for details.

[1737] In fact, this usually the way Pontryagin classes are defined.

Exercises for Chapter 145.

Exercise 145.1. Let M be a closed oriented smooth manifold of dimension $4k+3$. Show that $\operatorname{sign}(S^1 \times M) = 0$.

Exercise 145.2. Show that given any $n \in \mathbb{N}$ and $k \in \mathbb{N}_{\geq 2}$ there exists a CW-complex X with $\mathrm{H}_k(X;\mathbb{Q}) = 0$ and that admits a 2-fold covering $\widetilde{X}$ with $\mathrm{H}_k(\widetilde{X};\mathbb{Q}) \cong \mathbb{Q}^n$.
Hint. You can take X to be a mapping torus of some high-dimensional torus. Use the Mapping Torus-Homology Proposition 78.20 to compute homology groups.

Part XVI

3-dimensional Manifolds

146. Handlebodies and Heegaard splittings of 3-dimensional smooth manifolds

Given coprime $p, q \in \mathbb{N}$ we introduced the lens spaces $L(p,q)$ on page 1075. Using the fundamental groups it was very easy to see that homeomorphic lens spaces have the same p-parameter. But so far the more advanced invariants, i.e. higher homotopy groups, homology groups and cohomology groups failed miserably at providing us with more information.
In the Chapter 148 we will cleverly apply cup products to obtain information on lens spaces $L(p,q)$ which goes beyond detecting the first parameter p. But before we do so we find it convenient to introduce several more general definitions regarding smooth manifolds.

146.1. Heegaard splittings of 3-dimensional smooth manifolds.

Definition. Let M be a closed oriented connected 3-dimensional smooth manifold.

(1) A splitting of M consists of a triple (X, Y, F) where X and Y are compact 3-dimensional submanifolds of M with $M = X \cup Y$ and such that $F = X \cap Y = \partial X = \partial Y$. Given such a splitting we endow X and Y with the orientation coming from M and we endow F with the orientation coming from $F = \partial X$.[1738]

(2) A splitting (X, Y, F) of M is called a Heegaard splitting if X and Y are both diffeomorphic to handlebodies. We refer to the genus of the surface F as the genus of the Heegaard splitting.

Often, when there is no danger of confusion, we say "$M = X \cup Y$ is a splitting".

Remark. Heegaard splittings are named after the Danish mathematician Poul Heegaard (1871–1948) who proved the first important theorem regarding Heegaard splittings, see below. We had encountered Poul Heegaard before on page 2621.

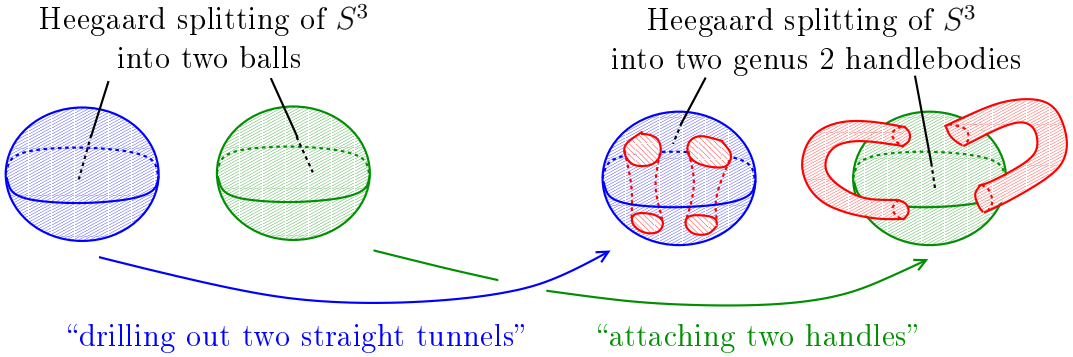
Examples.

(1) Let $n \in \mathbb{N}$. On page 152 we saw that we can write the n-sphere as the union of the upper hemisphere $S^n_{\geq 0}$ and the lower hemisphere $S^n_{\leq 0}$, both of which are diffeomorphic[1739] to $\overline{B}^n$ and which intersect in an $(n-1)$-sphere. This observation gives us two examples of Heegaard splittings at once:
   (a) We obtain a genus 0 Heegaard splitting $S^3 = S^3_{\geq 0} \cup S^3_{\leq 0}$.
   (b) We also obtain a genus 1 Heegaard splitting

$$S^1 \times S^2 \;=\; \underbrace{(S^1 \times S^2_{\geq 0})}_{\text{solid torus}} \cup \underbrace{(S^1 \times S^2_{\leq 0}).}_{\text{solid torus}}$$

(2) A closed 3-dimensional smooth manifold can have many different Heegaard splittings. For example we consider $S^3 = \left\{(z,w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1\right\}$ and the following two

[1738] Note that the orientation coming from $F = \partial Y$ would be the opposite orientation.



[1739] Actually one has to think for a minute about why the hemispheres are *diffeomorphic* to $\overline{B}^n$. On page 152 we saw that the projection from the hemispheres to $\overline{B}^n$ is a homeomorphism. But this is not a diffeomorphism (why not?). Fortunately stereographic projections, as defined in Lemma 2.18, can be used to give an explicit diffeomorphism.

subspaces of S^3:

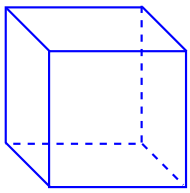
$$X := \{(z,w) \in \mathbb{C}^2 \,|\, |w|^2 + |z|^2 = 1 \text{ and } |z|^2 \geq \tfrac{1}{2}\}$$
and
$$Y := \{(z,w) \in \mathbb{C}^2 \,|\, |w|^2 + |z|^2 = 1 \text{ and } |w|^2 \geq \tfrac{1}{2}\}.$$

In Lemma 59.1 we showed that both X and Y are diffeomorphic to the solid torus $S^1 \times \overline{B}^2$. In particular Lemma 59.1 shows that $(X, Y, \partial X = \partial Y)$ is a genus 1 Heegaard splitting of S^3.

(3) The sphere S^3 admits in fact a Heegaard splitting of arbitrarily high genus. This can be seen as follows: we start out with the genus 0 Heegaard decomposition given by decomposing S^3 into two closed 3-balls X and Y. Now we "drill g unknotted open tunnels" out of X and we add (the closure of) what we just drilled out to Y, which has the effect of "adding g handles to Y". In this construction we turned X and Y into genus g handlebodies. This example is illustrated in the figure below.

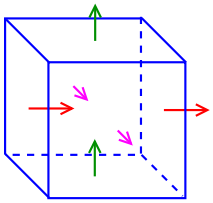
In fact we have now found all Heegaard splittings of S^3. More precisely, given a genus g Heegaard splitting (X, Y, F) of S^3 there exists a diffeomorphism f of S^3 which turns the Heegaard splitting into the Heegaard splittings of the same genus listed above. For $g = 0$ this statement is equivalent to the Generalized Smooth Schönflies Theorem 82.5 in dimension 3. For $g \geq 1$ the uniqueness of Heegaard splittings was shown in 1968 by Friedhelm Waldhausen **[Wald1968a, Schle2017]**.

(4) We consider the 3-dimensional cube $[0,1]^3$. We consider the equivalence relation $\sim$ that identifies the opposite sides of the cube. More precisely, on $[0,1]^3$ we denote by $\sim$ the equivalence relation that is generated by



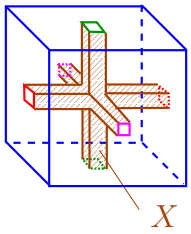
$$(0,a,b) \sim (1,a,b), \quad (a,0,b) \sim (a,1,b) \quad \text{and} \quad (a,b,0) \sim (a,b,1) \quad \text{for } a,b \in [0,1].$$

It follows easily from the Compact-Hausdorff Proposition 2.17 (3) that the map $[0,1]^3/\sim \to S^1 \times S^1 \times S^1$ given by $(x,y,z) \mapsto (\exp(2\pi \mathrm{i} x), \exp(2\pi \mathrm{i} y), \exp(2\pi \mathrm{i} z))$ is a homeomorphism. We use this homeomorphism to identify $[0,1]^3/\sim$ with the 3-dimensional torus $S^1 \times S^1 \times S^1$. In the figure below we show the cube $[0,1]$ and we show the subset



$$X := \{(x_1,x_2,x_3) \in [0,1]^3 \,|\, \text{at least two coordinates satisfy } |x_i - \tfrac{1}{2}| \leq \tfrac{1}{4}\}.$$

We leave it to the reader to show that $X/\sim$ is homeomorphic to the genus 3 handlebody and that $Y := \overline{([0,1]^3 \setminus X)/\sim}$ is also homeomorphic to the genus 3 handlebody. This shows that the 3-dimensional torus admits a genus 3 Heegaard splitting. It is



natural to ask whether the 3-dimensional torus admits a Heegaard splitting of smaller genus. We study this question in Exercise 146.3

the cube $[0,1]^3$

opposite sides get identified

(5) Let F be the surface of genus g and let $\varphi\colon F \to F$ be an orientation-preserving self-diffeomorphism. By the Manifold-Mapping Torus Lemma 16.25 the mapping torus

$$\mathrm{Tor}(F,\varphi) \;:=\; F \times [0,1] \,/\, (x,0) \sim (\varphi(x),1)$$

is a closed orientable 3-dimensional smooth manifold. In Exercise 146.4 we will see that $\mathrm{Tor}(F,\varphi)$ admits a Heegaard splitting of genus $2g+1$.

The following lemma gives us a slightly different point of view regarding Heegaard splittings.

Lemma 146.1.

(1) Let X and Y be two oriented handlebodies of the same genus. Given any diffeomorphism $\varphi\colon \partial X \to \partial Y$ we write

$$M(X,Y,\varphi) \;:=\; (X \sqcup Y)/\!\sim \qquad \text{with } x \sim \varphi(x) \text{ for } x \in X.$$

(a) $M(X,Y,\varphi)$ is a closed 3-dimensional smooth manifold.
(b) $M(X,Y,\varphi)$ admits a unique orientation such that the orientation of X, viewed as a codimension zero submanifold of $M(X,Y,\varphi)$, agrees with the orientation of $M(X,Y,\varphi)$.
(c) The images of X and Y in $M(X,Y,\varphi)$ define a Heegaard splitting.
(d) If $\varphi\colon \partial X \to \partial Y$ is an orientation-preserving diffeomorphism, then there exists an orientation-reversing diffeomorphism $\psi\colon \partial X \to \partial Y$ such that there exists an orientation-preserving diffeomorphism from $M(X,Y,\varphi)$ to $M(X,Y,\psi)$.
(e) Let $\varphi,\psi\colon \partial X \to \partial Y$ be two diffeomorphisms. If φ and ψ are diffeotopic, then there exists an orientation-preserving diffeomorphism from $M(X,Y,\varphi)$ to $M(X,Y,\psi)$.

(2) Let M be a closed oriented connected 3-dimensional smooth manifold and let (X,Y,F) be a Heegaard splitting of M. There exists an orientation-reversing diffeomorphism $\varphi\colon \partial X \to \partial Y$ such that the smooth embeddings $X \to M$ and $Y \to M$ induce an orientation-preserving diffeomorphism $M(X,Y,\varphi) \to M$.

Proof.

(1) Statements (a), (b) and (c) follow immediately from the Gluing-Smooth Manifolds-Proposition **??**. Statement (e) follows almost immediately from Lemma **??** and the Gluing-Smooth Manifolds-Proposition **??** (7). Finally Statement (d) follows from Lemma **??**.
(2) Let $\varphi = \mathrm{id}\colon \partial X \to \partial Y$. It follows immediately from the orientation conventions that φ is orientation-preserving. ■

In the following we want to consider Heegaard splittings of lens spaces in detail. Recall that given coprime $p, q \in \mathbb{N}$ the map

$$\begin{array}{rcl} \mathbb{Z}_p \times S^3 & \to & S^3 \\ (k + p\mathbb{Z}, (z, w)) & \mapsto & (\exp(2\pi \mathrm{i} k/p) \cdot z, \exp(2\pi \mathrm{i} kq/p) \cdot w) \end{array}$$

defines a free orientation-preserving action of the group $\mathbb{Z}_p$ on S^3. By definition we have $L(p, q) = S^3/\mathbb{Z}_p$ and, following the convention established on page 1075, we equip $L(p, q)$ with the obvious orientation coming from S^3. It follows immediately from the definitions that this action by $\mathbb{Z}_p$ on $S^3 = X \cup Y$ preserves the solid tori X and Y from page 3115 setwise. In fact the quotients $X/\mathbb{Z}_p$ and $Y/\mathbb{Z}_p$ are again diffeomorphic to the solid torus. More precisely, we pick $r \in \mathbb{N}$ with $r \cdot q \equiv -1 \bmod p$. Similar to the proof of Lemma 59.1 it is fairly straightforward to verify that the maps

$$\begin{array}{rcl} \Phi\colon X/\mathbb{Z}_p = \left\{(z, w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1 \text{ and } |z|^2 \geq \frac{1}{2}\right\}/\mathbb{Z}_p & \to & S^1 \times \overline{B}^2 \\ [(z, w)] & \mapsto & \left(\frac{z^p}{|z^p|}, \frac{z^{-q} w}{|z^{1-q}|}\right) \end{array}$$

and

$$\begin{array}{rcl} \Psi\colon Y/\mathbb{Z}_p = \left\{(z, w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1 \text{ and } |w|^2 \geq \frac{1}{2}\right\}/\mathbb{Z}_p & \to & S^1 \times \overline{B}^2 \\ [(z, w)] & \mapsto & \left(\frac{w^p}{|w^p|}, \frac{z w^r}{|w^{1+r}|}\right) \end{array}$$

are well-defined diffeomorphisms and that Φ is orientation-preserving.[1740] This shows that

$$L(p, q) \;=\; X/\mathbb{Z}_p \cup Y/\mathbb{Z}_p$$

is a genus 1 Heegaard decomposition of the lens space $L(p, q)$. In the following lemma we describe this Heegaard splitting in greater detail.

Lemma 146.2. (Lens Space-Splitting Lemma) Let $p \in \mathbb{N}$ and let $q \in \mathbb{Z}$ be coprime to p. We pick $r, s \in \mathbb{Z}$ such that $qr - ps = -1$. We write

$$A \;=\; \begin{pmatrix} q & p \\ s & r \end{pmatrix}$$

and we consider the orientation-reversing diffeomorphism

$$\begin{array}{rcl} \varphi\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [Av]. \end{array}$$

If we make the usual identification $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$, then there exists an orientation-preserving diffeomorphism

$$L(p, q) \;\xrightarrow{\cong}\; M(S^1 \times \overline{B}^2, S^1 \times \overline{B}^2, \varphi).$$

Proof. In this proof we continue to use the notation that we introduced before stating the lemma. Now we write $U = X/\mathbb{Z}_p$ and $V = Y/\mathbb{Z}_p$ and as above we consider the two diffeomorphisms $\Phi\colon U \to S^1 \times \overline{B}^2$ and $\Psi\colon V \to S^1 \times \overline{B}^2$. We denote by $\gamma\colon S^1 \times S^1 \to S^1 \times S^1$ the diffeomorphism that is given by

$$S^1 \times S^1 \;=\; \partial(S^1 \times \overline{B}^2) \;\xleftarrow{\Phi}\; \partial U \;=\; \partial V \;\xrightarrow{\Psi}\; \partial(S^1 \times \overline{B}^2) \;=\; S^1 \times S^1.$$

[1740] To show that Φ is orientation-preserving it suffices by Proposition 107.2 to show that Φ is orientation-preserving at a single point. Using that $p > 0$ one can calculate explicitly that Φ is orientation-preserving at the point $[(1, 0)] \in X/\mathbb{Z}_p$.

Since Φ and Ψ are diffeomorphisms the two maps together give rise to a well-defined diffeomorphism

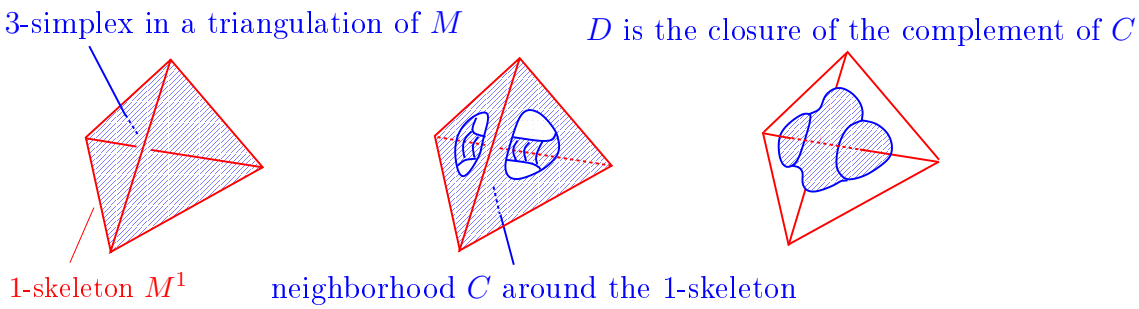
$$\begin{array}{rcl} L(p,q) = U \cup V & \to & M(S^1 \times \overline{B}^2, S^1 \times \overline{B}^2, \gamma) = (S^1 \times \overline{B}^2) \cup_\gamma (S^1 \times \overline{B}^2) \\ P & \mapsto & \begin{cases} \Phi(P) \text{ in the first solid torus,} & \text{if } P \in U, \\ \Psi(P) \text{ in the second solid torus,} & \text{if } P \in V. \end{cases} \end{array}$$

It follows from the orientation convention in Lemma 146.1 (1), together with the fact that Φ is orientation-preserving, that this diffeomorphism is in fact orientation-preserving.

We consider the following diagram of diffeomorphisms:

$$\begin{array}{ccccccccccc} S^1 \times S^1 & \xleftarrow{=} & \partial(S^1 \times \overline{B}^2) & \xleftarrow{\Phi} & \partial U & \xrightarrow{=} & \partial V & \xrightarrow{\Psi} & \partial(S^1 \times \overline{B}^2) & \xrightarrow{=} & S^1 \times S^1 \\ \downarrow{=} & & & & & & & & & & \downarrow{=} \\ \mathbb{R}^2/\mathbb{Z}^2 & & & & & & \xrightarrow{\qquad\qquad\varphi\qquad\qquad} & & & & \mathbb{R}^2/\mathbb{Z}^2. \end{array}$$

Starting from ∂U, it is straightforward to verify that the diagram commutes. But this just shows that, under the identification $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$, the two self-diffeomorphisms γ and φ of $S^1 \times S^1$ agree. ■



We have now given explicit Heegaard splittings of some basic examples of closed 3-manifolds. Perhaps somewhat surprisingly it is relatively straightforward to generalize these examples to all closed orientable 3-dimensional smooth manifolds. More precisely, in 1898 Poul Heegaard proved the following theorem in his PhD thesis [**Hee1898**]. This result is one of the earliest results in the topology of 3-dimensional smooth manifolds.

Theorem 146.3. Every closed orientable connected 3-dimensional smooth manifold admits a Heegaard splitting.

Remark. As we had mentioned on page 3115, for each $g \geq 1$ the 3-sphere S^3 admits (up to diffeomorphism) a unique Heegaard splitting. In general though closed orientable connected 3-dimensional smooth manifolds can admit inequivalent Heegaard splittings of a fixed genus, see e.g. [**Engm1970, BGAM1976**].

Sketch of proof. The idea of the proof of the theorem is quite simple. Let M be a closed orientable connected 3-dimensional smooth manifold. By the Smooth Manifold-Simplicial Structure Theorem 96.2 the smooth manifold M admits a triangulation, i.e. a simplicial structure. As usual we denote by M^1 the 1-skeleton of M. We pick a closed neighborhood C around the 1-skeleton M^1 such that the intersection of C with each 3-simplex is of the form shown in the middle of the figure below. Furthermore we write $D = \overline{M \setminus C}$. The claim is that both C and D are handlebodies. The idea is that C and D are built out of pieces as sketched in the figure below and thus C and D are "obviously" handlebodies. But if one looks more carefully into the argument one sees that one needs the hypothesis that M is orientable to conclude that C and D are indeed handlebodies. We will not fill in the details of the argument. Unfortunately the proofs in the literature tend to be equally short on details, in particular the role of the orientability condition gets all too often swiped under the carpet. We refer to [**Sav2012**, Theorem 1.1], [**Schar2002**, p. 924] [**Hem1976**, Theorem 2.5] for proofs of the theorem which follow the above line of argumentation.

As so often in topology, there is another proof of the theorem, which might be less intuitive and less visual, but which is much more rigorous. This proof uses Morse theory.

We refer to [**JohJ200707**, Theorem 4.29] or [**Mata2002**, Chapter 5.2] for details on how to obtain Heegaard splittings from Morse theory. ■

146.2. **Fundamental groups of 3-dimensional smooth manifolds.** Let $n \geq 4$. In the Fundamental Group-Manifold Realization Proposition 54.12 we saw that given any finitely presented group π there exists a closed orientable connected n-dimensional smooth manifold with fundamental group isomorphic to π. Using Theorem 146.3 we will shortly see that the class of finitely presented groups that appear as fundamental groups of closed orientable connected 3-dimensional smooth manifolds is much more restricted. Before we can state the result in detail we need to introduce the following group theoretic notion.

Definition. The deficiency of a finite presentation $\langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle$ is defined to be $k - l$.

Examples.

(1) The free group $\langle x_1, \ldots, x_k \rangle$ on k generators admits, by definition, a presentation of deficiency k.

(2) Let $m \in \mathbb{N}$. In Lemma 53.6 (2) we saw that there exists an isomorphism

$$\langle x_1, \ldots, x_m \mid [x_i, x_j] = e \text{ for all } i < j \in \{1, \ldots, m\} \rangle \xrightarrow{\cong} \mathbb{Z}^m.$$

This shows that $\mathbb{Z}^m$ admits a presentation of deficiency $m - \frac{m(m-1)}{2}$.

(3) Let $r \in \mathbb{N}$ and $d_1, \ldots, d_s \in \mathbb{N}$. It follows basically immediately from the above isomorphism in (2) that there exists an isomorphism

$$\left\langle x_1, \ldots, x_{r+s} \,\middle|\, \begin{array}{c} [x_i, x_j] = e \text{ for all } i < j \in \{1, \ldots, r+s\} \\ \text{and } x_1^{d_1} = \cdots = x_s^{d_s} = e \end{array} \right\rangle \xrightarrow{\cong} \mathbb{Z}^r \oplus \bigoplus_{i=1}^{s} \mathbb{Z}_{d_i}.$$

This shows that $\mathbb{Z}^r \oplus \bigoplus_{i=1}^{s} \mathbb{Z}_{d_i}$ admits a presentation of deficiency $r - \frac{(r+s)(r+s-1)}{2}$.

Given a finite presentation for a group π it is straightforward to find a finite presentation of smaller deficiency: we just add trivial relations to a given presentation. This observation naturally leads us to the following definition:

Definition. Let π be a finitely presented group. We define the deficiency $\mathrm{def}(\pi)$ of π as the maximal deficiency of a finite presentation for π.

The following lemma shows, in particular, that the deficiency is in fact a finite natural number.

Lemma 146.4. (Deficiency Lemma)

(1) If π is a finitely presented group, then[1741]

$$\mathrm{def}(\pi) \;\leq\; \mathrm{rank}(\pi_{\mathrm{ab}}).$$

(2) The deficiency of the free group $\langle x_1, \ldots, x_k \rangle$ equals k.

(3) The deficiency of $\mathbb{Z}^m$ equals $m - \frac{m(m-1)}{2}$.

(4) The deficiency of an abelian group is at most one. Furthermore, up to isomorphism, we have that

(a) the only abelian groups of deficiency 1 are $\mathbb{Z}$ and $\mathbb{Z}^2$, and

(b) the only abelian groups of deficiency 0 are $\mathbb{Z}_n$ and $\mathbb{Z} \oplus \mathbb{Z}_n$ with $n \neq 0$ and $\mathbb{Z}^3$.

Proof.

(1) Let π be a finitely presented group and let $\langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle$ be a finite presentation. It follows from the Abelianization Proposition 53.20 (5) that there exists a short exact sequence of the form

$$0 \;\to\; A \;\to\; \mathbb{Z}^k \;\to\; \pi_{\mathrm{ab}} \;\to\; 0$$

where A is an abelian group that admits an epimorphism $\mathbb{Z}^l \to A$. We obtain that

$$\begin{array}{ccccc} k - l & \underset{\uparrow}{\leq} & k - \mathrm{rank}(A) & \underset{\uparrow}{=} & \mathrm{rank}(\pi_{\mathrm{ab}}). \\ & \text{Lemma 51.9 (6)} & & \text{Rank Additivity Lemma 51.7 (2)} & \end{array}$$

It follows that $\mathrm{def}(\pi) \leq \mathrm{rank}(\pi_{\mathrm{ab}})$.

(2) Let $F = \langle x_1, \ldots, x_k \rangle$ be the free group on k generators. Evidently its deficiency is at least k. By the Abelianization Proposition 53.20 (4) we know that $F_{\mathrm{ab}} \cong \mathbb{Z}^k$. Thus it follows from (1) that the deficiency of F is also at most k.

(3) We had just seen that $\mathrm{def}(\mathbb{Z}^m) \geq m - \frac{m(m-1)}{2}$. It follows from [**Eps1961**, Lemma 1.3] that this inequality is in fact an equality.

(4) This statement also follows from the above examples of presentations and [**Eps1961**, Lemma 1.3]. ∎

Now we have all the tools to state, and partially prove, the following theorem, which gives a negative answer to Question 54.15.

Theorem 146.5. Let M be a closed orientable connected 3-dimensional smooth manifold.

(1) We have $\mathrm{def}(\pi_1(M)) \geq 0$,

(2) If $\pi_2(M) = 0$, then $\mathrm{def}(\pi_1(M)) = 0$.

(3) If $\pi_1(M)$ is abelian, then $\pi_1(M)$ is either isomorphic to $\mathbb{Z}^3$ or to $\mathbb{Z}_n$ for some $n \in \mathbb{N}_0$.

Remark. The list in (3) is complete, in the sense that all these abelian groups are realized by fundamental groups of closed orientable connected 3-dimensional smooth manifolds. Indeed, given $n \in \mathbb{N}$, we obtain from Corollary 48.18 and the Fundamental Group-of-Product Proposition 48.20 that

$$\pi_1(S^1 \times S^1 \times S^1) \cong \mathbb{Z}^3 \quad \pi_1(L(n,1)) \cong \mathbb{Z}_n, \qquad \text{and } \pi_1(S^1 \times S^2) \cong \mathbb{Z}.$$

[1741] Here we denote by π_{ab} the abelianization of π that we introduced on page 1203. Furthermore, given a finitely generated abelian group H we denote by $\mathrm{rank}(H)$ the rank that we introduced on page 1152.

Proof. Let M be a closed orientable connected 3-dimensional smooth manifold.

(1) By Theorem 146.3 there exists a genus g Heegaard splitting $M = X \cup_F Y$ for M. We pick a base point $x_0 \in F = X \cap Y$. By Lemma **??** and the Fundamental Group-of-Surfaces Proposition 54.5 we can make identifications $\pi_1(X, x_0) = \langle x_1, \dots, x_g \rangle$, $\pi_1(Y, x_0) = \langle y_1, \dots, y_g \rangle$ and

$$\pi_1(F, x_0) \;=\; \langle a_1, \dots, a_{2g} \,|\, [a_1, a_2] \cdot \dots \cdot [a_{2g-1}, a_{2g}] \rangle.$$

We denote by $\varphi\colon \pi_1(F, x_0) \to \pi_1(X, x_0)$ and $\psi\colon \pi_1(F, x_0) \to \pi_1(Y, x_0)$ the inclusion induced maps. Now we have

$$\begin{array}{rcl} & & \text{Seifert–van Kampen Theorem 54.4 for smooth manifolds} \\ & & \downarrow \\ \pi_1(M, x_0) & \cong & \pi_1(X, x_0) *_{\pi_1(F, x_0)} \pi_1(Y, x_0) \\ & = & \langle x_1, \dots, x_g, y_1, \dots, y_g \,|\, \varphi(a_1) = \psi(a_1), \dots, \varphi(a_{2g}) = \psi(a_{2g}) \rangle. \\ & & \uparrow \\ & & \text{Lemma 53.23} \end{array}$$

We have thus shown that $\pi_1(M)$ admits a presentation of deficiency zero.

(2) This statement is proved in [**Eps1961**, Lemma 3.1].

(3) It follows from (1) and the Deficiency Lemma 146.4 (4), that the only isomorphism types of abelian groups that can occur are $\mathbb{Z}_n$ for some $n \in \mathbb{N}_0$, $\mathbb{Z}^2$, $\mathbb{Z} \oplus \mathbb{Z}_n$ for some $n \geq 2$ and $\mathbb{Z}^3$. With somewhat more effort, see e.g. [**Eps1961**, Theorem 3.3] or [**Rei1936**, p. 28] one can also exclude the groups $\mathbb{Z}^2$ and $\mathbb{Z} \oplus \mathbb{Z}_n$ with $n \geq 2$ from the list. ■

We conclude this discussion of Heegaard splittings with a particularly fascinating aspect of Heegaard splittings: they can be used to give a purely group theoretic formulation of the Poincaré Conjecture in dimension three. More precisely, the following theorem was proved by John Stallings [**Stal1965a**, Chapter 3] and William Jaco [**Jaco1969**, Theorem 6.3]. The origin of the theorem lies in the description of the fundamental group of a closed oriented connected 3-dimensional smooth manifold in terms of a Heegaard splitting that we gave in the proof of Theorem 146.5.

Theorem 146.6. We introduce the following notation and language:

(a) Given $g \in \mathbb{N}_0$ we denote by π_g the fundamental group of the surface of genus g and we denote by F_g the free group of rank g.

(b) We say a homomorphism $\beta\colon G \to A * B$ from a group G to the free product of two groups A and B is *essential*, if there is no $h \in A * B$ such that $h\beta(G)h^{-1}$ is contained in A or B.

The following two statements are equivalent:

(1) Every homotopy 3-sphere[1742] is diffeomorphic to S^3.

(2) For any $g \in \mathbb{N}$ any epimorphism $\alpha\colon \pi_g \to F_g \times F_g$ factors through an essential monomorphism $\beta\colon \pi_g \to A * B$ from π_g to the free product of two groups A and B.

Put differently, by Perelman's proof of Theorem **??** we now know that the first statement of Theorem 146.6 holds, thus the second statement also holds. This is the only known proof of that purely group theoretic statement. Conversely, any proof of the second statement

[1742] See page 2625 for the definition of a homotopy sphere.

of Theorem 146.6 would immediately reprove Theorem **??**. Surely that is a quick and easy way to mathematical glory.

Remark.

(1) Perhaps by now it is no longer surprising that there is a huge literature on Heegaard splittings, see e.g. [**Schle2017**, Chapter 6] for an introduction.
(2) Recently the notion of a Heegaard splitting has been modified by David Gay and Rob Kirby [**GK2016**] to give the notion of a *trisection* of a closed orientable connected 4-dimensional smooth manifold. One remarkable feature of trisections is that by recent work of Aarons Abrams, David Gay and Rob Kirby [**AGK2018**] they allow for a purely group theoretic reformulation of the smooth Poincaré Conjecture in dimension 4 that we had formulated as Question **??**. This can be viewed as an analogue of Theorem 146.6.

146.3. **The mapping class group of 2-dimensional smooth manifolds.** In Section **??** we introduced the mapping class group of smooth manifolds. In this section we recall the definition and we discuss the mapping class groups of surfaces in more detail. We will use this discussion to show that every 3-dimensional smooth manifold with a genus 1 Heegaard decomposition is in fact a lens space.
First we recall the following definition from page 812.

Definition. Let M and N be two smooth manifolds. Two diffeomorphisms $f, g\colon M \to N$ are called diffeotopic, if there exists a diffeotopy from f to g, i.e. a smooth map[1743]

$$\begin{array}{rcl} H\colon M \times [0,1] & \to & N \\ (x,t) & \mapsto & H(x,t) \end{array}$$

such that the following hold:

(1) for all $x \in M$ we have $H(x,0) = f(x)$ and $H(x,1) = g(x)$, and
(2) for each $t \in [0,1]$ the map $M \to N$ given by $x \mapsto H(x,t)$ is a diffeomorphism.

Remark. In the following we will implicitly use on several occasions the fact, shown in the Smooth Isotopy Transitivity Proposition 33.3, that being diffeotopic is an equivalence relation.

We move on to introducing some notation.

Notation. Let M be an oriented smooth manifold.

(1) We write $\mathrm{Diff}(M)$ for the group of all self-diffeomorphisms of M.
(2) We denote by $\mathrm{Diff}_0(M)$ the set of all self-diffeomorphisms of M that are diffeotopic to the identity.
(3) We write $\mathrm{Diff}^+(M)$ for the group of all orientation-preserving self-diffeomorphisms of M.

We recall the following definition from page **??**.

Definition. Let M be a smooth manifold. The mapping class group $\mathrm{MCG}(M)$ of M is defined as

$$\mathrm{MCG}(M) \;:=\; \mathrm{Diff}(M)/\,\mathrm{Diff}_0(M).$$

[1743] See page 811 for the definition of what it means that a map on $M \times [0,1]$ is smooth.

If M is oriented, then the orientation-preserving mapping class group $\mathrm{MCG}^+(M)$ of M is defined as

$$\mathrm{MCG}^+(M) := \mathrm{Diff}^+(M)/\mathrm{Diff}_0(M).$$

Example.

(1) Let $n \in \mathbb{N}$. In the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3 and Exercise 34.1 we showed, with different language, that $\mathrm{MCG}^+(\mathbb{R}^n)$ and $\mathrm{MCG}^+(\overline{B}^1)$ and $\mathrm{MCG}^+([0,1)$ are the trivial group.
(2) We now consider the orientation-preserving mapping class group of 1-dimensional smooth manifolds. By the Smooth 1-Dimensional Manifold Classification Theorem 22.7 we know that we only need to consider the smooth manifolds $\mathbb{R}$, $[0,1)$, $[0,1]$ and S^1. In the Diffeotopies-of-$\mathbb{R}^n$-Classification Proposition 34.3, Exercise 34.4 and the Diffeotopies-of-S^1-Classification Proposition 34.5 we showed that $\mathrm{MCG}^+(\mathbb{R})$, $\mathrm{MCG}^+([0,1))$, $\mathrm{MCG}^+([0,1])$, and $\mathrm{MCG}^+(S^1)$ are the trivial group.
(3) Note that by the Smooth Isotopy-Orientation Proposition 34.2 an orientation-reversing self-diffeomorphism of a smooth manifold M always represents a non-trivial element of the mapping class group $\mathrm{MCG}(M)$.

For surfaces of genus 0 and 1, i.e. for the sphere S^2 and the torus $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$ the following theorem gives a complete description of the mapping class groups.

Theorem 146.7.

(1) $\mathrm{MCG}^+(S^2)$ is the trivial group.
(2) The group $\mathrm{MCG}(S^2)$ contains two elements, one is represented by the identity and the other one is represented by any reflection in a hyperplane.
(3) Let $T = \mathbb{R}^2/\mathbb{Z}^2$ be the 2-dimensional torus. We use the generators from Lemma 78.11 (2) to make the usual identification $\mathrm{H}_1(T;\mathbb{Z}) = \mathbb{Z}^2$ and we use this identification to make the corresponding identifications $\mathrm{Aut}(\mathrm{H}_1(T;\mathbb{Z})) = \mathrm{Aut}(\mathbb{Z}^2) = \mathrm{GL}(2,\mathbb{Z})$ and $\mathrm{SAut}(\mathrm{H}_1(T;\mathbb{Z})) = \mathrm{SAut}(\mathbb{Z}^2) = \mathrm{SL}(2,\mathbb{Z})$. The maps

$$\begin{aligned} \Phi\colon \mathrm{MCG}(T) &\mapsto \mathrm{GL}(2,\mathbb{Z}) \\ [f\colon T \to T] &\mapsto \underbrace{(f_*\colon \mathrm{H}_1(T) \to \mathrm{H}_1(T))}_{\in \mathrm{Aut}(\mathrm{H}_1(T;\mathbb{Z}))=\mathrm{GL}(2,\mathbb{Z})} \end{aligned} \quad \text{and} \quad \begin{aligned} \Psi\colon \mathrm{GL}(2,\mathbb{Z}) &\mapsto \mathrm{MCG}(T) \\ A &\mapsto \begin{bmatrix} \mathbb{R}^2/\mathbb{Z}^2 \mapsto \mathbb{R}^2/\mathbb{Z}^2 \\ [v] \mapsto [Av] \end{bmatrix} \end{aligned}$$

are inverses of one another.
(4) The same statement as in (3) holds if we replace $\mathrm{MCG}^+(\mathbb{R}^2/\mathbb{Z}^2)$ by $\mathrm{MCG}(\mathbb{R}^2/\mathbb{Z}^2)$ and if we replace $\mathrm{SL}(2,\mathbb{Z})$ by $\mathrm{GL}(2,\mathbb{Z})$.[1744]

Proof. The first two statements were proved in 1959 by James Munkres [**Mun1960b**] and independently by Stephen Smale [**Sma1959**].[1745] It is an amusing exercise to show that $\Phi \circ \Psi = \mathrm{id}$ on $\mathrm{GL}(2,\mathbb{Z})$. The fact that $\Psi \circ \Phi = \mathrm{id}$ on $\mathrm{MCG}(\mathbb{R}^2/\mathbb{Z}^2)$ is somewhat harder. We refer to [**FaM2011**, Theorem 2.5] or alternatively to [**Rolf1990**, Chapter 2.D] for proofs. The claim regarding the orientation-preserving mapping class group follows from the above result together with Lemma 114.15. ■

Remark.

[1744] We showed in Lemma 114.15 that the map $\Phi\colon \mathrm{MCG}^+(T) \to \mathrm{GL}(2,\mathbb{Z})$ takes values in $\mathrm{SL}(2,\mathbb{Z})$.
[1745] We had already encountered Stephen Smale in the proof of the Poincaré Conjecture in dimensions ≥ 5, see Theorem **??**.

(1) We will discuss the higher-dimensional analogues of Theorem 146.7 (1) in Theorem **??**.
(2) The obvious analogue of Theorem 146.7 (1) in higher dimensions does not hold. More precisely, Allen Hatcher and John Wagoner [**HatW1973**] and Kiyoshi Igusa [**Ig1979, Ig1984**] proved that given any $n \geq 5$ there exists a short exact sequence of the form:

$$0 \ \to \ \mathbb{Z}_2^\infty \ \to \ \mathrm{MCG}((S^1)^n) \ \to \ \mathrm{GL}(n,\mathbb{Z}) \ \to \ 1.$$

We refer to [**Hat1978**, Theorem 4.1] for more details and to [**HsSh1976**, Theorem 2.5] for an alternative proof if $n \geq 6$.

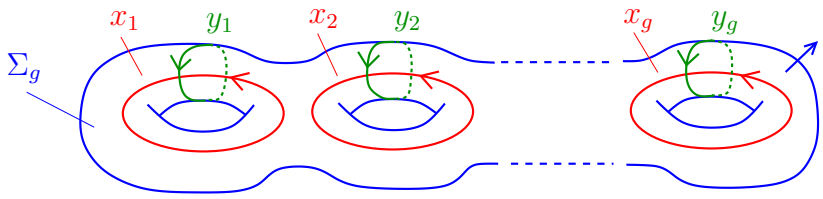
Now we can give the following characterization of lens spaces.

Corollary 146.8. If M is a closed orientable connected 3-dimensional smooth manifold, then the following two statements are equivalent:

M admits a genus 1 Heegaard splitting $\iff$ M is a lens space or $M \cong S^1 \times S^2$.

Proof. By the Lens Space-Splitting Lemma 146.2 and the discussion on page 3114 we know that lens spaces and $S^1 \times S^2$ admit genus 1 Heegaard splittings.

Now suppose that M is a closed orientable connected 3-dimensional smooth manifold that admits a genus 1 Heegaard splitting $M = (S^1 \times \overline{B}^2) \cup_\varphi (S^1 \times \overline{B}^2)$ where φ is an orientation-reversing self-diffeomorphism of $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$. It is an immediate consequence of Theorem 146.7 (3), Lemma 114.15 and Lemma **??** that, after a diffeotopy, we can assume that φ is given by multiplication by a matrix $\begin{pmatrix} q & p \\ s & r \end{pmatrix} \in \mathrm{GL}(2,\mathbb{Z})$ with $qr - ps = -1$.



First assume that $p = 0$. We leave it as an amusing exercise to show that in this case M is diffeomorphic to $S^1 \times S^2$. If $p > 0$, then it follows from the Lens Space-Splitting Lemma 146.2 that M is diffeomorphic to $L(p,q)$. Finally we consider the case that $p < 0$. We denote by ψ the self-diffeomorphism of $\mathbb{R}^2/\mathbb{Z}^2$ that is given by multiplication by the matrix $\begin{pmatrix} q & -p \\ -s & r \end{pmatrix} \in \mathrm{GL}(2,\mathbb{Z})$. The map

$$(S^1 \times \overline{B}^2) \cup_\varphi (S^1 \times \overline{B}^2) \ \to \ (S^1 \times \overline{B}^2 \cup_\psi S^1 \times \overline{B}^2),$$

given by reflection on both of the S^1 factors is easily seen to be a well-defined diffeomorphism. But as we had just shown, the right-hand side is diffeomorphic to the lens space $L(-p,q)$. ∎

We had just seen that the mapping class group of the 2-dimensional sphere and the torus are groups we are very familiar with. It is natural to ask, whether we can also understand the mapping class groups of higher genus surfaces.

Throughout the remainder of this section, given $g \geq 1$ we denote by Σ_g the surface of genus g. To facilitate the discussion, we equip $\mathrm{H}_1(\Sigma_g;\mathbb{Z})$ with the standard basis $x_1, \ldots, x_g, y_1, \ldots, y_g$ shown in the figure below and we use this basis to make the identification $\mathrm{H}_1(\Sigma_g;\mathbb{Z}) = \mathbb{Z}^{2g}$.
Here is a somewhat optimistic interpretation of the above question.

Question 146.9. Let $g \geq 2$. Is the map

$$\begin{array}{rcl} \Phi_g\colon \mathrm{MCG}(\Sigma_g) & \mapsto & \mathrm{GL}(2g,\mathbb{Z}) \\ [f\colon \Sigma_g \to \Sigma_g] & \mapsto & \underbrace{\left(f_*\colon \mathrm{H}_1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}_1(\Sigma_g;\mathbb{Z})\right)}_{\in \mathrm{Aut}(\mathrm{H}_1(\Sigma_g;\mathbb{Z}))=\mathrm{GL}(2g,\mathbb{Z})} \end{array}$$

an isomorphism?

It turns out that the answer to Question 146.9 is no. In fact we have already developed all the tools to show that Φ_g is not an epimorphism. At this point it is useful to introduce the following definition.

Definition.

(1) Given $g \in \mathbb{N}$ we write $J_g := \begin{pmatrix} 0 & \mathrm{id}_g \\ -\mathrm{id}_g & 0 \end{pmatrix}$.

(2) We say a matrix $A \in \mathrm{GL}(2g,\mathbb{Z})$ is symplectic[1746] if $A^T J_g A = J_g$.

(3) We define the symplectic group $\mathrm{Sp}(2g,\mathbb{Z})$ to be the group[1747] of all symplectic matrices.

Now we can formulate the following proposition.

Proposition 146.10. Let $g \in \mathbb{N}$. The homomorphism $\Phi_g\colon \mathrm{MCG}^+(\Sigma_g) \to \mathrm{GL}(2g,\mathbb{Z})$ takes values in $\mathrm{Sp}(2g,\mathbb{Z})$.

Proof. Recall that as above we use the homology classes represented by the curves $x_1,\dots,x_g$ and $y_1,\dots,y_g$ that are shown in the figure on page 3125 to make the identification $\mathbb{Z}^{2g} = \mathrm{H}_1(\Sigma_g;\mathbb{Z})$. It follows from the calculation of the intersection form of Σ_g on page 2881 that we have a commutative diagram

$$\begin{array}{ccc} \mathbb{Z}^{2g} \times \mathbb{Z}^{2g} & \xrightarrow{(v,w)\mapsto v^T J w} & \mathbb{Z} \\ \downarrow{=} & & \downarrow{=} \\ \mathrm{H}_1(\Sigma_g;\mathbb{Z}) \times \mathrm{H}_1(\Sigma_g;\mathbb{Z}) & \xrightarrow{Q_{\Sigma_g}} & \mathbb{Z}. \end{array}$$

Now let f be an orientation-preserving self-homeomorphism of Σ_g. We denote by A the matrix that represents the induced map $f_*\colon \mathrm{H}_1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}_1(\Sigma_g;\mathbb{Z})$ with respect to the above basis.

It is a consequence of Lemma 132.6 that the induced map f_* preserves the intersection form of Σ_g. Therefore we obtain from the commutative diagram that the induced map

[1746] The origin of the word "symplectic" is explained in the following webpage

`http://jeff560.tripod.com/mathword.html`

which explores the earliest known uses of some of the words of mathematics.

[1747] It is straightforward to verify that the set of all symplectic $(2g \times 2g)$-matrices is in fact a subgroup of $\mathrm{GL}(2g,\mathbb{Z})$.

on $\mathrm{H}_1(\Sigma_g;\mathbb{Z}) = \mathbb{Z}^{2g}$ also preserves the form on the top. But this means that for any two vectors $v, w \in \mathbb{Z}^g$ we have $v^T A^T J A w = (Av)^T J A w = v^T J w$. This in turn implies that $A^T J A = J$. ■

The question now arises, how big is the symplectic group? The following proposition summarizes some known results:

Proposition 146.11. (Symplectic Group Proposition) Let $g \in \mathbb{N}$.

(1) We have $\mathrm{Sp}(2g,\mathbb{Z}) \subset \mathrm{SL}(2g,\mathbb{Z})$.
(2) We have $\mathrm{Sp}(2,\mathbb{Z}) = \mathrm{SL}(2,\mathbb{Z})$.
(3) For $g \geq 2$ the symplectic group $\mathrm{Sp}(2g,\mathbb{Z})$ is a proper subgroup of $\mathrm{SL}(2g,\mathbb{Z})$.

Proof.

(1) The fact that every symplectic matrix has determinant equal to $+1$ is a somewhat non-trivial exercise in linear algebra. A proof is for example given in [**Serd2010**, Corollary 10.2] or [**McS2016**, Lemma 1.1.15].
(2) A short and amusing calculation (worth doing!) shows that every matrix in $\mathrm{SL}(2,\mathbb{Z})$ is in fact symplectic.
(3) Let $g \geq 2$. Unless one is very unlucky, almost any randomly picked matrix in $\mathrm{SL}(2g,\mathbb{Z})$ will not lie in $\mathrm{Sp}(2g,\mathbb{Z})$. For example an elementary calculation shows that the matrix

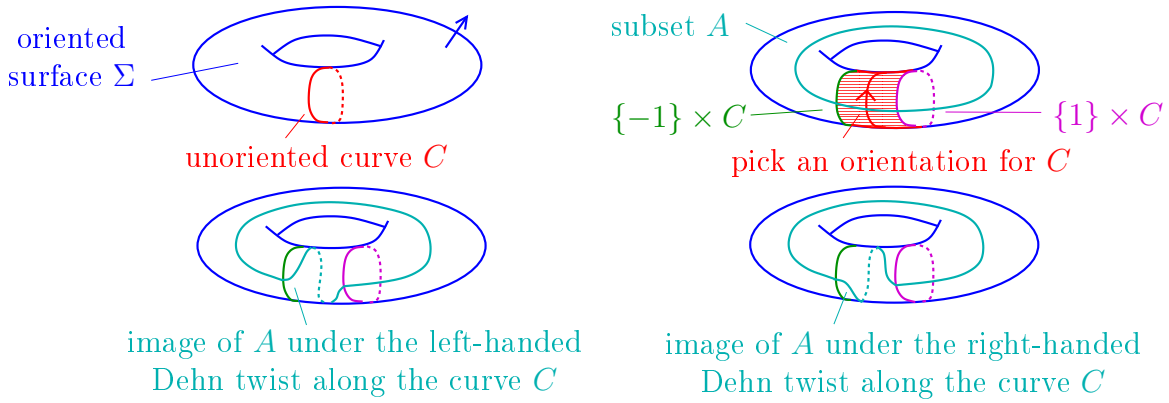
$$A := \begin{pmatrix} 2 & 0 & 5 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 3 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

does not satisfy $A^T J A = J$, i.e. A does not lie in $\mathrm{Sp}(4,\mathbb{Z})$. A straightforward modification of this example shows that given any $g \geq 2$ there exist matrices in $\mathrm{SL}(2g,\mathbb{Z})$ that do not lie in $\mathrm{Sp}(2g,\mathbb{Z})$. ■

In a last ditch effort to salvage Question 146.9 one could ask whether perhaps the map $\Phi_g \colon \mathrm{MCG}(\Sigma_g)^+ \to \mathrm{Sp}(2g,\mathbb{Z})$ is an isomorphism.
Now is perhaps a good moment to recall that we had already constructed diffeomorphisms of Σ_g. More precisely we recall the following definition from page 471.

Definition. Let Σ be an oriented surface and let $C \subset \Sigma$ be a closed curve on Σ, i.e. C is a submanifold of Σ diffeomorphic to S^1. We pick an orientation for C. By the Tubular Neighborhood Theorem **??** there exists an orientation-preserving smooth embedding $\Phi \colon [-1,1] \times S^1 \to \Sigma$ such that $\Phi \colon \{0\} \times S^1 \to C$ is an orientation-preserving diffeomorphism. By the Smooth Transition Function Lemma 19.4 we can pick a smooth map $\gamma \colon [-1,1] \to [0,2\pi]$ and with $\gamma(-1) = 0$ and $\gamma(1) = 2\pi$ that is constant close to -1 and 1.

(1) We refer to map



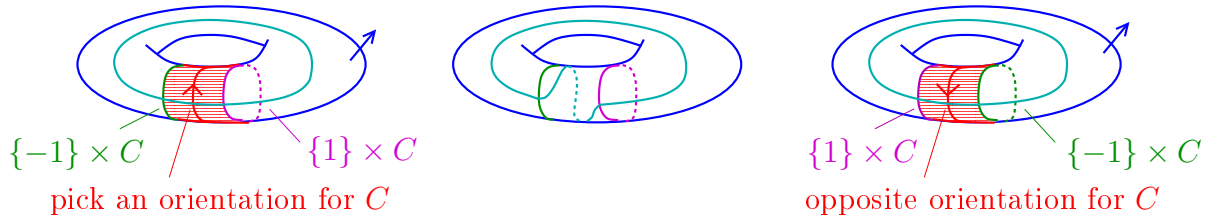
$$\begin{array}{ccc} \Sigma & \to & \Sigma \\ P & \mapsto & \begin{cases} P, & \text{if } P \notin \Phi([-1,1] \times S^1), \\ \Phi(t, z \cdot \exp(\gamma(t) \cdot \mathrm{i})) & \text{if } P = \Phi(t,z) \text{ for some } t \in [-1,1] \text{ and } z \in S^1, \end{cases} \end{array}$$

as a left-handed Dehn twist along the curve C.

(2) We refer to the orientation-preserving diffeomorphism

$$\begin{array}{ccc} \Sigma & \to & \Sigma \\ P & \mapsto & \begin{cases} P, & \text{if } P \notin \Phi([-1,1] \times S^1), \\ \Phi(t, z \cdot \exp(-\gamma(t) \cdot \mathrm{i})) & \text{if } P = \Phi(t,z) \text{ for some } t \in [-1,1] \text{ and } z \in S^1, \end{cases} \end{array}$$

as a right-handed Dehn twist along the curve C.



Remark.

(1) Dehn twists were introduced by Max Dehn [**Deh1938**, Chapter 2] in 1938.
(2) Our conventions of right-handed and left-handed Dehn twists match the definitions in [**BZH2014**, Definition 11.6] and in [**FaM2011**, Chapter 3.1.1]. At first glance our definition might look slightly different, but the only difference is that we prefer to work with $[-1,1] \times S^1$ instead of $S^1 \times [-1,1]$, since we always want to put the factor with non-empty boundary first.

Lemma 146.12. (Dehn Twist Lemma) Let Σ be an oriented surface and let C be a submanifold of Σ diffeomorphic to S^1.

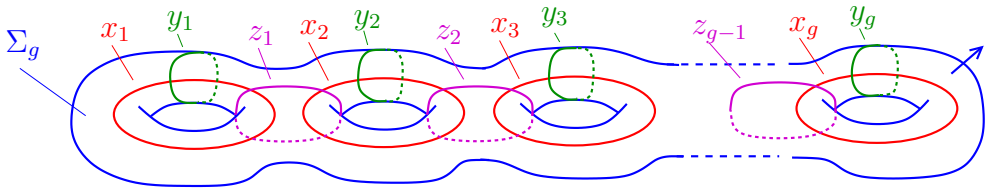
(1) Both Dehn twists are orientation-preserving diffeomorphisms and the left and right-handed Dehn twists are inverses of one another.
(2) The diffeotopy class of the left-handed Dehn twist along C neither depends on the choice of the orientation nor does it depend on the choice of the tubular neighborhood. In other words, the unoriented curve C gives rise to a well-defined element of $\mathrm{MCG}^+(\Sigma)$. The same statement also holds for right-handed Dehn twists.

Proof.

(1) It follows easily from the fact that γ is constant near the ends and the Smooth Pasting Proposition 19.23 that both Dehn twists are smooth. Furthermore it follows

from the Basics-of-Orientations Lemma 25.13 (3) that each Dehn twist is orientation-preserving. Finally note one can easily verify that the left-handed and right-handed Dehn twists are inverses of one another.

(2) In the following we will deal with left-handed Dehn twists. The argument for right-handed Dehn twists is evidently almost the same.



First note that by the usual interpolation one can show easily that the definition does not depend on the choice of γ. Next we show that the definition does not depend on the choice of the orientation of C. Indeed, if we pick the opposite orientation for C, then we need to replace the map $\Phi\colon [-1,1]\times S^1 \to \Sigma$ by the map $\widetilde{\Phi}$ that is given by $\widetilde{\Phi}(t,z) = \Phi(-t,\overline{z})$ and we need to replace γ by the map that is given by $\widetilde{\gamma}(t) = 2\pi - \gamma(-t)$. We claim that Φ, $\widetilde{\Phi}$ and $\widetilde{\gamma}$ give rise to the same self-diffeomorphism of Σ. Thus let $P \in M$. Since Φ and $\widetilde{\Phi}$ have the same image we only need to consider the case that $P = \Phi(t,z)$ for some $t \in [-1,1]$ and $z \in S^1$. Note that $P = \widetilde{\Phi}(-t,\overline{z})$. Then we have indeed that

$$\underbrace{\Phi(t, z\cdot\exp(\gamma(t)\cdot \mathrm{i}))}_{\text{definition using } \Phi} \;=\; \Phi(t, z\cdot\overline{\exp(\widetilde{\gamma}(-t))\cdot \mathrm{i})}) \;=\; \underbrace{\widetilde{\Phi}(-t, \overline{z}\cdot\exp(\widetilde{\gamma}(-t)\cdot \mathrm{i}))}_{\text{definition using } \widetilde{\Phi}}.$$

Finally note that it follows easily from the uniqueness of tubular neighborhoods, see Proposition **??**, that any choice of another map $\Phi\colon [-1,1]\times S^1 \to \Sigma$ leads to a diffeotopic self-diffeomorphism of Σ. ■

The following theorem shows that, in some sense, left-handed Dehn twists are all orientation-preserving diffeomorphisms we ever need.

Theorem 146.13. (Lickorish Twist Theorem) The left-handed Dehn twists along the $3g-1$ curves shown in the figure below form a generating set for $\mathrm{MCG}^+(\Sigma_g)$.

Remark. It is significantly harder to show that $\mathrm{MCG}^+(\Sigma_g)$ admits a finite presentation, see [**HT1980**] and [**Waj1983**] for details.

Proof. This proposition proved in 1963 by Raymond Lickorish [**Lic1964**], see also [**FaM2011**, Theorem 4.13] or [**Bir1974**, Theorem 4.3]. ■

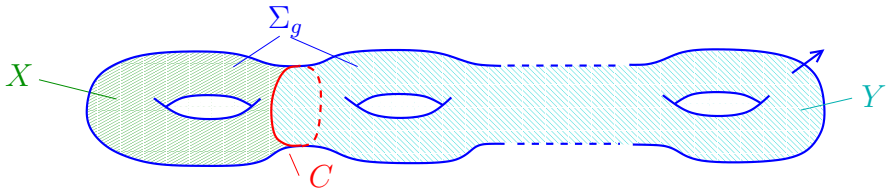
In fact this source of orientation-preserving diffeomorphisms is rich enough to prove the following proposition.

Proposition 146.14. For any $g \geq 1$ the above map $\Phi_g\colon \mathrm{MCG}^+(\Sigma_g) \to \mathrm{Sp}(2g,\mathbb{Z})$ is an epimorphism.

Proof. The result is proved in [**FaM2011**, Theorem 6.4]. ■

This leads us to the following definition.

Definition. Given $g \geq 1$ we refer to



$$T_g := \ker(\Phi_g \colon \mathrm{MCG}(\Sigma_g)^+ \to \mathrm{Sp}(2g, \mathbb{Z}))$$

as the Torelli group of Σ_g.[1748]

The question now becomes, whether the Torelli group T_g is non-trivial. In fact the next proposition shows precisely that.

Proposition 146.15. (Torelli Group Proposition) Let $g \in \mathbb{N}$.

(1) If C is a closed curve on Σ_g that is not null-homotopic, then the left-handed Dehn twist t_C defines a non-trivial element in $\mathrm{MCG}(\Sigma_g)$.
(2) If C is a closed curve on Σ_g that is null-homologous, then the left-handed Dehn twist t_C defines an element of the Torelli group T_g.
(3) For $g \geq 2$ the left-handed Dehn twist along the curve C shown in the figure below defines a non-trivial element in the Torelli group T_g.

Proof.

(1) The first statement is proved in [**FaM2011**, Proposition 3.1].
(2) This statement follows from [**FaM2011**, Proposition 3.2]. With some effort one could also prove this statement "by hand".
(3) By (1) and (2) it suffices to show that C is null-homologous but not null-homotopic. Note that C is the boundary of a submanifold X of Σ_g. We obtain from Corollary 106.28 (1) that $[C] = 0 \in \mathrm{H}_1(X; \mathbb{Z})$, which implies that C is also null-homologous in Σ_g. On the other hand we know by Proposition 55.18 that C is not null-homotopic. ■

There are still lots of open questions regarding mapping class groups of surfaces. For example the following question is an interesting open problem.

Question 146.16. Let Σ_g be the surface of genus $g \in \mathbb{N}_0$. Is the mapping class group $\mathrm{MCG}(\Sigma_g)$ linear, i.e. is it isomorphic to a subgroup of $\mathrm{GL}(n, \mathbb{C})$ for some large enough n?

We had just seen in Theorem 146.7 that the answer is yes for $g = 0$ and $g = 1$. Furthermore Stephen Bigelow and Ryan Budney [**BB2001**] showed in 2001 that the answer is yes for $g = 2$. The case $g \geq 3$ is still wide open.

As in almost any topic we have touched so far, there is again a tremendous amount of literature and work on mapping class groups. We refer to [**Bir1974, FaM2011, Hat2012**] for more information regarding mapping class groups and diffeomorphism groups of smooth manifolds in dimension 2 and in higher dimensions.

[1748] For slightly mysterious reasons this group is named after the Italian mathematician Ruggiero Torelli (1884–1915) who died in World War I.

Exercises for Chapter 146.

Exercise 146.1. Let H_g be the genus g handlebody and let $W = \mathrm{H}_g \cup \mathrm{H}_g$ be the double of H_g. Show that W is diffeomorphic to the connected sum of g copies of $S^1 \times S^2$.

Exercise 146.2. Let $p \in \mathbb{N}$ and let $q \in \mathbb{Z}$ be coprime to p. We consider the corresponding lens space $L(p,q)$. In the Lens Space Homology Lemma 98.9 we used a roundabout way to obtain the following result:

$$\mathrm{H}_n(L(p,q)) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0, 3, \\ 0, & \text{if } n = 2 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases}$$

Use the Lens Space-Splitting Lemma 146.2 and the Mayer–Vietoris Theorem 78.9 for Manifolds to give an alternative, and arguably more insightful, calculation of the homology groups of $L(p,q)$.
Remark. You might want to use the Action-on-Torus Homology Lemma 84.7.

Exercise 146.3. Let M be a closed oriented connected 3-dimensional smooth manifold. We define its *Heegaard genus* as follows:

$$g(M) \;:=\; \min\{g \in \mathbb{N}_0 \,|\, \text{there exists a Heegaard splitting of } M \text{ of genus } g\}.$$

(a) Show that $g(M)$ is greater of equal than the minimal number of generators of $\mathrm{H}_1(M;\mathbb{Z})$.
Remark. Note that it purposely fully says $g(M)$ instead of the less interesting bound $2g(M)$.
(b) Determine the Heegaard genus the 3-dimensional torus $S^1 \times S^1 \times S^1$.
(c) Given $k \in \mathbb{N}_0$ determine the Heegaard genus of the connected sum of k copies of $S^1 \times S^2$.

Exercise 146.4. Let F be the surface of genus g and let $\varphi\colon F \to F$ be an orientation-preserving self-diffeomorphism. By the Gluing-Smooth Manifolds-Proposition **??** we know that the mapping torus

$$\mathrm{Tor}(F,\varphi) \;:=\; F \times [0,1] \,/\, (x,0) \sim (\varphi(x),1)$$

is a closed orientable connected 3-dimensional smooth manifold. Show that $\mathrm{Tor}(F,\varphi)$ admits a Heegaard splitting of genus $2g+1$.

Exercise 146.5. Let $k, q \in \mathbb{N}$. Show that there exists a smooth embedding of a closed connected 2-dimensional smooth manifold F with $\chi(F) = 2-k$ into the lens space $L(2k,q)$.
Hint. Consider the Heegaard decomposition $L(2k,q) \cong M(S^1 \times \overline{B}^2, S^1 \times \overline{B}^2, \varphi)$ from the Lens Space-Splitting Lemma 146.2. Consider a disk $\{*\} \times \overline{B}^2$ in the first solid torus. Show that the intersection of this disk with the boundary of the second torus can be viewed as a torus knot. (We refer to page 1312 for the definition of a torus knot.)

Exercise 146.6. Let Σ be an oriented surface and let C and D be two closed curves on Σ which intersect transversally. We denote by T_C and T_D corresponding left-handed Dehn twists. Show that in the mapping class group $\mathrm{MCG}(\Sigma)$ the following equality holds:

$$T_C \circ T_D \circ T_C \;=\; T_D \, T_C \, T_D.$$

147. Surgeries on 3-dimensional smooth manifolds

In Chapter **??** we introduced the general setup for surgeries along thickened spheres in smooth manifolds. In this chapter we will study the particularly interesting case of surgery along thickened knots and links in 3-dimensional smooth manifolds.

147.1. **The Lickorish-Wallace Theorem.** We kick off our discussion with the following slight variations on the definition of a thickening of an oriented knot that we gave on page 2853 and of the notion of a surgery along a thickened sphere that we gave on page **??**.

Definition. Let $L \subset S^3$ be an oriented m-component link.

(1) A thickening of the oriented link L is defined as an orientation-preserving smooth embedding $F\colon \bigsqcup_{i=1}^{m}(\overline{B}^2 \times S^1) \to S^3$ that restricts to an orientation-preserving diffeomorphism $\bigsqcup_{i=1}^{m}(\{0\}^2 \times S^1) \to L$.

(2) We define the surgery along a thickened link as the simultaneous surgery along all the thickened components.

The following theorem was first proved independently by William Lickorish [**Lic1962**] and Andrew Wallace [**Walla1960**] in 1960.

Theorem 147.1. (Lickorish-Wallace Theorem) Every closed orientable connected 3-dimensional smooth manifold can be obtained through surgery along a thickened link.

The following lemma contains one of the key geometric ingredients in the proof of the Lickorish-Wallace Theorem 147.1.

Lemma 147.2. Let Σ be the surface of some genus g and let C be an oriented curve on Σ. We denote by $\tau\colon \Sigma \to \Sigma$ a corresponding Dehn twist along C. There exists a fattened 1-sphere $\varphi\colon \overline{B}^2 \times S^1 \to (-1,1) \times \Sigma$ with $\varphi(\{0\} \times S^1) = C$ and a diffeomorphism

$$\Psi\colon ([-1,0] \times \Sigma) \cup_\tau ([0,1] \times \Sigma) \;\to\; ([-1,1] \times \Sigma)(\varphi)$$

which is the identity in a neighborhood of $\{-1,1\} \times \Sigma$.

Remark. As on many other occasions we provide a formal proof of Lemma 147.2 with the full gory details. Less formal, but perhaps more readable proofs, are given in [**Rolf1990**, p. 275] and [**Sav2012**, p. 34].

Proof. To simplify the notation we will identify C with S^1 using an orientation-preserving diffeomorphism. Let $[-1,1] \times S^1 \subset \Sigma$ be a tubular neighborhood of $C = S^1$ and let $\gamma\colon [-1,1] \to [0,2\pi]$ a map as such that the Dehn twist τ is given by the map

$$\begin{array}{rccc} \tau\colon & [-1,1] \times S^1 & \to & [-1,1] \times S^1 \\ & (t,z) & \mapsto & (t, z \cdot \exp(\mathrm{i}\gamma(t))) \end{array}$$

We think of $\overline{B}^2$ and S^1 as subspaces of $\mathbb{C}$. We consider $B^2_+ = \{x + \mathrm{i}y \in \overline{B}^2 \,|\, y \geq 0\}$ and $B^2_- = \{x + \mathrm{i}y \in \overline{B}^2 \,|\, y \leq 0\}$. A variation on the tubular neighborhood theorem shows there exists a tubular neighborhood $\overline{B}^2 \times C \subset (-1,1) \times \Sigma$ such that $\overline{B}^2_- \times C \subset [-1,0] \times \Sigma$ and $\overline{B}^2_+ \times C \subset [0,1] \times \Sigma$ and such that $[-1,1] \times C$ is precisely the tubular neighborhood of C

in Σ. Next we consider the following composition of maps:

$$\begin{array}{rcl}\Theta\colon S^1\times\overline{B}^2 \xrightarrow{(a,b)\mapsto(b,a)} \overline{B}^2\times S^1 \xrightarrow{(c,d)\mapsto(cd^{-1},d)} \overline{B}^2\times S^1 & \to & (\overline{B}^2_+\times S^1)\cup_\tau(\overline{B}^2_-\times S^1)\\ (x{+}iy,z) & \mapsto & \begin{cases}(x{+}iy,z), & \text{if } y\geq 0,\\ (x{+}iy,z\cdot\exp(\mathrm{i}\gamma(x))), & \text{if } y\leq 0.\end{cases}\end{array}$$

Note that Θ is a diffeomorphism, in fact it is straightforward to write down an inverse. Note that Θ restricts to a self-diffeomorphism of the boundary torus $S^1\times S^1$.

Claim. The restriction of Θ to a map $\Theta\colon S^1\times S^1\to S^1\times S^1$ can be extended to a diffeomorphism $\varphi\colon\overline{B}^2\times S^1\to\overline{B}^2\times S^1$.[1749]

Proof. A charming little calculation shows that the induced map on $\mathrm{H}_1(S^1\times S^1)$ is represented by the matrix $\begin{pmatrix}-1 & 1\\ 0 & 1\end{pmatrix}$. Another map that induces this map on $\mathrm{H}_1(S^1\times S^1)$ is given by $\Xi(a,b)=(b\cdot\overline{a},b)$. By Theorem 146.7 we know that there exists a diffeotopy $F\colon S^1\times S^1\times[0,1]\to S^1\times S^1$ with $F_0=\Xi\circ\Theta^{-1}$ and $F_1=\mathrm{id}$. The map

$$\begin{array}{rcl}\varphi\colon\overline{B}^2\times S^1 & \to & \overline{B}^2\times S^1\\ (z,w) & \mapsto & \begin{cases}|z|\cdot F_{2\cdot|z|-1}(\Theta(\frac{z}{|z|},w)), & \text{if } |z|\geq\frac{1}{2}\\ (w\cdot\overline{z},w), & \text{if } |z|\leq\frac{1}{2}.\end{cases}\end{array}$$

is the desired extension. ⊞

We will now see that the map $\varphi\colon\overline{B}^2\times S^1\to[-1,2]\times\Sigma$ is the desired framing. To do so we set $W:=([-1,1]\times\Sigma)\setminus(\overline{B}^2\times C$. It follows from the above that the following map is a diffeomorphism:

$$\begin{array}{rcl}\Theta\colon\overbrace{((\overline{B}^2_+\times S^1)\cup_\tau(\overline{B}^2_-\times S^1))\cup_{\mathrm{id}\colon S^1\times S^1\to W}W}^{=([-1,0]\times\Sigma)\cup_\tau([0,1]\times\Sigma)} & \to & \overbrace{(S^1\times\overline{B}^2)\cup_{\varphi\colon S^1\times S^1\to W}W}^{=([-1,1]\times\Sigma)(\varphi)}\\ P & \mapsto & \begin{cases}P, & \text{if } P\in W,\\ \psi(P), & \text{otherwise.}\end{cases}\end{array}$$ ■

Now we have all the ingredients to provide the proof of the Lickorish-Wallace Theorem 147.1.

Proof of the Lickorish-Wallace Theorem 147.1. Let M be a closed orientable connected 3-dimensional smooth manifold. The first three steps of the proof are straightforward.

(1) By Theorem 146.3 we know that M admits a Heegaard splitting, as defined on page 3114. By Lemma 146.1 this means that there exist two handlebodies H and H' of some genus g and an orientation-reversing diffeomorphism $\varphi\colon\partial H\to\partial H'$ such that M is diffeomorphic to $H\cup_\varphi H'$.

(2) By the discussion on page 3115 we know that S^3 admits Heegaard splittings of any genus. It follows from Lemma 146.1 (1d) that there exists an orientation-reversing diffeomorphism $\psi\colon\partial H\to\partial H'$ such that S^3 is diffeomorphic to $H\cup_\psi H'$.

(3) We write $\Sigma=\partial H$.

[1749] Note the all important change in the order of S^1 and $\overline{B}^2$.

(4) By the Lickorish Twist Theorem 146.13 we know that the mapping class group $\mathrm{MCG}^+(\Sigma)$ is generated by Dehn twists. Note that the inverse of a Dehn twist along an oriented curve c is given by a Dehn twist along c with the opposite orientation. This implies that there exist oriented curves $C_1, \dots, C_k$ on ∂H such that the composition of Dehn twists along $C_1, \dots, C_k$ is diffeotopic to $\psi^{-1} \circ \varphi \colon \Sigma \to \Sigma$.
(5) We pick orientation-preserving tubular neighborhoods $[-1,1] \times C_i$. Furthermore we pick a smooth map $\gamma \colon [-1,1] \to [0, 2\pi]$ with $\gamma(-1) = 0$ and $\gamma(1) = 2\pi$ which is constant close to -1 and 1.
(6) For $i = 1, \dots, k$ we denote by t_i the corresponding Dehn twist along C_i.
(7) By the Smooth Collar Neighborhood Theorem 28.3 we can pick a Smooth Collar Neighborhood $\Sigma \times [0, k+1] \times \Sigma$ of $\Sigma = \partial H$.

The desired statement now follows from the above, together with Lemma **??** and the following claim.

Summarizing we have the following sequence of orientation-preserving diffeomorphisms.

$$
\begin{array}{l}
\text{follows from a collar neighborhood argument} \qquad\qquad \text{follows easily from } \psi^{-1} \circ \varphi = t_k \circ \cdots \circ t_1 \\
M \cong H \cup_{\varphi \colon \partial H \to \partial H'} H' \overset{\downarrow}{\cong} H \cup_{\mathrm{id}} ([0,k+1] \times \Sigma) \cup_{\varphi} H' \overset{\downarrow}{\cong} H \cup_{\mathrm{id}} ([0,k+1] \times \Sigma) \cup_{\psi \circ t_k \circ \cdots \circ t_1} H' \\
\cong H \cup_{\mathrm{id}} ([0,1] \times \Sigma) \cup_{t_1} ([1,2] \times \Sigma) \cup_{t_2} ([2,3] \times \Sigma) \cdots \cup_{t_k} ([k,k+1] \times \Sigma) \cup_{\psi} H' \\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \overbrace{\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad}^{\cong H \cup_{\mathrm{id}} ([0,k+1] \times \Sigma) \cup_{\psi} H' \cong H \cup_{\psi} H' \cong S^3} \\
\cong \text{surgery of } \overbrace{H \cup_{\mathrm{id}} ([0,1] \times \Sigma) \cup_{\mathrm{id}} ([1,2] \times \Sigma) \cup_{\mathrm{id}} ([2,3] \times \Sigma) \cdots \cup_{\mathrm{id}} \cup ([k,k+1] \times \Sigma) \cup_{\psi} H'}^{\text{along thickenings of the oriented curves } \{1\} \times C_1, \dots, \{k\} \times C_k.} \\
\uparrow \\
\text{by Lemma 147.2}
\end{array}
$$

We have thus shown that M is diffeomorphic to the surgery of S^3 along a thickened link. ∎

Theorem 147.3. (3-Manifolds Bound Theorem) Every closed orientable connected 3-dimensional smooth manifold is the boundary of a compact orientable connected 4-dimensional smooth manifold.

Remark.

(1) The theorem was first proved by Vladimir Rokhlin [**Rok1951**] in 1951. The argument is also sketched in [**GoS1999**, p. 159]. Alternative proofs are given by René Thom [**Tho1954b, Tho2007**], also particularly short proof that $\Omega_3 = 0$ is given by Colin Rourke [**Rou1985**].
(2) We will prove the 3-Manifolds Bound Theorem 147.3 via the Lickorish-Wallace Theorem 147.1. In Exercise 147.1 we will see that one can also go easily the other way, namely we will deduce the Lickorish-Wallace Theorem 147.1 from the 3-Manifolds Bound Theorem 147.3.

Proof. Let M be a closed orientable connected 3-dimensional smooth manifold. By the Lickorish-Wallace Theorem 147.1 we know that M can be obtained as the surgery of S^3 along a thickened link. This means that there exist orientation-preserving embeddings $\varphi_1, \dots, \varphi_m \colon \overline{B}^2 \times S^1 \to S^3$ with disjoint images such that M is the diffeomorphic to the surgery of S^3 along these thickened knots. As in the proof of the Handle-Surgery Proposition **??** we see that M is the boundary of the result of attaching 2-handles to $\overline{B}^4$ along these thickened curves. ∎

147.2. **Dehn surgery along knots.** In the remainder of this chapter we will only discuss the case of surgery along knots and links in S^3. An argument as in Exercise **??** shows that we do not loose anything if we restrict ourselves to orientation-preserving thickenings. To simplify the discussion we henceforth say "thickening" instead off "orientation-preserving thickening".
In Section 131.1 we discussed in detail the thickenings of knots. In the following we recall the main definitions and results from that section.

Definition. Let $K \subset S^3$ be an oriented knot.

(1) A thickening of K is an orientation-preserving smooth embedding $F\colon \overline{B}^2 \times S^1 \to S^3$ that restricts to an orientation-preserving diffeomorphism $\{0\} \times S^1 \to K$.[1750]
(2) Given a thickening F of K we refer to $X_K := S^3 \setminus F(B^2 \times S^1)$ as the knot exterior.
(3) Given a thickening F of K and given $* \in K$ we refer to the oriented submanifold $\mu_K := F(S^1 \times \{*\})$ of $S^3 \setminus K$ as the meridian of K.
(4) By Lemma 100.16 (5) the inclusion induced map $\mathrm{H}_1(X_K;\mathbb{Z}) \xrightarrow{\cong} \mathrm{H}_1(S^3 \setminus K;\mathbb{Z})$ is an isomorphism and we have $\mathrm{H}_1(X_K;\mathbb{Z}) = \mathbb{Z} \cdot [\mu_K]$. As on page 2853 we denote by ϕ_K the isomorphism
$$\begin{array}{rcl} \phi_K\colon \mathrm{H}_1(S^3 \setminus K;\mathbb{Z}) = \mathrm{H}_1(X_K;\mathbb{Z}) & \xrightarrow{\cong} & \mathbb{Z} \\ [\mu_K] & \to & 1. \end{array}$$
(5) Suppose we are given a thickening F for K. As on page 2853 we define
$$\text{self-linking number of } F \ := \ \phi_K(\underbrace{F_*([\{1\} \times S^1])}_{\in \mathrm{H}_1(X_K;\mathbb{Z})}).$$

Lemma 131.1. (Knot Thickening Lemma) Let K be an oriented knot in S^3.

(1) Let $F\colon \overline{B}^2 \times S^1 \to S^3$ be a thickening of K and let $s \in \mathbb{Z}$. If we set
$$\begin{array}{rcl} \Psi\colon \overline{B}^2 \times S^1 & \to & \overline{B}^2 \times S^1 \\ (z,w) & \mapsto & (z \cdot w^s, w), \end{array}$$
then the map $F \circ \Psi$ is a thickening with
$$\text{self-linking number of } F \circ \Psi \ = \ \text{self-linking number of } F + s.$$
(2) Given any $n \in \mathbb{Z}$ there exists a thickening of K with self-linking number n.
(3) If $F, F'\colon \overline{B}^2 \times S^1 \to S^3$ are two thickenings with self-linking number n, then there exists a diffeotopy $H\colon S^3 \times [0,1] \to S^3$ rel K with $H_0 = \mathrm{id}$ and $H_1 \circ F = F'$.

Remark. Given an oriented knot K and $n \in \mathbb{Z}$ sometimes we use the uniqueness statement of the Knot Thickening Lemma 131.1 to talk about *the thickening of K with self-linking number n*. Sometimes we shorten this cumbersome expression to *the n-thickening of K*.

Now we can also recall the following definition from page 2854.

Definition. Let $K \subset S^3$ be an oriented knot. We pick a thickening $F\colon \overline{B}^2 \times K \to S^3$ of self-linking number zero. We refer to $\lambda_K := F(\{1\} \times K)$ as longitude of K.

[1750] Readers who live on a carrot-rich diet will spot that the definition differs slightly from the definition on page 2853. But the difference is immaterial.

Let $K \subset S^3$ be an oriented knot and let $p, q \in \mathbb{N}_0$ be coprime. Our goal now is to define the "p/q-surgery $S^3_{p/q}(K)$ of S^3 along K" as the result of gluing the solid torus $S^1 \times \overline{B}^2$ in such a way to the knot exterior X_K such that boundary of $\overline{B}^2$ corresponds to $p \cdot \mu + q \cdot \lambda$. The following proposition turns this idea into a valid concept.

Proposition 147.4. (Dehn Surgery Proposition) Let $K \subset S^3$ be an oriented knot and let $p, q \in \mathbb{Z}$ be coprime. We pick a thickening $\Phi\colon \overline{B}^2 \times S^1 \to S^3$ of K of self-linking number zero.

(1) There exists an orientation-preserving diffeomorphism $\Theta\colon S^1 \times S^1 \to S^1 \times S^1$ such that $(\Phi \circ \Theta)_*([\{*\} \times S^1]) = p \cdot [\mu] + q \cdot [\lambda]$. We set
$$S^3_{p/q}(K) \;:=\; (S^1 \times \overline{B}^2) \cup_{\Phi \circ \Theta|_{S^1 \times S^1}} (\underbrace{S^3 \setminus \Phi(B^2 \times S^1)}_{=X_K}).$$
(2) $S^3_{p/q}(K)$ is a closed 3-dimensional smooth manifold which admits a unique orientation that restricts to the usual orientation of $X_K = S^3 \setminus \Phi(B^2 \times S^1)$.
(3) The oriented diffeomorphism type $of S^3_{p/q}(K)$ depends neither on the choice of the thickening of self-linking number zero nor on the choice of the orientation-preserving diffeomorphism Θ with $(\Phi \circ \Theta)_*([\{*\} \times S^1]) = p \cdot [\mu] + q \cdot [\lambda]$.
(4) There exists an orientation-preserving diffeomorphism $S^3_{p/q}(K) \to S^3_{-p/-q}(K)$.
(5) If $-K$ denotes the knot K with the opposite orientation, then $S^3_{p/q}(K)$ admits an orientation-preserving diffeomorphism to $S^3_{p/q}(-K)$.
(6) We have $\pi_1(S^3_{p/q}(K)) \cong \pi_1(X_K)/\langle\langle \mu_K^p \rangle\rangle$ and $\mathrm{H}_1(S^3_{p/q}(K)) \cong \mathbb{Z}_q \cdot [\mu_K]$.
(7) If $q = 1$, then $S^3_{p/1}(K)$ is the surgery on S^3 along the thickening of K of self-linking number p.

Proof.

(1) Since $p, q \in \mathbb{N}_0$ are coprime there exist $r, s \in \mathbb{N}_0$ with $qr - ps = 1$. We consider the map
$$\begin{aligned} \Theta\colon S^1 \times S^1 &\to S^1 \times S^1 \\ (z, w) &\mapsto (z^r \cdot w^p, z^s \cdot w^q). \end{aligned}$$
It follows from $qr - ps = 1$ and the Maps-on-Torus Lemma 19.37 that this map is an orientation-preserving diffeomorphism. Furthermore it follows easily from the Action-on-Torus Homology Lemma 84.7 (2) that $(\Phi \circ \Theta)_*([\{*\} \times S^1]) = p \cdot [\mu] + q \cdot [\lambda]$.
(2) This statement follows immediately from the Gluing-Smooth Manifolds-Proposition **??**.
(3) It follows easily from the Knot Thickening Lemma 131.1 that the definition does not depend on the choice of the thickening of self-linking number zero.

It remains to show that the choice of Θ is irrelevant. This proof consists of two steps. First we show that choice of r and s in (1) is irrelevant. Indeed, suppose we are given $\widetilde{r}, \widetilde{s} \in \mathbb{N}_0$ with $q\widetilde{r} - p\widetilde{s} = 1$. It follows that $qr - ps = q\widetilde{r} - p\widetilde{s}$, i.e. $q(\widetilde{r} - r) = p(\widetilde{s} - s)$. Since q and p are coprime we see that $\widetilde{r} = r + p \cdot m$ and $\widetilde{s} = s + q \cdot m$ for some $m \in \mathbb{Z}$. We define $\Theta_{r,s}$ and $\Theta_{\widetilde{r},\widetilde{s}}$ in the obvious way. It is

straightforward to verify that the map

$$\begin{array}{rcl}(S^1\times\overline{B}^2)\cup_{\Theta_{r,s}\circ\Phi|_{S^1\times S^1}}(S^3\setminus\Phi(B^2\times S^1)) & \to & (S^1\times\overline{B}^2)\cup_{\Theta_{\tilde{r},\tilde{s}}\circ\Phi|_{S^1\times S^1}}(S^3\setminus\Phi(B^2\times S^1))\\ P & \mapsto & \begin{cases} P, & \text{if } P\in S^3\setminus\Phi(B^2\times S^1),\\ (z,wz^m), & \text{if } P=(z,w)\in S^1\times\overline{B}^2\end{cases}\end{array}$$

is a diffeomorphism.

Now let $\Xi\colon S^1\times S^1\to S^1\times S^1$ be any orientation-preserving diffeomorphism $\Xi\colon S^1\times S^1\to S^1\times S^1$ with $(\Phi\circ\Xi)_*([\{*\}\times S^1])=p\cdot[\mu]+q\cdot[\lambda]$. We write $(\Phi\circ\Xi)_*([\{*\}\times S^1])=r\cdot[\mu]+s\cdot[\lambda]$. Since Θ is orientation-preserving we know by Lemma 114.15 that $qr-ps=1$. We use r and s to define the orientation-preserving diffeomorphism $\Theta\colon S^1\times S^1\to S^1\times S^1$ as above. Since Ξ and Θ are both orientation-preserving diffeomorphisms of $S^1\times S^1$ that induce the same map on $\mathrm{H}_1(S^1\times S^1)$ we know by Theorem 146.7 we know that there exists a diffeotopy $F\colon S^1\times S^1\times[0,1]\to S^1\times S^1$ with $F_0=\Xi\circ\Theta^{-1}$ and $F_1=\mathrm{id}$. It is straightforward to verify that the map

$$\begin{array}{rcl}(S^1\times\overline{B}^2)\cup_{\Theta\circ\Phi|_{S^1\times S^1}}(S^3\setminus\Phi(B^2\times S^1)) & \to & (S^1\times\overline{B}^2)\cup_{\Xi\circ\Phi|_{S^1\times S^1}}(S^3\setminus\Phi(B^2\times S^1))\\ P & \mapsto & \begin{cases} P, & \text{if } P\in S^3\setminus\Phi(B^2\times S^1),\\ |w|\cdot F_{2\cdot|w|-1}(z,\frac{w}{|w|}), & \text{if } P=(z,w) \text{ with } |w|\geq\frac{1}{2}\\ (z,w), & \text{if } P=(z,w) \text{ with } |w|\leq\frac{1}{2}.\end{cases}\end{array}$$

is a diffeomorphism.

(4) We consider the map

$$\begin{array}{rcl}\Xi\colon S^1\times S^1 & \to & S^1\times S^1\\ (z,w) & \mapsto & (\overline{z}^r\cdot\overline{w}^p,\overline{z}^s\cdot\overline{w}^q).\end{array}$$

It is straightforward to see that $(\Phi\circ\Xi)_*([\{*\}\times S^1])=-p\cdot[\mu]-q\cdot[\lambda]$. The map $\Xi\circ\Theta^{-1}\colon S^1\times S^1\to S^1\times S^1$ is given by $(z,w)\mapsto(\overline{z},\overline{w})$. Since this map extends to a diffeomorphism of $S^1\times\overline{B}^2$ in the obvious way. This observation now gives us the following orientation-preserving diffeomorphism

$$\begin{array}{rcl}\overbrace{(S^1\times\overline{B}^2)\cup_{\Theta\circ\Phi|_{S^1\times S^1}}(S^3\setminus\Phi(B^2\times S^1))}^{=S^3_{p/q}(K)} & \to & \overbrace{(S^1\times\overline{B}^2)\cup_{\Xi\circ\Phi|_{S^1\times S^1}}(S^3\setminus\Phi(B^2\times S^1))}^{=S^3_{-p/-q}(K)}\\ P & \mapsto & \begin{cases} P, & \text{if } P\in S^3\setminus\Phi(B^2\times S^1),\\ (\overline{z},\overline{w}), & \text{if } P=(z,w)\in S^1\times\overline{B}^2.\end{cases}\end{array}$$

(5) In the Longitude-Meridian Lemma 131.2 (6) we showed that swapping the orientation of K has the effect of swapping the orientation of the meridian and the longitude. Thus we see that this statement follows immediately from Statement (4).

(6) We have the following isomorphisms:

$$\begin{array}{ccccccc}
 & & \text{by the Seifert–van Kampen Theorem 54.4, where} & & & & \\
 & & \text{map } \pi_1(S^1\times S^1)\to\pi_1(X_K) \text{ is induced by the map } \varphi & & & & \\
 & & \downarrow & & & & \\
\pi_1(S^3_{p/q}(K)) & \cong & \pi_1(S^1\times\overline{B}^2)*_{\pi_1(S^1\times S^1)}\pi_1(X_K) & \cong & \langle s\rangle *_{\langle s\rangle\times\langle t\rangle}\pi_1(X_K) & & \\
 & \cong & \{e\}*_{\langle\langle t\rangle\rangle}\pi_1(X_K) & \cong & \pi_1(X_K)/\langle\langle\varphi_*(t)\rangle\rangle & \cong & \pi_1(X_K)/\langle\langle\mu_K^p\rangle\rangle. \\
 & & \uparrow & & \uparrow & & \uparrow \\
 & & \text{by the Amalgamated Product} & & \text{by the Amalgamated Product} & & \text{by definition of } \varphi \\
 & & \text{Lemma 53.22 (5) and (6)} & & \text{Lemma 53.22 (2)} & &
\end{array}$$

The statement regarding $\mathrm{H}_1(S^3_{p/q}(K))$ can be deduced easily from the above calculation together with the Hurewicz Theorem 84.5. Alternatively it is of course also a great pleasure to prove the statement directly using the Mayer-Vietoris Theorem 78.9.

(7) Suppose $q=1$. Then we can set $r=1$ and $s=0$. In this case the above map Θ extends to the diffeomorphism

$$\begin{array}{rcl}\Theta\colon \overline{B}^2\times S^1 & \to & \overline{B}^2\times S^1\\ (z,w) & \mapsto & (z\cdot w^p, w^q).\end{array}$$

Note that by the Knot Thickening Lemma 131.1 (1) we know that $\Phi\circ\Theta$ is a thickening of K of self-linking number p. We have

$$\begin{array}{ccccccc}
(S^3)(\Phi\circ\Theta) & = & (S^1\times\overline{B}^2)\cup_{\Theta\circ\Phi|_{S^1\times S^1}}(S^3\setminus\overbrace{(\Phi\circ\Theta)(B^2\times S^1)}^{=\Phi(B^2\times S^1)}) & = & S^3_{p/q}(K). & & \blacksquare \\
\uparrow & & & & \uparrow & & \\
\text{see definition on page ??} & & & & \text{by definition of } S^3_{p/q}(K) & &
\end{array}$$

Definition. Let $K\subset S^3$ be an knot and let $r\in\mathbb{Q}\cup\{\infty\}$. We pick an orientation for K.

(1) If $r\in\mathbb{Q}$, then we pick coprime $p,q\in\mathbb{Z}$ with $r=\frac{p}{q}$ and we define $S^3_r(K):=S^3_{p/q}(K)$.
(2) For $r=\infty$ we define $S^3_r(K):=S^3_{1/0}(K)$.

It follows from the Dehn Surgery Proposition 147.4 (4) and (5) that, up to an orientation-preserving diffeomorphism, the definition of $S^3_r(K)$ does not depend on any of the choices we just made. In either case we refer to $S^3_r(K)$ as the r-Dehn surgery along K. Sometimes we refer to this procedure as a rational Dehn surgery instead of just Dehn surgery. If $r\in\mathbb{Z}$, then we refer to this Dehn surgery as an integral Dehn surgery.

The following lemma gives us a few basic examples.

Lemma 147.5.

(1) Let $p,q\in\mathbb{N}$ be coprime. The $\frac{p}{q}$-Dehn surgery along the unknot admits an orientation-preserving diffeomorphism to the lens space $L(p,q)$.
(2) Given any $n\in\mathbb{Z}$ the $\frac{1}{n}$-Dehn surgery along the unknot is diffeomorphic to S^3.
(3) Given any knot $K\in S^3$ the ∞-Dehn surgery is diffeomorphic S^3.

Proof.

(1) Let $p\in\mathbb{N}$ and let $q\in\mathbb{Z}$ be coprime to p. We pick $r,s\in\mathbb{Z}$ such that $qr-ps=-1$. We consider the map

$$\begin{array}{rcl}\Theta\colon S^1\times S^1 & \to & S^1\times S^1\\ (z,w) & \mapsto & (z^r\cdot w^p, z^s\cdot w^q).\end{array}$$

We write

$$A = \begin{pmatrix} q & p \\ s & r \end{pmatrix} \quad \text{and we consider the orientation-reversing diffeomorphism} \quad \begin{array}{rcl} \varphi\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [Av]. \end{array}$$

If we make the usual identification $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$, then there exists an orientation-preserving diffeomorphism

$$L(p,q) \xrightarrow{\cong} M(S^1 \times \overline{B}^2, S^1 \times \overline{B}^2, \varphi).$$

This statement follows immediately from the Lens Space-Splitting Lemma 146.2.

(2) This statement follows immediately from (1). For entertainment we will also prove this statement in Exercise 147.2.

(3) Let K be a knot. We pick an orientation and a thickening $\Phi\colon \overline{B}^2 \times S^1 \to S^3$ of self-linking number 0. We consider the map $\Theta\colon S^1 \times S^1 \to S^1 \times S^1$ that is given by swapping the coordinates, i.e. it is given by $\Theta(z,w) = (w,z)$. It follows almost immediately from the definitions that $(\Phi \circ \Theta)_*([\{*\} \times S^1]) = 1 \cdot [\mu] + 0 \cdot [\lambda]$. Thus we see that

$$\begin{array}{rcl} S^3_\infty(K) = S^3_{1/0}(K) & \cong & (S^1 \times \overline{B}^2) \cup_{\Phi\circ\Theta|_{S^1\times S^1}} (S^3 \setminus \Phi(B^2 \times S^1)) \\ & \cong & (\overline{B}^2 \times S^1) \cup_{\Phi|_{S^1\times S^1}} (S^3 \setminus \Phi(B^2 \times S^1)) \cong S^3. \\ & \uparrow & \end{array}$$

diffeomorphism given by the obvious extension of Θ to a diffeomorphism $S^1 \times \overline{B}^2 \to \overline{B}^2 \times S^1$ ■

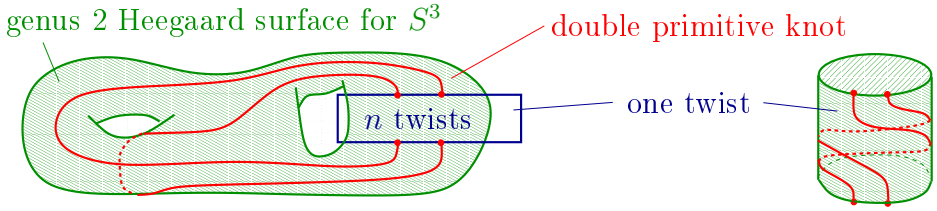
The following proposition shows that Dehn surgeries can behave rather unpredictably.

Proposition 147.6. Let $r, s \in \mathbb{N}$ be coprime and let $T(r,s)$ be the (r,s)-torus knot as defined on page 1312. Furthermore let $p, q \in \mathbb{Z}$.

(1) If $|rsp+q| = 1$, then the p/q-Dehn surgery along $T(r,s)$ is diffeomorphic to the lens space $L(|q|, ps^2)$.

(2) If $|rsp+q| = 0$, then the p/q-Dehn surgery along $T(r,s)$ is diffeomorphic to the connected sum $L(r,s)\#L(s,r)$.

Proof. The proof is basically elementary and can be performed as a challenging exercise. Alternatively the proposition is proved in [**Mos1971**, Propositions 3.2 and 4]. ■



Now the following subtle questions arises: which manifolds can arise through Dehn surgeries along knots? We state two very difficult sample theorems in this direction before we state two open problems, to give the reader a flavor of what is know and what is still left.

Theorem 147.7. (Property P Theorem) Let $K \subset S^3$ be a knot and let $r \in \mathbb{Q}$. If $\pi_1(S^3_r(K))$ is trivial, then K is smoothly isotopic to the unknot.

Proof. Let $K \subset S^3$ be a knot and let $r \in \mathbb{Q}$. Cameron Gordon and John Luecke [**GL1989**, Theorem 2] showed in the 1980s that if $S^3_r(K)$ is diffeomorphic to S^3, then K is the unknot. Thus the Property P Theorem follows from this fact together with the proof of the Poincaré Conjecture by Grigori Perelman in 2004, see Theorem **??**. An alternative proof of the Property P Theorem was given by Peter Kronheimer and Tomasz Mrowka [**KrM2004**], building on the Cyclic Surgery Theorem [**CGLS1987**]. ■

We just saw that all lens spaces arise as Dehn surgery along the unknot. The question arises, which knots admit a surgery that is diffeomorphic to a lens space? In 1990 John Berge [**Berge1990**] proved the following result.

Proposition 147.8. Let $K \subset S^3$ be a knot that lies on a Heegaard surface of genus two, such that for each of the two corresponding handlebody the knot K represents a primitive element in the fundamental group of the handlebody. (Such knots are called *double primitive*). Then K admits a Dehn surgery that is a lens space.

Rather surprisingly it is not known whether the converse to the proposition holds. More precisely, the following conjecture, which goes back to [**Berge1990**] and [**Gor1972**, Question 5.5] is still open.

Conjecture 147.9. (Berge Conjecture) If K is a knot that admits a Dehn surgery that is diffeomorphic to a lens space, then K is double primitive.

Even though there is no really good reason why the conjecture should indeed be true there is by now an impressive literature, see e.g. [**Ni2007, Greene2013**] supporting the conjecture.

147.3. **Dehn surgery along links.** We now generalize the above setup from the previous section to links in the obvious way.

Definition.

(1) A framed (oriented) link consists of an (oriented) link $L = L_1 \cup \cdots \cup L_m$ in S^3 together with am m-tuple $r = (r_1, \ldots, r_m)$ where each r_i lies in $\mathbb{Q} \cup \{\infty\}$.
(2) Give an framed link $(L = L_1 \cup \cdots \cup L_m, r = (r_1, \ldots, r_m))$ we define the corresponding Dehn surgery $S^3_r(L)$ by doing the r_i-Dehn surgeries along the components L_i simultaneously, using disjoint thickenings. If all the r_i are integers, then we refer to the Dehn surgery as an integral Dehn surgery along L. As for knots we sometimes refer to a Dehn surgery as a rational Dehn surgery to differentiate it from the special case of an integral Dehn surgery
(3) Let M be a closed smooth manifold. A surgery description for M is a framed link (L, r) such that M admits an orientation-preserving diffeomorphism to $S^3_r(L)$. We say the surgery description is integral if all the r_i lie in $\mathbb{Z}$.

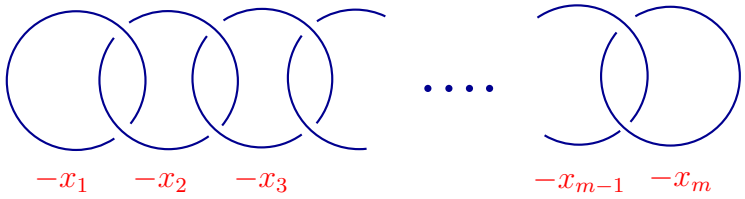
Lemma 147.10. Let (L, r) and $(\widetilde{L}, \widetilde{r})$ be two framed links in S^3 that are separated by a smoothly embedded sphere, i.e. we assume that there exists a smooth embedding $\varphi\colon S^2 \to S^3$ such that L is contained in one component of $S^3 \setminus \varphi(S^2)$ and $\widetilde{L}$ is contained in the other of $S^3 \setminus \varphi(S^2)$. Then $S^3_{r \cup \widetilde{r}}(L \cup \widetilde{L})$ admits an orientation-preserving diffeomorphism to the connected sum $S^3_r(L) \# S^3_{\widetilde{r}}(\widetilde{L})$.

Proof. It follows from the Generalized Smooth Schönflies Theorem 82.5 in dimension 3 that without loss of generality we can assume that $\varphi(S^2)$ is the "equatorial sphere" $S^3_{=0} = \{(x_1, x_2, x_3, x_4) \in S^3 \,|\, x_4 = 0\}$ and that L is contained in $S^3_{\geq 0}$ and that $\widetilde{L}$ is contained in $S^3_{\leq 0}$. Now let $f\colon \overline{B}^3 \to S^3_{\leq 0}$ be an orientation-preserving embedding and let $\rho\colon S^3 \to S^3$ be

the reflection in the $(x_4 = 0)$-hyperplane. We see that

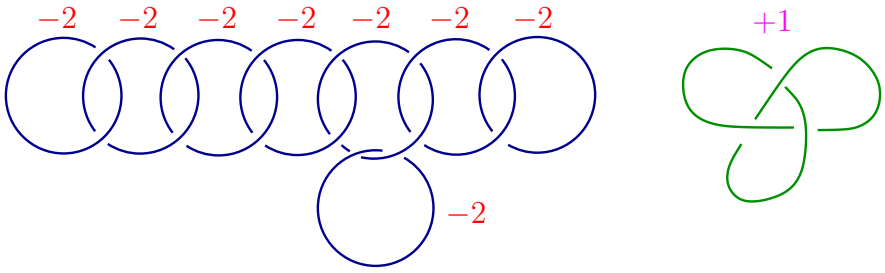
$$S^3_{r\cup\widetilde{r}}(L \cup \widetilde{L}) \underset{\text{since } S^3 = S^3_{\geq 0} \cup_{S^3_{=0}} S^3_{\leq 0}}{\cong} (S^3_r(L) \setminus f(B^3)) \cup_{S^3_{=0}} (S^3_{\widetilde{r}}(\widetilde{L}) \setminus (\rho \circ f)(B^3)) \underset{\text{by the definition of connected sum}}{\cong} S^3_r(L) \# S^3_{\widetilde{r}}(\widetilde{L}).$$

■



We can now give the following reformulation of the Lickorish-Wallace Theorem 147.1.

Theorem 147.11. (Lickorish-Wallace Theorem) Every closed orientable connected 3-dimensional smooth manifold M can be obtained through integral Dehn surgery along a link. In other words, M admits an integral surgery description.



Proof. Let M be a closed orientable connected 3-dimensional smooth manifold. In the proof of the Lickorish-Wallace Theorem 147.1 we showed that there exists a link L together with a thickening such that M is the surgery along this thickened link. But any such surgery is an integral Dehn surgery. In fact reading the proof carefully one sees that all the surgery coefficients are in fact equal to $+1$. ■

Examples.

(1) The Lickorish-Wallace Theorem 147.11 implies in particular that any lens space $L(p, q)$ can be obtained from integral Dehn surgery along a link. One possible way of doing this is as follows: Let $\frac{p}{q} = x_1 - \cfrac{1}{x_2 - \cfrac{1}{x_3 - \cfrac{1}{\cdots - \cfrac{1}{x_n}}}}$ be a continued fraction expansion with $x_1, \ldots, x_n \in \mathbb{Z}$. By [**Sav2012**, Theorem 2.3] we know that the figure below gives a surgery description for the lens space $L(p, q)$.

(2) By [**Sav2012**, p. 49] or [**KSc1979**] we know that the figure below gives two surgery descriptions for the Poincaré Homology Sphere that we introduced on page 2161.

This short discussion surely wets the reader's appetite for more. We refer the curious reader to [**Sav2012, GoS1999, Rolf1990**] for more examples.

Before we can state our next proposition we need to make a few preparations.

Definition. Let K be an oriented knot and let $\varphi\colon \overline{B}^2 \times S^1 \to S^3 = \partial \overline{B}^4$ be a framing for K. Since $\mathrm{H}_2(\overline{B}^4;\mathbb{Z}) = \mathrm{H}_1(\overline{B}^4;\mathbb{Z}) = 0$ we obtain from the Handle Attachment-H_*-Lemma 136.13 a natural isomorphism $\mathrm{H}_2((\overline{B}^2 \times \overline{B}^2) \cup_{\varphi|_{\overline{B}^2 \times S^1}} \overline{B}^4;\mathbb{Z}) \to \mathrm{H}_1(S^1;\mathbb{Z})$. There exists a unique class in $\mathrm{H}_2((\overline{B}^2 \times \overline{B}^2) \cup_{\varphi|_{\overline{B}^2 \times S^1}} \overline{B}^4;\mathbb{Z})$ that gets sent to $-[S^1]$. We refer to this class as the canonical generator.

Lemma 147.12. Let K be an oriented knot and let $\varphi\colon \overline{B}^2 \times S^1 \to S^3 = \partial \overline{B}^4$ be a framing for K. Let Σ be a Seifert surface for K and let $\widetilde{\Sigma}$ be a push-in of the Seifert surface into $\overline{B}^4$. The submanifold $\widetilde{\Sigma} \cup (\{0\} \times \overline{B}^2)$, with the orientation coming from the Seifert surface, represents the canonical generator of $\mathrm{H}_2((\overline{B}^2 \times \overline{B}^2) \cup_{\varphi|_{\overline{B}^2 \times S^1}} \overline{B}^4;\mathbb{Z})$.

Proposition 147.13. Let $(L = L_1 \cup \cdots \cup L_m, r = (r_1, \ldots, r_m))$ be a framed oriented link. For $i = 1, \ldots, m$ we pick a thickening $\varphi_i\colon \overline{B}^2 \times S^1 \to S^3$ for L_i. We assume that the images are disjoint. Let W be the compact oriented 4-dimensional smooth manifold that is obtained from $\overline{B}^4$ by attaching handles along $\varphi_1, \ldots, \varphi_m$. This smooth manifold has the following properties:

(1) $\partial(W) = S^3_r(L)$.
(2) For $i = 1, \ldots, m$ there exists a unique homology class $\alpha_i \in \overline{H}_2(W;\mathbb{Z})$ that lies in the image of $\mathrm{H}_2(\overline{B}^4 \cup_{\varphi(\overline{B})}$

Exercises for Chapter 147.

Exercise 147.1.

(a) Let X be a compact orientable 4-dimensional smooth manifold that has a handle decomposition consisting of a single 0-handle and k 1-handles. Show that there exists a compact orientable 4-dimensional smooth manifold $\widetilde{X}$ that has a handle decomposition consisting of a single 0-handle and k 2-handles with $\partial \widetilde{X} = \partial X$.
Hint. $\partial(S^1 \times \overline{B}^3) = \partial(\overline{B}^2 \times S^2)$.
(b) Let X be a compact orientable 4-dimensional smooth manifold. Show that there exists a compact orientable 4-dimensional smooth manifold $\widetilde{X}$ without 1-handles which satisfies $\partial X = \partial X$.
(c) Let M be a closed orientable connected 3-manifold that is the boundary a compact orientable 4-dimensional smooth manifold X. Show that there exists a link $L \subset S^3$ such that M is diffeomorphic to surgery along L.

Remark. This exercise shows that one can deduce the Lickorish-Wallace Theorem 147.1 from the 3-Manifolds Bound Theorem 147.3.

Exercise 147.2. Let K be a knot. Show "by hand" that the ∞-Dehn surgery along K is diffeomorphic to S^3.

Exercise 147.3. Let $K \subset S^3$ be a non-trivial knot and let $r \in \mathbb{Q} \cup \{\infty\}$. By the Property P Theorem 147.7 we know in particular that if $S^3_r(K)$ is diffeomorphic to S^3, then $r = \infty$.

Now let K and L be two knots such that the knot exteriors X_K and X_L are diffeomorphic. Show that K is smoothly isotopic to L or to the mirror image of L.
Hint. Show that a knot is determined by its knot exterior X_K *together* with the meridian $\mu_K \subset X_K$.

Exercise 147.4. Let M be a closed oriented 3-dimensional smooth manifold and let be a thickened link. What is surgery presentation for $-M$?

Exercise 147.5. Effect of surgery in the complement of a knot, i.e. get crossing change

148. The linking pairing on rational homology spheres

148.1. **Rational homology spheres.** We recall the following lemma.

Lemma 48.6. Let $p \in \mathbb{N}$ and furthermore let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. If $q \equiv \pm r^{\pm 1} \bmod p$,[1751] then $L(p,q)$ and $L(p,r)$ are diffeomorphic.

In Question 48.7 we had asked whether the converse to the Lens Spaces-Diffeomorphisms Lemma 48.6 holds. So far we have made little progress. On page 1089 we saw, using fundamental groups, that if two lens spaces $L(p,q)$ and $L(\widetilde{p},\widetilde{q})$ are homeomorphic, then $p = \widetilde{p}$. Afterwards, on page 1574 we saw that higher homotopy groups do not carry any additional information. In the Lens Space Homology Lemma 98.9 we had determined the homology groups of lens spaces, more precisely we showed that

$$\mathrm{H}_n(L(p,q);\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0,3, \\ \mathbb{Z}_p, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$

From the Universal Coefficient Theorem for Cohomology Groups 110.12 it follows that

$$\mathrm{H}^n(L(p,q);\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0,3, \\ \mathbb{Z}_p, & \text{if } n = 2, \\ 0, & \text{otherwise.} \end{cases}$$

This shows that homology groups and cohomology groups cannot be used to distinguish the lens spaces $L(p,q)$ and $L(p,q')$.

In Chapter 132 we had successfully applied the cup product to distinguish several smooth manifolds that could not be distinguished just using cohomology groups. It is therefore tempting to try to use cup products to distinguish lens spaces. But here we immediately encounter the problem, that all non-trivial cup products are trivially trivial. More precisely, all cup products of cohomology classes in degree ≥ 1 are zero, since too many cohomology groups are zero. For example, the cup product on the non-trivial group $\mathrm{H}^2(L(p,q);\mathbb{Z})$ with itself is zero since it takes values in $\mathrm{H}^4(L(p,q);\mathbb{Z}) = 0$.

In this chapter we will develop an analogue of the intersection form, namely the *linking pairing*. This is an invariant defined for lens spaces, or more generally, for odd-dimensional rational homology spheres, which are defined as follows:

Definition. Let R be a commutative ring and let M be an n-dimensional topological manifold.

(1) We say M is a topological R-homology sphere, if for each $k \in \mathbb{N}_0$ we have an isomorphism $\mathrm{H}_k(M;R) \cong \mathrm{H}_k(S^n;R)$, i.e. we have

$$\mathrm{H}_k(M;R) \cong \begin{cases} R, & \text{if } k = 0,n, \\ 0, & \text{otherwise.} \end{cases}$$

Sometimes we also just say R-homology sphere.

(2) Instead of $\mathbb{Z}$-homology sphere we usually say integral homology sphere and instead of $\mathbb{Q}$-homology sphere we usually say rational homology sphere.

[1751] By our hypothesis we have $\gcd(p,r) = 1$. This implies that there exists a multiplicative inverse of r modulo p, i.e. there exists an s with $r \cdot s \equiv 1 \bmod p$. We write $r^{-1} := s$.

(3) If M is actually a smooth manifold, then we say smooth R-homology sphere.

Examples.

(1) Integral homology spheres are precisely the homology spheres that we introduced on pages 2159 and 2710.
(2) It follows from the aforementioned calculation of the homology groups of lens spaces and Corollary 89.19 (which is a straightforward consequence of the Universal Coefficient Theorem 89.16), that lens spaces are smooth rational homology spheres.
(3) It follows from the Connected Sum-Invariants Proposition 132.11 that the connected sum of two n-dimensional R-homology spheres is again an n-dimensional R-homology sphere.

The following lemma gives an alternative description of rational homology spheres.

Lemma 148.1. Let M be an n-dimensional topological manifold M. Then the following holds:[1752]

$$M \text{ is a rational homology sphere} \iff \begin{array}{c} M \text{ is closed connected and orientable and} \\ \mathrm{H}_i(M;\mathbb{Z}) \text{ is finite for } i = 1, \dots, \lfloor \frac{n-1}{2} \rfloor. \end{array}$$

Proof. The proof of the lemma is basically an exercise in combining all the standard facts on homology groups of topological manifolds that we have gathered so far. More precisely, the "⇒" direction follows from Corollary 89.19, the Topological Manifolds-Invariants Proposition 104.14 (4), the H_0-Proposition 72.5 and Theorems 106.1 and 106.3. The proof of the "⇐" direction also requires the above ingredients, furthermore it also requires the Poincaré Duality Theorem 119.1. We leave it to the reader to connect the dots. ■

148.2. **The Bockstein homomorphisms.** Before we can introduce the linking pairing of rational homology spheres we need to give some harmless extensions of our definitions and results from (co-) homology theory. We will do so in the coming two sections.
Let X be a topological space and let $f\colon A \to B$ be a homomorphism of abelian groups. We recall that in Lemma 89.7 (2) we saw that the maps

$$\begin{array}{rcl} f_*\colon \mathrm{C}_*(X;A) & \to & \mathrm{C}_*(X;B) \\ \left[\sum_{i=1}^{k} \sigma_i \otimes a_i\right] & \mapsto & \left[\sum_{i=1}^{k} \sigma_i \otimes f(a_i)\right] \end{array}$$

form a chain map, in particular for each $n \in \mathbb{N}_0$ we obtain an induced map

$$f_*\colon \mathrm{H}_n(X;A) \to \mathrm{H}_n(X;B).$$

Similarly, it follows from the discussion on page 2401 that the maps

$$\begin{array}{rcl} f_*\colon \mathrm{C}^n(X;A) = \mathrm{Hom}(\mathrm{C}_n(X), A) & \to & \mathrm{C}^n(X;B) = \mathrm{Hom}(\mathrm{C}_n(X), B) \\ \varphi & \mapsto & f \circ \varphi \end{array}$$

define a cochain map, in particular we get for each $n \in \mathbb{N}_0$ an induced map

$$f_*\colon \mathrm{H}^n(X;A) \to \mathrm{H}^n(X;B)$$

In the following lemma we discuss one subtle example.

[1752]Here recall that given a real number r we denote by $\lfloor r \rfloor = \max\{n \in \mathbb{Z} \mid n \leq r\}$ the result of rounding r down.

Lemma 148.2. Let $k \in \mathbb{Z}$. We denote by $f\colon \mathbb{Z} \to \mathbb{Z}$ the map that is given by multiplication by k. Given any pair (X, A) of topological spaces and given any $n \in \mathbb{N}_0$ the maps $f_*\colon \mathrm{H}_n(X, A; \mathbb{Z}) \to \mathrm{H}_n(X, A; \mathbb{Z})$ and $f_*\colon \mathrm{H}^n(X, A; \mathbb{Z}) \to \mathrm{H}^n(X, A; \mathbb{Z})$ are given by multiplication by m.

Proof. It is arguable whether this lemma actually needs a proof. Nonetheless, since at one point we will make use of the statement for cohomology, we provide the proof for the induced maps on cohomology. Thus let $\gamma\colon \mathrm{C}_k(X, A) \to \mathbb{Z}$ be a cochain. We see that

$$f_*([\gamma]) = [f \circ \gamma] = \left[\begin{array}{r} \mathrm{C}_k(X, A) \to \mathbb{Z} \\ \sigma \mapsto \underbrace{n \cdot f(\sigma)}_{=(f\circ\gamma)(\sigma)} \end{array}\right] = \left[\begin{array}{r} \mathrm{C}_k(X, A) \to \mathbb{Z} \\ \sigma \mapsto (n \cdot f)(\sigma) \end{array}\right] = [n \cdot f] = n \cdot [\gamma].$$

this is the point where something happens ↑

■

These observations lead us to the definitions of the Bockstein homomorphisms.

Definition. Let X be a topological space and let $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ be a short exact sequence of abelian groups. Let $n \in \mathbb{N}_0$. It follows from the fact that $\mathrm{C}_n(X)$ is a free abelian group and from the natural isomorphisms of the Tensor Lemma 89.3 that

$$0 \;\to\; \mathrm{C}_n(X; A) \;\xrightarrow{i_*}\; \mathrm{C}_n(X; B) \;\xrightarrow{p_*}\; \mathrm{C}_n(X; C) \;\to\; 0$$

is also exact. Thus we obtain a short exact sequence

$$0 \;\to\; \mathrm{C}_*(X; A) \;\xrightarrow{i_*}\; \mathrm{C}_*(X; B) \;\xrightarrow{p_*}\; \mathrm{C}_*(X; C) \;\to\; 0$$

of chain complexes. Furthermore, from the LES Proposition 74.9 we obtain a long exact sequence

$$\ldots \xrightarrow[=:\beta_{n-1}]{\partial_{n-1}} \mathrm{H}_n(X; A) \xrightarrow{i_*} \mathrm{H}_n(X; B) \xrightarrow{p_*} \mathrm{H}_n(X; C) \xrightarrow[=:\beta_n]{\partial_n} \mathrm{H}_{n-1}(X; A) \to \ldots$$

which is called the Bockstein sequence in homology.[1753] Furthermore for each $n \in \mathbb{N}_0$ the connecting homomorphism $\beta = \partial_n\colon \mathrm{H}_n(X; C) \to \mathrm{H}_{n-1}(X; A)$ is called the n-th Bockstein homomorphism in homology.

The same setup also works in cohomology.

Definition. We continue with the notation from the previous definition. Since each $\mathrm{C}_n(X)$ is a free abelian group one sees easily that

$$0 \;\to\; \mathrm{C}^*(X; A) \;\xrightarrow{i}\; \mathrm{C}^*(X; B) \;\xrightarrow{p_*}\; \mathrm{C}^*(X; C) \;\to\; 0$$

is a short exact sequence of cochain complexes. From the Connecting Homomorphism Proposition 108.6 we obtain a natural long exact sequence of cohomology groups

$$\ldots \xrightarrow[=:\beta_{n-1}]{\delta_{n-1}} \mathrm{H}^n(X; A) \xrightarrow{i_*} \mathrm{H}^n(X; B) \xrightarrow{p_*} \mathrm{H}^n(X; C) \xrightarrow[=:\beta_n]{\delta_n} \mathrm{H}^{n+1}(X; A) \to \ldots$$

which is called the Bockstein sequence in cohomology. Furthermore for each $n \in \mathbb{N}_0$ the connecting homomorphism $\beta = \delta_n\colon \mathrm{H}^n(X; C) \to \mathrm{H}^{n+1}(X; A)$ is called the n-th Bockstein homomorphism in cohomology.

[1753] The Bockstein homomorphism is named after the Russian mathematician Meyer Bockstein (1913-1990).

Examples. Let X be a topological space. The following two instances of the Bockstein homomorphisms are arguably the ones which are most frequently used:

(1) Let $k \in \mathbb{N}$. We consider the short exact sequence $0 \to \mathbb{Z}_k \xrightarrow{\cdot k} \mathbb{Z}_{k^2} \xrightarrow{p} \mathbb{Z}_k \to 0$ where p stands for the natural projection. Given a topological space X we obtain Bockstein homomorphisms $\beta_n \colon \mathrm{H}_n(X;\mathbb{Z}_k) \to \mathrm{H}_{n-1}(X;\mathbb{Z}_k)$, $n \in \mathbb{N}_0$. In Exercise 148.1 we will see that $\beta_{n-1} \circ \beta_n \colon \mathrm{H}_n(X;\mathbb{Z}_k) \to \mathrm{H}_{n-2}(X;\mathbb{Z}_k)$ is the zero map.
(2) In Section 148.4 we will consider the short exact sequence $0 \to \mathbb{Z} \to \mathbb{Q} \to \mathbb{Q}/\mathbb{Z} \to 0$. It gives rise to Bockstein homomorphisms $\beta_n \colon \mathrm{H}_n(X;\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}_{n-1}(X;\mathbb{Z})$ and $\beta_n \colon \mathrm{H}^n(X;\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}^{n+1}(X;\mathbb{Z})$.

For completeness' sake we mention the following lemma.

Lemma 148.3. Let $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ be a short exact sequence of abelian groups.

(1) Let $n \in \mathbb{N}_0$. The n-th Bockstein homomorphisms β_n corresponding to the short exact sequence of abelian groups form a natural transformation from the contravariant functor $X \mapsto \mathrm{H}^n(X;C)$ to the contravariant functor $X \mapsto \mathrm{H}^{n+1}(X;A)$.
(2) Given a map $f \colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{array}{ccccccccccc}
\ldots & \xrightarrow{\beta_{n-1}} & \mathrm{H}^n(Y;A) & \xrightarrow{i_*} & \mathrm{H}^n(Y;B) & \xrightarrow{p_*} & \mathrm{H}^n(Y;C) & \xrightarrow{\beta_n} & \mathrm{H}^{n+1}(Y;A) & \longrightarrow & \ldots \\
 & & \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*} & & \\
\ldots & \xrightarrow{\beta_{n-1}} & \mathrm{H}^n(X;A) & \xrightarrow{i_*} & \mathrm{H}^n(X;B) & \xrightarrow{p_*} & \mathrm{H}^n(X;C) & \xrightarrow{\beta_n} & \mathrm{H}^{n+1}(X;A) & \longrightarrow & \ldots
\end{array}$$

Proof. The first statement is essentially a consequence of the Connecting Homomorphism Lemma 74.8 (2). The second statement follows from the first statement together with Lemma 108.9. ■

148.3. **The cup product and the cap product with coefficients.** On page 2513, given a topological space X, we introduced the cup product for the R-cohomology groups $\mathrm{H}^*(X;R)$ provided the coefficients are given by a commutative ring R. In this section we will generalize the notion of the cup product where we no longer demand that the coefficients lie in a commutative ring R. Furthermore we also define a slight variation on the cap product. It is advisable to quickly look at the definitions and then move on to the next section. All the statements proved in this section are basically the obvious generalizations of earlier results.
Before we introduce the more general cup product, we recall the following notation from page 2503.

Notation. Given any $i \in \{0,\ldots,n\}$ we write $v_i := (0,\ldots,1,0,\ldots,0) \in \mathbb{R}^{n+1}$ and secondly, given $a_0,\ldots,a_s \in \Delta^n$ we denote by $[a_0,\ldots,a_s]$ the unique affine linear map $\Delta^s \to \Delta^n$ that sends v_i to a_i for $i = 0,\ldots,s$.

Now we can give the quite simple-minded definition of the more general cup product.

Definition. Let X be a topological space and let A and B be abelian groups. We define

$$\begin{aligned} \mathrm{C}^p(X;A)\times\mathrm{C}^q(X;B) &\to \mathrm{C}^{p+q}(X;A\otimes B) \\ (\varphi,\psi) &\mapsto \left(\begin{array}{l} \varphi\cup_\otimes\psi\colon \mathrm{C}_{p+q}(X)\to A\otimes B \\ \quad (\sigma\colon \Delta^{p+q}\to X)\mapsto \underbrace{\varphi(\sigma\circ[v_0,\dots,v_p])}_{\in A}\otimes\underbrace{\psi(\sigma\circ[v_p,\dots,v_{p+q}])}_{\in B} \end{array} \right). \end{aligned}$$

We have the following elementary lemma. The proof is basically verbatim the same as the proof of Coboundary-Cup Product Lemma 114.2.

Lemma 148.4. Let X be a topological space and let A and B be two abelian groups. If $\varphi\in\mathrm{C}^p(X;A)$ and $\psi\in\mathrm{C}^q(X;B)$, then

$$\delta(\varphi\cup_\otimes\psi) \;=\; \delta\varphi\cup_\otimes\psi+(-1)^p\cdot\varphi\cup_\otimes\delta\psi \;\in\; \mathrm{C}^{p+q+1}(X;A\otimes B).$$

Now we can easily prove the following lemma. The proof again is basically the same as the proof of Lemma 114.3, we just need to replace Coboundary-Cup Product Lemma 114.2 by Lemma 148.4.

Lemma 148.5. Let X be a topological space and let A and B be abelian groups. Then the map

$$\begin{aligned} \cup_\otimes\colon \mathrm{H}^p(X;A)\times\mathrm{H}^q(X;B) &\to \mathrm{H}^{p+q}(X;A\otimes B) \\ ([\varphi],[\psi]) &\mapsto [\varphi\cup_\otimes\psi] \end{aligned}$$

is well-defined.

We refer to the pairing from Lemma 148.5 again as a *cup product*. The following lemma is an immediate consequence of the definitions.

Lemma 148.6. Let X be a topological space.

(1) If $\alpha\colon A\to A'$ and $\beta\colon B\to B'$ are homomorphisms between two abelian groups, then for any $k,l\in\mathbb{N}_0$ the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}^k(X;A)\times\mathrm{H}^l(X;B) & \xrightarrow{\cup_\otimes} & \mathrm{H}^{k+l}(X;A\otimes B) \\ \downarrow{\scriptstyle \alpha_*\times\beta_*} & & \downarrow{\scriptstyle (\alpha\otimes\beta)_*} \\ \mathrm{H}^k(X;A')\times\mathrm{H}^l(X;B') & \xrightarrow{\cup_\otimes} & \mathrm{H}^{k+l}(X;A'\otimes B'). \end{array}$$

(2) If $f\colon X\to X'$ is a map to another topological space X' and if A and B are two abelian groups, then for any $k,l\in\mathbb{N}_0$ the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}^k(X';A)\times\mathrm{H}^l(X';B) & \xrightarrow{\cup_\otimes} & \mathrm{H}^{k+l}(X';A\otimes B) \\ \downarrow{\scriptstyle f^*\times f^*} & & \downarrow{\scriptstyle f^*} \\ \mathrm{H}^k(X;A)\times\mathrm{H}^l(X;B) & \xrightarrow{\cup_\otimes} & \mathrm{H}^{k+l}(X;A\otimes B). \end{array}$$

To formulate the relationship to the earlier definition of the cup product we need to introduce the following definition.

Definition. Let R be a commutative ring. We refer to the homomorphism[17541755]

$$\begin{aligned} \mu\colon R\otimes R &\to R \\ \sum_{i=1}^n \underbrace{a_i}_{\in\mathbb{Z}}\cdot\underbrace{r_i}_{\in R}\otimes\underbrace{s_i}_{\in R} &\mapsto \sum_{i=1}^n a_i\cdot(\underbrace{r_i\cdot s_i}_{\in R}) \end{aligned}$$

as the multiplication induced map.

Now we can formulate the relationship between the two cup products.

Lemma 148.7. Let X be a topological space. If R is a commutative ring, then we have the following commutative diagram

$$\begin{array}{ccc} & \mathrm{H}^p(X;R)\times\mathrm{H}^q(X;R) & \\ {\scriptstyle\cup_\otimes}\swarrow & & \searrow{\scriptstyle\cup} \\ \mathrm{H}^{p+q}(X;R\otimes R) & \xrightarrow{\quad\mu_*\quad} & \mathrm{H}^{p+q}(X;R) \end{array}$$

where $\mu\colon R\otimes R\to R$ denotes the multiplication induced map.

The proof of the following proposition is almost identical to the proof of the earlier the Cup Product-Commutativity Proposition 114.8.

Proposition 148.8. Let X be a topological space and let A and B be abelian groups. Furthermore let $\varphi\in\mathrm{H}^p(X;A)$ and $\psi\in\mathrm{H}^q(X;B)$. If we denote by $\Theta\colon A\otimes B\to B\otimes A$ the natural isomorphism induced by $a\otimes b\mapsto b\otimes a$, see the Tensor Lemma 89.3 (1), then

$$\Theta_*\big(\underbrace{a\cup_\otimes b}_{\in\mathrm{H}^{p+q}(X;A\otimes B)}\big) \;=\; (-1)^{p\cdot q}\;\cdot\;\underbrace{b\cup_\otimes a}_{\in\mathrm{H}^{p+q}(X;B\otimes A)}.$$

We also need a barely visible variation on the cap product.

Definition. Let X be a topological space, let U be a subset of X and let G be an abelian group. Furthermore let $k\le l$. We define the cap product

$$\begin{array}{rcl} \mathrm{C}^k(X;G)\times\mathrm{C}_l(X,U) & \to & \mathrm{C}_{l-k}(X,U;G)=\mathrm{C}_{l-k}(X,U)\otimes G \\ (\varphi,[\sigma\colon\Delta^l\to X]) & \mapsto & \varphi\cap\sigma := \underbrace{\sigma\circ[v_k,\dots,v_l]}_{\in\mathrm{C}_{l-k}(X,U)}\otimes\underbrace{\varphi(\sigma\circ[v_0,\dots,v_k])}_{\in G}. \end{array}$$

For $k>l$ we define the cap product to be the zero map.

The following lemma summarizes the key properties of the more general cap product.

Lemma 148.9. Let X be a topological space, let U be a subset of X, let G be an abelian group and let $k,l\in\mathbb{N}_0$.

(1) The map

$$\begin{array}{rcl} \mathrm{H}^k(X;G)\times\mathrm{H}_l(X,U;\mathbb{Z}) & \to & \mathrm{H}_{l-k}(X,U;G) \\ ([\varphi],[\sigma]) & \mapsto & [\varphi]\cap[\sigma] := [\varphi\cap\sigma] \end{array}$$

is well-defined.

(2) For any $\varphi\in\mathrm{H}^k(X;G)$ and any $\sigma\in\mathrm{H}_k(X;\mathbb{Z})$ we have

$$\epsilon_X(\varphi\cap\sigma) \;=\; \langle\varphi,\sigma\rangle \;\in\; A,$$

where $\epsilon_X\colon\mathrm{H}_0(X;G)\to G$ is the augmentation map and $\langle\ ,\ \rangle$ denotes the Kronecker pairing that we introduced in Lemma 109.6.

(3) If $\rho\colon G\to B$ is a homomorphism of abelian groups, then for any $\varphi\in\mathrm{H}^k(X;G)$ and any $\sigma\in\mathrm{H}_l(X,U;\mathbb{Z})$ we have

$$\rho_*(\varphi)\cap\sigma \;=\; \rho_*(\varphi\cap\sigma) \;\in\; \mathrm{H}_{l-k}(X,U;B).$$

[1754] Note that this is indeed a homomorphism of abelian groups.

[1755] Here on the right-hand side we implicitly use that any abelian group, in particular R, is a $\mathbb{Z}$-module.

(4) If $f\colon (X,U) \to (Y,V)$ is a map between pairs of topological spaces, then for any $\varphi \in \mathrm{H}^k(Y;G)$ and any $\sigma \in \mathrm{H}_l(X,U;\mathbb{Z})$ we have
$$f_*(f^*(\varphi) \cap \sigma) \;=\; \varphi \cap f_*(\sigma) \;\in\; \mathrm{H}_{l-k}(Y,V;G).$$
Note that here f^* denotes the induced map $f^*\colon \mathrm{H}^k(Y;G) \to \mathrm{H}^k(X;G)$ on absolute cohomology, whereas f_* denotes the induced maps $\mathrm{H}_l(X,U;\mathbb{Z}) \to \mathrm{H}_l(Y,V;\mathbb{Z})$ and $\mathrm{H}_{l-k}(X,U;A) \to \mathrm{H}_{l-k}(Y,V;A)$ on relative homology groups.

(5) Let $\varphi \in \mathrm{H}^k(X;\mathbb{Z})$, $\psi \in \mathrm{H}^l(X;G)$ and furthermore let $\sigma \in \mathrm{H}_n(X;\mathbb{Z})$. We denote by $c\colon G \otimes \mathbb{Z} \to G$ and $c\colon \mathbb{Z} \otimes G \to G$ the obvious isomorphisms given by the Tensor Lemma 89.3. Then
$$\varphi \cap (\psi \cap \sigma) \;=\; \underbrace{c_*(\overbrace{\psi \cup_\otimes \varphi}^{\in \mathrm{H}^{k+l}(X;G\otimes\mathbb{Z})})}_{\in \mathrm{H}^{k+l}(X;G)} \cap \sigma \;=\; (-1)^{kl} \cdot \underbrace{c_*(\overbrace{\varphi \cup_\otimes \psi}^{\in \mathrm{H}^{k+l}(X;\mathbb{Z}\otimes G)})}_{\in \mathrm{H}^{k+l}(X;G)} \cap \sigma \;\in\; \mathrm{H}_{n-k-l}(X;G).$$

Proof. The proof of the first statement is entirely analogous to the proof of Lemma 116.2 or Lemma 90.6. The second statement and the third statement are an immediate consequence of the definitions. The fourth statement is a mild generalization of the Cap Product-Naturality Lemma 116.8 and it is also a straightforward consequence of the definitions. Furthermore the first equality of the last statement is an equally mild generalization of the Cup-Cap Lemma 116.7. Finally the last equality of the last statement is a consequence of Proposition 148.8. ■

Later on we will also need the following slight variation on the Poincaré Duality Theorem 119.1. The proof is verbatim the same as the proof of the Poincaré Duality Theorem 119.1.

Proposition 148.10. Let M be a compact oriented non-empty n-dimensional topological manifold and let G be an abelian group. For each $k \in \mathbb{N}_0$ the map
$$\begin{array}{ccc} \mathrm{H}^k(M;G) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(M,\partial M;G) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$
is an isomorphism.

The above proposition leads us to the following definition.

Definition. Let M be a closed oriented non-empty n-dimensional topological manifold and let G be an abelian group. We denote by
$$\mathrm{PD}_M^G\colon \mathrm{H}_k(M;G) \xrightarrow{\cong} \mathrm{H}^{n-k}(M;G)$$
the inverse of the isomorphism of the Poincaré Duality isomorphism given by Proposition 148.10.

The following lemma is an immediate consequence of the relevant definitions together with Lemma 148.9 (3).

Lemma 148.11. Let M be a closed oriented non-empty n-dimensional topological manifold. If $\rho\colon G \to H$ is a homomorphism of abelian groups, then for every $k \in \mathbb{N}_0$ the

following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_k(M;G) & \xrightarrow{\mathrm{PD}_M^G} & \mathrm{H}^{n-k}(M;G) \\ \downarrow{\scriptstyle \rho_*} & & \downarrow{\scriptstyle \rho_*} \\ \mathrm{H}_k(M;H) & \xrightarrow{\mathrm{PD}_M^H} & \mathrm{H}^{n-k}(M;H). \end{array}$$

148.4. **The linking pairing on odd-dimensional rational homology spheres.** Now we return to the study of rational homology spheres. We start out with the following elementary lemma.

Lemma 148.12. Let $n \geq 1$. For every $(2n+1)$-dimensional rational homology sphere M the Bockstein homomorphism $\beta\colon \mathrm{H}^n(M;\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}^{n+1}(M;\mathbb{Z})$ corresponding to the short exact sequence $0 \to \mathbb{Z} \to \mathbb{Q} \to \mathbb{Q}/\mathbb{Z} \to 0$ is an isomorphism.

Proof. It follows from our hypothesis together with the Cohomology-Field Coefficients Proposition 110.18 (or alternatively together with the Co-Homology Symmetry Theorem Theorem 119.6), that for the rational homology sphere M we have $\mathrm{H}^n(M;\mathbb{Q}) = \mathrm{H}^{n+1}(M;\mathbb{Q}) = 0$. Thus it follows from the Bockstein sequence in cohomology that the Bockstein homomorphism $\mathrm{H}^n(M;\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}^{n+1}(M;\mathbb{Z})$ is an isomorphism. ■

We continue with the following purely algebraic definition.

Definition. A linking pairing on an abelian group H is a pairing that takes values in $\mathbb{Q}/\mathbb{Z}$, i.e. it is a bilinear map $\lambda\colon H \times H \to \mathbb{Q}/\mathbb{Z}$.

Example. Let $n \in \mathbb{N}$ and let $k \in \mathbb{Z}$. The map

$$\begin{array}{rcl} \lambda\colon \mathbb{Z}_n \times \mathbb{Z}_n & \to & \mathbb{Q}/\mathbb{Z} \\ (a,b) & \mapsto & \frac{k}{n} \cdot a \cdot b \end{array}$$

is a symmetric linking pairing. It is an amusing exercise to show that this linking pairing is non-singular, in the sense of the definition on page 2656, if and only if k is coprime to n.

The following lemma is a variation on the Non-Singularity Lemma 121.1. It gives another rich source of linking pairings.

Lemma 148.13. (Linking Form-Matrix Lemma) If $A \in \mathrm{M}(n \times n, \mathbb{Z})$ is a symmetric matrix with $\det(A) \neq 0$, then the map

$$\begin{array}{rcl} \lambda(A)\colon \mathbb{Z}^n/A\mathbb{Z}^n \times \mathbb{Z}^n/A\mathbb{Z}^n & \to & \mathbb{Q}/\mathbb{Z} \\ ([v],[w]) & \mapsto & v^T A^{-1} w \end{array}$$

is well-defined and it defines a non-singular symmetric linking pairing.

Since we will not make use of the Linking Form-Matrix Lemma 148.13 we will only provide a sketch of a proof.

Sketch of proof. It follows easily from the symmetry of A that the linking pairing is well-defined, i.e. that it is independent of the choice of the representatives v and w. Furthermore it is straightforward to see that the linking pairing is symmetric. It remains to show that the linking pairing is non-singular. By the symmetry of the linking pairing it suffices to

show that the map

$$\begin{array}{rcl}\Phi\colon \mathbb{Z}^n/A\mathbb{Z}^n & \to & \mathrm{Hom}(\mathbb{Z}^n/A\mathbb{Z}^n, \mathbb{Q}/\mathbb{Z}) \\ [v] & \mapsto & ([w] \mapsto v^T A^{-1} w)\end{array}$$

is an isomorphism. We make the following three observations:

(1) From Lemma 51.8 and $\det(A) \neq 0$ we know that $\mathbb{Z}^n/A\mathbb{Z}^n$ is a torsion-group.
(2) It follows fairly easily from the Finitely Generated Abelian Group Classification see Theorem 51.4 that for any finite abelian group H the groups $\mathrm{Hom}(H, \mathbb{Q}/\mathbb{Z})$ and H have the same number of elements.
(3) By (1) and (2) the map Φ is a homomorphism between finite abelian groups with the same number of elements. Thus it suffices to show that Φ is a monomorphism.

Now let $v \in \mathbb{Z}^n$ such that $\Phi([v]) = 0$. This implies that for the i-th standard basis vector e_i the product $v^T A^{-1} e_i =: \mu_i$ lies in $\mathbb{Z}$. But this means that $v^T A^{-1} = (\mu_1 \ \dots \ \mu_n) \in \mathbb{Z}^n$, i.e. using the symmetry of A, we obtain that

$$v \ = \ A^T(\mu_1 \ \dots, \mu_n)^T \ = \ A(\mu_1 \ \dots \ \mu_n)^T \ \in \ A \cdot \mathbb{Z}^n. \qquad \blacksquare$$

Before we continue we fix some notation that we will use throughout the remainder of this chapter.

Notation. Let S be a commutative ring and let R be a subring of S. We adopt the following notations:

(1) We denote by $i\colon R \to S$ the inclusion map and we denote by $p\colon S \to R/S$ the projection .
(2) Given a topological space X we denote by β the Bockstein homomorphism corresponding to the short exact sequence $0 \to R \xrightarrow{i} S \xrightarrow{p} S/R \to 0$.
(3) Similar to the discussion on page 3147 we can consider the multiplication induced homomorphisms

$$\begin{array}{rcl} R \otimes S/R & \to & S/R \\ \sum_{i=1}^k r_i \otimes [s_i] & \mapsto & \sum_{i=1}^k [r_i \cdot s_i] \end{array} \quad \text{and} \quad \begin{array}{rcl} S/R \otimes R & \to & S/R \\ \sum_{i=1}^k [s_i] \otimes r_i & \mapsto & \sum_{i=1}^k [s_i \cdot r_i]. \end{array}$$

We denote both homomorphisms by ν.

The following definition can be viewed as an odd-dimensional analogue of the definition of the intersection form on a compact oriented even-dimensional smooth manifold that we gave on page 2800.

Definition. Let M be an oriented rational homology sphere of dimension $2n+1$ with $n \geq 1$. We refer to the map

$$\begin{array}{rcl}\lambda_M\colon \mathrm{H}_n(M;\mathbb{Z}) \times \mathrm{H}_n(M;\mathbb{Z}) & \to & \mathbb{Q}/\mathbb{Z} \\ (a,b) & \mapsto & \Big\langle \nu_*\big(\overbrace{\beta^{-1}(\mathrm{PD}(a))}^{\in \mathrm{H}^{n+1}(M;\mathbb{Q}/\mathbb{Z})} \cup_{\otimes} \overbrace{\mathrm{PD}(b)}^{\in \mathrm{H}^{n+1}(M;\mathbb{Z})}\big), [M] \Big\rangle \end{array}$$

$\in \mathrm{H}^{2n+1}(M;\mathbb{Q}/\mathbb{Z}\otimes\mathbb{Z})$

as the linking pairing λ_M of M.

Remark. With very minor efforts one can generalize the previous definition. More precisely, let M be a closed oriented $(2n+1)$-dimensional smooth manifold. We denote by

$\operatorname{Tor} \mathrm{H}_n(M;\mathbb{Z})$ the torsion subgroup of $\mathrm{H}_n(M;\mathbb{Z})$. In an almost identical fashion to the above one can define a pairing

$$\operatorname{Tor} \mathrm{H}_n(M;\mathbb{Z}) \times \operatorname{Tor} \mathrm{H}_n(M;\mathbb{Z}) \ \to \ \mathbb{Q}/\mathbb{Z}.$$

Furthermore, with similar proofs one can generalize the subsequent Propositions 148.16 and Proposition 148.17 to this more general setup. But since we will not make use of this generalization we leave it to the reader to fill in the details.

Lemma 148.14. Let $n \geq 1$ and let $f\colon M \to N$ be a homotopy equivalence between oriented $(2n+1)$-dimensional rational homology spheres. By the Homotopic Maps-and-Homology Proposition 73.6 there exists an $\epsilon \in \{-1,1\}$ with $f_*([M]) = \epsilon\cdot[N] \in \mathrm{H}_{2n+1}(N;\mathbb{Z})$. Then for any $x, y \in \mathrm{H}_n(M;\mathbb{Z})$ the following equality holds:

$$\lambda_N(f_*(x), f_*(y)) \ = \ \epsilon \cdot \lambda_M(x,y).$$

Proof. In the proof of Lemma 132.6 we had implicitly proved the following statement.[1756]

Statement 148.15. For any $c \in \mathrm{H}_k(M;\mathbb{Z})$ we have

$$f^*(\mathrm{PD}^{\mathbb{Z}}_N(f_*(c))) \ = \ \varepsilon \cdot \mathrm{PD}^{\mathbb{Z}}_M(c) \in \mathrm{H}^{2n+1-k}(M;\mathbb{Z}).$$

Now we can prove the desired equality. More precisely, we have the following equalities in $\mathbb{Q}/\mathbb{Z}$:

$$\begin{aligned}
\lambda_M(x,y) &\overset{\text{by definition of the linking pairing } \lambda_N}{\downarrow} \\
&= \left\langle \beta^{-1}(\mathrm{PD}^{\mathbb{Z}}_M(x)) \cup_{\otimes} \mathrm{PD}^{\mathbb{Z}}_M(y), [M] \right\rangle \\
&\overset{\text{by the above statement, the convenient truth that } \epsilon^2 = 1 \text{ and the definition of } \epsilon, \text{ we also used the naturality of } \beta, \text{ which is a consequence of the Connecting Homomorphism Proposition 108.6 (2)}}{=} \left\langle f^*(\beta^{-1}(\mathrm{PD}^{\mathbb{Z}}_N(f_*(x)))) \cup_{\otimes} f^*(\mathrm{PD}^{\mathbb{Z}}_N(f_*(y))), \epsilon\cdot(f_*)^{-1}([N]) \right\rangle \\
&\overset{\text{by Lemma 109.6 (3) and Lemma 148.6 (2)}}{=} \left\langle \beta^{-1}(\mathrm{PD}^{\mathbb{Z}}_N(f_*(x))) \cup_{\otimes} \mathrm{PD}^{\mathbb{Z}}_M(f_*(y)), \epsilon\cdot[N] \right\rangle \ \overset{\text{definition of } \lambda_N}{=} \ \epsilon \cdot \lambda_N(f_*(x), f_*(y)).
\end{aligned}$$

■

In the Intersection Form Proposition 132.4 we saw that the intersection form of a closed oriented even-dimensional topological manifold is (anti-) symmetric and non-singular. The following two propositions give us similar statements for linking pairings.

Proposition 148.16. (Linking Pairing-Symmetry Proposition) Let $n \geq 1$ and let M be an oriented $(2n+1)$-dimensional rational homology sphere. If n is odd, then the linking pairing λ_M on $\mathrm{H}_n(M;\mathbb{Z})$ is symmetric otherwise it is anti-symmetric.

Remark. Linking pairings were initially introduced in 1933 by Herbert Seifert [**Sei1933**, p. 814] for oriented 3-dimensional rational homology spheres. He gave a somewhat informal argument why the linking pairing is symmetric. The fact that linking pairings are (anti-) symmetric is well-known and implicitly or implicitly used many times. But published proofs of this statement are few and far between. The subsequent proof of the Linking Pairing-Symmetry Proposition 148.16 first appeared in [**CFH2016**].

[1756] Strictly speaking, in the proof of Lemma 132.6 the map f was a homeomorphism, but that makes no difference.

Proposition 148.17. Let $n \geq 1$. The linking pairing λ_M of any oriented $(2n+1)$-dimensional rational homology sphere is non-singular.

In these modest lecture notes we will not make use of Propositions 148.16 and 148.17. Since the proofs are somewhat technical we hide them in the next section.

148.5. **Proofs of Propositions 148.16 and 148.17.** We will see that the Linking Pairing-Symmetry Proposition 148.16 is a fairly straightforward consequence of the next lemma.

Lemma 148.18. Let S be a commutative ring and let R be a subring of S. Let X be a topological space. For any $x \in \mathrm{H}^k(X; S/R)$ and any $y \in \mathrm{H}^l(X; S/R)$ we have

$$\nu_*\big(\underbrace{\beta(x) \cup_\otimes y}_{\in \mathrm{H}^{k+l+1}(X; R\otimes S/R)}\big) \;=\; (-1)^{k+1} \cdot \nu_*\big(\underbrace{x \cup_\otimes \beta(y)}_{\in \mathrm{H}^{k+l+1}(X; S/R\otimes R)}\big) \;\in\; \mathrm{H}^{k+l+1}(X; S/R).$$

Proof of Proposition 148.16 assuming Lemma 148.18. Let $n \geq 1$ and let M be an oriented $(2n+1)$-dimensional rational homology sphere. Furthermore let $a, b \in \mathrm{H}_n(M; \mathbb{Z})$. We write $x = \beta^{-1}(\mathrm{PD}(a)) \in \mathrm{H}^n(M; \mathbb{Q}/\mathbb{Z})$ and $y = \beta^{-1}(\mathrm{PD}(b)) \in \mathrm{H}^n(M; \mathbb{Q}/\mathbb{Z})$. Then

$$\begin{aligned}
\lambda_M(a,b) &\overset{\text{by definition of } \lambda_M}{=} \langle \nu_*(x \cup_\otimes \beta(y)), [M]\rangle \overset{\text{by Lemma 148.18}}{=} (-1)^{n+1} \cdot \langle \nu_*(\beta(x) \cup_\otimes y), [M]\rangle \\
&= (-1)^{n+1} \cdot \langle \nu_*(y \cup_\otimes \beta(x)), [M]\rangle \;=\; (-1)^{n+1} \cdot \lambda_M(b,a).
\end{aligned}$$

(by Proposition 148.8 since $n(n+1)$ is even; by definition of λ_M) ∎

Proof of Lemma 148.18. First recall that we have a short exact sequence of cochain complexes:

$$0 \;\to\; \mathrm{C}^*(X; R) \;\xrightarrow{i_*}\; \mathrm{C}^*(X; S) \;\xrightarrow{p_*}\; \mathrm{C}^*(X; S/R) \;\to\; 0.$$

In particular we can and will pick $f \in \mathrm{C}^k(X; S)$ and $g \in \mathrm{C}^l(X; S)$ such that $[p_*(f)] = x$ and such that $[p_*(g)] = y$. Next recall that the Bockstein homomorphisms in cohomology are the connecting homomorphisms corresponding to the above short exact sequence of cochain complexes. It follows immediately from the definition of the connecting homomorphism, see page 2399 and the Connecting Homomorphism Proposition 108.6, that there exist unique cocycles $\beta(f) \in \mathrm{C}^{k+1}(X; R)$ and $\beta(g) \in \mathrm{C}^{l+1}(X; R)$ such that $i_*(\beta(f)) = \delta^k(f) \in C^{k+1}(X; S)$ and also such that $i_*(\beta(g)) = \delta^l(g) \in \mathrm{C}^{l+1}(X; S)$. We have the following equality in $\mathrm{H}^{k+l+1}(X; S \otimes S)$:

$$\begin{aligned}
(*) \qquad 0 \;&=\; [\delta(f \cup_\otimes g)] \overset{\text{see Lemma 148.4}}{=} [\delta(f) \cup_\otimes g \,+\, (-1)^k \cdot f \cup_\otimes \delta(g)] \\
&\uparrow \text{by cocycle condition} \qquad = \big[\underbrace{i_*(\beta(f)) \cup_\otimes g}_{\in \mathrm{C}^{k+l+1}(X; R\otimes S)} + (-1)^k \cdot \underbrace{f \cup_\otimes i_*(\beta(g))}_{\in \mathrm{C}^{k+l+1}(X; S\otimes R)}\big].
\end{aligned}$$

We consider the following diagram of group homomorphisms

$$\begin{array}{ccccc}
R \otimes S & \xrightarrow{i\otimes \mathrm{id}} & S \otimes S & \xleftarrow{\mathrm{id}\otimes i} & S \otimes R \\
\downarrow{\scriptstyle \mathrm{id}\otimes p} & & \downarrow{\scriptstyle \mu} & & \downarrow{\scriptstyle p\otimes \mathrm{id}} \\
R \otimes S/R & & S & & S/R \otimes R \\
& {\scriptstyle \nu}\searrow & \downarrow{\scriptstyle p} & \swarrow{\scriptstyle \nu} & \\
& & S/R & &
\end{array}$$

where, as usual, ν and μ stand for the obvious maps that are induced by multiplication in the ring S. It is straightforward to see that the diagram commutes. We have the following equalities in $\mathrm{H}^{k+l+1}(X;S/R)$:

$$\begin{aligned}
&\text{by the above equality } (*)\\
0 \;&\overset{\downarrow}{=}\; (p\circ\mu)_*\big(\big[i_*(\beta(f))\cup_\otimes g \;+\; (-1)^k\cdot f\cup_\otimes i_*(\beta(g))\big]\big)\\
&=\; \big[\nu_*\big(\beta(f)\cup_\otimes p_*(g)\big) \;+\; (-1)^k\cdot\nu_*\big(p_*(f)\cup_\otimes\beta(g)\big)\big]\\
&\text{by the above commutative diagram of group homomorphisms and some basic observations regarding the functoriality of the cup product in the coefficients}\\
&\overset{\uparrow}{=}\; \nu_*\big([\beta(f)]\cup_\otimes[p_*(g)]\big) \;+\; (-1)^k\cdot\nu_*\big([p_*(f)]\cup_\otimes[\beta(g)]\big)\\
&\text{by definition of } \cup_\otimes \text{ and since } \beta(f), p_*(g), p_*(f) \text{ and } \beta(g) \text{ are cocycles}\\
&\overset{\uparrow}{=}\; \nu_*(\beta(x)\cup_\otimes y) \;+\; (-1)^k\cdot\nu_*(x\cup_\otimes\beta(y)).\\
&\text{since } [\beta(f)]=\beta([p_*(f)])=:\beta(x) \text{ and } [p_*(g)]=y \text{ and similar for the second summand}
\end{aligned}$$

This of course implies the desired statement. ■

Before we give the proof of Proposition 148.17 we prove the following lemma which gives a slight reformulation of the linking pairing.

Lemma 148.19. Let $n\geq 1$ and let M be an oriented $(2n+1)$-dimensional rational homology sphere. For any choice of $a,b\in\mathrm{H}_n(M;\mathbb{Z})$ we have

$$\lambda_M(a,b) \;=\; \epsilon_M\big(\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))\cap b\big) \;=\; \big\langle\beta^{-1}(\overbrace{\mathrm{PD}_M^{\mathbb{Z}}(a)}^{\in\mathrm{H}^{n+1}(M;\mathbb{Z})}),b\big\rangle.$$

Proof. Let $a,b\in\mathrm{H}_n(M;\mathbb{Z})$. We have the following equalities in $\mathbb{Q}/\mathbb{Z}$:

$$\begin{aligned}
&\text{by definition and Lemma 148.9 (2)}\\
\lambda_M(a,b) \;&\overset{\downarrow}{=}\; \epsilon_M\big(\overbrace{\nu_*\big(\underbrace{\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))}_{\in\mathrm{H}^{n+1}(M;\mathbb{Q}/\mathbb{Z})}\cup_\otimes\underbrace{\mathrm{PD}_M^{\mathbb{Z}}(b)}_{\in\mathrm{H}^n(M;\mathbb{Z})}\big)}^{\in\mathrm{H}^{2n+1}(M;\mathbb{Q}/\mathbb{Z})}\cap[M]\big)\\
&=\; \epsilon_M\big(\underbrace{\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))}_{\in\mathrm{H}^n(M;\mathbb{Q}/\mathbb{Z})}\cap\underbrace{(\mathrm{PD}_M^{\mathbb{Z}}(b)\cap[M])}_{\in\mathrm{H}_n(M;\mathbb{Z})}\big) \;=\; \epsilon_M\big(\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))\cap b\big).\\
&\quad\uparrow\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\uparrow\\
&\text{by Lemma 148.9 (5) and the convenient fact that } n(n+1) \text{ is always even}\qquad\qquad\text{definition of } \mathrm{PD}_M^{\mathbb{Z}}(b)\\
&\overset{\uparrow}{=}\; \big\langle\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a)),b\big\rangle.\\
&\text{Lemma 148.9 (2)}
\end{aligned}$$

We have thus verified both desired equalities. ■

We conclude this technical section with the proof of Proposition 148.17.

Proof of Proposition 148.17. Let M be an oriented $(2n+1)$-dimensional rational homology sphere. We need to show that the linking pairing $\lambda_M\colon\mathrm{H}_n(M;\mathbb{Z})\times\mathrm{H}_n(M;\mathbb{Z})\to\mathbb{Q}/\mathbb{Z}$ is non-singular. To do so we consider the map

$$\Phi_M\colon\mathrm{H}_n(M;\mathbb{Z})\xrightarrow{\mathrm{PD}_M^{\mathbb{Z}}}\mathrm{H}^{n+1}(M;\mathbb{Z})\xrightarrow[\cong]{\beta^{-1}}\mathrm{H}^n(M;\mathbb{Q}/\mathbb{Z})\xrightarrow{\mathrm{ev}}\mathrm{Hom}_{\mathbb{Z}}(\mathrm{H}_n(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}).$$

Here the first map is given by Poincaré Duality, the second map is the inverse of the Bockstein isomorphism given by Lemma 148.12 and the third map is given by the evaluation map.

In the Linking Pairing-Symmetry Proposition 148.16 we showed that the linking pairing is (anti-) symmetric. Therefore it suffices to prove that the map

$$\begin{array}{rcl} \mathrm{H}_n(M;\mathbb{Z}) & \to & \mathrm{Hom}(\mathrm{H}_n(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}) \\ a & \mapsto & (b \mapsto \lambda_M(a,b)) \end{array}$$

is an isomorphism. But this in turn follows immediately from the following claim.

Claim.

(1) The map Φ_M is an isomorphism.
(2) For any $a, b \in \mathrm{H}_n(M;\mathbb{Z})$ we have $\lambda_M(a,b) = \Phi_M(a)(b)$.

Proof. First note that the second statement is an immediate consequence of Lemma 148.19. For the first statement it remains to show that the third map in the definition of Φ_M is an isomorphism. Recall that by the Universal Coefficient Theorem 110.12 for Cohomology Groups we have a short exact sequence

$$0 \to \mathrm{Ext}(\mathrm{H}_{n-1}(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}^n(M;\mathbb{Q}/\mathbb{Z}) \xrightarrow{\mathrm{ev}} \mathrm{Hom}(\mathrm{H}_n(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}) \to 0.$$

On page 2441 we remarked that the abelian group $\mathbb{Q}/\mathbb{Z}$ is divisible. By Proposition 110.6 this implies that the Ext-term to the left is zero. But this shows that the evaluation homomorphism to the right is an isomorphism. ■

148.6. **Linking pairings of lens spaces.** In the next section we will prove the following proposition.

Proposition 148.20. (Lens Space-Linking Pairing Proposition) Let $p, q \in \mathbb{N}$ be coprime. The linking pairing of the lens space $L(p,q)$ is isometric to[17571758]

$$\begin{array}{rcl} \mathbb{Z}_p \times \mathbb{Z}_p & \to & \mathbb{Q}/\mathbb{Z} \\ (x,y) & \mapsto & -\frac{q}{p} \cdot x \cdot y \mod \mathbb{Z}. \end{array}$$

Remark. There are many different approaches to calculating the linking pairing of lens spaces. The first calculation was given by Seifert [**Sei1933**, p. 824], see also [**ST1934**, p. 290] and [**ST1934**, p. 279]. Alternative calculations are given in [**Lic1985**], [**Hat2002**, p. 306], [**Mun1984**, Chapter 69] and [**Bre1993**, p. 364]. The proof of the Lens Space-Linking Pairing Proposition 148.20 that we give is rather different from the previous proofs. The approach taken below has the advantage that it can also be used to determine the linking pairing of any oriented 3-dimensional rational homology sphere in terms of a Heegaard splitting. We refer to [**CFH2016**] for details.

[1759] Recall that we have $L(p,q) = S^3/\mathbb{Z}_p$ and, that following the convention established on page 1075, we equip $L(p,q)$ with the obvious orientation coming from S^3.

[1760] By now I am fairly confident that the sign in the calculation of the linking pairing of the lens space $L(p,q)$ is correct. But the fact that, in my attempts to calculate the linking pairing, the sign flipped on numerous occasions means that one should take the result with a grain of salt.

Before we turn to the somewhat lengthy, and not overly enjoyable proof, we want to use this section to state and prove several corollaries of the Lens Space-Linking Pairing Proposition 148.20.

Corollary 148.21. Let $L(p,q)$ and $L(p,\widetilde{q})$ be lens spaces. Suppose there exists a homotopy equivalence $f\colon L(p,q) \to (p,\widetilde{q})$. By the Homotopic Maps-and-Homology Proposition 73.6 there exists an $\epsilon \in \{-1,1\}$ such that $f_*([L(p,q)]) = \epsilon \cdot [L(p,\widetilde{q})]$. Then there exists $r \in \mathbb{Z}$, coprime to p, such that

$$q \;\equiv\; \epsilon \cdot r^2 \cdot \widetilde{q} \bmod p.$$

Proof. We pick isomorphisms $\varphi\colon \mathbb{Z}_p \to \mathrm{H}_1(L(p,q);\mathbb{Z})$ and $\widetilde{\varphi}\colon \mathbb{Z}_p \to \mathrm{H}_1(L(p,\widetilde{q});\mathbb{Z})$ as provided by the Lens Space-Linking Pairing Proposition 148.20. The map $\widetilde{\varphi}^{-1} \circ f_* \circ \varphi\colon \mathbb{Z}_p \to \mathbb{Z}_p$ is an isomorphism, hence it is given by multiplication by some $r \in \mathbb{Z}$ that is coprime to p. Together with Lemma 148.14 we see that the following diagram commutes

$$\begin{array}{ccccc}
 & & \overset{(x,y)\mapsto -\frac{q}{p}\cdot x\cdot y}{\frown} & & \\
\mathbb{Z}_p \times \mathbb{Z}_p & \xrightarrow{\varphi\times\varphi} & \mathrm{H}_1(L(p,q);\mathbb{Z}) \times \mathrm{H}_1(L(p,q);\mathbb{Z}) & \xrightarrow{\lambda_{L(p,q)}} & \mathbb{Q}/\mathbb{Z} \\
\downarrow{\scriptstyle (x,y)\mapsto(rx,ry)} & & \downarrow{\scriptstyle f_*\times f_*} & & \downarrow{\scriptstyle \cdot(-1)} \\
\mathbb{Z}_p \times \mathbb{Z}_p & \xrightarrow[\widetilde{\varphi}\times\widetilde{\varphi}]{} & \mathrm{H}_1(L(p,\widetilde{q});\mathbb{Z}) \times \mathrm{H}_1(L(p,\widetilde{q});\mathbb{Z}) & \xrightarrow{\lambda_{L(p,\widetilde{q})}} & \mathbb{Q}/\mathbb{Z}. \\
 & & \underset{(x,y)\mapsto -\frac{\widetilde{q}}{p}\cdot x\cdot y}{\smile} & &
\end{array}$$

If we start out with $(1,1) \in \mathbb{Z}_p \times \mathbb{Z}_p$ on the upper left corner and we compare the different routes to the lower right corner we obtain that $-\epsilon \cdot \frac{q}{p} = r^2 \cdot \frac{\widetilde{q}}{p}$. Multiplying by p we obtain the desired equality. ■

This is a good moment to state the classification of lens spaces up to homotopy equivalences:

Theorem 148.22. (Lens Space-Homotopy Classification Theorem) Let $p \in \mathbb{N}$. If $q, \widetilde{q} \in \mathbb{N}$ are coprime to p, then

$$\begin{array}{c}\text{the lens spaces } L(p,q) \text{ and } L(p,\widetilde{q}) \\ \text{are homotopy equivalent}\end{array} \quad\Longleftrightarrow\quad \begin{array}{c}\text{there exists an } r \in \mathbb{Z}, \text{ coprime to } p, \\ \text{such that } q \equiv \pm r^2 \cdot \widetilde{q} \bmod p.\end{array}$$

Proof. The "⇒"-direction is precisely the statement of Corollary 148.21. The "⇐"-direction was first shown by John Whitehead [**WhdJ1941b**, Theorem 10]. A direct proof is also given in [**CoheM1973**, Chapter 29]. We will prove the "⇐"-direction later in the Lens Space-Homotopy Equivalence Proposition 162.4, using the Whitehead Theorem 162.1. ■

So, after a very long wait we have now finally made some serious progress towards answering Question 48.7. For example, one can easily verify, using Theorem 148.22 that the lens spaces $L(5,1)$ and $L(5,2)$ are not homotopy equivalent. Nonetheless, we have not yet completely answered Question 48.7. For example the lens spaces $L(7,1)$ and $L(7,4)$ are homotopy equivalent by Theorem 148.22. But it is not clear whether these two lens spaces are homeomorphic. We will solves this conundrum in the Lens Space-Homeomorphism Classification Theorem **??**.

Remark. For those who might get tired of chasing down lens spaces, I would like to quote from John F. Kennedy's speech at Rice University on September 12 1962, where he announced that the United States would attempt to land a man on the moon by the end of the decade:

> *But why, some say, the Moon? Why choose this as our goal? And they may well ask, why climb the highest mountain? Why, 35 years ago, fly the Atlantic? Why does Rice play Texas?*
>
> *We choose to go to the Moon! We choose to go to the Moon in this decade and do the other things, not because they are easy, but because they are hard; because that goal will serve to organize and measure the best of our energies and skills, because that challenge is one that we are willing to accept, one we are unwilling to postpone, and one we intend to win.*

John F. Kennedy speaking at Rice University in September 1962

In Question 107.7 we had asked whether the lens space $L(3,1)$ is amphichiral, i.e. we had asked $L(3,1)$ admits an orientation-reversing self-homeomorphism. Now we have the tools to address this question.

Proposition 148.23. If there exists an *orientation-reversing* homeomorphism between two lens spaces $L(p,q)$ and $L(p,\widetilde{q})$, then there exists an $r \in \mathbb{Z}$ such that $q = -r^2 \cdot \widetilde{q}^{\pm 1} \bmod p$.

Example. Note that $1 \neq -r^2 \bmod 3$ for any $r \in \mathbb{Z}$. Thus it follows from Proposition 148.23 that there is no orientation-reversing homeomorphism from the lens space $L(3,1)$ to itself, i.e. the lens space $L(3,1)$ is chiral. This now answers Question 107.7.

Proof. If $f\colon L(p,q) \to L(p,\widetilde{q})$ is an orientation-reversing homeomorphism, then we have $f_*([L(p,q)]) = -[L(p,\widetilde{q})]$, i.e. we have $\epsilon = -1$ in the statement of Corollary 148.21. The proposition now follows immediately from Corollary 148.21. ■

148.7. **The proof of the Lens Space-Linking Pairing Proposition 148.20.** This section is almost entirely dedicated to the proof of the Lens Space-Linking Pairing Proposition 148.20. Unless the reader suffers from an insatiable appetite for cup and cap products, it is recommended to skip this section.

We start out with the following lemma that relates the Bockstein homomorphisms in homology and cohomology via the Poincaré Duality

Lemma 148.24. Let M be a closed oriented m-dimensional topological manifold. If we are given a short exact sequence $0 \to P \xrightarrow{i} Q \xrightarrow{p} R \to 0$ of abelian groups, then for every

$k \in \{0, \dots, m\}$ the two diagrams

$$\begin{array}{ccc} \mathrm{H}^k(M;R) & \xrightarrow{\cap[M]} & \mathrm{H}_{m-k}(M;R) \\ \downarrow\beta & & \downarrow\beta \\ \mathrm{H}^{k+1}(M;P) & \xrightarrow{\cap[M]} & \mathrm{H}_{m-k-1}(M;P) \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{H}_{m-k}(M;R) & \xrightarrow{\mathrm{PD}_M^R} & \mathrm{H}^k(M;R) \\ \downarrow\beta & & \downarrow\beta \\ \mathrm{H}_{m-k-1}(M;P) & \xrightarrow{\mathrm{PD}_M^P} & \mathrm{H}^{k+1}(M;P) \end{array}$$

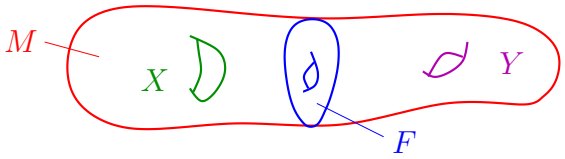
commute up to the sign $(-1)^{k+1}$.

Proof. We pick a cycle $\sigma \in \mathrm{C}_m(M;\mathbb{Z})$ that represents the fundamental class. Furthermore let $\psi \in \mathrm{C}^k(M;R)$ be a cocycle. We pick $\varphi \in \mathrm{C}^k(M;Q)$ with $p_*(\varphi) = \psi$. Then we have the following equalities in $\mathrm{H}_{m-k-1}(M;P)$:[1761]

$$\beta([\psi]) \cap [M] \overset{\text{by definition of the connecting homomorphism on page 2399}}{=} [\delta(\varphi) \cap \sigma] = [\partial(\varphi \cap \sigma)] \overset{\text{by definition of the connecting homomorphism on page 1620}}{=} \beta([p_*(\varphi \cap \sigma)]) = \beta([\psi] \cap [M]).$$

(the middle equality: by Lemma 116.1 since σ is a cycle)

But this implies that the left-hand diagram does indeed commute. The right-hand diagram is, by definition of the Poincaré Duality isomorphisms, basically the same diagram. ■



We continue with the following definition.

Definition. Let M be a 3-dimensional rational-homology sphere. Given a splitting (X, Y, F) of M, as defined on page 3114, we denote by $\Theta(X, Y, F)$ the homomorphism

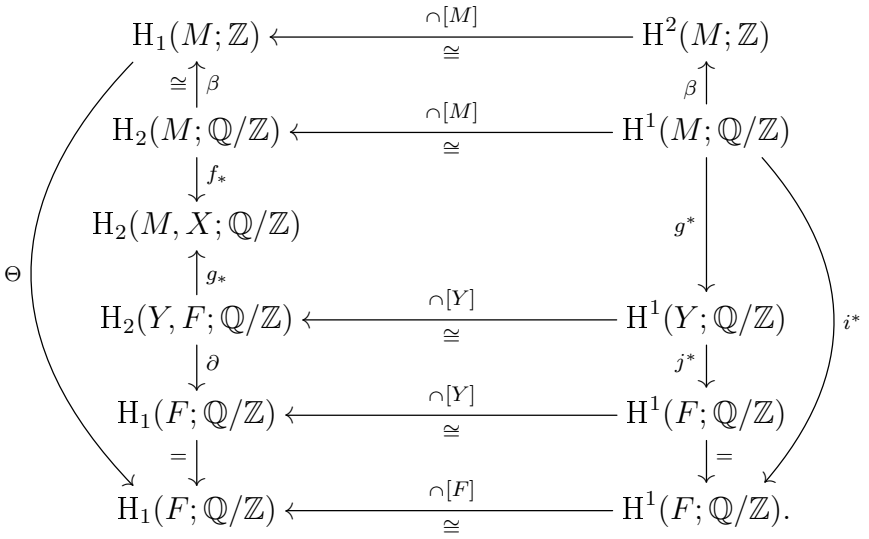
$$\mathrm{H}_1(M;\mathbb{Z}) \xrightarrow{\beta^{-1}} \mathrm{H}_2(M;\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}_2(M, X;\mathbb{Q}/\mathbb{Z}) \leftarrow \mathrm{H}_2(Y, F;\mathbb{Q}/\mathbb{Z}) \xrightarrow{\partial} \mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z}),$$

($\leftarrow$: isomorphism by the Excision Theorem 74.18 for smooth manifolds)

where "∂" denotes the connecting homomorphism of the long exact sequence of $\mathbb{Q}/\mathbb{Z}$-homology groups corresponding to the pair (Y, F). If the splitting (X, Y, F) is understood, then we just write Θ instead of $\Theta(X, Y, F)$.

awfully schematic picture of a splitting of M

The following lemma will allow us to compute the linking pairing of an oriented 3-dimensional rational homology sphere in terms of Poincaré Duality on the surface F.



Lemma 148.25. Let M be an oriented 3-dimensional rational homology sphere and let (X, Y, F) be a splitting of M, as defined on page 3114. We denote by $i\colon F \to M$ the

[1761] The perspicacious reader will have noticed that the commutativity of the left-hand diagram has little to do with the hypothesis that we are capping with the fundamental class of a closed oriented topological manifold. Since we do not need the more general statements we leave the lemma as it is.

inclusion map. Then the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}_1(M;\mathbb{Z}) & \xrightarrow{\mathrm{PD}_M^{\mathbb{Z}}} & \mathrm{H}^2(M;\mathbb{Z}) & \xrightarrow{\beta^{-1}} & \mathrm{H}^1(M;\mathbb{Q}/\mathbb{Z}) \\ \downarrow{\scriptstyle \Theta} & & & & \downarrow{\scriptstyle i^*} \\ \mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z}) & & \xrightarrow[\cong]{\mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}} & & \mathrm{H}^1(F;\mathbb{Q}/\mathbb{Z}). \end{array}$$

Proof. First of all, we denote the inclusion map $F \to X$ by j. Furthermore we denote by $f\colon (M,\varnothing) \to (M,X)$ and $g\colon (Y,F) \to (M,X)$ the obvious maps between pairs of topological spaces. We write also $g\colon Y \to M$ for the inclusion of Y into M. We consider the following diagram:

We consider the commutativity of the four rectangles in the diagram separately.

(1) The top rectangle commutes by Lemma 148.24. (Strictly speaking Lemma 148.24 says that the diagram commutes up to the sign $(-1)^{1+1} = 1$.)

(2) We turn to the second rectangle (or equivalently the first and only pentagon). Let $\varphi \in \mathrm{H}^1(M;\mathbb{Q}/\mathbb{Z})$. We have the following equalities in $\mathrm{H}_2(M,X;\mathbb{Q}/\mathbb{Z})$:

$$\begin{array}{ccccc} f_*(\varphi \cap [M]) & \underset{\uparrow}{=} & \varphi \cap f_*([M]) & \overset{\downarrow}{=} & \varphi \cap g_*([Y]) & \underset{\uparrow}{=} & g_*(g^*(\varphi) \cap [Y]). \\ \text{Lemma 148.9 (4) applied to } f\colon (M,\varnothing) \to (M,X) \text{ where we use that } f^* = \mathrm{id}\colon \mathrm{H}^1(M;\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}^1(M;\mathbb{Q}/\mathbb{Z}) & & & \text{by the Codimension Zero-Fundamental Class Lemma 106.24 we have } f_*([M]) = g_*([Y]) & & \text{Lemma 148.9 (4) applied to } g\colon (Y,F) \to (M,X) & & \end{array}$$

(3) The third rectangle anti-commutes[1762] by the obvious extension of Proposition 119.25 from $\mathbb{Z}$-coefficients to $\mathbb{Q}/\mathbb{Z}$-coefficients.

(4) It follows from our orientation convention from page 3114 that $F = -\partial Y$ as oriented smooth manifolds. By the discussion on page 2373 this implies $[F] = -\partial[Y]$. We obtain from this observation that the bottom rectangle anti-commutes.

[1762]Here by "anti-commutes" we mean that the left-down path agrees with the down-left path except for a minus sign.

Summarizing we see that the two approaches of going from $\mathrm{H}^2(M;\mathbb{Z})$ to $\mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z})$ agree. The lemma follows from the observation, that by definition PD_M is the inverse of the top horizontal map and that similarly $\mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}$ is the inverse of the bottom horizontal map. ■

Now we turn to lens spaces. In the following we will use the description of lens spaces that we had obtained in the Lens Space-Splitting Lemma 146.2. At this point it is convenient to recall and introduce some notation:

Notation.

(1) We write $F = S^1 \times S^1$. We write $a = [S^1 \times 1]$ and $b = [1 \times S^1]$ and we use this ordered basis of $\mathrm{H}_1(F;\mathbb{Z})$ to make the usual identification $\mathrm{H}_1(F;\mathbb{Z}) = \mathbb{Z}^2$. By a slight abuse of notation we also denote by a and b the corresponding elements in $\mathrm{H}_1(F;\mathbb{Q}) = \mathrm{H}_1(F;\mathbb{Z}) \otimes \mathbb{Q}$.

(2) Let $p, q \in \mathbb{N}$ be coprime. We pick $r, s \in \mathbb{N}$ such that $ps - qr = 1$. We write

$$A = \begin{pmatrix} q & p \\ s & r \end{pmatrix} \quad \text{and we consider the diffeomorphism} \quad \begin{array}{rcl} \varphi\colon F = \mathbb{R}^2/\mathbb{Z}^2 & \to & F = \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [Av]. \end{array}$$

By the Action-on-Torus Homology Lemma 84.7 (2) the induced map φ_* on the homology group $\mathrm{H}_1(F;\mathbb{Z}) = \mathbb{Z}^2$ is given by multiplication by the matrix A.

(3) We write $X = S^1 \times \overline{B}^2$ and we denote by Y another disjoint copy of the solid torus $S^1 \times \overline{B}^2$. We equip X and Y with the usual product orientation. In the Lens Space-Splitting Lemma 146.2 we gave an explicit orientation-preserving diffeomorphism

$$L(p,q) \xrightarrow{\cong} (X \sqcup Y)/x \sim \varphi(x) \quad \text{for } x \in F = \partial X$$

that we will use to identify $L(p,q)$ with the topological space to the right. By an abuse of notation we denote the images of the X and Y in $L(p,q)$ again by X and Y. Note that (X, Y, F) is a Heegaard splitting for $L(p,q)$.

(4) As usual, for want of a better notation, we denote by i the various inclusion maps $F \to X$, $X \to L(p,q)$ and $F \to L(p,q)$.

(5) We denote by $\rho\colon \mathbb{Q} \to \mathbb{Q}/\mathbb{Z}$ the natural projection.

(6) Finally we denote by $\Theta\colon \mathrm{H}_1(L(p,q);\mathbb{Z}) \to \mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z})$ the map that we introduced on page 3158.

Lemma 148.26. The following statements hold:

(1) $i_*(a) \in \mathrm{H}_1(L(p,q);\mathbb{Z})$ is a generator,

(2) the equality $\Theta(i_*(a)) = \rho_*(a - \frac{q}{p} \cdot b)$ holds in $\mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z})$.

Proof. By the Excisive Triad-Proposition 109.12 we can apply the Mayer–Vietoris Theorem 109.14 to the decomposition $L(p,q) = X \cup Y$ and we obtain the following long exact sequence

$$\mathrm{H}_1(F;\mathbb{Z}) \xrightarrow{\substack{i_* \\ -i_*}} \begin{matrix} \mathrm{H}_1(X;\mathbb{Z}) \\ \mathrm{H}_1(Y;\mathbb{Z}) \end{matrix} \to \mathrm{H}_1(L(p,q);\mathbb{Z}) \to 0.$$

Recall that we denote by $a, b \in \mathrm{H}_1(F;\mathbb{Z}) = \mathrm{H}_1(S^1 \times S^1;\mathbb{Z})$ the standard basis. Since $S^1 \times S^1$ is the boundary of $S^1 \times \overline{B}^2$ we denote by a also the corresponding generator of $\mathrm{H}_1(X;\mathbb{Z}) = \mathrm{H}_1(S^1 \times \overline{B}^2;\mathbb{Z})$. Furthermore we denote by $a' \in \mathrm{H}_1(Y;\mathbb{Z}) = \mathrm{H}_1(S^1 \times \overline{B}^2;\mathbb{Z})$ the obvious generator. It follows from the above discussion and conventions, in particular

the above description of φ_*, that with respect to our bases the above long exact sequence Mayer–Vietoris sequence becomes

$$\begin{matrix}\mathbb{Z}\cdot a\\ \mathbb{Z}\cdot b\end{matrix} \xrightarrow{\begin{pmatrix}1 & 0\\ q & p\end{pmatrix}} \begin{matrix}\mathbb{Z}\cdot a\\ \mathbb{Z}\cdot a'\end{matrix} \;\to\; \mathrm{H}_1(L(p,q);\mathbb{Z}) \;\to\; 0.$$

At this stage it is an elementary linear algebra exercise to show that the image of a in $\mathrm{H}_1(L(p,q);\mathbb{Z})$ is a generator.[1763]

Now we turn to the proof of the second statement. In the following we denote by $h\colon (L(p,q),\varnothing) \to (L(p,q),X)$ and $j\colon (Y,F) \to (L(p,q),X)$ the obvious maps of pairs of topological spaces. We recall that Θ is defined as the composition of the following maps:

$$\begin{array}{ccccccc}\mathrm{H}_1(L(p,q);\mathbb{Z}) & \xrightarrow{\beta^{-1}} & \mathrm{H}_2(L(p,q);\mathbb{Q}/\mathbb{Z}) & \xrightarrow{h_*} & \mathrm{H}_2(L(p,q),X;\mathbb{Q}/\mathbb{Z}) & \underset{\cong}{\xleftarrow{j_*}} & \mathrm{H}_2(Y,F;\mathbb{Q}/\mathbb{Z})\\ & & & & & & \downarrow\ \partial\\ & & & & & & \mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z}).\end{array}$$

As before we denote by $i\colon F \to L(p,q)$ the inclusion map. For clarity we recall in the following diagram all the maps that play a role in the definition of the Bockstein homomorphism $\beta\colon \mathrm{H}_2(L(p,q);\mathbb{Q}/\mathbb{Z}) \to \mathrm{H}_1(L(p,q);\mathbb{Z})$:

$$\begin{array}{ccccccc} & & & & \mathrm{C}_2(L(p,q);\mathbb{Q}) & \xrightarrow{\rho_*} & \mathrm{C}_2(L(p,q);\mathbb{Q}/\mathbb{Z}) \longrightarrow 0\\ & & & & \big\downarrow\partial & & \\ 0 \longrightarrow & \mathrm{C}_1(L(p,q);\mathbb{Z}) & \longrightarrow & \mathrm{C}_1(L(p,q);\mathbb{Q}). & & & \end{array}$$

Finally, we denote by $\widetilde{a}$ and $\widetilde{b}$ the obvious singular chains in F representing the homology classes a and b.

Now we turn to the actual proof of the equality $\Theta(i_*(a)) = \rho_*(a - \frac{q}{p}\cdot b)$ in $\mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z})$. We consider $a - \frac{q}{p}\cdot b \in \mathrm{H}_1(F;\mathbb{Q})$. Note that

$$\varphi_*\big(a - \tfrac{q}{p}\cdot b\big) \underset{\uparrow}{=} \begin{pmatrix}q & p\\ s & r\end{pmatrix}\cdot\begin{pmatrix}1\\ -\frac{q}{p}\end{pmatrix} = \begin{pmatrix}0\\ *\end{pmatrix} \in \mathrm{H}_1(F;\mathbb{Q}) = \begin{matrix}\mathbb{Q}\cdot a\\ \mathbb{Q}\cdot b\end{matrix},$$

by the Action-on-Torus Homology Lemma 84.7 and the naturality of the Universal Coefficient Theorem 89.17

i.e. the image of $\varphi_*\big(a - \frac{q}{p}\cdot b\big)$ in $\mathrm{H}_1(Y;\mathbb{Q})$ is zero.

This implies that there exists a singular 2-chain $\sigma \in \mathrm{C}_2(Y;\mathbb{Q})$ with $\partial(\sigma) = \widetilde{a} - \frac{q}{p}\cdot\widetilde{b}$. Furthermore b represents the zero element in $\mathrm{H}_1(X;\mathbb{Z})$, hence $\widetilde{b}$ is null-homologous in X,

[1763]This can be seen as follows. We consider the map

$$\begin{array}{rcccc}\operatorname{coker}\left\{\begin{pmatrix}1 & 0\\ q & p\end{pmatrix}\colon \begin{matrix}\mathbb{Z}\cdot a\\ \mathbb{Z}\cdot b\end{matrix} \to \begin{matrix}\mathbb{Z}\cdot a\\ \mathbb{Z}\cdot a'\end{matrix}\right\} & \to & \mathbb{Z}_p\\ ra + sa' & \mapsto & qr - s.\end{array}$$

It is straightforward to see that this map is well-defined. It follows from Lemma 51.8 that the group on the left has order p. Since the map is an epimorphism and since both groups have the same order, we see that the map is in fact an isomorphism. Since the image of a on the right-hand side is a generator (here we use that q is coprime to p) we see that a also represents a generator on the left.

which implies that there exists a singular 2-chain $\mu \in \mathrm{C}_2(X;\mathbb{Z})$ with $\partial(\mu) = \widetilde{b}$. Now we calculate that

$$\beta\big(\underbrace{\big[\rho_*\big(\overbrace{\sigma + \tfrac{q}{p}\cdot\mu}^{\in \mathrm{C}_2(L(p,q);\mathbb{Q})}\big)\big]}_{\text{cycle in } \mathrm{C}_2(L(p,q);\mathbb{Q}/\mathbb{Z})}\big) \;=\; \underset{\text{definition of } \beta}{\uparrow}\; \big[\partial\big(\sigma + \tfrac{q}{p}\cdot\mu\big)\big] \;=\; \underset{\text{since } \partial(\sigma) = a - \frac{q}{p}\cdot b}{\uparrow}\; \big[\widetilde{a} - \tfrac{q}{p}\cdot\widetilde{b} + \tfrac{q}{p}\cdot\widetilde{b}\big] \;=\; i_*(a) \in \mathrm{H}_1(L(p,q);\mathbb{Q}/\mathbb{Z}).$$

Since $\mu \in \mathrm{C}_2(X;\mathbb{Z})$ and since $\sigma \in \mathrm{C}_2(Y;\mathbb{Q})$ we have the equality

$$h_*\big(\rho_*\big(\sigma + \tfrac{q}{p}\mu\big)\big) \;=\; j_*(\rho_*(\sigma)) \in \mathrm{C}_2(L(p,q), X;\mathbb{Q}/\mathbb{Z}).$$

We conclude that we have the following equalities in $\mathrm{H}_1(F;\mathbb{Q}/\mathbb{Z})$:

$$\begin{aligned}\Theta(i_*(a)) \;&\underset{\text{since } \beta([\rho_*(\sigma + \frac{q}{p}\cdot\mu)]) = i_*(a)}{=}\; \partial\big(j_*^{-1}\big(h_*\big(\big[\rho_*\big(\sigma + \tfrac{q}{p}\mu\big)\big]\big)\big)\big) \;\underset{\text{since } h_*(\rho_*(\sigma + \frac{q}{p}\mu)) = j_*(\rho_*(\sigma))}{=}\; \partial([\rho_*(\sigma)]) \\ &\underset{\text{since } \rho_*(\sigma) \text{ lives in } \mathrm{C}_2(Y;\mathbb{Q}/\mathbb{Z}) \text{ we can calculate the connecting homomorphism of } [\rho_*(\sigma)] \text{ and we obtain } [\rho_*(\partial(\sigma))]}{=}\; [\rho_*(\partial(\sigma))] \;\underset{\text{by the above}}{=}\; \big[\rho_*\big(\widetilde{a} - \tfrac{q}{p}\cdot\widetilde{b}\big)\big] \\ &=\; \rho_*\big(a - \tfrac{q}{p}\cdot b\big).\end{aligned}$$

■

Now it is straightforward to provide the proof of the Lens Space-Linking Pairing Proposition 148.20.

Proof of the Lens Space-Linking Pairing Proposition 148.20. Let $p, q \in \mathbb{N}$ be coprime. We use the notation F, X, Y and a, b as above. We write $L = L(p,q)$. We denote by $\rho\colon \mathbb{Q} \to \mathbb{Q}/\mathbb{Z}$ the natural projection. To simplify the notation we use the convention that given any abelian group A we make the usual identification $\mathrm{H}_0(L;A) = A$ and $\mathrm{H}_0(F;A) = A$ from page 1914.

We start out this proof with the following claim.

Claim. If $x, y \in \mathrm{H}_1(F;\mathbb{Z})$, then

$$\mathrm{PD}_F^{\mathbb{Z}}(x) \cap y \;=\; Q_F(y,x) \;\in\; \mathrm{H}_0(F;\mathbb{Z}) = \mathbb{Z}.$$

Proof. This claim follows from a calculation which by now is standard fare for us. For completeness' sake we carry out the details. We have

$$\begin{aligned}\mathrm{PD}_F^{\mathbb{Z}}(x) \cap y \;&\underset{\text{by definition of } \mathrm{PD}_F^{\mathbb{Z}}}{=}\; \mathrm{PD}_F^{\mathbb{Z}}(x) \cap \big(\mathrm{PD}_F^{\mathbb{Z}}(y) \cap [F]\big) \;\underset{\text{Cup-Cap Lemma 116.7}}{=}\; \big(\mathrm{PD}_F^{\mathbb{Z}}(y) \cup \mathrm{PD}_F^{\mathbb{Z}}(x)\big) \cap [F] \\ &\underset{\text{Cap Product-Kronecker Lemma 116.4}}{=}\; \big\langle \mathrm{PD}_F^{\mathbb{Z}}(y) \cup \mathrm{PD}_F^{\mathbb{Z}}(x), [F]\big\rangle \;\underset{\text{by definition of } Q_F}{=}\; Q_F(y,x).\end{aligned}$$

⊞

From Lemma 148.26 we know that the map

$$\begin{array}{ccc} \mathbb{Z}_p & \to & \mathrm{H}_1(L(p,q);\mathbb{Z}) \\ x & \mapsto & x \cdot i_*(a) \end{array}$$

is an isomorphism. Thus it remains to prove the following claim.

Claim.

$$\lambda_L(i_*(a), i_*(a)) \;=\; \frac{q}{p} \in \mathbb{Q}/\mathbb{Z}.$$

Proof. We calculate that

$$\begin{array}{lll}
\lambda_L(i_*(a), i_*(a)) & = \overbrace{\beta^{-1}(\mathrm{PD}_L^{\mathbb{Z}}(i_*(a)))}^{\in \mathrm{H}^1(L;\mathbb{Q}/\mathbb{Z})} \cap \overbrace{i_*(a)}^{\in \mathrm{H}_1(L;\mathbb{Z})} & = \overbrace{i^*\big(\mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}(\Theta(i_*(a)))\big)}^{\in \mathrm{H}^1(L;\mathbb{Q}/\mathbb{Z})} \cap \overbrace{i_*(a)}^{\in \mathrm{H}_1(L;\mathbb{Z})} \\
\uparrow & & \uparrow \\
\text{Lemma 148.19} & & \text{Lemma 148.25 applied to } i_*(a) \in \mathrm{H}_1(L;\mathbb{Z}) \\
= \mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}\big(\rho_*\big(a - \tfrac{q}{p}\cdot b\big)\big) \cap a & & = \rho_*\big(\mathrm{PD}_F^{\mathbb{Q}}\big(a - \tfrac{q}{p}\cdot b\big)\big) \cap a \\
\uparrow & & \uparrow \\
\text{Lemmas 148.9 (4) and 148.26 (2)} & & \text{Lemma 148.11} \\
= \rho\big(\mathrm{PD}_F^{\mathbb{Q}}\big(a - \tfrac{q}{p}\cdot b\big) \cap a\big) & & = \rho\big(\mathrm{PD}_F^{\mathbb{Z}}(a) \cap a - \tfrac{q}{p}\cdot\big(\mathrm{PD}_F^{\mathbb{Z}}(b) \cap a\big)\big) \\
\uparrow & & \uparrow \\
\text{Lemma 148.9 (3)} & & \text{Lemma 148.11} \\
= \rho\big(Q_F(a,a) - \tfrac{q}{p}Q_F(a,b)\big) & & = -\rho\big(\tfrac{q}{p}\big). \\
\uparrow & & \uparrow \\
\text{by the claim} & & \text{by page 2881 we have } Q_F(a,a) = 0 \text{ and } Q_F(a,b) = 1
\end{array}$$

∎

148.8. **Computing the linking pairing by intersecting singular simplices.** Many working topologists would rather forgo the austere beauty of cup and cap products and they would rather work and calculate by "intersecting simplices". The following proposition shows that in many (most? all?) situations one can calculate linking pairings geometrically by determining algebraic intersection numbers of singular chains.

Proposition 148.27. Let $n \geq 1$, let M be an oriented $(2n+1)$-dimensional rational homology sphere and let $x, y \in \mathrm{H}_n(M;\mathbb{Z})$. Let σ and τ be cycles in $\mathrm{C}_n(M;\mathbb{Z})$ that represent x and y. From Lemma 148.1 we know that $\mathrm{H}_n(M;\mathbb{Z})$ is torsion, hence there exists a $d \in \mathbb{N}$ such that $d \cdot x = 0 \in \mathrm{H}_n(M;\mathbb{Z})$ which means that $d \cdot \sigma$ is null-homologous. Suppose $\Sigma \in \mathrm{C}_{n+1}(M;\mathbb{Z})$ is a singular chain with $\partial\Sigma = d \cdot \sigma$. If Σ and τ intersect transversally in the sense of the definition on page 2785, then

$$\lambda_M(x,y) \;=\; (-1)^n \cdot \frac{1}{d} \cdot \underbrace{\Sigma \cdot \tau}_{\substack{\text{algebraic intersection} \\ \text{number as defined on page 2785}}} \;\in \mathbb{Q}/\mathbb{Z}.$$

Remark. Alas, all too often in the literature the right-hand side of Proposition 148.27 gets confused with the actual definition of the linking pairing, see e.g. [**Frie2004**, p. 899] for a typical example.

The proof of the proposition rests on a variation on Theorem 127.9. Before we can formulate that variation we make the following observation.

Observation. Let M be an oriented m-dimensional topological manifold and let A and B be abelian groups. Basically the same definitions as on page 2785 allow us to say that chains $\sigma \in \mathrm{C}_k(M;A)$ and $\tau \in \mathrm{C}_{m-k}(M;B)$ are *transverse* and they allow us to define the *algebraic intersection invariant* $\sigma \cdot_{\otimes} \tau \in A \otimes B$.

Now we can formulate the following slight variation on Theorem 127.9.

Proposition 148.28. Let M be a closed oriented m-dimensional topological manifold, let A and B be abelian groups and let $\sigma \in \mathrm{C}_k(M;A)$ and $\tau \in \mathrm{C}_{m-k}(M;B)$ be two cycles. If σ and τ are transverse, then

$$\epsilon_M\Big(\big(\overbrace{\mathrm{PD}_M^A([\sigma])}^{\in \mathrm{H}^{m-k}(M;A)} \underbrace{\cup_\otimes}_{\in \mathrm{H}^m(M;A\otimes B)} \overbrace{\mathrm{PD}_M^B([\tau])}^{\in \mathrm{H}^k(M;B)}\big) \cap [M]\Big) \;=\; \sigma \cdot_\otimes \tau \;\in\; A \otimes B.$$

Proof. The proof of Theorem 127.9 generalizes without a hitch to give us this statement with more fancy coefficients. ∎

Proof of Proposition 148.27. As before we denote by $\nu\colon \mathbb{Q}/\mathbb{Z}\otimes\mathbb{Z} \to \mathbb{Q}/\mathbb{Z}$ the multiplication induced isomorphism. We perform the following calculation:

$$\begin{aligned}
\lambda_M(x,y) &\overset{\text{by the definition on page 3151, Lemma 148.9 (2) and Lemma 148.9 (3) applied to } \nu}{\downarrow} \\
&= \nu_*\big(\epsilon_M\big(\big(\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(x)) \cup_\otimes \mathrm{PD}_M^{\mathbb{Z}}(y)\big) \cap [M]\big)\big) \\
&= (-1)^n \cdot \nu_*\big(\epsilon_M\big(\big(\mathrm{PD}_M^{\mathbb{Q}/\mathbb{Z}}(\beta^{-1}(x)) \cup_\otimes \mathrm{PD}_M^{\mathbb{Z}}(y)\big) \cap [M]\big)\big) \\
&\overset{\text{Lemma 148.24}}{\uparrow} \\
&= (-1)^n \cdot \nu_*\big(\big(\tfrac{1}{d}\otimes\Sigma\big) \cdot_\otimes \tau\big) \;\underset{\text{follows immediately from the definitions}}{=}\; (-1)^n \cdot \tfrac{1}{d}\cdot\Sigma\cdot\tau \;\in\; \mathbb{Q}/\mathbb{Z}.
\end{aligned}$$

$\uparrow$ by Proposition 148.28 and the observation that $\frac{1}{d}\otimes\Sigma$ represents $\beta^{-1}(x)$

∎

148.9. **Linking pairings and intersection forms.** Let M be a compact oriented connected 4-dimensional topological manifold. We suppose that $Y = \partial M$ is a rational homology sphere. In this section we want to study, in favorable situations, the relationship between the intersection form Q_M on M and the linking pairing λ_Y on Y. Before we can state the relevant result let us recall the following definitions from pages 2800 and 2895.

Definition. Let M be a compact oriented connected $2n$-dimensional topological manifold M. The intersection form of M is defined as the form[1764]

$$\begin{aligned}
Q_M\colon \mathrm{FH}_n(M;\mathbb{Z}) \times \mathrm{FH}_n(M;\mathbb{Z}) &\to \mathbb{Z} \\
(a,b) &\mapsto \Big\langle \underbrace{\underbrace{\mathrm{PD}_M(a)}_{\in \mathrm{FH}^n(M,\partial M;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(b)}_{\in \mathrm{FH}^n(M,\partial M;\mathbb{Z})}}_{\in \mathrm{FH}^{2n}(M,\partial M;\mathbb{Z})}, [M] \Big\rangle.
\end{aligned}$$

Furthermore the asymmetric intersection pairing of M is defined as the map

$$\begin{aligned}
\widetilde{Q}_M\colon \mathrm{FH}_n(M;\mathbb{Z}) \times \mathrm{FH}_n(M,\partial M;\mathbb{Z}) &\to \mathbb{Z} \\
(v,w) &\mapsto \Big\langle \underbrace{\underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{FH}^n(M,\partial M;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{FH}^n(M;\mathbb{Z})}}_{\in \mathrm{FH}^{2n}(M,\partial M;\mathbb{Z})}, [M] \Big\rangle
\end{aligned}$$

For the reader's convenience we recall the following proposition.

[1764] Here, given an abelian group H we write $\mathrm{F}H := H/\text{torsion subgroup}$ for the maximal torsion-free quotient of H.

Proposition 132.15 (Reduced Intersection Form Proposition). Let M be a compact oriented connected $2n$-dimensional topological manifold. We denote by $p_*\colon \mathrm{H}_n(M;\mathbb{Z}) \to \mathrm{H}_n(M,\partial M;\mathbb{Z})$ the obvious map.

(1) The pairing $Q_M^{\mathrm{as}}\colon \mathrm{FH}_n(M;\mathbb{Z}) \times \mathrm{FH}_n(M,\partial M;\mathbb{Z}) \to \mathbb{Z}$ is non-singular.

(2) The following diagram commutes:

$$\begin{array}{ccc} \mathrm{FH}_n(M;\mathbb{Z}) \times \mathrm{FH}_n(M;\mathbb{Z}) & \xrightarrow{\quad Q_M \quad} & \mathbb{Z} \\ \downarrow{\scriptstyle \mathrm{id}\times p_*} & & \downarrow{\scriptstyle \mathrm{id}} \\ \mathrm{FH}_n(M;\mathbb{Z}) \times \mathrm{FH}_n(M,\partial M;\mathbb{Z}) & \xrightarrow{\quad Q_M^{\mathrm{as}} \quad} & \mathbb{Z}. \end{array}$$

(3) Let $v_1,\dots,v_m$ be a basis of the free abelian group $\mathrm{FH}_n(M;\mathbb{Z})$. By (1) together with Exercise 121.2 (a) there exists a unique basis $w_1,\dots,w_m$ of the free abelian group $\mathrm{FH}_k(M,\partial M;\mathbb{Z})$ with $Q_M^{\mathrm{as}}(v_i,w_j)=\delta_{ij}$ for all $i,j\in\{1,\dots,m\}$. We denote by A the $(m\times m)$–matrix that represents the intersection form Q_M with respect to the basis $v_1,\dots,v_n$, i.e. we have $A=(a_{ij})$ with $a_{ij}=Q_M(v_i,v_j)$. This matrix represents the map $p_*\colon \mathrm{FH}_n(M;\mathbb{Z}) \to \mathrm{FH}_n(M,\partial M;\mathbb{Z})$ with respect to the bases $v_1,\dots,v_m$ and $w_1,\dots,w_m$.

The following proposition is the main result of this section.

Proposition 148.29. (Linking Pairing-via-Intersection Form Proposition) Let M be a compact oriented connected 4-dimensional topological manifold such that $Y=\partial M$ is a rational homology sphere. We suppose that $\mathrm{H}_1(M;\mathbb{Z})=0$. The following statements hold:

(1) The groups $\mathrm{H}_2(M,Y;\mathbb{Z})$ and $\mathrm{H}_2(M;\mathbb{Z})$ are free abelian groups of finite rank.

(2) By (1) we can pick a basis $v_1,\dots,v_m$ for the free abelian group $\mathrm{H}_2(M;\mathbb{Z})$. By the Asymmetric Intersection Pairing Proposition 132.15 together with Exercise 121.2 (a) there exists a unique basis $w_1,\dots,w_m$ for the free abelian group $\mathrm{H}_2(M,Y;\mathbb{Z})$ with $Q_M^{\mathrm{as}}(v_i,w_j)=\delta_{ij}$. We denote by $A=(Q_M(v_i,v_j))$ the $(m\times m)$–matrix that represents the intersection form with respect to the basis $v_1,\dots,v_m$. The following three statements hold:

(a) If we denote by $\Psi\colon \mathbb{Z}^m \to \mathrm{H}_2(M,Y;\mathbb{Z})$ the isomorphism that is given by the basis $w_1,\dots,w_m$, then the map

$$\begin{array}{rcl} \Theta\colon \mathbb{Z}^m/A\mathbb{Z}^m & \to & \mathrm{H}_1(Y;\mathbb{Z}) \\ [u] & \mapsto & \partial(\Psi(u)) \end{array}$$

∂: connecting homomorphism $\partial\colon \mathrm{H}_2(M,Y;\mathbb{Z}) \to \mathrm{H}_1(Y;\mathbb{Z})$ of the pair (M,Y)

is well-defined and it is an isomorphism.

(b) The matrix A is symmetric and it satisfies $\det(A)\neq 0$.

(c) The isomorphism Θ from (a) is in fact an isometry from[1765]

$$\begin{array}{rcl} \mathbb{Z}^m/A\mathbb{Z}^m \times \mathbb{Z}^m/A\mathbb{Z}^m & \xrightarrow{\lambda(A)} & \mathbb{Q}/\mathbb{Z} \\ ([v],[w]) & \longmapsto & v^T A^{-1} w \end{array} \quad \text{to} \quad \underbrace{\mathrm{H}_1(Y;\mathbb{Z}) \times \mathrm{H}_1(Y;\mathbb{Z}) \xrightarrow{\lambda_Y} \mathbb{Q}/\mathbb{Z}.}_{\text{linking pairing}}$$

Remark.

[1765] It follows from (b) and the Linking Form-Matrix Lemma 148.13 that the form $\lambda(A)$ is in fact defined.

(1) We leave it to the reader to figure out what is a correct higher-dimensional analogue of the Linking Pairing-via-Intersection Form Proposition 148.29. The reader will found out, that determining the correct sign is a never ending source of hilarious entertainment.
(2) Often it is (psychologically) easier to compute intersection forms of smooth manifolds, thus on many occasions in the literature linking pairings are computed by calculating the intersection form of a suitable bounding smooth manifold.

The following lemma is the key technical ingredient in the proof of the Linking Pairing-via-Intersection Form Proposition 148.29.

Lemma 148.30. Let M be a compact oriented connected 4-dimensional topological manifold such that $Y = \partial M$ is a rational homology sphere. We denote by $i\colon Y \to M$ the inclusion and we denote by $p\colon \mathrm{C}_*(M) \to \mathrm{C}_*(M,Y)$ the projection . The following diagram commutes up to a minus sign:

$$\begin{array}{ccccc} \mathrm{H}^2(M;\mathbb{Z}) & \xrightarrow{i^*} & \mathrm{H}^2(Y;\mathbb{Z}) & \xrightarrow[\cong]{\beta^{-1}} & \mathrm{H}^1(Y;\mathbb{Q}/\mathbb{Z}) \\ \downarrow & & & & \downarrow{\scriptstyle \delta} \\ \mathrm{H}^2(M;\mathbb{Q}) & \xrightarrow[\cong]{(p^*)^{-1}} & \mathrm{H}^2(M,Y;\mathbb{Q}) & \longrightarrow & \mathrm{H}^2(M,Y;\mathbb{Q}/\mathbb{Z}). \end{array}$$

Remark. The encyclopedic reader will not have failed to notice that Lemma 148.30 is a special case of Exercise 74.13.

Proof of Lemma 148.30. Throughout the proof we adopt the following conventions:

(1) Given a cochain ψ that takes values in $\mathbb{Q}$ we denote by $\overline{\psi}$ the corresponding cochain that takes values in $\mathbb{Q}/\mathbb{Z}$.
(2) If ψ is a cochain that takes values in $\mathbb{Z}$, then we view it also as a cochain with values in $\mathbb{Q}$.

Now let $\phi \in \mathrm{C}^2(M;\mathbb{Z}) = \mathrm{Hom}(\mathrm{C}_2(M),\mathbb{Z})$ be a cochain. Note that the Poincaré Duality Theorem 119.1 implies that $\mathrm{H}^i(Y;\mathbb{Q}) \cong \mathrm{H}_i(Y;\mathbb{Q}) = 0$ for $i = 1,2$. Thus we obtain from the long exact sequence of the pair (M,Y) that the map $p^*\colon \mathrm{H}^2(M,Y;\mathbb{Q}) \to \mathrm{H}^2(M;\mathbb{Q})$ is an isomorphism. In particular we see that there exists a cochain $\psi \in \mathrm{C}^2(M,Y;\mathbb{Q})$ such that $[\phi] = [p^*\psi] \in \mathrm{H}^2(M;\mathbb{Q})$. This means that there exists some $\alpha \in \mathrm{C}^1(M;\mathbb{Q})$ such that $p^* \circ \psi - \phi = \delta\alpha$. We write $\varphi := \alpha|_{\mathrm{C}_1(Y)}$. We calculate that

$$\delta\overline{\varphi} \underset{\text{restriction is a cochain map}}{\overset{\uparrow}{=}} \overline{\delta\alpha}|_{\mathrm{C}_2(Y)} = \overline{p^*\circ\psi - \phi}|_{\mathrm{C}_2(Y)} \underset{\text{since } p^*\circ\psi \text{ vanishes on } \mathrm{C}_2(Y)}{\overset{\uparrow}{=}} \overline{\phi}|_{\mathrm{C}_2(Y)} \underset{\text{since } \phi \text{ takes integral values.}}{\overset{\uparrow}{=}} 0 \in \mathrm{C}^2(Y;\mathbb{Q}/\mathbb{Z}).$$

In other words, $\overline{\varphi}$ represents an element in $\mathrm{H}^1(Y;\mathbb{Q}/\mathbb{Z})$. The following claim computes the two possible connecting homomorphisms.

Claim. We have $\delta([\overline{\varphi}]) = [\overline{\psi}]$ and $\beta([\overline{\varphi}]) = -[i^*(\phi)]$.

Proof. The claim follows from considering the following two sequences of maps and elements:

$$\underbrace{\begin{array}{ccc} \overset{(4)\ \overline{\psi}}{\mathrm{C}^2(M,Y;\mathbb{Q}/\mathbb{Z})} & \overset{p^*}{\to} & \overset{(3)\ \overline{p^*\psi-\phi=p^*\psi}}{\mathrm{C}^2(M;\mathbb{Q}/\mathbb{Z})} \\ & & \delta\uparrow \\ & & \mathrm{C}^1(M;\mathbb{Q}/\mathbb{Z}) \overset{i^*}{\to} \underset{(1)\ \overline{\varphi}}{\mathrm{C}^1(Y;\mathbb{Q}/\mathbb{Z})} \end{array}}_{\text{defines the connecting homomorphism } \delta} \quad \& \quad \underbrace{\begin{array}{ccc} \overset{(4)\ -i^*\phi}{\mathrm{C}^2(Y;\mathbb{Z})} & \to & \overset{(3)\ \overbrace{i^*p^*\psi}^{=0}-i^*\phi}{\mathrm{C}^2(Y;\mathbb{Q})} \\ & & \delta\uparrow \\ & & \underset{(2)\ \varphi=i^*\alpha}{\mathrm{C}^1(Y;\mathbb{Q})} \longrightarrow \underset{(1)\ \overline{\varphi}}{\mathrm{C}^1(Y;\mathbb{Q}/\mathbb{Z})}. \end{array}}_{\text{defines the Bockstein homomorphism } \beta}$$

⊞

Now we are basically done. We consider $[\phi] \in \mathrm{H}^2(M;\mathbb{Z})$ and we consider its two possible journeys to $\mathrm{H}^2(M,Y;\mathbb{Q}/\mathbb{Z})$ through the following diagram:

$$\begin{array}{ccccc} \mathrm{H}^2(M;\mathbb{Z}) & \xrightarrow{i^*} & \mathrm{H}^2(Y;\mathbb{Z}) & \xrightarrow[\cong]{\beta^{-1}} & \mathrm{H}^1(Y;\mathbb{Q}/\mathbb{Z}) \\ \downarrow\Theta & & & & \downarrow\delta \\ \mathrm{H}^2(M;\mathbb{Q}) & \xrightarrow[\cong]{(p^*)^{-1}} & \mathrm{H}^2(M,Y;\mathbb{Q}) & \xrightarrow[[\omega]\mapsto[\overline{\omega}]]{\Omega} & \mathrm{H}^2(M,Y;\mathbb{Q}/\mathbb{Z}). \end{array}$$

First we go down and right. We see that

$$\Omega((p^*)^{-1}(\Theta([\phi\colon \mathrm{C}_2(M) \to \mathbb{Z}]))) \underset{\text{definition of } \Theta}{=} \Omega((p^*)^{-1}([\phi\colon \mathrm{C}_2(M) \to \mathbb{Q}])) \underset{\text{since } [\phi]=[p^*\psi]}{=} \Omega([\psi]) = [\overline{\psi}]$$

Next we go right and down. We see that

$$\delta(\beta^{-1}(i^*([\phi]))) = \delta(\beta^{-1}([i^*(\phi)])) \underset{\text{by the claim}}{=} -\delta([\overline{\varphi}]) \underset{\text{by the claim}}{=} -[\overline{\psi}]$$

This shows that the two possible outcomes differ by a minus sign. ■

The following lemma relates the linking pairing of a rational homology sphere to the intersection form of a bounding smooth manifold. The lemma is of interest also outside of the application to the Linking Pairing-via-Intersection Form Proposition 148.29.

Lemma 148.31. Let M be a compact oriented connected 4-dimensional topological manifold such that its boundary $Y = \partial M$ is a rational homology sphere. There exists a pairing $\chi\colon \mathrm{H}_2(M,Y;\mathbb{Z}) \times \mathrm{H}_2(M,Y;\mathbb{Z}) \to \mathbb{Q}$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_2(M;\mathbb{Z}) \times \mathrm{H}_2(M;\mathbb{Z}) & \xrightarrow{Q_M} & \mathbb{Z} \\ \downarrow{\scriptstyle p_*\times p_*} & & \downarrow \\ \mathrm{H}_2(M,Y;\mathbb{Z}) \times \mathrm{H}_2(M,Y;\mathbb{Z}) & \xrightarrow{\chi} & \mathbb{Q} \\ \downarrow{\scriptstyle \partial\times\partial} & & \downarrow \\ \mathrm{H}_1(Y;\mathbb{Z}) \times \mathrm{H}_1(Y;\mathbb{Z}) & \xrightarrow[\lambda_Y]{} & \mathbb{Q}/\mathbb{Z}. \end{array}$$

Proof. Let M be a compact oriented connected 4-dimensional topological manifold such that its boundary $Y = \partial M$ is a rational homology sphere. In the following we denote by $\varphi\colon \mathbb{Z} \to \mathbb{Q}$ the inclusion. Next we consider the following diagram:

$$\begin{array}{ccccc} \mathrm{H}_2(M;\mathbb{Z}) & \xrightarrow{p_*} & \mathrm{H}_2(M,Y;\mathbb{Z}) & \xrightarrow{\partial} & \mathrm{H}_1(Y;\mathbb{Z}) \\ \cong\downarrow \mathrm{PD}_M & & \cong\downarrow \mathrm{PD}_M & & \cong\downarrow \mathrm{PD}_Y \\ \mathrm{H}^2(M,Y;\mathbb{Z}) & \xrightarrow{p^*} & \mathrm{H}^2(M;\mathbb{Z}) & \xrightarrow{i^*} & \mathrm{H}^2(Y;\mathbb{Z}). \end{array}$$

By Proposition 119.25 the diagram commutes.[1766] The diagram with the vertical isomorphisms allows us to translate our above problem into a different task. Namely it follows from the diagram and the definition of the intersection form Q_M that it suffices to show that there exists a pairing $\chi\colon \mathrm{H}^2(M;\mathbb{Z}) \times \mathrm{H}^2(M;\mathbb{Z}) \to \mathbb{Q}$ such that the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}^2(M,Y\,\mathbb{Z}) \times \mathrm{H}^2(M,Y;\mathbb{Z}) & \xrightarrow{\cup} & \mathrm{H}^4(M,Y;\mathbb{Z}) & \xrightarrow{\langle -,[M]\rangle} & \mathbb{Z} \\ \downarrow p^*\times p^* & & & & \downarrow \varphi \\ \mathrm{H}^2(M;\mathbb{Z}) \times \mathrm{H}^2(M;\mathbb{Z}) & & \xrightarrow{\chi} & & \mathbb{Q} \\ \downarrow \mathrm{PD}_Y^{-1}\circ i^* \times \mathrm{PD}_Y^{-1}\circ i^* & & & & \downarrow \\ \mathrm{H}_1(Y;\mathbb{Z}) \times \mathrm{H}_1(Y;\mathbb{Z}) & & \xrightarrow[\lambda_Y]{} & & \mathbb{Q}/\mathbb{Z}. \end{array}$$

The key to proving the existence of such a pairing χ is the following daunting[1767] diagram:

$$\begin{array}{ccccccc}
\mathrm{H}^2(M,Y;\mathbb{Z})\times\mathrm{H}^2(M,Y;\mathbb{Z}) & & \xrightarrow{\cup} & & \mathrm{H}^4(M,Y;\mathbb{Z}) & \xrightarrow{\langle -,[M]\rangle} & \mathbb{Z} \\
\downarrow & \searrow^{\varphi_*\times\mathrm{id}} & \text{(I)} & & \downarrow\varphi_* & \text{(II)} & \downarrow\varphi \\
 & \mathrm{H}^2(M,Y;\mathbb{Q})\times\mathrm{H}^2(M,Y;\mathbb{Z}) & \xrightarrow[\cup]{} & \mathrm{H}^4(M,Y;\mathbb{Q}) & & \xrightarrow[\langle -,[M]\rangle]{} & \mathbb{Q} \\
p^*\times p^* \quad \text{(III)} & \mathrm{id}\downarrow \quad \downarrow p^* & \text{(IV)} & \downarrow = & & \text{(V)} & \downarrow = \\
 & \mathrm{H}^2(M,Y;\mathbb{Q})\times\mathrm{H}^2(M;\mathbb{Z}) & \xrightarrow[\cup]{} & \mathrm{H}^4(M,Y;\mathbb{Q}) & & \xrightarrow[\langle -,[M]\rangle]{} & \mathbb{Q} \\
 & p^*\downarrow \quad \downarrow \mathrm{id} & & & & & \\
\boxed{\mathrm{H}^2(M;\mathbb{Z})\times\mathrm{H}^2(M;\mathbb{Z})} & \xrightarrow{\varphi_*\times\mathrm{id}} & \boxed{\mathrm{H}^2(M;\mathbb{Q})\times\mathrm{H}^2(M;\mathbb{Z})} & & \text{(VI)} & & = \\
\downarrow & & (p^*)^{-1}\downarrow \quad \downarrow \mathrm{id} & & & & \downarrow \\
 & & \boxed{\mathrm{H}^2(M,Y;\mathbb{Q})\times\mathrm{H}^2(M;\mathbb{Z})} & \xrightarrow{\cup} & \boxed{\mathrm{H}^4(M,Y;\mathbb{Q})} & \xrightarrow{\langle -,[M]\rangle} & \boxed{\mathbb{Q}} \\
i^*\times i^* \quad \text{(VII)} & & \downarrow \quad \downarrow \mathrm{id} & \text{(VIII)} & \downarrow & \text{(IX)} & \downarrow \\
 & & \mathrm{H}^2(M,Y;\mathbb{Q}/\mathbb{Z})\times\mathrm{H}^2(M;\mathbb{Z}) & \xrightarrow{\cup} & \mathrm{H}^4(M,Y;\mathbb{Q}/\mathbb{Z}) & \xrightarrow{\langle -,[M]\rangle} & \mathbb{Q}/\mathbb{Z} \\
 & & \delta\uparrow \quad \downarrow i^* & \text{(X)} & \delta\uparrow & \text{(XI)} & \downarrow = \\
\mathrm{H}^2(Y;\mathbb{Z})\times\mathrm{H}^2(Y;\mathbb{Z}) & \xrightarrow{\beta^{-1}\times\mathrm{id}} & \mathrm{H}^1(Y;\mathbb{Q}/\mathbb{Z})\times\mathrm{H}^2(Y;\mathbb{Z}) & \xrightarrow{\cup} & \mathrm{H}^3(Y;\mathbb{Q}/\mathbb{Z}) & \xrightarrow{\langle -,[Y]\rangle} & \mathbb{Q}/\mathbb{Z} \\
\uparrow \mathrm{PD}_Y\times\mathrm{PD}_Y & & \text{(XII)} & & & & \downarrow = \\
\mathrm{H}_1(Y;\mathbb{Z}) \times \mathrm{H}_1(Y;\mathbb{Z}) & & \xrightarrow[\lambda_Y]{} & & & & \mathbb{Q}/\mathbb{Z}.
\end{array}$$

[1766] To be more precise, the square on the right commutes up to the $(-1)^2$, which happens to be $+1$.

[1767] As a wise person once said: if you want to do topology rigorously, then the diagrams become large.

The promised pairing χ is given by the traveling along the route that is traced out by the boxes. Thus it remains to prove that the diagram commutes. We make the following clarifications and observations:

(I) The lower cup product is the composition of the cup product as defined in Lemma 148.5 with the obvious map $\mathbb{Z} \otimes \mathbb{Q} \xrightarrow{\cong} \mathbb{Q}$. It follows basically immediately from the definitions that the square commutes, see also the Cup Product-Naturality Proposition 115.4 (2).
(II) This square commutes by Lemma 109.6 (2).
(III) This square commutes since changing coefficients is a natural transformation, see Lemma 108.9.
(IV) This square commutes by a mild generalization of the Cup Product-Naturality Proposition 115.4 (1).
(V) What a relief, there is nothing to show.
(VI) Note that the two vertical maps to the left of the square are inverses of one another. So we see that nothing happens in this square.
(VII) This rectangle commutes by Lemma 148.30.
(VIII) Similar to (I) the cup products are the composition of the cup product as defined in Lemma 148.5 with the obvious maps $\mathbb{Z} \otimes \mathbb{Q} \xrightarrow{\cong} \mathbb{Q}$ and $\mathbb{Z} \otimes \mathbb{Q}/\mathbb{Z} \xrightarrow{\cong} \mathbb{Q}/\mathbb{Z}$. As in (I) we see that the square commutes.
(IX) By the same argument as in (II) we see that the square commutes.
(X) A slight generalization of the Cup Product-Connecting Homomorphism Lemma 115.6 to more general coefficients shows that the square commutes up to the sign $(-1)^2 = 1$.
(XI) By the Fundamental Class-of-Boundary Proposition 106.27 we have $\partial([M]) = [Y]$. It follows from a minute generalization of the Cap Product-Connecting Homomorphism Lemma 116.10 (1) that this square commutes.
(XII) This rectangle commutes by definition of the linking pairing. ■

Proof of the Linking Pairing-via-Intersection Form Proposition 148.29. We consider the following maps:

$$\begin{array}{ccccccccc}
\mathrm{H}_2(M;\mathbb{Z}) & \xrightarrow{p_*} & \mathrm{H}_2(M,Y;\mathbb{Z}) & \xrightarrow{\partial} & \mathrm{H}_1(Y;\mathbb{Z}) & \to & \overbrace{\mathrm{H}_1(M;\mathbb{Z})}^{=0 \text{ by hypothesis}} & \to & \mathrm{H}_1(M,Y;\mathbb{Z}) \to 0. \\
\cong\downarrow \mathrm{PD}_M & & \cong\downarrow \mathrm{PD}_M & & & & & & \\
\mathrm{H}^2(M,Y;\mathbb{Z}) & & \mathrm{H}^2(M;\mathbb{Z}) & & & & & & \\
\cong\downarrow \mathrm{ev} & & \cong\downarrow \mathrm{ev} & & & & & & \\
\mathrm{Hom}(\mathrm{H}_2(M,Y;\mathbb{Z}),\mathbb{Z}) & & \mathrm{Hom}(\mathrm{H}_2(M;\mathbb{Z}),\mathbb{Z}). & & & & & &
\end{array}$$

We make the following observations:

(a) The horizontal sequence is the long exact sequence in reduced homology of the pair (M,Y).
(b) By hypothesis we have $\mathrm{H}_1(M;\mathbb{Z}) = 0$.
(c) It follows from (a) and (b) that $\mathrm{H}_1(M,Y;\mathbb{Z}) = 0$.
(d) The vertical maps PD_M are the Poincaré Duality isomorphisms given by the Poincaré Duality Theorem 119.1.

(e) It follows from (b), (c) and the Universal Coefficient Theorem 110.12 that both evaluation homomorphisms ev are isomorphisms.

(f) We obtain from the above discussion that $\mathrm{H}_2(M;\mathbb{Z}) \cong \mathrm{Hom}(\mathrm{H}_2(M,Y;\mathbb{Z}),\mathbb{Z})$ and that $\mathrm{H}_2(M,Y;\mathbb{Z}) \cong \mathrm{Hom}(\mathrm{H}_2(M;\mathbb{Z}),\mathbb{Z})$. It follows from the Topological Manifolds-Invariants Proposition 104.14 (4) and Lemma 96.8 (1) together with the Finitely Generated Abelian Group Classification Theorem 51.4 that $\mathrm{H}_2(M;\mathbb{Z})$ and $\mathrm{H}_2(M,Y;\mathbb{Z})$ are free abelian groups. In particular we have now shown Statement (1) of the proposition.

We pick a basis $v_1,\dots,v_m$ for the free abelian group $\mathrm{H}_2(M;\mathbb{Z})$. We denote by $w_1,\dots,w_m$ the unique basis for the free abelian group $\mathrm{H}_2(M,Y;\mathbb{Z})$ with $Q_M^{\mathrm{as}}(v_i,w_j)=\delta_{ij}$. We denote by $A=(a_{ij})$ the $(m\times m)$–matrix that is given by $a_{ij}=Q_M(v_i,v_j)$. Note that it follows from the Intersection Form Proposition 132.4 (2) that A is symmetric.

We denote by $\Phi\colon \mathbb{Z}^m \xrightarrow{\cong} \mathrm{H}_2(M;\mathbb{Z})$ and $\Psi\colon \mathbb{Z}^m \xrightarrow{\cong} \mathrm{H}_2(M,Y;\mathbb{Z})$ the isomorphisms that are given by the above bases. From the above long exact sequence together with the Asymmetric Intersection Pairing Proposition 132.15 we obtain the following commutative diagram:

$$\begin{array}{ccccccc}
\mathbb{Z}^m & \xrightarrow{u\mapsto A\cdot u} & \mathbb{Z}^m & \longrightarrow & \mathbb{Z}^m/A\mathbb{Z}^m & \longrightarrow & 0 \\
\downarrow{\scriptstyle\Phi}\cong & & \cong\downarrow{\scriptstyle\Psi} & & \vdots{\scriptstyle\Theta} & & \\
\mathrm{H}_2(M;\mathbb{Z}) & \xrightarrow{p_*} & \mathrm{H}_2(M,Y;\mathbb{Z}) & \xrightarrow{\partial} & \mathrm{H}_1(Y;\mathbb{Z}) & \longrightarrow & 0
\end{array}$$

Note that the lower sequence is exact by the discussion above. Furthermore note that the diagram commutes by the Asymmetric Intersection Pairing Proposition 132.15 (2). It follows immediately that the map $\partial\circ\Psi\colon \mathbb{Z}^m \to \mathrm{H}_1(Y;\mathbb{Z})$ descends to an isomorphism $\mathbb{Z}^m/A\mathbb{Z}^m \to \mathrm{H}_1(Y;\mathbb{Z})$. This concludes the proof of statement (2a).

Next note that it follows from statement (2a), the fact that $\mathrm{H}_1(Y;\mathbb{Z})$ is finite and Lemma 51.8 that $\det(A)\neq 0$. This concludes the proof of statement (2b).

It remains to prove statement (2c). By Lemma 148.31 we know that there exists a pairing $\chi\colon \mathrm{H}_2(M,Y;\mathbb{Z})\times\mathrm{H}_2(M,Y;\mathbb{Z})\to\mathbb{Q}$ such that the following diagram commutes:

$$\begin{array}{ccc}
\mathrm{H}_2(M;\mathbb{Z})\times\mathrm{H}_2(M;\mathbb{Z}) & \xrightarrow{Q_M} & \mathbb{Z} \\
\downarrow{\scriptstyle p_*\times p_*} & & \downarrow \\
\mathrm{H}_2(M,Y;\mathbb{Z})\times\mathrm{H}_2(M,Y;\mathbb{Z}) & \xrightarrow{\chi} & \mathbb{Q} \\
\downarrow{\scriptstyle\partial\times\partial} & & \downarrow \\
\mathrm{H}_1(Y;\mathbb{Z})\times\mathrm{H}_1(Y;\mathbb{Z}) & \xrightarrow[\lambda_Y]{} & \mathbb{Q}/\mathbb{Z}.
\end{array}$$

If we equip $\mathrm{H}_2(M;\mathbb{Z})$ and $\mathrm{H}_2(M,Y;\mathbb{Z})$ with the above bases, then we know by the Asymmetric Intersection Pairing Proposition 132.15 (3) that the map p_* is represented by the matrix

A. Furthermore, by definition A represents the intersection form Q_M. Now, for purely algebraic reasons we see that χ is represented by the rational matrix A^{-1}.[1768] Statement (2c) follows immediately from these observations and the above commutative diagram. ■

Exercises for Chapter 148.

Exercise 148.1. Let $k \in \mathbb{N}$. We consider the short exact sequence

$$0 \;\to\; \mathbb{Z}_k \;\xrightarrow{[a]\mapsto[a\cdot k]}\; \mathbb{Z}_{k^2} \;\xrightarrow{p([a]=[a]}\; \mathbb{Z}_k \;\to\; 0.$$

Given a topological space X we obtain Bockstein homomorphisms $\beta_n\colon \mathrm{H}_n(X;\mathbb{Z}_k) \to \mathrm{H}_{n-1}(X;\mathbb{Z}_k)$, $n \in \mathbb{N}_0$. Show that

$$\beta_{n-1} \circ \beta_n\colon \mathrm{H}_n(X;\mathbb{Z}_k) \;\to\; \mathrm{H}_{n-2}(X;\mathbb{Z}_k)$$

is the zero map.

Exercise 148.2. Let H be a finite abelian group and let $\lambda\colon H \times H \to \mathbb{Q}/\mathbb{Z}$ be a non-singular symmetric linking pairing. Given a subgroup $P \subset H$ we define

$$P^\perp \;:=\; \{v \in H \,|\, \lambda(v,w) = 0 \text{ for all } w \in P\}.$$

We say that a subgroup P is a *metabolizer of* λ if $P = P^\perp$. Now let $P \subset H$ be a subgroup with $P \subset P^\perp$. Prove the following equivalence of statements:

$$|P^2| = |H| \quad\Longleftrightarrow\quad P \text{ is a metabolizer.}$$

Exercise 148.3. Let $A \in \mathrm{M}(n \times n, \mathbb{Z})$ be a symmetric matrix with $\det(A) \neq 0$. We consider the pairings

$$\begin{array}{rcl} \mu(A)\colon \mathbb{Z}^n \times \mathbb{Z}^n & \to & \mathbb{Z} \\ ([v],[w]) & \mapsto & v^T A w \end{array} \quad \text{and} \quad \begin{array}{rcl} \lambda(A)\colon \mathbb{Z}^n/A\mathbb{Z}^n \times \mathbb{Z}^n/A\mathbb{Z}^n & \to & \mathbb{Q}/\mathbb{Z} \\ ([v],[w]) & \mapsto & v^T A^{-1} w. \end{array}$$

Given $n \in \{0,1,2,3\}$ we consider the matrices $A_n = \begin{pmatrix} 0 & 3 \\ 3 & n \end{pmatrix}$.

(a) For which $m, n \in \{0,1,2,3\}$ are the pairings $\mu(A_m)$ and $\mu(A_n)$ isometric?
(b) For which $m, n \in \{0,1,2,3\}$ are the pairings $\lambda(A_m)$ and $\lambda(A_n)$ isometric?

Exercise 148.4. Let M and N be oriented rational homology spheres of dimension $2n+1$ with $n \geq 1$. Show that linking pairing of the connected sum $M \# N$ is isometric to the orthogonal sum of the linking pairing of M and the linking pairing of N.

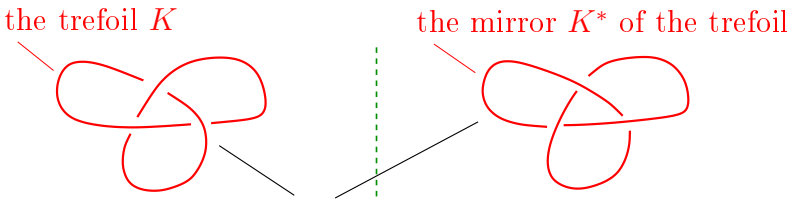
Exercise 148.5.

(a) Show that every lens space admits a handle decomposition with precisely one handle of index 0, 1,2 and 3.

[1768] The purely algebraic reason is the following. Suppose we are given a commutative diagram of the form

$$\begin{array}{ccc} \mathbb{Z}^m \times \mathbb{Z}^m & \xrightarrow{(x,y)\mapsto x^T P y} & \mathbb{Z} \\ \downarrow{\scriptstyle (x,y)\mapsto(Cx,Dx)} & & \downarrow \\ \mathbb{Z}^m \times \mathbb{Z}^m & \xrightarrow{(x,y)\mapsto x^T Q y} & \mathbb{Q}. \end{array}$$

Then $P = C^T Q D$. If C and D are invertible over $\mathbb{Q}$, then $Q = (C^T)^{-1} P D^{-1}$. In our case we have $C = D = P = A$. Furthermore A is symmetric and we know that $\det(A) \neq 0$. Thus we see that $Q = A^{-1} A A^{-1} = A^{-1}$.



(b) Let X and Y be two CW-complexes with precisely one cell in dimension 0,1,2 and no other cell. Show that X and Y are homotopy equivalent if and only if $\pi_1(X)$ is isomorphic to $\pi_1(Y)$.
Hint. What choices do you have for the attaching maps of the cells? Make use of the Mapping Cone Homotopy Equivalent Proposition 16.15.

(c) Let $p \in \mathbb{N}$ and $q, q' \in \mathbb{N}$. Furthermore let $\Phi\colon \overline{B}^3 \to L(p,q)$ and $\Psi\colon \overline{B}^3 \to L(p,q')$ be smooth embeddings. Show that $L(p,q) \setminus \Phi(B^3)$ and $L(p,q') \setminus \Psi(B^3)$ are homotopy equivalent.
Remark. Use the Handles-Cells Proposition 136.18.

149. Branched coverings and chiral knots

After this long and technical, and basically picture free chapter, it is time to return to some more concrete topological questions. We recall the following question from some time ago.

Question 59.9. Is the trefoil chiral, i.e. can the mirror of the trefoil be deformed into the trefoil itself? Put differently, are the two knots shown in the figure below smoothly isotopic in the sense of the definition on page 817?

are these two knots smoothly isotopic?

In the last chapters we had developed several tools for showing that certain closed smooth manifolds, e.g. the complex projective space $\mathbb{C}\mathrm{P}^2$ and the lens space $L(3,1)$, are chiral. In this section we will attack Question 59.9 by reducing it to a question that we had already dealt with. More precisely, the idea is to associate to a knot in S^3 an oriented rational homology sphere that retains at least some information on the knot. Then we will use the linking pairing of this rational homology sphere to draw conclusions on the chirality of the knot.

149.1. **Branched coverings.** In this section we will introduce branched coverings. We start out by recalling the following definition from page **??**.

Definition. Let M be a smooth manifold and let $W \subset M$ be a proper codimension two submanifold. A trivial tubular neighborhood for W is a smooth embedding

$$F\colon \overline{B}^2 \times W \;\to\; M$$

such that $F(0,P) = P$ for all $P \in W$ and such that $F(\overline{B}^2 \times \partial W) = \partial M \cap F(\overline{B}^2 \times W)$.

Examples.

(1) It is clear that every 0-dimensional submanifold of a 2-dimensional smooth manifold admits a trivial tubular neighborhood.
(2) It follows from the Tubular Neighborhood Theorem **??** that every closed 1-dimensional submanifold of a closed orientable 3-dimensional smooth manifold admits a trivial tubular neighborhood.
(3) In Proposition 126.14 we saw that the 2-dimensional submanifold $W = \mathbb{C}\mathrm{P}^1$ of the 4-dimensional smooth manifold $M = \mathbb{C}\mathrm{P}^2$ does not admit a trivial tubular neighborhood.

Convention. Let $\overline{B}^2 \times W \to M$ be a smooth embedding as above. On many occasions, by an abuse of notation, we will identify the image of the smooth embedding $\overline{B}^2 \times W \to M$ with $\overline{B}^2 \times W$. Put differently, we often use the phrase let "$\overline{B}^2 \times W$ be a trivial tubular neighborhood".

Definition. Let M be a smooth manifold and let $W \subset M$ be a compact proper submanifold of codimension two. We say a map $p\colon \widetilde{M} \to M$ is a k-fold branched covering with branch locus W if the following two conditions are satisfied:

(1) The restriction $p\colon \widetilde{M} \setminus p^{-1}(W) \to M \setminus W$ is a k-fold covering map in the usual sense.

(2) There exists a trivial tubular neighborhood $\overline{B}^2 \times W$ of W with the following properties:

(a) For each component X of $p^{-1}(\overline{B}^2 \times W)$ there exists an $m \in \mathbb{N}$ and a diffeomorphism $\Psi\colon X \to \overline{B}^2 \times W$ such that the following diagram commutes[1769]

$$\begin{array}{ccc} X & \xrightarrow{\Psi} & \overline{B}^2 \times W \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle (z,w)\mapsto(z^m,w)} & \\ & \overline{B}^2 \times W. & \end{array}$$

We refer to m as the branching degree of X.

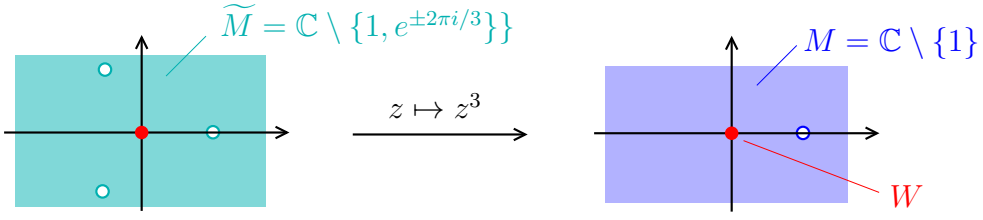
(b) There exists at least one component of $p^{-1}(\overline{B}^2 \times W)$ with branching degree ≥ 2.

We say the branched covering is simple if $m = k$ throughout. Furthermore we say that the branched covering is regular if the covering map $p\colon \widetilde{M} \setminus p^{-1}(W) \to M \setminus W$ is regular in the sense of the definition on page 1383. Otherwise we say that the branched covering is irregular.

Remark. The notion of a branched covering makes sense in a much more general context, not necessarily restricted to smooth manifolds, see e.g. [**Fox1957**].

Examples.

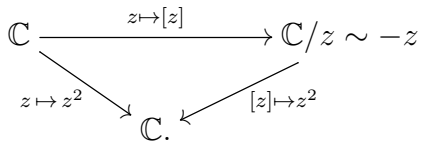
(1) The map $p\colon \widetilde{M} = \mathbb{C} \to M = \mathbb{C}$ given by $z \mapsto z^k$ is a simple k-fold branched covering with branch locus $W = \{0\}$. This is basically clear:



(a) On page 1070 we saw that the restriction of p to a map $\mathbb{C} \setminus \{0\} \to \mathbb{C} \setminus \{0\}$ is a k-fold covering map.

(b) We take the obvious trivial tubular neighborhood $\overline{B}^2$ for 0 and we denote by Ψ the identity map. It is obvious that the above diagram commutes.

(2) The same argument as in (1) shows that the map



$$\begin{array}{rcl} \widetilde{M} = \mathbb{C} \setminus \{\{\exp(2\pi \mathrm{i} k/3) \,|\, k = 0,1,2\} & \to & \mathbb{C} \setminus \{1\} \\ z & \mapsto & z^3 \end{array}$$

that is illustrated in the figure below is a simple 3-fold branched covering with branch locus $W = \{0\}$.

[1769] Here we view $\overline{B}^2 = \{z \in \mathbb{C} \,|\, |z| \leq 1\}$ as a subset of $\mathbb{C}$.

(3) The projection $\widetilde{M} = \mathbb{C} \to M := \mathbb{C}/z \sim -z$ is a simple 2-fold branched covering with branch locus $W = \{0\}$. To verify this statement we consider the following diagram

The diagram is clearly commutative and the right-hand diagonal map is easily seen to be a homeomorphism. We use this homeomorphism to equip $\mathbb{C}/z \sim -z$ with a smooth structure. In (1) we saw that the left diagonal map is a branched covering, thus the top horizontal map is also a branched covering.

(4) Let Σ be a closed 1-dimensional complex manifold (i.e. Σ is a closed 2-dimensional smooth manifold with a complex structure) and let $f\colon \Sigma \to \mathbb{C}$ be a meromorphic non-constant function. We consider the map

$$\begin{array}{rcl} \Sigma & \to & \mathbb{C}\mathrm{P}^1 = S^2 \\ z & \mapsto & \begin{cases} [f(z):1], & \text{if } f(z) \neq \infty \\ [1:0], & \text{otherwise.} \end{cases} \end{array}$$

It is straightforward to see that this map is holomorphic. Using [**Jä2011**, Satz 10] one can easily show that $f\colon \Sigma \to \mathbb{C}\mathrm{P}^1 = S^2$ is a branched covering.

Before we give more interesting examples of branched coverings we state and prove the following lemma that, given a simple branched covering $p\colon \widetilde{M} \to M$, relates the Euler characteristic of $\widetilde{M}$ to the Euler characteristic of M, the Euler characteristic of the branch locus and the degree of the branched covering.
The lemma carries a fancy name, even though it is quite elementary.

Lemma 149.1. (Riemann-Hurwitz Formula) Let M be a compact smooth manifold and let W be a compact proper codimension 2 submanifold of M. If $p\colon \widetilde{M} \to M$ is a simple k-fold branched covering with branch locus W, then

$$\chi\big(\widetilde{M}\big) \;=\; k \cdot \chi(M) + (1-k) \cdot \chi(W).$$

A similar statement also holds for non-simple branched coverings. The formulation becomes more messy, but the proof in this more general setting is equally trivial. Since we will not make use of this more general formula we decline to formulate it.

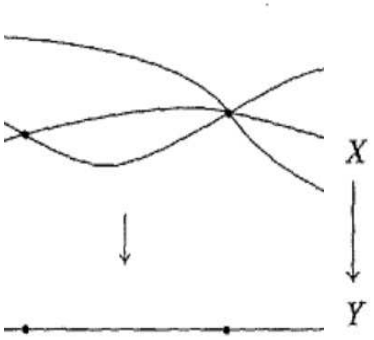
Proof. As usual, statements about Euler characteristics can be proved quite easily. To prove the Riemann-Hurwitz Formula we pick a tubular neighborhood $\overline{B}^2 \times W$ and a diffeomorphism $\Psi\colon p^{-1}(\overline{B}^2 \times W) \to \overline{B}^2 \times W$ as in the definition of a branched covering. Now

we calculate that

$$\begin{array}{l}\text{Manifold-}\chi\text{-Proposition 104.36 (3) applied to } \widetilde{M} = \big(\widetilde{M} \setminus \Psi(B^2 \times W)\big) \cup \Psi\big(\overline{B}^2 \times W\big) \\ \chi\big(\widetilde{M}\big) \overset{\downarrow}{=} \chi\big(\widetilde{M} \setminus \Psi(B^2 \times W)\big) + \chi\big(\Psi(\overline{B}^2 \times W)\big) - \chi\big(\Psi(S^1 \times W)\big) \\ \overset{\uparrow}{=} k{\cdot}\chi(M \setminus (B^2 \times W)) + \chi(W) \\ \text{by the Manifold-}\chi\text{-Proposition 104.36 (5) since } p\colon \widetilde{M} \setminus \Psi(B^2 \times W) \to M \setminus (B^2 \times W) \text{ is a } k\text{-fold covering} \\ \text{and using that the Manifold-}\chi\text{-Proposition 104.36 (2) implies that } \chi(\Psi(\overline{B}^2 \times W)) = \chi(W) \text{ and } \chi(\Psi(S^1 \times W)) = 0 \\ \overset{\uparrow}{=} k{\cdot}\chi(M) - k{\cdot}\chi(\overline{B}^2 \times W) + k{\cdot}\chi(W \times S^1) + \chi(W) \overset{\uparrow}{=} k{\cdot}\chi(M) + (1-k){\cdot}\chi(W). \\ \text{by the Manifold-}\chi\text{-Proposition 104.36 (3) applied to } M = M \setminus (B^2 \times W) \cup \overline{B}^2 \times W \qquad \text{again by the Manifold-}\chi\text{-Proposition 104.36 (2)}\end{array}$$

■

Remark. The concept of a map that is a covering outside of a sufficiently small subset also appears in other branches of mathematics. It is often also referred to as a "branched covering" or "ramified covering" or "ramification". In the figure below we show an extract of Jürgen Neukirch's book on algebraic number theory [**Neuk1999**].



6. Extensions. Let $\mathfrak{o}$ be a Dedekind domain with field of fractions K. Let $L|K$ be a finite separable extension, and $\mathcal{O}$ the integral closure of $\mathfrak{o}$ in L. Let $Y = \operatorname{Spec}(\mathfrak{o})$, $X = \operatorname{Spec}(\mathcal{O})$, and

$$f : X \longrightarrow Y$$

the morphism induced by the inclusion $\mathfrak{o} \hookrightarrow \mathcal{O}$. If $\mathfrak{p}$ is a maximal ideal of $\mathfrak{o}$ and

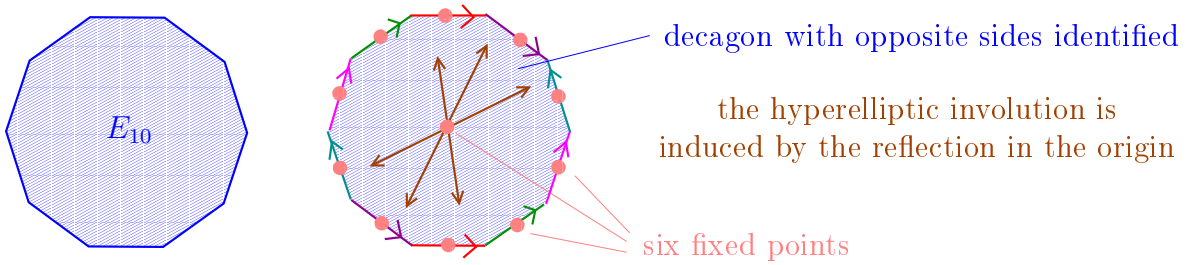
$$\mathfrak{p}\mathcal{O} = \mathfrak{P}_1^{e_1} \cdots \mathfrak{P}_r^{e_r}$$

the prime decomposition of $\mathfrak{p}$ in $\mathcal{O}$, then $\mathfrak{P}_1, \ldots, \mathfrak{P}_r$ are the different points of X which are mapped to $\mathfrak{p}$ by f. The morphism f is a "ramified covering." It is graphically represented by the following picture:

149.2. **The hyperelliptic involution and branched coverings of surfaces.** Before we can provide the reader with new examples of branched coverings we need to introduce the following fun object.

Definition. As on page 1880 we consider the surface Σ_g of genus g as the quotient of the regular $(4g+2)$-gon E_{4g+2} where we identify opposite sides by a translation. The map

$$\begin{array}{rccc}\Theta\colon & E_{4g+2}/\!\sim & \to & E_{4g+2}/\!\sim \\ & [z] & \mapsto & [-z]\end{array}$$



is called the hyperelliptic involution.[17701771] For $g = 2$ the surface $\Sigma_2 = E_{10}/\!\sim$ and the hyperelliptic involution are illustrated in the figure below.

The following lemma summarizes some properties of the hyperelliptic involution.

Lemma 149.2. Let $g \in \mathbb{N}_0$.

(1) The hyperelliptic involution $\Theta\colon \Sigma_g \to \Sigma_g$ is orientation-preserving.
(2) The hyperelliptic involution $\Theta\colon \Sigma_g \to \Sigma_g$ has precisely $2g+2$ fixed points.
(3) The map $\Theta_*\colon \mathrm{H}_1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}_1(\Sigma_g;\mathbb{Z})$ equals $-\mathrm{id}_{\mathrm{H}_1(\Sigma_g;\mathbb{Z})}$.

[1770] Recall that a map $f\colon X \to X$ is called an *involution* if $f \circ f = \mathrm{id}_X$.
[1771] I do not know where the fancy name "hyperelliptic" comes from.

(4) The quotient space $\Sigma_g/x \sim \Theta(x)$ is homeomorphic to the 2-sphere and it can be given a smooth structure such that the quotient map $\Sigma_g \to \Sigma_g/x \sim \Theta(x)$ is a 2-fold branched covering where the branch locus consists of $2g+2$ points.

Sketch of proof.

(1) It follows easily from Proposition 107.2, applied to the origin, that the hyperelliptic involution Θ is orientation-preserving.

(2) It is straightforward to show that the fixed points of the hyperelliptic involution are given by the origin and the points that are represented by the $4g+2$ midpoints of the sides of the $(4g+2)$-gon. Since opposite midpoints get identified we see that we have precisely $1+\frac{1}{2}(4g+2) = 2g+2$ fixed points.

(3) We equip E_{4g+2} with the obvious CW-structure with $2g+2$ 0-cells, $2g+2$ 1-cells and one 2-cell. Since the hyperelliptic involution identifies cells with cells we can equip $\Sigma_g = E_{4g+2}/\!\sim$ with a corresponding quotient CW-structure. The hyperelliptic involution is a cellular map and one can easily compute that the induced map on $\mathrm{H}_1^{\mathrm{CW}}(\Sigma_g;\mathbb{Z})$ is $-\mathrm{id}$. By the Singular-Cellular H_*-Isomorphism Proposition 80.4 we know that singular homology is *naturally* isomorphic to cellular homology. In our setting this means that we have a commutative diagram

$$\begin{array}{ccc} \mathrm{H}_1(\Sigma_g;\mathbb{Z}) & \longrightarrow & \mathrm{H}_1^{\mathrm{CW}}(\Sigma_g;\mathbb{Z}) \\ {\scriptstyle f_*}\downarrow & & \downarrow{\scriptstyle f_*} \\ \mathrm{H}_1(\Sigma_g;\mathbb{Z}) & \longrightarrow & \mathrm{H}_1^{\mathrm{CW}}(\Sigma_g;\mathbb{Z}), \end{array}$$

where the horizontal maps are the same. Since the right vertical map is $-\mathrm{id}$ we now see that the left vertical map is also $-\mathrm{id}$.

(4) We leave it to the conscientious reader to show that the quotient space $\Sigma_g/x \sim \Theta(x)$ is a closed orientable connected 2-dimensional smooth manifold such that the quotient map $\Sigma_g \to \Sigma_g/x \sim \Theta(x)$ is a 2-fold branched covering with branch locus given by the images of the fixed points.[1772] Once we believe this fact we can calculate that

$$2-2g \;=\; \chi(\Sigma_g) \underset{\uparrow}{=} 2\cdot\chi(\Sigma_g/\!\sim) - \chi(\text{branch locus}) \underset{\uparrow}{=} 2\cdot\chi(\Sigma_g/\!\sim) - (2g+2).$$

Lemma 149.1 — by (1) there exist $2g+2$ fixed points

[1772] In the verification of this statement it can be useful to keep the second example on page 3174 in mind.

Thus we see that $\chi(\Sigma_g/\!\sim) = 2$. It follows from Theorem 55.4 that $\Sigma_g/\!\sim$ is indeed diffeomorphic to the 2-dimensional sphere.[1773] ■

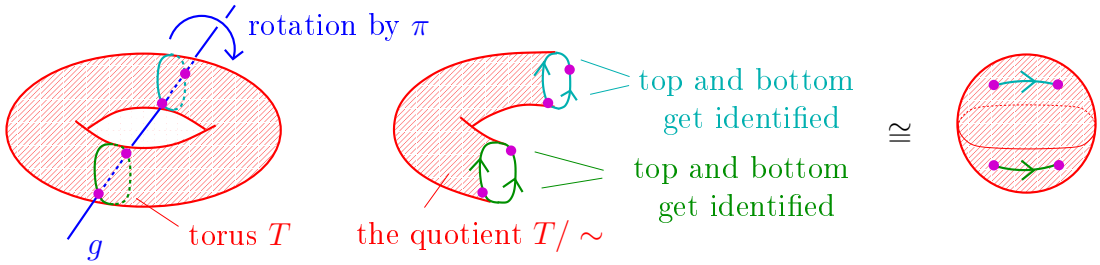
More interestingly, the hyperelliptic involution is in some sense fully determined by being an orientation-preserving involution and satisfying Statement (2) or Statement (3) of Lemma 149.2. More precisely, the following proposition holds:

Proposition 149.3. Let $g \in \mathbb{N}_0$ and let Ξ be an orientation-preserving involution of Σ_g. Suppose one of the following two conditions is satisfied:

(1) The map Ξ has precisely $2g+2$ fixed points.
(2) The map $\Xi_*\colon \mathrm{H}_1(\Sigma_g;\mathbb{Z}) \to \mathrm{H}_1(\Sigma_g;\mathbb{Z})$ equals $-\mathrm{id}$.

Then Ξ and the hyperelliptic involution Θ represent conjugate elements in the orientation-preserving mapping class group $\mathrm{MCG}^+(\Sigma_g)$.

Proof. This statement is proved in Proposition 7.15 and the discussion on page 216 of [**FaM2011**]. ■



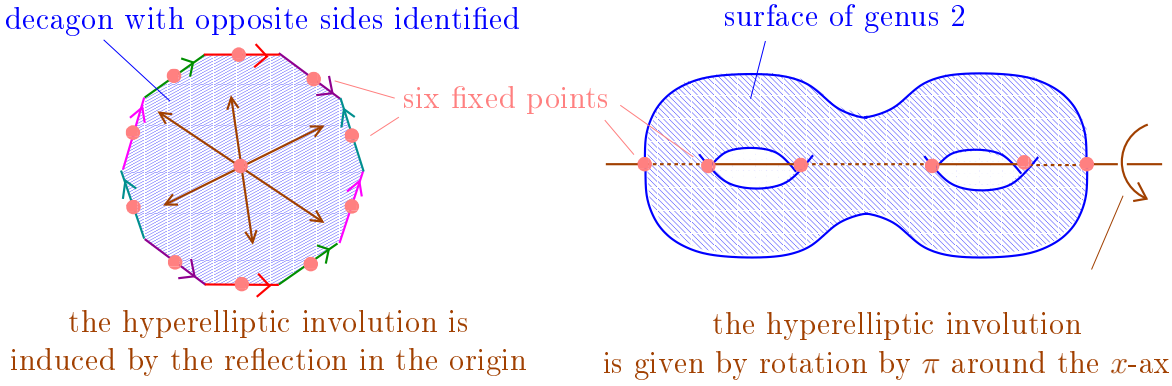
Examples.

(1) Using Proposition 149.3 one can show easily that the maps

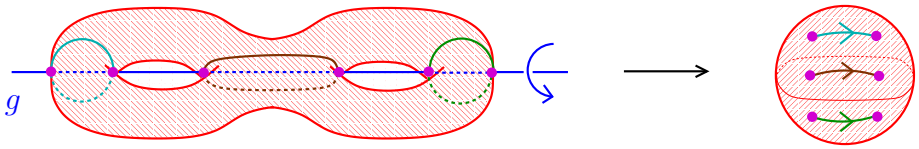
$$\begin{array}{ccc} \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [(x,y)] & \mapsto & [(-x,-y)] \end{array} \quad \text{and} \quad \begin{array}{ccc} S^1 \times S^1 & \to & S^1 \times S^1 \\ (z,w) & \mapsto & (z^{-1},w^{-1}), \end{array}$$

under a suitable diffeomorphism between $\mathbb{R}^2/\mathbb{Z}^2 = S^1 \times S^1$ and $E_6/\!\sim$, correspond to the hyperelliptic involution.[1774] In Lemma 5.7 we gave an explicit diffeomorphism between $S^1 \times S^1$ and a specific submanifold of $\mathbb{R}^3$. Under this diffeomorphism the above hyperelliptic involution corresponds to rotation by π around a line in the xy-plane through the origin.

In the figure below we show the torus as a submanifold of $\mathbb{R}^3$ together with the hyperelliptic involution. We do our best to visualize that the quotient of the torus is indeed given by the sphere.



(2) Using Proposition 149.3 we can now also visualize the hyperelliptic involution in our favorite "physical" model of the surface of genus g. More precisely, in the figure below on the right we show the surface of genus 2 as a submanifold of $\mathbb{R}^3$. Rotation by π around the x-axis is an orientation-preserving involution which has 6 fixed points.



[1773] It always feels like cheating to use the calculation of Euler characteristics together with the Surface Classification Theorem 55.4 to determine the diffeomorphism type of a given closed orientable connected 2-dimensional smooth manifold. Can you find a more direct proof that $\Sigma_g/\!\sim$ is diffeomorphic to S^2?

[1774] Clearly both maps are orientation-preserving involutions. Thus it remains to show that these involutions of $\mathbb{R}^2/\mathbb{Z}^2$ and $S^1 \times S^1$ have precisely four fixed points. What are they?

It follows from Proposition 149.3 that, under a suitable diffeomorphism to Σ_g, this involution corresponds to the hyperelliptic involution. For convenience we refer to this involution also as the hyperelliptic involution.

Finally, in the figure below we indicate why the quotient is indeed the sphere.

149.3. **Branched coverings of 3-dimensional smooth manifolds.** In this section we consider branched coverings of 3-dimensional smooth manifolds. Before we start out with definitions and examples we provide a word of caution. Whenever one wants to deal with "real-life topological spaces" it is very hard to write down everything absolutely rigorously. In this chapter we will therefore take some liberties and we will not write down every argument in full detail.

As a balm to our mathematical conscience we recall that we pointed out on page **??**, every 3-dimensional topological manifold admits a unique smooth structure. Hence we do not need to distinguish between the concepts of being "homeomorphic" and "diffeomorphic".[1775]

Before we give a 3-dimensional example of a branched covering we need to introduce one more definition.

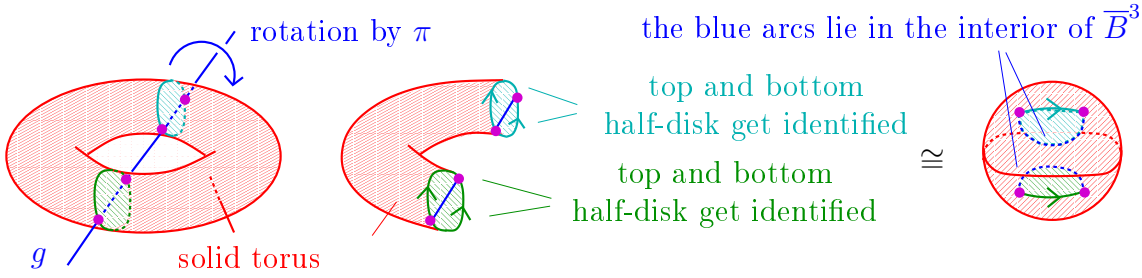
Definition.

(1) An arc in a 3-dimensional smooth manifold M is a proper submanifold of M that is diffeomorphic to the interval $[0,1]$.

(2) We say a finite set of arcs $A_1, \dots, A_m$ in $\overline{B}^3$ is unknotted if there exists a homeomorphism $f\colon \overline{B}^3 \to \overline{B}^2 \times [0,1]$ and distinct points $P_1, \dots, P_m$ such that for $i = 1, \dots, m$ we have $f(A_i) = P_i \times [0,1]$.

Example. In the figure below we show to the left an arc in the solid torus. To the right we show two arcs in $\overline{B}^3$ that are unknotted.

[1775]This fact that by smoothing we can always replace a homeomorphism by a diffeomorphism should not be overgeneralized. For example, Bing [**Bin1952**] gave an example of an involution f on S^3 that is not isotopic to a smooth involution. More precisely, we can isotope f to a smooth map, but we can no longer arrange that that map is an involution.



Now we can give the promised examples of branched coverings of 3-dimensional smooth manifolds.

Examples.

(1) We consider the map

$$\begin{array}{rcl} \Theta\colon \overline{B}^2 \times S^1 & \to & \overline{B}^2 \times S^1 \\ (r \cdot \exp(\mathrm{i}\varphi), z) & \mapsto & (r \cdot \exp(-\mathrm{i}\varphi), z^{-1}). \end{array}$$

The map Θ is an involution that restricts to the hyperelliptic involution on the boundary. In Lemma 5.7 we had identified the solid torus $\overline{B}^2 \times S^1$ with a submanifold of $\mathbb{R}^3$. Under this identification the above involution Θ corresponds to the rotation by π around a line in the xy-plane. This map restricts to an involution on the solid torus $\overline{B}^2 \times S^1 \subset \mathbb{R}^3$. As is illustrated in the figure below, the quotient $\overline{B}^2 \times S^1 / x \sim \Theta(x)$ is the 3-ball and the quotient map $p\colon \overline{B}^2 \times S^1 \to \overline{B}^3$ is a 2-fold branched covering where the branch locus is given by two unknotted arcs.[1776]

(2) Above we saw that the surface of genus g is the branched covering of S^2 with branch locus given by $2g+2$ points. Similarly to (1) we can now replace the surface of genus g by the handlebody H_g of genus g and we obtain a branched covering of H_g over the 3-ball $\overline{B}^3$ where the branch locus is given by $g+1$ unknotted arcs.

It follows from the classification of closed connected 2-dimensional smooth manifolds, see the Surface Classification Theorem 55.4, together with discussion on page 3179 that every closed orientable connected 2-dimensional smooth manifold Σ admits a simple branched covering over the 2-dimensional sphere. The following theorem says that a similar statement also holds in the 3-dimensional setting.

[1776] It is painful, but not impossible to prove this statement rigorously. Indeed, first of all we can replace $\overline{B}^2 \times S^1$ by $([-1,1]/-1 \sim 1) \times [0,2]^2$ where the involution is given by $(s,x,y) \sim (-s,x,2-y)$. The quotient space is then homeomorphic to $[0,1] \times [0,2]^2$ where $(0,x,y) \sim (0,x,2-y)$ and $(1,x,y) \sim (1,x,2-y)$. Using this description it is no longer that difficult to show that the quotient space is homeomorphic to $\overline{B}^2 \times [0,1]$ where the fixed point set is given by two arcs of the form $P_1 \times [0,1]$ and $P_2 \times [0,1]$. We leave it to the reader to fill in the details.

Theorem 149.4. (Hilden-Montesinos) Every closed orientable connected 3-dimensional smooth manifold M admits a map $p\colon M \to S^3$ which is a simple 3-fold branched covering (not necessarily regular) with branch locus a knot.

Remark. The theorem has its origins in the work of James Alexander [**Al1920**] from 1920. He had claimed that every closed orientable 3-dimensional smooth manifold admits a map $p\colon M \to S^3$ which is a branched covering with branch locus a link. But the definition of a branched covering map in [**Al1920**] is weaker than our notion and few details were provided in [**Al1920**].

Proof. The theorem was independently proved by Hugh Hilden [**Hild1976**] and José Montesinos [**Mon1976**] in the early 1970s. An exposition of the proof is also given in [**PrS1997**, Theorem 23.1]. The definition of a branched covering used in the above references is slightly less restrictive, but it is clear from the proofs that they provide branched coverings in our sense. ■

149.4. **Branched coverings defined by knots.** In the previous sections we saw that several maps $p\colon \widetilde{M} \to M$ between smooth manifolds are branched coverings and we had determined the branch locus of those branched coverings.
In this section we go the other way round. We set $M = S^3$, we prescribe the branch locus as a given knot K and we describe a degree m. Given this data we will construct an essentially unique m-fold branched covering $p\colon \Sigma_m(K) \to S^3$ with branch locus K.

Definition. Let K be a knot in S^3 and let $m \in \mathbb{N}$.

(1) By the Knot Thickening Lemma 131.1 (2) we can pick a thickening $F\colon \overline{B}^2 \times K \to S^3$ with self-linking number 0.
   (a) As usual we write $X_K := S^3 \setminus F(B^2 \times K)$.
   (b) We equip X_K with the natural orientation coming from S^3.
   (c) We denote by $f\colon S^1 \times K \to \partial X_K = \partial F(\overline{B}^2 \times K)$ the diffeomorphism that is given by restricting F to the boundary torus $S^1 \times K$.
   (d) We denote by $\phi_K\colon \pi_1(X_K) \to \mathrm{H}_1(X_K;\mathbb{Z}) \xrightarrow{\cong} \mathbb{Z}$ one of the two epimorphisms. (It will not matter which one we take.)

(2) By the Covering Existence Theorem 61.5 there exists a connected covering $p\colon \widetilde{X_K} \to X_K$ that corresponds to $\ker\big(\pi_1(X_K) \xrightarrow{\phi_K} \mathbb{Z} \to \mathbb{Z}_m\big)$, i.e. that satisfies

$$p_*(\pi_1(\widetilde{X_K})) \;=\; \ker\big(\pi_1(X_K) \xrightarrow{\phi_K} \mathbb{Z} \to \mathbb{Z}_m\big).$$

   Furthermore, by the Covering Uniqueness Theorem 61.9 this covering is in an appropriate sense unique. We equip $\widetilde{X_K}$ with the orientation coming from the Manifold Covering Proposition 49.2 and coming from the above orientation on X_K.

(3) We consider the branched covering

$$\begin{array}{rcl} q\colon \overline{B}^2 \times K & \to & \overline{B}^2 \times K \\ (z,p) & \mapsto & (z^m,p). \end{array}$$

   Since the self-linking number of F was chosen to be zero, and by the uniqueness statement of the Covering Uniqueness Theorem 61.9, we see that the restriction of

q to the boundary $S^1 \times K$ can be identified with the m-fold covering corresponding to

$$\ker\left(\pi_1(S^1 \times K) \xrightarrow{f_*} \pi_1(X_K) \to \mathbb{Z} \to \mathbb{Z}_m\right).$$

(4) It follows from (3) that f lifts to a diffeomorphism $\widetilde{f}\colon S^1 \times K \to \partial\widetilde{X_K}$ such that the following diagram commutes

$$\begin{array}{ccc} S^1 \times K & \xrightarrow{\widetilde{f}} & \partial\widetilde{X_K} \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle p} \\ S^1 \times K & \xrightarrow{f} & \partial X_K. \end{array}$$

(5) We define the m-fold branched covering of K to be the topological space

$$\Sigma_m(K) \ := \ \left(\overline{B}^2 \times K\right) \cup_{\widetilde{f}} \widetilde{X_K}.$$

The following proposition summarizes some basic properties of branched coverings of knots.

Proposition 149.5. (Knot-Branched Covering Proposition) Let K be a knot and let $m \in \mathbb{N}$.

(1) The m-fold branched covering $\Sigma_m(K)$ is a closed orientable 3-dimensional topological manifold. It admits a unique smooth structure and a unique orientation such that $\widetilde{X_K}$ is a submanifold and such that the orientation on the submanifold $\widetilde{X_K}$ agrees with the orientation coming from the Manifold Covering Proposition 49.2 and the natural orientation on $X_K \subset S^3$.

(2) The oriented diffeomorphism type of $\Sigma_m(K)$ is independent of all of our choices.

(3) The map

$$\begin{array}{ccccc} \Sigma_m(K) & = & \overline{B}^2 \times K & \cup_{\widetilde{f}} & \widetilde{X_K}. \\ \downarrow & & \downarrow q & & \downarrow p \\ S^3 & = & \overline{B}^2 \times K & \cup_f & X_K \end{array}$$

is well-defined and it is a regular simple m-fold branched covering with branch locus given by the knot K.

(4) If two knots K and J are smoothly isotopic, then there exists an orientation-preserving diffeomorphism $\Sigma_m(K) \to \Sigma_m(J)$.

(5) Let K be a knot in $\mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$. Let $K^{\text{mir}} \subset \mathbb{R}^3$ be a mirror image, i.e. $K^{\text{mir}} = \rho(K)$ where ρ is the reflection in a hyperplane of $\mathbb{R}^3$. There exists an *orientation-reversing* diffeomorphism from $\Sigma_m(K)$ to $\Sigma_m(K^{\text{mir}})$.

(6) If K is amphichiral, then $\Sigma_m(K)$ is amphichiral.

(7) We have isomorphisms

$$\mathrm{H}_1(\Sigma_m(K);\mathbb{Z}) \oplus \mathbb{Z} \cong \mathrm{H}_1(\widetilde{X}_K;\mathbb{Z}) \cong \mathrm{H}_1\left(\begin{matrix}\text{covering of } S^3 \setminus K \text{ corresponding to} \\ \text{the epimorphism } \pi_1(S^3 \setminus K) \to \mathbb{Z}_m\end{matrix};\mathbb{Z}\right).$$

(8) If p is a prime number and $r \in \mathbb{N}$, then the homology group $\mathrm{H}_1(\Sigma_{p^r}(K);\mathbb{Z})$ is finite.

Sketch of proof.

(1) The first statement follows from the Gluing-Smooth Manifolds-Proposition **??**.

(2) The second statement follows fairly easily from the Covering Uniqueness Theorem 61.9 and Proposition **??**.

(3) The third statement follows easily from the definitions.

(4) Suppose that K and J are smoothly isotopic. This means that there exists a smooth isotopy from the knot K to the knot J. As we pointed out in the proof of Proposition 58.4, the smooth isotopy can be extended to a smooth isotopy of S^3 carrying K to J. It now follows easily from the definitions that there exists an orientation-preserving diffeomorphism $\Sigma_m(K) \to \Sigma_m(J)$.
(5) Let ρ be a reflection in a hyperplane of $\mathbb{R}^3$. From Exercise 2.46 we obtain that, by setting $\rho(\infty) = \infty$, the map ρ extends to a homeomorphism of $S^3 = \mathbb{R}^3 \cup \{\infty\}$. We denote this homeomorphism again by ρ. It follows from Proposition 107.2, say applied to the origin, that $\rho\colon S^3 \to S^3$ is orientation-reversing. It follows again easily from the definitions that ρ induces an orientation-reversing homeomorphism $\Sigma_m(K) \to \Sigma_m(K^{\mathrm{mir}})$.
(6) This statement is an immediate consequence of (4) and (5).
(7) An amusing Mayer–Vietoris argument shows that there exists an isomorphism as stated on the left. The inclusion of the knot exterior into the knot complement is a homotopy equivalence, therefore it induces an isomorphism as stated on the right.
(8) The last statement is the only statement that is non-trivial. The case $p = 2$ and $r = 1$ is proved for example on [**Rolf1990**, p. 213]. The general case is proved in [**Gor1972**, p. 362]. ■

Remark. One could also define the m-fold branched covering of K as the set $K \cup \widetilde{Y}$, where $\widetilde{Y}$ is the m-fold cyclic covering of $Y = S^3 \setminus K$, together with a suitable topology. This approach, which is closer in spirit to discussion on page **??**, has the advantage that the definition of the m-fold branched covering involves fewer choices and gives an object that is more naturally defined. For didactical reasons we stuck to the more conventional definition given above.

Now we can consider some examples of branched coverings of knots.

Examples.

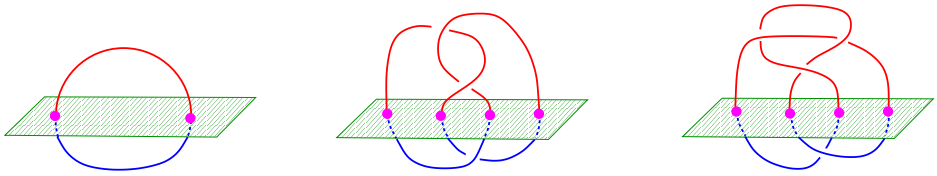
(1) The 1-fold branched covering of a knot K is, basically by definition, given by S^3.
(2) For K the trivial knot it is an amusing exercise to verify that all branched coverings are again diffeomorphic to S^3.
(3) The following converse to (2) holds: If K is a knot and $m \in \mathbb{N}_{\geq 2}$ such that $\Sigma_m(K)$ is diffeomorphic to S^3, then K is smoothly isotopic to the trivial knot. This is a consequence of the *Smith Conjecture* which was proved in 1984, see [**MB1984**].[1777]
(4) More generally one can ask to what degree branched coverings remember the original knot K. The bad news is that by [**Nak1981, Saku1981**] there are many examples of triples (K, K', m) where K and K' are "prime" knots which are not smoothly isotopic and where $m \in \mathbb{N}_{\geq 2}$ such that $\Sigma_m(K)$ is diffeomorphic to $\Sigma_m(K')$. The good news is that it is shown in [**Koj1986**] that if K and K' are two "prime" knots such that $\Sigma_m(K)$ and $\Sigma_m(K')$ are diffeomorphic for infinitely many $m \in \mathbb{N}$, then K and K' are smoothly isotopic.

[1777]The Smith Conjecture, which was originally formulated in 1949 [**Eil1949**, Problem 36], says that if f is a diffeomorphism of S^3 of finite order, i.e. such that there exists an $n \in \mathbb{N}$ with $f^n = \mathrm{id}_{S^3}$, then the fixed point set of f cannot be a non-trivial knot. The conjecture was proved in 1984 [**MB1984**]. By [**Gif1966**] the analogous statement is wrong for 4-dimensional smooth manifolds.

The idea now is of course to apply the Knot-Branched Covering Proposition 149.5 to settle Question 59.9, namely to show that the trefoil is not amphichiral. Therefore we need to determine at least one interesting branched covering of the trefoil.

Definition. Let $J \subset S^3$ be a knot.

(1) We write



$$\begin{array}{rcl} S^3_{\geq 0} & := & \{(x_1,x_2,x_3,x_4) \in S^3 \,|\, x_4 \geq 0\} \quad \text{and} \quad J_{\geq 0} := J \cap S^3_{\geq 0} \\ S^3_{\leq 0} & := & \{(x_1,x_2,x_3,x_4) \in S^3 \,|\, x_4 \leq 0\} \quad \text{and} \quad J_{\leq 0} := J \cap S^3_{\leq 0} \end{array}$$

and

$$S^3_{=0} := \{(x_1,x_2,x_3,x_4) \in S^3 \,|\, x_4 = 0\} \quad \text{and} \quad J_{=0} := J \cap S^3_{=0}.$$

(2) We say J is in m-bridge position if the following three conditions are satisfied:
   (a) J intersects the sphere $S^3_{=0} = \text{xy-plane} \cup \{\infty\}$ transversally,
   (b) the intersection $J_{\geq 0} = J \cap S^3_{\geq 0}$ consists of m trivial arcs in the 3-ball $S^3_{\geq 0}$,
   (c) the intersection $J_{\leq 0} = J \cap S^3_{\leq 0}$ consists of m trivial arcs in the 3-ball $S^3_{\leq 0}$.

Example. In the figure below we show three knots which are isotopic to the trivial knot, the trefoil and the figure-8 knot.[1778] The first knot is in 1-bridge position whereas the latter two knots are in 2-bridge position.

trivial knot | the trefoil | figure-8 knot

Lemma 149.6. Every knot K in S^3 is smoothly isotopic to a knot J that is in m-bridge position for some m.

Sketch of proof. If a knot K is represented by a diagram with m crossings, then it is already in an m-bridge position. We refer to [**BZH2014**, Chapter 2.D] for more details. ■

Definition. Given a knot $K \subset S^3$ we define its bridge number as

$$b(K) := \min\{m \in \mathbb{N} \,|\, K \text{ is smoothly isotopic to a knot in } m\text{-bridge position}\}.$$

If $b(K) = m$, then we also just say that K is an m-bridge knot.

Examples.

(1) If K is a knot with bridge number 1, then K is smoothly isotopic to the trivial knot. This sounds pretty convincing, but as so often, it is rather painful to write down a completely rigorous argument.
(2) It follows from (1) and the figure above that the trefoil and the figure-8 knot are 2-bridge knots.

[1778] We leave it to the reader to verify that the knots pictured in the figure below are in fact isotopic to the knots shown in the figure on page 1302.

Proposition 149.7. Let K be a knot. The 2-fold branched covering $\Sigma_2(K)$ admits a Heegaard splitting of genus $b(K)-1$.

Sketch of proof. By the Knot-Branched Covering Proposition 149.5(4) we can assume that K itself is already in m-bridge position. We denote by $p\colon \Sigma_2(K) \to S^3$ the branched covering with branch locus K. The restriction of p to $p^{-1}(S^3_{\geq 0}) \to S^3_{\geq 0}$ is a 2-fold branched covering with branch locus $K_{\geq 0}$. Since $K_{\geq 0}$ are unknotted arcs this branched covering is essentially the same as the branched covering considered on page 3180.[1779] But this implies that $p^{-1}(S^3_{\geq 0})$ is a genus $m-1$ handlebody. Similarly we see that $p^{-1}(S^3_{\leq 0})$ is a genus $m-1$ handlebody and that the intersection of these two handlebodies, which is given by $p^{-1}(S^3_{=0})$ is a surface of genus $m-1$. But that means precisely that $\Sigma_2(K)$ admits a genus $m-1$ Heegaard splitting. ■

Corollary 149.8. If K is a knot with bridge number $b(K)=2$, then $\Sigma_2(K)$ is diffeomorphic to a lens space.

Proof. Let K be a knot with bridge number $b(K)=2$. It follows from Proposition 149.7 that the 2-fold branched covering $\Sigma_2(K)$ admits a Heegaard splitting of genus one. It follows from the Knot-Branched Covering Proposition 149.5 (1) and Corollary 146.8 that $\Sigma_2(K)$ is either diffeomorphic to a lens space or to $S^1\times S^2$. In the Knot-Branched Covering Proposition 149.5 (8) we saw that $\mathrm{H}_1(\Sigma_2(K);\mathbb{Z})$ is finite, thus we can exclude the possibility that $\Sigma_2(K)$ is diffeomorphic to $S^1\times S^2$. ■

We had just seen that the trefoil and the figure-8 knot are 2-bridge knots. So their 2-fold branched coverings are lens spaces. The following proposition tells us what these 2-fold branched coverings are.

Proposition 149.9. [1780]

(1) The 2-fold branched covering of the trefoil is diffeomorphic to the lens space $L(3,2)$.
(2) The 2-fold branched covering of the figure-8 knot is diffeomorphic to the lens space $L(5,2)$.

Remark. Horst Schubert [**SchubH1956**] showed in 1956 that every lens space is the 2-fold branched covering of a 2-bridge knot.

Proof. Let K be a 2-bridge knot. There is a general algorithm that determines the lens space which equals the 2-fold branched covering $\Sigma_2(K)$, see e.g. [**BZH2014**, Proposition 12.3]. The statement about the trefoil is then implied by [**BZH2014**, Example 12.16]. The statement about the figure-8 knot is implicit in [**BZH2014**, Section 12].

There are also several other proofs for the first statement:

(1) Let K be the trefoil. It follows from the calculation on page 1336, the Hurewicz Theorem 84.5, the Knot-Branched Covering Proposition 149.5 and Lemma 51.9 (1) that $\mathrm{H}_1(\Sigma_2(K);\mathbb{Z}) \cong \mathbb{Z}_3$. Furthermore, by Corollary 149.8 we know that $\Sigma_2(K)$ is a

[1779] An argument similar to the proof of the Knot-Branched Covering Proposition 149.5 (2) shows that all 2-fold branched coverings of the 3-ball with branch locus given by two unknotted arcs are homeomorphic.
[1780] Since it is exceedingly painful to keep track of orientation conventions we will not attempt to determine whether there exist orientation-preserving or orientation-reversing diffeomorphisms between the branched coverings and the lens spaces.

lens space. Thus we see that $\Sigma_2(K)$ is diffeomorphic to $L(3,1)$ or to $L(3,2)$. But these two lens spaces are diffeomorphic by the Lens Spaces-Diffeomorphisms Lemma 48.6.

(2) We also refer to [**Sti1993**, Section 7.2.2] and [**Rolf1990**, p. 304] for two alternative proofs of the first statement. ■

Finally we can answer Question 59.9 in the negative.

Proposition 149.10. The trefoil is chiral.

Remark. In Proposition 131.5 we gave an alternative proof of Proposition 149.10 which is more elementary, but less conceptual.

Proof. Let K be the trefoil. By Proposition 149.9 (9) we know that $\Sigma_2(K)$ is diffeomorphic to the lens space $L(3,2)$. We know from Proposition 148.23 that $L(3,2)$ is chiral. But by the Knot-Branched Covering Proposition 149.5 (6) this implies that K is also chiral. ■

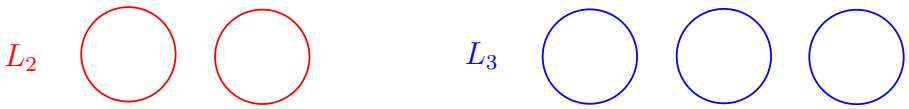
We have now shown that the trefoil is not smoothly isotopic to its mirror image. Therefore one often distinguishes in the literature between the left-handed trefoil (which equals our trefoil from before) and the right-handed trefoil. The names stem from the observation that if we equip the right-handed trefoil with either of the two orientations the following holds: if the thumb of the right-hand points in the direction of the overcrossing-strand, then the fingers point in the direction of the undercrossing-strand. (It is a fun exercise to verify this statement.)

left-handed trefoil

right-handed trefoil

Remark. On page 2392 we saw that $L(5,2)$ is amphichiral. This is consistent with the fact, illustrated in the figure on page 1316, that the figure-8 knot is amphichiral and Propositions 149.9 and 149.5 (6).

Remark. In this chapter we studied questions about smooth embeddings of a given closed k-dimensional smooth manifold W into a given closed $(k+2)$-dimensional smooth manifold M, namely of smooth embeddings of $W = S^1$ into $M = S^3$, by associating to a smooth embedding a branched covering. The same approach can also be used in many other contexts, for example it can and is being used to study smooth embeddings of surfaces into closed 4-dimensional smooth manifolds, see e.g. [**HsSz1971**].



Exercises for Chapter 149.

Exercise 149.1. The definition of the m-fold branched cover of a knot easily in S^3 generalizes to the notion of an m-fold branched cover of a link in S^3.

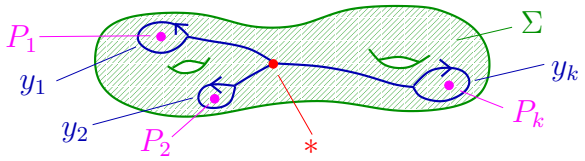
(a) We consider the trivial 2-component link L_2. What is the diffeomorphism type of the corresponding 2-fold branched cover?

(b) We consider the trivial 2-component link L_2. What is the diffeomorphism type of the corresponding 5-fold branched cover?

(c) We consider the trivial 2-component link L_3. What is the diffeomorphism type of the corresponding 2-fold branched cover?

Exercise 149.2. Let K and J be two oriented knots in S^3. We denote by $K\#J$ the connected sum of the two oriented knots as defined on page 1319. Show that for every $n \in \mathbb{N}$ the branched cover $\Sigma_n(K\#J)$ is diffeomorphic to the connected sum $\Sigma_n(K)\#\Sigma_n(J)$.

Exercise 149.3. Let K be the trefoil.



(a) Show that the square knot $K\#K$ is not smoothly isotopic to its mirror image.
(b) Show that the granny knot $K\#K^{\mathrm{mir}}$ is neither smoothly isotopic to the square knot $K\#K$ nor to its mirror image.

Hint. Use Exercise 149.2 and 148.4.

Exercise 149.4. Let Σ be the surface of genus g and let $P_1, \dots, P_k$ be disjoint points in Σ. We set $F := \Sigma \setminus \{P_1, \dots, P_k\}$. We pick a base point $* \in F$.

(a) Let $\Gamma \subset \pi_1(F, *)$ be a subgroup of finite index. By the Covering Existence Theorem 61.5 we know that there exists a finite covering $p\colon \widetilde{F} \to F$ with $p_*(\pi_1(\widetilde{F}), *) = \Gamma$. Show that the covering $p\colon \widetilde{F} \to F$ can be extended to a branched covering $q\colon \widetilde{\Sigma} \to \Sigma$.
(b) Let $\varphi\colon \pi_1(F, *) \to \mathbb{Z}_m$ be an epimorphism. We pick loops $y_1, \dots, y_k$ as illustrated in. We apply (a) to $\Gamma = \ker(\varphi)$ and we obtain a branched covering $q\colon \widetilde{\Sigma} \to \Sigma$. What is the genus of $\widetilde{\Sigma}$ in terms of g and the orders of the images of $\varphi([y_1]), \dots, \varphi([y_k])$?
(c) How does (b) generalize to the situation where $\varphi\colon \pi_1(F, *) \to G$ is an epimorphism onto some finite group?

Remark. The Preimage-of-Covering Proposition 63.5 might come in handy.

Exercise 149.5. Let $q(z) =$ be a non-constant complex polynomial. Show that the map

$$\begin{array}{rcl} \mathbb{C}\mathrm{P}^1 & \to & \mathbb{C}\mathrm{P}^1 \\ [z:w] & \mapsto & \begin{cases} [q(a):1], & \text{if } [z:w] = [a:1] \text{ for some } a \in \mathbb{C}, \\ [1:0], & \text{if } [z:w] = [1:0] \end{cases} \end{array}$$

is a branched covering. In particular determine the branch locus.
Hint. Use the Locally-a-Power Theorem 32.8.

look at proof of Proposition 150.10 First we recall the definition of an R-homology sphere from page 3143 and we introduce some, almost self-explanatory, related notions.

Definition. Let R be a commutative ring and let M be a compact orientable n-dimensional topological manifold. We introduce the following notions:

M is an R-homology sphere,	if for each $k \in \mathbb{N}_0$ we have	$\mathrm{H}_k(M;R) \cong \mathrm{H}_k(S^n;R)$
M is an R-homology ball,	if for each $k \in \mathbb{N}_0$ we have	$\mathrm{H}_k(M;R) \cong \mathrm{H}_k(\overline{B}^n;R)$
M is an R-cylinder,	if for each $k \in \mathbb{N}_0$ we have	$\mathrm{H}_k(M;R) \cong \mathrm{H}_k(S^{n-1}\times[0,1];R)$.

Instead of $\mathbb{Z}$-homology sphere we usually say integral homology sphere and instead of $\mathbb{Q}$-homology sphere we usually say rational homology sphere. The same convention holds also for balls and cylinders.

Remark. On pages 2159, 2710 and 3143 we defined homology spheres without the condition that M is compact and orientable. In fact we saw in Lemma 124.1 that the purely homological definition already implies that M is closed and orientable. A similar discussion applies to homology balls that we first introduced on page 2720.

Lemma 150.1. Let M be an n-dimensional topological manifold.

(1) If M is a rational homology n-ball, then ∂M is a rational homology $(n-1)$-sphere.[1781]
(2) Let M be a rational homology cylinder.
   (a) The boundary ∂M has precisely two components X and Y, each of which is a rational homology $(n-1)$-sphere.
   (b) The inclusion induced maps $\mathrm{H}_*(X;\mathbb{Q}) \to \mathrm{H}_*(M;\mathbb{Q})$ and $\mathrm{H}_*(Y;\mathbb{Q}) \to \mathrm{H}_*(M;\mathbb{Q})$ are isomorphisms.
(3) Let M be a rational homology ball. If $\varphi\colon \overline{B}^n \to M \setminus \partial M$ is a smooth embedding, then $M \setminus \varphi(B^n)$ is a rational homology cylinder.

The same statements also hold if we replace "rational" by "integral".

Proof. The lemma will be proved in Exercise 144.4. ■

Now we can modify the cobordism groups Ω_n to obtain new and interesting groups.

Definition. Let $n \in \mathbb{N}$. We define

$\Theta^n_{\mathbb{Q}} := \{\text{diffeomorphism classes of oriented } n\text{-dimensional rational homology spheres}\}/\!\sim_{\mathbb{Q}}$

where we write $M \sim_{\mathbb{Q}} N$ if there exists an oriented cobordism W between M to N that is a rational homology cylinder. Similarly we define

$\Theta^n_{\mathbb{Z}} := \{\text{diffeomorphism classes of oriented } n\text{-dimensional integral homology spheres}\}/\!\sim_{\mathbb{Z}}$

where we write $M \sim_{\mathbb{Z}} N$ if there exists an oriented cobordism W between M and N that is an integral homology cylinder. Furthermore we define $\Theta^{\mathrm{top},n}_{\mathbb{Q}}$ and $\Theta^{\mathrm{top},n}_{\mathbb{Z}}$ the same way as above except that we "throw over board" all smooth structures. More precisely, we make the following two changes:

(1) We consider homeomorphism classes of oriented n-dimensional rational homology spheres.

[1781] This statement is closely related to Lemma 124.8.

(2) We no longer demand that the cobordism W is a smooth manifold, we only assume that it is a topological manifold.

To simplify the discussion, and out of personal preference, henceforth we only consider the case $n = 3$ and we drop the decoration "3" from the notation. Recall that Theorem **??** says that in dimension *three* any topological manifold admits a smooth structure and two smooth manifolds are homeomorphic if and only if they are diffeomorphic. Put differently, there is basically no difference between the study of 3-dimensional topological manifolds and the study of 3-dimensional smooth manifolds. On the other hand, we saw in Theorem 135.9 that in dimension *four* there is a big difference between the theory of topological manifolds and the theory of smooth manifolds. In particular the above notions of cobordisms might change depending on whether or not we consider 4-dimensional topological manifolds or 4-dimensional smooth manifolds.

Proposition 150.2. In all four cases the connected sum operation defines an abelian group structure where the neutral element is given by S^3 and where the inverse of a homology sphere Y is given by $-Y$.

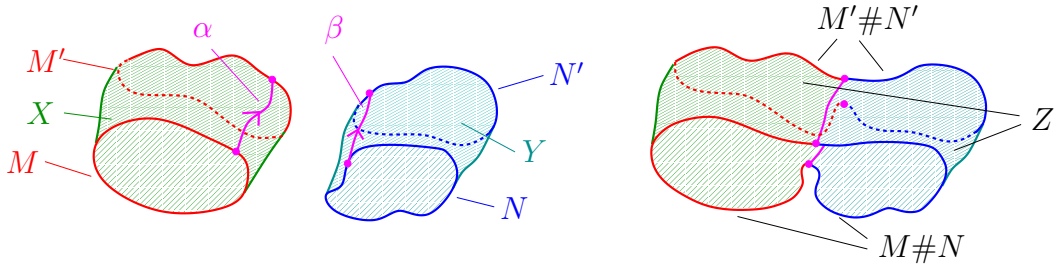
Example. Let Y be a 3-dimensional rational homology sphere. If Y is amphichiral, then we have the following equality in $\Theta_{\mathbb{Q}}$:

$$[Y]\#[Y] \underset{\substack{\uparrow \\ \text{since } Y \text{ amphichiral}}}{=} [Y]\#[-Y] \underset{\substack{\uparrow \\ \text{Proposition 150.2}}}{=} S^3 \in \Theta_{\mathbb{Q}}$$

This implies that an amphichiral 3-dimensional rational sphere defines either the trivial element in $\Theta_{\mathbb{Q}}$ or an element of order 2.

Sketch of proof. In the following steps we verify all the statements that are implicit in the formulation of the proposition for $\Theta_{\mathbb{Q}}$.

(1) It follows from the Connected Sum-H_*-Proposition 100.13 that the connected sum of two rational homology spheres is again a rational homology sphere.

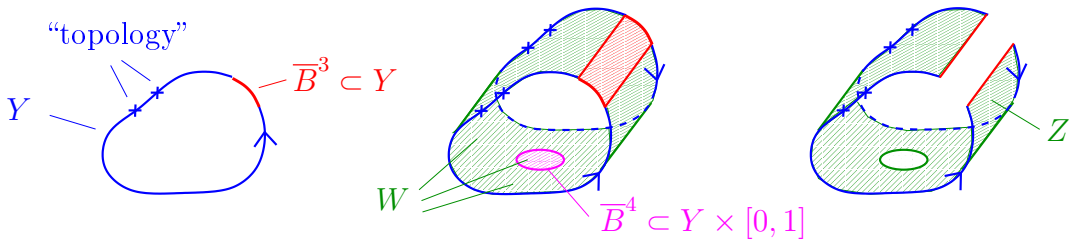


(2) We need to show that the connected sum operation descends to a well-defined operation on $\Theta_{\mathbb{Q}}$. Thus suppose that we are given oriented, rational homology spheres M and M' and also N and N' such that $M = M' \in \Theta_{\mathbb{Q}}$ and $N = N' \in \Theta_{\mathbb{Q}}$. We need to show that $M\#N = M'\#N' \in \Theta_{\mathbb{Q}}$. We pick compact oriented 4-dimensional smooth manifolds X and Y with $\partial X = M \sqcup -M'$ and $\partial Y = N \sqcup -N'$ as in the definition of $\sim_{\mathbb{Q}}$.

By Corollary 102.14 we can pick an oriented proper connected 1-dimensional submanifold $[0,1] \cong \alpha \subset X$ which connects a point on M to a point on M'. Similarly we can pick a proper connected 1-dimensional submanifold $[0,1] \cong \beta \subset Y$ which connects a point on N to a point on N'. By the Tubular Neighborhood Theorem **??** we can thicken the submanifolds α and β to submanifolds $[0,1] \times \overline{B}^3 = \alpha \times \overline{B}^3$ and $[0,1] \times \overline{B}^3 = \beta \times \overline{B}^3$. We can and will pick the former map to be orientation-preserving and the latter orientation-reversing. We define

$$Z := \big((X \setminus (\alpha \times B^3)) \sqcup (Y \setminus (\beta \times B^3))\big)/\sim$$

where we identify a point on $\alpha \times S^2 = [0,1] \times S^2$ with the corresponding point on $\beta \times S^2 = [0,1] \times S^2$. After smoothing corners, see [**Wall2016**, Proposition 2.6.2],



we can view Z as a compact oriented smooth manifold such that $\partial Z = (M\#N) \sqcup -(M'\#N')$. (This construction is illustrated in the figure below.) Using that X and Y are rational homology cylinders one can fairly easily show that Z itself is also a rational homology cylinder.

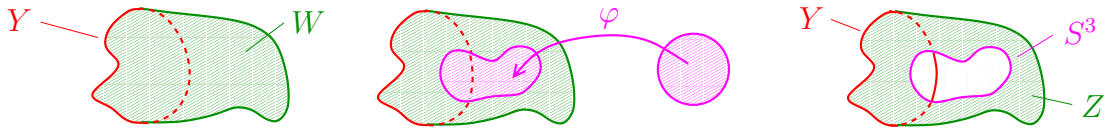
(3) It follows from Lemma **??** that the connected sum operation is commutative and associative. Furthermore it follows from Lemma **??** that S^3 is the neutral element with respect to the connected sum operation.

(4) Let Y be a rational homology sphere. We have to show that $(Y\# - Y) \sim_{\mathbb{Q}} S^3$. We pick a closed 3-ball $\overline{B}^3$ in Y. We consider $W = ([0,1] \times Y) \setminus ([0,1] \times B^3)$. After smoothing corners we have $\partial W = Y\# - Y$. Finally we remove an open 4-ball from W and we obtain a 4-manifold Z with $\partial Z = (Y\# - Y) \sqcup S^3$. We leave it to the reader to verify that Z is a rational homology cylinder. We illustrate this construction in the figure below.

The proof that $\Theta_{\mathbb{Z}}$ forms a group is basically identical to the above proof. The proof that $\Theta^{\text{top}}_{\mathbb{Q}}$ and $\Theta^{\text{top}}_{\mathbb{Z}}$ form groups is in principle the same, except that we need to replace the references dealing with smooth manifolds by references that take care of topological manifolds. For example, we need to replace the Tubular Neighborhood Theorem **??** by the fact that compact 1-dimensional submanifolds of compact topological manifolds admit trivial tubular neighborhoods, see the discussion on page **??**. ■

The following lemma gives a characterization of smooth manifolds representing the trivial element in the various groups that we just introduced.

Lemma 150.3. Let Y be a 3-dimensional rational homology sphere. Then



$$[Y] = 0 \in \Theta_{\mathbb{Q}} \iff \text{there exists a 4-dimensional smooth manifold } W \text{ that is a rational homology ball } W \text{ with } \partial W = Y.$$

There are obvious analogues to this statement for the groups $\Theta_{\mathbb{Z}}$, $\Theta^{\text{top}}_{\mathbb{Q}}$ and $\Theta^{\text{top}}_{\mathbb{Z}}$.

Proof. Let Y be a 3-dimensional rational homology sphere.

"⇒" If Y represents the trivial element in $\Theta_{\mathbb{Q}}$, then by definition there exists a 4-dimensional rational homology cylinder Z with $\partial Z = Y \sqcup -S^3$. A straightforward argument, using the Gluing-Smooth Manifolds-Proposition **??**, Lemma 150.1 and the Mayer–Vietoris Theorem 78.9 for Manifolds shows that $W = Z \cup_{\partial Z = S^3} \overline{B}^4$ is a rational homology ball. Evidently we have $\partial W = Y$.

"⇐" Now suppose that there exists a 4-dimensional smooth manifold W that is a rational homology ball W with $\partial W = Y$. We pick a smooth embedding $\varphi\colon \overline{B}^4 \to W \setminus \partial W$. It follows from Lemma 150.1 (3) that $Z = Y \setminus \varphi(B^4)$ is a rational cylinder which then shows that $[Y] = [S^3] = 0 \in \Theta_{\mathbb{Q}}$. We refer to the figure below for an illustration. ■

We start out with the investigation of the group $\Theta_{\mathbb{Q}}^{\text{top}}$.

Proposition 150.4. Let M be a 3-dimensional rational homology sphere. If $M = 0 \in \Theta_{\mathbb{Q}}^{\text{top}}$, then $|\mathrm{H}_1(M;\mathbb{Z})|$ is a square.

As we will see, Proposition 150.4 is an almost immediate consequence of Statement (1) of the following lemma.

Lemma 150.5. Let M be a 3-dimensional rational homology sphere and let W a rational homology ball W with $\partial W = M$.

(1) We have[17821783]
$$|\ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}))|^2 \;=\; |\mathrm{H}_1(M;\mathbb{Z})|.$$

(2) [1784] The linking pairing λ_M vanishes on $\ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}))$, more precisely, for any $x, y \in \ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}))$ we have $\lambda_M(x,y) = 0$.

(3) The subgroup $P := \ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}))$ is a metabolizer of the linking pairing. This means, according to the definition on page 3171, that $P = P^{\perp}$ where $P^{\perp} := \{v \in \mathrm{H}_1(M;\mathbb{Z}) \,|\, \lambda(v,w) = 0 \text{ for all } w \in P\}$.

Proof of Proposition 150.4 assuming Lemma 150.5. Let M be a 3-dimensional rational homology sphere which represents the trivial element in $\Theta_{\mathbb{Q}}^{\text{top}}$. By Lemma 150.3 there exists a 4-dimensional smooth manifold W that is a rational homology ball W with $\partial W = M$. Thus the proposition follows from Lemma 150.5 (1). ■

Proof of Lemma 150.5. Let M be a 3-dimensional rational homology sphere and let W a rational homology ball W with $\partial W = M$. First we note that the fact that M is a rational homology sphere and that W is a rational homology ball implies, by the argument of

[1784] This claim is precisely the content of Exercise 150.5.

[1783] Put differently, we can say that $|\ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}))| = \sqrt{|\mathrm{H}_1(M;\mathbb{Z})|}$. With this formulation the statement of the claim is quite similar to the statement of the Half-Live Half-Die Theorem 144.9. In fact we will see that the proof of the claim is a variation on the proof of the Half-Live Half-Die Theorem 144.9.

[1784] We will not make use of statements (1) and (2). But these two statements play an important ingredient in some branches of topology, for example it plays a crucial role in the seminal paper [**CaG1986**].

Lemma 148.1, that the homology groups $\mathrm{H}_1(M;\mathbb{Z})$, $\mathrm{H}_2(M;\mathbb{Z})$ and also $\mathrm{H}_1(W;\mathbb{Z})$, $\mathrm{H}_2(W;\mathbb{Z})$ are finite.

(1) We consider the long exact sequence in homology groups corresponding to the pair (W, M) with $\mathbb{Z}$-coefficients:

$$\begin{aligned}\ldots \quad &\to \overbrace{\mathrm{H}_2(M;\mathbb{Z})}^{\substack{\text{isomorphic to } \mathrm{H}^1(M;\mathbb{Z}) \cong \mathrm{Hom}(\mathrm{H}_1(M;\mathbb{Z}),\mathbb{Z}) \text{ by the Poincaré Duality Theorem 119.1,}\\ \text{and the First Cohomology Proposition 110.17, therefore zero since } \mathrm{H}_1(M;\mathbb{Z}) \text{ is finite}\\ \downarrow}} \to \mathrm{H}_2(W;\mathbb{Z}) \to \mathrm{H}_2(W,M;\mathbb{Z})\\ &\to \mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}) \to \mathrm{H}_1(W,M;\mathbb{Z}) \to \mathrm{H}_0(M;\mathbb{Z}) \underset{\substack{\uparrow\\ \text{isomorphism by the discussion on page 1594}}}{\to} \mathrm{H}_0(W;\mathbb{Z}) \to 0.\end{aligned}$$

By the Break-into-SES Lemma 78.4 we now get the following exact sequence:

$$0 \to \mathrm{H}_2(W;\mathbb{Z}) \to \mathrm{H}_2(W,M;\mathbb{Z}) \to \mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}) \to \mathrm{H}_1(W,M;\mathbb{Z}) \to 0.$$

We consider the group on the left. We have

$$\mathrm{H}_2(W,M;\mathbb{Z}) \underset{\substack{\uparrow\\ \text{Poincaré Duality}\\ \text{Theorem 119.1}}}{\cong} \mathrm{H}^2(W;\mathbb{Z}) \underset{\substack{\uparrow\\ \text{Universal Coefficient}\\ \text{Theorem 110.12}}}{\cong} \overbrace{\mathrm{Hom}(\mathrm{H}_2(W;\mathbb{Z}),\mathbb{Z})}^{=0 \text{ since } \mathrm{H}_2(W;\mathbb{Z}) \text{ is finite}} \oplus \underbrace{\mathrm{Ext}(\mathrm{H}_1(W;\mathbb{Z}),\mathbb{Z})}_{\substack{\text{by the Ext-Calculation Lemma 110.5 (5)}\\ \text{since } \mathrm{H}_1(W;\mathbb{Z}) \text{ is finite}}} \underset{\substack{\uparrow\\ \text{by the Ext-Calculation Lemma 110.5 (5)}\\ \text{since } \mathrm{H}_1(W;\mathbb{Z}) \text{ is finite}}}{\cong} \mathrm{H}_1(W;\mathbb{Z}).$$

Almost the same argument shows that $\mathrm{H}_2(W;\mathbb{Z}) \cong \mathrm{H}_1(W,M;\mathbb{Z})$. This shows that the above exact sequence is an exact sequence of finite abelian groups that is "symmetric" around $\mathrm{H}_1(M;\mathbb{Z})$. Therefore it remains to prove the following claim.

Claim. If

$$0 \to A_k \to \ldots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \ldots \to A_k \to 0$$

is an exact sequence of finite abelian groups, then

$$|\ker(\gamma\colon B \to A_1)|^2 = |B|.$$

Proof. The claim is proved by induction on k, exactly the same way as we proved the claim on page 3097. We leave the details to the reader.

(2) By Lemma 148.31 we know that exists a pairing $\chi\colon \mathrm{H}_2(W,M;\mathbb{Z}) \times \mathrm{H}_2(W,M;\mathbb{Z}) \to \mathbb{Q}$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_2(W,M;\mathbb{Z}) \times \mathrm{H}_2(W,M;\mathbb{Z}) & \xrightarrow{\quad\chi\quad} & \mathbb{Q} \\ \downarrow{\scriptstyle \partial\times\partial} & & \downarrow \\ \mathrm{H}_1(M;\mathbb{Z}) \times \mathrm{H}_1(M;\mathbb{Z}) & \xrightarrow[\lambda_M]{} & \mathbb{Q}/\mathbb{Z}. \end{array}$$

We make the following observations:

(a) By the long exact sequence in homology of the pair (W, M) we have

$$\ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z})) = \mathrm{im}(\partial\colon \mathrm{H}_2(W,M;\mathbb{Z}) \to \mathrm{H}_1(M;\mathbb{Z})).$$

(b) By the long exact sequence in homology and the above information on the homology groups of W and M we know that $\mathrm{H}_2(W,M;\mathbb{Z})$ is finite.

(c) Since $\mathrm{H}_2(W,M;\mathbb{Z})$ is finite we see that the pairing χ is the zero-pairing.

(d) It follows from (1), (3) and the commutative diagram that λ_M does indeed vanish for any $x, y \in \ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}))$.

(3) It follows from (1), (2) and Exercise 148.2 that $\ker(\mathrm{H}_1(M;\mathbb{Z}) \to \mathrm{H}_1(W;\mathbb{Z}))$ is a metabolizer for the linking pairing. ■

Corollary 150.6. Let M and N be two 3-dimensional rational homology spheres. If we have $[M] = [N] \in \Theta^{\mathrm{top}}_{\mathbb{Q}}$, then $|\mathrm{H}_1(M;\mathbb{Z})| \cdot |\mathrm{H}_1(N;\mathbb{Z})|$ is a square.

Proof. Let M and N be two 3-dimensional rational homology spheres which satisfy the equality $[M] = [N] \in \Theta^{\mathrm{top}}_{\mathbb{Q}}$. From Proposition 150.2 we obtain immediately the equality $[M\#(-N)] = [M]-[N] = 0 \in \Theta^{\mathrm{top}}_{\mathbb{Q}}$. Now Proposition 150.4 implies that $|\mathrm{H}_1(M\#(-N);\mathbb{Z})|$ is a square. The corollary follows from the Connected Sum-H_*-Proposition 100.13 which states that $\mathrm{H}_1(M\#(-N);\mathbb{Z}) \cong \mathrm{H}_1(M;\mathbb{Z}) \oplus \mathrm{H}_1(N;\mathbb{Z})$. ■

The following proposition shows that the groups $\Theta^{\mathrm{top}}_{\mathbb{Q}}$ and $\Theta_{\mathbb{Q}}$ are very much non-trivial.

Proposition 150.7.

(1) The groups $\Theta^{\mathrm{top}}_{\mathbb{Q}}$ and $\Theta_{\mathbb{Q}}$ admit an epimorphism onto $\mathbb{Z}_2^\infty$.

(2) The groups $\Theta^{\mathrm{top}}_{\mathbb{Q}}$ and $\Theta_{\mathbb{Q}}$ admit a subsummand isomorphic to $\mathbb{Z}_2^\infty$.[1785]

Remark. It follows from [**KK1980**, Theorems 5.2 and 6.1] and a generalization of the arguments used in the proof of Proposition 150.7 (1) that the group $\Theta^{\mathrm{top}}_{\mathbb{Q}}$ admits an epimorphism onto $\mathbb{Z}_2^\infty \oplus \mathbb{Z}_4^\infty \oplus \mathbb{Z}_4^\infty$.

The proof of Proposition 150.7 (2) relies on the following theorem from number theory. We refer to [**IR1990**, p. 251] for a proof.

Theorem 150.8. (Dirichlet's Theorem on Arithmetic Progressions) For any coprime $a, n \in \mathbb{N}$ there exist infinitely many primes of the form $a + kn$ with $k \in \mathbb{N}$.

Proof of Proposition 150.7.

(1) We have an obvious epimorphism $\Theta_{\mathbb{Q}} \to \Theta^{\mathrm{top}}_{\mathbb{Q}}$, so it suffices to show that the group $\Theta^{\mathrm{top}}_{\mathbb{Q}}$ admits an epimorphism onto $\mathbb{Z}_2^\infty$. For each prime p we consider the map

$$\begin{array}{rccl} \alpha_p\colon \Theta^{\mathrm{top}}_{\mathbb{Q}} & \to & \mathbb{Z}_2 \\ M & \mapsto & \max\{n \in \mathbb{N}_0 \,|\, p^n \text{ divides } |\mathrm{H}_1(M;\mathbb{Z})|\} \mod 2. \end{array}$$

It follows easily from Corollary 150.6, together with the uniqueness of the prime power decomposition of natural numbers and the fact that p is a prime, that this map is well-defined. Furthermore it follows from the Connected Sum-H_*-Proposition 100.13 that α_p is a group homomorphism.

It remains to show that the homomorphism

$$\begin{array}{rccl} \alpha\colon \Theta^{\mathrm{top}}_{\mathbb{Q}} & \to & \bigoplus\limits_{\text{prime } p} \mathbb{Z}_2 \\ M & \mapsto & \bigoplus\limits_{\text{prime } p} \alpha_p(M) \end{array}$$

[1785] Here we say that an abelian group G is a subsummand of an abelian group H if there exists an abelian group A such that $H \cong G \oplus A$.

is an epimorphism. But this follows immediately from considering lens spaces. More precisely, let p be a prime. By Corollary 84.6 we have $\mathrm{H}_1(L(p,1);\mathbb{Z}) \cong \mathbb{Z}_p$, i.e. we have $\alpha_p(L(p,1)) = 1$ and $\alpha_q(L(p,1)) = 0$ for every prime $q \neq p$.

(2) By Dirichlet's Theorem 150.8 there exist infinitely many primes $p_i, i \in \mathbb{N}$ such that $p_i \equiv 1 \bmod 4$. By the calculation of the Legendre symbol, see e.g. [**IR1990**, p. 52], given any such prime p_i there exists an $a_i \in \{1, \dots, p_i - 1\}$ such that $a_i^2 \equiv -1 \bmod p_i$. It follows from Lemma 107.6 that the lens spaces $L(p_i, a_i)$ are amphichiral. It follows from the discussion on page 3189 and from (1) that we have well-defined homomorphisms

$$\begin{array}{ccccc} \mathbb{Z}_2^\infty & \to & \Theta_{\mathbb{Q}}^{\mathrm{top}} & \to & \mathbb{Z}_2^\infty \\ & & M & \mapsto & \sum\limits_i \alpha_{p_i}(M) \\ (x_1, x_2, \dots) & \mapsto & \#\limits_{\substack{i \text{ with} \\ x_i = 1}} L(p_i, a_i), & & \end{array}$$

furthermore we see easily that the composition of these two maps is the identity. This shows that the right-hand map splits. Therefore it follows from Splitting Lemma 78.2 that $\mathbb{Z}_2^\infty$ is in fact a subsummand of $\Theta_{\mathbb{Q}}^{\mathrm{top}}$. Exactly the same argument applies to $\Theta_{\mathbb{Q}}$. ■

By definition any 3-dimensional integral homology sphere lies in the kernel of the epimorphism $\Theta_{\mathbb{Q}}^{\mathrm{top}} \to \mathbb{Z}_2^\infty$ that we had just constructed in the proof of Proposition 150.7.
In fact it was proved by Michael Freedman [**Fre1982**, Theorem 1.4'] in 1981 that every integral homology 3-dimensional sphere bounds a simply connected integral homology 4-dimensional ball.[1786] This result implies in particular the following theorem.

Theorem 150.9. The group $\Theta_{\mathbb{Z}}^{\mathrm{top}}$ is trivial.

It turns out that the situation is quite different if we consider the group $\Theta_{\mathbb{Z}}$ instead of the group $\Theta_{\mathbb{Z}}^{\mathrm{top}}$. In fact we have the following proposition.

Proposition 150.10. Given a 3-dimensional integral homology sphere M we define

$$\mu(M) \ := \ \tfrac{1}{8}\operatorname{sign}(W) \ \bmod 2$$

where W is a compact oriented 4-dimensional smooth manifold with $\partial W = M$, with $\mathrm{H}_1(W;\mathbb{Z}) = 0$ and with even intersection form.

(1) The number $\mu(M)$ is well-defined and it lies in $\mathbb{Z}_2$.

(2) The map

$$\begin{array}{rccc} \mu\colon \Theta_{\mathbb{Z}} & \to & \mathbb{Z}_2 \\ M & \mapsto & \mu(M), \end{array}$$

is a well-defined homomorphism, it is called the *Rokhlin homomorphism*.

(3) The Rokhlin homomorphism $\mu\colon \Theta_{\mathbb{Z}} \to \mathbb{Z}_2$ is an epimorphism, in particular $\Theta_{\mathbb{Z}}$ is non-trivial.

Remark. The Rokhlin homomorphism is the starting point for many developments in the study of 3-dimensional and 4-dimensional smooth manifolds. For example Andrew Casson

[1786] The methods that Michael Freedman used in the proof of this result are closely related to the methods in Freedman's proof of the topological Poincaré Conjecture in dimension 4, see Theorem **??**.

showed in the mid 1980s that there exists a map

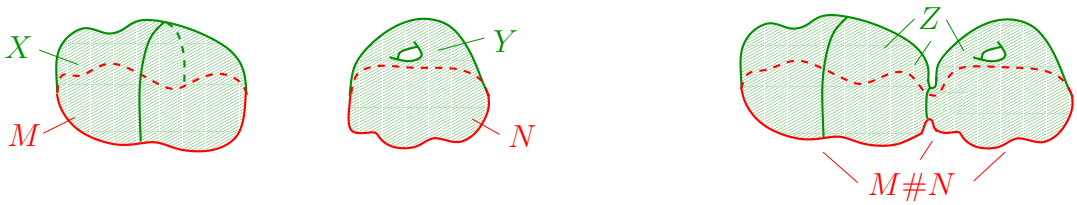
$$\lambda\colon \left\{ \begin{array}{c} \text{diffeomorphism classes of oriented} \\ \text{3-dimensional integral homology spheres} \end{array} \right\} \to \mathbb{Z}$$

that has the following properties:

(1) It is additive in the sense that for two 3-dimensional integral homology spheres M and N we have $\lambda(M\#N) = \lambda(M) + \lambda(N)$.
(2) For every 3-dimensional integral homology sphere we have $\mu(M) = \lambda(M) \bmod 2$.

More information on the Casson invariant λ can be found in [**Sav2002, AkM1990**].

Sketch of the proof of Proposition 150.10.



(1) Let M be a 3-dimensional integral homology sphere. The following arguments show that $\mu(M)$ is indeed defined, that it is well-defined and that it lies in $\mathbb{Z}_2$.
   (a) By [**Kap1979**], see also [**Sav2002**, p. 38], there exists a compact oriented 4-dimensional smooth manifold with $\partial W = M$, with $\mathrm{H}_1(W;\mathbb{Z}) = 0$ and with even intersection form.[1787]
   (b) Since ∂W is an integral homology sphere and since $\mathrm{H}_1(W;\mathbb{Z}) = 0$ one can easily adjust the argument of the proof of the Intersection Form Proposition 132.4 to show that the intersection form Q_W is non-singular.
   (c) Since the intersection form Q_W is even and non-singular it follows from the Even Forms Proposition 133.18 that $\mathrm{sign}(W) = \mathrm{sign}(Q_W)$ is divisible by 8, i.e. $\frac{1}{8}\mathrm{sign}(W) \in \mathbb{Z}$.
   (d) Now suppose that we have another compact oriented 4-dimensional smooth manifold W' with $\mathrm{H}_1(W';\mathbb{Z}) = 0$, with $\partial W' = M$ and with even intersection form. We need to show that $\mathrm{sign}(W) \equiv \mathrm{sign}(W') \bmod 16$.
   We consider the closed oriented 4-dimensional smooth manifold[1788]
   $$X \;:=\; W \cup_{\partial W = \partial W'} (-W')$$
   that we obtain from gluing W and $-W'$ along the common boundary given by M. Since $\mathrm{H}_1(W;\mathbb{Z}) = \mathrm{H}_1(W';\mathbb{Z}) = 0$ and since M is an integral homology sphere one can easily adapt the proof of the Connected Sum-H_*-Proposition 100.13 to show that $\mathrm{H}_1(X;\mathbb{Z}) = 0$ and one can modify the proof of the Intersection Form-Additivity Proposition 132.12 to conclude that $Q_X \cong Q_W \oplus -Q_{W'}$, in particular Q_X is even. Now we can apply Rokhlin's Theorem 135.5 to conclude that $\mathrm{sign}(X) \equiv 0 \bmod 16$. But by the isomorphism $Q_X \cong Q_W \oplus -Q_{W'}$ this implies that $\mathrm{sign}(W) - \mathrm{sign}(W') \equiv 0 \bmod 16$, which gives us the desired result.
(2) Now we have to show that μ defines a well-defined homomorphism $\Theta_{\mathbb{Z}} \to \mathbb{Z}_2$.
   (a) First we show that μ is additive. So let M and N be two 3-dimensional integral homology spheres. We pick 4-dimensional smooth manifolds X and Y such that $\partial X = M$ and $\partial Y = N$ and which have the extra properties that are required in the definition of $\mu(M)$ and $\mu(N)$. We denote by $Z = X\#_b Y$ the boundary connected sum that we introduced on page **??**. It follows from Proposition **??**

[1787] In fact in [**Kap1979**] it is shown that W can be chosen to be simply connected, which implies by the Hurewicz Theorem 84.5 that the first homology group vanishes.
[1788] Here we use the Gluing-Smooth Manifolds-Proposition **??** to conclude that X is indeed a closed oriented 4-dimensional smooth manifold.

that Z is a 4-dimensional smooth manifold with $\partial Z = M\#N$ and such that $\mathrm{H}_1(Z;\mathbb{Z}) = 0$. Furthermore a modest modification of the proof of the Intersection Form-Additivity Proposition 132.12 shows that $Q_Z \cong Q_X \oplus Q_Y$. This means that we can use Z to calculate $\mu(M\#N)$ and we obtain that

$$\mu(M\#N) \;=\; \tfrac{1}{8}\operatorname{sign}(Z) \;=\; \tfrac{1}{8}\operatorname{sign}(X) + \tfrac{1}{8}\operatorname{sign}(Y) \;=\; \mu(M) + \mu(N).$$

We refer to the figure below for an illustration of the argument.

(b) It follows easily from the definitions that for any integral homology sphere M we have $\mu(-M) = \mu(M)$.

(c) It remains to show that μ is well-defined. By (a) and (b) it suffices to show that if M represents the trivial element in $\Theta_{\mathbb{Z}}$, then $\mu(M) = 0$. Let such M be given. It follows from Lemma 150.3 that M is the boundary of an integral homology sphere W. Since $\mathrm{H}_2(W;\mathbb{Z}) = 0$ the intersection form is zero, in particular even. Since $\mathrm{H}_1(W;\mathbb{Z}) = 0$ we can use W to determine $\mu(M)$ and we get immediately that $\mu(M) = \frac{1}{8}\operatorname{sign}(W) = 0$.

(3) Finally we want to show that there exists a 3-dimensional integral homology sphere M with $\mu(M) = 1$. Let M be the Poincaré Homology Sphere that we introduced on page 2161. In [**Sav2002**, p. 38] it is shown that M is the boundary of a compact oriented simply connected 4-dimensional smooth manifold W with intersection form isometric to $-E_8$. As we saw on page 2913, the form $-E_8$ of rank 8 is negative-definite, hence its signature is -8. By the definition of the Rokhlin homomorphism this implies that $\mu(M) = 1$. ■

In fact a much stronger statement than Proposition 150.10 holds. Building on the techniques developed by Simon Donaldson [**Don1983, Don1987a**] Mikio Furuta [**Furu1990**] proved in 1990 the following theorem.

Theorem 150.11. The group $\Theta_{\mathbb{Z}}$ contains a subgroup that is isomorphic to $\mathbb{Z}^\infty$.

Among the four groups that we have studied in this section, the trivial group $\Theta^{\mathrm{top}}_{\mathbb{Z}}$ is the only one which has been fully calculated. At the moment we still know depressingly little about the remaining three groups. For example the following three questions are still open.

Question 150.12.

(1) Is the group $\Theta^{\mathrm{top}}_{\mathbb{Q}}$ isomorphic to $\mathbb{Z}_2^\infty \oplus \mathbb{Z}_4^\infty \oplus \mathbb{Z}_8^\infty$?

(2) Does the group $\Theta^{\mathrm{top}}_{\mathbb{Q}}$ contain elements of infinite order?

(3) Let $n \neq 1, 2$ be a natural number. Does there exist an element in the groups $\Theta_{\mathbb{Z}}$ or $\Theta_{\mathbb{Q}}$ of order n?

Exercises for Chapter 150.

Exercise 150.1. Let M be an oriented 3-dimensional rational homology sphere. We denote by $\lambda_M\colon \mathrm{H}_1(M;\mathbb{Z})\times \mathrm{H}_1(M;\mathbb{Z})\to \mathbb{Q}/\mathbb{Z}$ the linking pairing that we introduced on page 3151. Let W be a 4-dimensional rational homology ball with $\partial W = M$. We denote by $i\colon M\to W$ the inclusion and we write $K := \ker(i_*\colon \mathrm{H}_1(M;\mathbb{Z})\to \mathrm{H}_1(W;\mathbb{Z}))$. Show that λ_M vanishes on $K\times K$.

Exercise 150.2. Let Y_1 and Y_2 be two compact 3-dimensional smooth manifolds with one torus boundary component. Let $Y = Y_1\cup Y_2$ be the result of gluing Y_1 and Y_2 along the boundary. Show that if $b_1(Y)=0$, then $b_1(Y_1)=1$ and $b_1(Y_2)=1$.

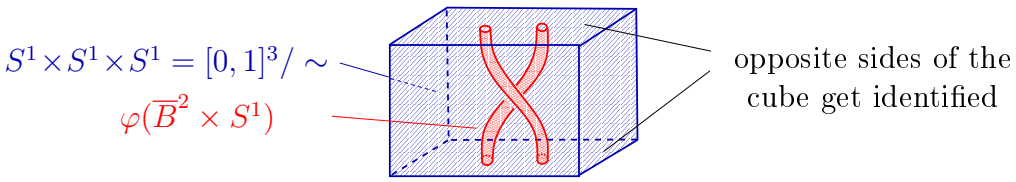
Exercise 150.3. Let W be compact orientable 3-dimensional smooth manifold such that $\mathrm{H}_1(W;\mathbb{Z})\cong\mathbb{Z}$ and such that the boundary ∂W is diffeomorphic to the torus. Show that there exists a homology 3-sphere Y and a knot $K\subset Y$ such that W is diffeomorphic to the exterior of K.
Remark. Recall that the exterior X_K of the knot K in Y is defined as $X_K = Y\setminus(B^2\times K)$ where $\overline{B}^2\times K$ is a tubular neighborhood of K in Y.

Exercise 150.4. Does there exist a compact simply connected 3-dimensional smooth manifold M such that ∂M has at least one boundary component that is a torus?

Exercise 150.5. Let Y be a 3-dimensional rational homology sphere. Now we suppose that there exists a compact orientable 4-dimensional topological manifold M such that $\mathrm{H}_*(M;\mathbb{Q})\cong \mathrm{H}_*(\overline{B}^4;\mathbb{Q})$ (sometimes such M is called a 4-dimensional rational homology ball) with $Y=\partial M$. Show that

$$|\ker(\mathrm{H}_1(Y;\mathbb{Z})\to \mathrm{H}_1(M;\mathbb{Z}))| \;=\; |\mathrm{H}_1(Y;\mathbb{Z})|.$$

Remark. The statement and the proof of the exercise are similar in spirit to the Half-Live Half-Die Theorem 144.9.



Exercise 150.6. We consider the 3-dimensional torus $S^1\times S^1\times S^1 = [0,1]^3/\!\sim$ and we consider the embedding $\varphi\colon \overline{B}^2\times S^1\to S^1\times S^1\times S^1 = [0,1]^3/\!\sim$ shown in the figure below. We set $M := (S^1\times S^1\times S^1)\setminus \varphi(B^2\times S^1)$.

(a) We denote by $i\colon \partial M\to M$ the inclusion map. Show that there exists isomorphisms $\varphi\colon \mathrm{H}_1(\partial M;\mathbb{Z})\to\mathbb{Z}^2$ and $\psi\colon \mathrm{H}_1(M;\mathbb{Z})\to\mathbb{Z}^3\oplus\mathbb{Z}_2$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_1(\partial M;\mathbb{Z}) & \longrightarrow & \mathrm{H}_1(M;\mathbb{Z}) \\ \downarrow\cong & & \downarrow\cong \\ \mathbb{Z}^2 & \xrightarrow{(a,b)\mapsto(2a,0,0,b)} & \mathbb{Z}^3\oplus\mathbb{Z}_2. \end{array}$$

(b) How does the calculation in (a) fit with Half-Live Half-Die Theorem 144.9 for the fields $\mathbb{F}=\mathbb{Q}$, $\mathbb{F}=\mathbb{F}_3$ and $\mathbb{F}=\mathbb{F}_2$?

Remark. We constructed an example with similar properties in Exercise 90.3.

$S^1 \times S^1 \times S^1 = [0,1]^3/\sim$
$\varphi(\overline{B}^2 \times S^1)$
opposite sides of the
cube get identified

Steenrod operations

151. Steenrod Operations

In this chapter we introduce the Steenrod operations. These are cohomology operations which satisfy several axioms. In the first three sections we will state the axioms and draw several interesting conclusions. Afterwards we will sketch a proof for the existence of the Steenrod operations.

151.1. The axioms of Steenrod operations.

Definition.

(1) Let A and B be abelian groups and let $m, n \in \mathbb{N}_0$. Any natural transformation from the contravariant functor

$$\mathrm{H}^m(-;A)\colon \text{category of topological spaces} \to \text{category of sets}$$

to the contravariant functor

$$\mathrm{H}^n(-;B)\colon \text{category of topological spaces} \to \text{category of sets}$$

is called a cohomology operation of degree $n-m$. In other words, a cohomology operation consists for any topological space X of a map $\Phi_X\colon \mathrm{H}^m(X;A) \to \mathrm{H}^n(X;B)$ of sets such that for any map $f\colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^m(Y;A) & \xrightarrow{f^*} & \mathrm{H}^m(X;A) \\ {\scriptstyle \Phi_Y}\downarrow & & \downarrow{\scriptstyle \Phi_X} \\ \mathrm{H}^n(Y;B) & \xrightarrow{f^*} & \mathrm{H}^n(X;B). \end{array}$$

(2) A cohomology operation is called additive if each map $\mathrm{H}^m(X;A) \to \mathrm{H}^n(X;B)$ is a homomorphism.

(3) A cohomology operation is called non-trivial if there exists a topological space X such that the map $\mathrm{H}^m(X;A) \to \mathrm{H}^n(X;B)$ is non-trivial in the sense that the image is not just the trivial element.

With the obvious modifications the same definitions also apply to relative cohomology viewed as functors from the category of pairs of topological spaces to the category of sets.

Perhaps somewhat surprisingly we have already assembled a substantial list of non-trivial cohomology operations.

Examples.

(1) Let $n \in \mathbb{N}_0$ and let G be an abelian group. Given a pair of topological spaces (X,A) we consider the connecting homomorphism $\mathrm{H}^n(X,A;G) \to \mathrm{H}^{n+1}(X;G)$. It follows from the Cohomological LES-Lemma 108.15 (3) that these homomorphisms define an additive cohomology operation of degree one.

(2) Let $\varphi\colon A \to B$ be a homomorphism between two abelian groups and let $n \in \mathbb{N}_0$. On page 2401 we saw that given any topological space X we obtain an induced homomorphism $\varphi_*\colon \mathrm{H}^n(X;A) \to \mathrm{H}^n(X;B)$. By Lemma 108.9 we know that these maps define an additive cohomology operation of degree zero.

(3) Let $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ be a short exact sequence of abelian groups. On page 3145 we introduced the n-th Bockstein homomorphism $\beta_n\colon \mathrm{H}^n(X;C) \to \mathrm{H}^{n+1}(X;A)$. In

Lemma 148.3 we saw that the n-th Bockstein homomorphisms define an additive cohomology operation of degree one.

(4) Let $k \in \mathbb{N}$. It follows from the Cup Product-Naturality Proposition 115.4 (1) that for any $m \in \mathbb{N}_0$ and any commutative ring R the maps[1789]

$$\begin{array}{rcl} \mathrm{H}^m(X,A;R) & \to & \mathrm{H}^{km}(X,A;R) \\ \varphi & \mapsto & \varphi^k = \underbrace{\varphi \cup \cdots \cup \varphi}_{k \text{ times}} \end{array}$$

define a cohomology operation of degree $km - m$. Note that this type of a cohomology operation is in general not additive. For example, if $k \geq 2$, then it follows easily from the calculation of the cup product of $\mathbb{C}\mathrm{P}^k$, see the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7, that the map $\mathrm{H}^2(\mathbb{C}\mathrm{P}^k;\mathbb{Z}) \to \mathrm{H}^{2k}(\mathbb{C}\mathrm{P}^k;\mathbb{Z})$ given by $\varphi \mapsto \varphi^k$ is not a homomorphism.

(5) If R is a commutative ring with $1+1=0$, then the cohomology operation $\varphi \mapsto \varphi^2$ is in fact additive. Indeed for any $\varphi, \psi \in \mathrm{H}^m(X,A;R)$ we have[1790]

$$\begin{array}{rcl} (\varphi+\psi)^2 & = & \varphi \cup \varphi + \varphi \cup \psi + \psi \cup \varphi + \psi \cup \psi \\ & \underset{\uparrow}{=} & \varphi \cup \varphi + (1+(-1)^{m^2}) \cdot \varphi \cup \psi + \psi \cup \psi \ \underset{\uparrow}{=}\ \varphi \cup \varphi + \psi \cup \psi \ = \ \varphi^2 + \psi^2. \end{array}$$

by the Cup Product-Commutativity Proposition 114.8 we have $\psi \cup \varphi = (-1)^{m^2} \cdot (\varphi \cup \psi)$

since $1-1=0=1+1$ in R

Note that all of the cohomology operations that we have introduced above are of non-negative degree. This raises the following amusing question.

Question 151.1. Does there exist a non-trivial cohomology operation of negative degree?

We will come back to this question in Proposition **??**.

The following theorem gives us new and interesting cohomology operations. The theorem was first proved by Norman Steenrod [**Stee1947**] in 1947.

Theorem 151.2. (Steenrod Theorem) There exists a family

$$\mathrm{Sq}^i \colon \mathrm{H}^n(X,A;\mathbb{Z}_2) \ \to \ \mathrm{H}^{n+i}(X,A;\mathbb{Z}_2) \quad \text{with } i \in \mathbb{N}_0 \text{ and } n \in \mathbb{N}_0$$

of additive cohomology operations which satisfies the following axioms:

(1) $\mathrm{Sq}^0 = \mathrm{id}$.

(2) For any $\varphi \in \mathrm{H}^i(X,A;\mathbb{Z}_2)$ we have $\mathrm{Sq}^i(\varphi) = \varphi^2 = \varphi \cup \varphi \in \mathrm{H}^{2i}(X,A;\mathbb{Z}_2)$.

(3) For any $\varphi \in \mathrm{H}^j(X,A;\mathbb{Z}_2)$ with $i > j$ we have $\mathrm{Sq}^i(\varphi) = 0$.

(4) Let (X,A,B) be an excisive triad of topological spaces. For any $\varphi \in \mathrm{H}^r(X,A;\mathbb{Z}_2)$ any $\psi \in \mathrm{H}^s(X,B;\mathbb{Z}_2)$ and any $k \in \mathbb{N}_0$ we have[1791]

$$\mathrm{Sq}^k(\varphi \cup \psi) \ = \ \sum_{i=0}^{k} \underbrace{\mathrm{Sq}^i(\varphi)}_{\in \mathrm{H}^{r+i}(X,A;\mathbb{Z}_2)} \ \cup \ \underbrace{\mathrm{Sq}^{k-i}(\psi)}_{\in \mathrm{H}^{s+k+i}(X,B;\mathbb{Z}_2)} \ \in \ \mathrm{H}^{r+s+k}(X, A \cup B; \mathbb{Z}_2).$$

This equality is often called the Cartan formula.

[1789] We refer to page 2536 for the definition of the relative cup product.

[1790] This can be viewed as the cohomological "freshman's dream". Perhaps it should called the incoming PhD student's dream.

In the next two sections we will discuss some properties and applications of these cohomology operations. Only after these two sections, once we are convinced that Steenrod operations are indeed useful and interesting, will we provide a proof for the Steenrod Theorem 151.2.

Remark.

(1) The first three axioms of the Steenrod Theorem 151.2 can be summarized as follows: Given any $\varphi \in \mathrm{H}^k(X, A; \mathbb{Z}_2)$ we obtain the following table

$\mathrm{Sq}^0(\varphi)$	$\mathrm{Sq}^1(\varphi)$	$\dots$	$\mathrm{Sq}^{k-1}(\varphi)$	$\mathrm{Sq}^k(\varphi)$	$\mathrm{Sq}^{k+1}(\varphi)$	$\dots$
φ	?	$\dots$	?	φ^2	0	$\dots$

(2) Throughout the remainder of this chapter we will almost invariably consider cohomology with $\mathbb{Z}_2$-coefficients. We point out that by the Cup Product-Commutativity Proposition 114.8 the cup product on the $\mathbb{Z}_2$-cohomology $\mathrm{H}^*(X, A; \mathbb{Z}_2)$ of a given pair of topological spaces (X, A) is actually *commutative*.

Theorem 151.3. Any two families of additive cohomology operations that satisfy Axioms (1) to (4) are identical.

Proof. This theorem is proved in [**SE1962**, Theorem VIII.3.10]. ■

This theorem allows us to give a name to the above cohomology operations.

Definition. We refer to the cohomology operations from the Steenrod Theorem 151.2 as the Steenrod operations.[1792]

The following theorem shows that the first Steenrod operation Sq^1 is actually an old acquaintance of ours.

Theorem 151.4. The first Steenrod operation Sq^1 is the Bockstein homomorphism corresponding to the short exact sequence $0 \to \mathbb{Z}_2 \xrightarrow{[a]\mapsto[2a]} \mathbb{Z}_4 \to \mathbb{Z}_2 \to 0$.

Proof. We will not make use of this theorem, thus we decline to provide a proof. The theorem is proved in [**Bre1993**, p. 418] or alternatively in [**MTa1968**, p. 23] or [**Hat2002**, Theorem 4.L.12]. ■

Evidently our goal now is to compute Steenrod operations in specific examples. We start out with the following slightly disappointing lemma.

Lemma 151.5. For any wedge of finitely many spheres all Steenrod operations in degrees ≥ 1 are zero.

Proof. We will prove the lemma in Exercise 151.2. ■

In remainder of this section we intend to compute the Steenrod operations for the real projective spaces $\mathbb{R}\mathrm{P}^n$ with $n \in \mathbb{N}_0$. Before we consider the real projective spaces in detail it is convenient to reformulate the Cartan formula.

[1791] We refer to page 2429 for the definition of an excisive triad. By the Excisive Triad-Proposition 109.12 most "reasonable" triads are in fact excisive. In fact we will only use the special cases that $A = B$, or that at least one of A or B is the empty set. We refer again to page 2536 for the definition of the relative cup product.

[1792] Sometimes they are also called Steenrod squares, and the term Steenrod operations is used for a more general concept.

For the reformulation we need the following notation:

Notation. Let (X, A) be a pair of topological spaces. Given $\varphi \in \mathrm{H}^k(X, A; \mathbb{Z}_2)$ we write

$$\mathrm{Sq}(\varphi) \ := \ \mathrm{Sq}^0(\varphi) + \mathrm{Sq}^1(\varphi) + \cdots + \mathrm{Sq}^k(\varphi) \ \in \ \mathrm{H}^*(X, A; \mathbb{Z}_2) = \bigoplus_{n \in \mathbb{N}_0} \mathrm{H}^n(X, A; \mathbb{Z}_2).$$

Furthermore we extend the homomorphism Sq in the obvious way to a homomorphism $\mathrm{Sq}\colon \mathrm{H}^*(X; \mathbb{Z}_2) \to \mathrm{H}^*(X; \mathbb{Z}_2)$.

Remark. Let (X, A) be a pair of topological spaces and let $\varphi \in \mathrm{H}^k(X, A; \mathbb{Z}_2)$. Recall that by Axiom (3) given $\varphi \in \mathrm{H}^k(X, A; \mathbb{Z}_2)$ we have $\mathrm{Sq}^i(\varphi) = 0$ for $i > k$. Thus we can write

$$\mathrm{Sq}(\varphi) \ = \ \mathrm{Sq}^0(\varphi) + \mathrm{Sq}^1(\varphi) + \cdots + \mathrm{Sq}^k(\varphi) \ = \ \sum_{i \in \mathbb{N}_0} \mathrm{Sq}^i(\varphi).$$

With this notation we can formulate the following lemma.

Lemma 151.6. Let (X, A) be a pair of topological spaces.

(1) Given any $\varphi, \psi \in \mathrm{H}^*(X, A; \mathbb{Z}_2)$ we have

$$\mathrm{Sq}(\varphi \cup \psi) \ = \ \mathrm{Sq}(\varphi) \cup \mathrm{Sq}(\psi).$$

(2) Given any $\varphi \in \mathrm{H}^*(X, A; \mathbb{Z}_2)$ and given any $k \in \mathbb{N}_0$ we have $\mathrm{Sq}(\varphi^k) = \mathrm{Sq}(\varphi)^k$.

Proof. The first statement follows easily from the Cartan formula. Indeed, we see that

$$\begin{aligned} \mathrm{Sq}(\varphi \cup \psi) = \sum_{k \in \mathbb{N}_0} \mathrm{Sq}^k(\varphi \cup \psi) \ &\overset{\text{Cartan formula, i.e. Axiom (4)}}{\downarrow} \\ &= \sum_{k \in \mathbb{N}_0} \sum_{i=0}^{k} \mathrm{Sq}^i(\varphi) \cup \mathrm{Sq}^{k-i}(\psi) \\ &= \sum_{r \in \mathbb{N}_0} \sum_{s \in \mathbb{N}_0} \mathrm{Sq}^r(\varphi) \cup \mathrm{Sq}^s(\psi) = \Big(\sum_{r \in \mathbb{N}_0} \mathrm{Sq}^r(\varphi) \Big) \cup \Big(\sum_{s \in \mathbb{N}_0} \mathrm{Sq}^s(\psi) \Big) = \mathrm{Sq}(\varphi) \cup \mathrm{Sq}(\psi). \end{aligned}$$

The second statement is an immediate consequence of the first statement. ∎

Before we state a corollary we introduce the following semi-obvious definition.

Definition. Let $r, s \in \mathbb{N}_0$. If $0 \leq r \leq s$, then we set $\binom{s}{r} = \frac{s!}{r!(s-r)!}$, otherwise we set $\binom{s}{r} = 0$.

Now we can state the promised corollary.

Corollary 151.7. Let X be a topological space. For any cohomology class $\varphi \in \mathrm{H}^1(X; \mathbb{Z}_2)$ of degree *one*, any $k \in \mathbb{N}$ and any $i \in \mathbb{N}$ we have

$$\mathrm{Sq}^i(\varphi^k) \ = \ \binom{k}{i} \cdot \varphi^{k+i} \ \in \ \mathrm{H}^{k+i}(X; \mathbb{Z}_2).$$

Examples.

(1) By the Cup Product-$\mathbb{R}\mathrm{P}^n$-Proposition 121.16 we know that given any $n \in \mathbb{N}_0$ we have a ring isomorphism $(\mathrm{H}^*(\mathbb{R}\mathrm{P}^n; \mathbb{Z}_2), \cup) \cong \mathbb{Z}_2[x]/(x^{n+1})$, where $x \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^n; \mathbb{Z}_2)$, and we have a ring isomorphism $(\mathrm{H}^*(\mathbb{R}\mathrm{P}^\infty; \mathbb{Z}_2), \cup) \cong \mathbb{Z}_2[x]$, where $x \in \mathrm{H}^1(\mathbb{R}\mathrm{P}^\infty; \mathbb{Z}_2)$. Since Steenrod operations are additive we see that the result of Corollary 151.7 gives us the promised calculations of all Steenrod operations for the real projective spaces.

(2) In Exercise 151.3 we will use a similar argument to calculate the Steenrod operations on $\mathrm{H}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2)$.

Proof. We calculate that

$$\mathrm{Sq}(\varphi^k) \underset{\text{Lemma 151.6 (2)}}{=} \mathrm{Sq}(\varphi)^k \underset{\substack{\text{by Axiom (3)}\\ \text{since } \varphi\in \mathrm{H}^1(X;\mathbb{Z}_2)}}{=} (\mathrm{Sq}^0(\varphi)+\mathrm{Sq}^1(\varphi))^k \underset{\text{Axioms (1) and (2)}}{=} (\varphi+\varphi^2)^k \underset{\substack{\text{since the ring } (\mathrm{H}^*(X;\mathbb{Z}_2),\cup)\\ \text{is commutative}}}{=} \varphi^k\cup(1+\varphi)^k = \sum_{j=0}^{k}\binom{k}{j}\varphi^{k+j}.$$

The desired conclusion follows from comparing the terms in degree $k+i$ on both sides. ■

151.2. **Steenrod operations and connecting homomorphisms.** This section is completely dedicated to the proof of the following proposition. In the subsequent section we will see that the proposition has powerful applications.

Proposition 151.8. (Steenrod-Coboundary Proposition) If (X,A) is a pair of topological spaces, then the Steenrod operations commute with the connecting homomorphisms in cohomology. More precisely, given any $i,n\in\mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^n(A;\mathbb{Z}_2) & \xrightarrow{\quad\delta\quad} & \mathrm{H}^{n+1}(X,A;\mathbb{Z}_2) \\ \downarrow{\scriptstyle \mathrm{Sq}^i} & & \downarrow{\scriptstyle \mathrm{Sq}^i} \\ \mathrm{H}^{n+i}(A;\mathbb{Z}_2) & \xrightarrow{\quad\delta\quad} & \mathrm{H}^{n+i+1}(X,A;\mathbb{Z}_2). \end{array}$$

In the proof of the Steenrod-Coboundary Proposition 151.8 we will make use of the cross product on cohomology which we now introduce.

Definition. Let R be a commutative ring, let X be a topological space and let (Y,B) be a pair of topological spaces. Furthermore let $\varphi\in\mathrm{H}^m(X;R)$ and $\psi\in\mathrm{H}^n(Y,B;R)$. We denote by $p\colon X\times Y\to X$ and $q\colon X\times Y\to Y$ the projections. We define the cross product[1793]

$$\varphi\times\psi := \underbrace{p^*(\varphi)}_{\text{lies in } \mathrm{H}^m(X\times Y;R)} \cup \underbrace{q^*(\psi)}_{\text{lies in } \mathrm{H}^n(X\times Y,X\times B;R)} \in \mathrm{H}^{m+n}(X\times Y, X\times B;R).$$

The following proposition basically says that in Axiom (4), i.e. in the Cartan formula, we can replace the cup product by the cross product.

Proposition 151.9. Let X be a topological space and let (Y,B) be a pair of topological spaces. For any $\varphi\in\mathrm{H}^r(X;\mathbb{Z}_2)$, $\psi\in\mathrm{H}^s(Y,B;\mathbb{Z}_2)$ and $n\in\mathbb{N}_0$ the following equality holds:

$$\mathrm{Sq}^n(\varphi\times\psi) = \sum_{i=0}^{n}\mathrm{Sq}^i(\varphi)\times\mathrm{Sq}^{n-i}(\psi) \in \mathrm{H}^{r+s+n}(X\times Y, X\times B;\mathbb{Z}_2).$$

Proof. Let X be a topological space and let (Y,B) be a pair of topological spaces. Furthermore let $\varphi\in\mathrm{H}^r(X;\mathbb{Z}_2)$ and $\psi\in\mathrm{H}^s(Y,B;\mathbb{Z}_2)$. We denote by $p\colon X\times Y\to X$ and $q\colon X\times Y\to Y$ the projections. We start out with the following claim.

[1793]Recall that on page 2498, given two *homology* classes $\mu\in\mathrm{H}_m(X;\mathbb{Z})$ and $\nu\in\mathrm{H}_n(Y;\mathbb{Z})$ we defined the *cross product* $\mu\times\nu\in\mathrm{H}_{m+n}(X\times Y;\mathbb{Z})$. It should usually be clear from the context whether in a given situation we mean the cross product on homology or on cohomology.

Claim. We have the following equalities:[1794]

(a) $p^*(\varphi) = \varphi \times 1_Y \in \mathrm{H}^r(X \times Y; \mathbb{Z}_2)$ and $q^*(\psi) = 1_X \times \psi \in \mathrm{H}^s(X \times Y; \mathbb{Z}_2)$.

(b) $\varphi \times \psi = (\varphi \times 1_Y) \cup (1_X \times \psi) \in \mathrm{H}^{r+s}(X \times Y; \mathbb{Z}_2)$.

Proof.

(a) We perform the following easy calculation:

$$\varphi \times 1_Y = p^*(\varphi) \cup q^*(1_Y) \underset{\uparrow}{=} p^*(\varphi) \cup 1_{X\times Y} \underset{\uparrow}{=} p^*(\varphi).$$

by definition we have $p^*(1_X) = q^*(1_Y) = 1_{X\times Y}$; $1_{X\times Y}$ is multiplicatively neutral, see the Cup Product-Ring Proposition 114.7

Evidently the same argument also shows that $q^*(\psi) = 1_X \times \psi$.

(b) This statement follows from (a) and the definition of the cross product.

⊞

Now we turn to the proof of the actual statement of the proposition. We have the following equalities in $\mathrm{H}^{r+s+n}(X \times Y; \mathbb{Z}_2)$:

$$\begin{aligned}
\mathrm{Sq}^n(\varphi \times \psi) &\underset{\downarrow}{=} \mathrm{Sq}^n\big((\varphi \times 1_Y) \cup (1_X \times \psi)\big) && \text{by the Cartan formula, i.e. by Axiom (4)} \\
&= \sum_{i=0}^{n} \mathrm{Sq}^i(\varphi \times 1_Y) \cup \mathrm{Sq}^{n-i}(1_X \times \psi) \\
&\underset{\uparrow}{=} \sum_{i=0}^{n} \mathrm{Sq}^i(p^*(\varphi)) \cup \mathrm{Sq}^{n-i}(q^*(\psi)) && \text{since } \mathrm{Sq}^i \text{ and } \mathrm{Sq}^{n-i} \text{ are natural transformations} \\
&\underset{\uparrow}{=} \sum_{i=0}^{n} p^*(\mathrm{Sq}^i(\varphi)) \cup q^*(\mathrm{Sq}^{n-i}(\psi)) && \text{part (a) of the claim} \\
&\underset{\uparrow}{=} \sum_{i=0}^{n} \mathrm{Sq}^i(\varphi) \times \mathrm{Sq}^{n-i}(\psi). && \text{by definition of the cross product}
\end{aligned}$$

We have thus obtained the desired equality. ■

The proof of the Steenrod-Coboundary Proposition 151.8 rests on the following lemma.

Lemma 151.10. Let X be a topological space, let (Y, B) be a pair of topological spaces and let R be a commutative ring. If $\varphi \in \mathrm{H}^m(X; R)$ and $\psi \in \mathrm{H}^n(B; R)$, then

$$\underset{\uparrow}{\delta}(\overbrace{\varphi \times \psi}^{\in \mathrm{H}^{m+n}(X\times B;R)}) = (-1)^m \cdot \varphi \times \overbrace{\underset{\uparrow}{\delta\psi}}^{\in \mathrm{H}^{n+1}(Y,B;R)} \in \mathrm{H}^{m+n+1}(X \times Y, X \times B; R).$$

connecting homomorphism in cohomology for the pair $(X \times Y, X \times B)$; connecting homomorphism in cohomology for the pair (Y, B)

Proof of Lemma 151.10. This equality follows fairly easily from Coboundary-Cup Product Lemma 114.2, the definition of the cross product via the cup product and the explicit description of the connecting homomorphism on page 2399. We leave it to the reader to fill in the details. ■

Proof of the Steenrod-Coboundary Proposition 151.8. We start out with a warm-up case.

[1794] Recall that given a topological space W we denote by $1_Z \in \mathrm{H}^0(W; \mathbb{Z}_2)$ the cohomology class that is represented by the cocycle that assigns to each singular 0-simplex the value $1 \in \mathbb{Z}_2$.

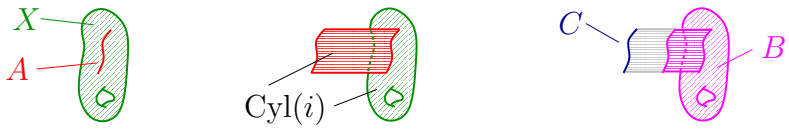
Claim 1. Let Z be a topological space and let $a < b$ be two real numbers. The conclusion of the proposition holds for the pair $(Z \times [a,b], Z \times \partial([a,b]))$ of topological spaces.

Proof. Let $\theta \in \mathrm{H}^n(Z \times \partial([a,b]); \mathbb{Z}_2) = \mathrm{H}^n(Z \times \{a,b\}; \mathbb{Z}_2)$. Recall that we need to show that $\mathrm{Sq}^i(\delta\theta) = \delta(\mathrm{Sq}^i(\theta))$. First note that θ can be written as $\theta = \varphi \times \psi$ for some $\varphi \in \mathrm{H}^n(Z; \mathbb{Z}_2)$ and some $\psi \in \mathrm{H}^0(\partial([a,b]); \mathbb{Z}_2) = \mathrm{H}^0(\{a,b\}; \mathbb{Z}_2)$.[1795] Note that we have the following equalities in $\mathrm{H}^{n+i+1}(Z \times [a,b], Z \times \partial([a,b]); \mathbb{Z}_2)$:

since $\theta = \varphi \times \psi$ — by Lemma 151.10, we also use that $(-1)^n = 1 \in \mathbb{Z}_2$ — Proposition 151.9 — since $\delta\psi \in \mathrm{H}^1([a,b], \partial([a,b]); \mathbb{Z}_2)$ and since $\mathrm{H}^i([a,b], \partial([a,b]); \mathbb{Z}_2) = 0$ for every $i \geq 2$ we know that $\mathrm{Sq}^j(\delta\psi) = 0$ for $j \geq 1$

$$\begin{array}{lllll} \mathrm{Sq}^i(\delta\theta) & = \mathrm{Sq}^i(\delta(\varphi\times\psi)) & = \mathrm{Sq}^i(\varphi \times \delta\psi) & = \sum_{j=0}^{i} \mathrm{Sq}^{i-j}(\varphi)\times\mathrm{Sq}^j(\delta\psi) & = \mathrm{Sq}^i(\varphi)\times\mathrm{Sq}^0(\delta\psi) \\ & = \mathrm{Sq}^i(\varphi) \times \delta\psi & = \delta(\mathrm{Sq}^i(\varphi) \times \psi) & = \delta(\mathrm{Sq}^i(\varphi\times\psi)) & = \delta(\mathrm{Sq}^i(\theta)). \end{array}$$

Axiom (1) says that $\mathrm{Sq}^0 = \mathrm{id}$ — Lemma 151.10 — by Proposition 151.9 together with Axioms (1) and (3) and the fact that $\psi \in \mathrm{H}^0(\partial([a,b]); \mathbb{Z}_2)$ ⊞



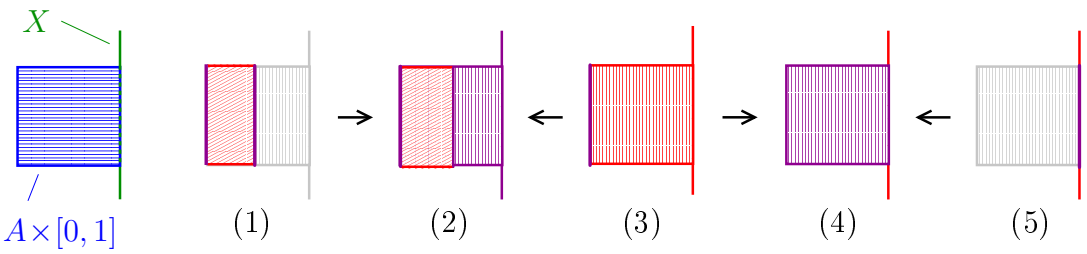
The remainder of the proof of the proposition consists in cleverly reducing the general case to the above special case. Thus let (X, A) be a pair of topological spaces. We denote by $i\colon A \to X$ the inclusion map. We set

$$\mathrm{Cyl}(i) = \begin{array}{c}\text{mapping cylinder of the} \\ \text{inclusion } i\colon A \to X\end{array} := ((A \times [0,1]) \sqcup X)/\!\sim \quad \text{where } (a,1) \sim a \text{ for all } a \in A.$$

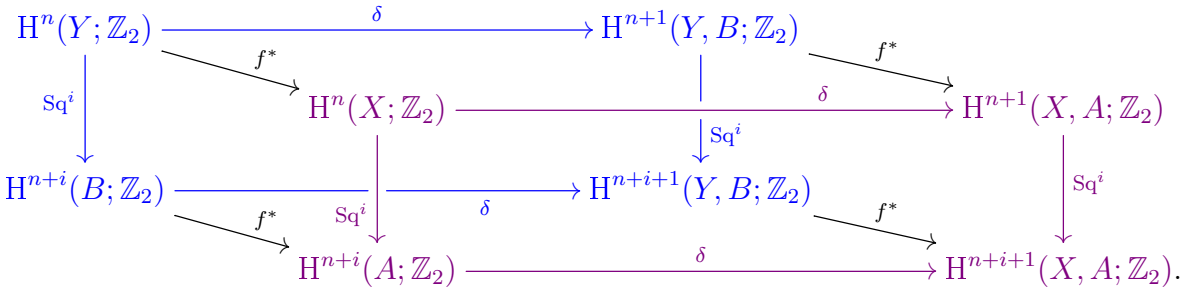
We point out that by Exercise 16.12 and the Mapping Cylinder Basics Lemma 16.10 we know that the obvious inclusions $A \times [0,1] \to \mathrm{Cyl}(i)$ and $X \to \mathrm{Cyl}(i)$ are embeddings. Thus we can view $A \times [0,1]$ and X as subsets of $\mathrm{Cyl}(i)$. Now we consider the following subsets of the mapping cylinder $\mathrm{Cyl}(i)$:

$$B := (A \times [\tfrac{1}{2}, 1]) \cup X \quad \text{and} \quad C := A \times \{0\}.$$

We refer to the figure below for an illustration. The five statements in the following claim



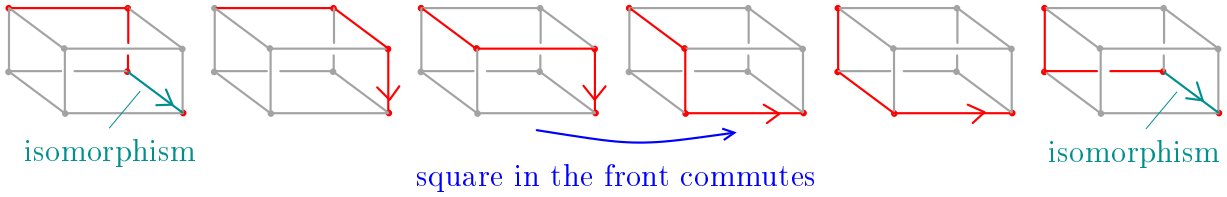
break the proof of the proposition into five manageable steps.



Claim 2.

(1) The conclusion of the proposition holds for $(A \times [0, \frac{1}{2}], A \times \partial([0, \frac{1}{2}]))$.
(2) The conclusion of the proposition holds for $(\mathrm{Cyl}(i), B \cup C)$.
(3) The conclusion of the proposition holds for $(\mathrm{Cyl}(i), C)$.
(4) The conclusion of the proposition holds for $(\mathrm{Cyl}(i), A \times [0,1])$.
(5) The conclusion of the proposition holds for (X, A).

[1795] This statement follows quite easily from the fact that $Z \times \partial([a,b]) = (Z \times \{a\}) \sqcup (Z \times \{b\})$, the observation that $\mathrm{H}^0(\{a,b\}) = \mathbb{Z} \cdot 1_{\{a\}} \oplus \mathbb{Z} \cdot 1_{\{b\}}$, the Cup Product-Ring Proposition 114.7 and the Cup-Cap Disjoint Union Lemma 116.9. We leave it to the assiduous reader to assemble these steps in the right logical order.



Proof. Before we work our way through the five steps we need to make two related observations. Let $f\colon (X, A) \to (Y, B)$ be a map of pairs of topological spaces. We obtain the following cubical diagram:

It follows from the naturality of the Steenrod operations that the parallelograms to the left and right commute. Furthermore, it follows from the naturality of the connecting homomorphism, see the Cohomological LES-Lemma 108.15, that the top and bottom parallelograms commute. Using these facts we can make the following two observations:

(i) If the square in the front commutes and if the map f^* to the bottom right is an isomorphism, then it follows from a stroll through the cube, as indicated in the figure below, that the square in the back also commutes.

(ii) If the square in the back commutes and if the map f^* to the top left is an isomorphism, then it follows as in (i) that the square in the front also commutes.

Now we turn to the actual proof of the five steps in the claim.

(1) This statement follows immediately from the previous claim.

(2) We consider the inclusion map $f\colon (A \times [0, \frac{1}{2}], A \times \partial([0, \frac{1}{2}])) \to (\mathrm{Cyl}(i), B \cup C)$ and we consider the corresponding cube. By (1) we know that the square in the front commutes. We leave it to the reader to cleverly apply the Excision Theorem for Cohomology Groups 109.1 to show that the map f^* to the bottom right of the cube is an isomorphism. Thus we obtain from (i) that the square in the back commutes.

(3) We consider the inclusion map $f\colon (\mathrm{Cyl}(i), C) \to (\mathrm{Cyl}(i), B \cup C)$ and we consider the corresponding cube. By (2) we know that the square in the back commutes. Since

on the first entry f is the identity we see that the top left map f^* is an isomorphism. Thus we obtain from (ii) that the square in the front also commutes.

(4) We consider the inclusion map $f\colon (\mathrm{Cyl}(i), A\times\{0\}) \to (\mathrm{Cyl}(i), \overbrace{A\times[0,1]}^{=C})$. By (3) we know that the square in the front commutes. Since $A\times\{0\}$ is a deformation retract of $A\times[0,1]$ we obtain from the Homotopic Maps-H*-Lemma 108.13 (4) that the map f^* to the bottom right of the cube is an isomorphism. Thus we obtain from (i) that the square in the back also commutes.

(5) We consider the obvious inclusion

$$\begin{array}{rcl} f\colon X & \to & \mathrm{Cyl}(i) \\ x & \mapsto & [(x,1)]. \end{array}$$

It also defines a map $f\colon (X,A) \to (\mathrm{Cyl}(i), A\times[0,1])$ of pairs of topological spaces. We consider the corresponding cube. By (4) we know that the square in the back commutes. By the Mapping Cylinder Basics Lemma 16.12 (1) the map $f\colon X \to \mathrm{Cyl}(i)$ is in fact a homotopy equivalence. Thus it follows from the Homotopic Maps-H*-Lemma 108.13 that the top left f^* is an isomorphism. Therefore we obtain from (ii) that the square in the front commutes.

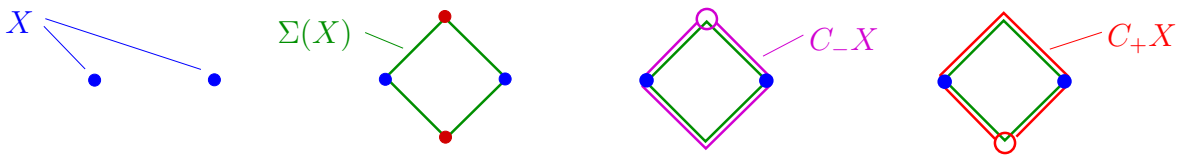
■

151.3. **Steenrod operations and suspensions.** In the Steenrod-Coboundary Proposition 151.8 we saw that Steenrod operations commute with connecting homomorphisms in cohomology. In this section we will use this fact to show that Steenrod operations behave well under taking suspensions. This fact will help us to obtain new information on homology groups of spheres.

First recall that in the Suspension-H$_*$-Proposition 76.7 we saw that taking the suspension $\Sigma(X)$ of a topological space shifts the reduced homology groups "upwards by one". The following proposition says that the same phenomenon occurs when we consider cohomology groups.

Proposition 151.11. Let X be a non-empty topological space, let $n \in \mathbb{N}$[1796] and let G be an abelian group. As on page 1681 we denote by C_-X and C_+X the "lower and upper half" of the suspension $\Sigma(X)$. We refer to the figure below for an illustration.

(1) The following maps are isomorphisms:[1797]



$$\mathrm{H}^n(X;G) \xrightarrow{\delta} \mathrm{H}^{n+1}(C_+X, X; G) \leftarrow \mathrm{H}^{n+1}(\Sigma(X), C_-X; G) \to \mathrm{H}^{n+1}(\Sigma(X); G).$$

Here the map to the left is the connecting homomorphism of the pair (C_+X, X) from the Cohomological LES-Lemma 108.15 The remaining two horizontal maps are induced by the obvious inclusion maps.

(2) The isomorphism

$$\Sigma_X\colon \mathrm{H}^n(X;G) \xrightarrow{\cong} \mathrm{H}^{n+1}(\Sigma(X);G)$$

that is given by the maps in (1) is in fact a natural isomorphism.

Proof. The proof is a slight variation on the proof of the Suspension-H_*-Proposition 76.7. We leave it to the reader to fill in the details. ■

The following proposition shows that Steenrod operations behave well under taking suspensions.

Proposition 151.12. (Steenrod-Suspension Proposition) Given any topological space X, any $n \in \mathbb{N}$ and any $i \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^n(X;\mathbb{Z}_2) & \xrightarrow[\cong]{\Sigma_X} & \mathrm{H}^{n+1}(\Sigma(X);\mathbb{Z}_2) \\ \downarrow{\scriptstyle \mathrm{Sq}^i} & & \downarrow{\scriptstyle \mathrm{Sq}^i} \\ \mathrm{H}^{n+i}(X;\mathbb{Z}_2) & \xrightarrow[\cong]{\Sigma_X} & \mathrm{H}^{n+i+1}(\Sigma(X);\mathbb{Z}_2). \end{array}$$

Remark. The proposition says in particular that if there exists a non-trivial Steenrod operation on a topological space X, then its suspension inherits a non-trivial Steenrod operation. This is in so far interesting as we know by the Suspension-Cup Product Lemma 115.7 that the cup product vanishes on suspensions. The fact that suspensions can have non-trivial Steenrod operations will allow us to prove several hitherto inaccessible results.

Proof. We consider the following diagram

$$\begin{array}{ccccccc} & & & \overset{\Sigma_X}{\frown} & & & \\ \mathrm{H}^n(X;\mathbb{Z}_2) & \xrightarrow[\delta]{} & \mathrm{H}^{n+1}(C_+X,X;\mathbb{Z}_2) & \xleftarrow[\cong]{} & \mathrm{H}^{n+1}(\Sigma(X),C_-X;\mathbb{Z}_2) & \xrightarrow[\cong]{} & \mathrm{H}^{n+1}(\Sigma(X);\mathbb{Z}_2) \\ \downarrow{\scriptstyle \mathrm{Sq}^i} & & \downarrow{\scriptstyle \mathrm{Sq}^i} & & \downarrow{\scriptstyle \mathrm{Sq}^i} & & \downarrow{\scriptstyle \mathrm{Sq}^i} \\ \mathrm{H}^{n+i}(X;\mathbb{Z}_2) & \xrightarrow{\delta} & \mathrm{H}^{n+1+i}(C_+X,X;\mathbb{Z}_2) & \xleftarrow{\cong} & \mathrm{H}^{n+1+i}(\Sigma(X),C_-X;\mathbb{Z}_2) & \xrightarrow{\cong} & \mathrm{H}^{n+1+i}(\Sigma(X);\mathbb{Z}_2). \\ & & & \underset{\Sigma_X}{\smile} & & & \end{array}$$

The first square commutes by the Steenrod-Coboundary Proposition 151.8. The two other squares commute by the naturality of the Steenrod operation Sq^i. Thus we see that, as desired, the diagram commutes. ■

Next we recall that by the definitions on pages 1576 and 2676 we have three different types of Hopf maps:

[1796] Basically the same statement works for $n = 0$, the only nuisance is that in that case we need to work with reduced cohomology groups.

[1797] Here we use the Cone-Suspension Basics Lemma 16.8 (3) to identify X with the subset $C_-X \cap C_+X$ of $\Sigma(X)$.

Definition. We consider the following maps

$$\underbrace{\underbrace{\begin{array}{rcl} H\colon S^3 & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ \underbrace{(z_1, z_2)}_{\in \mathbb{C}^2} & \mapsto & [z_1 : z_2] \end{array}}_{\text{the Hopf map}} \quad \underbrace{\begin{array}{rcl} H_{\mathbb{H}}\colon S^7 & \to & S^4 = \mathbb{H}\mathrm{P}^1 \\ \underbrace{(z_1, z_2)}_{\in \mathbb{H}^2} & \mapsto & [z_1 : z_2] \end{array}}_{\text{quaternionic Hopf map}} \quad \text{and} \quad \underbrace{\begin{array}{rcl} H_{\mathbb{O}}\colon S^{15} & \to & S^8 = \mathbb{O}\mathrm{P}^1 \\ \underbrace{(z_1, z_2)}_{\in \mathbb{O}^2} & \mapsto & [z_1 : z_2]. \end{array}}_{\text{octonionic Hopf map}}}$$

In Theorem 122.3 we showed that the Hopf map $H\colon S^3 \to S^2$ is not null-homotopic. The key to doing so were the following two observations:

(1) The mapping cone $\mathrm{Cone}(H\colon S^3 \to S^2)$ is homeomorphic to $\mathbb{C}\mathrm{P}^2$.
(2) The cup product on $\mathbb{C}\mathrm{P}^2$ has the property that for a generator $\varphi \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^2; \mathbb{Z})$ the square φ^2 is non-zero.

Since the Steenrod operations are a generalization of the mod 2 "cup product square" and since Steenrod operations behave well with respect to suspensions it seems reasonable that we can use Steenrod operations to show that the suspensions of the Hopf maps are not null-homotopic.
Indeed, we can prove the following theorem.

Theorem 151.13.

(1) For any $n \geq 2$ the $(n-2)$-fold suspension

$$\Sigma^{n-2}(H)\colon \underbrace{\Sigma^{n-2}(S^3)}_{=S^{n+1}} \to \underbrace{\Sigma^{n-2}(S^2)}_{=S^n}$$

of the Hopf map defines a non-trivial element in $\pi_{n+1}(S^n)$. In particular for any $n \geq 2$ we have $\pi_{n+1}(S^n) \neq 0$.

(2) For any $n \geq 4$ the $(n-4)$-fold suspension

$$\Sigma^{n-4}(H_{\mathbb{H}})\colon \underbrace{\Sigma^{n-4}(S^7)}_{=S^{n+3}} \to \underbrace{\Sigma^{n-4}(S^4)}_{=S^n}$$

of the quaternionic Hopf map defines a non-trivial element in $\pi_{n+3}(S^n)$. In particular for any $n \geq 4$ we have $\pi_{n+3}(S^n) \neq 0$.

(3) For any $n \geq 8$ the $(n-8)$-fold suspension

$$\Sigma^{n-8}(H_{\mathbb{O}})\colon \underbrace{\Sigma^{n-8}(S^{15})}_{=S^{n+7}} \to \underbrace{\Sigma^{n-8}(S^8)}_{=S^n}$$

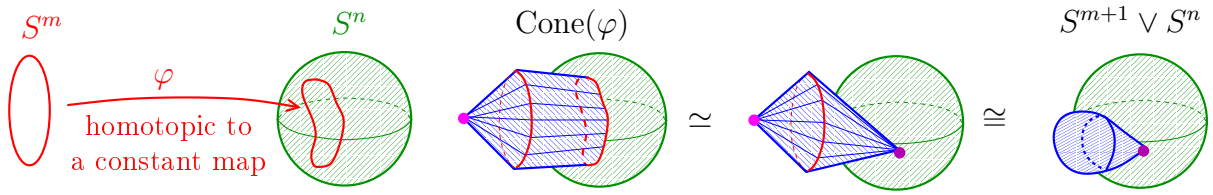
of the octonionic Hopf map defines a non-trivial element in $\pi_{n+7}(S^n)$. In particular for any $n \geq 8$ we have $\pi_{n+7}(S^n) \neq 0$.

Before we turn to the proof of Theorem 151.13 we recall, for the reader's convenience, the following, frequently overlooked, proposition which says that taking suspensions and taking mapping cones commutes.

Proposition 16.19. (Mapping Cone-Suspension Proposition) If $f\colon X \to Y$ is a map between topological spaces, then there exists a homeomorphism

$$g\colon \mathrm{Cone}(\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)) \xrightarrow{\cong} \Sigma(\mathrm{Cone}(f\colon X \to Y)).$$

We also state the following lemma which we are already dimly aware of.



Lemma 151.14. If a map $\varphi\colon S^m \to S^n$ is homotopic to a constant map, then the corresponding mapping cone $\mathrm{Cone}(\varphi\colon S^m \to S^n)$ is homotopy equivalent to $S^{m+1} \vee S^n$.

Proof. We have

$$\mathrm{Cone}(\varphi\colon S^m \to S^n) \underset{\uparrow}{\simeq} \mathrm{Cone}(\text{constant map}\colon S^m \to S^n) \underset{\uparrow}{\cong} S^{m+1} \vee S^n.$$

by the Mapping Cone Inclusion Lemma 16.16, since φ is homotopic to a constant map

Mapping Cone-of-Constant Map Lemma 122.1 ∎

Now we turn to the proof of Theorem 151.13. For clarity's sake we first provide a detailed proof of Theorem 151.13 (1). Afterwards we explain how to modify that proof to obtain statements (2) and (3) of Theorem 151.13.

Proof of Theorem 151.13 (1). In the following we will show that $\Sigma(H)\colon S^4 \to S^3$ is not homotopic to a constant map. The general statement regarding the $(n-2)$-fold suspension $\Sigma^{n-2}(H)$ follows easily from iterating the argument below.

For once we do a proof by contradiction. So let us assume that the map $\Sigma(H)\colon S^4 \to S^3$ is in fact homotopic to a constant map. We make the following preparations:

(1) To simplify the notation we denote the mapping cone of a map $f\colon X \to Y$ by $\mathrm{C}(f)$ instead of $\mathrm{Cone}(f)$. Furthermore we write $\mathbb{F} = \mathbb{Z}_2$.
(2) By the Mapping Cone-of-Hopf Map Lemma 122.2 there exists a homeomorphism $f\colon \mathrm{C}(H\colon S^3 \to S^2) \xrightarrow{\cong} \mathbb{C}\mathrm{P}^2$.
(3) We denote by $g\colon \Sigma(\mathrm{C}(H)) \xrightarrow{\cong} \mathrm{C}(\Sigma(H))$ the homeomorphism from the Mapping Cone-Suspension Proposition 16.19.
(4) Since we assume that the map H is homotopic to a constant map we obtain from Lemma 151.14 that there exists a homotopy equivalence $h\colon \mathrm{C}(\Sigma(H)) \to S^3 \vee S^5$.

Now we consider the following diagram:

$$\begin{array}{ccccccccc}
\mathrm{H}^2(\mathbb{C}\mathrm{P}^2;\mathbb{F}) & \xrightarrow[\cong]{f^*} & \mathrm{H}^2(\mathrm{C}(H);\mathbb{F}) & \xrightarrow[\cong]{\Sigma} & \mathrm{H}^3(\Sigma(\mathrm{C}(H));\mathbb{F}) & \xleftarrow[g^*]{\cong} & \mathrm{H}^3(\mathrm{C}(\overbrace{\Sigma(H)}^{S^4\to S^3});\mathbb{F}) & \xleftarrow[\cong]{h^*} & \mathrm{H}^3(S^5\vee S^3;\mathbb{F}) \\
{\scriptstyle x\mapsto x\cup x}\downarrow\ \downarrow{\scriptstyle \mathrm{Sq}^2} & & \downarrow{\scriptstyle \mathrm{Sq}^2} & & \downarrow{\scriptstyle \mathrm{Sq}^2} & & \downarrow{\scriptstyle \mathrm{Sq}^2} & & \downarrow{\scriptstyle \mathrm{Sq}^2} \\
\mathrm{H}^4(\mathbb{C}\mathrm{P}^2;\mathbb{F}) & \xrightarrow[\cong]{f^*} & \mathrm{H}^4(C(H);\mathbb{F}) & \xrightarrow[\cong]{\Sigma} & \mathrm{H}^5(\Sigma(\mathrm{C}(H));\mathbb{F}) & \xleftarrow[g^*]{\cong} & \mathrm{H}^5(\mathrm{C}(\Sigma(H));\mathbb{F}) & \xleftarrow[\cong]{h^*} & \mathrm{H}^5(S^5\vee S^3;\mathbb{F}).
\end{array}$$

We make the following observations:

(1) The maps Σ are the suspension isomorphisms given by Proposition 151.11.
(2) It follows from Axiom (2) that the two vertical maps on the left are actually the same.
(3) It follows from the naturality of Sq^2 that the first, third and the fourth square commute.

(4) It follows from the Steenrod-Suspension Proposition 151.12 that the second square commutes.
(5) Since f and g are homeomorphisms we see that the induced maps f^* and g^* are isomorphisms. Furthermore, since h is a homotopy equivalence we obtain from the Homotopic Maps-H^*-Lemma 108.13 (3) that the horizontal maps h^* are isomorphisms.
(6) By Proposition 121.13 we know that there exists a unique non-trivial $x \in \mathrm{H}^2(\mathbb{C}\mathrm{P}^2;\mathbb{F})$ and that this element satisfies $x \cup x \neq 0 \in \mathrm{H}^4(\mathbb{C}\mathrm{P}^2;\mathbb{F}) \cong \mathbb{F}$. In particular we see that the left vertical homomorphism is an isomorphism and that it is non-trivial.
(7) By Lemma 151.5 we know that the vertical homomorphism to the right is trivial.

In summary we have shown that the above diagram commutes, we have shown that all horizontal maps are isomorphisms, we have seen that the left vertical map is non-trivial and have pointed out that the right vertical map is trivial. But this is absurd. In other words, we have obtained a contradiction to our hypothesis that the map $\Sigma(H)\colon S^4 \to S^3$ is null-homotopic. ■

Proof of Theorem 151.13 (2) and (3). As we will see shortly, the proof for the quaternionic and octonionic Hopf maps is basically the same as the proof for the "classical" Hopf map.

Let us first consider the quaternionic Hopf. By the Mapping Cone-of-Hopf Map Lemma 122.2 (2) there exists a homeomorphism $f\colon \mathrm{C}(H_{\mathbb{H}}) \xrightarrow{\cong} \mathbb{H}\mathrm{P}^2$. If $\Sigma(H_{\mathbb{H}})\colon S^8 \to S^5$ was null-homotopic we would, as in the proof of (1), obtain a commutative diagram of the following form:

$$\begin{array}{ccccccccc}
\mathrm{H}^4(\mathbb{H}\mathrm{P}^2;\mathbb{F}) & \xrightarrow[\cong]{f^*} & \mathrm{H}^4(\mathrm{C}(H_{\mathbb{H}});\mathbb{F}) & \xrightarrow{\Sigma} & \mathrm{H}^5(\Sigma(\mathrm{C}(H_{\mathbb{H}}));\mathbb{F}) & \xleftarrow[g^*]{\cong} & \mathrm{H}^5(\mathrm{C}(\overbrace{\Sigma(H_{\mathbb{H}})}^{S^8\to S^5});\mathbb{F}) & \xleftarrow[\cong]{h^*} & \mathrm{H}^5(S^9\vee S^5;\mathbb{F}) \\
{\scriptstyle x\mapsto x\cup x}\downarrow & \downarrow{\scriptstyle \mathrm{Sq}^4} & \downarrow{\scriptstyle \mathrm{Sq}^4} & & \downarrow{\scriptstyle \mathrm{Sq}^4} & & \downarrow{\scriptstyle \mathrm{Sq}^4} & & \downarrow{\scriptstyle \mathrm{Sq}^4} \\
\mathrm{H}^8(\mathbb{H}\mathrm{P}^2;\mathbb{F}) & \xrightarrow[\cong]{f^*} & \mathrm{H}^8(C(H_{\mathbb{H}});\mathbb{F}) & \xrightarrow{\Sigma} & \mathrm{H}^9(\Sigma(\mathrm{C}(H_{\mathbb{H}}));\mathbb{F}) & \xleftarrow[g^*]{\cong} & \mathrm{H}^9(\mathrm{C}(\Sigma(H_{\mathbb{H}}));\mathbb{F}) & \xleftarrow[\cong]{h^*} & \mathrm{H}^9(S^9\vee S^5;\mathbb{F}).
\end{array}$$

By Proposition 121.20 (1) the cup product on the left is non-trivial. Thus the same logic as in the proof of (1) leads to a contradiction.

The argument for the octonionic Hopf map is almost identical to the argument for the quaternionic Hopf map. We just need to redo the above argument with the Mapping Cone-of-Hopf Map Lemma 122.2 (3) and with Proposition 121.20 (2). ■

For the record we jot down the following proposition that we proved in the proof of Theorem 151.13. We will make use of it later on.

Proposition 151.15. Given any $n \in \mathbb{N}_0$ the maps

$$\begin{array}{lrcl}
(1) & \mathrm{Sq}^2\colon \mathrm{H}^{2+n}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2) & \to & \mathrm{H}^{4+n}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2) \\
(2) & \mathrm{Sq}^4\colon \mathrm{H}^{4+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{H}}));\mathbb{Z}_2) & \to & \mathrm{H}^{8+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{H}}));\mathbb{Z}_2) \\
(3) & \mathrm{Sq}^8\colon \mathrm{H}^{8+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{O}}));\mathbb{Z}_2) & \to & \mathrm{H}^{16+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{O}}));\mathbb{Z}_2)
\end{array}$$

are isomorphisms.

151.4. **Proof of the Steenrod Theorem 151.2 I.** In the final two sections we will give a partial proof of the Steenrod Theorem 151.2. More precisely, we will construct the Steenrod

operations and we will provide the proof of some of the properties. The proof is split into two parts:

(1) The goal of this section is to construct a certain interesting sequence of natural maps $\Delta_n\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$, $n \in \mathbb{N}_0$, where the zeroth map Δ_0 is a diagonal approximation.
(2) In the subsequent section we will show how this sequence of maps can be used to define the Steenrod operations.

In preparation for the construction of the sequence Δ_n we recall some definitions and results from earlier on. First recall that on page 1940 we introduced the tensor product $A_* \otimes B_*$ of two chain complexes A_* and B_*. We will make use of the following harmless lemma.

Lemma 117.7. Let A_* and B_* be chain complexes. The unique map

$$T\colon A_* \otimes B_* \quad \to \quad B_* \otimes A_*$$

that for $a \in A_k$ and $b \in B_l$ is given by

$$a \otimes b \quad \mapsto \quad (-1)^{kl} \cdot b \otimes a$$

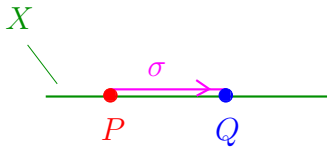
is a chain map.

Since we will make use of this later on, we point out that T is natural in A_* and B_* and we point out that $T^2 = \mathrm{id}$. Next we recall the following definition from page 2517.

Definition. A diagonal approximation consists of a natural chain map

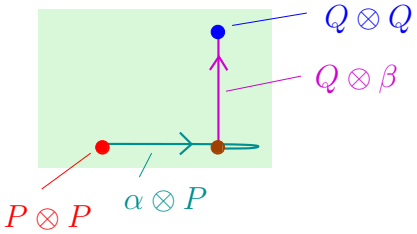
$$\Phi\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$$

for each topological space X, such that for each $x \in X$, viewed as a singular 0-simplex, the following equality holds in $(\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))_0 = \mathrm{C}_0(X) \otimes \mathrm{C}_0(X)$:



$$\Phi(x) = x \otimes x.$$

Example. We will try to rise to the challenge of finding a suitable illustration for a diagonal approximation Φ. We start out with the following observation: if $\sigma\colon \Delta^1 \to X$ is a singular 1-simplex from a point P to a point Q, then $\Phi(\sigma) \in (\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))_1$ needs to satisfy



$$\partial\Phi(\sigma) \underset{\uparrow}{=} \Phi(\partial\sigma) = \Phi(Q - P) = \Phi(Q) - \Phi(P) \underset{\uparrow}{=} Q \otimes Q - P \otimes P.$$

since Φ is a chain map; since Φ is determined on singular 0-simplices

For example $\Phi(\sigma) = (\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))_1 = \mathrm{C}_1(X) \otimes \mathrm{C}_0(X) \oplus \mathrm{C}_0(X) \otimes \mathrm{C}_1(X)$ could be of the form $\alpha \otimes P + Q \otimes \beta$ where $\alpha\colon \Delta^1 \to X$ and $\beta\colon \Delta^1 \to X$ are singular simplices from P to Q. This situation is illustrated, with artistic liberties, in the figure below.

diagonal approximation
$\Delta_0(\sigma) = \alpha \otimes P + Q \otimes \beta$

The following proposition contains the two key results on diagonal approximations.

Proposition 114.6.

(1) There exist diagonal approximations.

(2) Given any two diagonal approximations Φ and Ψ there exists a natural chain homotopy equivalence between Φ and Ψ.

Proof. We gave an explicit example of a diagonal approximation in the Alexander-Whitney Lemma 114.5. In the Diagonal Approximation Uniqueness Proposition 113.17 we gave a proof of (2) using the Acyclic Model Theorem 113.16 (2). ■

The following theorem shows that any diagonal approximation can be extended to a sequence of maps.

Theorem 151.16.

(1) Given any topological space X there exists a sequence of natural maps

$$\Delta_n \colon \mathrm{C}_*(X) \ \to \ \mathrm{C}_*(X) \otimes \mathrm{C}_*(X), \quad n \in \mathbb{N}_0$$

of degree n[1798] such that the following two conditions are satisfied:

(a) The map Δ_0 is a diagonal approximation.

(b) For every $n \in \mathbb{N}_0$ the following equality holds:[1799]

$$\partial \circ \Delta_{n+1} + (-1)^n \cdot \Delta_{n+1} \circ \partial \ = \ (T + (-1)^{n+1} \cdot \mathrm{id}) \circ \Delta_n.$$

(2) Given two sequences Δ_n, Δ'_n, $n \in \mathbb{N}_0$, as in (1) there exists a sequence of natural maps

$$H_n \colon \mathrm{C}_*(X) \ \to \ \mathrm{C}_*(X) \otimes \mathrm{C}_*(X), \quad n \in \mathbb{N}_0$$

of degree n such that the following two conditions are satisfied:

(a) H_0 is the zero map.

(b) For every $n \in \mathbb{N}_0$ the following equality holds:[1800]

$$\partial \circ H_{n+1} + (-1)^n \cdot H_{n+1} \circ \partial \ = \ \Delta_n - \Delta'_n - (T + (-1)^n \cdot \mathrm{id}) \circ H_n.$$

In the proof of Theorem 151.16 we will need the following innocuous variation on the definition of a chain map that we had given on page 1592.

Definition.

(1) A chain map $f \colon C_* \to D_*$ of degree d between two chain complexes consists of a family $\{f_n \colon \mathrm{C}_n \ \to \ D_{n+d}\}_{n \in \mathbb{N}_0}$ of maps such that for each $n \in \mathbb{N}_0$ the following equality holds:

$$f_{n-1} \circ \partial_n \ = \ \partial_{n+d} \circ f_n.$$

(2) An anti-chain map $f \colon C_* \to D_*$ of degree d is basically the same data as a chain map of degree d, except that for each $n \in \mathbb{N}_0$ the following equality holds:

$$f_{n-1} \circ \partial_n \ = \ -\partial_{n+d} \circ f_n.$$

Remark. Given an anti-chain map $\{f_n\}_{n \in \mathbb{N}_0}$ of degree d one can easily see that the maps $\{(-1)^n \cdot f_n\}_{n \in \mathbb{N}_0}$ form a chain map of degree d. This little trick makes it possible to

[1798] By a map of degree n between chain complexes C_* and D_* we mean a collection of maps $\mathrm{C}_k \to D_{k+n}$, $k \in \mathbb{N}_0$.

[1799] Note that both sides are maps $\mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ of degree n.

[1800] In other words, the map H_{n+1} is a chain homotopy between Δ_n and Δ'_n up to the "error term" $-(T + (-1)^n \cdot \mathrm{id}) \circ H_n$.

translate all kinds of statements about chain maps to anti-chain maps. For example, as in Lemma 72.7 we see that an anti-chain map induces a map on homology groups.

In the proof of Theorem 151.16 we will need the following consequence of the Acyclic Model Theorem 113.13.

Theorem 151.17. (Acyclic Model Theorem) Let $\mathcal{T}op$ be the category of topological spaces and let $\mathcal{C}$ be the category of generalized[1801] chain complexes.

(1) Let $S\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ be a natural chain map of degree d. If we have $d \geq 1$, then for any topological space X and any $k \in \mathbb{N}_0$ there exists a natural map $P_X\colon \mathrm{C}_k(X) \to (\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))_{k+d+1}$ such that for any $k \in \mathbb{N}_0$ we have
$$\partial \circ P_X + P_X \circ \partial \;=\; S_X\colon \mathrm{C}_k(X) \;\to\; (\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))_{k+d}.$$

(2) For a natural anti-chain map $S\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ of degree d the analogous data exists except that now we have
$$\partial \circ P_X - P_X \circ \partial \;=\; S_X\colon \mathrm{C}_k(X) \;\to\; (\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))_{k+d}.$$

Proof of the Acyclic Model Theorem 151.17.

(1) Given any topological space X we consider $G(X) := (\mathrm{C}_*(X) \otimes \mathrm{C}_*(X))[-d]$. Here we use the notation introduced on page 2571, namely given a chain complex D_* we denote by $D_*[-d]$ the chain complex D_* "shifted by d to the right". This shift turns $G(X)$ into a generalized chain complex. Furthermore, this shift turns $S\colon \mathrm{C}_*(X) \to G(X)$ into a natural chain map of degree 0.

Next note that for any $k \in \mathbb{N}_0$ and any $i \geq 0$ we have
$$\begin{array}{rcccl} \mathrm{H}_i(G(\Delta^k)) & = & \mathrm{H}_i((\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k))[-d]) & = & \mathrm{H}_{i+d}(\mathrm{C}_*(\Delta^k) \otimes \mathrm{C}_*(\Delta^k)) \\ & = & \bigoplus_{p+q=i+d} \mathrm{H}_p(\Delta^k) \otimes \mathrm{H}_q(\Delta^k) & = & 0. \\ & \uparrow & & \uparrow & \end{array}$$
by the Künneth Theorem 90.7 for chain complexes; by the calculation of $\mathrm{H}_*(\Delta^k)$ and since $d \geq 1$

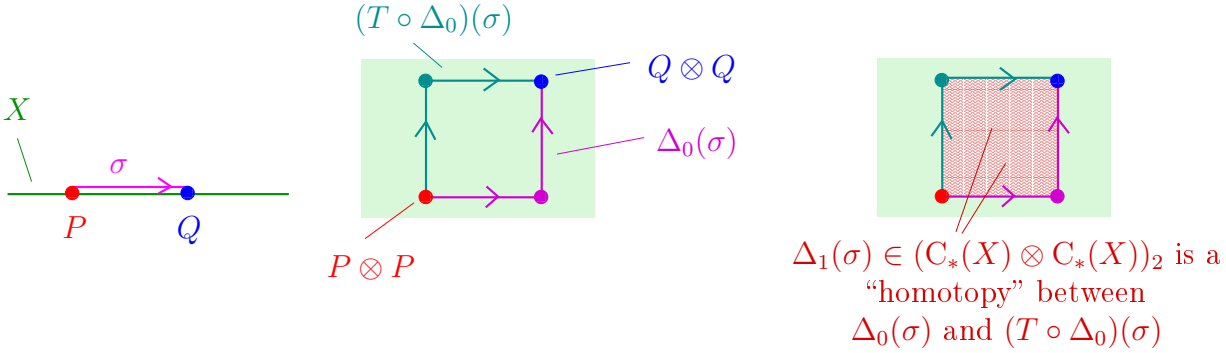
Thus we see that all the hypotheses of the Acyclic Model Theorem 113.13 are satisfied. Therefore we see that for any topological space X and any $k \in \mathbb{N}_0$ there exists a natural map $P_X\colon \mathrm{C}_k(X) \to G_{k+1}(X)$ such that for any $k \in \mathbb{N}_0$ we have
$$\partial \circ P_X + P_X \circ \partial \;=\; S_X\colon \mathrm{C}_k(X) \;\to\; G_k(X).$$

(2) Suppose we are given a natural anti-chain map S of degree d. As in the remark preceding the theorem we can turn S into a natural chain map T by setting $T_k = (-1)^k \cdot S_k$, $k \in \mathbb{N}_0$. We apply (1) and we obtain natural maps Q_X. Now we define $P_k := (-1)^k \cdot (Q_X)_k$, $k \in \mathbb{N}_0$. One easily verifies that the desired equality holds. ∎

Now, finally, we can turn to the actual proof of Theorem 151.16.

Proof of Theorem 151.16.

(1) We construct the maps $\Delta_n\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$, $n \in \mathbb{N}_0$ iteratively.



(i) First of all, we know by the Proposition 114.6 (1) above that there exists a diagonal approximation $\Delta_0\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$.

[1801] Recall that a generalized chain complex is like a chain complex except that we allow chain groups in negative degrees.

(ii) Note that $T \circ \Delta_0 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ is another diagonal approximation. It follows from Proposition 114.6 (2) that there exists a natural chain homotopy $\Delta_1 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ between Δ_0 and $T \circ \Delta_0$. In other words, there exists a natural map $\Delta_1 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ of degree one such that

$$\partial \circ \Delta_1 + \Delta_1 \circ \partial = \underbrace{T \circ \Delta_0 - \Delta_0}_{=(T-\mathrm{id}) \circ \Delta_0}.$$

Thus we are done with the construction of the map Δ_1. This step is illustrated in the figure below.

(iii) The starting point for defining the next map Δ_2 is the following amusing little calculation:[1802]

$$\begin{array}{ccccccc} & & \text{since } T^2 = \mathrm{id} & & & & \text{by (ii)} \\ & & \downarrow & & & & \downarrow \\ 0 & = & (T^2 - \mathrm{id}) \circ \Delta_0 & = & (T + \mathrm{id}) \circ (T - \mathrm{id}) \circ \Delta_0 & = & (T + \mathrm{id}) \circ (\partial \circ \Delta_1 + \Delta_1 \circ \partial) \\ & & & & = \partial \circ (T + \mathrm{id}) \circ \Delta_1 + (T + \mathrm{id}) \circ \Delta_1 \circ \partial. & & \\ & & & & \uparrow & & \\ & & & & \text{since } T \text{ and id are chain maps they commute with the boundary maps} & & \end{array}$$

This shows that the map $(T + \mathrm{id}) \circ \Delta_1 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ is a natural anti-chain map of degree one. By the Acyclic Model Theorem 151.17 (2) there exists a natural map $\Delta_2 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ of degree two such that

$$\partial \circ \Delta_2 - \Delta_2 \circ \partial = (T + \mathrm{id}) \circ \Delta_1.$$

This conclude the construction of the map Δ_2.

(iv) Just for kicks we do the calculation for the next stage as well. We perform the following calculation:

$$\begin{array}{ccccccc} & & \text{since } T^2 = \mathrm{id} & & & & \text{by (iii)} \\ & & \downarrow & & & & \downarrow \\ 0 & = & (T^2 - \mathrm{id}) \circ \Delta_1 & = & (T - \mathrm{id}) \circ (T + \mathrm{id}) \circ \Delta_1 & = & (T - \mathrm{id}) \circ (\partial \circ \Delta_2 - \Delta_2 \circ \partial) \\ & & & & = \partial \circ (T - \mathrm{id}) \circ \Delta_2 - (T - \mathrm{id}) \circ \Delta_2 \circ \partial. & & \\ & & & & \uparrow & & \\ & & & & \text{since } T \text{ and id are chain maps they commute with the boundary maps} & & \end{array}$$

This shows that the map $(T - \mathrm{id}) \circ \Delta_2 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ is a natural chain map of degree two. By the Acyclic Model Theorem 151.17 (1) there exists a natural map $\Delta_3 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ of degree three such that

$$\partial \circ \Delta_3 + \Delta_3 \circ \partial = (T - \mathrm{id}) \circ \Delta_2.$$

[1802] These are equalities of maps $\mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$.

This concludes the construction of the map Δ_3.

(iv) Now we iterate this procedure and we obtain the desired sequence of natural maps Δ_n.

(2) Given two sequences Δ_n, Δ'_n as in (1) we define the desired maps H_n, $n \in \mathbb{N}_0$ in a fashion that is quite similar to the approach taken in (1).

(i) We set $H_0 = 0$.

(ii) Next we point out that by definition Δ_0 and Δ'_0 are diagonal approximations. Thus it follows from Proposition 114.6 (2) that there exist natural maps H_1 such that $\partial \circ H_1 + H_1 \circ \partial = \Delta_0 - \Delta'_0$.

(iii) We calculate that

$$\begin{aligned}
&\partial \circ (\Delta_1 - \Delta'_1 - (T - \mathrm{id}) \circ H_1) + (\Delta_1 - \Delta'_1 - (T - \mathrm{id}) \circ H_1) \circ \partial \\
&\quad = (\partial \circ \Delta_1 + \Delta_1 \circ \partial) - (\partial \circ \Delta'_1 + \Delta'_1 \circ \partial) - \partial \circ (T - \mathrm{id}) \circ H_1 - (T - \mathrm{id}) \circ H_1 \circ \partial \\
&\quad = \underset{\substack{\uparrow \\ \text{since } \partial\circ\Delta_1 + \Delta_1\circ\partial = (T-\mathrm{id})\circ\Delta_0 \text{ (same for } \Delta'_0, \Delta'_1) \\ \text{and since } T \text{ and id are chain maps}}}{(T - \mathrm{id}) \circ (\Delta_0 - \Delta'_0)} - \underset{\substack{\uparrow \\ \text{since } \partial\circ H_1 + H_1\circ\partial = \Delta_0 - \Delta'_0}}{(T - \mathrm{id}) \circ (\partial \circ H_1 + H_1 \circ \partial)} = 0.
\end{aligned}$$

This shows that $\Delta_1 - \Delta'_1 - (T - \mathrm{id}) \circ H_1$ is an anti-chain map of degree one. By the Acyclic Model Theorem 151.17 (2) there exists a natural map H_2 with

$$H_2 \circ \partial - \partial \circ H_2 = -(T - \mathrm{id}) \circ H_1 + \Delta_1 - \Delta'_1.$$

(iv) Now we iterate this procedure to obtain the desired sequence of natural maps. One easily sees that we get the correct pattern for the signs involved. ∎

Remark. If there did exist a diagonal approximation $\Delta_0 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ that is symmetric in the sense that $T \circ \Delta_0 = \Delta_0$, then we could take $\Delta_1 = 0$ and we could also take all higher Δ_n to be zero. Later, in Chapter 151, we will see that this is in general not the case. So even though diagonal approximations are symmetric on the degree 0 level, they cannot be chosen to be symmetric in higher degrees.

151.5. **Proof of the Steenrod Theorem 151.2 II.** In this section we will use the sequence of natural maps $\Delta_n \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$, $n \in \mathbb{N}_0$, from Theorem 151.16 to define the Steenrod operations.

To get an inspiration for how to define the Steenrod operations we first recall the definition of the cup product. To do so we need the following lemma which is inspired by the definitions on from page 2512.

Lemma 151.18. Let $\mathcal{C}_*$ and $\mathcal{D}_*$ be chain complexes and let R be a commutative ring. Given $p, q \in \mathbb{N}_0$ we consider the map[1803]

$$\begin{aligned}
\Xi_{p,q} \colon \mathrm{Hom}(\mathcal{C}_p, R) \otimes \mathrm{Hom}(\mathcal{D}_q, R) &\to \mathrm{Hom}((\mathcal{C} \otimes \mathcal{D})_{p+q}, R) \\
\varphi \otimes \psi &\mapsto \left((\mathcal{C}_* \otimes \mathcal{D}_*)_{p+q} \xrightarrow{\text{projection}} \mathcal{C}_p \otimes \mathcal{D}_q \xrightarrow{\varphi\otimes\psi} R \otimes R \to R, \; a \otimes b \mapsto a \cdot b \right).
\end{aligned}$$

The corresponding map

$$\Xi := \bigoplus_{p,q \in \mathbb{N}_0} \Xi_{p,q} \colon \mathrm{Hom}(\mathcal{C}_*, R) \otimes \mathrm{Hom}(\mathcal{D}_*, R) \to \mathrm{Hom}(\mathcal{C}_* \otimes \mathcal{D}_*, R)$$

is a cochain map.

Proof. The statement follows basically immediately from the definitions. ■

The following lemma gives us a slight reformulation of the original definition of the cup product.

Lemma 151.19. Let X be a topological space and let R be a commutative ring. Furthermore let $\Delta_0 \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ be a diagonal approximation. We consider the cochain map

$$\mathrm{Hom}(\mathrm{C}_*(X), R) \otimes \mathrm{Hom}(\mathrm{C}_*(X), R) \xrightarrow{\Xi} \mathrm{Hom}(\mathrm{C}_*(X) \otimes \mathrm{C}_*(X), R) \xrightarrow{\Delta_0^*} \mathrm{Hom}(\mathrm{C}_*(X), R).$$

$$=: h_0$$

The corresponding map

$$\begin{array}{rcl} \mathrm{H}^p(X; R) \times \mathrm{H}^q(X; R) & \to & \mathrm{H}^{p+q}(X; R) \\ ([\varphi], [\psi]) & \mapsto & [h_0(\varphi \otimes \psi)] \end{array}$$

equals the cup product as defined on page 2513.

Proof. We denote by $d \colon X \to X \times X$ the diagonal map that is given by $d(x) = (x, x)$. Let $\Theta \colon \mathrm{C}_*(X \times X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ denote a Eilenberg-Zilber map from Theorem 113.1. For the purpose of this proof the only thing we need to know about the Eilenberg-Zilber map Θ is that, basically by definition, the map $\Theta \circ d \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X \times X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X)$ is a diagonal approximation. We consider the following diagram:

$$\begin{array}{ccccc} & & & =: h_0 & \\ & \curvearrowright & & \curvearrowright & \\ \mathrm{Hom}(\mathrm{C}_*(X), R) \otimes \mathrm{Hom}(\mathrm{C}_*(X), R) & \xrightarrow{\Xi} & \mathrm{Hom}(\mathrm{C}_*(X) \otimes \mathrm{C}_*(X), R) & \xrightarrow{\Delta_0^*} & \mathrm{Hom}(\mathrm{C}_*(X), R) \\ & & \downarrow \Theta^* & \nearrow_{d^*} & \\ & & \mathrm{Hom}(\mathrm{C}_*(X \times X), R). & & \end{array}$$

The lower sequence of maps is at the heart of the definition of the cup product on page 2513. Since $\Theta \circ d$ is a diagonal approximation we obtain from Proposition 114.6 that Δ_0 and $\Theta \circ d$ are chain homotopic. But by the Dual Cochain Map Lemma 108.8 (4) this means that the two maps induce the same map on cohomology. The lemma follows almost immediately from the above observations. ■

Now we turn to the actual construction of the Steenrod operations. To do so we pick a sequence of natural maps

$$\Delta_n \colon \mathrm{C}_*(X) \to \mathrm{C}_*(X) \otimes \mathrm{C}_*(X), \quad n \in \mathbb{N}_0$$

which satisfies the conditions set out in Theorem 151.16 (1). In light of Lemma 151.19 it is clear what we want to do next. Namely we want to replace Δ_0 by the "higher maps" Δ_n. This leads us straight to the following definition.

[1803] The tensor product of cochain complexes is defined basically the same way as we defined the tensor product of chain complexes, see page 1940.

Definition. Let X be a topological space and let R be a commutative ring. Given $i \in \mathbb{N}_0$ we define

$$\mathrm{Hom}(\mathrm{C}_*(X), R) \otimes \mathrm{Hom}(\mathrm{C}_*(X), R) \xrightarrow{\Xi} \mathrm{Hom}(\mathrm{C}_*(X) \otimes \mathrm{C}_*(X), R) \xrightarrow{\Delta_i^*} \mathrm{Hom}(\mathrm{C}_*(X), R).$$

$$=: h_i$$

Recall that Δ_i is a map of degree i. Since we dualize we see that h_i is a map of degree $-i$. For convenience we define $h_i := 0$ for $i \in \mathbb{Z}_{<0}$.

Now we can finally define the Steenrod operations.

Theorem 151.20. Let X be a topological space, let $A \subset X$ be a subset and let R be a commutative ring. If $1 + 1 = 0$ in R, then for any $q \in \mathbb{N}_0$ and any $i \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{Sq}^i \colon \mathrm{H}^q(X, A; R) & \to & \mathrm{H}^{q+i}(X, A; R) \\ [\underbrace{\varphi}_{\in \mathrm{C}^q(X;R)}] & \mapsto & [h_{q-i}(\underbrace{\varphi \otimes \varphi}_{\in \mathrm{C}^q \otimes \mathrm{C}^q})] \end{array}$$

is a well-defined natural homomorphism.

Remark. The proof of Theorem 151.20 that we give below is a long and winding calculation, with few interesting view points. Perhaps more interesting than the question, why the definition works, is the question, why does the map

$$\begin{array}{rcl} \mathrm{C}^q(X, A; R) \otimes \mathrm{C}^r(X, A; R) & \to & \mathrm{C}^{q+r+j}(X, A; R) \\ \varphi \otimes \psi & \mapsto & h_j(\underbrace{\varphi \otimes \psi}_{\in \mathrm{C}^q \otimes \mathrm{C}^r}) \end{array}$$

not descend to a map on cohomology?

The proof of Theorem 151.20 requires some preparations. First of all, note that the equalities in Theorem 151.16 translate into the following lemma.

Lemma 151.21. Let X be a topological space. Furthermore let R be a commutative ring with $1_R + 1_R = 0_R$. For any $\alpha, \beta \in \mathrm{C}^*(X; R)$ we have the following equality:

$$h_{n+1}(\delta(\alpha \otimes \beta)) + \delta(h_{n+1}(\alpha \otimes \beta)) \;=\; h_n(\alpha \otimes \beta + \beta \otimes \alpha) \;\in\; \mathrm{C}^*(X; R).$$

Proof. Recall, see Theorem 151.16, that one of the defining properties of the sequence Δ_n is that for every $n \in \mathbb{N}_0$ the following equality holds:

$$\partial \circ \Delta_{n+1} + (-1)^n \cdot \Delta_{n+1} \circ \partial \;=\; (T + (-1)^{n+1} \cdot \mathrm{id}) \circ \Delta_n.$$

We dualize this equality, we use the equality $1 + 1 = 0$, we use the fact, shown in Lemma 151.18 and that Ξ is a cochain map. After performing all these steps one obtains the desired equality. We leave it to the reader to fill in the few remaining details. ■

For elements of the form $\alpha \otimes \alpha$ the following lemma shows how the maps h_n relate to coboundaries.

Lemma 151.22. Let X be a topological space and let R be a commutative ring. If $1 + 1 = 0$ in R, then for any $\alpha \in \mathrm{C}^q(X; R)$ we have

$$h_{n+1}(\delta\alpha \otimes \delta\alpha) \;=\; \delta h_{n+1}(\alpha \otimes \delta\alpha) + \delta h_n(\alpha \otimes \alpha) \;\in\; \mathrm{C}^{n+1}(X; R).$$

Proof. Since we assume that $1+1=0$ in R we can ignore conveniently enough ignore signs throughout the proof. Thus we compute

$$\begin{array}{rcl} h_{n+1}(\delta\alpha\otimes\delta\alpha) & \overset{\text{since } \delta(c\otimes d)=\delta c\otimes d+c\otimes\delta d}{\downarrow} & \overset{\text{Lemma 151.21}}{\downarrow} \\ & h_{n+1}(\delta(\alpha\otimes\delta\alpha)) & = \delta h_{n+1}(\alpha\otimes\delta\alpha)+h_n(\alpha\otimes\delta\alpha+\delta a\otimes\alpha) \\ & = \delta h_{n+1}(\alpha\otimes\delta\alpha)+h_n(\delta(\alpha\otimes\alpha)) & = \delta h_{n+1}(\alpha\otimes\delta\alpha)+\delta h_n(\alpha\otimes\alpha). \\ & \uparrow & \uparrow \\ & \text{definition of } \delta \text{ on tensor product} & \text{by Lemma 151.21 and since } h_{n-1}(\underbrace{\alpha\otimes\alpha+\alpha\otimes\alpha}_{=0 \text{ since } 1+1=0})=0 \end{array}$$

■

In the proof of Theorem 151.20 we will need the following little lemma.

Lemma 151.23. Let X be a topological space and let R be a commutative ring with $1+1=0$. For any $\alpha,\beta\in \mathrm{C}^q(X;R)$ the following equality holds:

$$h_n((\alpha+\beta)\otimes(\alpha+\beta))=h_n(\alpha\otimes\alpha)+h_n(\beta\otimes\beta)+h_{n+1}(\delta(\alpha\otimes\beta))+\delta(h_{n+1}(\alpha\otimes\beta)).$$

Proof of Lemma 151.23. This follows from "multiplying out", the linearity of h_n and the equality

$$h_n(\alpha\otimes\beta+\beta\otimes\alpha) \underset{\text{by Lemma 151.21}}{\overset{\uparrow}{=}} h_{n+1}(\delta(\alpha\otimes\beta))+\delta(h_{n+1}(\alpha\otimes\beta)).$$

■

Now, after these lengthy preparations we can provide the proof of Theorem 151.20.

Proof of Theorem 151.20. Let X be a topological space, let $A\subset X$ be a subset and let R be a commutative ring. First we consider the case that $A=\varnothing$. Let $\varphi\in \mathrm{C}^q(X;R)$ be a representative of some element in $\mathrm{H}^q(X;R)$.

(1) Note that $\varphi\otimes\varphi$ is of degree $2q$. Thus $h_{q-i}(\varphi\otimes\varphi)$ is of degree $2q-(q-i)=q+i$.
(2) Let $\varphi\in \mathrm{C}^q(X;R)$ be a cocycle. We calculate that

$$\delta h_{q-i}(\varphi\otimes\varphi) \underset{\text{Lemma 151.21}}{\overset{\uparrow}{=}} h_{q-i}(\delta(\varphi\otimes\varphi))+h_{q-i-1}(\overbrace{\varphi\otimes\varphi+\varphi\otimes\varphi}^{=0 \text{ since } 1+1=0}) \underset{\text{definition of } \delta \text{ on tensor product}}{\overset{\uparrow}{=}} h_{q-i}(\delta\varphi\otimes\varphi+\varphi\otimes\delta\varphi) \underset{\text{since } \varphi \text{ is a cocycle}}{\overset{\uparrow}{=}} 0.$$

Thus we have shown that $h_{q-i}(\varphi\otimes\varphi)$ is a cocycle. In other words, we have shown that it defines an element in cohomology.
(3) Let $\psi\in \mathrm{C}^{q-1}(X;R)$. We have the following equality in $\mathrm{H}^{q+i}(X;R)$:

$$[h_{q-i}((\varphi+\delta\psi)\otimes(\varphi+\delta\psi))] \underset{\text{by Lemma 151.23, here we use that } \delta(\varphi\otimes\delta\psi)=\delta\varphi\otimes\delta\psi+\varphi\otimes\delta\delta\psi=0}{\overset{\uparrow}{=}} [h_{q-i}(\varphi\otimes\varphi)+h_{q-i}(\delta\psi\otimes\delta\psi)] \underset{\text{Lemma 151.22}}{\overset{\uparrow}{=}} [h_{q-i}(\varphi\otimes\varphi)].$$

This shows that the map Sq^i is well-defined, i.e. it does not depend on the choice of the representative of the cohomology class.
(4) It follows quite easily from Lemma 151.23 that Sq^i is in fact a homomorphism.

Finally we consider the case that $A\neq\varnothing$. Using the observation on page 2407 we make the identification

$$\mathrm{C}^q(X,A;R) \;=\; \{\varphi\in \mathrm{C}^q(X;R)=\mathrm{Hom}(\mathrm{C}_q(X),R)\,|\,\varphi \text{ vanishes on } \mathrm{C}_q(A)\subset \mathrm{C}_q(X)\}.$$

It follows from the naturality of h_n that if $\varphi\in \mathrm{C}^q(X)$ vanishes on $\mathrm{C}_q(A)$, then $h_{q-i}(\varphi\otimes\varphi)$ vanishes on the subgroup $\mathrm{C}_*(A)\otimes\mathrm{C}_*(X)+\mathrm{C}_*(X)\otimes\mathrm{C}_*(A)$ of $\mathrm{C}_*(X)\otimes\mathrm{C}_*(X)$. Thus we

see that the map

$$\begin{array}{rcl} \mathrm{Sq}^i\colon \mathrm{H}^q(X,A;R) & \to & \mathrm{H}^{q+i}(X,A;R) \\ [\underbrace{\varphi}_{\in \mathrm{C}^q(X;R)}] & \mapsto & [h_{q-i}(\varphi\otimes\varphi)] \end{array}$$

is well-defined. ■

We continue with the following proposition.

Proposition 151.24. The definition of the maps Sq^i does not depend on the choice of the natural maps Δ_n.

Proof. Suppose we are given another sequence of maps $\widetilde{\Delta}_n$ that have the properties described in Theorem 151.16 (1). We define the maps $\widetilde{h}_i$ in the obvious way. By Theorem 151.16 (2) there exists a sequence of natural maps

$$\mathrm{H}_n\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X)\otimes\mathrm{C}_*(X), \quad n\in\mathbb{N}_0$$

of degree n such that $H_0 = 0$ and such that for every $n\in\mathbb{N}_0$ the following equality holds:

$$(*) \qquad \partial\circ \mathrm{H}_{n+1} + (-1)^n\cdot \mathrm{H}_{n+1}\circ\partial \;=\; \Delta_n - \widetilde{\Delta}_n - (T+(-1)^n\cdot\mathrm{id})\circ \mathrm{H}_n.$$

Given a cocycle $\varphi\in \mathrm{C}^q(X,A;\mathbb{Z}_2)$ and $i\in\mathbb{N}_0$ we see that we have the following equality in $\mathrm{H}^{2q-i}(X,A;R)$:

$$\begin{array}{rcl} [h_i(\varphi\otimes\varphi)] - [\widetilde{h}_i(\varphi\otimes\varphi)] & \overset{\text{definition of } h_i,\widetilde{h}_i}{=} & [\Delta_i^*(\Xi(\varphi\otimes\varphi)) - \widetilde{\Delta}_i^*(\Xi(\varphi\otimes\varphi))] \\ & = & [\mathrm{H}^*_{i+1}(\delta(\Xi(\varphi\otimes\varphi)) + \underbrace{\delta(\mathrm{H}^*_{i+1}(\varphi\otimes\varphi))}_{\text{coboundary}} + \mathrm{H}^*_i((T+\mathrm{id})^*(\Xi(\varphi\otimes\varphi)))] \\ & \overset{\text{by } (*) \text{ and since } 1+1=0}{=} & [\mathrm{H}^*_{i+1}(\Xi(\underbrace{\delta(\varphi\otimes\varphi)}_{=0 \text{ since } \varphi \text{ cocycle}})) + \mathrm{H}^*_i(\Xi(\underbrace{\varphi\otimes\varphi+\varphi\otimes\varphi}_{=0 \text{ since } 1+1=0}))] \;=\; 0. \\ & \overset{\text{since } \Xi \text{ is a cochain map and since } \Xi \text{ commutes with } T}{=} & \end{array}$$

We have thus shown that the two definitions using Δ_n and $\widetilde{\Delta}_n$ agree. ■

By Proposition 151.24 the maps Sq^i are unambiguously defined. Thus we can make the following definition.

Definition. Given a pair of topological spaces (X,A) and $i\in\mathbb{N}_0$ we refer to each map

$$\mathrm{Sq}^i\colon \mathrm{H}^q(X,A;\mathbb{Z}_2) \to \mathrm{H}^{q+i}(X,A;\mathbb{Z}_2)$$

as the i-th Steenrod operation.

By Theorem 151.20 the Steenrod operations are additive cohomology operations. To complete the proof of the Steenrod Theorem 151.2 we need to verify that the maps Sq^i have all the other desired properties. In other words we need to prove the following theorem.

Theorem 151.25. The Steenrod operations Sq^i have the following properties:

(1) $\mathrm{Sq}^0 = \mathrm{id}$.
(2) For any $\varphi\in\mathrm{H}^i(X,A;\mathbb{Z}_2)$ we have $\mathrm{Sq}^i(\varphi) = \varphi^2$.
(3) For any $\varphi\in\mathrm{H}^j(X,A;\mathbb{Z}_2)$ with $j<i$ we have $\mathrm{Sq}^i(\varphi) = 0$.

(4) For any $\varphi \in \mathrm{H}^r(X, A; \mathbb{Z}_2)$ and $\psi \in \mathrm{H}^s(X, A; \mathbb{Z}_2)$ we have

$$\mathrm{Sq}^k(\varphi \cup \psi) \;=\; \sum_{i=0}^{k} \mathrm{Sq}^i(\varphi) \cup \mathrm{Sq}^{k-i}(\psi).$$

Proof.

(1) The notation might suggest that this statement is surely trivial, but that is not the case. For time, space and mental energy reasons we will not give the proof, which at first glance does not seem terribly enlightening anyway. Instead we refer to [**Spa1995**, p. 274] for details.

(2) First we deal with the absolute case. Thus let $\varphi \in \mathrm{C}^i(X; R)$ be a cocycle. We calculate

$$\mathrm{Sq}^i(\varphi) \underset{\text{by definition}}{\overset{\uparrow}{=}} [h_{i-i}(\varphi \otimes \varphi)] \;=\; [h_0(\varphi \otimes \varphi)] \underset{\text{Lemma 151.19}}{\overset{\uparrow}{=}} [\varphi] \cup [\varphi].$$

The case that we are dealing with a cocycle $\varphi \in \mathrm{C}^i(X, A; R)$ is proved basically the same way.

(3) Let $\varphi \in \mathrm{C}^j(X, A; \mathbb{Z}_2)$ be a cocycle and suppose that $i > j$. We have

$$\mathrm{Sq}^i([\varphi]) \underset{\text{by definition}}{\overset{\uparrow}{=}} [h_{j-i}(\varphi)] \underset{\text{since } j-i<0 \text{ we have } h_{j-i}=0}{\overset{\uparrow}{=}} [0].$$

(4) This statement is proved in [**Spa1995**, p. 274]. ∎

Exercises for Chapter 151.

Exercise 151.1.

(a) Show that for any $k \in \mathbb{N}_{\geq 3}$ and $m \in \mathbb{N}$ the map $\mathrm{H}^m(X; \mathbb{Z}_2) \to \mathrm{H}^{mk}(X; \mathbb{Z}_2)$ given by $\varphi \mapsto \varphi^k$ is not an additive cohomology operation.

(b) Is the map $\mathrm{H}^1(X; \mathbb{Z}_3) \to \mathrm{H}^3(X; \mathbb{Z}_3)$ given by $\varphi \mapsto \varphi^3$ an additive cohomology operation?

Exercise 151.2. Let $X = S^m \vee S^n$ be the wedge of two spheres. Show that for $i \geq 1$ all Steenrod operations $\mathrm{Sq}^i \colon \mathrm{H}^k(X; \mathbb{Z}_2) \to \mathrm{H}^k(X; \mathbb{Z}_2)$ are zero.
Hint. Reread the proof of Lemma 114.11.

Exercise 151.3. Find a closed formula for the i-th Steenrod operation on $\mathrm{H}^*(\mathbb{C}\mathrm{P}^\infty; \mathbb{Z}_2)$.
Hint. Use Proposition 121.13 (2).

152. The Adem relations

The following theorem was first proved by José Ádem [**Ade1952, Ade1957**] in 1952.

Theorem 152.1. (Adem Relations Theorem) For any $0 < a < 2b$ we have the following equality of cohomology operations:[1804]

$$\mathrm{Sq}^a \circ \mathrm{Sq}^b \;=\; \sum_{j=0}^{\lfloor \frac{a}{2} \rfloor} \binom{b-1-j}{a-2j} \cdot \mathrm{Sq}^{a+b-j} \circ \mathrm{Sq}^j \,.$$

These equalities are called the *Adem relations*.

Remark. As is remarked on [**SE1962**, p. 2], the Adem relations are a consequence of the properties of Steenrod operations that were stated in the Steenrod Theorem 151.2. This observation also follows from the uniqueness result stated in Theorem 151.3.

Proof. Since the proof would consume too much of our valuable time we will not provide it. Instead we refer to the original paper by Adem [**Ade1952, Ade1957**] or alternatively to [**BuM1982**], [**SE1962**, Theorem VIII.1.5], [**MTa1968**, p. 23], or [**Hat2002**, Theorem 4.L.13] for a proof. ■

Even though we will not prove the Adem relations, we will shamelessly exploit them in this chapter. Afterwards the conscientious reader will surely feel compelled to read the proof of the Adem relations.
Just to get a feeling for the Adem relations we determine for small values of a what the relations really look like.

Example. For $a = 1$ and for any $b \in \mathbb{N}$ we have

$$\mathrm{Sq}^1 \circ \mathrm{Sq}^b \;=\; \underbrace{\sum_{j=0}^{\lfloor \frac{a}{2} \rfloor} \binom{b-1-j}{a-2j} \cdot \mathrm{Sq}^{a+b-j} \circ \mathrm{Sq}^j}_{\text{with } a=1} \;=\; \underbrace{\binom{b-1}{1} \cdot \mathrm{Sq}^{1+b} \circ \mathrm{Sq}^0}_{j=0} \;=\; \underset{\text{since } \mathrm{Sq}^0 = \mathrm{id}}{\uparrow} \;(b-1) \cdot \mathrm{Sq}^{1+b} \,.$$

Furthermore, for $a = 2$ and any $b \in \mathbb{N}_{\geq 2}$ we have

$$\mathrm{Sq}^2 \circ \mathrm{Sq}^b \;=\; \underbrace{\binom{b-1}{2} \cdot \mathrm{Sq}^{2+b} \circ \mathrm{Sq}^0}_{j=0} + \underbrace{\binom{b-2}{0} \cdot \mathrm{Sq}^{1+b} \circ \mathrm{Sq}^1}_{j=1} \;=\; \underset{\text{since } \mathrm{Sq}^0 = \mathrm{id}}{\uparrow} \;\binom{b-1}{2} \cdot \mathrm{Sq}^{2+b} + \mathrm{Sq}^{1+b} \circ \mathrm{Sq}^1 \,.$$

In particular setting $b = 2$ we see that

$$\mathrm{Sq}^2 \circ \mathrm{Sq}^2 \;=\; \mathrm{Sq}^3 \circ \mathrm{Sq}^1 \,.$$

152.1. **Application of the Adem relations to homotopy groups of spheres.** Recall that in Theorem 151.13 we used Steenrod operations to show that the three Hopf maps $H\colon S^3 \to S^2$, $H_{\mathbb{H}}\colon S^7 \to S^4$ and $H_{\mathbb{O}}\colon S^{15} \to S^8$ and their suspensions define non-trivial elements in the corresponding homotopy groups of spheres.

[1804] These are equalities of cohomology operations $\mathrm{H}^n(X, A; \mathbb{Z}_2) \to \mathrm{H}^{n+a+b}(X, A; \mathbb{Z}_2)$. In particular, since we work over $\mathbb{Z}_2$-coefficients, we only care about the binomial coefficient modulo 2. We will discuss the mod 2 reductions of binomial coefficients in Lemma 152.3.

In this section we will use the Adem relations to show that the 2-fold iteration of these Hopf maps also define non-trivial elements in the homotopy groups of spheres. More precisely, we have the following theorem.

Theorem 152.2.

(1) For any $n \geq 2$ the map

$$\Sigma^{n-2}\Big(\underbrace{\overbrace{H}^{S^3\to S^2} \circ \overbrace{\Sigma(H)}^{S^4\to S^3}}_{\text{map } S^4\to S^2}\Big)\colon S^{n+2} \to S^n$$

defines a non-trivial element in $\pi_{n+2}(S^n)$. In particular for any $n \geq 2$ we have $\pi_{n+2}(S^n) \neq 0$.

(2) For any $n \geq 4$ the map

$$\Sigma^{n-4}\Big(\underbrace{\overbrace{H_{\mathbb{H}}}^{S^7\to S^4} \circ \overbrace{\Sigma^3(H_{\mathbb{H}})}^{S^{10}\to S^7}}_{\text{map } S^{10}\to S^4}\Big)\colon S^{n+6} \to S^n$$

defines a non-trivial element in $\pi_{n+6}(S^n)$. In particular for any $n \geq 4$ we have $\pi_{n+6}(S^n) \neq 0$.

(3) For any $n \geq 8$ the map

$$\Sigma^{n-8}\Big(\underbrace{\overbrace{H_{\mathbb{O}}}^{S^{15}\to S^8} \circ \overbrace{\Sigma^7(H_{\mathbb{O}})}^{S^{22}\to S^{15}}}_{\text{map } S^{22}\to S^8}\Big)\colon S^{n+14} \to S^n$$

defines a non-trivial element in $\pi_{n+14}(S^n)$. In particular for any $n \geq 8$ we have $\pi_{n+14}(S^n) \neq 0$.

For the reader's convenience we recall the two lemmas which will play a key role in the proof of Theorem 152.2.

Lemma 122.4. Let $f\colon A \to X$ be a map between two topological spaces. We denote by $j\colon X \to \mathrm{Cone}(f\colon A \to X)$ the obvious inclusion. Then there exists a natural long exact sequence of the form

$$\ldots \to \mathrm{H}^{k-1}(A;\mathbb{Z}_2) \xrightarrow{\delta} \widetilde{\mathrm{H}}^k(\mathrm{Cone}(f\colon A \to X);\mathbb{Z}_2) \xrightarrow{j^*} \mathrm{H}^k(X;\mathbb{Z}_2) \xrightarrow{f^*} \mathrm{H}^k(A;\mathbb{Z}_2) \xrightarrow{\delta} \ldots$$

As an example for the Mapping Cone-H*-Lemma 122.4 let us consider the mapping cone of the iterated suspension of the Hopf map.

Example. Let $k \in \mathbb{N}_0$. We consider $\Sigma^k(H)\colon S^{k+3} \to S^{k+2}$, i.e. we consider the k-fold suspension of the Hopf map $H\colon S^3 \to S^2$. As we saw in Lemma 122.5, it follows almost immediately from the long exact sequence of the Mapping Cone-H*-Lemma 122.4 that the maps

$$\widetilde{\mathrm{H}}^{k+2}(\mathrm{Cone}(\Sigma^k(H)\colon S^{k+3} \to S^{k+2});\mathbb{Z}_2) \xrightarrow[\cong]{j^*} \mathrm{H}^{k+2}(S^{k+2};\mathbb{Z}_2)$$

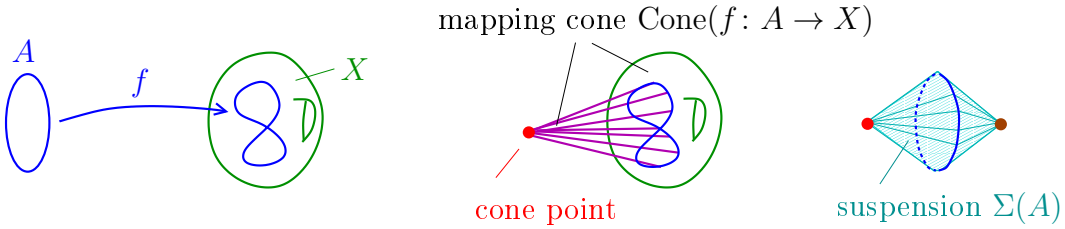
and

$$\mathrm{H}^{k+3}(S^{k+3};\mathbb{Z}_2) \xrightarrow[\cong]{\delta} \widetilde{\mathrm{H}}^{k+4}(\mathrm{Cone}(\Sigma^k(H)\colon S^{k+3} \to S^{k+2});\mathbb{Z}_2)$$

are isomorphisms, and that all the other reduced cohomology groups of the mapping cone vanish.

In the following we recall three statements of the Mapping Cone Basics Lemma 16.13 which are at the moment relevant to us. It might be helpful to have a peek at the figure below.

Lemma 16.13. Let $f\colon A \to X$ be a map between topological spaces.



(1) The inclusion $X \to \mathrm{Cone}(f\colon A \to X)$ is an embedding.

(2) The map

$$\begin{array}{rccc} h\colon & \mathrm{Cone}(f\colon A \to X)/X & \to & \Sigma(A) \\ & [(a,t)] & \mapsto & [(a,1-2t)] \end{array}$$

is a homeomorphism.

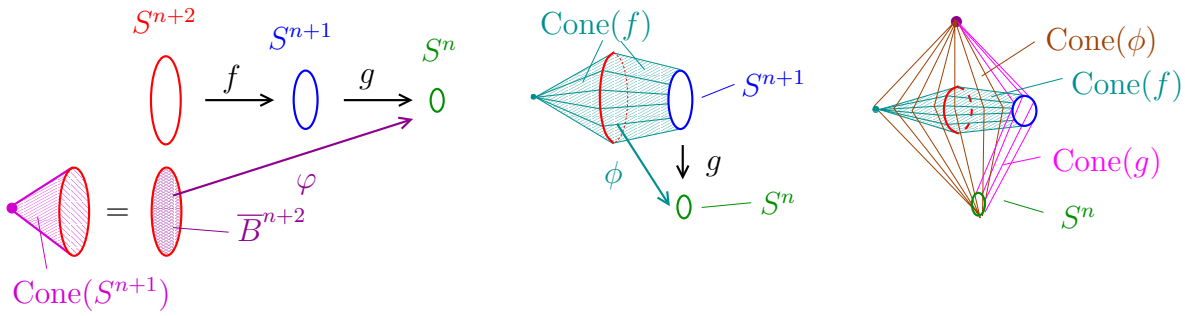
(4) The subset X is a deformation retract of the open neighborhood that is given by the complement of the cone point.

Now we turn to the proof of Theorem 152.2. As in the proof of Theorem 151.13 we first consider the case of the classical Hopf map, i.e. we first prove Statement (1).

Proof of Theorem 152.2 (1). Let $n \in \mathbb{N}_{\geq 2}$. We write

$$\Sigma^{n-2}(H \circ \Sigma(H)) \;=\; \overbrace{\underbrace{\Sigma^{n-2}(H)}_{=:g}}^{S^{n+1}\to S^n} \circ \overbrace{\underbrace{\Sigma^{n-1}(H)}_{=:f}}^{S^{n+2}\to S^{n+1}} : S^{n+2} \;\to\; S^n.$$

$\uparrow$ Suspension Functor Lemma 16.9 (2)



We need to show that $g\circ f\colon S^{n+2} \to S^n$ defines a non-trivial element in $\pi_{n+2}(S^n)$. As in the proof of Theorem 151.13 we do a proof by contradiction. Thus suppose that there exists a homotopy from $g \circ f\colon S^{n+2} \to S^n$ to a constant map. By the Trivial-in-π_n-Lemma 71.4 we can use this homotopy to construct a map[1805] $\varphi\colon \mathrm{Cone}(S^{n+2}) = \overline{B}^{n+3} \to S^n$ such that $\varphi|_{S^{n+2}} = g \circ f$. We consider the map[1806]

$$\begin{array}{rccl} \phi\colon & \overbrace{(\mathrm{Cone}(S^{n+2}) \sqcup S^{n+1})/\!\sim}^{=\mathrm{Cone}(f\colon S^{n+2}\to S^{n+1})} & \to & S^n \\ & [P] & \mapsto & \begin{cases} g(P), & \text{if } P \in S^{n+1}, \\ \varphi(P), & \text{if } P \in \mathrm{Cone}(S^{n+2}) = \overline{B}^{n+3}. \end{cases} \end{array}$$

Our main object of interest is now, perhaps rather confusingly, the mapping cone of ϕ. This mapping cone comes with two interesting maps:

[1805] As we discussed on page 450, given any $m \in \mathbb{N}_0$ the map $\mathrm{Cone}(S^m) \to \overline{B}^{m+1}$ given by $[(v,t)] \mapsto v \cdot t$ is a homeomorphism. We will use this map to make the identification $\overline{B}^{m+1} = \mathrm{Cone}(S^m)$.

[1806] It follows from $\varphi|_{S^{n+2}} = g \circ f$ that this map is well-defined. Furthermore we obtain immediately from the Topological Pushout Proposition 5.33 (1b) that this map is continuous.

(1) Since we have an inclusion $S^{n+1} \to \mathrm{Cone}(f)$ and since $\phi|_{S^{n+1}} = g$ we obtain, see the Mapping Cone Functor Lemma 16.14 (3), also an inclusion map

$$i\colon \mathrm{Cone}(g\colon S^{n+1} \to S^n) \;\to\; \mathrm{Cone}(\phi\colon \mathrm{Cone}(f) \to S^n).$$

(2) We also consider the projection

$$p\colon \mathrm{Cone}(\phi\colon \mathrm{Cone}(f) \to S^n) \;\to\; \mathrm{Cone}(\phi\colon \mathrm{Cone}(f) \to S^n)/S^n.$$

In the following two claims we will study the maps on cohomology induced by the inclusion i and the projection p.

Claim 1.

(a) The induced map

$$i^*\colon \mathrm{H}^k(\mathrm{Cone}(\phi);\mathbb{Z}_2) \;\to\; \mathrm{H}^k(\mathrm{Cone}(g);\mathbb{Z}_2)$$

is an isomorphism for $k \neq n+1$.

(b) We have $\mathrm{H}^{n+1}(\mathrm{Cone}(\phi);\mathbb{Z}_2) = 0$.

Proof. We consider the following diagram:

$$\begin{array}{ccccccccccc}
 & & \mathrm{H}^{k-2}(S^{n+2};\mathbb{Z}_2) & & & & & & \mathrm{H}^{k-1}(S^{n+2};\mathbb{Z}_2) & & \\
 & & \downarrow & & & & & & \downarrow & & \\
\to & \mathrm{H}^{k-1}(\mathrm{Cone}(f);\mathbb{Z}_2) & \to & \mathrm{H}^k(\mathrm{Cone}(\phi\colon \mathrm{Cone}(f) \to S^n);\mathbb{Z}_2) & \to & \mathrm{H}^k(S^n;\mathbb{Z}_2) & \xrightarrow{\phi^*} & \mathrm{H}^k(\mathrm{Cone}(f);\mathbb{Z}_2) & \to & & \\
 & \downarrow & & \downarrow{\scriptstyle i^*} & & \downarrow{\scriptstyle \mathrm{id}} & & \downarrow & & & \\
\longrightarrow & \mathrm{H}^{k-1}(S^{n+1};\mathbb{Z}_2) & \longrightarrow & \mathrm{H}^k(\mathrm{Cone}(g\colon S^{n+1} \to S^n);\mathbb{Z}_2) & \longrightarrow & \mathrm{H}^k(S^n;\mathbb{Z}_2) & \xrightarrow{f^*} & \mathrm{H}^k(S^{n+1};\mathbb{Z}_2) & \longrightarrow & & \\
 & \downarrow{\scriptstyle f^*} & & & & & & \downarrow{\scriptstyle f^*} & & & \\
 & \mathrm{H}^{k-1}(S^{n+2};\mathbb{Z}_2) & & & & & & \mathrm{H}^k(S^{n+2};\mathbb{Z}_2) & & &
\end{array}$$

Here the two horizontal and the two vertical sequences are obtained from the Mapping Cone-H^*-Lemma 122.4. The diagram commutes by the naturality of the long exact sequence. The two statements of the claim follow easily from the above diagram (see also the discussion on page 3224) and the calculation of the cohomology groups of spheres with $\mathbb{Z}_2$-coefficients. ⊞

Claim 2. The map

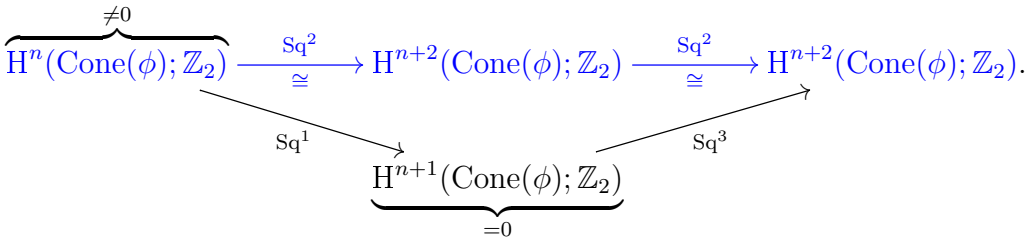
$$p^*\colon \mathrm{H}^k(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) \;\to\; \mathrm{H}^k(\mathrm{Cone}(\phi);\mathbb{Z}_2)$$

is an isomorphism for $k \neq n, n+1$.

Proof. We consider the following diagram:

$$\begin{array}{ccccccccc} \dots \longrightarrow \mathrm{H}^{k-1}(S^n;\mathbb{Z}_2) & \xrightarrow{\delta} & \mathrm{H}^k(\mathrm{Cone}(\phi), S^n;\mathbb{Z}_2) & \longrightarrow & \mathrm{H}^k(\mathrm{Cone}(\phi);\mathbb{Z}_2) & \longrightarrow & \mathrm{H}^k(S^n;\mathbb{Z}_2) & \longrightarrow & \dots \\ & & \downarrow & \nearrow_{p^*} & & & & & \\ & & \mathrm{H}^k(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) & & & & & & \end{array}$$

Here on top we see the long exact sequence in cohomology of the pair $(\mathrm{Cone}(\phi), S^n)$. Furthermore the vertical map is the natural map from the Cohomology-of-Quotients Proposition 109.2 which has in particular the property that it makes the diagram commute. Furthermore, it follows from the Cohomology-of-Quotients Proposition 109.2 (2) and the Mapping Cone Basics Lemma 16.13 (6) that the vertical map is an isomorphism. The desired statement follows immediately from this discussion and the calculation of the cohomology groups of S^n. ⊞



Next we consider the following diagram.

$$\begin{array}{ccccccc} \mathrm{H}^n(\mathrm{Cone}(\Sigma^{n-2}(H));\mathbb{Z}_2) & \xrightarrow[\cong]{\mathrm{Sq}^2} & \mathrm{H}^{n+2}(\mathrm{Cone}(\Sigma^{n-2}(H));\mathbb{Z}_2) & & & & \\ \downarrow{=} & & {=}\downarrow & & & & \\ \mathrm{H}^n(\mathrm{Cone}(g);\mathbb{Z}_2) & \xrightarrow[\cong]{\mathrm{Sq}^2} & \mathrm{H}^{n+2}(\mathrm{Cone}(g);\mathbb{Z}_2) & & & & \\ {i^*}\uparrow{\cong} & & {\cong}\uparrow{i^*} & & & & \\ \mathrm{H}^n(\mathrm{Cone}(\phi);\mathbb{Z}_2) & \xrightarrow{\mathrm{Sq}^2} & \mathrm{H}^{n+2}(\mathrm{Cone}(\phi);\mathbb{Z}_2) & \xrightarrow{\mathrm{Sq}^2} & \mathrm{H}^{n+4}(\mathrm{Cone}(\phi);\mathbb{Z}_2) & & \\ & & {p^*}\uparrow{\cong} & & {\cong}\uparrow{p^*} & & \\ & & \mathrm{H}^{n+2}(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) & \xrightarrow{\mathrm{Sq}^2} & \mathrm{H}^{n+4}(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) & & \\ & & {h^*}\uparrow{\cong} & & {\cong}\uparrow{h^*} & & \\ & & \mathrm{H}^{n+2}(\Sigma(\mathrm{Cone}(f));\mathbb{Z}_2) & \xrightarrow[\cong]{\mathrm{Sq}^2} & \mathrm{H}^{n+4}(\Sigma(\mathrm{Cone}(f));\mathbb{Z}_2) & & \\ & & {\theta^*}\downarrow{\cong} & & {\cong}\downarrow{\theta^*} & & \\ & & \mathrm{H}^{n+2}(\mathrm{Cone}(\Sigma(f));\mathbb{Z}_2) & \xrightarrow[\cong]{\mathrm{Sq}^2} & \mathrm{H}^{n+4}(\mathrm{Cone}(\Sigma(f));\mathbb{Z}_2) & & \\ & & {=}\downarrow & & \downarrow{=} & & \\ & & \mathrm{H}^{n+2}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2) & \xrightarrow[\cong]{\mathrm{Sq}^2} & \mathrm{H}^{n+4}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2). & & \end{array}$$

We make the following clarifications and observations:

(1) At the top and bottom we use that by definition $f = \Sigma^{n-1}(H)\colon S^{n+2} \to S^{n+1}$ and $g = \Sigma^{n-2}(H)\colon S^{n+1} \to S^n$.
(2) We obtain from Proposition 151.15 (1) that the top and bottom horizontal maps Sq^2 are isomorphisms.
(3) It follows from the above two claims that the vertical maps i^* and p^* are isomorphisms.
(4) The map $h\colon \mathrm{Cone}(\phi\colon \mathrm{Cone}(f) \to S^n)/S^n \to \Sigma(\mathrm{Cone}(f))$ is the homeomorphism from the Mapping Cone Basics Lemma 16.13 (4).
(5) The map $\theta\colon \mathrm{Cone}(\Sigma(f)\colon \Sigma(S^{n+2}) \to \Sigma(S^{n+1})) \to \Sigma(\mathrm{Cone}(f\colon S^{n+2} \to S^{n+1}))$ is the homeomorphism from the Mapping Cone-Suspension Proposition 16.19.
(6) It follows from the naturality of the Steenrod operations that all the squares commute.
(7) The combination of the above arguments implies that both of the maps Sq^2 in the third row are isomorphisms.

Finally we consider the following diagram.

We make the following observations:

(1) By the discussion preceding the diagram we know that the two maps on the top are isomorphisms.

(2) As we saw on page 3223, we have the Adem relation $\mathrm{Sq}^2 \circ \mathrm{Sq}^2 = \mathrm{Sq}^3 \circ \mathrm{Sq}^1$. This implies that the diagram commutes.

(3) We have isomorphisms

$$\mathrm{H}^n(\mathrm{Cone}(\phi);\mathbb{Z}_2) \underset{\text{Claim 1 (a)}}{\cong} \mathrm{H}^n(\mathrm{Cone}(\overbrace{\Sigma^{n-2}(H)}^{=g});\mathbb{Z}_2) \underset{\text{see the example on page 3224}}{\cong} \mathrm{H}^n(S^n;\mathbb{Z}_2) \cong \mathbb{Z}_2.$$

(4) In Claim 1 (b) we had shown that the group $\mathrm{H}^{n+1}(\mathrm{Cone}(\phi);\mathbb{Z}_2)$ is trivial.

By (1) and (3) the two horizontal maps in the diagram give us an isomorphism of a non-trivial group. On the other hand, by (2) and (4) this isomorphism factors through a trivial group. This is absurd. We have thus obtained a contradiction. ■

Now we turn to the proof of the remaining two statements of Theorem 152.2.

Proof of Theorem 152.2 (2) and (3). The proof for the quaternionic Hopf map $H_{\mathbb{H}}$ and the octonion Hopf map $H_{\mathbb{O}}$ is almost the same as the above proof that deals with the classical Hopf map H. We just need to replace Proposition 151.15 (1) by Proposition 151.15 (2) and (3) and we need to use the following Adem relations:

$$\begin{aligned} \mathrm{Sq}^4 \circ \mathrm{Sq}^4 &= \mathrm{Sq}^6 \circ \mathrm{Sq}^2 + \mathrm{Sq}^7 \circ \mathrm{Sq}^1 \\ \mathrm{Sq}^8 \circ \mathrm{Sq}^8 &= \mathrm{Sq}^{12} \circ \mathrm{Sq}^4 + \mathrm{Sq}^{14} \circ \mathrm{Sq}^2 + \mathrm{Sq}^{15} \circ \mathrm{Sq}^1 . \end{aligned}$$

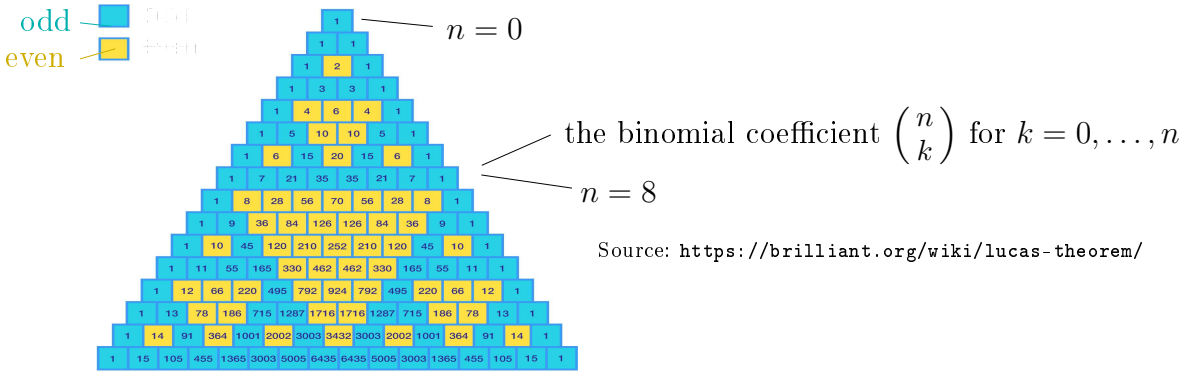
These relations can be obtained easily by hand from the Adem Relation Theorem 152.1. Alternatively one can use the Adem relations calculator:

`https://math.berkeley.edu/~kruckman/adem/`

As in the proof for the Hopf maps one sees that the initial Steenrod operations on the right hand side all end up in a cohomology group which is zero. Thus one obtains again a contradiction to the hypothesis that the maps $\Sigma^{n-4}(H_{\mathbb{H}} \circ \Sigma^3(H_{\mathbb{H}})) \colon S^{n+6} \to S^n$ and $\Sigma^{n-8}(H_{\mathbb{O}} \circ \Sigma^7(H_{\mathbb{O}})) \colon S^{n+14} \to S^n$ are null-homotopic. ■

152.2. **Decomposing Steenrod operations and the Hopf invariant revisited.** The key to extracting extra mileage out of Steenrod operations is the following innocuous lemma from elementary number theory.

Lemma 152.3. Let $n, k \in \mathbb{N}_0$. If we write $n = \sum_{i \in \mathbb{N}_0} n_i \cdot 2^i$ and $k = \sum_{i \in \mathbb{N}_0} k_i \cdot 2^i$ with $n_i, k_i \in \{0, 1\}$, then



$$\binom{n}{k} = \prod_{i \in \mathbb{N}_0} \binom{n_i}{k_i} \mod 2.$$

Remark.

(1) Note that for $r, s \in \{0, 1\}$ it follows easily from the definition on page 3203 that

$$\binom{s}{r} = \begin{cases} 1, & \text{if } r \leq s, \\ 0, & \text{otherwise.} \end{cases}$$

(2) Let $n \in \mathbb{N}$ and let $k \in \{0, \ldots, d\}$. We define n_i, k_i as above. It follows from Lemma 152.3 and (1) that $\binom{n}{k}$ is odd if and only if for each i we have $k_i \leq n_i$. If we draw the usual Pascal triangle, then by shading odd and even terms in different colors we obtain a Sierpinski triangle. We refer to the figure below for an illustration.[1807]

(3) In fact the obvious analogue of Lemma 152.3 holds with the prime 2 replaced by any prime p. This more general statement is known as Lucas' Theorem, a proof is for example provided in [**Fi1947**].

Proof. Let $n, k \in \mathbb{N}_0$. We write $n = \sum_{i \in \mathbb{N}_0} n_i \cdot 2^i$ and $k = \sum_{i \in \mathbb{N}_0} k_i \cdot 2^i$ with $n_i, k_i \in \{0, 1\}$ In the polynomial ring $\mathbb{Z}_2[x]$ we have the following equalities[1808]

$$\sum_{i=0}^{n} \binom{n}{i} x^i \underset{\text{binomial formula}}{\uparrow} = (1+x)^n = (1+x)^{\sum n_i 2^i} = \prod_{i \in \mathbb{N}_0} (1+x)^{2^i n_i} \underset{\text{since in } \mathbb{Z}_2[x] \text{ we have } (a+b)^2 = a^2 + b^2}{\uparrow} = \prod_{i \in \mathbb{N}_0} (1+x^{2^i})^{n_i} \underset{\text{binomial formula}}{\uparrow} = \prod_{i \in \mathbb{N}_0} \sum_{j_i=0}^{n_i} \binom{n_i}{j_i} x^{j_i \cdot 2^i}.$$

[1807] A more elaborate version of this figure can be found here:

https://upload.wikimedia.org/wikipedia/commons/8/87/Sierpinski_Pascal_triangle.svg

[1808] The argument has some similarities with the proof of the claim on page 2673.

Now we compare the x^k-coefficients, we see that[1809]

$$\binom{n}{k} = x^k\text{-coefficient of } \sum_{i=0}^{n}\binom{n}{i}x^i \underset{\text{by the above equality}}{=} x^k\text{-coefficient of } \prod_{i\in\mathbb{N}_0}\sum_{j_i=0}^{n_i}\binom{n_i}{j_i}x^{j_i\cdot 2^i} \underset{\substack{\text{by the uniqueness of the 2-adic description}\\ \text{of a natural number we only get } x^k\\ \text{if each variable } j_i \text{ equals } k_i}}{=} \prod_{i\in\mathbb{N}_0}\binom{n_i}{k_i}.$$

We have thus proved the desired equality. ■

This lemma allows us to prove the following theorem.

Theorem 152.4. Let $i \in \mathbb{N}_0$. If i is not a power of 2, then Sq^i is decomposable, in the sense that it can be written as the sum of compositions of Steenrod operations of smaller degree.

Example. By the discussion on page 3223 we know that for any $k \in \mathbb{N}_0$ we have

$$\mathrm{Sq}^{2k+1} = \mathrm{Sq}^1 \circ \mathrm{Sq}^{2k} \quad \text{and} \quad \mathrm{Sq}^{4k+2} = \mathrm{Sq}^2 \circ \mathrm{Sq}^{4k} + \mathrm{Sq}^{4k+1} \circ \mathrm{Sq}^1 .$$

In particular we see that

$$\mathrm{Sq}^3 = \mathrm{Sq}^1 \circ \mathrm{Sq}^2, \quad \mathrm{Sq}^5 = \mathrm{Sq}^1 \circ \mathrm{Sq}^4, \quad \mathrm{Sq}^6 = \mathrm{Sq}^2 \circ \mathrm{Sq}^4 + \mathrm{Sq}^5 \circ \mathrm{Sq}^1 \quad \text{and} \quad \mathrm{Sq}^7 = \mathrm{Sq}^1 \circ \mathrm{Sq}^6 .$$

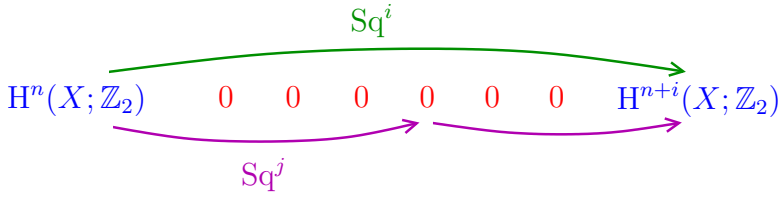
Proof. Suppose that we are given $i \in \mathbb{N}_0$ that is not a power of two. This means that we can write $i = a + b$ where $b = 2^k$ and $a \in \{1, \dots, 2^k - 1\}$. Since $0 < a < 2b$ we obtain an Adem relation for $\mathrm{Sq}^a \circ \mathrm{Sq}^b$ from the Adem Relations Theorem 152.1. This relation can be rewritten as follows:

$$\binom{b-1}{a} \cdot \mathrm{Sq}^{a+b} = \underbrace{\mathrm{Sq}^a \circ \mathrm{Sq}^b + \sum_{j=1}^{\lfloor \frac{a}{2} \rfloor} \binom{b-1-j}{a-2j} \cdot \mathrm{Sq}^{a+b-j} \circ \mathrm{Sq}^j}_{\text{compositions of Steenrod operations of degree} < a+b} .$$

It remains to show that $\binom{b-1}{a} = 1 \bmod 2$. We calculate

$$\binom{b-1}{a} \underset{\substack{\text{by Lemma 152.3 where } b-1 = \sum_{i\in\mathbb{N}_0} d_i\cdot 2^i \text{ and } a = \sum_{i\in\mathbb{N}_0} c_i\cdot 2^i \text{ with } c_i, d_i \in \{0,1\}\\ \downarrow}}{=} \prod_{i\in\mathbb{N}_0}\binom{d_i}{c_i} \underset{\uparrow}{=} \prod_{i=0}^{k-1}\binom{1}{c_i}\cdot\prod_{i=k}^{\infty}\binom{0}{0} = 1 \mod 2.$$

since $b-1 = 2^k - 1 = 1 + 2 + \cdots + 2^{k-1}$ we have $d_0 = \cdots = d_{k-1} = 1$ and $d_k = d_{k+1} = \cdots = 0$
furthermore, since $a < 2^k - 1$ we have $c_k = c_{k+1} = \cdots = 0$ ■



Corollary 152.5. Let X be a topological space and let $n \in \mathbb{N}_0$. We consider the Steenrod operation

$$\mathrm{Sq}^i \colon \mathrm{H}^n(X;\mathbb{Z}_2) \to \mathrm{H}^{n+i}(X;\mathbb{Z}_2).$$

If the cohomology groups inbetween vanish, i.e. if $\mathrm{H}^{n+1}(X;\mathbb{Z}_2) = \ldots = \mathrm{H}^{n+i-1}(X;\mathbb{Z}_2) = 0$, and if i is not a power of 2, then the Steenrod operation is the zero map.

[1809] Note that the equalities also make sense for $k > n$. In this setting one sees easily that all terms are in fact zero.

Proof. Since i is not a power of 2 we know by Theorem 152.4 that Sq^i can be written as the sum of compositions of Steenrod operations of smaller degree. But by our hypothesis for any $j \in \{1, \ldots, i-1\}$ we have $\mathrm{H}^{n+j}(X; \mathbb{Z}_2) = 0$. But this implies in particular that for any such j we have $\mathrm{Sq}^j \colon \mathrm{H}^n(X; \mathbb{Z}_2) \to \mathrm{H}^{n+j}(X; \mathbb{Z}_2) = 0$. ■

In Question 117.19 we asked whether all (reasonable) superalgebras can be realized as cohomology rings. We will now see that this is not the case. Before we can state the corresponding proposition we need to introduce the following definition.

Definition. Let $m \in \mathbb{N}$ be an even number and let $s \in \mathbb{Z}$. We define $R_m(s)$ to be the superalgebra which is given by the groups[1810]

$$R_m(s) = \begin{cases} \mathbb{Z} \cdot 1, & \text{in degree } 0, \\ \mathbb{Z} \cdot x, & \text{in degree } m, \\ \mathbb{Z} \cdot y, & \text{in degree } 2m, \\ 0, & \text{in all other degrees} \end{cases}$$

and where the multiplication is given by $x \cdot x = s \cdot y$. In other words, the multiplication table is given as follows

	1	x	y
1	1	x	y
x	x	$s \cdot y$	0
y	y	0	0.

Example.

(1) For any m the superalgebra $R_m(1)$ is evidently isomorphic to $\mathbb{Z}[x]/(x^3)$ where x is of degree m.

(2) By (1) together with the Cup Product-$\mathbb{C}\mathrm{P}^n$-Proposition 121.7 and Proposition 121.20 we have isomorphisms

$$(\mathrm{H}^*(\mathbb{C}\mathrm{P}^2; \mathbb{Z}), \cup) \cong R_2(1), \ (\mathrm{H}^*(\mathbb{H}\mathrm{P}^2; \mathbb{Z}), \cup) \cong R_4(1) \text{ and } (\mathrm{H}^*(\mathbb{O}\mathrm{P}^2; \mathbb{Z}), \cup) \cong R_8(1).$$

Next we prove the following proposition which gives a negative answer to Questions 117.19 and 121.21.

Proposition 152.6. Let m be an even number and let s be an odd number. If m is not a power of 2, then there is no topological space X such that $(\mathrm{H}^*(X; \mathbb{Z}), \cup)$ is isomorphic to $R_m(s)$.

In the proof of Proposition 152.6 we will need the following lemma.

[1810] It follows from the fact that m is even that this is indeed a superalgebra.

Lemma 152.7. Let $m \in \mathbb{N}$. We denote by $\varphi\colon \mathbb{Z} \to \mathbb{Z}_m$ the canonical map. Given any topological space X there exists a long exact sequence

$$\ldots \to \mathrm{H}^k(X;\mathbb{Z}) \xrightarrow{\cdot m} \mathrm{H}^k(X;\mathbb{Z}) \xrightarrow{\varphi_*} \mathrm{H}^k(X;\mathbb{Z}_m) \xrightarrow{\delta} \mathrm{H}^{k+1}(X;\mathbb{Z}) \to \ldots$$

Proof of Lemma 152.7. We denote by $\psi\colon \mathbb{Z} \to \mathbb{Z}$ the map that is given by multiplication by m. We have the short exact sequence

$$0 \to \mathbb{Z} \xrightarrow{\psi} \mathbb{Z} \xrightarrow{\varphi} \mathbb{Z}_m \to 0.$$

By the discussion on page 3145 we have the corresponding Bockstein sequence in cohomology which looks as follows:

$$\ldots \xrightarrow{\delta} \mathrm{H}^k(X;\mathbb{Z}) \xrightarrow{\psi_*} \mathrm{H}^k(X;\mathbb{Z}) \xrightarrow{\varphi_*} \mathrm{H}^k(X;\mathbb{Z}_2) \xrightarrow{\delta} \mathrm{H}^{k+1}(X;\mathbb{Z}) \to \ldots$$

By the almost, but not entirely trivial Lemma 148.2 we know that ψ_* is indeed multiplication by m. ∎

Proof of Proposition 152.6. Let m be an even number. Furthermore let X be a topological space such that $(\mathrm{H}^*(X;\mathbb{Z}), \cup) = R_m(s)$ for some odd number s. We need to show that m is a power of 2. We denote by $\varphi\colon \mathbb{Z} \to \mathbb{Z}_2$ the canonical map. We consider the following diagram

$$\begin{array}{ccc}
\mathrm{H}^m(X;\mathbb{Z}) & \xrightarrow{x \mapsto x^2 = x \cup x = s \cdot y} & \mathrm{H}^{2m}(X;\mathbb{Z}) \\
\downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\
\mathrm{H}^m(X;\mathbb{Z}_2) & \xrightarrow{z \mapsto z^2 = z \cup z} & \mathrm{H}^{2m}(X;\mathbb{Z}_2) \\
\downarrow & & \downarrow \\
\mathrm{H}^m(X;\mathbb{Z}_2) & \xrightarrow{z \mapsto \mathrm{Sq}^m(z)} & \mathrm{H}^{2m}(X;\mathbb{Z}_2).
\end{array}$$

We make the following clarifications and observations:

(1) It follows from the Cup Product-Naturality Proposition 115.4 (2) that the upper square commutes.
(2) It follows from Lemma 152.7 and our hypothesis on the topological space X that the map $\varphi_*\colon \mathrm{H}^{2m}(X;\mathbb{Z}) \to \mathrm{H}^{2m}(X;\mathbb{Z}_2)$ is an epimorphism and that $\mathrm{H}^{2m}(X;\mathbb{Z}_2) \cong \mathbb{Z}_2$. In particular we see that $\varphi_*(y) \in \mathrm{H}^{2m}(X;\mathbb{Z}_2)$ is a non-trivial element of order 2.
(3) Since s is odd we obtain from (2) that $\varphi_*(s \cdot y) = s \cdot \varphi_*(y)$ is a non-trivial element of $\mathrm{H}^{2m}(X;\mathbb{Z}_2)$.
(4) The lower square commutes by Axiom (2) of Steenrod operations, see the Steenrod Theorem 151.2 (2).
(5) By our hypothesis on X we know that the intermediate cohomology groups vanish, i.e. we have $\mathrm{H}^{m+1}(X;\mathbb{Z}_2) = \cdots = \mathrm{H}^{2m-1}(X;\mathbb{Z}_2) = 0$.

It follows from (3) and (4) that the bottom horizontal map has non-trivial image. But by Corollary 152.5 together with (5) this is only possible if m is indeed a power of 2. ∎

As promised in the title of the section, we now return to the Hopf invariant. Let $f\colon S^{2n-1} \to S^n$ be a map where $n \geq 2$. Recall that on page 2681 we introduced the Hopf invariant $\mathrm{Hopf}(f) \in \mathbb{Z}$. The following lemma translates the Hopf invariant into the language of the above discussion. The lemma can also be viewed as an alternative definition of the Hopf invariant, at least up to sign.

Lemma 152.8. Let $n \geq 2$. If $f\colon S^{2n-1} \to S^n$ is a map, then there exists an isomorphism

$$(\mathrm{H}^*(\mathrm{Cone}(f);\mathbb{Z}),\cup) \;\cong\; R_n(\mathrm{Hopf}(f))$$

of superalgebras.

Proof. This statement follows immediately from Lemma 122.5 and the definition of the Hopf invariant, see page 2681. ■

The following proposition is the summary of our previous discussion of the Hopf invariant.

Proposition 152.9. Let $n \geq 2$.

(1) The Hopf invariant $\mathrm{Hopf}\colon \pi_{2n-1}(S^n) \to \mathbb{Z}$ is a homomorphism.
(2) The Hopf invariant $\mathrm{Hopf}\colon \pi_{2n-1}(S^n) \to \mathbb{Z}$ is zero for odd n.
(3) If $\mathbb{R}^n$ can be equipped with the structure of a division algebra, then there exists a map $f\colon S^{2n-1} \to S^n$ with $\mathrm{Hopf}(f) = 1$.
(4) For $k = 1, 2, 4$ the Hopf maps $H, H_{\mathbb{H}}$ and $H_{\mathbb{O}}$ give elements in $\pi_{4k-1}(S^{2k})$ with Hopf invariant 1.
(5) Given any $k \in \mathbb{N}$ there exists a map $f\colon S^{4k-1} \to S^{2k}$ with $\mathrm{Hopf}(f) = 2$.

Proof. The proof follows from Proposition 122.7, Corollary 122.8, Lemma 122.11 and Propositions 122.13 and 122.12. ■

We recall the following question that we asked a while ago.

Question 122.17. For which $n \in \mathbb{N}_{\geq 2}$ does there exist a map $f\colon S^{2n-1} \to S^n$ with $\mathrm{Hopf}(f) = 1$?

The following theorem is an immediate consequence of Proposition 152.6 and Lemma 152.8.

Theorem 152.10. Let $n \geq 2$. If there exists a map $f\colon S^{2n-1} \to S^n$ with $\mathrm{Hopf}(f) = 1$, then n is a power of 2.

The combination of Proposition 152.9 (3) and Theorem 152.10 gives us an alternative proof of the following theorem.

Theorem 121.23. (Hopf 1940) If $\mathbb{R}^n$ admits the structure of a real division algebra, then n is a power of 2.

It is an amusing mental exercise, left to the reader, to compare the two proofs of Theorem 121.23. The first one relies on the calculation of the cup product of $\mathbb{R}\mathrm{P}^n \times \mathbb{R}\mathrm{P}^n$ with $\mathbb{Z}_2$-coefficients and a fact in elementary number theory that is proved on page 2673. The second proof uses Steenrod operations and a different input from elementary number theory, namely Lemma 152.3. Note that in some sense the former proof is more satisfactory since we could provide full details, whereas the latter proof relies on the Adem relations that we did not prove.

For completeness we remark that in 1960 Frank Adams [**Adam1960**] (see also [**AdA1966**], [**May1999a**, Chapter 24.6] and [**Hus1993**, Theorem 15.4.3]) proved the following strengthening of Theorem 152.10. Note that this theorem finally gives a complete answer to Question 122.17.

Theorem 152.11. Let $n \geq 2$. If there exists a map $f\colon S^{2n-1} \to S^n$ with $\mathrm{Hopf}(f) = 1$, then $n = 2, 4$ or $n = 8$.

The combination of Proposition 152.9 (3) and Theorem 152.11 gives us an alternative proof of the following beautiful theorem.

Theorem 121.25. Every finite-dimensional division algebra over $\mathbb{R}$ is of dimension 1,2, 4 or 8.

152.3. **The Steenrod cyclic reduced powers.** The Steenrod operations Sq^i are cohomology operations on cohomology groups with $\mathbb{Z}_2$-coefficients. It turns out that there exist also analogous cohomology operations for cohomology with $\mathbb{Z}_p$-coefficients. More precisely, the following theorem holds:

Theorem 152.12. (Steenrod Theorem) Let p be an odd prime. There exists a family[1811]

$$P^i\colon \mathrm{H}^n(X,A;\mathbb{Z}_p) \;\to\; \mathrm{H}^{n+2i(p-1)}(X,A;\mathbb{Z}_p) \quad \text{with } i\in\mathbb{N}_0 \text{ and } n\in\mathbb{N}_0$$

of additive cohomology operations which satisfies the following axioms:

(1) $P^0 = \mathrm{id}$.
(2) For any $\varphi\in\mathrm{H}^{2i}(X,A;\mathbb{Z}_p)$ we have $P^i(\varphi)=\varphi^p\in\mathrm{H}^{2pi}(X,A;\mathbb{Z}_p)$.
(3) For any $\varphi\in\mathrm{H}^j(X,A;\mathbb{Z}_p)$ with $i>j$ we have $P^i(\varphi)=0$.
(4) Let (X,A,B) be an excisive triad of topological spaces. For any $\varphi\in\mathrm{H}^r(X,A;\mathbb{Z}_p)$ any $\psi\in\mathrm{H}^s(X,B;\mathbb{Z}_p)$ and any $k\in\mathbb{N}_0$ we have[1812]

$$P^k(\varphi\cup\psi) \;=\; \sum_{i=0}^{k} \underbrace{P^i(\varphi)}_{\in\mathrm{H}^{r+2i(p-1)}(X,A;\mathbb{Z}_p)} \cup \underbrace{P^{k-i}(\psi)}_{\in\mathrm{H}^{s+2(k-i)(p-1)}(X,B;\mathbb{Z}_p)} \in \mathrm{H}^{r+s+2k(p-1)}(X,A\cup B;\mathbb{Z}_p).$$

This equality is often called the *Cartan formula*.

Proof. This theorem is proved in [**SE1962**, Chapter VI]. A very different proof is given in [**Hat2002**, Theorem 4.L.16]. ■

The following theorem plays the role of the Adem Relations Theorem 152.1.

Theorem 152.13. (Adem Relations Theorem) Let p be an odd prime.

(1) For any $0<a<pb$ we have the following equality of cohomology operations:

$$P^a\circ P^b \;=\; \sum_{j=0}^{\left\lfloor\frac{a}{p}\right\rfloor} (-1)^{a+j}\cdot\binom{(p-1)(b-j)-1}{a-pj}\cdot P^{a+b-j}\circ P^j.$$

(2) Given $i\in\mathbb{N}_0$ we denote by $\beta\colon \mathrm{H}^i(X;\mathbb{Z}_p)\to\mathrm{H}^{i+1}(X;\mathbb{Z}_p)$ the Bockstein homomorphism that corresponds to the short exact sequence $0\to\mathbb{Z}_p\to\mathbb{Z}_{p^2}\to\mathbb{Z}_p\to 0$. For

[1811] Note that if for argument's sake one plugs $p=2$ into the statements of the Steenrod Theorem 152.12, then one does *not* get the statements of the Steenrod Theorem 151.2 since the degree formulas are different. In other words there is no easy way to combine Theorems 151.2 and 152.12 into a single statement.

[1812] We refer to page 2429 for the definition of an excisive triad. By the Excisive Triad-Proposition 109.12 most "reasonable" triads are in fact excisive. In fact we will only use the special cases that $A=B$, or that at least one of A or B is the empty set. We refer again to page 2536 for the definition of the relative cup product.

any $0 < a \leq pb$ the following mystifying equality holds:

$$P^a \circ \beta \circ P^b = \sum_{j=0}^{\left\lfloor \frac{a}{p} \right\rfloor} (-1)^{a+j} \cdot \binom{(p-1)(b-j)}{a-pj} \cdot \beta \circ P^{a+b-j} \circ P^j - \sum_{j=0}^{\left\lfloor \frac{a-1}{p} \right\rfloor} (-1)^{a+j} \cdot \binom{(p-1)(b-j)-1}{a-pj-1} \cdot P^{a+b-j} \circ \beta \circ P^j.$$

These equalities are called the *Adem relations*.

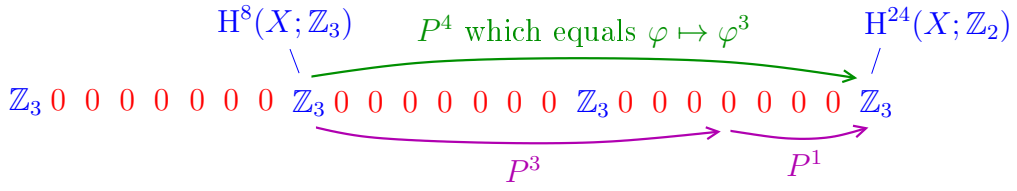
Example. Let us consider the case of the prime $p = 3$. In this case the corresponding reduced Steenrod operations are additive cohomology operations of the form

$$P^i \colon \mathrm{H}^n(X, A; \mathbb{Z}_3) \to \mathrm{H}^{n+4i}(X, A; \mathbb{Z}_3).$$

For $a = 1$ and $b = 3$ we obtain the Adem relation

$$P^1 \circ P^3 \underset{\text{Adem Relations Theorem 152.13 (1)}}{=} \sum_{j=0}^{\left\lfloor \frac{1}{3} \right\rfloor} (-1)^{1+j} \binom{2 \cdot (3-j) - 1}{1 - 3 \cdot j} \cdot P^{4-j} \circ P^j \underset{\text{only one summand, namely for } j=0}{=} (-1) \cdot \binom{5}{1} \cdot P^4 = -5 \cdot P^4 \underset{\text{we work in } \mathbb{Z}_3}{=} P^4.$$

The Steenrod cyclic reduced powers can, not surprisingly, be used to give more information on homotopy groups of spheres. We refer to [**SE1962**, Chapter VI.5] and [**Hat2002**, Example 4.L.6] for details.



Instead of providing more results on homotopy groups of spheres we want to give a different application of the Steenrod cyclic reduced powers, namely we want to prove the following proposition which gives a negative answer to Question 121.22.

Proposition 152.14. There is no topological space X such that $\mathrm{H}^*(X; \mathbb{Z}_3)$ is isomorphic to $\mathbb{Z}_3[\varphi]/(\varphi^4)$ with $\varphi \in \mathrm{H}^8(X; \mathbb{Z}_3)$.

Proof. We provide a proof by contradiction. So suppose there exists a topological space X such that $\mathrm{H}^*(X; \mathbb{Z}_3)$ is isomorphic to $\mathbb{Z}_3[\varphi]/(\varphi^4)$ with $\varphi \in \mathrm{H}^8(X; \mathbb{Z}_3)$. We see that

$$0 \underset{\substack{\text{since we assume that} \\ \mathrm{H}^*(X;\mathbb{Z}_3) \cong \mathbb{Z}_3[\varphi]/(\varphi^4)}}{\neq} \varphi^3 \overset{\text{Steenrod Theorem 152.12 (2)}}{=} P^4(\varphi) \underset{\text{since } P^4 = P^1 \circ P^3}{=} (P^1 \circ P^3)(\varphi) = P^1(\overbrace{P^3(\varphi)}^{\in \mathrm{H}^{8+3\cdot 4}(X;\mathbb{Z}_3)}) \underset{\text{since } \mathrm{H}^{20}(X;\mathbb{Z}_3) = 0}{=} 0.$$

We have thus obtained a contradiction. ∎

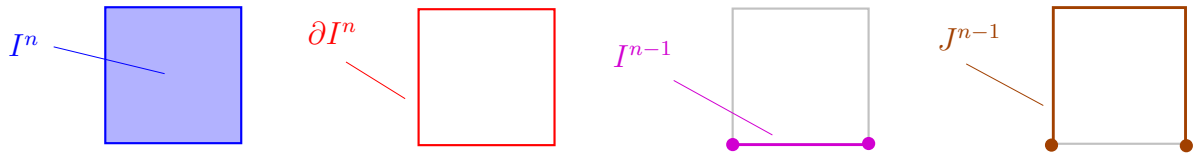
Remark. In Exercise 152.2 we will use Proposition 152.14 to give a negative answer to Question 92.11. So with most reasonable interpretations it is fair to say that there is no smooth manifold that deserves the name $\mathbb{O}\mathrm{P}^n$ with $n \geq 3$.

Exercises for Chapter 152.

Exercise 152.1. Let X be a topological space and let $x \in \mathrm{H}^1(X;\mathbb{Z}_2)$ be a cohomology class of degree *one*. Show that for any $k \in \mathbb{N}$ and any $i \in \mathbb{N}$ we have

$$\mathrm{Sq}^i(x^{2^k}) \;=\; \begin{cases} x^{2^k}, & \text{if } i = 0, \\ x^{2^{k+1}}, & \text{if } i = 2^k, \\ 0, & \text{otherwise.} \end{cases}$$

Exercise 152.2. Let $n \geq 3$. Show that there is no closed orientable $8n$-dimensional smooth manifold that admits a CW-structure with precisely one cell in dimensions $0, 8, 16, \ldots, 8n$.
Remark. This exercise gives a negative answer to Question 92.11.



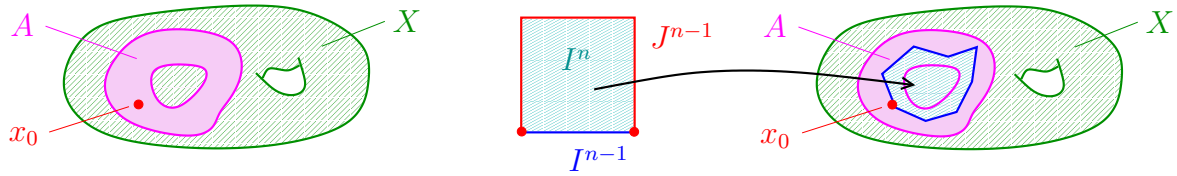
Part XVIII

Homotopy Theory and Eilenberg-Maclane Spaces

153.1. **The definition of relative homotopy groups.** While studying homology groups we saw at some point that it was convenient to introduce the relative homology groups $\mathrm{H}_k(X, A)$ corresponding to a pair of topological spaces (X, A). In our latest attempt to understand homotopy groups we will now, perhaps not surprisingly, introduce relative homotopy groups. We start out with introducing the following notation.

Notation. Throughout this chapter we write $I = [0, 1]$ for the unit interval. Furthermore, given $n \in \mathbb{N}$ we use the following notation:

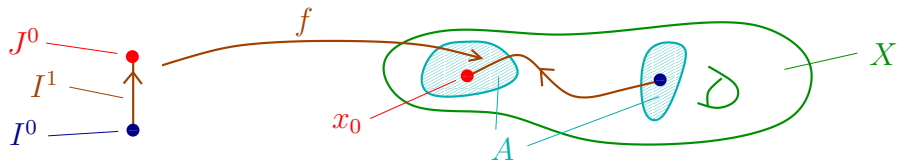
(1) we denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$,
(2) we denote by ∂I^n the boundary of I^n viewed as a subset of $\mathbb{R}^n$,
(3) by a slight abuse of notation we make the identification $I^{n-1} = I^{n-1} \times \{0\}$,
(4) we write $J^{n-1} := \overline{\partial I^n \setminus I^{n-1}}$.



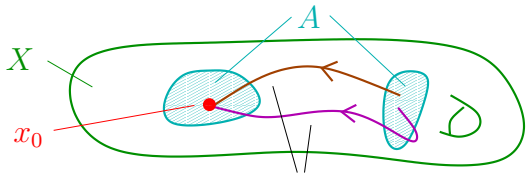
The following definition is a variation on the notion of a pointed topological space that we introduced on page 1061.

Definition. A pointed pair of topological spaces is a triple (X, A, x_0), where X is a topological space, A is a subset of X and x_0 is a point in A. A morphism between pointed pairs of topological spaces (X, A, x_0) and (Y, B, y_0) is a map $f \colon X \to Y$ with $f(A) \subset B$ and $f(x_0) = y_0$. We refer to the corresponding category as the category of pointed pairs of topological spaces.

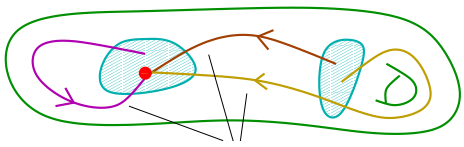
Definition. Let (X, A, x_0) be a pointed pair of topological spaces. Given $n \geq 1$ we define the n-th relative homotopy group of (X, A, x_0) to be[1813]



$$\pi_n(X, A, x_0) \ := \ \text{homotopy classes of maps } (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\}).$$



Examples.



(1) Let (X, A, x_0) be a pointed pair of topological spaces. We want to get a better understanding of elements in $\pi_1(X, A, x_0)$. For $n = 1$ we have $I^1 = [0, 1]$, $\partial I^1 = \{0, 1\}$ and $J^0 = \{1\}$. A map $(I^1, \partial I^1, J^0) \to (X, A, \{x_0\})$ is thus the same as a path in X that starts at a point in A and that ends in x_0. We refer to the figures below for an illustration.

[1813] On page 439 we defined the notion of maps between pairs of topological spaces and we defined the notion of a homotopy between such maps. These notions extend in an obvious way to triples of topological spaces.

the maps define the same element in $\pi_1(X, A, x_0)$

the maps define (presumably) three different elements in $\pi_1(X, A, x_0)$

(2) Let (X, x_0) be a pointed topological space. For any $n \geq 1$ the map

$$\begin{array}{rcl} \pi_n(X, x_0) & \to & \pi_n(X, \{x_0\}, x_0) \\ [f\colon (I^n, \partial I^n) \to (X, \{x_0\})] & \mapsto & [f\colon (I^n, \partial I^n, J^{n-1}) \to (X, \{x_0\}, \{x_0\})] \end{array}$$

defines, basically by definition, a natural bijection. In the following we will use this natural bijection to make the identification $\pi_n(X, x_0) = \pi_n(X, \{x_0\}, x_0)$.

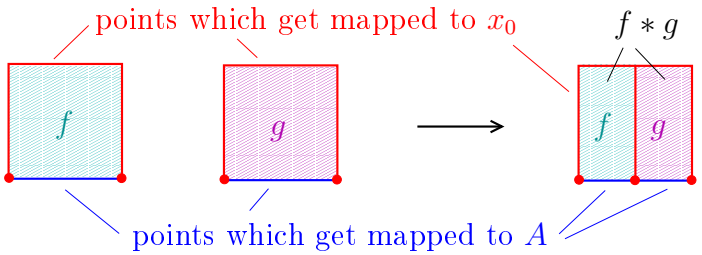
(3) Let X be a topological space, let A be a subset of X and let $x_0 \in A$ be a point. For any $n \geq 1$ the map

$$\begin{array}{rcl} \pi_n(X, x_0) & \to & \pi_n(X, A, x_0) \\ [f\colon (I^n, \partial I^n) \to (X, \{x_0\})] & \mapsto & [f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] \end{array}$$

is a natural map from absolute homotopy groups to relative homotopy groups.

In the previous discussion we already referred to $\pi_n(X, A, x_0)$ as a "relative homotopy group". This was slightly premature, but now we will actually deliver the goods and provide a group structure.

Definition. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \geq 2$.[1814] Given two maps $f, g\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ we define[1815]



$$\begin{array}{rcl} f * g\colon I^n & \to & X \\ (t_1, \ldots, t_n) & \mapsto & \begin{cases} f(2t_1, t_2, \ldots, t_n), & \text{if } t_1 \in [0, \frac{1}{2}], \\ g(2t_1 - 1, t_2, \ldots, t_n) & \text{if } t_1 \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

Note that $f * g$ is again a map $(I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ of triples. The definition of $f * g$ is illustrated in the figure below.

The following proposition finally gives the justification for the name *relative homotopy group*.

[1814] What, if anything, goes wrong for $n = 1$?

[1815] This map is continuous by the Pasting Proposition 2.6 (2).

Proposition 153.1. (Relative Homotopy Group Proposition) Let (X, A, x_0) be a pointed pair of topological spaces.

(1) Let $n \geq 2$. The map

$$\begin{array}{rcl} \pi_n(X,A,x_0) \times \pi_n(X,A,x_0) & \to & \pi_n(X,A,x_0) \\ ([f],[g]) & \mapsto & [f*g] \end{array}$$

is well-defined and it defines a group structure on $\pi_n(X, A, x_0)$. Furthermore the following two statements hold:

(a) the trivial element in $\pi_n(X, A, x_0)$ is represented by the constant map $I^n \to X$ that sends every point in I^n to x_0,

(b) the inverse of the relative homotopy class $[f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})]$ is represented by the map

$$\begin{array}{rcl} (I^n, \partial I^n, J^{n-1}) & \to & (X, A, \{x_0\}) \\ (t_1, t_2, \ldots, t_n) & \mapsto & (1 - t_1, t_2, \ldots, t_n). \end{array}$$

(2) For $n \geq 2$ the above natural bijection $\pi_n(X, x_0) \xrightarrow{=} \pi_n(X, \{x_0\}, x_0)$ is in fact a group isomorphism.

(3) For $n \geq 2$ the above natural map $\pi_n(X, x_0) \to \pi_n(X, A, x_0)$ is a group homomorphism.

(4) For $n \geq 3$ the group $\pi_n(X, A, x_0)$ is abelian.

(5) Let $n \in \mathbb{N}$. Given a morphism $f\colon (X, A, x_0) \to (Y, B, y_0)$ of pointed pairs of topological spaces the map

$$\begin{array}{rcl} f_*\colon \pi_n(X,A,x_0) & \to & \pi_n(Y,B,y_0) \\ [\varphi] & \mapsto & [f \circ \varphi] \end{array}$$

is well-defined. Furthermore the following four statements hold:

(a) For $n \geq 2$ the induced map f_* is a group homomorphism.

(b) The maps f_* define a functor from the category of pointed pairs of topological spaces to the category of sets (respectively groups for $n \geq 2$).

(c) Let $n \geq 1$ and let $f, g\colon (X, A) \to (Y, B)$ be two maps between pairs of topological spaces. If $f_*\colon \pi_n(X, A, x_0) \to \pi_n(Y, B, f(x_0))$ is a bijection for all $x_0 \in A$ and if g is homotopic[1816] to f, then $g_*\colon \pi_n(X, A, x_0) \to \pi_n(Y, B, g(x_0))$ is also a bijection for all $x_0 \in A$.

(d) Let $f\colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces and let $x_0 \in A$. If f is a homotopy equivalence, then the map

$$f_*\colon \pi_n(X,A,x_0) \to \pi_n(Y,B,f(x_0))$$

is a bijection (in particular it is an isomorphism if $n \geq 2$).

Sketch of proof.

(1) The proof of the first statement is quite similar to the proof of Proposition 71.1. We leave it to the reader to fill in the details.
(3) This statement requires just slightly more thought than one might think. More precisely, given two maps f and g from $(I^n, \partial I^n, J^{n-1})$ to $(X, \{x_0\}, \{x_0\})$, the "product maps" $f * g$ considered on page 1561 for $\pi_n(X, \{x_0\})$ (and illustrated in the figure on page 1561) and in the above proposition for $\pi_n(X, A, x_0)$ are not identical. Nonetheless, using Lemma 71.2 or the Addition-in-π_n-Proposition 85.11 it is straightforward to show that they are homotopic. This observation shows that the above identification of sets is in fact an identification of groups.
(2) We already know that the map is a bijection. Thus it suffices to show that it is a group homomorphism. But this follows from (3) applied to $A = \{x_0\}$.
(4) The proof of this statement is an entertaining variation on the proof of the Homotopy Group-Abelian Proposition 71.3. The proof is the content of Exercise 153.2.
(5) Statements (a) and (b) follow basically immediately from the definitions. Statement (c) and (d) are proved in a similar fashion to the Homotopy-π_n-Proposition 71.7. ■

Remark.

(1) We will see shortly that the relative homotopy group $\pi_2(X, A, x_0)$ is in general not abelian.
(2) For want of a better idea, given a pointed pair of topological spaces (X, A, x_0) we refer to $\pi_1(X, A, x_0)$ also as a *relative homotopy group* even though strictly speaking we did not define a group structure on $\pi_1(X, A, x_0)$.

In light of the Relative Homotopy Group Proposition 153.1 we adopt the following convention:

Convention. For $n \geq 3$ we usually use additive notation for the group structure on the relative homotopy groups $\pi_n(X, A, x_0)$.

Let X be a topological space and let $A \subset B \subset X$ be two subsets. In the Topological LES-Proposition 74.13 we saw that this data gives rise to a long exact sequence of homology groups. Shortly we will see that a similar statement holds for relative homotopy groups. We did not define a group structure on $\pi_1(X, A, x_0)$ and we did not define a group structure on $\pi_0(X, x_0)$. (In fact we will see in Exercise 153.3 that there is no natural way to turn these sets into groups.) Nonetheless we would like to include these objects at the lower end of the long exact sequence of (relative) homotopy groups. In fact, as it turns out, $\pi_1(X, A, x_0)$ and $\pi_0(X, x_0)$ have ever so slightly more structure than just the structure of a set.

Definition.

(1) A pointed set is a pair (S, s_0) where S is a set and $s_0 \in S$ is a point. We call s_0 the trivial element in S.

[1816] Here we mean of course, "homotopic as a map between pairs of topological spaces".

(2) A morphism from a pointed set (S, s_0) to a pointed set (T, t_0) is a map $f\colon S \to T$ with $f(s_0) = t_0$. Furthermore we adopt the following language:
   (a) Given a morphism $f\colon (S, s_0) \to (T, t_0)$ we refer to $\ker(f) := f^{-1}(t_0)$ as the kernel of f.
   (b) We say a morphism $f\colon (S, s_0) \to (T, t_0)$ is trivial if $\ker(f) = S$, put differently, if all elements in S get sent to t_0.
   (c) We say a morphism $f\colon (S, s_0) \to (T, t_0)$ is a monomorphism if $\ker(f) = \{s_0\}$.
   (d) We say a morphism $f\colon (S, s_0) \to (T, t_0)$ is an epimorphism if f is surjective.

(3) We say that a sequence

$$\ldots \xrightarrow{f_{n+2}} (S_{n+1}, s_{n+1}) \xrightarrow{f_{n+1}} (S_n, s_n) \xrightarrow{f_n} (S_{n-1}, s_{n-1}) \xrightarrow{f_{n-1}} \ldots$$

of morphisms of pointed sets is exact if for every $n \in \mathbb{N}_0$ we have the usual equality $\ker(f_n) = \operatorname{im}(f_{n+1})$.

Examples.

(1) Any group G gives rise to the pointed set $(G, \{e\})$ where $e \in G$ evidently denotes the trivial element. We will thus always view a group as a pointed set. Any group homomorphism is also a morphism of the corresponding pointed sets. Furthermore an exact sequence of homomorphisms of groups is also an exact sequence of pointed sets.

(2) If G is a group and H is a subgroup, then the set of right cosets G/H is a pointed set with trivial element given by $H \in G/H$. The natural projection $G \to G/H$ is a morphism of pointed sets.

Lemma 153.2. Let $\varphi\colon G \to H$ be a group homomorphism. Furthermore let (S, s_0) be a pointed set which is equipped with an H-action. Suppose that we have an exact sequence

$$\{e\} \to G \xrightarrow{\varphi} H \xrightarrow{\psi} (S, s_0) \to \{e\}$$

where ψ is a morphism of pointed sets that preserves the H-action. Then $\varphi(G)$ is a subgroup of H whose index equals the cardinality of the set S.

Proof. We will prove the lemma in Exercise 153.4. ■

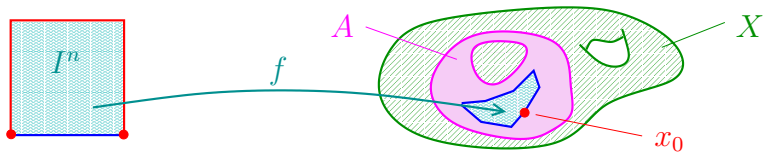
Example. The previous lemma might sound rather artificial. But we have seen it before in group theory: suppose that H is a group and G is a subgroup. As above we view the set of right cosets G/H as a pointed set. Left-multiplication by G defines an action on G/H. Evidently the projection $G \to G/H$ preserves the right-action and we get a short exact sequence $\{e\} \to G \to H \to G/H \to \{e\}$ as in Lemma 153.2.

We continue with pointed sets that arise in topology.

Examples.

(1) Let (X, x_0) be a pointed topological space. Recall that on page 1560 we defined $\pi_0(X, x_0)$ to be the set of homotopy classes of maps from the point I^0 to X. In other words, $\pi_0(X, x_0)$ is the set of path-components of X. We view $\pi_0(X, x_0)$ as a pointed set where the trivial element is given by the map that sends the unique point in I^0 to x_0. A map $f\colon X \to Y$ between topological spaces defines a morphism

$f_*\colon \pi_0(X, x_0) \to \pi_0(Y, f(x_0))$ of pointed sets in the obvious way. Sometimes, by an unfortunate abuse of language, we refer to $\pi_0(X, x_0)$ as a homotopy group of X.



(2) Similarly to the above, given a pointed pair of topological spaces (X, A, x_0) we view $\pi_1(X, A, x_0)$ as pointed set where the trivial element is once again represented by the constant path $I \to X$ given by sending all points to x_0.

We conclude this section with the following elementary lemma.

Lemma 153.3. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \geq 1$. Let $f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ be a map. If $f(I^n) \subset A$, then f represents the trivial element in $\pi_n(X, A, x_0)$.[1817][1818]

Proof. The lemma will be proved in Exercise 153.6. ■

Since it is much easier to convince oneself of a statement if one sees an explicit example, we show such a map with $f(I^n) \subset A$ in the figure below.

153.2. **The long exact homotopy sequence of a pair.** In the Topological LES-Proposition 74.13 we saw that we can associate to a pair (X, A) of topological spaces a long exact sequence of (relative) homology groups. The goal of this section is to do the same for homotopy groups. More precisely we will associate to a pointed pair (X, A, x_0) of topological spaces a long exact sequence of (relative) homotopy groups.

Proposition 153.4. (Homotopy Groups-LES Proposition) Let (X, A, x_0) be a pointed pair of topological spaces.

(1) For any $n \geq 1$ the map

$$\begin{array}{rcl} \partial_n\colon \pi_n(X, A, x_0) & \to & \pi_{n-1}(A, x_0) \\ [f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \mapsto & \left[\begin{array}{rcl} (I^{n-1}, \partial I^{n-1}) & \to & (A, \{x_0\}) \\ (x_1, \ldots, x_{n-1}) & \mapsto & f(x_1, \ldots, x_{n-1}, 0) \end{array}\right] \end{array}$$

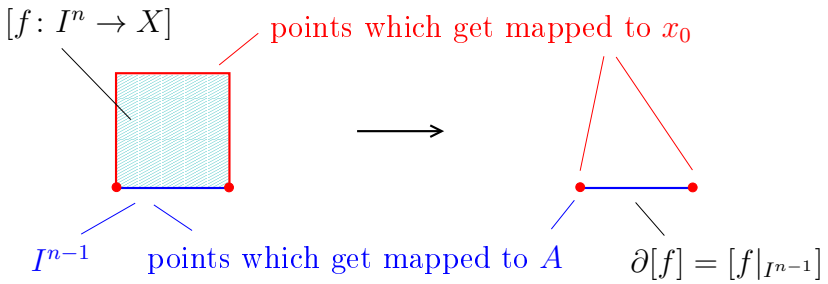
is well-defined. (See the figure below.) We refer to it as the *connecting morphism*. It has the following two properties:

(a) The connecting morphism is a morphism of pointed sets and it is a group homomorphism for $n \geq 2$.

(b) The connecting morphism is a natural transformation from the covariant functor $\pi_n(X, A, x_0)$ to the covariant functor $\pi_{n-1}(A, x_0)$. In everyday language this just simply means that for a map $f\colon (X, A, x_0) \to (Y, B, y_0)$ between pointed pairs

[1817] Put differently, as for relative homology groups, all objects that "land in A" are in fact trivial in the relative homotopy group.

[1818] Note that by the above discussion of pointed sets the statement of Lemma 153.3 is also meaningful for $n = 1$.

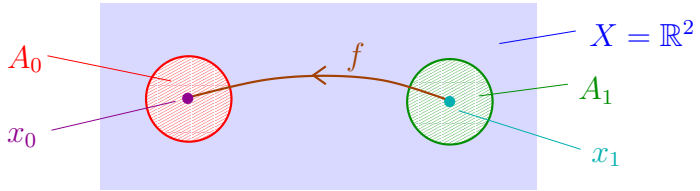


of topological spaces the following diagram commutes:

$$\begin{array}{ccc} \pi_n(X, A, x_0) & \xrightarrow{\partial} & \pi_{n-1}(A, x_0) \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ \pi_n(Y, B, y_0) & \xrightarrow{\partial} & \pi_{n-1}(B, y_0). \end{array}$$

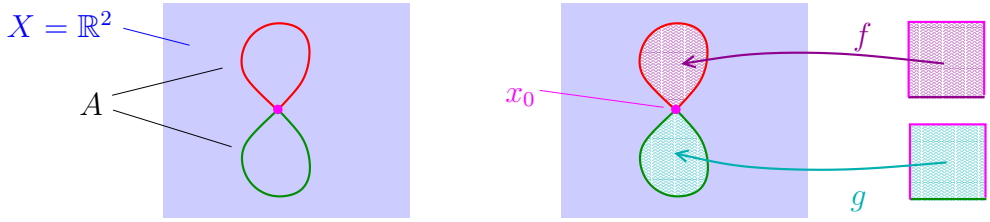
(2) The following sequence is exact

$$\cdots \to \pi_n(A, x_0) \xrightarrow{i_*} \pi_n(X, x_0) \to \pi_n(X, A, x_0) \xrightarrow{\partial_n} \pi_{n-1}(A, x_0) \to \cdots \to \pi_0(X, x_0).$$



Here $i\colon A \to X$ is the inclusion map and the map $\pi_n(X, x_0) \to \pi_n(X, A, x_0)$ is the natural map introduced on page 3239.

Examples.



(1) We consider $X = \mathbb{R}^2$ and we consider $A = A_0 \sqcup A_1$ which is the union of disjoint closed disks A_0 and A_1 in $X = \mathbb{R}^2$. We denote by $x_0 \in A_0$ and $x_1 \in A_1$ the centers of the two disks. Furthermore we denote by $f\colon I = [0, 1] \to X$ a map with $f(0) = x_1$ and $f(1) = x_0$. (We refer to the figure below for an illustration.) Finally, for any $n \in \mathbb{N}_0$ and any $i \in \{0, 1\}$ we denote by $c_{x_i}\colon I^n \to A_i$ the constant map that sends all points to x_i. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 together with the π_0-Homotopy Equivalence Lemma 15.3 and Propositions 50.3 (2) and 71.7 (2) that all the homotopy groups of A and X are generated by $[c_{x_0}]$ except for $\pi_0(A, x_0)$ that equals the set $\{[c_{x_0}], [c_{x_1}]\}$.

As discussed on page 3238, f defines an element in $\pi_1(X, A, x_0)$. Using the definitions one sees almost immediately that $\partial[f] = [c_{x_1}] \in \pi_0(A, x_0)$. It follows easily from this data and the Homotopy Groups-LES Proposition 153.4 (2) that $\pi_1(X, A, x_0)$ consists of precisely two elements, namely $[c_{x_0}]$ and $[f]$.

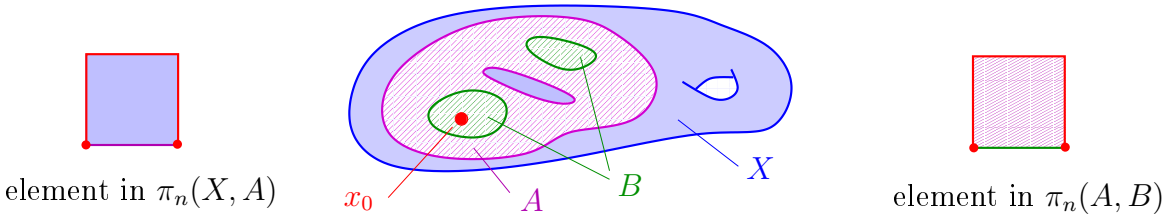
(2) Let $X = \mathbb{R}^2$. We denote by A the wedge of two circles, viewed as a subset of $X = \mathbb{R}^2$. Furthermore we denote by x_0 the wedge point. It follows from the Homotopy Groups-LES Proposition 153.4 (2) that $\pi_2(X, A, x_0) \xrightarrow{\cong} \pi_1(A, x_0)$. In Lemma 54.6 we saw that $\pi_1(A, x_0)$ is non-abelian, thus $\pi_2(X, A, x_0)$ is also non-abelian.

In fact we can identify two elements in $\pi_2(X, A, x_0)$ that do not commute. We consider the two maps $f, g\colon (I^2, \partial I^2, J^1) \to (X, A, \{x_0\})$ that are illustrated in the figure below. It follows easily from the definitions that $\partial[f], \partial[g]$ are the standard generators of the free group[1819] $\pi_1(S^1 \vee S^1, x_0)$. Since these do not commute we see that $[f]$ and $[g]$ do not commute either.

Proof. We start out with the proof of Statement (1). In fact this statement follows mostly easily from the definitions. One only needs to think for a minute about the question why the connecting homomorphism is in fact a homomorphism.

We turn to the proof of Statement (2). In fact we prove a slight variation on the second statement. More precisely, let X be a topological space, let A be a subset of X and let B be a subset of A. Finally let $x_0 \in B$. For any $n \geq 2$ the map

$$\begin{array}{rcl} \partial_n\colon \pi_n(X, A, x_0) & \to & \pi_{n-1}(A, B, x_0) \\ [f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \to & \left[\begin{array}{rcl} (I^{n-1}, \partial I^{n-1}, J^{n-2}) & \to & (A, B, \{x_0\}) \\ (x_1, \ldots, x_{n-1}) & \mapsto & f(x_1, \ldots, x_{n-1}, 0) \end{array}\right] \end{array}$$



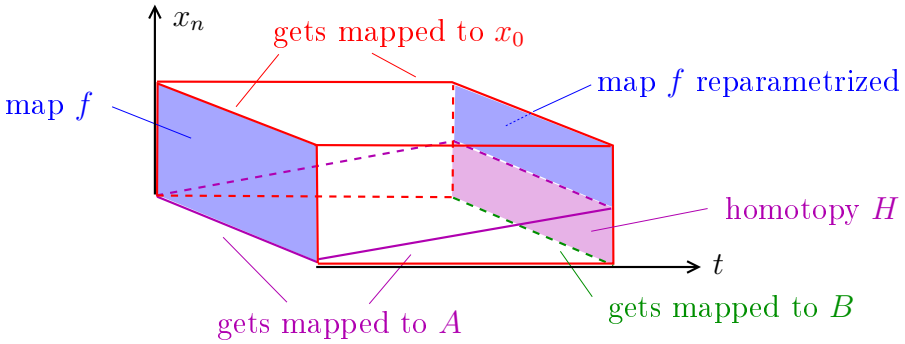
is easily seen to be a well-defined morphism of pointed sets. Our goal is to prove the following claim.

Claim. The following sequence is exact[1820]

$$\ldots \to \pi_n(A, B, x_0) \xrightarrow{i_*} \pi_n(X, B, x_0) \xrightarrow{j_*} \pi_n(X, A, x_0) \xrightarrow{\partial_n} \pi_{n-1}(A, B, x_0) \to \ldots \to \pi_1(X, A, x_0).$$

where $i\colon (A, B) \to (X, B)$ and $j\colon (X, B) \to (X, A)$ are the obvious morphisms of pointed pairs of topological spaces.

Note that this claim, applied to $B = \{x_0\}$ together with the Relative Homotopy Group Proposition 153.1 (2) almost implies that the sequence of the proposition is exact. The only problem is that the sequence of the claim stops slightly earlier, more precisely it stops at the subindex one instead of subindex zero. Thus the only piece missing is the exactness of the sequence of the proposition at the last three pointed sets. We leave the verification of exactness at these three spots as an elementary exercise to the conscientious reader.



[1819] We refer to page 1173 for the calculation of the fundamental group of $S^1 \vee S^1$.

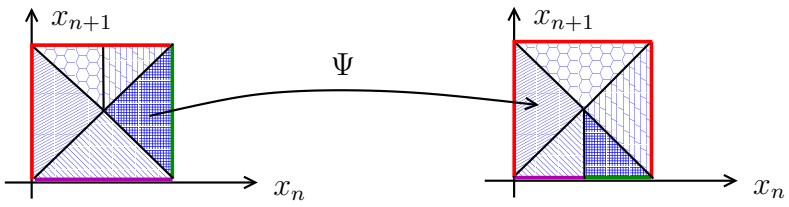
[1820] This sequence plays of course the role of the long exact sequence in homology groups of a triple of topological spaces, see the Topological LES-Proposition 74.13.

Proof. Not surprisingly the proof of the claim breaks up into three separate proofs, namely we need to verify exactness at the three different groups.
Exactness at $\pi_n(X, B, x_0)$. It follows easily from Lemma 153.3 that $j_* \circ i_* = (j \circ i)_*$ is the trivial morphism. We leave it to the reader to verify that $\ker(j_*) \subset \operatorname{im}(i_*)$.
Exactness at $\pi_n(X, A, x_0)$. It follows again easily from Lemma 153.3 and the definition of the connecting homomorphism ∂ that $\partial \circ j_*$ is the trivial morphism. Now suppose we are given $f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ such that the restriction of f to $I^{n-1} \times \{0\}$ represents the trivial element in $\pi_{n-1}(A, B, x_0)$. This means that there exists a homotopy $H\colon I^{n-1} \times I \to A$ (with all the required restrictions) from $f|_{I^n \times \{0\}}$ to the constant map. The map

$$\begin{array}{rcl} I^n \times [0,1] & \to & X \\ (x_1, \ldots, x_n, t) & \mapsto & \begin{cases} f\big(x_1, \ldots, x_{n-1}, \frac{t}{2} \cdot x_n + (1 - x_n)\big), & \text{if } x_n \in \left[\frac{t}{2}, 1\right] \\ H\big(x_1, \ldots, x_{n-1}, 2x_n - t\big), & \text{if } x_n \in \left[0, \frac{t}{2}\right] \end{cases} \end{array}$$

is continuous by the Homotopy Stacking Lemma 14.3 and it defines a homotopy (again with all the desired extra properties) from f to a map that represents an element in $\pi_n(X, B, x_0)$. The definition of the homotopy is sketched, to the best of my abilities, in the figure below.

Exactness at $\pi_n(A, B, x_0)$. First note that $i_* \circ \partial$ is the trivial morphism. Indeed, if $f\colon (I^{n+1}, \partial I^{n+1}, J^n) \to (X, A, \{x_0\})$ is a map, then $f\colon (I^n \times [0,1], \partial I^n \times [0,1]) \to (X, x_0)$ defines a homotopy from $\partial f = f|_{I^n \times \{0\}}$ to the constant map c_{x_0}. Thus $(i_* \circ \partial)[f] = [i_* \circ \partial f]$ is the trivial element in $\pi_n(X, B, x_0)$.



Now suppose that we are given a map $f\colon (I^n, \partial I^n, J^{n-1}) \to (A, B)$ such that $j \circ f$ represents the trivial element in $\pi_n(X, B, x_0)$. This means that there exists a homotopy H (with all the obvious conditions) from $j \circ f$ to the constant map c_{x_0}. We define

$$\begin{array}{rcl} g\colon I^n & \to & B \\ (x_1, \ldots, x_n) & \mapsto & H(x_1, \ldots, x_{n-1}, 0, x_n). \end{array}$$

We pick a homeomorphism $\Psi\colon I^2 \to I^2$ with the properties as illustrated in the figure below.[1821] (Here it is psychologically convenient to think of I^2 as the square in the plane with x_n and x_{n+1}-coordinates.) It follows immediately from the definitions that the map

$$\begin{array}{rcl} I^{n+1} & \to & X \\ (x_1, \ldots, x_n, x_{n+1}) & \to & H(x_1, \ldots, x_{n-1}, \Psi(x_n, x_{n+1})) \end{array}$$

[1821] The triangles in the figure below indicate how one could write down an explicit homeomorphism.

defines an element in $\pi_{n+1}(X, A, x_0)$ such that the connecting morphism sends it to the element in $\pi_n(A, B, x_0)$ represented by the map[1822]

$$\begin{array}{rcl} f * g \colon I^n & \to & X \\ (t_1, \ldots, t_n) & \mapsto & \begin{cases} f(t_1, \ldots, t_{n-1}, 2t_n), & \text{if } t_n \in [0, \frac{1}{2}], \\ g(t_1, \ldots, t_{n-1}, 2t_n - 1), & \text{if } t_n \in [\frac{1}{2}, 1] \end{cases} \end{array}$$

It remains to show that $f * g$ and f represent the same element in $\pi_n(A, B, x_0)$. This can be done in a fashion similar to the above proof of exactness. More precisely, a homotopy between f and $f * g$, again with all the desired properties, is given by

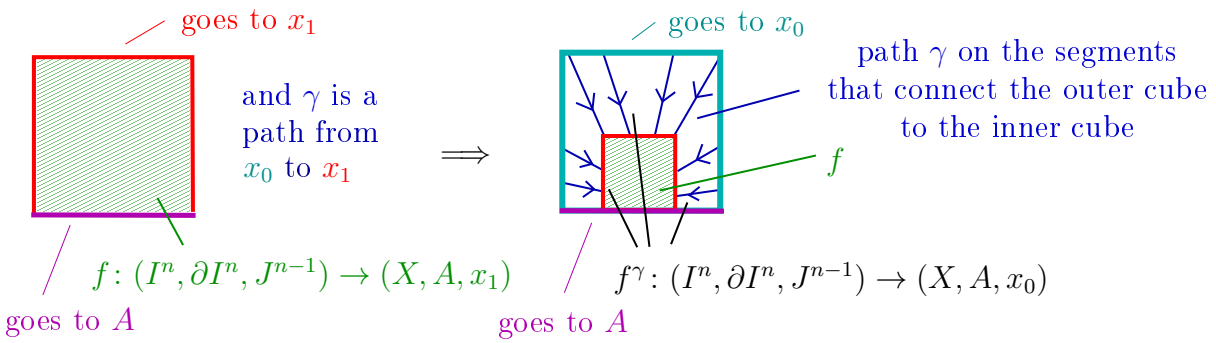
$$\begin{array}{rcl} I^n \times [0,1] & \to & X \\ (x_1, \ldots, x_n, t) & \mapsto & \begin{cases} f\big(x_1, \ldots, x_{n-1}, \frac{t}{2} \cdot x_n + (1 - x_n)\big), & \text{if } x_n \in \big[\frac{t}{2}, 1\big] \\ H\big(x_1, \ldots, x_{n-1}, 2x_n - t\big), & \text{if } x_n \in \big[0, \frac{t}{2}\big] \end{cases} \end{array}$$

■

153.3. **Paths acting on relative homotopy groups.** Let (X, x_0) be a pointed topological space. In Section 86.3 we saw that the fundamental group $\pi_1(X, x_0)$ of X acts on any homotopy group $\pi_n(X, x_0)$. In this section we will discuss an analogous construction for relative homotopy groups. In particular, given a pointed pair (X, A, x_0) of topological spaces we will see that the fundamental group $\pi_1(A, x_0)$ of A (let us stress that here we write A instead of X) acts on any relative homotopy group $\pi_n(X, A, x_0)$.
The following definition is quite similar to the definition on page 1869.

Definition. Let X be a topological space, let A be a subset of X and let $n \in \mathbb{N}_{\geq 2}$.[1823] Furthermore let $\gamma \colon [0,1] \to A$ be a path in the subset A[1824] from a point x_0 to a point x_1. Finally let

$$f \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_1\})$$



be a map. We define

$$f^\gamma \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$$

to be the map that is illustrated in the figure below. For our particularly pedantic readers we now also give a super-rigorous definition of f^γ: First of all, given $t \in [0,1]$ we define $\mathrm{C}_t = \big[\frac{t}{4}, \frac{4-t}{4}\big]^{n-1} \times [0, 1 - \frac{t}{2}]$. Now we define

$$\begin{array}{rcl} f^\gamma \colon (I^n, \partial I^n, J^{n-1}) & \to & (X, A, x_0) \\ (x_1, \ldots, x_n) & \to & \begin{cases} f\big(2x_1 - \frac{1}{2}, \ldots, 2x_n\big), & \text{if } (x_1, \ldots, x_n) \in \mathrm{C}_1 = \big[\frac{1}{4}, \frac{3}{4}\big]^{n-1} \times [0, \frac{1}{2}], \\ \gamma(t), & \text{if } (x_1, \ldots, x_n) \in \partial \mathrm{C}_t \text{ for } t \in [0,1]. \end{cases} \end{array}$$

[1822] Strictly speaking this definition of $f * g$ differs from the definition on page 3239 since we use a different coordinate to perform the product. But it is convenient to use the same notation.

The following proposition can be viewed as the "relative analogue" of the Change-of-Base Point Proposition 71.5.

Proposition 153.5. (Change-of-Base Point Proposition) Let X be a topological space, let A be a subset of X and let $n \in \mathbb{N}_{\geq 2}$.

(1) If $\gamma\colon [0,1] \to A$ is a path from x_0 to x_1, then the map

$$\begin{array}{rcl} \gamma_*\colon \pi_n(X, A, x_1) & \to & \pi_n(X, A, x_0) \\ [f] & \mapsto & [f^\gamma] \end{array}$$

is a well-defined map that is a group homomorphism.

(2) If x_0 and x_1 are two points in A which lie in the same path-component of A, then $\pi_n(X, A, x_0)$ is isomorphic to $\pi_n(X, A, x_1)$.

(3) Let $\varphi\colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces.

(a) If $\gamma\colon [0,1] \to A$ is a path from x_0 to x_1, then the following diagram commutes

$$\begin{array}{ccc} \pi_n(X, A, x_1) & \xrightarrow{\gamma_*} & \pi_n(X, A, x_0) \\ \downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\ \pi_n(Y, B, \varphi(x_1)) & \xrightarrow{(\varphi\circ\gamma)_*} & \pi_n(Y, B, \varphi(x_0)). \end{array}$$

(b) If $\varphi_*\colon \pi_n(X, A, x_0) \to \pi_n(Y, B, \varphi(x_0))$ is an isomorphism (epimorphism, monomorphism) for some base point $x_0 \in A$, then for any other point x_1 in the same path component of A the map $\varphi_*\colon \pi_n(X, A, x_1) \to \pi_n(Y, B, \varphi(x_1))$ is also an isomorphism (epimorphism, monomorphism).

(4) Let γ and δ be two paths in A from x_0 to x_1. If γ and δ are path-homotopic in A, then the corresponding maps γ_* and δ_* from $\pi_n(X, A, x_1)$ to $\pi_n(X, A, x_0)$ agree.

(5) If γ is a path in A from x_0 to x_1 and if δ is a path in A from x_1 to x_2, then[1825]

$$(\underbrace{\gamma * \delta}_{\text{path in } A \text{ from } x_0 \text{ to } x_2})_* = \gamma_* \circ \delta_*\colon \pi_n(X, A, x_2) \to \pi_n(X, A, x_0).$$

(6) The map

$$\begin{array}{rcl} \pi_1(A, x_0) \times \pi_n(X, A, x_0) & \to & \pi_n(X, A, x_0) \\ ([\gamma], [f]) & \mapsto & [\gamma] \cdot [f] := [f^\gamma] \end{array}$$

[1823] What is wrong with $n = 1$?

[1824] Note that in contrast to the definition on page 1869 we only consider paths in A. At this point we do not allow paths in X.

defines an action (in the sense of the definition on page 248) of the group $\pi_1(A, x_0)$ on the group $\pi_n(X, A, x_0)$.

(7) We denote by $i\colon A \to X$ the inclusion map and by $\varphi\colon \pi_n(X, x_0) \to \pi_n(X, A, x_0)$ the natural map. Then, with the convention from page 2538, the following diagram commutes

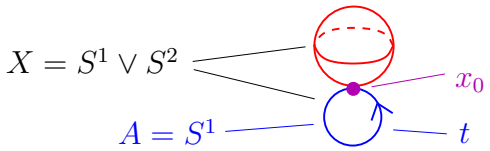
$$\begin{array}{ccc} \pi_1(X, x_0) \times \pi_n(X, x_0) & \longrightarrow & \pi_n(X, x_0) \\ {\scriptstyle i_*}\uparrow \quad \downarrow{\scriptstyle \varphi_*} & & {\scriptstyle \varphi_*}\downarrow \\ \pi_1(A, x_0) \times \pi_n(X, A, x_0) & \longrightarrow & \pi_n(X, A, x_0). \end{array}$$

(8) If $\gamma\colon [0,1] \to A$ is a path from x_0 to x_1, then the following diagram commutes:

$$\begin{array}{ccc} \pi_n(X, A, x_1) & \xrightarrow{[f]\mapsto[f^\gamma]} & \pi_n(X, A, x_0) \\ \downarrow{\scriptstyle \partial} & & {\scriptstyle \partial}\downarrow \\ \pi_{n-1}(A, x_1) & \xrightarrow{[f]\mapsto[f^\gamma]} & \pi_{n-1}(A, x_0). \end{array}$$

Proof. The proof of the first six statements of the proposition is basically identical to the proof of the Change-of-Base Point Proposition 86.9. The last two statements follow easily from the definitions. To protect the trees we will not carry out the details. ■

Remark. Let X be a topological space, let A be a non-empty subset and let $n \in \mathbb{N}_{\geq 2}$. If A is path-connected, then it follows from the Change-of-Base Point Proposition 153.5 (2) that the isomorphism type of the relative higher homotopy groups $\pi_n(X, A, x_0)$ does not depend on the choice of a base point in A. Thus if we are only interested in the isomorphism type of the n-th relative homotopy group of (X, A), then sometimes we just write $\pi_n(X, A)$, i.e. we suppress the base point from the notation.



Recall that for the relative homotopy groups $\pi_n(X, A, x_0)$ with $n \geq 3$ we use the additive notation for the group structure. Thus Lemma 86.13, Propositions 71.3, 153.1 (4) and 153.5 lead us to the following observation:

Observation. Let (X, A, x_0) be a pointed pair of topological spaces. If $n \geq 3$, then the abelian group $\pi_n(X, A, x_0)$ admits a natural $\mathbb{Z}[\pi_1(A, x_0)]$-left module structure.

Example. We consider the wedge $X = S^1 \vee S^2$ where we identify $i \in S^1$ with $(0, 0, -1) \in S^2$. We denote by x_0 the wedge point. Furthermore let $A = S^1 \subset X$. We denote by $t \in \pi_1(S^1, i)$ the standard generator. (We refer to the figure below for an illustration.) By the Wedge-π_1-Proposition 52.3 we know that the inclusion $A \to X$ induces an isomorphism $\pi_1(A, x_0) \to \pi_1(X, x_0)$. We use this isomorphism to make the identification $\pi_1(A, x_0) = \pi_1(X, x_0) = \langle t \rangle$. It follows from the Homotopy Groups-LES Proposition 153.4 and the Change-of-Base Point Proposition 153.5 (7) that the natural map $\pi_2(X, x_0) \to \pi_2(X, A, x_0)$ is an isomorphism of $\mathbb{Z}[t^{\pm 1}]$-modules. In particular, by Proposition 86.15, we have

$$\pi_2(X, A, x_0) \overset{\cong}{\leftarrow} \pi_2(S^1 \vee S^2) \overset{\cong}{\rightarrow} \mathbb{Z}[t^{\pm 1}].$$

[1825]Here it is worth remembering that by definition, see page 1052, the product path $\gamma * \delta$ is given by first traversing γ and then traversing δ.

153.4. **Alternative description of relative homotopy groups.** Let (X, x_0) be a pointed topological space. Recall that on page 1565 we had in particular introduced the following identifications:

$$\pi_n(X, x_0) \quad = \quad \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (I^n, \partial I^n) \to (X, x_0)\end{array} \quad = \quad \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (S^n, *) \to (X, x_0).\end{array}$$

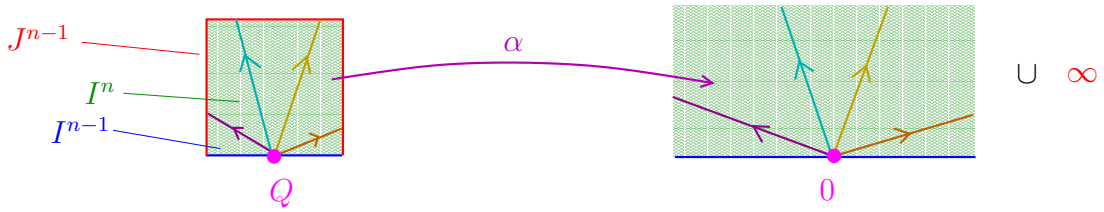
These identifications allowed us to go back and forth between different view points regarding homotopy groups.

Before we continue with our discussion of relative homotopy groups we also want to introduce a second view point regarding relative homotopy groups. The key to doing so is the following elementary lemma.

Lemma 153.6. Let $n \in \mathbb{N}$. There exists an explicit[1826] map $\varphi\colon I^n \to \overline{B}^n$ with the following three properties:

(1) we have $\varphi(J^{n-1}) = * := (0, \ldots, 0, 1)$ and $\varphi(I^{n-1}) = S^{n-1}$,
(2) the map φ descends to a homeomorphism $(I^n/J^{n-1}, I^{n-1}/\partial I^{n-1}) \xrightarrow{\cong} (\overline{B}^n, S^{n-1})$,
(3) the restriction of φ to the map $I^n \setminus \partial I^n \to B^n$ is an orientation-preserving diffeomorphism.

Sketch of a proof for Lemma 153.6. We write $Q = (\frac{1}{2}, \ldots, \frac{1}{2}, 0) \in I^n$. Given any point $x \in I^n \setminus \{Q\}$ we define



$$\rho(x) \;:=\; \sup\big\{\|rx\| \,\big|\, r \in \mathbb{R}_{>0} \text{ and } r(x-Q)+Q \in I^n\big\}.$$

We consider the map

$$\begin{array}{rcl} \alpha\colon I^n/J^{n-1} & \to & \overbrace{\{(x_1, \ldots, x_n) \in \mathbb{R}^n \,|\, x_n \geq 0\}}^{=H_n} \cup \{\infty\} \\ [x] & \mapsto & \begin{cases} \frac{x-Q}{\|x-Q\|} \cdot \tan\left(\frac{\pi}{2} \cdot \frac{\|x-Q\|}{\rho(x)}\right), & \text{if } x \neq Q, \\ 0, & \text{if } x = Q. \end{cases} \end{array}$$

This map stretches each of the segments from Q to a point on J^{n-1} to an infinite ray emanating from the origin. In particular all points in J^{n-1} get sent to infinity, i.e. the map is well-defined. We refer to the figure below for an illustration. Similar to the proof of the Convex-to-Ball Proposition 2.20 we see that the map α is a homeomorphism that restricts to a homeomorphism $I^{n-1}/\partial I^{n-1} \to (\mathbb{R}^{n-1} \times \{0\}) \cup \{\infty\}$. Let $\beta\colon \mathbb{R}^n \cup \{\infty\} \to S^n$

[1826] "Explicit" means that in the proof we explicitly write down such a map that does not depend on any choices. No reader will ever want to see the precise definition, but the fact that the map is explicitly given implies that there is no ambiguity involved when we write "let φ be the map from Lemma 153.6."

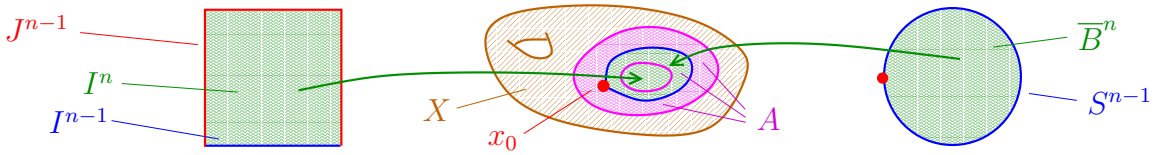
be the inverse of the stereographic projection that we introduced in Lemma 2.18. Note that $\beta(\infty) = (0, \ldots, 0, 1)$. Furthermore note that the homeomorphism β restricts to a homeomorphism[1827]

$$\beta\colon H^n \cup \{\infty\} \;\to\; S^n_{\geq 0} := \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_n \geq 0\}.$$

Finally we consider the following map:

$$\begin{array}{ccccccc} I^n & \to & I^n/J^{n-1} & \xrightarrow{\alpha} & H_n \cup \{\infty\} & \xrightarrow{\beta} & S^n_{\geq 0} \\ & & & & (x_1, \ldots, x_{n-1}, x_n, x_{n+1}) & \mapsto & (x_1, \ldots, x_{n-1}, x_{n+1}). \end{array} \quad \to \quad \overline{B}^n$$

Using Exercise 25.9 one can easily verify that this map has all the desired properties.[1828] ■



Convention. Using the map

$$\varphi\colon (I^n, \partial I^n, J^{n-1}) \;\to\; (\overline{B}^n, S^{n-1}, *)$$

from Lemma 153.6 we make the following identifications

$$\pi_n(X, A, x_0) \;=\; \begin{array}{c}\text{set (of homotopy classes) of} \\ \text{maps } (I^n, \partial I^n, J^{n-1}) \to (X, A, x_0)\end{array} \;=\; \begin{array}{c}\text{set (of homotopy classes) of} \\ \text{maps } (\overline{B}^n, S^{n-1}, *) \to (X, A, x_0).\end{array}$$

We refer to the figure below for an illustration.

Remark. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}$. As above we make the identifications

$$\pi_n(X, A, x_0) = \left\{ \begin{array}{c}\text{homotopy classes of maps} \\ (\overline{B}^n, S^{n-1}, *) \to (X, A, x_0)\end{array} \right\} \text{ and } \pi_{n-1}(A, x_0) = \left\{ \begin{array}{c}\text{homotopy classes of maps} \\ (S^{n-1}, *) \to (A, x_0)\end{array} \right\}.$$

We leave it to the interested reader to verify that the connecting homomorphism $\pi_n(X, A, x_0) \to \pi_{n-1}(A, x_0)$ from the Homotopy Groups-LES Proposition 153.4 is given by the map

$$\begin{array}{ccc} \partial_n\colon \pi_n(X, A, x_0) & \to & \pi_{n-1}(A, x_0) \\ [f\colon (\overline{B}^n, S^{n-1}, *) \to (X, A, x_0)] & \mapsto & [f|_{S^{n-1}}\colon (S^{n-1}, *) \to (A, x_0)]. \end{array}$$

[1827] Note that the condition $x_n \geq 0$ is not a typo.

[1828] More precisely, the author is somewhat optimistic that the signs are right and that the map is indeed orientation-preserving.

153.5. **Connected (pairs of) topological spaces.** For convenience we recall the following definition from page 1845.

Definition. Let $k \in \mathbb{N}_0$. We say a topological space X is k-connected, if $\pi_i(X) = 0$ for $i = 0, \ldots, k$.

This definition has the following obvious "relative" analogue.

Definition. Let X be a topological space, let $A \subset X$ and let $k \in \mathbb{N}$. We say (X, A) is k-connected if every path-component of X contains a point of A and if for every $i \in \{1, \ldots, k\}$ and every $x_0 \in A$ we have $\pi_i(X, A, x_0) = 0$.

The following lemma provides a convenient reformulation of the previous definition.

Lemma 153.7. Let X be a topological space, let $A \subset X$ and let $k \in \mathbb{N}$. The following two statements are equivalent:

(1) The pair (X, A) is k-connected.
(2) Every path-component of X contains a point of A, furthermore for every $a \in A$ and every $j \in \{1, \ldots, k-1\}$ the inclusion induced map $\pi_j(A, a) \to \pi_j(X, a)$ is an isomorphism and the inclusion induced map $\pi_k(A, a) \to \pi_k(X, a)$ is an epimorphism.

Example. Let X be a topological space and let $A \subset X$ be a deformation retract. It follows from the Homotopy-π_n-Proposition 71.7 (2) that for any $x_0 \in A$ and any $i \in \mathbb{N}_0$ the inclusion induced map $\pi_i(A, x_0) \to \pi_i(X, x_0)$ is an isomorphism. It follows from Lemma 153.7 that (X, A) is k-connected for every $k \in \mathbb{N}$.

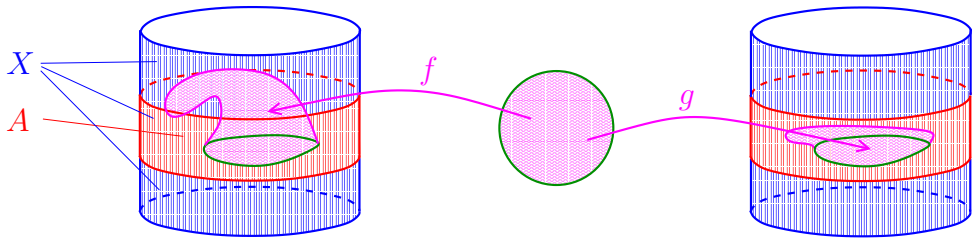
Proof. We denote by $i\colon A \to X$ the inclusion map. Let $a \in A$. By the Homotopy Groups-LES Proposition 153.4 we have the following long exact sequence of homotopy groups:

$$\ldots \to \pi_k(A, a) \xrightarrow{i_*} \pi_k(X, a) \to \pi_k(X, A, a) \xrightarrow{\partial} \pi_{k-1}(A, a) \xrightarrow{i_*} \pi_{k-1}(X, a) \to \ldots$$

The lemma is an immediate consequence of the existence of this long exact sequence. ∎

The following proposition gives a convenient characterization of the vanishing relative homotopy groups.

Proposition 153.8. Let X be a topological space and let $A \subset X$. For any $n \in \mathbb{N}$ the following two statements are equivalent:



(1) Every map $(\overline{B}^n, S^{n-1}) \to (X, A)$ is homotopic rel S^{n-1} to a map $\overline{B}^n \to A$,
(2) for every $x_0 \in A$ we have $\pi_n(X, A, x_0) = 0$.

Furthermore, for $n = 0$ the above statement (1) is equivalent to

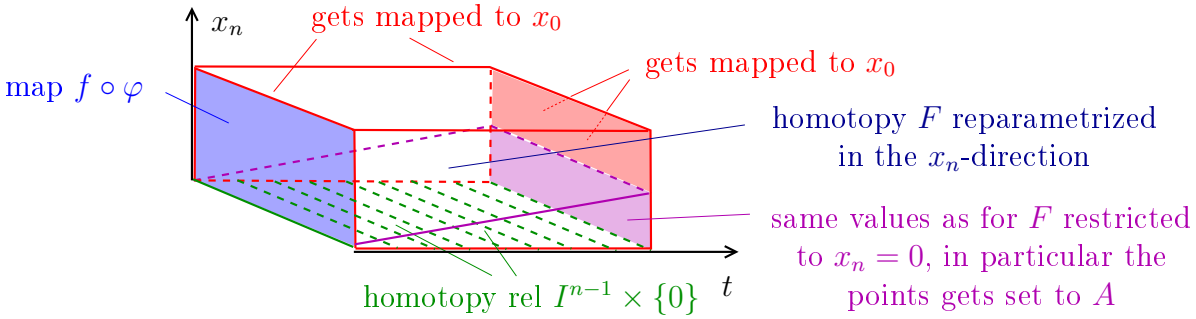
(2′) every path-component of X contains a point of A.

Example. We consider the infinite cylinder $X = S^1 \times \mathbb{R}$ and the annulus $A = S^1 \times [-1, 1]$. Evidently A is a deformation retract of X. Thus, by the previous example the pair (X, A) is k-connected for every $k \in \mathbb{N}_0$. In the figure below we show a map $f\colon (\overline{B}^2, S^1) \to (X, A)$. Furthermore we show a map $g\colon \overline{B}^2 \to A$ that is homotopic, rel S^1, to f.

Proof of Proposition 153.8. First note that it is elementary to see that for $n = 0$ the statements (1) and (2′) are equivalent. Now let $n \geq 1$. The implication (1) $\Rightarrow$ (2) is an immediate consequence of Lemma 153.3 and the by now well-known fact that there exists a homeomorphism $(I^n, \partial I^n) \xrightarrow{\cong} (\overline{B}^n, S^{n-1})$.

The most interesting statement of the proposition is the implication (2) $\Rightarrow$ (1). Thus we now assume that $\pi_n(X, A, x_0) = 0$ for every $x_0 \in A$. Let $f\colon (\overline{B}^n, S^{n-1}) \to (X, A)$ be a map. We need to show that f is homotopic rel S^{n-1} to a map that takes values only in A. Let $\varphi\colon I^n \to \overline{B}^n$ be the map from Lemma 153.6 with $\varphi(J^{n-1}) = (0, \ldots, 0, 1)$. We set $x_0 := f(0, \ldots, 0, 1)$. Note that the map $f \circ \varphi\colon I^n \to X$ is actually a map

$$f \circ \varphi\colon (I^n, \partial I^n, J^{n-1}) \;\to\; (X, A, \{x_0\})$$



of triples. Since $\pi_n(X, A, x_0) = 0$ we see that there exists a homotopy

$$F\colon (I^n, \partial I^n, J^{n-1}) \times [0,1] \;\to\; (X, A, \{x_0\})$$

which satisfies $F_0 = f \circ \varphi$ and $F_1 = c_{x_0}$. Now we consider the map

$$\begin{aligned} I^n \times [0,1] &\to X \\ (x_1, \ldots, x_n, t) &\mapsto \begin{cases} F\big(x_1, \ldots, x_{n-1}, \frac{1}{1-\frac{t}{2}} \cdot (x_n - \frac{t}{2}), t\big), & \text{if } x_n \in \big[\frac{t}{2}, 1\big] \\ F\big(x_1, \ldots, x_{n-1}, 0, 2 \cdot x_n\big), & \text{if } x_n \in \big[0, \frac{t}{2}\big]. \end{cases} \end{aligned}$$

The definition of the homotopy is sketched, with moderate success, in the figure below. This map has the following properties:

(0) the map is continuous by the Homotopy Stacking Lemma 14.3,
(1) the map is a homotopy rel $I^{n-1} \times \{0\}$,
(2) the map is a homotopy from $f \circ \varphi$ to a map that takes values in A,
(3) the map sends $J^{n-1} \times [0,1]$ to x_0.

It follows from Property (3), and using the above map $\varphi\colon (I^n, J^{n-1}) \to (\overline{B}^n, (0, \ldots, 0, 1))$, that F defines a homotopy $G\colon \overline{B}^n \times [0,1] \to X$. Property (1) implies that G is a homotopy rel S^{n-1}. Furthermore Property (2) says that G is a homotopy from f to a map that takes values in A. Thus G is the desired a homotopy. ∎

The following proposition gives us an important example of a k-connected pair of topological spaces.

Proposition 153.9. Let X be a CW-complex and let $k \in \mathbb{N}_0$.

(1) If A is a subcomplex such that all cells in $X \setminus A$ have dimension greater than k, then the pair (X, A) is k-connected.
(2) The pair (X, X^k) is k-connected.[1829]

Proof.

(1) Let X be a CW-complex, let A be a subcomplex and let $k \in \mathbb{N}_0$. Suppose that all cells in $X \setminus A$ have dimension greater than k. This implies in particular that every path-component of X contains at least one point in A. The remainder of the proof is almost the same as the proof of the CW-Skeleton-π_n-Proposition 71.9. The key difference is that we need to replace the Cellular Approximation Theorem 70.15 by the Cellular Approximation Theorem 70.16 for Pairs of CW-complexes and that now we use the (1) $\Rightarrow$ (2) implication of Proposition 153.8. We leave it to the reader to carry out the modest modifications of the proof of the CW-Skeleton-π_n-Proposition 71.9.
(2) This statement is of course an immediate consequence of the first statement. ■

The following corollary is an extremely useful consequence of Lemma 153.7 and Proposition 153.9 (2). We had proved it earlier in the guise of the CW-Skeleton-π_n-Proposition 71.9.

Corollary 153.10. Let X be a CW-complex, let $k \in \mathbb{N}_0$ and let $x \in X^k$. The following two statements hold:

(1) For $j = 1, \ldots, k-1$ the inclusion induced map $\pi_j(X^k, x) \to \pi_j(X, x)$ is an isomorphism.
(2) The inclusion induced map $\pi_k(X^k, x) \to \pi_k(X, x)$ is an epimorphism.

153.6. **The relative Hurewicz Theorem.** In this section we state the "Relative Hurewicz Theorem" that generalizes the original Hurewicz Theorem 85.5 to the relative setting.

Definition. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}$. We denote by $[I^n] \in \mathrm{H}_n(I^n, \partial I^n; \mathbb{Z})$ the fundamental class of I^n.[1830] We refer to the map

$$\begin{array}{rcl} \Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) & \to & \mathrm{H}_n(X, A; \mathbb{Z}) \\ [f \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \mapsto & f_*([I^n]) \end{array}$$

as the relative Hurewicz homomorphism.

The following lemma summarizes some elementary properties of the relative Hurewicz homomorphism.

Lemma 153.11.

(1) Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}_{\geq 2}$. The map

$$\begin{array}{rcl} \Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) & \to & \mathrm{H}_n(X, A; \mathbb{Z}) \\ [f \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \mapsto & f_*([I^n]) \end{array}$$

is well-defined and it is a homomorphism.

[1829] Recall that X^k denotes the k-skeleton of X, i.e. the union of all cells of dimension $\leq k$.
[1830] Here we endow $I^n \subset \mathbb{R}^n$ with the usual orientation coming from $\mathbb{R}^n$.

(2) Let (X, x_0) be a pointed topological space and let $n \geq 2$. The following diagram commutes

$$\begin{array}{ccc} \pi_n(X, x_0) & \xrightarrow{\Phi_{(X,x_0)}} & \mathrm{H}_n(X; \mathbb{Z}) \\ \cong\downarrow & & \downarrow\cong \\ \pi_n(X, \{x_0\}, x_0) & \xrightarrow{\Phi_{(X,\{x_0\},x_0)}} & \mathrm{H}_n(X, \{x_0\}; \mathbb{Z}). \end{array}$$

Here the left-hand vertical map is given by the identification from page 3239 and the right-hand vertical map is the obvious map from absolute to relative homology groups.

(3) Let (X, A, x_0) be a pointed pair of topological spaces. The following diagram commutes

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \pi_n(A, x_0) & \longrightarrow & \pi_n(X, x_0) & \longrightarrow & \pi_n(X, A, x_0) & \xrightarrow{\partial} & \pi_{n-1}(A, x_0) & \longrightarrow \ldots \to & \pi_1(X, x_0) \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\ \ldots & \longrightarrow & \mathrm{H}_n(A; \mathbb{Z}) & \longrightarrow & \mathrm{H}_n(X; \mathbb{Z}) & \longrightarrow & \mathrm{H}_n(X, A; \mathbb{Z}) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A; \mathbb{Z}) & \longrightarrow \ldots \to & \mathrm{H}_1(X; \mathbb{Z}). \end{array}$$

Here the horizontal sequences are the long exact sequences given by the Topological LES-Corollary 74.14 and by the Homotopy Groups-LES Proposition 153.4 and the vertical maps are the Hurewicz homomorphisms.

Sketch of proof.

(1) The proof of the first statement is evidently just a straightforward variation on the proof of Lemma 85.1. We refer to [**Bre1993**, Lemma VII.10.2] or [**Hat2002**, Proposition 4.36] for details.

(3) We have to show that each of the three squares commutes.
   (a) The first square commutes basically by definition, see also Lemma 85.1 (3).
   (b) The fact that the second square commutes is an immediate consequence of the definitions of the "absolute" and the "relative" Hurewicz homomorphisms, see above and page 1842.
   (c) Finally it follows fairly easily from the Codimension Zero-Fundamental Class Lemma 106.24 and the Fundamental Class-of-Boundary Proposition 106.27 that the third square commutes.

(2) This is just a special case of the second square considered in (3). ∎

Again the following question arises: to what degree is the relative Hurewicz homomorphism in fact an isomorphism? One might hope that if a pair (X, A) is $(n-1)$-connected, then the Hurewicz homomorphism $\Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) \to \mathrm{H}_n(X, A; \mathbb{Z})$ is an isomorphism. But the following example shows that this is *not* the case.

Example. We consider again $X = S^1 \vee S^2$ and $A = S^1 \subset X$. We denote by x_0 the wedge point. It follows easily from the long exact sequence of homotopy groups provided by the Homotopy Groups-LES Proposition 153.4 that (X, A) is 1-connected.[1831] We see that in

[1831] Alternatively we could view X as a CW-complex in the usual way. Then we obtain from Proposition 153.9 that the pair (X, A) is 1-connected.

this case the map

$$\Phi_{(X,A,x_0)}\colon \underbrace{\pi_2(X,A,x_0)}_{\cong \mathbb{Z}^\infty, \text{ see page 3249}} \to \underbrace{\mathrm{H}_2(X,A;\mathbb{Z})}_{\cong \mathbb{Z}}$$

is *not* an isomorphism.

The following lemma is the key to understanding why the relative Hurewicz homomorphism fails to be a monomorphism.

Lemma 153.12. Let (X,A,x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $\sigma \in \pi_n(X,A,x_0)$. For any $g \in \pi_1(A,x_0)$ we have

$$\Phi_{(X,A,x_0)}(g \cdot \sigma) \;=\; \Phi_{(X,A,x_0)}(\sigma).$$

Proof. Let (X,A,x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $[f] \in \pi_n(X,A,x_0)$ and let $[\gamma] \in \pi_1(A,x_0)$. As in the Change-of-Base Point Proposition 86.9 (7) we see that the maps $f\colon (I^n,\partial I^{n-1}) \to (X,A)$ and $f^\gamma\colon (I^n,\partial I^{n-1}) \to (X,A)$ are homotopic. We obtain that

$$\Phi_{(X,A,x_0)}([\gamma]\cdot[f]) \;=\; \Phi_{(X,A,x_0)}([f^\gamma]) \;=\; (f^\gamma)_*([I^n]) \underset{\uparrow}{=} f_*([I^n]) \;=\; \Phi_{(X,A,x_0)}([f]).$$

by Proposition 74.15, since f and f^γ are homotopic as maps $(I^n,\partial I^n) \to (X,A)$ ∎

The above lemma leads us to the following definition.

Definition. Let (X,A,x_0) be a pointed pair of topological spaces.[1832]

(1) For $n \in \mathbb{N}_{\geq 3}$ we define $\pi'_n(X,A,x_0)$ to be the quotient group[1833]

$$\pi'_n(X,A,x_0) \;:=\; \pi_n(X,A,x_0)\big/\langle\{g\cdot\sigma-\sigma \,|\, g \in \pi_1(A,x_0) \text{ and } \sigma \in \pi_n(X,A,x_0)\}\rangle.$$

(2) We define[1834]

$$\pi'_2(X,A,x_0) \;:=\; \pi_2(X,A,x_0)\big/\langle\!\langle\{(g\cdot\sigma)\cdot\sigma^{-1} \,|\, g \in \pi_1(A,x_0), \sigma \in \pi_2(X,A,x_0)\}\rangle\!\rangle.$$

(3) By Lemma 153.12 the Hurewicz homomorphism

$$\Phi_{(X,A,x_0)}\colon \pi_n(X,A,x_0) \;\to\; \mathrm{H}_n(X,A;\mathbb{Z})$$

descends to a homomorphism

$$\Phi_{(X,A,x_0)}\colon \pi'_n(X,A,x_0) \;\to\; \mathrm{H}_n(X,A;\mathbb{Z}).$$

We refer to this homomorphism again as the Hurewicz homomorphism.

Remark. Let (X,A,x_0) be a pointed pair of topological spaces. It is a fun exercise to show "by hand" that $\pi'_2(X,A,x_0)$ is an abelian group. We refer to [**Hat2002**, Lemma 4.39] for details.

Example. Once again we consider $X = S^1 \vee S^2$ and $A = S^1 \subset X$. We denote by x_0 the wedge point. As usual we write $\pi_1(A,x_0) = \langle t\rangle$. On page 3249 we already saw that

[1833] Here we use the common, but sometimes confusing, convention that we write the group structure on the abelian group $\pi_n(X,A,x_0)$, $n \geq 3$, additively whereas we write the group structure on $\pi_2(X,A,x_0)$ multiplicatively. Evidently there is no rule without an exception, hence, if $\pi_2(X,A,x_0)$ happens to be abelian after all, then we also like to use additive notation for $\pi_2(X,A,x_0)$.

[1834] Recall that given a group π and a subset $X \subset \pi$ we denote by $\langle\!\langle X\rangle\!\rangle$ the subgroup of π normally generated by X. We refer to page 1192 for details.

$\pi_2(X, A, x_0) \cong \mathbb{Z}[t^{\pm 1}]$ as $\mathbb{Z}[\pi_1(A, x_0)] = \mathbb{Z}[t^{\pm 1}]$-modules. Thus we have an isomorphism

$$\pi_2'(X, A, x_0) \;\cong\; \mathbb{Z}[t^{\pm 1}]/\{(t^k - 1) \cdot f \mid f \in \mathbb{Z}[t^{\pm 1}] \text{ and } k \in \mathbb{Z}\}.$$

It is an amusing algebra exercise to show that the group on the right-hand side is isomorphic to $\mathbb{Z}$.

The following theorem is a generalization of the Hurewicz Theorem 85.5 to the relative case.

Theorem 153.13. (Relative Hurewicz Theorem) Let (X, A, x_0) be a pointed pair of topological spaces such that X and A are path-connected. Let $n \geq 2$. If the pair (X, A) is $(n-1)$-connected, then the following two statements hold:

(1) We have $\mathrm{H}_k(X, A; \mathbb{Z}) = 0$ for $k = 1, \ldots, n-1$.

(2) The Hurewicz homomorphism

$$\Phi_{(X,A,x_0)} \colon \pi_n'(X, A, x_0) \;\to\; \mathrm{H}_n(X, A; \mathbb{Z})$$

is an isomorphism. In particular, if $\pi_1(A, x_0) = 0$, then the Hurewicz homomorphism

$$\Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) \;\to\; \mathrm{H}_n(X, A; \mathbb{Z})$$

is an isomorphism.

Proof. We will not provide a proof of the Relative Hurewicz Theorem. A full proof is given in [**Bre1993**, Theorem VII.10.7] or alternatively in [**Hat2002**, Theorem 4.37] and [**Spa1995**, Proposition 7.5.1]. If A is simply connected, then it is a great exercise to figure out to what degree the proof of the Hurewicz Theorem 85.5 can be modified to deal with the relative case. ■

The following theorem, which can be viewed as a corollary to the Relative Hurewicz Theorem 153.13, is a nice illustration of the usefulness of relative homotopy groups.

Theorem 153.14. Let X and Y be two topological spaces and furthermore let $f \colon X \to Y$ be a map. We pick a base point $x_0 \in X$ and we write $y_0 = f(x_0)$.

(1) If for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_* \colon \pi_i(X, x_0) \;\xrightarrow{\cong}\; \pi_i(Y, y_0)$$

is an isomorphism, then for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_* \colon \mathrm{H}_i(X; \mathbb{Z}) \;\xrightarrow{\cong}\; \mathrm{H}_i(Y; \mathbb{Z})$$

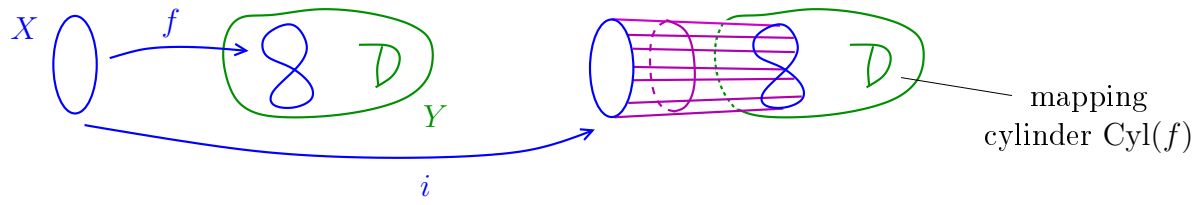
is also an isomorphism.

(2) If X and Y are simply connected, then the converse to (1) holds. More precisely, in this case, if for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_* \colon \mathrm{H}_i(X; \mathbb{Z}) \;\xrightarrow{\cong}\; \mathrm{H}_i(Y; \mathbb{Z})$$

is an isomorphism, then for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_* \colon \pi_i(X, x_0) \;\xrightarrow{\cong}\; \pi_i(Y, y_0)$$



is also an isomorphism.

Remark. In some textbooks, see e.g. [**Bre1993**, p. 481], [**DaK2001**, p. 162] and [**Spa1995**, p. 399], this theorem is referred to as the "Whitehead Theorem". We will reserve the name "Whitehead Theorem" for a much more interesting later result, namely Theorem 162.1.

Proof. The idea is to "replace" the map $f\colon X \to Y$ by an inclusion map so that we can apply the commutative diagram from Lemma 153.11. The key to doing so is the notion of the mapping cylinder that we introduced on page 454. Recall that the mapping cylinder corresponding to f is defined as the topological space

$$\mathrm{Cyl}(f) \;:=\; ((X \times [0,1]) \sqcup Y)/\!\sim \;\text{ where } (x,1) \sim f(x) \text{ for all } x \in X.$$

We consider the maps

$$i\colon X \to \mathrm{Cyl}(f),\; x \mapsto (x,0) \quad \text{respectively} \quad r\colon \mathrm{Cyl}(f) \to Y,\; P \mapsto \begin{cases} P, & \text{if } P \in Y, \\ f(Q), & \text{if } P = [(Q,t)] \text{ with } Q \in X, t \in [0,1]. \end{cases}$$

Note that we have $r \circ i = f\colon X \to Y$. Also note that in the Mapping Cylinder Basics Lemma 16.12 (2a) we showed that the retraction $r\colon \mathrm{Cyl}(f) \to Y$ is a homotopy equivalence. We use the inclusion $i\colon X \to \mathrm{Cyl}(f)$ to identify X with $i(X)$, i.e. we view X as a subset of $\mathrm{Cyl}(f)$.

In the following we prove Statement (2) of the theorem. Thus we assume that X and Y are simply connected and we assume that for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_*\colon \mathrm{H}_i(X;\mathbb{Z}) \;\xrightarrow{\cong}\; \mathrm{H}_i(Y;\mathbb{Z})$$

is an isomorphism. We need to show that for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_*\colon \pi_i(X,x_0) \;\xrightarrow{\cong}\; \pi_i(Y,y_0)$$

is also an isomorphism. We consider the following maps

$$\begin{array}{ccccccccccc}
 & & & & & & \pi_2(Y,y_0) & & & & \\
 & & & & & \overset{f_*}{\nearrow} & \uparrow{\scriptstyle r_*} & & & & \\
\ldots & \longrightarrow & \pi_3(\mathrm{Cyl}(f),X,x_0) & \xrightarrow{\partial} & \pi_2(X,x_0) & \xrightarrow{i_*} & \pi_2(\mathrm{Cyl}(f),x_0) & \longrightarrow & \pi_2(\mathrm{Cyl}(f),X,x_0) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\ldots & \longrightarrow & \mathrm{H}_3(\mathrm{Cyl}(f),X;\mathbb{Z}) & \xrightarrow{\partial} & \mathrm{H}_2(X;\mathbb{Z}) & \xrightarrow{i_*} & \mathrm{H}_2(\mathrm{Cyl}(f);\mathbb{Z}) & \longrightarrow & \mathrm{H}_2(\mathrm{Cyl}(f),X;\mathbb{Z}) & \longrightarrow & 0 \\
 & & & & & \underset{f_*}{\searrow} & \downarrow{\scriptstyle r_*} & & & & \\
 & & & & & & \mathrm{H}_2(Y;\mathbb{Z}) & & & &
\end{array}$$

where the vertical maps between the second and the third row are the Hurewicz homomorphisms. The desired statement follows from the following observations:

(a) The triangles commute since $f = r \circ i$. Furthermore the squares commute by Lemma 153.11.
(b) By our hypothesis the maps $f_*\colon \mathrm{H}_*(X;\mathbb{Z}) \to \mathrm{H}_*(Y;\mathbb{Z})$ are isomorphisms. Furthermore, since r is a deformation retraction we obtain from the Homotopy Equivalence-H_*-Corollary 73.9 that the maps $r_*\colon \mathrm{H}_*(\mathrm{Cyl}(f);\mathbb{Z}) \to \mathrm{H}_*(Y;\mathbb{Z})$ are isomorphisms.
(c) Since $f_* = (r \circ i)_* = r_* \circ i_*$ we obtain immediately from our result in (b) that the maps $i_*\colon \mathrm{H}_*(X;\mathbb{Z}) \to \mathrm{H}_*(\mathrm{Cyl}(f);\mathbb{Z})$ are also isomorphisms.
(d) It follows from (c) and the bottom long exact sequence that all the relative homology groups $\mathrm{H}_*(\mathrm{Cyl}(f), X;\mathbb{Z})$ vanishes.
(e) It follows easily from (d), the hypothesis that X is simply connected and the Relative Hurewicz Theorem 153.13 that all the relative homotopy groups $\pi_*(\mathrm{Cyl}(f), X, x_0)$ vanish.
(f) Using (e) we obtain immediately from the top long exact sequence that the maps $i_*\colon \pi_*(X, x_0) \to \pi_*(\mathrm{Cyl}(f), x_0)$ are isomorphisms.
(g) By the Homotopy-π_n-Proposition 71.7 (2) we know that the maps $r_*\colon \pi_*(\mathrm{Cyl}(f), x_0) \to \pi_*(Y, y_0)$ are isomorphisms.
(h) Finally note that it follows from $f_* = r_* \circ i_*$ together with (f) and (g) that the maps $f_*\colon \pi_*(X, x_0) \to \pi_*(Y, y_0)$ are indeed isomorphisms.

The proof of Statement (1) is very similar to the above argument. We leave it to the reader to fill in the details. ■

We conclude this section with a discussion of homotopy spheres. Recall that by the definition on page 2625 a homotopy n-sphere Σ is a closed n-dimensional topological manifold that is $(n-1)$-connected, i.e. the homotopy groups of Σ agree with the homotopy groups of S^n up to degree $n-1$.
The following pleasant corollary shows that in fact all homotopy groups of Σ are isomorphic to the corresponding homotopy groups of S^n.

Corollary 153.15. Let $n \in \mathbb{N}_{\geq 2}$. If Σ is a homotopy n-sphere, then for every $i \in \mathbb{N}_0$ we have $\pi_i(\Sigma) \cong \pi_i(S^n)$.

Proof. Let Σ be a homotopy n-sphere. Note that by Theorem 153.14 (2) it suffices to find a map $f\colon S^n \to \Sigma$ such that for every $i \in \mathbb{N}_{i\geq 2}$ the induced map $f_*\colon \mathrm{H}_i(S^n;\mathbb{Z}) \to \mathrm{H}_i(\Sigma;\mathbb{Z})$ is an isomorphism.

So let us try to find such a map f. We pick a base point $x_0 \in \Sigma$. By the definition and Proposition **??** we know that Σ is a closed connected non-empty n-dimensional topological manifold with $\mathrm{H}_i(\Sigma;\mathbb{Z}) \cong \pi_i(\Sigma, x_0) = 0$ for $i = 1, \ldots, n-1$. It follows from the Hurewicz Theorem 85.5 that the Hurewicz homomorphism

$$\begin{array}{rcl} \Phi\colon \pi_n(\Sigma, x_0) & \to & \mathrm{H}_n(\Sigma;\mathbb{Z}) \\ [f\colon (S^n, *) \to (\Sigma, x_0)] & \mapsto & f_*([S^n]) \end{array}$$

is an isomorphism. Note that the fact that $\pi_1(\Sigma, x_0) = 0$ together with the Non-Orientable $\mathbb{Z}_2$-Epimorphism Corollary 105.16 implies that Σ is orientable. Therefore by the Orientation-Top Homology Theorem 106.1 we know that $\mathrm{H}_n(\Sigma;\mathbb{Z}) \cong \mathbb{Z}$. Since the Hurewicz homomorphism is an isomorphism we can pick a map $f\colon S^n \to \Sigma$ such that $f_*([S^n]) \in \mathrm{H}_n(\Sigma;\mathbb{Z}) \cong \mathbb{Z}$ is a generator.

We claim that f has the desired properties. By choice of f we know that the map $f_*\colon \mathrm{H}_n(S^n;\mathbb{Z}) \to \mathrm{H}_n(\Sigma;\mathbb{Z})$ is an epimorphism. But since both groups are isomorphic to $\mathbb{Z}$ we see that the map is in fact an isomorphism. Since S^n and Σ are path-connected we obtain from the discussion on page 1594 that $f_*\colon \mathrm{H}_0(S^n;\mathbb{Z}) \to \mathrm{H}_0(\Sigma;\mathbb{Z})$ is also an isomorphism. Furthermore for all other dimensions f_* induces an isomorphism of homology groups for the rather banal reasons that all other homology groups of S^n and Σ are zero. (Indeed, we saw above that the homology groups in dimension less than n vanish and it follows from the Top-Homology Theorem 106.3 that the homology groups vanish in dimension greater than n.) ■

153.7. **Excision for relative homotopy groups?** We have now seen that the (relative) homotopy groups and (relative) homology groups have some properties in common:

(1) both invariants are functorial,
(2) in both cases homotopic maps induce the same maps on the invariants,
(3) a (pointed) pair of topological spaces gives rise to a long exact sequence.

These formal similarities between (relative) homotopy and (relative) homology groups makes one wonder whether an analogue of the Excision Theorem 74.17 holds for relative homotopy groups.
For better or worse this is not the case. More precisely, the next lemma shows that a naive analogue of the Excision Theorem 74.17 fails even in very simple situations.

Lemma 153.16. We consider the 2-dimensional sphere $X = S^2$ together with the subset $A := S^2_{\leq 0} = \{(x,y,z) \in S^2 \,|\, z \leq 0\}$ given by the lower hemisphere and together with the subset $Z = \{(0,0,-1)\}$ that is given by the South Pole. Then[1835]

$$\pi_3(X,A) \;\ncong\; \pi_3(X \setminus Z, A \setminus Z).$$

Proof. We start out with the following observations:

(1) On page 152 we saw that $A = S^2_{\leq 0}$ is homeomorphic to $\overline{B}^2$. In particular A is contractible which implies by the Homotopy-π_n-Proposition 71.7 (2) that $\pi_2(A) = \pi_3(A) = 0$.
(2) The above homeomorphism also shows that $A \setminus Z$ is homeomorphic to $\overline{B}^2 \setminus \{(0)\}$ which is homotopy equivalent to S^1. This implies that $\pi_2(A \setminus Z) = \pi_3(A \setminus Z) = 0$.
(3) Finally in Lemma 2.18 we saw that $X \setminus Z = S^2 \setminus \{(0,0,-1)\}$ is homeomorphic to $\mathbb{R}^2$ which implies that $\pi_2(X \setminus Z) = \pi_3(X \setminus Z) = 0$.

It follows from these observations and the long exact sequence of homotopy groups, provided by the Homotopy Groups-LES Proposition 153.4, that $\pi_3(X \setminus Z, A \setminus Z) \cong \pi_2(A \setminus Z) \cong \pi_2(S^1) = 0$ and furthermore that $\pi_3(X,A) \cong \pi_3(S^2)$. But in Theorem 122.3 we saw that

[1835] Here evidently the closure of Z is contained in the interior of A, i.e. the hypotheses for the Excision Theorem 74.17 for homology groups are satisfied.

$\pi_3(S^2)$ is non-trivial. We have thus shown that $\pi_3(X, A)$ is not isomorphic to $\pi_3(X \setminus Z, A \setminus Z)$. ■

Remark. We just used the fact that $\pi_3(S^2) \neq 0$ to show that relative homotopy groups do not satisfy excision. It is a good moment to remind ourselves of the Eilenberg-Steenrod Uniqueness Theorem 89.25. The theorem suggests that if relative homotopy groups did satisfy excision, then it would follow from the Homotopy Groups-LES Proposition 153.4 that, at least morally, (abelianized) homotopy groups would agree with homology groups.[1836] But the calculations $\pi_3(S^2) \neq 0$ and $\mathrm{H}_3(S^2) = 0$ show that this is not the case.

In much more restricted circumstances there is in fact an excision theorem. For the record we state the following theorem. We will not make use of it and therefore we will not provide the proof (which by all accounts seems to be somewhat messy.)

Theorem 153.17. (Blakers-Massey Theorem)

(1) Let X be a topological space and let A and B be subsets such that $X = \mathring{A} \cup \mathring{B}$. If $(A, A \cap B)$ is n-connected and if $(B, A \cap B)$ is m-connected, then the inclusion induced map
$$\pi_k(A, A \cap B) \ \to \ \pi_k(X, B)$$
is an isomorphism for $k < m + n$ and it is an epimorphism for $k = m + n$.

(2) The conclusion of (1) also holds if X is a CW-complex and A and B are two subcomplexes of X with $X = A \cup B$ such that $A \cap B$ is non-empty and connected.

Proof. The first statement was originally proved in 1952 by Albert Blakers and William Massey [**BlM1952**]. Proofs can also be found in [**Gra1975**, Corollary 16.27], [**tD2008**, Theorem 6.4.1], [**tDKP1970**, p. 211] or [**WhdG1978**, Chapter VII.7]. The second statement can presumably be deduced from the first statement. Alternatively see [**Hat2002**, Theorem 4.23]. ■

Exercises for Chapter 153.

Exercise 153.1. Show that the three paths to the right of the figure on page 3239 define three different elements in $\pi_1(X, A, x_0)$.

Exercise 153.2. Let (X, A, x_0) be a pointed pair of topological spaces. Show that if $n \geq 3$, then the relative homotopy group $\pi_n(X, A, x_0)$ is abelian.

Exercise 153.3. Let X be a topological space and $x_0 \in X$. We consider the set $\pi_0(X, x_0)$. We all know that $\pi_0(X, x_0)$ is "not a group". But why not? After all, every non-empty set can be equipped with a group structure (why is that?). So why is not possible to equip $\pi_0(X, x_0)$ with a group structure in a "meaningful way"? More precisely, if we could equip it with a group structure in a reasonable sense, what properties would we demand? Why can these not be satisfied?

Exercise 153.4. Let $\varphi\colon G \to H$ be a group homomorphism. Furthermore let (S, s_0) be a pointed set which is equipped with an H-action. Suppose that we have an exact sequence
$$\{e\} \ \to \ G \ \xrightarrow{\varphi} \ H \ \xrightarrow{\psi} \ (S, s_0) \ \to \ \{e\}$$

[1836] To turn this logic into a proper argument might be a little tricky because of base point issues.

where ψ is a morphism of pointed sets that preserves the H-action. Show that $\varphi(G)$ is a subgroup of H whose index equals the cardinality of the set S.

Exercise 153.5. Is a monomorphism of pointed sets necessarily injective?

Exercise 153.6. Provide a proof for Lemma 153.3.

Exercise 153.7. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}$. By the convention of page 3251 we can view elements in $\pi_n(X, A, x_0)$ as homotopy classes of maps $(\overline{B}^n, S^{n-1}, *) \to (X, A, \{x_0\})$. Using this point of view, how can we visualize the action of $\pi_1(A, x_0)$ on $\pi_n(X, A, x_0)$?

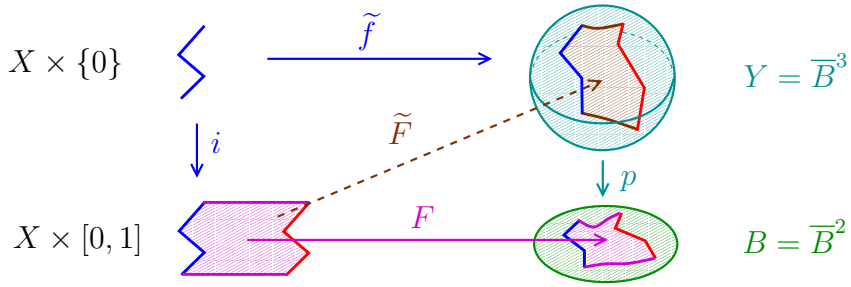
Exercise 153.8. Give an example of a connected CW-complex X, a connected subcomplex $A \subset X$ and an $n \in \mathbb{N}$ such that the homotopy group $\pi_n(X/A)$ is not isomorphic to the relative homotopy group $\pi_n(X, A)$.

154. Fibrations

In this chapter we introduce fibrations and we show that fibrations give rise to a long exact sequence of homotopy groups. In the subsequent two chapters we will give many more examples of fibrations and we will see that fibrations allow us to compute various interesting higher homotopy groups.

154.1. **Definition and examples of fibrations.** The following is the key definition of this chapter.

Definition. Let $p\colon Y \to B$ be a map between topological spaces.



(1) Let X be a topological space. We say that the map $p\colon Y \to B$ has the homotopy lifting property with respect to X if given any map $F\colon X \times [0,1] \to B$ and given any map $\widetilde{f}\colon X \times \{0\} \to Y$ with $p \circ \widetilde{f} = F \circ i$ there exists a map $\widetilde{F}\colon X \times [0,1] \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} X \times \{0\} & \xrightarrow{\widetilde{f}} & Y \\ \downarrow{\scriptstyle i} & \overset{\widetilde{F}}{\nearrow}{\scriptstyle ??} & \downarrow{\scriptstyle p} \\ X \times [0,1] & \xrightarrow[F]{} & B. \end{array}$$

Sometimes we refer to $\widetilde{F}\colon X \times [0,1] \to Y$ as a lift of $F\colon X \times [0,1] \to B$. (Note that we do *not* demand that the lift $\widetilde{F}$ is any way unique.) We refer to the figure below for an illustration of the definition.

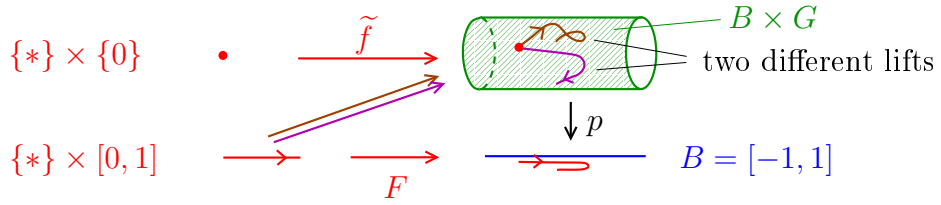
(2) We say that the map $p\colon Y \to B$ is a fibration if p has the homotopy lifting property with respect to all topological spaces.

(3) We say that the map $p\colon Y \to B$ is a Serre fibration if p has the homotopy lifting property with respect to all closed balls $\overline{B}^n$, $n \in \mathbb{N}_0$. So perhaps somewhat confusingly a Serre fibration is not necessarily a fibration.

Remark.

(1) Different textbooks mean different objects when they talk about "fibrations". Our definition coincides with the language used in [**Hat2002, Rot1988, DaK2001**]. In [**Bre1993**], what we call a "fibration" is called a "Hurewicz fibration".

(2) If $p\colon Y \to B$ is Serre fibration and if Y and B are CW-complexes, then it follows from [**StW1984, Cau1992**] that p is in fact a fibration. We will not make use of this result.



Examples.

(1) In the Path-Homotopy Lifting Proposition 48.12 we already showed that every covering $p\colon Y \to B$ has the homotopy lifting property (in fact with a unique lift) with respect to every topological manifold, in particular with respect to any closed ball $\overline{B}^n$. This implies in particular that every covering is a Serre fibration.

(2) Let B and G be topological spaces. We denote by $p\colon B\times G \to B$ and $q\colon B\times G \to G$ the two obvious projections. In the following we show that the projection $p\colon B\times G \to B$ is a fibration. Indeed, in the setting above the map

$$\begin{array}{rcl} \widetilde{F}\colon X\times[0,1] & \to & B\times G \\ (x,t) & \mapsto & \big(F(x,t), q\big(\underbrace{\widetilde{f}(x,0)}_{\in B\times G}\big)\big) \end{array}$$

makes the diagram commute. As is shown in the figure below, in contrast to the first example, the lift $\widetilde{F}$ is in general not unique.

(3) For every $n\in\mathbb{N}$ the map

$$\begin{array}{rcl} \overline{B}^{n+1} & \to & \overline{B}^n \\ (x_1,\dots,x_n,x_{n+1}) & \mapsto & (x_1,\dots,x_n) \end{array}$$

is a Serre fibration. With some effort this statement can be proved "by hand". The case $n=1$ is precisely the content of Exercise 154.1.

We conclude the list of examples with a "non-example". To make this example more readable we package it is as a lemma.

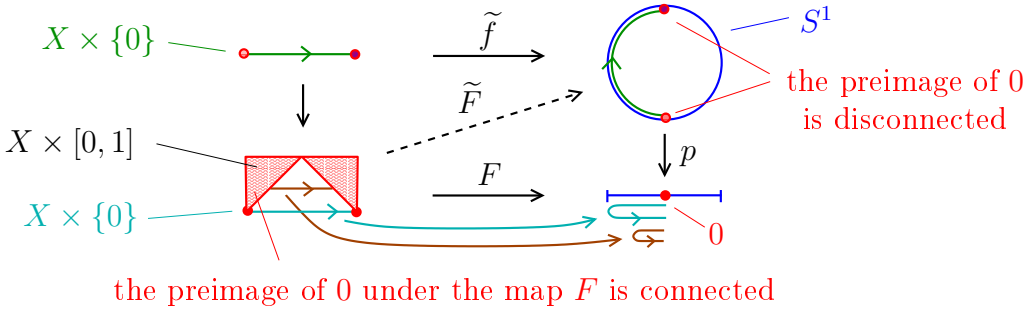
Lemma 154.1. The map $p\colon S^1 \to [-1,1]$ that is given by the projection onto the x-coordinate is not a Serre fibration.

Proof. We consider the topological space $X = \overline{B}^1 = [-1,1]$ together with the maps $\widetilde{f}\colon X\times\{0\}\to S^1$ and $F\colon [-1,1]\times[0,1]\to[-1,1]$ that are illustrated in the figure below. We claim that there is no lifting $\widetilde{F}\colon X\times[0,1]\to S^1$. More precisely, we prove the following claim.

Claim. If $\widetilde{F}\colon X\times[0,1]\to S^1$ is a map with $p\circ\widetilde{F}=F$, then $\widetilde{F}|_{X\times\{0\}}$ does not agree with $\widetilde{f}$.

Proof. Thus let $\widetilde{F}\colon X\times[0,1]\to S^1$ be a map with $p\circ\widetilde{F}=F$. We make the following observations:

(1) The preimage $F^{-1}(0)$ is connected by the definition of F.



(2) We obtain from (1) and the Image-Connected Lemma 2.24 that the image $\widetilde{F}(F^{-1}(0))$ is also connected.

(3) The fact that $p\circ\widetilde{F}=F$ implies that $\widetilde{F}(F^{-1}(0))\subset p^{-1}(0)$.[1837]

[1837] Since I always find these arguments confusing let me give the argument: Let $y\in\widetilde{F}(F^{-1}(0))$. This means that there exists a $P\in F^{-1}(0)$ with $y=\widetilde{F}(P)$. We have $p(y)=p(\widetilde{F}(P))=F(P)$, but $P\in F^{-1}(0)$, thus $p(y)=0$. In other words, we have $y\in p^{-1}(0)$.

(4) By definition of the map p we have $p^{-1}(0) = \{(0, \pm 1)\}$.
(5) It follows from (2), (3) and (4) that $\widetilde{F}$ restricted to $F^{-1}(0)$ is constant.
(6) The map $\widetilde{f}$ is not constant on $F^{-1}(0)$.

The combination of (5) and (6) proves our claim. ■

We continue with introducing some language and notation.

Notation.

(1) Given a fibration or a Serre fibration $p\colon Y \to B$ we sometimes refer to B as the base space and to Y as the total space.[1838] Furthermore, given a point $* \in B$ we refer to $F := p^{-1}(*)$ as a fiber. The last definition is somewhat dangerous since, as we see in the last of the above examples, the homeomorphism type $p^{-1}(*)$ depends on the choice of $*$. We will shortly discuss "uniqueness" of the fiber. Finally throughout this chapter we denote by $i\colon F \to Y$ the inclusion map.
(2) Given $n \in \mathbb{N}_0$ we define I, I^n and J^n as on page 3238.

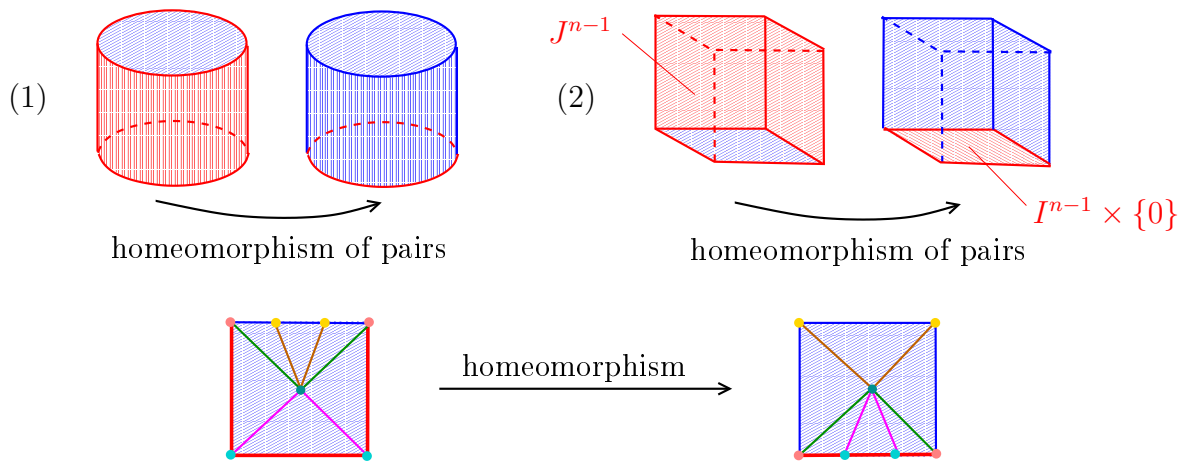
Before we can formulate the main theorem of this chapter we need to make some preparations.

Lemma 154.2.

(1) For each $n \in \mathbb{N}$ there exists an orientation-preserving homeomorphism

$$\big(\overline{B}^n \times [0,1], \overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1]\big) \xrightarrow{\cong} \big(\overline{B}^n \times [0,1], \overline{B}^n \times \{0\}\big)$$

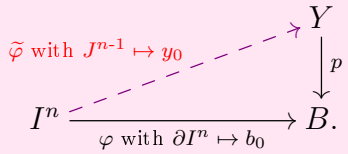
of pairs of topological spaces. (This statement is illustrated in the figure below on the left.)
(2) For each $n \in \mathbb{N}$ there exists a homeomorphism



$$(I^n, J^{n-1}) \xrightarrow{\cong} (I^n, I^{n-1} \times \{0\}).$$

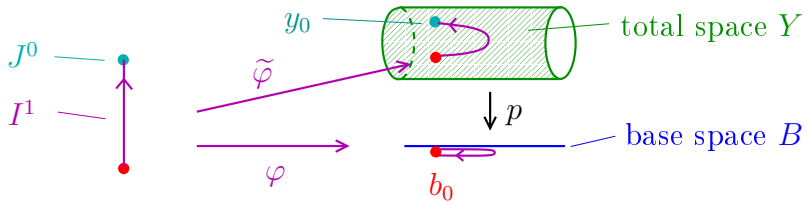
of pairs of topological spaces. (This statement is illustrated in the figure below on the right.)

Sketch of proof.

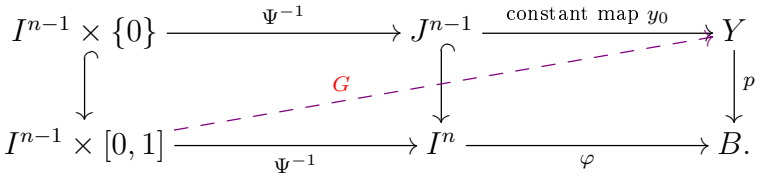


(1) For $n = 1$ such a homeomorphism is illustrated in the figure below. The general case is given by "rotating this homeomorphism around the $x_1 = 0$-axis in $\mathbb{R}^n$".
(2) Using the homeomorphism $\overline{B}^{n-1} \cong I^{n-1}$ from the Convex-to-Ball Proposition 2.20 (2) one can easily reduce the proof of (2) to the statement that we had just proved in (1). ■

[1838] This mirrors the language that we introduced on page 3058 for vector bundles.



We will also soon need the following elementary lemma.



Lemma 154.3. Let $p\colon Y \to B$ be a Serre fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$. Furthermore let $n \in \mathbb{N}$. Given any map $\varphi\colon (I^n, \partial I^n) \to (B, \{b_0\})$ there exists a map $\widetilde{\varphi}\colon (I^n, J^{n-1}) \to (Y, \{y_0\})$ such that the following diagram commutes:

We refer to the figure below for an illustration.

Proof. Let $\Psi\colon (I^n, J^{n-1}) \xrightarrow{\cong} (I^n, I^{n-1} \times \{0\})$ be a homeomorphism as in Lemma 154.2 (2). We consider the diagram

Note that the diagram without the red dashed arrow commutes. Since p is a Serre fibration and since I^{n-1} is homeomorphic to the $(n-1)$-ball, see the Convex-to-Ball Proposition 2.20 (2), it follows that a map $G\colon I^{n-1} \times I \to Y$ exists that makes the diagram commute. It is now straightforward to verify that $G \circ \Psi\colon I^n \to B$ has the desired properties. ∎

154.2. **The homotopy fiber of a fibration.** First we introduce the following, arguably long overdue notation.

Notation. Given two topological spaces X and Y we define $[X, Y]$ to be the set of homotopy equivalence classes of maps from X to Y.[1839]

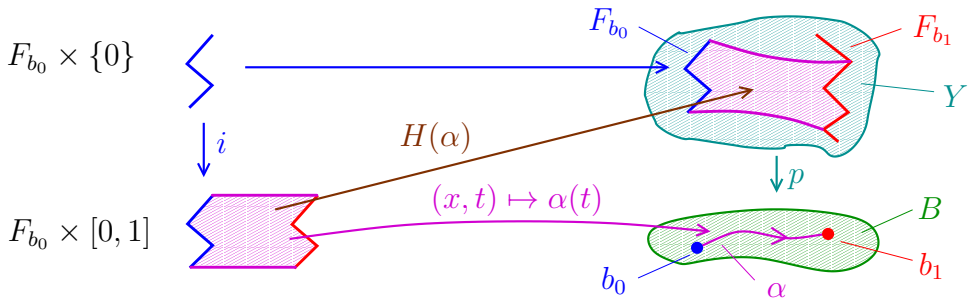
The following lemma is a reformulation of Lemma 14.6.

Lemma 154.4. Let X, Y and Z be topological spaces. The map

$$\begin{array}{ccc} [Y,Z] \times [X,Y] & \mapsto & [X,Z] \\ ([g],[f]) & \mapsto & [g \circ f] \end{array}$$

is well-defined.

Now we can formulate the key technical proposition of this section.



Proposition 154.5. Let $p\colon Y \to B$ be a fibration. Given $b \in B$ we write $F_b := p^{-1}(b)$. Let $\alpha\colon [0,1] \to B$ be a path from a point b_0 to a point b_1. We consider the following diagram

$$\begin{array}{ccc} F_{b_0} \times \{0\} & \xrightarrow{(x,0)\mapsto x} & Y \\ \downarrow{\scriptstyle i} & \nearrow{\scriptstyle H(\alpha)} & \downarrow{\scriptstyle p} \\ F_{b_0} \times [0,1] & \xrightarrow[(x,t)\mapsto \alpha(t)]{} & B. \end{array}$$

Since $p\colon Y \to B$ is a fibration there exists a diagonal map $H(\alpha)\colon F_{b_0} \times [0,1] \to Y$.[1840] (We refer to the figure below for an illustration.) We define $\Theta(\alpha) := H(\alpha)_1$. The following statements hold:

(1) The map $\Theta(\alpha)$ goes from F_{b_0} to F_{b_1}.
(2) The map $\Theta(\alpha)$, viewed as an element in $[F_{b_0}, F_{b_1}]$, is well-defined.
(3) The map $\Theta(\alpha)\colon F_{b_0} \to F_{b_1}$ is a homotopy equivalence.
(4) If two paths $\alpha, \beta\colon [0,1] \to B$ from b_0 to b_1 are path-homotopic, then $[\Theta(\alpha)] = [\Theta(\beta)]$.
(5) If c_b is the constant path at $b \in B$, then $[\Theta(c_b)] = [\mathrm{id}_{F_b}] \in [F_b, F_b]$.
(6) If α is a path in B from b_0 to b_1 and β is a bath in B from b_1 to b_2, then

$$\underbrace{[\Theta(\alpha * \beta)]}_{\in [F_{b_0}, F_{b_2}]} = \underbrace{[\Theta(\beta)]}_{\in [F_{b_1}, F_{b_2}]} \circ \underbrace{[\Theta(\alpha)]}_{\in [F_{b_0}, F_{b_1}]}.$$

[1839] Recall that in Lemma 14.5 we saw that "being homotopic" is an equivalence relation.

[1840] Recall that in general $H(\alpha)$ is not uniquely determined by the data, i.e. there might be many such maps.

Remark. The picture behind the statement of Proposition 154.5 is that while walking along B we can drag the fiber along. Thus any path defines a map between the corresponding fibers.

Proof. Let $p\colon Y \to B$ be a fibration over a topological space B. Given $b \in B$ we write $F_b := p^{-1}(b)$. Let $\alpha\colon [0,1] \to B$ be a path from a point b_0 to a point b_1. We consider the following diagram

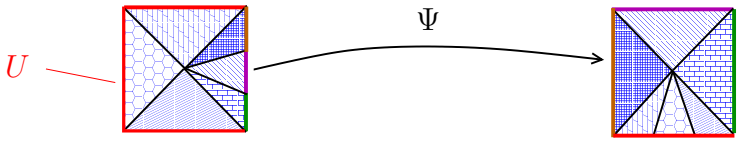
$$\begin{array}{ccc} F_{b_0} \times \{0\} & \xrightarrow{(p,0)\mapsto p} & Y \\ \downarrow{\scriptstyle i} & \overset{H(\alpha)}{\nearrow} & \downarrow{\scriptstyle p} \\ F_{b_0} \times [0,1] & \xrightarrow[(x,t)\mapsto \alpha(t)]{} & B. \end{array}$$

Since $p\colon Y \to B$ is by hypothesis a fibration there exists in fact such a diagonal map $H(\alpha)\colon F_{b_0} \times [0,1] \to Y$. Note that the map $H(\alpha)_0\colon F_{b_0} \to B$ is just the obvious inclusion. We turn to the proofs of the statements, albeit perhaps in an unexpected order:

(1) Since the above diagram commutes we see immediately that the map $H(\alpha)_1$ is a map from $F_{b_0} \to F_{b_1}$.

(4) Let $\alpha, \beta\colon [0,1] \to B$ be two paths from b_0 to b_1. We pick maps $H(\alpha)$ and $H(\beta)$ as above, keeping in mind that $H(\alpha)$ and $H(\beta)$ are not uniquely determined. Now we assume that α and β are path-homotopic. We need to show the following claim.

Claim. The maps $H(\alpha)_1, H(\beta)_1\colon F_{b_0} \to F_{b_1}$ are homotopic.



Proof. We start out with the following observation. It follows immediately from Lemma 154.2 (2), applied to $n = 2$, that there exists a self-homeomorphism

$$\Psi\colon [0,1] \times [0,1] \to [0,1] \times [0,1]$$

that restricts to a homeomorphism

$$\underbrace{([0,1] \times \{0,1\}) \cup (\{0\} \times [0,1])}_{=:U} \to [0,1] \times \{0\}.$$

For reassurance the construction of such a map is also sketched in the figure below. Now we pick a homotopy $G\colon [0,1] \times [0,1] \to B$ rel $\{0,1\}$ from α to β. We consider

the following diagram

$$\begin{array}{ccccc} F_{b_0} \times [0,1] \times \{0\} & \xrightarrow{\mathrm{id}_{F_{b_0}} \times \Psi^{-1}} & \overbrace{(F_{b_0} \times [0,1] \times \{0,1\}) \cup (F_{b_0} \times \{0\}) \times [0,1]}^{= F_{b_0} \times U} & \xrightarrow{\Omega} & Y \\ \downarrow & & \downarrow & \overset{\Xi}{\nearrow} & \downarrow{\scriptstyle p} \\ F_{b_0} \times [0,1] \times [0,1] & \xrightarrow[\mathrm{id}_{F_{b_0}} \times \Psi^{-1}]{} & F_{b_0} \times [0,1] \times [0,1] & \xrightarrow[(P,s,t)\mapsto G(s,t)]{} & B. \\ & \underset{\mathrm{id}_{F_{b_0}} \times \Psi}{\nwarrow} & & \overset{\Xi \circ (\mathrm{id}_{F_{b_0}} \times \Psi)}{\nearrow} & \end{array}$$

We make the following clarifications and observations:

(a) The map Ω is defined as follows:[1841]
  (i) on $F_{b_0} \times [0,1] \times \{0\} = F_{b_0} \times [0,1]$ the map Ω is given by $H(\alpha)$,
  (ii) on $F_{b_0} \times [0,1] \times \{1\} = F_{b_0} \times [0,1]$ the map Ω is given by $H(\beta)$,
  (iii) on $F_{b_0} \times \{0\} \times [0,1]$ the map Ω is given by the projection onto F_{b_0} followed by the inclusion into Y.

(b) It follows immediately from the definitions that the diagram commutes.

(c) Since $p\colon Y \to B$ is a fibration we see that there exists a map Ξ that makes the outer diagram commute.

(d) The map $\Xi \circ (\mathrm{id}_{F_{b_0}} \times \Psi)\colon F_{b_0} \times [0,1] \times [0,1] \to Y$ is a homotopy between $H(\alpha)$ and $H(\beta)$. In particular the map $(\Xi \circ (\mathrm{id}_{F_{b_0}} \times \Psi))_1\colon F_{b_0} \times [0,1] \to Y$ is the desired homotopy between $H(\alpha)_1$ and $H(\beta)_1$. ⊞

(5) This statement follows from the observation that for the constant path c_b at a point $b \in B$ we can choose $H(c_b)\colon F_b \times [0,1] \to F_b$ to be the projection. Evidently we obtain that $\Theta(c_b) = H(c_b)_1 = \mathrm{id}_{F_b}$.

(6) Let α be a path in B from b_0 to b_1 and let β be a bath in B from b_1 to b_2. Almost the same way that we define the product $\alpha * \beta$ we combine $H(\alpha)$ and $H(\beta)$. More precisely, we consider the map[1842]

$$\begin{array}{rcl} H(\alpha * \beta)\colon F_{b_0} \times [0,1] & \to & X \\ (P,t) & \mapsto & \begin{cases} H(\alpha)(P, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ H(\beta)\big(\underbrace{H(\alpha(P),1)}_{\in F_{b_1}}, 2t-1\big), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

One can easily verify that this map has all the properties that we expect from a map that is called $H(\alpha * \beta)$. The desired statement is now an immediate consequence of the observation that $H(\alpha * \beta)_1 = H(\beta)_1 \circ H(\alpha)_1$.

(3) Let $\alpha\colon [0,1] \to B$ be a path from b_0 to b_1. We pick a map $H(\alpha)\colon F_{b_0} \times [0,1] \to X$ as above. We want to show that the corresponding map $H(\alpha)_1\colon F_{b_0} \to F_{b_1}$ is a homotopy equivalence. We denote by $\overline{\alpha}\colon [0,1] \to B$ the inverse path of α, i.e. the path from b_1 to b_0 that is given by $\overline{\alpha}(t) = \alpha(1-t)$. We pick a map $H(\overline{\alpha})\colon F_{b_1} \times [0,1] \to X$ as above. It remains to prove the following claim.

Claim.
(a) The map $H(\overline{\alpha})_1 \circ H(\alpha)_1\colon F_{b_0} \to F_{b_0}$ is homotopic to the identity of F_{b_0}.
(b) The map $H(\alpha)_1 \circ H(\overline{\alpha})_1\colon F_{b_1} \to F_{b_1}$ is homotopic to the identity of F_{b_1}.

Proof. We prove the first statement. The proof of the second statement is verbatim the same. We have

$$\begin{array}{ccccc} [\, H(\overline{\alpha})_1 \circ H(\alpha)_1 \,] & = & [\, H(\alpha * \overline{\alpha}) \,] & = & [\, H(c_{b_0}) \,] & = & [\, \mathrm{id}_{F_{b_0}} \,]. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{by (6)} & & \text{by (4) and Proposition 47.5 (3)} & & \text{by (5).} & \end{array}$$

⊞

[1841] As on so many other occasions we can use Pasting Proposition 2.6 (2) to show that the map Ω is indeed continuous.

[1842] It follows again from the Homotopy Stacking Lemma 14.3 that this map is continuous.

(2) We apply the argument from (4) to $\beta = \alpha$ together with two maps $H(\alpha)$ and $H(\beta)$ that make the diagram commute. We obtain by (3) that $H(\alpha)$ and $H(\beta)$ are homotopic, i.e. we see that $[H(\alpha)] \in [F_{b_0}, F_{b_1}]$ is well-defined. ■

Using Proposition 154.5, and the proof thereof, we almost immediately obtain the following proposition.

Proposition 154.6. (Fiber-Homotopy Type Proposition) Let $p\colon Y \to B$ be a map between topological spaces. We assume that B is path-connected.

(1) If $p\colon Y \to B$ is a fibration, then for any two points $b_0, b_1 \in B$ the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$ are homotopy equivalent.
(2) If $p\colon Y \to B$ is a Serre fibration, then for any two points $b_0, b_1 \in B$ such that the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$ are discrete subsets, the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$ are homotopy equivalent.

Proof.

(1) This statement follows immediately from Proposition 154.5 (3) and the hypothesis that B is path-connected.
(2) Let $p\colon Y \to B$ be a Serre fibration with B a path-connected topological space. Let $b_0, b_1 \in B$ such that the fibers $F_{b_0} := p^{-1}(b_0)$ and $F_{b_1} := p^{-1}(b_1)$ are discrete subsets. In the proof of Proposition 154.5 (3) we used the homotopy lifting property for the topological spaces $X = F_{b_i} \times [0,1]^n$ with $i \in \{0,1\}$ and $n \in \{1,2\}$. Since F_{b_0} and F_{b_1} are discrete we see that each component of $X = F_{b_i} \times [0,1]^n$ is homeomorphic to $[0,1]^n$, i.e. each component is homeomorphic to $\overline{B}^n$. Since we can do the lifting component-wise it suffices in our context that we are given a Serre fibration. We leave it to the reader to fill in the details. ■

the Fiber-Homotopy Type Proposition 154.6 (1) allows us to make the following definition.

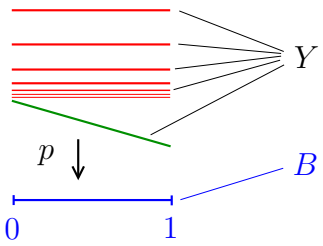
Definition. Let $p\colon Y \to B$ be a fibration over a path-connected topological space B. We refer to the homotopy type of the fibers as the homotopy fiber of the fibration.

Remark. A more precise statement of the Fiber-Homotopy Type Proposition 154.6 (1) holds: any path $\gamma\colon [0,1] \to B$ from b_0 to b_1 defines naturally a homotopy equivalence between the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$. We refer to [**DaK2001**, Theorem 6.12] for the precise formulation and proof of this statement.

Examples.

(1) Let $p\colon \widetilde{X} \to X$ be a covering map over a path-connected topological space. As discussed on page 3264 such a map is a Serre fibration. It follows immediately from the definition of a covering map that for each $x \in X$ the fiber $p^{-1}(x)$ is a discrete subset of $\widetilde{X}$. Therefore it follows from the π_0-Homotopy Equivalence Lemma 15.3 and the Fiber-Homotopy Type Proposition 154.6 (2) that given any two points $x_0, x_1 \in X$ there exists a bijection $p^{-1}(x_0) \to p^{-1}(x_1)$. In other words, we have found a new proof for Lemma 48.1.
(2) Let us consider again the "non-example" from Lemma 154.1, i.e. we consider the map

$$\begin{array}{rcl} p\colon Y = S^1 = \{(x,y) \in \mathbb{R}^2 \,|\, x^2 + y^2 = 1\} & \to & B = [-1,1] \\ (x,y) & \mapsto & x. \end{array}$$



In this case $p^{-1}(-1) = \{(-1,0)\}$ and $p^{-1}(0) = \{(0,\pm 1)\}$ are discrete subsets, but the number of components is different. From the π_0-Homotopy Equivalence Lemma 15.3 we deduce that $p^{-1}(-1)$ is not homotopy equivalent to $p^{-1}(0)$. Thus the Fiber-Homotopy Type Proposition 154.6 (2) gives a new proof (after the more hands-on proof provided by Lemma 154.1) that p is not a Serre fibration.

(3) We consider the map $p\colon Y \to B$ given by the total space

$$Y := \{\underbrace{(x,y)}_{\in\mathbb{R}^2} \,|\, y = 1-x \text{ and } x \in [0,1]\} \cup \bigcup_{n\in\mathbb{N}} \{\underbrace{(x,y)}_{\in\mathbb{R}^2} \,|\, x \in [0,1] \text{ and } y = 1 + \tfrac{1}{n}\}$$

the base space $B = [0,1]$ and the natural projection $p\colon Y \to X$. (This example is illustrated in the figure below.) It is an amusing exercise to show that $p\colon Y \to B$ is a Serre fibration. We saw in Exercise 15.8 that the fibers $p^{-1}(0)$ and $p^{-1}(1)$ are not homotopy equivalent. It follows from the Fiber-Homotopy Type Proposition 154.6 (1) that $p\colon Y \to B$ is not a fibration.[1843]

We can also show more directly that p is not a fibration: We consider $X = p^{-1}(1)$, the usual projection $f\colon X \times [0,1] \to B = [0,1]$ together with the obvious inclusion $\widetilde{f}\colon X \times \{0\} \to Y$. It is once again an amusing elementary exercise to show that there is no map $\widetilde{F}\colon X \times [0,1] \to B$ with all the desired properties. This shows that $p\colon Y \to B$ is not a fibration.

154.3. **The long exact homotopy sequence of a Serre fibration.** For us the most interesting aspect of Serre fibrations is that they give rise to long exact sequences of homotopy groups. More precisely, we have the following theorem.

Theorem 154.7. (Fibration-LES Theorem) Let $p\colon Y \to B$ be a Serre fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$.

(1) Given any $n \in \mathbb{N}$ the following map is well-defined:

$$\begin{aligned} \partial_n\colon \pi_n(B,b_0) &\to \pi_{n-1}(F,y_0) \\ [\varphi\colon (I^n,\partial I^n) \to (B,b_0)] &\mapsto \left[\begin{array}{c} \text{pick a map } \widetilde{\varphi}\colon (I^n,J^{n-1}) \to (Y,\{y_0\}) \text{ with } p\circ\widetilde{\varphi} = \varphi \\ \text{(we know from Lemma 154.3 that such a map exists)} \\ \text{and then restrict the map } \widetilde{\varphi} \text{ to } I^{n-1} = I^{n-1}\times\{0\} \end{array}\right]. \end{aligned}$$

[1843] The discussion of this example would be more intelligible if we followed the convention of [**Bre1993**, p. 450] and if we referred to "fibrations" as "Hurewicz fibrations" to better distinguish them from "Serre fibrations".

(The definition of ∂_n is moderately successfully illustrated in the figure below.) Furthermore, these maps ∂_n have the following properties:

(a) The maps are morphisms of groups (if $n \geq 2$) and of pointed sets (if $n = 1$).

(b) The maps are natural in the following two senses: Suppose we are given another Serre fibration $p' \colon Y' \to B'$ and suppose we are given a commutative diagram

$$\begin{array}{ccc} Y & \xrightarrow{p} & B \\ {\scriptstyle\Phi}\downarrow & & \downarrow{\scriptstyle\phi} \\ Y' & \xrightarrow{p'} & B'. \end{array}$$

If we write $y_0' = \Phi(y_0), b_0' = \phi(b_0)$ and $F' = (p')^{-1}(b_0')$, then for any $n \in \mathbb{N}$ the following diagram commutes

$$\begin{array}{ccc} \pi_n(B, b_0) & \xrightarrow{\partial_n} & \pi_{n-1}(F, y_0) \\ {\scriptstyle\phi_*}\downarrow & & \downarrow{\scriptstyle(\Phi|_F)_*} \\ \pi_n(B', b_0') & \xrightarrow{\partial_n} & \pi_{n-1}(F', y_0'). \end{array}$$

(c) Let $\alpha \colon [0,1] \to B$ be a path from b_0 to some point b_1.[1844] We write $F_1 = p^{-1}(b_1)$. If $\Theta(\alpha) \colon F \to F_1$ is a map as in Proposition 154.5, then the following diagram commutes

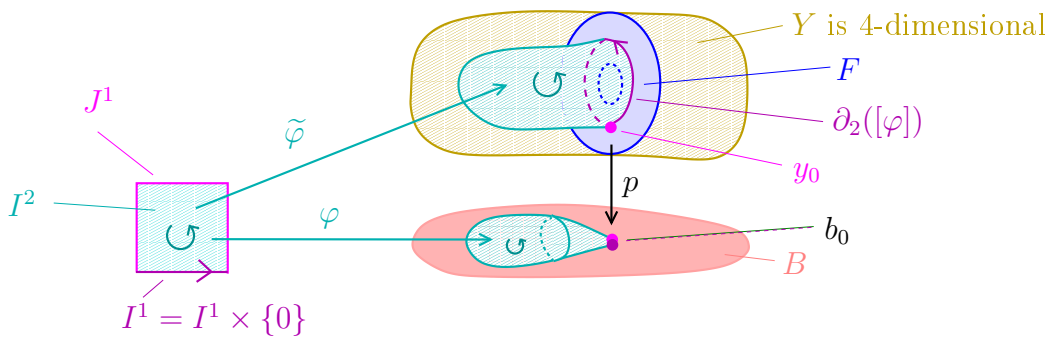
$$\begin{array}{ccc} \pi_n(B, b_0) & \xrightarrow{\partial_n} & \pi_{n-1}(F, y_0) \\ {\scriptstyle\alpha_*}\downarrow & & \downarrow{\scriptstyle\Theta(\alpha)_*} \\ \pi_n(B, b_1) & \xrightarrow{\partial_n} & \pi_{n-1}(F_1, y_1) \end{array}$$

where $y_1 = \Theta(\alpha)(y_0)$.

(2) The following sequence is exact:[1845]

$$\begin{aligned} \ldots \xrightarrow{\partial_{n+1}} \pi_n(F, y_0) \xrightarrow{i_*} \pi_n(Y, y_0) \xrightarrow{p_*} \pi_n(B, b_0) \xrightarrow{\partial_n} \\ \xrightarrow{\partial_n} \pi_{n-1}(F, y_0) \xrightarrow{i_*} \ldots\ldots\ldots \xrightarrow{p_*} \pi_1(B, b_0) \xrightarrow{\partial_1} \\ \xrightarrow{\partial_1} \pi_0(F, y_0) \xrightarrow{i_*} \pi_0(Y, y_0) \xrightarrow{p_*} \twoheadrightarrow \pi_0(B, b_0). \end{aligned}$$

(3) If the inclusion map $i \colon F \to Y$ is actually homotopic rel y_0 to the constant map $c_{y_0} \colon F \to \{y_0\}$, then for any $n \in \mathbb{N}_{\geq 2}$ the above long exact sequence breaks into a short exact sequence



$$0 \;\to\; \pi_n(Y, y_0) \;\xrightarrow{p_*}\; \pi_n(B, b_0) \;\xrightarrow{\partial_n}\; \pi_{n-1}(F, y_0) \;\to\; 0.$$

Furthermore the short exact sequence splits, which implies that for any $n \in \mathbb{N}_{\geq 2}$ we have an isomorphism

$$\pi_n(B, b_0) \;\cong\; \pi_n(Y, y_0) \oplus \pi_{n-1}(F, y_0).$$

[1844] Here we allow of course that $b_1 = b_0$.

[1845] Here, at the lower end, we mean "exact" in the sense of the definition on page 3242.

Before we head towards the proof of the Fibration-LES Theorem 154.7 we want to see what the theorem tells us in two types of fibrations that we had considered above, namely for coverings and products.

Example. Let $p\colon Y \to B$ be a covering of path-connected topological spaces. As mentioned above, by the Path-Homotopy Lifting Proposition 48.12 we know that p is a Serre fibration. We pick $y_0 \in Y$ and we write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$. It follows immediately from the definition of a covering map that F, equipped with the subspace topology coming from Y, is a discrete space, in particular $\#\pi_0(F, y_0) = \#F$ and $\pi_i(F, y_0) = 0$ for $i \geq 1$. From the long exact sequence provided by the Fibration-LES Theorem 154.7 we obtain the following two pieces of information:

(1) At the lower end the long exact sequence looks as follows:

$$\underbrace{\pi_1(F, y_0)}_{=\{e\}} \to \pi_1(Y, y_0) \xrightarrow{p_*} \pi_1(B, b_0) \xrightarrow{\partial} \underbrace{\pi_0(F, y_0)}_{\#\pi_0(F,y_0)=\#F} \to \underbrace{\pi_0(Y, y_0)}_{=\{e\}} \to \underbrace{\pi_0(B, b_0)}_{=\{e\}}.$$

In other words we obtain the short exact sequence

$$\{e\} \to \pi_1(Y, y_0) \xrightarrow{p_*} \pi_1(B, b_0) \xrightarrow{\partial} \pi_0(F, y_0) \to \{e\}.$$

We draw the following two conclusions:

(a) The map $p_*\colon \pi_1(Y, y_0) \to \pi_1(B, b_0)$ is a monomorphism.

(b) With a little bit of extra thought[1846] we obtain from the short exact sequence, Proposition 154.5, the Fibration-LES Theorem 154.7 (1c) and Lemma 153.2 that $p_*(\pi_1(Y, y_0))$ is a subgroup of $\pi_1(B, b_0)$ of index $\#\pi_0(F, y_0) = \#F = [Y : B]$.

These two statements are precisely the content of Lemma 47.18 and Lemma 48.15 (3).

(2) Since all other homotopy groups of F vanish we see that for any $n \geq 2$ the map $p_*\colon \pi_n(Y, x_0) \to \pi_n(B, b_0)$ is an isomorphism. This result recovers the Coverings-π_n-Proposition 71.13.

We move on to the next application. More precisely we want to apply the Fibration-LES Theorem 154.7 to the case of a Serre fibration of the form $X \times Y \to X$. This leads to a new proof of Propositions 48.20 and 71.8.

[1846] We leave this extra thinking as a mental exercise to the reader.

Proposition 71.8. Let X and Y be two topological spaces and let $x_0 \in X$ and $y_0 \in Y$. We consider the maps

$$\begin{array}{rcl} i\colon X & \to & X \times Y \\ x & \mapsto & (x, y_0) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon Y & \to & X \times Y \\ y & \mapsto & (x_0, y). \end{array}$$

For any $n \in \mathbb{N}$ the map[1847]

$$\begin{array}{rcl} \Phi\colon \pi_n(X, x_0) \times \pi_n(Y, y_0) & \to & \pi_n(X \times Y, (x_0, y_0)) \\ (\varphi, \psi) & \to & i_*(\varphi) \cdot j_*(\psi) \end{array}$$

is an isomorphism.

Proof. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the two obvious projections. On page 3264 we saw that both projections are fibrations. We concentrate on the first projection $p\colon X \times Y \to X$. It is a fibration with fiber $p^{-1}(x_0) = \{x_0\} \times Y$. Using the obvious homeomorphism $Y \to \{x_0\} \times Y$ we obtain from the Fibration-LES Theorem 154.7 the long exact sequence

$$\ldots \to \pi_n(Y, y_0) \xrightarrow{j_*} \pi_n(X \times Y, (x_0, y_0)) \xrightarrow{p_*} \pi_n(X, x_0) \to \pi_{n-1}(Y, y_0)) \xrightarrow{j_*} \ldots.$$

Evidently we have $q \circ j = \mathrm{id}_Y$ which implies that $q_* \circ j_* = \mathrm{id}_{\pi_1(Y, y_0)}$. It follows that for every $n \in \mathbb{N}_0$ the map $j_*\colon \pi_n(F, (x_0, y_0)) \to \pi_n(X \times Y, (x_0, y_0))$ is a monomorphism. Thus for each $n \in \mathbb{N}$ we see that

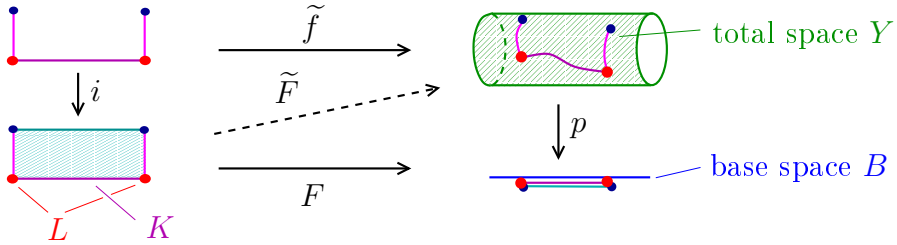
$$0 \to \pi_n(Y, y_0) \xrightarrow{j_*} \pi_n(X \times Y, (x_0, y_0)) \xrightarrow{p_*} \pi_n(X, x_0) \to 0$$

is exact. Once again using that $q_* \circ j_* = \mathrm{id}$ we obtain from Splitting Lemma 78.2 that the given map

$$\begin{array}{rcl} \Phi\colon \pi_n(X, x_0) \times \pi_n(Y, y_0) & \to & \pi_n(X \times Y, (x_0, y_0)) \\ (\varphi, \psi) & \to & i_*(\varphi) \cdot j_*(\psi) \end{array}$$

is indeed an isomorphism. ■

Even these modest applications should already convince the reader that it is worth proving the Fibration-LES Theorem 154.7. After the proof we will give many more examples of fibrations and we will find many more interesting applications.



154.4. **Proof of the Fibration-LES Theorem 154.7.** The proof of the Fibration-LES Theorem 154.7 requires some preparations, i.e. we first need to prove some propositions.

Proposition 154.8. Let $p\colon Y \to B$ be a Serre fibration and let (K, L) be a pair of CW-complexes. We denote by $i\colon K \times \{0\} \cup L \times [0, 1] \to K \times [0, 1]$ the inclusion map. Given any map $F\colon K \times [0, 1] \to B$ and given any map $\widetilde{f}\colon K \times \{0\} \cup L \times [0, 1] \to Y$ with $p \circ \widetilde{f} = F \circ i$

[1847] Note that for $n \geq 2$ the map is a group homomorphism since in this case the group on the right-hand side is abelian. It is a priori not completely clear that the map is also a homomorphism for $n = 1$, but we will see in the proof that the map is indeed a homomorphism.

there exists a map $\widetilde{F}\colon K \times [0,1] \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} K \times \{0\} \cup L \times [0,1] & \xrightarrow{\widetilde{f}} & Y \\ \downarrow{\scriptstyle i} & \overset{\widetilde{F}}{\nearrow ??} & \downarrow{\scriptstyle p} \\ K \times [0,1] & \xrightarrow[F]{} & B. \end{array}$$

Proof. We start out with a reformulation of our task: Given $n = 0, 1, 2, 3, \ldots$ we need to define maps

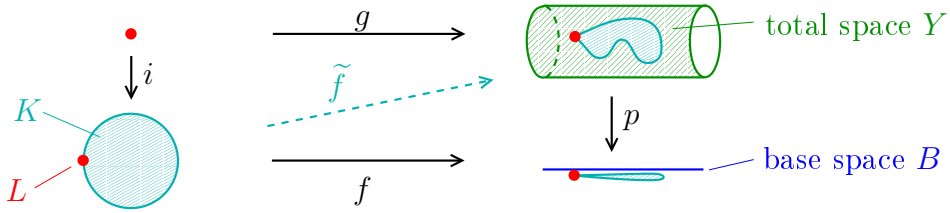
$$\widetilde{F}^n\colon (K \times \{0\}) \cup (K^n \cup L) \times [0,1] \;\to\; Y$$

that make the above diagram commute and which have the property that for $n < m$ the maps $\widetilde{F}^n$ and $\widetilde{F}^m$ agree on the common domain.

We set $\widetilde{F}^{-1} = \widetilde{f}$. Suppose we have already defined maps $\widetilde{F}^{-1}, \ldots, \widetilde{F}^{n-1}$ as above. Let $\{\Phi_i\colon (\overline{B}^n, S^{n-1}) \to (K^n, L^{n-1})\}_{i \in I}$ be the characteristic maps of the n-cells of K that do not lie in L. Recall that by Lemma 154.2 (1) there exists a homeomorphism

$$\Psi\colon \big(\overline{B}^n \times [0,1], (\overline{B}^n \times \{0\}) \cup (S^{n-1} \times [0,1])\big) \;\overset{\cong}{\to}\; \big(\overline{B}^n \times [0,1], \overline{B}^n \times \{0\}\big).$$

For each $i \in I$ we consider the following diagram



$$\begin{array}{ccccc} \overline{B}^n \times \{0\} & \xrightarrow{\Psi^{-1}} & \overline{B}^n \times \{0\} \cup S^{n-1} \times \{1\} & \xrightarrow{\widetilde{F}^{n-1} \circ \Phi_i} & Y \\ \downarrow & & \downarrow & \overset{\Xi_i}{\nearrow} & \downarrow{\scriptstyle p} \\ \overline{B}^n \times [0,1] & \xrightarrow[\Psi^{-1}]{} & \overline{B}^n \times [0,1] & \xrightarrow[F \circ \Phi_i]{} & B. \end{array}$$

One can easily verify that the two rectangles commute. Since $p\colon Y \to B$ is a Serre fibration there exists a map $\Xi_i\colon \overline{B}^n \times [0,1] \to Y$ that makes the diagram commute. These maps $\{\Xi_i\}_{i \in I}$ can now be used to extend $\widetilde{F}^{n-1}$ to the desired map $\widetilde{F}^n$. ∎

Proposition 154.9. Let $p\colon Y \to B$ be a Serre fibration and let (K, L) be a pair of CW-complexes such that L is a deformation retract of K. We denote by $i\colon L \to K$ the inclusion map. Given any map $f\colon K \to B$ and given any map $g\colon L \to Y$ with $f \circ i = p \circ g\colon L \to B$ there exists a map $\widetilde{f}\colon K \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} L & \xrightarrow{g} & Y \\ {\scriptstyle i}\downarrow & \overset{\widetilde{f}}{\nearrow} & \downarrow{\scriptstyle p} \\ K & \xrightarrow[f]{} & B. \end{array}$$

Example. Later on we will apply Proposition 154.9 to the special case that $K = \overline{B}^n$ and that $L = \{(0, \ldots, 0, 1)\}$. We refer to the figure below for an illustration.

Proof. We make the following preparations:

(1) Since L is a deformation retract of K there exists by definition of a deformation retraction, see page 433, a homotopy $H\colon K \times [0,1] \to K$ rel L such that $H_0 = \mathrm{id}_K$ and $H_1(K) \subset L$. We denote by $r = H_1\colon K \to L$ the corresponding retraction.

(2) We denote by $\mathrm{proj}\colon L \times [0,1] \to L$ the obvious projection.

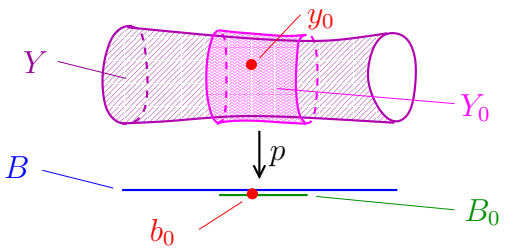
Now we consider the following commutative diagram

$$\begin{array}{ccccccc} L \times \{0\} & \hookrightarrow & K \times \{1\} \cup L \times [0,1] & \xrightarrow{r \cup \mathrm{proj}} & L & \xrightarrow{g} & Y \\ \downarrow & & \downarrow & & \downarrow & & \downarrow p \\ K \times \{0\} & \hookrightarrow & K \times [0,1] & \xrightarrow[H]{} & K & \xrightarrow[f]{} & B. \end{array}$$

To be somewhat more precise, the map $r \cup \mathrm{proj}\colon K \times \{1\} \cup L \times [0,1]$ is defined via the retraction r on $K = K \times \{1\}$ and the projection $L \times [0,1] \to L$. The right-hand square commutes by our hypothesis. One easily verifies that the middle square commutes. It follows from Proposition 154.8 that there exists a map $\Phi\colon K \times [0,1] \to Y$ that makes the diagram commute. For any $k \in K$ we have

$$(p \circ \Phi)(k,0) \;=\; f(H(k,0)) \;=\; f(\mathrm{H}_0(k)) \;=\; f(k)$$

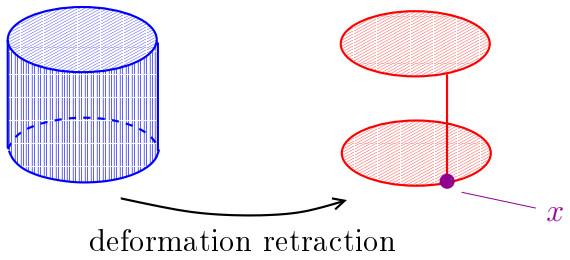
and for any $l \in L$ we have



$$\Phi(l,0) \;=\; (g \circ \mathrm{proj})(l,0) \;=\; g(\mathrm{proj}(l,0)) \;=\; g(l).$$

This shows that the restriction of Φ to $K = K \times \{0\}$ has the desired properties. ∎

Proposition 154.10. Let $p\colon Y \to B$ be a Serre fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$. Let $B' \subset B$ be any subset with $b_0 \in B'$. We set $Y' := p^{-1}(B')$. Then

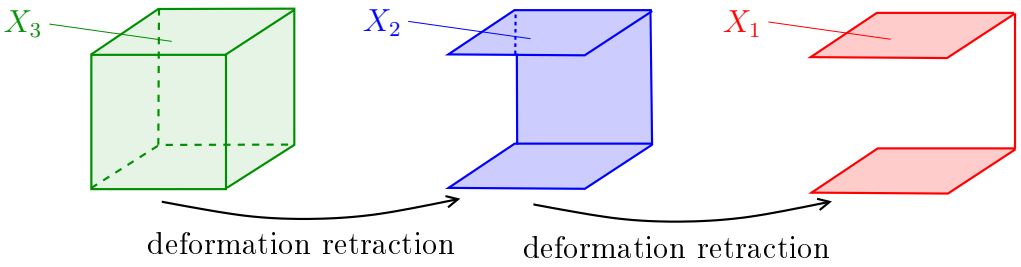


$$p_*\colon \pi_n(Y, Y', y_0) \;\to\; \pi_n(B, B', b_0)$$

is an isomorphism for all $n \in \mathbb{N}$. (We refer to the figure below for an illustration.)

In the proof of Proposition 154.10 we will need the following elementary lemma.

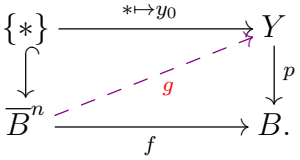
Lemma 154.11. Let $n \in \mathbb{N}$. If $x \in S^{n-1}$, then $(\overline{B}^n \times \partial[0,1]) \cup (\{x\} \times [0,1])$ is a deformation retract of $\overline{B}^n \times [0,1]$.



Proof of Lemma 154.11. As usual we write $I = [0,1]$. Given $k \in \{1, \ldots, n\}$ we consider

$$X_k \;:=\; (I^{n-1} \times \partial I) \;\cup\; (\{\underbrace{(1,1,\ldots,1)}_{\in \mathbb{R}^{n-k}}\} \times I^k).$$

(We refer to the figure below for an illustration.) Using the Convex-to-Ball Proposition 2.20 (2) and the Orthogonal Action Lemma 5.26 (3) one can show easily that there exists a homeomorphism



$$(\overline{B}^n \times [0,1], (\overline{B}^n \times \{0,1\}) \cup (\{x\} \times [0,1])) \;\overset{\cong}{\to}\; (X_n, X_1).$$

Thus it suffices to show that each X_i is a deformation retract of X_{i+1}. But such deformation retractions one can actually write down by hand. ∎

Proof of Proposition 154.10. Let $p\colon Y \to B$ be a Serre fibration and let $n \in \mathbb{N}$. Furthermore let $y_0 \in Y$. We write $b_0 = p(y_0)$. Finally let $B' \subset B$ be any subset with $b_0 \in B'$. We set $Y' := p^{-1}(B')$. Throughout this proof we use the identification from page 3251, i.e. we view elements in a relative homotopy group $\pi_n(X, A, x_0)$ as homotopy classes of maps $(\overline{B}^n, S^{n-1}, *) \to (X, A, x_0)$.

First we show that $p_*\colon \pi_n(Y, Y', y_0) \to \pi_n(B, B', b_0)$ is an epimorphism. Thus suppose we are given a map $f\colon (\overline{B}^n, S^{n-1}, *) \to (B, B', b_0)$. It follows from Proposition 154.9, applied to $(K, L) = (\overline{B}^n, *)$, that there exists a map $g\colon \overline{B}^n \to Y$ such that the following diagram commutes:

Basically by definition g is a map $(\overline{B}^n, S^{n-1}, *) \to (Y, Y', y_0)$. Since $f = p \circ g$ we have $[f] = p_*([g])$.

Next we show that $p_*\colon \pi_n(Y, Y', y_0) \to \pi_n(B, B', b_0)$ is also a monomorphism. Therefore suppose that we are given two maps $g_0, g_1\colon (\overline{B}^n, S^{n-1}, *) \to (Y, Y', y_0)$ such that the equality $p_*([g_0]) = p_*([g_1]) \in \pi_n(B, B', b_0)$ holds. This equality means that $p \circ g_0$ is homotopic to $p \circ g_1$ via a homotopy $F\colon (\overline{B}^n, S^{n-1}, *) \times [0,1] \to (B, B', b_0)$. We consider the following commutative diagram (first without the dashed arrow):

$$\begin{array}{ccc} (\overline{B}^n \times \{0,1\}) \cup (\{*\} \times [0,1]) & \xrightarrow{\text{via } g_0, g_1} & Y \\ \big\downarrow & \overset{\widetilde{F}}{\nearrow} & \big\downarrow p \\ \overline{B}^n \times [0,1] & \xrightarrow[F]{} & B. \end{array}$$

By Proposition 154.9 and Lemma 154.11 there exists a map $\widetilde{F}\colon \overline{B}^n \times [0,1] \to Y$ such that the above diagram commutes. This map $\widetilde{F}\colon \overline{B}^n \times [0,1] \to Y$ is easily seen to be a homotopy between g_0 and g_1 which shows that $[g_0] = [g_1] \in \pi_n(Y, Y', y_0)$. ■

With these preparations it is surprisingly easy to provide a proof of the Fibration-LES Theorem 154.7 (1) and (2).

Proof of the Fibration-LES Theorem 154.7 (1) and (2). Let $p\colon Y \to B$ be a Serre fibration. Furthermore let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$. We denote by $i\colon F \to Y$ the inclusion map. We consider the following diagram of maps

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \pi_n(F, y_0) & \xrightarrow{i_*} & \pi_n(Y, y_0) & \longrightarrow & \pi_n(Y, F, y_0) & \xrightarrow{\partial_n} & \pi_{n-1}(F, y_0) & \xrightarrow{i_*} & \ldots \\ & & & & & & \cong \big\downarrow p_* & & & & \\ & & & & & & \pi_n(B, \{b_0\}, b_0) & & & & \\ & & & & & & \big\downarrow = & & & & \\ & & & & & & \pi_n(B, b_0). & & & & \end{array}$$

We make the following comments:

(a) The top sequence of maps is the long exact sequence of homotopy groups of the pointed pair of topological spaces (Y, F, y_0), see the Homotopy Groups-LES Proposition 153.4 for details.
(b) The top vertical map is an isomorphism by Proposition 154.10.
(c) The bottom vertical map is the identification given on page 3239.
(d) It follows immediately from the definitions that the left-hand triangle commutes.
(e) The right-hand triangle commutes by definition of the diagonal map.

It follows immediately from the definition of p_* that given any $n \in \mathbb{N}$ the map

$$\partial_n \circ p_*^{-1}\colon \pi_n(B, b_0) \to \pi_{n-1}(F, y_0)$$

is given by

$$[\varphi\colon (I^n, \partial I^n) \to (B, b_0)] \mapsto \left[\begin{array}{c} \text{the restriction of } \widetilde{\varphi} \text{ to } I^{n-1} = I^{n-1} \times \{0\} \\ \text{where } \widetilde{\varphi} \text{ is a map } (I^n, J^{n-1}) \to (Y, \{y_0\}) \\ \text{with } p \circ \widetilde{\varphi} = \varphi \end{array}\right].$$

This observation shows that the map given in Statement (1) of the theorem is well-defined and that it is a homomorphism (respectively a morphism of pointed sets). We leave it to the few readers who made it that far to verify that the maps ∂_n have the two properties stated in (1b) and (1c).

Furthermore, since the top sequence is exact and since the vertical maps are isomorphisms we see that the sequence given in Statement (2) of the theorem is indeed exact. ■

Proof of the Fibration-LES Theorem 154.7 (3). Let $p\colon Y \to B$ be a Serre fibration. Furthermore let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$. We denote by $i\colon F \to Y$ the inclusion map. Now we suppose that the inclusion map $i\colon F \to Y$ is homotopic rel y_0 to the constant map $c_{y_0}\colon F \to \{y_0\}$. Put differently, we suppose that there exists a homotopy $G\colon F \times [0,1] \to Y$ rel y_0 such that $G_0 = i$ and $G_1(f) = y_0$ for every $f \in F$.

It follows almost immediately from Lemmas 78.2 and 78.4 that it suffices to show that for any $n \in \mathbb{N}_{\geq 2}$ there exists a homomorphism $\lambda\colon \pi_{n-1}(F, y_0) \to \pi_n(B, b_0)$ such that $\partial_n \circ \lambda = \mathrm{id}_{\pi_{n-1}(F,y_0)}$. We consider the map[1848]

$$\begin{aligned} \lambda\colon \pi_{n-1}(F, y_0) &\to \pi_n(Y, F, y_0) \xrightarrow{p_*} \pi_n(B, \{b_0\}, b_0) = \pi_n(B, b_0) \\ [\varphi\colon (I^{n-1}, \partial I^{n-1}) \to (F, y_0)] &\mapsto \left[\begin{array}{c}(I^n, \partial I^n, J^{n-1}) \to (Y, F, \{y_0\}) \\ (x,t) \mapsto G(\varphi(x), t)\end{array}\right] \end{aligned}$$

It is elementary to verify that λ is in fact a homomorphism. It follows almost immediately from the definitions that $\partial_n \circ \lambda = \mathrm{id}_{\pi_{n-1}(F,y_0)}$. ■

154.5. **The path space fibration.** We recall the following, long dormant, definition from page 392.

Definition. Let X and Y be topological spaces.

(1) We denote by $X^Y = C(Y, X)$ the set of all maps[1849] from Y to X.

(2) The compact-open topology on X^Y is the topology generated, in the sense of the definition on page 135, by all the sets of the form

$$M(K, U) := \{f \in X^Y \mid f(K) \subset U\}$$

where $K \subset Y$ is compact and where $U \subset X$ is open.

In the following we state slightly simplified versions of two technical results which we proved a long time ago.

Proposition 12.4. Let X be a topological space.

(1) The evaluation map

$$\begin{aligned} e\colon X^{[0,1]} \times [0,1] &\to X \\ ((f\colon [0,1] \to X), y) &\mapsto f(y) \end{aligned}$$

is continuous.

[1848] It takes a second to actually verify that the map $(x,t) \mapsto G(\varphi(x), t)$ defines in fact a map $(I^n, \partial I^n, J^{n-1}) \to (Y, F, \{y_0\})$.

[1849] Of course here we mean "all continuous maps".

(2) For each $y \in [0,1]$ the evaluation map

$$\begin{array}{rcl} e\colon X^{[0,1]} & \to & X \\ (f\colon [0,1] \to X) & \mapsto & f(y) \end{array}$$

is continuous.

Proposition 12.6. Let X and T be two topological spaces. Let $H\colon T \times [0,1] \to X$ be a map. Given $t \in T$ we denote by $H_t\colon [0,1] \to X$ the map defined by $H_t(y) = H(t,y)$. Then

$$H\colon T\times[0,1] \to X \text{ is continuous } \Leftrightarrow \begin{array}{l} (1)\ \text{each } H_t\colon [0,1] \to X \text{ is continuous, and} \\ (2)\ \text{the map } T \to X^{[0,1]} \text{ given by } t \mapsto H_t \text{ is continuous.} \end{array}$$

This reminder allows us to introduce our latest best friends.

Definition. Let X be a topological space.

(1) We define

$$\text{free path space } X^{[0,1]} \ := \ \text{set of all maps } [0,1] \to X$$

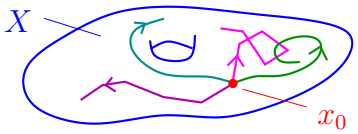
where $X^{[0,1]}$ is as usual equipped with the compact-open topology. Furthermore we introduce the

$$\text{free loop space } \Omega(X) \ := \ \{f \in X^{[0,1]} \mid f(0) = f(1)\}.$$

We equip the free loop space with the compact-open topology coming from $X^{[0,1]}$.

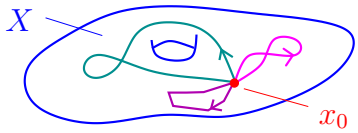
(2) Suppose we are also given a base point $x_0 \in X$. We introduce the

$$\begin{array}{rcl} \text{path space } P(X,x_0) & := & \{f \in X^{[0,1]} \mid f(0) = x_0\} \\ \text{loop space } \Omega(X,x_0) & := & \{f \in X^{[0,1]} \mid f(0) = f(1) = x_0\}. \end{array}$$



and the

We equip both sets with the compact-open topology coming from $X^{[0,1]}$.



(3) We denote by $c_{x_0}\colon [0,1] \to X$ the constant path given by sending all t's to x_0.

elements in the free path space $X^{[0,1]}$

elements in the path space $P(X,x_0)$

elements in the loop space $\Omega(X,x_0)$

Examples.

(1) Let (X,x_0) be a pointed topological space and let $\alpha, \beta \in \Omega(X,x_0)$. It follows from the Compact-Open Exponential Proposition 12.6 that a path in $\Omega(X,x_0)$ from α to β is basically the same as a homotopy between the maps α and β viewed as loops in (X,x_0). Thus we see that we have a natural identification

$$\pi_0(\Omega(X,x_0)) \ = \ \pi_1(X,x_0).$$

(2) Let (X,x_0) be a pointed topological space. It follows from Proposition 12.4 that the map

$$\begin{array}{rcl} e\colon P(X,x_0) & \to & X \\ f & \mapsto & f(1) \end{array}$$

is continuous. We can ask whether this map has a left-inverse. More precisely, the question is whether there exists a continuous map $s\colon X \to P(X, x_0)$ such that $e(s(x)) = x$ for all $x \in X$. This sounds like a rather random question, so let us reformulate it. The question is, can we *continuously* assign to each $x \in X$ a path from x_0 to x? Clearly that is possible say for $(X, x_0) = (\mathbb{R}^2, 0)$, we just assign to each $x \in \mathbb{R}^2$ the direct path $e(x)$ that is given by $t \mapsto t \cdot x$. But can we do so say for $X = S^1$ or $X = S^2$?[1850] We will answer this question in Exercise 154.2.

For the record we state the following lemma.

Lemma 154.12. The maps

$$\begin{array}{rcl} (X, x_0) & \mapsto & (\Omega(X, x_0), c_{x_0}) \\ (f\colon (X, x_0) \to (Y, y_0)) & \mapsto & \left(\begin{array}{rcl} \Omega(X, x_0) & \to & \Omega(Y, y_0) \\ (\gamma\colon [0,1] \to X) & \mapsto & (f \circ \gamma\colon [0,1] \to Y) \end{array} \right) \end{array}$$

define a covariant functor from the category $\mathcal{PTop}$ of pointed topological spaces to the category $\mathcal{PTop}$ of pointed topological spaces. We refer to this functor as the *loop space functor*.

Proof. Let $f\colon (X, x_0) \to (Y, y_0)$ be a map between pointed topological spaces. It follows from the Compact-Open Functoriality Lemma 12.5 (1) that the map

$$\begin{array}{rcl} \Omega(X, x_0) & \to & \Omega(Y, y_0) \\ (\gamma\colon [0,1] \to X) & \mapsto & (f \circ \gamma\colon [0,1] \to Y) \end{array}$$

is actually continuous. With this observation out of the way it is straightforward to prove the lemma. ∎

The following lemma says that in some sense (free) path spaces, in isolation, are not particularly interesting examples of topological spaces.

Lemma 154.13.

(1) Let X be a topological space. We view X as a subset of the free path space $X^{[0,1]}$ via the inclusion $x \mapsto c_x$.[1851] Then X is a deformation retract of the free path space $X^{[0,1]}$.

(2) If (X, x_0) is a pointed topological space, then $\{c_{x_0}\}$ is a deformation retract of the path space $P(X, x_0)$, in particular the path space $P(X, x_0)$ is contractible.

Proof. We prove Statement (2). The proof of Statement (1) is basically identical. Thus let (X, x_0) be a pointed topological space. We consider the "obvious" deformation retraction given by

[1850] This question is somewhat similar to Question 83.7 and it also falls into the vaguely defined realm of "topological robotics".

[1851] Note that this inclusion $X \to X^{[0,1]}$ is by the Constant Map Lemma 12.3 an embedding.

$$\begin{array}{rcl} F\colon P(X,x_0)\times[0,1] & \to & P(X,x_0) \\ ((f\colon [0,1]\to X),t) & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & X \\ s & \mapsto & f(s\cdot(1-t)) \end{array}\right) \end{array}$$

The only reason why we are not already done is that we still need to verify that F is in fact continuous. As we will see this is slightly delicate. We consider the map

$$G\colon \underbrace{X^{[0,1]}\times[0,1]}_{=:T} \to X^{[0,1]}$$

that is defined in exactly the same way as F. Since $F = G|_{P(X,x_0)\times[0,1]}$ it suffices to show that G is continuous. By the "$\Rightarrow$"-direction of the Compact-Open Exponential Proposition 12.6 applied to $T = X^{[0,1]}\times[0,1]$ it suffices to show that the map

$$\begin{array}{rcl} H\colon [0,1]\times\overbrace{(X^{[0,1]}\times[0,1])}^{=T} & \to & X \\ (s,((g\colon [0,1]\to X),x)) & \mapsto & g(s\cdot x) \end{array}$$

is continuous. But the map H can be written as the composition

$$\begin{array}{rcccl} H\colon [0,1]\times X^{[0,1]}\times[0,1] & \to & X^{[0,1]}\times[0,1] & \to & X \\ (s,g,x) & \mapsto & (g,s\cdot(1-x)) & & \\ & & (g,t) & \mapsto & g(t). \end{array}$$

The first map is continuous by the Topological-Product Proposition 5.1 (1) and the second map is continuous by the Evaluation Map Proposition 12.4 (1). Thus we see that H itself is continuous. ■

In contrast to the previous proposition the following theorem shows that (free) path spaces give rise to interesting *maps*.

Theorem 154.14. (Path Space-Fibration Theorem)

(1) Let X be a topological space. The evaluation map

$$\begin{array}{rcl} p\colon X^{[0,1]} & \to & X \\ (f\colon [0,1]\to X) & \mapsto & f(1) \end{array}$$

is a fibration. Furthermore, given any $x_0\in X$ the fiber $p^{-1}(x_0)$ is the topological space of all paths $[0,1]\to X$ that *end* in x_0.

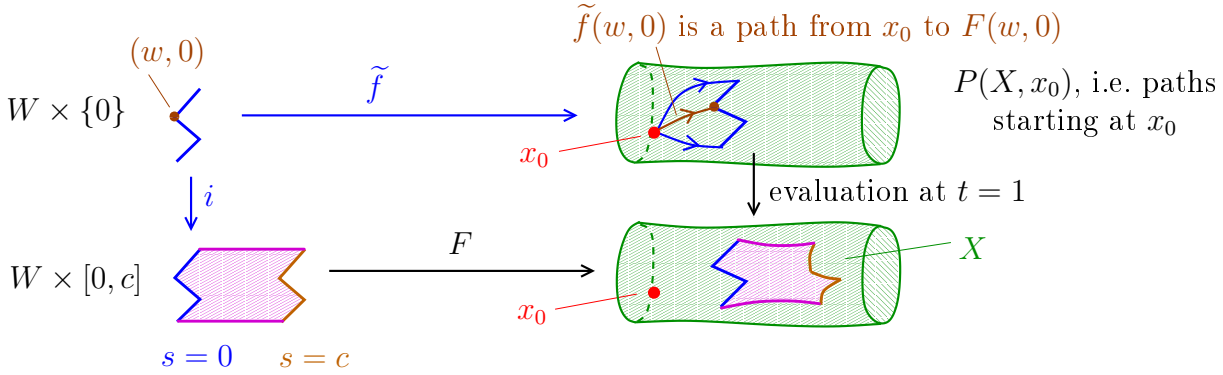
(2) Let (X,x_0) be a pointed topological space. The evaluation map

$$\begin{array}{rcl} p\colon P(X,x_0) & \to & X \\ (f\colon [0,1]\to X) & \mapsto & f(1) \end{array}$$

is a fibration with fiber $p^{-1}(x_0) = \Omega(X,x_0)$.

the Path Space-Fibration Theorem 154.14 leads us to the following definition.

Definition.



(1) Let X be a topological space. We refer to the above fibration $p\colon X^{[0,1]}\to X$ as the free path space fibration of X.

(2) Let (X,x_0) be a pointed topological space. In the following we refer to the above fibration $p\colon P(X,x_0)\to X$ as the path space fibration of (X,x_0).

Proof. We prove Statement (2). The proof of Statement (1) is basically identical and is thus left to the reader. Thus let (X, x_0) be a pointed topological space. First note that the map $p\colon P(X, x_0) \to X$ is continuous by the Evaluation Map Proposition 12.4 (2). Next recall that we need to solve the following type of extension problem for some topological space W and $c > 0$: [1852]

$$\begin{array}{ccc} W \times \{0\} & \xrightarrow{\widetilde{f}} & P(X, x_0) \subset X^{[0,1]} \\ \downarrow & \overset{\widetilde{F}}{\nearrow} & \Big\downarrow p \quad \Big\downarrow \gamma \mapsto \gamma(1) \\ W \times [0, c] & \xrightarrow[F]{} & X. \end{array}$$

We refer to the figure below for an illustration.

The idea for the proof is quite simple: Given $(w, s) \in W \times [0, c]$ we have to "systematically" find an element $\gamma \in P(X, x_0)$ with $p(\gamma) = F(w, s)$, i.e. we have to find a path $\gamma\colon [0, 1] \to X$ from x_0 to $F(w, s)$. But there is an obvious path, namely we first travel along $\widetilde{f}(w, 0)$ from x_0 to $F(w, 0)$ and then we use the path $t \mapsto F(w, t)$ to get from $F(w, 0)$ to $F(w, s)$. That is exactly what we will do, except that we need to be a little careful with our parametrizations.

Now we have to turn this idea into a proper proof. We consider the map

$$\begin{array}{rcl} \widetilde{F}\colon W \times [0, c] & \to & P(X, x_0) \\ (w, s) & \mapsto & \left(\begin{array}{rcl} [0, 1] & \to & X \\ t & \mapsto & \begin{cases} \widetilde{f}(w, 0)\big(\frac{t}{1 - \frac{s}{2c}}\big), & \text{if } t \in [0, 1 - \frac{s}{2c}], \\ F(w, 2 \cdot (t - 1 + \frac{s}{2})), & \text{if } t \in [1 - \frac{s}{2c}, 1] \end{cases} \end{array} \right). \end{array}$$

We claim that this map has all the desired properties:

(1) Let $(w, s) \in W \times [0, c]$. We make the following observations:
   (a) The given map $[0, 1] \to X$ starts at x_0.
   (b) It follows easily from Pasting Proposition 2.6 (2) that the given map $[0, 1] \to X$ is indeed continuous.

   In other words, the given map $[0, 1] \to X$ does indeed define an element in $P(X, x_0)$.

[1852] In the diagram we write $W \times [0, c]$ instead of the more customary $W \times [0, 1]$ for purely psychological reasons, it makes it easier to distinguish the two types of intervals which arise throughout the proof and which play very different roles.

(2) For each $(w,s) \in W \times [0,c]$ we have by construction that $\widetilde{F}(w,s)(t=1) = F(w,s)$. In other words, we have $p \circ \widetilde{F} = F$.

Thus it remains to prove the following claim:

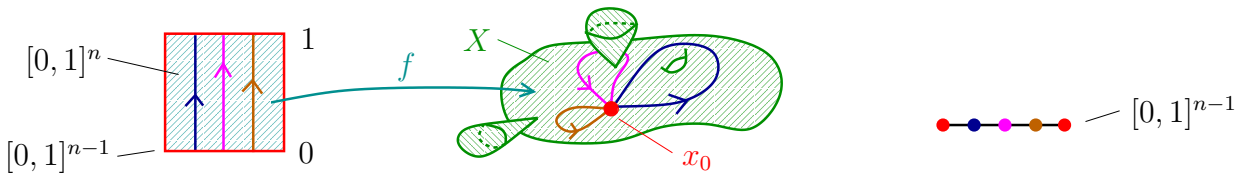
Claim. The map $\widetilde{F}\colon W \times [0,c] \to P(X,x_0)$ is continuous.

Proof. We consider the map

$$\begin{array}{rcl} \widetilde{G}\colon W \times [0,c] \times [0,1] & \to & X \\ (w,s,t) & \mapsto & \widetilde{F}(w,s)(t) = \begin{cases} \widetilde{f}(w,0)\big(\frac{t}{1-\frac{s}{2c}}\big), & \text{if } t \in [0,1-\frac{s}{2c}], \\ F(w,2\cdot(t-1+\frac{s}{2})), & \text{if } t \in [1-\frac{s}{2c},1]. \end{cases} \end{array}$$

It follows easily from the fact that F and $\widetilde{f}$ are continuous that the restrictions of $\widetilde{G}$ to the closed subsets

$$\begin{array}{rcl} A_1 & := & W \times \{(s,t) \in [0,c] \times [0,1] \,|\, t \in [0,1-\frac{s}{2c}]\}, \\ \text{and} \quad A_2 & := & W \times \{(s,t) \in [0,c] \times [0,1] \,|\, t \in [1-\frac{s}{2c},1]\} \end{array}$$



are continuous. Therefore it follows from the Pasting Proposition 2.6 (2) that $\widetilde{G}$ is continuous. Finally we deduce from the "$\Rightarrow$"-direction of the Compact-Open Exponential Proposition 12.6 applied to $T = W \times [0,c]$, $Y = [0,1]$ and $H = \widetilde{G}$ that $\widetilde{F}$ is also continuous. ∎

We obtain the following amusing corollary which later on will turn out to play an important role.

Corollary 154.15. (Loop Space-Homotopy Groups Corollary) Given any pointed topological space (X,x_0) and any $n \geq 1$ the map[1853]

$$\begin{array}{rcl} \partial_n\colon \pi_n(X,x_0) & \stackrel{\cong}{\to} & \pi_{n-1}(\Omega(X,x_0),c_{x_0}) \\ [f\colon ([0,1]^n,\partial([0,1]^n)) \to (X,x_0)] & \mapsto & \left[\begin{array}{r} ([0,1]^{n-1},\partial([0,1]^{n-1})) \to (\Omega(X,x_0),c_{x_0}) \\ x \mapsto \left(\begin{array}{r} [0,1] \to X \\ t \mapsto f(x,t) \end{array} \right) \end{array} \right] \end{array}$$

is a natural isomorphism.

Remark. For $n = 1$ the statement of the Loop Space-Homotopy Groups Corollary 154.15 recovers the result from page 3280 where we saw that there exists a natural identification

$$\pi_0(\Omega(X,x_0),c_{x_0}) \;=\; \pi_1(X,x_0).$$

Proof. There are two approaches to proving the corollary, namely one can prove it by "the machine" and one can prove it "by hand".

[1853] Using the Compact-Open Exponential Proposition 12.6 one can show directly, with some slight effort, that the map ∂_n is well-defined.

(1) Let $f\colon (X,x_0)\to(Y,y_0)$ be a map between pointed topological spaces. It is clear that we obtain a commutative diagram

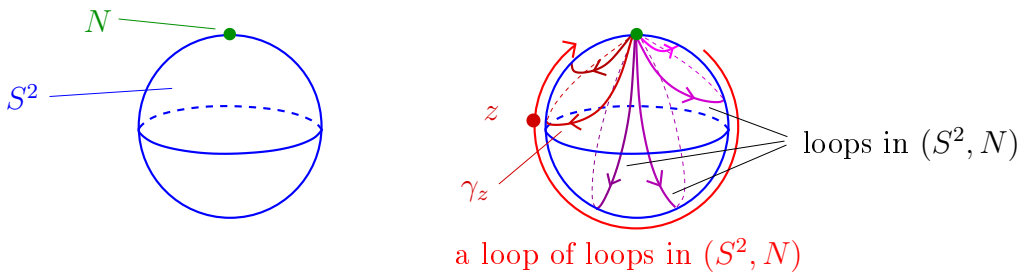
$$\begin{array}{ccc} P(X,x_0) & \xrightarrow{\gamma\mapsto f\circ\gamma} & P(Y,y_0) \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{\quad f\quad} & Y. \end{array}$$

It follows from Theorems 154.14 (1) and (2) and 154.7 that we have commutative diagram of long exact sequences

$$\begin{array}{ccccccccc} \ldots\to\pi_n(P(X,x_0),c_{x_0}) & \to & \pi_n(X,x_0) & \xrightarrow{\partial} & \pi_{n-1}(\Omega(X,x_0),c_{x_0}) & \to & \pi_{n-1}(P(X,x_0),c_{x_0}) & \to & \ldots \\ \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ \ldots\to\pi_n(P(Y,y_0),c_{y_0}) & \to & \pi_n(Y,y_0) & \xrightarrow{\partial} & \pi_{n-1}(\Omega(Y,y_0),c_{y_0}) & \to & \pi_{n-1}(P(Y,y_0),c_{y_0}) & \to & \ldots \end{array}$$

We obtain from Lemma 154.13 and the Homotopy-π_n-Proposition 71.7 (2) that the homotopy groups of the path spaces $P(X,x_0)$ and $P(Y,y_0)$ are trivial. Thus the connecting homomorphisms are *natural* isomorphisms. We leave it to the reader to verify that in our situation the connecting homomorphisms from the Fibration-LES Theorem 154.7 are precisely the maps that we wrote down. Incidentally this then also shows that the maps, as written down, actually do make sense.

(2) In Exercise 154.4 we will prove the corollary "by hand". ■



Example. We consider the loop space of the 2-dimensional sphere with the base point given by the North Pole $N=(0,0,1)$. We calculate that

$$\pi_1(\Omega(S^2,N),c_N) \quad \underset{\uparrow}{\overset{\cong}{\leftarrow}} \quad \pi_2(S^2,N) \quad \underset{\uparrow}{\overset{\cong}{\rightarrow}} \quad \mathbb{Z}.$$

Loop Space-Homotopy Groups Corollary 154.15 Corollary 85.6 (1)

In the figure below we see a loop $\{\gamma_z\}_{z\in S^1}$ of loops in the pointed topological space (S^2,N). Put differently, we see a loop in the pointed topological space $(\Omega(S^2,N),c_N)$. It is an amusing and instructive exercise to run through the above two isomorphisms to verify that our loop in the pointed topological space $(\Omega(S^2,N),c_N)$ is actually a generator of $\pi_1(\Omega(S^2,N),c_N)$.

So what does this example actually really mean? It means that even though each individual loop γ_z is null-homotopic in S^2, we cannot continuously deform all the loops γ_z altogether into the constant loop. It is a good idea to think about what it would mean for $[z\mapsto\gamma_z]\in\pi_1(\Omega(S^2,N),c_N)$ to be null-homotopic and why, pictorially, this is not the case in our situation.

Note that the statement of the Loop Space-Homotopy Groups Corollary 154.15 can be summarized as follows: The loop space functor

$$\begin{array}{rccc} \Omega\colon & \begin{array}{c}\text{category } \mathcal{PTop} \text{ of pointed}\\ \text{topological spaces}\end{array} & \to & \begin{array}{c}\text{category } \mathcal{PTop} \text{ of pointed}\\ \text{topological spaces}\end{array} \\ & (X,x_0) & \mapsto & (\Omega(X,x_0),c_{x_0}) \end{array}$$

shifts homotopy groups down by one degree, i.e. for every pointed topological space (X,x_0) and every $n\in\mathbb{N}$ we have a natural isomorphism

$$\pi_n(X,x_0) \xrightarrow{\cong} \pi_{n-1}(\Omega(X,x_0),c_{x_0}).$$

This should be compared to the fact that in the Suspension-H_*-Proposition 76.7 we saw that the suspension functor

$$\begin{array}{rccc} \Sigma\colon \text{category } \mathcal{Top} \text{ of topological spaces} & \to & \text{category } \mathcal{Top} \text{ of topological spaces} \\ X & \mapsto & \Sigma(X) \end{array}$$

shifts reduced homology groups up by one degree, i.e. for every topological space X and any $n\in\mathbb{N}$ we have a natural isomorphism

$$\widetilde{\mathrm{H}}_n(X) \xrightarrow{\cong} \widetilde{\mathrm{H}}_{n+1}(\Sigma(X)).$$

In Exercise 154.8 we will discuss whether we can also shift homotopy groups *upwards* and whether we can shift reduced homology groups *downwards* in a functorial way.

154.6. **Every map can be replaced by a fibration.** In this section we will see that one can "replace" any map $f\colon X\to Y$ between topological spaces by a fibration $P_f\to Y$ that has very similar properties to the map f.
We start out with the notion of the pullback of a fibration. Perhaps not surprisingly the definition is almost identical to the definition of the pullback of a vector bundle that we gave on page 3069.

Lemma 154.16. (Fibration-Pullback Lemma) Let $f\colon A\to B$ be a map between topological spaces and let $q\colon Z\to B$ be a fibration. As in the Topological-Pullback Lemma 56.16 (1) we consider the pullback

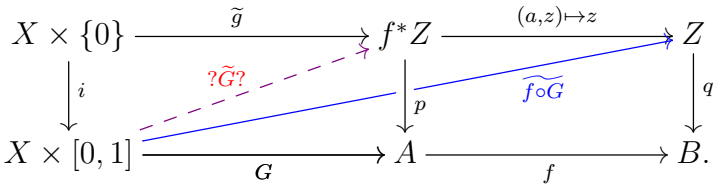
$$f^*Z := \{(a,z)\,|\,a\in A \text{ and } \overbrace{z\in q^{-1}(f(a))}^{\text{i.e. } q(z)=f(a)}\} \subset A\times Z.$$

The following statements hold:

(1) The pullback map

$$\begin{array}{rccc} p\colon f^*Z := \{(a,z)\,|\,a\in A \text{ and } z\in q^{-1}(f(a))\} & \to & A \\ (a,z) & \mapsto & a \end{array}$$

is also a fibration. Furthermore for any $a\in A$ the fiber $p^{-1}(a)$ is homeomorphic to the fiber $q^{-1}(f(a))$.



(2) The following diagram commutes

$$\begin{array}{ccc} f^*Z & \xrightarrow{(a,z)\mapsto z} & Z \\ \downarrow{\scriptstyle p} & & \downarrow{\scriptstyle q} \\ A & \xrightarrow{f} & B. \end{array}$$

Proof.

(2) It is straightforward to verify that the diagram commutes.

(1) Let X be any topological space. We consider the following diagram where initially we ignore the diagonal arrows:

Here the maps $G\colon X \times [0,1] \to A$ and $\widetilde{g}\colon X \times \{0\} \to f^*Z$ are "the challenge" we have to deal with in the definition of a fibration. Since $q\colon Z \to B$ is a fibration there exists a map $\widetilde{f \circ G}\colon X \times [0,1] \to Z$ that makes the diagram commute. It is now straightforward to verify that the map

$$\begin{array}{rcl} X \times [0,1] & \to & f^*Z = \{(a,z) \,|\, a \in A \text{ and } z \in q^{-1}(f(a))\} \\ (x,t) & \mapsto & \big(G(x,t), \big(\widetilde{f \circ G}\big)(x,t)\big) \end{array}$$

makes the above diagram commute. We have thus shown that $p\colon f^*Z \to A$ is also a fibration.

Finally we have to prove the statement regarding the fibers. Thus let $a \in A$. It follows immediately from the definitions that $p^{-1}(a) = \{a\} \times q^{-1}(f(a)) \subset A \times Z$. It follows from the Product Topology-Basics Lemma 5.4 (2a) that the fiber $p^{-1}(a)$ is homeomorphic to the fiber $q^{-1}(f(a))$. ■

Definition. Using the notation from the Fibration-Pullback Lemma 154.16 we refer to $f^*Z \to A$ as the pullback of the fibration $q\colon Z \to B$ under the map $f\colon A \to B$.

Now we turn to the actual problem that we had stated in the beginning of this section.

Definition. Let $f\colon X \to Y$ be a map between topological spaces. Similar to the free path space fibration we now consider the fibration[1854]

$$\begin{array}{rcl} q\colon Y^{[0,1]} & \to & Y \\ \gamma & \mapsto & \gamma(0). \end{array}$$

We refer to the map

$$\begin{array}{rcl} p\colon P_f := f^*(Y^{[0,1]}) = \{(x, \gamma\colon [0,1] \to Y) \in X \times Y^{[0,1]} \,|\, \gamma(0) = f(x)\} & \to & Y \\ (x,\gamma) & \mapsto & \gamma(1) \end{array}$$

as the mapping path fibration.[1855]

In the Replace-by-Cofibration Proposition 17.5 we saw that any map $f\colon X \to Y$ between topological spaces can be "replaced" by a cofibration $X \to \mathrm{Cyl}(f)$. The following proposition is the analogue of the Replace-by-Cofibration Proposition 17.5 for fibrations.

Proposition 154.17. (Replace-by-Fibration Proposition) Let $f\colon X \to Y$ be a map between topological spaces. We denote by $p\colon P_f \to Y$ the corresponding mapping path fibration.

(1) The map

$$\begin{array}{rccl} h\colon & X & \to & P_f \\ & x & \mapsto & (x, \text{constant path } c_{f(x)}) \end{array}$$

is a homotopy equivalence and it has the property that it makes the following diagram commute:

$$\begin{array}{ccc} X & \xrightarrow{\quad h \quad} & P_f \\ & {\scriptstyle f}\searrow \quad \swarrow{\scriptstyle p} & \\ & Y. & \end{array}$$

(2) The map $p\colon P_f \to Y$ is a fibration.[1856] Given any $y \in Y$ the fiber is given by

$$\{(x,\gamma) \,|\, x \in X \text{ and } \gamma\colon [0,1] \to Y \text{ is a path from } f(x) \text{ to } y\}.$$

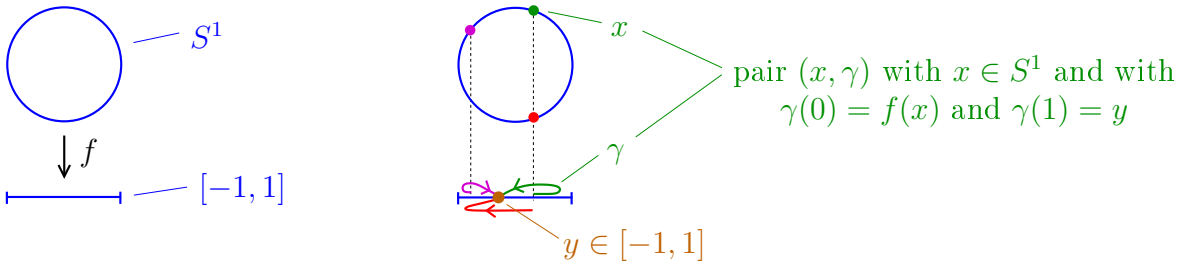
Definition. Let $f\colon X \to Y$ be a map between topological spaces. We suppose that Y is path-connected. We refer to the homotopy type of the fiber of the corresponding mapping path fibration $P_f \to Y$[1857] as the homotopy fiber of f.

Remark. If $f\colon X \to Y$ is a fibration, then it is shown in [**DaK2001**, Theorem 6.18] that the map $h\colon X \to P_f$ in the Replace-by-Fibration Proposition 154.17 (1) is a "fiber homotopy equivalence", thus, loosely speaking, the original fibration $f\colon X \to Y$ and the new fibration $p\colon P_f \to Y$ are essentially the same. We will not make use of this fact.

Example. the Replace-by-Fibration Proposition 154.17 thus says that any map $f\colon X \to Y$ between topological spaces can be "replaced" by a fibration. As a reality check let us consider again the "non-example" from Lemma 154.1, i.e. we consider the map $f\colon S^1 \to [-1,1]$ that is given by the projection onto the x-coordinate. Lemma 154.1 says that f is not a fibration. Let us see what the above construction does in this case.

As pointed out in the Replace-by-Fibration Proposition 154.17 (2), given any $y \in [-1,1]$ the preimage of y under the map $p\colon P_f \to Y = [-1,1]$ is given by

$$p^{-1}(y) \;=\; \{(x,\gamma) \,|\, x \in S^1 \text{ and } \gamma\colon [0,1] \to [-1,1] \text{ is a path from } f(x) \text{ to } y\}.$$



In the figure below we strive to illustrate three points in the preimage of a point $y \in [-1,1]$. In Exercise 154.3 we will see that for each $y \in [-1,1]$ the preimage $p^{-1}(y)$ is homotopy equivalent to S^1. In particular this shows that the homotopy fiber of $f\colon S^1 \to [-1,1]$ is S^1. This exercise does not quite show yet that the map $p\colon P_f \to [-1,1]$ is a fibration, but at the very least it is consistent with the Fiber-Homotopy Type Proposition 154.6 (1).

[1854] This map is basically the same as the free path space fibration except that now we consider the evaluation $\gamma(0)$ instead of the evaluation $\gamma(1)$.

[1855] Note that it follows from the Evaluation Map Proposition 12.4 (2) that this map is in fact continuous.

[1856] This statement justifies the name "mapping path *fibration*".

[1857] Recall that the Fiber-Homotopy Type Proposition 154.6 (1) says that the homotopy type of the fiber of a fibration over a path-connected topological space is well-defined.

Proof of the Replace-by-Fibration Proposition 154.17. Let $f\colon X \to Y$ be a map between topological spaces. We consider the map

$$\begin{array}{rcl} p\colon P_f = f^*(Y^{[0,1]}) = \{(x, \gamma\colon [0,1] \to Y) \in X \times Y^{[0,1]} \,|\, \gamma(0) = f(x)\} & \to & Y \\ (x,\gamma) & \mapsto & \gamma(1). \end{array}$$

We turn to the proof of the two statements:

(1) Given $y \in Y$ we denote, as usual, by $c_y\colon [0,1] \to Y$ the constant path given by $c_y(t) = y$ for all $t \in [0,1]$. We consider the map $h\colon X \to P_f$ that is given by $x \mapsto (x, c_{f(x)})$.[1858] We claim it has the desired properties. It is obvious that $p \circ h = f$, i.e. the diagram given in the proposition commutes. So it remains to show that h is a homotopy equivalence. We consider the map $g\colon P_f \to X$ given by $g(x,\gamma) = x$. Evidently we have $g \circ h = \mathrm{id}_X$. We are done once we have shown that $h \circ g$ is homotopic to id_{P_f}. In fact such a homotopy is given by[1859]

$$\begin{array}{rcl} H\colon P_f \times [0,1] & \to & P_f \\ ((x,\gamma),t) & \mapsto & \left(x, \left(\begin{array}{rcl} [0,1] & \to & Y \\ s & \mapsto & \gamma(s \cdot t) \end{array}\right)\right). \end{array}$$

$\uparrow$

$\gamma\colon [0,1] \to Y$ is a path with $\gamma(0) = f(x)$

One easily verifies that $H_0 = h \circ g$ and that $H_1 = \mathrm{id}_{P_f}$.

(2) We want to show that the map $p\colon P_f \to Y$ is a fibration. Thus let A be any topological space. Let $c > 0$. We consider the following "challenge diagram":[1860]

$$\begin{array}{ccc} A \times \{0\} & \xrightarrow{\widetilde{g}} & P_f = \{(x, \gamma\colon [0,1] \to Y) \in X \times Y^{[0,1]} \,|\, \gamma(0) = f(x)\} \\ \downarrow{\scriptstyle i} & \overset{\widetilde{G}}{\nearrow}{\scriptstyle ??} & \downarrow{\scriptstyle p} \quad (x,\gamma) \mapsto \gamma(1) \\ A \times [0,c] & \xrightarrow[G]{} & Y. \end{array}$$

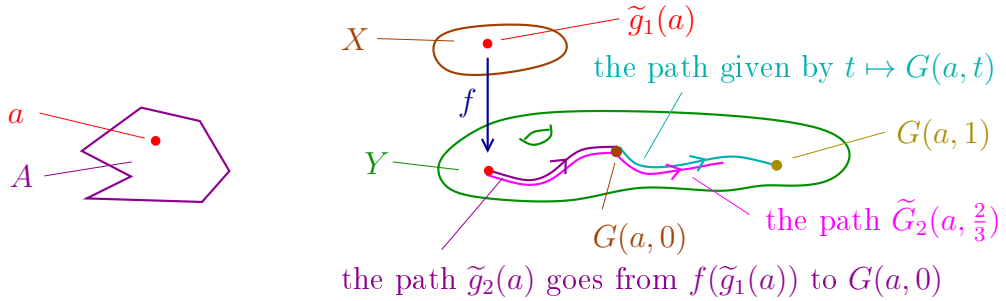
To define $\widetilde{G}$ we first split up the map $\widetilde{g}$ into its components. More precisely, we define maps $\widetilde{g}_1\colon A \to X$ and $\widetilde{g}_2\colon A \to Y^{[0,1]}$ via the equality

$$\widetilde{g}(a,0) \;=\; \big(\widetilde{g}_1(a), \widetilde{g}_2(a)\big) \;\in\; P_f \subset X \times Y^{[0,1]} \qquad \text{for all } a \in A.$$

[1858] It follows from the Product Topology-Basics Lemma 5.4 (3) and the Constant Map Lemma 12.3 that this map is continuous.

[1859] An argument as in the proof of Lemma 154.13 (2) shows that the map H is indeed continuous.

[1860] As in the proof of the Path Space-Fibration Theorem 154.14 we prefer to work, for purely psychological reasons, with $A \times [0,c]$ instead of $A \times [0,1]$.



Note that by definition of P_f the path $\widetilde{g}_2(a) \in Y^{[0,1]}$ is a path from $f(\widetilde{g}_1(a))$ to $G(a,0)$. We need to define a suitable map $\widetilde{G}\colon A \times [0,c] \to P_f \subset X \times Y^{[0,1]}$. We consider the two factors separately:

(a) We already have the map $A \times [0,c] \to A \xrightarrow{\widetilde{g}_1} X$.

(b) To each $(a,s) \in A \times [0,c]$ we need to assign "systematically" a path $[0,1] \to Y$ from $f(x)$ to $G(a,s)$. The idea is quite simple: Given $(a,s) \in A \times [0,c]$ we consider the path $[0,1] \to Y$ that is given by first traveling along the path $\widetilde{g}_2(a)$ from $f(\widetilde{g}_1(a))$ to $G(a,0)$ and then we travel along the path $t \mapsto G(a,t)$ from $G(a,0)$ to $G(a,s)$. More precisely, similar to the proof of the Path Space-Fibration Theorem 154.14 we consider the map[1861]

$$\begin{array}{rcl} \widetilde{G}_2\colon A \times [0,c] & \to & Y^{[0,1]} \\ (a,s) & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & Y \\ t & \mapsto & \begin{cases} \widetilde{g}_2(a)\big(\frac{t}{1-\frac{s}{2c}}\big), & \text{if } t \in [0, 1-\frac{s}{2c}], \\ G(a, 2\cdot(t-1+\frac{s}{2})), & \text{if } t \in [1-\frac{s}{2c}, 1] \end{cases} \end{array} \right). \end{array}$$

We refer to the figure below for an illustration of the definition of $\widetilde{G}_2$.

Finally we consider the following map:

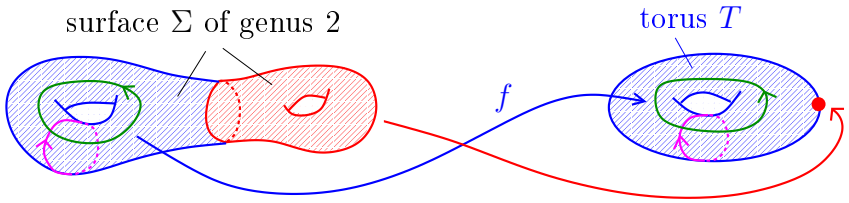
$$\begin{array}{rcl} \widetilde{G}\colon A \times [0,c] & \to & P_f \\ (a,s) & \mapsto & \big(\widetilde{g}_1(a), \widetilde{G}_2(a,s)\big). \end{array}$$

We make the following observations:

(a) It follows easily from the definitions that $\widetilde{G}$ takes values in P_f.

(b) It follows from the above and the Product Topology-Basics Lemma 5.4 (3) that $\widetilde{G}$ is continuous.

(c) It is straightforward to verify that $\widetilde{G}$ makes the diagram commute.



We have thus verified that $\widetilde{G}$ has all the desired properties. ■

The statement of the Replace-by-Fibration Proposition 154.17 that any map $f\colon X \to Y$ between topological spaces can be "replaced" by a fibration is quite surprising and perhaps also somewhat puzzling. Therefore we want to consider one more example.

Example. We denote by Σ the surface of genus 2 and we denote by T the torus. We consider the map $f\colon \Sigma \to T$ that is illustrated in the figure below. We denote by $p\colon P_f \to T$

[1861] The argument in the proof of the Path Space-Fibration Theorem 154.14 also shows that the map $\widetilde{G}_2$ does indeed take values in $Y^{[0,1]}$ and that the map $\widetilde{G}_2\colon A \times [0,c] \to Y^{[0,1]}$ is continuous.

the mapping path fibration and we denote by F the corresponding homotopy fiber. So what can we say about the mysterious homotopy fiber F?

We have the following diagram

$$\begin{array}{ccccccccccccc} \ldots & \longrightarrow & \pi_2(F) & \longrightarrow & \pi_2(P_f) & \xrightarrow{p_*} & \pi_2(T) & \xrightarrow{\partial} & \pi_1(F) & \longrightarrow & \pi_1(P_f) & \xrightarrow{p_*} & \pi_1(T) & \longrightarrow & \ldots \\ & & & & \uparrow{\scriptstyle h_*}\cong & \nearrow{\scriptstyle f_*} & & & & & \uparrow{\scriptstyle h_*}\cong & \nearrow{\scriptstyle f_*} & & & \\ & & & & \pi_2(\Sigma) & & & & & & \pi_1(\Sigma). & & & & \end{array}$$

We make the following explanations and observations:

(1) The top sequence is the long exact sequence coming from the Fibration-LES Theorem 154.7. The vertical maps are induced by the homotopy equivalence $h\colon \Sigma \to P_f$ from the Replace-by-Fibration Proposition 154.17 (1). In particular the vertical maps are isomorphisms by the Homotopy-π_n-Proposition 71.7 (2).
(2) Since $p \circ h = f$ we see that the diagram commutes.
(3) By the discussion on page 1575 we know that $\pi_n(T) = \pi_n(\Sigma) = 0$ for $n \geq 2$.
(4) It is pretty clear that the map $f_*\colon \pi_1(\Sigma) \to \pi_1(T)$ is an epimorphism.
(5) We obtain from the above discussion and from Proposition 64.8 that F is path-connected, that $\pi_n(F) = 0$ for $n \geq 2$ and that $\pi_1(F)$ is an *infinitely generated* free group.

Thus we see that the homotopy groups of F are isomorphic to the homotopy groups of an infinite wedge of circles.

154.7. **Adjoint functors.** In Chapter 17 we introduced the notion of a "cofibration" and we just got acquainted with the notion of a "fibration". In this section we will discuss the relationship between these two notions.
First we point out a formal similarity between fibrations and cofibrations, namely they both give rise to long exact sequences:

(1) Let $p\colon Y \to B$ be a fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$ and we denote by $F = p^{-1}(b_0)$ the homotopy fiber of p. Let $i\colon F \to Y$ be the inclusion map. By the Fibration-LES Theorem 154.7 we obtain the following long exact sequence of homotopy groups:

$$\ldots \xrightarrow{\partial} \pi_n(F, y_0) \xrightarrow{i_*} \pi_n(Y, y_0) \xrightarrow{p_*} \pi_n(B, b_0) \xrightarrow{\partial} \pi_{n-1}(F, y_0) \xrightarrow{i_*} \ldots.$$

(2) Let $i\colon A \to X$ be a cofibration. We refer to the mapping cone $C := \mathrm{Cone}(i)$ as the *cofiber*. If $i(A)$ is a closed non-empty subset of X, then it follows easily from the Topological LES-Corollary 74.14 and Corollary 78.16 that we obtain a long exact sequence of reduced homology groups of the following form:

$$\ldots \xrightarrow{\partial} \widetilde{\mathrm{H}}_n(A) \xrightarrow{i_*} \widetilde{\mathrm{H}}_n(X) \xrightarrow{p_*} \widetilde{\mathrm{H}}_n(C) \xrightarrow{\partial} \widetilde{\mathrm{H}}_{n-1}(A) \xrightarrow{i_*} \ldots.$$

This basically recovers the statement of the Mapping Cone-H_*-Lemma 78.17.

Here is another similarity between fibrations and cofibrations:

(1) Let $p\colon Y \to B$ be a fibration and let $f\colon A \to B$ be a map. As in the Topological-Pullback Lemma 56.16 (1) we consider the pullback

$$\begin{array}{ccc} f^*Y & \longrightarrow & Y \\ \downarrow & & \downarrow{\scriptstyle p} \\ A & \xrightarrow[f]{} & B \end{array}$$

where $f^*Y = \{(a, y) \in A \times Y \mid f(a) = p(y)\}$. In the Fibration-Pullback Lemma 154.16 we saw that the pullback $f^*Y \to A$ is also a fibration.

(2) Now let $i\colon A \to X$ be a cofibration and let $f\colon A \to B$ be a map to another topological space. As on page 1260 we consider the pushout

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ {\scriptstyle i}\downarrow & & \downarrow \\ X & \longrightarrow & f_*X \end{array}$$

where $f_*X = (X \sqcup B)/i(a) \sim f(a)$ for all $a \in A$. By the Opposite Map-Cofibration Proposition 17.18 (1) we will know that the pushout $B \to f_*X$ is again a cofibration.

So, to summarize: *the pullback of a fibration is again a fibration* and *the pushout of a cofibration is again a cofibration.*

The main goal of this section though is to formulate an arguably more direct relationship between the notions of a fibration and a cofibration. The key to doing so is the following definition from category theory.

Definition. We say that two covariant functors $F\colon \mathcal{C} \to \mathcal{D}$ and $G\colon \mathcal{D} \to \mathcal{C}$ between categories $\mathcal{C}$ and $\mathcal{D}$ form an adjoint pair if given any $c \in \mathrm{Ob}(\mathcal{C})$ and $d \in \mathrm{Ob}(\mathcal{D})$ there exists a bijection

$$\mathrm{Mor}_{\mathcal{D}}(F(c), d) \;\to\; \mathrm{Mor}_{\mathcal{C}}(c, G(d))$$

that is natural in c and d.[1862] We also say that the functor F is the left adjoint of G and that G is the right adjoint of F.

Examples.

(1) Let $\mathcal{S}$ be the category of sets and let $\mathcal{G}$ be the category of groups. We consider the two functors

$$\begin{array}{rcl} F\colon \mathcal{S} & \to & \mathcal{G} \\ S & \mapsto & \langle S \rangle \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{G} & \to & \mathcal{S} \\ (\pi,\ \cdot\ ) & \mapsto & \pi. \end{array}$$

In other words, F associates to a set S the free group $\langle S \rangle$ generated by S that we defined on page 1158.[1863] Furthermore, G assigns to a group $(\pi,\ \cdot\ )$ the underlying

[1862] We leave it to our reader to figure out what "natural in c and d" means.

[1863] In what sense is this a functor?

set π.[1864] Using Lemma 51.15 one sees that for a set S and a group π the map

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{S}}(S, \overbrace{\pi}^{=G(\pi,\ \cdot\ )}) & \to & \mathrm{Mor}_{\mathcal{G}}(\overbrace{\langle S \rangle}^{=F(S)}, (\pi,\ \cdot\ )) \\ (\text{map } h\colon S \to \pi \text{ of sets}) & \mapsto & \begin{array}{l}\text{the unique homomorphism } \langle S \rangle \to (\pi,\ \cdot\ ) \\ \text{that restricts to } h \text{ on the subset } S \subset \langle S \rangle\end{array} \end{array}$$

is a natural bijection. Thus we see that the functors F and G are adjoint.

(2) Let $\mathcal{AbGroup}$ be the category of abelian groups and let A be an abelian group. We consider the two functors

$$\begin{array}{rcl} F\colon \mathcal{AbGroup} & \to & \mathcal{AbGroup} \\ B & \mapsto & A \otimes B \end{array} \quad \text{and} \quad \begin{array}{rcl} G\colon \mathcal{AbGroup} & \to & \mathcal{AbGroup} \\ B & \mapsto & \mathrm{Hom}(A, B). \end{array}$$

Now let $B, C \in \mathcal{AbGroup}$. We consider the map[1865]

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{AbGroup}}(\overbrace{A \otimes B}^{=F(B)}, C) & \to & \mathrm{Mor}_{\mathcal{A}}(B, \overbrace{\mathrm{Hom}(A, C)}^{=G(C)}) \\ (f\colon A \otimes B \to C) & \mapsto & \left(\begin{array}{rcl} B & \to & \mathrm{Hom}(A, C) \\ b & \mapsto & \left(\begin{array}{rcl} A & \to & Y \\ a & \mapsto & f(a \otimes b) \end{array} \right) \end{array} \right). \end{array}$$

Using Lemma 89.2 (3) one can easily show that this map is a bijection. This shows that F and G form an adjoint pair.

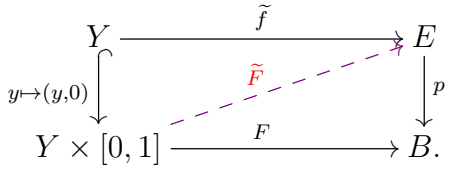
(3) Let $\mathcal{Top}$ be the category of topological spaces. Rather similarly to the previous example we consider the two functors[1866]

$$\begin{array}{rcl} F\colon \mathcal{Top} & \to & \mathcal{Top} \\ X & \mapsto & X \times [0,1] \end{array} \quad \text{and} \quad \begin{array}{rcl} G\colon \mathcal{Top} & \to & \mathcal{Top} \\ X & \mapsto & X^{[0,1]}. \end{array}$$

Now let $X, Y \in \mathrm{Ob}(\mathcal{Top})$, i.e. let X and Y be topological spaces. We consider the map

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{Top}}(\overbrace{X \times [0,1]}^{=F(X)}, Y) & \to & \mathrm{Mor}_{\mathcal{Top}}(X, \overbrace{Y^{[0,1]}}^{=G(Y)}) \\ (f\colon X \times [0,1] \to Y) & \mapsto & \left(\begin{array}{rcl} X & \to & Y^{[0,1]} \\ x & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & Y \\ t & \mapsto & f(x,t) \end{array} \right) \end{array} \right). \end{array}$$

It follows from the Compact-Open Exponential Proposition 12.6 that this map is well-defined and that it is a bijection.[1867] We have thus shown that F and G form an adjoint pair.

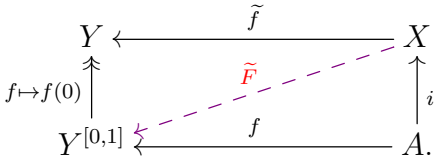


[1864] Such a functor, where we "forget" some of the given structure is often called a *forgetful functor*.

[1865] For abelian groups X and Y we have by definition that $\mathrm{Mor}_{\mathcal{AbGroup}}(X, Y) = \mathrm{Hom}(X, Y)$.

[1866] Here we equip $X \times [0,1]$ with the product topology and we equip $X^{[0,1]}$ with the compact-open topology.

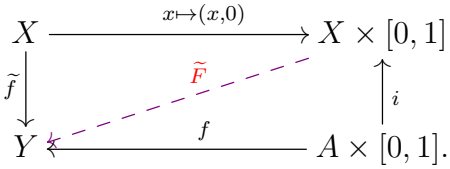
[1867] More precisely, if we consider this map in the category of sets, then it is obviously a bijection. Note that the Compact-Open Exponential Proposition 12.6 shows that the map f on the left is continuous if and only if the corresponding map on the right is continuous. This shows that we also have a bijection between the sets of continuous maps, i.e. between the sets of morphisms in the category of topological spaces.



Now we can explain the formal relationship between fibrations and cofibrations. Let E and B be topological spaces and let $p\colon E \to B$ be a map. Recall that by definition $p\colon E \to B$ is a fibration if we can always complete the following diagram:

Now we "dualize" this diagram as follows:

(1) we reverse the orientation of each arrow,
(2) we replace monomorphisms by epimorphisms,
(3) we replace $Y \times [0,1]$ by $Y^{[0,1]}$,
(4) for purely psychological reasons we replace $p\colon E \to B$ by $i\colon A \to X$.



We obtain the following diagram:

Finally recall that we had just shown in Example (3) that given two topological spaces A and B we have a natural identification

$$\mathrm{Mor}(A \times [0,1], B) \;=\; \mathrm{Mor}(A, B^{[0,1]}).$$

Thus (with a few other more or less mysterious changes) the previous challenge diagram translates into the following challenge diagram:

But this challenge diagram looks familiar: it is precisely the diagram that appears in the definition of a cofibration.

We conclude this chapter with three quotes:

(1) "In the mathematical disciplines of algebraic topology and homotopy theory, Eckmann–Hilton duality in its most basic form, consists of taking a given diagram for a particular concept and reversing the direction of all arrows [...]."[1868] [1869]
(2) "Eckmann–Hilton duality can be extremely helpful as an organizational principle, reducing significantly what one has to remember, and providing valuable hints on how to proceed in various situations." [**Hat2002**, p. 464]

[1868] `https://en.wikipedia.org/wiki/Eckmann-Hilton_duality`
[1869] Note that the notion of pullback and pushout are related by Eckmann-Hilton duality.

(3) "In mathematics [...] currying[1870] is the technique of translating the evaluation of a function that takes multiple arguments into evaluating a sequence of functions, each with a single argument. For example, a function that takes two arguments, one from X and one from Y, and produces outputs in Z, by currying is translated into a function that takes a single argument from X and produces as outputs functions from Y to Z."[1871]

So we see that in the above discussion we performed Eckmann-Hilton duality combined with some currying.

Exercises for Chapter 154.

Exercise 154.1. Show that the projection

$$\begin{array}{rcl} \overline{B}^2 & \to & \overline{B}^1 = [-1,1] \\ (x,y) & \mapsto & x \end{array}$$

is a Serre fibration.

Exercise 154.2. . Let $n \in \mathbb{N}_0$ and let x_0 be a point on S^n. It follows from Proposition 12.4 that the map

$$\begin{array}{rcl} e\colon P(S^n, x_0) & \to & S^n \\ \{f\colon [0,1] \to S^n \mid f(0) = x_0\} & \mapsto & f(1) \end{array}$$

is continuous. For which $n \in \mathbb{N}_0$ does e admit a left-inverse?

Exercise 154.3. We consider the map $f\colon S^1 \to [-1,1]$ that is given by the projection onto the x-coordinate. We define the mapping path fibration $q\colon P_f \to [-1,1]$ as in the Replace-by-Fibration Proposition 154.17. Show that for each $y \in [-1,1]$ the preimage $q^{-1}(y)$ admits a deformation retraction to a circle.
Remark. See the figure on page 3289 for an illustration of the mapping path fibration.

Exercise 154.4. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}$. Show "with your bare hands" that the map

$$\begin{array}{rcl} \partial_n\colon \pi_n(X,x_0) & \overset{\cong}{\to} & \pi_{n-1}(\Omega(X,x_0), c_{x_0}) \\ [f\colon ([0,1]^n, \partial([0,1]^n)) \to (X,x_0)] & \mapsto & \left[\begin{array}{rcl} ([0,1]^{n-1}, \partial([0,1]^{n-1})) & \to & (\Omega(X,x_0), c_{x_0}) \\ x & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & X \\ t & \mapsto & f(x,t) \end{array} \right) \end{array} \right] \end{array}$$

is a natural isomorphism.
Remark. This is of course the statement of the Loop Space-Homotopy Groups Corollary 154.15.

[1870] This notion is named after the American mathematician Haskell Brooks Curry (1900-1982) who was an American mathematician and logician. There are three programming languages named after him, namely Haskell, Brook and Curry.
[1871] https://en.wikipedia.org/wiki/Currying#Algebraic_topology

Exercise 154.5. Let (X, x_0) be a pointed topological space. In the Loop Space-Homotopy Groups Corollary 154.15 we give for any $n \geq 1$ a natural isomorphism

$$\pi_n(X, x_0) \stackrel{\cong}{\to} \pi_{n-1}(\Omega(X, x_0), c_{x_0}).$$

What does this statement mean for $n = 1$? It seems to say that $\pi_0(\Omega(X, x_0), c_{x_0})$ admits a natural group structure. Can you define such a natural group structure without using the above isomorphism?

Exercise 154.6. Convince yourself, without using the Loop Space-Homotopy Groups Corollary 154.15, that the loop in the pointed topological space $(\Omega(S^2, N), c_N)$ that is shown in the figure on page 3285 is not null-homotopic.

Exercise 154.7. Let X be a topological space and let $x_0 \in X$ be a base point. Recall that the loop space $\Omega(X, x_0)$ is defined as the set $\Omega(X, x_0) = \{f \in X^{[0,1]} \mid f(0) = f(1) = x_0\}$ together with the compact-open topology. We denote by $\sim$ the equivalence relation on $\Omega(X, x_0)$ given by homotopy of paths. By definition we have $\pi_1(X, x_0) = \Omega(X, x_0)/\!\sim$. We equip $\pi_1(X, x_0)$ with the quotient topology. We can thus view $\pi_1(X, x_0)$ as a topological space. Show that $\pi_1(S^1, 1)$ is a discrete space.
Hint. It is possibly easier to show that for any pointed topological space (X, x_0) that admits a universal covering the fundamental group $\pi_1(X, x_0)$ is a discrete space.
Remark. There are examples of pointed topological spaces for which $\pi_1(X, x_0)$ is not a discrete space. For example the fundamental group of the Hawaiian Earrings, introduced in Exercise 56.1, is not a discrete space. We refer to [**Fab2005, Fab2011**] for details.

Exercise 154.8.

(a) Show that there is no functor

$$\Phi\colon \begin{array}{c}\text{category } \mathcal{PTop} \text{ of pointed}\\ \text{topological spaces}\end{array} \to \begin{array}{c}\text{category of } \mathcal{PTop} \text{ pointed}\\ \text{topological spaces}\end{array}$$

which admits for every $n \in \mathbb{N}$ a natural isomorphism

$$\pi_n(X, x_0) \stackrel{\cong}{\to} \pi_{n+1}(\Phi(X, x_0)).$$

(b) Show that there is no functor

$$\Psi\colon \text{category of topological spaces} \to \text{category of topological spaces}$$

which admits for every $n \in \mathbb{N}$ a natural isomorphism

$$\widetilde{\mathrm{H}}_n(X) \stackrel{\cong}{\to} \widetilde{\mathrm{H}}_{n-1}(\Psi(X)).$$

Hint. In Exercise 74.4 (b) we proved the following statement. If X is a topological space with $\widetilde{\mathrm{H}}_0(X) \cong \mathbb{Z}$, then given any map $f\colon X \to X$ the induced map f_* on $\widetilde{\mathrm{H}}_0(X)$ is given by multiplication by some $\epsilon \in \{-1, 0, 1\}$.

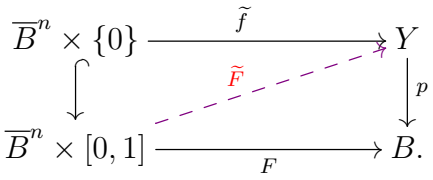
Exercise 154.9. Let X be a topological space. We consider the map

$$\begin{array}{rcl} p\colon X^{[0,1]} & \to & X \times X \\ (f\colon [0,1] \to X) & \mapsto & (f(0), f(1)) \end{array}$$

(a) Show that $p\colon X^{[0,1]} \to X \times X$ is a fibration.

(b) Show that there exists a left inverse to p, i.e. a map $s\colon X \times X \to X^{[0,1]}$ with $p \circ s = \mathrm{id}$, if and only if X is contractible.

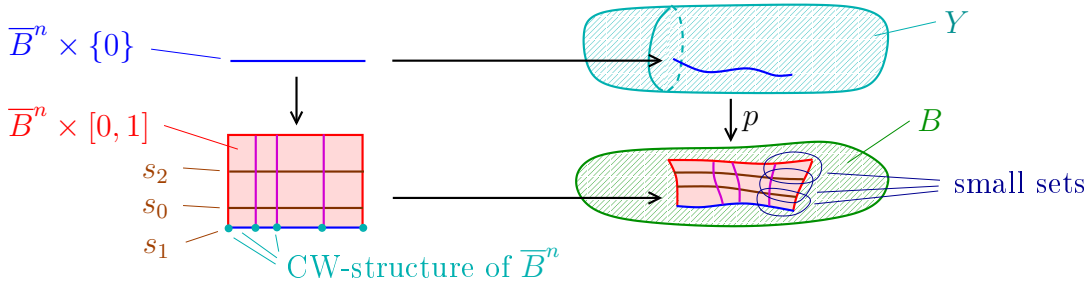
155. Fiber bundles



In this chapter we will introduce fiber bundles. For us they will be the most important source of fibrations. In this and the following chapter one of our favorite games will be to find more and more fiber bundles to obtain lots of non-trivial information on homotopy groups of various topological spaces.

155.1. **The definition of fiber bundles.** The following proposition says that being a Serre fibration is a "local property".

Proposition 155.1. Let $p\colon Y \to B$ be a map between topological spaces. If for every $b \in B$ there exists an open neighborhood U of b such that $p\colon p^{-1}(U) \to U$ is a Serre fibration, then $p\colon Y \to B$ itself is a Serre fibration.

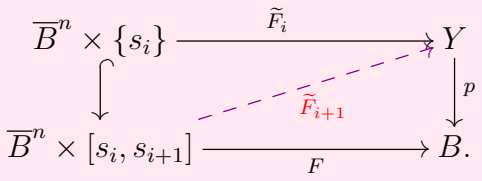


Proof. Let $p\colon Y \to B$ be a map between topological spaces. In this proof we say $U \subset B$ is *small* if $p\colon p^{-1}(U) \to U$ is a Serre fibration.

Now assume that $p\colon Y \to B$ has the property that B can be covered by small sets. We want to show that this hypothesis implies that the map $p\colon Y \to B$ is a Serre fibration. Therefore let $n \in \mathbb{N}_0$, let $F\colon \overline{B}^n \times [0,1] \to B$ and let $\widetilde{f}\colon \overline{B}^n \times \{0\} \to Y$ be maps such that the rectangle in the following diagram commutes:

We need to show that there exists a diagonal map $\widetilde{F}\colon \overline{B}^n \times [0,1] \to Y$ such that the above diagram commutes.

Claim. There exists a CW-structure X on $\overline{B}^n$ and real numbers $0 = s_0 < s_1 < \cdots < s_k = 1$ such that for each cell e of X and each $i \in \{0, \ldots, k-1\}$ the image $F(e \times [s_i, s_{i+1}])$ is small.



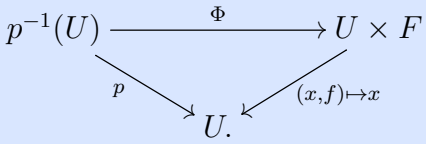
Proof. By the Standard Simplex Homeomorphism Lemma 72.1 we can identify $\overline{B}^n$ with $[0,1]^n$. Since B is by hypothesis covered by small open subsets and since any subset of a small set is again small we obtain from the Lebesgue Corollary 6.6 that there exists a $k \in \mathbb{N}$ such that each

$$F\Big(\underbrace{\left[\tfrac{a_1}{k}, \tfrac{a_1+1}{k}\right] \times \ldots \left[\tfrac{a_n}{k}, \tfrac{a_n+1}{k}\right]}_{\subset [0,1]^n = \overline{B}^n} \times \underbrace{\left[\tfrac{a_{n+1}}{k}, \tfrac{a_{n+1}+1}{k}\right]}_{\subset [0,1]}\Big)$$

is small for all $a_1, \dots, a_{n+1} \in \{0, \dots, k-1\}$. We equip $[0,1]^n = \overline{B}^n$ with the CW-structure defined on page 1499 given by the "subcubes" of side length $\frac{1}{k}$. Furthermore we set $s_i = \frac{i}{k}$, $i = 0, \dots, k$. By design this CW-structure and this choice of s_i has the desired properties. ⊞

We continue with the following claim.

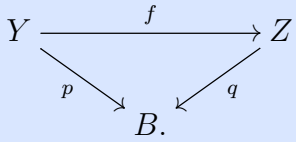
Claim. Let $i \in \{0, \dots, k-1\}$. Given a map $\widetilde{F}_i \colon \overline{B}^n \times \{s_i\} \to Y$ with $p \circ \widetilde{F}_i = F|_{\overline{B}^n \times \{s_i\}}$ there exists a map $\widetilde{F}_{i+1} \colon \overline{B}^n \times [s_i, s_{i+1}] \to Y$ such that the following diagram commutes:



Proof. In fact the claim follows immediately from the argument of the proof of Proposition 154.8 applied to the CW-complex $K := X = \overline{B}^n$ and the subcomplex $L = \varnothing$. Indeed, in the proof of Proposition 154.8 we did not need to assume that $p \colon Y \to B$ is a Serre fibration, all we ever used is that for every cell e of B the image $F(e)$ is small in the above sense. But in our present setting this is guaranteed by our choice of the CW-structure on $\overline{B}^n$. ⊞

We set $\widetilde{F}_0 = \widetilde{f}_0 \colon \overline{B}^n \times \{0\} \to Y$. Iteratively applying the previous claim we obtain maps $\widetilde{F}_i \colon \overline{B}^n \times [s_i, s_{i+1}] \to Y$ that agree on the overlaps of the domains. By the Homotopy Stacking Lemma 14.3 all these maps together define a continuous map $\widetilde{F} \colon \overline{B}^n \times [0,1] \to Y$ which by construction has the desired properties. ■

As we saw on page 3264, every projection $p \colon B \times F \to B$ is a (Serre) fibration. This observation, together with Proposition 155.1 leads us naturally to the following definition.



Definition. Let F be a topological space.

(1) A map $p \colon Y \to B$ between two topological spaces is called an F-bundle over B if given any $b \in B$ there exists an open neighborhood U of b and a homeomorphism $\Phi \colon p^{-1}(U) \to U \times F$ such that the following diagram commutes:

Alternatively we call such a map $p \colon Y \to B$ a bundle projection with fiber F. As for fibrations we sometimes refer to B as the base space and to Y as the total space. Furthermore we refer to the map $p \colon Y \to B$ as the projection.

(2) We say that two F-bundles $p \colon Y \to B$ and $q \colon Z \to B$ are equivalent if there exists a homeomorphism $f \colon Y \to Z$ such that the following diagram commutes:

The following proposition will be the incarnation of the Fibration-LES Theorem 154.7 that we will use most often.

Proposition 155.2. (Fiber-LES Proposition) Let $p\colon Y \to B$ be a fiber bundle with fiber F.

(1) The map $p\colon Y \to B$ is a Serre fibration.

(2) We pick $y_0 \in Y$ and we write $b_0 = p(y_0)$. We pick an identification $F \xrightarrow{\cong} p^{-1}(b_0)$. We denote by $i\colon F = p^{-1}(b_0) \to Y$ the inclusion. We use the fact from (1) that $p\colon Y \to B$ is a Serre fibration to define maps $\partial_n\colon \pi_n(B, b_0) \to \pi_{n-1}(F, y_0)$, $n \in \mathbb{N}$, as in the Fibration-LES Theorem 154.7. The following sequence is exact:

$$\begin{aligned}\ldots \xrightarrow{\partial_{n+1}} \pi_n(F, y_0) \xrightarrow{i_*} \pi_n(Y, y_0) \xrightarrow{p_*} \pi_n(B, b_0) \xrightarrow{\partial_n} \\ \xrightarrow{\partial_n} \pi_{n-1}(F, y_0) \xrightarrow{i_*} \ldots\ldots\ldots \xrightarrow{p_*} \pi_1(B, b_0) \xrightarrow{\partial_1} \\ \xrightarrow{\partial_1} \pi_0(F, y_0) \xrightarrow{i_*} \pi_0(Y, y_0) \xrightarrow{p_*} \pi_0(B, b_0).\end{aligned}$$

(3) If we are given a commutative diagram

$$\begin{array}{ccc} Y' & \xrightarrow{g} & Y \\ {\scriptstyle p'}\downarrow & & \downarrow{\scriptstyle p} \\ B' & \xrightarrow{f} & B \end{array}$$

where $p'\colon Y' \to B'$ is a fiber bundle with fiber F', then given any base point $y_0' \in Y'$ the obvious diagram of the long exact sequences of homotopy groups corresponding to the fiber bundles $p\colon Y \to B$ and $p'\colon Y' \to B'$ is commutative.

(4) If the fiber F and the base space B are path-connected, then the total space Y is also path-connected.

Proof.

(1) This part of the proposition is an immediate consequence of the definitions, Proposition 155.1 and the discussion on page 3264.

(2) The second statement follows immediately from (1) and the Fibration-LES Theorem 154.7 (2).

(3) This statement follows easily from the Fibration-LES Theorem 154.7 (1b).

(4) This statement follows immediately from (2). ■

the Fiber-LES Proposition 155.2 sparks our interest in fiber bundles. Fortunately, in the following discussion we will see that fiber bundles are ubiquitous and can be found throughout the notes.

Examples.

(1) For any two topological spaces B and F the projection $p\colon B \times F \to B$ onto the first factor is evidently a fiber bundle with fiber F. Any F-bundle that is equivalent to such a bundle is called *trivial*, otherwise it is called non-trivial.

(2) The "obvious projection" from the Möbius band to the circle S^1, i.e. the map

$$\begin{array}{rcl} Y = ([0,1] \times [-1,1])/(0,y) \sim (1,-y) & \to & S^1 \\ (x,y) & \mapsto & \exp(2\pi \mathrm{i} x) \end{array}$$

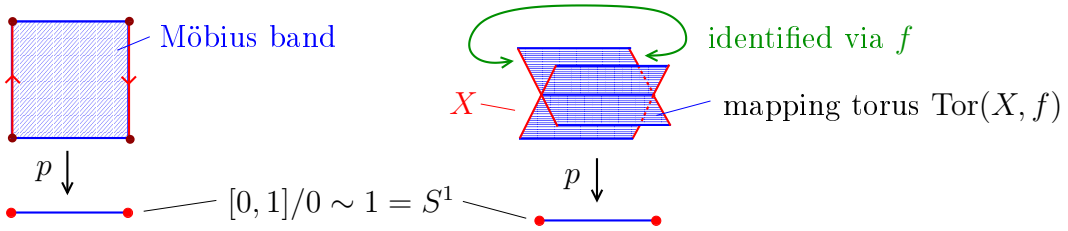
is easily seen to be a fiber bundle with fiber $[-1,1]$. Since the Möbius band is not homeomorphic to the trivial bundle $S^1 \times [-1,1]$ we see that the bundle is non-trivial.

(3) The same argument as in (2) shows that the Klein bottle is a non-trivial S^1-bundle over S^1. In Lemma **??** (1) we saw that the connected sum $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is homeomorphic to the Klein bottle. We have thus shown that $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is a non-trivial S^1-bundle over S^1. Amusingly an analogous statement holds in dimension four, namely the connected sum $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}^2}$ is a non-trivial S^2-bundle over S^2. It is a challenging exercise to prove this fact by hand, alternatively a proof can be found in [**GoS1999**, p. 107] or [**Scor2005**, p. 124]. Similarly, one can show that the connected sum $\mathbb{H}\mathrm{P}^2 \# \overline{\mathbb{H}\mathrm{P}^2}$ is a non-trivial S^4-bundle over S^4.

(4) An n-dimensional vector bundle $p\colon W \to B$, in the sense of the definition on page 3058, is by definition an $\mathbb{R}^n$-bundle over B.

We consider the next example in greater detail.

Lemma 155.3.



(1) Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. The natural projection

$$\begin{array}{rcl} \overbrace{\mathrm{Tor}(X,f) = ([0,1]\times X)/(0,x) \sim (1,f(x))}^{\text{basically the mapping torus of } (X,f)} & \to & [0,1]/0 \sim 1 = S^1 \\ [(t,x)] & \mapsto & [t] = \exp(2\pi\,\mathrm{i}t) \end{array}$$

is an X-bundle over S^1.

(2) Let X be a topological space and let $f_0, f_1\colon X \to X$ be two homeomorphisms. If f_0 and f_1 are isotopic, then the two X-bundles $\mathrm{Tor}(X,f_0) \to S^1$ and $\mathrm{Tor}(X,f_1) \to S^1$ are equivalent.

(3) Let V be an n-dimensional real vector space and let $\varphi\colon V \to V$ be an isomorphism of vector spaces. We equip V with the topology given on page 153. For each $t \in [0,1)$ we equip $\{t\} \times V \subset M(V,\varphi)$ with the obvious vector space structure. This turns the projection $M(V,\varphi) \to S^1$ into an n-dimensional vector bundle.

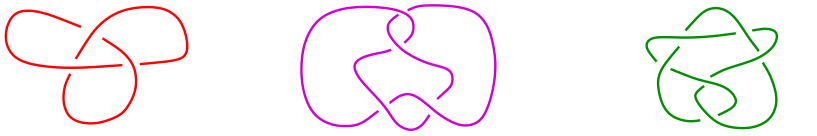
Proof.

(1) We denote by $\pi\colon [0,1] \to [0,1]/0 \sim 1$ the natural projection. We consider the two open sets $U_1 := \pi((\frac{1}{4},\frac{3}{4}))$ and $U_2 := \pi([0,\frac{1}{3}) \cup (\frac{2}{3},1])$ in $[0,1]/0 \sim 1$. Furthermore we consider the maps

$$\begin{array}{rcl} p^{-1}(U_1) & \xrightarrow{\Phi_1} & U_1 \times X \\ [(t,x)] & \mapsto & (t,x) \end{array} \quad \text{and} \quad \begin{array}{rcl} p^{-1}(U_2) & \xrightarrow{\Phi_2} & U_2 \times X \\ [(t,x)] & \mapsto & \begin{cases} (t,f(x)), & \text{if } t \in [0,\frac{1}{3}), \\ (t,x) & \text{if } t \in (\frac{2}{3},1]. \end{cases} \end{array}$$

Note that the map on the right is indeed well-defined. Using the Topological-Quotient Proposition 5.15 (1b) and using Lemma 14.3 one can show quite easily that both maps are homeomorphisms. Furthermore it is basically clear that Φ_1 and Φ_2 respect the projections onto U_1 and U_2. Therefore, since the two open subsets U_1 and U_2 cover all of $[0,1]/0 \sim 1$, we have shown that $p\colon \mathrm{Tor}(X,f) \to [0,1]/0 \sim 1$ is indeed an X-bundle.

(2) This statement will be proved in Exercise 155.3.



(3) The proof of this statement is basically the same as the proof of (1). We only have to make the extra observation that for each $i \in \{1,2\}$ and each $t \in U_i$ the map

$$\Phi_i\colon V = [\{t\} \times V] = p^{-1}(t) \;\to\; \{t\} \times V = V$$

is either given by id or ϕ. Thus in either case the map is given by an *isomorphism* of vector spaces. ■

Remark. The previous lemma shows that any self-homeomorphism of $\mathbb{R}^n$ gives rise to an $\mathbb{R}^n$-bundle over S^1, whereas any isomorphism of $\mathbb{R}^n$ gives rise to an n-dimensional vector bundle over S^1. The question arises whether every $\mathbb{R}^n$-bundle is secretly a vector bundle. More precisely, the question arises whether every $\mathbb{R}^n$-bundle is equivalent to an n-dimensional vector bundle. In Exercise 155.4 we will answer this question in the affirmative if $f\colon \mathbb{R}^n \to \mathbb{R}^n$ is a diffeomorphism.[1872]

It follows from the discussion on page 470 and Lemma 155.3 that the complement of the trefoil and the complement of the figure-8 knot are fiber bundles over S^1. Of course there are many other knots, for example consider the stevedore knot shown in the figure below. The following question arises:

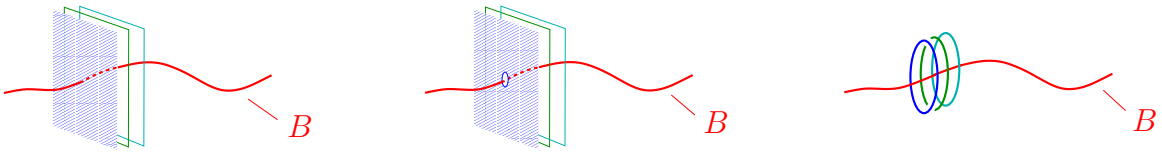
trefoil figure-8 knot stevedore knot

Question 155.4. Is the complement of the stevedore knot a fiber bundle over S^1?

We continue with more examples of fiber bundles.

Examples.

(1) As we pointed out above, any n-dimensional vector bundle $p\colon W \to B$ is by definition an $\mathbb{R}^n$-bundle over B. In fact p gives rise to two other bundles which are much more interesting topological objects:



(a) We denote by $s\colon B \to W$ the zero-section, i.e. the map given by sending each $b \in B$ to the zero-element of the vector space $p^{-1}(y)$. We write $W^* := W \setminus s(B)$. It follows easily from the definitions that $p\colon W^* \to B$ is a fiber bundle with fiber $\mathbb{R}^n \setminus \{0\}$.

[1872] Frankly, I am not sure whether the same statement holds if f is a homeomorphism.

(b) Let $\lambda \in \mathbb{R}$. By definition of a vector bundle we have a well-defined multiplication by λ on each fiber. We define

$$SW := W^*/\sim \qquad \text{where } v \sim w \text{ if } p(v) = p(w) \text{ and if there exists a } \lambda > 0 \text{ with } \lambda v = w.$$

The map $p\colon W^* \to B$ descends to a map $p\colon SW \to B$. We leave it as an entertaining exercise to verify that $p\colon SW \to B$ is an S^{n-1}-bundle.

$\mathbb{R}^n$-bundle $p\colon W \to B$ $(\mathbb{R}^n\backslash\{0\})$-bundle $p\colon W^* \to B$ S^{n-1}-bundle $p\colon SW \to B$

(2) A smooth $\overline{B}^n$-bundle $p\colon W \to M$ over a smooth manifold M, in the sense of the definition on page **??**, is by definition an $\overline{B}^n$-bundle in the above sense. Slightly more interesting, if M has no boundary and if we restrict p to a map $\partial W \to M$, then it follows easily from Proposition 19.31 that the restriction of p to ∂W defines an S^{n-1}-bundle $p\colon \partial W \to M$.

The following lemma is almost verbatim the same as the Vector Bundle Pullback Lemma 143.9.

Lemma 155.5. Let $g\colon C \to B$ be a map between topological spaces and let $p\colon Y \to B$ be a fiber bundle with fiber F. As in the Topological-Pullback Lemma 56.16 (1) we consider the pullback

$$g^*Y := \{(c, f) \,|\, c \in C \text{ and } f \in p^{-1}(g(c))\} \subset C \times Y,$$

which is equipped with the subspace topology. Then the map

$$\begin{aligned} q\colon g^*Y := \{(c, f) \,|\, c \in C \text{ and } f \in p^{-1}(g(c))\} &\to C \\ (c, f) &\mapsto c \end{aligned}$$

is also an F-bundle.

Proof. The proof is, not surprisingly, also almost identical to the proof of the Vector Bundle Pullback Lemma 143.9. ∎

Remark. The pullback of bundles satisfies basically the same statements as the pullback of vector bundles, see the Vector Bundle Pullback Lemma 143.9. There is surely no need to spell out these properties again.

The following lemma classifies bundles over compact intervals $[a, b]$ and also over the circle S^1.

Lemma 155.6.

(1) Every bundle over a compact interval $[a, b]$ is trivial.
(2) If $p\colon Y \to S^1$ is a fiber bundle with fiber X, then there exists a homeomorphism $f\colon X \to X$ such that p is equivalent to the above fiber bundle $\mathrm{Tor}(X, f) \to S^1$.

Sketch of proof.

(1) This statement will be proved in Exercise 155.2.

(2) Suppose we are given a fiber bundle $p\colon Y \to S^1$ with fiber X. Let $\varphi\colon [0,2\pi] \to S^1$ be the map that is given by $\varphi(t) = \exp(\mathrm{i}t)$. It follows from (1) that the pullback bundle

$$q\colon \varphi^*Y = \{(t,v) \in [0,2\pi] \times Y \,|\, v \in p^{-1}(\varphi(t))\} \;\to\; [0,2\pi]$$

is trivial, i.e. there exists a homeomorphism $\Phi\colon [0,2\pi] \times X \to \varphi^*Y$ such that the following diagram commutes

$$\begin{array}{ccc} [0,2\pi] \times X & \xrightarrow{\quad\Phi\quad} & \varphi^*Y \\ & {\scriptstyle (t,x)\mapsto t} \searrow \quad \swarrow {\scriptstyle q} & \\ & [0,2\pi]. & \end{array}$$

We define $f\colon X \to X$ to be the homeomorphism that is given by

$$\begin{array}{ccccccccccc} & & & & & & \varphi(0) = 1 = \varphi(2\pi) & & & & \\ & & & & & & \downarrow & & & & \\ X & \xrightarrow{x\mapsto(0,x)} & \{0\}\times X & \xrightarrow{\Phi} & q^{-1}(0) & \to & p^{-1}(1) & \leftarrow & q^{-1}(2\pi) & \xleftarrow{\Phi} & \{2\pi\}\times X \xrightarrow{(2\pi,x)\mapsto x} X. \\ & & & & (0,v) & \mapsto & v & & & & \\ & & & & & & v & \mapsto & (2\pi,v). & & \end{array}$$

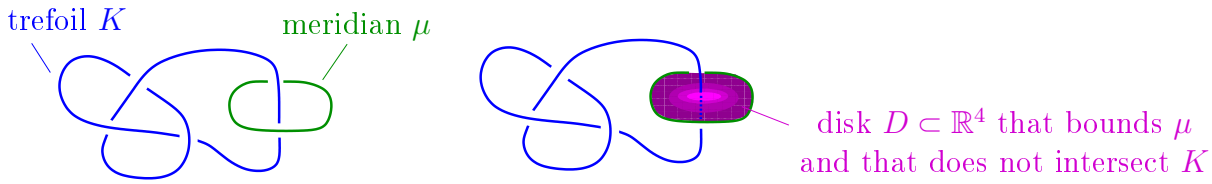
We leave it as a mildly interesting exercise to the reader to verify that $p\colon Y \to S^1$ is equivalent to the fiber bundle $\mathrm{Tor}(X,f) \to S^1$. ■

For the record we mention the following generalization of Lemma 155.6 (1).

Proposition 155.7. Let X be a topological space. If X is paracompact and contractible, then every bundle over X is trivial.

Proof. The statement of the proposition is almost the same as the statement of the Vector Bundles-Homotopies Proposition 143.13 (3) for vector bundles. The reference we gave for vector bundles, namely [**Hat2**, Theorem 1.6], also applies to general bundles. ■

We conclude this section with an example that shows how the above results can be used in practice. Thus let $n \in \mathbb{N}$ and K be a closed k-dimensional submanifold of the smooth manifold S^n. We calculate that for $i = 1, \ldots, n-k-2$ we have



$$\begin{array}{ccccc} \mathrm{H}_i(S^n \setminus K;\mathbb{Z}) & \cong & \mathrm{H}^{n-i-1}(K;\mathbb{Z}) & = & 0. \\ & \uparrow & & \uparrow & \\ & \text{Alexander Duality} & & \text{by the Top-Cohomology Proposition 110.14 (5) and} & \\ & \text{Theorem 123.6} & & \text{the fact that } n-i-1 > k = \dim(K) & \end{array}$$

The following proposition shows that not only do the first $n-k-2$ homology vanish, but the first $n-k-2$ homotopy groups also vanish.

Proposition 155.8. Let $n \in \mathbb{N}$ and let K be a closed k-dimensional submanifold of the smooth manifold S^n. For $i = 1, \ldots, n-k-2$ we have $\pi_i(S^n \setminus K) = 0$.

Example. Let K be the trefoil in $\mathbb{R}^3$ and let $\mu \subset \mathbb{R}^3$ be a meridian as defined on page 1305. (See also the figure below to the left.) In Lemma 78.13 we saw that μ represents a non-zero element in $\mathrm{H}_1(S^3 \setminus K)$. It follows from the naturality of the Hurewicz homomorphism, see Proposition 84.2 (5), that μ also represents a non-trivial element in $\pi_1(S^3 \setminus K)$. Via the usual smooth embedding $\mathbb{R}^3 \to \mathbb{R}^3 \times \{0\} \to \mathbb{R}^4$ we can view K and μ as submanifolds of $S^4 = \mathbb{R}^4 \cup \{\infty\}$. By Proposition 155.8 we have $\pi_1(S^4 \setminus K) = 0$. In particular we obtain

that μ is trivial in $\pi_1(S^4 \setminus K)$. In fact in the figure below we show an embedded disk D in $\mathbb{R}^4 \subset S^4$ whose boundary is given by μ and that does not intersect K. Here we use the convention from page **??**, i.e. "pinkness" of a point measures how large is the fourth coordinate.

Proof. Let $n \in \mathbb{N}$ and K be a closed k-dimensional submanifold of the smooth manifold S^n. If $n-k-2 \leq 0$, then there is nothing to prove. Thus we assume that $n-k-2 \geq 1$, i.e. we assume that $n \geq k+3$.

We want to show that $\pi_i(S^n \setminus K) = 0$ for $i = 1, \dots, n-k-2$. We already know that the corresponding homology groups vanish. Thus by the Hurewicz Corollary 85.7 it suffices to show that $\pi_1(S^n \setminus K) = 0$. That is precisely what we will do in the remainder of this proof.

In the following we consider the case that K is connected. We leave it to the reader to modify the proof to deal with the case that K is disconnected. By the General Tubular Neighborhood Theorem **??** the closed submanifold K admits a tubular neighborhood $p\colon W \to K$. Recall that W is a compact n-dimensional submanifold of S^n and that p is in particular a $\overline{B}^{n-k}$-bundle over K. As we pointed out on page 3303, the projection $p\colon \partial W \to K$ is an S^{n-k-1}-bundle.

We write $X = S^n \setminus \mathring{W}$. By Proposition 123.4 and Lemma 123.1 we know that $\pi_1(S^n \setminus K)$ is isomorphic to $\pi_1(X)$. Thus it suffices to show that X is simply connected.

By the Codimension-Zero Submanifold Proposition 19.38 we know that X is a compact n-dimensional submanifold of S^n with $W \cap X = \partial W = \partial X$. From Proposition 155.2 (4) we know that ∂W is connected. We pick a base point $x_0 \in \partial W$. By the Seifert–van Kampen Theorem 54.4 for smooth manifolds we know that the inclusion induced map

$$\pi_1(X, x_0) *_{\pi_1(\partial W, x_0)} \pi_1(W, x_0) \ \to \ \underbrace{\pi_1(S^n, x_0)}_{=0}$$

is an isomorphism. We recall that the Amalgamated Product Lemma 53.22 says that $A *_G G \cong A$. Thus, if we want to show that $\pi_1(X, x_0) = 0$ it follows from the Amalgamated Product Lemma 53.22 that it suffices to prove the following claim.

Claim. The inclusion induced map $\pi_1(\partial W, x_0) \to \pi_1(W, x_0)$ is an isomorphism.

Proof. We denote both of the inclusions $\partial W \to W$ and $S^{n-k-1} \to \overline{B}^{n-k}$ by i. We have a commutative diagram

$$\begin{array}{ccc} \partial W & \xrightarrow{\ i\ } & W \\ & \searrow \quad \swarrow & \\ & K & \end{array}$$

of fiber bundles with fibers S^{n-k-1} and $\overline{B}^{n-k}$. From the Fiber-LES Proposition 155.2 (3) we obtain the following commutative diagram of long exact sequences of morphisms between

pointed sets:

$$\begin{array}{ccccccccccc}
\ldots & \longrightarrow & \pi_2(K) & \xrightarrow{\partial} & \pi_1(S^{n-k-1}) & \longrightarrow & \pi_1(\partial W) & \longrightarrow & \pi_1(K) & \xrightarrow{\partial} & \pi_0(S^{n-k-1}) & \longrightarrow & \ldots \\
 & & \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle i_*} & & \\
\ldots & \longrightarrow & \pi_2(K) & \xrightarrow{\partial} & \pi_1(\overline{B}^{n-k}) & \longrightarrow & \pi_1(W) & \longrightarrow & \pi_1(K) & \xrightarrow{\partial} & \pi_0(\overline{B}^{n-k}) & \longrightarrow & \ldots
\end{array}$$

Since $n-k \geq 3$ we have $n-k-1 \geq 2$, thus $\pi_1(S^{n-k-1}) = 0$ by the Sphere-π_1-Proposition 47.13. It follows from a slight generalization[1873] of the Five Lemma 74.10 that the middle vertical map $i_*\colon \pi_1(\partial W) \to \pi_1(W)$ is an isomorphism. ■

Remark. We want to sketch an alternative approach to proving Proposition 155.8. Thus let $n \in \mathbb{N}$, let K be a closed k-dimensional submanifold of the smooth manifold S^n and finally let $i \in \{1, \ldots, n-k-2\}$. We want to show that $\pi_i(S^n \setminus K, x_0) = 0$ for some base point $x_0 \in S^n \setminus K$. Let $[\varphi\colon (S^i, *) \to (S^n \setminus K, x_0)] \in \pi_i(S^n \setminus K, x_0)$ be a random element. We make the following observations:

(1) By the Whitney Approximation Theorem 29.1 we can assume that φ is smooth.
(2) Since $i < n$ we know that $\pi_i(S^n, x_0) = 0$. It follows from the Trivial-in-π_n-Lemma 71.4 that there exists a map $\psi\colon \overline{B}^{i+1} \to S^n$ with $\psi|_{S^i} = \varphi$.
(3) Once again, by the Whitney Approximation Theorem 29.1 we can assume that ψ is also smooth.
(4) Since $k+i+1 < n$ one would like to argue, similar to the Transversality Theorem 42.4, that we can homotop ψ rel S^i to a map that does not intersect K, i.e. we would like to homotop ψ rel S^i to a map $\overline{B}^{i+1} \to S^n \setminus K$. By the Trivial-in-$\pi_n$-Lemma 71.4 this would then imply that $[\varphi] = 0 \in \pi_i(S^n \setminus K, x_0)$.

This approach can be turned into a proper proof, but we will not do so.

155.2. Hopf fibrations arising from complex and quaternionic projective spaces.

In this section we will see that the complex projective spaces $\mathbb{C}\mathrm{P}^n$ and the quaternionic projective spaces[1874] $\mathbb{H}\mathrm{P}^n$ give rise to interesting fiber bundles. In particular we will see that the Hopf map $S^3 \to S^2$ that we introduced on page 1576 is in fact an S^1-bundle.
In the following we introduce two straightforward higher-dimensional analogues of the original Hopf map.

Definition. Let $n \in \mathbb{N}$. We refer to the maps

$$\begin{array}{rcl}
p\colon S^{2n+1} = \{(z_0, \ldots, z_n) \in \mathbb{C}^{n+1} \,|\, |z_0|^2 + \cdots + |z_n|^2 = 1\} & \to & \mathbb{C}\mathrm{P}^n \\
(z_0, \ldots, z_n) & \mapsto & [z_0 : \cdots : z_n]
\end{array}$$

and[1875]

$$\begin{array}{rcl}
q\colon S^{4n+3} = \{(h_0, \ldots, h_n) \in \mathbb{H}^{n+1} \,|\, |h_0|^2 + \cdots + |h_n|^2 = 1\} & \to & \mathbb{H}\mathrm{P}^n \\
(h_0, \ldots, h_n) & \mapsto & [h_0 : \cdots : h_n]
\end{array}$$

as Hopf maps.

[1873] More precisely, if one goes through the proof of the Five Lemma 74.10, then one realizes that it suffices that the right most vertical map is an injective morphism of pointed sets, i.e. the right most vertical map does not need to be a homomorphism of groups.
[1874] We refer to page 1970 for the slightly subtle definition of the quaternionic projective spaces.

The following proposition, together with the Fiber-LES Proposition 155.2, explains our interest in the Hopf maps.[1876]

Proposition 155.9. (Hopf-Bundle Proposition) Let $n \in \mathbb{N}$.
(1) The Hopf map $p\colon S^{2n+1} \to \mathbb{C}\mathrm{P}^n$ is an S^1-bundle.
(2) The Hopf map $q\colon S^{4n+3} \to \mathbb{H}\mathrm{P}^n$ is an S^3-bundle.

Proof. We only provide the proof of (2). The proof of (1) is a straightforward modification of the proof of (2). Given $j \in \{0, \dots, n\}$ we define

$$V_j \;:=\; \{[h_0 : \cdots : h_n] \in \mathbb{H}\mathrm{P}^n \,|\, h_j \neq 0\}.$$

The same argument as in the proof of the Complex Projective Space-is-Complex Manifold Lemma 32.16 shows that V_j is an open subset of $\mathbb{H}\mathrm{P}^n$.

Claim. The map

$$\begin{aligned}\Phi_j\colon q^{-1}(V_j) = \left\{(h_0, \dots, h_n) \in \mathbb{H}^{n+1} \;\middle|\; \sum_{i=0}^{n} |h_i|^2 = 1 \text{ and } h_j \neq 0\right\} &\to V_j \times S^3 \\ (h_0, \dots, h_n) &\mapsto \left([h_0 : \cdots : h_n], \tfrac{1}{|h_j|} \cdot h_j\right)\end{aligned}$$

is a homeomorphism.

Proof. We consider the map

$$\begin{aligned}\Psi_j\colon V_j \times S^3 &\to q^{-1}(V_j) \\ ([h_0 : \cdots : \underbrace{h_j}_{\neq 0} : \cdots : h_n], u) &\mapsto \text{the normalization to length one of the non-zero vector} \\ &\qquad \left(u \cdot h_j^{-1} \cdot h_0, \dots, \underbrace{u \cdot h_j^{-1} \cdot h_j}_{=u}, \dots, u \cdot h_j^{-1} \cdot h_n\right) \in \mathbb{H}^{n+1}.\end{aligned}$$

This map Ψ_j is well-defined. Indeed, a short calculation shows that if we pick a different representative for $[h_0 : \cdots : h_n]$, i.e. if we plug in $[\lambda \cdot h_0 : \cdots : \lambda \cdot h_n]$ for some $\lambda \in \mathbb{H} \setminus \{0\}$ then we obtain the same result.[1877] Using the Topological-Quotient Proposition 5.15 (1b) one can show that the map Ψ_j is continuous. One easily verifies that Ψ_j and Φ_j are inverses of one another. ⊞

It is clear that the open sets V_j cover all of $\mathbb{H}\mathrm{P}^n$ and that the triangles

$$\begin{array}{ccc} q^{-1}(V_j) & \xrightarrow{\Phi_j} & V_j \times S^3 \\ & {\scriptstyle q}\searrow \quad \swarrow{\scriptstyle (v,h)\mapsto h} & \\ & S^3 & \end{array}$$

commute. This shows, according to the definition on page 3299, that $q\colon S^{4n+3} \to \mathbb{H}\mathrm{P}^n$ is an S^3-bundle. ■

The Hopf-Bundle Proposition 155.9, combined with the Fiber-LES Proposition 155.2 gives us two interesting theorems.

[1875] Recall that on page 1960 we defined the norm of a quaternion $h = a \cdot 1 + b \cdot i + c \cdot j + d \cdot k$ as $|h| = \sqrt{a^2 + b^2 + c^2 + d^2}$.

[1876] For mysterious reasons the Hopf maps are almost invariably called "Hopf fibrations", even though the name "Hopf fiber bundle" would be more precise.

[1877] Note though that the order of the factors in the definition of Ψ_j is important since $\mathbb{H}$ is not commutative.

Theorem 155.10.
(1) For all $n \geq 3$ we have $\pi_n(S^3) \cong \pi_n(S^2)$.
(2) We have $\pi_3(S^2) \cong \mathbb{Z}$ and $\pi_3(S^2)$ is generated by the Hopf map $S^3 \to S^2$.

The second statement gives in particular an answer to Question 122.15 (1).

Proof.

(1) On page 258 we gave an identification of $\mathbb{C}\mathrm{P}^1$ with S^2. Thus the Hopf-Bundle Proposition 155.9 (1), applied to $n = 1$, tells us that the Hopf map $p\colon S^3 \to S^2 = \mathbb{C}\mathrm{P}^1$ defines an S^1-bundle. the Fiber-LES Proposition 155.2 gives us the long exact sequence[1878]

$$\ldots \to \pi_n(S^1) \to \pi_n(S^3) \xrightarrow{p_*} \pi_n(S^2) \xrightarrow{\partial} \pi_{n-1}(S^1) \to \pi_{n-1}(S^3) \to \ldots$$

The desired statement now follows from the example on page 1573 where we saw that $\pi_k(S^1) = 0$ for $k \geq 2$.

(2) In Corollary 85.6 (1) we saw that $\pi_3(S^3) = \mathbb{Z} \cdot [\mathrm{id}_{S^3}]$. By (1) the Hopf map $p\colon S^3 \to S^2 = \mathbb{C}\mathrm{P}^1$ induces an isomorphism $p_*\colon \pi_3(S^3) \xrightarrow{\cong} \pi_3(S^2)$. The image of $[\mathrm{id}_{S^3}]$ under p_* is by definition precisely the class in $\pi_3(S^2)$ represented by the Hopf map. Thus we see that $\pi_3(S^2) \cong \mathbb{Z}$ and that $\pi_3(S^2)$ is generated by the Hopf map. ∎

Theorem 155.11.
(1) For all $n \geq 2$ we have $\pi_n(S^4) \cong \pi_n(S^7) \oplus \pi_{n-1}(S^3)$.
(2) For $n \in \{1, \ldots, 6\}$ we have $\pi_n(S^4) \cong \pi_{n-1}(S^3)$.

Remark. From Corollary 85.6 (1) we know that $\pi_7(S^7) \cong \mathbb{Z}$. Thus it follows from Theorem 155.11 (1) that $\pi_7(S^4) \cong \pi_7(S^7) \oplus \pi_6(S^3)$ admits an epimorphism onto $\mathbb{Z}$. In fact in Corollary 122.8 we already saw that the Hopf invariant is an epimorphism $\pi_7(S^4) \to \mathbb{Z}$.

Proof.

(1) By the Quaternion-Projective Space Lemma 92.9 (2) we can identify the quaternionic projective space $\mathbb{H}\mathrm{P}^1$ with S^4. Therefore if we apply the Hopf-Bundle Proposition 155.9 (2) with $n = 1$ we obtain an S^3-bundle $q\colon S^7 \to \mathbb{H}\mathrm{P}^1 = S^4$. We pick $y_0 \in S^7$ and we write $b_0 = q(y_0)$. We pick an identification $S^3 = q^{-1}(b_0)$ and we denote by $i\colon S^3 \to S^7$ the map that is given by the inclusion of the fiber $F = S^3$ into S^7. From the Fiber-LES Proposition 155.2 we obtain the following long exact sequence

$$\cdots \to \pi_n(S^3, y_0) \xrightarrow{i_*} \pi_n(S^7, y_0) \xrightarrow{q_*} \pi_n(S^4, b_0) \xrightarrow{\partial} \pi_{n-1}(S^3, y_0) \xrightarrow{i_*} \pi_{n-1}(S^7, y_0) \to \ldots.$$

By Proposition 71.10 we know that $\pi_3(S^7, y_0) = 0$. By definition this implies that the map $i\colon S^3 \to S^7$ is homotopic rel y_0 to the constant map $c_{y_0}\colon S^3 \to \{y_0\}$. By the

[1878] It is actually worth having a glance at the lower end of this sequence. We have the exact sequence

$$\pi_2(S^3) \xrightarrow{p_*} \pi_2(S^2) \xrightarrow{\partial} \pi_1(S^1) \to \pi_1(S^3).$$

From Proposition 71.10 we know that $\pi_1(S^3) = \pi_2(S^3) = 0$ and Proposition 48.17 we know that $\pi_1(S^1) \cong \mathbb{Z}$. Thus we obtain that $\pi_2(S^2) \cong \mathbb{Z}$. In Exercise 155.11 we will see that using this exact sequence we can obtain a new proof that id_{S^2} is a generator of $\pi_2(S^2)$.

Fibration-LES Theorem 154.7 (3) this implies that the above long exact sequence splits into short exact sequences

$$0 \to \pi_n(S^7, y_0) \xrightarrow{q_*} \pi_n(S^4, b_0) \xrightarrow{\partial} \pi_{n-1}(S^3, y_0) \to 0.$$

Furthermore the Fibration-LES Theorem 154.7 (3) says that these short exact sequences split, therefore we obtain the promised isomorphisms $\pi_n(S^4, b_0) \cong \pi_n(S^7, y_0) \oplus \pi_{n-1}(S^3, y_0)$.

(2) The statement holds trivially Proposition 71.10 for $n = 1$. For $n \geq 2$ this statement follows from (1) and Proposition 71.10 which says in this context that $\pi_n(S^7) = 0$ for $n = 1, \ldots, 6$. ■

As we will see, the Fiber-LES Proposition 155.2 is a goose that just cannot stop laying golden eggs. For example we have the following theorem.

Theorem 155.12. We use the homeomorphism from page 258 to make the identification $\mathbb{C}\mathrm{P}^1 = S^2$ and as on page 256 we view $\mathbb{C}\mathrm{P}^1$ as a subspace of each $\mathbb{C}\mathrm{P}^n$ and of $\mathbb{C}\mathrm{P}^\infty$.

(1) Let $n \in \mathbb{N}$. If we denote by $p\colon S^{2n+1} \to \mathbb{C}\mathrm{P}^n$ the Hopf map from page 3306, then

$$\pi_k(\mathbb{C}\mathrm{P}^n) = \begin{cases} \mathbb{Z} \cdot [\mathrm{id}_{\mathbb{C}\mathrm{P}^1}], & \text{if } k = 2, \\ 0, & \text{if } k = 1, 3, 4, 5, \ldots, 2n, \\ \mathbb{Z} \cdot [p], & \text{if } k = 2n+1. \end{cases}$$

(2)
$$\pi_k(\mathbb{C}\mathrm{P}^\infty) = \begin{cases} \mathbb{Z} \cdot [\mathrm{id}_{\mathbb{C}\mathrm{P}^1}], & \text{if } k = 2, \\ 0, & \text{if } k = 1, 3, 4, 5, 6, \ldots. \end{cases}$$

Remark. Let $k < l$. In Question 85.4 we had asked whether the complex projective space $\mathbb{C}\mathrm{P}^k$ is a retract of $\mathbb{C}\mathrm{P}^l$. In Proposition 121.14 we used the calculation of the cup product to give a negative answer. Now we can also use homotopy groups for the same purpose. More precisely, from Theorem 155.12, we obtain that $\pi_{2k+1}(\mathbb{C}\mathrm{P}^k) \cong \mathbb{Z}$ but that $\pi_{2k+1}(\mathbb{C}\mathrm{P}^l) = 0$. The usual argument, see Lemma 47.16 implies that once again we obtain a negative answer to Question 85.4, i.e. $\mathbb{C}\mathrm{P}^k$ is not a retract of $\mathbb{C}\mathrm{P}^l$.

Proof.

(1) By the Hopf-Bundle Proposition 155.9 (1) we know that for every $n \in \mathbb{N}$ the Hopf map $p\colon S^{2n+1} \to \mathbb{C}\mathrm{P}^n$ is an S^1-bundle. Thus we obtain from the Fiber-LES Proposition 155.2 the following long exact sequence of homotopy groups:

$$\ldots \to \pi_k(S^1) \to \pi_k(S^{2n+1}) \xrightarrow{p_*} \pi_k(\mathbb{C}\mathrm{P}^n) \xrightarrow{\partial} \pi_{k-1}(S^1) \to \ldots$$

We recall that $\pi_k(S^{2n+1}) = 0$ for $k = 1, \ldots, 2n$, that $\pi_{2n+1}(S^{2n+1}) \cong \mathbb{Z} \cdot [\mathrm{id}_{S^{2n+1}}]$ and that $\pi_k(S^1) = 0$ for $k \geq 2$. Putting everything together implies immediately that $\pi_k(\mathbb{C}\mathrm{P}^n) = 0$ for $k = 3, \ldots, 2n$ and that $\pi_{2n+1}(\mathbb{C}\mathrm{P}^n) \cong \mathbb{Z} \cdot [p]$.[1879] Only the lower end of the long exact sequence requires slightly more thought. More precisely, we have the exact sequence

$$\underbrace{\pi_2(S^{2n+1})}_{=0} \to \pi_2(\mathbb{C}\mathrm{P}^n) \xrightarrow{\partial} \pi_1(S^1) \to \underbrace{\pi_1(S^{2n+1})}_{=0} \to \pi_1(\mathbb{C}\mathrm{P}^n) \to \pi_0(S^1) \to \pi_0(S^{2n+1}).$$

[1879] Here we use the trivial, but useful observation that $p_*([\mathrm{id}_{S^n}]) = [p]$.

Since S^1 and S^{2n+1} are path-connected we see that the map on the right is an isomorphism of pointed sets. It follows that $\pi_2(\mathbb{C}\mathrm{P}^n) \xrightarrow{\cong} \pi_1(S^1) \cong \mathbb{Z}$ and that $\pi_1(\mathbb{C}\mathrm{P}^n) = 0$. (We had of course known the latter statement for a long time, see e.g. page 1533.) The only thing which is not entirely clearly from this argument is why $\mathrm{id}_{\mathbb{C}\mathrm{P}^1}$ represents a generator of $\pi_2(\mathbb{C}\mathrm{P}^n)$. One could either heroically fight one's way through the above isomorphism, in the same vein as in Exercise 155.11, and use that we know explicitly the generator of $\pi_1(S^1)$.

But fortunately we do not have to go down that route since in Corollary 85.6 (2) we already saw that $\mathrm{id}_{\mathbb{C}\mathrm{P}^1}$ represents a generator of $\pi_2(\mathbb{C}\mathrm{P}^n)$.

(2) We calculate that

$$\pi_k(\mathbb{C}\mathrm{P}^\infty) \;=\; \pi_k\Big(\bigcup_{k\in\mathbb{N}} \mathbb{C}\mathrm{P}^n\Big) \;\underset{\uparrow}{=}\; \varinjlim \pi_k(\mathbb{C}\mathrm{P}^n) \;\underset{\uparrow}{=}\; \begin{cases} \mathbb{Z}\cdot[\mathrm{id}_{\mathbb{C}\mathrm{P}^1}], & \text{if } k=2, \\ 0, & \text{if } k = 1,3,4,5,\dots. \end{cases}$$

by the Direct Limit-π_n-Proposition 71.11 since by Lemma 68.6 we can view $\mathbb{C}\mathrm{P}^\infty$ as a CW-complex where each k-skeleton is given by $\mathbb{C}\mathrm{P}^n \subset \mathbb{C}\mathrm{P}^\infty$

by (1)

■

155.3. **The Hopf fibration arising from the octonions** (∗). In the Hopf-Bundle Proposition 155.9 we had in particular seen that the Hopf map $p\colon S^3 \to \mathbb{C}\mathrm{P}^1 = S^2$ is an S^1-bundle and that the Hopf map $q\colon S^7 \to \mathbb{H}\mathrm{P}^1 = S^4$ is an S^3-bundle. We exploited these fiber bundles in Theorems 155.10 and 155.11 to obtain non-trivial information on higher homotopy groups of spheres.

In our discussion of division algebras in Section 92.1 we gave the quaternions as a first example of a non-commutative division algebra. The algebra structure on the quaternions is still nonetheless quite reasonable, in particular the algebra structure is associative which was enough to define the quaternionic projective spaces on page 1970.

Next on the list of ever weirder division algebras were the octonions $\mathbb{O}$ that we introduced on page 1963. Recall that the underlying vector space of the octonions is $\mathbb{R}^8$ but that this time the algebra structure is neither commutative nor associative. The only redeeming feature is that $\mathbb{O}$ is still a division algebra.

Since the octonions are no longer associative one cannot just copy-paste the definition of the quaternionic projective spaces on page 1970 to define octonionic projective spaces in any obvious way. But we can make a prediction: if there was a first octonionic projective space, then it would presumably give rise to a Hopf fibration $r\colon S^{15} \to \mathbb{O}P^1 = S^8$ with fiber S^7. Alas, octonionic projective spaces do not exist. But as we will see, we can still use octonions to produce such a fiber bundle. More precisely, our goal in this section is to prove the following proposition.

Proposition 155.13. There exists a fiber bundle $p\colon S^{15} \to S^8$ with fiber S^7.

The proof of Proposition 155.13 is rather longish, thus we will first point out that it allows us to prove the following theorem.

Theorem 155.14.

(1) For all $n \geq 2$ we have $\pi_n(S^8) \cong \pi_n(S^{15}) \oplus \pi_{n-1}(S^7)$.

(2) For $n \in \{1,\dots,14\}$ we have $\pi_n(S^8) \cong \pi_{n-1}(S^7)$.

Proof. The proof is basically the same as the proof of Theorem 155.11. We just need to replace the Hopf-Bundle Proposition 155.9 (2) by Proposition 155.13. ■

We can copy-paste the remark after Theorem 155.11:

Remark. From Corollary 85.6 (1) we know that $\pi_{15}(S^{15}) \cong \mathbb{Z}$. Thus it follows from Theorem 155.11 (1) that $\pi_{15}(S^8)$ admits an epimorphism onto $\mathbb{Z}$. In fact in Corollary 122.8 we already saw that the Hopf invariant is an epimorphism $\pi_{15}(S^8) \to \mathbb{Z}$.

The remainder of this chapter is occupied with providing a proof of Proposition 155.13. We will need the notion of the join of two topological spaces that we introduced on page 446.

Definition. Let X and Y be two non-empty topological spaces. We define the join $X * Y$ to be the topological space obtained from $X \times [0,1] \times Y$, equipped with the product topology, by performing the following two types of identifications:

(1) for every $x \in X$ we identify all points in $\{x\} \times \{0\} \times Y$ to a single point and
(2) for every $y \in Y$ we identify all points in $X \times \{1\} \times \{y\}$ to a single point.

Furthermore, if one of X or Y is the empty topological space, then we define $X * Y$ to be the other topological space.

We remind the reader of the following lemma.

Lemma 16.4. Given any $m, n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} S^m * S^n & \to & S^{m+n+1} \\ [(x,t,y)] & \mapsto & \underbrace{\left(x \cdot \cos\left(\frac{\pi t}{2}\right), y \cdot \sin\left(\frac{\pi t}{2}\right)\right)}_{\in \mathbb{R}^{m+1} \times \mathbb{R}^{n+1} = \mathbb{R}^{m+n+2}} \end{array}$$

is a homeomorphism.

The following proposition explains our sudden interest in the join of two topological spaces.

Proposition 155.15. Let X be a topological space that is compact and Hausdorff. Furthermore let $\varphi\colon X \times X \to X$ be a map. Given $x \in X$ we consider the maps[1880]

$$\begin{array}{rcl} L_x\colon X & \to & X \\ a & \mapsto & \varphi(x,a) \end{array} \quad \text{and} \quad \begin{array}{rcl} R_x\colon X & \to & X \\ a & \mapsto & \varphi(a,x). \end{array}$$

If each map $L_x\colon X \to X$ and each map $R_x\colon X \to X$ is a homeomorphism, then the map

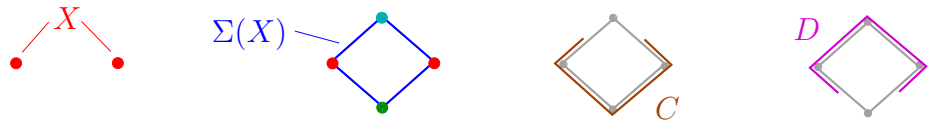
$$\begin{array}{rcl} h_\varphi\colon X * X & \to & \Sigma(X) \\ [(x,t,y)] & \mapsto & [(\varphi(x,y), 2t-1)] \end{array}$$

is a fiber bundle with fiber X.[1881]

Example. We write $S^3 = \{z \in \mathbb{H} \,|\, |z| = 1\}$. By the Quaternion Lemma 92.1 (7) we know that for any $w, z \in \mathbb{H}$ we have $|w \cdot z| = |w| \cdot |z|$. Thus multiplication of quaternions defines a map $\varphi\colon S^3 \times S^3 \to S^3$. Given any $z \in S^3$ the map L_z is a homeomorphism. In fact an inverse is given by $L_{z^{-1}}$ since for any $x \in S^3$ we have

$$(L_{z^{-1}} \circ L_z)(x) \;=\; z^{-1} \cdot (z \cdot x) \;\underset{\text{since } \mathbb{H} \text{ is associative}}{=}\; (z^{-1} \cdot z) \cdot x \;=\; x,$$

[1880] Here the mnemonic device is that "L" should suggest "left-multiplication" and "R" should suggest "right-multiplication".



[1881] It is a good exercise to first verify that the map is actually well-defined.

and similarly we have $L_z \circ L_{z^{-1}} = \mathrm{id}_{S^3}$. The same argument shows that R_z is also a homeomorphism. Thus we obtain from Proposition 155.15 and the Join of Spheres Lemma 16.4 a fiber bundle $p\colon S^7 \to S^4$ with fiber S^3. We leave it to the heroically inclined reader to verify that this S^3-bundle is equivalent to the S^3-bundle $q\colon S^7 \to \mathbb{HP}^1 = S^4$ that we had constructed in the proof of the Hopf-Bundle Proposition 155.9.

Proof. We consider the following two subsets of $\Sigma(X)$:

$$C \;:=\; ([-1, \tfrac{1}{2}] \times X) \,/\, \{-1\} \times X \quad \text{and} \quad D \;:=\; ([-\tfrac{1}{2}, 1] \times X) \,/\, \{1\} \times X.$$

We refer to the figure below for an illustration. Since the interiors of these two sets cover $\Sigma(X)$ it suffices to find trivializations of the map $h_\varphi\colon X * X \to \Sigma(X)$ with fiber X over C and over D.

We start out with finding a trivialization over C.

Claim. The map
$$\begin{array}{rcl} \Psi\colon X \times C & \to & X * X \\ (x, [(y,t)]) & \mapsto & [(x, \frac{2}{3}(t+1), L_x^{-1}(y))] \end{array}$$
is continuous and it restricts to a homeomorphism onto $h_\varphi^{-1}(C)$.

Proof. By now the reader is surely aware of the fact that whenever we mix quotients with products we need to tread carefully. Thus let us first consider the maps

$$\begin{array}{rcl} \alpha\colon X \times X & \to & X \times X \\ (x,y) & \mapsto & (x, \varphi(x,y)) = (x, L_x(y)) \end{array} \quad \text{and} \quad \begin{array}{rcl} \beta\colon X \times X & \to & X \times X \\ (x,y) & \mapsto & (x, L_x^{-1}(y)). \end{array}$$

Note that these two maps are inverses of one another. Also note that α is continuous by the Product Topology-Basics Lemma 5.4 (3). Furthermore note that α is a bijection, in fact the inverse is given by β. Since X is compact and Hausdorff we obtain from the Product Topology Properties Proposition 5.6 and the Compact-Hausdorff Proposition 2.17 (3) that α is a homeomorphism. In particular $\beta = \alpha^{-1}$ is also continuous.

Next we consider the map

$$\begin{array}{rcl} \psi\colon X \times ([-1, \frac{1}{2}] \times X) & \to & X \times [0,1] \times X \\ (x,t,y) & \mapsto & (x, \frac{2}{3}(t+1), L_x^{-1}(y)). \end{array}$$

Since $\beta(x,y) = (x, L_x^{-1}(y))$ and since β is continuous we see that ψ is also continuous. Finally we consider the following commutative diagram

$$\begin{array}{ccc} X \times [-1, \frac{1}{2}] \times X & \xrightarrow{(x,t,y)\mapsto(x,[(t,y)])} & \overbrace{X \times \big(([-1, \frac{1}{2}] \times X) \,/\, (\{-1\} \times X)\big)}^{= X \times C} \\ \Big\downarrow{\scriptstyle \psi} & \searrow^{f := p \circ \psi} & \Big\downarrow{\scriptstyle \Psi} \\ X \times [0,1] \times X & \xrightarrow[p(x,t,y) := [(x,t,y)]]{} & X * X. \end{array}$$

Claim. The map Ψ is continuous.

Proof. We had just seen that $f = p \circ \psi$ is continuous. Note that by the Quotient Map Lemma 13.3 (1) the projection $q\colon [-1, \frac{1}{2}] \times X \to ([-1, \frac{1}{2}] \times X) \,/\, (\{-1\} \times X)$ is a quotient map. Since X is compact and Hausdorff we know by Lemma 2.41 that X is regionally compact.[1882] Thus it follows from the Whitehead Quotient Theorem 13.4 that the top horizontal map $\mathrm{id}_X \times q$ is a quotient map. Thus it follows from Lemma 13.5 (2) that ψ is continuous. ⊞

One easily verifies that Ψ defines a bijection

$$\Psi\colon \underbrace{X \times C}_{\subset X * X} \to \underbrace{h_\varphi^{-1}(C)}_{\subset \Sigma(X)}.$$

Since X is compact we know by Lemma 16.2 (1) that the left-hand side is compact. By the Cone-Suspension Basics Lemma 16.8 (2) and our hypothesis that X is Hausdorff we know that the right-hand side is Hausdorff. Therefore it follows from the Compact-Hausdorff Proposition 2.17 (3) that the continuous bijection $\Psi\colon X \times C \to h_\varphi^{-1}(C)$ is indeed a homeomorphism. ⊞

We consider the following diagram

$$\begin{array}{ccc} X \times C & \xrightarrow{\quad\Psi\quad} & h_\varphi^{-1}(C) \\ & {\scriptstyle (x,c)\mapsto c} \searrow \quad \swarrow {\scriptstyle h_\varphi} & \\ & C. & \end{array}$$

It is straightforward to verify that this diagram commutes. Since the top map is homeomorphism by the previous claim we have found a trivialization of h_φ over C. We leave it to the reader to make the minor modifications needed to find a trivialization of h_φ over D.[1883] ■

Evidently the idea now is to replace the quaternions in the example on page 3312 by the octonions. In the following we recall the most salient bits from the discussion of octonions on page 1963. The octonions $\mathbb{O}$ are $\mathbb{R}^8$ together with an algebra structure over $\mathbb{R}$ that has the following properties:

(1) The octonions $\mathbb{O}$ are a division algebra, i.e. for all $a \neq 0$ and $b \in \mathbb{O}$ there exists an $x \in \mathbb{O}$ with $a \cdot x = b$ and a $y \in \mathbb{O}$ with $y \cdot a = b$.
(2) The algebra structure is neither commutative nor associative.
(3) Multiplication on $\mathbb{O}$ respects the euclidean norm, more precisely, given $a, b \in \mathbb{O}$ we have $\|a \cdot b\| = \|a\| \cdot \|b\|$.

It follows from (3) that the algebra multiplication induces a map $\varphi\colon S^7 \times S^7 \to S^7$.

Lemma 155.16. Given any $z \in S^7$ the maps $L_z\colon S^7 \to S^7$ and $R_z\colon S^7 \to S^7$, as defined in Proposition 155.15, are homeomorphisms.

Proof. First note that we can *not* recycle the argument from page 3311 since there we used that the quaternions are associative.

[1882] If the reader is unhappy about using Lemma 2.41 we point out that in our application of the proposition the topological space will be $X = S^n$ and thus obviously regionally compact.
[1883] Note that in this second part we will need to use that the maps $R_x\colon X \to X$ are homeomorphisms.

By Corollary 82.9 (2) it suffices to show that the maps L_z and R_z are injective. First we show that given any $z \in S^7$ the map $L_z \colon S^7 \to S^7$ is injective. So suppose that we have $a, b \in S^7$ with $L_z(a) = L_z(b)$. We obtain that

$$\|a-b\| \underset{\substack{\uparrow \\ \text{since } z \in S^7}}{=} \|z\| \cdot \|a-b\| \underset{\substack{\uparrow \\ \text{by (3)}}}{=} \|z \cdot (a-b)\| \underset{\substack{\uparrow \\ \text{since } \mathbb{O} \text{ is an algebra}}}{=} \|z \cdot a - z \cdot b\| \underset{\substack{\uparrow \\ \text{by definition of } L_z}}{=} \|L_z(a) - L_z(b)\| \underset{\substack{\uparrow \\ \text{since } L_z(a) = L_z(b)}}{=} 0.$$

Thus we see that $a = b$. Almost the same argument shows that R_z is injective.[1884] ■

Now we are basically done with the proof of Proposition 155.13.

Proof of Proposition 155.13. It follows immediately from Lemma 155.16, Proposition 155.15 and the Join of Spheres Lemma 16.4 that there exists a fiber bundle $p \colon S^{15} \to S^8$ with fiber S^7. ■

Exercises for Chapter 155.

Exercise 155.1. Let F be a topological space and let $p \colon Y \to B$ be an F-bundle. Suppose that the fiber F and the base space B are path-connected. Show directly, without making use of Proposition 155.2 (2), that the total space Y is also path-connected.

Exercise 155.2. Let $p \colon Y \to [0,1]$ be a bundle with fiber F. Show with your bare hands (i.e. without using Proposition 155.7) that p is trivial, i.e. show that p is equivalent to the trivial bundle $F \times [0,1] \to [0,1]$.

Exercise 155.3. Let X be a topological space and let $f_0, f_1 \colon X \to X$ be homeomorphisms. Suppose that f_0 and f_1 are isotopic. Show that the two X-bundles $\mathrm{Tor}(X, f_0) \to S^1$ and $\mathrm{Tor}(X, f_1) \to S^1$ are equivalent.

Exercise 155.4. Let $f \colon \mathbb{R}^n \to \mathbb{R}^n$ be a diffeomorphism. Show that the corresponding $\mathbb{R}^n$-bundle $\mathrm{Tor}(\mathbb{R}^n, f) \to S^1$ is equivalent to an n-dimensional vector bundle.
Hint. Use Lemma 76.15 and Lemma 155.3 (2), the latter is a. k. a. Exercise 155.3.

Exercise 155.5. Use the Ehresmann Fibration Theorem, see Exercise **??**, to give an alternative proof of the fact that the Hopf map $S^3 \to \mathbb{C}\mathrm{P}^1$ defines an S^1-bundle over $\mathbb{C}\mathrm{P}^1 = S^2$.

Exercise 155.6. As on page 1576 we consider the Hopf map:

$$\begin{array}{rcl} H \colon S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ (z_1, z_2) & \mapsto & [z_1 : z_2]. \end{array}$$

(a) Let $P, Q \in S^2$ be two distinct points. Show that $\mathrm{H}^{-1}(P) \cup \mathrm{H}^{-1}(Q)$ is isotopic to a Hopf link, that we defined in the figure on page 2863.
(b) Let $P, Q, R \in S^2$ be two distinct points. Sketch the link $\mathrm{H}^{-1}(P) \cup \mathrm{H}^{-1}(Q) \cup \mathrm{H}^{-1}(\{R\})$.

Exercise 155.7. Let $n \in \mathbb{N}$. We consider the map

$$\begin{array}{rcl} \varphi \colon \mathrm{U}(n) = \{A \in \mathrm{M}(n \times n, \mathbb{C}) \,|\, A \cdot \overline{A}^T = \mathrm{id}\} & \to & \mathbb{C} \setminus \{0\} \\ A & \mapsto & \det(A). \end{array}$$

[1884] At first glance it might appear odd that we never used that the octonions are a division algebra, we only used the innocuous looking third property. But it is clear that (3) already implies that $\mathbb{O}$ has no zero-divisors. By Lemma 92.5 this forces $\mathbb{O}$ to be a division algebra.

(a) Show that φ takes values in S^1.
(b) Show that the map $\varphi\colon \mathrm{U}(n) \to S^1$ is a fiber bundle.
Hint. You can use the Ehresmann Fibration Theorem from Exercise **??**.

Exercise 155.8. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. By the discussion on page 3301 and the Fiber-LES Proposition 155.2 we know that the map

$$\begin{array}{rcl} \mathrm{Tor}(X,f) = (X \times [0,1])/(x,0) \sim (f(x),1) & \to & S^1 \\ [(x,t)] & \mapsto & \exp(2\pi \mathrm{i} t) \end{array}$$

is a fibration. We make the obvious identification $X = X \times \{0\} \subset \mathrm{Tor}(X,f)$. Let $k \in \mathbb{N}_0$ and let $\alpha\colon [0,1] \to S^1$ be the usual loop given by $\alpha(t) = \exp(2\pi \mathrm{i} t)$. By Proposition 154.5 and Lemma 73.2 we get a well-defined map

$$\Theta(\alpha)_*\colon \mathrm{H}_k(X;\mathbb{Z}) \to \mathrm{H}_k(X;\mathbb{Z}).$$

Show that $\Theta(\alpha)_* = (f_*)^{-1}$.

Exercise 155.9. Let W be an n-dimensional smooth manifold and let K be a compact proper connected k-dimensional submanifold with $k \leq n-3$. Show that the inclusion induced map $\pi_1(W \setminus K) \to \pi_1(W)$ is an isomorphism.
Hint. Use the Amalgamated Product Lemma 53.22 (3).

Exercise 155.10. The same way that we defined the infinite complex projective space $\mathbb{C}\mathrm{P}^\infty$, see page 1480, we define the infinite quaternionic projective space $\mathbb{H}\mathrm{P}^\infty$ as the direct limit of the finite-dimensional quaternionic projective spaces $\mathbb{H}\mathrm{P}^k$. Show that for any $i \in \mathbb{N}_{\geq 2}$ we have an isomorphism $\pi_i(\mathbb{H}\mathrm{P}^\infty) \cong \pi_{i-1}(S^3)$.

Exercise 155.11. Let $p\colon S^3 \to S^2$ the Hopf fibration. In the Hopf-Bundle Proposition 155.9 we saw that it is an S^1-fiber bundle. We consider the connecting homomorphism $\partial\colon \pi_2(S^2) \to \pi_1(S^1)$ of the long exact sequence of homotopy groups from the Fiber-LES Proposition 155.2 (2). Show, just using the definition of the connecting homomorphism, that $\partial([\mathrm{id}_{S^2}]) = [\mathrm{id}_{S^1}]$.

Exercise 155.12. Show that the homotopy groups of S^2 and $S^3 \times \mathbb{C}\mathrm{P}^\infty$ are isomorphic.

Exercise 155.13. Let $m,k \in \mathbb{N}$ and let $p\colon M \to S^k$ be a fiber bundle with fiber S^m. We denote by $i\colon S^m \to M$ the homeomorphism to any of the fibers.

(a) Show that M is a closed $(m+k)$-dimensional topological manifold.
(b) We suppose that $m < k$ and we suppose that M is orientable. Show that the maps $p_*\colon \mathrm{H}_k(M) \to \mathrm{H}_k(S^k)$ and $i_*\colon \mathrm{H}_m(S^m) \to \mathrm{H}_m(M)$ are isomorphisms and show that $\mathrm{H}_i(M) = 0$ for $i \neq 0,k,m,m+n$.
Hint. Use Theorems 154.7 and 153.14 and use Poincaré Duality.
(c) We suppose again that M is orientable. Show that the conclusion in (b) does not necessarily hold if we drop the hypothesis that $m < k$.

156. Homotopy groups of Lie groups

In this chapter our focus will lie on the study of the homotopy groups of the matrix groups $\mathrm{O}(n)$ and $\mathrm{U}(n)$. Later on in the section we will see that we should also define a third type of groups, namely the groups $\mathrm{Sp}(n)$ which can be viewed as the quaternionic analogue of $\mathrm{O}(n)$ and $\mathrm{U}(n)$.
Since these groups are Lie groups and since this structure is helpful in our study of $\mathrm{O}(n)$ and $\mathrm{U}(n)$ we first give a short introduction to Lie groups.

156.1. **Topological groups and Lie groups.** First we recall the following definition from page 267.

Definition. A topological group is a topological space X together with a group structure such that the two maps

$$\begin{array}{ccc} X\times X & \to & X \\ (x,y) & \mapsto & x\cdot y \end{array} \quad \text{and} \quad \begin{array}{ccc} X & \to & X \\ x & \mapsto & x^{-1} \end{array}$$

are continuous. A morphism between topological groups X and Y is a homomorphism $f\colon X\to Y$ that is furthermore continuous.

Examples.

(1) On page 268 we already saw that for any $n\in\mathbb{N}$ the matrix groups $\mathrm{SL}(n,\mathbb{R})$, $\mathrm{O}(n)$, $\mathrm{SO}(n)$, $\mathrm{GL}(n,\mathbb{C})$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$ are topological groups.

(2) Let X be a topological space and let $x_0\in X$ be a base point. We consider the loop space $\Omega(X,x_0)$, i.e. the set

$$\Omega(X,x_0) \;=\; \{\gamma\colon [0,1]\to X \,|\, \gamma(0)=\gamma(1)=x_0\}/\text{homotopy}$$

equipped with the compact-open topology. As in Exercise 154.7 we equip the set $\pi_1(X,x_0)=\Omega(X,x_0)/\sim$ with the quotient topology, i.e. we view $\pi_1(X,x_0)$ as a topological space. Evidently $\pi_1(X,x_0)$ admits a group structure, but somewhat surprisingly, the multiplication map $\pi_1(X,x_0)\times\pi_1(X,x_0)\to\pi_1(X,x_0)$ is in general *not* continuous. In fact such an example is given by the Hawaiian Earrings, introduced in Exercise 56.1. We refer to [**Fab2011**] for details.[1885]

We leave the elementary proof of the following lemma to the reader.

Lemma 156.1. Let G be a topological group and let H be a subgroup of G. The map

$$\begin{array}{ccc} G\times H & \to & G \\ (g,h) & \mapsto & g\cdot h \end{array}$$

defines a right-action of H on G that is free and continuous.

To avoid any misunderstanding we introduce the following convention.

Convention. Let G be a topological group and let H be a subgroup. We denote by G/H the topological space that is given by the equivalence relation[1886]

$$g_1\sim g_2 \quad\Longleftrightarrow\quad \text{there exists an } h\in H \text{ with } g_1\cdot h=g_2.$$

[1885] In fact, as is pointed out in [**Fab2011**], the failure of $\pi_1(X,x_0)$ to be a topological group is another instance of the phenomenon, discussed in Section 13.1, that in general product and quotient topologies do not mix well.

The following definition of a Lie group is quite similar to the above definition of a topological group.

Definition. A Lie group is a smooth manifold X with empty boundary together with a group structure such that the two maps[1887]

$$\begin{array}{ccc} X \times X & \to & X \\ (x,y) & \mapsto & x \cdot y \end{array} \quad \text{and} \quad \begin{array}{ccc} X & \to & X \\ x & \mapsto & x^{-1} \end{array}$$

are smooth.

Remark.

(1) It follows immediately from Lemma 19.22 that a Lie group is also a topological group.
(2) As we will see in Exercise 156.2, strictly speaking one does not need to demand that the map $x \mapsto x^{-1}$ is smooth, since it follows already from the other properties.

Examples.

(1) It is straightforward to see that the smooth manifold $\mathbb{R}$ with the group structure given by addition and the smooth manifold S^1 with the group structure given by multiplication are Lie groups.
(2) The product $G_1 \times G_2$ of two Lie groups G_1 and G_2 admits a canonical smooth manifold structure by the Smooth Manifold Product Proposition 19.31 and the group structures on G_1 and G_2 define a group structure on $G_1 \times G_2$. One can easily verify that $G_1 \times G_2$ is again a Lie group. In particular the torus $S^1 \times S^1$ is a Lie group.

As mentioned in the beginning of this chapter, we are now interested in the homotopy groups of the groups

$$\begin{aligned} \mathrm{O}(n) &= \{A \in \mathrm{M}(n \times n, \mathbb{R}) \,|\, A^T A = \mathrm{id}\} \\ \mathrm{U}(n) &= \{A \in \mathrm{M}(n \times n, \mathbb{C}) \,|\, \overline{A}^T A = \mathrm{id}\}. \end{aligned}$$

As we will see later on, even if we are only interested in these groups it makes sense to extend our gaze and to consider the quaternionic analogue of $\mathrm{O}(n)$ and $\mathrm{U}(n)$:

Definition. Let $n \in \mathbb{N}$. We set[1888]

$$\mathrm{Sp}(n) := \{A \in \mathrm{M}(n \times n, \mathbb{H}) \,|\, \overline{A}^T A = \mathrm{id}\}.$$

We will first discuss $\mathrm{Sp}(n)$ a little bit before we settle on a name for it:

Lemma 156.2.

(1) We have $\mathrm{Sp}(1) = S^3$.
(2) Let $n \in \mathbb{N}$. Matrix multiplication turns $\mathrm{Sp}(n)$ into a group.

[1886]The point of this convention is that in principle G/H could mean the quotient of the topological space G by the subset H.
[1887]Here we equip $X \times X$ with the product smooth manifold structure introduced in the Smooth Manifold Product Proposition 19.31.
[1888]Recall that the conjugate of a quaternion $h = a \cdot 1 + b \cdot \mathrm{i} + c \cdot \mathrm{j} + d \cdot \mathrm{k}$ is defined as $\overline{h} = a \cdot 1 - b \cdot \mathrm{i} - c \cdot \mathrm{j} - d \cdot \mathrm{k}$. Given a matrix $A = (a_{ij})$ over $\mathbb{H}$ we define $\overline{A} = (\overline{a}_{ij})$.

(3) Let $n \in \mathbb{N}$. We write $J = \begin{pmatrix} 0 & \mathrm{id}_n \\ -\mathrm{id}_n & 0 \end{pmatrix}$. The map

$$\begin{aligned} \Phi\colon \mathrm{Sp}(n) &\to \{X \in \mathrm{U}(2n) \mid JXJ^{-1} = \overline{X}\} \\ P &\mapsto \begin{pmatrix} A & B \\ -\overline{B} & \overline{A} \end{pmatrix} \quad \text{where } A, B \in \mathrm{M}(n \times n, \mathbb{C}) \text{ with}^{1889}\ P = A + B\mathrm{j} \end{aligned}$$

is a group isomorphism.

Proof.

(1) In the Quaternion Lemma 92.1 (5) we saw that for any quaternion $h \in \mathbb{H}$ we have $h \cdot \overline{h} = \|h\|^2$. It follows immediately that $\mathrm{Sp}(1) = S^3$.

(2) We start out with the following observation: A straightforward calculation[1890] shows that for any two matrices $A, B \in \mathrm{M}(n \times n, \mathbb{H})$ we have $\overline{(AB)}^T = \overline{B}^T \overline{A}^T$. Now we turn to the proof that $\mathrm{Sp}(n)$ is a group:
   (a) The fact that $\mathbb{H}$ is associative implies immediately that the multiplication of matrices in $\mathrm{M}(n \times n, \mathbb{H})$ is associative.
   (b) The identity matrix is as usual a neutral element.
   (c) Given $A \in \mathrm{Sp}(n)$ we have by definition that $\overline{A}^T A = \mathrm{id}$, i.e. $\overline{A}^T$ is a left-inverse. The above observation implies that $\overline{A}^T$ is also a right-inverse.
   (d) It follows from the above observation that $\mathrm{Sp}(n)$ is closed under matrix multiplication and taking inverses.

   We have thus shown that $\mathrm{Sp}(n)$ is indeed a group.

(3) We will only use this isomorphism to justify the name for $\mathrm{Sp}(n)$, otherwise it will not play a role. Therefore we will not provide the fairly elementary proof of this statement, instead we refer to [**Bre1993**, p. 103] for the proof. ■

Not surprisingly we will now see that $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ are Lie groups.

Lemma 156.3.

(1) Let $n \in \mathbb{N}$.
   (a) The set $\mathrm{O}(n)$ is a submanifold of $\mathrm{M}(n \times n, \mathbb{R}) = \mathbb{R}^{n^2}$ of dimension $\frac{1}{2}n(n-1)$.
   (b) The set $\mathrm{U}(n)$ is a submanifold of $\mathrm{M}(n \times n, \mathbb{C}) = \mathbb{C}^{n^2} = \mathbb{R}^{2n^2}$ of dimension n^2.
   (c) The set $\mathrm{Sp}(n)$ is a submanifold of $\mathrm{M}(n \times n, \mathbb{H}) = \mathbb{H}^{n^2} = \mathbb{R}^{4n^2}$ of dimension $2n^2 + n$.

   Furthermore, if we view $\mathrm{O}(n)$ as a subspace of $\mathrm{O}(n+1)$ in the obvious way, then $\mathrm{O}(n)$ is a submanifold of $\mathrm{O}(n+1)$. The same statements apply to $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$.

(2) $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$, viewed as smooth manifolds in their own right, are closed, in particular they are compact.

(3) The usual matrix multiplication turns $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ into Lie groups.

Remark.

[1889] It follows from $\mathrm{i} \cdot \mathrm{j} = \mathrm{k}$ that any quaternion $a \cdot 1 + b \cdot \mathrm{i} + c \cdot \mathrm{j} + d \cdot \mathrm{k}$ can be uniquely written as $(a \cdot 1 + b \cdot \mathrm{i}) + (c \cdot 1 + d \cdot \mathrm{i}) \cdot \mathrm{j}$ where $a \cdot 1 + b \cdot \mathrm{i}$ and $c \cdot 1 + d \cdot \mathrm{i}$ are complex numbers. The same statement applies to matrices.

[1890] In the calculation we need to use the fact, mentioned in the Quaternion Lemma 92.1 (3), that for quaternions $w, z \in \mathbb{H}$ we have $\overline{z \cdot w} = \overline{w} \cdot \overline{z}$.

(1) Recall that on page 3125 we defined the symplectic group $\mathrm{Sp}(2g,\mathbb{Z})$ as follows:

$$\mathrm{Sp}(2g,\mathbb{Z}) \;=\; \{A \in \mathrm{GL}(2g,\mathbb{Z}) \,|\, A^T J A = A\} \quad \text{where} \quad J = \begin{pmatrix} 0 & \mathrm{id}_g \\ -\mathrm{id}_g & 0 \end{pmatrix}.$$

This definition, together with Lemmas 156.2 and 156.3, leads us to calling $\mathrm{Sp}(n)$ the *n-th compact symplectic group*.

(2) The statements regarding the groups $\mathrm{O}(n)$ and $\mathrm{U}(n)$ are mostly already contained in the Matrix Group-Smooth Manifold Proposition 26.7.

Proof. In the Matrix Group-Smooth Manifold Proposition 26.7 we had basically proved statements (1) and (2) for the groups $\mathrm{O}(n)$ and $\mathrm{U}(n)$. The only aspect that we did not mention explicitly so far is that $\mathrm{O}(n)$ is a submanifold of $\mathrm{O}(n+1)$. We leave it to the reader to verify that this statement holds. The proof of (1) and (2) for $\mathrm{Sp}(n)$ is basically the same.

In Lemma 5.38 we showed that $\mathrm{O}(n)$ and $\mathrm{U}(n)$ are topological groups. Almost the same argument given in that proof shows that matrix multiplication and taking inverses are smooth maps. This implies that $\mathrm{O}(n)$ and $\mathrm{U}(n)$ are Lie groups. Furthermore it is clear that multiplication in $\mathrm{Sp}(n)$ is smooth. It remains to show that the map

$$\begin{array}{ccc} \mathrm{Sp}(n) & \to & \mathrm{Sp}(n) \\ A & \mapsto & A^{-1} \end{array}$$

is smooth. We will show this fact in Exercise 156.4. ■

Basically by definition we have $\mathrm{O}(1) = S^0$ and $\mathrm{U}(1) = S^1$, furthermore by Lemma 156.2 (1) we have $\mathrm{Sp}(1) = S^3$. Thus it follows from Lemma 156.3 that these three spheres can be viewed as Lie groups. The question arises, whether perhaps other (all?) spheres can be equipped with the structure of a Lie group. The following lemma gives an easy way to rule out the existence of Lie group structures on some smooth manifolds.

Lemma 156.4. Every Lie group is parallelizable.[1891]

Examples. Recall that on page 3066 we saw that $2n$-dimensional spheres with $n \geq 1$ are not parallelizable. Furthermore on page 3066 we showed that for $g \neq 1$ the surface of genus g is not parallelizable. Thus it follows from Lemma 156.4 that these spheres and surfaces cannot be equipped with a Lie group structure.

Sketch of proof. Let G be an n-dimensional Lie group with trivial element e. We denote by $R_g \colon G \to G$ the map that is given by right-multiplication by g. Since G is a Lie group this map is in fact a diffeomorphism. The map

$$\begin{array}{ccc} G \times T_eG & \to & TG = \{(g,h) \,|\, g \in G \text{ and } w \in T_hG\} \\ (g,v) & \mapsto & (g,(R_g)_*(v)) \end{array}$$

is an isomorphism of vector bundles. (This statement is basically obvious, except that perhaps it is not completely clear why the map is continuous, we refer to [**Lee2002**, Corollary 8.39] for more details.) But this shows that G is parallelizable. ■

The following lemma gives us more examples of Lie groups.

[1891] Recall that according to the definition on page 3063 a smooth manifold is called parallelizable if its tangent bundle is trivial.

Lemma 156.5. Let G be a Lie group and let K be a finite normal subgroup. The quotient G/K admits a unique smooth manifold structure such that the projection $G \to G/K$ is a local diffeomorphism. Furthermore the group structure on the quotient group G/K defines a Lie group structure on G/K.

Example. It follows from Lemma 156.5 that for any $n \in \mathbb{N}$ the quotients $\mathrm{SU}(n)/\{\pm \mathrm{id}\}$ and $(\mathrm{SU}(n) \times \mathrm{SU}(n))/\{\pm(\mathrm{id}, \mathrm{id})\}$ are Lie groups.

Proof. In Lemma 156.1 we already saw that the action of K on G is free and continuous. Since G is a Lie group one also sees that the action is smooth. Finally, since G is finite we get for free that the action is proper. Thus we obtain from the Manifold Quotient-by-Group Action Proposition 19.32 that G/K admits a unique smooth manifold structure (without boundary) such that the projection $G \to G/K$ is a local diffeomorphism. We leave it to the reader to verify that the induced multiplication map $G/K \times G/K \to G/K$ is again smooth. ■

Above we have seen that subgroups of matrix groups often give rise to Lie groups. Perhaps somewhat surprisingly, in a sense, all compact Lie groups arise that way. More precisely, the following theorem holds:[1892] Theorem 156.6 as an analogue of the Euclidean Embedding Theorem 27.1.

Theorem 156.6. Any compact Lie group is isomorphic (in the obvious sense) to a Lie subgroup of $\mathrm{GL}(n, \mathbb{R})$ for some $n \in \mathbb{N}$.

The theorem is a consequence of the so-called Peter-Weyl Theorem. We only stated the theorem for "general culture". We will not make use of it and thus we refer to [**BtD1995**, Theorem III.4.1] or alternatively to [**Sep2007**, Theorem 3.28] for a proof.

156.2. **The homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$.** In this chapter we want to see what we can say about the homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$.

Convention.

(1) Given $n \in \mathbb{N}$ we have the obvious monomorphism

$$\begin{array}{rcl} \mathrm{O}(n) & \to & \mathrm{O}(n+1) \\ A & \mapsto & \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix} \end{array}$$

Often we will use it to identify $\mathrm{O}(n)$ with its image in $\mathrm{O}(n+1)$. Similarly we view $\mathrm{U}(n)$ as a subgroup of $\mathrm{U}(n+1)$ and we view $\mathrm{Sp}(n)$ as a subgroup of $\mathrm{Sp}(n+1)$.

(2) We will view any subgroup of $\mathrm{GL}(n, \mathbb{R})$, $\mathrm{GL}(n, \mathbb{C})$ or $\mathrm{GL}(n, \mathbb{H})$ as a topological space that is equipped with the base point given by the identity matrix. Thus in the remainder of this chapter we will suppress the base point in the discussion of fundamental groups.

The following lemma evidently uses the convention from page 3316.

[1892] One could view

Lemma 156.7. Let $n \in \mathbb{N}$. The maps

$$\begin{array}{rcl} \mathrm{O}(n+1)/\mathrm{O}(n) & \xrightarrow{p} & S^n \\ [(v_1 \ldots v_{n+1})] & \mapsto & v_{n+1} \end{array} \qquad \begin{array}{rcl} \mathrm{U}(n+1)/\mathrm{U}(n) & \xrightarrow{q} & S^{2n+1} \\ [(v_1 \ldots v_{n+1})] & \mapsto & v_{n+1} \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{Sp}(n+1)/\mathrm{Sp}(n) & \xrightarrow{r} & S^{4n+3} \\ [(v_1 \ldots v_{n+1})] & \mapsto & v_{n+1} \end{array}$$

are well-defined and they are homeomorphisms.

Proof.

(1) First we show that the given map $p\colon \mathrm{O}(n+1)/\mathrm{O}(n) \to S^n$ is well-defined. To do so we consider the map[1893]

$$\begin{array}{rcl} \mathrm{O}(n+1) & \to & S^n \\ V := (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} = V \cdot e_{n+1}. \end{array}$$

Note that if we multiply V on the right by a matrix of the form $\begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix}$, then the multiplication with e_{n+1} is not affected. Therefore the above map $\mathrm{O}(n+1) \to S^n$ descends to a map $\mathrm{O}(n+1)/\mathrm{O}(n) \to S^n$ which is exactly the map p we consider in the lemma. This shows that p is well-defined.

Also note that basic linear algebra tells us that given any point $v_{n+1} \in S^n$ there exist vectors $v_1, \ldots, v_n \in \mathbb{R}^n$ such that $v_1, \ldots, v_n, v_{n+1}$ form an orthonormal basis $\mathbb{R}^{n+1}$. This shows that the given map p is a surjection. Similarly, elementary linear algebra shows that p is injective. Finally note that S^n is Hausdorff and note that Lemmas 156.3 and 2.13 imply that $\mathrm{O}(n+1)/\mathrm{O}(n)$ is compact. Therefore it follows from the Compact-Hausdorff Proposition 2.17 (3) that the map p is indeed a homeomorphism.

(2),(3) The proof for (2) and (3) is basically identical to the proof in (1), except that the linear algebra aspects require slightly more thought. ■

The following proposition gives us new interesting examples of fiber bundles.

Proposition 156.8. (Matrix Group-Fiber Proposition) Let $n \in \mathbb{N}$. The maps

$$\begin{array}{rcl} \mathrm{O}(n+1) & \to & S^n \\ (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} \end{array} \qquad \begin{array}{rcl} \mathrm{U}(n+1) & \to & S^{2n+1} \\ (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{Sp}(n+1) & \to & S^{4n+3} \\ (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} \end{array}$$

are bundle projections with fibers given by $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ respectively.

Remark. Without too much effort one can show that the bundle projections $\mathrm{O}(n+1) \to S^n$ with fiber $\mathrm{O}(n)$ and $\mathrm{U}(n+1) \to S^{2n+1}$ with fiber $\mathrm{U}(n)$ from the proposition restrict to bundle projections $\mathrm{SO}(n+1) \to S^n$ with fiber $\mathrm{SO}(n)$ and $\mathrm{SU}(n+1) \to S^{2n+1}$ with fiber $\mathrm{SU}(n)$.

We will outline two approaches to proving the Matrix Group-Fiber Proposition 156.8. The first approach relies on the following proposition that shows more generally that Lie groups (and sometimes topological groups) give rise to fiber bundles.

Proposition 156.9. (Lie Group-Fiber Proposition)

(1) Let G be a Lie group. If H is a closed subgroup of G, then the projection $G \to G/H$ is a bundle projection with fiber H.

[1893] It follows easily from $A^T A = \mathrm{id}$ that every column v of A satisfies $\|v\| = 1$, i.e. every column lies in S^n.

(2) Let G be a topological group and H be a closed subgroup of G. If H admits the structure of a Lie group, then the projection $G \to G/H$ is a bundle projection with fiber H.

Remark. One might hope that the Lie Group-Fiber Proposition 156.9 (1) generalizes to all topological groups and subgroups. But as shown in [**Karu1958**, p. 347], there exists a topological group G and a closed subgroup H such that the projection $G \to G/H$ is not a bundle projection.

Proof of the Lie Group-Fiber Proposition 156.9.

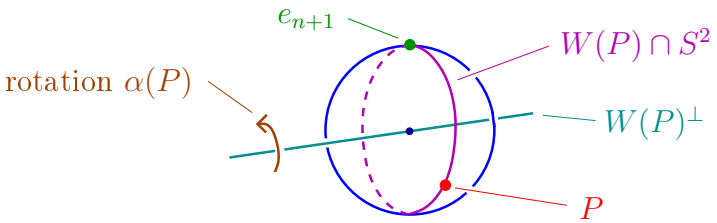
(1) This statement is proved in [**Kiri2008**, Theorem 2.11]. Alternatively, if G is a closed subgroup of some $\mathrm{GL}(n, \mathbb{C})$, then the proposition is proved in [**Bre1993**, p. 110].
(2) This statement is proved in [**Pal1961**, Corollary 4.1]. ■

First proof of the Matrix Group-Fiber Proposition 156.8. These three statements are an immediate consequence of Lemma 156.7 and the Lie Group-Fiber Proposition 156.9 (1). ■

Second proof of the Matrix Group-Fiber Proposition 156.8. In the following we give an outline of a "bare hands only" proof that the first projection $p\colon \mathrm{O}(n+1) \to S^n$ is indeed a bundle projection with fiber $\mathrm{O}(n)$. We leave it to the reader to modify the proof to deal with the two other cases.[1894]

Thus let $n \in \mathbb{N}$. As usual we equip $\mathbb{R}^{n+1}$ with the euclidean inner product $\langle\,,\,\rangle$. In this proof we identify $\mathrm{O}(n+1)$ with the group of isometries of $(\mathbb{R}^{n+1}, \langle\,,\,\rangle)$. More precisely, we do not distinguish in the notation between an isometry of $(\mathbb{R}^{n+1}, \langle\,,\,\rangle)$ and the matrix it represents with respect to the standard basis of $\mathbb{R}^{n+1}$.

We consider the two compact subsets



$$V \;=\; \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \leq \tfrac{1}{2}\} \quad \text{and } W \;=\; \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \geq -\tfrac{1}{2}\}.$$

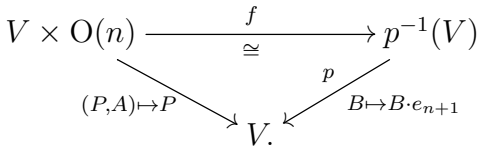
We continue with the following claim.

Claim. Let $P \in V$. We write $W(P) := \mathrm{span}\{e_{n+1}, P\}$. There exists a unique orientation-preserving isometry $\alpha(P)$ of $\mathbb{R}^{n+1} = W(P) \oplus W(P)^\perp$ that satisfies the following two conditions:

(1) the restriction of $\alpha(P)$ to $W(P)$ is an orientation-preserving isometry of $W(P)$ that sends e_{n+1} to P,
(2) it equals the identity on $W(P)^\perp$.

Proof. We illustrate the definition of $\alpha(P)$ in the figure below. In the 3-dimensional setting the isometry $\alpha(P)$ is the unique rotation around "the $W(P)^\perp$-axis" that sends e_{n+1} to P.

[1894] Alternatively the reader can look up the proof of the Lie Group-Fiber Proposition 156.9 (1).



Note that $(W(P), \langle\,,\,\rangle)$ and $(\mathbb{R}^2, \langle\,,\,\rangle)$ are both positive-definite and symmetric forms. Thus it follows from Exercise 133.1 that both forms are also non-singular. Therefore we obtain from Sylvester's Theorem 133.10 that the two forms $(W(P), \langle\,,\,\rangle)$ and $(\mathbb{R}^2, \langle\,,\,\rangle)$ are isometric. In the latter case the orientation-preserving isometries are given by $\mathrm{SO}(2)$. Since $\mathrm{SO}(2) = S^1$ acts freely and transitively on S^1 we see that given any two points $X, Y \in \mathbb{R}^2$ with $\|X\| = \|Y\|$ there exists a unique orientation-preserving isometry β of $(\mathbb{R}^2, \langle\,,\,\rangle)$ with $\beta(X) = Y$. Since $(W(P), \langle\,,\,\rangle)$ is isometric to $(\mathbb{R}^2, \langle\,,\,\rangle)$ the same uniqueness statement applies to $W(P)$ and the two points $e_{n+1}, P \in W(P)$. The claim immediately follows from this observation. ⊞

We leave it to the reader to verify that the map $\alpha\colon V \to \mathrm{O}(n+1)$ that we had just defined is indeed continuous. Next we consider the map

$$\begin{array}{rcl} f\colon V \times \mathrm{O}(n) & \to & \mathrm{O}(n+1) \\ (P, A) & \mapsto & \alpha(P) \circ \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix}. \end{array}$$

An entertaining exercise in linear algebra shows that the map f restricts to a bijection $V \times \mathrm{O}(n) \to p^{-1}(V)$. Since V and $\mathrm{O}(n)$ are compact we obtain from the Compact-Hausdorff Proposition 2.17 (3) that f defines a homeomorphism $V \times \mathrm{O}(n) \to p^{-1}(V)$.

Now recall that for any $P \in V$ we have, by design, that $\alpha(P)(e_{n+1}) = P$. Using this observation we see almost immediately that the following diagram commutes:

This shows that we have found a trivialization of p over V. With very minor modifications one can also find a trivialization of p over W. Since the interiors of V and W cover all of S^n we see that these two trivializations show that $p\colon \mathrm{O}(n+1) \to S^n$ is indeed a fiber bundle with fiber $\mathrm{O}(n)$. ■

Now we can continue with the actual study of the homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$.

Proposition 156.10. Let $n \in \mathbb{N}$.

(1) The inclusion induced map[1895]

$$\pi_k(\mathrm{O}(n)) \;\to\; \pi_k(\mathrm{O}(n+1)) \quad \text{is an} \quad \begin{cases} \text{isomorphism for } k < n-1, \\ \text{epimorphism for } k = n-1. \end{cases}$$

(2) The inclusion induced map

$$\pi_k(\mathrm{U}(n)) \;\to\; \pi_k(\mathrm{U}(n+1)) \quad \text{is an} \quad \begin{cases} \text{isomorphism for } k < 2n, \\ \text{epimorphism for } k = 2n. \end{cases}$$

(3) The inclusion induced map

$$\pi_k(\mathrm{Sp}(n)) \;\to\; \pi_k(\mathrm{Sp}(n+1)) \quad \text{is an} \quad \begin{cases} \text{isomorphism for } k < 4n+2, \\ \text{epimorphism for } k = 4n+2. \end{cases}$$

Example.

(1) We know that $\mathrm{U}(1) = S^1$. Thus we obtain from Proposition 156.10 (2) that all unitary groups $\mathrm{U}(n)$ are path-connected.
(2) Recall that in Lemma 156.2 (1) we pointed out that $\mathrm{Sp}(1) = S^3$. Thus we obtain from Proposition 156.10 (3) that all compact symplectic groups $\mathrm{Sp}(n)$ are simply connected.

Proof. We prove the first statement. The proofs of the remaining two statements are almost identical.[1896] By the Matrix Group-Fiber Proposition 156.8 we have a bundle projection $p\colon \mathrm{O}(n+1) \to S^n$ with fiber $\mathrm{O}(n)$. From the Fiber-LES Proposition 155.2 we obtain a long exact sequence of the form

$$\ldots \to \pi_{k+1}(S^n) \xrightarrow{\partial} \pi_k(\mathrm{O}(n)) \to \pi_k(\mathrm{O}(n+1)) \to \pi_k(S^n) \xrightarrow{\partial} \ldots$$

The desired statement now follows from the familiar fact that by Proposition 71.10 we have $\pi_i(S^k) = 0$ for $i < k$. ∎

As a corollary to Proposition 156.10 (1) we can now finally answer Question 83.5. More precisely, we have the following proposition.

Proposition 156.11.

(1) For any $n \in \mathbb{N}$ the inclusions $i\colon \mathrm{SO}(n) \to \mathrm{SL}(n,\mathbb{R})$ and $j\colon \mathrm{SL}(n,\mathbb{R}) \to \mathrm{GL}_+(n,\mathbb{R})$[1897] are homotopy equivalences.
(2) Let $n \in \mathbb{N}_{\geq 2}$. We have isomorphisms

$$\pi_1(\mathrm{SO}(n)) \underset{i_*}{\xrightarrow{\cong}} \pi_1(\mathrm{SL}(n,\mathbb{R})) \underset{j_*}{\xrightarrow{\cong}} \pi_1(\mathrm{GL}_+(n,\mathbb{R})) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 2, \\ \mathbb{Z}, & \text{if } n \geq 3. \end{cases}$$

(3) In each of the three fundamental groups of (2) a generator of the group is represented by the loop

$$\begin{array}{ccc} S^1 & \to & \mathrm{SO}(n) \\ \exp(\mathrm{i}\varphi) & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-2} \end{pmatrix}. \end{array}$$

Proof.

(1) We proved this statement in the Matrix Groups Deformation Retract Proposition 15.7.
(2) First we consider the case $n = 2$. We have isomorphisms

$$\mathbb{Z} \underset{\uparrow}{\cong} \pi_1(S^1, \mathrm{id}) = \pi_1(\mathrm{SO}(2), \mathrm{id}) \underset{\uparrow}{\xrightarrow{\cong}} \pi_1(\mathrm{SL}(2,\mathbb{R}), \mathrm{id}) \underset{\uparrow}{\xrightarrow{\cong}} \pi_1(\mathrm{GL}_+(2,\mathbb{R}), \mathrm{id}).$$

Proposition 48.17 — by (1) and the Homotopy-π_1-Proposition 50.3 (1)

[1895] Recall that in the Matrix Group Path-Component Proposition 2.37 (3) we saw that $\mathrm{O}(n)$ is disconnected. Thus in principle it is not completely clear what we mean by $\pi_k(\mathrm{O}(n))$. But, as we pointed out on page 3320, we always consider $\mathrm{O}(n)$ as equipped with the base point that is given by the identity. Also note that it follows easily from Lemma 5.40 that for a topological group the isomorphism type of the homotopy groups does not depend on the choice of a base point.
[1896] The only catch is that one needs to be careful about the degrees involved.
[1897] Recall that we write $\mathrm{GL}_+(n,\mathbb{R}) = \{A \in \mathrm{GL}(n,\mathbb{R}) \mid \det(A) > 0\}$.

Now we consider the case $n \geq 3$. We have isomorphisms

$$\begin{array}{ccccccc} \mathbb{Z}_2 & \cong & \pi_1(\mathrm{SO}(3), \mathrm{id}) & \cong & \pi_1(\mathrm{SO}(n), \mathrm{id}) & \xrightarrow{\cong} & \pi_1(\mathrm{SL}(n, \mathbb{R}), \mathrm{id}) \xrightarrow{\cong} \pi_1(\mathrm{GL}_+(n, \mathbb{R}), \mathrm{id}). \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \text{Corollary 83.4} & & \text{by Proposition 156.10 and the fact that by the Matrix Group Path-Component Proposition 2.37 (2) } \mathrm{SO}(k) \text{ is the path-component of } \mathrm{O}(k) \text{ that contains id} & & & & \text{by (1) and the Homotopy-}\pi_1\text{-Proposition 50.3 (1)} \end{array}$$

(3) We consider the loop

$$\begin{array}{rcl} \gamma\colon S^1 & \to & \mathrm{SO}(2) \\ \exp(\mathrm{i}\varphi) & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix}. \end{array}$$

Since $\mathrm{SO}(2) = S^1$ we know by Proposition 48.17 that γ represents a generator of $\pi_1(\mathrm{SO}(2))$. By Proposition 156.10 we know that the inclusion $\mathrm{SO}(2) \to \mathrm{SO}(n)$ induces an epimorphisms of fundamental groups. It follows immediately that the loop given in (3) is indeed a generator of $\pi_1(\mathrm{SO}(n))$. Since the inclusions i and j induce isomorphisms of fundamental groups we see that the given loop also represents a generator of $\pi_1(\mathrm{SL}(n, \mathbb{R}))$ and $\pi_1(\mathrm{GL}(n, \mathbb{R}))$. ■

156.3. **Spin groups.** Let $n \geq 3$. Recall that in the Matrix Group Path-Component Proposition 2.37 (3) we showed that $\mathrm{SO}(n)$ is path-connected and in Corollary 156.11 (2) we had just seen that $\pi_1(\mathrm{SO}(n)) \cong \mathbb{Z}_2$. By Lemma 48.15 this implies that the universal covering, as defined on page 1372, of $\mathrm{SO}(n)$ is a 2-fold covering of $\mathrm{SO}(n)$.[1898] For example in the SU(2)-SO(3)-Covering Theorem 83.2 we showed that the 2-fold covering of SO(3) is diffeomorphic to SU(2).
Thus the following question arises:

Question 156.12. Let $n \geq 3$.
(1) Is the universal covering of $\mathrm{SO}(n)$ a group?
(2) If yes, is it a group "we already know"?

It turns out that the answer to Question 156.12 (1) is yes. In fact, the following, initially perhaps somewhat surprising proposition holds. The proof turns out to be almost disappointingly easy.

Proposition 156.13. (Covering-of-Lie Group Proposition) Let G be a connected Lie group and let $p\colon \widetilde{G} \to G$ be some covering (e.g. it could be the universal covering). We denote by 1_G the neutral element in G. We pick a point $1_{\widetilde{G}} \in p^{-1}(1_G)$. Then $\widetilde{G}$ admits a unique Lie group structure such that $p\colon \widetilde{G} \to G$ is a smooth map and a homomorphism and such that $1_{\widetilde{G}}$ is the neutral element in $\widetilde{G}$.

Remark.
(1) Let G be a topological group that is connected and locally path-connected. The proof of the Covering-of-Lie Group Proposition 156.13 also shows that given any covering $p\colon \widetilde{G} \to G$ of G together with a choice of $\widetilde{e} \in \widetilde{G}$ with $p(\widetilde{e}) = e$ there exists a unique

[1898] Note that here we use that $\mathrm{SO}(n)$ is a smooth manifold, which implies by the discussion on page 1372 that the universal covering does indeed exist.

topological group structure on $\widetilde{G}$ with trivial element $\widetilde{e}$ which turns p into a group homomorphism.

(2) Let $k \in \mathbb{N}_{\geq 2}$. By the Covering-of-Lie Group Proposition 156.13 the universal covering $\widetilde{\mathrm{SL}(k,\mathbb{R})}$ of the Lie group $\mathrm{SL}(k,\mathbb{R})$ is again Lie group. In [**HallB2015**, Theorem C.12] it is shown that $\widetilde{\mathrm{SL}(k,\mathbb{R})}$ is *not* isomorphic to any subgroup of $\mathrm{GL}(n,\mathbb{R})$ for any $n \in \mathbb{N}$. This shows that Theorem 156.6 does not extend to non-compact Lie groups.

Sketch of the proof. First note that we saw in the Manifold Covering Proposition 49.2 that $\widetilde{G}$ is a topological manifold that admits a unique smooth structure such that $p\colon \widetilde{G} \to G$ is a smooth map. Now we turn towards defining the Lie group structure on the smooth manifold $\widetilde{G}$. In fact we will give two equivalent definitions of the group structure on $\widetilde{G}$:

(1) First note that by the Fundamental Group-of-Product Proposition 48.20 we know that $\widetilde{G} \times \widetilde{G}$ is also simply connected. We consider the maps

$$\begin{array}{ccc} & & \widetilde{G} \\ & & \big\downarrow p \\ \widetilde{G} \times \widetilde{G} & \xrightarrow[(x,y)\mapsto p(x)\cdot p(y)]{} & G. \end{array}$$

It follows from the Map Lifting Criterion 61.2 that there exists a unique lift

$$\begin{array}{ccc} & \overset{(1_{\widetilde{G}},1_{\widetilde{G}})\mapsto 1_{\widetilde{G}}}{\nearrow} & \widetilde{G} \\ & & \big\downarrow p \\ \widetilde{G} \times \widetilde{G} & \xrightarrow[(x,y)\mapsto p(x)\cdot p(y)]{} & G. \end{array}$$

(2) By the Covering Existence Theorem 61.5 and Corollary 61.11 we can assume that $\widetilde{G}$ equals the canonical universal covering, i.e. we can assume that

$$\widetilde{G} \;=\; \{\text{paths in } G \text{ starting at } 1_G\}/\ \text{homotopies that fix the starting point and the endpoint}$$

With that explicit description we define

$$\begin{array}{rcl} \widetilde{G} \times \widetilde{G} & \to & \widetilde{G} \\ ([a(t)],[b(t)]) & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & G \\ t & \mapsto & a(t)\cdot b(t) \end{array}\right]. \end{array}$$

Using the fact that the multiplication map $\widetilde{G} \times \widetilde{G} \to \widetilde{G}$ is continuous one can show fairly easily that this map is well-defined.

We leave it as a charming exercise to show that the two given definitions of the group structure agree and that in both cases we defined a Lie group structure on $\widetilde{G}$.[1899]

It remains to show that the group structure on $\widetilde{G}$ is the unique Lie group structure on the smooth manifold $\widetilde{G}$ for which $1_{\widetilde{G}}$ is the neutral element and that turns p into a homomorphism. Suppose we are given a smooth map $\varphi\colon \widetilde{G} \times \widetilde{G} \to \widetilde{G}$ that has the same properties. We obtain the following commutative diagram:

$$\begin{array}{ccc} \widetilde{G} \times \widetilde{G} & \xrightarrow{\varphi} & \widetilde{G} \\ {\scriptstyle p\times p}\big\downarrow & \overset{(x,y)\mapsto p(x)\cdot p(y)}{\searrow} & \big\downarrow{\scriptstyle p} \\ G \times G & \xrightarrow[(x,y)\mapsto x\cdot y]{} & G. \end{array}$$

[1899] The smoothness of the group multiplication is perhaps easier to prove with the first point of view, the fact that it is a group structure is possibly less confusing to verify with the second point of view.

Since the diagram commutes we see that $\varphi\colon \widetilde{G} \times \widetilde{G} \to \widetilde{G}$ is precisely a lift of the blue map $\widetilde{G} \times \widetilde{G} \to G$ that sends $(1_{\widetilde{G}}, 1_{\widetilde{G}})$ to $1_{\widetilde{G}}$. Thus by the uniqueness of the lift we see that the Lie group structure on $\widetilde{G}$ is uniquely determined by our wish list. ■

This proposition leads us to the following definition.

Definition. Let $n \geq 3$. We refer to the natural universal covering[1900] of the pointed topological space $(\mathrm{SO}(n), \mathrm{id})$ as the spin group $\mathrm{Spin}(n)$. By the Covering-of-Lie Group Proposition 156.13 there exists a unique Lie group structure on $\mathrm{Spin}(n)$ for which the canonical base point is the neutral element and which has the property that the projection $p\colon \mathrm{Spin}(n) \to \mathrm{SO}(n)$ is a smooth map and a group homomorphism.

The combination of Propositions 156.11 (2) and 156.13 and Corollary 61.11 shows that $\mathrm{Spin}(n)$ is indeed a Lie group and that $p\colon \mathrm{Spin}(n) \to \mathrm{SO}(n)$ is a 2-fold covering that is a group homomorphism.

Remark. By Corollary 61.11 the universal covering of a smooth manifold, even if it is equipped with a base point, is only well-defined up to "equivalence". This slightly awkward issue can be circumvented in two different ways:

(1) either we use the explicit model of the universal covering of a based smooth manifold in terms of equivalence classes of paths, or
(2) in this particular situation there is a more elegant solution, one can give a purely algebraic explicit description of $\mathrm{Spin}(n)$. We refer to [**Mein2013**, Chapter 3.1] for details.

It is harder to give an answer to Question 156.12 (2). For reasonably low dimensions the following proposition gives a positive answer.

Proposition 156.14.

(1) There exist Lie group isomorphisms[1901]

(a) $\mathrm{SO}(3) \cong \mathrm{SU}(2)/\{\pm \mathrm{id}\}$
(b) $\mathrm{SO}(4) \cong (\mathrm{SU}(2) \times \mathrm{SU}(2))/\{\pm(\mathrm{id}, \mathrm{id})\}$
(c) $\mathrm{SO}(5) \cong \mathrm{Sp}(2)/\{\pm \mathrm{id}\}$.

(2) There exist Lie group isomorphisms

(a) $\mathrm{Spin}(3) \cong \mathrm{SU}(2)$
(b) $\mathrm{Spin}(4) \cong \mathrm{SU}(2) \times \mathrm{SU}(2)$
(c) $\mathrm{Spin}(5) \cong \mathrm{Sp}(2)$
(d) $\mathrm{Spin}(6) \cong \mathrm{SU}(4)$.

Proposition 156.14 (b) thus says that for $n = 3, 4, 5, 6$ the spin group $\mathrm{Spin}(n)$ is isomorphic to Lie groups that we are already familiar with. But according to [**Mein2013**, p. 53] "for $n \geq 7$, there are no further accidental isomorphisms of this type." In other words, in general the answer to Question 156.12 (2) is negative.

Proof.

[1900] We refer to page 1372 for the definition of the canonical universal covering of a suitable pointed topological space and to the definition of the corresponding canonical base point.
[1901] Note that it follows from Lemma 156.5 that the groups on the right-hand side are indeed Lie groups.

(1) (a) This statement follows immediately from Lemma 83.1 and the SU(2)-SO(3)-Covering Theorem 83.2.

(b) In Proposition 92.2 we saw that the quaternion multiplication defines a group structure on $S^3 = \{h \in \mathbb{H} \,|\, |h| = 1\}$ where the trivial element is given by $1 \in \mathbb{H}$. Furthermore in Proposition 92.2 we had also seen that the Lie groups SU(2) and S^3 are isomorphic. Thus it suffices to show that the Lie groups $(S^3 \times S^3)/\{\pm(1,1)\}$ and SO(4) are diffeomorphic. We consider the following map:

$$\begin{array}{rcl} \Phi\colon S^3 \times S^3 & \to & \mathrm{SO}(4) \\ (q_1, q_2) & \mapsto & \left(\begin{array}{rcl} \mathbb{R}^4 = \mathbb{H} & \to & \mathbb{R}^4 = \mathbb{H} \\ z & \mapsto & q_1 z q_2^{-1} \end{array} \right). \end{array}$$

We make the following observations:

(i) In Exercise 92.3 we showed that the map $z \mapsto q_1 z q_2^{-1}$ does indeed define an element in SO(4).

(ii) One can easily verify that the map Φ is smooth and that it is a homomorphism.

(iii) We leave it to the energetic reader to verify that the differential of Φ at each point is invertible.

(iv) We note that the kernel of this homomorphism is given by $\{\pm(1,1)\}$. Indeed, the kernel of this homomorphism is given by the set of all $(q_1, q_2) \in S^3 \times S^3$ such that $q_1 z q_2^{-1} = z$ for all $z \in \mathbb{H}$. By setting $z = 1$ we obtain that $q_1 = q_2$. Furthermore, since $q_1 z q_1^{-1} = z$ for all $z \in S^3$ we see that $q_1 = q_2$ lies in the center of the group S^3. An elementary calculation shows that the center of S^3 is given by ± 1. Thus the kernel of Φ contains precisely the two elements $(1,1)$ and $(-1,-1)$.

It follows from the above, the Topological-Quotient Proposition 5.15 (1b) and Lemma 156.5 and elementary group theory[1902] that the above map Φ descends to a smooth and injective map

$$\overline{\Phi}\colon (S^3 \times S^3)/\{\pm(1,1)\} \to \mathrm{SO}(4)$$

such that the differential at each point is invertible. By Lemmas 156.3 and 156.5 both sides are closed connected 6-dimensional smooth manifolds. Thus it follows from Corollary 82.9 (2) that the map $\overline{\Phi}$ is also surjective. It follows from the above results and the Inverse Mapping Theorem 24.1 (2) that $\overline{\Phi}$ is in fact a diffeomorphism.

(c) Let V be the real vector space of quaternionic Hermitian 2×2-matrices with trace 0. In other words we consider

$$V = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{M}(2 \times 2, \mathbb{H}) \,\middle|\, a + d = 0, a, d \in \mathbb{R} \text{ and } b = \overline{c} \right\}.$$

[1902] More precisely, we use the elementary fact that if $\alpha\colon G \to H$ is a group homomorphism, then the induced map $G/\ker(\alpha) \to H$ is injective.

Note that V is a 5-dimensional real vector space. The group $\mathrm{Sp}(2)$ acts by conjugation on V.[1903] One easily verifies that the kernel is given by $\{\pm \mathrm{id}\}$. Furthermore by [**Pro2007**, Chapter 4.5.3] there exists a positive-definite symmetric form on V that is preserved by this action. Thus, by Sylvester's Theorem 133.10 this action defines a homomorphism $\mathrm{Sp}(2) \to \mathrm{SO}(5)$. Similar to (b) we obtain a diffeomorphism $\mathrm{Sp}(2)/\{\pm \mathrm{id}\} \xrightarrow{\cong} \mathrm{SO}(5)$.

(2) (a) By (2a) we can make the identification $\mathrm{SO}(3) = \mathrm{SU}(2)/\{\pm \mathrm{id}\}$ of Lie groups. By the SU(2)-SO(3)-Covering Theorem 83.2 we know that $\mathrm{SU}(2)$ is homeomorphic to S^3, in particular we see that $\mathrm{SU}(2)$ is simply connected. By Lemma 156.5 the quotient map $\mathrm{SU}(2) \to \mathrm{SU}(2)/\{\pm 1\}$ is a covering map, it is smooth and it is a homomorphism. Thus we see that $\mathrm{SU}(2)$ is in fact the universal covering of $\mathrm{SU}(2)/\{\pm \mathrm{id}\} = \mathrm{SO}(3)$ and we deduce from the Covering-of-Lie Group Proposition 156.13 that $\mathrm{Spin}(3) \cong \mathrm{SU}(2)$.

(b) By the same argument as in (2a) this statement can be deduced from (1b).

(c) By the same argument as in (2a) this statement can be deduced from (1c).

(d) We will not make use of this results, hence we will not provide a proof, instead we refer to [**Mein2013**, p. 84] for details. ■

Remark. Initially the spin groups might appear as amusing curiosities. In fact they arise naturally in many parts of mathematics and physics. We refer to [**LaM1989, Morg1996, Mein2013**] for more details.

156.4. **The Bott Periodicity Theorem.** We continue with the following definition.

Definition. We define[1904]

$$\mathrm{O} := \varinjlim \mathrm{O}(n) = \left\{ A = (a_{ij})_{i,j\in\mathbb{N}} \;\middle|\; \begin{array}{l} \text{there exists an } n \in \mathbb{N} \\ \text{and a } B \in \mathrm{O}(n) \text{ with } \end{array} A = \begin{pmatrix} B & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \ddots \end{pmatrix} \right\}$$

where O has the obvious group structure and where O has the topology that is defined by the condition that subset $U \subset \mathrm{O}$ is open if and only if for each n the intersection $U \cap \mathrm{O}(n)$ is open. Similarly we define

$$\mathrm{U} := \varinjlim \mathrm{U}(n), \quad \mathrm{Sp} := \varinjlim \mathrm{Sp}(n)$$

In the Direct Limit Existence Proposition 56.1 we saw that every direct system $\{G_i\}_{i\in I}$ of groups admits a direct limit $\varinjlim G_i$. In fact for the above direct limit $\mathrm{O} = \varinjlim \mathrm{O}(n)$ the group structure is the "obvious" one given above. The following shows that these group structure are continuous, i.e. O, U and Sp are topological groups.

Lemma 156.15. The above group structures on O, U and Sp are continuous.

[1903] The group $\mathrm{Sp}(2)$ acts evidently by conjugation on all quaternionic 2×2-matrices, in principle one now needs to verify that this action restricts to an action on V.

[1904] When we talk about the direct limit we have to say what category we consider. Here we want to consider the category of groups and of topological spaces at the same time. Since we have obvious inclusions maps $\mathrm{O}(n) \to \mathrm{O}(n+1)$ we obtain from the Direct Limit-of-Topological Spaces Lemma 56.3 that in both settings we obtain the same underlying set, which we can then equip with a group structure and a topology.

Remark. Initially one might be tempted to dismiss Lemma 156.15 as obvious. But in general there is a subtle issue. If $\{G_i\}_{i\in I}$ is a direct system of topological groups, then the above multiplication on the direct limit $\varinjlim G_i$ might not be continuous. Such examples are for example provided in [**TSH1998**]. If one thinks about it for a while one realizes that this failure for the multiplication map to be continuous is another instance of the observation made in Section 13.1, that mixing product and quotient topologies is fraught with dangers.

Proof. This lemma can surely be proved, with a little effort, "by hand". Alternatively one can use [**TSH1998**, Theorem 2.7] which shows that for a direct system $\{X_i\}_{i\in\mathbb{N}}$ of compact topological groups the above multiplication on $\varinjlim X_i$ is indeed continuous. ■

For later usages of O, U and Sp we have to get the following technical lemma out of the way.

Lemma 156.16. The topological spaces O, U and Sp admit CW-structures such that each $\mathrm{O}(n) \subset \mathrm{O}$, $\mathrm{U}(n) \subset \mathrm{U}$ and $\mathrm{Sp}(n) \subset \mathrm{Sp}$ is a subcomplex.

Proof. In [**WhdJ1944**] it is shown that we can equip the $\mathrm{O}(n)$ with CW-structures such that for each n the subset $\mathrm{O}(n) \subset \mathrm{O}(n+1)$ is actually a subcomplex. Analogous statements for $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ are proved in [**Yok1955**, Theorem 5.3 and 5.5] or alternatively in [**Stro2011**, Chapter 9.3.3]. It follows from the Ascending Union-CW Complex Lemma 68.34 that O is a CW-complex. ■

Now we turn to the study of the homotopy groups of O, U and Sp.

Lemma 156.17. Given any $k \in \mathbb{N}$ we have

$$\begin{aligned}
&(1) \quad \pi_k(\mathrm{O}) = \varinjlim \pi_k(\mathrm{O}(n)) \xleftarrow{\cong} \pi_k(\mathrm{O}(N)) \quad \text{for any } N \in \mathbb{N} \text{ with } N > k+1,\\
&(2) \quad \pi_k(\mathrm{U}) = \varinjlim \pi_k(\mathrm{U}(n)) \xleftarrow{\cong} \pi_k(\mathrm{U}(N)) \quad \text{for any } N \in \mathbb{N} \text{ with } 2N > k,\\
&(3) \quad \pi_k(\mathrm{Sp}) = \varinjlim \pi_k(\mathrm{Sp}(n)) \xleftarrow{\cong} \pi_k(\mathrm{Sp}(N)) \quad \text{for any } N \in \mathbb{N} \text{ with } 4N > k-2.
\end{aligned}$$

Proof. We prove (1). The proofs of (2) and (3) are almost identical. We start out with the following claim.

Claim. Given any compact subset K of O there exists an $n \in \mathbb{N}$ with $K \subset \mathrm{O}(n)$.

Proof. Let K be a compact subset of O. Given $n \in \mathbb{N}$ we write $X_n := \{1,\ldots,n\}\times\{1,\ldots,n\}$. First recall that $\mathrm{O}(n)$ is equipped with the subspace topology coming from the inclusion map $g_n\colon \mathrm{O}(n) \subset \mathrm{M}(n\times n,\mathbb{R}) = \mathbb{R}^{X_n} = \mathbb{R}^{n^2}$. Given $n \in \mathbb{N}$ we denote by $f_n\colon \mathbb{R}^{X_n} \to \mathbb{R}^{X_{n+1}}$ the obvious inclusion map. These have the property that for any $n \in \mathbb{N}$ the following diagram commutes:

$$\begin{array}{ccc}
\mathrm{O}(n) & \xrightarrow{\quad g_n \quad} & \mathbb{R}^{X_n} \\
\big\downarrow & & \big\downarrow{\scriptstyle f_n} \\
\mathrm{O}(n+1) & \xrightarrow{\quad g_{n+1} \quad} & \mathbb{R}^{X_{n+1}}.
\end{array}$$

The above inclusion maps $g_n\colon \mathrm{O}(n) \to \mathbb{R}^{X_n}$ induce a map $g\colon \mathrm{O} = \varinjlim \mathrm{O}(n) \hookrightarrow \varinjlim \mathbb{R}^{X_n}$. By our hypothesis that K is compact and the Compact Image Lemma 2.13 we know that $g(K) \subset \varinjlim \mathbb{R}^{X_n}$ is also compact. Basically the same argument as in the proof of

Lemma 68.3 shows that there exists an $n \in \mathbb{N}$ with $g(K) \subset \mathbb{R}^{X_n}$. But this implies that $K \subset \mathrm{O}(n)$. ⊞

Now let $N \in \mathbb{N}$ with $N > k+1$. We have

$$\begin{array}{ccccc} \pi_k(\mathrm{O}) & = & \varinjlim \pi_k(\mathrm{O}(n)) & = & \pi_k(\mathrm{O}(N)). \\ & & \uparrow & & \uparrow \\ & & \text{by the Direct Limit-}\pi_n\text{-Proposition 71.11} & & \text{by Proposition 156.10 (1) and the} \\ & & \text{and the claim} & & \text{Direct Limit Stabilization Lemma 56.2} \end{array}$$

■

We will now state two versions of the Bott Periodicity Theorem which implies in particular that the homotopy groups of O, U and Sp are periodic.
The first theorem requires just a little bit of preparation.

(1) As above we equip U, Sp and O with the base point given by the infinite identity matrix. We use these base points to form the loop spaces ΩU, $\Omega\,\mathrm{Sp}$ and ΩO.
(2) Given a point x in a topological space X we denote by c_x the corresponding constant path.
(3) We use notation (2) to equip each loop space $\Omega(X, x_0)$ with the base c_{x_0} and we can thus iterate the loop space construction.
(4) The obvious isomorphism $\mathbb{H} \xrightarrow{\cong} \mathbb{R}^4$ of real vector spaces defines inclusion maps $\mathrm{Sp}(n) \to \mathrm{O}(4n)$ and $\mathrm{Sp} \to \mathrm{O}$.
(5) The inclusion $\mathbb{R} \to \mathbb{H}$ defines inclusions $\mathrm{O}(n) \to \mathrm{Sp}(n)$ and thus $\mathrm{O} \to \mathrm{Sp}$.

Theorem 156.18. (Bott Periodicity Theorem) There exist homotopy equivalences

$$(1) \quad \mathrm{U} \to \Omega^2\,\mathrm{U} \qquad (2) \quad \mathrm{Sp} \to \Omega^4\,\mathrm{O} \qquad \text{and} \qquad (3) \quad \mathrm{O} \to \Omega^4\,\mathrm{Sp}.$$

Before we talk about the proof of the Bott Periodicity Theorem 156.18 let us move on to the following direct consequence.

Theorem 156.19. (Bott Periodicity Theorem) For any $i \in \mathbb{N}_0$ we have[1905]

$$\begin{array}{lll} (1) & \pi_{i+2}(\mathrm{U}) & \cong \pi_i(\mathrm{U}), \\ (2) & \pi_{i+4}(\mathrm{Sp}) & \cong \pi_i(\mathrm{O}), \\ (3) & \pi_{i+4}(\mathrm{O}) & \cong \pi_i(\mathrm{Sp}). \end{array}$$

In particular, combining (2) and (3) we have for any $i \in \mathbb{N}_0$ that

$$\begin{array}{lll} (4) & \pi_{i+8}(\mathrm{O}) & \cong \pi_i(\mathrm{O}), \\ (5) & \pi_{i+8}(\mathrm{Sp}) & \cong \pi_i(\mathrm{Sp}). \end{array}$$

Proof of the Bott Periodicity Theorems 156.18 and 156.19. First note that Theorem 156.19 follows immediately from Theorem 156.18 together with the Loop Space-Homotopy Groups Corollary 154.15. All the known proofs are non-trivial and go well-beyond what we can do in these modest notes.

Theorem 156.18 was first proved by Raoul Bott [**Bot1957, Bot1959, Bot1970**] in 1957. Another proof, using Morse theory, is given in [**Miln1963a**, p. 129, 142]. There explicit maps that give these homotopy equivalences, they are described well in [**DL61**]. Nonetheless the description is too long for us to write down at this point.

There are many proofs of Theorem 156.19 which use a slightly different language, in particular it is at first glance not entirely clear whether they also imply Theorem 156.18.

[1905] For $i = 0$ we actually have an isomorphism of pointed sets.

We refer to [**Stro2011**, Chapter 32.6], [**AGP2002**, Chapter 9.5], [**APr1999**] and [**Hat2**, Theorem 2.16] for a discussions and proofs of Theorem 156.19. ■

Using the Bott Periodicity Theorem 156.19 we can completely determine the homotopy groups of O, U and Sp.

Proposition 156.20. The homotopy groups of O, U and Sp are as follows:

$i \bmod 8$	0	1	2	3	4	5	6	7
$\pi_i(\mathrm{U})$	0	$\mathbb{Z}$	0	$\mathbb{Z}$	0	$\mathbb{Z}$	0	$\mathbb{Z}$
$\pi_i(\mathrm{O})$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	0	$\mathbb{Z}$	0	0	0	$\mathbb{Z}$
$\pi_i(\mathrm{Sp})$	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	0	$\mathbb{Z}$.

Proof. The homotopy groups of U are straightforward to determine. More precisely, let $i \in \mathbb{N}_0$. We have

$$\pi_i(\mathrm{U}) \underset{\text{Bott Periodicity Theorem 156.19}}{=} \pi_{i \bmod 2}(\mathrm{U}) \underset{\text{Lemma 156.17 (2)}}{\cong} \pi_{i \bmod 2}(\mathrm{U}(1)) \underset{\text{since } \mathrm{U}(1) = S^1}{=} \pi_{i \bmod 2}(S^1) \underset{\substack{\text{see the Matrix Group Path-Component} \\ \text{Proposition 2.37 and Proposition 48.17}}}{\cong} \begin{cases} 0, & \text{if } i = 0 \bmod 2, \\ \mathbb{Z}, & \text{if } i = 1 \bmod 2. \end{cases}$$

Now we consider the homotopy groups of O and Sp. By the Bott Periodicity Theorem 156.19 it suffices to compute the homotopy groups $\pi_i(\mathrm{O})$ and $\pi_i(\mathrm{Sp})$ for $i = 0, 1, 2, 3$.[1906] So let $i \in \{0, 1, 2, 3\}$. We have

$$\pi_i(\mathrm{Sp}) \underset{\text{Lemma 156.17 (3)}}{\cong} \pi_i(\mathrm{Sp}(1)) \underset{\text{since } \mathrm{Sp}(1) = S^3}{=} \pi_i(S^3) \underset{\text{Proposition 71.10 and Corollary 85.6 (1)}}{\cong} \begin{cases} 0, & \text{if } i = 0, 1, 2, \\ \mathbb{Z}, & \text{if } i = 3. \end{cases}$$

We turn to the calculation of the homotopy groups of O. First we note that for any $i \geq 1$ we have

$$\pi_i(\mathrm{O}) \underset{\text{Lemma 156.17 (3)}}{\cong} \pi_i(\mathrm{O}(i+2)) \underset{\substack{\text{Matrix Group Path-Component Proposition 2.37} \\ \text{and Lemma 5.40}}}{\cong} \pi_i(\mathrm{SO}(i+2)).$$

Thus it remains to prove the following claim.

Claim.
(a) $\pi_0(\mathrm{O}(2)) \cong \mathbb{Z}_2$
(b) $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$
(c) $\pi_2(\mathrm{SO}(4)) \cong 0$
(d) $\pi_3(\mathrm{SO}(5)) \cong \mathbb{Z}$.

Proof.

(a) By the Matrix Group Path-Component Proposition 2.37 (3) we know that $\mathrm{O}(2)$ consists of two path components, thus $\pi_0(\mathrm{O}(2))$ is by definition a pointed set with two elements.
(b) By Proposition 156.11 we know that $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$.

[1906] We will see that $\pi_0(\mathrm{O})$ is the pointed set with two elements. It follows from the Bott Periodicity Theorem 156.19 that $\pi_{4+8k}(\mathrm{Sp})$ and $\pi_{8k}(\mathrm{O})$, $k \geq 1$, are also pointed sets with two elements. But these pointed sets are also groups. Since there is only one group structure on a pointed set with two elements we see that all these groups are isomorphic to $\mathbb{Z}_2$.

(c) We have the following isomorphisms:

$$\begin{array}{ccccccccc} \pi_2(\mathrm{SO}(4)) & \cong & \pi_2((S^3\times S^3)/\mathbb{Z}_2) & \cong & \pi_2(S^3\times S^3) & \cong & \pi_2(S^3)\oplus\pi_2(S^3) & = & 0. \\ \uparrow & & \uparrow & & \downarrow & & \uparrow & & \\ \text{by Proposition 156.14 (1b) and Proposition 92.2} & & \text{by Lemma 156.5 and the Coverings-}\pi_n\text{-Proposition 71.13} & & \text{by the Homotopy Groups-of-Product Proposition 71.8} & & \text{Proposition 71.10} & & \end{array}$$

(d) We have the following isomorphisms:

$$\begin{array}{ccccccccc} \pi_3(\mathrm{SO}(5)) & \cong & \pi_3(\mathrm{Sp}(2)/\{\pm\mathrm{id}\}) & \cong & \pi_3(\mathrm{Sp}(2)) & \cong & \pi_3(\mathrm{Sp}) & \cong & \mathbb{Z}. \\ \uparrow & & \uparrow & & \uparrow & & \uparrow & & \\ \text{Proposition 156.14 (1c)} & & \text{by Lemma 156.5 and the Coverings-}\pi_n\text{-Proposition 71.13} & & \text{Proposition 156.10} & & \text{see above} & & \end{array}$$

■

156.5. **H-spaces.** In this final section of this chapter we want to state two general statements about homotopy groups of Lie groups. In fact these statements hold for a much wider class of topological spaces that we introduce now:

Definition. We say a topological space X is an H-space[1907] if there exists a map[1908]

$$\mu\colon X\times X\ \to\ X$$

and an element $e\in X$ such that $\mu(e,e)=e$ and such that the maps

$$\begin{array}{rcl}(X,e) & \mapsto & (X,e)\\ x & \mapsto & \mu(x,e)\end{array}\qquad\text{and}\qquad\begin{array}{rcl}(X,e) & \mapsto & (X,e)\\ x & \mapsto & \mu(e,x)\end{array}$$

of pairs of topological spaces are homotopic to the identity.

Examples.

(1) Evidently Lie groups and more generally, topological groups are H-spaces, where μ is given by the group structure and e is the trivial element of the group. In particular we see that the Lie groups S^1 and S^3 are H-spaces.
(2) The topological space S^7 together with the multiplication given by the octonion structure on $\mathbb{O}=\mathbb{R}^8$ and with $e=1=(1,0,\dots,0)\in S^7$ is an H-space.[1909] Since octonion multiplication is not associative we see that, at least with this multiplication, S^7 is not a topological group.

We have just seen that the spheres S^1, S^3 and S^7 are H-space. Before we continue with more examples we point out that we have all the tools to show that no other spheres have H-space structures.

Theorem 156.21. Let $n\in\mathbb{N}$. If S^n admits the structure of an H-space, then $n\in\{1,3,7\}$.

Proof. Let $\mu\colon S^n\times S^n\to S^n$ be the multiplication map of an H-space structure and let $e\in X$ be the "neutral" element. It follows immediately from the definition of the bidegree, see page 2687, together with the Homotopic Maps-and-Homology Proposition 73.6 and the

[1907] According to [**Hub1999**, p. 747] the term H-space was coined by Jean-Pierre Serre to honor the work of Heinz Hopf.
[1908] As usual, whenever we deal with topological spaces, all maps are understood to be continuous.
[1909] Recall that by the discussion on page 1963 we know that for octonions $w,z\in\mathbb{O}=\mathbb{R}^8$ we have $\|w\cdot z\|=\|w\|\cdot\|z\|$, in particular the multiplication restricts to a map on S^7. Also note that multiplication by $e=1$ is the identity.

existence of e, that the map μ has bidegree $(1,1)$. From Proposition 122.12 we obtain a map $S^{2n+1} \to S^{n+1}$ with Hopf invariant ± 1. By the Adams Theorem 152.11[1910] we know that $n+1 \in \{2,4,8\}$. ■

We continue with one more amusing example of an H-space.

Example. Given a non-zero polynomial $p(t) = \sum_{i=0}^{n} a_i t^i \in \mathbb{C}[t]$ we define

$$[p(t)] \;:=\; [a_0 : a_1 : \cdots : a_n : 0 : \ldots] \;\in\; \mathbb{C}\mathrm{P}^\infty.$$

Evidently every element in $\mathbb{C}\mathrm{P}^\infty$ is of that form. We consider the "multiplication" map

$$\begin{array}{rcl} \mu\colon \mathbb{C}\mathrm{P}^\infty \times \mathbb{C}\mathrm{P}^\infty & \to & \mathbb{C}\mathrm{P}^\infty \\ ([p(t)],[q(t)]) & \mapsto & [\underbrace{p(t)\cdot q(t)}_{\in \mathbb{C}[t]}]. \end{array}$$

We leave it to the reader to verify that μ is continuous. It is clear that left and right "multiplication" by $e = [1] = [1:0:\ldots]$ is the identity. This shows that $\mathbb{C}\mathrm{P}^\infty$ together with μ and e is an H-space. Note that this multiplication μ is commutative and associative, but it does not have inverses[1911], thus μ does not define a group structure on $\mathbb{C}\mathrm{P}^\infty$.

We formulate the last example as a lemma.

Lemma 156.22. Let (X, x_0) be a pointed topological space. We denote by $\Omega(X,x_0)$ the loop space as defined on page 3280.

(1) The map

$$\begin{array}{rcl} \mu\colon \Omega(X,x_0) \times \Omega(X,x_0) & \to & \Omega(X,x_0) \\ (f\colon [0,1] \to X, g\colon [0,1] \to X) & \mapsto & (\underbrace{f * g}_{\substack{\text{multiplication of loops} \\ \text{as defined on page 1052}}} : [0,1] \to X) \end{array}$$

is continuous.

(2) The map $\mu\colon \Omega(X,x_0) \times \Omega(X,x_0) \to \Omega(X,x_0)$ from (1) together with the constant loop given by $e(t) \equiv x_0$, turns $\Omega(X,x_0)$ into an H-space.

Remark.

(1) Note that for the H-space $\Omega(X,x_0)$ "multiplication" by e is not the identity, it is only homotopy equivalent to the identity.

(2) We had hinted at the existence of a multiplication map on $\Omega(X,x_0)$ in Exercise 154.5.

Proof. Let (X,x_0) be a pointed topological space. To simplify the notation we write ΩX instead of $\Omega(X,x_0)$.

(1) We need to show that the map $\mu\colon \Omega X \times \Omega X \to \Omega X$ is in fact continuous. By the "⇒"-direction of the Compact-Open Exponential Proposition 12.6, applied to $T = \Omega X \times \Omega X$ and the regionally compact space $Y = [0,1]$, it suffices to show that the following map is continuous:

$$\Phi\colon (\Omega X \times \Omega X) \times [0,1] \xrightarrow{\mu\times \mathrm{id}} \Omega X \times [0,1] \xrightarrow{(f,t)\mapsto f(t)} X.$$

[1910] We partially proved the somewhat weaker Theorem 152.10.

[1911] Why are there elements in $\mathbb{C}\mathrm{P}^\infty$ which do not have multiplicative inverses?

On the subset $(\Omega X \times \Omega X) \times [0, \frac{1}{2}]$ this map is equal to

$$(\Omega X \times \Omega X) \times [0, \tfrac{1}{2}] \xrightarrow{((f,g)\mapsto f)\times(t\mapsto 2t))} \Omega X \times [0,1] \xrightarrow{(f,t)\mapsto f(t)} X.$$

The first map is evidently continuous. Furthermore, the second map is continuous by the Evaluation Map Proposition 12.4. Thus we have shown that the restriction of Φ to the subset $(\Omega X \times \Omega X) \times [0, \frac{1}{2}]$ is continuous. Basically the same argument shows that the restriction of Φ to $(\Omega X \times \Omega X) \times [\frac{1}{2}, 1]$ is continuous. it follows from the Homotopy Stacking Lemma 14.3 that Φ itself is continuous.

(2) Let $e \in \Omega(X, x_0)$ be the constant loop given by $e(t) \equiv x_0$. It is clear that $\mu(e, e) = e$. Thus it remains to show that the maps

$$\begin{array}{rcl} (\Omega(X,x_0),e) & \mapsto & (\Omega(X,x_0),e) \\ f & \mapsto & \mu(f,e) \end{array} \quad \text{and} \quad \begin{array}{rcl} (\Omega(X,x_0),e) & \mapsto & (\Omega(X,x_0),e) \\ f & \mapsto & \mu(e,f) \end{array}$$

of pairs of topological spaces are homotopic to the identity. We consider the map

$$\begin{array}{rcl} H\colon \Omega(X,x_0)\times[0,1] & \to & \Omega(X,x_0) \\ ((f\colon [0,1]\to X),t) & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & X \\ s & \mapsto & \begin{cases} f(\frac{2s}{t+1}), & \text{if } s \in [0, \frac{t+1}{2}], \\ x_0, & \text{otherwise.} \end{cases} \end{array} \right) \end{array}$$

We leave it to the underchallenged reader to show, using the "$\Rightarrow$"-direction of the Compact-Open Exponential Proposition 12.6, that this map H is in fact continuous. Note that we have $H(e,t) = e$ for all $t \in [0,1]$. With these observations it is basically clear that it is the desired homotopy between the map $f \mapsto \mu(f,e)$ and the identity.

Almost exactly the same way we deal with the second map $f \mapsto \mu(e,f)$. ■

The following lemma is the only statement on H-spaces that we can prove with our limited space resources.

Lemma 156.23. If X is a path-connected H-space, then $\pi_1(X)$ is abelian.

Remark. Let (Y, y_0) be a pointed topological space. We recall the following two facts:

(a) Recall that in the Loop Space-Homotopy Groups Corollary 154.15 we saw that given any $k \in \mathbb{N}$ there exists an isomorphism $\pi_{k+1}(Y,y_0) \xrightarrow{\cong} \pi_k(\Omega(Y,y_0))$.

(b) We pointed out above that the loop space $\Omega(Y,y_0)$ is an H-space.

The combination of (a), (b) and Lemma 156.23 implies that given any $k \in \mathbb{N}_{\geq 2}$ we have

$$\pi_k(Y,y_0) \underset{\text{by (a)}}{\cong} \pi_{k-1}(\Omega(Y,y_0)) \cong \ldots \underset{\text{by (a)}}{\cong} \pi_1(\overbrace{\Omega(\Omega\ldots\Omega}^{k \text{ times}}(Y,y_0))) \underset{\text{by (b) and since } k\geq 2}{=} \pi_1(\text{H-space}) \underset{\text{Lemma 156.23}}{=} \text{abelian}.$$

We have thus shown that $\pi_k(Y,y_0)$ is abelian for every $k \geq 2$. In other words, we have obtained a new proof for the Homotopy Group-Abelian Proposition 71.3.

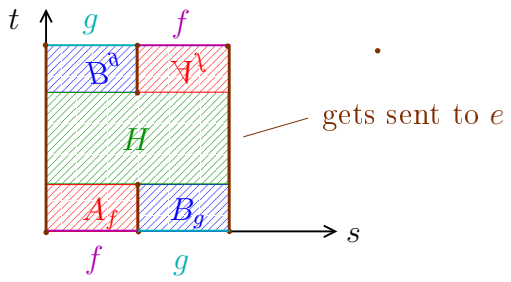
Just for kicks we provide two different proofs for Lemma 156.23. The first proof, which we provide here is "down to earth". The second proof, which we will provide in the next section, is more structural.

First proof of Lemma 156.23. We denote by $\mu\colon X \times X \to X$ and $e \in X$ the objects in the definition of an H-space. Let $f, g\colon [0,1] \to X$ be loops in e. We need to show that the path $f * g$ is path-homotopic to the path $g * f$.

We denote by $\mu(f, e)$ the path $t \mapsto \mu(f(t), e)$ and similarly we define $\mu(e, g)$. We consider the map

$$\begin{array}{rccc} F\colon [0,1] \times [0,1] & \to & X \\ (s,t) & \mapsto & \mu(f(s), g(t)). \end{array}$$

Note that this map is continuous by the Product Topology-Basics Lemma 5.4 (3) and the fact that μ is continuous. Furthermore we consider the following path-homotopy:[1912]



$$\begin{array}{rccl} H\colon [0,1] \times [0,1] & \to & X & \\ (s,t) & \mapsto & \begin{cases} F(2s \cdot (1-t,t)), & \text{if } s \leq \frac{1}{2} \\ F((2-2s) \cdot (1-t,t) + (2s-1) \cdot (1,1)), & \text{if } s > \frac{1}{2}. \end{cases} \end{array}$$

By carefully plugging in $t = 0$ and $t = 1$ we see that H is a path-homotopy from the loop $\mu(f, e) * \mu(e, g)$ to the loop $\mu(e, g) * \mu(f, e)$.

By definition of an H-space there exists a homotopy $A\colon X \times [0,1] \to X$ rel $\{e\}$ with $A_0 = \mathrm{id}$ and $A_1 = \mu(-, e)$ and there exists a homotopy $B\colon X \times [0,1] \to X$ rel $\{e\}$ with $B_0 = \mathrm{id}$ and $B_1 = \mu(e, -)$. We consider the maps

$$\begin{array}{rccc} A_f\colon [0,1] \times [0,1] & \to & X \\ (s,t) & \mapsto & A(\underbrace{f(s)}_{\in X}, t) \end{array} \quad \text{and} \quad \begin{array}{rccc} B_g\colon [0,1] \times [0,1] & \to & X \\ (s,t) & \mapsto & B(\underbrace{g(s)}_{\in X}, t). \end{array}$$

Note that A_f is a path-homotopy from the loop f to the loop $\mu(f, e)$ and B_g is a path-homotopy from the loop g to the loop $\mu(e, g)$. The path-homotopy between the loops $f * g$ and $g * f$ is given by combining H with A_f and B_g as indicated in the figure below. We leave it to the reader to conscientiously write down the precise homotopy. ■

The following theorem was proved by William Browder [**Browd1960**, Theorem 2] [**Browd1961**, Theorem 6.11] in 1961.

Theorem 156.24. Let X be a path-connected H-space. If the group $\bigoplus_{i=0}^{\infty} \mathrm{H}_i(X; \mathbb{Z})$ is finitely generated, then

$$\min\{m \in \mathbb{N}_{\geq 2} \,|\, \pi_m(X) \neq 0\}$$

is odd. In particular we have $\pi_2(X) = 0$.

Examples.

[1912] It follows easily from Pasting Proposition 2.6 (2′) that this map is continuous.

(1) On page 3334 we saw that $\mathbb{C}\mathrm{P}^\infty$ is an H-space. Furthermore in Corollary 85.6 (2) we saw that $\pi_2(\mathbb{C}\mathrm{P}^\infty) \neq 0$. Thus we see that in the statement of Theorem 156.24 we cannot drop the hypothesis that $\bigoplus_{i=0}^{\infty} \mathrm{H}_i(X;\mathbb{Z})$ is a finitely generated group.

(2) Let $k \in \mathbb{N}$. It follows from Theorem 156.24, together with Theorem 155.12 and the discussion on page 1772, that the finite complex projective space $\mathbb{C}\mathrm{P}^k$ does *not* admit an H-space structure.

We conclude this chapter with a corresponding theorem for Lie groups.

Theorem 156.25. If G is a path-connected Lie group, then

$$\min\{m \in \mathbb{N}_{\geq 2} \,|\, \pi_m(G) \neq 0\}$$

is odd. In particular $\pi_2(G) = 0$.

Remark. There are many direct proofs in the literature for the statement that given a path-connected Lie group G the second homotopy group $\pi_2(G)$ vanishes, see e.g. [**Carta1936**] or [**Miln1963a**, Theorem 21.7] or [**BtD1995**, Proposition V.7.5].

Note that Theorem 156.25 has no conditions on the Lie group except that it needs to be path-connected. The reason why we can get away with so few conditions is given by the following proposition.

Proposition 156.26. Let G be a Lie group. There exists a compact Lie subgroup K[1913] such that G is homeomorphic to $K \times \mathbb{R}^n$ for some $n \in \mathbb{N}_0$.

Proof of Proposition 156.26. Like many other foundational results on Lie groups this proposition has its origins in the work of Henri Cartan [**Carta1936**]. A full proof is given in [**Mal1945**, Theorem 11] or [**Mos1949**, Theorem 2]. A sketch of the proof is provided in [**Sam1952**, Chapter 7]. ■

Example. We consider the group $\mathrm{Isom}(\mathbb{R}^n)$ of isometries of the vector space $\mathbb{R}^n$ equipped with the usual inner product. It is an elementary, but not totally trivial fact, see [**Rees1983**, p. 11], that

$$\mathrm{Isom}(\mathbb{R}^n) \;=\; \{\text{all maps of the form } x \mapsto Ax + v \text{ where } A \in \mathrm{O}(n) \text{ and } v \in \mathbb{R}^n\}.$$

The maps

$$\begin{array}{rcl} \mathrm{O}(n) \times \mathbb{R}^n & \to & \mathrm{Isom}(\mathbb{R}^n) \\ (A, v) & \mapsto & (x \mapsto Ax + v) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \mathrm{Isom}(\mathbb{R}^n) & \to & \mathrm{O}(n) \times \mathbb{R}^n \\ f & \mapsto & (\underbrace{(x \mapsto (f(x) - f(0))}_{\text{represented by matrix in } \mathrm{O}(n)}, f(0)) \end{array}$$

are inverses of one another. Thus we can use the smooth manifold structure on $\mathrm{O}(n) \times \mathbb{R}^n$ to turn $\mathrm{Isom}(\mathbb{R}^n)$ into a smooth manifold and it is quasi-obvious to see that this turns $\mathrm{Isom}(\mathbb{R}^n)$ into a Lie group. We can view $\mathbb{R}^n$ and $\mathrm{O}(n)$ as subgroups of $\mathrm{Isom}(\mathbb{R}^n)$ in an obvious way. But one easily verifies that the map $\mathrm{O}(n) \times \mathbb{R}^n \to \mathrm{Isom}(\mathbb{R}^n)$ is not an isomorphism. In other words, as predicted by Proposition 156.26 the Lie group $\mathrm{Isom}(\mathbb{R}^n)$ splits topologically into a product. But the Lie group does not split as a Lie group.

[1913] In fact a Lie group contains a maximal compact Lie subgroup which is furthermore unique up to conjugation. We will not make use of this fact.

Proof of Theorem 156.25. Let G be a path-connected Lie group. By Proposition 156.26 we know that G is homotopy equivalent to a compact path-connected Lie group K. By the Homotopy-π_n-Proposition 71.7 (2) it suffices to prove the desired statement for K. Since K is in particular a compact smooth manifold we obtain from the Smooth Manifolds-Invariants Proposition 96.6 that $\bigoplus_{i=0}^{\infty} \mathrm{H}_i(X;\mathbb{Z})$ is a finitely generated abelian group. Thus we can conclude the proof by appealing to Theorem 156.24. ■

156.6. **The Eckmann-Hilton Theorem.** In this section we will state and prove a theorem that was provided by Bruno Eckmann and Peter Hilton [**EcH1962**] in 1962. The theorem is totally elementary, but at the same time it is surprisingly useful. In particular it will be the key to giving the second proof of Lemma 156.23.
The formulation of the Eckmann-Hilton Theorem requires the following harmless definition.

Definition. Let X be a set.
(1) A binary operation is nothing but a map $X \times X \to X$.
(2) A binary operation $\mu\colon X \times X \to X$ is called unital if there exists an element $1 \in X$ such that $\mu(1,x) = \mu(x,1) = x$ for all $x \in X$.

Example. The multiplication map on a group is evidently a unital binary operation.

The following theorem is in some sense quite elementary, but the cleverness lies in its formulation.

Theorem 156.27. (Eckmann-Hilton Theorem) Let X be a set equipped with two binary operations "$\circ$" and "$\otimes$". Suppose the following two conditions are satisfied:
(a) "$\circ$" and "$\otimes$" are both unital.
(b) For every $a,b,c,d \in X$ we have the equality

$$(a \otimes b) \circ (c \otimes d) \;=\; (a \circ c) \otimes (b \circ d).$$

Then "$\circ$" and "$\otimes$" are the same and they are commutative and associative.

Proof. First we show that the units of the two operations "$\circ$" and "$\otimes$" coincide:

$$1_\circ \;=\; 1_\circ \circ 1_\circ \;=\; (1_\otimes \otimes 1_\circ) \circ (1_\circ \otimes 1_\otimes) \underset{\text{by (b)}}{=} (1_\otimes \circ 1_\circ) \otimes (1_\circ \circ 1_\otimes) \;=\; 1_\otimes \otimes 1_\otimes \;=\; 1_\otimes.$$

Next we show that the two operations "$\circ$" and "$\otimes$" are the same and that they are commutative. Thus let $x,y \in X$. Then

$$x \circ y = (1 \otimes x) \circ (y \otimes 1) \underset{\text{by (b)}}{=} (1 \circ y) \otimes (x \circ 1) = y \otimes x = (y \circ 1) \otimes (1 \circ x) \underset{\text{again by (b)}}{=} (y \otimes 1) \circ (1 \otimes x) = y \circ x.$$

Finally we show that the operations are associative. Thus let $x,y,z \in X$. We have the following equality:

$$(x \otimes y) \otimes z \;=\; (x \otimes y) \otimes (1 \otimes z) \underset{\text{one last time by (b)}}{=} (x \otimes 1) \otimes (y \otimes z) \;=\; x \otimes (y \otimes z).$$

■

Now we can prove the following lemma, which in particular gives the promised second, more structural proof of Lemma 156.23.

Lemma 156.28. Let X be a path-connected H-space and let $x_0 \in X$. In the following we denote by $\mu\colon X \times X \to X$ the multiplication map of the H-space. We consider the following two binary operations on $\pi_1(X, x_0)$:

$$\begin{array}{rcl} \pi_1(X,x_0)\times\pi_1(X,x_0) & \xrightarrow{\circ} & \pi_1(X,x_0) \\ ([f],[g]) & \mapsto & [f * g] \end{array} \quad \text{and} \quad \begin{array}{rcl} \pi_1(X,x_0)\times\pi_1(X,x_0) & \xrightarrow{\otimes} & \pi_1(X,x_0) \\ ([f],[g]) & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & X \\ t & \mapsto & \mu(f(t),g(t)) \end{array}\right] \end{array}.$$

The following two statements hold:

(1) The two binary operations agree.
(2) The group $\pi_1(X, x_0)$ is abelian.

Proof. Let X be a path-connected H-space and let $x_0 \in X$. We denote by $\mu\colon X \times X \to X$ the multiplication map of the H-space. Since μ is an H-space structure one sees easily that "$\otimes$" is a unital binary operation. Furthermore we have known ever since Proposition 47.6 that "$\circ$" is a unital binary operation. In Exercise 156.9 we will show that Condition (b) of the Eckmann-Hilton Theorem 156.27 is satisfied. Thus we obtain from the Eckmann-Hilton Theorem 156.27 the amusing fact that the two operations agree and we obtain that both operations are commutative. In particular this means that $\pi_1(X, x_0)$ is abelian. ■

Exercises for Chapter 156.

Exercise 156.1. Let X be the torus minus one open disk. Does X admit the structure of a topological group?

Exercise 156.2. Let M be a smooth manifold without boundary and let $g\colon M \times M \to M$ be a map that is smooth and that defines a group structure on M. Show that (M, g) is a Lie group. In other words, show that the map $M \to M$ given by $x \mapsto x^{-1}$ is smooth.
Hint. Use the Implicit Function Theorem, see e.g. [**Lee2002**, p. 661].

Exercise 156.3. Let $n \in \mathbb{N}$. We define

$$\mathrm{GL}(n,\mathbb{H}) \;=\; \left\{ A \in \mathrm{M}(n\times n,\mathbb{H}) \;\middle|\; \begin{array}{c} \text{there exist matrices } X, Y \in \mathrm{M}(n\times n,\mathbb{H}) \\ \text{such that } AX = YA = \mathrm{id} \end{array} \right\}.$$

Is $\mathrm{GL}(n, \mathbb{H})$ an open subset of $\mathrm{M}(n \times n, \mathbb{H})$?

Exercise 156.4. Let $n \in \mathbb{N}$. In the proof of Lemma 156.3 we already saw that $\mathrm{Sp}(n)$ is a smooth manifold and that matrix multiplication turns $\mathrm{Sp}(n)$ into a group. Show that the map

$$\begin{array}{rcl} \mathrm{Sp}(n) & \to & \mathrm{Sp}(n) \\ A & \mapsto & A^{-1} \end{array}$$

is a smooth map.
Note: The argument in the proof of Lemma 5.38 can be used to show that taking inverses in $\mathrm{GL}(n, \mathbb{R})$ and $\mathrm{GL}(n, \mathbb{C})$ is smooth. Does this help us in any way?
Remark. In principle one could use Exercise 156.2. But what do readers do who are still traumatized by the Implicit Function Theorem?

Exercise 156.5. Use the Ehresmann Fibration Theorem that we had stated in Exercise **??** to give a third proof that the map $p\colon \mathrm{O}(n+1) \to S^n$ from the Matrix Group-Fiber Proposition 156.8 is a fiber bundle.

Exercise 156.6. Determine all closed non-orientable 2-dimensional smooth manifolds that admit a Lie group structure.

Exercise 156.7. We define $\mathrm{SU} = \varinjlim \mathrm{SU}(n)$ the same way as we defined U. Determine the homotopy groups of SU.
Remark. You might want to use Exercise 155.7.

Exercise 156.8.

(a) Let X be a CW-complex and let $e \in X^0$ be a point in the 0-skeleton. Suppose we are given a map $\mu\colon X \times X \to X$ such that the two maps

$$\begin{array}{ccc} X & \to & X \\ x & \mapsto & \mu(x,e) \end{array} \quad \text{and} \quad \begin{array}{ccc} X & \to & X \\ x & \mapsto & \mu(e,x) \end{array}$$

are homotopic to the identity. Show that μ is homotopic to a map $\nu\colon X \times X \to X$ such that $\nu(x,e) = \nu(e,x) = x$ for all $x \in X$.

(b) Show that ν in (a) defines an H-space structure on X.

(c) Let X be a CW-complex. Suppose there exists a homotopy equivalence $f\colon X \to Y$ to an H-space Y. Show that X itself admits an H-space structure.

Exercise 156.9. Let (X, x_0) be a pointed path-connected H-space. Let $\mu\colon X \times X \to X$ be the multiplication of the H-space structure. We consider the following two binary operations on $\pi_1(X, x_0)$:

$$\begin{array}{rcl} \pi_1(X,x_0)\times\pi_1(X,x_0) & \xrightarrow{\circ} & \pi_1(X,x_0) \\ ([f],[g]) & \mapsto & [f * g] \end{array} \quad \text{and} \quad \begin{array}{rcl} \pi_1(X,x_0)\times\pi_1(X,x_0) & \xrightarrow{\otimes} & \pi_1(X,x_0) \\ ([f],[g]) & \mapsto & \begin{pmatrix} [0,1] \to X \\ t \mapsto \mu(f(t),g(t)) \end{pmatrix}. \end{array}$$

Show that "$\circ$" and "$\otimes$" satisfy Condition (b) of the Eckmann-Hilton Theorem 156.27.

Exercise 156.10. Let (X, x_0) be a pointed topological space and let $k \in \mathbb{N}_{\geq 2}$. Define the multiplication $*\colon \pi_k(X,x_0) \times \pi_k(X,x_0) \to \pi_k(X,x_0)$ as on page 1561. Provide a different multiplication $\otimes\colon \pi_k(X,x_0) \times \pi_k(X,x_0) \to \pi_k(X,x_0)$ such that "$*$" and "$\otimes$" satisfy the conditions of the Eckmann-Hilton Theorem 156.27. Conclude, once again, that $\pi_k(X,x_0)$ is abelian.

Exercise 156.11. Let $n \in \mathbb{N}_{\geq 3}$. In Proposition 156.11 we saw that $\pi_1(\mathrm{SO}(n), \mathrm{id}) \cong \mathbb{Z}_2$. Give an example of a loop that is a generator of $\pi_1(\mathrm{SO}(n), \mathrm{id})$ and show explicitly why it has order 2 in the fundamental group.

Exercise 156.12. Let $n \in \mathbb{N}$. Use the approach of the proof of Proposition 156.10 to show that $\mathrm{SO}(n)$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$ are path-connected.
Remark. This exercise provides a new and perhaps more satisfactory proof to some of the statements of the Matrix Group Path-Component Proposition 2.37.

157. Thom-Pontryagin Theory I: The basics

In this chapter we will introduce the Thom-Pontryagin approach to calculating homotopy groups of spheres. Furthermore we will see that it allows us to reprove several earlier results. In Chapters 158 and 159 we will use the Thom-Pontryagin approach to obtain new results.

Before we start with discussing the Thom-Pontryagin theory we fix some notations and conventions.

Notation. Let $n \in \mathbb{N}_0$.

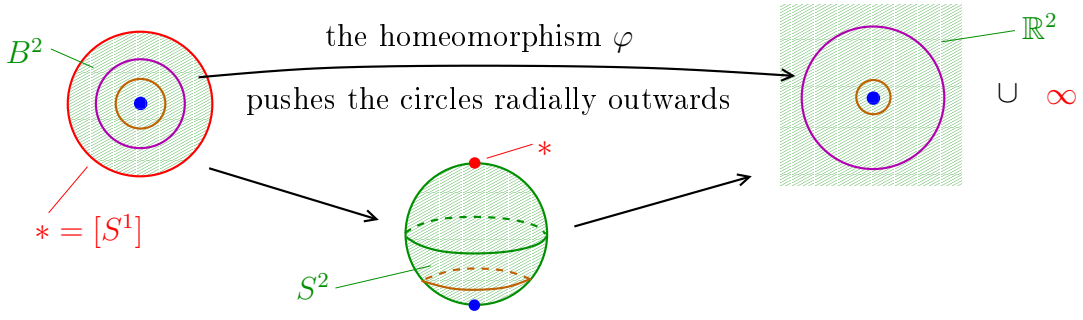
(1) We denote by $*$ the point in $\overline{B}^n/S^{n-1}$ that is given by $[S^{n-1}]$.
(2) We denote by $*$ the "North Pole" $(0,\ldots,0,1) \in S^n$.

We make the following identifications:

(a) We use the homeomorphism $S^n \to \mathbb{R}^n \cup \{\infty\}$ from Lemma 2.18, which is given by stereographic projection, that sends the North Pole $*$ to ∞ to make the identification $S^n = \mathbb{R}^n \cup \{\infty\}$.

(b) In the Ball-Quotient Sphere Lemma 5.20 we wrote down an explicit homeomorphism $\overline{B}^n/S^{n-1} \to S^n$. This homeomorphism sends $*$ to $(0,\ldots,0,1)$. $(x_1,\ldots,x_{n+1}) \mapsto (x_{n+1},x_2,\ldots,x_n,-x_1)$. This way we obtain a homeomorphism $\overline{B}^n/S^{n-1} \to S^n$ that sends $*$ to $(0,\ldots,0,1)$.

(c) Putting the two homeomorphisms from (a) and (b) together we obtain a homeomorphism



$$\varphi\colon \overline{B}^n/S^{n-1} \;\to\; \mathbb{R}^n \cup \{\infty\}.$$

It follows fairly easily from the definitions of the two maps in (a) and (b) that φ restricts to a diffeomorphism $B^n \to \mathbb{R}^n$ and that φ is of the form

$$x \;\mapsto\; \begin{cases} \eta(\|x\|)\cdot x, & \text{if } x \in B^n, \\ \infty, & \text{if } x = *, \end{cases}$$

where $\eta\colon [0,1) \to [0,\infty)$ is a strictly monotonously increasing function with $\eta(0)=0$ and $\lim\limits_{t\to 1}\eta(t) = \infty$.

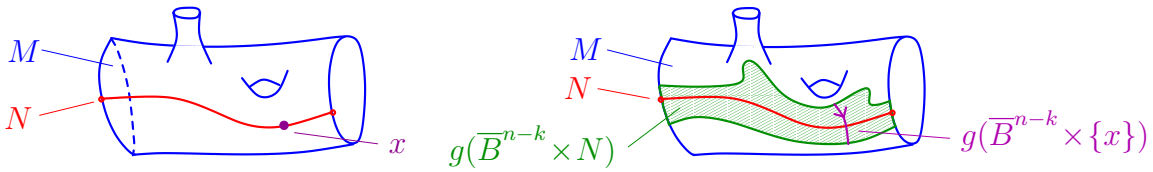
Summarizing we have the identifications $S^n = \mathbb{R}^n \cup \{\infty\} = \overline{B}^n/S^{n-1}$ and under these identifications the points $* \in S^n$, ∞ and $* \in \overline{B}^n/S^{n-1}$ get identified. We refer to the figure below for an illustration.

157.1. **The generalized Thom-Pontryagin construction.** On page 2839 we saw that a proper oriented codimension-one submanifold of a compact oriented smooth manifold M

gives rise, via the Thom-Pontryagin construction, to a map $M \to S^1$. In this section we will generalize this construction.

The key objects in the more general construction of Thom-Pontryagin maps are "thickened" submanifolds:

Definition. Let M be an orientable n-dimensional smooth manifold.



(1) Let N be a compact orientable proper k-dimensional submanifold of M. A thickening of N is an injective map $g\colon \overline{B}^{n-k} \times N \to M$ with the following properties:[1914][1915]
   (a) for all $P \in N$ we have $g(0, P) = P$,
   (b) the image $g(\overline{B}^{n-k} \times N)$ is a submanifold with corner of M,
   (c) we have $g(\overline{B}^{n-k} \times N) \cap \partial M = g(\overline{B}^{n-k} \times \partial N)$.
   We refer to the figure below for an illustration.

(2) A thickened submanifold of M is a pair (N, g) where N is a compact orientable proper[1917] submanifold of M and g is a thickening for N.

(3) Let $\varphi\colon M \to W$ be a smooth embedding of M into a smooth manifold W of the same dimension. Given a thickened k-dimensional submanifold $(N, g\colon \overline{B}^{n-k} \times N)$ of $M \setminus \partial M$ we equip $\varphi(N)$ with the "obvious thickening", namely with the thickening that is given by

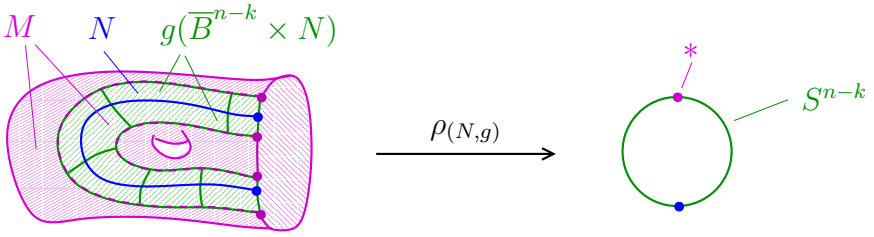
$$\begin{array}{rcl} \varphi_*(g)\colon \overline{B}^{n-k} \times \varphi(N) & \to & W \\ (v, P) & \mapsto & g(v, \varphi^{-1}(P)). \end{array}$$

   Evidently $(\varphi(N), \varphi_*(g))$ is a thickened submanifold of W.

The following definition can be viewed as a generalization of the Thom-Pontryagin map introduced on page 2839.

Definition. Let M be an orientable n-dimensional smooth manifold. Given a thickened k-dimensional submanifold $(N, g\colon \overline{B}^{n-k} \times N \to M)$ we refer to the map[1918]

$$\begin{array}{rcl} \rho_{(N,g)}\colon M & \to & S^{n-k} = \overline{B}^{n-k}/S^{n-k-1} \\ P & \mapsto & \begin{cases} [x], & \text{if } P = g(x, y) \text{ with } (x, y) \in \overline{B}^{n-k} \times N, \\ *, & \text{otherwise} \end{cases} \end{array}$$



[1914] Here one really would like to say that $g\colon \overline{B}^{n-k} \times N \to M$ is an "smooth embedding", but if N has boundary, then it is not entirely clear in what sense $\overline{B}^{n-k} \times N$ is a smooth manifold and what "smooth embedding" is supposed to mean.

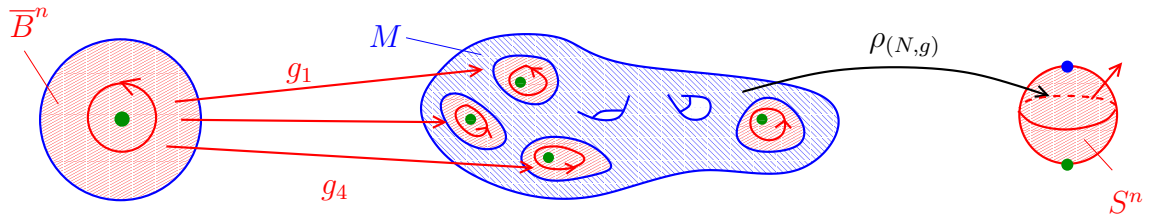
[1915] The definition looks very similar to the definition of a tubular neighborhood. In fact a thickening is the same data as a trivial tubular neighborhood, it is just phrased in slightly different words.

[1916] On page 2853 we introduced the thickening of an *oriented* knot. For knots the present definition is the same as before, except that we no longer demand that the knot is oriented.

[1917] Note that here, in the definition of a thickened submanifold, we sneaked in the adjectives "compact", "orientable" and "proper", so that we will not have to carry them around all the time.

as the Thom-Pontryagin map. (We refer to the figure below for an illustration.) Sometimes we refer to this approach of assigning to a thickened k-dimensional submanifold a map $M \to S^{n-k}$ as the Thom-Pontryagin construction.

Remark.



(1) Let N be a compact *oriented* proper codimension-one submanifold of an *oriented* smooth manifold M. It follows immediately from Proposition **??** that N admits a thickening $[-1,1] \times N$ such that the inclusion $(-1,1) \times N \to M$ is orientation-preserving.[1919] The map $\rho_N \colon M \to S^1$ that we defined on page 2839 is basically the same as the above map $\rho_{(N,g)} \colon M \to S^1$. The only difference is that the two maps differ by multiplication by $i \in S^1$.

(2) We saw in Proposition 126.14 that the submanifold $\mathbb{C}\mathrm{P}^1$ of $\mathbb{C}\mathrm{P}^2$ does *not* admit a trivial tubular neighborhood, in particular it does not admit a thickening.

Example. Let $n \in \mathbb{N}$ and let M be a closed orientable n-dimensional smooth manifold together with a 0-dimensional submanifold $N = \{P_1, \dots, P_m\}$. Suppose N is equipped with a thickening

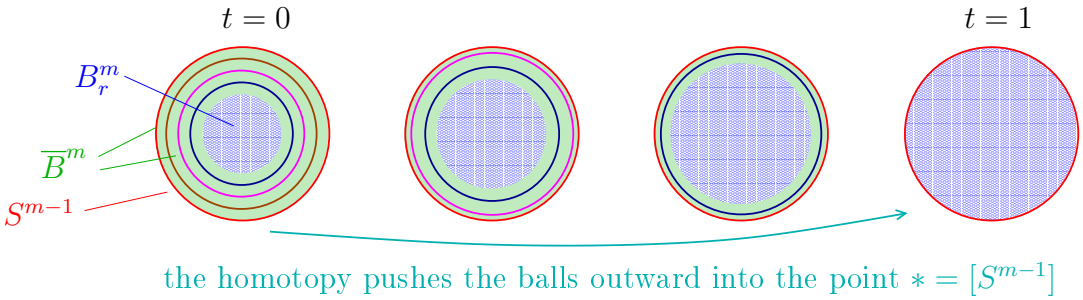
$$g = g_1 \sqcup \cdots \sqcup g_m \colon (\overline{B}^n \times \{P_1\}) \sqcup \cdots \sqcup (\overline{B}^n \times \{P_m\}) \;\to\; M.$$

From the Thom-Pontryagin construction we obtain a map $\rho_{(N,g)} \colon M \to S^n$. It might not be clear what this is good for, but it is kind of fun. This example is illustrated in the figure below.

The following lemma gives us a first interesting example of a Thom-Pontryagin map.

Lemma 157.1. Let $n \in \mathbb{N}$ and let $P \in B^n$. We equip the 0-dimensional smooth manifold $\{P\}$ with any thickening $g \colon \overline{B}^n \times \{P\} \to B^n$ that is orientation-preserving[1920]. The corresponding map

$$\rho_{(\{P\},g)} \colon \overline{B}^n / S^{n-1} \;\to\; \overline{B}^n / S^{n-1}$$



is homotopic rel $*$ to the identity map of $\overline{B}^n / S^{n-1}$.

[1918] It follows easily from Lemma 120.1 and Pasting Proposition 2.6 (2) that this map is indeed continuous.
[1919] Furthermore we saw in Proposition **??** that this thickening is essentially unique.

The proof of Lemma 157.1 relies on the following lemma which we will use on several occasions.

Lemma 157.2. Let $m \in \mathbb{N}$. Given any real number $r \in (0,1)$ there exists a homotopy $F\colon \overline{B}^m/S^{m-1} \times [0,1] \to \overline{B}^m/S^{m-1}$ rel $*$ with the following three properties:

(1) $F_0 = \mathrm{id}$,
(2) the restriction of F_1 to B^m_r is given by multiplication by $\frac{1}{r}$,
(3) for any point $x \notin B^m_r$ we have $F_1(x) = *$.

Proof. Let $r \in (0,1)$. We consider the map

$$\begin{array}{rcl} (\overline{B}^m/S^{m-1}) \times [0,1] & \to & \overline{B}^m/S^{m-1} \\ ([x],t) & \mapsto & \begin{cases} [x \cdot (1-t+t\cdot\frac{1}{r})], & \text{if } x \in B^m \text{ and } t < \frac{1-\|x\|}{(\frac{1}{r}-1)\cdot\|x\|} \\ *, & \text{otherwise.} \end{cases} \end{array}$$

We leave as to the engaged reader to verify that this map is indeed continuous. It is clear that F has the desired properties. ∎

Now we can easily prove Lemma 157.1.

Sketch of proof of Lemma 157.1. It follows quite easily[1921] from the Smooth Ball Embedding Theorem 37.8 that we can assume without loss of generality that $P = 0$ and that we can assume that g is the thickening $g\colon \overline{B}^n \times \{0\} \to B^n$ given by $g(v,0) = \frac{1}{2}v$. By Lemma 157.2 there exists a homotopy $F\colon (\overline{B}^n/S^{n-1}) \times [0,1] \to \overline{B}^n/S^{n-1}$ rel $*$ with the following three properties:

(1) $F_0 = \mathrm{id}$,
(2) the restriction of F_1 to $B^n_{\frac{1}{2}}$ is given by the map $x \mapsto 2 \cdot x$,
(3) for any point $x \notin B^n_{\frac{1}{2}}$ we have $F_1(x) = *$.

If one thinks about it for a second, then one realizes that F_1 equals $\rho_{(0,g)}$ "on the nose". Thus we have found the desired homotopy. ∎

157.2. **The Thom-Pontryagin construction and homotopy groups.** The following is the key observation which justifies our renewed interest in the Thom-Pontryagin construction.

[1920] We equip $\overline{B}^n$ and B^n with the usual orientation.
[1921] The slightly hesitant "quite easily" refers to the fact that, if one thinks about it, we need that the diffeotopy of $\mathbb{R}^{m+k}$ given by the Smooth Ball Embedding Theorem 37.8 has compact support.

Observation. Let $n, k \in \mathbb{N}_0$ and let $(N, g\colon \overline{B}^n \times N \to \mathbb{R}^{n+k})$ be a thickened k-dimensional submanifold of $\mathbb{R}^{n+k}$. We can view $(N, g\colon \overline{B}^n \times N \to \mathbb{R}^{n+k})$ also as a thickened submanifold of $\mathbb{R}^{n+k} \cup \{\infty\}$.[1922] Note that the corresponding Thom-Pontryagin map

$$\begin{array}{rcl} \rho_{(N,g)}\colon S^{n+k} = \mathbb{R}^{n+k} \cup \{\infty\} & \to & \overline{B}^n / S^{n-1} = S^n \\ P & \mapsto & \begin{cases} [x], & \text{if } P = g(x,y) \text{ with } (x,y) \in \overline{B}^n \times N, \\ *, & \text{otherwise,} \end{cases} \end{array}$$

sends ∞ to $*$. In particular $\rho_{(N,g)}$ defines an element in $\pi_{n+k}(S^n, *)$. It is worth repeating this observation:

thickened k-dimensional submanifolds of $\mathbb{R}^{n+k}$ give rise to elements in $\pi_{n+k}(S^n, *)$.

The following questions immediately arise:

Question 157.3. Let $n, k \in \mathbb{N}_0$.

(1) Which elements in $\pi_{n+k}(S^n, *)$ can be realized by Thom-Pontryagin maps?
(2) When do two thickened k-dimensional submanifolds of $\mathbb{R}^{n+k}$ give rise to the same element in $\pi_{n+K}(S^n, *)$.

Before we address this question we intend to discuss two examples in greater detail:

(1) the case of thickened 0-dimensional submanifolds of some $\mathbb{R}^n$, and
(2) the case of thickened 1-dimensional submanifolds of $\mathbb{R}^3$.

We start out with the first case. Dealing with this case requires one definition.

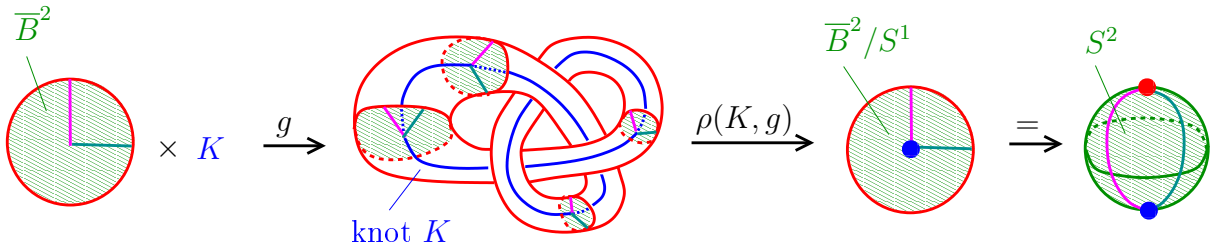
Definition. Let $P \in \mathbb{R}^n$ be a point and let $g\colon \{P\} \times \overline{B}^n \to \mathbb{R}^n$ be a thickening of P. We equip $\{P\} \times \overline{B}^n = \overline{B}^n$ and $\mathbb{R}^n$ with the standard orientations. We define

$$\operatorname{sign}(g) := \begin{cases} +1, & \text{if } g \text{ is orientation-preserving,} \\ -1, & \text{if } g \text{ is orientation-reversing.} \end{cases}$$

Now we can discuss the case of thickened 0-dimensional submanifolds.

Example. Let $N = \{P_1, \dots, P_m\}$ be a 0-dimensional submanifold of some $\mathbb{R}^n$ and suppose N is equipped with a thickening

$$g = g_1 \sqcup \dots \sqcup g_m\colon (\overline{B}^n \times P_1) \sqcup \dots \sqcup (\overline{B}^n \times P_m) \to \mathbb{R}^n.$$



It follows almost immediately from the Addition-in-π_n-Proposition 85.11 that

$$[\rho_{(N,g)}] = \sum_{i=1}^{m} \operatorname{sign}(g_i) \cdot [\mathrm{id}_{S^n}] \in \pi_n(S^n, *).$$

We continue our discussion of examples of the Thom-Pontryagin construction with knots and links. By the above discussion every thickened knot or link in $\mathbb{R}^3$, i.e. every thickened 1-dimensional submanifold of $\mathbb{R}^3$, gives rise to an element in $\pi_3(S^2, *)$. For the trefoil together with some thickening we illustrate the corresponding map $S^3 \to S^2$ in the figure below.

Before we continue we need to introduce the following slight variation on a definition from page 2853.

[1922] Why can we do so?

Definition. Let K be a knot and let $g\colon \overline{B}^2 \times K \to S^3$ be a thickening. We pick an orientation for K and we equip $g(\{1\}\times K)$ with the corresponding definition. We define[1923]

$$\text{self-linking number of } g \;:=\; \mathrm{lk}(K, g(\{1\}\times K)).$$

It follows from Proposition 131.11 (2) that this definition does not depend on the choice of the orientation of K.

The following lemma deals with two basic, but important examples. Later on both examples will follow (at least up to sign) from a more general result, but for the geometrically inclined person it can be fun to consider the more direct arguments provided in the proof of the lemma.

Lemma 157.4. Let K be the trivial knot and let $g\colon \overline{B}^2 \times K \to \mathbb{R}^3$ be a thickening.

(1) If g is a thickening with self-linking number zero, then $[\rho_{(K,g)}] = 0 \in \pi_3(S^2, *)$.
(2) If g is a thickening with self-linking number one, then[1924] $[\rho_{(K,g)}] = [H] \in \pi_3(S^2, *)$ where $H\colon (S^3, *) \to (S^2, *)$ denotes the Hopf map, that we defined on page 1576.

Sketch of proof. It follows easily from the Knot Thickening Lemma 131.1[1925] that any two thickenings with the same self-linking number give rise to the same element in $\pi_3(S^2, *)$. Furthermore it follows almost immediately from Lemma 59.1 that we can make the identification

$$S^3 \;=\; (S^1 \times \overline{B}^2) \cup_{S^1\times S^1} (\overline{B}^2 \times S^1)$$

such that $K = \{0\}\times S^1$. Furthermore it follows from Lemma 59.2 that the obvious inclusion of $\overline{B}^2 \times S^1$ into the above decomposition of S^3 is a thickening of the trivial knot $K = S^1$ with self-linking number zero.

(1) Let g be the thickening of the trivial knot K with self-linking number zero. We want to show that $[\rho_{(K,g)}] = 0 \in \pi_3(S^2, *)$. By the Change-of-Base Point Proposition 86.9 it suffices to show that the map $\rho_{(K,g)}\colon S^3 \to S^2$ is homotopic to a constant map. (More precisely, the Change-of-Base Point Proposition 86.9 (7) says that in this context we do not need to worry about base points since S^2 is path-connected.) Using the above preparations we will prove in Exercise 157.1 that the map $\rho_{(K,g)}\colon S^3 \to S^2$ is indeed homotopic to a constant map.

[1923] We refer to page 2865 for the definition of the linking number $\mathrm{lk}(K, J)$ of two disjoint oriented knots K and J.
[1924] The sign should be correct. Hopefully. Perhaps.
[1925] Note that here we need that in the statement of the Knot Thickening Lemma 131.1 for $\mathbb{R}^3$ we stated that there exists a diffeotopy of $\mathbb{R}^3$ with compact support.

(2) First we note that under the above identification of S^3 the Hopf map is given as follows:[1926]

$$\begin{array}{rcl} H\colon \overbrace{(S^1\times\overline{B}^2)\cup_{S^1\times S^1}(\overline{B}^2\times S^1)}^{=S^3} & \to & \mathbb{C}\mathrm{P}^1 \\ [(z,w)] & \mapsto & \begin{cases} [\frac{w}{z}:1], & \text{if } z\in S^1 \text{ and } w\in\overline{B}^2, \\ [1:\frac{z}{w}], & \text{if } z\in\overline{B}^2 \text{ and } w\in S^1. \end{cases} \end{array}$$

Now note that it follows from the Knot Thickening Lemma 131.1 (1) that the map

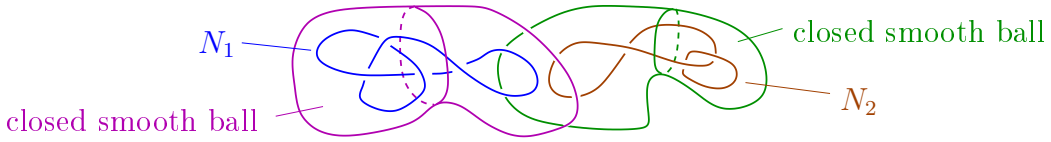
$$\begin{array}{rcl} g\colon \overline{B}^2\times S^1 & \to & \overline{B}^2\times S^1 \subset S^3 = (S^1\times\overline{B}^2)\cup_{S^1\times S^1}(\overline{B}^2\times S^1) \\ (z,w) & \mapsto & (z\cdot w,w) \end{array}$$

is a thickening of the trivial knot of self-linking number one. Furthermore by definition the corresponding map $\rho_{(K,g)}$ is easily seen to be the map[1927]

$$\begin{array}{rcl} \rho_{(K,g)}\colon (S^1\times\overline{B}^2)\cup_{S^1\times S^1}(\overline{B}^2\times S^1) & \to & \overline{B}^2/S^1 \\ [(z,w)] & \mapsto & \begin{cases} \infty=[S^1], & \text{if } z\in S^1 \text{ and } w\in\overline{B}^2, \\ \left[\frac{z}{w}\right], & \text{if } z\in\overline{B}^2 \text{ and } w\in S^1.. \end{cases} \end{array}$$

Comparing the definitions of the Hopf map H and the map $\rho_{(K,g)}$ on $\overline{B}^2\times S^1$ we see that we are perhaps not that far off.

Next we need to relate the targets $\mathbb{C}\mathrm{P}^1$ and $\overline{B}^2/S^1$. To do so we consider the map $\Theta\colon \mathbb{C}\mathrm{P}^1\to\overline{B}^2/S^1$ that is given by $\Theta([1:z])=\frac{z}{1+|z|}$ for $z\in\mathbb{C}$ and that is given by $\Theta([0:1])=[S^1]=*\in\overline{B}^2/S^1$. It follows easily from the Compact-Hausdorff Proposition 2.17 (3) that Θ is a homeomorphism. The particularly audacious reader can verify that this map is homotopic to the "official" identification $\mathbb{C}\mathrm{P}^1=\overline{B}^2/S^1$ which is given by the identification $\mathbb{C}\mathrm{P}^1=S^2$ from page 258 and the above identification $S^2=\overline{B}^2/S^1$. Note that the image of the first solid torus $\overline{B}^2\times S^1$ under the map $\Theta\circ H$ equals the disk of radius $\frac{1}{2}$, i.e. it equals $\overline{B}^2_{\frac{1}{2}}\subset\overline{B}^2/S^1$.



We apply Lemma 157.2 to obtain a homotopy F of $\overline{B}^2/S^1$ with the following properties:
(a) $F_0=\mathrm{id}$,
(b) the restriction of F_1 to $B^2_{\frac{1}{2}}$ is given by multiplication by 2,
(c) for any point $x\notin B^2_{\frac{1}{2}}$ we have $F_1(x)=*$.
The map $F_0\circ\Theta\circ H=\Theta\circ H$ is homotopic rel $*$ to $F_1\circ\Theta\circ H$. It is now straightforward to show that $F_1\circ\Theta\circ H$ is homotopic rel $*$ to $\rho_{(K,g)}$. We leave it to the reader to fill in the details. ■

We conclude this list of basic examples of the Thom-Pontryagin construction with the following lemma.

[1926]As a reality check one can verify that the map is well-defined, i.e. for $[(z,w)]$ with $(z,w)\in S^1\times S^1$ we get consistent answers.
[1927]Why does it say $[\frac{z}{w}]$ instead of $[z\cdot w]$, which might look more natural?

Lemma 157.5. Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$. Let (N_i, g_i), $i = 1, \ldots, m$ be thickened k-dimensional submanifolds of $\mathbb{R}^{n+k}$. If the images $g_i(\overline{B}^n \times N_i)$ are contained in m disjoint closed smooth $(n+k)$-dimensional balls[1928], then

$$\rho_{(N_1 \sqcup \cdots \sqcup N_m, g_1 \sqcup \cdots \sqcup g_m)} \;=\; \rho_{(N_1,g_1)} + \cdots + \rho_{(N_m,g_m)} \;\in\; \pi_{n+k}(S^n, *).$$

Proof. This lemma follows easily from the Addition-in-π_n-Proposition 85.11. We leave it to the reader to fill in the details. ■

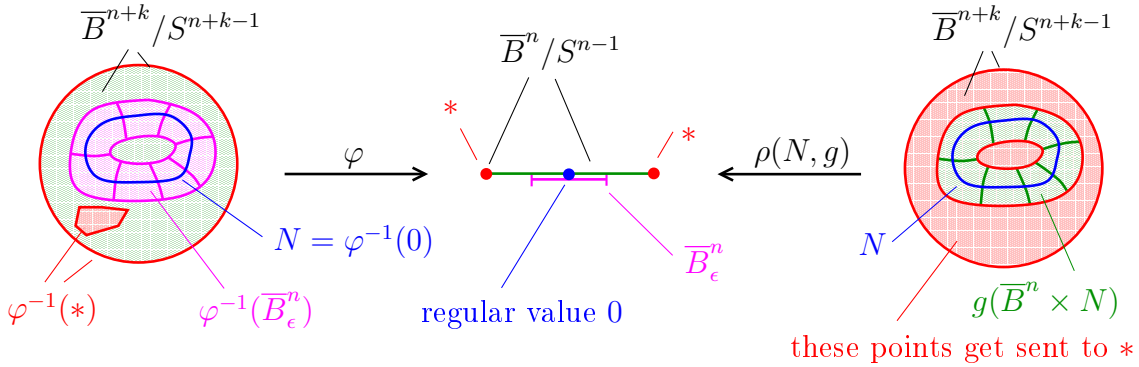
The following proposition gives an affirmative answer to Question 157.3.

Proposition 157.6. Let $k, n \in \mathbb{N}_0$. Given any $\varphi \in \pi_{n+k}(S^n, *)$ there exists a thickened k-dimensional submanifold (N, g) of $\mathbb{R}^{n+k}$ with $[\rho_{(N,g)}] = \varphi$.

Proof. Throughout this proof we find it convenient to view each m-dimensional sphere as the quotient $\overline{B}^m/S^{m-1}$. So suppose we are given a map $\varphi\colon \overline{B}^{n+k}/S^{n+k-1} \to \overline{B}^n/S^{n-1}$ with $\varphi(*) = *$. As we pointed out in the proof of Proposition 71.10, it is a consequence of the Whitney Approximation Theorem 29.1 and the Replace-by-Smooth Homotopy Proposition 29.5 that we can arrange that φ is in fact a smooth map. It follows immediately from Sard's Theorem 31.1 and the Full Measure-Density Proposition 30.3 (2) that there exists a regular value $z \in \overline{B}^n/S^{n-1}$ such that $\varphi^{-1}(z)$ does not contain the point $*$. By Proposition 36.4 (2)[1929] we can without loss of generality assume that the origin 0 is a regular value. By the Regular Value Theorem **??** we know that the preimage $N := \varphi^{-1}(0)$ is a closed orientable k-dimensional submanifold of B^{n+k}. Furthermore by Statement (4) of the Regular Value Theorem **??** we know that there exists an $\epsilon > 0$ and a thickening $g\colon \overline{B}^n \times N \to B^{n+k}$ such that $\varphi^{-1}(\overline{B}^n_\epsilon) = g(\overline{B}^n \times N)$ and such that the following diagram commutes[19301931]

$$\begin{array}{ccc} \overline{B}^n \times N & \xrightarrow{\quad g \quad} & B^{n+k} \\ \downarrow{\scriptstyle (p,x)\mapsto \epsilon\cdot p} & & \downarrow{\scriptstyle \varphi} \\ \overline{B}^n_\epsilon & \hookrightarrow & \overline{B}^n/S^{n-1}. \end{array}$$

This thickening g allows us to consider the map $\rho_{(N,g)}\colon \overline{B}^{n+k}/S^{n+k-1} \to \overline{B}^n/S^{n-1}$. Note that in general φ and $\rho_{(N,g)}$ are quite different maps. (We refer to the figure below for an illustration of the two maps φ and $\rho_{(N,g)}$.) But that does not bother us too much, since it suffices to prove the following claim.



[1928] Here a "closed smooth $(n+k)$-dimensional ball" is shorthand for the image of a smooth embedding of $\overline{B}^{n+k}$ in $\mathbb{R}^{n+k}$.

[1929] To be more precise, we apply Proposition 36.4 to the smooth manifold $\overline{B}^n/S^{n-1} = \mathbb{R}^n \cup \{\infty\}$ with $P_1 = z$, $P_2 = \infty$ and $Q_1 = 0$ and $Q_2 = \infty$.

[1930] Note the discretely hidden multiplication by ϵ in the left-vertical map.

[1931] Note that the above information implies in particular that $\varphi^{-1}(B^n_\epsilon) = g(B^n \times N)$.

Claim. The maps φ and $\rho_{(N,g)}$ from $\overline{B}^{n+k}/S^{n+k-1}$ to $\overline{B}^{n}/S^{n-1}$ are homotopic rel $*$.

Proof. First we remind the reader that in Lemma 157.2 (1) we showed that there exists a homotopy $F\colon (\overline{B}^n/S^{n-1}) \times [0,1] \to \overline{B}^n/S^{n-1}$ rel $*$ with the following properties:

(1) $F_0 = \mathrm{id}$,
(2) the restriction of F_1 to B^n_ϵ is given by multiplication by $\frac{1}{\epsilon}$,
(3) for any point $x \notin B^n_\epsilon$ we have $F_1(x) = *$.

We define $\psi = F_1 \circ \varphi$. It follows from (1) that ψ is homotopic rel $*$ to φ. Therefore we are done once we have shown that ψ in fact equals $\rho_{(N,g)}$. As a reminder, see the definition on page 3343, the map $\rho_{(N,g)}$ is given as follows:[1932]

$$\begin{array}{rcl} \rho_{(N,g)}\colon \overline{B}^{n+k}/S^{n+k-1} & \to & S^n = \overline{B}^n/S^{n-1} \\ P & \mapsto & \begin{cases} x, & \text{if } P = g(x,y) \text{ with } (x,y) \in B^n \times N, \\ *, & \text{otherwise.} \end{cases} \end{array}$$

Now we verify that ψ does indeed agree with $\rho_{(N,g)}$. Thus first suppose we are given a point $P = g(x,y)$ with $(x,y) \in B^n \times N$. We have

$$\psi(P) \underset{\text{definition of } \psi}{\overset{\uparrow}{=}} F_1(\varphi(g(x,y))) \underset{\text{by the above commutative diagram}}{\overset{\uparrow}{=}} F_1(\epsilon \cdot x) \underset{\text{by Property (2) of } F_1 \text{ and since } \epsilon \cdot x \in B^n_\epsilon}{\overset{\uparrow}{=}} \tfrac{1}{\epsilon} \cdot \epsilon \cdot x = x = \rho_{(N,g)}(g(x,y)) = \rho_{(N,g)}(P).$$

Finally suppose that we are given a point $P \in \overline{B}^{n+k}/S^{n+k-1}$ that does not lie in the subset $g(B^n \times N)$. In this case we calculate that

$$\psi(P) \underset{\text{definition of } \psi}{\overset{\uparrow}{=}} F_1(\varphi(P)) \underset{\text{since } \varphi^{-1}(B^n_\epsilon) = g(B^n \times N) \text{ and by choice of } P}{\overset{\uparrow}{=}} F_1(\text{point that does not lie in } B^n_\epsilon) \underset{\text{by Property (3) of } F_1}{\overset{\uparrow}{=}} * = \rho_{(N,g)}(P).$$

■

[1932] Eyes which profited from a carrot-rich diet might notice that the description is not verbatim the same as on page 3343. But with either description of the map the points $P = g(x,y)$ with $x \in S^{n-1}$ and $y \in N$ get sent to $*$. So we really do consider the same map as before.

157.3. **The thickened cobordism groups and the Thom-Pontryagin Theorem.** Recall that the Thom-Pontryagin construction from page 3343 makes the assignment

$$\text{thickened } k\text{-dimensional submanifold of } \mathbb{R}^{n+k} \quad \rightsquigarrow \quad \text{map } (S^{n+k},*) \to (S^n,*).$$

Now we would like to answer Question 157.3 (2), i.e. we would like to determine when do two thickened k-dimensional submanifolds give rise to the same homotopy class of maps $(S^{n+k},*) \to (S^n,*)$. Loosely speaking we would like to fill in the left-hand side of

$$?? \quad \rightsquigarrow \quad \text{map } (S^{n+k}\times[0,1], *\times[0,1]) \to (S^n,*).$$

A quick look at the Thom-Pontryagin construction suggests that the left-hand side should be filled in with a suitable thickened $(k+1)$-dimensional submanifold of $\mathbb{R}^{n+k}\times[0,1]$. This makes sense, except that in the Smooth Manifold Product Proposition 19.31 we saw that for products of two smooth manifolds it is advisable to have the smooth manifold with boundary as a first factor. Thus we will consider submanifolds of $[0,1]\times\mathbb{R}^{n+k}$.[1933]
Before we continue we introduce the following straightforward convention.

Convention. Given a topological space X and an interval I and some $t \in I$ we make at times the identification $X = \{t\}\times X$ via the obvious bijection.

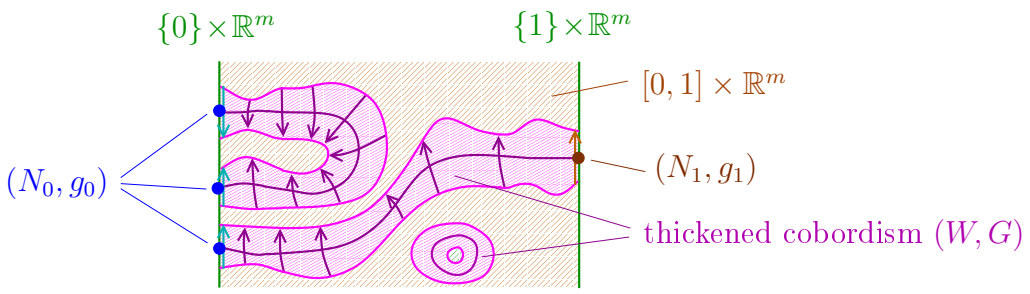
The above observation leads us to the following definition which looks awfully similar to the definition of the notion of a cobordism of smooth manifolds that we introduced on page 3089.

Definition. Let $k, m \in \mathbb{N}_0$.

(1) Let N_0 and N_1 be two closed orientable k-dimensional submanifolds of $\mathbb{R}^m$. A cobordism between N_0 and N_1 is a compact orientable proper $(k+1)$-dimensional submanifold W of $[0,1]\times\mathbb{R}^m$ with $\partial W = (\{0\}\times N_0)\cup(\{1\}\times N_1)$.[1934]

(2) Let (N_0,g_0) and (N_1,g_1) be two thickened k-dimensional submanifolds of $\mathbb{R}^m$. A thickened cobordism between (N_0,g_0) and (N_1,g_1) is a thickened $(k+1)$-dimensional submanifold (W,G) of $[0,1]\times\mathbb{R}^m$ where W is a cobordism between N_0 and N_1 and G is a thickening of W with the following two properties:[1935]
   (a) $G|_{\{0\}\times\overline{B}^m} = g_0$ under the identification $\{0\}\times\overline{B}^m = \overline{B}^m$,
   (b) $G|_{\{1\}\times\overline{B}^m} = g_1$ under the identification $\{1\}\times\overline{B}^m = \overline{B}^m$.
   If such a thickened cobordism exists, then we say that (N_0,g_0) and (N_1,g_1) are cobordant.[1936] If (N,g) is cobordant to the empty submanifold, then we say N is a thickened null-cobordism and we say that (N,g) is null-cobordant. The definition of a thickened cobordism is illustrated in the figure below.

The following lemma shows that diffeotopies give rise to thickened cobordisms.



Lemma 157.7. Let (M,g) be a thickened submanifold of $\mathbb{R}^m$ and let φ be a diffeomorphism of $\mathbb{R}^m$. If φ is diffeotopic to the identity, then $(\varphi(M),\varphi_*(g))$ is cobordant to (M,g).

[1933] Perhaps in hindsight we should have defined homotopies as maps $[0,1]\times X \to Y$ instead of defining them as maps $X\times[0,1]\to Y$?

[1934] Note that we work with submanifolds that are orientable, but we do not assume that they are equipped with an orientation.

[1935] Note that it follows from property (d) of a thickened submanifold, see page 3342, that we know that in fact $G|_{\{0\}\times\overline{B}^m} \subset \{0\}\times\mathbb{R}^m$ and $G|_{\{1\}\times\overline{B}^m} \subset \{1\}\times\mathbb{R}^m$.

[1936] We spare the reader the even more logical name "thickened cobordant".

Example. Let $m \in \mathbb{N}$. Any map $\mathbb{R}^m \to \mathbb{R}^m$ of the form $x \mapsto r \cdot x + P$ for some $r > 0$ and $P \in \mathbb{R}^m$ is clearly diffeotopic to the identity. Thus Lemma 157.7 says that given a thickened submanifold (M, g) we can translate and shrink it without changing the thickened cobordism class.

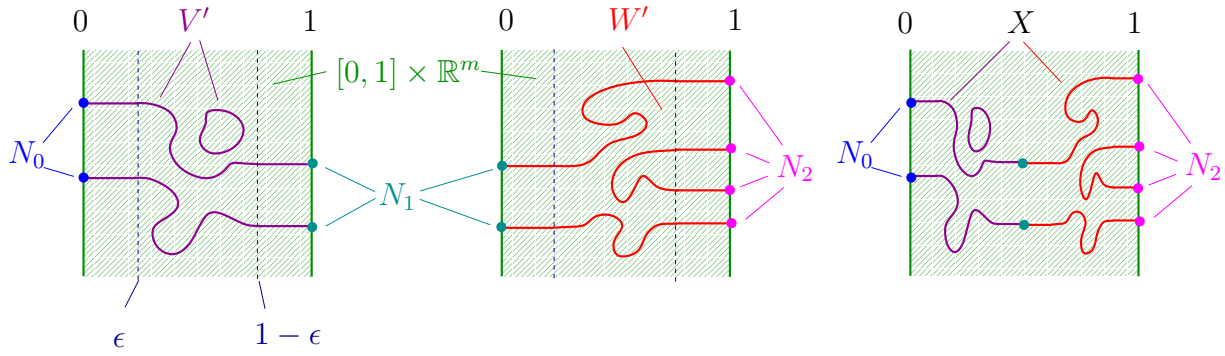
Proof. Let $(M, g\colon \overline{B}^{m-k} \times M \to \mathbb{R}^m)$ be a thickened k-dimensional submanifold of $\mathbb{R}^m$ and furthermore let $F\colon \mathbb{R}^m \times [0,1] \to \mathbb{R}^m$ be a diffeotopy from the identity to a diffeomorphism φ. It is straightforward to verify that the map

$$\begin{array}{rcl} [0,1]\times M & \to & [0,1]\times\mathbb{R}^m \\ (t,P) & \mapsto & (t,F(P,t)) \end{array}$$

is a smooth embedding. We write $W := F([0,1]\times M)$. It is straightforward to verify that W together with the thickening given by

$$\begin{array}{rcl} \overline{B}^{m-k}\times W & \to & [0,1]\times\mathbb{R}^m \\ (v,(t,F(P,t))) & \mapsto & (t,F(g(v,P),t)) \end{array}$$

is a thickened cobordism between (M, g) and $(\varphi(M), \varphi_*(g))$. ■



Lemma 157.8. "Being cobordant" is an equivalence relation on the set of thickened k-dimensional submanifolds of $\mathbb{R}^m$.

Sketch of proof. To simplify the discussion we ignore throughout the proof the thickenings. The reader should have no major troubles modifying the proof to also include the thickenings.

It is straightforward to see that "being cobordant" is reflexive and symmetric: Indeed, given a closed k-dimensional submanifold N a cobordism from N to itself is given by $[0,1]\times N \subset [0,1]\times\mathbb{R}^m$. Furthermore, suppose there exists a cobordism W between N_0 and N_1. "Flipping" W along $\mathbb{R}^m \times \{\frac{1}{2}\}$ we obtain a cobordism between N_1 and N_0.

The proof of transitivity takes more efforts. Initially the idea is quite simple. Given a cobordism V from N_0 to N_1 and another cobordism W from N_1 to N_2 one would like to stick them together to obtain a cobordism from N_0 to N_2. Unfortunately, as we had discussed on page **??**, the resulting object is in general not a (smooth) submanifold of the smooth manifold $\mathbb{R}^m$.

Fortunately we had already developed all the tools to deal with the situation. More precisely, in Proposition **??** we saw that we can modify the cobordisms V and W to obtain cobordisms V' and W' that are products on $[0,\epsilon]\times\mathbb{R}^m$ and $[1-\epsilon,1]\times\mathbb{R}^m$ for a suitable $\epsilon \in (0,\frac{1}{2})$. Now we can stick V' and W' together to obtain the desired cobordism X. We refer to the figure below for an illustration. ■

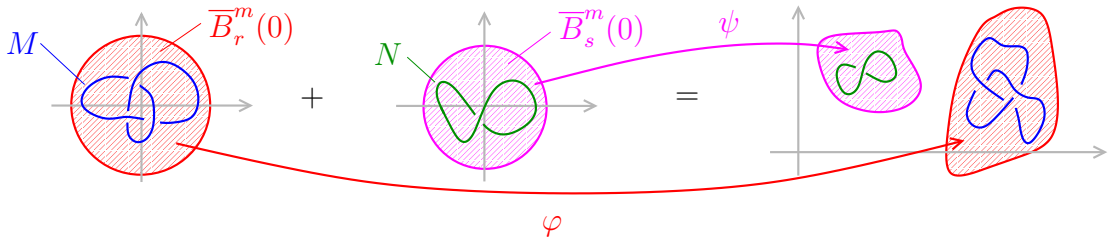
The previous lemma allows us to make the following definition.

Definition. We denote by $\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$ the set of thickened cobordism classes of thickened k-dimensional submanifolds of $\mathbb{R}^m$. In light of the subsequent Proposition 157.9 we refer to $\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$ as a thickened cobordism group.

The definition of $\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$ is reminiscent of the definition of the cobordism group Ω_k that we gave on page 3091. The group structure on Ω_k that we had introduced in Lemma 144.2 is given by "disjoint union". We will now see that $\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$ also admits a group structure that is defined quite similarly.

Proposition 157.9. Let $k\in\mathbb{N}_0$ and let $m\in\mathbb{N}_{\geq 2}$. Let (M,g) and (N,h) be two thickened k-dimensional submanifolds of $\mathbb{R}^m$. Since M and N are compact we can pick $r,s\in\mathbb{R}_{>0}$ with $g(\overline{B}^{m-k}\times M)\subset B_r^m(0)$ and $h(\overline{B}^{m-k}\times N)\subset B_s^m(0)$. Furthermore we pick two orientation-preserving smooth embeddings $\varphi\colon \overline{B}_r^m(0)\to\mathbb{R}^m$ and $\psi\colon \overline{B}_s^m(0)\to\mathbb{R}^m$ with disjoint images. We define

$$[(M,g)]+[(N,h)] \;:=\; [(\varphi(M)\sqcup\psi(N),\varphi_*(g)\sqcup\psi_*(h))] \;\in\; \Omega_k^{\mathrm{th}}(\mathbb{R}^m).$$



(The definition of the operation "+" is illustrated in the figure below.)

(1) The definition of "+" on $\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$ is well-defined and commutative.

(2) The operation "+" defines a group structure on $\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$. Here the following two statements hold:

(a) The neutral element is represented by the empty submanifold.[1937]

(b) Let $\rho\colon\mathbb{R}^m\to\mathbb{R}^m$ be the reflection in a hyperplane. The inverse of $[(M,g)]$ is given by $[(\rho(M),\rho_*(g))]$.

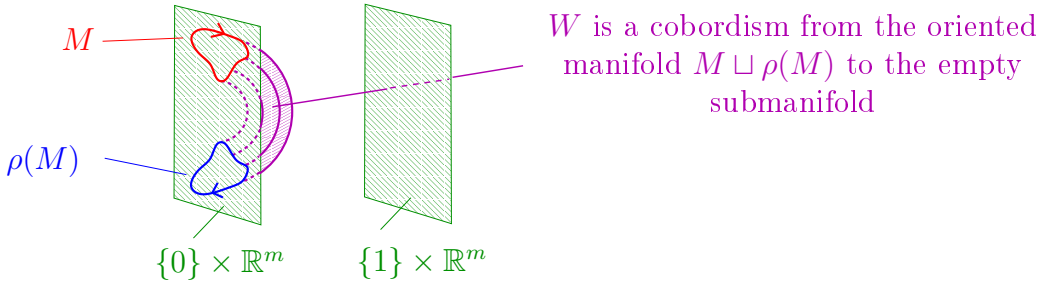
Proof.

[1937] It is worth remembering that the empty set is a submanifold of any dimension.

(1) It follows from the Smooth Ball Embedding Theorem 37.8 and Lemma 157.7 that "+" is well-defined and commutative. Note that here we use that $m \geq 2$.

(2) It is basically obvious that "+" is associative and that the empty submanifold is a neutral element. Thus it remains to prove the statement regarding the inverse. It follows from Lemmas 157.7 and 33.9 that without loss of generality we can assume that the reflection $\rho\colon \mathbb{R}^m \to \mathbb{R}^m$ is the reflection in the $(x_m = 0)$-hyperplane. So let $(M, g\colon \overline{B}^{m-k} \times M \to \mathbb{R}^m)$ be a thickened k-dimensional submanifold of $\mathbb{R}^m$. We set $\epsilon = \frac{1}{4}$. It follows immediately from the discussion on page 3351 that we can assume that $g(\overline{B}^{m-k} \times M)$ is contained in the ball $\overline{B}^m_\epsilon(\underbrace{(0,\dots,0,2\epsilon)}_{\in\mathbb{R}^m})$. We consider the map

$$\begin{array}{rcl} \varphi\colon \overline{B}^{m-k} \times (M \times [0,\pi]) & \to & [0,1] \times \mathbb{R}^m \\ (v,(P,\gamma)) & \mapsto & \begin{pmatrix} \cos(\gamma) & \sin(\gamma) & 0 \\ -\sin(\gamma) & \cos(\gamma) & 0 \\ 0 & 0 & \mathrm{id}_{m-1} \end{pmatrix} \cdot \underbrace{\begin{pmatrix} 0 \\ g(v,P) \end{pmatrix}}_{\in\mathbb{R}^{m+1}}. \end{array}$$



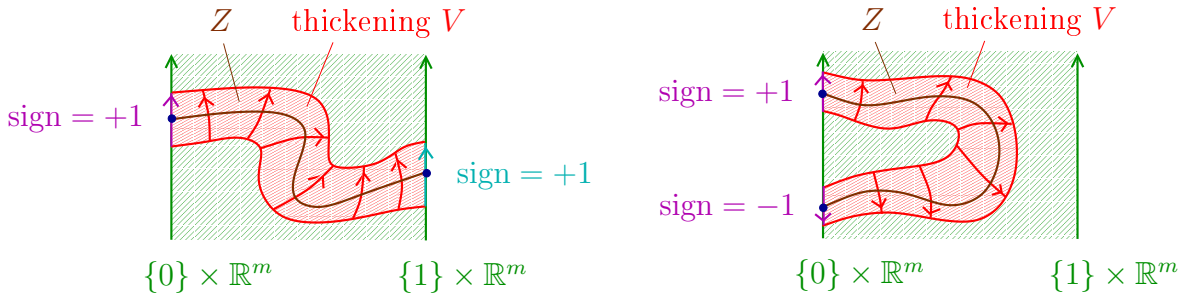
Using that $g(\overline{B}^{m-k} \times M)$ is contained $\overline{B}^m_\epsilon((0,\dots,0,2\epsilon))$ we can make the following three observations:

(a) The image of φ does indeed lie in $[0,1] \times \mathbb{R}^m$.

(b) The restriction to $\{0\} \times M \times [0,\pi]$ is a proper smooth embedding. Therefore we can now consider the compact orientable proper $(k+1)$-dimensional submanifold $W = \varphi(\{0\} \times M \times [0,\pi])$ of $[0,1] \times \mathbb{R}^m$.

(c) The map φ gives rise to a thickening for W.

It is now basically clear that we have constructed a thickened cobordism from the thickened submanifold $(M \sqcup \rho(M), g \sqcup \rho_*(g))$ to the empty submanifold. (We refer to the figure below for an illustration.) But by the definition of "+" this implies that $(\rho(M), \rho_*(g))$ represents the inverse of (M, g). ■



Evidently our challenge now is to compute the groups $\Omega^{\mathrm{th}}_k(\mathbb{R}^m)$ for suitable values of m and k. In general this might be quite difficult, but the following proposition gives a reasonably amusing calculation.

Proposition 157.10. Let $m \geq 2$. The map[1938]

$$\begin{array}{rcl} \varphi\colon \Omega^{\mathrm{th}}_0(\mathbb{R}^m) & \to & \mathbb{Z} \\ [(\{P_1\}, g_1) \sqcup \dots \sqcup (\{P_k\}, g_k)] & \mapsto & \sum_{i=1}^{k} \mathrm{sign}(g_i) \end{array}$$

is well-defined and it is an isomorphism.

Sketch of proof. First we need to show that $\varphi\colon \Omega_0^{\text{th}}(\mathbb{R}^m) \to \mathbb{Z}$ is well-defined. It suffices to show that for any *connected* thickened 1-dimensional cobordism $(Z, V) \subset [0,1] \times \mathbb{R}^m$ between two 0-dimensional thickened submanifolds (N_0, g_0) and (N_1, g_1) we have the equality $\varphi([(N_0, g_0)]) = \varphi([(N_1, g_1)])$. This statement follows from the Smooth 1-Dimensional Manifold Classification Theorem 22.7 and some orientation considerations. Since writing down the precise arguments regarding the orientations will only obfuscate the argument we refer to the figure below for convincing pictures, and we leave it to the reader to fill in the details.

Next note that the map $\varphi\colon \Omega_0^{\text{th}}(\mathbb{R}^m) \to \mathbb{Z}$ is, basically by definition, a homomorphism. Finally note that it is clear that φ is an epimorphism. Thus it remains to show that φ is a monomorphism. A straightforward induction argument shows that it suffices to prove the following claim.

Claim. For points $P, Q \in \mathbb{R}^m$ and thickenings g and h of P and Q with $\operatorname{sign}(g) = -\operatorname{sign}(h)$ we have $[(P, g)] + [(Q, h)] = 0 \in \Omega_0^{\text{th}}(\mathbb{R}^m)$.

Proof. In the following let $\rho\colon \mathbb{R}^m \to \mathbb{R}^m$ be the reflection in a hyperplane. By the discussion on page 3351 we can assume, after possibly applying a translation, that $Q = \rho(P)$. Since ρ is orientation-reversing we see that $\operatorname{sign}(\rho_*(g)) = -\operatorname{sign}(g) = \operatorname{sign}(h)$. Now we calculate that

$$[(P,g)] + [(Q,h)] = [(P,g)] + [(\rho(P),h)] \underset{\uparrow}{=} [(P,g)] + [(\rho(P),\rho_*(g))] \underset{\uparrow}{=} 0 \in \Omega_0^{\text{th}}(\mathbb{R}^m).$$

by $\operatorname{sign}(h) = \operatorname{sign}(\rho_*(g))$, by the Smooth Ball Embedding Theorem 37.8 and Lemma 157.7

by Proposition 157.9 (2b)

■

Considering the discussion on page 3350, the following theorem does not come as a big surprise. It justifies our interest in the groups $\Omega_k^{\text{th}}(\mathbb{R}^m)$.

Theorem 157.11. (Thom-Pontryagin Theorem) Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$. The map

$$\begin{aligned} \Psi\colon \Omega_k^{\text{th}}(\mathbb{R}^{n+k}) &\to \pi_{n+k}(S^n, *) \\ [(N, g)] &\mapsto [\rho_{(N,g)}] \end{aligned}$$

is well-defined and it is an isomorphism.

Sketch of proof. Fortunately we have already done basically all the work:

(1) First we argue that Ψ is well-defined. Thus suppose that we are given thickened k-dimensional submanifolds (M, g) and (N, h) of $\mathbb{R}^{n+k}$ that are cobordant. We pick

[1938] We refer to page 3345 for the definition of the sign of a thickening of a point.

a thickened cobordism $(W, F\colon \overline{B}^n \times W \to [0,1] \times \mathbb{R}^{n+k})$ in $[0,1] \times \mathbb{R}^{n+k}$. The corresponding map

$$\rho_{(W,F)}\colon [0,1] \times \mathbb{R}^{n+k} \to S^n$$

has the property that it sends a neighborhood of $[0,1] \times \{\infty\}$ to $*$. Therefore it follows easily from the Homotopy Stacking Lemma 14.3 that the following map is continuous:

$$\begin{array}{rcl} S^{n+k} \times [0,1] = (\mathbb{R}^{n+k} \cup \{\infty\}) \times [0,1] & \to & S^n \\ (P,t) & \mapsto & \begin{cases} \rho_{(W,F)}(t,P), & \text{if } P \in \mathbb{R}^{n+k}, \\ *, & \text{if } P = \infty. \end{cases} \end{array}$$

It follows from the above that this map is in fact a homotopy rel $*$ between the map $\rho_{(M,g)}\colon (S^{n+k}, *) \to (S^n, *)$ and the map $\rho_{(N,h)}\colon (S^{n+k}, *) \to (S^n, *)$. In particular we have $[\rho_{(M,g)}] = [\rho_{(N,h)}] \in \pi_{n+k}(S^n, *)$.

(2) It follows immediately from Lemma 157.5 that Ψ is a homomorphism.

(3) The statement of Proposition 157.6 is equivalent to saying that Ψ is an epimorphism.

(4) Finally it remains to show that Ψ is in fact a monomorphism. So suppose that we are given two thickened k-dimensional submanifolds (M,g) and (N,h) of $\mathbb{R}^{n+k}$ such that $[\rho_{(M,g)}] = [\rho_{(N,h)}] \in \pi_{n+k}(S^n, *)$, i.e. such that there exists a homotopy $F\colon S^{n+k} \times [0,1] \to S^n$ rel $*$ from $\rho_{(M,g)}$ to $\rho_{(N,h)}$.

The proof of Proposition 157.6 can be modified without too many problems to show that the homotopy F gives rise to a thickened cobordism between (M,g) and (N,h). We leave it to the reader to fill in the details. See also [**Kos1993**, Theorem 9.5.5] or [**Bre1993**, Chapter 16] for similar claims stated with more authority. ∎

From our above results we obtain the following corollary. Of course we proved this result earlier in Corollary 85.6, using very different methods.

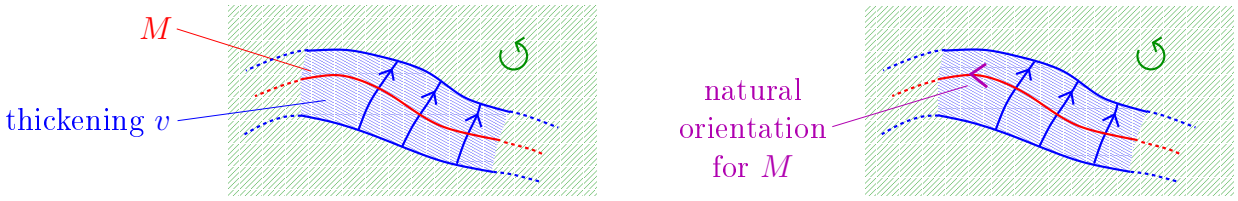
Corollary 157.12. For any $m \geq 2$ the map

$$\begin{array}{rcl} \mathbb{Z} & \to & \pi_m(S^m, *) \\ n & \mapsto & n \cdot [\mathrm{id}_{S^m}] \end{array}$$

is an isomorphism.

Proof. Let $P \in \mathbb{R}^m$ and let g be a thickening for the submanifold $\{P\}$. We consider the two maps

$$\begin{array}{rcl} \mathbb{Z} & \to & \Omega_0^{\mathrm{th}}(\mathbb{R}^m) \\ n & \mapsto & n \cdot [(\{0\}, g \text{ with } \mathrm{sign}(g) = 1)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \Omega_0^{\mathrm{th}}(\mathbb{R}^m) & \to & \pi_m(S^m, *) \\ [(N,g)] & \mapsto & [\rho_{(N,g)}]. \end{array}$$



The first map is an isomorphism by Proposition 157.10 and the second map is an isomorphism by the Thom-Pontryagin Theorem 157.11, applied to $k = 0$ and $m \geq 2$. Thus the composition of the two maps is an isomorphism. Finally it follows from Lemma 157.1 that the composition of these two maps sends n to $n \cdot [\mathrm{id}_{S^m}]$. ∎

157.4. **The calculation of the thickened cobordism group $\Omega_1^{\mathrm{th}}(\mathbb{R}^3)$.** Surely the most interesting calculation of a higher homotopy group that we have performed so far is that in Theorem 155.10 (2) we saw $\pi_3(S^2) \cong \mathbb{Z}$. Our goal now is to give a new proof of this fact using the Thom-Pontryagin Theorem 157.11. Thus we need to show that $\Omega_1^{\mathrm{th}}(\mathbb{R}^3) \cong \mathbb{Z}$. We start out with the following slightly subtle definition.

Definition. Let $m \in \mathbb{N}$.

(1) Let $(M, v\colon \overline{B}^{m-k} \times \mathbb{R}^m)$ be a thickened $(m-k)$-dimensional submanifold of $\mathbb{R}^m$. The natural orientation of M is the unique orientation that turns v into an orientation-preserving map.[1939]

(2) Similarly we define the natural orientation of a thickened cobordism.

This definition leads us to the following convention.

Convention. In this section we equip any thickened submanifold and any thickened cobordism with the natural orientation.

Before we write down an explicit isomorphism we introduce the following definition which generalizes the definition of the self-linking number of a thickened knot that we introduced on page 2853.

Definition.

(1) Let $K = K_1 \sqcup \cdots \sqcup K_m$ and $L = L_1 \sqcup \cdots \sqcup L_n$ be two disjoint oriented links. We define the linking number of K and L as

$$\operatorname{lk}(K, L) \;:=\; \sum_{i=1}^{m} \sum_{j=1}^{n} \operatorname{lk}(K_i, L_j).$$

(2) Let (L, g) be a thickened link. We write $L' = g(\{1\} \times L)$. We define the self-linking number of (L, g) as $\operatorname{slk}(L, g) := \operatorname{lk}(L, L')$.[1940]

The following elementary lemma is at times useful for determining self-linking numbers of thickened links.

Lemma 157.13. If $(L, g) = (L_1 \sqcup \cdots \sqcup L_m, g_1 \sqcup \cdots \sqcup g_m)$ is a thickened link, then

$$\operatorname{slk}(L, g) \;:=\; \sum_{i \neq j} \operatorname{lk}(L_i, L_j) \;+\; \sum_{i=1}^{m} \operatorname{slk}(L_i, g_i).$$

Proof. We will prove the lemma in Exercise 157.2. ∎

Now we can give the promised isomorphism.

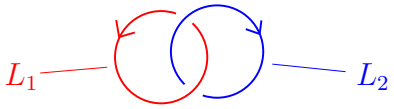
Theorem 157.14. The map

$$\begin{array}{rcl} \Psi\colon \Omega_1^{\text{th}}(\mathbb{R}^3) & \to & \mathbb{Z} \\ [(L, g)] & \mapsto & \text{self-linking number } \operatorname{slk}(L, g) \end{array}$$

is well-defined and it is an isomorphism. In particular we have $\pi_3(S^2) \cong \mathbb{Z}$.

[1939] Recall that M is assumed to be orientable, but a priori it does not come with an orientation. It is not difficult to see that there exists a unique orientation on M such that, if we equip $\overline{B}^{m-k} \times M$ with the product orientation, v becomes orientation-preserving.

[1940] Here we use the above convention to view L as an *oriented* submanifold of $\mathbb{R}^3$, and we equip $L' = g(\{1\} \times L)$ with the obvious corresponding orientation.



Examples.

(1) We consider the trivial knot K with a thickening g of self-linking number $+1$. By Theorem 157.14 the thickened knot (K, g) defines a generator of $\Omega_1^{\text{th}}(\mathbb{R}^3)$. It follows from the isomorphism provided by the Thom-Pontryagin Theorem 157.11 that $\rho_{(K,g)}\colon S^3 \to S^2$ represents a generator of $\pi_3(S^2, *)$. In Lemma 157.4 we saw that $\rho_{(K,g)}$ represents the same element of $\pi_3(S^2, *)$ as the Hopf map $H\colon S^3 \to S^2$. Thus we see once again that the Hopf map represents a generator of $\pi_3(S^2)$.

(2) We consider the Hopf link $L = L_1 \sqcup L_2$ with the orientations shown in the figure below. We equip $L = L_1 \sqcup L_2$ with a "trivial thickening" $g_1 \sqcup g_2$, i.e. where the thickening g_i of each component L_i has self-linking number 0. We see that

$$\operatorname{slk}(L_1 \sqcup L_2, g_1 \sqcup g_2) \underset{\text{Lemma 157.13}}{=} \operatorname{lk}(L_1, L_2) + \operatorname{lk}(L_2, L_1) + \overbrace{\operatorname{slk}(L_1, g_1)}^{=0} + \overbrace{\operatorname{slk}(L_2, g_2)}^{=0} \underset{\text{pick your favorite method from Section 131.4}}{=} 1 + 1 = 2.$$

This shows that the Hopf link, perhaps slightly counter-intuitively, gives rise to *twice* the generator of $\pi_3(S^2, *)$.

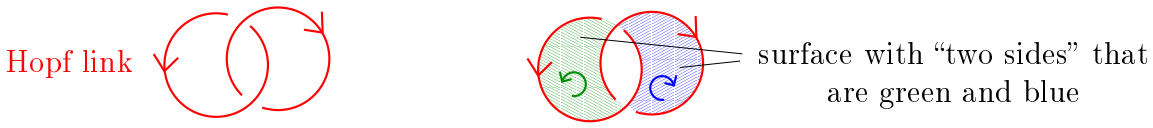
Since we already have an independent proof of Theorem 157.14 we will take the liberty to cut a few corners in the new proof of the theorem. The new proof of Theorem 157.14 will build on the following four lemmas. The first two lemmas generalize the Seifert Surface-Existence Proposition 131.6 and Lemma 131.15 from knots to links. They are perhaps interesting in their own right.

Lemma 157.15. Given any oriented link $L \subset S^3$ there exists a compact oriented connected surface $F \subset S^3$ such that $\partial F = L$.[1941]

Proof of Lemma 157.15. Let $L \subset S^3$ be an oriented link. A modest generalization of the Seifert Surface-Existence Proposition 131.6 shows that there exists a compact oriented surface $G \subset S^3$ with $\partial G = L$. In Exercise 157.5 we will show that we can turn G into a compact oriented *connected* surface F with $\partial F = L$.[1942] ■

Lemma 157.16. If $K = K_1 \sqcup \cdots \sqcup K_m$ and $L = L_1 \sqcup \cdots \sqcup L_n$ are two oriented links, then the following statements hold:

(1) There exist compact oriented proper 2-dimensional submanifolds S and T of $\overline{B}^4$ with $\partial S = K$ and $\partial T = L$ such that S and T are transverse.



(2) Let S, T be two oriented proper 2-dimensional submanifolds of $\overline{B}^4$ with $\partial S = K$ and $\partial T = L$. If S and T are transverse, then[1943]

$$\operatorname{lk}(K, L) \;=\; S \cdot_{\overline{B}^4} T.$$

[1941] Here the equality $\partial F = L$ is understood to be an equality of *oriented* submanifolds.

[1942] Frankly it can be slightly annoying to give a completely rigorous proof that such a surface F exists. This is one of the main reasons why we made the caveat above that we are going to cut a few corners in the argument.

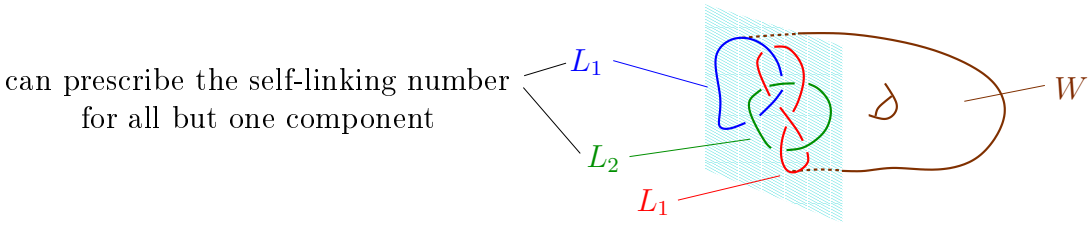
Example. As on page 2220 we consider the Hopf link that is illustrated in the figure below on the left. On the right of the figure below we show a compact oriented connected surface whose boundary equals the Hopf link.

Proof of Lemma 157.16.

(1) The proof of this statement is virtually the same as the proof of Lemma 131.15, we just need to replace the Seifert Surface-Existence Proposition 131.6 by Lemma 157.15.

(2) We leave it to the reader to verify that the proof of Lemma 131.15 (2) can be modified to deal not only with knots but also with links. ■

The following two lemmas that we need for the proof of Theorem 157.14 are arguably more technical.



Lemma 157.17. Let K be an oriented *knot* in $\mathbb{R}^3$ and let g and h be two thickenings for K in $\mathbb{R}^3$. If $\operatorname{slk}(K,g) = \operatorname{slk}(K,h)$, then $[(K,g)] = [(K,h)] \in \Omega_1^{\text{th}}(\mathbb{R}^3)$.

Proof of Lemma 157.17. Since $\operatorname{slk}(K,g) = \operatorname{slk}(K,h)$ it follows from the Knot Thickening Lemma 131.1 that there exists a smooth isotopy $F\colon (\overline{B}^2 \times K) \times [0,1] \to \mathbb{R}^3$ between g and h which has compact support and which has the property that $F(0,k,t) = k$ for all $k \in K$ and all $t \in [0,1]$. We consider $W = [0,1] \times K$ with the thickening given by

$$\begin{array}{rcl} j\colon \overline{B}^2 \times ([0,1] \times K) & \to & [0,1] \times \mathbb{R}^3 \\ (v,(t,x)) & \mapsto & (t, F((v,x),t)). \end{array}$$

The thickened smooth manifold (W,j) is a thickened cobordism between (K,g) and (K,h). ■

Lemma 157.18. Let W be a compact oriented proper connected 2-dimensional submanifold of $\mathbb{R}^3 \times [0,1)$ with boundary components $L_1, \ldots, L_m$. Given $s_1, \ldots, s_{m-1} \in \mathbb{Z}$ there exists a thickening h for W such that for $i = 1, \ldots, m-1$ we have $\operatorname{slk}(L_i, h|_{L_i}) = s_i$.

Proof. Evidently we can assume that $m \geq 1$. In this case W is a compact oriented proper connected 2-dimensional submanifold with non-empty boundary. Thus by Proposition ?? (3) there exists a thickening $f\colon \overline{B}^2 \times W \to \mathbb{R}^3 \times [0,1)$ for W. For $i = 1, \ldots, m-1$ we write $r_i := \operatorname{slk}(L_i, g|_{L_i})$.

[1943] Here $S \cdot_{\overline{B}^4} T$ denotes the algebraic intersection number of the oriented transverse surfaces S and T in the oriented smooth manifold $\overline{B}^4$. We refer to page 2748 for the definition of the algebraic intersection number.

By Lemma 55.12 there exists a map $\varphi\colon W \to L_1 \vee \cdots \vee L_{m-1}$[1944] that is the identity on each L_i. We pick a map $\psi\colon L_1 \vee \cdots \vee L_{m-1} \to \mathrm{SO}(2) = S^1$ with the following property: under an orientation-preserving identification $L_i = S^1$ the restriction of ψ to L_i is given by $z \mapsto z^{s_i - r_i}$. Now we consider the thickening

$$\begin{aligned} h\colon \overline{B}^2 \times W &\to W \\ (v, P) &\mapsto f(\overbrace{(\psi \circ \varphi)(P)}^{\in \mathrm{SO}(2)} \cdot \underbrace{v, P)}_{\in \overline{B}^2 \times W}). \end{aligned}$$

By the Knot Thickening Lemma 131.1 (1) we know that for any $i \in \{1, \ldots, m-1\}$ we added $s_i - r_i$ to the self-linking number of L_i. Thus the thickening h has all the desired properties. ■

Now we are in a position to provide the proof of Theorem 157.14.

Sketch of proof of Theorem 157.14.

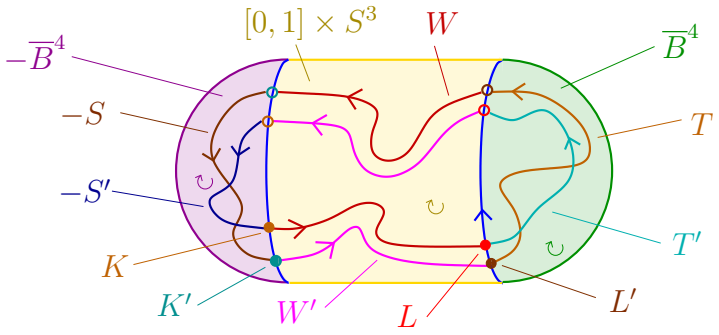
(1) First we need to show that $\Psi\colon \Omega_1^{\mathrm{th}}(\mathbb{R}^3) \to \mathbb{Z}$ is well-defined. In the proof of this fact we borrow some ideas from the proof of Lemma 131.15 (2). So let (W, F) be a thickened cobordism between (K, g) and (L, h). We write $W' = F(\{1\} \times W)$, $K' = g(\{1\} \times K)$ and $L' = h(\{1\} \times L)$. By Lemma 157.16 (1) there exist oriented proper 2-dimensional submanifolds S and S' of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$ such that S and S' are transverse. Similarly there exist T, T' for L and L'.

We can make the identification $S^4 = (-\overline{B}^4) \cup [0,1] \times S^3 \cup \overline{B}^4$[1945] (See the figure below for an illustration.) Using Proposition **??** we can arrange that both $(-S) \cup W \cup T$ and $(-S') \cup W' \cup T'$ are oriented submanifolds of the smooth manifold S^4. We calculate that

$$\begin{aligned} -\operatorname{slk}(K, g) + \operatorname{slk}(L, h) &\overset{\text{by definition of slk}}{=} -\operatorname{lk}(K, K') + \operatorname{lk}(L, L') \overset{\text{Lemma 157.16 (2)}}{=} (-S) \cdot_{\overline{B}^4} S' + T \cdot_{\overline{B}^4} T' \\ &= (-S) \cdot_{-\overline{B}^4} (-S') + T \cdot_{\overline{B}^4} T' \overset{\text{since the only intersections appear between } S, S' \text{ and } T, T', \text{ here we use that } W \text{ and } W' \text{ are disjoint}}{=} (-S \cup W \cup T) \cdot_{S^4} (-S' \cup W' \cup T') \overset{\text{by Theorem 127.7 and since } \mathrm{H}_2(S^4; \mathbb{Z}) = 0}{=} 0. \end{aligned}$$

We have thus shown that the self-linking numbers of (K, g) and (L, h) agree. This shows that the map $\Psi\colon \Omega_1^{\mathrm{th}}(\mathbb{R}^3) \to \mathbb{Z}$ is indeed well-defined.

(2) It follows easily from Exercise 131.6 that Ψ is a homomorphism.



(3) By the Knot Thickening Lemma 131.1 there exists a knot in $\mathbb{R}^3$ with a thickening in $\mathbb{R}^3$ with self-linking number one, thus Ψ is an epimorphism.

(4) It remains to show that $\Psi\colon \Omega_1^{\mathrm{th}}(\mathbb{R}^3) \to \mathbb{Z}$ is a monomorphism. So suppose we are given a thickened m-component link $(L, g) = \bigsqcup_{i=1}^{m} (L_i, g_i)$ with $\Psi([(L, g)]) = 0$.

Note that by Lemma 157.15 there exists a compact oriented connected surface W in $\mathbb{R}^3 \times [0, 1)$ whose boundary equals $L \subset \mathbb{R}^3 = \mathbb{R}^3 \times \{0\}$. Next note that by

[1944] Here, as a reminder, $L_1 \vee \cdots \vee L_{m-1}$ denotes the wedge of the topological spaces $L_1, \ldots, L_{m-1}$.

[1945] If the reader does not feel like making this identification, then we point out that we only need that the right-hand side is a smooth manifold and that the second homology vanishes.

Lemma 157.18 we can equip W with a thickening h such that for $i = 1, \dots, m-1$ we have $\mathrm{slk}(L_i, h|_{L_i}) = \mathrm{slk}(L_i, g_i)$.

Claim. We also have $\mathrm{slk}(L_m, h|_{L_m}) = \mathrm{slk}(L_m, g_m)$.

Proof. Note that (W, h) is a thickened cobordism between $(L, h|_L)$ and the empty link. In particular we obtain from (1) that $\mathrm{slk}(L, h|_L) = 0$. By our hypothesis on (L, g) we also have $\mathrm{slk}(L, g) = 0$. We had already arranged that for $i = 1, \dots, m-1$ we have $\mathrm{slk}(L_i, h|_{L_i}) = \mathrm{slk}(L_i, g_i)$. It now follows immediately from Lemma 157.13 that $\mathrm{slk}(L_m, h|_{L_m}) = \mathrm{slk}(L_m, g_m)$. ⊞

Now we are done, since

$$[(L,g)] \underset{\text{Lemma 157.17}}{=} [(L, h|_g)] \underset{\text{since } (W,h) \text{ is a null-cobordism for } (L,h|_g)}{=} 0 \in \Omega_1^{\mathrm{th}}(\mathbb{R}^3).$$

■

157.5. **The linking number.** In the next section we will show that there exists an epimorphism $\Omega^{\mathrm{th}}_{2n-1}(\mathbb{R}^{4n-1}) \to \mathbb{Z}$. The key to doing so is the notion of the linking number which we discuss in this section.

Notation. Let $n \in \mathbb{N}$.

(1) Given a closed oriented m-dimensional submanifold K of S^{2m+1} we denote by

$$\beta_K \colon \mathrm{H}_m(K;\mathbb{Z}) \to \mathrm{H}^m(S^{2m+1} \setminus K;\mathbb{Z})$$

the inverse of the isomorphism given by the Alexander Duality Theorem 123.10.

(2) Given a compact oriented proper $(m+1)$-dimensional submanifold W of $[0,1]\times S^{2m+1}$ we denote by

$$\beta_W \colon \mathrm{H}_{m+1}(W, \partial W;\mathbb{Z}) \to \mathrm{H}^m(([0,1]\times S^{2m+1}) \setminus W;\mathbb{Z})$$

the inverse of the isomorphism given by the Alexander Duality Theorem 123.10.

With this notation we can introduce the following definition.

Definition. Let $m \in \mathbb{N}$ and let K and L be two disjoint closed oriented m-dimensional submanifolds of S^{2m+1}. We define the linking number of K and L as

$$\mathrm{lk}(K,L) := \langle \beta_K([K]), [L] \rangle \in \mathbb{Z}$$

where we view the fundamental class $[L]$ of L as a homology class in $\mathrm{H}_m(S^{2m+1} \setminus K;\mathbb{Z})$.

Remark. The vigilant reader will not have failed to notice that in the 3-dimensional setting it is a priori not clear that the above definition of the linking number agrees with

the definition given on page 2865. In Exercise 157.6 we will prove that in the 3-dimensional setting the two competing notions of linking numbers agree.

The following proposition is a generalization of the Linking Number-Symmetry Proposition 131.12.

Proposition 157.19. Let $m \in \mathbb{N}$. Given any two two disjoint closed oriented m-dimensional submanifolds K and L of S^{2m+1} we have the following equality

$$\mathrm{lk}(K,L) \;=\; (-1)^{m+1} \cdot \mathrm{lk}(L,K).$$

Proof. We leave it to the reader to modify the proof of the Linking Number-Symmetry Proposition 131.12 to obtain the desired statement. ■

157.6. **The Hopf invariant and the thickened cobordism group $\Omega^{\mathrm{th}}_{2n-1}(\mathbb{R}^{4n-1})$.** In Corollary 122.14 we had sketched a proof that given any $n \in \mathbb{N}$ there exists an epimorphism $\pi_{4n-1}(S^{2n}) \to \mathbb{Z}$. By the Thom-Pontryagin Theorem 157.11 this statement is equivalent to saying that there exists an epimorphism $\Omega^{\mathrm{th}}_{2n-1}(\mathbb{R}^{4n-1}) \to \mathbb{Z}$.
First of all we work with the same convention as in the last section.

Convention. In this section we equip any thickened submanifold and any thickened cobordism with the natural orientation that we introduced on page 3356.

Proposition 157.20. Let $n \in \mathbb{N}$ and let $* \in \overline{B}^{2n}$. The map

$$\begin{array}{rcl} \mathrm{Hopf}\colon \Omega^{\mathrm{th}}_{2n-1}(\mathbb{R}^{4n-1}) & \to & \mathbb{Z} \\ [(N, g\colon \overline{B}^{2n} \times N \to \mathbb{R}^{4n-1})] & \mapsto & \mathrm{lk}(N, g(* \times N)) \end{array}$$

is a well-defined homomorphism.

Remark. Let $n \in \mathbb{N}$. We recall that on page 2681 we used the cup product to define the Hopf invariant

$$\mathrm{Hopf}\colon \pi_{4n-1}(S^{2n}, *) \;\to\; \mathbb{Z}$$

which is, as shown in Proposition 122.7, in fact a homomorphism. The audacious reader can attempt to show that, under the above isomorphism $\Omega^{\mathrm{th}}_{2n-1}(\mathbb{R}^{4n-1}) \xrightarrow{\cong} \pi_{4n-1}(S^{2n}, *)$, the Hopf invariant and the homomorphism $\mathrm{Hopf}\colon \Omega^{\mathrm{th}}_{2n-1}(\mathbb{R}^{4n-1}) \to \mathbb{Z}$ from Proposition 157.20 agree up to sign.[1946]

Proof. In Exercise 157.7 we will verify that Hopf is a homomorphism. Now let us actually show that Hopf is well-defined. Thus suppose that we are given thickened $(2n-1)$-dimensional submanifolds (N_0, g_0) and (N_1, g_1) of $\mathbb{R}^{4n-1}$ that are cobordant via a thickened cobordism (W, G). We denote by $i_0\colon \{0\} \times S^{4n-1} \to [0,1] \times S^{4n-1}$ the inclusion. Similarly we define i_1. We also use i_0, i_1 in a rather obvious way for restrictions of the above inclusion maps to suitable subsets. It follows immediately from the Alexander Duality

[1946] Attempting to determine the correct sign with confidence might have negative effects on one's mental health.

Theorem 123.10 that we have the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}_{2n}(W, \partial W; \mathbb{Z}) & \xrightarrow[\beta_W]{\cong} & \mathrm{H}^{2n-1}(([0,1] \times S^{4n-1}) \setminus W; \mathbb{Z}) \\ \downarrow \partial & & i_0^* \\ & & i_1^* \downarrow \\ \mathrm{H}_{2n-1}(\{0\} \times N_0; \mathbb{Z}) & \xrightarrow[\cong]{\begin{pmatrix} \beta_{N_0} & 0 \\ 0 & \beta_{N_1} \end{pmatrix}} & \mathrm{H}^{2n-1}(\{0\} \times (S^{4n-1} \setminus N_0); \mathbb{Z}) \\ \mathrm{H}_{2n-1}(\{1\} \times N_1; \mathbb{Z}) & & \mathrm{H}^{2n-1}(\{1\} \times (S^{4n-1} \setminus N_1); \mathbb{Z}) \end{array}$$

where all horizontal maps are isomorphisms and where the left-hand vertical map is the connecting homomorphism of the long exact sequence in homology of the pair $(W, \partial W)$.

It follows that

$$\begin{array}{rcll} \mathrm{lk}(N_0, g_0(* \times N_0)) & = & \langle \beta_{N_0}([N_0]), [g_0(* \times N_0)] \rangle & \overset{\text{follows from the above diagram and the fact that by Fundamental Class-of-Boundary Proposition 106.27 we know that } [\partial W] = [\{0\} \times N_0] + [\{1\} \times N_1]}{=} \langle i_0^*(\beta_W([W])), [g_0(* \times N_0)] \rangle \\ & \overset{\text{Lemma 109.6 (3)}}{=} & \langle \beta_W([W]), (i_0)_*([g_0(* \times N_0)]) \rangle & \overset{\text{it follows from } \partial(G(* \times W)) = g_0(* \times N_0) \cup g_1(* \times N_1) \text{ together with Corollary 106.28 (2) that } (i_0)_*([g_0(* \times N_0)]) = (i_1)_*([g_1(* \times N_1)])}{=} \langle \beta_W([W]), (i_1)_*([g_1(* \times N_1)]) \rangle \\ & \overset{\text{same argument backwards}}{=} & \mathrm{lk}(N_1, g_1(* \times N_1)). & \end{array}$$

We have thus shown that Hopf is indeed well-defined. ∎

Of course an invariant is only interesting if we can show that it assumes non-trivial values. If $n = 1$, then we already know[1947] that the trivial knot K together with the thickening g of self-linking number one satisfies $\mathrm{Hopf}([(N, g)]) = 1$. In particular we see that $\mathrm{Hopf} \colon \Omega_1^{\mathrm{th}}(\mathbb{R}^3) \to \mathbb{Z}$ is an epimorphism.

Lemma 157.21. For any $n \in \mathbb{N}$ the Hopf invariant $\Omega_{2n}^{\mathrm{th}}(\mathbb{R}^{4n+1}) \to \mathbb{Z}$ is the zero map.

Proof. Let $(N, g \colon \overline{B}^{2n+1} \times N \to \mathbb{R}^{4n+1})$ be a thickened $2n$-dimensional submanifold of $\mathbb{R}^{4n+1}$. We calculate that

$$\overbrace{\mathrm{lk}(N, g(* \times N))}^{=\mathrm{Hopf}([(N,g)])} \overset{\text{Proposition 157.19}}{=} (-1)^{\dim(N)+1} \cdot \mathrm{lk}(g(* \times N), N) \overset{\text{since } N \sqcup g(* \times N) \text{ and } g(* \times N) \sqcup N \text{ are isotopic}}{=} -\overbrace{\mathrm{lk}(N, g(* \times N))}^{=\mathrm{Hopf}([(N,g)])}.$$

This calculation shows that $\mathrm{Hopf}([(N, g)]) = 0$. ∎

Recall that the combination of Propositions 122.7 and 122.13 shows that given any $n \in \mathbb{N}$ there exists a map $f \colon S^{4n-1} \to S^{2n}$ such that the Hopf invariant equals 2. The following proposition that can be viewed as an analogue of this fact.

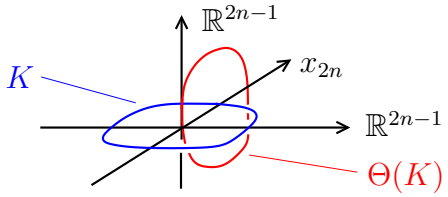
Proposition 157.22. For any $n \in \mathbb{N}$ there exists a thickened $(2n-1)$-dimensional submanifold (N, g) in $\mathbb{R}^{4n-1}$ with $\mathrm{Hopf}([(N, g)]) = 2$.

Sketch of proof. We consider the "trivial $(2n-1)$-dimensional knot"

$$K \;=\; S^{2n-1} \times \{0\} \;=\; \{(z_1, \ldots, z_{2n}, 0, \ldots, 0) \in \mathbb{R}^{4n-1} \mid z_1^2 + \cdots + z_{2n}^2 = 1\}$$

[1947] Here we assume for convenience that we already know that the two different definitions of the linking pairing in the 3-dimensional setting agree.

together with the map[1948]



$$\begin{array}{rcl} g\colon \overline{B}^{2n} \times K & \to & \mathbb{R}^{4n-1} \\ \big((x, \underbrace{(y_1,\dots,y_{2n-1})}_{=:y\in\mathbb{R}^{2n-1}}), \underbrace{(z,0)}_{\in K}\big) & \mapsto & (z+\frac{1}{4}x\cdot z, y). \end{array}$$

One can easily verify that, with a suitable orientation for K, the pair (K,g) is a thickened $(2n-1)$-dimensional submanifold of $\mathbb{R}^{4n-1}$. It is not particularly difficult to show that $[g(*\times K)] = 0 \in \mathrm{H}_{2n-1}(\mathbb{R}^{4n-1}\setminus K)$. Unfortunately this implies that $\mathrm{lk}(K, g(*\times K)) = 0$.

The first idea would be to modify the thickening g in a similar vein as in the Knot Thickening Lemma 131.1. This might work in principle, but at least your author does not know how to make this work in general.[1949] Instead we will recycle the example from page 3357 where we saw that the Hopf link gives rise to a non-trivial element in $\Omega_1^{\mathrm{th}}(\mathbb{R}^3)$. More precisely, we consider the diffeomorphism

$$\begin{array}{rcl} \Theta\colon \mathbb{R}^{4n-1} & \to & \mathbb{R}^{4n-1} \\ (\underbrace{x_1,\dots,x_{2n}}_{=x}, \underbrace{y_1,\dots,y_{2n-1}}_{=y}) & \mapsto & (y,x) + (0,\dots,0,\underbrace{1}_{2n\text{-th coordinate}},0,\dots,0). \end{array}$$

Similar to the discussion on page 3357 one can now fairly easily show (voluntary exercise!) that $\mathrm{Hopf}([K\sqcup\Theta(K), g\sqcup\Theta_*(g)]) = \pm 2$. Since Hopf is a homomorphism we see that there exists a thickened $(2n-1)$-dimensional submanifold (N,g) in $\mathbb{R}^{4n-1}$ with $\mathrm{Hopf}([(N,g)]) = 2$. ■

Remark. In Theorem 152.11 we saw that, unless $n = 2, 4, 8$, there does not exist a map $f\colon S^{2n-1} \to S^n$ with $\mathrm{Hopf}(f) = 1$. If we believe for a second that the Hopf invariant corresponds to the above homomorphisms Hopf, then this shows that Proposition 157.22 is optimal for $n \notin \{1,2,4\}$.

In summary, the Thom-Pontryagin Theorem 157.11 together with Propositions 157.20 and 157.22 give us the following result, which is precisely the content of Corollary 122.14.

Proposition 157.23. Given any *even* $n \in \mathbb{N}$ there exists an epimorphism $\pi_{2n-1}(S^n) \to \mathbb{Z}$.

Exercises for Chapter 157.

Exercise 157.1. We consider the map

$$\begin{array}{rcl} f\colon (S^1\times\overline{B}^2)\cup_{S^1\times S^1}(\overline{B}^2\times S^1) & \to & \overline{B}^2/S^1 \\ P & \mapsto & \begin{cases} [Q], & \text{if } P=[(Q,z)] \text{ with } Q\in\overline{B}^2 \text{ and } z\in S^1, \\ [S^1], & \text{if } P=[(z,Q)] \text{ with } z\in S^1 \text{ and } Q\in\overline{B}^2. \end{cases} \end{array}$$

[1948] This map g is basically just the "obvious" thickening of $S^{2n-1}\subset\mathbb{R}^{2n}$ extended to higher dimensions.
[1949] Also the remark after the proof might temper one's optimism.

Show that f is null-homotopic.

Exercise 157.2. Let $(L = L_1 \sqcup \cdots \sqcup L_m, g = g_1 \sqcup \cdots \sqcup g_m)$ be a thickened link. Show that

$$\operatorname{slk}(L, g) \;:=\; \sum_{i \neq j} \operatorname{lk}(L_i, L_j) \;+\; \sum_{i=1}^{m} \operatorname{slk}(L_i, g_i).$$

Exercise 157.3. Let $m \geq 2$. The Thom-Pontryagin Theorem 157.11 implies in particular that $\Omega^{\text{th}}_{m-1}(\mathbb{R}^m) \cong \pi_1(S^m) = 0$. This implies that every thickened submanifold of $\mathbb{R}^m$ of codimension-one is null-cobordant. Prove this statement without making use of the Thom-Pontryagin Theorem 157.11.
Hint. Use Lemma 130.3.

Exercise 157.4. We consider the Hopf link H as shown in the figure below. Draw an explicit oriented connected compact surface whose boundary equals the oriented link H.
Remark. Note that the orientation of one of the components is different from the Hopf link that we had considered above in the figure on page 3358.

Exercise 157.5. Let $L \subset S^3$ be an oriented link and let $G \subset S^3$ be a compact oriented surface with $\partial G = L$. We assume that G has no closed components.

(a) Show that $S^3 \setminus G$ is path-connected.
(b) Give an outline of an argument why there exists a compact oriented *connected* surface F with $\partial F = L$.

Exercise 157.6. Let K and J be two oriented disjoint knots in S^3. Show that the two definitions of the linking number $\operatorname{lk}(K, J)$ given on pages 2865 and 3360 agree.

Exercise 157.7. Show that the map

$$\begin{array}{rcl} \Psi \colon \Omega^{\text{th}}_{2n-1}(\mathbb{R}^{4n-1}) & \to & \mathbb{Z} \\ [(N, g \colon \overline{B}^{2n} \times N \to \mathbb{R}^{4n-1})] & \mapsto & \operatorname{lk}(N, g(* \times N)) \end{array}$$

considered in Proposition 157.20 is a homomorphism.

Exercise 157.8. In Section 157.6 we had just seen that given any even $n \in \mathbb{N}$ there exists an epimorphism $\Omega^{\text{th}}_{n-1}(\mathbb{R}^{2n-1}) \to \mathbb{Z}$. What about the group $\Omega^{\text{th}}_{n-1}(\mathbb{R}^{2n-1})$ if n is odd? Can we use linking numbers to define a homomorphism to $\mathbb{Z}$? Can we use them to find an epimorphism from $\Omega^{\text{th}}_{n-1}(\mathbb{R}^{2n-1})$ to $\mathbb{Z}$?

158. Thom-Pontryagin Theory II: The Freudenthal Suspension Theorem

158.1. **The framed cobordism group.** In Chapter 157 we introduced the thickened cobordism groups $\Omega_k^{\text{th}}(\mathbb{R}^{n+k})$ and we showed that they are isomorphic to $\pi_{n+k}(S^n, *)$. Furthermore we computed that $\Omega_0^{\text{th}}(\mathbb{R}^n) \cong \mathbb{Z}$ and $\Omega_1^{\text{th}}(\mathbb{R}^3) \cong \mathbb{Z}$. Finally we showed that given any $n \in \mathbb{N}$ there exists an epimorphism $\Omega_{2n-1}^{\text{th}}(\mathbb{R}^{4n-1}) \to \mathbb{Z}$. These calculations gave us new proofs for Corollary 85.6, Theorem 155.10 (2) and Corollary 122.14.

Even though these new proofs were very pleasant, it is now time for some new results. In this section we will prove the Freudenthal Suspension Theorem and we will calculate the homotopy groups $\pi_{n+1}(S^n)$ for $n \geq 3$. For the subsequent calculations it is better though to work with the "framed cobordism groups" $\Omega_k^{\text{fr}}(\mathbb{R}^n)$ that we introduce in this section. As we will see, the framed cobordism groups are isomorphic to the thickened cobordism group, but at times they are easier to calculate since they allow us to reduce many issues to linear algebra.

First we introduce the following definitions in linear algebra.

Definition. Given $m, k \in \mathbb{N}_0$ we write

$$\begin{aligned} \mathrm{GL}(m,k) &:= \text{set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^m \\ \mathrm{O}(m,k) &:= \text{set of } k\text{-tuples of orthonormal vectors of } \mathbb{R}^m. \end{aligned}$$

We adopt the following conventions:

(1) Given $v \in \mathrm{GL}(m,k)$ we denote by $v_1, \ldots, v_k$ the corresponding column vectors.
(2) Throughout we view both $\mathrm{GL}(m,k)$ and $\mathrm{O}(m,k)$ as subsets of the smooth manifold $\mathrm{M}(m \times k, \mathbb{R}) = \mathbb{R}^{mk}$.

Now we can give the topological definition we are really interested in.

Definition. Let $m \in \mathbb{N}_0$ and let N be an m-dimensional submanifold of $\mathbb{R}^m$. (Later on we will only be interested in $N = \mathbb{R}^m$, $N = [0,1] \times \mathbb{R}^{m-1}$ and the case that $N = \overline{B}_r^m(P)$ is a closed m-dimensional ball.)

(1) Let M be a compact orientable proper k-dimensional submanifold of N.
   (a) Let $P \in M$. We say $v = (v_1, \ldots, v_{m-k}) \in \mathrm{GL}(m, m-k)$ is a frame of M at P if the vectors $v_1, \ldots, v_{m-k}$, together with $\mathrm{T}_P M$[1950] spans $\mathbb{R}^m$.
   (b) A framing for M is a smooth[1951] map $v\colon M \to \mathrm{GL}(m, m-k)$ such that for each $P \in M$ the vectors $v_1(P), \ldots, v_{m-k}(P)$ are a frame of M at P.
   (c) We say that a framing $v = (v_1, \ldots, v_{m-k})$ is perpendicular if for each $P \in M$ the vectors $v_1(P), \ldots, v_{m-k}(P)$ lie in the orthogonal complement of $\mathrm{T}_P M$, i.e. if they lie in the vector space

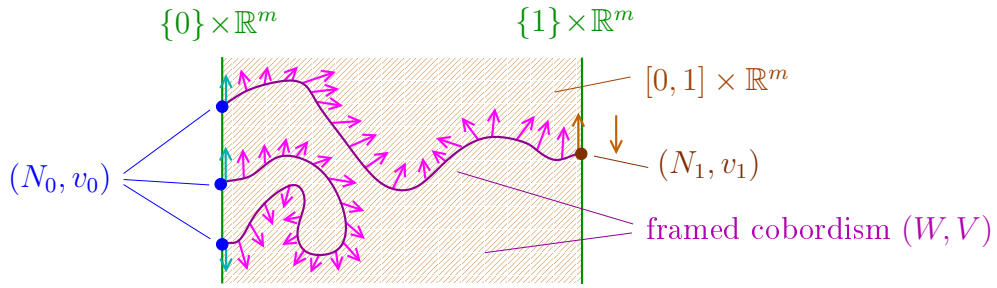
$$(\mathrm{T}_P M)^\perp = \{v \in \mathbb{R}^m \mid \langle v, w \rangle = 0 \text{ for all } w \in \mathrm{T}_P M\}.$$

   If the framing is perpendicular and if all the vectors are orthonormal, then we that the framing is orthonormal .
(2) A framed k-dimensional submanifold of N is a pair (M, v) where M is a compact orientable proper k-dimensional submanifold of N and v is a framing for M.
(3) Let (M, v) be a framed k-dimensional submanifold of N and let $\varphi\colon N \to W$ be a smooth embedding of N into a smooth manifold of the same dimension. We consider

the map

$$\begin{array}{rccl} \varphi_*(v)\colon \varphi(M) & \to & \mathrm{GL}(m, m-k) \\ P & \mapsto & (\varphi_*(v_1(\varphi^{-1}(P))), \ldots, \varphi_*(v_{m-k}(\varphi^{-1}(P)))). \end{array}$$

The pair $(\varphi(M), \varphi_*(v))$ is a framed submanifold of W.



Some of the above definitions are illustrated in the figure below.

Definition. Let $k, m \in \mathbb{N}_0$ and let (N_0, v_0) and (N_1, v_1) be two framed k-dimensional submanifolds of $\mathbb{R}^m$. A framed cobordism between (N_0, v_0) and (N_1, v_1) is a framed $(k+1)$-dimensional submanifold (W, V) of $[0,1] \times \mathbb{R}^m$ such that the following three conditions are satisfied:

(1) $\partial W = (\{0\} \times N_0) \cup (\{1\} \times N_1)$,
(2) $V|_{\{0\}\times N_0} = v_0$ under the identification $\{0\} \times \mathbb{R}^m = \mathbb{R}^m$,
(3) $V|_{\{1\}\times N_1} = v_1$ under the identification $\{1\} \times \mathbb{R}^m = \mathbb{R}^m$,

If such a framed cobordism exists, then we say that (N_0, v_0) and (N_1, v_1) are cobordant. The definition of a framed cobordism is illustrated in the figure below.

Basically the same proof as in Lemma 157.8 gives us the following lemma.

Lemma 158.1. The property of "being cobordant" is an equivalence relation on the set of framed k-dimensional submanifolds of $\mathbb{R}^m$.

This lemma leads us, not surprisingly, to the following definition.

Definition. We denote by $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$ the set of cobordism classes of framed k-dimensional submanifolds of $\mathbb{R}^m$. We refer to $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$ as a framed cobordism group.

The following proposition, which is the analogue of Proposition 157.9, justifies the name "framed cobordism group".

[1950] Here we use the isomorphism from the Tangent Space-Isomorphism Proposition 23.16 to identify $\mathrm{T}_P M$ with the vector subspace $\widetilde{\mathrm{T}}_P M$ of $\mathbb{R}^m$.

[1951] Since we view $\mathrm{GL}(m, m-k)$ as a subset of the smooth manifold $\mathrm{M}(m \times (m-k), \mathbb{R}) = \mathbb{R}^{m\cdot(m-k)}$ it makes sense to say that a map $M \to \mathrm{GL}(m, m-k)$ is smooth.

Proposition 158.2. Let $k \in \mathbb{N}$ and let $m \in \mathbb{N}_{\geq 2}$. Let (M, v) and (N, w) be two framed k-dimensional submanifolds of $\mathbb{R}^m$. Since M and N are compact we can pick $r, s \in \mathbb{R}_{>0}$ with $M \subset B_r^m(0)$ and $N \subset B_s^m(0)$. Furthermore we pick two orientation-preserving smooth embeddings $\varphi\colon \overline{B}_r^m(0) \to \mathbb{R}^m$ and $\psi\colon \overline{B}_s^m(0) \to \mathbb{R}^m$ with disjoint images. We define

$$[(M, v)] + [(N, w)] := [(\varphi(M) \sqcup \psi(N), \varphi_*(v) \sqcup \psi_*(w))] \in \Omega_k^{\mathrm{fr}}(\mathbb{R}^m).$$

This operation "$+$" has the following properties:

(1) The definition of "$+$" on $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$ is well-defined and commutative.
(2) The operation "$+$" defines a group structure on $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$. The following statements hold:
   (a) The neutral element is represented by the empty submanifold.
   (b) Let $\rho\colon \mathbb{R}^m \to \mathbb{R}^m$ be the reflection in a hyperplane. The inverse of $[(M, v)]$ is given by $[(\rho(M), \rho_*(v))]$.

Proof. The proof is basically identical to the proof of Proposition 157.9. We leave it to the reader to carry out the minor adjustments that are necessary to make the transition from thickened cobordisms groups to framed cobordism groups. ■

Lemma 158.3. Let $m \in \mathbb{N}_{\geq 2}$ and $k \in \{0, \ldots, m\}$.

(1) Every framed k-dimensional submanifold (M, v) of $\mathbb{R}^m$ is cobordant to (M, w) where w is an orthonormal framing.
(2) Let (W, V) be a framed cobordism between two framed k-dimensional submanifolds (M_0, v_0) and (M_1, v_1) of $\mathbb{R}^m$. If v_0 and v_1 are orthonormal, then there exist an orthonormal framing V' for W such that (W, V') is a framed cobordism between (M_0, v_0) and (M_1, v_1).

Proof. We prove Statement (1) of the lemma. The proof of Statement (2) is a mild variation on the proof of Statement (1). Thus let (M, u) be a framed k-dimensional submanifold of $\mathbb{R}^m$. Using the fact that being cobordant is transitive, the proof of the lemma can be broken up into two stages:

(1) First we show that there exists a perpendicular framing v such that (M, u) is cobordant to (M, v).
(2) Then we show that there exists an orthonormal framing w such that (M, v) is cobordant to (M, w).

We carry out the two steps:

(1) Let $(M, u\colon M \to \mathrm{GL}(m, m-k))$ be a framed k-dimensional submanifold of $\mathbb{R}^m$. Given $P \in M$ we write $U_P M := \mathrm{span}\{u_1(P), \ldots, u_k(P)\}$ and furthermore we write $Z_P M := (\mathrm{T}_P M)^\perp$. For each $P \in M$ the decomposition $\mathbb{R}^m = \mathrm{T}_P M \oplus Z_P M$ defines a projection of $\mathbb{R}^m$ onto $Z_P M$. We denote the restriction of this projection to $U_P M$ by $\rho_P\colon U_P M \to Z_P M$. By definition of a framing this map is an isomorphism. We consider the product cobordism $W = [0, 1] \times M$ equipped with the framing[1952]

$$\begin{array}{rcl} V\colon W = [0,1] \times M & \to & \mathrm{GL}(m, m-k) \\ (t, P) & \mapsto & (u(P) \cdot (1-t) + \rho_P(u(P)) \cdot t). \end{array}$$

[1952]It takes a little bit of thought to show that this is indeed a smooth map.

Basically by definition this is a framed cobordism from (M,u) to (M,v) where $v = V_1$ is a perpendicular framing.

(2) In the Matrix Groups Smooth Deformation Retract Proposition 33.10 (1) we showed that there exists a smooth deformation retraction $R\colon \mathrm{GL}(m,m-k)\times[0,1]\to \mathrm{O}(m,m-k)$ from $\mathrm{GL}(m,m-k)$ to $\mathrm{O}(m,m-k)$ which has the following extra property:

($*$) For any $v=(v_1,\ldots,v_{m-k})\in \mathrm{GL}(m,m-k)$ and any $t\in[0,1]$ we have

$$\text{span of } R_t(v_1),\ldots,R_t(v_{m-k}) \;=\; \text{span of } v_1,\ldots,v_{m-k}.$$

Now let (M,v) be a framed k-dimensional submanifold. We consider the product cobordism $W=[0,1]\times M$ equipped with the framing

$$\begin{array}{rcl} V\colon W=[0,1]\times M & \to & \mathrm{GL}(m,m-k) \\ (t,P) & \mapsto & R_t(v(P)). \end{array}$$

It follows from the fact that R is smooth and that ($*$) holds that this is a framed cobordism from (M,v) to (M,w) where $w=V_1$ is an orthonormal framing. ■

The following proposition shows that the two types of cobordism groups that we introduced in this and the last chapter are in fact isomorphic.

Proposition 158.4. Let $m\in\mathbb{N}_{\geq 2}$ and let $k\in\{0,\ldots,m\}$. The map

$$\begin{array}{rcl} \Phi\colon \Omega_k^{\mathrm{th}}(\mathbb{R}^m) & \to & \Omega_k^{\mathrm{fr}}(\mathbb{R}^m) \\ [(N, g\colon \overline{B}^{m-k}\times N)] & \mapsto & \left[\begin{array}{l} N \text{ equipped with the framing that associates to } P\in N \\ \text{the frame } \mathrm{D}f_{(0,P)}(e_1),\ldots,\mathrm{D}f_{(0,P)}(e_{m-k}) \end{array}\right] \end{array}$$

is well-defined and it is an isomorphism.

Convention. Let $n,k\in\mathbb{N}_0$ with $n+k\geq 2$. We use the isomorphisms from the Thom-Pontryagin Theorem 157.11 and Proposition 158.4 to make the identifications

$$\pi_{n+k}(S^n,*) \;=\; \Omega_k^{\mathrm{th}}(\mathbb{R}^{n+k}) \;=\; \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}).$$

Sketch of proof.

(1) It follows basically from the definitions that the framing associated to a thickened submanifold is indeed a framing. Applying the same procedure to a thickened cobordism between thickened submanifolds we obtain a framed cobordism between framed submanifolds. This shows that Φ is well-defined.

(2) It follows immediately from the definitions of the group structures that Φ is a homomorphism.

(3) We sketch the construction of the inverse to Φ. Let $(N,\{v_1,\ldots,v_{m-k}\})$ be a framed k-dimensional submanifold of $\mathbb{R}^m$. We consider the map

$$\begin{array}{rcl} g(v)\colon \mathbb{R}^{m-k}\times N & \to & \mathbb{R}^m \\ ((t_1,\ldots,t_{m-k}),P) & \mapsto & P+t_1\cdot v_1(P)+\cdots+t_{m-k}\cdot v_{m-k}(P). \end{array}$$

The same argument as in the proof of Theorem **??** shows that there exists an $\epsilon>0$ such that $g(v)$ restricts to a smooth embedding $\overline{B}_\epsilon^k(0)\times N\to\mathbb{R}^m$. After rescaling the ball we thus get a thickening $\overline{B}^k\times N\to\mathbb{R}^m$ of N. It is straightforward to see

that the class $[(N, g(v)] \in \Omega_k^{\mathrm{th}}(\mathbb{R}^m)$ does not depend on the choice of $\epsilon > 0$. Since the same approach also works for cobordisms we obtain a well-defined map

$$\Psi\colon \Omega_k^{\mathrm{fr}}(\mathbb{R}^m) \ \to \ \Omega_k^{\mathrm{th}}(\mathbb{R}^m).$$

It remains to show that Φ and Ψ are inverses of one another. It follows basically immediately from the definitions and Lemma 158.3 (1) that $\Phi \circ \Psi$ is the identity on $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$. The fact that $\Psi \circ \Phi$ is the identity on $\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$ follows fairly immediately from the uniqueness of tubular neighborhoods, see Proposition **??**, together with Lemma **??**. ■

Definition. Let N be an orientable k-dimensional submanifold of $\mathbb{R}^m$ and let $n \geq m$.

(1) We write $N_n := N \times \{0\} \subset \mathbb{R}^n$.

Now suppose we are given a framing $v\colon N \to \mathrm{GL}(m, m-k)$ for N.

(2) We define

$$\begin{array}{rcl} v_n\colon N_n & \to & \mathrm{GL}(n, n-k) \\ (P, 0) & \mapsto & \begin{pmatrix} v(P) & 0 \\ 0 & \mathrm{id}_{n-m} \end{pmatrix}. \end{array}$$

It is clear that v_n is a framing for N_n. Note that $N_m = N$ and $v_m = v$.

(3) We refer to (N_n, v_n) as the $(n-m)$-fold suspension of (N, v). In particular we refer to (N_{m+1}, v_{m+1}) as the suspension of (N, v).

The same notation applies in an obvious way to (framed) submanifolds of $[0,1] \times \mathbb{R}^m$.

The following lemma justifies the name "suspension" that we had used in the above definition.

Lemma 158.5. Let $m \in \mathbb{N}_{\geq 2}$ and let $k \in \{0, \dots, m\}$.

(1) The map

$$\begin{array}{rcl} \Omega_k^{\mathrm{fr}}(\mathbb{R}^m) & \to & \Omega_k^{\mathrm{fr}}(\mathbb{R}^{m+1}) \\ [(N, v)] & \mapsto & [\text{the suspension of } (N, v)] \end{array}$$

is well-defined and it is a homomorphism. We refer to it as the *suspension homomorphism*.

(2) Under the identification from the convention on page 3368 the suspension homomorphisms on $\pi_{n+k}(S^n, *)$ and $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k})$ agree up to sign,[1953] in other words, the following diagram commutes up to sign:

$$\begin{array}{ccc} \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) & \xrightarrow{\text{suspension}} & \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1}) \\ \downarrow \cong & & \downarrow \cong \\ \pi_{n+k}(S^n, *) & \xrightarrow{\text{suspension}} & \pi_{n+k+1}(S^{n+1}, *). \end{array}$$

Proof.

(1) The first statement is almost obvious.

(2) We leave it to the reader to go through all the definitions to verify this statement. ■

[1953] To be more precise, they might agree on the nose, but we will not spend valuable time on figuring out the sign.

158.2. **The Freudenthal Suspension Theorem.** In this section we will prove the following theorem that was first proved in 1937 by Hans Freudenthal [**Freu1937**, p. 300].

Theorem 158.6. (Freudenthal Suspension Theorem) Let $n, k \in \mathbb{N}_0$. We suppose that $n + k \geq 2$. The suspension homomorphism $\pi_{n+k}(S^n) \to \pi_{n+k+1}(S^{n+1})$ from the Suspension Homomorphism Lemma 71.19 is an isomorphism if $n > k + 1$ and it is an epimorphism if $n = k + 1$.

Remark.

(1) The Freudenthal Suspension Theorem 158.6 can be reformulated as follows: given $n \in \mathbb{N}$ the suspension homomorphism $\pi_m(S^n) \to \pi_{m+1}(S^{n+1})$ is an isomorphism if $m < 2n-1$ and that it is an epimorphism if $m = 2n-1$. We consider two situations in slightly more detail:
   (a) The Freudenthal Suspension Theorem 158.6 says that the suspension homomorphism $\pi_3(S^2) \to \pi_4(S^3)$ is an epimorphism and it says that for any $n \geq 3$ the suspension homomorphism $\pi_{n+1}(S^n) \to \pi_{n+2}(S^{n+1})$ is an isomorphism. This special case will play an important role shortly.
   (b) The Freudenthal Suspension Theorem 158.6 almost recovers Theorems 155.11 (2) and 155.14 (2). Recall that these theorems stated that for $m \in \{0, \ldots, 5\}$ we have $\pi_m(S^3) \cong \pi_{m+1}(S^4)$ and that for $m \in \{0, \ldots, 13\}$ we have $\pi_m(S^7) \cong \pi_{m+1}(S^8)$.

(2) Let $n \in \mathbb{N}_0$. Recall that on page 452 we saw that the suspension $\Sigma(S^n)$ is homeomorphic to S^{n+1}. Thus we see that the Freudenthal Suspension Theorem 158.6 is a consequence of the following stronger statement: Let X be an $(n-1)$-connected space and let $* \in X$ be a good base point.[1954] Then the suspension homomorphism $\pi_{n+k}(X, *) \to \pi_{n+k+1}(\Sigma(X), *)$ is an isomorphism for all $n > k + 1$ and it is an epimorphism for $n = k + 1$. This statement is proved in most textbooks on homotopy theory, see e.g. [**Gra1975**, Theorem 16.34], [**WhdG1978**, Theorem VII.7.13] or [**DaK2001**, Theorem 8.7 and Chapter 10.3]. If X is a CW-complex, then the statement is also proved in [**Hat2002**, Corollary 4.24]. The proof of [**Hat2002**, Corollary 4.24] is actually a corollary to the Blakers-Massey Theorem 153.17 that we had stated but not proved.

It follows from Lemma 158.5 that the Freudenthal Suspension Theorem 158.6 is equivalent to the following theorem.

Theorem 158.7. Let $n, k \in \mathbb{N}$.

(1) The suspension homomorphism $\Omega^{\mathrm{fr}}_k(\mathbb{R}^{n+k}) \to \Omega^{\mathrm{fr}}_k(\mathbb{R}^{n+k+1})$ is an epimorphism whenever $n \geq k + 1$.
(2) The suspension homomorphism $\Omega^{\mathrm{fr}}_k(\mathbb{R}^{n+k}) \to \Omega^{\mathrm{fr}}_k(\mathbb{R}^{n+k+1})$ is a monomorphism whenever $n > k + 1$.

The basic behind the proof of Theorem 158.7 (1) is quite simple: given a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$ we want to use the "room provided by a large enough n" to show that it is cobordant to a framed submanifold coming from $\mathbb{R}^{n+k} = \mathbb{R}^{n+k} \times \{0\}$. This idea is for the most part carried out in the following two lemmas.

[1954] We refer to page 1171 for the definition of a good point.

Lemma 158.8. Let (M, v) be a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$. If $n \geq k+1$, then there exists a framed cobordism from (M, v) to a framed k-dimensional submanifold (N, w) of $\mathbb{R}^{n+k+1}$ with $N \subset \mathbb{R}^{n+k} \times \{0\}$.

Proof. Let $(M, v\colon M \to \mathrm{GL}(n+k+1, n+1))$ be a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$. We point out that by Lemma 158.3 (1) we can assume that v is an orthonormal framing.

It follows from $n \geq k+1$ and Lemma 30.8 that there exists a vector $\nu \in \mathbb{R}^{n+k+1}$ which satisfies the following condition:

(∗) the vector ν does not lie in any tangent space $\mathrm{T}_P M$[1955] and ν is not secant to M, i.e. for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to ν.

By the Orthogonal Action Lemma 5.26 (4) there exists a matrix $A \in \mathrm{SO}(n+k+1)$ with $A \cdot \nu = e_{n+k+1}$. By the Diffeotopies-via-Matrices Lemma 33.8 there exists a diffeotopy of $\mathbb{R}^{n+k+1}$ from $\mathrm{id}_{\mathbb{R}^{n+k+1}}$ to the diffeomorphism given by multiplying by A. Therefore, by the obvious analogue of Lemma 157.7 for the framed cobordism group, we can assume without loss of generality that $\nu = e_{n+k+1}$.

Claim. The map

$$\begin{array}{rcl} \Psi\colon [0,1] \times M & \to & [0,1] \times \mathbb{R}^{n+k+1} \\ (t, \underbrace{(x_1, \ldots, x_{n+k+1})}_{\in M}) & \mapsto & (t, \underbrace{x_1, \ldots, x_{n+k}, (1-t) \cdot x_{n+k+1}}_{\in \mathbb{R}^{n+k+1}}) \end{array}$$

is a proper smooth embedding. The definition of Ψ is illustrated in the figure below.

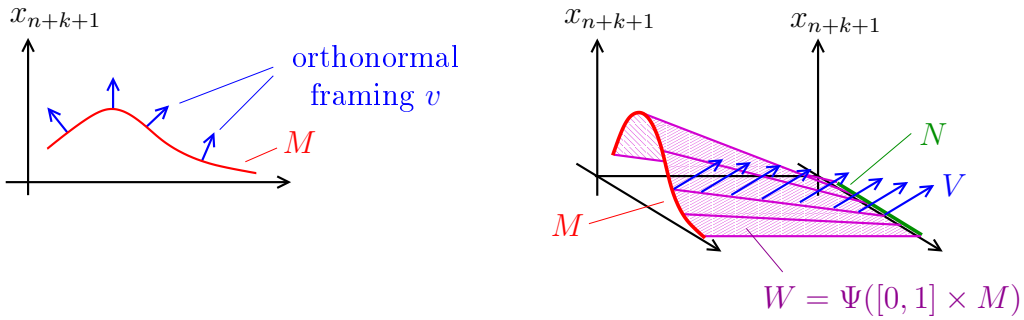
Proof. It follows from the fact that for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to $\nu = e_{n+k+1}$ that the map is injective. Furthermore note that the map Ψ is the composition of the inclusion $i\colon [0,1] \times M \to [0,1] \times \mathbb{R}^{n+k+1}$ with the map

$$\begin{array}{rcl} \Theta\colon [0,1] \times \mathbb{R}^{n+k+1} & \to & [0,1] \times \mathbb{R}^{n+k+1} \\ (t, (x_1, \ldots, x_{n+k+1})) & \mapsto & (t, x_1, \ldots, x_{n+k}, (1-t) \cdot x_{n+k+1}). \end{array}$$

A straightforward calculation shows that

$$D\Theta_{(t, x_1, \ldots, x_{n+k+1})} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \mathrm{id}_{n+k} & 0 \\ -x_{n+k+1} & 0 & 1-t \end{pmatrix}.$$

It follows immediately from this calculation and the fact that e_{n+k+1} is not contained in any tangent space $\mathrm{T}_P M$ that $\Psi = \Theta \circ i$ is an immersion. Together with the injectivity of Θ, the fact that M is compact and the ever-popular the Compact-Hausdorff Proposition 2.17 (2) we obtain that $\Psi = \Theta \circ i$ is in fact a smooth embedding. It is also clear that the smooth embedding is proper. ⊞



We set $W := \Psi([0,1] \times M)$. By the claim together with the Smooth Embedding Theorem 24.10 (2) we know that W is a proper $(k+1)$-dimensional submanifold of $[0,1] \times \mathbb{R}^{n+k+1}$. Basically by definition W is a cobordism between $M \subset \mathbb{R}^{n+k+1}$ and some submanifold $N \subset \mathbb{R}^{n+k} \times \{0\}$.

[1955] Here and throughout this proof we use the Tangent Space-Isomorphism Proposition 23.16 to view the tangent spaces of submanifolds of some $\mathbb{R}^m$ as vector subspaces of $\mathbb{R}^m$.

It remains to extend the orthonormal framing $v\colon M \to \mathrm{GL}(n+k+1, n+1)$ of M to a framing of W. In fact, we obtain a framing of $W = \Psi([0,1] \times M)$ by using the "same vectors" as for M. More precisely, we consider the map

$$\begin{array}{rcl} V\colon W = \Psi([0,1]\times M) & \to & \mathrm{GL}(n+k+2, n+1) \\ \Psi(t,P) & \mapsto & \begin{pmatrix} 0 \\ v(P) \end{pmatrix}. \end{array}$$

Evidently under the identification $\{0\} \times \mathbb{R}^{n+k+1} = \mathbb{R}^{n+k+1}$ we have $V|_M = v$. Thus it remains to show that V is indeed a framing. A short moment's thought shows that V is smooth. The definition of W and V are illustrated in the figure below.

Therefore it suffices to prove the following claim.

Claim. For any $t \in [0,1]$ and any $P \in M$ the matrix $V(\Psi(t,P)) \in \mathrm{GL}(n+k+2, n+1)$ is a frame for $W = \Psi([0,1] \times M)$ at $\Psi(t,P)$.

Proof. Let $t \in [0,1]$ and let $P \in M$. We point out that the columns of $V(\Psi(t,P))$ span an $(n+1)$-dimensional vector subspace of $\mathbb{R}^{n+k+2}$. Since $\mathrm{T}_{\Phi(t,P)}(W)$ is a vector subspace of the complementary dimension $k+1$ it suffices to show that the intersection of these two vector subspaces is trivial.

We note that

$$\underbrace{\mathrm{T}_{\Phi(t,P)}(W) \cap \begin{array}{c}\text{span of the}\\ \text{columns of}\\ V(\Psi(t,P))\end{array}}_{\subset \mathbb{R}^{1+n+k+1}} \overset{\text{by definition of } W = \Psi([0,1]\times M) = (\Theta \circ i)([0,1]\times M) \text{ and the calculation of } D\Theta}{\downarrow} = \underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & \mathrm{id}_{n+k} & 0 \\ -x_{n+k+1} & 0 & 1-t \end{pmatrix} \cdot \begin{pmatrix} \mathbb{R} \\ \oplus \\ \mathrm{T}_P M \end{pmatrix} \cap \begin{array}{c}\text{span of the}\\ \text{columns of}\\ V(\Psi(t,P))\end{array}}_{\subset \mathbb{R}^{1+n+k+1}}$$

$$\cong \underbrace{\begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \cdot \mathrm{T}_P(M) \cap \begin{array}{c}\text{span of the}\\ \text{columns of } v(P)\end{array}}_{\subset \mathbb{R}^{n+k+1}} = \begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \cdot \mathrm{T}_P(M) \cap (\mathrm{T}_P M)^\perp.$$

$\uparrow$ since the first row of V is zero we can "ignore" the first coordinate

$\uparrow$ since v is an orthonormal framing

Now let $u \in \mathrm{T}_P M$ be a non-zero vector. We write $u = \begin{pmatrix} u' \\ u_{n+k+1} \end{pmatrix}$ with $u' \in \mathbb{R}^{n+k}$ and $u_{n+k+1} \in \mathbb{R}$. Note that u' is non-zero since we had arranged that $e_{n+k+1} \notin \mathrm{T}_P M$. Now we

calculate that

$$\left\langle \begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \begin{pmatrix} u' \\ u_{n+k+1} \end{pmatrix}, \underbrace{\begin{pmatrix} u' \\ u_{n+k+1} \end{pmatrix}}_{=u\in \mathrm{T}_P M} \right\rangle = \langle u', u' \rangle + (1-t)\cdot u_{n+k+1}^2 > 0.$$

since $u' \neq 0$ and $(1-t) \geq 0$

But this shows that $\begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \cdot u$ is not orthogonal to $\mathrm{T}_P M$, in other words, this vector does not lie in $(\mathrm{T}_P M)^\perp$. ■

Lemma 158.9. Let (M, v) be a framed k-dimensional submanifold in $\mathbb{R}^{n+k} \times \{0\} \subset \mathbb{R}^{n+k+1}$. If $n \geq k+1$, then there exists a framed cobordism to $(M, w = (w_1, \ldots, w_{n+1}))$ where we have $w_{n+1}(P) = e_{n+k+1}$ for all $P \in M$.

Proof. Let $(M, u = (u_1, \ldots, u_{n+1})\colon M \to \mathrm{GL}(n+k+1, n+1))$ be a framed k-dimensional submanifold that is contained in $\mathbb{R}^{n+k} \times \{0\} \subset \mathbb{R}^{n+k+1}$. By Lemma 158.3 (1) and Lemma 158.1 we can assume that u is orthonormal. We write $e := e_{n+k+1}$.

Claim 1. There exists an orthonormal framing $v = (v_1, \ldots, v_{n+1})$ for M such that (M, u) is cobordant to (M, v) and such that for every $P \in M$ we have $v_{n+1}(P) \neq -e$.

Proof. Let $x \in M$. Since M is contained in $\mathbb{R}^{n+k} \times \{0\}$ we know that e is orthogonal to $\mathrm{T}_x M$. Therefore we can uniquely write $e = \sum_{i=1}^{n+1} \lambda_i(x) \cdot u_i(P)$. Since $\|e\| = 1$ and since u is an orthonormal framing we actually have $\sum_{i=1}^{n+1} \lambda_i^2(P) = 1$. Thus we obtain a map

$$\begin{array}{rcl} \lambda\colon M & \to & S^n \\ x & \mapsto & (\lambda_1(x), \ldots, \lambda_{n+1}(x)) \end{array}$$

which is fairly easily seen to be smooth. If $(0, \ldots, 0, -1) \notin \lambda(M)$, then we can just take $u = v$ and we are done.[1956] If not we proceed as follows. Since $\dim(M) = k < n$ it follows from the Full Measure-Density Proposition 30.3 that there exists a $\nu \in S^n$ with $\nu \notin \lambda(M)$. By the Orthogonal Action Lemma 5.26 (4) there exists a matrix $A \in \mathrm{SO}(n+1)$ with $\nu = A \cdot (-e) \in S^n$. By the Matrix Group Path-Component Proposition 2.37 and the Smooth Path-Connectivity Proposition 19.29 there exists a smooth path $\gamma\colon [0,1] \to \mathrm{SO}(n+1)$ from id to A. The desired framed cobordism is now given by the smooth manifold $[0,1] \times M$ together with the framing[1957]

$$\begin{array}{rcl} [0,1] \times M & \to & \mathrm{GL}(n+k+2, n+1) \\ (t, x) & \mapsto & \underbrace{\begin{pmatrix} 0 \\ u(x) \end{pmatrix}}_{\in \mathrm{GL}(n+k+2, n+1)} \cdot \gamma(t). \end{array}$$

⊞

[1956] Indeed, if $v_{n+1}(x) = -e$, then $e = -v_{n+1}(x)$, i.e. $\lambda(x) = (0, \ldots, 0, -1)$.

[1957] That this framing has the correct properties can be seen as follows. Let v be the new framing at $\{1\} \times M$. If we denote by $\lambda_u, \lambda_v\colon M \to S^n$ the corresponding maps, then one easily sees that for each $x \in M$ we have $\lambda_v(x) = A^{-1} \cdot \lambda_u(x)$. Thus the fact that ν does not lie in the image of λ_u implies that $-e = A^{-1}\nu$ does not lie in the image of λ_v.

As a final step we want to "rotate v_{n+1} into e". To do this smoothly for every point we need to introduce two maps. Given $u \in \mathbb{R}^{n+1} \setminus \{0\}$ we write

$$\underbrace{\begin{array}{rcl} T_u \colon \mathbb{R}^{n+k+1} & \to & \mathbb{R}^{n+k+1} \\ y & \to & 2 \cdot \langle y, u \rangle \cdot u - y \end{array}}_{\text{reflection in the line } \mathbb{R} \cdot u} \quad \text{and} \quad \underbrace{\begin{array}{rcl} R_u \colon \mathbb{R}^{n+k+1} & \to & \mathbb{R}^{n+k+1} \\ y & \mapsto & T_e(T_u(y)). \end{array}}_{\text{orientation-preserving diffeomorphism}}$$

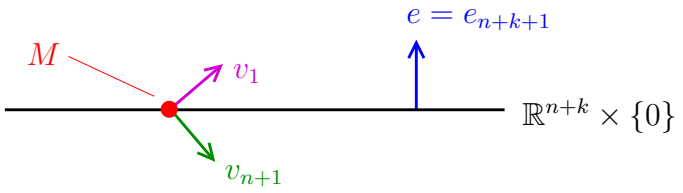
We will need the following elementary observation from linear algebra.

Claim 2. Let $w \in \mathbb{R}^{n+k+1}$ with $\|w\| = 1$. Let $u = \frac{w+e}{\|w+e\|}$ be the normalized midpoint between w and e. Then $R_u(w) = e$.

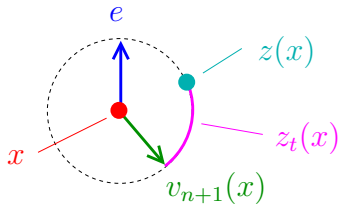
Proof. We have

$$R_u(w) \;=\; T_e(T_u(w)) \;=\; T_e\Big(2 \cdot \Big\langle w, \tfrac{w+e}{\|w+e\|} \Big\rangle \cdot \tfrac{w+e}{\|w+e\|} - w\Big) \underset{\text{short calculation using } \langle w,w\rangle = \langle e,e\rangle}{\uparrow} = T_e(e) \;=\; e.$$

⊞



The above claim now allows us to come to the denouement of the argument. More precisely, given $t \in [0,1]$ and $x \in M$ we write



$$z(x) \;:=\; \underbrace{\frac{v_{n+1}(x)+e}{\|v_{n+1}(x)+e\|}}_{\text{note that } v_{n+1}(x)+e \neq 0} \quad \text{and} \quad z_t(x) \;=\; \underbrace{\frac{(1-t)\cdot e + t \cdot z(x)}{\|(1-t)\cdot e + t \cdot z(x)\|}}_{\text{note that } t \cdot e + (1\text{-}t) \cdot z(x) \neq 0}.$$

Note that $z_0 = e$ and $R_{z_0} = \mathrm{id}$. Furthermore note that $z_1 = z(x)$. Thus we obtain from the above claim that $R_{z_1(x)}(v_{n+1}(x)) = e$. Finally we consider the framed cobordism that is given by the submanifold $Z = [0,1] \times M$ of $[0,1] \times \mathbb{R}^{n+k+1}$ together with the framing

$$\begin{array}{rcl} W \colon Z = [0,1] \times M & \to & \mathrm{GL}(n+k+2, n+1) \\ (t,x) & \mapsto & \begin{pmatrix} 0 \\ R_{z_t(x)} \circ v(x) \end{pmatrix}. \end{array}$$

We leave it to the reader to verify that the map W is indeed a framing for the cobordism $Z = [0,1] \times M \subset [0,1] \times \mathbb{R}^{n+k+1}$. The discussion above shows that $(Z = [0,1] \times M, W)$ is a framed cobordism from (M, v) to a framed smooth manifold $(M, w = w_1, \ldots, w_n, e)$. ■

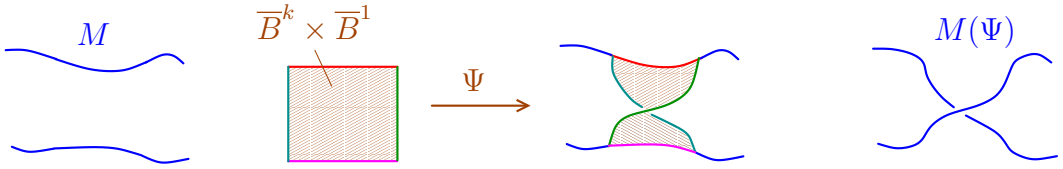
Now we turn to the actual proof of Theorem 158.7 and thus of the Freudenthal Suspension Theorem 158.6.

Proof. Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$.

(1) Suppose that $n \geq k+1$. We want to show that the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is an epimorphism. Thus let (M, v) be a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$. It follows immediately from Lemmas 158.8 and 158.9 that (M, v) is cobordant to a k-dimensional framed submanifold (N, w) such that $N \subset \mathbb{R}^{n+k} \times \{0\}$ and such that $w_{n+1}(P) = e_{n+k+1}$ for all $P \in N$. But this

means that $[(M,v])] = [(N,w)]$ lies in the image of the suspension homomorphism. Thus the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is an epimorphism.

(2) Suppose that $n > k+1$. We want to show that the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is a monomorphism. Therefore let (M,v) and (N,w) be two framed k-dimensional submanifolds of $\mathbb{R}^{n+k}$. Suppose there exists a framed cobordism (W,V) in $[0,1]\times\mathbb{R}^{n+k+1}$ between the suspensions of (M,v) and (N,w). Since $n > k+1$, an argument as in Lemmas 158.8 and 158.9 shows that we can turn (W,V) into a cobordism (W',V') with $W' \subset [0,1]\times\mathbb{R}^{n+k}\times\{0\}$ and such that $V'(P) = e_{n+k+1}$ for all $P \in W'$. But this shows that (M,v) and (N,w) are already cobordant. Thus we have shown that for $n > k+1$ the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is a monomorphism. ■



158.3. **Framed internal surgery.** We start out with the following general definition that is somewhat similar to the construction of the internal connected sum that we gave in Section 102.7.

Definition. Let M be a k-dimensional submanifold of $\mathbb{R}^{n+k}$. Let $\Psi\colon \overline{B}^k \times \overline{B}^1 \to \mathbb{R}^{n+k}$ be a smooth embedding with the following properties:

(1) $M \cap \Psi(\overline{B}^k \times \overline{B}^1) = \Psi(\overline{B}^k \times S^0)$,

(2) M intersects $\Psi(S^k \times \overline{B}^1)$ transversally.

We refer to
$$M(\Psi) := \underbrace{\Psi(S^k \times \overline{B}^1) \cup (M \setminus \Psi(B^k \times S^0))}_{\text{with corner } \Psi(S^{k-1}\times S^0) \text{ rounded as in Section 102.7}}$$
as the internal surgery along Ψ.

Remark. Note that $M(\Psi)$, viewed as a smooth manifold in its own right, is diffeomorphic to the surgery of M along $\Psi|_{\overline{B}^k\times S^0}$ as defined on page **??**.

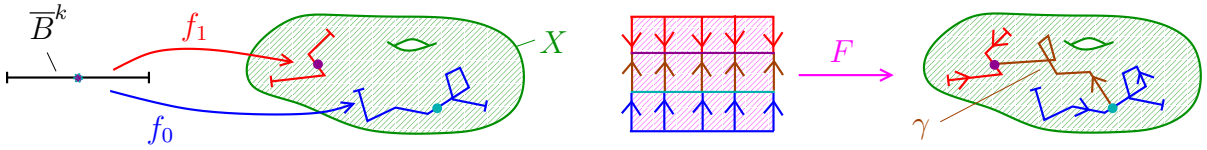
Proposition 158.10. Let (M,v) be a framed k-dimensional submanifold of $\mathbb{R}^{n+k}$. Note that the framing and the orientation induced an orientation on M. Let $\Psi\colon \overline{B}^k\times\overline{B}^1 \to \mathbb{R}^{n+k}$ be a smooth embedding with the following properties:

(1) $M \cap \Psi(\overline{B}^k \times \overline{B}^1) = \Psi(\overline{B}^k \times S^0)$,

(2) M intersects $\Psi(S^k \times \overline{B}^1)$ transversally,

(3) the map
$$\Psi\colon \underbrace{\overline{B}^k \times S^0}_{\text{product orientation}} \to M$$
is orientation-preserving.

Then $M(\Psi)$ admits a framing w such that (M,v) and $(M(\Psi),w)$ are framed cobordant.



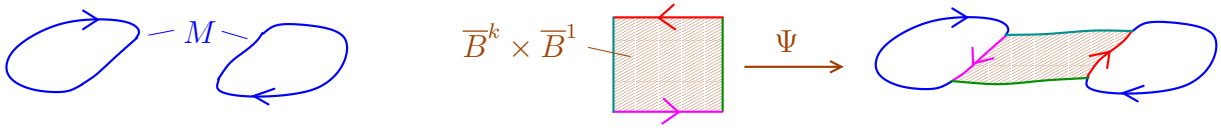
The proof of Proposition 158.10 makes use of the following lemma, which is basically the same statement as Exercise 14.2.

Lemma 158.11. Let X be a topological space and let $f_0, f_1 \colon \overline{B}^k \to X$ be two maps. If X is path-connected, then there exists a map $F \colon \overline{B}^k \times [0,1] \to X$ with $F_0 = f_0$ and with $F_1 = f_1$.

Proof of Lemma 158.11. Since X is path-connected there exists a map $\gamma \colon [\frac{1}{3}, \frac{2}{3}] \to X$ with $\gamma(\frac{1}{3}) = f_0(0)$ and with $\gamma(\frac{2}{3}) = f_1(0)$. Now we consider the map

$$\begin{array}{rcl} F \colon \overline{B}^k \times [0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} f_0(x \cdot (1-3t)), & \text{if } t \in [0, \frac{1}{3}], \\ \gamma(t), & \text{if } t \in [\frac{1}{3}, \frac{2}{3}], \\ f_1(x \cdot (3 \cdot t - 2)), & \text{if } t \in [\frac{2}{3}, 1]. \end{cases} \end{array}$$

It follows from the Homotopy Stacking Lemma 14.3 that F is continuous. It is clear that F has all the desired properties. ∎



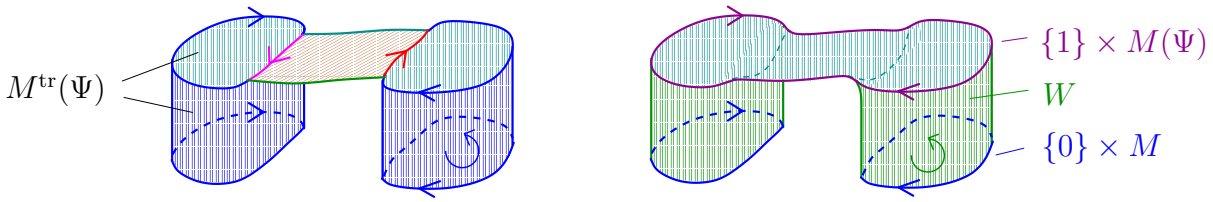
Sketch of a proof of Proposition 158.10. Let (M, v) be a framed k-dimensional submanifold of $\mathbb{R}^{n+k}$ and let $\Psi \colon \overline{B}^k \times \overline{B}^1 \to \mathbb{R}^{n+k}$ be a smooth embedding with the following properties:

(1) $M \cap \Psi(\overline{B}^k \times \overline{B}^1) = \Psi(\overline{B}^k \times S^0)$,
(2) M intersects $\Psi(S^k \times \overline{B}^1)$ transversally,
(3) the map

$$\Psi \colon \underbrace{\overline{B}^k \times S^0}_{\text{product orientation}} \to M$$

is orientation-preserving.

Note that by Lemma 158.3 we can assume that v is an orthonormal framing.



Similar to the discussion on page **??** and the proof of the Trace-of-Surgery Proposition **??** we consider the trace of the surgery

$$M^{\mathrm{tr}}(\Psi) \;:=\; ([0,1] \times M) \cup (\{1\} \times \Psi(\overline{B}^k \times \overline{B}^1)) \qquad \subset\; [0,1] \times \mathbb{R}^{n+k}.$$

In the Trace-of-Surgery Proposition **??** we saw that $M^{\mathrm{tr}}(\Psi)$ is a $(k+1)$-dimensional smooth manifold and we saw that we can equip $M^{\mathrm{tr}}(\Psi)$ with the orientation coming from the product orientation on $[0,1] \times M$. If we view $M^{\mathrm{tr}}(\Psi)$ as an oriented abstract smooth manifold, then its boundary is $(\{1\} \times M(\Psi)) \sqcup -(\{0\} \times M)$. Similar to the definition on

page ?? and Lemma ?? we can push $\Psi(B^k \times \overline{B}^1) \subset M^{\mathrm{tr}}(\Psi)$ into $(0,1) \times \mathbb{R}^{n+k}$ while keeping $\Psi(S^{k-1} \times \overline{B}^1)$ fixed. After rounding corners we obtain the desired cobordism.[1958]

For simplicity we now write $W = ([0,1] \times M) \cup \Psi(\overline{B}^k \times \overline{B}^1)$. Note that $\Psi(\overline{B}^k \times \overline{B}^1)$ is contractible and compact. Therefore it follows from the Vector Bundles-Homotopies Proposition 143.13 that the normal bundle of $\Psi(\overline{B}^k \times \overline{B}^1)$ is trivial. We pick a trivialization. Once we pick a trivialization an orthonormal framing is the same as a map $\Psi(\overline{B}^k \times \overline{B}^1) \to \mathrm{O}(n)$. Since $\Psi(\overline{B}^k \times \{0\})$ is connected we can as well assume that the map $\Psi(\overline{B}^k \times \{0\}) \to \mathrm{O}(n)$ takes values in $\mathrm{SO}(n)$. It follows from our hypothesis (3) that the map $\Psi(\overline{B}^k \times \{1\}) \to \mathrm{O}(n)$ also takes values in $\mathrm{SO}(n)$.

By Lemma 2.38 we know that $\mathrm{SO}(n)$ is path-connected. Thus it follows from Lemma 158.11 that the framing $\Psi(\overline{B}^k \times \{0,1\}) \to \mathrm{O}(n)$ extends to a framing $\Psi(\overline{B}^k \times [0,1]) \to \mathrm{O}(n)$. ■

158.4. **Suspension and the Hopf invariant.** The following theorem was also proved in 1937 by Hans Freudenthal [**Freu1937**, Satz I].

Theorem 158.12. (Freudenthal Suspension Theorem II) Let $n \in \mathbb{N}$. As above let $\Sigma\colon \pi_{2n}(S^n) \to \pi_{2n+1}(S^{n+1})$ be the suspension homomorphism and let $\mathrm{Hopf}\colon \pi_{2n+1}(S^{n+1}) \to \mathbb{Z}$ be Hopf invariant. With this notation we have

$$\mathrm{Im}(\Sigma\colon \pi_{2n}(S^n) \to \pi_{2n+1}(S^{n+1})) \;=\; \ker(\mathrm{Hopf}\colon \pi_{2n+1}(S^{n+1}) \to \mathbb{Z}).$$

Before we turn to the proof of the Freudenthal Suspension Theorem 158.12 let us state the following corollary.

Corollary 158.13. For every $n \in \mathbb{N}$ the suspension homomorphism

$$\Sigma\colon \pi_{4n}(S^{2n}) \;\to\; \pi_{4n+1}(S^{2n+1})$$

is an epimorphism.

Remark. In Theorem 159.9, when we show that $\pi_{n+2}(S^n) \cong \mathbb{Z}_2$ for $n \geq 2$, we will make essential use of the fact that by Corollary 158.13 we know that the suspension homomorphism $\Sigma\colon \pi_4(S^2) \to \pi_5(S^3)$ is an epimorphism.

Proof of Corollary 158.13. This corollary follows immediately from the Freudenthal Suspension Theorem 158.12 and the fact, shown in Lemma 157.21, that the Hopf invariant

$$\mathrm{Hopf}\colon \pi_{4n+1}(S^{2n+1}) \;\to\; \mathbb{Z}$$

is the zero map. ■

[1958] As the reader will have noticed, at this stage the author swiped some technicalities under a big carpet. This is way why we refer to this only as a "sketch of proof".

We now turn to the proof of the Freudenthal Suspension Theorem 158.12]. We follow the argument given in [**Put**, Chapter 9]. Let $n \in \mathbb{N}$. We need to show that

$$\mathrm{Im}(\Sigma\colon \pi_{2n}(S^n) \to \pi_{2n+1}(S^{n+1})) \;=\; \ker(\mathrm{Hopf}\colon \pi_{2n+1}(S^{n+1}) \to \mathbb{Z}).$$

We prove the "$\subset$"-inclusion and "$\supset$"-inclusion separately.

Proof of the Freudenthal Suspension Theorem 158.12 "$\subset$"-inclusion. Let $n \in \mathbb{N}$. We need to show that

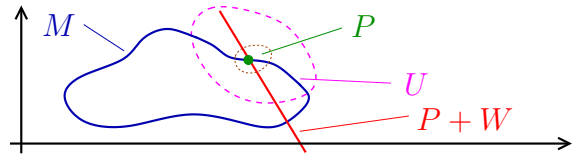
$$\mathrm{Im}(\Sigma\colon \pi_{2n}(S^n) \to \pi_{2n+1}(S^{n+1})) \;\subset\; \ker(\mathrm{Hopf}\colon \pi_{2n+1}(S^{n+1}) \to \mathbb{Z}).$$

First let us show the "$\subset$"-inclusion. So let (M, v) be a framed n-dimensional submanifold of $\mathbb{R}^{2n}$. We write $\widehat{M} := M \times \{0\}$ and we denote by $\widehat{v})$ the framing on $\widehat{M}$ given by $P \mapsto (v(P), e_{2n+1})$. Then

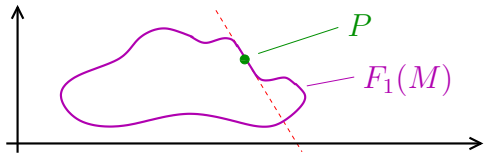
$$\mathrm{Hopf}(\Sigma([M,v])) \;=\; \mathrm{Hopf}(\widetilde{M}, \widetilde{v}) \;=\; \mathrm{lk}(\widetilde{M}, \widetilde{M} + e_{n+1}) \;=\; 0.$$

$\uparrow$ since $[\widetilde{M} + e_{n+1}] = 0 \in \mathrm{H}_n(\mathbb{R}^{2n} \pm e_{n+1})$ and since $\mathbb{R}^{2n} + e_{n+1} \subset \mathbb{R}^{2n+1} \setminus M$

■



The proof of the reverse inclusion is much more interesting. Our proof relies on several preparations. We start out with the following proposition, that is mildly interesting in its own right.

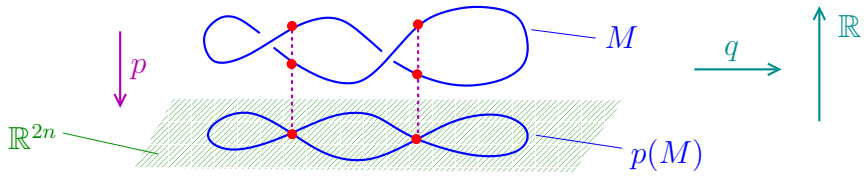


Proposition 158.14. Let M be an oriented n-dimensional submanifold of $\mathbb{R}^{2n+1}$. There exists an oriented cobordism from M to an oriented k-dimensional submanifold N of $\mathbb{R}^{2n+1}$ with $N \subset \mathbb{R}^{2n} \times \{0\}$.

Our proof of Proposition 158.14 relies on the Flattening Lemma 33.15, which we now recall for the reader's convenience.

Lemma 33.15. (Flattening Lemma) Let $M \subset \mathbb{R}^m$ be a smooth submanifold, let $P \in M$, let $W \subset \mathbb{R}^m$ be a vector subspace and let $\varphi\colon \mathbb{R}^m \to W$ be a homomorphism such that $\varphi\colon \widetilde{\mathrm{T}}_P M \to W$ is a monomorphism. Given any open neighborhood U of P there exists a smooth isotopy $F\colon M \times [0,1] \to \mathbb{R}^m$ rel $(M \setminus U) \cup \{P\}$ and an open neighborhood $\widetilde{U}$ of P with the following properties:

(1) $F_0 = \mathrm{id}$,
(2) $\widetilde{\mathrm{T}}_P F_1(M) = \varphi(\widetilde{\mathrm{T}}_P M)$,
(3) $F_1(\widetilde{U}) \subset P + W$,
(4) for each $x \in M$ and $t \in [0,1]$ the point $F(x,t)$ lies on the segment between x and $\varphi(x) + P$.



Proof. We consider the projections

$$\begin{array}{rcl} p\colon M & \to & \mathbb{R}^{2n} \\ (x_1, \ldots, x_{2n}, x_{2n+1}) & \to & (x_1, \ldots, x_{2n}) \end{array} \quad \text{and} \quad \begin{array}{rcl} p\colon M & \to & \mathbb{R}^{2n} \\ (x_1, \ldots, x_{2n}, x_{2n+1}) & \to & x_{2n+1}. \end{array}$$

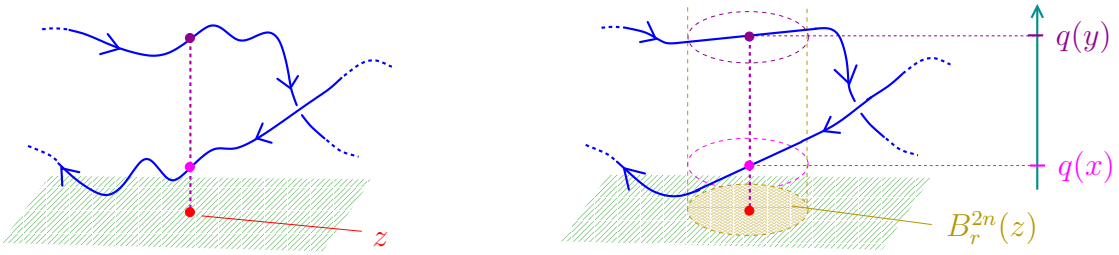
By the same argument as in the proof of Lemma 59.20 we see that, after possibly applying a rotation to M, we can assume that the projection $p\colon M \to \mathbb{R}^{2n}$ has the following properties:

(1) the map $p\colon M \to \mathbb{R}^{2n}$ is an immersion,
(2) whenever $x \neq y$ in M satisfy $p(x) = p(y)$, then $\mathrm{D}p_x(\mathrm{T}_xM) \cap \mathrm{D}p_y(\mathrm{T}_yM) = \{0\}$,
(3) for every $z \in \mathbb{R}^{2n}$ the preimage $p^{-1}(z)$ contains at most two points in M.

As in Lemma 59.17 we see that it follows from the first two properties that there exist only finitely many $z_1, \ldots, z_m \in \mathbb{R}^{2n}$ whose preimage consists of more than one point.

Claim. There exist disjoint orientation-preserving embeddings $\Psi_i\colon \overline{B}^n \times \{0,1\} \to M$, $i = 1, \ldots, m$ with disjoint images such that the restriction of p to $M(\Psi_1, \ldots, \Psi_m)$ is an injective immersion.

Proof. To simplify we deal in the following with the case $m = 1$. The general case is done in almost the same way, we just need to consider all points $z_1, \ldots, z_m$ separately. Thus suppose that we have $z \in \mathbb{R}^{2n}$ such that $p^{-1}(z)$ consists of two points x and y.



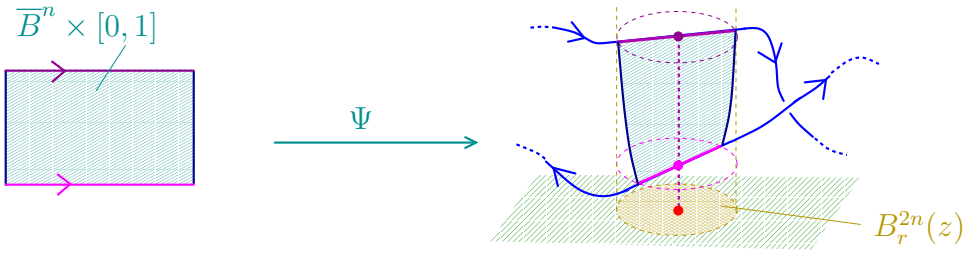
We apply the Flattening Lemma 33.15 to x, y and the homomorphism $p\colon \mathbb{R}^{2n+1} \to \mathbb{R}^{2n}$. Thus, after a smooth isotopy, we can assume that locally around x, y is contained in some $\mathbb{R}^{2n} \times \{*\}$.

Next we apply the Flattening Lemma 33.15 to x, y, to the above open neighborhoods and to the orthogonal projection onto the physical tangent spaces of these points.

We have now arranged that there exists an $r > 0$ such that[1959]

$$p^{-1}(\overline{B}^{2n}_{r_1}(z)) \;=\; (\overline{B}^{2n}_{r_1}(z_1) \cap ((\widetilde{\mathrm{T}}M_x + x) \times \{q(x)\}) \cup ((\widetilde{\mathrm{T}}M_{x_y} + y) \times \{q(y)\}).$$

We consider the subspaces $V := \mathrm{D}p_x(\widetilde{\mathrm{T}}_xM)$ and $W := \mathrm{D}p_x(\widetilde{\mathrm{T}}_xM)$. These are n-dimensional



vector spaces of $\mathbb{R}^{2n}$ with $V \cap W = \{0\}$. We pick a *negative* basis $v_1, \ldots, v_n$ and we pick a *positive* basis $w_1, \ldots, w_n$ for W. Finally we consider the map

$$\begin{array}{rcl} \Psi\colon \overline{B}^n \times [0,1] & \to & \mathbb{R}^{2n+1} \\ (\underbrace{(u_1, \ldots, u_m)}_{=u}, t) & \mapsto & \Big(P + \underbrace{\sum_{j=1}^{n} u_j \cdot (v_j \cdot \cos(\tfrac{\pi}{2} \cdot t) + w_j \cdot \sin(\tfrac{\pi}{2} \cdot t))}_{\text{ball spanned by } v_j \cdot \cos(\frac{\pi}{2} \cdot t) + w_j \cdot \sin(\frac{\pi}{2} \cdot t)}, q(x) \cdot (1-t) + t \cdot q(y)\Big). \end{array}$$

[1959] If we were dealing with points $z_1, \ldots, z_m$ then we would of course pick $r_1, \ldots, r_m \in \mathbb{R}_{>0}$ such that the closed balls $\overline{B}^{2n}_{r_1}(z_1), \ldots, \overline{B}^{2n}_{r_1}(z_m)$ are disjoint.

Note that each $\Psi\colon \overline{B}^n \times [0,1] \to \mathbb{R}^{2n+1}$ is a smooth embedding. Also note that the restriction of p to $\Psi(S^{n-1} \times [0,1])$ is injective. This follows from the observation that it is injective, almost by default, on each $\Psi(S^{n-1} \times \{t\})$ and the fact that t can be obtained from consider the plane spanned by say v_1 and W_1. ■

The following corollary is the analogue of Lemma 158.8. Note that the corollary has nothing to do with the Hopf invariant.

Corollary 158.15. Let (M, v) be a framed n-dimensional submanifold of $\mathbb{R}^{2n+1}$. There exists a framed cobordism from (M, v) to a framed k-dimensional submanifold (N, w) of $\mathbb{R}^{2n+1}$ with $N \subset \mathbb{R}^{2n} \times \{0\}$.

Proof. We equip M with orientation coming from the framing. In the proof of Proposition 158.14 we constructed a cobordism from M to a k-dimensional submanifold $N \subset \mathbb{R}^{2n} \times \{0\}$. By doing surgeries along It follows from Proposition 158.10. ■

Proof of the Freudenthal Suspension Theorem 158.12 "$\subset$"-inclusion. Let $n \in \mathbb{N}$. We need to show that

$$\operatorname{Im}(\Sigma\colon \pi_{2n}(S^n) \to \pi_{2n+1}(S^{n+1})) \ \subset\ \ker(\text{Hopf}\colon \pi_{2n+1}(S^{n+1}) \to \mathbb{Z}).$$

Let (M, v) be a framed $2n$-dimensional submanifold in $\mathbb{R}^{4n+1}$ with Hopf invariant zero. We need to show that there exists a framed $2n$-dimensional submanifold $(\widetilde{M}, \widetilde{v})$ in $\mathbb{R}^{4n}$ such that there exists a framed cobordism from the suspension of $(\widetilde{M}, \widetilde{v})$ to (M, v).

By Corollary 158.15 we know that there exists a framed cobordism from (M, v) to a framed k-dimensional submanifold (N, w) of $\mathbb{R}^{2n+1}$ with $N \subset \mathbb{R}^{2n} \times \{0\}$.

As in Lemma 158.9 we need to show that w is equivalent to a framing such that the last vector is e_{2n+1}.

Here we are supposed to use that the Hopf invariant is zero.

Putman argues roughly as follows. Since $N \subset \mathbb{R}^{2n} \times \{0\}$ we know that e_{2n+1} is orthogonal to all tangent spaces of N. Next recall that $w\colon N \times \mathbb{R}^{n+1} \to \mathbb{R}^{2n+1}$ is an orthonormal framing. This means that for each $x \in N$ there exists a $g(x) \in S^{n+1}$ with $w(g(x)) = e_{2n+1}$. This defines a map $g\colon N \to S^n$. The degree of this map is supposedly the Hopf invariant of (N, w).

Since we assume that the Hopf invariant is zero it follows from the Hopf Degree Theorem that the map $N \to S^n$ is null-homotopic. Now proceed as in page 8 of Putman ■

Exercise for Chapter 158.

Exercise 158.1. In the proof of Proposition 159.4 we used the Freudenthal Suspension Theorem 158.6 to show that the map

$$\begin{array}{rcl} \mathbb{Z} & \to & \Omega_1^{\mathrm{fr}}(\mathbb{R}^4) \\ [k] & \mapsto & k \cdot [(\mathrm{C}_4, h_4)] \end{array}$$

is an epimorphism. Use Exercise **??** to give an alternative argument, which does not rely on the Freudenthal Suspension Theorem 158.6.

159. Thom-Pontryagin Theory III: The groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ and $\Omega_2^{\mathrm{fr}}(\mathbb{R}^{n+2})$

In this chapter we will calculate the framed cobordism groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ and $\Omega_2^{\mathrm{fr}}(\mathbb{R}^{n+2})$ "by hand" for $n \geq 3$. By the Thom-Pontryagin Theorem 157.11 and Proposition 158.4 this means that we calculate the homotopy groups $\pi_{n+1}(S^n)$ and $\pi_{n+2}(S^n)$ for $n \geq 3$ By now there might be more modern and efficient ways for computing these homotopy groups. But the geometric approach using Thom-Pontryagin theorem is still very charming, in particular it lets us use many techniques we have developed so far, and it gives us an opportunity to introduce a few new tricks. In particular we will get to introduce quadratic forms and the Arf invariant, which are purely algebraic objects, and are of great interest in the own right.

159.1. **The calculation of the framed cobordism groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ for $n \geq 3$.** In Theorem 155.10 (2) (and alternatively in Theorem 157.14) we saw that $\pi_3(S^2) \cong \mathbb{Z}$ and we saw that the Hopf map represents a generator of $\pi_3(S^2)$. Furthermore, by the Freudenthal Suspension Theorem 158.6 we know that for every $n \geq 3$ the suspension homomorphism $\pi_3(S^2) \to \pi_{n+1}(S^n)$ is an epimorphism. Thus we know that $\pi_{n+1}(S^n)$ is isomorphic to a quotient of $\mathbb{Z}$ and that $\pi_{n+1}(S^n)$ is generated by the $(n-2)$-fold suspension of the Hopf map. The goal of this section is to prove the following theorem which determines this quotient.

Theorem 159.1. For every $n \geq 3$ there exists an isomorphism $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$.

Remark.

(1) In Theorem 151.13 we already saw that for every $n \geq 3$ we have $\pi_{n+1}(S^n) \neq 0$. The proof of Theorem 159.1 below is independent of Theorem 151.13. In particular we will not make use of Steenrod operations.

(2) By the Thom-Pontryagin Theorem 157.11 and Proposition 158.4 the theorem is equivalent to showing that for every $n \geq 3$ we have an isomorphism $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1}) \cong \mathbb{Z}_2$. This is exactly what we will do below. The approach that we take below to calculate $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ differs, to the best of my knowledge, from the other proofs in the literature. We refer to [**Pon1959**, Chapter 14] for Pontryagin's original proof, which makes for challenging reading for the modern reader. A third, quite readable approach is presented in [**Put**].

(3) There are various alternative proofs of Theorem 159.1. The first proof was given by Hans Freudenthal [**Freu1937**, p. 301] in 1937. Another proof is given in [**Hat**, p. 549] using "spectral sequences".

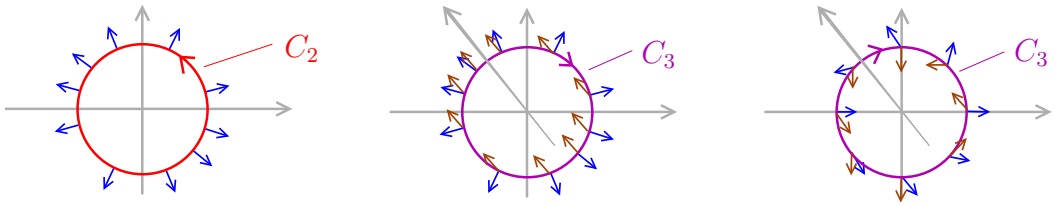
(4) The discussion preceding the theorem shows that the suspension of the Hopf map defines a non-trivial element in $\pi_4(S^3)$. This gives in particular an affirmative answer to Question 71.20.

As we had just mentioned above, proving Theorem 159.1 is equivalent to showing that for every $n \geq 3$ there exists an isomorphism $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1}) \cong \mathbb{Z}_2$. We will perform this calculation in the remainder of this section.

We start out our calculation of $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ for $n \geq 3$ with the following definition.

Definition.

(1) We refer to $C := S^1$ as the standard circle in $\mathbb{R}^2$.
(2) We refer to the framing of $C \subset \mathbb{R}^2$ that is given by



$$\begin{array}{rcl} t\colon C & \to & \mathbb{R}^2 \\ \begin{pmatrix} x \\ y \end{pmatrix} & \mapsto & \begin{pmatrix} x \\ y \end{pmatrix} \end{array}$$

as the trivial framing t of C.
(3) Let $n \in \mathbb{N}_{\geq 2}$. We adopt the convention from page 3369 to define the standard standard circle C_n in $\mathbb{R}^n$. Furthermore, using the definition from page 3369 we define the trivial framing t_n for C_n.
(4) We refer to the framing of $\mathrm{C}_3 \subset \mathbb{R}^3$ that is given by the map[1960]

$$\begin{array}{rcl} h\colon \mathrm{C}_3 & \to & \mathbb{R}^3 \\ \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} & \mapsto & t_3 \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} = \begin{pmatrix} \cos(\varphi) & 0 \\ \sin(\varphi) & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} \end{array}$$

$\uparrow$ don't overlook the t_3

as the Hopf framing h of C_3.
(5) Let $n \in \mathbb{N}_{\geq 3}$. As in (3) we use the convention from page 3369 to define the Hopf framing h_n of C_n. These definitions are illustrated in the figure below.

trivial framing t_2 trivial framing t_3 Hopf framing h_3

Throughout this section we also use the following notation:

Notation.

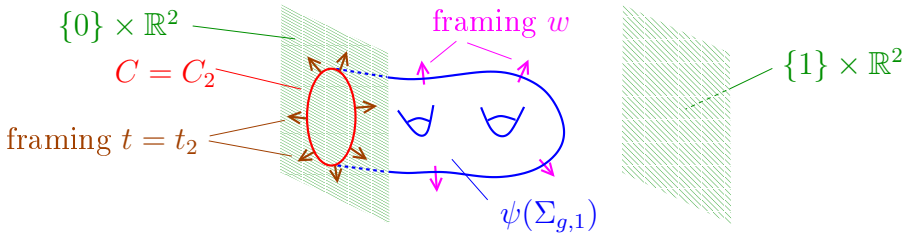
(1) Given $g \in \mathbb{N}_0$ we denote by $\Sigma_{g,1}$ the surface of genus g minus one open disk. We pick once and for all an orientation for $\Sigma_{g,1}$.
(2) For any $n \in \mathbb{N}_{\geq 2}$ we denote by

$$\begin{array}{rcl} \rho\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ (x_1, x_2, x_3, \ldots, x_n) & \mapsto & (x_1, -x_2, x_3, \ldots, x_n) \end{array}$$

the reflection in the $(x_2 = 0)$-hyperplane.
(3) Given $n \in \mathbb{N}_0$ we make the identification $\mathbb{R}^n = \{0\} \times \mathbb{R}^n \subset [0,1] \times \mathbb{R}^n$.

The following two lemmas justify the names "trivial framing" and "Hopf framing".

Lemma 159.2.



[1960] We leave the task of showing that this map is smooth to the every-ready reader.

(1) Given any $g \in \mathbb{N}_0$ there exists a proper smooth embedding $\psi\colon \Sigma_{g,1} \to [0,1]\times\mathbb{R}^2$ and a framing w for $\psi(\Sigma_{g,1})$ such that $\partial\psi(\Sigma_{g,1}) = \mathrm{C}_2$ and such that the restriction of w to C_2 equals t.
(2) For every $n \geq 2$ we have $[(C_n, t_n)] = 0 \in \Omega^{\mathrm{fr}}_1(\mathbb{R}^n)$.

Sketch of proof.

(1) By now the seasoned reader should be fairly convinced that there exists a proper smooth embedding $\psi\colon \Sigma_{g,1} \to [0,1] \times \mathbb{R}^2$ with $\psi(\partial\Sigma_{g,1}) = \mathrm{C}_2$ and such that the smooth embedding is a "product near the boundary". More precisely, such that for some $\epsilon \in (0,1)$ we have the equality $\psi(\Sigma_{g,1}) \cap ([0,\epsilon]\times\mathbb{R}^2) = [0,\epsilon]\times\mathrm{C}_2$. Since $\psi(\Sigma_{g,1})$ is an oriented connected submanifold of $[0,1]\times\mathbb{R}^2$ of codimension two we see that $\psi(\Sigma_{g,1})$ has precisely two normal fields of length one. We refer to the figure below for an illustration.

It follows almost immediately from the fact that $\psi(\Sigma_{g,1})$ is a product near $\{0\}\times\mathbb{R}^2$ that one of the above two normal vectors fields agrees with t on $\{0\}\times S^1$.
(2) It follows from (1) that $[(\mathrm{C}_2, t_2)] = 0 \in \Omega^{\mathrm{fr}}_1(\mathbb{R}^2)$. From Lemma 158.5 we obtain that $[(C_n, t_n)] = 0 \in \Omega^{\mathrm{fr}}_1(\mathbb{R}^n)$ for any $n \in \mathbb{N}_{\geq 2}$. ■

Lemma 159.3.

(1) Under the isomorphism $\Omega^{\mathrm{fr}}_1(\mathbb{R}^3) \cong \pi_3(S^2, *)$ the element $[(\mathrm{C}_3, h_3)]$ corresponds, up to a sign, to the element represented by the Hopf map $S^3 \to S^2$.
(2) Let $n \geq 4$. Under the isomorphism $\Omega^{\mathrm{fr}}_1(\mathbb{R}^n) \cong \pi_n(S^{n-1}, *)$ the element $[(C_n, h_n)]$ corresponds, up to a sign, to the element represented by the $(n-3)$-fold suspension of the Hopf map $S^3 \to S^2$.

Proof. The first statement follows easily from Lemma 157.4. The second statement is a straightforward consequence of Lemma 158.5 (2). ■

The following proposition is the first key ingredient in the calculation of $\Omega^{\mathrm{fr}}_1(\mathbb{R}^n)$ for $n \geq 4$.

Proposition 159.4. Let $n \in \mathbb{N}_{\geq 4}$. The map

$$\begin{array}{ccc} \mathbb{Z}_2 & \to & \Omega^{\mathrm{fr}}_1(\mathbb{R}^n) \\ [k] & \mapsto & k \cdot [(C_n, h_n)] \end{array}$$

is well-defined and it is an epimorphism.

Our proof of Proposition 159.4 requires one definition and two lemmas.

Definition. Let $n \in \mathbb{N}_{\geq 2}$ and let $\gamma\colon S^1 \to \mathbb{R}^n$ be a smooth embedding. Furthermore let $f\colon \gamma(S^1) \to \mathrm{GL}(n, n-1)$ be a framing for $\gamma(S^1)$ and let $\alpha\colon S^1 \to \mathrm{GL}_+(n-1, \mathbb{R})$ be a

smooth map. We define

$$\begin{array}{rcl} f(\alpha)\colon \gamma(S^1) & \to & \mathrm{GL}(n,n-1) \\ \gamma(z) & \mapsto & \underbrace{f(\gamma(z))}_{\in \mathrm{GL}(n,n-1)} \cdot \underbrace{\alpha(z)}_{\in \mathrm{GL}(n-1,\mathbb{R})}. \end{array}$$

It follows easily from the fact that α takes values in $\mathrm{GL}_+(n-1,\mathbb{R})$ that $f(\alpha)$ is again a framing of $\gamma(S^1)$.

The first lemma that goes into the proof of Proposition 159.4 is really just a crucial example masquerading as a lemma.

Lemma 159.5. Let $n \in \mathbb{N}_{\geq 3}$ and let $\gamma\colon S^1 \to C_n$ be the obvious diffeomorphism. We consider the loop

$$\begin{array}{rcl} \alpha\colon S^1 & \to & \mathrm{GL}_+(n-1,\mathbb{R}) \\ z = \exp(\mathrm{i}\varphi) & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-3} \end{pmatrix}. \end{array}$$

As above let t_n be the trivial framing for C_n and let h_n be the Hopf framing for C_n. We have the following two equalities of framings of C_n:

(1) We have $t_n(\alpha) = h_n$.
(2) We have $t_n(\overline{\alpha}) = \rho_*(h_n)$.[1961]

Proof. The first statement follows immediately from the definitions. We turn to the proof of the second statement. As we will see, the proof of the second statement is given by a slightly tedious calculation. To simplify the notation we only deal with the case $n = 3$.

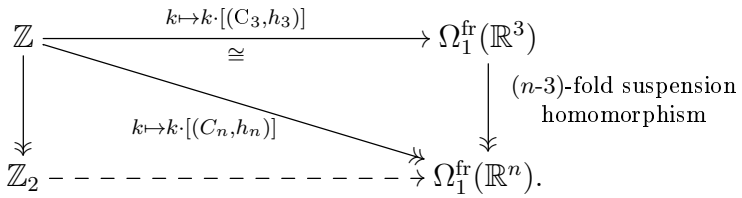
At a given point $P = \gamma(\exp(\mathrm{i}\varphi)) = \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \in \mathrm{C}_3$ we have

$$\begin{aligned} t_n(\overline{\alpha}) \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} &= t_n \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \cdot \underbrace{\alpha(\exp(-\mathrm{i}\varphi))}_{=\overline{\alpha}(\exp(\mathrm{i}\varphi))} = \begin{pmatrix} \cos(\varphi) & 0 \\ \sin(\varphi) & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \cos(-\varphi) & -\sin(-\varphi) \\ \sin(-\varphi) & \cos(-\varphi) \end{pmatrix} \\ &= \rho \left(\begin{pmatrix} \cos(-\varphi) & 0 \\ \sin(-\varphi) & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} \cos(-\varphi) & -\sin(-\varphi) \\ \sin(-\varphi) & \cos(-\varphi) \end{pmatrix} \right) = \rho \left(h_n \begin{pmatrix} \cos(-\varphi) \\ \sin(-\varphi) \\ 0 \end{pmatrix} \right) \\ &\quad \uparrow \text{ since } \rho \text{ is reflection in the second coordinate together with the symmetries of sin and cos} \qquad \uparrow \text{ definition of } h_n, \text{ see page 3383} \\ &= \rho \left(h_n \left(\rho^{-1} \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \right) \right) = \rho_*(h_n) \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix}. \\ &\quad \uparrow \text{ definition of } \rho \qquad \uparrow \rho_*(h_n) \text{ as defined on page 3366} \end{aligned}$$

This concludes the mind-numbing verification of the second statement. ∎

[1961] Here $\overline{\alpha}$ is the "inverse of the loop α", i.e. it is the loop given by $\overline{\alpha}(\exp(\mathrm{i}\varphi)) = \alpha(\exp(-\mathrm{i}\varphi))$. As above $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ is the reflection in the $(x_2 = 0)$-hyperplane. Finally the framing $\rho_*(h_n)$ is defined as on page 3366.

Lemma 159.6. Let $n \in \mathbb{N}_{\geq 2}$ and let $\gamma\colon S^1 \to \mathbb{R}^n$ be a smooth embedding. Furthermore let $f\colon \gamma(S^1) \to \mathrm{GL}(n, n-1)$ be a framing for $\gamma(S^1)$. Finally let $\alpha, \beta\colon S^1 \to \mathrm{GL}_+(n-1, \mathbb{R})$ be two smooth maps. If α and β are smoothly homotopic, then



$$[(\gamma(S^1), f(\alpha))] \;=\; [(\gamma(S^1), f(\beta))] \;\in\; \Omega_1^{\mathrm{fr}}(\mathbb{R}^n).$$

Proof of Lemma 159.6. We write $M = \gamma(S^1)$. Since $\alpha, \beta\colon S^1 \to \mathrm{GL}_+(n-1, \mathbb{R})$ are smoothly homotopic we can pick a smooth homotopy $H\colon S^1 \times [0,1] \to \mathrm{GL}_+(n-1, \mathbb{R})$ with $H_0 = \alpha$ and $H_1 = \beta$. We consider the product cobordism $[0,1] \times M$ equipped with the framing

$$\begin{array}{rcl} V\colon [0,1] \times M & \to & \mathrm{GL}(n+1, n) \\ (t, \gamma(z)) & \mapsto & \begin{pmatrix} 1 & 0 \\ 0 & f(\gamma(z)) \cdot H(z,t) \end{pmatrix} \end{array}$$

It is clear that $([0,1] \times M, V)$ is a framed cobordism between $(\gamma(S^1), f(\alpha))$ and $(\gamma(S^1), f(\beta))$. ∎

Proof of Proposition 159.4. Let $n \in \mathbb{N}_{\geq 4}$. We consider the following diagram

We make the following observations:

(1) It follows quite easily from Theorem 157.14, Lemma 159.3 and Proposition 158.4 that the top horizontal map is an isomorphism.
(2) The right vertical map is given by the $(n-3)$-fold application of the suspension homomorphism defined on page 3369. Note that the right vertical map is an epimorphism by the Freudenthal Suspension Theorem 158.7.
(3) The top right triangle commutes by definition of the suspension homomorphism and by definition of (C_n, h_n).

The above diagram and the above discussion show that it remains to prove the following claim.

Claim. The element $2 \cdot [(C_n, h_n)]$ is trivial in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$.

Proof. We consider the loop

$$\begin{array}{rcl} \alpha\colon S^1 & \to & \mathrm{GL}_+(n-1, \mathbb{R}) \\ z = \exp(\mathrm{i}\varphi) & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-3} \end{pmatrix}. \end{array}$$

We have the following equalities in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$:

$$2\cdot[(C_n,h_n)] \underset{\uparrow}{=} [(C_n,h_n)]+[(C_n,t_n(\alpha))] \underset{\uparrow}{=} [(C_n,h_n)]+[(C_n,t_n(\overline{\alpha}))]$$

Lemma 159.5 (1): since $n\geq 4$ we know by Proposition 156.11 (2) that $\pi_1(\mathrm{GL}_+(n-1,\mathbb{R}))\cong\mathbb{Z}_2$, therefore we see that $[\alpha]\cdot[\alpha]=0\in\pi_1(\mathrm{GL}_+(n-1,\mathbb{R}))$, this implies by Proposition 47.6 that α is path-homotopic to $\overline{\alpha}$, in fact, by the Whitney Approximation Theorem 29.1 we see that α is actually smoothly homotopic to $\overline{\alpha}$, by Lemma 159.6 this gives us the equality $[(C_n,t_n(\alpha))]=[(C_n,t_n(\overline{\alpha}))]$

$$\underset{\uparrow}{=} [(C_n,h_n)]+[(\rho_*(\mathrm{C}_n),\rho_*(h_n))] \underset{\uparrow}{=} [(C_n,h_n)]+(-[(C_n,h_n)]) = 0.$$

Lemma 159.5 (2); Proposition 158.2 ■

Let $n\geq 4$. Note that by Proposition 159.4 we now know that there exists an epimorphism $\mathbb{Z}_2\to\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)\cong\pi_n(S^{n-1})$. In Theorem 151.13 we showed that $\pi_{n+1}(S^n)$ is non-trivial. Therefore it follows that $\pi_{n+1}(S^n)\cong\mathbb{Z}_2$, which means we have proved Theorem 159.1. The readers who studied Steenrod operations *and* who happen to be tired of Thom-Pontryagin theory can thus move on to next section.
For all others we provide a proof of Theorem 159.1 that does not rely on Theorem 151.13. More precisely, we prove the following proposition which is the main technical result of this section.

Proposition 159.7. For any $n\in\mathbb{N}_{\geq 4}$ the map

$$\begin{array}{rcl}\mathbb{Z}_2 & \to & \Omega_1^{\mathrm{fr}}(\mathbb{R}^n)\\ [k] & \mapsto & k\cdot[(C_n,h_n)]\end{array}$$

is an isomorphism.

As we had mentioned many times, Theorem 159.1 is an immediate consequence of the Thom-Pontryagin Theorem 157.11 and Proposition 158.4 together with Proposition 159.7.

Proof. Let $n\in\mathbb{N}_{\geq 4}$. By Proposition 159.4 it remains to show that (C_n,h_n) represents a non-trivial element in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$.

We start out with a more general discussion. Given any $m\in\mathbb{N}_{\geq 2}$ we make the identification $\mathrm{C}_m=\{0\}\times\mathrm{C}_m\subset[0,1]\times\mathbb{R}^m$. The following claim applies to all dimensions.

Claim. Let $m\in\mathbb{N}_{\geq 2}$. Let F be a compact orientable connected proper 2-dimensional smooth manifold in $[0,1]\times\mathbb{R}^m$ with $\partial F=\mathrm{C}_m$. At most one of the two framings t_m and h_m can be extended to a framing of F.

Proof. Suppose there exist framings T and H on F with $T|_{\mathrm{C}_m}=t_m$ and $H|_{\mathrm{C}_m}=h_m$. It follows from Lemma 158.3 that we can assume that T and H are orthonormal. We consider the map[1962]

$$\begin{array}{rcl}\Psi\colon F & \to & \mathrm{GL}(m-1,\mathbb{R})\\ P & \mapsto & \text{the unique matrix } \Psi(P)\in\mathrm{GL}(m-1,\mathbb{R}) \text{ with } T(P)\cdot\Psi(P)=H(P).\end{array}$$

We denote by $i\colon\mathrm{C}_m\to F$ the inclusion map and we denote by $\gamma\colon S^1\to\mathrm{C}_m$ the usual diffeomorphism given by $\gamma(\exp(\mathrm{i}\varphi))=(\cos(\varphi),\sin(\varphi),0,\ldots,0)$. We make the following

[1962]Let $P\in F$. The fact that T and H are orthonormal means that the columns of $T(P)$ and $H(P)$ are bases for the same vector space, namely $(\mathrm{T}_PF)^\perp$. Therefore there exists a matrix $\Psi(P)\in\mathrm{GL}(m-1,\mathbb{R})$ such that $T(P)\cdot\Psi(P)=H(P)$. We leave it to the reader to verify that the map $P\mapsto\Psi(P)$ is continuous.

key observation: it follows immediately from the definitions and Lemma 159.5 that the map $\Psi \circ i \circ \gamma \colon S^1 \to \mathrm{GL}(m-1,\mathbb{R})$ is precisely, on the nose, given by the map

$$\begin{array}{rcl} \alpha \colon S^1 & \to & \mathrm{GL}(m-1,\mathbb{R}) \\ \exp(\mathrm{i}\varphi) & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{m-3} \end{pmatrix}. \end{array}$$

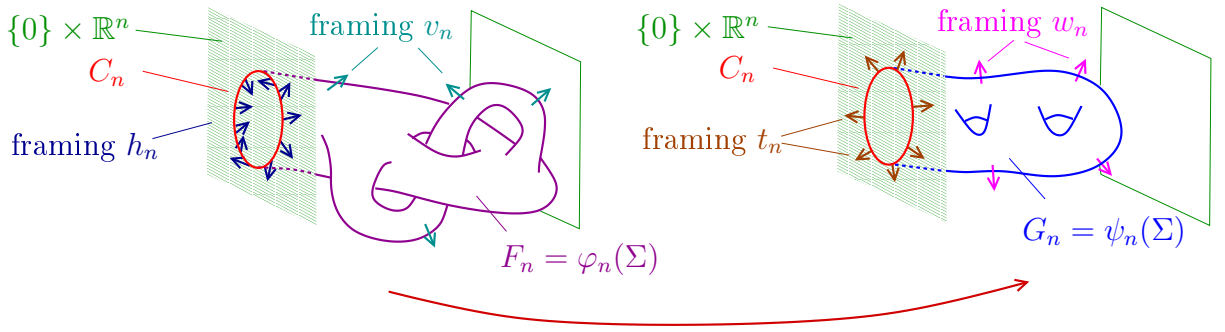
Now we consider the following diagram

$$\begin{array}{ccccc} \mathrm{H}_1(\partial F;\mathbb{Z}) & \xleftarrow{\gamma_*} & \mathrm{H}_1(S^1;\mathbb{Z}) & \xleftarrow[\cong]{\text{Hurewicz isom.}} & \pi_1(S^1,1) \\ \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle \alpha_*} & & \downarrow{\scriptstyle \alpha_*} \\ \mathrm{H}_1(F;\mathbb{Z}) & \xrightarrow{\Psi_*} & \mathrm{H}_1(\mathrm{GL}(m-1,\mathbb{R})) & \xleftarrow[\text{Hurewicz isom.}]{\cong} & \pi_1(\mathrm{GL}(m-1,\mathbb{R}),\mathrm{id}). \end{array}$$

We make the following observations:

(1) The left-hand square commutes by the above equality $\alpha = \Psi \circ i \circ \gamma$.
(2) The two horizontal maps to the right are the Hurewicz homomorphisms that we introduced on page 1832. The Hurewicz homomorphisms are isomorphisms by the Hurewicz Theorem 84.5 together with the fact that the fundamental groups on the right are both abelian.
(3) The right-hand square commutes by the naturality of the Hurewicz homomorphisms, see Proposition 84.2 (5).
(4) By Proposition 156.11 (2) and (3) we know that the loop $\alpha \colon S^1 \to \mathrm{GL}(m-1,\mathbb{R})$ represents a non-trivial element in $\pi_1(\mathrm{GL}(m-1,\mathbb{R}),\mathrm{id})$. This implies that the right vertical map $\alpha_* \colon \pi_1(S^1,1) \to \pi_1(\mathrm{GL}(m-1,\mathbb{R}),\mathrm{id})$ is non-trivial.
(5) It follows from (1) – (4) that the left vertical map is also non-trivial. But this contradicts Lemma 80.9 (1). ⊞

Now we start out with the actual proof of the theorem. Thus let $n \in \mathbb{N}_{\geq 4}$. As we pointed out above, we need to show that (C_n, h_n) represents a non-trivial element in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$. Suppose that (C_n, h_n) represents in fact the trivial element in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$. This means that there exists a framed cobordism $(F, v) = (F_n, v_n)$ in $[0,1] \times \mathbb{R}^n$ from (C_n, h_n) to the empty smooth manifold. In other words, $F = F_n$ is a compact orientable proper 2-dimensional submanifold of $[0,1] \times \mathbb{R}^n$ with $\partial F_n = C_n$ and $v = v_n$ is a framing with $v|_{\mathrm{C}_n} = h_n$. By throwing away all closed components of F_n we can assume that F_n is connected.



By the Surface Classification Theorem 55.4 we know that there exists a $g \in \mathbb{N}_0$ such that F is diffeomorphic to $\Sigma := \Sigma_{g,1}$. In other words, there exists a proper smooth embedding $\varphi \colon \Sigma \to [0,1] \times \mathbb{R}^n$ with $\varphi(\Sigma) = F_n$. Given any $m \geq n$ we denote by $\varphi_m \colon \Sigma \to [0,1] \times \mathbb{R}^m$ the smooth embedding that is given by the composition of the smooth embedding φ with the obvious smooth embedding $[0,1] \times \mathbb{R}^n \to [0,1] \times \mathbb{R}^m$.

By Lemma 159.2 (1) there exists a proper smooth embedding $\psi \colon \Sigma \to [0,1] \times \mathbb{R}^2$ and a framing $w_2 = w$ for $G_2 = G := \psi(\Sigma)$ such that $\partial\psi(\Sigma) = \mathrm{C}_2$ and such that the restriction of $w_2 = w$ to C_2 equals t_2. Given $m \geq 2$ we denote by $\psi_m \colon \Sigma \to [0,1] \times \mathbb{R}^m$ the smooth embedding that is given by the composition of the smooth embedding ψ with the obvious smooth embedding $[0,1] \times \mathbb{R}^2 \to [0,1] \times \mathbb{R}^m$.

Now we consider the two proper smooth embeddings $\psi_n, \varphi_n \colon \Sigma \to [0,1] \times \mathbb{R}^n$. We can arrange[1963] that $\psi_n|_{\partial\Sigma} = \varphi_n|_{\partial\Sigma}$.

It follows from Proposition **??** (2) and the Isotopy Extension Theorem 36.1 that there exists an $m \geq n$ and a diffeomorphism Ψ of the smooth manifold $[0,1] \times \mathbb{R}^m$ such that $\Psi(F_m) = G_m$ and such that the restriction of Ψ to $\{0\} \times \mathbb{R}^m$ is the identity. We refer to the figure below for an illustration.

Since (F_m, v_m) is an extension of (C_m, h_m) and since the restriction of Ψ to $\{0\} \times \mathbb{R}^m$ is the identity we see that $(\Psi(F_m), \Psi_*(v_m)) = (G_m, \Psi_*(v_m))$ is an extension of (C_m, h_m). On the other hand we saw (G_m, w_m) is an extension of (C_m, t_m). Thus both h_m and t_m can be extended over G_m. But this contradicts the above claim. ■

In summary we have the following proposition.

Proposition 159.8.

(1) The map

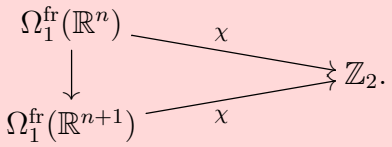
$$\begin{array}{ccccc} \Omega_1^{\mathrm{fr}}(\mathbb{R}^3) & \xleftarrow[\cong]{\text{given by Proposition 158.4}} & \Omega_1^{\mathrm{fat}}(\mathbb{R}^3) & \to & \mathbb{Z} \\ & & [(C,g)] & \mapsto & \text{self-linking number } \mathrm{slk}(C,g) \end{array}$$

is an isomorphism.

(2) For $n \geq 4$ the map

$$\begin{array}{ccc} \mathbb{Z}_2 & \to & \Omega_1^{\mathrm{fr}}(\mathbb{R}^n) \\ [k] & \mapsto & k \cdot [(C_n, h_n)] \end{array}$$

is an isomorphism.



For $n \in \mathbb{N}_{\geq 3}$ we denote by

$$\chi \colon \Omega_1^{\mathrm{fr}}(\mathbb{R}^n) \to \mathbb{Z}_2$$

[1963] This sentence contains a slight technical nuisance which we cleverly hide in a footnote. First of all, it should be pretty clear by now that Σ admits an orientation-reversing self-diffeomorphism. Thus, after possibly precomposing φ_n with such a diffeomorphism we can assume that $\psi_n^{-1} \circ \varphi_n$ is orientation-preserving. Next note that it follows from the Diffeotopies-of-S^1-Classification Proposition 34.5 and Corollary 34.10 that if C and D are two oriented smooth manifolds that are diffeomorphic to S^1, then any two orientation-preserving diffeomorphisms $C \to D$ are diffeotopic. In our context this implies that, using the Smooth Collar Neighborhood Theorem 28.3, we can then arrange, after possibly precomposing φ_n by another diffeomorphism, that $\psi_n|_{\partial\Sigma} = \varphi_n|_{\partial\Sigma}$.

the corresponding epimorphism.

(3) Given any $n \geq 3$ the following diagram commutes:

Proof.

(1) This statement is the content of Proposition 157.14.
(2) This statement is precisely the content of Proposition 159.7.
(3) This statement follows immediately from Theorem 158.7. ■

159.2. **Further results obtained using the Thom-Pontryagin approach.** In this final section we summarize a few more results that have been proved using the Thom-Pontryagin approach. First of all, using the Thom-Pontryagin method Pontryagin [**Pon1950b**] proved in 1950 the following theorem.

Theorem 159.9. For any $n \geq 2$ we have $\pi_{n+2}(S^n) \cong \mathbb{Z}_2$.

Remark.

(1) Recall that by Theorem 155.10 (1) we have for every $n \geq 3$ we have an isomorphism $\pi_n(S^3) \cong \pi_n(S^2)$. Furthermore we know by Theorem 159.1 that for every $n \geq 3$ we have $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$. Putting these two results together shows that $\pi_4(S^2) \cong \mathbb{Z}_2$.
(2) In Theorem 152.2 we used Steenrod operations to show that $\pi_{n+2}(S^n) \neq 0$ for all $n \geq 2$.
(3) By the Freudenthal Suspension Theorem 158.6 we know that the suspension homomorphism $\pi_5(S^3) \to \pi_6(S^4)$ is an epimorphism and we know that for $n > k+1$ the suspension homomorphism $\pi_{n+2}(S^n) \to \pi_{n+3}(S^{n+1})$ if an isomorphism for $n \geq 5$.
(4) Unfortunately (1), (2) and (3) are *not* strong enough to give an alternative proof of Theorem 159.9.

Proof. Let $n \geq 2$. First note that we have the following the isomorphisms and epimorphisms:

$$\mathbb{Z}_2 \underset{\text{Theorem 159.1}}{\cong} \pi_4(S^3) \underset{\text{Theorem 155.10 (1)}}{\cong} \pi_4(S^2) \underset{\text{Corollary 158.13}}{\twoheadrightarrow} \pi_5(S^3) \underset{\substack{\text{Freudenthal Suspension} \\ \text{Theorem 158.6}}}{\twoheadrightarrow} \pi_6(S^4) \cong \pi_{n+2}(S^n).$$

Now there are two ways to proceed:

(1) In Theorem 152.2 we used Steenrod operations to show that $\pi_{n+2}(S^n) \neq 0$ for all $n \geq 2$.

Either of these two statements shows that the maps sequence of maps are all necessarily isomorphisms. ■

Proof.

(1) As mentioned before, the theorem was proved by Lev Pontryagin [**Pon1950b, Pon1959**]. See also [**Scor2005**, p. 233] and [**WX2010**, Chapter 2.5] for outlines of the proof.

The most readable account of the Thom-Pontryagin approach to proving the theorem is surely [**Put**].

(2) At the same time as Pontryagin two very different proofs that $\pi_{n+2}(S^n) \cong \mathbb{Z}_2$ for $n \geq 2$ were given by George W. Whitehead [**WhdG1950**] and Jean-Pierre Serre [**Ser1953**, Proposition 10]. We also refer to [**Hat**, Theorem 1.40 (a)] for a proof using spectral sequences and Steenrod operations. Alternatively see also [**Hu1959**, Theorem XI.15.2]. ■

Finally Rokhlin [**Rok1952, Rok1986a**] used the Thom-Pontryagin approach to prove the following theorem.

Theorem 159.10.

(1) We have[1964] $\pi_5(S^3) \cong \mathbb{Z}_2$, $\pi_6(S^3) \cong \mathbb{Z}_{12}$, $\pi_7(S^4) \cong \mathbb{Z} \oplus \mathbb{Z}_{12}$.

(2) For any $n \geq 5$ we have $\pi_{n+3}(S^n) \cong \mathbb{Z}_{24}$.

Remark.

(1) In Theorem 151.13 we used Steenrod operations to show the weaker statement that $\pi_{n+3}(S^n) \neq 0$ for all $n \geq 2$.

(2) Note that Theorem 159.10 (1) gives a negative answer to Question 122.15 (2).

Proof.

(a) The theorem was proved by Vladimir Rokhlin [**Rok1952**][**Rok1986a**, p. 21] in 1952, using the above Thom-Pontryagin approach.[1965]

(b) A somewhat different proof is sketched in [**WX2010**, Chapter 2.6]. Some of the results can also be found in [**Ser1953**, Proposition 10]. Other proofs are given in [**Hat**, Theorem 1.40 (b)] and [**Hu1959**, Chapter XI.16]. ■

The results of the last two chapters summarize most (or all?) of the calculations of homotopy groups of spheres that have been obtained using the Thom-Pontryagin approach.

Exercises for Chapter 159.

Exercise 159.1. Let $n \in \mathbb{N}_{\geq 2}$. We consider the loops

$$\begin{array}{ccc} \alpha\colon S^1 \to \mathrm{GL}_+(n,\mathbb{R}) & & \overline{\alpha}\colon S^1 \to \mathrm{GL}_+(n,\mathbb{R}) \\ z = \exp(\mathrm{i}\varphi) \mapsto \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-2} \end{pmatrix} & \text{and} & z = \exp(\mathrm{i}\varphi) \mapsto \begin{pmatrix} \cos(\varphi) & \sin(\varphi) & 0 \\ -\sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-2} \end{pmatrix}. \end{array}$$

Recall that in the proof of Lemma 159.6 we used the fact, proved in Proposition 156.11 (2), that $\pi_1(\mathrm{GL}_+(n-1,\mathbb{R})) \cong \mathbb{Z}_2$, to show that α is path-homotopic to $\overline{\alpha}$. Give a direct proof that the loop α is path-homotopic to the loop $\overline{\alpha}$.

[1964] In fact the first isomorphism $\pi_5(S^3) \cong \mathbb{Z}_2$ is a consequence of Theorem 155.10 and Theorem 159.9.

[1965] In fact Rokhlin [**Rok1986b**] initially thought that for $n \geq 5$ the groups $\pi_{n+3}(S^n)$ are isomorphic to $\mathbb{Z}_{12}$. The key to fixing the mistake is Rokhlin's Theorem 135.5 regarding signatures of certain 4-dimensional smooth manifolds.

160. Summary of homotopy groups of spheres

The results from last chapter conclude our calculations of homotopy groups of spheres. Throughout the course we employed a long and varied list of tools to compute homotopy groups of spheres:

(1) Covering theory, see page 1573.
(2) The Cellular Approximation Theorem 70.15, see Proposition 71.10.
(3) The Simplicial Approximation Theorem 94.8, see Corollary 94.10 and Exercise 94.6.
(4) Homology theory and the Hurewicz Theorem 85.5, see Corollary 85.6.
(5) The cup product, see Corollary 122.14.
(6) Steenrod operations, see Theorems 151.13 and 152.2.
(7) The long exact sequence of a fibration, see Theorem 155.10.
(8) The Thom-Pontryagin Theory, see the Freudenthal Suspension Theorem 158.6 and Theorem 159.1.

In the following we summarize the results we have obtained on homotopy groups of spheres:

(1) On page 1573 we saw that $\pi_n(S^1) = 0$ for $n \geq 2$.
(2) Proposition 71.10, or alternatively Exercise 94.6, says that for any $n \in \mathbb{N}$ we have $\pi_1(S^n) = \cdots = \pi_{n-1}(S^n) = 0$.
(3) In Corollary 94.10 we showed that the homotopy groups of spheres are countable.
(4) Corollary 85.6 (or alternatively by Corollary 157.12) we know that for any $n \in \mathbb{N}$ we have $\pi_n(S^n) \cong \mathbb{Z}$.
(5) By Theorem 155.10 (1) we know that for every $n \geq 3$ we have an isomorphism $\pi_n(S^3) \cong \pi_n(S^2)$. In particular, together with (4) we know that $\pi_3(S^2) \cong \mathbb{Z}$. An alternative proof of the fact that $\pi_3(S^2) \cong \mathbb{Z}$ is given by the combination of the Thom-Pontryagin Theorem 157.11 and Theorem 157.14.
(6) In Corollary 122.14, and alternatively in Proposition 157.23 we saw that given any even $n \in \mathbb{N}$ there exists an epimorphism $\pi_{2n-1}(S^n) \twoheadrightarrow \mathbb{Z}$.
(7) By Theorem 155.11 (1) we know that for every $n \geq 2$ we have an isomorphism $\pi_n(S^4) \cong \pi_n(S^7) \oplus \pi_{n-1}(S^3)$. Furthermore, by Theorem 155.11 (1) we know that for every $n \geq 2$ we have an isomorphism $\pi_n(S^8) \cong \pi_n(S^{15}) \oplus \pi_{n-1}(S^7)$.
(8) By the Freudenthal Suspension Theorem 158.6 we know that for $n = k + 1$ we have an epimorphism $\pi_{n+k}(S^n) \twoheadrightarrow \pi_{n+k+1}(S^{n+1})$ and we know that for $n > k + 1$ we have an isomorphism $\pi_{n+k}(S^n) \cong \pi_{n+k+1}(S^{n+1})$.
(9) By Theorem 155.11 (2) we know that $\pi_6(S^4) \cong \pi_5(S^3)$ and by Theorem 155.14 (3) we know that $\pi_{14}(S^8) \cong \pi_{13}(S^7)$.
(10) In Theorem 151.13 we proved the following three statements:
  (a) for any $n \geq 2$ the group $\pi_{n+1}(S^n)$ is non-trivial,
  (b) for any $n \geq 4$ the group $\pi_{n+3}(S^n)$ is non-trivial,
  (c) for any $n \geq 8$ the group $\pi_{n+7}(S^n)$ is non-trivial.
(11) By Theorem 159.1 we know that for every $n \geq 3$ we have $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$. This is a refinement of statement (10a). Note that it follows from this fact together with (5) that $\pi_4(S^2) \cong \mathbb{Z}_2$.
(12) In Theorem 152.2 we proved the following three statements:
  (a) for any $n \geq 2$ the group $\pi_{n+2}(S^n)$ is non-trivial,
  (b) for any $n \geq 4$ the group $\pi_{n+6}(S^n)$ is non-trivial,

(c) for any $n \geq 8$ the group $\pi_{n+14}(S^n)$ is non-trivial.

We recall that Serre's Theorem 86.17 says that all homotopy groups of spheres are finitely generated abelian groups. In the discussion above we saw that some of the homotopy groups of spheres are infinite.
The following theorem can be summarized as saying that we have picked up all elements of infinite order. In particular the theorem gives a complete answer to Question 122.16. This theorem can also be viewed as a strengthening of Serre's Theorem 86.17. In fact, the strengthening is also due to Jean-Pierre Serre.

Theorem 160.1.
(1) If n is odd, then $\pi_k(S^n)$ is finite for $k \geq n+1$.
(2) If n is even, then the following two statements hold:
  (a) The group $\pi_k(S^n)$ is finite for $k \geq n+1$ and $k \neq 2n-1$.
  (b) The group $\pi_{2n-1}(S^n)$ is isomorphic to the direct sum of $\mathbb{Z}$ with a finite group.

Proof. The theorem was first proved by Serre [**Ser1953**] using "spectral sequences". Expositions of the proof are also given in [**Hat**, Theorem 1.21] and [**Spa1995**, p. 515f]. ■

The following table, obtained from [**Tod1962**, Chapter XIV], shows the low-dimensional homotopy groups of low-dimensional spheres. The entries colored in blue have been proved in these lecture notes.

	π_1	π_2	π_3	π_4	π_5	π_6	π_7	π_8	π_9	π_{10}	π_{11}	π_{12}	π_{13}	π_{14}	π_{15}
S^1	$\mathbb{Z}$	0	0	0	0	0	0	0	0	0	0	0	0	0	0
S^2	0	$\mathbb{Z}$	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{12}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_3$	$\mathbb{Z}_{15}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^2$	$\mathbb{Z}_{12}\times\mathbb{Z}_2$	$\mathbb{Z}_{84}\times\mathbb{Z}_2^2$	$\mathbb{Z}_2^2$
S^3	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{12}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_3$	$\mathbb{Z}_{15}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^2$	$\mathbb{Z}_{12}\times\mathbb{Z}_2$	$\mathbb{Z}_{84}\times\mathbb{Z}_2^2$	$\mathbb{Z}_2^2$
S^4	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}\times\mathbb{Z}_{12}$	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^2$	$\mathbb{Z}_{24}\times\mathbb{Z}_3$	$\mathbb{Z}_{15}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^3$	$\mathbb{Z}_{120}\times\mathbb{Z}_{12}\times\mathbb{Z}_2$	$\mathbb{Z}_{84}\times\mathbb{Z}_2^5$
S^5	0	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{30}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^3$	$\mathbb{Z}_{72}\times\mathbb{Z}_2$
S^6	0	0	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_{60}$	$\mathbb{Z}_{24}\times\mathbb{Z}_2$	$\mathbb{Z}_2^3$
S^7	0	0	0	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}_{120}$	$\mathbb{Z}_2^3$
S^8	0	0	0	0	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}\times\mathbb{Z}_{120}$
S^9	0	0	0	0	0	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$

Note that we showed in Theorem 155.10 (1) that the second and the third row, starting with π_3, are the same.

Recall that the Freudenthal Suspension Theorem 158.6 says that for any $n, k \in \mathbb{N}_0$ with $n > k+1$ the suspension homomorphism $\pi_{n+k}(S^n) \to \pi_{n+k+1}(S^{n+1})$ is an isomorphism. Thus we see that the groups $\pi_{n+k}(S^n)$ "stabilize" as $n \to \infty$. It is therefore perhaps more instructive to shift in the above diagram the i-th row leftward by $i-1$ terms. This way the diagonal lines become vertical. In other words we consider the following diagram where

π_{n+k} is short for $\pi_{n+k}(S^n)$.

n	π_{n+0}	π_{n+1}	π_{n+2}	π_{n+3}	π_{n+4}	π_{n+5}	π_{n+6}	π_{n+7}	π_{n+8}	π_{n+9}	π_{n+10}
1	$\mathbb{Z}$	0	0	0	0	0	0	0	0	0	0
2	$\mathbb{Z}$	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{12}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_3$	$\mathbb{Z}_{15}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^2$
3	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{12}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_3$	$\mathbb{Z}_{15}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^2$	$\mathbb{Z}_{12}\times\mathbb{Z}_2$
4	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}\times\mathbb{Z}_{12}$	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^2$	$\mathbb{Z}_{24}\times\mathbb{Z}_3$	$\mathbb{Z}_{15}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^3$	$\mathbb{Z}_{120}\times\mathbb{Z}_{12}\times\mathbb{Z}_2$
5	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{30}$	$\mathbb{Z}_2$	$\mathbb{Z}_2^3$	$\mathbb{Z}_{72}\times\mathbb{Z}_2$
6	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_{60}$	$\mathbb{Z}_{24}\times\mathbb{Z}_2$	$\mathbb{Z}_2^3$	$\mathbb{Z}_8\times\mathbb{Z}_2\times\mathbb{Z}_9$
7	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}_{120}$	$\mathbb{Z}_2^3$	$\mathbb{Z}_2^4$	$\mathbb{Z}_8\times\mathbb{Z}_3\times\mathbb{Z}_2$
8	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}\times\mathbb{Z}_{120}$	$\mathbb{Z}_2^4$	$\mathbb{Z}_2^5$	$\mathbb{Z}_8^2\times\mathbb{Z}_2\times\mathbb{Z}_3^2$
9	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}_{240}$	$\mathbb{Z}_2^3$	$\mathbb{Z}_2^4$	$\mathbb{Z}_8\times\mathbb{Z}_6$
10	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}_{240}$	$\mathbb{Z}_2^2$	$\mathbb{Z}\times\mathbb{Z}_2^3$	$\mathbb{Z}_4\times\mathbb{Z}_6$
11	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}_{240}$	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^3$	$\mathbb{Z}_2^2\times\mathbb{Z}_3$
11	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_{24}$	0	0	$\mathbb{Z}_2$	$\mathbb{Z}_{240}$	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^3$	$\mathbb{Z}_2\times\mathbb{Z}_3$

Here for convenience we colored the "diagonal" $\pi_n(S^{2n})$ in red, since the Freudenthal Suspension Theorem 158.6 implies that below the diagonal the groups on each column are the same.
We conclude this discussion of the precise homotopy groups of spheres with the following sobering fact:

Fact 160.2. There is no sphere S^n with $n \geq 2$ for which we[1966] know the isomorphism types of all homotopy groups.

As we had mentioned above, the Freudenthal Suspension Theorem 158.6 says that homotopy groups of spheres "stabilize". This leads us to the following definition.

Definition. Let $k \in \mathbb{N}_0$. We refer to[1967]

$$\pi_k^s := \varinjlim \pi_{n+k}(S^n)$$

as the k-th stable homotopy group of spheres.[1968]

Note that it follows from Theorem 160.1 that for any $k \geq 1$ the k-th stable homotopy group π_k^s is finite. The following table obtained from [**Wiki**] gives the stable homotopy groups up to $k = 63$. It seems like 64 is the first dimension for which we do not know the

[1966]Here "we" is defined as members of our species.
[1967]Given $k \in \mathbb{N}_0$ the groups $\{\pi_{n+k}(S^n)\}_{n\in\mathbb{N}}$ together with the suspension homomorphisms form a direct system. Thus it makes sense to consider the direct limit.
[1968]Note that for any n, k with $n > k + 1$ the Freudenthal Suspension Theorem 158.6, together with Lemma 111.2 (4) and the Limit-over-Subset Lemma 111.3, says that the natural map $\pi_{n+k}(S^n) \to \pi_k^s$ is an isomorphism.

corresponding stable homotopy groups.

π^s_{48+n}	$\mathbb{Z}_4\,\mathbb{Z}_2^4$	$\mathbb{Z}_2^2\,\mathbb{Z}_3$	$\mathbb{Z}_2^3\,\mathbb{Z}_3$	$\mathbb{Z}_4\,\mathbb{Z}_2^2\,\mathbb{Z}_{8\cdot 3}$	$\mathbb{Z}_2^3\,\mathbb{Z}_3$	$\mathbb{Z}_2^4$	$\mathbb{Z}_4\,\mathbb{Z}_2$	$\mathbb{Z}_3\,\mathbb{Z}_{16\cdot 3\cdot 5\cdot 29}$
π^s_{56+n}	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^4$	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^2\,\mathbb{Z}_{8\cdot 9\cdot 7\cdot 11\cdot 31}$	$\mathbb{Z}_4$	0	$\mathbb{Z}_2^2\,\mathbb{Z}_{4\cdot 3}$	$\mathbb{Z}_2^3\,\mathbb{Z}_{128\cdot 3\cdot 5\cdot 17}$

This concludes our discussion of the homotopy groups of spheres. We refer to [**May1999b, WX2010, IWX2001, Wiki**] and [**Hat2002**, Chapter 4] for a more detailed discussion.

Exercises for Chapter 160.

Exercise 160.1.

(a) Show that $\pi_4(\mathbb{HP}^\infty) \cong \mathbb{Z}$.
(b) Show that $\pi_n(\mathbb{HP}^\infty)$ is finite for $n \neq 4$.
(c) Show that $\pi_5(\mathbb{HP}^\infty) \cong \mathbb{Z}_2$.

Remark. Use the Hopf-Bundle Proposition 155.9 together with the results of this chapter.

161. The CW-Approximation Theorem

In the following chapters we will work a lot with CW-complexes. In this chapter we will first prove a hotchpotch of results on CW-complexes. Afterwards we will use these results to prove the CW-Approximation Theorem 161.8 which often allows us to replace a topological space X by a CW-complex that is "weakly homotopy equivalent" to X. The study of "weak homotopy equivalences" will also play an essential role in the next chapter, when we prove the Whitehead Theorem 162.1.

161.1. **Modifying CW-complexes.** As mentioned in the beginning of the chapter, CW-complexes will play a major role in this and the subsequent chapters. Thus, before we start out with proving the enticing theorems mentioned above, we intend to improve our understanding of CW-complexes.
The following, fairly self-evident convention will be in use in the coming chapters.

Convention.

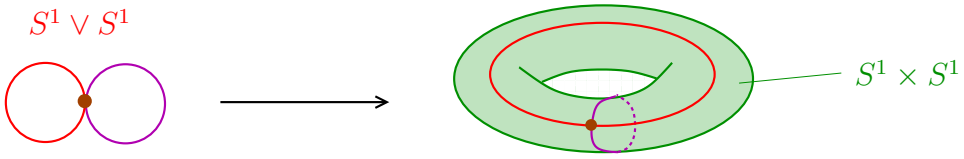
(1) Given $n \in \mathbb{N}_0$ we write $* = (0, \dots, 0, 1) \in S^n$. We view S^n as a CW-complex with one 0-cell $\{*\}$ and one n-cell.
(2) We always form any wedge of spheres $\bigvee_{i \in I} S_i^{n_i}$ by identifying the points $*$. By the CW-Complex Construction Lemma 68.32 (4) we can view the wedge $\bigvee_{i \in I} S_i^{n_i}$ as a CW-complex in the obvious way, i.e. we have one 0-cell $\{*\}$ and for each $i \in I$ we have one n_i-cell.

Before we do anything else we will introduce the following definition which will accompany us in the near future.

Definition. Let $f\colon X \to Y$ be a map between topological spaces.

(1) We say the map $f\colon X \to Y$ is 0-connected if $f_*\colon \pi_0(X) \to \pi_0(Y)$ is a surjection, in other words, each path-component of Y contains a point in $f(X)$.
(2) Let $k \in \mathbb{N}$. We say the map $f\colon X \to Y$ is k-connected if the following two conditions are satisfied:
   (a) the map $f_*\colon \pi_0(X) \to \pi_0(Y)$ is a bijection,
   (b) for every $x_0 \in X$ the induced map

$$f_*\colon \pi_i(X, x_0) \to \pi_i(Y, f(x_0)) \text{ is an } \begin{cases} \text{isomorphism for } i = 1, \dots, k-1, \\ \text{epimorphism for } i = k. \end{cases}$$



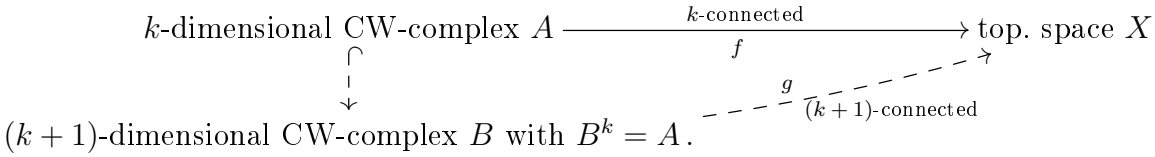
Remark. Let $f\colon X \to Y$ be a map between path-connected topological spaces and let $k \in \mathbb{N}$. It follows from the Change-of-Base Point Proposition 71.5 that to verify that f is k-connected it suffices to check the Condition (2b) for a single base point $x_0 \in X$.

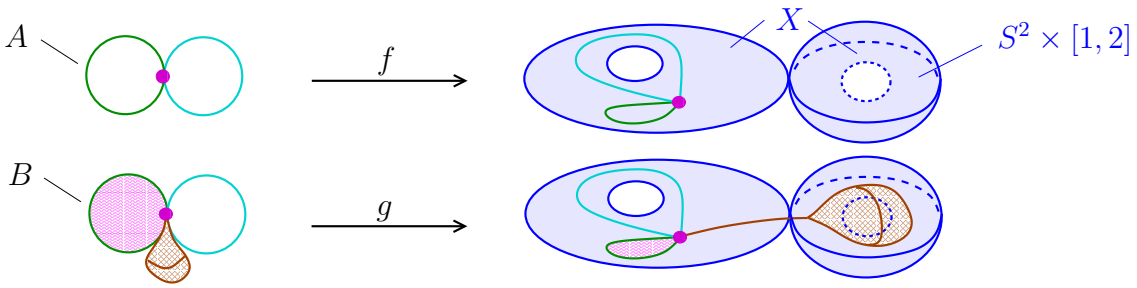
Examples.

(1) The map $f\colon S^1 \vee S^1 \to S^1 \times S^1$ that is illustrated in the figure below@ is easily seen to be 1-connected, but it is not 2-connected.
(2) Let X be a CW-complex and let $k \in \mathbb{N}_0$. Corollary 153.10 says that the inclusion $X^k \to X$ of the k-skeleton[1969] is a k-connected map. In fact, the previous example

[1969]Since we did not work with CW-complexes for a while we remind the reader that for a CW-complex X and $l \in \mathbb{N}_0$ we denote by X^l the l-skeleton i.e. the union of all cells of dimension $\leq l$.

is of such type if we consider $X = S^1 \times S^1$ with the usual CW-structure, where the 1-skeleton is precisely $S^1 \vee S^1$.





The following is the main technical result which underpins many of the later results.

Proposition 161.1. (Higher Connected Map Proposition) Let $k \in \mathbb{N}_0$, let A be a CW-complex and let $f\colon A \to X$ be a map to a topological space. If the map $f\colon A \to X$ is k-connected, then there exists CW-complex B and a map $g\colon B \to X$ such that the following statements hold:

(1) A is a subcomplex of B,
(2) the only extra cells of B are $(k+1)$-dimensional, in particular the k-skeleton of B equals the k-skeleton of A,
(3) the restriction of g to A equals f,
(4) the map $g\colon B \to X$ is $(k+1)$-connected.

Remark. In most applications of the Higher Connected Map Proposition 161.1 we start out with a k-dimensional CW-complex. In this case we obtain a $(k+1)$-dimensional CW-complex such that k-skeleton equals A and such that we can complete the map $f\colon A \to X$ to the following diagram:

Before we turn to the proof of the Higher Connected Map Proposition 161.1 let us first formulate and prove the following corollary.

Corollary 161.2. Let A be a CW-complex and let $f\colon A \to X$ be a map to a topological space. There exists a CW-complex B and a map $g\colon B \to X$ such that the following statements hold:

(1) A is a subcomplex of B,
(2) the restriction of g to A equals f,
(3) the map $g\colon B \to X$ is k-connected for every $k \in \mathbb{N}_0$.

Proof of Corollary 161.2. Let A be a CW-complex and let $f\colon A \to X$ be a map to a topological space. Without loss of generality we can and will assume that A and X are 0-connected. We set $B_0 := A$ and $g_0 := f$. We apply the Higher Connected Map Proposition 161.1 to B_0 and g_0 and iterate this procedure to obtain a sequence of CW-complexes $\{B_n\}_{n\in\mathbb{N}_0}$ and maps $\{g_n\colon B_n \to X\}_{n\in\mathbb{N}_0}$ such that for each $n \in \mathbb{N}$ the following statements hold:

(a) A is a subcomplex of B_n and B_{n-1} is a subcomplex of B_n,
(b) the only cells of B_n that do not lie in B_{n-1} are n-dimensional,
(c) the restriction of g_n to A equals f,
(d) the map $g_n\colon B_n \to X$ is $(n+1)$-connected.

We set $B := \varinjlim B_n$ and we equip with the CW-structure given by the Ascending Union-CW Complex Lemma 68.34. Furthermore we denote by $g\colon B \to X$ the map that is uniquely determined by the property that for each $n \in \mathbb{N}_0$ we have $g|_{B_n} = g_n$. We claim that (B, g) have the desired properties. In fact (1) and (2) are clear by construction. Now let $k \in \mathbb{N}_0$. For a fixed base point in B_{k+1} we consider the following commutative diagram

$$\begin{array}{ccccccc}
\pi_k(B) & \xleftarrow{\cong} & \pi_k((k+1)\text{-skeleton of } B) & \xrightarrow{\mathrm{id}} & \pi_k((k+1)\text{-skeleton of } B_{k+1}) & \xrightarrow{=} & \pi_k(B_{k+1}). \\
& {\scriptstyle g_*}\searrow & \downarrow{\scriptstyle g_*} & \swarrow{\scriptstyle g_*} & & {\scriptstyle \cong}\searrow{\scriptstyle g_*} & \\
& & \pi_k(X) & & & &
\end{array}$$

Note that by construction the $(k+1)$-skeleton of B equals the $(k+1)$-skeleton of B_{k+1}, thus the middle map is indeed the identity. It follows from the CW-Skeleton-π_n-Proposition 71.9 (1) that the outer horizontal maps are isomorphisms. Finally note that $g|_{B^{k+1}} = g_{k+1}$, which induces an isomorphism on π_k. Thus the left diagonal map is, as promised, an isomorphism. Keeping in mind the remark on page 3396 we see that the map $g\colon B \to X$ is k-connected for every $k \in \mathbb{N}_0$. ■

Now we turn to the proof of the Higher Connected Map Proposition 161.1.

Proof of the Higher Connected Map Proposition 161.1. To simplify the discussion we only deal with the case that A and X are 0-connected. We leave it to the reader to handle the case that at least one of A and Y is not 0-connected. In particular we will not deal with the case $k = 0$.

So in the following, let $k \in \mathbb{N}$, let A be a 0-connected CW-complex and let $f\colon A \to X$ be a k-connected map to a path-connected topological space. We pick a base point a_0 in the 0-skeleton of A. We write $x_0 = f(a_0)$. We note that in general the map $f\colon A \to X$ fails to be $(k+1)$-connected for the following two reasons:[1970]

(a) the map $\pi_k(A, a_0) \to \pi_k(X, x_0)$ is not a monomorphism,
(b) the map $\pi_{k+1}(A, a_0) \to \pi_{k+1}(X, x_0)$ is not an epimorphism.

[1970]Here and throughout the proof we will implicitly use the remark on page 3396 regarding k-connected maps.

Both issues will be fixed by attaching $(k+1)$-cells to A and by extending f to the $(k+1)$-cells in a suitable way. More precisely, we construct the CW-complex B and a map $g\colon B \to X$ as follows:

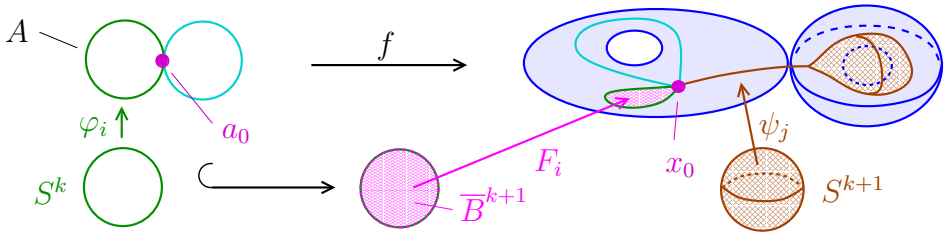
(a) As usual we denote by A^k the k-skeleton of A. Note that by the CW-Skeleton-π_n-Proposition 71.9 the map $\pi_k(A^k, x_0) \to \pi_k(A, a_0)$ is an epimorphism. This implies that we can pick a family $\{\varphi_i\colon (S^k, *) \to (A^k, a_0)\}_{i\in I}$ of maps that *go into the k-skeleton of A*, and that represent a generating set for $\ker(f_*\colon \pi_k(A, a_0) \to \pi_k(X, x_0))$.[1971] Note that by definition each map $f \circ \varphi_i\colon (S^k, *) \to (X, x_0)$ represents the trivial element in $\pi_k(X, x_0)$. Thus it follows from the Trivial-in-π_n-Lemma 71.4 that for each $i \in I$ where exists a map $F_i\colon \overline{B}^{k+1} \to X$ such that $F_i|S^k = f \circ \varphi_i$.

(b) Next we pick a family $\{\psi_j\colon (S^{k+1}, *) \to (X, x_0)\}_{j\in J}$ of maps that represent a generating set for $\pi_{k+1}(X, x_0)$.

(c) We set

$$B = \Big(A \sqcup \bigsqcup_{i\in I} \overline{B}_i^{k+1}\Big)/\!\sim \;\vee \bigvee_{j\in J} S_j^{k+1} \quad \text{with } \varphi_i(s) \sim s \text{ for } s \in S_i^k = \partial\overline{B}_i^{k+1}.$$

Note that B is a CW-complex in the following sense:



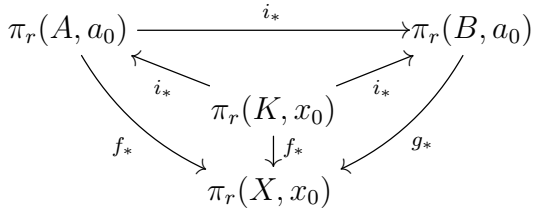
(i) We start out with the CW-complex that is given by the k-skeleton of A.

(ii) We attach one $(k+1)$-cell for each $i \in I$ with attaching map given by φ_i.

(iii) Afterwards we form the wedge with $\bigvee_{j\in J} S_j^{k+1}$. In other words, we attach one $(k+1)$-cell for each $j \in J$ where the attaching map is given by sending all points in $S_j^k = \partial\overline{B}_j^{k+1}$ to a_0.[1972]

(iv) Finally we attach the cells of A of dimension $\geq k+1$ as usual to the above.

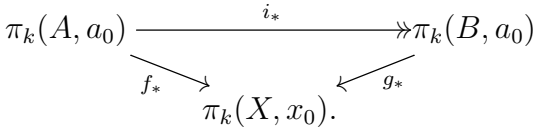
(d) We extend the original map $f\colon A \to X$ to a map $g\colon B \to X$ by defining it to be F_i on each $\overline{B}_i^{k+1}$ and by defining it to be ψ_j on each S_j^{k+1}. It follows easily from the CW-Complex Pasting Lemma 68.20 that this map $g\colon B \to X$ is indeed continuous.



By construction A is a subcomplex of B and the only extra cells of B are $(k+1)$-dimensional. Furthermore, by construction the restriction of g to A equals f. Thus it remains to show

[1971] A generating set for the kernel is for example given by taking all elements in the kernel.

[1972] Here we implicitly use the convention from page 3396 to view the wedge of spheres, and thus also B, as a CW-complex.



that the map $g\colon B \to X$ is $(k+1)$-connected. We denote by $K := A^k = B^k$ the k-skeleton of A which equals by construction the k-skeleton of B.

(a) First we show that the map $g\colon B \to X$ is k-connected. To do so we note that for any $r \in \mathbb{N}_0$ we have the following commutative diagram

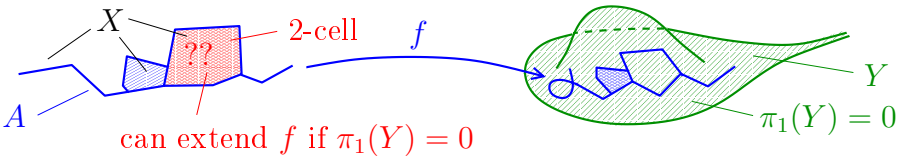
where i always denotes an inclusion map. Since K is the k-skeleton of A and B we obtain from Corollary 153.10 that the maps $K \to A$ and $K \to B$ are k-connected. By hypothesis the map $f\colon A \to X$ is k-connected. It follows almost immediately from this discussion and the commutative diagram that $g\colon B \to X$ is also k-connected. Note that this discussion also implies that the inclusion $A \to B$ is k-connected.

(b) Next we show that $g_*\colon \pi_k(B, a_0) \to \pi_k(X, x_0)$ is a monomorphism. Similar to (a) we consider the following commutative diagram:

As we pointed out in (a), we know that the top map $i_*\colon \pi_k(A, a_0) \to \pi_k(B, a_0)$ is an epimorphism. Thus it suffices to show that

$$\ker(f_*\colon \pi_k(A, a_0) \to \pi_k(X, x_0)) \;\subset\; \ker(i_*\colon \pi_k(A, a_0) \to \pi_k(B, a_0)).$$

But this inclusion holds basically by definition of B. More precisely, it follows from the definition of B that for each $i \in I$ the map $\varphi_i\colon (S^k, *) \to (A, a_0)$ extends to a map $(\overline{B}^{k+1}, *) \to (B, a_0)$. But by the Trivial-in-$\pi_n$-Lemma 71.4 we know that this implies that the maps $\varphi_i\colon (S^k, *) \to (A, a_0)$ represent elements in the kernel of i_*. On other hand, by definition, these maps represent a generating set for $\ker(f_*\colon \pi_k(A, a_0) \to \pi_k(X, x_0))$. The desired inclusion of kernels is now a consequence of Lemma 51.3.



(c) It remains to show that the map $g_*\colon \pi_{k+1}(B, a_0) \to \pi_{k+1}(X, x_0)$ is an epimorphism. In fact this is true almost by definition of B. More precisely, given $j \in J$ we have $g_*([\mathrm{id}_{S^{k+1}_j}] = [g|_{S^{k+1}_j}] = [\psi_j]$. This shows that the classes $\{[\psi_j]\}_{j\in J}$ lie in the image of g_*. But since these classes generate $\pi_{k+1}(X, x_0)$ we obtain from Lemma 51.3 that g_* is an epimorphism. ∎

The following lemma gives a simple but useful criterion for extending maps from a subcomplex to the whole CW-complex.

Lemma 161.3. Let (X, A) be a pair of CW-complexes and let $f\colon A \to Y$ be a map to a path-connected topological space. Suppose the following condition holds:

(∗) For every $n \in \mathbb{N}$ such that $X \backslash A$ contains an n-cell we have the equality[1973] $\pi_{n-1}(Y) = 0$.

Then f can be extended to a map $\widetilde{f}\colon X \to Y$. This statement is illustrated in the figure below.

Proof. We start out with the following claim.

Claim. Given any $n \in \mathbb{Z}_{\geq -1}$ we can extend $f\colon A \to Y$ to a map $A \cup X^n \to Y$.

Proof. We prove the claim by induction on $n \in \mathbb{Z}_{\geq -1}$. For $n = -1$ there is nothing to prove. So suppose the statement holds for some $n \in \mathbb{Z}_{n \geq -1}$. By the slightest of all abuses we denote the given extension $A \cup X^n \to Z$ again by f. We denote by $\{\Phi_i\colon S^n \to X^n\}_{i\in I}$ the family of the attaching maps of all $(n+1)$-dimensional cells of X that are not contained in A. If $I = \varnothing$, then there is nothing to do. On the other hand if $I \neq \varnothing$, then we know by the hypothesis $(*)$ that $\pi_n(Y) = 0$. It follows from the Trivial-in-π_n-Lemma 71.4 that for each $i \in I$ there exists a map $g_i\colon \overline{B}^{n+1} \to Y$ with $g_i|_{S^n} = f \circ \Phi_i\colon S^n \to Y$. We consider the following map:

$$\begin{array}{rcl} A \cup X^{n+1} = \Big((A \cup X^n) \sqcup \bigsqcup\limits_{i\in I} \overline{B}_i^{n+1}\Big)/\!\sim & \to & Y \\ [P] & \mapsto & \begin{cases} f(P), & \text{if } P \in A \cup X^n, \\ g_i(P), & \text{if } P \in \overline{B}_i^{n+1}. \end{cases} \end{array}$$

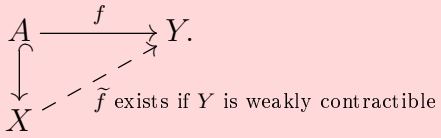
It follows from $g_i|_{S^n} = f \circ \Phi_i$ that this map is well-defined. Furthermore we obtain from the Topological-Quotient Proposition 5.15 (1b) that the map is continuous. ⊞

The sequence of maps from the claim defines a map $\widetilde{f}\colon X = A \cup X = \bigcup\limits_{n\in\mathbb{N}_0} (A \cup X^n) \to Y$. Since the map is continuous on each $A \cup X^n$ we obtain from the CW-Complex Pasting Lemma 68.20 that $\widetilde{f}$ is also continuous. It now clear that this map $\widetilde{f}$ is the desired extension. ■

We conclude this section with the formulation of a special case Lemma 161.3.

Definition. We say a topological space Y is weakly contractible if[1974] $\pi_n(Y) = 0$ for all $n \in \mathbb{N}_0$.

Example. By Corollary 71.12 we know that the infinite-dimensional sphere S^∞ is weakly contractible.



The following corollary is an immediate consequence of Lemma 161.3.

Corollary 161.4. (Weakly Contractible Domain Corollary) Let (X, A) be a pair of CW-complexes and let $f\colon A \to Y$ be a map to a topological space. If Y is weakly contractible, then f can be extended to a map $\widetilde{f}\colon X \to Y$. In other words, we have the

[1973] Since Y is path-connected we know by the Change-of-Base Point Proposition 71.5 that we do not need to worry about base points.

[1974] Recall that by the definition on page 167 the statement $\pi_0(Y) = 0$ means that Y is *non-empty* and path-connected.

following situation

161.2. **Weak homotopy equivalences and the CW-Approximation Theorem.** The definition of a k-connected map between topological spaces naturally leads to the following definition which we had encountered once before on page 2062.

Definition. We say that a map $f\colon X \to Y$ between topological spaces is a weak homotopy equivalence if f is k-connected for all $k \in \mathbb{N}_0$.

The following lemma gives in particular a practical approach to showing that a given map is a weak homotopy equivalence.

Lemma 161.5. (Weak Homotopy Equivalence Criteria Lemma) Let $f\colon X \to Y$ be a map between topological spaces.

(1) If f is a homotopy equivalence, then it is also a weak homotopy equivalence.
(2) If $g\colon X \to Y$ is a map that is homotopic to f, then

$$f \text{ is a weak homotopy equivalence} \iff g \text{ is a weak homotopy equivalence}$$

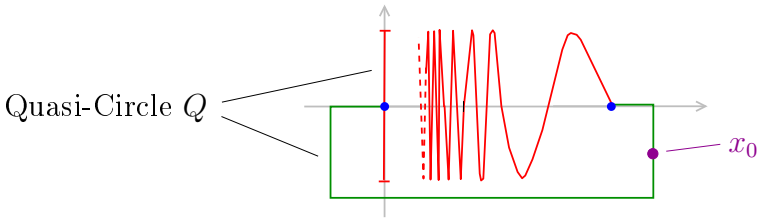
(3) If X and Y are path-connected, then the following holds:

$$f \text{ is a weak homotopy equivalence} \iff \begin{array}{c}\text{there exists an } x_0 \in X \text{ such that} \\ \text{for every } k \in \mathbb{N} \text{ the induced map} \\ f_*\colon \pi_k(X, x_0) \to \pi_k(Y, f(x_0)) \\ \text{is an isomorphism.}\end{array}$$

Proof.

(1) This statement is an immediate consequence of the Homotopy-π_n-Proposition 71.7 (2).
(2) This statement follows immediately from the Homotopy-π_n-Proposition 71.7 (1).
(3) This statement follows easily from the definitions, the fact that X and Y are path-connected and the Change-of-Base Point Proposition 86.9 (3). ■

As we just saw in the Weak Homotopy Equivalence Criteria Lemma 161.5, a homotopy equivalence is also a weak homotopy equivalence. But the following example shows that in general the converse does not hold.



Example. Let

$$S := \left\{(0, y) \,\middle|\, y \in [-1, 1]\right\} \cup \left\{(x, \sin(\tfrac{1}{x})) \,\middle|\, x \in (0, \tfrac{1}{\pi}]\right\} \subset \mathbb{R}^2$$

be the "Topologist's Sine Curve" from page 164. We turn the Topologist's Sine curve into the *Quasi-Circle* Q by connecting the point $(0, 0)$ with $(\frac{1}{\pi}, 0)$ via the green curve shown in the figure below. We make the following observations:

(1) One can easily show that the quasi-circle is path-connected, i.e. $\pi_0(Q) = 0$.
(2) In Exercise 2.48 we showed that the Topologist's Sine Curve is not path-connected. As we saw in Exercise 71.9, this fact easily implies that all homotopy groups $\pi_n(Q)$, $n \geq 1$ are zero.

(3) Pick $x_0 \in Q$. It follows from (1) and (2) that the inclusion $i\colon \{x_0\} \to Q$ is a weak homotopy equivalence.
(4) In Exercise 15.14 we showed that Q is not contractible.[1975] By the Contractibility Criterion Lemma 15.2 this implies that the inclusion i is not a homotopy equivalence.

We conclude this discussion of weak homotopies with the following proposition which relates weak homotopy equivalences to induced maps on homology groups.

Proposition 161.6. (Weak Homotopy-vs-Homology Isomorphisms Proposition) Let $f\colon X \to Y$ be a map between topological spaces.

(1) If f is a weak homotopy equivalence, then for any abelian group G and any $n \in \mathbb{N}_0$ the induced maps $f_*\colon \mathrm{H}_n(X;G) \to \mathrm{H}_n(Y;G)$ and $f^*\colon \mathrm{H}^n(Y;G) \to \mathrm{H}^n(X;G)$ are isomorphisms.
(2) If X and Y are simply connected and if $f_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y)$ is an isomorphism for every $n \geq 2$, then f is a weak homotopy equivalence.

In fact we can basically generalize (2) to the following less readable statement:

(2′) Suppose the following conditions are satisfied:
  (a) X and Y are both path-connected, both are locally path-connected and both are semi-locally simply connected. (As discussed in Corollary 61.11 this means that both topological spaces admit universal coverings.)
  (b) For some $x \in X$ the induced map $f_*\colon \pi_1(X,x)) \to \pi_1(Y, f(x))$ is an isomorphism.

  We write $y = f(x)$ and we denote by $p\colon (\widetilde{X},\widetilde{x}) \to (X,x))$ and $q\colon (\widetilde{Y},\widetilde{y}) \to (Y,y)$ the universal covers of (X,x) and (Y,y). By (a) and the Map Lifting Criterion 61.2 we know that the map f lifts to a map $\widetilde{f}\colon (\widetilde{X},\widetilde{x}) \to (\widetilde{Y},\widetilde{y})$. We also demand the following:
  (c) The map $\widetilde{f}_*\colon \mathrm{H}_n(\widetilde{X}) \to \mathrm{H}_n(\widetilde{Y})$ is an isomorphism for every $n \geq 2$.

  Then f is a weak homotopy equivalence.

Proof.

[1975] The argument we provided in Exercise 15.14 is rather ad hoc. There are several other approaches. For example one can use the Čech cohomology groups $\check{\mathrm{H}}(X;\mathbb{Z})$ of a topological space X, which are for example defined in [**Dol1980**, Chapter VIII.6]. Note that

$$\underset{\text{by the Duality Theorem [Dol1980, Theorem VIII.7.2]}}{\check{\mathrm{H}}(Q;\mathbb{Z}) \cong \widetilde{\mathrm{H}}_0(\mathbb{R}^2 \setminus Q;\mathbb{Z})} \underset{\text{by Exercise 43.11 we know that } \mathbb{R}^2 \setminus Q \text{ has two path-components}}{\cong \mathbb{Z} \neq 0 \cong \mathrm{H}^1(\{*\};\mathbb{Z})} \underset{\text{by Proposition VIII.6.12 in [Dol1980]}}{\cong \check{\mathrm{H}}^1(\{*\};\mathbb{Z})}.$$

By [**Dol1980**, Proposition VIII.6.6] the Čech cohomology groups are homotopy invariants. Thus the above argument shows that Q and $\{*\}$ are not homotopy equivalent. A more direct calculation of $\check{\mathrm{H}}(Q;\mathbb{Z}) \cong \mathbb{Z}$ is provided in [**MillH2021**, Chapter 34].

(1) Let $f\colon X \to Y$ be a weak homotopy equivalence. It follows easily from Lemmas 72.14 and Lemmas 108.14 that we can assume, without loss of generality, that X and Y are path-connected. Let $x_0 \in X$. By our hypothesis we know that the map $f_*\colon \pi_n(X, x_0) \to \pi_n(Y, f(x_0))$ is an isomorphism for all $n \in \mathbb{N}_0$. It follows from Theorem 153.14 (1), which in turn is a consequence of the Relative Hurewicz Theorem 153.13, that the induced maps $f_*\colon \mathrm{H}_n(X;\mathbb{Z}) \to \mathrm{H}_n(Y;\mathbb{Z})$ are isomorphisms for all $n \in \mathbb{N}_0$. The desired statement is now a consequence of Corollary 108.20.
(2) This statement is just a reformulation of Theorem 153.14 (2).
(3) By (b) together with the Weak Homotopy Equivalence Criteria Lemma 161.5 it remains to show that $f_*\colon \pi_n(X, x)) \to \pi_n(Y, y)$ is an isomorphism for every $n \geq 2$. Now let $n \geq 2$. We consider the following diagram:

$$\begin{array}{ccc} \pi_n(\widetilde{X}, \widetilde{x}) & \xrightarrow{\widetilde{f}_*} & \pi_n(\widetilde{Y}, \widetilde{y}) \\ {\scriptstyle p_*}\downarrow & & \downarrow{\scriptstyle q_*} \\ \pi_n(X, x) & \xrightarrow{f_*} & \pi_n(Y, y). \end{array}$$

We make the following observations:
(a) The diagram commutes by definition of $\widetilde{f}$.
(b) It follows from the Coverings-π_n-Proposition 71.13 that the vertical maps are isomorphisms.
(c) By (2) and by our hypothesis (c) we know that $\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}$ is a weak homotopy equivalence. This implies that the top horizontal map is an isomorphism.

It follows from the above that the bottom horizontal map is an isomorphism. ■

In the remainder of this section we will study CW-approximations of topological spaces.

Definition. Let X be a topological space. A CW-approximation is a CW-complex Z together with a weak homotopy equivalence $f\colon Z \to X$.

Example. Let X be the quasi-circle. As we had just discussed, the inclusion of the CW-complex $\{x_0\}$, consisting of a single 0-cell, into the quasi-circle X is a CW-approximation of the quasi-circle X.

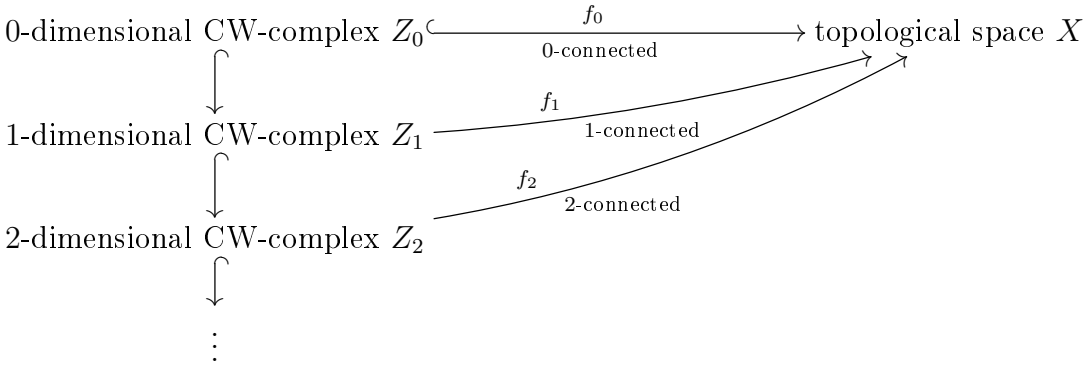
Before we state a general theorem we turn to the delicate topic of products of CW-complexes. More precisely, if X and Y are CW-complex with only countably many cells, then it follows from Proposition 68.23 that the product $X \times Y$ has a product CW-structure. But, as we pointed out in Lemma 68.24, in general this is not true for arbitrary CW-complexes. This leads us to the following lemma.

Lemma 161.7. Let X and Y be two CW-complexes. We define the topological space $X \otimes Y$, whose underlying *set* is the product $X \times Y$, as on page 1500. The identity map $\mathrm{id}\colon X \otimes Y \to X \times Y$ is a CW-approximation.

Proof. By Proposition 68.23 we know that $X \otimes Y$ is a CW-complex and we know that the identity map $\mathrm{id}\colon X \otimes Y \to X \times Y$ is continuous. In Proposition 68.26 we showed that the induced maps on fundamental groups are isomorphisms. Basically the same argument, with the obvious extension of Lemma 68.27 to higher dimensions, shows that the map $\mathrm{id}\colon X \otimes Y \to X \times Y$ is a weak homotopy equivalence. ■

The following theorem says that CW-approximations always exist.

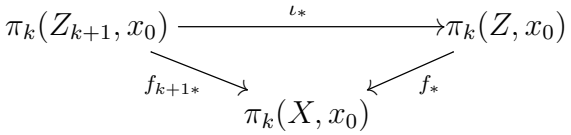
Theorem 161.8. (CW-Approximation Theorem)



(1) Every topological space X admits a CW-approximation $f\colon Z \to X$.
(2) Let $k \in \mathbb{N}_0$. If X is a k-connected space, then there exists a CW-approximation $f\colon Z \to X$ such that Z has a single 0-cell and such that Z has no cells in dimensions $1, \ldots, k$.

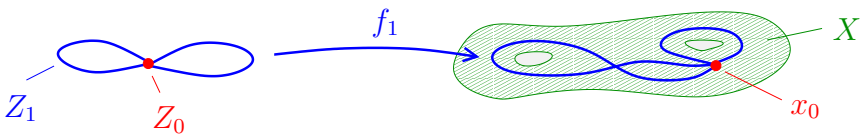
In both cases, given a point $x_0 \in X$ we can find f and $z_0 \in Z^0$ such that $f(z_0) = x_0$.

Proof of the CW-Approximation Theorem 161.8. Let X be a topological space.



(1) We need to show that X admits a CW-approximation. By considering each path-component of X separately we can assume that X is path-connected.

Thus let X be a path-connected topological space. We pick a point $x_0 \in X$. We set $Z_0 = \{x_0\}$ and we define $f_0\colon Z_0 \to X$ as the inclusion map. By iteratively appealing to the Higher Connected Map Proposition 161.1 we obtain the following commutative diagram

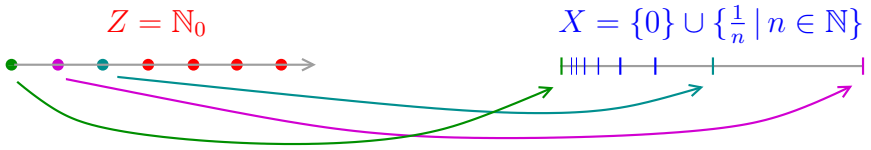


such that the $(k-1)$-skeleton of each Z_k equals Z_{k-1}. We set $Z = \bigcup_{k \in \mathbb{N}_0} Z_k$ and we define $f\colon Z \to X$ in the obvious way. Note that by construction Z is a CW-complex such that for each $k \in \mathbb{N}_0$ the k-skeleton is given by Z_k. Furthermore it follows from the CW-Complex Pasting Lemma 68.20 that f is continuous.

It remains to show that $f\colon Z \to X$ is indeed a weak homotopy equivalence. So let $k \in \mathbb{N}_0$. We consider the following commutative diagram

where $\iota\colon Z_{k+1} \to Z$ denotes the inclusion map. The left-hand diagonal map is an isomorphism by construction of $f_{k+1}\colon Z_{k+1} \to X$. Furthermore the top horizontal map is an isomorphism by the CW-Skeleton-π_n-Proposition 71.9 and the fact that Z_{k+1} is the $(k+1)$-skeleton of Z. We deduce from the commutative diagram that the right-hand diagonal map is also an isomorphism.

(2) Let $k \in \mathbb{N}_0$. If X is k-connected, then in the proof given in (1) we can start out with the CW-complexes $\{x_0\} = Z_0 = Z_1 = \cdots = Z_k$ and where $f_0 = f_1 = \cdots = f_k$ are the inclusion maps. Only beginning with f_{k+1} do we appeal to the Higher Connected Map Proposition 161.1 to provide the further CW-complexes Z_j and maps $f_j\colon Z_j \to X$.

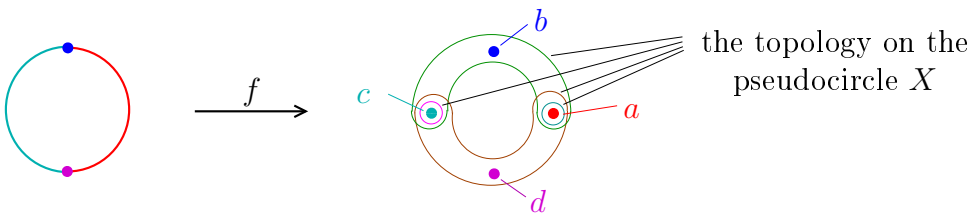


For the remainder of the proof of (2) we now proceed as in (1). Since the k-skeleton of $Z = \bigcup_{k\in\mathbb{N}_0} Z_k$ equals $Z_k = \{x_0\}$ we see that Z has the desired properties. ■

Examples.

(1) We consider the topological space $X = \{0\} \cup \{\frac{1}{n} \,|\, n \in \mathbb{N}\} \subset \mathbb{R}$ equipped with the subspace topology coming from $\mathbb{R}$. Note that X is not a CW-complex.[1976] Furthermore we consider $Z = \mathbb{N}_0 \subset \mathbb{R}$ with the discrete topology. This is a 0-dimensional CW-complex and the map

$$\begin{array}{rcl} f\colon Z = \mathbb{N}_0 & \to & X = \{0\} \cup \{\frac{1}{n} \,|\, n \in \mathbb{N}\} \subset \mathbb{R} \\ n & \mapsto & \begin{cases} 0, & \text{if } n = 0, \\ \frac{1}{n}, & \text{otherwise} \end{cases} \end{array}$$



is easily seen[1977] to be a weak homotopy equivalence. Thus $f\colon Z \to X$ is a CW-approximation. We refer to the figure below for an illustration.

(2) We consider the pseudocircle that we introduced on page 141. Recall that the pseudocircle is the set $X = \{a, b, c, d\}$ where the topology is given by the set

$$\mathcal{T} \;:=\; \{\varnothing, \{a\}, \{c\}, \{a, c\}, \{a, b, c\}, \{a, c, d\}, X\}.$$

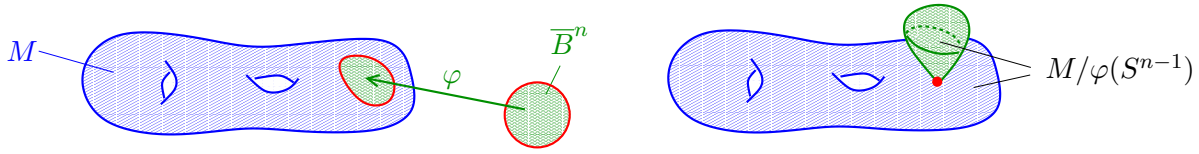
On page 141 we gave an explicit map $f\colon S^1 \to X$ that is also illustrated in the figure below. In Exercise 48.15 we showed that $f_*\colon \pi_1(S^1, 1) \to \pi_1(X, a)$ is an isomorphism. A slight variation on the definition of f also shows that X is path-connected. Furthermore, by the discussion on page 1573 and by Exercise 71.5 we know that $\pi_n(S^1, 1) = \pi_n(X, a) = 0$ for $n \geq 2$. Thus we obtain from the Weak Homotopy Equivalence Criteria Lemma 161.5 that f is a weak homotopy equivalence. Since S^1 is a CW-complex we see that the map $f\colon S^1 \to X$ is a CW-approximation for the pseudocircle X.

[1976] Why is it not a CW-complex?
[1977] What is so easy about this?

Exercises for Chapter 161.

Exercise 161.1.

(a) Give an explicit CW-approximation for the Cantor set, as defined on page 130.
(b) Give an explicit CW-approximation for the Topologist's Sine Curve, as defined on page 164.



Exercise 161.2.

(1) Let M be a connected non-empty n-dimensional smooth manifold. Furthermore let $\varphi\colon \overline{B}^n \to M$ be a smooth embedding. Show that there exists a homeomorphism $\varphi\colon M/\varphi(S^{n-1}) \to M \vee S^n$ such that the map $M \to M/\varphi(S^{n-1}) \xrightarrow{\varphi} M \vee S^n \to M$ is homotopic to the identity.
(2) We consider the map

$$\Theta\colon S^1 \times S^2 \xrightarrow{\text{projection}} (S^1 \times S^2) \vee S^3 \xrightarrow{\text{as in (1)}} (S^1 \times S^2) \vee S^3 \to S^1 \times S^2.$$

(the last map: given by id on $S^1 \times S^2$ and by the Hopf map $S^3 \to S^2$ on S^3)

Show the following statements:
(a) Θ induces the identity on all homology groups.
(b) Θ induces the identity on π_1 and π_2.
(c) Θ does not induce the identity on π_3.

162. The Whitehead Theorem

In this chapter we will prove the Whitehead Theorem 162.1 which says that if a map $f\colon X \to Y$ between CW-complexes is a weak homotopy equivalence, i.e. if it induces an isomorphism of all homotopy groups, then f is in fact a homotopy equivalence. Afterwards we will study several applications of the Whitehead Theorem 162.1. In particular we will be able to complete the classification of lens spaces up to homotopy equivalence.

162.1. **The Whitehead Theorem.** Usually, in algebraic topology one goes from topological situations to algebra using various functors. For example, any map between (pointed) topological spaces gives rise to a map between homology groups and homotopy groups. Unfortunately almost invariably in the passage from topology to algebra some information gets lost. For example there are many non-homeomorphic topological spaces with isomorphic homology groups.

In the Homotopy-π_n-Proposition 71.7 (2) we saw that a homotopy equivalence between topological spaces gives rise to isomorphisms of higher homotopy groups. The following theorem shows that, rather amazingly, in this particular case the converse holds, at least if we restrict ourselves to maps between CW-complexes.

Theorem 162.1. (Whitehead Theorem)[1978] Let $f\colon X \to Y$ be a map between two connected CW-complexes.[1979]

(1) If $f\colon X \to Y$ is a weak homotopy equivalence, then f is a homotopy equivalence.

In fact, there is a more refined version dealing with base points:

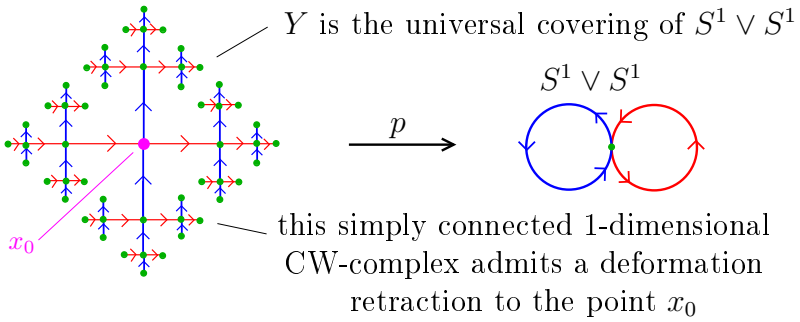
(2) Let $x_0 \in X^0$ and $y_0 \in Y^0$ be base points in the 0-skeleta of X respectively Y. If $f\colon X \to Y$ is a weak homotopy equivalence with $f(x_0) = y_0$, then there exists a homotopy equivalence between the pointed topological spaces (X, x_0) and (Y, y_0).

For inclusion maps we have the following very useful variation on the Whitehead Theorem 162.1.

Proposition 162.2. (Whitehead Deformation Retract Proposition) Let Y be a connected CW-complex.

(1) Let X be a connected subcomplex and let $x_0 \in X$ be a point. We denote by $i\colon X \to Y$ the inclusion map. If the induced maps $i_*\colon \pi_n(X, x_0) \to \pi_n(Y, x_0)$ are isomorphisms for all $n \in \mathbb{N}$, then X is a deformation retract of Y.

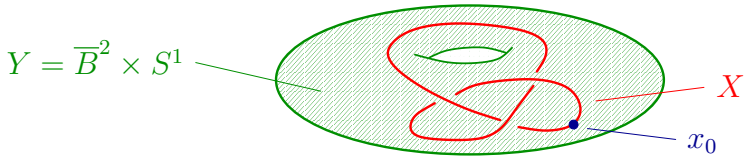
(2) If Y is weakly contractible, then for every point $y_0 \in Y$ the one-point subset $\{y_0\}$ is a deformation retract of Y. In particular Y is contractible.



Examples.

(1) Let Y be a simply connected 1-dimensional CW-complex and let x_0 be a point in the 0-skeleton of Y. By Lemma 71.15 (or alternatively Lemma 85.8) we know that $\pi_n(Y, x_0) = 0$ for all $n \in \mathbb{N}$. It follows from the Whitehead Deformation Retract Proposition 162.2 (2) that Y admits a deformation retraction to $\{x_0\}$, in particular Y is contractible.

[1978] As we pointed out on page 3258, the name "Whitehead Theorem" is sometimes also used for Theorem 153.14. Our naming convention agrees with [**Hat2002**, Theorem 4.5] and [**Rot1988**, p. 370].



[1979] Note that we do not assume that the map f is cellular.

For example, let Y be the universal covering of $S^1 \vee S^1$. We view $S^1 \vee S^1$ as a CW-complex in the obvious way. By the CW-complex Covering Proposition 68.37 we can equip Y with the structure of a 1-dimensional CW-complex. By definition of a universal covering we know that Y is simply connected. It follows from the above discussion that any point x_0 in the 0-skeleton of Y is a deformation retract. We refer to the figure below for an illustration.

(2) On page 3401 we pointed out that Corollary 71.12 says that S^∞ is weakly contractible. Thus it follows from the Whitehead Deformation Retract Proposition 162.2 (2) that S^∞ is contractible.[1980]

(3) We consider the knotted curve X in the solid torus $Y = \overline{B}^2 \times S^1$ that is shown in the figure below. It follows from the Smooth Manifold-Simplicial Structure Theorem 96.2 (3) together with the Simplicial-Implies-CW Lemma 93.24 that we can equip Y with a CW-structure such that X is a subcomplex. It should be pretty clear that the inclusion induced map $\pi_1(X, x_0) \to \pi_1(Y, x_0)$ is an isomorphism. Furthermore, since X and Y are homotopy equivalent to S^1 we see that the higher homotopy groups of X and Y vanish. In particular for every $n \in \mathbb{N}_{\geq 2}$ the induced maps $i_*\colon \pi_n(X, x_0) \to \pi_n(Y, y_0)$ are isomorphisms. In other words we see that all the hypotheses of the Whitehead Deformation Retract Proposition 162.2 are satisfied. This shows that X is a retract of Y. This answers the question that we had posed on page 1061.

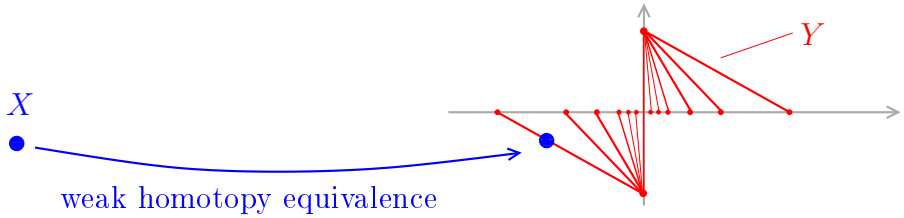
Remark. One might be tempted to interpret the Whitehead Theorem 162.1 as saying that if two CW-complexes have isomorphic homotopy groups, then they are homotopy equivalent. But this statement is false.

(1) For example let us consider the lens spaces $L(5, 1)$ and $L(5, 2)$. Recall that both are quotients of S^3 by some action of $\mathbb{Z}_5$ and both are closed 3-dimensional smooth manifolds. In particular both are CW-complexes by the Smooth Manifold-CW Structure

[1980] In fact in Lemma 68.4 we gave an explicit homotopy from the identity of S^∞ to a constant map. By the Contractibility Criterion Lemma 15.2 this implies that S^∞ is contractible.

Theorem 96.5 .[1981] On page 1574 we saw that the homotopy groups of these two lens spaces are isomorphic. On the other hand we seen on page 3156 that $L(5,1)$ and $L(5,2)$ are not homotopy equivalent.

(2) We consider the topological spaces S^2 and $S^3 \times \mathbb{C}\mathrm{P}^\infty$. Evidently S^2 and S^3 are CW-complexes. It follows from Lemma 68.6 and Proposition 68.23 that $S^3 \times \mathbb{C}\mathrm{P}^\infty$ is also a CW-complex. In Exercise 155.12 we saw that S^2 and $S^3 \times \mathbb{C}\mathrm{P}^\infty$ have isomorphic homotopic groups.[1982] On the other hand it follows immediately from the discussion on page 1772 and the Künneth Theorem 90.8 that the homology groups of S^2 and $S^3 \times \mathbb{C}\mathrm{P}^\infty$ are (dramatically) different. Thus the two CW-complexes are not homotopy equivalent.



Remark. The analogous statement of the Whitehead Theorem 162.1, respectively the Whitehead Deformation Retract Proposition 162.2, does not hold if we drop the hypothesis that X and Y are CW-complexes, in other words, the statement does not hold for general topological spaces. We can provide two examples:

(1) On page 3402 we already discussed the fact that the Quasi-Circle is weakly contractible but not contractible.

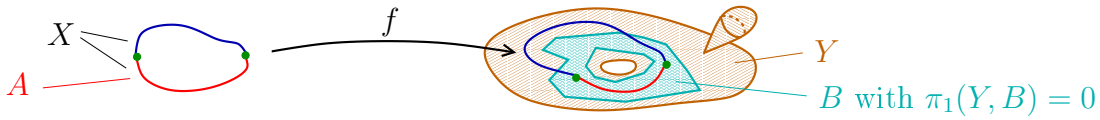
(2) Since weird topological spaces are so much fun, let us consider another example. More precisely, let us consider the following subset of $\mathbb{R}^2$ which is also illustrated in the figure below:

$$\begin{aligned} Y := \text{line segment from } (0,1) \text{ to } (0,-1) \cup \bigcup_{n\in\mathbb{N}} \text{line segment from } (0,1) \text{ to } (\tfrac{1}{n},0) \\ \cup \bigcup_{n\in\mathbb{N}} \text{line segment from } (0,-1) \text{ to } (-\tfrac{1}{n},0). \end{aligned}$$

We equip Y with the subspace topology. In Exercise 162.4 (a) we will see that the homotopy groups of Y are trivial, i.e. Y is weakly contractible. On the other hand we show in Exercise 162.4 (b) that Y is not contractible. The readers who are less inclined towards doing the exercises are referred to [**Mau1980**, p. 301] instead.[1983]

(3) In Exercise 162.13 we will see that the long line $\mathbb{L}$, which we introduced on page 613, is weakly contractible but not contractible.

(4) On [**Barm2011**, p. 54] it is shown that there exists a finite topological space that is weakly contractible but not contractible.



[1981] It is also a moderately amusing exercise to find an explicit CW-structure on lens spaces. One could start either from the definition of a lens space or the reinterpretation given by the Lens Space-Splitting Lemma 146.2.

[1982] In fact this follows easily from the fact that $\pi_k(S^2) = \pi_k(S^3)$ for $k \geq 3$ (see Theorem 155.10) and the fact that $\pi_k(\mathbb{C}\mathrm{P}^\infty) = \mathbb{Z}$ for $k = 2$ and $\pi_k(\mathbb{C}\mathrm{P}^\infty) = 0$ for $k \neq 2$ (see Theorem 155.12 (2)).

[1983] This shows in particular that Y is not a CW-complex. Is there a more direct way for showing that Y is not a CW-complex?

The proof of the Whitehead Theorem 162.1 relies on the following lemma.

Lemma 162.3. Let (X, A) be a pair of CW-complexes and let (Y, B) be a pair of topological spaces with $B \neq \varnothing$. We make the following assumption: For every $n \in \mathbb{N}_0$ such that $X \setminus A$ has at least one n-dimensional cell we assume that $\pi_n(Y, B, y_0) = 0$ for all $y_0 \in B$. Then every map $f\colon (X, A) \to (Y, B)$ is homotopic rel A to a map $X \to B$.

Proof. We start out with the following claim.

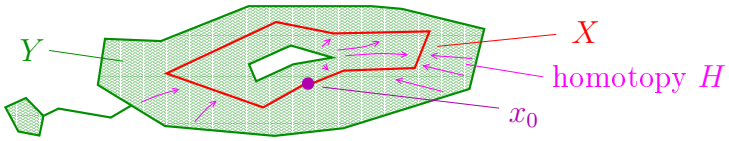
Claim. Let $k \in \mathbb{N}$. Let $f\colon (X, A) \to (Y, B)$ be a map. If $f(X^{k-1}) \subset B$, then there exists a homotopy rel $A \cup X^{k-1}$ from f to a map g with $g(X^k) \subset B$.

Proof. If there are no k-cells in $X \setminus A$, then we have $X^k \subset X^{k-1} \cup A$, in particular we already have $f(X^k) \subset B$, and we are thus done. Now suppose that there exists at least one k-cell in $X \setminus A$. By our hypothesis this implies that $\pi_k(Y, B, y_0) = 0$ for every $y_0 \in B$. Let $\{\Phi_i\colon \overline{B}^k \to X\}_{i \in I}$ be the characteristic maps of the k-cells in $X \setminus A$. Given $i \in I$ we denote by $\phi_i\colon S^{k-1} \to X$ the corresponding attaching map. It follows from $f(X^{k-1}) \subset B$, from $\pi_k(Y, B, y_0) = 0$ and Proposition 153.8 (2) $\Rightarrow$ (1) that there exists a homotopy F_i rel S^{k-1} from the map $f \circ \Phi_i\colon \overline{B}^k \to Y$ to a map whose image is contained in B. It follows from the Homotopy Pushout Lemma 14.9, applied to $A \cup X^k = (A \cup X^{k-1}) \cup_{\bigsqcup_{i \in I} \phi_i} \left(\bigsqcup_{i \in I} \overline{B}_i^k \right)$ that these homotopies on all such cells, together with the constant homotopy on $A \cup X^{k-1}$, give rise to a homotopy H on $A \cup X^k$ rel $A \cup X^{k-1}$ with $\mathrm{H}_0|_{A \cup X^k} = f$ and with $\mathrm{H}_1(X^k) \subset B$. By the Homotopy Extension Theorem 70.1 we can extend this homotopy H to a homotopy $\widetilde{H}\colon X \times [0, 1] \to Y$ with $\widetilde{\mathrm{H}}_0 = f$. This homotopy has all the desired properties. ⊞

First suppose that X is a finite-dimensional CW-complex. It is clear that the hypothesis of the claim holds for $k = -1$ since, by definition, $X^{-1} = \varnothing$. Now we can apply the claim iteratively finitely many times. Combining these finitely many homotopies together as in the Homotopy Combination the Homotopy Combination Lemma 14.4 we obtain the desired homotopy.

In the case that X is infinite-dimensional we obtain an infinite sequence of homotopies. We can combine these homotopies using the rather tricky Lemma 70.13 and we obtain again the desired homotopy. ■

Now we are already in a position to provide the proof of the Whitehead Deformation Retract Proposition 162.2.



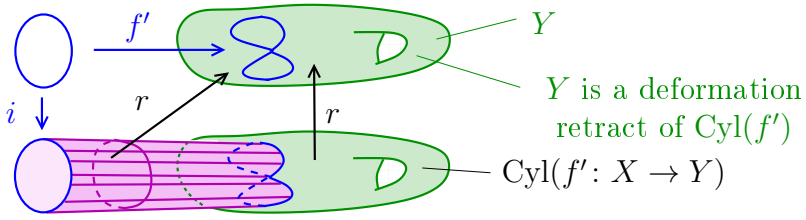
Proof of the Whitehead Deformation Retract Proposition 162.2. Let Y be a connected CW-complex.

(1) Let X be a connected subcomplex and let $x_0 \in X$. We denote by $i\colon X \to Y$ the inclusion map. We suppose that the induced maps $i_*\colon \pi_n(X, x_0) \to \pi_n(Y, x_0)$ are isomorphisms for all $n \in \mathbb{N}$. We need to show that X is a deformation retract of Y.

Recall that by our hypothesis Y is connected, in particular it is path-connected by the CW-Complex Properties Proposition 68.10 (7). Thus it follows from the Change-of-Base Point Proposition 86.9 that the induced maps $i_*\colon \pi_n(X, x_0) \to \pi_n(Y, x_0)$ are

in fact isomorphisms for all $x_0 \in X$. Next we note that it follows from our hypothesis and the long exact sequence of homotopy groups given by the Homotopy Groups-LES Proposition 153.4 that all relative homotopy groups $\pi_n(Y, X, x_0)$ are trivial for all $x_0 \in X$. This observation allows us apply Lemma 162.3 to the identity map $(Y, X) \to (Y, X)$. From Lemma 162.3 we obtain a homotopy H rel X from id_Y to a map whose image lies in X. But this means, by definition, that H is a deformation retraction from Y to X.

(2) We assume that Y is weakly contractible. Let $y_0 \in Y$. We denote by $i\colon \{y_0\} \to Y$ the inclusion. Since Y is weakly contractible we see that for each $n \in \mathbb{N}$ the map $i_*\colon \pi_n(\{y_0\}, y_0) \to \pi_n(Y, y_0)$ is an isomorphism, for the silly reason, that the groups on both sides are trivial. It follows from (1) that $\{y_0\}$ is a deformation retract of Y. The elementary the Point Deformation Retract Lemma 15.6 now tells us that Y is contractible. ■

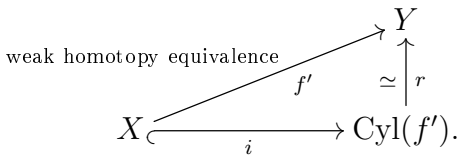


We will reduce the proof of the Whitehead Theorem 162.1 to the Whitehead Deformation Retract Proposition 162.2. The trick hereby is to use the notion of a mapping cylinder that we introduced on page 454. For the reader's convenience we recall the definition.

Definition. Given a map $f\colon X \to Y$ between topological spaces we define the corresponding mapping cylinder to be the topological space

$$\mathrm{Cyl}(f) \;:=\; \mathrm{Cyl}(f\colon X \to Y) \;:=\; ((X \times [0,1]) \sqcup Y)/\!\sim \quad \text{where } (x,1) \sim f(x) \text{ for all } x \in X.$$

We illustrate the definition in the figure below.



Now we can provide the actual proof of the Whitehead Theorem 162.1.

Proof of the Whitehead Theorem 162.1. Let X and Y be two connected CW-complexes. Let $x_0 \in X$ be a base point. Furthermore let $f\colon X \to Y$ be a map such that the induced maps $f_*\colon \pi_n(X, x_0) \to \pi_n(Y, f(x_0))$ are isomorphisms for all $n \in \mathbb{N}$.

(1) By the Cellular Approximation Theorem 70.15 the map f is homotopic to a cellular map f'. We make the following two observations:
   (i) By the Homotopy-Equivalence Basics Lemma 15.1 (3) the map f is a homotopy equivalence if and only if f' is a homotopy equivalence.
   (ii) By the Weak Homotopy Equivalence Criteria Lemma 161.5 (2) the map f is a weak homotopy equivalence if and only if f' is a weak homotopy equivalence.

   As usual we denote by $\mathrm{Cyl}(f')$ the mapping cylinder of $f'\colon X \to Y$. We consider the following diagram of maps:

We make the following comments and observations:[1984]

(a) The map $r\colon \mathrm{Cyl}(f') \to Y$ is the obvious map given by the identity on Y and given by sending $[(x,t)]$ to $f'(x)$.
(b) The map $i\colon X \to \mathrm{Cyl}(f')$ is the obvious inclusion given by $x \mapsto [(x,0)]$.
(c) It is clear that the above diagram commutes.
(d) By (ii) and our hypothesis the map $f'\colon X \to Y$ is a weak homotopy equivalence.
(e) By the Mapping Cylinder Basics Lemma 16.12 (2) we know that the map $r\colon \mathrm{Cyl}(f) \to Y$ is a homotopy equivalence. In particular we obtain from the Weak Homotopy Equivalence Criteria Lemma 161.5 (1) that r is a weak homotopy equivalence.
(f) It follows from (c), (d) and (e) that i is a weak homotopy equivalence.
(g) Since $f'\colon X \to Y$ is cellular we use the CW-Complex Cone Corollary 68.35 (3) to equip $\mathrm{Cyl}(f'\colon X \to Y)$ with a natural CW-structure such that $X \times \{0\} = i(X)$ is a subcomplex.
(h) It follows immediately from (f) and (g) together with the Whitehead Deformation Retract Proposition 162.2 that the map $i\colon X \to \mathrm{Cyl}(f')$ is homotopy equivalence.
(i) We obtain from (e) and (h) and the Homotopy-Equivalence Basics Lemma 15.1 (1) that f is indeed a homotopy equivalence.

(2) Now suppose we are given $x_0 \in X^0$ and $y_0 \in Y^0$ such that $f(x_0) = y_0$. Since f is cellular on the subcomplex $\{x_0\}$ we obtain from the Cellular Approximation Theorem 70.15 that the map f is homotopic *rel* x_0 to a cellular map f'. Note that we still have $f'(x_0) = y_0$. Using this input it is not difficult to convince oneself that the argument in (1) can be modified to give the desired homotopy rel $\{x_0\}$. We leave it to the punctilious reader to go through the details. ■

In the remainder of this chapter we will discuss many applications of the Whitehead Theorem 162.1 to various problems.

162.2. **Homotopy classification of lens spaces.** One of the recurring themes of these notes is the classification of lens spaces. Using the Whitehead Theorem 162.1 we can now finish the classification of lens spaces up to homotopy equivalence. It is worth recalling the following definition from page 1075, so that we are all on the same sheet.

Definition. We consider the 3-sphere $S^3 = \{(z_1,z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\}$ as a submanifold of $\mathbb{C}^2$. Let $p \in \mathbb{N}$. Furthermore let $q \in \mathbb{Z}$ with $\gcd(p,q) = 1$. The map

$$\begin{array}{rcl} \mathbb{Z}_p \times S^3 & \to & S^3 \\ (k + p\mathbb{Z}, (z_1,z_2)) & \mapsto & (\exp(2\pi \mathrm{i} k/p) \cdot z_1, \exp(2\pi \mathrm{i} kq/p) \cdot z_2) \end{array}$$

defines a smooth, orientation-preserving and discrete action of $\mathbb{Z}_p$ on S^3. We refer to $L(p,q) := S^3/\mathbb{Z}_p$ as a lens space.[1985]

[1984] Some of the arguments below overlap with the proof of the Mapping Cylinder Basics Lemma 16.12 (2). The reason for not appealing to the Mapping Cylinder Basics Lemma 16.12 (2) is that in Statement (2) of the Whitehead Theorem 162.1 we also want to do the case rel a fixed point.

Recall that in Corollary 148.21 we showed that if two lens spaces $L(p, q_1)$ and $L(p, q_2)$ are homotopy equivalent, then there exists an $\epsilon \in \{-1, 1\}$ and an $r \in \mathbb{Z}$, coprime to p, such that $q_1 = \epsilon \cdot r^2 \cdot q_2 \bmod p$. We can now prove the converse of this result.

Proposition 162.4. (Lens Space-Homotopy Equivalence Proposition) Let $p \in \mathbb{N}$ and let $q_1, q_2 \in \mathbb{Z}$ with $\gcd(p, q_1) = \gcd(p, q_2) = 1$. If there exists an $m \in \mathbb{Z}$ with $q_1 \equiv \pm m^2 \cdot \cdot q_2 \bmod p$, then the lens spaces $L(p, q_1)$ and $L(p, q_2)$ are homotopy equivalent.

Remark. This proposition was first shown by John Whitehead [**WhdJ1941b**, Theorem 10]. A direct proof, that does not make use of the Whitehead Theorem 162.1, is also given in [**CoheM1973**, Chapter 29].

Before we turn to the proof of the Lens Space-Homotopy Equivalence Proposition 162.4 let us remind the reader that we have now proved the following theorem, which for convenience we had stated already at an earlier occasion.

Theorem 148.22. (Lens Space-Homotopy Classification Theorem) Let $p \in \mathbb{N}$. If $q, \widetilde{q} \in \mathbb{Z}$ are coprime to p, then

$$\begin{array}{c}\text{the lens spaces } L(p,q) \text{ and } L(p,\widetilde{q}) \\ \text{are homotopy equivalent}\end{array} \iff \begin{array}{c}\text{there exists an } r \in \mathbb{Z}, \text{ coprime to } p, \\ \text{such that } q \equiv \pm r^2 \cdot \widetilde{q} \bmod p.\end{array}$$

Remark. The classification of lens spaces up to homeomorphism will have to wait till the Lens Space-Homeomorphism Classification Theorem **??**.

Proof. The "$\Rightarrow$"-direction is precisely the statement of Corollary 148.21 and the "$\Leftarrow$"-direction is the content of the Lens Space-Homotopy Equivalence Proposition 162.4. ■

The proof of the Lens Space-Homotopy Equivalence Proposition 162.4 requires several preparations. The key idea is to make use of the recently acquired Whitehead Theorem 162.1. In fact the Whitehead Theorem 162.1 is the key ingredient in the proof of the following lemma.

Lemma 162.5. Let M and N be closed oriented n-dimensional smooth manifolds such that the universal covering in both cases is S^n. Let $g\colon M \to N$ be a map. If $\deg(g) = \pm 1$ and if $g_*\colon \pi_1(M) \to \pi_1(N)$ is an isomorphism, then g is a homotopy equivalence.

Proof. First note that by the Smooth Manifold-CW Structure Theorem 96.5 we know that M and N admit CW-structures.[1986] Thus, by the Whitehead Theorem 162.1, it remains to show that $g\colon M \to N$ is a weak homotopy equivalence.

Let $p\colon S^n \to M$ and $q\colon S^n \to N$ be the universal coverings. It follows from the Map Lifting Criterion 61.2 that there exists a map $\widetilde{g}\colon S^n \to S^n$ such that the following diagram commutes:

[1985] As we mentioned on page 1075, it follows from the Manifold Quotient-by-Group Action Proposition 19.32 and the Orientation-Action Proposition 25.19 that $L(p, q)$ is a closed 3-dimensional smooth manifold that comes with a natural orientation.

[1986] Alternatively it follows from Topological Manifold-Simplicial Complex Retract Theorem 104.13 together with the brand-new CW-Complex Domination Proposition 162.8 or from the Morse Functions-Cells Proposition 138.6 that M and N are homotopy equivalent to CW-complexes, which is good enough for our purpose.

$$\begin{array}{ccc} S^n & \xrightarrow{\widetilde{g}} & S^n \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ M & \xrightarrow{g} & N. \end{array}$$

It follows from our hypothesis that $g_*\colon \pi_1(M) \to \pi_1(N)$ is an isomorphism together with the Weak Homotopy-vs-Homology Isomorphisms Proposition 161.6 $(2')$ that it suffices to prove the following claim.

Claim. For each $k \in \mathbb{N}_0$ the map $\widetilde{g}_*\colon \mathrm{H}_k(S^n) \to \mathrm{H}_k(S^n)$ is an isomorphism.

Proof. Evidently we only have to consider the case $k = n$. It follows from the above simple-minded commutative diagram, the Degree Multiplicativity Theorem 38.4, the hypothesis that $\deg(g) = 1$ and the observation that by the Covering Map-Degree Proposition 101.7 we have $\deg(p) = \#\pi_1(M) = \#\pi_1(N) = \deg(q)$, that $\deg(\widetilde{g}) = 1$. But this implies that $\widetilde{g}_*\colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n)$ is an isomorphism. ∎

It follows from Lemma 162.5 that, in the setting of the Lens Space-Homotopy Equivalence Proposition 162.4, it suffices to show that there exists a map $L(p, q_1) \to L(p, q_2)$ of degree ± 1. The following lemma is the first step towards the construction of such a map.

Lemma 162.6. Let $p \in \mathbb{Z} \setminus \{0\}$ and let $q_1, q_2 \in \mathbb{Z}$ with $\gcd(p, q_1) = \gcd(p, q_2) = 1$. Given any $t_1, t_2 \in \mathbb{Z}$ with $q_1 \cdot t_1 \equiv q_2 \cdot t_2 \bmod p$ the map

$$\begin{array}{rcl} f\colon L(p, q_1) & \to & L(p, q_2) \\ [(z, w)] & \mapsto & [(z^{t_2}, w^{t_1})] \end{array}$$

is well-defined, it is smooth and it has degree $t_1 \cdot t_2$.

Proof. First we show that the map $f\colon L(p, q_1) \to L(p, q_2)$ is well-defined. To do so we introduce two pieces of notation. We write $\xi := \exp(2\pi \mathrm{i}/p)$ and for $i = 1, 2$ we denote by $\sim_i$ the equivalence relation on S^3 that is defined by the action of $\mathbb{Z}_p$ on S^3 with parameter q_i. In other words

$$(z, w) \sim_i (\widetilde{z}, \widetilde{w}) \iff \text{there exists a } k \in \mathbb{Z} \text{ with } (z, w) = (\xi^k \cdot \widetilde{z}, \xi^{k \cdot q_i} \cdot \widetilde{w}).$$

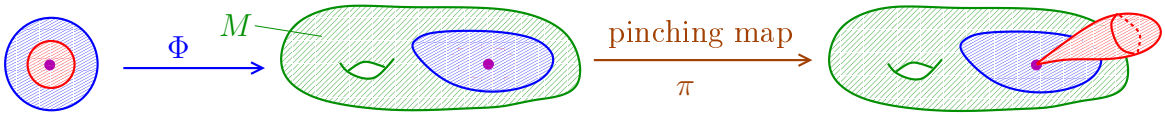
We need to show that if we are given $(z, w), (\widetilde{z}, \widetilde{w}) \in S^3$ with $(z, w) \sim_1 (\widetilde{z}, \widetilde{w})$, then $(f(z), f(w)) \sim_2 (f(\widetilde{z}), f(\widetilde{w}))$. This follows from the following sequence of implications:

$$\begin{array}{rcll} (z, w) \sim_1 (\widetilde{z}, \widetilde{w}) & \implies & (z, w) = (\xi^k \cdot \widetilde{z}, \xi^{k \cdot q_1} \cdot \widetilde{w}) & \text{(definition of } \sim_1) \\ & \implies & (z^{t_2}, w^{t_1}) = (\xi^{k \cdot t_2} \cdot \widetilde{z}^{t_2}, \xi^{k \cdot q_1 \cdot t_1} \cdot \widetilde{w}^{t_1}) & \text{(since take same powers)} \\ & \implies & (z^{t_2}, w^{t_1}) = (\xi^{k t_2} \cdot \widetilde{z}^{t_2}, \xi^{k t_2 \cdot q_2} \cdot \widetilde{w}^{t_1}) & \text{(since } q_1 \cdot t_1 \equiv q_2 \cdot t_2 \bmod p) \\ & \implies & (z^{t_2}, w^{t_1}) \sim_2 (\widetilde{z}^{t_2}, \widetilde{w}^{t_1}) & \text{(definition of } \sim_2) \\ & \implies & (f(z), f(w)) \sim_2 (f(\widetilde{z}), f(\widetilde{w})) & \text{(definition of } f). \end{array}$$

We have thus shown that the map $f\colon L(p, q_1) \to L(p, q_2)$ is well-defined. Next note that it follows easily from the Smooth Map-Descends-to-Quotient Corollary 19.33 that f is smooth. It remains to calculate the degree of the map. We consider the following diagram:

$$\begin{array}{ccc} S^3 & \xrightarrow{(z,w) \mapsto (z^{t_1}, w^{t_2})} & S^3 \\ {\scriptstyle (z,w) \mapsto [(z,w)]_1}\downarrow & & \downarrow{\scriptstyle (z,w) \mapsto [(z,w)]_2} \\ L(p, q_1) & \xrightarrow{f} & L(p, q_2). \end{array}$$

We make the following observations:



(1) It is clear that the diagram commutes.
(2) The vertical maps are covering maps of degree d. It follows from the Covering Map-Degree Proposition 101.7 that the vertical also have degree p in terms of fundamental classes.
(3) One can easily show, using the definition of the degree on page 898, that the degree of top horizontal map equals $t_1 \cdot t_2$.

It follows from these three observations together with the Degree Multiplicativity Theorem 38.4 that the degree of the bottom horizontal map f also equals $t_1 \cdot t_2$. ■

Lemma 162.7. Let M be a closed oriented connected non-empty n-dimensional smooth manifold. We pick an orientation-preserving smooth embedding $\Phi\colon \overline{B}^n_2 \to M$. Let $\Theta\colon \overline{B}^n/S^{n-1} \to S^n$ be the homeomorphism from the Ball-Quotient Sphere Lemma 5.20. We refer to the map[19871988]

$$\begin{array}{rcl} \pi\colon M & \to & M \vee S^n \\ P & \mapsto & \begin{cases} \Phi(2(t-1)\cdot x), & \text{if } P = \Phi(t\cdot x) \text{ for } t \in [1,2] \text{ and } x \in S^{n-1}, \\ \Theta(y), & \text{if } P = \Phi(y) \text{ with } y \in \overline{B}^n, \\ P, & \text{otherwise.} \end{cases} \end{array}$$

as the pinching map. This map has the property that the maps $M \xrightarrow{\pi} M \vee S^n \to M$ and $M \xrightarrow{\pi} M \vee S^n \to S^n$ both have degree 1.

Proof. This statement can be verified easily using the Local-Global Degree Proposition 101.6. We leave it to the reader to fill in the details. ■

Now we have assembled all the tools that we need for provide the proof of the Lens Space-Homotopy Equivalence Proposition 162.4.

Proof of Proposition 162.4. First let $p \in \mathbb{Z} \setminus \{0\}$. Furthermore let $q_1, q_2 \in \mathbb{Z}$ with $\gcd(p, q_1) = \gcd(p, q_2) = 1$. We suppose that there exists an $m \in \mathbb{Z}$ and an $\epsilon \in \{-1, 1\}$ with $q_1 \equiv \epsilon \cdot q_2 \cdot m^2 \bmod p$. We need to show that $L(p, q_1)$ and $L(p, q_2)$ are homotopy equivalent. By Lemma 162.5 it suffices to show that there exists a map $g\colon L(p, q_1) \to L(p, q_2)$ of degree ϵ. We will construct such g in several steps:

(1) Since $\gcd(p, q_1) = \gcd(p, q_2) = 1$ we can pick $s_1, s_2 \in \mathbb{Z}$ with $s_i \cdot q_i \equiv 1 \bmod p$.
(2) By Lemma 162.6, applied to $t_i = q_2 m \cdot s_i$, there exists a map $f\colon L(p, q_1) \to L(p, q_2)$ of degree $(q_2 m)^2 \cdot s_1 \cdot s_2$.
(3) Note that

$$(q_2 m)^2 \cdot s_1 \cdot s_2 \;\equiv\; q_2 \cdot m^2 \cdot s_1 \cdot q_2 \cdot s_2 \underset{\substack{\uparrow \\ \text{since } q_1 \equiv \epsilon \cdot q_2 \cdot m^2 \bmod p}}{\equiv} \epsilon \cdot q_1 \cdot s_1 \cdot q_2 \cdot s_2 \;\equiv\; \epsilon \mod p.$$

[1986]It follows from the Pasting Proposition 2.6 together with the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 that π is continuous.
[1986]In Exercise 100.16 we introduced the pinching map $M \# N \to M \vee N$. Our pinching map is homotopic to the map $M \cong M \# S^n \to (M \# S^n) \vee S^n \to M \vee S^n$.

This calculation shows that there exists a $d \in \mathbb{Z}$ with $(q_2 m)^2 \cdot s_1 \cdot s_2 = \epsilon + d \cdot p$.

(4) By the Degree Realization Proposition 38.13 there exists a map $h\colon S^3 \to S^3$ of degree $-d$.

We now consider the following map

$$L(p,q_1) \xrightarrow{\pi} L(p,q_1) \vee S^3 \xrightarrow{f \vee h} L(p,q_2) \vee S^3 \underset{\uparrow}{\to} L(p,q_2)$$

given by id on $L(p,q_2)$ and given by the covering map $S^3 \to L(p,q_2)$ on S^3

It follows from Lemma 162.7, the choice of f and h and the Covering Map-Degree Proposition 101.7 that the induced maps on homology groups are given as follows:

$$\underbrace{\mathrm{H}_3(L(p,q_1))}_{\mathbb{Z}\cdot[L(p,q_1)]} \xrightarrow{\begin{pmatrix}1\\1\end{pmatrix}} \underbrace{\mathrm{H}_3(L(p,q_1)\vee S^3)}_{\mathbb{Z}\cdot[L(p,q_1)]\oplus\mathbb{Z}\cdot[S^3]} \xrightarrow{\begin{pmatrix}(q_2m)^2\cdot s_1\cdot s_2 & 0\\ 0 & -d\end{pmatrix}} \underbrace{\mathrm{H}_3(L(p,q_2)\vee S^3)}_{\mathbb{Z}\cdot[L(p,q_2)]\oplus\mathbb{Z}\cdot[S^3]} \xrightarrow{(1\ p)} \underbrace{\mathrm{H}_3(L(p,q_2))}_{\mathbb{Z}\cdot[L(p,q_2)]}.$$

In summary we see that the map $L(p,q_1) \to L(p,q_2)$ has degree $(q_2m)^2 \cdot s_1 \cdot s_2 - d \cdot p = \epsilon$. ■

162.3. **Topological spaces dominated by CW-complexes.** We move on to another application of the Whitehead Theorem 162.1. We recall the following definition from page 2307.

Definition. We say that a topological space X is dominated by a topological space Y if there exist maps $i\colon X \to Y$ and $r\colon Y \to X$ such that $r \circ i$ is homotopic to the identity id_X.

The goal of this section is to prove the following result which we already mentioned in Section 104.5.

Proposition 162.8. (CW-Complex Domination Proposition) Let X be a topological space. If X is dominated by a CW-complex, then X is homotopy equivalent to a CW-complex.

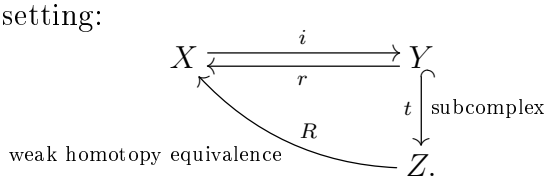
Remark.

(1) An alternative proof for the CW-Complex Domination Proposition 162.8, that does not use the Whitehead Theorem 162.1, but that uses a mapping telescope construction similar to the telescope construction from page 1546, is given in [**Hat2002**, Proposition A.11].

(2) In Section 104.5 we stated, without proofs but with detailed references, several generalizations of refinements of the CW-Complex Domination Proposition 162.8.

The following simply definition will prove convenient in the proof of the CW-Complex Domination Proposition 162.8.

Definition. Let $f\colon X \to Y$ be a map between topological spaces. A map $g\colon Y \to X$ is called a homotopy left inverse of f if $g \circ f$ is homotopic to id_X. Furthermore, a map $h\colon Y \to X$ is called a homotopy right inverse of f if $f \circ h$ is homotopic to id_Y.



For the reader's convenience we recall the following elementary lemma.

Lemma 15.11. Let $f\colon X \to Y$ be a map between topological spaces. If f admits a homotopy left inverse g and a homotopy right inverse h, then f is in fact a homotopy equivalence and both g and h are homotopy inverses.

Now it is fairly straightforward to provide a proof of the CW-Complex Domination Proposition 162.8.

Proof of the CW-Complex Domination Proposition 162.8. Let X be a topological space that is dominated by a CW-complex Y. Recall that this means that there exist maps $i\colon X \to Y$ and $r\colon Y \to X$ such that $r \circ i$ is homotopic to the identity id_X. Without loss of generality we can and will assume that X and Y are path-connected. We pick a base point $y_0 \in Y$ and we write $x_0 := r(x_0)$. Since $r \circ i$ is homotopic to the identity we obtain from the Homotopy-π_n-Proposition 71.7 (1) that the map $r_* \circ i_* = (r \circ i)_*\colon \pi_j(X, x_0) \to \pi_j(X, x_0)$ is an isomorphism for all $j \in \mathbb{N}_0$. In particular we see that $r_*\colon \pi_j(Y, y_0) \to \pi_j(X, x_0)$ is an epimorphism for all $j \in \mathbb{N}_0$.

By Corollary 161.2 there exists a CW-complex Z which contains Y as a subcomplex and a map $R\colon Z \to X$ that extends r and that is a weak homotopy equivalence. Thus we are now in the following setting:

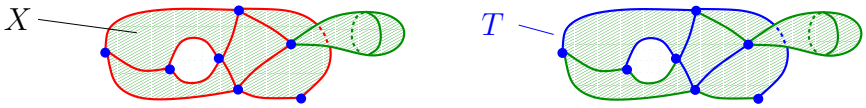
Here denote by $t\colon X \to Z$ the inclusion map. (Note though that we do not claim that the diagram commutes.) It remains to prove the following claim.

Claim. The map $t \circ i\colon X \to Z$ is a homotopy equivalence.

Proof. Since $R \circ (t \circ i) = (R \circ t) \circ i = r \circ i$ is homotopic to id_X we know that R is homotopy left inverse of $t \circ i$. Furthermore, we obtain from the Homotopy-π_n-Proposition 71.7 (1) that $R \circ (t \circ i)$ is a weak homotopy equivalence.[1987] Since R is a weak homotopy equivalence we see that $t \circ i$ is also a weak homotopy equivalence. Thus we see that $(t \circ i) \circ R\colon Z \to Z$ is a weak homotopy equivalence. Since Z is a CW-complex it follows from the Whitehead Theorem 162.1 that the map $(t \circ i) \circ R$ is a homotopy equivalence. This implies that there exists a map $k\colon Z \to Z$ such that $(t \circ i) \circ R \circ k$ is homotopic to id_Z. We have thus shown that $R \circ k$ is a homotopy right inverse for $t \circ i$. Since we already pointed out above that $t \circ i$ admits is a homotopy left inverse we obtain from Lemma 15.11 that $t \circ i$ is a homotopy equivalence. ∎

162.4. Highly connected CW-complexes.

In this section we want to discuss the following natural question.



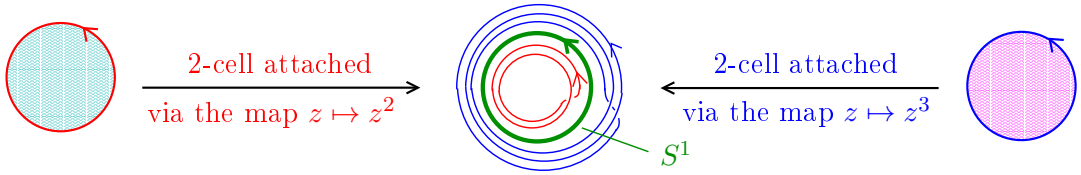
Question 162.9. Let X be a CW-complex which is n-connected for some $n \in \mathbb{N}_0$. Is X homotopy equivalent to a CW-complex Y which has one 0-cell and no cells in dimensions $1, \ldots, n$?

It turns out that we already dealt with the not entirely trivial case, that $n = 0$. For the convenience of the reader we recall Proposition 70.4. Its precise statement gives us one possible approach to answering Question 162.9.

[1987] Throughout the proof we use the characterization of weak homotopy equivalences given by the Weak Homotopy Equivalence Criteria Lemma 161.5 (3).

Proposition 70.4. Let X be a 0-connected CW-complex.

(1) There exists a contractible 1-dimensional subcomplex T which contains all 0-cells.[1988]
(2) Given any T as in (1) the quotient X/T is a CW-complex with precisely one 0-cell. Furthermore the projection $X \to X/T$ is a homotopy equivalence.



Proposition 70.4 suggests the following approach to answering Question 162.9: Given an n-connected CW-complex X we need to find a contractible subcomplex S that contains the n-skeleton X^n. The catch is, as the following example shows, in general such a subcomplex just does not exist.

Example. Let X be the 2-dimensional CW-complex corresponding to the presentation $\langle x \,|\, x^2 = e, x^3 = e\rangle$.[1989] This CW-complex is constructed by attaching two 2-cells to S^1 via the attaching maps $z \mapsto z^2$ and $z \mapsto z^3$. We refer to the figure below for an illustration. We have

$$\pi_1(X) \underset{\text{Corollary 69.12}}{\cong} \langle x \,|\, x^2 = e, x^3 = e\rangle \underset{\text{since } \langle x\rangle \cong \mathbb{Z}}{\cong} \mathbb{Z}/\text{subgroup generated by 2 and 3} \underset{\text{since 2 and 3 are coprime}}{=} 0.$$

We have thus shown that X is 1-connected. In Exercise 162.8 we will see that X does not admit a contractible subcomplex S which contains the 1-skeleton of X and which has the property that X/S is homotopy equivalent to X.

In light of the example it comes perhaps as a surprise that Question 162.9 actually does have an affirmative answer:

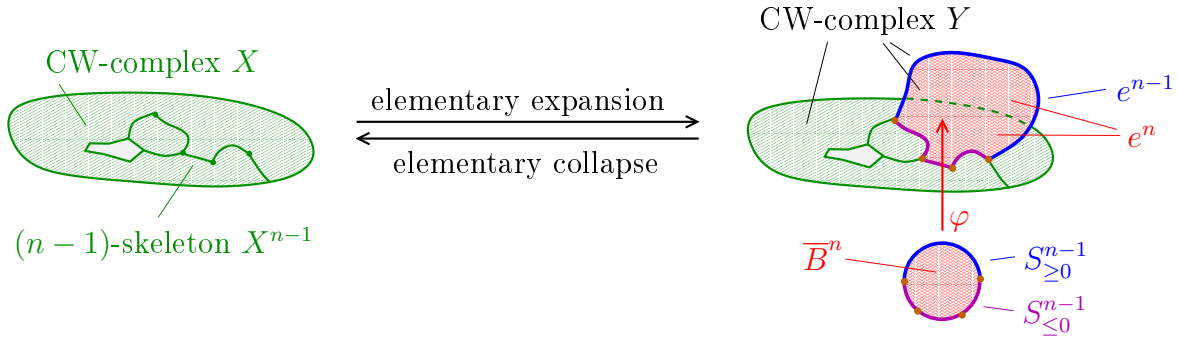
Proposition 162.10. Let X be a CW-complex, let $x_0 \in X$ and let $n \in \mathbb{N}_0$. If X is n-connected, then there exists a CW-complex Y which has one 0-cell y_0 and no cells in dimensions $1, \ldots, n$ such that the pair (X, x_0) is homotopy equivalent to the pair (Y, y_0).

Proof. Let X be an n-connected CW-complex and let $x_0 \in X$. By the CW-Approximation Theorem 161.8 (2) there exists a CW-complex Y which has a single 0-cell $\{y_0\}$ and no cells in dimensions $1, \ldots, n$ and a map $f\colon (Y, y_0) \to (X, x_0)$ which is a weak homotopy equivalence. Thus we can apply the Whitehead Theorem 162.1 (2) to the map f and we see that f is in fact a homotopy equivalence of pointed topological spaces. Well, that was quick. ∎

Remark. The construction of the CW-complex Y in the proof of Proposition 162.10 is quite wasteful. In particular, without any refinement of the construction, it will almost invariably provide an infinite-dimensional CW-complex Y. It turns out that often one

[1988] Such a subcomplex is basically what we called a spanning tree on page 317.

[1989] Recall that on page 1531 we showed that any finite presentation $\langle g_1, \ldots, r_k \,|\, r_1, \ldots, r_l\rangle$ naturally gives rise to a CW-complex with one 0-cell, k 1-cells and l 2-cells.



can do better. More precisely, in [**Hat2002**, Proposition 4.C.1] the following statement is shown: given a finite n-connected CW-complex X there exists a CW-approximation $f\colon Y \to X$ where Y is a finite CW–complex with a single 0-cell and such that Y has no cells in dimensions $1, \ldots, n$.

162.5. **Elementary collapses.** It is not always easy to determine whether two topological spaces are homotopy equivalent. The following definition is useful for systematizing the search for homotopy equivalences between CW-complexes.

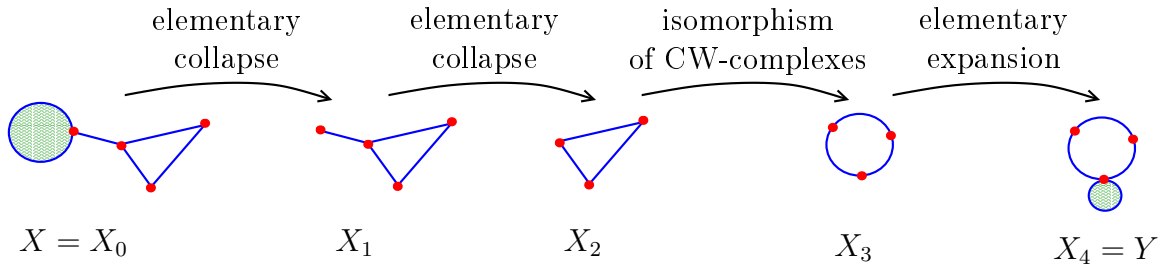
Definition. Let X be a CW-complex. We say that a CW-complex Y is an elementary expansion of X if the following holds:

(1) $Y = X \cup e^{n-1} \cup e^n$ where e^{n-1} is an $(n-1)$-cell that is not contained in X and e^n is an n-cell that is not contained in X.
(2) There exists a map $\varphi\colon \overline{B}^n \to Y$ with the following properties:
   (a) The map φ is the characteristic map for the n-cell e^n.
   (b) The map[1990] $\overline{B}^{n-1} \xrightarrow{\cong} S^{n-1}_{\geq 0} \xrightarrow{\varphi} Y$ is the characteristic map for the $(n-1)$-cell e^{n-1}.
   (c) We have $\varphi(S^{n-1}_{\leq 0}) \subset X^{n-1}$.

Conversely we also say that the CW-complex X is an elementary collapse of Y. We refer to the figure below for an illustration.

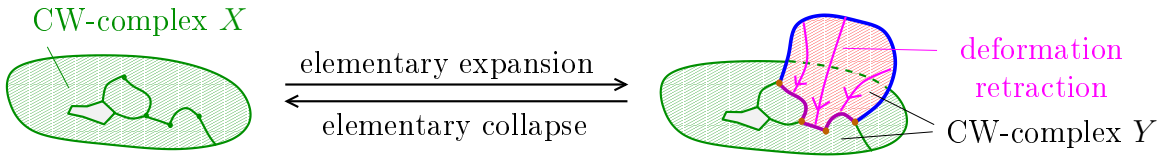
We continue with another definition.

Definition. Let X and Y be CW-complexes. We say X and Y are simple homotopy equivalent if there exists a sequence $X = X_0, X_1, \ldots, X_k = Y$ such that for $i = 1, \ldots, k$ one of the following three statements holds:



(1) X_i is an elementary expansion of X_{i-1}, or
(2) X_i is an elementary collapse of X_{i-1}, or
(3) X_i is isomorphic, as a CW-complex, to X_{i-1}.

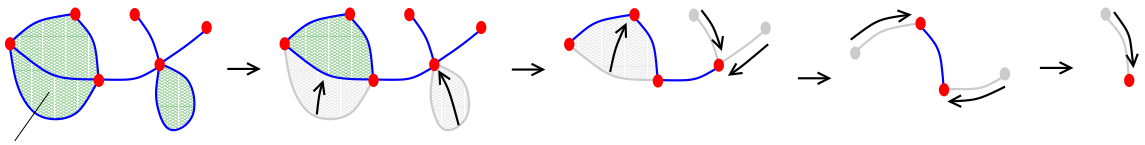
The following lemma justifies the name "simple homotopy equivalent".



Lemma 162.11. Let X and Y be CW-complexes. If X and Y are simple homotopy equivalent, then they are homotopy equivalent.

Proof. By the Homotopy-Equivalence Basics Lemma 15.1 the notion of being homotopy equivalent is an equivalence relation. Thus it suffices to show that if a CW-complex X is an elementary collapse of a CW-complex Y, then X is homotopy equivalent to Y. In

[1990] Here we use the explicit homeomorphism $\overline{B}^{n-1} \xrightarrow{\cong} S^{n-1}_{\geq 0}$ from page 152.



fact, by the Deformation Retract-Homotopy Equivalence Lemma 15.5 it suffices to show that X is a deformation retract of Y. We saw on page 434 that there exists a deformation retraction from $\overline{B}^n$ to $S^{n-1}_{\leq 0}$. It follows from the Homotopy Pushout Lemma 14.9 that this deformation retraction, together with the constant homotopy on X, defines a deformation retraction from Y to X. ■

It is also interesting to consider an interesting special case.

Definition. A finite CW-complex is called collapsible if there exists a sequence of elementary collapses that abuts in a CW-complex consisting of a single point.

collapsible CW-complex

The following lemma is an immediate consequence of Lemma 162.11.

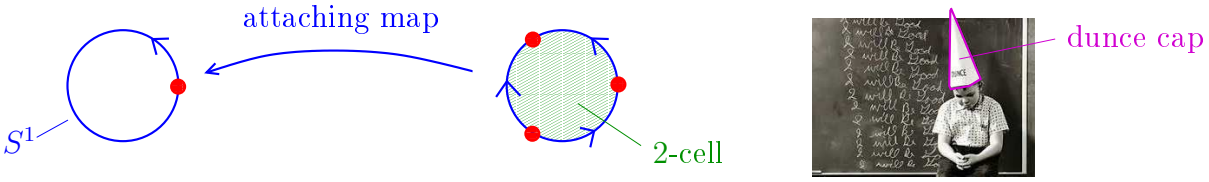
Lemma 162.12. Let X be a CW-complex. If X is collapsible, then X is contractible.

It is natural to ask whether the converses of Lemmas 162.11 and 162.12 hold. More precisely, we have the following questions.

Question 162.13.

(1) Let X be a finite CW-complex. If X is homotopy equivalent to a point, does it follow that X is collapsible?
(2) Let X and Y be finite CW-complexes.
   (a) If X and Y are homeomorphic, does it follow that X and Y are simple homotopy equivalent?
   (b) If X and Y are homotopy equivalent, does it follow that X and Y are simple homotopy equivalent?

In the remainder of this chapter we will discuss Question 162.13 (1). We will answer Question 162.13 (2) when we discuss Chapman's Theorem ?? and Proposition ??. To address Question 162.13 (1) it is useful to formulate the following corollary to the Whitehead Theorem 162.1.



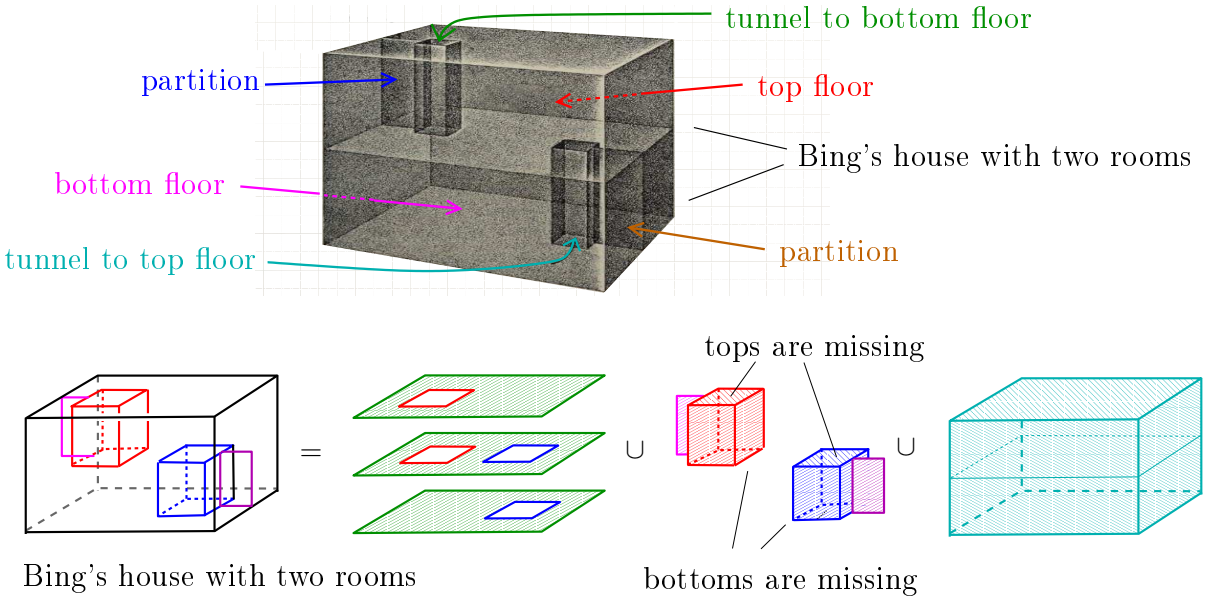
Corollary 162.14. (CW-Complex-Contractible Corollary) Let X be a CW-complex. If X is simply connected and if we have $\mathrm{H}_n(X;\mathbb{Z}) = 0$ for all $n \geq 2$, then X is contractible, i.e. X is homotopy equivalent to a point.

Proof. We let $Y = \{*\}$ be the topological space that consists of a single point and let $f\colon X \to Y = \{*\}$ be the only map there is. It follows immediately from the Weak Homotopy-vs-Homology Isomorphisms Proposition 161.6 that f is a weak homotopy equivalence. Thus the desired statement follows from the Whitehead Theorem 162.1 (1). ■

In the following we will use the CW-Complex-Contractible Corollary 162.14 to give not one, but two examples of CW-complexes that give a negative answer to Question 162.13 (1).

Examples.

(1) We equip S^1 with the usual CW-structure with one 0-cell $1 \in S^1$ and one 1-cell. Let $\gamma = \mathrm{id}\colon S^1 \to S^1$ be the identity map. The *dunce cap* is defined as the CW-complex X that is given by attaching one 2-cell to S^1 where the attaching map $S^1 \to S^1$ is given by the loop $\gamma * \overline{\gamma} * \gamma$,[1991] i.e. by the loop that is given by the composition of γ, $\overline{\gamma}$ and γ. Using the Cell Attachment-π_1-Proposition 69.11 (2) it is straightforward to show that X is simply connected. Furthermore it follows almost from the Cellular Boundary Map-via-Degrees Proposition 80.8 that the cellular homology, and thus by the Singular-Cellular H_*-Isomorphism Proposition 80.4 also the singular homology, vanishes in dimensions ≥ 2. It follows from the CW-Complex-Contractible Corollary 162.14 that the dunce cap is contractible.[1992] On the other hand it is clear that the dunce cap is not collapsible since there is only one cell in dimensions 0, 1 and 2 and no two of them can be matched to allow for an elementary collapse.



(2) It is also possible to give an example of a CW-complex that can be visualized as a subset of $\mathbb{R}^3$. More precisely, consider the topological space X that is shown in the two figures. It is commonly referred to as *Bing's house with two rooms*.[1993] We equip X with the fairly obvious CW-structure. In Exercise 162.10 we will see that X is simply connected and that $\mathrm{H}_n(X;\mathbb{Z}) = 0$ for $n \geq 2$. Thus, as in the previous example we can appeal to the CW-Complex-Contractible Corollary 162.14 to conclude that

[1991] The conscientious reader will notice that we had encountered this topological space in Exercise 70.2.

[1992] One could of course also prove this "by hand", but I am pretty sure that few people will enjoy doing this exercise. In fact I have not yet found a book which gives a down-to-earth proof that the dunce cap is contractible.

[1993] This example was given by R. H. Bing [**Bin1964**, p. 109] in 1964. In fact the picture we show in the first figure below is a slightly modified version of Bing's original drawing.

the house with two rooms is contractible.[1994] We leave the arduous task of showing that X is not collapsible to the reader.

Let X be the dunce cap. In 1963 Christopher Zeeman [**Zee1963a**, Theorem 1] showed that $X \times [0,1]$, equipped with the product CW-structure, is in fact collapsible. This result prompted Zeeman in 1963 to propose the following conjecture [**Zee1963a**, Conjecture 1].

Conjecture 162.15. (Zeeman Conjecture) If X is a finite contractible 2-dimensional CW-complex, then $X \times [0,1]$ is collapsible.

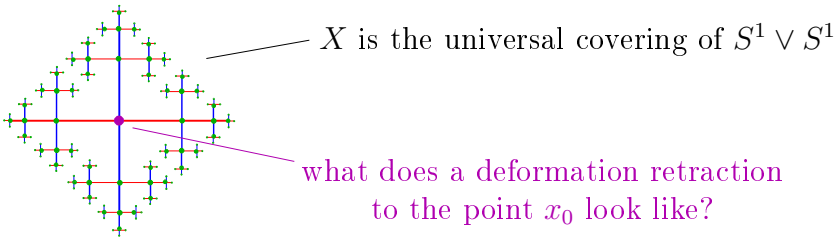
Like many other conjectures on CW-complexes, this conjecture sounds deceptively simple and elementary. In fact Zeeman was fully aware of the fact that the conjecture is almost certainly very difficult since he showed [**Zee1963a**, Theorem 2] that a proof of the Zeeman Conjecture 162.15 would lead to a new proof of the Poincaré Conjecture in dimension three, which was finally proved in 2003 by Perelman using a heavy dose of analysis, see Theorem **??**. Furthermore, Sergey Matveev [**Matv1987**] (see also [**Kupe2017a**, Proposition 4.2] and [**Barm2011**, Chapter 11]) showed that the Andrews-Curtis Conjecture 53.18 is a special case of the Zeeman Conjecture 162.15. We refer to [**MR1993, Matv2007, Kupe2017a**] for more on the Zeeman Conjecture.

Exercises for Chapter 162.

Exercise 162.1. Let $p \in \mathbb{N}$ and let $q_1, \dots, q_n \in \mathbb{Z}$ be integers that are coprime to p. We consider the following action of $\mathbb{Z}_p$ on $S^{2n-1} = \{(z_1, \dots, z_n) \in \mathbb{C}^n \,|\, |z_1|^2 + \cdots + |z_n|^2 = 1\}$:

$$\begin{array}{rcl} \mathbb{Z}_p \times S^{2n-1} & \to & S^{2n-1} \\ ([k], (z_1, \dots, z_n)) & \mapsto & (z_1 \cdot e^{2\pi \mathrm{i} k \dot{q}_1/p}, \dots, z_n \cdot e^{2\pi \mathrm{i} k \dot{q}_n/p}). \end{array}$$

[1994] A more direct argument for showing that Bing's house with two rooms is contractible is given on [**Hat2002**, p. 4].



One can easily verify that this action is smooth, orientation-preserving and discrete action. Thus it follows from the Manifold Quotient-by-Group Action Proposition 19.32 and the Orientation-Action Proposition 25.19 that the quotient $L(p;q_1,\dots,q_n) := S^{2n-1}/\mathbb{Z}_p$ is a closed orientable $(2n-1)$-dimensional smooth manifold.

Let $q_1,\dots,q_n$ and $\widetilde{q}_1,\dots,\widetilde{q}_n$ be integers that are coprime to p. Show that if there exists an $m \in \mathbb{Z}$ with $q_1 \cdot \dots \cdot q_n \equiv m^n \cdot \widetilde{q}_1 \cdot \dots \cdot \widetilde{q}_n$, then $L(p;q_1,\dots,q_n)$ and $L(p;\widetilde{q}_1,\dots,\widetilde{q}_n)$ are homotopy equivalent.

Remark. For $n = 2$ this is just a slight reformulation of the Lens Space-Homotopy Equivalence Proposition 162.4.

Exercise 162.2. Let $X = \mathbb{R}$. We equip X with the CW-structure where the 0-skeleton is given by $\mathbb{Z}$. The proof of the Whitehead Deformation Retract Proposition 162.2 provides a fairly explicit deformation retraction from $X = \mathbb{R}$ to $\{0\}$. What does this deformation retraction look like?

Exercise 162.3. Let X be the universal covering of $S^1 \vee S^1$. On page 3409 we saw that X admits a deformation retraction to $x_0 \in X$. What does an explicit deformation retraction of X to the point x_0 look like? We refer to the figure below for an illustration.

Exercise 162.4. We consider the following subset of $\mathbb{R}^2$:

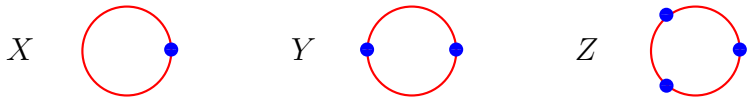
$$X := \text{line segment from } (0,1) \text{ to } (0,-1) \cup \bigcup_{n\in\mathbb{N}} \text{line segment from } (0,1) \text{ to } (\tfrac{1}{n},0) \cup \bigcup_{n\in\mathbb{N}} \text{line segment from } (0,-1) \text{ to } (-\tfrac{1}{n},0).$$

We equip X with the subspace topology coming from $\mathbb{R}^2$. We refer to the figure on page 3410 for an illustration.

(a) Show that all of the homotopy groups of X are trivial.

(b) Show that X is not contractible.
You might want to make use of the Contractibility Criterion Lemma 15.2 and Exercise 15.10.

Exercise 162.5. Let X and Y be two CW-complexes of dimension at most n. Furthermore let $f\colon X \to Y$ be a map that is $(n+1)$-connected. Show that f is a homotopy equivalence.



Exercise 162.6. Let $f\colon X \to Y$ be a map between path-connected CW-complexes. Let $x_0 \in X$. We assume that $f_*\colon \pi_k(X,x_0) \to \pi_k(Y,f(x_0))$ is the trivial map for every $k \in \mathbb{N}$. Does it follow that f is homotopic to a constant map?

Exercise 162.7. Let X be a connected CW-complex and let $k \leq l$ be natural numbers. We suppose that $\pi_i(X) = \mathrm{H}_i(X;\mathbb{Z}) = 0$ for $i = k,\dots,l$. Does it follow that X is homotopy

equivalent to a CW-complex which has no cells in dimensions $k, \dots, l$?
Remark. If $k = 1$, then this question is precisely Question 162.9.

Exercise 162.8. Let X be the 2-dimensional CW-complex corresponding to the presentation $\langle x \,|\, x^2 = e, x^3 = e \rangle$. We refer to the figure on page 3419 for an illustration. Show that X does not admit a contractible subcomplex S which contains the 1-skeleton of X and which has the property that X/S is homotopy equivalent to X.
Hint. Use the long exact sequence coming from Theorem 74.3.

Exercise 162.9. Show that the three CW-complexes shown in the figure below are simple homotopy equivalent.
Remark. It is possibly less confusing to first consider Y and Z.

Exercise 162.10. Let X be Bing's house with two rooms, i.e. X is the CW-complex that we defined in the figure on page 3423.

(a) Show that X is simply connected.
(b) Show that $\mathrm{H}_n(X; \mathbb{Z}) = 0$ for $n \geq 2$.
Hint. Using the Homology-of-CW-Complex Proposition 80.6 and using Euler characteristics will cut down the work considerably.
(c) Show that X is not collapsible.

Exercise 162.11. Let $n \in \mathbb{N}$ and furthermore let $f, g \colon S^n \to S^n$ be two maps. Show that if $f_* = g_* \colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n)$, then f and g are homotopic.

Exercise 162.12. Let $T = S^1 \times S^1$ be the 2-dimensional torus, equipped with the usual CW-structure. We attach two 2-cells along $S^1 \times \{0\}$ and along $\{0\} \times S^1$ and we obtain a CW-complex X.

(a) Show that X that is homotopy equivalent to S^2.
(b) Show that there is no embedding $S^2 \to X$.
Remark. You might want to use Exercise 82.3.

Exercise 162.13. Show that the long line $\mathbb{L}$, which we introduced on page 613, is weakly contractible but not contractible.
Hint. Use Proposition 22.14.

Exercise 162.14. Show that there exists a compact 4-dimensional smooth manifold that does not admit a smooth structure.
Hint. Use Hatcher's Theorem [**Hat1983**] that every orientation-preserving diffeomorphism of S^3 is diffeotopic to the identity.

163. Eilenberg-Maclane Spaces

In this chapter we introduce Eilenberg-Maclane spaces. Even though the definition is quite straightforward, these topological spaces will henceforth play an essential role.

163.1. **The definition and basic examples of Eilenberg-Maclane Spaces.** We recall the following definition from page 1761.

Definition. Let π be an abelian group and let $n \in \mathbb{N}$. We say that a non-empty topological space X is a Moore space of type $\mathrm{M}(\pi, n)$ if the following conditions are satisfied:

(1) X admits a CW-structure,
(2) for any $i \neq n$ we have $\widetilde{\mathrm{H}}_i(X;\mathbb{Z}) = 0$,
(3) $\mathrm{H}_n(X) \cong \pi$.
(4) If $n \geq 2$, then we demand that X is simply connected.

For the reader's convenience we recall the main result that we proved regarding Moore spaces.

Proposition 79.11. (Moore Space Existence Proposition) Given any $n \in \mathbb{N}$ and given any abelian group π there exists an $(n+1)$-dimensional CW-complex that has no cells in dimensions $1, \ldots, n-1$ and that is a Moore space of type $\mathrm{M}(\pi, n)$.

In light of the topics discussed in this chapter it is perhaps helpful to give a quick recap of the proof of the Moore Space Existence Proposition 79.11.

Sketch of proof. Since π is abelian it follows immediately from Lemma 89.14 (1) that there exists a free resolution of π of the following form:

$$0 \to \mathbb{Z}^{(A)} \xrightarrow{\varphi} \mathbb{Z}^{(B)} \xrightarrow{\rho} \pi \to 0.$$

We let $X := \bigvee_{a \in A} S^n_a$ and we let $Y := \bigvee_{b \in B} S^n_b$. We equip X and Y with the obvious CW-structures and we can make the identifications $\mathrm{H}_n(X;\mathbb{Z}) = \mathbb{Z}^{(A)}$ and $\mathrm{H}_n(Y;\mathbb{Z}) = \mathbb{Z}^{(B)}$. We construct a cellular map $h\colon X \to Y$ such that the induced map $\mathrm{H}_n(X;\mathbb{Z}) \to \mathrm{H}_n(Y;\mathbb{Z})$ agrees with φ under the above identifications. The mapping cone $\mathrm{Cone}(h\colon X \to Y)$ then has the desired properties. ■

The definition of an Eilenberg-Maclane space is almost identical to the definition of a Moore space, we just swap homology groups for homotopy groups:

Definition. Let π be a group and let $n \in \mathbb{N}$. Let X be a topological space.

(1) We say that X is an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$ if the following conditions hold:
   (a) X admits a CW-structure,
   (b) for any $i \neq n$ we have $\pi_i(X) = 0$,
   (c) $\pi_n(X) \cong \pi$.[1995]
(2) Let $x_0 \in X$. We say (X, x_0) is a pointed Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$ if X is an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$ and if X admits a CW-structure such that x_0 lies in the 0-skeleton of X.

[1995] It is perhaps worth recalling that $\pi_0(X) = 0$ means, by the definition on page 167, that X is non-empty and path-connected. In particular, by the Change-of-Base Point Proposition 86.9 (2) the isomorphism type of the homotopy groups $\pi_n(X)$, $n \in \mathbb{N}$, does not depend on the choice of the base point.

Remark.

(1) Our definition of an Eilenberg-Maclane space agrees with the definition in [**DaK2001**, p. 177]. Conversely in [**WhdG1978**, p. 239], [**Spa1995**, p. 424], [**Bre1993**, p. 488] and [**Hat2002**, p. 365] it does not say (at least explicitly) that an Eilenberg-Maclane space needs to admit a CW-structure.
(2) If a topological space X is an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$, then often in the literature one just says that X *is a* $\mathrm{K}(\pi, n)$. We will refrain from using this language.

It is perhaps initially not clear why the concept of an Eilenberg-Maclane space is useful, but at the very least it is a fun exercise to go through our long list of topological spaces that we have studied and to determine which ones are Eilenberg-Maclane spaces:

(1) We start with the trivial group $\{e\}$. Let $n \in \mathbb{N}$. In this case it is easy to find Eilenberg-Maclane spaces of type $\mathrm{K}(\{e\}, n)$. In fact it follows from the Homotopy-π_n-Proposition 71.7 (2) that any contractible CW-complex is an Eilenberg-Maclane space of type $\mathrm{K}(\{e\}, n)$. Thus we see in particular that for any $k \in \mathbb{N}_0$ the open ball B^k and the closed ball $\overline{B}^k$ are Eilenberg-Maclane spaces of type $\mathrm{K}(\{e\}, n)$.
(2) Let $k \in \mathbb{N}$. It follows from Corollary 48.18 and the discussion on page 1573 that the k-dimensional torus $(S^1)^k$ is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}^k, 1)$.
(3) Let $g \in \mathbb{N}_{\geq 2}$ and let Σ_g be a surface of genus g. On page 1575 we saw that $\pi_i(\Sigma_g) = 0$ for $i \geq 2$. Thus we see that Σ_g is an Eilenberg-Maclane space of type $\mathrm{K}(\pi_1(\Sigma_g), 1)$.
(4) Let $k \in \mathbb{N}$ and let $F = \langle x_1, \ldots, x_k \rangle$ be the free group on k generators. It follows from the discussion on page 1173 and Lemma 71.15 that the wedge $\bigvee_{i=1}^{k} S^1$ of k circles is an Eilenberg-Maclane space of type $\mathrm{K}(F, 1)$.
(5) It follows from Lemma 68.5 (3) together with the Coverings-π_n-Proposition 71.13 and Corollary 71.12 that the infinite real projective space $\varinjlim \mathbb{R}\mathrm{P}^k =: \mathbb{R}\mathrm{P}^\infty \cong S^\infty / x \sim -x^{1996}$ is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}_2, 1)$.

type $(\mathbb{Z}, 1)$ type $(\mathbb{Z}^2, 1)$ type $(\pi_1(\Sigma_2), 1)$ type $(\langle x, y \rangle, 1)$

We have now obtained a short but pleasant list of Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, 1)$. It is harder to find examples of Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, n)$ with $n \geq 2$ for a non-trivial group π. It turns out that we had found one interesting example of that type:

(6) Recall that by Lemma 68.6 we know that $\mathbb{C}\mathrm{P}^\infty$ admits a CW-structure. It follows from Theorem 155.12 (2) that the infinite complex projective space $\mathbb{C}\mathrm{P}^\infty$ is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, 2)$.

Remark.

[1996] In Lemma 68.5 (4c) we showed that there exists a homeomorphism $\mathbb{R}\mathrm{P}^\infty \cong S^\infty / x \sim -x$.

(1) One might initially hope that perhaps $\mathbb{H}\mathrm{P}^\infty$ could be an Eilenberg-Maclane space of type $\mathrm{K}(\pi, 4)$. First note that by the Quaternion-Projective Space Lemma 92.9 (7) we know that $\mathbb{H}\mathrm{P}^\infty$ is indeed a CW-complex. Furthermore, in in Exercise 160.1 we obtained the following results:
   (a) There exists an isomorphism $\pi_4(\mathbb{H}\mathrm{P}^\infty) \cong \mathbb{Z}$.
   (b) The group $\pi_n(\mathbb{H}\mathrm{P}^\infty)$ is finite for $n \neq 4$, in particular $\pi_n(\mathbb{H}\mathrm{P}^\infty) \otimes \mathbb{Q} = 0$ for $n \neq 4$.
   (c) There exists an isomorphism $\pi_5(\mathbb{H}\mathrm{P}^\infty) \cong \mathbb{Z}_2$.
   So we see that "rationally" $\mathbb{H}\mathrm{P}^\infty$ looks like an Eilenberg-Maclane space, but it is just not an Eilenberg-Maclane space.
(2) In the following chapters we will give many examples of "perfectly reasonable" topological spaces that are Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, 1)$. For $n \geq 2$ it seems like $\mathbb{C}\mathrm{P}^\infty$ is basically[1997] the only Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$ for some non-trivial group π which appears "in nature".

Our next goal is to find Eilenberg-Maclane spaces of type $\mathrm{K}(\mathbb{Z}_m, 1)$ for arbitrary m. For $m = 2$ we had just seen that $\mathbb{R}\mathrm{P}^\infty$ is such an Eilenberg-Maclane space. We recall that in Lemma 68.5 (3) we saw that we can make the identification $\mathbb{R}\mathrm{P}^\infty = S^\infty/\{\pm 1\}$ where the group $\{\pm 1\} \cong \mathbb{Z}_2$ acts in the obvious way on S^∞. The idea is to generalize this example. More precisely we want to find appropriate actions of any finite cyclic group on S^∞.
At this point it is convenient to recall that given coprime $p, q \in \mathbb{N}$ we defined on page 1075 the lens spaces $L(p, q) = S^3/\mathbb{Z}_p$ as the quotient of S^3 by a suitable action of $\mathbb{Z}_p$ on S^3. If one ponders for a while about the definition of lens spaces one is led to the following lemma.

Lemma 163.1. Let $m \in \mathbb{N}$ and let $r_1, r_2, \dots \in \mathbb{N}$ be natural numbers that are coprime to m.

(1) The map[1998]
$$\begin{array}{rcl} \mathbb{Z}_m \times S^\infty & \to & S^\infty \\ ([k], \underbrace{(z_1, z_2, z_3, \dots)}_{\in \mathbb{C}^\infty}) & \mapsto & (e^{2\pi \mathrm{i} k r_1/m} \cdot z_1, e^{2\pi \mathrm{i} k r_2/m} \cdot z_2, \dots) \end{array}$$
   defines a continuous and discrete action of $\mathbb{Z}_m$ on S^∞.
(2) The quotient space $L(m, r_1, r_2, \dots) := S^\infty/\mathbb{Z}_m$ admits a CW-structure.
(3) The quotient space $L(m, r_1, r_2, \dots) := S^\infty/\mathbb{Z}_m$ is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}_m, 1)$.

On page 3156 we saw, using the linking pairing, that lens spaces with isomorphic fundamental groups are not necessarily homotopy equivalent. We cannot define a linking pairing on the topological spaces $L(m, r_1, r_2, \dots)$. Thus the following question arises:

Question 163.2. How can one show that given $m \in \mathbb{N}$ the homotopy type of the topological spaces $L(m, r_1, r_2, \dots)$ depends on the choice of the parameters r_i?

Proof.

[1997] The slightly hesitant "basically" refers to the fact that out of $\mathbb{C}\mathrm{P}^\infty$ one can build a few other examples of Eilenberg-Maclane spaces, e.g. one can consider $\mathbb{C}\mathrm{P}^\infty \times \overline{B}^k$ or, as we will see shortly, the product $\mathbb{C}\mathrm{P}^\infty \times \mathbb{C}\mathrm{P}^\infty$ is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}^2, 2)$.
[1998] Here we view S^∞ as a subset of $\mathbb{C}^\infty$ via the identification $\mathbb{C}^\infty = \mathbb{R}^\infty$ from page 1476.

(1) The proof of this statement is quite similar to the task performed in Exercise 68.4. We leave it to the motivated reader to prove the desired statement. As always it takes a little effort to work rigorously with the topology of $S^\infty = \varinjlim S^n$.

(2) Given $n \in \mathbb{N}$ the action of $\mathbb{Z}_m$ on S^∞ restricts to an action on $S^{2n-1} \subset S^\infty$. In [**Hat2002**, p. 144] or alternatively [**Shas2014**, p. 196] an explicit CW-structure for $S^{2n-1}/\mathbb{Z}_m$ is constructed. These CW-structures have the property that for $k < l$ the $(2k-1)$-skeleton of $S^{2l-1}/\mathbb{Z}_m$ is precisely the CW-complex $S^{2k-1}/\mathbb{Z}_m$. It follows quite easily from Lemma 56.5 that the CW-structures on the $S^{2n-1}/\mathbb{Z}_m$ give rise to a CW-structure on $S^\infty/\mathbb{Z}_m$.

(3) (a) Let $n \geq 2$. We calculate that

$$\pi_n(L(m, r_1, r_2, \dots)) \quad \cong \quad \pi_n(S^\infty/\mathbb{Z}_m) \quad \underset{\uparrow}{\cong} \quad \pi_n(S^\infty) \quad \underset{\uparrow}{=} \quad 0.$$

follows from (1), the Actions-Covering Proposition 48.9 and Coverings-π_n-Proposition 71.13 and from the fact that $n \geq 2$ — Corollary 71.12

(b) It follows immediately from (1), the Fundamental Group-via-Actions Theorem 48.16 and Corollary 71.12 that we have isomorphisms $\pi_1(L(m, r_1, r_2, \dots)) = \pi_1(S^\infty/\mathbb{Z}_m) \cong \mathbb{Z}_m$. ■

The following proposition allows us to construct more Eilenberg-Maclane spaces out of given ones.

Proposition 163.3. (Eilenberg-Maclane Construction Proposition)

(1) Let X be an Eilenberg-Maclane space of type $\mathrm{K}(A, n)$ and let Y be an Eilenberg-Maclane space of type $\mathrm{K}(B, n)$.
   (a) The CW-complex $X \otimes Y$, that is defined on page 1500, is an Eilenberg-Maclane space of type $\mathrm{K}(A \times B, n)$.
   (b) If at least one of X or Y has only countably many cells, then the product $X \times Y$ is an Eilenberg-Maclane space of type $\mathrm{K}(A \times B, n)$.

The remaining two statements only apply to the case $n = 1$.

(2) Let X be an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$. We pick a base point $x_0 \in X$ and we pick an isomorphism $\varphi\colon \pi_1(X, x_0) \to \pi$. Let Γ be a subgroup of π. We denote by $\widetilde{X}$ the covering space of X corresponding to the subgroup[1999] $\varphi^{-1}(\Gamma) \subset \pi_1(X, x_0)$. Then $\widetilde{X}$ is an Eilenberg-Maclane space of type $\mathrm{K}(\Gamma, n)$.

(3) Let X be an Eilenberg-Maclane space of type $\mathrm{K}(A, 1)$ and let Y be an Eilenberg-Maclane space of type $\mathrm{K}(B, 1)$. We pick CW-structures for X and Y. Then any wedge[2000] $X \vee Y$ is an Eilenberg-Maclane space of type $\mathrm{K}(A * B, 1)$.

Remark. The restriction in the Eilenberg-Maclane Construction Proposition 163.3 (1) on the CW-complexes X and Y is a major nuisance. Even though this condition on the number

[1999] Since X is a CW-complex we know from the CW-Complex Properties Proposition 68.10 (6) that X is locally simply connected. Therefore it follows from the Covering Existence Theorem 61.5 that the covering exists and it follows from the Covering Uniqueness Theorem 61.9 that the covering corresponding to the subgroup $\varphi^{-1}(\Gamma) \subset \pi_1(X, x_0)$ is essentially unique.

[2000] Recall our convention from page 1507: whenever we take the wedge of CW-complexes, we only use points in the 0-skeleton. The "any" now refers to the fact that, under this restriction, any wedge is in fact an Eilenberg-Maclane space.

of cells is not an issue for the Eilenberg-Maclane spaces that we have considered above, the "canonical" Eilenberg-Maclane spaces that we will construct shortly do *not* satisfy this condition. Thus one should apply the Eilenberg-Maclane Construction Proposition 163.3 (1) with great caution.

Proof.

(1) Recall that by construction and by Proposition 68.23 we know $X \otimes Y$ is a CW-complex whose underlying set is $X \times Y$. Let $\mathrm{id}\colon X \otimes Y \to X \times Y$ be the identity map. We pick $x \in X$ and $y \in Y$. Given any $k \in \mathbb{N}_0$ we have the following isomorphisms

$$\pi_k(X \otimes Y, (x,y)) \xrightarrow[\uparrow]{\cong} \pi_k(X \times Y, (x,y)) \xrightarrow[\uparrow]{\cong} \pi_k(X,x) \times \pi_k(Y,y) \xrightarrow{\cong} \begin{cases} A \times B, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Lemma 161.7 — Propositions 48.20 and 71.8

Since $X \otimes Y$ is a CW-complex we obtain from this discussion that $X \otimes Y$ is an Eilenberg-Maclane space of type $\mathrm{K}(A \times B, n)$.

If at least one of X or Y has only countably many cells, then we know by Proposition 68.23 that $X \otimes Y = X \times Y$, i.e. $X \times Y$ itself is an Eilenberg-Maclane space of type $\mathrm{K}(A \times B, n)$.

(2) First note that we know by the CW-complex Covering Proposition 68.37 that $\widetilde{X}$ is a CW-complex. It now follows immediately from the Coverings-π_n-Proposition 71.13 that $\widetilde{X}$ is an Eilenberg-Maclane space of type $\mathrm{K}(\Gamma, n)$.

(3) Let $x \in X^0$ and $y \in Y^0$ be points in the 0-skeleta of X and Y. By the CW-Complex Properties Proposition 68.10 (5) we know that the points x and y are good. Thus it follows from the Wedge-π_1-Proposition 52.3 that we have isomorphisms $\pi_1(X \vee Y) \cong \pi_1(X) * \pi_1(Y) \cong A * B$. Furthermore we obtain basically immediately from Exercise 85.3 that all higher homotopy groups of $X \vee Y$ vanish. Finally we know by the CW-Complex Construction Lemma 68.32 (4) that $X \vee Y$ is a CW-complex. ■

The following lemma summarizes a few basic facts about Eilenberg-Maclane spaces.

Lemma 163.4. Let $n \in \mathbb{N}$ and let π be a group. If X is an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$, then given any abelian group G the following statements hold:

(1) We have $\mathrm{H}_0(X;G) \cong G$ and $\mathrm{H}^0(X;G) \cong G$.
(2) For $i = 1, \ldots, n-1$ we have $\mathrm{H}_i(X;G) = 0$ and $\mathrm{H}^i(X;G) = 0$.
(3) Given any $x_0 \in X$ the Hurewicz homomorphism $\pi_n(X,x_0)_{\mathrm{ab}} \to \mathrm{H}_n(X;\mathbb{Z})$ is an isomorphism. In particular $\mathrm{H}_n(X;\mathbb{Z}) \cong \pi_{\mathrm{ab}}$.
(4) The evaluation map $\mathrm{H}^n(X;G) \to \mathrm{Hom}(\mathrm{H}_n(X;\mathbb{Z}), G)$ is an isomorphism.

Proof. The statements follow easily from the Hurewicz Theorems 84.5 and 85.5 and from the Universal Coefficient Theorems 89.17 and 110.12. The experienced reader will have no troubles with filling in the details. ■

163.2. **Killing higher homotopy groups.** In the subsequent section we will give a general construction of Eilenberg-Maclane spaces. To streamline the discussion we outsource a few preparations to the present section.

First we point out that the following, fairly self-evident convention will be in effect in the coming chapters.

Convention.

(1) Given $n \in \mathbb{N}_0$ we write $* = (0, \ldots, 0, 1) \in S^n$. We equip S^n with the canonical CW-structure from page 1472, i.e. we view S^n as a CW-complex with one 0-cell $\{*\}$ and one n-cell.

(2) We always form any wedge of spheres $\bigvee_{i \in I} S_i^{n_i}$ by identifying the points $* \in S_i^{n_i}$. By the CW-Complex Construction Lemma 68.32 (4) we can and will view the wedge $\bigvee_{i \in I} S_i^{n_i}$ as a CW-complex in the obvious way, i.e. we have one 0-cell $\{*\}$ and for each $i \in I$ we have one n_i-cell.

(3) By a slight abuse of notation we sometimes say X is a k-dimensional CW-complex if the highest dimension of a cell is $\leq k$.

We start out with the following calculation.

Proposition 163.5. (Wedge-of-Spheres-π_n-Proposition) Let I be a set, let $n \in \mathbb{N}$ and for each $i \in I$ let S_i^n be a copy of S^n. For each $i \in I$ we denote by $\varphi_i \colon S^n \to S_i^n$ the obvious homeomorphism. By a slight abuse of notation we denote by φ_i also the composition of φ_i with the canonical inclusion map $S_i^n \to \bigvee_{i \in I} S_i^n$.

(1) For any $i \in \{1, \ldots, n-1\}$ we have $\pi_i\Big(\bigvee_{i \in I} S_i^n, *\Big) = 0$.

(2) If $n = 1$, then the homomorphism[2001]

$$\begin{array}{rcl} \overbrace{\langle \{x_i\}_{i \in I} \rangle}^{\text{free group}} & \to & \pi_1\Big(\bigvee_{i \in I} S_i^1, *\Big) \\ x_i & \mapsto & [\varphi_i] \end{array}$$

is an isomorphism.

(3) If $n \geq 2$, then the homomorphism[2002]

$$\begin{array}{rcl} \overbrace{\mathbb{Z}^{(I)} = \bigoplus_{i \in I} \mathbb{Z} \cdot i}^{\text{free abelian group}} & \to & \pi_n\Big(\bigvee_{i \in I} S_i^n, *\Big) \\ i & \mapsto & [\varphi_i] \end{array}$$

is an isomorphism.

Proof.

(1) As we pointed out above, we can view $\bigvee_{i \in I} S_i^n$ as a CW-complex with one 0-cell and no other cells outside of dimension n. It follows from the CW-Skeleton-π_n-Proposition 71.9 that all homotopy groups in dimension $1, \ldots, n-1$ vanish.

(2) In the case that I is a finite set, then, as we saw in the proof of the Fundamental Group-Wedge-of-Circles Lemma 52.4, the statement follows easily from applying the Wedge-π_1-Proposition 52.3 altogether $k - 1$ times. The general case is proved in Proposition 52.7.

[2001] By Lemma 51.15 the given data does indeed determine a unique homomorphism.

[2002] Since $n \geq 2$ we know by the Homotopy Group-Abelian Proposition 71.3 that the right-hand side is an abelian group. Thus it follows from Lemma 51.1 that the given data does indeed determine a unique homomorphism.

(3) Let $n \in \mathbb{N}_{\geq 2}$. We consider the maps

$$\mathbb{Z}^{(I)} = \bigoplus_{i\in I} \mathbb{Z}\cdot i \xrightarrow[\uparrow]{\cong} \bigoplus_{i\in I} \mathrm{H}_n(S_i^n;\mathbb{Z}) \xrightarrow[\uparrow]{\cong} \mathrm{H}_n\Big(\bigvee_{i\in I} S_i^n;\mathbb{Z}\Big) \xleftarrow[\uparrow]{\cong} \pi_n\Big(\bigvee_{i\in I} S_i^n, *\Big).$$

given by $i \mapsto [S_i^n]$ — Wedge-H$_*$-Proposition 79.9 — by the Hurewicz Theorem 85.5 which we can apply by (1)

It is straightforward to verify that this composition of isomorphisms is precisely the isomorphism under consideration. ■

We continue with the following two propositions which basically says that for a given CW-complex one can "kill" all homotopy groups beyond a chosen degree.

Proposition 163.6. (Kill-Higher-π_*-Proposition) Let $k \in \mathbb{N}$, let X be a connected $(k+1)$-dimensional CW-complex[2003] and let $x_0 \in X$ be a base point.

(1) There exists a $(k+2)$-dimensional CW-complex Y with the following properties:
   (a) the $(k+1)$-skeleton of Y agrees with X,
   (b) for $i = 1, \ldots, k$ the inclusion induced map $\pi_i(X, x_0) \to \pi_i(Y, x_0)$ is an isomorphism, and
   (c) we have $\pi_{k+1}(Y, x_0) = 0$.

(2) The CW-complex Y in (1) can be chosen canonically.[2004]

(3) If X has countably many cells, then Y as in (1) can be chosen to have countably many cells.[2005]

Proof.

(1) We pick a set $\{\varphi_j \colon (S^{k+1}, *) \to (X, x_0)\}_{j\in J}$ of maps that represent a generating set for the group $\pi_{k+1}(X, x_0)$. We set

$$Y = \Big(X \sqcup \bigsqcup_{j\in J} \overline{B}_j^{k+2}\Big)/\!\sim \qquad \text{with } \varphi_j(s) \sim s \text{ for } s \in S_j^{k+1} = \partial\overline{B}_j^{k+2}.$$

Put differently, Y is the $(k+2)$-dimensional CW-complex that is obtained from X by attaching one $(k+2)$-cell for each $j \in J$ with attaching map given by φ_j. We denote by $i \colon X \to Y$ the inclusion map. Now we verify that Y has all the desired qualities.

   (a) By construction Y is a $(k+2)$-dimensional CW-complex such that the $(k+1)$-skeleton equals X.

   (b) It follows immediately from the CW-Skeleton-π_n-Proposition 71.9 and (a) that the inclusion induced map $i_* \colon \pi_s(X, x_0) \to \pi_s(Y, x_0)$ is an isomorphism for $s = 1, \ldots, k$ and that the map $i_* \colon \pi_{k+1}(X, x_0) \to \pi_{k+1}(Y, x_0)$ is an epimorphism.

[2003] We follow the convention established on pages 1469 and 3431, i.e. when we say "n-dimensional CW-complex" we allow for the possibility that the highest dimension of a cell is $< n$.

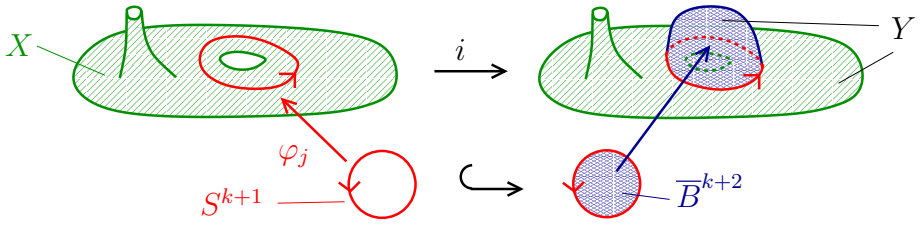
[2004] Here "canonical" is shorthand for saying that in the proof of the proposition we provide an explicit construction of Y does not depend on any choices.

[2005] Note though that we do *not* claim that we can find a canonical Y with countably many cells.

(c) Let $j \in J$. We have the following simple but useful commutative diagram:

$$\begin{array}{ccccc} S^{k+1} & & \xrightarrow{\quad\varphi_j\quad} & & X \\ \downarrow & & & & \downarrow i \\ \overline{B}^{k+2} & \xrightarrow{\text{id}} & \overline{B}_j^{k+2} & \hookrightarrow & X \sqcup \bigsqcup_{j\in J} \overline{B}_j^{k+2} \twoheadrightarrow Y. \end{array}$$

In other words, the map $i \circ \varphi_j \colon S^{k+1} \to Y$ extends to a map $\overline{B}^{k+2} \to Y$. By the Trivial-in-π_n-Lemma 71.4 this implies that $i_*([\varphi_j]) = [i \circ \varphi_j] = 0 \in \pi_{k+1}(Y, x_0)$.



(d) Since $\{[\varphi_j]\}_{j\in J}$ is by choice a generating set for $\pi_{k+1}(X, x_0)$ we obtain from (c) that $i_* \colon \pi_{k+1}(X, x_0) \to \pi_{k+1}(Y, x_0)$ has trivial image.

(e) It follows from (b) and (d) that $\pi_{k+1}(Y, x_0) = 0$.

We have thus verified that Y has all the desired properties.

(2) It is easy to come up with a canonical Y: in the construction provided in (1) we just need to consider the set of all maps $(S^{k+1}, *) \to (X, x_0)$. Evidently this set is canonical and evidently it represents a generating set for $\pi_{k+1}(X, x_0)$. The resulting CW-complex Y is the canonical CW-complex we desired.

(3) Finally suppose that X has countably many cells. It follows from the rather non-trivial Proposition 104.21 that $\pi_{k+1}(X, x_0)$ is countable. Therefore we can pick a countable family $\{\varphi_j \colon (S^{k+1}, *) \to (X, x_0)\}_{j\in J}$ of maps that represent a generating set for the group $\pi_{k+1}(X, x_0)$. The resulting CW-complex Y evidently has only countably many cells. ■

We conclude this technical section with the following proposition that is mostly just an iterated application of the Kill-Higher-π_*-Proposition 163.6.

Proposition 163.7. (Kill-All Higher-π_n-Proposition) Let $k \in \mathbb{N}$, let Y be a connected $(k+1)$-dimensional CW-complex and let $y_0 \in Y$.

(1) There exists a CW-complex Z with the following three properties:
  (a) the $(k+1)$-skeleton of Z equals Y,
  (b) we have $\pi_i(Z) = 0$ for $i \geq k+1$,
  (c) for any $i \in \{1, \ldots, k\}$ the inclusion induced map $\pi_i(Y, y_0) \xrightarrow{\cong} \pi_i(Z, y_0)$ is an isomorphism.

(2) The CW-complex Z in (1) can be chosen canonically.

(3) If Y has countably many cells, then Z as in (1) can be chosen to have countably many cells.

Proof. Let $k \in \mathbb{N}$ and let Y be a connected $(k+1)$-dimensional CW-complex. Let $y_0 \in Y$.

(1) We define $Z_{k+1} = Y$. For $i = k+1, k+2, \ldots$ we iteratively apply the Kill-Higher-π_*-Proposition 163.6 to Z_i to obtain a sequence of CW-complexes $Z_{k+1}, Z_{k+2}, \ldots$ with the following properties:
   (i) each Z_i is an i-dimensional CW-complex,
   (ii) for each $i \geq k+1$ the i-skeleton of Z_{i+1} is given by Z_i,
   (iii) for each $i \geq k+1$ we have $\pi_i(Z_{i+1}, y_0) = 0$.

   We set $Z := \varinjlim Z_i = \bigcup_{i=k+1}^{\infty} Z_i$ and we equip it with the obvious CW-structure such that for each $i \geq k+1$ the i-skeleton of Z is given by Z_i. We claim that Z has the desired three properties:
   (a) It follows from (ii) that the $(k+1)$-skeleton of Z equals Y.
   (b) Let $i \geq k+1$. We have

$$\pi_i(Z, y_0) \underset{\substack{\uparrow \\ \text{CW-Skeleton-}\pi_n\text{-Proposition 71.9}}}{\overset{\cong}{\leftarrow}} \pi_i((i+1)\text{-skeleton } Z^{i+1} \text{ of } Z, y_0) \underset{\substack{\uparrow \\ \text{since } Z^{i+1} = Z_{i+1}}}{=} \pi_i(Z_{i+1}, y_0) \underset{\substack{\uparrow \\ \text{by (iii)}}}{=} 0.$$

   (c) This statement follows immediately from (a) and the CW-Skeleton-π_n-Proposition 71.9.

(2) This statement follows immediately from the Kill-Higher-π_*-Proposition 163.6 (2).

(3) This statement follows immediately from the Kill-Higher-π_*-Proposition 163.6 (3). ■

163.3. **Existence of Eilenberg-Maclane Spaces.** Using the examples from the first section and using the Eilenberg-Maclane Construction Proposition 163.3 we can "by hand" construct Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, 1)$ for many groups π. One can ask for which pairs (π, n) there exist corresponding Eilenberg-Maclane spaces. There is one obvious restriction: since homotopy groups $\pi_n(X)$ with $n \geq 2$ are abelian, see the Homotopy Group-Abelian Proposition 71.3, we see that for $n \geq 2$ we can only hope to find an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$ if π is abelian. Perhaps somewhat surprisingly this is the only restriction on the existence of Eilenberg-Maclane spaces.

Theorem 163.8. (Eilenberg-Maclane Existence Theorem) Let $n \in \mathbb{N}$ and let π be a group. If $n \geq 2$, then we demand that π is abelian. There exists a *canonical* triple $(X, x_0, \varphi\colon \pi_n(X, x_0) \to \pi)$ with the following properties:
(1) X is an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$.
(2) X is a CW-complex with one 0-cell $\{x_0\}$ and with no cells in dimensions $1, \ldots, n-1$.
(3) $\varphi\colon \pi_n(X, x_0) \to \pi$ is an isomorphism.

Definition. We refer to the canonical CW-complex from the Eilenberg-Maclane Existence Theorem 163.8 as the canonical Eilenberg-Maclane space $\mathrm{K}(\pi, n)$.

Remark. As we will see shortly, the canonical Eilenberg-Maclane spaces that we construct in the proof of the Eilenberg-Maclane Existence Theorem 163.8 are monstrously large. More precisely, the CW-complex of type $\mathrm{K}(\pi, n)$ has uncountably many cells in each dimension $\geq n+1$. The cautionary remark from page 3430 about taking products of Eilenberg-Maclane spaces thus applies to the canonical Eilenberg-Maclane spaces.

After the discussion of the previous section the approach to producing an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$ is presumably pretty clear:

(1) Start out with a CW-complex with one 0-cell, no cells in dimension $1, \ldots, n-1$ and "sufficiently" many n-cells to be able to "generate" the group π.
(2) Attach $(n+1)$-cells to chop down the n-th homotopy group to obtain the desired group π.
(3) Attach cells of dimension $\geq n+2$ to kill all homotopy groups in dimensions $\geq n+1$.

We basically know how to perform (1) and (3), so it remains to do (2) carefully. The combination of steps (1) and (2) is performed in the following proposition.

Proposition 163.9. (Homotopy Group-Realization Proposition)

(1) Let π be any group. There exists a canonical triple $(Y, x_0, \varphi\colon \pi_1(Y, x_0) \to \pi)$ with the following properties:
   (a) Y is a 2-dimensional CW-complex with one 0-cell $\{x_0\}$,
   (b) $\varphi\colon \pi_1(Y, x_0) \to \pi$ is an isomorphism.
(2) Let π be an abelian group π and let $n \in \mathbb{N}_{\geq 2}$. There exists a canonical triple $(Y, x_0, \varphi\colon \pi_n(Y, x_0) \to \pi)$ with the following properties:
   (a) Y is an $(n+1)$-dimensional CW-complex with one 0-cell $\{x_0\}$ and no cells in dimensions $1, \ldots, n-1$,
   (b) $\varphi\colon \pi_n(Y, x_0) \to \pi$ is an isomorphism.

Remark. The first result is related to Corollary 69.12 which says that given any *finitely presented* group π there exists a *finite* connected 2-dimensional CW-complex Y with $\pi_1(Y) \cong \pi$.

Before we provide the proof of the Homotopy Group-Realization Proposition 163.9 we convince ourselves of the fact that this proposition, together with the Kill-All Higher-π_n-Proposition 163.7, does indeed imply the Eilenberg-Maclane Existence Theorem 163.8.

Proof of the Eilenberg-Maclane Existence Theorem 163.8. In the following we discuss the case $n \geq 2$. The proof for $n = 1$ is almost identical. Thus let $n \in \mathbb{N}_{\geq 2}$ and let π be an abelian group. By the Homotopy Group-Realization Proposition 163.9 (2) there exists a canonical triple $(Y, x_0, \varphi\colon \pi_n(Y, x_0) \to \pi)$ with the following properties:

(1) Y is an $(n+1)$-dimensional CW-complex with one 0-cell $\{0\}$ and no cells in dimensions $1, \ldots, n-1$,
(2) $\varphi\colon \pi_n(Y, x_0) \to \pi$ is an isomorphism.

We plug this data into the Kill-All Higher-π_n-Proposition 163.7 and we obtain a canonical CW-complex Z with the following three properties:

(3) the $(n+1)$-skeleton of Z equals Y (here we use that Y equals its own $(n+1)$-skeleton),
(4) we have $\pi_j(Z) = 0$ for $j \geq n+1$,
(5) the inclusion $i\colon Y \to Z$ induces an isomorphism $\pi_n(Y, x_0) \xrightarrow{\cong} \pi_n(Z, x_0)$.

Note that it follows from (1) and (3) together with the CW-Skeleton-π_n-Proposition 71.9 that the following holds:

(6) We have $\pi_j(Z, x_0) = 0$ for $j = 1, \ldots, n-1$.

It follows immediately from all of the above statements that the canonical triple

$$\big(Z, x_0, \varphi \circ i_*^{-1} \colon \pi_n(Z, x_0) \xleftarrow[\cong]{i_*} \pi_1(Y, x_0) \xrightarrow[\cong]{\varphi} \pi\big)$$

has all the desired properties. ■

Now we turn to the proof of the Homotopy Group-Realization Proposition 163.9. The proof naturally splits into the two cases $n = 1$ and $n \geq 2$.

Proof of the Homotopy Group-Realization Proposition 163.9 (1). Let π be a group. Given $g \in \pi$ we write $S^1_g := S^1 \times \{g\}$, i.e. S^1_g is a copy of S^1. Let $* = (0, 1) \in S^1$ be the usual base point of S^1. We consider the wedge $X := \bigvee_{g \in \pi} S^1_g$ which is given by identifying all the points $(*, g) \in S^1_g$. We denote by $x_0 \in X$ the wedge point. We apply the convention from page 3431 to view X as a CW-complex in the obvious way.

By the Wedge-of-Spheres-π_n-Proposition 163.5 (2) we have a canonical identification $\langle \{x_g\}_{g \in \pi} \rangle = \pi_1(X, x_0)$. Thus, by Lemma 51.15, there exists a unique homomorphism $\psi \colon \pi_1(X, x_0) = \langle \{x_g\}_{g \in \pi} \rangle \to \pi$ such that $\psi(x_g) = g$ for every $g \in \pi$. This homomorphism is, by construction, an epimorphism. We set $\Gamma = \ker(\psi)$.

Next let $\{\alpha_j \colon (S^1, *) \to (X, x_0)\}_{j \in J}$ be the family of all loops that represent an element in $\Gamma = \ker(\psi \colon \pi_1(X, x_0) \to \pi)$. We set

$$Y \;=\; \Big(X \sqcup \bigsqcup_{j \in J} \overline{B}^2_j\Big)/\!\sim \qquad \text{with } \alpha_j(s) \sim s \text{ for } s \in S^1_j = \partial \overline{B}^2_j.$$

Put differently, Y is the 2-dimensional CW-complex that is obtained from X by attaching one 2-cell for each $j \in J$ with attaching map given by α_j. By construction Y is a 2-dimensional CW-complex such that the 1-skeleton equals X. We denote by $i \colon X \to Y$ the inclusion map.

Claim. The map $i_* \colon \pi_1(X, x_0) \to \pi_1(Y, x_0)$ descends to a map

$$\varphi \colon \pi_1(X, x_0)/\Gamma \;\to\; \pi_1(Y, x_0)$$

and this map is an isomorphism.

Proof. The proof naturally breaks into several parts.

(1) Let $j \in J$. The same elementary argument as in the proof of the Kill-Higher-π_*-Proposition 163.6 shows that the map $i \circ \alpha_j \colon S^1 \to Y$ extends to a map $\overline{B}^2 \to Y$. By the Extension-to-Disk Lemma 47.1 this observation implies that $i_*([\alpha_j]) = [i \circ \alpha_j] = 0 \in \pi_1(X, x_0)$. Since $\{[\alpha_j]\}_{j \in J}$ contains every single element of Γ we see that $i_* \colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$ descends to a map

$$\varphi \colon \pi_1(X, x_0)/\Gamma \;\to\; \pi_1(Y, x_0).$$

(2) It follows from $X = Y^1$ and the CW-Skeleton-π_n-Proposition 71.9 that the map $i_* \colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$ is an epimorphism. This implies that φ is also an epimorphism.

(3) We still need to show that the map $\varphi \colon \pi_1(X, x_0)/\Gamma \to \pi_1(Y, y_0)$ is a monomorphism. At this stage this is equivalent to showing that $\ker(i_* \colon \pi_1(X, x_0) \to \pi_1(Y, y_0)) = \Gamma$. Thus let $g \in \ker(i_* \colon \pi_1(X, x_0) \to \pi_1(Y, y_0))$. We start out with the following claim.

Claim. There exists a finite subset $\{i_1, \dots, i_m\} \subset I$ such that g lies in the kernel of the inclusion induced map $\pi_1(X, x_0) \to \pi_1\big(\big(X \sqcup \big(\overline{B}^2_{i_1} \cup \dots \cup \overline{B}^2_{i_m}\big)\big)/\!\sim, x_0\big)$.

Proof. By Lemma 56.9 there exists a compact subset K of Y such that g lies in the kernel of the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup K, x_0)$. The claim now follows easily from Lemma 68.16 (2). ⊞

Let $I = \{i_1, \dots, i_m\}$ be such a finite subset. It follows from the Cell Attachment-π_1-Proposition 69.11 (2), applied altogether m times, together with Exercise 53.1 that we have the following commutative diagram

$$\begin{array}{ccc} \pi_1(X, x_0) & \longrightarrow & \pi_1\big(\big(X \sqcup \big(\overline{B}^2_{i_1} \cup \dots \cup \overline{B}^2_{i_m}\big)\big)/\!\sim, x_0\big) \\ & \searrow & \downarrow \\ & & \pi_1(X, x_0)/\langle\!\langle [\alpha_{i_1}], \dots, [\alpha_{i_m}] \rangle\!\rangle. \end{array}$$

Thus we see that $g \in \langle\!\langle [\alpha_{i_1}], \dots, [\alpha_{i_m}] \rangle\!\rangle$. Since $[\alpha_{i_1}], \dots, [\alpha_{i_m}]$ lie by definition in Γ we see that $g \in \Gamma$.

We are now basically done. Indeed, the CW-complex Y is 2-dimensional, it has a single 0-cell x_0 and it is canonical. Furthermore the map $\psi\colon \pi_1(X, x_0) \to \pi$ induces an isomorphism $\overline{\psi}\colon \pi_1(X, x_0)/\Gamma \to \pi$. Thus we see that the canonical triple

$$\Big(Y, x_0, \pi_1(Y, x_0) \underset{\cong}{\overset{\varphi}{\leftarrow}} \pi_1(X, x_0)/\Gamma \underset{\cong}{\overset{\overline{\psi}}{\to}} \pi\Big)$$

has all the desired properties. ■

Now we turn to the proof of the Homotopy Group-Realization Proposition 163.9 (2).

Proof of the Homotopy Group-Realization Proposition 163.9 (2). Let π be an abelian group and let $n \geq 2$. If we do not care about a canonical construction, then we could just use the Moore Space Existence Proposition 79.11 to obtain an $(n+1)$-dimensional CW-complex Y with one 0-cell and no cells in dimensions $1, \dots, n-1$ and with $\mathrm{H}_n(Y; \mathbb{Z}) \cong \pi$. By the Hurewicz Theorem 85.5 this implies that $\pi_n(Y) \cong \pi$. Unfortunately this construction is not canonical.

Since we are really eager to have canonical constructions we need to provide a different argument. Evidently, in the following discussion, we will try for as long as possible to roll over ideas from the proof of the Homotopy Group-Realization Proposition 163.9 (1).

For each $g \in \pi$ we write $S^n_g := S^n \times \{g\}$. We consider $* = (0, \dots, 0, 1) \in S^n$. As in (1) we consider the wedge $X := \bigvee_{g \in \pi} S^n_g$ and we view X canonically as a CW-complex. We denote by $x_0 \in X$ the wedge point.

By the Wedge-of-Spheres-π_n-Proposition 163.5 (3) we have a canonical identification $\pi_n(X, *) = \mathbb{Z}^{(\pi)}$. Since π is an abelian group we know from Lemma 51.1 that there exists a unique homomorphism $\psi\colon \pi_n(X, *) = \mathbb{Z}^{(\pi)} \to \pi$ with $\psi(g) = g$ for every $g \in \pi$. This homomorphism is, by construction, an epimorphism. We set $\Gamma = \ker(\psi)$.

Next let $\{\alpha_j\colon (S^n, *) \to (X, x_0)\}_{j \in J}$ be the family of all maps that represent an element in $\Gamma = \ker(\psi\colon \pi_n(X, *) \to \pi)$. As in the proof of (1) we set

$$Y \;=\; \Big(X \sqcup \bigsqcup_{j \in J} \overline{B}^{n+1}_j\Big)/\!\sim \qquad \text{with } \alpha_j(s) \sim s \text{ for } s \in S^n_j = \partial \overline{B}^n_j.$$

By construction Y is an $(n+1)$-dimensional CW-complex such that the n-skeleton equals X. We denote by $i\colon X \to Y$ the inclusion map.

Claim. The map $i_*\colon \pi_n(X,x_0) \to \pi_n(Y,x_0)$ descends to a map

$$\varphi\colon \pi_n(X,x_0)/\Gamma \;\to\; \pi_n(Y,x_0)$$

and this map is an isomorphism.

Proof. We consider the following diagram

$$\begin{array}{ccccccc}
 & & \Gamma & \hookrightarrow & \pi_n(X,x_0) & \xrightarrow{i_*} & \pi_n(Y,x_0) \longrightarrow 0 \\
 & & {\scriptstyle a_j\mapsto[\alpha_j]}\uparrow\!\!\uparrow & & \downarrow{=} & & \downarrow{=} \\
 & \bigoplus_{j\in J}\mathbb{Z}\cdot a_j & \xrightarrow{a_j\mapsto[\alpha_j]} & \pi_n(X,x_0) & \xrightarrow{i_*} & \pi_n(Y,x_0) & \longrightarrow 0 \\
 & \downarrow{=} & & \downarrow{\cong} & & \downarrow{\cong} & \\
 & \bigoplus_{j\in J}\mathbb{Z}\cdot a_j & \xrightarrow{a_j\mapsto\alpha_{j*}([S^n])} & \mathrm{H}_n(X;\mathbb{Z}) & \xrightarrow{i_*} & \mathrm{H}_n(Y;\mathbb{Z}) & \longrightarrow 0.
\end{array}$$

We make the following clarification and observations:

(1) The squares at the top commute basically by definition. Note that the vertical map to the top left is an epimorphism by definition of the family $\{\alpha_j\}_{j\in J}$.
(2) The vertical maps between the second and the third row, which are located in the middle and to the right, are the Hurewicz homomorphisms from page 1842.
(3) It follows from the naturality of the Hurewicz homomorphism, see Lemma 85.1 (3), that the square to the bottom right commutes.
(4) It follows basically immediately from the definition of the Hurewicz homomorphism that the square to the bottom left commutes.
(5) By construction we know that X and Y have precisely one 0-cell and no cells in dimension $1,\dots,n-1$. This implies by the CW-Skeleton-π_n-Proposition 71.9 that X and Y are $(n-1)$-connected. Now we obtain from the Hurewicz Theorem 85.5 that the vertical maps in the middle and to the right are both isomorphisms.
(6) It follows from a modest generalization of the Cell Attachment-H_*-Lemma 78.18 that the bottom horizontal sequence is exact.[2006]

It follows from all the information assembled above that the top horizontal sequence is also exact. But this fact is just a reformulation of the statement that we are supposed to prove in the claim. ⊞

As in the proof of (1) we are now basically done. Indeed, the CW-complex Y is $(n+1)$-dimensional, it has a single 0-cell x_0, it has no cells in dimensions $1,\dots,n$ and it is canonical. Furthermore the map $\psi\colon \pi_n(X,x_0) \to \pi$ induces an isomorphism $\overline{\psi}\colon \pi_n(X,x_0)/\Gamma \to \pi$. Thus we see that the canonical triple

$$\Big(Y, x_0, \pi_n(Y,x_0) \xleftarrow[\cong]{\varphi} \pi_n(X,x_0)/\Gamma \xrightarrow[\cong]{\overline{\psi}} \pi\Big)$$

has all the desired properties. ■

[2006] the Cell Attachment-H_*-Lemma 78.18 was formulated for attaching a single $(n+1)$-cell, but basically the same argument also works for attaching an arbitrary family of $(n+1)$-cells.

We have now seen that given any group there exists a CW-complex that is an Eilenberg-Maclane space. But it is pretty clear that the construction provided by the proof of the Eilenberg-Maclane Existence Theorem 163.8 is pretty wasteful, except for the trivial group the construction provides an infinite-dimensional CW-complex. In many cases, e.g. for the groups $\pi = \mathbb{Z}^m$, there are, as we have seen on page 3427, much simpler, finite-dimensional Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, 1)$. This point towards a common tension:

(1) On the one hand it is nice to have "small constructions" with few cells. For example it is much easier to visualize finite CW-complexes and it is usually much easier to calculate invariants for finite CW-complexes.
(2) On the other hand it is nice to have canonical constructions which do not depend on any choices. But such constructions are almost invariably humongous.

This situation is comparable to the discussion of free resolutions of abelian groups. On the one hand, for actual calculations one prefers "small" free resolutions. On the hand, say to give unambiguous definitions of Tor-groups and Ext-groups one needs to work with the canonical free resolution from page 1922 which is outrageously wasteful.

It is natural to ask whether "small" groups also admit "small" Eilenberg-Maclane spaces. For example the following question arises:

Question 163.10. Let $m \in \mathbb{N}_{\geq 2}$. Can we find a finite-dimensional Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}_m, 1)$?

In some instances one can also attempt to perform the three-step-process from page 3435 with more care to provide "smaller" Eilenberg-Maclane spaces. In the remainder of this section we want to discuss the construction of the Eilenberg-Maclane spaces $\mathrm{K}(\mathbb{Z}, n)$. For $n = 1$ everything that can be said had been said on page 3427.
We will now construct an explicit Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, 2)$ using the above procedure:

(1) We start with $X_2 := \mathbb{C}\mathrm{P}^1 = S^2$. We have $\pi_1(X_2 = \mathbb{C}\mathrm{P}^1) = 0$ and $\pi_2(X_2 = \mathbb{C}\mathrm{P}^1) \cong \mathbb{Z}$.
(2) By Theorem 155.12 we know that $\pi_3(\mathbb{C}\mathrm{P}^1) = [p]$ where $p\colon S^3 \to \mathbb{C}\mathrm{P}^1$ denotes the Hopf map from page 3306.
(3) We set $X_4 := \overline{B}^4 \cup_{p\colon S^3 \to \mathbb{C}\mathrm{P}^1} \mathbb{C}\mathrm{P}^1$.
(4) By the Mapping Cone-of-Hopf Map Lemma 122.2 (1) we know that X_4 is homeomorphic to $\mathbb{C}\mathrm{P}^2$.[2007]

[2007] For the convenience of the reader we repeat the argument. For the convenience of the author we prove a slight generalization of the Mapping Cone-of-Hopf Map Lemma 122.2 (1). Thus let $n \in \mathbb{N}$. We consider the maps

$$\begin{array}{rcl} f\colon \mathrm{Cone}(S^{2n+1}) & \to & \mathbb{C}\mathrm{P}^{n+1} \\ [(z_0, \ldots, z_n), r] & \mapsto & [(r \cdot z_0, \ldots, r \cdot z_n, 1 - r)] \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{C}\mathrm{P}^n & \to & \mathbb{C}\mathrm{P}^{n+1} \\ [z_0 : \cdots : z_n] & \mapsto & [z_0 : \cdots : z_n : 0]. \end{array}$$

These maps are continuous by the Topological-Quotient Proposition 5.15 (1b) and the Topological-Quotient Proposition 5.15 (1a). It follows immediately from the definitions that these two maps define a map

$$\underbrace{\mathrm{Cone}(p\colon S^{2n+1} \to \mathbb{C}\mathrm{P}^n)}_{=(\mathrm{Cone}(S^{2n+1}) \cup \mathbb{C}\mathrm{P}^n)/\sim} \to \mathbb{C}\mathrm{P}^{n+1}$$

(5) By Theorem 155.12 we know that $\pi_3(\mathbb{C}\mathrm{P}^2) = 0$ and[2008] $\pi_4(\mathbb{C}\mathrm{P}^2) = 0$. Furthermore it tells us that $\pi_5(\mathbb{C}\mathrm{P}^2) = [p]$ where $p\colon S^5 \to \mathbb{C}\mathrm{P}^2$ denotes the Hopf map from page 3306.
(6) Similar to (3) we consider $X_6 := \overline{B}^6 \cup_{p\colon S^3 \to \mathbb{C}\mathrm{P}^1} \mathbb{C}\mathrm{P}^1$.
(7) As in (4), using Footnote 2007, we see that X_6 is homeomorphic to $\mathbb{C}\mathrm{P}^3$.

Iterating this process we obtain the sequence $\mathbb{C}\mathrm{P}^2, \mathbb{C}\mathrm{P}^4, \ldots$ and we end up with the infinite complex projective space $\mathbb{C}\mathrm{P}^\infty$. This shows, once again, that $\mathbb{C}\mathrm{P}^\infty$ is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, 2)$. A similar discussion, shows how to construct an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}_2, 1)$ starting with $X_2 = \mathbb{R}\mathrm{P}^2$, by imitating the above approach one once again ends up with $\mathbb{R}\mathrm{P}^\infty$.
For $n \geq 3$ there seem to be no straightforward models for $\mathrm{K}(\mathbb{Z}, n)$. But the following lemma gives us at least a little bit of extra control, which will play a crucial role at a later point.

Lemma 163.11. Given any $n \in \mathbb{N}$ there exists an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, n)$ with precisely one 0-cell, precisely one n-cell, no cell of dimension $n+1$ and only countably many cells in dimensions $\geq n+2$.

Remark. Let $n \in \mathbb{N}$. Note that the canonical Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, n)$ that we constructed in the proof of the Eilenberg-Maclane Existence Theorem 163.8 is *not* of the form as described in Lemma 163.11. We will discuss this in more detail in Exercise 163.4.

Proof. Let $n \in \mathbb{N}$. We consider $Y = S^n$. Recall that by Corollary 85.6 we know that $\pi_n(S^n) \cong \mathbb{Z}$. By the Kill-All Higher-π_n-Proposition 163.7 (3) there exists a CW-complex Z with the following four properties:

(1) the $(n+1)$-skeleton of Z equals $Y = S^n$, in particular Z has only one 0-cell, no cells in dimension $1, \ldots, n-1$, one cell in dimension n and no cell in dimension $n+1$,
(2) we have $\pi_i(Z) = 0$ for $i \geq n+1$,
(3) for any $i \in \{1, \ldots, n\}$ and any base point $x_0 \in S^n$ the inclusion induced map $\pi_i(Y, x_0) \xrightarrow{\cong} \pi_i(Z, x_0)$ is an isomorphism,
(4) the CW-complex Z has only countably many cells.

By Proposition 71.10 we know that $\pi_i(Y, x_0) = 0$ for $i = 1, \ldots, n-1$. Thus Z is the desired Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, n)$. ∎

163.4. **Uniqueness of Eilenberg-Maclane Spaces.** Next we turn to the question to what degree Eilenberg-Maclane spaces of a given type are unique. Evidently the homeomorphism type is not unique, since given an Eilenberg-Maclane space X we obtain Eilenberg-Maclane spaces of the same type by considering say the products $X \times \overline{B}^m$. Nonetheless the following theorem says that the homotopy type of Eilenberg-Maclane spaces of a given type are in fact unique:

---

which is easily seen to be a bijection. It follows from the Topological-Quotient Proposition 5.15 (1b) that this map is continuous. Furthermore, using the Compact-Hausdorff Proposition 2.17 (3) and the Projective Spaces-Compact+Hausdorff Proposition 5.30 one sees that the map is in fact a homeomorphism.
[2008] Here we are lucky, we did everything to kill $\pi_3(\mathbb{C}\mathrm{P}^2)$, but without any effort on our side we also managed to dispose of $\pi_4(\mathbb{C}\mathrm{P}^2)$.

Theorem 163.12. (Eilenberg-Maclane Uniqueness Theorem) Let $n \in \mathbb{N}$ and let π be an (abelian) group[2009]. The following two statements hold:

(1) Any two Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, n)$ are homotopy equivalent.
(2) If (X, x_0) and (Y, y_0) are two pointed Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, n)$ with $x_0 \in X^0$ and $y_0 \in Y^0$ and if $\varphi\colon \pi_n(X, x_0) \to \pi_n(Y, y_0)$ is an isomorphism, then there exists a homotopy equivalence $f\colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces with $f_* = \varphi\colon \pi_n(X, x_0) \to \pi_n(Y, y_0)$.

Before we turn to the proof of the Eilenberg-Maclane Uniqueness Theorem 163.12 it is worth, and fun, to discuss several immediate consequences thereof. For example, the Eilenberg-Maclane Uniqueness Theorem 163.12 settles Question 163.2 in a perhaps unexpected way: Given $m \in \mathbb{N}$ the homotopy type of the topological spaces $L(m, r_1, r_2, \dots)$ does *not* depend on the choice of the parameters r_i, since all of these topological spaces are Eilenberg-Maclane spaces of type $\mathrm{K}(\mathbb{Z}_m, 1)$, but these are therefore homotopy equivalent by the Eilenberg-Maclane Uniqueness Theorem 163.12.

For convenience we record the following corollary which is an immediate consequence of the Eilenberg-Maclane Uniqueness Theorem 163.12, the Homotopy Equivalence-H_*-Corollary 73.9 and the discussion on page 1914.

Corollary 163.13. Let π be a group and let $n \in \mathbb{N}$. If X and Y are two Eilenberg-Maclane spaces of the type $\mathrm{K}(\pi, n)$, then for any $i \in \mathbb{N}$ and any abelian group G we have an isomorphism $\mathrm{H}_i(X; G) \cong \mathrm{H}_i(Y; G)$.

Perhaps somewhat surprisingly we can use Corollary 163.13 to give a negative answer to Question 163.10 for $m = 2$.

Corollary 163.14. There is no finite-dimensional Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}_2, 1)$.

Proof. Let K be an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}_2, 1)$. Given any $i \in \mathbb{N}$ we calculate that

$$\mathrm{H}_i(K; \mathbb{Z}_2) \underset{\text{by Corollary 163.13}}{\uparrow} \cong \mathrm{H}_i(\text{any Eilenberg-Maclane space of type } \mathrm{K}(\mathbb{Z}_2, 1); \mathbb{Z}_2) \underset{\text{see page 3427}}{\uparrow} \cong \mathrm{H}_i(\mathbb{R}\mathrm{P}^\infty; \mathbb{Z}_2) \underset{\text{see page 1916}}{\uparrow} \cong \mathbb{Z}_2.$$

It follows from the discussion on page 1915 that K is of dimension $> i$ for all $i \in \mathbb{N}$, in other words, K is infinite-dimensional. ■

Evidently this suggests that the answer to Question 163.10 is negative. But right now we lack the tools to calculate the homology groups of the quotients $S^\infty/\mathbb{Z}_m$ that we constructed in Lemma 163.1. We will return to this question on page **??**

The following proposition basically says that it is easy to construct maps from CW-complexes to Eilenberg-Maclane spaces. This statement is the key to proving the Eilenberg-Maclane Uniqueness Theorem 163.12. As we will see shortly, the proposition is of interest in its own right.

Proposition 163.15. (Maps-to-$\mathrm{K}(\pi, n)$-Proposition) Let $n \in \mathbb{N}$ and let π be an (abelian) group. Furthermore let Y be an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$ and

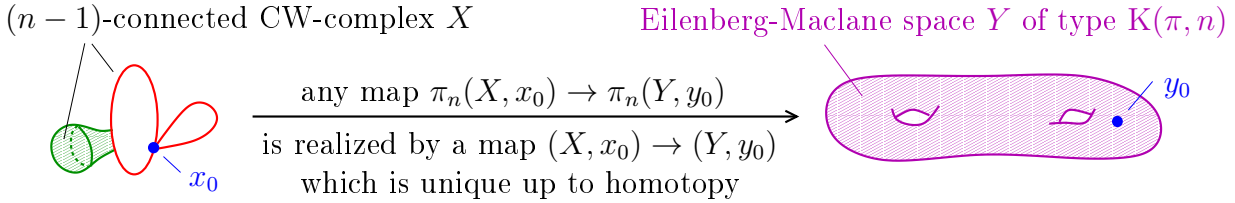
[2009] Whenever we deal with Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, n)$ with $n \geq 2$ it is understood throughout these lecture notes that π is abelian.

let $y_0 \in Y$. Finally let X be a CW-complex and let $x_0 \in X$ be a point in the 0-skeleton X^0. If X is $(n-1)$-connected, then the following two statements hold:

(1) Let $\varphi\colon \pi_n(X,x_0) \to \pi_n(Y,y_0)$ be a homomorphism. There exists a map $f\colon X \to Y$ with $f(x_0) = y_0$ such that $f_* = \varphi\colon \pi_n(X,x_0) \to \pi_n(Y,y_0)$.

(2) Suppose we are given two maps $f_0, f_1\colon X \to Y$ such that $f_0(x_0) = f_1(x_0) = y_0$. If $f_{0*} = f_{1*}\colon \pi_n(X,x_0) \to \pi_n(Y,y_0)$, then there exists a homotopy rel x_0 from f_0 to f_1.

We write



$$\langle (X,x_0),(Y,y_0)\rangle := \{\text{maps } (X,x_0) \to (Y,y_0)\}/\sim \qquad \text{where } f \sim g \text{ if there exists a homotopy rel } \{x_0\} \text{ between } f \text{ and } g.$$

With this notation Statements (1) and (2) can be summarized to obtain the following statement:

(3) The map

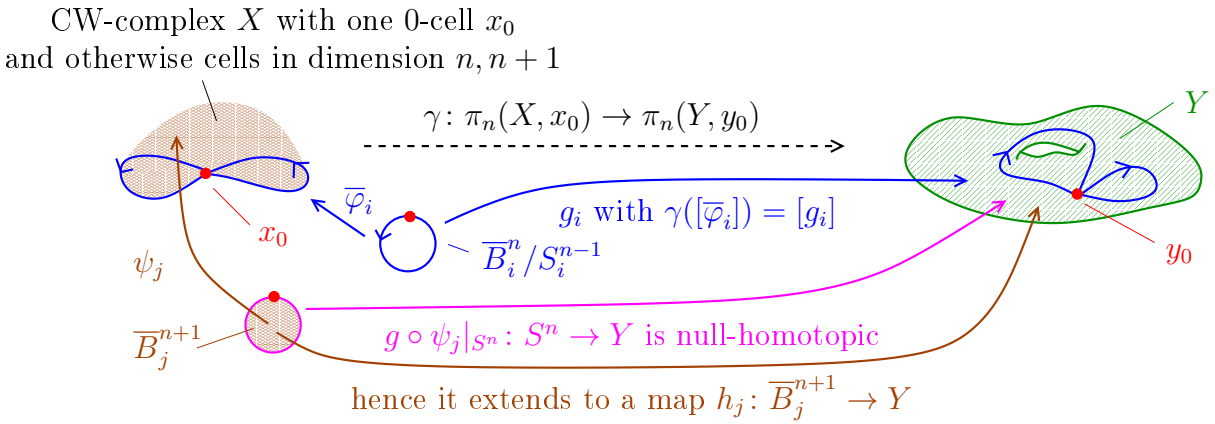
$$\begin{array}{ccc} \langle (X,x_0),(Y,y_0)\rangle & \to & \mathrm{Hom}(\pi_n(X,x_0),\pi_n(Y,y_0)) \\ [f] & \mapsto & [f_*] \end{array}$$

is a bijection.

Remark. In the Maps-to-S^1 Proposition 118.13, with $n = 1$ and $Y = S^1$, we proved a "smooth manifold version" of the Maps-to-K(π,n)-Proposition 163.15.

Proof of Theorem 163.12 assuming Proposition 163.15. Let $n \in \mathbb{N}$ and let π be an (abelian) group. Statement (1) is basically an immediate consequence of Statement (2). Therefore it now remains to prove Statement (2). Thus let (X,x_0) and (Y,y_0) be two pointed Eilenberg-Maclane spaces of type K(π,n) where $x_0 \in X^0$ and $y_0 \in Y^0$. Furthermore let $\varphi\colon \pi_n(X,x_0) \to \pi_n(Y,y_0)$ be an isomorphism. Since X is, as an Eilenberg-Maclane space of type K(π,n), $(n-1)$-connected, we can appeal to the Maps-to-K(π,n)-Proposition 163.15 (1) to obtain a map $f\colon X \to Y$ with $f(x_0) = y_0$ such that $f_* = \varphi\colon \pi_n(X,x_0) \to \pi_n(Y,y_0)$. It suffices to prove the following claim.

Claim. The map f is a homotopy equivalence $(X,x_0) \to (Y,y_0)$ of pointed topological spaces.



Proof. As above we obtain from the Maps-to-K(π,n)-Proposition 163.15 (1) the existence of a map $g\colon Y \to X$ with $g(y_0) = x_0$ such that $g_* = \varphi^{-1}\colon \pi_n(Y,y_0) \to \pi_n(X,x_0)$. Note that

$$(g \circ f)_* \;=\; \varphi^{-1} \circ \varphi \;=\; \mathrm{id}_{\pi_n(X,x_0)} \;=\; (\mathrm{id}_X)_*$$

and note that $(g \circ f)(x_0) = x_0 = (\mathrm{id}_X)(x_0)$. Thus it follows from the Maps-to-K(π,n)-Proposition 163.15 (2) that $g \circ f$ is homotopic rel x_0 to id_X. Basically the same argument shows that $f \circ g$ is homotopic rel y_0 to id_Y. But this means that g is indeed the desired homotopy inverse. ∎

At this point it remains to prove the Maps-to-K(π, n)-Proposition 163.15. The proof of the proposition relies on the following two lemmas. The following lemma is the key ingredient in the proof of the Maps-to-K(π, n)-Proposition 163.15.

Lemma 163.16. Let $n \in \mathbb{N}$. Let X be a CW-complex that consists of a single 0-cell x_0 and that otherwise contains only cells in dimensions n and $n+1$. Furthermore let (Y, y_0) be a pointed topological space and let $\gamma\colon \pi_n(X, x_0) \to \pi_n(Y, y_0)$ be a homomorphism. There exists a map $h\colon (X, x_0) \to (Y, y_0)$ such that $h_* = \gamma$.

Proof of Lemma 163.16. We proceed in the following steps.

(1) We note that by our hypothesis we have $X^{n-1} = \{x_0\}$.

(2) Let $\{\varphi_i\colon (\overline{B}^n, S^{n-1}) \to (X^n, X^{n-1} = \{x_0\})\}_{i \in I}$ be the characteristic maps of the n-cells of the CW-complex X. Note that since $X^{n-1} = \{x_0\}$ each map φ_i descends to a map $\overline{\varphi}_i\colon \overline{B}^n / S^{n-1} \to X^n$.

(3) By the Skeleton-Quotient Lemma 68.33 (2) the maps $\overline{\varphi}_i$ induce a homeomorphism $\Phi\colon \bigvee_{i \in I} \overline{B}^n_i / S^{n-1}_i \to X^n$. By a slight abuse of notation we denote by x_0 the wedge point of the wedge.

(4) Let $i \in I$. Note that the map $\overline{\varphi}_i$ defines an element in $\pi_n(X, x_0)$. We pick a map $g_i\colon \overline{B}^n / S^{n-1} \to (Y, y_0)$ with $\gamma([\overline{\varphi}_i]) = [g_i]$.

(5) We consider the map

$$\begin{array}{rccl} g\colon \bigvee\limits_{i \in I} \overline{B}^n_i / S^{n-1}_i & \to & Y & \\ [x] & \mapsto & g_i([x]) & \text{if } x \in \overline{B}^n_i. \end{array}$$

(6) We consider the following diagram:

$$\begin{array}{ccccc} \pi_n(X^n, x_0) & \xleftarrow[\cong]{\Phi_*} & \pi_n\Big(\bigvee\limits_{i \in I} \overline{B}^n_i / S^{n-1}_i, x_0\Big) & \xrightarrow{g_*} & \pi_n(Y, y_0). \\ & {\scriptstyle i_*}\searrow & & \nearrow{\scriptstyle \gamma} & \\ & & \pi_n(X, x_0) & & \end{array}$$

where the left diagonal map is induced by the inclusion $i\colon X^n \to X$.

(7) It follows immediately from the construction of g that if we send any of the classes $[\mathrm{id}\colon \overline{B}^n \to \overline{B}_i] \in \pi_n(X^n, x)$ on a journey through the diagram, then we obtain the same result. But by the Wedge-of-Spheres-π_n-Proposition 163.5 (3) the classes

$[\mathrm{id}\colon \overline{B}^n \to \overline{B}_i]$, $i \in I$, form a generating set for $\pi_n\Big(\bigvee_{i\in I} \overline{B}^n_i/S^{n-1}_i, x_0\Big)$. Thus it follows that the diagram commutes.

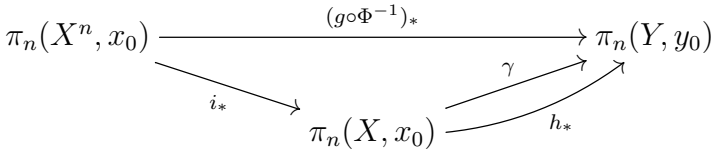
(8) Let $* = (0,\dots,0,1) \in S^n \subset \overline{B}^{n+1}$ the usual base point. Let $\{\psi_j\colon \overline{B}^{n+1} \to X^{n+1}\}_{j\in J}$ be the characteristic maps of the $(n+1)$-cells of X. It follows from the Orthogonal Action Lemma 5.26 that we can arrange that for every $j \in J$ we have $\psi_j(*) = x_0$

(9) Let $j \in J$. Note that

$$[g\circ\Phi^{-1}\circ\psi_j|_{S^n}] \;=\; (g_*\circ\Phi_*^{-1})(\overbrace{[\psi_j|_{S^n}]}^{\in\pi_n(X^n,x_0)}) \;\underset{\uparrow}{=}\; \overbrace{\gamma([\psi_j|_{S^n}])}^{\in\pi_n(X,x_0)} \;\underset{\uparrow}{=}\; \gamma([0]) \;\underset{\downarrow}{=}\; 0 \in \pi_n(Y,y_0).$$

by the above commutative diagram

since $\psi_j|_{S^n}$ extends to a map $\overline{B}^{n+1} \to X$ we have $[\psi_j|_{S^n}] = 0 \in \pi_n(X,x_0)$ by Trivial-in-π_n-Lemma 71.4



since γ is a homomorphism

Thus we obtain from the Trivial-in-π_n-Lemma 71.4 that there exists a map $h_j\colon \overline{B}^{n+1} \to Y$ such that $h_j|_{S^n} = g \circ \Phi^{-1} \circ (\psi_j|_{S^n})$.

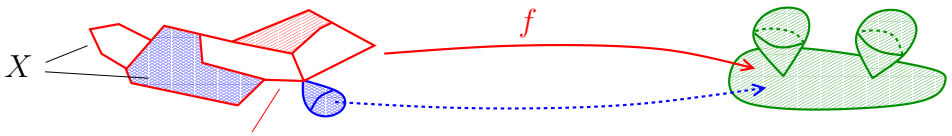
(10) Since for each $j \in J$ we have $h_j|_{S^n} = g \circ \Phi^{-1} \circ (\psi_j|_{S^n})$ we can use the maps h_j to extend $g \circ \Phi^{-1}$ to a map

$$h\colon X = \Big(X^n \cup \bigsqcup_{j\in J} \overline{B}^{n+1}_j\Big)/\!\sim \;\to\; Y \qquad \text{where } \psi_j(x) \sim x \text{ for any } x \in S^n_j.$$

(11) We obtain the following diagram

(12) We already saw that the diagram commutes for γ. Since $h|_{X^n} = g \circ \Phi^{-1}$ we see that the diagram commutes also for the map h_*.

(13) The left diagonal map $i_*\colon \pi_n(X^n,x_0) \to \pi_n(X,x_0)$ is an epimorphism by the CW-Skeleton-π_n-Proposition 71.9.



(14) It follows from (12) and (13) that the maps γ and h_* from $\pi_n(X,x_0)$ to $\pi_n(Y,y_0)$ agree. ■

The second lemma is just a convenient special case of Lemma 161.3.

Lemma 163.17. Let X be a CW-complex, let $n \in \mathbb{N}$ and let $f\colon A \to Y$ be a map from a subcomplex $A \subset X$ to a path-connected topological space with $X^n \subset A$.

(1) If $\pi_n(Y) = 0$, then we can extend f to a map $f\colon A \cup X^{n+1} \to Y$.

(2) If $\pi_i(Y) = 0$ for every $i \geq n$, then we can extend f to a map $f\colon X \to Y$.

We break the proof of the Maps-to-K(π,n)-Proposition 163.15 into two parts. In the first part we deal with the situation that the $(n-1)$-skeleton consists just of a point. Afterwards we will discuss how the general case can be reduced to this special case.

Proof of the Maps-to-K(π,n)-Proposition 163.15 if $X^{n-1}=\{x_0\}$. Let $n\in\mathbb{N}$ and let π be an (abelian) group. Furthermore let Y be an Eilenberg-Maclane space of type K(π,n) and let $y_0\in Y$. Finally let X be a CW-complex and let $n\in\mathbb{N}$. We assume that $X^{n-1}=\{x_0\}$.

(1) Let $\varphi\colon \pi_n(X,x_0)\to\pi_n(Y,y_0)$ be a homomorphism. We need to show that there exists a map $f\colon X\to Y$ with $f(x_0)=y_0$ such that $f_*=\varphi\colon \pi_n(X,x_0)\to\pi_n(Y,y_0)$. We denote by $i\colon X^{n+1}\to X$ the inclusion map. By the CW-Skeleton-π_n-Proposition 71.9 we know that $i_*\colon \pi_n(X^{n+1},x_0)\to\pi_n(X,x_0)$ is an isomorphism. The following diagram contains all the maps of interest to us:

$$\begin{array}{ccc} \pi_n(X^{n+1},x_0) & \overset{h_*}{\dashrightarrow} & \\ {\scriptstyle i_*}\downarrow{\scriptstyle \cong} & \overset{f_*}{\nearrow} & \\ \pi_n(X,x_0) & \xrightarrow[\varphi]{} & \pi_n(Y,y_0). \end{array}$$

Since $X^{n-1}=\{x_0\}$ we can apply Lemma 163.16 to the CW-complex X^{n+1}. We obtain from Lemma 163.16 that there exists a map $h\colon X^{n+1}\to Y$ with $h(x_0)=y_0$ such that $h_*=\varphi\circ i_*\colon \pi_n(X^{n+1},x_0)\to\pi_n(Y,y_0)$. Since Y is an Eilenberg-Maclane space of type K(π,n) we know that $\pi_j(Y)=0$ for $j\geq n+1$. Thus we obtain from Lemma 163.17 (2) that we can extend $h\colon X^{n+1}\to Y$ to a map $f\colon X\to Y$. It remains to show that $f_*=\varphi\colon \pi_n(X,x_0)\to\pi_n(Y,y_0)$. This is indeed the case since

$$f_* \underset{\text{since } i_* \text{ is an isomorphism}}{=} f_*\circ i_*\circ i_*^{-1} = (f\circ i)_*\circ i_*^{-1} \underset{\text{since } h \text{ extends } f}{=} h_*\circ i_*^{-1} \underset{\text{since } h_*=\varphi\circ i_*}{=} (\varphi\circ i_*)\circ i_*^{-1} = \varphi.$$

(2) Suppose we are given two maps $f_0,f_1\colon X\to Y$ such that $f_0(x_0)=f_1(x_0)=y_0$ and such that $f_{0*}=f_{1*}\colon \pi_n(X,x_0)\to\pi_n(Y,y_0)$. We need to show that there exists a homotopy rel x_0 from f_0 to f_1. We consider the product $X\times[0,1]$ and we equip it with the product CW-structure coming from Proposition 68.23. Given $k\in\mathbb{N}_0$ we write

$$Z^k = (X\times\{0\})\cup\underbrace{(X^{k-1}\times[0,1])}_{k\text{-dimensional}}\cup(X\times\{1\}) \subset X\times[0,1].$$

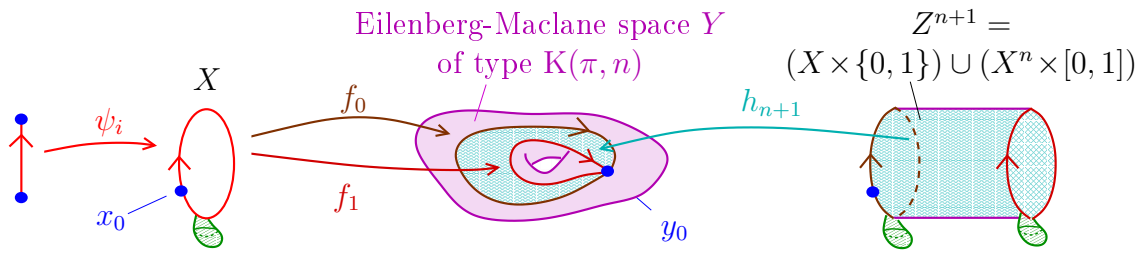
The idea is define the homotopy on $X\times[0,1]=\bigcup\limits_{n\in\mathbb{N}_0} Z^n$ by breaking the task into three steps.

(a) First we note that the fact that $X^0=\cdots=X^{n-1}$ implies that $Z^1=\cdots=Z^n$. Now let $h\colon Z^1=Z^n\to Y$ be the map that is given by f_0 on $X\times\{0\}$, f_1 on $X\times\{1\}$ and the constant map c_{x_0} on $\{x_0\}\times[0,1]$.

(b) We denote by $\{\varphi_i\colon \overline{B}_i^n\to X\}_{i\in I}$ the characteristic maps of the n-cells of X. Since $X^{n-1}=\{x_0\}$ we see that each φ_i descends to a map $\psi_i\colon \overline{B}_i^n/S_i^{n-1}\to X$. We denote by $*=[S_i^{n-1}]$ the obvious base point of the sphere $\overline{B}_i^n/S_i^{n-1}$. Now recall that by hypothesis we have $f_{0*}=f_{1*}\colon \pi_n(X,x_0)\to\pi_n(Y,y_0)$. This implies that for every $i\in I$ we have $[f_0\circ\psi_i]=[f_1\circ\psi_i]\in\pi_n(Y,y_0)$. In other words,

for every $i \in I$ there exists a map $F_i \colon \overline{B}_i^n / S_i^{n-1} \times [0,1] \to Y$ with $F_{i0} = f_0 \circ \psi_i$, $F_{i1} = f_1 \circ \psi_i$ and $F_i(*,t) = y_0$ for all $t \in [0,1]$. We define

$$\begin{array}{rcl} h_{n+1} \colon Z^{n+1} & \to & Y \\ P & \mapsto & \begin{cases} h_0(P), & \text{if } P \in Z^1 = Z^n, \\ F_i(Q,t), & \text{if } P = (\varphi_i(Q),t) \text{ with } Q \in \overline{B}_i^n. \end{cases} \end{array}$$



It follows immediately from the properties of the F_i that this map is well-defined. Furthermore, it follows almost immediately from the Characteristic Maps Lemma 68.7 (4) that h_{n+1} is continuous.

(c) Finally we are in the following situation:

$$\begin{array}{ccc} Z^{n+1} & \xrightarrow{h_{n+1}} & Y \\ \downarrow & \nearrow_{H} & \\ X \times [0,1]. & & \end{array}$$

By definition of the CW-structure on $X \times [0,1]$ we know that the $(n+1)$-skeleton of $X \times [0,1]$ is contained in Z^{n+1}. In other words, any cell of $X \times [0,1]$ that is not contained in Z^{n+1} is of dimension $\geq n+2$. Since Y is an Eilenberg-Maclane space of type $\mathrm{K}(\pi,n)$ we know that $\pi_k(Y,y_0) = 0$ for $k \geq n+1$. Thus we obtain from Lemma 163.17 (2) that there exists a map $H \colon X \times [0,1] \to Y$ which makes the above diagram commute. Evidently this is the desired homotopy between f_0 and f_1.

(3) The last statement is just a reformulation of Statement (1) together with Statement (2). ■

Proof of the Maps-to-K(π,n)-Proposition 163.15 for the general case. Let X be a CW-complex and let $x_0 \in X$ be a point in the 0-skeleton X^0. We suppose that X is $(n-1)$-connected. By Proposition 162.10 we know that there exists a homotopy equivalence $f \colon (X,x_0) \to (\widetilde{X},\widetilde{x}_0)$ where $\widetilde{X}$ is a CW-complex that has one 0-cell $\{\widetilde{x}_0\}$ and no cells in dimensions $1,\ldots,n$. By the Homotopy-π_n-Proposition 71.7 we know that $f_* \colon \pi_n(X,x_0) \to \pi_n(\widetilde{X},\widetilde{x}_0)$ is an isomorphism. By the above argument we know that the desired conclusions hold for $(\widetilde{X},\widetilde{x}_0)$. It is now fairly elementary to see that the statements of the Maps-to-K(π,n)-Proposition 163.15 also hold for (X,x_0). ■

Before we move on we prove an important addendum to the Homotopy-π_1-Proposition 50.3. To motivate its relevance we recall an earlier result: If $f_0, f_1 \colon (X,x_0) \to (Y,y_0)$ are two

maps between pointed topological spaces, then by the Homotopy-π_1-Proposition 50.3 (1) the following two statements hold:

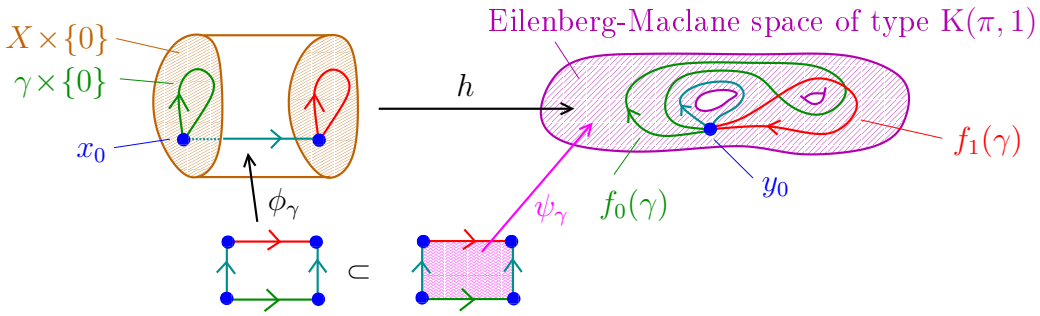
(1) If f_0 and f_1 are homotopic rel x_0, then $f_{0*} = f_{1*}$.
(2) If f_0 and f_1 are homotopic (with no constraints on the base point), then there exists an $\alpha \in \pi_1(Y, y_0)$ such that $f_{0*}(z) = \alpha \cdot f_{1*}(z) \cdot \alpha^{-1}$ for all $z \in \pi_1(Y, y_0)$.

One can view the Maps-to-K(π, n)-Proposition 163.15 (2) as a partial converse to (1). The following proposition is the analogous partial converse to (2).

Proposition 163.18. Let π be a group, let Y be an Eilenberg-Maclane space of type $K(\pi, 1)$ and let $y_0 \in Y$. Furthermore let X be a 0-connected CW-complex and let $x_0 \in X$ be a point in the 0-skeleton X^0. Suppose we are given two maps $f_0, f_1 \colon X \to Y$ such that $f_0(x_0) = f_1(x_0) = y_0$. If there exists an $\alpha \in \pi_1(Y, y_0)$ such that $f_{0*}(z) = \alpha \cdot f_{1*}(z) \cdot \alpha^{-1}$ for all $z \in \pi_1(Y, y_0)$, then there exists a homotopy[2010] from f_0 to f_1.

Proof. The proof of the proposition is similar to the proof of the Maps-to-K(π, n)-Proposition 163.15 (2). In the following provide a sketch of the argument. We leave it to the reader to fill in the details. First of all we point out that by Proposition 162.10 we can assume that X has a single 0-cell $\{x_0\}$. Now we consider the product $X \times [0,1]$ and we equip it with the product CW-structure coming from Proposition 68.23. Given $k \in \mathbb{N}_0$ we write

$$Z^k \;=\; (X \times \{0\}) \cup \underbrace{(X^{k-1} \times [0,1])}_{k\text{-dimensional}} \cup (X \times \{1\}) \;\subset\; X \times [0,1].$$



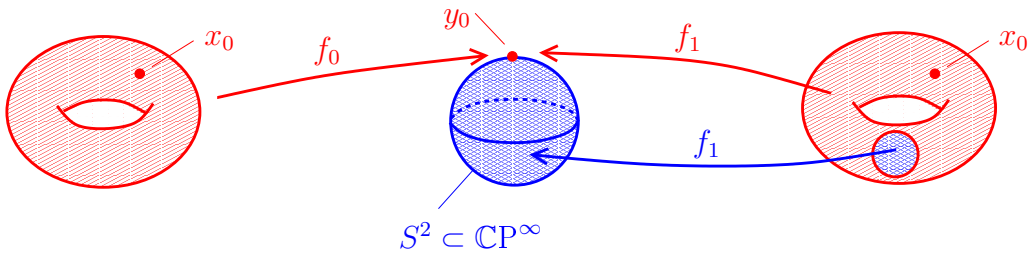
As above we define the homotopy on $X \times [0,1] = \bigcup_{n \in \mathbb{N}_0} Z^n$ by breaking the task into three friendly steps.

(1) We pick a map $\beta \colon [0,1] \to Y$ that represents $\alpha \in \pi_1(Y, y_0)$. Let $h \colon Z^1 = Z^n \to Y$ be the map that is given by f_0 on $X \times \{0\}$, f_1 on $X \times \{1\}$ and the map β on $\{x_0\} \times [0,1] = [0,1]$.
(2) Given a 1-cell γ of X we denote by $\phi_\gamma \colon S^1 = \partial([0,1]^2) \to Z^1$ the attaching map of the product cell $\gamma \times [0,1]$. We have

$$\begin{array}{rcl} & & \text{by definition of } h \\ & & \downarrow \\ h_*([\phi_\gamma]) & = & [h|_{\gamma\times 0}] \cdot [h|_{\{x_0\}\times[0,1]}] \cdot \overline{[h|_{\gamma\times 1}]} \cdot \overline{[h|_{\{x_0\}\times[0,1]}]} \\ & = & \alpha \cdot [f_{1*}(\gamma)] \cdot \alpha^{-1} \cdot \alpha \cdot [f_{1*}(\gamma)]^{-1} \cdot \alpha^{-1} \\ & & \uparrow \\ & & \text{by hypothesis and choice of } \beta \end{array} \qquad \begin{array}{rcl} & & \text{by a generous interpretation of the notation} \\ & & \downarrow \\ & = & [f_{0*}(\gamma)] \cdot [\beta] \cdot [f_{1*}(\gamma)]^{-1} \cdot [\beta]^{-1} \\ & = & e \;\in \pi_1(Y, y_0). \end{array}$$

It follows from the Extension-to-Disk Lemma 47.1 that the map $h \circ \phi_\gamma \colon \partial([0,1]^2) \to Y$ extends to a map $\psi_\gamma \colon [0,1]^2 \to Y$. We use this map to extend h over the 2-cell $\gamma \times [0,1]$. If we do this for all 1-cells of X we obtain the desired extension of h to a map $Z^2 \to Y$.
(3) We use Lemma 163.17 (2) and the fact that Y is an Eilenberg-Maclane space of type $K(\pi, 1)$ to extend the map h to a homotopy $F \colon X \times [0,1] \to Y$. ∎

[2010] Note that in contrast to the Maps-to-K(π, n)-Proposition 163.15 (2) it does *not* say "rel x_0".



We conclude this section with a discussion of the statement of the Maps-to-K(π, n)-Proposition 163.15. It is not unreasonable to ask whether one really needs in the Maps-to-K(π, n)-Proposition 163.15 the hypothesis that X is $(n-1)$-connected. But we will now see that in neither of the two parts can we drop this condition.

(1) By Theorem 155.10 we know that there exists an isomorphism $\varphi\colon \pi_3(S^2, *) \xrightarrow{\cong} \mathbb{Z}$. Now let (Y, y_0) be any pointed Eilenberg-Maclane space of type K$(\mathbb{Z}, 3)$. At a very first glance one might hope that there exists a map $f\colon (S^2, *) \to (Y, y_0)$ such that $f_* = \varphi\colon \pi_3(S^2, *) \to \pi_3(Y, y_0) = \mathbb{Z}$. But this is not the case. Indeed, since Y is an Eilenberg-Maclane space of type K$(\mathbb{Z}, 2)$ we know that $\pi_2(Y, y_0) = 0$. This means that any map $f\colon (S^2, *) \to (Y, y_0)$ is homotopic to the constant map. In particular any such map induces the zero map on π_3. Thus we cannot realize φ by a map $(S^2, *) \to (Y, y_0)$.

(2) On page 3427 we pointed out that the infinite complex projective space $\mathbb{C}\mathrm{P}^\infty$ is an Eilenberg-Maclane space of type K$(\mathbb{Z}, 2)$. By the discussion on page 258 we can view $S^2 = \mathbb{C}\mathrm{P}^1$ as a subset of $\mathbb{C}\mathrm{P}^\infty$. We denote by $y_0 \in S^2$ the North Pole. We pick some point x_0 on the torus $S^1 \times S^1$. We consider the following two maps from the torus $S^1 \times S^1 \to S^2 \subset \mathbb{C}\mathrm{P}^\infty$:
   (a) The map f_0 is the constant map that sends all points to y_0.
   (b) The map $f_1\colon S^1 \times S^1 \to \overline{B}^2/S^1 = S^2$ is a map that sends the points of a given embedded disk to $\overline{B}^2$ and sends all other points to the single point $[S^1] = y_0$.

   (These two maps f_0 and f_1 are illustrated in the figure below.) Now we claim that we have $f_{0*} = f_{1*}\colon \pi_2(S^1 \times S^1, *) \to \pi_2(\mathbb{C}\mathrm{P}^\infty, *)$, but that f_0 and f_1 are, contrary to what one might expect, *not* homotopic. To prove this claim we recall that on page 1573 we saw that $\pi_2(S^1 \times S^1) = 0$. In particular both maps induce the same map on π_2. Nonetheless the two maps are not homotopic. This can be seen by studying the induced map on H_2. It is clear that f_0 induces the trivial map on H_2. On the other hand we saw in the proof of the Degree Realization Proposition 38.13 that f_1 induces an isomorphism $\mathrm{H}_2(S^1 \times S^1; \mathbb{Z}) \to \mathrm{H}_2(S^2; \mathbb{Z})$. By the discussion on page 1773 we know that the inclusion induced map $\mathrm{H}_2(S^2; \mathbb{Z}) \to \mathrm{H}_2(\mathbb{C}\mathrm{P}^\infty; \mathbb{Z})$ is an isomorphism. Therefore we see that the map $f_{1*}\colon \mathrm{H}_2(S^1 \times S^1; \mathbb{Z}) \to \mathrm{H}_2(\mathbb{C}\mathrm{P}^\infty)$ is non-trivial. Thus we obtain from the Homotopic Maps-and-Homology Proposition 73.6 that the maps f_0 and f_1 are in fact not homotopic.

At least in terms of invariants any Eilenberg-Maclane space $\mathrm{K}(\pi, n)$ is a particularly simple topological space. Therefore it seems not totally unreasonable to hope that given a CW-complex X one can perhaps classify the maps from X to $\mathrm{K}(\pi, n)$, say up to homotopy. The above examples show that the maps are *not* classified by $\mathrm{Hom}(\pi_n(X), \pi)$. But perhaps there is some other way? Let us record this as a question:

Question 163.19. Let $n \in \mathbb{N}$ and let π be an (abelian) group. Let X be a CW-complex. Can we classify the maps $X \to \mathrm{K}(\pi, n)$ up to homotopy?

163.5. **First applications of Eilenberg-Maclane spaces.** We recall the following definition from page 2605.

Definition. Let G be a group, let Y be a topological space and let $y_0 \in Y$ be a point with an identification $\pi_1(Y, y_0) \xrightarrow{=} G$. Given another topological space X and $x_0 \in X$ we say that a homomorphism $\varphi\colon \pi_1(X, x_0) \to G = \pi_1(Y, y_0)$ is realized by a map $g\colon X \to Y$ if $g(x_0) = y_0$ and if $g_* = \varphi$. If there is no danger of confusion we will drop the base points from the notation.

Next we recall the following question that we had formulated a while ago.

Question 118.12 and and Question118.14. Let X be a connected CW-complex.[2011]

(0) Can every homomorphism $\pi_1(X) \to \mathbb{Z} = \pi_1(S^1)$ be realized by a map $X \to S^1$?

(1) Let $g \geq 1$ and let Σ_g be the surface of genus $g \geq 1$. Can every homomorphism $\pi_1(X) \to \pi_1(\Sigma_g)$ be realized by a map $X \to \Sigma_g$?

(2) Can every homomorphism $\pi_1(X) \to \pi_1\Big(\bigvee_{i=1}^{k} S^1\Big) = \langle x_1, \ldots, x_k \rangle$ be realized by a map $X \to \bigvee_{i=1}^{k} S^1$?

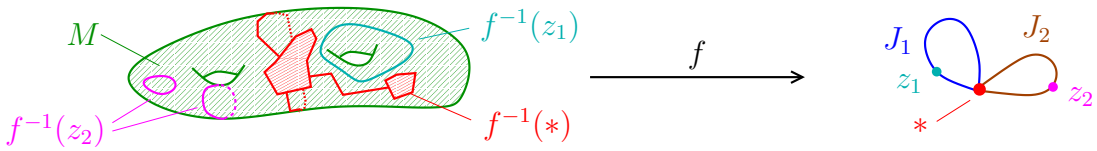
(3) Can every homomorphism $\pi_1(X) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}\mathrm{P}^2)$ be realized by a map $X \to \mathbb{R}\mathrm{P}^2$?

In the Maps-to-S^1 Proposition 118.13 we had used de Rham cohomology to give an affirmative answer to (0) if X is a smooth manifold. Furthermore in Exercise 121.8 we gave, by considering the isomorphism $\pi_1(\mathbb{R}\mathrm{P}^3) \xrightarrow{\cong} \mathbb{Z}_2$, a negative answer to (3). Fortunately we can now give a complete answer to (0), (1) and (2).

Proposition 163.20.

[2011] If M is a smooth manifold, then we saw in the Smooth Manifold-Simplicial Structure Theorem 96.2 and the Simplicial-Implies-CW Lemma 93.24 that M admits a CW-structure.

(a) The answer to (0), (1) and (2) is "yes". Furthermore, if in the formulation of (3) we replace $\mathbb{R}\mathrm{P}^2$ by $\mathbb{R}\mathrm{P}^\infty$, then the answer to (3) is also yes.
(b) If X is a smooth manifold, then the following two statements hold:
(א) In (0) and (1) we can find smooth realizations.
(ב) In (2) we can find a realization $f\colon X \to \bigvee_{i=1}^{k} S_i^1$ which has the property that the restriction of f to the complement of f^{-1}(wedge point) is smooth.



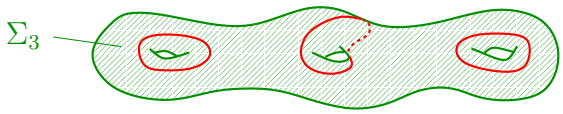
Proof.

(a) The desired statement follows immediately from the Maps-to-K(π, n)-Proposition 163.15 and the fact that on page 3427 we saw that S^1, $\bigvee_{i=1}^{k} S^1$, Σ_g and $\mathbb{R}\mathrm{P}^\infty$ are Eilenberg-Maclane spaces.
(b) (א) This statement follows from the Whitney Approximation Theorem 29.1.
(ב) As we pointed out on page 759, this statement is a consequence of Proposition 29.9. ■

Using Proposition 163.20 we obtain the following pleasant proposition.

Proposition 163.21. If M is a compact orientable connected n-dimensional smooth manifold, then the following two statements are equivalent:
(1) there exists an epimorphism $\pi_1(M) \to \langle x_1, \dots, x_k \rangle$,
(2) there exist disjoint connected non-empty $(n-1)$-dimensional submanifolds $F_1, \dots, F_k$ of M such that $M \setminus (F_1 \cup \dots \cup F_k)$ is connected.

Sketch of a proof. First note that the "(2) $\Rightarrow$ (1)" implication is precisely the content of the Epimorphism-onto-Free Group Proposition 130.8. Thus it remains to prove the "(1) $\Rightarrow$ (2)" implication. Therefore suppose that there exists an epimorphism $\pi_1(M) \to \langle x_1, \dots, x_k \rangle$. We consider the wedge $\bigvee_{i=1}^{k} S_i^1$. We denote by $*$ the wedge point and for $i = 1, \dots, k$ we write $J_i := S_i^1 \setminus \{*\}$. By Proposition 163.20 (b) we can realize this epimorphism by a map $f\colon M \to \bigvee_{i=1}^{k} S_i^1$ which is smooth on $M \setminus f^{-1}(*)$. Let $i \in \{1, \dots, k\}$. It follows from Sard's Theorem 31.1 that there exists a regular value $z_i \in J_i$. We obtain from the Preimage-of-Point-in-Ball Lemma 29.10 that the preimage $G_i := f^{-1}(z_i)$ is an orientable proper $(n-1)$-dimensional submanifold of M. In Exercise 163.3 we will prove the following two statements:
(1) each G_i is non-empty,
(2) for each $i \in \{1, \dots, k\}$ we can find a component F_i of G_i such that $M \setminus (F_1 \cup \dots \cup F_k)$ is connected. ■



Now is a good time to recall the following question.

Question 130.9. Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g.

(1) What is the maximal number $k = k(g) \in \mathbb{N}_0$ for which we can find k disjoint curves $F_1, \dots, F_k$ on Σ_g such that $\Sigma_g \setminus (F_1 \cup \dots \cup F_k)$ is connected?
(2) What is the maximal $l = l(g) \in \mathbb{N}_0$ for which there exists an epimorphism from $\pi_1(\Sigma_g)$ onto a free group of l generators?

We make the following easy observations:

(1) As we already observed on page 2843, it follows immediately from peeking at the figure below that $k(g) \geq g$.

there exist three curves such that the complement is still connected

(2) It follows from Lemma 53.13 that we have an epimorphism

$$\overbrace{\langle x_1, y_1, \dots, x_g, y_g \,|\, x_1 y_1 x_1^{-1} y_1^{-1} \cdot \dots \cdot x_g y_g x_g^{-1} y_g^{-1} \rangle}^{\cong \pi_1(\Sigma_g) \text{ by the Fundamental Group-of-Surfaces Proposition 54.5}} \quad \begin{array}{rcl} \to & \langle x_1, \dots, x_g \rangle \\ x_i & \mapsto & x_i \\ y_i & \mapsto & e \end{array}$$

from $\pi_1(\Sigma_g)$ onto a free group on g generators.

More interestingly, by Proposition 163.21 we now know that the two questions actually give the same answer. Even better, we can now give a complete answer:

Proposition 163.22. Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g. If there exists an epimorphism Σ_g onto a free group on k generators, then $k \leq g$.

Proof. Let $g \in \mathbb{N}$, let Σ_g be the surface of genus g and let $* \in \Sigma_g$ be a base point. Let $\varphi\colon \pi_1(\Sigma_g, *) \to F_k$ be an epimorphism onto a free group on k generators. We start out with the following preparations:

(1) By the discussion on page 3427 we know that $X := \bigvee_{i=1}^{k} S^1$ is an Eilenberg-Maclane space of type $\mathrm{K}(F_k, 1)$. We pick $x_0 \in X$ and as usual we make the identification $\pi_1(X, x_0) = F_k$.
(2) It follows from the Maps-to-K(π, n)-Proposition 163.15 that there exists a map $f\colon (\Sigma_g, *) \to (X, x_0)$ with $f_* = \varphi\colon \pi_1(\Sigma_g, *) \to \pi_1(X, x_0) = F_k$. Note that the map $f_*\colon \pi_1(\Sigma_g, *) \to \pi_1(X, x_0)$ is an epimorphism.
(3) The Hurewicz Theorem 84.5, together with the Abelianization Proposition 53.20 (9), implies that the induced map $f_*\colon \mathrm{H}_1(\Sigma_g; \mathbb{Z}) \to \mathrm{H}_1(X; \mathbb{Z})$ is an epimorphism.
(4) In general, if $\alpha\colon A \to B$ is an epimorphism between two groups, then elementary algebra tells us that the induced map $\mathrm{Hom}(B, \mathbb{Z}) \to \mathrm{Hom}(A, \mathbb{Z})$ is a monomorphism. From this elementary observation, together with (3), we obtain that the induced map $f^*\colon \mathrm{Hom}(\mathrm{H}_1(X; \mathbb{Z}), \mathbb{Z}) \to \mathrm{Hom}(\mathrm{H}_1(\Sigma_g; \mathbb{Z}), \mathbb{Z})$ is a monomorphism.
(5) It follows immediately from (4) together with the First Cohomology Proposition 110.17 that the induced map $f^*\colon \mathrm{H}^1(X; \mathbb{Z}) \to \mathrm{H}^1(\Sigma_g; \mathbb{Z})$ is also a monomorphism.
(6) Since X is a 1-dimensional CW-complex we obtain almost immediately from the Singular-Cellular H^*-Isomorphism Proposition 109.4 that $\mathrm{H}^2(X; \mathbb{Z}) = 0$. In particular the cup product on $\mathrm{H}^1(X; \mathbb{Z})$ vanishes.

Now we consider the form

$$\begin{array}{rcl}\varphi\colon \mathrm{H}^1(\Sigma_g;\mathbb{Z}) \times \mathrm{H}^1(\Sigma_g;\mathbb{Z}) & \to & \mathbb{Z} \\ (\alpha,\beta) & \mapsto & \langle \alpha \cup \beta, [\Sigma_g]\rangle.\end{array}$$

Given $U \subset \mathrm{H}^1(\Sigma_g;\mathbb{Z})$ we write as usual

$$U^\perp \;=\; \{v \in \mathrm{H}^1(\Sigma_g;\mathbb{Z}) \,|\, \varphi(u,v) = 0 \text{ for all } u \in U\}.$$

Now we see that

since $X = \bigvee_{i=1}^{k} S^1$ — since i^* is a monomorphism — by the Manifold-Non Singularity Proposition 121.2 we know that φ is non-singular hence we obtain the equality from Exercise 121.3

$$\begin{array}{rcl} k & \overset{\downarrow}{=} & \mathrm{rank}(\mathrm{H}^1(X;\mathbb{Z})) \overset{\downarrow}{=} \mathrm{rank}(i^*\mathrm{H}^1(X;\mathbb{Z})) \overset{\downarrow}{=} \mathrm{rank}(\mathrm{H}^1(\Sigma_g;\mathbb{Z})) - \mathrm{rank}\left((i^*\mathrm{H}^1(X;\mathbb{Z}))^\perp\right) \\ & \underset{\uparrow}{\leq} & \mathrm{rank}(\mathrm{H}^1(\Sigma_g;\mathbb{Z})) - \mathrm{rank}(i^*\mathrm{H}^1(X;\mathbb{Z})) \underset{\uparrow}{=} 2g-k. \end{array}$$

it follows from (6) and the Cup Product-Naturality Lemma 114.10 that $i^*\mathrm{H}^1(X;\mathbb{Z}) \subset (i^*\mathrm{H}^1(X;\mathbb{Z}))^\perp$ — as above we have $\mathrm{rank}(i^*(\mathrm{H}^1(X;\mathbb{Z}))) = k$ and by the discussion on page 2422 we know that $\mathrm{rank}(\mathrm{H}^1(\Sigma_g;\mathbb{Z})) = 2g$

Thus we see that $k \leq 2g-k$, i.e. we see that $k \leq g$. ■

163.6. **Eilenberg–Maclane spaces and the social choice problem ❀.** In this section we give a fun, but perhaps not entirely serious application of Eilenberg-Maclane spaces. Let us recall the following definition from page 1864.

Definition. Let X be a topological space and let $n \in \mathbb{N}$. A social choice of type n is a map

$$f\colon X^n \;=\; \underbrace{X \times \cdots \times X}_{n \text{ times}} \;\to\; X$$

such that the following three axioms are satisfied:

(a) The map f is continuous.
(b) For every $x \in X$ we have $f(x,\ldots,x) = x$.
(c) For every permutation $\sigma \in S_n$ and any $(x_1,\ldots,x_n) \in X^n$ we have

$$f(x_{\sigma(1)},\ldots,x_{\sigma(n)}) \;=\; f(x_1,\ldots,x_n).$$

We say that a topological space is social, if for every $n \in \mathbb{N}$ it admits a social choice of type n.

We refer to Section 86.1 for a discussion why social topological spaces are interesting. Now let X be a topological space. The combination of Lemmas 86.4 and 86.5 shows that if X is social, then for every $k \in \mathbb{N}$ the homotopy group $\pi_k(X)$ is abelian and it is strongly divisible, i.e. given any $n \in \mathbb{N}$ the map $g \mapsto n \cdot g$ is an isomorphism. Furthermore, Proposition 86.2 together with the Whitehead Theorem 162.1 show that if X is in fact a CW-complex, with the property that in any dimension it has only finitely many cells, then X is contractible. Back in Section 86.1 this discussion lead us to the following question.

Question 86.7. Does there exist a non-empty CW-complex that is social but that is not contractible?

It turns out that we can now formulate a positive answer to Question 86.7.

Theorem 163.23.

(1) Any CW-complex that is homotopy equivalent to the product of a family of Eilenberg-Maclane spaces of type $\mathrm{K}(\mathbb{Q}, k_i)$, $i \in I$ is social.
(2) Conversely, if X is a connected social CW-complex, then it is homotopy equivalent to the product of a family of Eilenberg-Maclane spaces of type $\mathrm{K}(\mathbb{Q}, k_i)$, $i \in I$.

Proof. This theorem is proved in [**EGH1962**, p. 90] and [**Weinb2004**, Theorem 1.3], see also [**Eckm2004**, Theorems 4 and 7]. For the most part the proofs do not go much beyond what we have covered so far, except that they build on a result of Alexander Grothendieck [**Groth1957**, Chapter V], see also [**HZ1974**, p. 32] and [**Hirz1969**, p. 254]. ■

Remark. As always there are various variations and generalizations of Theorem 163.23. For example by [**Weinb2004**, Example 1.4] any Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}_2, 1)$, e.g. according to the discussion on page 3427 we could take $\mathbb{R}\mathrm{P}^\infty$, has the property that given any *odd* $n \in \mathbb{N}$ it admits a social choice of type n.

163.7. **An extension of the Hurewicz Theorem 85.5.** In this last section we will use Eilenberg-Maclane spaces in a surprising way to obtain an addendum to the Hurewicz Theorem 85.5. To formulate the theorem it is convenient to introduce the following definition.

Definition. Given a group π and $n \in \mathbb{N}_0$ we define $\mathrm{H}_n(\pi) := \mathrm{H}_n(\mathrm{K}(\pi, 1), \mathbb{Z})$ where $\mathrm{K}(\pi, 1)$ denotes the canonical Eilenberg-Maclane space introduced in the Eilenberg-Maclane Existence Theorem 163.8. We refer to $\mathrm{H}_n(\pi)$ as the n-th homology group of the group π.

Remark. The concept of the homology groups $\mathrm{H}_n(\pi)$ of a group π will play an important role in this section. Afterwards it takes a well-earned rest before it will take center stage in Chapter **??**.

The following lemma is an immediate consequence of Corollary 163.13.

Lemma 163.24. Let π be a group and let $n \in \mathbb{N}_0$. For any Eilenberg-Maclane space X of type $\mathrm{K}(\pi, 1)$ we have $\mathrm{H}_n(\pi) \cong \mathrm{H}_n(X; \mathbb{Z})$.

Example. Let $m \in \mathbb{N}$ and let $n \in \mathbb{N}_0$. We calculate that

$$\mathrm{H}_n(\text{the group } \mathbb{Z}^m) \underset{\text{by Lemma 163.24}}{\cong} \mathrm{H}_n(\text{any Eilenberg-Maclane space } \mathrm{K}(\mathbb{Z}^m, 1)) \underset{\substack{\text{by the discussion on page 3427 we know that } (S^1)^m \\ \text{is an Eilenberg-Maclane space of type } \mathrm{K}(\mathbb{Z}^m, 1)}}{\cong} \mathrm{H}_n((S^1)^m) \underset{\text{see page 1948}}{\cong} \mathbb{Z}^{\binom{m}{n}}.$$

We continue with the following lemma.

Lemma 163.25. Let (X, x_0) be a pointed 0-connected space. There exists a natural map

$$\eta\colon \mathrm{H}_2(X; \mathbb{Z}) \ \to\ \mathrm{H}_2(\pi_1(X, x_0))$$

which has the following property: whenever (Y, y_0) is a pointed Eilenberg-Maclane space of type $\mathrm{K}(\pi_1(X, x_0), 1)$ and $f\colon (X, x_0) \to (Y, y_0)$ is a map of pointed topological spaces that induces an isomorphism of fundamental groups, then there exists an isomorphism

$\mu\colon \mathrm{H}_2(Y;\mathbb{Z}) \to \mathrm{H}_2(\pi_1(X,x_0))$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_2(X;\mathbb{Z}) & \xrightarrow{\quad\eta\quad} & \mathrm{H}_2(\pi_1(X,x_0)) \\ & {\scriptstyle f_*}\searrow \quad \nearrow{\scriptstyle \mu}\ {\scriptstyle \cong} & \\ & \mathrm{H}_2(Y;\mathbb{Z}). & \end{array}$$

Proof. Let (X,x_0) be a pointed 0-connected space. We write $\pi = \pi_1(X,x_0)$. We denote by $(Z,z_0,\varphi\colon \pi_1(Z,z_0)\to\pi)$ the canonical triple introduced in the Eilenberg-Maclane Existence Theorem 163.8. By the CW-Approximation Theorem 161.8 there exists a CW-approximation $f\colon (Y,y_0)\to(X,x_0)$. Note that by the Weak Homotopy-vs-Homology Isomorphisms Proposition 161.6 we know that f induces isomorphisms on all homology groups.

By the Maps-to-K(π,n)-Proposition 163.15 (1) we know that there exists a map $g\colon (Y,y_0)\to(Z,z_0)$ such that $g_* = \varphi^{-1}\circ f_*\colon \pi_1(Y,y_0)\to\pi_1(Z,z_0)$. We set

$$\eta \;:=\; g_*\circ(f_*)^{-1}\colon \mathrm{H}_2(X;\mathbb{Z}) \;\to\; \mathrm{H}_2(Z;\mathbb{Z}) =: \mathrm{H}_2(\pi_1(X,x_0)).$$

Using the Maps-to-K(π,n)-Proposition 163.15 (1) it is not difficult to verify that η has the desired properties. ■

Now we can formulate the following theorem.

Theorem 163.26. (Hurewicz Theorem) Let $n\in\mathbb{N}$ and let X be an $(n-1)$-connected space and let $x_0\in X$.

(1) If $n=1$, then the sequence

$$\pi_2(X,x_0) \;\xrightarrow{\Phi_{(X,x_0)}}\; \mathrm{H}_2(X;\mathbb{Z}) \;\xrightarrow{\eta}\; \mathrm{H}_2(\pi_1(X,x_0)) \;\to\; 0$$

is exact. This implies in particular that the cokernel of the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_2(X,x_0)\to\mathrm{H}_2(X;\mathbb{Z})$ is isomorphic to $\mathrm{H}_2(\pi_1(X))$.

(2) If $n>1$, then the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_{n+1}(X,x_0)\to\mathrm{H}_{n+1}(X;\mathbb{Z})$ is an epimorphism.

Remark.

(1) We refer to [**WhdG1978**, Theorem V.7.9] for a generalization of the above theorem.

(2) Let $n>1$. Furthermore let X be an $(n-1)$-connected space. By the above Hurewicz Theorem 163.26 (2) we now know that the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_{n+1}(X,x_0)\to\mathrm{H}_{n+1}(X;\mathbb{Z})$ is an epimorphism. For $n\geq 3$ the kernel of the Hurewicz homomorphism is discussed in [**Hilt1953**, p.105] and [**WhdJ1950**, p. 72]. Furthermore, for the more tricky case $n=2$ the kernel of the Hurewicz homomorphism is determined in [**WhdJ1950**, pages 72, 76 and Theorem 20].

Example. Let X be a simply connected space and let $x_0\in X$. By Theorem 163.26, applied to the case $n=2$, the Hurewicz homomorphism $\pi_3(X,x_0)\to\mathrm{H}_3(X;\mathbb{Z})$ is in fact an epimorphism. It is natural to wonder whether Theorem 163.26 can be improved upon. For example it is a priori not unreasonable to ask whether the Hurewicz homomorphism $\pi_k(X,x_0)\to\mathrm{H}_k(X;\mathbb{Z})$ is an epimorphism for every $k\in\mathbb{N}_{\geq 3}$. But it turns out, we have a counterexample at hand, namely $X=\mathbb{C}\mathrm{P}^\infty$. By Theorem 155.12 we know that $\mathbb{C}\mathrm{P}^\infty$ is simply connected and that $\pi_k(\mathbb{C}\mathrm{P}^\infty)=0$ for $k\geq 3$. But by the discussion on page 1772 we

know that $\mathrm{H}_k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong \mathbb{Z}$ for every even k. In particular the Hurewicz homomorphism $\pi_4(\mathbb{C}\mathrm{P}^\infty) \to \mathrm{H}_4(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$ is not an epimorphism.

The proof of Theorem 163.26 crucially relies on the following lemma.

Lemma 163.27. Let π be an abelian group and let $n \in \mathbb{N}_{\geq 2}$. If Y is an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$, then $\mathrm{H}_{n+1}(Y;\mathbb{Z}) = 0$.

Examples.

(1) The statement of Lemma 163.27 is somewhat surprising since it is emphatically wrong for $n = 1$. For example by the discussion on page 3427 we know that $S^1 \times S^1$ is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}^2, 1)$ and we have $\mathrm{H}_2(S^1 \times S^1;\mathbb{Z}) \neq 0$.

(2) As a reality check, let us consider the only Eilenberg-Maclane space for $n \geq 2$ that we understand, namely $\mathbb{C}\mathrm{P}^\infty$ which is by the discussion on page 3427 an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, 2)$. By the calculation on page 1772 we do know that $\mathrm{H}_3(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$ is indeed trivial.

Proof of Lemma 163.27. Let $n \in \mathbb{N}_{\geq 2}$ and let π be an abelian group. It follows from Corollary 163.13 that it suffices to show that there exists a single Eilenberg-Maclane space Z of type $\mathrm{K}(\pi, n)$ with $\mathrm{H}_{n+1}(Z;\mathbb{Z}) = 0$.

By the Moore Space Existence Proposition 79.11 we know that there exists an $(n+1)$-dimensional CW-complex that is a Moore space Y of type $\mathrm{K}(\pi, n)$. Recall that this means that

(1) Y is simply connected,
(2) $\mathrm{H}_n(Y;\mathbb{Z}) \cong \pi$,
(3) for any $i \neq n$ we have $\widetilde{\mathrm{H}}_i(Y;\mathbb{Z}) = 0$.

We pick a base point $y_0 \in Y$. By the Hurewicz Corollary 85.7 we now know that (1), (2) and (3) imply that

(4) $\pi_i(Y, y_0) = 0$ for $i = 1, \ldots, n-1$ and that $\pi_n(Y, y_0) \cong \pi$.

By the Kill-All Higher-π_n-Proposition 163.7 there exists a CW-complex Z with the following properties:

(5) The $(n+1)$-skeleton of Z equals Y.[2012]
(6) We have $\pi_i(Z) = 0$ for $i \geq n+1$.
(7) For $i = 1, \ldots, n$ the inclusion $Y \to Z$ induces an isomorphism $\pi_i(Y, y_0) \xrightarrow{\cong} \pi_i(Z, y_0)$.

It follows from (4), (6) and (7) that Z is an Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$.

Since Y is the $(n+1)$-skeleton of the CW-complex Z we obtain from the Skeleton-Homology Lemma 80.1 (4) that the map $\mathrm{H}_{n+1}(Y;\mathbb{Z}) \to \mathrm{H}_{n+1}(Z;\mathbb{Z})$ is an epimorphism. Together with (3) this implies that $\mathrm{H}_{n+1}(Z;\mathbb{Z}) = 0$.[2013] We have thus found the desired Eilenberg-Maclane space Z. ∎

Now we turn to the actual proof of Theorem 163.26. For convenience we break the proof into three parts:

(1) First we prove Theorem 163.26 (1) for 2-dimensional CW-complexes.

[2012] Here we use that Y is its own $(n+1)$-skeleton.

[2013] The reader will not have failed to notice that this proof shares some ideas with the proof of Lemma 163.11.

(2) Then we prove Theorem 163.26 (2) for $(n+1)$-dimensional CW-complexes.
(3) Finally we deal with the general case of Theorem 163.26.

Proof of Theorem 163.26 (1) for 2-dimensional CW-complexes. Let X be a 2-dimensional CW-complex that is 0-connected. Let $x_0 \in X$. By the Kill-All Higher-π_n-Proposition 163.7 there exists a CW-complex Y with the following properties:

(1) The 2-skeleton of Y equals X.
(2) We have $\pi_i(Y, x_0) = 0$ for $i \geq 2$.
(3) The inclusion map $i\colon X \to Y$ induces an isomorphism $i_*\colon \pi_1(X, x_0) \xrightarrow{\cong} \pi_1(Y, x_0)$.

It follows from (1), (2) and (3) that Y is an Eilenberg-Maclane space of type $\mathrm{K}(\pi_1(X, x_0), 1)$. Next we consider the following diagram:

$$\begin{array}{ccccccccc}
\pi_3(Y,X,x_0) & \xrightarrow{\partial} & \pi_2(X,x_0) & \longrightarrow & \overbrace{\pi_2(Y,x_0)}^{=0} & \longrightarrow & \pi_2(Y,X,x_0) & \xrightarrow{\partial} & \pi_1(X,x_0) \xrightarrow[\cong]{i_*} \pi_1(Y,x_0) \\
\downarrow{\scriptstyle \Phi_{(Y,X,x_0)}} & & \downarrow{\scriptstyle \Phi_{(X,x_0)}} & & \downarrow{\scriptstyle \Phi_{(Y,x_0)}} & & \downarrow{\scriptstyle \Phi_{(Y,X,x_0)}} & & \\
\mathrm{H}_3(Y,X;\mathbb{Z}) & \xrightarrow{\partial} & \mathrm{H}_2(X;\mathbb{Z}) & \twoheadrightarrow & \mathrm{H}_2(Y;\mathbb{Z}) & \longrightarrow & \underbrace{\mathrm{H}_2(Y,X;\mathbb{Z})}_{=0}. & & \\
 & & \downarrow{\scriptstyle \eta} & \overset{\cong}{\swarrow}{\scriptstyle \mu} & & & & & \\
 & & \mathrm{H}_2(\pi_1(X,x_0)) & & & & & &
\end{array}$$

We make the following clarifications and observations:

(a) The horizontal sequences are the long exact sequences of homology and homotopy groups of the pair (Y, X), given by the Topological LES-Corollary 74.14 and by the Homotopy Groups-LES Proposition 153.4.
(b) The vertical maps are the (relative) Hurewicz homomorphisms that we introduced on pages 1842 and 3254
(c) The diagram commutes by Lemma 153.11 (3).
(d) It follows from (2), (3) and the lower end of the upper long exact sequence that $\pi_j(Y, X) = 0$ for $j = 0, 1$. In other words, the pair (Y, X) is 2-connected.
(e) It follows from (d) and the Relative Hurewicz Theorem 153.13 that the left-hand vertical map is an epimorphism.[2014]
(f) The map η and the isomorphism μ are given by Lemma 163.25. In particular these maps turn the lower triangle into a commutative triangle.
(g) Since X is the 2-skeleton of Y we obtain from the Skeleton-Homology Lemma 80.1 that $\mathrm{H}_2(Y, X; \mathbb{Z}) = 0$.

From this data one can easily deduce that the sequence

$$\pi_2(X, x_0) \xrightarrow{\Phi_{(X,x_0)}} \mathrm{H}_2(X;\mathbb{Z}) \xrightarrow{\eta} \mathrm{H}_2(\pi_1(X, x_0)) \to 0$$

is exact. ∎

[2014]People with shaky memories, like your author, might be surprised that it does not say that the map is an isomorphism. The point is that the Relative Hurewicz Theorem 153.13 shows that the Hurewicz homomorphism $\pi_3(Y, X, x_0)' \to \mathrm{H}_3(Y, X; \mathbb{Z})$ is an isomorphism where $\pi_3(Y, X, x_0)'$ is the quotient of $\pi_3(Y, X, x_0)$ by a suitable action of $\pi_1(X, x_0)$. Thus the Hurewicz homomorphism $\pi_3(Y, X, x_0) \to \mathrm{H}_3(Y, X; \mathbb{Z})$ is an epimorphism, but in general it is not an isomorphism.

Proof of Theorem 163.26 (2) for $(n+1)$-dimensional CW-complexes. Let $n \in \mathbb{N}_{\geq 2}$ and let X be an $(n+1)$-dimensional CW-complex that is $(n-1)$-connected. Let $x_0 \in X$. By the Kill-All Higher-π_n-Proposition 163.7 there exists a CW-complex Y with the following properties:

(1) The $(n+1)$-skeleton of Y equals X.
(2) We have $\pi_i(Y, x_0) = 0$ for $i \geq n+1$.
(3) For every $j \in \{1, \ldots, n\}$ the inclusion map $i\colon X \to Y$ induces an isomorphism $i_*\colon \pi_j(X, x_0) \xrightarrow{\cong} \pi_j(Y, x_0)$.

It follows from (1), (2) and (3) that Y is an Eilenberg-Maclane space of type $\mathrm{K}(\pi_n(X, x_0), n)$. Next we consider the following diagram:[2015]

$$\begin{array}{ccccccccccc}
\pi_{n+2}(Y,X) & \xrightarrow{\partial} & \pi_{n+1}(X) & \longrightarrow & \overbrace{\pi_{n+1}(Y)}^{=0} & \longrightarrow & \pi_{n+1}(Y,X) & \xrightarrow{\partial} & \pi_n(X) & \xrightarrow[\cong]{i_*} & \pi_n(Y) \longrightarrow \ldots \\
\cong\downarrow{\scriptstyle \Phi_{(X,Y)}} & & \downarrow{\scriptstyle \Phi_X} & & \downarrow{\scriptstyle \Phi_Y} & & & & & & \\
\mathrm{H}_{n+2}(Y,X) & \xrightarrow{\partial} & \mathrm{H}_{n+1}(X) & \longrightarrow & \underbrace{\mathrm{H}_{n+1}(Y)}_{=0 \text{ by Prop. 163.27}}. & & & & & &
\end{array}$$

We make the following clarifications and observations:

(a) As in the previous proof, the horizontal sequences are long exact sequences of the pair (Y, X). Furthermore the vertical maps are the (relative) Hurewicz homomorphisms and the diagram commutes by Lemma 153.11 (3).
(b) It follows from (2), (3) and the lower end of the upper long exact sequence that $\pi_j(Y, X) = 0$ for $j = 0, \ldots, n+1$. In other words, the pair (Y, X) is $(n+1)$-connected.
(c) It follows immediately from (a) and the Relative Hurewicz Theorem 153.13, together with the fact that $\pi_1(X, x_0) = 0$, that the left-hand vertical map is an isomorphism.
(d) Since Y is an Eilenberg-Maclane space of type $\mathrm{K}(\pi_n(X, x_0), n)$ and since $n \geq 2$ we obtain from Lemma 163.27 that $\mathrm{H}_{n+1}(Y) = 0$.

It follows from the above that the second vertical map $\pi_{n+1}(X) \to \mathrm{H}_{n+1}(X)$ is, as promised, an epimorphism. ■

Proof of the general Theorem 163.26. First we consider the case that $n \geq 2$. In the following let X be an $(n-1)$-connected space. Let $x_0 \in X$. By the CW-Approximation Theorem 161.8 there exists a CW-complex Y together with a weak homotopy equivalence $f\colon Y \to X$. Since f is a weak homotopy equivalence we see that Y itself is $(n-1)$-connected. We denote by $i\colon Y^{n+1} \to Y$ the inclusion of the $(n+1)$-skeleton Y^{n+1} into Y. We pick $y_1 \in Y^{n+1}$ and we write $x_1 = f(y_1)$. Since X is in particular path-connected we can pick a path γ from x_0 to x_1. We consider the following diagram

$$\begin{array}{ccccccc}
\pi_{n+1}(Y^{n+1}, y_1) & \xrightarrow{i_*} & \pi_{n+1}(Y, y_1) & \xrightarrow[\cong]{f_*} & \pi_{n+1}(X, x_1) & \xrightarrow[\cong]{\gamma_*} & \pi_{n+1}(X, x_0) \\
\downarrow{\scriptstyle \Phi_{(Y^{n+1}, y_1)}} & & \downarrow{\scriptstyle \Phi_{(Y,y_1)}} & & \downarrow{\scriptstyle \Phi_{(X,x_1)}} & & \downarrow{\scriptstyle \Phi_{(X,x_0)}} \\
\mathrm{H}_{n+1}(Y^{n+1}; \mathbb{Z}) & \xrightarrow{i_*} & \mathrm{H}_{n+1}(Y; \mathbb{Z}) & \xrightarrow[\cong]{f_*} & \mathrm{H}_{n+1}(X; \mathbb{Z}) & \xrightarrow{\mathrm{id}} & \mathrm{H}_{n+1}(X; \mathbb{Z}).
\end{array}$$

[2015] For evident space reasons we drop the base points from the discussion.

We make the following clarifications and observations:

(1) The vertical maps are the Hurewicz homomorphisms.
(2) The horizontal map to the top right is the isomorphism that is induced by the path γ_*, see the Change-of-Base Point Proposition 71.5.
(3) The two squares to the left commute by Proposition 84.2.
(4) The square to the right commutes by Lemma 85.1 (2).
(5) We know from the above proof of Theorem 163.26 for $(n+1)$-dimensional CW-complexes, and the fact that Y^{n+1} is $(n-1)$-connected, that the left vertical map is an epimorphism.
(6) By the Skeleton-Homology Lemma 80.1 (4) we know that the bottom left horizontal map is an epimorphism.
(7) Since f is a weak homotopy equivalence we know that the top middle horizontal map is an isomorphism. Furthermore we obtain from the Weak Homotopy-vs-Homology Isomorphisms Proposition 161.6 that the bottom middle horizontal map is also an isomorphism.
(8) It follows from all the information assembled above that the right vertical map is an epimorphism.

The proof for $n = 1$ is quite similar, with a few minor extra complications. We leave it to the reader to fill in the details. ■

Theorem 163.26 (2) says that given a pointed 0-connected space (X, x_0) there is a curious interplay between $\pi_2(X, x_0)$, $\mathrm{H}_2(X)$ and the second homology of $\pi_1(X, x_0)$. We want to get a better intuition for what is happening by considering two corollaries to Theorem 163.26 (2).

Corollary 163.28. Let (X, x_0) be some pointed 0-connected space. If $\pi_1(X, x_0) \cong \mathbb{Z}$, then the Hurewicz homomorphism $\Phi_{(X,x_0)} \colon \pi_2(X, x_0) \to \mathrm{H}_2(X; \mathbb{Z})$ is an epimorphism.

Proof. In the discussion on page 3453 we saw that $\mathrm{H}_2(\pi_1(X, x_0)) \cong \mathrm{H}_2(\mathbb{Z}) \cong \mathrm{H}_2(S^1) = 0$. Thus it follows immediately from Theorem 163.26 (2) that the Hurewicz homomorphism $\pi_2(X, x_0) \to \mathrm{H}_2(X; \mathbb{Z})$ is an epimorphism. ■

Remark. The proof of Corollary 163.28 is in many ways beyond reproach, it is clear and rigorous. The only catch is that it is not very geometric and we do not really get a good understanding why the statement is true. To rectify this we will sketch an alternative, quite geometric, proof for Corollary 163.28 in Exercise 163.10.

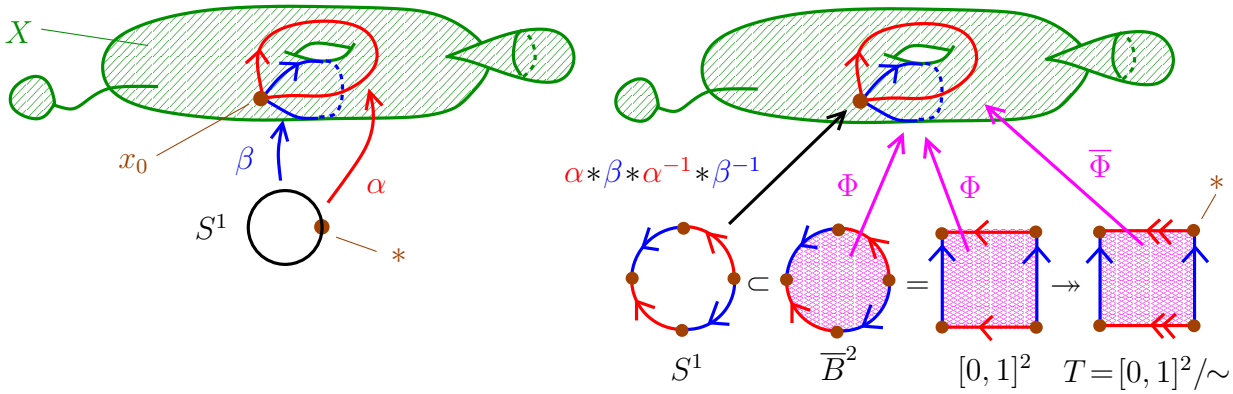
We move on to the second corollary to Theorem 163.26 (2).

Corollary 163.29. If X is a 0-connected space such that $\pi_1(X) \cong \mathbb{Z}^m$ for some $m \in \mathbb{N}_{\geq 2}$, then for any $x_0 \in X$ we have

$$\operatorname{coker}\left(\Phi_{(X,x_0)} \colon \pi_2(X, x_0) \to \mathrm{H}_2(X; \mathbb{Z})\right) \underset{\text{Theorem 163.26 (1)}}{\overset{\uparrow}{\cong}} \mathrm{H}_2(\pi_1(X)) \cong \mathrm{H}_2(\mathbb{Z}^m) \underset{\text{by the example on page 3453}}{\overset{\uparrow}{\cong}} \mathbb{Z}^{\binom{m}{2}}.$$

In particular we see that $\mathrm{H}_2(X; \mathbb{Z})$ is non-trivial.

In the following we want to get a better understanding how this "extra" homology in $\mathrm{H}_2(X;\mathbb{Z})$ arises. To simplify the discussion let us consider the case $m = 2$. Thus let (X, x_0) be a pointed 0-connected space with $\pi_1(X, x_0) \cong \mathbb{Z}^2$. We proceed as follows:



(1) We pick two loops $\alpha, \beta\colon (S^1, *) \to (X, x_0)$ that represent a generating set for the group $\pi_1(X, x_0) \cong \mathbb{Z}^2$.

We consider the loop $\varphi = \alpha * \beta * \overline{\alpha} * \overline{\beta}\colon (S^1, *) \to (X, x_0)$. Since $\pi_1(X, x_0)$ is abelian we see that the loop φ represents the trivial element in $\pi_1(X, x_0)$. By the Extension-to-Disk Lemma 47.1 this means that we can extend the loop to a map $\Phi\colon \overline{B}^2 \to X$.

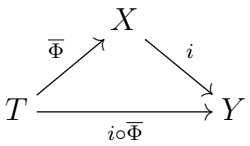
(2) We make the "obvious" identification[2016] $\overline{B}^2 = [0,1]^2$ which identifies the "quartercircles" on S^1 with the four sides of the square.

(3) Let $\sim$ be the usual equivalence relation on $[0,1]^2$ given by $(x, 0) \sim (x, 1)$ and $(y, 0) \sim (y, 1)$. The quotient $T := [0,1]^2/\sim$ is the 2-dimensional torus. We equip T with the base point $*$ that is represented by any of the vertices.

(4) The map $\Phi\colon \overline{B}^2 = [0,1]^2 \to X$ descends to a map $\overline{\Phi}\colon T := [0,1]^2/\sim \to X$.

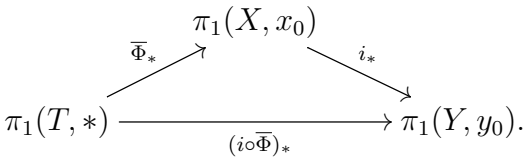
This approach feels like we are creating surfaces ex nihilo. But the following lemma shows that miraculously this approach works.

Lemma 163.30. We continue with the above notation. The map



$$\begin{array}{rcl} \mu\colon \overbrace{\mathrm{H}_2(T;\mathbb{Z})}^{=\mathbb{Z}\cdot[T]} & \to & \operatorname{coker}(\pi_2(X, x_0) \to \mathrm{H}_2(X;\mathbb{Z})) \\ \sigma & \mapsto & [\overline{\Phi}_*(\sigma)] \end{array}$$

is an isomorphism.



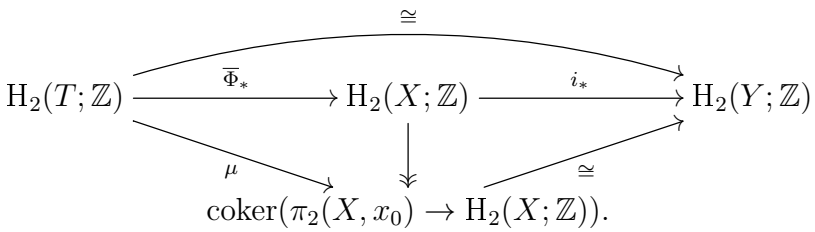
Sketch of proof. As in the proof of Theorem 163.26 (2) we can assume that X is a 3-dimensional CW-complex. Furthermore, by the proof of Theorem 163.26 (2) we know that there exists an inclusion $i\colon X \to Y$ of X into an Eilenberg-Maclane space Y of type $\mathrm{K}(\mathbb{Z}^2, 1)$ such that the inclusion induced map $i_*\colon \pi_1(X, x_0) \to \pi_1(Y, x_0)$ is an isomorphism.

[2016] The identification is given by rotation by $\frac{\pi}{4}$ followed by "outward" stretching as in the proof of the Convex-to-Ball Proposition 2.20.

We consider the following simple minded diagram

and we consider the induced diagram

We make the following observations:



(1) The map $\overline{\Phi}_*\colon \pi_1(T,*) \to \pi_1(X,x_0)$ is by design an epimorphism. Since both groups are isomorphic to $\mathbb{Z}^2$ we obtain from Lemma 51.9 (5) that $\overline{\Phi}_*$ is in fact an isomorphism.

(2) As we mentioned above, the map $i_*\colon \pi_1(X,x_0) \to \pi_1(Y,x_0)$ is an isomorphism.

(3) By (1) and (2) we know that $(i\circ\overline{\Phi})_* = i_*\circ\overline{\Phi}_*\colon \pi_1(T,*) \to \pi_1(Y,x_0)$ is an isomorphism. By the discussion on page 3427 and by the above we know that both T and Y are Eilenberg-Maclane spaces of type $\mathrm{K}(\mathbb{Z}^2,1)$. Thus we obtain from the Whitehead Theorem 162.1 that $i\circ\overline{\Phi}\colon T \to Y$ is in fact a homotopy equivalence.

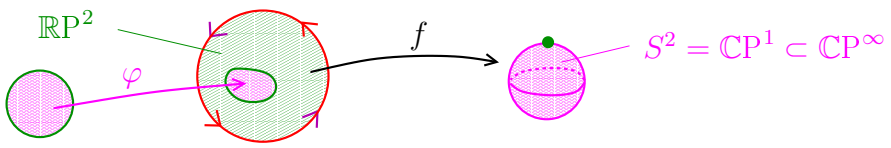
(4) Since $i\circ\overline{\Phi}$ is a homotopy equivalence we obtain from the Homotopy Equivalence-H_*-Corollary 73.9 that the induced map $(i\circ\overline{\Phi})_* = i_*\circ\overline{\Phi}_*\colon \mathrm{H}_2(T;\mathbb{Z}) \to \mathrm{H}_2(Y;\mathbb{Z})$ is an isomorphism.

It remains to consider the following diagram

By the above discussion we know that the composition of the top two horizontal maps is an isomorphism and by Theorem 163.26, together with Lemma 163.25, we know that the diagonal map to the right is an isomorphism. It follows that the diagonal map to the left is also an isomorphism. ■

Exercises for Chapter 163.

Exercise 163.1. We consider the real projective plane $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$ where for $x \in S^1$ we have $x \sim -x$. Let $\varphi\colon \overline{B}^2 \to \mathbb{R}\mathrm{P}^2$ be a smooth embedding. We consider the map



$$\begin{aligned} f\colon \mathbb{R}\mathrm{P}^2 &\to \overline{B}^2/S^1 = S^2 = \mathbb{C}\mathrm{P}^1 \subset \mathbb{C}\mathrm{P}^\infty \\ P &\mapsto \begin{cases} [Q], & \text{if } P = \varphi(Q) \text{ for some } Q \in \overline{B}^2, \\ [S^1], & \text{otherwise.} \end{cases} \end{aligned}$$

Is the map f homotopic to the constant map?

Exercise 163.2. Let X be a connected k-dimensional CW-complex and let $k \in \mathbb{N}$.

(a) Does there exist a CW-complex Y with $Y^k = X$ and $\pi_k(Y) = 0$?

(b) Does there exist a CW-complex Y with $Y^k = X$ and $\mathrm{H}_k(Y;\mathbb{Z}) = 0$?

Exercise 163.3. Finish the proof of Proposition 163.21.
Hint. Use Lemma 130.5.

Exercise 163.4. Let $n \in \mathbb{N}$. In Lemma 163.11 we showed that there exists an Eilenberg-Maclane space X of type $\mathrm{K}(\mathbb{Z}, n)$ with precisely one 0-cell, precisely one n-cell and no cell of dimension $n+1$. What is the minimal dimension in which the canonical Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, n)$ has more cells than X?

Exercise 163.5. Let $n \in \mathbb{N}$. We consider $n \cdot \mathbb{R}\mathrm{P}^2$, i.e. we consider the connected sum of n copies of $\mathbb{R}\mathrm{P}^2$.

(a) What is the maximal number $k \in \mathbb{N}_0$ for which we can find k disjoint curves $F_1, \ldots, F_k$ on $n \cdot \mathbb{R}\mathrm{P}^2$ such that $n \cdot \mathbb{R}\mathrm{P}^2 \setminus (F_1 \cup \cdots \cup F_k)$ is connected?
(b) What is the maximal $l \in \mathbb{N}_0$ for which there exists an epimorphism from $\pi_1(n \cdot \mathbb{R}\mathrm{P}^2)$ onto a free group of l generators?

Remark. By the Fundamental Group-of-Surfaces Proposition 54.9 we know that there exists an isomorphism

$$\pi_1(n \cdot \mathbb{R}\mathrm{P}^2) \;\cong\; \langle x_1, \ldots, x_n \mid x_1^2 \cdot \cdots \cdot x_n^2 \rangle.$$

Remark. This exercise is basically a variation on Question 130.9.

Exercise 163.6. In Lemma 114.9 we proved the following statement:

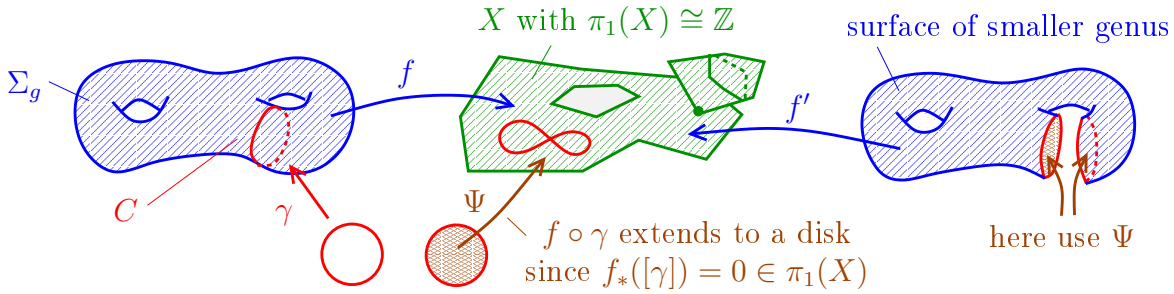
($*$) Let X be a topological space. For any $\phi \in \mathrm{H}^1(X; \mathbb{Z})$ we have $\phi \cup \phi = 0$.

Our goal is to give an alternative proof of this statement:

(a) Show that ($*$) holds for $X = S^1$.
(b) Let X be a CW-complex. Use (a) and the Maps-to-$\mathrm{K}(\pi, n)$-Proposition 163.15 to provide a proof of ($*$) for CW-complexes.
(c) Use the CW-Approximation Theorem 161.8 and the Weak Homotopy-vs-Homology Isomorphisms Proposition 161.6 to show, using (b), that ($*$) holds for all topological spaces.

Exercise 163.7. Show that there exists an abelian group π and Moore spaces X and Y of type $\mathrm{K}(\pi, 1)$ that are not homotopy equivalent.
Hint. You could use the fundamental group to distinguish X and Y.
Remark. In Exercise 163.8 we will deal with Moore spaces of type $\mathrm{K}(\pi, n)$ with $n \geq 2$.

Exercise 163.8. Let π be an abelian group and let $n \in \mathbb{N}_{\geq 2}$. In this exercise we will show that any two Moore spaces of type $\mathrm{M}(\pi, n)$ are in fact homotopy equivalent. First note that by the Moore Space Existence Proposition 79.11 there exists an $(n+1)$-dimensional CW-complex X that has no cells in dimensions $1, \ldots, n-1$ and that is a Moore space of type $\mathrm{M}(\pi, n)$. It suffices to show that X is homotopy equivalent to any other Moore space Y of type $\mathrm{M}(\pi, n)$. This task is broken up into two steps:



(a) Use Lemma 163.16 to show that there exists a map $f\colon X \to Y$ that induces an isomorphism $f_*\colon \pi_n(X) \to \pi_n(Y)$.
(b) Use Lemma 85.1, the Weak Homotopy-vs-Homology Isomorphisms Proposition 161.6 and the Whitehead Theorem 162.1 (1) to show that f is a homotopy equivalence.

Remark. Together with Exercise 163.7 this gives a complete answer to Question 79.14.

Exercise 163.9. Let $n \in \mathbb{N}$. We set $M = (S^1)^n$. Let $\varphi\colon \pi_1(M) \to \mathbb{Z}^n$ be an isomorphism. Show that it is not possible to extend φ over a bounding $(n+1)$-dimensional smooth manifold. More precisely, show that there is no pair $(W, \psi\colon \pi_1(W) \to \mathbb{Z}^n)$ where W is a compact orientable connected smooth manifold with $\partial W = M$ and where ψ is a homomorphism that satisfies $\varphi = \psi \circ i_*$ where $i\colon M \to W$ denotes the inclusion.
Remark. By the Smooth Manifold-CW Structure Theorem 96.5 we know that any compact smooth manifold W admits a CW-structure.

Exercise 163.10. Let X be a 1-connected space with $\pi_1(X) \cong \mathbb{Z}$. By Corollary 163.28 we know that the Hurewicz homomorphism $\pi_2(X) \to \mathrm{H}_2(X;\mathbb{Z})$ is an epimorphism. The goal of this exercise is to sketch an alternative geometric proof. Thus let $\varphi \in \mathrm{H}_2(X;\mathbb{Z})$. By the Realization-by-Surface Proposition 102.3 there exists a surface Σ_g of some genus $g \in \mathbb{N}_0$ and a map $f\colon \Sigma_g \to X$ such that $f_*([\Sigma_g]) = \varphi \in \mathrm{H}_2(X;\mathbb{Z})$. If $g = 0$, then we are done. So suppose that $g \geq 1$. We proceed with the following steps:

(a) Show that there exists a curve $C \subset \Sigma_g$ with $[C] \neq 0 \in \mathrm{H}_1(\Sigma_g;\mathbb{Z})$ but such that $f_*([C]) = \pi_1(X)$.
Remark. You might want to use Corollary 102.17 at some point.
(b) Get inspired by the figure below.
(c) Complete the proof of the statement.

Exercise 163.11. Let π be a group, let $\varphi\colon \pi \to \pi$ be an endomorphism and let K be an Eilenberg-Maclane space of type $\mathrm{K}(\pi, 1)$. By the Maps-to-$\mathrm{K}(\pi, n)$-Proposition 163.15 we know that there exists a map $f\colon (\mathrm{K}(\pi,1), *) \to (\mathrm{K}(\pi,1))$ such that $f_* = \varphi$. Now suppose that φ is an isomorphism. Can always find such a map f which is furthermore a homeomorphism?

Exercise 163.12. Let $F_n := \langle x_1, \ldots, x_n \rangle$ the free group on n generators $x_1, \ldots, x_n$ and let $\varphi\colon F_n \to F_n$ be an isomorphism. We consider the semidirect product $\pi := F_n \rtimes \mathbb{Z}$ as defined on page 1127. Show that there exists a 2-dimensional Eilenberg-Maclane space of type $\mathrm{K}(\pi, 1)$.

Hint. Note that $X := \bigvee_{i=1}^{n} S^1_i$ is an Eilenberg-Maclane space of type $\mathrm{K}(F_n, 1)$. By the Maps-to-$\mathrm{K}(\pi, n)$-Proposition 163.15 there exists a map $f\colon (X, *) \to (X, *)$ with $f_* = \varphi$. Now

consider the mapping torus $\mathrm{Tor}(X, f)$. Use the Mapping Torus-π_1-Proposition 50.6. It might also be useful to consider Mapping Torus Covering Lemma 16.29.

Exercise 163.13. Let X be a connected aspherical CW-complex, let $U \subset X$ be a connected open subset and let $x_0 \in U$. We suppose that $\pi_1(U, x_0) \to \pi_1(X, x_0)$ is trivial. Show that the inclusion $\iota\colon U \to X$ is homotopic to a constant map.
Hint. Use the universal covering of X.

Exercise 163.14. Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem **??** there exists a smooth embedding $\Phi\colon \overline{B}^2 \times K \to S^3$ such that $\Phi(0, P) = P$ for all $P \in K$. As on page 2213 we refer to $X_K := S^3 \setminus \Phi(B^2 \times K)$ as the *exterior of* K.

(a) Recall that by Lemma 100.16 we know that $\mathrm{H}_1(X_K) \cong \mathbb{Z}$. Show that there exists a map $f\colon X_K \to S^1$ that induces an isomorphism on H_1.

(b) Show that there exists a map $f\colon X_K \to \overline{B}^2 \times S^1$ of degree ± 1, i.e. a map such that $f_*\colon \mathrm{H}_3(X_K, \partial X_K) \to \mathrm{H}_3(\overline{B}^2 \times S^1, S^1 \times S^1)$ is an isomorphism.
Hint. Make use of the Smooth Collar Neighborhood Theorem 28.3.

Exercise 163.15. Let $\{r_k\}_{k\in\mathbb{N}}$ be a sequence of natural numbers. We consider the topological space

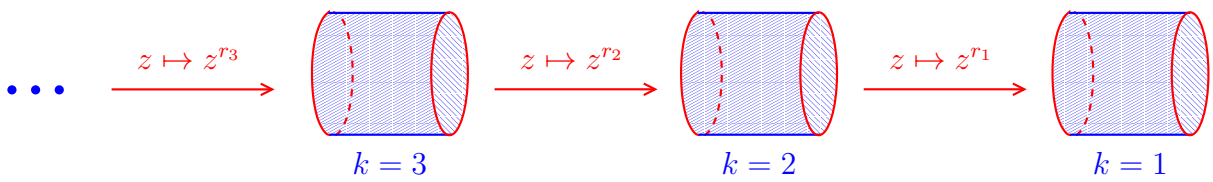
$$X \;:=\; ((S^1 \times [0,1]) \times \mathbb{Z})/\sim \quad \text{where } ((z,1),k) \sim ((z^{r_{k-1}},0),k-1) \text{ for } z \in S^1 \text{ and } k \in \mathbb{N}.$$

(a) Show, say using the CW-Complex Construction Lemma 68.32, that X is a 2-dimensional CW-complex.

(b) Let Π be the direct limit of the direct system of abelian groups $\{\mathbb{Z}\}_{k\in\mathbb{N}}$ where for $k \le l$ we consider the homomorphism that is given by multiplication by $r_k \cdot \dots \cdot r_{l-1}$. Show that X is an Eilenberg-Maclane space of type $\mathrm{K}(\Pi, 1)$.
Hint. What can you say about the subcomplexes where k just runs between 1 and some $n \in \mathbb{N}$?

(c) Suppose that $r_k = k$. Show that X is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Q}, 1)$.
Remark. This statement follows from (a) and (b) together with Exercise 56.3.

(d) Suppose that $r_k = 2$. Show that X is an Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}[\frac{1}{2}], 1)$.



Given a group π we define its *geometric dimension*

$$\mathrm{gd}(\pi) \;:=\; \text{minimal dimension of an Eilenberg-Maclane space of type } \mathrm{K}(\pi,1) \;\in\; \mathbb{N}_0 \cup \{\infty\}.$$

the Eilenberg-Maclane Construction Proposition 163.3 (1) shows that we always have $\mathrm{gd}(A \times B) \le \mathrm{gd}(A) + \mathrm{gd}(B)$. The following exercises shows that equality does not always hold.

(e) Show that $\mathrm{gd}(\mathbb{Q}) = 2$.

(f) Show that $\mathrm{gd}(\mathbb{Q} \times \mathbb{Q}) \le 3$.
Hint. Write $\mathbb{Q} \times \mathbb{Q} = \mathbb{Q}^2$ as the direct limit of a direct system of endomorphisms of $\mathbb{Z}^2$.

$z \mapsto z^{r_3}$
$z \mapsto z^{r_2}$
$z \mapsto z^{r_1}$
$k = 3$
$k = 2$
$k = 1$

164. Invariants obtained through Eilenberg-Maclane spaces

In this chapter we will see how one can use Eilenberg-Maclane spaces to define contravariant functors from the category of CW-complexes to the category of abelian groups. In this chapter and in Chapter ?? we will relate these functors to the cohomology functors.
Before we jump into the chapter we remind the reader that given topological spaces X and Y we denote by Y^X the set of all continuous maps from X to Y. Throughout this and the coming chapters we always equip Y^X with the compact-open topology that we introduced on page 392.

164.1. **The homotopy category of topological spaces.** In this short section we recall some definitions and results regarding topological spaces and the homotopy category of topological spaces. This section partly serves as a warm-up for the discussion of pointed topological spaces in the following sections.
First we recall the following definition from page 441.

Definition. Given two topological spaces X and Y we define

$$[X,Y] := \underbrace{\{\text{continuous maps } X \to Y\}}_{=Y^X}/\sim \quad \text{where } f \sim g \text{ if there exists a homotopy between } f \text{ and } g.$$

We also recall the following definition from page 441.

Definition. The homotopy category $\mathcal{H}$ is defined to be the category where the objects are topological spaces and where the set of morphisms between two topological spaces X and Y is given by the set $[X,Y]$.[2017]

The following lemma is basically an immediate consequence of the definitions.

Lemma 164.1. Let $f\colon X \to Y$ be a map between topological spaces. The corresponding morphism $[f] \in \mathrm{Mor}_{\mathcal{H}}(X,Y)$ is invertible in the sense of the definition on page 198 if and only if f is a homotopy equivalence.

Proof. Note that by definition $[f] \in \mathrm{Mor}_{\mathcal{H}}(X,Y)$ is invertible if and only if there exists $[g] \in \mathrm{Mor}_{\mathcal{H}}(Y,X)$ with $[f \circ g] = [\mathrm{id}_Y]$ and $[g \circ f] = [\mathrm{id}_X]$. Now the statement of the lemma is indeed clear. ∎

In the following we show how some constructions of topological spaces interact with the homotopy category $\mathcal{H}$. First we have following rather dull lemma.

Lemma 164.2. Let X, Y and Z be topological spaces. The map

$$\begin{array}{rcl} \chi\colon [X,Y] \times [X,Z] & \to & [X, Y \times Z] \\ ([f\colon X \to Y], [g\colon X \to Z]) & \mapsto & [f \times g\colon X \to Y \times Z] \end{array}$$

is well-defined.

Proof. Nothing can possibly go wrong in any attempt to prove this lemma. ∎

[2017] The composition of $[f\colon X \to Y]$ and $[g\colon Y \to Z]$ is evidently defined to be $[g \circ f\colon X \to Z]$, by Lemma 15.10 this definition does not depend on the choice of representatives.

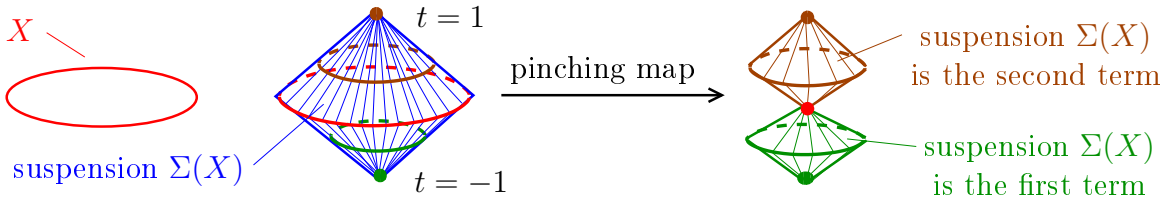
Lemma 164.3. The maps

$$\begin{array}{rcl} X & \mapsto & \text{free loop space } \Omega(X) := \{\varphi \in X^{[0,1]} \mid \varphi(0) = \varphi(1)\} \\ [f\colon X \to Y] & \mapsto & \left[\begin{array}{rcl} \Omega(f)\colon \Omega(X) & \to & \Omega(Y) \\ (\varphi\colon [0,1] \to X) & \mapsto & (f \circ \varphi\colon [0,1] \to Y) \end{array}\right] \end{array}$$

and

$$\begin{array}{rcl} X & \mapsto & \text{suspension } \Sigma(X) := (X \times [-1,1])/\sim \\ [f\colon X \to Y] & \mapsto & \left[\begin{array}{rcl} \Sigma(f)\colon \Sigma(X) & \to & \Sigma(Y) \\ [(x,t)] & \mapsto & [(f(x),t)] \end{array}\right] \end{array}$$

both define covariant functors from $\mathcal{H}$ to itself.



Proof. There are only two statements one needs to think about: given a map $f\colon X \to Y$ one needs to show that $\Omega(f)$ and $\Sigma(f)$ are continuous, and given homotopic maps $f, g\colon X \to Y$ one needs to show that the corresponding maps on the right hand side are also homotopic. For the free loop spaces the statements follow from the Compact-Open Functoriality Lemma 12.5 (1) and (3). For suspensions these two statements follow immediately from the Suspension Functor Lemma 16.9 (1) and (4). ■

Just for kicks we also mention the following definition, which is reminiscent of the definition that we gave on page 1565. We will make use of this definition, with a slight twist, in the near future.

Definition. Let X be a topological space. We consider the wedge $\Sigma(X) \vee \Sigma(X)$ that is given by identifying the "South Pole $[X \times \{-1\}]$" on the left with the "North Pole $[X \times \{1\}]$" on the right. We refer to the map

$$\begin{array}{rcl} \Sigma(X) & \to & \Sigma(X) \vee \Sigma(X) \\ [(x,t)] & \mapsto & \begin{cases} [(x, 2t+1)] \text{ in the first term}, & \text{if } t \in [-1,0], \\ [(x, 2t-1)] \text{ in the second term}, & \text{if } t \in [0,1]. \end{cases} \end{array}$$

as the pinching map.[2018]

In some instances the sets $[X, Y]$ have some extra structure. For example we have the following elementary but cute lemma.

Lemma 164.4. Let X be a topological space and let G be an (abelian) topological group, e.g. we could take $G = S^1$. The set $[X, G]$ together with the multiplication map

$$\begin{array}{rcl} \nu\colon [X,G] \times [X,G] & \to & [X,G] \\ [f],[g] & \mapsto & \left[\begin{array}{rcl} X & \to & G \\ x & \mapsto & f(x) \cdot g(x) \end{array}\right] \end{array}$$

is an (abelian) group.

[2018] It follows easily from the Topological-Quotient Proposition 5.15 (1b) and Pasting Proposition 2.6 (2) that the pinching map is continuous.

Remark. Let X be a topological space and let G be a topological group. In Lemma 12.12 we showed, under the extra hypothesis that G is regionally compact, that the set G^X with the obvious multiplication map $G^X \times G^X \to G^X$ is in fact a topological group. We could equip $[X, G] = G^X/\sim$ with the quotient topology, but the discussion on page 3316 shows that in general the resulting multiplication map $\nu\colon [X, G] \times [X, G] \to [X, G]$ is no longer continuous. Thus in general we cannot view $[X, G]$ as a topological group.

Proof. In fact the only thing one needs to verify is that the map ν is actually well-defined. But this follows easily from the fact that the group multiplication $G \times G \to G$ is continuous. We leave it to the reader to fill in the details. ■

There are several drawbacks to considering topological spaces which are not equipped with base points.

(1) Without a base point the homotopy groups $\pi_n(X)$ are at best defined up to isomorphism, but they are not defined "on the nose".
(2) The operation of taking wedges is not well-defined.

In the following section we will introduce the analogue of the homotopy category for pointed topological spaces. This will take care of the above issues, but it will require some adjustments at other places.

164.2. **The homotopy category of pointed topological spaces.** In the latter part of this chapter it will be essential that we always work with pointed topological spaces. To prepare for this discussion we need to rephrase all the concepts and results from the previous section in the language of pointed topological spaces.
We start out with a few definitions. Some of them we have encountered before on page 1542 and in the formulation of the Maps-to-K(π, n)-Proposition 163.15.

Definition.

(1) A pointed topological space is a pair (X, x_0) where X is a topological space and $x_0 \in X$ is a point. We refer to x_0 as the base point of the pointed topological space.
(2) A map $f\colon (X, x_0) \to (Y, y_0)$ between pointed topological spaces is a map $f\colon X \to Y$ with $f(x_0) = y_0$.
(3) We say that two maps $f, g\colon (X, x_0) \to (Y, y_0)$ between pointed topological spaces are homotopic if there exists a homotopy $F\colon X \times [0, 1] \to Y$ rel $\{x_0\}$ from f to g. We use this notion of "homotopic" to define the notion of a homotopy equivalence between pointed topological spaces.
(4) A pointed CW-complex is a pair (X, x_0) where X is a CW-complex and x_0 is a point in the 0-skeleton X^0 of X.
(5) Given two pointed topological spaces (X, x_0) and (Y, y_0) we write[2019]
$$\langle (X, x_0), (Y, y_0) \rangle := \{\text{maps } (X, x_0) \to (Y, y_0)\}/\sim$$
where $f \sim g$ if there exists a homotopy in the above sense between f and g.
Given a map $f\colon (X, x_0) \to (Y, y_0)$ we denote its equivalence class by $[f]$ as usual.
(6) Let (X, x_0) and (Y, y_0) be two topological spaces. Let $0 \in \langle (X, x_0), (Y, y_0) \rangle$ be the element that is represented by constant map $X \to Y$ given by $x \mapsto y_0$.[2020] We refer to 0 as the trivial element.

The following lemma is the analogue of Lemma 15.10.

Lemma 164.5. Let (X, x_0), (Y, y_0) and (Z, z_0) be pointed topological spaces. The map

$$\begin{array}{rcl} \langle (X,x_0), (Y,y_0)\rangle \times \langle (Y,y_0), (Z,z_0)\rangle & \to & \langle (X,x_0), (Z,z_0)\rangle \\ ([f],[g]) & \mapsto & [g \circ f] \end{array}$$

is well-defined.

Proof. The proof of this lemma is almost identical to the proof of Lemma 15.10 and it is left to the insomniac reader. ∎

Lemma 164.5 shows that the following definition makes sense.

Definition. The pointed homotopy category $\mathcal{PHomTop}$ is the category where the objects are pointed topological spaces and where the set of morphisms between two pointed topological spaces (X, x_0) and (Y, y_0) is given by the set $\langle (X, x_0), (Y, y_0)\rangle$.

The following lemma is the analogue of Lemma 164.1.

Lemma 164.6. Let (X, x_0) and (Y, y_0) be pointed topological spaces.

(1) Let $f\colon (X, x_0) \to (Y, y_0)$ be a map. The corresponding morphism[2021]

$$[f] \in \mathrm{Mor}_{\mathcal{PHomTop}}((X, x_0), (Y, y_0)) = \langle (X, x_0), (Y, y_0)\rangle$$

is invertible if and only if f is a homotopy equivalence.

(2) In the category $\mathcal{PHomTop}$ we have[2022]

$$\langle (X, x_0), (Y, y_0)\rangle_{\mathrm{inv}} = \text{all elements of } \langle (X, x_0), (Y, y_0)\rangle \text{ that are represented by a homotopy equivalence.}$$

Proof. The first statement is, as in the case of Lemma 164.1, an immediate consequence of the definitions. The second statement is a reformulation of the first statement. ∎

In the following we discuss the operations of taking products, wedges, loop spaces and suspensions in the context of the pointed homotopy category. We start out with the following convention.

Convention. Given pointed topological spaces (X, x_0) and (Y, y_0) we equip the product $X \times Y$ with the point (x_0, y_0).

For completeness we mention the following uninspiring analogue to Lemma 164.2.

Lemma 164.7. Let (X, x_0), (Y, y_0) and (Z, z_0) be pointed topological spaces. The map

$$\begin{array}{rcl} \chi\colon \langle (X,x_0), (Y,y_0)\rangle \times \langle (X,x_0), (Z,z_0)\rangle & \to & \langle (X,x_0), (Y \times Z, (y_0,z_0))\rangle \\ ([f\colon X \to Y], [g\colon X \to Z]) & \mapsto & [f \times g\colon X \to Y \times Z] \end{array}$$

is well-defined and it is natural.

Proof. Conveniently enough the proof is identical to the proof of Lemma 164.2. ∎

As discussed on page 1132, one advantage of working with pointed topological spaces is that we have an unambiguous wedge operation.

[2019] The notation $\langle X, Y\rangle$ goes back to [**Hat2002**, p. 357], where it says "the notation $\langle \ldots \rangle$ is intended to suggest pointed homotopy classes".

[2020] At the moment this notation might sound a little risqué. But it will turn out to be a useful notation.

[2021] We refer to page 198 for the definition of an invertible morphism.

[2022] On page 198 we defined $\mathrm{Mor}_{\mathcal{C}}(X, Y)_{\mathrm{inv}}$ to be the set of all invertible morphisms.

Definition. Given a family $\{(X_i, x_i)\}_{i\in I}$ of pointed topological spaces we define the wedge

$$\bigvee_{i\in I}(X_i, x_i) \;:=\; \Big(\bigcup_{i\in I} X_i\Big)/\!\sim \qquad \text{where } x_i \sim x_j \text{ for any } i, j \in I.$$

We equip this wedge with the base point given by the wedge point.

Lemma 164.8. Let (X, x_0), (Y, y_0) and (Z, z_0) be pointed topological spaces. The map

$$\begin{array}{rcl} \nu\colon \langle (X,x_0), (Z,z_0)\rangle \times \langle (Y,y_0), (Z,z_0)\rangle & \to & \langle (X,x_0) \vee (Y,y_0), (Z,z_0)\rangle \\ ([f\colon X \to Z], [g\colon Y \to Z]) & \mapsto & [f \vee g] \end{array}$$

is well-defined.

Proof. The statement of the lemma is, in contrast to Lemma 164.5 and 164.7, non-trivial. It is a reformulation of Lemma 50.12 which traces its ancestry to the formidable Whitehead Quotient Theorem 13.4. ∎

Now we would like to generalize the free loop space $\Omega(X)$ and the suspension $\Sigma(X)$ to pointed topological spaces. It is pretty clear what we do about loop spaces:

Definition. Given a pointed topological space (X, x_0) we consider the

$$\text{loop space } \Omega(X, x_0) \;:=\; \{f \in X^{[0,1]} \mid f(0) = f(1) = x_0\}$$

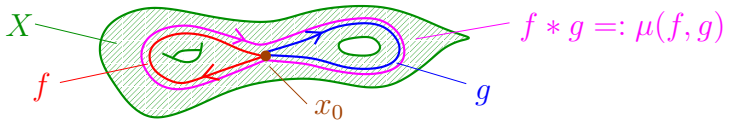
and we equip the loop space $\Omega(X, x_0)$ with the base point c_{x_0} which is just the constant path $[0, 1] \to X$, $t \mapsto x_0$. Often we will suppress the base point from the notation, but throughout the subsequent chapters we will always view $\Omega(X, x_0)$ as a pointed topological space.

For completeness we write down explicitly the following fairly obvious lemma which is the analogue of the first statement of Lemma 164.3.

Lemma 164.9. The maps

$$\begin{array}{rcl} (X, x_0) & \mapsto & (\Omega(X, x_0), c_{x_0}) \\ [f\colon (X, x_0) \to (Y, y_0)] & \mapsto & \left[\begin{array}{rcl} \Omega(X, x_0) & \to & \Omega(Y, y_0) \\ (\gamma\colon [0, 1] \to X) & \mapsto & (f \circ \gamma\colon [0, 1] \to Y) \end{array}\right] \end{array}$$

define a covariant functor from the category *PHomTop* to itself.



Proof. The lemma follows easily basically from the Compact-Open Functoriality Lemma 12.5 (1) and (3), one just needs to make a few minute modifications to factor in the base points. We leave this elementary task to the inexhaustible reader. ∎

The loop spaces $\Omega(X, x_0)$ have one big advantage over the free loop spaces $\Omega(X)$. Given two loops in (X, x_0) we can form the product, as defined on page 1052. As we had already hinted at in Lemma 156.22, this multiplication turns $\Omega(X, x_0)$ into a group "up to homotopy". More precisely we have the following definition and lemma which hark back to the happy days when our biggest worry was to define the fundamental group of a pointed topological space.

Definition. Let (X, x_0) be a pointed topological space. We consider the map

$$\begin{array}{rcl} \mu\colon \Omega(X,x_0)\times\Omega(X,x_0) & \to & \Omega(X,x_0) \\ (f,g) & \mapsto & f*g = \left(\begin{array}{rcl} [0,1] & \to & X \\ t & \mapsto & \begin{cases} f(2t), & \text{if } t\in[0,\frac{1}{2}], \\ g(2t-1), & \text{if } t\in(\frac{1}{2},1] \end{cases} \end{array}\right). \end{array}$$

For entertainment the definition of this map is illustrated in the figure below.

The following lemma summarizes many important properties of μ.

Lemma 164.10. Let (X, x_0) be a pointed topological space. The multiplication map

$$\mu\colon \Omega(X,x_0)\times\Omega(X,x_0) \to \Omega(X,x_0)$$

has the following properties.

(1) The map $\mu\colon \Omega(X,x_0)\times\Omega(X,x_0)\to\Omega(X,x_0)$ is continuous[2023], it is base-point preserving and it is natural in (X,x_0).[2024]

(2) The two maps

$$\begin{array}{rcl} \lambda\colon \Omega(X,x_0) & \to & \Omega(X,x_0) \\ f & \mapsto & \mu(c_{x_0},f) \end{array} \quad \text{and} \quad \begin{array}{rcl} \rho\colon \Omega(X,x_0) & \to & \Omega(X,x_0) \\ f & \mapsto & \mu(f,c_{x_0}) \end{array}$$

between pointed topological spaces are both homotopic to the identity.

(3) The map

$$\begin{array}{rcl} \eta\colon \Omega(X,x_0) & \to & \Omega(X,x_0) \\ f & \mapsto & \overline{f} := \left(\begin{array}{rcl} [0,1] & \to & X \\ t & \mapsto & f(1-t) \end{array}\right) \end{array}$$

is a homeomorphism and base point preserving.

(4) The map

$$\begin{array}{rcl} \Omega(X,x_0) & \to & \Omega(X,x_0) \\ f & \mapsto & \mu(f,\overline{f}) \end{array}$$

between pointed topological spaces is homotopic to the constant map $f\mapsto c_{x_0}$.

(5) The two maps

$$\begin{array}{rcl} \Omega(X,x_0)\times\Omega(X,x_0)\times\Omega(X,x_0) & \to & \Omega(X,x_0) \\ (f,g,h) & \mapsto & \mu(\mu(f,g),h) \end{array}$$

and

$$\begin{array}{rcl} (f,g,h) & \mapsto & \mu(f,\mu(g,h)) \end{array}$$

between pointed topological spaces are homotopic.

[2023] Recall that $\Omega(X,x_0)$ is equipped with the compact-open topology and $\Omega(X,x_0)\times\Omega(X,x_0)$ is correspondingly equipped with the product topology. Furthermore we view $\Omega(X,x_0)$ and $\Omega(X,x_0)\times\Omega(X,x_0)$ as pointed topological spaces.

[2024] Here "natural" means that if $f\colon (X,x_0)\to(Y,y_0)$ is a map between pointed topological spaces, then the following diagram commutes:

$$\begin{array}{ccc} \Omega(X,x_0)\times\Omega(X,x_0) & \xrightarrow{\mu} & \Omega(X,x_0) \\ \downarrow{\scriptstyle f_*\times f_*} & & \downarrow{\scriptstyle f_*} \\ \Omega(Y,y_0)\times\Omega(Y,y_0) & \xrightarrow{\mu} & \Omega(Y,y_0). \end{array}$$

Remark.

(1) In many ways Lemma 164.10 is quite similar to the Path-Homotopy Concatenation Proposition 47.5. In fact it is not difficult to formulate and prove a result which combines both. As it is, the two results are stated at the appropriate level of generality for what they are aimed for.

(2) Let (X, x_0) be a pointed topological space. In Lemma 164.10 (2) we just showed that the multiplication map $\Omega(X, x_0) \times \Omega(X, x_0) \to \Omega(X, x_0)$ is continuous. The fundamental group $\pi_1(X, x_0) := \Omega(X, x_0)/\sim$ is a quotient of $\Omega(X, x_0)$, hence it can be equipped with the quotient topology. It turns out, see the discussion on page 3316, that the induced multiplication map $\pi_1(X, x_0) \times \pi_1(X, x_0) \to \pi_1(X, x_0)$ is in general *not* continuous.

Proof. Let (X, x_0) be a pointed topological space.

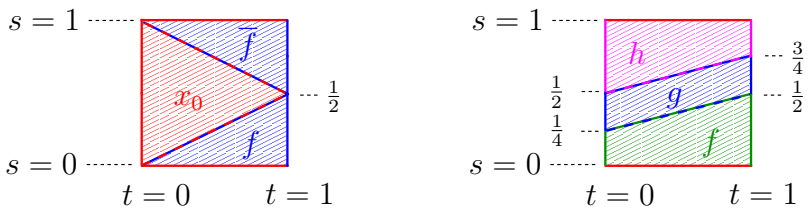
(1) The statement that μ is continuous is precisely the content of Lemma 156.22 (1). The statements that μ is base-point preserving and natural follows basically immediately from the definitions.

(2) This statement is a reformulation of Lemma 156.22 (2).

(3) Evidently the map $\eta\colon \Omega(X, x_0) \to \Omega(X, x_0)$ is base point preserving. It follows immediately from the Compact-Open Functoriality Lemma 12.5 (5), applied to the homeomorphism $[0, 1] \to [0, 1]$ that is given by $t \mapsto 1-t$, that the map $\eta\colon \Omega(X, x_0) \to \Omega(X, x_0)$ is continuous. Since $\eta \circ \eta = \mathrm{id}$ we see that η is in fact a homeomorphism.

(4) We consider the map

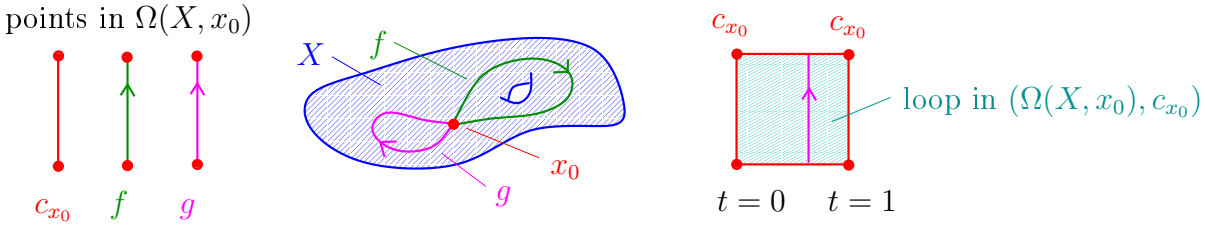
$$\begin{array}{rcl} H\colon \Omega(X, x_0) \times [0, 1] & \to & \Omega(X, x_0) \\ (f, t) & \mapsto & \left(\begin{array}{rcl} [0, 1] & \to & X \\ s & \mapsto & \begin{cases} f(2s \cdot t), & \text{if } s \in [0, \frac{1}{2}], \\ f(2t - 2s \cdot t), & \text{if } s \in \left(\frac{1}{2}, 1\right] \end{cases} \end{array} \right). \end{array}$$



Again, using the argument in the proof of Lemma 156.22 (1) we see that H is continuous. It is now clear that H is a homotopy between the constant map $f \mapsto c_{x_0}$ and the map $f \mapsto \mu(f, \overline{f})$. We refer to the figure below for an illustration.

(5) To simplify the notation we write $\Omega(X)$ instead of $\Omega(X, x_0)$. We consider the map

$$\begin{array}{rcl} H\colon (\Omega(X) \times \Omega(X) \times \Omega(X)) \times [0, 1] & \to & \Omega(X) \\ ((f, g, h), t) & \mapsto & \left(\begin{array}{rcl} [0, 1] & \to & X \\ s & \mapsto & \begin{cases} f(\frac{4s}{t+1}), & \text{if } s \in [0, \frac{t+1}{4}), \\ g(4s - t - 1), & \text{if } s \in [\frac{t+1}{4}, \frac{t+2}{4}), \\ h\left(\frac{4s-2-t}{2-t}\right), & \text{if } s \in [\frac{t+2}{4}, 1] \end{cases} \end{array} \right). \end{array}$$



The same argument as in the proof of Lemma 156.22 (1) shows that the map H is continuous. One can now easily verify that the map H defines a homotopy between $(f, g, h) \mapsto \mu(\mu(f, g), h)$ and $(f, g, h) \mapsto \mu(f, \mu(g, h))$. We refer to the figure below for an illustration. ∎

The loop space construction is so much fun that one might as well apply it several times. This leads us to the following notation:

Notation. Let (X, x_0) be a pointed topological space. We define

$$\Omega^k(X, x_0) \;:=\; \Omega\cdots\Omega(\underbrace{\Omega(X, x_0)}_{\text{pointed topological space}}) \quad \text{where we apply the } \Omega\text{-functor } k \text{ times.}$$

In the figure above we do our best at illustrating a loop in the pointed topological space $(\Omega(X, x_0), c_{x_0})$. What should become apparent is that such a loop is basically the same as a map $([0,1]^2, \partial[0,1]^2) \to (X, x_0)$. The following proposition makes this idea precise.

Proposition 164.11. (Iterated Loop Space Proposition) Let (X, x_0) be a pointed topological space and let $k \in \mathbb{N}$. The map

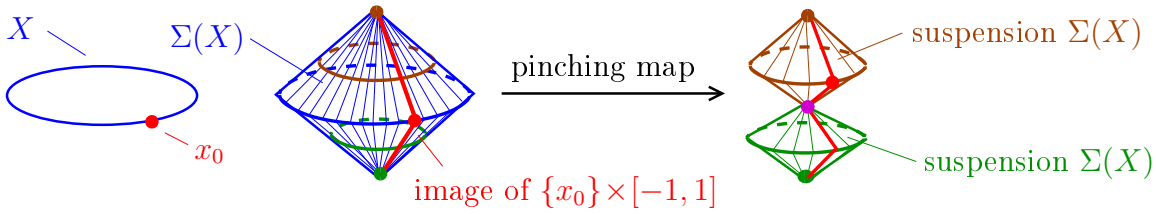
$$\begin{array}{rcl} \overbrace{\{F \in X^{[0,1]^k} \mid F(\partial[0,1]^k) = \{x_0\}\}}^{\text{subset of the topological space } X^{[0,1]^k}} & \to & \Omega^k(X, x_0) \\ F & \mapsto & (t_k \mapsto (t_{k-1} \mapsto \ldots (\underbrace{t_1 \mapsto F(t_1, \ldots, t_k)}_{\in \Omega(X, x_0)}) \ldots)) \end{array}$$

is a homeomorphism.

Proof. To simplify the notation we only discuss the case $k = 2$. The general case is treated the same way. We write $I = J = [0,1]$. We start out with the following subtle observation:

(∗) The inclusion $\Omega(X, x_0) \to X^I$ induces a map $\Omega(X, x_0)^J \to (X^I)^J$. By the Compact-Open Functoriality Lemma 12.5 (2) this map is an embedding. This means that it is legitimate to view the topological space $\Omega(\Omega(X, x_0), c_{x_0})$ as a subspace of $(X^I)^J$.

This preamble implies that it suffices to show that the map



$$\begin{array}{rcl} \Phi\colon \{F \in X^{I\times J} \mid F(\partial(I \times J)) = \{x_0\}\} & \to & \Omega(\Omega(X, x_0), c_{x_0}) \subset (X^I)^J \\ F & \mapsto & \left(\begin{array}{ccc} J & \to & \Omega(X, x_0) \subset X^I \\ t & \mapsto & \left(\begin{array}{ccc} I & \to & X \\ s & \mapsto & F(s,t) \end{array} \right) \end{array} \right) \end{array}$$

is a homeomorphism. First note that the map Φ is, basically by definition, a bijection. Next note that Φ is a restriction of the map

$$\begin{array}{rcl} \Psi\colon X^{I\times J} & \to & (X^I)^J \\ (F\colon I\times J\to X) & \mapsto & \begin{pmatrix} J & \to & X^I \\ t & \mapsto & (s\mapsto F(s,t)) \end{pmatrix}. \end{array}$$

But it follows from the intricate Exponential Proposition 12.7, and the fact that $I = J = [0,1]$ are regionally compact and Hausdorff, that the map Ψ is a homeomorphism. Thus we have shown that our original map Φ is also a homeomorphism. ■

Now let us turn towards the suspension operation. Given a pointed topological space (X, x_0) ideally we would like to equip the suspension $\Sigma(X)$ with a base point in a "systematic" way. The obvious idea is to fix some $t \in [-1,1]$ once and for all and to equip every suspension $\Sigma(X)$ with the base point represented by $[(x_0,t)]$. As we will see later on, we really really want the pinching map to be a map of pointed topological spaces. But if one thinks about it, and if one keeps an eye on the figure below, one see that for every single choice of fixed t the pinching map (and note that for the wedge operation we also have to use our specified base points) will fail to be base point preserving.

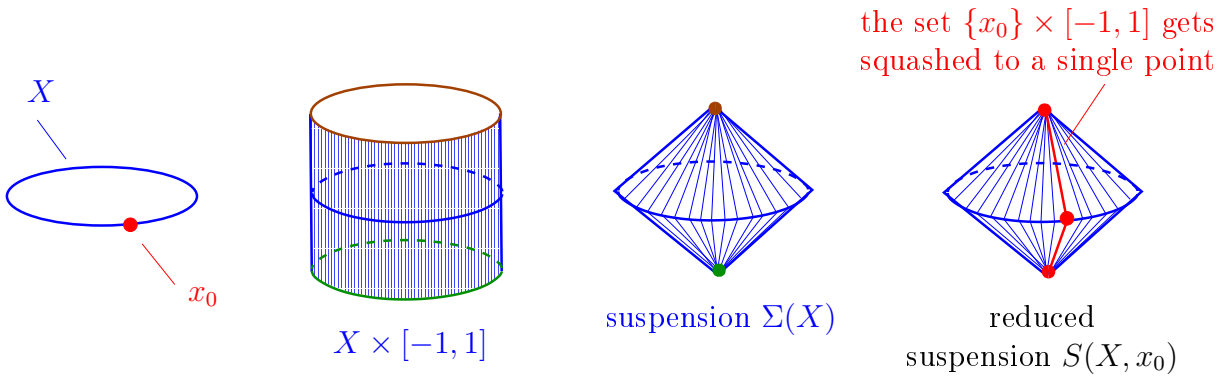
There is a rather "brutal" solution to the dilemma: We solve the conundrum of which $[(x_0,t)]$ to choose by declaring all these points to be the same. More precisely, we consider the following modified version of the suspension.

Definition. Given a pointed topological space (X, x_0) we defined the reduced suspension of (X, x_0) to be the topological space[2025]

$$S(X,x_0) := \Sigma(X)/[\{x_0\}\times[-1,1]] \underset{\uparrow}{=} (X\times[-1,1])/(X\times\{-1,1\}\cup\{x_0\}\times[-1,1]).$$

strictly speaking we are using the Twice Quotient Lemma 5.23 (1)

We always equip $S(X,x_0)$ with the base point $s_{x_0} := [\{x_0\}\times[-1,1]]$. We refer to the figure below for an illustration.



The following lemma summarizes the key properties of the reduced suspension. The lemma can partly be viewed as the "pointed" version of the second part of Lemma 164.3.

Lemma 164.12.

(1) The maps[2026]

$$\begin{array}{rcl} (X,x_0) & \mapsto & (S(X,x_0), s_{x_0}) \\ (f\colon (X,x_0)\to(Y,y_0)) & \mapsto & \begin{pmatrix} S(f)\colon S(X,x_0) & \to & S(Y,y_0) \\ [(x,t)] & \mapsto & [(f(x),t)] \end{pmatrix} \end{array}$$

[2025]Note that given a topological space X we denote the usual suspension by $\Sigma(X)$ and given a pointed topological space we denote its reduced suspension by $S(X,x_0)$. Rather confusingly this notation is the opposite of the notation used in [**Hat2002**].

define a covariant functor from the category $\mathcal{PHomTop}$ to itself.

(2) The natural projection $\Sigma(X) \to S(X, x_0)$ defines a natural transformation between the functors $(X, x_0) \mapsto \Sigma(X)$ and $(X, x_0) \mapsto S(X, x_0)$. In other words, in plain English, given a map $f\colon (X, x_0) \to (Y, y_0)$ between pointed topological spaces the following diagram commutes:

$$\begin{array}{ccc} \Sigma(X) & \xrightarrow{\Sigma(f)} & \Sigma(Y) \\ \downarrow & & \downarrow \\ S(X, x_0) & \xrightarrow{S(f)} & S(Y, y_0). \end{array}$$

(3) Given any pointed topological space (X, x_0) the pinching map

$$\begin{array}{rcl} \omega\colon S(X, x_0) & \to & S(X, x_0) \vee S(X, x_0) \\ [(x,t)] & \mapsto & \begin{cases} [(x, 2t+1)] \text{ in the first term}, & \text{if } t \in [-1, 0], \\ [(x, 2t-1)] \text{ in the second term}, & \text{if } t \in [0, 1]. \end{cases} \end{array}$$

is continuous and base point preserving.

(4) If (X, x_0) is a pointed CW-complex, then the following two statements hold:

(a) The reduced suspension $S(X, x_0)$ has a natural CW-structure such that the natural projection $\Sigma(X) \to S(X, x_0)$ is a cellular map and such that $\{s_{x_0}\}$ is a 0-cell. In particular $(S(X, x_0), s_{x_0})$ is a pointed CW-complex.

(b) Given any $t \in [-1, 1]$ the projection $\Sigma(X) \to S(X, x_0)$ is a homotopy equivalence of the pointed topological spaces $(\Sigma(X), [(x_0, t)]) \to (S(X, x_0), s_{x_0})$.

Convention. Given a pointed CW-complex (X, x_0) we always equip the reduced suspension $S(X, x_0)$ with the CW-structure coming from Lemma 164.12 (4a).

Proof.

(1) The first statement is proved basically the same way as we proved the Suspension Functor Lemma 16.9. Note that the proof of the statement that if $f, g\colon (X, x_0) \to (Y, y_0)$ are homotopic implies that $S(f), S(g)$ are homotopic is somewhat delicate, see the proof of the Suspension Functor Lemma 16.9 (4).

(2) This statement follows almost immediately from the definitions.

(3) This statement follows easily from the Topological-Quotient Proposition 5.15 (1b).

[2026]It follows from the Topological-Quotient Proposition 5.15 (1b) that the map $S(f)$ is actually continuous.

(4) The last statement is slightly more subtle. We proceed as follows:
   (a) By Proposition 68.23 (3b) we can equip $X \times [-1,1]$ with the product CW-structure.
   (b) As the CW-Complex Cone Corollary 68.35 we equip the suspension $\Sigma(X) = (X \times [-1,1])/\sim$ with the quotient CW-structure.
   (c) This CW-structure has the property that the image of $\{x_0\} \times [-1,1]$ in $\Sigma(X)$ is a subcomplex which we now denote by A.
   (d) It follows from the CW-Complex Construction Lemma 68.32 that the quotient $\Sigma(X)/A = S(X,x_0)$ admits a natural CW-structure which has the convenient property that the projection $\Sigma(X) \to \Sigma(X)/A = S(X,x_0)$ is cellular and which has the property that s_{x_0} is a 0-cell.

   By the Subcomplex Cofibration Theorem 17.9 we know that the inclusion map $i\colon A \to X$ is a cofibration. Since $[(x_0,t)]$ is a deformation retract of A we obtain from the Cofibration-Quotient Lemma 17.7 (3) that the natural projection $\Sigma(X) \to S(X,x_0)$ is a homotopy equivalence of the pointed topological spaces $(\Sigma(X),[(x_0,t)]) \to (S(X,x_0),s_{x_0})$. ■

The following innocuous looking proposition is one of the main building stones for the subsequent discussion.

Proposition 164.13. Let (X,x_0) and (Y,y_0) be pointed topological spaces. The map

$$\begin{array}{rcl} \Upsilon\colon \langle (S(X,x_0),s_{x_0}),(Y,y_0)\rangle & \to & \langle (X,x_0),(\Omega(Y,y_0),c_{y_0})\rangle \\ \left[\begin{array}{rcl} f\colon S(X,x_0) & \to & Y \\ [(x,t)] & \mapsto & f([(x,t)]) \end{array}\right] & \mapsto & \left[\begin{array}{rcl} X & \to & \Omega(Y,y_0) \\ x & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & Y \\ t & \mapsto & f([(x,2t-1)]) \end{array}\right) \end{array}\right] \end{array}$$

is a bijection. Furthermore this bijection is natural in (X,x_0) and (Y,y_0).[2027]

Remark. Recall that we denote by *PHomTop* the pointed homotopy category that we introduced on page 3468. In the language of the definition on page 3292 the proposition says

[2027]Put somewhat more precisely: if we are given a pointed topological space (Y,y_0), then the two maps $(X,x_0) \mapsto \langle (S(X,x_0),s_{x_0}),(Y,y_0)\rangle$ and $(X,x_0) \mapsto \langle (X,x_0),(\Omega(Y,y_0),c_{y_0})\rangle$ define contravariant functors from the category of pointed topological spaces to the category of sets. The map Υ defines a natural isomorphism between these two functors. The analogous statement holds with the roles of (X,x_0) and (Y,y_0) reversed.

that the functors

$$\begin{array}{rcl} F\colon \mathcal{PHomTop} & \to & \mathcal{PHomTop} \\ (X,x_0) & \mapsto & S(X,x_0) \\ [f] & \mapsto & [S(f)] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{PHomTop} & \to & \mathcal{PHomTop} \\ (X,x_0) & \mapsto & \Omega(X,x_0) \\ [f] & \mapsto & [\Omega(f)] \end{array}$$

which are defined by

are adjoint.

Proof. Let (X,x_0) and (Y,y_0) be pointed topological spaces. First we consider the map

$$\begin{array}{ccc} \overbrace{\{\text{set of maps } X\times[-1,1]\to Y\}}^{=Y^{X\times[-1,1]}} & \to & \overbrace{\{\text{set of maps } X\to Y^{[0,1]}\}}^{=(Y^{[0,1]})^X} \\ \left(\begin{array}{rcl} f\colon X\times[-1,1] & \to & Y \\ (x,t) & \mapsto & f(x,t) \end{array}\right) & \mapsto & \left(\begin{array}{rcl} X & \to & Y^{[0,1]} \\ x & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & Y \\ t & \mapsto & f(x,2t-1) \end{array}\right) \end{array}\right). \end{array}$$

It follows from the Compact-Open Exponential Proposition 12.6 and the fact that $[0,1]\cong[-1,1]$ is regionally compact that this map is well-defined[2028] and that it is a bijection. Using Lemma 5.18 it is not hard to see that the given map induces a bijection

$$\{\text{set of maps } (S(X,x_0),s_{x_0})\to(Y,y_0)\} \;\to\; \{\text{set of maps } (X,x_0)\to(\Omega(Y,y_0),c_{y_0})\}.$$

Basically the same approach also deals with homotopies. More precisely, it follows from the Compact-Open Exponential Proposition 12.6 and the fact that $[0,1]\cong[-1,1]$ is regionally compact that the "obvious" map

$$Y^{[-1,1]\times(X\times[0,1])} \;\to\; \left(Y^{[0,1]}\right)^{X\times[0,1]}$$

is a bijection. Using the Homotopy Quotient Theorem 14.7 one can now show that this bijection induces a bijection between homotopies of maps $(S(X,x_0),s_{x_0})\to(Y,y_0)$ and homotopies of maps $(X,x_0)\to(\Omega(Y,y_0),c_{y_0})$. In summary this shows that the map

$$\Upsilon\colon \langle(S(X,x_0),s_{x_0}),(Y,y_0)\rangle \;\to\; \langle(X,x_0),(\Omega(Y,y_0),c_{y_0})\rangle$$

is indeed a bijection. We leave it to the reader to fill in the details.

Finally we point out that it follows immediately from the definitions that Υ is natural in (X,x_0) and (Y,y_0). ∎

164.3. **Eilenberg-Maclane spaces give rise to invariants of topological spaces.** Ideally we prefer to work, for as long as possible, with CW-complexes. Alas not all interesting constructions of new topological spaces necessarily turn CW-complexes into CW-complexes. For example, if (X,x_0) is a pointed CW-complex it is not clear whether the loop space $\Omega(X,x_0)$ is again a CW-complex.[2029]
This leads us to the following definition.

[2028] Here "well-defined" means that the map $X\to Y^{[0,1]}$ that we associate to $f\colon X\times[-1,1]\to Y$ is indeed continuous.

[2029] I could not find an example where $\Omega(X,x_0)$ does not admit a CW-structure and I could not find a theorem that says that $\Omega(X,x_0)$ always admits a CW-structure.

Notation. We denote by $\mathcal{W}$ the class of all pointed topological spaces (X, x_0) such that there exists a pointed CW-complex (Y, y_0) which is homotopy equivalent to (Y, y_0).

The following theorem was first proved by Milnor in 1958.

Theorem 164.14. If $(X, x_0) \in \mathcal{W}$, then for any $k \in \mathbb{N}$ the iterated loop space $\Omega^k(X, x_0)$ also lies in $\mathcal{W}$.

Proof. If (X, x_0) is a pointed CW-complex, then [**Miln1959a**, Corollary 3] implies that the pointed topological space $(\Omega(X, x_0), c_{x_0})$ lies in $\mathcal{W}$. (Alternatively we refer to [**FrPi1990a**, Corollary 5.3.7] for a proof of a very similar statement.) More generally, if $(X, x_0) \in \mathcal{W}$, then it follows from the Compact-Open Functoriality Lemma 12.5 (5) and the above that $(\Omega(X, x_0), c_{x_0})$ again lies in $\mathcal{W}$. Iterating this argument we also obtain the statement for every $k \geq 2$. ■

This leads us to the following definition:

Definition. Let $n \in \mathbb{N}$ and let G be an (abelian) group[2030].

(1) A weak pointed Eilenberg-Maclane space of type $\mathrm{K}(G, n)$ is a pair $(X, x_0) \in \mathcal{W}$ such that for any $i \neq n$ we have $\pi_i(X, x_0) = 0$ and such that $\pi_n(X, x_0) \cong G$.
(2) A polarized Eilenberg-Maclane space[2037] of type $\mathrm{K}(G, n)$ is a triple (X, x_0, α) where (X, x_0) is a weak pointed Eilenberg-Maclane space of type $\mathrm{K}(G, n)$ and α is an isomorphism $\pi_n(X, x_0) \xrightarrow{\cong} G$.

Examples.

(1) We equip S^1 with the base point $* = (1, 0)$. Let $\varphi\colon \pi_1(S^1, *) \xrightarrow{\cong} \mathbb{Z}$ be the standard isomorphism from page 1573. We see that $(S^1, *, \varphi)$ is a polarized Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, 1)$.
(2) We equip $\mathbb{C}\mathrm{P}^\infty$ with the base point $* = [1 : 0 : 0 \ldots]$. Let $\psi\colon \pi_2(\mathbb{C}\mathrm{P}^\infty, *) \xrightarrow{\cong} \mathbb{Z}$ be the usual isomorphism from Theorem 155.12 (2). We see that $(\mathbb{C}\mathrm{P}^\infty, *, \psi)$ is a polarized Eilenberg-Maclane space of type $\mathrm{K}(\mathbb{Z}, 2)$.

Now we turn to more general constructions of polarized Eilenberg-Maclane spaces.

Examples. Let $n \in \mathbb{N}$ and let G be an (abelian) group.

(1) We denote by $\mathrm{K}(G, n)$ the canonical Eilenberg-Maclane space of type $\mathrm{K}(G, n)$ that was introduced in the Eilenberg-Maclane Existence Theorem 163.8. We denote its canonical base point by $*$. Furthermore we recall that the canonical Eilenberg-Maclane space $\mathrm{K}(G, n)$ comes with a canonical isomorphism $\varphi_G\colon \pi_n(\mathrm{K}(G, n), *) \xrightarrow{\varphi} G$.

[2036] As explained in Footnote 2009, whenever we deal with Eilenberg-Maclane spaces of type $\mathrm{K}(\pi, n)$ with $n \geq 2$ it is understood that π is abelian.
[2037] Our language now allows for the slightly awkward possibility that a polarized Eilenberg-Maclane space is not an Eilenberg-Maclane space since the underlying topological space might not be a CW-complex. We are confident though that this will not become an issue.

(2) Let (X, x_0) be a pointed topological space. By the Loop Space-Homotopy Groups Corollary 154.15 we know that for any $k \in \mathbb{N}$ the map

$$\begin{array}{rcl} \partial_{k+1} \colon \pi_{k+1}(X, x_0) & \to & \pi_k(\Omega(X, x_0), c_{x_0}) \\ \left[[0,1]^{k+1} \xrightarrow{f} X\right] & \mapsto & \left[\begin{array}{rcl} [0,1]^k & \to & \Omega(X, x_0) \\ x & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & X \\ t & \mapsto & f(x,t) \end{array}\right) \end{array}\right] \end{array}$$

is a natural isomorphism. This observation, together with Theorem 164.14, shows that if (X, x_0, α) is a polarized Eilenberg-Maclane space of type $\mathrm{K}(G, n+1)$, then $(\Omega(X, x_0), c_{x_0}, \alpha \circ \partial_{n+1}^{-1})$ is a polarized Eilenberg-Maclane space of type $\mathrm{K}(G, n)$.

The discussion above shows that given any $k \in \mathbb{N}_0$ we can and will view $\Omega^k(\mathrm{K}(G, n+k))$ as a polarized Eilenberg-Maclane of type $\mathrm{K}(G, n)$.

The following lemma shows that in the based homotopy category all polarized Eilenberg-Maclane spaces of a given type are essentially the same.

Lemma 164.15. Let (K, k_0, φ) and (L, l_0, ψ) be two polarized Eilenberg-Maclane spaces of the same type. There exists a unique class[2038] $\Xi = \Xi_{(K,k_0),(L,l_0)} \in \langle (K, k_0), (L, l_0) \rangle_{\mathrm{inv}}$ such that the induced map $\Xi_* \colon \pi_n(K, k_0) \to \pi_n(L, l_0)$ agrees with $\psi^{-1} \circ \varphi$. When there is no danger of confusion we just write $\Xi = \Xi_{(K,k_0),(L,l_0)}$.

Proof. Let $n \in \mathbb{N}$, let G be an (abelian) group and let (K, k_0, φ) and (L, l_0, ψ) be two polarized Eilenberg-Maclane spaces of type $\mathrm{K}(G, n)$. Since (K, k_0) and (L, l_0) lie in $\mathcal{W}$ we know that there exist pointed CW-complexes (X, x_0) and (Y, y_0) together with homotopy equivalences $\kappa \colon (X, x_0) \to (K, k_0)$ and $\lambda \colon (Y, y_0) \to (L, l_0)$ of pointed topological spaces. We consider the following diagram

$$\begin{array}{ccc} \langle (K, k_0), (L, l_0) \rangle_{\mathrm{inv}} & \xrightarrow{[f] \mapsto f_*} & \mathrm{Hom}(\pi_n(K, k_0), \pi_n(L, l_0)) \\ \downarrow{\scriptstyle \kappa^*} & & \downarrow{\scriptstyle \kappa^*} \\ \langle (X, x_0), (L, l_0) \rangle_{\mathrm{inv}} & \xrightarrow{[f] \mapsto f_*} & \mathrm{Hom}(\pi_n(X, x_0), \pi_n(L, l_0)) \\ \downarrow{\scriptstyle \lambda_*} & & \downarrow{\scriptstyle \lambda_*} \\ \langle (X, x_0), (Y, y_0) \rangle_{\mathrm{inv}} & \xrightarrow{[f] \mapsto f_*} & \mathrm{Hom}(\pi_n(X, x_0), \pi_n(Y, y_0)). \end{array}$$

It follows almost immediately from the definitions that this diagram commutes. We obtain from Lemmas 164.6 and 3.4 that the vertical maps to the left are bijections. Furthermore we obtain from the Homotopy-π_n-Proposition 71.7 that the vertical maps to the right are bijections. It follows from the Eilenberg-Maclane Uniqueness Theorem 163.12 and the Maps-to-$\mathrm{K}(\pi, n)$-Proposition 163.15 that any isomorphism in $\mathrm{Hom}(\pi_n(X, x_0), \pi_n(Y, y_0))$ is realized by a unique element in $\langle (X, x_0), (Y, y_0) \rangle_{\mathrm{inv}}$. By the diagram this information propagates to the top. ■

Notation. Let $n \in \mathbb{N}$, let G be an abelian group and let $k \in \mathbb{N}_0$. From the discussion on page 3478 and Lemma 164.15 we obtain a canonical element $\Xi \in \langle \mathrm{K}(G, n), \Omega^k \mathrm{K}(G, n+$

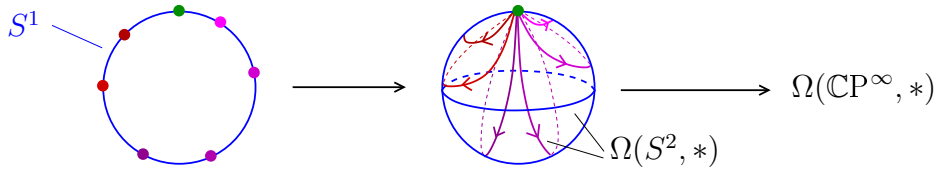
[2038] To lessen the burden on the reader's eyes we do not include φ and ψ in the notation.

$k)\rangle_{\text{inv}}$. By Lemma 3.4 we know that the map

$$\begin{array}{rcl} \Xi_*\colon \langle (X,x_0),\ \overbrace{\mathrm{K}(G,n)}^{\text{viewed as a pointed topological space}}\ \rangle & \to & \langle (X,x_0),\ \overbrace{\Omega^k\,\mathrm{K}(G,n+k)}^{\text{viewed as a pointed topological space}}\ \rangle \\ [g] & \mapsto & \Xi\circ[g] \end{array}$$

is a bijection. Sometimes we use the bijection Ξ_* to identify the left-hand side with the right-hand side. We make the analogous identification if (X,x_0) is the target instead of the domain.

We formulate the next example as a lemma. Since we will not directly make use of it we take a few liberties in its formulation.



Lemma 164.16. We equip S^1 with the base point $*=(1,0)$ and we equip $\mathbb{C}\mathrm{P}^\infty$ with the base point $[1:0:0\ldots]$. As on page 3477 we consider the polarized Eilenberg-Maclane spaces $(S^1,*,\varphi)$ of type $\mathrm{K}(\mathbb{Z},1)$ and we consider the polarized Eilenberg-Maclane space $(\mathbb{C}\mathrm{P}^\infty,*,\psi)$ of type $\mathrm{K}(\mathbb{Z},2)$. We have the following homeomorphisms and inclusions maps

$$\begin{array}{ccccccccc} [0,1]^2/\partial[0,1]^2 & \overset{\cong}{\to} & \overline{B}^2/S^1 & \overset{\cong}{\to} & S^2 & \overset{\cong}{\to} & \mathbb{C}\mathrm{P}^1 & \hookrightarrow & \mathbb{C}\mathrm{P}^\infty. \\ & & \uparrow & & \uparrow & & \uparrow & & \uparrow \\ & & \text{page 158} & & \text{Lemma 5.20} & & \text{page 258} & & \text{page 1481} \end{array}$$

We use these maps to view $[0,1]^2/\partial([0,1]^2)$ as a subset of $\mathbb{C}\mathrm{P}^\infty$.[2039] The map

$$\begin{array}{rcl} \Xi\colon S^1 & \to & \Omega(\mathbb{C}\mathrm{P}^\infty,*) \\ \exp(\mathrm{i}s) & \mapsto & \left(\begin{array}{ccc} [0,1] & \to & [0,1]^2/\partial([0,1]^2)\subset\mathbb{C}\mathrm{P}^\infty \\ t & \mapsto & [(s,t)] \end{array}\right) \end{array}$$

represents the class $\Xi\in\langle(S^1,*),\Omega(\mathbb{C}\mathrm{P}^\infty,*)\rangle$ given by Lemma 164.15.

Proof. Let $i\colon [0,1]^2/\partial([0,1]^2)\to\mathbb{C}\mathrm{P}^\infty$ be the above inclusion map. It follows immediately from the definition of $\Xi\colon S^1\to\Omega(\mathbb{C}\mathrm{P}^\infty,*)$ that the map Ξ factors through a map $\eta\colon S^1\to\Omega([0,1]^2/\partial([0,1]^2),*)$. We consider the following diagram:

$$\begin{array}{ccc} \pi_2([0,1]^2/\partial([0,1]^2),*) & \xrightarrow[\cong]{\partial_2} & \pi_1(\Omega([0,1]^2/\partial([0,1]^2),*)) \\ \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle \Omega(i)_*} \\ \pi_2(\mathbb{C}\mathrm{P}^\infty,*) & \xrightarrow[\cong]{\partial_2} & \pi_1(\Omega(\mathbb{C}\mathrm{P}^\infty,*)). \end{array} \qquad \begin{array}{c} \xleftarrow{\eta_*} \\ \pi_1(S^1,*) \\ \xrightarrow{\Xi_*} \end{array}$$

We make the following observations:

(1) The horizontal maps are defined in the Loop Space-Homotopy Groups Corollary 154.15. Furthermore note that the Loop Space-Homotopy Groups Corollary 154.15 tells us that the horizontal maps are isomorphisms and that the square commutes.

[2039] Note that by the definition of the above maps the point $\partial([0,1]^2)$ corresponds to the point $*=[1\colon 0\colon 0\colon\ldots]\in\mathbb{C}\mathrm{P}^\infty$.

(2) The triangle commutes since $\Xi = \Omega(i) \circ \eta$.
(3) The left-hand vertical map is an isomorphism by Corollary 85.6.
(4) By Corollary 85.6 we know that $\pi_2([0,1]^2/\partial([0,1]^2), *) = \mathbb{Z} \cdot \mathrm{id}_{[0,1]^2}$ and by Proposition 48.17 (1) we know that $\pi_1(S^1, *) = \mathbb{Z} \cdot \mathrm{id}_{[0,1]}$.
(5) It follows easily from the definition of ∂_2, see the Loop Space-Homotopy Groups Corollary 154.15, that ∂_2 and η_* send their respective generators to the same element in $\pi_1(\Omega([0,1]^2/\partial([0,1]^2), *))$. Since all groups are isomorphic to $\mathbb{Z}$ and since ∂_2 is an isomorphism we see that η_* is an isomorphism.
(6) We obtain from the above data that Ξ_* is an isomorphism. It is now basically clear that Ξ represents the desired element in $\langle (S^1, *), \Omega(\mathbb{C}\mathrm{P}^\infty, *) \rangle$. ■

So far it seems like we have been rambling. But the following amazing definition puts us finally on an interesting track.

Definition. Let $n \in \mathbb{N}$ and let G be an abelian group. Furthermore let $X = (X, x_0)$ be a pointed topological space. To simplify the notation we suppress the base point x_0 throughout the subsequent discussion.[2040] We refer to the following map as the multiplication map on $\langle X, \mathrm{K}(G,n) \rangle$:

$$\begin{array}{ccc}
\langle X, \mathrm{K}(G,n)\rangle \times \langle X, \mathrm{K}(G,n)\rangle & \overset{\text{since } G \text{ is abelian the Eilenberg-Maclane space } \Omega\,\mathrm{K}(G,n+1) \text{ exists for every } n \text{, thus we can use the identification } \Xi_* \text{ from page 3479}}{=} & \langle X, \Omega\,\mathrm{K}(G,n+1)\rangle \times \langle X, \Omega\,\mathrm{K}(G,n+1)\rangle \\
& & \downarrow \text{map } \chi \text{ from Lemma 164.7} \\
& & \langle X, \Omega\,\mathrm{K}(G,n+1) \times \Omega\,\mathrm{K}(G,n+1)\rangle \\
& & \downarrow \mu_* \text{ defined on page 3470} \\
& & \langle X, \Omega\,\mathrm{K}(G,n+1)\rangle \\
& & \overset{\text{again using the identification } \Xi_* \text{ from page 3479}}{=} \langle X, \mathrm{K}(G,n)\rangle.
\end{array}$$

Remark.

(1) It is worth stressing what we just we did. In the definition of the multiplication on $\langle (X, x_0), \mathrm{K}(G,n) \rangle$ we used two essential facts:
   (a) We could replace $\mathrm{K}(G,n)$ by the loop space $\Omega(\mathrm{K}(G,n+1))$.
   (b) The loop space $\Omega(\mathrm{K}(G,n+1))$ comes with a multiplication.
   Later on we will use these two ideas in a more general context.
(2) It is perhaps worth pointing out that in general topological spaces are *not* even homotopy equivalent to loop spaces. For example we know by Lemma 156.22 together with Theorem 156.21, the discussion on page 3337 and Exercise 156.8 that S^n with $n \neq 1, 3, 7$ and $\mathbb{C}\mathrm{P}^n$ with $n \in \mathbb{N}$ are *not* homotopy equivalent to loop spaces.

The following proposition says that the above definition is actually meaningful.

Proposition 164.17. Let $n \in \mathbb{N}$, let G be an abelian group and let (X, x_0) be a pointed topological space. The above multiplication turns the set $\langle (X, x_0), \mathrm{K}(G,n) \rangle$ into a group.

[2040] It is though essential that all maps we consider are in fact base point preserving. In particular, recall that $\mathrm{K}(G,n)$ and $\Omega(\mathrm{K}(G,n))$ are pointed topological spaces.

Furthermore the neutral element of the group $\langle (X,x_0), \mathrm{K}(G,n)\rangle$ is given, not surprisingly, by 0.[2041]

Proof. Let $n \in \mathbb{N}$, let G be an abelian group and let (X,x_0) be a pointed topological space. Recall that we have the identification

$$\Xi_* \colon \langle (X,x_0), \mathrm{K}(G,n)\rangle \;=\; \langle (X,x_0), \Omega\,\mathrm{K}(G,n+1)\rangle$$

from page 3479. Note that $\Xi_*(0) = 0$. Thus the proposition follows from the next lemma. ∎

Lemma 164.18. Let (K,k_0) be a pointed topological space. The map

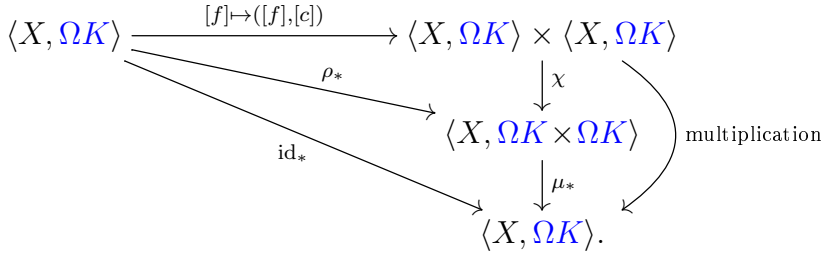
$$\begin{array}{c} \langle (X,x_0), \Omega(K,k_0)\rangle \times \langle (X,x_0), \Omega(K,k_0)\rangle \\ \big\downarrow \text{map } \chi \text{ from Lemma 164.7} \\ \langle (X,x_0), \Omega(K,k_0) \times \Omega(K,k_0)\rangle \\ \big\downarrow \mu_* \\ \langle (X,x_0), \Omega(K,k_0)\rangle. \end{array}$$

defines a group structure. The group structure has the following properties:

(1) The neutral element is given by 0.

(2) We consider the map[2042]

$$\begin{array}{rcl} \eta \colon \Omega(K,k_0) & \to & \Omega(K,k_0) \\ f & \mapsto & \overline{f}. \end{array}$$



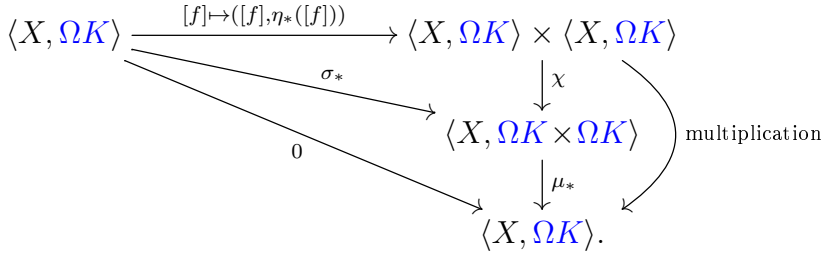
The inverse of $[f] \in \langle (X,x_0), \Omega(K,k_0)\rangle$ is given by $\eta_*([f])$.

Proof. As we will see shortly, this statement follows fairly easily from Lemma 164.10. In particular we will see that the statements have preciously little to do with (X,x_0). In an effort to lighten the notation we henceforth write X instead of the more accurate (X,x_0) and similarly we write K instead of (K,k_0). This time we denote by $c \in \Omega K$ the constant path at $k_0 \in K$. We consider the maps

$$\begin{array}{rcl} \rho \colon \Omega K & \to & \Omega K \times \Omega K \\ f & \mapsto & (f,c) \end{array} \qquad \begin{array}{rcl} \lambda \colon \Omega K & \to & \Omega K \times \Omega K \\ f & \mapsto & (c,f) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \sigma \colon \Omega K & \to & \Omega K \times \Omega K \\ f & \mapsto & (f,\overline{f}). \end{array}$$

Now we turn to the actual proofs of the various statements.

(1) Let us first show that $0 = [c]$ is a neutral element in $\langle X, \Omega K\rangle$. We consider the following diagram



[2041] Recall that on page 3467 we defined $0 \in \langle (X,x_0), (Y,y_0)\rangle$ to be the class that is represented by the constant map $X \to Y$, $x \mapsto y_0$.

[2042] In Lemma 164.10 (3) we showed that η is continuous.

The upper triangle commutes basically by definition of the maps. Now let us turn to the lower triangle. It follows from Lemma 164.10 (2) that the map $\mu \circ \rho \colon \Omega K \to \Omega K$ is homotopic to the identity rel the base point. In other words, we have the equality $[\mu \circ \rho] = [\mathrm{id}] \in \langle \Omega K, \Omega K \rangle$. Thus it follows, if you want from Lemma 3.6, that the triangle does indeed commute.

Now we start out with $[f] \in \langle X, \Omega K \rangle$ at the top left. Since going right-down is precisely right-multiplication by $[c] = 0$ we see that 0 is indeed a right-neutral element with respect to the product structure. Basically the same argument, with ρ replaced by λ shows that 0 is also a left-neutral element.

(2) We consider the following diagram:

As in (1) we obtain from Lemma 164.10 (4) that the diagram commutes. It follows that $\eta_*([f])$ is a right-inverse to $[f]$. The same argument shows that it is also a left-inverse to $[f]$.

(3) Using Lemma 164.10 (5) one can show, with the same approach as above, that the product structure on $\langle X, \Omega K \rangle$ is associative. Filling in the details is the content of Exercise 164.3. ■

The reader of the previous proof might ask the following question:

Question 164.19. Why do we actually consider the sets $\langle (X, x_0), \mathrm{K}(G, n) \rangle$ instead of the sets $\langle (X, x_0), \Omega\, \mathrm{K}(G, n+1) \rangle$? After all, we just showed that the group structure is really defined on the latter set.

The group structure on $\langle (X, x_0), \mathrm{K}(G, n) \rangle$ is certainly rather mysterious. The following lemma hopefully elucidates the group structure in the case $\mathrm{K}(\mathbb{Z}, 1)$.

Lemma 164.20. Let $\Xi \colon S^1 \to \Omega(\mathbb{C}\mathrm{P}^\infty, *)$ be the homotopy equivalence defined in Lemma 164.16. Given any topological space X we have the following commutative diagram where the horizontal maps are bijections:

$$\begin{array}{ccc} [X, S^1] \times [X, S^1] & \xrightarrow{\Xi_* \times \Xi_*} & [X, \Omega\mathbb{C}\mathrm{P}^\infty] \times [X, \Omega\mathbb{C}\mathrm{P}^\infty] \\ \downarrow \nu & & \downarrow \mu_* \\ [X, S^1] & \xrightarrow{\Xi_*} & [X, \Omega\mathbb{C}\mathrm{P}^\infty]. \end{array}$$

Here the left vertical map is given by Lemma 164.4.

Proof. The statement of the lemma has nothing to do with X. In fact, it suffices to show that the following map agrees up to homotopy:

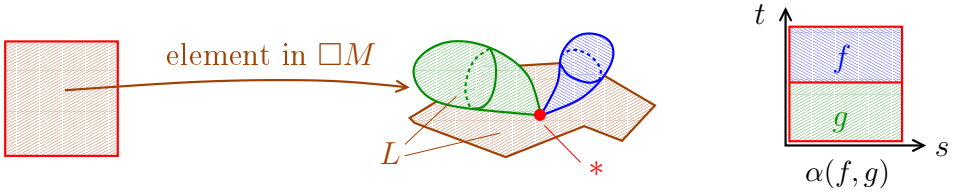
$$\begin{array}{ccc} S^1 \times S^1 & \xrightarrow{\Xi\times\Xi} & (\Omega\mathbb{C}\mathrm{P}^\infty, *) \times (\Omega\mathbb{C}\mathrm{P}^\infty, *) \\ \downarrow{\scriptstyle (z,w)\mapsto z\cdot w} & & \downarrow{\scriptstyle \mu} \\ S^1 & \xrightarrow{\Xi} & \Omega(\mathbb{C}\mathrm{P}^\infty, *). \end{array}$$

We outsource this verification to Exercise 164.1. ■

Perhaps the first question that arises when we introduce a group is whether the group abelian. It turns out that in this case we can answer this question in the affirmative.

Proposition 164.21. Let $n \in \mathbb{N}$ and let G be an abelian group. For every pointed topological space (X, x_0) the group $\langle (X, x_0), \mathrm{K}(G, n)\rangle$ is abelian.

Proof. Let $n \in \mathbb{N}$ and let G be an abelian group. We write $L = \mathrm{K}(G, n+1)$ and we write $M = \mathrm{K}(G, n+2)$. Finally let (X, x_0) be a pointed topological space. We make the following preparations.



(1) By the discussion on page 3478 we know that $\mathrm{K}(G, n)$, ΩL and $\Omega(\Omega M)$ are polarized Eilenberg-Maclane spaces of type $\mathrm{K}(G, n)$. Thus we obtain from Lemma 164.15 homotopy equivalences $f\colon (\mathrm{K}(G, n), *) \to (\Omega L, *)$ and $g\colon (\Omega L, *) \to (\Omega(\Omega M), *)$.

(2) We define
$$\square M \;:=\; \{f\colon [0,1]^2 \to M \mid f(\partial[0,1]^2) = \{*\}\}.$$
As always we equip $\square M$ with the compact-open topology. Furthermore let
$$\begin{array}{rcl} \Theta\colon \square M & \to & \Omega(\Omega M) \\ (f\colon [0,1]^2 \to M) & \mapsto & (t \mapsto (s \mapsto f(s,t))) \end{array}$$
be the *homeomorphism* from the Iterated Loop Space Proposition 164.11.

(3) We consider the map
$$\begin{array}{rcl} \alpha\colon \square M \times \square M & \to & \square M \\ (f, g) & \mapsto & \left(\begin{array}{rcl} [0,1]^2 & \to & M \\ (s,t) & \mapsto & \begin{cases} f(s, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ g(s, 2t-1), & \text{if } t \in (\frac{1}{2}, 1] \end{cases} \end{array} \right). \end{array}$$
The same argument as in the proof of Lemma 156.22 (1) shows that α is continuous.

(4) Since the pointed topological space (X, x_0) is really just a bystander we will abbreviate it to X.

Some of the above objects are illustrated in the figure below.

Claim. The following diagram commutes:

$$\begin{array}{ccccc}
\langle X, \mathrm{K}(G,n)\rangle \times \langle X, \mathrm{K}(G,n)\rangle & & \xrightarrow{\text{group multiplication}} & & \langle X, \mathrm{K}(G,n)\rangle \\
\downarrow{\scriptstyle (\Theta^{-1}\circ g\circ f)_* \times (\Theta^{-1}\circ g\circ f)_*} & & & & \downarrow{\scriptstyle (\Theta^{-1}\circ g\circ f)_*} \\
\langle X, \square M\rangle \times \langle X, \square M\rangle & \xrightarrow{\chi} & \langle X, \square M \times \square M\rangle & \xrightarrow{\alpha_*} & \langle X, \square M\rangle.
\end{array}$$

Furthermore the vertical maps are bijections.

Proof. To show that the above diagram commutes we expand it into an even larger diagram. More precisely, we consider the following diagram:

$$\begin{array}{ccccc}
\langle X, \mathrm{K}(G,n)\rangle \times \langle X, \mathrm{K}(G,n)\rangle & & \xrightarrow{\text{group multiplication}} & & \langle X, \mathrm{K}(G,n)\rangle \\
\downarrow{\scriptstyle f_* \times f_*} & & & & \downarrow{\scriptstyle f_*} \\
\langle X, \Omega L\rangle \times \langle X, \Omega L\rangle & \xrightarrow{\chi} & \langle X, \Omega L \times \Omega L\rangle & \xrightarrow{\mu_*} & \langle X, \Omega L\rangle \\
\downarrow{\scriptstyle g_* \times g_*} & & \downarrow{\scriptstyle (g_* \times g_*)_*} & & \downarrow{\scriptstyle g_*} \\
\langle X, \Omega(\Omega M)\rangle \times \langle X, \Omega(\Omega M)\rangle & \xrightarrow{\chi} & \langle X, \Omega(\Omega M) \times \Omega(\Omega M)\rangle & \xrightarrow{\mu_*} & \langle X, \Omega(\Omega M)\rangle \\
\downarrow{\scriptstyle \Theta_*^{-1} \times \Theta_*^{-1}} & & \downarrow{\scriptstyle (\Theta_*^{-1} \times \Theta_*^{-1})_*} & & \downarrow{\scriptstyle \Theta_*^{-1}} \\
\langle X, \square M\rangle \times \langle X, \square M\rangle & \xrightarrow{\chi} & \langle X, \square M \times \square M\rangle & \xrightarrow{\alpha_*} & \langle X, \square M\rangle.
\end{array}$$

We make the following observations:

(1) By Lemma 3.4 we know that the vertical maps between the first and second and between the second and the third row are bijections.
(2) Since Θ is a homeomorphism we see that the bottom vertical maps are also bijections.
(3) By definition of the group multiplication on $\langle X, \mathrm{K}(G,n)\rangle$ the top rectangle commutes.
(4) It follows immediately from the definition of χ that the two smaller rectangles on the left commute.
(5) It follows from Lemma 164.10 (1) that the middle right rectangle commutes.
(6) It follows immediately from the definition of the maps μ, α and Θ that

$$\alpha \circ (\Theta \times \Theta) \;=\; \Theta \circ \mu \colon \Omega(\Omega M) \times \Omega(\Omega M) \;\to\; \square M.$$

This equality implies that the lower right rectangle commutes. ⊞

The claim can be summarized as saying that it suffices to show that the bottom multiplication map on $\langle X, \square M\rangle$ is commutative. Next we consider the swap map

$$\begin{array}{rcl}
\sigma \colon \square M \times \square M & \to & \square M \times \square M \\
(f, g) & \mapsto & (g, f).
\end{array}$$

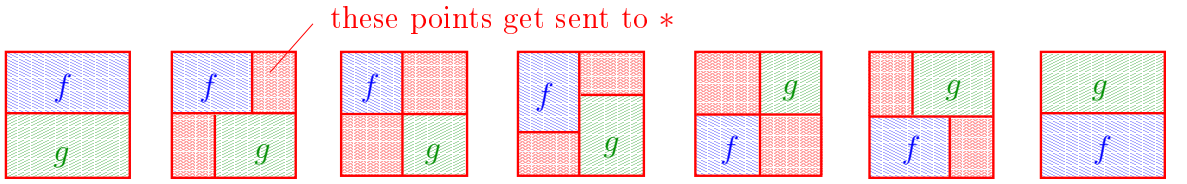
We obtain the following diagram:

$$\begin{array}{ccccc}
\langle X, \square M\rangle \times \langle X, \square M\rangle & \xrightarrow{\chi} & \langle X, \square M \times \square M\rangle & \xrightarrow{\alpha_*} & \langle X, \square M\rangle \\
\downarrow{\scriptstyle (a,b)\mapsto(b,a)} & & \downarrow{\scriptstyle \sigma_*} & & \downarrow{\scriptstyle \mathrm{id}} \\
\langle X, \square M\rangle \times \langle X, \square M\rangle & \xrightarrow{\chi} & \langle X, \square M \times \square M\rangle & \xrightarrow{\alpha_*} & \langle X, \square M\rangle
\end{array}$$

We make the following observations:

(1) The statement that the multiplication on $\langle X, \square M\rangle$ is commutative is, by definition, equivalent to the statement that the large rectangle commutes.

(2) It follows immediately from the definitions of the various maps that the smaller rectangle on the left commutes. Thus it suffices to show that the smaller rectangle on the right commutes.



In particular, since $\alpha_* \circ \sigma_* = (\alpha \circ \sigma)_*$ it suffices to prove the following claim.[2043]

Claim. The maps α and $\alpha \circ \sigma$ from the pointed topological space $\square M \times \square M$ to the pointed topological space $\square M$ are homotopic.

Proof. In the figure below we indicate how one can define a homotopy from α to $\alpha \circ \sigma$. We leave it to the punctilious reader to write down a precise formula for a homotopy[2044]

$$(\square M \times \square M) \times [0,1] \ \to \ \square M.$$

As in the proof of Lemma 164.10 one can use the "⇒"-direction of the Compact-Open Exponential Proposition 12.6 to show that the map provided by the reader is actually continuous. ■

Remark. As the reader with a well-developed long-term memory will have noticed, the proof of Proposition 164.21 eventually is very similar to the proof of the Homotopy Group-Abelian Proposition 71.3. In particular the above figure looks almost the same as the figure on page 1564.

164.4. **Alternative description of the group structure.** Once again let $n \in \mathbb{N}$, let G be an abelian group and let (X, x_0) be a pointed topological space. In this section we give an alternative description of the group structure on

$$\langle (X,x_0), \mathrm{K}(G,n) \rangle \underset{\uparrow}{\overset{\Xi}{\to}} \langle (X,x_0), \Omega\,\mathrm{K}(G,n+1) \rangle \underset{\uparrow}{\overset{\Upsilon}{\to}} \langle S(X,x_0), \mathrm{K}(G,n+1) \rangle.$$

bijection from page 3478 — bijection from Proposition 164.13

Before we state the relevant proposition we recall some of the objects that we have introduced recently:

(1) On page 3474 we introduced the pinching map

$$\omega \colon S(X,x_0) \ \to \ S(X,x_0) \vee S(X,x_0)$$

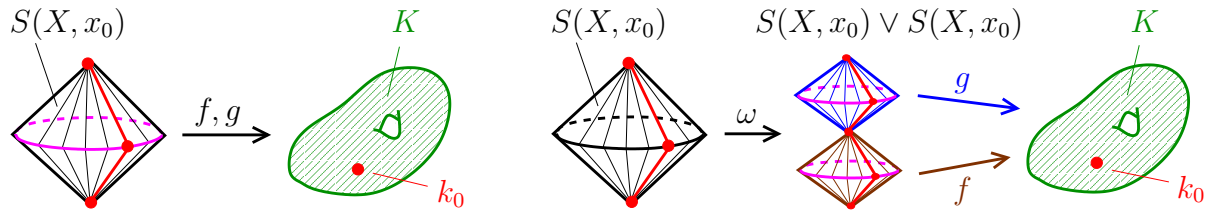
where $S(X,x_0)$ denotes the reduced suspension.

(2) In Lemmas 164.7 and 164.8 we introduced the maps

$$\begin{array}{rcl} \chi \colon \langle (X,x_0), (Y,y_0) \rangle \times \langle (X,x_0), (Z,z_0) \rangle & \to & \langle (X,x_0), (Y \times Z, (y_0,z_0)) \rangle \\ ([f \colon X \to Y], [g \colon X \to Z]) & \mapsto & [f \times g \colon X \to Y \times Z] \end{array}$$

and

[2043] Thus once again X plays no role in the argument.



[2044] For example this could be done using the maps introduced in the proof of Lemma 71.2.

$$\begin{array}{rcl} \nu\colon \langle (X,x_0),(Z,z_0)\rangle \times \langle (Y,y_0),(Z,z_0)\rangle & \to & \langle (X,x_0)\vee(Y,y_0),(Z,z_0)\rangle \\ ([f\colon X\to Z],[g\colon Y\to Z]) & \mapsto & [f\vee g] \end{array}$$

The following proposition shows that instead of the map μ on the loop space we can also use the pinching map on the reduced suspension to define the group structure.

Proposition 164.22. Let (X,x_0) and (K,k_0) be pointed topological spaces. The following diagram commutes:

$$\begin{array}{ccc} \langle (X,x_0),\Omega(K,k_0)\rangle \times \langle (X,x_0),\Omega(K,k_0)\rangle & \xrightarrow{\Upsilon\times\Upsilon} & \langle S(X,x_0),(K,k_0)\rangle \times \langle S(X,x_0),(K,k_0)\rangle \\ \downarrow{\scriptstyle \chi} & & \downarrow{\scriptstyle \nu} \\ \langle (X,x_0),\Omega(K,k_0)\times\Omega(K,k_0)\rangle & & \langle S(X,x_0)\vee S(X,x_0),(K,k_0)\rangle \\ \downarrow{\scriptstyle \mu_*} & & \downarrow{\scriptstyle \omega^*} \\ \langle (X,x_0),\Omega(K,k_0)\rangle & \xrightarrow{\qquad\Upsilon\qquad} & \langle S(X,x_0),(K,k_0)\rangle. \end{array}$$

Remark. The multiplication map on $\langle S(X,x_0),(K,k_0)\rangle$ is arguably more geometric surely more appealing to some readers. Nonetheless, any attempt to prove that this multiplication map defines an (abelian) group structure promises to be notationally somewhat messy.

Proof. Let $f,g\colon (X,x_0)\to\Omega(K,k_0)$ be two maps. One can easily verify that

$$(\Upsilon\circ\mu_*\circ\chi)([f],[g]) = \left[\begin{array}{rcl} S(X,x_0) & \to & (K,k_0) \\ [(x,t)] & \mapsto & \begin{cases} f(t+1), & \text{if } t\in[-1,0], \\ g(t), & \text{if } t\in[0,1] \end{cases} \end{array}\right] = (\omega^*\circ\nu)(\Upsilon([f]),\Upsilon([g])).$$

This shows that the diagram does indeed commute. ∎

164.5. **Functoriality.** Let $n\in\mathbb{N}$. In this section we will see, perhaps not surprisingly, that the abelian groups $\langle (X,x_0),\mathrm{K}(G,n)\rangle$ are functorial in (X,x_0) and G. To make this precise we need to introduce the following piece of notation.

Definition. Let $n\in\mathbb{N}$ and let $\varphi\colon G\to H$ be a homomorphism between two (abelian) groups. We denote by $[\varphi]\in\langle \mathrm{K}(G,n),\mathrm{K}(H,n)\rangle$ the canonical homotopy class of maps defined in the Maps-to-K(π,n)-Proposition 163.15.[2045]

We have the following lemma.

[2045]More precisely, by the Maps-to-K(π,n)-Proposition 163.15 there exists a unique $[f]\in\langle \mathrm{K}(G,n),\mathrm{K}(H,n)\rangle$ such that the map $f_*\colon G=\pi_n(\mathrm{K}(G,n))\to\pi_n(\mathrm{K}(H,n))=H$ agrees with φ. Here we used that the canonical Eilenberg-Maclane spaces $\mathrm{K}(J,n)$ are pointed and that they come with an identification $\pi_n(\mathrm{K}(J,n))=J$.

Lemma 164.23. Let $n \in \mathbb{N}$. The maps

$$\begin{array}{rcl} G & \mapsto & \mathrm{K}(G,n) \\ (\varphi\colon G \to H) & \mapsto & [\varphi] \in \langle \mathrm{K}(G,n), \mathrm{K}(H,n)\rangle \end{array}$$

define a covariant functor from the category of (abelian) groups to the pointed homotopy category.

Proof. The fact that the maps define a covariant functor is an immediate consequence of the uniqueness statement in the Maps-to-K(π,n)-Proposition 163.15. ■

If one thinks about this lemma for a second, then one realizes that this lemma is actually quite astounding. So far we spent almost all our time trying to define functors from topological spaces to (abelian) groups in the hope of being able to use algebra to understand topological spaces. But now we have functors which go the other way around. In principle this will allow us to use tools from topology to gain a better understanding of groups. In fact we already saw a glimpse of this phenomenon in Proposition 163.22. Unfortunately at this very moment we cannot develop this theme. But in Chapter **??** this idea will come back with a vengeance.

After this short digression we can formulate the following proposition.

Proposition 164.24. Let $n \in \mathbb{N}$.

(1) Let G be an abelian group. The maps

$$\begin{array}{rcl} (X,x_0) & \mapsto & \langle (X,x_0), \mathrm{K}(G,n)\rangle \\ (f\colon (X,x_0) \to (Y,y_0)) & \mapsto & \left(\begin{array}{rcl} \langle (Y,y_0), \mathrm{K}(G,n)\rangle & \to & \langle (X,x_0), \mathrm{K}(G,n)\rangle \\ [\gamma] & \mapsto & [\gamma \circ f] \end{array} \right) \end{array}$$

define a contravariant functor from the category of pointed topological spaces to the category of abelian groups.

(2) Let (X,x_0) be a pointed topological space. The maps

$$\begin{array}{rcl} G & \mapsto & \langle (X,x_0), \mathrm{K}(G,n)\rangle \\ (\varphi\colon G \to H) & \mapsto & \left(\begin{array}{rcl} \langle (X,x_0), \mathrm{K}(G,n)\rangle & \to & \langle (X,x_0), \mathrm{K}(H,n)\rangle \\ [\gamma] & \mapsto & [\varphi \circ \gamma] \end{array} \right) \end{array}$$

define a covariant functor from the category of abelian groups to the category of abelian groups.

Proof. Let $n \in \mathbb{N}$.

(1) We fix an abelian group G. First note that it follows from Lemma 3.7 that the assignment $(X,x_0) \to \langle (X,x_0), \mathrm{K}(G,n)\rangle$ is a contravariant functor from the category of pointed topological spaces to the category of sets. Thus it remains to show that this assignment defines actually a functor to the category of abelian groups. More precisely, it remains to show that for any map $f \in \langle (X,x_0),(Y,y_0)\rangle$ the induced map $\langle (Y,y_0), \mathrm{K}(G,n)\rangle \to \langle (X,x_0), \mathrm{K}(G,n)\rangle$ is actually a group homomorphism. But that is basically obvious since the above definition of the group structure on $\langle (X,x_0), \mathrm{K}(G,n)\rangle$ has nothing to do with X. We leave it to the skeptical reader to fill in the details.

(2) Let (X, x_0) be a pointed topological space. By Lemmas 3.6 and Lemma 164.23 we know that the assignment $G \mapsto \langle (X, x_0), \mathrm{K}(G, n)\rangle$ defines a covariant functor from the category of abelian groups to the category of sets. As in (1) it remains to show that the assignment actually defines a functor to the category of abelian groups. This requires a little more effort than (1). The argument breaks up into two parts, namely we have to deal with the "horizontal" and the "vertical" aspects of the definition on page 3480.

(a) Recall that in the Loop Space-Homotopy Groups Corollary 154.15 we gave an explicit *natural* isomorphism

$$\alpha_k \colon \pi_k(K, k_0) \xrightarrow{\cong} \pi_{k-1}(\Omega(K, k_0), c_{x_0}) \qquad \text{for every } k \in \mathbb{N}.$$

It follows from the naturality of these isomorphisms, and the precise definition of the maps Ξ on page 3478, that for a given homomorphism $\varphi \colon G \to H$ of (abelian) groups we obtain a commutative diagram

$$\begin{array}{ccc} \langle (X, x_0), \mathrm{K}(G, n)\rangle & \xrightarrow[\Xi_*]{=} & \langle (X, x_0), \Omega\,\mathrm{K}(G, n+1)\rangle \\ \downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\ \langle (X, x_0), \mathrm{K}(H, n)\rangle & \xrightarrow[\Xi_*]{=} & \langle (X, x_0), \Omega\,\mathrm{K}(H, n+1)\rangle. \end{array}$$

This takes care of the "horizontal" part.

(b) It follows from Lemma 164.7, Lemma 164.10 (1) and Lemma 164.23 that the "vertical" part of the definition on page 3480 is functorial in φ. ■

As the reader will know by now, base points are something of a nuisance. Fortunately in Proposition 70.9 we already saw that on many occasions we can stop worrying about base points, the following proposition nicely complements Proposition 70.9.

Proposition 164.25. Let (X, x_0) and (Y, y_0) be two pointed CW-complexes. If Y is path-connected, if $\pi_1(Y, y_0)$ is abelian and if $\pi_i(Y, y_0) = 0$ for $i \geq 2$,[2046] then the natural map $\langle (X, x_0), (Y, y_0)\rangle \to [X, Y]$ is also a bijection.

Remark. We equip S^1, S^2 and $S^1 \vee S^2$ with the usual base point $*$. In Exercise 164.2 we will show that the map $[(S^2, *), (S^1 \vee S^2, *)] \to [S^2, S^1 \vee S^2]$ is not an injection. This shows that in Proposition 164.25 we cannot just drop the hypothesis that $\pi_i(Y, y_0) = 0$ for $i \geq 2$.

Proof. Let (Y, y_0) be a pointed path-connected CW-complex such that the fundamental group $\pi_1(Y, y_0)$ is abelian and such that $\pi_i(Y, y_0) = 0$ for $i \geq 2$. By Proposition 70.9 (1) it remains to show that the map $\langle (X, x_0), (Y, y_0)\rangle \to [X, Y]$ is injective. Despite initial appearances, the argument will be quite different from the argument provided in the proof of Proposition 70.9 (1) (2). So let $f_0, f_1 \colon (X, x_0) \to (Y, y_0)$ be two maps that are homotopic as maps $X \to Y$. By the Homotopy-π_1-Proposition 50.3 (1) we know that there exists a $\gamma \in \pi_1(Y, y_0)$ such that $f_{0*}(g) = \gamma \cdot f_{1*}(g) \cdot \gamma^{-1} \in \pi_1(Y, y_0)$ for every $g \in \pi_1(X, x_0)$. But since $\pi_1(Y, y_0)$ is abelian we see that $f_{0*} = f_{1*}$. Since by hypothesis we have $\pi_i(Y, y_0) = 0$ for $i \geq 2$ we can appeal to the Maps-to-K(π, n)-Proposition 163.15 (2) which now shows that there exists a homotopy from f_0 to f_1 rel x_0. ■

[2046] In other words, (Y, y_0) is a pointed Eilenberg-Maclane space of type $\mathrm{K}(\pi, 1)$ where $\pi \cong \pi_1(Y, y_0)$ is an abelian group.

In the following discussion we will use Proposition 164.24 (1) to dispose of the base points.

Definition. Let $n \in \mathbb{N}$ and let G be an abelian group.

(1) Let X be a connected CW-complex. We pick a point $x_0 \in X^0$. By Propositions 70.9 and 164.25[2047] the natural map

$$\begin{array}{rccc} \Psi_{(X,x_0)} \colon & \langle (X,x_0), (\mathrm{K}(G,n),*)\rangle & \to & [X,\mathrm{K}(G,n)] \\ & [f] & \mapsto & [f] \end{array}$$

is a bijection. We use this bijection, together with the group structure on the left-hand side defined in Proposition 164.17, to turn the right-hand side $[X,\mathrm{K}(G,n)]$ into a group. In Corollary 164.26 below we will see that this definition does not depend on the choice of x_0.

(2) Now let X be any CW-complex. Let $\{X_i\}_{i\in I}$ be the set of its components. We have

$$[X,\mathrm{K}(G,n)] \underset{\uparrow}{=} \prod_{i\in I} [X_i,\mathrm{K}(G,n)]$$

by the Topological-Coproduct Proposition 5.11 (1)

We define the group structure on each $[X_i,\mathrm{K}(G,n)]$ as in (1) and for $i \neq j$ we define the multiplication on $[X_i,\mathrm{K}(G,n)] \times [X_j,\mathrm{K}(G,n)]$ to be the trivial map. One easily verifies that this defines an abelian group structure on $[X,\mathrm{K}(G,n)]$.

The following corollary to Proposition 164.24 (1) shows that this definition of the group structure on $[X,\mathrm{K}(G,n)]$ does not depend on the choice of the base point $x_0 \in X^0$.

Corollary 164.26. Let $n \in \mathbb{N}$, let G be an abelian group and let X be a connected CW-complex. The definition of the group structure on $[X,\mathrm{K}(G,n)]$ does not depend on the choice of $x_0 \in X^0$.

Proof. Let $n \in \mathbb{N}$, let G be an abelian group and let X be a connected CW-complex. Now let $x_0, x_1 \in X$ be two points in the 0-skeleton of X. Since X is connected we know by Proposition 70.12 that there exists a map $f \colon X \to X$ with the following properties:

(a) The map f is homotopic to the identity.
(b) We have $f(x_0) = x_1$.
(c) The map f defines a homotopy equivalence $(X,x_0) \to (X,x_1)$ of pointed topological spaces.

We consider the following diagram

$$\begin{array}{ccc} \langle (X,x_1), (\mathrm{K}(G,n),*)\rangle & \xrightarrow[[g]\mapsto[g\circ f]]{f^*} & \langle (X,x_0), (\mathrm{K}(G,n),*)\rangle \\ \Big\downarrow{\scriptstyle \Psi_{(X,x_1)}}\ {\scriptstyle [g]\mapsto[g]} & & \Big\downarrow{\scriptstyle \Psi_{(X,x_0)}}\ {\scriptstyle [g]\mapsto[g]} \\ [X,\mathrm{K}(G,n)] & \xrightarrow[[g]\mapsto[g\circ f]]{f^*} & [X,\mathrm{K}(G,n)]. \end{array}$$

We make the following observations:

(1) It follows basically immediately from the definitions that the diagram commutes.
(2) It follows from (c) and Lemmas 3.7 and 3.10 that the top horizontal map is a bijection.
(3) By Proposition 164.24 (1) we know that top horizontal map is in fact an isomorphism.
(4) By (a) we know that the bottom map is in fact the identity.

[2047] Note that here we use that G is an abelian group, even for $n = 1$.

It follows immediately from the above that it does not matter whether we use $\Psi_{(X,x_1)}$ or $\Psi_{(X,x_0)}$ to define the group structure on $[X, \mathrm{K}(G,n)]$. ■

164.6. **Basic calculations.** In this section we want to do a few bare-hands calculation of our new invariant $\langle (X,x_0), \mathrm{K}(G,n)\rangle$. Before we start with the calculations it is useful to introduce the following notation.

Notation. Let $n \in \mathbb{N}$ and let G be an abelian group. Furthermore let (X,x_0) be a pointed topological space. For the purpose of this section we write

$$h^n((X,x_0);G) \;:=\; \langle (X,x_0), \mathrm{K}(G,n)\rangle.$$

Before we state the second main calculation it is helpful to introduce the following convention.

Convention. Let G be an abelian group. We make the identifications

$$\mathrm{H}_1(\mathrm{K}(G,1);\mathbb{Z}) \underset{\uparrow}{=} \pi_1(\mathrm{K}(G,1),*)_{\mathrm{ab}} \underset{\uparrow}{=} G_{\mathrm{ab}} \underset{\uparrow}{=} G.$$

Hurewicz Theorem 84.5 — by the Eilenberg-Maclane Existence Theorem 163.8 — since G is abelian

Lemma 164.27. Let G be an abelian group. Let X be a connected CW-complex and let $x_0 \in X^0$ be a point. The map

$$\begin{array}{rcl} h^1((X,x_0);G) & \to & \mathrm{Hom}(\mathrm{H}_1(X;\mathbb{Z}),G) \\ [f\colon (X,x_0) \to (\mathrm{K}(G,1),*)] & \to & (f_*\colon \mathrm{H}_1(X;\mathbb{Z}) \to \mathrm{H}_1(\mathrm{K}(G,1);\mathbb{Z}) = G) \end{array}$$

is a natural isomorphism.

Proof.

(1) It follows from the Maps-to-K(π,n)-Proposition 163.15 and the Hurewicz Theorem 84.5 that the given map is a bijection.
(2) It follows immediately from the definitions that the map is natural in X.
(3) It remains to show that the given map is a homomorphism. We write $Y = \mathrm{K}(G,2)$. We make the usual identification $\langle X, \mathrm{K}(G,1)\rangle = \langle X, \Omega Y\rangle$. Furthermore we use the natural isomorphism

$$\begin{array}{rcl} \mathrm{Hom}(\mathrm{H}_1(X;\mathbb{Z}),G) & \to & \mathrm{Hom}(\pi_1(X,x_0),\pi_1(\Omega Y)) \\ \varphi & \mapsto & (\pi_1(X,x_0) \to \pi_1(X,x_0)_{\mathrm{ab}} = \mathrm{H}_1(X;\mathbb{Z}) \xrightarrow{\varphi} G = \pi_1(\Omega Y)) \end{array}$$

to identify the group on the left with the group on the right. Next we consider the following diagram

$$\begin{array}{ccc} \langle X,\Omega Y\rangle \times \langle X,\Omega Y\rangle & \xrightarrow{([f],[g])\mapsto(f_*,g_*)} & \mathrm{Hom}(\pi_1(X),\pi_1(\Omega Y)) \times \mathrm{Hom}(\pi_1(X),\pi_1(\Omega Y)) \\ \downarrow{\scriptstyle ([f],[g])\mapsto[f\times g]} & & \downarrow{\scriptstyle (\varphi,\psi)\mapsto(g\mapsto(\varphi(g),\psi(g)))} \\ \langle X,\Omega Y\times\Omega Y\rangle & \longrightarrow & \mathrm{Hom}(\pi_1(X),\pi_1(\Omega Y)\times\pi_1(\Omega Y)) \\ \downarrow{\scriptstyle \mu_*} & & \downarrow{\scriptstyle \mu_*} \\ \langle X,\Omega Y\rangle & \longrightarrow & \mathrm{Hom}(\pi_1(X),\pi_1(\Omega Y)) \end{array}$$

We make the following clarifications and observations:
(a) The upper rectangle commutes basically by definition.
(b) The lower square also commutes basically by definition. Slightly more precisely, let $[f] \in \langle X, \Omega Y \times \Omega Y \rangle$. We consider the maps $X \xrightarrow{f} \Omega Y \times \Omega Y \xrightarrow{\mu} \Omega Y$. By functoriality we have $(\mu \circ f)_* = \mu_* \circ f_*$. But this equality just means that in the lower square it does not matter whether we take the down-right route or the right-down route.
(c) It follows from Lemma 156.28 that the right vertical maps give precisely the group multiplication on $\mathrm{Hom}(\pi_1(X), \pi_1(\Omega Y))$.

This shows that the given map is indeed a group homomorphism. ∎

164.7. **Product structures.** Let (X, x_0) be a pointed CW-complex and let $m, n \in \mathbb{N}$. Our goal in this section is to define a potentially interesting map

$$\langle (X, x_0), \mathrm{K}(\mathbb{Z}, m) \rangle \times \langle (X, x_0), \mathrm{K}(\mathbb{Z}, n) \rangle \ \to \ \langle (X, x_0), \mathrm{K}(\mathbb{Z}, m+n) \rangle.$$

The key to defining such a map is the following humble construction.

Definition. Given two pointed topological spaces (X, x_0) and (Y, y_0) the smash product is defined as

$$X \wedge Y \ := \ (X \times Y)/(X \vee Y) \quad \text{where we use Exercise 50.6 to make the identification } X \vee Y := (X \times \{y_0\}) \times (\{x_0\} \times Y).$$

We equip $X \wedge Y$ with the base point given by $[X \vee Y]$.

Remark. As we discussed in Exercise 68.12 and on page 1502, in the category of pointed topological spaces the smash product is actually the categorical product.

In Exercise 50.6 we already showed that $S^m \wedge S^n$ is homeomorphic to S^{m+n}. For our purpose it is useful to have a canonical homeomorphism that we can all agree upon. This is given in the following lemma.

Lemma 164.28. Given $m, n \in \mathbb{N}$ there exists a canonical homeomorphism

$$S^m \wedge S^n \ \xrightarrow{\cong} \ S^{m+n}.$$

Convention. We will use the canonical homeomorphism from Lemma 164.28 to make the identification $S^m \wedge S^n = S^{m+n}$.

Proof. We write $I = [0, 1]$. Given any $k \in \mathbb{N}_0$ we have the following identifications of pointed topological spaces:

$$(I^k/\partial I^k, [\partial I^k]) \ \underset{\uparrow}{\xrightarrow{\cong}} \ (\overline{B}^k/S^{k-1}, [S^{k-1}]) \ \underset{\uparrow}{\xrightarrow{\cong}} \ (S^k, *).$$

page 158 Lemma 5.20

Let $m, n \in \mathbb{N}_0$. Using the above identification we obtain the following homeomorphism

homeomorphism by the Twice Quotient Lemma 5.23 (1)

$$S^m \wedge S^n \xrightarrow{\cong} I^m/\partial I^m \wedge I^n/\partial I^n \underset{[([x],[y])] \mapsto [(x,y)]}{\overset{\downarrow \cong}{\to}} (I^{m+n})/(I^m \times \partial I^n \cup \partial I^m \times I^n) = I^{m+n}/\partial I^{m+n} \xleftarrow{\cong} S^{m+n}.$$

We have thus given an explicit homeomorphism between $S^m \wedge S^n$ and S^{m+n}. ∎

The following lemma is basically just a mild reformulation of Lemma 163.11.

Lemma 164.29. Let $k \in \mathbb{N}$. There exists a polarized Eilenberg-Maclane space $(Y_k, *, \varphi)$ of type $\mathrm{K}(\mathbb{Z}, k)$ with the following properties:

(1) The k-skeleton of Y_k equals S^k with the usual CW-structure defined on page 3431.
(2) The CW-complex Y_k has no cell of dimension $k+1$.
(3) The CW-complex Y_k has only countably many cells in dimensions $\geq k+2$.

Now we turn to the actual definition of the product structure.

Definition. Let $m, n \in \mathbb{N}$. In the following discussion all topological spaces are viewed as pointed objects.

(1) We consider the polarized Eilenberg-Maclane spaces Y_m and Y_n that we introduced in Lemma 164.29. Recall that from Lemma 164.15 we obtain canonical elements $\Xi_m \in \langle \mathrm{K}(\mathbb{Z}, m), Y_m \rangle_{\mathrm{inv}}$ and $\Xi_n \in \langle \mathrm{K}(\mathbb{Z}, n), Y_n \rangle_{\mathrm{inv}}$.
(2) Since Y_m and Y_n are CW-complexes with *countably* many cells we can equip the product $Y_m \times Y_n$ with the CW-structure defined in the CW-Complex Construction Lemma 68.32.
(3) We denote by $p\colon Y_m \times Y_n \to Y_m \wedge Y_n = (Y_m \times Y_n)/\sim$ the obvious projection.
(4) It follows from the explicit description of the CW-structure defined in the CW-Complex Construction Lemma 68.32 that $Y_m \wedge Y_n = (Y_m \times Y_n)/\sim$ has precisely one cell in dimension 0, no cells in dimension $1, \ldots, m+n-1$, one cell in dimension $m+n$ and no cell in dimension $m+n+1$. Furthermore it follows immediately from the definitions that the map
$$S^{m+n} \;=\; S^m \wedge S^n \;\to\; Y_m \wedge Y_n$$
defines a homeomorphism onto the $(m+n+1)$-skeleton of $Y_m \wedge Y_n$. In particular we obtain from the CW-Skeleton-π_n-Proposition 71.9 that Y_{m+n} is $(m+n-1)$-connected and we obtain that the map $\varphi\colon \mathbb{Z} = \pi_{m+n}(S^{m+n}) \to \pi_{m+n}(Y_m \wedge Y_n)$ is an isomorphism.
(5) Since $Y_m \times Y_n$ is an $(m+n-1)$-connected CW-*complex* we obtain from the Maps-to-$\mathrm{K}(\pi, n)$-Proposition 163.15 a unique class $\mu \in \langle Y_m \wedge Y_n, \mathrm{K}(\mathbb{Z}, m+n) \rangle$ that induces the preferred isomorphism $\varphi^{-1}\colon \pi_{m+n}(Y_m \wedge Y_n, *) \xrightarrow{\cong} \mathbb{Z}$.

After these preparations we consider the following diagram

$$\begin{array}{ccccc}
\langle X, Y_m \rangle \times \langle X, Y_n \rangle & \xrightarrow{\times} & \langle X, Y_m \times Y_n \rangle & \xrightarrow{p_*} & \langle X, Y_m \wedge Y_n \rangle \\
{\scriptstyle \Xi_{m*} \times \Xi_{n*}} \uparrow & & & & \searrow^{\mu_*} \\
\langle X, \mathrm{K}(\mathbb{Z}, m) \rangle \times \langle X, \mathrm{K}(\mathbb{Z}, n) \rangle & & \xrightarrow{\text{definition of cup product } \cup} & & \langle X, \mathrm{K}(\mathbb{Z}, m+n) \rangle .
\end{array}$$

We refer to the bottom horizontal map, which we defined through the upper path of maps, as the cup product.

Theorem 164.30. Let $X = (X, x_0)$ be a pointed CW-complex and let $m, n \in \mathbb{N}$. The cup product
$$\cup\colon \langle X, \mathrm{K}(\mathbb{Z}, m) \rangle \times \langle X, \mathrm{K}(\mathbb{Z}, n) \rangle \;\to\; \langle X, \mathrm{K}(\mathbb{Z}, m+n) \rangle$$

is bilinear. Furthermore the cup product is associative and graded commutative in the sense that for $\varphi \in \langle X, \mathrm{K}(\mathbb{Z}, m)\rangle$ and $\psi \in \langle X, \mathrm{K}(\mathbb{Z}, n)\rangle$ we have

$$\varphi \cup \psi \;=\; (-1)^{m\cdot n} \cdot \psi \cup \varphi.$$

Proof. We will not make use of this theorem, thus we will also not provide a proof. Instead we refer to [**Stro2011**, Theorem 21.61] for the proof. Note that [**Stro2011**, Theorem 21.61] does not explicitly say that X needs to be a CW-complex, but implicitly the discussion on [**Stro2011**, Chapter 21] seems to assume that the setting is a convenient category in the sense of Theorems 68.28 and 68.30. We will discuss this issue in more detail right after this proof. ■

The above definition of the cup product is in a way rather awkward, it is esthetically wrong to introduce the CW-complexes Y_m and Y_n. We conclude this section with a longish but hopefully quite interesting discussion which explains why we introduced the CW-complexes Y_m and Y_n and how we can get around introducing them.

Definition.

(1) Let A and B be CW-complexes. We denote by $A \otimes B$ the product CW-complex that we defined on page 1500. Recall that the underlying set is just $A \times B$.

(2) Let (A, a_0) and (B, b_0) be pointed CW-complexes. We write

$$A \circledcirc B \;:=\; (A \otimes B)/(A \times \{b_0\} \cup \{a_0\} \times B).$$

We equip $A \circledcirc B$ with the CW-structure given by the CW-structure on $A \otimes B$ and the quotient structure defined in the CW-Complex Construction Lemma 68.32.

(3) We denote by $\eta\colon A \otimes B \to A \times B$ the identity map. Note that η is continuous by Proposition 68.26 (1).

Now let $X = (X, x_0)$ be a pointed topological space and let $m, n \in \mathbb{N}$. We introduce the following notation:

(1) Let $r \in \mathbb{N}$. We write $K_r = \mathrm{K}(\mathbb{Z}, r)$. We consider the polarized Eilenberg-Maclane spaces Y_r that we introduced in Lemma 164.29 and we denote by $\Xi_r \in \langle K_r, Y_r\rangle_{\mathrm{inv}}$ the canonical element given by Lemma 164.15.

(2) Given topological spaces A and B we denote by $p\colon A \times B \to A \wedge B$ the natural projection. Similarly, given CW-complexes A and B we denote by $p\colon A \otimes B \to A \circledcirc B$ the natural projection.

We consider the following diagram

$$\begin{array}{ccccccc}
\langle X, Y_m\rangle \times \langle X, Y_n\rangle & \xrightarrow{\times} & \langle X, Y_m \times Y_n\rangle & \xrightarrow{p_*} & \langle X, Y_m \wedge Y_n\rangle & & \\
\uparrow{\scriptstyle \Xi_{m*}\times\Xi_{n*}} & & & & & \searrow^{\mu_*} & \\
\langle X, K_m\rangle \times \langle X, K_n\rangle & \xrightarrow[(f,g)\mapsto f\times g]{\times} & \langle X, K_m \times K_n\rangle & \xrightarrow{p_*} & \langle X, K_m \wedge K_n\rangle & \xrightarrow{???} & \langle X, K_{m+n}\rangle. \\
\downarrow{\scriptstyle (f,g)\mapsto f\widetilde{\times}g} & & \uparrow{\scriptstyle \eta_*} & & & \nearrow_{\nu_*} & \\
\langle X, K_m \widetilde{\times} K_n\rangle & \xrightarrow[\Theta_*]{} & \langle X, K_m \otimes K_n\rangle & \xrightarrow{p_*} & \langle X, K_m \circledcirc K_n\rangle & &
\end{array}$$

We make the following observations:

(1) Since K_m and K_n have uncountably many cells the product $K_m \times K_n$ is not a CW-complex.

(2) It follows from (1) that $K_m \wedge K_n$ has no obvious CW-structure. Thus there is no clear path to constructing a map $K_m \wedge K_n \to K_{m+n}$.[2048]
(3) It follows from (2) that the "direttissima" approach to defining the cup product by going straight from left to right runs into a major obstacle.
(4) Since Y_m and Y_n have countably many cells we know, by Lemmas 68.32 and 68.32 that $Y_m \times Y_n$ and $Y_m \wedge Y_n$ are CW-complexes. As discussed above, we obtain from the Maps-to-K(π, n)-Proposition 163.15 a canonical class $\mu \in \langle Y_m \wedge Y_n, \mathrm{K}(\mathbb{Z}, m+n)\rangle$.
(5) One way of getting around (3) is to use (4), i.e. we take the "upper route" in the diagram. This is how in the above we defined the cup product.
(6) As for $Y_m \wedge Y_n$ one sees that $K_m \owedge K_n$ is $(m+n-1)$-connected and that we have a canonical map $\pi_{m+n}(K_m \owedge K_n) \to \mathbb{Z}$. Since $K_m \owedge K_n$ is a CW-complex we obtain from the Maps-to-K(π, n)-Proposition 163.15 a canonical element $\nu \in \langle K_m \owedge K_n, K_{m+n}\rangle$.
(7) Unfortunately the issue in (1) also means that the map $\eta\colon K_m \otimes K_n \to K_m \times K_n$ is not a homeomorphism. Thus there is no obvious way how we can take the lower route in the diagram.

Now we switch to the category of CGWH-spaces that we introduced on page 1504. In particular we now assume that X is a CGWH-space. Recall that by the CGWH-Category Theorem 68.30 (2) we know that every CW-complex is a CGWH-space.

(8) Given two CGWH-spaces A and B we know by the CGWH-Category Theorem 68.30 that there exists a product *in the category of* CGWH-*spaces*. As on page 1505 we denote this categorical product by $A \widetilde{\times} B$ and we denote by $p\colon A \widetilde{\times} B \to A$ and $q\colon A \widetilde{\times} B \to B$ the two projections maps.
(9) Let $f\colon X \to K_m$ and $g\colon X \to K_n$ be maps. Since X, K_m and K_n are CGWH-spaces we know, by definition of the product in a category, that there exists a unique map $f \widetilde{\times} g\colon X \to K_m \widetilde{\times} K_n$ such that $f = p \circ (f \widetilde{\times} g)$ and $g = q \circ (f \widetilde{\times} g)$.
(10) Since K_m and K_n are CW-complexes we know by the CGWH-Category Theorem 68.30 (5) that the identity map $\Theta\colon K_m \widetilde{\times} K_n \to K_m \otimes K_n$ is actually a homeomorphism.[2049]
(11) It follows from (9) and (10) that we have a "lower route" from $\langle X, K_m\rangle \times \langle X, K_n\rangle$ to $\langle X, K_{m+n}\rangle$. This gives us an approach to defining the cup product without introducing the slightly artificial Y_m and Y_n.
(12) It follows easily from the definitions that in the diagram the square to the lower left commutes. One can now see reasonably easily that the two definitions of the cup product agree.

The second approach to defining the cup product is much more natural than the initial approach. In particular, using a similar circle of ideas one can define a cup product

$$\langle X, \mathrm{K}(R, m)\rangle \times \langle X, \mathrm{K}(R, n)\rangle \to \langle X, \mathrm{K}(R, m+n)\rangle$$

for any commutative ring R. We refer to [**Stro2011**, Chapter 21.4] for details.

Exercises for Chapter 164.

[2048] In fact it is also not immediately clear whether $K_m \wedge K_n$ is say $(m+n-1)$-connected.
[2049] For our purpose we only need the weaker result that $\Theta\colon K_m \widetilde{\times} K_n \to K_m \otimes K_n$ is continuous.

Exercise 164.1. We consider the following diagram:

$$\begin{array}{ccc} S^1 \times S^1 & \xrightarrow{\Xi\times\Xi} & (\Omega\mathbb{C}\mathrm{P}^\infty, *) \times (\Omega\mathbb{C}\mathrm{P}^\infty, *) \\ \downarrow{\scriptstyle (z,w)\mapsto z\cdot w} & & \downarrow{\scriptstyle \mu} \\ S^1 & \xrightarrow{\Xi} & \Omega(\mathbb{C}\mathrm{P}^\infty, *). \end{array}$$

The map $\Xi\colon S^1 \to \Omega(\mathbb{C}\mathrm{P}^\infty, *)$ is defined in Lemma 164.16 and the map μ is defined on page 3470. Show that the diagram commutes up to homotopy.

Exercise 164.2. We equip S^1, S^2 and $S^1 \vee S^2$ with the usual base points which in each case we call $*$. Show that the map $\langle (S^2, *), (S^1 \vee S^2, *)\rangle \to [S^2, S^1 \vee S^2]$ is not an injection.

Exercise 164.3. Let (X, x_0) and (K, k_0) be pointed topological spaces. Show that the multiplication on $\langle (X, x_0), (K, k_0)\rangle$ defined in Lemma 164.18 is actually associative.

Exercise 164.4. Let (X, x_0) and $(K, *)$ be pointed topological spaces. We consider the double loop space $\Omega^2(K, *) = \Omega(\Omega(K, *))$. By the construction on page 3480 we have a binary operation

$$\circ\colon \langle (X, x_0), \Omega(\Omega(K, *))\rangle \times \langle (X, x_0), \Omega(\Omega(K, *))\rangle \to \langle (X, x_0), \Omega(\Omega(K, *))\rangle.$$

In Proposition 164.17 we showed in particular that this binary operation is unital. Provide another binary unital operation "$\otimes$" on $\langle (X, x_0), \Omega(\Omega(K, *))\rangle$ such that the conditions of the Eckmann-Hilton Theorem 156.27 are satisfied.
Remark. Once we have shown that we can apply the Eckmann-Hilton Theorem 156.27 we see that "$\circ$" defines a group structure on $\langle (X, x_0), \Omega^2(K, *)\rangle$ and we obtain that this group is abelian. Thus this provides an alternative approach to proving Proposition 164.21 and to proving some of the statements of Proposition 164.17.
Remark. Coming up with an idea for defining "$\otimes$" is not difficult. Providing a complete proof that Condition (b) of the Eckmann-Hilton Theorem 156.27 is satisfied might be more painful. Especially once one starts wondering why certain maps are actually continuous.

Exercise 164.5. Let $n \in \mathbb{N}$ and let G be an abelian group. Let $k \in \mathbb{N}$. We denote by $*$ the usual base point of S^k. Compute the groups $\langle (S^k, *), \mathrm{K}(G, n)\rangle$.
Remark. Once one unravels the definitions one can fairly easily write down *bijections* to familiar groups. The only catch is that one really needs to show that these bijections are in fact group isomorphisms. The Eckmann-Hilton Theorem 156.27 might once again ride to the rescue.

Exercise 164.6. Let (X, x_0) be a pointed topological space. We equip S^1 with the base point $* = (0, 1)$. Show that the smash product $X \wedge S^1$ is homeomorphic to the reduced suspension $S(X, x_0)$.
Remark. Personally I like the Twice Quotient Lemma 5.23 (1).

Exercise 164.7. To simplify the notation, given a pointed topological space (Y, y_0) we now write $SY = S(Y, y_0)$ and $\Omega Y = \Omega(Y, y_0)$.

(a) Let (Y, y_0) be a point topological space. Show that the set $\pi_0(\Omega Y)$ has a natural group structure.
(b) Let (X, x_0) be a point topological space.

(1) Show that there exists a natural isomorphism from $\pi_0(\Omega(SX))$ to the free group on the set $\pi_0(X)$.
(2) Let (X, x_0) be a point topological space. Show that there exists a natural isomorphism from $\pi_0(\Omega^2(S^2X))$ to the free *abelian* group on the set $\pi_0(X)$.
(3) How does the sequence continue?

Part XIX

(Co-) homology with twisted and local coefficients

The goal of this part of the lecture notes is to introduce and study (co-) homology with twisted coefficients and (co-) homology with local coefficients. In both settings we start out with a topological space that is equipped with extra data, namely either a module over the group ring of the fundamental group, or a local coefficient system.

The two theories are quite similar and in many settings they give isomorphic results. Even though in most settings the theories of (co-) homology with twisted coefficients and of (co-) homology with local coefficients are isomorphic both are of interest and relevant:

(1) (Co-) homology with twisted coefficients requires the choice of a base point. This makes it less flexible when it comes to considering maps between topological spaces. But the definition of (co-) homology with twisted coefficients is closer to the theory that we have developed so far and makes it easier to apply results that we have proved earlier. Furthermore there is a cellular version of (co-) homology with twisted coefficients that is very useful when it comes to doing actual calculations.

(2) (Co-) homology with local coefficients does not need the choice of a base point. It works particularly well when one wants to study maps that are induced by maps between topological spaces. But the definitions are further from our known concepts and it requires more work to make sure that all the definitions actually make sense.

We start out with a chapter on (homological) algebra over rings. We will apply these to the case where the ring is the group ring $\mathbb{Z}[\pi_1(X, x_0)]$ of the fundamental group of a based topological space (X, x_0). This allows us define in a fairly painless fashion (co-) homology with twisted coefficients. Afterwards we introduce the (co-) homology with local coefficients. The latter concept is more elegant, but it requires more of an effort to make it work and for most applications it suffices to work with (co-) homology with twisted coefficients.

165. Modules over rings

In the previous chapters we mostly worked with abelian groups or vector spaces. In the future chapters we will also work with modules over possibly non-commutative rings. To prepare the reader for these future chapters we will summarize the algebra involved in this and the following chapter.

We start out with recalling the following definitions from page 98.

Definition.

(1) A ring is a triple $(R, +\colon R \times R \to R,\ \cdot\ \colon R \times R \to R)$ where $(R, +)$ is an abelian group and such that the following conditions are satisfied:
   (a) the multiplication "$\cdot$" is associative,
   (b) the multiplication "$\cdot$" is distributive,
   (c) there exists a multiplicatively neutral element $1 = 1_R$ with $1 \neq 0$.

(2) A ring R is called commutative, if given any $r, s \in R$ we have $r \cdot s = s \cdot r$.

(3) A ring homomorphism between two rings $(R, +, \cdot)$ and $(S, +, \cdot)$ is a map $R \to S$ that preserves the additive and multiplicative structures and that sends 1_R to 1_S.

(4) A field is a commutative ring such that every non-zero element has a multiplicative inverse.

Throughout the lecture notes we developed various algebraic concepts over commutative rings. In the following chapters we will be interested in (possibly) non-commutative rings, the prime example being the group ring of a (possibly) non-abelian group.

Example. Let R be a ring and $n \in \mathbb{N}$. The matrices $\mathrm{M}(n \times n, R)$, with the usual addition and multiplication of square matrices form a ring. Furthermore, if $\varphi\colon R \to S$ is a ring homomorphism, then the induced map

$$\begin{array}{ccc} \mathrm{M}(n \times n, R) & \to & \mathrm{M}(n \times n, S) \\ (a_{ij}) & \mapsto & (\varphi(a_{ij})) \end{array}$$

is also a ring homomorphism.

Definition. Let R be a commutative ring (in most applications $R = \mathbb{Z}$) and let G be a group. We set

$$R[G] \ := \ \left\{ \sum_{i=1}^{m} r_i \cdot g_i \,\middle|\, r_1, \ldots, r_m \in R \text{ and } g_1, \ldots, g_m \in G \right\}.$$

We equip $R[G]$ with the multiplication that is given by[2050]

$$\left(\sum_{i=1}^{m} r_i \cdot g_i \right) \cdot \left(\sum_{j=1}^{n} s_j \cdot h_j \right) \ := \ \sum_{i=1}^{m} \sum_{j=1}^{n} \underbrace{r_i \cdot_R s_j}_{\in R} \cdot \underbrace{(g_i \cdot_G h_j)}_{\in G}.$$

We refer to $R[G]$ as the group ring of G with coefficients in R.

[2050] In Lemma 86.10 we showed that the group ring $R[G]$ is indeed a ring.

Convention. Let R be a commutative ring. If $G = \langle t \rangle$ is the infinite cyclic group generated by some symbol t, then we have a ring isomorphism

$$\begin{array}{rcl} R[\langle t \rangle] & \to & R[t^{\pm 1}] \\ r \cdot t^n & \mapsto & r \cdot t^n. \end{array}$$

We use this isomorphism to identify the group ring $R[\langle t \rangle]$ with the Laurent-polynomial ring $R[t^{\pm 1}]$, which is more familiar and easier on the eyes.

Definition. Given two rings R and S we denote by $R \times S$ the ring whose underlying set is the product $R \times S$ and where addition and multiplication is defined component wise.

165.1. Modules over rings.

Definition. Let R be a ring.

(1) An R-left module is an abelian group A together with a map

$$\begin{array}{rcl} R \times A & \to & A \\ (r, a) & \mapsto & r \cdot a \end{array}$$

such that the following conditions are satisfied:

(a)	$r \cdot (a+b)$	$=$	$r \cdot a + r \cdot b$	for all $r \in R$ and $a, b \in A$,
(b)	$1 \cdot a$	$=$	a	for all $a \in A$,
(c)	$(r+s) \cdot a$	$=$	$r \cdot a + s \cdot a$	for all $r, s \in R$ and $a \in A$,
(d)	$s \cdot (r \cdot a)$	$=$	$(s \cdot r) \cdot a$	for all $r, s \in R$ and $a \in A$.

(2) An R right-module is an abelian group A together with a map

$$\begin{array}{rcl} R \times A & \to & A \\ (r, a) & \mapsto & a \cdot r \end{array}$$

such that the following conditions are satisfied:

(a)	$(a+b) \cdot r$	$=$	$a \cdot r + b \cdot r$	for all $r \in R$ and $a, b \in A$,
(b)	$a \cdot 1$	$=$	a	for all $a \in A$,
(c)	$a \cdot (r+s)$	$=$	$a \cdot r + a \cdot s$	for all $r, s \in R$ and $a \in A$,
(d)	$(a \cdot r) \cdot s$	$=$	$a \cdot (r \cdot s)$	for all $r, s \in R$ and $a \in A$.

Remark.

(1) If one is not used to dealing with R-left modules and R right-modules, then it is perhaps difficult to spot the essential difference. The fact that we write multiplication by R on the left respectively right is not essential, it is just a mnemonic device. What matter is the different given by the (c). To make the difference clear we write it out in words:

Left R-module: multipl. by r followed by multipl. by s equals multipl. by $s \cdot r$.
Right R-module: multipl. by r followed by multipl. by s equals multipl. by $r \cdot s$.

In practice the notation is set up in such a way that it should be clear what is allowed and what is not.

(2) If R is a commutative ring, then any R-module in the usual sense satisfies both conditions (1d) and (2d). In other words, if R is a commutative ring, then any R-module is automatically an R-left module and also an R right-module.

Example.

(1) Let A be an abelian group. Given $n \in \mathbb{N}$ and $a \in A$ we define

$$n \cdot a := \underbrace{a + \cdots + a}_{n \text{ times}} \qquad \text{and} \qquad -n \cdot a := \underbrace{-a - \cdots - a}_{n \text{ times}}.$$

This defines $\mathbb{Z}$-left module and $\mathbb{Z}$-right module structure on A. Thus we can, and will, view any abelian group as a $\mathbb{Z}$-left module and a $\mathbb{Z}$-right module.

(2) Let R be a ring and $n \in \mathbb{N}$. The matrices $\mathrm{M}(n \times n, R)$, with the usual addition and multiplication of square matrices form a ring. The map

$$\begin{array}{ccc} \mathrm{M}(n \times n, R) \times R^n & \to & \mathrm{M}(n \times n, R) \\ (A, v) & \mapsto & A \cdot v \end{array}$$

defines a $\mathrm{M}(n \times n, R)$-left module structure on R^n.

In the remainder of these notes we will encounter a large number of left and right modules. As of right now we only give a few simple examples.

Many of our future objects have two "compatible" modules structures at the same time. This leads us to the following definition:

Definition. Let R and S be two rings.

(1) A (R, S)-bimodule is an abelian group A together with R-left module structure and an S-right module structure, such that for any $r \in R$, any $s \in S$ and any $a \in A$ we have $r \cdot (a \cdot s) = (r \cdot a) \cdot s$.

(2) A (R, S)-left left module is an abelian group A together with a R-left module structure and an S-left module structure, such that for any $r \in R$, any $s \in S$ and any $a \in A$ we have $r \cdot (s \cdot a) = s \cdot (r \cdot a)$. The same way we define an (R, S)-right right module.

Remark. Note that an (R, S)-left left module is essentially the same as an $(R \times S)$-left module.

Examples.

(1) If R is a commutative ring, then any R-left module is automatically also an (R, R)-bimodule and an (R, R)-left module.

(2) If R is a ring, then any R-left module is also automatically an $(R, \mathbb{Z})$-bimodule and an $(R, \mathbb{Z})$-left left module. This simple observation will get used frequently.

(3) Let R be a ring and let $k \in \mathbb{N}$. Using the usual left and right multiplication we can view R^k as an (R, R)-bimodule.

(4) Let $\varphi \colon R \to S$ be a ring homomorphism. The maps

$$\begin{array}{ccc} R \times S & \to & S \\ (r, s) & \mapsto & \varphi(r) \cdot s \end{array} \qquad \text{and} \qquad \begin{array}{ccc} S \times R & \to & S \\ (s, r) & \mapsto & s \cdot \varphi(r) \end{array}$$

turn S into an R-left module and into an R right-module, these satisfy the condition of a bimodule, thus we can view S as an (R, R)-bimodule. By using these maps and multiplication by S we can also view S as an (R, S)-bimodule and an (S, R)-bimodule.

Definition. Let $\varphi\colon R \to S$ be a homomorphism between two rings and let M be an S-left module. We denote by φ^*M the R-left module that is given by

$$\begin{array}{rcl} R \times M & \to & M \\ (r, m) & \mapsto & \varphi(r) \cdot M. \end{array}$$

We use analogous notation if we are dealing with right modules, bimodules, etc. Note that, with the obvious interpretation, we have $\mathrm{id}^* M = M$ and $(\varphi \circ \psi)^* M = \psi^*(\varphi^* M)$.

165.2. Homomorphisms between modules.

Notation. Let R be a ring. We denote by ${}_R\mathcal{Mod}$ the category of R-left modules and we denote by $\mathcal{Mod}_R$ the category of R-right modules.

In this very straightforward section we collect a few very elementary definitions and statements on homomorphisms between modules.

Notation. Let R be a ring. Given two R-left modules A and B we denote by $\mathrm{Hom}_{R\text{-left}}(A, B)$ the abelian group of all R-left module homomorphisms $A \to B$. Furthermore we denote by $\mathrm{Aut}_{R\text{-left}}(A)$ the abelian group of all R-left module automorphisms of R. We define $\mathrm{Hom}_{\text{right-}R}(A, B)$ and $\mathrm{Aut}_{\text{right-}R}(A)$ in the obvious way.

Lemma 165.1. Let R and S be rings, let M be an R-left module and let N be an (R, S)-left left module. Then

$$\begin{array}{rcl} S \times \mathrm{Hom}_{R\text{-left}}(M, N) & \to & \mathrm{Hom}_{R\text{-left}}(M, N) \\ (s, \varphi) & \mapsto & (m \mapsto s \cdot \varphi(m)) \end{array}$$

is a well-defined S-left module structure. The evident variations on this statement also hold. ■

Lemma 165.2. Let R be a ring, let L, M and N be R-left modules and let $f\colon L \to M$ and $g\colon M \to N$ be R-left module homomorphisms. The maps

$$\begin{array}{rcl} f^*\colon \mathrm{Hom}_{R\text{-left}}(M, N) & \to & \mathrm{Hom}_{R\text{-left}}(L, N) \\ \varphi & \mapsto & \varphi \circ f \end{array} \quad \text{and} \quad \begin{array}{rcl} g_*\colon \mathrm{Hom}_{R\text{-left}}(L, M) & \to & \mathrm{Hom}_{R\text{-left}}(L, N) \\ \varphi & \mapsto & f \circ \varphi \end{array}$$

are both well-defined and functorial in the obvious sense. ■

Lemma 165.3. Let $f\colon R \to S$ be a ring homomorphism. Let M and N be S-left modules. We consider the corresponding R-left modules f^*M and f^*N, as defined on page 3502. The map

$$\begin{array}{rcl} f_*\colon \mathrm{Hom}_{S\text{-left}}(M, N) & \to & \mathrm{Hom}_{R\text{-left}}(f^*M, f^*N) \\ \varphi & \mapsto & \varphi \end{array}$$

is well-defined and functorial in the obvious sense. ■

165.3. Rings with involution.

In this short section we introduce rings with involution. As is clear from the color of the section, this section consists only of definitions.

Definition. Let R be a ring.

(1) An involution on R is a map $R \to R$, usually written $z \mapsto \overline{z}$, with the following properties:
   (a) $\overline{z + w} = \overline{z} + \overline{w}$ for all $z, w \in R$,
   (b) $\overline{z \cdot w} = \overline{w} \cdot \overline{z}$ for all $z, w \in R$,

(c) $\overline{\overline{z}} = z$ for all $z \in R$.

(2) A homomorphism between rings with involution is a ring homomorphisms that respects the involutions.

Convention.

(1) Unless we say something else we will view the complex numbers a ring with the usual involution $\overline{x + \mathrm{i}y} := x - \mathrm{i}y$.

(2) Let R be a ring (possibly with involution). We will view the ring of Laurent polynomials $R[t_1^{\pm 1}, \ldots, t_m^{\pm 1}]$ as a ring that is equipped with the involution that is given by the involution on R and $\overline{t_i} := t_i^{-1}$.

(3) Given a group π we will view the group ring $\mathbb{Z}[\pi]$ always as a ring with involution, where the involution is given by $\overline{g} := g^{-1}$.

Notation. Let R be a ring with involution (e.g. a group ring $\mathbb{Z}[\pi]$) and let M be an R-left module. We denote by $\overline{M}$ the R-right module that is given by $m \cdot_{\overline{M}} r := \overline{r} \cdot_M m$. We proceed in the analogous way if M is an R-right module.

Definition. Let R be a ring with involution, let M and N be R-left modules and let $f\colon M \to N$ be a map. We say that f is R-antilinear, if it is a homomorphism of abelian groups and if for any $m \in M$ and $r \in R$ we have $f(r \cdot m) = \overline{r} \cdot f(m)$.

165.4. **Free modules.** The following definition is modelled on the definition of a free abelian group that we gave on page 1148.

Definition. Let R be a ring.

(1) Let M be an R-left module. We say M is a free R-left module on a set $S \subset M$ if given any map $\phi\colon S \to N$ to an R-left module N there exists a unique homomorphism $\psi\colon M \to N$ of R-left modules that makes the following diagram commute

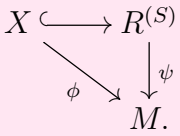
$$\begin{array}{ccc} S & \hookrightarrow & M \\ & \searrow^{\phi} & \downarrow{\scriptstyle \psi} \\ & & N. \end{array}$$

(2) We say an R-left module is free if there exists a subset $S \subset M$ such that R is a free R-left module on the set S. We refer to S also as a basis for M.

In a totally analogous fashion we also introduce the corresponding notions for R-right modules.

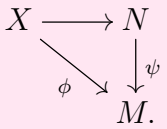
Definition. Let R be a ring. Given any set X we set

$$R^{(X)} := \text{ all maps from } X \text{ to } R \text{ which are non-zero for only finitely many } x \in X.$$



We equip $R^{(X)}$ with the obvious structure of an R-left module. We refer to $R^{(X)}$ as the free R-left module generated by X or as the free R-left module on the generating set X.

The following lemma justifies the above name.



Lemma 165.4. Let R be a ring.

(1) Let X be a set and let $\phi\colon X \to M$ be a map to an R-left module M. There exists a unique homomorphism $\psi\colon R^{(X)} \to M$ of R-left modules that makes the following

diagram commute

(2) Conversely let N be an R-left module that admits a subset X with the following universal property: given any map $\phi\colon X \to M$ to an R-left module M there exists a unique R-left module homomorphism $\psi\colon N \to M$ that makes the following diagram commute

Then N is isomorphic to $R^{(X)}$.

Proof. The proof of the lemma is basically the same as the proof of the analogous Lemma 51.1. ■

Remark.

(1) It follows immediately from the definitions that a free abelian group is basically the same as a free $\mathbb{Z}$-module.
(2) In many ways free R left/right modules are quite similar to free abelian groups. There is one major difference though. By the Subgroup-of-Free Abelian Group Lemma 51.2 (1) we know that any submodule of a free $\mathbb{Z}$-module is itself a free $\mathbb{Z}$-module. The analogous statement is in general *not true* for free R-left modules. For example, consider the ring $R = \mathbb{Z}[x]$ of polynomials. We consider the ideal $I = (2, 1 - x)$ that is generated by 2 and $1 - x$. It is a submodule of $\mathbb{Z}[x]$, which is of course a free $\mathbb{Z}[x]$-module in its own right. In Exercise 165.1 we will show that I, viewed as a $\mathbb{Z}[x]$-module, is *not free*.
(3) In Section **??** we will study the question whether the cardinality of a basis of a free module is an invariant of the free module.

In the coming chapters we will work a lot with homomorphisms between free R-left modules. One of most popular bits in linear algebra is the fact that any homomorphism between vector spaces can be represented by a matrix. The same applies in the context of homomorphisms between free R-left modules, except that one is forced to multiply by matrices *on the right*. More precisely, we have the following somewhat confusing lemma.

Lemma 165.5. Let R be a ring.

(1) If A is a $(k \times l)$–matrix over R, then the map

$$\begin{array}{ccc} R^k & \to & R^l \\ v & \mapsto & v \cdot A \\ \uparrow & & \uparrow \\ \text{viewed as row vectors} & & \end{array}$$

is a homomorphism of R-left modules.
(2) Given any homomorphism $\varphi\colon R^k \to R^l$ of R-left modules there exists a $(k \times l)$–matrix over R such that φ is given by *right* multiplication by A.

Proof. Both statements are essentially clear. The reader who is unfamiliar with dealing with non-commutative rings should think for a second about the question, why left-multiplication by A is *not* a homomorphism of R-left modules. ■

On page 1715 we defined the notion of a splitting of a short exact sequence of (not necessarily abelian) groups. We now have the analogue of modules.

Definition. Let R be a ring. We say that a short exact sequence

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

of R-left modules splits, if there exists a splitting $s\colon C \to B$, i.e. an R-left module homomorphism $s\colon C \to B$ such that $p \circ s = \mathrm{id}_C$.

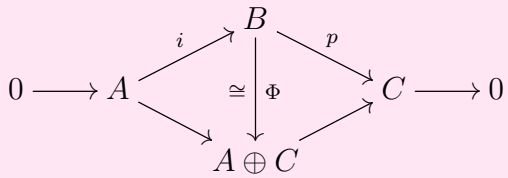
The following lemma is a generalization of Lemma 78.1.

Lemma 165.6. Let R be a ring and let

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of R-left modules. If C is a free R-left module, then the short exact sequence splits as a sequence of R-left modules.

Proof. The proof is basically the same as the proof of Lemma 78.1. ■



We continue with the following variation on the Splitting Lemma 78.2.

Lemma 165.7. (Splitting Lemma for Rings) Let R be a ring and let

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of R-left modules. The following three statements are equivalent:

(1) There exists a homomorphism of R-left modules$t\colon B \to A$ such that $t \circ i = \mathrm{id}_A$.
(2) There exists an isomorphism $\Phi\colon B \to A \oplus C$ of R-left modules such that the following diagram commutes:

where the lower left diagonal map is the obvious inclusion and the lower right diagonal map is the natural projection.
(3) The short exact sequence splits.

Proof. The proof is a mild variation on the proof of the Splitting Lemma 78.2. We leave the details to the reader. ■

Lemma 165.8. Let R and S be rings and let

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of S-left modules and let M be an (S, R)-left left module. If the short exact sequence splits (by Lemma 165.6 this holds if C is a free S-left module), then

$$0 \to \mathrm{Hom}_{S\text{-left}}(C, M) \xrightarrow{i^*} \mathrm{Hom}_{S\text{-left}}(B, M) \xrightarrow{p^*} \mathrm{Hom}_{S\text{-left}}(A, M) \to 0$$

is also a short exact sequence of R-left modules and it also splits as a short exact sequence of R-left modules.

Proof. The proof is almost identical to the proof of the Tensor-Split-SES Lemma 89.6. ■

165.5. **Modules over group rings I. Basics.** On page 248 we introduced the notion of an action of a group G on a set X. Since we are now carefully distinguish between left and right module structures it is worth renaming the notion of an left action as a "left-action".

Definition. Let X be a set and let G be a group with trivial element e.

(1) A left action of G on X is a map

$$\begin{array}{rcl} G \times X & \to & X \\ (g, x) & \mapsto & g \cdot x \end{array}$$

with the following properties

$$\begin{array}{rcll} e \cdot x & = & x, & \text{for all } x \in X, \\ g \cdot (h \cdot x) & = & (g \cdot_G h) \cdot x, & \text{for all } x \in X \text{ and } g, h \in G. \end{array}$$

($g \cdot (h \cdot x)$: $g \cdot$ group action, $h \cdot x$ group action; $g \cdot_G h$: multiplication in the group G)

A right action is defined in the hopefully obvious way.

(2) The left action is called free, if $g \cdot x = x$ for some $x \in X$ implies that $g = e$.

(3) We say G acts transitively, if for every x and y in X there exists a $g \in G$ with $g \cdot x = y$.

For modules over group rings we recall the following lemma.

Lemma 86.13. Let G be a group. Let A be an abelian group (with additive notation for the group structure). Suppose we are given a homomorphism

$$\varphi \colon G \to \mathrm{Aut}(A),$$

then the map

$$\begin{array}{rcl} \mathbb{Z}[G] \times A & \to & A \\ \left(\sum_{i=1}^m r_i \cdot g_i, a \right) & \mapsto & \sum_{i=1}^m r_i \cdot \underbrace{\varphi(g_i)(a)}_{\in A} \end{array}$$

defines a natural $\mathbb{Z}[G]$-left module structure on A.

Notation. In the setting of Lemma 86.13 we denote the corresponding $\mathbb{Z}[G]$-left module by ${}_\varphi A$.

Example. Let G be a group and let S be a set together with a G-left action. The map

$$\begin{array}{rcl} G \times \mathbb{Z}^{(S)} & \to & \mathbb{Z}^{(S)} \\ \left(g, \sum_{i=1}^k n_i \cdot s_i \right) & \mapsto & \sum_{i=1}^k n_i \cdot \underbrace{(g \cdot s_i)}_{\in S} \end{array}$$

defines a G- left action on the abelian group $\mathbb{Z}^{(S)}$. It follows from Lemma 86.13 that $\mathbb{Z}^{(S)}$ inherits a $\mathbb{Z}[G]$-left module structure in a natural way.

[2050] If the left action is continuous, then the map $x \mapsto g \cdot x$ is in fact a homeomorphism with inverse map given by $x \mapsto g^{-1} \cdot x$.

Definition. Let G be a group and let R be a ring. Given an R-left module M we denote by ${}_{\text{tr}}M$ the $(\mathbb{Z}[G], R)$-left left module where the $\mathbb{Z}[G]$-left module structure is given by the trivial g-action $g \cdot m := m$ for each $g \in G$ and $m \in M$.

We continue with a more interesting example.

Definition. Let G be a group and let R be a ring.

(1) Let M be an R-left module and let $\varphi\colon G \to \mathrm{Aut}_{R\text{-left}}(M)$ be a representation. We use this representation to define a $\mathbb{Z}[G]$-left module structure on M via $g \cdot m := \varphi(g)(m)$. We denote by ${}_{\varphi}M$ this $\mathbb{Z}[G]$-left module. Note that the two modules structures combine to define an $(\mathbb{Z}[G], R)$-left left module structure on ${}_{\varphi}M$.

(2) Let $\alpha\colon G \to \mathrm{GL}(n, R)$ be a homomorphism. We consider[2051]
$$\begin{array}{rcl} G \times R^n & \to & R^n \\ g \cdot \underbrace{(v_1, \ldots, v_n)}_{\text{row vector}} & \mapsto & \underbrace{(v_1, \ldots, v_n)}_{\text{row vector}} \cdot \alpha(g^{-1}). \end{array}$$
We view R^n as an R-left module in the obvious ways. The above left action defines a representation $G \to \mathrm{Aut}_{R\text{-left}}(R^n)$. We denote the corresponding $(\mathbb{Z}[G], R)$-left left module by ${}_{\alpha}R^d$.

(3) The case $n = 1$ corresponds to a ring homomorphism $\alpha\colon \mathbb{Z}[G] \to R$. In this case the left-multiplication by g is defined as $g \cdot r := r \underset{R}{\cdot} \alpha(g^{-1})$. We denote the corresponding $(\mathbb{Z}[G], R)$-left left module by ${}_{\alpha}R$.

The next lemma gives us a much interesting source for free modules.

Definition. Suppose that a group G admits a left action on a set S. We say $T \subset S$ is a complete set of representatives if given any $s \in S$ there exists a unique $t \in T$ such that $s = g \cdot t$.

Lemma 165.9. Let G be a group and let S be a set together with a G-left action. We suppose that the left action of G on S is free. If $T \subset S$ is a complete set of representatives[2052], then $\mathbb{Z}^{(S)}$ is a free $\mathbb{Z}[G]$-left module with generating set T.

Example. In this section figures are few and far between, so let us take this opportunity to look at one pictorial example. We consider the set $S = \mathbb{Z} \times \{A, B, C, D\}$ with the obvious $\mathbb{Z}$-action. This left action is free. There are many choices of complete sets of representatives.

Proof. Let $T \subset S$ be a complete set of representatives of the G-action on S. Recall that the hypothesis that the left action of G on S is free means that if $g \cdot s = s$ for some $s \in S$, then $g = e$. It follows easily from the axioms of an left action that this translates into the statement that given any $s, t \in S$ with $[s] = [t]$ where exists a *unique* $g \in G$ with $g \cdot s = t$.

[2051] The convention that we act on row vectors by right multiplication $\alpha(g)^{-1}$ might initially come as a surprise. But it is forced on us if we want to get an R-left module isomorphism. The case of a non-commutative ring R will occur naturally later on, for example in Proposition 168.2.

[2052] It follows from the Axiom of Choice 0.1 that such a T always exists.

Now let N be a $\mathbb{Z}[G]$-left module and let $\phi\colon T \to N$ be any map. We extend ϕ to a map $\widetilde{\phi}\colon S \to N$ as follows:

$$\begin{array}{rcl} \widetilde{\phi}\colon S & \to & N \\ s & \mapsto & g \cdot \phi(t) \text{ where } [t] = [s] \text{ and where } g \in G \text{ is} \\ & & \qquad \text{the unique element with } g \cdot t = s. \end{array}$$

By the definition of a free abelian group there exists a unique homomorphism $\psi\colon \mathbb{Z}^{(S)} \to N$ of abelian groups that makes the following diagram commute:

$$\begin{array}{ccc} S & \longrightarrow & \mathbb{Z}^{(S)} \\ & \searrow^{\widetilde{\phi}} & \downarrow \psi \\ & & N. \end{array}$$

We need to show that ψ is in fact a homomorphism of $\mathbb{Z}[G]$-left modules. Note that one can easily verify that for any $s \in S$ and any $g \in G$ we have $\psi(g \cdot s) = g \cdot \psi(s)$. Since S is a generating set for $\mathbb{Z}^{(S)}$ as an abelian group we see that $\psi\colon \mathbb{Z}^{(S)} \to N$ is in fact a homomorphism of $\mathbb{Z}[G]$-left modules.

The proof of the fact that ψ is unique can be reduced, with the same arguments as above, to the uniqueness of the homomorphism $\mathbb{Z}^{(S)} \to N$ of abelian groups. We leave it to the reader to fill in the details. ■

We continue with the following slight generalization of Lemma 86.13.

Lemma 165.10. Let G be a group. Let R be a ring and let A be an R-left module and suppose we are given a homomorphism

$$\varphi\colon G \to \mathrm{Aut}_{R\text{-left}}(A).$$

Then the map

$$\begin{array}{rcl} \mathbb{Z}[G] \times A & \to & A \\ \left(\sum_{i=1}^m r_i \cdot g_i, a\right) & \mapsto & \sum_{i=1}^m r_i \cdot \varphi(g_i)(a), \end{array}$$

together with the given R-left module structure defines a natural $(\mathbb{Z}[G], R)$-left left module structure on A.

165.6. Modules over group rings II: Finite dimensional representations.

Definition. Let π be a group, let R be a ring and let M be an R-left ring.

(1) An R-representation of π is a homomorphism $\alpha\colon \pi \to \mathrm{Aut}_{R\text{-left}}(M)$.
(2) If $R = \mathbb{Z}$, $R = \mathbb{Q}$, $R = \mathbb{R}$ or $R = \mathbb{C}$, then we also say integral, rational, real or complex representation.

(3) If R is a field and M is d-dimensional, then we say that α is a d-dimensional representation. If $d < \infty$, then we call the representation finite dimensional.

We camouflage our first example as a definition.

Definition. Let π be a group and let R be a commutative ring. The representation

$$\begin{array}{rcl} \pi & \to & \mathrm{Aut}_{R\text{-left}}(R[\pi]) \\ g & \mapsto & (f \mapsto f \cdot g^{-1}) \end{array}$$

is called the R-regular representation of π.

Definition. Let π be a group and let R be a ring.

(1) A representation of $\alpha\colon \pi \to \mathrm{Aut}_R(M)$ is called reducible, if M admits an R-submodule N with $0 \subsetneq N \subsetneq M$ such that π preserves M. Otherwise we say that the representation is irreducible.

(2) Given two representations $\alpha\colon \pi \to \mathrm{Aut}_R(M)$ and $\beta\colon \pi \to \mathrm{Aut}_R(N)$ we define the direct sum of the two representations as follows:

$$\begin{array}{rcl} \alpha \oplus \beta\colon \pi & \to & \mathrm{Aut}_R(M \oplus N) \\ g & \mapsto & (m \oplus n \mapsto \alpha(g) \cdot m \oplus \alpha(g) \cdot n)). \end{array}$$

(3) A representation of π that is the direct sum of irreducible representations is called semisimple

Example.

(1) We consider the representation

$$\begin{array}{rcl} \pi = \mathbb{Z} & \to & \mathrm{GL}(2, \mathbb{C}) \\ n & \mapsto & \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix} \end{array}$$

This representation is reducible, since $N = \{(z, 0) \,|\, z \in \mathbb{C}\}$ is preserved by π. But one can easily show that the representation is not semisimple.

(2) Let G be a finite group and let R be a commutative ring. The submodule

$$R \cdot \sum_{g \in G} g$$

is preserved by G. Thus we see that if G is a non-trivial group, then the R-regular representation of G is reducible.

Proposition 165.11. If π is an abelian group, then every complex representation $\pi \to \mathrm{Aut}_{\mathbb{C}}(M)$ of dimension ≥ 2 is reducible.

Proof. Let π be an abelian group and let $\varphi\colon \pi \to \mathrm{Aut}_{\mathbb{C}}(M)$ be a finite-dimensional complex representation. Given $g \in \pi$, $\lambda \in \mathbb{C} \setminus \{0\}$ and $N \subset M$ we set

$$E^N_{g,\lambda} \;:=\; \{v \in N \,|\, \varphi(g)(v) = \lambda \cdot v\}.$$

We start out with two claims.

Claim 1. Let $g \in \pi$ and let $N \subset M$ be a non-zero complex vector subspace with $\varphi(g)(N) \subset N$. Then there exists a $\lambda \in \mathbb{C} \setminus \{0\}$ with $E^N_{g,\lambda} \neq 0$.

Proof. Let

$$p(t) \ := \ \det(\varphi(g) - t \cdot \mathrm{id}_N)$$

be the characteristic polynomial. This is a polynomial with $\deg(p(t)) = \dim_{\mathbb{C}}(N) > 0$. By the Fundamental Theorem of Algebra 26.3, which we proved multiple times, the polynomial has a zero $\lambda \in \mathbb{C}$. Elementary linear algebra shows that $E^N_{g,\lambda} \neq 0$. Since $\varphi(g)$ is an automorphism we see that $\lambda \neq 0$. ⊞

Claim 2. Given any $g, h \in \pi$ and $\lambda \in \mathbb{C}$ we have $\varphi(h)(E^N_{g,\lambda}) \subset E^N_{g,\lambda}$.

Proof. Let $v \in E^N_{g,\lambda}$. Then

$$\begin{array}{ccccccc} & & \text{since } \varphi \text{ is a representation} & & \text{since } \pi \text{ is abelian} & & \text{since } \varphi \text{ is a representation} \\ \varphi(g)(\varphi(h)(v)) & \overset{\downarrow}{=} & \varphi(g \cdot h)(v) & \overset{\downarrow}{=} & \varphi(h \cdot g)(v) & \overset{\downarrow}{=} & \varphi(h)(\varphi(g)(v) \\ & = & \varphi(h)(\lambda \cdot v) & = & \lambda \cdot \varphi(h)(v). & & \\ & & \uparrow & & \uparrow & & \\ & & \text{since } \lambda \in E^N_{g,\lambda} & & \text{since } \varphi(h) \in \mathrm{Aut}_{\mathbb{C}}(M) & & \end{array}$$

This shows that $\varphi(h)(v) \in E^N_{g,\lambda}$. ⊞

If there exists a $g \in \pi$ and a $\lambda \in \mathbb{C} \setminus \{0\}$ with $0 < \dim_{\mathbb{C}}(E^N_{g,\lambda}) < \dim_{\mathbb{C}}(M)$ then it follows from Claim 2 that $E^N_{g,\lambda}$ is a vector subspace that is preserved by π. Thus we have shown that the representation is reducible.

Otherwise each $\varphi(g)$ acts by multiplication by some $\lambda(g) \in \mathbb{C} \setminus \{0\}$. Thus we see that each vector subspace is preserved by π. Since $\dim_{\mathbb{C}}(M) \geq 2$ we see that the representation is reducible. ■

165.7. **The tensor product over rings.** On page 1907 we introduced the tensor product of two abelian groups. In this section we will introduce the tensor product of modules over a given ring R.

The following definition is an almost shameless copy-paste from page 1907.

Definition. Let R be a ring, let A be a right R-module and let B be a left R-module. We define the tensor product $A \otimes_R B$ as follows:

$$A \otimes_R B \ := \ \left\{ \begin{array}{l} \text{free abelian group which is generated by all} \\ \text{symbols of the form } a \otimes b \text{ with } a \in A,\ b \in B \end{array} \right\} / \, N(A, B)$$

where $N(A, B)$ is the subgroup generated by the elements of the form

$$\begin{array}{lll} \text{(i)} & (a + a') \otimes b - (a \otimes b + a' \otimes b) & \text{with } a, a' \in A \text{ and } b \in B, \\ \text{(ii)} & a \otimes (b + b') - (a \otimes b + a \otimes b') & \text{with } a \in A \text{ and } b, b' \in B, \\ \text{(iii)} & a \cdot r \otimes b - a \otimes r \cdot b & \text{with } a \in A, b \in B \text{ and } r \in R. \end{array}$$

For $a \in A$ and $b \in B$ we denote, by a slight abuse of notation, the image of $a \otimes b$ in $A \otimes B$ again by $a \otimes b$.

Remark.

(1) Note that in the notation we use the subscript R to denote the tensor product $A \otimes_R B$. To simplify the subsequent notation, given elements $a \in A$ and $b \in B$ we write $a \otimes b$ instead of the more logical $a \otimes_R b$. It should be clear from the context what we mean.

(2) We consider the case that $R = \mathbb{Z}$. Any abelian group is a $\mathbb{Z}$-module, in particular, any abelian group is a $\mathbb{Z}$-left module and a $\mathbb{Z}$-right module. It follows immediately

from Lemma 165.12 (2) that we have an equality

$$\underbrace{A \otimes_{\mathbb{Z}} B}_{\substack{\text{tensor product} \\ \text{of modules}}} = \underbrace{A \otimes B.}_{\substack{\text{tensor product of} \\ \text{abelian groups}}}$$

(3) In Exercise **??** we will discuss the question whether it makes sense to define the tensor product if we are given say two R-right modules.

We summarize some elementary properties of the tensor product in the following lemma.

Lemma 165.12. Let R be a ring, let A be an R-right module and let B be an R-left module.

(1) For any $a, a' \in A$ and $b, b' \in B$ we have

$$\begin{aligned} (a + a') \otimes b &= a \otimes b + a' \otimes b \in A \otimes_R B \\ a \otimes (b + b') &= a \otimes b + a \otimes b' \in A \otimes_R B. \end{aligned}$$

(2) For any $a \in A, b \in B$ and any $r \in R$ we have

$$(a \cdot r) \otimes b = a \otimes (r \cdot b).$$

(3) Any element in $A \otimes_R B$ is of the form $\sum_{i=1}^{n} a_i \otimes b_i$.

Proof. The statements are basically just notationally convenient equalities that follow immediately from the definition of the tensor product $A \otimes_R B$. ■

The tensor product can be characterized by the following universal property.

Lemma 165.13. Let R be a ring, let A be an R-right module and let B be an R-left module.

(1) The homomorphism

$$\begin{aligned} \mu \colon A \times B &\to A \otimes_R B \\ (a, b) &\mapsto a \otimes b \end{aligned}$$

has the property that for any $a \in A, b \in B$ and $r \in R$ we have $\mu(a \cdot r, b) = \mu(a, r \cdot b)$.

(2) Given any homomorphism $\varphi \colon A \times B \to Y$ of abelian groups with the property that for any $a \in A, b \in B$ and $r \in R$ we have $\varphi(a \cdot r, b) = \varphi(a, r \cdot b)$ there exists a *unique* homomorphism $\psi \colon A \otimes_R B \to Y$ of abelian groups such that the following diagram commutes:

$$\begin{array}{ccc} A \times B & \xrightarrow[\mu]{(a,b) \mapsto a \otimes b} & A \otimes_R B \\ & \searrow^{g} & \downarrow \psi \text{ unique} \\ & & Y. \end{array}$$

(3) If Y is an abelian group and $\nu \colon A \times B \to Y$ is a homomorphism that satisfies (1) and (2), then there exists an isomorphism $\Theta \colon Y \to A \otimes_R B$ with $\nu = \mu \circ \Theta$.

Proof. One can easily verify that $\psi(a \otimes b) := \varphi(a, b)$ defines a homomorphism that makes the diagram commute and that it is uniquely determined. ■

For completeness' sake we state the following analogue of Lemma 165.1.

Lemma 165.14. Let R and S be rings, let A be an (S,R)-bimodule and let B be an R-left module. Then

$$\begin{array}{rcl} S \times A \otimes_R B & \to & A \otimes_R B \\ (s, a \otimes b) & \mapsto & (s \cdot a) \otimes b \end{array}$$

is a well-defined R-left module structure. The evident variations on this statement also hold. ■

Lemma 165.15. Let S be a ring.

(1) Let $f\colon A \to A'$ a homomorphism of S-right modules and let $g\colon B \to B'$ be a homomorphism of S-left modules. The map

$$\begin{array}{rcl} f \otimes g\colon A \otimes_S B & \to & A' \otimes_S B' \\ \sum_{i=1}^m a_i \otimes b_i & \to & \sum_{i=1}^m f(a_i) \otimes g(b_i) \end{array}$$

is well-defined and it is a homomorphism of abelian groups. If R is a ring and $f\colon A \to A'$ is a homomorphism of (R,S)-bimodules, then the above map $f \otimes g$ is a homomorphism of R-left modules. Obvious variations on this observation also hold.

(2) Let $f\colon A \to A'$ and $f'\colon A' \to A''$ be two homomorphisms of S-right modules and let $g\colon B \to B'$ and $g'\colon B' \to B''$ be homomorphisms of S-left modules. Then we have

$$(f' \otimes g') \circ (f \otimes g) \;=\; (f' \circ f) \otimes (g' \otimes g).$$

(3) Given an S-right module A the maps

$$B \mapsto A \otimes_S B \quad \text{and} \quad (f\colon B \to B') \mapsto (\mathrm{id} \otimes f\colon A \otimes_S B \to A \otimes_S B')$$

form a functor from the category ${}_S\mathcal{M}od$ of S-left modules to the category $\mathcal{A}b\mathcal{G}roup$ of abelian groups.

(4) The analogous statement as in (3) holds if we start out with an S-left module B.

Proof. We leave it to the reader to verify the statements. ■

The following lemma is a crucial example for the tensor product.

Lemma 165.16. Let R and S be rings. Let A be an (R,S)-bimodule and let B be an S-left module. We view S as S-left module and as an S-right module where the module structure is given by left respectively right multiplication. The maps

$$(1) \quad \begin{array}{rcl} A \otimes_S S & \to & A \\ \sum_{i=1}^n a_i \otimes r_i & \mapsto & \sum_{i=1}^n a_i \cdot r_i \end{array} \qquad \text{and} \qquad (2) \quad \begin{array}{rcl} S \otimes_S B & \to & B \\ \sum_{i=1}^n r_i \otimes b_i & \mapsto & \sum_{i=1}^n r_i \cdot b_i \end{array}$$

are well-defined and they are natural isomorphisms of (R,S)-bimodules.

Proof. Let us show that the map (1) is in fact well-defined. By Lemma 51.1 there exists a unique homomorphism

$$\Phi\colon \text{free abelian group generated by all symbols } a \otimes r \;\to\; A, \quad a \otimes r \mapsto a \cdot r.$$

of abelian groups that satisfies

We need to show that all the elements of the types (i), (ii) and (iii) as defined on page 3510 lie in the kernel of Φ. For (i) and (ii) that is basically obvious. We consider (iii) in slightly

more detail. Let $a \in A$, let $s \in S$ and let $s \in S$. We have

$$\Phi(a \cdot r \otimes s - a \otimes r \cdot s) \underset{\text{since } \Phi \text{ is a homomorphism of abelian groups}}{=} \Phi(a \cdot r \otimes s) - \Phi(a \otimes r \cdot s) \underset{\text{by definition of } \Phi \text{ and since we view } S \text{ as a left } S\text{-module via left multiplication}}{=} (a \cdot r) \cdot s - a \cdot (r \cdot s) \underset{\text{since } A \text{ is a } S\text{-right module}}{=} 0.$$

This shows that the map (1) is in fact well-defined. We leave it to the reader to verify that an inverse is given by map

$$\begin{array}{ccc} A & \to & A \otimes_S S \\ a & \mapsto & a \otimes 1. \end{array}$$

Basically the same argument also shows that the map (2) is a well-defined isomorphism. ■

On many occasions we will also make use of the following lemma which is a partial analogue of the Tensor Lemma 89.3.

Lemma 165.17. Let R be a ring. Let A and $\{A_i\}_{i \in I}$ be R-left modules and let B and $\{B_i\}_{i \in I}$ be R-right modules.

(1) The maps

$$\begin{array}{ccc} \left(\bigoplus_{i \in I} A_i\right) \otimes_R B & \to & \bigoplus_{i \in I} A_i \otimes_R B \\ \left(\sum_{i=1}^n a_i\right) \otimes b & \mapsto & \sum_{i=1}^n a_i \otimes b \end{array} \quad \text{and} \quad \begin{array}{ccc} A \otimes_R \left(\bigoplus_{i \in I} B_i\right) & \to & \bigoplus_{i \in I} A_i \otimes_R B \\ a \otimes \left(\sum_{i=1}^n b_i\right) & \mapsto & \sum_{i=1}^n a \otimes b_i \end{array}$$

are well-defined and they are natural isomorphisms.

(2) Suppose $(I, \leq)$ is an ordered set and $(\{A_i\}_{i \in I}, \{\varphi_{ij}\}_{i \leq j})$ is a direct system of R-left modules, then

$$\varinjlim (A_i \otimes_R B) = \left(\varinjlim A_i\right) \otimes_R B.$$

Proof. The proof is basically the same as the proof of the Tensor Lemma 89.3. ■

Remark. In Lemma 165.17 we saw that the tensor product commutes with forming direct sums. Note that in Exercise 89.11 we already saw that tensor products, even just over the ring $R = \mathbb{Z}$, do not commute with forming direct products.

The following lemma is an analogue of Lemma 165.8.

Lemma 165.18. Let R and S be rings and let

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of S-left modules and let M be an (R, S)-bimodule. If the short exact sequence splits as an exacts sequence of S-left modules (by Lemma 165.6 this is the case if C is a free S-left module), then

$$0 \to M \otimes_S A \xrightarrow{\mathrm{id} \otimes i} M \otimes_S B \xrightarrow{\mathrm{id} \otimes p \otimes} M \otimes_S C \to 0$$

is also a short exact sequence and it also splits.

Proof. The proof is almost identical to the proof of the Tensor-Split-SES Lemma 89.6. ■

Lemma 165.19. Let $\varphi\colon R \to S$ be a ring homomorphism, let A be an S-right module and let B be an S-left module. As explained on page 3502 we obtain, via φ, an R-right

module φ^*A and an R-left module φ^*B. With these conventions the map

$$\begin{array}{rcl} \varphi^*A \otimes_R \varphi^*B & \to & A \otimes_S B \\ a \otimes b & \mapsto & a \otimes b \end{array}$$

is well-defined. ■

Lemma 165.20. Let $\varphi\colon R \to S$ be a ring homomorphism, let M be an S-right module and let N be an R-left module. The maps[2053]

$$\begin{array}{rcl} M \otimes_S (S \otimes_R N) & \to & \varphi^*M \otimes_R N \\ (m \otimes (s \otimes n)) & \mapsto & m \cdot s \otimes n \end{array} \quad \text{and} \quad \begin{array}{rcl} \varphi^*M \otimes_R N & \to & M \otimes_S (S \otimes_R N) \\ m \otimes n & \mapsto & m \otimes (1 \otimes n) \end{array}$$

are well-defined and inverses of one another, in particular they are both isomorphism. ■

Lemma 165.21. Let R be a ring and let $\varphi\colon R \to S$ be a ring homomorphism. We use this ring homomorphism to view S as an R-right module.

(1) For any $k \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} S \otimes_R R^k & \to & S^k \end{array}$$

that is determined by

$$\begin{array}{rcl} s \otimes (r_1, \ldots, r_k) & \mapsto & (s \cdot \varphi(r_1), \ldots, s \cdot \varphi(r_k)) \end{array}$$

is an isomorphism.

(2) Let X be a set. The map

$$\begin{array}{rcl} S \otimes_R R^{(X)} & \to & S^{(X)} \end{array}$$

that is determined by

$$\begin{array}{rcl} \sum_{i=1}^n s_i \otimes (r_i \cdot x_i) & \mapsto & \sum_{i=1}^n (s_i \cdot \varphi(r_i)) \cdot x_i \end{array}$$

is an isomorphism. If T is a ring and M is a (T,S)-bimodule, then the obvious map

$$\begin{array}{rcl} M \otimes_R R^{(X)} & \to & \varphi^*M \otimes_S S^{(X)} \end{array}$$

is an isomorphism.

(3) Let $A = (a_{ij})$ be a $k \times l$–matrix over R. If we write $\varphi(A) := (\varphi(a_{ij}))$, then the following diagram commutes[2054]

$$\begin{array}{ccc} S \otimes_R R^k & \xrightarrow{v \mapsto v \cdot A} & S \otimes_R R^l \\ \cong \downarrow & & \downarrow \cong \\ S^k & \xrightarrow{w \mapsto \varphi(A) \cdot w} & S^l. \end{array}$$

(4) Let R be a ring and let M free R-left module on a set X. If $\varphi\colon R \to S$ is a ring homomorphism, then $S \otimes_R M$ is a free S-left module on the set $\{1 \otimes x\}_{x \in X}$.

[2053]Here we view S as an (S,R)-bimodule, thus by Lemma 165.14 we can view $S \otimes_R N$ as an S-left module to define the tensor product $M \otimes_S (S \otimes_R N)$.

[2054]The vertical isomorphisms are of course the natural maps defined in (2).

Lemma 165.22. Let $\varphi: R \to S$ be a ring homomorphism, let be an S-left module and let M be an S-left module. The map

$$\begin{array}{rcl} \mathrm{Hom}_{R\text{-left}}(R \otimes_S C, \varphi^* M) & \to & \mathrm{Hom}_{S\text{-left}}(C, M) \\ \gamma & \mapsto & (c \mapsto \gamma(1_R \otimes c)) \end{array}$$

is well-defined. If C is a free S-left module, then the above map is in fact an isomorphism.

Remark. In Exercise 165.3 we will see that in general the conclusion of Lemma 165.22 does not hold, if C is not a free S-left module.

Proof. One can easily verify that the map is well-defined. If C is a free S-left module, then using Lemma 165.21 (2) and using the definition of a free module one can easily verify that the map is an isomorphism. ■

Finally in many cases we will be interested in the tensor product over a group ring. The following elementary lemma simplifies the discussion of such tensor products a little bit.

Lemma 165.23. Let π be a group, R be a ring, let M be a $(R, \mathbb{Z}[\pi])$-bimodule and let N be a $\mathbb{Z}[\pi]$-left module. The map

$$\begin{array}{rcl} M \otimes_{\mathbb{Z}} \mathbb{Z} \Big/ \left\{ \begin{array}{l} \text{subgroup of } M \otimes_{\mathbb{Z}} N \text{ generated by the elements} \\ m \cdot g \otimes n - m \otimes g \cdot n \text{ with } m \in M, n \in N, g \in \pi \end{array} \right\} & \to & M \otimes_{\mathbb{Z}[\pi]} N \\ [m \otimes n] & \mapsto & m \otimes n \end{array}$$

is a natural isomorphism of R-left modules.

Proof. The proof follows easily from the definitions and is left to the reader. ■

Lemma 165.24. Given any group π and given any $\mathbb{Z}[\pi]$-left module M the maps

$$\begin{array}{rcl} M \otimes_{\mathbb{Z}} {}_{\mathrm{tr}}\mathbb{Z} & \to & M \\ m \otimes n & \mapsto & n \cdot m \end{array} \quad \text{and} \quad \begin{array}{rcl} {}_{\mathrm{tr}}\mathbb{Z} \otimes_{\mathbb{Z}} M & \to & M \\ n \otimes m & \mapsto & n \cdot m \end{array}$$

are natural isomorphisms of $\mathbb{Z}[\pi]$-left modules.

Proof. The lemma can be proved easily, say using Lemma 165.23. ■

165.8. Modules over skew fields and PIDS.

Definition. A ring R is called a principal ideal domain (PID) if R is commutative[2055] and if every ideal of R is generated by a single element.

The following theorem generalizes the Subgroup-of-Free Abelian Group Lemma 51.2 (1).

Theorem 165.25. Let R be a PID. Every submodule of a free R-module is again free.

Proof. This theorem is proved in [**Rot2002**, Theorem 8.9]. ■

We now introduce skew fields. In most applications the skew fields we use are in fact just ordinary fields. On the other hand, it costs little to generalize to skew fields and working with (possibly) non-commutative skew fields actually makes some of the future arguments clearer since it prevents us from using "accidents" in the commutative setting, e.g. the fact that over a commutative ring every left-module is automatically a right module.

Definition.

[2055] One could also define a non-commutative analogue of PIDs, but we will refrain from doing so.

(1) A skew field is a ring $\mathbb{K}$ such that given any $a \in \mathbb{K}$ there exist $x, y \in \mathbb{K}$ with $a \cdot x = y \cdot a = 1$.[2056]
(2) If $\mathbb{K}$ is a skew field, then we refer to a $\mathbb{K}$-left module also as a $\mathbb{K}$-left vector space.

As we will see, many results of modules over fields (i.e. commutative skew fields) generalize in a suitable sense to modules over skew fields.

Proposition 165.26. Let $\mathbb{K}$ be a skew field.

(1) Every $\mathbb{K}$-left module M is a free $\mathbb{K}$-left module.
(2) Every epimorphism $\varphi\colon M \to N$ of $\mathbb{K}$-left modules admits a left inverse $s\colon N \to M$.
(3) Every submodule A of a $\mathbb{K}$-left module M is a summand, i.e. there exists another submodule B such that $M = A \oplus B$.
(4) Every $\mathbb{K}$-left module M has a uniquely defined dimension $\dim_{\mathbb{K}}(M) \in \mathbb{N}_0 \cup \{\infty\}$.
(5) Let $\varphi\colon M \to N$ be a $\mathbb{K}$-module homomorphism between two $\mathbb{K}$-left modules of the same finite dimension. Then the following are equivalent:
  (a) φ is an isomorphism,
  (b) φ is a monomorphism,
  (c) φ is an epimorphism.
(6) Every short exact sequence $0 \to A \to B \to C \to 0$ of $\mathbb{K}$-left modules splits and we have the equality $\dim_{\mathbb{K}}(B) = \dim_{\mathbb{K}}(A) + \dim_{\mathbb{K}}(C)$.

Proof. We leave it to the reader to dig out their books on linear algebra and verify that in the proofs of the corresponding statements over fields one never really needed to use that fields are commutative. ■

Exercises for Chapter 165.

Exercise 165.1.

(a) We consider the ring $R = \mathbb{Z}[x]$ of polynomials and we consider the ideal $I = (2, 1-x)$ that is generated by 2 and $1 - x$. Show that I is not a free $\mathbb{Z}[x]$-module.
(b) Show that the Laurent polynomial ring $R = \mathbb{Z}[x^{\pm 1}]$ admits submodules that are not free.

Exercise 165.2. Let R be a ring, let M be an R-left module let G be a group, let H be a subgroup of G and let $\varphi\colon H \to \mathrm{Aut}_{R\text{-left}}(M)$ a representation. We view $\mathbb{Z}[G]$ as a $(\mathbb{Z}[G], \mathbb{Z}[H])$-bimodule in the obvious way. We consider the tensor product

$$\mathrm{Ind}_H^G M \ := \ \mathbb{Z}[G] \otimes_{\mathbb{Z}[H]} M$$

which is a $\mathbb{Z}[G]$-left module and thus also a representation of G, which is called the *induced representation*.

(a) Show that if R is a skew field, then $\dim_{\mathbb{K}}(\mathbb{Z}[G] \otimes_{\mathbb{Z}[H]} M) = [G : H] \cdot \dim_{\mathbb{K}}(M)$.
(b) A representation of a group is called *faithful* if it is a monomorphism. Show that if M is a faithful representation of H, then $\mathrm{Ind}_H^G M$ is a faithful representation of G.

Exercise 165.3. We consider the polynomial ring $\mathbb{Q}[x]$.

[2056] If such that x, y exist, then as always $x = y$. Indeed, we have $x = 1 \cdot x = (y \cdot a) \cdot x = y \cdot (a \cdot x) = y \cdot 1 = y$.

(a) Given a polynomial $p(x) \in \mathbb{Q}[x]$ we view $\mathbb{Q}[x]/(p(x))$ as a $\mathbb{Q}[x]$-module in the obvious way. Show that the map

$$\begin{array}{rcl} \mathbb{Q} \otimes_{\mathbb{Q}[x]} \mathbb{Q}[x]/(p(x)) & \to & \mathbb{Q}/(p(1)) \\ n \otimes [f(x)] & \mapsto & n \cdot f(1) \end{array}$$

is an isomorphism.

(b) We consider the ring homomorphism $\varphi\colon \mathbb{Q} \to \mathbb{Q}[x]$ that is given by the inclusion and we consider the $\mathbb{Q}[x]$-modules $C := \mathbb{Q}[x]/(1-x)$ and $M := \mathbb{Q}[x]/(1+x)$. Show that the map

$$\begin{array}{rcl} \mathrm{Hom}_{\mathbb{Q}}(\mathbb{Q} \otimes_{\mathbb{Q}[x]}, \varphi^* M) & \to & \mathrm{Hom}_{\mathbb{Q}[x]}(C, M) \\ \gamma & \mapsto & (c \mapsto \gamma(1_{\mathbb{Q}} \otimes c)) \end{array}$$

is not an isomorphism.

Remark. This shows that in Lemma 165.22 we cannot drop the hypothesis that the module C is a free $\mathbb{Q}[x]$-module.

166. Homological algebra over rings

166.1. **Chain complexes over rings.** In this section we generalize the theory of chain complexes of abelian groups to chain complexes of R-left modules. Basically everything we do in this section is self-explanatory. First we have the following generalization of the definitions on pages 1591, and 1592

Definition. Let R be a ring.

(1) An R-left chain complex (C_*, ∂_*) is a sequence
$$\ldots \to C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \ldots C_1 \xrightarrow{\partial_1} C_0 \to 0$$
of R-left homomorphisms between R-left modules such that for every $i \in \mathbb{N}$ we have $\partial_{i-1} \circ \partial_i = 0$. As before we introduce the convention that $C_n = 0$ for $n \in \mathbb{Z}_{<0}$.

(2) We define the n-th homology module of the R-left chain complex as
$$\mathrm{H}_n(C) \ := \ \ker(\partial_n \colon C_n \to C_{n-1}) \,/\, \mathrm{im}(\partial_{n+1} \colon C_{n+1} \to C_n).$$
Note that $\mathrm{H}_n(C)$ inherits the structure of an R-left module.

(3) An chain map $f \colon C_* \to D_*$ between two R-left chain complexes consists of a family $\{f_n \colon C_n \to D_n\}_{n \in \mathbb{N}_0}$ of R-left homomorphisms such that for each $n \in \mathbb{N}_0$ we have $f_{n-1} \circ \partial_n \ = \ \partial_n \circ f_n$.

Lemma 166.1. Let R be a ring and let $f \colon C_* \to D_*$ be a chain map between chain complexes of R-left modules. Then the boundary map of C_* defines a chain complex structure on the R-left modules $\ker(C_k \to D_k)$ and the boundary map of D_* descends to a chain complex structure on the R-left modules $\mathrm{coker}(C_k \to D_k)$.

Proof. The statement follows easily from the definitions. ∎

Definition.

(1) Let $f, g \colon C_* \to D_*$ be chain maps between chain complexes C_* and D_*. A chain homotopy $P = \{P_n\}_{n \in \mathbb{N}_0}$ between f and g consists of family $\{P_n \colon \mathrm{C}_n \to D_{n+1}\}_{n \in \mathbb{N}_0}$ of R-left homomorphisms such that for each $n \in \mathbb{N}_0$ we have
$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \ = \ f_n - g_n.$$
If there exists a chain homotopy between chain maps f and g, then we say that f and g are chain homotopic and we write $f \simeq g$.

(2) Let C_* and D_* be two chain complexes.
   (a) A chain map $f \colon \mathrm{C}_* \to D_*$ is called a chain homotopy equivalence between C_* and D_*, if it admits a chain homotopy inverse, i.e. a chain map $g \colon D_* \to \mathrm{C}_*$ with $g \circ f \simeq \mathrm{id}_{C_*}$ and $f \circ g \simeq \mathrm{id}_{D_*}$.
   (b) If there exists a chain homotopy equivalence between C_* and D_*, then we say that the chain complexes C_* and D_* are chain homotopy equivalent and we write $C_* \simeq D_*$.

The following lemma generalizes the earlier results of Lemmas 73.1, 72.7 and 73.2 and Corollary 73.4.

Lemma 166.2. Let R be a ring and let C_* and D_* be two R-left chain complexes.

(1) For every chain map $f: C_* \to D_*$ the following map is well-defined:
$$\begin{array}{rcl} f_*: \mathrm{H}_n(C_*) & \to & \mathrm{H}_n(D_*) \\ [c] & \mapsto & [f_n(c)]. \end{array}$$
(2) Let $f, g: C_* \to D_*$ be two chain maps between chain complexes. If f and g are chain homotopic, then $f_* = g_*: \mathrm{H}_n(C) \to \mathrm{H}_n(D)$ for all $n \in \mathbb{N}_0$.
(3) If $f: C_* \to D_*$ is a chain homotopy equivalence, then the maps $f_*: \mathrm{H}_n(C) \to \mathrm{H}_n(D)$ are isomorphisms.

Proof. The proof of the lemma is basically the same as the, frankly rather boring, proofs of Lemmas 73.1, 72.7 and 73.2 and Corollary 73.4. ■

On page 1912 we saw that we can tensor a chain complex C_* of abelian groups with an abelian group G to obtain a new chain complex $C_* \otimes G$. Furthermore, on page 2400 we saw that we can consider the cochain complex $\mathrm{Hom}(C_*, G)$. The same constructions also in the more general settings of chain complexes of modules over rings. We summarize the key statements in the following two lemmas.

Lemma 166.3. (Tensoring Chain Complex Lemma) Let R and S be rings and let M be an (R, S)-bimodule.

(1) If (C_*, ∂_*) is an S-left chain complex, then $(M \otimes_S C_*, \mathrm{id}_M \otimes \partial_*)$ is an R-left chain complex.
(2) If $f_*: C_* \to D_*$ is a chain map (chain homotopy equivalence) of S-left chain complexes, then the maps $\mathrm{id}_M \otimes f_*: M \otimes_S C_* \to M \otimes_S D_*$ form a chain map (chain homotopy equivalence) of R-left chain complexes.
(3) If (C_*, ∂_*) is an S-left chain complex and if $\varphi: M \to N$ is a homomorphism of (R, S)-bimodules, then the maps $\varphi: \mathrm{id}: M \otimes_S C_* \to N \otimes_S C_*$ form a chain map of R-left chain complexes.

Proof.

(1) Let $n \in \mathbb{N}_0$. We calculate that
$$(\mathrm{id}_M \otimes \partial_{n-1}) \circ (\mathrm{id}_M \otimes \partial_n) \underset{\uparrow}{=} \mathrm{id}_M \otimes (\partial_{n-1} \circ \partial_n) = \mathrm{id}_M \otimes 0 = 0.$$
Lemma 165.15
This shows that $(M \otimes_{SR} C_*, \mathrm{id}_M \otimes \partial_*)$ is chain complex. It follows from Lemma 165.14 that it is in fact a chain complex of S-left modules.
(2) The proof of this statement is almost as trivial as the proof of Statement (1).
(3) See the proof of Statement (2). ■

166.2. Cochain complexes over rings.

Definition. Let R be a ring.

(1) An R-left cochain complex is a sequence
$$\leftarrow D^n \xleftarrow{\delta_{n-1}} D^{n-1} \xleftarrow{\delta_{n-2}} \ldots \xleftarrow{\delta_1} D^1 \xleftarrow{\delta_0} D^0 \leftarrow 0$$
of R-left homomorphism between R-left modules such that for all $i \in \mathbb{N}_0$ we have $\delta_{i+1} \circ \delta_i = 0$. We refer to the maps δ_* as coboundary maps.

(2) We define the n-th cohomology group of the R-left cochain complex (D^*, δ_*) to be

$$\mathrm{H}^n(D) \;:=\; \frac{\ker(\delta_n\colon D^n \to D^{n+1})}{\mathrm{im}(\delta_{n-1}\colon D^{n-1} \to D^n)}.$$

Note that $\mathrm{H}^n(D)$ inherits the structure of an R-left module.

(3) The notion of a cochain map, cochain homotopy and cochain homotopy equivalence that we introduced on page 2397 for cochain complexes of abelian groups generalize in the obvious way to the more general setting.

For the reader's convenience we recall the following slightly shortened version of the Cochain Map Lemma 108.5.

Lemma 108.5.

(1) If $f\colon C^* \to D^*$ is a cochain map between cochain complexes C^* and D^*, then the map

$$\begin{array}{rcl} f_*\colon \mathrm{H}^n(C) & \to & \mathrm{H}^n(D) \\ [c] & \mapsto & [f_n(c)] \end{array}$$

is well-defined.

(2) Two cochain maps that are cochain homotopic induce the same map on cohomology groups.

(3) Every cochain homotopy equivalence induces an isomorphism of cohomology groups.

As before the key source of cochain complexes is given by dualizing a chain complex. More precisely, we have the following generalization of the definition from page 2400.

Definition. Let S and be a ring and let

$$(C_*, \partial_*)\colon \quad \to\; C_{n+1} \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} \ldots \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \;\to\; 0$$

be an S-left chain complex and let M be an S-left module. For each $n \in \mathbb{N}_0$ we write

$$\delta_n \;:=\; \partial_{n+1}^*\colon \mathrm{Hom}_{S\text{-left}}(C_n, M) \;\to\; \mathrm{Hom}_{S\text{-left}}(C_{n+1}, M).$$

Note that $\delta_n \circ \delta_{n-1} = (\partial_n)^* \circ (\partial_{n-1})^* = (\partial_{n-1} \circ \partial_n)^* = 0$, thus we obtain the following cochain complex

$$\ldots \xleftarrow{\delta_2} \mathrm{Hom}_{S\text{-left}}(C_2, M) \xleftarrow{\delta_1} \mathrm{Hom}_{S\text{-left}}(C_1, M) \xleftarrow{\delta_0} \mathrm{Hom}_{S\text{-left}}(C_0, M) \leftarrow 0.$$

We refer to it as cochain complex dual to (C_*, ∂_*) and we denote it by $\mathrm{Hom}_{S\text{-left}}(C_*, M)$. We define the n-th cohomology group of the chain complex (C_*, ∂_*) with M-coefficients as the cohomology of the cochain complex $(\mathrm{Hom}(C_*, M), \delta_*)$, i.e. we define

$$\mathrm{H}^n(C; G) \;:=\; \frac{\ker(\delta_n\colon \mathrm{Hom}_{S\text{-left}}(C_n, M) \to \mathrm{Hom}_{S\text{-left}}(C_{n+1}, M))}{\mathrm{im}(\delta_{n-1}\colon \mathrm{Hom}_{S\text{-left}}(C_{n-1}, M) \to \mathrm{Hom}_{S\text{-left}}(C_n, M))}.$$

The following lemma is a generalization of the classical the Dual Cochain Map Lemma 108.8 and it can be viewed as an analogue of the Tensoring Chain Complex Lemma 166.3.

Lemma 166.4. (Dualizing Chain Complex Lemma) Let R and S be rings and let M be an (S,R)-left left module.

(1) If (C_*, ∂_*) is an S-left chain complex, then the R-left modules $\mathrm{Hom}_{S\text{-left}}(C_*, M)$ together with the maps

$$\begin{array}{rcl} \delta\colon \mathrm{Hom}_{S\text{-left}}(C_n, M) & \to & \mathrm{Hom}_{S\text{-left}}(C_{n+1}, M) \\ (\varphi\colon C_n \to M) & \mapsto & (\varphi \circ \partial\colon C_{n+1} \to M) \end{array}$$

form a cochain complex of R-left modules.

(2) If $f_*\colon C_* \to D_*$ is a chain map (chain homotopy equivalence) of R-left chain complexes, then the maps

$$\begin{array}{rcl} f^*\colon \mathrm{Hom}_{S\text{-left}}(D_n, M) & \to & \mathrm{Hom}_{S\text{-left}}(C_n, M) \\ (\varphi\colon D_n \to M) & \mapsto & (f \circ \varphi\colon C_n \to M) \end{array}$$

form a cochain map (cochain homotopy equivalence) of R-left cochain complexes.

(3) If (C_*, ∂_*) is an R-left chain complex and if $\alpha\colon M \to N$ is a homomorphism of (S,R)-bimodule, then the maps

$$\begin{array}{rcl} \alpha_*\colon \mathrm{Hom}_{S\text{-left}}(C_n, M) & \to & \mathrm{Hom}_{S\text{-left}}(C_n, N) \\ (\varphi\colon C_n \to M) & \mapsto & (\alpha \circ \varphi\colon C_N \to N) \end{array}$$

form a chain map of S-left chain complexes.

Proof. We leave the straightforward verification of this lemma to the reader. ■

166.3. **Free resolutions.** In several chapters we already developed the theory of chain complexes of free abelian groups. Many statements generalize without problems to the setting of chain complexes of free modules. More precisely, all statements that only made use of the universal property of free abelian groups generalize with basically the same proof. On several occasions we did use the fact, see the Subgroup-of-Free Abelian Group Lemma 51.2 , that any subgroup of a free abelian group is again a free abelian group. This statement does *not* generalize to rings.

The following generalizes the notion of a (free) resolution of an abelian group that we gave on page 1791.

Definition. Let R be a ring and let M be an R-left module. A (free) resolution of an abelian group M is an exact sequence

$$\ldots \xrightarrow{f_3} F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} M \to 0$$

where the F_i are (free) R-left modules.

In the following definition, which is modelled on the definition on page 1922, we show that every R-left module admits a canonical free resolution.

Definition. Let R be a ring. We recall the following basic fact: if K is an R-left module, then by Lemma 165.4 there exists a unique homomorphism $\alpha(M)\colon R^{(K)} \to K$ such that for each $k \in K$ we have $\alpha(K)(k) = k$. Now let M be any R-left module. We consider the sequence

$$R^{(K)} \xrightarrow{\alpha(K)} K \to 0.$$

The group $R^{(K)}$ is free abelian and $\alpha(K)$ is an epimorphism. In particular the sequence is exact. We set $K_1 := \ker\left(R^{(K)} \xrightarrow{\alpha(K)} K\right)$. Then

$$K_1 \hookrightarrow R^{(K)} \xrightarrow{\alpha(K)} K \to 0$$

is exact. Now we consider

$$R^{(K_1)} \xrightarrow{\alpha(K_1)} R^{(K)} \xrightarrow{\alpha(K)} K \to 0.$$

This sequence is exact and both the groups $R^{(K_1)}$ and $R^{(K)}$ are free abelian. Now we set $K_2 := \ker\left(R^{(K_1)} \xrightarrow{\alpha(K)} K\right)$ and we iterate this procedure. This way we obtain a free resolution of K. We refer to this free resolution of K as the canonical free resolution of K.

The following theorem is a straightforward generalization of the Fundamental Theorem of Homological Algebra 81.1.

Theorem 166.5. (Fundamental Theorem of Homological Algebra over Rings) Let R be a ring and let $\alpha\colon H \to H'$ be an R-left module homomorphism between R-left modules. Furthermore let F_* be a free resolution of H and let F'_* be a resolution[2057] of H'.

(1) There exists an extension of α to the free resolutions F_* and F'_*.
(2) Any two extensions α_* and α'_*, viewed as chain maps, are chain homotopic.

Remark. In fact we only need that F_* is a projective resolution of H.

Proof. The proof is basically identical to the proof of the Fundamental Theorem of Homological Algebra 81.1. ■

Definition. Let $f\colon C_* \to D_*$ be a chain map between chain complexes. We say f is a quasi-isomorphism if for each $k \in \mathbb{N}_0$ the induced map $f_*\colon \mathrm{H}_k(C_*) \to \mathrm{H}_k(D_*)$ is an isomorphism.

We also have the following generalization of the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4.

Proposition 166.6. (Quasi Isomorphisms-are-Homotopy Equivalences Proposition) Let R be a ring and let $f\colon C_* \to \mathrm{C}'_*$ be a chain map between chain complexes of free R-left modules. If f induces an isomorphism of all homology groups, then f is in fact a chain homotopy equivalence.

Proof. The proof is identical to the proof of the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4. ■

The following corollary is a generalization of Corollary 166.7.

Corollary 166.7. [2058]Let R be a ring and let

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_* & \longrightarrow & B_* & \longrightarrow & C_* & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & A'_* & \longrightarrow & B'_* & \longrightarrow & C'_* & \longrightarrow & 0 \end{array}$$

[2057]Note that we do not demand that F'_* is a *free* resolution.

be a commutative diagram of short exact sequences of chain complexes of free R-left modules. If two of the vertical maps are chain homotopy equivalences, then the third is also a chain homotopy equivalence.

Proof. The same way that we deduced the Two-Out-Of-Three-Homotopy Equivalence Corollary 81.6 from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 one can also deduce Corollary 166.7 from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 166.6. ■

Remark. It is also useful to know the results that do not generalize. In the proofs of Proposition 81.5 and the Lift-to-Chain Map-Proposition 81.13 we used the Subgroup-of-Free Abelian Group Lemma 51.2 which says that subgroups of free abelian groups are free abelian. Furthermore in the proof of the Finite-Rank Chain Complex Lemma 81.14 we used the Finitely Generated Abelian Group Classification Theorem 51.4. Thus the proofs of these results do not generalize in a one-to-one fashion to the setting of chain complexes over rings.

166.4. **Free imitations of chain complexes.** Recall that in the definition of a chain complex we did not demand that the chain groups are free modules. In this section we will see that we can replace any chain complex by a "similar looking" chain complex consisting of free modules. To make this precise we need the following definition.

Definition. Let R be a ring and let C_* be a chain complex of R-left modules. A free imitation of C_* is a chain complex F_* of R-left modules together with a chain map $\varphi\colon F_* \to C_*$ of R-left chain complexes that has the following two properties:

(1) The chain map is a quasi-isomorphism $\varphi\colon F_* \to C_*$, i.e. it induces an isomorphism on all homology groups.
(2) Each $\varphi\colon F_k \to C_k$ is an epimorphism.

We will now see that free imitations always exist and that they are unique up to chain homotopy equivalence.

Lemma 166.8. (Free Imitation Existence Lemma) Let R be a ring. Every chain complex of R-left modules admits a free imitation.

Remark. For $R = \mathbb{Z}$ the statement of the Free Imitation Existence Lemma 166.8 is the content of Exercise 72.16.

Proof. Let R be a ring and let (C_*, ∂_*) be a chain complex of R-left modules. We need to show that there exists a chain complex $(F_*, \widetilde{\partial}_*)$ of free R-left modules together with a chain map $\varphi\colon F_* \to C_*$ that is a quasi-isomorphism and that is an epimorphism at each degree. Most of the work is done by formulating the following claim.

Claim. Suppose that we are in the following setting

$$\begin{array}{ccccccccccccc}
 & & 0 & \longrightarrow & F_k & \xrightarrow{\widetilde{\partial}_k} & F_{k-1} & \xrightarrow{\widetilde{\partial}_{k-1}} & \dots & \xrightarrow{\widetilde{\partial}_2} & F_1 & \xrightarrow{\widetilde{\partial}_1} & F_0 & \xrightarrow{0} & 0 \\
 & & & & \downarrow{\scriptstyle \varphi_k} & & \downarrow{\scriptstyle \varphi_{k-1}} & & & & \downarrow{\scriptstyle \varphi_1} & & \downarrow{\scriptstyle \varphi_0} & & \\
\dots & \longrightarrow & C_{k+1} & \xrightarrow[\partial_{k+1}]{} & C_k & \xrightarrow[\partial_k]{} & C_{k-1} & \xrightarrow[\partial_{k-1}]{} & \dots & \xrightarrow[\partial_2]{} & C_1 & \xrightarrow[\partial_1]{} & C_0 & \xrightarrow[0]{} & 0
\end{array}$$

where the following statements hold:

(1) The top sequence of maps is a chain complex of free R-left modules.
(2) The vertical maps define a chain map.
(3) For $i = 0, \dots, k-1$ the map $\varphi_*\colon \mathrm{H}_i(F_*) \to \mathrm{H}_i(C_*)$ is an isomorphism.
(4) The map $\varphi_*\colon \mathrm{H}_k(F_*) \to \mathrm{H}_k(C_*)$ is an epimorphism.
(5) Each vertical map is an epimorphism.

Then we can extend the above horizontal sequence by one term to the left such that the extensions of the above statements hold.

Proof. Fortunately formulating the claim takes (almost) longer than proving it. We set

$$\begin{aligned} A &:= \{(f,c) \in \underbrace{\varphi_k^{-1}(\mathrm{im}(\partial_{k+1}\colon C_{k+1} \to C_k)) \cap \ker(\widetilde{\partial}_k)}_{\subset F_k} \times C_{k+1} \mid \varphi_k(f) = \partial_{k+1}(c)\} \\ B &:= \ker(\partial_{k+1}\colon C_{k+1} \to C_k). \end{aligned}$$

Next we set $F_{k+1} := R^{(A)} \oplus R^{(B)}$. We consider the map

$$\widetilde{\partial}_{k+1}\colon F_{k+1} = R^{(A)} \oplus R^{(B)} \to F_k$$

that is induced by sending each $(f,c) \in A$ to $f \in F_k$ and by sending each $b \in B$ to 0. Furthermore we consider the map

$$\varphi_{k+1}\colon F_{k+1} = R^{(A)} \oplus R^{(B)} \to C_{k+1}$$

that is induced by sending each $(f,c) \in A$ to c and by sending each $b \in B$ to $b \in C_{k+1}$. We now claim that F_{k+1} together with the above maps gives the desired extension:

(1) Evidently F_{k+1} is a free R-left module. Note that it follows easily from the definitions that $\partial_k \circ \partial_{k+1} = 0$. This implies that we do indeed have a chain complex of free R-left modules.
(2) For $(f,c) \in A$ we have

$$(\partial_{k+1} \circ \varphi_{k+1})(f,c) \underset{\text{definition of } \varphi_{k+1}}{\overset{\uparrow}{=}} \partial_{k+1}(c) \underset{\text{definition of } A}{\overset{\uparrow}{=}} \varphi_k(f) \underset{\text{definition of } \widetilde{\partial}_{k+1}}{\overset{\uparrow}{=}} (\varphi_k \circ \widetilde{\partial}_{k+1})(f,c).$$

Furthermore for $b \in B$ we have

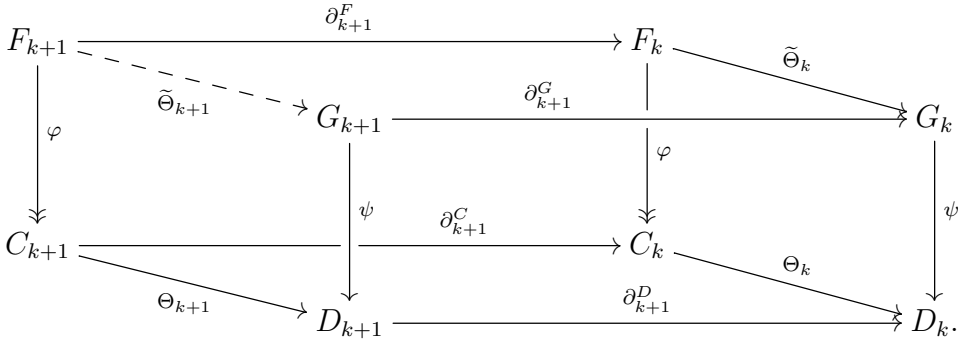
$$(\partial_{k+1} \circ \varphi_{k+1})(b) = \partial_{k+1}(\varphi_{k+1}(b)) \underset{\text{definition of } \varphi_{k+1}}{\overset{\uparrow}{=}} \partial_{k+1}(b) \overset{\text{since } b \in B = \ker(\partial_{k+1})}{\overset{\downarrow}{=}} 0 \underset{\text{definition of } \widetilde{\partial}_{k+1}}{\overset{\uparrow}{=}} (\varphi_k \circ \widetilde{\partial}_{k+1})(b).$$

Thus the vertical maps form a chain map.

(3) We denote by F_* the chain complex starting at F_k and we denote by F'_* the chain complex starting at F_{k+1}. Recall that we assume that $\varphi_*\colon \mathrm{H}_k(F_*) \to \mathrm{H}_k(C_*)$ is an epimorphism. It follows almost immediately that $\varphi_*\colon \mathrm{H}_k(F'_*) \to \mathrm{H}_k(C_*)$ is also an epimorphism. It remains to show that $\varphi_*\colon \mathrm{H}_k(F'_*) \to \mathrm{H}_k(C_*)$ is also a monomorphism. Thus let $[\sigma] \in \mathrm{H}_k(F'_*)$ with $\varphi_*([\sigma]) = 0$. This means that $\varphi_k(\sigma) \in \mathrm{im}(\partial_{k+1}\colon C_{k+1} \to C_k)$. Also note that $\sigma \in \ker(\widetilde{\partial}_k)$. This shows that $\sigma \in \varphi_k^{-1}(\mathrm{im}(\partial_{k+1}\colon C_{k+1} \to C_k)) \cap \ker(\widetilde{\partial}_k)$. Evidently we can pick $c \in C_{k+1}$ with $\partial_{k+1}(c) = \varphi_k(\sigma)$. Note that $\widetilde{\partial}_{k+1}(\sigma, c) = \sigma$. In other words, we have shown that $\sigma \in \mathrm{im}(\widetilde{\partial}_{k+1}\colon F_{k+1} \to F_k)$. But this implies that $[\sigma] = 0 \in \mathrm{H}_k(F'_*)$.

(4) By construction the map $\varphi_{k+1}\colon \ker(\widetilde{\partial}_{k+1}\colon F_{k+1} \to F_k) \to \ker(\partial_{k+1}\colon C_{k+1} \to C_k)$ is an epimorphism. But this implies that $\varphi_*\colon \mathrm{H}_k(F_*) \to \mathrm{H}_k(C_*)$ is an epimorphism.
(5) Let $c \in C_{k+1}$. Since $\varphi_k\colon F_k \to C_k$ is an epimorphism there exists an $f \in F_k$ with $\varphi_k(f) = \partial_{k+1}(c)$. Note that $(f, c) \in A$ and note that $\varphi_{k+1}(f, c) = c$. Thus we have shown that $\varphi_{k+1}\colon F_{k+1} \to C_{k+1}$ is an epimorphism. ⊞

Now we start the iterative procedure with $k = -1$ by considering the chain complex consisting only of the zero group. By applying the claim iteratively we obtain the desired chain complex and the desired quasi-isomorphism consisting of epimorphisms. ■



Lemma 166.9. (Homomorphism Lifting Lemma) Let R be a ring, let C_* and D_* be two chain complexes of R-left modules and let $\Theta\colon C \to D$ be a chain map of R-left chain complexes. We assume that we are given another two chain maps:

(1) Let $\varphi\colon F_* \to C_*$ be a chain map such that each F_k is a free R-left module and such that each $\varphi\colon F_k \to C_k$ is an epimorphism.
(2) Let $\varphi\colon G_* \to D_*$ be a quasi-isomorphism.

There exists a chain map $\widetilde{\Theta}\colon F \to G$ such that the following diagram commutes:

$$\begin{array}{ccc} F & \xrightarrow{\widetilde{\Theta}} & G \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ C & \xrightarrow{\Theta} & D. \end{array}$$

Proof. We construct the chain map $\widetilde{\Theta}$ inductively. We define $\widetilde{\Theta}_{-1}\colon F_{-1} = 0 \to 0 = G_{-1}$ to be, evidently, the zero map. Now suppose we have already constructed maps $\widetilde{\Theta}_i\colon F_i \to G_i$, $i = 0, \ldots, k$ which form a (partial) chain map and such that the corresponding diagram commutes. Now let us consider the following diagram:

By hypothesis F_{k+1} is a free R-left module. We pick a basis B for F_{k+1}. It suffices to define $\widetilde{\Theta}_{k+1}(b) \in G_{k+1}$ for each $b \in B$ in such that a way that the above diagram commutes for b. Thus let $b \in B$. We proceed as follows:

(a) By hypothesis (1) we know that $\psi\colon G_{k+1} \to D_{k+1}$ is an epimorphism. Therefore there exists a $g_{k+1} \in G_{k+1}$ with $\psi(g_{k+1}) = (\Theta_{k+1} \circ \varphi)(b)$.

(b) Note that the four sides of the hyperrectangle that do not involve the unknown dotted arrow commute. This implies that

$$\begin{array}{rcl} (\psi \circ \widetilde{\Theta}_k \circ \partial^F_{k+1})(b) & = & (\Theta_k \circ \varphi \circ \partial^F_{k+1})(b) \\ & = & (\partial^D_{k+1} \circ \Theta_{k+1} \circ \varphi)(b) \end{array} \begin{array}{rcl} & = & (\Theta_k \circ \partial^C_{k+1} \circ \varphi) \\ & \underset{\uparrow}{=} & (\partial^D_{k+1} \circ \psi)(g_{k+1}) \\ & & \text{definition of } g_{k+1} \end{array} \begin{array}{rcl} & = & (\psi \circ \partial^G_{k+1})(g_{k+1}). \end{array}$$

(c) It follows in particular from (b) that $\psi((\widetilde{\Theta}_k \circ \partial^F_{k+1})(b))$ and $\psi(\partial^G_{k+1}(g_{k+1}))$ are homologous in D_*.

(d) By hypothesis (2) we know that $\mathrm{H}_k(G_*) \to \mathrm{H}_k(D_*)$ is a monomorphism. This observation together with (c) implies that $(\widetilde{\Theta}_k \circ \partial^F_{k+1})(b)$ and $\partial^G_{k+1}(g_{k+1})$ are homologous in G_*.

(e) By (d) there exists an $r_{k+1} \in G_{k+1}$ with $\partial^G_{k+1}(r_{k+1}) = \partial^G_{k+1}(g_{k+1}) - (\widetilde{\Theta}_k \circ \partial^F_{k+1})(b)$.

(f) Note that

$$\partial^D_k(\psi(r_{k+1})) \underset{\substack{\uparrow \\ \text{since } \psi \text{ is a chain map}}}{=} \psi(\partial^G_k(r_{k+1})) \underset{\substack{\uparrow \\ \text{by (e)}}}{=} \psi\big(\partial^G_{k+1}(g_{k+1}) - (\widetilde{\Theta}_k \circ \partial^F_{k+1})(b)\big) \underset{\substack{\uparrow \\ \text{by (b)}}}{=} 0.$$

In other words, $\psi(r_{k+1}) \in D_{k+1}$ is a cycle in the chain complex D_*.

(g) By hypothesis (2) we know that $\mathrm{H}_{k+1}(G_*) \to \mathrm{H}_{k+1}(D_*)$ is an epimorphism. Note that it follows from this observation and (f) that there exists a *cycle* $s_{k+1} \in G_{k+1}$ with $\psi(s_{k+1}) = \psi(r_{k+1})$.

Claim. If we set $\widetilde{\Theta}_{k+1}(b) := g_{k+1} - r_{k+1} + s_{k+1}$, then the diagram commutes for b.

Proof.

- We first consider the upper parallelogram. We have the following equality in G_k:

$$(\partial^G_{k+1} \circ \widetilde{\Theta}_{k+1})(b) \underset{\substack{\uparrow \\ \text{by definition of } \widetilde{\Theta}_{k+1}(b)}}{=} \partial^G_{k+1}(g_{k+1} - r_{k+1} + s_{k+1}) \underset{\substack{\uparrow \\ \text{since } s_{k+1} \text{ is a cycle}}}{=} \partial^G_{k+1}(g_{k+1} - r_{k+1}) \underset{\substack{\uparrow \\ \text{by (e)}}}{=} \widetilde{\Theta}_k(\partial^F_{k+1}(b)).$$

- We consider the parallelogram to the left. We have the following equality in D_{k+1}:

$$(\psi \circ \widetilde{\Theta}_{k+1})(b) \underset{\substack{\uparrow \\ \text{by definition of } \widetilde{\Theta}_{k+1}(b)}}{=} \psi(g_{k+1} - r_{k+1} + s_{k+1}) \underset{\substack{\uparrow \\ \text{since } \psi(r_{k+1}) = \psi(s_{k+1})}}{=} \psi(g_{k+1}) \underset{\substack{\uparrow \\ \text{by (a)}}}{=} (\Theta_{k+1} \circ \varphi)(b).$$

■

Lemma 166.10. (Free Imitation Uniqueness Lemma) Let R be a ring and let (C_*, ∂_*) be a chain complex of R-left modules. If $\varphi\colon F_* \to C_*$ and $\varphi'\colon F'_* \to C_*$ are two free imitations, then there exists a chain homotopy equivalence $\Theta\colon F_* \to F'_*$ of R-left chain complexes such that $\varphi' \circ \Theta = \varphi$.

Proof. By the Homomorphism Lifting Lemma 166.9 there exists a chain map $\widetilde{\Theta}\colon F \to F'$ such that the following diagram commutes:

$$\begin{array}{ccc} F & \xrightarrow{\widetilde{\Theta}} & F' \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\varphi'} \\ C & \xrightarrow{\mathrm{id}} & C. \end{array}$$

Note that Θ is a quasi-isomorphism. Since F and F' are chain complexes of free R-left modules we obtain from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 166.6 that $\widetilde{\Theta}\colon F_* \to F'_*$ is in fact a chain homotopy equivalence. ■

166.5. **Connecting homomorphisms.**

Definition. Let R be a ring and let

$$0 \to A_* \xrightarrow{i} B_* \xrightarrow{p_*} C_* \to 0$$

be a short exact sequence of R-left modules. Using the recipe from page 1620 we define a connecting homeomorphism

$$\partial_n\colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)$$

as follows:

(1) Let $z \in \mathrm{H}_n(C)$.
(2) We pick $c \in C_n$ with $z = [c]$.
(3) By the surjectivity of p we have $c = p(b)$ for some $b \in B_n$.
(4) We have
$$p(\partial b) \underset{\text{since the diagram commutes}}{=} \partial p(b) = \partial c \underset{\text{since } c \text{ is a cycle}}{=} 0.$$
(5) It follows easily from (4) that $\partial b = i(a)$ for some uniquely determined $a \in A_{n-1}$.
(6) We put $\partial_n(z) := [a]$.

We refer to this map $\partial_n\colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)$ as the connecting homomorphism.

The following lemma is the analogue of the Connecting Homomorphism Lemma 74.8 of the LES Proposition 74.9.

Lemma 166.11. (LES Lemma) Let R be a ring.

(1) Let $0 \to A_* \xrightarrow{i} B_* \xrightarrow{p} C_* \to 0$ be a short exact sequence of chain complexes of R-left modules. The connecting homomorphism $\partial_n\colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)$ is well-defined and it is a homomorphism of R-left modules
(2) The connecting homomorphism is natural.
(3) The sequence
$$\ldots \to \mathrm{H}_n(A) \xrightarrow{i_*} \mathrm{H}_n(B) \xrightarrow{p_*} \mathrm{H}_n(C) \xrightarrow{\partial} \mathrm{H}_{n-1}(A) \xrightarrow{i_*} \mathrm{H}_{n-1}(B) \xrightarrow{p_*} \ldots$$
is exact.

Proof. The proof is basically the same as the proof of the Connecting Homomorphism Lemma 74.8 and of the LES Proposition 74.9. ■

166.6. **Homological algebra over skew fields.** In this section we introduce skew fields. In most applications the skew fields we use are in fact just ordinary fields. On the other hand, it costs little to generalize to skew fields and working with (possibly) non-commutative skew fields actually makes some of the future arguments clearer since it prevents us from using "accidents" in the commutative setting, e.g. the fact that over a commutative ring every left-module is automatically a right module.

We have the following generalization of Theorems **??** and Theorem 110.20.

Theorem 166.12. Let $\mathbb{K}$ be a skew field and let (V_*, ∂_*) be a chain complex of $\mathbb{K}$-left modules. The map

$$\begin{array}{rcl} \mathrm{ev}_{\mathbb{K}} \colon \mathrm{H}^k(V;\mathbb{K}) & \to & \mathrm{Hom}_{\mathbb{K}\text{-left}}(\mathrm{H}_k(V),\mathbb{K}). \\ (\varphi \colon V_k \to \mathbb{K}) & \mapsto & \begin{pmatrix} \mathrm{H}_k(V) & \to & \mathbb{K} \\ [c] & \mapsto & \varphi(c) \end{pmatrix} \end{array}$$

is well-defined and it is an isomorphism of $\mathbb{K}$-right modules.

The proof of Theorem 166.12 is almost verbatim the same as the proof of Theorem **??**. For the reader's convenience we nonetheless provide the proof.

Auxiliary Lemma 166.13. Let $\mathbb{K}$ be a skew field and let $0 \to B \xrightarrow{i} Z \xrightarrow{p} H \to 0$ be a short exact sequence of $\mathbb{K}$-left modules. Then the sequence

$$0 \to \mathrm{Hom}_{\mathbb{K}\text{-left}}(H,\mathbb{K}) \xrightarrow{p^*} \mathrm{Hom}_{\mathbb{K}\text{-left}}(Z,\mathbb{K}) \xrightarrow{i^*} \mathrm{Hom}_{\mathbb{K}\text{-left}}(B,\mathbb{K}) \to 0$$

is also exact.

Proof of Lemma 166.13. This statement follow easily from the fact, see Proposition 165.26, that any short exact sequence of $\mathbb{K}$-left modules splits. We leave it to the reader to fill in the few remaining details. ∎

Proof of Theorem 166.12. Let $\mathbb{K}$ be a skew field and let $(\mathrm{C}_*, \partial_*)$ be a chain complex of $\mathbb{K}$-left modules. For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \mathrm{im}(\partial_{n+1})$. We consider the following short exact sequence of vertical chain complexes:

$$\begin{array}{ccccccccc} & & \vdots & & \vdots & & \vdots & & \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & Z_n & \longrightarrow & \mathrm{C}_n & \xrightarrow{\partial_n} & B_{n-1} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle 0} & & \downarrow{\scriptstyle \partial_n} & & \downarrow{\scriptstyle 0} & & \\ 0 & \longrightarrow & Z_{n-1} & \longrightarrow & \mathrm{C}_{n-1} & \xrightarrow{\partial_{n-1}} & B_{n-2} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ & & \vdots & & \vdots & & \vdots & & \end{array}$$

We apply the functor $\mathrm{Hom}(-,\mathbb{K}) := \mathrm{Hom}_{\mathbb{K}\text{-left}}(-,\mathbb{K})$ to the above short exact sequence of chain complexes and we obtain the following diagram:

$$\begin{array}{ccccccccc} & & \vdots & & \vdots & & \vdots & & \\ & & \uparrow & & \uparrow & & \uparrow & & \\ 0 & \longrightarrow & \mathrm{Hom}(B_{n-1},\mathbb{K}) & \xrightarrow{\partial_n^*} & \mathrm{Hom}(C_n,\mathbb{K}) & \longrightarrow & \mathrm{Hom}(Z_n,\mathbb{K}) & \longrightarrow & 0 \\ & & \uparrow{\scriptstyle 0} & & \uparrow{\scriptstyle \partial_n^*} & & \uparrow{\scriptstyle 0} & & \\ 0 & \longrightarrow & \mathrm{Hom}(B_{n-2},\mathbb{K}) & \xrightarrow{\partial_{n-1}^*} & \mathrm{Hom}(C_{n-1},\mathbb{K}) & \longrightarrow & \mathrm{Hom}(Z_{n-1},\mathbb{K}) & \longrightarrow & 0 \\ & & \uparrow & & \uparrow & & \uparrow & & \\ & & \vdots & & \vdots & & \vdots & & \end{array}$$

This is a sequence of cochain complexes. Since we work over a skew field we obtain from Lemma 166.13 that the above horizontal sequences of cochain complexes are still exact. By the obvious analogue of the Connecting Homomorphism Proposition 108.6 we obtain the following long exact sequence

$$\to \mathrm{Hom}(Z_{n-1},\mathbb{K}) \xrightarrow{d_n} \mathrm{Hom}(B_{n-1},\mathbb{K}) \to \mathrm{H}^n(C;\mathbb{K}) \xrightarrow{\partial_n} \mathrm{Hom}(Z_n,\mathbb{K}) \xrightarrow{d_{n-1}} \mathrm{Hom}(B_n,\mathbb{K}) \to \dots$$

where the maps d_n are the connecting homomorphisms of the long exact sequence. One can show easily that the connecting homomorphism $d_n \colon \mathrm{Hom}(Z_n,\mathbb{K}) \to \mathrm{Hom}(B_n,\mathbb{K})$ is the

map $d_n = i_n^*$ where $i_n \colon B_n \to Z_n$ is the inclusion map. By the Break-into-SES Lemma 78.4 we obtain the following short exact sequence

$$0 \to \underbrace{\operatorname{coker}(\operatorname{Hom}(Z_{n-1}, \mathbb{K}) \to \operatorname{Hom}(B_{n-1}, \mathbb{K}))}_{= 0 \text{ by Lemma 166.13 applied to the short exact sequence } 0 \to B_l \to Z_l \to \mathrm{H}_l(C) \to 0} \to \mathrm{H}^n(C; \mathbb{K}) \to \underbrace{\ker(\operatorname{Hom}(Z_n, \mathbb{K}) \to \operatorname{Hom}(B_n, \mathbb{K}))}_{\cong \operatorname{Hom}(\mathrm{H}_n(C), \mathbb{K}) \text{ by Lemma 166.13 applied to the short exact sequence } 0 \to B_l \to Z_l \to \mathrm{H}_l(C) \to 0} \to 0.$$

■

166.7. Tor-modules.

Definition. Let S and S be rings and let M be an (R, S)-bimodule. We take the canonical free resolution

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} M \to 0$$

of free (R, S)-bimodules and we define

$$\operatorname{Tor}_n^S(M, N) := \mathrm{H}_n(F_* \otimes_S N).$$

Note that each $\operatorname{Tor}_n^S(M, N)$ is naturally an R-left module.

Many, but not all, of our results on the Tor groups of abelian groups generalize to this new setting. The following lemma is a generalization of the Tor_0–Lemma 89.13.

Lemma 166.14. Let S be a ring, let M be an (R, S)-bimodule and let N be an S-left module. There exists a natural isomorphism

$$\operatorname{Tor}_0^S(M, N) \xrightarrow{\cong} M \otimes_R N$$

of R-left modules.

Proof. The proof is basically the same as the proof of the Tor_0–Lemma 89.13. We just need to replace Lemma 89.10 by Lemma **??**. ■

Here the following statements hold:

(1) As in the Tor-Free Resolution Proposition 89.12 one can show that the isomorphism type of $\operatorname{Tor}_n^S(M, N)$ can be determined using any free resolution for M.
(2) The argument of page 1923 shows that for each $n \in \mathbb{N}_0$ the S-torsion module $\operatorname{Tor}_n^S(M, N)$ is covariantly functorial in both entries.
(3) The obvious analogues of the Tor-Properties Lemma 89.15 (1) and (2) also hold in the more general context. Furthermore the obvious analogues of the Tor-Properties Lemma 89.15 (3) and (4) hold if we replace "torsion-free abelian group" by "free S-module".[2059] In general there are no analogues of the Tor-Properties Lemma 89.15 (5), (6) and (7).
(4) For general commutative rings it is no longer true though that $\operatorname{Tor}_i^S(M, N) = 0$ for $i \geq 2$. For example for $S = \mathbb{Q}[t_1, \ldots, t_k]$ the S-torsion modules can be non-zero for $i = 1, \ldots, k$ and they are only zero for $i > k$. We refer to [**Mac1975**, Chapter VII.4] for details.

Proposition 166.15. If $\mathbb{K}$ is a skew field, then for any $\mathbb{K}$-left module M and any $n \geq 1$ we have $\operatorname{Tor}_n(M, \mathbb{K}) = 0$.

Proof. This follows from Proposition 165.26. ■

[2059] Note that in general "S-torsion free module" is not going to be strong enough.

The following theorem is a generalization of the Algebraic Universal Coefficient Theorem 89.16 and of the UCT-Splitting Proposition 89.21 from the PID $\mathbb{Z}$ to general PIDs.

Theorem 166.16. (Algebraic Universal Coefficient Theorem over Rings) Let S be a PID[2060], let (C_n, ∂_n) be a chain complex of free S modules and let M be an S-module. For each $n \in \mathbb{N}_0$ there exists a natural homomorphism

$$p\colon \mathrm{H}_n(M \otimes_S C_*) \ \to\ \mathrm{Tor}_S(\mathrm{H}_{n-1}(C), M)$$

of S-modules such that the following sequence is exact:

$$0 \ \to\ \mathrm{H}_n(C) \otimes_S M \ \xrightarrow{\mu}\ \mathrm{H}_n(M \otimes_S C_*) \ \xrightarrow{p}\ \mathrm{Tor}_S(\mathrm{H}_{n-1}(C), M) \ \to\ 0.$$

This short exact sequence splits and there exists therefore an isomorphism

$$\mathrm{H}_n(M \otimes_S C_*) \ \cong\ \mathrm{H}_n(C) \otimes_S M \oplus \mathrm{Tor}_S(\mathrm{H}_{n-1}(C), M).$$

of S-modules.

Proof. The proof of Theorem 166.16 is basically identical to the proof of the Algebraic Universal Coefficient Theorem 89.16 and the UCT-Splitting Proposition 89.21. All one really has to do is to the following replacements:

(1) Replace the Subgroup-of-Free Abelian Group Lemma 51.2 (1) by Theorem 165.25.
(2) Replace Lemma 78.1 by Lemma 78.1.
(3) Replace the Tensor-Split-SES Lemma 89.6 by Lemma 165.18.
(4) Replace the LES Proposition 74.9 by the LES Lemma 166.11.
(5) Replace the Tor_0–Lemma 89.13 by Lemma 166.14.
(6) Replace the Splitting Lemma 78.2 by the Splitting Lemma 165.7 for Rings. ■

On the other hand, if R is not a principal ideal, then as we pointed out above, the higher torsion groups are in general non-zero and the problem becomes much more subtle. The torsion-terms and the homology with M-coefficients are then related by a "spectral sequence", see e.g. [**Rot2009**, Theorem 10.90] for details.

166.8. **Ext-modules.** We have the following generalization of the Hom-Left Exact Lemma 110.1.

Lemma 166.17. Let S be a ring. For any S-left module M the contravariant functor $\mathrm{Hom}_{S\text{-left}}(-, M)$ is left-exact.

Proof. The proof is basically the same as the proof of the Hom-Left Exact Lemma 110.1. ■

Definition. Let S and S be rings and let M be an (R, S)-left left module. We take the canonical free resolution

$$\cdots \to\ F_2 \ \xrightarrow{f_2}\ F_1 \ \xrightarrow{f_1}\ F_0 \ \xrightarrow{f_0}\ M \ \to\ 0$$

of free (R, S)-left left modules and we define

$$\mathrm{Ext}^n_{S\text{-left}}(M, N) \ :=\ \mathrm{H}^n(\mathrm{Hom}_{S\text{-left}}(F_*, N)).$$

Note that each $\mathrm{Ext}^n_{S\text{-left}}(M, N)$ is naturally an R-left module.

[2060] Recall that according to the definition on page 3515 a PID is commutative. So we do not need to worry about left and right module structures.

Here the following statements hold:

(1) As in the Ext-Free Resolution Proposition 110.2 one can show that the isomorphism type of $\mathrm{Ext}^n_{S\text{-left}}(M,N)$ can be determined using any free resolution for M.

Proposition 166.18. If $\mathbb{K}$ is a skew field, then for any $\mathbb{K}$-left module M and any $n \geq 1$ we have $\mathrm{Ext}^n_{\mathbb{K}\text{-left}}(M,\mathbb{K}) = 0$.

Proof. This follows from Proposition 165.26. ■

Definition. Let S be a ring, let $(\mathrm{C}_*, \partial_*)$ be a chain complex of S-left modules and let M be an S-left module. We refer to the map[2061]

$$\begin{array}{rcl} \mathrm{ev}\colon \mathrm{H}^n(C;M) & \to & \mathrm{Hom}_{S\text{-left}}(\mathrm{H}_n(C),M) \\ [\varphi\colon \mathrm{C}_n \to M] & \mapsto & \begin{pmatrix} \mathrm{H}_n(C) & \to & M \\ [c] & \mapsto & \langle \varphi(c) \end{pmatrix} \end{array}$$

as the evaluation homomorphism.

Theorem 166.19. (Universal Coefficient Theorem for Cohomology Modules) Let S be a PID, let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free S-modules and let M be an S-module. For each $n \in \mathbb{N}_0$ there exists a homomorphism

$$\epsilon\colon \mathrm{Ext}_S(\mathrm{H}_{n-1}(C),M) \to \mathrm{H}^n(C;M)$$

of S-modules which is natural in the chain complex C_* and natural in the S-module M and which has the property that the following sequence is exact:

$$0 \to \mathrm{Ext}_S(\mathrm{H}_{n-1}(C),M) \xrightarrow{\epsilon} \mathrm{H}^n(C;M) \xrightarrow{\mathrm{ev}} \mathrm{Hom}_S(\mathrm{H}_n(C),M) \to 0.$$

This short exact sequence splits and there exists therefore an isomorphism[2062]

$$\mathrm{H}^n(C;M) \cong \mathrm{Ext}_S(\mathrm{H}_{n-1}(C),M) \oplus \mathrm{Hom}_S(\mathrm{H}_n(C),M)$$

of S-modules.

Proof. The proof of Theorem 166.19 is again basically identical to the proof of the Algebraic Universal Coefficient Theorem 110.11. ■

Exercises for Chapter 166.

[2061] One can easily verify that the evaluation homomorphism is well-defined.

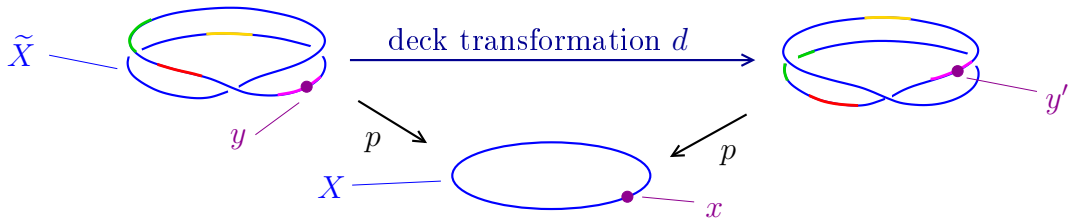
[2062] Since this cannot be mentioned often enough, recall that in Exercise 110.1 we saw that this isomorphism is not natural.

167. Twisted (co-) homology

In the last two chapters we studied (homological) algebra over a possibly non-commutative ring. Our favorite ring in this chapter are going to be the group rings $\mathbb{Z}[\pi_1(X, x_0)]$ of the fundamental group of a pointed topological space (X, x_0). Furthermore our favorite modules are going to be the chain groups $\mathrm{C}_*(\widetilde{X}_{x_0})$ of the natural universal covering of a pointed topological space. (X, x_0). As we will see, these are naturally $\mathbb{Z}[\pi_1(X, x_0)]$-left modules.

167.1. **Basics of covering theory.** We recall some concepts and results from our earlier study of covering theory. We start out our recap with the following definition from page 1383.

Definition. Let $p\colon \widetilde{X} \to X$ be a covering in the sense of the definition on page 1067.



(1) A deck transformation is a homeomorphism $d\colon \widetilde{X} \to \widetilde{X}$ such that $p(d(x)) = p(x)$ for all $x \in \widetilde{X}$, i.e. such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{X} & \xrightarrow[\cong]{d} & \widetilde{X} \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle p} & \\ & X. & \end{array}$$

The group of deck transformations is called the deck transformation group of the covering $p\colon \widetilde{X} \to X$ and we denote it by $\mathrm{Deck}(p\colon \widetilde{X} \to X)$.

(2) We say that the covering is regular if for every $x \in X$ the deck transformation group $\mathrm{Deck}(p\colon \widetilde{X} \to X)$ acts transitively on $p^{-1}(x)$, i.e. if given any two points $y, y' \in \widetilde{X}$ with $p(y) = p(y') = x$ there exists a deck transformation d with $d(y) = y'$. Otherwise we say that the covering is irregular.

(3) Let P be a property of isomorphism types of groups, e.g. cyclic, free, nilpotent, solvable etc. We say the covering $p\colon \widetilde{X} \to X$ is a P-covering if the covering is regular and if the deck transformation group has the property P.

In the following we recall some basic statements about deck transformation groups.

Lemma 62.2. Given any covering $p\colon \widetilde{X} \to X$ of path-connected topological spaces and given any $x_0 \in X$ the deck transformation group $\mathrm{Deck}(p\colon \widetilde{X} \to X)$ acts freely on $p^{-1}(x_0)$.

The following simplified version of the Regular Covering-Characterization Corollary 62.8 gives us a criterion for a covering to be regular.

Corollary 62.8. Let $p\colon (\widetilde{X},\widetilde{x}_0) \to (X,x_0)$ be a covering of pointed topological spaces that are path-connected and locally path-connected. Then the following statements are equivalent:

(1) The covering is regular.
(2) The deck transformation group $\mathrm{Deck}(p\colon \widetilde{X} \to X)$ acts transitively on $p^{-1}(x_0) \subset \widetilde{X}$.
(3) The subgroup $p_*(\pi_1(\widetilde{X},\widetilde{x}_0))$ is a normal subgroup of $\pi_1(X,x_0)$.

Proposition 167.1. Let $p\colon (\widetilde{X},\widetilde{x}_0) \to (X,x_0)$ be a *regular* covering of pointed topological spaces. We suppose that $\widetilde{X}$ and X are both path-connected and locally path-connected.

(1) The map[2063]

$$\begin{aligned}\Xi_{\widetilde{X},\widetilde{x}_0}\colon \mathrm{Deck}(p\colon \widetilde{X} \to X) &\to \pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0))\\ d &\mapsto \big[p \circ (\text{path in } \widetilde{X} \text{ from } \widetilde{x}_0 \text{ to } d(\widetilde{x}_0))\big].\end{aligned}$$

is an isomorphism.

(2) Let $q\colon (\widetilde{Y},\widetilde{y}_0) \to (Y,y_0)$ be another *regular* covering of pointed topological spaces such that $\widetilde{Y}$ and Y are both path-connected and locally path-connected. Suppose we are given maps $\Phi\colon \widetilde{X} \to \widetilde{Y}$ and $\varphi\colon X \to Y$ such that $\Phi(\widetilde{x}_0) = \widetilde{y}_0$ and such that the following diagram commutes:

$$\begin{array}{ccc}\widetilde{X} & \xrightarrow{\Phi} & \widetilde{Y}\\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q}\\ X & \xrightarrow{\varphi} & Y.\end{array}$$

Then the following diagram commutes:

$$\begin{array}{ccc}\mathrm{Deck}(p\colon \widetilde{X} \to X) & \xrightarrow{\Xi_{\widetilde{X},\widetilde{x}_0}} & \pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0))\\ \downarrow & & \downarrow{\scriptstyle \varphi_*}\\ \mathrm{Deck}(q\colon \widetilde{Y} \to Y) & \xrightarrow{\Xi_{\widetilde{Y},y_0}} & \pi_1(Y,x_0)/q_*(\pi_1(\widetilde{Y},y_0)),\end{array}$$

where the horizontal maps are the maps we introduced (1), where the left vertical map is the map given by the Induced-Deck Transformation Proposition 62.9 and the right vertical map is the projection.[2064]

Proof. The first statement is a simplified version of Proposition 62.6. The second statement is the content of Lemma 62.11. ∎

Convention. Let $p\colon (\widetilde{X},\widetilde{x}_0) \to (X,x_0)$ be a *regular* covering of pointed topological spaces. We suppose that $\widetilde{X}$ and X are both path-connected and locally path-connected. The

[2063]Since $p\colon \widetilde{X} \to X$ is a regular covering we know by the Regular Covering-Characterization Corollary 62.8 that $p_*(\pi_1(\widetilde{X},\widetilde{x}_0))$ is a normal subgroup of $\pi_1(X,x_0)$, thus $\pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0))$ is a group.
[2064]It follows from $p = q \circ r$ that $p_*(\pi_1(\widetilde{X},\widetilde{x}_0)) \subset q_*(\pi_1(\widetilde{Y},y_0))$.

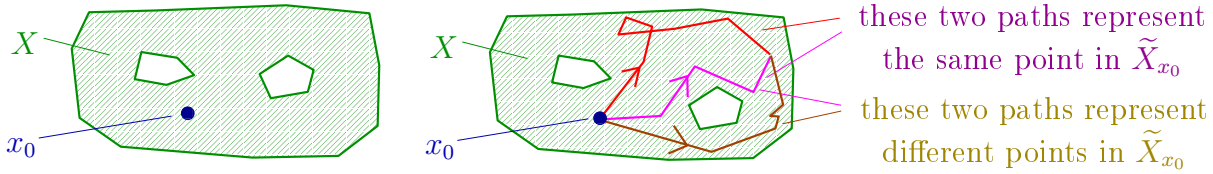
isomorphism

$$\begin{array}{rccl}\Xi_{\widetilde{X},\widetilde{x}_0}\colon & \mathrm{Deck}(p\colon \widetilde{X}\to X) & \to & \pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0)) \\ & d & \mapsto & \big[p\circ(\text{path in } \widetilde{X} \text{ from } \widetilde{x}_0 \text{ to } d(\widetilde{x}_0))\big]\end{array}$$

from the above Proposition 167.1 allows us to equip $\widetilde{X}$ with a natural left action by the group $\pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0))$. More precisely, we equip $\widetilde{X}$ with the left action

$$\begin{array}{rcl}\pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0))\times\widetilde{X} & \to & \widetilde{X} \\ (g,y) & \mapsto & \underbrace{((\Xi_{\widetilde{X},\widetilde{x}_0})^{-1})(g)}_{\in\mathrm{Deck}(p\colon \widetilde{X}\to X)}(y).\end{array}$$

We move on to covering that will be most relevant for us throughout the following chapters.



Notation. Let X be a topological space that is locally contractible and path-connected and let $x_0\in X$.

(1) We set

$$\widetilde{X}_{x_0} \;=\; \{\gamma\colon[0,1]\to X\,|\,\gamma(0)=x_0\}/\!\sim \qquad \begin{array}{l}\text{where } \alpha\sim\beta \text{ if } \alpha(1)=\beta(1) \text{ and} \\ \alpha*\overline{\beta} \text{ is a null-homotopic loop in } (X,x_0)\end{array}$$

and we equip $\widetilde{X}_{x_0}$ with the topology that we introduced in the proof of the Covering Existence Theorem 61.5.

(2) We denote by $p\colon\widetilde{X}_{x_0}\to X$ the evaluation map $[\gamma]\mapsto\gamma(1)$. In the proof of the Covering Existence Theorem 61.5 we showed that $\widetilde{X}_{x_0}$ is simply connected and we showed that $p\colon\widetilde{X}_{x_0}\to X$ is a covering map. As on page 1370 we refer to $p\colon\widetilde{X}_{x_0}\to X$ as the natural universal covering of (X,x_0). Furthermore we equip $\widetilde{X}_{x_0}$ with the natural base point $\widetilde{x}_0$ that is given by the constant path.

Remark. Let X be a topological space that is locally contractible and path-connected and let $x_0\in X$. We denote by $p\colon\widetilde{X}_{x_0}\to X$the corresponding natural universal covering. By the discussion on page 3534 we have a natural $\pi_1(X,x_0)$ left action on $\widetilde{X}_{x_0}$. As we saw in Exercise 62.7 this left action is given by

$$\begin{array}{rcl}\pi_1(X,x_0)\times\widetilde{X}_{x_0} & \to & \widetilde{X}_{x_0} \\ ([\alpha],[\gamma]) & \mapsto & [\alpha*\gamma].\end{array}$$

Remark. In the following chapters, when we discuss (co-) homology with twisted coefficients, we will only be interested in topological spaces that are locally contractible. Throughout these chapters we frequently and often subconsciously make use of the following two facts:

(1) By the Topological Manifolds-Local Properties Lemma 18.8 every topological manifold is locally contractible and by the CW-Complex Properties Proposition 68.10 (6) every CW-complex is locally contractible.

(2) If X is a locally contractible, then it follows from Lemmas 2.40 and 15.3 that X is path-connected if and only if X is connected. For no particular reason we usually write "locally contractible and path-connected" instead of the equivalent notion "locally contractible and connected".

167.2. **Definition of twisted (co-) homology.** At this stage it is worth recalling the following proposition.

Proposition 61.2. (Map Lifting Criterion) Let $p\colon (\widetilde{X},\widetilde{x}_0) \to (X,x_0)$ be a covering of pointed topological spaces. Furthermore let Z be a path-connected topological space and let $f\colon (Z,z_0) \to (B,b_0)$ be a map.

(1) If Z is locally path-connected, then we have the following equivalence of statements:

$$\begin{array}{ccc} & & (\widetilde{X},\widetilde{x}_0) \\ & \overset{\text{there exists a lift } \widetilde{f}}{\nearrow} & \downarrow p \\ (Z,z_0) & \xrightarrow[f]{} & (X,x_0) \end{array} \qquad \Longleftrightarrow \qquad \operatorname{im}(f_*) \subset \operatorname{im}(p_*).$$

(2) There exist at most one such lift, in other words, any two such lifts agree.

We will now apply the Map Lifting Criterion 61.2 to the study of the singular chain complex of a regular covering:

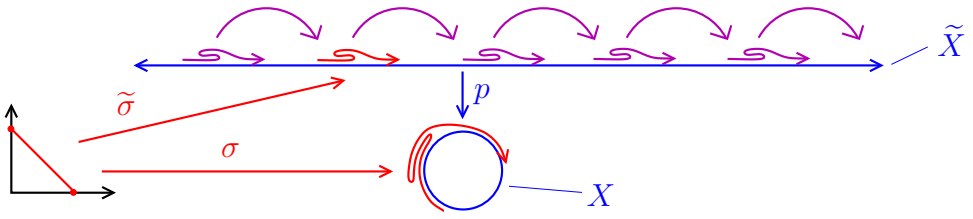
Lemma 167.2. (Regular Covering-Chain Complex Lemma) Let X be a topological space that is locally path-connected and path-connected. Furthermore let $p\colon \widetilde{X} \to X$ be a regular covering and let $A \subset X$. We write $\widetilde{A} := p^{-1}(A)$. We write $D := \operatorname{Deck}(p\colon \widetilde{X} \to X)$. Note that the natural left action of D on $\widetilde{X}$ preserves $\widetilde{A}$. This allows us to view each $\mathrm{C}_k(\widetilde{X},\widetilde{A})$ as a $\mathbb{Z}[D]$-left module.

(1) For each singular simplex $\sigma\colon \Delta^k \to X$ there exists a singular simplex $\widetilde{\sigma}\colon \Delta^k \to \widetilde{X}$ with $p \circ \widetilde{\sigma} = \sigma$.

(2) For each singular simplex $\sigma\colon \Delta^k \to X$ that is not contained in A we pick a lift $\widetilde{\sigma}\colon \Delta^k \to X$.[2065] The set of singular simplices

$$\{\widetilde{\sigma}\colon \Delta^k \to \widetilde{X} \,|\, \sigma\colon \Delta^k \to X \text{ with } \sigma(\Delta^k) \not\subset A\}$$

is a basis for the $\mathbb{Z}[D]$-left module $\mathrm{C}_k(\widetilde{X},\widetilde{A})$. In particular $\mathrm{C}_k(\widetilde{X},\widetilde{A})$ is a free $\mathbb{Z}[D]$-left module.



(3) The usual boundary map $\partial_k\colon \mathrm{C}_k(\widetilde{X},\widetilde{A}) \to \mathrm{C}_{k-1}(\widetilde{X},\widetilde{A})$ is a homomorphism of $\mathbb{Z}[D]$-left modules.

(4) $(\mathrm{C}_*(\widetilde{X},\widetilde{A}),\partial_*)$ is a chain complex of free $\mathbb{Z}[D]$-left modules.

Proof.

(1) First recall that a covering is by definition surjective. Since Δ^k is evidently locally path-connected and path-connected we thus obtain from the Map Lifting Criterion 61.2 (1) that we can lift any map $\sigma\colon \Delta^k \to X$ to a map $\widetilde{\sigma}\colon \Delta^k \to \widetilde{X}$.

[2065] It follows from Statement (1) and the Axiom of Choice 0.1 that we can do so.

(2) Let $k \in \mathbb{N}_0$. We start out with some notation. Given a singular simplex $\sigma\colon \Delta^k \to X$ with $\sigma(\Delta^k) \not\subset A$ we consider

$$L(\sigma) \;=\; \{\text{all lifts of } \sigma \text{ to maps } \Delta^k \to \widetilde{X}\}.$$

We make two observations:

(a) It follows easily from our hypothesis that $p\colon \widetilde{X} \to X$ is a regular covering, together with the Deck Group-Free Action Lemma 62.2 and the Map Lifting Criterion 61.2 (1), that the obvious action of D on $L(\sigma)$ is free and transitive.

(b) It follows easily from the definitions that as an abelian group $\mathrm{C}_k(\widetilde{X}, \widetilde{A})$ is generated by the union of all the $L(\sigma)$.

It follows from these two observations, together with Lemma 165.9, that $\mathrm{C}_k(\widetilde{X}, \widetilde{A})$ is a free $\mathbb{Z}[D]$-left module and that a basis is given by a choice of a lift for each such σ.

(3) By Lemma 72.9 we know that the boundary maps are natural, which implies in particular that the boundary map $\partial_k\colon \mathrm{C}_k(\widetilde{X}, \widetilde{A}) \to \mathrm{C}_{k-1}(\widetilde{X}, \widetilde{A})$ commute with the D-action. This means that ∂_k is a homomorphism of $\mathbb{Z}[D]$-left modules.

(4) This statement is just a summary of (1) and (2). ■

Convention. Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let $A \subset X$.

(1) Let $\Gamma \subset \pi_1(X, x_0)$ be a normal subgroup. If $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ is any path-connected covering with $p_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) = \Gamma$[2066], then it follows from the convention on page 3534 together with the Regular Covering-Chain Complex Lemma 167.2 that we can view $\mathrm{C}_*(\widetilde{X}, \widetilde{A})$ as a chain complex of free $\mathbb{Z}[\pi_1(X, x_0)/\Gamma]$-left modules.

(2) In particular we can view $\mathrm{C}_*(\widetilde{X}_{x_0}, \widetilde{A})$ as a chain complex of free $\mathbb{Z}[\pi_1(X, x_0)]$-left modules.

the Regular Covering-Chain Complex Lemma 167.2 is very powerful since, in the setting of the above convention, we can apply all kinds of algebraic tools from the last two chapters to the chain complex $\mathrm{C}_*(\widetilde{X}_{x_0}, \widetilde{A})$ of free $\mathbb{Z}[\pi_1(X, x_0)]$-left modules to define new invariants. Before we introduce these new invariants, let us recall the following notation from page 3503.

Notation. Let G be a group and let M be a $\mathbb{Z}[G]$-left module. We denote by $\overline{M}$ the $\mathbb{Z}[G]$-right module that is given by $m \underset{\overline{M}}{\cdot} g := g^{-1} \underset{M}{\cdot} m$.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Furthermore let $A \subset X$. Finally let R be a ring and let M be a

[2066] It follows from the Covering Existence Theorem 61.5 that such a covering does indeed exist.

$(\mathbb{Z}[\pi_1(X_0,x_0)],R)$-left left module. We denote by $p\colon \widetilde{X}_{x_0}\to X$ the natural universal covering and we write $\widetilde{A}:=p^{-1}(A)$. Given $k\in\mathbb{N}_0$ we define the R-left modules[2067]

$$\begin{array}{lcll} \mathrm{C}_k^{\mathrm{tw}}(X,A;M) & := & \overline{M}\otimes_{\mathbb{Z}[\pi_1(X,x_0)]}\mathrm{C}_k(\widetilde{X}_{x_0},\widetilde{A}) & (\text{twisted chain complex})\\ \mathrm{C}^k_{\mathrm{tw}}(X,A;M) & := & \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}(\mathrm{C}_k(\widetilde{X}_{x_0},\widetilde{A}),M) & (\text{twisted cochain complex}).\end{array}$$

Since the boundary maps are $\mathbb{Z}[\pi_1(X,x_0)]$-left module homomorphisms we obtain from the Tensoring Chain Complex Lemma 166.3 and the discussion on page 3520 that $\mathrm{id}\otimes\partial$ and $\mathrm{Hom}(\partial,\mathrm{id})$ define (co-) boundary maps. Thus we can define the R-left modules

$$\begin{array}{lcll} \mathrm{H}_k^{\mathrm{tw}}(X,A;M) & := & \mathrm{H}_k\big(\overline{M}\otimes_{\mathbb{Z}[\pi_1(X,x_0)]}\mathrm{C}_*(\widetilde{X}_{x_0},\widetilde{A})\big) & (\text{twisted homology})\\ \mathrm{H}^k_{\mathrm{tw}}(X,A;M) & := & \mathrm{H}^k\big(\mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}(\mathrm{C}_*(\widetilde{X}_{x_0},\widetilde{A}),M)\big) & (\text{twisted cohomology}).\end{array}$$

As always, if $A=\varnothing$, then we drop it from the notation.
To discuss our first example let us recall the following definition from page 3507.

Definition. Let G be a group and let R be a ring. Given an R-left module M we denote by ${}_{\mathrm{tr}}M$ the $(\mathbb{Z}[G],R)$-left left module where the $\mathbb{Z}[G]$-left module structure is given by the trivial g-action $g\cdot m:=m$ for each $g\in G$ and $m\in M$.

Let (X,A) be a pair of topological spaces and let G be an abelian group. On page 1913 we introduced the singular homology groups $\mathrm{H}_k(X,A;G)$ with coefficients in G. Furthermore from the outset we introduced on page 2402 the singular cohomology groups $\mathrm{H}^k(X,A;G)$. If G has an R-left module structure over a ring R, then it follows immediately from the definitions, see also the discussion on page 1914, that both $\mathrm{H}_k(X,A;G)$ and $\mathrm{H}^k(X,A;G)$ can be equipped with a natural R-left module structure in an obvious way.

The following little lemma shows that these two earlier types of (co-) homology groups are basically special cases of the present more general setting.

Lemma 167.3. (Twisted (co-) homology with trivial coefficients) Let X be a topological space that is locally contractible and path-connected, let $x_0\in X$ and let $A\subset X$. We write $\pi:=\pi_1(X,x_0)$ and we denote by $p\colon\widetilde{X}_{x_0}\to X$ the natural universal covering. We write $\widetilde{A}:=p^{-1}(A)$. Furthermore let R be a ring and let M be an R-left module. As above we consider the $(Z[\pi_1(X,x_0)],R)$-left left module ${}_{\mathrm{tr}}M$. The maps

$$\overbrace{\overline{{}_{\mathrm{tr}}M}\underset{\mathbb{Z}[\pi]}{\otimes}\mathrm{C}_k(\widetilde{X}_{x_0},\widetilde{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(X,A;{}_{\mathrm{tr}}M)}\to\mathrm{C}_k(X,A)\underset{\mathbb{Z}}{\otimes}M \quad\&\quad \mathrm{Hom}\underset{\mathbb{Z}}{}(\mathrm{C}_k(X,A),M)\to\overbrace{\underset{\mathbb{Z}[\pi]\text{-left}}{\mathrm{Hom}}(\mathrm{C}_k(\widetilde{X}_{x_0},\widetilde{A}),{}_{\mathrm{tr}}M)}^{=\mathrm{C}^k_{\mathrm{tw}}(X,A;{}_{\mathrm{tr}}M)}$$
$$m\otimes\sigma\mapsto p_*(\sigma)\otimes m \qquad\qquad \varphi\mapsto\varphi\circ p_*$$

are natural isomorphisms of R-left module chain complexes. Thus they give rise to natural isomorphisms

$$T\colon\underbrace{\mathrm{H}_k^{\mathrm{tw}}(X,A;{}_{\mathrm{tr}}M)}_{\text{twisted coefficients}}\xrightarrow{\cong}\underbrace{\mathrm{H}_k(X,A;M)}_{\text{see page 1913}}\quad\text{and}\quad T\colon\underbrace{\mathrm{H}^k(X,A;M)}_{\text{see page 2402}}\xrightarrow{\cong}\underbrace{\mathrm{H}^k_{\mathrm{tw}}(X,A;{}_{\mathrm{tr}}M)}_{\text{twisted coefficients}}$$

of R-left modules.

[2067]It follows from Lemma 165.14 and Lemma 165.1 that $\mathrm{C}_k^{\mathrm{tw}}(X,A;M)$ and $\mathrm{C}^k_{\mathrm{tw}}(X,A;M)$ are both R-left modules.

Proof. One can easily verify that the maps are well-defined and that both maps are (co-) chain maps. It remains to show that both maps are isomorphisms.

(1) We consider the map

$$\begin{array}{rcccl} \overline{{}_{\mathrm{tr}}M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A}) & \to & \overline{{}_{\mathrm{tr}}M} \otimes_{\mathbb{Z}} ({}_{\mathrm{tr}}\mathbb{Z} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})) & \to & \mathrm{C}_k(X, A) \underset{\mathbb{Z}}{\otimes} M \\ m \otimes \sigma & \mapsto & m \otimes (1 \otimes \sigma) & & \\ & & m \otimes (n \otimes \sigma) & \mapsto & n \cdot p_*(\sigma) \otimes m. \end{array}$$

The first map is an isomorphism by Lemma 165.20. Furthermore it follows easily from the Regular Covering-Chain Complex Lemma 167.2 together with Lemma 165.21 (2), that the second map is an isomorphism. The composition of these two maps is precisely the map that we were supposed to consider.

(2) Using Lemma 165.22 one can easily verify that the map on the "Hom-level" is also an isomorphism. We leave it to the reader to provide the details. ■

The definition of (co-) homology with twisted coefficients depends in many ways on the basis point. The following lemma explains how a path between different base points induces isomorphisms on (co-) homology with twisted coefficients.

In Lemmas 89.7 and 108.9 we saw that singular (co-) homology is covariantly functorial in the coefficients. The following definition generalizes this fact to our more general setting.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the corresponding natural universal covering. Let $A \subset X$. We write $\widetilde{A} := p^{-1}(A)$. Let R be a ring and let M and N be $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left modules and let $\Theta\colon M \to N$ be a homomorphism of $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left modules. The R-left homomorphisms

$$\begin{array}{rcl} \Theta_*\colon \overbrace{\overline{M} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(X,A;M)} & \to & \overbrace{\overline{N} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(X,A;N)} \\ m \otimes \sigma & \mapsto & \Theta(m) \otimes \sigma \end{array}$$

$$\begin{array}{rcl} \Theta_*\colon \overbrace{\mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}(\mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A}), M)}^{=\mathrm{C}^k_{\mathrm{tw}}(X,A;M)} & \to & \overbrace{\mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}(\mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A}), N)}^{=\mathrm{C}^k_{\mathrm{tw}}(X,A;N)} \\ \gamma & \mapsto & \Theta \circ \gamma \end{array}$$

are chain maps and thus induce maps on twisted (co-) homology which we denote by Θ_*.

The following lemma now says that (co-) homology with twisted coefficients is indeed covariantly functorial in the $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module.

Lemma 167.4. We suppose that we are in the setting of the above definition.

(1) For $\mathrm{id}\colon M \to M$ we have $\mathrm{id}_* = \mathrm{id}$ on the (co)-chain complexes and on the (co)-homology groups.

(2) For $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module homomorphisms $\Phi\colon L \to M$ and $\Psi\colon M \to N$ we have $(\Phi \circ \Psi)_* = \Phi_* \circ \Psi_*$ on the (co)-chain complexes and on the (co)-homology groups.

Proof. Both statements are essentially trivial. ■

Using functoriality of (co-) homology with twisted coefficients we can easily state and prove the following little lemma.

Lemma 167.5. (Direct Sum-of-Coefficients Lemma) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the corresponding natural universal covering. Let $A \subset X$. We write $\widetilde{A} := p^{-1}(A)$. Let R be a ring and let M and N be $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left modules. We consider the direct sum $M \oplus N$, which is again a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module. We denote by $i\colon M \to M \oplus N$ and $j\colon N \to M \oplus N$ the natural inclusions and we denote by $p\colon M \oplus N \to M$ and $q\colon M \oplus N \to N$ the natural projections. The maps

$$\begin{array}{rcl} p_* \oplus q_*\colon \mathrm{C}_k^{\mathrm{tw}}(X,A;M \oplus N) & \to & \mathrm{C}_k^{\mathrm{tw}}(X,A;M) \oplus \mathrm{C}_k^{\mathrm{tw}}(X,A;N) \\ p_* \oplus q_*\colon \mathrm{C}_{\mathrm{tw}}^k(X,A;M \oplus N) & \to & \mathrm{C}_{\mathrm{tw}}^k(X,A;M) \oplus \mathrm{C}_{\mathrm{tw}}^k(X,A;N) \end{array}$$

are isomorphisms of R-left module (co)-chain complexes with inverse given by $i_* \circ j_*$. In particular they induce isomorphism on (co-) homology with twisted coefficients.

Proof. The lemma is an immediate consequence of Lemma 167.4 since $i_* \oplus j_*$ and $p_* \oplus q_*$ are inverses of one another. ∎

(Co-) homology with twisted coefficients depends in two ways on the choice of a base point x_0: we use it to define the fundamental group $\pi_1(X,x_0)$ which in turn we need to define the corresponding group ring $\mathbb{Z}[\pi_1(X,x_0)]$, and we need the base point to define the natural universal covering $\widetilde{X}_{x_0}$. The following proposition describes how we can go from one base point to another.

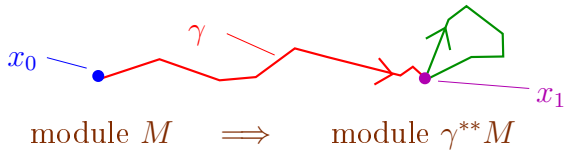
Proposition 167.6. (Change of Base Point Proposition) Let X be a topological space that is locally contractible and path-connected and let $A \subset X$. Let $\gamma\colon [0,1] \to X$ be a path from $x_0 = \gamma(0)$ to $x_1 = \gamma(1)$. For $i = 0,1$ we denote by $p_i\colon \widetilde{X}_{x_i} \to X$ the natural universal covering and we write $\widetilde{A}_i := p_i^{-1}(A)$. Finally let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module. As in the Change-of-Base Point Proposition 47.10 we consider the isomorphism

$$\begin{array}{rcl} \gamma^*\colon \pi_1(X,x_1) & \to & \pi_1(X,x_0) \\ [\alpha] & \mapsto & [\gamma * \alpha * \overline{\gamma}]. \end{array}$$

The isomorphism γ^* gives rise to a ring homomorphism $\gamma^*\colon \mathbb{Z}[\pi_1(X,x_1)] \to \mathbb{Z}[\pi_1(X,x_0)]$. Thus, as defined on page 3502, we can consider the $\mathbb{Z}[\pi_1(X,x_1)]$-left module $\gamma^{**}M$. Furthermore, as in Lemma 61.10 we consider the homeomorphism

$$\begin{array}{rcl} \gamma^*\colon \widetilde{X}_{x_1} & \to & \widetilde{X}_{x_0} \\ [\beta] & \mapsto & [\gamma * \beta]. \end{array}$$

(1) With the above notation the maps



$$\begin{array}{rcl} \gamma^*\colon \overline{\gamma^{**}M} \otimes_{\mathbb{Z}[\pi_1(X,x_1)]} \mathrm{C}_k(\widetilde{X}_{x_1},\widetilde{A}_1) & \to & \overline{M} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{X}_{x_0},\widetilde{A}_0) \\ m \otimes \sigma & \mapsto & m \otimes \gamma^*(\sigma) \end{array}$$

form an isomorphism of R-left module chain complexes and the maps

$$\begin{array}{rcl} \gamma^*\colon \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_1)]-\mathrm{left}}(\mathrm{C}_k(\widetilde{X}_{x_1},\widetilde{A}_1),\gamma^{**}M) & \to & \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]-\mathrm{left}}(\mathrm{C}_k(\widetilde{X}_{x_0},\widetilde{A}_0),M) \\ \varphi & \mapsto & \varphi \circ \gamma^* \end{array}$$

form an isomorphism of R-left module cochain complexes. In particular we get induced isomorphisms on (co-) homology with twisted coefficients.

(2) If $\gamma_0, \gamma_1 \colon [0,1] \to X$ are path-homotopic[2068], then $\gamma_0^* = \gamma_1^*$.
(3) Given paths $\alpha \colon [0,1] \to X$ and $\beta \colon [0,1] \to X$ with $\alpha(1) = \beta(0)$ we have $(\alpha * \beta)^* = \beta^* \circ \alpha^*$.

the path γ from x_0 to x_1 induces an isomorphism $\gamma_* \colon \pi_1(X, x_1) \to \pi_1(X, x_0)$

Proof.

(1) First let us show that the chain map given in the proposition is well-defined. To do so we need to consider the corresponding $\mathbb{Z}[\pi_1(X, x_0)]$-right module $\overline{M}$ and the corresponding $\mathbb{Z}[\pi_1(X, x_1)]$-right module $\overline{\gamma^{**}M}$. Note that given any $h \in \pi_1(X, x_1)$ and given any $m \in M$ we have the following equalities

$$m \underset{\overline{\gamma^{**}M}}{\cdot} h \;=\; h^{-1} \underset{\gamma^{**}M}{\cdot} m \;=\; \gamma^*(h^{-1}) \underset{M}{\cdot} m \;=\; m \underset{\overline{M}}{\cdot} \gamma^*(h).$$

Now we turn to the map γ^* on the chain level. Given any $m \in M$, given any singular simplex $\sigma \colon \Delta^k \to \widetilde{X}_{x_1}$ and given any $h \in \pi_1(X, x_1)$ we have the following equalities:

$$\begin{aligned} \gamma^*\big(m \underset{\overline{\gamma^{**}M}}{\cdot} h \otimes \sigma\big) \;=\; m \underset{\overline{\gamma^{**}M}}{\cdot} h \otimes \gamma^*(\sigma) \;&\overset{\text{by the above observation}}{=}\; m \underset{\overline{M}}{\cdot} \gamma^*(h) \otimes \sigma \;=\; m \otimes \gamma^*(h) \cdot \gamma^*(\sigma) \\ &=\; m \otimes \gamma^*(h \cdot \sigma) \;=\; \gamma^*(m \otimes h \cdot \sigma). \end{aligned}$$

This shows that the map on the chain level is well-defined. Furthermore it follows easily from the definitions that these maps form a chain map. Similarly one can show easily that the given map form a cochain map. It follows easily from Statements (2), which we will discuss shortly, that the (co-) chain maps are isomorphisms.

(2) If γ_0 and γ_1 are path-homotopic, then it follows easily from the definitions that $\gamma_0^* = \gamma_1^* \colon \pi_1(X, x_1) \to \pi_1(X, x_0)$ and $\gamma_0^* = \gamma_1^* \colon \widetilde{X}_{x_1} \to \widetilde{X}_{x_0}$. This observation implies Statement (2).

(3) This statement follows easily from the definitions. ∎

Remark. We suppose that we are in the setting of the Change of Base Point Proposition 167.6 with $x_0 = x_1$. If M is a $\mathbb{Z}[\pi_1(X, x_0)]$-module that has the property that the map $\pi_1(X, x_0) \to \mathrm{Aut}_{R\text{-left}}(M)$ factors through the abelianization of $\pi_1(X, x_0)$, then one can easily see that for any loop γ in (X, x_0) we have $\gamma^* M = M$. It follows from Change of Base Point Proposition 167.6 (2) and (3) that the map

$$\begin{array}{rcl} \pi_1(X, x_0) \times \mathrm{H}^k_{\mathrm{tw}}(X, A; M) & \to & \mathrm{H}^k_{\mathrm{tw}}(X, A; M) \\ ([\gamma], h) & \mapsto & \overline{\gamma}^*(h) \end{array}$$

defines a left action by $\pi_1(X, x_0)$ on $\mathrm{H}^k_{\mathrm{tw}}(X, A; M)$. In Exercise 167.2 we will see that this left action is in general, e.g. for $S^1 \vee S^2$, non-trivial.

[2068] Recall that according to the definition on page 1045 two paths maps $\gamma_0, \gamma_1 \colon [0,1] \to X$ are called *path-homotopic* if γ_0 and γ_1 are homotopic rel $\{0,1\}$.

167.3. **Functoriality.** In this section we will consider the functoriality of (co-) homology with twisted coefficients. The formulations of the statements require some care, since we have to deal with maps between *pointed* topological spaces and since we also have to worry about the module structures we are dealing with. The discussion of module structures leads us to the following definition.

Definition. Let $f\colon (X,x_0) \to (Y,y_0)$ be a map between pointed topological spaces. Furthermore let M be a $\mathbb{Z}[\pi_1(Y,y_0)]$-left module. We denote by f^*M the $\mathbb{Z}[\pi_1(X,x_0)]$-left module that is induced by the ring homomorphism $f_*\colon \mathbb{Z}[\pi_1(X,x_0)] \to \mathbb{Z}[\pi_1(Y,y_0)]$.[2069]

Definition. Let $f\colon (X,x_0) \to (Y,y_0)$ be a map between pointed topological spaces. We assume that X is locally path-connected and path-connected. Let $p\colon (\widehat{X},\widehat{x}_0) \to (X,x_0)$ and $q\colon (\widehat{Y},\widehat{y}_0) \to (Y,y_0)$ be two path-connected coverings with $f_*(p_*(\pi_1(\widehat{X},\widehat{x}_0))) \subset q_*(\pi_1(\widehat{Y},\widehat{y}_0))$. By the Map Lifting Criterion 61.2, applied to the map $f\circ p\colon (\widehat{X},\widehat{x}_0) \to (Y,y_0)$ and the covering $q\colon (\widehat{Y},\widehat{y}_0) \to (Y,y_0)$, there exists a unique map $\widetilde{f}\colon (\widehat{X},\widehat{x}_0) \to (X,x_0) \to (\widehat{Y},\widehat{y}_0)$ such that the following diagram commutes

$$\begin{array}{ccc} (\widehat{X},\widehat{x}_0) & \xrightarrow{\widetilde{f}} & (\widehat{Y},\widehat{y}_0)\ . \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ (X,x_0) & \xrightarrow{f} & (Y,y_0) \end{array}$$

We refer to $\widetilde{f}$ as the induced map.

Example. Let $f\colon (X,x_0) \to (Y,y_0)$ be a map between pointed topological spaces that are locally contractible and path-connected. We obtain an induced map

$$\widetilde{f}\colon \widetilde{X}_{x_0} \ \to\ \widetilde{Y}_{y_0}$$

between the natural universal coverings. It follows almost immediately from the definitions that it is given by

$$\underbrace{[\alpha\colon [0,1] \to X]}_{\in \widetilde{X}_{x_0}} \ \mapsto\ \underbrace{[f\circ\alpha\colon [0,1] \to Y]}_{\in \widetilde{Y}_{y_0}}.$$

Lemma 167.7. Let $f\colon (X,x_0) \to (Y,y_0)$ and $g\colon (Y,y_0) \to (Z,z_0)$ be maps between pointed topological spaces. We assume that X and Y are locally path-connected and path-connected. Let $p\colon (\widehat{X},\widehat{x}_0) \to (X,x_0)$, $q\colon (\widehat{Y},\widehat{y}_0) \to (Y,y_0)$ and $r\colon (\widehat{Z},\widehat{z}_0) \to (Z,z_0)$ be coverings with $f_*(p_*(\pi_1(\widehat{X},\widehat{x}_0))) \subset q_*(\pi_1(\widehat{Y},\widehat{y}_0))$ and $g_*(p_*(\pi_1(\widehat{Y},\widehat{y}_0))) \subset r_*(\pi_1(\widehat{Z},\widehat{z}_0))$. Then we have an equality of maps

$$\widetilde{g\circ f} \ =\ \widetilde{g}\circ\widetilde{f}\colon (\widehat{X},\widehat{x}_0) \ \to\ (\widehat{Z},\widehat{z}_0).$$

Proof. We will prove the lemma in Exercise 167.1. ∎

[2069] Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(Y,y_0)],R)$-left left module. Then f^*M is naturally a $(\mathbb{Z}[\pi_1(X,x_0)],R)$ left left module.

Proposition 167.8. (Chain Complex-Equivariance Proposition) Let $f\colon (X,x_0)\to(Y,y_0)$ be a map between pointed topological spaces. We assume that X is locally path-connected and path-connected. Let $p\colon (\widehat{X},\widehat{x}_0)\to(X,x_0)$ and $q\colon(\widehat{Y},\widehat{y}_0)\to(Y,y_0)$ be two *regular* coverings with $f_*(p_*(\pi_1(\widehat{X},\widehat{x}_0)))\subset q_*(\pi_1(\widehat{Y},\widehat{y}_0))$. We consider the induced map $\widetilde{f}\colon(\widehat{X},\widehat{x}_0)\to(\widehat{Y},\widehat{y}_0)$.

(1) Suppose that we are given subsets $A\subset X$ and $B\subset Y$ with $f(A)\subset B$. We write $\widehat{A}:=p^{-1}(A)$ and $\widehat{B}:=q^{-1}(B)$. The induced map $\widetilde{f}$ has the property that given any $Q\in\widehat{X}_{x_0}$ and given any $g\in\pi_1(X,x_0)/\operatorname{im}(p_*)$ we have

$$\widetilde{f}(g\cdot Q) \quad = \quad \underbrace{f_*(g)}_{\in\pi_1(Y,y_0)/\operatorname{im}(q_*)}\cdot\widetilde{f}(Q).$$

(2) Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(Y,y_0)],R)$-left left module. The maps[2070]

$$\begin{array}{rcl}\overline{f^*M}\otimes_{\mathbb{Z}[\pi_1(X,x_0)/\operatorname{im}(p_*)]}\mathrm{C}_k(\widehat{X},\widehat{A}) & \to & \overline{M}\otimes_{\mathbb{Z}[\pi_1(Y,y_0)/\operatorname{im}(q_*)]}\mathrm{C}_k(\widehat{Y},\widehat{B})\\ m\otimes(\sigma\colon\Delta^k\to\widehat{X}) & \mapsto & m\otimes(\widetilde{f}\circ\sigma)\end{array}$$

and

$$\begin{array}{rcl}\operatorname{Hom}_{\mathbb{Z}[\pi_1(Y,y_0)/\operatorname{im}(q_*)]\text{-left}}(\mathrm{C}_k(\widehat{Y},\widehat{B}),M) & \to & \operatorname{Hom}_{\mathbb{Z}[\pi_1(X,x_0)/\operatorname{im}(p_*)]\text{-left}}(\mathrm{C}_k(\widehat{X},\widehat{A}),f^*M)\\ \varphi & \mapsto & (\sigma\mapsto\varphi(\widetilde{f}\circ\sigma))\end{array}$$

are well-defined (co-) chain maps.

Proof.

(1) This statement is a slight variation on Proposition 62.13.

(2) This statement follows easily from (a) and Lemmas 165.15 and 165.19, respectively Lemmas 165.2 and 165.3. ■

Definition. Let $f\colon(X,x_0)\to(Y,y_0)$ be a map between pointed topological spaces that are locally contractible and path-connected. We write $\pi_X:=\pi_1(X,x_0)$, $\pi_Y:=\pi_1(Y,y_0)$. Furthermore let R be a ring and let M be a $(\mathbb{Z}[\pi_Y],R)$-left left module. We denote by $p\colon\widetilde{X}_{x_0}\to X$ and $q\colon\widetilde{Y}_{y_0}\to Y$ the natural universal coverings. Suppose that we are given subsets $A\subset X$ and $B\subset Y$ with $f(A)\subset B$. We write $\widetilde{A}:=p^{-1}(A)$ and $\widetilde{B}:=q^{-1}(B)$. We denote by $\widetilde{f}\colon\widetilde{X}_{x_0}\to\widetilde{Y}_{y_0}$ the map that is induced by $f\colon X\to Y$. Using the Chain Complex-Equivariance Proposition 167.8 we define

$$\begin{array}{rcl}f_*\colon \overbrace{\overline{f^*M}\otimes_{\mathbb{Z}[\pi_X]}\mathrm{C}_k(\widetilde{X}_{x_0},\widehat{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(X,A;f^*M)} & \to & \overbrace{\overline{M}\otimes_{\mathbb{Z}[\pi_Y]}\mathrm{C}_k(\widetilde{Y}_{y_0},\widehat{B})}^{=\mathrm{C}_k^{\mathrm{tw}}(Y,B;M)}\\ m\otimes(\sigma\colon\Delta^k\to\widetilde{X}_{x_0}) & \mapsto & m\otimes(\widetilde{f}\circ\sigma\colon\Delta^k\to\widetilde{Y}_{y_0})\end{array}$$

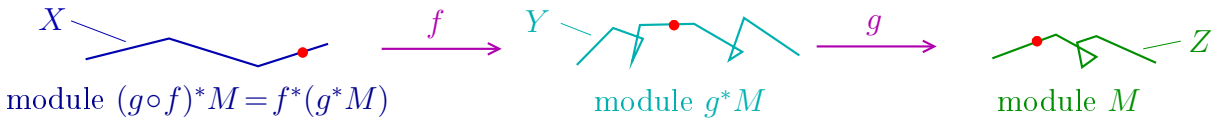
and

$$\begin{array}{rcl}f^*\colon \overbrace{\operatorname{Hom}_{\mathbb{Z}[\pi_Y]\text{-left}}(\mathrm{C}_k(\widetilde{Y}_{y_0},\widehat{B}),M)}^{=\mathrm{C}^k_{\mathrm{tw}}(Y,B;M)} & \to & \overbrace{\operatorname{Hom}_{\mathbb{Z}[\pi_X]\text{-left}}(\mathrm{C}_k(\widetilde{X}_{x_0},\widehat{A}),f^*M)}^{=\mathrm{C}^k_{\mathrm{tw}}(X,A;f^*M)}\\ \varphi & \mapsto & (\sigma\mapsto\varphi(r\circ\sigma))\end{array}$$

and we define the corresponding induced maps

$$\begin{aligned} f_*\colon \mathrm{H}_k^{\mathrm{tw}}(X; f^*M) &\to \mathrm{H}_k^{\mathrm{tw}}(Y; M) \\ f^*\colon \mathrm{H}^k_{\mathrm{tw}}(Y; M) &\to \mathrm{H}^k_{\mathrm{tw}}(X; f^*M). \end{aligned}$$

The following proposition says that (co-) homology with twisted coefficients is (co-) variantly functorial, at least if we take care with the choice of coefficients we are dealing with.



Proposition 167.9. (Twisted Homology-Functoriality Proposition) Let Z be a topological space that is locally contractible and path-connected. Furthermore let M be a $\mathbb{Z}[\pi_1(Z, z_0)]$-left module and let $C \subset Z$.

(1) We have $(\mathrm{id}_Z)^*M = M$ and the induced maps $\mathrm{id}_*\colon \mathrm{C}_k^{\mathrm{tw}}(Z, C; \mathrm{id}_Z^* M) \to \mathrm{C}_k^{\mathrm{tw}}(Z, C; M)$ and $\mathrm{id}^*\colon \mathrm{C}_k^{\mathrm{tw}}(Z; M) \to \mathrm{C}_k(Z; \mathrm{id}_Z^* M)$ are the identity.

(2) Let X and Y be topological spaces that are locally contractible and path-connected and let $A \subset X$ and $B \subset Y$. Let $f\colon (X, x_0) \to (Y, y_0)$ and $g\colon (Y, Y_0) \to (Z, Z_0)$ be maps between pointed topological spaces. We assume that $f(A) \subset B$ and $g(B) \subset C$. Then $(g \circ f)^*M = f^*(g^*M)$ and

$$\begin{aligned} (g \circ f)_* = g_* \circ f_*\colon \mathrm{C}_k^{\mathrm{tw}}(X, A; (g \circ f)^*M) &\to \mathrm{C}_k^{\mathrm{tw}}(Z, C; M) \\ (g \circ f)^* = f^* \circ g^*\colon \mathrm{C}^k_{\mathrm{tw}}(Z, C; M) &\to \mathrm{C}^k_{\mathrm{tw}}(X, A; (g \circ f)^*M). \end{aligned}$$

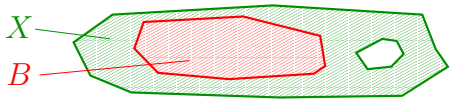
In both cases the identities on maps between (co-) chain complexes induce of course identities of maps between (co-) homology groups.

Proof. The proposition follows easily from Lemma 167.7. We leave the details to the reader. ∎

In the following we want to prove twisted analogues of earlier results, in particular we want to show the existence of a long exact sequence of a pair and we want to prove an excision theorem for twisted (co-) homology. In these two instances, and also many other settings, we will need the following slightly subtle proposition.

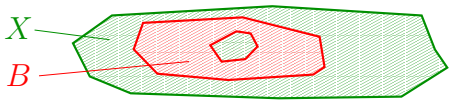
Proposition 167.10. (Change of Covering Proposition) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $q\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Let $B \subset X$ be a subspace with $x_0 \in B$. We assume that B is also locally contractible and path-connected. We write $\widetilde{B} := p^{-1}(B)$ and we denote by $p\colon \widehat{B}_{x_0} \to B$ the natural universal covering. Finally let $A \subset X$. We write $\widehat{A} := p^{-1}(A)$ and $\widetilde{A} := q^{-1}(A)$. We denote by $i\colon B \to X$ the inclusion map and we denote by $\widetilde{i}\colon \widehat{B}_{x_0} \to \widetilde{X}_{x_0}$ the induced map as defined on page 3541.

(1) The maps



$$\begin{aligned} \overbrace{i^*M \otimes_{\mathbb{Z}[\pi_1(B,x_0)]} \mathrm{C}_k(\widehat{B}_{x_0}, \widehat{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(B,A;i^*M)} &\to M \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{B}, \widetilde{A}) \\ m \otimes \sigma &\mapsto m \otimes \widetilde{i}_*(\sigma) \end{aligned}$$

are well-defined and they are natural isomorphisms of R-left module chain complexes.



(2) For each $k \in \mathbb{N}_0$ the map

$$\overbrace{i^*M \underset{\mathbb{Z}[\pi_1(B,x_0)]}{\otimes} \mathrm{C}_k(\widehat{B}_{x_0}, \widehat{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(B,A;i^*M)} \to \underset{\uparrow}{} \underset{\text{isomorphism from (1)}}{} M \underset{\mathbb{Z}[\pi_1(X,x_0)]}{\otimes} \mathrm{C}_k(\widetilde{B}, \widetilde{A}) \xrightarrow{\mathrm{id} \otimes \text{inclusion}} \overbrace{M \underset{\mathbb{Z}[\pi_1(X,x_0)]}{\otimes} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(X,A;M)}$$

is on the nose the map $i_*\colon \mathrm{C}_k^{\mathrm{tw}}(B, A; i^*M) \to \mathrm{C}_k^{\mathrm{tw}}(X, A; M)$ that we defined on page 3542.

$q\colon \widetilde{B} \to B$ is an infinite covering, but in this case $\widehat{B} = B$

we have $\widetilde{B} = B$, but in this setting $p\colon \widehat{B} \to B$ is an infinite covering

Remark. We will develop the theme of the Change of Covering Proposition 167.10 further in the eagerly awaited sequel, the Change of Covering Proposition II 169.4.

Proof.

(1) To simplify the notation a little bit we assume that $A = \varnothing$. Furthermore we write $\pi_B := \pi_1(B, x_0)$ and we write $\pi_X := \pi_1(X, x_0)$. Let $\widetilde{i}\colon \widehat{B}_{x_0} \to \widetilde{X}_{x_0}$ be the induced map as defined on page 3541. Note that it follows easily from the definitions that $\widetilde{i}(\widehat{B}) \subset \widetilde{B}$. In the Chain Complex-Equivariance Proposition 167.8 we saw that the map

$$i^*M \otimes_{\mathbb{Z}[\pi_B]} \mathrm{C}_k(\widehat{B}_{x_0}) \to M \otimes_{\mathbb{Z}[\pi_X]} \mathrm{C}_k(\widetilde{X}_{x_0})$$

is well-defined. The current map under consideration is exactly the same map, except that it follows from $\widetilde{i}(\widehat{B}) \subset \widetilde{B}$ that the map we are really interested in actually takes values in $M \otimes_{\mathbb{Z}[\pi_X]} \mathrm{C}_k(\widetilde{B})$. This shows that the map in our proposition is well-defined.

Claim. The map

$$\begin{aligned} \mathbb{Z}[\pi_X] \otimes_{\mathbb{Z}[\pi_B]} \mathrm{C}_k(\widehat{B}_{x_0}) &\to \mathrm{C}_k(\widetilde{B}) \\ g \otimes \sigma &\mapsto g \cdot (\widetilde{i} \circ \sigma) \end{aligned}$$

is an isomorphism of $\mathbb{Z}[\pi_X]$-left modules.

Proof. Given any singular k-simplex σ in B we pick a lift $\widetilde{\sigma}$ to $\widehat{B}_{x_0}$. In the Regular Covering-Chain Complex Lemma 167.2 we showed that these lifts form a basis of the free $\mathbb{Z}[\pi_B]$-left module $\mathrm{C}_k(\widehat{B}_{x_0})$. Furthermore by the Regular Covering-Chain Complex Lemma 167.2 we also know that the singular simplices $\widetilde{i}_* \circ \widetilde{\sigma}$ form a basis of the free $\mathbb{Z}[\pi_X]$-left module $\mathrm{C}_k(\widetilde{B})$. It follows from this observation, together with Lemma 165.21 (2), that the map sends a basis of the free $\mathbb{Z}[\pi_X]$-left module $\mathbb{Z}[\pi_X] \otimes_{\mathbb{Z}[\pi_B]} \mathrm{C}_k(\widehat{B}_{x_0})$ to a basis of the free $\mathbb{Z}[\pi_X]$-left module $\mathrm{C}_k(\widetilde{B})$. Thus we see that the map is indeed an isomorphism of $\mathbb{Z}[\pi_X]$-left modules. ⊞

Note that the map we are supposed to study equals the composition of the following maps:

$$\begin{array}{rcccl} i^*M \otimes_{\mathbb{Z}[\pi_B]} \mathrm{C}_k(\widehat{B}_{x_0}) & \to & M \otimes_{\mathbb{Z}[\pi_X]} (\mathbb{Z}[\pi_X] \otimes_{\mathbb{Z}[\pi_B]} \mathrm{C}_k(\widehat{B}_{x_0}) & \to & M \otimes_{\mathbb{Z}[\pi_X]} \mathrm{C}_k(\widetilde{B}) \\ m \otimes \sigma & \mapsto & m \otimes (1 \otimes \sigma) & & \\ & & m \otimes (g \otimes \sigma) & \mapsto & m \otimes g \cdot (\widetilde{i}_* \circ \sigma). \end{array}$$

It follows from Lemma 165.20 that the map to the left is well-defined and an isomorphism of R-left modules. It follows from the claim that the map to the right is an isomorphism of R-left modules.

(2) This statement follows immediately from the definitions. ■

By the Topological LES-Proposition 74.13 we know that a triple (X, A, B) of topological spaces gives rise to a long exact sequence of relative singular homology groups. We now have an analogous statement in the present setting.

Proposition 167.11. (Twisted-LES Proposition) Let X be a topological space that is locally contractible and path-connected, let B be subspace of X that is also locally contractible and path-connected, let $A \subset B$ be a further subspace and let $b_0 \in B$. We denote by $i\colon B \to X$ the inclusion. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, b_0)], R)$-left left module. Given any $n \in \mathbb{N}_0$ there exists a natural R-left module homomorphism

$$\partial_n\colon \mathrm{H}_n^{\mathrm{tw}}(X, B; M) \to \mathrm{H}_{n-1}^{\mathrm{tw}}(B, A; i^*M)$$

such that the following sequence is exact

$$\ldots \xrightarrow{\partial_{n+1}} \mathrm{H}_n^{\mathrm{tw}}(B, A; i^*M) \xrightarrow{i_*} \mathrm{H}_n^{\mathrm{tw}}(X, A; M) \underset{\uparrow}{\to} \mathrm{H}_n^{\mathrm{tw}}(X, B; M) \xrightarrow{\partial_n} \mathrm{H}_{n-1}^{\mathrm{tw}}(B, A; i^*M) \to \ldots$$

induced by the obvious map $(X, A) \to (X, B)$

An analogous statement also holds for cohomology groups with twisted coefficients.

Proof. We denote by $p\colon \widehat{B}_{b_0} \to B$ and $q\colon \widetilde{X}_{b_0} \to X$ the natural universal coverings. We write $\widehat{A} := p^{-1}(A)$, $\widetilde{A} := q^{-1}(A)$ and $\widetilde{B} := q^{-1}(B)$. The map $i\colon B \to X$ induces a map $\widetilde{i}\colon \widehat{B} \to \widetilde{X}$. Evidently $\widetilde{i}(\widehat{B}) \subset \widetilde{B}$. First let us consider the sequence

$$0 \to \mathrm{C}_k(\widetilde{B}, \widetilde{A}) \to \mathrm{C}_k(\widetilde{X}, \widetilde{B}) \to \mathrm{C}_k(\widetilde{X}, \widetilde{A}) \to 0.$$

Note that by the Regular Covering-Chain Complex Lemma 167.2 we know that this is sequence of $\mathbb{Z}[\pi_1(X, x_0)]$-left homomorphisms between free $\mathbb{Z}[\pi_1(X, x_0)]$-left modules. Furthermore, as in the proof of the Topological LES-Proposition 74.13, we obtain from the third isomorphism theorem that the sequence is exact. Since $\mathrm{C}_k(\widetilde{X}, \widetilde{A})$ is a free $\mathbb{Z}[\pi_1(X, x_0)]$-left module we obtain from Lemma 165.18 that

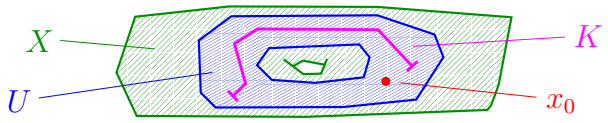
$$0 \to M \otimes_{\mathbb{Z}[\pi_1(X,b_0)]} \mathrm{C}_k(\widetilde{B}, \widetilde{A}) \to M \otimes_{\mathbb{Z}[\pi_1(X,b_0)]} \mathrm{C}_k(\widetilde{X}, \widetilde{B}) \to M \otimes_{\mathbb{Z}[\pi_1(X,b_0)]} \mathrm{C}_k(\widetilde{X}, \widetilde{A}) \to 0$$

is a short exact sequence of R-left modules. From the LES Lemma 166.11 we get a connecting homomorphism and a long exact sequence of the homology modules. We obtain the desired connecting homomorphism and the desired long exact sequence by replacing the homology modules of the chain complex $M \otimes_{\mathbb{Z}[\pi_1(X,b_0)]} \mathrm{C}_k(\widetilde{B}, \widetilde{A})$ by the homology groups $\mathrm{H}_k^{\mathrm{tw}}(B, A; i^*M)$ using the isomorphism that is provided by the Change of Covering Proposition 167.10 (1). Note that the Change of Covering Proposition 167.10 (2) implies that

the resulting connecting homomorphism does indeed give rise to the desired long exact sequence.

Finally note that the cohomological analogue is proved in a very similar fashion. We leave the proof to the exercise-deprived reader. ■

167.4. **Excision for (co-) homology with twisted coefficients.** As we have seen, excision theorems play an essential role when dealing with ordinary (co-) homology groups. The reader will thus be greatly relieved to hear that analogous statements also hold in the twisted context. More precisely we have the following analogue of the Excision Theorems 74.17, 74.18 and 109.1.



Theorem 167.12. (Excision Theorem for Twisted (Co-) Homology) Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module.

(1) Let $Z \subset A \subset X$ be subsets such that the closure of Z is contained in the interior of A and such that $x_0 \notin Z$. If $X \setminus Z$ is locally contractible and path-connected, then the inclusion $i\colon (X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ isomorphisms

$$\begin{aligned} i^*\colon \mathrm{H}_n^{\mathrm{tw}}(X \setminus Z, A \setminus Z; i^*M) &\xrightarrow{\cong} \mathrm{H}_n^{\mathrm{tw}}(X, A; M) \\ i^*\colon \mathrm{H}^n_{\mathrm{tw}}(X, A; M) &\xrightarrow{\cong} \mathrm{H}^n_{\mathrm{tw}}(X \setminus Z, A \setminus Z; i^*M). \end{aligned}$$

(2) Let K be a subset of X and let U be a neighborhood of the closure of K in X[2071]. If $x_0 \in U$ and if U is locally contractible and path-connected, then the inclusion $i\colon (U, U \setminus K) \to (X, X \setminus K)$ induces for each $n \in \mathbb{N}_0$ isomorphisms

$$\begin{aligned} i_*\colon \mathrm{H}_n^{\mathrm{tw}}(U, U \setminus K; i^*M) &\xrightarrow{\cong} \mathrm{H}_n^{\mathrm{tw}}(X, X \setminus K; M) \\ i^*\colon \mathrm{H}^n_{\mathrm{tw}}(X, X \setminus K; M) &\xrightarrow{\cong} \mathrm{H}^n_{\mathrm{tw}}(U, U \setminus K; i^*M). \end{aligned}$$

Proof.

(2) We denote by $o\colon \widetilde{X}_{x_0} \to X$ the natural universal covering and we write $\widetilde{U} := p^{-1}(U)$ and $\widetilde{K} := p^{-1}(K)$.

Claim. The inclusion induced map

$$i_*\colon \mathrm{C}_n(\widetilde{U}, \widetilde{U} \setminus \widetilde{K}) \to \mathrm{C}_n(\widetilde{X}, \widetilde{X} \setminus \widetilde{K})$$

is a chain homotopy equivalence of free $\mathbb{Z}[\pi_1(X, x_0)]$-left modules.

Proof. We make the following two observations:

(a) First note that

$$\text{closure of } \widetilde{K} \underset{\text{see Exercise 48.7}}{=} p^{-1}(\text{closure of } K) \underset{\text{by hypothesis}}{\subset} p^{-1}(\text{interior of } U) \underset{\text{see Exercise 48.7}}{=} \text{interior of } \widetilde{U}.$$

[2071] These conditions are satisfied for example if X is Hausdorff, if K is compact and if U is an open neighborhood of K.

Thus it follows from the original Excision Theorem 74.18 that for every $n \in \mathbb{N}_0$ the inclusion i induces an isomorphism

$$i_*\colon \mathrm{H}_n(\widetilde{U}, \widetilde{U} \setminus \widetilde{K}) \xrightarrow{\cong} \mathrm{H}_n(\widetilde{X}, \widetilde{X} \setminus \widetilde{K}).$$

(b) Next we consider the map

$$i_*\colon \mathrm{C}_n(\widetilde{U}, \widetilde{U} \setminus \widetilde{K}) \to \mathrm{C}_n(\widetilde{X}, \widetilde{X} \setminus \widetilde{K}).$$

In the Regular Covering-Chain Complex Lemma 167.2 we saw that both sides are free $\mathbb{Z}[\pi_1(X, x_0)]$-left modules. By definition of the module structure the map i_* is actually a homomorphism between two free $\mathbb{Z}[\pi_1(X, x_0)]$-left modules.

The claim now follows from (a) and (b) combined with Quasi Isomorphisms-are-Homotopy Equivalences Proposition 166.6. ⊞

Now let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. It follows immediately from the claim together with Lemmas 166.3 and 166.2 that the map

$$\mathrm{id}_M \otimes i_*\colon \overline{M} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_n(\widetilde{U}, \widetilde{U} \setminus \widetilde{K}) \to \overline{M} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_n(\widetilde{X}, \widetilde{X} \setminus \widetilde{K})$$

induces an R-left isomorphism of homology modules. It follows from this observation together with the Change of Covering Proposition 167.10 (1) and (2) that the map

$$i_*\colon \mathrm{H}_n^{\mathrm{tw}}(U, U \setminus K; i^*M) \to \mathrm{H}_n^{\mathrm{tw}}(X, X \setminus K; M)$$

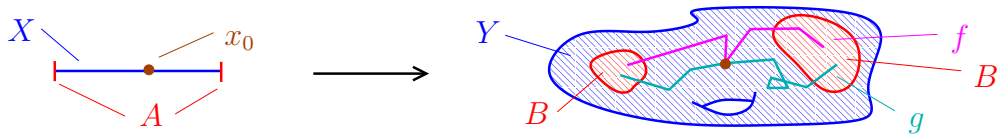
is an R-left isomorphism. The statement regarding cohomology groups is proved in a very similar fashion, using the Dualizing Chain Complex Lemma 166.4 and the Cochain Map Lemma 108.5. We leave the details to the reader.

(1) This statement follows from Statement (1) by setting $U = X \setminus Z$ and $K = X \setminus A$. Again we leave the few details to the reader. ■

167.5. **Homotopic maps and (co-) homology with twisted coefficients.** In the Homotopic Maps-and-Homology Proposition 73.6 and in the Homotopic Maps-H*-Lemma 108.13 we saw that homotopic maps induce the same map on homology. A similar statement also holds in the present context, but, as we will see, one needs to be careful about the twistings because of base point issues.

First let us recall the following definition from page 439.

Definition. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets. Let $f, g\colon (X, A) \to (Y, B)$ be two maps of pairs of topological spaces.



(1) A homotopy between f and g is a map

$$H\colon X \times [0, 1] \to Y$$

such that the following two conditions are satisfied:
(a) $H_0 = f$ and $H_1 = g$, and
(b) $H(a, t) \in B$ for all $a \in A$ and all $t \in [0, 1]$.

(2) Let $x_0 \in X$. We say a map $F\colon X \times [0, 1] \to Y$ is a homotopy rel x_0 if for all $s, t \in [0, 1]$ we have $F(x_0, s) = F(x_0, t)$.

Proposition 167.13. Let X and Y be topological spaces that are both locally contractible and path-connected. Let $A \subset X$ and $B \subset Y$ be subspaces. Let $f_0, f_1\colon (X, A) \to (Y, B)$ be two maps of pairs of topological spaces. Let $x_0 \in X$ and $y_0 \in Y$ with $f_0(x_0) =$

$f, g\colon (X, A) \to (Y, B)$ are homotopic rel x_0

y_0. Furthermore let R be a ring and let M be a $(\mathbb{Z}[\pi_1(Y, y_0)], R)$-left left module. Let $F\colon X \times [0,1] \to Y$ be a homotopy between f_0 and f_1. We denote by $\gamma\colon [0,1] \to Y$ the path that is given by $t \mapsto F(x_0, t)$. We have the following equality of $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left modules:

notation from the Change of Base Point Proposition 167.6

$$f_1^*(\overset{\downarrow}{\gamma^{**}}M) \;=\; f_0^*M.$$

Furthermore the maps

$$\begin{aligned} \mathrm{C}_k^{\mathrm{tw}}(X, A; f_0^*M) &\xrightarrow{f_{0*}} \mathrm{C}_k^{\mathrm{tw}}(Y, B; M) \\ \mathrm{C}_k^{\mathrm{tw}}(X, A; \underbrace{f_0^*M}_{=f_1^*(\gamma^{**}M)}) &\xrightarrow{f_{1*}} \mathrm{C}_k^{\mathrm{tw}}(X, A; \gamma^{**}M) \xrightarrow[\uparrow]{\gamma_*} \mathrm{C}_k^{\mathrm{tw}}(Y, B; M) \end{aligned}$$

isomorphism given by the Change of Base Point Proposition 167.6

are chain homotopic as chain maps between chain complexes of R-left modules. An analogous statement also holds for cochain complexes.

As the reader will have spotted, the statement becomes a little neater, if γ happens to be the constant path. This leads us to the following useful special case of Proposition 167.13.

Corollary 167.14. Let X and Y be topological spaces that are both locally contractible and path-connected. Let $A \subset X$ and $B \subset Y$ be subspaces and let $x_0 \in X$ and $y_0 \in Y$. Furthermore let R be a ring and let M be a $(\mathbb{Z}[\pi_1(Y, y_0)], R)$-left left module. Let $f, g\colon (X, A) \to (Y, B)$ be two maps of pairs of topological spaces with $f(x_0) = g(x_0) = y_0$. If f and g are homotopic rel x_0, then by the Homotopy-π_1-Proposition 50.3 we know that $f_* = g_*\colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$, thus $f^*M = g^*M$, and we see that

$$f_*, g_*\colon \mathrm{C}_k^{\mathrm{tw}}(X, A; f^*M) \to \mathrm{C}_k^{\mathrm{tw}}(Y, B; M) \text{ and } f_*, g_*\colon \mathrm{C}_{\mathrm{tw}}^k(Y, B; M) \to \mathrm{C}_{\mathrm{tw}}^k(X, A; f^*M)$$

are (co-) chain homotopic. In particular the induced maps

$$f_*, g_*\colon \mathrm{H}_k^{\mathrm{tw}}(X, A; f^*M) \to \mathrm{H}_k^{\mathrm{tw}}(Y, B; M) \text{ and } f_*, g_*\colon \mathrm{H}_{\mathrm{tw}}^k(Y, B; M) \to \mathrm{H}_{\mathrm{tw}}^k(X, A; f^*M)$$

are equal.

Proof of Corollary 167.14. The proposition follows immediately from Proposition 167.13 and the observation that under the given hypotheses the path γ in the statement of Proposition 167.13 is just the constant path. ∎

For reader's convenience we recall the following classic lemma, which will play an essential role in the proof of Proposition 167.13.

Lemma 73.8. Let V and W be topological spaces and let $\widetilde{F}\colon V \times [0,1] \to W$ be a homotopy. Let $\Omega_n \in \mathrm{C}_{n+1}(\Delta^n \times [0,1])$, $n \in \mathbb{N}_0$, be the sequence of singular chains that we defined on page 1605.[2072] The maps

$$\begin{array}{rcl} P_n\colon \mathrm{C}_n(V) & \to & \mathrm{C}_{n+1}(W) \\ (\sigma\colon \Delta^n \to V) & \mapsto & (\widetilde{F} \circ (\sigma \times \mathrm{id}_{[0,1]}))_*(\Omega_n). \end{array}$$

satisfy

$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; \widetilde{F}_{0*} - \widetilde{F}_{1*}$$

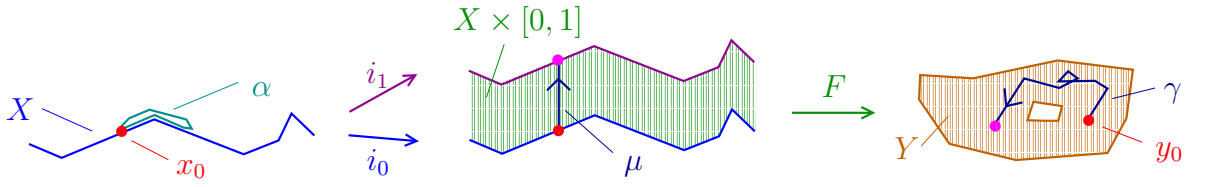
as maps from $\mathrm{C}_n(V)$ to $\mathrm{C}_n(W)$.

Proof of Proposition 167.13. To simplify the notation we assume that $A = B = \varnothing$. Mathematically this extra hypothesis makes no real difference. In the following we will only prove the statement regarding chain homotopies between chain complexes. We leave it to the reader to adapt the argument below to produce a cochain homotopy between the given cochain maps.

Without further ado, let $f_0, f_1\colon X \to Y$ be two maps of topological spaces. Let $x_0 \in X$ and $y_0 \in Y$ with $f_0(x_0) = y_0$. Furthermore let R be a ring and let M be a $(\mathbb{Z}[\pi_1(Y, y_0)], R)$-left left module. Furthermore let $F\colon X \times [0,1] \to Y$ be a homotopy between f_0 and f_1. We denote by $i_0, i_1\colon X \to X \times [0,1]$ the obvious embeddings. Note that by definition of a homotopy we have $F \circ i_0 = f_0$, $F \circ i_1 = f_1$. We denote by $\gamma\colon [0,1] \to X$ the path that is given by $t \mapsto F(x_0, t)$.

Claim 1. We have the following equality of $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left modules.

$$f_1^*(\gamma^{**}M) \;=\; f_0^*M.$$



Proof. We need to show that the maps

$$\begin{array}{rccccc} & \pi_1(X,x_0) & \xrightarrow{f_{0*}} & \pi_1(Y,y_0) & & \\ \text{and} & \pi_1(X,x_0) & \xrightarrow{f_{1*}} & \pi_1(X,f_1(x_0)) & \xrightarrow{\gamma^*} & \pi_1(Y,y_0) \end{array}$$

agree. Thus let $\alpha\colon [0,1] \to X$ be a loop in x_0. We denote by $\mu\colon [0,1] \to X \times [0,1]$ the path that is given by $t \mapsto (x_0, t)$. Then we have the following equalities:

$$\begin{array}{rcccccc} & & & & & & \text{there is an explicit path homotopy between } i_0 \circ \alpha \text{ and } \mu * i_1 \circ \alpha * \overline{\mu} \\ & & & & & & \downarrow \\ f_{0*}([\alpha]) & = & [f_0 \circ \alpha] & = & [F \circ (i_0 \circ \alpha)] & = & [F \circ (\mu * i_1 \circ \alpha * \overline{\mu})] \\ & & & = & [(F \circ \mu) * (F \circ i_1 * \alpha) * (F \circ \overline{\mu})] & = & [\gamma] * f_{1*}([\alpha]) * [\overline{\gamma}] \end{array}$$

⊞

As usual we denote by $p\colon \widetilde{X}_{x_0} \to X$ and $q\colon \widetilde{Y}_{y_0} \to Y$ the natural universal coverings. One can easily see that $p \times \mathrm{id}_{[0,1]}\colon \widetilde{X}_{x_0} \times [0,1] \to X \times [0,1]$ is a universal covering.[2073] Thus it follows from the Lift-to-Universal Coverings Proposition 61.13 that there exists a unique

[2072]The precise definition of the Ω_n is completely irrelevant for what follows.

[2073]But not that this is *not* the natural universal covering of $X \times [0,1]$.

map $\widetilde{F}\colon \widetilde{X}_{x_0} \times [0,1] \to \widetilde{Y}_{y_0}$ with $\widetilde{F}(\widetilde{x}_0, 0) = \widetilde{y}_0$ such that the following diagram commutes:

$$\begin{array}{ccc} \widetilde{X}_{x_0} \times [0,1] & \overset{\widetilde{F}}{\dashrightarrow} & \widetilde{Y}_{y_0} \\ {\scriptstyle p\times \mathrm{id}_{[0,1]}}\downarrow & & \downarrow{\scriptstyle q} \\ X \times [0,1] & \xrightarrow{\qquad F \qquad} & Y. \end{array}$$

Again we denote by $i_0, i_1\colon \widetilde{X}_{x_0} \to \widetilde{X}_{x_0} \times [0,1]$ the obvious embeddings. Below we will need the following subtle claim.

Claim 2. We write $y_1 = f_1(x_0) \in Y$. We denote by $q\colon \widetilde{Y}_{y_1} \to Y$ the corresponding natural universal covering. The following diagram commutes:

$$\begin{array}{ccc} \widetilde{X}_{x_0} & \xrightarrow{\qquad f_1 \qquad} & \widetilde{Y}_{y_1} \\ \downarrow{\scriptstyle i_1} & & \downarrow{\scriptstyle \gamma^*} \\ \widetilde{X}_{x_0} \times [0,1] & \xrightarrow{\qquad \widetilde{F} \qquad} & \widetilde{Y}_{y_0}. \end{array}$$

Proof. We start with two observations:

(a) By inspection one sees that both maps send the natural base point of $\widetilde{X}_{x_0}$ to the point of $\widetilde{Y}_{y_0}$ that is represented by the path γ.

(b) Both maps are lifts of the map $f_1 \circ p\colon \widetilde{X}_{x_0} \to Y$ to a map $\widetilde{X}_{x_0} \to \widetilde{Y}_{y_0}$.

Since $\widetilde{X}_{x_0}$ is path-connected and locally path-connected we obtain from the uniqueness statement of the Map Lifting Criterion 61.2 (2) that the two maps from $\widetilde{X}_{x_0} \to \widetilde{Y}_{y_0}$ agree. But this implies that the diagram commutes. ⊞

Now we can turn to the construction of the desired chain homotopy. Thus let $\Omega_n \in \mathrm{C}_{n+1}(\Delta^n \times [0,1])$, $n \in \mathbb{N}_0$, be the sequence of singular chains that we defined on page 1605. By Lemma 73.8 we know that the maps

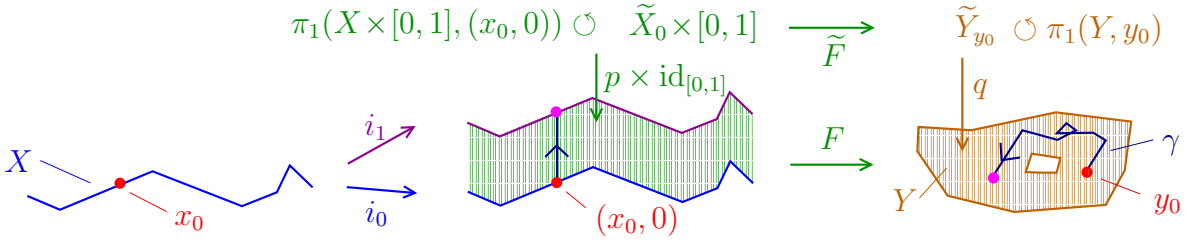
$$\begin{array}{rcl} P_n\colon \mathrm{C}_n(\widetilde{X}_{x_0}) & \to & \mathrm{C}_{n+1}(\widetilde{Y}_{y_0}) \\ (\sigma\colon \Delta^n \to \widetilde{X}_{x_0}) & \mapsto & (\widetilde{F} \circ (\sigma \times \mathrm{id}_{[0,1]}))_*(\Omega_n) \end{array}$$

satisfy

$$(*) \qquad \partial \circ P_n + P_{n-1} \circ \partial \;=\; (\widetilde{F} \circ i_0)_* - (\widetilde{F} \circ i_1)_*$$

as maps from $\mathrm{C}_n(\widetilde{X}_{x_0})$ to $\mathrm{C}_n(\widetilde{Y}_{y_0})$.

Claim 3. Given any singular simplex $\sigma\colon \Delta^n \to X$ and given any $g \in \pi_1(X, x_0)$ we have



$$P_n(g \cdot \sigma) \;=\; \underbrace{(F \circ i_0)_*(g)}_{\in \pi_1(Y, y_0)} \cdot P_n(\sigma).$$

Proof. First note that by Proposition 62.13 the map $\widetilde{F}\colon \widetilde{X}_{x_0} \times [0,1] \to \widetilde{Y}$ has the following property: given any $\widetilde{z} \in \widetilde{X}_{x_0} \times [0,1]$ and given any $h \in \pi_1(X \times [0,1], (x_0, 0))$ we have

$$\widetilde{F}(h \cdot \widetilde{z}) \;=\; \underbrace{F_*(h)}_{\in \pi_1(Y, y_0)} \cdot \widetilde{F}(\widetilde{z}).$$

Now let $\sigma\colon \Delta^n \to X$ be a singular simplex and let $g \in \pi_1(X, x_0)$. Then

$$\begin{array}{rcl@{\qquad}rcl}
 & & \text{by definition of } P_n & & & \text{by Proposition 62.13} \\
 & & \downarrow & & & \downarrow \\
P_n(g\cdot\sigma) & = & (\widetilde{F}\circ((g\cdot\sigma\times \mathrm{id}_{[0,1]})))_*(\Omega_n) & & = & (\widetilde{F}\circ(i_{0*}(g)\cdot(\sigma\times\mathrm{id}_{[0,1]})))_*(\Omega_n) \\
 & = & (F_*(i_{0*}(g))\cdot(\widetilde{F}\circ(\sigma\times\mathrm{id}_{[0,1]})))_*(\Omega_n) & & = & (F\circ i_0)_*(g)\cdot P_n(\sigma). \\
 & & \uparrow & & & \uparrow \\
 & & \text{by the above equality applied} & & & \text{by definition of } P_n \\
 & & \text{to } h = i_{0*}(g) \in \pi_1(X\times[0,1],(x_0,0)) & & &
\end{array}$$

It follows from Claim 3 together with Lemma 165.23 that we get an induced R-left module homomorphism

$$\mathrm{id}\otimes P_n\colon \overline{(F\circ i_0)^*M}\otimes_{\mathbb{Z}[\pi_1(X,x_0)]}\mathrm{C}_n(\widetilde{X}_{x_0}) \;\to\; \overline{M}\otimes_{\mathbb{Z}[\pi_1(Y,y_0)]}\mathrm{C}_n(\widetilde{Y}_{y_0}).$$

It follows from $(*)$ that these maps have the property that

$$(\mathrm{id}\otimes\partial)\circ(\mathrm{id}\otimes P_n)+(\mathrm{id}\otimes P_{n-1})\circ(\mathrm{id}\otimes\partial) \;=\; \mathrm{id}\otimes(\widetilde{F}\circ i_0)_* - \mathrm{id}\otimes(\widetilde{F}\circ i_1)_*$$

as maps from $\overline{(F\circ i_0)^*M}\otimes_{\mathbb{Z}[\pi_1(X,x_0)]}\mathrm{C}_n(\widetilde{X}_{x_0})$ to $\overline{M}\otimes_{\mathbb{Z}[\pi_1(Y,y_0)]}\mathrm{C}_n(\widetilde{Y}_{y_0})$. In other words, we have found a chain homotopy between the maps $\mathrm{id}\otimes(\widetilde{F}\circ i_0)_*$ and $\mathrm{id}\otimes(\widetilde{F}\circ i_1)_*$. It remains to show that these two maps are the chain maps we are supposed to study:

(1) It follows immediately from the definitions that $\mathrm{id}\otimes(\widetilde{F}\circ i_0)_* = f_{0*}$.
(2) It follows easily from Claim 1 and 2 that $\mathrm{id}\otimes(\widetilde{F}\circ i_1)_* = \gamma_*\circ f_{1*}$. ■

In the Homotopy Equivalence-H$_*$-Corollary 73.9 and the Homotopic Maps-Cohomology Lemma 108.13 we saw that homotopy equivalent topological spaces have isomorphic (co-) homology groups. Now we have similar statements in the context of (co-) homology with twisted coefficients. But as usual some care needs to be taken regarding base points and modules involved.

We start out with the following, slightly restrictive proposition.

Proposition 167.15. (Homotopy Equivalence-H$_*$-Proposition) Let (X, x_0) and (Y, y_0) be pointed topological spaces that are both locally contractible and path-connected. Let $A \subset X$ and $B \subset Y$ be subspaces and let $x_0 \in X$ and $y_0 \in Y$. Furthermore let $f\colon (X, A) \to (Y, B)$ be a map with $f(x_0) = y_0$. We suppose that there exists a map $g\colon (Y, B) \to (X, A)$ such that $g \circ f\colon (X, A) \to (X, A)$ is homotopic rel x_0 to $\mathrm{id}_X\colon (X, A) \to (X, A)$ and such that $f \circ g\colon (Y, B) \to (Y, B)$ is homotopic rel y_0 to $\mathrm{id}_Y\colon (Y, A) \to (Y, B)$. Then f induces isomorphisms on twisted (co-) homology, i.e. given any $\mathbb{Z}[\pi_1(Y, y_0)]$-left module M the induced maps

$$\begin{array}{rcl}
f_*\colon \mathrm{H}_k^{\mathrm{tw}}(X, A; f^*M) & \to & \mathrm{H}_k^{\mathrm{tw}}(Y, B; M) \\
f^*\colon \mathrm{H}^k_{\mathrm{tw}}(Y, B; M) & \to & \mathrm{H}^k_{\mathrm{tw}}(X, A; f^*M)
\end{array}$$

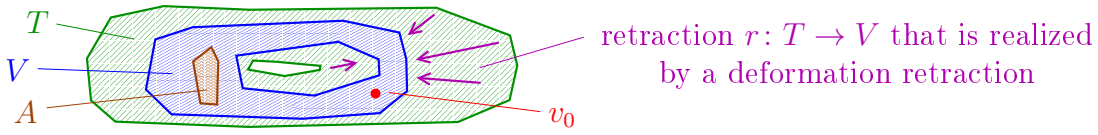
are isomorphisms.

Proof. First note that by hypothesis there exists a homotopy $S\colon X\times[0,1]\to X$ rel x_0 with $S_0=g\circ f\colon (X,A)\to(X,A)$ and $S_1=\mathrm{id}_X\colon (X,A)\to(X,A)$ and there exists a homotopy $T\colon Y\times[0,1]\to Y$ rel y_0 with $T_0=f\circ g\colon (Y,B)\to(Y,B)$ and $T_1=\mathrm{id}_Y\colon (Y,B)\to(Y,B)$. It follows from Corollary 167.14 and the Twisted Homology-Functoriality Proposition 167.9 that the composition of the following two maps

$$\mathrm{H}_k^{\mathrm{tw}}(X,A;\overbrace{f^*(g^*(f^*M))}^{=(g\circ f)^*f^*M=\mathrm{id}^*\,f^*M=f^*M})\xrightarrow{f_*}\mathrm{H}_k^{\mathrm{tw}}(Y,B;\overbrace{g^*(f^*M)}^{=(f\circ g)^*M=\mathrm{id}^*\,M=M})\xrightarrow{g_*}\mathrm{H}_k^{\mathrm{tw}}(X,A;f^*M)$$

is the identity and that the composition of the following two maps

$$\mathrm{H}_k^{\mathrm{tw}}(Y,B;\underbrace{g^*(f^*M)}_{=(f\circ g)^*M=\mathrm{id}^*\,M=M})\xrightarrow{g_*}\mathrm{H}_k^{\mathrm{tw}}(X,A;f^*M)\xrightarrow{f_*}\mathrm{H}_k^{\mathrm{tw}}(Y,B;M)$$



is also the identity. This shows that f_* is an isomorphism. Basically the same argument also works for twisted cohomology instead of twisted homology.[2074] ■

The following corollary considers an important special case of a homotopy equivalence.

Corollary 167.16. (Deformation Retract-Twisted Homology Corollary) Let T be a topological space and let $A\subset V\subset T$ be subspaces. We assume that T and V are both locally contractible and path-connected. Furthermore let $r\colon T\to V$ be a retraction. We assume that r is realized by a deformation retraction $F\colon T\times[0,1]\to T$, i.e. according to the definition on page 433 we assume that there exists a homotopy $F\colon T\times[0,1]\to T$ rel V with $F_0=\mathrm{id}_T$ and with $F_1=r$. For any $v_0\in V$ and any $\mathbb{Z}[\pi_1(V,v_0)]$-left module M the induced maps

$$\begin{aligned} r_*\colon \mathrm{H}_k^{\mathrm{tw}}(T,A;r^*M) &\to \mathrm{H}_k^{\mathrm{tw}}(V,A;M)\\ r^*\colon \mathrm{H}^k_{\mathrm{tw}}(V,A;M) &\to \mathrm{H}^k_{\mathrm{tw}}(T,A;r^*M)\end{aligned}$$

are isomorphisms.

Proof. We denote by $i\colon V\to T$ the inclusion. Note that $r\circ i=\mathrm{id}_V$. The desired statement follows immediately from the Homotopy Equivalence-H_*-Proposition 167.15 since the homotopy $F\colon T\times[0,1]\to T$ between $F_0=\mathrm{id}_T$ and $F_1=r=i\circ r$ and fixes the base point v_0, and since for $r\circ i$ we can use the constant homotopy, which of course also fixes the base point v_0. ■

Using the Deformation Retract-Twisted Homology Corollary 167.16 we can prove the following statement that does not bother with niceties regarding base points.

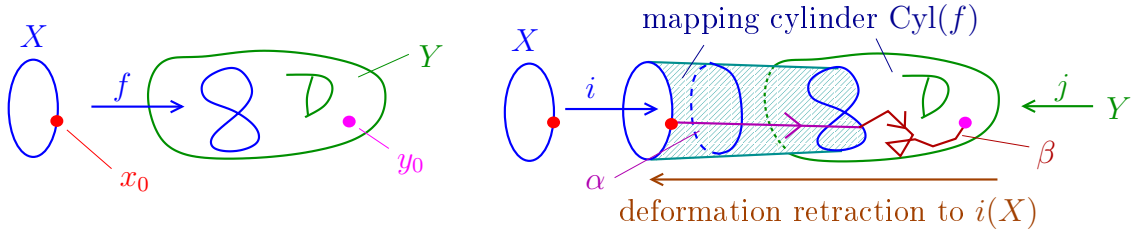
Corollary 167.17. Let X and Y be topological spaces that are both locally contractible and path-connected. We assume that X and Y are homotopy equivalent. Given any $x_0\in X$, $y_0\in Y$, given any ring R and given any $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left module M there exists a $(\mathbb{Z}[\pi_1(Y,y_0)],R)$-left module N, which as an R-left module is isomorphic to M,

[2074] Note that this argument is formally the same as the argument that we used in the proof of the Homotopy Equivalence-H_*-Corollary 73.9.

such that the twisted homology groups $\mathrm{H}_k^{\mathrm{tw}}(X;M)$ and $\mathrm{H}_k^{\mathrm{tw}}(Y;N)$ are isomorphic R-left modules and such that the twisted cohomology groups $\mathrm{H}^k_{\mathrm{tw}}(X;M)$ and $\mathrm{H}^k_{\mathrm{tw}}(Y;N)$ are isomorphic R-left modules.

Proof. Let $f\colon X \to Y$ be a homotopy equivalence. As on page 454 we consider the mapping cylinder

$$\mathrm{Cyl}(f) := \mathrm{Cyl}(f\colon X \to Y) := ((X \times [0,1]) \sqcup Y)/\sim \text{ where } (x,1) \sim f(x) \text{ for all } x \in X.$$



In the Mapping Cylinder Basics Lemma 16.10 we saw that the two maps

$$\begin{array}{rcl} i\colon X & \to & \mathrm{Cyl}(f\colon X \to Y) \\ x & \mapsto & [(x,0)] \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon Y & \to & \mathrm{Cyl}(f\colon X \to Y) \\ y & \mapsto & [y] \end{array}$$

are closed embeddings. Furthermore in the proof of Corollary 17.17 we saw that $i(X)$ is a deformation retract of $\mathrm{Cyl}(f)$ and we saw that $j(Y)$ is a deformation retract of $\mathrm{Cyl}(f)$. We denote by $r\colon \mathrm{Cyl}(f) \to i(X)$ the corresponding retraction. Let $\alpha\colon [0,1] \to \mathrm{Cyl}(f)$ be the path that is given by $t \mapsto [(x_0,t)]$ and let $\beta\colon [0,1] \to Y$ be any path from $f(x_0)$ to y_0. We see that[2075]

$$\begin{array}{ccccc} & & \text{given by the homeomorphism } i\colon X \to i(X) & & \text{isomorphism by (2)} \\ & & \downarrow & & \downarrow \\ \mathrm{H}_k^{\mathrm{tw}}(X;M) & \xrightarrow{\cong} & \mathrm{H}_k^{\mathrm{tw}}(i(X);(i^{-1})^*M) & \cong & \mathrm{H}_k^{\mathrm{tw}}(\mathrm{Cyl}(f);r^*(i^{-1})^*M) \\ & \cong & \mathrm{H}_k^{\mathrm{tw}}(\mathrm{Cyl}(f);\beta^{**}\alpha^{**}r^*(i^{-1})^*M) & \cong & \mathrm{H}_k^{\mathrm{tw}}(Y;j^*\beta^{**}\alpha^{**}r^*(i^{-1})^*M). \\ & & \uparrow & & \uparrow \\ & & \text{isomorphism by the Change of Base Point Proposition 167.6} & & \text{isomorphism by (2) and since } j\colon Y \to j(Y) \text{ is a homeomorphism} \end{array}$$

This concludes the arguments regarding twisted homology modules. The argument regarding twisted cohomology modules is very similar. We leave the details to the reader. ∎

Exercises for Chapter 167.

Exercise 167.1. Let $f\colon (X,x_0) \to (Y,y_0)$ and $g\colon (Y,y_0) \to (Z,z_0)$ be maps between pointed topological spaces. We assume that X and Y are locally path-connected and path-connected. Let $p\colon (\widehat{X},\widehat{x}_0) \to (X,x_0)$, $q\colon (\widehat{Y},\widehat{y}_0) \to (Y,y_0)$ and $r\colon (\widehat{Z},\widehat{z}_0) \to (Z,z_0)$ be coverings with $f_*(p_*(\pi_1(\widehat{X},\widehat{x}_0))) \subset \pi_1(\widehat{Y},\widehat{y}_0)$ and $g_*(p_*(\pi_1(\widehat{Y},\widehat{y}_0))) \subset \pi_1(\widehat{Z},\widehat{z}_0)$. We consider the induced maps $\widetilde{f}\colon (\widehat{X},\widehat{x}_0) \to (\widehat{Y},\widehat{y}_0)$, $\widetilde{g}\colon (\widehat{Y},\widehat{y}_0) \to (\widehat{Z},\widehat{z}_0)$ and $\widetilde{g \circ f}\colon (\widehat{X},\widehat{x}_0) \to (\widehat{Z},\widehat{z}_0)$ that we defined on page 3541. Show that we have an equality of maps

$$\widetilde{g \circ f} \;=\; \widetilde{g} \circ \widetilde{f}\colon (\widehat{X},\widehat{x}_0) \;\to\; (\widehat{Z},\widehat{z}_0).$$

[2075] In Exercise 16.19 we saw, using in particular an argument as in the proof of the Mapping Cylinder Basics Lemma 16.12 (1), that if X and Y are locally contractible, then the mapping cylinder $\mathrm{Cyl}(f\colon X \to Y)$ is also locally contractible. Thus it makes sense to consider the twisted homology groups of $\mathrm{Cyl}(f)$.

Exercise 167.2. We consider the topological space $X = S^1 \vee S^2$ and we take as base point the wedge point x_0. Note that $\pi_1(S^1 \vee S^2, x_0) \cong \pi_1(S^1, x_0)$ is abelian. Thus it follows from the Change of Base Point Proposition 167.6 that $\pi_1(X, x_0)$ acts on any on any twisted homology module $\mathrm{H}_k^{\mathrm{tw}}(X; M)$ and $\mathrm{H}_{\mathrm{tw}}^k(X; M)$. Given any example of a $\mathbb{Z}[\pi_1(X, x_0)]$-left module for which this left action is non-trivial.

168. Calculations and examples of twisted (co-) homology

168.1. **(Co-) homology with twisted coefficients in degree 0.** In the H_0-Proposition 72.5 and on page 1914 we saw that it is straightforward to calculate singular (co-) homology in degree 0. As we will see, it is also pretty straightforward to calculate singular (co-) homology with twisted coefficients in degree 0. To state the corresponding result we need the following definition.

Definition. Let π be a group, let R be a ring and let M be a $(\mathbb{Z}[\pi], R)$-left left module. We define

$$\begin{array}{rcll} M_\pi & := & M \Big/ \left\{ \sum_{i=1}^{k} (g_i \cdot v_i - v_i) \,\middle|\, g_i \in \pi \text{ and } v_i \in M \right\} & \pi\text{-coinvariants} \\ M^\pi & := & \{v \in M \,|\, g \cdot v = v \text{ for all } g \in \pi\} & \pi\text{-invariants} \end{array}$$

Note that M_π and M^π are both R-left modules.

Examples. Let π be a group.

(1) If π acts trivially on an abelian group M, then it follows immediately from the definitions that M_π is naturally isomorphic to M and furthermore $M^\pi = M$.
(2) We consider the case $M = \mathbb{Z}[\pi]$ and $R = \mathbb{Z}$. We equip M with the $\mathbb{Z}[\pi]$-left module structure that is given by $g \cdot m := m \cdot g^{-1}$. In Exercise 168.1 we will show that

$$\begin{array}{rcl} \mathbb{Z}[\pi]_\pi & \to & \mathbb{Z} \\ \left[\sum_{i=1}^{k} r_i \cdot g_i \right] & \mapsto & \sum_{i=1}^{k} r_i \end{array}$$

is an isomorphism and we will see that

$$\mathbb{Z}[\pi]^\pi = \begin{cases} 0, & \text{if } \pi \text{ is infinite,} \\ \mathbb{Z} \cdot \sum_{g \in \pi} g, & \text{if } \pi \text{ is finite.} \end{cases}$$

Before we can state our calculation of twisted (co-) homology in degree 0 it is convenient to recall the following notation from page 1590.

Notation. Let X be a topological space. Given a point $P \in X$ we denote by P also the singular 0-simplex $\Delta^0 \to X$ that is given by sending the single point in Δ^0 to P.

The following lemma is the analogue of the H_0-Proposition 72.5 and the discussion on page 1914.

Proposition 168.1. (Twisted H_0-Proposition) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We write $\pi := \pi_1(X, x_0)$. Let R be a ring and let M be a $(\mathbb{Z}[\pi], R)$-left left module. We consider the natural universal covering $p\colon \widetilde{X}_{x_0} \to X$ and we denote by $\widetilde{x}_0$ the natural base point of $\widetilde{X}_{x_0}$. The augmentation map

$$\begin{array}{rcl} \epsilon_X\colon H_0^{\mathrm{tw}}(X; M) & \to & M_\pi \\ \left[\sum_{i=1}^{k} m_i \otimes_{\mathbb{Z}[\pi]} \sigma_i \right] & \mapsto & \left[\sum_{i=1}^{k} m_i \right] \end{array}$$

and the evaluation map

$$\begin{array}{rcl} \mathrm{ev}_X\colon \mathrm{H}^0_{\mathrm{tw}}(X;M) & \to & M^\pi \\ [\varphi\colon \mathrm{C}_0(\widetilde{X}_{x_0}) \to M)] & \mapsto & \varphi(\widetilde{x}_0) \\ & & \uparrow \\ & & \text{here } \widetilde{x}_0 \text{ is short for the constant map } \Delta^0 \to \widetilde{X}_{x_0} \text{ that sends 1 to } \widetilde{x}_0 \end{array}$$

are natural isomorphisms of R-left modules

Example. We suppose that we are in the setting of the Twisted H_0-Proposition 168.1. If π acts trivially on M, then the Twisted H_0-Proposition 168.1 says that $\mathrm{H}_0^{\mathrm{tw}}(X;{}_{\mathrm{tr}}M)$ and $\mathrm{H}^0_{\mathrm{tw}}(X;{}_{\mathrm{tr}}M)$ are both naturally isomorphic to the R-left module M. This result is consistent with the fact, shown in Lemma 167.3, that $\mathrm{H}_0^{\mathrm{tw}}(X;{}_{\mathrm{tr}}M) \cong \mathrm{H}_0(X;M)$ and $\mathrm{H}^0_{\mathrm{tw}}(X;{}_{\mathrm{tr}}M) \cong \mathrm{H}^0(X;M)$ and our earlier results in the H_0-Proposition 72.5 and on page 1914.

Proof. In the following we will deal with $\mathrm{H}_0^{\mathrm{tw}}(X;M)$. We will prove the statement regarding $\mathrm{H}^0_{\mathrm{tw}}(X;M)$ in Exercise 168.3.

Claim. The map
$$\begin{array}{rcl} \epsilon_X\colon \mathrm{H}_0^{\mathrm{tw}}(X;M) & \to & M_\pi \\ \left[\sum_{i=1}^k m_i \otimes_{\mathbb{Z}[\pi]} \sigma_i\right] & \mapsto & \left[\sum_{i=1}^k m_i\right] \end{array}$$
is well-defined.

Proof. First we need to show that the map is well-defined on the twisted chain level, i.e. we need to show that the map is well-defined as a map $\overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_0(\widetilde{X}_{x_0}) = \mathrm{C}_0^{\mathrm{tw}}(X;M) \to M_\pi$. Note that for $m \in M$, $\sigma \in \mathrm{C}_0(\widetilde{X}_{x_0})$ and $g \in \pi$ we have

$$\epsilon_X([m \underset{\overline{M}}{\cdot} g \otimes \sigma]) \underset{\substack{\uparrow \\ \text{definition of } \overline{M}}}{=} \epsilon_X([g^{-1} \underset{M}{\cdot} m \otimes \sigma] = [g^{-1} \underset{M}{\cdot} m] \underset{\substack{\uparrow \\ \text{since } g^{-1}\cdot m - m = (g^{-1}-1)\cdot m = 0 \in M_\pi}}{=} [m] = \epsilon_X([m \otimes g \cdot \sigma]) \in M_\pi.$$

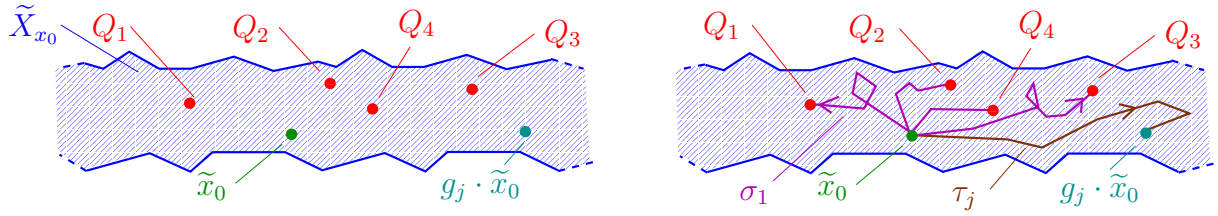
Note that it follows easily from this little calculation together with Lemma 165.23 that the map $\overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_0(\widetilde{X}_{x_0}) = \mathrm{C}_0^{\mathrm{tw}}(X;M) \to M_\pi$ is well-defined.

Next let $m \in M$ and let $\sigma\colon \Delta^1 \to \widetilde{X}_{x_0}$ be a singular 1-simplex. Then

$$\epsilon_X(\partial(m \otimes \sigma)) \underset{\substack{\uparrow \\ \text{see the Tensoring Chain Complex Lemma 166.3}}}{=} \epsilon_X(m \otimes \partial\sigma) \underset{\substack{\uparrow \\ \text{see page 1585}}}{=} \epsilon_X(m \otimes \sigma(0,1) - m \otimes \sigma(1,0)) = m - m = 0.$$

This shows that $\epsilon_X\colon \mathrm{H}_0^{\mathrm{tw}}(X;M) \to M_\pi$ is indeed well-defined. ⊞

It follows basically immediately from the fact that X is non-empty that the map $\epsilon_X\colon \mathrm{H}_0^{\mathrm{tw}}(X;M) \to M_\pi$ is an epimorphism. It remains to show that it is a monomorphism. Thus suppose we are given $\sum_{i=1}^k m_i \otimes Q_i \in \overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_0(\widetilde{X}_{x_0}) = \mathrm{C}_0^{\mathrm{tw}}(X;M)$ which represents an element in the kernel of ϵ_X. This means that for $j = 1, \ldots, l$ there exist $g_j \in \pi$ and $v_j \in M$ such that the following equality holds in M:



$$\sum_{i=1}^k m_i = \sum_{j=1}^l (g_j \cdot v_j - v_j).$$

Since X is path-connected there exist singular 1-simplices $\sigma_1, \ldots, \sigma_k\colon \Delta^1 \to \widetilde{X}_{x_0}$ with $\partial\sigma_i = Q_i - x_0$. Furthermore there exist singular 1-simplices $\tau_1, \ldots, \tau_l\colon \Delta^1 \to \widetilde{X}_{x_0}$ with

$\partial\tau_j = g_j \cdot x_0 - x_0$. We now see that

$$\begin{aligned}\partial_1\Big(\sum_{i=1}^{k} m_i \otimes \sigma_i \;-\; \sum_{j=1}^{l} v_j \otimes \tau_j\Big) \;&=\; \sum_{i=1}^{k}(m_i \otimes Q_i - m_i \otimes x_0) \;-\; \sum_{j=1}^{l}\big(\underbrace{v_j \otimes g_j \cdot x_0}_{=v_j\cdot g_j \otimes x_0} - v_j \otimes x_0\big)\Big)\\ &=\; \sum_{i=1}^{k} m_i \otimes Q_i - \underbrace{\Big(\sum_{i=1}^{k} m_i - \sum_{j=1}^{l}(g_j \cdot v_j - v_j)\Big)}_{=0} \otimes x_0 \;=\; \sum_{i=1}^{k} m_i \otimes Q_i.\end{aligned}$$

We have thus shown that $\sum_{i=1}^{k} m_i \otimes Q_i$ represents the zero element in $\mathrm{H}_0^{\mathrm{tw}}(X;M)$. In other words, we have shown that $\epsilon_X\colon \mathrm{H}_0^{\mathrm{tw}}(X;M) \to M_\pi$ is a monomorphism. ■

168.2. **Twisted homology and homology of covering spaces.** In this section we will see that for certain twistings we can calculate twisted homology groups in terms of ordinary homology of covering spaces. In practice this is one of the most useful tricks for calculating twisted homology groups.

Proposition 168.2. Let X be a topological space that is locally contractible and path-connected. We pick $x_0 \in X$ and we write $\pi := \pi_1(X, x_0)$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the corresponding universal covering which we equip with the natural base point $\widetilde{x}_0$. Let $A \subset X$. We write $\widetilde{A} := p^{-1}(A)$. Furthermore let $\Gamma \subset \pi$ be a subgroup. Let S be a *commutative* ring. We equip the free S-module $S[\Gamma\backslash\pi]$ that is generated by the set $\Gamma\backslash\pi$ with the $\mathbb{Z}[\pi]$-left module structure given by $h \cdot (\Gamma g) = \Gamma g h^{-1}$. Let $p\colon (Y_\Gamma, y_0) \to (X, x_0)$ be a covering of pointed topological spaces with $p_*(\pi_1(Y_\Gamma, y_0)) = \Gamma$. By Corollary 61.11 we know that there exists a unique covering $q\colon \widetilde{X}_{x_0} \to Y_\Gamma$ with $q(\widetilde{x}_0) = y_0$.

(1) The maps[2076]

$$\begin{aligned}\Omega\colon \mathrm{C}_k^{\mathrm{tw}}(X, A; S[\Gamma\backslash\pi]) = \overline{S[\Gamma\backslash\pi]} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A}) \;&\to\; \mathrm{C}_k(Y_\Gamma; S) = \mathrm{C}_k(Y) \otimes S\\ s \cdot \Gamma g \otimes (\sigma\colon \Delta^k \to Y_\Gamma; S) \;&\mapsto\; q \circ (g \cdot \sigma\colon \Delta^k \to Y_\Gamma) \otimes s\end{aligned}$$

form an isomorphism of chain complexes of S-modules. In particular for each $k \in \mathbb{N}_0$ these maps induce an isomorphism

$$\Omega_*\colon \underbrace{\mathrm{H}_k^{\mathrm{tw}}(X, A; S[\Gamma\backslash\pi])}_{\text{twisted homology}} \;\to\; \underbrace{\mathrm{H}_k(Y_\Gamma; S)}_{\substack{\text{singular homology}\\ \text{with } S\text{-coefficients}}}$$

of S-modules.

(2) We now suppose that Γ is a normal subgroup of π. This allows us to equip $S[\Gamma\backslash\pi]$ with an $S[\Gamma\backslash\pi]$-left module structure that is given by left multiplication.[20772078] Furthermore we equip Y_γ, and thus also $\mathrm{C}_k(Y_\Gamma; S)$ and $\mathrm{H}_k(Y_\Gamma; S)$ with the $\Gamma\backslash\pi$-left

action given by Proposition 167.1. With these actions the above maps

$$\begin{aligned} \Omega\colon \mathrm{C}_k^{\mathrm{tw}}(X,A;S[\Gamma\backslash\pi]) &\to \mathrm{C}_k(Y_\Gamma;S) \\ \Omega_*\colon \mathrm{H}_k^{\mathrm{tw}}(X,A;S[\Gamma\backslash\pi]) &\to \mathrm{H}_k(Y_\Gamma;S) \end{aligned}$$

are isomorphisms of $S[\Gamma\backslash\pi]$-left modules.

Remark. Everybody who tries to write up the story of twisted (co-) homology groups and modules will notice that sooner or later it is necessary to make choices about the type of actions that are considered. Whichever choice one takes will sooner or later haunt the author at some other point. Our choices are designed in such a way that we get the clean statement in Proposition 168.2 about $S[\Gamma\backslash\pi]$-left modules. In particular this leads us to the popular topic of left-left modules.

Proof.

(1) Let us show that the given map

$$\begin{aligned} \Omega\colon \mathrm{C}_k^{\mathrm{tw}}(X,A;S[\Gamma\backslash\pi]) = \overline{S[\Gamma\backslash\pi]} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0},\widetilde{A}) &\to \mathrm{C}_k(Y_\Gamma;S) \\ s\cdot\Gamma g\otimes(\sigma\colon\Delta^k\to Y_\Gamma) &\mapsto q\circ(g\cdot\sigma\colon\Delta^k\to Y_\Gamma)\otimes s \end{aligned}$$

is well-defined. Given $k\in\pi$ we denote by $d_k\colon \widetilde{X}_{x_0}\to\widetilde{X}_{x_0}$ the corresponding deck transformation that is given by Proposition 167.1. First we show that the map is independent of the representative $g\in\pi$. Indeed, if $h\in\Gamma$, then

$$q\circ hg\cdot\sigma \;=\; q\circ d_h\circ d_g\circ\sigma \;\underset{\uparrow}{=}\; q\circ d_g\circ\sigma \;=\; q\circ g\cdot\sigma.$$

it follows from Proposition 167.1 that $q\circ d_h = q$

Next let us show, using Lemma 165.23, that the map Ω respects the tensor product $\overline{S[\Gamma\backslash\pi]}\otimes_{\mathbb{Z}[\pi]}\mathrm{C}_k(\widetilde{X}_{x_0})$. Thus let $\Gamma f\in\Gamma\backslash\pi$ and let $\sigma\in\mathrm{C}_k(\widetilde{X}_{x_0})$. Then given any $g\in\pi$ we have

$$\Omega((\Gamma f)\cdot g\otimes\sigma) \;\underset{\uparrow}{=}\; \Omega(\Gamma f\cdot g\otimes\sigma) \;=\; q\circ(f\cdot g)\cdot\sigma \;=\; q\circ f\cdot(g\cdot\sigma) \;=\; \Omega(\Gamma f\otimes g\cdot\sigma).$$

follows from our definition of the $\mathbb{Z}[\pi]$-left module structure on $S[\Gamma\backslash\pi]$ and definition of the $\mathbb{Z}[\pi]$-right module $\overline{S[\Gamma\backslash\pi]}$

Recall that in Lemma 72.9 we showed that the boundary maps ∂ are natural. It is now straightforward to verify that the maps Ω are chain maps. It remains to show that the maps Ω are isomorphisms. To do so we consider the map

$$\begin{aligned} \mathrm{C}_k(Y_\Gamma;S) &\to \mathrm{C}_k^{\mathrm{tw}}(X;S[\Gamma\backslash\pi]) = \overline{S[\Gamma\backslash\pi]}\otimes_{\mathbb{Z}[\pi]}\mathrm{C}_k(\widetilde{X}_{x_0}) \\ (\sigma\colon\Delta^k\to Y_\Gamma)\otimes s &\mapsto s\otimes\text{ any lift of }\sigma\text{ to a map }\Delta^k\to\widetilde{X}_{x_0}. \end{aligned}$$

It follows easily from Proposition 62.12 that this map is well-defined. It is straightforward to verify that this map is an inverse to Ω.

[2076] Note that the corresponding $\mathbb{Z}[\pi]$-right module structure on $\overline{S[\Gamma\backslash\pi]}$ is actually the obvious one given by right multiplication.

[2077] This follows from the usual observation that $(\Gamma\cdot a)\cdot(\Gamma\cdot b) := \Gamma\cdot ab$ is independent of the choice of representatives g,h, if Γ is normal. Indeed, if $g,h\in\Gamma$, then $\Gamma\cdot gahb = \Gamma\cdot g\underbrace{aha^{-1}}_{\in\Gamma}ab$, thus $\Gamma\cdot gahb = \Gamma\cdot ab$.

[2078] Note that these two left module structures turn $S[\Gamma\backslash\pi]$ into a $(\mathbb{Z}[\pi],S[\Gamma\backslash\pi])$-left left module.

(2) We only need to show that Ω is $S[\Gamma\backslash\pi]$-left linear. Thus let $\Gamma g, \Gamma h \in \Gamma\backslash\pi$ and let $\sigma \in \mathrm{C}_k(\widetilde{X}_{x_0})$. Then

$$\Omega(\Gamma h \cdot (\Gamma g \otimes \sigma)) \;=\; \Omega(\Gamma hg \otimes \sigma) \;=\; q \circ h \cdot g \circ \sigma \;\underset{\uparrow}{=}\; h \cdot q \circ g \cdot \sigma \;=\; \Gamma h \cdot \Omega(g \otimes \sigma).$$

follows from Proposition 167.1 ■

Example. Let X be a topological space that is locally contractible and path-connected. We pick $x_0 \in X$ and we write $\pi := \pi_1(X, x_0)$. If we apply Proposition 168.2 to the trivial subgroup $\Gamma = \{e\}$, then we see that for every $k \in \mathbb{N}_0$ we have an isomorphism

$$\mathrm{H}_k^{\mathrm{tw}}(X; \mathbb{Z}[\pi_1(X, x_0)]) \;\cong\; \mathrm{H}_k(\text{universal covering of } X).$$

For example, if we consider the n-dimensional torus $X = (S^1)^n$, then

$$\mathrm{H}_k^{\mathrm{tw}}((S^1)^n; \mathbb{Z}[\pi_1(X)]) \underset{\uparrow}{\cong} \mathrm{H}_k(\text{universal covering of } (S^1)^n) \underset{\uparrow}{\cong} \mathrm{H}_k(\mathbb{R}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ 0, & \text{else.} \end{cases}$$

Proposition 168.2 — see page 1372

Example. $X = S^1 \vee S^2$.

Remark. Proposition 168.2 is very appealing since for many twistings it gives us back our intuition for what homology with twisted coefficients means. Note though that the analogous statement for *cohomology* with twisted coefficients does not hold. For example consider $X = S^1$ with base point $x_0 = 1 \in S^1$. We write $\pi := \pi_1(S^1, 1)$. Then

$$\mathrm{H}^0_{\mathrm{tw}}(S^1; \mathbb{Z}[\pi]) \underset{\uparrow}{\cong} \mathbb{Z}[\pi]^\pi \underset{\uparrow}{=} 0 \neq \mathbb{Z} \cong \mathrm{H}^0(\mathbb{R}) = \mathrm{H}^0(\text{universal covering of } S^1).$$

Twisted H_0-Proposition 168.1 — see the discussion on page 3555 here we use that π is infinite

For our next example let us recall the following definition from page 467.

Definition. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism[2079]. We refer to

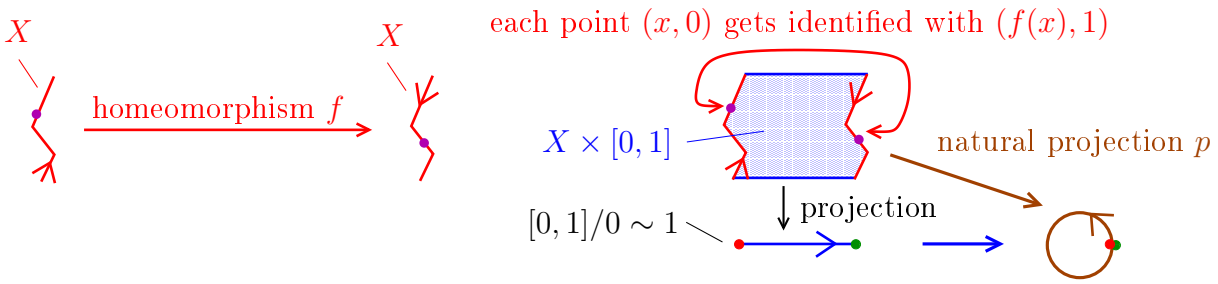
$$\mathrm{Tor}(X, f) \;:=\; (X \times [0,1])/\!\sim \qquad \text{where } (x,0) \sim (f(x),1) \text{ for all } x \in X,$$

as the mapping torus of (X, f). We adopt the following language:

(1) We refer to the map

$$\begin{array}{rccc} p\colon & \mathrm{Tor}(X,f) = (X \times [0,1])/(x,0) \sim (f(x),1) & \to & S^1 \\ & [(x,t)] & \mapsto & \exp(2\pi i t) \end{array}$$

as the natural projection onto S^1. Furthermore, given any $x \in X$ we refer to the map



$$\pi_1(\mathrm{Tor}(X,f), [(x,0)]) \xrightarrow{p_*} \pi_1(S^1, 1) \underset{\uparrow}{\xrightarrow{\cong}} \langle t \rangle$$

unique isomorphism that sends the loop $s \mapsto \exp(2\pi i s)$ to t

as a standard epimorphism.

(2) If f is a homeomorphism, then we refer to X as fiber of the mapping torus and we refer to f as the monodromy of the mapping torus.

[2079] Before we defined the mapping torus for an arbitrary map $f\colon X \to X$, but in this section we are only interested in the case that f is a homeomorphism.

Notation. Let R be a commutative ring, let A be an R-module and let $\phi \in \mathrm{Aut}_R(A)$. We denote by $(A, t = \phi)$ the $R[t^{\pm 1}]$-module where the underlying R-module is given by A and where t acts by multiplication by ϕ, thus t^n acts by application of the automorphism $\phi^n = \phi \circ \cdots \circ \phi$.

Proposition 168.3. Let X be a topological space that is locally contractible and path-connected. Furthermore let $f\colon X \to X$ be a homeomorphism. We pick $x \in X$. We denote by $\phi\colon \pi_1(\mathrm{Tor}(X, f), [(x, 0)]) \to \langle t \rangle$ the corresponding standard epimorphism. Given any commutative ring R and given any $k \in \mathbb{N}_0$ we have a natural isomorphism[2080]

$$\text{the } R[t^{\pm 1}]\text{-module } (\mathrm{H}_k(X; R), t = f_*) \;\cong\; \mathrm{H}_k^{\mathrm{tw}}(\mathrm{Tor}(X, f); {}_\phi R[t^{\pm 1}])$$

of $R[t^{\pm 1}]$-modules.

Proof. Since f is a homeomorphism we can consider the map

$$\begin{array}{rcll} p\colon X \times \mathbb{R} & \to & \mathrm{Tor}(X, f) & \\ (x, t) & \mapsto & [(f^n(x), x - n)] & \text{where } n \in \mathbb{Z} \text{ with } x \in [n, n+1). \end{array}$$

One can easily verify that p is a covering. It follows almost immediately from the Mapping Torus-π_1-Proposition 50.6 that $p_*(\pi_1(X \times \mathbb{R})) = \ker(\varphi_*)$. We denote by $\mu\colon X \times \mathbb{R} \to X \times \mathbb{R}$ the deck transformation that is given by $(x, s) \mapsto (x, s + 1)$. By Proposition 168.2 we have a natural isomorphism

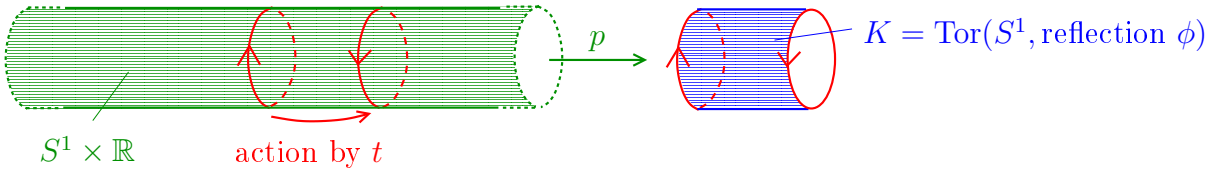
$$\Omega\colon \mathrm{H}_k(X; {}_\phi R[t^{\pm 1}]) \;\xrightarrow{\cong}\; \mathrm{H}_k(X \times \mathbb{R}; S)$$

of $R[t^{\pm 1}]$-modules where the t action is given by the map induced by the deck transformation μ. In other words, we have a natural isomorphism

$$\Omega\colon \mathrm{H}_k(X; {}_\phi R[t^{\pm 1}]) \;\xrightarrow{\cong}\; (\mathrm{H}_k(X \times \mathbb{R}; S), t = \mu_*)$$

of $R[t^{\pm 1}]$-modules. The proposition now follows from the following claim.

Claim. The $R[t^{\pm 1}]$-modules $(\mathrm{H}_k(X \times \mathbb{R}; S), t = \mu_*)$ and $(\mathrm{H}_k(X; R), t = f_*)$ are isomorphic.



Proof. We denote by $p\colon X \times \mathbb{R} \to X$ the projection. We consider the following diagram:

$$\begin{array}{ccc} \mathrm{H}_k(X \times \mathbb{R}; S) & \xrightarrow{\mu_*} & \mathrm{H}_k(X \times \mathbb{R}; S) \\ {\scriptstyle p_*}\downarrow & & \downarrow{\scriptstyle p_*} \\ \mathrm{H}_k(X; R) & \xrightarrow{f_*} & \mathrm{H}_k(X; R). \end{array}$$

[2080] Here use the convention introduced on page 3500 to identify the group ring $\mathbb{Z}[\langle t \rangle]$ with the Laurent polynomial ring $\mathbb{Z}[t^{\pm 1}]$.

It follows from $p \circ \mu = f \circ p$ that the diagram commutes. Furthermore p is evidently a homotopy equivalence. Thus the two vertical maps are isomorphisms. The desired statement is an immediate consequence of these two observations. ∎

Example. We consider the Klein bottle K, which we now think of as $K := \mathrm{Tor}(S^1, \phi)$, where $\phi(z) = \overline{z}$ is the reflection in the real axis. Just for fun we mention that in this case the covering of the proof of Proposition 168.3 is given by a map $p\colon S^1 \times \mathbb{R} \to K := \mathrm{Tor}(S^1, f)$ where the t^n-action on $S^1 \times K$ is given by the map $t^n \cdot (x, s) \mapsto (x + n, (-1)^n \cdot s)$.

We want to use Proposition 168.3 to calculate the homology groups $\mathrm{H}_k^{\mathrm{tw}}(K; {}_\varphi\mathbb{Z}[t^{\pm 1}])$. We start out with the following observations:

(0) By the discussion on page 1594 we know that $\phi_*\colon \mathrm{H}_0(S^1) \to \mathrm{H}_0(S^1)$ is the identity.
(1) By the Sphere Degree Lemma 76.11 (6) we know that $\phi_*\colon \mathrm{H}_1(S^1) \to \mathrm{H}_1(S^1)$ is multiplication by -1.
(2) By Proposition 74.4 we have $\mathrm{H}_k(S^1) = 0$ for $k \geq 2$.

It follows that for $k \in \mathbb{N}$ we have the following isomorphisms:

$$\mathrm{H}_k^{\mathrm{tw}}(K; {}_\varphi\mathbb{Z}[t^{\pm 1}]) \underset{\text{follows from Proposition 168.3 together with (0), (1) and (2)}}{\cong} \begin{cases} (\mathbb{Z}, t = \mathrm{id}), & \text{if } k = 0, \\ (\mathbb{Z}, t = -1), & \text{if } k = 1, \\ 0, & \text{if } k \geq 2 \end{cases} \underset{\text{see Exercise 168.5}}{\cong} \begin{cases} \mathbb{Z}[t^{\pm 1}]/(t-1)\mathbb{Z}[t^{\pm 1}], & \text{if } k = 0, \\ \mathbb{Z}[t^{\pm 1}]/(t+1)\mathbb{Z}[t^{\pm 1}], & \text{if } k = 1, \\ 0, & \text{if } k \geq 2. \end{cases}$$

168.3. **Twisted cohomology and cohomology of finite-index coverings.** The following proposition is a cohomological version of Proposition 168.2. But note that it only gives something interesting for *finite index* subgroups.

Proposition 168.4. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We write $\pi := \pi_1(X, x_0)$. Let R be a commutative ring. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the corresponding universal covering which we equip with the natural base point $\widetilde{x}_0$. Furthermore let $\Gamma \subset \pi_1(X, x_0)$ be a subgroup. Let $p\colon (Y_\Gamma, y_0) \to (X, x_0)$ be a covering of pointed topological spaces with $p_*(\pi_1(Y_\Gamma, y_0)) = \Gamma$. By Corollary 61.11 we know that there exists a unique covering $q\colon \widetilde{X}_{x_0} \to Y_\Gamma$ with $q(\widetilde{x}_0) = y_0$. As in Proposition 168.2 we equip the abelian group $R[\Gamma\backslash\pi]$ with the $\mathbb{Z}[\pi]$-left module structure given by $h \cdot (\Gamma g) = \Gamma g h^{-1}$.

(1) The maps

$$\Phi\colon \underset{\mathbb{Z}[\pi]\text{-left}}{\mathrm{Hom}}(\mathrm{C}_k(\widetilde{X}_{x_0}), R[\Gamma\backslash\pi]) \to \mathrm{Hom}_R(\mathrm{C}_k(Y_\Gamma), R)$$

$$\gamma \mapsto \left(\begin{array}{rcl} \mathrm{C}_k(Y_\Gamma) & \to & R \\ \sigma & \mapsto & \text{pick a lift } \widetilde{\sigma}\colon \Delta^k \to \widetilde{X}_{x_0} \text{ and take the} \\ & & \Gamma = \Gamma e\text{-coefficient of } \gamma(\widetilde{\sigma}) \in R[\Gamma\backslash\pi] \end{array} \right)$$

are well-defined and they form a cochain map.

(2) If Γ is a subgroup *of finite index*, then the maps

$$\begin{array}{rcl} \Psi\colon \operatorname{Hom}_R(\mathrm{C}_k(Y_\Gamma), R) & \to & \operatorname{Hom}_{\mathbb{Z}[\pi]\text{-left}}(\mathrm{C}_k(\widetilde{X}), R[\Gamma\backslash\pi]) \\ \gamma & \mapsto & \left(\begin{array}{rcl} \mathrm{C}_k(\widetilde{X}) & \to & R[\Gamma\backslash\pi] \\ \sigma & \mapsto & \underbrace{\sum\limits_{\Gamma g \in \Gamma\backslash\pi} \gamma(g \cdot (q \circ \sigma\colon \Delta^k \to Y_\Gamma)) \cdot \Gamma g}_{\in R[\Gamma\backslash\pi] \text{ since } \Gamma \text{ is a subgroup of finite index}} \end{array} \right) \end{array}$$

are well-defined and they form a cochain map.

(3) If Γ is a subgroup of *finite index*, then the maps Φ and Ψ are both defined and they are inverses of one another. In particular we see that in this setting the maps Φ induce for each $k \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}^k_{\mathrm{tw}}(X; R[\Gamma\backslash\pi]) \ \to \ \mathrm{H}^k(Y_\Gamma; R).$$

(4) We suppose that Γ is a *normal* subgroup of π of finite index. We introduce two conventions:

- Note that $R[\Gamma\backslash\pi]$ is a $R[\Gamma\backslash\pi]$-left module in the obvious way and $R[\Gamma\backslash\pi]$-becomes a $(\mathbb{Z}[\pi], R[\Gamma\backslash\pi])$-left left module and $\mathrm{H}^k_{\mathrm{tw}}(X; R[\Gamma\backslash\pi])$ becomes a $R[\Gamma\backslash\pi]$-left module.
- Since Γ is a normal subgroup we can equip Y_Γ with the $\Gamma\backslash\pi$-left action given by Proposition 167.1. This allows us to view $\mathrm{H}^k(Y_\gamma; R)$ as a $R[\Gamma\backslash\pi]$-left module by setting $g \cdot \varphi := (g^{-1})^*(\varphi)$.[2081]

With the conventions the above maps Φ and Ψ are $R[\Gamma\backslash\pi]$-left module isomorphisms.

Proof. As with so many of these propositions, as long as the definitions are right, the proofs are dull and elementary. Thus we leave the verification of most aspects of (1) and (2) to the reader. But for peace of mind let us verify in (2) that $\Psi(\gamma)$ is indeed a homomorphism of $\mathbb{Z}[\pi]$-left modules. Thus let $\gamma \in \operatorname{Hom}_R(\mathrm{C}_k(Y_\Gamma), R)$. Then for any $\sigma \in \mathrm{C}_k(\widetilde{X})$ and any $h \in \pi$ we obtain the following equality in $R[\Gamma\backslash\pi]$:

$$\begin{array}{rcccl} \Psi(\gamma)(h \cdot \sigma) & \overset{\text{definition of } \Psi}{=} & \sum\limits_{\Gamma g \in \Gamma\backslash\pi} \gamma(g \cdot (q \circ h \cdot \sigma)) \cdot g & \overset{\text{by Proposition 167.1 we have } q \cdot h = h \cdot q}{=} & \sum\limits_{\Gamma g \in \Gamma\backslash\pi} \gamma(gh \cdot (q \circ \sigma)) \cdot g \\ & = & \sum\limits_{\Gamma g \in \Gamma\backslash\pi} \gamma(gh \cdot (q \circ \sigma)) \cdot gh \cdot h^{-1} & \overset{\text{by definition of } \Psi \text{ and since } \Gamma g \mapsto \Gamma g \cdot h \text{ is a bijection of } \Gamma\backslash\pi}{=} & \Psi(\gamma)(\sigma) \cdot h^{-1} \overset{\text{definition of left-module structure}}{=} h \cdot \Psi(\gamma)(\sigma). \end{array}$$

[2081] Since cohomology is covariant this does indeed define a $R[\Gamma\backslash\pi]$-left module structure on $\mathrm{H}^k_{\mathrm{tw}}(Y_\gamma; R)$.

Next we turn to the proof of (3). Let Γ be a normal subgroup of finite index. Let us verify that $\Psi \circ \Phi = \mathrm{id}$. Thus let $\sigma \in \mathrm{C}_k(\widetilde{X})$ and let $\mu \in \mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(\mathrm{C}_k(\widetilde{X}), R[\Gamma\backslash\pi])$. Then

$$\begin{aligned}((\Psi\circ\Phi)(\mu))(\sigma) &\overset{\text{definition of } \Psi}{\underset{\downarrow}{=}} \sum_{\Gamma g\in\Gamma\backslash\pi} \Phi(\mu)(g\cdot(q\circ\sigma\colon \Delta^k\to Y_\Gamma))\cdot g \overset{\text{since } g\cdot\sigma \text{ is a lift of } g\cdot(q\circ\sigma)}{\underset{\downarrow}{=}} \sum_{\Gamma g\in\Gamma\backslash\pi} (e\text{-coefficient of } \mu(g\cdot\sigma))\cdot g\\ &= \sum_{\Gamma g\in\Gamma\backslash\pi} (g\text{-coefficient of } \mu(\sigma))\cdot g \qquad = \mu(\sigma).\\ &\underset{\uparrow}{=}\\ &\text{since } \mu \text{ is } \mathbb{Z}[\pi]\text{-left linear we have } \mu(g\cdot\sigma)=\mu(\sigma)\cdot g^{-1}\end{aligned}$$

The verification that $\Phi \circ \Psi = \mathrm{id}$ is very similar.

Finally we turn to the proof of Statement (4). Since Φ and Ψ are inverses of one another it suffices to show that Ψ is a $R[\Gamma\backslash\pi]$-left module isomorphism. Let $\Gamma h \in \Gamma\backslash\pi$. Then given $\sigma \in \mathrm{C}_k(\widetilde{X})$ and $\gamma \in \mathrm{Hom}_R(\mathrm{C}_k(Y_\Gamma), R)$ we have

$$\begin{aligned}\underbrace{\Psi(h\cdot\gamma)(\sigma)}_{=\Psi((h^{-1})^*\gamma)(\sigma)} &= \sum_{\Gamma g\in\Gamma\backslash\pi} ((h^{-1})^*\gamma)(g\cdot(q\circ\sigma))\cdot g \qquad = \sum_{\Gamma g\in\Gamma\backslash\pi} \gamma(h^{-1}g\cdot(q\circ\sigma))\cdot g\\ &= \sum_{\Gamma g\in\Gamma\backslash\pi} \gamma(h^{-1}g\cdot(q\circ\sigma))\cdot h\cdot h^{-1}g \;=\; h\cdot\sum_{k\in\Gamma\backslash\pi}\gamma(k\cdot(q\circ\sigma))\cdot k \qquad = h\cdot\Psi(\gamma)(\sigma).\end{aligned}$$

■

168.4. **Twisted (co-) homology groups of lens spaces.** We turn to our old nemesis, the lens spaces, which so far have escaped our attempts at classifying them. Recall that in Corollary 48.18 we saw that $\pi_1(L(p,q)) \cong \mathbb{Z}_p$. This shows that $\pi_1(L(p,q))$ has at least some non-trivial representations. But since $\pi_1(L(p,q))$ is abelian we know by Proposition **??** that every finite dimensional complex representation is the direct sum of one-dimensional complex representations. Thus by the Direct Sum-of-Coefficients Lemma 167.5 we only need to understand invariants corresponding to one-dimensional complex representations.

For trivial one-dimensional representations we know by Lemma 167.3 that we only recover classical invariants. Thus in the following lemma we restrict ourselves to non-trivial one-dimensional complex representations.

Proposition 168.5. Let $p, q \in \mathbb{N}$ be coprime. We consider the corresponding lens space $L(p,q)$. If $\rho\colon \pi_1(L(p,q)) \to \mathrm{GL}(1,\mathbb{C})$ is a non-trivial representation, then for all $k \in \mathbb{N}_0$ we have $\mathrm{H}_k^{\mathrm{tw}}(L(p,q);{}_\rho\mathbb{C}) = 0$ and $\mathrm{H}^k_{\mathrm{tw}}(L(p,q);{}_\rho\mathbb{C}) = 0$.

Remark.

(1) Proposition 168.5 is at first glance quite disappointing, it shows that homology with twisted complex coefficients cannot be used to distinguish lens spaces. But in Section **??** we will see, counter intuitively, that this calculation is in fact a big step towards solving the conundrum of the classification of lens spaces.

(2) The eternal optimist might hope to use twisted (co-) homology with other coefficients to distinguish lens spaces. But by Corollary 167.17 we know that the (co-) homology groups with twisted coefficients that can occur only depend on the homotopy type of lens spaces. But by Theorem 148.22 there exist lens spaces that are homotopy equivalent albeit not homeomorphic.

Proof. Let $p, q \in \mathbb{N}$ be coprime. We pick an identification $\pi_1(L(p,q), x_0) = \mathbb{Z}_p$. Let $n \in \mathbb{N}$. Given $z \in \mathbb{C}$ with $z^p = 1$ we consider the representation

$$\begin{array}{rccc} \rho_z \colon & \mathbb{Z}_p & \to & \mathrm{U}(1) \\ & [k] & \mapsto & z^k. \end{array}$$

By Proposition **??** we know the following two facts:

(1) The complex regular representation $\mathbb{C}[\mathbb{Z}_p]$ of the cyclic group $\pi_1(L(p,q), x_0) = \mathbb{Z}_p$ is isomorphic to the direct sum of the representations $\rho_{\exp(2\pi i k/p)}$, $k = 0, \dots, p-1$.
(2) Every non-trivial irreducible representation of $\mathbb{Z}_p$ is isomorphic to one of the ρ_z with $z \neq 1$.

In the following we first deal with the twisted homology modules. We see that

$$\begin{array}{ccccc} & & \text{follows from (1) and the Direct Sum-of-Coefficients Lemma 167.5, together with observation that we have } {}_{\mathrm{tr}}\mathbb{C} = \mathbb{C}_{\rho_1} & & \\ & & \downarrow & & \\ \mathrm{H}_k^{\mathrm{tw}}(L(p,q); {}_{\mathrm{tr}}\mathbb{C}) \oplus \bigoplus_{\substack{z^p=1,\\ z\neq 1}} \mathrm{H}_k^{\mathrm{tw}}(L(p,q); {}_{\rho_z}\mathbb{C}) & \cong & \mathrm{H}_k^{\mathrm{tw}}(L(p,q); \bigoplus_{z^p=1} {}_{\rho_z}\mathbb{C}) & & \\ & & \cong \uparrow & & \cong \uparrow \\ & & \mathrm{H}_k^{\mathrm{tw}}(L(p,q); \mathbb{C}[\mathbb{Z}_p]) & \cong & \mathrm{H}_k(S^3; \mathbb{C}). \\ & & \text{by Proposition ??} & & \text{by Proposition 168.2, since } S^3 \text{ is a universal covering of } L(p,q) \end{array}$$

Note that it follows from (2) and the above calculation that it suffices to show that $\mathrm{H}_k(L(p,q); {}_{\mathrm{tr}}\mathbb{C}) \cong \mathrm{H}_k(S^3; \mathbb{C})$ and that both are finite-dimensional complex vector spaces. Indeed we have

$$\begin{array}{ccccccc} \mathrm{H}_k^{\mathrm{tw}}(L(p,q); {}_{\mathrm{tr}}\mathbb{C}) & \cong & \mathrm{H}_k(L(p,q); \mathbb{C}) & \cong & \begin{cases} \mathbb{C}, & \text{if } k = 0,3 \\ 0, & \text{else} \end{cases} & \cong & \mathrm{H}_k(S^3; \mathbb{C}). \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \text{by Lemma 167.3} & & \text{follows from the Universal Coefficient Theorem 89.17 together with the Tor-Properties Lemma 89.15 and the calculations of } \mathrm{H}_*(L(p,q)) \text{ and } \mathrm{H}_*(S^3) \text{ in Proposition 74.4 and the Lens Space Homology Lemma 98.9} & & & & \end{array}$$

The argument for calculating the twisted cohomology groups is very similar, the main difference is that we need to replace Proposition 168.2 by Proposition 168.4. We can do so, since $S^3 \to L(p,q)$ is a finite covering. ∎

168.5. **Replacing the universal covering.** In the definition of twisted (co-) homology we work with the universal covering. In many settings the following propositions allows us to work with "smaller coverings", which in practice can simplify life quite a bit. To formulate the corresponding statement it is convenient to introduce the following convention.

Proposition 168.6. (Replace Universal Covering Proposition) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p \colon \widetilde{X}_{x_0} \to X$ the corresponding universal covering. Let $A \subset X$. We write $\widetilde{A} := p^{-1}(A)$. We set $\pi := \pi_1(X, x_0)$. Let $\Gamma \subset \pi$ a normal subgroup. We denote by $\rho \colon \pi \to \pi/\Gamma$ the projection and we denote by $\rho \colon \mathbb{Z}[\pi] \to \mathbb{Z}[\pi/\Gamma]$ also the corresponding ring homomorphism. Let R be a ring and let M be a $(\mathbb{Z}[\pi/\Gamma], R)$-left left module. Let $q \colon (Y, y_0) \to (X, x_0)$ be any path-connected regular covering with $q_*(\pi_1(Y, y_0)) \subset \Gamma$. We set $B := q^{-1}(A)$. By Corollary 61.11 there exists a unique covering $r \colon (\widetilde{X}_{x_0}, \widetilde{x}_0) \to (Y, y_0)$ with $q \circ r = p$. The

natural maps[20822083]

$$\begin{array}{rcl} \overbrace{\overline{\rho^*M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})}^{\mathrm{C}_k^{\mathrm{tw}}(X,A;\rho^*M)} & \to & \overline{M} \otimes_{\mathbb{Z}[\pi/\Gamma]} \mathrm{C}_k(Y,B) \\ m \otimes (\sigma\colon \Delta^k \to \widetilde{X}_{x_0}) & \mapsto & m \otimes (r \circ \sigma\colon \Delta^k \to Y) \end{array}$$

and

$$\begin{array}{rcl} \mathrm{Hom}_{\mathbb{Z}[\pi/\Gamma]\text{-left}}(\mathrm{C}_k(Y,B), M) & \to & \overbrace{\mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(\mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A}), \rho^*M)}^{=\mathrm{C}_{\mathrm{tw}}^k(X,A;\rho^*M)} \\ \varphi & \mapsto & (\sigma \mapsto \varphi(r \circ \sigma)) \end{array}$$

are isomorphisms of (co-) chain complexes of R-left modules. In particular we get induced isomorphisms of (co-) homology modules.

Remark. Let π be a group and let Γ be a normal subgroup. We denote by $\rho\colon \pi \to \pi/\Gamma$ the projection. Let M be a $\mathbb{Z}[\pi]$-left module. If every $g \in \Gamma$ acts trivially on M, then there exists an obvious $\mathbb{Z}[\pi/\Gamma]$-left module $\widetilde{M}$ such that $\rho^*\widetilde{M} = M$. In practice that is often how the Replace Universal Covering Proposition 168.6 gets applied.

Remark. This also works for the cellular twisted (co-) homology, where it is perhaps more useful.

Proof. We denote by $\rho\colon \pi \to \pi/\Gamma$ the projection and we also denote by $\rho\colon \mathbb{Z}[\pi] \to \mathbb{Z}[\pi/\Gamma]$ the corresponding ring homomorphism.

Claim. The map

$$\begin{array}{rcl} \mathbb{Z}[\pi/\Gamma] \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A}) & \to & \mathrm{C}_k(Y,B) \\ g \otimes \sigma & \mapsto & \rho(g) \cdot (r \circ \sigma) \end{array}$$

is well-defined and it is an isomorphism of $\mathbb{Z}[\Gamma\backslash\pi]$-left modules.

Proof. First note that it follows from Proposition 167.1 (2) that for any $g \in \pi_1(X, x_0)$ and any $w \in \widetilde{X}_{x_0}$ we have $r(g \cdot w) = \rho(g) \cdot r(w)$. It follows that the map is well-defined.

Given any singular simplex $\sigma\colon \Delta^k \to X$ that is not contained in A we pick a lift $\widetilde{\sigma}\colon \Delta \to \widetilde{X}$. In the Regular Covering-Chain Complex Lemma 167.2 we showed that these lifts form a basis of the free $\mathbb{Z}[\pi]$-left module $\mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})$. Furthermore by the Regular Covering-Chain Complex Lemma 167.2 we also know that the singular simplices $r \circ \widetilde{\sigma}$ form a basis of the free $\mathbb{Z}[\pi/\Gamma]$-left module $\mathrm{C}_k(Y,B)$. It follows from this observation, together with Lemma 165.21, that the map sends a basis of the free $\mathbb{Z}[\pi/\Gamma]$-left module $\mathbb{Z}[\pi/\Gamma] \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})$ to a basis of the free $\mathbb{Z}[\pi/\Gamma]$-left module $\mathrm{C}_k(Y,B)$. Thus we see that the map is indeed an isomorphism. ⊞

Note that the first map we are supposed to study equals the composition of the following maps:

$$\begin{array}{rcl} \overline{\rho^*M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A}) & \to & \overline{M} \otimes_{\mathbb{Z}[\pi/\Gamma]} (\mathbb{Z}[\pi/\Gamma] \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}, \widetilde{A})) \\ m \otimes \sigma & \mapsto & m \otimes (1 \otimes \sigma) \end{array} \to \overline{M} \otimes_{\mathbb{Z}[\pi/\Gamma]} \mathrm{C}_k(Y,B)$$

$$m \otimes (n \otimes \sigma) \mapsto m \otimes r_*(n \cdot \sigma).$$

[2082]Note that our hypothesis that $Y \to X$ is a regular covering is, by the Regular Covering-Characterization Corollary 62.8, equivalent to the statement that $\Gamma := q_*(\pi_1(Y, y_0))$ is a normal subgroup of $\pi = \pi_1(X, x_0)$

[2083]As we discussed on page 3534 we have a natural left action of $\pi/\Gamma = \pi_1(X, x_0)/q_*(\pi_1(Y, y_0))$ on Y.

It follows from Lemma 165.20 that the map to the left is well-defined and an isomorphism. It follows from the claim that the map to the right is an isomorphism. In summary, we are done.

The second statement regarding the cochain complexes can be proved, using Lemma 165.22, in a very similar fashion. We leave the details to the reader. ■

168.6. **The Bockstein sequence and non-orientable topological manifolds.** On page 3145 we saw that given a topological space X any short exact sequence $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ of abelian groups gives rise to a short exact sequence of chain complexes and thus to a long exact sequence of homology groups. We now see that an analogous statement holds for homology with twisted coefficients.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the corresponding natural universal covering. Let $A \subset X$. We write $\widetilde{A} := p^{-1}(A)$. Let R be a ring and let

$$0 \;\to\; L \;\xrightarrow{\varphi}\; M \;\xrightarrow{\psi}\; N \;\to\; 0$$

be a short exact sequence of $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left modules. Let $n \in \mathbb{N}_0$. It follows easily from the fact, proved in the Regular Covering-Chain Complex Lemma 167.2 that $\mathrm{C}_n(\widetilde{X}_{x_0},\widetilde{A})$ is a free $\mathbb{Z}[\pi_1(X,x_0)]$-left module and from the natural isomorphisms of Lemma 165.17 that

$$0 \;\to\; \mathrm{C}_n^{\mathrm{tw}}(X,A;L) \;\xrightarrow{\varphi_*}\; \mathrm{C}_n^{\mathrm{tw}}(X,A;M) \;\xrightarrow{\psi_*}\; \mathrm{C}_n^{\mathrm{tw}}(X,A;N) \;\to\; 0$$

is also exact. Thus we obtain a short exact sequence

$$0 \;\to\; \mathrm{C}_*^{\mathrm{tw}}(X,A;L) \;\xrightarrow{\varphi_*}\; \mathrm{C}_*^{\mathrm{tw}}(X,A;M) \;\xrightarrow{\psi_*}\; \mathrm{C}_*^{\mathrm{tw}}(X,A;N) \;\to\; 0$$

of chain complexes of R-left modules. Furthermore, from the LES Lemma 166.11 we obtain natural connecting homomorphisms $\beta_n := \partial_n\colon \mathrm{H}_n^{\mathrm{tw}}(X,A;N) \to \mathrm{H}_{n-1}^{\mathrm{tw}}(X,A;L)$ that give us a long exact sequence

$$\ldots \xrightarrow[=:\beta_{n+1}]{\partial_{n+1}} \mathrm{H}_n^{\mathrm{tw}}(X,A;L) \xrightarrow{\varphi_*} \mathrm{H}_n^{\mathrm{tw}}(X,A;M) \xrightarrow{\psi_*} \mathrm{H}_n^{\mathrm{tw}}(X,A;N) \xrightarrow[=:\beta_n]{\partial_n} \mathrm{H}_{n-1}^{\mathrm{tw}}(X,A;L) \to \ldots$$

For each $n \in \mathbb{N}_0$ the connecting homomorphism $\beta = \partial_n\colon \mathrm{H}_n^{\mathrm{tw}}(X,A;N) \to \mathrm{H}_{n-1}^{\mathrm{tw}}(X,A;L)$ is called the n-th Bockstein homomorphism in homology with twisted coefficients and the long exact sequence is called the Bockstein sequence in homology with twisted coefficients.

Remark. Similar to the discussion on page 3145 there is also an analogous Bockstein sequence in twisted cohomology, but we will not make use of it.

Example. We consider the group $\langle x \,|\, x^2\rangle$, which is nothing but the group $\mathbb{Z}_2$ written multiplicatively. We denote by $\widetilde{\mathbb{Z}}$ the $\mathbb{Z}[\langle x \,|\, x^2\rangle]$-left module that is given by $x \cdot n := -n$. We leave it to the reader to verify that

$$0 \;\to\; \widetilde{\mathbb{Z}} \;\xrightarrow{n\mapsto n\cdot(1-x)}\; \mathbb{Z}[\langle x \,|\, x^2\rangle] \;\xrightarrow{x\mapsto 1}\; {}_{\mathrm{tr}}\mathbb{Z} \;\to\; 0$$

and

$$0 \;\to\; {}_{\mathrm{tr}}\mathbb{Z} \;\xrightarrow{n\mapsto n\cdot(1+x)}\; \mathbb{Z}[\langle x \,|\, x^2\rangle] \;\xrightarrow{x\mapsto -1}\; \widetilde{\mathbb{Z}} \;\to\; 0$$

are short exact sequences of $\mathbb{Z}[\langle x \,|\, x^2\rangle]$-left modules.

Proposition 168.7. Let X be a compact *non-orientable* path-connected non-empty n-dimensional topological manifold and let $x_0 \in X$. We denote by $\widetilde{X} \to X$ the natural path-connected 2-fold covering from the Orientation Covering-Proposition 105.15 where $\widetilde{X}$ is an n-dimensional topological manifold that comes with a natural orientation. We denote by

$$w_1 \colon \pi_1(X, x_0) \;\to\; \pi_1(X, x_0)/p_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) \;\underset{\text{unique isomorphism}}{\underset{\uparrow}{=}}\; \langle x \,|\, x^2 \rangle$$

the orientation-character that we introduced on page 2341. The following three statements hold:

(1) There exists an isomorphism $\mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^* \widetilde{\mathbb{Z}}) \cong \mathbb{Z}$.
(2) There exists a natural generator of $\mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^* \widetilde{\mathbb{Z}}) \cong \mathbb{Z}$.
(3) For each $Q \in X \setminus \partial X$ the map $\mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^* \widetilde{\mathbb{Z}}) \to \mathrm{H}_n^{\mathrm{tw}}(X, X \setminus \{Q\}; w_1^* \widetilde{\mathbb{Z}})$ is an isomorphism.

Proposition 168.7 shows, that for a compact non-orientable path-connected non-empty n-dimensional topological manifold we have a naturally defined generator which has, in a slightly different setup, the defining property of a fundamental class as defined on page 2350. This motivates the following definition.

Definition. Let X be a compact non-orientable path-connected non-empty n-dimensional topological manifold. We refer to the natural generator of $\mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^* \widetilde{\mathbb{Z}})$ as the twisted fundamental class $[X]_{\mathrm{tw}}$ of X.

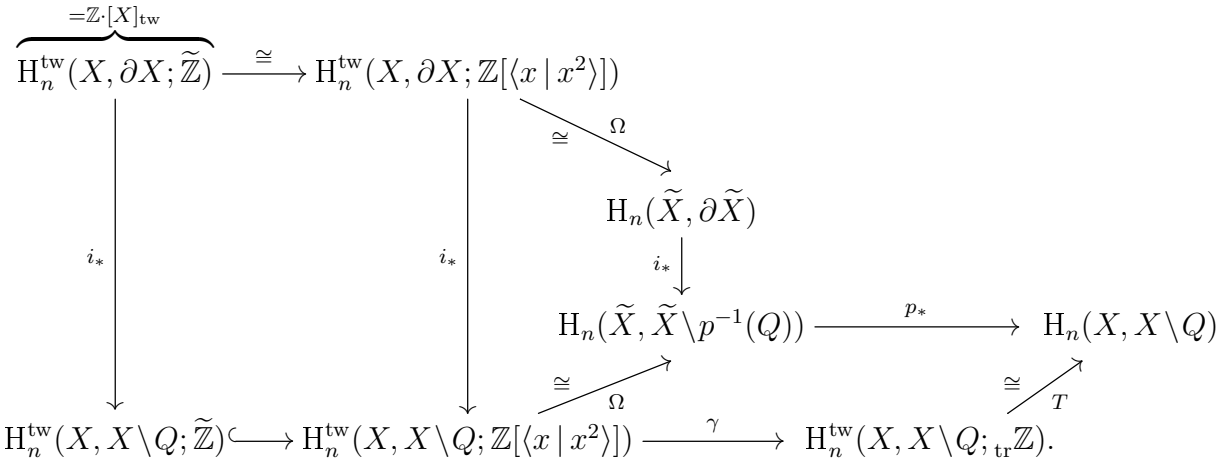
Remark. A statement similar to Proposition 168.7 is proved in [**Hat2002**, p. 327].

Proof. As in the previous example we consider the following short exact sequence of $\mathbb{Z}[\langle x \,|\, x^2 \rangle]$-modules:

$$0 \;\to\; \widetilde{\mathbb{Z}} \;\xrightarrow{n \mapsto n \cdot (1-x)}\; \mathbb{Z}[\langle x \,|\, x^2 \rangle] \;\underset{=:\gamma}{\xrightarrow{x \mapsto 1}}\; {}_{\mathrm{tr}}\mathbb{Z} \;\to\; 0.$$

Via the homomorphism $w_1 \colon \pi_1(X, x_0) \to \langle x \,|\, x^2 \rangle$ we obtain a corresponding short exact sequence of $\mathbb{Z}[\pi_1(X, x_0)]$-modules. Note that $w_1^* \, {}_{\mathrm{tr}}\mathbb{Z} = {}_{\mathrm{tr}}\mathbb{Z}$. Next we consider the following diagram:

$$\begin{array}{ccccccc}
\mathrm{H}_{n+1}^{\mathrm{tw}}(X, \partial X; {}_{\mathrm{tr}}\mathbb{Z}) & \xrightarrow{\beta_{n+1}} & \mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^* \widetilde{\mathbb{Z}}) & \to & \mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^* \mathbb{Z}[\langle x \,|\, x^2 \rangle]) & \to & \mathrm{H}_n^{\mathrm{tw}}(X, \partial X; {}_{\mathrm{tr}}\mathbb{Z}) \\
\cong \big\downarrow T & & & & \cong \big\downarrow \Omega & & \cong \big\downarrow T \\
\underbrace{\mathrm{H}_{n+1}(X, \partial X; \mathbb{Z})}_{=0} & & & & \underbrace{\mathrm{H}_n(\widetilde{X}; \mathbb{Z})}_{=\mathbb{Z} \cdot [\widetilde{X}]} & & \underbrace{\mathrm{H}_n(X, \partial X; \mathbb{Z})}_{=0}
\end{array}$$



We make the following clarifications and observations:

(a) The top horizontal sequence is the Bockstein sequence corresponding to the above short exact sequence of $\mathbb{Z}[\pi_1(X, x_0)]$-left modules.
(b) The vertical map in the first and fourth column are the isomorphisms provided by Lemma 167.3.

(c) Since $\dim(X) = n$ we obtain from the Top-Homology Theorem 106.3 that $\mathrm{H}_{n+1}(X, \partial X; \mathbb{Z}) = 0$.
(d) Since X is non-orientable we obtain from the Top-Homology Theorem 106.3 that $\mathrm{H}_n(X, \partial X; \mathbb{Z}) = 0$.
(e) The vertical map in the third column is given by Proposition 168.2.
(f) Since $\widetilde{X}$ is path-connected, non-empty and naturally oriented we know by the Fundamental Class-Corollary 106.4 that $\mathrm{H}_n(\widetilde{X}, \partial\widetilde{X}; \mathbb{Z}) = \mathbb{Z} \cdot [\widetilde{X}]$.

The above discussion shows that $\mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^*\widetilde{\mathbb{Z}})$ is isomorphic to $\mathbb{Z}$ and we see that the natural isomorphisms and the natural generator $[\widetilde{X}]$ of $\mathrm{H}_n(\widetilde{X}, \partial\widetilde{X}; \mathbb{Z})$ give rise to a natural generator of $\mathrm{H}_n^{\mathrm{tw}}(X, \partial X; w_1^*\widetilde{\mathbb{Z}})$. This concludes the proof of Statements (1) and (2).

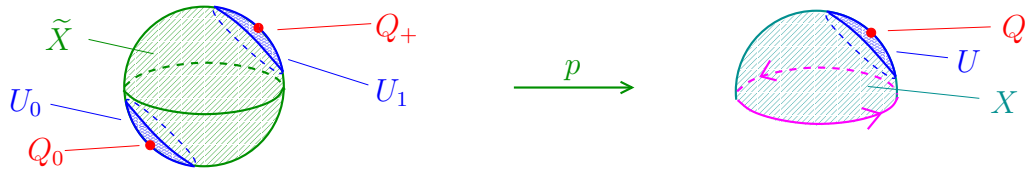
It remains to prove Statement (3). Thus let $Q \in X \setminus \partial X$. We consider the following diagram:

We make the following clarifications and observations:

(a) As before we see that the horizontal map at the top left is an isomorphism and the horizontal map at the bottom left is a monomorphism.
(b) All vertical maps are induced by the obvious inclusions.
(c) The rectangle to the left commutes by naturality of i_*. The middle quadrilateral commutes by the naturality of Ω. We leave it to the reader to show, by inspecting the maps, that the quadrilateral to the right commutes.
(d) The bottom sequence is exact.

We want to show that $i_*([X]_{\mathrm{tw}})$ is a generator of $\mathrm{H}_n^{\mathrm{tw}}(X, X \setminus Q; \widetilde{\mathbb{Z}})$. By the above diagram and by definition of $[X]_{\mathrm{tw}}$ it suffices to prove the following claim.

Claim. The image of $[\widetilde{X}] \in \mathrm{H}_n(\widetilde{X}, \partial\widetilde{X})$ in $\mathrm{H}_n(\widetilde{X}, \widetilde{X} \setminus p^{-1}(Q))$ is a generator of the kernel of p_*.



Proof. Let $\tau\colon \widetilde{X} \to \widetilde{X}$ be the orientation-reversing deck transformation of the covering $p\colon \widetilde{X} \to X$. We pick a point $Q_0 \in p^{-1}(Q)$ and we write $Q_1 := \tau(Q_1)$. We pick an open neighborhood U_0 around Q_0 such that U_0 and $U_1 := \tau(U_0)$ are disjoint. We set $\widetilde{U} := U_0 \cup U_1$

and $U := p(\widetilde{U})$. We consider the following little diagram:

$$\begin{array}{ccccc}
 & & \mathrm{H}_n(\widetilde{X},\partial\widetilde{X}) & & \\
 & & \downarrow{\scriptstyle i_*} & & \\
\ker(p_*) & \hookrightarrow & \mathrm{H}_n(\widetilde{X},\widetilde{X}\setminus p^{-1}(Q)) & \xrightarrow{p_*} & \mathrm{H}_n(X,X\setminus Q) \\
 & & \uparrow\cong \quad \searrow^{\mu_X} & & \uparrow\cong \\
 & & \mathrm{H}_n(\widetilde{X},\widetilde{X}\setminus\{Q_0\}) & & \\
 & & \uparrow\cong & & \\
 & & \mathrm{H}_n(\widetilde{U},\widetilde{U}\setminus\{Q_0\}) & & \\
 & & \uparrow\cong \quad \nearrow_{\mu_U} & & \\
\underbrace{\{\sigma\oplus-\tau_*\sigma\,|\,\sigma\in\mathrm{H}_n(U_0,U_0\setminus\{Q_0\})\}}_{\subset \mathrm{H}_n(U_0,U_0\setminus\{Q_0\})\oplus\mathrm{H}_n(U_1,U_1\setminus\{Q_1\}} & \to & \mathrm{H}_n(\widetilde{U},\widetilde{U}\setminus p^{-1}(Q)) & \xrightarrow{p_*} & \mathrm{H}_n(U,U\setminus Q)
\end{array}$$

We make the following observations:

(1) The three vertical maps that are decorated by "$\cong$" are induced by inclusions and they are isomorphisms by the Excision Theorem 74.18.
(2) The maps μ_X and μ_U are induced by the obvious map of pairs of topological spaces.
(3) The diagram commutes by functoriality of homology.
(4) Since $\mathrm{H}_n(\widetilde{U},\widetilde{U}\setminus p^{-1}(Q)) = \mathrm{H}_n(U_0,U_0\setminus p^{-1}(Q_0))\oplus\mathrm{H}_n(U_+,U_+\setminus p^{-1}(Q_+))$ one can easily verify that the bottom horizontal sequence is exact.
(5) It follows easily from (4) that the restriction of μ_U to $\ker(p_*)$ is an isomorphism.
(6) It follows from (3) and (5) that the restriction of μ_X to $\ker(p_*)$ is an isomorphism.
(7) By definition of a fundamental class, see page 2350, we know that the image of $[\widetilde{X}]$ under the map $\mu_X\circ i_*$ in $\mathrm{H}_n(\widetilde{X},\widetilde{X}\setminus\{Q_0\})$ is a generator.
(8) It follows from (6) and (7) that $i_*([\widetilde{X}])$ is indeed a generator of $\ker(p_*)$. ■

Exercises for Chapter 168.

Exercise 168.1. Let π be a group. We equip $M = \mathbb{Z}[\pi]$ with the $\mathbb{Z}[\pi]$-left module structure that is given by $g\cdot m := m\cdot g^{-1}$. We consider the π-coinvariants $\mathbb{Z}[\pi]_\pi$ and the π-invariants $\mathbb{Z}[\pi]^\pi$ as defined on page 3555.

(a) Show that the following map is an isomorphism:

$$\begin{array}{ccc} \mathbb{Z}[\pi]_\pi & \to & \mathbb{Z} \\ \left[\sum_{i=1}^k r_i\cdot g_i\right] & \mapsto & \sum_{i=1}^k r_i. \end{array}$$

(b) Show that

$$\mathbb{Z}[\pi]^{\pi} \;=\; \begin{cases} 0, & \text{if } \pi \text{ is infinite,} \\ \mathbb{Z} \cdot \sum\limits_{g \in \pi} g, & \text{if } \pi \text{ is finite.} \end{cases}$$

Exercise 168.2.

(a) Let G be a finite group that acts on the left on some $\mathbb{Q}^n$. Show that M^G and M_G are isomorphic.

(b) Let G be a finite group that acts on the left on some $\mathbb{Z}^n$. Show that M^G and M_G are in general not isomorphic.

Exercise 168.3. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We write $\pi := \pi_1(X, x_0)$. Let R be a ring and let M be a $(\mathbb{Z}[\pi], R)$-left left module. We consider the natural universal covering $p\colon \widetilde{X}_{x_0} \to X$ and we denote by $\widetilde{x}_0$ the natural base point of $\widetilde{X}_{x_0}$. Show that the map

$$\begin{array}{rcl} \epsilon_X\colon \mathrm{H}_0^{\mathrm{tw}}(X; M) & \to & M^{\pi} \\ [\varphi\colon \mathrm{C}_0(\widetilde{X}_{x_0}) \to M)] & \mapsto & \varphi(\widetilde{x}_0) \\ & & \uparrow \\ & & \text{here } \widetilde{x}_0 \text{ is short for the constant map } \Delta^0 \to \widetilde{X}_{x_0} \text{ that sends 1 to } \widetilde{x}_0 \end{array}$$

is a natural isomorphism of R-left modules.

Exercise 168.4. We consider the group $\langle x \,|\, x^2 \rangle$, which is nothing but the group $\mathbb{Z}_2$ written multiplicatively.

(a) We denote by $\widetilde{\mathbb{Z}}$ the $\mathbb{Z}[\langle x \,|\, x^2 \rangle]$-left module that is given by $x \cdot n := -n$. Show that the short exact sequence

$$0 \;\to\; {}_{\mathrm{tr}}\mathbb{Z} \;\xrightarrow{n \mapsto n \cdot (1+x)}\; \mathbb{Z}[\langle x \,|\, x^2 \rangle] \;\xrightarrow{x \mapsto -1}\; \widetilde{\mathbb{Z}}\; 0$$

of $\mathbb{Z}[\langle x \,|\, x^2 \rangle]$-left modules does not split.

(b) Show that if in (a) replace "$\mathbb{Z}$" throughout by "$\mathbb{Q}$", then the short exact sequence of $\mathbb{Q}[\langle x \,|\, x^2 \rangle]$-left modules splits.

Exercise 168.5.

(a) Show that the $\mathbb{Z}[t^{\pm 1}]$-modules $(\mathbb{Z}, t = +1)$ and $\mathbb{Z}[t^{\pm 1}]/(t-1)\mathbb{Z}[t^{\pm 1}]$ are isomorphic.

(b) Show that the $\mathbb{Z}[t^{\pm 1}]$-modules $(\mathbb{Z}, t = -1)$ and $\mathbb{Z}[t^{\pm 1}]/(t+1)\mathbb{Z}[t^{\pm 1}]$ are isomorphic.

Exercise 168.6. Let M be the Möbius band. Determine an explicit cycle in $\mathrm{C}_2^{\mathrm{tw}}(M, \partial M; w_1^* \widetilde{\mathbb{Z}})$ that is a generator of $\mathrm{H}_2^{\mathrm{tw}}(M, \partial M; w_1^* \widetilde{\mathbb{Z}})$.

169. Universally excisive triads and Mayer-Vietoris sequences

In this short chapter we will introduce the concept of a universally excisive triad, which is a variation on the notion of an excisive triad that we introduced on page 2429. Excisive triads played roles on two different occasions. They allowed us to formulate Mayer-Vietoris type theorems and they allowed us to define relative cup and cap products. Universally excisive triads will play the same role in the setting of (co-) homology with twisted coefficients.

In this chapter we will also introduce internal twisted (co-) homology. This slightly clunky concept allows us to work with disconnected spaces and will come in handy on several occasions.

169.1. **Universally excisive triads.** We start out by recalling the following definition from page 2429.

Definition.

(1) A triad of topological spaces is a triple (X, A_1, A_2) where X is a topological space and where both A_1 and A_2 are subsets of X.

(2) A map $f\colon (X, A_1, A_2) \to (Y, B_1, B_2)$ of triads is a map $f\colon X \to Y$ with $f(A_1) \subset B_1$ and $f(A_2) \subset B_2$.

(3) Given a triad (X, A_1, A_2) of topological spaces we consider the following subgroup of $\mathrm{C}_n(A_1 \cup A_2)$:

$$\mathrm{C}_n^{\{A_1,A_2\}}(A_1 \cup A_2) := \left\{ \sum_{j=1}^{k} a_j \sigma_j \in \mathrm{C}_n(A_1 \cup A_2) \;\middle|\; \begin{array}{l} \text{for each } j \text{ there exists an } i \in \{1,2\} \\ \text{such that the image of } \sigma_j \text{ lies in } A_i \end{array} \right\}.$$

The usual boundary map on the groups $\mathrm{C}_*(A_1 \cup A_2)$ restricts to a boundary map on $\mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2)$, so we can view $\mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2)$ as a chain complex. We denote the corresponding homology groups by $\mathrm{H}_*^{\{A_1,A_2\}}(A_1 \cup A_2)$.

(4) We say a triad (X, A_1, A_2) is excisive if the inclusion map

$$\mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2) \;\to\; \mathrm{C}_*(A_1 \cup A_2)$$

is a chain homotopy equivalence of chain complexes.

To these familiar definitions we now add a new one:

(5) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. We say a (X, A_1, A_2) is universally excisive if the triad $(\widetilde{X}_{x_0}, p^{-1}(A_1), p^{-1}(A_2))$ is excisive.

Lemma 169.1. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Let (X, A_1, A_2) be a universally excisive triad. We write $\widetilde{A}_1 := p^{-1}(A_1)$ and $\widetilde{A}_2 := p^{-1}(A_2)$. The following three statements hold:

(1) $\mathrm{C}_*^{\{\widetilde{A}_1,\widetilde{A}_2\}}(\widetilde{A}_1 \cup \widetilde{A}_2)$ is a free $\mathbb{Z}[\pi_1(X, x_0)]$-left module.

(2) The inclusion map

$$\mathrm{C}_*^{\{\widetilde{A}_1,\widetilde{A}_2\}}(\widetilde{A}_1 \cup \widetilde{A}_2) \;\to\; \mathrm{C}_*(\widetilde{A}_1 \cup \widetilde{A}_2)$$

is a chain homotopy equivalence of free $\mathbb{Z}[\pi_1(X, x_0)]$-left module chain complexes.

(3) The triad (X, A_1, A_2) is also excisive.

Proof.

(1) The same argument as in the Regular Covering-Chain Complex Lemma 167.2 shows that $\mathrm{C}_*^{\{\widetilde{A}_1,\widetilde{A}_2\}}(\widetilde{A}_1 \cup \widetilde{A}_2)$ is a free $\mathbb{Z}[\pi_1(X,x_0)]$-left module. For example a basis is given by picking a lift for each singular simplex that is contained in A_1 or in A_2.

(2) By definition $\mathrm{C}_*^{\{\widetilde{A}_1,\widetilde{A}_2\}}(\widetilde{A}_1 \cup \widetilde{A}_2) \to \mathrm{C}_*(\widetilde{A}_1 \cup \widetilde{A}_2)$ is a homotopy equivalence. By the super classical Corollary 73.4 this implies that the map induces an isomorphism of homology groups, i.e. it is a quasi-isomorphism. By the Regular Covering-Chain Complex Lemma 167.2 and (1) we know that we have in fact a quasi-isomorphism of chain complexes of free $\mathbb{Z}[\pi_1(X,x_0)]$-left module. Thus it follows from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 166.6 that the map is in fact a chain homotopy equivalence of free $\mathbb{Z}[\pi_1(X,x_0)]$-left module chain complexes.

(3) We consider the following diagram:

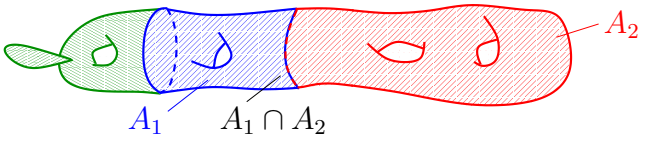
$$\begin{array}{ccc} {}_{\mathrm{tr}}\mathbb{Z} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_*^{\{\widetilde{A}_1,\widetilde{A}_2\}}(\widetilde{A}_1 \cup \widetilde{A}_2) & \longrightarrow & {}_{\mathrm{tr}}\mathbb{Z} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_*(\widetilde{A}_1 \cup \widetilde{A}_2) \\ \cong \downarrow n\otimes\sigma \mapsto n\cdot p_*(\sigma) & & \cong \downarrow n\otimes\sigma \mapsto n\cdot p_*(\sigma) \\ \mathrm{C}_*^{\{A_1,A_2\}}(A_1 \cup A_2) & \longrightarrow & \mathrm{C}_*(A_1 \cup A_2). \end{array}$$

Here the horizontal maps are induced by the inclusions and the vertical maps are basically the natural isomorphisms from Lemma 167.3. It is clear that the diagram commutes. It follows from (1) and (2) together with the Tensoring Chain Complex Lemma 166.3 that the top horizontal map is a chain homotopy equivalence. But then the bottom map is also a chain homotopy equivalence. That is exactly what we needed to show. ■

In the Excisive Triad-Proposition 109.12 we gave many convenient examples of excisive triads. The following proposition now says that these triads from the Excisive Triad-Proposition 109.12 are not only excisive but they are - how exciting - even universally excisive.

Proposition 169.2. Let (X, A_1, A_2) be a triad of topological spaces. We assume that X is locally contractible and path-connected. The triad is universally excisive if one of the following conditions is satisfied:

(1) $A_1 \subset A_2$ or $A_2 \subset A_1$,



(2) $A_1 = \varnothing$ or $A_2 = \varnothing$ or $A_1 = A_2$,

(3) $A_1 \cup A_2 = \mathring{A}_1 \cup \mathring{A}_2$ where we denote by $\mathring{A}_1$ and $\mathring{A}_2$ the interiors of A_1 and A_2 in $A_1 \cup A_2$,

(4) A_1 and A_2 are both open subsets of $A_1 \cup A_2$,

(5) $A_1 \cup A_2$ is a topological manifold and A_1 and A_2 are codimension-zero submanifolds which are both closed subsets and such that each component of $A_1 \cap A_2$ is a boundary component of A_1 and a boundary component of A_2,

(6) X is a CW-complex and A_1 and A_2 are both subcomplexes.

(X, A_1, A_2) is universally excisive

Proof. Let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. We write $\widetilde{A}_i := p^{-1}(A_i)$. By the Excisive Triad-Proposition 109.12 it suffices to prove the following claim.

Claim. If (X, A_1, A_2) satisfies one of the Conditions (1)–(6), then so does $(\widetilde{X}, \widetilde{A}_1, \widetilde{A}_2)$.

Proof. Conditions (1), (2) and (4) are clear. For Condition (3) note that for a covering we say in Exercise 48.7 that taking the preimage and taking the interior commutes. With this observation Condition (3) is also clear.

Now let us consider Condition (5). By the Manifold Covering Proposition 49.2 we know that any path-connected covering of a topological manifold is again a topological manifold. Since being a submanifold is a local condition we see that $(\widetilde{X}, \widetilde{A}_1, \widetilde{A}_2)$ also satisfies Condition (5). Finally the last condition is dealt with by the CW-complex Covering Proposition 68.37. ∎

169.2. **Internal twisted (co-) homology.** In this section we introduce what we call internal twisted (co-) homology. This concept is rather technical, but it can be very useful when one wants to consider the relationship between the twisted invariants of a topological space X and of (possibly disconnected) subspaces of X. In particular we will use this concept to prove a first Mayer–Vietoris style theorem and the concept will play a key role in our proof of the Poincaré Duality Theorem 172.1 with Twisted Coefficients.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering.

(1) Given any subset $A \subset B \subset X$ we write $\widetilde{A} := p^{-1}(A)$ and $\widetilde{B} := p^{-1}(B)$ and we set

$$\begin{aligned} \mathrm{C}_k^{X,M}(B, A) &:= \overline{M} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{B}, \widetilde{A}) \\ \mathrm{C}^k_{X,M}(B, A) &:= \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}(\mathrm{C}_k(\widetilde{B}, \widetilde{A}), M). \end{aligned}$$

These are (co-) chain complexes in the obvious way and we obtain the corresponding (co-) homology groups $\mathrm{H}_k^{X,M}(B, A)$ and $\mathrm{H}^k_{X,M}(B, A)$. We refer to these as internal (co-) homology groups with twisted coefficients.

(2) Given pairs (B_1, A_1) and (B_2, A_2) of subspaces of X with $B_1 \subset B_2$ and $A_1 \subset A_2$ we obtain, with the hopefully obvious notation, an inclusion induced chain map $\mathrm{C}_k(\widetilde{B_1}, \widetilde{A_1}) \to \mathrm{C}_k(\widetilde{B_2}, \widetilde{A_2})$ which is a $\mathbb{Z}[\pi_1(X, x_0)]$-left homomorphism. Thus we get induced maps

$$\begin{aligned} i_*\colon \mathrm{H}_k^{X,M}(B_1, A_1) &\to \mathrm{H}_k^{X,M}(B_2, A_2) \\ i^*\colon \mathrm{H}^k_{X,M}(B_2, A_2) &\to \mathrm{H}^k_{X,M}(B_1, A_1). \end{aligned}$$

Evidently internal (co-) homology is functorial under inclusions.

Note that in the setting of internal (co-) homology with twisted coefficients the subspaces are not required to be path-connected. This leads us to the following lemma.

Lemma 169.3. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Let $B \subset X$ be a subspace with path-components $\{B_j\}_{j \in J}$. Given $j \in J$ we denote by

$i_j\colon B_j \to B$ the inclusion map. For each $n \in \mathbb{N}_0$ the maps

$$\bigoplus_{j\in J} i_{j*}\colon \bigoplus_{j\in J} \mathrm{H}_n^{X,M}(B_j) \to \mathrm{H}_n^{X,M}(B) \quad \text{and} \quad \prod_{j\in J} i_j^*\colon \mathrm{H}_n^{X,M}(B) \to \prod_{j\in J} \mathrm{H}_n^{X,M}(B_j)$$

are isomorphisms.

Proof. This lemma follows easily from Lemma 72.14. We leave it to the reader to fill in the details. ■

As the reader will have noticed, the Change of Covering Proposition 167.10 relates internal (co-) homology with twisted coefficients to ordinary (co-) homology with twisted coefficients. For the reader's convenience we state the Change of Covering Proposition 167.10 with our new language.

Proposition 169.4. (Change of Covering Proposition II) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $q\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module. Let $B \subset X$ be a subspace with $x_0 \in B$. We assume that B is also locally contractible and path-connected. We write $\widetilde{B} := q^{-1}(B)$ and we denote by $p\colon \widehat{B}_{x_0} \to B$ the natural universal covering. Finally let $A \subset B$. We write $\widehat{A} := p^{-1}(A)$ and $\widetilde{A} := q^{-1}(A)$. We denote by the $i\colon B \to X$ the inclusion map and we denote by $\widetilde{i}\colon \widehat{B}_{x_0} \to \widetilde{X}_{x_0}$ the induced map as defined on page 3541.

(1) The maps

$$\begin{array}{rccc} \Omega_{B,A}^X\colon & \overbrace{i^*M \otimes_{\mathbb{Z}[\pi_1(B,x_0)]} \mathrm{C}_k(\widehat{B}_{x_0},\widehat{A})}^{=\mathrm{C}_k^{\mathrm{tw}}(B,A;i^*M)} & \to & \overbrace{M \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{B},\widetilde{A})}^{=\mathrm{C}_k^{X,M}(B,A)} \\ & m\otimes\sigma & \mapsto & m \otimes \widetilde{i}_*(\sigma) \end{array}$$

are well-defined and they are natural isomorphisms of R-left module chain complexes. Similarly the maps

$$\begin{array}{rccc} \Omega_{B,A}^X\colon & \overbrace{\mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}(\mathrm{C}_k(\widetilde{B},\widetilde{A}),M)}^{=\mathrm{C}_{X,M}^k(B,A)} & \to & \overbrace{\mathrm{Hom}_{\mathbb{Z}[\pi_1(B,x_0)]\text{-left}}(\mathrm{C}_k(\widehat{B}_{x_0},\widehat{A}),i^*M)}^{=\mathrm{C}_{\mathrm{tw}}^k(B,A;i^*M)} \\ & \varphi & \mapsto & (\sigma \mapsto \varphi(\widetilde{i}_*(\sigma))) \end{array}$$

are well-defined (co-) chain maps and they are natural isomorphisms of R-left module cochain complexes. When $A = \varnothing$, then we just write Ω_B^X.

(2) The maps Ω from (1) are natural in the following sense. Suppose we have subspaces $S \subset T \subset X$ which are both locally contractible and path-connected and such that $x_0 \in S$. Furthermore suppose we have $A \subset S$ and $B \subset T$ with $A \subset B$. We denote by $i\colon S \to T$ and by $j\colon T \to X$ the inclusion. The following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_k^{\mathrm{tw}}(S,A;i^*j^*M) & \xrightarrow{\quad i_*\quad} & \mathrm{H}_k^{\mathrm{tw}}(T,B;j^*M) \\ {\scriptstyle\Omega_S^X}\big\downarrow{\scriptstyle\cong} & & {\scriptstyle\Omega_T^X}\big\downarrow{\scriptstyle\cong} \\ \mathrm{H}_k^{X,M}(S,A) & \xrightarrow{\quad i_*\quad} & \mathrm{H}_k^{X,M}(T,B). \end{array}$$

The analogous statements for cohomology groups also holds.

Proof. The first statement is just the content of the Change of Covering Proposition 167.10 (1). The second statement is new. We denote by $s\colon \overline{S}_{x_0} \to S$, $t\colon \widehat{T}_{x_0} \to T$ and $p\colon \widetilde{X}_{x_0} \to X$ the natural universal coverings.

We write $k = i \circ j\colon S \to X$. By the discussion on page 3541 we get induced maps $\widetilde{i}\colon \overline{S}_{x_0} \to \widehat{T}_{x_0}$, $\widetilde{j}\colon \widehat{T}_{x_0} \to \widetilde{X}_{x_0}$ and $\widetilde{k}\colon \overline{S}_{x_0} \to \widetilde{X}_{x_0}$. One can easily verify that $\widetilde{k} = \widetilde{j} \circ \widetilde{i}$. The second statement follows in a straightforward fashion from this observation. ■

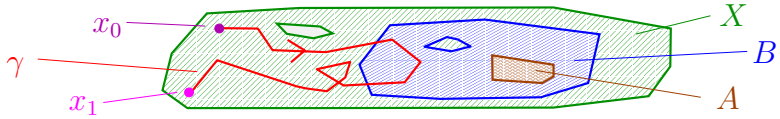
The following proposition is a refinement of the Change of Base Point Proposition 167.6 in our present context.

Proposition 169.5. (Change of Base Point Proposition II) Let X be a topological space that is locally contractible and path-connected and let $A \subset B \subset X$. Furthermore let $\gamma\colon [0,1] \to X$ be a path from $x_0 = \gamma(0)$ to $x_1 = \gamma(1)$. For $i = 0, 1$ we denote by $p_i\colon \widetilde{X}_{x_i} \to X$ the natural universal covering and we write $\widetilde{A}_i := p_i^{-1}(A)$ and $\widetilde{B}_i := p_i^{-1}(B)$. Finally let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. As in the Change-of-Base Point Proposition 47.10 we consider the isomorphism

$$\begin{array}{rcl} \gamma^*\colon \pi_1(X, x_1) & \to & \pi_1(X, x_0) \\ [\alpha] & \mapsto & [\gamma * \alpha * \overline{\gamma}]. \end{array}$$

The isomorphism γ^* gives rise to a ring homomorphism $\gamma^*\colon \mathbb{Z}[\pi_1(X, x_1)] \to \mathbb{Z}[\pi_1(X, x_0)]$. Thus, as defined on page 3502, we can consider the $\mathbb{Z}[\pi_1(X, x_1)]$-left module $\gamma^{**}M$. Furthermore, as in Lemma 61.10 we consider the homeomorphism

$$\begin{array}{rcl} \gamma^*\colon \widetilde{X}_{x_1} & \to & \widetilde{X}_{x_0} \\ [\beta] & \mapsto & [\gamma * \beta]. \end{array}$$



With this notation the maps

$$\begin{array}{rcl} \gamma^*\colon \overline{\gamma^{**}M} \otimes_{\mathbb{Z}[\pi_1(X,x_1)]} \mathrm{C}_k(\widetilde{B}_1, \widetilde{A}_1) & \to & \overline{M} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{B}_0, \widetilde{A}_0) \\ m \otimes \sigma & \mapsto & m \otimes \gamma^*(\sigma) \end{array}$$

form an isomorphism of R-left module chain complexes and the maps

$$\begin{array}{rcl} \gamma^*\colon \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_1)]-\mathrm{left}}(\mathrm{C}_k(\widetilde{B}_1, \widetilde{A}_1), \gamma^{**}M) & \to & \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]-\mathrm{left}}(\mathrm{C}_k(\widetilde{B}_0, \widetilde{A}_0), M) \\ \varphi & \mapsto & \varphi \circ \gamma^* \end{array}$$

form a natural isomorphism of R-left module cochain complexes.

Proof. The proof is basically identical to the proof of the original Change of Base Point Proposition 167.6. ■

Many results on ordinary twisted (co-) homology have fairly obvious analogues to the context of internal twisted (co-) homology. For example we have the following variation on the Excision Theorem 167.12 for Twisted (Co-) Homology.

Theorem 169.6. (Excision Theorem for Internal Twisted (Co-) Homology) Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$. Suppose

we are given subsets $K \subset U \subset V$ where U is a neighborhood of the closure of K in V. The inclusion $i\colon (U, U \setminus K) \to (V, V \setminus K)$ induces for each $n \in \mathbb{N}_0$ isomorphisms

$$\begin{aligned} i_*\colon \mathrm{H}_n^{X,M}(U, U \setminus K) &\xrightarrow{\cong} \mathrm{H}_n^{X,M}(V, V \setminus K) \\ i^*\colon \mathrm{H}^n_{X,M}(V, V \setminus K; M) &\xrightarrow{\cong} \mathrm{H}^n_{X,M}(U, U \setminus K). \end{aligned}$$

Proof. The proof is similar to the proof of the Excision Theorem 167.12. We leave it to the reader to make the necessary changes. ■

169.3. **Mayer-Vietoris Theorems for (co-) homology with twisted coefficients.** Working with internal twisted cohomology one can easily formulate Mayer–Vietoris type theorems.

Theorem 169.7. (Mayer–Vietoris Theorem for Internal Twisted homology) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Let (X, A, B) be a universally excisive triad with $X = A \cup B$. For every $n \in \mathbb{N}_0$ there exists a natural connecting R-left module homomorphism

$$\partial_n\colon \mathrm{H}_n^{X,M}(A \cup B) \xrightarrow{\partial_n} \mathrm{H}_{n-1}^{X,M}(A \cap B)$$

such that the following sequence

$$\begin{aligned} \cdots \to\ & \mathrm{H}_n^{X,M}(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n^{X,M}(A) \oplus \mathrm{H}_n^{X,M}(B) \xrightarrow{i_A + i_B} \mathrm{H}_n^{X,M}(A \cup B) \xrightarrow{\partial_n} \\ & \xrightarrow{\partial_n} \mathrm{H}_{n-1}^{X,M}(A \cap B) \to \dots \end{aligned}$$

of R-left module homomorphisms is exact.

Proof. As usual we denote by $p\colon \widetilde{A} \cup \widetilde{B} \to X$ the natural universal covering and we write $\pi := \pi_1(X, x_0)$. We write $\widetilde{A} := p^{-1}(A)$ and $\widetilde{B} := p^{-1}(B)$. Note that $\widetilde{A} \cap \widetilde{B} = p^{-1}(A \cap B)$ and $\widetilde{A} \cup \widetilde{B} = p^{-1}(A \cup B)$. In the proof of the original Mayer–Vietoris Theorem 78.5 we showed that the sequence

$$0 \to \mathrm{C}_*(\widetilde{A} \cap \widetilde{B}) \xrightarrow{i_{\widetilde{A}\cap\widetilde{B}} \oplus -i_{\widetilde{A}\cap\widetilde{B}}} \mathrm{C}_*(\widetilde{A}) \oplus \mathrm{C}_*(\widetilde{B}) \xrightarrow{i_{\widetilde{A}} + i_{\widetilde{B}}} \mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B}) \to 0$$

of chain maps of $\mathbb{Z}[\pi]$-left chain complexes is exact. By Lemma 169.1 (1) we know that $\mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B})$ is a free $\mathbb{Z}[\pi]$-left module. It follows from this observation together with Lemma 165.18 that the sequence

$$0 \to M \underset{\mathbb{Z}[\pi]}{\otimes} \mathrm{C}_*(\widetilde{A} \cap \widetilde{B}) \xrightarrow{i_{\widetilde{A}\cap\widetilde{B}} \oplus -i_{\widetilde{A}\cap\widetilde{B}}} M \underset{\mathbb{Z}[\pi]}{\otimes} \mathrm{C}_*(\widetilde{A}) \oplus M \underset{\mathbb{Z}[\pi]}{\otimes} \mathrm{C}_*(\widetilde{B}) \xrightarrow{i_{\widetilde{A}} + i_{\widetilde{B}}} M \underset{\mathbb{Z}[\pi]}{\otimes} \mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B}) \to 0$$

of R-left module chain maps is also exact. We deduce from the LES Lemma 166.11 that we get natural connecting homomorphism which give rise to a long exact sequence of R-left module homomorphisms.

Recall that we assume that (X, A, B) is in fact universally excisive with $X = A \cup B$. It follows from Lemma 169.1 (2) that the inclusion map

$$\mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B}) \to \mathrm{C}_*(\widetilde{A} \cup \widetilde{B})$$

is a chain homotopy equivalence of free $\mathbb{Z}[\pi]$-left module chain complexes. Hence for every $n \in \mathbb{N}_0$ it induces an isomorphism

$$\Xi\colon \mathrm{H}_n\big(M \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B})\big) \xrightarrow{\cong} \underbrace{\mathrm{H}_n\big(M \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*(\widetilde{A} \cup \widetilde{B})\big)}_{=\mathrm{H}_n^{X,M}(A \cup B)}.$$

The idea now is to use Ξ to obtain the desired long exact sequence. To do so we consider the following diagram

$$\begin{array}{ccccc} \mathrm{H}_n^{X,M}(A) \oplus \mathrm{H}_n^{X,M}(B) & \xrightarrow{\mathrm{id}_M \otimes i_{\widetilde{A}} + \mathrm{id}_M \otimes i_{\widetilde{B}}} & \mathrm{H}_n\big(M \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B})\big) & \xrightarrow{\partial_n} & \mathrm{H}_n^{X,M}(A \cap B) \\ & \searrow^{i_A + i_B} & \cong \big\downarrow \Xi & \nearrow_{=:\partial_n} & \\ & & \mathrm{H}_n^{X,M}(A \cup B). & & \end{array}$$

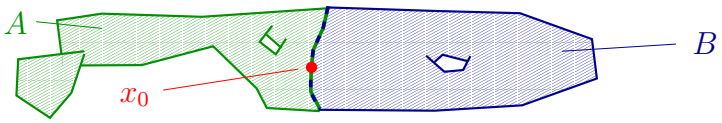
The crucial observation is that the triangle to the left commutes. Thus going "via the bottom" we do indeed obtain the desired connecting homomorphism that gives rise to the promised long exact sequence. ■

The Mayer–Vietoris Theorem 169.7 for Internal Twisted Homology, as it is formulated, will play a major role in the proof of the Poincaré Duality Theorem 172.1 for Twisted Coefficients. But the alert reader will have noticed that the Mayer–Vietoris Theorem 169.7 for Internal Twisted Homology is not all that useful for performing calculations since it is formulated in terms of the unwieldy internal homology modules. Of course, by the Change of Covering Proposition II 169.4 together with Lemma 169.3, we know that each such internal homology module is isomorphic to an appropriate twisted homology module of each of the components. The catch is, that it becomes increasingly unclear what are the "inclusion induced maps" at this point.

The following theorem gives us a clean statement if all subspaces involved are path-connected.

Theorem 169.8. (Mayer–Vietoris Theorem for homology with twisted coefficients) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Let $A, B \subset X$ be subspaces such that the following conditions are satisfied:

(1) (X, A, B) is a universally excisive triad,
(2) we have $X = A \cup B$,
(3) A, B and $A \cap B$ are locally contractible and path-connected,
(4) $x_0 \in A \cap B$.



There exists a natural connecting R-left module homomorphism[2084]

$$\partial_n\colon \mathrm{H}_n^{\mathrm{tw}}(X; M) \xrightarrow{\partial_n} \mathrm{H}_{n-1}^{\mathrm{tw}}(A \cap B; i_{A\cap B}^* M)$$

such that the following sequence

$$\ldots \to \mathrm{H}_n^{\mathrm{tw}}(A \cap B; i_{A\cap B}^* M) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n^{\mathrm{tw}}(A; i_A^* M) \oplus \mathrm{H}_n^{\mathrm{tw}}(B; i_B^* M) \xrightarrow{i_A + i_B} \mathrm{H}_n^{\mathrm{tw}}(X; M) \xrightarrow{\partial_n} \xrightarrow{\partial_n} \mathrm{H}_{n-1}^{\mathrm{tw}}(A \cap B; i_{A\cap B}^* M) \to \ldots$$

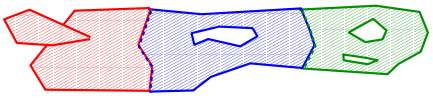
of R-left module homomorphisms is exact.[2085]

Proof of the Mayer–Vietoris Theorem 169.8. By the Mayer–Vietoris Theorem 169.7 for Internal Twisted homology there exists a natural connecting R-left module homomorphism

$$\partial_n \colon \mathrm{H}_n^{X,M}(X) \xrightarrow{\partial_n} \mathrm{H}_{n-1}^{X,M}(A \cap B)$$

such that the following sequence is exact:

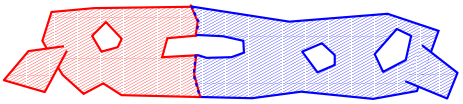
$$\cdots \to \mathrm{H}_n^{X,M}(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n^{X,M}(A) \oplus \mathrm{H}_n^{X,M}(B) \xrightarrow{i_A + i_B} \mathrm{H}_n^{X,M}(X) \xrightarrow{\partial_n} \xrightarrow{\partial_n} \mathrm{H}_{n-1}^{X,M}(A \cap B) \to \dots$$



The Change of Covering Proposition 169.4 II (1) gives us isomorphisms

$$\Omega^X_{A\cap B} \colon \mathrm{H}_k^{\mathrm{tw}}(A \cap B; i^*_{A\cap B} M) \to \mathrm{H}_k^{X,M}(A \cap B),$$

and similarly for A and B. After making all these replacement we obtain a long exact sequence with the right modules at the right place. It remains to show that the maps in the resulting diagram are the maps we promised. But this is an immediate consequence of the Change of Covering Proposition 169.4 II (2). ■



The most restrictive extra condition that we impose in the above Mayer–Vietoris Theorem 169.8 compared to the traditional Mayer–Vietoris Theorem 109.14 is that we now demand that $A \cap B$ is path-connected. If $A \cap B$ is not path-connected then sometimes we can get around this issue by applying Theorem 169.8 iteratively while moving the base point. But this approach does not always work.

decomposition of a topological space X

can iteratively apply Mayer-Vietoris for connected intersection

decomposition of a topological space X

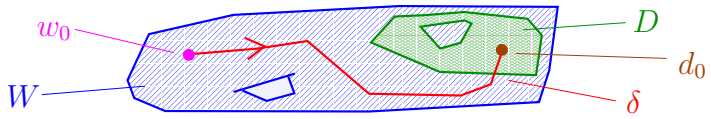
cannot iteratively apply Mayer-Vietoris for connected intersection

The following theorem gets rid of the hypothesis in the Mayer–Vietoris Theorem 169.8 that the intersection $A \cap B$ needs to be path-connected. The price we pay for this flexibility is another layer of notation which obfuscates the statement even further. Before we can state this generalization we need to introduce one more piece of notation:

Notation. Let W be a topological space that is locally contractible and path-connected and let $w_0 \in W$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(W, w_0)], R)$-left left module. Let $D \subset W$ be a subspace that is locally contractible and path-connected, let $d_0 \in D$ and let $\delta \colon [0,1] \to W$ be a path from w_0 to d_0. We denote by $i \colon D \to W$ the inclusion and we

[2084]Recall that hypothesis that (X, A, B) is a universally excisive triad implies in particular that A, B and $A \cap B$ are locally contractible. Since A, B and $A \cap B$ are path-connected it makes sense to consider twisted homology modules of A, B and $A \cap B$.

[2084]Here $A \cap B$, A, B and X are all equipped with the base point x_0. The various maps denoted by i are the obvious inclusion (induced) maps, with our choice of base point, all maps are base point preserving.



denote by i^δ the chain map

$$\mathrm{C}_k^{\mathrm{tw}}(D; i^*\delta^{**}M) \xrightarrow[\uparrow]{i} \mathrm{C}_k^{\mathrm{tw}}(W; \delta^{**}M) \xrightarrow[\uparrow]{\delta_*} \mathrm{C}_k^{\mathrm{tw}}(W; M)$$

map that is induced by the inclusion $i\colon (D, d_0) \to (W, w_0)$, see page 3542

isomorphism given by the Change of Base Point Proposition 167.6

of R-left chain complexes. Furthermore we denote by $i^\delta\colon \mathrm{H}_k^{\mathrm{tw}}(D; i^*\delta^{**}M) \to \mathrm{H}_k^{\mathrm{tw}}(W; M)$ the induced map. Finally we simplify $\delta^*{*}$ and $i^*\delta^{**}M$ to δ_*M.

Theorem 169.9. (Mayer–Vietoris Theorem for homology with twisted coefficients) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Let $A, B \subset X$ be subspaces such that the following conditions are satisfied:

(1) (X, A, B) is a universally excisive triad,
(2) we have $X = A \cup B$,
(3) A and B are path-connected,
(4) A, B and $A \cap B$ are locally contractible,
(5) $A \cap B$ consists of finitely many path-components $C_1, \ldots, C_k$.

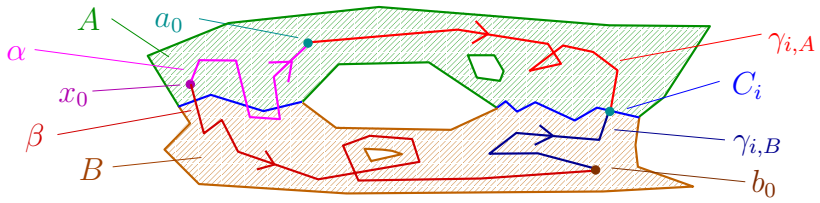
We pick $a_0 \in A$, $b_0 \in B$, we pick $c_j \in C_j$, $j = 1, \ldots, k$, we pick a path $\alpha\colon [0,1] \to X$ from x_0 to a_0, we pick a path $\beta\colon [0,1] \to X$ from x_0 to b_0, we pick paths $\gamma_{j,A}\colon [0,1] \to A$ from a_0 to c_j and we pick paths $\gamma_{j,B}\colon [0,1] \to B$ from b_0 to c_j. There exist natural R-left module homomorphisms

$$\partial_n\colon \mathrm{H}_n^{\mathrm{tw}}(X; M) \xrightarrow{\partial_n} \bigoplus_{j=1}^{k} \mathrm{H}_{n-1}^{\mathrm{tw}}(C_j; (\alpha * \gamma_{j,A})_* M)$$

and natural homomorphisms[2085]

$$\Psi_j\colon \mathrm{H}_n^{\mathrm{tw}}(C_j; (\alpha * \gamma_{j,A})_* M) \to \mathrm{H}_n^{\mathrm{tw}}(B; \beta_* M)$$

such that the following sequence



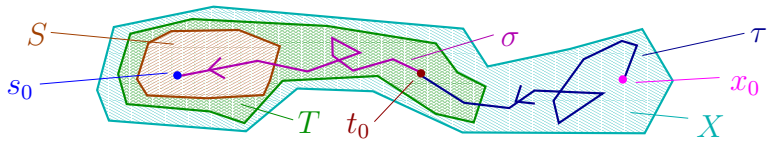
$$\to \bigoplus_{j=1}^{k} \mathrm{H}_n^{\mathrm{tw}}(C_j; (\alpha * \gamma_{j,A})_* M) \xrightarrow{\oplus_j i^{\gamma_{j,A}} \oplus -\oplus_j \Psi_j} \mathrm{H}_n^{\mathrm{tw}}(A; \alpha_* M) \oplus \mathrm{H}_n^{\mathrm{tw}}(B; \beta_* M) \xrightarrow{i^\alpha + i^\beta} \mathrm{H}_n^{\mathrm{tw}}(X; M) \xrightarrow{\partial_n}$$
$$\xrightarrow{\partial_n} \bigoplus_{j=1}^{k} \mathrm{H}_{n-1}^{\mathrm{tw}}(C_j; (\alpha * \gamma_{j,A})_* M) \to \ldots$$

of R-left module homomorphisms is exact.

Remark.

(1) At this stage it should be clear to the reader that one does not necessarily need to assume that A and B are path-connected. With even more messy notation one

[2085] These homomorphisms are described in the proof of the theorem. There does not seem to be a snappy description of these maps.



can formulate a generalization to the non path-connected case. We leave the task of texing this to the reader.

(2) In practice it can be very hard to compute honestly and rigorously the involved maps.

For the proof of the above Mayer–Vietoris Theorem 169.9 we will need the following technical lemma.

Lemma 169.10. Let X be a topological space and let $S \subset T \subset X$ be subspaces. We assume that S, T and X are locally contractible and path-connected. Let $s_0 \in S$, $t_0 \in T$ and $x_0 \in X$ be points and let $\sigma\colon [0,1] \to T$ be a path from t_0 to s_0 and let $\tau\colon [0,1] \to X$ be a path from x_0 to t_0. We denote by $i\colon S \to T$ and $j\colon T \to X$ the inclusions. Finally let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X,x_0)], R)$-left left module. With all this notation, together with the notation from page 3579 the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{H}_n^{X,M}(S) & \xrightarrow{(\tau*\sigma)_*} & \mathrm{H}_n^{X,(\tau*\sigma)_*M}(S) & \xrightarrow{\Omega_S^X} & \mathrm{H}_n^{\mathrm{tw}}(S;(\tau*\sigma)_*M) \\ \downarrow{\scriptstyle i} & & \downarrow{\scriptstyle i^\sigma} & & \downarrow{\scriptstyle i} \\ \mathrm{H}_n^{X,M}(T) & \xrightarrow{\tau_*} & \mathrm{H}_n^{X,\tau_*M}(T) & \xrightarrow{\Omega_T^X} & \mathrm{H}_n^{\mathrm{tw}}(T;\tau_*M). \end{array}$$

Proof. We leave it to the reader to verify this lemma. ■

Proof. It follows from the Mayer–Vietoris Theorem 169.7 for Internal Twisted homology together with Lemma 169.3 that there exists a natural R-left module homomorphism

$$\partial_n\colon \mathrm{H}_n^{tw}(X;M) \xrightarrow{\partial_n} \bigoplus_{j=1}^{k} \mathrm{H}_{n-1}^{X,M}(C_j)$$

such that the following sequence

$$\cdots \to \bigoplus_{j=1}^{k} \mathrm{H}_n^{X,M}(C_j) \xrightarrow{\oplus i_{C_j} \oplus -\oplus i_{C_j}} \mathrm{H}_n^{X,M}(A) \oplus \mathrm{H}_n^{X,M}(B) \xrightarrow{i_A+i_B} \mathrm{H}_n^{\mathrm{tw}}(M) \xrightarrow{\partial_n} \xrightarrow{\partial_n} \bigoplus_{j=1}^{k} \mathrm{H}_{n-1}^{X,M}(C_j) \to \dots$$

of R-left module homomorphisms is exact. As before we want replace these internal homology groups by honest-to-G*d twisted homology groups. But this time we are in a sea of troubles since we surrendered all control over base points. Nonetheless, we will give it a

try. We have the isomorphisms

$$\begin{array}{ccccc}
\mathrm{H}_n^{X,M}(C_j) & \xrightarrow{(\alpha*\gamma_{j,A})_*} & \mathrm{H}_n^{X,(\alpha*\gamma_{j,A})_*M}(C_j) & \xrightarrow{\Omega^X_{C_j}} & \mathrm{H}_n^{\mathrm{tw}}(C_j;(\alpha*\gamma_{j,A})_*M) \\
\mathrm{H}_n^{X,M}(A) & \xrightarrow{\alpha_*} & \mathrm{H}_n^{X,\alpha_*M}(A) & \xrightarrow{\Omega^X_{A}} & \mathrm{H}_n^{\mathrm{tw}}(A;\alpha_*M) \\
\mathrm{H}_n^{X,M}(B) & \xrightarrow{\beta_*} & \mathrm{H}_n^{X,\beta_*M}(B) & \xrightarrow{\Omega^X_{B}} & \mathrm{H}_n^{\mathrm{tw}}(B;\beta_*M).
\end{array}$$

Here the isomorphisms to the left are provided by the Change of Base Point Proposition II 169.5 and the isomorphisms to the right are provided by the Change of Covering Proposition II 169.4. Fortunately Lemma 169.10 sails to our rescue. It implies that in most cases, if we use the above isomorphisms to replace our previous inclusion induced maps, we get again inclusion induced maps. For example for each $j \in \{1,\dots,k\}$ we get that the following diagram commutes:

$$\begin{array}{ccccc}
\mathrm{H}_n^{X,M}(C_j) & \xrightarrow[\cong]{(\alpha*\gamma_{j,A})_*} & \mathrm{H}_n^{X,(\alpha*\gamma_{j,A})^*M}(C_j) & \xrightarrow[\cong]{\Omega^X_{C_j}} & \mathrm{H}_n^{\mathrm{tw}}(C_j;(\alpha*\gamma_{j,A})_*M) \\
\downarrow{\scriptstyle i} & & \downarrow{\scriptstyle i^{\gamma_{j,A}}} & & \downarrow{\scriptstyle i} \\
\mathrm{H}_n^{X,M}(A) & \xrightarrow[\cong]{alpha_*} & \mathrm{H}_n^{X,\alpha_*M}(A) & \xrightarrow[\cong]{\Omega^X_{A}} & \mathrm{H}_n^{\mathrm{tw}}(A;\alpha_*M).
\end{array}$$

A similar, in fact much simpler logic, applies to i_A and i_B. But the inclusion from C_j to B gets screwed up, since the paths do not match up. In fact the map Ψ_j is the following composition of maps, for which this particular author cannot find a pleasant shortcut:

$$\begin{array}{ccccc}
\mathrm{H}_n^{X,M}(C_j) & \xrightarrow[\cong]{(\alpha*\gamma_{j,B})_*} & \mathrm{H}_n^{X,(\alpha*\gamma_{j,B})^*M}(C_j) & \xrightarrow[\cong]{\Omega^X_{C_j}} & \mathrm{H}_n^{\mathrm{tw}}(C_j;(\alpha*\gamma_{j,B})_*M) \\
\downarrow{\scriptstyle i} & & & & \downarrow{\scriptstyle =:\Psi_j} \\
\mathrm{H}_n^{X,M}(B) & \xrightarrow[\cong]{\beta_*} & \mathrm{H}_n^{X,\beta_*M}(B) & \xrightarrow[\cong]{\Omega^X_{B}} & \mathrm{H}_n^{\mathrm{tw}}(B;\beta_*M).
\end{array}$$

■

Exercises for Chapter 169.

Exercise 169.1. Use the Mayer–Vietoris theorem to show that given any lens space and given any non-trivial one-dimensional complex representation all twisted homology groups are zero.

170. Twisted cellular (co-) homology

170.1. **Twisted cellular (co-) homology.** We start out with a few preliminaries.

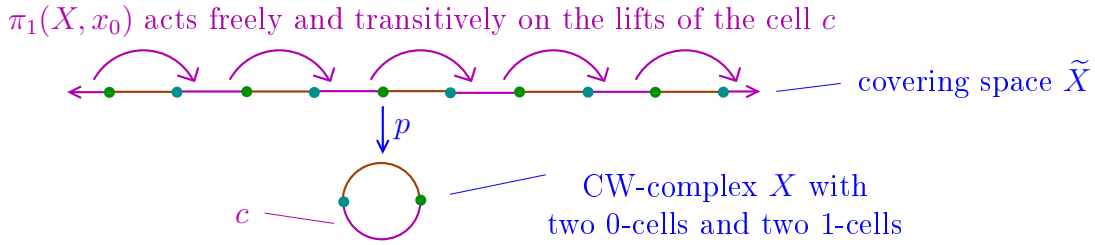
Notation. Let X be a CW-complex and let A be a subcomplex.

(1) Given $k \in \mathbb{N}_0$ we denote by X^k the k-skeleton of X, as defined on page 1469.
(2) As on page 1492 we say that a map $g\colon X \to Y$ between two CW-complexes is cellular if for each $k \in \mathbb{N}_0$ we have $g(X^k) \subset Y^k$.
(3) As on page 1770 we set
$$\mathrm{C}_n^{\mathrm{CW}}(X) \ := \ \mathrm{H}_n(X^n, X^{n-1})$$
and we define the cellular chain map as on page 1769. The corresponding homology groups are the cellular homology groups $\mathrm{H}_n^{\mathrm{CW}}(X)$. Furthermore we consider the relative chain complex
$$\mathrm{C}_*^{\mathrm{CW}}(X, A) \ := \ \mathrm{coker}\left(i_*\colon \mathrm{C}_*^{\mathrm{CW}}(A) \to \mathrm{C}_*^{\mathrm{CW}}(X)\right),$$
and we refer to the corresponding homology groups as the relative cellular homology groups $\mathrm{H}_*^{\mathrm{CW}}(X, A)$.
(4) By the CW-Complex Properties Proposition 68.10 we know that X is locally contractible. Thus, if X is path-connected, then given any $x_0 \in X$ we know that the natural universal covering $p\colon \widetilde{X}_{x_0} \to X$ exists.
(5) If $q\colon Y \to X$ is any covering, e.g. the natural universal covering, then it follows from the CW-complex Covering Proposition 68.37 that we can equip Y with a natural CW-structure which has the property, that each deck transformation of $q\colon Y \to X$ acts cellularly. If $A \subset X$ is a subcomplex, then $p^{-1}(A)$ is, basically by construction, a subcomplex of Y.

There are three reasons why we were and are interested in cellular chain complexes:

(1) Cellular chain complexes are incomparably smaller than the unwieldy singular chain complexes.
(2) In the Cellular Boundary Map-via-Degrees Proposition 80.8 we gave a practical way for determining the boundary maps in the cellular chain complex.
(3) In the Singular-Cellular H_*-Isomorphism Proposition 80.4 and the Singular-Cellular H^*-Isomorphism Proposition 109.4 we saw that given a CW-complex X the singular (co-) homology groups and the cellular (co-) homology groups are naturally isomorphic.

Our goal in this chapter is to repeat this success story in the present context of twisted (co-) homology.



Notation. Let X be a CW-complex and let A be a subcomplex.

(1) By the CW-Complex Properties Proposition 68.10 we know that X is locally contractible. Thus, if X is path-connected, then given any $x_0 \in X$ we know that the natural universal covering $p\colon \widetilde{X}_{x_0} \to X$ exists.
(2) If $q\colon Y \to X$ is any covering, e.g. the natural universal covering, then it follows from the CW-complex Covering Proposition 68.37 that we can equip Y with a natural CW-structure which has the property, that each deck transformation of $q\colon Y \to X$

acts cellularly. If $A \subset X$ is a subcomplex, then $p^{-1}(A)$ is, basically by construction, a subcomplex of Y.

Lemma 170.1. Let X be a path-connected CW-complex, let $x_0 \in X$ and let $A \subset X$ be a subcomplex. Let $p\colon \widetilde{X} \to X$ be a regular covering. We write $\widetilde{A} := p^{-1}(A)$ and we denote by $D := \mathrm{Deck}(p\colon \widetilde{X} \to X)$ the corresponding deck transformation group.

(1) Let $k \in \mathbb{N}_0$. For each open k-cell σ in X that is not contained in A we pick a single open cell $\widetilde{\sigma} \subset \widetilde{X}$ with $p(\widetilde{\sigma}) = \sigma$. These cells $\widetilde{\sigma}$ are a basis for $\mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}, \widetilde{A})$ as a free $\mathbb{Z}[D]$-left module.
(2) Each cellular chain group $\mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}, \widetilde{A})$ is a free $\mathbb{Z}[D]$-left module where the cardinality of the basis is given by the cardinality of the set of k-cells of the CW-complex X that are not contained in A.
(3) If X is compact, then each cellular chain group $\mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}, \widetilde{A})$ is a finitely generated free $\mathbb{Z}[D]$-left module.
(4) The cellular boundary maps $\partial\colon \mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}, \widetilde{A}) \to \mathrm{C}_{k-1}^{\mathrm{CW}}(\widetilde{X}, \widetilde{A})$ are $\mathbb{Z}[D]$-left module homomorphisms.

Proof.

(1) This statement follows from the explicit description of the CW-structure on $\widetilde{X}$ that is described in the proof of the CW-complex Covering Proposition 68.37 together with the explicit description of the cellular chain groups in the Skeleton-Homology Lemma 80.1.
(2) This statement is just a slightly more reader friendly version of Statement (1).
(3) If X is compact, then it follows from the CW-Complex Compactness Corollary 68.15 that X has only finitely many cells. Thus this statement follows immediately from Statement (1).
(4) This statement follows almost immediately from the naturality of the cellular boundary maps, see Lemma 80.3 and the fact, observed above, that each deck transformation is a cellular self-map of $\widetilde{X}$. ■

We can now introduce the cellular analogues of the twisted (co-) homology groups that we defined on page 3537.

Definition. Let X be a path-connected CW-complex, let $x_0 \in X$ and let $A \subset X$ be a subcomplex. We write $\pi := \pi_1(X, x_0)$. Furthermore let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X_0, x_0)], R)$-left left module. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal

covering and we write $\widetilde{A} := p^{-1}(A)$. Given $k \in \mathbb{N}_0$ we define the R-left modules

$$\begin{aligned} \mathrm{C}_k^{\mathrm{tw,CW}}(X, A; M) &:= \overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}_{x_0}, \widetilde{A}) && \text{(twisted cellular chain complex)} \\ \mathrm{C}^k_{\mathrm{tw,CW}}(X, A; M) &:= \mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(\mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}_{x_0}, \widetilde{A}), M) && \text{(twisted cellular cochain complex).} \end{aligned}$$

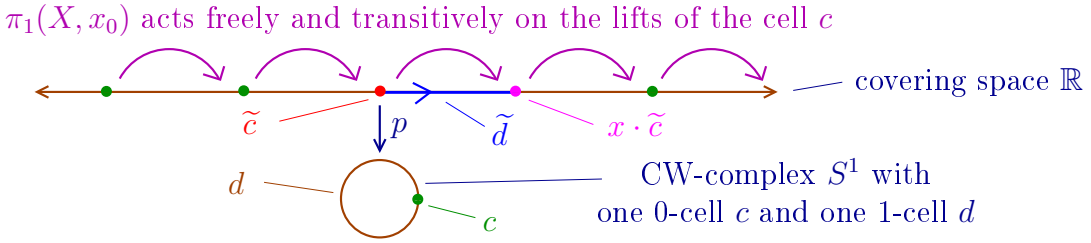
By Lemma 170.1 we know that the boundary maps of $\mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}_{x_0}, \widetilde{A})$ are $\mathbb{Z}[\pi]$-left module homomorphisms. Thus we see that $\mathrm{id} \otimes \partial$ and $\mathrm{Hom}(\partial, \mathrm{id})$ induce (co-) chain maps. Thus we can define the R-left modules

$$\begin{aligned} \mathrm{H}_k^{\mathrm{tw,CW}}(X, A; M) &:= \mathrm{H}_k\big(\overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*^{\mathrm{CW}}(\widetilde{X}_{x_0}, \widetilde{A})\big) && \text{(twisted cellular homology)} \\ \mathrm{H}^k_{\mathrm{tw,CW}}(X, A; M) &:= \mathrm{H}^k\big(\mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(\mathrm{C}_*^{\mathrm{CW}}(\widetilde{X}_{x_0}, \widetilde{A}), M)\big) && \text{(twisted cellular cohomology).} \end{aligned}$$

As always, if $A = \varnothing$, then we drop it from the notation.

Example. We consider the topological space $S^1 \subset \mathbb{C}$ which we equip with the CW-structure that consists of a single 0-cell $c = \{1\}$ and a single 1-cell d. Let $\varphi\colon \pi_1(S^1, 1) \to \langle x \rangle$ be the usual isomorphism. We denote by $p\colon \mathbb{R} \to S^1$ the universal covering that is given by $p(t) = \exp(2\pi \mathrm{i} t)$. We pick the lift $\widetilde{c} = \{0\} \subset \mathbb{R}$ and as a lift of the 1-cell d we pick the 1-cell $\widetilde{d}$ with attaching map $\Phi\colon (-1, 1) \to \mathbb{R}$ that is given by $\Phi(s) = \frac{1}{2}(1 + s)$. With respect to these lifts the cellular chain $\mathrm{C}_*^{\mathrm{CW}}(\mathbb{R})$ is given by

$$0 \;\to\; \mathbb{Z}[x^{\pm 1}] \cdot \widetilde{d} \;\xrightarrow{\widetilde{d} \mapsto (x-1)\cdot \widetilde{c}}\; \mathbb{Z}[x^{\pm 1}] \cdot \widetilde{c} \;\to\; 0.$$



Given $\xi \in \mathbb{C} \setminus \{0\}$ we consider the representation

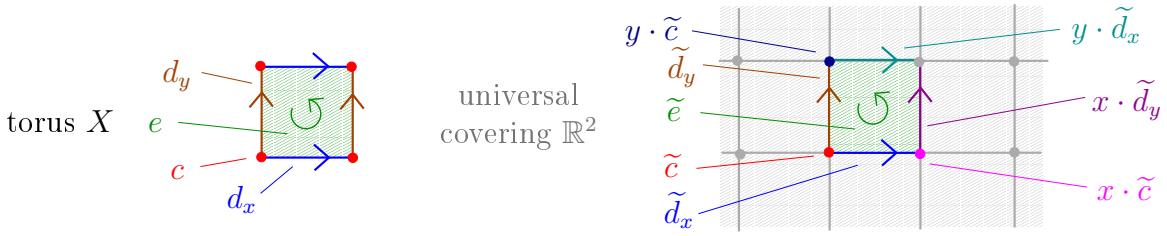
$$\rho_\xi\colon \pi_1(S^1, 1) \;\xrightarrow{\varphi}\; \langle x \rangle \;\xrightarrow{x \mapsto \xi}\; \mathrm{GL}(1, \mathbb{C}).$$

We see that[2086]

$$\begin{aligned} \mathrm{H}_1^{\mathrm{CW}}(S^1; {}_{\rho_\xi}\mathbb{C}) &\cong \ker\big({}_{\rho_\xi}\mathbb{C} \otimes_{\mathbb{Z}[x^{\pm 1}]} \mathbb{Z}[x^{\pm 1}] \cdot \widetilde{d} \xrightarrow{\mathrm{id} \otimes (x-1)} {}_{\rho_\xi}\mathbb{C} \otimes_{\mathbb{Z}[x^{\pm 1}]} \mathbb{Z}[x^{\pm 1}] \cdot \widetilde{c}\big) \\ &\cong \ker(\mathbb{C} \xrightarrow{\cdot(\xi - 1)} \mathbb{C}) \cong \begin{cases} 0, & \text{if } \xi \neq 1, \\ \mathbb{C}, & \text{if } \xi = 1. \end{cases} \end{aligned}$$

For $k = 1$ we consider the cokernel instead of the kernel and, lo and behold, we end up with the same result.

Example. We consider the torus



$$X := ([0, 1] \times [0, 1])/\sim \qquad \text{where } (x, 0) \sim (x, 1) \text{ and } (0, y) \sim (1, y).$$

[2086] We know by the Replace Universal Covering Proposition 168.6 that we can determine the isomorphism type of (co-) homology with twisted coefficients using any universal covering, i.e. for the isomorphism type we do not have to work with the natural universal covering. This logic also applies to twisted cellular (co-) homology. We will use this little observation on numerous occasions.

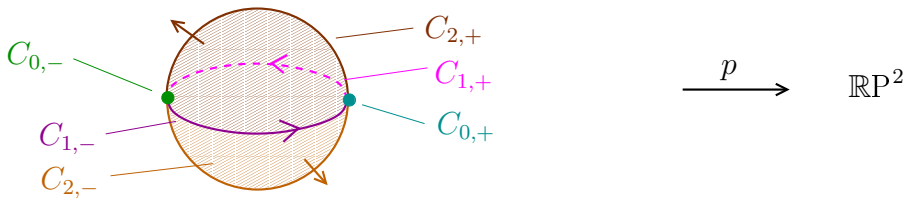
We equip X with the usual CW-structure that we introduced on page 1471 which has one 0-cell c, two 1-cells d_x and d_y and one 2-cell e. We equip each cell with the (fairly) obvious characteristic map. We make the usual identification $\pi_1(X,(0,0)) = \mathbb{Z}\cdot x \oplus \mathbb{Z}\cdot y$. Furthermore, if we make the usual identification $X = S^1 \times S^1$, then we have a universal covering $p\colon \mathbb{R}^2 \to X$. The resulting CW-structure on $\mathbb{R}^2$, and lifts of c, d_x, d_y and e are shown in the figure. Using the Cellular Boundary Map-via-Degrees Proposition 80.8 we can calculate the cellular chain complex of the universal covering and we see that it is of the form[2087]

$$0 \to \mathbb{Z}[x^{\pm1},y^{\pm1}]\cdot\widetilde{e} \xrightarrow{\begin{pmatrix}1-y\\x-1\end{pmatrix}} \begin{matrix}\mathbb{Z}[x^{\pm1},y^{\pm1}]\cdot\widetilde{d}_x\\ \mathbb{Z}[x^{\pm1},y^{\pm1}]\cdot\widetilde{d}_y\end{matrix} \to \xrightarrow{((x-1)\ (y-1))} \mathbb{Z}[x^{\pm1},y^{\pm1}]\cdot\widetilde{c} \to 0.$$

Now one can calculate all the (co-) homology modules of the torus without any problems.

Example. Let $n \in \mathbb{N}_{\geq 2}$. We consider the real projective space $\mathbb{R}\mathrm{P}^n = S^n/P \sim -P$. By Corollary 48.18 there exists an isomorphism $\pi_1(\mathbb{R}\mathrm{P}^n) \cong \langle x \,|\, x^2\rangle$. We denote by $p\colon S^n \to \mathbb{R}\mathrm{P}^n$ the projection . We equip $\mathbb{R}\mathrm{P}^n$ with the CW-structure that we introduced in Lemma 68.1, which has one cell in each of the dimensions $0,\ldots,n$. The corresponding CW-structure on S^n has precisely two cells in each of the dimensions $0,\ldots,n$. In fact the open cells are precisely

$$\begin{aligned} C_{i,+} &:= \{(x_0,\ldots,x_i,0,\ldots,0) \in S^n \,|\, x_i > 0\}\\ \text{and}\quad C_{i,-} &:= \{(x_0,\ldots,x_i,0,\ldots,0) \in S^n \,|\, x_i < 0\}. \end{aligned}$$



With an appropriate choice of characteristic maps we see, using the Cellular Boundary Map-via-Degrees Proposition 80.8, that the cellular chain complex of S^n is isomorphic to the chain complex

$$0 \to \mathbb{Z}[\langle x \,|\, x^2\rangle] \xrightarrow{1+(-1)^{n+1}\cdot x} \ldots \to \mathbb{Z}[\langle x \,|\, x^2\rangle] \xrightarrow{1+x} \mathbb{Z}[\langle x \,|\, x^2\rangle] \xrightarrow{1-x} \mathbb{Z}[\langle x \,|\, x^2\rangle] \to 0.$$

It we take the trivial representation $\rho\colon \pi_1(\mathbb{R}\mathrm{P}^n) = \langle x \,|\, x^2\rangle \to \mathrm{GL}(1,\mathbb{Z})$, i.e. the representation that is given by $\rho(x) = 1$, then we recover exactly the cellular chain complex that we had obtained in the proof of Proposition 80.11, when we calculated the ordinary (cellular) homology groups of $\mathbb{R}\mathrm{P}^n$.

We will now see that twisted cellular (co-) homology is functorial in a suitable sense. First we have the following variation on the definition on page 3542.

[2087] Note that it follows from the subtle sign in the boundary map ∂_2 that this is indeed a chain complex, as it should be.

Definition. Let $f\colon (X,x_0)\to(Y,y_0)$ be a map between pointed connected CW-complexes. We write $\pi_X := \pi_1(X,x_0)$, $\pi_Y := \pi_1(Y,y_0)$. Furthermore let R be a ring and let M be a $(\mathbb{Z}[\pi_Y],R)$-left left module. We denote by $p\colon \widetilde{X}_{x_0}\to X$ and $q\colon \widetilde{Y}_{y_0}\to Y$ the natural universal coverings. Suppose that we are given subsets $A\subset X$ and $B\subset Y$ with $f(A)\subset B$. We write $\widetilde{A} := p^{-1}(A)$ and $\widetilde{B} := q^{-1}(B)$. We denote by $\widetilde{f}\colon \widetilde{X}_{x_0}\to\widetilde{Y}_{y_0}$ the map that is induced by $f\colon X\to Y$. It follows easily from the fact that f is cellular that $\widetilde{f}$ is also cellular. Using the cellular analogue of the Chain Complex-Equivariance Proposition 167.8 we define

$$\begin{array}{rcl} f_*\colon \overbrace{\overline{f^*M}\otimes_{\mathbb{Z}[\pi_X]}\mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}_{x_0},\widehat{A})}^{=\mathrm{C}_k^{\mathrm{tw,CW}}(X,A;f^*M)} & \to & \overbrace{\overline{M}\otimes_{\mathbb{Z}[\pi_Y]}\mathrm{C}_k^{\mathrm{CW}}(\widetilde{Y}_{y_0},\widehat{B})}^{=\mathrm{C}_k^{\mathrm{tw,CW}}(Y,B;M)} \\ m\otimes(\sigma\colon\Delta^k\to\widetilde{X}_{x_0}) & \mapsto & m\otimes(\widetilde{f}\circ\sigma\colon\Delta^k\to\widetilde{Y}_{y_0}) \end{array}$$

and

$$\begin{array}{rcl} f^*\colon \overbrace{\underset{\mathbb{Z}[\pi_Y]\text{-left}}{\mathrm{Hom}}(\mathrm{C}_k^{\mathrm{CW}}(\widetilde{Y}_{y_0},\widehat{B}),M)}^{=\mathrm{C}^k_{\mathrm{tw,CW}}(Y,B;M)} & \to & \overbrace{\underset{\mathbb{Z}[\pi_X]\text{-left}}{\mathrm{Hom}}(\mathrm{C}_k^{\mathrm{CW}}(\widetilde{X}_{x_0},\widehat{A}),f^*M)}^{=\mathrm{C}^k_{\mathrm{tw,CW}}(X,A;f^*M)} \\ \varphi & \mapsto & (\sigma\mapsto\varphi(r\circ\sigma)) \end{array}$$

and we define the corresponding induced maps

$$\begin{array}{rcl} f_*\colon \mathrm{H}_k^{\mathrm{tw,CW}}(X;f^*M) & \to & \mathrm{H}_k^{\mathrm{tw,CW}}(Y;M) \\ f^*\colon \mathrm{H}^k_{\mathrm{tw,CW}}(Y;M) & \to & \mathrm{H}^k_{\mathrm{tw,CW}}(X;f^*M). \end{array}$$

We leave it to the reader to formulate the obvious analogue of the Twisted Homology-Functoriality Proposition 167.9.

170.2. **The interaction between twisted cellular and singular (co-) homology.** In the Singular-Cellular H_*-Isomorphism Proposition 80.4 and the Singular-Cellular H^*-Isomorphism Proposition 109.4 we saw that given a CW-complex X the singular (co-) homology groups and the cellular (co-) homology groups are naturally isomorphic. The following theorem gives us an analogous statement for twisted (co-) homology.

Theorem 170.2. (Singular-Cellular Twisted Isomorphism Theorem) Let X be a connected CW-complex, let $A\subset X$ be a subcomplex, let $x_0\in X$, let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module. Then there exist natural isomorphisms

(1) $\Phi_{(X,A)}\colon \mathrm{H}_k^{\mathrm{tw}}(X,A;M) \to \mathrm{H}_k^{\mathrm{tw,CW}}(X,A;M)$

(2) $\Phi_{(X,A)}\colon \mathrm{H}^k_{\mathrm{tw}}(X,A;M) \to \mathrm{H}^k_{\mathrm{tw,CW}}(X,A;M)$

of R-left modules. Here natural means the following: if $f\colon (X,A)\to(Y,B)$ is a cellular map between pairs of CW-complexes, if X and Y are connected, if $x_0\in X$, if R is a ring,

and if M is a $(\mathbb{Z}[\pi_1(Y, f(x_0))], R)$-left left module, then the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}_k^{\mathrm{tw}}(X, A; f^*M) & \xrightarrow{\Phi_{(X,A)}} & \mathrm{H}_k^{\mathrm{tw,CW}}(X, A; f^*M) \\ \downarrow{\scriptstyle f_*} & & {\scriptstyle f_*}\downarrow \\ \mathrm{H}_k^{\mathrm{tw}}(Y, B; M) & \xrightarrow{\Phi_{(Y,B)}} & \mathrm{H}_k^{\mathrm{tw,CW}}(Y, B; M) \end{array}$$

and the corresponding diagram for twisted cohomology also commutes.

Remark.

(1) The proof we give of the Singular-Cellular Twisted Isomorphism Theorem **??** is based on the proof given in [**Lü1998**, Lemma 4.2] and [**Lü1989**, p. 263], see also [**Wall1966a**, Lemma 1]. An alternative proof is given in [**KwS2018**, Theorem 4.1]. It seems like the naturality statement was not dealt with in great detail in the earlier references.

(2) Let K be an *ordered* abstract simplicial complex. By the Simplicial-Singular Chain Complex Theorem 95.25 the maps

$$\begin{array}{rccl} \Theta_n \colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n(|K|) \\ s & \mapsto & (\Phi_s^{\leq} \colon \Delta^n \to |K|) \end{array}$$

are a natural chain homotopy equivalence. Note that naturality implies that if we work with the universal covering of an ordered simplicial complex, then the above map is a chain homotopy equivalence of free $\mathbb{Z}[\pi_1(K)]$-chain complexes, and thus induces an isomorphism between "twisted simplicial" (co-) homology and twisted singular (co-) homology groups. We leave it to the reader to fill in the details.

Example. Let X be a CW-complex, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. If X has no k-cells, then it follows almost immediately from Theorem 170.2 that $\mathrm{H}_k^{\mathrm{tw}}(X; M) = 0$ and $\mathrm{H}^k_{\mathrm{tw}}(X; M) = 0$.

The proof of the Singular-Cellular Twisted Isomorphism Theorem 170.2 will require the remainder of this section. The idea is to generalize the proof of the Singular-Cellular H_*-Isomorphism Proposition 80.4 that we gave in Section 81.4. The key idea was to introduce a suitable intermediate chain complex $\mathrm{C}_*^{\mathrm{int}}(W)$, which allowed us to relate the singular chain complex $\mathrm{C}_*(W)$ to the cellular chain complex $\mathrm{C}_*^{\mathrm{int}}(W)$. In the following we recall and expand on this concept.

Definition. Let W be a CW-complex.

(1) Given $n \in \mathbb{N}_0$ we define the intermediate cellular chain complex

$$\mathrm{C}_n^{\mathrm{int}}(W) \ := \ \ker\big(\mathrm{C}_n(W^n) \xrightarrow{\partial} \mathrm{C}_{n-1}(W^n) \to \mathrm{C}_{n-1}(W^n, W^{n-1})\big).$$

In Lemma 81.9 we saw that $\mathrm{C}_*^{\mathrm{int}}(W)$ is a subcomplex of $\mathrm{C}_*(W)$ and that $\mathrm{C}_*^{\mathrm{int}}(W)$ is covariantly functorial under cellular maps.

(2) Let B be a subcomplex of W. We denote by $i \colon B \to W$ the inclusion. It follows easily from the definitions that the induced map $i_* \colon \mathrm{C}_n^{\mathrm{int}}(B) \to \mathrm{C}_n^{\mathrm{int}}(W)$ is a monomorphism. We set

$$\mathrm{C}_n^{\mathrm{int}}(W, B) \ := \ \mathrm{coker}\big(i_* \colon \mathrm{C}_n^{\mathrm{int}}(B) \to \mathrm{C}_n^{\mathrm{int}}(W)\big).$$

(3) Given any subcomplex B of W we have natural chain maps

$$\iota\colon \mathrm{C}_*^{\mathrm{int}}(W,B) \hookrightarrow \mathrm{C}_*(W,B) \qquad \text{and} \qquad \pi\colon \mathrm{C}_*^{\mathrm{int}}(W,B) \twoheadrightarrow \mathrm{C}_*^{\mathrm{CW}}(W,B)$$

which are induced by the obvious inclusion and the natural projection.

Proposition 170.3. Let W be a CW-complex and let B be a subcomplex of W. For each $n \in \mathbb{N}_0$ the natural maps

(1) $\quad \iota_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(W,B)) \to \mathrm{H}_n(\mathrm{C}_*(W,B))$

(2) $\quad \pi_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(W,B)) \to \mathrm{H}_n(\mathrm{C}_*^{\mathrm{CW}}(W,B))$

are isomorphisms.

Proof. In the Intermediate Chain Complex Proposition 81.11 we proved both statements in the absolute case, i.e. if $B = \varnothing$. Using generic little tricks, which we know from Exercise 74.11 and the proof of the Two-Out-Of-Three-Homotopy Equivalence Corollary 81.6, we will now deduce the relative case from the absolute case. To deal with Statement (1) let us consider the following diagram:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{C}_*^{\mathrm{int}}(B) & \longrightarrow & \mathrm{C}_*^{\mathrm{int}}(W) & \longrightarrow & \mathrm{C}_*^{\mathrm{int}}(W,B) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \iota_*} & & \downarrow{\scriptstyle \iota_*} & & \downarrow{\scriptstyle \iota_*} & & \\
0 & \longrightarrow & \mathrm{C}_*(B) & \longrightarrow & \mathrm{C}_*(W) & \longrightarrow & \mathrm{C}_*(W,B) & \longrightarrow & 0.
\end{array}$$

It follows easily from the definitions that the diagram commutes and that the horizontal sequences are short exact sequences of chain complexes. Therefore, by the LES Proposition 74.9, we get a commutative diagram of long exact sequences:

$$\begin{array}{ccccccccc}
\ldots & \longrightarrow & \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(B)) & \longrightarrow & \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(W)) & \longrightarrow & \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(W,B)) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\mathrm{C}_*^{\mathrm{int}}(B)) \longrightarrow \ldots \\
 & & \downarrow{\scriptstyle \iota_*} & & \downarrow{\scriptstyle \iota_*} & & \downarrow{\scriptstyle \iota_*} & & \downarrow{\scriptstyle \iota_*} \\
\ldots & \longrightarrow & \mathrm{H}_n(\mathrm{C}_*(B)) & \longrightarrow & \mathrm{H}_n(\mathrm{C}_*(W)) & \longrightarrow & \mathrm{H}_n(\mathrm{C}_*(W,B)) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\mathrm{C}_*(B)) \longrightarrow \ldots.
\end{array}$$

By the Intermediate Chain Complex Proposition 81.11 (1) we know that the two vertical maps relating the absolute cases are isomorphisms. It follows from the Five Lemma 74.10 that the vertical maps dealing with the relative case are also isomorphisms. This concludes the proof of Statement (1).

We turn to the proof of Statement (2). Using basically the same approach as above we can deduce from the Intermediate Chain Complex Proposition 81.11 (2) that the maps $\pi_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(W,B)) \to \mathrm{H}_n(\mathrm{C}_*^{\mathrm{CW}}(W,B))$ are isomorphisms. ■

We recall the following definition from page 2.

Definition. Let R be a ring and let C_* be a chain complex of R-left modules. A free imitation of C_* is a chain complex F_* of R-left modules together with a quasi-isomorphism $\varphi\colon F_* \to C_*$.[2088]

[2088] Recall that a quasi-isomorphism is a chain map that induces isomorphisms on homology groups.

We now turn the actual proof of the Singular-Cellular Twisted Isomorphism Theorem 170.2. We break it up into several steps:

(i) First we construct the isomorphisms $\Phi_{(X,A)}\colon \mathrm{H}_k^{\mathrm{tw}}(X,A;M) \to \mathrm{H}_k^{\mathrm{tw,CW}}(X,A;M)$ in twisted homology.
(ii) Secondly we show that the isomorphisms are natural.
(iii) Thirdly we quickly outline how to modify (i) and (ii) to prove the corresponding statements for twisted cohomology.

Proof of Theorem 170.2 (1) – Construction of Isomorphism. Let X be a connected CW-complex, let $A \subset X$ be a subcomplex, let $x_0 \in X$, let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module. We write $\pi := \pi_1(X,x_0)$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering and we write $\widetilde{A} := p^{-1}(A)$.

We equip $\widetilde{X}$ with the CW-structure given by the CW-complex Covering Proposition 68.37. By Proposition 167.1 we have a natural isomorphism $\pi \cong \mathrm{Deck}(p\colon \widetilde{X} \to X)$. Thus, via Lemma 170.1, we obtain a cellular and free left action by π on $\widetilde{X}$.

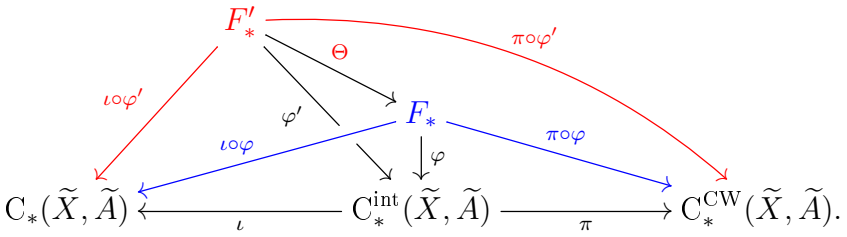
Note that in our present setting the Free Imitation Existence Lemma 166.8 says that there exists a chain complex (F_*,∂_*) of *free* $\mathbb{Z}[\pi]$-left modules together with a quasi-isomorphism $\varphi\colon F_* \to \mathrm{C}_*^{\mathrm{int}}(\widetilde{X},\widetilde{A})$ of $\mathbb{Z}[\pi]$-left modules. Now we consider the following little diagram:

$$\begin{array}{ccccc} & & F_* & & \\ & \swarrow^{\iota\circ\varphi} & \downarrow{\scriptstyle \varphi} & \searrow^{\pi\circ\varphi} & \\ \mathrm{C}_*(\widetilde{X},\widetilde{A}) & \xleftarrow{\ \iota\ } & \mathrm{C}_*^{\mathrm{int}}(\widetilde{X},\widetilde{A}) & \xrightarrow{\ \pi\ } & \mathrm{C}_*^{\mathrm{CW}}(\widetilde{X},\widetilde{A}). \end{array}$$

Note that the action of π on $\widetilde{X}$ turns all three chain complexes at the bottom into chain complexes of $\mathbb{Z}[\pi]$-left modules and the naturality of ι and π implies that these maps commute with the π-action, in other words, the horizontal maps ι and π are homomorphisms of $\mathbb{Z}[\pi]$-left modules. It follows from the above together with Proposition 170.3 that $i\circ\varphi\colon F_* \to \mathrm{C}_*(\widetilde{X},\widetilde{A})$ and $\pi\circ\varphi\colon F_* \to \mathrm{C}_*^{\mathrm{CW}}(\widetilde{X},\widetilde{A})$ are quasi-isomorphisms between chain complexes of free $\mathbb{Z}[\pi]$-left modules. Thus it follows from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 166.6 that $i\circ\varphi$ and $\pi\circ\varphi$ are chain homotopy equivalences.[2089] Next we consider the induced map

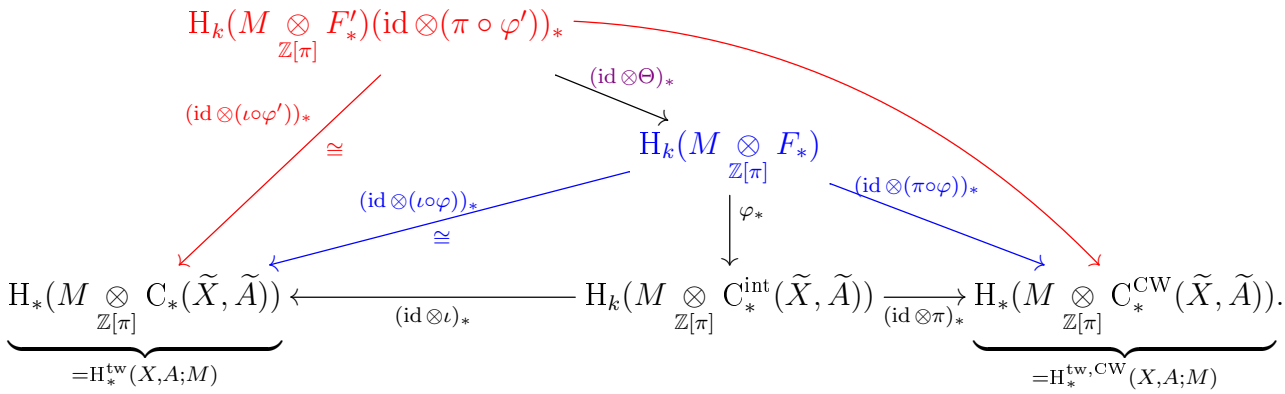
$$\begin{array}{ccccc} & & \mathrm{H}_k(M \otimes_{\mathbb{Z}[\pi]} F_*) & & \\ & \swarrow^{(\mathrm{id}\otimes(\iota\circ\varphi))_*} & \downarrow{\scriptstyle (\mathrm{id}\otimes\varphi)_*} & \searrow^{(\mathrm{id}\otimes(\pi\circ\varphi))_*} & \\ \underbrace{\mathrm{H}_k(M \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*(\widetilde{X},\widetilde{A}))}_{\mathrm{H}_k^{\mathrm{tw}}(X,A;M)} & \xleftarrow{(\mathrm{id}\otimes\iota)_*} & \mathrm{H}_k(M \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*^{\mathrm{int}}(\widetilde{X},\widetilde{A})) & \xrightarrow{(\mathrm{id}\otimes\pi)_*} & \underbrace{\mathrm{H}_k(M \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*^{\mathrm{CW}}(\widetilde{X},\widetilde{A}))}_{\mathrm{H}_k^{\mathrm{tw,CW}}(X,A;M)}. \end{array}$$

[2089] By Proposition 170.3 the chain maps $\iota\colon \mathrm{C}_*^{\mathrm{int}}(\widetilde{X},\widetilde{A}) \to \mathrm{C}_*(\widetilde{X},\widetilde{A})$ and $\pi\colon \mathrm{C}_*^{\mathrm{int}}(\widetilde{X},\widetilde{A}) \to \mathrm{C}_*^{\mathrm{CW}}(\widetilde{X},\widetilde{A})$ are quasi-isomorphisms. But there is no reason to believe that $\mathrm{C}_n^{\mathrm{int}}(\widetilde{X},\widetilde{A})$ is a *free* (or even just projective) $\mathbb{Z}[\pi]$-left module. Thus there is no reason why these chain maps should be chain homotopy equivalences of $\mathbb{Z}[\pi]$-left chain complexes. The case $\pi = \{e\}$ is much easier, since by the Subgroup-of-Free Abelian Group Lemma 51.2 we know that any subgroup of a free abelian group is again free abelian.



Since $\iota \circ \varphi$ and $\pi \circ \varphi$ are both chain homotopy equivalence we obtain from Lemmas 166.3 and 166.2 that the diagonal maps are isomorphisms of R-left modules. Therefore we can now define

$$\Phi_{(X,A)} := (\mathrm{id} \otimes (\pi \circ \varphi))_* \circ (\mathrm{id} \otimes (\iota \circ \varphi))_*^{-1} \colon \mathrm{H}_k^{\mathrm{tw}}(X, A; M) \ \to \ \mathrm{H}_k^{\mathrm{tw,CW}}(X, A; M).$$



As we just discussed, the above diagonal maps are isomorphisms of R-left modules. Thus we see that $\Phi_{(X,A)} \colon \mathrm{H}_k^{\mathrm{tw}}(X, A; M) \to \mathrm{H}_k^{\mathrm{tw,CW}}(X, A; M)$ is indeed an isomorphism of R-left modules. ■

Proof of Theorem 170.2 (1) – Well-definedness. We now want to show that the isomorphism we just constructed does not depend on the choice of the free imitation (F_*, φ_*) of $\mathrm{C}_*^{\mathrm{int}}(\widetilde{X}, \widetilde{A})$.

Thus let (F'_*, φ'_*) be another free imitation of $\mathrm{C}_*^{\mathrm{int}}(\widetilde{X}, \widetilde{A})$. It follows from the Homomorphism Lifting Lemma 166.9 that there exists a chain map $\Theta \colon F_* \to F'_*$ with $\varphi = \Theta \circ \varphi'$. We now consider the following diagram:

Note that the diagram commutes by construction and the choice of Θ. Tensoring with M we obtain the following commutative diagram:

Since the diagram commutes we see that (F_*, φ) and (F'_*, φ') lead to the same definition of the isomorphism $\Phi_{(X,A)} \colon \ = \mathrm{H}_*^{\mathrm{tw}}(X, A; M) \to = \mathrm{H}_*^{\mathrm{tw,CW}}(X, A; M)$. ■

Proof of Theorem 170.2 – Naturality. To unburden the notation from unnecessary baggage we will prove naturality only for absolute twisted homology. The argument for the relative case is basically the same, one just needs to carry a little bit more data around.

Thus let $f \colon X \to Y$ be a cellular map between two connected CW-complexes. Let $x_0 \in X$, let R be a ring, and let M be a $(\mathbb{Z}[\pi_1(Y, f(x_0))], R)$-left left module. We write $\pi_X := \pi_1(X, x_0)$ and $\pi_Y := \pi_1(Y, f(x_0))$. We denote by $p \colon \widetilde{X} \to X$ and $q \colon \widetilde{Y} \to Y$ the natural coverings corresponding to the base points x_0 and $f(x_0)$. Furthermore we denote by

$\widetilde{x}_0 \in \widetilde{X}$ and $\widetilde{y}_0 \in \widetilde{Y}$ the natural base points. We denote by $\widetilde{f}\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0) \to (\widetilde{Y}, \widetilde{y}_0)$ the induced map, as defined on page 3541.

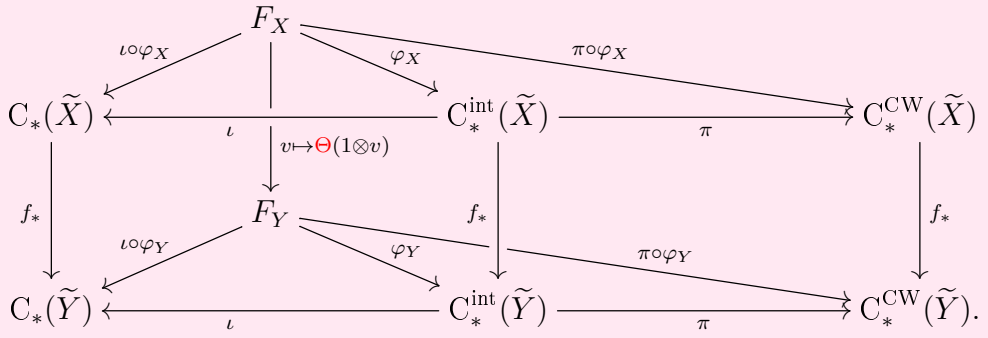
From the Free Imitation Existence Lemma 166.8 we obtain the following:

(1) A chain complex (F_{X*}, ∂_*) of free $\mathbb{Z}[\pi_X]$-left modules together with a quasi-isomorphism $\varphi_X\colon F_{X*} \to \mathrm{C}_*^{\mathrm{int}}(\widetilde{X})$ of $\mathbb{Z}[\pi_X]$-left chain complexes.
(2) A chain complex (F_{Y*}, ∂_*) of free $\mathbb{Z}[\pi_Y]$-left modules together with a quasi-isomorphism $\varphi_Y\colon F_{Y*} \to \mathrm{C}_*^{\mathrm{int}}(\widetilde{Y})$ of $\mathbb{Z}[\pi_Y]$-left chain complexes.

Claim 1. There exists a chain map

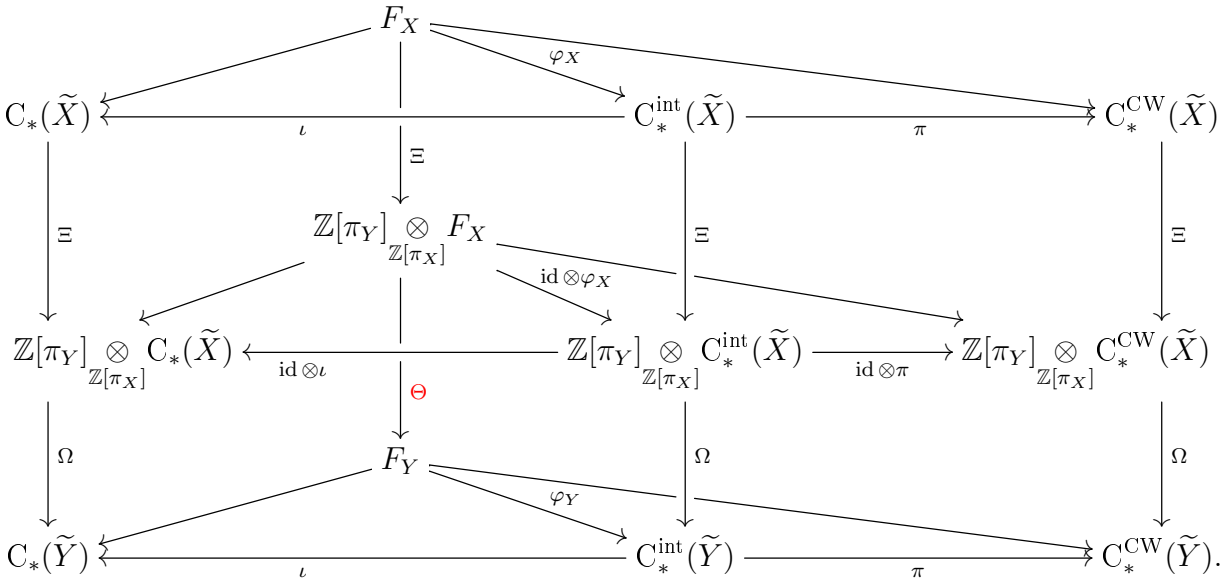
$$\Theta\colon \mathbb{Z}[\pi_Y] \otimes_{\mathbb{Z}[\pi_X]} F_X \;\to\; F_Y$$

of $\mathbb{Z}[\pi_Y]$-left chain complexes such that the following diagram commutes:



$$\begin{array}{ccc} \mathbb{Z}[\pi_Y] \otimes_{\mathbb{Z}[\pi_X]} F_X & \xrightarrow{\mathrm{id}\otimes\varphi_X} & \mathbb{Z}[\pi_Y] \otimes_{\mathbb{Z}[\pi_X]} \mathrm{C}_*^{\mathrm{int}}(\widetilde{X}) \\ \downarrow{\scriptstyle \Theta} & & \downarrow{\scriptstyle g\otimes\sigma\mapsto g\cdot(f_*\sigma)} \\ F_Y & \xrightarrow{\varphi_Y} & \mathrm{C}_*^{\mathrm{int}}(\widetilde{Y}). \end{array}$$

Proof. We make the following three observations:



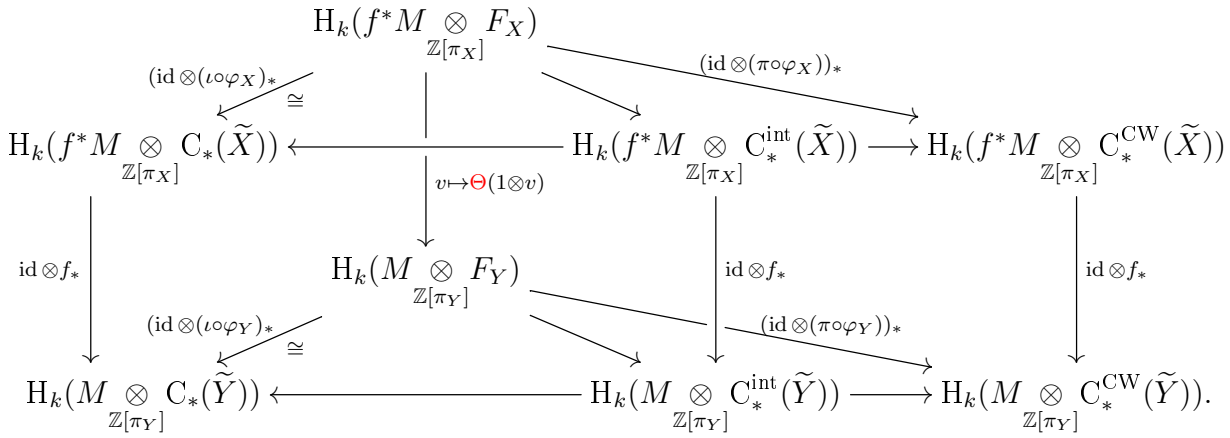
- It follows easily from the Chain Complex-Equivariance Proposition 167.8 that the right vertical map is a chain map of $\mathbb{Z}[\pi_Y]$-left chain complexes.
- By Lemma 165.21 we know that $\mathbb{Z}[\pi_Y] \otimes_{\mathbb{Z}[\pi_X]} F_X$ is a chain complex of *free* $\mathbb{Z}[\pi_Y]$-left modules.
- By construction we know that $\varphi_Y\colon F_{Y*} \to \mathrm{C}_*^{\mathrm{int}}(\widetilde{Y})$ is a quasi-isomorphism.

It follows from these observations together with the Homomorphism Lifting Lemma 166.9 that there exists a chain map $\Theta\colon \mathbb{Z}[\pi_Y] \otimes_{\mathbb{Z}[\pi_X]} F_X \to F_Y$ with the desired properties. ⊞

Claim 2. The following diagram commutes:

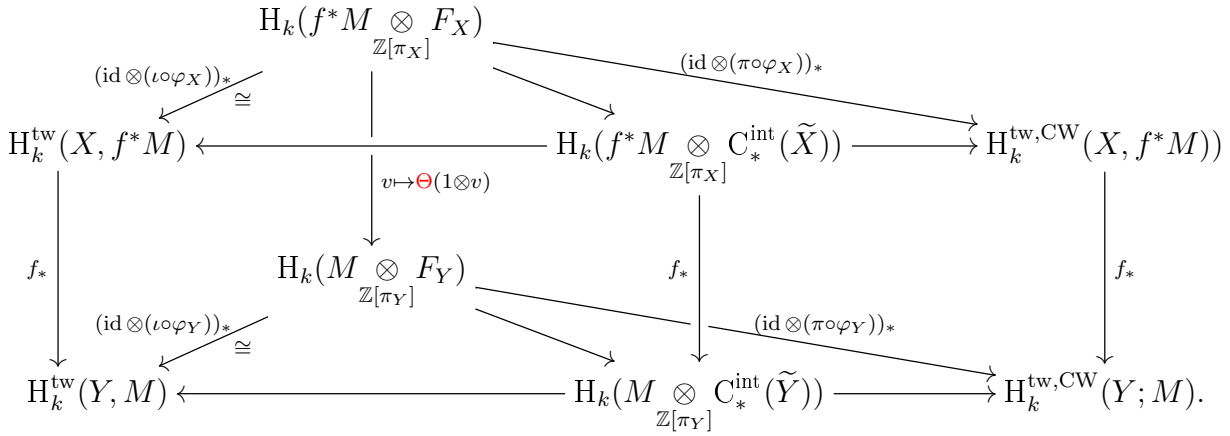
Proof. We consider the following even more excessive diagram:

We make the following clarifications:



- The undecorated diagonal maps are, as before, given by the composition of the corresponding two other maps. For example the top left diagonal map is $\iota \circ \varphi_X$.
- The curved maps $\widetilde{f}_*$ are induced by the cellular map $\widetilde{f} \colon \widetilde{X} \to \widetilde{Y}$.
- The top vertical maps Ξ are the purely algebraic maps given by $\sigma \mapsto 1 \otimes \sigma$.
- The bottom vertical maps Ω are all given by $g \otimes \sigma \mapsto g \cdot f_*(\sigma)$.

Now we want to argue that the diagram commutes:



- The top part of the diagram commutes basically by definition.
- It follows immediately from the definitions that the two bottom rectangles commute.
- The bottom center parallelogram involving Θ commutes by the choice of Θ. The two other bottom parallelograms commute since they are defined in terms of the other maps.

In summary we see that the big diagram commutes. Finally note that the composition $\Omega \circ \Xi$ in each case equals, basically by definition, the map f_*. This final observation implies that the commutativity of the big diagram gives us also the commutativity of the diagram given in the claim. ⊞

Next note that it follows easily from the claim that the following diagram also commutes:

In other words, the following diagram commutes:

By definition of Φ_X and Φ_Y this just means that the following diagram does indeed commute, fulfilling our deepest wishes:

$$\begin{array}{ccc} \mathrm{H}^{\mathrm{tw}}_k(X; f^*M) & \xrightarrow{\Phi_X} & \mathrm{H}^{\mathrm{tw,CW}}_k(X; f^*M) \\ \downarrow{\scriptstyle f_*} & & {\scriptstyle f_*}\downarrow \\ \mathrm{H}^{\mathrm{tw}}_k(Y; M) & \xrightarrow{\Phi_Y} & \mathrm{H}^{\mathrm{tw,CW}}_k(Y; M). \end{array}$$

■

It remains prove the statement of Theorem 170.2 regarding twisted cohomology.

Proof of Theorem 170.2 (2). The proof of the statement regarding twisted cohomology is evidently almost identical to the proof for twisted homology. All one needs to is to replace the Tensoring Chain Complex Lemma 166.3 by the Dualizing Chain Complex Lemma 166.4. We leave it to the reader to fill in the details. ■

170.3. **Twisted (co-) homology of compact CW-complexes and manifolds.** We recall the following definition from page 1519.

Definition. Given a finite CW-complex X we define its Euler characteristic $\chi(X)$ as follows:

$$\chi(X) \;:=\; \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \text{number of } n\text{-cells}.$$

In the Euler Characteristic-H_*-Proposition 87.1 we saw that given a finite CW-complex X we have the following relation between the Euler characteristic X and its homology groups $\mathrm{H}_n(X)$:

$$(*) \qquad \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \operatorname{rank}(\mathrm{H}_n(X)) \;=\; \chi(X).$$

Furthermore on page 1915 we saw that a similar result holds if replace the ordinary homology groups $\mathrm{H}_n(X)$ by homology groups $\mathrm{H}_n(X;\mathbb{F})$ where $\mathbb{F}$ is a field. On page 1882 we used $(*)$ to define the Euler characteristic also for suitable topological spaces that are not CW-complexes.

We can now generalize the above results to twisted homology for suitable coefficients.

Proposition 170.4. Let X be a topological space that is locally contractible and path-connected. Let $x_0 \in X$, let $\mathbb{K}$ be a skew field and let M be a $(\mathbb{Z}[\pi_1(X,x_0)],\mathbb{K})$-left left module with $\dim_{\mathbb{K}}(M) < \infty$. If X is homotopy equivalent to a finite CW-complex, then the following two equalities hold:

$$\begin{aligned}
\sum_{n\in\mathbb{N}_0} (-1)^n \cdot \dim_{\mathbb{K}}(\mathrm{H}^{\mathrm{tw}}_n(X;M)) &= \dim_{\mathbb{K}}(M)\cdot\chi(X)\\
\sum_{n\in\mathbb{N}_0} (-1)^n \cdot \dim_{\mathbb{K}}(\mathrm{H}^{n}_{\mathrm{tw}}(X;M)) &= \dim_{\mathbb{K}}(M)\cdot\chi(X).
\end{aligned}$$

Remark. It follows from the Smooth Manifold-CW Structure Theorem 96.5, or alternatively the Smooth Manifold-CW-Homotopy Type Proposition 139.8, that Proposition 170.4 applies to compact smooth manifolds. In fact by Corollary 104.25 it also applies to compact topological manifolds. But the later statement is perhaps less satisfactory since we did not even come close to proving Corollary 104.25.

Example. Let $X = S^1 \vee \cdots \vee S^1$ be the wedge of k circles, let $x_0 \in X$ and finally let $\varphi\colon \pi_1(X,x_0) \to \mathrm{GL}(1,\mathbb{C})$ be a one-dimensional non-trivial representation. We view X as a CW-complex in the obvious way. Since X has no cells of dimension ≥ 2 we obtain from the discussion on page 3587 that $\mathrm{H}^{\mathrm{tw}}_k(X;{}_\varphi\mathbb{C}) = 0$ for $k \geq 2$. Since φ is a one-dimensional non-trivial representation we obtain easily from the Twisted H_0-Proposition 168.1 that $\mathrm{H}^{\mathrm{tw}}_0(X;{}_\varphi\mathbb{C}) = 0$. Since X has Euler characteristic $1-k$ we now obtain from Proposition 170.4 that $\mathrm{H}^{\mathrm{tw}}_k(X;{}_\varphi\mathbb{C}) \cong \mathbb{C}^{k-1}$.

Proof. In the following we only prove the equality regarding homology with twisted coefficients. The proof for cohomology with twisted coefficients is very similar. We leave it to the reader to make the necessary changes.

First assume that X itself is already a finite k-dimensional CW-complex. In this case the proof of Proposition 170.4 is almost identical to the proof of the Euler Characteristic-H_*-Proposition 87.1. But for fun, let us go through the motions. We start out with the following claim which is a variation on Lemma 87.3.

Claim. Let $\quad C_* \;:=\; 0 \;\to\; \mathrm{C}_k \xrightarrow{\partial_k} \mathrm{C}_{k-1} \xrightarrow{\partial_{k-1}} \ldots\; \mathrm{C}_1 \xrightarrow{\partial_1} \mathrm{C}_0 \;\to\; 0$

be a chain complex of finite dimensional $\mathbb{K}$-left vector spaces. The following equality holds:

$$\sum_{n=0}^{k}(-1)^n \cdot \dim_{\mathbb{K}}(\mathrm{C}_n) \;=\; \sum_{n=0}^{k}(-1)^n \dim_{\mathbb{K}}(\mathrm{H}_n(C_*)).$$

Proof. The proof of the claim is identical to the proof Lemma 87.3, except that we need to replace the Rank Additivity Lemma 51.7 by Proposition 165.26 (6). ⊞

We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. We perform the following calculation:

$$\begin{array}{ccc} & \text{follows from Lemma 170.1 (2), together with Lemma 165.17 (1) and Lemma 165.21} & \\ & \downarrow & \\ \dim_{\mathbb{K}}(M)\cdot\chi(X) = \sum_{n=0}^{k}(-1)^n\cdot\dim_{\mathbb{K}}(M)\cdot\#n\text{-cells} & = & \sum_{n=0}^{k}(-1)^n\cdot\dim_{\mathbb{K}}(\overline{M}\otimes_{\mathbb{Z}[\pi_1(X,x_0)]}\mathrm{C}_n^{\mathrm{CW}}(\widetilde{X}_{x_0})) \\ = \sum_{n=0}^{k}(-1)^n\cdot\dim_{\mathbb{K}}(\mathrm{H}_n^{\mathrm{tw,CW}}(X;M)) & = & \sum_{n=0}^{k}(-1)^n\cdot\dim_{\mathbb{K}}(\mathrm{H}_n^{\mathrm{tw}}(X;M)). \\ \uparrow & & \uparrow \\ \text{by the claim} & & \text{Proposition 170.2} \end{array}$$

Now assume that X is homotopy equivalent to a finite CW-complex Y. We pick $y_0 \in Y$. By Corollary 167.17 there exists a $(\mathbb{Z}[\pi_1(Y,y_0)],\mathbb{K})$-left left module, which as a $\mathbb{K}$-left vector space is isomorphic to M, such that for all $n \in \mathbb{N}_0$ the $\mathbb{K}$-left vector spaces $\mathrm{H}_k^{\mathrm{tw}}(X;M)$ and $\mathrm{H}_k^{\mathrm{tw}}(Y;N)$ are isomorphic. Now we see that

$$\begin{array}{ccccc} & & \text{by the choice of } N & & \\ & & \downarrow & & \\ \sum_{n\in\mathbb{N}_0}(-1)^n\cdot\dim_{\mathbb{K}}(\mathrm{H}_n^{\mathrm{tw}}(X;M)) & = & \sum_{n\in\mathbb{N}_0}(-1)^n\cdot\dim_{\mathbb{K}}(\mathrm{H}_n^{\mathrm{tw}}(Y;N)) & & \\ & = & \dim_{\mathbb{K}}(N)\cdot\chi(Y) & = \dim_{\mathbb{K}}(N)\cdot\chi(X) & = \dim_{\mathbb{K}}(M)\cdot\chi(X). \\ & & \uparrow & \uparrow & \uparrow \\ & & \text{by the above since } Y & \text{by Corollary 73.9} & \text{since } M \text{ and } N \text{ are isomorphic} \\ & & \text{is a finite CW-complex} & & \mathbb{K}\text{-left vector spaces} \end{array}$$ ■

Next recall that in Propositions 96.6 and 104.14 we showed that the ordinary homology groups of compact smooth and topological manifolds are finitely generated. In the remainder of this section we will generalize these results to (co-) homology with twisted coefficients. To control the "size" of (co-) homology of topological spaces we need control over the rings involved and we need some control over the topological spaces involved. Let us start out with a definition from the realm of algebra (see [**Lang2002b**, p. 186] or [**Lam1991**, p. 20]).

Definition. Let R be a ring. If every R-left submodule of R is finitely generated, then we call R left Noetherian. If R is commutative, then we also say Noetherian instead of left Noetherian.

The following proposition shows that many rings that are close to our heart are (left) Noetherian.

Proposition 170.5.

(1) Every principal ideal domain, in particular the ring $\mathbb{Z}$, is Noetherian.
(2) Every (skew) field is left Noetherian.
(3) Let A be a commutative Noetherian ring
  (a) If $S \subset M$ is a multiplicatively closed subset, then the ring $S^{-1}A$ is Noetherian.
  (b) Every multivariable polynomial ring $A[t_1,\ldots,t_m]$ is Noetherian.
  (c) Every multivariable Laurent polynomial ring $A[t_1^{\pm 1},\ldots,t_k^{\pm 1}]$ is Noetherian.

Proof.

(1) This statement is proved in [**Lang2002b**, Corollary III.7.2].
(2) This statement can be deduced easily from Proposition 165.26.
(3) (a) This statement is [**Lang2002b**, Proposition X.1.6].
(b) If A is Noetherian, then it follow from [**Lang2002b**, Theorem IV.4.1] that $A[t]$ is Noetherian ring. Applying this principle m times we see that $A[t_1, \ldots, t_m]$ is Noetherian.
(c) This statement follows from (a) and (b), since we obtain the multivariable Laurent polynomial ring $A[t_1^{\pm 1}, \ldots, t_k^{\pm 1}]$ by inverting the multiplicatively closed subset that is given all monomials in $t_1, \ldots, t_k$. ■

The following proposition states the key property of left Noetherian rings that we are interested in.

Proposition 170.6. Let R be a left Noetherian ring. If P is a finitely generated R-left module, then every R-left submodule is also finitely generated.

Proof. This proposition is proved in [**Lam1991**, Proposition 1.21]. The commutative case is also proved in [**Lang2002b**, Proposition X.1.1]. ■

The following proposition explains why we are suddenly interested in left Noetherian rings.

Proposition 170.7. Let X be a *compact* path-connected space, let $x_0 \in X$, let R be a left Noetherian ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. We suppose that one of the following topological conditions is satisfied:

(T1) X is a CW-complex.
(T2) X is a smooth manifold.
(T3) X is a topological manifold.

Then for any $k \in \mathbb{N}_0$ the twisted (co-) homology modules $\mathrm{H}_k(X; M)$ and $\mathrm{H}^k_{\mathrm{tw}}(X; M)$ are finitely generated R-left modules.

Proof. We write $\pi := \pi_1(X, x_0)$ and we write $\widetilde{X} := \widetilde{X}_{x_0}$.

(T1) First we consider the case that X is a CW-complex. We see that

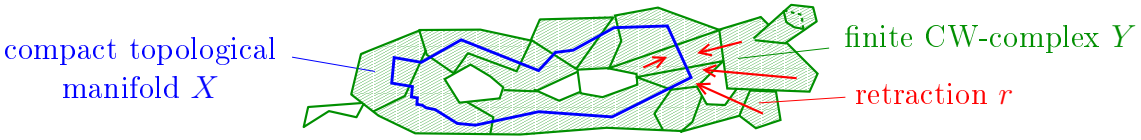
$$\mathrm{H}^{\mathrm{tw}}_k(X; M) \underset{\text{follows from Theorem 170.2}}{\underset{\uparrow}{=}} \mathrm{H}^{\mathrm{tw,CW}}_k(X; M) = \mathrm{H}_k(\overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}^{\mathrm{CW}}_*(\widetilde{X}))$$

By Lemma 170.1 (1) we know that each $\mathrm{C}^{\mathrm{CW}}_k(\widetilde{X})$ is a free $\mathbb{Z}[\pi]$-left module. Since X is assumed to be compact we obtain in fact from Lemma 170.1 (3) that each $\mathrm{C}^{\mathrm{CW}}_k(\widetilde{X})$ is a finitely generated free $\mathbb{Z}[\pi]$-left module. Since M is a finitely generated R-left module we see that each $\overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}^{\mathrm{CW}}_*(\widetilde{X})$ is a finitely generated R-left module.[2090] It now follows from Proposition 170.6 that each

$$\ker\left(\mathrm{id} \otimes \partial_k \colon \overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}^{\mathrm{CW}}_k(\widetilde{X}) \to \overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}^{\mathrm{CW}}_{k-1}(\widetilde{X})\right)$$

is also a finitely generated R-left module. Thus we see that $\mathrm{H}^{\mathrm{tw}}_k(X; M)$ is a quotient of finitely generated R-left module, which implies of course that $\mathrm{H}^{\mathrm{tw}}_k(X; M)$ is also

[2090] Indeed, if M is generated by $a_1, \ldots, a_r$ and if $\mathrm{C}^{\mathrm{CW}}_k(\widetilde{X})$ is generated by $b_1, \ldots, b_s$, then one can easily verify that the R-left module $\overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}^{\mathrm{CW}}_*(\widetilde{X})$ is generated by $a_i \otimes b_j$.



a finitely generated R-left module. A very similar argument also proves the corresponding statement for the twisted cohomology modules $\mathrm{H}^k_{\mathrm{tw}}(X;M)$. We leave it to the reader to make the necessary changes.

(T2) If X is a smooth manifold, then we know by the Smooth Manifold-CW Structure Theorem 96.5 that X admits a CW-structure and we are done by (T1).

(T3) Finally we suppose that X is a compact topological manifold. By the Topological Manifold-Simplicial Complex Retract Theorem 104.13 we know that X is a retract of a finite CW-complex. More precisely, there exists a finite CW-complex Y that contains X together with a retraction $r\colon Y \to X$. We now see that

$$\mathrm{H}^{\mathrm{tw}}_k(X;M) \underset{\text{since } r\circ i = \mathrm{id}_X}{\overset{\uparrow}{=}} (r\circ i)_*(\mathrm{H}^{\mathrm{tw}}_k(X;(r\circ i)_*M)) \underset{\text{by functoriality, see the Twisted Homology-Functoriality Proposition 167.9}}{\overset{\uparrow}{\subset}} r_*(\mathrm{H}^{\mathrm{tw}}_k(Y;r_*M)).$$

Thus we see that $\mathrm{H}^{\mathrm{tw}}_k(X;M)$ is isomorphic to a quotient of the finitely generated R-left module $\mathrm{H}^{\mathrm{tw}}_k(Y;r_*M)$. This implies that $\mathrm{H}^{\mathrm{tw}}_k(X;M)$ itself is a finitely generated R-left module.[2091] ■

Exercises for Chapter 170.

Exercise 170.1. Let X be a path-connected finite CW-complex and let $x_0 \in X$. We consider the product topological space $X \times S^1$. We denote by $p\colon X \times S^1 \to S^1$ the projection. Furthermore let $\Phi\colon \pi_1(S^1,1) \to \mathbb{Z}$ be the isomorphism given by Proposition 48.17. Given $z \in S^1$ we consider the representation

$$\rho_z\colon \pi_1(X \times S^1,(x_0,1)) \xrightarrow{p_*} \pi_1(S^1,1) \xrightarrow{\Phi} \mathbb{Z} \xrightarrow{n\mapsto z^n} \mathrm{GL}(1,\mathbb{C}).$$

Show that if $z \neq 1$, then for all $k \in \mathbb{N}_0$ we have $\mathrm{H}^{\mathrm{tw}}_k(X \times S^1;{}_{\rho_z}\mathbb{C}) = 0$.
Hint. Consider the product CW-structure on $X \times S^1$ as defined on page 1498.

Exercise 170.2. Let X be a path-connected finite CW-complex and let $x_0 \in X$ be a point in the 0-skeleton. We consider the wedge product topological space $X \vee S^1$ that is given by identifying $x_0 \in X$ with $(1,0) \in S^1$. We denote by $p\colon X \vee S^1 \to S^1$ the natural map. Furthermore let $\Phi\colon \pi_1(S^1,1) \to \mathbb{Z}$ be the isomorphism given by Proposition 48.17. Given $z \in S^1$ we consider the representation

$$\rho_z\colon \pi_1(X \vee S^1,(x_0,1)) \xrightarrow{p_*} \pi_1(S^1,1) \xrightarrow{\Phi} \mathbb{Z} \xrightarrow{n\mapsto z^n} \mathrm{GL}(1,\mathbb{C}).$$

Determine the twisted homology groups $\mathrm{H}^{\mathrm{tw}}_k(X \vee S^1;{}_{\rho_z}\mathbb{C})$ in terms of k, z and the usual homology groups of X.

[2091] In Corollary 104.25 we mentioned that every compact topological manifold is homotopy equivalent to a finite CW-complex. This would also have allowed us to prove the desired statement. But we try to avoid using Corollary 104.25 as much as possible, since we did not provide a proof .

Hint. Using the CW-Complex Construction Lemma 68.32 you can equip $X \vee S^1$ with a CW-structure.

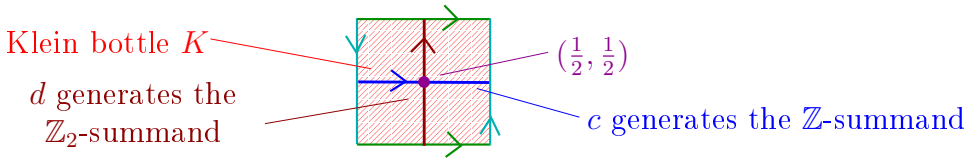
Exercise 170.3. Let $g \in \mathbb{N}$ and let Σ_g the surface of genus g. We pick $x_0 \in \Sigma_g$. Let $\alpha\colon \pi_1(\Sigma_g, x_0) \to \mathrm{GL}(1,\mathbb{C})$ be a non-trivial one-dimensional representation. Determine the twisted homology groups $\mathrm{H}_k^{\mathrm{tw}}(\Sigma_g; {}_\alpha\mathbb{C})$.
Remark. The way the exercise is formulated already indicates, that the answer does not depend on the precise choice of the non-trivial one-dimensional representation.

Exercise 170.4. Wedge of two circles.

Exercise 170.5. Let

$$K \;=\; ([0,1]\times[0,1])/\sim \qquad \text{where } (x,0)\sim(x,1) \text{ and } (0,y)\sim(1,1-y)$$

be the Klein bottle as defined on page 265. We consider the two singular 1-cycles



$$\begin{array}{rcl} c\colon \Delta^1 & \to & K \\ (t,1-t) & \mapsto & [(\frac{1}{2},t)] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} d\colon \Delta^1 & \to & K \\ (t,1-t) & \mapsto & [(\frac{1}{2},t)] \end{array}$$

In Lemma 78.12 we saw that $\mathrm{H}_1(K) = \mathbb{Z}\cdot[c] \oplus \mathbb{Z}_2\cdot[d]$. Let

$$\alpha\colon \pi_1(K;[(\tfrac{1}{2},\tfrac{1}{2})]) \;\underset{\uparrow}{\to}\; \mathrm{H}_1(K) \;\to\; \mathrm{GL}(1,\mathbb{C})$$

Hurewicz homomorphism as defined on page 1832

be a 1-dimensional representation. Compute the twisted homology groups $\mathrm{H}_i^{\mathrm{tw}}(K; {}_\alpha\mathbb{C})$ in terms of $\alpha([c])$ and $\alpha([d])$.

Exercise 170.6. Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let $\varphi\colon \pi_1(X,x_0) \to \langle t\rangle$ be an epimorphism.

(a) Show that for each commutative ring S there exists a long exact sequence of the form

$$\ldots \to \mathrm{H}_{k+1}(X;S) \to \mathrm{H}_k^{\mathrm{tw}}(X;S[t^{\pm1}]) \xrightarrow{(t-1)\cdot} \mathrm{H}_k^{\mathrm{tw}}(X;S[t^{\pm1}]) \to \mathrm{H}_k(X;S) \to \ldots$$

(b) Suppose that X is finite CW-complex and with $\mathrm{H}_*(X;\mathbb{Q}) \cong \mathrm{H}_*(S^1;\mathbb{Q})$. Show that each $\mathbb{Q}[t^{\pm1}]$-module $\mathrm{H}_k^{\mathrm{tw}}(X;\mathbb{Q}[t^{\pm1}])$ is a torsion $\mathbb{Q}[t^{\pm1}]$-module.

Exercise 170.7. Let R be a left Noetherian ring.

(a) Show that if $0 \to A \to B \to C \to 0$ is a short exact sequence of R-left modules and if two are finitely generated, then so is the third.

(b) Let X be a compact path-connected topological manifold and let A be a union of boundary components. Furthermore let $x_0 \in X$ and let M be a $(\mathbb{Z}[\pi_1(X,x_0)], R)$-left left module that is finitely generated as an R-left module. Show that the twisted R-left modules $\mathrm{H}_k^{\mathrm{tw}}(X,A;M)$ are finitely generated.

Exercise 170.8. We consider the topological space $X = S^1$ with the base point $1 \in S^1$. Let R be a ring.

(a) Show that for any $(\mathbb{Z}[\pi_1(S^1, 1)], R)$-left left module and any $i \in \{0, 1\}$ we have an isomorphism

$$\mathrm{H}^i_{\mathrm{tw}}(S^1; M) \ \to \ \mathrm{H}^{\mathrm{tw}}_{1-i}(S^1; M)$$

of R-left modules.

Remark. This slightly mystifying result foreshadows the Poincaré Duality Theorem 172.1 with Twisted Coefficients.

(b) Show that in general $\mathrm{H}^1_{\mathrm{tw}}(S^1; M)$ and $\mathrm{H}^{\mathrm{tw}}_1(S^1; M)$ are not isomorphic.

171. The cup and cap-product on twisted (co-) homology

In this section we will introduce cup- and cap-products on twisted (co-) homology. Recall that, in its simplest form the cup- and cap-product for a topological space X together with a commutative ring R were defined as maps

$$\mathrm{H}^k(X;R) \times \mathrm{H}^l(X;R) \ \to \ \mathrm{H}^{k+l}(X;R) \qquad \text{and} \qquad \mathrm{H}^k(X;R) \times \mathrm{H}_l(X;R) \ \to \ \mathrm{H}_{l-k}(X;R).$$

If we start out with (co-) homology with twisted coefficients it is a priori not entirely clear what coefficients the target should have. To answer this questions we first need to introduce a little more algebra which we will do in our first section.

171.1. Algebraic preparations.

Lemma 171.1. Let R and S be rings. The abelian group $R \otimes_{\mathbb{Z}} S$ together with the multiplication that is defined by

$$\Big(\sum_{i=1}^{k} r_i \otimes s_i\Big) \cdot \Big(\sum_{j=1}^{l} \widetilde{r}_j \otimes \widetilde{s}_j\Big) \ := \ \sum_{i=1}^{k}\sum_{j=1}^{l} r_i \cdot \widetilde{r}_j \otimes s_i \cdot \widetilde{s}_j$$

is a ring. If R and S are commutative, then so $R \otimes_{\mathbb{Z}} S$.

Convention. Let R and S be rings. We will always use Lemma 171.1 to view $R \otimes_{\mathbb{Z}} S$ as a ring.

Proof. One can easily verify that the multiplication on $R \otimes_{\mathbb{Z}} S$ is actually well-defined and that it satisfies all the properties of a ring, as laid out in the definition on page 98. For example a multiplicatively neutral element is given by $1_R \otimes 1_S$. Furthermore it is clear that if R and S are commutative, then so is $R \otimes_{\mathbb{Z}} S$. We leave it to the reader to fill in the details. ■

Lemma 171.2. Let R and S be rings and let G be a group.

(1) If M is an R-left module and N is an S-left module, then

$$\Big(\sum_{i=1}^{k} r_i \otimes s_i\Big) \cdot \Big(\sum_{j=1}^{l} m_j \otimes n_j\Big) \ := \ \sum_{i=1}^{k}\sum_{j=1}^{l} r_i \cdot m_j \otimes s_i \cdot n_j$$

defines an $R \otimes_{\mathbb{Z}} S$-left module structure on $M \otimes_{\mathbb{Z}} N$.

(2) If M is a $\mathbb{Z}[G]$-left module and N is a $\mathbb{Z}[G]$-left module, then

$$g \cdot (m \otimes n) \ := \ g \cdot m \otimes g \cdot n$$

defines a $\mathbb{Z}[G]$-left module structure on $M \otimes_{\mathbb{Z}} N$.

(3) If M is a $(\mathbb{Z}[G], R)$-left module and N is a $(\mathbb{Z}[G], S)$-left module, then the module structures given in (1) and (2) define a $(\mathbb{Z}[G], R \otimes_{\mathbb{Z}} S)$-left module structure on $M \otimes_{\mathbb{Z}} N$.

Proof. We leave the elementary proof to the reader. ■

Convention. Let R and S be rings, let G be a group, let M be a $(\mathbb{Z}[G], R)$-left module and let N be a $(\mathbb{Z}[G], S)$-left module. We will always equip $M \otimes_{\mathbb{Z}} N$ with the $(\mathbb{Z}[G], R \otimes_{\mathbb{Z}} S)$-left module structure that we defined in Lemma 171.2.

171.2. **The cup product on twisted cohomology.** First we recall the following definition from page 2503.

Notation. For $i = 0, \dots, n$ we write

$$v_i \ := \ (0, \dots, 1, 0, \dots, 0) \ \in \ \mathbb{R}^{n+1}.$$

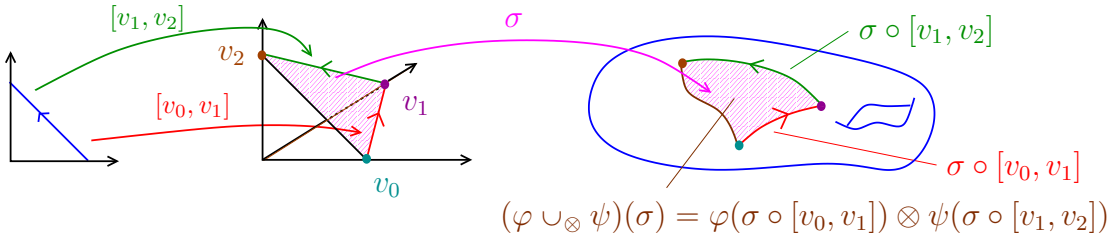
Furthermore for $a_0, \dots, a_k \in \Delta^n$ we consider the map

$$\begin{aligned} [a_0, \dots, a_k] \colon \Delta^k \ &\to \ \Delta^n \\ \sum_{j=0}^{k} \lambda_j \cdot v_j \ &\mapsto \ \sum_{j=0}^{k} \lambda_j \cdot a_j. \end{aligned}$$

We now adapt the definition of the cup product on singular cohomology, which we gave on pages 2513 and 3147, to the twisted setting.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p \colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Furthermore let M and N be $\mathbb{Z}[\pi_1(X, x_0)]$-left modules and let $p, q \in \mathbb{N}_0$. Finally let $\varphi \in \mathrm{C}^p_{\mathrm{tw}}(X; M)$ and $\psi \in \mathrm{C}^q_{\mathrm{tw}}(X; N)$ be cochains. We define the cup product of φ and ψ to be the map

$$\begin{aligned} \varphi \cup_{\otimes} \psi \colon \mathrm{C}_{p+q}(\widetilde{X}_{x_0}) \ &\to \ M \otimes_{\mathbb{Z}} N \\ (\sigma \colon \Delta^{p+q} \to \widetilde{X}_{x_0}) \ &\mapsto \ \underbrace{\varphi(\sigma \circ [v_0, \dots, v_p])}_{\in M} \otimes \underbrace{\psi(\sigma \circ [v_p, \dots, v_{p+q}])}_{\in N}. \end{aligned}$$



that is given by

This map is evidently a $\mathbb{Z}[\pi_1(X, x_0)]$-left module homomorphism, thus $\varphi \cup_{\otimes} \psi$ is an element in $\mathrm{C}^{p+q}_{\mathrm{tw}}(X; M \otimes_{\mathbb{Z}} N)$. In other words, the cup product defines a map

$$\cup_{\otimes} \colon \mathrm{C}^p_{\mathrm{tw}}(X; M) \times \mathrm{C}^q_{\mathrm{tw}}(X; N) \ \to \ \mathrm{C}^{p+q}_{\mathrm{tw}}(X; M \otimes_{\mathbb{Z}} N).$$

In Lemma 171.3 we will show that this map descends to a well-defined map

$$\cup_{\otimes} \colon \mathrm{H}^p_{\mathrm{tw}}(X; M) \times \mathrm{H}^q_{\mathrm{tw}}(X; N) \ \to \ \mathrm{H}^{p+q}_{\mathrm{tw}}(X; M \otimes_{\mathbb{Z}} N).$$

Lemma 171.3. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Furthermore let M and N be $\mathbb{Z}[\pi_1(X, x_0)]$-left modules and let $p, q \in \mathbb{N}_0$.

(1) Given any cochains $\varphi \in \mathrm{C}^p_{\mathrm{tw}}(X; M)$ and $\psi \in \mathrm{C}^q_{\mathrm{tw}}(X; N)$ we have the equality

$$\delta(\varphi \cup_{\otimes} \psi) \ = \ \delta\varphi \cup_{\otimes} \psi \ + (-1)^p \cdot \varphi \cup_{\otimes} \delta\psi \ \in \ \mathrm{C}^{p+q+1}(X; M \otimes_{\mathbb{Z}} N).$$

(2) The cup product $\cup_{\otimes}$ on cochains descends to a well-defined map on cohomology with twisted coefficients.

Proof.

(1) The proof of this statement is basically the same as the proof of Coboundary-Cup Product Lemma 114.2. Throughout that long and unpleasant calculation we just need to replace multiplication "$\cdot$" in R by the tensor product $\otimes$.

(2) This statement follows, as we saw already in the corresponding Lemma 114.3, easily from Statement (1). ■

We now turn to the definition of the relative cup product with twisted coefficients, which will generalize the relative cup product on ordinary singular cohomology that we introduced in Chapter 115. As the reader surely remembers, even that definition already took some effort. In the following we will go through the key steps again and make appropriate modifications where necessary.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Let (X, A, B) be a triad of topological spaces. We write $\widetilde{A} := p^{-1}(A)$ and $\widetilde{B} := p^{-1}(B)$. As on page 3571 we write

$$\mathrm{C}_n^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B}) := \left\{ \sum_{j=1}^{k} n_j \cdot \sigma_j \in \mathrm{C}_n(\widetilde{A} \cup \widetilde{B}) \,\middle|\, \begin{array}{c} \text{for each } j \text{ the image of } \sigma_j \\ \text{lies in } \widetilde{A} \text{ or it lies in } \widetilde{B} \end{array} \right\}$$

Given a ring R and given a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module M we set

$$\mathrm{C}^n_{\mathrm{tw}}(X, \{A, B\}; M) := \ker\Big(\mathrm{C}^n_{\mathrm{tw}}(X; M) \underset{\uparrow}{\to} \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}\big(\mathrm{C}_n^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B}), M\big)\Big).$$

we restrict a homomorphism $\mathrm{C}_n(\widetilde{X}_{x_0}) \to M$ to the submodule $\mathrm{C}_n^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A} \cup \widetilde{B})$

This is again a cochain complex of R-left modules and we denote the corresponding cohomology groups by $\mathrm{H}^*_{\mathrm{tw}}(X, \{A, B\}; M)$.

Before we continue we also need to introduce the following convention which is a slight variation on a convention that we had introduced on page 2534.

Convention. Let R be a ring. Given an R-left module C, an R-left submodule D and an R-left module M we have a natural isomorphism

$$\begin{array}{rcl} \mathrm{Hom}_{R\text{-left}}(C/D, M) & \xrightarrow{\cong} & \{f\colon C \to G \,|\, f \text{ vanishes on } D\} \\ (\varphi\colon C/D \to G) & \mapsto & (C \to C/D \xrightarrow{\varphi} G). \end{array}$$

We will use this isomorphism to identify the groups left and right.

Lemma 171.4. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a ring and let W be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Furthermore let $A, B \subset X$ such that (X, A, B) is a universally excisive triad of topological spaces. By the above convention we have R-left module homomorphisms

$$\mathrm{C}^*_{\mathrm{tw}}(X, A \cup B; W) \to \mathrm{C}^*_{\mathrm{tw}}(X, \{A, B\}; W).$$

These maps induce for every $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}^n_{\mathrm{tw}}(X, A \cup B; W) \xrightarrow{\cong} \mathrm{H}^n_{\mathrm{tw}}(X, \{A, B\}; W).$$

Proof. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. We write $\widetilde{A} := p^{-1}(A)$ and $\widetilde{B} := p^{-1}(B)$. We have the following commutative diagram of short exact sequences of

chain complexes

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A}\cup\widetilde{B}) & \longrightarrow & \mathrm{C}_*(\widetilde{X}_{x_0}) & \longrightarrow & \dfrac{\mathrm{C}_*(\widetilde{X}_{x_0})}{\mathrm{C}_*^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A}\cup\widetilde{B})} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow{\scriptstyle =\mathrm{id}} & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{C}_*(\widetilde{A}\cup\widetilde{B}) & \longrightarrow & \mathrm{C}_*(\widetilde{X}_{x_0}) & \longrightarrow & \mathrm{C}_*(\widetilde{X}_{x_0},\widetilde{A}\cup\widetilde{B}) & \longrightarrow & 0 \end{array}$$

of $\mathbb{Z}[\pi_1(X,x_0)]$-left modules. It follows immediately from the Regular Covering-Chain Complex Lemma 167.2 that all but possibly the top right module are free $\mathbb{Z}[\pi_1(X,x_0)]$-left modules. But the argument of the Regular Covering-Chain Complex Lemma 167.2 shows that the top right module is also free $\mathbb{Z}[\pi_1(X,x_0)]$-left module, for example a basis is given by taking for each singular simplex in X, that is neither contained in A nor in B, a lift to $\widetilde{X}_{x_0}$. Next note that by our hypothesis the triad (X,A,B) is universally excisive. By definition this means that the left vertical map is a chain homotopy equivalence. The middle vertical map is the identity. It now follows from Corollary 166.7 that the right vertical map is also a chain homotopy equivalence of free $\mathbb{Z}[\pi_1(X,x_0)]$-left modules.

Note that by the above convention we have an identification

$$\mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}\left(\frac{\mathrm{C}_n(\widetilde{X}_{x_0})}{\mathrm{C}_n^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A}\cup\widetilde{B})},W\right) \;=\; \mathrm{C}^n_{\mathrm{tw}}(X,\{A,B\};W).$$

The lemma follows from the above vertical chain homotopy equivalence, the above observation and the Dual Cochain Map Lemma 108.8. ■

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let M and N be $\mathbb{Z}[\pi_1(X,x_0)]$-left modules. If (X,A,B) is a universally excisive triad of topological spaces, then we refer to the composition

$$\mathrm{H}^p_{\mathrm{tw}}(X,A;M)\times\mathrm{H}^q_{\mathrm{tw}}(X,B;N) \;\underset{\uparrow}{\to}\; \mathrm{H}^{p+q}_{\mathrm{tw}}(X,\{A,B\};M\underset{\mathbb{Z}}{\otimes}N) \;\underset{\uparrow}{\overset{\cong}{\leftarrow}}\; \mathrm{H}^{p+q}_{\mathrm{tw}}(X,A\cup B;M\underset{\mathbb{Z}}{\otimes}N)$$

as in Lemma 115.2 we see that the usual formula for $\cup_\otimes$ defines such a map

isomorphism by Lemma 171.4

again as a cup product (or sometimes as a relative cup product) and we denote it as usual by the "$\cup_\otimes$"-symbol.

We continue with a frequently used variation on the cup product.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We write $\pi := \pi_1(X,x_0)$. Furthermore let R be a ring with (possibly trivial) involution and let $\varphi\colon \mathbb{Z}[\pi]\to R$ be a homomorphism of rings with involution.[2092] Recall that according to the definition on page 3507 we denote by ${}_\varphi R$ the $\mathbb{Z}[\pi]$-left module, where $g\in\pi$ acts on $r\in R$ via $g\cdot r := r\cdot_R \varphi(g^{-1})$. We define the multiplication map

$$\begin{array}{rccc} \mu\colon & {}_\varphi R\underset{\mathbb{Z}}{\otimes}{}_\varphi R & \to & {}_{\mathrm{tr}}R \\ & r\otimes s & \mapsto & r\cdot\overline{s}. \end{array}$$

Note that this is a homomorphism of $\mathbb{Z}[\pi]$-left modules. If (X, A, B) is a universally excisive triad of topological spaces, then we define[2093]

$$\begin{aligned} \cup_R \colon \mathrm{H}^k_{\mathrm{tw}}(X, A; {}_{\varphi}R) \times \mathrm{H}^l_{\mathrm{tw}}(X, B; {}_{\varphi}R) &\to \mathrm{H}^{k+l}_{\mathrm{tw}}(X, A \cup B; {}_{\mathrm{tr}}R) \\ (\alpha, \beta) &\mapsto \mu_*\big(\underbrace{\alpha \cup_{\otimes} \beta}_{\in \mathrm{H}^{k+l}_{\mathrm{tw}}(X, A\cup B; {}_{\varphi}R \otimes_{\mathbb{Z}} {}_{\varphi}R)} \big). \end{aligned}$$

Lemma 171.5. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R and S be rings, let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module and let N be a $(\mathbb{Z}[\pi_1(X, x_0)], S)$-left left module. Furthermore let (X, A, B) be a universally excisive triad of topological spaces. The relative cup product

$$\cup_{\otimes} \colon \mathrm{H}^p_{\mathrm{tw}}(X, A; M) \otimes_{\mathbb{Z}} \mathrm{H}^q_{\mathrm{tw}}(X, B; N) \to \mathrm{H}^{p+q}_{\mathrm{tw}}(X, A \cup B; M \otimes_{\mathbb{Z}} N)$$

is a homomorphism of $R \otimes_{\mathbb{Z}} S$-left modules.[2094]

Proof. This lemma follows immediately from the definitions. ■

The following lemma shows that we recover our classical cup product in all relevant cases from the twisted cup product.

Lemma 171.6. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$ and let (X, A, B) be a universally excisive triad of topological spaces. Let R be a commutative ring. We consider the trivial $\mathbb{Z}[\pi_1(X, x_0)]$-left module ${}_{\mathrm{tr}}R$. In other words we consider the homomorphism $\mathbb{Z}[\pi_1(X, x_0)] \to R$ that is given by $g \mapsto 1_R$. If we equip $\mathbb{Z}[\pi_1(X, x_0)]$ with the usual involution and if we equip R with the trivial involution, then this is a homomorphism between rings with involution, thus the cup product $\cup_R$ is defined. The following diagram, where the vertical maps are the natural isomorphisms T from Lemma 167.3, commutes:[2095]

$$\begin{array}{ccccc} \mathrm{H}^k(X, A; R) & \times & \mathrm{H}^l(X, B; R) & \xrightarrow[\text{as defined on page 2513}]{\cup} & \mathrm{H}^{k+l}(X, A \cup B; R) \\ \cong \big\downarrow T & & T \big\downarrow \cong & & T \big\downarrow \cong \\ \mathrm{H}^k_{\mathrm{tw}}(X, A; {}_{\mathrm{tr}}R) & \times & \mathrm{H}^l_{\mathrm{tw}}(X, B; {}_{\mathrm{tr}}R) & \xrightarrow{\cup_R} & \mathrm{H}^{k+l}_{\mathrm{tw}}(X, A \cup B; {}_{\mathrm{tr}}R). \end{array}$$

Proof. The proof follows easily from the definitions. ■

The following proposition can be viewed as an analogue of the "classical" the Cup Product-Commutativity Proposition 114.8.

[2092] As we mentioned on page 3503, we will always view the group ring $\mathbb{Z}[\pi]$ as equipped with the involution $\overline{g} := g^{-1}$.

[2093] Recall that on page 3538 we showed that a homomorphism of $\mathbb{Z}[\pi]$-left modules induces a map on twisted cohomology.

[2094] We can use Lemma 171.2 to view $\mathrm{H}^p_{\mathrm{tw}}(X, A; M) \otimes_{\mathbb{Z}} \mathrm{H}^q_{\mathrm{tw}}(X, B; N)$ and $M \otimes_{\mathbb{Z}} N$ as $R \otimes_{\mathbb{Z}} S$-left modules. Thus both sides have a natural $R \otimes_{\mathbb{Z}} S$-left module structure.

[2095] By Lemma 169.1 we know that universally excisive triads are also excisive, this shows that the bottom relative cup product is indeed defined.

Proposition 171.7. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let M and N be $\mathbb{Z}[\pi_1(X,x_0)]$-left modules. We denote by

$$\begin{array}{rcl} \tau\colon M_{\otimes_{\mathbb{Z}}} N & \to & N \otimes_{\mathbb{Z}} M \\ \sum_{i=1}^{k} m_i \otimes n_i & \mapsto & \sum_{i=1}^{k} n_i \otimes m_i \end{array}$$

the $\mathbb{Z}[\pi_1(X,x_0)]$-left module isomorphism that swaps the two factors. Given any subset $A \subset X$ and given any $\varphi \in \mathrm{H}^k_{\mathrm{tw}}(X,A;M)$ and $\psi \in \mathrm{H}^l_{\mathrm{tw}}(X,A;N)$ the following equality holds:

$$\tau(\underbrace{\varphi \cup_{\otimes} \psi}_{\in M\otimes_{\mathbb{Z}} N}) \;=\; (-1)^{k\cdot l} \cdot \psi \cup_{\otimes} \varphi \;\in\; \mathrm{H}^{k+l}_{\mathrm{tw}}(X,A,N \otimes_{\mathbb{Z}} M).$$

Proof. We leave it to the reader to verify that the not entirely proof of the Cup Product-Commutativity Proposition 114.8 does indeed generalize to the present setting. Again we mostly have to replace multiplication "$\cdot$" in a commutative ring by taking the tensor product "$\otimes$". ■

The following proposition is the analogue of our old and much-used friend, the Cup Product-Naturality Proposition 115.4.

Proposition 171.8. Let X and Y be topological spaces that are locally contractible and path-connected and let $x_0 \in X$ and $y_0 \in Y$. Furthermore let (X,A,B) and (Y,C,D) be universally excisive triads of topological spaces and let R be a ring.

(1) Let M and N be $(\mathbb{Z}[\pi_1(Y,y_0)],R)$-left left modules. Let $f\colon (X,A,B) \to (Y,C,D)$ be a map with $f(x_0) = y_0$. For all $k,l \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(Y,C;M) \times \mathrm{H}^l_{\mathrm{tw}}(Y,D;N) & \xrightarrow{\cup_{\otimes}} & \mathrm{H}^{k+l}_{\mathrm{tw}}(Y,C\cup D; M\otimes_{\mathbb{Z}} N) \\ \downarrow{\scriptstyle f^*} \quad \downarrow{\scriptstyle f^*} & & \downarrow{\scriptstyle f^*} \\ \mathrm{H}^k_{\mathrm{tw}}(X,A;f^*M) \times \mathrm{H}^l_{\mathrm{tw}}(X,B;f^*N) & \xrightarrow{\cup_{\otimes}} & \mathrm{H}^{k+l}_{\mathrm{tw}}(X,A\cup B; \underbrace{f^*M \otimes_{\mathbb{Z}} f^*N}_{=f^*(M\otimes_{\mathbb{Z}} N)}). \end{array}$$

(2) If $\varphi\colon M \to M'$ and $\psi\colon N \to N'$ are homomorphisms of $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left modules, then for all $k,l \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X,A;M) \times \mathrm{H}^l_{\mathrm{tw}}(X,B;N) & \xrightarrow{\cup_{\otimes}} & \mathrm{H}^{k+l}_{\mathrm{tw}}(X,A\cup B; M\otimes_{\mathbb{Z}} N) \\ \downarrow{\scriptstyle \psi_*} \quad \downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*\otimes\psi_*} \\ \mathrm{H}^k_{\mathrm{tw}}(X,A;M') \times \mathrm{H}^l_{\mathrm{tw}}(X,B;N') & \xrightarrow{\cup_{\otimes}} & \mathrm{H}^{k+l}_{\mathrm{tw}}(X,A\cup B; M'\otimes_{\mathbb{Z}} N'). \end{array}$$

Here the vertical maps are the maps defined on page 3538.

Proof. As in the proof of the classical the Cup Product-Naturality Proposition 115.4 one sees that the statements follow easily from the definitions. ■

171.3. **The cap product on twisted (co-) homology.** Next we want to generalize the definition of the cap-product that we gave on page 2551 for singular (co-) homology.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Furthermore

let M and N be $\mathbb{Z}[\pi_1(X,x_0)]$-left modules and let $p,q\in\mathbb{N}_0$. Given $\varphi\in \mathrm{C}^p_{\mathrm{tw}}(X;M)$, given $\sigma\colon \Delta^q\to X$ with $p\le q$ and given $n\in N$ we define the cap product as[2096]

$$\varphi\cap_\otimes (n\underset{\mathbb{Z}[\pi]}{\otimes}\sigma) \;:=\; \big(\underbrace{\varphi(\sigma\circ[v_0,\dots,v_p])}_{\in M}\underset{\mathbb{Z}}{\otimes} n\big)\underset{\mathbb{Z}[\pi]}{\otimes}\underbrace{\sigma\circ[v_p,\dots,v_q]}_{\text{map }\Delta^{q-p}\to\widetilde{X}_{x_0}} \;\in\; \underbrace{(\overline{M}\underset{\mathbb{Z}}{\otimes}N)\underset{\mathbb{Z}[\pi]}{\otimes}\mathrm{C}^{\mathrm{tw}}_{q-p}(\widetilde{X}_{x_0})}_{=\mathrm{C}^{\mathrm{tw}}_{q-p}(X;M\otimes_{\mathbb{Z}}N)}.$$

(We will show in Lemma 171.9 below that this definition makes sense.) We extend this definition linearly to $\mathrm{C}^{\mathrm{tw}}_p(X;N)=\overline{N}\otimes_{\mathbb{Z}[\pi_1(X,x_0)]}\mathrm{C}_q(\widetilde{X}_{x_0})$ and we obtain the cap product

$$\cap_\otimes\colon \mathrm{C}^p_{\mathrm{tw}}(X;M)\times\mathrm{C}^{\mathrm{tw}}_q(X;N)\;\to\;\mathrm{C}^{\mathrm{tw}}_{q-p}(X;M\otimes_{\mathbb{Z}}N).$$

For $p>q$ we define the cap product to be the zero map. In Lemma 171.9 we see that the above map $\cap_\otimes$ descends to a well-defined map

$$\cap_\otimes\colon \mathrm{H}^p_{\mathrm{tw}}(X;M)\times\mathrm{H}^{\mathrm{tw}}_q(X;N)\;\to\;\mathrm{H}^{\mathrm{tw}}_{q-p}(X;M\otimes_{\mathbb{Z}}N).$$

The following lemma is the analogue of Lemmas 116.1 and 116.2 in the untwisted case.

Lemma 171.9. Let X be a topological space that is locally contractible and path-connected and let $x_0\in X$. We denote by $p\colon\widetilde{X}_{x_0}\to X$ the natural universal covering. Furthermore let M and N be $\mathbb{Z}[\pi_1(X,x_0)]$-left modules and let $p,q\in\mathbb{N}_0$.

(0) The above definition of the cap product on the (co-) chain level makes sense.

(1) Given $\varphi\in\mathrm{C}^p_{\mathrm{tw}}(X;M)$, given $\sigma\colon\Delta^q\to\widetilde{X}_{x_0}$ with $p\le q$ and given $n\in N$ we have

$$\partial(\varphi\cap_\otimes n\otimes\sigma)\;=\;(-1)^p\cdot(-\delta\varphi\cap_\otimes n\otimes\sigma+\varphi\cap_\otimes n\otimes\partial\sigma)\;\in\;\mathrm{C}^{\mathrm{tw}}_{l-k-1}(X;M\otimes_{\mathbb{Z}}N).$$

(2) The cap product on the (co-) chain level descends to a map on the (co-) homological level.

Proof. Let X be a topological space that is locally contractible and path-connected and let $x_0\in X$. We write $\pi=\pi_1(X,x_0)$ and we denote by $p\colon\widetilde{X}_{x_0}\to X$ the natural universal covering. Furthermore let M and N be $\mathbb{Z}[\pi]$-left modules and let $p,q\in\mathbb{N}_0$ with $p\le q$. We start out with the following claim.

Claim. Given $\varphi\in\mathrm{C}^p_{\mathrm{tw}}(X;M)$, given $\sigma\colon\Delta^q\to\widetilde{X}_{x_0}$ with $p\le q$ and given $n\in N$ we have the following equality in $(\overline{M\otimes_{\mathbb{Z}}N})\otimes_{\mathbb{Z}[\pi_1(X,x_0)]}\mathrm{C}_{q-p}(\widetilde{X}_{x_0})$:

$$\big(\varphi(\sigma\circ[v_0,\dots,v_p])\otimes n\cdot g\big)\otimes\sigma\circ[v_p,\dots,v_q]\;=\;\big(\varphi((g\cdot\sigma)\circ[v_0,\dots,v_p])\otimes n\big)\otimes(g\cdot\sigma)\circ[v_p,\dots,v_q].$$

Proof. The claim follows from a careful little calculation in $(\overline{M\otimes_{\mathbb{Z}}N})\otimes_{\mathbb{Z}[\pi]}\mathrm{C}_{q-p}(\widetilde{X}_{x_0})$:

$$\begin{array}{ll}
\big(\varphi(\sigma\circ[v_0,..,v_p])\underset{\mathbb{Z}}{\otimes}n\cdot g\big)\underset{\mathbb{Z}[\pi]}{\otimes}\sigma\circ[v_p,..,v_q] & =\big(\varphi(\sigma\circ[v_0,..,v_p])\cdot g^{-1}\cdot g\underset{\mathbb{Z}}{\otimes}n\cdot g\big)\underset{\mathbb{Z}[\pi]}{\otimes}\sigma\circ[v_p,..,v_q]\\
\uparrow= \big(\varphi(\sigma\circ[v_0,..,v_p])\cdot g^{-1}\underset{\mathbb{Z}}{\otimes}n\big)\underset{\mathbb{Z}[\pi]}{\otimes}g\cdot(\sigma\circ[v_p,..,v_q]) & \uparrow= \big(\varphi((g\cdot\sigma)\circ[v_0,..,v_p])\underset{\mathbb{Z}}{\otimes}n\big)\underset{\mathbb{Z}[\pi]}{\otimes}(g\cdot\sigma)\circ[v_p,..,v_q].
\end{array}$$

by definition of the tensor product over $\mathbb{Z}[\pi]$ and the definition of the $\mathbb{Z}[\pi]$-right module structure on $\overline{M\otimes_{\mathbb{Z}}N}$

since $(g\cdot\sigma)([v_i,\dots,v_j])=g\cdot(\sigma\circ[v_i,\dots,v_j])$, since φ is a $\mathbb{Z}[\pi]$-left module homomorphism, and by definition of the $\mathbb{Z}[\pi]$-right module structure on $\overline{M}$ ⊞

Now we turn to the proofs of the three statements of the lemma.

(0) This statement follows immediately from the claim.

(1) The proof of this statement is almost identical to the proof of Lemma 116.1. In fact, as we already explained in the proof of Lemma 171.3, we just need to replace multiplication "$\cdot$" in $\mathbb{R}$ by the tensor product $\otimes$.

(2) As in the proof of Lemma 116.2 we see that Statement (2) is a straightforward consequence of Statement (1). ■

Before we discuss properties of the cap product with twisted coefficients let us immediately move on to the slightly more tricky definition of the relative cap product on twisted (co-) homology. As in the classical setting this requires a little bit of an effort. We start out with the following definition.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Let R be a commutative ring and let N be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module. Let (X,A,B) be a triad of topological spaces. We write $\widetilde{A} := p^{-1}(A)$ and $\widetilde{B} := p^{-1}(B)$. We write

$$\mathrm{C}_n^{\mathrm{tw}}(X,\{A,B\};N) \;:=\; \mathrm{coker}\left(\overline{N} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_n^{\{\widetilde{A},\widetilde{B}\}}(\widetilde{A}\cup\widetilde{B}) \to \overline{N} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_n(\widetilde{X}_{x_0})\right).$$

As always the boundary map on the chain complex $\overline{N} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_n(\widetilde{X}_{x_0})$ descends to a boundary map on $\mathrm{C}_n^{\mathrm{tw}}(X,\{A,B\};N)$ which we can thus view as a chain complex of R-left modules. We denote the corresponding homology groups by $\mathrm{H}_*^{\mathrm{tw}}(X,\{A,B\};N)$.

The following lemma is the analogue of the "untwisted" Lemma 116.6.

Lemma 171.10. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a commutative ring and let N be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module. If (X,A,B) is a universally excisive triad of topological spaces, then the obvious homomorphism

$$\mathrm{C}_*^{\mathrm{tw}}(X,\{A,B\};N) \quad\to\quad \mathrm{C}_*^{\mathrm{tw}}(X,A\cup B;N)$$

of R-left modules induces for every $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n^{\mathrm{tw}}(X,\{A,B\};N) \quad\xrightarrow{\cong}\quad \mathrm{H}_n^{\mathrm{tw}}(X,A\cup B;N).$$

Proof. In the proof of Lemma 171.4 we already showed that the map

$$\mathrm{C}_*(\widetilde{X},\{\widetilde{A},\widetilde{B}\}) \;\to\; \mathrm{C}_*(\widetilde{X},\widetilde{A}\cup\widetilde{B})$$

is a chain homotopy equivalence of free $\mathbb{Z}[\pi_1(X,x_0)]$-left modules. The lemma now follows from the Tensoring Chain Complex Lemma 166.3 together with Lemma 166.2. ■

The following definition can be viewed as the twisted analogue of the definition on page 2557.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Furthermore let M and N be $\mathbb{Z}[\pi_1(X,x_0)]$-left modules and let $p,q \in \mathbb{N}_0$. Finally suppose that we are given a universally excisive triad (X,A,B). We refer to the map

$$\begin{array}{ccc} \mathrm{H}_{\mathrm{tw}}^k(X,A;M) \times \mathrm{H}_l^{\mathrm{tw}}(X,A\cup B;N) & \xleftarrow{\cong} & \mathrm{H}_{\mathrm{tw}}^k(X,A;M) \times \mathrm{H}_l^{\mathrm{tw}}(X,\{A,B\};N) \\ & \xrightarrow{\cap_\otimes} & \mathrm{H}_{l-k}^{\mathrm{tw}}(X,B;M\otimes_{\mathbb{Z}} N) \end{array}$$

(the left arrow: isomorphism given by Lemma 171.10; the right arrow: argument of Lemma 116.5 shows that the same explicit map as on page 3606 descends to a well-defined map)

as the cap product (sometimes we refer to it as the relative cap product) that we also denote by "$\cap_\otimes$". For $k > l$ we define the cap product to be the zero map.

Remark. As in the case of the original cap product, see the discussion on page 2558, the relative cap product

$$\cap_{\otimes}\colon \mathrm{H}^k_{\mathrm{tw}}(X,A;M)\times \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;N) \;\to\; \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;M\otimes_{\mathbb{Z}} N)$$

is given by the explicit formula if $A=\varnothing$, or $B=\varnothing$ or $A=B$.

The following lemma is the analogue of Lemma 171.5.

Lemma 171.11. Let X be a topological space that is locally contractible and path-connected and let $x_0\in X$. Let R and S be rings, let M be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module and let N be a $(\mathbb{Z}[\pi_1(X,x_0)],S)$-left left module. Furthermore let (X,A,B) be a universally excisive triad of topological spaces. The relative cap product

$$\cap_{\otimes}\colon \mathrm{H}^k_{\mathrm{tw}}(X,A;M)\otimes_{\mathbb{Z}} \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;N) \;\to\; \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;M\otimes_{\mathbb{Z}} N)$$

is a homomorphism of $R\otimes_{\mathbb{Z}} S$-left modules.

Proof. The lemma follows immediately from the definitions. ■

On page 3603 we defined the cup product with coefficients in a ring. We have the following analogous definition in the context of the cap product.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0\in X$. We write $\pi:=\pi_1(X,x_0)$. Furthermore let R be a ring with (possibly trivial) involution and let $\varphi\colon \mathbb{Z}[\pi]\to R$ be a homomorphism of rings with involution. We consider again the multiplication map

$$\begin{aligned}\mu\colon {}_{\varphi}R\underset{\mathbb{Z}}{\otimes}{}_{\varphi}R &\to {}_{\mathrm{tr}}R\\ r\otimes s &\mapsto r\cdot\overline{s}\end{aligned}$$

which is a homomorphism of $\mathbb{Z}[\pi]$-left modules. If (X,A,B) is a universally excisive triad of topological spaces, then we define[2097]

$$\begin{aligned}\cap_R\colon \mathrm{H}^k_{\mathrm{tw}}(X,A;{}_{\varphi}R)\times \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;{}_{\varphi}R) &\to \mathrm{H}^{l-k}_{\mathrm{tw}}(X,B;{}_{\mathrm{tr}}R)\\ (\alpha,\beta) &\mapsto \mu_*\Big(\underbrace{\alpha\cap_{\otimes}\beta}_{\in \mathrm{H}^{l-k}_{\mathrm{tw}}(X,B;{}_{\varphi}R\underset{\mathbb{Z}}{\otimes}{}_{\varphi}R)}\Big).\end{aligned}$$

The following, rather unsurprising analogue of Lemma 171.6 says we that we can recover our classical cap product in all relevant cases from the twisted cap product.

Lemma 171.12. Let X be a topological space that is locally contractible and path-connected and let $x_0\in X$ and let (X,A,B) be a universally excisive triad of topological spaces. Let R be a commutative ring. We consider the trivial $\mathbb{Z}[\pi_1(X,x_0)]$-left module ${}_{\mathrm{tr}}R$. In other words we consider the homomorphism $\mathbb{Z}[\pi_1(X,x_0)]\to R$ that is given by $g\mapsto 1_R$. If we equip $\mathbb{Z}[\pi_1(X,x_0)]$ with the usual involution and if we equip R with the trivial involution, then this is a homomorphism between rings with involution, thus the cup product $\cup_R$ is defined. The following diagram, where the vertical maps are the natural

[2097] Recall that on page 3538 we showed that a homomorphism of $\mathbb{Z}[\pi]$-left modules induces a map on twisted homology.

isomorphisms T from Lemma 167.3, commutes:

$$\begin{array}{ccccc} \mathrm{H}^k_{\mathrm{tw}}(X,A;{}_{\mathrm{tr}}R) & \times & \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;{}_{\mathrm{tr}}R) & \xrightarrow{\cap_R} & \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;{}_{\mathrm{tr}}R) \\ {\scriptstyle T}\uparrow\cong & & {\scriptstyle T}\downarrow\cong & & {\scriptstyle T}\downarrow\cong \\ \mathrm{H}^k(X,A;R) & \times & \mathrm{H}_l(X,A\cup B;R) & \xrightarrow[\text{as defined on page 2551}]{\cap} & \mathrm{H}_{l-k}(X,B;R). \end{array}$$

Proof. The lemma follows again easily from plugging in all the definitions. ∎

Next we want to introduce an important variation on the cap product, which allows us - perhaps counter intuitively - to cap a twisted cohomology class with an untwisted ordinary homology class.

Definition. Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let (X,A,B) be a universally excisive triad of topological spaces. Furthermore let R be a ring, let M be a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module and let $k,l \in \mathbb{N}_0$. We consider the two natural isomorphisms

$$\begin{array}{rcl} T\colon \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;{}_{\mathrm{tr}}\mathbb{Z}) & \to & \mathrm{H}_l(X,A\cup B) \\ [n\otimes\sigma] & \mapsto & [p_*(\sigma)\cdot n] \end{array} \quad \text{and} \quad \begin{array}{rcl} \mu\colon M\otimes_{\mathbb{Z}}{}_{\mathrm{tr}}\mathbb{Z} & \to & M \\ m\otimes n & \mapsto & n\cdot m \end{array}$$

$p\colon \widetilde{X}_{x_0}\to X$ is the natural universal covering

from Lemma 167.3 (together with the remark on page 1913) and Lemma 165.24. We define

$$\begin{array}{rcl} \cap_{\mathbb{Z}}\colon \mathrm{H}^k_{\mathrm{tw}}(X,A;M)\times \mathrm{H}_l(X,A\cup B) & \to & \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;M) \\ (\varphi,\sigma) & \mapsto & \mu_*(\underbrace{\varphi\cap_{\otimes} T^{-1}(\sigma)}_{\in \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;M\otimes_{\mathbb{Z}}{}_{\mathrm{tr}}\mathbb{Z})}). \end{array}$$

It follows easily from Lemma 171.11 that given $\sigma\in \mathrm{H}_l(X,A\cup B)$ the map $\varphi\mapsto \varphi\cap_{\mathbb{Z}}\sigma$ is a R-left homomorphism.

The following proposition is a sibling of Proposition 171.8 and it contains the twisted analogue of the Cap Product-Naturality Lemma 116.8.

Proposition 171.13. Let X and Y be topological spaces that are locally contractible and path-connected and let $x_0\in X$ and $y_0\in Y$. Furthermore let (X,A,B) and (Y,C,D) be universally excisive triads of topological spaces.

(1) Let $f\colon (X,A,B)\to(Y,C,D)$ be a map with $f(x_0)=y_0$ and let $k,l\in\mathbb{N}_0$.
   (a) Let M and N be $\mathbb{Z}[\pi_1(Y,y_0)]$-left modules. The following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(Y,C;M)\times \mathrm{H}^{\mathrm{tw}}_l(Y,C\cup D;N) & \xrightarrow{\cap_{\otimes}} & \mathrm{H}^{\mathrm{tw}}_{l-k}(Y,D;M\otimes_{\mathbb{Z}}N) \\ {\scriptstyle f^*}\downarrow \quad \uparrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f^*} \\ \mathrm{H}^k_{\mathrm{tw}}(X,A;f^*M)\times \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;f^*N) & \xrightarrow{\cap_{\otimes}} & \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;\underbrace{f^*M\otimes_{\mathbb{Z}} f^*N}_{=f^*(M\otimes_{\mathbb{Z}}N)}). \end{array}$$

(b) Let M be a $\mathbb{Z}[\pi_1(Y,y_0)]$-left module. The following diagram commutes:[2098]

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(Y,C;M) \times \mathrm{H}_l(Y,C\cup D) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{\mathrm{tw}}_{l-k}(Y,D;M) \\ {\scriptstyle f^*}\downarrow \quad\quad \uparrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f^*} \\ \mathrm{H}^k_{\mathrm{tw}}(X,A;f^*M) \times \mathrm{H}_l(X,A\cup B) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;f^*M). \end{array}$$

(2) If $\varphi\colon M \to M'$ and $\psi\colon N \to N'$ are homomorphisms of $\mathbb{Z}[\pi_1(X,x_0)]$-left modules, then for all $k,l \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X,A;M) \times \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;N) & \xrightarrow{\cap_{\otimes}} & \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;M\otimes_{\mathbb{Z}} N) \\ {\scriptstyle \psi_*}\downarrow & \downarrow{\scriptstyle \varphi_*} & \downarrow{\scriptstyle \varphi_*\otimes\psi_*} \\ \mathrm{H}^k_{\mathrm{tw}}(X,A;M') \times \mathrm{H}^{\mathrm{tw}}_l(X,A\cup B;N') & \xrightarrow{\cap_{\otimes}} & \mathrm{H}^{\mathrm{tw}}_{l-k}(X,B;M'\otimes_{\mathbb{Z}} N'). \end{array}$$

Here the vertical maps are the maps defined on page 3538.

Proof. All statements follow easily from the definitions. ■

The following lemma is the generalization of the Cup-Cap Lemma 116.7 to the present context.

Lemma 171.14. Let X be a topological space that is locally contractible and path-connected. Let $x_0 \in X$ and let L, M and N be $\mathbb{Z}[\pi_1(X,x_0)]$-left modules. Furthermore let $A \subset X$ be a subset and let $C,D \in \{\varnothing, A\}$. Given any $\varphi \in \mathrm{H}^k_{\mathrm{tw}}(X,C;L)$, $\psi \in \mathrm{H}^l_{\mathrm{tw}}(X,D;M)$ and $\sigma \in \mathrm{H}^{\mathrm{tw}}_n(X,C\cup D;N)$ we have[2099]

$$\varphi \cap_{\otimes} (\psi \cap_{\otimes} \sigma) \;=\; (\psi \cup_{\otimes} \varphi) \cap_{\otimes} \sigma \;\in\; \mathrm{H}^{\mathrm{tw}}_{n-k-l}(X; L\otimes_{\mathbb{Z}} M\otimes_{\mathbb{Z}} N).$$

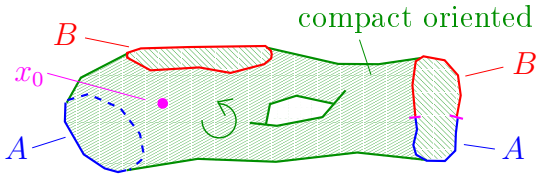
If $\sigma \in \mathrm{H}_n(X,C\cup D)$, then

$$\varphi \cap_{\otimes} (\psi \cap_{\mathbb{Z}} \sigma) \;=\; (\psi \cup_{\otimes} \varphi) \cap_{\mathbb{Z}} \sigma \quad\in\; \mathrm{H}^{\mathrm{tw}}_{n-k-l}(X; L\otimes_{\mathbb{Z}} M).$$

Proof. As in the case of the Cup-Cap Lemma 116.7 the statement follows immediately from the definitions. ■

[2098] Statement (1b) is essentially Statement (1a) with $N = {}_{\mathrm{tr}}\mathbb{Z}$. Since this special case will be needed frequently we decided to formulate it separately.

[2099] As we discussed on page 1909, for tensor products over $\mathbb{Z}$ we decided - with a slightly guilty conscience - to drop parenthesis.



172. Poincaré Duality with twisted coefficients

172.1. **Statement of the Poincaré Duality Theorem with twisted coefficients.** The Poincaré Duality Theorem 119.1 was surely the most important result so far that we proved regarding the topology of compact topological manifolds. Now we have all the tools to formulate and prove a significant generalization of Poincaré Duality Theorem 119.1.

Theorem 172.1. (Poincaré Duality Theorem with Twisted Coefficients) Let X be a compact oriented path-connected n-dimensional topological manifold and let $x_0 \in X$. We denote by $[X] \in \mathrm{H}_n(X, \partial X)$ the fundamental class. Furthermore suppose that we are given a decomposition $\partial X = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂X such that $A \cap B = \partial A = \partial B$. For every $\mathbb{Z}[\pi_1(X, x_0)]$-left module M and each $k \in \mathbb{N}_0$ the map[2100]

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X, A; M) & \xrightarrow{\cong} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X, B; M) \\ \sigma & \mapsto & \sigma \cap_{\mathbb{Z}} [X] \end{array}$$

is an isomorphism.

Remark.

(1) For $M = {}_{\mathrm{tr}}\mathbb{Z}$ we recover the $R = \mathbb{Z}$-statement of the Poincaré Duality Theorem 119.1.

(2) The Poincaré Duality Theorem 172.1 with Twisted Coefficients gets commonly used in the literature. But proofs in the literature a few and far between. The proof we provide is a "twisted version" of our proof of the original Poincaré Duality Theorem 119.1. Another "twisted version" of a classical proof is provided in [**FNOP2019**] and in [**Sun2017**]. Somewhat different approaches are given in [**KwS2018**] and [**Wall1970**, Chapter 2].

(3) Let M be a closed oriented smooth manifold. By the Smooth Manifold-Simplicial Structure Theorem 96.2 we know that M admits a smooth simplicial structure. In Chapter 103 we used this fact to provide for such M an alternative proof of the Poincaré Duality Theorem 119.1. Using equivariant versions of the chain homotopy equivalence used in the proof of the Simplicial Poincaré Duality Theorem 103.4 one can surely provide an alternative proof of the Poincaré Duality Theorem 172.1 with Twisted Coefficients for closed oriented smooth manifolds. Our well developed taste for brevity prevents us from carrying out this program.

[2100] Note that if M is a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module M where R is some ring, then it follows from the discussion on page 3609 that the map

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X, A; M) & \xrightarrow{\cong} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X, B; M) \\ \sigma & \mapsto & \sigma \cap_{\mathbb{Z}} [X] \end{array}$$

is a homomorphism of R-left modules, thus in our setting it is an isomorphism of R-left modules.

Notation. The isomorphism of the Poincaré Duality Theorem 172.1 with Twisted Coefficients is called the Poincaré Duality isomorphism. We denote it and its inverse both by PD_X, i.e. with the notation of the Poincaré Duality Theorem 172.1 we have the isomorphism

$$\begin{array}{rcl} \mathrm{PD}_X\colon \mathrm{H}^k_{\mathrm{tw}}(X,A;M) & \overset{\cong}{\to} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X,B;M) \\ \sigma & \mapsto & \sigma \cap_{\mathbb{Z}} [X] \end{array}$$

together with the inverse

$$\mathrm{PD}_X\colon \mathrm{H}^{\mathrm{tw}}_{n-k}(X,B;M) \overset{\cong}{\to} \mathrm{H}^k_{\mathrm{tw}}(X,A;M).$$

Note that if R is a ring and M is a $(\mathbb{Z}[\pi_1(X,x_0)],R)$-left left module, then it follows easily from Lemma 171.11 that the Poincaré Duality isomorphisms are isomorphisms of R-left modules.

Example. Could show that the Alexander polynomial is symmetric

We will prove the Poincaré Duality Theorem 172.1 in the following sections. We will try to stick as closely as possible to the earlier proof of the untwisted Poincaré Duality Theorem 119.1, and we will try to outline where the differences lie.

Before we get to the proof of the Poincaré Duality Theorem 172.1 let us formulate the following variation on the Poincaré Duality Theorem 172.1.

Theorem 172.2. (Poincaré Duality Theorem for Non-Orientable Topological Manifolds) Let X be a compact *non-orientable* path-connected n-dimensional topological manifold and let $x_0 \in X$. We denote by

$$w_1\colon \pi_1(X,x_0) \;\to\; \pi_1(X,x_0)/p_*(\pi_1(\widetilde{X},\widetilde{x}_0)) \underset{\text{unique isomorphism}}{\overset{\uparrow}{=}} \langle x \,|\, x^2\rangle$$

the orientation-character that we introduced on page 2341 and we denote by $\widetilde{\mathbb{Z}}$ the $\mathbb{Z}[\langle x \,|\, x^2\rangle]$-left module that is given by $x\cdot n := -n$. We denote by $[X]_{\mathrm{tw}} \in \mathrm{H}_n(X,\partial X; w_1^*\widetilde{\mathbb{Z}})$ the twisted fundamental class that we introduced on page 3567. Furthermore suppose that we are given a decomposition $\partial X = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂X such that $A \cap B = \partial A = \partial B$. For each $k \in \mathbb{N}_0$ and every $\mathbb{Z}[\pi_1(X,x_0)]$-left module M the map

$$\begin{array}{rcl} \mathrm{H}^k_{\mathrm{tw}}(X,A;M) & \overset{\cong}{\to} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X,B;M\otimes_{\mathbb{Z}} w_1^*\widetilde{\mathbb{Z}}) \\ \sigma & \mapsto & \sigma \cap_{\mathbb{Z}} [X]_{\mathrm{tw}} \end{array}$$

is an isomorphism.

Proof. The proof of the Poincaré Duality Theorem for Non-Orientable Topological Manifolds 172.2 is in principle quite similar to the proof of the Poincaré Duality Theorem 172.1. The key property of the twisted fundamental class $[X]_{\mathrm{tw}} \in \mathrm{H}^{\mathrm{tw}}_n(X,\partial X; w_1^*\widetilde{\mathbb{Z}})$ which one uses, and which we proved in Proposition 168.7, is the fact that for each $Q \in X \setminus \partial X$ the map $\mathrm{H}^{\mathrm{tw}}_n(X,\partial X; w_1^*\widetilde{\mathbb{Z}}) \to \mathrm{H}^{\mathrm{tw}}_n(X, X\setminus\{Q\}; w_1^*\widetilde{\mathbb{Z}})$ is an isomorphism. Like every author that is known to this author we will not work out the details of the proof of this Poincaré Duality Theorem. We hope that the next generation of authors will step up and finally provide a proof of this well-known folklore theorem. ■

172.2. **The proof of Theorem 172.1 for topological manifolds without boundary.** In this section we will prove the Poincaré Duality Theorem 172.1 for closed topological manifolds. More precisely, we will prove the following theorem.

Theorem 172.3. Let X be a closed oriented path-connected n-dimensional topological manifold and let $x_0 \in X$. We denote by $[X] \in \mathrm{H}_n(X)$ the fundamental class. For each $k \in \mathbb{N}_0$ and every $\mathbb{Z}[\pi_1(X, x_0)]$-left module M the map

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X; M) & \xrightarrow{\cong} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X; M) \\ \sigma & \mapsto & \sigma \cap_{\mathbb{Z}} [X] \end{array}$$

is an isomorphism.

As in the proof of the Poincaré Theorem 119.1 we want to reduce the proof eventually to the fairly trivial case of an open ball in $\mathbb{R}^n$. To do so we need a version of Poincaré Duality for every topological manifold (not necessarily compact) with empty boundary. Formulating this generalized Poincaré Duality Theorem requires some preparations.

In the proof of Poincaré Theorem 119.1 we used cohomology with compact support. But in fact we did not work with the actual definition of cohomology with compact support but with a reformulation that was given in the H^n_c-via-Direct Limits Proposition 112.4. We use this reformulation to define cohomology with compact support and twisted coefficients.

Definition.

(1) Given a topological space X we denote by $\mathcal{K}(X)$ the set of all compact subsets of X. We equip $\mathcal{K}(X)$ with the partial order that is given by inclusion.

(2) Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Using the functoriality of cohomology with twisted coefficients we can define the cohomology of X with compact support and twisted coefficient corresponding to M to be the following R-left module:

$$\mathrm{H}^k_{\mathrm{tw},c}(X; M) \ := \ \varinjlim_{K \in \mathcal{K}(X)} \mathrm{H}^k_{\mathrm{tw}}(X, X \setminus K; M).$$

Notation. Let X be an n-dimensional topological manifold with empty boundary. If X is equipped with an orientation $\{\mu_x \in \mathrm{H}_n(X, X \setminus \{x\})\}_{x \in X}$, then we saw in the Homology-Section Theorem 106.10 (i) that given any compact subset K of X there exists a unique class $\mu^X_K \in \mathrm{H}_n(X, X \setminus K)$ such that for any $x \in K$ the image of μ^X_K under the map

$$\mathrm{H}_n(X, X \setminus K) \ \to \ \mathrm{H}_n(X, X \setminus \{x\})$$

equals the given orientation μ_x at x. If X is understood, then we drop it from the notation, i.e. we just write μ_K instead of μ^X_K.

Lemma 172.4. Let X be an oriented path-connected n-dimensional topological manifold with $\partial X = \varnothing$ and let $x_0 \in X$. Let R be a ring and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. For any $k \in \mathbb{N}_0$ there exists a unique R-left module homomorphism

$$\mathrm{PD}_X \colon \mathrm{H}^k_{\mathrm{tw},c}(X; M) \ \to \ \mathrm{H}^{\mathrm{tw}}_{n-k}(X; M)$$

such that for each compact subset $K \subset X$ the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X, X \setminus K; M) & \xrightarrow{\cap_{\mathbb{Z}} \mu_K} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X; M). \\ & \searrow \quad \nearrow_{\mathrm{PD}_X} & \\ & \mathrm{H}^k_{\mathrm{tw,c}}(X; M) & \end{array}$$

Proof. The proof is basically identical to the proof of Lemma 119.17, we only need to replace the Cap Product-Naturality Lemma 116.8 by Proposition 171.13 (1b). ■

We will now actually prove a generalization of Theorem 172.3 where we replace the hypothesis that X is closed by the hypothesis that the boundary is empty. This more general version of Poincaré Duality will not only be useful for the divide-et-impera approach to the proof of Theorem 172.3, but surprisingly it will also be of interest when we deal with Poincaré Duality for topological manifolds with non-empty boundary.

Theorem 172.5. Let X be an oriented path-connected n-dimensional topological manifold with $\partial X = \varnothing$. Let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. For each $k \in \mathbb{N}_0$ the map

$$\mathrm{PD}_X \colon \mathrm{H}^k_{\mathrm{tw},c}(X; M) \xrightarrow{\cong} \mathrm{H}^{\mathrm{tw}}_{n-k}(X; M)$$

from Lemma 172.4 is an isomorphism.

As a warm up for the proof of Theorem 172.5 we will deal with the case $X = B^n$ by hand.[2101] More precisely, we will prove the following lemma.

Lemma 172.6. Let X be an oriented topological manifold that is homeomorphic to the open ball B^n, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. For each $k \in \mathbb{N}_0$ the map

$$\mathrm{PD}_X \colon \mathrm{H}^k_{\mathrm{tw},c}(X; M) \xrightarrow{\cong} \mathrm{H}^{\mathrm{tw}}_{n-k}(X; M)$$

is an isomorphism.

Proof. Since X is homeomorphic to the open ball B^n we see that $\pi_1(X, x_0)$ is the trivial group, which implies that M is the trivial $\mathbb{Z}[\pi_1(X, x_0)]$-module ${}_{\mathrm{tr}}M$. We consider the following diagram:

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw},c}(X; {}_{\mathrm{tr}}M) & \xrightarrow{\cap_{\mathbb{Z}} \mu_X} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X; {}_{\mathrm{tr}}M) \\ {\scriptstyle T}\uparrow\cong & & \cong\downarrow{\scriptstyle T} \\ \mathrm{H}^k_c(X; M) & \xrightarrow{\cap_{\mathbb{Z}} \mu_X} & \mathrm{H}_{n-k}(X; M) \end{array}.$$

We make the following clarifications and observations:

(1) By Lemma 167.3 we have a natural isomorphism

$$T \colon \mathrm{H}^{\mathrm{tw}}_{n-k}(X; {}_{\mathrm{tr}}M) \to \mathrm{H}_{n-k}(X; M).$$

This gives us the vertical isomorphism on the right.

(2) Again by Lemma 167.3 we have a natural isomorphism

$$T \colon \mathrm{H}^k_{\mathrm{tw}}(X, X \setminus K; M) \to \mathrm{H}^k_{\mathrm{tw}}(X, X \setminus K; {}_{\mathrm{tr}}M).$$

[2101] We use the convention that any n-dimensional submanifold of $\mathbb{R}^n$ is equipped with the orientation induced from the standard orientation of $\mathbb{R}^n$, see the Topological Manifold-Induced Orientation Lemma 105.17.

By the naturality of these isomorphisms, these isomorphisms induce the vertical isomorphism on the left.

(3) It follows easily from the definitions, similar to Lemma 171.12, that the diagram commutes.

(4) In Lemma 119.19 we showed, using an explicit calculation, that the bottom horizontal map is an isomorphism for $X = B^n$. But since X is homeomorphic to B^n it follows immediately that the bottom horizontal map is also an isomorphism in our case. ■

One of key ideas in the proof of the Poincaré Duality Theorem 119.1, and in the intermediate the Non-Compact PD Theorem 119.18, was to reduce the general case to the rather trivial case of an open ball. To reduce the general case to the trivial case we needed to show that if Poincaré Duality holds on two open subsets U and V of a given topological manifold X, then it also holds in the union $U \cup V$ of the two open subsets. To show this result we had to state and prove in Proposition 172.9 a Mayer–Vietoris type result that relates U, V to $U \cup V$ and also the intersection $U \cap V$. The technical nuisance that arises is that there is no way that we can assume that the intersection $U \cap V$ is again path-connected, thus we cannot talk about twisted (co-) homology of $U \cap V$. This means that we have to revert to working with internal twisted (co-) homology that we introduced in Section 169.2. For the reader's convenience we recall the definitions.

Definition. Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering.

(1) Given any subset $S \subset T \subset X$ we write $\widetilde{S} := p^{-1}(S)$ and $\widetilde{T} := p^{-1}(T)$ and we set

$$\begin{aligned} \mathrm{C}_k^{X,M}(T,S) &:= \overline{M} \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_k(\widetilde{T},\widetilde{S}) \\ \mathrm{C}^k_{X,M}(T,S) &:= \mathrm{Hom}_{\mathbb{Z}[\pi_1(X,x_0)]\text{-left}}(\mathrm{C}_k(\widetilde{T},\widetilde{S}), M). \end{aligned}$$

These are (co-) chain complexes in the obvious way and we obtain the corresponding (co-) homology groups $\mathrm{H}_k^{X,M}(T,S)$ and $\mathrm{H}^k_{X,M}(T,S)$. We refer to these as internal (co-) homology groups with twisted coefficients.

(2) Given pairs (T_1, S_1) and (T_2, S_2) of subspaces of X with $T_1 \subset T_2$ and $S_1 \subset S_2$ we obtain, with the hopefully obvious notation, an inclusion induced chain map $\mathrm{C}_k(\widetilde{T}_1, \widetilde{S}_1) \to \mathrm{C}_k(\widetilde{T}_2, \widetilde{S}_2)$ which is a $\mathbb{Z}[\pi_1(X, x_0)]$-left homomorphism. Thus we get induced maps

$$\begin{aligned} i_*\colon \mathrm{H}_k^{X,M}(T_1,S_1) &\to \mathrm{H}_k^{X,M}(T_2,S_2) \\ i^*\colon \mathrm{H}^k_{X,M}(T_2,S_2) &\to \mathrm{H}^k_{X,M}(T_1,S_1). \end{aligned}$$

Evidently internal (co-) homology is functorial under inclusions.

We add some new definitions:

(3) Let (T, S) be a pair of subspaces of X. As on page 3609 we define a cap product

$$\cap_{\mathbb{Z}}\colon \mathrm{H}^k_{X,M}(T,S) \times \mathrm{H}_n(T,S) \to \mathrm{H}^{X,M}_{n-k}(T).$$

(4) Given $S \subset X$ we can use (2) to define internal cohomology with compact support and twisted coefficients

$$\mathrm{H}^k_{X,M,c}(S) := \varinjlim_{K \in \mathcal{K}(S)} \mathrm{H}^k_{X,M}(S, S \setminus K).$$

The next lemma allows us to go back and forth between internal twisted (co-) homology and usual twisted (co-) homology.

Lemma 172.7. Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module.

(1) Let (T, S) be a pair of subspaces of X with $x_0 \in T$. We assume that T is locally contractible and path-connected. We denote by $i\colon T \to X$ the inclusion. We have isomorphisms
$$\begin{aligned} \Omega^X_{T,S}\colon \mathrm{H}^{\mathrm{tw}}_k(T, S; i^*M) &\to \mathrm{H}^{X,M}_k(T, S) \\ \Omega^X_{T,S}\colon \mathrm{H}^k_{X,M}(T, S) &\to \mathrm{H}^k_{\mathrm{tw}}(T, S; i^*M) \end{aligned}$$
that are natural under inclusions.

(2) The following diagram commutes:
$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(T, S; i^*M) \times \mathrm{H}_n(T, S) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{\mathrm{tw}}_{n-k}(T; i^*M) \\ \cong\uparrow \Omega^X_{T,S} \quad \downarrow \mathrm{id} & & \cong\uparrow \Omega^X_T \\ \mathrm{H}^k_{X,M}(T, S) \times \mathrm{H}_n(T, S) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{X,M}_{n-k}(T). \end{array}$$

Proof. The first statement is a simplified version of the Change of Covering Proposition II 169.4. The second statement follows easily from the definitions. ∎

We will need the following reformulation of Lemma 172.4.

Lemma 172.8. Let X be an oriented path-connected n-dimensional topological manifold with $\partial X = \varnothing$, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. For any open subset $U \subset X$ and any $k \in \mathbb{N}_0$ there exists a unique map
$$\mathrm{PD}_U\colon \mathrm{H}^k_{X,M,\mathrm{c}}(U) \to \mathrm{H}^{X,M}_{n-k}(U)$$
such that for each compact subset $K \subset U$ the following diagram commutes
$$\begin{array}{ccc} \mathrm{H}^k_{X,M}(U, U \setminus K) & \xrightarrow{\cap_{\mathbb{Z}}\mu_K} & \mathrm{H}^{X,M}_{n-k}(U). \\ & \searrow \quad \nearrow_{\mathrm{PD}_U} & \\ & \mathrm{H}^k_{X,M,\mathrm{c}}(U) & \end{array}$$

Proof. The proof of the lemma is basically the same as the proof of the analogous statements in Lemma 119.17 and Lemma 172.4. Alternatively one sees that the lemma follows immediately from Lemma 172.4 together with Lemma 172.7. ∎

Before we can formulate our next results we need to introduce some notation.

Notation. Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module.

(1) Given $A \subset X$ we denote by $i_*\colon \mathrm{H}^{X,M}_k(A) \to \mathrm{H}^{X,M}_k(X)$ and $i^*\colon \mathrm{H}^{X,M}_k(X) \to \mathrm{H}^{X,M}_k(A)$ the inclusion induced map.

(2) Suppose that X is Hausdorff and that U is an open subset of X with $x_0 \in U$. Then we denote by $i\colon \mathrm{H}^k_{X,M,c}(U) \to \mathrm{H}^k_{X,M,c}(X)$ the map that is defined by

$$\overbrace{\varinjlim_{K\in\mathcal{K}(U)} \mathrm{H}^k_{X,M}(U, U\setminus K)}^{=\mathrm{H}^k_{X,M,\mathrm{c}}(U)} \xleftarrow{\cong} \underbrace{\varinjlim_{K\in\mathcal{K}(U)} \mathrm{H}^k_{X,M}(X, X\setminus K)}_{\text{isomorphism by the Excision Theorem 169.6}} \to \overbrace{\varinjlim_{K\in\mathcal{K}(X)} \mathrm{H}^k_{X,M}(X, X\setminus K)}^{=\mathrm{H}^k_{X,M,\mathrm{c}}(X)}.$$

As in Lemma 112.5 we see that these maps $\mathrm{H}^k_{X,M,c}(U) \to \mathrm{H}^k_{X,M,c}(X)$ are covariantly functorial with respect to compositions of inclusions.

Now we can state the key technical ingredient to the proof of Theorem 172.5:

Proposition 172.9. Let X be an oriented path-connected n-dimensional topological manifold with $\partial X = \varnothing$. Let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. Let U and V be open subsets of X with $X = U \cup V$. Then there exists a diagram

$$\begin{array}{ccccccccc}
\dots \to \mathrm{H}^k_{X,M,\mathrm{c}}(U\cap V) & \xrightarrow{i\oplus -i} & \mathrm{H}^k_{X,M,\mathrm{c}}(U)\oplus \mathrm{H}^k_{X,M,\mathrm{c}}(V) & \xrightarrow{i+i} & \overbrace{\mathrm{H}^k_{X,M,\mathrm{c}}(X)}^{=\mathrm{H}_{\mathrm{tw},\mathrm{c}}(X;M)} & \to & \mathrm{H}^{k+1}_{X,M,\mathrm{c}}(U\cap V) & \to \dots \\
\downarrow{\scriptstyle \mathrm{PD}_{U\cap V}} & & \downarrow{\scriptstyle \mathrm{PD}_U \oplus \mathrm{PD}_V} & & \downarrow{\scriptstyle \mathrm{PD}_X} & & \downarrow{\scriptstyle \mathrm{PD}_{U\cap V}} & \\
\dots \to \mathrm{H}^{X,M}_{n-k}(U\cap V) & \xrightarrow{i\oplus -i} & \mathrm{H}^{X,M}_{n-k}(U)\oplus \mathrm{H}^{X,M}_{n-k}(V) & \xrightarrow{i+i} & \underbrace{\mathrm{H}^{X,M}_{n-k}(X)}_{=\mathrm{H}^{\mathrm{tw}}_{n-k}(X;M)} & \to & \mathrm{H}^{X,M}_{n-k-1}(U\cap V) & \to \dots
\end{array}$$

with the following properties:

(1) the first two squares commute, the third square commutes up to the sign $(-1)^{k+1}$,
(2) the lower exact sequence is the long exact Mayer–Vietoris sequence for $X = U \cup V$ that we constructed in the Mayer–Vietoris Theorem 169.7 for Internal Twisted Homology,
(3) the upper horizontal sequence is also exact.

The proof of Proposition 172.9 requires several preparations. The reader might want to put their finger on the fast-forward button. First of all we will need the following "inverted" Mayer–Vietoris Theorem, which is the twisted analogue of Theorem 119.22.

Theorem 172.10. (Inverted Mayer–Vietoris Theorem for Cohomology groups) Let X be a topological space that is locally contractible and path-connected, let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. Furthermore let A and B be open subsets of X.

(1) For every $n \in \mathbb{N}_0$ and every cochain $\varphi \in \mathrm{C}^n_{X,M}(X, A\cup B)$ there exist $\varphi_A \in \mathrm{C}^n_{X,M}(X, A)$ and $\varphi_B \in \mathrm{C}^n_{X,M}(X, B)$ such that $\varphi_A + \varphi_B = \varphi$.
(2) For all $n \in \mathbb{N}_0$ there exists a unique homomorphism

$$\delta\colon \mathrm{H}^n_{X,M}(X, A\cap B) \ \to\ \mathrm{H}^{n+1}_{X,M}(X, A\cup B)$$

which has the following property: for every $\varphi_A \in \mathrm{C}^n_{X,M}(X, A)$ and $\varphi_B \in \mathrm{C}^n_{X,M}(X, B)$ such that $\varphi_A + \varphi_B$ is a cocycle in $\mathrm{C}^n_{X,M}(X, A\cap B)$ we have

$$\delta([\varphi_A + \varphi_B]) \ =\ [\delta\varphi_A] \ \xleftarrow{\cong}\ -[\delta\varphi_B] \ \in \mathrm{H}^{n+1}_{X,M}(X, \{A, B\}) = \mathrm{H}^{n+1}_{X,M}(X, A\cup B).$$

(3) The sequence

$$\ldots \to \mathrm{H}^n_{X,M}(X, A\cup B) \xrightarrow{i^*\oplus -i^*} \mathrm{H}^n_{X,M}(X,A)\oplus \mathrm{H}^n_{X,M}(X,B) \xrightarrow{i^*\oplus i^*} \mathrm{H}^n_{X,M}(X, A\cap B) \xrightarrow{\delta} \mathrm{H}^{n+1}_{X,M}(X, A\cup B) \to \ldots$$

is exact.

Proof of Theorem 172.10. We start out with the following two observations:

(1) Similar to the discussion on page 3602 we set

$$\mathrm{C}^k_{X,M}(X,\{A,B\}) = \begin{array}{l}\text{all } \mathbb{Z}[\pi_1(X,x_0)]\text{-left homomorphisms } \mathrm{C}_k(\widetilde{X}_{x_0}) \to M \\ \qquad\text{that vanish on } \mathrm{C}_k(\widetilde{A}) \text{ and on } \mathrm{C}_k(\widetilde{B}).\end{array}$$

This is again a cochain complex and we denote the corresponding cohomology groups by $\mathrm{H}^k_{X,M}(X,\{A,B\})$. It follows easily from the Regular Covering-Chain Complex Lemma 167.2 together with Lemma 165.8 that the following sequence of cochain maps between cochain complexes is exact:

$$0 \to \mathrm{C}^*_{X,M}(X,\{A,B\}) \xrightarrow{i^*\oplus -i^*} \mathrm{C}^*_{X,M}(X,A)\oplus \mathrm{C}^*_{X,M}(X,B) \xrightarrow{i^*\oplus i^*} \mathrm{C}^*_{X,M}(X,A\cap B) \to 0.$$

(2) Since the subsets A and B are open we know from Proposition 169.2 (4) that the triad (X,A,B) is universally excisive. Therefore it follows from the argument of Lemma 171.4 that the obvious map $\mathrm{C}^*_{X,M}(X,A\cup B) \to \mathrm{C}^*_{X,M}(X,\{A,B\})$ induces for every $n\in\mathbb{N}_0$ an isomorphism $\mathrm{H}^n_{X,M}(X,A\cup B) \xrightarrow{\cong} \mathrm{H}^n_{X,M}(X,\{A,B\})$.

With these two observations it is straightforward to modify the proof of Theorem 78.5 to obtain the theorem. We leave it to the reader to fill in the details. ■

In the proof of Proposition 172.9 we will also need to recycle the following two technical lemmas.

Lemma 119.20. (Compact Subset Decomposition Lemma) Let X be a topological manifold and let U,V be open subsets such that $X = U\cup V$. Then given any compact subset $C\subset X$ there exist compact subsets $K\subset U$ and $L\subset V$ such that $C = K\cup L$.

Lemma 119.21. (Fundamental Cycle Decomposition Lemma) Let X be a compact oriented n-dimensional topological manifold and let U,V be open subsets such that $X = U\cup V$ and let $K\subset U$ and $L\subset V$ be compact subsets. Then there exist singular n-chains $\alpha_{U\setminus L}$, $\alpha_{U\cap V}$ and $\alpha_{V\setminus K}$ in $U\setminus L$, $U\cap V$ and $V\setminus K$ such that the following three equalities hold:

(a) $\mu^X_{K\cup L} = [\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}]$ in $\mathrm{H}_n(X, X\setminus(K\cup L))$

(b) $\mu^{U\cap V}_{K\cap L} = [\alpha_{U\cap V}]$ in $\mathrm{H}_n(U\cap V, U\cap V\setminus(K\cap L))$

(c) $\mu^U_K = [\alpha_{U\setminus L} + \alpha_{U\cap V}]$ in $\mathrm{H}_n(U, U\setminus K)$.

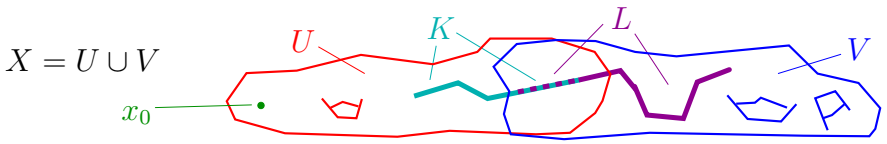
Proof of Proposition 172.9. Let X be an oriented path-connected n-dimensional topological manifold with $\partial X = \varnothing$. Let $x_0\in X$ and let M be a $\mathbb{Z}[\pi_1(X,x_0)]$-left module. We start with two preliminaries:

(1) Given any two subsets $A\subset B$ and $i\in\mathbb{N}_0$ we write $\mathrm{H}^i_{X,M}(B|A) := \mathrm{H}^i_{X,M}(B, B\setminus A)$.

(2) If U is an open subset of X and $K\subset U$ is compact, then, by the definition on page 3615, we obtain a map

$$-\cap_{\mathbb{Z}} \mu^U_K \colon \mathrm{H}^k_{X,M}(U|K) \to \mathrm{H}^{X,M}_{n-k}(U).$$

Now let let U and V be open subsets with $X = U \cup V$. Furthermore let $K \subset U$ and $L \subset V$ be compact subsets. We consider the following diagram



$$\begin{array}{ccccccccc}
.. \to \mathrm{H}^k_{X,M}(X|K\cap L) & \to & \mathrm{H}^k_{X,M}(X|K)\oplus \mathrm{H}^k_{X,M}(X|L) & \longrightarrow & \mathrm{H}^k_{X,M}(X|K\cup L) & \xrightarrow{\delta} & \mathrm{H}^{k+1}_{X,M}(X|K\cap L) & \to .. \\
\downarrow\cong & & \downarrow\cong & & & & \downarrow\cong & \\
\mathrm{H}^k_{X,M}(U\cap V|K\cap L) & & \mathrm{H}^k_{X,M}(U|K)\oplus \mathrm{H}^k_{X,M}(V|L) & & \downarrow\cap_{\mathbb{Z}}\mu^X_{K\cup L} & & \mathrm{H}^{k+1}_{X,M}(U\cap V|K\cap L) & \\
\downarrow\cap_{\mathbb{Z}}\mu^{U\cap V}_{K\cap L} & & \downarrow\cap_{\mathbb{Z}}\mu^U_K\oplus\cap_{\mathbb{Z}}\mu^V_L & & & & \downarrow\cap_{\mathbb{Z}}\mu^{U\cap V}_{K\cap L} & \\
.. \longrightarrow \mathrm{H}^{X,M}_{n-k}(U\cap V) & \longrightarrow & \mathrm{H}^{X,M}_{n-k}(U)\oplus \mathrm{H}^{X,M}_{n-k}(V) & \longrightarrow & \mathrm{H}^{X,M}_{n-k}(X) & \xrightarrow{\partial} & \mathrm{H}^{X,M}_{n-k-1}(U\cap V) & \longrightarrow ..
\end{array}$$

which we now explain in more detail:

(1) We write $A := X \setminus K$ and $B := X \setminus L$. The upper horizontal sequence is the inverted Mayer–Vietoris Sequence for cohomology groups from Theorem 172.10.
(2) The lower horizontal sequence is the long exact sequence coming from the Mayer–Vietoris Theorem 169.7 for Internal Twisted Homology, corresponding to the decomposition $X = U \cup V$.
(3) The vertical maps on the top are all induced by inclusions of pairs of topological spaces, they are isomorphisms by the Excision Theorem 169.6.

The following is the key claim of the proof.

Claim. The first two rectangles of the above diagram commute and the third rectangle commutes up to the sign $(-1)^{k+1}$.

Before we prove the claim we show that it implies the lemma. For each group appearing in the above diagram we take the direct limit over the directed set[2102]

$$\mathcal{K}(U,V) \;=\; \{(K,L) \mid K \text{ compact subset of } U \text{ and } L \text{ compact subset of } V\}$$

and we consider the induced maps of direct limits that were introduced on page 1753. We make the following remarks regarding this new diagram:

(1) Using the Cofinal-Isomorphism Lemma 111.4 one can show that the groups that we obtain taking the direct limit over $\mathcal{K}(U,V)$ are naturally isomorphic to the corresponding cohomology groups with compact support. We carry out the argument for two groups:

$$\varinjlim_{(K,L)\in\mathcal{K}(U,V)} \mathrm{H}^k_{X,M}(U\cap V|K\cap L) \;=\; \varinjlim_{C\in\mathcal{K}(U\cap V)} \mathrm{H}^k_{X,M}(U\cap V|C) \;=\; \mathrm{H}^k_{X,M,c}(U\cap V).$$

we apply the Cofinal-Isomorphism Lemma 111.4 to the cofinal morphism of directed sets given by $(K,L) \mapsto K \cap L$

and

[2102] We view $\mathcal{K}(U,V)$ as a directed set given by the relation $(K,L) \le (K',L')$ if $K \subset K'$ and $L \subset L'$. It is clear that each of the groups in the diagram forms a direct system with respect to this directed set.

$$\varinjlim_{(K,L)\in\mathcal{K}(U,V)} \mathrm{H}^k_{X,M}(X|K\cup L) \;=\; \varinjlim_{C\in\mathcal{K}(X)} \mathrm{H}^k_{X,M}(X|C) \;=\; \mathrm{H}^k_{X,M,c}(X).$$

we apply the Cofinal-Isomorphism Lemma 111.4 to the morphism of directed sets given by $(K,L)\mapsto K\cup L$, this morphism is cofinal by the Compact Subset Decomposition Lemma 119.20

All other cases are treated in a very similar fashion.

(2) By the functoriality of direct limits, and since the signs in the commutativity do not depend on K and L, the new diagram also commutes (up to the same signs).

(3) Using (2) and the definition of the "PD-maps" in Lemma 172.8 one can easily verify that the direct limit of the diagram does indeed give rise to the above diagram specified in the statement of the lemma.

(4) the Direct Limit-Exactness Proposition 79.2 says that the direct limit of exact sequences is again exact.

All these remarks put together show that the direct limit of the above diagram gives rise precisely to the diagram that we claimed exists and that all claimed statements are satisfied. This concludes the proof that the claim implies the lemma.

Proof. Now we turn to the actual proof of the claim. We show in three separate subclaims that the three rectangles commute. The proof of the first two subclaims consists of a clever usage of Proposition 171.13 (1b). The proof of the third subclaim is much more sophisticated since it relies on understanding the connecting homomorphisms in the Mayer-Vietoris sequences in (co-) homology.

Subclaim 1. The first rectangle of the diagram on page 3619 commutes.

So we need to show that the following diagram commutes:

$$\begin{array}{ccc}
\mathrm{H}^k_{X,M}(X, X\setminus(K\cap L)) & \xrightarrow{i\oplus -i} & \mathrm{H}^k_{X,M}(X, X\setminus K)\oplus \mathrm{H}^k_{X,M}(X, X\setminus L) \\
\downarrow\cong & \searrow^{i\oplus -i} & \downarrow\cong \\
\mathrm{H}^k_{X,M}(U\cap V, (U\cap V)\setminus(K\cap L)) & & \mathrm{H}^k_{X,M}(U, U\setminus K)\oplus \mathrm{H}^k_{X,M}(V, V\setminus L) \\
\downarrow\cap_{\mathbb{Z}}\mu^{U\cap V}_{K\cap L} & & \downarrow\cap_{\mathbb{Z}}\mu^{U}_{K}\oplus\cap_{\mathbb{Z}}\mu^{V}_{L} \\
\mathrm{H}^{X,M}_{n-k}(U\cap V) & \xrightarrow{i\oplus -i} & \mathrm{H}^{X,M}_{n-k}(U)\oplus \mathrm{H}^{X,M}_{n-k}(V).
\end{array}$$

Evidently the triangle commutes. We note that the remaining pentagon breaks up into the "direct sum" of two diagrams. By symmetry reasons it suffices to consider the left-hand summands. So let $\phi\in \mathrm{H}^k_{X,M}(X, X\setminus(K\cap L))$. We consider the following diagram of maps between pairs of topological spaces

$$\begin{array}{ccc}
(U\cap V, (U\cap V)\setminus(K\cap L)) & \xrightarrow{=:\alpha} & (U, U\setminus(K\cap L)) \\
\downarrow f\circ\alpha & \swarrow^{f} & \uparrow{\scriptstyle =:\beta} \\
(X, X\setminus(K\cap L)) & \xleftarrow[f\circ\beta]{} & (U, U\setminus K).
\end{array}$$

With this notation we need to show that

$$\alpha_*\big((f\circ\alpha)^*(\phi)\cap_{\mathbb{Z}}\mu^{U\cap V}_{K\cap L}\big) \;=\; (f\circ\beta)^*(\phi)\cap_{\mathbb{Z}}\mu^{U}_{K}.$$

But this is indeed the case, since

$$\begin{array}{ccccc}
\alpha_*\big(\underbrace{(f\circ\alpha)^*}_{=\alpha^*\circ f^*}(\phi)\cap_{\mathbb{Z}}\mu_{K\cap L}^{U\cap V}\big) & = & f^*(\phi)\cap_{\mathbb{Z}}\alpha_*(\mu_{K\cap L}^{U\cap V}) & = & f^*(\phi)\cap_{\mathbb{Z}}\mu_{K\cap L}^{U} \\
\uparrow & & \uparrow & & \uparrow \\
\text{Proposition 171.13 (1b)} & & \text{by Corollary 106.12 we have } \alpha_*(\mu_{K\cap L}^{U\cap V})=\mu_{K\cap L}^{U} & & \\
\beta_*\big((f\circ\beta)^*(\phi)\cap_{\mathbb{Z}}\mu_K^U\big) & = & (f\circ\beta)^*(\phi)\cap_{\mathbb{Z}}\mu_K^U & & \\
\uparrow & & \uparrow & & \\
\text{same argument backwards with the roles of } \alpha \text{ and } \beta \text{ exchanged} & & \text{since } \beta \text{ is on the first coordinate the identity} & &
\end{array}$$

This concludes the proof of the Subclaim 1.

Subclaim 2. The second rectangle of the diagram on page 3619 commutes.

The proof of that subclaim is very similar to the proof of the previous subclaim. Thus we leave it to the reader to fill in the details.

Subclaim 3. The third rectangle of the diagram on page 3619 commutes up to the sign $(-1)^{k+1}$.

As a reminder, we need to show that the following diagram commutes up to the sign $(-1)^{k+1}$:

$$\begin{array}{ccccc}
\mathrm{H}^k_{X,M}(X, X\setminus K\cup L) & \xrightarrow{\delta} & \mathrm{H}^{k+1}_{X,M}(X, X\setminus(K\cap L)) & \xrightarrow{\cong} & \mathrm{H}^{k+1}_{X,M}(U\cap V, (U\cap V)\setminus(K\cap L)) \\
\downarrow{\scriptstyle \cap_{\mathbb{Z}}\mu_{K\cup L}} & & & & \downarrow{\scriptstyle \cap_{\mathbb{Z}}\mu_{K\cap L}} \\
\mathrm{H}^{X,M}_{n-k}(X) & & \xrightarrow{\qquad\qquad\partial\qquad\qquad} & & \mathrm{H}^{X,M}_{n-k-1}(U\cap V).
\end{array}$$

So let $[\varphi]\in \mathrm{H}^k_{X,M}(X, X\setminus(K\cup L)) = \mathrm{H}^k_{X,M}(X, A\cap B)$. We start out with the following preparations:

(1) By Theorem 172.10 (1) we can find $\varphi_A\in \mathrm{C}^k_{X,M}(X,A)$ and $\varphi_B\in \mathrm{C}^k_{X,M}(X,B)$ such that $\varphi=\varphi_A+\varphi_B$.
(2) By the Fundamental Cycle Decomposition Lemma 119.21 there exist singular chains $\alpha_{U\setminus L}$, $\alpha_{U\cap V}$ and $\alpha_{V\setminus K}$ in $U\setminus L$, $U\cap V$ and $V\setminus K$ such that the following three equalities hold:

$$\begin{array}{lrcll}
\text{(2a)} & \mu_{K\cup L} & = & [\alpha_{U\setminus L}+\alpha_{U\cap V}+\alpha_{V\setminus K}] & \text{in } \mathrm{H}_n(X, X\setminus(K\cup L)) \\
\text{(2b)} & \mu_{K\cap L}^{U\cap V} & = & [\alpha_{U\cap V}] & \text{in } \mathrm{H}_n(U\cap V, (U\cap V)\setminus(K\cap L)) \\
\text{(2c)} & \mu_K^U & = & [\alpha_{U\setminus L}+\alpha_{U\cap V}] & \text{in } \mathrm{H}_n(U, U\setminus K).
\end{array}$$

After these preparations we obtain the following equalities in $\mathrm{H}^{X,M}_{n-k-1}(U \cap V)$:[2103]

$$\begin{array}{ccccc}
\text{maps in the rectangle applied clockwise} & & \overset{\text{Theorem 172.10 and (2b)}}{\overset{\downarrow}{=}} & & [\delta\varphi_A \cap_{\mathbb{Z}} \alpha_{U\cap V}] \\
\text{to some } [\varphi] \in \mathrm{H}^k_{X,M}(M, M\setminus(K\cup L)) & & & & \\
= & [\varphi_A \cap_{\mathbb{Z}} \partial\alpha_{U\cap V}] & = & [\varphi_A \cap_{\mathbb{Z}} \partial\alpha_{U\cap V} - \underbrace{\varphi_A \cap_{\mathbb{Z}} \partial(\alpha_{U\cap V} + \alpha_{U\setminus L})}_{=0}] & = [-\varphi_A \cap_{\mathbb{Z}} \partial\alpha_{U\setminus L}] \\
& \uparrow & & \uparrow & \\
& \text{Lemma 171.9} & & \text{note that (2c) implies that } \partial(\alpha_{U\cap V}+\alpha_{U\setminus L}) \text{ is a singular chain in } U\setminus K, & \\
& & & \text{but } \varphi_A \text{ vanishes on singular chains in } A = X\setminus K & \\
= & [-\varphi_A \cap_{\mathbb{Z}} \partial\alpha_{U\setminus L} - \underbrace{\varphi_B \cap_{\mathbb{Z}} \partial\alpha_{U\setminus L}}_{=0}] & = & [-(\varphi_A+\varphi_B) \cap_{\mathbb{Z}} \partial\alpha_{U\setminus L}] & = [-\varphi \cap_{\mathbb{Z}} \partial\alpha_{U\setminus L}] \\
\uparrow & & & & \uparrow \\
\text{since } \varphi_B \text{ vanishes on singular chains in } B = X\setminus L & & & & \text{since } \varphi = \varphi_A + \varphi_B \\
= & [(-1)^{k+1} \cdot \partial(\varphi \cap_{\mathbb{Z}} \alpha_{U\setminus L})] & = & (-1)^{k+1} \cdot \partial[\underbrace{(\varphi \cap_{\mathbb{Z}} \alpha_{U\setminus L})}_{\in \mathrm{C}_{n-k}(U)} + \underbrace{(\varphi \cap_{\mathbb{Z}} \alpha_{U\cap V} + \varphi \cap_{\mathbb{Z}} \alpha_{V\setminus K})}_{\in \mathrm{C}_{n-k}(V)}] & \\
\uparrow & & \uparrow & & \\
\text{by Lemma 171.9 and since } \delta\varphi = 0 & & \text{by the definition of the connecting homomorphism } \partial \text{ in the Mayer–Vietoris sequence, see Theorem 169.7} & & \\
= & (-1)^{k+1} \cdot \partial\big([\varphi] \cap \mu^X_{K\cup L}\big) = (-1)^{k+1} \cdot & \text{maps in the rectangle applied counterclockwise to } [\varphi]. & & \\
\uparrow & & & & \\
\text{by equality (2a)} & & & &
\end{array}$$

This concludes the proof of Subclaim 3, thus of the claim and thus also of the lemma. ■

Now we turn to the actual proof of Theorem 172.5.

Proof of Theorem 172.5. We fix a dimension n. Throughout this proof by a "manifold" we mean a path-connected oriented n-dimensional topological manifold without boundary.

We introduce two closely related notions.

(1) We say *Poincaré Duality holds for a manifold* X if for each $x_0 \in X$, each $\mathbb{Z}[\pi_1(X, x_0)]$-left module M and for each $k \in \mathbb{N}_0$ the following map is an isomorphism:

$$\mathrm{PD}_X \colon \mathrm{H}^k_{\mathrm{tw},c}(X; M) \to \mathrm{H}^{\mathrm{tw}}_{n-k}(X; M).$$

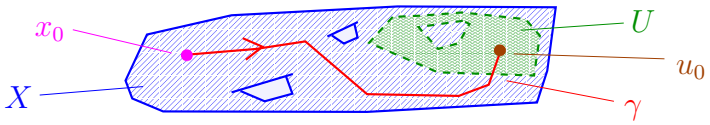
(2) Let X be a manifold and let $U \subset X$ be an open subset. We say *Internal Poincaré Duality holds for* U *within* X if for each $x_0 \in X$, each $\mathbb{Z}[\pi_1(X, x_0)]$-left module M and for each $k \in \mathbb{N}_0$ the following map is an isomorphism:

$$\mathrm{PD}_U \colon \mathrm{H}^k_{X,M,c}(U) \to \mathrm{H}^{X,M}_{n-k}(U).$$

Our goal is to show that Poincaré Duality holds for all manifolds. We try to follow the logic of the proof of Theorem 172.5. But now we need an extra initial claim.

Claim 0. Let X be a manifold and let $U \subset X$ be an open subset. If each path-component of U, viewed as a manifold in its own right, satisfies Poincaré Duality, then U satisfies Internal Poincaré Duality within X.

Proof. Let X be a path-connected manifold.



(1) First let $U \subset X$ be a path-connected open subset that, if viewed as n-dimensional topological manifold in its own right, satisfies Poincaré Duality. We need to show

[2103] The maps δ and ∂ written in blue are the connecting homomorphisms in the Mayer–Vietoris sequences coming from Theorem 169.7 and Theorem 172.10.

that U also satisfies Internal Poincaré Duality within X. Let $x_0 \in X$. We pick $u_0 \in U$. Since X is path-connected there exists a path $\gamma\colon [0,1] \to X$ from x_0 to u_0. We denote by $i\colon U \to X$ the inclusion. We consider the following diagram:

$$\begin{array}{ccccc}
\mathrm{H}^k_{\mathrm{tw},c}(U; i^*\gamma_* M) & \xleftarrow[\cong]{\Omega^X_U} & \mathrm{H}^k_{X,\gamma_* M,c}(U) & \xrightarrow[\cong]{\gamma_*} & \mathrm{H}^k_{X,M,c}(U) \\
\cong\downarrow \mathrm{PD}_U & & \downarrow \mathrm{PD}_U & & \downarrow \mathrm{PD}_U \\
\mathrm{H}^{\mathrm{tw}}_{n-k}(U; i^*\gamma_* M) & \xrightarrow[\cong]{\Omega^X_U} & \mathrm{H}^{X,\gamma_* M}_{n-k}(U) & \xrightarrow[\cong]{\gamma_*} & \mathrm{H}^{X,M}_{n-k}(U).
\end{array}$$

Here the horizontal maps to the left are given by Lemma 172.7. The horizontal maps to the right are isomorphisms that are defined as in the Change of Base Point Proposition II 169.5. It follows easily from Lemma 172.7 (2) that the square to the left commutes. Furthermore it is straightforward to verify that the square to the right commutes. By hypothesis the vertical map to the left is an isomorphism. It follows from the above that the vertical map to the right is also an isomorphism.

(2) Now suppose that U has path-components $U_1, \ldots, U_k$ such that each U_i satisfies Poincaré Duality viewed as a manifold. By (1) we know that each U_i also satisfies Internal Poincaré Duality within X. As in the Cup-Cap Disjoint Union Lemma 116.9 one can show easily, using Lemma 169.3, that $U_1 \cup \cdots \cup U_k$ also satisfies Internal Poincaré Duality within X. ⊞

Claim 1. Let X be a manifold.

(A) If Poincaré Duality holds for X equipped with an orientation, then it also holds for any other orientation of X.

(B) If X is homeomorphic to a manifold for which Poincaré Duality holds, then Poincaré Duality also holds for X.

(C) Suppose that X is the union of two open subsets U and V. If Poincaré Duality holds for each path-component of U, V and $U \cap V$, then it also holds for X.

(D) If X is the union of a nested sequence $U_1 \subset U_2 \subset \ldots$ of open subsets such that Poincaré Duality holds for each path-component of U_i, then it also holds for X.

Proof. So let X be a manifold.

(A) Recall that by our convention in this proof every manifold is path-connected. By Lemma 105.10 the oriented path-connected manifold X admits only one other orientation, namely the reverse orientation $-X$. It follows from that $[-X] = -[X]$ that Poincaré Duality also holds for $-X$.

(B) If we have an orientation-preserving homeomorphism, then this statement follows immediately from the Proposition 171.8. For a non-orientation-preserving homeomorphism this statement follows from (A).

(C) We suppose that Poincaré Duality holds for each path-component of U, V and $U \cap V$. It follows from Claim 0 that Internal Poincaré Duality holds for U, V and $U \cap V$ within X. The combination of Proposition 172.9 and the Five Lemma 74.10 now

shows that also each PD_X is an isomorphism, i.e. Poincaré Duality also holds for $X = U \cup V$.

(D) Let $k \in \mathbb{N}_0$. We suppose that each path-component of each $U_i \subset X$ satisfies Poincaré Duality. We need to show that X also satisfies Poincaré Duality. Let $x_0 \in X$ and let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. By hypothesis and Claim 0 we know that for every $i \in \mathbb{N}$ the map $\mathrm{PD}_{U_i} \colon \mathrm{H}^k_{X,M,\mathrm{c}}(U_i) \to \mathrm{H}^{X,M}_{n-k}(U_i)$ is an isomorphism. Using the pretty obvious variation on Proposition 171.13 and using Lemma 172.8 it is straightforward to verify that for any $i \leq j$ the following diagram commutes:

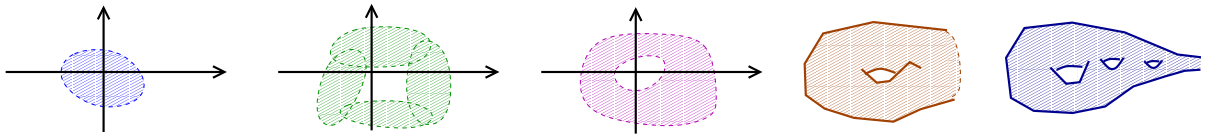
$$\begin{array}{ccc} \mathrm{H}^k_{X,M,c}(U_i) & \xrightarrow{\mathrm{PD}_{U_i}} & \mathrm{H}^{X,M}_{n-k}(U_i) \\ \downarrow & & \downarrow \\ \mathrm{H}^k_{X,M,c}(U_j) & \xrightarrow{\mathrm{PD}_{U_j}} & \mathrm{H}^{X,M}_{n-k}(U_j). \end{array}$$

We obtain isomorphisms

$$\overbrace{\mathrm{H}^k_{X,M,\mathrm{c}}(X)}^{=\mathrm{H}^k_{\mathrm{tw},c}(X;M)} \underset{\uparrow}{=} \varinjlim \mathrm{H}^k_{X,M,\mathrm{c}}(U_i) \underset{\uparrow}{\xrightarrow{\varinjlim \mathrm{PD}_{U_i}}} \varinjlim \mathrm{H}^{X,M}_{n-k}(U_i) \underset{\uparrow}{=} \overbrace{\mathrm{H}^{X,M}_{n-k}(X).}^{=\mathrm{H}^{\mathrm{tw}}_{n-k}(X;M)}$$

by a straightforward generalization of Exhaustion-H^*_c-Proposition 112.6

isomorphism by our hypothesis and since the above diagram commutes



by a straightforward generalization of the Homology-via-Exhaustions Proposition 79.4

We leave it to the reader to verify that the map from left to right is indeed given by PD_X. ⊞

The following claim completes the proof of the theorem.

Claim 2.

(A) Poincaré Duality holds for every open bounded convex subset of $\mathbb{R}^n$.
(B) For every $m \in \mathbb{N}$ Poincaré Duality holds for every path-connected sum of $\mathbb{R}^n$ that is the union of m open bounded convex subsets of $\mathbb{R}^n$.
(C) Poincaré Duality holds for every path-connected open subset of $\mathbb{R}^n$.
(D) For every $m \in \mathbb{N}$ Poincaré Duality holds for all manifolds that admit an atlas with m charts.
(E) Poincaré Duality holds for all manifolds.

Proof. [2104]

(1) Let X be an open bounded convex subset of $\mathbb{R}^n$. If X is empty, then there is nothing to show. Now assume that X is non-empty. By the Convex-to-Ball Proposition 2.20

[2104] The proof is basically the same as the proof of Claim 2 on page 2638 of the untwisted case.

(1) there exists a homeomorphism $X \to B^n$. It follows from Lemma 172.6 and Claim 1 (B) that Poincaré Duality also holds for X.

(2) We prove the claim by induction on m. By (A) we know that the statement holds for $m = 1$. Now suppose it holds for all path-connected subsets of $\mathbb{R}^n$ that are unions of $m-1$ open bounded convex subsets of $\mathbb{R}^n$. Let X be a path-connected subset of $\mathbb{R}^n$ that is the union of m open bounded convex subsets $U_1, \ldots, U_m$. We set $V = U_1 \cup \cdots \cup U_{m-1}$. By our hypothesis and by induction the statement holds for U_m, for V and also for each path-component of $V \cap U_m = (U_1 \cap U_m) \cup \cdots \cup (U_{m-1} \cap U_m)$, since each path-component is the union of $(m-1)$ open bounded convex subsets. It follows from Claim 1 (C) that Poincaré Duality also holds for

$$X \;=\; V \cup U_m \;=\; (U_1 \cup \cdots \cup U_{m-1}) \cup U_m.$$

(3) Let X be an arbitrary path-connected open subset of $\mathbb{R}^n$. By the Rational Open Balls Lemma 118.4 we can write X as the union of countably many open balls $B_i, i \in \mathbb{N}$. For $i \in \mathbb{N}$ we set $U_i := \bigcup_{j \le i} B_j$. Each path-component of any U_i is evidently also the union of finitely many open balls. Thus we obtain from (B) that Poincaré Duality holds for each path-component of each $U_i \in \mathbb{N}$. But then it follows from Claim 1 (D) that Poincaré Duality also holds for X.

(4) We prove this statement by induction on m. The case $m = 1$ is taken care of by (C) and Claim 1 (B). Now suppose Poincaré Duality holds for all manifolds that admit an atlas with $m-1$ charts. Let X be a manifold that admits an atlas $\{\phi_i \colon U_i \to V_i\}_{i=1,\ldots,m}$ with m charts. We write $U = U_1 \cup \cdots \cup U_{m-1}$ and $V = U_m$. Both are open subsets of a manifold. Note that U and V admit an atlas with $m-1$ charts respectively one chart. Similarly $U \cap V = (U_1 \cap U_m) \cup \cdots \cup (U_{m-1} \cap U_m)$ admits an atlas with $m-1$ charts. It follows easily from induction that Poincaré Duality holds for each path-component of U, V and $U \cap V$. Thus it follows from Claim 1 (C) that Poincaré Duality also holds for X itself.

(5) Finally let X be any manifold. By the Countable Covering Lemma 9.2 we know that X admits a countable atlas $\{\Phi_j \colon U_j \to V_j\}_{j \in \mathbb{N}}$. For $i \in \mathbb{N}$ we set $X_i := \bigcup_{j \le i} U_j$. It follows easily from (D) that Poincaré Duality holds for each path-component of each X_i. It follows from Claim 1 (D) that Poincaré Duality also holds for X. ∎

172.3. **The proof of Poincaré Duality for topological manifolds with boundary.** Now we will finally prove the general statement of the Poincaré Duality Theorem 172.1. For the reader's convenience we recall the statement.

Theorem 172.1. (Poincaré Duality Theorem with Twisted Coefficients) Let X be a compact oriented path-connected n-dimensional topological manifold and let $x_0 \in X$. We denote by $[X] \in \mathrm{H}_n(X, \partial X)$ the fundamental class. Furthermore suppose that we are given a decomposition $\partial X = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂X such that $A \cap B = \partial A = \partial B$. For each $k \in \mathbb{N}_0$ and every $\mathbb{Z}[\pi_1(X, x_0)]$-left module M the map

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X, A; M) & \xrightarrow{\cong} & \mathrm{H}^{\mathrm{tw}}_{n-k}(X, B; M) \\ \sigma & \mapsto & \sigma \cap_{\mathbb{Z}} [X] \end{array}$$

is an isomorphism.

In the following we will prove the Poincaré Duality Theorem 172.1 using Theorem 172.5 and formal arguments that have basically nothing to do with twisted coefficients. The proofs below are very very similar to the arguments for the untwisted case that we provided in Section 119.4. For peace of mind let us nonetheless go through the arguments.

Proof of Theorem 172.1 for $A = \partial X$ and $B = \varnothing$. Let X be a compact oriented path-connected n-dimensional topological manifold and let $x_0 \in X$. As usual we denote by $[X] \in \mathrm{H}_n(X, \partial X)$ the fundamental class. Let M be a $\mathbb{Z}[\pi_1(X, x_0)]$-left module. We want to show that for each $k \in \mathbb{N}_0$ the map

$$- \cap_{\mathbb{Z}} [X] \colon \mathrm{H}^k_{\mathrm{tw}}(X, \partial X; M) \ \to \ \mathrm{H}^{\mathrm{tw}}_{n-k}(X; M)$$

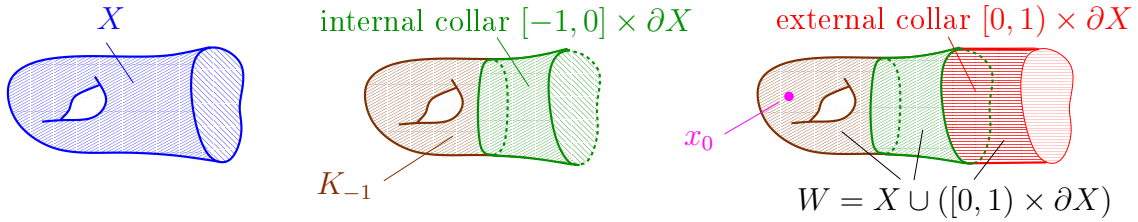
is an isomorphism. To do so we first introduce the following objects:

(a) From the Topological Collar Neighborhood Theorem 75.5 we obtain a collar neighborhood $[-1, 0] \times \partial X$ of $\partial X = \{0\} \times X$. We refer to it as the "internal collar".

(b) We define

$$W \ := \ X \cup ([0, 1) \times \partial X)/\sim \qquad \text{with } x \sim (x, 0) \text{ for every } x \in \partial X.$$

Sometimes $[0, 1) \times \partial X$ is called an *external collar of* X. Furthermore, given any $t \in [-1, 1)$ we write



$$K_t \ := \ (X \setminus ([-1, 0] \times \partial X)) \cup ([-1, t] \times \partial X)/\sim .$$

(c) We denote by $i \colon X \to W$ the obvious map. By the Topological Pushout-Maps Lemma 5.34 (3) and (4) this map is a closed embedding. We will use this to view X as a closed subset of W. Note that it follows easily from the Homotopy Pushout Lemma 14.9 that $X = i(X)$ is a deformation retract of W.

(d) We denote by $i \colon (X, \partial X) \to (W, W \setminus K_{-1})$ the inclusion map.

(e) We equip W with the base point x_0.

(f) By the Homotopy-π_1-Proposition 50.3 we know that $i_* \colon \pi_1(X, x_0) \to \pi_1(W, x_0)$ is an isomorphism. This allows us to consider the $\mathbb{Z}[\pi_1(W, x_0)]$-left module $(i_*)^{-1}M$.

By elementary arguments and using the Topological Manifold Boundary Proposition 75.2 (1) one can easily show the following statements:

(A) W is an n-dimensional topological manifold with empty boundary.

(B) W admits an orientation such that X is a submanifold and such that $X \to W$ is orientation-preserving.

(C) Every K_t is a compact subset of W and given any compact subset K of W there exists a $t \in [-1, 1)$ with $K \subset K_t$.

We obtain the following diagram:

$$\begin{array}{ccccc} \mathrm{H}^k_{\mathrm{tw}}(X,\partial X;M) & \xleftarrow{i^*} & \mathrm{H}^k_{\mathrm{tw}}(W,W\setminus K_{-1};(i_*)^{-1}M) & \longrightarrow & \mathrm{H}^k_{\mathrm{tw,c}}(W;(i_*)^{-1}M) \\ \downarrow{\scriptstyle \cap_{\mathbb{Z}}[X]} & & \downarrow{\scriptstyle \cap_{\mathbb{Z}}\mu_{K_t}} & & \downarrow{\scriptstyle \mathrm{PD}_W} \\ \mathrm{H}^{\mathrm{tw}}_{n-k}(X;M) & \xrightarrow{i_*} & \mathrm{H}^{\mathrm{tw}}_{n-k}(W;(i_*)^{-1}M) & \xrightarrow{\mathrm{id}} & \mathrm{H}^{\mathrm{tw}}_{n-k}(W;(i_*)^{-1}M). \end{array}$$

It remains to prove the following claim.

Claim. The following three statements hold:

(1) the diagram commutes,
(2) the right vertical map is an isomorphism, and
(3) all horizontal maps are isomorphisms.

Proof.

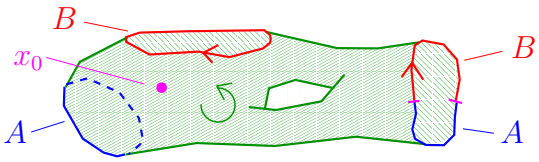
(1) The right-hand square commutes by definition of PD_W. Using (B) one can show easily, using Proposition 171.13, that the left-hand square commutes.
(2) Theorem 172.5 implies that the right vertical map is an isomorphism.
(3) It follows easily from the discussion in (c) together with the Deformation Retract-Twisted Homology Corollary 167.16 that the left horizontal maps are isomorphisms. Since the bottom right map is the identity it remains to show that the top right horizontal map is an isomorphism. We consider the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(W,W\setminus K_{-1};(i_*)^{-1}M) & \longrightarrow & \overbrace{\varinjlim_{K\in\mathcal{K}(W)} \mathrm{H}^k_{\mathrm{tw}}(W,W\setminus K;(i_*)^{-1}M)}^{=\mathrm{H}^k_{\mathrm{tw,c}}(W;(i_*)^{-1}M)}. \\ & \searrow \quad \nearrow & \\ & \varinjlim_{t\in[-1,1)} \mathrm{H}^k_{\mathrm{tw}}(W,W\setminus K_t;(i_*)^{-1}M) & \end{array}$$

We make the following two observations:

- By (C) every compact subset of W is contained in some K_t. Therefore it follows from the Limit-over-Subset Lemma 111.3 that the right diagonal map is an isomorphism.
- It follows easily from the Homotopy Equivalence-H_*-Proposition 167.15 (2) and Lemma 111.2 (4) that the left diagonal map is an isomorphism.

These two observations together imply that the horizontal map is also an isomorphism.



This concludes the proof of the claim and it concludes the proof of the Poincaré Duality Theorem 172.1 in the special case that $A = \partial X$ and $B = \varnothing$. ∎

Proof of Theorem 172.1 for the general case. Let X be a compact oriented path-connected n-dimensional topological manifold and let $x_0 \in X$. As always we denote by $[X] \in \mathrm{H}_n(X,\partial X)$ the fundamental class. Let M be a $\mathbb{Z}[\pi_1(X,x_0)]$-left module M. Finally suppose that we are given a decomposition $\partial X = A \cup B$ where A and B are compact

$(n-1)$-dimensional submanifolds of ∂X such that $A \cap B = \partial A = \partial B$. We want to show that for each $k \in \mathbb{N}_0$ the map

$$\cap_{\mathbb{Z}}[X] \colon \mathrm{H}^k_{\mathrm{tw}}(X, A; M) \;\to\; \mathrm{H}^{\mathrm{tw}}_{n-k}(X, B; M)$$

is an isomorphism.

We equip ∂X and then also B with the orientations coming from the Topological Manifold-Boundary Orientation Proposition 105.19 and the Topological Manifold-Induced Orientation Lemma 105.17. As before we work again with internal twisted (co-) homology. We consider the following diagram:

$$\begin{array}{ccccccccc}
\dots & \longrightarrow & \mathrm{H}^k_{X,M}(X, \partial X) & \longrightarrow & \overbrace{\mathrm{H}^k_{X,M}(X, A)}^{=\mathrm{H}^k_{\mathrm{tw}}(X,A;M)} & \longrightarrow & \mathrm{H}^k_{X,M}(\partial X, A) & \xrightarrow{\delta} & \mathrm{H}^{k+1}_{X,M}(X, \partial X) \longrightarrow \dots \\
 & & \cong \downarrow -\cap_{\mathbb{Z}}[X] & & \downarrow -\cap_{\mathbb{Z}}[X] & & \cong \downarrow i^* & & \cong \downarrow -\cap_{\mathbb{Z}}[X] \\
 & & & & & & \mathrm{H}^k_{X,M}(B, \partial B) & & \\
 & & & & & & \cong \downarrow -\cap_{\mathbb{Z}}[B] & & \\
\dots & \longrightarrow & \mathrm{H}^{X,M}_{n-k}(X) & \longrightarrow & \underbrace{\mathrm{H}^{X,M}_{n-k}(X, B)}_{=\mathrm{H}^{\mathrm{tw}}_{n-k}(X,B;M)} & \xrightarrow{\partial} & \mathrm{H}^{X,M}_{n-k-1}(B) & \longrightarrow & \mathrm{H}^{X,M}_{n-k-1}(X) \longrightarrow \dots
\end{array}$$

We make the following observations:

(1) The top and bottom horizontal sequences are the long exact sequence in internal (co-) homology with twisted coefficients of the triple $(X, \partial X, A)$ and the pair (X, B), that we implicitly constructed in the proof of Proposition 167.11.
(2) The above vertical map $i^* \colon \mathrm{H}^k_{X,M}(\partial X, A) \to \mathrm{H}^k_{X,M}(B, \partial B)$ is induced by the inclusion $i \colon (B, \partial B) \to (\partial X, A)$. It is an isomorphism by Proposition 169.2 (5) together with the obvious twisted version of the Excisive Characterization Lemma 109.13 (3).
(3) The other maps decorated with "$\cong$" are isomorphisms by the special case of the Poincaré Duality Theorem 172.1 that we have already dealt with.

By the Five Lemma 74.10 it remains to prove the following claim.

Claim. The above diagram commutes up to signs, more precisely:
(1) the first rectangle commutes,
(2) the second rectangle commutes up to the sign $(-1)^k$,
(3) the third rectangle commutes.

Proof. We consider the three rectangles separately.

(1) We consider the following diagram:

$$\begin{array}{ccc}
\mathrm{H}^k_{X,M}(X,\partial X)\times \mathrm{H}_n(X,\partial X) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{X,M}_{n-k}(X) \\
{\scriptstyle =}\uparrow \quad \downarrow{\scriptstyle =} & & \downarrow \\
\mathrm{H}^k_{X,M}(X,\partial X)\times \mathrm{H}^{X,M}_n(X,\partial X) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}_{n-k}(X,B) \\
\downarrow \quad \uparrow{\scriptstyle =} & & {\scriptstyle =}\uparrow \\
\mathrm{H}^k_{X,M}(X,A)\times \mathrm{H}^{X,M}_n(X,\partial X) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}_{n-k}(X,B).
\end{array}$$

We can convince ourselves that the diagram commutes by applying Proposition 171.13 (1b) to the maps $(X,\partial X,\varnothing)\to(X,\partial X,B)$ and $(X,A,B)\to(X,\partial X,B)$ of universally excisive triads. It follows easily from this observation that the first rectangle of the claim commutes.

Before we continue with the discussion of the other two rectangles we need to make one remark. We denote by $j\colon (B,\partial B)\to(\partial X,A)$ the inclusion map and we denote by $\partial\colon \mathrm{H}_n(X,\partial X)\to \mathrm{H}_{n-1}(\partial X,A)$ the connecting homomorphism in the long exact sequence of the triple $(X,\partial X,A)$. It follows from the Fundamental Class-of-Boundary Proposition 106.27 (1), the Codimension Zero-Fundamental Class Lemma 106.24 and the remark on page 1629 that the following equality holds

$$(*)\qquad\qquad j_*([B]) \;=\; \partial[X]\in \mathrm{H}_{n-1}(\partial X,A).$$

Now we continue with the proof of the claim.

(2) We apply the twisted analogue of the Cap Product-Connecting Homomorphism Lemma 116.10 (2) to the universally excisive triad (X,A,B). (Recall that $A\cup B=\partial X$ and $A\cap B=\partial B$.) We obtain that for any $k\in\mathbb{N}_0$ the following diagram commutes up to the sign $(-1)^k$:

$$\begin{array}{ccc}
\mathrm{H}^k_{X,M}(X,A)\times \mathrm{H}_n(X,\partial X) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{X,M}_{n-k}(X,B) \\
{\scriptstyle i^*}\downarrow \quad \partial\downarrow & & \\
\mathrm{H}^k_{X,M}(\partial X,A)\times \mathrm{H}_{n-1}(\partial X,A) & & \Big\downarrow{\scriptstyle \partial} \\
{\scriptstyle j^*}\downarrow{\scriptstyle \cong} \quad {\scriptstyle (j_*)^{-1}}\downarrow{\scriptstyle \cong} & & \\
\mathrm{H}^k_{X,M}(B,\partial B)\times \mathrm{H}_{n-1}(B,\partial B) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{X,M}_{n-k-1}(B).
\end{array}$$

Together with $(*)$ we obtain that the second rectangle of the claim does indeed commute up to the sign $(-1)^k$.

(3) We consider the following diagram:

$$\begin{array}{ccc}
\mathrm{H}^k_{X,M}(B,\partial B)\times \mathrm{H}_{n-1}(B,\partial B) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{X,M}_{n-k-1}(B) \\
{\scriptstyle i^*}\uparrow \quad \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle i_*} \\
\mathrm{H}^k_{X,M}(\partial X,A)\times \mathrm{H}_{n-1}(\partial X,A) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{X,M}_{n-k-1}(\partial X) \\
{\scriptstyle \delta}\downarrow \quad \uparrow{\scriptstyle \partial} & & \downarrow{\scriptstyle i_*} \\
\mathrm{H}^{k+1}_{X,M}(X,\partial X)\times \mathrm{H}_n(X,\partial X) & \xrightarrow{\cap_{\mathbb{Z}}} & \mathrm{H}^{X,M}_{n-k-1}(X).
\end{array}$$

The upper part of this diagram commutes by Proposition 171.13 (1b) applied to the map $(B, \partial B, \varnothing) \to (\partial X, A, \varnothing)$ between excisive triads. The lower part commutes by the twisted analogue of the Cap Product-Connecting Homomorphism Lemma 116.10 (1) applied to the triple $(X, \partial X, A)$. This discussion, together with $(*)$, implies that the third rectangle of the diagram in the claim commutes.

This concludes the proof of the claim and thus also of the Poincaré Duality Theorem 172.1. ■

Exercises for Chapter 172.

Exercise 172.1. Let Σ_g be the surface of genus g and let $x_0 \in X$. Furthermore let $\varphi\colon \pi_1(\Sigma_g, x_0) \to \mathrm{GL}(1, \mathbb{C})$ be a one-dimensional non-trivial representation. Use the Poincaré Duality Theorem with Twisted Coefficients 172.1 together with Propositions 168.1 and 170.4 to calculate the twisted homology modules $\mathrm{H}_k^{\mathrm{tw}}(\Sigma_g; {}_\varphi\mathbb{C}) \cong \mathbb{C}^{k-1}$ in a pain-free way.

173. Twisted intersection pairings

We continue our discussion of twisted invariants. In this chapter we introduce and discuss the twisted intersection pairings, which is the twisted cousin of the intersection pairings that we introduced on page 2895.

173.1. **Definition of twisted intersection pairings.** Before we turn to topology it is worth introducing some algebraic notions which are generalizations and analogues of the concepts introduced on page 2656.

Definition.

(1) Let V, W, Z be abelian groups. We refer to any homomorphism $V \otimes_{\mathbb{Z}} W \to Z$ of abelian groups as a pairing.

(2) Let G be a group, let V, W be two $\mathbb{Z}[G]$-left modules and let Z be an abelian group. We say a pairing $\varphi\colon V \otimes_{\mathbb{Z}} W \to Z$ is preserved by the G-action if φ is a homomorphism of $\mathbb{Z}[G]$-left modules where we equip $V \otimes_{\mathbb{Z}} W$ with the $\mathbb{Z}[G]$-left module structure from Lemma 171.2 and where we equip Z with the trivial $\mathbb{Z}[G]$-left module structure.

Now let R be a ring with (possibly trivial) involution, let V and W be R-left modules and let $\varphi\colon V \otimes_{\mathbb{Z}} W \to R$ be a pairing. We equip $V \otimes_{\mathbb{Z}} W$ with the $R \otimes_{\mathbb{Z}} R$-left module structure from Lemma 171.2.

(3) The pairing φ is called R-sesquilinear if $\varphi\colon V \otimes_{\mathbb{Z}} W \to R$ is a $R \otimes_{\mathbb{Z}} R$-left module homomorphism where we equip R with the $R \otimes_{\mathbb{Z}} R$-left module structure given by $(r \otimes s) \cdot t := r \cdot t \cdot \overline{s}$.

(4) Let $\varphi\colon V \otimes_{\mathbb{Z}} V \to R$ be an R-sesquilinear pairing.

(a) We say that φ is hermitian if $\varphi(v \otimes w) = \overline{\varphi(w \otimes v)}$ for all $v, w \in V$.

(b) We say that φ is anti-hermitian if $\varphi(v \otimes w) = -\overline{\varphi(w \otimes v)}$ for all $v, w \in V$.

If the involution is trivial, then usually we say R-bilinear instead of R-sesquilinear and we say (anti-) symmetric instead of (anti-) hermitian.

For readers who would rather avoid tensor products we have the following definition.

Definition. Let V and W be abelian groups and let Z be an abelian group. We say a map $\varphi\colon V \times W \to Z$ is a pairing if the map

$$\begin{array}{rcl} \varphi\colon V \otimes_{\mathbb{Z}} W & \to & Z \\ \sum_{i=1}^{k} v_i \otimes w_i & \mapsto & \sum_{i=1}^{k} \varphi(v_i, w_i) \end{array}$$

is well-defined and if it is a pairing.[2105] Using this definition one can translate the above notions into arguably more familiar language. For example if G is a group and V and W are two $\mathbb{Z}[G]$-left modules, then a pairing $\varphi\colon V \times W \to Z$ is preserved by the G-action precisely if for all $v \in V, w \in W$ and $g \in G$ we have $\varphi(g \cdot v, g \cdot w) = \varphi(v, w)$.

We also recall the following definition that we made in the Twisted H_0-Proposition 168.1.

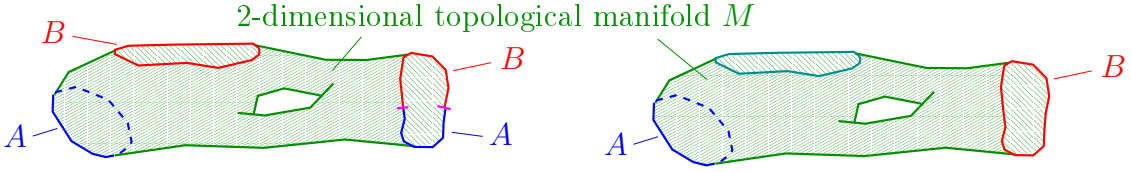
[2105] It follows easily from the definitions that a map $\psi\colon V \times W \to Z$ is a pairing in this sense if and only if it is a pairing in the sense of the definition 2656. Using this translation many concepts that we define in this chapter correspond to the eponymous concepts of Section 121.1.

Definition. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let S be a ring. We consider the $\mathbb{Z}[\pi_1(X,x_0)]$-module ${}_{\mathrm{tr}}S$ that is given by the trivial $\pi_1(X,x_0)$-action. We refer to the map

$$\begin{aligned} \epsilon_X \colon \mathrm{H}_0({}_{\mathrm{tr}}S \otimes_{\mathbb{Z}[\pi_1(X,x_0)]} \mathrm{C}_*(\widetilde{X}_{x_0}) = \mathrm{H}_0^{\mathrm{tw}}(X;{}_{\mathrm{tr}}S) &\to S \\ \Big[\sum_{i=1}^k r_i \otimes \sigma_i\Big] &\mapsto \sum_{i=1}^k r_i \end{aligned}$$

as the augmentation map. By the Twisted H_0-Proposition 168.1 it is an isomorphism of S-left modules.

Now we can finally introduce twisted intersection pairings.



Definition. Let X be a compact oriented path-connected n-dimensional topological manifold and let $x_0 \in X$. We write $\pi = \pi_1(X,x_0)$. We denote by $[X] \in \mathrm{H}_n(X,\partial X)$ the fundamental class. Furthermore suppose that we are given compact $(n-1)$-dimensional submanifolds A and B of ∂X such that $A \cap B = \partial A = \partial B$. Let R be a ring with involution and let M be a $(\mathbb{Z}[\pi],R)$-left left module. Furthermore let

$$\Theta \colon M \otimes_{\mathbb{Z}} M \to R$$

be an R-sesquilinear pairing that is preserved by the π-action, i.e. such that given any $v,w \in M$ and given any $g \in \pi$ we have $\Theta(g\cdot v, g\cdot w) = \Theta(v,w)$. We write $C := \partial X \setminus \mathring{A}$ and $D := \partial X \setminus \mathring{B}$.[2106] For each $k \in \mathbb{N}_0$ we refer to the map[210721082109]

$$\begin{aligned} Q^M_{X,A,B} \colon \mathrm{H}_k^{\mathrm{tw}}(X,A;M) \times \mathrm{H}_{n-k}^{\mathrm{tw}}(X,B;M) &\to R \\ (v,w) &\mapsto \epsilon_X\big(\Theta_*\big(\underbrace{\underbrace{\mathrm{PD}_X(v)}_{\in \mathrm{H}^{n-k}_{\mathrm{tw}}(X,C;M)} \cup_{\otimes} \underbrace{\mathrm{PD}_X(w)}_{\in \mathrm{H}^{k}_{\mathrm{tw}}(X,D;M)}}_{\in \mathrm{H}^{n}_{\mathrm{tw}}(X,\partial X;M\otimes_{\mathbb{Z}} M)}\big) \cap_{\mathbb{Z}} \underbrace{[X]}_{\in \mathrm{H}^{\mathrm{tw}}_n(X,\partial X)}\big). \end{aligned}$$

as a twisted intersection pairing. If X is closed, then $A = B = \varnothing$ and we just write Q^M_X. Furthermore if $M = {}_{\mathrm{tr}}\mathbb{Z}$, then we drop the superscript.[2110]

[2106] Note that by Proposition 75.3 we know that C and D are also compact submanifolds of ∂M with $\partial C = \partial D = A \cap C$ and $\partial D = \partial B = B \cap D$.

[2107] We have

$$C \cup D = (\partial X \setminus \mathring{A}) \cup (X \setminus \mathring{B}) \underset{\text{Proposition 75.3 (3)}}{=} ((\partial X \setminus A) \cup \partial A) \cup ((\partial X \setminus B) \cup \partial B) = (\partial X \setminus (A \cap B)) \cup \partial A \cup \partial B = \partial X.$$

[2108] Note that in the settings (i) and (ii), it follows from Proposition 169.2 (5) and (3) that (M,C,D) is a universally excisive triad. In particular it follows, see the definition on page 3603, that the cup product is actually defined.

[2109] As we discussed above, Θ gives rise to a homomorphism $\Theta \colon M \otimes_{\mathbb{Z}} M \to {}_{\mathrm{tr}}R$ of $\mathbb{Z}[G]$-left modules.

[2110] We now have a minuscule discrepancy in our notation, on pages 2800 and 2895 we defined the intersection form on $\mathrm{FH}_l(X;\mathbb{Z}) := \mathrm{H}_l(X;\mathbb{Z})/\text{torsion}$.

Remark. If we work with the trivial ${}_{\mathrm{tr}}\mathbb{Z}$-coefficients, then it follows from Lemma 171.6 and Lemma 171.12 that the twisted intersection form is isomorphic to the usual intersection form, except that now we do not mod out the torsion on the homology groups.

With the above definition we can now summarize a few basic properties of twisted intersection pairings.

Proposition 173.1. Let X be a compact oriented path-connected n-dimensional topological manifold and let $x_0 \in X$. Furthermore suppose that we are given compact $(n-1)$-dimensional submanifolds A and B of ∂X such that $A \cap B = \partial A = \partial B$. Let R be a ring with involution and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], R)$-left left module. Finally suppose that we are given an R-sesquilinear pairing

$$\Theta\colon M \otimes M \ \to \ R$$

that is preserved by the $\pi_1(X, x_0)$-action. Then the following statements hold:

(1) The pairing $Q^M_{X,A,B}$ is R-sesquilinear.
(2) If $n = 2m$, if $A = B$ and if Θ is hermitian, then the pairing

$$Q^M_{X,A,B}\colon \mathrm{H}^{\mathrm{tw}}_m(X, A; M) \times \mathrm{H}^{\mathrm{tw}}_m(X, A; M) \ \to \ R$$

is hermitian if m is even and it is anti-hermitian if m is odd. If Θ is anti-hermitian, then the statements flips in the obvious way.

Proof. We start out with the following observations:

(a) As we mentioned on page 3612, the Poincaré Duality isomorphism is an isomorphism of R-left modules.
(b) It follows from (a) and Lemma 171.5 that the map

$$\begin{aligned} \varphi\colon \mathrm{H}^{\mathrm{tw}}_k(X, A; M) \otimes_{\mathbb{Z}} \mathrm{H}^{\mathrm{tw}}_{n-k}(X, B; M) &\to \mathrm{H}^n_{\mathrm{tw}}(X; M \otimes_{\mathbb{Z}} M) \\ (v, w) &\mapsto \mathrm{PD}_X(v) \cup_{\otimes} \mathrm{PD}_X(w) \end{aligned}$$

is a homomorphism of $R \otimes_{\mathbb{Z}} R$-left modules.
(c) The augmentation isomorphism $\mathrm{H}^n_{\mathrm{tw}}(X; M \otimes_{\mathbb{Z}} M) \to M \otimes_{\mathbb{Z}} M$ from the Twisted H_0-Proposition 168.1 is an isomorphism of $R \otimes_{\mathbb{Z}} R$-left modules.
(d) By hypothesis the pairing $\Theta\colon M \otimes_{\mathbb{Z}} M \to R$ is R-sesquilinear and hermitian.

Now we turn to the proof of the proposition:

(1) This statement follows immediately from (b), (c) and (d).
(2) We now suppose that $n = 2m$, $A = B$ and that $\Theta\colon M \times M \to R$ is hermitian. We set $C := X \setminus \mathring{A}$. If follows from (a), (b) and (c) together with Proposition 171.7 that given $v, w \in \mathrm{H}^{\mathrm{tw}}_n(X, A; M)$ we have the following equality:

$$\overbrace{\epsilon_X(\Theta_*((\underbrace{\mathrm{PD}_X(v)}_{\in \mathrm{H}^m_{\mathrm{tw}}(X,C;M)} \cup_{\otimes} \underbrace{\mathrm{PD}_X(w)}_{\in \mathrm{H}^n_{\mathrm{tw}}(X,C;M)}) \cap_{\mathbb{Z}} [X]))}^{=Q^M_{X,A,A}(v,w)} = (-1)^{m\cdot m} \cdot \overbrace{\epsilon_X(\Theta_*((\underbrace{\mathrm{PD}_X(w)}_{\in \mathrm{H}^m_{\mathrm{tw}}(X,C;M)} \cup_{\otimes} \underbrace{\mathrm{PD}_X(v)}_{\in \mathrm{H}^n_{\mathrm{tw}}(X,C;M)}) \cap_{\mathbb{Z}} [X]))}^{=Q^M_{X,A,A}(w,v)}.$$

The statement follows from the observation that $(-1)^{m\cdot m} = (-1)^m$. ∎

Examples. Let X be a compact oriented path-connected non-empty n-dimensional topological manifold and let $x_0 \in X$. We write $\pi := \pi_1(X, x_0)$. Furthermore suppose that we

are given compact $(n-1)$-dimensional submanifolds A and B of ∂X such that $A \cap B = \partial A = \partial B$.

(1) Let G be a group and let $\varphi\colon \pi \to G$ be a homomorphism. Given $f \in \mathbb{Z}[G]$ and $g \in \pi$ we set $g \cdot f := f \cdot g^{-1}$. This allows us to view $\mathbb{Z}[G]$ as a $\mathbb{Z}[\pi]$-left module.[2111] This allows us to view $\mathbb{Z}[G]$ as a $(\mathbb{Z}[\pi], \mathbb{Z}[G])$-left left module. As always we view $\mathbb{Z}[G]$ as a ring with involution. The multiplication map

$$\begin{array}{rcl} \mu\colon \mathbb{Z}[G] \times \mathbb{Z}[G] & \to & \mathbb{Z}[G] \\ (r,s) & \mapsto & r \cdot \overline{s} \end{array}$$

has the required properties[2112] and we obtain the twisted intersection pairing

$$Q_X^{\mathbb{Z}[G]}\colon \mathrm{H}_k^{\mathrm{tw}}(X;\mathbb{Z}[G]) \times \mathrm{H}_{n-k}^{\mathrm{tw}}(X;\mathbb{Z}[G]) \to \mathbb{Z}[G].$$

By Proposition 173.1 (1) this pairing is $\mathbb{Z}[G]$-sesquilinear. If $A = B$, if $n = 4m$ and if $k = 2m$, then it follows from Proposition 173.1 (2) that the pairing is hermitian.

(2) Let $\alpha\colon \pi \to \mathrm{U}(d) := \{A \in \mathrm{M}(d \times d, \mathbb{C}) \,|\, \overline{A}^T A = \mathrm{id}\}$ be a unitary representation. We obtain the corresponding $\mathbb{Z}[\pi]$-left module $\mathbb{C}^d_\varphi$. We equip $\mathbb{C}$ with the standard involution $\overline{x + y\mathrm{i}} := x - y\mathrm{i}$ and we consider the $\mathbb{C}$-sesquilinear map

$$\begin{array}{rcl} \Theta\colon \mathbb{C}^d \times \mathbb{C}^d & \to & \mathbb{C} \\ (v,w) & \mapsto & v^T \cdot \overline{w}. \end{array}$$

Since α is a unitary representation we see that the corresponding left action of π on $\mathbb{C}^d$ preserves Θ. Thus we obtain the twisted intersection pairing

$$Q_X^{\mathbb{C}^d}\colon \mathrm{H}_k^{\mathrm{tw}}(X;{}_\alpha\mathbb{C}^d) \times \mathrm{H}_{n-k}^{\mathrm{tw}}(X;{}_\alpha\mathbb{C}^d) \to \mathbb{C}.$$

By Proposition 173.1 (1) this pairing is $\mathbb{C}$-sesquilinear. If $A = B$, if $n = 4m$ and if $k = 2m$, then it follows from Proposition 173.1 (2) that this pairing is hermitian.

(3) Let $\alpha\colon \pi \to \mathrm{SL}(2,\mathbb{C})$ be a unitary representation. We consider the corresponding $\mathbb{Z}[\pi]$-left module ${}_\alpha\mathbb{C}^2$. We equip $\mathbb{C}$ with the *trivial* involution and we consider the $\mathbb{C}$-bilinear map

$$\begin{array}{rcl} \Theta\colon \mathbb{C}^2 \times \mathbb{C}^2 & \to & \mathbb{C} \\ (v,w) & \mapsto & \det(v\ w). \end{array}$$

Since α takes values in $\mathrm{SL}(2,\mathbb{C})$ it follows from a straightforward argument that the corresponding left action of π on $\mathbb{C}^2$ preserves Θ. Thus we obtain the twisted intersection pairing

$$Q_X^{\mathbb{C}^2}\colon \mathrm{H}_k^{\mathrm{tw}}(X;{}_\alpha\mathbb{C}^2) \times \mathrm{H}_{n-k}^{\mathrm{tw}}(X;{}_\alpha\mathbb{C}^2) \to \mathbb{C}.$$

By Proposition 173.1 (1) this pairing is $\mathbb{C}$-bilinear. If $A = B$, if $n = 4m+2$ and if $k = 2m+1$, then it follows from Proposition 173.1 (2) that this pairing is symmetric.

Given a commutative ring we defined on pages 2656 and 2894 the notion of non-singular and non-degenerate R-bilinear pairings. We now extend these notions in the obvious way to the more general setting of R-sesquilinear pairings.

[2111] We pick this $\mathbb{Z}[\pi]$-left module structure to stay in tune with Proposition 168.2.

[2112] Indeed, given $r, s \in \mathbb{Z}[G]$ and $g \in \pi$ we have

$$\Theta(g \cdot r, g \cdot s) = \Theta(r \cdot g^{-1}, s \cdot g^{-1}) = (r \cdot g^{-1}) \cdot \overline{(s \cdot g^{-1})} r \cdot g^{-1} \cdot g \cdot \overline{s} = r \cdot \overline{s} = \Theta(r,s).$$

Definition. Let R be a ring with involution and let V and W be two R-left modules. We say that an R-sesquilinear pairing $\varphi\colon V \otimes_{\mathbb{Z}} W \to R$ is non-singular if the induced maps

$$\underbrace{\begin{array}{ccc} V & \to & \mathrm{Hom}_{R\text{-right}}(\overline{W}, R) \\ v & \mapsto & \left(\begin{array}{ccc} \overline{W} & \to & R \\ w & \mapsto & \varphi(v\otimes w)\end{array}\right)\end{array}}_{\text{homomorphism of } R\text{-left modules}} \quad \text{and} \quad \underbrace{\begin{array}{ccc} \overline{W} & \to & \mathrm{Hom}_{R\text{-left}}(V, R) \\ w & \mapsto & \left(\begin{array}{ccc} V & \to & R \\ v & \mapsto & \varphi(v\otimes w)\end{array}\right)\end{array}}_{\text{homomorphism of } R\text{-right modules}}$$

are both[21132114] isomorphisms. Otherwise we say that the pairing is non-singular. We say that the R-sesquilinear pairing is non-degenerate if the above two maps are both monomorphisms. Otherwise we say that the R-bilinear pairing is degenerate.

Proposition 173.2. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let $\mathbb{K}$ be a skew field with involution and let M be a $(\mathbb{Z}[\pi_1(X,x_0)],\mathbb{K})$-left left module. Finally suppose that we are given a non-singular $\mathbb{K}$-sesquilinear pairing

$$\Theta\colon M \otimes_{\mathbb{Z}} M \to \mathbb{K}$$

that is preserved by the $\pi_1(X,x_0)$-action. We denote by $\epsilon_X\colon \mathrm{H}_0^{\mathrm{tw}}(X;{}_{\mathrm{tr}}\mathbb{K}) \to \mathbb{K}$ the augmentation isomorphism from the Twisted H_0-Proposition 168.1. Then for any $A \subset X$ the $\mathbb{K}$-left linear map

$$\begin{array}{ccc} \mathrm{H}^k_{\mathrm{tw}}(X,A;M) & \to & \mathrm{Hom}_{\mathbb{K}\text{-left}}(\mathrm{H}^{\mathrm{tw}}_k(X,A;M), \mathbb{K}) \\ \varphi & \mapsto & (\mu \mapsto \epsilon_X(\Theta_*(\underbrace{\varphi \cap_{\otimes} \mu}_{\in \mathrm{H}_0^{\mathrm{tw}}(X;M\otimes_{\mathbb{Z}}M)}))) \end{array}$$

($\mathbb{K}$-left module via $k\cdot m := m\cdot_{\mathbb{K}} \overline{k}$)

is an isomorphism of $\mathbb{K}$-left modules. (For this statement the $\mathbb{K}$-left module structures on $\mathrm{H}^k_{\mathrm{tw}}(X,A;M)$ is given by the given $\mathbb{K}$-left module structure on M and the $\mathbb{K}$-left module structure on $\mathrm{Hom}_{\mathbb{K}\text{-left}}(\mathrm{H}^{\mathrm{tw}}_k(X,A;M),\mathbb{K})$ is given by the obvious $\mathbb{K}$-left module structure on $\mathbb{K}$.)

Proof. To simplify the notation we assume that $A = \varnothing$. It follows from the little remark on page 3608 that mathematically it makes no difference in the argument that follows. We write $\pi := \pi_1(X,x_0)$ and we write $C_* := \mathrm{C}_*(\widetilde{X}_{x_0})$.

Claim 1. The map

$$\begin{array}{ccc} \Xi\colon \mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(C_*, M) & \to & \mathrm{Hom}_{\mathbb{K}\text{-left}}(\overline{M}\otimes_{\mathbb{Z}[\pi]} C_*, \mathbb{K}) \\ \varphi & \mapsto & \left(\begin{array}{ccc} \overline{M}\otimes_{\mathbb{Z}[\pi]} C_* & \to & \mathbb{K} \\ m\otimes\sigma & \mapsto & \Theta(\varphi(\sigma)\otimes m)\end{array}\right)\end{array}$$

($\mathbb{K}$-left module via $k\cdot m := m\cdot_{\mathbb{K}} \overline{k}$)

is a well-defined chain map and it is a homomorphism of $\mathbb{K}$-left modules. (For this statement the $\mathbb{K}$-left module structures are given by the given $\mathbb{K}$-left module structure on M and the obvious $\mathbb{K}$-left module structure on $\mathbb{K}$.)

[2113] We equip the target R with the obvious (R,R)-bimodule structure.

[2114] If the pairing $\varphi\colon V\otimes_{\mathbb{Z}} W \to R$ is (anti-) hermitian, then one can easily verify that if one map is an isomorphism (respectively monomorphism), then so is the other.

Proof. As always, if the claim is correct, it is trivially correct. But since these arguments always produce anxieties for this famously anxious author, let us nonetheless provide some details. First we need to verify that the map $\Xi(\varphi)\colon \overline{M} \otimes_{\mathbb{Z}[\pi]} C_* \to \mathbb{K}$ respects the tensor product. Thus let $m \in \overline{M}$, $\sigma \in C_k$ and $g \in \pi$. Then

$$\overbrace{\Theta(\varphi(\sigma) \otimes m \cdot g)}^{=\Xi(\varphi)(mg\otimes\sigma)} \underset{\uparrow}{=} \Theta(\varphi(\sigma) \otimes g^{-1} \cdot m) \underset{\uparrow}{=} \Theta(g \cdot \varphi(\sigma) \otimes gg^{-1} \cdot m) \underset{\uparrow}{=} \overbrace{\Theta(\varphi(g \cdot \sigma) \otimes m)}^{=\Xi(\varphi)(m\otimes g\sigma)}.$$

by definition of Ξ and by definition of the $\mathbb{Z}[\pi]$-right module $\overline{M}$ — since π preserves Θ — since φ is $\mathbb{Z}[\pi]$-left linear

Next we need to verify that the map $\Xi(\varphi)\colon \overline{M} \otimes_{\mathbb{Z}[\pi]} C_* \to \mathbb{K}$ is $\mathbb{K}$-left linear. Thus let $m \in \overline{M}$, let $\sigma \in C_k$ and let $k \in \mathbb{K}$, then

$$\Xi(\varphi)(k \cdot (m \otimes \sigma)) \underset{\uparrow}{=} \Theta(\varphi(\sigma) \otimes k \cdot \sigma) \underset{\uparrow}{=} \overbrace{\Theta(\varphi(\sigma) \otimes m)}^{=\Xi(\varphi)(m\otimes\sigma)} \cdot \overline{k} \underset{\uparrow}{=} k \cdot \Xi(\varphi)(m \otimes \sigma).$$

$\mathbb{K}$-left structure on $\overline{M} \otimes_{\mathbb{Z}[\pi]} C_*$ — since Θ is $\mathbb{K}$-sesquilinear — $\mathbb{K}$-left structure on $\mathbb{K}$

Now we need to show that $\Xi\colon \mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(C_*, M) \to \mathrm{Hom}_{\mathbb{K}\text{-left}}(\overline{M} \otimes_{\mathbb{Z}[\pi]} C_*, \mathbb{K})$ is a homomorphism of $\mathbb{K}$-left modules. Fortunately, given $\varphi \in \mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(C_*, M)$ and $k \in M$ we indeed have

$$\Xi(k\cdot\varphi)(m \otimes \sigma) \underset{\uparrow}{=} \Theta((k\cdot\varphi)(s) \otimes m) \overset{\downarrow}{=} \Theta(k\cdot\varphi(s) \otimes m) \underset{\uparrow}{=} k\cdot\Theta(\varphi(\sigma) \otimes m) \overset{\downarrow}{=} k\cdot\Xi(\varphi)(m \otimes \sigma).$$

definition of Ξ — definition of the $\mathbb{Z}[\pi]$–left structure — since Θ is $\mathbb{K}$-sesquilinear — definition of Ξ

We leave it to the reader to verify that the maps Ξ are chain maps. ⊞

Our next goal is to show, using the hypothesis that Θ is non-singular, that the maps Ξ are isomorphisms. This leads us to the following claim.

Claim 2. Given $\psi \in \mathrm{Hom}_{\mathbb{K}\text{-left}}(\overline{M} \otimes_{\mathbb{Z}[\pi]} C_n, \mathbb{K})$ and given $\sigma \in C_n$ the map

$$\begin{array}{rcl} M & \to & \mathbb{K} \\ v & \mapsto & \psi(v \otimes \sigma) \end{array}$$

is $\mathbb{K}$-left linear. (Recall that $\mathbb{K}$ is here equipped with the $\mathbb{K}$-left linear structure given by $k \cdot m := m \cdot_{\mathbb{K}} m^{-1}$.) Since $\Theta\colon M \otimes_{\mathbb{Z}} M \to \mathbb{K}$ is non-singular there exists a unique $f(\psi, \sigma) \in M$ such that

$$\psi(v \otimes \sigma) \;=\; \Theta(f(\psi, \sigma) \otimes v) \qquad \text{for all } v \in V.$$

With this observation and definition we can now consider the map

$$\begin{array}{rcl} \Omega\colon \mathrm{Hom}_{\mathbb{K}\text{-left}}(\overline{M} \otimes_{\mathbb{Z}[\pi]} C_*, \mathbb{K}) & \to & \mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(C_*, M) \\ \psi & \mapsto & \begin{pmatrix} C_* & \to & M \\ \sigma & \mapsto & f(\psi, \sigma) \end{pmatrix} \end{array}$$

We claim these maps are well-defined and that they are inverses to the map Ξ in Claim 1.

Proof. For well-definedness we only have to show that for $\psi \in \mathrm{Hom}_{\mathbb{K}\text{-left}}(\overline{M} \otimes_{\mathbb{Z}[\pi]} C_k, \mathbb{K})$ the map $\Omega(\psi)\colon C_k \to M$ is $\mathbb{Z}[\pi]$-linear. So let $\sigma \in C_*$ and let $g \in \pi$. Given any $v \in V$ we have

$$\begin{array}{lcccc} \Theta(f(\psi, g\cdot\sigma)\otimes v) & \overset{\text{by definition of } f(\psi,g\cdot\sigma)}{\overset{\downarrow}{=}} & \psi(v\otimes g\cdot\sigma) & \overset{\text{tensor product over } \mathbb{Z}[\pi]}{\overset{\downarrow}{=}} & \psi(v\cdot g\otimes\sigma) \\ & & & = & \Theta(f(\psi,\sigma)\otimes g^{-1}\cdot v) \\ & & & \overset{\text{by definition of } f(\psi,\sigma)}{\uparrow} & \\ & & & \overset{\text{definition of } \pi\text{-right left action on } \overline{M}}{\overset{\downarrow}{=}} & \psi(g^{-1}\cdot v\otimes\sigma) \\ & & & \overset{\text{since } \pi \text{ preserves } \Theta}{=} & \Theta(g\cdot f(\psi,\sigma)\otimes v). \end{array}$$

Since Θ is non-singular we obtain that $f(\psi, g\cdot\sigma) = g\cdot f(\psi,\sigma)$. We have thus verified that $\sigma \mapsto f(\psi,\sigma)$ is indeed π-left linear.

It remains to show that Ξ and Ω are inverses of one another. First we show that $\Omega\circ\Xi = \mathrm{id}$. Thus let $\varphi \in \mathrm{Hom}_{\mathbb{Z}[\pi]\text{-left}}(C_*, M)$ and let $\sigma \in C_*$. Note that by definition of Ξ we have

$$\Xi(\varphi)(v\otimes\sigma) \;=\; \Theta(\varphi(\sigma)\otimes v) \qquad \text{for all } v\in M \text{ and } \sigma \in C_*.$$

But this means, by definition of f, that $f(\Xi(\varphi),\sigma) = \varphi(\sigma)$. Thus we see that

$$(\Omega\circ\Xi)(\varphi)(\sigma) \;=\; \Omega(\Xi(\varphi))(\sigma) \;\overset{\text{definition of } \Omega}{=}\; f(\Xi(\varphi),\sigma) \;\overset{\text{see above}}{=}\; \varphi(\sigma).$$

Thus we have shown that $\Omega\circ\Xi = \mathrm{id}$. Finally let us check that $\Xi\circ\Omega = \mathrm{id}$. Thus let $\psi \in \mathrm{Hom}_{\mathbb{K}\text{-left}}(\overline{M}\otimes_{\mathbb{Z}[\pi]} C_n, \mathbb{K})$. Given any $\sigma \in C_n$ and $v \in M$ we have

$$(\Xi\circ\Omega)(\psi)(v\otimes\sigma) \;=\; \Xi(\Omega(\psi))(v\otimes\sigma) \;\overset{\text{definition of } \Xi}{=}\; \Theta(\Omega(\psi)(\sigma)\otimes v) \;\overset{\text{definition of } \Omega}{=}\; \Theta(f(\psi,\sigma)\otimes v) \;\overset{\text{definition of } f}{=}\; \psi(v\otimes\sigma).$$

Thus we have shown that $\Omega\circ\Xi = \mathrm{id}$. ⊞

Claim 3. Given any $\varphi \in \mathrm{Hom}_{\mathbb{Z}[\pi]}(\mathrm{C}_*(\widetilde{X}), M)$ and $m\otimes\sigma \in \overline{M}\otimes_{\mathbb{Z}[\pi]} C_k(\widetilde{X})$ we have

$$\epsilon_X(\Theta_*(\varphi\cap_\otimes (m\otimes\sigma))) \;=\; \Xi(\varphi)(m\otimes\sigma).$$

Proof. Let $\varphi \in \mathrm{Hom}_{\mathbb{Z}[\pi]}(\mathrm{C}_*(\widetilde{X}), M)$ and let $m\otimes\sigma \in \overline{M}\otimes_{\mathbb{Z}[\pi]} C_k(\widetilde{X})$. Then

$$\begin{array}{lcccc} \epsilon_X(\Theta_*(\varphi\cap_\otimes (m\otimes\sigma))) & \overset{\text{see definition of } \cap_\otimes \text{ on page 3606}}{\overset{\downarrow}{=}} & \epsilon_X(\Theta_*(\varphi(\sigma)\otimes m\otimes(\sigma\circ[v_k]))) & & \\ & = & \epsilon_X(\Theta(\varphi(\sigma))\otimes m)\otimes(\sigma\circ[v_k]) & = & \Theta(\varphi(\sigma)\otimes m) \\ & \overset{\text{definition of } \Theta_* \text{ on page 3538}}{\uparrow} & & \overset{\text{Twisted H}_0\text{-Proposition 168.1}}{\uparrow} & \\ & & & & = \quad \Xi(\varphi)(m\otimes\sigma). \\ & & & & \overset{\text{definition } ⊞}{\uparrow} \end{array}$$

We can now finally conclude the argument. To do so we consider the following diagram

$$\begin{array}{ccc} \mathrm{H}^k(X;M) & \xrightarrow{\varphi\mapsto(m\otimes\sigma\mapsto\epsilon_X(\Theta_*(\varphi\cap_\otimes m\otimes\sigma)))} & \mathrm{Hom}_{\mathbb{K}\text{-left}}(\mathrm{H}_k(X;M),\mathbb{K}) \\ \cong\big\downarrow \Xi & & \big\downarrow \mathrm{id} \\ \mathrm{H}^k(\overline{M}\otimes_{\mathbb{Z}[\pi]}\mathrm{C}_*(\widetilde{X});\mathbb{K}) & \xrightarrow[\text{isomorphism by Theorem 166.12}]{\varphi\mapsto(\mu\mapsto\varphi(\mu))} & \mathrm{Hom}_{\mathbb{K}\text{-left}}(\mathrm{H}_k(\overline{M}\otimes_{\mathbb{Z}[\pi]}\mathrm{C}_*(\widetilde{X})),\mathbb{K}). \end{array}$$

We make the following observations:

(1) By Claim 2 we know that the vertical map Ξ is an isomorphism.
(2) By Claim 3 we know that the diagram commutes.

(3) Since $\mathbb{K}$ is a skew field we obtain from Theorem 166.12, applied to the chain complex $V_* := \overline{M} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_*(\widetilde{X})$ of $\mathbb{K}$-left modules, that the bottom horizontal map is an isomorphism.

It follows from the above that the top horizontal map is indeed an isomorphism. ■

The following proposition is the analogue of the Intersection Form Proposition 132.4 (3).

Proposition 173.3. Let X be a compact oriented path-connected non-empty n-dimensional topological manifold and let $x_0 \in X$. Furthermore suppose that we are given compact $(n-1)$-dimensional submanifolds A and B of ∂X such that $A \cap B = \partial A = \partial B$. Let $\mathbb{K}$ be a skew field with involution and let M be a $(\mathbb{Z}[\pi_1(X, x_0)], \mathbb{K})$-left left module. Finally suppose that we are given a non-singular $\mathbb{K}$-sesquilinear pairing

$$\Theta\colon M \otimes_{\mathbb{Z}} M \ \to\ \mathbb{K}$$

such that the $\pi_1(X, x_0)$-action preserves Θ, i.e. such that given any $v, w \in M$ and given any $g \in \pi_1(X, x_0)$ we have $\Theta(g \cdot v \otimes g \cdot w) = \Theta(v \otimes w)$. If $A \cup B = \partial X$, then the twisted intersection pairing

$$Q^M_{X,A,B}\colon \mathrm{H}^{\mathrm{tw}}_k(X, A; M) \times \mathrm{H}^{\mathrm{tw}}_{n-k}(X, B; M) \ \to\ \mathbb{K}$$

is non-singular.

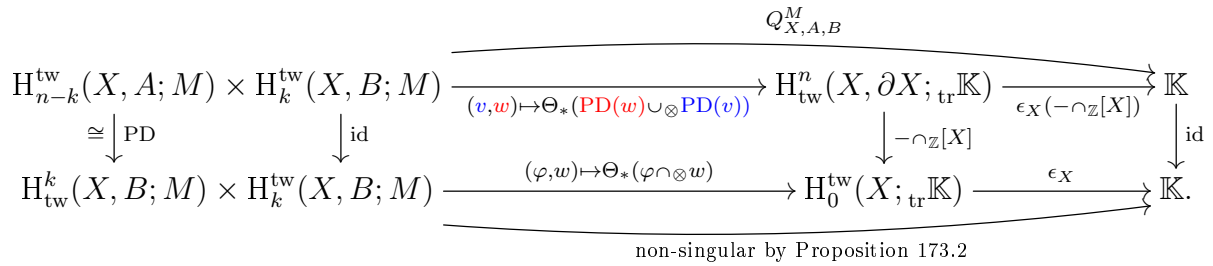
Proof. Note that it follows from the hypothesis that $A \cap B = \partial A = \partial B$ and $A \cup B = \partial X$ that the Poincaré Duality Theorem 172.1 with Twisted Coefficients gives us the Poincaré Duality isomorphism

$$\mathrm{PD}\colon \mathrm{H}^{\mathrm{tw}}_{n-k}(X, A; M) \ \to\ \mathrm{H}^{n-k}_{\mathrm{tw}}(X, B; M).$$

We continue with the following claim.

Claim. The following diagram commutes

$$\begin{array}{ccccc}
\mathrm{H}^{\mathrm{tw}}_{n-k}(X, A; M) \times \mathrm{H}^{\mathrm{tw}}_k(X, B; M) & \xrightarrow{(v,w)\mapsto \mathrm{PD}(w)\cup_{\otimes}\mathrm{PD}(v)} & \mathrm{H}^n_{\mathrm{tw}}(X, \partial X; M \underset{\mathbb{Z}}{\otimes} M) & \xrightarrow{\Theta_*} & \mathrm{H}^n_{\mathrm{tw}}(X, \partial X; {}_{\mathrm{tr}}\mathbb{K}) \\
\downarrow \mathrm{PD} \qquad \downarrow \mathrm{id} & & \downarrow -\cap_{\mathbb{Z}}[X] & & \downarrow -\cap_{\mathbb{Z}}[X] \\
\mathrm{H}^k_{\mathrm{tw}}(X, B; M) \times \mathrm{H}^{\mathrm{tw}}_k(X, B; M) & \xrightarrow{\cap_{\otimes}} & \mathrm{H}^{\mathrm{tw}}_0(X; M \underset{\mathbb{Z}}{\otimes} M) & \xrightarrow{\Theta_*} & \mathrm{H}^{\mathrm{tw}}_0(X; {}_{\mathrm{tr}}\mathbb{K}).
\end{array}$$



Proof. We consider the two squares separately.

(1) For the first square let $v \in \mathrm{H}^{\mathrm{tw}}_{n-k}(X, A; M)$ and $w \in \mathrm{H}^{\mathrm{tw}}_k(X, B; M)$. Then

$$(\mathrm{PD}(w) \cup_{\otimes} \mathrm{PD}(v)) \cap_{\mathbb{Z}} [X] \underset{\text{Lemma 171.14}}{=} \mathrm{PD}(v) \cap_{\otimes} (\mathrm{PD}(w) \cap_{\mathbb{Z}} [X]) \underset{\text{by definition of PD}(w)}{=} \mathrm{PD}(v) \cap_{\otimes} w.$$

(2) It follows from Proposition 171.8 (2) that the second square commutes. ⊞

Next we consider the following diagram:

We make the following observations:

(1) The top sequences is by definition the intersection pairing $Q^M_{X,A,B}$.
(2) It follows from Claim 1 that the square to the left commutes.
(3) The square to the right commutes by fiat.
(4) As we mentioned before, by the Poincaré Duality Theorem 172.1 with Twisted Coefficients the vertical map PD is an isomorphism of $\mathbb{K}$-left modules.
(5) By Proposition 173.2 we know that the $\mathbb{K}$-sesquilinear pairing at the bottom is non-singular.

All these statements combined show that the $\mathbb{K}$-sesquilinear intersection pairing $Q^M_{X,A,B}$ is indeed non-singular. ■

173.2. **Twisted signatures.** state that twisted signatures of closed manifolds are just multiples of ordinary signatures

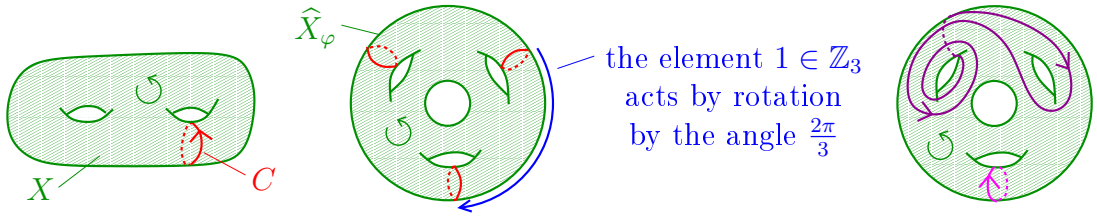
173.3. **Twisted invariants and finite covers.**

Proposition 173.4. Let X be a closed oriented path-connected n-dimensional topological manifold, let $x_0 \in X$ and let $\varphi\colon \pi_1(X,x_0) \to G$ be an epimorphism onto a *finite* group G. We denote by $p\colon \widehat{X}_\varphi \to X$ the covering corresponding to the subgroup $\ker(\varphi)$. We consider the isomorphism

$$\begin{array}{rcl}\Omega\colon \mathrm{C}^{\mathrm{tw}}_k(X;\mathbb{Z}[G]) = \overline{\mathbb{Z}[G]} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widetilde{X}_{x_0}) & \to & \mathrm{C}_k(\widehat{X}_\varphi) \\ g \otimes (\sigma\colon \Delta^k \to Y_\Gamma) & \mapsto & q \circ (g\cdot\sigma\colon \Delta^k \to Y_\Gamma)\end{array}$$

of $\mathbb{Z}[G]$-left modules from Proposition 168.2. Given any $\mu \in \mathrm{H}^{\mathrm{tw}}_k(X;\mathbb{Z}[G])$ and given any $\nu \in \mathrm{H}^{\mathrm{tw}}_{n-k}(X;\mathbb{Z}[G])$ we have[2115]

$$Q^{\mathbb{Z}[G]}_X(\mu,\nu) \;=\; \sum_{g\in G} Q^{\mathbb{Z}}_{\widehat{X}_\varphi}\big(\underbrace{\Omega(\mu)}_{\in \mathrm{H}^{\mathrm{tw}}_k(\widehat{X}_\varphi)}, g\cdot \underbrace{\Omega(\nu)}_{\in \mathrm{H}^{\mathrm{tw}}_{n-k}(\widehat{X}_\varphi)}\big)\cdot g \;\in\; \mathbb{Z}[G].$$



Example. Let X be the surface of genus 2and let $C \subset X$ be a non-separating closed orientable path-connected 1-dimensional submanifold. The homology class $[C] \in \mathrm{H}^{\mathrm{tw}}_1(X;\mathbb{Z})$ determines, via the isomorphisms

$$\mathrm{H}^{\mathrm{tw}}_1(X;\mathbb{Z}) \;\cong\; \mathrm{H}^1_{\mathrm{tw}}(X;\mathbb{Z}) \;\to\; \mathrm{Hom}(\mathrm{H}^{\mathrm{tw}}_1(X),\mathbb{Z}) \;=\; \mathrm{Hom}(\pi_1(X),\mathbb{Z}),$$

an epimorphism $\varphi\colon \pi_1(X) \to \mathbb{Z} \to \mathbb{Z}_3$. In the Cyclic-Covering Proposition 130.11 we saw how one can explicitly construct the covering $\widehat{X}_\varphi$ corresponding to $\ker(\varphi)$. Thus

[2115] It is a good reality check, see Exercise 173.1 to verify that the map on the right hand side is indeed $\mathbb{Z}[G]$-sesquilinear.

Proposition 173.4 allows us to compute the twisted intersection form $Q_X^{\mathbb{Z}[\mathbb{Z}_3]}$ by considering the usual intersection form on the explicit covering $\widehat{X}_\varphi$.

Proof. In the following we use the Replace Universal Covering Proposition 168.6 to replace the universal covering of X by the covering $p\colon \widehat{X}_\varphi \to X$. This approach simplifies the notation quite a bit. In particular we now consider the isomorphism

$$\begin{array}{rcl} \Omega\colon \mathrm{C}_k^{\mathrm{tw}}(X;\mathbb{Z}[G]) = \overline{\mathbb{Z}[G]} \otimes_{\mathbb{Z}[\pi]} \mathrm{C}_k(\widehat{X}_\varphi) & \to & \mathrm{C}_k(\widehat{X}_\varphi) \\ g \otimes (\sigma\colon \Delta^k \to Y_\Gamma) & \mapsto & (g \cdot \sigma\colon \Delta^k \to Y_\Gamma) \end{array}$$

of $\mathbb{Z}[G]$-left modules from Proposition 168.2. Furthermore, since G is finite we obtain from Proposition 168.4 that the maps

$$\begin{array}{rcl} \Phi\colon \mathrm{C}^k_{\mathrm{tw}}(X;\mathbb{Z}[G]) & \to & \mathrm{C}^k(\widehat{X}_\varphi;\mathbb{Z}) \\ \varphi & \mapsto & \sigma \mapsto e\text{-coefficient of } \varphi(\sigma) \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon \mathrm{C}^k(\widehat{X}_\varphi;\mathbb{Z}) & \to & \mathrm{C}^k_{\mathrm{tw}}(X;\mathbb{Z}[G]) \\ \gamma & \mapsto & \sum\limits_{g\in G} g^*(\gamma)\cdot g \end{array}$$

are well-defined $\mathbb{Z}[G]$-left homomorphisms and inverses of one another.

Claim 1. Given any $\mu \in \mathrm{H}_k^{\mathrm{tw}}(X;\mathbb{Z}[G])$ we have

$$|G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\mu)) \;=\; |G| \cdot \Phi(\mathrm{PD}_X(\mu)) \;\in\; \mathrm{H}^{\dim(X)-k}_{\mathrm{tw}}(\widehat{X}_\varphi).$$

Proof. We start out with a little calculation. Namely let $\alpha \in \mathrm{C}^k(X;\mathbb{Z}[G])$ and let $\sigma\colon \Delta^{k+l} \to \widehat{X}_\varphi$. Then we have the following equality in $\mathrm{C}_{l-k}(\widehat{X}_\varphi)$:

$$\begin{aligned} \sum_{g\in G} g\cdot(g^*\Phi(\alpha) \cap_{\mathbb{Z}} (1\otimes\sigma)) &= \overbrace{\alpha(\sigma\circ[v_0,..,v_k])}^{\in\mathbb{Z}[G]}\cdot\sigma\circ[v_k,..,v_l]) \\ &\quad \uparrow \\ &\quad \text{follows from plugging in, as in the proof of } \Xi\circ\Phi = \mathrm{id} \\ &= \Omega(\underbrace{(\alpha(\sigma\circ[v_0,..,v_k])\otimes 1)}_{\in\mathbb{Z}[G]\otimes_{\mathrm{tr}}\mathbb{Z}} \otimes \sigma\circ[v_k,..,v_l]) \;= \Omega(\alpha\cap_\otimes 1\otimes\sigma). \end{aligned}$$

Now we turn to the actual proof of the claim. Given any $\mu \in \mathrm{H}_k^{\mathrm{tw}}(X;\mathbb{Z}[G])$ we have the following equalities in $\mathrm{H}_k^{\mathrm{tw}}(\widehat{X}_\varphi)$:

$$\begin{array}{rcll} & & \text{definition of } \mathrm{PD}_{\widehat{X}_\varphi} & \text{definition of } \mathrm{PD}_X \\ |G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\mu)) \cap_{\mathbb{Z}} [\widehat{X}_\varphi] & \overset{\downarrow}{=} & |G| \cdot \Omega(\mu) & \overset{\downarrow}{=} \Omega(\mathrm{PD}_X(\mu) \cap_{\mathbb{Z}} |G| \cdot [X]) \\ & = & \Omega(\mathrm{PD}_X(\mu) \cap_{\mathbb{Z}} p_*([\widehat{X}_\varphi])) & = \sum_{g \in G} g \cdot (g^* \Phi(\mathrm{PD}_X(\mu)) \cap_{\mathbb{Z}} [\widehat{X}_\varphi]). \\ & & \uparrow & \uparrow \\ & & \text{Fundamental Class-Covering Proposition 106.25 follows from the above calculation} & \\ & = & \sum_{g \in G} \Phi(\mathrm{PD}_X(\mu)) \cap_{\mathbb{Z}} g \cdot [\widehat{X}_\varphi] & = |G| \cdot \Phi(\mathrm{PD}_X(\mu)) \cap_{\mathbb{Z}} [\widehat{X}_\varphi]. \\ & & \uparrow & \uparrow \\ & & \text{by Proposition 171.13 (1b) we have in general } f_*(f^*\gamma \cap_{\mathbb{Z}} \sigma) = f_*(\sigma) & \text{since } g \text{ acts in an orientation-preserving way we see that } g \cdot [\widehat{X}_\varphi] = [\widehat{X}_\varphi] \end{array}$$

Since the map $- \cap_{\mathbb{Z}} [\widehat{X}_\varphi]$ is an isomorphism we obtain the desired statement. ⊞

Claim 2. Given any $\widetilde{\mu} \in \mathrm{C}^r(\widehat{X}_\varphi;\mathbb{Z})$ and $\widetilde{\nu} \in \mathrm{C}^s(\widehat{X}_\varphi;\mathbb{Z})$ we have

$$\Psi(\widetilde{\mu}) \underset{\mathbb{Z}[G]}{\cup} \Psi(\widetilde{\nu}) = |G| \cdot \sum_{k \in G} \Big(\underbrace{\widetilde{\mu} \cup k \cdot \widetilde{\nu}}_{\in \mathrm{Hom}_{\mathbb{Z}}(\mathrm{C}_{r+s}(\widetilde{X}),\mathbb{Z})} \Big) \cdot k \quad \in \mathrm{Hom}_{\mathbb{Z}[G]-\mathrm{left}}(\mathrm{C}_{r+s}(\widetilde{X}),\mathbb{Z}[G]).$$

Proof. Given any $\widetilde{\mu} \in \mathrm{C}^r(\widehat{X}_\varphi;\mathbb{Z})$ and $\widetilde{\nu} \in \mathrm{C}^s(\widehat{X}_\varphi;\mathbb{Z})$ we perform the following calculation in $\mathbb{Z}[G]$:

$$\begin{array}{rcll} & & \text{definition of } \Psi & \text{definition of } \cup_{\mathbb{Z}[G]} \text{ on page 3603} \\ \Psi(\widetilde{\mu}) \underset{\mathbb{Z}[G]}{\cup} \Psi(\widetilde{\nu}) & \overset{\downarrow}{=} & \sum_{g \in G} g^*\widetilde{\mu} \cdot g \underset{\mathbb{Z}[G]}{\cup} \sum_{h \in G} h^*\widetilde{\nu} \cdot h & \overset{\downarrow}{=} \sum_{g \in G} \sum_{h \in G} (g^*\widetilde{\mu} \cup h^*\widetilde{\nu}) \cdot gh^{-1} \\ & = & \sum_{g \in G} \sum_{h \in G} (\widetilde{\mu} \cup \underbrace{(g^{-1})^* h^*(\widetilde{\nu})}_{=(hg^{-1})^*}) \cdot gh^{-1} & = \sum_{g \in G} \sum_{k \in G} (\widetilde{\mu} \cup (k^{-1})^*\widetilde{\nu}) \cdot k \\ & & \uparrow & \uparrow \\ & & \text{since by the Cup Product-Naturality Lemma 114.10 we know we rename } k = gh^{-1}, \text{ that } f^*\alpha \cup g^*\beta = f^*(\alpha \cup \beta) & \\ & = & \sum_{g \in G} \sum_{k \in G} (\widetilde{\mu} \cup k \cdot \widetilde{\nu}) \cdot k & = |G| \cdot \sum_{k \in G} (\widetilde{\mu} \cup \underbrace{(k^{-1})^* \cdot \widetilde{\nu}}_{k \cdot \widetilde{\nu}}) \cdot k \\ & & \uparrow & \uparrow \\ & & \text{by definition, see Proposition 168.2, we have } k \cdot \widetilde{\nu} = (k^{-1})^*\widetilde{\nu} & \text{since the } g\text{-summands are independent of } g \end{array}$$

⊞

Given any $\mu \in \mathrm{H}_k^{\mathrm{tw}}(X;\mathbb{Z}[G])$ and $\nu \in \mathrm{H}_{n-k}^{\mathrm{tw}}(X;\mathbb{Z}[G])$ we perform the following calculation in $\mathbb{Z}[G]$:

$$\begin{array}{rcll} & & \text{definition of } Q_X & \text{since } \Psi \circ \Phi = \mathrm{id} \\ |G|^3 \cdot Q_X(\mu,\nu) & \overset{\downarrow}{=} & \epsilon_X((|G| \cdot \mathrm{PD}_X(\mu) \underset{\mathbb{Z}[G]}{\cup} |G| \cdot \mathrm{PD}_X(\nu)) \cap_{\mathbb{Z}} |G| \cdot [X]) & \overset{\downarrow}{=} \\ & = & \epsilon_X\big(\big(\Psi(\underbrace{\Phi(|G| \cdot \mathrm{PD}_X(\mu))}_{=|G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\mu))}) \underset{\mathbb{Z}[G]}{\cup} \Psi(\underbrace{\Phi(|G| \cdot \mathrm{PD}_X(\nu))}_{=|G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\nu))}) \big) \cap_{\mathbb{Z}} |G| \cdot [X]\big) & = (*) \end{array}$$

We pick $\widetilde{\mu} \in \mathrm{C}^{n-k}(\widehat{X}_\varphi;\mathbb{Z})$ that represents $|G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\nu))$ and we pick $\widetilde{\nu} \in \mathrm{C}^k(\widehat{X}_\varphi;\mathbb{Z})$ that represents $|G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\nu))$. Furthermore we pick $\sigma \in \mathrm{C}_n(\widehat{X}_\varphi)$ that represents the fundamental class $[\widehat{X}_\varphi]$. Note that it follows from the Fundamental Class-Covering Proposition 106.25 that $p_*(\sigma)$ represents $|G| \cdot [X]$. Then we obtain the following equalities in

$\mathbb{Z}[G]$:

$$
\begin{array}{lll}
 & \text{definition of } \widetilde{\mu}, \widetilde{\nu} \text{ and } \sigma & \text{Claim 2} \\
 & \downarrow & \downarrow \\
(*) & = \epsilon_X\big((\Psi(\widetilde{\mu}) \cup_{\mathbb{Z}[G]} \Psi(\widetilde{\nu})) \cap_{\mathbb{Z}} p_*(\sigma)\big) & = |G| \cdot \epsilon_X\Big(\sum_{k \in G} ((\widetilde{\mu} \cup k \cdot \widetilde{\nu}) \cdot k) \cap_{\mathbb{Z}} p_*(\sigma)\Big) \\
 & = |G| \cdot \epsilon_X\Big(\sum_{k \in G} p_*((\widetilde{\mu} \cup k \cdot \widetilde{\nu}) \cap_{\mathbb{Z}} \sigma) \cdot k\Big) & = |G| \cdot \sum_{k \in G} \epsilon_{\widehat{X}}\big((\widetilde{\mu} \cup k \cdot \widetilde{\nu}) \cap_{\mathbb{Z}} \sigma\big) \cdot k \\
 & \uparrow & \uparrow \\
 & \text{by explicit definitions of the cap products} & \text{by explicit definition of } \epsilon_X \text{ and } \epsilon_{\widehat{X}_\varphi} \\
 & = |G| \cdot \sum_{k \in G} \epsilon_{\widehat{X}}\big(|G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\mu)) \cup k \cdot |G| \cdot \mathrm{PD}_{\widehat{X}_\varphi}(\Omega(\nu))) \cap_{\mathbb{Z}} [X]\big) \cdot k & \\
 & \uparrow & \\
 & \text{choice of } \widetilde{\mu} \text{ and } \widetilde{\nu} & \\
 & = |G|^3 \cdot \sum_{k \in G} Q_{\widehat{X}_\varphi}(\Omega(\mu), k \cdot \Omega(\nu)) \cdot k \ \in \ \mathbb{Z}[G]. & \\
 & \uparrow & \\
 & \text{definition of } Q_{\widehat{X}_\varphi} &
\end{array}
$$

Since multiplication by $|G|^3$ is injective in $\mathbb{Z}[G]$ we obtain the desired result.[2116] ■

Exercises for Chapter 173.

Exercise 173.1. Let G be a finite group, let M be a $\mathbb{Z}[G]$-left module and let $\Theta\colon M \times M \to \mathbb{Z}$ be a pairing. Show that

$$
\begin{array}{rcl}
M \times M & \to & \mathbb{Z}[G] \\
(r, s) & \mapsto & \sum_{g \in G} \Theta(r, g \cdot s) \cdot g \ \in \ \mathbb{Z}[G]
\end{array}
$$

is $\mathbb{Z}[G]$-bilinear.

[2116] Frankly I find it weird that this fact gets used, one would naively think that the same statement also holds if we replace $\mathbb{Z}$ by $\mathbb{F}_2$.

174. Local coefficients

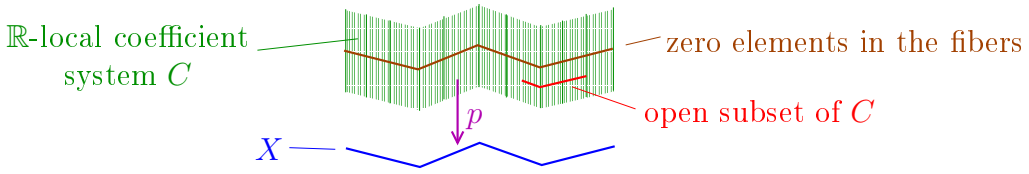
In the last chapters we introduced and discussed the main properties of (co-) homology with twisted coefficients. It was fairly easy to develop this theory with off-the-shelves methods and it works quite well when we want to study a single topological spaces.

But it has the awkward feature that it depends on the choice of a base point and that it is very difficult to study maps between different topological spaces. In the next chapter we will introduced (co-) homology with local coefficients. This concept rectifies many of the issues we had with (co-) homology with twisted coefficients. But before we can talk about (co-) homology with local coefficients we need to introduce the notion of a local coefficient system over a topological space. That is what we will do in this chapter.

174.1. **Local coefficients.**

Definition. Let X be a topological space and let G be an abelian group. A G-local coefficient system on X consists of the following:

(1) a topological space C,
(2) a map $p\colon C \to X$,
(3) a group structure on each fiber $C_x := p^{-1}(x)$, with $x \in X$.



such that the following condition is satisfies: Given any $x \in X$ there exists an open neighborhood U of x and a homeomorphism $f\colon p^{-1}(U) \to G \times U$, where we equip G with the discrete topology, such that the following two conditions are satisfied:[2117]

(1) The following diagram commutes:

$$\begin{array}{ccc} p^{-1}(U) & \xrightarrow[\cong]{f} & G \times U \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle (g,x)\mapsto x} & \\ & U. & \end{array}$$

(2) For each $x \in U$ the map $C_x = p^{-1}(x) \to G \times \{x\}$ is an isomorphism of groups.[2118]

Given a ring R we define in a very similar way an R-left module local coefficient system on X. If the group or the module are irrelevant, then we just talk of a local coefficient system.

Our first example of a local coefficient system gets an immediate upgrade to a definition.

Definition. Let X be a topological space and let G be an abelian group. We equip G with the discrete topology and we equip $G \times X$ with the product topology. We denote by $p\colon G \times X \to X$ the natural projection. It is clear that p defines a G-local coefficient system on X. We refer to it as the trivial G-local coefficient system and we denote it by ${}_{\mathrm{tr}}G$.

[2117] Later we will call such a map f a *local trivialization*.
[2118] Here we give $G \times \{x\}$ the obvious group structure coming from G.

The following definition shows that a local coefficient system gives to many other local coefficient systems.

Definition. Let X be a topological space, let G be an abelian group, and let $p\colon C \to X$ be a G-local coefficient system. Given any subspace $U \subset X$ we refer to

$$p|_U\colon p^{-1}(U) \;\to\; X$$

as the restriction of $p\colon C \to X$ to U. It is straightforward to verify that this is again a G-local coefficient system.

Lemma 174.1. Let X be a topological space and let G be an abelian group. Every G-local coefficient system $p\colon C \to X$ is a covering map, in the sense of the definition on page 1067.

Proof. This lemma is a special case of Lemma **??** (1). For the reader's convenience let us recall the argument. Since groups are by definition non-empty we see that $p\colon C \to X$ is surjective. Now let $x \in X$. By definition there exists an open neighborhood U of x and a homeomorphism $f\colon p^{-1}(U) \to G \times U$, where we equip G with the discrete topology, such that the following diagram commutes:

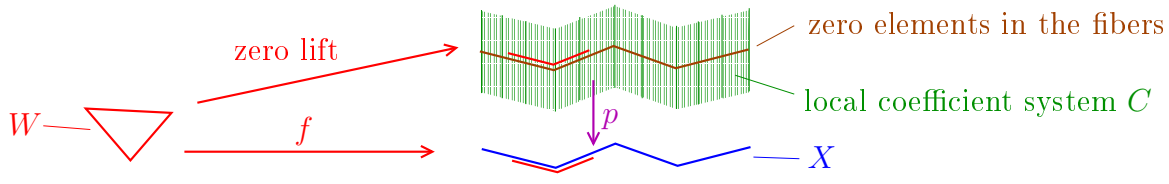
$$\begin{array}{ccc} p^{-1}(U) & \xrightarrow[\cong]{f} & G \times U \\ & {\scriptstyle p}\searrow \quad \swarrow{\scriptstyle (g,x)\mapsto x} & \\ & U. & \end{array}$$

It follows now easily from Exercise 5.4 that U is evenly covered. ∎

The following lemma can be viewed as an analogue of Lemma 143.3.

Lemma 174.2. Let $p\colon C \to X$ be a local coefficient system and let W be a topological space.

(1) Let $f\colon W \to X$ be a map. The map



$$\begin{array}{rcl} \widetilde{f}\colon W & \to & C \\ w & \mapsto & \text{the unique zero element in } p^{-1}(f(w)) \end{array}$$

is continuous. We refer to it as the *zero-lift of* f.

(2) Let $f, g\colon W \to C$ be two maps with $p \circ f = p \circ g$. Then the maps

$$\begin{array}{rcl} W & \to & C \\ w & \mapsto & \underbrace{f(w) + g(w)}_{\substack{\text{addition in the abelian} \\ \text{group } p^{-1}(f(w))}} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} W & \to & C \\ w & \mapsto & -f(w) \end{array}$$

are also continuous.

Proof. Note that by the Pasting Proposition 2.6 we have to verify continuity only locally. But locally the statement follows easily from the definition of a local coefficient system. ∎

The following definition is the analogue of the definition of a bundle map of vector bundles that we introduced on page 3068.

Definition. Let G and H be abelian groups.

(1) Let X and Y be topological spaces, let $p\colon C \to X$ be a G-local coefficient system and let $q\colon D \to X$ be an H-local coefficient system. A morphism from the G-local coefficient system $p\colon C \to Y$ to the H-local coefficient system $q\colon D \to Y$ is a pair of maps $\Phi\colon E \to F$ and $\varphi\colon X \to Y$ such that the following two conditions are satisfied:
   (a) The following diagram commutes:

$$\begin{array}{ccc} C & \xrightarrow{\Phi} & D \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{\varphi} & Y. \end{array}$$

   (b) For each $x \in X$ the map $f\colon C_x = p^{-1}(x) \to q^{-1}(\varphi(x)) = D_{\varphi(x)}$ is a homomorphism of abelian groups.

(2) Let X be a topological space, let $p\colon C \to X$ be a G-local coefficient system and let $q\colon D \to X$ be an H-local coefficient system. A morphism over X from the G-local coefficient system $p\colon C \to X$ to the H-local coefficient system $q\colon D \to X$ is a morphisms as in (1) but with $\varphi = \mathrm{id}_X$. This notion turns the local coefficient systems over a given topological space into a category. In particular it also allows us to say what it means for two local coefficient systems over a topological space X to be isomorphic.

The following definition is the analogue of the definition of a trivialization of a vector bundle that we gave on page 3063.

Definition. Let $p\colon F \to X$ be a G-local coefficient system.

(1) We say p is trivializable if p is isomorphic to the trivial G-local coefficient system ${}_{\mathrm{tr}}G = G \times X$.

(2) Any choice of an isomorphism $E \to {}_{\mathrm{tr}}G = G \times X$ is called a trivialization of the G-local coefficient system.

We have the following analogue of Proposition 143.18.

Proposition 174.3. Let $p\colon C \to X$ be a G-local coefficient system over a topological space X and let $\Phi\colon C \to {}_{\mathrm{tr}}G = G \times X$ be a trivialization. We denote by $q\colon G \times X \to G$ the projection. We equip $\mathrm{Aut}(G)$ with the discrete topology.

(1) If $f\colon X \to \mathrm{Aut}(G)$ is a continuous map, then the map

$$\begin{array}{ccc} C & \to & G \times X \\ c & \mapsto & (p(c), \underbrace{f(p(c))}_{\in \mathrm{Aut}(G)}(\underbrace{q(\Phi(c))}_{\in G}) \end{array}$$

   is also a trivialization.

(2) Every trivialization of $p\colon C \to X$ is of the form described in (1).

Proof. The proof is similar to the rather terse proof of Proposition 143.18. ∎

174.2. **Local coefficient systems and modules over group rings.** In the Vector Bundles-from-Representation 143.1 we showed that representations $\pi_1(X, x_0) \to \mathrm{GL}(n, \mathbb{R})$

gives rise to n-dimensional real vector bundles. The following lemma now shows that representations also give rise to local coefficient systems.

Proposition 174.4. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We write $\pi := \pi_1(X, x_0)$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering that defined on page 1370. Furthermore let M be a $\mathbb{Z}[\pi]$-left module, i.e. let M be an abelian group and suppose we are given a group homomorphism $\varphi\colon \pi \to \mathrm{Aut}(M)$. As on page 3503 we denote by $\overline{M}$ the $\mathbb{Z}[G]$-left module that is given by $m \underset{\overline{M}}{\cdot} g := g^{-1} \underset{M}{\cdot} m$. With slightly risque notation we set

$$ {}_{\varphi}M \;:=\; \overline{M} \times_{\pi} \widetilde{X}_{x_0} \;:=\; (\overline{M} \times \widetilde{X}_{x_0})/\!\sim \qquad \text{where } (m \cdot g, x) \sim (m, g \cdot x) $$

We equip $\overline{M}$ with the discrete topology, we equip $\overline{M} \times \widetilde{X}_{x_0}$ with the product topology and finally we equip ${}_{\varphi}M := (\overline{M} \times \widetilde{X}_{x_0})/\sim$ with the quotient topology.

(1) The map

$$ \begin{array}{rcl} q\colon \overline{M} \times_{\pi} \widetilde{X}_{x_0} & \to & X \\ [(m, x)] & \mapsto & p(x) \end{array} $$

is continuous.

(2) Let $x \in X$. We pick a path $\mu\colon [0,1] \to X$ from x_0 to x. The map

$$ \begin{array}{rcl} q^{-1}(x) & \to & M \\ [(m, [\alpha])] & \mapsto & \varphi([\underbrace{\mu * \overline{\alpha}}_{\text{loop in } x_0}])(m) \end{array} $$

$\uparrow$ path from x_0 to x

is well-defined and a bijection. We use the abelian group structure on M and this bijection to define a group structure on $q^{-1}(x)$. This group structure does not depend on the choice of μ.

All this data combined defines an M-local coefficient system on X.

Proof. The proof of the proposition is almost the same as the proof of the Vector Bundles-from-Representation 143.1. We leave it to the reader to make the necessary modifications. ■

Example. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. We denote by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. Furthermore let V be an abelian group. Let $\mathrm{tr}\colon \pi_1(X, x_0) \to \mathrm{Aut}(V)$ be the trivial homomorphism. One can easily verify that the map

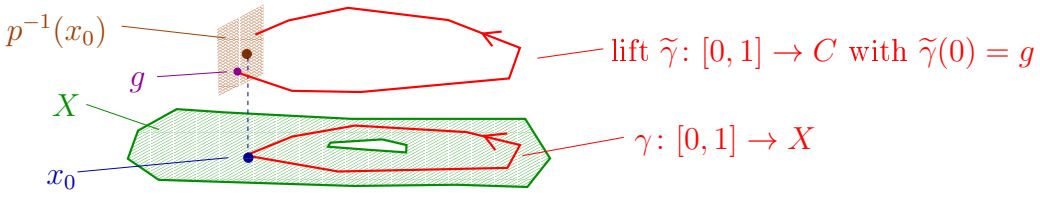
$$ \begin{array}{rcl} {}_{\mathrm{tr}}V = \overline{V} \times_{\pi_1(X,x_0)} \widetilde{X}_{x_0} & \to & {}_{\mathrm{tr}}V = V \times X \\ (v, \widetilde{x}) & \mapsto & (v, p(\widetilde{x})) \end{array} $$

is an isomorphism of local coefficient systems, in other words, it is a trivialization of the V-local coefficient system ${}_{\mathrm{tr}}V$.

If X is locally contractible and path-connected, then the converse holds. More precisely we have the following proposition.

Proposition 174.5. Let X be a topological space that is locally contractible and path-connected and let $p\colon C \to X$ be a G-local coefficient system. Let $x_0 \in X$. We denote

by $p\colon \widetilde{X}_{x_0} \to X$ the natural universal covering. There exists a $\mathbb{Z}[\pi_1(X,x_0)]$-left module structure on G such that the corresponding local coefficient system is isomorphic to the given G-local coefficient system $p\colon C \to X$.



Proof. Let x_0. Since $p\colon C \to X$ is a G-local coefficient system we know that the fiber $p^{-1}(x_0)$ is isomorphic to G.

Claim. The map

$$\begin{array}{rcl} \varphi\colon \pi_1(X,x_0) & \to & \mathrm{Aut}(p^{-1}(x_0)) \\ [\gamma] & \to & \left(\begin{array}{rcl} p^{-1}(x_0) & \to & p^{-1}(x_0) \\ & & \text{by Lemma 174.1 and Proposition 48.11 there exists} \\ g & \mapsto & \text{a unique lift } \widetilde{\gamma}\colon [0,1] \to C \text{ of } \gamma\colon [0,1] \to X, \\ & & \text{with } \gamma(0) = g, \text{ we set } \varphi([\gamma])(g) := \widetilde{\gamma}(1) \end{array} \right) \end{array}$$

is well-defined.

Proof. It follows immediately from Corollary 48.13 that the definition does not depend on the choice of the representative $\gamma\colon [0,1] \to X$ of the given element in $\pi_1(X,x_0)$. Furthermore it follows easily from Lemma 174.2 that given $[\gamma] \in \pi_1(X,x_0)$ the corresponding map $\varphi([\gamma])\colon p^{-1}(x_0) \to p^{-1}(x_0)$ is indeed a group homomorphism, i.e. it defines an element in $\mathrm{End}(p^{-1}(x_0))$. But one can also easily show that φ is a homomorphism of monoids, which then also implies that each $\varphi(g)$ is actually an automorphism of $p^{-1}(x_0)$. ⊞

Now we need to show that the G-local coefficient system that is defined by φ is isomorphic to the G-local coefficient system we started out with. We consider the map

$$\begin{array}{rcl} \Theta\colon p^{-1}(x_0) \times \widetilde{X}_{x_0} & \to & C \\ & & \text{by Lemma 174.1 and Proposition 48.11 there exists a unique} \\ (g,[\gamma]) & \mapsto & \text{lift } \widetilde{\gamma}\colon [0,1] \to C \text{ of } \gamma\colon [0,1] \to X \text{ with } \gamma(0) = g, \\ & & \text{we set } \Theta([\gamma])(g) := \widetilde{\gamma}(1) \end{array}$$

It follows again almost immediately from Corollary 48.13 that the definition does not depend on the choice of the representative $\gamma\colon [0,1] \to X$ of the given point in $\widetilde{M}$. One can easily verify that the map Θ descends to a map

$$p^{-1}(x) \times_{\pi_1(X,x_0)} \widetilde{X}_{x_0} \to C.$$

This map commutes with the projections to X and one can easily verify that it is an isomorphism on the fibers. It follows easily from the definition of a local coefficient system that this implies that the map is in fact an isomorphism of local coefficient systems. ■

174.3. Pullbacks of local coefficient systems.

Definition. Let $\varphi\colon X \to Y$ be a map between topological spaces and let $q\colon C \to Y$ be a G-local coefficient system on Y. We consider the pullback

$$\varphi^*C \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(\varphi(x))\} \;\subset\; X \times C,$$

which is equipped with the subspace topology and we consider the map

$$\begin{aligned} p\colon \varphi^*C \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(\varphi(x))\} &\to X \\ (x,v) &\mapsto x. \end{aligned}$$

Furthermore given any $x \in X$ we equip $p^{-1}(x) = \{x\} \times q^{-1}(\varphi(x))$ with the group structure that is already given on $q^{-1}(\varphi(x))$.

The pullback of a G-local coefficient system behaves in a similar fashion as the pullback of (vector) bundles that we had studied earlier. Since these statements are at times somewhat subtle it is worth spelling them out again.

The following lemma is the analogue of Lemmas **??** and 143.8.

Lemma 174.6. Let $\varphi\colon X \to Y$ be a map between topological spaces and let $q\colon C \to Y$ be a G-local coefficient system on Y. We consider the pullback

$$\varphi^*C \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(\varphi(x))\} \;\subset\; X \times C.$$

which we equip with the subspace topology, the map $p\colon \varphi^*C \to X$ and the group structure on the fibers as described above.

(1) The map $p\colon \varphi^*C \to X$ together with the group structures on the fibers is a G-local coefficient system over X.

(2) The maps $(x,v) \mapsto v$ and φ define a morphism of local coefficient systems:

$$\begin{array}{ccc} \varphi^*C & \xrightarrow{(x,v)\mapsto v} & C \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{\varphi} & Y. \end{array}$$

(3) If we are given a morphism of local coefficients

$$\begin{array}{ccc} C & \xrightarrow{\Phi} & D \\ {\scriptstyle r}\downarrow & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{\varphi} & Y \end{array}$$

such that for each $x \in X$ the map $\Phi|_{C_x}\colon C_x \to D_{\varphi(x)}$ is an isomorphism, then the local coefficient system $C \to D$ is naturally isomorphic to the pullback $\varphi^*D \to X$.

Proof. The proof is almost identical to the straightforward proof of Lemmas **??** and 143.8. ∎

We continue with the analogue of Lemmas **??** and 143.9.

Lemma 174.7. Let $\varphi\colon X \to Y$ be a map between topological spaces and let $q\colon F \to Y$ be a G-local coefficient system on Y. We consider the pullback

$$\varphi^*F \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(\varphi(x))\} \;\subset\; X \times F.$$

which we equip with the subspace topology, the map $p\colon \varphi^*F \to X$ and the group structure on the fibers as described above.

(1) The pullbacks of isomorphic G-local coefficient systems are isomorphic.
(2) Let $q\colon G \times Y = {}_{\mathrm{tr}}G \to Y$ be the trivial G-local coefficient system. The map
$$\begin{array}{ccc} \varphi^*\,{}_{\mathrm{tr}}G & \to & {}_{\mathrm{tr}}G \\ (x,(g,y)) & \mapsto & (g,x) \end{array}$$
is a natural isomorphism from the pullback of the trivial G-local coefficient system on Y to the trivial G-local coefficient system on X.
(3) The pullback of a trivializable G-local coefficient system is trivializable.
(4) If $q\colon F \to Y$ is a G-local coefficient system and if X is a subset of Y with inclusion map $i\colon X \to Y$, then
$$\begin{array}{ccc} i^*F & \to & q^{-1}(X) \\ (x,v) & \mapsto & v \end{array}$$
is a natural isomorphism from the G-local coefficient system $i^*F \to X$ to the restriction of F to the G-local coefficient system $q^{-1}(X) \to X$.

Proof. The proof is almost identical to the straightforward proof of Lemmas **??** and 143.9. ∎

Finally the next lemma says that pullbacks are contravariantly functorial. The lemma is the analogue of Lemmas **??** and 143.10.

Lemma 174.8.

(1) Let $q\colon F \to Z$ be a G-local coefficient system. Then
$$\begin{array}{ccc} \mathrm{id}_Z^*\,F & \to & F \\ (z,v) & \mapsto & v \end{array}$$
is a natural isomorphism from the pullback G-local coefficient system $\mathrm{id}_Z^*\,F \to Z$ to the original G-local coefficient system $q\colon F \to Z$.
(2) Let $q\colon F \to Z$ be a G-local coefficient system. If $\varphi\colon X \to Y$ and $\psi\colon Y \to Z$ are maps between topological spaces, then
$$\begin{array}{ccc} \varphi^*(\psi^*F) & \to & (\psi\circ\varphi)^*F \\ (x,(y,v)) & \mapsto & (x,v) \end{array}$$
is a natural isomorphism between the double pullback G-local coefficient system $\varphi^*(\psi^*F) \to X$ to the pullback G-local coefficient system $(\psi\circ\varphi)^*F \to X$.

Proof. The proof is almost identical to the straightforward proof of Lemmas **??**, **??** and 143.8. ∎

Lemma 174.9. Let X be a topological space that is locally contractible and path-connected. Let $x_0 \in X$. We write $\pi := \pi_1(X,x_0)$. Furthermore let M be a $\mathbb{Z}[\pi]$-left module, i.e. let M be an abelian group and suppose we are given a group homomorphism $\varphi\colon \pi_1(X,x_0) \to \mathrm{Aut}(M)$. Let $A \subset X$ be a subspace that is also locally contractible and path-connected and that contains x_0. We denote by $i\colon A \to X$ the inclusion map and we write $\Gamma := \pi_1(A,a_0)$.

We equip A with the representation $\varphi \circ i_* \colon \Gamma = \pi_1(A, x_0) \to \mathrm{Aut}(M)$. Then the map

$$\begin{array}{ccc} {}_{\varphi\circ i_*}M & \to & i^*{}_{\varphi}M \\ (v, [\alpha]) & \mapsto & (\alpha(1), \underbrace{[(v, [\alpha])]}_{\in M \times_\pi \widetilde{X}_{x_0}}) \\ \uparrow & & \\ \alpha \text{ is a path in } A \text{ with } \alpha(0) = x_0 & & \end{array}$$

is a natural isomorphism from the M-local coefficient system ${}_{\varphi\circ i_*}M \to A$ corresponding to the representation $\varphi \circ i_* \colon \pi_1(A, x_0) \to \mathrm{Aut}(M)$ to the pullback M-local coefficient system $i^*{}_{\varphi}M \to A$.

Proof. We consider the following heroic map:

$$\begin{array}{ccc} i^*{}_{\varphi}M & \to & {}_{\varphi\circ i_*}M \\ (a, [(v, [\gamma])]) & \mapsto & [(\varphi([\gamma * \overline{\alpha}])(v), \alpha)] \\ \uparrow & & \uparrow \\ \gamma \text{ is a path in } M & & \text{we pick a path } \alpha \text{ in } A \\ \text{with } \gamma(0) = x_0 & & \text{with } \alpha(0) = x_0 \text{ and } \alpha(1) = a \end{array}$$

We leave it to the reader to show that the given maps ${}_{\varphi\circ i_*}M \to i^*{}_{\varphi}M$ and $i^*{}_{\varphi}M \to {}_{\varphi\circ i_*}M$ are morphisms of M-local coefficients and that they are inverses of one another. ∎

174.4. **Local coefficient systems and homotopies.** In the Vector Bundles-Homotopies Proposition 143.13 we studied pullbacks of vector bundles under homotopic maps. The following is now the analogue of the Vector Bundles-Homotopies Proposition 143.13 in our present context.

Proposition 174.10. Let G be an abelian group.

(1) Let $q \colon F \to Y$ be a G-local coefficient system, let X be a topological space and finally let $\varphi_0, \varphi_1 \colon X \to Y$ be two maps.
   (a) Every homotopy $\Phi \colon X \times [0,1] \to Y$ between φ_0 and φ_1 naturally defines an isomorphism between the G-local coefficient systems $\varphi_0^* F \to X$ and $\varphi_1^* F \to X$.
   (b) In particular, if φ_0 and φ_1 are homotopic, then the G-local coefficient systems $\varphi_0^* F \to X$ and $\varphi_1^* F \to X$ are isomorphic.

(2) Let X be a topological space. If X is contractible, then every G-local coefficient system over X is trivializable.

Definition. Let G be an abelian group.

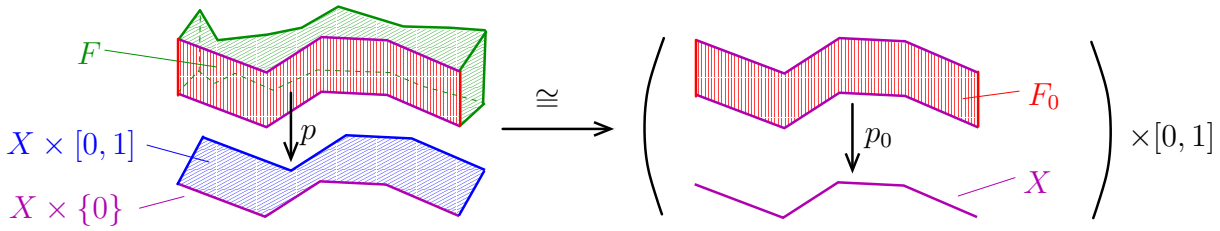
(1) If $q \colon F \to X$ is a G-local coefficient system and if Y is a topological space, then the product topological space $F \times Y$ together with the map

$$\begin{array}{rccc} q \times \mathrm{id}_Y \colon & F \times Y & \to & X \times Y \\ & (v, y) & \mapsto & (q(v), y) \end{array}$$

defines a G-local coefficient system in the obvious way

(2) Let $p \colon F \to X \times [0,1]$ be a G-local coefficient system. Given $t \in [0,1]$ we consider the G-local coefficient system

$$p_t \colon F_t := p^{-1}(X \times \{t\}) \xrightarrow{p} X \times \{t\} \xrightarrow{(x,t)\mapsto x} X.$$



Lemma 174.11. Let X be a topological space and let $p \colon F \to X \times [0,1]$ be a G-local coefficient system. As above we consider the G-local coefficient system $p_0 \colon F_0 := p_0^{-1}(X \times$

$\{0\}) \to X$. There exists a *unique* isomorphism of G-local coefficient systems

$$\begin{array}{ccc} F & \xrightarrow[\cong]{\Phi} & F_0 \times [0,1] \\ & {\scriptstyle p} \searrow \quad \swarrow {\scriptstyle p_0 \times \mathrm{id}_{[0,1]}} & \\ & X \times [0,1] & \end{array}$$

over $X \times [0,1]$ such that for any $x \in X$ and $v \in p^{-1}(x,0)$ we have

$$\Phi(v) \;=\; (v,0).$$

Proof of Lemma 174.11. We start out with the following claim.

Claim 1. Let $p\colon F \to Y \times [a,c]$ be a G-local coefficient system and let $b \in [a,c]$. If the restrictions of p to $Y \times [a,b]$ and to $Y \times [b,c]$ are both trivializable, then so is the restriction of p to $Y \times [a,c]$.

Proof. Since the restrictions of p to $Y \times [a,b]$ and to $Y \times [b,c]$ are both trivializable we can pick trivializations $\Phi\colon p^{-1}(Y \times [a,b]) \to G \times Y \times [a,b]$ and $\Psi\colon p^{-1}(Y \times [b,c]) \to G \times Y \times [b,c]$. We denote by $q\colon G \times Y \times [a,c] \to G$ the projection. It follows almost immediately from Proposition 174.3 that there exists a continuous map $\Theta\colon Y \times \{b\} \to \mathrm{Aut}(G)$ such that for all $v \in p^{-1}(Y \times \{b\})$ we have $q(\Phi(v)) = \Theta(p(v)) \cdot q(\Psi(v)) \in G$. It is straightforward to verify that

$$\begin{array}{rcl} p^{-1}(Y \times [a,c]) & \to & G \times Y \times [a,c] \\ v & \mapsto & \begin{cases} \Phi(v), & \text{if } p(v) \in Y \times [a,b], \\ (p(v), \Theta(p(y,b)) \cdot q(\Psi(v))), & \text{if } p(v) = (y,t) \in Y \times [b,c] \end{cases} \end{array}$$

is an isomorphism of G-local coefficient systems. ⊞

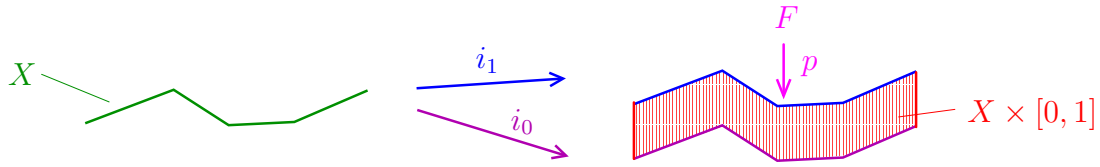
Now we turn to the actual setting of the lemma. Thus let $p\colon F \to X \times [0,1]$ be G-local coefficient system over a topological space X.

Claim 2. For every $x \in X$ there exists an open neighborhood U_x of $x \in X$ and a trivialization

$$\Theta_x\colon p^{-1}(U_x \times [0,1]) \;\to\; G \times U_x \times [0,1].$$

of the restriction of the G-local coefficient system $p\colon E \to X \times [0,1]$ to $U_x \times [0,1]$.

Proof. Let $x \in X$. By definition of a local coefficient system and by compactness of $[0,1]$ there exist neighborhoods $V_1, \ldots, V_m$ of x and $0 = t_0 < \cdots < t_m = 1$ such that the restriction of $p\colon E \to X \times [0,1]$ to each $V_i \times [t_{i-1}, t_i]$ is trivializable. It follows from Claim 1 that the restriction of p to $(V_1 \cap \cdots \cap V_m) \times [0,1]$ is also trivializable. Thus $U_x := V_1 \cap \cdots \cap V_m$ admits such a trivialization Φ_x. ⊞



We denote by $r\colon X \times [0,1] \to X$ and $s\colon X \times [0,1] \to [0,1]$ the obvious projection. Now let $x \in X$. We define

$$\begin{array}{rcl} \Phi_{U_x}\colon p^{-1}(U_x \times [0,1]) & \to & p^{-1}(U_x \times \{0\}) \times [0,1] \\ v & \mapsto & \text{we write } \Theta_x(v) = (g,y,t) \in G \times U_x \times [0,1] \text{ and} \\ & & \text{we set } \Phi_{U_x}(v) = (\Theta_x(y,0,g),t). \end{array}$$

Note that this map is continuous and an isomorphism on the fibers. Let $y \in X$. It follows from Proposition 174.3 together with the Connected-to-Discrete Lemma 2.27 applied to the map $y \times [0,1] \to p^{-1}(\{(y,0)\})$ that this map does not depend on the choice of $x \in X$ with $y \in U_x$. Thus it follows from the Pasting Proposition 2.6 that these maps Φ_x define a continuous map $\Phi\colon F \to F_0 \times [0,1]$ that is an isomorphism of local coefficient systems. Basically by definition we $\Phi(v) = (v,0)$ for every $x \in X$ and $v \in p^{-1}(x,0)$. ■

The following corollary is somewhat similar to Lemma 143.14.

Corollary 174.12. Let X be a topological space. We denote by $i_0\colon X \xrightarrow{x \mapsto (x,0)} X \times [0,1]$ and $i_1\colon X \xrightarrow{x \mapsto (x,1)} X \times [0,1]$ the obvious embeddings. Given any G-local coefficient system $p\colon F \to X \times [0,1]$ the pullbacks i_0^*F and i_1^*F are naturally isomorphic.

Proof of Corollary 174.12. Let $\Phi\colon F \to F_0 \times [0,1]$ be the unique isomorphism of G-local coefficient systems over $X \times [0,1]$ from Lemma 174.11. Note that for $t \in [0,1]$ we have

$$i_t^*(F_0 \times [0,1]) \;=\; \{(x,v,t) \in X \times F_0 \times [0,1] \,|\, v \in p^{-1}(x,0)\}.$$

Then we see that

$$\begin{array}{ccccccc} i_0^*F & \cong & i_0^*(F_0 \times [0,1]) & \cong & i_1^*(F_0 \times [0,1]) & \cong & i_1^*F. \\ \uparrow & & \uparrow & & \uparrow & & \\ \text{via the isomorphism } \Phi & & \text{a natural isomorphism is} & & \text{via the isomorphism } \Phi^{-1} & & \\ & & \text{given by } (x,v,0) \mapsto (x,v,1) & & & & \end{array}$$

■

The same way as we deduced the Vector Bundles-Homotopies Proposition 143.13 from Lemma 143.14 we can now deduce Proposition 174.10 from Corollary 174.12

Proof of Proposition 174.10.

(1) Let $q\colon F \to Y$ be a G-local coefficient system, let X be a topological space and let $H\colon X \times [0,1] \to Y$ be a homotopy between two maps $f_0, f_1\colon X \to Y$. We denote by $i_0, i_1\colon X \to X \times [0,1]$ the two obvious inclusions. Now we see that we have the following natural isomorphism

$$\begin{array}{ccccccccc} f_0^*F & = & (H \circ i_0)^*F & \cong & i_0^*(H^*F) & \cong & i_1^*(H^*F) & \cong & (H \circ i_1)^*F & = & f_1^*F. \\ \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \\ \text{since } f_0 = H \circ i_0 & & \text{Lemma 174.7} & & \text{Corollary 174.12} & & \text{Lemma 174.7} & & \text{since } f_1 = H \circ i_1 & & \end{array}$$

(2) Let $F \to X$ be a G-local coefficient system over a topological space that is contractible. We pick $x_0 \in X$. By the Contractibility Criterion Lemma 15.2 the inclusion map $i\colon \{x_0\} \to X$ is a homotopy equivalence. We denote by $p\colon X \to \{x_0\}$

the unique map. Note that $p \circ i$ is homotopic to i. Thus we have the following isomorphisms of G-local coefficient systems on X:

$$\begin{array}{ccccccc} F & \cong & (\mathrm{id}_X)^*F & \cong & (i \circ p)^*F & \cong & p^*(i^*F). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Lemma 174.7} & & \text{Statement (1)} & & \text{Lemma 174.7.} & \end{array}$$

Note that i^*F is a local coefficient system on a point, hence trivializable. Thus F is isomorphic to the pullback of a trivializable local coefficient system. Thus we obtain from Lemma 174.7 that F is trivializable. ■

174.5. **Tensor products of local coefficient systems.** The reader will have noticed that G-local coefficients are somewhat similar in spirit to vector bundles. In Section 143.8 we saw that many well-known constructions in linear algebra also work for vector bundles. For example we saw how to take the tensor product of two vector bundles. Similarly we can now construct new local coefficient systems out of given ones. This leads us to the following definition, which is modelled on the definition of the tensor product of vector bundles that we gave on page 3080.

Definition. Let X be a topological space, let $p\colon E \to X$ be a G-local coefficient system and let $q\colon F \to X$ be an H-local coefficient system. We consider the set

$$E \otimes_{\mathbb{Z}} F \;:=\; \bigsqcup_{x \in X} \underbrace{p^{-1}(x) \otimes_{\mathbb{Z}} q^{-1}(x)}_{\text{abelian group}} \quad \text{with the obvious map } r\colon E \otimes_{\mathbb{Z}} F \to X.$$

We equip $E \otimes_{\mathbb{Z}} F$ with the smallest topology that has the property that for any open subset $U \subset X$ and any two trivializations $\phi\colon p^{-1}(U) \to G \times U$ and $\psi\colon q^{-1}(U) \to U \times H$ the map

$$\begin{array}{ccc} r^{-1}(U) & \to & U \times \overbrace{(G \otimes_{\mathbb{Z}} H)}^{\text{discrete topology}} \\ v_x \otimes w_x & \mapsto & (x, \phi_x(v_x) \otimes \psi_x(w_x)) \end{array}$$

is a homeomorphism. One can now easily show that $r\colon E \otimes_{\mathbb{Z}} F \to X$ is a $G \otimes H$-local coefficient system. It is called the tensor product of the local coefficient systems E and F.

Lemma 174.13. Let X be a topological space and let $p\colon E \to X$ be a G-local coefficient system.

(1) The map

$$\begin{array}{ccc} \mu\colon E \otimes_{\mathbb{Z}\ {}_{\mathrm{tr}}\mathbb{Z}} & \to & E \\ (e \otimes n) & \mapsto & n \cdot e \end{array}$$

is a natural isomorphism of G-local coefficient systems.[2119]

(2) If $q\colon F \to X$ is another local coefficient system, then

$$\begin{array}{ccc} \tau\colon E \otimes_{\mathbb{Z}} F & \to & F \otimes_{\mathbb{Z}} E \\ e \otimes_{\mathbb{Z}} f & \mapsto & f \otimes_{\mathbb{Z}} e \end{array}$$

is a natural isomorphism of G-local coefficient systems.

Proof. We leave the verification of both statements to the reader. ■

[2119] Note that if G and G' are isomorphic abelian groups, then a G-local coefficient system is the same as a G'-local coefficient system. In particular every $G \otimes_{\mathbb{Z}} \mathbb{Z}$-local coefficient system is also a G-local coefficient system.

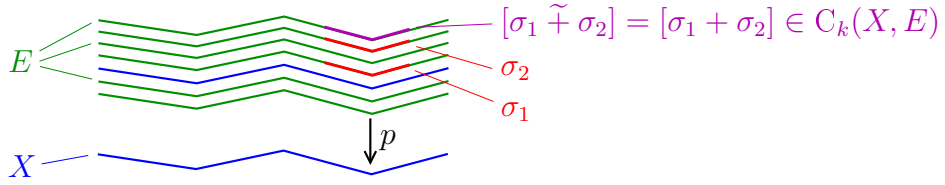
Exercises for Chapter 174.

Exercise 174.1. Let X be a topological space that is locally contractible and path-connected and let $x_0 \in X$. Let M and N be abelian groups and let $\varphi\colon \mathrm{Aut}(M)$ and $\psi\colon \mathrm{Aut}(N)$ be representations. We consider the corresponding $\mathbb{Z}[\pi_1(X, x_0)]$-left modules M and N and we consider the corresponding $\mathbb{Z}[\pi_1(X, x_0)]$-left module $M \otimes_{\mathbb{Z}} N$. As we saw in Proposition 174.4 these modules give rise to local coefficient systems that we denote by ${}_{\varphi}M$, ${}_{\varphi}N$ and ${}_{\varphi\otimes\psi}M \otimes_{\mathbb{Z}} N$. Show that the tensor product of the local coefficient systems ${}_{\varphi}M$ and ${}_{\varphi}N$ is isomorphic to the ${}_{\varphi\otimes\psi}M \otimes_{\mathbb{Z}} N$.

Exercise 174.2. Let X be a topological space and let $0 \to A \to B \to C \to 0$ be a short exact sequence of local coefficient systems over X. Show that this give rise to short exact sequences of (co-) homology groups with local coefficients.

175. (Co-) homology with local coefficients

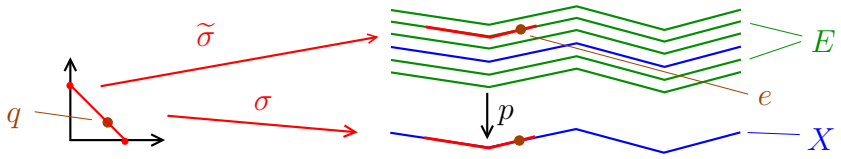
175.1. Homology with local coefficients.



Definition. Let X be a topological space, let G be an abelian group and let $p\colon E \to X$ be a G-local coefficient system.

(1) Given two singular k-simplices $\sigma_1, \sigma_2\colon X \to E$ in C with $p \circ \sigma_1 = p \circ \sigma_2$ we now define[21202121]
$$\begin{aligned} \sigma_1 \widetilde{+} \sigma_2\colon \Delta^k &\to E \\ x &\mapsto \underbrace{\sigma_1(x) + \sigma_2(x)}_{\text{sum in the fiber } E_x}. \end{aligned}$$

(2) As usual we denote by $\mathrm{C}_k(E)$ the set of singular k-chains in the topological space E. Now we set
$$\mathrm{C}_k^{\mathrm{lc}}(X; E) \;:=\; \mathrm{C}_k(E)/\sim$$
where $\sim$ is the equivalence relation generated by the relation that for two singular k-simplices σ_1, σ_2 in E with $p \circ \sigma_1 = p \circ \sigma_2$ we set $\sigma_1 + \sigma_2 \sim \sigma_1 \widetilde{+} \sigma_2$.



(3) Given a singular k-simplex $\sigma\colon X \to E$ we refer to corresponding element in $\mathrm{C}_k^{\mathrm{lc}}(X; E)$ as a singular k-simplex with coefficients in E.

(4) We refer to an element of $\mathrm{C}_k^{\mathrm{lc}}(X; E)$ as a singular k-chain with coefficients in E.

Convention. Let X be a topological space and let $p\colon E \to X$ be a local coefficient system. To preserve sanity in our notation we will usually not distinguish between a singular k-simplex with coefficients in E and the element it represents in $\mathrm{C}_k^{\mathrm{lc}}(X; E)$.

Lemma 175.1. (Unique Simplex Lifting Lemma) Let X be a topological space and let $p\colon E \to X$ be a local coefficient system. Furthermore let $\sigma\colon \Delta^n \to X$ be a singular simplex, let $q \in \Delta^n$ and let $e \in E$ such that $p(e) = \sigma(q)$. There exists a unique singular simplex $\widetilde{\sigma}\colon \Delta^n \to E$ with $p \circ \widetilde{\sigma} = \sigma\colon \Delta^n \to X$ and $\widetilde{\sigma}(q) = e$.

Proof. By Lemma 174.1 we know that $p\colon E \to X$ is a covering map. Thus the statement follows from general covering theory. More precisely, it follows from the Map Lifting Criterion 61.2 together with with the observation that Δ^n is simply connected and locally path-connected. ∎

[2120] By Lemma 174.2 we know that $\sigma_1 \widetilde{+} \sigma_2\colon \Delta^k \to E$ is continuous.

[2121] Since G is abelian we see that $\sigma_1 \widetilde{+} \sigma_2 = \sigma_2 \widetilde{+} \sigma_1$. It is a fun exercise to figure out where this actually gets used.

On page 1585 we introduced the boundary maps in the ordinary singular chain complexes. Since $\mathrm{C}_k^{\mathrm{lc}}(X;E)$ is a quotient of $\mathrm{C}_k(E)$ we do not need to be very creative when it comes to defining a boundary map on $\mathrm{C}_k^{\mathrm{lc}}(X;E)$:

Definition. Let X be a topological space and let $p\colon E \to X$ be a local coefficient system We refer to[2122]

$$\begin{array}{rcl} \partial_n\colon \mathrm{C}_k^{\mathrm{lc}}(X;E) & \to & \mathrm{C}_{k-1}^{\mathrm{lc}}(X;E) \\ \Big[\underbrace{\sum_{i=1}^{k}(\sigma_i\colon \Delta^n \to E)}_{\in \mathrm{C}_k(E)}\Big] & \mapsto & \Big[\sum_{i=1}^{k}\underbrace{\partial_k\sigma_i}_{\in \mathrm{C}_{k-1}(E)}\Big] \end{array}$$

as the k-th boundary map.

By Proposition 72.2 we know that each $\partial_{k-1}\circ\partial_k\colon \mathrm{C}_k(E) \to \mathrm{C}_{k-2}(E)$ is the zero map. It follows immediately that $(\mathrm{C}_*^{\mathrm{lc}}(X;E),\partial_*)$ is a chain complex. Thus we can define the corresponding homology groups.

Definition. Let X be a topological space and let $p\colon E \to X$ be a local coefficient system. Given $n \in \mathbb{N}_0$ we define the n-th singular homology group of X with E-coefficients as the quotient group

$$\mathrm{H}_n^{\mathrm{lc}}(X;E) \;:=\; \frac{\ker(\partial_n\colon \mathrm{C}_n^{\mathrm{lc}}(X;E) \to \mathrm{C}_{n-1}^{\mathrm{lc}}(X;E))}{\mathrm{im}(\partial_{n+1}\colon \mathrm{C}_{n+1}^{\mathrm{lc}}(X;E) \to \mathrm{C}_n^{\mathrm{lc}}(X;E))}.$$

Remark. The literature contains many different, but essentially equivalent, definitions of homology groups with coefficients in a local coefficient systems. We refer to [**KwS2018**, p. 284], [**DaK2001**, Chapter 5.3], [**WhdG1978**, Chapter VI.2] for slightly different definitions. Our definition is basically the same as the definition given in [**Hat2002**, Chapter 3.H]. There are few sources that study homology with local coefficients in details, the most thorough source seems to be [**WhdG1978**, Chapter VI].

From ordinary homology we are used to the fact that maps between topological spaces induces maps between homology groups. A similar statements holds for homology with local coefficients, but, as in the case of homology with twisted coefficients that we studied on page 3542, some care needs to be taken to work with matching local coefficient systems.

Definition. Let $f\colon X \to Y$ be a map between topological spaces and let $p\colon E \to Y$ be a G-local coefficient system on Y. We denote by $q\colon f^*E \to E$ the projection. We define

$$\begin{array}{rcl} f_*\colon \mathrm{C}_k^{\mathrm{lc}}(X;f^*E) & \to & \mathrm{C}_k^{\mathrm{lc}}(Y;E) \\ [\sigma\colon \Delta^k \to f^*E] & \to & [q\circ\sigma\colon \Delta^k \to E] \end{array}$$

One can easily verify that these maps are well-defined and that they form a chain map. Thus we obtain induced maps

$$f_*\colon \mathrm{H}_k^{\mathrm{lc}}(X;f^*E) \;\to\; \mathrm{H}_k^{\mathrm{lc}}(Y;E).$$

The previous definition now also allows us to introduce relative homology with local coefficients.

[2122] Let $i_j^k\colon \Delta^{k-1} \to \Delta^k$ be the face maps as defined on page 1585. Let $\sigma_1,\sigma_2\colon \Delta^k \to X$ be two singular simplices with $p\circ\sigma_1 = p\circ\sigma_2$. It follows easily from the definitions that $i_j^k\circ\sigma_1 \mathbin{\widetilde{+}} i_j^k\circ\sigma_2 = i_j^k\circ(\sigma_1 \mathbin{\widetilde{+}} \sigma_2)$. It follows from this observation that the usual boundary map ∂_n descends to a map $\mathrm{C}_k^{\mathrm{lc}}(X;E) \to \mathrm{C}_{k-1}^{\mathrm{lc}}(X;E)$.

Definition.

(1) Let X be a topological space, let $A \subset X$, let G be an abelian group and let $p\colon E \to X$ be a G-local coefficient system. We denote by $i\colon A \to X$ the inclusion. We set
$$\mathrm{C}^{\mathrm{lc}}_n(X, A; E) \;:=\; \mathrm{coker}(i_*\colon \mathrm{C}^{\mathrm{lc}}_n(A; i^*E) \to \mathrm{C}^{\mathrm{lc}}_n(X; E)).$$
By Lemma 166.1 we know that the chain map on $\mathrm{C}^{\mathrm{lc}}_n(X; E)$ descends to a chain map on $\mathrm{C}^{\mathrm{lc}}_n(X, A; E)$. Thus we can set
$$\mathrm{H}^{\mathrm{lc}}_n(X, A; E) \;:=\; \mathrm{H}_n(\mathrm{C}^{\mathrm{lc}}_*(X, A; E)).$$

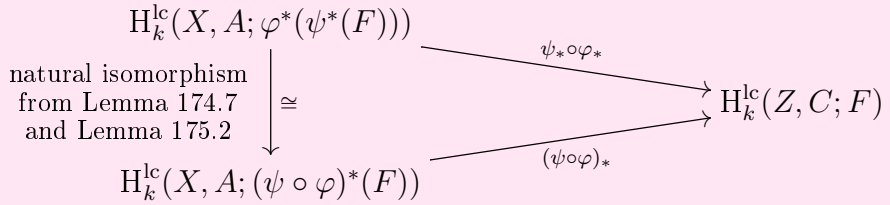
(2) If we are given a map $f\colon (X, A) \to (Y, B)$ of pairs of topological spaces and if we are given a G-local coefficient system E on Y, then as before we get induced maps $f_*\colon \mathrm{C}^{\mathrm{lc}}_k(X, A; f^*E) \to \mathrm{C}^{\mathrm{lc}}_k(Y, B; E)$ and $f_*\colon \mathrm{H}^{\mathrm{lc}}_k(X, A; f^*E) \to \mathrm{H}^{\mathrm{lc}}_k(Y, B; E)$.

The following lemma, which can be viewed as a generalization of Lemma 89.7 and an analogue of Lemma 167.4 says that singular homology with local coefficients is covariantly functorial in the local coefficient system.

Lemma 175.2. Let X be a topological space and let $A \subset X$.

(1) Let $\varphi\colon E \to F$ be a morphism from a G-local coefficient system $p\colon E \to X$ to an H-local coefficient system $q\colon F \to X$. The maps
$$\begin{aligned} \varphi_*\colon \mathrm{C}^{\mathrm{lc}}_k(X, A; E) &\to \mathrm{C}^{\mathrm{lc}}_k(X, A; F) \\ [\sigma\colon \Delta^k \to E] &\to [\varphi \circ \sigma\colon \Delta^k \to F] \end{aligned}$$
are a well-defined chain map and thus they induce maps
$$\varphi_*\colon \mathrm{H}^{\mathrm{lc}}_k(X, A; E) \;\to\; \mathrm{H}^{\mathrm{lc}}_k(X, A; F).$$

(2) With the obvious interpretations we have $(\psi \circ \varphi)_* = \psi_* \circ \varphi_*$ and $\mathrm{id}_* = \mathrm{id}$.



Proof. We leave the elementary proof of the lemma to the reader. ∎

The following lemma shows that homology with local coefficients is "almost" covariantly functorial.

Lemma 175.3. Let $p\colon F \to Z$ be a G-local coefficient system on a topological space Z and let $C \subset Z$.

(1) The natural isomorphism between the G-local coefficient systems $\mathrm{id}^* F$ and F that we gave in Lemma 174.7 induces the map $\mathrm{id}_*\colon \mathrm{H}^{\mathrm{lc}}_k(Z, C; \mathrm{id}^* F) \to \mathrm{H}^{\mathrm{lc}}_k(Z, C; F)$.

(2) Let $\varphi\colon (X, A) \to (Y, B)$ and $\psi\colon (Y, B) \to (Z, C)$ be maps between pairs of topological spaces We have the following commutative diagram:

Remark. Lemma 175.3 plays the same role as the Twisted Homology-Functoriality Proposition 167.9 did for homology with twisted coefficients. Note that the statement for homology with twisted coefficients is much neater though, since we do not need the awkward

vertical map to go from one coefficient system to another. On the other hand, when we are dealing with twisted coefficients we have to constantly worry about base points.

Proof. All the statements follows immediately from the definitions. We leave it to the reader to provide the details. ■

We formulate our first example as a lemma. It says that homology with local coefficients in a trivial G-local coefficient system is basically the same as our old friend, namely singular homology with G-coefficients.

Lemma 175.4. Let X be a topological space, let $A \subset X$ and let G be an abelian group. We denote by $p\colon {}_{\mathrm{tr}}G := G \times X \to X$ the corresponding trivial G-local coefficient system that we introduced on page 3643.

(1) The maps

$$\begin{array}{rcl} T\colon \mathrm{C}_k(X,A) \otimes_{\mathbb{Z}} G & \to & \mathrm{C}_k^{\mathrm{lc}}(X,A;{}_{\mathrm{tr}}G) = \mathrm{C}_k^{\mathrm{lc}}(X,A;G\times X) \\ \sigma \otimes g & \mapsto & \text{the lift } \sigma \to G\times X \text{ given by } x \mapsto (\sigma(x),g) \end{array}$$

define a chain isomorphism that is natural in the sense that given a homomorphism $\varphi\colon G \to H$ between abelian groups the following diagram commutes:

$$\begin{array}{ccc} \mathrm{C}_k(X,A;G) & \xrightarrow{\qquad\varphi_*\qquad} & \mathrm{C}_k(X,A;H) \\ {\scriptstyle T}\big\downarrow & & \big\downarrow{\scriptstyle T} \\ \mathrm{C}_k^{\mathrm{lc}}(X,A;{}_{\mathrm{tr}}G) & \xrightarrow{\qquad\varphi_*\qquad} & \mathrm{C}_k^{\mathrm{lc}}(X,A;H\,{}_{\mathrm{tr}}H) \end{array}$$

and it is natural in the sense that given any map $f\colon (X,A) \to (Y,B)$ between pairs of topological spaces the following diagram commutes:

$$\begin{array}{ccccc} \mathrm{C}_k(X,A;G) & & \xrightarrow{\qquad f_*\qquad} & & \mathrm{C}_k(Y,B;G) \\ {\scriptstyle T}\big\downarrow & & & & \big\downarrow{\scriptstyle T} \\ \mathrm{C}_k^{\mathrm{lc}}(X,A;{}_{\mathrm{tr}}G) & \xrightarrow[\text{Lemma 174.7}]{\text{isomorphism from}} & \mathrm{C}_k^{\mathrm{lc}}(X,A;f^*({}_{\mathrm{tr}}G)) & \xrightarrow{f_*} & \mathrm{C}_k^{\mathrm{lc}}(Y,B;{}_{\mathrm{tr}}G). \end{array}$$

(2) The natural chain isomorphisms from (1) give rise to isomorphisms

$$\mathrm{H}_k(X,A;G) \xrightarrow{\cong} \mathrm{H}_k^{\mathrm{lc}}(X,A;{}_{\mathrm{tr}}G)$$

that are natural in the above sense.

Proof. We denote by $p\colon G\times X \to X$ and $q\colon G\times X \to G$ the two projections. We consider the map

$$\begin{array}{rcl} \mathrm{C}_k^{\mathrm{lc}}(X,A;G\times X) & \to & \mathrm{C}_k(X,A)\otimes_{\mathbb{Z}} G \\ [\sigma\colon \Delta^k \to G\times X] & \mapsto & \sigma\otimes g, \text{where } g \text{ is the unique } g\in G \text{ with } q(\sigma(\Delta^k)) = \{g\}. \end{array}$$

We leave it to the reader to show that the two given maps are chain maps, that they are natural in the stated sense and that they are inverses of one another. ■

In the Homotopy Equivalence-H_*-Corollary 73.9 and Proposition 74.15 we showed that homotopic maps induce chain homotopic maps on (relative) singular chain complexes. In Corollary 167.14 we saw that an analogous statement also holds for (co-) homology with twisted coefficients. The following proposition is the "local coefficient" analogue.

[2122]By the Unique Simplex Lifting Lemma 175.1 we know that such a lift exists and that it is unique.

Proposition 175.5. Let $h_0, h_1 \colon (X, A) \to (Y, B)$ be two maps between pairs of topological spaces and let $p \colon F \to Y$ be a G-local coefficient system on Y.

(1) If $H \colon X \times [0,1] \to Y$ is a homotopy between h_0 and h_1, then we obtain from Proposition 174.10 an explicit isomorphism Θ_H between the G-local coefficient systems h_0^*F and h_1^*F. If for each $t \in [0,1]$ we have $H_t(A) \subset B$, then the maps

$$\begin{array}{rcl} (h_0)_* \colon \mathrm{C}_k^{\mathrm{lc}}(X, A; h_0^*F) & \to & \mathrm{C}_k^{\mathrm{lc}}(Y, B; F) \\ \text{and} \quad (h_1)_* \circ (\Theta_H)_* \colon \mathrm{C}_k^{\mathrm{lc}}(X, A; h_0^*F) & \to & \mathrm{C}_k^{\mathrm{lc}}(X, A; h_1^*F) \to \mathrm{C}_k^{\mathrm{lc}}(Y, B; F) \end{array}$$

are chain homotopic, in particular they induce the same map on homology.

(2) Homotopy equivalences induces isomorphisms on homology groups with local coefficients.

In the Homotopy Equivalence-H_*-Corollary 73.9 we showed the analogous statement for ordinary singular homology. The idea for the proof of Proposition 175.5 is that, by carefully reading the proof of the Homotopy Equivalence-H_*-Corollary 73.9, we can modify the proof of the Homotopy Equivalence-H_*-Corollary 73.9 to give us the statement we are presently interested in. It is thus convenient to recall the main concepts behind the proof of the Homotopy Equivalence-H_*-Corollary 73.9.

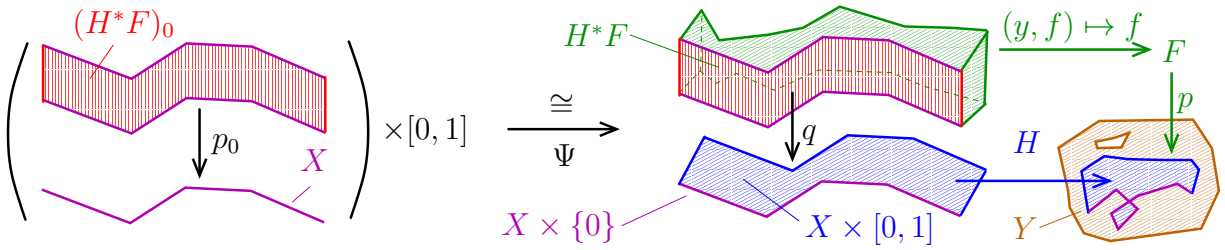
Lemma 73.8. Let W and F be topological spaces and let $\widetilde{H} \colon W \times [0,1] \to F$ be a homotopy. Let $\Omega_n \in \mathrm{C}_{n+1}(\Delta^n \times [0,1])$, $n \in \mathbb{N}_0$, be the sequence of singular chains that we defined on page 1605.[2123] The maps

$$\begin{array}{rcl} P_n \colon \mathrm{C}_n(W) & \to & \mathrm{C}_{n+1}(F) \\ (\sigma \colon \Delta^n \to W) & \mapsto & (\widetilde{F} \circ (\sigma \times \mathrm{id}_{[0,1]}))_*(\Omega_n). \end{array}$$

satisfy

$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \ = \ \widetilde{H}_{0*} - \widetilde{H}_{1*}$$

as maps from $\mathrm{C}_n(W)$ to $\mathrm{C}_n(F)$.



Proof of Proposition 175.5. To simplify the notation we assume that $A = B = \varnothing$. Mathematically this extra hypothesis makes no real difference. Thus let $h_0, h_1 \colon X \to Y$ be two maps between topological spaces and let $p \colon F \to Y$ be a G-local coefficient system on Y. Furthermore let $H \colon X \times [0,1] \to Y$ be a homotopy between h_0 and h_1. We consider the G-local coefficient system $q \colon H^*F \to X \times [0,1]$. As on page 3650 we consider the G-local coefficient system

$$\begin{array}{rcl} q_t \colon (H^*F)_t := q^{-1}(X \times \{t\}) & \to & X \\ v & \mapsto & \text{unique } x \in X \text{ with } q(v) = (x,t). \end{array}$$

Recall that by Lemma 174.11 there exists a unique isomorphism of G-local coefficient systems $\Psi \colon (H^*F)_0 \times [0,1] \to H^*F$ over $X \times [0,1]$ such that for any $x \in X$ and $v \in q^{-1}(x,0)$ we have $\Psi(v,0) = v$. Next we consider the map

$$\begin{array}{rcccl} \widetilde{H} \colon (H^*F)_0 \times [0,1] & \to & H^*F & \to & F \\ (v,t) & \mapsto & \Psi(v,t) & & \\ & & (z,f) & \mapsto & f. \end{array}$$

[2123] The precise definition of the Ω_n is completely irrelevant for what follows.

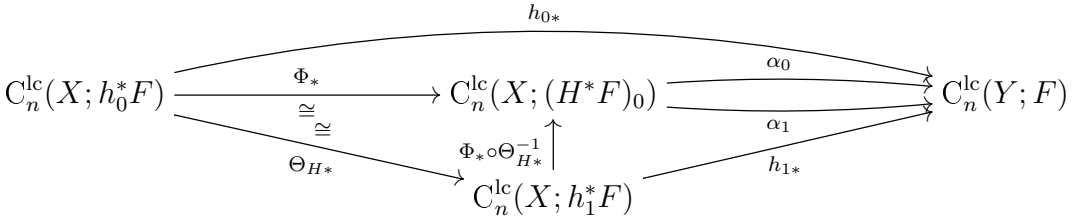
Claim. The explicit chain homotopy

$$P_n \colon \mathrm{C}_n((H^*F)_0) \;\to\; \mathrm{C}_{n+1}(F)$$

from Lemma 73.8 between $\widetilde{H}_{0*} \colon \mathrm{C}_n((H^*F)_0) \to \mathrm{C}_n(F)$ and $\widetilde{H}_{1*} \colon \mathrm{C}_n((H^*F)_0) \to \mathrm{C}_n(F)$ descends to a chain homotopy

$$Q_n \colon \underbrace{\mathrm{C}^{\mathrm{lc}}_n(X;(H^*F)_0)}_{=\mathrm{C}_n((H^*F)_0)/\sim} \;\to\; \underbrace{\mathrm{C}^{\mathrm{lc}}_{n+1}(Y;F)}_{=\mathrm{C}_{n+1}(F)/\sim}$$

between



$$\begin{array}{rcl} \alpha_0 \colon \mathrm{C}^{\mathrm{lc}}_n(X;(H^*F)_0) & \to & \mathrm{C}^{\mathrm{lc}}_n(Y;F) \\ [\sigma] & \mapsto & [\widetilde{H}_{0*}(\sigma)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \alpha_1 \colon \mathrm{C}^{\mathrm{lc}}_n(X;(H^*F)_0) & \to & \mathrm{C}^{\mathrm{lc}}_n(Y;F) \\ [\sigma] & \mapsto & [\widetilde{H}_{1*}(\sigma)]. \end{array}$$

Proof. We need to show that the equivalence relation that we introduced on page 3655 is respected. Thus let $\sigma_1, \sigma_2 \colon X \to (H^*F)_0$ be two singular n-simplices with $p \circ \sigma_1 = p \circ \sigma_2$. It follows easily from the explicit definitions of the maps P_n in Lemma 73.8 that $P_n(\sigma_1 \widetilde{+} \sigma_2) = P_n(\sigma_1) \widetilde{+} P_n(\sigma_2)$. ⊞

Before we come to the denouement of the argument we need to introduce the following isomorphism of local coefficient systems over X:

$$\begin{array}{rcl} \Phi \colon h_0^*F & \to & (H^*F)_0 \\ (x,v) & \mapsto & ((x,0),v). \end{array}$$

Finally we consider the following diagram

It follows easily from the definition that this diagram commutes??? By the claim the two maps $\alpha_0, \alpha_1 \colon \mathrm{C}^{\mathrm{lc}}_n(X;(H^*F)_0) \to \mathrm{C}^{\mathrm{lc}}_n(Y;F)$ are chain homotopic. Since the diagram commutes we see that the two maps $\mathrm{C}^{\mathrm{lc}}_n(X;h_0^*F) \to \mathrm{C}^{\mathrm{lc}}_n(Y;F)$ are also chain homotopic. But that is what we had to show. ■

We have the following analogue of Proposition 168.2.

Proposition 175.6. Let X be a topological space that is locally contractible and path-connected. We pick $x_0 \in X$ and we write $\pi := \pi_1(X,x_0)$. We denote by $p \colon \widetilde{X}_{x_0} \to$

X the corresponding universal covering which we equip with the natural base point $\widetilde{x}_0$. Furthermore $\Gamma \subset \pi_1(X, x_0)$ be a subgroup[2124]. Let let $p\colon (Y_\Gamma, y_0) \to (X, x_0)$ be a covering of pointed topological spaces with $p_*(\pi_1(Y_\Gamma, y_0)) = \Gamma$. By Corollary 61.11 we know that there exists a unique covering $q\colon \widetilde{X}_{x_0} \to Y_\Gamma$ with $q(\widetilde{x}_0) = y_0$. We equip the abelian group $\mathbb{Z}[\Gamma\backslash\pi]$ with the $\mathbb{Z}[\pi]$-left module structure φ that is given by $\varphi(g) \cdot \Gamma h := \Gamma h \cdot g^{-1}$. As in Proposition 174.4 we consider the coefficient system

$$\begin{array}{rcl} {}_\varphi\mathbb{Z}[\Gamma\backslash\pi] := \mathbb{Z}[\Gamma\backslash\pi] \times_\pi \widetilde{X}_{x_0} & \to & X \\ [(m,x)] & \mapsto & p(x). \end{array}$$

(1) The maps ????

$$\begin{array}{rcl} \mathrm{C}_k^{\mathrm{lc}}(X; {}_\varphi\mathbb{Z}[\Gamma\backslash\pi]) & \to & \mathrm{C}_k(Y_\Gamma) \\ \sigma\colon \Delta^k & \mapsto & \text{pick lift } (\sigma_1, \sigma_2) \text{ to } \mathbb{Z}[\Gamma\backslash\pi] \times \widetilde{X}_{x_0} \text{ and consider } \sigma_1(\Delta^k) \cdot q \circ \sigma_2 \end{array}$$

form an isomorphism of chain complexes.

(2) If Γ is normal in π, then we equip $\mathbb{Z}[\Gamma\backslash\pi]$ with the obvious $\mathbb{Z}[\Gamma\backslash\pi]$-left module structure and we equip Y_Γ with the $\Gamma\backslash\pi$- left action given by Proposition 167.1. In this setting the above isomorphism is an isomorphism of $\mathbb{Z}[\Gamma\backslash\pi])$-left modules.

(3) For each $k \in \mathbb{N}_0$ the above maps induce an isomorphism

$$\mathrm{H}_k^{\mathrm{lc}}(X; {}_\varphi\mathbb{Z}[\Gamma\backslash\pi]) \to \mathrm{H}_k(Y_\Gamma).$$

Proof. We can write down explicit inverse maps. More precisely we consider the map

$$\begin{array}{rcl} \mathrm{C}_k(Y_\Gamma) & \to & \mathrm{C}_k^{\mathrm{lc}}(X; {}_\varphi\mathbb{Z}[\Gamma\backslash\pi]) \\ (\sigma\colon \Delta^k \to Y_\Gamma) & \mapsto & \begin{array}{c} \text{pick lift } \widetilde{\sigma}\colon \Delta^k \to \widetilde{X}_{x_0} \text{ and consider the} \\ \text{map } \Delta^k \to \mathbb{Z}[\Gamma\backslash\pi] \times \widetilde{X}_{x_0} \text{ that is given by } x \mapsto [(1, \widetilde{\sigma}(x))]. \end{array} \end{array}$$

We leave it to the reader to show that the maps are both chain maps and that they are inverses of one another. ■

Example. We consider the usual covering $p\colon \mathbb{R} \to S^1$ that is given by $p(t) = \exp(2\pi \mathrm{i} t)$. The corresponding coefficient system is isomorphic to the local coefficient system ${}_\varphi\mathbb{Z}[t^{\pm 1}]$ that we introduced on page **??**. Thus we see that for each $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k^{\mathrm{lc}}(S^1; {}_\varphi\mathbb{Z}[t^{\pm 1}]) \underset{\uparrow}{\cong} \mathrm{H}_k^{\mathrm{lc}}(\mathbb{R}; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Proposition 175.6

175.2. **Cohomology with local coefficients.** On page 2402 we defined singular cohomology by a purely formal method, namely by taking the dual of the singular chain complex. A similar, purely formal, approach allowed us on page 3537 to define cohomology with twisted coefficients. Perhaps somewhat surprisingly singular cohomology with local coefficients is defined independently of the chain complex with local coefficients. First let us introduce the following notation.

Notation. Given a topological space Y and given $n \in \mathbb{N}_0$ we set

$$\mathrm{S}_n(Y) := \text{the set of all singular } n\text{-simplices in } Y,$$

[2124]Note that we do not demand that the subgroup is normal.

in other words, $\mathrm{S}_n(Y)$ is the set of all maps $\Delta^n \to Y$.

Definition. Let X be a topological space and let $p\colon E \to X$ be a local coefficient system.

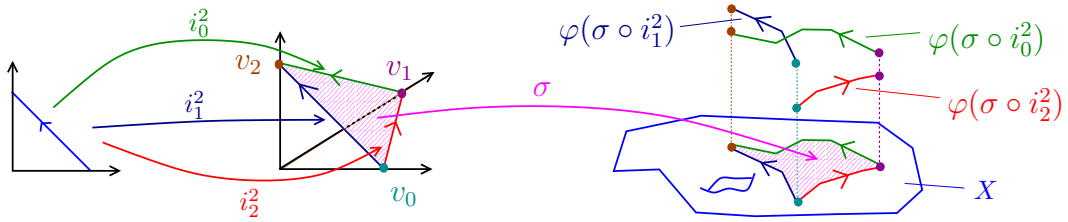
(1) A *n-cochain with respect to the local coefficient system $p\colon E \to X$* is a map

$$\varphi\colon \mathrm{S}_n(X) \to \mathrm{S}_n(E)$$

such that for every $\sigma\colon \Delta^n \to X$ the corresponding map $\varphi(\sigma)\colon \Delta^n \to E$ is a lift of σ, i.e. we have $p \circ \varphi(\sigma) = \sigma$.

(2) Given two n-cochains $\varphi, \psi\colon \mathrm{S}_n(X) \to \mathrm{S}_n(E)$ we define

$$\begin{aligned} \varphi + \psi\colon \mathrm{S}_n(X) &\to \mathrm{S}_n(E) \\ \sigma &\mapsto \left(\begin{array}{ccc} \Delta^n & \to & E \\ x & \mapsto & \underbrace{(\varphi(\sigma))(x) + (\psi(\sigma))(x)}_{\substack{\text{addition in the group } p^{-1}(x), \\ \text{continuous by Lemma 174.2}}} \end{array} \right). \end{aligned}$$



One can easily verify that this addition turns the set of cochains into an abelian group, where the trivial element is the cochain that sends every simplex to the zero-lift.

(3) We denote by $\mathrm{C}^n_{\mathrm{lc}}(X; E)$ the group of all n-cochains.

(4) Given $n \in \mathbb{N}_0$ we define the *coboundary*[2125]

$$\begin{aligned} \delta^n\colon \mathrm{C}^n_{\mathrm{lc}}(X;E) &\to \mathrm{C}^{n+1}_{\mathrm{lc}}(X;E) \\ \varphi &\mapsto \left(\begin{array}{ccc} \mathrm{S}_{n+1}(X) & \to & \mathrm{S}_{n+1}(E) \\ \sigma & \mapsto & \sum_{j=0}^{n+1} (-1)^j \cdot \text{the unique lift}^{2126}\ \widetilde{\sigma}\colon \Delta^{n+1} \to E \text{ such that } \varphi(\sigma \circ i^{n+1}_j) \text{ and } \widetilde{\sigma} \circ i^n_j \text{ agree} \end{array} \right). \end{aligned}$$

It follows easily from the definitions that δ^n is a homomorphism.

One of the most fundamental facts in algebraic topology, proved in Proposition 72.2, is the fact that the composition of two boundary maps $\partial_n\colon \mathrm{C}_n(X) \to \mathrm{C}_{n-1}(X)$ and $\partial_{n-1}\colon \mathrm{C}_{n-1}(X) \to \mathrm{C}_{n-2}(X)$ is the zero map. The following proposition now says that the analogous statement also holds for the above coboundary maps.

Proposition 175.7. Let X be a topological space and let $p\colon E \to X$ be a local coefficient system. For any $n \in \mathbb{N}_0$ the composition

$$\delta^{n+1} \circ \delta^n\colon \mathrm{C}^n_{\mathrm{lc}}(X;E) \to \mathrm{C}^{n+2}_{\mathrm{lc}}(X;E)$$

is the zero map.

Proof.

[2125] We define the sum of two lifts and the inverse of a lift by the usual fiberwise operations.

[2126] By the Unique Simplex Lifting Lemma 175.1 we know that such a lift exists and that it is unique.

If we are dealing with a trivial local coefficient system, then Proposition 175.7 boils down very quickly to the setting for the usual singular cochains. For a general local coefficient system the situation is initially much more puzzling, since we cannot compare the various fibers in a coherent way. What saves the day is the observation that we only have to work with a singular simplex $\sigma\colon \Delta^{n+2} \to X$ at a time, and that the pullback of the local coefficient system E to Δ^{n+2} is trivializable, since Δ^{n+2} is contractible. Thus we can deduce the desired statement after all from the classical statement.

We start out with several preparations:

(a) Let $\mu\colon D \to X$ be a map between topological spaces and let $p\colon E \to X$ be a G-local coefficient system on X. We define

$$\begin{array}{rcl} \mu^*\colon \mathrm{C}^k_{\mathrm{lc}}(X;E) & \to & \mathrm{C}^k_{\mathrm{lc}}(D;\mu^*E) \\ \psi & \mapsto & \left(\begin{array}{rcl} \mathrm{S}_k(D) & \to & \mathrm{S}_k(\mu^*E) \\ (\sigma\colon \Delta^k \to D) & \mapsto & \left(\begin{array}{rcl} \Delta^k & \to & \mu^*E \\ z & \mapsto & (\sigma(z), \underbrace{\psi(\underbrace{\mu \circ \sigma}_{\in \mathrm{S}_k(X)})}_{\in \mathrm{S}_k(E)}(z)) \end{array} \right) \end{array} \right) \end{array}$$

We make the following two observations:

- It follows easily from the definitions that $\delta \circ \mu^* = \mu^* \circ \delta$.
- We denote by $q\colon \mu^*E \to E$ the projection. If $\sigma\colon \Delta^k \to D$ is a simplex, then it follows immediately from the definitions that $q \circ \mu^*(\psi)(\sigma) = \psi(\mu \circ \sigma)\colon \Delta^k \to E$.

(b) Let $\Theta\colon A \to B$ be a morphism from a G-local coefficient system $p\colon A \to D$ to an H-local coefficient system $q\colon B \to D$. We consider the maps

$$\begin{array}{rcl} \Theta_*\colon \mathrm{C}^k_{\mathrm{lc}}(D;A) & \to & \mathrm{C}^k_{\mathrm{lc}}(D;B) \\ (\psi\colon \mathrm{S}_k(X) \to \mathrm{S}_k(A)) & \to & (\Theta_* \circ \psi\colon \mathrm{S}_k(X) \to \mathrm{S}_k(B)). \end{array}$$

It follows easily from the definitions that $\delta \circ \Theta^* = \Theta^* \circ \delta$. If Θ is an isomorphism of local coefficient systems, then Θ_* is evidently also an isomorphism.

(c) By Proposition 174.10 we know that every G-local coefficient system over a contractible topological space D is trivializable, i.e. it is isomorphic to ${}_{\mathrm{tr}}G$.

(d) By the Standard Simplex Homeomorphism Lemma 72.1 (1) we know that each Δ^k is contractible.

(e) Let D be a topological space, let G be an abelian group and let $p\colon G \times D \to D$ be the trivial G-local coefficient system. One can easily verify that the maps

$$\begin{array}{l} \Xi\colon \mathrm{C}^k(D;G) \to \mathrm{C}^k_{\mathrm{lc}}(D;{}_{\mathrm{tr}}G) \\ (\mathrm{C}_k(D) \xrightarrow{\psi} G) \mapsto \left(\begin{array}{l} \mathrm{S}_k(D) \to \mathrm{S}_k(G \times D) \\ \quad \sigma \mapsto \text{the lift } \sigma\colon \Delta^k \to G \times D \text{ given by } x \mapsto (\sigma(x), \psi(\sigma)) \end{array} \right) \end{array}$$

define an isomorphism of cochain groups such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{C}^k(D;G) & \xrightarrow{\quad\Xi\quad} & \mathrm{C}^k_{\mathrm{lc}}(D;{}_{\mathrm{tr}}G) \\ \downarrow{\scriptstyle (\partial_{k+1})^*} & & \downarrow{\scriptstyle \delta} \\ \mathrm{C}^{k+1}(D;G) & \xrightarrow{\quad\Xi\quad} & \mathrm{C}^{k+1}_{\mathrm{lc}}(D;{}_{\mathrm{tr}}G), \end{array}$$

here $\partial_k\colon \mathrm{C}_{k+1}(D;G) \to \mathrm{C}_k(D;G)$ is the usual boundary map in the singular chain complex and the dual $\partial_k^*\colon \mathrm{C}^k(D;G) \to \mathrm{C}^{k+1}(D;G)$ is the usual coboundary map in the singular cochain complex.

Now we turn to the actual proof of the proposition. Thus let X be a topological space, let $p\colon E \to X$ be a local coefficient system and let $n \in \mathbb{N}_0$. We need to show that the composition $\delta^{n+1} \circ \delta^n\colon \mathrm{C}^n_{\mathrm{lc}}(X;E) \to \mathrm{C}^{n+2}_{\mathrm{lc}}(X;E)$ is the zero map.

By the above we have the following commutative diagram:

$$\begin{array}{ccccccc}
\mathrm{C}^n_{\mathrm{lc}}(X;E) & \xrightarrow{\mu^*} & \mathrm{C}^n_{\mathrm{lc}}(\Delta^{n+2};\mu^*E) & \xrightarrow[\cong]{\Theta_*} & \mathrm{C}^n_{\mathrm{lc}}(\Delta^{n+2};{}_{\mathrm{tr}}G) & \xleftarrow[\cong]{\Xi_*} & \mathrm{C}^n(\Delta^{n+2};G) \\
\downarrow{\scriptstyle\delta} & & \downarrow{\scriptstyle\delta} & & \downarrow{\scriptstyle\delta} & & \downarrow{\scriptstyle\partial^*_{n+1}} \\
\mathrm{C}^{n+1}_{\mathrm{lc}}(X;E) & \xrightarrow{\mu^*} & \mathrm{C}^{n+1}_{\mathrm{lc}}(\Delta^{n+2};\mu^*E) & \xrightarrow[\cong]{\Theta_*} & \mathrm{C}^{n+1}_{\mathrm{lc}}(\Delta^{n+2};{}_{\mathrm{tr}}G) & \xleftarrow[\cong]{\Xi_*} & \mathrm{C}^{n+1}(\Delta^{n+2};G) \\
\downarrow{\scriptstyle\delta} & & \downarrow{\scriptstyle\delta} & & \downarrow{\scriptstyle\delta} & & \downarrow{\scriptstyle\partial^*_{n+2}} \\
\mathrm{C}^{n+2}_{\mathrm{lc}}(X;E) & \xrightarrow{\mu^*} & \mathrm{C}^{n+2}_{\mathrm{lc}}(\Delta^{n+2};\mu^*E) & \xrightarrow[\cong]{\Theta_*} & \mathrm{C}^{n+2}_{\mathrm{lc}}(\Delta^{n+2};{}_{\mathrm{tr}}G) & \xleftarrow[\cong]{\Xi_*} & \mathrm{C}^{n+2}(\Delta^{n+2};G).
\end{array}$$

Recall that

$$\begin{array}{ccccccc}
\partial^*_{n+1} \circ \partial^*_{n+2} & = & (\partial_{n+2} \circ \partial_{n+1})^* & = & 0^* & = & 0. \\
& & \uparrow & & \uparrow & & \\
& & \text{since } \mathrm{Hom}_{\mathbb{Z}}(-,G) \text{ is contravariant} & & \text{by Proposition 72.2} & &
\end{array}$$

Thus we see that the two composition of the two vertical maps in the fourth column, and thus also the third and the second column, is zero. In summary we see that we have the following equality of lifts of $\mu\colon \Delta^{n+2} \to X$ to a map $\Delta^{n+2} \to E$:

$$\begin{array}{ccccccc}
 & & & & & & \text{follows from the discussion in (a), applied to } \sigma = \mathrm{id}_{\Delta^{n+2}} \text{ and } \psi = (\delta\circ\delta)(\varphi) \\
 & & & & & & \text{where } q\colon \mu^*E \to E \text{ denotes the projection} \\
(\delta(\delta(\mu)))(\varphi)(\mu) & = & (\delta\circ\delta)(\varphi)(\mu) & = & (\delta\circ\delta)(\varphi)(\mu\circ\mathrm{id}_{\Delta^{n+2}}) & \overset{\downarrow}{=} & q\circ\mu^*((\delta\circ\delta)(\varphi))(\mathrm{id}_{\Delta^{n+2}}) \\
 & & & = & q\circ((\delta\circ\delta)(\mu^*\varphi))(\mathrm{id}_{\Delta^{n+2}}) & = & q(\text{zero-lift of } \mathrm{id}_{\Delta^{n+2}} \text{ to } \mu^*E) \\
 & & & & \uparrow & & \uparrow \\
 & & & & \text{since the squares to the left commute} & & \text{since the composition of the vertical} \\
 & & & & & & \text{maps in the second column is zero} \\
 & & & & = & & \text{zero-lift of } \mu\colon \Delta^{n+2} \to X \text{ to } E. \\
 & & & & \uparrow & & \\
 & & & & \text{follows easily from the definition of } \mu^*E \text{ and the definition of } q & &
\end{array}$$

■

Proposition 175.7 allows us to introduce the following definition.

Definition. Let X be a topological space and let $p\colon E \to X$ be a local coefficient system. Given $n \in \mathbb{N}_0$ we define the n-th singular cohomology group of X with E-coefficients as the quotient group

$$\mathrm{H}^n_{\mathrm{lc}}(X;E) := \frac{\ker(\delta_n\colon \mathrm{C}^n_{\mathrm{lc}}(X;E) \to \mathrm{C}^{n+1}_{\mathrm{lc}}(X;E))}{\mathrm{im}(\delta_{n-1}\colon \mathrm{C}^{n-1}_{\mathrm{lc}}(X;E) \to \mathrm{C}^n_{\mathrm{lc}}(X;E))}.$$

On page 3656 we saw that maps between topological spaces induce maps between homology groups with local coefficients. We now have the analogous statement for cohomology with local coefficients.

Definition. Let $f\colon X \to Y$ be a map between topological spaces and let $p\colon E \to Y$ be a G-local coefficient system on Y. We define

$$\begin{array}{rcl} f^*\colon \mathrm{C}^n_{\mathrm{lc}}(Y;E) & \to & \mathrm{C}^n_{\mathrm{lc}}(X;f^*E) \\ \varphi & \mapsto & \left(\begin{array}{rcl} \mathrm{S}_n(X) & \to & \mathrm{S}_n(f^*E) \\ (\sigma\colon \Delta^n \to X) & \mapsto & \left(\begin{array}{rcl} \Delta^n & \to & f^*E \\ z & \mapsto & (\sigma(z), \underbrace{\varphi(\underbrace{f\circ\sigma}_{\in \mathrm{S}_n(Y)})}_{\in \mathrm{S}_n(E)}(z)) \end{array} \right) \end{array} \right) \end{array}$$

One can easily verify that these maps are well-defined and that they form a chain map. Thus we obtain induced maps

$$f^*\colon \mathrm{H}^n_{\mathrm{lc}}(Y;E) \to \mathrm{H}^n_{\mathrm{lc}}(X;f^*E).$$

The previous definition now also allows us to introduce relative cohomology with local coefficients.

Definition. Let X be a topological space, let $A \subset X$, let G be an abelian group and let $p\colon E \to X$ be a G-local coefficient system. We denote by $i\colon A \to X$ the inclusion. We set

$$\mathrm{C}^n_{\mathrm{lc}}(X,A;E) := \ker(i^*\colon \mathrm{C}^{\mathrm{lc}}_n(X;E) \to \mathrm{C}^n_{\mathrm{lc}}(A;i^*E)).$$

One can easily show that the cochain map on $\mathrm{C}^*_{\mathrm{lc}}(X;E)$ descends to a cochain map on $\mathrm{C}^*_{\mathrm{lc}}(X,A;E)$. Thus we can set

$$\mathrm{H}^n_{\mathrm{lc}}(X,A;E) := \mathrm{H}^n(\mathrm{C}^*_{\mathrm{lc}}(X,A;E)).$$

In Lemma 108.9 we saw that singular homology is covariantly functorial in the coefficients. The following lemma generalizes this statement to the setting of cohomology with local coefficients.

Lemma 175.8. Let X be a topological space and let $A \subset X$.

(1) Let $\Theta\colon E \to F$ be a morphism from a G-local coefficient system $p\colon E \to X$ to an H-local coefficient system $q\colon F \to X$. The maps

$$\begin{array}{rcl} \Theta_*\colon \mathrm{C}^k_{\mathrm{lc}}(X,A;E) & \to & \mathrm{C}^k_{\mathrm{lc}}(X,A;F) \\ (\varphi\colon \mathrm{S}_k(X) \to \mathrm{S}_k(E)) & \to & (\Theta_* \circ \varphi\colon \mathrm{S}_k(X) \to \mathrm{S}_k(F)) \end{array}$$

are a well-defined cochain map and thus they induce maps

$$\varphi_*\colon \mathrm{H}^k_{\mathrm{lc}}(X,A;E) \to \mathrm{H}^k_{\mathrm{lc}}(X,A;F).$$

(2) With the obvious interpretations we have $(\psi\circ\varphi)_* = \psi_* \circ \varphi_*$ and $\mathrm{id}_* = \mathrm{id}$.

Proof. Once again we leave the elementary proof of the lemma to the reader. ∎

The following lemma is the cohomological analogue of Lemma 175.4.

Lemma 175.9. Let X be a topological space, let $A \subset X$, let G be an abelian group and let $p\colon G \times X \to X$ be the trivial G-local coefficient system. The maps

$$\begin{array}{rcl} \mathrm{C}^k(X,A;G) & \to & \mathrm{C}^k_{\mathrm{lc}}(X,A;{}_{\mathrm{tr}}G) \\ (\psi\colon \mathrm{C}_k(X,A) \to G) & \mapsto & \left(\begin{array}{rcl} \mathrm{S}_k(X) & \to & \mathrm{S}_k(G\times X) \\ \sigma & \mapsto & \text{the lift } \sigma\colon \Delta^k \to G\times X \text{ given by } x \mapsto (\sigma(x), \psi(\sigma)) \end{array} \right) \end{array}$$

defines an isomorphism of cochain complexes that is natural in the sense of Lemma 175.4. Furthermore, as for homology groups, these natural chain isomorphisms give rise to a natural isomorphism

$$\mathrm{H}^k(X, A; G) \xrightarrow{\cong} \mathrm{H}^k_{\mathrm{lc}}(X, A; G_{\mathrm{lc}})$$

Proof. The lemma follows easily from the definitions. The less said, the clearer. ■

In the Homotopic Maps-H*-Lemma 108.13 we saw that singular cohomology is contravariantly functorial and in the Twisted Homology-Functoriality Proposition 167.9 we saw that cohomology with twisted coefficients is in a suitable sense contravariantly functorial. In Lemma 175.3 we showed that homology with local coefficients is close to being covariantly functor. In a similar vein we now have the following lemma.

Lemma 175.10. Let $p\colon F \to Z$ be a G-local coefficient system on a topological space Z and let $C \subset Z$.

(1) The natural isomorphism between the G-local coefficient systems $\mathrm{id}^* F$ and F that we gave in Lemma 174.7 induces the map $\mathrm{id}^*\colon \mathrm{H}^k_{\mathrm{lc}}(Z, C; F) \to \mathrm{H}^k_{\mathrm{lc}}(Z, C; \mathrm{id}^* F)$.

(2) Let $\varphi\colon (X, A) \to (Y, B)$ and $\psi\colon (Y, B) \to (Z, C)$ be maps between topological spaces We have the following commutative diagram:

$$\begin{array}{ccc} & & \mathrm{H}^{\mathrm{lc}}_k(X, A; \varphi^*(\psi^*(F))) \\ & \overset{\varphi^*\circ\psi^*}{\nearrow} & \Big\downarrow \cong \text{ natural isomorphism from Lemma 174.7 and Lemma 175.2} \\ \mathrm{H}^{\mathrm{lc}}_k(Z, C; F) & & \\ & \underset{(\psi\circ\varphi)^*}{\searrow} & \mathrm{H}^{\mathrm{lc}}_k(X, A; (\psi \circ \varphi)^*(F)) \end{array}$$

Proof. As so often, the lemma follows almost immediately from the definitions. ■

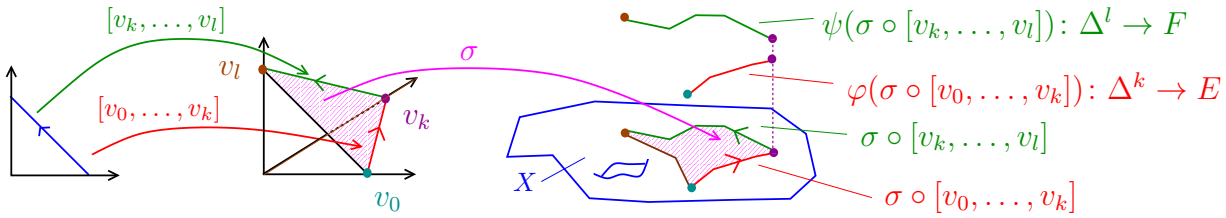
175.3. **Cup product with local coefficients.** Given a topological space X and a commutative ring R we defined on page 2513 the cup product $\cup\colon \mathrm{H}^k(X; R) \times \mathrm{H}^l(X; R) \to \mathrm{H}^{k+l}(X; R)$. The cup product, together with its sibling the cap product, gave us many of the most interesting applications of cohomology groups. It is thus natural to try to introduce a cup product on cohomology with local coefficients.

First we recall the following definition from page 2503.

Notation. For $i = 0, \ldots, n$ we write

$$v_i \;:=\; (0, \ldots, 1, 0, \ldots, 0) \in \mathbb{R}^{n+1}.$$

Furthermore for $a_0, \ldots, a_k \in \Delta^n$ we consider the map



$$\begin{array}{rccc} [a_0, \ldots, a_k]\colon & \Delta^k & \to & \Delta^n \\ & \sum_{j=0}^{k} \lambda_j \cdot v_j & \mapsto & \sum_{j=0}^{k} \lambda_j \cdot a_j. \end{array}$$

Now we can provide the definition of the cup product on cohomology with local coefficients.

Definition. Let X be a topological space, let $p\colon E \to X$ be a G-local coefficient system and let $q\colon F \to X$ be an H-local coefficient system. We consider the $G \otimes_{\mathbb{Z}} H$-local coefficient system $E \otimes_{\mathbb{Z}} F$ that we defined on page 3653. Given $\varphi \in \mathrm{C}^k_{\mathrm{lc}}(X; E)$ and

$\psi \in \mathrm{C}^l_{\mathrm{lc}}(X;F)$ we define $\varphi \cup_\otimes \psi \in \mathrm{C}^{k+l}_{\mathrm{lc}}(X; E \otimes_{\mathbb{Z}} F)$ to be the following map:[2127]

$$\begin{array}{rcl} \varphi \cup_\otimes \psi\colon \mathrm{S}_{k+l}(X) & \to & \mathrm{S}_{k+l}(E \otimes_{\mathbb{Z}} F) \\ (\sigma\colon \Delta^{k+l} \to X) & \mapsto & \text{the unique lift of } \sigma \text{ to a map } \widetilde{\sigma}\colon \Delta^{k+l} \to E \otimes_{\mathbb{Z}} F \text{ such that} \\ & & \widetilde{\sigma}(v_k) = (\underbrace{\varphi(\sigma \circ [v_0,\dots,v_k])}_{\Delta^k \to E})(v_k) \otimes (\underbrace{\psi(\sigma \circ [v_k,\dots,v_l])}_{\Delta^l \to F})(v_0) \end{array}$$

As for the cup product on singular homology we would like to show that the above definition on the cochain level descends to a map on cohomology. This leads us to the following analogue of Coboundary-Cup Product Lemma 114.2.

Lemma 175.11. Let X be a topological space and let $p\colon E \to X$ and $q\colon F \to X$ be local coefficient systems. Given any $\varphi \in \mathrm{C}^p_{\mathrm{lc}}(X;E)$ and given any $\psi \in \mathrm{C}^q_{\mathrm{lc}}(X;F)$ we have

$$\delta(\varphi \cup_\otimes \psi) \;=\; \delta\varphi \cup_\otimes \psi + (-1)^p \cdot \varphi \cup_\otimes \delta\psi \;\in\; \mathrm{C}^{p+q+1}_{\mathrm{lc}}(X; E \otimes_{\mathbb{Z}} F).$$

Proof. In the proof of Proposition 175.7 we used a very general approach to reducing proofs on (co-) homology with local coefficients to the well-known case of ordinary singular (co-) homology. Entirely the same approach allows us to reduce the present setting to the our previous original Coboundary-Cup Product Lemma 114.2. ■

Lemma 175.12. Let X be a topological space, let $p\colon E \to X$ be a G-local coefficient system and let $q\colon F \to X$ be an H-local coefficient system. The map

$$\begin{array}{rcl} \cup\colon \mathrm{H}^k_{\mathrm{lc}}(X;E) \times \mathrm{H}^l_{\mathrm{lc}}(X;F) & \to & \mathrm{H}^{k+l}_{\mathrm{lc}}(X; E \otimes_{\mathbb{Z}} F) \\ ([\varphi],[\psi])] & \mapsto & [\varphi] \cup_\otimes [\psi] := [\varphi \cup_\otimes \psi] \end{array}$$

is well-defined.

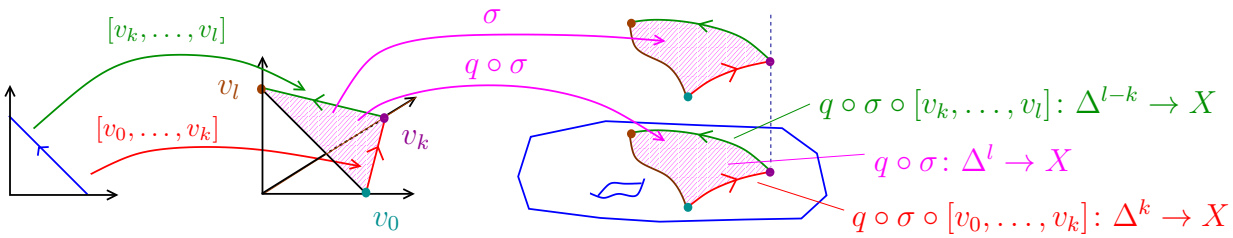
Proof. The proof of Lemma 175.12 is basically the same as the rather elementary proof of Lemma 114.3. We just need to replace Coboundary-Cup Product Lemma 114.2 by Lemma 175.11. ■

Definition. We refer to the pairing of Lemma 175.12 as the cup product on cohomology with local coefficients.

Proposition 175.13. Let X be a topological space and let $p\colon E \to X$ and $q\colon F \to X$ be local coefficient systems. Let $\tau\colon E \otimes_{\mathbb{Z}} F \to F \otimes_{\mathbb{Z}} E$ be the natural isomorphism from Lemma 174.13 (2). Then given any $\varphi \in \mathrm{C}^p_{\mathrm{lc}}(X;E)$ and given any $\psi \in \mathrm{C}^q_{\mathrm{lc}}(X;F)$ we have

$$\varphi \cup \psi \;=\; (-1)^{kl} \cdot \tau_*(\psi \cup \varphi).$$

Proof. Recall that we proved Lemma 175.11 by modifying the "classical" proof of Coboundary-Cup Product Lemma 114.2 in a suitable way. The same approach can also be applied



[2127] Implicitly we are using once again the Unique Simplex Lifting Lemma 175.1.

to obtain a of Proposition 175.13 by suitably modifying the proof of the Cup Product-Commutativity Proposition 114.8. We leave the unpleasant task of turning this slogan into a proper proof to the reader. ■

175.4. Cap product with local coefficients.

Definition. Let X be a topological space and let $p\colon E \to X$ be a G-local coefficient system and let $q\colon F \to X$ be an H-local coefficient system. We consider the $G \otimes_{\mathbb{Z}} H$-local coefficient system $E \otimes_{\mathbb{Z}} F$ that we defined on page 3653. Given $\varphi \in \mathrm{C}^k_{\mathrm{lc}}(X;E)$ and $\sigma\colon \Delta^l \to F$ we define $\varphi \cap_{\otimes} \sigma\colon \Delta^{k-l} \to E \otimes_{\mathbb{Z}} F$ to be the following map:[2128]

$$\varphi\cap_{\otimes}\sigma \;:=\; \text{the unique lift of } q\circ\sigma\circ[v_k,\dots,v_l]\colon \Delta^{l-k}\to X \text{ to a map } \widetilde{\mu}\colon \Delta^{l-k}\to E\otimes_{\mathbb{Z}} F$$
$$\text{such that } \widetilde{\mu}(v_0) = \underbrace{(\varphi(q\circ\sigma\circ[v_0,\dots,v_k]))}_{\Delta^k\to E}(v_k)\otimes(\underbrace{\sigma}_{\Delta^k\to F})(v_k)$$

Lemma 175.14. Let X be a topological space and let $p\colon E \to X$ and $q\colon F \to X$ be local coefficient systems.

(1) The map $\cap_{\otimes}$ descends to a well-defined map
$$\cap_{\otimes}\colon \mathrm{C}^k_{\mathrm{lc}}(X;E)\times \mathrm{C}^{\mathrm{lc}}_l(X;F) \;\to\; \mathrm{C}^{\mathrm{lc}}_{l-k}(X;E\otimes_{\mathbb{Z}} F).$$

(2) Given any $\varphi \in \mathrm{C}^k_{\mathrm{lc}}(X;E)$ and given any $\sigma \in \mathrm{C}^{\mathrm{lc}}_l(X;F)$ we have
$$\partial(\varphi\cap_{\otimes}\sigma) \;=\; (-1)^k\cdot(-\delta\varphi\cap_{\otimes}\sigma + \varphi\cap_{\otimes}\partial\sigma) \;\in\; \mathrm{C}_{l-k-1}(X;E\otimes_{\mathbb{Z}} F).$$

(3) The map $\cap_{\otimes}$ descends to a well-defined map
$$\cap_{\otimes}\colon \mathrm{H}^k_{\mathrm{lc}}(X;E)\times \mathrm{H}^{\mathrm{lc}}_l(X;F) \;\to\; \mathrm{H}^{\mathrm{lc}}_{l-k}(X;E\otimes_{\mathbb{Z}} F).$$

Proof.

(1) One can easily show that if $\sigma_1,\sigma_2\colon X\to F$ are two simplices with $q\circ\sigma_1 = q\circ\sigma_2$, then $\varphi\cap_{\otimes}(\sigma_1 \mathbin{\widetilde{+}} \sigma_2) = \varphi\cap_{\otimes}\sigma_1 \mathbin{\widetilde{+}} \varphi\cap_{\otimes}\sigma_2$. From this observation it follows that we do indeed get a well-defined map $\mathrm{C}^k_{\mathrm{lc}}(X;E)\times \mathrm{C}^{\mathrm{lc}}_l(X;F)\to \mathrm{C}^{\mathrm{lc}}_{l-k}(X;E\otimes_{\mathbb{Z}} F)$.

(2) Using the approach of the proof of Proposition 175.7 one can reduce the proof of Statement (2) to Lemma 116.1. We leave the details to the reader.

(3) This statement is a straightforward consequence of Statement (2). ■

The following variation of the cap product is the analogue of the definition of $\cap_{\mathbb{Z}}$ that we gave on page 3609.

Definition. Let X be a topological space and let $p\colon E\to X$ be a local coefficient system. Let $\varphi \in \mathrm{H}^k_{\mathrm{lc}}(X;E)$ and let $\sigma \in \mathrm{H}_l(X;\mathbb{Z})$. We denote by $T\colon \mathrm{H}_l(X;\mathbb{Z})\to \mathrm{H}^{\mathrm{lc}}_l(X;\mathbb{Z}_{\mathrm{tr}}H)$ the

[2128] Implicitly we are using once again the Unique Simplex Lifting Lemma 175.1.

natural isomorphism from Lemma 175.4 and we denote by $\mu\colon E\otimes_{\mathbb{Z}}\mathbb{Z}_{\mathrm{tr}}\mathbb{Z}\to E$ the natural isomorphism of local coefficient systems from Lemma 174.13. We define

$$\varphi\cap_{\mathbb{Z}}\sigma \;:=\; \mu(\underbrace{\varphi\cap_{\otimes}T(\sigma)}_{\in \mathrm{H}^{\mathrm{lc}}_{l-k}(X;E\otimes_{\mathbb{Z}}\mathbb{Z}_{\mathrm{tr}}\mathbb{Z})})\;\in\;\mathrm{H}^{\mathrm{lc}}_{l-k}(X;E).$$

175.5. **Excision with local coefficients.** We recall some definitions from page 2429.

Definition.

(1) A triad of topological spaces is a triple (X,A_1,A_2) where X is a topological space and where both A_1 and A_2 are subsets of X.

(2) Given a triad (X,A_1,A_2) of topological spaces and given a local coefficient system $p\colon E\to X$ we consider the following subgroup of $\mathrm{C}^{\mathrm{lc}}_n(A_1\cup A_2;E)$:

$$\mathrm{C}^{\mathrm{lc},\{A_1,A_2\}}_n(A_1\cup A_2)\;:=\;\left\{\sum_{j=1}^k\sigma_j\;\middle|\;\begin{array}{c}\text{for each } j \text{ there exists an } i\in\{1,2\}\\ \text{such that } \sigma_j \text{ lies in } \mathrm{C}^{\mathrm{lc}}_n(A_i;E)\end{array}\right\}.$$

The usual boundary map on the groups $\mathrm{C}^{\mathrm{lc}}_*(A_1\cup A_2;E)$ restricts to a boundary map on $\mathrm{C}^{\mathrm{lc},\{A_1,A_2\}}_*(A_1\cup A_2;E)$, so we can view $\mathrm{C}^{\mathrm{lc},\{A_1,A_2\}}_*(A_1\cup A_2;E)$ as a chain complex.

(3) We say a triad (X,A_1,A_2) is excisive with respect to local coefficients if if for any local coefficient system $p\colon E\to X$ the inclusion map

$$\mathrm{C}^{\{A_1,A_2\}}_*(A_1\cup A_2;E)\;\to\;\mathrm{C}^{\mathrm{lc}}_*(A_1\cup A_2;E)$$

is a chain homotopy equivalence of chain complexes.

In the Excisive Triad-Proposition 109.12 we gave many convenient examples of excisive triads. The following proposition now says that these triads are not only excisive but they are universally excisive and in Proposition 169.2 we saw that the examples of the Excisive Triad-Proposition 109.12 are also universally excisive.

Proposition 175.15. Let (X,A_1,A_2) be a triad of topological spaces. We assume that X is locally contractible and path-connected. The triad is excisive with respect to local coefficients if one of the following conditions is satisfied:

(1) $A_1\subset A_2$ or $A_2\subset A_1$,
(2) $A_1=\varnothing$ or $A_2=\varnothing$ or $A_1=A_2$,
(3) $A_1\cup A_2=\mathring{A}_1\cup\mathring{A}_2$ where we denote by $\mathring{A}_1$ and $\mathring{A}_2$ the interiors of A_1 and A_2 in $A_1\cup A_2$,
(4) A_1 and A_2 are both open subsets of $A_1\cup A_2$,

Remark. In the Excisive Triad-Proposition 109.12 and Proposition 169.2 we also proved the following two statements:

(1) if $A_1\cup A_2$ is a topological manifold and A_1 and A_2 are codimension-zero submanifolds which are both closed subsets and such that each component of $A_1\cap A_2$ is a boundary component of A_1 and a boundary component of A_2, then (X,A_1,A_2) is excisive and universally excisive.
(2) If X is a CW-complex and A_1 and A_2 are both subcomplexes, then (X,A_1,A_2) is excisive and universally excisive.

Currently we cannot show that these are excisive with respect to local coefficients. Presumably one can prove it using Proposition 169.2 (4).

Proof. The first two statements are clear and Statement (4) is just a special case of Statement (3). So let us deal with Statement (3).

Let $p\colon E \to X$ be a local coefficient system over X. For each $n \in \mathbb{N}_0$ we denote by

$$u_n\colon \mathrm{C}_n(E) \ \to \ \mathrm{C}_n(E)$$

the subdivision map that we introduced on page 1640. We recall the following statements:

(1) In the Chain Subdivision Lemma 74.24 we saw that the maps u_n form a chain map.
(2) In Lemma 74.25 we saw that the maps u_n are natural.
(3) In Lemma 74.26 we saw the u_n are chain homotopic to the identity. Even though we did not say so explicitly, the proof of Lemma 74.26 shows that we can find a natural chain homotopy inverse $v_n\colon \mathrm{C}_(X) \to \mathrm{C}_n(X)$ to u_n.

The constructions of u_n and v_n show that they preserve $\widetilde{+}$, i.e. they descend to maps $\mathrm{C}_n^{\mathrm{lc}}(X;E) \to \mathrm{C}_n^{\mathrm{lc}}(X;E)$. Now the statement should be fairly obvious. ■

175.6. **The interaction between twisted (co-) homology and (co-) homology with local coefficients.** Recall that in Proposition 174.4 and ???? we saw that for a locally contractible and path-connected space we have a natural bijection between the class of representations and the class of local systems.

Proposition 175.16. Let X be a path-connected space and let $x_0 \in X$. There exists a natural isomorphism between (co-) homology with twisted coefficients and (co-) homology with local coefficients.

Let M be a connected smooth manifold and let $x_0 \in M$. Let $w_1\colon \pi_1(M, x_0) \to \{\pm 1\}$ be the orientation character that we defined on page 1114. Furthermore let $\wedge^n \mathrm{T}M^*$ be orientation bundle as defined on page 3082. The vector bundle defined by the orientation character is basically the orientation bundle.

Need to explain that vector bundles with *discrete* fibers are in one-to-one correspondence with representations, but not true if look at them without discrete fibers. See e.g. Hopf bundle over S^2.

175.7. **Poincaré Duality with local coefficients.**

Notation. Let X be a compact oriented non-empty n-dimensional topological manifold. We denote by $[X] \in \mathrm{H}_n^{\mathrm{lc}}(X, \partial X; \mathbb{Z}_{\mathrm{tr}}\mathbb{Z})$ the image of the fundamental class $\mathrm{H}_n(X, \partial X; \mathbb{Z})$ under the natural isomorphism $\mathrm{H}_n(X, \partial X; \mathbb{Z}) \to \mathrm{H}_n^{\mathrm{lc}}(X, \partial X; \mathbb{Z}_{\mathrm{tr}}\mathbb{Z})$ from Lemma 175.4.

Theorem 175.17. (Poincaré Duality Theorem with Local Coefficients) Let X be a compact oriented non-empty n-dimensional topological manifold. We denote by $[X] \in \mathrm{H}_n^{\mathrm{lc}}(X, \partial X; \mathbb{Z}_{\mathrm{tr}}\mathbb{Z})$ the fundamental class. Furthermore suppose that we are given a decomposition $\partial X = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂X such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ and every local coefficient system $p\colon E \to X$ the map

$$\begin{array}{ccc} \mathrm{H}^k(X, A; E) & \xrightarrow{\cong} & \mathrm{H}_{n-k}(X, B; E) \\ \sigma & \mapsto & \sigma \cap_{\mathbb{Z}} [X] \end{array}$$

is an isomorphism.

Example. We consider the topological manifold S^1 with the local coefficient system ${}_\varphi\mathbb{Z}[t^{\pm 1}]$ that we introduced on page **??**. We see that

$$\mathrm{H}^k_{\mathrm{lc}}(S^1; {}_\varphi\mathbb{Z}[t^{\pm 1}]) \;\cong\; \mathrm{H}^{\mathrm{lc}}_{1-i}(S^1; {}_\varphi\mathbb{Z}[t^{\pm 1}])$$

Proof. The theorem follows immediately from the Poincaré Duality Theorem 172.1 with Twisted Coefficients and the various propositions translating between (co-) homology with twisted coefficients and (co-) homology with local coefficients. ■

Proposition 175.18. Let X be an n-dimensional topological manifold with $\partial X = \varnothing$. We consider the set

$$C \;:=\; \bigsqcup_{x\in X} \mathrm{H}_n(X, X\setminus\{x\}).$$

Given an open subset $U \subset X$ and an element $\varphi \in \mathrm{H}_n(X, X\setminus U)$ we consider

$$M(U,\varphi) \;:=\; \bigsqcup_{x\in u} \text{image of } \varphi \text{ in } \mathrm{H}_n(X, X\setminus\{x\}).$$

(1) The subsets $M(U,\varphi)$ of C have the basis property that we introduced on page 131.
(2) We equip C with the topology that is defined by the sets $M(U,\varphi)$ and the Topology-from-Basis Lemma 1.27. The natural projection $C \to X$ is a local coefficient system for X.
(3) The local coefficient system in (2) is isomorphic to the local coefficient system defined by the orientation-character $w_1(\pi_1(M,x_0)) \to \mathbb{Z}_2$ from page 2341, combined with the unique isomorphism $\mathbb{Z}_2 \to \mathrm{Aut}(\mathbb{Z}) = \{\pm 1\}$.

Definition. Let X be an n-dimensional topological manifold with $\partial X = \varnothing$. We refer to the local coefficient system from Proposition 175.18 as the orientation local coefficient system.

Proof. Should be straightforward. ■

Heegaard genus, 3130

Heegaard splitting, 3114
Hilbert Cube, 353
Hilbert cube, 822
HNN-extension, 1291
homeomorphism, 152
homeotopy, 420
homogeneous element of a graded module, 1935
homologous, 1587
homology
  cellular, 1770
  handle, 3013
  locally finite, 2381
  relative homology with local coefficients, 3657, 3665
  simplicial, 2036, 2038
  singular, 1587
  singular with local coefficients, 3656
homology ball, 2720
homology class realized by a smooth manifold, 2234
homology class represented by a submanifold, 2246, 2836
homology group of a chain complex, 1591
homology group of an R-left chain complex, 3518
homology groups of a group, 3453
homology manifold, 1672, 2287, 2330
homology sphere, 1672, 2159, 2710
homotopy, 439
  compact support, 822, 861, 1118
  proper, 429
  regular, 952
  rel a subset, 419, 439
  smooth, 811
  trivial near the ends, 814
homotopy ball, 2646
homotopy between maps, 418
homotopy between pairs of topological spaces, 439, 924, 3547
homotopy category, 441, 1609, 3465
homotopy equivalence, 430, 1608
homotopy equivalence between pairs of topological spaces, 440
homotopy fiber, 3270, 3288
homotopy group, 1560
homotopy inverse, 430, 1608
homotopy left inverse, 441, 3417
homotopy lifting property, 3263
homotopy sphere, 2625
homotopy type of a topological space, 430
Hopf invariant, 2681, 2682
Hopf link, 2220
Hopf manifold, 800
Hopf map, 1576, 2676, 3210, 3306
  octonion, 2676, 3210
  quaternion, 3210
  quaternionic, 2676
Hurewicz cofibration, 478
Hurewicz fibration, 3263
Hurewicz homomorphism, 1832, 1842, 3256
hyperbolic disk, 1429
hyperbolic half-plane, 1427
hyperbolic line, 1431
hyperelliptic involution, 3176
hyperrectangle, 1562
  non-degenerate, 1562

Icosian game, 1906
index of an intersection point, 2779
induced representation, 3516
inductive limit, 1274
infinite complex Grassmannian, 3074
infinite real Grassmannian, 3074
integral Dehn surgery along a link, 3139
integral homology sphere, 2159, 3143, 3188
interior of a subset of a topological space, 116
intermediate cellular chain complex, 1801, 3587
internal connected sum of submanifolds, 2258
intersection form
  $\mathbb{F}_2$-valued, 2922
  $\mathbb{Z}$-valued, 2800, 2880
intersection number
  algebraic, 989, 996, 1017, 2748, 2757
  geometric, 988, 2748

intersection orientation for submanifolds, 969
interval, 110
inverse limit, 1274, 2466
inverse of a knot, 2856
inverse path, 1048
inverse system, 1273, 2466
involution on a ring, 1975, 3502
isometry, 1426
isomorphism in a category, 198
isomorphism problem, 1346
isotopy, 420, 471

join of topological spaces, 446, 2001, 3311
Jordan curve, 795, 2742

K3-surface, 2939
Kirby-Siebenmann invariant, 2943

  square knot, 1319
  trefoil, 1301, 1312
  trivial, 1301, 1302, 1338
  trivial knot, 1312
  unknot, 1312
knot diagram, 1321
knots
  smoothly isotopic, 1302, 1311
Kronecker pairing, 2179, 2425, 2452
Krull topology, 1466
Kummer surface, 2939

Löhlein covering, 1382
large inductive dimension, 390, 788
lattice, 577
lattices
  homothetic, 1400
Lebesgue number, 286
left left module, 3501
length of a curve, 1434
length of a resolution, 1921
lens space, 1075
  high-dimensional, 3424
level of a ring, 945
lexicographic order, 92, 1998
Lie group, 2134, 3317
lift of a map, 838, 1080, 1100, 1353
lift of a path, 1078
Light bulb trick, 2773
limit, 1274
limit map, 300
line with a point at infinity, 122
line with two zeros, 122
link, 2219, 2700, 2862
  boundary link, 2875
  classical, 2700
  split, 1015, 2875
  trivial link, 1015, 2863
link of a simplex in an abstract simplicial complex, 2018, 2101
linking number, 3360
linking number of two oriented disjoint knots, 2865
linking pairing, 3150, 3151
local biholomorphism, 798
local biholomorphism at a point, 796
local coefficient system, 3643
  trivializable, 3645
local degree, 898, 1694, 2379
local diffeomorphism at a point, 547
local homology of a pointed topological space, 1655, 2136, 2324
local homology of a topological space, 2324
local property of a map, 179
local property of a topological space, 175, 1352

local propery of a map at a point, 179
Locally finite homology, 2381
Loch Ness monster, 1241
long exact sequence in homology, 1622
long exact sequence in homology of a pair, 1629
long exact sequence of a triple, 1627
long knots
  equivalent, 1344
long line, 613
longitude of a knot, 2219, 2854, 3134
loop, 1045, 1048, 1054
  null-homotopic, 1045, 1048
  orientation-preserving, 881, 1114
  orientation-reversing, 881, 1114
loop in an abstract graph, 307
loop in an undirected abstract graph, 313
loop space, 3280
Lusternik-Schnirelmann category, 2544

Möbius band, 252, 264
Möbius bundle, 3060
Möbius isomorphism, 1448
Möbius manifold, 1439
Möbius map, 1448
Möbius structure, 1439
Möbius transformation, 1427, 1429
manifold, 543
  amphichiral, 2388
  chiral, 2388
  cut along a submanifold, 2845
  parallelizable, 3063, 3319
manifold cut along a submanifold of codimension one, 2844
map
  k-connected, 3396
  bilinear, 1908, 2425
  cellular, 1492, 1770, 3582
  cellular isomorphism, 1492
  closed, 148
  continuous, 141
  continuous at a point, 301
  covering, 1067, 1104
  covering of a complex manifold, 1105
  covering of a smooth manifold, 1105
  differentiable, 535
  discontinuous, 141
  holomorphic, 789, 796–798
  homotopy equivalence, 430
  immersion, 651, 952
  locally P, 179
  nowhere monotonic, 306
  null-homotopic, 418
  of bounded displacement, 787, 1652
  open, 148
  order-preserving, 91
  orientation-preserving, 669, 682, 2335
  orientation-reversing, 669, 682, 2335
  piecewise linear, 1552, 2090
  proper, 180, 1506, 2381, 2481
  quotient map, 407
  smooth on any subset of $\mathbb{R}^n$, 532, 2081
  smooth on any subset of a smooth manifold, 549
  smooth on open subset of $\mathbb{R}^n$, 531
  submersion, 732
  uniformly continuous, 287
map between topological manifolds
  proper, 650, 718
mapping class group, 830, 3122
mapping cone, 457, 477, 1735, 2677
mapping cylinder, 454, 477
mapping path fibration, 3287
mapping torus, 467, 1741, 2610, 3559
maps
  ϵ-close, 747
  diffeotopic, 812
  homeotopic, 420
  homotopic, 418, 439, 1604
  homotopy equivalent, 1608
  isotopic, 420, 471
  path-homotopic, 1085
  regularly homotopic, 952
  smoothly homotopic, 811
matrix
  elementary, 1167
  symplectic, 3125
maximal elemen of a partially ordered set, 93, 2442
maximal tree, 317, 1521

Mayer–Vietoris sequence, 1719
meridian, 1733, 2853, 3134
meridian of an oriented knot, 1305, 2213
mesh of a linear simplicial complex, 2023
metabolizer, 3171
metric
  discrete, 346
  Euclidean metric, 104, 109
  Manhattan metric, 104, 106, 137
  maximum's metric, 133
  Paris metric, 1142
  SNCF metric, 104, 106, 137
  trivial, 104
metric space, 103, 283
  complete, 289
  incomplete, 289
metric spaces
  equivalent, 109
microbundle, 2317
minus n open disks, 1233
mirror of a knot, 1315, 2387, 2856
Mittag-Leffler condition, 2470
module
  free, 98
monodromy, 3559
monoid, 3088
monomorphism, 208
Moore space of type $\mathrm{M}(\pi, n)$, 3461
Moore space of type $\mathrm{M}(\pi, n)$, 1761, 3426
morphism
  identity morphism, 195
  inverse morphism, 199
  invertible, 198
morphism of a category, 194
Morse function, 2979
  lacunary, 3029
  perfect, 3025
  self-indexing, 3009
Morse inequalities
  sharp, 3025
Morse-Smale function, 2998

natural covering corresponding to a subgroup, 1370
natural isomorphism, 203, 2593
natural orientation of a complex manifold, 804
natural orientation of a complex vector space, 803
natural transformation, 203, 2592
natural universal covering, 1370
NDR-pair, 489
neighborhood, 113
neighborhood deformation retract pair, 489
neighborhood retract, 2291
nerve complex, 2062
nice intersection point, 2778
nice neighborhood, 1694, 2778
Nielsen automorphism of a free group, 1202
Nielsen operation, 1202
non-loop in an undirected abstract graph, 313
non-orientable surface of genus g, 266
norm
  l^∞-norm, 102
  Euclidean, 102
  integral norm, 183
  maximum norm, 102
  supremum norm, 183
norm ball, 102
norm of a matrix, 190
norm on a real vector space, 101, 150
normal bundle, 3059
normal core of a subgroup, 1417
normalizer of a subgroup, 1387
North Pole, 112
null-homologous cycle, 1587, 1591
nullbordant, 2936, 3089
nullity of a form, 2916
number of ends of a topological space, 187, 1254

object
  initial, 197
  terminal, 197
object of a category, 194
octonionic projective plane, 1972
octonions, 1963

one-point compactification, 193
open annulus, 264
open cell of a CW-complex, 1469, 1478
open cube, 762
open cylinder, 264
open long ray, 612
open Möbius band, 252
open neighborhood, 113
open regular neighborhood, 2695
open simplex, 1991
open solid torus, 230
opposite category, 197
opposite orientation of an oriented real vector space, 669
opposite orientation of an oriented smooth manifold, 677
order
  of a family of subsets, 369, 725, 1708
order on an abstract simplicial complex, 1982
order type, 92
ordered n-simplex, 2038, 2141
orientation
  direct sum orientation, 671
  intersection orientation, 673
  preimage orientation, 673
orientation character of a smooth manifold, 1114
orientation character of a topological manifold, 2341
orientation covering, 1109, 2341
orientation of a pseudomanifold, 2142, 2184
orientation of a real vector bundle, 3082
orientation of a smooth manifold of dimension 0, 2204
orientation of a smooth manifold of dimension ≥ 1, 675
orientation of a topological manifold, 2335
orientation of a vector space of dimension 0, 669
orientation of a vector space of dimension ≥ 1, 668
orientation-preserving mapping class group, 3123
orientations
  compatible, 671
  incompatible, 671
oriented curve, 1123
oriented smooth manifold, 675
Osgood curve, 295
overcrossing, 1321

Pachner move, 2109
pair of CW-complexes, 1549
pair of pants, 1234
pair of pants decomposition, 1252
pair of topological spaces, 924
  k-connected, 3252
pairing, 99, 2656, 2877
  R-bilinear, 99, 2656, 2877, 3631
  anti-hermitian, 3631
  anti-symmetric, 2877, 3631
  degenerate, 2894, 3635
  hermitian, 3631
  non-degenerate, 2894, 3635
  non-singular, 2656
  positive-definite, 99, 100
  positive-semidefinite, 99, 100
  singular, 2656
  symmetric, 2877, 3631
parametrization of a smooth manifold, 2543
parity of a form, 2918
partial mapping torus, 1516
partial order, 91, 609, 1982
partially ordered set, 1982, 2442
partition between two subsets, 389, 788
partition of a natural number, 3105
partition of unity, 360, 586
path, 161, 791, 1045, 1048
  trivial near the ends, 862, 880
path space, 3280
path space fibration, 3282
path-component, 167
path-homotopy between paths, 1048
paths
  path-homotopic, 792, 1045, 1048

physical tangent space, 620
piecewise linear triangulation, 2095
pinching map, 1565, 2221, 3466
PL n-ball, 2092
PL n-sphere, 2092
PL-homeomorphism, 2091
PL-manifold, 2093

pointed CW-complex, 1542, 3467
pointed homotopy category, 3468
pointed pair of topological spaces, 3238
pointed set, 213, 221, 3241
pointed smooth manifold, 627
pointed topological space, 1061, 1542, 3467
Polish Circle, 276
polygon
  regular, 1893
polyhedron, 1552
  regular, 1896
Pontryagin class, 3102
preorder, 1256
preordered set, 1256
presentation, 1195
  balanced, 3034
presentation for a group, 1195
prime integer topology, 139
primitive element of an abelian group, 1164, 2834
product in a category, 211, 1502
product of two oriented smooth manifolds, 694
product of two smooth manifolds, 560, 583, 694
product of two topological manifolds, 515
product orientation, 695, 2502
profinite completion of a group, 1283
profinite integers, 1279, 1288
projective limit, 1258
proper smooth isotopy, 812
pseudomanifold, 2140
  closed, 2140
  orientable, 2142
pullback, 218, 1280
pullback fibration, 3287
pullback of a bundle, 3303
pullback of a covering, 1101
pullback of a vector bundle, 3069
pullback of a vector field, 641
pullback system, 1280
punctured surface, 1447
push-pull set, 1256
pushout, 220, 1260
pushout system, 1258

quasi-circle, 276
quasi-isomorphism, 1794, 3522
quasi-morphism, 1166
quaternions, 1960

radical of a form, 2903
rank of a (finitely generated) abelian group, 1152
rank of a finitely generated abelian group, 1879
rank of a free abelian group, 1147
rank of a free group, 1411
rational Dehn surgery along a link, 3139
rational homology sphere, 3143, 3188
rational Pontryagin class, 3105
ray, 1433
real division algebra, 2670

real Grassmannian, 3074
real line bundle, 3058
real projective space, 251
real vector bundle, 3058
reduced homology, 1611
reduced intersection form, 2902
reduced suspension, 3473
Reeb foliation, 986
refinement of a cover, 354
  open, 354
reflection in a hyperbolic line, 1459
reflection in a hyperplane, 819
regional property of a topological space, 175
regular dodecahedron, 1897
regular hexahedron, 1897
regular homotopy, 952
regular icosahedron, 1897
regular neighborhood of a subcomplex, 2096
regular neighborhood of a subset of a topological manifold, 2695
regular octahedron, 1896
regular tetrahedron, 1896
Reidemeister moves, 1328
Reidemeister-Schreier process, 1337
relation, 89
  antisymmetric, 91
  connex, 93
  reflexive, 89
  symmetric, 89
  transitive, 89
relative cellular chain complex, 1790, 3582
relative handle decomposition, 3001
  standard, 3001
relative handle homology groups, 3028
relative homology group, 1624
relative homotopy group, 3238
relative Hurewicz homomorphism, 3254
Remainder term, 535
rendezvous value, 138
reparametrization, 1052
representation, 3508
  complex, 3508
  faithful, 3516
  finite dimensional, 3509
  irreducible, 3509
  real, 3508
  reducible, 3509
  semisimple, 3509
  simple, 3509
resolution of a module, 3521
  free, 3521
resolution of an abelian group, 1791, 1921
  free, 1791, 1921
retract, 1241
retract of a group, 1201
retract of a map, 443
retraction, 186, 433, 753, 783, 1061, 2291
  realized by a deformation retraction, 433
reverse of a knot, 2856
Riemannian manifold, 1426
Riemannian manifolds
  isometric, 1427
Riemannian structure, 1426
  hyperbolic, 1439
right right module, 3501
right-hand rule, 669
ring, 98, 3499
  commutative, 98, 3499
  left Noetherian, 3595
  Noetherian, 3595
  ring with involution, 1975, 3502
Rokhlin homomorphism, 3194
Roman surface, 662
rotation index, 955
rotation number, 955
rounding corners, 2953

section of a vector bundle, 3063
sedenions, 1967
Seifert surface, 2859
self-linking number of a thickened knot, 2853, 3134
semi-group, 3088
semidirect product of groups, 1127, 1146
  non-trivial, 1127
separation axioms, 349

sequence of maps
converges pointwise, 300
Serre fibration, 3263

Nomenclature

$(M\#N, K\#L)$	connected sum of pairs (M, K) and (N, L)
$*\mathbb{C}\mathrm{P}^2$	fake $\mathbb{C}\mathrm{P}^2$ with non-trivial Kirby-Siebenmann invariant
$-M$	smooth manifold equipped with the opposite orientation
1_K	multiplicatively neutral element in $\mathrm{H}^*_{\mathrm{simp}}(K; R)$
1_X	multiplicatively neutral element in $\mathrm{H}^*(X; R)$
$[\widetilde{M}]_{\mathrm{tw}}$	fundamental class of a compact non-orientable path-connected topological manifold
$[K]$	fundamental class of a closed oriented pseudomanifold
$[K]_{\mathbb{F}_2}$	$\mathbb{F}_2$-fundamental class of a closed pseudomanifold
$[M]$	fundamental class of a compact oriented smooth manifold
$[M]$	fundamental class of a compact oriented topological manifold
$[M]^*$	dual fundamental class of a compact oriented topological manifold
$[M]_{\mathbb{R}}$	real fundamental class of a compact oriented smooth manifold
$[M]_{\mathbb{F}_2}$	$\mathbb{F}_2$-fundamental class of a compact smooth manifold
$[M]_{\mathbb{F}_2}$	$\mathbb{F}_2$ fundamental class of a compact oriented smooth manifold
$[M]_{\mathbb{F}_2}$	$\mathbb{F}_2$-fundamental class of a compact topological manifold
$[s]$	equivalence class of $s \in S$
$[S^n]$	standard generator of $\mathrm{H}_n(S^n)$
$[X, Y]$	maps $X \to Y$ up to homotopy
$[X, Y]$	set of homotopy classes of maps $X \to Y$
$[x, y]$	commutator $xyx^{-1}y^{-1}$
$[z_0, \ldots, z_k]$	map $\Delta^k \to \mathbb{R}^n$ defined by $z_0, \ldots, z_k \in \mathbb{R}^n$
$\#S$	cardinality of a set
$\cap$	cap product
$\cap_\otimes$	cap product with twisted coefficients
$\alpha * \beta$	concatenation of paths
$\angle M$	corner of a smooth manifold with corner
$\mathcal{AbGroup}$	category of abelian groups
$\mathcal{AbsGraph}$	category of abstract graphs
$\mathcal{CGWH}$	category of CGWH-spaces
$\mathcal{ChCplx}$	category of chain complexes
$\mathcal{CplxMfd}$	category of complex manifolds
$\mathcal{CRing}$	category of commutative rings
$\mathcal{CW}$	category of CW-complexes
$\mathcal{FullCW}$	full category of CW-complexes
$\mathcal{FullPairCW}$	full category of pairs of CW-complexes

$\mathcal{G}roup$	category of groups
$\mathcal{G}rad\mathcal{A}b$	category of S-graded abelian groups
$\mathcal{G}rad\mathcal{M}od_R$	category of S-graded R-modules
$\mathcal{G}r\mathcal{R}ing$	category of graded rings
$\mathcal{H}om\mathcal{T}op$	homotopy category of topological spaces
$\mathcal{M}ap\mathcal{T}op$	category of maps between topological spaces
${}_R\mathcal{M}od$	category of R-left modules
$\mathcal{M}od_R$	category of R-right modules
$\mathcal{P}air\mathcal{S}et$	category of pairs of sets
$\mathcal{P}air\mathcal{T}op$	category of pairs of topological spaces
$\mathcal{P}\mathcal{S}m\mathcal{M}fd$	category of pointed smooth manifolds
$\mathcal{P}\mathcal{T}op$	category of pointed topological spaces
$\mathcal{R}ing$	category of rings
$\mathcal{S}et$	category of sets
$\mathcal{S}impCplx$	category of abstract simplicial complexes
$\mathcal{S}impCplx$	category of simplicial complexes
$\mathcal{S}m\mathcal{M}fd_{\partial=\varnothing}$	category of smooth manifolds with empty boundary
$\mathcal{S}m\mathcal{M}fd$	category of smooth manifolds
$\mathcal{S}m\mathcal{M}fd_{\mathbb{R}^n}$	category of smooth submanifolds of some $\mathbb{R}^n$
$\mathcal{T}op$	category of topological spaces
$\mathcal{T}op\mathcal{G}r$	category of topological groups
$\mathcal{T}op\mathcal{P}rop\mathcal{M}ap$	category of topological maps where morphisms are proper maps
$\mathcal{U}ndir\mathcal{A}bs\mathcal{G}raph$	category of undirected abstract graphs
$\mathcal{V}ec_{\mathbb{K}}$	category of $\mathbb{K}$-vector spaces
$\chi(X)$	Euler characteristic of a CW-complex
$\chi(X)$	Euler characteristic of a CW-complex
$\chi(X)$	Euler characteristic of a topological space
$\chi^{\mathrm{sm}}(M)$	smooth Euler characteristic of a smooth manifold
$\mathrm{C}^*(X, A; G)$	relative cochain complex
$\mathrm{C}^*_n(X; \mathbb{R})$	bounded cochain complex
$\mathrm{C}^*_{\mathrm{smooth}}(M; G)$	smooth singular cochain complex
Δ^n	standard n-simplex
Δ_M	diagonal of a smooth manifold
δ_{ij}	Kronecker delta
$\varinjlim F$	limit of a diagram
$\varnothing$	the empty set
ϵ_X	augmentation map $\mathrm{C}_0(X) \to \mathbb{Z}$
$\Gamma^A_R(M)$	set of all R-sections along A
$\mathbb{H}^n$	upper half-space in $\mathbb{R}^n$
$\mathring{\Delta}^n$	$\Delta^n \setminus \partial\Delta^n$
$\mathrm{St}(\mathring{K}, s)$	open star of the simplex s
$\mathring{A}$	interior of a subset A
$\varprojlim F$	colimit of a diagram
$\mathbb{L}$	long line

$\mathbb{L}^+$	open long ray
$\Lambda(\varphi)$	Lefschetz number of a map φ
$\Lambda(\varphi, \mathbb{F})$	$\mathbb{F}$-Lefschetz number of a map φ
$\langle (X, x_0), (Y, y_0) \rangle$	maps $(X, x_0) \to (Y, y_0)$ up to homotopy
$\langle (X, x_0), (Y, y_0) \rangle$	maps $(X, x_0) \to (Y, y_0)$ up to homotopy
$\langle\ ,\ \rangle$	Kronecker pairing with R-coefficients
$\langle X \mid R \rangle$	presentation with generating set X and relator set R
$\langle x_1, \dots, x_k \mid r_1, \dots, r_l \rangle$	presentation with generators $x_1, \dots, x_k$ and relators $r_1, \dots, r_l$
$\langle\ ,\ \rangle$	Kronecker pairing
$\triangle$	planar n-simplex
я	map from ordinary to relative homology
ж	map from reduced to ordinary homology
ж	map from reduced to relative homology
ю	map from relative homology to homology of the quotient
$\mathbb{Z}_n$	$\mathbb{Z}/n\mathbb{Z}$
$\mathbb{C}\mathrm{P}^\infty$	infinite-dimensional complex projective space
$\mathbb{C}\mathrm{P}^n$	complex projective space
$\mathbb{H}\mathrm{P}^\infty$	infinite-dimensional quaternionic projective space
$\mathbb{H}\mathrm{P}^n$	quaternionic projective space
$\mathbb{N}$	the natural numbers $1, 2, \dots$
$\mathbb{N}_0$	the natural numbers $0, 1, 2, \dots$
$\mathbb{O}\mathrm{P}^1$	octonionic projective line
$\mathbb{O}\mathrm{P}^2$	octonionic projective plane
$\mathbb{R}\mathrm{P}^\infty$	infinite-dimensional real projective space
$\mathbb{R}\mathrm{P}^n$	real projective space
$\mathbb{Z}^{(S)}$	free abelian group generated by the set S
$\mathcal{N}_n$	unoriented cobordism group
$\mathcal{P}(X)$	power set of the set X
∇f	gradient vector field of f
$\Omega(X)$	free path space
$\Omega(x, x_0)$	loop space
$\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$	framed cobordism group
$\Omega_k^{\mathrm{th}}(\mathbb{R}^m)$	thickened cobordism group
Ω_n	n-th cobordism group
$\mathrm{Sp}(n)$	compact symplectic group
$\mathrm{Aut}(\pi)$	automorphism group of a group π
$\mathrm{Conf}_k(M)$	configuration space of k points in M
$\mathrm{Ind}(X)$	large inductive dimension of a topological space
$\mathrm{ind}(X)$	small inductive dimension of a topological space
$\mathrm{Inn}(\pi)$	inner automorphism group of a group π
$\mathrm{Out}(\pi)$	outer automorphism group of a group π
$\mathrm{cat}(X)$	Lusternik-Schnirelmann category of a topological space X
$\mathrm{cdim}(X)$	covering dimension of a topological space
$\mathrm{cl}(X)$	cup length of a topological space X
$\mathrm{Cone}(f\colon A \to X)$	mapping cone of a map $f\colon A \to X$

$\mathrm{Cone}(K)$	simplicial cone on an abstract simplicial complex K
$\mathrm{Cone}(X)$	cone of a topological space X
$\mathrm{Cyl}(f\colon A \to X)$	mapping cylinder of a map $f\colon A \to X$
$\mathrm{C}^*_{\mathrm{tw,CW}}(X, A; M)$	twisted cellular cochain complex
$\mathrm{C}^*_{\mathrm{tw}}(X, A; M)$	twisted cochain complex
$\mathrm{C}^n_{\mathrm{lc}}(X, A; E)$	relative n-cochain group with local coefficients
$\mathrm{C}_*^{\mathrm{tw,CW}}(X, A; M)$	twisted cellular chain complex
$\mathrm{C}_*^{\mathrm{tw}}(X, A; M)$	twisted chain complex
$\mathrm{C}_n(X)$	n-th singular chain group of X
$\mathrm{C}_n^{\mathrm{lc}}(X, A; E)$	relative n-chain group with local coefficients
$\mathrm{C}_n^{\mathrm{lc}}(X; E)$	n-chain group with local coefficients
$\mathrm{C}^n_{\mathrm{lc}}(X; E)$	n-cochain group with local coefficients
$\mathrm{Deck}(p\colon X \to B)$	deck transformation group
$\deg(\Phi)$	degree of an automorphism of a group isomorphic to $\mathbb{Z}$
$\deg(f)$	degree of a map $f\colon S^n \to S^n$
$\deg(f, x)$	local degree of a map f at a point x
$\mathrm{diam}(A)$	diameter of a subset A of a metric space
$\mathrm{Diff}(M, N)$	set of diffeomorphisms
$\mathrm{Diff}^+(M, N)$	set of orientation-preserving diffeomorphisms
$\mathrm{Emb}(M, N)$	set of diffeomorphisms
$\mathrm{Emb}^+(M, N)$	set of orientation-preserving diffeomorphisms
$\mathrm{ev}\colon \mathrm{H}^n(C; G) \to \mathrm{Hom}(\mathrm{H}_n(C), G)$	evaluation map
$\mathrm{ev}\colon \mathrm{H}^n(X; \mathbb{F}) \to \mathrm{Hom}_{\mathbb{F}}(\mathrm{H}_n(X; \mathbb{F}), \mathbb{F})$	evaluation map with $\mathbb{F}$-coefficients
$\mathrm{Ext}(H, G)$	G-Ext-group of H
$\mathrm{Ext}^n(H, G)$	n-th G-Ext-group of H
$\mathrm{Ext}^n_{S\text{-left}}(M, N)$	n-th N-Ext-module of M
$\mathrm{F}\,H$	maximal torsion-free quotient of H
$\mathrm{F}\,H$	maximal torsion-free quotient of an abelian group
$\mathrm{genus}(M)$	genus of a surface M
$\mathrm{GL}_+(n, \mathbb{R})$	real matrices of positive determinant
$\mathrm{Homeo}(X)$	group of self-homeomorphism of X
$\mathrm{Hom}_{\text{right-}R}(A, B)$	group of R-left module homomorphisms $A \to B$
$\mathrm{H}^n_{\mathrm{lc}}(X, A; E)$	n-th singular cohomology group with local coefficients
$\mathrm{H}_n^{\mathrm{lc}}(X, A; E)$	n-th singular homology group with local coefficients
$\mathrm{H}_n^{\mathrm{lc}}(X; E)$	n-th singular homology group with local coefficients
$\mathrm{H}_n^{\mathrm{tw,CW}}(X, A; M)$	twisted cellular cohomology group
$\mathrm{H}_n^{\mathrm{tw,CW}}(X, A; M)$	twisted cellular homology group
$\mathrm{H}_n^{\mathrm{tw}}(X, A; M)$	twisted cohomology group
$\mathrm{H}_n^{\mathrm{tw}}(X, A; M)$	twisted homology group
$\mathrm{H}^n_{\mathrm{lc}}(X; E)$	n-th singular cohomology group with local coefficients
id_X	identity morphism
$\mathrm{index}(f, g, P)$	index of an intersection point of two maps f and g
$\mathrm{index}(f, z)$	index of a map f at a fixed point z
$\mathrm{index}(v, x)$	index of a vector field v at a zero x

$\operatorname{index}(v, x)$	index of a vector field v at a zero x
$\operatorname{int}(A)$	interior of a subset A
$\operatorname{Isom}(M, g)$	group of isometries of the Riemannian manifold (M, g)
$\operatorname{Isom}^+(M, g)$	group of orientation-preserving isometries of the Riemannian manifold (M, g)
$\mathrm{K}(\pi, n)$	canonical Eilenberg-Maclane space of type $\mathrm{K}(\pi, n)$
$\lim^1$	lim one of an inverse system of abelian groups
$\operatorname{link}(K, s)$	link of the simplex s
$\operatorname{lk}(K, J)$	linking number of oriented knots K and J
$\operatorname{mesh}(Y)$	the largest diameter of a simplex
$\operatorname{Mor}_{\mathcal{C}}(X, Y)_{\mathrm{inv}}$	set of invertible morphisms
$\mathrm{M}(\pi, n)$	Moore space of type $\mathrm{M}(\pi, n)$
$\mathrm{M}(\varphi)$	algebraic mapping cone of $\varphi\colon C_* \to D_*$
O	infinite orthogonal group
PD_M	Poincaré Duality isomorphism
$\operatorname{rank}(A)$	rank of an abelian group A
$\operatorname{rank}(A)$	rank of an abelian group
$\operatorname{rank}(M)$	rank of a module over a commutative domain R.
$\operatorname{sd}(K)$	barycentric subdivision of the simplicial complex K
$\operatorname{sign}(M)$	signature of a $4n$-dimensional topological manifold
$\operatorname{Spin}(n)$	spin group
$\operatorname{St}(K, s)$	star of the simplex s
$\operatorname{supp}(f)$	support of a map $f\colon X \to \mathbb{R}$
$\operatorname{supp}(f\colon X \to \mathbb{R})$	support of the map f
$\mathrm{S}_n(X)$	set of all singular n-simplices in Y
$\operatorname{topval}(x, X)$	topological valence of a point
$\operatorname{Tor}(A)$	torsion subgroup of an abelian group A
$\operatorname{Tor}(H, G)$	G-torsion of H
$\operatorname{Tor}(X, f)$	mapping torus of a map $f\colon X \to X$
$\operatorname{Tor}_n(H, G)$	n-th G-torsion group of H
$\operatorname{Tor}_n^S(M, N)$	n-th N-torsion module of M
$\operatorname{tr}(\varphi)$	trace of the endomorphism φ
U	infinite unitary group
$\operatorname{Vect}_{\mathbb{C}}^n(X)$	set of isomorphism classes of n-dimensional $\mathbb{C}$-vector bundles over X
$\operatorname{Vect}_{\mathbb{R}}^n(X)$	set of isomorphism classes of n-dimensional $\mathbb{R}$-vector bundles over X
$\operatorname{Vect}_{\mathbb{R}}^{n,+}(X)$	set of isomorphism classes of oriented n-dimensional $\mathbb{R}$-vector bundles over X
$\operatorname{sign}(\sigma)$	sign of the permutation σ
Sp	infinite symplectic group
$\operatorname{Sp}(2g, \mathbb{Z})$	symplectic group
$\overline{\mathbb{L}_{\geq 0}}$	closed long ray
$\overline{\mathbb{L}}$	long ray
$\overline{A}$	closure of a subset A
$\overline{B}^n$	n-dimensional closed ball in $\mathbb{R}^n$

$\overline{B}_r^n(y)$	closed r-ball around $y \in \mathbb{R}^n$
$\partial\Delta^n$	all points on Δ^n where at least one coordinate is zero
∂M	boundary of a smooth manifold with corner
∂M	boundary of a smooth manifold
∂X	boundary of a topological manifold
$\partial_0 X$	$\partial_0 X = \partial X \setminus \partial M$ of a submanifold X of a manifold M
∂_0	∂_0 of a submanifold with corner
$\partial_1 X$	$\partial_1 X = \partial X \cap \partial M$ of a submanifold X of a manifold M
∂_1	∂_1 of a submanifold with corner
$\partial_{\mathrm{c}} M$	corner set of a submanifold M with corner
$\Phi_s^{\leq}$	characteristic map in a totally ordered simplicial complex
$\pi_0(X)$	the set of path-components of a topological space X
$\pi_1(X, x_0)$	fundamental group of (X, x_0)
π_k^s	stable homotopy group
$\pi_n(X, A, x_0)$	relative homotopy group
$\pi_n(X, x_0)$	n-th homotopy group of (X, x_0)
${}_{\varphi}A$	$\mathbb{Z}[G]$-left module corresponding to $\varphi\colon G \to \mathrm{Aut}(A)$
$\mathbb{R}^n_{++}$	the upper right quadrant of $\mathbb{R}^n$.
$\prod_{i \in I} X_i$	product of sets
$\coprod_{i \in I} X_i$	product of sets
$\Sigma(K)$	simplicial suspension of an abstract simplicial complex K
$\Sigma(X)$	Suspension of X
$\Sigma(X)$	suspension of a topological space X
Σ_g	surface of genus g
$\Sigma_{g,n}$	surface of genus g minus n open disks
$\theta_{\mathbb{R}}$	the canonical singular cochain in $\mathrm{C}^1; \mathbb{R})$
$\theta_{\mathbb{R}}$	the canonical singular cochain in $\mathrm{C}^1; \mathbb{Z})$
$\varprojlim$	inverse limit of an inverse system
$\varinjlim$	direct limit of a direct system
$\mathrm{C}_*^{\mathrm{CW}}(X, A)$	cellular chain complex
$\mathrm{H}_n^{\mathrm{CW}}(X, A)$	n-th relative cellular homology group
$\mathrm{H}_n^{\mathrm{lf}}(X; G)$	locally finite homology
$\mathrm{H}_{\mathrm{dR}}^k(M, A)$	relative de Rham cohomology groups
$\mathrm{C}_{\mathrm{c}}^*(X; G)$	chain complex with compact support
$\mathrm{C}_{\mathrm{simp},\leq}^*(K; G)$	simplicial cochain complex
$\mathrm{C}_{\mathrm{simp}}^*(K; G)$	simplicial cochain complex
$\mathrm{C}_*^{\mathrm{CW}}(X)$	cellular chain complex
$\mathrm{C}_*^{\mathrm{CW}}(X)$	cellular cochain complex
$\mathrm{C}_*^{\mathrm{CW}}(X, A)$	cellular chain complex
$\mathrm{C}_*^{\mathrm{han}}(M)$	handle chain complex
$\mathrm{C}_*^{\mathrm{simp},\leq}(K)$	simplicial chain complex of an ordered abstract simplicial complex
$\mathrm{C}_*^{\mathrm{simp}}(K)$	simplicial chain complex of an abstract simplicial complex

$\mathrm{C}_n(X, A)$	relative singular chain group
$\mathrm{C}_n^{\mathrm{simp},\leq}(K)$	n-th simplicial chain group of an ordered abstract simplicial complex K
$\mathrm{C}_n^{\mathrm{simp}}(K)$	n-th simplicial chain group of the abstract simplicial complex K
$\mathrm{D}_W M$	double of a topological (smooth) manifold M along W
$\mathrm{D} f_P$	differential of a smooth map $f\colon M \to N$ at $P \in M$
$\mathrm{D} M$	double of a topological (smooth) manifold M
$\mathrm{H}^k_{\mathrm{simp},\leq}(K; G)$	k-th simplicial cohomology group
$\mathrm{H}^k_{\mathrm{simp}}(K; G)$	k-th simplicial cohomology group
$\mathrm{H}^n(X, A; G)$	n-th relative singular cohomology
$\mathrm{H}^n_{\mathrm{CW}}(X)$	n-th cellular cohomology group
$\mathrm{H}^n_{\mathrm{smooth}}(M; G)$	n-th smooth singular cohomology group
$\mathrm{H}^{\mathrm{han}}_k(M)$	n-th handle homology group
$\mathrm{H}_n(\pi)$	n-th homology group of a group π
$\mathrm{H}_n(X)$	n-th singular homology group
$\mathrm{H}_n(X; G)$	singular homology with G-coefficients
$\mathrm{H}^{\mathrm{CW}}_n(X)$	n-th cellular homology group
$\mathrm{H}^{\mathrm{CW}}_n(X, A)$	n-th relative cellular homology group
$\mathrm{H}^{\mathrm{simp},\leq}_n(K)$	n-th simplicial homology group of an ordered abstract simplicial complex
$\mathrm{H}^{\mathrm{simp}}_n(K)$	n-th simplicial homology group of an abstract simplicial complex
$\mathrm{H}^{\mathrm{simp}}_n(K; G)$	simplicial homology with G-coefficients
$\mathrm{H}_{\mathbb{H}}$	quaternionic Hopf map
$\mathrm{H}_{\mathbb{O}}$	octonionic Hopf map
$\mathrm{H}^n_{\mathrm{b}}(X; \mathbb{R})$	n-th bounded cohomology group
$\mathrm{H}^n_{\mathrm{c}}(X; G)$	cohomology with compact support
$\mathrm{T}_P M$	tangent space of a smooth manifold M at P
$\varphi \cup \psi$	cup product
$\varphi \cap \sigma$	cap product on (co-) homology
$\varphi \cup \psi$	relative cup product on cohomology
$\varphi \cup \psi$	relative cup product
$\varphi \cup_{\otimes} \psi$	relative cup product on cohomology with twisted coefficients
$\varphi \times \psi$	cross product on cohomology
$\widetilde{\mathrm{Diff}}(M, N)$	set of diffeomorphisms up to diffeotopy
$\widetilde{\mathrm{Diff}}^+(M, N)$	set of orientation-preserving diffeomorphisms up to diffeotopy
$\widetilde{\mathrm{Emb}}(M, N)$	set of diffeomorphisms up to diffeotopy
$\widetilde{\mathrm{Emb}}^+(M, N)$	set of orientation-preserving diffeomorphisms up to diffeotopy
$\widetilde{\mathrm{T}}_P M$	physical tangent space of a smooth submanifold of some $\mathbb{R}^n$
$\widetilde{C}_*(X)$	reduced chain complex
$\widetilde{p}_I(M)$	I-Pontryagin number of a smooth manifold M
$\widetilde{X}_{x_0}$	natural universal covering corresponding of (X, x_0)
$\widetilde{X}^{\Gamma}_{x_0}$	natural covering corresponding to $\Gamma \subset \pi_1(X, x_0)$
$\widetilde{\mathrm{H}}_n(X)$	n-th reduced homology group
$A \otimes B$	tensor product of two abelian groups A and B

$A \otimes_{\mathbb{K}} B$	tensor product of two real vector spaces A and B
$A \subset B$	A is a subset of B
$A \subsetneq B$	A is a subset of B with $A \neq B$
B^n	n-dimensional open ball in $\mathbb{R}^n$
$B^n_r(y)$	open r-ball around $y \in \mathbb{R}^n$
$b_n(X)$	the n-th Betti number of a topological space
$b_n(X, A)$	the n-th Betti number of a pair of topological space
$C^\infty(M, N)$	set of all smooth maps between smooth manifolds M and N
$C_* \otimes D_*$	tensor product of chain complexes
c_y	the constant map that sends all points to y
$d(A, B)$	distance between two subsets of a metric space
E_8	the 8×8-matrix E_8
$f \cdot g$	algebraic intersection of two maps that intersect nicely
$f^{-1}(y)$	preimage of the one-point subset $\{y\}$
$G \rtimes_\varphi \pi$	semidirect product of two groups G and π
H	Hopf map
i^n_j	the j-th face map $\Delta^{n-1} \to \Delta^n$
K^{inv}	inverse of a knot
K^{mir}	mirror image of a knot K
K^{mir}	mirror of a knot
K^{rev}	reverse of a knot
$K_1 * \cdots * K_m$	simplicial join of abstract simplicial complexes
$L(p, q)$	lens space
L^{cl}	closure of a long knot L
$M \# N$	connected sum of topological manifolds M and N
$M \setminus\setminus F$	the smooth manifold M cut along a codimension-one submanifold F
M^π	π-invariants
$M^{\mathrm{h}}(\varphi)$	handle attachment to M along φ
M_π	π-coinvariants
$N \rtimes_\varphi \mathbb{Z}_k$	semidirect product of groups N and $\mathbb{Z}_k$
$N(\mathcal{U})$	nerve complex of a cover $\mathcal{U}$
N_g	non-orientable surface of genus g
$N_{g,n}$	non-orientable surface of genus g minus n open disks
$p(E)$	total Pontryagin class of a vector bundle E
$P(x, x_0)$	path space
$p_i(E)$	i-th Pontryagin class of a vector bundle E
$p_I(M)$	I-Pontryagin class of a smooth manifold M
$p_i(M, \mathbb{Q})$	i-th rational Pontryagin class of a smooth manifold
$Q^{\mathrm{as}}_{M,A,B}$	asymmetric intersection pairing
$Q^{\mathrm{red}}(M)$	reduced intersection form
Q_M	intersection form of an even dimensional topological manifold
$Q^{\mathbb{F}_2}_M$	$\mathbb{F}_2$-value intersection form of an even dimensional topological manifold
$R^{(X)}$	free R-left module generated by the set X
$S(X, x_0)$	reduced suspension

$S/\sim$	set of equivalence classes
$S^3_r(L)$	Dehn surgery along the framed link (L, r)
$S^3_r(K)$	Dehn surgery along K
S^∞	infinite-dimensional sphere
S^n	n-dimensional sphere in $\mathbb{R}^{n+1}$
$S^n_r(y)$	n-dimensional sphere of radius r around y
$S^n_{=0}$	equator of S^n
$S^n_{\geq 0}$	upper hemisphere of S^n
$S^n_{\leq 0}$	lower hemisphere of S^n
$s^\dagger$	dual chain of a simplex s
w_1	orientation character of a smooth manifold
w_1	orientation character of a topological manifold
$X * X$	join of topological spaces X and Y
$X * Y * Z$	join of topological spaces X, Y and Z
X/A	quotient of topological space X by subset A
$X \cdot Y$	algebraic intersection number of X and Y
$X \cdot f$	algebraic intersection number of X and f
$X \cdot X$	algebraic self-intersection number of a submanifold
$X \cdot Y$	algebraic intersection number of X and Y
$X \cdot_{\mathbb{Z}_2} f$	$\mathbb{Z}_2$-valued intersection number of X and f
$X \cdot_{\mathbb{Z}_2} Y$	$\mathbb{Z}_2$-valued intersection number of X and Y
$X \otimes Y$	product of two CW-complexes
$X \pitchfork f$	X and Y intersect transversally
$X \pitchfork f$	X and f intersect transversally
$X \vee Y$	wedge of the topological spaces X and Y
$X \wedge Y$	smash product of X and Y
$X \widetilde{\times} Y$	product in the category of CGWH-spaces
X^Y	set of continuous maps $Y \to X$
$Y \cup_\varphi Z$	Y glued to Z via φ
$Y \cup_Z X$	pushout of $Y \leftarrow Z \to X$

Results and statements about topological spaces:

- Criteria for maps to be homeomorphisms, see 2.17 (3), 2.19, 2.43
- Product of quotient map with identity is quotient map, see 13.4.
- Cones are contractible, see 16.7.
- the topological space $\mathbb{R}^{\mathbb{N}}$ is metrizable, see 9.5.

Results and statements about smooth manifolds:

- Dimension of a non-empty smooth manifold is well-defined, see 19.28.
- Points in path-connected smooth manifolds can be connected via smooth paths, 19.29 and 19.29.
- Smooth manifolds are homogeneous, see 36.4 and 33.14.
- Smooth map is homotopic to its linearization, see 76.15.
- Smooth embeddings of smooth manifolds into some $\mathbb{R}^n$, see 27.1 (1), 30.7, **??**, **??**, **??**.
- Smooth manifolds are diffeomorphic to smooth submanifolds of some $\mathbb{R}^n$, see 27.2.
- Map between smooth manifolds is homotopic to map without triple points, see **??**.
- Existence of partitions of unity, see 21.1.
- Existence of a locally finite atlas, see 21.3.
- Continuous maps are homotopic to smooth maps, see 19.29, 29.1.
- Smooth orientation-preserving embeddings of collection of balls are unique up to smooth isotopy, see 37.8.
- For $n \geq 4$ every finitely presented group is the fundamental group of an n-dimensional smooth manifold, see 54.12 and page 3031.
- Smooth manifolds admit simplicial structures, see 95.37 and 96.2.
- The Hauptvermutung holds for smooth simplicial structures, see 96.4.
- Compact smooth manifolds admit Morse functions, see the Morse Function-Existence Proposition 137.6.
- Compact smooth manifold admit handle decompositions, see 138.5.
- Handle decompositions give rise to CW-complex, see 136.18.
- CW-structures on smooth manifolds, see 95.37, 96.5, 98.14, 98.16, 104.20, 138.6, 139.8, 136.18.
- There exist only countably many diffeomorphism types of compact n-dimensional smooth manifolds, see 60.3.
- The diffeomorphism problem is unsolvable in dimension ≥ 4, see 60.4.
- Continuous maps between smooth manifolds are homotopic to smooth maps, see 29.1.
- Maps from manifolds to topological spaces can be smoothed on preimages of open balls, see 29.8.
- Homology classes that can be represented by (embeddings) of smooth manifolds, see 102.4, 102.3, 102.14, 102.17, 130.4, 130.6, **??**, 102.18, and **??**.
- Explicit construction of cyclic coverings of topological spaces, see 130.11.
- Submanifolds can be made transverse, see 42.4
- The signature of closed smooth manifolds is multiplicative under finite coverings, see 145.10.
- Classification of 1-dimensional smooth manifolds, see 22.7 and 142.1.

- Classification of compact 2-dimensional smooth manifolds, see 55.4.
- Results on $\mathrm{Diff}(S^n)$, see page **??**.
- Closed smooth manifolds of Euler characteristic zero admit nowhere-vanishing vector field, see 129.6.
- Homology groups of compact smooth manifolds are finitely generated and fundamental groups of compact smooth manifold are finitely presented, see 96.6, **??**, 170.7 and page 2997.
- De Rham cohomology groups of compact smooth manifolds are finite dimensional, see **??**.
- Homology groups and fundamental groups of smooth manifolds are countable, see 49.1 and 96.7.
- Homotopy balls of dimension $n \geq 6$ are diffeomorphic to $\overline{B}^n$, see **??**.
- $\mathrm{SL}(n, \mathbb{R})$, $\mathrm{O}(n)$, $\mathrm{SL}(n, \mathbb{C})$, $\mathrm{U}(n)$ and $\mathrm{U}(n)$ are submanifolds, 26.7.

Results and statements about submanifolds of smooth manifolds:

- Submanifolds admit unique tubular neighborhoods, see **??**, **??**, **??** and **??**.
- Isotopies of submanifolds can be extended, see 36.1.
- The Lefschetz Fixed Point Theorem for smooth manifolds, see 97.10.

Results and statements about topological manifolds:

- Topological manifolds are homogeneous, see 36.4.
- Topological manifolds can be embedded in some $\mathbb{R}^n$, see 27.1 (2).
- Existence of partitions of unity, see 21.1.
- Topological manifolds are paracompact, see **??**.
- Topological manifolds are normal, see **??**.
- Topological manifolds are completely metrizable, see **??**.
- Existence of a locally finite atlas, see 21.3.
- Dimension of a non-empty topological manifold is well-defined, see 75.4.
- There exist only countably many homeomorphism types of compact n-dimensional topological manifolds, see 60.3.
- Every compact topological manifold is a retract of a finite simplicial complex, see 104.13.
- Every compact topological manifold is homotopy equivalent to a CW-complex, see 104.20, 104.26 and 104.27.
- CW-structures on topological manifolds, see 104.29, 104.30 and 104.32
- Homology groups of compact topological manifolds are finitely generated and fundamental group of compact topological manifold are finitely presented, see 104.14 and 170.7.
- Homology groups and fundamental groups of topological manifolds are countable, see 49.1 and 104.15.
- The homeomorphism problem is unsolvable in dimension ≥ 4, see 60.4.
- The Lefschetz Fixed Point Theorem for topological manifolds, see 104.12.
- Result on homology groups and homotopy groups of topological manifolds, see 104.14, 104.19, 106.3 and 98.6.
- Classification of 1-dimensional topological manifolds, see 22.1 and 22.15.
- Classification of compact 2-dimensional topological manifolds, see 55.4.

– The self-homeomorphism group of a topological manifold is locally contractible, see ??.

Results and statements about simplicial complexes:

– Simplicial complexes are Hausdorff, 93.5.
– Maps are homotopic to simplicial maps, see 94.8.
– Simplicial structures give rise to CW-structures, see 93.24.
– Simplicial (co-) homology is naturally isomorphic to singular (co-) homology, see 95.22, 95.25, 95.27, 95.30, 99.6, 99.11 and 99.17.
– Simplicial complexes are PL-homeomorphic if and only if they are stellar equivalent, see 96.22.
– The Lefschetz Fixed Point Theorem for simplicial complexes, see 97.9.

Results and statements about topological graphs and CW-complexes:

– CW-complexes are Hausdorff, normal, locally contractible and locally path-connected, see 68.10.
– Every point on a CW-complex is good, see 68.10.
– CW-complexes have the homotopy extension property, see 70.1.
– Maps are homotopic to cellular maps, see 70.15.
– Products of CW-complexes, see 68.23, the Fundamental Group-of-1-Complex Theorem 69.9, 69.11. 68.25.
– Every finite CW-complex can be embedded in some $\mathbb{R}^n$, see 104.10.
– Fundamental groups of CW-complexes, see 52.5
– Homotopy groups of countable CW-complexes are countable, see 104.21.
– Every CW-complex is homotopy equivalent to a simplicial complex, see 94.12.
– Singular and cellular (co-) homology are naturally isomorphic, see 80.4, 81.12, 109.4, and 170.3
– The singular and cellular chain complexes are chain homotopy equivalent, see 81.12 and ??.
– A topological space that is dominated by a CW-complex is homotopy equivalent to a CW-complex, see 162.8.
– The higher homotopy groups of any countable 0-connected CW-complex are countable, see 104.21.
– Every k-connected CW-complex is homotopy equivalent to a CW-complex with a single 0-cell and no cells in dimension $1, \ldots, k$, see 70.4 and 162.10.
– Taking the quotient by a contractible subcomplex is a homotopy equivalence, see 69.8 and 70.3.
– The Lefschetz Fixed Point Theorem for CW-complexes, see 104.12.
– Every finite CW-complex admits a thickening, i.e. it is homotopy equivalent to a compact smooth manifold, see 141.7.

Results and statements about surfaces, knots and links:

– Classification of curves on surfaces, 55.16.
– Calculation of the fundamental group of the complement of the trefoil, see 59.5.
– Every knot, after a rotation, admits a projection that is a knot diagram, see 59.19.
– Two knot diagrams for a given knot are related by Reidemeister moves, 59.21.
– Characterization of the meridian of a knot, see 58.10.

- Definition of the connected sum of two oriented knots, see 1319.
- Knots of genus zero are trivial, see 58.8.
- Calculation of the fundamental group of any knot complement, see 59.23.
- Abelianization of the fundamental group of a knot complement, see 59.25.
- Homology groups of a knot complement, see 100.16.
- Knots admit Seifer surfaces, see 131.6.
- Knots of genus zero are trivial, see 58.8.
- Linking numbers are symmetric, see 131.12.
- Linking numbers can be calculated from Seifert surfaces, see 131.13.
- Linking numbers can be calculated from link diagrams, see 131.14.
- 4-dimensional interpretation of linking numbers, see 131.15.
- Different definitions of linking numbers agree, see 131.16
- Any two knots in $\mathbb{R}^3$ become smoothly isotopic in $\mathbb{R}^4$, see **??**.
- The trefoil is chiral, see 131.5 and 149.10.
- Existence of a knot that is neither amphichiral, nor reversible nor invertible, see 131.4.
- Existence of non-trivial high-dimensional knots, see 59.38.
- Wild knots exist, see 124.13.

Results and statements about groups:

- Classification of finitely generated abelian groups, see 51.4.
- Retract of a finitely presented group is again finitely presented, see 53.16.
- Maps in amalgamated products and HNN-extensions are monomorphisms, see 53.24 and 57.2.
- The word problem, the conjugacy problem and the isomorphism problem are unsolvable for finitely presented groups, see 60.2.
- Subgroups of free groups are free groups, see 64.4 and 69.10.
- Subgroups of free abelian groups are free abelian groups, see 51.2.
- The Ping-Pong Lemma, see 51.13.
- Any two finite presentations are related by Tietze transformations, see 53.7.
- Free groups are residually finite, see 51.15 and 64.15.
- Surface groups are linear and residually finite, see 66.19.
- Surface groups are not free, see 64.17.
- Finite-index subgroups of finitely presented groups are finitely presented, see 69.15.

Results and statements about (co-) homology groups:

- Isomorphisms between homology groups are induced by chain maps, see 81.13.
- Maps that induce isomorphisms on homology are chain homotopy equivalences, see 81.4 and 81.5.
- Singular and cellular (co-) homology are naturally isomorphic, see 80.4, 81.12 and 109.4.
- Singular and cellular chain complexes are chain homotopy equivalent, see 81.12 and 99.1.
- Singular and simplicial (co-) homology are naturally isomorphic, see 95.22, 95.25, 95.27 and 99.6.
- Singular and simplicial chain complexes are chain homotopy equivalent, see 95.25.

– Singular and handle homology are isomorphic, see 140.3.
– Relationship between relative homology and homology of quotient space, see 74.20 and 78.16.
– Explicit representatives of homology classes, see 76.2, 76.3 and page 2054.
– Linking pairing is (anti-) symmetric, see 148.16.
