$$\begin{array}{ccc} \mathbb{R} & \xrightarrow{\widetilde{f}} & \mathbb{R} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ \mathbb{R}/\mathbb{Z} & \xrightarrow{f} & \mathbb{R}/\mathbb{Z}. \end{array}$$

We make the following observations:

(a) The map $\widetilde{f}$ is in particular smooth.
(b) Since $\widetilde{f}$ is orientation-preserving we know, by Exercise 25.18, that $\widetilde{f}$ is a strictly monotonously increasing function.
(c) Since $\widetilde{f}$ is a diffeomorphism the restriction of $\widetilde{f}$ to the interval $[x, x+1)$ defines a bijection with $[f(x), f(x+1))$.
(d) Given $x \in \mathbb{R}$ we obtain from the commutative diagram that $\widetilde{f}(x+1) - \widetilde{f}(x) \in \mathbb{Z}$.
(e) It follows from (a), (b), (c) and (d) that for any $x \in \mathbb{R}$ we have $\widetilde{f}(x+1) = \widetilde{f}(x) + 1$.

Now we consider the map

$$\begin{array}{rcl} \widetilde{F}\colon \mathbb{R} \times [0,1] & \to & \mathbb{R} \\ (x, t) & \mapsto & \widetilde{f}(x) \cdot (1-t) + x \cdot t. \end{array}$$

This map is evidently smooth. Since $x \mapsto x$ is a strictly monotonously increasing diffeomorphism of $\mathbb{R}$ one can see easily that for any $t \in [0,1]$ the map $\widetilde{F}_t\colon \mathbb{R} \to \mathbb{R}$ has the above Properties (a) to (e). This implies in particular that the map $\widetilde{F}$ descends to a map

$$\begin{array}{rcl} F\colon (\mathbb{R}/\mathbb{Z}) \times [0,1] & \to & \mathbb{R}/\mathbb{Z} \\ ([x], t) & \mapsto & \widetilde{f}(x) \cdot (1-t) + x \cdot t \end{array}$$

where each $F_t\colon \mathbb{R}/\mathbb{Z} \to \mathbb{R}/\mathbb{Z}$ is a homeomorphism. Since each $\widetilde{F}_t$ is a local diffeomorphism and since p is a local diffeomorphism we obtain from the Smooth Pasting Proposition 19.23

(2) that each F_t is in fact a diffeomorphism. We have thus shown that F is indeed a diffeotopy from f to the identity.

Finally we consider the case that f is orientation-reversing. In this case $r \circ g$ is orientation-preserving. We apply the above result to $r \circ g$ and we easily obtain the desired diffeotopy from f to r. ■

63.2. **Complex one-dimensional tori.** The following definition is inspired by Lemma 32.18 and Exercise 19.34.

Notation.

(1) A lattice in $\mathbb{C}$ is a subgroup of $\mathbb{C}$ that is of the form $\mathbb{Z} \cdot a + \mathbb{Z} \cdot b$ where $a, b \in \mathbb{C}$ are two complex numbers that are linearly independent over $\mathbb{R}$.
(2) Given a lattice Λ we write $T(\Lambda) = \mathbb{C}/\Lambda$. The holomorphic analogue of the Manifold Quotient-by-Group Action Proposition 19.32 shows that $T(\Lambda)$ is naturally a 1-dimensional complex manifold such that the projection $p\colon \mathbb{C} \to T(\Lambda)$ is a covering map of complex manifolds, in particular it is a local biholomorphism.
(3) We say that two lattices Λ and $\widetilde{\Lambda}$ in $\mathbb{C}$ are homothetic if there exists an $r \in \mathbb{C} \setminus \{0\}$ such that $r \cdot \Lambda = \widetilde{\Lambda}$.

The following proposition gives a complete and satisfactory characterization for when two lattices define biholomorphic complex manifolds.

Proposition 63.1. Let Λ and $\widetilde{\Lambda}$ be two lattices in $\mathbb{C}$. The complex manifolds $T(\Lambda)$ and $T(\widetilde{\Lambda})$ are biholomorphic if and only if Λ and $\widetilde{\Lambda}$ are homothetic.

Proof. Let Λ and $\widetilde{\Lambda}$ be two lattices in $\mathbb{C}$. We denote by $p\colon \mathbb{C} \to T(\Lambda)$ and $\widetilde{p}\colon \mathbb{C} \to T(\widetilde{\Lambda})$ the natural projections. Note that there local holomorphisms.

First assume that Λ and $\widetilde{\Lambda}$ are homothetic, i.e. we assume that there exists an $r \in \mathbb{C}\setminus\{0\}$ such that $r \cdot \Lambda = \widetilde{\Lambda}$. In this case we obtain the following commutative diagram:

$$\begin{array}{ccc} \mathbb{C} & \xrightarrow{z \mapsto r \cdot z} & \mathbb{C} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle \widetilde{p}} \\ T(\Lambda) & \xrightarrow{[z] \mapsto [r \cdot z]} & T(\widetilde{\Lambda}). \end{array}$$

Note that our hypothesis shows that bottom horizontal map is defined and a bijection. The top horizontal map is of course a biholomorphism. Since the vertical maps are local biholomorphisms we see that the bottom horizontal map is a bijection and a local biholomorphism. In other words, it is a biholomorphism.

Now we assume that there exists a biholomorphism $f\colon T(\Lambda) \to T(\widetilde{\Lambda})$. By the Lift-to-Universal Coverings Proposition 61.13 there exists a biholomorphism $\widetilde{f}\colon \mathbb{C} \to \mathbb{C}$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathbb{C} & \xrightarrow{\widetilde{f}} & \mathbb{C} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle \widetilde{p}} \\ T(\Lambda) & \xrightarrow{f} & T(\widetilde{\Lambda}). \end{array}$$

Next we make the following observations and preparations:

(a) We equip the universal covering $\mathbb{C}$ with the actions of $\pi_1(T(\Lambda),[0])$ and $\pi_1(T(\widetilde{\Lambda}),[s])$ that we introduced on page 1391.

(b) By Proposition 62.13 we know that for all $z \in \mathbb{C}$ and all $g \in \pi_1(T(\Lambda), x_0)$ we have

$$\widetilde{f}(g \cdot z) \;=\; \underbrace{f_*(g) \cdot \widetilde{f}(z)}_{\in \pi_1(T(\widetilde{\Lambda}),[s])}.$$

(c) Note that the Fundamental Group-via-Actions Theorem 48.16 provides us with explicit isomorphisms $\Theta\colon \Lambda \to \pi_1(T(\Lambda), x_0)$ and $\widetilde{\Theta}\colon \widetilde{\Lambda} \to \pi_1(T(\widetilde{\Lambda}), x_0)$.

(d) It follows from the discussion on page 1390 that (c) translates into the statement that for all $z \in \mathbb{C}$ and all $\lambda \in \Lambda$ we have

$$\widetilde{f}(\lambda + z) \;=\; (\widetilde{\Theta} \circ f_* \circ \Theta^{-1})(\lambda) + \widetilde{f}(z).$$

(e) Since $\widetilde{f}\colon \mathbb{C} \to \mathbb{C}$ is a biholomorphism we know by Theorem 32.11 that there exist $r, s \in \mathbb{C}$ such that $f(z) = r \cdot z + s$ for all $z \in \mathbb{C}$.

(f) The combination of (d), applied to $z = 0$, and (e) shows that for all $\lambda \in \Lambda$ we have

$$r \cdot \lambda + s \;=\; (\widetilde{\Theta} \circ f_* \circ \Theta^{-1})(\lambda) + s.$$

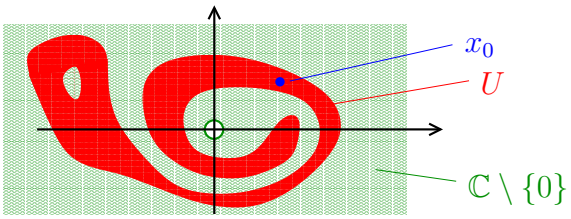
(g) The map $f_*\colon \pi_1(T(\Lambda),[0]) \to \pi_1(T(\widetilde{\Lambda}),[s])$ is an isomorphism since f is in particular a homeomorphism. In particular $\widetilde{\Theta} \circ f_* \circ \Theta^{-1}\colon \Lambda \to \widetilde{\Lambda}$ is an isomorphism.

The combination of (f) and (g) shows that $r \cdot \Lambda = \widetilde{\Lambda}$. We have thus shown that the lattices Λ and $\widetilde{\Lambda}$ are homothetic. ■

Corollary 63.2. There are closed complex manifolds that are diffeomorphic but that are not biholomorphic.

Proof. Let Λ and $\widetilde{\Lambda}$ be two lattices in $\mathbb{C}$. It follows from Exercise 19.34 that the tori $T(\Lambda)$ and $T(\widetilde{\Lambda})$, viewed as smooth manifolds, are diffeomorphic. In Exercise 63.1 we will see that there exist lattices Λ and $\widetilde{\Lambda}$ in $\mathbb{C}$ that are not homothetic. It follows from Proposition 63.1 that $T(\Lambda)$ and $T(\widetilde{\Lambda})$ are not biholomorphic. ■

63.3. **Complex logarithms.** In this short section we will discuss complex logarithms. This discussion does not play a role in the remainder of these notes, but it is a fun application of covering theory.



Definition. Let $U \subset \mathbb{C} \setminus \{0\}$ be a subset. We say the complex logarithm exists on U if there exists a map[740] $\ln\colon U \to \mathbb{C}$ such that $\exp(\ln(z)) = z$ for all $z \in U$.

The following proposition gives a very pleasing sufficient and necessary criterion for complex logarithms to exist.

Proposition 63.3. Let $U \subset \mathbb{C} \setminus \{0\}$ be an open path-connected subset. The following statement holds:[741]

$$\text{the complex logarithm exists on } U \quad\Longleftrightarrow\quad \begin{array}{c}\text{for some } x_0 \in U \text{ the inclusion induced map}\\ \pi_1(U, x_0) \to \pi_1(\mathbb{C} \setminus \{0\}, x_0)\\ \text{is the trivial map.}\end{array}$$

[740] As always, all maps are understood to be continuous.

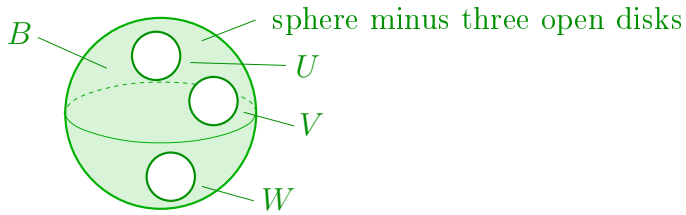
the map $\pi_1(U, x_0) \to \pi_1(\mathbb{C} \setminus \{0\}, x_0)$
is the trivial map, hence
the complex logarithm exists on U

Proof. Let $U \subset \mathbb{C} \setminus \{0\}$ be an open path-connected subset and let $x_0 \in U$. We consider the following rather simple minded diagram

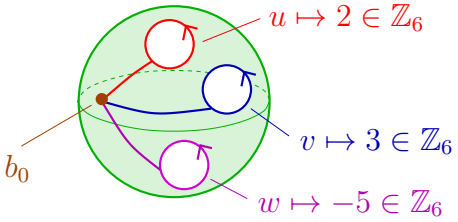
$$\begin{array}{ccc} & & \mathbb{C} \\ & \overset{\nearrow}{} & \big\downarrow {\scriptstyle z \mapsto \exp(z)} \\ U & \xhookrightarrow[i]{} & \mathbb{C} \setminus \{0\}. \end{array}$$

We make the following observations:

(1) As on page 1067 one can show that the vertical map exp is actually a covering map.
(2) The question whether the complex logarithm exists on U is equivalent to the question whether the inclusion map $i\colon U \to \mathbb{C} \setminus \{0\}$ lifts to a map $U \to \mathbb{C}$.
(3) Since $\exp\colon \mathbb{C} \to \mathbb{C} \setminus \{0\}$ is surjective we can pick a $y_0 \in \mathbb{C}$ with $\exp(y_0) = x_0$.
(4) Note that $\mathbb{C}$ is simply connected. The image $\operatorname{im}(\exp_*\colon \pi_1(\mathbb{C}, y_0) \to \pi_1(\mathbb{C} \setminus \{0\}, x_0))$ is therefore the trivial group.
(5) Since U is an open subset of $\mathbb{C} \setminus \{0\}$ it is in particular locally path-connected. Thus we can apply the Map Lifting Criterion 61.2. Together with (4) we obtain from the Map Lifting Criterion 61.2 the statement



$$\begin{array}{c}\text{there exists a lift of} \\ \text{the map } i\colon U \to \mathbb{C} \setminus \{0\}\end{array} \iff \begin{array}{c}\text{the map } i_*\colon \pi_1(U, x_0) \to \pi_1(\mathbb{C} \setminus \{0\}, x_0) \\ \text{is the trivial map.}\end{array}$$



(6) The combination of (2) and (5) is precisely the statement we had set out to prove. ■

63.4. **Preimages of subsets under coverings.** Let (B, b_0) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. In the Covering Existence Theorem 61.5 (2) we saw that subgroups of $\pi_1(B, b_0)$ give rise to coverings of B. Arguably the most common source of subgroups is given by considering kernels of group homomorphisms $\pi_1(B, b_0) \to G$.

Example. Let B be the 2-dimensional sphere S^2 minus three open disks. We pick a base point b_0 for B and we pick loops u, v, w as shown in the figure below. From Lemma 55.11 we know that $\pi_1(B, b_0) = \langle u, v, w \,|\, uvw \rangle$. By Lemma 53.4 there exists a unique homomorphism $\varphi\colon \pi_1(B, b_0) \to \mathbb{Z}_6$ with $\varphi(u) = 2$, $\varphi(v) = 3$ and $\varphi(w) = -5$. Let $p\colon X \to B$ be the covering corresponding to $\ker(\varphi)$. By the Manifold Covering Proposition 49.2 we know that X is again a compact orientable 2-dimensional smooth manifold, where the boundary is given by $\partial X = p^{-1}(\partial B)$. Thus we know from the Surface Classification Theorem 55.4 that there exist unique $g \in \mathbb{N}_0$ and $n \in \mathbb{N}$ such that X is homeomorphic to $\Sigma_{g,n}$, i.e. such that X is homeomorphic to the surface of genus g minus n open disks.

[741] It follows from Proposition 47.20 that the condition on the right-hand side does not depend on the choice of the base point.

Therefore the following question arises:

Question 63.4. In the previous example, what are g and n?

The final proposition of this chapter will allow us to answer one half of Question 63.4, namely we can determine n. We will determine g in Exercise 64.3.

Proposition 63.5. (Preimage-of-Covering Proposition) Let (B, b_0) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. Let $\varphi\colon \pi_1(B, b_0) \to G$ be a group epimorphism and let $p\colon (X, x_0) \to (B, b_0)$ be the covering with $p_*(\pi_1(X, x_0)) = \ker(\varphi)$. Finally let A be a path-connected subset of B and let $a_0 \in A$. We denote by $i\colon A \to B$ the inclusion map and we pick a path γ from b_0 to a_0. We consider the homomorphism

$$\psi := \varphi \circ \gamma_* \circ i_*\colon \pi_1(A, a_0) \xrightarrow{i_*} \pi_1(B, a_0) \xrightarrow{\gamma_*} \pi_1(B, b_0) \xrightarrow{\varphi} G.$$

With these preparations the following two statements hold:

(1) Each path-component of $p^{-1}(A)$ is a covering of A corresponding to the subgroup $\ker(\psi\colon \pi_1(A, a_0) \to G)$.

(2) If G is a finite group, then

$$\text{number of path-components of } p^{-1}(A) \;=\; [G : \operatorname{im}(\psi\colon \pi_1(A, a_0) \to G)].$$

(3) Let $\widetilde{A}$ be a path-component of $p^{-1}(A)$. The following diagram commutes:

$$\begin{array}{ccc} \operatorname{Deck}(p\colon p^{-1}(A) \to A) & \xrightarrow{\Xi_{(A,a_0)}} & \pi_1(A, a_0)/\ker(\psi) \\ \downarrow & & \downarrow{\scriptstyle \gamma_* \circ i_*} \\ \operatorname{Deck}(p\colon X \to B) & \xrightarrow{\Xi_{(B,a_0)}} & \pi_1(B, a_0)/\ker(\varphi \circ \gamma_*). \end{array}$$

Here the horizontal maps are the isomorphisms that we introduced on page 1388 and the left vertical map is the map that we introduced in the Induced-Deck Transformation Proposition 62.9.

Example. As promised we can now determine the number n of boundary components of the covering X in the previous example. More precisely, denote by U, V, W the three boundary components of B. We make the following three observations:

(1) The image of $\pi_1(V)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(u) = 2$, thus the subgroup has index two, which by the Preimage-of-Covering Proposition 63.5 implies that $p^{-1}(U)$ consists of two components.

(2) The image of $\pi_1(W)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(v) = 3$, thus $p^{-1}(V)$ consists of three components.

(3) The image of $\pi_1(U)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(w) = -5$. Since -5 is coprime to 6 we see that this subgroup is all of $\mathbb{Z}_6$, thus $p^{-1}(W)$ consists of precisely one component.

Altogether we see that X has $2 + 3 + 1 = 6$ boundary components.

Remark. The reader who is in need of a brain teaser might want to come up with an appropriate generalization of the Preimage-of-Covering Proposition 63.5 to the case where we consider coverings of B coming from a non-normal subgroup.

Proof. To simplify the notation a little bit we assume that $a_0 = b_0$, in particular we ignore the role of γ. Throughout the proof we refer to the figure below for an illustration.

(1) Let W be a path-component of $p^{-1}(A)$. We pick a point $w_0 \in W$ with $p(w_0) = a_0$. We start out with the following slightly subtle claim.

Claim. We have the following equality:

$$p_*(\pi_1(X, w_0)) \;=\; \ker(\varphi\colon \pi_1(B, a_0) \to G).$$

Proof. We pick a path γ in X from x_0 to w_0. Since $p \circ \gamma$ is a loop in a_0 we can write $h := [p \circ \gamma] \in \pi_1(B, a_0)$. We consider the following diagram

$$\begin{array}{ccc}
\pi_1(X, w_0) & \xrightarrow[\cong]{\gamma_*} & \pi_1(X, x_0) \\
\downarrow{\scriptstyle p_*} & & \downarrow{\scriptstyle p_*} \\
\pi_1(B, a_0) & \xrightarrow[\cong]{g \mapsto hgh^{-1}} & \pi_1(B, a_0) \\
\downarrow{\scriptstyle \varphi} & & \downarrow{\scriptstyle \varphi} \\
G & \xrightarrow[\cong]{g \mapsto \varphi(h) g \varphi(h)^{-1}} & G.
\end{array}$$

The top square commutes by the Change-of-Base Point Proposition 47.10 (2) and (5). Evidently the bottom square also commutes. By definition of (X, x_0) we have

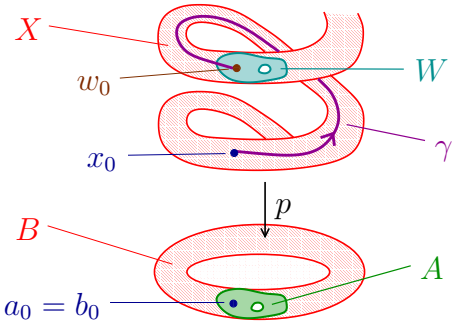
$$p_*(\pi_1(X, x_0)) \;=\; \ker(\varphi\colon \pi_1(B, a_0) \to G).$$

The claim now follows from the fact that the diagram commutes and that the horizontal maps are isomorphisms.

In the following we denote by $j\colon W \to X$ the inclusion map. We consider the following diagram

$$\begin{array}{ccc}
\pi_1(W, w_0) & \xrightarrow{j_*} & \pi_1(X, w_0) \\
\downarrow{\scriptstyle p_*} & & \downarrow{\scriptstyle p_*} \\
\pi_1(A, a_0) & \xrightarrow{i_*} & \pi_1(B, a_0) \\
& {\scriptstyle \psi}\searrow & \downarrow{\scriptstyle \varphi} \\
& & G.
\end{array}$$

Recall that we need to show the equality $p_*(\pi_1(W, w_0)) = \ker(\psi)$. We show the two inclusions separately.



"$\subset$" This inclusion follows immediately from the definitions, from the commutativity of the above diagram and from the claim.

"$\supset$" Thus let $g \in \ker(\psi)$. We represent it by a loop γ in (A, a_0). By the above claim and Lemma 48.15 the loop $i \circ \gamma$ in (B, a_0) lifts to a loop $\widetilde{\gamma}$ in (X, w_0). By definition

the image of $\widetilde{\gamma}$ lies in $p^{-1}(A)$ and it contains w_0. In particular the image of $\widetilde{\gamma}$ lies in the path-component of $p^{-1}(A)$ that contains w_0, in other words, $\widetilde{\gamma}$ is actually a loop in (W, w_0). Since $g = p_*([\widetilde{\gamma}])$ we obtain that $g \in p_*(\pi_1(W, w_0))$.

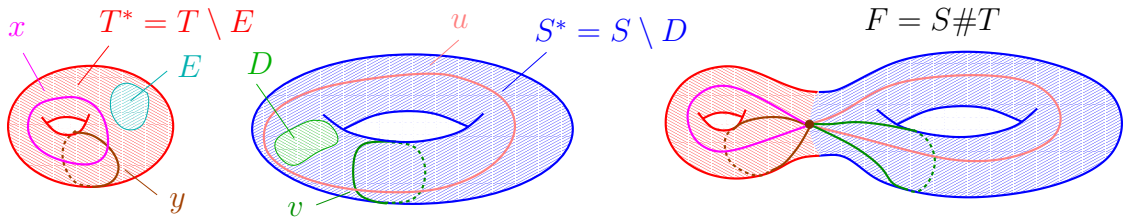
(2) We write $n = |G|$ and $k = |\operatorname{im}(\psi\colon \pi_1(A, a_0) \to G)|$. It follows from Lemma 48.15 and (1) that each path-component of $p^{-1}(A)$ is a k-fold covering of A. By Lemma 48.15 the map $p\colon X \to B$ is an n-fold covering. Evidently $p\colon p^{-1}(A) \to A$ is also an n-fold covering. It follows almost immediately that $p^{-1}(A)$ has necessarily n/k path-components. But $n/k = |G|/|\operatorname{im}(\psi)|$ is by definition the degree of $\operatorname{im}(\psi)$ in G.

(3) This statement follows easily from the definition of the horizontal maps. We leave the details to the reader. ∎

63.5. **Covering spaces of surfaces.** Suppose we start out with a surface F of genus g and a finite index subgroup Γ of $\pi_1(F)$, then by the Covering Existence Theorem 61.5 we obtain a corresponding finite covering $p\colon \widetilde{F} \to F$. By the Manifold Covering Proposition 49.2 and Lemma 48.3 (4) the topological space $\widetilde{F}$ is again a closed orientable connected 2-dimensional smooth manifold. From the Surface Classification Theorem 55.4 we know that $\widetilde{F}$ is again a surface of some genus h. How can we determine h from g and Γ?
For future reference we record the question.

Question 63.6. Given a surface F of genus g and a finite index subgroup Γ of $\pi_1(F)$, what is the genus of the corresponding finite cover?

It will take a while till we can give a satisfactory answer. In fact we will obtain a complete answer only once we have introduced the Euler characteristic.

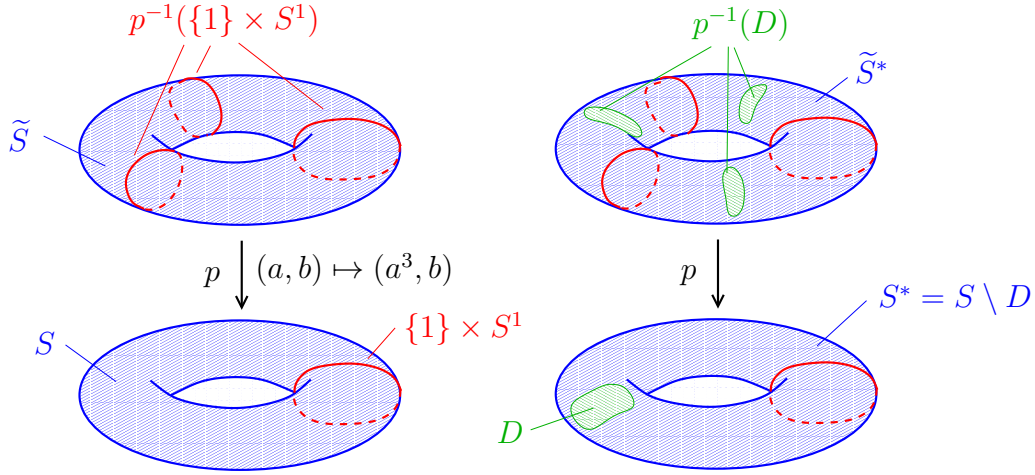


But we want to discuss one example in detail. We consider the surface F of genus two that we view as the connected sum of two tori $S = S^1 \times S^1$ and $T = S^1 \times S^1$. We denote by u, v the standard generators for $\pi_1(S)$ given by the two copies of S^1 in each torus. Similarly we denote by x, y the standard generators for $\pi_1(T)$. We pick an embedded closed disk in S and an embedded closed disk in T which both lie in the complement of the standard generators. We denote the corresponding open disks by D and E and we write $S^* = S \setminus D$ and $T^* \setminus E$. We build the connected sum $S\#T$ by gluing S^* to T^* along the boundary.[742] Furthermore, by a slight abuse of notation, we denote by u, v and x, y also the generators of $\pi_1(S^*) = \langle u, v\rangle$ and $\pi_1(T^*) = \langle x, y\rangle$.

[742]It follows from Corollary **??** that we can be a bit casual in our language, i.e. we can talk about "gluing surfaces" without specifying explicit diffeomorphisms of boundary components, as long as we take into account orientations.

By the discussion on page 1225 the abelianization of $\pi_1(S\#T) = \pi_1(S^* \cup_{\partial S^* = \partial T^*} T^*)$ is the free abelian group on u, v, x, y. Now we consider the epimorphism

$$\varphi\colon \pi_1(S\#T) \;\to\; \pi_1(S\#T)/[\pi_1(S\#T), \pi_1(S\#T)] \;\to\; \mathbb{Z}_3$$

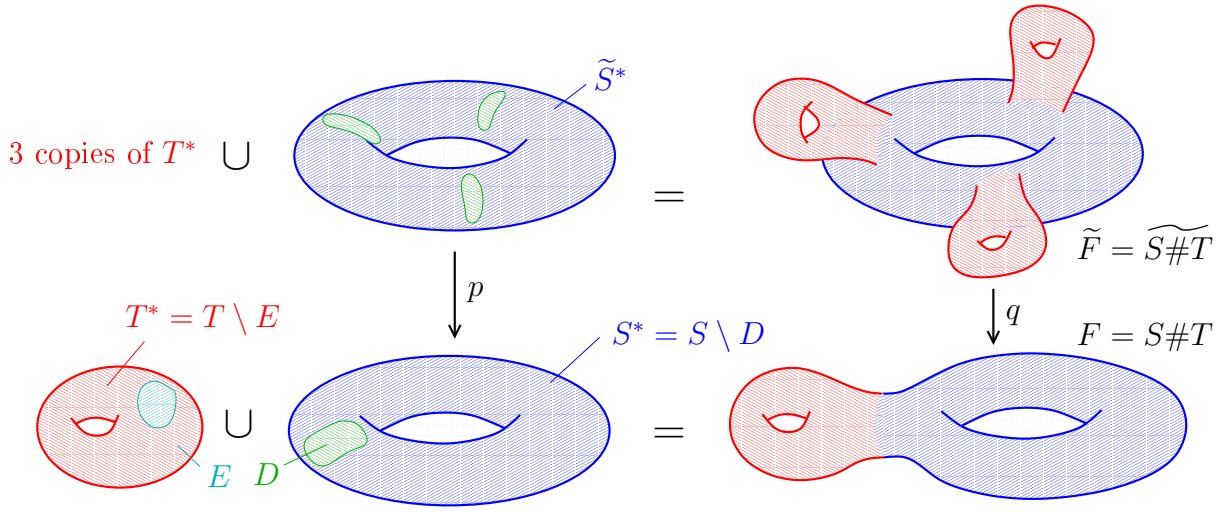


given by $u \mapsto 1, v \mapsto 0, x \mapsto 0$ and $y \mapsto 0$. Our goal in the following discussion is to visualize the covering $p\colon \widetilde{F} \to F = S\#T$ corresponding to $\ker(\varphi)$. Since φ is an epimorphism onto a group of order 3 we see that $\ker(\varphi)$ is a subgroup of index 3. By Lemma 48.15 this implies that p is a 3-fold covering.

We first consider the torus $S = S^1 \times S^1$ and furthermore we consider the epimorphism $\psi\colon \pi_1(S) = \langle u, v \mid [u,v]\rangle \to \mathbb{Z}_3$ given by $\psi(u) = 1$ and $\psi(v) = 0$. The covering corresponding to $\ker(\psi) \subset \pi_1(S)$ is equivalent to the covering[743]

$$\begin{array}{ccc} \widetilde{S} = S^1 \times S^1 & \to & S = S^1 \times S^1 \\ (a,b) & \mapsto & (a^3, b). \end{array}$$

Now we consider the epimorphism $\psi^*\colon \pi_1(S^*) \to \mathbb{Z}_3$ given by $\psi^*(u) = 1$ and $\psi^*(v) = 0$. By the argument of Footnote 743 the covering corresponding to $\ker(\psi^*)$ is then given by $p\colon \widetilde{S}^* := \widetilde{S} \setminus p^{-1}(D) \to S^* = S \setminus D$. Recall that we perform the connected sum operation



$S\#T$ by gluing $T^* := T \setminus E$ to $S^* = S \setminus D$ to obtain $F = S\#T$. The same way we can also glue three copies of T^*, i.e. $T^* \times \{1,2,3\}$, to the three boundary components of $\widetilde{S}^*$ to obtain a closed smooth manifold $\widetilde{F}$. It follows from the Pasting Proposition 2.6 $(2')$ that

[743] Indeed, since $\widetilde{S} \to S$ is a connected 3-fold covering we know from Lemma 48.15 that $p_*(\pi_1(\widetilde{S}))$ is a subgroup of $\pi_1(S)$ of index three. Furthermore it is contained in the subgroup $\ker\big(\pi_1(S) \xrightarrow{\psi} \mathbb{Z}_3\big)$ which also has index three, thus $p_*(\pi_1(\widetilde{S})) = \ker(\psi\colon \pi_1(S) \to \mathbb{Z}_3)$. But by the Covering Uniqueness Theorem 61.9 all path-connected coverings that correspond to the same subgroup are equivalent.

the map

$$\begin{array}{rcl} q\colon \widetilde{F} & \to & F \\ P & \mapsto & \begin{cases} p(P), & \text{if } P \in \widetilde{S}^*, \\ Q, & \text{if } P = Q \times \{n\} \text{ with } Q \in T^* \text{ and } n \in \{1,2,3\} \end{cases} \end{array}$$

is continuous. Similar to Footnote 743 one can now see that $q\colon \widetilde{F} \to F$ is indeed the covering of F corresponding to $\ker(\varphi)$. This construction is illustrated in the figure below which also shows that $\widetilde{F}$ is a surface of genus 4.

Exercise for Chapter 63.

Exercise 63.1. Show that there exist lattices Λ and $\widetilde{\Lambda}$ in $\mathbb{C}$ that are not homothetic, i.e. such that there exists no $r \in \mathbb{C} \setminus \{0\}$ such that $r \cdot \Lambda = \widetilde{\Lambda}$.

Exercise 63.2. We write $\mathbb{C}^* := \mathbb{C} \setminus \{0\}$.

(a) Let $m \in \mathbb{N}$. Show that the map

$$\begin{array}{rcl} \mathbb{C}^* & \to & \mathbb{C}^* \\ z & \mapsto & z^m \end{array}$$

is a holomorphic map between complex manifolds and show that this map is a covering map with degree $= m$.

(b) Show that the exponential map

$$\begin{array}{rcl} \exp\colon \mathbb{C} & \to & \mathbb{C}^* := \mathbb{C} \setminus \{0\} \\ z & \mapsto & \exp(z) \end{array}$$

is a holomorphic map between complex manifolds and show that this map is a covering map of infinite degree.

(c) A *complex logarithm* on an open subset $U \subset \mathbb{C}^*$ is a map $f\colon U \to \mathbb{C}$ such that for all $z \in U$ we have $f(\exp(z)) = z$.

(i) Show that every complex logarithm is holomorphic.

(ii) Show that on any simply connected open subset $U \subset \mathbb{C}^*$ one can define a complex logarithm.

(iii) Show that it is not possible to define a complex logarithm on all of $\mathbb{C}^*$.

Exercise 63.3. Let Σ be a compact oriented connected 2-dimensional smooth manifold and let $f\colon \partial\Sigma \to \partial\Sigma$ be a diffeomorphism. Show that there exists a diffeomorphism $\Sigma \to \Sigma$ with $F|_{\partial\Sigma} = f$ if and only if f is either orientation-preserving or orientation-reversing.
Hint. Use the Boundary Curve-Permutation Lemma 55.14 , the Diffeotopies-of-S^1-Classification Proposition 34.5 and the Smooth Collar Neighborhood Theorem 28.3.

Exercise 63.4. Let $n \in \mathbb{N}_{\geq 3}$.

(a) We consider the connected sum $M = \mathbb{R}\mathrm{P}^n \# \mathbb{R}\mathrm{P}^n$. We consider the following homomorphism

$$\begin{array}{lcccccc} \varphi\colon \pi_1(\mathbb{R}\mathrm{P}^n \# \mathbb{R}\mathrm{P}^n) & \xrightarrow{\cong} & \pi_1(\mathbb{R}\mathrm{P}^n) * \pi_1(\mathbb{R}\mathrm{P}^n) & \xrightarrow{\cong} & \mathbb{Z}_2 * \mathbb{Z}_2 = \langle a \,|\, a^2\rangle * \langle b \,|\, b^2\rangle & \to & \mathbb{Z}_2. \\ & & \uparrow & & \uparrow & & a \mapsto 1 \\ & & \text{Connected Sum-}\pi_1\text{-Proposition 52.12} & & \text{Corollary 48.18} & & b \mapsto 1 \end{array}$$

We denote by $\widetilde{M}$ the cover corresponding to $\ker(\varphi\colon \pi_1(M) \to \mathbb{Z}_2)$. Show that $\widetilde{M}$ is diffeomorphic to $S^1 \times S^{n-1}$.
Hint. Use the Preimage-of-Covering Proposition 63.5.

(b) Let $k \in \mathbb{N}$. We consider the connected sum M of k copies of $\mathbb{R}\mathrm{P}^n$. As in (a) we have an obvious epimorphism $\pi_1(M) \to \mathbb{Z}_2$. It turns out that the corresponding covering space $\widetilde{M}$ is diffeomorphic to the connected sum of m copies of $S^1 \times S^{n-1}$. Determine m in terms of k.

64. Coverings of topological graphs and applications to group theory

In this chapter we will apply the results obtained in Chapter 61 to prove several results in group theory.

64.1. **Coverings of topological graphs.** In our proofs of the promised group-theoretic results we will need the following proposition which is also of interest in its own right.

Proposition 64.1. (Covering-of-Graph Proposition) Let $G = (V, E, i, t)$ be a connected abstract graph and let $p\colon \widetilde{X} \to |G|$ be a covering of the topological realization $X := |G|$ of G. Then there exists a natural[744] abstract graph $\widetilde{G} = (\widetilde{V}, \widetilde{E}, i, t)$, a natural homeomorphism $f\colon |\widetilde{G}| \to \widetilde{X}$ and a natural map $q\colon \widetilde{G} \to G$ of abstract graphs with the following properties:

(1) We have $\#\widetilde{V} = [\widetilde{X} : X] \cdot \#V$ and $\#\widetilde{E} = [\widetilde{X} : X] \cdot \#E$.
(2) The following diagram commutes:

$$\begin{array}{ccc} |\widetilde{G}| & \xrightarrow{\ f\ } & \widetilde{X} \\ {\scriptstyle |q|}\downarrow & & \downarrow{\scriptstyle p} \\ |G| & \xrightarrow{\ \mathrm{id}\ } & X. \end{array}$$

Here $|q|$ denotes the topological realization of the map q, as defined in Lemma 7.2.

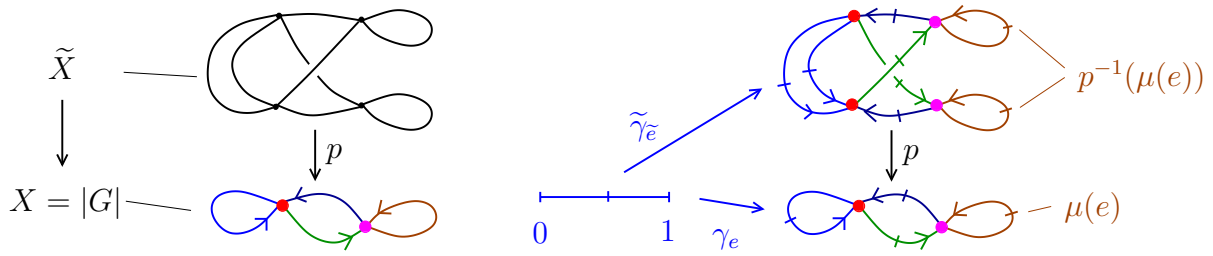
Remark. In the CW-complex Covering Proposition 68.37 we will generalize the above proposition to the setting of "CW-complexes".

Proof. Let $G = (V, E, i, t)$ be a connected abstract graph. Recall that on page 308 we defined the topological realization of G as follows:

$$|G| \ := \ \big(V \ \sqcup \ (E \times [0,1])\big)/\!\sim \quad \text{where for } e \in E \text{ we have } (e,0) \sim i(e) \text{ and } (e,1) \sim t(e).$$

Note that by the Abstract Graph-Topological Realization Lemma 7.1 we know that $|G|$ is connected. Given $e \in E$ we set $\mu(e) := [(e, \frac{1}{2})]$, i.e. $\mu(e)$ is the "midpoint" of e. Furthermore, given $e \in E$ we denote by $\gamma_e\colon [0,1] \to X$ the path given by $t \mapsto [(e,t)]$.

Note that in Exercise 50.14 we showed that $X = |G|$ is locally contractible, in particular it is locally path-connected. Thus in the following discussion we will have no troubles with applying the results from Chapter 61.



Now let $p\colon \widetilde{X} \to |G|$ be a covering of the topological realization $X = |G|$ of G. We set $\widetilde{V} := p^{-1}(V) \subset \widetilde{X}$ and we set $\widetilde{E} := p^{-1}(\{\mu(e) \,|\, e \in E\}) \subset \widetilde{X}$. Since $X = |G|$ is connected we know that the degree $[\widetilde{X} : X]$ is defined. By definition, or if you want, by Lemma 48.1, we have $\#\widetilde{V} = [\widetilde{X} : X] \cdot \#V$ and $\#\widetilde{E} = [\widetilde{X} : X] \cdot \#E$.

Now let $\widetilde{e} \in \widetilde{E}$. We denote by $\varphi(\widetilde{e})$ the unique edge in E with $p(\widetilde{e}) = \mu(\varphi(\widetilde{e}))$. By the Map Lifting Criterion 61.2 there exists a unique lift $\widetilde{\gamma}_{\widetilde{e}}\colon [0,1] \to \widetilde{X}$ of $\gamma_{\varphi(\widetilde{e})}\colon [0,1] \to X$ with $\widetilde{\gamma}(\frac{1}{2}) = \widetilde{e}$. We set $i(\widetilde{e}) = \widetilde{\gamma}(0)$ and $t(\widetilde{e}) = \widetilde{\gamma}(1)$. Since $\widetilde{\gamma}_{\widetilde{e}}$ is a lift of γ_e we see that $i(\widetilde{e})$ and $t(\widetilde{e})$ actually lie in $\widetilde{V}$. In other words, $(\widetilde{V}, \widetilde{E}, i, t)$ is actually an abstract graph. Furthermore note that the two maps $p\colon \widetilde{V} \to V$ and $\varphi\colon \widetilde{E} \to E$ define by, basically by construction, a map $q\colon \widetilde{G} = (\widetilde{V}, \widetilde{E}, i, t) \to (V, E, i, t) = G$ of abstract graphs.

[744] We leave the pleasure of figuring out what "natural" means to the reader.

Next we define $f\colon |\widetilde{G}| \to \widetilde{X}$ via the inclusion $\widetilde{V} \to \widetilde{X}$ and by sending $(\widetilde{e}, t)$ to $\widetilde{\gamma}_{\widetilde{e}}(t)$. It follows immediately from the Topological-Quotient Proposition 5.15 (1b) that f is continuous. Furthermore, using the existence and uniqueness statement of the Map Lifting Criterion 61.2 it is not difficult to see that the map f is actually a bijection. Next note that, with a little bit of an effort, one can also show that f is an open map. Thus we obtain from the Open -Injective Map Lemma 2.16 that f is actually a homeomorphism.

Finally note that it is straightforward to see that the given diagram in the proposition does indeed commute. ■

64.2. **Fundamental group of countable topological graphs.** In the Fundamental Group-of-Graph Proposition 52.5 we showed that the fundamental group of any finite topological graph is a free group. We generalize this result to countable topological graphs.

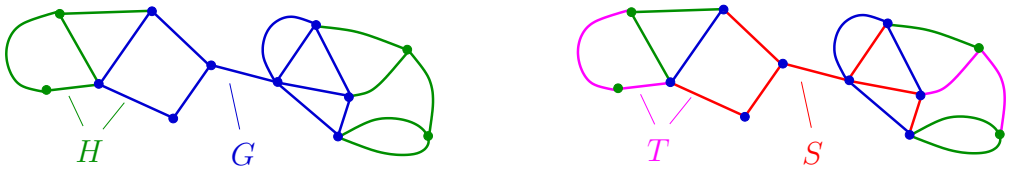
Proposition 64.2. If X is a countable connected non-empty topological graph, then $\pi_1(X)$ is a free group.

Remark. In the Fundamental Group-of-1-Complex Theorem 69.9 we will show that the fundamental of any (not necessarily countable) connected topological graph is a free group. Since the proof of this more general statement is technically rather demanding we feel that it is worth to prove this intermediate statement.

The proof of Proposition 64.2 builds on the following reasonably straightforward lemma.

Lemma 64.3. Let H be a finite connected graph and let G be a connected non-empty subgraph of H. Let v be a vertex of G. We denote by $i\colon |G| \to |H|$ the inclusion. We set $s := \chi(H) - \chi(G)$. Then there exists a homomorphism $\varphi\colon \langle x_1, \ldots, x_s\rangle \to \pi_1(|H|, v)$ such that the map

$$i_* * \varphi\colon \pi_1(|G|, v) * \langle x_1, \ldots, x_s\rangle \;\to\; \pi_1(|H|, v)$$



is an isomorphism.

Proof of Lemma 64.3. Let $H = (W, F, i, t)$ be a finite connected graph. Furthermore let $G = (V, E, i, t)$ be a connected non-empty subgraph of H. By the Spanning Tree Existence Proposition 7.10 (1) there exists a spanning tree S for G. By a rather elementary argument, which we outsourced to Exercise 64.1, there exists a spanning tree T of H such that $T \cap G = S$. Let $e_1, \ldots, e_m$ be the edges of G not contained in S and let $e_{m+1}, \ldots, e_n$ be the edges of H not contained in T. For $j = 1, \ldots, m$ we pick a path α_j in $|S|$ from v to $i(e_j)$, we denote by β_j the obvious path form $i(e_j)$ to $t(e_j)$ and we pick a path γ_j in $|S|$ from $t(e_j)$ to v. We proceed analogously for $j = m+1, \ldots, n$, except that now can no longer demand that the paths α_j and γ_j lie in $|S|$, but we will demand that they lie in $|T|$.

Finally we consider the following diagram:

$$\begin{array}{ccc} & & \pi_1(|G|,v) * \langle y_{m+1},\dots,y_{m+n}\rangle \\ & \overset{\Theta_G * \mathrm{id}}{\nearrow} & \searrow \\ \langle y_1,\dots,y_m\rangle * \langle y_{m+1},\dots,y_{m+n}\rangle & \xrightarrow{\qquad\qquad\Theta_H\qquad\qquad} & \pi_1(|H|,v). \end{array}$$

Here the homomorphisms Θ_G and Θ_H are the maps induced by $y_j \mapsto [\alpha_j * \beta_j * \gamma_j]$. By the Fundamental Group-of-Graph Proposition 52.5 we know that both Θ_G and Θ_H are isomorphisms. This shows that the homomorphism $\langle x_1,\dots,x_{n-m}\rangle \to \pi_1(|H|,v)$ given by $x_j \mapsto \Theta_H(y_{m+j})$ has the desired properties. Finally one can easily verify that $\chi(G) = 1+m$ and $\chi(H) = 1+n$. Thus we see that $n-m = \chi(H) - \chi(G)$. ■

Proof of Proposition 64.2. Let $G = (V,E,i,t)$ be a countable connected non-empty abstract graph. We pick a vertex $v \in V$. We need to show that $\pi_1(G,v)$ is a free group. By Exercise 7.8 we know that there exists a sequence $\{G_j\}_{j\in\mathbb{N}}$ of subgraphs with the following properties:

(1) Each G_j is finite connected.
(2) Each G_j contains v.
(3) We have $G = \bigcup\limits_{i\in\mathbb{N}} G_j$ in the sense that $V = \bigcup\limits_{j\in\mathbb{N}} V_j$ and $E = \bigcup\limits_{j\in\mathbb{N}} G_j$.

We see that

$$\pi_1(|G|,v) \;=\; \pi_1\Big(\bigcup_{j\in\mathbb{N}} |G_j|, v\Big) \;\underset{\uparrow}{=}\; \varinjlim \pi_1(|G_j|,v) \;\underset{\uparrow}{=}\; \text{free group.}$$

by Exercise 7.5 and the Direct Limit-π_1-Proposition 56.7

follows from Lemma 64.3 and discussion on page 1259

■

64.3. **Subgroups of free groups.** In this section we will apply our topological results to the study of free groups. First we introduce the following definition.

Definition. Given a free group F, i.e. given a group F that is isomorphic to the free group $\langle S\rangle$ generated by some set S, we refer to the cardinality of S as the rank of F.[745]

The following proposition is arguably the most interesting result of this chapter. The statement is purely group-theoretical, but as we will see, a topological point of view leads to a very neat proof.

Proposition 64.4. Let F be a free group of countable rank.

(1) Every subgroup of F is again a free group.
(2) If F is finitely generated and if G is a finite-index subgroup of F, then[746]

$$\mathrm{rank}(G) - 1 \;=\; [F:G]\cdot(\mathrm{rank}(F)-1).$$

[745] It follows from the discussions on the pages 1206 and 1149 that the rank of F is well-defined.

Examples.

(1) If $F = \mathbb{Z}$ then the formula from Proposition 64.4 does indeed show that every finite-index subgroup of $\mathbb{Z}$ is again a free group of rank one, i.e. every finite-index subgroup of $\mathbb{Z}$ is isomorphic to $\mathbb{Z}$.

(2) Let $\alpha\colon F := \langle a, b\rangle \to \mathbb{Z}_3$ be the epimorphism defined given by $\alpha(a) = 1$ and $\alpha(b) = 0$. It follows from Proposition 64.4 that the kernel $G := \ker(\alpha)$ is a free group of rank $[F : G] \cdot (\mathrm{rank}(F) - 1) + 1 = 3 \cdot 1 + 1 = 4$. In Exercise 64.2 we will determine four elements of $G = \ker(\alpha)$ that are generators for this free group.

Remark.

(1) In the Subgroup-of-Free Group Corollary 69.10 we will extend the statement to all free groups, i.e. we will drop the condition that the rank should be countable. The idea of the proof is fairly similar to the one used below, but the proof of the more general statement is overall "technologically" somewhat more fancy.

(2) There are purely group theoretic proofs of Proposition 64.4 and of the Subgroup-of-Free Group Corollary 69.10, see e.g. [**Schre1927**], [**HallM1976**, Theorem 7.2.1] or [**Bau1993**, Chapter III.3], but the topological proof that we had just provided is arguably conceptually the clearest proof.

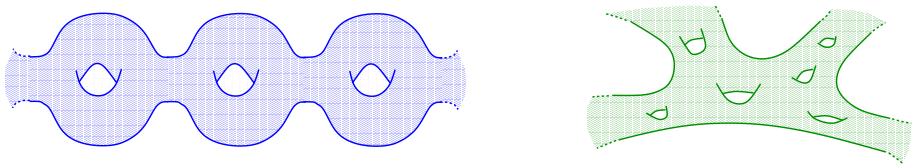
(3) the Subgroup-of-Free Group Corollary 69.10 and Proposition 64.4 are a special case of the *Kurosh Subgroup Theorem*. This theorem says that if G is the product of groups $A_i, i \in I$ and if H is a subgroup of G, then H is a free product of a free group and groups $B_i, i \in I$ where each B_i is a (potentially trivial) group that is conjugate to a subgroup of A_i. We refer to [**LyS1977**, Theorem IV.1.10] for details and a proof.

Proof. Let $F = \langle E\rangle$ be a free group on a countable generating set E and let G be a subgroup of F. Note that it follows easily from the Countability Lemma 0.8 that G is a countable set. Let $\Gamma = (\{x_0\}, E, i, t)$ be the abstract graph with one vertex and one edge for each element of E. By the discussion on page 1133 we know that the topological realization $X := |G|$ is homeomorphic to the wedge $\bigvee_{e\in E} S^1_e$. It follows from the Fundamental Group-Wedge-of-Circles Lemma 52.4 that there exists an isomorphism $\varphi\colon F = \langle E\rangle \to \pi_1(X, x_0)$. By the CW-Complex Properties Proposition 68.10 (6) and the Covering Existence Theorem 61.5 there exists a path-connected covering $p\colon (Y, y_0) \to (X, x_0)$ of degree $[F : G]$ such that $p_*(\pi_1(Y, y_0)) = G$. By Corollary 48.14 the map p_* is injective. Thus we see that $\pi_1(Y, y_0)$ itself is isomorphic to G. By the Covering-of-Graph Proposition 64.1 we can equip Y with the structure of a topological graph. Since E and G are countable we see that Y is a countable topological graph. We deduce from Proposition 64.2 that $G \cong \pi_1(Y, y_0)$ is a free group. This completes the proof of (1).

Now suppose that F is finitely generated and that G is a finite-index subgroup of F. We see that we have the following equalities:

$$\underbrace{\mathrm{rank}(\pi_1(Y, y_0))}_{=\mathrm{rank}(G)} - 1 \overset{\text{Fundamental Group-of-Graph Proposition 52.5 (2)}}{\overset{\downarrow}{=}} \chi(Y) \overset{\text{Covering-of-Graph Proposition 64.1}}{=\!\!\uparrow} [Y : X] \cdot \chi(X) \overset{\downarrow}{=} [F : G] \cdot (\underbrace{\mathrm{rank}(\pi_1(X, x_0))}_{=\mathrm{rank}(F)} - 1).$$

[746] Does the equality hold if G is infinite-index and if we interpret $[F : G] \cdot (\mathrm{rank}(F) - 1)$, as usual, as $\infty \cdot (\mathrm{rank}(F) - 1) = \infty$ for $F \ncong \mathbb{Z}$?



This completes the proof of (2). ■

64.4. **Subgroups of surface groups.** We start out with the following proposition that is similar in spirit to Proposition 64.2, but potentially it is more surprising.

Proposition 64.5. If M is a connected 2-dimensional smooth manifold that is non-compact, then $\pi_1(M)$ is a free group.

Remark. A somewhat different proof of Proposition 64.5 is given in [**Sti1993**, p. 142].

Example. The 2-dimensional smooth manifolds shown in the figure below are non-compact and thus their fundamental groups are free. For the example on the left we saw this already in Lemma 56.11.

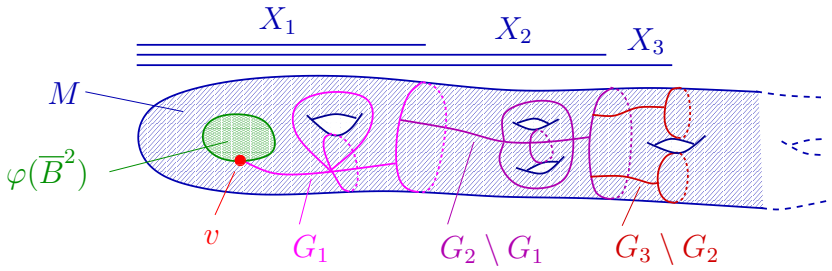
Proof. Let M be a connected 2-dimensional smooth manifold that is non-compact. In Corollary 75.7 we will show, using the Smooth Collar Neighborhood Theorem 28.3, that M is homotopy equivalent to a smooth manifold with empty boundary. So we might as well assume that M has no boundary.

By the Compact Submanifold Exhaustion Proposition 31.2 we know that there exists a sequence $X_1, X_2, \ldots$ of n-dimensional smooth submanifolds of M with the following four properties:

(1) The sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$.
(2) Each X_i is compact and connected.
(3) The X_i are submanifolds in the sense of the definition on page 524.
(4) We have $\bigcup_{i\in\mathbb{N}} \overset{\circ}{X}_i = M$.

We pick an embedding $\varphi\colon \overline{B}^2 \to X_1 \backslash \partial X_1$ and given any $i \in \mathbb{N}$ we set $X_i' := X_i \backslash \varphi(B^2)$. With a moderate effort we see, by iteratively applying the Surface Classification Theorem 55.4 and Lemma 55.12, that there exists a sequence of finite topological graphs $\{G_i\}_{i\in I}$ with the following properties:

(5) G_1 contains a point $v \in \varphi(S^1)$.
(6) For each $i \in \mathbb{N}$ we have $G_i \subset G_{i+1}$.
(7) Each G_i is a deformation retract of X_i'.



We see that

$$\begin{array}{ccccc} \pi_1(M \setminus \varphi(B^2), v) & = & \pi_1\Big(\bigcup_{j\in\mathbb{N}} X_j', v\Big) & \overset{\text{follows from (4) and the Direct Limit-}\pi_1\text{-Proposition 56.7}}{=} & \varinjlim \pi_1(X_j', v) \\ & = & \varinjlim \pi_1(|G_j|, v) & = & \pi_1(G_1, v) * \text{free group.} \\ & \overset{\text{by (7) and the Homotopy-}\pi_1\text{-Proposition 50.3}}{\uparrow} & & \overset{\text{follows from Lemma 64.3 and the discussion on page 1259}}{\uparrow} & \end{array}$$

Now we can perform the following calculation:

$$\begin{array}{rcl} \pi_1(M,v) & = & \pi_1((M \setminus \varphi(B^2)) \cup_C \varphi(\overline{B}^2), v) \overset{\text{Seifert–van Kampen Theorem 54.4}}{\cong} \pi_1(M \setminus \varphi(B^2), v) *_{\pi_1(C,v)} \overbrace{\pi_1(\varphi(\overline{B}^2), v)}^{=\{e\}} \\ & \cong & (\pi_1(G_1, v) * \text{free group})/\langle\langle \pi_1(C,v) \rangle\rangle \overset{\text{by Lemma 55.12 we know that we can write } \pi_1(G_1,v) = \pi_1(C,v) * \text{free group}}{=} \text{free group}. \\ & & \uparrow \text{by the above calculation of } \pi_1(M \setminus \varphi(B^2), v) \text{ together with the Amalgamated Product Lemma 53.22 (2)} \end{array}$$

■

Next we address the following question.

Question 54.8. Let π be the fundamental group of the surface of genus $g \geq 2$. What isomorphism types of subgroups can appear? Is every subgroup again a free group or the fundamental group of a surface?

The following proposition gives an affirmative answer.

Proposition 64.6. (Subgroups-of-Surface Groups Proposition) Let M be the surface of genus g and let $\Gamma \subset \pi_1(M)$ be a subgroup.

(1) If the index $[\pi : \Gamma]$ is finite, then Γ is the fundamental group of the surface of genus $[\pi : \Gamma] \cdot (g-1) + 1$.
(2) If the index $[\pi : \Gamma]$ is infinite, then Γ is a free group.

Remark. In Exercise 64.6 we will consider the case of subgroups of the fundamental group of a *non-orientable* surface of some genus $g \in \mathbb{N}$.

Proof. Let $g \in \mathbb{N}_{\geq 2}$ and let Σ be the surface of genus g. We pick a base point $x_0 \in \Sigma$. Let $\Gamma \subset \pi_1(\Sigma, x_0)$ be a subgroup. We obtain from the CW-Complex Properties Proposition 68.10 (6) and the Covering Existence Theorem 61.5 that there exists a path-connected covering $p\colon (\widetilde{\Sigma}, \widetilde{x}_0) \to (\Sigma, x_0)$ of index $[\pi_1(M, x_0) : \Gamma]$ with $p_*(\pi_1(\Sigma, \widetilde{x}_0)) = \Gamma$. By the Manifold Covering Proposition 49.2 we know that $\widetilde{\Sigma}$ is an orientable 2-dimensional smooth manifold with empty boundary.

(1) If the index $[\pi : \Gamma]$ is finite, then we know by Lemma 48.3 (4) that $\widetilde{\Sigma}$ is again compact. This implies that we now know that $\widetilde{\Sigma}$ is a closed 2-dimensional smooth manifold. In Exercise 64.6 we will show that the genus is given by the slightly weird formula
(2) By Lemma 48.3 (5) we know that $\widetilde{\Sigma}$ is non-compact. Thus it follows from Proposition 64.5 that $\Gamma \cong \pi_1(\widetilde{\Sigma})$ is a free group. ■

Note that the following lemma gives an affirmative answer to Question 54.11 (1).

Corollary 64.7. For every $g \in \mathbb{N}$ the fundamental group of the surface of genus g is torsion-free.

Proof. We will prove the corollary to the Subgroups-of-Surface Groups Proposition 64.6 in Exercise 64.4. ■

We conclude this section with the following proposition which is closely related to Proposition 53.14. We will not prove the proposition, but we will it use at one occasion later on.

Proposition 64.8. Let M be a surface of genus ≥ 2. If $\Gamma \subset \pi_1(M)$ is a *normal* non-trivial subgroup of infinite-index, then $\pi_1(M)$ is a free group of *infinite* rank.

Proof. Let M be a surface of genus ≥ 2 and let $\Gamma \subset \pi_1(M)$ be a *normal* non-trivial subgroup of infinite-index. By the Subgroups-of-Surface Groups Proposition 64.6 it remains to show that Γ is infinitely generated. A proof for this statement is given in [**Cat2003**, Lemma 3.4], alternatively one can prove the second statement using [**Lü1997**, Theorem 0.7]. A significantly stronger statement is proved in [**BrH2007**, Theorem 1]. ■

64.5. **Residually finite groups and Hopfian groups.** Let (X, x_0) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. In the Covering Uniqueness Theorem 61.9 we saw that there exists a bijection between the set of subgroups of $\pi_1(X, x_0)$ and the set of equivalence classes of path-connected coverings of (X, x_0).
Let (X, x_0) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected that is compact. It follows from the above, that given a (finite-index) subgroup of $\pi_1(X, x_0)$ we can associate to (X, x_0) a (finite) covering $p\colon \widetilde{X} \to X$. For the most part we like to stick to the world of compact spaces X. By Lemma 48.3 this means that we are interested in finite-index subgroups of $\pi_1(X, x_0)$. This leads us to the following, purposefully vague question.

Question 64.9. Which (finitely generated) groups have lots of finite-index subgroups?

In this section we will try to address Question 64.9. The following definition, which we already stated in Exercise 51.15, gives one popular way to turn Question 64.9 into a proper mathematical question.

Definition. A group π is called residually finite if given any non-trivial element $g \in \pi$ there exists a homomorphism $\alpha\colon \pi \to G$ to a finite group G such that $\alpha(g)$ is non-trivial.

Examples.

(1) The group $\mathbb{Z}$ is residually finite, indeed given $g \in \mathbb{Z}$ we can consider the epimorphism $\alpha\colon \mathbb{Z} \to \mathbb{Z}/(|g|+1)\cdot\mathbb{Z}$ onto a finite group, which evidently satisfies $\alpha(g) \neq 0$.
(2) It follows easily from the Finitely Generated Abelian Group Classification Theorem 51.4, a slight generalization of (1), that every finitely generated abelian group is residually finite.
(3) In Exercise 64.12 we will see that the group $(\mathbb{Q}, +)$ is not residually finite.

The following is now a meaningful interpretation of Question 64.9.

Question 64.10. Which (finitely generated) groups are residually finite?

Before we address Question 64.10 let us heighten the interest in Question 64.10 by stating a surprising property of residually finite groups.

Definition. A group π is called Hopfian[747] if every epimorphism $\varphi\colon \pi \to \pi$ is in fact a monomorphism.

Example.

(1) It follows immediately from Lemma 51.9 (5) that every finitely generated abelian group is Hopfian.
(2) Note that in contrast to (1), the *infinitely generated* free abelian group $\mathbb{Z}^{(\mathbb{N})}$ is actually not Hopfian. Indeed, the homomorphism $\varphi\colon \mathbb{Z}^{(\mathbb{N})} \to \mathbb{Z}^{(\mathbb{N})}$ which is given by $\varphi(x_1, x_2, x_3, \dots) = (x_2, x_3, \dots)$ is an epimorphism, but evidently it is not a monomorphism.

It is self-evident that being Hopfian is a convenient property. As we will see later in the Hopf Conjecture 101.13, the notion of a Hopfian group also naturally arises in topology. The following proposition relates the two concepts that we just introduced.

Proposition 64.11. (Residually Finite-Hopfian Proposition) Let π be a finitely generated group. If π is residually finite, then it is Hopfian.

Remark. Shortly we will see that the converse to the Residually Finite-Hopfian Proposition 64.11 does not hold.

Proof. Let π be a finitely generated group that is residually finite. Let $\varphi\colon \pi \to \pi$ be an epimorphism. Now we assume that φ is not a monomorphism. We pick a non-trivial element $g \neq e \in \ker(\varphi)$. Since π is residually finite there exists a homomorphism $\alpha\colon \pi \to G$ onto a finite group G such that $\alpha(g) \neq e$.

Since π is finitely generated we know by the rather elementary Exercise 53.3 that the set $\mathrm{Hom}(\pi, G)$ of homomorphisms from π to G is finite. We set $n := \#\,\mathrm{Hom}(\pi, G)$ and we denote by $\beta_1, \dots, \beta_n\colon \pi \to G$ the distinct homomorphisms.

Next we consider the homomorphisms $\beta_1 \circ \varphi, \dots, \beta_n \circ \varphi\colon \pi \to G$. Since φ is an epimorphism we see that these homomorphisms are also distinct. But note they all satisfy $(\beta_i \circ \varphi)(g) = \beta_i(\varphi(g)) = \beta_i(e) = e$. So these n homomorphisms are different from our initial homomorphism $\alpha\colon \pi \to G$. This means that we have found $n+1$ distinct homomorphisms from $\pi \to G$. This is a contradiction to the definition of n. ∎

Now that we are fully convinced of the value of residually finite groups, let us explore this class of groups in greater detail. The following proposition gives a convenient characterization of residually finite groups.

Proposition 64.12. Let π be a group. The following two statements are equivalent.

(1) The group is residually finite.
(2) Given any non-trivial element $g \in \pi$ there exists a finite-index subgroup Γ with $g \notin \Gamma$.

If π is countable, then the above are also equivalent to the following statement:

(3) There exists a sequence $\pi \supset \pi_0 \supset \pi_1 \supset \pi_2 \supset \dots$ of finite index normal subgroups of π such that $\bigcap_{i \in \mathbb{N}} \pi_i = \{e\}$.

The proof of Proposition 64.12 rests on the following group-theoretic concept.

[747] This notion is once again named after Heinz Hopf.

Definition. Let G be a group and let H be a subgroup. We refer to

$$H^c := \bigcap_{g\in G} gHg^{-1}$$

as the normal core of G.

The following lemma is the key ingredient for the proof of Proposition 64.12. But note that the lemma is also interesting in its own right.

Lemma 64.13. (Normal Core Lemma) Let G be a group and let H be a subgroup.

(1) The normal core of H is a normal subgroup of G.
(2) If X is a subgroup of G that is contained in H and that is normal in G, then $X \subset H^c$.
(3) If H is of finite-index d in G, then H^c is a subgroup of G of index at most $d!$, in particular H^c is also of finite-index in G.

Proof of the Normal Core Lemma 64.13.

(1) Let $k \in G$. We have

$$kH^ck^{-1} = \bigcap_{g\in G} k\cdot gHg^{-1}\cdot k^{-1} = \bigcap_{g\in G}(kg)H(kg)^{-1} = \bigcap_{g\in G} gHg^{-1} = H^c.$$

(2) Let X be a subgroup of G that is contained in H and that is normal in G. Then

$$\begin{array}{ccccc} X & = & \bigcap_{g\in G} gXg^{-1} & \subset & \bigcap_{g\in G} gHg^{-1} = H^c. \\ & & \uparrow & & \uparrow \\ & & \text{since } X \text{ normal in } G & & \text{since } X\subset H \end{array}$$

(3) The proof of the last statement is arguably more interesting. Thus let H be a subgroup of index $d \in \mathbb{N}$ of G. We consider the set G/H of right coset of G with respect to H. We denote by $\mathrm{Perm}(G/H)$ the group of permutations of G/H, i.e. it is the group of all bijections of the set G/H. Note that G/H and thus also $\mathrm{Perm}(G/H)$ are finite. We consider the map

$$\begin{array}{rcl} \varphi\colon G & \mapsto & \mathrm{Perm}(G/H) \\ g & \mapsto & \begin{pmatrix} G/H & \to & G/H \\ xH & \mapsto & gxH \end{pmatrix}. \end{array}$$

This map is easily seen to be a homomorphism. Since $\mathrm{Perm}(G/H)$ is finite we see that $\ker(\varphi)$ is a finite-index normal subgroup of G. We claim that $\ker(\varphi)\subset H$. Thus let $g\in\ker(\varphi)$. This implies in particular that $\varphi(g)(H)=H$, but that means that $gH=H$, i.e. that $g\in H$. We have thus shown that indeed $\ker(\varphi)\subset H$. From (2) and the above observation that $\ker(\varphi)$ is normal in G we obtain that $\ker(\varphi)\subset H^c$. But since the index of $\ker(\varphi)$ in G is at most $d!$ we see that the index of the normal H^c in G is also at most $d!$. ∎

Proof of Proposition 64.12. Let π be a group.

(1)⇒(2) Let $g\in\pi$ be a non-trivial element. Since π is residually finite there exists a homomorphism $\alpha\colon \pi\to G$ to some finite group G such that $\alpha(g)$ is non-trivial. The kernel $\Gamma := \ker(\alpha)$ is a finite-index subgroup of π with $g\notin\Gamma$.

(2)⇒(1) Let $g\in\pi$ be a non-trivial element and let Γ be a finite-index subgroup of π with $g\notin\Gamma$. By the Normal Core Lemma 64.13 we know that the normal core

Γ^c is a finite-index normal subgroup of π. Thus we see that the homomorphism $\alpha\colon \pi \to \pi/\Gamma^c$ is an epimorphism onto a finite group with $\gamma(g) \neq e$.

(3)⇒(1) This statement is trivial. Note that here we do not need that π is countable.

(1)⇒(3) We outsource the straightforward proof to Exercise 64.9. ■

The following lemma gives a topological criterion for a (fundamental) group to be residually finite.

Lemma 64.14. Let (X, x_0) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. The following two statements are equivalent:

(1) The group $\pi_1(X, x_0)$ is residually finite.

(2) Given any loop $\gamma\colon [0,1] \to X$ in (X, x_0) that represents a non-trivial element in $\pi_1(X, x_0)$ there exists a finite covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ such that the corresponding lift $\widetilde{\gamma}\colon [0,1] \to \widetilde{X}$ is not a loop.

Proof. Let (X, x_0) be a topological space that is path-connected, locally path-connected and semi-locally simply connected. First we prove the (1)⇒(2)-implication. Thus we assume that the group $\pi_1(X, x_0)$ is residually finite. Let $\gamma\colon [0,1] \to X$ be a loop in (X, x_0) that represents a non-trivial element in $\pi_1(X, x_0)$. By Proposition 64.12 there exists a finite-index subgroup Γ of $\pi_1(X, x_0)$ such that $[\gamma] \notin \Gamma$. Since X is locally path-connected and semi-locally simply connected we know by the Covering Existence Theorem 61.5 that there exists a covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ of X of degree $[\pi : \Gamma]$ with $p_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) = \Gamma$. By Lemma 48.15 we know that the corresponding lift $\widetilde{\gamma}\colon [0,1] \to \widetilde{X}$ is not a loop.

Now we prove the (2)⇒(1)-implication. Let $g \in \pi_1(X, x_0)$ be a non-trivial element. We pick a representative loop $\gamma\colon [0,1] \to (X, x_0)$. By hypothesis there exists a finite covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ such that the corresponding lift $\widetilde{\gamma}\colon [0,1] \to \widetilde{X}$ is not a loop. By Lemma 48.15 we know that $g = [\gamma]$ does not lie in $p_*(\pi_1(\widetilde{X}, \widetilde{x}_0))$ and that this is a finite-index subgroup of $\pi_1(X, x_0)$. It follows from Proposition 64.12 that $\pi_1(X, x_0)$ is residually finite. ■

Proposition 64.15. (Free Groups-are-Residually Finite Proposition) Every free group is residually finite.

In the following we will provide two proofs of the Free Groups-are-Residually Finite Proposition 64.15. The first is algebraic, very short and elegant. The other proof is topological in nature and great fun. The eagle-eyed reader will notice that the basic ideas of the two proofs are actually not that dissimilar.

Remark. In Exercise 51.15 we gave a third proof for the Free Groups-are-Residually Finite Proposition 64.15. Furthermore, a completely different proof of the Free Groups-are-Residually Finite Proposition 64.15, based again on topology, is given in [**Hem1972**].

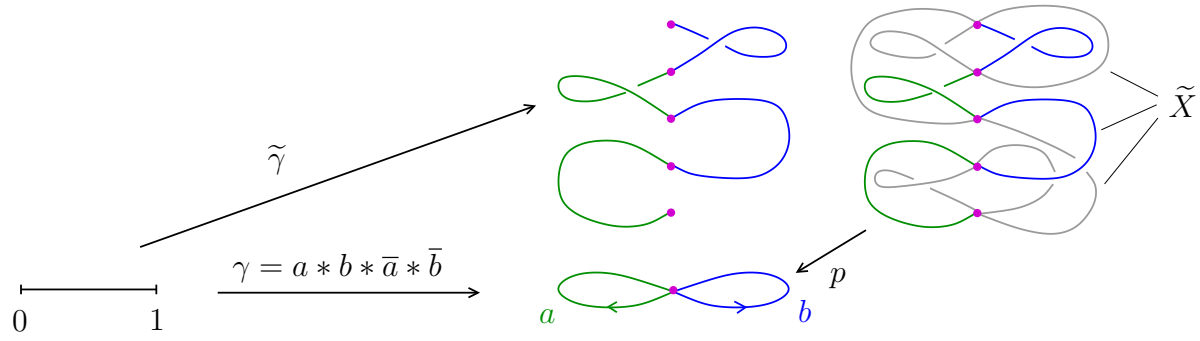
First proof of the Free Groups-are-Residually Finite Proposition 64.15. Let X be a set and let $g \in \langle X \rangle$ be a non-trivial element in the free group generated by the set X. We can and will write g as a product $g = y_1^{\epsilon_1} \cdot \cdots \cdot y_k^{\epsilon_k}$ with $y_1, \ldots, y_k \in X$ and $\epsilon_1, \ldots, \epsilon_k \in \{-1, 1\}$ such that the following condition is satisfied:

(∗) For every $i \in \{1, \ldots, k-1\}$ we have $(y_i, \epsilon_i) \neq (y_{i+1}, -\epsilon_{i+1})$.

It follows easily from $(*)$ that for every $x \in X$ we can pick a permutation $\sigma_x \in S_{k+1}$ with the following two properties:

(1) For every $i \in \{1, \ldots, k\}$ with $x = y_i$ and $\epsilon_i = 1$ we have $\sigma_x(i+1) = i$.
(2) For every $i \in \{1, \ldots, k\}$ with $x = y_i$ and $\epsilon_i = -1$ we have $\sigma_x(i) = i+1$. In other words, we have $\sigma_x^{-1}(i+1) = i$.

By Lemma 51.15 there exists a unique homomorphism $\varphi\colon \langle X \rangle \to S_{k+1}$ such that $\varphi(x) = \sigma_x$ for every $x \in X$. We claim that $\varphi(g) \in S_{k+1}$ is a non-trivial permutation. In fact we have



$$\varphi(g)(k+1) = \varphi(y_1^{\epsilon_1} \cdot \ldots \cdot y_k^{\epsilon_k})(k+1) = \varphi(y_1)^{\epsilon_1}(\ldots(\underbrace{\varphi(y_k)^{\epsilon_k}(k+1)}_{=k})\ldots) = \ldots = \varphi(y_1)^{\epsilon_1}(2) = 1.$$

This shows that the permutation $\varphi(g) \in S_{k+1}$ sends $k+1$ to 1, in other words, it is a non-trivial permutation. ■

Sketch of second proof of the Free Groups-are-Residually Finite Proposition 64.15. For simplicity we only provide the proof that the free group on two generators is residually finite. Recall that by the Fundamental Group-Wedge-of-Circles Lemma 52.4 we can make an identification $\langle a, b \rangle = \pi_1(S_a^1 \vee S_b^1, *)$ where a and b correspond to loops around S_a^1 and S_b^1. It follows fairly easily from Lemma 48.15 and Lemma 64.14 that it remains to show that for any loop $\gamma = a_1^{m_1} * b_1^{n_1} * \cdots * a_k^{m_k} * b_k^{n_k}\colon [0,1] \to X = S_a^1 \vee S_b^1$ there exists a finite-covering $p\colon \widetilde{X} \to X$ such that the lift of γ is not a loop. In the figure below we show the following two-step construction of such a covering for the loop $\gamma = a * b * \overline{a} * \overline{b}$.[748]

(1) First we build an "upward turning lift $\widetilde{\gamma}$ of γ".
(2) Afterward we complete the "image of $\widetilde{\gamma}$" to a finite covering $\widetilde{X}$.

It is an extraordinary charming exercise to turn the above idea into a rigorous argument for the general case. We would not dream of robbing the reader from this experience. ■

Basically for free we now get the following result.

Corollary 64.16. Every finitely generated free group is Hopfian.

Proof. This statement follows immediately from the Free Groups-are-Residually Finite Proposition 64.15 together with the Residually Finite-Hopfian Proposition 64.11. An alternative proof of the corollary is given in [**MKS1976**, p. 109]. ■

[748] The reader will notice that this is basically the solution to Exercise 48.12.

In Question 54.7 we had asked whether the fundamental group of the surface of genus g is isomorphic to the free group F_{2g} on $2g$ generators. Now we can answer this question in the negative.

Proposition 64.17. If $g \geq 1$, then the group

$$\pi_1(\text{surface of genus } g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \,|\, [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \rangle$$

is not isomorphic to the free group F_{2g} on $2g$ generators.[749]

Remark. We will give alternative proofs of Proposition 64.17 on page 1887 and in Corollary ??.

In fact Proposition 64.17 is an immediate consequence of the following more general statement.

Proposition 64.18. Let $X = \{x_1, \ldots, x_k\}$ be a finite set with k elements. If r is a non-trivial element in the free group $\langle x_1, \ldots, x_k \rangle$, then the group $\langle x_1, \ldots, x_k \mid r \rangle$ is not isomorphic to $\langle x_1, \ldots, x_k \rangle$.

Proof. Let X is a finite set and let r be an element in $\langle X \rangle$. Suppose there exists an isomorphism $\varphi\colon \langle X \,|\, r \rangle \to \langle X \rangle$. We denote by $\psi\colon \langle X \rangle \to \langle X \,|\, r \,\rangle$ the obvious epimorphism. Then $\varphi \circ \psi\colon \langle X \rangle \to \langle X \rangle$ is an epimorphism. It follows from Corollary 64.16 that $\varphi \circ \psi$ is actually an isomorphism. This implies in particular that ψ is a monomorphism. But r lies in the kernel of ψ, this is only possible if $r = e \in \langle X \rangle$. ■

Our next goal is to give a useful criterion for a group to be residually finite. To do so we need to introduce the following definition.

Definition. Let R be a ring. We say that a group G is linear over R if there exists an $n \in \mathbb{N}$ and a monomorphism $G \to \mathrm{GL}(n, R)$.

Examples.

(1) In Exercise 51.14 we showed that the free group on two generators is linear over $\mathbb{Z}$.
(2) Let G be a group and let R be a ring. In Exercise 64.15 we will show that if G admits a finite-index subgroup which is linear over R, then G itself is linear over R.

Now we can formulate the promised proposition.

Proposition 64.19. Let G be a finitely generated group. If G is linear over $\mathbb{C}$, then G is residually finite.

Sketch of proof. We only provide a full proof of the following easier claim which is the content of Exercise 51.15 (a).

Claim. The group $\mathrm{GL}(n, \mathbb{Z})$ is residually finite.

Proof. Let $A = (a_{ij}) \in \mathrm{GL}(n, \mathbb{Z})$ be a matrix with $A \neq \mathrm{id}$. We pick some $m \in \mathbb{N}$ such that $m > \max\{|a_{ij} - \delta_{ij}| \,|\, i, j = 1, \ldots, n\}$. The ring homomorphism $\mathbb{Z} \to \mathbb{Z}_m$ induces a group homomorphism $\alpha\colon \mathrm{GL}(n, \mathbb{Z}) \to \mathrm{GL}(n, \mathbb{Z}_m)$. Basically by construction we have $\alpha(A) \neq \mathrm{id}$. Since $\mathrm{GL}(n, \mathbb{Z}_m)$ is a finite group we are done. ⊞

[749] It follows from considering the abelianizations, see the Fundamental Group-of-Surfaces Proposition 54.5, that $\pi_1(\text{surface of genus } g)$ cannot be isomorphic to any other free group either.

Now let G be a finitely generated subgroup of $\mathrm{GL}(n,\mathbb{C})$. The proof that G is residually finite consists of two steps:

(1) First, since G is finitely generated one sees, almost immediately, that there exists a finitely generated subring S of $\mathbb{C}$ such that $G \subset \mathrm{GL}(n,S)$.
(2) Next one needs to show that S is a "residually finite ring", i.e. one needs to show that given any non-zero $s \in S$ there exists a ring homomorphism $\alpha\colon S \to T$ to some finite ring T with $\alpha(s) \neq 0$. This part requires some input from ring theory.

Once one has proved (1) and (2) it is straightforward to modify the proof of the claim to conclude that G is residually finite.

The full details for the above proof are given in [**Mal1940, Mal1965**] and also in [**Weh1973**, Theorems 4.1, 4.3] and in [**Hem87**]. ■

We already mentioned that $(\mathbb{Q},+)$ is not residually finite and that $\mathbb{Z}^{(\mathbb{N})}$ is not Hopfian. These are amusing observations, but most group theorists and geometric topologists restrict their interest to finitely generated groups. Thus the question arises, whether perhaps every finitely generated group is residually finite or Hopfian.

Proposition 64.20. Given $m,n \in \mathbb{N}$ we consider the Baumslag-Solitar group

$$\mathrm{BS}(m,n) \;=\; \langle x,y \,|\, x^{-1}y^m x \,=\, y^n \rangle.$$

The following statements hold:

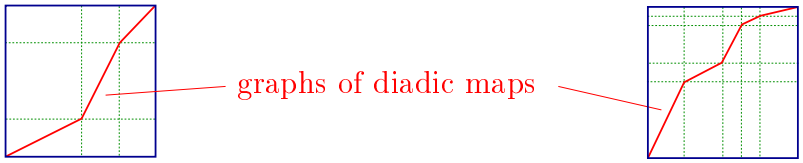
(1) The group $\mathrm{BS}(m,n)$ is Hopfian if and only if m and n are "meshed", i.e. if and only if m or n divides the other or if m and n have precisely the same prime divisors.
(2) The group $\mathrm{BS}(m,n)$ is residually finite if and only if $|m| = 1$, or if $|n| = 1$ or if $|m| = |n|$.

Example. By Proposition 64.20 the group $\mathrm{BS}(2,6)$ is Hopfian but not residually finite. This shows, as promised, that the converse to the Residually Finite-Hopfian Proposition 64.11 does not hold.

Proof. The first statement was proved in 1962 by Gilbert Baumslag and Solitar [**BaS1962**]. The second statement is proved in [**Mes1972**, Theorem C] and also [**Cam1990**, p. 61]. ■

By Proposition 64.20 we now know that there exist finitely generated groups which do not have "many" finite quotients. The question arises, does every non-trivial group admit at least some finite index subgroups? It is now time to recall the following standard definition from group theory.

Definition. A group G is called simple if the only normal subgroups are the trivial group $\{e\}$ and the whole group G.



Example. One of the most basic statements in the theory of finite groups is the fact that for $n \geq 5$ the alternating group A_n is actually simple, we refer to [**Bog2008**, Chapter 1.12] for a proof.

It is now natural to ask whether there exist infinite simple groups. The answer is yes, but one needs to be rather creative when it comes to producing such groups. This discussion leads us to the following groups which were introduced by Richard Thompson in 1965.

Definition.

(1) A continuous self-homeomorphism $f\colon [0,1] \to [0,1]$ is called dyadic if there exists an $m \in \mathbb{N}$ such that the restriction of f to each interval $[\frac{i}{2^m}, \frac{i+1}{2^m}]$ is linear and the slope on each such interval is a (possibly negative) power of 2.

(2) We say a map $g\colon S^1 \to S^1$ is dyadic if there exists a dyadic map $f\colon [0,1] \to [0,1]$ such that $g(\exp(2\pi \mathrm{i} t)) = \exp(2\pi \mathrm{i} f(t))$.

We leave it to the reader to verify that the set of dyadic self-homeomorphisms of $[0,1]$ and of S^1 actually form groups. This observation leads us to the key definition.

Definition.

(1) Thompson's group F is defined as the group of dyadic self-homeomorphisms of $[0,1]$.

(2) Thompson's group T is defined as the subgroup of the self-homeomorphisms of S^1 that is generated by the dyadic self-homeomorphisms together with the homeomorphism given by $z \mapsto -z$.

The following theorem summarizes some of the many interesting properties of Thompson's groups.

Theorem 64.21.

(1) Thompson's group F and Thompson's group T are both finitely presented.

(2) The commutator subgroup of Thompson's group F is simple, in particular Thompson's group F is not residually finite.

(3) Thompson's group T is simple, in particular it is not residually finite.

Proof.

(1) The statements are proved in [**CFP1996**] and [**Geo2008**, Chapters 9.2].

(2) By [**CFP1996**] and [**Geo2008**, Chapters 9.2] the commutator subgroup of Thompson's group F is simple. One can easily verify that Thompson's group F is non-abelian and torsion-free. It now follows from an elementary argument that it is not residually finite.

(3) It is shown in [**CFP1996**] and [**Geo2008**, Theorem 9.4.3] that Thompson's group T is simple. Clearly T is infinite, hence it cannot be residually finite. ■

In this section we have shown, among many other statements, that free groups are residually finite. It is natural to ask which of the other friendly groups which we have encountered are actually residually finite. Let us pose two questions:

Question 64.22.

(1) Are the fundamental groups of closed 2-dimensional smooth manifolds residually finite?

(2) Is the fundamental group of every knot complement residually finite?

We will return to these questions later on in Proposition 66.19.

Exercises for Chapter 64.

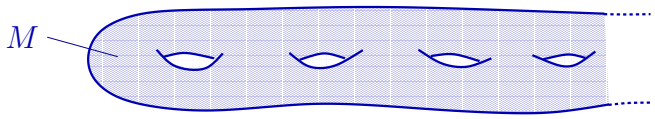
Exercise 64.1. Let H be a finite connected graph and let G be a connected non-empty subgraph of H. Let S be a spanning tree of G. Show that there exists a spanning tree T of H such that $T \cap G = S$.
Remark. This exercise is a rather straightforward generalization of the Spanning Tree Existence Proposition 7.10 (1).

Exercise 64.2. Let $\alpha\colon \langle a, b\rangle \to \mathbb{Z}_3$ be the epimorphism defined given by $\alpha(a) = 1$ and $\alpha(b) = 0$. Furthermore let X be the wedge of two circles A and B. As usual we equip X with the CW-structure with one 0-cell P and two 1-cells a and b. Furthermore we make the identification $\pi_1(X) = \langle a, b\rangle$.

(a) "Construct" the covering $p\colon \widetilde{X} \to X$ corresponding to $\ker(\alpha)$, i.e. construct the covering p such that $p_*(\pi_1(\widetilde{X})) = \ker(\alpha)$. More precisely, give the CW-structure on $\widetilde{X}$ and indicate, e.g. using colors, the cellular map p.
(b) We know from Proposition 64.4 (2) that $\ker(\alpha)$ is a free group on four generators. Determine four elements of $\ker(\alpha)$ that generate $\ker(\alpha)$ as a free group. You do not have to justify your answer.

Exercise 64.3. In Question 63.4 we had considered an explicit 6-fold covering $X \to B$ where B is the 2-dimensional sphere minus three open disks. On page 1404 we saw that X has six boundary components. Determine the genus of X.

Exercise 64.4. Let $g \in \mathbb{N}_{\geq 2}$. Use Proposition 64.5 to show that the fundamental group of the surface of genus g is torsion-free.
Remark. We posed this already as Exercise 56.12 but with different instructions.



Exercise 64.5. Let P be a property of groups. We say a group G is *virtually* P if G admits a finite-index subgroup that has property P. Let G be a finitely generated group. Show that if G is virtually abelian, then there exists a short exact sequence of the form $0 \to \mathbb{Z}^d \to G \to A \to 1$ where $d \in \mathbb{N}_0$ and A is a finite group.

Exercise 64.6. Let $p\colon \widetilde{\Sigma} \to \Sigma$ be a covering map of degree d between two closed *non-orientable* connected 2-dimensional smooth manifolds. Show that the following equality holds:

$$\operatorname{genus}(\widetilde{\Sigma}) \;=\; d \cdot (\operatorname{genus}(\Sigma) - 1) + 1.$$

Hint. Let $\varphi\colon \overline{B}^2 \to \Sigma$ be an embedding. Consider the compact connected 2-dimensional smooth manifolds $M := \Sigma \setminus \varphi(B^2)$ and $\widetilde{M} := p^{-1}(M)$. What can you say about the fundamental group and the number of boundary components of $\widetilde{M}$?
Remark. This exercise is meant as the non-orientable analogue of the Subgroups-of-Surface Groups Proposition 64.6. In Lemma 87.9 we will use "Euler characteristics" to give an alternative proof of this equality.

Exercise 64.7. We consider the non-compact 2-dimensional smooth manifold M shown in the figure below. Does there exist a closed 2-dimensional smooth manifold N such that M is a covering space of N?

Exercise 64.8. In Exercise 51.15 we introduced the notion of a residually finite group and we showed that the free group on two generators is residually finite.

(a) Show that every finitely generated free group is residually finite.
Remark. Use Proposition 64.4 (2).
(b) Show that every free group is residually finite.

Exercise 64.9. Let π be a countable residually finite group. Show that there exists a descending sequence $\pi \supset \pi_0 \supset \pi_1 \supset \pi_2 \supset \dots$ of finite index normal subgroups of π such that we have $\bigcap_{i \in \mathbb{N}} \pi_i = \{e\}$.

Exercise 64.10. Let G be a finitely generated group. Show that given any $n \in \mathbb{N}$ there exist only finitely many subgroups of G of index n.

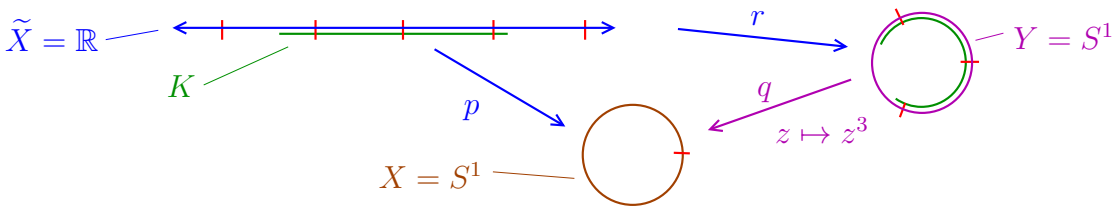
Exercise 64.11. Let G be a group. A subgroup Γ of G is called *characteristic* if for every automorphism $\varphi\colon G \to G$ we have $\varphi(\Gamma) = \Gamma$.

(a) Show that if subgroup is characteristic, then it is also normal.
(b) Let H be a subgroup of G. Suppose that G is finitely generated. Show that there exists a characteristic subgroup $K \subset G$ with $K \subset H$ and such that K has finite index in G.
(c) Show that in (b) we cannot drop the hypothesis that G is finitely generated.

Exercise 64.12. Show that the group $(\mathbb{Q}, +)$ is not residually finite.

Exercise 64.13. Let $\varphi\colon A \to B$ be a homomorphism between free groups of the same finite rank. Suppose that $\varphi_*\colon A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is an isomorphism. Show that φ is a monomorphism.
Hint. Use Proposition 64.4 and Corollary 64.16.

Exercise 64.14. Let G be a group and let $\varphi\colon G \to G$ be an automorphism. We suppose that G is residually finite and finitely generated. Show that the semidirect product $G \rtimes_\varphi \mathbb{Z}$, that we defined on page 1127, is also residually finite.
Hint. Make good use of Exercise 64.11.



Exercise 64.15. Let R be a ring, let G be a group and let H be a subgroup of finite index $d \in \mathbb{N}$. Suppose there exists a monomorphism $\varphi\colon H \to \mathrm{GL}(n, R)$. Show that there exists a monomorphism $\varphi\colon G \to \mathrm{GL}(n \cdot d, R)$.

Exercise 64.16.

(a) Provide an example of an infinitely generated group that is Hopfian.
(b) Show that every infinite simple group is Hopfian.

Exercise 64.17. Let $k \in \mathbb{N}_{\geq 2}$. We consider the direct product $\langle x_1, \dots, x_k \rangle \times \mathbb{Z}$. Show that given any $N \in \mathbb{N}$ there exists a finitely generated free group F of rank $\geq N$ and an automorphism φ of F such that $\langle x_1, \dots, x_k \rangle \times \mathbb{Z}$ is isomorphic to the semidirect product $F \rtimes_\varphi \mathbb{Z}$.
Remark. Most of the hard work was already done in Exercise 50.19.

Exercise 64.18. Let X be a path-connected non-empty topological space. We denote by $p\colon \widetilde{X} \to X$ the universal covering. Let $K \subset \widetilde{X}$ be a compact subset. Show that if $\pi_1(X)$ is residually finite, then there exists a finite covering $q\colon Y \to X$ such that for the induced covering $r\colon \widetilde{X} \to Y$, that is given by Corollary 61.11, the restriction of r to $r|_K\colon K \to Y$ is an embedding.

65. Hyperbolic geometry

In this chapter we will switch gears and we will introduce some basics on hyperbolic geometry. The reason for doing so is that in Chapter 66 we will see that every surface of genus ≥ 2 admits a hyperbolic structure, and this fact will be extremely helpful in getting a better understanding of surfaces.

65.1. Hyperbolic space.

We start out with the following definition.

Definition. Let V be a real vector space. A symmetric form on V is a map[750]

$$g\colon V \times V \to \mathbb{R}$$

that is bilinear, i.e. for all $u, v, w \in V$ and $\mu, \lambda \in \mathbb{R}$ we have

$$\begin{aligned} g(\lambda \cdot u + \mu v, w) &= \lambda \cdot g(u, w) + \mu g(v, w) \\ g(u, \lambda \cdot v + \mu \cdot w) &= \lambda \cdot g(u, v) + \mu \cdot g(u, w) \end{aligned}$$

and that is symmetric, i.e. for all $v, w \in V$ we have

$$g(v, w) = g(w, v).$$

We say g is positive-definite if for all $v \in V \setminus \{0\}$ we have

$$g(v, v) > 0.$$

Now we can recall the following key definition from the theory of smooth manifolds, see e.g. [**Lee2002**, Chapter 17].

Definition.

(1) A Riemannian structure on a smooth manifold M is a smooth[751] map g which assigns to each point P a positive-definite symmetric form g_P on the tangent space $\mathrm{T}_P M$.
(2) A Riemannian manifold is a pair (M, g) consisting of a smooth manifold M together with a Riemannian structure g.

As so often in mathematics, given some structure one is very much interested in maps that preserve the given structure. This leads us to the following definition.

Definition.

(1) Given a smooth map $f\colon M \to N$ between smooth manifolds and given $P \in M$ we denote by $\mathrm{D}f_P = f_*\colon \mathrm{T}_P M \to \mathrm{T}_{f(P)} N$ the differential, i.e. the induced homomorphism from the tangent space $\mathrm{T}_P M$ to the tangent space $\mathrm{T}_{f(P)} N$.
(2) Let $f\colon M \to N$ be a local diffeomorphism. Given a Riemannian structure h on N we denote by f^*h the Riemannian structure on M that at each point $P \in M$ is given by $(f^*h)(v, w) = h(f_* v, f_* w)$.[752]
(3) We say that a map $f\colon (M, g) \to (N, h)$ between Riemannian manifolds is a (local) isometry if f is a (local) diffeomorphism and if $g = f^*h$.
(4) Given a Riemannian manifold (M, g) we denote by $\mathrm{Isom}(M, g)$ the group of isometries of (M, g). If M is orientable, then we denote by $\mathrm{Isom}^+(M, g)$ the group of orientation-preserving isometries of (M, g).

[750] Sometimes such a structure is called a *bilinear symmetric form*, but we abbreviate this to *symmetric form*.
[751] The notion of "smooth" in this context is made precise in [**Lee2002**, Chapter 17]. Once one has digested the definition of a "smooth map" it is straightforward to see that all examples below satisfy this condition.

(5) We say that Riemannian manifolds (M, g) and (N, h) are isometric if there exists an isometry from (M, g) to (N, h).

In this chapter and the following chapter we are mostly interested in Riemannian structures on surfaces, and more specifically, in hyperbolic structures. Now we give the definition of hyperbolic space.

Definition. The hyperbolic half-plane is the smooth manifold

$$\mathbb{H} \;=\; \{(x, y) \in \mathbb{R}^2 \mid y > 0\} \;=\; \{z = x + \mathrm{i}y \in \mathbb{C} \mid y > 0\}$$

together with the Riemannian structure that assigns to the tangent space $\mathrm{T}_z\mathbb{H} = \mathbb{R}^2$ at a point $z = x + \mathrm{i}y \in \mathbb{H}$ the positive-definite symmetric form

$$\begin{array}{rcl} g\colon \mathbb{R}^2 \times \mathbb{R}^2 & \to & \mathbb{R} \\ (v, w) & \mapsto & \frac{1}{y^2} \cdot \langle v, w \rangle \end{array}$$

where $\langle v, w \rangle$ denotes the usual scalar product on $\mathbb{R}^2$.

Example. In the figure below we see a decomposition of $\mathbb{H}$ into angels and devils. With respect to the hyperbolic metric all the angels have the same size and all the devils have the same size, even though they differ in the usual Euclidean sense.

As we mentioned before, we are very much interested in the group $\mathrm{Isom}^+(\mathbb{H})$ of orientation-preserving isometries of the Riemannian manifold $\mathbb{H}$. This leads us to the following definition.

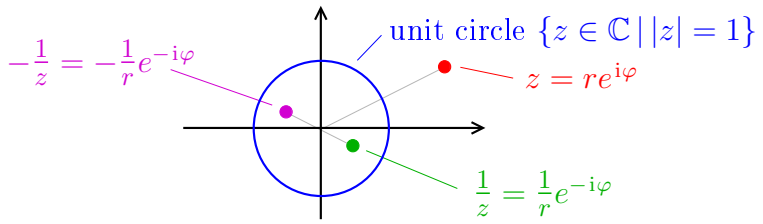
Definition. A Möbius transformation of $\mathbb{H}$ is a map of the form[753]

$$\begin{array}{rcl} \mathbb{H} & \to & \mathbb{H} \\ z & \mapsto & \dfrac{az + b}{cz + d} \end{array}$$

where $a, b, c, d \in \mathbb{R}$ with $ad - bc = 1$.

Examples. We give three special types of Möbius transformations of $\mathbb{H}$:

(1) given $r > 0$ the scalar multiplication $z \mapsto rz = \frac{\sqrt{r}\cdot z + 0}{0 \cdot z + \frac{1}{\sqrt{r}}}$ is a Möbius transformation,



(2) given $d \in \mathbb{R}$ the horizontal translation $z \mapsto z + d = \frac{1 \cdot z + d}{0 \cdot z + 1}$ is a Möbius transformation,

(3) the map $z \mapsto -\frac{1}{z} = \frac{0 \cdot z + 1}{(-1) \cdot z + 0}$ is a Möbius transformation.

[752] It follows from [**Lee2002**, Proposition 13.9] that f^*h is indeed a Riemannian structure on M. Note that in the proof, to show that f^*h is indeed non-degenerate, one needs that f is a local diffeomorphism.

[753] An elementary calculation shows that the image of a Möbius transformation $\mathbb{H} \to \mathbb{C}$ does indeed lie again in $\mathbb{H}$.

The third Möbius transformation is the composition of taking the inverse $z \mapsto \frac{1}{z}$ and the reflection $z \mapsto -z$ in the origin. We illustrate this map in the figure below. For simplicity we refer to the map $z \mapsto -\frac{1}{z}$ as an inversion.

Rather amazingly we are already done with listing all elements in $\mathrm{Isom}^+(\mathbb{H})$. More precisely, we have the following proposition.

Proposition 65.1. The map

$$\begin{array}{ccc} \mathrm{SL}(2,\mathbb{R}) & \to & \mathrm{Isom}^+(\mathbb{H}) \\ \begin{pmatrix} a & b \\ c & d \end{pmatrix} & \mapsto & \begin{pmatrix} \mathbb{H} & \to & \mathbb{H} \\ z & \mapsto & \frac{az+b}{cz+d} \end{pmatrix} \end{array}$$

is a group isomorphism.

Sketch of proof. One can easily calculate by hand that each Möbius transformation is an orientation-preserving isometry of $\mathbb{H}$. Furthermore, it is an amusing calculation to verify that the given map is indeed a group homomorphism. It is elementary to see that the map is a monomorphism. The only bit of the proposition which requires some thought is the statement that every orientation-preserving isometry is already a Möbius transformation. This statement is for example shown in [**And2005**, Theorem 3.19]. ■

Now that we have seen that every orientation-preserving isometry of $\mathbb{H}$ is a Möbius transformation it makes sense to study Möbius transformations in greater detail.

Proposition 65.2. Every Möbius transformation of $\mathbb{H}$ is the composition of scalar multiplications, horizontal translations and inversions.

Proof. Let $a, b, c, d \in \mathbb{R}$ with $ad - bc = 1$ and denote by

$$\Phi(z) \;=\; \frac{az+b}{cz+d}$$

the corresponding Möbius transformation. If $c = 0$, then

$$\Phi(z) \;=\; \frac{a}{d}z + \frac{b}{d}$$

is the composition of the scalar multiplication[754] $z \mapsto \frac{a}{d}z$ with the horizontal translation $z \mapsto \frac{b}{d} + z$. If $c \neq 0$, then

$$\Phi(z) \;=\; \frac{az+b}{cz+d} \;=\; \frac{acz+bc}{c^2z+dc} \underset{\substack{\uparrow \\ \text{since } ad-bc=1}}{=} \frac{acz+ad-1}{c^2z+cd} \;=\; \frac{-1+a(cz+d)}{c^2z+cd} \;=\; \frac{-1}{c^2z+dc} + \frac{a}{c}.$$

Thus we see that Φ is the composition of the following maps

$$z \mapsto c^2z, \quad z \mapsto z+dc, \quad z \mapsto \frac{-1}{z} \quad \text{and } z \mapsto z + \frac{a}{c}.$$

■

[754] Note that $c = 0$ implies that $1 = ad - bc = ad$, in particular $ad > 0$, hence $\frac{a}{d} > 0$.

Definition.

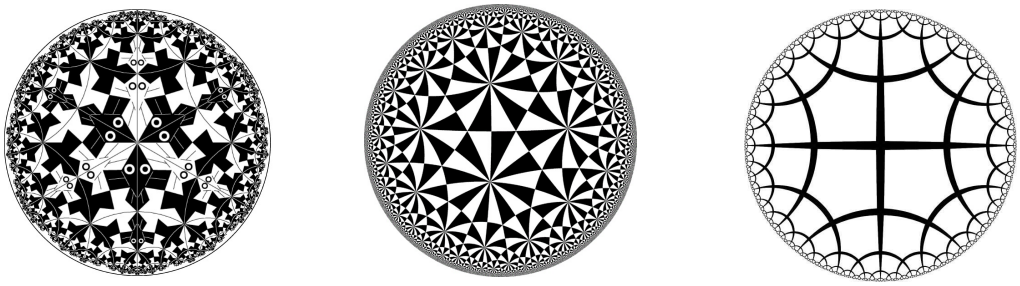
(1) The hyperbolic disk[755] is the smooth manifold

$$\mathbb{D} \;=\; \{z \in \mathbb{C} \mid |z|^2 < 1\}$$

together with the Riemannian structure which assigns to the tangent space $\mathrm{T}_z\mathbb{D} = \mathbb{R}^2$ at a point $z \in \mathbb{D}$ the positive-definite symmetric form

$$\begin{array}{rcl} g_z \colon \mathbb{R}^2 \times \mathbb{R}^2 & \to & \mathbb{R} \\ (v,w) & \mapsto & \dfrac{2}{(1-|z|^2)^2}\langle v, w\rangle \end{array}$$

where, as above, $\langle v, w\rangle$ denotes the usual scalar product on $\mathbb{R}^2$.



(2) A Möbius transformation of $\mathbb{D}$ is a map of the form[756]

$$\begin{array}{rcl} \mathbb{D} & \to & \mathbb{D} \\ z & \mapsto & \exp(\mathrm{i}\theta) \cdot \frac{z-a}{1-\bar{a}z} \end{array}$$

for some $\theta \in \mathbb{R}$ and $a \in \mathbb{D}$.

Examples.

(1) In the figure below we see three different decompositions of $\mathbb{D}$ into subsets. In each of the three cases these subsets have the same hyperbolic size, even though they differ in the usual Euclidean sense.

(2) If we set $a = 0$ in the definition of a Möbius transformation of $\mathbb{D}$, then we obtain precisely the rotation by the angle θ. Put differently, the Möbius transformations preserving 0 are precisely given by rotations around the origin.

The following proposition will allow us to go back and forth between the hyperbolic half-plane and the hyperbolic disk.

Proposition 65.3. The maps

$$\begin{array}{rcl} \Phi \colon \mathbb{H} & \to & \mathbb{D} \\ z & \mapsto & \frac{z-\mathrm{i}}{z+\mathrm{i}} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \Psi \colon \mathbb{D} & \to & \mathbb{H} \\ w & \mapsto & \frac{\mathrm{i}+\mathrm{i}w}{1-w} \end{array}$$

have the following properties:

(1) Φ and Ψ are inverses to one another, in particular they are biholomorphisms,

[755] The hyperbolic disk is often also called the *Poincaré model for hyperbolic space*.

[756] An elementary calculation shows that the image of a Möbius transformation $\mathbb{D} \to \mathbb{C}$ does indeed lie again in $\mathbb{D}$.

(2) they extend to homeomorphisms between $\overline{\mathbb{H}} = \{z \in \mathbb{C} \mid \mathrm{Im}(z) \geq 0\} \cup \{\infty\}$[757] and $\overline{\mathbb{D}} = \{z \in \mathbb{C} \mid |z| \leq 1\}$,
(3) they are orientation-preserving,[758]
(4) they are isometries,
(5) they give a bijection between the Möbius transformations of $\mathbb{D}$ and $\mathbb{H}$.[759]

Proof. All five statements follow from a straightforward calculation. The statements can also be deduced, more or less directly, from any book that deals with Möbius transformations, see e.g. [**Schwe1979**, Chapter 6] and [**And2005**, Chapter 2]. ■

Remark. Proposition 65.3 says that $\mathbb{D}$ and $\mathbb{H}$ are two equivalent ways to describe hyperbolic space. In fact there are several other ways to describe hyperbolic space, for example we could also use the Beltrami-Klein model

`https://en.wikipedia.org/wiki/Beltrami-Klein_model`

or the hyperboloid model

`https://en.wikipedia.org/wiki/Hyperboloid_model`.

Some of the connections between these models are explained in the following video of Henry Segerman and Saul Schleimer:

`https://www.youtube.com/watch?v=eGEQ_UuQtYs`.

The following proposition summarizes some of the key properties of Möbius transformations.

Proposition 65.4. [760]

(1) Compositions of Möbius transformations are again Möbius transformations and the inverse of a Möbius transformation is again a Möbius transformation.
(2) Möbius transformations are biholomorphisms, they are isometries and they are orientation-preserving.
(3) Möbius transformations act transitively, i.e. given any two points P and Q there exists a Möbius transformation which sends P to Q.
(4) Given $P, Q \in \mathbb{D}$ and non-zero vectors $v \in \mathrm{T}_P\mathbb{D}$ and $w \in \mathrm{T}_Q\mathbb{D}$ with $\|v\|_g = \|w\|_g$ there exists a Möbius transformation ϕ with $\phi(P) = Q$ and $d\phi_P(v) = w$.
(5) Let ϕ and ψ be two Möbius transformations. Suppose there exists a $P \in \mathbb{D}$ such that $\phi(P) = \psi(P)$ and such that $d\phi_P = d\psi_P$. Then $\phi = \psi$.

Proof. By Proposition 65.3 it suffices to prove the statements for $\mathbb{D}$ or for $\mathbb{H}$, whichever is more convenient.

(1),(2) The first two statements follow from a straightforward calculation, see e.g. [**Schwe1979**, p. 43].

[757] Here $\overline{\mathbb{H}}$ has the same topology as defined on page 122.
[758] The hyperbolic half-plane $\mathbb{H}$ and the hyperbolic disk $\mathbb{D}$ are both subsets of $\mathbb{C} = \mathbb{R}^2$ and inherit from $\mathbb{C} = \mathbb{R}^2$ the natural orientation.
[759] More precisely, if α is a Möbius transformation of $\mathbb{H}$, then $\Phi \circ \alpha \circ \Psi$ is a Möbius transformation of $\mathbb{D}$ and conversely, if α is a Möbius transformation of $\mathbb{D}$, then $\Psi \circ \alpha \circ \Phi$ is a Möbius transformation of $\mathbb{H}$.
[760] The statement of the proposition applies to Möbius transformations of $\mathbb{D}$ and to Möbius transformations of $\mathbb{H}$.

(3) We prove this statement for $\mathbb{D}$. Note that by (1) it suffices to show that given any $P \in \mathbb{D}$ there exists a Möbius transformation ψ with $\psi(P) = 0$. But such a Möbius transformation is given by

$$\psi(z) \;=\; \tfrac{z-P}{1-\overline{P}z}.$$

(4) Using (3) we see that we only have to deal with the case that $P = Q = 0$. But then the desired Möbius transformation is given by a rotation.

(5) By (3) there exists a Möbius transformation θ such that $\theta(0) = P$ and there exists a Möbius transformation ω such that $\omega(\phi(P)) = \omega(\psi(P)) = 0$. We consider the Möbius transformations $\phi' = \omega \circ \phi \circ \theta$ and $\psi' = \omega \circ \psi \circ \theta$. It follows from our hypothesis that both ϕ' and ψ' fix 0. As we pointed out above, the only Möbius transformations of $\mathbb{D}$ that fix 0 are rotations.

By our hypothesis we have $d\phi'_0 = d\psi'_0$, which means that the rotations ϕ' and ψ' agree. But this implies that ϕ and ψ also agree. ■

Note that Möbius transformations extend in an obvious way uniquely to homeomorphisms of $\overline{\mathbb{D}} = \{z \in \mathbb{C} \mid |z| \leq 1\}$ and $\overline{\mathbb{H}} = \{z \in \mathbb{C} \mid \mathrm{Im}(z) \geq 0\} \cup \{\infty\}$. We will denote the extension of a Möbius transformation with the same symbol.

Lemma 65.5. Let $\{P, Q, R\}$ and let $\{S, T, U\}$ be two sets of three distinct points on the boundary $\partial\overline{\mathbb{H}} = \mathbb{R} \cup \{\infty\}$. Then there exists a Möbius transformation ψ of $\mathbb{H}$ with $\psi(P) = S$ and $\psi(\{Q, R\}) = \{T, U\}$.

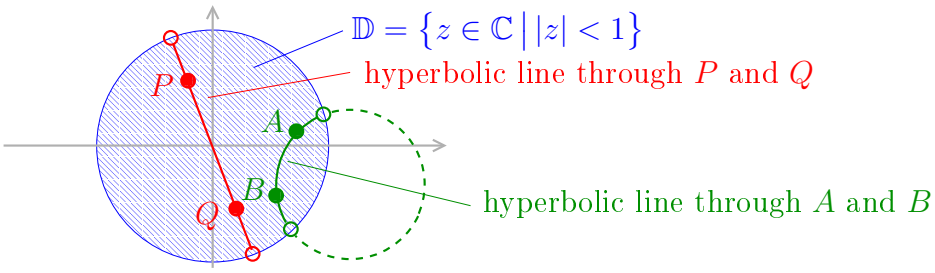
Proof. Let P, Q, R be three distinct points on $\partial\overline{\mathbb{H}} = \mathbb{R} \cup \{\infty\}$. It suffices to show that there exists a Möbius transformation ψ with $\psi(P) = \infty$ and with $\psi(\{Q, R\}) = \{0, 1\}$. We proceed as follows:

(1) We first claim that there exists a Möbius transformation α with $\alpha(P) = \infty$. Indeed, if $P = \infty$ then we just take $\alpha = \mathrm{id}$. Otherwise we can combine a horizontal translation with the inversion to obtain a Möbius transformation α with $\alpha(P) = \infty$. Given such α we write $Q' = \alpha(Q)$ and $R' = \alpha(R)$. Note that the points Q', R' lie on $\mathbb{R} = \overline{\mathbb{H}} \backslash \{\infty\}$. Without loss of generality we can assume that $Q' < R'$.

(2) Next we pick a horizontal translation such that $\beta(Q') = 0$. Note that we still have $(\beta \circ \alpha)(P) = \beta(\infty) = \infty$. Also note that it follows from $Q' < R'$ that $\beta(R') > 0$.

(3) Finally we pick a scalar multiplication γ such that $(\gamma \circ \beta)(R') = 1$. Note that γ fixes 0 and ∞. Thus we see that $\psi = \gamma \circ \beta \circ \alpha$ has the desired property. ■

Definition. A hyperbolic line is a subset of $\mathbb{D}$ of one of the following two types:



(1) it is the intersection of $\mathbb{D}$ with a Euclidean line through the origin,

(2) it is the intersection of $\mathbb{D}$ with a Euclidean circle that intersects the circle $S^1 = \partial\overline{\mathbb{D}}$ orthogonally.

In each of the two cases we refer to the intersection of the Euclidean object with $S^1 = \partial\overline{\mathbb{D}}$ as the endpoints of the hyperbolic line.

Lemma 65.6.

(1) For any two distinct points P and Q in $\mathbb{D}$ there exists a unique hyperbolic line that contains P and Q.

(2) For any two distinct points P and Q in $\partial\overline{\mathbb{D}}$ there exists a unique hyperbolic line with P and Q as endpoints.
(3) Let P and Q be two distinct points in $\partial\overline{\mathbb{D}}$. Every Möbius transformation ϕ sends the hyperbolic line with endpoints P and Q to the hyperbolic line with endpoints $\phi(P)$ and $\phi(Q)$.
(4) Möbius transformations act transitively on hyperbolic lines, i.e. given any two hyperbolic lines g and h there exists a Möbius transformation ϕ with $\phi(g) = h$.

Proof. In principle one can prove the lemma directly in $\mathbb{D}$. But it is easier to prove it using $\mathbb{H}$. In $\mathbb{H}$ the hyperbolic lines are defined to be vertical lines $\{x + \mathrm{i}y \mid y > 0\}$ and Euclidean half-circles such that the origin lies on $\mathbb{R}$. It is straightforward to see that the diffeomorphisms of Proposition 65.3 define a bijection between the hyperbolic lines in $\mathbb{D}$ and in $\mathbb{H}$.

The corresponding statements for hyperbolic lines in $\mathbb{H}$ are straightforward to prove. They can also be obtained from any textbook on hyperbolic geometry, see e.g. [**And2005**] and [**Bon2009**, Chapter 2]. ■

65.2. **Angles in Riemannian manifolds.** We continue our quick introduction to Riemannian manifolds and hyperbolic space with a short discussion of angles.

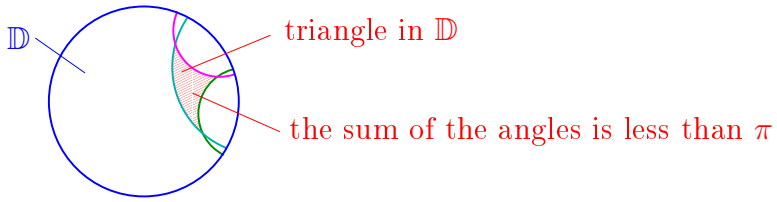
Definition.

(1) Let g be a positive-definite symmetric form on a real vector space V. Given two non-zero vectors $v, w \in V \setminus \{0\}$ we define[761]

$$\text{angle between } v \text{ and } w \;:=\; \text{unique } \alpha \in [0, \pi] \text{ with } g(v, w) = \cos(\alpha) \cdot \|v\| \cdot \|w\|.$$

(2) Given a Riemannian manifold (M, g) and non-zero vectors $v, w \in \mathrm{T}_P M$ we use the form g_P to define the angle between v and w.

Examples.



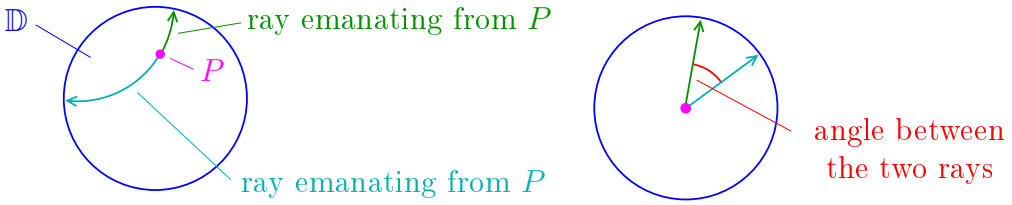
(1) Let U be an open subset of $\mathbb{R}^n$ and let $f\colon U \to \mathbb{R}_{>0}$ be a smooth function. For any $P \in U$ we can define a positive-definite symmetric form g_P on $\mathrm{T}_P U = \mathbb{R}^n$ via

$$g_P(v, w) \;=\; f(P) \cdot \langle v, w \rangle,$$

where $\langle\,,\,\rangle$ denotes the usual scalar product. A straightforward calculation shows that in this Riemannian structure the angle at any point is the usual Euclidean angle in $\mathbb{R}^n$. This argument implies in particular to the Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$, in both cases the hyperbolic angle, defined by the hyperbolic Riemannian structure, is the same as the Euclidean angle.

[761] We have $|g(v, w)| \leq \big|\|v\| \cdot \|w\|\big|$ by the Cauchy-Schwarz Inequality 0.12.

(2) A hyperbolic triangle is defined to be a compact subset of $\mathbb{H}$ whose boundary is given by segments of three hyperbolic lines. One of the many elegant theorems in hyperbolic geometry, see [**And2005**, Theorem 5.16], says that given such a hyperbolic triangle its angle sum equals π minus its "area". Even without the definition of "area" it is pretty clear that this result implies that the angle sum of a hyperbolic triangle is always less than π.



The following lemma follows easily from the definitions and from Proposition 65.4 (2).

Lemma 65.7. Local isometries, in particular Möbius transformations, preserve angles.

Definition.

(1) Let $P \in \mathbb{D}$ and let g be a hyperbolic line through P. Let Q be one of the two endpoints of g. We refer to the set of points between P and Q as a ray emanating from P.

(2) Let $P \in \mathbb{D}$ and let r, s be two rays emanating from P. We refer to the angle between the tangent vectors of r and s at P as the angle between the rays r and s.

Examples.

(1) Given $\varphi \in [0, 2\pi)$ the set $S_\varphi := \{r \cdot \exp(\mathrm{i}\varphi) \mid r \in [0, 1)\}$ is a ray emanating from 0.

(2) It follows from the above discussion of angles in $\mathbb{D}$, that given $\varphi, \theta \in [0, 2\pi)$ the angle between the two rays S_φ and S_θ in $\mathbb{D}$ is the usual Euclidean angle.

Lemma 65.8. Let r, s be two rays emanating from $P \in \mathbb{D}$ and let r', s' be two rays emanating from $P' \in \mathbb{D}$. Then the following holds:

$$\text{there is a Möbius transformation } \phi \text{ with } \phi(r \cup s) = r' \cup s' \iff \text{angle between } r, s = \text{angle between } r', s'.$$

Furthermore, if such a Möbius transformation exists, then it is unique.

Proof. By Lemma 65.7 Möbius transformations preserve angles and by Proposition 65.4 Möbius transformations act transitively on $\mathbb{D}$. Therefore we can without loss of generality assume that $P = P' = 0$. The lemma follows from the observation, made on page 1429, that Möbius transformations preserving 0 are precisely given by rotations around the origin. ■

65.3. The distance metric of a Riemannian manifold.

Definition. Let (M, g) be a connected Riemannian manifold.

(1) Given $v \in \mathrm{T}_P M$ we write $\|v\|_g := \sqrt{g_P(v,v)}$. If g is understood from the context, then we just write $\|v\|$.

(2) Let $\gamma\colon [a,b] \to M$ be a piecewise smooth path. By definition we can pick a subdivision $a = s_0 < s_1 < \cdots < s_m = b$ such that for $i = 0, \ldots, m-1$ the map $\gamma|_{[s_i, s_{i+1}]}$ is smooth. We define the length of γ as[762]

$$\ell_{(M,g)}(\gamma) := \sum_{i=0}^{m-1} \int_{t=s_i}^{t=s_{i+1}} \|\gamma'(t)\|_g \, dt.$$

If (M, g) is understood from the context, then we write $\ell(\gamma)$ instead of $\ell_{(M,g)}(\gamma)$.

(3) Let P and Q be two points on M.

$$d_{(M,g)}(P,Q) := \inf\{\ell(\gamma) \mid \underbrace{\gamma \text{ is a smooth path in } M \text{ from } P \text{ to } Q}_{\text{exists by the Smooth Path-Connectivity Proposition 19.29}} \}.$$

If (M, g) is understood from the context, then we just write $d(P, Q)$.

We start our discussion of the distance function d on Riemannian manifolds with the following somewhat technical proposition.

Proposition 65.9. Let (M, g) be a connected Riemannian manifold. The following statements hold:

(1) The pair $(M, d_{(M,g)})$ is a metric space.

(2) The topology defined by the metric $d_{(M,g)}$ agrees with the topology of M.

(3) Given any $P \in M$ and given any open neighborhood U of P there exists an $r > 0$ such that

$$B_r^{(M,g)}(P) := \{Q \in M \mid d_{(M,g)}(P,Q) < r\} \subset U.$$

Proof. Let (M, g) be a connected n-dimensional Riemannian manifold. We first show that $(M, d_{(M,g)})$ is a metric space.

It is clear that $d = d_{(M,g)}$ is symmetric. It follows easily from the definitions and the fact that the concatenation of two piecewise smooth paths is again piecewise smooth that d satisfies the triangle inequality.

Now let $P \neq Q$ be two distinct points in M. We need to show that $d(P,Q) > 0$. Since M is Hausdorff and since it is locally diffeomorphic to open subsets of $\mathbb{R}^n$ we can find a chart $\Phi\colon U \to B_{2r}(0)$ for P with $\Phi(P) = 0$ and such that $Q \notin U$. We write $\Psi = \Phi^{-1}$. Before we continue we introduce the following definitions:

(1) We write $U_r = \Phi^{-1}(\{x \in \mathbb{R}^n \mid \|x\| = r\})$ and given a subset $I \subset [0, 2r)$ we write $U_I = \Phi^{-1}(\{x \in \mathbb{R}^n \mid \|x\| \in I\})$.

(2) For a positive-definite bilinear form h on $\mathbb{R}^n$ we set

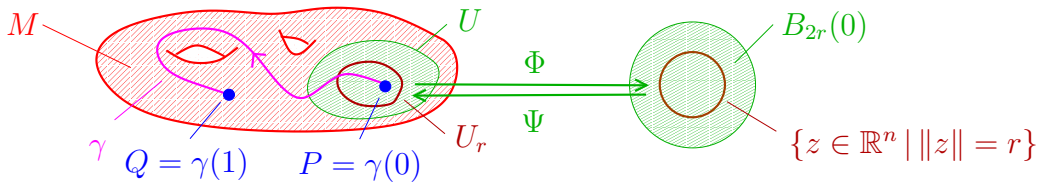
$$\|h\| := \min\left\{\sqrt{h(v,v)} \,\middle|\, v \in S^{n-1}\right\}.$$

Note that h is positive-definite, that $h\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is continuous and that S^{n-1} is compact. It follows from the Compact Image Lemma 2.13 that the minimum exists

[762] Recall that given a smooth path $\delta\colon [a,b] \to M$ and given any $t \in [a,b]$ the path defines, basically by definition of the tangent space $\mathrm{T}_{\delta(t)}M$, an element in $\mathrm{T}_{\delta(t)}M$. We denote this vector by $\delta'(t)$.

and that $\|h\| > 0$. It is straightforward to see that for any $v \in \mathbb{R}^n$ we have

$$h(v,v) \;\geq\; \|h\| \cdot \|v\|_{\text{eucl}}.$$



(3) We set

$$C \;:=\; \min\left\{ \|(\Psi^* g)_P\| \;\middle|\; P \in \overline{B_r(0)} \right\}.$$

Since $P \mapsto \|(\Psi^* g)_P\|$ is continuous and since $\overline{B_r(0)}$ is compact it follows from the Compact Image Lemma 2.13 that $C > 0$.

Claim. Let $\gamma\colon [0,1] \to M$ be a piecewise smooth path from P to Q. There exists a $t \in [0,1]$ with $\gamma(t) \in U_r$.

Proof. Suppose there is no $t \in (0,1)$ with $\gamma(t) \in U_r$. We consider the sets $A = U_{[0,r)}$ and $B = M \setminus U_{[0,r]}$. The set A is clearly open. Furthermore it follows from Lemma 18.11 that $U_{[0,r]}$ is closed, hence B is open. Since $\gamma([0,1]) \cap U_r = \varnothing$ we have $[0,1] = \gamma^{-1}(A) \sqcup \gamma^{-1}(B)$. But both sets $\gamma^{-1}(A)$ and $\gamma^{-1}(B)$ are open by the continuity of γ and both are non-empty since $0 \in \gamma^{-1}(A)$ and $1 \in \gamma^{-1}(B)$. But this contradicts the fact, established with some effort in the Interval-Connectedness Proposition 2.22, that $[0,1]$ is connected. ⊞

Now it suffices to prove the following claim.

Claim. Let $\gamma\colon [0,1] \to M$ be a piecewise smooth path from P to Q. Then $\ell_g(\gamma) \geq C \cdot r$.

Proof. Let $T := \inf\{t \in (0,1) \mid \gamma(t) \in U_r\}$. By the above claim this definition makes sense since we take the infimum of a non-empty set. By Lemma 18.11 the set U_r is a closed subset of M. Since γ is continuous we also have $\gamma(T) \in U_r$. Now we have

$$\begin{aligned}
\ell_g(\gamma) \;\geq\; \ell_g(\gamma|_{[0,T]}) \;&= \ell_{\Psi^* g}(\Phi \circ \gamma|_{[0,T]}) && = \int_{t=0}^{t=T} \|(\Phi\circ\gamma)'(t)\|_{\Psi^* g}\, dt \\
&\geq \int_{t=0}^{t=T} C \cdot \|(\Phi\circ\gamma)'(t)\|_{\text{eucl}}\, dt && \geq C \cdot \left\| \int_{t=0}^{t=T} (\Phi\circ\gamma)'(t)\, dt \right\|_{\text{eucl}} \\
&\uparrow && \uparrow \\
&\text{for any } v \in \mathrm{T}_P\overline{B_r(0)} = \mathbb{R}^n \text{ we have} && \text{Integral Inequality Lemma 0.16} \\
&\|v\|_{(\Psi^* g)_P} \;\geq\; \|(\Psi^* g)_P\| \cdot \|v\|_{\text{eucl}} \\
&= C \cdot \|\underbrace{(\Phi\circ\gamma)(T)}_{\|-\|_{\text{eucl}} = r} - \underbrace{(\Phi\circ\gamma(0))}_{=0}\|_{\text{eucl}} \;=\; C \cdot r.
\end{aligned}$$

This concludes the proof of the claim and therefore the proof of Statement (1) of the proposition.

Next we turn to the proof of Statement (2). This means that we need to show that the topology defined by d is the same as the original topology of M. The proof is again somewhat technical and uses ideas similar to the proof of (1). We refer to [**Lee1997**, Lemma 6.2] for the proof.

Finally Statement (3) is just an immediate consequence of the definitions and of Statement (2). ■

Lemma 65.10. Let (M, g) and (N, h) be two connected Riemannian manifolds. Furthermore let $f\colon (M, g) \to (N, h)$ be a local isometry. Then the following hold:

(1) For any piecewise smooth path $\gamma\colon [a, b] \to M$ we have
$$\ell_{(N,h)}(f \circ \gamma) \;=\; \ell_{(M,g)}(\gamma).$$
(2) For any $P, Q \in M$ we have
$$d_{(N,h)}(f(P), f(Q)) \;\leq\; d_{(M,g)}(P, Q).$$

Proof. Let $f\colon (M, g) \to (N, h)$ be a local isometry. We start out with the following claim.

Claim.

(1) For a smooth path $\gamma\colon [c, d] \to M$ and $t \in (c, d)$ we have $\|(f\circ\gamma)'(t)\|_{(N,h)} = \|\gamma'(t)\|_{(M,g)}$.
(2) For any piecewise smooth path $\gamma\colon [a, b] \to M$ we have $\ell_{(N,h)}(f \circ \gamma) = \ell_{(M,g)}(\gamma)$.

Proof.

(1) The first statement is an immediate consequence of the definitions and the hypothesis that f is a local isometry.
(2) By the additivity of the lengths of piecewise smooth paths it suffices to consider the case that $\gamma\colon [a, b] \to M$ is a smooth path. But in that case the equality follows immediately from the definitions and from (1). ⊞

Now let P and Q be two points on M. For any piecewise smooth path p in M from P to Q we have
$$d_{(N,h)}(f(P), f(Q)) \underset{\substack{\uparrow \\ \text{by definition of } d_{(N,h)}}}{\leq} \ell_{(N,h)}(f \circ p) \underset{\substack{\uparrow \\ \text{by the claim}}}{=} \ell_{(M,g)}(p).$$
It follows that the left-hand side is also less or equal than the infimum over all paths on the right-hand side. Thus $d_{(N,h)}(f(P), f(Q)) \leq d_{(M,g)}(P, Q)$. ■

65.4. The hyperbolic distance function.

We start out with the following definition.

Definition. Let (M, g) be a Riemannian manifold. A path $\gamma\colon [0, a] \to M$ is called a geodesic if the following conditions are satisfied:

(1) γ is smooth,
(2) $\|\gamma'(t)\|_g = 1$ for every $t \in [0, a]$ and
(3) $\ell(\gamma) = d_{(M,g)}(\gamma(0), \gamma(a))$.

The following proposition summarizes the key facts about the distance metric on $\mathbb{D}$.

Proposition 65.11.

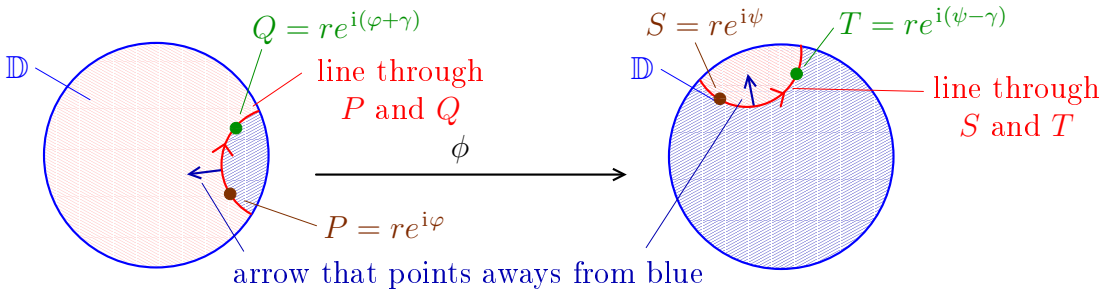
(1) Let $r \in (0, 1)$ and $\varphi \in \mathbb{R}$. In the Riemannian manifold $\mathbb{D}$ the path
$$\begin{array}{rcl} \gamma\colon [0, r] & \to & \mathbb{D} \\ t & \mapsto & t \exp(\mathrm{i}\varphi) \end{array}$$
is, up to reparametrization, the unique shortest path from 0 to $r \cdot \exp(\mathrm{i}\varphi)$.
(2)

$$d_{(\mathbb{D},g)}\big(0, r\cdot\exp(\mathrm{i}\varphi)\big) \;=\; \ell(\gamma) \;=\; \int_{t=0}^{t=r} \frac{\sqrt{2}}{1-|\gamma(t)|^2}\|\gamma'(t)\|_{\mathrm{eucl}}\,dt \;=\; \int_{t=0}^{t=r} \frac{\sqrt{2}}{1-t^2}\,dt.$$

(3) Given $\varphi \in \mathbb{R}$ we have

$$\lim_{r\to 1} d_{(\mathbb{D},g)}\big(0, r\cdot\exp(\mathrm{i}\varphi)\big) \;=\; \infty.$$

(4) Given any P and Q in $\mathbb{D}$ there is a unique geodesic from P to Q.



Proof. The first statement can be deduced easily from [**Bon2009**, Lemma 2.4 and Proposition 2.22]. The second statement follows immediately from the first statement, and the third statement is a straightforward consequence of the second statement. For the fourth statement, note that it suffices to prove it for $P = 0$. In that case it is a straightforward consequence of (1). ■

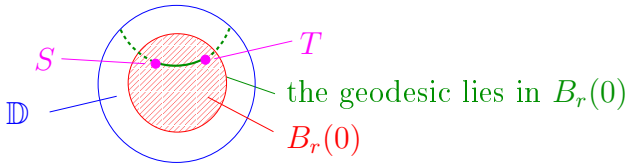
Lemma 65.12. Let (P, Q) and (S, T) be two pairs of distinct points on $\mathbb{D}$ such that $d(P, Q) = d(S, T)$. Then there exists a unique Möbius transformation ϕ with $\phi(P) = S$ and $\phi(Q) = T$.

Example. Let $r \in (0, 1)$, $\varphi \in [0, 2\pi]$, $\psi \in [0, 2\pi]$ and $\gamma \in (0, \pi)$. We consider the pairs of points $P = r\cdot\exp(\mathrm{i}\varphi), Q = r\cdot\exp(\mathrm{i}(\varphi+\gamma))$ and $S = r\cdot\exp(\mathrm{i}\psi), T = r\cdot\exp(\mathrm{i}(\psi-\gamma))$. We then have

$$d(S,T) \;=\; d(T,S) \;=\; d(r\cdot\exp(\mathrm{i}(\psi-\gamma)), r\cdot\exp(\mathrm{i}\psi)) \underset{\substack{\uparrow\\ \text{since rotation by } \varphi+\gamma-\psi \text{ is an isometry}}}{=} d(r\cdot\exp(\mathrm{i}\varphi), r\cdot\exp(\mathrm{i}(\varphi+\gamma))).$$

By Lemma 65.12 there exists a Möbius transformation ϕ with $\phi(P) = S$ and $\phi(Q) = T$. This Möbius transformation is illustrated in the figure below. Recall that from Proposition 65.4 and Lemma 65.6 we know that Möbius transformations preserve hyperbolic lines and that they are orientation-preserving. In particular ϕ sends the hyperbolic line through P and Q to the hyperbolic line through S and T. Since ϕ is orientation-preserving it "swaps" the two sides of the hyperbolic line. We refer to the figure below for an illustration.

Proof of Lemma 65.12. It follows from Proposition 65.4 (3) that, without loss of generality, we can assume that $P = 0$ and $S = 0$. We write $Q = r\cdot\exp(\mathrm{i}\varphi)$ and $T = \exp(\mathrm{i}\psi)$. It is a direct consequence of Proposition 65.11 (1) and our hypothesis that



$$d(0, r\cdot\exp(\mathrm{i}\varphi)) \;=\; d(P,Q) \;=\; d(S,T) \;=\; d(0, s\cdot\exp(\mathrm{i}\psi))$$

that we have $r = s$. But this means that we can apply the rotation by the angle $\varphi - \psi$, which is a Möbius transformation, to turn (P, Q) into (S, T). This proves the existence of

ϕ. The uniqueness follows from the observation, that we had made already on page 1429, that the only Möbius transformations that fix 0 are precisely rotations. ■

Lemma 65.13. Let $P \in \mathbb{D}$ and $r > 0$. Let $S, T \in B_r(P)$. Then the image of the unique geodesic in $\mathbb{D}$ from S to T lies in $B_r(P)$.

Proof. As usual, this time by Propositions 65.4, 65.6 and 65.11, it suffices to prove the lemma for $P = 0$. In this special case the reader will have no troubles providing the elementary argument. We also refer to the figure below for an illustration. ■

Next we recall the following definition from page 289.

Definition. We say that a metric space (X, d) is complete if every Cauchy sequence in (X, d) converges.

The present setting motivates the following definition.

Definition. We say that a connected Riemannian manifold (M, g) is complete if the corresponding metric space $(M, d_{(M,g)})$ is complete.

In the Compact-Complete Proposition 6.10 we showed that every compact metric space is complete. The Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$ are of course not compact, but nonetheless, as we will now see, we can use the Compact-Complete Proposition 6.10 to show that $\mathbb{D}$ and $\mathbb{H}$ are complete.

Lemma 65.14. The Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$ are complete.

Proof. By Proposition 65.3 the two Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$ are isometric. Therefore it suffices to show that $\mathbb{D}$ is complete. We denote by $d = d_{(\mathbb{D},g)}$ the metric on $\mathbb{D}$ corresponding to the Riemannian structure. Let $\{a_n\}_{n\in\mathbb{N}}$ be a Cauchy sequence with respect to d. An elementary argument using the triangle inequality and the definition of a Cauchy sequence shows that there exists a $C \in \mathbb{R}$ such that $d(0, a_n) \leq C$ for all $n \in \mathbb{N}$.

It follows from Proposition 65.11 that there exists an $r \in (0, 1)$ such that all a_n are contained in the closed Euclidean ball $\overline{B}_r^{eucl}(0)$. By the Heine-Borel Theorem 1.24 this ball is a compact subset of $\mathbb{R}^2$, viewed with the usual topology. It follows from Proposition 65.9 that $\overline{B}_r^{eucl}(0)$ is also compact in the topology defined by d. Now we see that $\{a_n\}_{n\in\mathbb{N}}$ is a Cauchy sequence in the compact metric space $(\overline{B}_r^{eucl}(0), d)$. It follows from the Compact-Complete Proposition 6.10 that the sequence converges. ■

Exercises for Chapter 65.

Exercise 65.1. Does the smooth manifold $B^2 \setminus \{0\}$ admit a complete Riemannian metric?

66. The universal covering of surfaces

Throughout this chapter we mean by a *surface* a connected 2-dimensional smooth manifold. For example the surface of genus g, $g \geq 0$, but also $\mathbb{C}$, $\mathbb{C} \setminus \{0,1\}$ and the result of removing finitely many points from Σ_g are surfaces.

Definition. Let M be a surface. We say that a Riemannian structure g on M is hyperbolic if the following two conditions are satisfied:

(1) (M,g) is locally isometric to $\mathbb{D}$, i.e. if given any $P \in M$ there exists an isometry $\Phi\colon U \to V$ from an open neighborhood U of P to an open subset V of $\mathbb{D}$,
(2) (M,g) is complete.

If g is hyperbolic, then we refer to (M,g) as a hyperbolic surface.

Remark. By the Compact-Complete Proposition 6.10 the condition (2) of the definition is automatically satisfied if M is a closed surface.

In this chapter we will pursue the following three goals:

(1) we want to show that for any $g \geq 2$ the surface of genus g is a complex manifold,
(2) we intend to prove that for any $g \geq 2$ the surface of genus g is hyperbolic,
(3) given $g \geq 2$ we want to determine the universal covering of the surface of genus g.

66.1. Hyperbolic surfaces.

In this section we will show that the surfaces of genus ≥ 2 are complex manifolds and that they are hyperbolic. In the subsequent subsection we will then consider more general types of surfaces.

Definition. Let M be a 2-dimensional topological manifold without boundary. A Möbius structure for M is a family of homeomorphisms $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ from open subsets of M to open subsets of $\mathbb{D}$ such that $\bigcup_{i\in I} U_i = M$ and such that for any $i,j \in I$ the transition map

$$\underbrace{\Phi_i(U_i \cap U_j)}_{\subset \mathbb{D}} \xrightarrow{\left(\Phi_i|_{U_i\cap U_j}\right)^{-1}} U_i \cap U_j \xrightarrow{\Phi_j|_{U_i\cap U_j}} \underbrace{\Phi_j(U_i \cap U_j)}_{\subset \mathbb{D}}$$

is given by a Möbius transformation. Sometimes we refer to a smooth manifold together with a Möbius structure as a Möbius manifold.

Example.

(1) We will always view $\mathbb{D}$ as equipped with the Möbius structure that is given by the chart $\mathrm{id}\colon \mathbb{D} \to \mathbb{D}$.
(2) Any open subset of a Möbius manifold is also a Möbius manifold.

The following lemma says that Möbius structures are useful for solving two problems at once: we can use them to show that a smooth manifold is a complex manifold and we can use them to show that a smooth manifold has a hyperbolic structure.

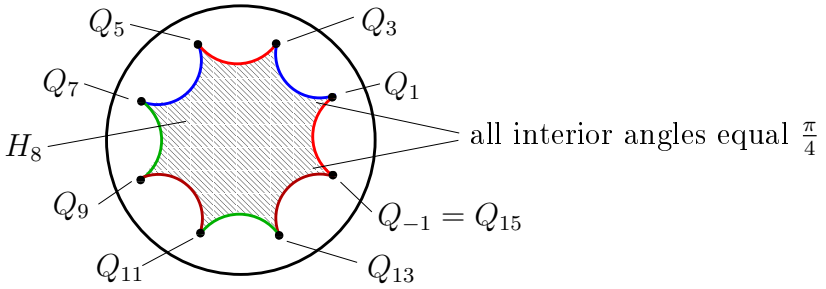
Lemma 66.1. Let M be a surface and let $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ be a Möbius structure for M. Then the following hold:

(1) The charts form a holomorphic atlas for M, in particular M is a complex 1-dimensional smooth manifold.

(2) (a) The smooth manifold M admits a unique Riemannian structure g such that all the charts in the atlas $\{\Phi_i \colon U_i \to V_i\}_{i\in I}$ are isometries.
(b) If the Riemannian structure from (a) is complete, then (M, g) is hyperbolic.

In the following we will always view a Möbius manifold as a 1-dimensional complex manifold and as a Riemannian manifold with the structures coming from Lemma 66.1.

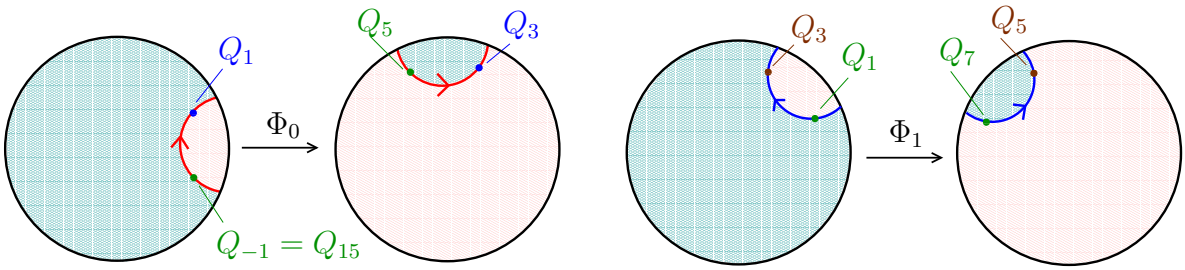
Proof. Let M be a surface and let $\{\Phi_i \colon U_i \to V_i\}_{i\in I}$ be a Möbius structure for M.



(1) The first statement is an immediate consequence of the definitions and of the fact, proved in Proposition 65.4 (2), that Möbius transformations are biholomorphisms.
(2) (a) We denote by g the Riemannian structure on $\mathbb{D}$. We define a Riemannian structure on M as follows. Let $P \in M$. We pick a chart $\Phi_i \colon U_i \to V_i$ from our Möbius structure and we define $h_P := \Phi_i^*(g_{\Phi_i(P)})$. Now suppose that we had picked a different chart Φ_j from the Möbius structure. The transition map from Φ_i to Φ_j is by definition a Möbius transformation, which is an isometry by Proposition 65.4 (2). It follows easily that Φ_j gives rise to the same definition of h_P. It is now straightforward to verify that this defines a Riemannian structure on M and that it has the desired properties.
(b) This statement is an immediate consequence of (a) and of the definition of a hyperbolic surface. ■

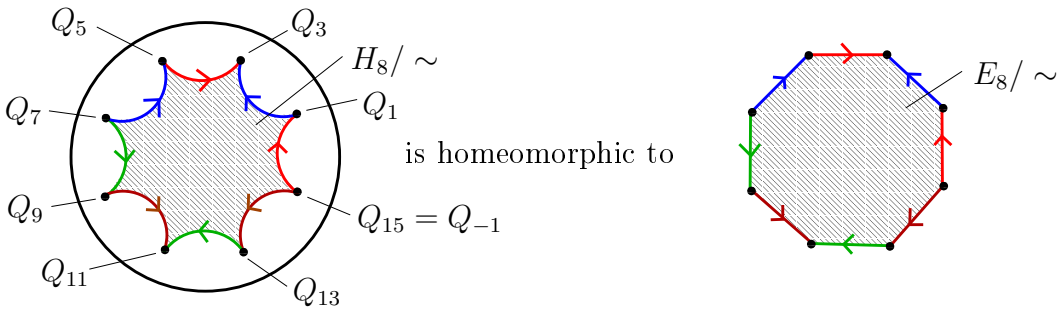
The following proposition gives in particular an affirmative answer to Question 32.25.

Proposition 66.2. Let $g \geq 2$. Then the following hold:
(1) The surface of genus g admits a Möbius structure.
(2) The surface of genus g admits the structure of a 1-dimensional complex manifold.
(3) The surface of genus g admits a hyperbolic Riemannian structure.



Proof. We prove the proposition for the case that $g = 2$. The general case is proved by almost the same argument.

We first show that the surface of genus 2 admits a Möbius structure. By [**Bon2009**, Lemma 5.3] (see also [**Frie2016a**, Lemma 21.5]) there exists an $r > 0$ such that the interior angle at any vertex of the hyperbolic octagon H_8 in $\mathbb{D}$, defined by $Q_k = r \cdot \exp(2\pi \mathrm{i} k/16)$, $k = 1, 3, \ldots, 15$, equals $\frac{\pi}{4}$.[763]



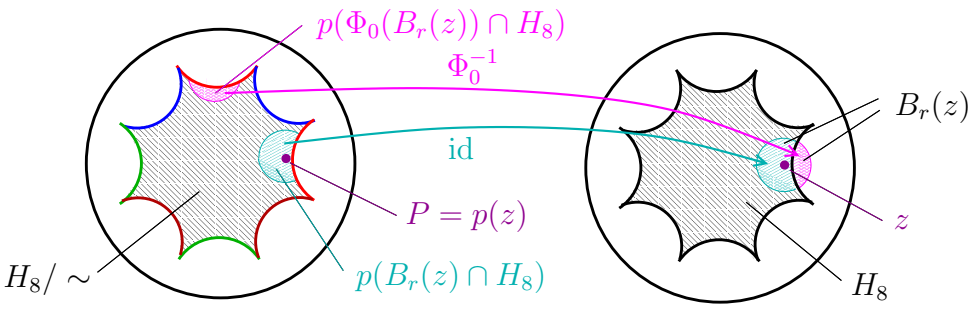
[763]Here is a sketch for the proof: For $r \to 0$ the interior angle converges to the interior angle of a Euclidean regular octagon, namely $\frac{3\pi}{4}$, whereas for $r \to \infty$ the interior angle converges to 0. The interior angle changes continuously with r (that is sort of clear, except that it is somewhat painful to provide a rigorous proof), so by the Intermediate Value Theorem there exists an r such that the interior angle equals $\frac{\pi}{4}$.

Let $k \in \{0,1,4,5\}$. By Lemma 65.12 and the example on page 1437 there exists a unique Möbius transformation Φ_k with $\Phi_k(Q_{2k-1}) = Q_{2k+5}$ and $\Phi_k(Q_{2k+1}) = Q_{2k+3}$. The Möbius transformations Φ_0 and Φ_1 are illustrated in the figure below.

Given $k \in \{0,1,4,5\}$ we declare any point P on the edge connecting Q_{2k-1} and Q_{2k+1} to be equivalent to $\Phi_k(P)$. We denote by $\sim$ the equivalence relation that is generated by these equivalences. It is straightforward to see that $H_8/\sim$ is homeomorphic to the surface of genus 2 that we defined on page 265 as $E_8/\sim$. In the following we denote by $p\colon H_8 \to H_8/\sim$ the natural projection.

Now we will give an explicit Möbius structure for $H_8/\sim$. More precisely, given any $P \in H_8/\sim$ we will give a chart ψ_P such that the transitions maps are given by Möbius transformations. So let $P \in H_8/\sim$.

(1) If $P = p(z)$ for some $z \in \mathring{H}_8$, then the map



$$\begin{array}{rcl} \psi_P\colon p\big(\mathring{H}_8\big) & \to & \mathring{H}_8 \\ p(w) & \mapsto & w \end{array}$$

is a chart around $P = p(z)$.

(2) Now suppose that $P = p(z)$ where z lies in the interior of one of the eight edges of ∂H_8. In the following we deal with the case that z lies on the edge from Q_{-1} to Q_1. We pick an $r > 0$ such that $B_{2r}(z)$ does not contain any of the vertices $Q_1, Q_3, \ldots, Q_{15}$ and does not hit any of the other edges. Then we consider the map

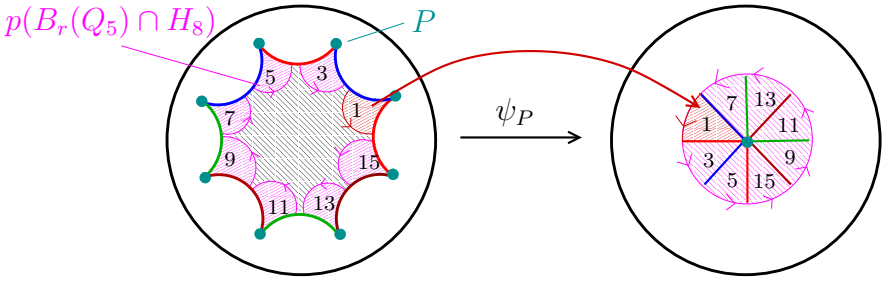
$$\begin{array}{rcl} \psi_P\colon p(B_r(z) \cap H_8) \cup p(\Phi_0(B_r(z)) \cap H_8) & \to & B_r(z) \\ p(w) & \mapsto & \begin{cases} w, & \text{if } w \in B_r(z) \cap H_8 \\ \Phi_0^{-1}(w), & \text{if } w \in \Phi_0(B_r(z)) \cap H_8. \end{cases} \end{array}$$

This map is a chart around $P = p(z)$. We refer to the figure below for an illustration of the definition of the map ψ_P.

(3) Finally suppose that $P = p(Q_1) = \cdots = p(Q_{15})$. We choose $r \in (0, \frac{1}{2}d(Q_{-1}, Q_1))$. Given $k \in \{1, 3, \ldots, 15\}$ we define $\gamma(k)$ via the following table:

k	1	3	5	7	9	11	13	15
$\gamma(k)$	$\frac{3}{4}\pi$	π	$\frac{5}{4}\pi$	$\frac{1}{2}\pi$	$\frac{7}{4}\pi$	0	$\frac{1}{4}\pi$	$\frac{3}{2}\pi$.

Recall that we had chosen the octagon H_8 such that the angle at any vertex equals $\frac{\pi}{4}$. For $k = 1, 3, \ldots, 15$ we can therefore apply Lemma 65.8 to find a unique Möbius transformation θ_k with the following two properties:



(a) $\theta_k(Q_k) = 0$,

(b) The map θ_k applied to the two rays emanating from Q_k equals the two rays $\{s \cdot \exp(\mathrm{i}\gamma(k)) \mid s \geq 0\}$ and $\{s \cdot \exp(\mathrm{i}(\gamma(k) + \frac{\pi}{4})) \mid s \geq 0\}$ emanating from 0.

We consider the map

$$\begin{aligned} \psi_P \colon p(B_r(Q_1) \cap H_8) \cup \cdots \cup p(B_r(Q_{15}) \cap H_8) &\to B_r(0) \\ p(z) &\mapsto \theta_k(z), \quad \text{if } z \in B_r(Q_k) \cap H_8. \end{aligned}$$

We leave it to the reader to verify that ψ_P is well-defined and that it is indeed a homeomorphism. This map is a chart around $P = p(z)$. We refer to the figure below for an illustration of the definition of the map ψ_P.

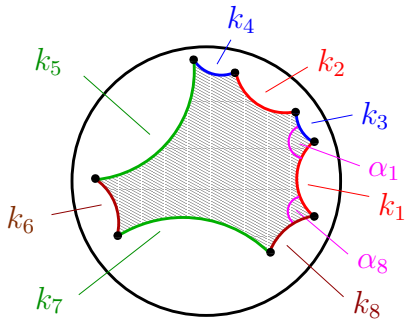
It is straightforward to verify that all the transition maps between the above maps are given by Möbius transformations. We have thus shown that the maps $\{\psi_P\}_{P \in H_8}$ form a Möbius structure for $H_8/\sim$. This concludes the proof of (1).

Now we turn to the proof of (2). The existence of a Möbius structure together with Lemma 66.1 (2) shows immediately that the surface of genus 2 is a 1-dimensional complex manifold.

Finally we provide the proof of (3). In light of (1) and Lemma 66.1 (2) it suffices to show that the Riemannian manifold $(H_8/\sim, g)$ is complete. By Proposition 65.9 the topology on M defined by the metric $d_{(M,g)}$ agrees with the given topology of M. Since M is compact it now follows from the Compact-Complete Proposition 6.10 that (M, g) is complete. ∎

66.2. **More hyperbolic structures on the surfaces of genus $g \geq 2$p.** Now we want to study the question, how many hyperbolic metrics does a surface of genus g admit. To make this question more precise, we introduce the following definition.

Definition. Let M be a surface of genus $g \geq 2$ and let h, h' be two hyperbolic metrics on M. We say h and h' are equivalent if there exists an isometry from (M, h) to (M, h').



This raises the question, whether a surface of genus $g \geq 2$ admits non-equivalent hyperbolic metrics. We return to the construction of a hyperbolic metric in Proposition 66.2. In our construction we started out with a regular $4g$-gon with interior angle $\frac{2\pi}{4g}$ and we identified pairs of sides. Two facts were crucial to obtain a hyperbolic metric:

(1) the sides were identified via an isometry,
(2) the sum of the interior angles equals 2π.

Or put differently, any choice of a $4g$-gon with side lengths $k_1, \dots, k_{4g}$ and interior angles $\alpha_1, \dots, \alpha_{4g}$ that satisfy the equations

$$k_1 = k_3,\ k_2 = k_4,\ \dots,\ k_{4g-3} = k_{4g-1},\ k_{4g-2} = k_{4g} \quad \text{and} \quad \alpha_1 + \dots + \alpha_{4g} = 2\pi$$

gives rise to a hyperbolic metric on a topological space that is homeomorphic to the surface of genus g. It is of course not clear whether different parameters give rise to non-equivalent hyperbolic structures. One way to distinguish them, in principle at least, is to look at the shortest length of a closed curve that is not null-homotopic. We will not elaborate on this procedure.

How many such $4g$-gons are there? On the one hand we have parameters $k_1, k_3, \dots, k_{4g-1}$ and $\alpha_1, \dots, \alpha_{4g}$. On the other hand we have the condition that $\alpha_1 + \dots + \alpha_{4g} = 2\pi$. Furthermore we want a $4g$-gon, so the last angle and the length of the last edge are determined by the others. Thus we obtain two other conditions. Summarizing we have $2g + 4g = 6g$ parameters that need to satisfy 3 conditions. Of course it is not clear which of these Riemannian structures are isometric. This naive discussion suggests that the space of hyperbolic metrics is $(6g-3)$-dimensional. Surprisingly this is not too far off the correct answer, in fact in [**BP1992**, Chapter B.4] the following proposition is proved.

Proposition 66.3. The topological space of hyperbolic metrics on a surface of genus $g \geq 2$ can be viewed as a smooth manifold of dimension $6g - 6$.

We will not make use of this proposition. The topological space of hyperbolic metric is called the *Teichmüller space*, more information can be found at

`https://en.wikipedia.org/wiki/Teichmueller_space`.

The theory is named after Oswald Teichmüller (1913-1943) who was a brilliant mathematician and an ardent Nazi, see

`https://en.wikipedia.org/wiki/Oswald_Teichmueller`

`http://www-history.mcs.st-andrews.ac.uk/Biographies/Teichmuller.html`

and

`https://de.wikipedia.org/wiki/Oswald_Teichmueller`.

66.3. **More examples of hyperbolic surfaces.** In this section we will generalize the discussion from the previous section to surfaces that are non-compact.
In the following let $Q_1 = 1, Q_2 = \mathrm{i}, Q_3 = -1$ and $Q_0 = Q_4 = -\mathrm{i}$. We denote by H_4 the closed, non-compact subset of $\mathbb{D}$ that is bounded by the four hyperbolic lines with endpoints Q_k, Q_{k+1} where $k = 0, 1, 2, 3$. We refer to the figure on page 1445 for an illustration.
We consider the Möbius transformations[764]

$$\Phi_1(z) := (-\mathrm{i}) \cdot \frac{z - \frac{-1+\mathrm{i}}{2}}{1 - \frac{-1-\mathrm{i}}{2} z} \quad \text{and} \quad \Phi_2(z) := (-\mathrm{i}) \cdot \frac{z + \frac{-1-\mathrm{i}}{2}}{1 + \frac{-1+\mathrm{i}}{2} z}.$$

We record a few key properties of Φ_1 and Φ_2 in a lemma.

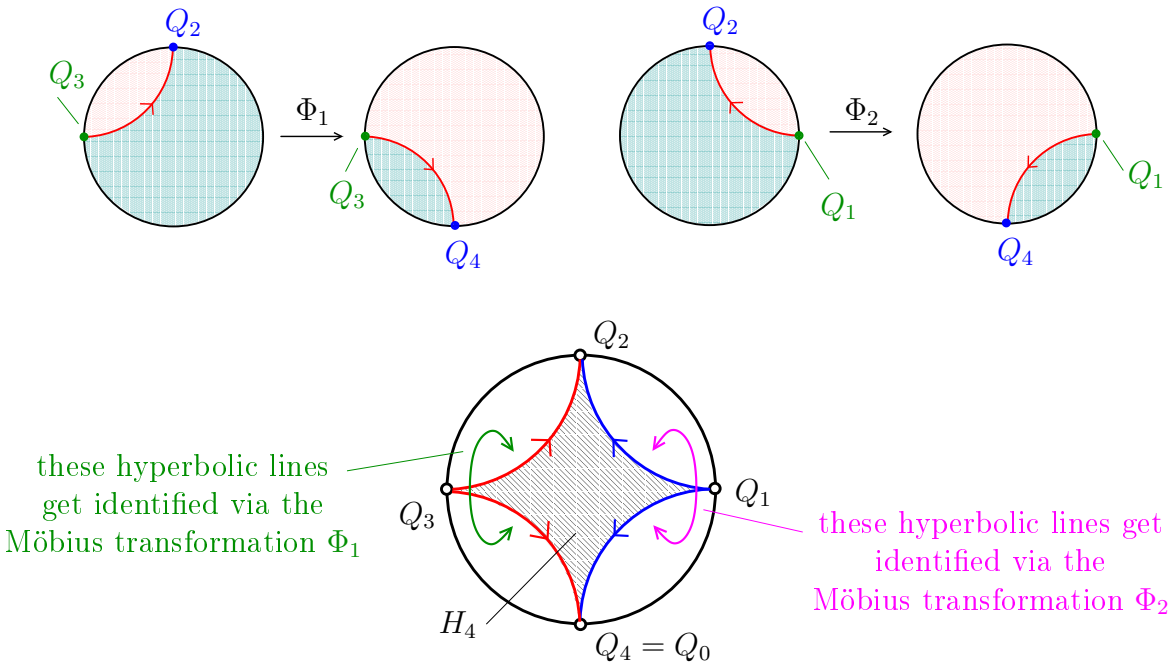
Lemma 66.4.

(1) We have $\Phi_1(Q_2) = Q_4$ and $\Phi_1(Q_3) = Q_3$ and we also have $\Phi_2(Q_2) = Q_4$ and $\Phi_1(Q_1) = Q_1$.
(2) The restriction of Φ_1 to the hyperbolic line with endpoints Q_3 and Q_2 is given by reflection in the x-axis.[765]
(3) The restriction of Φ_2 to the hyperbolic line with endpoints Q_1 and Q_2 is given by reflection in the x-axis.

Proof. The first statement follows immediately from plugging in the points. A straightforward, albeit slightly painful calculation shows that for any $\alpha \in \mathbb{R}$ we have

$$\Phi_1\big(-1 + \mathrm{i} + e^{-\mathrm{i}\alpha}\big) \;=\; -1 - \mathrm{i} + \exp(\mathrm{i}\alpha).$$

This proves the second statement. The third statement is proved by a similarly tedious calculation. ∎



Remark. We consider the Möbius transformation Φ_1 in more detail. It sends the hyperbolic line with endpoints Q_3 and Q_2 to the hyperbolic line with endpoints Q_3 and Q_4. In particular it sends the two halves determined by the hyperbolic lines to one another. Which half gets sent to which half is determined by the fact that Φ_1 is orientation-preserving. We refer to the figure below for an illustration of the Möbius transformations Φ_1 and Φ_2.

Given $k \in \{1, 2\}$ we declare any point P on the line with the endpoints Q_k and Q_{k+1} to be equivalent to $\Phi_{3-k}(P)$. We denote by $\sim$ the equivalence relation that is generated by these equivalences.

---

[764] Recall that a Möbius transformation of $\mathbb{D}$ is a map of the form $\psi(z) = e^{\mathrm{i}\theta} \cdot \frac{z-a}{1-\bar{a}z}$ for some $\theta \in \mathbb{R}$ and $a \in \mathbb{D}$.

[765] The Möbius transformation Φ_1 sends the hyperbolic line with endpoints Q_3 and Q_2 to the hyperbolic line with endpoints Q_3 and Q_4. There are many such Möbius transformations, but the Möbius transformation we picked has the extra property, that on the hyperbolic line it is the "obvious map".

Proposition 66.5.

(1) The topological space $H_4/\sim$ admits a Möbius structure. In particular it is a 1-dimensional complex manifold.
(2) The Riemannian structure on $H_4/\sim$ coming from (1) and Lemma 66.1 is complete.
(3) The topological space $H_4/\sim$ admits a hyperbolic metric.

Proof. We start out with the proof of (1). We have to show that $H_4/\sim$ admits a Möbius structure. The following argument is almost identical to the proof of Proposition 66.2 (1).

We denote by $p\colon H_4 \to H_4/\sim$ the projection . In the following let $P \in H_4/\sim$.

(1) If $P = p(z)$ for some $z \in \mathring{H}_4$, then

$$\begin{array}{rcl} \psi_P\colon p\big(\mathring{H}_4\big) & \to & \mathring{H}_4 \\ p(w) & \mapsto & w \end{array}$$

is a chart around $P = p(z)$.

(2) Now suppose that $P = p(z)$ where z lies on ∂H_4. In the following we deal with the case that z lies on the edge from Q_1 to Q_2. All other cases are dealt with almost the same way. We pick an $r > 0$ such that $B_{2r}(z)$ intersects no other component of ∂H_4. We consider the map

$$\begin{array}{rcl} \psi_P\colon p(B_r(z) \cap H_4) \cup p(\Phi_2(B_r(z)) \cap H_4) & \to & B_r(z) \\ p(w) & \mapsto & \begin{cases} w, & \text{if } w \in B_r(z) \cap H_4 \\ \Phi_2^{-1}(w), & \text{if } w \in \Phi_1^{-1}(B_r(z)) \cap H_4. \end{cases} \end{array}$$

This map is a chart around $P = p(z)$.

The charts that we just constructed form an atlas for $H_4/\sim$. It follows immediately from the definitions that all transition maps are given by Möbius transformations. It follows that the maps ψ_P form a Möbius structure for $H_4/\sim$. As in the proof of Proposition 66.2

it follows that $H_4/\!\sim$ is a 1-dimensional complex manifold and that these charts satisfy the conditions of Lemma 66.1. This concludes the proof of (1).

We continue with the proof of (2). We have to show that the Riemannian structure on $H_4/\!\sim$ coming from (1) and Lemma 66.1 is complete. The subsequent argument is a variation on the proof of the Compact-Complete Proposition 6.10.

We denote by d the metric corresponding to the Riemannian structure on $H_4/\!\sim$. Let $\{a_n\}_{n\in\mathbb{N}}$ be a Cauchy sequence in $H_4/\!\sim$ with respect to d. As in the proof of the Compact-Complete Proposition 6.10 we see that there exists a $C \in \mathbb{R}$ such that $d(0, a_n) \leq C$ for all $n \in \mathbb{N}$.

Claim. There exists an $r \in [0, 1)$ such that for any $z \in H_4$ with $d(0, p(z)) \leq C$ we have $|z| \leq r$.

Proof. Given $s \in [0, 1)$ we set

$$g(s) \;:=\; \int_{t=0}^{t=s} \frac{\sqrt{2}}{1-t^2}\, dt.$$

Clearly we have $\lim_{s\to 1} g(s) = \infty$. In particular there exists an $r \in [0, 1)$ such that $g(s) > C+1$ for all $s \geq \frac{1}{2}r$.

We claim that r has the desired property. So let $z = x + \mathrm{i}y \in H_4$ with $|z| > r$. Since H_4 is a subset of the square spanned by ± 1 and $\pm i$ we see that we have $|z| \leq |x| + |y|$. Put differently, we have $|x| \geq \frac{1}{2}r$ or $|y| \geq \frac{1}{2}r$. Without loss of generality we can assume that $|x| \geq \frac{1}{2}r$.

We need to show that $d(0, p(z)) \geq C + 1$. It suffices to show that for any piecewise smooth path $\gamma\colon [0, a] \to H_4/\!\sim$ with $\gamma(0) = 0$ and $\gamma(a) = p(z)$ we have $\ell(\gamma) \geq C + 1$.

We denote by

$$\begin{array}{rcl} q\colon H_4/\!\sim & \to & (-1, 1) \\ [x + \mathrm{i}y] & \mapsto & x \end{array}$$

the projection onto the real part. It follows from Lemma 66.4 that this map is indeed well-defined. A straightforward calculation shows that for all $t \in [0, a]$ we have

$$\big\|\gamma'(t)\big\|_{H_4/\!\sim} \;\geq\; \big\|(q\circ\gamma)'(t)\big\|_{\mathbb{D}}.$$

It follows that

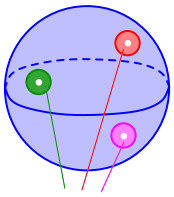
$$\ell(\gamma) \;=\; \int_0^a \big\|\gamma'(t)\big\|_{H_4/\!\sim} dt \;\underset{\text{above inequality}}{\geq} \int_0^a \big\|(q\circ\gamma)'(t)\big\|_{\mathbb{D}}\, dt \;\underset{\text{definition of } d_{(\mathbb{D},g)}}{\geq} d_{(\mathbb{D},g)}(0, \overbrace{q(\gamma(a))}^{=x}) \;=\; g(|x|) \underset{\text{Proposition 65.11}}{\overset{\text{since } |x|\geq \frac{1}{2}r}{\geq}} C+1.$$

⊞

By the above claim the sequence $\{a_n\}_{n\in\mathbb{N}}$ lies in the compact set $p(\{z \in H_4 \mid |z| \leq r\})$. But by the Compact-Complete Proposition 6.10 the metric space $p(\{z \in H_4 \mid |z| \leq r\})$ is complete, so the sequence $\{a_n\}_{n\in\mathbb{N}}$ converges in $p(\{z \in H_4 \mid |z| \leq r\})$, in particular it converges in $p(H_4) = H_4/\!\sim$. Thus we have proved that $H_4/\!\sim$ is complete. This concludes the proof of (2).

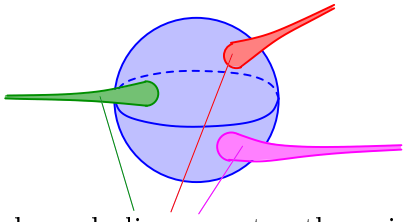
Finally Statement (3) is an immediate consequence of the definition of a hyperbolic metric and of Statement (2). ■

We had just seen in Proposition 66.5 that $H_4/\!\sim$ admits a Möbius structure, in particular it is a 1-dimensional complex manifold. It is relatively straightforward to show that $H_4/\!\sim$ is homeomorphic to the sphere minus three points, or equivalently, to $\mathbb{C}$ minus two points.



Now we show the much stronger statement that $H_4/\sim$ is actually biholomorphic to $\mathbb{C} \setminus \{0,1\}$.

Proposition 66.6. There exists a biholomorphism $H_4/\sim \to \mathbb{C} \setminus \{0,1\}$.



Remark. We equip $H_4/\sim$ with the Riemannian metric g coming from the Möbius structure and we equip $\mathbb{C} \setminus \{0,1\}$ with the usual Euclidean Riemannian metric that we denote by h.

By Proposition 66.5 the metric space $(H_4/\sim, g)$ is complete whereas $(\mathbb{C} \setminus \{0,1\}, h)$ is evidently not complete. Thus we see that the biholomorphism $H_4/\sim \to \mathbb{C} \setminus \{0,1\}$ from Proposition 66.6 is *not* an isometry.

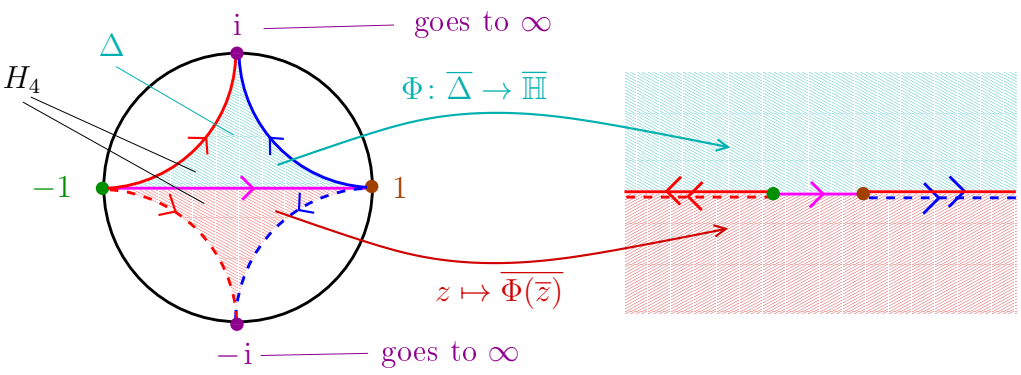
sphere minus three points

neighborhoods of the points we removed

in hyperbolic geometry the neighborhoods become infinitely long open annuli, called cusps

Proof of Proposition 66.6. We denote by Δ the open subset of $\mathbb{D}$ bounded by the three hyperbolic lines with endpoints $-1, 1$ and i. (We refer to the figure below for an illustration of Δ.) It follows from applying the Riemann Mapping Theorem 32.12 together with Carathéodory's Theorem 32.13 that there exists a biholomorphism $\Psi\colon \Delta \to \mathbb{D}$ that extends to a homeomorphism $\Psi\colon \overline{\Delta} \to \overline{\mathbb{D}}$. We combine Ψ with the biholomorphism from $\mathbb{D}$ to $\mathbb{H}$ coming from Proposition 65.3. This way we obtain a biholomorphism $\Phi\colon \Delta \to \mathbb{H}$ that extends to a homeomorphism $\Phi\colon \overline{\Delta} \to \overline{\mathbb{H}}$.

Using Lemma 65.5 we can, if necessary, compose Φ with a Möbius transformation of $\mathbb{H}$, to arrange that $\Phi(i) = \infty$ and that $\Phi(\{-1,1\}) = \{0,1\}$.

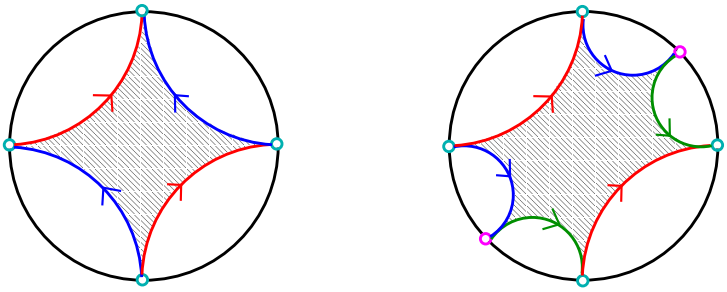


Note that Φ restricts to a homeomorphism $\Phi\colon \partial\overline{\Delta} \to \partial\overline{\mathbb{H}} = \mathbb{R} \cup \{\infty\}$. By the above we have $\Phi(\partial\overline{\Delta}) = \mathbb{R} \setminus \{0,1\}$. Now we consider the map

$$\begin{aligned} \Psi\colon H_4 &\to \mathbb{C} \setminus \{0,1\} \\ z &\mapsto \begin{cases} \Phi(z), & \text{if } z \in \overline{\Delta}, \\ \overline{\Phi(\overline{z})}, & \text{if } \overline{z} \in \overline{\Delta}, \end{cases} \end{aligned}$$

Note that by the above we have $f((-1,1)) = (0,1)$. Thus it follows from the Schwarz Reflection Principle, see Proposition 32.7, that the restriction of Ψ to the interior of H_4 is holomorphic. It follows from Lemma 66.4 that if P and Q are two equivalent points on ∂H_4, then $\Psi(P) = \Psi(Q)$. Therefore the map Ψ factors through a map $H_4/\sim \to \mathbb{C} \setminus \{0,1\}$. Using once again the Schwarz Reflection Principle one can show that this map is in fact a biholomorphism. We leave the verification of this step to the reader. ∎

Definition. Given $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$ we now denote by $F_{g,n}$ the surface that is obtained from the surface of genus g by removing n points. We refer to $F_{g,n}$ as the n-punctured surface of genus g.



For example the three-punctured sphere $F_{0,3}$ is the sphere with three points removed. As we pointed out above, $F_{0,3}$ is diffeomorphic to $\mathbb{C} \setminus \{0,1\}$. In particular, as we have just

seen, the three-punctured sphere admits a hyperbolic structure. The following theorem says that "most" surfaces admit a hyperbolic structure.

Theorem 66.7. Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}_0$. If $2g + n - 2 > 0$, then $F_{g,n}$ admits a hyperbolic structure.

Sketch of a proof. Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}_0$. If $2g + n - 2 > 0$ then variations on the argument of Propositions 66.2 and 66.5 show that $F_{g,n}$ admits a hyperbolic metric. In the figure below we sketch the constructions needed to show that the once-punctured and the twice-punctured torus have a Möbius structure. The proof that the corresponding Riemannian manifolds are complete is similar to the proof of Proposition 66.5. ■

once punctured torus twice punctured torus

66.4. The universal covering of surfaces.

Definition. Let $f\colon M \to N$ be a map between two Möbius manifolds.

(1) We say that f is a Möbius map if for every two chart $\Phi\colon U \to V$ in the Möbius structure of M and any chart $\Psi\colon X \to Y$ in the Möbius structure of N the restriction of the map

$$\underbrace{\Phi(U \cap f^{-1}(X))}_{\subset \mathbb{D}} \xrightarrow{\Psi \circ f \circ \Phi^{-1}} \underbrace{\Psi(X \cap f(U))}_{\subset \mathbb{D}}$$

to any component of $\Phi(U \cap f^{-1}(X))$ is given by a Möbius transformation.

(2) We say that f is a Möbius isomorphism, if f is a Möbius map, if f is a bijection, and if f^{-1} is also a Möbius map.

The following lemma is an immediate consequence of the definitions and the fact, proved in Proposition 65.4, that Möbius transformations are biholomorphisms and isometries.

Lemma 66.8. Let M and N be two Möbius manifolds and let $f\colon M \to N$ be a Möbius map. Then the following two statements hold:

(1) the map f is a local biholomorphism,
(2) the map f is a local isometry.

The following theorem is the main result of this chapter.

Theorem 66.9. (Hadamard's Theorem) Let $g \geq 2$, and let $M = H_{4g}/\sim$ be the surface of genus g with the Möbius structure constructed in Proposition 66.2. Then there exists a covering map $p\colon \mathbb{D} \to M$ with the following properties:

(1) p is a Möbius map,
(2) p is a local isometry,
(3) p is a local biholomorphism.

The hyperbolic disk $\mathbb{D}$ is of course simply connected. The theorem thus says that for any $g \geq 2$ the hyperbolic disk $\mathbb{D}$ is the universal covering of the surface of genus g. Thus we have now answered Question 61.12.
The proof of Theorem 66.9 will require the following two sections.

66.5. **Proof of Theorem 66.9 I.** In this section we will lay the technical foundations for the proof of Theorem 66.9.
In the following lemma we first summarize a few properties of Möbius maps.

Lemma 66.10.

(1) If $U \subset \mathbb{D}$ is a connected subset and if $f\colon U \to \mathbb{D}$ is a Möbius map, then f is given by a Möbius transformation.
(2) Let $f\colon M \to N$ be a map between two Möbius manifolds. If f is locally a Möbius map, then f is a Möbius map.
(3) The composition of two Möbius maps is again a Möbius map.
(4) A bijective Möbius map is a Möbius isomorphism.

Proof.

(1) Let $U \subset \mathbb{D}$ be a connected subset and let $f\colon U \to \mathbb{D}$ be a Möbius map. It follows from Proposition 65.4 (4) that given $P \in U$ there exists a unique Möbius transformation ϕ_P such that $f = \phi_P$ in an open neighborhood of P. We consider the map

$$\begin{array}{rcl} \phi\colon U & \to & \text{set of all Möbius transformations} \\ P & \mapsto & \phi_P. \end{array}$$

We equip the right-hand side of the map ϕ with the discrete topology. It follows from the definitions that this map is continuous. But then it follows from the Connected-to-Discrete Lemma 2.27 that this map is constant. But that is exactly what we had tried to show.
(2) This statement follows immediately from (1) and the definitions.
(3) This statement is an immediate consequence of definitions and the fact, proved in Proposition 65.4, that the compositions of two Möbius transformations is again a Möbius transformation.
(4) Let $f\colon M \to N$ be a bijective Möbius map. In Proposition 65.4 we saw that the inverse of a Möbius transformation is again a Möbius transformation. It follows that

f^{-1} is locally a Möbius map. But then it follows from (2), that f^{-1} is in fact a Möbius map. ■

Lemma 66.11. Let U be an open connected subset of $\mathbb{D}$ and let M be a Möbius manifold. Furthermore let $\Phi, \Psi \colon U \to M$ be two Möbius maps.[766] Suppose one of the following two conditions is satisfied:

(1) There exists an open non-empty subset of U on which Φ and Ψ agree, or
(2) there exists a point $Q \in U$ with $\Phi(Q) = \Psi(Q)$ and a non-zero vector $v \in \mathrm{T}_Q\mathbb{D}$ such that $\mathrm{D}\Phi_Q(v) = \mathrm{D}\Psi_Q(v)$,

then the Möbius maps Φ and Ψ agree on all of U.

Proof. Let U be an open connected subset of $\mathbb{D}$, let M be a Möbius manifold and let $\Phi, \Psi \colon U \to M$ be two Möbius maps. We consider one more statement:

(3) There exists a point $Q \in U$ such that $\Phi(Q) = \Psi(Q)$ and such that $\mathrm{D}\Phi_Q = \mathrm{D}\Psi_Q$.

Clearly we have (1) $\Rightarrow$ (3). We also have (2) $\Rightarrow$ (3). Indeed, the differentials $\mathrm{D}\Phi_Q$ and $\mathrm{D}\Psi_Q$ are homomorphisms between two 1-dimensional complex vector spaces. So if they are agree on one non-zero vector, then they agree on all of the vector space $\mathrm{T}_Q\mathbb{D}$.

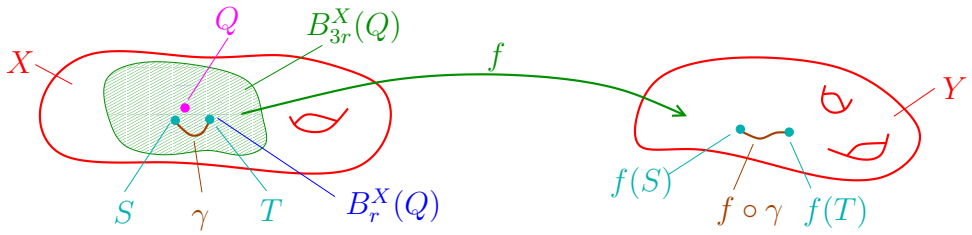
So it suffices to show that if (3) is satisfied, then the maps Φ and Ψ agree on all of U. So suppose that there exists a point $Q \in U$ such that $\Phi(Q) = \Psi(Q)$ and such that $\mathrm{D}\Phi_Q = \mathrm{D}\Psi_Q$. We consider

$$Y \;:=\; \{P \in U \mid \Phi(P) = \Psi(P) \text{ and } \mathrm{D}\Phi_P = \mathrm{D}\Psi_P\}.$$

By our hypothesis we know that Y contains Q, in particular Y is non-empty. Since Φ and Ψ are smooth it follows that Y is closed. It remains to show that Y is open.

So let $P \in Y$. We pick a map $\Theta \colon W \to \mathbb{D}$ from the Möbius structure of M such that W is an open neighborhood of $\Phi(P) = \Psi(P)$. We denote by V the component of $\Phi^{-1}(W) \cap \Psi^{-1}(W)$ that contains P. Since Φ and Ψ are Möbius maps it follows from Lemma 66.10 (3) that the maps $\Theta \circ \Phi \colon V \to \mathbb{D}$ and $\Theta \circ \Psi \colon V \to \mathbb{D}$ are also Möbius maps. Since V is connected it follows from Lemma 66.10 (1) that both maps are given by Möbius transformations. These two Möbius transformations agree at P and they have the same differential at P. It follows from Proposition 65.4 (5) that Φ and Ψ agree on an open neighborhood of P. This shows that Y is also open. ■

Definition. Let M be a Möbius manifold and let $Q \in M$ and $r > 0$. We say $B_r^M(Q)$ is small if there exists a Möbius isomorphism $\Omega \colon B_r^{\mathbb{D}}(0) \to B_r^M(Q)$ with $\Omega(0) = Q$.



Proposition 66.12. Let M be a Möbius manifold and let $Q \in M$. Then there exists an $r > 0$ such that $B_r^M(Q)$ is small.

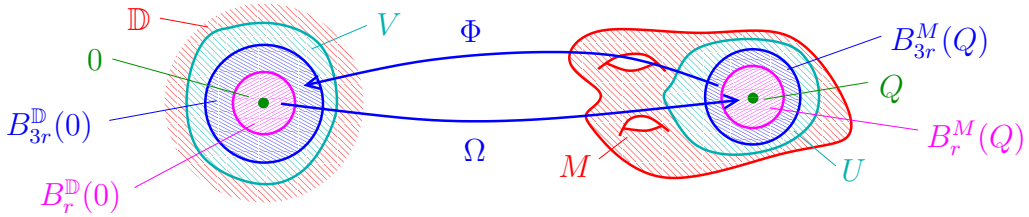
In the proof of Proposition 66.12 we will make use of the following lemma.

Lemma 66.13. Let (X, g) and (Y, h) be Riemannian manifolds. Let $Q \in X$ and $r > 0$. Let $f \colon B_{3r}^X(Q) \to (Y, h)$ be a local isometry and let $S, T \in B_r^X(Q)$. Then we have

$$d_Y(f(S), f(T)) \;\leq\; d_X(S, T).$$

[766] Here we view $U \subset \mathbb{D}$ as equipped with the obvious Möbius structure.

Proof. Let $S, T \in B^X_r(Q)$. Furthermore let $\epsilon > 0$. By the triangle inequality we have $d_X(S,T) < 2r$. In particular there exists a piecewise smooth path γ in X from S to T such that $\ell_X(\gamma) < 2r$ and with $\ell_X(\gamma) < d_X(S,T) + \epsilon$. Given any t we have



$$d_X(Q, \gamma(t)) \;\leq\; d_X(Q,S) + d_X(S, \gamma(t)) \;<\; r + \ell_X(\gamma) \;<\; 3r.$$

Thus we have shown that the image of γ lies in $B^X_{3r}(Q)$. In particular the image of γ lies in the domain of f. Thus we see that

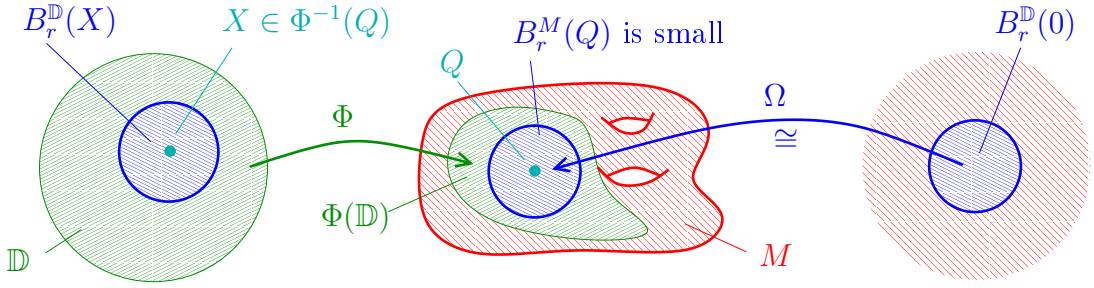
$$d_Y(f(S), f(T)) \underset{\substack{\uparrow \\ \text{since } f\circ\gamma \text{ is a path from} \\ f(S) \text{ to } f(T)}}{\leq} \ell_Y(f \circ \gamma) \underset{\substack{\uparrow \\ \text{by Lemma 65.10, since} \\ f \text{ is a local isometry}}}{=} \ell_X(\gamma) \;<\; d_X(S,T) + \epsilon.$$

Since this inequality holds for all $\epsilon > 0$ we see that $d_Y(f(S), f(T)) \leq d_X(S,T)$. ∎

Proof of Proposition 66.12. Let M be a Möbius manifold and let $Q \in M$. We pick a map $\Phi\colon U \to V$ from the Möbius structure of M such that U is an open neighborhood of Q. By Proposition 65.4 (3), after possibly composing Φ with a Möbius transformation, we can furthermore assume that $\Phi(Q) = 0$. We write $\Omega := \Phi^{-1}$. By Proposition 65.9 (3) and by the openness of V there exists an $r > 0$ such that $B^M_{3r}(Q) \subset U$ and such that $B^{\mathbb{D}}_{3r}(0) \subset V$.[767]

It follows immediately from Lemmas 66.8 and 66.13 and from our choice of r that the following holds:

(1) For any $S, T \in B^M_r(Q)$ we have $d_{\mathbb{D}}(\Phi(S), \Phi(T)) \leq d_M(S,T)$.
(2) For any $S, T \in B^{\mathbb{D}}_r(Q)$ we have $d_M(\Omega(S), \Omega(T)) \leq d_{\mathbb{D}}(S,T)$.



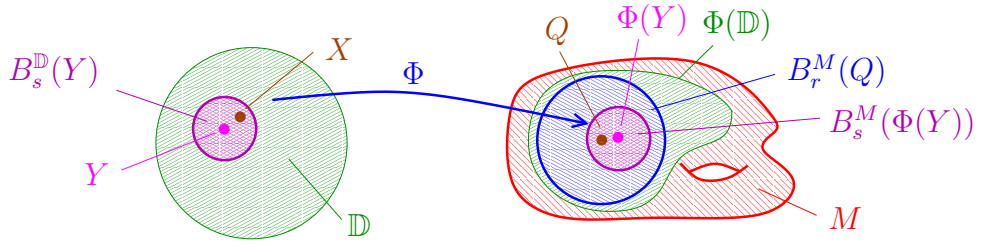
It follows immediately from these two inequalities, from $\Phi(Q) = 0$ and from the fact that $\Phi = \Omega^{-1}$ that Ω restricts to an isometry $\Omega\colon (B^{\mathbb{D}}_r(0), d_{\mathbb{D}}) \to (B^M_r(Q), d_M)$ of metric spaces which is furthermore a bijection. Furthermore, since Φ is a Möbius isomorphism it follows that the inverse map $\Omega = \Phi^{-1}\colon (B^{\mathbb{D}}_r(0), d_{\mathbb{D}}) \to (B^M_r(Q), d_M)$ is also a Möbius isomorphism. ∎

[767] Note the discrete factor 3 in the radius of the ball.

Lemma 66.14. Let M be a Möbius manifold. Let $Q \in M$ and let $r > 0$ such that $B_r^M(Q)$ is small. Let $\Phi\colon \mathbb{D} \to M$ be a Möbius map such that $B_r^M(Q) \subset \Phi(\mathbb{D})$. Then the following hold:

(1) For any $X \in \Phi^{-1}(Q)$ the map Φ restricts to a Möbius isomorphism $B_r^{\mathbb{D}}(X) \to B_r^M(Q)$.
(2) Let $s \leq \frac{r}{2}$ and let $Y \in \mathbb{D}$ such that $\Phi(Y) \in B_s^M(Q)$. Then there exists an $X \in \Phi^{-1}(Q)$ with $Y \in B_s^{\mathbb{D}}(X)$.

Proof. Let M be a Möbius manifold. Let $Q \in M$ and let $r > 0$ such that $B_r^M(Q)$ is small. We pick a Möbius isomorphism $\Omega\colon B_r^{\mathbb{D}}(0) \to B_r^M(Q)$ as in the definition of "small". Let $\Phi\colon \mathbb{D} \to M$ be a Möbius map such that $B_r^M(Q) \subset \Phi(\mathbb{D})$.



(1) Let $X \in \Phi^{-1}(Q)$. It follows immediately from the fact that Möbius maps are local isometries and from Lemma 66.13 that $\Phi(B_r^{\mathbb{D}}(X)) \subset B_r^M(Q)$. Therefore we can consider the Möbius map $\Omega^{-1} \circ \Phi\colon B_r^{\mathbb{D}}(X) \to B_r^{\mathbb{D}}(0)$. By Lemma 66.10 this Möbius map is the restriction of a Möbius transformation. In particular it is a Möbius isomorphism. But since Ω is a Möbius isomorphism as well we obtain that $\Phi\colon B_r^{\mathbb{D}}(X) \to B_r^M(Q)$ is also a Möbius isomorphism.

(2) Let $s \leq \frac{r}{2}$ and let $Y \in \mathbb{D}$ such that $\Phi(Y) \in B_s^M(Q)$, i.e. such that $d_M(Q, \Phi(Y)) < s$. By the triangle inequality we have

$$B_s^M(\Phi(Y)) \subset B_{2s}^M(Q) \subset B_r^M(Q).$$

The same argument as in (1) shows that the map Φ restricts to a Möbius isomorphism $B_s^{\mathbb{D}}(Y) \to B_s^M(\Phi(Y))$. We have $d_M(Q, \Phi(Y)) < s$, i.e. we have $Q \in B_s^M(\Phi(Y))$. Hence there exists an $X \in B_s^{\mathbb{D}}(Y)$ with $\Phi(X) = Q$. ∎

66.6. **Proof of Theorem 66.9 II.** In this section we will now finally provide the proof of Theorem 66.9. We will only cover the case $g = 2$, the proof of the general case is almost identical.

Throughout this section let $M = H_8/\sim$ be the surface of genus 2 with the Möbius structure constructed in Proposition 66.2. In the following we will show that there exists a Möbius

map $p\colon \mathbb{D} \to M$ that is in fact a covering map. It then follows from Lemma 66.8 that p is also a local isometry and a local biholomorphism.
For the remainder of the proof we adopt the following notation and conventions.

(1) We view $\mathring{H}_8$ as a subset of $\mathbb{D}$ and also of $H_8/\!\sim$.
(2) Given $Z \in \mathbb{D}$ we denote by
$$\begin{array}{rccc} \gamma_Z\colon [0,1] & \to & \mathbb{D} \\ t & \mapsto & t \cdot Z \end{array}$$
the radial path from the origin $0 \in \mathbb{D}$ to Z.
(3) We say that $U \subset \mathbb{D}$ is *convex* if it is convex in the usual Euclidean sense, i.e. if given any $P, Q \in U$ the points $t \cdot P + (1-t) \cdot Q$, $t \in [0,1]$ also lie in U. On several occasions throughout the proof we will make use of the following elementary observations:
(a) convex sets are path-connected,
(b) the intersection of two convex sets is also convex,
in particular, combining (a) and (b) we get
(c) the intersection of two convex sets is path-connected.

Our first goal is to construct a suitable map $p\colon \mathbb{D} \to M = H_8/\!\sim$. So let $Z \in \mathbb{D}$. We write $\gamma = \gamma_Z$. We say $t \in [0,1]$ is *good* if there exists a convex open neighborhood U of $\gamma([0,t])$ and a map $\Psi\colon U \to M$ which has the following properties:

(i) Ψ is a Möbius map,
(ii) it restricts to the identity on $\mathring{H}_8 \cap U \subset M$.

We start out with the following lemma.

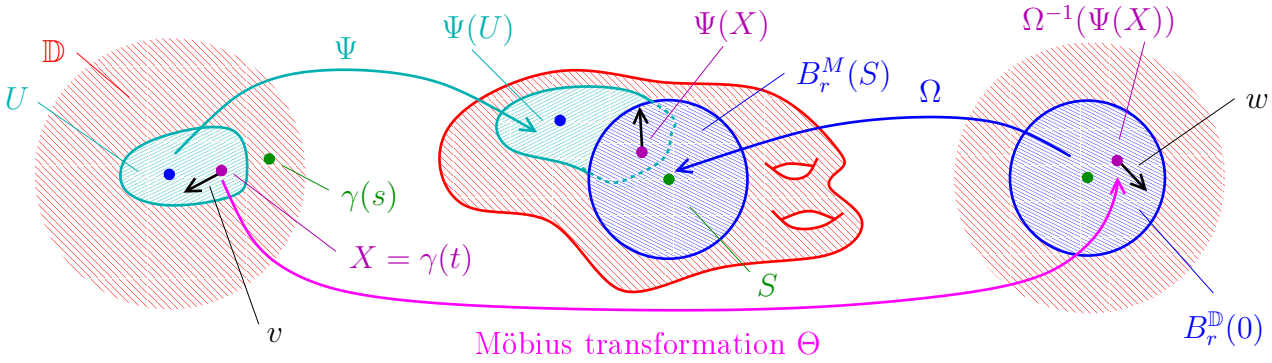
Lemma 66.15. The point $t = 1$ is good.

Proof. We set
$$T \;:=\; \{t \in [0,1] \mid t \text{ is good}\}.$$
We start out with the following observations:

(1) We have that $0 \in T$ since the identity on the open neighborhood $\mathring{H}_8$ of 0 has the required properties.[768]
(2) Being good is clearly an open condition, hence $T \subset [0,1]$ is open.

We want to show that $T = [0,1]$. By the above, and since $[0,1]$ is connected, it suffices to show that $s := \sup(T)$ is good.

Since $0 \in S$ and since T is open we see that $s > 0$. Therefore there exists an increasing sequence $\{t_n\}_{n\in\mathbb{N}}$ of good numbers $t_n \in [0,t)$ that converges to s. Since each t_n is good we can pick for each n a convex open neighborhood U_n of $\gamma([0,t_n])$ and a map $\Psi_n\colon U_n \to M$ that has the desired properties (i) and (ii).



Let $m, n \in \mathbb{N}$. The Möbius maps Ψ_m and Ψ_n agree on the open non-empty connected subset $\mathring{H}_8 \cap U_n \cap U_m$. It follows from Lemma 66.11 that the maps Ψ_m and Ψ_n agree on $U_n \cap U_m$.

By the continuity of γ the sequence $\{\gamma(t_n)\}_{n\in\mathbb{N}}$ converges to $\gamma(t)$, in particular it is a Cauchy sequence with respect to $d_{\mathbb{D}}$. It follows from Lemma 65.10 that $\{\Psi_n(\gamma(t_n))\}_{n\in\mathbb{N}}$

[768]Here we use that for each point $Z \in \mathring{H}_8$ the identity map $\mathrm{id}\colon \mathring{H}_8 \to \mathring{H}_8$ is part of the Möbius structure of M.

is a Cauchy sequence with respect to d_M.[769] It follows from Proposition 66.2 that the metric space $(M = H_8/\!\sim, d_M)$ is complete. Therefore the Cauchy sequence $\{\Psi_n(\gamma(t_n))\}_{n\in\mathbb{N}}$ converges to a point $S \in M$.

It follows from Proposition 66.12 that there exists an $r > 0$ and a Möbius isomorphism $\Omega\colon B_r^{\mathbb{D}}(0) \to B_r^M(S)$ such that $\Omega(0) = S$. We pick an n such that $\Psi_n(\gamma(t_n)) \in B_r^M(S)$ and such that $d_{\mathbb{D}}(\gamma(t), \gamma(s)) < r$. We write $t = t_n, \Psi = \Psi_n, U = U_n$ and we write $X = \gamma(t)$. Let $v \in \mathrm{T}_X\mathbb{D}$ be a non-zero vector. We let $w := d(\Omega^{-1} \circ \Psi)_X(v)$. The Möbius maps Ω and Ψ are in particular local isometries, therefore we have $\|w\| = \|v\|$. It follows from Proposition 65.4 (4) that there exists a Möbius transformation Θ with $\Theta(X) = \Omega^{-1}(\Psi(X))$ and such that $d\Theta_X(v) = w$.

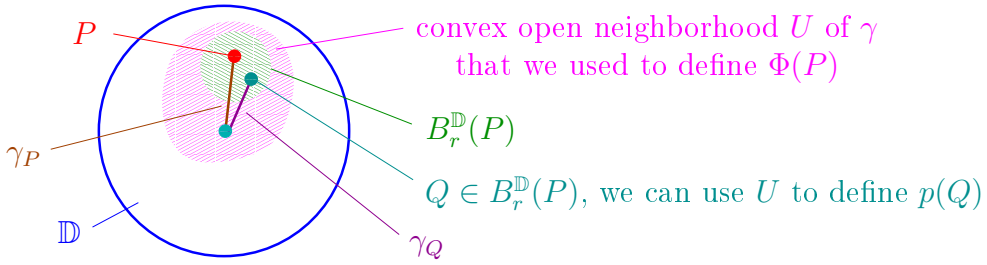
The Möbius maps $\Omega \circ \Theta\colon B_r^{\mathbb{D}}(X) \to M$ and $\Psi\colon U \to M$ agree at $X = \gamma(t)$ and we have $\mathrm{D}(\Omega \circ \Theta)_X(v) = \mathrm{D}\Psi_X(v)$. It follows from Lemma 66.11 that $\Omega \circ \Theta$ and Ψ agree on the path-connected set $B_r^{\mathbb{D}}(X) \cap U$.

Now we consider the map

$$\begin{array}{rcl} \Phi\colon U \cup B_r^{\mathbb{D}}(\gamma(t)) & \to & M \\ Q & \mapsto & \begin{cases} \Psi(Q), & \text{if } Q \in U, \\ \Omega^{-1}(\Theta(Q)), & \text{if } Q \in B_r^{\mathbb{D}}(\gamma(t)). \end{cases} \end{array}$$

By the above discussion this map is well-defined and it is locally a Möbius map. It follows from Lemma 66.10 (3) that this map is a Möbius map. It follows from $d_{\mathbb{D}}(\gamma(t), \gamma(s)) < r$ and the fact that γ is a geodesic in $\mathbb{D}$ that $\gamma([t, s]) \subset B_r^{\mathbb{D}}(\gamma(t))$, in particular $U \cup B_r^{\mathbb{D}}(\gamma(t))$ is an open subset of $\mathbb{D}$ that contains $\gamma([0, t]) \cup \gamma([t, s]) = \gamma([0, s])$. It is now straightforward to see that we can find a *convex* open subset W of $U \cup B_r^{\mathbb{D}}(\gamma(t))$ that contains $\gamma([0, s])$. The Möbius map $\Phi\colon W \to M$ now certifies that s is also good. ∎

Thus we have now shown that there exists a convex open neighborhood U of $\gamma([0, 1])$ and a local isometry $\Psi\colon U \to H_8/\!\sim$ which agrees with the identity map on $U \cap \mathring{H}_8$. We define $p(Z) := \Psi(Z)$. By Lemma 66.11 this definition does not depend on the choice of U and Ψ.



---

[769] Indeed, suppose we have $\epsilon > 0$. Since $\{\gamma(t_n)\}_{n\in\mathbb{N}}$ is a Cauchy sequence there exists an N such that $d_{\mathbb{D}}(\gamma(t_m), \gamma(t_n)) < \epsilon$ for all $m, n \geq N$. Now let $m, n \geq N$. Without loss of generality we have $m > n$. Then

$$d_M(\Psi_m(\gamma(t_m)), \Psi_n(\gamma(t_n))) \underset{\uparrow}{=} d_M(\Psi_m(\gamma(t_m)), \Psi_m(\gamma(t_n))) \underset{\uparrow}{\leq} d_{\mathbb{D}}(\gamma(t_m), \gamma(t_n)) < \epsilon.$$

since Ψ_m and Ψ_n agree on $\gamma|_{[0,t_n]}$ — Lemma 65.10

Lemma 66.16. The map $p\colon \mathbb{D} \to M$ is a Möbius map.

Proof. By Lemma 66.10 (2) it suffices to show that p is locally a Möbius map. This means that it suffices to show that every point $P \in \mathbb{D}$ admits an open neighborhood W such that the restriction of p to W is a Möbius map. Thus let $P \in \mathbb{D}$. By the above claim there exists a convex open neighborhood U of $\gamma_P([0,1])$ and a Möbius map $\Psi\colon U \to H_8/\!\sim$ which restricts to the identity on $U \cap \mathring{H}_8$. Since U is open we can find an $r > 0$ such that for all $Q \in B_r^{\mathbb{D}}(P)$ the image of the radial path γ_Q from 0 to Q also lies in U. (We refer to the above figure for an illustration.) This implies that we can use the Möbius map $\Psi\colon U \to M$ to define p for any $Q \in B_r^{\mathbb{D}}(P)$. Put differently, $p = \Psi$ on $B_r^{\mathbb{D}}(P)$. We have thus shown that the restriction of p to the open neighborhood $W = B_r^{\mathbb{D}}(P)$ of P is a Möbius map. ∎

The following lemma now concludes the proof of Theorem 66.9

Lemma 66.17. The map $p\colon \mathbb{D} \to M = H_8/\!\sim$ is a covering map.

Proof. First we show that the map $p\colon \mathbb{D} \to M = H_8/\!\sim$ is surjective. Recall that by construction p is the identity on $\mathring{H}_8$. Since p is continuous[770] it follows that the restriction of p to $H_8 \to M = H_8/\!\sim$ is surjective.[771]

It remains to show that every $Q \in M$ admits a uniformly covered neighborhood. Let $Q \in M$. By Proposition 66.12 there exists an $r > 0$ such that $B_{2r}^M(Q)$ is small.[772] We claim that $B_r^M(Q)$ is uniformly covered. More precisely, we make the following claims:

(1) $p^{-1}(B_r^M(Q)) = \bigcup_{X \in p^{-1}(Q)} B_r^{\mathbb{D}}(X)$,
(2) for $X \neq X' \in p^{-1}(Q)$ we have $B_r^{\mathbb{D}}(X) \cap B_r^{\mathbb{D}}(X') = \varnothing$,
(3) given any $X \in p^{-1}(Q)$ the restriction of p to $B_r^{\mathbb{D}}(X) \to B_r^M(Q)$ is a homeomorphism.

We apply Lemma 66.14 to the map $p\colon \mathbb{D} \to M$. It gives us the following three facts:

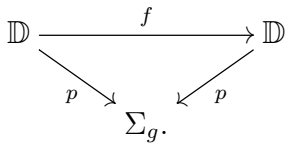
(a) If $Y \in \mathbb{D}$ satisfies $p(Y) \in B_r^M(Q)$, then there exists an $X \in p^{-1}(Q)$ with $Y \in B_r^{\mathbb{D}}(X)$.
(b) For any $X \in p^{-1}(Q)$ the restriction of p to $B_r^{\mathbb{D}}(X) \to B_r^M(Q)$ is a Möbius isomorphism, in particular it is a homeomorphism.
(c) For any $X \in p^{-1}(Q)$ the restriction of p to $B_{2r}^{\mathbb{D}}(X)$ is injective.

Now the desired properties (1) and (3) follow immediately from (a) and (b). It remains to prove (2). Suppose that we have $X \neq X' \in p^{-1}(Q)$ with $B_r^{\mathbb{D}}(X) \cap B_r^{\mathbb{D}}(X') \neq \varnothing$. We

[770] The map p is a Möbius map, in particular it is a local biholomorphism which implies that it is a local homeomorphism. Thus it follows from the Pasting Proposition 2.6 that p itself is continuous.
[771] This is the only part of the proof where we actually use that we work with $H_8/\!\sim$, the remainder of the proof works for any smooth manifold M with a Möbius structure such that the corresponding Riemannian manifold is complete.
[772] Note the factor 2.

need to show $X = X'$. We pick $Y \in B_r^{\mathbb{D}}(X) \cap B_r^{\mathbb{D}}(X')$. The triangle inequality implies that $X' \in B_{2r}^{\mathbb{D}}(X)$. But p restricted to $B_{2r}^{\mathbb{D}}(X)$ is injective by (c). Hence $X = X'$. ■

66.7. **Fundamental groups of surfaces.** In this section we will combine Hadamard's Theorem 66.9 and the discussion of the deck transformation group in Chapter 62 to draw some interesting consequences on the structure of fundamental groups of surfaces. First we have the following proposition.



Proposition 66.18. Let $g \in \mathbb{N}_{\geq 2}$. We denote by Σ_g the surface of genus g. We pick a base point $x_0 \in \Sigma_g$. There exists a monomorphism $\pi_1(\Sigma_g, x_0) \to \mathrm{SL}(2, \mathbb{R})$.

Proof. Throughout the proof we will make use of the notion of a Möbius structure, of a Möbius manifold and of a Möbius map between Möbius manifolds. We refer to pages 1439 and 1448 for the definitions, in case the reader needs a refresher.

Now let $g \geq 2$. As in the proof of Proposition 66.2 we can and will make the identification $\Sigma_g = H_{4g}/\sim$ where H_{4g} is a regular hyperbolic $4g$-gon in $\mathbb{D}$ with interior angle $\frac{\pi}{2g}$. Furthermore, as in the proof of Proposition 66.2 we equip $\Sigma_g = H_{4g}/\sim$ with the canonical Möbius structure. By Hadamard's Theorem 66.9 there exists a covering map $p\colon \mathbb{D} \to \Sigma_g$ such that p is a Möbius map.

Claim. Every deck transformation of the covering map $p\colon \mathbb{D} \to \Sigma_g$ is a Möbius transformation.

Proof. Let $f\colon \mathbb{D} \to \mathbb{D}$ be a deck transformation. Recall that this means that the following diagram commutes:

Since p is a Möbius map and since p is a local diffeomorphism we see that f is locally a Möbius map. By Lemma 66.11 (2) this implies that f is in fact a Möbius map. It now follows from Lemma 66.11 (1) that f is in fact a Möbius transformation. ⊞

Now we can easily conclude the proof of the proposition, indeed we have the following isomorphisms:

$$\pi_1(\Sigma_g, x_0) \underset{\text{by Proposition 62.6}}{\overset{\cong}{\uparrow}} \mathrm{Deck}(p\colon \mathbb{D} \to \Sigma_g) \underset{\text{by the claim}}{\overset{\subset}{\uparrow}} \text{group of Möbius transformations of } \mathbb{D} \underset{\text{by Proposition 65.1}}{\overset{\cong}{\uparrow}} \mathrm{SL}(2, \mathbb{R}).$$

■

The following proposition gives in particular a positive answer to Question 64.22.

Proposition 66.19. Let Σ be a closed connected 2-dimensional smooth manifold. We pick a base point $x_0 \in \Sigma$. The following two statements hold:

(1) The group $\pi_1(\Sigma, x_0)$ is linear over $\mathbb{R}$.
(2) The group $\pi_1(\Sigma, x_0)$ is residually finite.

Remark.

(1) In [**NewM1985**, Lemma 1], see also [**Scot1978**, Section 3] together with [**Bou1981**, Chapitre V, §4, Section 4], it shown that $\pi_1(\Sigma, x_0)$ is in fact linear over $\mathbb{Z}$.
(2) There are many other proofs that $\pi_1(\Sigma, x_0)$ is residually finite, see e.g. [**Chis1999**, Corollary 4.9] and [**Hem1972**] for alternative arguments.

Proof. Let Σ be a closed connected 2-dimensional smooth manifold. By Proposition 49.4 we know that there exists a finite covering $p\colon (\widetilde{\Sigma}, \widetilde{x}_0) \to (\Sigma, x_0)$ such that $\widetilde{\Sigma}$ is a closed orientable connected 2-dimensional smooth manifold. By Proposition 66.18 we know that $\pi_1(\widetilde{\Sigma}, \widetilde{x}_0)$ is isomorphic to a subgroup of $\mathrm{SL}(2, \mathbb{R})$. In particular we see that $\pi_1(\widetilde{\Sigma}, \widetilde{x}_0)$ is linear over $\mathbb{R}$.

By Corollary 48.14 and Lemma 48.15 we know that $\pi_1(\widetilde{\Sigma}, \widetilde{x}_0)$ is isomorphic to a finite-index subgroup of $\pi_1(\Sigma, x_0)$. Thus it follows from the above together with Exercise 64.15 that $\pi_1(\Sigma, x_0)$ is also linear over $\mathbb{R}$. By Proposition 64.19 this implies that $\pi_1(\Sigma, x_0)$ is residually finite. ■

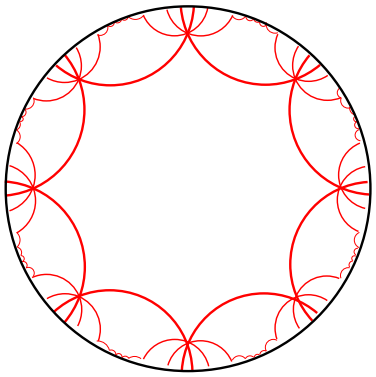
66.8. **Picard's Theorem ❀.** We also have the following variation on Theorem 66.9.

Proposition 66.20. Let $H_4/\!\sim$ be the three-punctured sphere with the Möbius structure constructed in Proposition 66.5. Then there exists a covering map $p\colon \mathbb{D} \to H_4/\!\sim$ with the following properties:

(1) p is a Möbius map,
(2) p is a local isometry,
(3) p is a local biholomorphism.

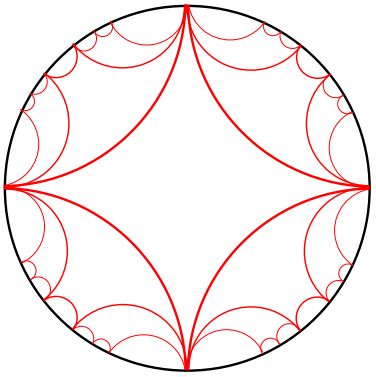
Proof. The proof of Proposition 66.20 is almost the same as the proof of Theorem 66.9. In the proof of Theorem 66.9 we used that $H_8/\!\sim$ is complete. In the present case it follows from Proposition 66.5 (3) that $H_4/\!\sim$ is complete. The construction of the Möbius map $\Phi\colon \mathbb{D} \to H_4/\!\sim$ is verbatim the same as the construction of the Möbius map $\Phi\colon \mathbb{D} \to H_8/\!\sim$. The same argument as before shows that $\Phi\colon \mathbb{D} \to H_4/\!\sim$ is surjective and that it is a covering map. ■

Remark. We consider again the covering $p\colon \mathbb{D} \to H_8/\!\sim$ that we had just constructed. It follows from Corollary 61.4 that the interior of H_8 is uniformly covered. In particular we see that



$$\mathbb{D} \setminus \underbrace{p^{-1}(\partial H_8)}_{\text{“1-dimensional”}} \;=\; \bigsqcup \text{copies of } \mathring{H}_8.$$

Put differently, up to the “one-dimensional” subset $p^{-1}(\partial H_8)$ we can cover $\mathbb{D}$ by infinitely many disjoint copies of the open hyperbolic octagon. Such a decomposition is often called a *tessellation*. This tessellation is shown in the figure below on the left. The same argument also applies to the covering $\mathbb{D} \to H_4/\!\sim$ that we also had just constructed. The corresponding tessellation of $\mathbb{D}$ is shown in the figure below on the right.



At the end of this chapter we return to complex analysis. There are different types of holomorphic functions defined on $\mathbb{C}$.

(1) There are the (rather dull) constant functions.
(2) There are holomorphic functions $f\colon \mathbb{C} \to \mathbb{C}$ that are surjective. For example it is an easy consequence of the fundamental theorem of algebra that all maps defined by non-constant polynomials are surjective.
(3) There are also non-constant maps that are not surjective, for example the exponential function $z \mapsto \exp(z)$ is never zero[773], in fact its image is $\mathbb{C} \setminus \{0\}$.

[773] Why not?

preimages of $\mathring{H}_8$ under the universal cover $p\colon \mathbb{D} \to H_8/\sim$

preimages of $\mathring{H}_4$ under the universal cover $p\colon \mathbb{D} \to H_4/\sim$

On the other hand it is fairly easy prove, using Liouville's Theorem 32.6, that the image of a non-constant holomorphic function on $\mathbb{C}$ is dense.
Now we can prove Picard's Theorem[774] which is a significantly stronger statement than the above statement that the image is dense.

Theorem 66.21. (Picard's Theorem) Let $f\colon \mathbb{C} \to \mathbb{C}$ be a non-constant holomorphic function. Then there exists at most one $z \in \mathbb{C}$ which does not lie in the image of f.

Proof. Let $f\colon \mathbb{C} \to \mathbb{C}$ be a holomorphic function such that there exist two different complex numbers a, b that do not lie in the image of f. We need to show that f is constant. We consider the biholomorphism

$$\begin{array}{rcl} \alpha\colon \mathbb{C} \setminus \{a,b\} & \to & \mathbb{C} \setminus \{0,1\} \\ z & \mapsto & \dfrac{z-a}{b-a}. \end{array}$$

Furthermore we denote by $\beta\colon \mathbb{C}\setminus\{0,1\} \to H_4/\sim$ the biholomorphism from Proposition 66.6. Now we consider the following diagram of maps

$$\begin{array}{ccccccc} & & & & & & \mathbb{D} \\ & & & & & & \downarrow \Phi \\ \mathbb{C} & \xrightarrow{f} & \mathbb{C} \setminus \{a,b\} & \xrightarrow[\cong]{\alpha} & \mathbb{C} \setminus \{0,1\} & \xrightarrow[\cong]{\beta} & H_4/\sim \end{array}$$

where $\Phi\colon \mathbb{D} \to H_4/\sim$ is the covering map from Proposition 66.20. Recall that Φ is a Möbius map which implies by Lemma 66.8 that Φ is a local biholomorphism.

Since $\mathbb{C}$ is simply connected we can appeal to the Map Lifting Criterion 61.2 to obtain a lift of the map $\beta \circ \alpha \circ f\colon \mathbb{C} \to H_4/\sim$ to the universal covering. More precisely, there

[774] Emile Picard (1856-1941) was a French mathematician. Many readers will have encountered him already in real analysis, as one of the two namesakes of the Picard-Lindelöf Theorem.

exists a map $\widetilde{\beta \circ \alpha \circ f} \colon \mathbb{C} \to \mathbb{D}$ such that the following diagram commutes

$$\begin{array}{ccccccc} \mathbb{C} & \xrightarrow[f]{} & \mathbb{C} \setminus \{a,b\} & \xrightarrow[\alpha]{\cong} & \mathbb{C} \setminus \{0,1\} & \xrightarrow[\beta]{\cong} & H_4/\!\sim \\ & \searrow^{\widetilde{\beta\circ\alpha\circ f}} & & & & & \downarrow \Phi \\ & & & & & & \mathbb{D} \end{array}.$$

Note that it follows from the fact that $\beta \circ \alpha \circ f$ is holomorphic and the fact that Φ is a local biholomorphism, that the map $\widetilde{\beta \circ \alpha \circ f} \colon \mathbb{C} \to \mathbb{D}$ is also holomorphic. But $\mathbb{D}$ is of course bounded. Therefore it follows from Liouville's Theorem 32.6 that $\widetilde{\beta \circ \alpha \circ f}$ is constant. But then $\beta \circ \alpha \circ f$ is also constant. Since α and β are biholomorphisms this implies that f itself is already constant. ∎

Remark. In the literature Theorem 66.21 is sometimes referred to as Picard's Little Theorem, to distinguish it from Picard's Great Theorem which says that if z_0 is an essential singularity of a holomorphic function, then in any neighborhood of z_0 the function f assumes all, but possibly one, value *infinitely* many times. We refer to [**Conw78**, Section 12] for details.

66.9. **Triangle groups.** In this short bonus section we will discuss the triangle groups. But before we can do so we need to introduce the notion of the reflection in a hyperbolic plane.

Definition. We define the reflection in the hyperbolic line $l := \{x + 0\mathrm{i} \mid x \in (-1,1)\} \subset \mathbb{D}$ to be the orientation-reversing isometry

$$\begin{array}{rcl} \rho_l \colon \mathbb{D} & \to & \mathbb{D} \\ z = x + \mathrm{i}y & \mapsto & \overline{z} = x - \mathrm{i}y. \end{array}$$

Now let k be any hyperbolic line in $\mathbb{D}$. By Lemma 65.6 there exists a Möbius transformation Φ with $\Phi(k) = l$. We define the reflection in k to be the map

$$\begin{array}{rcl} \rho_k \colon \mathbb{D} & \to & \mathbb{D} \\ x & \mapsto & \Phi^{-1} \circ \rho_l \circ \Phi \end{array}$$

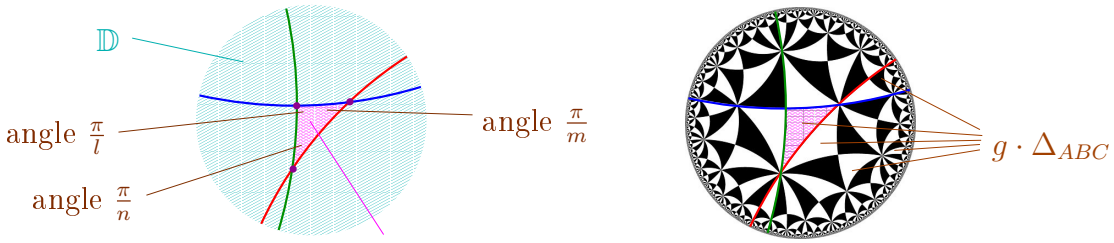
In Exercise 66.1 we will see that the definition of ρ_k does not depend on the choice of Φ.

Next recall that given any two distinct points $P, Q \in \mathbb{D}$ there exists by Lemma 65.6 a unique hyperbolic line $g(P,Q)$ through P and Q. Now we can formulate the key proposition of this section.

Proposition 66.22. Let $l, m, n \in \mathbb{N}$ with $\frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1$.

(1) There exists a hyperbolic triangle Δ_{ABC} with interior angles $\frac{\pi}{l}$, $\frac{\pi}{m}$ and $\frac{\pi}{n}$ at the vertices A, B and C.

Let G be the subgroup of that is generated by the reflections in the hyperbolic lines $g(C,A)$, $g(A,B)$ and $g(B,C)$. The following statements hold:



(2) (a) Given any $g \neq h \in G$ the intersection $g \cdot \Delta_{ABC} \cap h \cdot \Delta_{ABC}$ is either empty or a vertex or a side.

(b) $\bigcup_{g \in G} g \cdot \Delta_{ABC} = \mathbb{D}$.

(3) The map

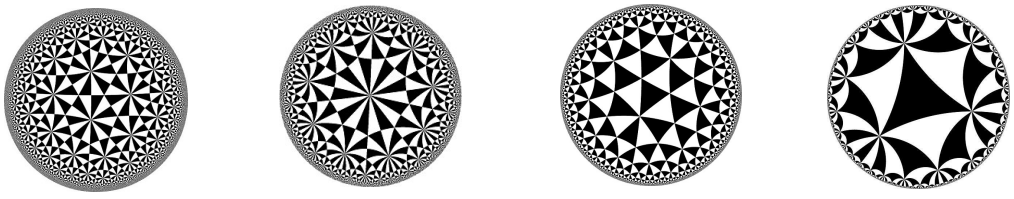
$$\begin{array}{rcl} \langle x, y, z \,|\, x^2, y^2, z^2, (xy)^l = (yz)^m = (zx)^n \rangle & \to & G \\ x & \mapsto & \text{reflection in } g(C, A) \\ y & \mapsto & \text{reflection in } g(A, B) \\ z & \mapsto & \text{reflection in } g(B, C). \end{array}$$

is an isomorphism.

Proof.

(1) This statement is shown in [**Rat2019**, Theorem 3.5.6]. In fact in that reference it is also shown that the triangle is unique up to an isometry.

(2) The statements (2a) and (2b) are both shown in [**Cara1954**, p. 177-182] or alternatively in [**Mask1971**].



(3) (a) First note that the map is actually well-defined. In fact this follows from the observation that every reflection has order 2 and that xy, yz and zx get sent to a rotation around a vertex with rotation angles $\frac{2\pi}{l}$, $\frac{2\pi}{m}$ and $\frac{2\pi}{n}$.

(b) The fact that the map is in fact an isomorphism is shown in [**Mag1974**, Theorem 2.8]. ■

Remark.

(1) A decomposition of the euclidean plane $\mathbb{R}^2$ or the hyperbolic disk $\mathbb{D}$ into isometric geometric shapes that only overlap on the boundary is called a *tessellation*. Proposition 66.22 thus shows that the hyperbolic disk $\mathbb{D}$ can be tessellated by any hyperbolic triangle with angles $\frac{\pi}{l}$, $\frac{\pi}{m}$ and $\frac{\pi}{n}$ for $l, m, n \in \mathbb{N}$ with $\frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1$. Tessellations for various values of (l, m, n) are shown in the figure below.

(2) Note that, as illustrated in the figure on page 1458, Hadamard's Theorem 66.9 and Proposition 66.20 also provide tessellations of $\mathbb{D}^2$.

$(2, 3, 7)$ $(2, 3, 9)$ $(3, 3, 4)$ $(6, 6, 6)$

Proposition 66.22 partly motivates the following definition.

Definition. Let $l, m, n \in \mathbb{N}$.

(1) The group

$$T^*(l,m,n) := \langle x, y, z \,|\, x^2, y^2, z^2, (xy)^l = (yz)^m = (zx)^n \rangle$$

is called the (l,m,n)-triangle group.

(2) The group

$$T(l,m,n) := \ker \left\{ \begin{array}{ccc} T^*(l,m,n) & \to & \mathbb{Z}_2 \\ x,y,z & \mapsto & 1 \end{array} \right\}$$

is called the (l,m,n)$-von Dyck group$.

Remark. Let $l, m, n \in \mathbb{N}$.

(1) (a) If $\frac{1}{l}+\frac{1}{m}+\frac{1}{n} < 1$, then we saw in Proposition 66.22 that $T^*(l,m,n)$ is isomorphic to the subgroup of $\mathrm{Isom}(\mathbb{D})$ generated by reflections in the hyperbolic lines defined by a hyperbolic triangle with interior angles $\frac{\pi}{l}$, $\frac{\pi}{m}$ and $\frac{\pi}{n}$.

(b) If $\frac{1}{l}+\frac{1}{m}+\frac{1}{n} = 1$, then it is shown in [**Mag1974**, Section II.4] that $T^*(l,m,n)$ is isomorphic to the subgroup of $\mathrm{Isom}(\mathbb{R}^2)$ generated by reflections in the euclidean lines defined by a *euclidean* triangle with interior angles $\frac{\pi}{l}$, $\frac{\pi}{m}$ and $\frac{\pi}{n}$.

(c) Finally, if $\frac{1}{l}+\frac{1}{m}+\frac{1}{n} > 1$, then it is shown in [**Mag1974**, Section II.4] that $T^*(l,m,n)$ is isomorphic to the subgroup of $\mathrm{Isom}(S^2)$ generated by reflections in the great circles defined by a *spherical* triangle with interior angles $\frac{\pi}{l}$, $\frac{\pi}{m}$ and $\frac{\pi}{n}$.

(2) In each of the three cases above the (l,m,n)-von Dyck group is the intersection of the (l,m,n)-triangle group with the subgroup of orientation-preserving isometries.

The following lemma gives a particularly simple presentation of the von Dyck groups.

Lemma 66.23. Given any $l, m, n \in \mathbb{N}$ the map

$$\begin{array}{ccc} \langle a, b \,|\, a^l, b^m, (ab)^n \rangle & \to & T(l,m,n) \\ a & \mapsto & xy \\ b & \mapsto & yz \end{array}$$

is an isomorphism.

Proof. We will prove Lemma 66.23 in Exercise 66.3. ∎

We conclude this chapter with the following corollary to Proposition 66.22.

Corollary 66.24. Let $l, m, n \in \mathbb{N}$. If $\frac{1}{l}+\frac{1}{m}+\frac{1}{n} < 1$, then the triangle group $T^*(l,m,n)$ and the von Dyck group $T(l,m,n)$ are infinite.

Proof. Let $l, m, n \in \mathbb{N}$ with $\frac{1}{l}+\frac{1}{m}+\frac{1}{n} < 1$. We denote by G the group introduced in Proposition 66.22. Note that it follows from Proposition 66.22 (2), the fact that Δ_{ABC} is compact and the fact that $\mathbb{D}$ is non-compact that G is infinite. By Proposition 66.22 (3) this implies that the triangle group $T^*(l,m,n)$ is infinite. The index two subgroup $T(l,m,n)$ is evidently also infinite. ∎

Exercises for Chapter 66.

Exercise 66.1. We define reflection in the hyperbolic line $l := \{x \,|\, x \in (-1,1)\} \subset \mathbb{D}$ to be the map

$$\begin{array}{rcl} \rho_l\colon \mathbb{D} & \to & \mathbb{D} \\ z = x + \mathrm{i}y & \mapsto & \overline{z} = x - \mathrm{i}y. \end{array}$$

Now let k be any hyperbolic line in $\mathbb{D}$. By Lemma 65.6 there exists a Möbius transformation Φ with $\Phi(k) = l$. We define the *reflection in* k to be the map

$$\begin{array}{rcl} \rho_k\colon \mathbb{D} & \to & \mathbb{D} \\ x & \mapsto & \Phi^{-1} \circ \rho_l \circ \Phi \end{array}$$

Show that the definition of ρ_k does not depend on the choice of Φ.

Exercise 66.2. Show that the map

$$\begin{array}{rcl} \mathrm{SL}(2,\mathbb{R}) \times \mathbb{H} & \to & \mathbb{H} \\ \left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}, z\right) & \mapsto & \dfrac{az+b}{cz+d} \end{array}$$

defines an action of the group $\mathrm{SL}(2,\mathbb{R})$ on $\mathbb{H}$ and show that this action is transitive.

Exercise 66.3. Let $l, m, n \in \mathbb{N}$. Show that the map

$$\begin{array}{rcl} \langle a, b \,|\, a^l, b^m, (ab)^n \rangle & \to & T(l,m,n) \\ a & \mapsto & xy \\ b & \mapsto & yz \end{array}$$

is an isomorphism.
Hint. First use Proposition 59.32 to find an explicit presentation for $T(l,m,n)$.

67. Related constructions in algebraic geometry and Galois theory

In this short chapter we indicate some connections between the topics that we have covered so far to algebraic geometry and Galois theory. Since the author of these notes does not know much about either field the following discussion should be taken with a grain of salt. In particular for an expert the subsequent discussion will certainly look too simplistic.

67.1. The fundamental group of an algebraic variety.

Definition. Let $\mathbb{K}$ be a field.[775]

(1) Given a set of multivariable polynomials S, i.e. given a subset $S \subset \mathbb{K}[t_1, \ldots, t_n]$ we denote by

$$V(S) \;=\; \{(x_1, \ldots, x_n) \in \mathbb{K}^n \mid f(x_1, \ldots, x_n) = 0 \text{ for all } f \in S\}$$

the vanishing set of S, i.e. the set of all points in $\mathbb{K}^n$ where all the polynomials in S, viewed as maps $\mathbb{K}^n \to \mathbb{K}$, vanish.

(2) We say $U \subset \mathbb{K}^n$ is Zariski open,[776] if there exists a subset S of $\mathbb{K}[t_1, \ldots, t_n]$ such that $U = \mathbb{K}^n \setminus V(S)$.

Remark. Let S be a subset of $\mathbb{K}[t_1, \ldots, t_n]$. Since the ring $\mathbb{K}[t_1, \ldots, t_n]$ is Noetherian there exists a finite set $\{f_1, \ldots, f_k\} \subset \mathbb{K}[t_1, \ldots, t_n]$ such that $V(S) = V(f_1, \ldots, f_k)$.

Lemma 67.1. Let $\mathbb{K}$ be a field. The Zariski open subsets form a topology on $\mathbb{K}^n$.

Remark.

(1) The topology defined by the Zariski open subsets is of course called the *Zariski topology on* $\mathbb{K}^n$.

(2) If $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, then every Zariski open subset is also open with respect to the usual topology on $\mathbb{R}^n$ or $\mathbb{C}^n = \mathbb{R}^{2n}$. But for $n \geq 1$ the converse does not hold, in fact "most" subsets that are open with respect to the usual topology are not open with respect to the Zariski topology.

Proof. Let $\mathbb{K}$ be a field.

(1) The vanishing set of the empty set, i.e. $V(\varnothing)$ is all of $\mathbb{K}^n$, hence the empty set $\varnothing = \mathbb{K}^n \setminus V(\varnothing)$ is open.

(2) The vanishing set of the constant polynomial $f = 1$ is the empty set, therefore $\mathbb{K}^n = \mathbb{K}^n \setminus V(1)$ is open.

(3) We need to show that the intersection of finitely many Zariski open sets is again Zariski open. By induction it suffices to consider the case of two Zariski open sets. So suppose we are given Zariski open sets $X = \mathbb{K}^n \setminus V(S)$ and $Y = \mathbb{K}^n \setminus V(T)$. Then

$$\mathbb{K}^n \setminus (X \cap Y) \;=\; (\mathbb{K}^n \setminus X) \cup (\mathbb{K}^n \setminus Y) \;=\; V(S) \cup V(T) \;=\; V\big(\{s \cdot t\}_{s \in S, t \in T}\big).$$

[775] For example we could take $\mathbb{K} = \mathbb{Q}, \mathbb{R}, \mathbb{C}$ but $\mathbb{K}$ could also be a field of non-zero characteristic, e.g. for a prime p we could take $\mathbb{K} = \mathbb{F}_p$ or $\mathbb{K}$ could be the algebraic closure $\overline{\mathbb{F}}_p$ of $\mathbb{F}_p$.

[776] Oscar Zariski (1899-1986) was a Russian-American mathematician working in algebraic geometry.

(4) We need to show that the union of Zariski open sets is again Zariski open. So suppose we are given a family of Zariski open sets $X_i = \mathbb{K}^n \setminus V(S_i)$, $i \in I$. Then

$$\mathbb{K}^n \setminus \bigcup_{i\in I} X_i \;=\; \bigcap_{i\in I}(\mathbb{K}^n \setminus X_i) \;=\; \bigcap_{i\in I} V(S_i) \;=\; V\Big(\bigcup_{i\in I} S_i\Big).$$

Thus we have verified that the Zariski open sets have all the properties of a topology. ■

Definition. Let $\mathbb{K}$ be a field.

(1) A variety over $\mathbb{K}$ is defined as the vanishing set of a set of multivariable polynomials.
(2) The Zariski topology on a variety $V \subset \mathbb{K}^n$ is defined as the subspace topology on V induced from the Zariski topology on $\mathbb{K}^n$.

Example. Let $\mathbb{K}$ be a field and let and $f(s,t) = s^2 + t^2 - 1$. We define

$$S^1_{\mathbb{K}} \;:=\; V(f) \;=\; \{(x,y) \in \mathbb{K}^2 \mid f(x,y) = x^2 + y^2 - 1 = 0\} \;=\; \{(x,y) \in \mathbb{K}^2 \mid x^2 + y^2 = 1\}.$$

For $\mathbb{K} = \mathbb{R}$ we obtain the usual circle S^1.

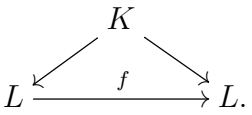
Any variety V is again a topological space, so in principle one could study the usual fundamental group. But in many cases, e.g. if the characteristic of $\mathbb{K}$ is non-zero, one will see that all continuous maps $S^1 \to V$ are constant, hence the usual fundamental group is trivial.
The correct analogue of a finite covering $p\colon X \to B$ between topological spaces for varieties is a finite étale morphism. The precise definition of a finite étale morphism is irrelevant for our purpose.[777] A heuristic fact is that varieties tend to have many finite étale morphisms, but there is no well-behaved analogue of an infinite covering in the context of varieties. In particular usually there is no concept of a "universal" étale morphism. The question is now, whether one can recover the notion of a fundamental group from the knowledge of finite covers.
Given a variety V we can consider all finite regular étale morphisms $p_i\colon W_i \to V$, $i \in I$. The corresponding deck transformations groups $\mathrm{Deck}(p_i\colon W_i \to V)$, $i \in I$ are finite groups that form an inverse system. Now we can define the étale fundamental group of V as

$$\pi_1^{\text{ét}}(V) \;:=\; \varprojlim_i \mathrm{Deck}(p_i\colon W_i \to V).$$

By Proposition 56.18 the étale fundamental group $\pi_1^{\text{ét}}(V)$ is naturally a compact topological group. In algebraic geometry the étale fundamental group of a variety plays a role similar to the role of the fundamental group of a topological space in topology.
If V is a complex variety without singularities, then the étale fundamental group is isomorphic to the profinite completion[778] of the usual topological fundamental group $\pi_1(V)$, i.e. we have

$$\pi_1^{\text{ét}}(V) \;\cong\; \widehat{\pi_1(V)}.$$

We refer to [**Groth1971**] for a proof of this statement.
More information on this topic can be found at



`https://en.wikipedia.org/wiki/etale_fundamental_group`

[777] Furthermore it is unknown to the author of these lecture notes.
[778] Recall that on page 1283 we introduced the profinite-completion $\widehat{\pi}$ of a group π.

67.2. **Galois theory.** The theory of coverings of topological spaces has some similarities to the Galois theory of field extensions.
Throughout this section let K be a field of characteristic zero[779] and let L/K be a field extension of K, i.e. L is a field which contains K as a subfield. The dimension of L as a K vector space is denoted by $[L:K]$. We consider the group

$$\mathrm{Gal}(L/K) = \text{ all field automorphisms of } L \text{ which are the identity on } K.$$

Put differently, a field automorphism $f\colon L \to L$ lies in $\mathrm{Gal}(L/K)$ if and only if the following diagram commutes:

We consider two examples:

(1) $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$ is a field extension with $[\mathbb{Q}(\sqrt{2})\colon \mathbb{Q}] = 2$ and $\mathrm{Gal}(\mathbb{Q}(\sqrt{2})/\mathbb{Q})$ consists of the identity and the homomorphism $a + b\sqrt{2} \mapsto a - b\sqrt{2}$.
(2) $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ is a field extension with $[\mathbb{Q}(\sqrt[3]{2})\colon \mathbb{Q}] = 3$ and the group $\mathrm{Gal}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q})$ consists only of the identity.

Given a field K we denote by $\overline{K}$ the algebraic closure of K. A field extension L/K is called *Galois*, if for each $f \in \mathrm{Gal}(\overline{K}/K)$ we have $f(L) = L$.[780] In the usual course on Galois theory one shows that L/K is Galois if and only if each polynomial in $K[x]$ which admits a zero in L splits over L, i.e. all other zeros of f lies also in L. For a Galois extension L/K we refer to $\mathrm{Gal}(L/K)$ as the *Galois group* of the field extension.
We return to the above two examples:

(1) $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$ is a Galois field extension.
(2) $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ is not a Galois field extension, since $\sqrt[3]{2}$ is a zero of x^3-2, but the complex zero $\sqrt[3]{2}\cdot\exp(2\pi\mathrm{i}/3)$ of f does not lie in $\mathbb{Q}(\sqrt[3]{2})$.[781]

If L/K is a finite extension, then the main theorem of Galois theory says that the following two statements are equivalent:

(1) The field extension L/K is Galois.
(2) $\#\,\mathrm{Gal}(L/K) = [L:K]$.

The statement is formally very similar to the statement of the Regular Covering-Characterization Corollary 62.8 which says that for some finite covering $p\colon X \to B$ of topological spaces the following statements are equivalent:

(1) The covering $p\colon X \to B$ is regular.
(2) $\#\,\mathrm{Deck}(p\colon X \to B) = [X:B]$.

The analogy between Galois theory and covering theory goes considerably further. Many statements about the Galois group of a Galois extension have a corresponding statement for the deck transformation group of a normal covering. For example, given a finite extension L/K the (normal) subgroups of Galois group $\mathrm{Gal}(L/K)$ correspond to (normal)

[779] This restriction to characteristic zero is not necessary, but it simplifies the discussion.
[780] Strictly speaking this is the definition of a normal extension, but since K is a field of characteristic zero, a normal extension is already Galois.
[781] We put $z = \sqrt[3]{2}$ and $w = \exp(2\pi\mathrm{i}/3)$. It is a good exercise to show that $\mathbb{Q}(z,w)/\mathbb{Q}$ is a normal field extension with $[\mathbb{Q}(z,w)\colon \mathbb{Q}] = 6$. The group $\mathrm{Gal}(\mathbb{Q}(z,w)/\mathbb{Q})$ is isomorphic to the permutation group S_3.

intermediate fields and (normal) subgroups of the deck transformation group correspond to (regular) intermediate coverings.
Now let L/K be a Galois extension of infinite degree. All finite intermediate Galois extensions of K, i.e. all finite Galois extensions F/K with $F \subset L$, form a preordered set via the inclusion. The corresponding Galois groups form an inverse set. Indeed, given two finite Galois extensions F/K and G/K with $F \subseteq G$ the restriction of an automorphism of G to an automorphism of F defines a group homomorphisms $\mathrm{Gal}(G/K) \to \mathrm{Gal}(F/K)$. Therefore we can form the inverse limit of these Galois groups. By [**FJ2008**, Section 1.3] there exists a canonical isomorphism of groups

$$\mathrm{Gal}(L/K) \;=\; \varprojlim_{\substack{F/K \text{ finite} \\ \text{Galois extension}}} \mathrm{Gal}(F/K).$$

On the right-hand side we consider the inverse limit of an inverse system of finite groups. It follows from Proposition 56.18 that the right-hand side, and thus also the Galois group $\mathrm{Gal}(L/K)$, is naturally a compact topological group. This topology on $\mathrm{Gal}(L/K)$ is called the *Krull topology*.

Example. Let p be a prime. We denote by $\mathbb{F}_p$ the finite field with p elements and we denote by $\overline{\mathbb{F}}_p$ its algebraic closure. It is shown in [**FJ2008**, Section 1.5] that there exists a canonical isomorphism

$$\mathrm{Gal}\left(\overline{\mathbb{F}}_p/\mathbb{F}_p\right) \;\cong\; \widehat{\mathbb{Z}}$$

where $\widehat{\mathbb{Z}}$ denotes the profinite completion of $\mathbb{Z}$, or equivalently the profinite integers that we introduced on page 1279.

Part VII

CW-complexes

68. CW-complexes I: Definitions, basic properties and constructions

In this chapter we will introduce CW-complexes. Initially the definition of a CW-complex might look rather confusing and artificial. But in this and in Chapters 69 and 70 we will see that the notion of a CW-complex strikes the right balance:

(1) CW-complexes are topological space that have many desirable properties,
(2) the notion is flexible enough so that most of the topological spaces that we are interested in are actually CW-complexes.

68.1. **Definition of finite-dimensional CW-complexes and examples.** We start out with the definition of a finite-dimensional CW-complex and its topological realization.

Definition.

(a) A CW-complex X of dimension ≤ -1 is defined to be the empty set. Its topological realization $|X|$ is also defined to be the empty set.
(b) We define inductively higher dimensional CW-complexes. Let $n \in \mathbb{N}_0$. A CW-complex X^n of dimension $\leq n$ is a pair $(X^{n-1}, \{\{\varphi_i \colon S^{n-1} \to |X^{n-1}|\}_{i \in I_n}\})$ where the following holds:
   (i) X^{n-1} is a CW-complex X^{n-1} of dimension $\leq n-1$, with topological realization denoted by $|X^{n-1}|$,
   (ii) $\{\varphi_i \colon S^{n-1} \to |X^{n-1}|\}_{i \in I_n}$ is a set of maps.
   The topological realization $|X^n|$ of X^n is defined as the topological space
$$|X^n| := \Big(|X^{n-1}| \sqcup \bigsqcup_{i \in I_n} \overline{B}^n\Big)/\sim$$
   where for each $i \in I_n$ we use the map φ_i to identify the points on the corresponding copy of $S^{n-1} = \partial \overline{B}^n$ with the corresponding points in $|X^{n-1}|$.
(c) A CW-structure for a topological space Y is a CW-complex X together with a homeomorphism $f \colon |X| \to Y$.

Remark.

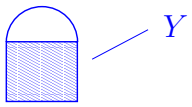
(1) Let X be a CW-complex as above and let $n \in \mathbb{N}_0$. It follows from the the Topological Pushout-Maps Lemma 5.34 (3)that the obvious map $|X^{n-1}| \to |X^n|$ is an embedding. Thus we can and will view $|X^{n-1}|$ as a subspace of $|X^n|$.
(2) Note that $\overline{B}^0$ consists of a point and that $S^{-1} = \varnothing$. It follows from the above definition that a CW-complex of dimension ≤ 0 is exactly the same as set of points with the discrete topology.
(3) CW-complexes were introduced by John H. C. Whitehead[782]. The name comes from "C" for "closure-finite", and the "W" for "weak topology". We will explain on pages 1479 and 1491 what "closure-finite" and "weak topology" mean. Some people also say it goes back to the initials C. W. of Whitehead. Some authors, see e.g. [**Lee2000**, p. 132] and [**Mun1984**, p. 214] require "closure-finiteness" as part of the definition, but as we will see, this property follows from the definition as given.

[782] John Henry Constantine Whitehead (1904-1960) was a British mathematician.

(4) In the notation we usually do not distinguish between the CW-complex and its topological realization, i.e. we usually denote the topological realization of a CW-complex X again by X.

Before we discuss a long list of examples of CW-complexes we want to introduce a few more definitions.

Definition. Let X be a CW-complex as above and let $k \in \mathbb{N}_0$. We continue with the notation used in the previous definition



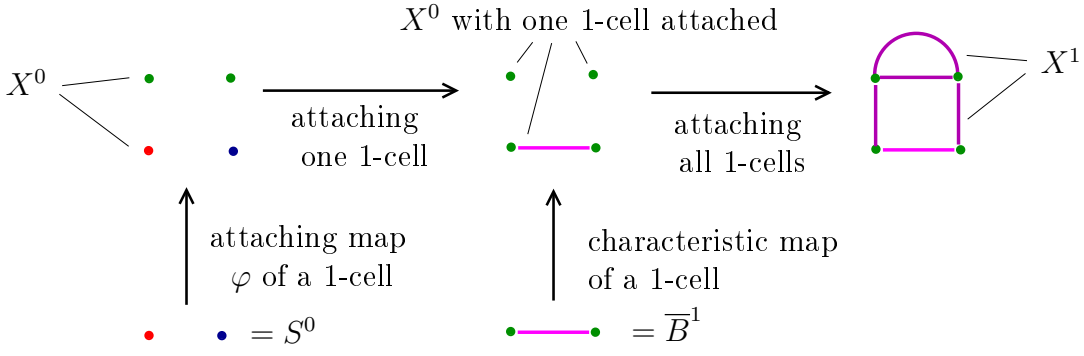
(1) The images of the $\overline{B}_i^k$, $i \in I_k$, in X are called the k-dimensional cells, or often short k-cells, of X.
(2) The images of the B_i^k, $i \in I_k$, in X are called the open k-cells of X.
(3) The maps $\varphi_i \colon S_i^{k-1} \to X$[783] are called the attaching maps of the k-cells and the obvious maps $\overline{B}_i^k \to X$ are referred to as the characteristic maps of the k-cells.
(4) We refer to the CW-complex X^k as the k-skeleton of X.
(5) If X is empty, then we define its dimension to be -1. If X is non-empty, then we define the dimension $\dim(X) \in \mathbb{N}_0 \cup \{\infty\}$ as the maximal dimension of a cell.

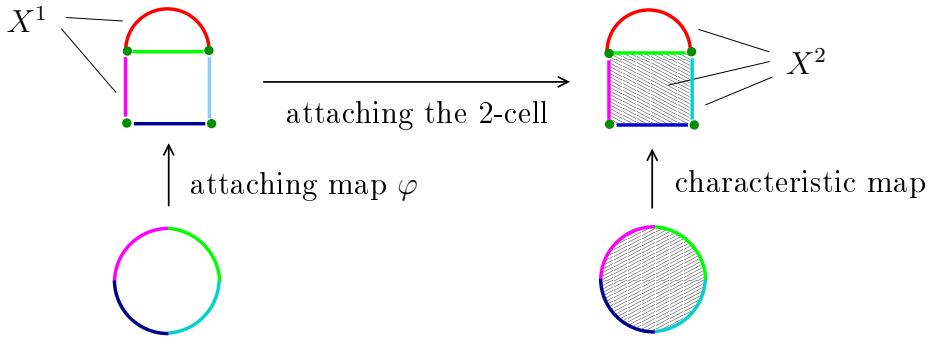
Remark. At times, when we say that "a CW-complex X is k-dimensional", we allow the possibility, that the highest dimension of a cell is actually less than k. This slightly fuzzy language should not pose a problem in practice.

Example. We consider the topological space which is sketched in the figure below, namely

$$Y := ([-1,1] \times [-1,1]) \cup \{(x,y) \in \mathbb{R}^2 \,|\, x^2 + (y-1)^2 = 1 \text{ and } y \geq 1\}.$$

The topological space X thus consists of a square together together with a semicircle.

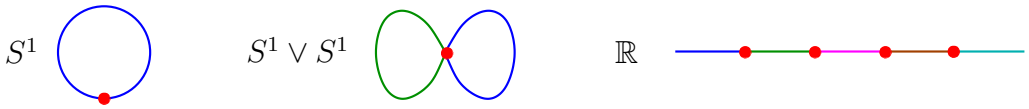




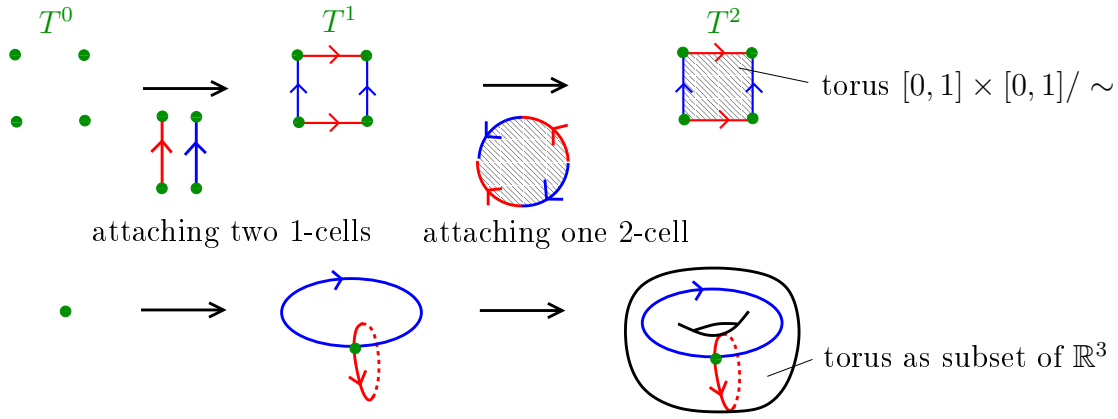
Our goal is to find a CW-structure for X. First we consider the 0-dimensional CW-complex which consists of the 4 vertices of the square. Next we add a 1-cell. To do so we consider the map φ which sends $\partial\overline{B}^1 = \{\pm 1\}$ to the two points $\pm 1 \times -1$. The topological space $X^0 \cup_\varphi \overline{B}^1$ consists of the four points $\{\pm 1, \pm 1\}$ together with an edge which connects the lower two points. This topological space is sketched in the center of the figure below. The same way we attach four more 1-cells and we obtain the 1-dimensional CW-complex which is sketched on the right of the figure below. Finally we attach a 2-cell to X^1 with the attaching map shown in the figure below and we obtain a CW-complex X^2 whose topological realization is homeomorphic to Y.

Now we will see that most of the topological spaces that we have encountered so far can be described as CW-complexes.

(1) It follows almost immediately from the definitions that every topological graph, as defined on page 310, admits naturally the structure of a one-dimensional CW-complex where the vertices correspond precisely to the 0-cells and the edges correspond precisely to the 1-cells. Conversely, every 1-dimensional CW-complex admits naturally

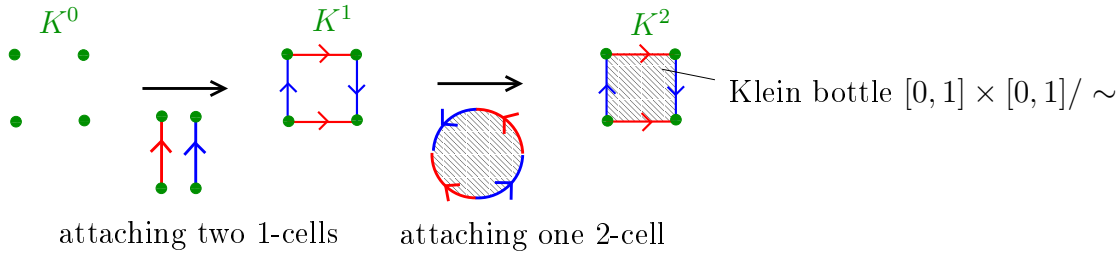


[783] Here we already use the convention that in our notation we do not distinguish between a CW-complex and its topological realization.



the structure of a topological graph. Therefore in the following we will freely go back and forth between these objects.

(2) As a special case of (1) we see that S^1 can be viewed as a CW-complex with one 0-cell and one 1-cell. Furthermore we can view the wedge $S^1 \vee S^1$ as a CW-complex with one 0-cell and two 1-cells. Finally $\mathbb{R}$ can be viewed as a CW-complex where the 0-cells are given by the integers $\mathbb{Z}$ and the 1-cells are given by the intervals $[k, k+1]$ with $k \in \mathbb{Z}$. We refer to the figure below for an illustration.

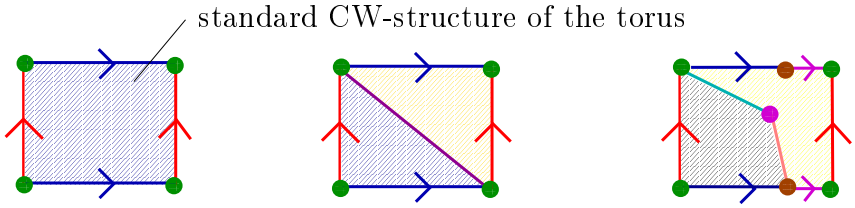


(3) Now we consider the torus $T = ([0,1] \times [0,1])/\sim$. We denote by $p\colon [0,1] \times [0,1] \to T$ the natural projection. We can view T as a CW-complex with one 0-cell corresponding to the point $p(0,0) = p(0,1) = p(1,0) = p(1,1)$, two 1-cells corresponding to $p(0 \times [0,1]) = p(1 \times [0,1])$ and to $p([0,1] \times 0) = p([0,1] \times 1)$ and one 2-cell corresponding to $p([0,1] \times [0,1])$. Note that since we have only one 0-cell there is a unique choice of attaching map for the 1-cells. Finally the attaching map for the 2-cell is illustrated in

the figure below.[784] In the figure below we sketch the CW-structure of the torus and also the corresponding CW-structure of the torus viewed as a subset of $\mathbb{R}^3$. We refer to it as the *standard* CW-*structure* of the torus.

(4) Next we consider the Klein bottle $K = ([0,1]\times[0,1])/\sim$. As usual we denote by $p\colon [0,1]\times[0,1]\to K$ the projection . Similar to the torus we can view K as CW-complex with one 0-cell corresponding to $p(0,0) = p(0,1) = p(1,0) = p(1,1)$, two 1-cells corresponding to $p(0\times[0,1]) = p(1\times[0,1])$ and to $p([0,1]\times 0) = p([0,1]\times 1)$ and one 2-cell corresponding to $p([0,1]\times[0,1])$ with the attaching map sketched in the figure below.[785]

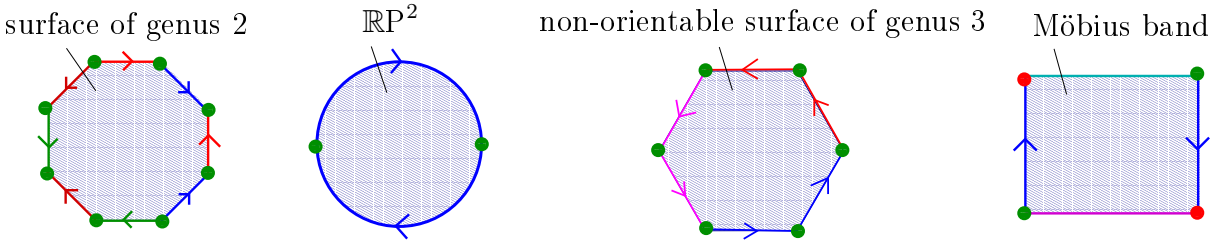
The 1-skeleta of the torus and the Klein bottle are both wedges of two circles. Furthermore both CW-complexes have precisely one 2-cell. The difference between the torus and the Klein bottle is that the attaching maps for the 2-cells are different.



(5) In the figure below we show that we can endow the torus with different CW-structures.

[784]Strictly speaking the attaching map is given by

$$\begin{array}{rcl} S^1 & \to & T^1 \\ \exp(it) & \mapsto & \begin{cases} p(\frac{2}{\pi}t, 0), & \text{if } t\in[0,\frac{\pi}{2}] \\ p(1, \frac{2}{\pi}(t-\frac{\pi}{2})), & \text{if } t\in[\frac{\pi}{2},\pi] \\ p(1-\frac{2}{\pi}(t-\pi), 1), & \text{if } t\in[\pi,\frac{3\pi}{2}] \\ p(0, 1-\frac{2}{\pi}(t-\frac{3}{2}\pi)), & \text{if } t\in[\frac{3\pi}{2},2\pi]. \end{cases} \end{array}$$



But writing out the attaching map with explicit formulas is clearly not very instructive.

[785]Evidently, as in Footnote 784, one could spell out the attaching map with precise formulas, but there is no point in doing it.

one	0-cell	one	0-cell	three	0-cells
two	1-cells	three	1-cells	five	1-cells
one	2-cell	two	2-cells	two	2-cells

(6) In the figure below we sketch how we can view the surface of genus 2, the projective plane $\mathbb{R}\mathrm{P}^2$, the non-orientable surface of genus 3 and the Möbius band as CW-complexes.[786]

one	0-cell	one	0-cell	one	0-cell	two	0-cells
four	1-cells	one	1-cell	three	1-cells	three	1-cells
one	2-cell	one	2-cell	one	2-cell	one	2-cell

(7) We conclude this discussion of surfaces with the 2-sphere. Since it makes no difference, we will immediately discuss the case of any sphere. We can describe the n-dimensional sphere S^n as a CW-complex X as follows: We take a single 0-cell given by a point P and one n-cell where the attaching map $\varphi\colon S^{n-1} \to X^0 = \{P\}$ sends the whole boundary S^{n-1} to the point P. The topological realization of X is thus given by

$$X^0 \cup_\varphi \overline{B}^n \;=\; \{P\} \cup_{P=\partial\overline{B}^n} \overline{B}^n \;=\; \overline{B}^n/S^{n-1} \;\underset{\uparrow}{\overset{\cong}{\Rightarrow}}\; S^n.$$

identification from the Ball-Quotient Sphere Lemma 5.20

We refer to this CW-structure on S^n as the *canonical* CW-*structure on* S^n. Note that the identification from the Ball-Quotient Sphere Lemma 5.20 identifies the unique 0-cell to the left with the North Pole $(0,\dots,0,1)$. Unless we say something else we will equip S^n with the above CW-structure.

We continue the discussion of CW-complexes with two more explicit examples, namely the real projective spaces and the complex projective spaces which we had already defined on page 255. In the following let $\mathbb{A} = \mathbb{R}$ or $\mathbb{A} = \mathbb{C}$. We denote by $\sim$ the equivalence relation on $\mathbb{A}^{n+1} \setminus \{0\}$ given by multiplication by an element in $\mathbb{A} \setminus \{0\}$ and we define

$$\mathbb{A}\mathrm{P}^n \;:=\; (\mathbb{A}^{n+1} \setminus \{0\})/\sim .$$

[786] What does the 1-skeleton of the given CW-structure for the surface of genus two look like, if we view the surface Σ as a "physical object" in $\mathbb{R}^3$?

On page 564 and the Complex Projective Space-is-Complex Manifold Lemma 32.16 we saw that $\mathbb{A}\mathrm{P}^n$ is a smooth manifold. Given a point $(v_0, \ldots, v_n) \in \mathbb{A}^{n+1} \setminus \{0\}$ we denote by $[v_0 : \ldots : v_n]$ its equivalence class. For $k \leq n$ the map

$$\begin{array}{rcl} \mathbb{A}\mathrm{P}^k & \to & \mathbb{A}\mathrm{P}^n \\ [v_0 : \ldots : v_k] & \mapsto & [v_0 : \ldots : v_k : 0 : \ldots : 0] \end{array}$$

is easily seen to be a smooth embedding and we use it to view $\mathbb{A}\mathrm{P}^k$ as a submanifold of $\mathbb{A}\mathrm{P}^n$.

We can give an explicit description of $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$ as CW-complexes.

Lemma 68.1. Let $n \in \mathbb{N}_0$.

(1) We can view $\mathbb{R}\mathrm{P}^n$ as a CW-complex with the following properties:
   (a) the CW-structure has exactly one cell in the dimensions $0, 1, \ldots, n$ and no other cells,
   (b) for each $k \leq n$ the k-skeleton of $\mathbb{R}\mathrm{P}^n$ is given by $\mathbb{R}\mathrm{P}^k$.

(2) We can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex with the following properties:
   (a) the CW-structure has exactly one cell in the dimensions $0, 2, \ldots, 2n$ and no other cells,
   (b) for each $k \leq n$ the $2k$-skeleton of $\mathbb{C}\mathrm{P}^n$ is given by $\mathbb{C}\mathrm{P}^k$.

Proof.

(1) We prove the statement by induction on n. For $n = 0$ the topological space $\mathbb{R}\mathrm{P}^0$ consists of a single point which means that it is a CW-complex with a single 0-cell. Now suppose that we have equipped $\mathbb{R}\mathrm{P}^{n-1}$ with a CW-structure with the properties stated in (a) and (b). We view $\mathbb{R}\mathrm{P}^{n-1}$ as the subspace of $\mathbb{R}\mathrm{P}^n$ that is given by setting the last coordinate to zero. We consider the attaching map

$$\begin{array}{rcl} \varphi\colon S^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ (x_1, \ldots, x_n) & \mapsto & [x_1 : \ldots : x_n]. \end{array}$$

It remains to show that there exists a homeomorphism $\mathbb{R}\mathrm{P}^{n-1} \cup_\varphi \overline{B}^n \to \mathbb{R}\mathrm{P}^n$ that restricts to the identity on $\mathbb{R}\mathrm{P}^{n-1}$. We consider the map

$$\begin{array}{rcl} \Theta\colon \mathbb{R}\mathrm{P}^{n-1} \cup_\varphi \overline{B}^n & \to & \mathbb{R}\mathrm{P}^n \\ [P] & \mapsto & \begin{cases} [x_1 : \cdots : x_n : 0], & \text{if } P = [x_1 : \cdots : x_n] \in \mathbb{R}\mathrm{P}^{n-1}, \\ [P : 1 - \|P\|], & \text{if } P \in \overline{B}^n. \end{cases} \end{array}$$

It follows immediately from the definition of φ that the map Θ is well-defined. Furthermore it follows easily from the Topological-Quotient Proposition 5.15 (1b) that the map Θ is continuous. It is basically clear that the map Θ is a surjection and it is straightforward to verify that the map Θ is an injection. Using the Projective Spaces-Compact+Hausdorff Proposition 5.30, the Topological-Quotient Proposition 5.15 (1b) and the Compact-Hausdorff Proposition 2.17 (3) one can easily verify that the map is a homeomorphism. Finally it is clear that the restriction of the map Θ to $\mathbb{R}\mathrm{P}^{n-1}$ is the identity.

(2) The proof for $\mathbb{C}\mathrm{P}^n$ is basically identical to the proof of (1). We just need to view S^{2n-1} and $\overline{B}^{2n}$ as subsets of $\mathbb{C}^n$. We leave it to the reader to make the necessary minuscule modifications. ■

To enhance the reader's interest in CW-complexes we now give a sneak preview of a later result.

Theorem 96.5. Every compact connected n-dimensional smooth manifold M admits a finite CW-structure with the following properties:

(1) the maximal dimension of a cell is n,
(2) the boundary ∂M is a subcomplex.

Furthermore, if $M = A \cup B$ is a decomposition into two n-dimensional submanifolds such that $A \cap B$ is a union of boundary components of A and a union of boundary components of B, then we can find a CW-structure on M which has all the above properties and such that A and B are subcomplexes.

In the above discussion we have seen that many of the topological spaces we are interested in can be viewed as CW-complexes. But note that not every topological space can be described as a CW-complex. For example consider the topological space X which consists of precisely two points P and Q and which is endowed with the trivial topology. (Recall that this means that the only open sets are the empty set and all of X.) Then we cannot view X as CW-complex since any CW-complex with finitely many points consists only of 0-cells together with the *discrete* topology. For the same reason $\{0\} \cup \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$ is not a CW-complex.

68.2. **Two topologies on $\mathbb{R}^\infty$.** In the next section we want to introduce infinite-dimensional CW-complexes. Before we do so we want to get more acquainted with $\mathbb{R}^\infty$ and topologies on the set $\mathbb{R}^\infty$. First of all we write

$$\mathbb{R}^\infty \;:=\; \mathbb{R}^{(\mathbb{N})} \;:=\; \{(x_1, x_2, \dots) \,|\, \text{only finitely many } x_i \text{ are non-zero}\}.$$

As in the finite-dimensional case we can equip $\mathbb{R}^\infty$ with the Euclidean metric[787]

$$d((x_1, x_2, \dots), (y_1, y_2, \dots)) \;:=\; \sqrt{\sum_{i=1}^{\infty} |x_i - y_i|^2}.$$

By Metric-Topology Lemma 1.1 the metric d defines a topology on $\mathbb{R}^\infty$, more precisely

$$\mathcal{S} \;:=\; \{U \subset \mathbb{R}^\infty \,|\, \text{ for every } P \in U \text{ there exists an } \epsilon > 0 \text{ such that } B_\epsilon(P) \subset U\}$$

is a topology on $\mathbb{R}^\infty$.
This topology might feel like it is the "right topology" on $\mathbb{R}^\infty$. But the next two examples might sow some doubts.

Examples.

(1) We claim that the map

$$\begin{aligned} \alpha \colon \mathbb{R}^\infty &\to \mathbb{R} \\ (x_1, x_2, \dots) &\mapsto \sum_{i=1}^{\infty} 2^i \cdot x_i \end{aligned}$$

is not continuous with respect to $\mathcal{S}$. To show this claim we consider the open subset $(-1, 1) \subset \mathbb{R}$, then $\alpha^{-1}((-1, 1))$ contains the origin 0. We claim that there is no $\epsilon > 0$

[787] Note that the series on the right is in fact a finite sum, since all but finitely many terms are zero. It is again straightforward to verify that d is a metric.

with $B_\epsilon(0) \subset \alpha^{-1}((-1,1))$. Indeed, suppose such $\epsilon > 0$ exists. We pick $i \in \mathbb{N}$ with $\frac{1}{2^i} < \epsilon$ and we consider the point

$$Q \;=\; (0, \dots, 0, \tfrac{1}{2^i}, 0, \dots).$$

Then $Q \in B_\epsilon(0)$ but $\alpha(Q) = 1$, i.e. $Q \notin \alpha^{-1}((-1,1))$.

(2) Let B be the infinite diagonal matrix where the diagonal entries are given by 2^i for $i = 1, 2, \dots$, i.e. let

$$B \;:=\; \begin{pmatrix} 2 & 0 & 0 & \dots \\ 0 & 4 & 0 & \dots \\ 0 & 0 & 8 & \dots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}.$$

We claim that the map

$$\begin{array}{rcl} \beta\colon \mathbb{R}^\infty & \to & \mathbb{R}^\infty \\ x & \mapsto & B \cdot x \end{array}$$

is not continuous with respect to $\mathcal{S}$. Indeed, an argument similar to (1) shows that the preimage of the open set $U = B_1(0)$ is not open.

The maps α and β feel quite natural, so we might want to look around for a different topology on $\mathbb{R}^\infty$ for which these two maps are in fact continuous. Of course that would be achieved by equipping $\mathbb{R}^\infty$ with the discrete topology, but clearly that's not what we want. Another reasonable condition on the desired topology is that for any $n \in \mathbb{N}_0$ the inclusion map

$$\begin{array}{rcl} \iota_n\colon \mathbb{R}^n & \hookrightarrow & \mathbb{R}^\infty \\ (x_1, \dots, x_n) & \mapsto & (x_1, \dots, x_n, 0, \dots) \end{array}$$

should also be continuous. This immediately eliminates the discrete topology as a contender for the "right topology".

In fact this last condition leads us almost immediately to an alternative topology on $\mathbb{R}^\infty$. We saw in the proof of the Direct Limit Existence Proposition 56.1 that in the category of topological spaces we have

$$\varinjlim \mathbb{R}^n \;=\; \mathbb{R}^\infty,$$

where $\mathbb{R}^\infty$ is equipped with the "weak topology", i.e. with the topology

$$\mathcal{T} \;:=\; \{U \subset \mathbb{R}^\infty \mid \text{for every } n \in \mathbb{N} \text{ the set } U \cap \mathbb{R}^n \text{ is open in } \mathbb{R}^n\}.$$

Put differently, a map $f\colon \mathbb{R}^\infty \to X$ to a topological space X is continuous with respect to $\mathcal{T}$ if and only if for each $n \in \mathbb{N}$ the map $\mathbb{R}^n \hookrightarrow \mathbb{R}^\infty \xrightarrow{f} X$ is continuous.

Examples.

(1) By definition of $\mathcal{T}$ the inclusion map $\mathbb{R}^n \to \mathbb{R}^\infty$ is continuous with respect to $\mathcal{T}$.
(2) The above map $\alpha\colon \mathbb{R}^\infty \to \mathbb{R}$ is continuous with respect to the topology $\mathcal{T}$. Indeed, for any $n \in \mathbb{N}$ the restriction $\mathbb{R}^n \to \mathbb{R}^\infty \to \mathbb{R}$ is a linear map, hence continuous.
(3) In Exercise 68.2 we will see that $\mathcal{S} \subset \mathcal{T}$. This implies in particular that the identity map defines a continuous map $(\mathbb{R}^\infty, \mathcal{T}) \to (\mathbb{R}^\infty, \mathcal{S})$.

(4) Let a_i, b_i, $i \in \mathbb{N}$ be real numbers. The infinite hyperrectangle

$$(a_1, b_1) \times (a_2, b_2) \times (a_3, b_3) \times \dots$$

is easily seen to be an open subset of $(\mathbb{R}^\infty, \mathcal{T})$.[788]

The following lemma shows in particular that the above map $\beta\colon \mathbb{R}^\infty \to \mathbb{R}^\infty$ is continuous with respect to the topology $\mathcal{T}$.

Lemma 68.2. Let $C = (c_{ij})_{i,j\in\mathbb{N}}$ be an infinite diagonal matrix. Then the map[789]

$$\begin{aligned} \gamma\colon \mathbb{R}^\infty &\to \mathbb{R}^\infty \\ x &\mapsto C \cdot x \end{aligned}$$

is continuous with respect to the topology $\mathcal{T}$.

Proof. Let $U \in \mathcal{T}$. We need to show that $\gamma^{-1}(U)$ lies in $\mathcal{T}$. So given any $n \in \mathbb{N}$ we need to show that $\gamma^{-1}(U) \cap \mathbb{R}^n$ is an open subset of $\mathbb{R}^n$. So let $n \in \mathbb{N}$. Given $m \in \mathbb{N}$ we denote by $C_{m,n}$ the submatrix of C given by the top left $m \times n$-submatrix of C and we denote by $\gamma_{m,n}\colon \mathbb{R}^n \to \mathbb{R}^m$ the map given by $x \mapsto C_{m,n} \cdot x$. We have[790]

$$\begin{aligned} \gamma^{-1}(U) \cap \mathbb{R}^n &= \big\{x \in \mathbb{R}^n \,\big|\, C \cdot x \in U\big\} = \big\{x \in \mathbb{R}^n \,\big|\, C \cdot x \in \bigcup_{m\in\mathbb{N}} (U \cap \mathbb{R}^m)\big\} \\ &= \bigcup_{m\in\mathbb{N}} \big\{x \in \mathbb{R}^n \,\big|\, C \cdot x \in U \cap \mathbb{R}^m\big\} = \bigcup_{m\in\mathbb{N}} \big\{x \in \mathbb{R}^n \,\big|\, C_{m,n} \cdot x \in U \cap \mathbb{R}^m\big\}. \\ &= \bigcup_{m\in\mathbb{N}} \underbrace{\gamma_{m,n}^{-1}\big(\overbrace{U \cap \mathbb{R}^m}^{\text{open in } \mathbb{R}^m}\big)}_{\substack{\text{open in } \mathbb{R}^n \text{ since} \\ \gamma_{m,n} \text{ is continuous}}}. \end{aligned}$$

This shows that $\gamma^{-1}(U) \cap \mathbb{R}^n$ is a union of open subsets of $\mathbb{R}^n$, hence itself is open. ∎

This discussion shows hopefully that the following convention is reasonable.

Convention. Unless we say something else we will view $\mathbb{R}^\infty$ as a topological space with the topology $\mathcal{T}$. Put differently, we think of $\mathbb{R}^\infty$ as $\mathbb{R}^\infty = \varinjlim \mathbb{R}^n$. Similarly we define $\mathbb{C}^\infty = \varinjlim \mathbb{C}^n$ as topological spaces.

Remark. In Exercise 68.3 we will verify that the map

$$\begin{aligned} \mathbb{C}^\infty &\to \mathbb{R}^\infty \\ (x_1 + \mathrm{i}y_1, x_2 + \mathrm{i}y_2, \dots) &\mapsto (x_1, y_1, x_2, y_2, \dots) \end{aligned}$$

is a homeomorphism. At times we will use this homeomorphism to make the identification $\mathbb{C}^\infty = \mathbb{R}^\infty$.

In the future, the more we work with $\mathbb{R}^\infty$ and $\mathbb{C}^\infty$, the more we will see that the "direct limit topology" is in fact the "right" topology to work with.
To get acquainted with this new topological space we want to prove the following lemma.

---

[788] This example is less obvious. The topology $\mathcal{T}$ has more open sets than $\mathcal{S}$ which made it easier in (2) to argue that the map α is continuous. But here in (3) it also makes it harder, since we have to check the continuity for more open sets on the right-hand side.

[789] Does this also work for any infinite-square matrix?

[790] For each $k \in \mathbb{N}$ we view $\mathbb{R}^k$ as a subset of $\mathbb{R}^\infty$ via the inclusion ι_k.

Lemma 68.3. Given any compact subset K of $\mathbb{R}^\infty$ there exists an $n \in \mathbb{N}$ with $K \subset \mathbb{R}^n$.

Proof. So let $K \subset \mathbb{R}^\infty$ be a compact set. Suppose that there is no $n \in \mathbb{N}$ such that $K \subset \mathbb{R}^n$. Then there exists an infinite increasing sequence $n_1, n_2, n_3, \dots$ of natural numbers and points $x_1, x_2, x_3, \dots$ in K such that $x_i \in \mathbb{R}^{n_i} \setminus \mathbb{R}^{n_i - 1}$. We denote by X the set whose elements are precisely the x_i.

Claim 1. The set X is a discrete subset of $\mathbb{R}^\infty$.

Proof. To simplify the notation we assume that $n_i = i$ for all $i \in \mathbb{N}$. For each i we denote by z_i the i-coefficient of x_i. Put differently, z_i is the highest non-zero coefficient of x_i. Furthermore for each $i \in \mathbb{N}$ we pick $\epsilon_i \in (0, \frac{\|z_i\|}{2})$. Finally, given $x \in \mathbb{R}$ and $\epsilon > 0$ we write $I_\epsilon(x) = (x - \epsilon, x + \epsilon)$. We define

$$\begin{array}{rcccccccccc} U_1 & = & I_{\epsilon_1}(z_1) & \times & I_{\epsilon_2}(0) & \times & I_{\epsilon_3}(0) & \times & I_{\epsilon_4}(0) & \times & \dots \\ U_2 & = & \mathbb{R} & \times & I_{\epsilon_2}(z_2) & \times & I_{\epsilon_3}(0) & \times & I_{\epsilon_4}(z_4) & \times & \dots \\ U_3 & = & \mathbb{R} & \times & \mathbb{R} & \times & I_{\epsilon_3}(z_3) & \times & I_{\epsilon_4}(0) & \times & \dots \\ \vdots & & & & & & & & & & \end{array}$$

As we remarked on page 1476, each U_i is an open subset of $\mathbb{R}^\infty$. Evidently U_i contains x_i and thus each U_i is an open neighborhood of x_i. Furthermore the sets U_i, $i \in \mathbb{N}$ are easily seen to be disjoint. But this shows, by definition of the subspace topology, that X is discrete. ⊞

Claim 2. The set X is a closed subset of K.

Proof. We need to show that $X \setminus K$ is open. By definition of the subspace topology it suffices to show that $\mathbb{R}^\infty \setminus X$ is open. In the following we continue with the notation from the previous claim. Thus let $y \in \mathbb{R}^\infty$. We pick $n \in \mathbb{N}$ such that $y \in \mathbb{R}^n$. In $\mathbb{R}^n$ we can and will pick an open neighborhood U of $(y_1, \dots, y_n)$ that does not contain $x_1, \dots, x_n \in \mathbb{R}^n$. One can now verify easily that

$$V \ := \ U \times I_{\epsilon_{n+1}}(0) \times I_{\epsilon_{n+2}}(0) \times \dots$$

is an open neighborhood of $y \in \mathbb{R}^\infty$ that does not intersect X. ⊞

It follows from Claim 1, Claim 2 and the Compact-Discrete Lemma 1.22 (2) that X is indeed finite. But that is a contradiction to our assumption that there is no $n \in \mathbb{N}$ such that K is contained in $\mathbb{R}^n$. ■

We conclude this section with a short discussion of the infinite-dimensional sphere S^∞.

Definition. We refer to

$$S^\infty \ := \ \{x \in \mathbb{R}^\infty \,|\, d(x, \text{origin}) = 1\} \ = \ \Big\{(x_1, x_2, \dots) \in \mathbb{R}^\infty \,\Big|\, \sum_{i=1}^{\infty} x_i^2 = 1\Big\},$$

equip with the subspace topology coming from $\mathbb{R}^\infty$, as the infinite-dimensional sphere.

Even though we did not show it yet, we strongly expect that the finite-dimensional spheres S^n are not contractible. In contrast to this expectation we have the following mind-bending lemma.

Lemma 68.4. The infinite-dimensional sphere S^∞ is contractible.

Proof. We want to show that S^∞ is contractible. We recall that by the π_0-Homotopy Equivalence Lemma 15.3 it suffices to show that there exists a homotopy H from id_{S^∞} to

a constant map. Our goal is to find such H. We set

$$X \;:=\; \{(0, p_2, p_3, \dots) \in \mathbb{R}^\infty \mid p_i \in \mathbb{R}\}.$$

Next we consider the maps

$$\begin{aligned} F\colon \mathbb{R}^\infty \times [0,1] &\to \mathbb{R}^\infty \\ (P,t) &\mapsto \underbrace{P\cdot(1-t) + (0,P)\cdot t}_{\neq 0 \text{ if } P \neq 0} \end{aligned} \quad \text{and} \quad \begin{aligned} G\colon X \times [0,1] &\to \mathbb{R}^\infty \\ (P,t) &\mapsto \underbrace{P\cdot(1-t) + (1,0,\dots)\cdot t}_{\neq 0 \text{ if } P \neq 0}. \end{aligned}$$

For non-zero $P \in \mathbb{R}^\infty$ and $P \in X$ we define $\widetilde{F}(P,t)$ and $\widetilde{G}(P,t)$ to be the normalization of $F(P,t)$ and $G(P,t)$ to length one. Next we consider the map

$$\begin{aligned} H\colon S^\infty \times [0,1] &\to S^\infty \\ (P,t) &\mapsto \begin{cases} \widetilde{F}(P, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ \widetilde{G}(\widetilde{F}(P,1), 2t-1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{aligned}$$

Clearly $H_0 = \mathrm{id}$ and it is straightforward to see that H_1 is a constant map. It is tempting to conclude that we are done. But in fact we still need to show the following claim.

Claim. The map H is continuous.

Proof. By the Homotopy Stacking Lemma 14.3 it suffices to show that the restriction of H to the subsets $S^\infty \times [0, \frac{1}{2}]$ and $S^\infty \times [\frac{1}{2}, 1]$ are continuous. Since intervals are regionally compact it follows from the Direct Limits-and-Products Lemma 56.4 that it suffices to show for each $n \in \mathbb{N}$ the restrictions of H to the subsets $S^n \times [0, \frac{1}{2}]$ and $S^n \times [\frac{1}{2}, 1]$ are continuous. But now we are in familiar territory and the continuity is a consequence of elementary arguments. ∎

68.3. **Infinite-dimensional CW-complexes.** The following definition now generalizes the notion of a CW-complex.

Definition.

(a) A CW-complex X is defined as a sequence

$$X^{-1} \;:=\; \varnothing \subset X^0 \subset X^1 \subset X^2 \subset \dots$$

of CW-complexes (in the sense of the definition of page 1468) such that for each $m \leq n$ the CW-complex X^m is the m-skeleton of X^n. Let $n \in \mathbb{N}_0$. We adopt the following language:

(i) The (open) n-cells of X^n are called the (open) n-cells of X.

(ii) We refer to X^n as the *n-skeleton of X*

(b) We define the topological realization $|X|$ of such a CW-complex X as

$$|X| \;:=\; \varinjlim |X^n|.$$

Recall that on page 1468 we argued that for each $n \in \mathbb{N}_0$ we can view $|X^n|$ as a subset of $|X^{n+1}|$. Thus it follows from the Direct Limit-of-Topological Spaces Lemma 56.3 that we can and will write

$$|X| \;:=\; \bigcup_{n \in \mathbb{N}_0} |X^n|$$

where a subset $U \subset |X|$ is open if and only if for every $n \in \mathbb{N}_0$ the intersection $U \cap |X^n|$ is an open subset of $|X^n|$. As before, in the notation we usually do not distinguish between the notation for a CW-complex and its topological realization.

(c) We define the dimension $\dim(X) \in \mathbb{N}_0 \cup \{\infty\}$ of a non-empty CW-complex X as the maximal dimension of a cell.[791] We define the dimension of the empty CW-complex to be -1.

(d) We say a CW-complex is finite if it has only finitely many cells and we say it is countable if it has only countably many cells.

(e) A CW-structure for a topological space Y is a CW-complex X together with a homeomorphism $f\colon |X| \to Y$.

Remark.

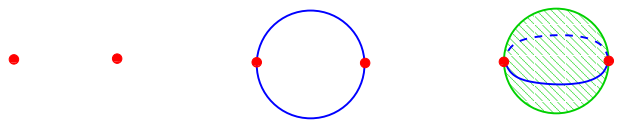
(1) Let X be a CW-complex and let $n \in \mathbb{N}_0$. By the Direct Limit-of-Topological Spaces Lemma 56.3 we know that the inclusion map $|X^n| \to |X|$ is an embedding. Thus we can and will view the n-skeleton as a subset of X.

(2) The topology given in (b) on a union of topological spaces is sometimes called the the *weak topology*. This explains the "W" of the name CW-complex.

(3) It follows almost immediately from the definitions that the topological realization $|X|$ of a CW-complex is, *as a set*, the disjoint union of all the open cells.

(4) On a few occasions we will refer to $X^\infty := X$ as the ∞-skeleton.

Examples.



(1) We consider the infinite sphere

$$S^\infty \;=\; \{x \in \mathbb{R}^\infty \,|\, d(x, \text{origin}) = 1\} \;=\; \left\{(x_1, x_2, \dots) \in \mathbb{R}^\infty \,\middle|\, \sum_{i=1}^{\infty} x_i^2 = 1\right\}$$

which equip with the subspace topology coming from $\mathbb{R}^\infty$. It follows easily from the fact that $\mathbb{R}^\infty = \varinjlim \mathbb{R}^n$ that we have the equality $S^\infty = \varinjlim S^n$. We consider iteratively the spheres S^n as CW-complexes, where S^0 consists of two 0-cells and where S^n is built starting from S^{n-1} by attaching two n-cells ("the upper hemisphere and the lower hemisphere") to S^{n-1}. We then obtain an ascending sequence

$$S^0 \;\subset\; S^1 \;\subset\; S^2 \;\subset\; \dots$$

of CW-complexes which satisfies precisely the required properties of a CW-complex as defined above. This shows that the sphere S^∞ is an infinite-dimensional CW-complex. We refer to the figure below for an illustration.[792]

S^0 S^1 S^2

[791] Here we define $\dim(X) := \infty$ if X admits cells of arbitrarily large dimensions.

[792] If we equip S^∞ with the topology $\mathcal{S}$ coming from the Euclidean metric on $\mathbb{R}^\infty$, then this argument does not work and it is not clear (and presumably wrong), that $(S^\infty, \mathcal{S})$ is a CW-complex.

(2) Let I be a set and for each $i \in I$ let $n_i \in \mathbb{N}$. In Exercise 68.10 we will see that the wedge $\bigvee_{i\in I} S_i^{n_i}$ has a natural CW-structure with one 0-cell and where for each $n \in \mathbb{N}_0$ the n-cells correspond precisely to the n-dimensional spheres in our family of spheres $\{S_i^{n_i}\}_{i\in I}$.

The following definition and notation is the obvious infinite-dimensional analogue of the finite-dimensional definitions introduced on page 255.

Definition. Let $\mathbb{A} = \mathbb{R}$ or $\mathbb{A} = \mathbb{C}$.

(1) We define the infinite-dimensional projective space $\mathbb{A}\mathrm{P}^\infty$ as the set
$$\mathbb{A}\mathrm{P}^\infty \;=\; (\mathbb{A}^\infty \setminus \{0\})/(\mathbb{A} \setminus \{0\})$$
together with the quotient topology.

(2) Given a point $(x_1, x_2, \dots) \in \mathbb{A}^\infty \setminus \{0\}$ we denote its equivalence class in $\mathbb{A}\mathrm{P}^\infty$ by $[x_1 : x_2 : \dots]$.

(3) Given $n \in \mathbb{N}$ we view $\mathbb{A}\mathrm{P}^n$ as a subset of $\mathbb{A}\mathrm{P}^\infty$ via the inclusion map
$$\begin{array}{rcl} \mathbb{A}\mathrm{P}^n & \to & \mathbb{A}\mathrm{P}^\infty \\ [x_0 : \cdots : x_n] & \mapsto & [x_0 : \cdots : x_n : 0 : \dots]. \end{array}$$

The following lemma shows in particular that we can view the real infinite projective space $\mathbb{R}\mathrm{P}^\infty$ as an infinite-dimensional CW-complex.

Lemma 68.5.

(1) For each $n \in \mathbb{N}$ the obvious map $\mathbb{R}\mathrm{P}^n \to \mathbb{R}\mathrm{P}^\infty$ is an embedding. Furthermore these maps define a homeomorphism $\varinjlim \mathbb{R}\mathrm{P}^n \xrightarrow{\cong} \mathbb{R}\mathrm{P}^\infty$.

(2) The topological space $\mathbb{R}\mathrm{P}^\infty$ admits a CW-structure such that for every $n \in \mathbb{N}$ the n-skeleton is given by $\mathbb{R}\mathrm{P}^n \to \mathbb{R}\mathrm{P}^\infty$ where $\mathbb{R}\mathrm{P}^n$ is equipped with the CW-structure coming from Lemma 68.1.

(3) The infinite real projective space $\mathbb{R}\mathrm{P}^\infty$ admits a CW-structure which has precisely one n-cell for every $n \in \mathbb{N}_0$.

(4) (a) The action $\{\pm 1\} \times S^\infty \to S^\infty$ given by $(\epsilon, v) \mapsto \epsilon \cdot v$ is continuous and discrete.
(b) The natural projection $S^\infty \to S^\infty/x \sim -x$ is a 2-fold covering.
(c) The map
$$\begin{array}{rcl} S^\infty/x \sim -x & \to & \mathbb{R}\mathrm{P}^\infty \\ [(x_1, x_2, \dots)] & \mapsto & [x_1 : x_2 : \dots] \end{array}$$
is a homeomorphism.

Proof.

(1) We leave it as a very mildly interesting exercise to the reader to show that for each $n \in \mathbb{N}$ the obvious map $\mathbb{R}\mathrm{P}^n \to \mathbb{R}\mathrm{P}^\infty$ is an embedding. Next we note that we have the following equalities:
$$\begin{aligned} \varinjlim \mathbb{R}\mathrm{P}^n \;=\; \varinjlim (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) &\xrightarrow[\cong]{\text{homeomorphism by Lemma 56.5}} \left(\varinjlim (\mathbb{R}^{n+1} \setminus \{0\})\right)/(\mathbb{R} \setminus \{0\}) \\ &= (\mathbb{R}^\infty \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \;=\; \mathbb{R}\mathrm{P}^\infty. \end{aligned}$$

It follows easily from the definitions that this homeomorphism is the inclusion induced map.

(2) This statement follows immediately from (1) and the definition of a CW-complex on page 1478.

(3) This statement is an immediate consequence of (2) and the definition of the CW-structure on each $\mathbb{R}\mathrm{P}^n$.

(4) (a) The statement is not difficult to prove, but one needs to argue carefully with the given topology on S^∞. We will fill in the details in Exercise 68.4.

(b) This statement follows from (a) and the Actions-Covering Proposition 48.9.

(c) It is straightforward to verify that the given map is a bijection. We leave it to the reader to verify that the map is continuous and that its inverse is continuous. ■

The following lemma is the complex sibling of Lemma 68.5.

Lemma 68.6.

(1) For each $n \in \mathbb{N}$ the obvious map $\mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^\infty$ is an embedding. Furthermore the maps $\mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^\infty$ define a homeomorphism $\varinjlim \mathbb{C}\mathrm{P}^n \xrightarrow{\cong} \mathbb{C}\mathrm{P}^\infty$.

(2) The topological space $\mathbb{C}\mathrm{P}^\infty$ admits a CW-structure such that for every $n \in \mathbb{N}$ the $2n$-skeleton is given by $\mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^\infty$ where $\mathbb{C}\mathrm{P}^n$ is equipped with the CW-structure coming from Lemma 68.1.

(3) The infinite complex projective space $\mathbb{C}\mathrm{P}^\infty$ admits a CW-structure which has precisely one n-cell for every even $n \in \mathbb{N}_0$.

Proof. The proof of this lemma is basically verbatim the same as the proof of the corresponding parts of Lemma 68.5. ■

Convention. We will use Lemmas 68.5 (1) and 68.6 as an excuse to view each $\mathbb{R}\mathrm{P}^n$ as a subset of $\mathbb{R}\mathrm{P}^\infty$ and to view each $\mathbb{C}\mathrm{P}^n$ as a subset of $\mathbb{C}\mathrm{P}^\infty$.

The following lemma says that characteristic maps are continuous and it gives a convenient approach to showing that a map starting at a CW-complex is continuous.

Lemma 68.7. (Characteristic Maps Lemma) Let X be a CW-complex. We denote by $\{\Phi_i \colon \overline{B}^{n_i} \to X\}_{i \in I}$ the characteristic maps of all the cells of X. The following four statements hold:

(1) Every characteristic map Φ_i is continuous.

(2) A subset $U \subset X$ is open if and only if for each $i \in I$ the preimage of U under the characteristic map Φ_i is open, i.e. if each $\Phi_i^{-1}(U) \subset \overline{B}^{n_i}$ is an open subset of $\overline{B}^{n_i}$.

(3) The statement in (2) also holds if we replace "open" by "closed".

(4) A map $f \colon X \to Y$ to a topological space Y is continuous if and only if each map $f \circ \Phi_i \colon \overline{B}^{n_i} \to Y$ is continuous.

Proof. Given $n \in \mathbb{N}_0$ we denote by $I_n \subset I$ the indices corresponding to the characteristic maps of the n-dimensional cells.

(1) Let $i \in I_n$. The characteristic map $\Phi \colon \overline{B}^n \to X$ is the composition of the maps

$$\overline{B}^n = \overline{B}^n_i \to |X^{n-1}| \sqcup \bigsqcup_{j \in I_n} \overline{B}^n_j \to |X^n| = \Big(|X^{n-1}| \sqcup \bigsqcup_{j \in I_n} \overline{B}^n_j\Big)/\sim \to |X| = \varinjlim |X^k|.$$

All these maps are obviously continuous, hence the composition is also continuous.

(2) Once one has unraveled the definition of the topology on a CW-complex one sees that the first statement of the lemma is obvious. In the following we will try to convince the reader that this glib statement is actually correct.

Thus let $U \subset X$ be a subset. By the definition on page 1479 we know that U is open if and only if for each $n \in \mathbb{N}_0$ the intersection $U \cap |X_n|$ is an open subset of $|X_n|$. The statement follows from this observation together with the following claim.

Claim. Let $n \in \mathbb{N}$ and let U be a subset of $|X_n|$. The following two statements are equivalent:
(a) U is an open subset of $|X_n|$.
(b) $U \cap |X_{n-1}|$ is an open subset of $|X_{n-1}|$ and for every $i \in I_n$ the preimage $\Phi_i^{-1}(U)$ is an open subset of $\overline{B}^n$.

Proof. By the definition on page 1468 we have

$$|X^n| \;=\; \Big(|X^{n-1}| \;\sqcup\; \bigsqcup_{i\in I_n} \overline{B}_i^n\Big)/\!\sim \;\text{ where } \Phi_i(x) \sim x \text{ for } x \in \partial\overline{B}_i^n.$$

The statement now follows easily from the definition of the quotient topology and the disjoint union topology. We leave it to the reader to weave these slogans into a coherent argument. ⊞

(3) The "only if"-direction follows from the Characteristic Maps Lemma 68.7 (1). The "if"-direction follows from (1) and a slight generalization of Lemma 2.7 which one can easily prove using the Image-Preimage Lemma 0.2 (8). We leave it to the reader to make sense of this cryptic remark.

(4) Let $f\colon X \to Y$ be a map to a topological space. If f is continuous, then it follows from the Characteristic Maps Lemma 68.7 (1) that each map $f \circ \Phi_i\colon \overline{B}^{n_i} \to Y$ is continuous. Now suppose conversely that each map $f \circ \Phi_i\colon \overline{B}^{n_i} \to Y$ is continuous. Let $U \subset Y$ be an open subset. We need to show that $f^{-1}(U)$ is an open subset of X. By (1) it suffices to show that each preimage $\Phi_i^{-1}(f^{-1}(U))$ is an open subset of $\overline{B}^{n_i}$. But this follows from the observation that $\Phi_i^{-1}(f^{-1}(U)) = (f \circ \Phi_i)^{-1}(U)$ and the hypothesis that each $f \circ \Phi_i$ is continuous. ■

68.4. **Homotopies on infinite CW-complexes.** On several occasions throughout these notes, in particular in the next section, we will want to construct a homotopy on an infinite-dimensional CW-complex by working our way up through the skeleta. In the end one needs to combine infinitely many homotopies which obviously leads to continuity issues. This rather technical section deals with these issues. It is best to initially skip this section and to go back to it if later on one really wants to know how an argument works.

For the undaunted reader we start out with the following subtle lemma.

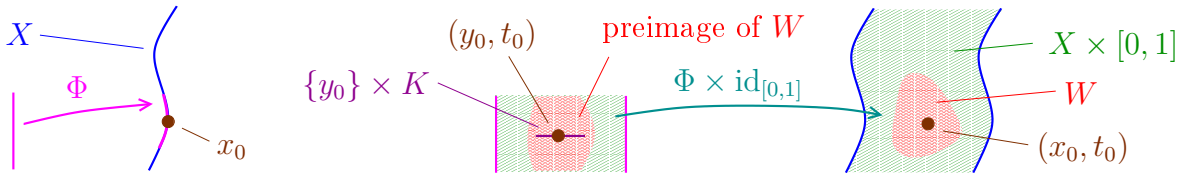
Lemma 68.8. (Intervall CW-Product Lemma) Let X be a CW-complex. The following three topologies on $X \times [0,1]$ agree:
(1) The product topology on the product $X \times [0,1]$.
(2) The topology on $X \times [0,1]$ viewed as the direct limit $\varinjlim (X^k \times [0,1])$.[793]

(3) The topology which is defined on the set $X \times [0,1]$ by the condition that a given subset $U \subset X \times [0,1]$ is open if and only if for each characteristic map $\Phi\colon \overline{B}^n \to X$ the preimage $(\Phi \times \mathrm{id}_{[0,1]})^{-1}(U)$ is an open subset of $\overline{B}^n \times [0,1]$.

Proof. Let X be a CW-complex. First note that it follows immediately from the fact that $X = \varinjlim X_k$ together with the Product Topology-Basics Lemma 5.4 (4) that any subset that is open with respect to (1) is also open with respect to (2). Furthermore it follows from the Characteristic Maps Lemma 68.7 (1) together with the Product Topology-Basics Lemma 5.4 (3) that any subset that is open with respect to (2) is also open with respect to (3). Thus it suffices to show that any set that is open with respect to (3) is also open with respect to (1).

Let $W \subset X \times [0,1]$ be a subset that is open with respect to (3). We need to show that W is also open with respect to the product topology on $X \times [0,1]$. Let $(x_0, t_0) \in W$ be a point. By the Product Topology-Basics Lemma 5.4 it suffices to show the following statement:

(∗) There exists a neighborhood V of $x_0 \in X$ and a neighborhood K of $t_0 \in [0,1]$ such that $V \times K$ is contained in W.



To prove (∗) we start out with the following claim.

Claim. There exists a compact neighborhood K of $t_0 \in [0,1]$ such that $\{x_0\} \times K \subset W$.

Proof. Let $\Phi\colon \overline{B}^n \to X$ be the characteristic map of the open cell that contains x_0. Note that $\Phi\colon B^n \to X$ is injective. Thus there exists a unique $y_0 \in B^n$ with $\Phi(y_0) = x_0$. We write $\Psi := \Phi \times \mathrm{id}_{[0,1]}$. Since W is open with respect to (3) we know that $\Psi^{-1}(W)$ is an open subset of $\overline{B}^n \times [0,1]$. Since $(y_0, t_0) \in \Psi^{-1}(W)$ we obtain from the definition of the product topology on $\overline{B}^n \times [0,1]$ there exists in particular an open neighborhood J of $t_0 \in [0,1]$ such that $\{y_0\} \times J \subset \Psi^{-1}(W)$. Since $[0,1]$ is regionally compact we see that there exists a compact neighborhood K of t_0 that is contained in J. Now we see that

$$\{x_0\} \times K \;=\; \{\Phi(y_0)\} \times K \;\underset{\text{definition of } \Psi}{=}\; \Psi(\{y_0\} \times K) \;\subset\; \Psi(\{y_0\} \times J) \;\underset{\text{since } \{y_0\} \times J \subset \Psi^{-1}(W)}{\subset}\; \Psi(\Psi^{-1}(W)) \;\underset{\text{Image-Preimage Lemma 0.2 (2)}}{\subset}\; W.$$

Thus K has the desired property. ⊞

Next we consider $V := \{x \in X \mid \{x\} \times K \subset W\}$. By the choice of K we have $x_0 \in V$. Thus to prove (∗) it remains to prove the following claim.

Claim. The subset V is open in X.

[793] Recall that we showed in the Direct Limit-of-Topological Spaces Lemma 56.3 that this is the topology where a given subset W of $X \times [0,1] = \varinjlim (X^k \times [0,1])$ is open if and only each intersection $W \cap (X^k \times [0,1])$ is an open subset of $X^k \times [0,1]$.

Proof. We use the Characteristic Maps Lemma 68.7 (2) to show that V is open in X. Thus let $\Phi\colon \overline{B}^n \to X$ be the characteristic map of an n-cell of X. We need to show that the preimage $\Phi^{-1}(V)$ is open in $\overline{B}^n$. We write $U := (\Phi \times \mathrm{id}_{[0,1]})^{-1}(W)$. Since W is open with respect to (3) we see that U is an open subset of $\overline{B}^n \times [0,1]$. Basically by definition we have the equality

$$\Phi^{-1}(V) \;=\; \{y \in \overline{B}^n \mid \{y\} \times K \subset U\}.$$

It follows from elementary point-set topology, see Exercise 5.10, that the set on the right-hand side is indeed open. This concludes the proof of the second claim and thus of the lemma. ■

Later on we will frequently need the following corollary.

Corollary 68.9. (Interval CW-Product Corollary) Let X be a CW-complex and let $\Phi\colon X \times [0,1] \to Y$ be a map to a topological space Y. The following statements are equivalent:

(1) The map f is continuous.
(2) For every $k \in \mathbb{N}_0$ the restriction of f to $X^k \times [0,1]$ is continuous.
(3) For every characteristic map $\Phi\colon \overline{B}^n \to X$ the map

$$\overline{B}^n \times [0,1] \xrightarrow{(v,t)\mapsto(\Phi(v),t)} X \times [0,1] \xrightarrow{f} Y$$

is continuous.

Proof. The corollary follows immediately from the equivalence of the three topologies in the Intervall CW-Product Lemma 68.8. ■

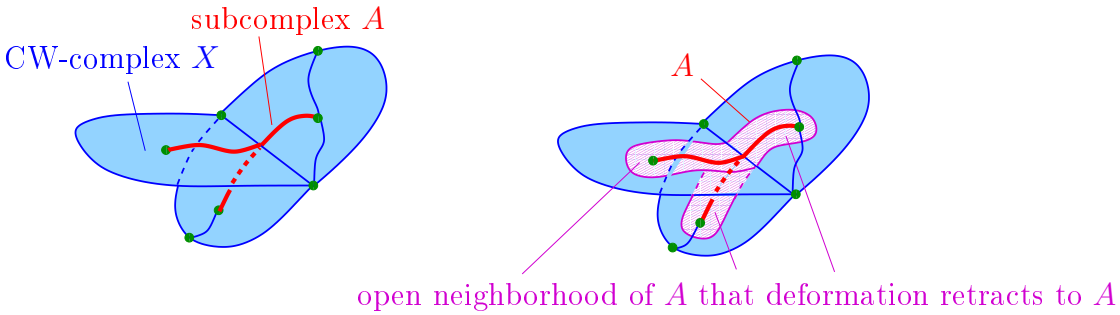
68.5. **Properties of CW-complexes.** We have seen, as promised, that many topological spaces that we are interested in are indeed CW-complexes. In this section we will prove a somewhat technical proposition that shows that CW-complexes have, again as promised, many nice topological properties.
To formulate the key result of this section we need the following definition which we will explore in much greater detail in the subsequent section.

Definition. A subcomplex of a CW-complex X is a subset of X that is the union of arbitrarily many cells of X. We say a subcomplex is finite it contains only finitely many cells of X.

Now we can state the main result of this section.

Proposition 68.10. (CW-Complex Properties Proposition)

(1) Every point on a CW-complex is closed.[794]
(2) (a) CW-complexes are Hausdorff.
    (b) CW-complexes are normal.[795]
(3) (a) Every cell of a CW-complex X is compact and it is a closed subset of X.
    (b) Every finite CW-complex is compact.
    (c) The closure of an open cell is the corresponding cell. More precisely, given a characteristic map $\Phi\colon \overline{B}^n \to X$ the closure of $\Phi(B^n)$ is indeed $\Phi(\overline{B}^n)$.
    (d) If a closed subset of X contains an open cell, then it also contains the corresponding cell.



(4) Let X be a CW-complex, let $x \in X$ and let U be an open neighborhood U of x.
   (a) There exists an open neighborhood V of x that is contained in U and that admits a deformation retraction to $\{x\}$.
   (b) There exists a closed neighborhood V of x that is contained in U and that admits a deformation retraction to $\{x\}$.

(5) Every point on a CW-complex is good in the sense of the definition on page 1171.

(6) CW-complexes are locally contractible, locally path-connected, locally simply-connected and semi-locally simply connected.

(7) Let X be a CW-complex. The following statements are equivalent:
   (a) X is connected.
   (b) X is path-connected.
   (c) The 1-skeleton X^1 is connected.
   (d) The 1-skeleton X^1 is path-connected.
   (e) Given any two distinct points P, Q in the 0-skeleton of X there exists an embedding $\gamma\colon [0,1] \to X^1$ with $\gamma(0) = P$, $\gamma(1) = Q$ and such that $\gamma([0,1])$ is a subcomplex of X^1.

(8) There exists a map Φ which assigns to each subcomplex A a subset $\Phi(A) \subset X$ such that the following statements hold:
   (a) for each subcomplex A the set $\Phi(A)$ is an open neighborhood of A such that A is a deformation retract of $\Phi(A)$,
   (b) for any two subcomplexes A_1 and A_2 we have
   $$\Phi(A_1 \cap A_2) = \Phi(A_1) \cap \Phi(A_2) \quad \text{and} \quad \Phi(A_1 \cup A_2) = \Phi(A_1) \cup \Phi(A_2),$$
   (c) for any two subcomplexes A and B with $A \subset B$ we have $\Phi(A) \subset \Phi(B)$.

Remark.

(1) In a slightly simplified form the CW-Complex Properties Proposition 68.10 (8) says that we can assign to each subcomplex A in a "systematic way" an open neighborhood $\Phi(A)$ that deformation retracts to A.

[794]Note that we need (1) in the proof of (2), thus we cannot just use the Points-in-Hausdorff Space Lemma 1.15 (1) to deduce (2) from (1).

[795]Recall that on page 123 we introduced the definition that a topological space X is called *normal* if any two disjoint closed subsets A and B of X are separated by neighborhoods, i.e. if there exist disjoint neighborhoods U of A and V of B.

(2) In the CW-Complex Properties Proposition 68.10 (8) it is essential that A is a subcomplex. For example, if we consider $X = \mathbb{R}$ and $A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$, then A does not admit an open neighborhood U such that A is a deformation retract of U.[796]
(3) the CW-Complex Properties Proposition 68.10 (6) sounds somewhat technical, but it ensures that later on we can apply the Covering Existence Theorem 61.5 to obtain coverings of CW-complexes.
(4) Many other useful properties of CW-complexes are proved in [**LW1969**, Section II.3].
(5) There is a limit to what degree CW-complexes are nice, for example in Exercise 50.11 we saw that the wedge $\bigvee_{i \in \mathbb{N}_0} [0,1]_i$, which is easily seen to be a CW-complex, is not metrizable.

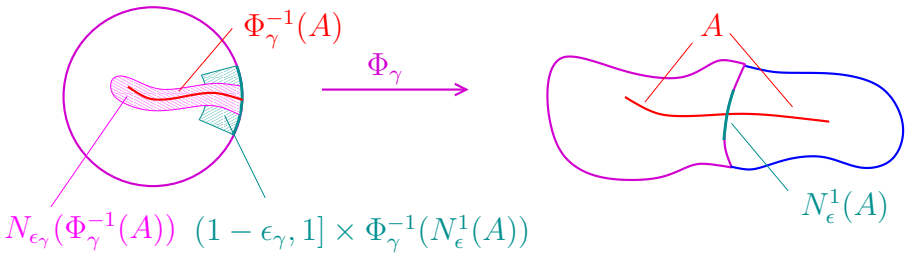
Proof. We start out with the following notation. Given a subset A of $\overline{B}^n$ and $\epsilon > 0$ we denote by

$$N_\epsilon(A) \;:=\; \big\{x \in \overline{B}^n \;\big|\; \text{ there exists an } y \in A \text{ with } \|x - y\| < \epsilon\big\}$$

the ϵ-neighborhood around A. One easily verifies that $N_\epsilon(A)$ is an open subset of $\overline{B}^n$. Furthermore given two non-empty subsets X and Y of $\overline{B}^n$ we follow the notation introduced on page 283 and we write

$$d(X,Y) \;:=\; \inf\{\|x - y\| \,|\, x \in X \text{ and } y \in Y\}.$$

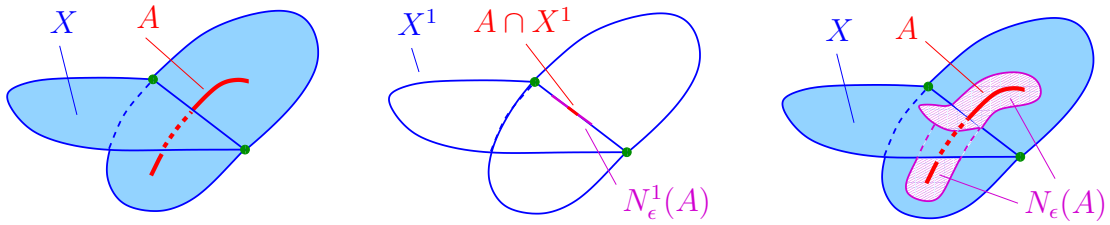
Furthermore, if X or Y is empty, then we define $d(X,Y) = \infty$ and evidently we write $\infty > 0$.



Now let X be a CW-complex. We denote by Γ the set of cells of X and given $n \in \mathbb{N}_0$ we denote by Γ_n the set of n-cells. Given a cell γ we denote by Φ_γ the corresponding characteristic map.

Let $A \subset X$ be a subset and let ϵ be a map that assigns to each $\gamma \in \Gamma$ a positive number ϵ_γ. Given $n \in \mathbb{N}_0$ we define a subset $N^n_\epsilon(A)$ inductively as follows:

(i) For $n = 0$ we define $N^0_\epsilon(A) := A \cap X^0$.
(ii) Suppose that $N_\epsilon(A)^n$ has already been defined. We define

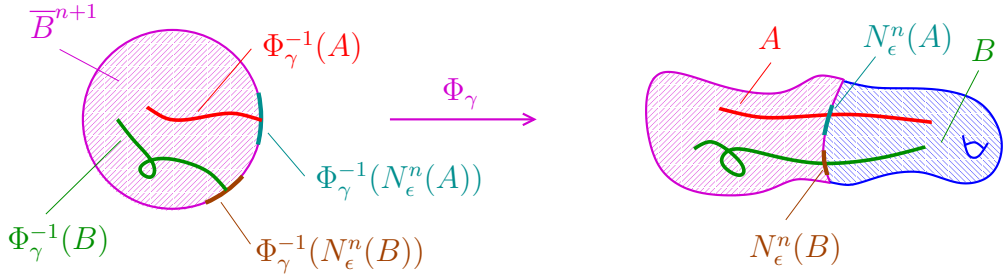


$$N^{n+1}_\epsilon(A) \;:=\; N^n_\epsilon(A) \cup \bigcup_{\gamma \in \Gamma_{n+1}} \Phi_\gamma\Big(N_{\epsilon_\gamma}(\overbrace{\Phi^{-1}_\gamma(A)}^{\subset \overline{B}^{n+1}}) \cup \underbrace{(1-\epsilon_\gamma, 1] \times \overbrace{\Phi^{-1}_\gamma(N^n_\epsilon(A))}^{\subset S^n}}_{\text{radial coordinates on } \overline{B}^{n+1}}\Big).$$

It is straightforward to verify that each $N^n_\epsilon(A)$ is an open neighborhood of $A \cap X^n$ in X^n. The definition of $N^{n+1}_\epsilon(A)$ is illustrated in the figure below. Finally we set $N_\epsilon(A) :=$

[796] Why not?

$\bigcup_{n\in\mathbb{N}} N_\epsilon^n(A)$. It follows easily from the definition of the topology of a CW-complex that $N_\epsilon(A)$ is an open neighborhood of A in X. The definition of $N_\epsilon(A)$ is illustrated in the figure below.



Now we turn to the proofs of the eight statements:

(1) This statement follows fairly easily from the the Topological Pushout-Maps Lemma 5.34 (4). We will fill in the details in Exercise 68.6.

(2) Since by (1) we know that points are closed it suffices to show that CW-complexes are normal. Thus let A and B of X be disjoint closed subsets of X. We need to show that there exist open disjoint neighborhoods of A and B.
So let A and B be two disjoint closed subsets of X. We will find ϵ as above such that $N_\epsilon(A)$ and $N_\epsilon(B)$ are disjoint. We will define the values of ϵ inductively on the dimension of the cells. For 0-cells we take $\epsilon = 1$. Now suppose that we have already found disjoint open sets $N_\epsilon^n(A)$ and $N_\epsilon^n(B)$. Let γ be an $(n+1)$-cell with characteristic map $\Phi_\gamma\colon \overline{B}^{n+1} \to X$.

Claim. We have the following inequalities:

$$\begin{array}{lrcl} \text{(a)} & \mu_1 := d(\Phi_\gamma^{-1}(N_\epsilon^n(A)), \Phi_\gamma^{-1}(B)) & > & 0, \\ \text{(b)} & \mu_2 := d(\Phi_\gamma^{-1}(N_\epsilon^n(B)), \Phi_\gamma^{-1}(A)) & > & 0, \\ \text{(c)} & \mu_3 := d(\Phi_\gamma^{-1}(B), \Phi_\gamma^{-1}(A)) & > & 0. \end{array}$$

Proof. We deal with the three inequalities separately:

(a) We first consider μ_1. Suppose that $\mu_1 = 0$. If this was the case then there would exist a sequence of points in $\Phi_\gamma^{-1}(B)$ that converges to a point of $\Phi_\gamma^{-1}(B)$ in $\partial\overline{B}^{n+1}$ of distance zero from $\Phi_\gamma^{-1}(N_\epsilon^n(A))$. But this is impossible since $\Phi_\gamma^{-1}(N_\epsilon^n(B))$ is a neighborhood of $\Phi_\gamma^{-1}(B) \cap \partial\overline{B}^{n+1}$ in $\partial\overline{B}^{n+1}$ which is disjoint from $\Phi_\gamma^{-1}(N_\epsilon^n(A))$.

(b) The proof of the second inequality $\mu_2 > 0$ is proved exactly the same as the proof of the inequality $\mu_1 > 0$.

(c) It follows from the Characteristic Maps Lemma 68.7 (1) and our hypothesis that A and B are disjoint closed subsets that the preimages $\Phi_\gamma^{-1}(A)$ and $\Phi_\gamma^{-1}(B)$ are disjoint closed subsets of $\overline{B}^{n+1}$. By the Compact-Closed Lemma 1.21 (1) we know that they are in fact disjoint compact subsets of $\overline{B}^n$. Thus it follows from Lemma 6.3 that $\mu_3 = d(\Phi_\gamma^{-1}(B), \Phi_\gamma^{-1}(A)) > 0$. ⊞

We set $\epsilon_\gamma := \frac{1}{2}\min\{\mu_1, \mu_2, \mu_3\}$. We do this for all $(n+1)$-cells γ. It then follows immediately from the definitions that $N_\epsilon^{n+1}(A)$ and $N_\epsilon^{n+1}(B)$ are disjoint.

(3) (a) Every k-cell is the image of the compact set $\overline{B}^k$, hence it is compact by the Compact Image Lemma 2.13. It follows from the Compact-Closed Lemma 1.21 (2) and the fact, proved in (2), that X is Hausdorff that every k-cell is also a closed subset of X.

(b) A finite CW-complex is the union of finitely many cells. Thus it follows from (3a) together with the Compact-Union-Intersection Lemma 1.20 that a finite CW-complex is compact.

(c) Let $\Phi\colon \overline{B}^n \to X$ be a characteristic map. We have the following inclusions

$$\begin{array}{ccccccc} \Phi(\overline{B}^n) & \subset & \overline{\Phi(B^n)} & = & \bigcap \text{ closed subsets containing } \Phi(B^n) & \subset & \Phi(\overline{B}^n). \\ \uparrow & & \uparrow & & & & \uparrow \\ \text{Closure-Interior} & & \text{definition of the closure} & & & & \text{by (3a)} \\ \text{Mapping Lemma 2.5} & & & & & & \end{array}$$

We have thus shown that we indeed have $\overline{\Phi(B^n)} = \Phi(\overline{B}^n)$.

(d) This statement follows immediately from (3b) and the definition of the closure of a set.

(4) Let $x \in X$ and let U be an open neighborhood of x. We need to prove the following two statements;

(a) There exists an open neighborhood V of x that is contained in U and that admits a deformation retraction to $\{x\}$.

(b) There exists a closed neighborhood V of x that is contained in U and that admits a deformation retraction to $\{x\}$.

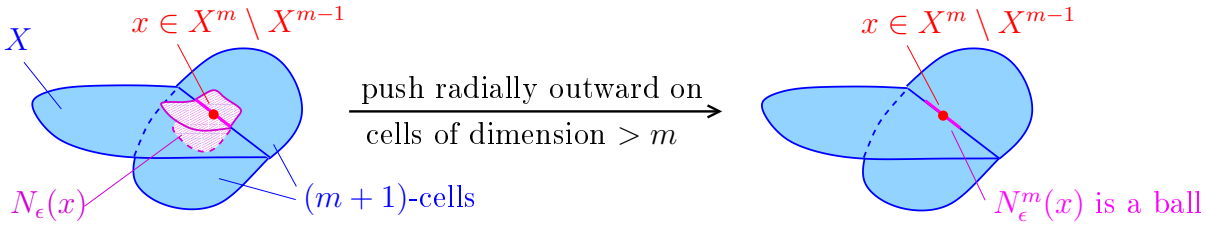
In the following we will prove Statement (a). We leave it to the reader to make the slight modifications to obtain Statement (b).

So let us start with the proof of Statement (a). We leave it to the long-suffering reader to show that there exists an ϵ such that $N_\epsilon(x)$ is contained in U.

It remains to show that $N_\epsilon(x)$ admits a deformation retraction to $\{x\}$. We denote by m the unique natural number with $x \in X^m \setminus X^{m-1}$. It follows easily from the definitions that $N_\epsilon^m(x)$ is an open ball around x, in particular $N_\epsilon^m(x)$ deformation retracts onto $\{x\}$. Therefore it suffices to find a deformation retraction from $N_\epsilon(x)$ to $N_\epsilon^m(x)$.

First note that for $n > m$ "sliding radially outward" we obtain a deformation retraction

$$R(n)\colon N_\epsilon^n(x) \times [0,1] \;\to\; N_\epsilon^n(x)$$



from $N_\epsilon^n(x)$ to $N_\epsilon^{n-1}(x)$. We denote by $r_n := R(n)_1 \colon N_\epsilon^n(x) \to N_\epsilon^{n-1}(x)$ the corresponding retraction. For each $k \in \mathbb{N}_{\geq m+1}$ we consider the map

$$\begin{array}{rcl} f_k \colon N_\epsilon(x) & \to & N_\epsilon^{k-1}(x) \\ y & \mapsto & \begin{cases} (r_k \circ \cdots \circ r_l)(y), & \text{if } y \in N_\epsilon^l(x) \text{ and } l \geq k, \\ y, & \text{if } y \in N_\epsilon^{k-1}(x). \end{cases} \end{array}$$

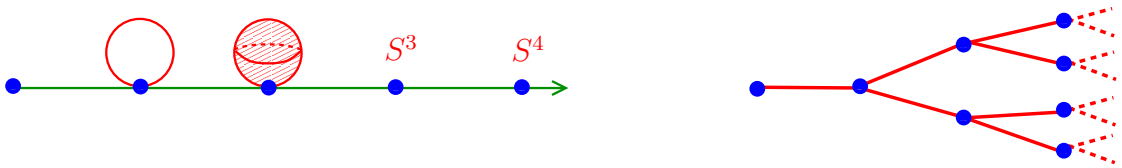
It follows from the Interval CW-Product Corollary 68.9 that this map f_k is continuous. Now we consider the following map

$$\begin{array}{rcl} F \colon N_\epsilon(x) \times [0,1] & \to & N_\epsilon(x) \\ (y,s) & \mapsto & \begin{cases} y, & \text{if } x \in N_\epsilon^k(x) \text{ and } s \in [0, \frac{1}{2^{k+1}}], \\ r_k\big(y, 2^{k+1} \cdot (s - \frac{1}{2^{k+1}})\big), & \text{if } x \in N_\epsilon^k(x) \text{ and } s \in [\frac{1}{2^{k+1}}, \frac{1}{2^k}], \\ f_k(y), & \text{if } x \in N_\epsilon^k(x) \text{ and } s \in [\frac{1}{2^k}, 1]. \end{cases} \end{array}$$

We refer to the figure below for an illustration. It follows from the Homotopy Stacking Lemma 14.3 that the restriction of F to each $N_\epsilon^k(x) \times [0,1]$ is continuous. Thus it follows from the Interval CW-Product Corollary 68.9 that $F \colon N_\epsilon(x) \times [0,1] \to N_\epsilon(x)$ is continuous. This map is the desired deformation retraction.

(5) This statement follows immediately from (2) and (4).

(6) Note that this statement follows immediately from (4) since every topological space that admits a deformation retraction to a point is contractible, and since every contractible topological space is path-connected and simply connected. Finally note that a topological space that is locally simply connected is in particular semi-locally simply connected.



(7) By Locally Path-Connected Lemma 2.40 an locally path-connected topological space is connected if and only if it is path-connected. This shows the equivalence (a) $\Leftrightarrow$ (b) and (c) $\Leftrightarrow$ (d). It follows from the Abstract Graph-Topological Realization Lemma 7.1 (5) and the discussion on page 1470 that we also have (d) $\Leftrightarrow$ (e). We will prove (d) $\Rightarrow$ (b) and (a) $\Rightarrow$ (c) in Exercise 68.7.

(8) We pick an $\epsilon \in (0,1)$. Given a subcomplex A of X we set $\Phi(A) := N_\epsilon(A)$. In each cell of $X \setminus A$ the set $N_\epsilon(A)$ is a product neighborhood of the boundary of this cell. So a deformation retraction of $N_\epsilon(A)$ onto A can be constructed as in (4). We leave the details to the reader. It is clear that Φ has all the other desired properties. ■

Our next goal is to formulate an addendum to the CW-Complex Properties Proposition 68.10. To do so we need to introduce the following definition.

Definition. We say that a CW-complex is locally finite if every cell is disjoint from all but finitely many cells of X.

Examples. The CW-complex $\mathbb{C}\mathrm{P}^\infty$ is not locally finite, whereas the CW-complexes illustrated in the figure below are locally finite.

The following proposition is the promised addendum to the CW-Complex Properties Proposition 68.10.

Proposition 68.11. A CW-complex is regionally compact if and only if it is locally finite.

Proof. We will not make use of Proposition 68.11, except that in the negative sense, that now we know that many CW-complexes we are interested in are unfortunately not regionally compact. The proposition is proved in [**Geo2008**, Proposition 10.1.8]. ■

One of the curses of the working topologist is the unfortunate fact that a bijection continuous map between topological spaces does not need to be a homeomorphism. The following lemma gives a nice criterion for a map between CW-complexes to be a homeomorphism.

Lemma 68.12. (CW-Complex Homeomorphism Lemma) Let $f\colon X \to Y$ be a map between CW-complexes. Suppose the following three conditions are satisfied:

(1) f is a bijection,
(2) f is continuous,
(3) the images of the cells of X are precisely the cells of Y.

Then $f\colon X \to Y$ is a homeomorphism.

Proof. We denote by $g = f^{-1}\colon Y \to X$ the inverse of f. It remains to show that g is continuous. Let $\{\Phi_i\colon \overline{B}^{m_i} \to X\}_{i\in I}$ be the characteristic maps of the CW-complex X and let $\{\Phi_j\colon \overline{B}^{n_j} \to Y\}_{j\in J}$ be the characteristic maps of the CW-complex Y. By the Characteristic Maps Lemma 68.7 it suffices to show that for each $j \in J$ the map $g \circ \Psi_j\colon \overline{B}^{n_j} \to X$ is continuous. We consider the cell $\Psi_j(\overline{B}^{n_j})$. By hypothesis (3) there exists an $i \in I$ such that $f(\Phi_i(\overline{B}^{m_i})) = \Psi_j(\overline{B}^{n_j})$. Since $\Phi_i(\overline{B}^{m_i})$ is compact and since we know by the CW-Complex Properties Proposition 68.10 that $\Psi_j(\overline{B}^{n_j}) \subset Y$ is Hausdorff it follows from the Compact-Hausdorff Proposition 2.17 (3) that $f\colon \Phi_i(\overline{B}^{m_i}) \to \Psi_j(\overline{B}^{n_j})$ is a homeomorphism. But this implies that $f^{-1} = g$ is continuous on $\Psi_j(\overline{B}^{n_j})$. It follows that, as desired, the map $g \circ \Psi_j$ is continuous. ■

We conclude this section with the following proposition.

Proposition 68.13. (CW-Complex Paracompactness Proposition) Every CW-complex is paracompact.

Proof. As always, when it comes to CW-complexes, the proof is slightly delicate. Since we will not really make use of the proposition we refer instead to [**FrPi1990a**, Theorem 1.3.5], or alternatively to [**Hat2**, Proposition 1.20], [**Lee2000**, Theorem 5.22], [**LW1969**, Theorem II.4.2] and [**Miy1952**], for a proof. ■

68.6. **The Finiteness Theorem for CW-complexes.** The following proposition is one of the key technical results about infinite CW-complexes.

Theorem 68.14. (CW-Complex-Finiteness Theorem) Every compact (connected) subset of a CW-complex X is contained in a finite (connected) subcomplex.

Remark. The statement of the proposition and also its proof have more than a passing resemblance with Lemma 68.3.

Example. We consider the wedge $X := \bigvee_{i\in\mathbb{N}_0} S^1_i$. As discussed on page 1480, we can view X as a CW-complex with one 0-cell, given by the wedge point, and 1-cells indexed by $i \in \mathbb{N}_0$. It follows from the CW-Complex-Finiteness Theorem 68.14 that each compact subset of X is contained in the union of finitely many S^1_i. In fact this statement already follows from Exercise 50.9.

Before we start out with the proof of the CW-Complex-Finiteness Theorem 68.14 we formulate the following pretty corollary.

Corollary 68.15. (CW-Complex Compactness Corollary) A CW-complex is compact if and only if it is finite.

Proof. In the CW-Complex Properties Proposition 68.10 (3) we showed that every finite CW-complex is compact. Now we want to prove the converse. Thus let X be a compact CW-complex. It follows from the CW-Complex-Finiteness Theorem 68.14 that X is contained in a finite subcomplex Y of X. But from $X \subset Y \subset X$ it follows that $X = Y$, i.e. X is a finite CW-complex. ■

The proof of the CW-Complex-Finiteness Theorem 68.14 will be a fairly straightforward consequence of the following rather technical lemma.

Lemma 68.16. Let X be a CW-complex.

(1) Let $A \subset X$ be a subset. If every open cell of X contains at most one point of A, then A is closed and discrete.
(2) If $C \subset X$ is a compact subset, then C is contained in a finite union of open cells.
(3) Every cell of X is contained in a finite subcomplex of X.[797]

Remark. Lemma 68.16 (3) together with the CW-Complex Properties Proposition 68.10 (3a) and (3c) shows in particular that the *closure* of each open cell is contained in the union of *finitely* many open cells. This property is sometimes referred to as X being "closure finite" which explains the "C" in the name CW-complex.

Proof of Lemma 68.16. We start out with the following claim.

Claim. Let Y be a CW-complex. Then the statements (1), (2) and (3) are equivalent.

Proof. Let Y be a CW-complex. First we show (1) $\Rightarrow$ (2). Let $C \subset Y$ be a compact subset. For each cell that intersects C we pick a single point. We denote the resulting set of points by A. By (1) the set A is closed and discrete. Since A is a closed subset of compact set we obtain from the Compact-Closed Lemma 1.21 (1) that A is compact. Since A is compact and discrete we obtain from the Compact-Discrete Lemma 1.22 (1) that A is in fact finite. But that means that C intersects only finitely many cells, i.e. C is contained in a finite union of open cells as claimed.

[797] Recall that by definition, see page 1484, a subcomplex is *finite* if it contains only finitely many cells of X. So even a subcomplex that is given by a single cell might a priori contain many other cells.

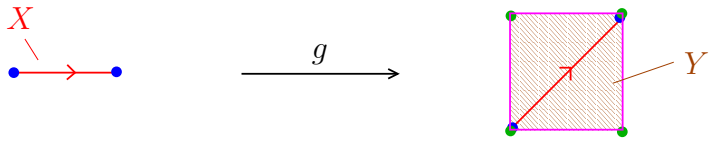
Now we will prove (2) $\Rightarrow$ (3). So let $C_\sigma \subset Y$ be an n-cell. We denote by U_σ the corresponding open cell. By the CW-Complex Properties Proposition 68.10 (3) and by definition of a cell we know that $C_\sigma \setminus U_\sigma$ is a compact subset of the $(n-1)$-skeleton Y^{n-1}. It follows from (2) that the subset $C_\sigma \setminus U_\sigma$ is contained in a finite union of open cells of dimension $\leq n-1$. By the same argument each of these lower-dimensional closed cells is again contained in a finite union of open cells of smaller dimension, except again for the cell itself. A straightforward induction argument now shows that we end up with finitely many cells which form a subcomplex of Y.

Next we will show (3) $\Rightarrow$ (1). Let $A \subset Y$ be a subset such that no two points lie in the same open cell. We consider the intersection of A with a closed cell. By (3) this intersection is contained in a finite subcomplex Y'. Since A has at most one point in common with any open cell this intersection $A \cap Y'$ must be finite and hence closed in $A \cap Y'$ by the CW-Complex Properties Proposition 68.10 (2). By the CW-Complex Properties Proposition 68.10 (3) the finite subcomplex Y' is a closed subset of X. Hence $A \cap Y'$ is a closed subset of X. For any point $x \in A$ the set $A \setminus \{x\}$ also satisfies the hypothesis for A, and so it must also be a closed subset of X. Hence $\{x\}$ is open in A, so A is discrete. ⊞

Now let X be a CW-complex. First note that Statement (1) holds for X^0 by definition of the topology on X^0. Now suppose we know (1) for the n-skeleton X^n for some $n \in \mathbb{N}_0$. By claim we know that (2) and (3) also for X^n. But the proof of (2) $\Rightarrow$ (3) for a given n-cell only used (2) for subsets of X^{n-1}. Thus we actually have (3) for X^{n+1}. Thus we also have (1) for X^{n+1}. Summarizing we have all three statements for X^n for all n. But any cell lies in some X^n, and so we know (3) for X itself, and by the claim this implies that (1) and (2) also hold for X. ■

Proof of the CW-Complex-Finiteness Theorem 68.14. Let X be a CW-complex and let $C \subset X$ be a compact subset. By Lemma 68.16 (2) the subset C is contained in a union of finitely many open cells. By Lemma 68.16 (3) each of these open cells is contained in a finite subcomplex. The union of these finitely many finite subcomplexes is a finite subcomplex Z which contains C.
If C is connected, then we take the component of Z that contains C. By Lemma 68.21 (3) this is again a subcomplex. ■

68.7. **Cellular maps.** Before we move on to considering subcomplexes and constructions of CW-complexes let us quickly introduce the type of maps between CW-complexes that are reasonable.



Definition.

(1) A map $g\colon X \to Y$ between two CW-complexes is called cellular if for each $n \in \mathbb{N}_0$ we have $g(X^n) \subset Y^n$.
(2) A map $g\colon X \to Y$ between two CW-complexes is called a cellular isomorphism if f is cellular, if f is a bijection and continuous, and if f^{-1} is also cellular.

Example. In general maps between CW-complexes are not cellular. For example consider the CW-complex $X = [0,1]$ with two 0-cells and one 1-cell and we consider the CW-complex $Y = [0,1] \times [0,1]$ with four 0-cells, two 1-cells and one 2-cell. Then the diagonal map

$$\begin{array}{rccc} g\colon X = [0,1] & \to & Y = [0,1] \times [0,1] \\ t & \mapsto & (t,t) \end{array},$$

which is illustrated in the figure below is not a cellular map.

It is clear that the composition of two cellular maps is again cellular. This leads us to the following definition.

Definition. We call the category $\mathcal{CW}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{CW}) &:= \text{all CW-complexes,} \\ \mathrm{Mor}(X,Y) &:= \text{all } \textit{cellular} \text{ maps from } X \text{ to } Y, \end{aligned}$$

together with the usual composition of maps the category of CW-complexes. This category should not be confused with the *full category of* CW*-complexes* that is given by

$$\begin{aligned} \mathrm{Ob}(\mathcal{FullCW}) &:= \text{all CW-complexes,} \\ \mathrm{Mor}(X,Y) &:= \text{all } \textit{continuous} \text{ maps from } X \text{ to } Y. \end{aligned}$$

Now is as good as any other moment to introduce a little more categorical language.

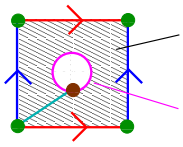
Definition. A covariant functor $F\colon \mathcal{C} \to \mathcal{D}$ between two categories is called faithful if for every two objects $X, Y \in \mathrm{Ob}(\mathcal{C})$ the map $\mathrm{Mor}(X,Y) \to \mathrm{Mor}(F(X),F(Y))$ is an injection. If the map is in fact a bijection, then we call the functor fully faithful. The same definition applies, with the obvious modifications, to contravariant functors.

To practice the definitions we formulate the following lemma.

Lemma 68.17. The maps

$$\begin{aligned} \text{CW-complex } X &\mapsto |X| \\ (f\colon X \to Y) &\mapsto (f\colon |X| \to |Y|) \end{aligned}$$

define a covariant functor from the category $\mathcal{CW}$ of CW-complexes to the category of topological spaces. The functor is faithful but not fully faithful. The maps also define a covariant functor from the full category $\mathcal{FullCW}$ of CW-complexes to the category of topological spaces, this time the functor is fully faithful.



Proof. The statements are basically obvious. The fact that we just found a continuous map which is not cellular gives us that the functor $\mathcal{CW} \to \mathcal{Top}$ is not fully faithful. ■

68.8. **Subcomplexes.** In this section we will discuss in great deal the concept of a subcomplex. We defined the notion on a subcomplex in a perfunctory way on page 1484, but to give the concept its due prominence let us repeat the definition.

Definition. A subcomplex of a CW-complex X is a subset of X that is the union of arbitrarily many cells of X.

Examples.

(1) In the figure below we consider the smooth manifold X that is given by removing an open disk from a torus. We see that X has the structure of a CW-structure such that the boundary ∂X is a CW-subcomplex.

(2) Let X be a CW-complex. For each $n \in \mathbb{N}_0$ the n-skeleton X^n is a subcomplex.

The name "subcomplex" suggests that a subcomplex should again be a CW-complex. That is indeed the case.

Lemma 68.18. (Subcomplex Lemma) Let X be a CW-complex and let A be a subcomplex of X.

(1) The subset A admits a CW-structure such that for each $n \in \mathbb{N}_0$ we have the equality $|A^n| = A \cap |X^n|$ and such that the characteristic maps of A correspond precisely to the characteristic maps of X that take values in A.
(2) The inclusion map $A \to X$ is a closed embedding, in particular A is a closed subset of X.

Proof. We start out with the proof of Statement (1). We set $Y^{-1} = |Y^{-1}| := \varnothing$. For $n = 0, 1, 2, 3, \ldots$ we iteratively do the following:

(1) Let $\{\varphi_i \colon S^{n-1} \to |Y^{n-1}|\}_{i \in I}$ be the attaching maps from the CW-structure of X that correspond to n-cells that lie in A. We define $Y^n = (Y^{n-1}, \{\varphi_i \colon S^{n-1} \to |Y^{n-1}|\}_{i \in I})$.
(2) We set $|Y^n| := \left(|Y^{n-1}| \sqcup \bigsqcup_{i \in I} \overline{B}^n\right)/\sim$.

Finally we define Y to be the CW-complex that is given by the sequence of CW-complexes $Y_{-1} \subset Y_0 \subset Y_1 \subset \ldots$.

Since A is by definition the union of cells we see that the obvious map $\varphi \colon |Y| \to A$ is a bijection. It remains to show that the map φ is actually a homeomorphism. Note that by definition, if $\Phi \colon \overline{B}^n \to |Y|$ is a characteristic map of the CW-complex Y, then $\varphi \circ \Phi \colon \overline{B}^n \to |X|$ is a characteristic map of the CW-complex X. Thus it follows from the Characteristic Maps Lemma 68.7 (1) and (4) that φ is continuous.

By the Open -Injective Map Lemma 2.16 (1) it remains to show that the map $\varphi \colon |Y| \to X$ is a closed map.

Claim. The map $\varphi \colon |Y| \to X$ is a closed map.

Proof. Lt $C \subset |Y|$ be a closed subset. We need to show that $\varphi(C)$ is also a closed subset of A. By the Characteristic Maps Lemma 68.7 (1) and (3) it suffices to show that for each cell $e \subset X$ the set $\varphi(C) \cap e$ is closed. By Lemma 68.16 we know that e intersects only finitely many cells. In particular there are only finitely many cells contained in $A \cap e$. We denote these by $a_1, \ldots, a_m$. Now we see that

$$\varphi(C) \cap e \underset{\substack{\uparrow \\ \text{since } \varphi(C) \subset A}}{=} \varphi(C) \cap (A \cap e) \underset{\substack{\uparrow \\ \text{since } A \text{ is a subcomplex}}}{=} \varphi(C) \cap \bigcup_{i=1}^m a_i = \bigcup_{i=1}^m (\varphi(C) \cap a_i)$$

$$\underset{\substack{\uparrow \\ \text{since } C \text{ is closed in } |Y| \text{ and since} \\ a_1, \ldots, a_m \in S \text{ are cells of } Y}}{=} \bigcup_{i=1}^m \text{closed subset of } a_i \underset{\substack{\uparrow \\ \text{by the Open -Closed Inclusion Lemma 2.10 (2) since the } a_i \\ \text{are closed subsets of } e}}{=} \bigcup_{i=1}^m \text{closed subset of } e = \text{closed subset of } e.$$

⊞

Now we turn to the proof of Statement (2). In fact this follows immediately from the claim. Indeed, evidently $|Y|$ is a closed subset of $|Y|$ and from the claim we obtain that $\varphi(|Y|)$ is a closed subset of X. But $\varphi(|Y|) = A$. Thus we have shown that A is a closed subset of X. ■

Definition. Let A and X be CW-complex. A map $f\colon A \to X$ is called a cellular embedding if f is injective and if the image of a cell of A is a cell of X.

Lemma 68.19. (Cellular Embedding Lemma) Let $f\colon A \to X$ be a cellular embedding between two CW-complexes. The following statements hold:

(1) The image $f(A)$ is a subcomplex of A and the map $f\colon A \to f(A)$ is a cellular isomorphism.
(2) The map $f\colon A \to X$ is a closed embedding.

Proof. It follows immediately from the above definition of a subcomplex and of a cellular embedding that the image of a cellular embedding $f\colon A \to X$ is a subcomplex. Next we consider the map $f^{-1}\colon f(A) \to A$. We deduce from the Characteristic Maps Lemma 68.7 together with the Compact-Hausdorff Proposition 2.17 (3) that the map $f^{-1}\colon f(A) \to A$ is continuous. It follows almost immediately that $f\colon A \to f(A)$ is a cellular isomorphism. Finally we obtain from the above together with the Subcomplex Lemma 68.18 that $f\colon A \to X$ is a closed embedding. ■

Lemma 68.20. (CW-Complex Pasting Lemma) Let X be a CW-complex and let $\{X_i\}_{i\in I}$ be a family of subcomplexes such that $\bigcup_{i\in I} X_i = X$. The following three statements hold:

(1) A subset $U \subset X$ is open if and only if each $X_i \cap U$ is an open subset of X_i.
(2) A subset $A \subset X$ is closed if and only if each $X_i \cap A$ is a closed subset of X_i.
(3) A map $f\colon X \to Y$ to a topological space Y is continuous if and only if each map $f|_{X_i}\colon X_i \to Y$ is continuous.

Proof.

(1) This statement is an easy consequence of the Characteristic Maps Lemma 68.7 (2).
(2) The "only if"-direction is an immediate consequence of the Neighborhood Openness Criterion 1.5 (2). The "if"-direction follows from (1) and Lemma 2.7 (1) ⇒ (2).
(3) The "only if"-direction is an immediate consequence of Lemma 2.1 (3). The "if"-direction follows from (1) and Lemma 2.7 (1) ⇒ (3). ■

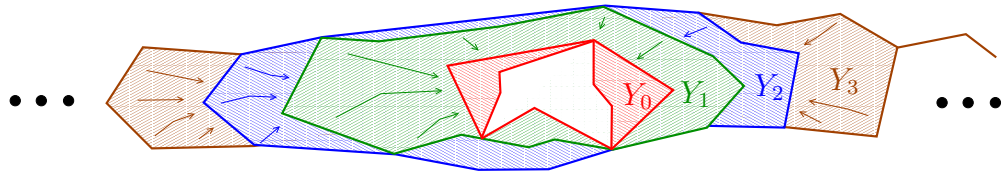
The following lemma shows in particular that some straightforward constructions provide examples of subcomplexes.

Lemma 68.21. Let X be a CW-complex.

(1) For any $n \in \mathbb{N}_0$ the n-skeleton X^n is a subcomplex of X.
(2) The union and also the intersection of arbitrarily many subcomplexes is again a subcomplex.
(3) Every path-component of a complex is again a subcomplex.

Proof.

(1) This statement is clear.



(2) This statement is also clear.
(3) This statement is basically obvious since each closed ball is path-connected. ■

We conclude this section with the following proposition.

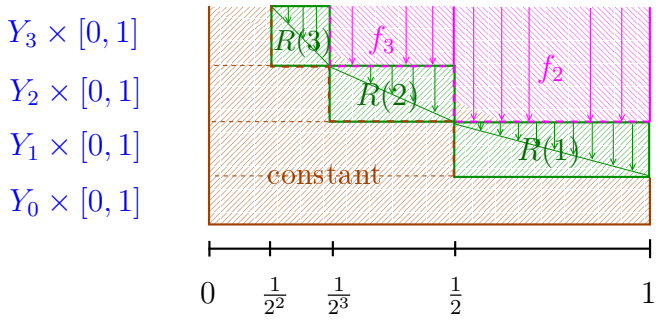
Proposition 68.22. (Iterated Deformation Retracts Proposition) Let X be a CW-complex and let $Y = Y_0 \subset Y_1 \subset Y_2 \subset \dots$ be a sequence of subcomplexes such that the following two conditions are satisfied:

(1) we have $X = \bigcup_{i \in \mathbb{N}} Y_i$,
(2) each Y_i is a deformation retract of Y_{i+1}.

Then Y_0 is a deformation retract of X.

Proof. By hypothesis there exists for each $k \in \mathbb{N}_0$ a deformation retraction

$$R(k)\colon Y_k \times [0,1] \;\to\; Y_{k-1}.$$



We denote by $r_k := R(k)_1\colon Y_k \to Y_{k-1}$ the corresponding retraction. For each $k \in \mathbb{N}_0$ we consider the map

$$\begin{array}{rcl} f_k\colon X \times [0,1] & \to & Y_{k-1} \times [0,1] \\ (x,t) & \mapsto & \begin{cases} (r_k \circ \dots \circ r_l)(x), & \text{if } x \in Y_l \text{ and } l \geq k, \\ x, & \text{if } x \in Y_{k-1}. \end{cases} \end{array}$$

It follows from the Interval CW-Product Corollary 68.9 that this map f_k is continuous. Now we consider the following map

$$\begin{array}{rcl} F\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} x, & \text{if } x \in Y_k \text{ and } t \in [0, \frac{1}{2^{k+1}}], \\ r_k\big(x, 2^{k+1} \cdot (t - \frac{1}{2^{k+1}})\big), & \text{if } x \in Y_k \text{ and } t \in [\frac{1}{2^{k+1}}, \frac{1}{2^k}], \\ f_k(x), & \text{if } x \in Y_k \text{ and } t \in [\frac{1}{2^k}, 1]. \end{cases} \end{array}$$

We refer to the figure below for an illustration. It follows from the Homotopy Stacking Lemma 14.3 that the restriction of F to each $Y_k \times [0,1]$ is continuous. Thus it follows from the Interval CW-Product Corollary 68.9 that $F\colon X \times [0,1] \to X$ is continuous. This map is the desired deformation retraction. ■

68.9. **Products of CW-complexes I.** Let X and Y be two CW-complexes. We can form the product topological space $X \times Y$. Ideally one would like to equip $X \times Y$ with a CW-structure. Throughout this section we use the homeomorphism from the Convex-to-Ball Proposition 2.20 (2) to identify the n-dimensional closed ball $\overline{B}^n$ with the n-dimensional cube $I^n = [0,1]^n$ and we use it to make the identification $S^{n-1} = \partial I^n$. For $p+q=n$ we evidently have $I^n = I^p \times I^q$ and we have

$$\partial(I^n) \;=\; \partial I^p \times I^q \;\cup\; I^p \times \partial I^q.$$

The idea is now to define a CW-structure on $X \times Y$ such that the product of a p-cell in X with a q-cell in Y corresponds to a $(p+q)$-cell in $X \times Y$.
In the following we want to execute this idea rigorously. First, to be on the safe side, we consider the case of two finite complexes.

Definition. Let X and Y be two CW-complexes. Given $p \in \mathbb{N}_0$ let $\{\varphi_j \colon S^{p-1} \to X^{p-1}\}_{j \in J_p}$ and $K_p := \{\psi_k \colon S^{p-1} \to Y^{p-1}\}_{k \in K_p}$ be the set of attaching maps of p-dimensional cells of X and Y. Furthermore we denote by $\{\Phi_j \colon \overline{B}^p \to X^p\}_{j \in J_p}$ and $\{\Psi_k \colon \overline{B}^p \to Y^p\}_{k \in K_p}$ the corresponding characteristic maps of the cells. We define a new CW-complex Z as follows:

(1) We put $Z^{-1} = \varnothing$.
(2) Suppose Z^{n-1} is already defined for some $n \in \mathbb{N}_0$. Given $j \in J_p$ and $k \in K_{n-p}$ we define[798]
$$\begin{aligned} \theta_{(j,k)} \colon \partial I^n = \partial I^p \times I^{n-p} \;\cup\; I^p \times \partial I^{n-p} &\to Z^{n-1} \\ (x,y) &\mapsto (\Phi_j(x), \Psi_k(y)). \end{aligned}$$
We set
$$Z^n \;:=\; \Big(Z^{n-1} \;\sqcup \bigsqcup_{p+q=n} \bigsqcup_{j \in J_p, k \in K_{n-p}} \underbrace{\big(I^p \times I^{n-p}\big)}_{=\overline{B}^n}{}_{(j,k)} \Big) / \sim$$
where for each $j \in J_p$, $k \in K_{n-p}$ we define $(x,y) \in (I^p \times I^{n-p})_{(j,k)}$ with the point $\theta_{(i,j)}(x,y) \in Z^{n-1}$.
(3) Given $j \in J_p$ and $k \in K_{n-p}$ we denote by $\Theta_{(j,k)} \colon I^n = I^p \times I^{n-p} \to Z^n$ the corresponding characteristic map.
(4) We set $Z := \varinjlim Z^n$.

As the discussion suggests, the above construction does indeed (often) define a CW-structure on the topological space $X \times Y$. To simplify the initial discussion we first consider the case that X and Y are two finite CW-complexes.

Proposition 68.23. (CW-Complex Product Proposition) Let X and Y be two CW-complexes. We use the notation from the above definition.

(1) The above data turns Z into a CW-complex.
(2) The characteristic maps $\Theta_{(i,j)}$ define a continuous bijection $\Theta \colon Z \to X \times Y$.
(3) Suppose we are in one of the following two settings:
   (a) X and X are both finite CW-complexes, or
   (b) $Y = [0,1]$ where Y is equipped with the usual CW-structure with two 0-cells and one 1-cell,

[798] Why does the image of this attaching map lie in $(X \times Y)^{n-1}$?

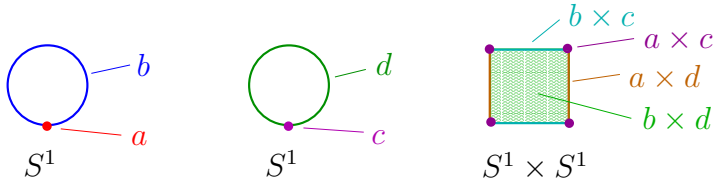
then the map $\Theta\colon Z \to X \times Y$ from (2) is a homeomorphism. In particular the topological space $X \times Y$ has a CW-structure such that for each $n \in \mathbb{N}_0$ we have

$$\underbrace{(X \times Y)^n}_{n\text{-skeleton of } X \times Y} = \bigcup_{p+q=n} X^p \times Y^q.$$

Definition. Let X and Y be finite CW-complexes. Suppose we are in one of the two settings of the CW-Complex Product Proposition 68.23 (3).

(1) We refer to the above CW-structure on $X \times Y$ as the product CW-structure.
(2) Given a p-cell e for X and given a q-cell for Y we denote by $e \times f$ the corresponding $(p+q)$-cell for $X \times Y$.

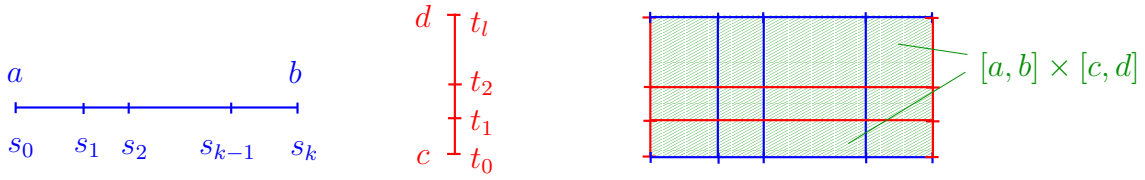
Remark. The second case of the CW-Complex Product Proposition 68.23 (3) might appear somewhat random, but it will actually prove important for showing that several constructions, like mapping cylinders and mapping cones, give rise to CW-complexes.



Proof. Let X and Y be two CW-complexes.

(1) This statement follows basically immediately from the definitions.
(2) It follows from the Characteristic Maps Lemma 68.7 (4) that the map $\Theta\colon Z \to X \times Y$, which is defined via the characteristic maps $\Theta_{(i,j)}$, is continuous.
(3) (a) Suppose that X and X are both finite CW-complexes. In this case Z has only finitely many cells, hence Z is compact by the CW-Complex Compactness Corollary 68.15. Furthermore note that $X \times Y$ is Hausdorff by the CW-Complex Properties Proposition 68.10 (2) and the Product Topology Properties Proposition 5.6. It follows from the Compact-Hausdorff Proposition 2.17 (3) that $\Theta\colon Z \to X \times Y$ is indeed a homeomorphism.
(b) Suppose we have $Y = [0,1]$ with the obvious CW-structure. It follows basically immediately from the equivalence of the topologies (1) and (3) of the Intervall CW-Product Lemma 68.8 that the map $\Theta\colon Z \to X \times Y$ is a homeomorphism.

Since $\Theta\colon Z \to X \times Y$ is a homeomorphism and since Z is a CW-complex we have endowed $X \times Y$ with a CW-structure. The statement about the skeleta follows immediately from the definition of the CW-structure on Z. ■



Examples.

(1) If we equip $S^1 = [0,1]/0 \sim 1$ with the usual CW-structure with one 0-cell and one 1-cell, then the product CW-structure on the torus $S^1 \times S^1 = ([0,1] \times [0,1])/\sim$ is precisely the CW-structure that we had already encountered on page 1471. We refer to the figure below for an illustration.

(2) Given $a = s_0 < s_1 < \cdots < s_k = b$ and $c = t_0 < t_1 < \cdots < t_l = d$ we can view the intervals $[a,b]$ and $[c,d]$ as CW-complexes where the 1-cells are given precisely by the intervals $[s_i, s_{i+1}]$, $i = 0, \ldots, k-1$ and $[t_j, t_{j+1}]$, $j = 0, \ldots, l-1$. The product

CW-complex is the topological space $[a,b]\times[c,d]$ where the 2-cells are given by the rectangles $[s_i,s_{i+1}]\times[t_j,t_{j+1}]$ with $i\in\{0,\dots,k-1\}$ and $j\in\{0,\dots,l-1\}$. The analogous statement holds also for higher-dimensional hyperrectangles. For example, given $k\in\mathbb{N}$ and $n\in\mathbb{N}$ we can equip the cube $[0,1]^n$ with a CW-structure where the n-cells are precisely given by the cubes $[\frac{s_1}{k},\frac{s_1+1}{k}]\times\cdots\times[\frac{s_n}{k},\frac{s_n+1}{k}]$ with $s_1,\dots,s_n\in\{0,\dots,k-1\}$.

The formulation of Proposition 68.23 already suggests that the conclusion does not hold without some assumptions on X and Y. In fact, the following lemma, which goes back to **[Dow1952]**, shows that there are indeed examples of CW-complexes X and Y such that the map $\Theta\colon Z\to X\times Y$ is *not* a homeomorphism. In other words, in general the "naive" attempt to endow a product of CW-complexes with a CW-structure fails.

Lemma 68.24. Let $S:=\{(s_1,s_2,\dots)\,|\,s_i\in\mathbb{N}\}$ be the set of all infinite sequences of positive integers. Let $X=\bigvee_{i\in[0,1]}[0,1]_s$ be the wedge of uncountably many copies of $[0,1]$, obtained by wedging all the $0\in[0,1]_s$. Similarly we form the wedge $Y=\bigvee_{j\in\mathbb{N}}[0,1]_j$ of countably many copies of $[0,1]$. We equip X and Y with the "obvious CW-structure", see e.g. the CW-Complex Construction Lemma 68.32 (4). In this setting the map $\Theta\colon Z\to X\times Y$ from the CW-Complex Product Proposition 68.23 is *not* a homeomorphism.

Proof. For $s\in S$ and $j\in\mathbb{N}$ we consider $(\frac{1}{s_j},\frac{1}{s_j})\in[0,1]_s\times[0,1]_j\in X\times Y$. We denote by $P\subset X\times Y$ the subset defined by all these points. Since each 2-cell of the CW-complex Z contains a single point of P we obtain from the Characteristic Maps Lemma 68.7 (3) that P is a closed subset of Z. To show that Θ is not a homeomorphism it remains to prove the following claim.

Claim. The set P is not closed with respect to the product topology on $X\times Y$.

Proof. We denote by $x_0\in X$ and $y_0\in Y$ the wedge points. Note that $(x_0,y_0)\notin P$. Thus it suffices to show that every neighborhood of $(x_0,y_0)\in X\times Y$ contains a point of P. In fact, by definition of the product topology, see page 224, it suffices to show that any subset $U\times V$ of $X\times Y$ of the form $U=\bigvee_{s\in S}[0,a_s]\subset X$ and $V=\bigvee_{j\in\mathbb{N}}[0,b_j]\subset Y$ contains a point of P. We pick a sequence $t=(t_1,t_2,\dots)\in S$ such that for every $j\in\mathbb{N}$ we have $t_j>j$ and such that $t_j>\frac{1}{b_j}$. Furthermore we pick a $k\in\mathbb{N}$ with $k>\frac{1}{a_t}$. It follows that $t_k>k>\frac{1}{a_t}$, which implies that $\frac{1}{t_k}<a_t$. Recall that by construction we also have $\frac{1}{t_k}<b_k$. Thus we see that $(\frac{1}{t_k},\frac{1}{t_k})$ is a point of P that lies in $[0,a_t]\times[0,b_k)$. Hence it also lies in $U\times V$. ∎

68.10. **Products of CW-complexes II.** In this section we will discuss the product of two infinite CW-complexes in somewhat greater detail. We will not make use of the results of this and the coming section, thus these two sections can be skipped safely.

First we mention the following proposition which can be viewed as a generalization of the CW-Complex Product Proposition 68.23.

Proposition 68.25. Let X and Y be two CW-complexes. If at least one of the two CW-complexes has only countably many cells, then the map $\Theta\colon Z \to X \times Y$ from the CW-Complex Product Proposition 68.23 (2) is a homeomorphism, in particular $X \times Y$ has a natural CW-structure.

Proof. This statement is proved in [**LW1969**, Theorem II.5.2]. If one of X or Y is a finite CW-complex, then the statement is also proved in [**Hat2002**, Theorem A.6]. If both CW-complexes have countably many cells, then the statement is also proved in [**FrPi1990a**, Proposition 2.2.3] or [**Miln1956b**, Lemma 2.1]. ■

Definition. Let X and Y be two CW-complexes.

(1) If at least one of the two CW-complexes has only countably many cells, then we refer to the above CW-structure on $X \times Y$ as the product CW-structure.
(2) Following [**LW1969**, p. 56] we denote by $X \otimes Y$ the topological space whose underlying set is given by $X \times Y$ but whose topology is the unique topology that turns the map $\Theta\colon Z \to X \otimes Y$ from Proposition 68.23 into a homeomorphism.

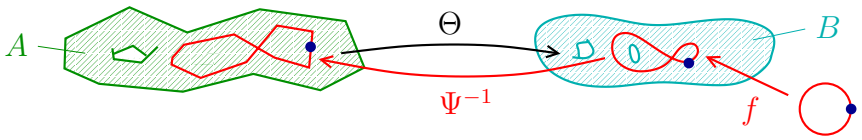
Remark. Note that [**Brooke2017**, Theorem 1] gives a necessary and sufficient condition for the product of two CW-complexes to be a CW-complex.

We conclude this section with a short discussion on the relationship between $X \otimes Y$ and $X \times Y$.

Proposition 68.26. Let X and Y be two CW-complexes.

(1) The identity map $\mathrm{id}\colon X \otimes Y \to X \times Y$ is a continuous bijection.
(2) A subset $K \subset X \otimes Y$ is compact if and only if it is compact in $X \times Y$.
(3) Given any $(x, y) \in X \times Y$ the induced map $\pi_1(X \otimes Y, (x, y)) \to \pi_1(X \times Y, (x, y))$ is an isomorphism.
(4) If at least one of the two CW-complexes has only countably many cells, then the map $X \otimes Y \to X \times Y$ is a homeomorphism.

The proof of Proposition 68.26 (3) is mostly outsourced to the following lemma.



Lemma 68.27. Let $\Theta\colon A \to B$ be a continuous bijection between two topological spaces which has the property that a subset $K \subset A$ is compact if and only if $\Theta(K) \subset B$ is compact. If A is Hausdorff, then for any $a_0 \in A$ the map $\Theta_*\colon \pi_1(A, a_0) \to \pi_1(B, f(a_0))$ is an isomorphism.

Proof. We write $b_0 := f(a_0)$. The proof of the lemma naturally breaks up into showing that $\Theta_*\colon \pi_1(A, a_0) \to \pi_1(B, b_0)$ is an epimorphism and that it is a monomorphism.

Let us first show that the map Θ_* is an epimorphism. Suppose we are given an element $[f\colon (S^1, *) \to (B, b_0)] \in \pi_1(B, b_0)$. By the Compact Image Lemma 2.13 we know that $L := f(S^1)$ is a compact subset of B. We set $K := \Theta^{-1}(L)$. Since Θ is a bijection we have $\Theta(K) = L$. It follows from our hypothesis that K is a compact subset of A. Since Θ is a bijection, since K is compact and since L is Hausdorff we obtain from the Compact-Hausdorff Proposition 2.17 (3) that $\Psi := \Theta|_K\colon K \to L$ is a homeomorphism. In particular the inverse $\Psi^{-1}\colon L \to K$ is continuous. Next we set $g := \Psi^{-1} \circ f\colon (S^1, *) \to (A, a_0)$.

We have $\Theta_*([g]) = [\Theta \circ g] = [\Theta|_K \circ \Psi^{-1} \circ f] = [f]$. Thus we have shown that Θ_* is an epimorphism.

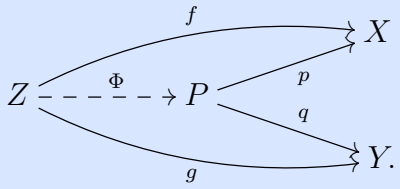
The proof that Θ_* is a monomorphism is quite similar. The key observation is that the image of a homotopy in B between two loops is a compact subset. We leave it to the reader to fill in the few remaining details. ■

Proof of Proposition 68.26. Let X and Y be two CW-complexes.

(1) It follows immediately from Proposition 68.23 (2) and the definition of the topological space $X \otimes Y$ that the identity map $\mathrm{id}\colon X \otimes Y \to X \times Y$ is a continuous bijection.

(2) Let $K \subset X \otimes Y$. If K is compact in $X \otimes Y$. It follows from (1) and the Compact Image Lemma 2.13 that K is also compact in $X \times Y$. Now suppose conversely that K is compact in the product topological space $X \times Y$.
   (a) Note that $X \times Y$ is Hausdorff by the CW-Complex Properties Proposition 68.10 (2) and the Product Topology Properties Proposition 5.6. Thus it follows from the Compact-Closed Lemma 1.21 (2) that K is a closed subset of $X \times Y$. It follows from (1) that K is closed in $X \otimes Y$.
   (b) We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the obvious projections. It follows from the Compact Image Lemma 2.13 that $p(K)$ and $q(K)$ are compact. By the CW-Complex-Finiteness Theorem 68.14 we know that there exist finite subcomplexes $X' \subset X$ and $Y' \subset Y$ such that $p(K) \subset X'$ and $q(K) \subset Y'$. But this implies that K is contained in the finite subcomplex $X' \otimes Y'$ of $X \otimes Y$. By the CW-Complex-Finiteness Theorem 68.14 we know that $X' \otimes Y'$ is compact. Together with (a) we see that K is a closed subset of $X \otimes Y$ that is contained in a compact subset $X' \otimes Y'$. It follows from the Compact-Closed Lemma 1.21 (1) that K itself is compact.

(3) This statement follows immediately from (1) and (2), the fact that $X \times Y$ is Hausdorff and Lemma 68.27.



(4) This statement is just a reformulation of Proposition 68.23 (3). ■

68.11. **A convenient category of topological spaces.** Let X and Y be two CW-complexes. We can equip the set $X \times Y := \{(x, y) \,|\, x \in X \text{ and } y \in Y\}$ with two different topologies, namely the familiar product topology from the Topological-Product Proposition 5.1 and the less familiar topology $X \otimes Y$ from the previous section. As we saw in Lemma 68.24, in general these two topologies are different.

This is quite a nuisance. In this section we will discuss one approach to addressing this issue. We will not make much use of the ideas discussed in this section, thus the reader can safely move on to the next section.

Let us first reflect about what "product" is supposed mean in the first place. After contemplating on the concept of "product" for a while one will surely arrive at the following definition that we already gave on page 211.

Definition. Let $\mathcal{C}$ be a category and let $X, Y \in \mathrm{Ob}(\mathcal{C})$ be two objects. A product of X and Y in the category $\mathcal{C}$ is some object $P \in \mathrm{Ob}(\mathcal{C})$ together with two morphisms $p\colon P \to X$ and $q\colon P \to Y$ such that the following property is satisfied: Whenever we are given two morphisms $f\colon Z \to X$ and $g\colon Z \to Y$ there exists a unique morphism $\Phi\colon Z \to P$ such that $f = p \circ \Phi$ and $g = q \circ \Phi$. The situation is summarized in the following diagram

Sometimes we refer to P also as the categorical product of X and Y if we want to distinguish it from the usual set-theoretic product.

Remark. The definition of the product can be formulated in terms of inverse limits. More precisely, we consider the set $I = \{*, \star\}$ with the trivial preorder. An inverse system over I in a category $\mathcal{C}$ is just the data of two objects X and Y in $\mathcal{C}$. The corresponding inverse limit, if it exists, is *by definition*[799] precisely a product of X and Y in $\mathcal{C}$.

The usual "formal nonsense" shows that the product, if it exists, is unique up to a canonical isomorphism. Thus we will use usual parlance and we will speak of *the product*, if it exists.

Examples.

(1) Let $\mathcal{Set}$ be the category of sets and let $X, Y \in \mathrm{Ob}(\mathcal{Set})$. As we mentioned already on page 212, one can easily verify that the product is given by the set $X \times Y := \{(x, y) \,|\, x \in X \text{ and } y \in Y\}$ together with the obvious maps $X \times Y \to X$ and $X \times Y \to Y$.

(2) Let $\mathcal{Top}$ be the category of topological spaces and let $(X, \mathcal{A}), (Y, \mathcal{B}) \in \mathrm{Ob}(\mathcal{Top})$. Let $\mathcal{P}$ be the product topology on the set $X \times Y$ that we defined on page 224. Recall that in the Topological-Product Proposition 5.1 we showed that in the category of topological space the product is given by the topological space $(X \times Y, \mathcal{P})$ together with the obvious maps $X \times Y \to X$ and $X \times Y \to Y$.

(3) Let $\mathcal{PTop}$ be the category of pointed topological spaces that we introduced on page 1061. Furthermore let $(X, x_0), (Y, y_0) \in \mathrm{Ob}(\mathcal{PTop})$ together with the obvious maps. In Exercise 68.12 we will see that the product in $\mathcal{PTop}$ is given by the smash product $(X, x_0) \wedge (Y, y_0)$ that we introduced on page 1143, together with the obvious morphisms $(X, x_0) \wedge (Y, y_0) \to (X, x_0)$ and $(X, x_0) \wedge (Y, y_0) \to (Y, y_0)$.

(4) Let $\mathcal{SmMfd}_{\partial=\varnothing}$ be the category of smooth manifolds with empty boundary that we introduced on page 637 In the Smooth Manifold Product Proposition 19.31 we saw that "the obvious construction" implies that this category admits a product. Note though that this does not apply to the category $\mathcal{SmMfd}$ of all smooth manifolds. In Exercise 68.19 we will see that this category does not have products.[800]

[799] We refer to page 1273 for the definition of an inverse limit.

[800] Note that in Propositions 20.6 and ?? we saw two hacks which at times allow us to get around this annoying issue.

The following theorem shows that if we move from considering all topological spaces to a slightly more constrained setup, then we can combine the two concepts of products that we introduced for CW-complexes.

Theorem 68.28. (Convenient Category Theorem) There exists a full subcategory $\mathcal{C}$ of the category of topological spaces with the following properties:

(1) Every regionally compact Hausdorff space is an object of $\mathcal{C}$.
(2) Every CW-complex is an object of $\mathcal{C}$.
(3) Every direct system in $\mathcal{C}$ has a direct limit and every inverse system in $\mathcal{C}$ has an inverse limit.
(4) If X and Y are two CW-complexes, then the CW-complex $X \otimes Y$ is in fact the product in $\mathcal{C}$.

Remark. A category as in the Convenient Category Theorem 68.28 is often called a *convenient category*. Note though that the notion of a convenient category might be used somewhat differently by different authors. In fact there are many "convenient categories", possibly with somewhat different properties from the ones we stated. We refer to [**Stee1967, Miln1959a, Spa1963, VogR1971, McCor1967, Stri, Pre2002, BrownR1963**] and [**Stro2011**, Chapter 3.4] for more examples and for the discussion of various notions of a "convenient category".

We will outline the proof of the Convenient Category Theorem 68.28 by giving an explicit example of a convenient category. We will need the following definitions.

Definition.

(1) A subset A of a topological space X is called compactly closed if for every map $\varphi\colon K \to X$, where K is a compact Hausdorff space, the preimage $\varphi^{-1}(A)$ is a closed subset of K.[801]
(2) A topological space X is called compactly generated if every compactly closed subset of X is actually closed.[802]
(3) A topological space X is called weakly Hausdorff if for every map $\varphi\colon K \to X$, where K is a compact Hausdorff space, the image $\varphi(K)$ is closed.[803]
(4) A topological space X is called a CGWH-space[804] if it is compactly generated and if it is weakly Hausdorff.

First, for the readers who like weird topological spaces we give some non-examples.

Examples.

(1) We equip the set $X = (\mathbb{N} \times \mathbb{N}) \cup \{*\}$ with the topology where $U \subset X$ is open if one of the following holds:
   (a) the point $*$ is contained in U, or
   (b) for all but finitely many $n \in \mathbb{N}$ the set U contains all but finitely many points in $\{n\} \times \mathbb{N}$.

[801] It follows from the Continuity-via-Closed Subsets Lemma 2.4 that every closed subset of X is actually compactly closed.
[802] Sometimes in the literature a compactly generated topological space is also called a *k-space*.
[803] By the Compact-Closed Lemma 1.21 (2) we know that a topological space that is Hausdorff is also, as it should be, weakly Hausdorff.
[804] Evidently the acronym CGWH stands for Compactly Generated and Weakly Hausdorff.

In Exercise 68.13 we will see that X is not compactly generated.

(2) We consider $X = \mathbb{R} \setminus \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$ and we consider $Y = \mathbb{R}/Z$ where $Z \subset \mathbb{R}$ is the subset given by integers.[805] In Exercise 68.16 we will see that the product topological space $X \times Y$ is not compactly generated.

(3) In Exercise 68.17 we will give an example of a topological space that is weakly Hausdorff but that is not Hausdorff.

We proceed with an actual example of a CGWH-space.

Proposition 68.29. Every CW-complex is a CGWH-space.

Proof. Let X be a CW-complex.

(1) Let A be a compactly closed subset of X. It follows easily from the Characteristic Maps Lemma 68.7 (3) that A is in fact a closed subset of X.

(2) By the CW-Complex Properties Proposition 68.10 (2) we know that X is Hausdorff. It follows from the Compact-Closed Lemma 1.21 (2) that X is in fact weakly Hausdorff. ∎

We continue with the following simple-minded definition.

Definition. The category $\mathcal{CGWH}$ of CGWH-spaces is the full subcategory of the category of topological spaces whose objects are precisely the CGWH-spaces.

Remark. The category of CGWH-spaces was introduced by Michael McCord [**McCor1969**], building on work by Norman Steenrod [**Stee1967**].

The following theorem shows that the category of CGWH-spaces has many charming properties. The theorem provides us in particular with a proof of the Convenient Category Theorem 68.28.

Theorem 68.30. (CGWH-Category Theorem) The category $\mathcal{CGWH}$ of CGWH-spaces has the following properties:

(0) The category $\mathcal{CGWH}$ is a full subcategory of the category of topological spaces.

(1) Every regionally compact Hausdorff space is an object of $\mathcal{CGWH}$.

(2) Every CW-complex is an object of $\mathcal{CGWH}$.

(3) Every direct system in $\mathcal{CGWH}$ has a direct limit and every inverse system in $\mathcal{CGWH}$ has an inverse limit.

(4) Given any two objects X and Y in $\mathcal{CGWH}$ there exists a product in the category $\mathcal{CGWH}$.

(5) Let X and Y be two objects in $\mathcal{CGWH}$. The following statements hold:

(a) The product of X and Y in $\mathcal{CGWH}$ is given by the set $X \times Y$ together with a topology $\mathcal{T}$ that contains the usual product topology $\mathcal{P}$. In particular the identity map
$$(X \times Y, \mathcal{T}) \;\to\; (X \times Y, \mathcal{P})$$
is a bijection and continuous.

(b) If X and Y are compact and Hausdorff, then $\mathcal{T} = \mathcal{P}$, i.e. the map in (a) is a homeomorphism.

[805] We use this cumbersome notation to make sure that we do not confuse the quotient space $\mathbb{R}/Z$ with the quotient of $\mathbb{R}$ by the obvious action of the group $(\mathbb{Z}, +)$ on the topological space $\mathbb{R}$.

(c) If X and Y are two CW-complexes, then the identity map $(X \times Y, \mathcal{T}) \to X \otimes Y$ is a homeomorphism.

Remark. Let X and Y be two CGWH-spaces. We denote by $X \widetilde{\times} Y$ the categorical product of X and Y in the category of CGWH-spaces. the CGWH-Category Theorem 68.30 (4) can be reformulated as saying that we have a continuous bijection $X \widetilde{\times} Y \to X \times Y$. Furthermore, if X and Y are two CW-complexes, then the identity map $X \widetilde{\times} Y \to X \otimes Y$ is a homeomorphism.

Sketch of proof. Most of the statements below were first proved by Michael McCord [**McCor1969**], building on work by Norman Steenrod [**Stee1967**]. Arguably the best account of the proof is given in [**Stri**]. In the following we show that our theorem, as formulated, can be deduced from the statements in [**Stri**].

(0) This statement holds by definition.
(1) [**Stri**, Proposition 1.7] says that every regionally compact Hausdorff space is in fact a CGWH-space.
(2) In Proposition 68.29 we just saw that every CW-complex is a CGWH-space.
(3) In [**Stri**, Propositions 2.23 and 2.30] it is shown that every direct system and every inverse system in the category of CGWH-spaces actually has a limit in the category of CGWH-spaces.
(4) As we discussed on page 1502, this is just a special case of (3).
(5) Let X and Y be two topological spaces. Let $\mathcal{T}$ be the usual product topology on $X \times Y$. Furthermore let $\mathcal{P}$ be the topology on $X \times Y$ that is generated by all compactly closed subsets of $(X \times Y, \mathcal{T})$. By the Continuity-via-Closed Subsets Lemma 2.4 we know that every closed subset is compactly closed, thus we see that $\mathcal{T} \subset \mathcal{P}$. It follows from [**Stri**, Proposition 2.4 and Corollary 2.16] that $(X \times Y, \mathcal{P})$ is the product in the category of CGWH-spaces.
   (a) This statement follows immediately from the above discussion.
   (b) Now suppose that X and Y are compact and Hausdorff. By the Product Topology Properties Proposition 5.6 we know that the product topological space $X \times Y$ is also compact and Hausdorff. But it follows almost immediately from the definitions that in a compact Hausdorff space a subset is compactly closed if and only if it is closed. Thus we see that $\mathcal{P} = \mathcal{T}$.
   (c) Now let X and Y be CW-complexes. We denote by $\mathcal{X}$ the topology of $X \widetilde{\times} Y$ that we introduced on page 1500. We need to show that $\mathcal{P} = \mathcal{X}$. We make the following two observations:
      (i) By definition a subset $A \subset X \times Y$ is closed in $\mathcal{P}$ if and only if the intersection of A with each compact subset of $(X \times Y, \mathcal{T})$ is closed.
      (ii) By definition a subset $A \subset X \times Y$ is closed in $\mathcal{X}$ if and only if the intersection of A with each cell of the CW-complex $X \otimes Y$ is closed.

   Using the Characteristic Maps Lemma 68.7 (3), the CW-Complex-Finiteness Theorem 68.14 and Exercise 5.17 one can show that $\mathcal{P}$ and $\mathcal{X}$ have the same closed subsets. We leave it to the reader to fill in the details. ■

Remark. Given CGWH-spaces X and Y it is also convenient to equip X^Y with a slight modification of the usual compact-open topology. We refer to [**Stri**, Proposition 2.24] for details.

We conclude this section with the following proposition that gives us three other convenient properties of the category of CGWH-spaces. The reader who has struggled with the intricacies of the Whitehead Quotient Theorem 13.4 and Proposition 13.11 will surely appreciate these statements.

Proposition 68.31.

(1) Let $f\colon X \to Y$ be a bijection between two topological spaces. If f is proper in the sense of the definition on page 180, i.e. if the preimage of every compact subset of Y is a compact subset of X, and if X and Y are CGWH-spaces, then f is actually a homeomorphism.

(2) Let $f\colon W \to X$ and $g\colon Y \to Z$ be quotient maps. If W, X, Y and Z are CGWH-spaces, then $f \times g\colon W \times Y \to X \times Z$ is also a quotient map.

(3) Let X and Y be topological spaces and let $B \subset Y$ be a closed subset. If X and Y are CGWH-spaces, then the obvious map $(X \times Y)/(X \times B) \to X \times (Y/B)$ is a homeomorphism.

Proof. This proposition is proved in [**Stri**, Propositions 2.20, 2.40 and 3.17]. ■

Remark. The category of CGWH-spaces admits a fully faithfully embedding into the category of "quasiseparated condensed sets". The category of "quasiseparated condensed sets" is particularly well-suited for dealing with technical problems that arise in topology. We refer to [**Scholz2019**, Theorem 2.16] and [**Scholz2019b**, Proposition 1.2] for details.

68.12. **Constructions of more CW-complexes.** In this section we will see how one can build new CW-complexes out of given CW-complexes. We start out with the following lemma.

Lemma 68.32. (CW-Complex Construction Lemma)

(1) Let $\{X_i\}_{i\in I}$ be a family of CW-complexes. The disjoint union $\bigsqcup_{i\in I} X_i$ admits a natural CW-structure such that each X_i is a subcomplex.

(2) Let X and Y be CW-complexes, let A be a subcomplex of X and let $f\colon A \to Y$ be a cellular map. As on page 259 we consider the topological pushout:

$$X \cup_A Y \;:=\; (X \sqcup Y)/\!\sim \qquad \text{where } a \sim f(a) \text{ for } a \in A$$

Furthermore we consider the following pushout diagram:

$$\begin{array}{ccc} A & \hookrightarrow & X \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle x \mapsto [x]} \\ Y & \xrightarrow{y \mapsto [y]} & X \cup_A Y. \end{array}$$

The following statements hold:[806]

(a) The map pushout $X \cup_A Y$ admits a natural CW-structure.

(b) The map $Y \to X \cup_A Y$ is a cellular embedding and for any subcomplex B of X that is disjoint from A, the map $B \to X \cup_A Y$ is also a cellular embedding.

(c) If $f\colon A \to Y$ is cellular embedding, then the opposite map $X \to X \cup_A Y$ is also a cellular embedding.

(3) Let X be a CW-complex and let A be a subcomplex. The quotient X/A admits a natural CW-structure such that the projection $X \to X/A$ is cellular and where the cells of X/A are in one-to-one correspondence to the cells of X that do not entirely lie in A together with one 0-cell given by the point $[A]$.[807]

(4) Let $\{X_i\}_{i\in I}$ be a family of CW-complexes and suppose that for each $i \in I$ we are given a point $a_i \in X_i^0$. If we use these points to form the wedge $\bigvee_{i\in I} X_i$, then the wedge admits a natural CW-complex structure such that each X_i is a subcomplex.

(5) Let (X, x_0) and (Y, y_0) be pointed CW-complexes. If at least one of X or Y has only countably many cells, then the smash product

$$X \wedge Y \;=\; (X \times Y)/((X \times \{y_0\}) \cup (\{x_0\} \times Y)),$$

as defined in Exercise 50.6, has a natural CW-structure.

(6) Let X be a CW-complex, let A be a complex of X and let $f\colon A \to X$ be a cellular map with the following properties:
   (a) For each n-cell σ of A we have either $f(\sigma) \subset X^{n-1}$ or $f|_\sigma$ is a homeomorphism.
   (b) The image of f is contained in a subcomplex of X that is disjoint from A.

   Then $X/\!\sim$, where $a \sim f(a)$ for all $a \in A$, admits a natural CW-structure such that for any subcomplex B that is disjoint from $f(A)$ the natural map $B \to X/\!\sim$ is a cellular embedding.

(We point out that by the Cellular Embedding Lemma 68.19 we know that the image of a cellular embedding is in fact a cellular homeomorphism onto a subcomplex and we will often use this cellular isomorphism to identify the domain with its image.)

Convention. When we form the wedge of a family of a CW-complexes, then we always use a point that lies in the 0-skeleton, so that we can view the wedge in a natural way as a CW-complex.

Proof.

(1) The first statement is basically obvious.

(2) First note that it is pretty clear what the CW-structure on $X \cup_A Y$ should be. The problem that arises is that one needs to show that the topology of the new CW-complex agrees in fact with the intended topology. If X (and Y) are finite CW-complexes then this follows easily from the Compact-Hausdorff Proposition 2.17 (3). The general case gets more technical. We refer to [**LW1969**, p. 60 and Theorem 5.11] or alternatively to [**FrPi1990a**, Theorem 2.31 on p. 62] for complete proofs. The remaining two statements follow easily from the actual definition of the CW-structure on $X \cup_A Y$.

(3) Note that this statement is the special case of (2) where we consider the constant map $f\colon A \to Y = \{*\}$ where $Y = \{*\}$ is a topological space consisting of a single point.

[806] The statements below should be viewed as an extension of the discussion of the properties of the pushout that we gave in the Topological Pushout-Maps Lemma 5.34.

[807] It is worth considering the case that $A = \varnothing$ is the empty subcomplex. By the definition on page 242 we know that $X/A = X/\varnothing$ equals the disjoint union of X with the topological space $\{\varnothing\}$ consisting of a single point. The above definition of the CW-structure on X/A still makes, namely it is given by the disjoint union of the CW-complex with $\{\varnothing\}$ viewed as a CW-complex in the only possible way.

(4) This follows easily from (1) and (2).
(5) This statement follows immediately from Proposition 68.23 (3) and (2).
(6) This statement follows from [**LW1969**, Proposition 5.8]. We can apply [**LW1969**, Proposition 5.8] since our hypothesis on f ensures that f defines a "cellular equivalence relation" in the sense of [**LW1969**, p. 32]. ■

Later on we will make good use of the following lemma.

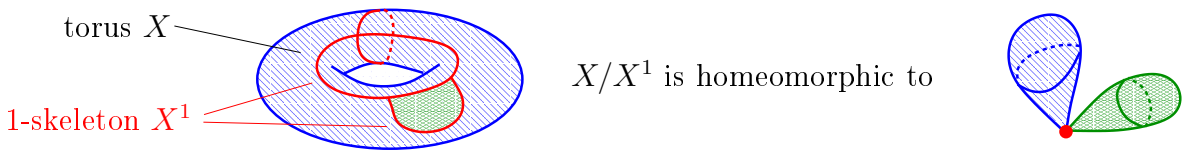
Lemma 68.33. (Skeleton-Quotient Lemma) Let X be a CW-complex and let $n \in \mathbb{N}$. Let $\{\varphi_i \colon \overline{B}^{n+1} \to X^n\}_{i \in I}$ be the characteristic maps of the $(n+1)$-cells of X. For each $i \in I$ let $\overline{B}_i^{n+1}$ be a copy of $\overline{B}^{n+1}$ and let S_i^n be a copy of S^n. We write $S_i^n = \partial \overline{B}_i^{n+1}$.

(1) The map

$$\begin{aligned} f \colon \bigvee_{i \in I} \overbrace{(\overline{B}_i^{n+1}/S_i^n)}^{\text{homeomorphic to } S^{n+1}\text{, see Lemma 5.20}} &\to X^{n+1}/X^n \\ [x] &\mapsto [\varphi_i(x)] \quad \text{if } x \in \overline{B}_i^{n+1} \end{aligned}$$

is a homeomorphism.

(2) If X has only one 0-cell $\{x_0\}$ and no cells in dimensions $1, \dots, n$, then the homeomorphism f, together with the homeomorphism $\overline{B}^{n+1}/S^n \to S^{n+1}$ from the Ball-Quotient Sphere Lemma 5.20 induces a homeomorphism



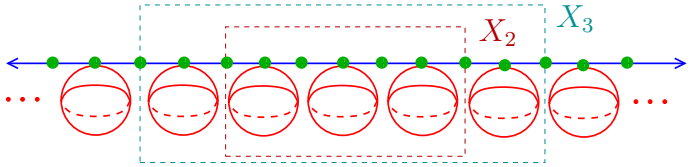
$$\bigvee_{i \in I} S_i^{n+1} \to X^{n+1}.$$

(3) For every $i \in I$ the subset $X^{n+1} \setminus \Phi_i(B_i^{n+1})$ is a subcomplex of X^{n+1} and the map

$$\begin{aligned} \overline{B}_i^{n+1}/S_i^n &\to X^{n+1}/(X^{n+1} \setminus \Phi_i(B_i^{n+1})) \\ [x] &\mapsto [\Phi_i(x)] \end{aligned}$$

is a homeomorphism.

Example. In the figure below we see the torus together with a CW-structure X that has two 2-dimensional cells. It follows from the Skeleton-Quotient Lemma 68.33 (1) that $X/X^1 = X^2/X^1$ is homeomorphic to the wedge of two spheres.



Proof.

(1) First note that it is basically clear that the given map f is a bijection. Furthermore it follows immediately from Lemma 50.10 that f is continuous. We use the CW-Complex Construction Lemma 68.32 to view both sides of the Skeleton-Quotient Lemma 68.33 as CW-complexes. The map f gives a bijection between the cells of the two sides. Thus it follows from the CW-Complex Homeomorphism Lemma 68.12 that f is a homeomorphism.
(2) This statement follows immediately from (1).

(3) Since we remove a "top-dimensional" open cell from X^{n+1} it follows immediately from the definitions that $X^{n+1} \setminus \Phi_i(B_i^{n+1})$ is a subcomplex of X^{n+1}. Similar to the argument in (1) we now see that the map is a homeomorphism. ■

Lemma 68.34. (Ascending Union-CW Complex Lemma) Let $f_i \colon X_i \to X_{i+1}$, $i \in \mathbb{N}$ be a sequence of cellular inclusion maps between CW-complexes. Then the direct limit[808] $\varinjlim X_i = \bigcup_{i \in I} X_i$ admits a CW-structure such that each X_i is a subcomplex of $\varinjlim X_i = \bigcup_{i \in I} X_i$.

Example. The Ascending Union-CW Complex Lemma 68.34 allows us to view the line with infinitely many spheres attached as a CW-complex.[809] We refer to the figure below for an illustration.

the topological space
$X = \bigcup_{i \in \mathbb{N}} X_i$

Proof. We leave it to the reader to write down the, notationally messy but mathematically elementary, proof. ■

We conclude this section with the following corollary that shows that several constructions that we are familiar with can also be performed in the category of CW-complexes.

Corollary 68.35. (CW-Complex Cone Corollary) Let X be a CW-complex.[810]

(1) The cone

$$\mathrm{Cone}(X) \;=\; (X \times [0,1])/\!\sim \qquad \text{where } (x,0) \sim (y,0) \text{ for every } x, y \in X$$

admits a natural CW-structure such that the inclusion map $X \to \mathrm{Cone}(X)$ given by $x \mapsto [(x,1)]$ is a cellular embedding.

(2) The suspension

$$\Sigma(X) \;=\; (X \times [-1,1])/\!\sim \qquad \text{where for every } x, y \in X \text{ we have } (x,-1) \sim (y,-1) \text{ and } (x,1) \sim (y,1)$$

admits a natural CW-structure such that the map $X \to \Sigma(X)$ given by $x \mapsto [(x,0)]$ is a cellular embedding.

(3) If A is a CW-complex and if $f \colon A \to X$ is a cellular map, then the mapping cone

$$\mathrm{Cone}(f \colon A \to X) \;=\; (\;)/\!\sim \;\text{ where } (a,1) \sim f(a) \text{ for all } a \in A$$

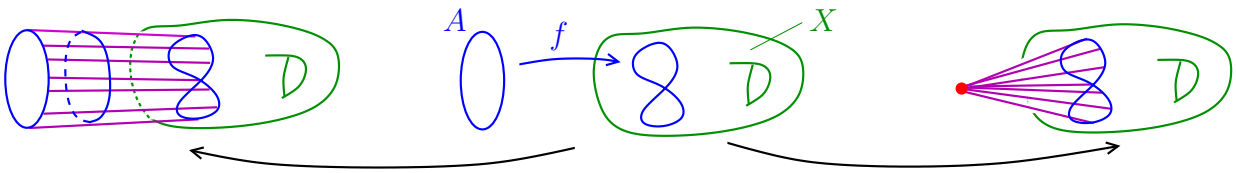
and the mapping cylinder

$$\mathrm{Cyl}(f \colon A \to X) \;=\; (A \times [0,1] \sqcup X)/\!\sim \;\text{ where } (a,1) \sim f(a) \text{ for all } a \in A$$

---

[808] We write explicitly "direct limit" to remind the reader that, according to the discussion on page 1259, the topology on $\varinjlim X_i = \bigcup_{i \in I} X_i$ is given by the condition that a subset U is open if and only if each intersection $U \cap X_i$ is an open subset of X_i.

[809] It follows from the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19 that the topology on the "line with infinitely many spheres" coming from $\mathbb{R}^3$ agrees with the topology coming from the CW-structure.



admit natural CW-structures. Furthermore the obvious maps $X \to \mathrm{Cone}(f\colon A \to X)$ and $\mathrm{Cyl}(f\colon A \to X)$ are cellular embeddings and the map $A \mapsto \mathrm{Cyl}(f\colon A \to X)$ given by $a \mapsto [(a,0)]$ is a cellular embedding.

(4) If $f\colon X \to X$ is a cellular map, then the mapping torus

$$\mathrm{Tor}(X,f) \;:=\; (X \times [0,1])\,/\!\sim \qquad \text{where } (x,0) \sim (f(x),1) \text{ for all } x \in X$$

admits a natural CW-structure such that the natural embedding $X \to \mathrm{Tor}(X,f)$ given by $x \mapsto (x,0)$ is in fact a cellular embedding.

(As in the statement of the CW-Complex Construction Lemma 68.32 we point out that often we will use a cellular embedding to identify the domain with its image.)

mapping cylinder $\mathrm{Cyl}(f\colon X \to Y)$ mapping cone $\mathrm{Cone}(f\colon A \to X)$

Proof. All four statements can be proved fairly easily using Proposition 68.23 (3b) and the CW-Complex Construction Lemma 68.32. We only point out that the CW-structure on the mapping torus $\mathrm{Tor}(X,f)$ is obtained in a 2-stage process, first we equip the mapping cylinder $\mathrm{Cyl}(f\colon X \to X)$ with the natural CW-structure given by (3). Afterwards we apply the CW-Complex Construction Lemma 68.32 (6). We leave it to the reader to fill all the other details. ■

We conclude this discussion of constructions of CW-structures with the following slightly sobering proposition.

Proposition 68.36. There exists a finite 3-dimensional CW-complex that admits an open subset that does not admit a CW-structure.

Proof. This statement is proved in [**Cau1992**, Exemple 2]. ■

68.13. **Coverings of CW-complexes.** In this section we will see that a covering of a CW-complex inherits a natural CW-structure.

Proposition 68.37. (CW-complex Covering Proposition) Let $p\colon \widetilde{X} \to X$ be a covering of a connected CW-complex X. We can equip $\widetilde{X}$ with a natural structure of a CW-complex such that the following statements hold:

(1) The map $p\colon \widetilde{X} \to X$ is a cellular map.

(2) For any $k \in \mathbb{N}_0$ we have[811]

$$\#k\text{-cells of } \widetilde{X} \;=\; \big[\widetilde{X} : X\big] \cdot \#k\text{-cells of } X.$$

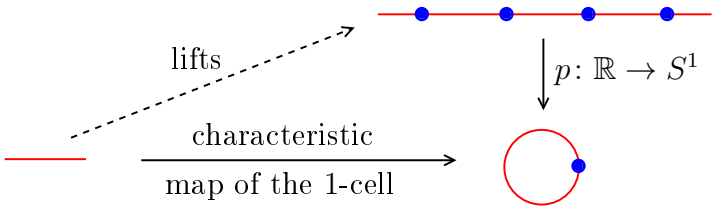
(3) The dimension of $\widetilde{X}$ is the same as the dimension of X.

(4) If A is a subcomplex of X, then $p^{-1}(A)$ is a subcomplex of $\widetilde{X}$.

[810] Strictly speaking, or Bourbakily speaking if that's an adverb, we should really specify in each case what the "natural CW-structure" is. But this should hopefully be clear in each case, and we do not encumber the reader with unnecessary extra notation.

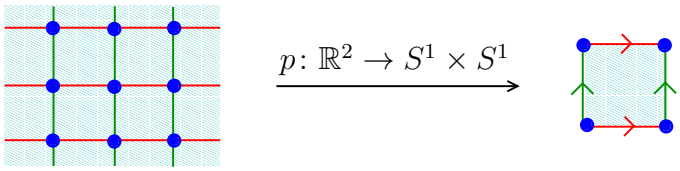
Remark. The CW-complex Covering Proposition 68.37 is a generalization of the Covering-of-Graph Proposition 64.1 where we showed that any covering of a topological graph is again a topology graph. In fact, as we will see, the proofs are structurally very similar.

Proof. Let $p\colon \widetilde{X} \to X$ be a covering of a connected CW-complex X of degree $n := [\widetilde{X} : X]$. Let $\psi\colon \overline{B}^k \to X$ be a characteristic map of a k-cell of X. We write $x = \psi(0)$. We consider the following diagram



$$\begin{array}{ccc} & & \widetilde{X} \\ & \overset{\widetilde{\psi}}{\nearrow} & \big\downarrow p \\ \overline{B}^k & \xrightarrow[\psi]{} & X. \end{array}$$

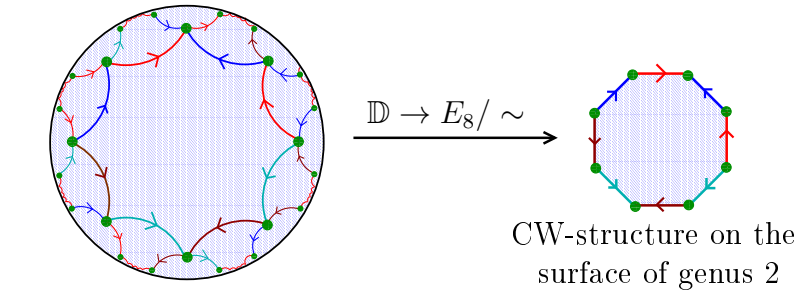
Since $\overline{B}^k$ is simply connected and locally path-connected we can apply the Map Lifting Criterion 61.2 which says in this context that for each $\widetilde{x} \in p^{-1}(x)$ there exists a unique lift $\overline{B}^k \to \widetilde{X}$ with $\widetilde{\psi}(0) = \widetilde{x}$. By the definition on page 1069, the degree $n = [\widetilde{X} : X]$ of the covering equals the cardinality of $p^{-1}(x)$. Thus we see that ψ gives rise to n maps $\overline{B}^k \to \widetilde{X}$. It is straightforward to verify that all these lifts of the characteristic maps for the cells of X define a CW-structure for $\widetilde{X}$. We leave the joyful task of verifying the details to the reader. Alternatively we refer to [**Bre1993**, Theorem IV.8.10] for details.



It follows immediately from the above construction and the definitions that the CW-structure we had just defined on $\widetilde{X}$ has the desired properties (1) to (4). ■

Examples.

(1) We equip S^1 with the CW-structure consisting of one 0-cell and one 1-cell. We denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto \exp(2\pi i t)$ the universal covering of S^1. If we apply the construction of the CW-structure on $\mathbb{R}$ given in the proof of the CW-complex Covering Proposition 68.37, then we end up equipping $\mathbb{R}$ with the CW-structure where the 0-cells correspond to $\mathbb{Z}$ and the 1-cells are precisely the intervals $[k, k+1]$, with $k \in \mathbb{Z}$. We illustrate the CW-structure of $\mathbb{R}$ in the figure below.



(2) Almost the same approach as in (1), applied to the universal covering $\mathbb{R}^2 \to S^1 \times S^1$, endows $\mathbb{R}^2$ with a CW-structure that is illustrated in the figure below.

[811] Note that this is an equality of cardinalities. For example, if $[\widetilde{X} : X]$ is infinite countable and if X has finitely many k-cells, then $\widetilde{X}$ has infinitely many, but countably many, k-cells.

(3) In the proof of Hadamard's Theorem 66.9 we constructed an explicit covering map $\mathbb{D} \to H_8/\sim \cong E_8/\sim$. If we equip $E_8/\sim$ with the "usual" CW-structure then we obtain from the CW-complex Covering Proposition 68.37 the CW-structure on $\mathbb{D}$ that is shown in the figure below.

induced CW-structure on $\mathbb{D}$

CW-structure on the surface of genus 2

Exercises for Chapter 68.

Exercise 68.1.

(a) Does every compact subset of $\mathbb{R}^2$ admit a CW-structure?
(b) Let $n \in \mathbb{N}$. Does the open ball $B_1^n(0)$ admit a CW-structure?
(c) Let C be the Cantor set as defined on page 130. Does C admit a CW-structure?

Exercise 68.2.

(a) We equip $\mathbb{R}^\infty$ with the metric that is given by

$$d((x_1, x_2, \dots), (y_1, y_2, \dots)) \;:=\; \sqrt{\sum_{i=1}^{\infty} |x_i - y_i|^2}.$$

We consider the following two topologies on $\mathbb{R}^\infty$:

$$\mathcal{S} \;:=\; \{U \subset \mathbb{R}^\infty \mid \text{for every } P \in U \text{ there exists } \epsilon > 0 \text{ such that } B_\epsilon(P) \subset U\}$$

and

$$\mathcal{T} \;:=\; \{U \subset \mathbb{R}^\infty \mid \text{for every } n \in \mathbb{N} \text{ the set } U \cap \mathbb{R}^n \text{ is open in } \mathbb{R}^n\}.$$

Show that $\mathcal{S} \subset \mathcal{T}$.

(b) We view $\mathbb{R}^\infty$ as equipped with the topology $\mathcal{S}$. Does the Heine-Borel Theorem hold in $\mathbb{R}^\infty$? More precisely, is every bounded closed subset of $\mathbb{R}^\infty$ compact?

(c) We view $\mathbb{R}^\infty$ as equipped with the topology $\mathcal{T}$. Show that the projection $p\colon \mathbb{R}^\infty \to \mathbb{R}^n$ is continuous and open.

Exercise 68.3. Show that the map

$$\begin{array}{rcl} \mathbb{C}^\infty & \to & \mathbb{R}^\infty \\ (x_1 + \mathrm{i}y_1, x_2 + \mathrm{i}y_2, \dots) & \mapsto & (x_1, y_1, x_2, y_2, \dots) \end{array}$$

is a homeomorphism.

Exercise 68.4. Show that the action

$$\begin{array}{rcl} \{\pm 1\} \times S^\infty & \to & S^\infty \\ (\epsilon, v) & \mapsto & \epsilon \cdot v \end{array}$$

of the group $\{\pm 1\}$ on the topological space S^∞ is continuous and discrete.

Exercise 68.5. Let $P, Q \in S^\infty$. Show that there exists a homeomorphism h of S^∞ with $h(P) = Q$.

Exercise 68.6. Let X be a CW-complex and let $x \in X$. Show that $\{x\}$ is a closed subset of $|X|$.
Hint. Make good use of the Topological Pushout-Maps Lemma 5.34 (4).

Exercise 68.7. Let X be a CW-complex.

(a) Show that if the 1-skeleton X^1 is path-connected, then X itself is path-connected.
(b) Show that if X is connected, then X^1 is also connected.

Hint. Make good use of Lemma 2.24, the Ball-Sphere-Connected Lemma 2.25 and Lemma 2.28.

Exercise 68.8. Show that a CW-complex is locally finite if and only if it is regionally compact.

Exercise 68.9. We equip $\mathbb{R}\mathrm{P}^2$ with the CW-structure with one cell in dimensions $0, 1, 2$. Let $p\colon S^2 \to \mathbb{R}\mathrm{P}^2 = S^2/\pm 1$ be the usual 2-fold covering. The CW-structure on $\mathbb{R}\mathrm{P}^2$ induces a CW-structure on S^2. What does this CW-structure on S^2 look like?

Exercise 68.10. Let I be a set and for each $i \in I$ let $n_i \in \mathbb{N}$. Show that the wedge $\bigvee_{i\in I} S_i^{n_i}$ has a natural CW-structure with one 0-cell and where for each $n \in \mathbb{N}_0$ the n-cells correspond precisely to the n-dimensional spheres in the family of spheres $\{S_i^{n_i}\}_{i\in I}$.
Hint. Use the Twice Quotient Lemma 5.23 and use the fact, shown in the Ball-Quotient Sphere Lemma 5.20, that for each $n \in \mathbb{N}$ the sphere S^n is homeomorphic to $\overline{B}^n/S^{n-1}$.

Exercise 68.11. Let X be a finite CW-complex. Show that there exists an $n \in \mathbb{N}_0$ and a map $\varphi\colon |X| \to \mathbb{R}^n$ that is an embedding.

Exercise 68.12. Recall that we denote by $\mathcal{PT}op$ the category of pointed topological spaces. Suppose we are given $(X, x_0), (Y, y_0) \in \mathrm{Ob}(\mathcal{PT}op)$. Show that the direct product of (X, x_0) and (Y, y_0) in $\mathcal{PT}op$ is given by the smash product $(X, x_0) \wedge (Y, y_0)$ that we introduced on page 1143.
Hint. This exercise is very similar to Exercise 4.6.

Exercise 68.13. We consider the set $X = (\mathbb{N} \times \mathbb{N}) \cup \{*\}$. We say $U \subset X$ is open if $* \notin U$ or if for all but finitely many $n \in \mathbb{N}$ the set U contains all but finitely many points in $\{n\} \times \mathbb{N}$.

(a) Show that these open sets do indeed define a topology on X.
(b) Show that X is Hausdorff.
(c) Show that every infinite subset of X contains an infinite closed and discrete subset.
(d) Show that every compact subset of X is finite.
(e) Show that the compactly generated topology on X is the discrete topology.

These steps show that X is not compactly generated.

Exercise 68.14. Let $\mathcal{C}$ be a convenient category of topological spaces, i.e. let $\mathcal{C}$ be a full subcategory $\mathcal{C}$ of the category of topological spaces that has the properties stated in the Convenient Category Theorem 68.28. Let X and Y be CW-complexes. Show that if the

usual product $X \times Y$ lies in $\mathcal{C}$, then $X \times Y$ is homeomorphic to the product CW-complex $X \otimes Y$.

Exercise 68.15. Let X and Y be CGWH-spaces. We denote by $X \widetilde{\times} Y$ the product in the category of CGWH-spaces, which exists by the CGWH-Category Theorem 68.30 (4). Show that for each $n \in \mathbb{N}$, each $x_0 \in X$ and $y_0 \in Y$ the natural maps $p\colon X \widetilde{\times} Y \to X$ and $q\colon X \widetilde{\times} Y \to Y$ induce an isomorphism

$$p_* \times q_*\colon \pi_n(X \widetilde{\times} Y, (x_0, y_0)) \xrightarrow{\cong} \pi_n(X, x_0) \times \pi_n(Y, y_0).$$

Remark. The exercise is to verify that the proofs of Propositions 48.20 and 71.8 also apply to $X \widetilde{\times} Y$ instead of the usual product topological space $X \times Y$.

Exercise 68.16. We consider $X = \mathbb{R} \setminus \{\frac{1}{n} \mid n \in \mathbb{N}\}$ and we consider $Y = \mathbb{R}/Z$ where $Z \subset \mathbb{R}$ is the subset given by integers. We consider the subset

$$A \;=\; \big\{\big(\tfrac{1}{i} + \tfrac{a_i}{j}, i + \tfrac{1}{2j}\big) \in X \times Y \,\big|\, i, j \in \mathbb{N}\big\} \qquad \text{where } a_i = \tfrac{1}{2}\big(\tfrac{1}{i} - \tfrac{1}{i+1}\big).$$

(a) Show that the closure of A contains $(0, [0])$.
(b) Show that for any compact subset $K \subseteq X \times Y$, the set $K \cap A$ has only finitely many points.
(c) Show that X is not compactly generated.

Exercise 68.17.

(a) We consider

$$X \;:=\; \{0\} \cup \bigcup_{n,m \in \mathbb{N}} \{\tfrac{1}{n} + \tfrac{1}{m+n}\} \;\subset\; \mathbb{R}.$$

We equip X with the usual metric coming from $\mathbb{R}$. We set $x := 0$.
(i) Show that each point in $X \setminus \{x\}$ is open.
(ii) Show that X is not regionally compact at x.

(b) Let X be a countable metric space which admits a point $x \in X$ such that the following conditions are satisfied:
(i) Each point in $X \setminus \{x\}$ is open.
(ii) The topological space X is not regionally compact at x.
Let $Y := X \cup \{\infty\}$ be the one-point compactification as defined in Exercise 2.59.
(α) Show that compact sets of Y are closed. (This implies that Y is weakly Hausdorff.)
(β) Show, by considering the points x and ∞, that Y is not Hausdorff.

Remark. The combination of (a) and (b) shows that there exist topological spaces that are weakly Hausdorff but not Hausdorff.

Exercise 68.18. Let X be a CW-complex with countably many cells.

(a) Show that there exists a sequence $A_1 \subset A_2 \subset \ldots$ of *finite* subcomplexes A_i of X such that $X = \bigcup_{i \in \mathbb{N}_0} A_i$.
(b) If X is connected, then show that we can arrange in (a) that every A_i is connected.

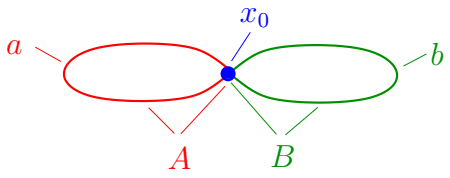
Exercise 68.19. Let $\mathcal{SmMfd}$ be the category of all smooth manifolds that we introduced on page 637 (in particular there are no restrictions on the boundary). Show that this category does not have a product in the sense of the definition on page 211.

69. CW-complexes II: Fundamental groups

In this chapter we will consider fundamental groups of CW-complexes. First we collect a few general statements. Then we will show that fundamental groups of 1-dimensional CW-complexes are free groups. Finally we will see how can calculate fundamental groups of more general CW-complexes in practice.

69.1. **Fundamental groups of CW-complexes.** Using the CW-Complex Properties Proposition 68.10 we can now prove the following very useful version of the Seifert–van Kampen Theorem 54.1. In view of the Smooth Manifold-CW Structure Theorem 96.5 , which we mentioned already on page 1474, this can be viewed as a generalization of the Seifert–van Kampen Theorem 54.4 for smooth manifolds.

Theorem 69.1. (Seifert–van Kampen Theorem for CW-complexes) Let X be a CW-complex and let $X = A \cup B$ be a decomposition of X in two subcomplexes such that $A \cap B$ is path-connected. Let $x_0 \in A \cap B$. Then



$$\pi_1(X, x_0) \;\cong\; \pi_1(A, x_0) *_{\pi_1(A\cap B, x_0)} \pi_1(B, x_0).$$

Examples.

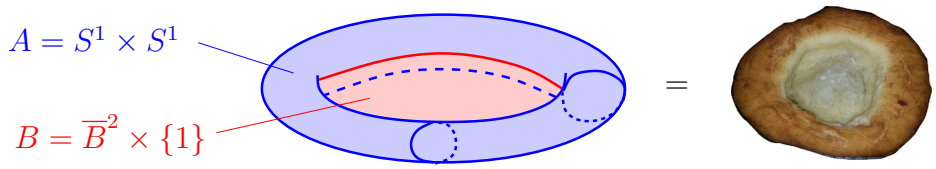
(1) Let X be the wedge of two circles. We can view X as a CW-complex with one 0-cell x_0 and two 1-cells a and b. Then $A = \{x_0, a\}$ and $B = \{x_0, b\}$ are subcomplexes, each of which is homeomorphic to S^1. We refer to the figure below for an illustration. It follows, as on page 1173, that

$$\pi_1(X, x_0) \underset{\uparrow}{\cong} \pi_1(A, x_0) *_{\pi_1(A\cap B, x_0)} \pi_1(B, x_0) \underset{\uparrow}{\cong} \langle a\rangle * \langle b\rangle \;=\; \langle a, b\rangle.$$

Seifert-van Kampen Theorem 69.1 — since A and B are homeomorphic to S^1

(2) We consider

$$K \;:=\; \underbrace{(S^1 \times S^1)}_{=:A} \cup \underbrace{(\overline{B}^2 \times \{1\})}_{=:B},$$



i.e. K is given by a torus where the "central hole" is filled in with a disk. We refer to the figure below for an illustration.[812] In the above definition of K we already wrote K as the union of two subsets. It is quite straightforward to see that K can be given a CW-structure such that A and B are subcomplexes.[813] We pick the base point $x_0 = (1, 1)$. We obtain that

Theorem 69.1 — since $A \cap B = S^1 \times \{1\}$ — Amalgamated Product Lemma 53.22

$$\pi_1(K, x_0) \underset{\downarrow}{\cong} \pi_1(A, x_0) *_{\pi_1(A\cap B, x_0)} \pi_1(B, x_0) \underset{\downarrow}{\cong} \underbrace{\langle x, y | [x, y]\rangle *_{\langle s\rangle} \{e\}}_{\text{with } x \leftrightarrow s} \underset{\downarrow}{\cong} \langle y\rangle.$$

[812] Here the name K stands for "kiacherl".

[813] How would you define the CW-structures?

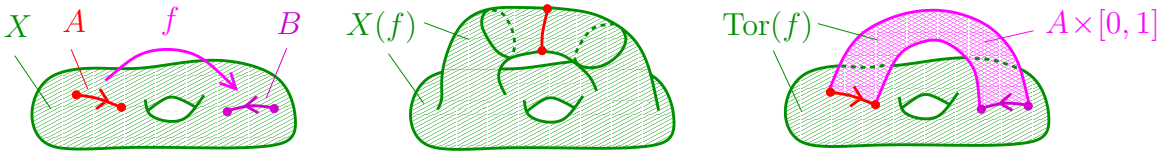
Kiacherl

Proof of Theorem 69.1. [814] Let X be a CW-complex and let $X = A \cup B$ be a decomposition of X in two subcomplexes such that $A \cap B$ is path-connected. Note that $A \cap B$ is also a subcomplex. Let $x_0 \in A \cap B$.

We use the notation of the CW-Complex Properties Proposition 68.10 (8). We write $U = \Phi(A)$ and $V = \Phi(B)$. Note that by the CW-Complex Properties Proposition 68.10 (8b) we have $U \cap V = \Phi(A \cap B)$. Since $A \cap B$ is path-connected and since $A \cap B$ is a deformation retract of $\Phi(A \cap B)$ we see that $U \cap V = \Phi(A \cap B)$ is also path-connected. Therefore we can apply the Seifert–van Kampen Theorem 54.1 to the decomposition $X = U \cup V$. We obtain the following commutative diagram

$$\begin{array}{ccc} \pi_1(U, x_0) *_{\pi_1(U\cap V, x_0)} \pi_1(V, x_0) & \xrightarrow{\cong} & \pi_1(X, x_0) \\ \uparrow & & =\uparrow \\ \pi_1(A, x_0) *_{\pi_1(A\cap B, x_0)} \pi_1(B, x_0) & \longrightarrow & \pi_1(X, x_0), \end{array}$$

where the two vertical maps are induced by the inclusions. By the CW-Complex Properties Proposition 68.10 (8a) and the Homotopy-π_1-Proposition 50.3 (2) the three inclusion induced maps $\pi_1(A, x_0) \to \pi_1(U, x_0)$, $\pi_1(B, x_0) \to \pi_1(V, x_0)$ and $\pi_1(A \cap B, x_0) \to \pi_1(U \cap V, x_0)$ are isomorphisms. The top horizontal map is an isomorphism by the Seifert–van Kampen Theorem 54.1. It follows that the bottom horizontal map is also an isomorphism. ■



Next we want to compute the fundamental group of a CW-complex that is obtained by gluing two subcomplexes of a connected CW-complex. We recall and introduce the following two definitions.

Definition. Let X be a topological space, let A be a subset of X and let $f\colon A \to X$ be an embedding. Following the discussion on page 1290 we define

$$X(f) \;:=\; X(f\colon A \to X) \;:=\; X/\!\sim \qquad \text{where } f(a) \sim a \text{ for every } a \in A.$$

Furthermore we define the partial mapping torus[815]

$$\mathrm{Tor}(f) \;:=\; \mathrm{Tor}(f\colon A \to X) \;:=\; (X \sqcup (A \times [0,1]))/\!\sim \qquad \text{where } (a,0) \sim a \text{ and } (a,1) \sim f(a) \text{ for every } a \in A.$$

Continuing with the above notation, note that the projection $A \times [0,1] \to A$ induces a map $p\colon \mathrm{Tor}(f) \to X(f)$. In Proposition 70.5 we will see that under reasonably mild hypotheses

[814] The proof is very similar to the proof of the Seifert–van Kampen Theorem for Smooth Manifolds 54.4.

[815] If $A = X$, then one can easily show that the partial mapping torus is naturally homeomorphic to the mapping torus that we introduced on page 467.

the map $p\colon \mathrm{Tor}(f) \to X(f)$ is a homotopy equivalence. In particular by the Homotopy-π_1-Proposition 50.3 we see that p induces an isomorphism of fundamental groups.
Now we can formulate, prove and discuss the following theorem.

Theorem 69.2. (HNN-Seifert–van Kampen Theorem for CW-complexes) Suppose we are given a path-connected CW-complex X and two path-connected disjoint subcomplexes A and B. Let $f\colon A \to B$ be a cellular isomorphism. We pick a base point $x_0 \in A$. Let $\gamma\colon [0,1] \to X$ be an embedding with $\gamma(0) = x_0$ and with $\gamma(1) = f(x_0)$ such that $\gamma([0,1])$ is a subcomplex of the 1-skeleton X^1.[816] We write $\Gamma = \pi_1(A, x_0)$. Finally we denote by

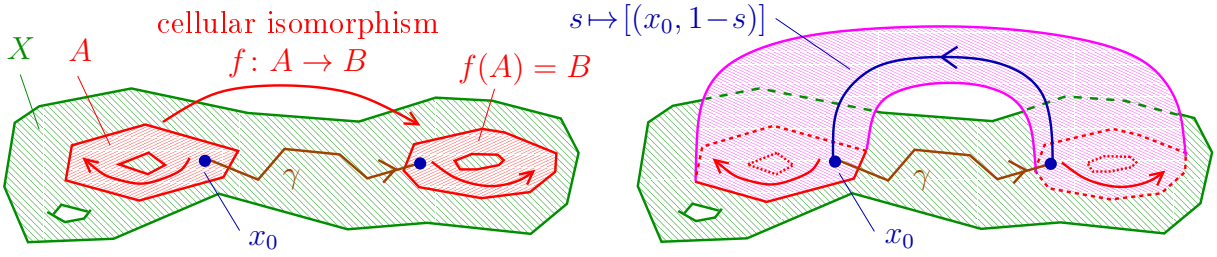
$$\alpha\colon \Gamma = \pi_1(A, x_0) \to \pi_1(X, x_0)$$

the inclusion induced map and we denote by

$$\beta\colon \Gamma = \pi_1(A, x_0) \xrightarrow{f_*} \pi_1(B, f(x_0)) \to \pi_1(X, f(x_0)) \xrightarrow{\gamma_*} \pi_1(X, x_0)$$

the concatenation of the maps induced by f, the inclusion and the base point change isomorphism from the Change-of-Base Point Proposition 47.10, using the path γ. Then there exists an isomorphism

$$\Phi\colon \pi_1(\mathrm{Tor}(f), x_0) \xrightarrow{\cong} \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle$$



which has the following two properties:

(1) The diagram

$$\begin{array}{ccc} & \pi_1(X, x_0) & \\ \swarrow & & \searrow \\ \pi_1(\mathrm{Tor}(f), x_0) & \xrightarrow{\Phi} & \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \end{array}$$

with the obvious diagonal maps commutes.

(2) The closed loop in $\mathrm{Tor}(f)$ given by the composition of γ with the path $s \mapsto [(x_0, 1-s)]$ corresponds under the isomorphism Φ to t.

Remark.

(1) Basically the same way that we obtained the HNN-Seifert–van Kampen Theorem 57.3 from the Seifert–van Kampen Theorem 54.1 one can also obtain the above HNN-Seifert–van Kampen Theorem 69.2 for CW-complexes from the Seifert–van Kampen Theorem 69.1 for CW-complexes. Below we will give a different proof of the HNN-Seifert–van Kampen Theorem 57.3 for CW-complexes which is easier than the argument provided in the proof of the HNN-Seifert–van Kampen Theorem 69.2.

[816] Note that it follows from our hypothesis that X is path-connected together with the CW-Complex Properties Proposition 68.10 (7) that such γ exists.

(2) The original HNN-Seifert–van Kampen Theorem 57.3 is more general than the above HNN-Seifert–van Kampen Theorem 57.3 for CW-complexes, but for most applications the latter result will be just fine.
(3) Using Proposition 70.5 one can also deal with certain situations where the map $f\colon A \to B$ is not a cellular isomorphism. We leave it to the reader to figure out what these generalized statements might be.

Sketch of a proof of Theorem 69.2. Let X be a path-connected CW-complex X and let $f\colon A \to B$ be a cellular isomorphism between two path-connected disjoint subcomplexes of X. Let $x_0 \in A$ and let $\gamma\colon [0,1] \to X$ be an embedding with $\gamma(0) = x_0$ and with $\gamma(1) = f(x_0)$ such that $C := \gamma([0,1])$ is a subcomplex.

It follows from the CW-Complex Product Proposition 68.23 (3b) and the CW-Complex Construction Lemma 68.32 that $\mathrm{Tor}(f)$ is equipped with a natural CW-structure such that we can view $A \times [0,1]$ and X as subcomplexes of $\mathrm{Tor}(f)$.

We consider $Y := (X \sqcup (\{x_0\} \times [0,1])/\sim$ where $(x_0, 0) \sim x_0$ and $(x_0, 1) \sim f(x_0)$. We view Y as a CW-complex given by attaching a single 1-cell to X. We denote by D the image of $\{x_0\} \times [0,1]$ in Y. Furthermore we denote by $\delta\colon [0,1] \to D$ the path given by $s \mapsto (x_0, 1-s)$. Now note that we have the following two isomorphisms:

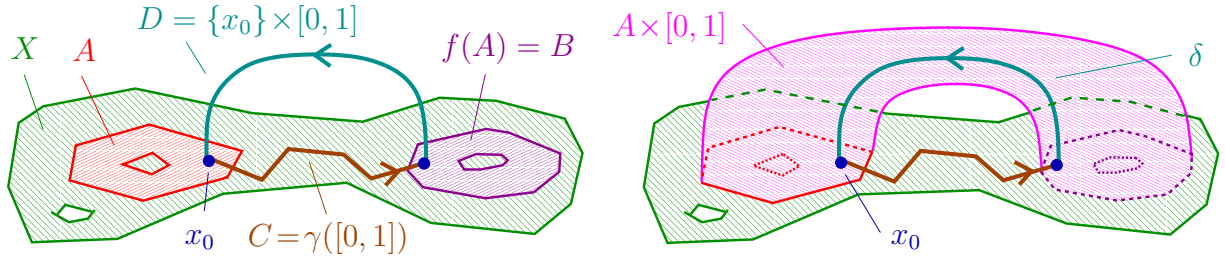
$$\pi_1(Y, x_0) \underset{\uparrow}{\cong} \pi_1(X, x_0) *_{\pi_1(C, x_0)} \pi_1(C \cup D, x_0) \underset{\uparrow}{\cong} \pi_1(X, x_0) * \langle t = [\gamma * \delta] \rangle$$

Seifert–van Kampen Theorem 69.1 for CW-complexes

since C contractible and since $C \cup D$ is homeomorphic to S^1

and

$$\pi_1(A, x_0) * \pi_1(B, f(x_0)) \underset{\uparrow}{\cong} \pi_1(A, x_0) * \pi_1(D \cup B, x_0) \underset{\uparrow}{\cong} \pi_1(A \cup D \cup B, x_0).$$



by the Seifert–van Kampen Theorem 69.1 and the base point change $f(x_0) \mapsto x_0$ induced by δ

Finally we also have the isomorphism:

$$\pi_1(\mathrm{Tor}(f), x_0) \underset{\uparrow}{\cong} \pi_1(Y, x_0) *_{\pi_1(A \cup D \cup B, x_0)} \underbrace{*\pi_1(A \times [0,1], x_0)}_{\cong \pi_1(A, x_0)}.$$

by the Seifert–van Kampen Theorem 69.1, here we use that $Y \cap (A \times [0,1]) = A \cup D \cup B$ is connected

Note that in the above discussion basically all maps are induced by the obvious inclusion maps We leave it to the intrepid reader to go through the explicit descriptions of the various homomorphisms and the description of the amalgamated product in Proposition 53.21 to show that we do indeed end up with the promised description of $\pi_1(\mathrm{Tor}(f), x_0)$. ■

We conclude this section with the following proposition that is an immediate consequence of the Direct Limit-π_1-Proposition 56.7 and the Finiteness the CW-Complex-Finiteness Theorem 68.14

Proposition 69.3. Let X be a CW-complex and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subcomplexes such that $X = \bigcup_{i\in\mathbb{N}} X_i$. Then for any $w \in X_1$ we have

$$\pi_1(X, w) \;=\; \varinjlim \pi_1(X_i, w).$$

Examples.

(1) We have[817]

$$\pi_1(\mathbb{R}\mathrm{P}^\infty) \;\underset{\text{see page 1480}}{=}\; \pi_1\Big(\bigcup_{n\in\mathbb{N}} \mathbb{R}\mathrm{P}^n\Big) \;\underset{\text{Proposition 69.3}}{=}\; \varinjlim \begin{array}{c} \uparrow \\ \pi_1(\mathbb{R}\mathrm{P}^3) \\ \uparrow \\ \pi_1(\mathbb{R}\mathrm{P}^2) \\ \uparrow \\ \pi_1(\mathbb{R}\mathrm{P}^1) \end{array} = \varinjlim \begin{array}{c} \uparrow\cong \\ \mathbb{Z}_2 \\ \uparrow\cong \\ \mathbb{Z}_2 \\ \uparrow \\ \mathbb{Z} \end{array} \;\cong\; \mathbb{Z}_2.$$

(2) In Exercise 69.1 we will use Proposition 69.3 to show that there exists a CW-complex X with $\pi_1(X) \cong (\mathbb{Q}, +)$.

69.2. **The Euler characteristic of a CW-complex.** In the following sections we will give ea complete calculation of the fundamental group of a 1-dimensional CW-complex. In the subsequent discussion it will be convenient to have the following definition at our disposal.

Definition. Given a finite CW-complex X we define its Euler characteristic $\chi(X)$ as follows:

$$\chi(X) \;:=\; \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \text{number of } n\text{-cells}.$$

Examples.

(1) If G is a finite topological graph, then, according to the discussion on page 1470, we can view G as a 1-dimensional CW-complex where the number of 0-cells equals the number of vertices and the number of 1-cells equals the number of edges of G. Thus it follows immediately from the definitions that in this case the above Euler characteristic agrees with the definition of the Euler characteristic of a topological graph that we gave on page 315.

(2) For the CW-structures provided by Lemma 68.1 we have $\chi(\mathbb{R}\mathrm{P}^n) = \frac{1}{2}(1+(-1)^n)$ and $\chi(\mathbb{C}\mathrm{P}^n) = n+1$.

(3) A short glance at the three examples in the figure below shows that these three different CW-structures for the torus have the same Euler characteristic. Later on, in Chapter 87, we will find out whether or not that is a coincidence.

The following three propositions give us several convenient statements about the Euler characteristic of a finite CW-complex.

Proposition 69.4. (Covering-χ-Proposition) Let $p\colon \widetilde{X} \to X$ be a finite covering of a finite CW-complex X. We equip $\widetilde{X}$ with the structure of a CW-complex given by the

[817] By Corollary 48.18 we know that $\pi_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$ for $n \geq 2$. But why is $\pi_1(\mathbb{R}\mathrm{P}^1) \cong \mathbb{Z}$?

CW-complex Covering Proposition 68.37. Then

$$\chi(\widetilde{X}) \;=\; [\widetilde{X} : X] \cdot \chi(X).$$

Proof. Let $d := [\widetilde{X} : X]$. As we mentioned in the CW-complex Covering Proposition 68.37 (2), it follows immediately from the construction of the CW-structure on $\widetilde{X}$ that for each k we have

$$\#k\text{-cells of } \widetilde{X} \;=\; \big[\widetilde{X} : X\big] \cdot \#k\text{-cells of } X.$$

The proposition is an immediate consequence of this equality. ■

The following lemma can be viewed as a generalization of the Quotient Abstract Graph Lemma 7.14.

Lemma 69.5. (Quotient-χ-Lemma) Let X be a finite CW-complex and let A be a subcomplex. We equip the quotient X/A with the CW-structure given by the CW-Complex Construction Lemma 68.32 (3). Then

$$\chi(X/A) \;=\; \chi(X) - \chi(A) + 1.$$

Proof. It follows immediately from the construction of the CW-structure on X/A given in the CW-Complex Construction Lemma 68.32 (3) that for each $k \in \mathbb{N}_0$ we have the following equalities:

$$\#k\text{-cells of } X/A \;=\; \begin{cases} \#k\text{-cells of } X \text{ not in } A, & \text{if } k > 0, \\ \#k\text{-cells of } X \text{ not in } A \;+\; 1, & \text{if } k = 0. \end{cases}$$

Evidently these equalities implies the equality $\chi(X/A) = \chi(X) - \chi(A) + 1$. ■

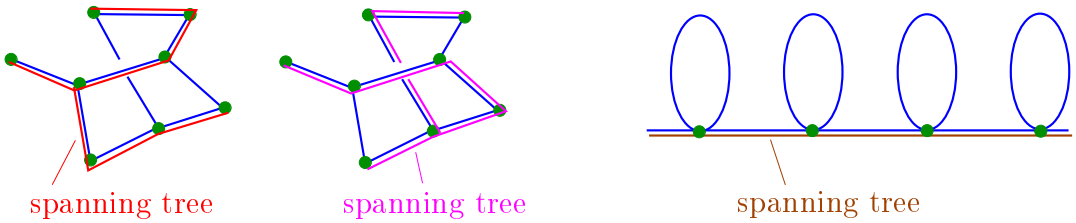
Proposition 69.6. Let X be a non-empty finite connected 1-dimensional CW-complex. Then $\chi(X) = 0$ if and only if X is contractible.

Proof. This statement is an immediate consequence of the Fundamental Group-of-Graph Proposition 52.5 and the fact that we can view any 1-dimensional CW-complex as a topological graph of the same Euler characteristic. ■

We have now assembled enough information to get us through this chapter. Later on in Chapter 87 we will give a much more elaborate discussion of the Euler characteristic of a CW-complex.

69.3. **The fundamental group of 1-dimensional CW-complexes.** The goal in this section is to show that the fundamental group of a connected non-empty 1-dimensional CW-complex X is a free group. The idea is quite simple:

(1) If the CW-complex X has a single 0-cell, then it follows basically from Proposition 52.7 that $\pi_1(X)$ is a free group.
(2) In the general case we show that X is homotopy equivalent to a 1-dimensional CW-complex with a single 0-cell.



The following definition is the key to proving Statement (2).

Definition.

(1) A tree is a 1-dimensional CW-complex that admits a deformation retraction to a 0-cell.
(2) Let G be a 1-dimensional CW-complex. A spanning tree is a subcomplex T that is a tree and that contains all vertices of G.

Remark.

(1) On page 315 we defined a *tree* to be a finite connected non-empty topological graph with Euler characteristic 1. It follows from Proposition 69.6 that the above definition of a tree is consistent with the definition that we had given on page 315.
(2) We leave it to the reader to show that for a finite topological graph the above definition of a spanning tree is equivalent to the one we had given on page 317.
(3) A spanning tree is often also called a *maximal tree*.

In the figure below we give examples of spanning trees in topological graphs. We see in particular that in general there is no unique spanning tree.

Proposition 69.7. (Spanning Tree Existence Proposition)

(1) Given any connected 1-dimensional CW-complex G and given any tree $S \subset G$ there exists a spanning tree T that contains S and such that S is a deformation retract of T.
(2) Every connected non-empty 1-dimensional CW-complex admits a spanning tree.

Remark.

(1) the Spanning Tree Existence Proposition 69.7 can be viewed as a generalization of the Spanning Tree Existence Proposition 7.10.
(2) A somewhat different proof of the Spanning Tree Existence Proposition 69.7 is given in [**FrPi1990a**, Lemma 2.6.3].

Proof. Statement (2) follows from Statement (1) by applying Statement (1) to a tree that is given by a single vertex. Thus it remains to prove Statement (2). Now let G be a connected 1-dimensional CW-complex and let $S \subset G$ be a tree.

Claim. There exists a sequence $S = Y_0 \subset Y_1 \subset Y_2 \subset \dots$ of subcomplexes of G with the following properties:

(1) The union $Y := \bigcup_{i \in \mathbb{N}} Y_i$ contains all 0-simplices of G.
(2) Each Y_i is a deformation retract of Y_{i+1}.

Proof. To prove the claim we first construct a sequence $S = X_0 \subset X_1 \subset X_2 \subset \dots$ of subcomplexes of G as follows.

(a) We set $X_0 := S$.
(b) Given X_i we define X_{i+1} to be the union of X_i with all 1-dimensional cells which contain at least one 0-cell of X_i.

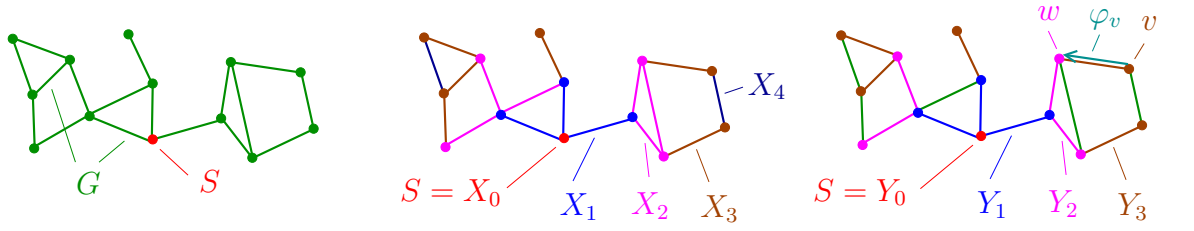
We make the following observations:

(i) It follows from Lemma 68.21 (2) that X_{i+1} is a subcomplex of G.

(ii) We claim that $G = \bigcup_{i\in\mathbb{N}} X_i =: X$. This can be seen as follows. Basically by construction we have for each characteristic map[818] $\Phi\colon \overline{B}^n \to G$, $n = 0, 1$ that $\Phi^{-1}(X) = \varnothing$ or $\Phi^{-1}(X) = \overline{B}^n$. Since G is 1-dimensional it follows from the Characteristic Maps Lemma 68.7 that X is a subset of G that is closed and that is open. Since G is connected and since X is non-empty we see that $X = G$.

Next we do the following iterative construction:

(a) We set $Y_0 := X_0 = S$.



(b) Suppose we are given Y_i. For each 0-cell v in Y_{i+1} that is not contained in Y_i we pick precisely one 1-cell e_v of Y_{i+1} that contains v. We define Y_{i+1} to be the union of Y_i with all these 1-cells. By Lemma 68.21 (2) we know that Y_{i+1} is a subcomplex of Y_i.

By construction the 0-cells of each Y_i are precisely the 0-cells of X_i. It follows from (ii) that $Y := \bigcup_{i\in\mathbb{N}} Y_i$ contains all 0-cells of G. It remains to show that each Y_i is a deformation retract of Y_{i+1}. As we will see, this is almost obvious, except that we need to worry a little bit about continuity issues. Let V be the set of 0-cells in Y_{i+1} that are not contained in Y_i. Note that the corresponding 1-cell e_v contains two 0-cells, namely v and one 0-cell w in Y_i. Let $\varphi_v\colon e_v \times [0,1] \to e_v$ be the obvious deformation retraction to w. Finally we consider the map

$$\begin{array}{rcl} F\colon \overbrace{\left(Y_i \cup \bigsqcup_{v\in V} e_v\right)}^{=Y_{i+1}} \times [0,1] & \to & Y_{i+1} = Y_i \cup \bigsqcup_{v\in V} e_v \\ ([P], t) & \mapsto & \begin{cases} P, & \text{if } P \in Y_i, \\ \varphi_v(P,t), & \text{if } P \in e_v. \end{cases} \end{array}$$

It follows almost immediately from the Interval CW-Product Corollary 68.9 that the map is continuous. It is now basically clear that F defines a deformation retraction from Y_{i+1} to Y_i. ⊞

We set $Y := \bigcup_{i\in\mathbb{N}} Y_i$ By Lemma 68.21 (2) we know that Y is a subcomplex of G. We need to show that Y is contractible. Since S is contractible it follows from the Homotopy-Equivalence Basics Lemma 15.1 (2) and the Deformation Retract-Homotopy Equivalence Lemma 15.5 that it suffices to that S is a deformation retract of Y. But this is an immediate consequence of Statement (2) of the claim together with the Iterated Deformation Retracts Proposition 68.22. ■

[818] For $n = 0$ the statement is a tautology. For $n = 1$ note that if $\Phi^{-1}(X) \neq \varnothing$, then there exists an i with $\Phi^{-1}(X_i) \neq \varnothing$. Since X_i is a subcomplex we see that $\Phi^{-1}(X_i)$ contains at least one 0-cell. But by construction this means that $\Phi^{-1}(X_{i+1}) = \overline{B}^1$.

Proposition 69.8. (Quotient-by-Tree Proposition) Let X be a 1-dimensional CW-complex.

(1) For every spanning tree T of X the following holds:
   (a) The projection $p\colon X \to X/T$ is a homotopy equivalence.
   (b) The quotient X/T X is homeomorphic to a wedge of circles. If X is finite, then X/T is homeomorphic to the wedge of $1-\chi(X)$ circles.

(2) If X is connected and non-empty, then X is homotopy equivalent to the wedge of circles. Furthermore if X is finite, then X is homotopy equivalent to the wedge of $1-\chi(X)$ circles.

Remark.

(1) the Quotient-by-Tree Proposition 69.8 is a fairly straightforward generalization of Proposition 50.15. In fact the proof below is at times verbatim the same as the proof of Proposition 50.15.

(2) Later on, in the Quotient-by-Contractible Corollary 70.3, we will generalize the Quotient-by-Tree Proposition 69.8 in a suitable way to the case of arbitrary CW-complexes.

Proof. Let X be a 1-dimensional CW-complex.

(1a) Let T be a spanning tree of X. By hypothesis and by definition there exists a 0-cell t_0 of T such that there exists a deformation retraction from T to $\{t_0\}$, i.e. there exists a homotopy $R\colon T\times[0,1]\to T$ such that $R_1 = \mathrm{id}$ and such that $R_0 = c_{t_0}$ is the constant map. For notational convenience we make the obvious identification $\overline{B}^1 = [-2,2]$. Now let $\{\Phi_i\colon [-2,2]\to X\}_{i\in I}$ be the characteristic maps of the 1-cells of X that are not contained in T. We write $a_i = \Phi_i(-2)$ and $b_i = \Phi_i(2)$.

By the CW-Complex Construction Lemma 68.32 (3) we can view X/T as a 1-dimensional CW-complex with a single 0-cell $*$ and one 1-cell for each $i\in I$. We denote by $\{\Psi_i\colon [-2,2]\to X/T\}_{i\in I}$ the characteristic maps of these 1-cells. We consider the map

$$\begin{array}{rcl} q\colon X/T & \to & X \\ x & \mapsto & \begin{cases} R(a_i, -y-1), & \text{if } x=\Psi_i(y) \text{ for some } y\in[-2,-1], \\ \Psi_i(2\cdot y), & \text{if } x=\Psi_i(y) \text{ for some } y\in[-1,1], \\ R(b_i, y-1), & \text{if } x=\Psi_i(y) \text{ for some } y\in[1,2]. \end{cases} \end{array}$$

It follows from the Characteristic Maps Lemma 68.7 (1) and (4) that q is continuous. (We refer to the figure below from a long time ago for an illustration of q.) It remains to prove the following claim.

Claim. The maps p and q are homotopy inverses of one another.

Proof. The proof of the claim is fairly elementary, just notationally a little messy. First we consider the following map

$$\begin{array}{rcl} F\colon (X/T)\times[0,1] & \to & X/T \\ (x,t) & \mapsto & \begin{cases} *, & \text{if } x=\Psi_i(y) \text{ for some } y\in[-2,-1-t], \\ \Psi_i(\frac{2y}{1+t}), & \text{if } x=\Psi_i(y) \text{ for some } y\in[-1-t,1+t], \\ *, & \text{if } x=\Psi_i(y) \text{ for some } y\in[1+t,2]. \end{cases} \end{array}$$

Using the Interval CW-Product Corollary 68.9 (3) one can easily show that F is continuous. It follows immediately from the definitions that $F_0 = p \circ q$ and $F_1 = \mathrm{id}_{X/T}$. Next we consider the following map

$$G\colon X \times [0,1] \to X$$
$$(x,t) \mapsto \begin{cases} R(x,t), & \text{if } x \in T, \\ R(a_i, y+2+t), & \text{if } x = \Phi_i(y) \text{ for some } y \in [-2,-1-t], \\ \Phi_i(\frac{2y}{1+t}), & \text{if } x = \Phi_i(y) \text{ for some } y \in [-1-t, 1+t], \\ R(b_i, -y+2+t), & \text{if } x = \Phi_i(y) \text{ for some } y \in [1+t, 2]. \end{cases}$$

Again, using the Interval CW-Product Corollary 68.9 (3) one can easily show that G is continuous. Furthermore it follows again immediately from the definitions that $G_0 = q \circ p$ and $G_1 = \mathrm{id}_X$. ⊞

(1b) Let T be a spanning tree of X. We denote by I the set of 1-cells of X that are not contained in T. As mentioned in (1), it follows from the CW-Complex Construction Lemma 68.32 (3) that we can view X/T as a 1-dimensional CW-complex with a single 0-cell $*$ and one 1-cell for each $i \in I$. By the Skeleton-Quotient Lemma 68.33 we know that X/T is homeomorphic to the wedge $\bigvee_{i \in I} S^1_i$.

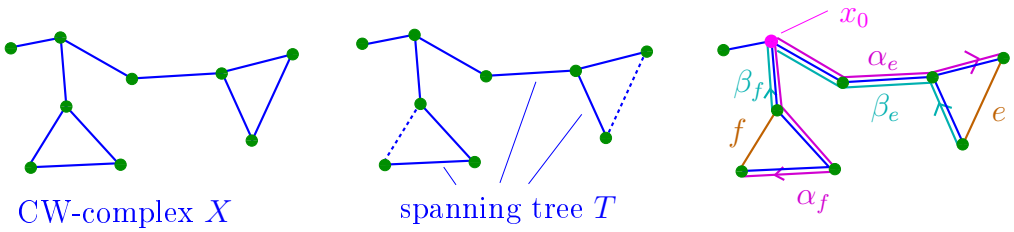
Finally we suppose that X is finite. At this point it suffices to show that X/T is homeomorphic to the wedge of $1 - \chi(X)$ circles, in other words, we want to show that $|I| = 1 - \chi(X)$. This in turn follows from the following calculation:

$$1 - |I| \underset{\uparrow}{=} \chi\Big(\bigvee_{i \in I} S^1_i\Big) = \chi(X/T) \underset{\uparrow}{=} \chi(X) - \chi(T) \underset{\uparrow}{=} \chi(X).$$

see page 1480 — by the Quotient-χ-Lemma 69.3 — Proposition 69.6

(2) Now we assume that X is connected and non-empty. By the Spanning Tree Existence Proposition 69.7 we know that X admits a spanning tree T. The desired conclusion now follows from (1) together with (2). ■

Now we no longer have any troubles with computing the fundamental group of 1-dimensional CW-complexes. More precisely, we have the following theorem which generalizes the Fundamental Group-of-Graph Proposition 52.5 and 64.2



Theorem 69.9. (Fundamental Group-of-1-Complex Theorem) Let X be a connected non-empty 1-dimensional CW-complex. Furthermore let $x_0 \in X$. Then the following holds:

(1) The group $\pi_1(X, x_0)$ is isomorphic to a free group. In fact, if T is a spanning tree for X, then the cardinality of the generating set of the free group equals the cardinality of the set of edges in $X \setminus T$.
(2) If X is a finite CW-complex, then $\pi_1(X, x_0)$ is a free group with $1 - \chi(X)$ generators.
(3) An explicit description of the isomorphism in (1) is given as follows. Pick a base point x_0 in the spanning tree and for each 1-cell e that is not contained in T we pick a path α_e from p to one of the endpoints and pick a path β_e from the other endpoint back to p[819] and let t_e be the loop given by first going along α_e, then going through

e and then going back to the base point via β_e. Then the map

$$\begin{array}{rcl} \langle \{x_e\}_{e \text{ cell not in } T} \rangle & \to & \pi_1(X, x_0) \\ x_e & \mapsto & [t_e] \end{array}$$

is an isomorphism.

Proof. Let X be a connected non-empty 1-dimensional CW-complex. By the Spanning Tree Existence Proposition 69.7 we know that X admits a spanning tree T. We denote by E the set of 1-cells of X that are not contained in T. Let x_0 be a point in T. We denote by $p\colon X \to X/T$ the projection . We write $* = p(x_0)$. We have the following isomorphisms:

$$\pi_1(X, x_0) \xrightarrow{p_*} \pi_1(X/T, *) \xrightarrow{\cong} \pi_1\Big(\bigvee_{e \in E} S^1_e, *\Big) \xleftarrow{\cong} \langle \{x_e\}_{e \in E} \rangle.$$

by the Quotient-by-Tree Proposition 69.8 we know that the map $p\colon X \to X/T$ is a homotopy equivalence, from the Fundamental Group-Homotopy Proposition 50.3 (1a) we obtain that p_* is an isomorphism

Fundamental Group-Homotopy Proposition 50.3 (1b)

isomorphism given by Proposition 52.7

If one goes through the explicit isomorphism, then one sees that the map given in (3) is indeed an isomorphism.

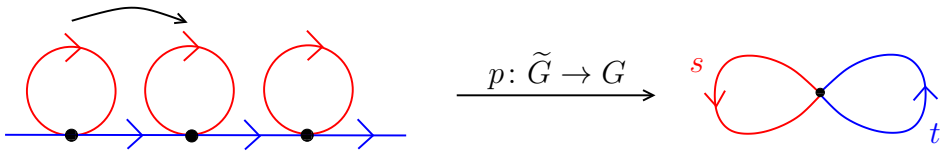
Finally suppose that X is a finite 1-dimensional CW-complex. It is not terribly hard to show directly that E has cardinality $1-\chi(X)$. But since we proved the desired statement regarding the rank of $\pi_1(X, x_0)$ already in the Fundamental Group-of-Graph Proposition 52.5 we will not work out the details of the argument. ■

We conclude this discussion of CW-complexes with an application to group theory, namely to the study of free groups. Recall that in Proposition 64.4 we used topological graphs to show that if F is a free group of countable rank, then every subgroup is also a free group. Now that we have developed the theory of CW-complexes we can remove the slightly artificial restriction on the cardinality of the generating set. More precisely, we have the following corollary to our previous results.

Corollary 69.10. (Subgroup-of-Free Group Corollary) Every subgroup of a free group (of any rank) is again a free group.

Remark. Even for free groups of countable rank the proof of the Subgroup-of-Free Group Corollary 69.10 might be of interest, since it differs somewhat from the proof of Proposition 64.4.

[819] The two paths exist since a tree is in particular connected.



Proof. Let $F = \langle S \rangle$ be a free group on a set S and let G be a subgroup of F.

(1) By attaching one 1-cell for each $s \in S$ to a one-point set $\{P\}$ we obtain a 1-dimensional CW-complex X with one 0-cell P and with one 1-cell for each $s \in S$. By the Fundamental Group-of-1-Complex Theorem 69.9 we have $\pi_1(X, P) \cong F$. By the CW-Complex Properties Proposition 68.10 (6) and the Covering Existence Theorem 61.5 there exists a covering $p\colon (Y, Q) \to (X, P)$ of degree $[F : G]$ such that $p_*(\pi_1(Y, Q)) = G$. By Corollary 48.14 the map p_* is injective. Thus we see that $\pi_1(Y, Q)$ itself is isomorphic to G. By the CW-complex Covering Proposition 68.37 we can equip Y with the structure of a 1-dimensional CW-structure. We deduce from the Fundamental Group-of-1-Complex Theorem 69.9 that $G \cong \pi_1(Y, Q)$ is a free group.

(2) Now suppose that F is a free group of finite rank m and suppose that G is a finite-index subgroup of F. By Proposition 69.4 we know that $\chi(Y) = [F : G] \cdot \chi(X)$. It is now a consequence of the Fundamental Group-of-1-Complex Theorem 69.9 that $\operatorname{rank}(G) - 1 = [F : G] \cdot (\operatorname{rank}(F) - 1)$. ■

Example. Let G be the CW-complex consisting of one 0-cell v and two 1-cells which we denote by s and t. By a slight abuse of notation we denote the corresponding elements in $\pi_1(G, v)$ by s and t as well. By the Fundamental Group-of-Graph Proposition 52.5 we can identify $\pi_1(G, v)$ with the free group $\langle s, t \rangle$ on the generators s and t. Now let $\phi\colon \pi_1(G, v) = \langle s, t \rangle \to \mathbb{Z}$ be the homomorphism that is given by $\phi(s) = 0$ and $\phi(t) = 1$. By the Covering Existence Theorem 61.5 there exists a covering $q\colon (\widehat{G}, \widehat{v}) \to (G, v)$ with $q_*(\pi_1(\widehat{G}, \widehat{v})) = \ker(\phi)$, furthermore by the Covering Uniqueness Theorem 61.9 this covering is unique up to equivalence, in the sense of the definition on page 1368.

We consider the infinite covering illustrated in the figure below, which is very similar to the finite covering studied on pages 1385.[820] For $i \in \mathbb{Z}$ we denote by x_i the loop in $(\widetilde{G}, \widetilde{v})$ as

illustrated in the figure below. We denote by x_i also the corresponding element in $\pi_1(\widetilde{G}, \widetilde{v})$. It follows from the Fundamental Group-of-1-Complex Theorem 69.9 that $\pi_1(\widetilde{G}, \widetilde{v})$ equals the free group $\langle \dots x_{-2}, x_{-1}, x_0, x_1, x_2 \dots \rangle$. It is straightforward to see that

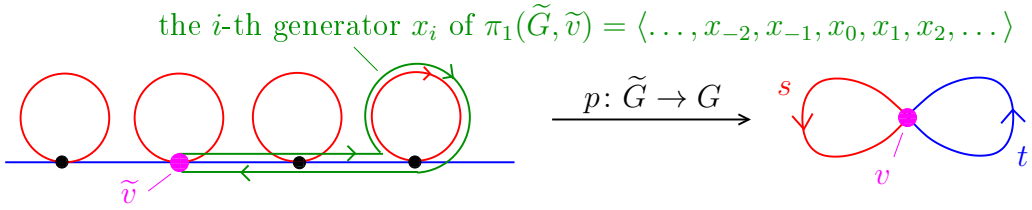
$$p_*(x_i) = t^i s t^{-i}.$$

[820] This covering can also be described rigorously. More precisely, we view G as the union of two copies A and B of S^1 glued along the common point 1. We define

$$\widetilde{G} = (\mathbb{R} \sqcup (S^1 \times \mathbb{Z}))/(n \sim (1, n)) \text{ for } n \in \mathbb{Z}.$$

Then the projection

$$p\colon (\mathbb{R} \sqcup (S^1 \times \mathbb{Z}))/\sim \to G = (S^1 \times \{A\} \sqcup S^1 \times \{B\})/(1, A) \sim (1, B)$$



is given by $p(x) = (\exp(2\pi \mathrm{i} x), A)$ for $x \in \mathbb{R}$ and $p((z, n)) = (z, B)$ for $(z, n) \in S^1 \times \mathbb{Z}$.

By Corollary 48.14 the homomorphism p_* is a monomorphism. Thus we see that $t^i s t^{-i}$, $i \in \mathbb{Z}$, generate an infinitely generated free subgroup of the finitely generated generated free group $\langle s, t\rangle$. Furthermore we see that $p_*(\pi_1(\widetilde{G}, \widetilde{v})) \subset \ker(\phi\colon \pi_1(G, v) \to \mathbb{Z})$. It is easy to see that the deck transformation group is isomorphic to $\mathbb{Z}$.

Now we claim that the coverings $p\colon \widetilde{G} \to G$ and $q\colon \widehat{G} \to G$ are equivalent. By the Covering Uniqueness Theorem 61.9 it suffices to show that $p_*(\pi_1(\widetilde{G}, \widetilde{v})) = q_*(\pi_1(\widehat{G}, \widehat{v}))$. We consider the following sequence of maps

$$\begin{array}{ccccccccc} \mathbb{Z} & \cong & \mathrm{Deck}(p\colon \widetilde{G} \to G) & \cong & \pi_1(G,v)/p_*(\pi_1(\widetilde{G},\widetilde{v})) & \twoheadrightarrow & \pi_1(G,v)/\ker(\phi\colon \pi_1(G,v) \to \mathbb{Z}) & \xrightarrow[\cong]{\phi} & \mathbb{Z} \\ & \uparrow & & & \uparrow & & \uparrow & & \\ & \text{see above} & & & \text{isomorphism of Proposition 62.7} & & \text{since } p_*(\pi_1(\widetilde{G},\widetilde{v})) \subset \ker(\phi\colon \pi_1(G,v) \to \mathbb{Z}) & & \end{array}$$

Thus, reading from left to right, we get an epimorphism from $\mathbb{Z}$ onto itself. But any such epimorphism has to be an isomorphism. It follows that the third map is also an isomorphism, i.e. $p_*(\pi_1(\widetilde{G}, \widetilde{v})) = \pi_1(G, v)/\ker(\phi\colon \pi_1(G, v) \to \mathbb{Z})$, but the latter group is precisely $q_*(\pi_1(\widehat{G}, \widehat{v}))$. So we get the desired equality of subgroups.

69.4. **Fundamental groups of CW-complexes.** In this section we will discuss fundamental groups of CW-complexes. For the statement of our first proposition it is useful to introduce the following definition.
The following definition is evidently inspired by the definition of a CW-complex.

Definition. Let X be a topological space and let $\varphi\colon S^{n-1} \to X$ be a map. We refer to $X \cup_\varphi \overline{B}^n$ as the topological space X with an n-cell attached via the attaching map φ. We refer to the image of $\overline{B}^n$ in $X \cup_\varphi \overline{B}^n$ as an n-cell.

Remark. On page 450 we gave an explicit homeomorphism $\mathrm{Cone}(S^{n-1}) \xrightarrow{\cong} \overline{B}^n$. Using this homeomorphism one sees almost immediately that, using the notation from the above definition, we have a homeomorphism $\mathrm{Cone}(\varphi\colon S^{n-1} \to X) \xrightarrow{\cong} X \cup_\varphi \overline{B}^n$ which is the identity on X. In other words, attaching a cell is just a special case of taking a mapping cone.

The following proposition now tells us how attaching a cell affects the fundamental group of a given topological space.

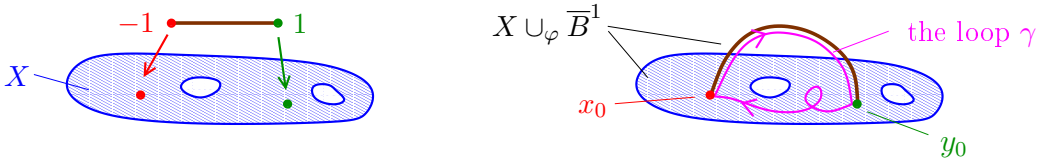
Proposition 69.11. (Cell Attachment-π_1-Proposition) Let X be a topological space, let $n \geq 1$, let $\varphi\colon S^{n-1} \to X$ be a map and let x_0 be a point in $\varphi(S^{n-1})$. Then the following hold:

($n > 2$) The inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B}^n, x_0)$ is an isomorphism.
($n = 2$) The map $\varphi\colon S^1 \to X$ defines an element in $\pi_1(X, x_0)$ that we denote by $[\varphi]$, and the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B}^n, x_0)$ descends to an

isomorphism

$$\pi_1(X, x_0)/\langle\langle[\varphi]\rangle\rangle \xrightarrow{\cong} \pi_1\big(X \cup_\varphi \overline{B}^2, x_0\big).$$

($n = 1$) Let $\epsilon \in \{-1, 1\}$ such that $x_0 = \varphi(\epsilon)$. We set $y_0 := \varphi(-\epsilon)$.



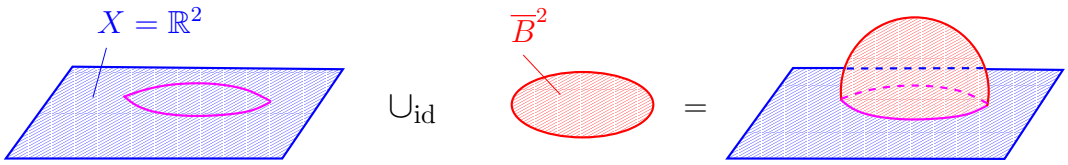
(a) Suppose that x_0 and y_0 lie in the same path-component of X. Let γ be a loop in $X \cup_\varphi \overline{B}^1$ that is given by the concatenation of the obvious path in the 1-cell from $x_0 = \varphi(\epsilon)$ to $y_0 = \varphi(-\epsilon)$ and some path in X from $y_0 = \varphi(-\epsilon)$ to $x_0 = \varphi(\epsilon)$. With this notation the map

$$\pi_1(X, x_0) * \langle t\rangle \;\to\; \pi_1(X \cup_\varphi \overline{B}^1, x_0)$$

that is given by the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B}^1, x_0)$ and given by $t \mapsto [\gamma]$ is an isomorphism.

(b) Suppose that x_0 and y_0 lie in two different path components of X. Then we get an isomorphism

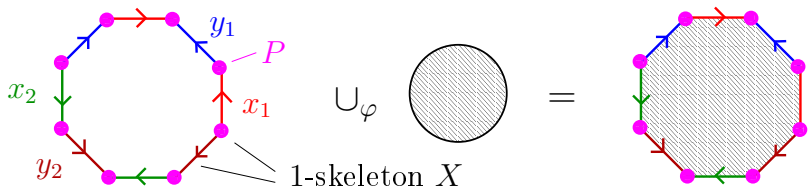
$$\pi_1(X, x_0) * \pi_1(X, y_0) \;\to\; \pi_1(X \cup_\varphi \overline{B}^1, x_0).$$



Examples.

(1) Let $X = S^1$ and let $n \in \mathbb{N}$. We attach to S^1 a 2-cell via the attaching map $\varphi\colon S^1 \to S^1$ that is given by $\varphi(z) = z^n$. Then[821]

$$\pi_1\big(S^1 \cup_\varphi \overline{B}^2, 1\big) \underset{\uparrow}{=} \pi_1(S^1, 1)/\langle[\varphi]\rangle \underset{\uparrow}{=} \langle x\rangle/\langle x^n\rangle \cong \mathbb{Z}_n.$$



Cell Attachment-π_1-Proposition 69.11 — see Proposition 48.17

(2) We attach a 2-cell to $X = \mathbb{R}^2$ via the attaching map $\mathrm{id} = \varphi\colon S^1 \to S^1$ that is given by the identity. The resulting topological space is illustrated in the figure below. This topological space is again simply connected by the Cell Attachment-π_1-Proposition 69.11.

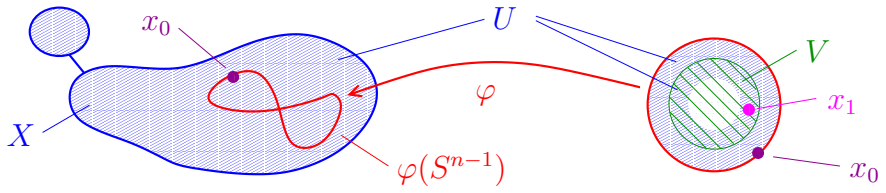
(3) Using the Fundamental Group-of-1-Complex Theorem 69.9 and the Cell Attachment-π_1-Proposition 69.11 we can now easily compute fundamental groups of finite CW-complexes. For example, as in the figure below we view the surface Σ of genus 2 as a CW-complex with one 0-cell P, four 1-cells x_1, y_1, x_2, y_2 and one 2-cell. We denote by X the 1-skeleton of Σ and we denote by $\varphi\colon S^1 \to X$ the attaching map of the

[821] We leave it to the reader to show that for $n = 2$ the topological space $S^1 \cup_\varphi \overline{B}^2$ is actually homeomorphic to $\mathbb{R}\mathrm{P}^2$.

2-cell. We have

$$\pi_1(\Sigma, P) \;=\; \pi_1\big(X \cup_\varphi \overline{B}^2, P\big) \underset{\uparrow}{=} \pi_1(X, P)/\langle\langle [\varphi] \rangle\rangle \underset{\uparrow}{=} \langle x_1, y_1, x_2, y_2 \rangle / \langle\langle [x_1, y_1][x_2, y_2] \rangle\rangle.$$

Cell Attachment-π_1-Proposition 69.11 — by the Fundamental Group-of-1-Complex Theorem 69.9 and since $[\varphi] = [x_1, y_1][x_2, y_2]$



Of course we had obtained the same result much earlier. The advantage of CW-complexes is that the Cell Attachment-π_1-Proposition 69.11 absorbs many of the technical arguments we had to deal with in the proof of the Fundamental Group-of-Surfaces Proposition 54.5, i.e. in our initial calculation of $\pi_1(\Sigma, P)$.

Proof of the Cell Attachment-π_1-Proposition 69.11 for $n \geq 2$. Let X be a topological space, let $n \geq 2$, let $\varphi\colon S^{n-1} \to X$ be a map and let x_0 be a point in $\varphi(S^{n-1})$. The key idea of the proof is to apply the Seifert–van Kampen Theorem 54.1 to the following two open[822] subsets of $X \cup_\varphi \overline{B}^n$

$$U \;=\; X \cup_\varphi \big\{ z \in \overline{B}^n \,\big|\, \|z\| > \tfrac{1}{4} \big\} \quad \text{and} \quad V \;=\; \big\{ z \in \overline{B}^n \,\big|\, \|z\| < \tfrac{3}{4} \big\}.$$

The remainder of the proof consists in showing that the resulting isomorphism implies the desired, a priori slightly different, isomorphism.

We pick a point $x_1 \in U \cap V$ and we pick a path in U from x_0 to x_1. We refer to the figure below for an illustration. Note that V is a ball, hence $\pi_1(V, x_1)$ is the trivial group.

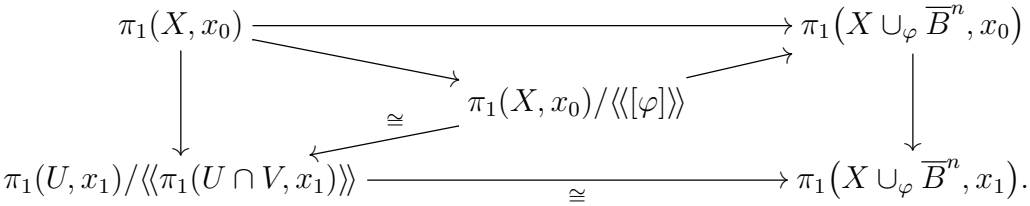
[822] Why are they open subsets?

We consider the following diagram of maps

$$\begin{array}{ccc}
\pi_1(X,x_0) & \longrightarrow & \pi_1(X\cup_\varphi \overline{B}^n,x_0)\\
\cong\downarrow & & =\downarrow\\
\pi_1(U,x_0) & \longrightarrow & \pi_1(X\cup_\varphi \overline{B}^n,x_0)\\
\cong\downarrow & & \downarrow\cong\\
\pi_1(U,x_1) & \longrightarrow & \pi_1(X\cup_\varphi \overline{B}^n,x_1)\\
\downarrow & & \downarrow=\\
\pi_1(U,x_1)/\langle\langle\pi_1(U\cap V,x_1)\rangle\rangle & \longrightarrow & \pi_1(X\cup_\varphi \overline{B}^n,x_1)\\
\cong\big\downarrow \text{theAmalgamatedProductLemma 53.22} & & \big\downarrow=\\
\pi_1(U,x_1)*_{\pi_1(U\cap V,x_1)} \underbrace{\pi_1(V,x_1)}_{=\{e\}} & \xrightarrow[\text{Seifert–van Kampen}]{\cong} & \pi_1(X\cup_\varphi \overline{B}^n,x_1).
\end{array}$$

We want to prove the following three statements:

(i) the diagram commutes,
(ii) all vertical maps except possibly the third vertical map on the left are isomorphisms,
(iii) the bottom horizontal map is an isomorphism.



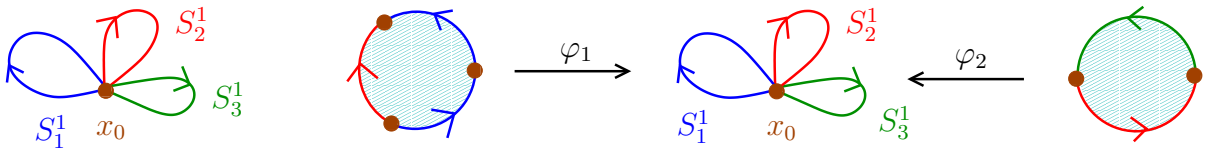
The two vertical maps on the second level are the isomorphisms induced by the choice of base point coming from the chosen path from x_0 to x_1. All the other vertical and horizontal maps are induced by inclusions or they are the obvious algebraic map. It follows easily that the diagram commutes.

Most of the maps are obviously isomorphisms. Using the Homotopy Pushout Lemma 14.9 one can easily show that X is a deformation retract of U. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 and the Homotopy-π_1-Proposition 50.3 (2) that the top left vertical map is an isomorphism. The bottom vertical map on the left is an isomorphism by the Amalgamated Product Lemma 53.22.

Finally the bottom horizontal map is an isomorphism by the Seifert–van Kampen Theorem 54.1.

Now we consider the case $n \geq 3$. In this case $\pi_1(U\cap V,x_1)$ is trivial since $U\cap V$ is homotopy equivalent to S^{n-1} which has trivial fundamental group by the Sphere-π_1-Proposition 47.13. It is now clear that the one missing vertical map on the left is also an isomorphism. Since all vertical maps are now isomorphisms and since the bottom horizontal map is an isomorphism it follows that the top horizontal map is an isomorphism.

Finally we consider the case $n = 2$. In this case $U\cap V$ is homotopy equivalent to S^1 which implies that $\pi_1(U\cap V,x_1)\cong\mathbb{Z}$. Under the isomorphism $\Phi\colon \pi_1(X,x_0)\to\pi_1(U,x_1)$ this infinite cyclic subgroup corresponds to $\langle[\varphi]\rangle$. It is straightforward to see that we get a commutative diagram



This concludes the proof of the proposition. ■

Proof of the Cell Attachment-π_1-Proposition 69.11 for $n = 1$. The proof of the case $n = 1$ is quite similar to the proof of the case $n \geq 2$. The only serious difference is that we need to replace the Seifert–van Kampen Theorem 54.1 by Corollary 57.5, which in turn is a corollary to the HNN-Seifert–van Kampen Theorem 57.3. We leave it to the reader to fill in the details. ■

In the following corollary we will see that every finitely presented group is the fundamental group of a finite CW-complex. The key to proving the corollary is the following construction, which associates to any finite presentation a 2-dimensional CW-complex. The construction is illustrated in the figure below. If the reader feels comfortable with that illustration it might be best to skip the official definition.

2-dimensional CW-complex for the presentation

$\langle g_1, g_2, g_3 \,|\, g_1 \cdot g_2^{-1} \cdot g_1, g_3 \cdot g_2 \rangle$

CW-complex is given by attaching two 2-cells to $S_1^1 \vee S_2^1 \vee S_3^1$

Construction. Let $\langle g_1, \ldots, g_k \,|\, r_1, \ldots, r_m \rangle$ be a finite presentation. For $i = 1, \ldots, k$ let S_i^1 be a copy of S^1. For $j = 1, \ldots, m$ we do the following:

(1) We write the relation r_j as a reduced word $g_{s(1)}^{\epsilon_1} \cdot \cdots \cdot g_{s(n)}^{\epsilon_n}$ with $\epsilon_1, \ldots, \epsilon_n \in \{-1, 1\}$.

(2) We denote by $\varphi_j \colon S^1 = [0,1]/0 \sim 1 \to \bigvee_{i=1}^{k} S_i^1$ the (hopefully obvious) path which on the interval $[\frac{i-1}{n}, \frac{i}{n}]$ travels through $S_{s(i)}^1$ at constant speed in the direction determined by ϵ_i.

We denote by X the CW-complex that is given by attaching m 2-cells to $\bigvee_{i=1}^{k} S_i^1$ along the attaching maps $\varphi_1, \ldots, \varphi_m$. We refer to X as the CW-complex associated to the presentation.

Now we can state the corollary that we promised above.

Corollary 69.12. Let $\langle g_1, \ldots, g_k \,|\, r_1, \ldots, r_m \rangle$ be a finite presentation for a group π. If Y is the associated 2-dimensional CW-complex, then $\pi_1(Y) \cong \pi$.

Proof. Let $\pi = \langle g_1, \ldots, g_k \,|\, r_1, \ldots, r_m \rangle$ be a finitely presented group. We use the notation introduced in the above construction of the CW-complex associated to π. We denote by X the wedge of the k circles and we denote by x_0 the wedge point. Following the discussion on page 1173 we can make the identification $\pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle$. This identification has the property that for $j = 1, \ldots, m$ the corresponding loop $\varphi_j \colon S^1 \to X$ represents $r_j \in \pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle$. We write $Y_0 = X$ and for $j = 1, \ldots, m$ we iteratively define Y_j to be the 2-dimensional CW-complex that is given by attaching a 2-cell to Y_{j-1} with the

attaching map φ_j. We obtain that

$$\begin{array}{ccccc} & \text{Cell Attachment-}\pi_1\text{-Proposition 69.11, applied } m \text{ times} & & \text{since } [\varphi_j] = r_j & \\ & \downarrow & & \downarrow & \\ \pi_1(Y_m, x_0) & \cong & \langle g_1, \ldots, g_k \rangle / \langle\langle [\varphi_1] \rangle\rangle \ldots / \langle\langle [\varphi_m] \rangle\rangle & = & \langle g_1, \ldots, g_k \rangle / \langle\langle r_1 \rangle\rangle \ldots / \langle\langle r_m \rangle\rangle \\ & = & \langle g_1, \ldots, g_k \rangle / \langle\langle r_1, \ldots, r_m \rangle\rangle & = & \langle g_1, \ldots, g_k \,|\, r_1, \ldots, r_m \rangle. \\ & \uparrow & & \uparrow & \\ & \text{by Exercise 53.1} & & \text{by definition} & \end{array}$$

■

The following proposition says in particular that for many CW-complexes the fundamental group of a CW-complex is the same as the fundamental group of its 2-skeleton.

Proposition 69.13. (CW-Skeleton-π_1-Proposition) Let X be a connected CW-complex and let x_0 be a point in the 0-skeleton of X.

(1) If X has finitely many cells in each dimension, then the following statements hold:
   (a) The inclusion induced map[823] $\pi_1(X^1, x_0) \to \pi_1(X, x_0)$ is an epimorphism.
   (b) For any $k \geq 2$ the inclusion induced map $\pi_1(X^k, x_0) \to \pi_1(X, x_0)$ is an isomorphism.

(2) If X has only finitely many cells in dimensions 0 and 1, then $\pi_1(X, x_0)$ is finitely generated.

(3) If X has only finitely many cells in dimensions 0, 1 and 2, then $\pi_1(X, x_0)$ is finitely presented.

Remark. In the CW-Skeleton-π_n-Proposition 71.9 we will generalize the CW-Skeleton-π_1-Proposition 69.13 to all connected CW-complexes.

Example. Let $X = \mathbb{R}\mathrm{P}^\infty$ be the infinite real projective space with the CW-structure from page 1480. For this CW-complex the 1-skeleton is $X^1 = \mathbb{R}\mathrm{P}^1 \cong S^1$ and the 2-skeleton is $X^2 = \mathbb{R}\mathrm{P}^2$. It follows from the CW-Skeleton-π_1-Proposition 69.13 (1) that $\mathbb{Z} \cong \pi_1(S^1) \to \pi_1(\mathbb{R}\mathrm{P}^\infty)$ is an epimorphism and it follows from the CW-Skeleton-π_1-Proposition 69.13 (1) that $\mathbb{Z}_2 \cong \pi_1(\mathbb{R}\mathrm{P}^2) \to \pi_1(\mathbb{R}\mathrm{P}^\infty)$ is an isomorphism. This calculation of $\pi_1(\mathbb{R}\mathrm{P}^\infty)$ is certainly easier than the argument from page 1519.

Proof.

(1) We first suppose that X is a finite CW-complex. Then the two statements follow immediately from iteratively applying the Cell Attachment-π_1-Proposition 69.11 finitely many times. If X is an infinite CW-complex, but with finitely many cells in each dimension, then one can reduce the two statements to the finite case using Propositions 69.3. We leave the details to the reader.

(2) Now we turn to the proof of (2). By (1) it suffices to show that the fundamental group of a finite connected 1-dimensional CW-complex is finitely generated, but we showed this in the Fundamental Group-of-1-Complex Theorem 69.9.

(3) Finally we turn to the proof of (3). By (1) it suffices to show that a finite connected 2-dimensional CW-complex X has a finitely presented fundamental group. We pick $x_0 \in X$. We denote by $\varphi_1, \ldots, \varphi_k$ the attaching maps of the 2-cells. For $i = 1, \ldots, k$ we pick a path p_i from x_0 to a point on $\varphi_i(S^1)$ and we write $\psi_i = p_i * \varphi_i * \overline{p}_i$. We then have

[823] Recall that for $k \in \mathbb{N}$ we denote by X^k the k-skeleton of X, i.e. the union of all cells of dimension $\leq k$.

$$\pi_1(X) \underset{\uparrow}{\cong} \pi_1(X^1)/\langle\langle [\psi_1] \rangle\rangle \dots /\langle\langle [\psi_k] \rangle\rangle \underset{\uparrow}{=} \pi_1(X^1)/\langle\langle [\psi_1], \dots, [\psi_k] \rangle\rangle$$

Propositions 47.10 and 69.11 — by Exercise 53.1

$$= \underset{\uparrow}{} \{\text{finitely generated free group}\}/\langle\langle [\psi_1], \dots, [\psi_k] \rangle\rangle.$$

Statement (2)

We have thus shown that $\pi_1(X)$ is a finitely presented group. ■

Remark. On page 1474 we already mentioned the Smooth Manifold-CW Structure Theorem 96.5 which says in particular that every compact smooth manifold admits the structure of a finite CW-complex. Together with the CW-Skeleton-π_1-Proposition 69.13 (3) we now obtain that the fundamental group of any connected compact smooth manifold M is finitely presented.

The following corollary is an immediate but rather convenient consequence of the CW-Skeleton-π_1-Proposition 69.13 (1).

Corollary 69.14. Let X be a connected CW-complex with countably many cells. If X has no 1-cells, then X is simply connected, i.e. $\pi_1(X) = 0$.

Examples.

(1) On page 1472 we pointed out that for $n \geq 2$ the sphere S^n admits a CW-structure with one 0-cell and one n-cell. From Corollary 69.14 we now recover the result from the Sphere-π_1-Proposition 47.13 that S^n is simply connected.
(2) It follows from Lemma 68.1 and Corollary 69.14 that for any n we have $\pi_1(\mathbb{C}\mathrm{P}^n) = 0$. Similarly it follows, using Lemma 68.6, that $\pi_1(\mathbb{C}\mathrm{P}^\infty) = 0$.

We conclude this chapter with a purely group theoretic result. To put the result in context, first recall that in Exercise 53.2 we saw that every finite-index subgroup of a finitely generated group is finitely generated. Now we can prove the following analogue.

Proposition 69.15. Every finite-index subgroup of a finitely presented group is finitely presented.

Remark. We will provide a proof of Proposition 69.15 that makes heavy use of topological methods. Not surprisingly one can also give a purely group theoretic proof. In fact such a proof can be given by the Reidemeister-Schreier process that we alluded to in Section 59.7. We refer to [**LyS1977**, p. 103] and [**MKS1976**, p. 90] for details.

Proof. Let $\pi = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_m \rangle$ be a finitely presented group. Let Y be the finite 2-complex associated to this presentation that we constructed on page 1531. By Corollary 69.12 we know that $\pi_1(Y) \cong \pi$. Now let Γ be a finite-index subgroup of π. By the CW-Complex Properties Proposition 68.10 together with the Covering Existence Theorem 61.5 there exists a finite covering $p\colon \widetilde{Y} \to Y$ such that $\pi_1(\widetilde{Y}) \cong \Gamma$. By the CW-complex Covering Proposition 68.37 (2) the 2-complex $\widetilde{Y}$ has finitely many 1-cells and 2-cells. Thus it follows from the CW-Skeleton-π_1-Proposition 69.13 (3) that $\Gamma \cong \pi_1(\widetilde{Y})$ is a finitely presented group. ■

Exercises for Chapter 69.

Exercise 69.1. Let $A = S^1 \times [0,1]$ be an annulus.

(a) (i) We consider

$$X := \Big(\bigcup_{k\in\mathbb{N}_0} A \times \{k\} \Big) / (z,0,k) \sim (z^2,1,k-1) \quad \text{for } z \in S^1, k \in \mathbb{N}.$$

Determine $\pi_1(X)$.

(ii) We consider

$$Y := \Big(\bigcup_{k\in\mathbb{N}_0} A \times \{-k\} \Big) / (z,0,-k) \sim (z^2,1,-k-1) \quad \text{for } z \in S^1, k \in \mathbb{N}.$$

Determine $\pi_1(Y)$.

In both cases the group you obtain is an abelian group that is isomorphic to a subgroup of $(\mathbb{R},+)$.

(b) Give an example of topological space Z such that $\pi_1(Z) \cong (\mathbb{Q},+)$.

Exercise 69.2. Next let X and Y be two finite CW-complexes. On page 1498 we introduced the product CW-structure which by Proposition 68.23 is indeed a CW-structure for the topological space $X \times Y$. Is $\chi(X \times Y)$ determined by $\chi(X)$ and $\chi(Y)$?

70. CW-complexes III: Advanced properties

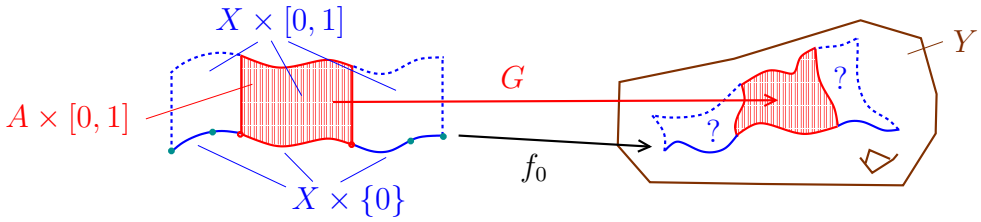
In this chapter we will prove several key technical theorems on CW-complexes, in particular we will prove the Homotopy Extension Theorem 70.1 and the Cellular Approximation Theorem 70.15. The reader who is in a hurry could just have a look at the Cellular Approximation Theorem 70.15 and then move on.

70.1. **The Homotopy Extension Theorem.** We recall the following definition from page 478.

Definition.

(1) A map $i\colon A \to X$ between topological spaces is called a cofibration if it has the homotopy extension property, i.e. if given any topological space Y and any two maps $f\colon X \times \{0\} \to Y$ and $G\colon A \times [0,1] \to Y$ with $f(i(a),0) = G(a,0)$ for all $a \in A$ there exists a map $F\colon X \times [0,1] \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} A \times \{0\} & \hookrightarrow & A \times [0,1] \\ \downarrow{\scriptstyle i} & \overset{f}{\nearrow} \; \underset{F}{\nwarrow} \; \overset{G}{\swarrow} & \downarrow{\scriptstyle i\times \mathrm{id}} \\ X \times \{0\} & \hookrightarrow & X \times [0,1]. \end{array} \qquad \begin{array}{l} \\ Y \\ \\ \end{array}$$



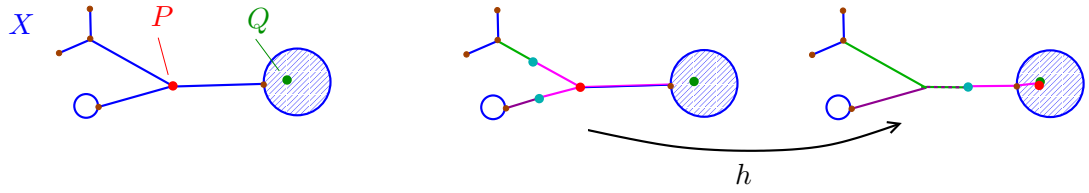
We illustrate the definition in the figure below.

(2) If $i\colon A \to X$ is a cofibration such that $i(A)$ is a closed subset of X, then we refer to i as a closed cofibration.

Theorem 70.1. (Homotopy Extension Theorem) Let X be a CW-complex and let A be a subcomplex of X.

(1) The inclusion map $A \to X$ is a closed cofibration.

(2) In slightly different words: let Y be a topological space and let $f_0\colon X \to Y$ be map. Furthermore, suppose that $A \subset X$ is a subcomplex and suppose we are given a homotopy $G\colon A \times [0,1] \to Y$ from $g_0 := f_0|_A$ to some map $g_1\colon A \to Y$. Then there exists a homotopy $F\colon X \times [0,1] \to Y$ starting from f_0 such that the restriction $F|_{A\times[0,1]}$ equals G.



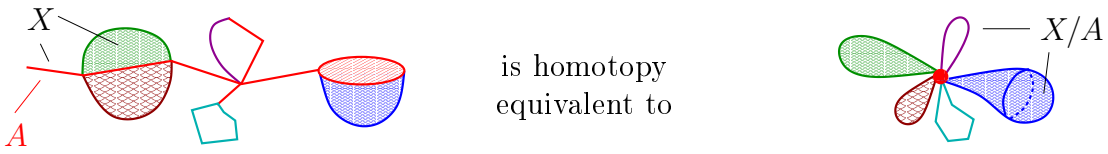
We postpone the long and strenuous proof of the Homotopy Extension Theorem 70.1 to the following section. Let us first revel in some exciting corollaries of the Homotopy Extension Theorem 70.1.

Corollary 70.2. Let X be connected CW-complex, let P be a point in the 0-skeleton of X and let Q be some other point on Y.

(1) Given any path $\gamma\colon [0,1] \to X$ with $\gamma(0) = P$ and $\gamma(1) = Q$ there exists a homotopy $F\colon X \times [0,1] \to X$ with $F(P,t) = \gamma(t)$ for all $t \in [0,1]$ and such that $F_0 = \mathrm{id}$.
(2) There exists a map $h\colon X \to X$ with $h(P) = Q$ that is homotopic to the identity.

Example. We consider the CW-complex X and the two points P and Q shown in the figure below. It should be pretty clear that there is no homeomorphism f of X with $f(P) = Q$. But Corollary 70.2 gives us a decent replacement, namely a map $h\colon X \to X$ with $h(P) = Q$ which is homotopic to the identity.

Proof. Let X be connected CW-complex, let P be a point in the 0-skeleton of X and let Q be some other point on Y.



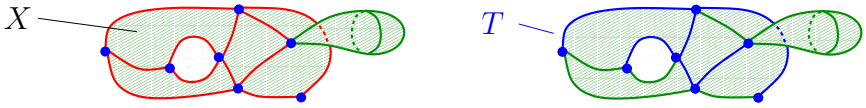
(1) Let $\gamma\colon [0,1] \to X$ be a path with $\gamma(0) = P$ and $\gamma(1) = Q$. We write $A := \{P\}$. Since P is a point in the 0-skeleton of X we see that A is a subcomplex of A. We apply the Homotopy Extension Theorem 70.1 to $f_0 = \mathrm{id}\colon X \to X$, $g_0(P) := P$, $g_1(P) = Q$ and $G(P,t) = \gamma(t)$. The resulting homotopy $F\colon X \times [0,1] \to X$ has all the desired properties.
(2) Since X is connected we obtain from the CW-Complex Properties Proposition 68.10 that there exists a map $\gamma\colon [0,1] \to X$ with $\gamma(0) = P$ and $\gamma(1) = Q$. From (1) we obtain a homotopy $F\colon X \times [0,1] \to X$ with $F_0 = \mathrm{id}$ and $F_1(P) = Q$. The map $h := F_1$ evidently has all the promised properties. ∎

We can now dip into the theory of cofibrations that we developed in Chapter 17. In particular we obtain the following useful corollary.

Corollary 70.3. (Quotient-by-Contractible Corollary) Let X be a CW-complex and let $A \subset X$ be a subcomplex.

(1) If A is contractible, then the projection $X \to X/A$ is a homotopy equivalence.
(2) If $a_0 \in A$ is a point such that $\{a_0\}$ is a deformation retract of A, then the projection $X \to X/A$ is a homotopy equivalence between the pointed topological spaces (X, a_0) and $(X/A, [A])$.

Remark. the Quotient-by-Contractible Corollary 70.3 (1) is a generalization of the Quotient-by-Tree Proposition 69.8.



Proof. By the Subcomplex Cofibration Theorem 17.9 we know that the inclusion $A \to X$ is a closed cofibration. The two statements now follow immediately from the corresponding statements in the Cofibration-Quotient Lemma 17.7. ■

The following proposition is a neat corollary to the Quotient-by-Contractible Corollary 70.3.

Proposition 70.4. Let X be a 0-connected CW-complex.

(1) There exists a contractible 1-dimensional subcomplex T which contains all 0-cells.[824]
(2) Given any T as in (1) the quotient X/T is a CW-complex with precisely one 0-cell. Furthermore the projection $X \to X/T$ is a homotopy equivalence.

Remark.

(1) Using the Cell Attachment-π_1-Proposition 69.11 it is very easy to calculate the fundamental group of a finite 0-connected CW-complex with a single 0-cell. Proposition 70.4 says in particular that given a finite 0-connected CW-complex we can always reduce the calculation of the fundamental group to the case of a finite CW-complex with a single 0-cell.
(2) Let X be a 0-connected CW-complex with countably many 1-cells. Let $x_0 \in X$ be a 0-cell. By the CW-Skeleton-π_n-Proposition 71.9 the inclusion $X^1 \to X$ of the 1-skeleton induces an epimorphism $\pi_1(X^1, x_0) \to \pi_1(X, x_0)$. Furthermore it follows from Proposition 70.4 and 52.7 that $\pi_1(X^1, x_0)$ is a free group on a countable generating set. It follows from this discussion, together with the Countability Lemma 0.8 (2), that $\pi_1(X, x_0)$ is countable.

Proof. Let X be a 0-connected CW-complex.

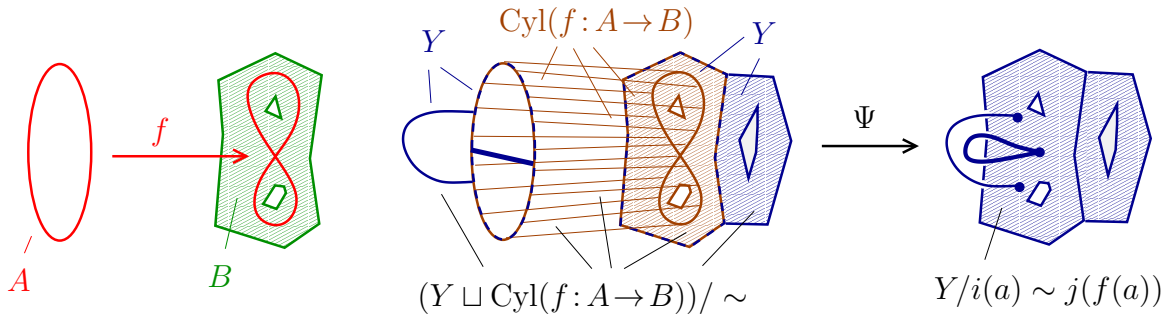
(1) In the Spanning Tree Existence Proposition 69.7 (1) we showed that the 1-skeleton X^1 admits a subcomplex T that contains all 0-cells of X and that admits a deformation retraction to x_0.
(2) By the CW-Complex Construction Lemma 68.32 the quotient X/T admits a CW-structure with one 0-cell. Furthermore note that it follows from the Quotient-by-Contractible Corollary 70.3 (2) that the projection $X \to X/T$ is a homotopy equivalence between. ■

The following proposition gives another typical application of the Homotopy Extension Theorem 70.1.

Proposition 70.5. Let $f\colon A \to B$ be a cellular map between CW-complexes that has the following property:

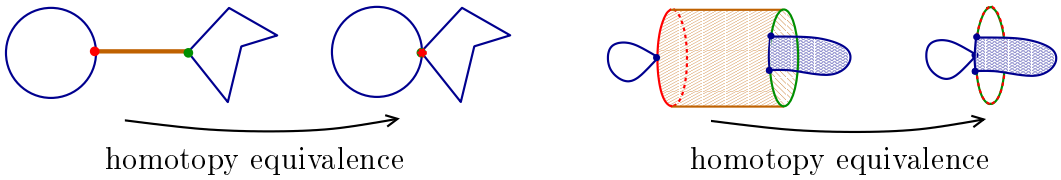
($*$) For each n-cell σ of A we have either $f(\sigma) \subset B^{n-1}$ or $f|_\sigma$ is a homeomorphism.

We consider the corresponding mapping cylinder



$$\mathrm{Cyl}(f) := \mathrm{Cyl}(f\colon A \to B) := ((A \times [0,1]) \sqcup B)/\sim \text{ where } (a,1) \sim f(a) \text{ for all } a \in A.$$

[824] Such a subcomplex is basically what we called a spanning tree on page 317.

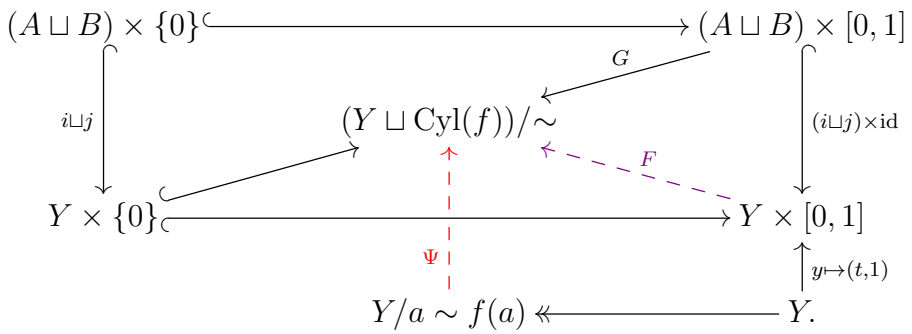


that we defined on page 454. Finally let Y be a CW-complex together with a cellular embedding $i \sqcup j \colon A \sqcup B \to Y$. The map

$$\begin{array}{rcl} \Phi \colon (Y \sqcup \mathrm{Cyl}(f \colon A \to B))/\sim & \to & Y/i(a) \sim j(f(a)) \\ [P] & \mapsto & \begin{cases} [P], & \text{if } P \in Y, \\ [i(a)], & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1], \\ [j(b)], & \text{if } P = [b] \text{ with } b \in B \end{cases} \end{array}$$

is a homotopy equivalence.

Example. In many applications the map f will actually be a cellular isomorphism. In this special case Proposition 70.5 basically says that one can compress a product $A \times [0,1]$ to a single copy of A without changing the homotopy type. Two such examples are shown in the figure below.



Remark. Note that the statement of Proposition 70.5 is related in spirit to the statement of the Cofibration-Quotient Lemma 17.7 (2).

Proof. First note that by the Cellular Embedding Lemma 68.19 we can and will view $A \sqcup B$ as a subcomplex of Y. In the following let $R \colon \mathrm{Cyl}(f \colon A \to B) \times [0,1] \to B$ be the natural deformation retraction given by the Mapping Cylinder Basics Lemma 16.12. Furthermore note that it follows quite easily from the CW-Complex Cone Corollary 68.35 (3) and the CW-Complex Construction Lemma 68.32 (2) that we can and will equip $\mathrm{Cyl}(f)$ and $(Y \sqcup \mathrm{Cyl}(f))/\sim$ with natural CW-structures. Finally, it follows from our slightly technical hypothesis on f together with the CW-Complex Construction Lemma 68.32 (6) that $Y/\sim$ also admits a natural CW-structure. Next we consider the homotopy

$$\begin{array}{rcl} G \colon (A \sqcup B) \times [0,1] & \to & \mathrm{Cyl}(f) \subset (Y \sqcup \mathrm{Cyl}(f))/\sim \\ [(Q,t)] & \mapsto & \begin{cases} R([(Q,0)],t), & \text{if } Q \in A, \\ Q, & \text{if } Q \in B. \end{cases} \end{array}$$

We obtain the following diagram:

We make the following observations and clarifications:

(1) The map $i \sqcup j \colon A \sqcup B \to Y$ is the inclusion map.
(2) It follows from the Homotopy Extension Theorem 70.1 and the fact that $A \sqcup B$ is a subcomplex of Y that there exists a map $F \colon Y \times [0,1] \to (Y \sqcup \mathrm{Cyl}(f))/\sim$ that makes the two triangles involving F commute.
(3) For any $a \in A$ we have

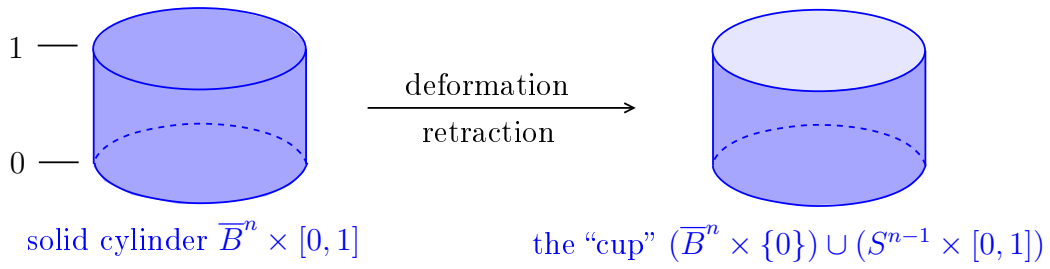
$$F_1(a) = F(a,1) = G(a,1) = \underbrace{f(a)}_{\in B} = G(f(a),1) = F(f(a),1) = F_1(f(a)).$$

It follows from this calculation that the map $F_1 \colon Y \to (Y \sqcup \mathrm{Cyl}(f))/\sim$ descends to a map $\Psi \colon Y/a \sim f(a) \to (Y \sqcup \mathrm{Cyl}(f))/\sim$.

It remains to show the following claim.

Claim. The maps $\Phi \colon (Y \sqcup \mathrm{Cyl}(f))/\sim \to Y/a \sim f(a)$ and $\Psi \colon Y/a \sim f(a) \to (Y \sqcup \mathrm{Cyl}(f))/\sim$ are homotopy inverses of one another.

Proof. First we consider the map



$$\begin{array}{rcl} H \colon (Y/a \sim f(a)) \times [0,1] & \to & Y/a \sim f(a) \\ (\underbrace{[P]}_{\in Y}, t) & \mapsto & \Phi(F(P,t)). \end{array}$$

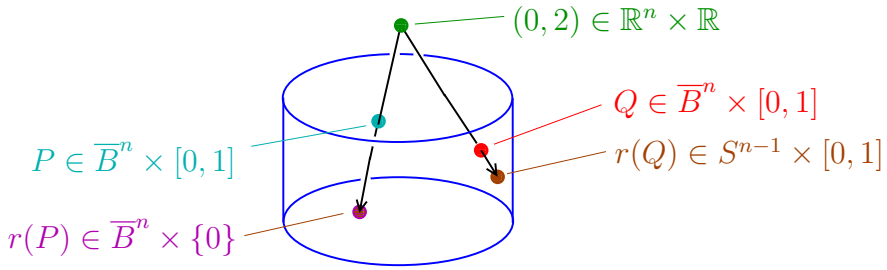
One can easily verify that the map is, despite first appearances, actually well-defined. Using the fact that $Y/a \sim f(a)$ is a CW-complex and using the Interval CW-Product Corollary 68.9 one can show quite easily that H is continuous. Basically by construction we have $H_0 = \mathrm{id}$ and $H_1 = \Phi \circ \Psi$. Thus we have found our first homotopy. Finally we consider the map

$$\begin{array}{rcl} H \colon (Y \sqcup \mathrm{Cyl}(f))/\sim & \to & (Y \sqcup \mathrm{Cyl}(f))/\sim \\ ([P], t) & \mapsto & \begin{cases} R(P,t), & \text{if } P \in \mathrm{Cyl}(f), \\ F(P,t), & \text{if } P \in Y. \end{cases} \end{array}$$

Similar to the above one sees that H is continuous, that $H_0 = \mathrm{id}$ and that $H_1 = \Psi \circ \Phi$. ∎

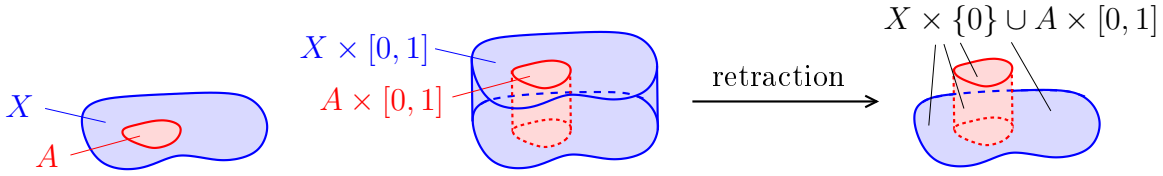
70.2. **Proof of the Homotopy Extension Theorem 70.1.** Before we can provide the proof of Theorem 70.1 we will need to formulate and prove several lemmas.

Lemma 70.6. For any $n \in \mathbb{N}_0$ there exists a deformation retraction from the solid cylinder $\overline{B}^n \times [0,1]$ to the "cup" $\overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1]$.



Proof. It is straightforward to verify that the map

$$\begin{array}{rcl} r\colon \overline{B}^n \times [0,1] & \to & (\overline{B}^n \times \{0\}) \cup (S^{n-1} \times [0,1]) \\ P & \mapsto & \text{the unique point on } \overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1] \text{ that} \\ & & \text{gets hit by the ray from } (0,2) \in \mathbb{R}^n \times \mathbb{R} \text{ through } P. \end{array}$$



is a retraction. We refer to the figure below for an illustration. Since $\overline{B}^n \times [0,1]$ is convex we can define the corresponding deformation retraction as follows:

$$\begin{array}{rcl} (\overline{B}^n \times [0,1]) \times [0,1] & \to & \overline{B}^n \times [0,1] \\ (P,t) & \mapsto & P \cdot (1-t) + r(P) \cdot t. \end{array}$$

■

Lemma 70.7. If X is a CW-complex and if A is a subcomplex of X, then there exists a deformation retraction from $X \times [0,1]$ to the subcomplex $(X \times \{0\}) \cup (A \times [0,1])$.

Proof. Let X be a CW-complex and let A be a subcomplex. For each $n \in \mathbb{N}_0$ we set

$$Z_n \;:=\; X \times \{0\} \;\cup\; (X^{n-1} \cup A) \times [0,1].$$

Note that each Z_n is a subcomplex of the product CW-complex $X \times [0,1]$. Evidently we have a sequence

$$(X \times \{0\}) \cup (A \times [0,1]) = Z_0 \;\subset\; Z_1 \;\subset\; Z_2 \;\subset\; \ldots \qquad \text{with } X \times [0,1] \;=\; \bigcup_{n \in \mathbb{N}_0} Z_n.$$

Thus it follows from the Iterated Deformation Retracts Proposition 68.22 that it suffices to prove the following claim.

Claim. For every $n \in \mathbb{N}_0$ there exists a deformation retraction from Z_{n+1} to Z_n.

Proof. Let $n \in \mathbb{N}_0$. We denote by $\Phi_i \colon \overline{B}^n \to X$, $i \in I$, the characteristic maps of all the n-cells of X that do not lie in A. By Lemma 70.6 there exists a deformation retraction $r \colon \overline{B}^n \times [0,1] \times [0,1] \to \overline{B}^n \times [0,1]$ from $\overline{B}^n \times [0,1]$ to $\overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1]$. The idea is to apply this retraction to all k-cells of X to obtain the desired deformation retraction. More precisely we consider the map

$$\begin{aligned} r_n \colon \overbrace{(X \times \{0\} \cup (X^n \cup A) \times [0,1])}^{=Z_{n+1}} \times [0,1] &\to \overbrace{X \times \{0\} \cup (X^n \cup A) \times [0,1]}^{=Z_{n+1}} \\ ((P,t),s) &\mapsto \begin{cases} \Phi_i(r((Q,t),s)), & \text{if } P = \Phi_i(Q) \text{ with} \\ & \quad Q \in \overline{B}^n \text{ and } i \in I, \\ (P,t), & \text{otherwise.} \end{cases} \end{aligned}$$

This map is easily seen to be a deformation retraction from Z_{n+1} to Z_n.[825] ∎

Proof of the Homotopy Extension Theorem 70.1. Let X be a CW-complex and let $A \subset X$ be a subcomplex. We need to show that the inclusion map $i \colon A \to X$ is a closed cofibration. Note that by the Subcomplex Lemma 68.18 (2) we know that A is a closed subset of X. It remains to show tht $i \colon A \to X$ is a cofibration.

Thus let Y be a topological space, let $f_0 \colon X \to Y$ be a map and let $G \colon A \times [0,1] \to Y$ be a homotopy from $g_0 := f_0|_A$ to some map $g_1 \colon A \to Y$. We need to show that we can extend G to a homotopy on all of $X \times [0,1]$.

Note that by Lemma 70.7 there exists a retraction

$$H \colon X \times [0,1] \to (X \times \{0\}) \cup (A \times [0,1]).$$

Therefore the theorem follows from the Cofibration Characterization Lemma 17.2 or, equivalently, from the following claim.

Claim. The map

$$\begin{aligned} F \colon X \times [0,1] \xrightarrow{H} (X \times \{0\}) \cup (A \times [0,1]) &\to Y \\ (x,0) &\mapsto f_0(x), \quad \text{for } x \in X, \\ (a,t) &\mapsto G(a,t), \quad \text{for } (a,t) \in A \times [0,1]. \end{aligned}$$

has all the desired properties.

Proof. First we have to verify that the map is continuous. In fact, for continuity we do have to worry a little bit about the right-hand map. But note that the Subcomplex Lemma 68.18 (2) says that the subcomplex A is a closed subset of X. Thus we see that the map on the right-hand side is continuous when restricted to the *closed* subsets $X \times \{0\}$ and $A \times [0,1]$. Thus it is continuous by the Pasting Proposition 2.6 (2). Note it is clear that F has the desired properties, i.e. that it is a homotopy $F \colon X \times [0,1] \to Y$ starting from f_0 such that the restriction $F|_{A \times [0,1]}$ equals G. ∎

[825] It follows from the Characteristic Maps Lemma 68.7 (4) that the map is in fact continuous.

70.3. **Dropping base points.** Even though base points are necessary and valuable, in practice they are frequently a major nuisance. Fortunately, using the Homotopy Extension Theorem 70.1, we can prove a proposition that often allows us to stop worrying about base points.

We start out with a few definitions. Some of them we have encountered before.

Definition.

(1) A pointed topological space is a pair (X, x_0) where X is a topological space and $x_0 \in X$ is a point. We refer to x_0 as the base point of the pointed topological space.
(2) A map $f\colon (X, x_0) \to (Y, y_0)$ between pointed topological spaces is a map $f\colon X \to Y$ with $f(x_0) = y_0$.
(3) We say that two maps $f, g\colon (X, x_0) \to (Y, y_0)$ between pointed topological spaces are homotopic if there exists a homotopy $F\colon X \times [0,1] \to Y$ rel $\{x_0\}$ from f to g.
(4) Given two pointed topological spaces (X, x_0) and (Y, y_0) we write[826]

$$\langle (X, x_0), (Y, y_0) \rangle := \{\text{maps } (X, x_0) \to (Y, y_0)\}/\sim$$

where $f \sim g$ if there exists a homotopy in the above sense between f and g.

Example. Let (X, x_0) be a pointed topological space, let $n \in \mathbb{N}$ and let $*$ be the usual base point of S^n. By definition we have $\langle (S^n, *), (X, x_0) \rangle = \pi_n(X, x_0)$.

We have a natural map $\langle (X, x_0), (Y, y_0) \rangle \to [X, Y]$. It is worth spending a minute on trying to find examples that show that in general this map is neither an injection nor a surjection. In this section we want to give some criteria that give us some control over this map. We start out with the following easy, albeit fairly restrictive, example.

Proposition 70.8. Let (Y, y_0) be a path-connected topological space. If $\pi_1(Y, y_0)$ is abelian, then the map

$$\begin{array}{rcl} \langle (S^1, *), (Y, y_0) \rangle & \to & [S^1, Y] \\ [f] & \mapsto & [f] \end{array}$$

is a bijection.

Proof. It follows from the fact that Y is path-connected together with the Homotopies-of-Loops Proposition 50.16 (1) that the map is a surjection. Furthermore it follows from the hypothesis that $\pi_1(Y, y_0)$ is abelian together with the Homotopies-of-Loops Proposition 50.16 (2) that the map is an injection. ∎

Now we want to move away from the fairly simple topological space S^1. In the proof of the Homotopies-of-Loops Proposition 50.16 we had to construct fairly explicitly maps on S^1 and $S^1 \times [0,1]$. In the following we will now replace S^1 by CW-complexes, we have now developed several tools for building maps *out* of a CW-complex. This leads us to the following definition.

Definition. A pointed CW-complex is a pair (X, x_0) where X is a CW-complex and x_0 is a point in the 0-skeleton X^0 of X.

[826] The notation $\langle X, Y \rangle$ goes back to [**Hat2002**, p. 357], where it says "the notation $\langle \dots \rangle$ is intended to suggest pointed homotopy classes".

Proposition 70.9. Let (X, x_0) be pointed a CW-complex and let (Y, y_0) be a pointed topological space. We consider the map

$$\begin{array}{rcl} \langle (X,x_0),(Y,y_0)\rangle & \to & [X,Y] \\ [f] & \mapsto & [f]. \end{array}$$

The following two statements hold:

(1) If Y is path-connected, then the map $\langle (X, x_0), (Y, y_0)\rangle \to [X, Y]$ is a surjection.
(2) If Y is simply connected, then the map $\langle (X, x_0), (Y, y_0)\rangle \to [X, Y]$ is a bijection.

Remark. In Proposition 164.25 we will formulate a variation on Proposition 70.9 for CW-complexes with abelian fundamental groups.

For the record we state the following corollary to our results.

Corollary 70.10.

(1) Let (X, x_0) be a path-connected pointed topological space and let $n \in \mathbb{N}$. If $n = 1$, then we assume that $\pi_1(X, x_0)$ is abelian and if $n \geq 2$ we assume that $\pi_1(X, x_0)$ is trivial. In this setting the map

$$\underbrace{\langle (S^n, x_0), (X, x_0)\rangle}_{=\pi_n(X,x_0)} \xrightarrow{[f]\mapsto[f]} [S^n, X]$$

is a bijection.
(2) Given any $n \in \mathbb{N}$ and given any base point $x_0 \in S^n$ the map

$$\langle (S^n, x_0), (S^n, x_0)\rangle \xrightarrow{[f]\mapsto[f]} [S^n, S^n]$$

is a bijection.

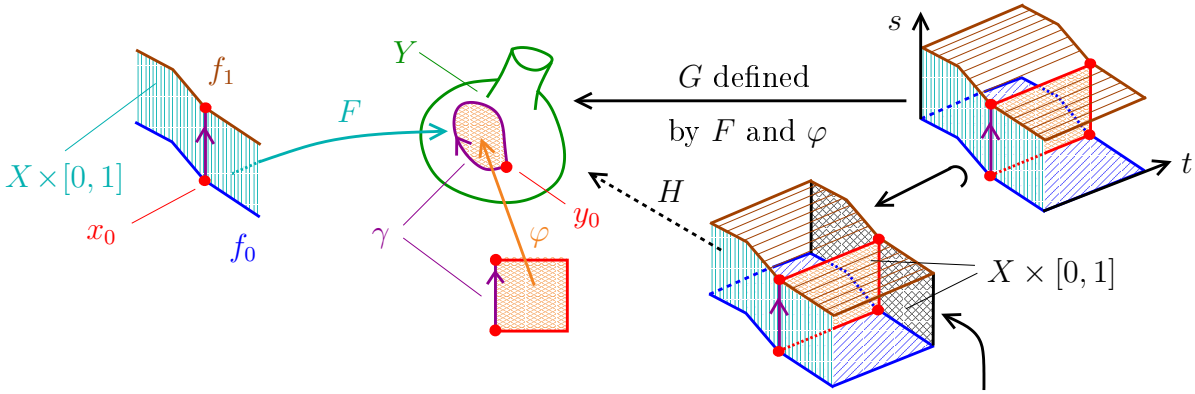
Proof of Corollary 70.10.

(1) (a) The case $n = 1$ is precisely the content of Proposition 70.8.
(b) Now let $n \in \mathbb{N}_{\geq 2}$. We can and will equip S^n with a CW-structure such that x_0 is a 0-cell. The desired statement now follows from Proposition 70.9 (2).
(2) This statement follows immediately from (1) and the fact, established in Corollary 48.18 and the Sphere-π_1-Proposition 47.13, that for $n \geq 2$ the fundamental group $\pi_1(S^n)$ is trivial. ∎

Now we turn to the proof of Proposition 70.9. This proof relies very much on the following lemma.

Lemma 70.11. Let (X, x_0) and (Y, y_0) be pointed CW-complexes and let $F\colon X \times [0, 1] \to Y$ be a homotopy with $F_0(x_0) = F_1(x_0) = y_0$. We consider the loop $\gamma\colon [0, 1] \to Y$ that is given by $\gamma(t) := F(x_0, t)$. If the loop γ is null-homotopic, then there exists a homotopy $J\colon X \times [0, 1] \to Y$ with $J_0 = F_0$ and $J_1 = F_1$ and such that $J(x_0, t) = y_0$ for all $t \in [0, 1]$.

Proof of Lemma 70.11. We prove the lemma in three easily digestible steps:

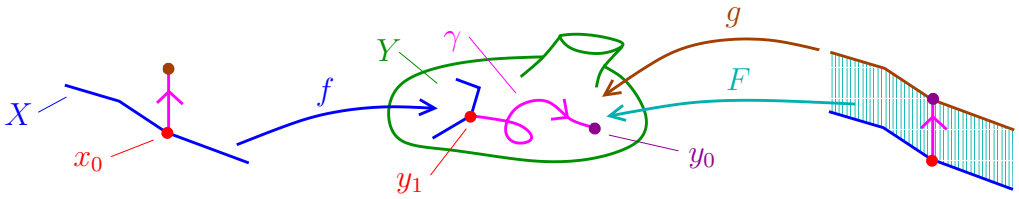


(1) We consider the loop $\gamma\colon [0, 1] \to Y$ that is given by $\gamma(t) := F(x_0, t)$. By our hypothesis the loop γ is null-homotopic. By definition this means that there exists a map $\varphi\colon [0, 1] \times [0, 1] \to Y$ with $\varphi(t, 0) = \gamma(t)$ for all $t \in [0, 1]$ and such that $\varphi(x, y) = y_0$ for all other points in $\partial([0, 1] \times [0, 1])$.

(2) We consider the map[827]

$$G\colon \overbrace{(X\times[0,1])\times\{0\}\cup\underbrace{(X\times\{0,1\}\cup\{x_0\}\times[0,1])\times[0,1]}_{\text{subcomplex of } X\times[0,1]}}^{\text{subcomplex of } (X\times[0,1])\times[0,1]} \to Y$$
$$(x,s,t)\mapsto\begin{cases}F(x,s), & \text{if } t=0,\\ F(x,s), & \text{if } s=0,1,\\ \varphi(s,t), & \text{if } x=x_0.\end{cases}$$

It follows from the CW-Complex Pasting Lemma 68.20 that this map G is continuous.



(3) By the Homotopy Extension Theorem 70.1 the map G from (2) extends to a map $H\colon (X\times[0,1])\times[0,1]\to Y$. It follows basically immediately from the definitions that $J:=H_1\colon X\times[0,1]\to Y$ has the desired properties. ■

Now we turn to the actual proof of Proposition 70.9.

Proof of Proposition 70.9. Let (X,x_0) and (Y,y_0) be pointed CW-complexes.

(1) We suppose that Y is path-connected. Let $f\colon X\to Y$ be map. We set $y_1=f(x_0)$. Since Y is path-connected there exists a path $\gamma\colon[0,1]\to Y$ with $\gamma(0)=y_1$ and $\gamma(1)=y_0$. Since $\{x_0\}$ is a subcomplex of X we obtain from Corollary 70.2 that we can extend γ, viewed as a homotopy $\{x_0\}\times[0,1]\to Y$, to a homotopy $F\colon X\times[0,1]\to Y$. This shows that $f=F_0$ is homotopic to a map $g:=F_1$ with $g(x_0)=y_0$. This implies that the map $\langle(X,x_0),(Y,y_0)\rangle\to[X,Y]$ is a surjection.

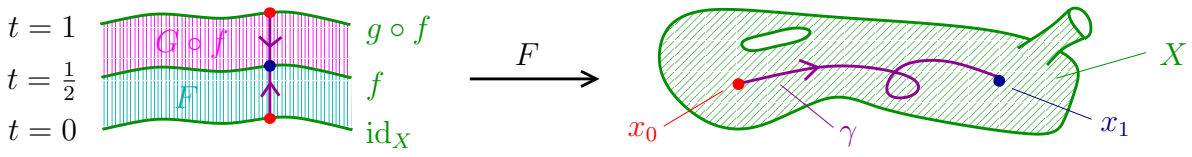
(2) By (1) it remains to show that the map $\langle(X,x_0),(Y,y_0)\rangle\to[X,Y]$ is injective. Thus let $f_0,f_1\colon(X,x_0)\to(Y,y_0)$ be two maps which represent the same element in $[X,Y]$. This means that there exists a homotopy $F\colon X\times[0,1]\to Y$ with $F_0=f_0$ and $F_1=f_1$. We need to show that there exists a homotopy $J\colon X\times[0,1]\to Y$ with

[827] Secretly we use Proposition 68.23 which tells us in this instance that the product CW-structure $X\times[0,1]\times[0,1]$ is indeed a CW-structure for the topological space $X\times[0,1]\times[0,1]$.

$J_0 = f_0$ and $J_1 = f_1$ and such that $J(x_0, t) = y_0$ for all $t \in [0,1]$. We consider the loop $\gamma\colon [0,1] \to Y$ that is given by $\gamma(t) := F(x_0, t)$. Since Y is simply connected we know that γ is null-homotopic. Thus we can apply Lemma 70.11 and we obtain the desired homotopy J. ■

We conclude this section with the following proposition.

Proposition 70.12. Let X be a CW-complex and let x_0 and x_1 be two points in the 0-skeleton of X. If X is connected, then there exists a map $f\colon X \to X$ with the following properties:



(1) The map f is homotopic to the identity.
(2) We have $f(x_0) = x_1$.
(3) The map f defines a homotopy equivalence $(X, x_0) \to (X, x_1)$ of pointed topological spaces.

Proof. Since X is connected we obtain from the CW-Complex Properties Proposition 68.10 (7) that there exists a path $\gamma\colon [0,1] \to X$ with $\gamma(0) = x_0$ and $\gamma(1) = x_1$. Since x_0, x_1 lie in the 0-skeleton of X we can apply Corollary 70.2 and we obtain a homotopy $F\colon X \times [0,1] \to X$ with $F(x_0, t) = \gamma(t)$ for all $t \in [0,1]$ and such that $F_0 = \mathrm{id}$. We set $f := F_1$. Evidently f is homotopic to the identity and $f(x_0) = x_1$. It remains to show that $f\colon (X, x_0) \to (X, x_1)$ is a homotopy equivalence of pointed topological spaces.

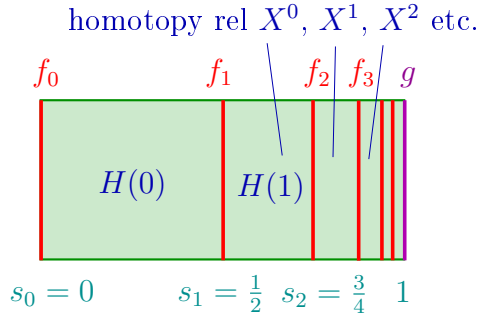
We need to find a homotopy inverse to f. Once again we appeal to Corollary 70.2 to obtain a homotopy $G\colon X \times [0,1] \to X$ with $G(x_1, t) = \overline{\gamma}(t) := \gamma(1-t)$ for all $t \in [0,1]$ and such that $G_0 = \mathrm{id}$. We set $g := G_1$. We need to show that $g \circ f\colon (X, x_0) \to (X, x_0)$ and $f \circ g\colon (X, x_1) \to (X, x_1)$ are homotopic[828] to the identity. We consider the homotopy[829]

$$\begin{array}{rcl} F\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} F(x, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ G(f(x), 2t-1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

Note that this is a homotopy from id_X to $g \circ f\colon X \to X$. Furthermore note that the loop given by $\gamma(t) = F(x_0, t)$ is precisely the loop $\gamma * \overline{\gamma}$. By the Path-Homotopy Concatenation Proposition 47.5 (3) we know that this loop is null-homotopic. Thus we can apply Lemma 70.11. We obtain a homotopy $J\colon X \times [0,1] \to X$ with $J_0 = F_0 = \mathrm{id}_X$, $J_1 = F_1 = g \circ f$ and $J(x_0, t) = x_0$ for all $t \in [0,1]$. But that is precisely what we needed. ■

70.4. **Combining infinitely many homotopies and the telescope construction.** In the Homotopy Combination the Homotopy Combination Lemma 14.4 we saw that one can combine finitely many homotopies. Later on we will want to combine infinitely many homotopies of CW-complexes. This slightly delicate procedure can be performed using the following lemma.

[828] Here, as a reminder, "homotopic" means "homotopic as maps of pointed topological spaces".
[829] It follows from the Homotopy Stacking Lemma 14.3 that F is indeed continuous.



Lemma 70.13. Let X be a CW-complex, let A be a subset of X and let Y be a topological space. Finally let $W_0 \subset W_1 \subset W_2 \subset \ldots$ be a sequence of subcomplexes of X such that for each $k \in \mathbb{N}_0$ there exists an $l \in \mathbb{N}_0$ such that the k-skeleton X^k is contained in W_l. (In many applications we have $W_k = X^k$.) Let $f_0, f_1, \ldots$ be maps from X to Y. Suppose that for each $k \in \mathbb{N}_0$ we are given a homotopy $H(k)\colon X \times [0,1] \to Y$ rel $A \cup W_k$ from f_k to f_{k+1}. (Since it is easy to overlook this bit of the hypothesis we stress that $H(k)$ is in particular a homotopy rel W_k). We define[830]

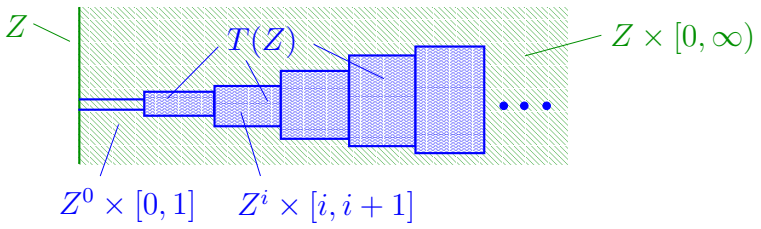
$$\begin{array}{rcl} g\colon X & \to & Y \\ x & \mapsto & f_k(x) \quad \text{where } k \in \mathbb{N}_0 \text{ such that } x \in W_k. \end{array}$$

For $k = 0, 1, 2, \ldots$ we write $s_k = \sum_{j=1}^{k} \frac{1}{2^j}$. Then the map

$$\begin{array}{rcl} H\colon X \times [0,1] & \to & Y \\ (x,t) & \mapsto & \begin{cases} H(k)(x, 2^{k+1} \cdot (t - s_k)), & \text{if } t \in [s_k, s_{k+1}), \\ g(x), & \text{if } t = 1 \end{cases} \end{array}$$

that is illustrated in the figure below is a homotopy rel A from f_0 to g. We refer to the homotopy H as the *combination of* $\{H(k)\}_{k \in \mathbb{N}_0}$.

Proof. We only need to show that H is continuous. Note that for each $l \in \mathbb{N}_0$ it follows from our choice of maps f_l and the Homotopy Stacking Lemma 14.3 that the restriction of H to $W_l \times [0,1]$ is continuous. Since each X^k is contained in some W_l we see that the restriction of H to each $X^k \times [0,1]$ is continuous. But now it follows from the Interval CW-Product Corollary 68.9 that $H\colon X \times [0,1] \to Y$ is also continuous. ■



We conclude this technical section with an application that we will need once, namely in the proof Proposition **??**. But the application doubles also as a nice illustration for how to apply the previous lemma.

Definition. Let Z be a CW-complex. We equip $[0,\infty)$ with the CW-structure where the 0-skeleton is given by $\mathbb{N}_0$. We equip $Z \times [0,\infty)$ with the product CW-structure. We refer to the subcomplex

$$T(Z) \;:=\; \bigcup_{i \in \mathbb{N}_0} Z^i \times [i, i+1] \quad \subset \; Z \times [0,\infty)$$

as the telescope of Z. .

[830] It follows easily from the setup that the map g is well-defined, i.e. given $x \in X$ the point $g(x)$ does not depend on the choice of k.

The following lemma shows that the telescope $T(Z)$ is homotopy equivalent to Z.

Lemma 70.14. (Telescope Lemma) Let Z be a CW-complex. The following statements hold:

(1) $T(Z)$ is a deformation retract of $Z \times [0, \infty)$.
(2) The telescope $T(Z)$ is homotopy equivalent to Z.

Remark. One can also show that the Telescope Lemma 70.14 is a consequence of the much more general the Whitehead Deformation Retract Proposition 162.2.

Proof. First note that $Z = Z \times \{0\}$ is clearly a deformation retract of $Z \times [0, \infty)$. Thus it follows from Lemmas 15.5 and 15.1 that (2) is a consequence of (1). Therefore it remains to prove (1).

As in the definition of the telescope $T(Z)$ we view $[0, \infty)$, $X := Y := Z \times [0, \infty)$ and $T(Z)$ as CW-complexes. It follows from Lemma 70.7 that for each $k \in \mathbb{N}_0$ there exists a deformation retraction

$$r_k \colon (Z \times [0,1]) \times [0,1] \;\to\; Z \times [0,1]$$

from $Z \times [0,1]$ to $(Z^k \times [0,1]) \cup (Z \times \{1\})$. We denote by

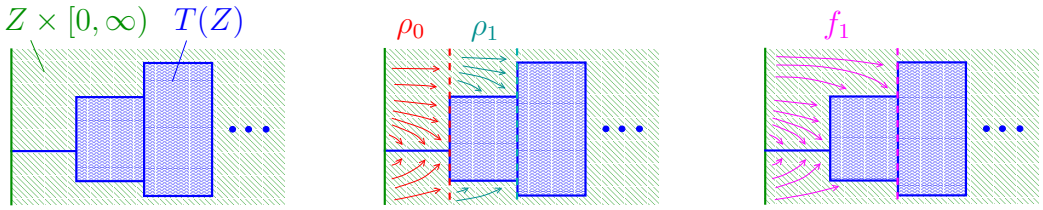
$$\begin{array}{rcl} \rho_k \colon Z \times [k, k+1] & \to & (Z^{k-1} \times [k, k+1]) \cup (Z^k \times \{k+1\}) \\ (z,t) & \mapsto & (r_k(z, t-k) + (0,k), 1) \end{array}$$

the corresponding retraction, with the intervals shifted by k. We make the following preparations:

(1) Given $k \in \mathbb{N}_0$ we define $W_k := Z^k \times [0, \infty)$. Note that it follows from the definition of the product CW-structure on $Z \times [0, \infty)$ that the k-skeleton of $X = Z \times [0, \infty)$ is contained in W_{k+1}.
(2) For each $k \in \mathbb{N}_0$ we consider the map

$$\begin{array}{rcl} f_k \colon X = Z \times [0,\infty) & \to & Y = Z \times [0,\infty) \\ (z,t) & \mapsto & \begin{cases} (z,t), & \text{if } x \in Z^k \text{ and } t \geq k+1, \\ (\rho_k \circ \cdots \circ \rho_1 \circ \rho_0)(x), & \text{if } z \in Z^k \text{ and } t < k+1. \end{cases} \end{array}$$

(3) We consider the map



$$\begin{array}{rcl} H(k) \colon X \times [0,1] & \to & Y = Z \times [0,\infty) \\ ((z,t),s) & \to & \begin{cases} (z,t), & \text{if } t \geq k+1, \\ r_{k+1}(\rho_k(z,t),s), & \text{if } t < k+1. \end{cases} \end{array}$$

This defines a homotopy from f_k to f_{k+1} rel W_k. Note that $H(0)_1 = \mathrm{id}_X$.

As in the statement of Lemma 70.13 we consider the map

$$\begin{array}{rcl} g\colon X & \to & Y \\ x & \mapsto & f_k(x) \quad \text{where } k \in \mathbb{N}_0 \text{ such that } x \in W_k. \end{array}$$

One can easily verify that this is a retraction of $X = Z \times [0,\infty)$ to the telescope $T(Z)$. It follows from Lemma 70.13 that there exists a homotopy from $H(0)_1 = \mathrm{id}$ to g, i.e. $T(Z)$ is in fact a deformation retract of $X = Z \times [0,\infty)$. ■

70.5. **The Cellular Approximation Theorem.** We recall the following definition from page 1492.

Definition. A map $g\colon X \to Y$ between CW-complexes is called cellular if for each $n \in \mathbb{N}_0$ we have $g(X^n) \subset Y^n$

It will be instructive to return to the example of a non-cellular map that we gave on page 1492.

Example. In general maps between CW-complexes are not cellular. For example consider the CW-complex $X = [0,1]$ with two 0-cells and one 1-cell and we consider the CW-complex $Y = [0,1] \times [0,1]$ with four 0-cells, two 1-cells and one 2-cell. Then the diagonal map

$$\begin{array}{rcl} g\colon X = [0,1] & \to & Y = [0,1] \times [0,1] \\ t & \mapsto & (t,t) \end{array},$$

which is illustrated in the figure below on the left, is not a cellular map.

The following theorem is the main result of this section.

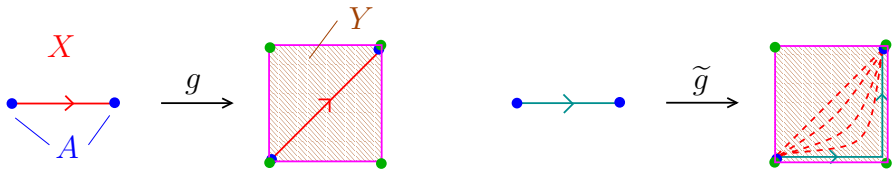
Theorem 70.15. (Cellular Approximation Theorem) Let $g\colon X \to Y$ be a map between CW-complexes and let A be a subcomplex of X such that the restriction of g to A is a cellular map.[831] The map g is homotopic rel A to a cellular map $\widetilde{g}\colon X \to Y$.

Remark. Let $g\colon X \to Y$ be a *homeomorphism* between CW-complexes. By the Cellular Approximation Theorem 70.15 we know that g is homotopic to a cellular map h. But in general we cannot arrange that h is again a *homeomorphism*. For example consider the torus $T = ([0,1] \times [0,1])/\sim\, = \mathbb{R}^2/\mathbb{R}^2$ with the standard CW-structure from page 1471 which has precisely one 0-cell $*$ that corresponds to the origin. As in the Fundamental Group-via-Actions Theorem 48.16 we make the identification $\pi_1(\mathbb{R}^n/\mathbb{Z}^2, *)$ with $\mathbb{Z}^2$. Let $P = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix} \in \mathrm{GL}(2,\mathbb{Z})$. We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ v & \mapsto & P \cdot v. \end{array}$$

[831] For example $f\colon X \to Y$ could be any map between CW-complexes, then the hypothesis is satisfied for A the empty set.

In the Maps-on-Torus Lemma 19.37 we saw that this map is a homeomorphism. Furthermore, in Exercise 48.18 we saw that the induced map on $\pi_1(\mathbb{R}^2/\mathbb{Z}^2, *) = \mathbb{Z}^2$ is given by multiplication by P. On the other hand the map on $\pi_1(\mathbb{R}^2/\mathbb{Z}^2, *) = \mathbb{Z}^2$ induced by any *cellular homeomorphism* $\widetilde{g}$ on $\mathbb{R}^2/\mathbb{Z}^2$ is represented by a matrix of the form[832] $\begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix}$ or $\begin{pmatrix} 0 & \pm 1 \\ \pm 1 & 0 \end{pmatrix}$. It follows from Exercise 50.12 (a) that g cannot be homotopic, rel $*$, to any such $\widetilde{g}$.



Example. We consider again the above example of a non-cellular map. More precisely, we consider again the above diagonal map

$$\begin{array}{rcl} g\colon X = [0,1] & \to & Y = [0,1] \times [0,1] \\ t & \mapsto & (t,t). \end{array}$$

We want to deform g into a cellular map, while keeping the endpoints fixed. Put differently, we want to find a homotopy rel $A = \{(0,0),(1,1)\}$ from g to a cellular map $\widetilde{g}$. Such a map $\widetilde{g}$ is given by

$$\begin{array}{rcl} \widetilde{g}\colon X = [0,1] & \to & Y = [0,1] \times [0,1] \\ t & \mapsto & \begin{cases} (2t,0), & \text{if } t \in [0,\frac{1}{2}] \\ (1,2t-1), & \text{if } t \in [\frac{1}{2},1] \end{cases} \end{array}$$

One way of stating this example is that we turn g into a cellular map $\widetilde{g}$ by "pushing g off the

g is not a cellular map $\widetilde{g}$ is a cellular map

high-dimensional cell". The proof of Cellular Approximation Theorem 70.15 is built on the same concept. But somewhat similar to the proof of the Sphere-π_1-Proposition 47.13, we have to worry about space-filling curves that exist by the Space-Filling Curve Theorem 6.13.

Before we attack the proof of the Cellular Approximation Theorem 70.15 we want to formulate a relative version thereof. To formulate this relative version we need the following semi-obvious definition.

Definition. A pair of CW-complexes is a pair (X, A) where X is a CW-complex and A is a subcomplex of X.

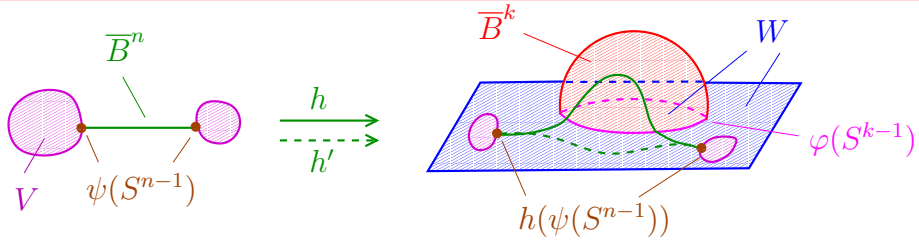
Now we can formulate the promised theorem.

Theorem 70.16. (Cellular Approximation Theorem for Pairs) Suppose we are given a map $g\colon (X, A) \to (Y, B)$ between pairs of CW-complexes. Let Z be a subcomplex of A such that the restriction of g to Z is a cellular map. Then g is homotopic rel Z to a cellular map $\widetilde{g}\colon (X, A) \to (Y, B)$.[833]

[832] Why is that?

[833] Here we refer to page 440 for the discussion on the notion of homotopies of pairs of topological spaces rel a subset.

Proof assuming the Cellular Approximation Theorem 70.15. The desired homotopy is constructed as follows:

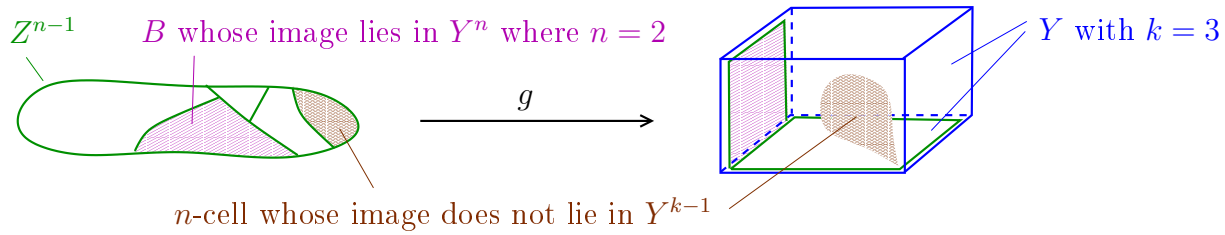


(1) By the Cellular Approximation Theorem 70.15 applied to $g|_A\colon A \to B$ there exists a homotopy F rel Z from $g|_A\colon A \to B$ to a cellular map.
(2) By the Homotopy Extension Theorem 70.1 we can extend the homotopy F from (1) to a homotopy $G\colon X \times [0,1] \to Y$. Note that G is still a homotopy rel Z. We write $h = g_1\colon X \to Y$. Note that $h|_A$ is cellular and that $h(A) \subset B$.
(3) We apply the Cellular Approximation Theorem 70.15 to h and we obtain a homotopy H rel A from h to a cellular map.
(4) The combination of the homotopies G and H has all the desired properties. ■

Now we turn to the proof of Cellular Approximation Theorem 70.15. The following proposition is the key step towards the desired proof.

Proposition 70.17. Let V be a CW-complex and W be a topological space. Furthermore let $\psi\colon S^{n-1} \to V^{n-1}$ be a map to the $(n-1)$-skeleton of V and let $\varphi\colon S^{k-1} \to W$ be another map. Finally let

$$h\colon V \cup_\psi \overline{B}^n \;\to\; W \cup_\varphi \overline{B}^k$$



be a map with $h(\psi(S^{n-1})) \subset W$. If $n < k$, then h is homotopic rel V to a map h' such that $h'(B^n)$ does not intersect B^k.

The statement of Proposition 70.17 is fairly obvious, if there exists a point $P \in B^k$ that does not get hit by $h(B^n)$. Indeed, if such a point P exists, then we can use the deformation retraction $\overline{B}^n \setminus \{p\} \to S^{n-1}$ to push h on B^n off the ball B^k. Put in general such a point P does not exist, since even for $n < k$ there exist continuous surjective maps $B^n \to B^k$. To get around this problem requires a fairly hard, not particularly inspiring, argument which we will give later on in Section 70.6.
In the following we will use Proposition 70.17 to prove the Cellular Approximation Theorem 70.15.

Corollary 70.18. Let Z be a finite n-dimensional CW-complex.

(1) Let $g\colon Z \to Y$ be a map to a k-dimensional CW-complex Y with $g(Z^{n-1}) \subset Y^{n-1}$. Let B be a subcomplex of Z with $g(B) \subset Y^n$. If $n < k$, then g is homotopic rel $Z^{n-1} \cup B$ to a map g' with $g'(Z) \subset Y^{k-1}$.
(2) Let $g\colon Z \to Y$ be a map to a CW-complex Y such that $g(Z^{n-1}) \subset Y^{n-1}$. Let B be a subcomplex of Z with $g(B) \subset Y^n$. The map g is homotopic rel $Z^{n-1} \cup B$ to a map g' with $g'(Z) \subset Y^n$.

Proof. Let Z be a finite n-dimensional CW-complex. By the CW-Complex Properties Proposition 68.10 (3) the CW-complex Z is compact. It follows from the CW-Complex-Finiteness Theorem 68.14 that the image of the compact set Z in a CW-complex is contained in a finite subcomplex. Therefore we can assume in both (1) and (2) that Y is in fact a finite CW-complex.

(1) Let $g\colon Z \to Y$ be a map to a finite k-dimensional CW-complex Y with $g(Z^{n-1}) \subset Y^{n-1}$. Let B be a subcomplex of Z with $g(B) \subset Y^n$. We suppose that $n < k$. We denote by $\widehat{Z}$ the union of Z^{n-1} with all the n-cells of Z whose image is contained in Y^{k-1}. In other words we can write $Z = \widehat{Z} \cup e_1 \cup \cdots \cup e_r$ where $e_1, \ldots, e_r$ are the n-cells such that the image is not contained in Y^{k-1}. We denote by $f_1, \ldots, f_s$ the k-cells of Y. Note that by hypothesis on B the interiors of the cells $e_1, \ldots, e_r$ are disjoint from B.

In the following we apply Proposition 70.17 precisely $r \cdot s$ times to get the desired homotopy. More precisely, we do the following:

(a) We apply Proposition 70.17 to the map

$$h\colon (\widehat{Z} \cup e_1 \cup \cdots \cup e_{r-1}) \cup e_r \;\to\; (Y \cup f_1 \cup \cdots \cup f_{s-1}) \cup f_s$$

to obtain a homotopy rel $\widehat{Z} \supset Z^{n-1} \cup B$ to a map h_{rs} such that the image of the interior of e_r under the map h_{rs} does not intersect the interior of f_s. Next we apply Proposition 70.17 to the map

$$h_{rs}\colon (\widehat{Z} \cup e_1 \cup \cdots \cup e_{r-2} \cup e_r) \cup e_{r-1} \;\to\; (Y \cup f_1 \cup \cdots \cup f_{s-1}) \cup f_s.$$

Iterating this process we obtain a homotopy rel $\widehat{Z}$ to a map such that the image of the interiors of the cells $e_1, \ldots, e_r$ does not intersect the interior of f_s.

(b) Again iterating the process above we obtain a homotopy rel $\widehat{Z}$ to a map such that image of the interiors of the cells $e_1, \ldots, e_r$ does not intersect the interior of any of the f_i. But that means that the image of Z lies in Y^{k-1}.

(2) Let $g\colon Z \to Y$ be a map to a CW-complex Y such that $g(Z^{n-1}) \subset Y^{n-1}$ and let B be a subcomplex of Z with $g(B) \subset Y^n$. As we pointed out in the beginning of the proof, we can assume that Y is finite-dimensional, we denote the dimension by k. But then Statement (2) is just an immediate consequence of applying (1) iteratively $k - n$ times. ∎

Now we turn to the proof of the Cellular Approximation Theorem 70.15.

Proof. Let X be a CW-complex and let A be a (possibly empty) subcomplex of X. Furthermore let Y be a CW-complex. We prove the Cellular Approximation Theorem 70.15 only in the special case that X has finitely many cells. The general case is dealt with in [**Hat2002**, Theorem 4.8].

Let $g\colon X \to Y$ be map.

(1) We say an n-cell e of X is *g-bad* if $g(e)$ is not contained in Y^n.
(2) If g is non-cellular, then we define

$$n(g) \;:=\; \text{minimal dimension of a cell that is } g\text{-bad.}$$

If g is cellular, then we define $n(g) := \infty$.

Claim. Let $g\colon X \to Y$ be a non-cellular map such that the restriction of g to A is a cellular map. Then there exists a homotopy from g to a map g' rel A such that $n(g') > n(g)$.

Proof. We write $n = n(g)$. We apply Corollary 70.18 (2) to $g\colon Z := X^n \to Y$ and $B = A^n$.[834] We obtain a homotopy G rel $X^{n-1} \cup A^n$ from $g\colon Z = X^n \to Y$ to a map $g'\colon Z = X^n \to Y$ with $g'(X^n) \subset Y^n$. We can extend this homotopy to a homotopy G on $(X^n \cup A) \times [0,1]$ via the trivial homotopy on $A \times [0,1]$. Now we apply the Homotopy Extension Theorem 70.1 to obtain a homotopy rel $X^n \cup A$ from $g\colon X \to Y$ to a map $g'\colon X \to Y$ such that $g'(X^n) \subset Y^n$. Note that by the choice of our homotopy we have $g'|_{X^{n-1}} = g|_{X^{n-1}}$. By definition of $n(g)$ the map $g'|_{X^{n-1}} = g|_{X^{n-1}}$ is cellular. Thus we see that $n(g') \geq n+1 = n(g)+1$. ⊞

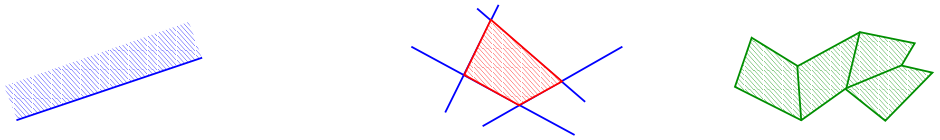
Finally let $g\colon X \to Y$ be a non-cellular map such that the restriction of g to A is a cellular map. We apply the claim iteratively as many times as possible to obtain a sequence of maps $g = g_1, g_2, g_3, \ldots : X \to Y$, each of which is homotopic to g rel A, such that $n(g) = n(g_1) < n(g_2) < \ldots$. Note that n can take on only finitely many values, namely $\{0, \ldots, \dim(X), \infty\}$. This means that the sequence is finite which implies that the last map is cellular. ■

70.6. **Proof of Proposition 70.17 (∗).** [835] Before we can even think of proving Proposition 70.17 we need to introduce a few more definitions and we need to prove a rather technical lemma.

Definition.

(1) A closed half-space in $\mathbb{R}^n$ is a set of the form $\{v \in \mathbb{R}^n \mid \langle v, w\rangle \geq 0\}$, for some fixed non-zero vector $w \in \mathbb{R}^n$.
(2) A convex polyhedron in $\mathbb{R}^n$ is a bounded subset of $\mathbb{R}^n$ that is the intersection of finitely many closed half-spaces.
(3) A polyhedron in $\mathbb{R}^n$ is the union of a finite number of convex polyhedra.[836]
(4) Given a polyhedron P a map $f\colon P \to \mathbb{R}^k$ is called piecewise linear if there exists a subdivision of P into finitely many convex polyhedra $Q_1, \ldots, Q_m$ such that the restriction of f to each Q_i is affine linear.[837]

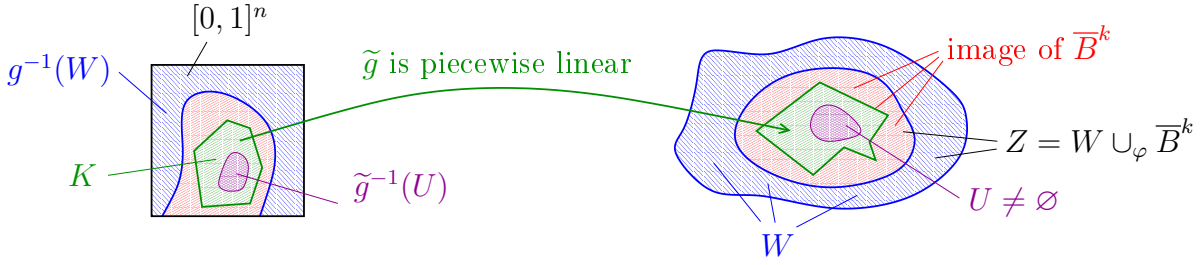
The following, very technical lemma, will get us around the problem of space-filling curves, i.e. it will get us around the problem that we saw in Space-Filling Curve Theorem 6.13 that there exist surjective continuous maps $\overline{B}^n \to \overline{B}^k$ even if $n < k$.



---

[834] Note that by definition of n we have $g(X^{n-1}) \subset Y^{n-1}$.

[835] Here the (∗) indicates once again that we do not provide the proof in the lecture. You are reading this section at your own risk.



[836] Note that the union of zero convex polyhedra is the empty set.

[837] A map $f\colon V \to \mathbb{R}^k$ from a subset V of $\mathbb{R}^n$ is called *affine linear* if there exists a $P \in \mathbb{R}^k$ and a $k \times n$–matrix A such that $f(v) = P + Av$ for all $v \in V$.

Lemma 70.19. Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be map. Furthermore let $g\colon [0,1]^n \to Z := W \cup_\varphi \overline{B}^k$ be a map. Then there exists a (possibly empty) polyhedron $K \subset [0,1]^n$ and a map $\widetilde{g}\colon [0,1]^n \to Z$ with the following properties:

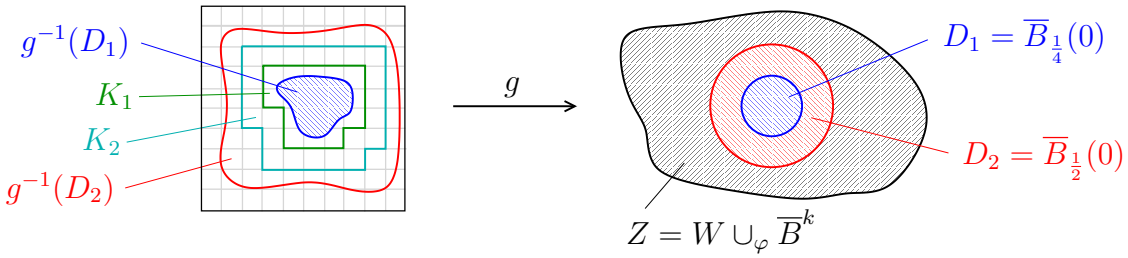
(1) The map $\widetilde{g}$ is homotopic to g rel $g^{-1}(W)$.
(2) We have $\widetilde{g}(K) \subset B^k$.
(3) The restriction $\widetilde{g}|_K\colon K \to B^k$ is piecewise linear.
(4) There exists an open non-empty subset $U \subset B^k$ such that $\widetilde{g}^{-1}(U) \subset K$.

Example. Suppose that in the setting of Lemma 70.19 there exists an open subset $U \subset B^k$ such that $g([0,1]^n) \cap U = \varnothing$. Then the empty polyhedron $K = \varnothing$ and the map $\widetilde{g} = g$ already have the desired property.

Proof. Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be map. Furthermore let $g\colon [0,1]^n \to Z := W \cup_\varphi \overline{B}^k$ be a map. We write $D_1 := \overline{B}_{\frac{1}{4}}(0) \subset B^k$ and $D_2 := \overline{B}_{\frac{1}{2}}(0) \subset B^k$. The set $g^{-1}(D_2) \subset [0,1]^n$ is closed and therefore compact by the Heine-Borel Theorem 1.24. We obtain from Proposition 6.7 that g is uniformly continuous on $g^{-1}(D_2)$.[838] This implies that we can find an $\epsilon > 0$ with the following two properties:

(i) For any $x, y \in g^{-1}(D_2)$ with $\|x - y\| < \epsilon$ we have $\|g(x) - g(y)\| < \frac{1}{8}$.
(ii) We have[839]

$$\epsilon \;<\; \text{distance between } g^{-1}(D_1) \text{ and } [0,1]^n \setminus g^{-1}\big(\mathring{D}_2\big).$$



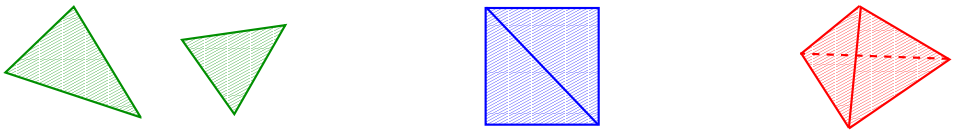
We divide $[0,1]^n$ into cubes such that the diameter of each cube is less than ϵ. We denote by K_1 the union of all the cubes that meet $g^{-1}(D_1)$ and we denote by K_2 the union of all the cubes meeting K_1. By the second property of ϵ we have $K_2 \subset g^{-1}(D_2)$. We refer to the figure below for an illustration.

[838] Why can't we conclude that g is uniformly continuous on all of $[0,1]^n$?

[839] Here recall that, according to the definition on page 283, for two non-empty subsets A and B of $\mathbb{R}^n$ we refer to

$$d(A,B) \;:=\; \inf\{\|P - Q\| \,|\, P \in A \text{ and } Q \in B\}$$

as the distance between A and B. If A and B are compact and disjoint, then it follows from Lemma 6.3 that $d(A,B) > 0$.



We need one more definition: Suppose we are given points $P_1, \ldots, P_{n+1} \in \mathbb{R}^n$ such that the vectors $P_2 - P_1, \ldots, P_{n+1} - P_1$ are linearly independent. We refer to

$$\text{convex hull of } P_1, \ldots, P_{n+1} \;=\; \Big\{ \sum_{i=1}^{n+1} t_i \cdot P_i \;\Big|\; \sum_{i=1}^{n+1} t_i = 1 \Big\}$$

as a *simplex* in $\mathbb{R}^n$.[840] We will make use of the following trivial observation: if we are given $w_1, \ldots, w_{n+1} \in \mathbb{R}^k$, then there exists a unique affine linear map Φ with $\Phi(P_i) = w_i$, namely the map that is given by

$$\Phi\Big(\sum_{i=1}^{n+1} t_i \cdot P_i \Big) \;:=\; \sum_{i=1}^{n+1} t_i w_i.$$

We leave it to the reader to show that each cube can be subdivided[841] into simplices. We also refer to the figure below for an illustration.

simplices in $\mathbb{R}^2$ | a square can be decomposed into two simplices | simplex in $\mathbb{R}^3$

Now we subdivide all the cubes in K_2 into simplices. By the above discussion there exists a map $h\colon K_2 \to \mathbb{R}^k$ that equals g on all the vertices of the simplices in the subdivision of the cubes.[842] Furthermore we choose a map $\psi\colon K_2 \to [0,1]$ with $\psi|_{\partial K_2} \equiv 0$ and $\varphi|_{K_1} \equiv 1$.[843]

---

[840] Given a subset S of $\mathbb{R}^k$ we defined on page 157 the *convex hull* of S as the intersection of all convex subsets of $\mathbb{R}^k$ that contain S. As we saw in Exercise 2.38, if S is a finite subset of $\mathbb{R}^k$, then the *convex hull* of S is given by

$$\Big\{ \sum_{s \in S} a_s \cdot s \;\Big|\; a_s \in [0,1] \text{ and } \sum_{s \in S} a_s = 1 \Big\}.$$

[841] Here, by "subdivide" we mean that given any cube K there exist simplices $S_1, \ldots, S_k$ such that the interiors of the S_i are disjoint and such that $K = S_1 \cup \cdots \cup S_k$.

[842] Note that it follows from the uniqueness statement above that the map g is in fact continuous.

[843] Such a map can be constructed as follows: we assign the value 1 to all vertices in K_1 and we assign the value 0 to all other vertices in K_2. By the above "trivial observation" this defines a map on K_2 with the desired property.

Now we consider the homotopy[844]

$$\begin{array}{rcl} F\colon [0,1]^n \times [0,1] & \to & Z = W \cup_\varphi \overline{B}^k \\ (P,t) & \mapsto & \begin{cases} (1 - t\cdot\psi(P))\cdot g(P) + t\cdot\psi(P)\cdot h(P), & \text{if } P \in K_2 \\ g(P), & \text{otherwise.} \end{cases} \end{array}$$

This is a homotopy from g to a map $\widetilde{g}\colon [0,1] \to Z = W \cup_\varphi \overline{B}^k$ that restricts to the piecewise linear map h on K_1.

Claim. The point $0 \in D_1$ does not lie in $\widetilde{g}\big(\overline{[0,1]^n \setminus K_1}\big)$.

Proof. The claim is proved in two steps:

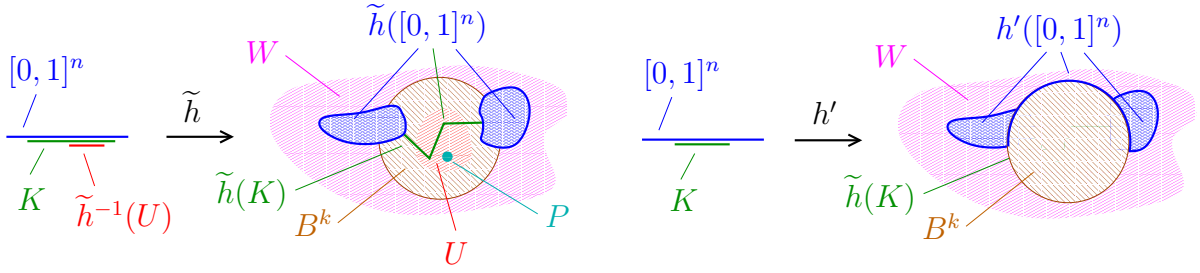
(1) On $[0,1]^n \setminus K_2$ we have $\widetilde{g} = g$. By Property (ii) of ϵ we have $g^{-1}(D_1) \subset K_2$. It follows that the image of $[0,1]^n \setminus K_2$ lies outside of D_1.
(2) Now let σ be a simplex of K_2 that does not lie in K_1. Note that $K_2 \subset g^{-1}(D_2)$. It follows from Property (i) of ϵ that $g(\sigma)$ is contained in some ball B_σ of radius $\frac{1}{8}$. Since $g(\sigma) \subset B_\sigma$ and since B_σ is convex we also have $h(\sigma) \subset B_\sigma$. Again by the convexity of B_σ we have $\widetilde{g}(\sigma) \subset B_\sigma$. We know that B_σ is not contained in D_1 since σ contains points outside K_1, hence outside $g^{-1}(D_1)$. The radius of B_σ is half that of D_1, so it follows that 0 is not in B_σ, and hence 0 does not lie in $\widetilde{g}(\sigma)$. ⊞

Since $\widetilde{g}\big(\overline{[0,1]^n \setminus K_1}\big)$ is compact it follows from the claim that there exists in fact an open neighborhood U of 0 that does not intersect the image of $[0,1]^n \setminus K_1$. Put differently, we have $\widetilde{g}^{-1}(U) \subset K_1$. It is now straightforward to verify that $K = K_1$, $\widetilde{g}$ and U have the desired properties. ■

Lemma 70.20. Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be the attaching map of a k-cell. Furthermore let $h\colon \overline{B}^n \to Z := W \cup_\varphi \overline{B}^k$ be a map with $h(S^{n-1}) \subset W$. If $n < k$, then h is homotopic rel S^{n-1} to a map h' that misses B^k.

Proof. Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be the attaching map of a k-cell. Furthermore let $h\colon \overline{B}^n \to Z := W \cup_\varphi \overline{B}^k$ be a map with $h(S^{n-1}) \subset W$. We suppose that $n < k$. We have to show that h is homotopic rel S^{n-1} to a map h' that misses B^k.

By the Convex-to-Ball Proposition 2.20 there exists a homeomorphism $\Phi\colon [0,1]^n \to \overline{B}^n$. So after precomposing h with Φ we might as well assume that the domain of h is $[0,1]^n$, i.e. that h is a map $h\colon [0,1]^n \to Z := W \cup_\varphi \overline{B}^k$ with $h(\partial[0,1]^n) \subset W$.



We pick a polyhedron K, a map $\widetilde{h}\colon [0,1]^n \to Z$ and an open non-empty subset $U \subset B^n$ with $\widetilde{h}^{-1}(U) \subset K$ as in the statement of Lemma 70.19. Since $n < k$ and since $\widetilde{h}|_K\colon K \to B^k$ is piecewise linear we deduce that $\widetilde{h}(K)$ cannot contain the open subset U of B^n.[845] We pick a point $P \in U \setminus \widetilde{h}(K)$. By Statement (4) of Lemma 70.19 we know that P does not lie in the image of $\widetilde{h}\colon [0,1]^n \to Z$.

As we pointed out on page 434, there exists a deformation retraction from $\overline{B}^k \setminus \{P\}$ to S^{k-1}. We can extend this deformation retraction via the identity map to a deformation

[844] Since $\varphi|_{\partial K_2} \equiv 0$ we see that F is indeed continuous.

[845] Indeed, since $\widetilde{h}|_K\colon K \to B^k$ is piecewise linear and since $n < k$ we know that the image $\widetilde{h}(K)$ is set of Lebesgue-measure zero in B^n whereas an open non-empty subset has positive Lebesgue-measure.

retraction from $Z = W \cup_\varphi (\overline{B}^k \setminus \{P\})$ to W. If we compose $\widetilde{h}$ with this deformation retraction we obtain a homotopy, rel S^{n-1}, from $\widetilde{h}$ to a map h' that misses B^k. ■

Now we can finally provide the proof of Proposition 70.17.

Proof of Proposition 70.17. Let V be a CW-complex and let W be some topological space. Furthermore let $\psi\colon S^{n-1} \to V^{n-1}$ be a map to the $(n-1)$-skeleton of V and let $\varphi\colon S^{k-1} \to W$ be another map. Finally let

$$h\colon V \cup_\psi \overline{B}^n \;\to\; W \cup_\varphi \overline{B}^k$$

be a map with $h(\psi(S^{n-1})) \subset W$. We suppose that $n < k$.

We denote by θ the obvious map $\overline{B}^n \to V \cup_\psi \overline{B}^n$, furthermore we write $h = g \circ \theta$. By our hypothesis we have $h(S^{n-1}) \subset W$. By Lemma 70.20 there exists a homotopy G rel S^{n-1} from h to a map $h'\colon \overline{B}^n \to W$ that misses B^k. The desired homotopy is now given by[846][847]

$$\begin{array}{rcl} F\colon (V \cup_\psi \overline{B}^n) \times [0,1] & \to & W \cup_\varphi \overline{B}^k \\ (P,t) & \mapsto & \begin{cases} G(Q,t), & \text{if } P = \theta(Q), \text{ for some } Q \in \overline{B}^k, \\ g(P), & \text{otherwise.} \end{cases} \end{array}$$

■

Exercises for Chapter 70.

Exercise 70.1. Let X be a contractible CW-complex and let $x_0 \in X$. Show that X admits a deformation retraction to the point x_0.
Hint. Use the Homotopy Extension Theorem 70.1.

Exercise 70.2. We consider the map

$$\begin{array}{rcl} \varphi\colon S^1 & \to & S^1 \\ \exp(\mathrm{i}t) & \mapsto & \begin{cases} \exp(3\mathrm{i}t), & \text{if } t \in [0, \frac{2\pi}{3}], \\ \exp(-3\mathrm{i}t), & \text{if } t \in [\frac{2\pi}{3}, \frac{4\pi}{3}], \\ \exp(3\mathrm{i}t), & \text{if } t \in [\frac{4\pi}{3}, 2\pi]. \end{cases} \end{array}$$

[846] We view $V \cup_\psi \overline{B}^n$ as a CW-complex where V is a subcomplex and the image of $\overline{B}^n$ is an n-cell. Furthermore we equip $V \cup_\psi \overline{B}^n$ with the product CW-structure. It follows from the Intervall CW-Product Lemma 68.8 and the CW-Complex Pasting Lemma 68.20, applied to the subcomplexes given by $V \times [0,1]$ and $\theta(\overline{B}^n) \times [0,1]$, that the map F is continuous.

[847] One might be tempted to use a different approach to show that F is continuous: Namely one might want to write $(V \cup_\psi \overline{B}^n) \times [0,1] = (V \times [0,1]) \cup_{\psi \times \mathrm{id}_{[0,1]}} (\overline{B}^n \times [0,1])$ and then argue using the Topological Pushout Proposition 5.33 (1b) that the given map is continuous. But this approach is problematic since it is not clear that the two topologies on $(V \cup_\psi \overline{B}^n) \times [0,1] = (V \times [0,1]) \cup_{\psi \times \mathrm{id}_{[0,1]}} (\overline{B}^n \times [0,1])$ agree.

Put differently, φ wraps S^1 first around S^1 clockwise, then counter clockwise and then once again clockwise. We write $Y = S^1$ and we consider

$$X \ := \ Y \cup_\varphi \overline{B^2},$$

where we identify $z \in \partial\overline{B}^2 = S^1$ with $\varphi(z) \in S^1 = Y$.

(a) Show that X is homotopy equivalent to $\overline{B}^2$.

(b) Is X homeomorphic to $\overline{B}^2$?

Exercise 70.3. Let X be a CW-complex which admits a single 0-cell. Show that every subcomplex Y of X is path-connected.

Exercise 70.4. Let X be a CW-complex. Use the Cellular Approximation Theorem 70.15 to give a direct proof that if X is path-connected, then its 1-skeleton X^1 is also path-connected.

Remark. We gave a roundabout proof of this statement in the CW-Complex Properties Proposition 68.10 (7).

Part VIII

Singular Homology

71. Higher homotopy groups: a primer

After these rather technical chapters on CW-complexes we now return to our original goal, namely trying to distinguish topological spaces. Using the fundamental group we had established several non-trivial results, for example we proved that

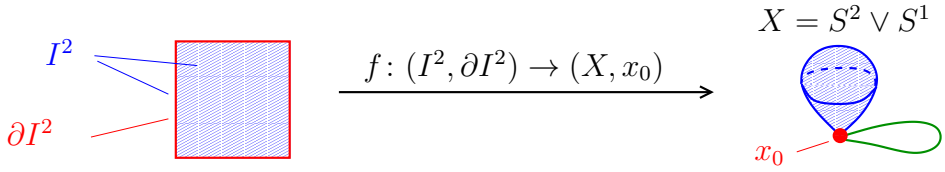
(1) S^1 and S^k with $k \geq 2$ are not homeomorphic,
(2) $\mathbb{R}^2$ and $\mathbb{R}^n$ with $n \geq 3$ are not homeomorphic,
(3) surfaces of different genus are not homeomorphic,
(4) we showed that S^1 is not a deformation retract of $\overline{B}^2$,
(5) the trefoil is not isotopic to the trivial knot.

On the other hand there are still many even rather elementary questions we cannot answer. For example at the moment we cannot show that for $k \neq l$ with $k, l \geq 2$ the spheres S^k and S^l are not homeomorphic and we cannot show that for $k \neq l$ with $k, l \geq 3$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic. Also, the somewhat mysterious lens spaces $L(p, q)$ still evaded our attempts at distinguishing them for a given p.
The problem with fundamental groups is that we only probe a topological space X with loops. The natural idea is now to go from using maps $S^1 \to X$ to studying maps $S^n \to X$ for $n \geq 2$. As we will see, this idea leads us naturally to the definition of the "higher homotopy groups" of a topological space.

71.1. Definition of the higher homotopy groups.

Notation. Throughout this chapter we write $I = [0, 1]$ for the unit interval. Given $n \in \mathbb{N}$ we denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$ and we denote, as usual, by ∂I^n its boundary as a subset of $\mathbb{R}^n$.

Now let X be a topological space and let $x_0 \in X$. With the definitions from page 439 we can write



$$\pi_1(X, x_0) \;=\; \text{homotopy classes of maps } (I, \partial I) \to (X, x_0).$$

This definition can be easily generalized to higher dimensions:

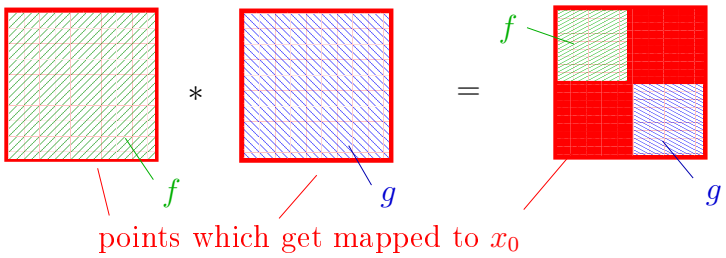
Definition. Given a pointed topological space (X, x_0) and $n \in \mathbb{N}_0$ we define

$$\pi_n(X, x_0) \;:=\; \text{homotopy classes of maps } (I^n, \partial I^n) \to (X, x_0).$$

For $n \geq 1$ we refer to $\pi_n(X, x_0)$ as the n-th homotopy group.

Remark. This definition makes in particular sense for $n = 0$, we can thus consider $\pi_0(X, x_0)$. In Section 2.5 we had already defined $\pi_0(X)$ as the set of path-components of X. In fact it is straightforward to see that the map

$$\begin{array}{rcl} \pi_0(X, x_0) & \to & \pi_0(X) \\ [\gamma\colon I^0 = \{0\} \to X] & \mapsto & \text{path-component of } X \text{ that contains } \gamma(0) \end{array}$$



is a bijection.

Note that $\pi_n(X, x_0)$ is a priori only a set. So to justify the name "homotopy group" we need to define a group structure on $\pi_n(X, x_0)$ which for $n = 1$ agrees with our previous definition of the group structure. Here is what we do:

Definition. Let (X, x_0) be a pointed topological space and let $n \geq 1$. Furthermore let $f, g\colon (I^n, \partial I^n) \to (X, x_0)$ be two maps. We define

$$\begin{array}{rcl} f * g\colon (I^n, \partial I^n) & \to & (X, x_0) \\ (x_1, \ldots, x_n) & \mapsto & \begin{cases} f(2x_1, \ldots, 2x_n), & \text{if } (x_1, \ldots, x_n) \in [0, \frac{1}{2}]^n, \\ g(2x_1 - 1, \ldots, 2x_n - 1), & \text{if } (x_1, \ldots, x_n) \in [\frac{1}{2}, 1]^n, \\ x_0, & \text{otherwise.} \end{cases} \end{array}$$

This map is illustrated in the figure below.[848] Applying the Homotopy Stacking Lemma 14.3 several times one sees that this map is indeed continuous.

It is straightforward to see that the homotopy class of $f * g$ only depends on the homotopy classes of f and g. This leads us to the following definition:

Definition. Let (X, x_0) be a pointed topological space and let $n \geq 1$. We define

$$\begin{array}{rcl} \pi_n(X, x_0) \times \pi_n(X, x_0) & \to & \pi_n(X, x_0) \\ ([f], [g]) & \mapsto & [f] \cdot [g] := [f * g]. \end{array}$$

Note that for $n = 1$ this is precisely the same definition of the product structure that we had we already introduced in Chapter 47.2.

Now we can formulate the following proposition:

Proposition 71.1. Let (X, x_0) be a pointed topological space and let $n \geq 1$. The following two statements hold:

(1) The map

$$\begin{array}{rcl} \pi_n(X, x_0) \times \pi_n(X, x_0) & \to & \pi_n(X, x_0) \\ ([f], [g]) & \mapsto & [f] \cdot [g] := [f * g] \end{array}$$

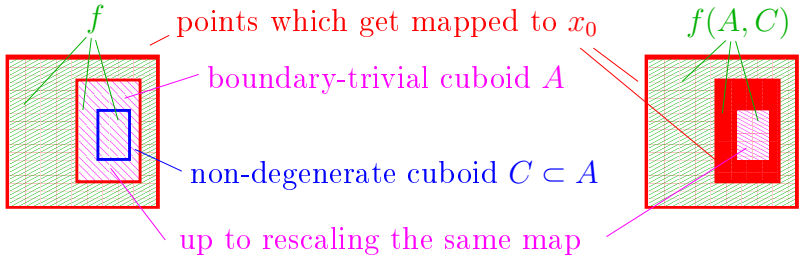
defines a group structure on $\pi_n(X, x_0)$.

(2) Given a map $f\colon (I^n, \partial I^n) \to (X, x_0)$ the inverse of $[f] \in \pi_n(X, x_0)$ is represented by the map $f \circ \Phi\colon (I^n, \partial I^n) \to (X, x_0)$ where $\Phi\colon I^n \to I^n$ is the homeomorphism given by $\Phi(x_1, x_2, \ldots, x_n) = (1 - x_1, x_2, \ldots, x_n)$.

As we will see, the proof of Proposition 71.1 is very similar to the proof of Proposition 47.6 and the proof of the Path-Homotopy Concatenation Proposition 47.5. To deal with the technical differences between the case $n = 1$ and the general case we need a few more definitions and one lemma.

[848] For mysterious reasons in all figures of this chapter the origin $(0, 0)$ is in the top left corner and the point $(1, 1)$ is the vertex at the bottom right.

Definition.



(1) A hyperrectangle is any subset of $\mathbb{R}^n$ of the form $[c_1, d_1] \times \cdots \times [c_n, d_n]$.
(2) We say a hyperrectangle $[c_1, d_1] \times \cdots \times [c_n, d_n]$ is non-degenerate if for all $i = 1, \ldots, n$ we have $d_i > c_i$.

Let X be a topological space, let $x_0 \in X$ and let $f\colon I^n \to X$ be a map.

(3) We say a hyperrectangle $A \subset I^n$ is boundary-trivial if f sends all points on the boundary ∂A of A to x_0.
(4) Let $A = [a_1, b_1] \times \cdots \times [a_n, b_n] \subset I^n$ be a boundary-trivial hyperrectangle and furthermore let $C = [c_1, d_1] \times \cdots \times [c_n, d_n]$ be a non-degenerate hyperrectangle that is contained in A. We define

$$\begin{aligned} f(A,C)\colon I^n &\to X \\ x = (x_1, \ldots, x_n) &\mapsto \begin{cases} f(x), & \text{if } x \notin A, \\ x_0, & \text{if } x \in A \setminus C, \\ f\left(a_1 + (x_1 - c_1)\frac{b_1 - a_1}{d_1 - c_1}, \ldots, a_n + (x_n - c_n)\frac{b_n - a_n}{d_n - c_n}\right) & \text{if } x \in C. \end{cases} \end{aligned}$$

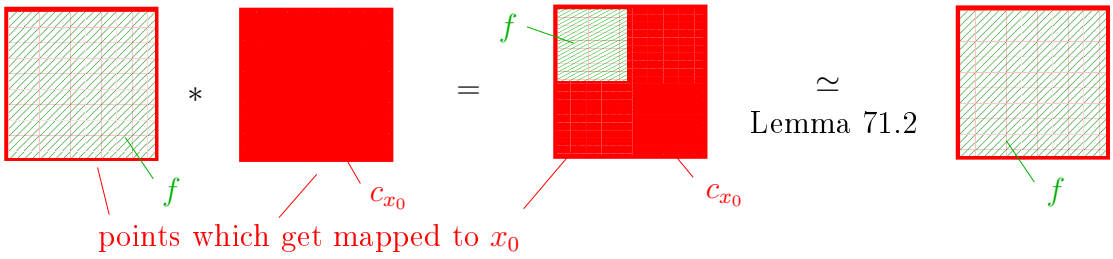
By applying the Homotopy Stacking Lemma 14.3 several times one can easily verify that this map is continuous.

Lemma 71.2. Let (X, x_0) be a pointed topological space and let $f\colon (I^n, \partial I^n) \to (X, x_0)$ be a map. Furthermore let $A \subset I^n$ be a boundary-trivial hyperrectangle and let C be a non-degenerate hyperrectangle that is contained in A. Then the maps f and $f(A, C)$ from $(I^n, \partial I^n)$ to (X, x_0) are homotopic.

Proof. Let $f\colon (I^n, \partial I^n) \to (X, x_0)$ be a map, let $A = [a_1, b_1] \times \cdots \times [a_n, b_n] \subset I^n$ be a boundary-trivial hyperrectangle and let $C = [c_1, d_1] \times \cdots \times [c_n, d_n]$ be a non-degenerate hyperrectangle that is contained in A. For $t \in [0, 1]$ we write

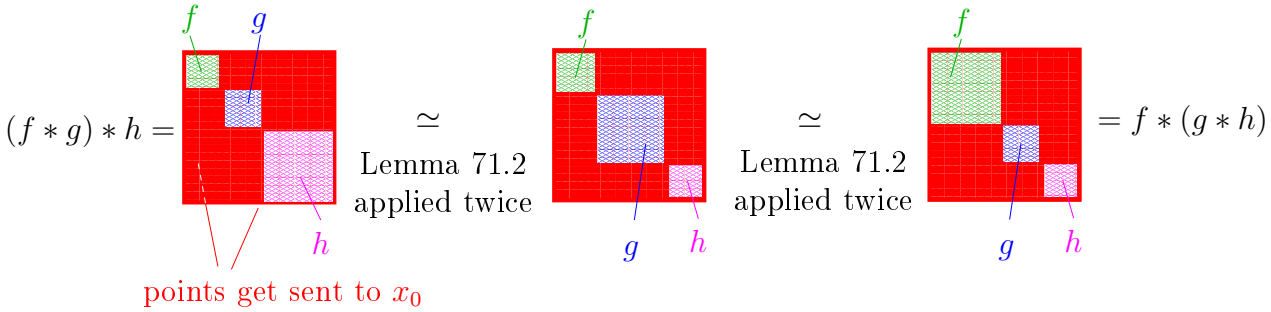
$$o_t = \big[a_1(1-t) + c_1 t, b_1(1-t) + d_1 t\big] \times \cdots \times \big[a_n(1-t) + c_n t, b_n(1-t) + d_n t\big].$$

Note that $C_0 = A$ and $C_1 = C$. It is now straightforward to see that the map



$$\begin{aligned} I^n \times [0,1] &\to X \\ (x, t) &\mapsto f(A, C_t)(x) \end{aligned}$$

is a homotopy between f and $f(A, C)$. ∎



Proof of Proposition 71.1. The neutral element of the product structure is given by the equivalence class of the constant map

$$\begin{aligned} c_{x_0}\colon I^n &\to X \\ x &\mapsto x_0. \end{aligned}$$

Indeed, it follows immediately from Lemma 71.2, applied to $A = [0,1]^n$ and $C = [0,\frac{1}{2}]^n$, that given any map $f\colon (I^n, \partial I^n) \to (X, x_0)$ we have $f * c_{x_0} \simeq f$. Basically the same argument shows also that $c_{x_0} * f \simeq f$.

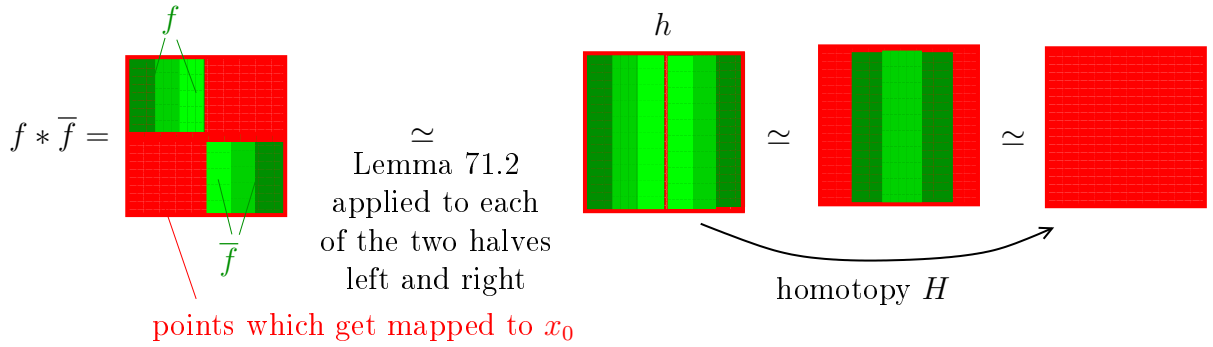
Now consider three maps $f, g, h\colon (I^n, \partial I^n) \to (X, x_0)$. By applying Lemma 71.2 several times one can easily show that $(f*g)*h \simeq f*(g*h)$, see e.g. the figure below. This proves that the multiplication on $\pi_n(X, x_0)$ is associative.

Now we turn to the most interesting question, namely finding the inverse of a given element in $\pi_n(X, x_0)$. Thus suppose we are given a map $f\colon (I^n, \partial I^n) \to (X, x_0)$. We consider the map

$$\begin{array}{rcl} \overline{f}\colon I^n & \to & X \\ (x_1, \ldots, x_n) & \mapsto & f(1 - x_1, x_2, \ldots, x_n). \end{array}$$

We claim that $[f] \cdot [\overline{f}] = [f * \overline{f}] = [c_{x_0}]$. Thus we need to show that $f * \overline{f}$ is homotopic to c_{x_0}. It follows from Lemma 71.2 that $f * \overline{f}$ is homotopic to the map

$$\begin{array}{rcl} h\colon (I^n, \partial I^n) & \to & (X, x_0) \\ (x_1, \ldots, x_n) & \mapsto & \begin{cases} f(2x_1, x_2, \ldots, x_n), & \text{if } x_1 \in [0, \frac{1}{2}], \\ \underbrace{\overline{f}(2x_1 - 1, x_2, \ldots, x_n)}_{= f(2-2x_1, x_2, \ldots, x_n)}, & \text{if } x_1 \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$



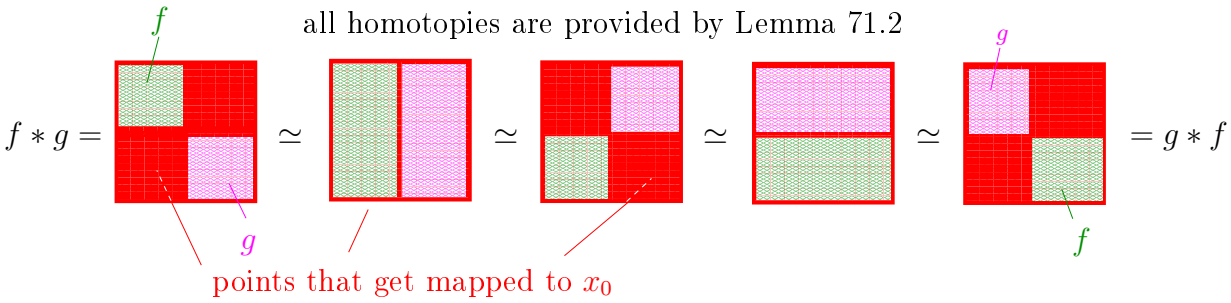
Thus it suffices to show that h is homotopic to c_{x_0}. It is in fact straightforward to see that the map[849][850]

$$\begin{array}{rcl} H\colon I^n \times [0,1] & \to & X \\ (x_1, \ldots, x_n, t) & \mapsto & \begin{cases} f(2(x_1 - \frac{t}{2}), x_2, \ldots, x_n), & \text{if } x_1 \in [\frac{t}{2}, \frac{1}{2}], \\ f(2 - 2(x_1 + \frac{t}{2}), x_2, \ldots, x_n), & \text{if } x_1 \in (\frac{1}{2}, 1 - \frac{t}{2}], \\ x_0, & \text{otherwise} \end{cases} \end{array}$$

[849] This map is continuous by the Homotopy Stacking Lemma 14.3.

[850] Even for $n = 1$ this homotopy is different from the homotopy used in the Path-Homotopy Concatenation Proposition 47.5 (3). Why is that?

is a homotopy from h to c_{x_0}. We refer to the figure below for an illustration of the argument. Basically the same argument also shows that $[\overline{f}]\cdot[f] = [\overline{f} * f] = [c_{x_0}]$. We have thus verified both statements of the proposition. ■



Example. There is one non-empty topological space for which we can immediately compute the higher homotopy groups, namely the topological space consisting of a single point P. In this case the only map $I^n \to \{P\}$ is the constant map, hence we see that $\pi_n(\{P\}) = 0$ for any $n \geq 1$.

The higher homotopy groups $\pi_n(X, x_0)$ seem even more complicated than the fundamental group. Surprisingly at least their algebraic structure is much simpler.

Proposition 71.3. (Homotopy Group-Abelian Proposition) For any pointed topological space (X, x_0) and any $n \geq 2$ the homotopy group $\pi_n(X, x_0)$ is abelian.

Remark. The higher homotopy groups were initially introduced by Eduard Čech in 1932 [**Čec1932**]. Since it was quickly noticed that they are abelian it was initially assumed that higher homotopy groups are of little interest. This perception changed soon afterwards.

Proof. Suppose we are given two maps $f, g\colon (I^n, \partial I^n) \to (X, x_0)$. We have to show that $f * g$ is homotopic to $g * f$. The homotopy is described in the figure below for $n = 2$. It is straightforward to write down an explicit homotopy between $f * g$ and $g * f$ by composing four instances of the homotopy provided by Lemma 71.2. We leave the details to the reader. ■

71.2. **Alternative descriptions of homotopy groups.** In this short section we present several alternative points of views regarding elements in homotopy groups. In the following let $n \in \mathbb{N}$.

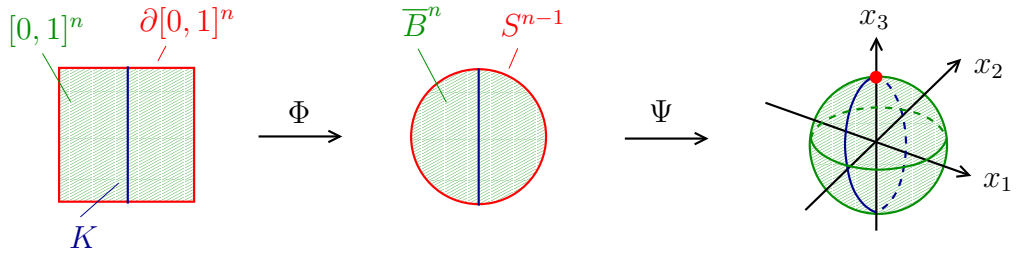
(1) We denote by $\Phi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ the homeomorphism from page 158.

(2) We write $* = (0, \dots, 0, 1) \in S^n$. We denote by $\Psi\colon (\overline{B}^n/S^{n-1}, [S^{n-1}]) \to (S^n, *)$ the homeomorphism from the Ball-Quotient Sphere Lemma 5.20.

Now let X be a topological space and let $x_0 \in X$. The above homeomorphisms Φ and Ψ, together with Lemma 5.18, define bijections

$$\begin{array}{rl} & \text{(homotopy classes) of maps } (I^n, \partial^n) \to (X, x_0) \\ \iff & \text{(homotopy classes) of maps } (\overline{B}^n, S^{n-1}) \to (X, x_0) \\ \iff & \text{(homotopy classes) of maps } (\overline{B}^n/S^{n-1}, [S^{n-1}]) \to (X, x_0) \\ \iff & \text{(homotopy classes) of maps } (S^n, *) \to (X, x_0). \end{array}$$

The four equivalences combined say that we can view elements in $\pi_n(X, x_0)$ as homotopy classes of maps $(S^n, *) \to (X, x_0)$. This point of view is perhaps closest to our visual approach to thinking about topological spaces. But as we have seen above, for technical purposes it is often much easier to work with the maps $(I^n, \partial I^n) \to (X, x_0)$.



Remark. It is visually most natural to work with the last point of view, namely to think of elements in $\pi_n(X, x_0)$ as homotopy classes of maps $(S^n, *) \to (X, x_0)$. Unfortunately with this definition it is a little less clear how the group structure on $\pi_n(X, x_0)$ is defined. To visualize the group structure we need to work a little:

(1) First note that the homeomorphism $\Phi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ descends to a homeomorphism $\overline{\Phi}\colon I/\partial I^n \to \overline{B}^n/S^{n-1}$.

(2) We consider the homeomorphism $\Theta := \overline{\Phi}^{-1} \circ \Psi^{-1}\colon S^n \to I^n/\partial I^n$. Note that it identifies the North Pole $(0, \dots, 0, 1)$ with the point $[\partial I^n]$.

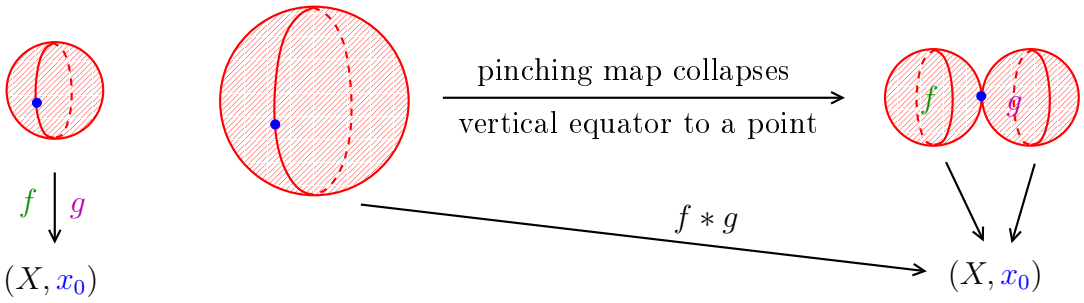
(3) We write $K := \{(x_1, \dots, x_n) \in I^n \,|\, x_1 = \frac{1}{2}\}$.

In the figure below we show K and its journey through the maps Φ and Ψ.

(4) We denote by $S^n_1 \vee S^n_2$ the wedge of two copies of S^n along the point $* \in S^n$.

(5) We refer to the map[851]

$$\begin{array}{rcl} S^n \xrightarrow{\Theta} I^n/\partial I^n \to I^n/(\partial I^n \cup K) & \to & S^n_1 \vee S^n_2 \\ [x_1, \dots, x_n] & \mapsto & \begin{cases} \Theta^{-1}([2x_1, x_2, \dots, x_n]) \in S^n_1, & \text{if } x_1 \in [0, \frac{1}{2}), \\ \Theta^{-1}([2x_1 - 1, x_2, \dots, x_n]), & \text{if } x_1 \in [\frac{1}{2}, 1] \end{cases} \end{array}$$



as the *pinching map*.

(6) It follows basically immediately from the definitions that the group structure on $\pi_n(X, x_0)$ is given as follows:

$$\begin{array}{rcl} \pi_n(X, x_0) \times \pi_n(X, x_0) & \to & \pi_n(X, x_0) \\ ([f_1\colon S^n \to X], [f_2\colon S^n \to X]) & \mapsto & \big[S^n \to S^n_1 \vee S^n_2 \xrightarrow{f_1 \vee f_2} X\big]. \end{array}$$

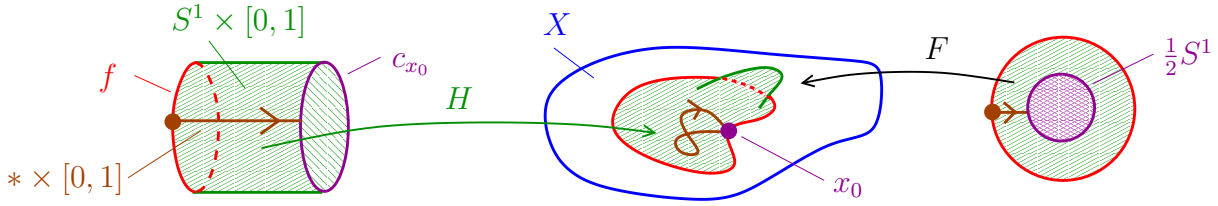
[851] It follows easily from the Pasting Proposition 2.6 (2′) that this map is continuous.

In the figure below we sketch the pinching map and we sketch the corresponding definition of the group structure on $\pi_n(X, x_0)$.[852]

We conclude this section with the following lemma that can be viewed as a generalization of the Extension-to-Disk Lemma 47.1.

Lemma 71.4. (Trivial-in-π_n-Lemma) Let X be a topological space, let $x_0 \in X$ and let $n \geq 1$. Furthermore let $f\colon (S^n, *) \to (X, x_0)$ be a map. Then the following statements are equivalent:

(1) the map $f\colon S^n \to X$ is homotopic to a constant map,
(2) there exists a map $F\colon \overline{B}^{n+1} \to X$ so that $F|_{S^n} = f$,
(3) f represents the trivial element in $\pi_n(X, x_0)$.



Proof. The equivalence of (2) and (3) is proved in a similar way as the Extension-to-Disk Lemma 47.1. We leave it to the reader to make the fairly straightforward modifications.

We turn to the proof that (3) implies (2). This is basically obvious. Indeed, the fact that f represents the trivial element in $\pi_n(X, x_0)$ means that there exists a homotopy of maps of pairs $(S^n, *) \to (X, x_0)$ from f to the constant map. But this means in particular that f is homotopic to the constant map c_{x_0}.

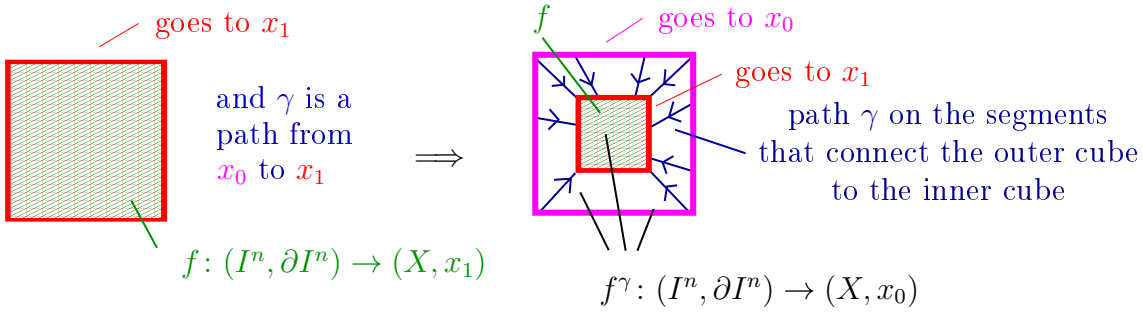
Finally suppose that (1) holds. This means that we assume that there exists a homotopy $H\colon S^n \times [0,1] \to X$ with $H_0 = f$ and $H_1 = c_{x_0}$. This time we do not assume that $H(*, t) = *$ for all $\in [0,1]$. We consider the map

$$\begin{array}{rcl} F\colon \overline{B}^{n+1} & \to & X \\ P & \mapsto & \begin{cases} H(Q, 2-2t), & \text{if } P = Q \cdot t \text{ with } Q \in S^n \text{ and } t \in [1, \frac{1}{2}], \\ x_0, & \text{otherwise.} \end{cases} \end{array}$$

It follows from the Pasting Proposition 2.6 (2) that this map is indeed continuous. By construction we have $F|_{S^n} = f$. Thus we see that (2) is satisfied. This concludes the proof that all three statements are equivalent. ■

[852] The meticulous reader will notice that it is perhaps not completely clear how the maps f and g are defined on the two smaller spheres.

71.3. **Properties and basic calculations of higher homotopy groups.** Now we want to understand some of the basic properties of higher homotopy groups. Perhaps not surprisingly, many of the basic statements about the fundamental group can be easily generalized to the setup of higher homotopy groups.
For example the following proposition can be viewed as a generalization of the Change-of-Base Point Proposition 47.10.



Proposition 71.5. (Change-of-Base Point Proposition) Let X be a topological space, let x_0 and x_1 be two points in X and let $\gamma\colon [0,1] \to X$ be a path from x_0 to x_1. Given a map $f\colon (I^n, \partial I^n) \to (X, x_1)$ we consider the map[853][854]

$$\begin{array}{rcl} f^\gamma\colon (I^n, \partial I^n) & \to & (X, x_0) \\ (t_1, \dots, t_n) & \mapsto & \begin{cases} f\big(2t_1 - \frac{1}{2}, \dots, 2t_n - \frac{1}{2}\big), & \text{if } (t_1, \dots, t_n) \in \big[\frac{1}{4}, \frac{3}{4}\big]^n, \\ \gamma(t), & \text{if } (t_1, \dots, t_n) \in \partial\big(\big[\frac{t}{4}, \frac{4-t}{4}\big]^n\big) \text{ for } t \in [0,1]. \end{cases} \end{array}$$

The definition of f^γ is illustrated in the figure below. The map

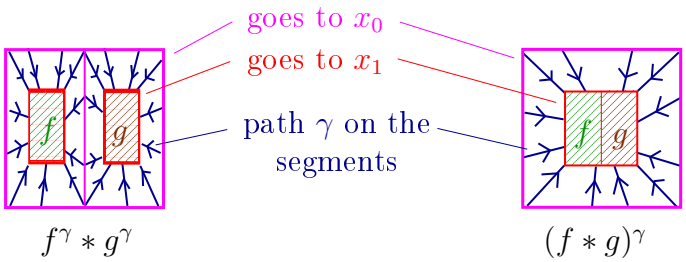
$$\begin{array}{rcl} \gamma_*\colon \pi_n(X, x_1) & \to & \pi_n(X, x_0) \\ [f] & \mapsto & [f^\gamma] \end{array}$$

is well-defined and it is a group isomorphism.

Remark. If X is a path-connected topological space and if we are only interested in the isomorphism type of the n-th homotopy group of X, then sometimes we use this proposition as an excuse to just write $\pi_n(X)$, i.e. we suppress the base point from the notation.

Proof. Let X be a topological space, let x_0 and x_1 be two points in X and let $\gamma\colon [0,1] \to X$ be a path from x_0 to x_1. We need to prove the following claim.

Claim.



(1) The map $\Phi\colon \pi_n(X, x_1) \to \pi_n(X, x_0)$ given by $[f] \mapsto [f^\gamma]$ is well-defined,
(2) the map Φ is a bijection, and
(3) the map Φ is a group homomorphism.

Proof.

(1) This statement can be verified easily by hand.
(2) As usual we denote by $\overline{\gamma}$ the path given by $\overline{\gamma}(t) = \gamma(1-t)$. It is straightforward to verify that the map $\Psi\colon \pi_n(X, x_0) \to \pi_n(X, x_1)$ given by $[g] \mapsto [f^{\overline{\gamma}}]$ is an inverse to Φ.

[853] If we view elements in $\pi_1(X, x_i)$ as represented by maps $(S^1, *) \to (X, x_i)$, what does the corresponding map $\pi_1(X, x_1) \to \pi_1(X, x_0)$ look like?
[854] Using Pasting Proposition 2.6 (2) one can easily verify that the map is continuous.

(3) Now let $f, g\colon (I^n, \partial I^n) \to (X, x_0)$ be maps. We need to show that $f^\gamma * g^\gamma$ is homotopic to $(f * g)^\gamma$. (These two maps are illustrated in the figure below.) It should be clear that verifying this statement is elementary, in the sense that one can write down an explicit homotopy. On the other hand it should also be clear that writing down an explicit homotopy is supremely painful and highly non-instructive. Thus we will skip this step and leave it to the eager reader to fill in the details. ■

Next we will see that higher homotopy groups are functorial.

Definition. Let $f\colon X \to Y$ be a map between two topological spaces, let $n \in \mathbb{N}$ and let $x_0 \in X$. We write $y_0 = f(x_0)$. The map

$$\begin{array}{rcl} f_*\colon \pi_n(X, x_0) & \to & \pi_n(Y, y_0) \\ [\sigma\colon (I^n, \partial I^n) \to (X, x_0)] & \mapsto & [f \circ \sigma\colon (I^n, \partial I^n) \xrightarrow{\sigma} (X, x_0) \xrightarrow{f} (Y, y_0)] \end{array}$$

is well-defined map and it is a group homomorphism for every $n \geq 1$.[855] As usual we say that f_* is the map induced by f.

The following proposition is a straightforward generalization of Proposition 47.15.

Proposition 71.6. Let $n \geq 1$. Recall that we denote by $\mathcal{PTop}$ the category of pointed topological spaces and that we denote by $\mathcal{Group}$ be the category of groups. Then

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{PTop}) & \to & \mathrm{Ob}(\mathcal{Group}) \\ (X, x_0) & \mapsto & \pi_n(X, x_0) \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}(\mathcal{PTop}) & \to & \mathrm{Mor}(\mathcal{Group}) \\ (f\colon (X, x_0) \to (Y, y_0)) & \mapsto & (f_*\colon \pi_n(X, x_0) \to \pi_n(Y, y_0)) \end{array}$$

is a covariant functor.

Proof. It follows immediately from the definitions that

$$\mathrm{id}_* = \mathrm{id} \qquad \text{for all pointed pairs } (X, x_0),$$

and that

$$(g \circ f)_* = g_* \circ f_* \qquad \text{for all maps } f\colon (X, x_0) \to (Y, y_0) \text{ and } g\colon (Y, y_0) \to (Z, z_0).$$

But this is exactly what we need to show. ■

We continue with the following fairly elementary but useful proposition, which generalizes the Homotopy-π_1-Proposition 50.3.

[855] Both statements follow basically immediately from the definitions.

Proposition 71.7. (Homotopy-π_n-Proposition) Let $n \geq 1$.

(1) Let $f, g\colon X \to Y$ be two maps between topological spaces and let $x_0 \in X$. If f and g are homotopic, then

$$\begin{array}{c} f_*\colon \pi_n(X, x_0) \to \pi_n(Y, f(x_0)) \\ \text{is an isomorphism} \end{array} \iff \begin{array}{c} f_*\colon \pi_n(X, x_0) \to \pi_n(Y, g(x_0)) \\ \text{is an isomorphism.} \end{array}$$

The analogous statement holds if we replace "isomorphism" by "epimorphism" or "monomorphism".

(2) Let $f\colon X \to Y$ be a map between topological spaces and let $x_0 \in X$ be a point. If f is a homotopy equivalence, then

$$f_*\colon \pi_n(X, x_0) \ \to \ \pi_n(Y, f(x_0))$$

is an isomorphism.

(3) If X is a contractible topological space, then the following two statements hold:
   (a) for any base point $x_0 \in X$ we have $\pi_n(X, x_0) = 0$,
   (b) any map $f\colon S^n \to X$ can be extended to a map $\overline{B}^{n+1} \to X$.

(4) Let (X, x_0) be a pointed topological space. If we denote by Y the component of X that contains x_0 and if we denote by $i\colon Y \to X$ the inclusion map, then the map

$$i_*\colon \pi_n(Y, x_0) \ \to \ \pi_n(X, x_0)$$

is an isomorphism.

Proof.

(1) This statement is proved basically the same way as the Homotopy-π_1-Proposition 50.3 (1). We leave it to the reader to make the necessary changes to the argument.

(2) As in the case of the Homotopy-π_1-Proposition 50.3 one can easily deduce Statement (2) from Statement (1).

(3) Let X be a contractible topological space.
   (a) By definition of "contractible" the topological space X is homotopy equivalent to a topological space consisting of a single point $\{*\}$. Evidently $\pi_n(\{*\}, *) = 0$, which by (2) implies that $\pi_n(X, x_0) = 0$ for some base point x_0. In the π_0-Homotopy Equivalence Lemma 15.3 we saw that a contractible topological space is path-connected. Thus it follows from the Change-of-Base Point Proposition 71.5 that $\pi_n(X, x_0) = 0$ for any base point x_0.
   (b) This statement is proved basically the same way as the Extension-to-Disk Lemma 47.1. For completeness' sake we carry out the argument. So let $f\colon S^n \to X$ be a map. We pick a base point $*$ for S^n and we set $x_0 := f(*)$. By (a) we know that $\pi_n(X, x_0) = 0$. We take the point of view from page 1565. Thus we can view $[f]$ as an element in $\pi_n(X, x_0) = 0$. By definition $[f] = 0$ means that there exists a homotopy $F\colon S^n \times [0, 1] \to X$ such that $F(p, 0) = f(p)$ for all $p \in S^n$, that $F(p, 1) = x_0$ for all $p \in S^n$ and that $F(*, t) = x_0$ for all $t \in [0, 1]$. We consider the map

$$\begin{array}{rcl} \overline{B}^{n+1} & \to & X \\ r \cdot v & \mapsto & F(v, (1 - r)) \end{array}$$

where we write a point in $\overline{B}^{n+1}$ as $r \cdot v$ with $r \in [0,1]$ and $v \in S^n$. It follows from Lemma 5.19 (2) that this map is indeed continuous. Clearly this is the desired extension.

(c) This statement is an easy consequence of Lemma 2.35 and the fact that I^n is path-connected. ■

Example. The topological space $\mathbb{R}^n$ is homotopy equivalent to a point P. Thus it follows from the Homotopy-π_n-Proposition 71.7 (2) and the discussion on page 1564 that $\pi_k(\mathbb{R}^n) \cong \pi_k(P) \cong 0$. Exactly the same way, using the discussion on page 432, one can show that all the higher homotopy groups of convex subsets of $\mathbb{R}^n$ vanish, e.g. we have $\pi_k\big(\overline{B}^n\big) = \pi_k(B^n) = 0$.

The following proposition is the high-dimensional analogue of the Fundamental Group-of-Product Proposition 48.20.

Proposition 71.8. (Homotopy Groups-of-Product Proposition) Let A and B be two topological spaces and let $a_0 \in A$ and $b_0 \in B$. We consider the inclusion maps

$$\begin{array}{rcl} i\colon A & \to & A \times B \\ a & \mapsto & (a, b_0) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon B & \to & A \times B \\ b & \mapsto & (a_0, b) \end{array}$$

and we consider the projection s

$$\begin{array}{rcl} p\colon A \times B & \to & A \\ (a,b) & \mapsto & a \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon A \times B & \to & B \\ (a,b) & \mapsto & b. \end{array}$$

(1) The maps

$$\begin{array}{rcl} \Phi\colon \pi_n(A,a_0) \times \pi_n(B,b_0) & \to & \pi_n(A \times B, (a_0,b_0)) \\ (x,y) & \mapsto & i_*(x) \cdot j_*(y) \end{array}$$

and

$$\begin{array}{rcl} \Psi\colon \pi_n(A \times B, (a_0,b_0)) & \to & \pi_n(A,a_0) \times \pi_n(B,b_0) \\ z & \mapsto & (p_*(z), q_*(z)) \end{array}$$

are both homomorphisms[856] and they are inverses of one another, in particular both are isomorphisms.

(2) The map Φ agrees with the map

$$\begin{array}{rcl} \Theta\colon \pi_n(A,a_0) \times \pi_n(B,b_0) & \to & \pi_n(A \times B, (a_0,b_0)) \\ ([f\colon (S^n,*) \to (A,a_0)], [g\colon (S^n,*) \to (B,b_0)]) & \mapsto & \left[\begin{array}{rcl} (S^n,*) & \to & (A \times B, (a_0,b_0)) \\ z & \mapsto & (f(z), g(z)) \end{array}\right]. \end{array}$$

In particular we obtain from (1) that Θ is a homomorphism.

Proof. The proof of this proposition is almost verbatim the same as the proof of the Fundamental Group-of-Product Proposition 48.20. We leave it to the reader to make the minute modifications. ■

We continue with the following very general and actually very convenient proposition regarding homotopy groups of CW-complexes. The proposition greatly generalizes the CW-Skeleton-π_1-Proposition 69.13 (1).

[856] In fact in this case it follows immediately from the Homotopy Group-Abelian Proposition 71.3 and Lemma 48.19 that Φ is a homomorphism.

Proposition 71.9. (CW-Skeleton-π_n-Proposition)

(1) Let X be a CW-complex and let $k \in \mathbb{N}_0$. As usual we denote by X^k the k-skeleton of X. Let $x_0 \in X^k$. The following two statements hold:
   (a) For $j = 1, \ldots, k-1$ the inclusion induced map $\pi_j(X^k, x_0) \to \pi_j(X, x_0)$ is an isomorphism.
   (b) The inclusion induced map $\pi_k(X^k, x_0) \to \pi_k(X, x_0)$ is an epimorphism.

(2) Let X be a CW-complex with a single 0-cell x_0 and let $n \in \mathbb{N}$. If X has no cells in dimensions $1, \ldots, n$, then $\pi_n(X, x_0) = 0$ for $k = 1, \ldots, n$.

Note that the above proposition is a generalization of Corollary 69.14.

Proof.

(1) Let X be a CW-complex and let $x_0 \in X^k$. We denote by $i\colon X^k \to X$ the inclusion. We take the point of view from page 1565, i.e. we view elements of $\pi_j(X, x_0)$ as homotopy classes of maps $(S^j, *) \to (X, x_0)$. As on page 1472 we consider the j-sphere S^j as a CW-complex with one 0-cell $*$ and one j-cell.
   (a) First we show that for $j = 1, \ldots, k$ the map $i_*\colon \pi_j(X^k, x_0) \to \pi_j(X, x_0)$ is an epimorphism.
   Let $[g] \in \pi_j(X, x_0)$ be some element. In other words, we are given a map $g\colon (S^j, *) \to (X, x_0)$ be a map. By the Cellular Approximation Theorem 70.15, applied to $g\colon S^j \to X$ and the subcomplex $\{*\} \subset S^j$, there exists a homotopy F rel $\{*\}$ from the map g to a cellular map $\widetilde{g}$. Since F is a homotopy rel $\{*\}$ we see that F also defines a homotopy of maps $(S^j, *) \to (X, x_0)$ of pairs of topological spaces. Thus we see that $[g] = [\widetilde{g}] \in \pi_j(X, x_0)$.
   Since $\widetilde{g}$ is cellular we know that $\widetilde{g}(S^j)$ lies in the j-skeleton of X. Since $j \leq k$ we see in particular that $\widetilde{g}(S^j)$ is contained in X^k. In other words, $\widetilde{g}$ is a map $(S^k, *) \to (X^k, x_0)$. This shows that $[g] = [\widetilde{g}] = [i \circ \widetilde{g}] = i_*([\widetilde{g}])$ lies in the image of $\pi_j(X^k, x_0)$.
   (b) Now we show that for $j = 1, \ldots, k-1$ the map $i_*\colon \pi_j(X^k, x_0) \to \pi_j(X, x_0)$ is a monomorphism. So suppose that we are given $[f_0], [f_1] \in \pi_j(X^k, x_0)$ with $i_*([f_0]) = i_*([f_1])$. By the Cellular Approximation Theorem 70.15 we can assume that the maps $f_0, f_1\colon (S^j, *) \to (X^k, x_0)$ are cellular. The fact that $i_*([f_0]) = i_*([f_1])$ means that there exists a homotopy $H\colon S^j \times [0,1] \to X$ with $H_0 = f_0$ and $H_1 = f_1$. This time we apply the Cellular Approximation Theorem 70.15 to the map $H\colon S^j \times [0,1] \to X$ and the subcomplex $(S^j \times \{0\}) \cup (S^j \times \{1\})$ and we obtain a cellular map $\widetilde{H}\colon S^j \times [0,1] \to X$ such that $\widetilde{\mathrm{H}}_0 = H_0 = f_0$ and $\widetilde{H}_1 = H_1 = f_1$. Since $\widetilde{H}$ is cellular it takes values in the $(j+1)$-skeleton of $X \times [0,1]$. Since $j < k$ we see in particular that $\widetilde{H}$ takes values in $X^k \times [0,1]$. But this means that we can use $\widetilde{H}$ to show that $[f_0] = [f_1] \in \pi_j(X^k, x_0)$.

(2) Let $n \in \mathbb{N}$. Let X be a CW-complex with a single 0-cell x_0 and which has no cells in dimensions $1, \ldots, n$. Let $k \in \{1, \ldots, n\}$. By hypothesis the k-skeleton of X equals $\{x_0\}$. By (1a) we know that the map $\pi_k(\{x_0\}, x_0) \to \pi_k(X, x_0)$ is an epimorphism. But the former group is evidently trivial, hence $\pi_k(X, x_0)$ is trivial as well. ∎

In the Sphere-π_1-Proposition 47.13 we saw that $\pi_1(S^n) = 0$ for $n \geq 2$. Now we can prove the analogous statement for higher homotopy groups. Now we obtain, basically for free, the following much more general proposition.

Proposition 71.10. Let $n \in \mathbb{N}$. For any $k \in \{1, \dots, n-1\}$ we have

$$\pi_k(S^n) \;=\; 0.$$

Proof.

(1) Again, as on page 1472 we consider the n-sphere S^n as a CW-complex with one 0-cell and one n-cell. With this CW-structure it follows immediately from the CW-Skeleton-π_n-Proposition 71.9 that $\pi_k(S^n) = 0$ for $k = 1, \dots, n-1$.

(2) An alternative approach to proving Proposition 71.10 is given by the point of view taken on page 1059 where we used the Whitney Approximation Theorem 29.1, the Replace-by-Smooth Homotopy Proposition 29.5 and Proposition 30.3 to show that for an $n \geq 2$ we have $\pi_1(S^n) = 0$. ■

The following proposition is also a straightforward generalization from the setting of fundamental groups to the setting of higher homotopy groups. The proof is almost verbatim the same as the proof of Proposition 69.3 and of the Direct Limit-π_1-Proposition 56.7.

Proposition 71.11. (Direct Limit-π_n-Proposition) Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that $X = \bigcup_{i \in \mathbb{N}} X_i$ and such that of one the following three conditions holds:

(1) every compact subset of X is already contained in one of the X_i, or
(2) each X_i is open in X, or
(3) X is a CW-complex and each X_i is a subcomplex.

Then for any $w \in X_1$ and any $n \in \mathbb{N}$ the inclusion induced maps $\pi_n(X_i, w) \to \pi_n(X, w)$ induce an isomorphism

$$\pi_n(X, w) \;=\; \varinjlim \pi_n(X_i, w).$$

In Lemma 68.4 we already saw that S^∞ is contractible, thus we know by that all homotopy groups are trivial. But it is also illuminating to apply the Direct Limit-π_n-Proposition 71.11 to obtain this result.

Corollary 71.12. For every $n \in \mathbb{N}$ we have $\pi_n(S^\infty) = 0$.

Proof. We equip S^∞ and all spheres S^k, $k \in \mathbb{N}$ with the CW-complex structure that we defined on page 1479. We have

$$\pi_n(S^\infty) \;=\; \pi_n\Big(\bigcup_{k \in \mathbb{N}} S^k\Big) \;\overset{\text{by the Direct Limit-}\pi_n\text{-Proposition 71.11 and by definition of the topology of } S^\infty}{=}\; \varinjlim \pi_n(S^k) \;\overset{\text{by Proposition 71.10 we have } \pi_n(S^k) = 0 \text{ for } k > n}{=}\; 0.$$

■

71.4. **Covering spaces and higher homotopy groups.** One of the main tools in studying fundamental groups was to study the relationship between the fundamental group of a topological space and coverings of the given topological space. Perhaps somewhat surprisingly, for $n \geq 2$ we have a completely different relationship between the n-th homotopy group and coverings.

Proposition 71.13. (Coverings-π_n-Proposition) Let $p\colon (X,x_0)\to(B,b_0)$ be a covering of pointed topological spaces. Let $n\geq 2$. Then the following two statements hold:

(1) The map $p_*\colon \pi_n(X,x_0)\to\pi_n(B,b_0)$ is an isomorphism.

(2) The map[857]

$$\begin{array}{rcl}\pi_n(B,b_0) & \to & \pi_n(X,x_0)\\ [f\colon (S^n,*)\to(B,b_0)] & \mapsto & [\text{unique lift of } f \text{ to a map } (S^n,*)\to(X,x_0)]\end{array}$$

is well-defined and it is the inverse to p_*.

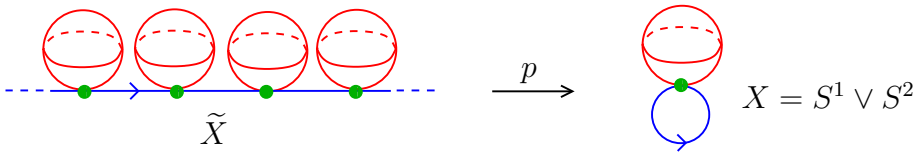
Before we provide the proof of the Coverings-π_n-Proposition 71.13 let us first state an immediate, and very useful, corollary to the Coverings-π_n-Proposition 71.13 and let us give a few examples.

Corollary 71.14. Let X be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Given any $n\geq 2$ the universal covering $p\colon \widetilde{X}\to X$ induces an isomorphism[858]

$$p_*\colon \pi_n(\text{universal covering } \widetilde{X} \text{ of } X) \xrightarrow{\cong} \pi_n(X).$$

Now we present some examples for Corollary 71.14. We will consider a few more examples after the proof of the Coverings-π_n-Proposition 71.13.

Examples.



(1) Let $k\in\mathbb{N}$ and $n\geq 2$. We have

$$\pi_n((S^1)^k) \;=\; \pi_n(\mathbb{R}^k/\mathbb{Z}^k) \xleftarrow[\uparrow]{\cong} \pi_n(\mathbb{R}^k) \underset{\uparrow}{=} 0.$$

Coverings-π_n-Proposition 71.13 — page 1570

In particular we see that all of the higher homotopy groups of S^1 and the torus $S^1\times S^1$ vanish.

(2) We consider $X=S^1\vee S^2$. On page 1373 we had determined its universal covering $\widetilde{X}$. For convenience we picture it again in the figure below. It follows from the Coverings-π_n-Proposition 71.13 that $\pi_2(S^1\vee S^2)$ is isomorphic to $\pi_2(\widetilde{X})$. At the moment we cannot determine $\pi_2(\widetilde{X})$, but since $\widetilde{X}$ has "infinitely many spheres" one might expect $\pi_2(\widetilde{X})$ to be pretty big.

(3) One of our goals is still to complete the classification of lens spaces, in particular we would like to answer Question 48.7. So let $L(p,q)$ and $L(p,r)$ be two lens spaces.

[857] Here we take the point of view from page 1565 where we saw that we view the elements of $\pi_n(B,b_0)$ as homotopy classes of maps $(S^n,*)\to(B,b_0)$.

[858] In Corollary 61.11 we showed that every topological space X that is path-connected, locally path-connected and semi-locally simply connected admits a universal covering $p\colon \widetilde{X}\to X$, i.e. a covering such that $\widetilde{X}$ is simply connected.

Then for any $n \geq 2$ we have

$$\pi_n(L(p,q)) \underset{\uparrow}{\overset{\cong}{\longleftarrow}} \pi_n(S^3) \underset{\uparrow}{\overset{\cong}{\longrightarrow}} \pi_n(L(p,r)).$$

Coverings-π_n-Proposition 71.13

We do not know the higher homotopy groups of S^3, but this argument shows that higher homotopy groups are useless for distinguishing lens spaces.

Proof of the Coverings-π_n-Proposition 71.13. Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces and furthermore let $n \geq 2$. Our goal is to construct an inverse to the map $p_*\colon \pi_n(X,x_0) \to \pi_n(B,b_0)$.

We saw on page 1565 that we can think of elements in $\pi_n(B,b_0)$ as homotopy classes of maps $(S^n,*) \to (B,b_0)$. Thus let $f\colon (S^n,*) \to (B,b_0)$ be given. We are in the following setting[859]

$$\begin{array}{ccc} & & (X,x_0) \\ & & \downarrow p \\ (S^n,*) & \xrightarrow[f]{} & (B,b_0). \end{array} \qquad \overset{\text{by the Map Lifting Criterion 61.2}}{\underset{\text{since } \pi_1(S^n)=0}{\rightsquigarrow}} \qquad \begin{array}{ccc} & \overset{\text{exists}}{\overset{\text{unique } \widetilde{f}}{\nearrow}} & (X,x_0) \\ & \swarrow & \downarrow p \\ (S^n,*) & \xrightarrow[f]{} & (B,b_0). \end{array}$$

Furthermore it follows again from the Map Lifting Criterion 61.2, applied to $Z = S^n \times [0,1]$, that the lifts of two homotopic maps $(S^n,*) \to (B,b_0)$ are two homotopic maps $(S^n,*) \to (X,x_0)$.[860] Summarizing we just constructed a map

$$\begin{array}{rcl} \lambda\colon \pi_n(B,b_0) & \to & \pi_n(X,x_0) \\ [f] & \mapsto & [\widetilde{f}]. \end{array}$$

Now we have to show that λ is an inverse to p_*. First of all, given any $[f] \in \pi_n(B,b_0)$ we have

$$(p_* \circ \lambda)([f]) \;=\; p_*\big([\widetilde{f}]\big) \;=\; \big[p \circ \widetilde{f}\big] \;=\; [f].$$

Now let $[g] \in \pi_n(X,x_0)$. We then have

$$(\lambda \circ p_*)([g]) \;=\; \lambda([p \circ g]) \underset{\uparrow}{=} [g].$$

since g is the unique lift of $p \circ g$ to x_0.

■

Now we give a few more applications of the Coverings-π_n-Proposition 71.13.

Examples.

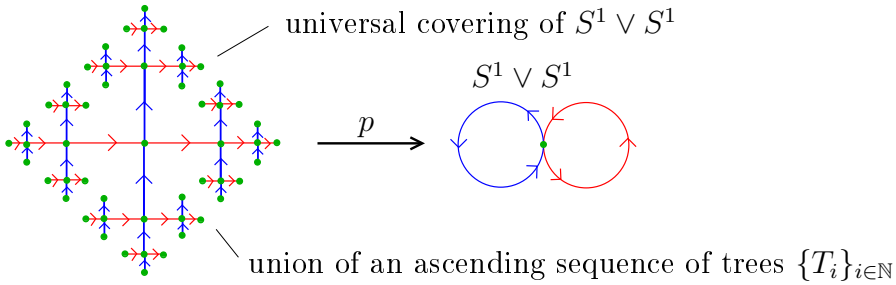
(1) Let Σ be a surface of genus ≥ 2. In Theorem 66.9 we have seen that there exists a covering $p\colon \mathbb{D} \to \Sigma$ where $\mathbb{D} = B_1(0) \subset \mathbb{C}$. Since $\mathbb{D}$ is convex it follows from

[859] In the Map Lifting Criterion 61.2 we need that the sphere S^n is of path-connected and locally path-connected, but there are no hypotheses on B or X.

[860] Here there is a little hidden subtlety: if $F\colon S^n \times [0,1] \to B$ is a homotopy between two maps $f,g\colon (S^n,*) \to (B,b_0)$, then we can lift f,g to maps $\widetilde{f},\widetilde{g}\colon (S^n,*) \to (X,x_0)$. Furthermore we can apply the Map Lifting Criterion 61.2 to lift F to a map $\widetilde{F}\colon S^n \times [0,1] \to X$ such that $\widetilde{F}(*,0) = x_0$. We still need to show that $\widetilde{F}(*,t) = x_0$ for all $t \in [0,1]$. We know that for every $t \in [0,1]$ we have $\widetilde{F}(*,t) \in p^{-1}(b_0)$. By Lemma 48.3 the preimage $p^{-1}(b_0)$ is discrete. Since $[0,1]$ is connected it follows that the map $p\colon [0,1] \to p^{-1}(b_0)$ is constant by the Connected-to-Discrete Lemma 2.27. But since it takes the value x_0 for $t=0$ it takes the value x_0 for all $t \in [0,1]$.

the Coverings-π_n-Proposition 71.13 and the discussion on page 1570 that $\pi_n(\Sigma) \cong \pi_n(\mathbb{D}) = 0$ for all $n \geq 2$.

Together with the example on page 1573 we have now shown that the higher homotopy groups of every surface of genus ≥ 1 vanish.



(2) Let Σ be a surface of genus ≥ 1 and let $f\colon \Sigma \to \Sigma$ be a self-homeomorphism. We denote by $\mathrm{Tor}(\Sigma, f)$ the mapping torus that we introduced on page 467. For $n \geq 2$ we have

$$\pi_n(\mathrm{Tor}(\Sigma, f)) \underset{\text{by the Mapping Torus Covering Lemma 11.29 and the Coverings-}\pi_n\text{-Proposition 71.13}}{\cong} \pi_n(\Sigma \times \mathbb{R}) \underset{\text{Homotopy-}\pi_n\text{-Proposition 71.7}}{\cong} \pi_n(\Sigma) \underset{\text{previous example}}{=} 0.$$

Lemma 71.15. Let X be a 1-dimensional CW-complex and let $x_0 \in X$ be base point. Then $\pi_n(X, x_0) = 0$ for every $n \geq 2$.

Sketch of proof. Let X be a 1-dimensional CW-complex, let $x_0 \in X$ and let $n \geq 2$. We first assume that X is finite and connected. We write $k = 1 - \chi(X)$. We have

$$\pi_n(X) \underset{\text{Quotient-by-Tree Proposition 69.8 (2) and Homotopy-}\pi_n\text{-Proposition 71.7}}{\cong} \pi_n\Big(\bigvee_{i=1}^{k} S^1\Big) \underset{\text{by the Coverings-}\pi_n\text{-Proposition 71.13}}{\cong} \pi_n\Big(\text{universal covering of } \bigvee_{i=1}^{k} S^1\Big) \underset{\text{by the Direct Limit-}\pi_n\text{-Proposition 71.11 and the figure below}}{\cong} \varinjlim \pi_n(\text{trees } T_i) \underset{\text{by Proposition 50.14 and Homotopy-}\pi_n\text{-Proposition 71.7}}{=} \varinjlim 0 = 0.$$

Now suppose that X is an arbitrary 1-dimensional CW-complex. Let $[f] \in \pi_n(X, x_0)$. It follows from the CW-Complex-Finiteness Theorem 68.14 that the image of f lies in a finite connected subcomplex Y of X. But by the above discussion $[f] = 0 \in \pi_n(Y, x_0)$, hence, by functoriality of π_n, we also have $[f] = 0 \in \pi_n(X, x_0)$. ■

The discussion of $\pi_2(S^1 \vee S^2)$ on page 1573 strongly suggests that even simple topological spaces can have surprisingly large higher homotopy groups. This raises the following anxious question, which after these examples is no longer totally absurd.

Question 71.16. Are the homotopy groups of a countable CW-complex countable?

Remark. On page 1537 we saw that at least the fundamental of a countable CW-complex is countable.

We will answer this question in Proposition 104.21.

71.5. **Are there any higher homotopy groups that are non-trivial?** We have now computed lots of higher homotopy groups, but so far the results have been rather dull, all the groups we have computed so far are trivial.
So are there are any higher homotopy groups that are non-trivial? A natural candidate for a non-trivial group is surely $\pi_n(S^n)$. The following question naturally arises:

Question 71.17. Let $n \geq 2$. Does the identity map $\mathrm{id}\colon S^n \to S^n$ define a non-trivial element in the homotopy group $\pi_n(S^n, *)$?

We will answer Question 71.17 in Lemma 85.2 and Corollary 85.6. For readers familiar with the degree of a smooth map between smooth manifolds, that we introduced on page 898, we will alternatively answer Question 71.17 in Exercise 71.6. In a similar vein we will use smooth methods to answer the question in Corollary 157.12.
We can also ask, what are the higher homotopy groups of spheres, i.e. what can we say about $\pi_k(S^n)$ for $k > n$? On page 1573 we saw that all these groups are trivial for $n = 1$. But what happens for $n > 1$? Can the higher homotopy groups of spheres be non-trivial?
To construct our first example of a potentially interesting map from a higher-dimensional to a lower-dimensional sphere we recall that on page 258 we gave an identification $\mathbb{C}\mathrm{P}^1 = S^2$. We consider the following map which is usually referred to as the *Hopf*[861] *map*:

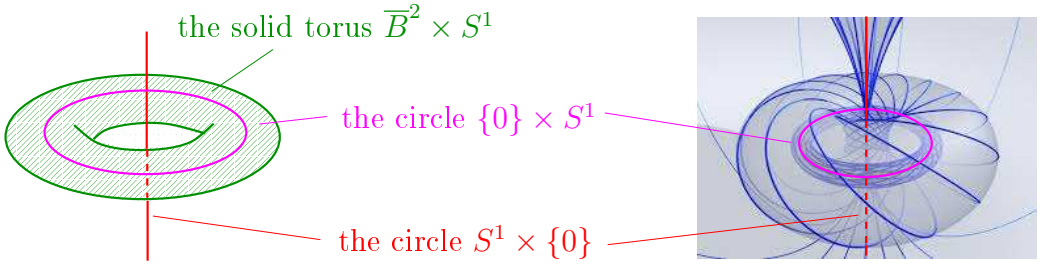
$$\begin{array}{rcl} H\colon S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ (z_1, z_2) & \mapsto & [z_1 : z_2]. \end{array}$$

The homotopy class of H defines an element in $\pi_3(S^2)$.

Question 71.18. Does the Hopf map $H\colon S^3 \to S^2$ represent a non-trivial element in the homotopy group $\pi_3(S^2)$?

Remark. The definition of the Hopf map is very elegant, but unfortunately we pay for the elegance by loosing any intuition for what the map looks like. So how are supposed to think about the Hopf map? A straightforward calculation shows that for each $P \in S^2$ the preimage $H^{-1}(P)$ is a circle. Furthermore, if we use the explicit homeomorphism from Lemma 2.18 to make the identification of S^3 with $\mathbb{R}^3 \cup \{\infty\}$ then we can make the following observations:

(1) the circle $S^1 \times \{0\}$ corresponds to the points $(z, 0) \in S^3$, in particular the circle gets sent to the point $[1 : 0] \in \mathbb{C}\mathrm{P}^1$,
(2) the circle that is given by the z-axis together with ∞ corresponds to the points $(0, z) \in S^3$, in particular the circle gets sent to the point $[0 : 1] \in \mathbb{C}\mathrm{P}^1$.



Next recall that Lemma 59.1 we gave an explicit identification[862]

$$\left(S^1 \times \overline{B}^2\right) \cup_{S^1 \times S^1} \left(\overline{B}^2 \times S^1\right) \xrightarrow{\cong} S^3.$$

It follows from the definition of this identification that on the torus $S^1 \times S^1$ the "diagonal circle" $\{(z, z) \,|\, z \in S^1\}$ is the preimage of the point $[1 : 1] \in \mathbb{C}\mathrm{P}^1$. In the figure below we show the preimages of H for some points in $\mathbb{C}\mathrm{P}^2 = S^2$.

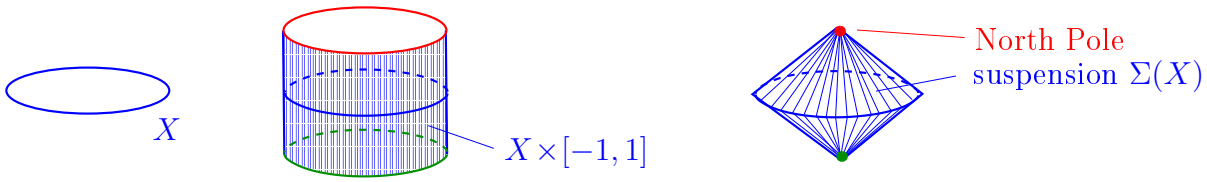
[861] Heinz Hopf (1894-1971) was a German mathematician.

[862] Note that in Lemma 59.2 we saw that the corresponding smooth embedding $S^1 \times \overline{B}^2 \to S^3$ is essential given by the standard smooth embedding.

We introduce one more construction of maps that represent potentially non-trivial elements in homotopy groups of spheres.

Definition.

(1) Let X be a topological space. Recall that on page 451 we defined the suspension of X to be the topological space



$$\Sigma(X) \;:=\; (X \times [-1,1])/\!\sim$$

where we identify all points in $X \times \{-1\}$ to a single point and we identify all points in $X \times \{1\}$ to a single point. We refer to the point $[X \times \{1\}]$ as the North Pole of $\Sigma(X)$.

(2) Given a map $f\colon X \to Y$ between topological spaces we denote by

$$\begin{array}{rcl} \Sigma(f)\colon \Sigma(X) & \to & \Sigma(Y) \\ [(x,t)] & \mapsto & [(f(x),t)] \end{array}$$

the suspension of f.

Remark. Let $n \in \mathbb{N}_0$. Recall that on page 452 we wrote down an explicit homeomorphism $\Sigma(S^n) \to S^{n+1}$ that sends the North Pole of $\Sigma(S^n)$ to the North Pole $(0,\ldots,0,1)$ of S^{n+1}. We will use this homeomorphism to identify $\Sigma(S^n)$ with S^{n+1}.

Now we have the following elementary lemma.

Lemma 71.19. (Suspension Homomorphism Lemma) Let $k \in \mathbb{N}_0$.

(1) Let (X, x_0) be a pointed topological space. We denote by $*$ the North Pole of $\Sigma(X)$. The map

$$\begin{array}{rcl} \pi_k(X,x_0) & \to & \pi_{k+1}(\Sigma(X),*) \\ [f\colon S^k \to X] & \mapsto & \big[\Sigma(f)\colon \Sigma(S^k) = S^{k+1} \to \Sigma(X)\big] \end{array}$$

is a well-defined group homomorphism. We refer to it as the suspension homomorphism.

(2) Let $n \in \mathbb{N}_0$. We denote by $*$ the North Pole of S^n and S^{n+1}. The map

$$\begin{array}{rcl} \pi_k(S^n,*) & \to & \pi_{k+1}(S^{n+1},*) \\ [f\colon S^k \to S^n] & \mapsto & \big[\Sigma(f)\colon \Sigma(S^k) = S^{k+1} \to \Sigma(S^n) = S^{n+1}\big] \end{array}$$

is a well-defined group homomorphism. We refer to it also as the suspension homomorphism.

Proof.

(1) It follows from the Suspension Functor Lemma 16.9 (4) that this map is well-defined.[863] We leave it the task of verifying that the map is in fact a group homomorphism as a somewhat challenging exercise to the reader. Alternatively we refer to [**Hilt1953**, Theorem 2.1] for a proof.

(2) This statement follows immediately from (1). ■

We conclude this chapter with the following question:

Question 71.20. Let $H\colon S^3 \to S^2$ be the Hopf map. Is the image of $[H] \in \pi_3(S^2)$ under the iterated suspension homomorphisms $\pi_3(S^2, x_0) \to \pi_{3+k}(S^{2+k}, x_1)$ non-trivial?

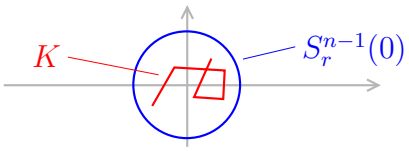
Unfortunately at the moment we do not have the tools to answer any of the above questions. In general it is very hard to compute higher homotopy groups as there are few computational techniques that can be used to show that higher homotopy groups are non-zero. One of the key problems is that there is no analogue to the Seifert–van Kampen Theorem 54.1. We will get to know a few techniques to compute higher homotopy groups of spheres, but we will cover these only in much later chapter, since the calculations will require the use of singular homology groups. But even then we will only be able to determine some homotopy groups of spheres. The results we obtain are summarized in Chapter 160. But note that the full computation of homotopy groups of spheres is still an open problem.

This sorry state of affairs means that as of right now we cannot use higher homotopy groups to distinguish any of the topological spaces that we could not distinguish already using the fundamental group. In particular we still cannot show that for $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic. We will only be able to do so after developing a new tool, namely the singular homology groups, in the coming sections.

Exercises for Chapter 71.

Exercise 71.1. Let X be a topological space, let $x_0 \in X$ and let $f\colon (I^n, \partial I^n) \to (X, x_0)$ be a map with $n \geq 1$. We consider the map

$$\begin{array}{rcl} \overline{f}\colon I^n & \to & X \\ (x_1, \ldots, x_n) & \mapsto & f(1-x_1, 1-x_2, \ldots, 1-x_n). \end{array}$$



Is $[\overline{f}] \in \pi_n(X, x_0)$ the inverse of $[f] \in \pi_n(X, x_0)$?

Exercise 71.2. Let $k \leq l$ be natural numbers, let $f\colon S^k \to S^l$ be a map and let $x_0 \in S^k$. Show that for any $i \in \mathbb{N}$ the map $f_*\colon \pi_i(S^k, x_0) \to \pi_i(S^l, f(x_0))$ is the trivial map.
Hint. Use Proposition 71.10.

Exercise 71.3. In this exercise you can assume that we already know that $\pi_3(S^2) \cong \mathbb{Z}$. Show that there exists an epimorphism $\pi_3(S^1 \vee S^2) \to \mathbb{Z}^3 \oplus \mathbb{Z}_4$.

[863] In an earlier version of these it was written that "it is straightforward to see that the map is well-defined". If one traces through the ancestry of the Suspension Functor Lemma 16.9 (4) one realizes that this lemma is, despite appearances, by no means obvious.

Exercise 71.4. Let $n \in \mathbb{N}$ and let K be a non-empty compact subset of $\mathbb{R}^n$. Let $r \in \mathbb{R}$ such that $r > \sup\{\|P\| \,|\, P \in K\}$. Show that for any $k \in \mathbb{N}$ the inclusion induced map $\pi_k(S_r^{n-1}(0)) \to \pi_k(\mathbb{R}^n \setminus K)$ is a monomorphism.

Exercise 71.5. We consider the pseudocircle, i.e. we consider the slightly weird topological space $X = \{A, B, C, D\}$ from page 141. Show that $\pi_n(X, A) = 0$ for any $n \geq 2$.
Hint. Find a convenient covering of X.

Exercise 71.6. Let $n \in \mathbb{N}$. Given a smooth map $f\colon S^n \to S^n$ we introduced on page 899 the corresponding degree $\deg(S^n) \in \mathbb{Z}$. Now let $f\colon S^n \to S^n$ be any (not necessarily smooth) map. By the Whitney Approximation Theorem 29.1 we know that f is homotopic to a smooth map $g\colon M \to N$. It follows from the Degree Homotopy Invariance Theorem 38.3 that the map

$$\begin{array}{rcl} \deg\colon \pi_n(S^n, x_0) & \to & \mathbb{Z} \\ [f] & \mapsto & \deg(g\colon S^n \to S^n \text{ a smooth map homotopic to } f) \end{array}$$

is well-defined.

(a) Show that $\deg\colon \pi_n(S^n, x_0) \to \mathbb{Z}$ is well-defined.
(b) Show that $\deg\colon \pi_n(S^n, x_0) \to \mathbb{Z}$ is an epimorphism.
(c) The adventurous reader can try to show that $\deg\colon \pi_n(S^n, x_0) \to \mathbb{Z}$ is actually a monomorphism. For example, suppose that we have a smooth map $f\colon S^n \to S^n$ with $\deg(f\colon S^n \to S^n) = 0$. Pick a regular value $y \in S^n$. If $\#f^{-1}(y) > 0$ there exist two points x_0, x_1 in the preimage with $\deg(f, x_0) = -\deg(f, x_1)$. Can one find a homotopy from f to a map g such that $g^{-1}(y)$ has two preimages less?

Exercise 71.7. Let (X, x_0) be a topological space. We denote by $\Sigma(X)$ the suspension of X and we denote by $*$ the North Pole of $\Sigma(X)$. Is the suspension homomorphism

$$\pi_1(X_0, x_0) \;\to\; \pi_2(\Sigma(X), *),$$

that we introduced in the Suspension Homomorphism Lemma 71.19, necessarily a monomorphism?

Exercise 71.8. Let M be a smooth manifold, let $Y \subset M$ be a compact submanifold and let $P \in M \setminus Y$.

(a) Show that for every $i < \dim(M) - \dim(Y) - 1$ the map $\pi_i(M \setminus Y, P) \to \pi_1(M, P)$ is an isomorphism.
(b) Show that for $i = \dim(M) - \dim(Y) - 1$ the map $\pi_i(M \setminus Y, P) \to \pi_1(M, P)$ is an epimorphism.

Hint. Use the Transversality Theorem 42.4.

Exercise 71.9. On page 164 we introduced the Topologist's Sine Curve

$$S \;:=\; \big\{(0, y) \,\big|\, y \in [-1, 1]\big\} \cup \big\{(x, \sin(\tfrac{1}{x})) \,\big|\, x \in (0, \tfrac{1}{\pi}]\big\} \;\subset\; \mathbb{R}^2.$$

As on page 276 we refer to quotient space $W := S/(0,0) \sim (\frac{1}{\pi}, 0)$ as the *Warsaw Circle*.

(a) Show that the image of every map $S^n \to W$ lies in a contractible subset of W.
Hint. Use Exercise 2.48 and use the fact that each S^n is path-connected.

(b) Show that for every $n \in \mathbb{N}$ we have $\pi_n(W, [(0,0)]) = 0$.

72. The homology groups of a topological space

One of our main goals is to show that for $m \neq n$ the spheres S^m and S^n are not homeomorphic. We have seen that for most cases fundamental groups are of no use. Furthermore, it might be that in principle higher homotopy groups can distinguish such spheres, but since we cannot compute higher homotopy groups, those are of no use either. So we need a new approach to finding invariants that can distinguish spheres.
In this chapter we want to introduce a new functor from the category of topological spaces to an algebraic category, more precisely, we will introduce a functor from the category of topological spaces to the category of abelian groups.

72.1. Singular chains.

Definition. Let $n \in \mathbb{N}_0$.

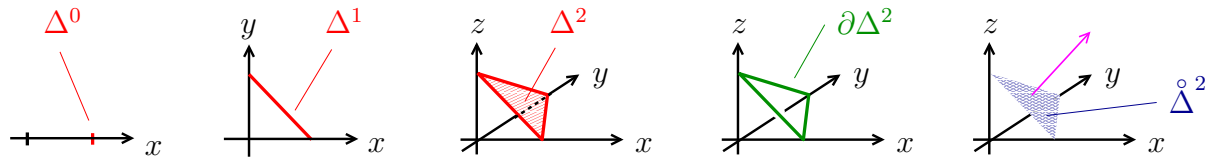
(1) Given k points $P_1, \dots, P_k$ in $\mathbb{R}^n$ such that $P_2 - P_1, \dots, P_k - P_1$ are linearly independent we refer to the convex hull of $P_1, \dots, P_k$ as a k-simplex.

(2) Given $n \in \mathbb{N}_0$ we refer to the convex hull of the standard basis vectors $e_1, \dots, e_{n+1}$ of $\mathbb{R}^{n+1}$, i.e. to

$$\Delta^n := \{(x_0, \dots, x_n) \in \mathbb{R}^{n+1} \,|\, x_0 + \dots + x_n = 1 \text{ and } x_i \geq 0 \text{ for all } i = 0, \dots, n\}$$

as the standard n-simplex.[864]

(3) Given the standard n-simplex Δ^n we define its boundary as[865]



$$\partial\Delta^n := \bigcup_{i=0}^{n} \{(t_0, \dots, t_n) \in \Delta^n \,|\, t_i = 0\}.$$

(4) We write

$$\mathring{\Delta}^n := \Delta^n \setminus \partial\Delta^n.$$

Sometimes it will be helpful to view $\mathring{\Delta}^n$ as a smooth manifold where a smooth atlas for $\mathring{\Delta}^n$ is given by projection to the first n coordinates. We equip the smooth manifold $\mathring{\Delta}^n$ with the orientation where for each $P \in \mathring{\Delta}^n$ a basis $v_1, \dots, v_n$ of $\widetilde{\mathrm{T}}_P\mathring{\Delta}^n$ is positive if the vectors $\{(1, \dots, 1), v_1, \dots, v_n\}$ are a positive basis for $\mathbb{R}^{n+1}$.

Example. The standard 0-simplex Δ^0 is just the point $\{1\} \in \mathbb{R}$, the standard 1-simplex Δ^1 equals the segment in $\mathbb{R}^2$ from $(1, 0)$ to $(0, 1)$ and the standard 2-simplex Δ^2 is the triangle in $\mathbb{R}^3$ spanned by the vertices $(1, 0, 0), (0, 1, 0)$ and $(0, 0, 1)$. We refer to the figure below for an illustration of the standard simplices in dimension 0, 1 and 2 and for an illustration of the boundary of the standard 2-simplex.

[864] In Exercise 2.38 (a) we showed that the standard n-simplex Δ^n is the convex hull of $e_i \in \mathbb{R}^{n+1}$, $i = 1, \dots, n+1$. In particular the standard n-simplex is an n-simplex.

[865] The definition of the "boundary" of the standard n-simplex Δ^n is the "obvious one". Nonetheless note that if we had taken the original definition of the boundary of a subset A in some subspace X as introduced on page 116 and applied it to $\Delta^n \subset \mathbb{R}^{n+1}$, then the boundary of Δ^n in $\mathbb{R}^{n+1}$ would be all of Δ^n.

For the record we state the following elementary lemma.

Lemma 72.1. (Standard Simplex Homeomorphism Lemma) Let $n \in \mathbb{N}$.

(1) Every n-simplex, in particular the standard n-simplex Δ^n, is compact and contractible.

We set

$$\triangle_n := \left\{(x_1, \ldots, x_n) \in [0,1]^n \,\middle|\, \sum_{i=1}^{n} x_i \in [0,1]\right\}$$

and refer to it as the planar n-simplex. The following statements hold:

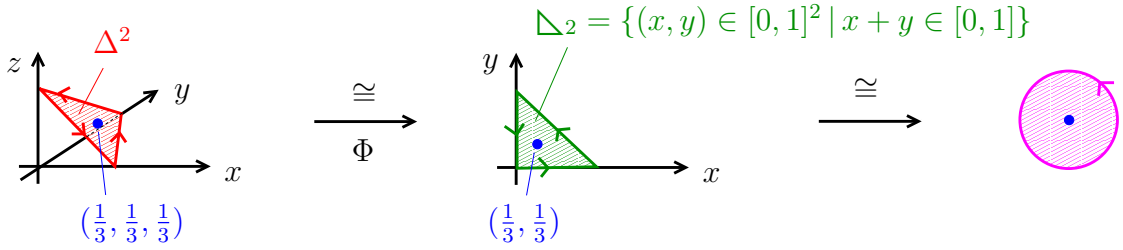
(2) The maps

$$\begin{array}{rcl} \Phi\colon \Delta^n & \to & \triangle_n \\ (t_0, \ldots, t_n) & \mapsto & (t_0, \ldots, t_{n-1}) \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon \triangle_n & \to & \Delta^n \\ (s_0, \ldots, s_{n-1}) & \mapsto & \left(x_1, \ldots, x_n, 1 - \sum_{i=1}^{n} x_i\right) \end{array}$$

are homeomorphisms that are inverses of one another.

(3) The map

$$\Delta^n \xrightarrow{\Phi} \triangle_n \xrightarrow[\text{applied to } \triangle_n \text{ and } Q = (\frac{1}{n+1}, \ldots, \frac{1}{n+1})]{\text{the homeomorphism } \Xi \text{ obtained from the Convex-to-Ball Proposition 2.20 (2)}} \overline{B}^n$$



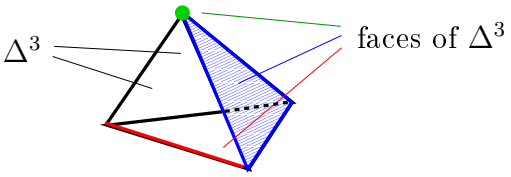
is a homeomorphism that restricts to a homeomorphism from $\partial\Delta^n$ to the sphere S^{n-1}.

Proof.

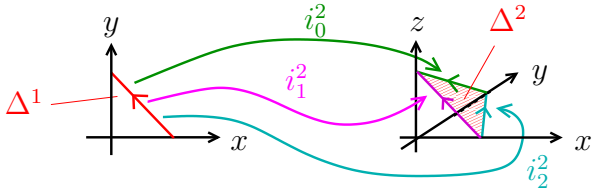
(1) We had proved in Exercise 2.38 (b) that each n-simplex is compact. (Of course it is not difficult to prove the statement using Heine-Borel Theorem 1.24.) Note that each n-simplex is convex, thus star-shaped, thus it is contractible by the elementary discussion on page 432.

(2) Note that Φ extends "by the same formula" to a map $\mathbb{R}^{n+1} \to \mathbb{R}^n$ which is evidently continuous. Hence the restriction to Δ^n is also continuous. Now that this is settled we see that the remaining statements are basically trivial.

(3) This statement follows easily from (1) and the Convex-to-Ball Proposition 2.20 (2). ■



Convention. Let $n \in \mathbb{N}$. We use the homeomorphism from the Standard Simplex Homeomorphism Lemma 72.1 to make the identifications $\Delta^n = \overline{B}^n$ and $\partial\Delta^n = S^{n-1}$.



Definition. An r-dimensional face of the standard n-simplex is defined as a subset of the form

$$\{(t_0, \ldots, t_n) \in \Delta^n \,|\, t_{d_1} = t_{d_2} = \cdots = t_{d_{n-r}} = 0\},$$

where $d_1 < d_2 < \cdots < d_{n-r} \in \{0, \ldots, n\}$ are fixed.

Remark.

(1) The boundary $\partial\Delta^n$ of the standard n-simplex is the union of all $(n-1)$-dimensional faces of Δ^n.
(2) Every r-dimensional face of Δ^r is homeomorphic to the standard r-simplex. For later we fix homeomorphism in the case of $(n-1)$-dimensional faces. More precisely, for $j \in \{0, \dots, n\}$ we consider the map

$$\begin{array}{rcl} i_j^n \colon \Delta^{n-1} & \to & \Delta^n \\ (t_0, \dots, t_{n-1}) & \mapsto & (t_0, \dots, t_{j-1}, 0, t_j, \dots, t_{n-1}). \end{array}$$

This map is sometimes called the *j-th face map*. It is straightforward to see that these face maps are homeomorphisms. The face maps $i_0^2, i_1^2, i_2^2 \colon \Delta^1 \to \Delta^2$ are illustrated in the figure below on the right.

The first idea for the definition of homology groups is now the following. In the definition of the fundamental group $\pi_1(X, x_0)$ we had considered all maps $f \colon [0,1] \to X$ with the extra condition $f(0) = f(1) = x_0$. Using this extra condition we could concatenate loops to eventually end up with a group structure. Now given $n \in \mathbb{N}_0$ we want to consider all maps from Δ^n to X with no extra condition on the boundary. This time there is no reasonable way how two such maps can be composed to give a new map. Since we nonetheless want the notion of a group we turn the set of all maps $\Delta^n \to X$ into a group by "brute force", i.e. by considering the free abelian group generated by these maps.
This leads us to the following definition.

Definition. Let X be a topological space and let $n \in \mathbb{N}_0$.
(1) A singular n-simplex is a map $\sigma \colon \Delta^n \to X$.
(2) We define

$$\mathrm{C}_n(X) \ := \ \text{free abelian group generated by the set of singular } n\text{-simplices in } X.$$

For $n \in \mathbb{Z}_{<0}$ we set $\mathrm{C}_n(X) = 0$.
(3) We refer to an element in $\mathrm{C}_n(X)$ as a singular n-chain in X.

Remark. In principle, given a map $\sigma \colon \Delta^n \to X$ to some topological space X we need to show that this map is actually continuous. If one really feels compelled to give an argument, then often it is more convenient to show the equivalent statement that the map $\sigma \circ \Psi \colon \triangle_n \to X$ is continuous, where $\Psi \colon \triangle_n \to \Delta^n$ is the homeomorphism given in the Standard Simplex Homeomorphism Lemma 72.1 (1).

Examples.

(1) For $n = 0$ a singular n-simplex is a map from Δ^0 to X. Such a map is uniquely determined by the corresponding point in X. Therefore frequently we will identify singular 0-simplices with points in X.

(2) For points $z_0, \dots, z_k \in \mathbb{R}^n$ we consider the map[866]

$$\begin{aligned} [z_0, \dots, z_k] \colon \Delta^k &\to \mathbb{R}^n \\ (t_0, \dots, t_k) &\mapsto \sum_{j=0}^{k} t_j \cdot z_j. \end{aligned}$$

The map $[z_0, \dots, z_k]$ thus sends the standard k-simplex Δ^k to the simplex spanned by $z_0, \dots, z_k$ in $\mathbb{R}^n$. Put differently, $[z_0, \dots, z_k]$ is a singular k-simplex in $\mathbb{R}^n$.

Remark. Let X be a topological space. By the discussion on page 1147 we can view every element in $\mathrm{C}_n(X)$, i.e. every singular n-chain, as a linear combination $a_1\sigma_1 + \cdots + a_k\sigma_k$ where $a_1, \dots, a_k \in \mathbb{Z}$ and where $\sigma_1, \dots, \sigma_k$ are singular n-simplices.

Now let $f \colon X \to Y$ be a map between topological spaces. For each n we consider

$$\begin{aligned} f_* \colon \mathrm{C}_n(X) &\to \mathrm{C}_n(Y) \\ \sum_{i=1}^{k} a_i \cdot \sigma_i &\mapsto \sum_{i=1}^{k} a_i \cdot (f \circ \sigma_i). \end{aligned}$$

It is easy to verify that $X \mapsto \mathrm{C}_n(X)$ and $f \mapsto f_*$ defines a functor from the category of topological spaces to the category of abelian groups.
Have we made any progress towards our goal of distinguishing topological spaces? Not really. For example, if X is a smooth manifold of dimension ≥ 1, then given any $n \in \mathbb{N}_0$ there exist uncountably many maps $\Delta^n \to X$, i.e. the group $\mathrm{C}_n(X)$ is a free abelian group with uncountably many generators. Such groups are totally useless for distinguishing non-homeomorphic topological spaces.

72.2. **Definition of the homology groups of a topological space.** Before we give the definition of homology groups it is perhaps helpful to recall the definition of de Rham cohomology.
Let M be a smooth manifold. We write

$$\Omega^n(M) \;:=\; \{\text{smooth } n\text{-forms on } M\}.$$

The isomorphism type of this vector space is an invariant of the diffeomorphism type of the smooth manifold M, but it is rather useless, since for $1 \leq n \leq \dim(M)$ this is a vector space of uncountable dimension. To cut $\Omega^n(M)$ into something much smaller we defined linear maps $d_n \colon \Omega^n(M) \to \Omega^{n+1}(M)$ with $d_{n+1} \circ d_n = 0$. Finally we defined the n–th de Rham cohomology group of M as

$$\mathrm{H}^n_{\mathrm{dR}}(M) \;:=\; \ker(d_n \colon \Omega^n(M) \to \Omega^{n+1}(M)) / \operatorname{im}(d_{n-1} \colon \Omega^{n-1}(M) \to \Omega^n(M)).$$

We are now in a similar situation: to a topological space X we associated the free abelian group $\mathrm{C}_n(X)$ which is "too big". The idea now is to introduce a "differential" as for the case of differential forms. But in this case there is no good way to associate to a map $\Delta^n \to X$ a new map $\Delta^{n+1} \to X$. But by restricting the map $\Delta^n \to X$ to each of the $(n-1)$-dimensional faces of Δ^n which are, as we have seen, homeomorphic to the standard $(n-1)$-simplex, we can associate to a singular n-simplex $\sigma \colon \Delta^n \to X$ a sum of singular $(n-1)$-simplices, i.e. a singular $(n-1)$-chain. To do this we will use the maps $i^n_k \colon \Delta^{n-1} \to \Delta^n$, $k = 0, \dots, n$ from

[866] Using the Standard Simplex Homeomorphism Lemma 72.1 (2) one can easily show that this map is continuous.

page 1585 to identify the standard $(n-1)$-simplex with the $(n-1)$-dimensional faces of Δ^n. Now we can define

$$\widetilde{\partial}_n\sigma \;:=\; \sum_{j=0}^{n}\sigma\circ i_j^n.$$

By Lemma 51.1 this defines a map $\widetilde{\partial}_n\colon \mathrm{C}_n(X)\to\mathrm{C}_{n-1}(X)$. But it is quite straightforward to see that for this definition the composition of the maps $\widetilde{\partial}_n\colon \mathrm{C}_n(X)\to\mathrm{C}_{n-1}(X)$ and $\widetilde{\partial}_{n-1}\colon \mathrm{C}_{n-1}(X)\to\mathrm{C}_{n-2}(X)$ is not zero[867]. But we can rectify this problem by cleverly introducing signs.

Now we are ready to define homology groups. For clarity we first repeat the definition of the face maps. Afterwards we will provide the definition of homology groups.

Definition. Let $n\in\mathbb{N}_0$. For $j\in\{0,\dots,n\}$ we define the j-th face map as follows:

$$\begin{array}{rcl} i_j^n\colon \Delta^{n-1} & \to & \Delta^n \\ (t_0,\dots,t_{n-1}) & \mapsto & (t_0,\dots,t_{j-1},0,t_j,\dots,t_{n-1}). \end{array}$$

Definition. Let X be a topological space and let $\sigma\colon\Delta^n\to X$ be a singular n-simplex. The boundary $\partial_n\sigma\in\mathrm{C}_{n-1}(X)$ of σ is defined as

$$\partial_n\sigma \;:=\; \sum_{j=0}^{n}(-1)^j\cdot\sigma\circ i_j^n.$$

By Lemma 51.1 the map $\sigma\mapsto\partial_n\sigma$ extends uniquely to a linear map

$$\begin{array}{rcl} \partial_n\colon \mathrm{C}_n(X) & \to & \mathrm{C}_{n-1}(X) \\ \displaystyle\sum_{r=1}^{k} a_r\cdot\sigma_r & \mapsto & \displaystyle\sum_{r=1}^{k} a_r\cdot\partial\sigma_r, \end{array}$$

which we refer to as the n-th boundary map. If it is clear with what dimension we are working with, then we just write ∂ instead of ∂_n.

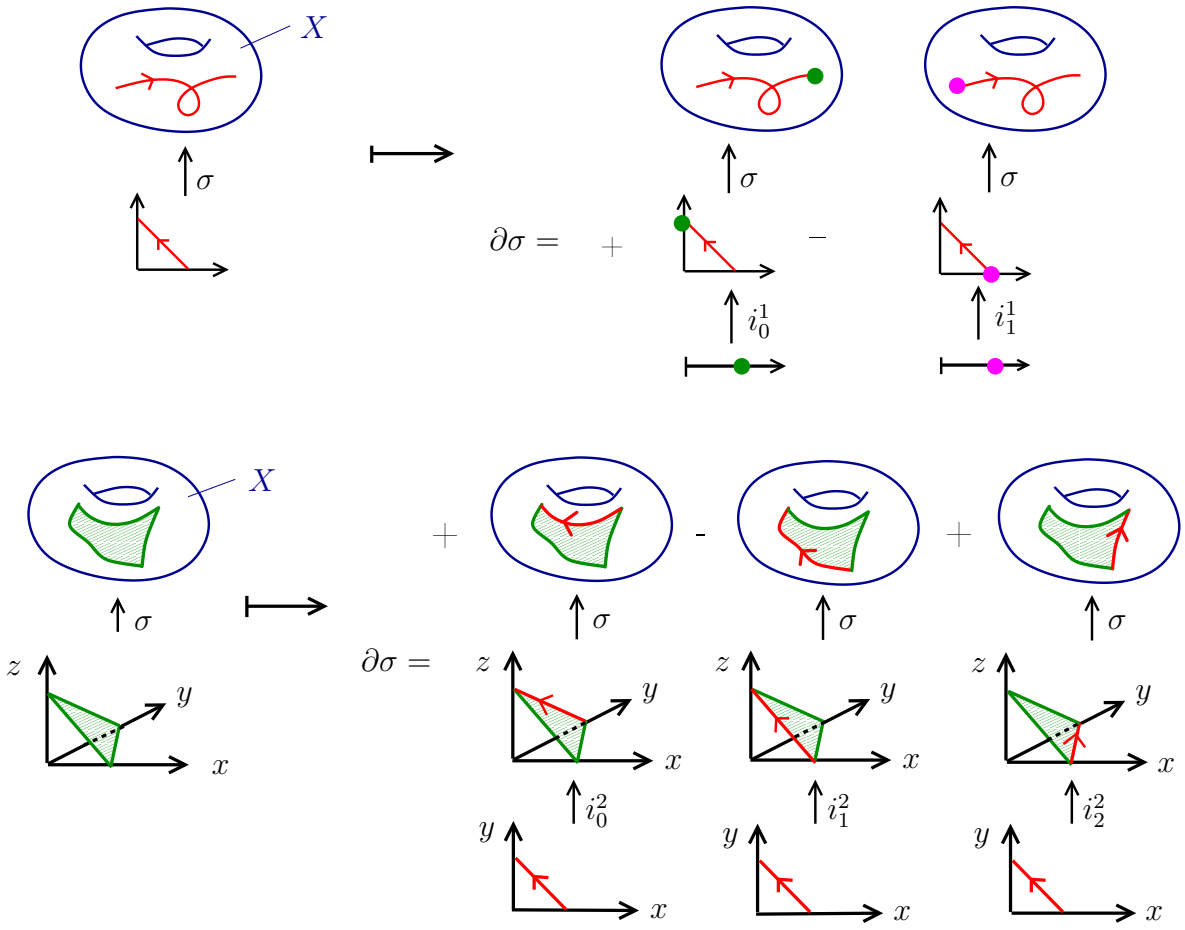
Examples.

(1) For any singular 1-simplex $\sigma\colon\Delta^1\to X$ we have[868]

$$\partial\sigma \;=\; (-1)^0\cdot\sigma\circ i_0^1+(-1)^1\cdot\sigma\circ i_1^1 \;=\; \sigma(0,1)-\sigma(1,0).$$

Put differently, a singular 1-simplex can be viewed as a map σ from the "interval" Δ^1 to X. The boundary of σ is thus the "endpoint" $\sigma(0,1)$ "minus" the "starting point" $\sigma(1,0)$. Here we view points in X again as singular 0-simplices. We sketch the definition of a singular 1-simplex in the figure below.

(2) In the figure below we sketch the boundary of a singular 2-simplex.



As promised, these boundary maps have the following fundamental property:

Proposition 72.2. Let X be a topological space. For any $n\in\mathbb{N}_0$ the composition

$$\partial_{n-1}\circ\partial_n\colon \mathrm{C}_n(X)\;\to\;\mathrm{C}_{n-2}(X)$$

[867]Indeed, let S be a set and let $\mathbb{Z}^{(S)}$ be the free abelian group generated by S. We define $\epsilon\colon\mathbb{Z}^{(S)}\to\mathbb{Z}$ to be the linear map that assigns to each $s\in S$ the value 1. It follows easily from the definitions that for any $\sigma\colon\Delta^n\to X$ we have $\epsilon(\widetilde{\partial}_n\sigma)=n+1$ and $\epsilon((\widetilde{\partial}_{n-1}\circ\widetilde{\partial}_n)(\sigma))=n\cdot(n+1)$.

[868]Here we again use the convention that given a point $x\in X$ we denote by x also the corresponding singular 0-simplex.

is the zero map.

Proof. It suffices to show that $\partial_{n-1}(\partial_n(\sigma)) = 0$ for every singular n-simplex $\sigma\colon \Delta^n \to X$. Thus let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. Then it follows immediately from the definitions that

$$\begin{aligned}\partial_{n-1}(\partial_n(\sigma)) &= \partial_{n-1}\Big(\sum_{j=0}^{n}(-1)^j\cdot\sigma\circ i_j^n\Big) = \sum_{k=0}^{n-1}(-1)^k\cdot\sum_{j=0}^{n}(-1)^j\cdot(\sigma\circ i_j^n)\circ i_k^{n-1}\\ &= \sum_{0=k<j\le n}(-1)^{k+j}\cdot\sigma\circ(i_j^n\circ i_k^{n-1}) + \sum_{0=j\le k\le n-1}(-1)^{k+j}\cdot\sigma\circ(i_j^n\circ i_k^{n-1}) =: (*).\end{aligned}$$

Now we want to show that each expression $\sigma\circ(i_j^n\circ i_k^{n-1})$ appears precisely twice, but with opposite signs. From the definitions it follows easily that for $j\le k$ we have[869]

$$i_j^n\circ i_k^{n-1} = i_{k+1}^n\circ i_j^{n-1}.$$

[869] Indeed, if $j\le k$, then the zero-entries of $(i_j^n\circ i_k^{n-1})(t_0,\dots,t_{n-1})$ are the entries j and $k+1$.

Now we continue with the above calculation:

$$(*) \;\underset{\substack{\uparrow\\ \text{above calculation of } i^n_j \circ i^{n-1}_k}}{=}\; \sum_{0=k<j\le n} (-1)^{k+j} \cdot \sigma \circ (i^n_j \circ i^{n-1}_k) + \sum_{0=j\le k\le n-1} (-1)^{k+j} \cdot \sigma \circ (i^n_{k+1} \circ i^{n-1}_j)$$

$$\underset{\substack{\uparrow\\ \text{substitution } l=k+1}}{=} \sum_{0=k<j\le n} (-1)^{k+j} \cdot \sigma \circ (i^n_j \circ i^{n-1}_k) + \sum_{0=j<l\le n} (-1)^{l+j-1} \cdot \sigma \circ (i^n_l \circ i^{n-1}_j) \underset{\substack{\uparrow\\ \text{all summands left and right cancel}}}{=} 0. \qquad \blacksquare$$

The following is arguably the most important definition of algebraic topology.

Definition. Let X be a topological space and let $n \in \mathbb{N}_0$. We define the n-th singular homology group of X as the quotient group[870]

$$\mathrm{H}_n(X) \;:=\; \frac{\ker(\partial_n \colon \mathrm{C}_n(X) \to \mathrm{C}_{n-1}(X))}{\mathrm{im}(\partial_{n+1} \colon \mathrm{C}_{n+1}(X) \to \mathrm{C}_n(X))}.$$

For $n \in \mathbb{Z}_{<0}$ we extend this definition to $\mathrm{H}_n(X) := 0$. Throughout the lecture notes we will mostly shorten the name "singular homology" to "homology".[871]

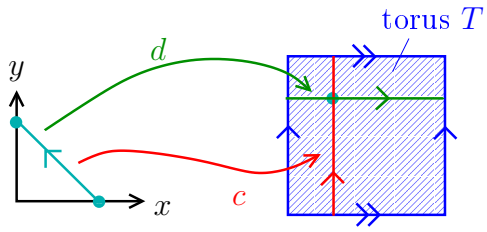
One of the key goals of this course is to develop tools for computing homology groups of topological spaces. In particular we want to compute the homology groups for all spheres. In the subsequent discussions it is helpful to introduce a few more definitions.

Definition. Let X be a topological space.

(1) We say $c \in \mathrm{C}_n(X)$ is a singular n-cycle, or short n-cycle, if $\partial c = 0$.
(2) If c is an n-cycle, then we refer to $[c] \in \mathrm{H}_n(X)$ as the homology class of c.
(3) We say two singular n-chains c and d are homologous if there exists a singular $(n+1)$-chain e with $\partial e = c - d$. In particular, if c and d are cycles, then they are homologous if they represent the same homology class.
(4) An n-cycle c is called null-homologous, if $[c] = 0 \in \mathrm{H}_n(X)$.
(5) Given a singular 1-simplex $\sigma \colon \Delta^1 \to X$ we denote by $\overline{\sigma}$ the singular 1-simplex that is given by $\overline{\sigma}(t, 1-t) = \sigma(1-t, t)$. Put differently, $\overline{\sigma}$ is given by reversing the orientation of σ.

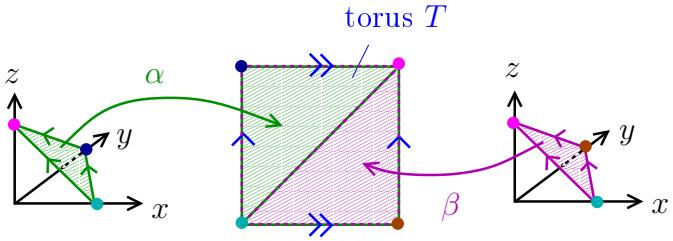
Example. In the figure below we show that torus $T = ([0,1] \times [0,1])/\sim$ together with two singular 1-simplices c and d and together with two singular 2-simplices α and β. It follows easily from the definitions that c and d are 1-cycles. It is a good exercise to verify that $\alpha - \beta$ is a 2-cycle. With our present knowledge it is impossible though to determine whether these cycles represent non-trivial homology classes.

The following lemma will be proved in Exercises 72.3 and 72.6.



---

[870] It follows from Proposition 72.2 that we have the following inclusion:



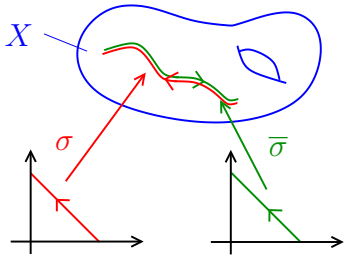
$$\mathrm{im}(\partial_{n+1} \colon \mathrm{C}_{n+1}(X) \to \mathrm{C}_n(X))) \;\subset\; \ker(\partial_n \colon \mathrm{C}_n(X) \to \mathrm{C}_{n-1}(X)).$$

Furthermore the groups $\mathrm{C}_*(X)$ are abelian, in particular any subgroup is also abelian and normal. Therefore it does indeed make sense to consider the quotient group.

[871] Later on, in Chapters 80 and 95, we will also introduce "cellular homology" and "simplicial homology". At that point it will be useful to remember that our present homology groups have a more precise name, namely singular homology groups.

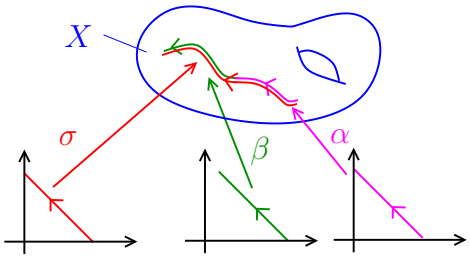
c and d are 1-cycles

$\alpha - \beta$ is a 2-cycle



Lemma 72.3. Let X be a topological space and let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex.

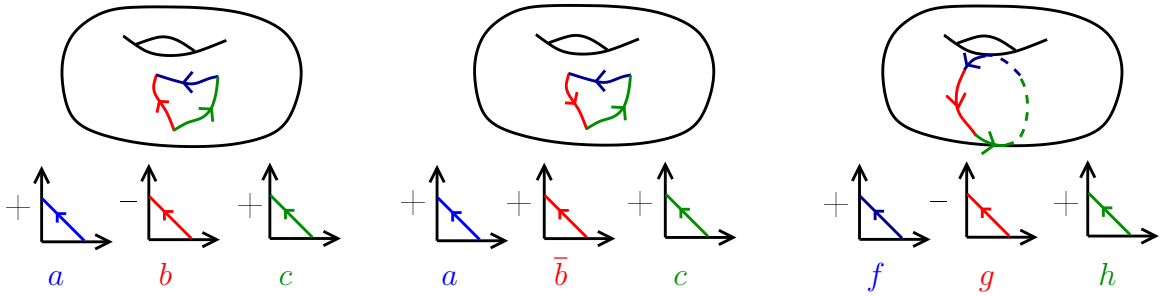
(1) If σ is a constant map, then σ is null-homologous.
(2) The singular 1-chains $-\sigma$ and $\overline{\sigma}$ are homologous.
(3) Let $s \in (0,1)$ and consider the singular 1-simplices



$$\begin{array}{rcl} \alpha\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(st, 1-st) \end{array} \quad \text{and} \quad \begin{array}{rcl} \beta\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(s+t(1-s), 1-(s+t(1-s))). \end{array}$$

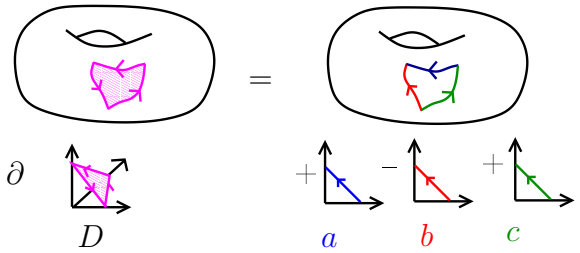
Then the singular 1-chains σ and $\alpha + \beta$ are homologous.

The second part of the lemma says that for a singular 1-simplex the geometric operation of reversing the orientation is (up to the boundary of a simplicial 2-chain) the same as algebraically inverting the sign. Furthermore, the third part of the lemma says that for a singular 1-simplex (again up to the boundary of a simplicial 2-chain) it does not make a difference whether or not we split the singular 1-simplex into two singular 1-simplices.



σ and $-\overline{\sigma}$ are homologous

σ and $\alpha + \beta$ are homologous

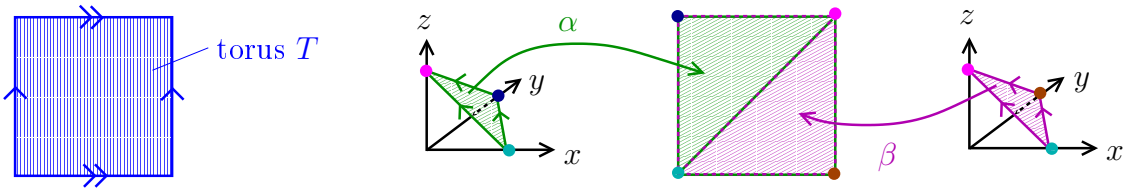


Examples.

(1) We consider the figure below. We see three singular chains on the torus, and it is straightforward to show that all three singular chains are cycles. Now the question

arises, which of these cycles are in fact null-homologous. In the figure below we

see that the first cycle $a - b + c$ in the figure below is the boundary of a singular 2-simplex D. One can easily see that the second cycle, $a + \overline{b} + c$ in the figure below



is *not* the boundary of a singular 2-simplex. On the other hand by Lemma 72.3 we know that $b + \overline{b}$ is a null-homologous cycle, i.e. there exists an $E \in \mathrm{C}_2(X)$ such that $b + \overline{b} = \partial E \in \mathrm{C}_1(X)$. Thus it follows that

$$a + \overline{b} + c \;=\; a + \partial E - b + c \;=\; a - b + c + \partial E = \partial D + \partial E \;=\; \partial(D + E),$$

i.e. $a + \overline{b} + c$ is null-homologous.

It is not clear whether the third cycle in the figure below is the boundary of a 2-dimensional singular chain. We will see later that this not the case. But it will take us quite some time to develop the techniques which will allow us to prove this statement.

(2) In the figure below we show the torus $T = ([0,1] \times [0,1])/\sim$ and two singular simplices $\alpha\colon \Delta^2 \to T$ and $\beta\colon \Delta^2 \to T$ that are given by affine linear maps.[872] It is straightforward to verify that $\alpha - \beta$ is a cycle, hence it represents an element in $\mathrm{H}_2(T)$. We will see later on page 1589 whether or not this element is zero in $\mathrm{H}_2(T)$.

(3) In Exercise 72.8 we will try to generalize the approach taken for the torus to other 2-dimensional smooth manifolds, namely the sphere, the Klein bottle and the projective space $\mathbb{R}P^2$.

72.3. **First calculations of homology groups.** Given a topological space the corresponding homology groups are defined as the quotient of two abelian groups which in general will be infinitely generated. Somewhat surprisingly we will see in the coming chapters that the homology groups are nonetheless very frequently finitely generated abelian groups.

We start out our computations of homology groups with the 0-th homology of a path-connected topological space. The key to the calculation is the following definition.

[872] More precisely, α is the unique affine linear map with $\alpha(1,0,0) = [(0,0)]$, $\alpha(0,1,0) = [(1,0)]$ and $\alpha(0,0,1) = [(1,1)]$ whereas β is the unique affine linear map with $\beta(1,0,0) = [(0,0)]$, $\beta(0,1,0) = [(0,1)]$ and $\beta(0,0,1) = [(1,1)]$.

Definition. Given a topological space X we refer to the map

$$\begin{array}{rcl} \epsilon_X \colon \mathrm{C}_0(X) & \to & \mathbb{Z} \\ \sum_{i=1}^{k} a_i \sigma_i & \mapsto & \sum_{i=1}^{k} a_i \end{array}$$

as the augmentation map.

The following lemma shows that the augmentation map is a neat addition to the singular chain complex of a topological space.

Lemma 72.4. Let X be a topological space.

(1) The map $\epsilon_X \circ \partial_1 \colon \mathrm{C}_1(X) \to \mathbb{Z}$ is the zero map.

(2) The map

$$\begin{array}{rcl} \epsilon_X \colon \mathrm{H}_0(X) & \to & \mathbb{Z} \\ [\sigma] & \mapsto & [\epsilon_X(\sigma)] \end{array}$$

is well-defined. In the following we refer to this map also as the *augmentation map*.

Proof. Let X be a topological space.

(1) Let $c = \sum_{i=1}^{n} b_i \sigma_i \in \mathrm{C}_1(X)$. We calculate that

$$\epsilon(\partial_1(c)) = \epsilon\Big(\sum_{i=1}^{n} b_i \cdot \partial_1(\sigma_i)\Big) \underset{\uparrow}{=} \epsilon\Big(\sum_{i=1}^{n} b_i \cdot \sigma_i(0,1) - b_i \cdot \sigma_i(1,0)\Big) \underset{\uparrow}{=} \sum_{i=1}^{n} b_i - \sum_{i=1}^{n} b_i = 0.$$

for every singular 1-simplex σ we have $\partial\sigma = \sigma(0,1) - \sigma(1,0)$, see page 1585

by definition of ϵ

(2) Note that

$$\begin{array}{rcl} \mathrm{H}_0(X) & = & \ker(\partial_0 \colon \mathrm{C}_0(X) \to \mathrm{C}_{-1}(X)) \,/\, \mathrm{im}(\partial_1 \colon \mathrm{C}_1(X) \to \mathrm{C}_0(X)) \\ & \underset{\uparrow}{=} & \mathrm{C}_0(X) \,/\, \mathrm{im}(\partial_1 \colon \mathrm{C}_1(X) \to \mathrm{C}_0(X)). \end{array}$$

since $\mathrm{C}_{-1}(X) = 0$

Thus we see that Statement (2) is an immediate consequence of Statement (1). ∎

Before we can state the key result of this section let us introduce the following handy convention.

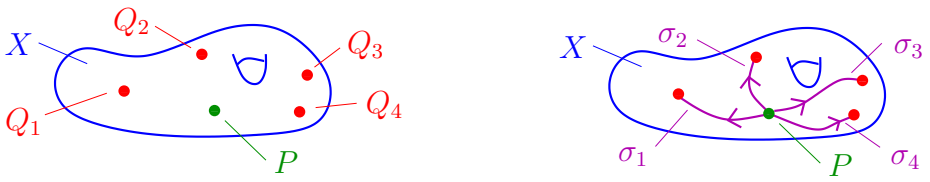
Notation. Let X be a topological space. Given a point $P \in X$ we denote by P also the singular 0-simplex $\Delta^0 \to X$ that is given by sending the single point in Δ^0 to P.

Now we can formulate the following proposition.

Proposition 72.5. (H_0-Proposition) Let X be a path-connected non-empty topological space and let P be a point in X. Then the augmentation map

$$\begin{array}{rcl} \epsilon = \epsilon_X \colon \mathrm{H}_0(X) & \to & \mathbb{Z} \end{array}$$

is a natural isomorphism where the inverse is given by the map



$$\begin{array}{rcl} \iota \colon \mathbb{Z} & \to & \mathrm{H}_0(X) \\ n & \mapsto & n \cdot [P]. \end{array}$$

Proof. Let X be a non-empty path-connected topological space. Let P be a point in X. It is clear that $\epsilon \circ \iota = \mathrm{id}_{\mathbb{Z}}$, in particular the homomorphism ϵ is surjective. It remains to show that ϵ is injective.

Thus let $c \in \mathrm{C}_0(X)$ with $\epsilon(c) = 0$. By definition of $\mathrm{C}_0(X)$ we can find points $Q_1, \ldots, Q_k$ in X and $a_1, \ldots, a_k \in \mathbb{Z}$ such that $c = \sum_{i=1}^{k} a_i \cdot Q_i$. We choose a point P in X. Since X is path-connected we can find, for $i = 1, \ldots, k$, a path from P to Q_i. Put differently, for each $i = 1, \ldots, k$ we can find a singular 1-simplex σ_i with $\partial\sigma_i = Q_i - P$. Then we have

$$\partial\Big(\sum_{i=1}^{k} a_i \cdot \sigma_i\Big) \;=\; \sum_{i=1}^{k} a_i \cdot \partial\sigma_i \;=\; \sum_{i=1}^{k} a_i \cdot (Q_i - P) \;=\; \sum_{i=1}^{k} a_i \cdot Q_i - \underbrace{\Big(\sum_{i=1}^{k} a_i\Big)}_{=\epsilon(c)=0} \cdot P \;=\; \sum_{i=1}^{k} a_i \cdot Q_i.$$

This implies that $[c] = 0 \in \mathrm{H}_0(X)$. Thus we have shown that ϵ is injective. ■

Lemma 72.6. (Single Point-Homology Lemma) Let X be a topological space which consists of a single point. Then the following holds

$$\mathrm{H}_n(X) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ 0, & \text{if } n \neq 0. \end{cases}$$

Proof. The proof of the lemma is the content of Exercise 72.5. ■

The calculation of $\mathrm{H}_0(X)$ in the H_0-Proposition 72.5 and the calculation of the homology of a point in the Single Point-Homology Lemma 72.6 are the only calculations of homology groups of path-connected topological spaces that one can do "by hand". For all other topological spaces we will need to work significantly harder.

72.4. **Algebraic chain complexes.** Before we continue with the discussion of homology groups it is convenient to introduce several algebraic definitions. The following definitions are just the obvious algebraic abstractions of the definitions that we had already introduced.

Definition.

(1) An (algebraic) chain complex (C_*, ∂_*) is a sequence

$$\ldots \to C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \ldots C_1 \xrightarrow{\partial_1} C_0 \to 0$$

of maps between abelian groups[873] such that for every $i \in \mathbb{N}$ we have $\partial_{i-1} \circ \partial_i = 0$. As before we introduce the convention that $C_n = 0$ for $n \in \mathbb{Z}_{<0}$.

(2) We define the n-th homology group of the chain complex precisely the same way as we defined the homology of a topological space, namely we set

$$\mathrm{H}_n(C) \;:=\; \ker(\partial_n \colon C_n \to C_{n-1}) \,/\, \mathrm{im}(\partial_{n+1} \colon C_{n+1} \to C_n).$$

(3) As before we refer to elements in the kernel of $\partial_n \colon C_n \to C_{n-1}$ as cycles. Furthermore we say that a cycle $z \in C_n$ is null-homologous if $[z] = 0 \in \mathrm{H}_n(C)$.

(4) An algebraic chain complex (C_*, ∂_*) is called acyclic if all homology groups are zero.

On some occasions we will need the following generalization:

(5) A generalized (algebraic) chain complex (C_*, ∂_*) is a sequence

$$\ldots \to C_3 \xrightarrow{\partial_3} C_2 \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \xrightarrow{\partial_0} C_{-1} \xrightarrow{\partial_{-1}} C_{-2} \to \ldots$$

of maps between abelian groups such that for every $i \in \mathbb{Z}$ we have $\partial_{i-1} \circ \partial_i = 0$. Basically all present and future definitions and results for chain complexes also make sense for generalized chain complexes. In most cases we will not explicitly state the generalization to generalized chain complex.

Now we introduce a new notion, namely the notion of a chain map between chain complexes.

Definition. A chain map $f\colon C_* \to D_*$ between two chain complexes[874] consists of a family $\{f_n\colon C_n \to D_n\}_{n\in\mathbb{N}_0}$ of maps such that for each n the following equality holds:[875]

$$f_{n-1} \circ \partial_n \;=\; \partial_n \circ f_n.$$

Put differently the maps f_n have the property that the following diagram commutes:

$$\begin{array}{ccccccccc}
\ldots & \xrightarrow{\partial} & C_{n+1} & \xrightarrow{\partial_{n+1}} & C_n & \xrightarrow{\partial_n} & C_{n-1} & \xrightarrow{\partial_{n-1}} & \ldots \\
 & & \downarrow{\scriptstyle f_{n+1}} & & \downarrow{\scriptstyle f_n} & & \downarrow{\scriptstyle f_{n-1}} & & \\
\ldots & \xrightarrow{\partial} & D_{n+1} & \xrightarrow{\partial_{n+1}} & D_n & \xrightarrow{\partial_n} & D_{n-1} & \xrightarrow{\partial_{n-1}} & \ldots
\end{array}$$

Remark. On many occasions we will use the elementary observation that the composition of two chain maps $f\colon C_* \to D_*$ and $g\colon D_* \to E_*$ defines a chain map $g \circ f\colon C_* \to E_*$.

Now we can prove the following lemma:

Lemma 72.7. Let $f\colon C_* \to D_*$ be a chain map between chain complexes C_* and D_*. Then the map

$$\begin{array}{rcl} f_*\colon \mathrm{H}_n(C_*) & \to & \mathrm{H}_n(D_*) \\ [c] & \mapsto & [f_n(c)] \end{array}$$

is well-defined.

Definition. In the setting of Lemma 72.7 we refer to the map $f_*\colon \mathrm{H}_n(C) \to \mathrm{H}_n(D)$ as the induced map on homology.

Proof. Let $c \in C_n$ be a cycle. First we have to show that $f_n(c)$ is again a cycle. Indeed we have

$$\partial_n(f_n(c)) \underset{\substack{\uparrow \\ \text{definition of a chain map}}}{=} f_{n-1}(\partial_n c) \underset{\substack{\uparrow \\ \text{since } c \text{ is a cycle}}}{=} f_n(0) \;=\; 0.$$

[873] Note that we do not assume that the chain groups C_* are free abelian groups.

[874] As usual we suppress bits from the notation which are understood from the context. In this instance we suppress the notation for the boundary maps in the chain complexes. Put differently, instead of saying "let (C_*, ∂_*) be a chain complex" we say simply "let C_* be a chain complex".

[875] More precisely, for any $c \in C$ we have $f_{n-1}(\partial_n(c)) = \partial_n(f_n(c))$ where on the left-hand side we consider the boundary map $C_n \to C_{n-1}$, and on the right-hand side we consider the boundary map $D_n \to D_{n-1}$ which we also denote by ∂_n. Usually it is obvious from the context which boundary map we consider.

Now let $c, d \in C_n$ be two cycles which represent the same element in $\mathrm{H}_n(C)$. We have to show that $[f_n(c)] = [f_n(d)]$. Indeed we have

$$[f_n(c)] - [f_n(d)] \;=\; [f_n(c-d)] \underset{\substack{\text{since } c,d \text{ are homologous there} \\ \text{exists an } e \in C_{n+1} \text{ with } \partial_{n+1}e = c-d}}{\uparrow =} [f_n(\partial_{n+1}(e))] \underset{\text{definition of a chain map}}{\uparrow =} [\partial_{n+1}(f_{n+1}(e))] \;=\; 0 \;\in \mathrm{H}_n(D).$$

■

We can state the above results more formally. To do so it is convenient to introduce the following definition.

Definition. We refer to category *ChCplx* that is given by

$$\mathrm{Ob}(\mathcal{ChCplx}) \;:=\; \text{all chain complexes,}$$

and with morphisms

$$\mathrm{Mor}(C_*, D_*) \;:=\; \text{all chain maps from } C_* \text{ to } D_*.$$

with the obvious composition of morphisms as the category of chain complexes.

The following lemma follows easily from Lemma 72.7 and from the definitions:

Lemma 72.8. For each $n \in \mathbb{N}_0$ the maps

$$\begin{array}{rcl} C_* & \mapsto & \mathrm{H}_n(C_*) \\ (f\colon C_* \to D_*) & \mapsto & (f_*\colon \mathrm{H}_n(C_*) \to \mathrm{H}_n(D_*)) \end{array}$$

define a functor from the category *ChCplx* of chain complexes to the category *AbGroup* of abelian groups.

72.5. **The functoriality of homology groups.** Let $f\colon X \to Y$ be a map between topological spaces. We already saw on page 1584 that for each $n \in \mathbb{N}_0$ the map f induces a map

$$\begin{array}{rcl} f_*\colon \mathrm{C}_n(X) & \to & \mathrm{C}_n(Y) \\ \sum_{i=1}^{k} a_i \cdot \sigma_i & \mapsto & \sum_{i=1}^{k} a_i \cdot f \circ \sigma_i. \end{array}$$

Now we can formulate the following lemma:

Lemma 72.9.

(1) The boundary maps $\partial_n\colon \mathrm{C}_n(X) \to \mathrm{C}_{n-1}(X)$ are natural transformations. Put differently, in plain English, if $f\colon X \to Y$ is a map between topological spaces, then given any $c \in \mathrm{C}_n(X)$ we have

$$f_*(\partial_n c) \;=\; \partial_n(f_*(c)) \;\in\; \mathrm{C}_n(Y).$$

In particular $f_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y)$ is a chain map.

(2) The maps

$$\begin{array}{rcl} \text{topological space } X & \mapsto & \mathrm{C}_*(X) \\ (f\colon X \to Y) & \mapsto & (f_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y)) \end{array}$$

and

define a functor from the category *Top* of topological spaces to the category *ChCplx* of chain complexes.

Proof.

(1) Let $f\colon X \to Y$ be a map between topological spaces. Given any singular n-simplex $\sigma\colon \Delta^n \to X$ we have

$$f_*(\partial\sigma) = f_*\Big(\sum_{j=0}^{n}(-1)^j\cdot\sigma\circ i_j^n\Big) = \sum_{j=0}^{n}(-1)^j\cdot f\circ(\sigma\circ i_j^n) = \sum_{j=0}^{n}(-1)^j\cdot(\underbrace{f\circ\sigma}_{=f_*\sigma})\circ i_j^n = \partial(f_*\sigma).$$

Since the singular n-simplices generate $\mathrm{C}_n(X)$ we obtain the desired equality for all singular n-chains. By definition this means that $f_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y)$ is a chain map.

(2) The second statement is an almost immediate consequence of the first statement. ■

In particular, using Lemma 72.7 we immediately obtain the following lemma.

Lemma 72.10. Let $f\colon X \to Y$ be a map between topological spaces. Then the map

$$\begin{array}{rcl} f_*\colon \mathrm{H}_n(X) & \to & \mathrm{H}_n(Y) \\ \Big[\sum_{i=1}^{k} a_i\cdot\sigma_i\Big] & \mapsto & \Big[\sum_{i=1}^{k} a_i\cdot(f\circ\sigma_i)\Big] \end{array}$$

is well-defined.

Example. Let $f\colon X \to Y$ be a map between two topological spaces. It follows immediately from the definitions that the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}_0(X) & \xrightarrow{\quad f_*\quad} & \mathrm{H}_0(Y). \\ & {\scriptstyle\epsilon_X}\searrow \quad \swarrow{\scriptstyle\epsilon_Y} & \\ & \mathbb{Z} & \end{array}$$

where the maps ϵ_X and ϵ_Y denote the augmentation maps. In particular, if X and Y are path-connected topological spaces, then it follows easily from the H_0-Proposition 72.5 that the map $f_*\colon \mathrm{H}_0(X) \to \mathrm{H}_0(Y)$ is an isomorphism. Furthermore, if $X = Y$, i.e. if f is a self-map on a path-connected topological space X, then f_* is in fact the identity on $\mathrm{H}_0(X)$.

The combination of Lemmas 72.9 and 72.8 now gives us the following lemma.

Lemma 72.11. For each $n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} X & \mapsto & \mathrm{H}_n(X) \end{array}$$

together with the map

$$\begin{array}{rcl} (f\colon X \to Y) & \mapsto & \left(\begin{array}{rcl} f_*\colon \mathrm{H}_n(X) & \to & \mathrm{H}_n(Y) \\ \Big[\sum_{i=1}^{k} a_i\cdot\sigma_i\Big] & \mapsto & \Big[\sum_{i=1}^{k} a_i\cdot(f\circ\sigma_i)\Big] \end{array}\right) \end{array}$$

defines a functor from the category of topological spaces to the category of abelian groups.

Example. Let X and Y be non-empty topological spaces. Let $f\colon X \to Y$ be a map. We suppose that f is constant, i.e. we suppose that there exists a $y \in Y$ such that $f(X) = \{y\}$. We denote by $i\colon \{y\} \to Y$ the inclusion. Let $n \in \mathbb{N}$. We consider the commutative diagram

$$\begin{array}{ccc} & \{y\} & \\ {\scriptstyle f}\nearrow & & \searrow{\scriptstyle i} \\ X & \xrightarrow{\quad f\quad} & Y \end{array}$$

which gives rise to the commutative diagram

$$\begin{array}{ccc} & \mathrm{H}_n(\{y\}) & \\ {\scriptstyle f_*}\nearrow & & \searrow{\scriptstyle i_*} \\ \mathrm{H}_n(X) & \xrightarrow{\quad f_*\quad} & \mathrm{H}_n(Y). \end{array}$$

By the Single Point-Homology Lemma 72.6 we know that $\mathrm{H}_n(\{y\}) = 0$. Thus we see that $f_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y)$ factors through the trivial group, i.e. the map is the trivial map. On many occasions we will make use of this observation without referring to this discussion.

72.6. **Direct products and direct sums** (∗). In this short section we recall the definition of the direct product and the direct sum of a family of abelian groups.

Definition. Let $G_i, i \in I$ be a family of abelian groups. We define the direct product as

$$\prod_{i\in I} G_i := \Big\{\text{all maps } g\colon I \to \bigcup_{i\in I} G_i \text{ such that for all } i \in I \text{ we have } g(i) \in G_i\Big\}.$$

Given such a map we usually write $g_i := g(i)$ for $i \in I$ and we denote such a map by $\{g_i\}_{i\in I}$. The direct product is again a group with respect to the group structure

$$\begin{array}{rcl} \prod_{i\in I} G_i \times \prod_{i\in I} G_i & \to & \prod_{i\in I} G_i \\ \big((a_i)_{i\in I}, (b_i)_{i\in I}\big) & \mapsto & (a_i + b_i)_{i\in I}. \end{array}$$

Furthermore we consider the direct sum

$$\bigoplus_{i\in I} G_i := \Big\{(g_i)_{i\in I} \in \prod_{i\in I} G_i \,\Big|\, \text{there exists only finitely many } i \in I \text{ with } g_i \neq e\Big\}.$$

The same way one can also define the direct product respectively the direct sum of rings, algebras, vector spaces, modules and so on.

Example. Let $I = \mathbb{N}$ and for each $i \in I = \mathbb{N}$ we pick $G_i = \mathbb{R}$. Then

$$\prod_{i\in\mathbb{N}} \mathbb{R} = \text{all real-valued sequences } i \mapsto a_i$$

and

$$\bigoplus_{i\in\mathbb{N}} \mathbb{R} = \text{all real-valued sequences with only finitely many non-zero terms.}$$

In general the direct product is "significantly larger" than the direct sum. For example the direct product $\prod_{i\in\mathbb{N}} \mathbb{Z}$ is uncountable while the direct sum $\bigoplus_{i\in\mathbb{N}} \mathbb{Z}$ is countable.[876]

Convention. Let $\{G_i\}_{i\in I}$ be family of abelian groups.

(1) For some element $g_j \in G_j$, following the discussion on page 1147, we sometimes denote by g_j also the element in $\bigoplus_{i\in I} G_i$ that is given by $i \mapsto 0$ if $i \neq j$ and $j \mapsto g_j$. In particular we can view each G_j as a subgroup of $\bigoplus_{i\in I} G_i$.

(2) Given $i_1, \ldots, i_l \in I$ and $g_{i_j} \in G_{i_j}$ we can use (1) to consider the corresponding element

$$g_{i_1} + \cdots + g_{i_l} \in \bigoplus_{i\in I} G_i.$$

It follows immediately from the definitions that any element of $\bigoplus_{i\in I} G_i$ is of that form.

Finally we introduce the following notation.

[876] Why is that the case?

Notation.

(I) Let $\{G_i\}_{i\in I}$ be a family of abelian groups and let H be an abelian group. Furthermore let $\{\varphi_i\colon G_i \to H\}_{i\in I}$ be a family of homomorphisms. We refer to

$$\begin{aligned} \bigoplus_{i\in I}\varphi_i\colon \bigoplus_{i\in I} G_i &\to H \\ g_{i_1}+\cdots+g_{i_l} &\mapsto \underbrace{\varphi_{i_1}(g_{i_1})}_{\in H}+\cdots+\underbrace{\varphi_{i_l}(g_{i_l})}_{\in H} \end{aligned}$$

as the direct sum of the homomorphisms $\{\varphi_i\}_{i\in I}$.

(II) Let G be an abelian group, let $\{H_i\}_{i\in I}$ be a *finite* family of abelian groups and let $\{\varphi_i\colon G \to H_i\}_{i\in I}$ be a family of homomorphisms. We refer to

$$\begin{aligned} \bigoplus_{i\in I}\varphi_i\colon G &\to \bigoplus_{i\in I} H_i \\ g &\mapsto \sum_{i\in I}\underbrace{\varphi_i(g)}_{\in H_i} \end{aligned}$$

also as the direct sum of the family of homomorphisms $\{\varphi\}_{i\in I}$.

(III) Let $\{\varphi_i\colon G_i \to H_i\}_{i\in I}$ be a *finite* family of homomorphisms between abelian groups. We refer to

$$\begin{aligned} \bigoplus_{i\in I}\varphi_i\colon \bigoplus_{i\in I} G_i &\to \bigoplus_{i\in I} H_i \\ \sum_{i\in I} g_i &\mapsto \sum_{i\in I}\underbrace{\varphi_i(g_i)}_{\in H_i} \end{aligned}$$

also as the direct sum of the homomorphisms $\{\varphi_i\}_{i\in I}$.

The notation is arguably somewhat ambiguous. But usually it should be clear from the context what we precisely mean when we write $\bigoplus_{i\in I}\varphi_i$. Sometimes, in desperation, we will refer to $\bigoplus_{i\in I}\varphi_i$ a direct sum of type (I), (II) or (III).

For reference we jot down the following lemma which follows immediately from the definitions.

Lemma 72.12. Let I be a finite set and let $\{\varphi_i\colon G_i \to H_i\}_{i\in I}$ be a family of homomorphisms between abelian groups.

(1) Let F be an abelian group and let $\{\alpha\colon F \to G_i\}_{i\in I}$ be a family of homomorphisms. Then
$$\left(\bigoplus_{i\in I}\varphi_i\right)\circ\left(\bigoplus_{i\in I}\alpha_i\right) = \bigoplus_{i\in I}\alpha_i\circ\varphi_i\colon F \to \bigoplus_{i\in I} G_i.$$

(2) Let $\{\alpha_i\colon F_i \to G_i\}_{i\in I}$ be another family of homomorphisms between abelian groups. Then
$$\left(\bigoplus_{i\in I}\varphi_i\right)\circ\left(\bigoplus_{i\in I}\alpha_i\right) = \bigoplus_{i\in I}\alpha_i\circ\varphi_i\colon \bigoplus_{i\in I} F_i \to \bigoplus_{i\in I} G_i.$$

72.7. **The homology groups of a direct sum.** Now we return to the study of chain complexes. Let C_* and D_* be two chain complexes. The same way as we introduced the direct sum of abelian groups we can also define the direct sum of chain complexes. The following lemma says that homology commutes with direct sums and direct products. The proof is a standard exercise in homological algebra, which oddly enough nobody ever feels like doing, see [**Weib1994**, p. 5].

Lemma 72.13. If $\{C_a\}_{a\in A}$ is a family of chain complexes, then the obvious inclusion maps $C_a \to \bigoplus_{a\in A} C_a$ and $C_a \to \prod_{a\in A} C_a$ induce isomorphisms

$$\bigoplus_{a\in A} \mathrm{H}_n(C_a) \xrightarrow{\cong} \mathrm{H}_n\Big(\bigoplus_{a\in A} C_a\Big) \quad \text{and} \quad \prod_{a\in A} \mathrm{H}_n(C_a) \xrightarrow{\cong} \mathrm{H}_n\Big(\prod_{a\in A} C_a\Big).$$

Now we can formulate and prove the following lemma.

Lemma 72.14. Let X be a topological space with path-components $\{X_a\}_{a\in A}$. Given $a \in A$ we denote by $i_a\colon X_a \to X$ the inclusion map. Then the map

$$\bigoplus_{a\in A} i_a\colon \quad \bigoplus_{a\in A} \mathrm{C}_*(X_a) \quad \to \quad \mathrm{C}_*(X)$$

is an isomorphism of chain complexes. In particular for each $n \in \mathbb{N}_0$ the map

$$\bigoplus_{a\in A} i_{a*}\colon \quad \bigoplus_{a\in A} \mathrm{H}_n(X_a) \quad \to \quad \mathrm{H}_n(X)$$

is an isomorphism.

The lemma says in particular that the homology groups of a topological space X are the direct sum of the homology groups of the path-components of X. Put differently, this shows that in most cases it suffices to consider the homology groups of path-connected topological spaces.

Examples.

(1) One of our goals is to calculate the homology groups of the spheres. Now we can calculate the homology groups of the 0-dimensional sphere $S^0 = \{\pm 1\}$. More precisely, by Lemmas 72.6 and 72.14 we have

$$\mathrm{H}_n(S^0) \cong \begin{cases} \mathbb{Z}^2, & \text{if } n = 0, \\ 0, & \text{if } n \neq 0. \end{cases}$$

Later in the proof of Proposition 74.4 we will cleverly reduce the computation of the homology groups of all other spheres to this calculation.

(2) Let X be a topological space and let $\{U_a\}_{a\in A}$ be a family of disjoint open subsets of X. It follows fairly easily from Lemma 72.14 together with the Component Lemma 2.33 (4) and (5) that the map

$$\bigoplus_{a\in A} i_{a*}\colon \bigoplus_{a\in A} \mathrm{H}_n(U_a) \to \mathrm{H}_n\Big(\bigcup_{a\in A} U_a\Big)$$

is an isomorphism.

Proof. Evidently the standard simplex Δ^n is path-connected. Thus it follows from Lemma 2.35 that the image of a map $\sigma\colon \Delta^n \to X$ is contained in a path-component X_a. This shows that

$$\bigsqcup_{a\in A} \text{singular } n\text{-simplices in } X_a \quad = \quad \text{singular } n\text{-simplices in } X.$$

It follows that the map

$$\begin{aligned} \bigoplus_{a\in A} i_a\colon \bigoplus_{a\in A} \mathrm{C}_n(X_a) &\to \mathrm{C}_n(X) \\ \Big(\sum_{i=1}^k c_i(\sigma\colon \Delta^n \to X_{a_i})\Big) &\mapsto \Big(\sum_{i=1}^k c_i(\sigma\colon \Delta^n \to X_{a_i})\Big) \end{aligned}$$

is an isomorphism of free abelian groups. From the definitions it follows immediately that this a chain map. The second statement of the lemma now follows from Lemma 72.13. ■

The following corollary is an immediate consequence of the H_0-Proposition 72.5 and Lemma 72.13.

Corollary 72.15. Let X be a topological space. As on page 167 we denote by $\pi_0(X)$ the set of path-components of X. Then

$$H_0(X) \;\cong\; \mathbb{Z}^{(\pi_0(X))}.$$

In particular, if X consists of n path-components with $n \in \mathbb{N}_0$, then

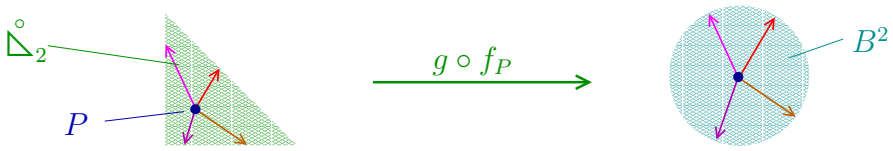
$$H_0(X) \;\cong\; \mathbb{Z}^n.$$

Exercises for Chapter 72.

Exercise 72.1. How many faces does the standard simplex Δ^n have?

Exercise 72.2. Let $n \in \mathbb{N}$. As in the Standard Simplex Homeomorphism Lemma 72.1 we consider

$$\triangleleft_n \;:=\; \left\{(x_1,\ldots,x_n) \in [0,1]^n \;\middle|\; \sum_{i=1}^{n} x_i \in [0,1]\right\} \;\subset\; \mathbb{R}^n.$$



We denote by $\Phi\colon \Delta^n \to \triangleleft_n$ the natural projection. We pick any $P \in \overset{\circ}{\triangleleft}_n$. Next we consider the maps

$$\begin{array}{rcl} f_P\colon \overset{\circ}{\triangleleft}_n \to \mathbb{R}^n & & g\colon \mathbb{R}^n \to B^n \\ (x_1,\ldots,x_n) \mapsto \frac{((x_1,\ldots,x_n)-P)}{x_1\cdot\cdots\cdot x_n\cdot(1-x_1-\cdots-x_n)} & \text{and} & (x_1,\ldots,x_n) \mapsto \frac{x_1^2+\cdots+x_n^2}{1+x_1^2+\cdots+x_n^2}\cdot(x_1,\ldots,x_n) \end{array}$$

Note that f_P is defined in such a way that it sends rays emanating from P to rays emanating from the origin.

(a) Show that $f_P\colon \overset{\circ}{\triangleleft}_n \to \mathbb{R}^n$ is an orientation-preserving diffeomorphism.
(b) Show that $g\colon \mathbb{R}^n \to B^n$ is an orientation-preserving diffeomorphism.
Note that for the most part we had solved this problem on page 645.
(c) Show that $g \circ f_P\colon \overset{\circ}{\triangleleft}_n \to B^n$ extends to a homeomorphism $\Theta\colon \triangleleft_n \to \overline{B}^n$.
(d) Let $\Xi\colon \triangleleft_n \to \overline{B}^n$ be the homeomorphism obtained from the Convex-to-Ball Proposition 2.20 (2) applied to P. Show that Θ and Ξ are homotopic rel P.

Remark. The composition $\Psi \circ \Phi\colon \Delta^n \to \overline{B}^n$ is now a homeomorphism such that the restriction $\overset{\circ}{\Delta}^n \to B^n$ is a diffeomorphism. Furthermore this diffeomorphism is orientation-preserving if and only if n is even. Here we use the definitions on page 1581 to view $\overset{\circ}{\Delta}^n$ as an oriented smooth manifold.

Exercise 72.3.

(a) Let X be a topological space and let $x \in X$. For each $n \in \mathbb{N}_0$ denote by σ_n the singular n-simplex $\sigma_n\colon \Delta^n \to X$ which is defined by $\sigma_n(P) = x$ for all $P \in \Delta^n$. Determine $\partial\sigma_n \in C_{n-1}(X)$.

(b) Let X be a topological space and let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex. Show that if σ is a constant map, then σ is null-homologous.

Exercise 72.4. Let (C_*, c_*) and (D_*, d_*) be a chain complex and let $\varphi\colon C_* \to D_*$ be a chain map. Show that the groups $K_n := \ker(\varphi_n\colon C_n \to D_n)$ form a subcomplex of (C_*, c_*).

Exercise 72.5. Let X be a topological space which consists of a single point. Show that the following holds:

$$\mathrm{H}_n(X) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ 0, & \text{if } n \neq 0. \end{cases}$$

Exercise 72.6.

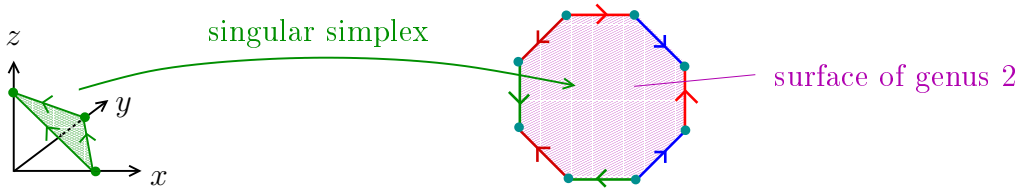
(a) Let X be a topological space and let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex. We consider the singular 1-simplices

$$\begin{array}{rcl} \sigma_1\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(\frac{1}{2}t, 1-\frac{1}{2}t) \end{array} \quad \text{and} \quad \begin{array}{rcl} \sigma_2\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & (\frac{1}{2}+\frac{1}{2}t, \frac{1}{2}-\frac{1}{2}t). \end{array}$$

Show that σ and $\sigma_1 + \sigma_2$ are homologous.

(b) Let X be a topological space and let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex. We consider the singular 1-simplex

$$\begin{array}{rcl} \overline{\sigma}\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(1-t, t). \end{array}$$



Show that $\sigma + \overline{\sigma}$ is a 1-cycle and that this 1-cycle is null-homologous.

We refer to the figure below for an illustration of the definitions.

Exercise 72.7. Let $\Sigma = E_8/\!\sim$ be the surface of genus 2. Provide an example of a 2-cycle $\sum_{i=1}^{m} a_i \cdot \sigma_i \in \mathrm{C}_2(\Sigma)$ with the following three properties:

(1) At least one a_i is non-zero.
(2) The images of the singular 2-simplices cover the whole surface.
(3) The images of the singular 2-simplices overlap only in "1-dimensional" subsets.

Remark. Note that on page 1589 we provided an example of such a 2-cycle for the torus $\Sigma = ([0,1] \times [0,1])/\!\sim$.

Exercise 72.8.

(a) Try to find "interesting" elements in the following homology groups:
(i) $\mathrm{H}_2(S^2)$,
(ii) H_2(surface Σ of genus 2),
(iii) H_2(Klein bottle K) and
(iv) $\mathrm{H}_2(\mathbb{R}\mathrm{P}^2)$.

More precisely, try to find 2-cycles which have the properties (1), (2) and (3) from Exercise 72.7.

(b) Make a guess for which surfaces you expect H_2 to be zero and for which it is non-zero.

Exercise 72.9. Let $n \in \mathbb{N}$.

(a) Provide an example of an n-cycle $\sum_{i=1}^{m} a_i \cdot \sigma_i \in \mathrm{C}_n(S^n)$ which has the properties (1), (2) and (3) from Exercise 72.7.

(b) Make an educated guess what the homology groups of S^n might be.

Exercise 72.10. Provide an example of a chain complex $(\mathrm{C}_*, \partial_*)$ such that all C_* are finitely generated free abelian groups and such that $\mathrm{H}_i(C_*) = 0$ for all even $i \in \mathbb{N}_0$ and such that $\mathrm{H}_i(C_*) = \mathbb{Z}_2$ for all odd $i \in \mathbb{N}_0$.

Exercise 72.11.

(a) Determine the isomorphism types of the homology groups of the chain complex

$$0 \;\to\; C_1 = \mathbb{Z}^2 \;\xrightarrow{\begin{pmatrix} 3 & 7 \\ 4 & 2 \end{pmatrix}}\; C_0 = \mathbb{Z}^2 \;\to\; 0.$$

(b) Determine the isomorphism types of the homology groups of the chain complex

$$0 \;\to\; C_2 = \mathbb{Z}^2 \xrightarrow{\begin{pmatrix} 2 & 5 \\ 4 & 10 \end{pmatrix}} C_1 = \mathbb{Z}^2 \;\xrightarrow{\begin{pmatrix} -2 & 1 \end{pmatrix}}\; C_0 = \mathbb{Z} \;\to\; 0.$$

(Why is this a chain complex?)

Exercise 72.12. Given a topological space X and $n \in \mathbb{N}_0$ we consider the map

$$\begin{array}{rcl} \epsilon \colon \mathrm{C}_n(X) & \to & \mathbb{Z} \\ \sum_{i=1}^{k} a_i \sigma_i & \mapsto & \sum_{i=1}^{k} a_i. \end{array}$$

(a) Show that the following diagram commutes

$$\begin{array}{ccccccccccccc} \ldots & \longrightarrow & \mathrm{C}_3(X) & \xrightarrow{\partial_3} & \mathrm{C}_2(X) & \xrightarrow{\partial_2} & \mathrm{C}_1(X) & \xrightarrow{\partial_1} & \mathrm{C}_2(X) & \xrightarrow{\partial_0} & 0 \\ & & \downarrow{\scriptstyle \epsilon} & & \downarrow{\scriptstyle \epsilon} & & \downarrow{\scriptstyle \epsilon} & & \downarrow{\scriptstyle \epsilon} & & \\ \ldots & \xrightarrow{\mathrm{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \xrightarrow{\mathrm{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \longrightarrow & 0. \end{array}$$

(b) Show that if n is even, then for every cycle $\sigma \in \mathrm{C}_n(X)$ we have $\epsilon(\sigma) = 0$.

Exercise 72.13. Let $f \colon C \to B$ be a homomorphism between abelian groups and let A be a subgroup of B with the following two properties:

(1) We have $f(C) \cap A = 0$.

(2) The subgroups $f(C)$ and A generate B.

Show that the map

$$\begin{array}{rcl} A & \to & \operatorname{coker}(f) = B/\operatorname{im}(f) \\ a & \mapsto & [a] \end{array}$$

is an isomorphism.

Exercise 72.14. Suppose we are chain complex of the following form

$$D_* \;=\; \ldots \;\to\; C_{k+2} \;\xrightarrow{\partial_{k+2}}\; A_{k+1} \oplus B_{k+1} \;\xrightarrow{\partial_{k+1}}\; A_k \oplus B_k \;\xrightarrow{\partial_k} C_{k-1} \;\to\; \ldots$$

Given $m \in \{k, k+1\}$ we denote by $i_m \colon A_m \to A_m \oplus B_m$ and $j_m \colon B_m \to A_m \oplus B_m$ the natural inclusions and we denote by $p_m \colon A_m \oplus B_m \to A_m$ and $q_m \colon A_m \oplus B_m \to B_m$ the natural projections. We suppose that $p_k \circ \partial_{k+1} \circ i_{k+1} \colon A_{k+1} \to A_k$ is an isomorphism. Show that we can "cancel" A_{k+1} and A_k from the chain complex without changing the isomorphism type of the homology groups. More precisely, consider the following chain complex:

$$\widetilde{D}_* \;=\; \ldots \;\to\; C_{k+2} \;\xrightarrow{p_{k+1} \circ \partial_{k+2}}\; B_{k+1} \;\xrightarrow{q_k \circ \partial_{k+1} \circ j_{k+1}}\; B_k \;\xrightarrow{\partial_k \circ j_k} C_{k-1} \;\to\; \ldots$$

Show that for each $i \in \mathbb{N}_0$ there exists an isomorphism $\mathrm{H}_i(D_*) \to \mathrm{H}_i(\widetilde{D}_*)$.

Remark. This implies in particular that D_* is acyclic if and only if $\widetilde{D}_*$ is acyclic.

Exercise 72.15. We define the direct sum of two chain complexes (C_*, ∂_*) and (D_*, ∂_*) in the obvious way. A chain complex is called *indecomposable* if it cannot be written as the direct sum of two non-zero chain complexes. Show that every chain complex (C_*, ∂_*), where the groups C_i are all finitely generated free abelian groups, can be written as a direct sum of chain complexes of the form

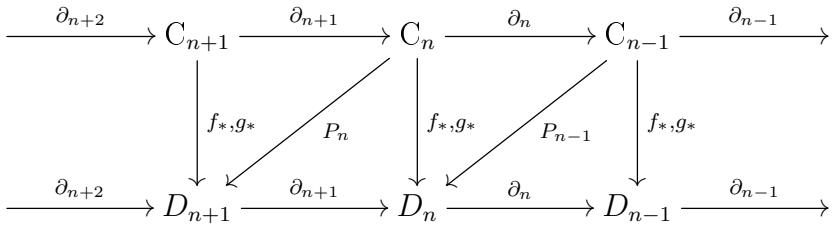
$$0 \;\to\; \underset{\substack{\uparrow \\ \text{degree } i}}{\mathbb{Z}} \;\to\; 0 \qquad \text{and} \qquad 0 \;\to\; \underset{\substack{\uparrow \\ \text{degree } i}}{\mathbb{Z}} \;\xrightarrow{\cdot n}\; \underset{\substack{\uparrow \\ \text{degree } i-1}}{\mathbb{Z}} \;\to\; 0.$$

Remark. Use the Smith Normal Form Theorem 51.5.

Exercise 72.16. Let (C_*, ∂_*) be a chain complex of abelian groups. Show that there exists a chain complex (F_*, ∂_*) of *free abelian groups* together with a chain map $\varphi \colon F_* \to C_*$ such that the induced maps $f_* \colon \mathrm{H}_k(F_*) \to \mathrm{H}_k(C_*)$ are isomorphisms for all $k \in \mathbb{N}_0$.

73. Homology and homotopies

It was not overly difficult to introduce the homology groups of a topological space. We also proved several straightforward properties of homology groups. But so far we are unable to calculate any interesting homology group. In this section we will show in particular that homotopy equivalent topological spaces have isomorphic homology groups. That does not yet lead to the calculation of non-trivial homology groups, but this result will play an important role in the calculation of the homology groups of spheres that we will give in Proposition 74.4.



73.1. **Chain homotopies.** In this section we introduce a criterion that ensures that two chain maps $f, g\colon C_* \to D_*$ induce the same maps on the corresponding homology groups.

Definition. Let $f, g\colon C_* \to D_*$ be chain maps between chain complexes C_* and D_*. A chain homotopy $P = \{P_n\}_{n\in\mathbb{N}_0}$ between f and g consists of family $\{P_n\colon \mathrm{C}_n \to D_{n+1}\}_{n\in\mathbb{N}_0}$ such that for each $n \in \mathbb{N}_0$ we have

$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; f_n - g_n.$$

If there exists a chain homotopy between chain maps f and g, then we say that f and g are chain homotopic and we write $f \simeq g$.

For the definition of a chain homotopy and the subsequent discussion of chain homotopies it is sometimes helpful to keep in mind the following diagram that combines all objects involved in the definition:

Lemma 73.1. Let C_* and D_* be two chain complexes.

(1) Chain homotopy defines an equivalence relation on the set of all chain maps from C_* to D_*. In particular, if $f, g, h\colon C_* \to D_*$ are chain maps with $f \simeq g$ and $g \simeq h$, then $f \simeq h$.
(2) Let $f, g\colon C_* \to D_*$ be chain maps, and let $e\colon B_* \to \mathrm{C}_*$ and $h\colon D_* \to E_*$ be two other chain maps. Then

$$f \simeq g \quad\Longrightarrow\quad f \circ e \simeq g \circ e \quad\text{and}\quad h \circ f \simeq h \circ g.$$

Proof. The lemma will be proved in Exercise 73.1. ∎

Now we can formulate the following lemma.

Lemma 73.2. Let $f, g\colon C_* \to D_*$ be two chain maps between chain complexes. If f and g are chain homotopic, then $f_* = g_*\colon \mathrm{H}_n(C) \to \mathrm{H}_n(D)$ for all $n \in \mathbb{N}_0$.

Proof. Let $P = \{P_n\}_{n\in\mathbb{N}_0}$ be a chain homotopy between f and g. Then for any cycle $z \in C_n$ we get the equalities

$$f(z) - g(z) \;=\; (f-g)(z) \;=\; (\partial_{n+1}P_n + P_{n-1}\partial_n)(z) \;=\; (\partial_{n+1}P_n)(z) + P_{n-1}\underbrace{\partial_n z}_{=0} \;=\; \partial P_n z,$$

i.e. $f(z)$ and $g(z)$ are homologous. ■

Definition. Let C_* and D_* be two chain complexes.

(1) A chain map $f\colon \mathrm{C}_* \to D_*$ is called a chain homotopy equivalence between C_* and D_*, if it admits a chain homotopy inverse, i.e. a chain map $g\colon D_* \to \mathrm{C}_*$ with $g\circ f \simeq \mathrm{id}_{C_*}$ and $f\circ g \simeq \mathrm{id}_{D_*}$.

(2) If there exists a chain homotopy equivalence between C_* and D_*, then we say that the chain complexes C_* and D_* are chain homotopy equivalent and we write $C_* \simeq D_*$.

Lemma 73.3. The relation "homotopy equivalence" of chain complexes is indeed an equivalence relation on the class of all chain complexes.

Proof. This statement follows easily from the definitions.We fill in the details in Exercise 73.2. ■

For later we record the following straightforward corollary to Lemma 73.2.

Corollary 73.4. If $f\colon C_* \to D_*$ is a chain homotopy equivalence between chain complexes, then the induced maps $f_*\colon \mathrm{H}_n(C) \to \mathrm{H}_n(D)$ are isomorphisms.

Proof. Let $g\colon D_* \to C_*$ be a chain homotopy inverse to f. Then we see that

$$g_* \circ f_* \quad = \quad (g\circ f)_* \quad \underset{\uparrow}{=} \quad (\mathrm{id}_{C_*})_* \quad = \quad \mathrm{id}_{\mathrm{H}_n(C)}\,.$$

by Lemma 73.2 since $g\circ f$ is chain homotopic to the identity

The same way we see that $f_* \circ g_* = \mathrm{id}_{\mathrm{H}_n(D)}$. ■

We also record the following useful little lemma.

Lemma 73.5. Let $(\mathrm{C}_*, \partial_*)$ be a chain complex. If there exist "diagonal" maps P_n, $n \in \mathbb{Z}_{\geq -1}$, to obtain a diagram[877]

$$\begin{array}{ccccccccccccc}
\ldots & \longrightarrow & C_3 & \xrightarrow{\partial_3} & C_2 & \xrightarrow{\partial_2} & C_1 & \xrightarrow{\partial_1} & C_0 & \xrightarrow{\partial_0} & 0 \\
 & \swarrow^{P_3} & \downarrow{\scriptstyle \mathrm{id}} & \swarrow^{P_2} & \downarrow{\scriptstyle \mathrm{id}} & \swarrow^{P_1} & \downarrow{\scriptstyle \mathrm{id}} & \swarrow^{P_0} & \downarrow{\scriptstyle \mathrm{id}} & & \\
\ldots & \longrightarrow & C_3 & \xrightarrow[\partial_3]{} & C_2 & \xrightarrow[\partial_2]{} & C_1 & \xrightarrow[\partial_1]{} & C_0 & \xrightarrow[\partial_0]{} & 0
\end{array}$$

such that for every $n \in \mathbb{N}_0$ we have the equality

$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; \mathrm{id}_{\mathrm{C}_n},$$

then all homology groups of $(\mathrm{C}_*, \partial_*)$ vanish.

Proof. Let D_* be the zero chain complex and for each $n \in \mathbb{N}_0$ let $f_n\colon \mathrm{C}_n \to D_n = 0$ be the trivial map. Since the homology groups of D_* it suffices, by Corollary 73.4, to show that f_* is a chain homotopy equivalence. For each $n \in \mathbb{N}_0$ let $g_n\colon D_n \to C_n$ be the trivial map.

[877] The diagram has no particular role, except that it shows the domain and the target of the maps P_n and that it is convenient for keeping track of the various maps.

Evidently $f_n \circ g_n = \mathrm{id}_{D_*}$. Thus it remains to show that $g_* \circ f_* \simeq \mathrm{id}_{C_*}$. In other words we need to show that $0 \simeq \mathrm{id}_{C_*}$. But that is exactly what the maps P_n do. ■

73.2. **Homology and homotopic maps.** The name *chain homotopy* introduced in the previous section suggests that this concept is related to the notion of a homotopy between two topological spaces. As we will see shortly, this is indeed the case. For the reader's convenience we recall that if $f, g\colon X \to Y$ are two maps between topological spaces, then a *homotopy between the maps f and g* is a map

$$F\colon X \times [0,1] \to Y,$$

such that

$$F(x,0) = f(x) \text{ and } F(x,1) = g(x) \text{ for all } x \in X.$$

If there exists a homotopy between f and g, then we say that f and g are *homotopic* and we write $f \simeq g$.

Proposition 73.6. (Homotopic Maps-and-Homology Proposition) Let X and Y be two topological spaces and let $f, g\colon X \to Y$ be two maps. If f and g are homotopic, then the following hold:

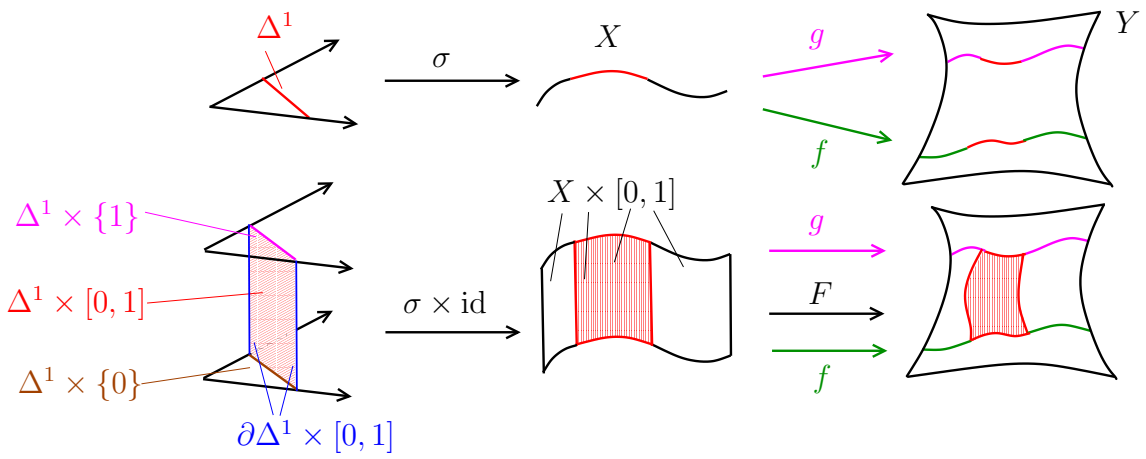
(1) the induced maps f_* and g_* from $\mathrm{C}_*(X)$ to $\mathrm{C}_*(Y)$ are chain homotopic,
(2) for each $n \in \mathbb{N}_0$ we have $f_* = g_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y)$.

Remark. The proposition can be stated more succinctly as follows:

$$f \simeq g\colon X \to Y \quad \Longrightarrow \quad f_* \simeq g_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y) \quad \Longrightarrow \quad f_* = g_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y).$$

We start out with a discussion of the key idea behind the proof of the Homotopic Maps-and-Homology Proposition 73.6. Afterwards we will fill in the details. So let $f, g\colon X \to Y$ be two maps between topological spaces and let $F\colon X \times [0,1] \to Y$ be a homotopy between the maps f and g. Our goal is to find a chain homotopy between f_* and g_*. Thus let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. We need to find $P(\sigma) \in \mathrm{C}_{n+1}(Y)$ and $P(\partial\sigma) \in \mathrm{C}_n(Y)$ such that

$$\partial P(\sigma) \;=\; -P(\partial\sigma) + f_*(\sigma) - g_*(\sigma).$$



Note that $F \circ (\sigma \times \mathrm{id}_{[0,1]})$ defines a map $\Delta^n \times [0,1] \to Y$. Now we can rewrite the above desired equality as follows:

$$\partial P(\sigma) \;=\; -P(\partial\sigma) + \underbrace{\begin{matrix}\text{map } F \circ (\sigma \times \mathrm{id}_{[0,1]}) \\ \text{restricted to } \Delta^n \times \{0\}\end{matrix}}_{=\Delta^n} - \underbrace{\begin{matrix}\text{map } F \circ (\sigma \times \mathrm{id}_{[0,1]}) \\ \text{restricted to } \Delta^n \times \{1\}\end{matrix}}_{=\Delta^n}.$$

To get an idea we consider the figure below. We make the following trivial observation: we have

$$\partial(\Delta^n \times [0,1]) \;=\; \partial\Delta^n \times [0,1] \;\cup\; \Delta^n \times \{0\} \;\cup\; \Delta^n \times \{1\}.$$

Comparing the desired equality of maps and the equality of sets suggests that each map $P_k\colon \mathrm{C}_k(X) \to \mathrm{C}_{k+1}(Y)$ should take the role of replacing a singular k-simplex $\mu\colon \Delta^k \to X$ by the map $F \circ (\mu \times \mathrm{id}_{[0,1]})\colon \Delta^k \times [0,1] \to Y$. This is a good idea, but the problem is that $\Delta^k \times [0,1]$ is not a $(k+1)$-simplex. The idea now is to write $\Delta^k \times [0,1]$ as the union of $(k+1)$-simplices. In the figure below we see for example that we can view $\Delta^1 \times [0,1]$ as the union of the triangles with the vertices v_0, w_0, w_1 respectively v_0, v_1, w_1.
To generalize this observation we have to introduce some more notation.

Notation. Let $n \in \mathbb{N}_0$.

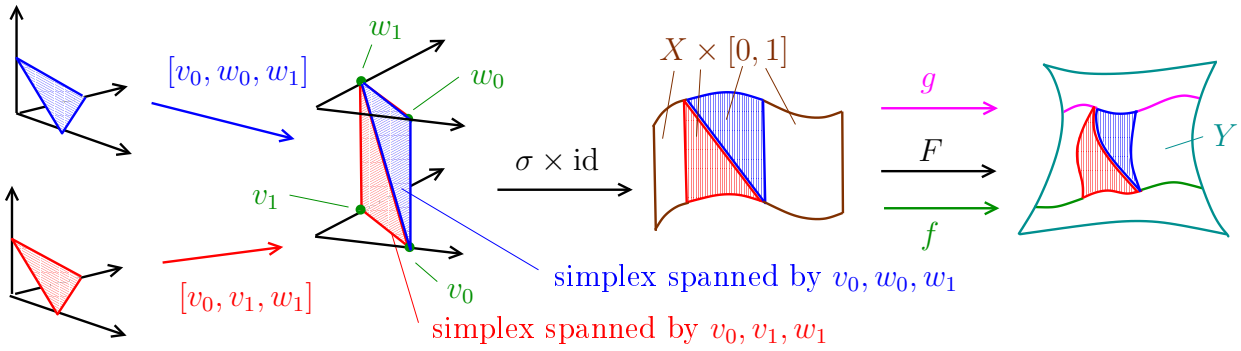
(1) For $i = 0, \ldots, n$ we write

$$v_i := (0, \ldots, 1, 0, \ldots, 0) \times \{0\} \in \mathbb{R}^{n+1} \times \{0\},$$

and

$$w_i := (0, \ldots, 1, 0, \ldots, 0) \times \{1\} \in \mathbb{R}^{n+1} \times \{1\}.$$

The points $v_0, \ldots, v_n$ thus span the simplex $\Delta^n \times 0$ and the points $w_0, \ldots, w_n$ span the simplex $\Delta^n \times 1$. Furthermore for each i the points $v_0, \ldots, v_i, w_i, \ldots, w_n$ span an $(n+1)$-simplex that is a subset of $\Delta^n \times [0,1]$.[878]



(2) For $a_0, \ldots, a_k \in \Delta^n \times [0,1]$ we consider, as on page 1584, the map

$$\begin{aligned} [a_0, \ldots, a_k] \colon \Delta^k &\to \Delta^n \times [0,1] \\ (\lambda_0, \ldots, \lambda_k) &\mapsto \sum_{j=0}^{k} \lambda_j \cdot a_j. \end{aligned}$$

The map $[a_0, \ldots, a_k]$ thus sends the standard k-simplex Δ^k to the simplex spanned by $a_0, \ldots, a_k$ in $\Delta^n \times [0,1]$.

(3) We set

$$\Omega_n := \sum_{j=0}^{n} (-1)^j \cdot \underbrace{[v_0, \ldots, v_j, w_j, \ldots, w_n]}_{\Delta^{n+1} \to \Delta^n \times [0,1]} \in \mathrm{C}_{n+1}(\Delta^n \times [0,1]).$$

[878] It is a straightforward exercise to show that the union of these $(n+1)$-dimensional simplices is precisely $\Delta^n \times [0,1]$. We will not make use of this fact.

In the following lemma we compute the boundary of $\Omega_n \in \mathrm{C}_{n+1}(\Delta^n \times [0,1])$. The statement might not be particularly visually appealing, but it will turn out to be very useful.

Lemma 73.7. (Prism Boundary Lemma) Let $n \in \mathbb{N}_0$. Given $t \in \{0,1\}$ we write

$$\begin{array}{rccc} \eta_t \colon & \Delta^n & \to & \Delta^n \times [0,1] \\ & x & \mapsto & (x,t). \end{array}$$

With this notation we have

$$\partial_{n+1}(\Omega_n) + \sum_{j=0}^{n} (-1)^j \cdot (i_j^n \times \mathrm{id}_{[0,1]})_*\Big(\underbrace{\Omega_{n-1}}_{\in \mathrm{C}_n(\Delta^{n-1}\times[0,1])} \Big) \;=\; \eta_1 - \eta_0 \;\in\; \mathrm{C}_n(\Delta^n \times [0,1]).$$

Proof. The proof of the lemma is basically an elementary, albeit slightly confusing calculation. First note that

$$\begin{aligned} \partial\Omega_n &= \partial\Big(\sum_{j=0}^{n} (-1)^j \cdot [v_0, \dots, v_j, w_j, \dots, w_n] \Big) \\ &= \sum_{k=0}^{n+1} (-1)^k \cdot \sum_{j=0}^{n} (-1)^j \cdot [v_0, \dots, v_j, w_j, \dots, w_n] \circ i_k^{n+1}. \end{aligned}$$

It is straightforward to see that for any $k \in \{0, \dots, n+1\}$ we have[879]

$$[v_0, \dots, v_j, w_j, \dots, w_n] \circ i_k^{n+1} \;=\; \begin{cases} [v_0, \dots, \widehat{v_k}, \dots, v_j, w_j, \dots, w_n], & \text{if } k \le j, \\ [v_0, \dots, v_j, w_j, \dots, \widehat{w_{k-1}}, \dots, w_n], & \text{if } k > j. \end{cases}$$

Thus it follows that[880]

$$\begin{aligned} \partial\Omega_n \;=\; & \sum_{0 \le k \le j \le n} (-1)^k \cdot (-1)^j \cdot [v_0, \dots, \widehat{v_k}, \dots, v_j, w_j, \dots, w_n] \\ & + \sum_{n+1 \ge k > j \ge 0} (-1)^k \cdot (-1)^j \cdot [v_0, \dots, v_j, w_j, \dots, \widehat{w_{k-1}}, \dots, w_n]. \end{aligned}$$

Now we split the first sum into the cases $k = j$ and $k < j$ and we split the second sum into the cases $k = j+1$ and $k > j+1$. This leads us to the following equality:

$$\begin{aligned} \partial\Omega_n \;=\; & \sum_{k=0}^{n} (-1)^{2k} \cdot [v_0, \dots, v_{k-1}, w_k, \dots, w_n] \\ & + \sum_{k=1}^{n+1} (-1)^{2k+1} \cdot [v_0, \dots, v_{k-1}, w_k, \dots, w_n] \\ & + \sum_{0 \le k < j \le n} (-1)^k \cdot (-1)^j \cdot [v_0, \dots, \widehat{v_k}, \dots, v_j, w_j, \dots, w_n] \\ & + \sum_{n+1 \ge k > j+1 \ge 1} (-1)^k \cdot (-1)^j \cdot [v_0, \dots, v_j, w_j, \dots, \widehat{w_{k-1}}, \dots, w_n]. \end{aligned}$$

[879] The first case, $k \le j$ is slightly easier: one has to figure out, where the h-th vertex e_h of the standard n-simplex gets sent to. If $h < k$, then i_k^{n+1} sends the h-th vertex again to the h-th vertex, and $[v_0, \dots, v_j, w_j, \dots, w_n]$ sends this vertex to v_h. If $h \ge k$, then i_k^{n+1} sends the h-th vertex again to the $(h+1)$-th vertex, and $[v_0, \dots, v_j, w_j, \dots, w_n]$ sends this vertex to v_{h+1}. If $k \le j$ this corresponds just to the map $[v_0, \dots, \widehat{v_k}, \dots, v_j, w_j, \dots, w_n]$.
The second case, $k > j$ is proved precisely the same way.

[880] Here we use the usual notation that $\widehat{v_k}$ means that we do not plug in $\widehat{v_k}$, the same applies to $\widehat{w_{k-1}}$.

Next we consider the first two sums. The summands cancel each other, except for the summands for $k = 0$ and $k = n + 1$. Thus we obtain that

$$
\begin{aligned}
\partial\Omega_n \;&=\; [w_0, \ldots, w_n] - [v_0, \ldots, v_n] \\
(*) \qquad &+ \sum_{0 \le k < j \le n} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, \widehat{v_k}, \ldots, v_j, w_j, \ldots, w_n] \\
&+ \sum_{n+1 \ge k > j+1 \ge 1} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, v_j, w_j, \ldots, \widehat{w_k}, \ldots, w_n].
\end{aligned}
$$

The first summand is just η_1 and the second is $-\eta_0$. It remains to show that the remaining summand corresponds to the remaining term in the formula. Thus we continue our proof with the discussion of the one term in the statement of the lemma that we have not studied yet. We have[881]

$$
\sum_{j=0}^{n} (-1)^j \cdot (i_j^n \times \mathrm{id}_{[0,1]})_*(\Omega_{n-1}) = \sum_{r=0}^{n} \sum_{s=0}^{n-1} (-1)^r \cdot (-1)^s \cdot (i_r^n \times \mathrm{id}_{[0,1]}) \circ [v_0, \ldots, v_s, w_s, \ldots, w_{n-1}].
$$

$\uparrow$ definition of $(i_j^n \times \mathrm{id}_{[0,1]})_*$ and substitution $r = j$

It follows from an elementary (but arguably confusing) argument, using only the definitions, that we have the following equalities of maps $\Delta^n \to \Delta^n \times [0,1]$:

$$
(i_r^n \times \mathrm{id}_{[0,1]}) \circ [v_0, \ldots, v_s, w_s, \ldots, w_{n-1}] \;=\; \begin{cases} [v_0, \ldots, \widehat{v_r}, \ldots, v_{s+1}, w_{s+1}, \ldots, w_n], & \text{if } r \le s, \\ [v_0, \ldots, v_s, w_s, \ldots, \widehat{w_{r+1}}, \ldots, w_n], & \text{if } r > s. \end{cases}
$$

Thus we see that

$$
\begin{aligned}
\sum_{j=0}^{n} (-1)^j \cdot (i_j^n \times \mathrm{id}_{[0,1]})_*(\Omega_{n-1}) \;&=\; \sum_{0 \le r \le s \le n-1} (-1)^s \cdot (-1)^r \cdot [v_0, \ldots, \widehat{v_r}, \ldots, v_{s+1}, w_{s+1}, \ldots, w_n] \\
&+ \sum_{n \ge r > s \ge 0} (-1)^s \cdot (-1)^r \cdot [v_0, \ldots, v_s, w_s, \ldots, \widehat{w_{r+1}}, \ldots, w_n].
\end{aligned}
$$

In the first term we perform the substitutions $r = k$ and $s = j - 1$ and in the second term we perform the substitutions $r = k - 1$, $s = j$. We obtain the following equality:

$$
\begin{aligned}
\sum_{j=0}^{n} (-1)^j \cdot (i_j^n \times \mathrm{id}_{[0,1]})_*(\Omega_{n-1}) \;&=\; \sum_{0 \le k \le j-1 \le n-1} (-1)^{j-1} \cdot (-1)^k \cdot [v_0, \ldots, \widehat{v_k}, \ldots, v_j, w_j, \ldots, w_n] \\
&+ \sum_{n \ge k-1 > j \ge 0} (-1)^j \cdot (-1)^{k-1} \cdot [v_0, \ldots, v_j, w_j, \ldots, \widehat{w_k}, \ldots, w_n].
\end{aligned}
$$

We see immediately that these terms are just the negatives of the corresponding terms in the above equation $(*)$. ∎

The following lemma implies in particular the first statement of the Homotopic Maps-and-Homology Proposition 73.6. The second statement of the Homotopic Maps-and-Homology Proposition 73.6 regarding the induced maps on homology follows immediately from the first statement together with Lemma 73.2. In other words, the following lemma completes the proof of the Homotopic Maps-and-Homology Proposition 73.6.

[881] Here $v_0, \ldots, v_{n-1}, w_0, \ldots, w_{n-1}$ are now, unfortunately somewhat confusingly, the corresponding vertices of $\Delta^{n-1} \times [0,1]$.

Lemma 73.8. Let X be a topological space and let $F\colon X \times [0,1] \to Y$ be a homotopy from a map f to a map g. Given any $n \in \mathbb{N}_0$ we define

$$\begin{array}{rcl} P_n\colon \mathrm{C}_n(X) & \to & \mathrm{C}_{n+1}(Y) \end{array}$$

to be the map that is induced by

$$\begin{array}{rcl} (\sigma\colon \Delta^n \to X) & \mapsto & (F \circ (\sigma \times \mathrm{id}_{[0,1]}))_*(\Omega_n). \end{array}$$

Then for any $n \in \mathbb{N}_0$ we have

$$\partial P_n + P_{n-1}\partial \;=\; g_* - f_*$$

as maps from $\mathrm{C}_n(X)$ to $\mathrm{C}_n(Y)$.

Proof. Let X be a topological space and let $F\colon X \times [0,1] \to X$ be a homotopy from a map f to a map g. Furthermore let $\sigma\colon \Delta^n \to X$ be a singular k-simplex. Then

$$\begin{aligned} (\partial P_n + P_{n-1}\partial)(\sigma) \;&=\; \partial(P_n(\sigma)) + P_{n-1}\Big(\sum_{j=0}^{n}(-1)^j \cdot \sigma \circ i_j^n\Big) \;=\; \partial(P_n(\sigma)) + \sum_{j=0}^{n}(-1)^j \cdot P_{n-1}(\sigma \circ i_j^n) \\ &=\; \partial((F \circ (\sigma \times \mathrm{id}_{[0,1]}))_*(\Omega_n)) + \sum_{j=0}^{n}(-1)^j \cdot (F \circ (\sigma \circ_j^n \times \mathrm{id}_{[0,1]}))_*(\Omega_{n-1}) \\ &=\; (F \circ (\sigma \times \mathrm{id}_{[0,1]}))_*\Big(\partial(\Omega_n)) + \sum_{j=0}^{n}(-1)^j \cdot (i_j^n \times \mathrm{id}_{[0,1]})_*(\Omega_{n-1})\Big) \\ &\quad\uparrow \\ &\quad\text{by Lemma 72.9 (1) and since } (\sigma \times \mathrm{id}) \circ (i_j^n \times \mathrm{id}) = (\sigma \circ i_j^n) \times \mathrm{id} \\ &=\; (F \circ (\sigma \times \mathrm{id}_{[0,1]}))_*(\eta_1 - \eta_0) \;\underset{\uparrow}{=}\; f \circ \sigma - g \circ \sigma \;=\; g_*(\sigma) - f_*(\sigma). \end{aligned}$$

Prism Boundary Lemma 73.7 — since F is a homotopy from f to g ∎

We recall the following definition from page 430.

Definition. Let X and Y be topological spaces.

(1) A map $f\colon X \to Y$ is a homotopy equivalence between X and Y, if there exists a homotopy inverse to f, i.e. if there exists a continuous map $g\colon Y \to X$ with $g \circ f \simeq \mathrm{id}_X$ and $f \circ g \simeq \mathrm{id}_Y$.

(2) If there exists a homotopy equivalence between X and Y, then we say that the topological spaces X and Y are homotopy equivalent and we write $X \simeq Y$.

(3) We say X is contractible, if X is homotopy equivalent to $Y = \{*\}$, i.e. if X is homotopy equivalent to a topological space which consists of precisely one point.

Now we obtain the following corollary to the Homotopic Maps-and-Homology Proposition 73.6. This corollary mirrors the fact, proved in Propositions 50.3 (2) and 71.7 (2), that homotopy equivalences induce isomorphisms of fundamental groups and higher homotopy groups.

Corollary 73.9. (Homotopy Equivalence-H_*-Corollary) Let X and Y be topological spaces and let $n \in \mathbb{N}_0$.

(1) If $f\colon X \to Y$ is a homotopy equivalence (e.g. a homeomorphism), then the induced map $f_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y)$ is an isomorphism.

(2) If X and Y are homotopy equivalent, then $\mathrm{H}_n(X) \cong \mathrm{H}_n(Y)$.

(3) If X is contractible, then $\mathrm{H}_0(X) \cong \mathbb{Z}$ and $\mathrm{H}_n(X) = 0$ for $n \geq 1$.

(4) If X is a deformation retract of Y, then the inclusion induced map $\mathrm{H}_n(X) \to \mathrm{H}_n(Y)$ is an isomorphism.

Proof.

(1) Let $f\colon X \to Y$ be a homotopy equivalence and let $g\colon Y \to X$ be a homotopy inverse of f, i.e. g is a map such that $f \circ g \simeq \mathrm{id}_Y$ and $g \circ f \simeq \mathrm{id}_X$. It follows from the Homotopic Maps-and-Homology Proposition 73.6 and the functoriality of homology that $f_* \circ g_* = (f \circ g)_* = \mathrm{id}_{\mathrm{H}_n(Y)}$ and similarly $g_* \circ f_* = \mathrm{id}_{\mathrm{H}_n(X)}$. But that means precisely that $f_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y)$ is an isomorphism.

(2) This statement follows immediately from (1).

(3) This statement follows immediately from (2) and the Single Point-Homology Lemma 72.6.

(4) This statement follows immediately from (1) and the Deformation Retract-Homotopy Equivalence Lemma 15.5. ■

Examples.

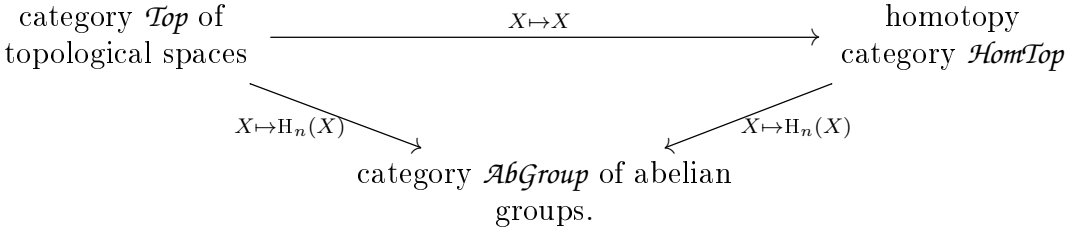
(1) On page 432 we saw that every convex subset of $\mathbb{R}^n$, e.g. the open disk B^n, the closed disk $\overline{B}^n$, any simplex or $\mathbb{R}^n$, is contractible. Thus it follows from the Homotopy Equivalence-H_*-Corollary 73.9, that

$$\mathrm{H}_i(\text{convex subset of } \mathbb{R}^n) \;\cong\; \mathrm{H}_i(B^n) \;\cong\; \mathrm{H}_i(\overline{B}^n) \;\cong\; \mathrm{H}_i(\mathbb{R}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0, \\ 0, & \text{if } i > 0. \end{cases}$$

(2) In Exercise 73.3 we will use the Homotopy Equivalence-H_*-Corollary 73.9 to show that if A is a compact convex subset of $\mathbb{R}^n$ and if x is a point in the interior of A, then the inclusion $\mathbb{R}^n \setminus A \to \mathbb{R}^n \setminus \{x\}$ induces isomorphisms $\mathrm{H}_i(\mathbb{R}^n \setminus A) \to \mathrm{H}_i(\mathbb{R}^n \setminus \{x\})$ for all i.

Remark. Given a map $f\colon X \to Y$ between topological spaces we denote by $[f]$ the homotopy equivalence class of f, and we denote by $[X, Y]$ the set of equivalence classes of maps from X to Y. As we pointed out on page 441,

$$\begin{aligned} \mathrm{Ob}(\mathcal{HomTop}) &:= \text{ all topological spaces,} \\ \mathrm{Mor}(X, Y) &:= [X, Y] \end{aligned}$$



together with the composition

$$\begin{aligned} \mathrm{Mor}(X, Y) \times \mathrm{Mor}(Y, Z) &\to \mathrm{Mor}(X, Z) \\ ([f], [g]) &\mapsto [g \circ f] \end{aligned}$$

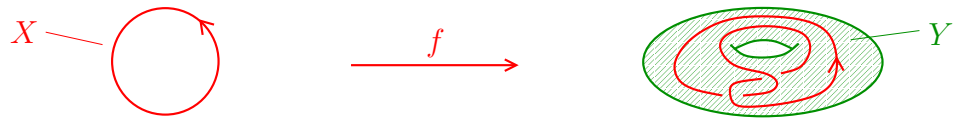
defines a category $\mathcal{HomTop}$, called the *homotopy category*. the Homotopic Maps-and-Homology Proposition 73.6 thus says that for each $n \in \mathbb{N}_0$ the maps

$$\begin{aligned} X &\mapsto \mathrm{H}_n(X) \\ \text{and} \qquad [f] &\mapsto (f_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y)) \end{aligned}$$

define a functor from the category $\mathcal{HomTop}$ to the category $\mathcal{AbGroup}$ of abelian groups. In particular we now have the following commutative diagram of categories and functors:

Exercises for Chapter 73.

Exercise 73.1. Let C_* and D_* be two chain complexes.



(a) Show that chain homotopy defines an equivalence relation on the set of all chain maps from C_* to D_*.

(b) Let $f, g\colon C_* \to D_*$ be chain maps, and let $e\colon B_* \to \mathrm{C}_*$ and $h\colon D_* \to E_*$ be two other chain maps. Show that if $f \simeq g$, then $f \circ e \simeq g \circ e$ and $h \circ f \simeq h \circ g$.

Exercise 73.2. Show that the relation "homotopy equivalence" of chain complexes is indeed an equivalence relation on the class of all chain complexes.

Exercise 73.3. Let A be a compact convex subset of $\mathbb{R}^n$ and let $x \in A$ be a point. Show that the inclusion $\mathbb{R}^n \setminus A \to \mathbb{R}^n \setminus \{x\}$ induces isomorphisms $\mathrm{H}_i(\mathbb{R}^n \setminus A) \to \mathrm{H}_i(\mathbb{R}^n \setminus \{x\})$ for all i.
Hint. Use Exercise 15.5.

Exercise 73.4. Let $X = S^1$ and let $Y = \overline{B}^2 \times S^1$. We consider the map $f\colon X \to Y$ shown in the figure below. Show that for every $i \in \mathbb{N}$ the induced map $f_*\colon \mathrm{H}_i(X) \to \mathrm{H}_i(Y)$ is the zero map.

74. The Excision Theorem

In this section, given a topological space X and a "good" subset A we will relate the homology groups of X, A and the quotient space X/A via a long exact sequence. We will use this long exact sequence to fulfill our dream of calculating the homology groups of all spheres. Unfortunately it will take a very long time to prove the existence of this long exact sequence.

74.1. **Reduced homology groups.** In this section we introduce the reduced homology groups of a topological space. These are a minute but at times surprisingly useful variation on the usual homology groups.

Definition. Let X be a topological space. By Lemma 72.4 (1) we know that the following is a generalized[882] chain complex

$$\begin{array}{ccccccccccc} & & & & & & \text{degree } 0 & & \text{degree } -1 & & \\ & & & & & & \downarrow & & \downarrow & & \\ \ldots & \xrightarrow{\partial_3} & \mathrm{C}_2(X) & \xrightarrow{\partial_2} & \mathrm{C}_1(X) & \xrightarrow{\partial_1} & \mathrm{C}_0(X) & \xrightarrow{\epsilon} & \mathbb{Z} & \to & 0. \\ & & & & & & \sum_{i=1}^k r_i \cdot \sigma_i & \mapsto & \sum_{i=1}^k r_i & & \end{array}$$

augmentation map from page 1590

We introduce the following three definitions.

(1) We refer to this chain complex as the augmented chain complex $\widetilde{\mathrm{C}}_*(X)$ of X.
(2) Given $n \in \mathbb{Z}_{\geq -1}$ we define the n-th reduced homology group $\widetilde{\mathrm{H}}_n(X)$ of X to be the n-th homology group of the augmented chain complex.
(3) If $f\colon X \to Y$ is a map between topological spaces we denote by $f_*\colon \widetilde{\mathrm{C}}_*(X) \to \widetilde{\mathrm{C}}_*(Y)$ the map that is the usual map on $\widetilde{\mathrm{C}}_n(X) = \mathrm{C}_n(X)$ for $n \geq 0$ and that is the identity on the final $\mathbb{Z}$-term.

The following elementary lemma summarizes a few properties of reduced homology groups.

Lemma 74.1. (Reduced Homology Lemma)

(0) Given a topological space X we have[883]

$$\widetilde{\mathrm{H}}_{-1}(X) = \begin{cases} 0, & \text{if } X \neq \varnothing, \\ \mathbb{Z}, & \text{if } X = \varnothing. \end{cases}$$

(1) If $f\colon X \to Y$ is a map between two topological spaces, then the induced maps $f_*\colon \widetilde{\mathrm{C}}_*(X) \to \widetilde{\mathrm{C}}_*(Y)$ are chain maps. In particular we see that for each $n \in \mathbb{Z}_{\geq -1}$ we get a well-defined induced map $f_*\colon \widetilde{\mathrm{H}}_n(X) \to \widetilde{\mathrm{H}}_n(Y)$.
(2) For every $n \in \mathbb{Z}_{\geq -1}$ the maps

$$\begin{array}{rcl} X & \mapsto & \widetilde{\mathrm{H}}_n(X) \\ (f\colon X \to Y) & \mapsto & (f_*\colon \widetilde{\mathrm{H}}_n(X) \to \widetilde{\mathrm{H}}_n(Y)) \end{array}$$

define a functor from the category of topological spaces to the category of abelian groups.

[882] Recall that a generalized chain complex is like a chain complex, but we also allow non-zero groups in negative degrees.

(3) For each $n \in \mathbb{Z}_{\geq -1}$ the maps

$$\begin{array}{rcl} \text{ж}\colon \widetilde{\mathrm{H}}_n(X) & \to & \mathrm{H}_n(X) \\ [\sigma] & \mapsto & [\sigma] \end{array}$$

are well-defined. Furthermore they define a natural transformation from the functor $X \mapsto \widetilde{\mathrm{H}}_n(X)$ to the functor $X \mapsto \mathrm{H}_n(X)$.

(4) For every topological space X the following statements hold:

(a) Given any point $P \in X$ the map

$$\begin{array}{rcl} \widetilde{\mathrm{H}}_0(X) \oplus \mathbb{Z} & \to & \mathrm{H}_0(X) \\ [\sigma] \oplus n & \mapsto & [\sigma] + [n \cdot P] \end{array}$$

is an isomorphism.

(b) For every $n \geq 1$ the natural map $\text{ж}\colon \widetilde{\mathrm{H}}_n(X) \to \mathrm{H}_n(X)$ is the identity.

(5) If X is a topological space with $n \in \mathbb{N}$ path-components, then $\widetilde{\mathrm{H}}_0(X) \cong \mathbb{Z}^{n-1}$. In particular X is path-connected if and only if $\widetilde{\mathrm{H}}_0(X) = 0$.

(6) The statements of the Homotopy Equivalence-H_*-Corollary 73.9 (1), (2) and (4) also hold the same way for reduced homology groups and the corresponding induced maps. For example, if X is a deformation retract of some topological space Y, then the inclusion induced maps $\widetilde{\mathrm{H}}_k(X) \to \widetilde{\mathrm{H}}_k(Y)$ are isomorphisms for all $k \in \mathbb{Z}_{\geq -1}$.

(7) If X is a contractible topological space, then $\widetilde{\mathrm{H}}_k(X) = 0$ for all $k \in \mathbb{Z}_{\geq -1}$.

The lemma shows in particular that reduced homology groups are almost the same as the usual homology groups. So it might sound slightly silly to introduce them. But we will see that on several occasions reduced homology groups make it easier to formulate some statements.

Remark.

(1) If X is a non-empty topological space, then it follows from the Reduced Homology Lemma 74.1 (4) that we have isomorphisms

$$\mathrm{H}_n(X) \;\cong\; \begin{cases} \widetilde{\mathrm{H}}_0(X) \oplus \mathbb{Z}, & \text{if } n = 0, \\ \widetilde{\mathrm{H}}_n(X), & \text{if } n \neq 0. \end{cases}$$

Furthermore, by the Reduced Homology Lemma 74.1 (3) we know that for $n \geq 1$ the isomorphism is natural. On other hand for $n = 0$ the isomorphism depends on the choice of a point.

(2) In Lemma 74.2 we will formulate a useful variation on the Reduced Homology Lemma 74.1 (3).

(3) By the Reduced Homology Lemma 74.1 (7) we know for any $k \in \mathbb{N}_0$ and any $n \in \mathbb{Z}_{\geq -1}$ we have

$$\widetilde{\mathrm{H}}_n(\Delta^k) \;=\; \widetilde{\mathrm{H}}_n(B^k) \;=\; \widetilde{\mathrm{H}}_n(\overline{B}^k) \;=\; \widetilde{\mathrm{H}}_n(\mathbb{R}^k) \;=\; 0.$$

(4) We will often use the Reduced Homology Lemma 74.1 without explicitly mentioning it. For example we will refer to earlier results about homology groups and state the corresponding results for reduced homology groups.

[883] This calculation shows that in almost all cases we can ignore $\widetilde{\mathrm{H}}_{-1}(X)$. Nonetheless, some formulas later on become cleaner if we take into account that $\widetilde{\mathrm{H}}_{-1}(\varnothing) = \mathbb{Z}$.

Proof.

(0) First let X be a non-empty topological space. It follows immediately from the definitions that the augmentation map ϵ is an epimorphism which entails that $\widetilde{\mathrm{H}}_{n-1}(X) = 0$. The fact that $\widetilde{\mathrm{H}}_{-1}(\varnothing) = \mathbb{Z}$ is clear.

(1) Let $f\colon X \to Y$ be a map between two topological spaces. It is a straightforward consequence of the definition of the augmentation maps that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{C}_0(X) & \xrightarrow{\quad f_* \quad} & \mathrm{C}_0(Y) \\ & {\scriptstyle\epsilon}\searrow \quad \swarrow{\scriptstyle\epsilon} & \\ & \mathbb{Z}. & \end{array}$$

It follows almost immediately from the fact that this diagram commutes that the induced maps $f_*\colon \widetilde{\mathrm{C}}_*(X) \to \widetilde{\mathrm{C}}_*(Y)$ are chain maps. Furthermore we obtain from Lemma 72.7 that we get induced maps on reduced homology.

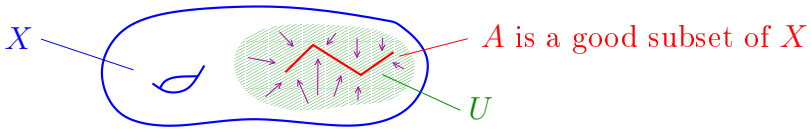
(2) This statement is basically obvious.

(3) This statement follows easily from the definitions.

(4) Let X be a topological space. By the definition of $\widetilde{\mathrm{H}}_n(X)$ we only have to deal with the case $n = 0$. Let $P \in X$ be a point. It is straightforward to show that the maps

$$\begin{array}{rcl} \widetilde{\mathrm{H}}_0(X) \oplus \mathbb{Z} & \to & \mathrm{H}_0(X) \\ [\sigma] \oplus n & \mapsto & [\sigma] + [n \cdot P] \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{H}_0(X) & \to & \widetilde{\mathrm{H}}_0(X) \oplus \mathbb{Z} \\ [\sigma] & \mapsto & [\sigma - \epsilon_X(\sigma) \cdot P] + \epsilon_X(\sigma) \end{array}$$

are inverses of one another. In particular both maps are isomorphisms.



(5) This statement follows immediately from (1), Corollary 72.15 and Lemma 51.9 (4).

(6) This statement is proved exactly the same way as the Homotopy Equivalence-H_*-Corollary 73.9.

(7) This final statement follows immediately from (5) and (6). ∎

74.2. **Long exact sequences.** We need two more definitions before we can formulate one of the key theorems of homology theory.

Definition. Let X be a topological space and let $A \subset X$ be a subset. We say A is good if A is closed and if there exists an open neighborhood U of A in X such that A is a deformation retract of U.

Remark. Our definition of a good subset is the same as on [**Hat2002**, p. 114], except that we do not demand that a good subset is non-empty.

Examples.

(1) Let $x \in X$ be a point. Basically by definition the subset $\{x\} \subset X$ is good in the above sense if and only the point is good in the sense of the definition on page 1171.

(2) The sphere S^{n-1} is a good subset of the closed ball $\overline{B}^n$. Indeed, it is clear that S^{n-1} is a closed subset. Furthermore, if we consider the open neighborhood $U = \overline{B}^n \setminus \{0\}$,

then a deformation retraction is given by the map

$$\begin{array}{rcl}(\overline{B}^n \setminus \{0\}) \times [0,1] & \to & \overline{B}^n \setminus \{0\} \\ (x,t) & \mapsto & \left(1 - t \cdot \frac{1-\|x\|}{\|x\|}\right) \cdot x.\end{array}$$

(3) We can generalize the second example: It follows easily from the Smooth Manifold Boundary Proposition 19.26 (3) and the Smooth Collar Neighborhood Theorem 28.3 that every boundary component of a smooth manifold is good.
(4) Finally it follows from the Subcomplex Lemma 68.18 (2) and the CW-Complex Properties Proposition 68.10 (8a) that every subcomplex A of a CW-complex X is good.

The following definition might be familiar from earlier algebra courses.

Definition. A sequence of group homomorphisms

$$\ldots A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \to \ldots$$

is called exact, if for each n we have

$$\ker(f_n) = \operatorname{im}(f_{n+1}).$$

Example. Let A and B be abelian groups. The sequence

$$0 \to A \xrightarrow{a \mapsto (a,0)} A \oplus B \xrightarrow{(a,b) \mapsto b} B \to 0$$

is easily seen to be exact.

Remark. We collect a few basic statements about exact sequences which we will use frequently.

(1) In any exact sequence the composition of two consecutive maps is necessarily zero.
(2) We have the following equivalences of statements:

$$\begin{array}{rcl}\text{the sequence } 0 \to A \xrightarrow{f} B \text{ is exact} & \iff & f \text{ is injective} \\ \text{the sequence } A \xrightarrow{f} B \to 0 \text{ is exact} & \iff & f \text{ is surjective} \\ \text{the sequence } 0 \to A \xrightarrow{f} B \to 0 \text{ is exact} & \iff & f \text{ is an isomorphism.}\end{array}$$

(3) Sometimes we also use the following observations:

$$\begin{array}{rcl}\text{the sequence } 0 \to A \to B \xrightarrow{f} C \text{ is exact} & \implies & A \cong \ker(f) \\ \text{the sequence } A \xrightarrow{f} B \to C \to 0 \text{ is exact} & \implies & C \cong \operatorname{coker}(f).\end{array}$$

The following lemma gives us the first slightly interesting example of an exact sequence.

Lemma 74.2. If X is a non-empty topological space, then the natural sequence

$$0 \to \widetilde{\mathrm{H}}_0(X) \xrightarrow{\text{ж}} \mathrm{H}_0(X) \xrightarrow[\text{from Lemma 72.4}]{\text{augmentation map } \epsilon_X} \mathbb{Z} \to 0$$

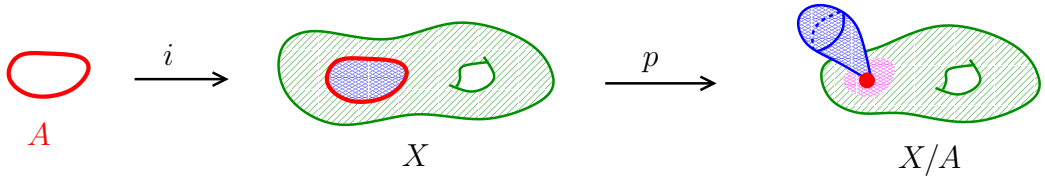
is exact.

Proof. Let $P \in X$ be a point. We consider the following diagram:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \widetilde{\mathrm{H}}_0(X) & \xrightarrow{\text{ж}} & \mathrm{H}_0(X) & \xrightarrow{\epsilon_X} & \mathbb{Z} & \longrightarrow & 0 \\ & & & \searrow^{v\mapsto(v,0)} & \cong\uparrow{\scriptstyle (v,n)\mapsto(\text{ж}(v),[n\cdot P])} & & \nearrow_{(v,n)\mapsto n} & & \\ & & & & \widetilde{\mathrm{H}}_0(X)\oplus\mathbb{Z} & & & & \end{array}$$

We make the following observations:

(1) It follows immediately from the definitions that the diagram commutes.
(2) By the Reduced Homology Lemma 74.1 (4) we know that the vertical map is an isomorphism.
(3) The "bottom sequence" via $\widetilde{\mathrm{H}}_0(X)\oplus\mathbb{Z}$ is precisely of the form of the above example, i.e. this sequence is exact.
(4) It follows easily from the above that the original sequence is also exact. ■



Now we can formulate the following theorem.

Theorem 74.3. Let X be a topological space and let $A \subset X$ be a good subset.[884] We denote by $i\colon A \to X$ the inclusion map and we denote by $p\colon X \to X/A$ the projection . For each $n \in \mathbb{N}_0$ there exists a natural[885] homomorphism $\partial\colon \widetilde{\mathrm{H}}_n(X/A) \to \widetilde{\mathrm{H}}_{n-1}(A)$ such that the sequence

$$\begin{array}{ccccccccc} & & & & \ldots & \xrightarrow{p_*} & \widetilde{\mathrm{H}}_{n+1}(X/A) & \xrightarrow{\partial} & \\ \to & \widetilde{\mathrm{H}}_n(A) & \xrightarrow{i_*} & \widetilde{\mathrm{H}}_n(X) & \xrightarrow{p_*} & \widetilde{\mathrm{H}}_n(X/A) & \xrightarrow{\partial} & & \\ \to & \widetilde{\mathrm{H}}_{n-1}(A) & \xrightarrow{i_*} & \ldots & & & & & \end{array}$$

is exact.

Example. In the figure below we show a topological space X together with a good subset A and we show the inclusion map $i\colon A \to X$ and the projection $p\colon X \to X/A$. Theorem 74.3 relates the (reduced) homology groups of A, X and X/A in a mysterious way.

Remark.

(1) In Exercise 74.19 we will see that in general the conclusion of Theorem 74.3 does not hold, if we do not assume that A is a good subset.
(2) If A is non-empty, then it follows from the Reduced Homology Lemma 74.1 that the last term that is possibly non-zero is $\widetilde{\mathrm{H}}_0(X/A)$.

[884] The most common situation is that X is a CW-complex and that A is a subcomplex.

[885] Here natural means the following: If $f\colon (X,A) \to (Y,B)$ is a map between pairs of topological spaces and if A and B are good subsets, then the following diagram commutes:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_n(X/A) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{n-1}(A) \\ {\scriptstyle f_*}\downarrow & & \downarrow{\scriptstyle f_*} \\ \widetilde{\mathrm{H}}_n(Y/B) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{n-1}(B). \end{array}$$

It will take a while to prove Theorem 74.3. Therefore we will first consider several applications which will convince us that proving Theorem 74.3 is worth the effort.

74.3. **The homology groups of spheres.** Using Theorem 74.3 we can now determine the homology groups of spheres and we get a nice and satisfactory result.

Proposition 74.4. For each $n \in \mathbb{Z}_{\geq -1}$ we have

$$\widetilde{\mathrm{H}}_k(S^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}$$

Remark.

(1) Put differently, the combination of the Reduced Homology Lemma 74.1 and Proposition 74.4 says that for any $n > 0$ we have

$$\mathrm{H}_k(S^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0 \text{ or } k = n, \text{ and} \\ 0, & \text{if } k \neq 0, n. \end{cases}$$

Furthermore we have

$$\mathrm{H}_k(S^0) \;\cong\; \begin{cases} \mathbb{Z}^2, & \text{if } k = 0, \text{ and} \\ 0, & \text{if } k \neq 0. \end{cases}$$

(2) Note that the statement of Proposition 74.4 is in marked contrast to the situation for higher homotopy groups. As formulated in Question 71.18 we have the strong suspicion that $\pi_3(S^2) \neq 0$.

By the Smooth Manifold-Dimension Proposition 19.28 we know that for $k \neq l$ the spheres S^k and S^l are not diffeomorphic. The following corollary is a serious upgrade of this fact.

Corollary 74.5. For $k \neq l$ the spheres S^k and S^l are not homeomorphic.

So we have finally managed to distinguish spheres of different dimensions. Our initial idea had been to use higher homotopy groups to prove that result. Even though the definition of higher homotopy groups is arguably much more natural than the definition of homology groups, it turns out that the latter groups are significantly easier to compute.

Proof of Proposition 74.4 assuming Theorem 74.3. We prove the proposition by induction on n. First note that for $n = -1$ we have $S^n = S^{-1} = \varnothing$, thus the statement follows immediately from the Reduced Homology Lemma 74.1 (0).[886]

Now we suppose that the statement of the proposition holds for $n - 1$. We want to determine the reduced homology of S^n. In the Ball-Quotient Sphere Lemma 5.20 we had shown that S^n is homeomorphic to $\overline{B}^n/S^{n-1}$. We had just seen on page 1614 that S^{n-1} is a good subset of $\overline{B}^n$. Therefore we can apply Theorem 74.3 to $X = \overline{B}^n$ and the closed subset $A = S^{n-1}$ and we obtain the following exact sequence

$$\begin{array}{rcccccc} & \ldots & \longrightarrow & \widetilde{\mathrm{H}}_{k+1}(\overline{B}^n) & \xrightarrow{p_*} & \widetilde{\mathrm{H}}_{k+1}(\overline{B}^n/S^{n-1}) & \xrightarrow{\partial} \\ \to & \widetilde{\mathrm{H}}_k(S^{n-1}) & \xrightarrow{i_*} & \widetilde{\mathrm{H}}_k(\overline{B}^n) & \xrightarrow{p_*} & \widetilde{\mathrm{H}}_k(\overline{B}^n/S^{n-1}) & \xrightarrow{\partial} \\ \to & \widetilde{\mathrm{H}}_{k-1}(S^{n-1}) & \xrightarrow{i_*} & \ldots & & & \end{array}$$

From the induction hypothesis, from the homeomorphism $S^n \cong \overline{B}^n/S^{n-1}$ and from the fact that $\widetilde{\mathrm{H}}_i(\overline{B}^n) = 0$ for all i (obtained on page 1612) we now see that the above long exact

[886] To readers who prefer S^0 as a starting point we point out that S^0 consists of precisely two points. Thus the promised isomorphisms follow from Lemmas 72.6, 72.14 and 74.1.

sequence gives rise to the following exact sequence:

$$\begin{array}{rcccccc} & \dots & \longrightarrow & 0 & \xrightarrow{p_*} & \widetilde{\mathrm{H}}_{k+1}(S^n) & \xrightarrow{\partial} \\ \to & \widetilde{\mathrm{H}}_k(S^{n-1}) & \xrightarrow{i_*} & 0 & \xrightarrow{p_*} & \widetilde{\mathrm{H}}_k(S^n) & \xrightarrow{\partial} \\ \to & \widetilde{\mathrm{H}}_{k-1}(S^{n-1}) & \xrightarrow{i_*} & \dots & & & \end{array}$$

In particular we obtain for each k an exact sequence

$$0 \;\to\; \widetilde{\mathrm{H}}_{k+1}(S^n) \;\xrightarrow{\partial}\; \widetilde{\mathrm{H}}_k(S^{n-1}) \;\to\; 0.$$

But this means that the maps ∂ are isomorphisms, and using our induction hypothesis we obtain the desired result that

$$\widetilde{\mathrm{H}}_k(S^n) \;=\; \widetilde{\mathrm{H}}_{k-1}(S^{n-1}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k-1 = n-1, \text{ i.e. if } k = n \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}$$

■

In Lemma 2.26 we had used elementary arguments to show that $\mathbb{R}$ is not homeomorphic to $\mathbb{R}^2$. Furthermore, in Lemma 50.4 we had used the fundamental group to prove that $\mathbb{R}^2$ is not homeomorphic to $\mathbb{R}^n$ for $n \geq 3$. Now we can finally show that for any $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic.

Proposition 74.6. For any $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic.

Proof. Clearly we only have to deal with the case $k, l \geq 1$. Let $k, l \in \mathbb{N}$ and suppose there exists a homeomorphism $f\colon \mathbb{R}^k \to \mathbb{R}^l$. Then we obtain that

$$\begin{array}{ccccccc} & & & & \text{follows from the Homotopy Equivalence-H}_*\text{-Corollary 73.9} & & \\ & & & & \downarrow & & \\ \mathbb{Z} & \underset{\uparrow}{\cong} & \widetilde{\mathrm{H}}_{k-1}(S^{k-1}) & \cong & \widetilde{\mathrm{H}}_{k-1}(\mathbb{R}^k \setminus \{0\}) & \xrightarrow[\uparrow]{f_*} & \widetilde{\mathrm{H}}_{k-1}(\mathbb{R}^l \setminus \{f(0)\}) \;\underset{\downarrow}{\cong}\; \widetilde{\mathrm{H}}_{k-1}(S^{l-1}). \\ & \text{Proposition 74.4} & & & & \text{isomorphism since } f \text{ is a homeomorphism} & \end{array}$$

So we have $\widetilde{\mathrm{H}}_{k-1}(S^{l-1}) \cong \mathbb{Z}$. But by Proposition 74.4 that is only possible if $k = l$. ■

74.4. **The Brouwer Fixed Point Theorem II.** In Lemma 47.16 we had used the fundamental group to show that S^1 is not a retract of $\overline{B}^2$. Precisely the same argument, together with Proposition 74.4, now gives us the following proposition.

Proposition 74.7. For every $n \in \mathbb{N}$ the sphere $S^{n-1} = \partial\overline{B}^n$ is not a retract of the closed ball $\overline{B}^n$.

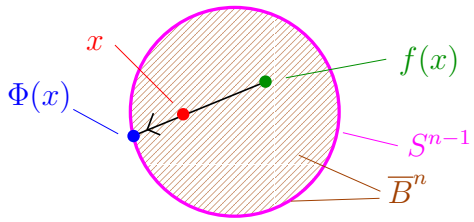
Remark. I found the following amusing description of Proposition 74.7 online:
"Suppose a shark jumps into a shoal of fish (a kind of big ball). The small fishes start escaping in all directions towards the border of the shoal, where the fishes stand still. Yet they escape with a certain disposition to follow a continuous flow, as they usually do, since everybody tends to follow its neighborhoods. But since there is no continuous retraction to the boundary, somebody doesn't know where to go, and stay there for a moment, much to the shark's satisfaction. There is also a 2D version, with a wolf entering into a herd of sheep."

Proof. Suppose there exists a retraction $r\colon \overline{B}^n \to S^{n-1}$. We denote by $i\colon S^{n-1} \to \overline{B}^n$ the inclusion map. We consider the following diagram

$$\begin{array}{ccc} & \widetilde{\mathrm{H}}_{n-1}(\overline{B}^n) & \\ {\scriptstyle i_*}\nearrow & & \searrow{\scriptstyle r_*} \\ \widetilde{\mathrm{H}}_{n-1}(S^{n-1}) & \xrightarrow{\quad (r\circ i)_* \quad} & \widetilde{\mathrm{H}}_{n-1}(S^{n-1}). \end{array}$$

This diagram commutes since it follows from the functoriality of the homology groups that $r_* \circ i_* = (r \circ i)_*$. Since r is a retraction it follows that $r \circ i = \mathrm{id}_{S^{n-1}}$, i.e. $(r \circ i)_* = (\mathrm{id}_{S^{n-1}})_*$ is the identity map on $\widetilde{\mathrm{H}}_{n-1}(S^{n-1})$ which, by Proposition 74.4, is isomorphic to $\mathbb{Z}$. The lower map is thus an isomorphism, but the upper map factorizes through the trivial group, i.e. the composition of i_* and r_* cannot be an isomorphism of $\mathbb{Z}$. Thus we have obtained a contradiction. ■

Now we can again provide a proof of Brouwer Fixed Point Theorem 31.4.



Theorem (Brouwer Fixed Point Theorem 31.4. Every map $f\colon \overline{B}^n \to \overline{B}^n$ admits a fixed point, i.e. for every map $f\colon \overline{B}^n \to \overline{B}^n$ there exists a point $x \in \overline{B}^n$ such that $f(x) = x$.

Remark. We already provided on proof on page 784 and we will provide another proof on page 2118.

Proof. The proof of the Brouwer Fixed Point Theorem 31.4 is basically identical to the one provided on page 1618. We just need to replace the Boundary Non-Retraction Proposition 31.3 by Proposition 74.7. For the reader's convenience we provide the argument, minus the technical details, again.

Suppose there exists a map $f\colon \overline{B}^n \to \overline{B}^n$ without a fixed point. Since f admits no fixed points we saw on page 784 that for each $x \in \overline{B}^n$ the open ray $\{f(x) + t \cdot (x - f(x)) \,|\, t > 0\}$ which starts at $f(x)$ and which goes through x contains precisely one point in S^{n-1}. Thus we can consider the following map:

$$\begin{array}{rcl} \Phi\colon \overline{B}^n & \to & \overline{B}^n \\ x & \mapsto & \text{the intersection point of } S^{n-1} \text{ with the} \\ & & \text{uniquely determined open ray from } f(x) \text{ to } x. \end{array}$$

As we saw on page 785, it is elementary to show that Φ is continuous. It is evident that $\Phi(x) = x$ for all $x \in S^{n-1}$ and that $\Phi(x) \in S^{n-1}$ for all $x \in S^{n-1}$. The map Φ is thus a retraction from $\overline{B}^n$ to S^{n-1}. But according to Proposition 74.7 this not possible. Thus we have obtained a contradiction. ■

As we mentioned already in Section 31.2, the Brouwer Fixed Point Theorem pops up many times in mathematics. For example we can use it to prove the following theorem in linear algebra.

Theorem 31.5. (Perron-Frobenius Theorem) Let $A = (a_{ij})$ be an $n \times n$-real matrix. If all entries are positive, then A has a positive eigenvalue λ with an eigenvector v such that all entries of v are non-negative.

Proof. For the reader's convenience we recall the proof from page 785. We need to introduce two players:

(1) Given $v = (v_1, \dots, v_n) \in \mathbb{R}^n$ we write $|v| := \sum_{i=1}^{n} |v_i|$.
(2) We consider again the standard $(n-1)$-simplex

$$\Delta^{n-1} := \{(t_1, \dots, t_n) \in [0,1]^n \,\big|\, |v| = 1\}.$$

We saw in the Standard Simplex Homeomorphism Lemma 72.1 that Δ^{n-1} is homeomorphic to $\overline{B}^{n-1}$. It follows immediately from this observation and from the Brouwer Fixed Point Theorem 31.4 that any self-map $f\colon \Delta^{n-1} \to \Delta^{n-1}$ has a fixed point.

Now let $A = (a_{ij})$ be an $n \times n$-real matrix such that all entries are positive. We consider the map

$$\begin{array}{rcl} f\colon \Delta^{n-1} & \to & \Delta^{n-1} \\ v = (v_1, \dots, v_n) & \mapsto & \frac{A \cdot v}{|A \cdot v|}. \end{array}$$

Note that this map is defined since our hypothesis that all a_{ij} are positive and the fact that all entries of v are non-negative and that at least one entry of v is positive imply that $A \cdot v \neq 0$. As we had just discussed above, the map $f\colon \Delta^{n-1} \to \Delta^{n-1}$ has a fixed point $v \in \Delta^{n-1}$. But this means that $A \cdot v = |A \cdot v| \cdot v$. Put differently, we have just shown that v is an eigenvector to the positive eigenvalue $|A \cdot v|$. ■

74.5. **Basic homological algebra.** Now that we have made use of Theorem 74.3 we also need to provide a proof of Theorem 74.3. In this chapter we will first develop several algebraic methods which later on will be used in the proof of the existence of the exact sequence of Theorem 74.3.

Definition. A short exact sequence is an exact sequence of the form

$$0 \to A \to B \to C \to 0,$$

which consists of at most three non-trivial groups. A short exact sequence of chain complexes

$$0 \to A_* \xrightarrow{i} B_* \xrightarrow{p} \mathrm{C}_* \to 0$$

consists of chain complexes A_*, B_*, C_* and chain maps $i\colon A_* \to B_*$ and $p\colon B_* \to \mathrm{C}_*$ such that for each n the maps

$$0 \to A_n \xrightarrow{i} B_n \xrightarrow{p} \mathrm{C}_n \to 0$$

form a short exact sequence.

Remark. Throughout the subsequent discussion in the following pages it is helpful to keep in mind the following commutative diagram of short exact sequences:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & A_{n+1} & \xrightarrow{i} & B_{n+1} & \xrightarrow{p} & \mathrm{C}_{n+1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \partial_{n+1}} & & \downarrow{\scriptstyle \partial_{n+1}} & & \downarrow{\scriptstyle \partial_{n+1}} & & \\
0 & \longrightarrow & A_{n} & \xrightarrow{i} & B_{n} & \xrightarrow{p} & \mathrm{C}_{n} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \partial_{n}} & & \downarrow{\scriptstyle \partial_{n}} & & \downarrow{\scriptstyle \partial_{n}} & & \\
0 & \longrightarrow & A_{n-1} & \xrightarrow{i} & B_{n-1} & \xrightarrow{p} & \mathrm{C}_{n-1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \partial_{n-1}} & & \downarrow{\scriptstyle \partial_{n-1}} & & \downarrow{\scriptstyle \partial_{n-1}} & & \\
0 & \longrightarrow & A_{n-2} & \xrightarrow{i} & B_{n-2} & \xrightarrow{p} & \mathrm{C}_{n-2} & \longrightarrow & 0.
\end{array}$$

Definition. Now suppose that we are given such a short exact sequence of chain complexes. We will define a map

$$\partial_n \colon \mathrm{H}_n(C) \ \to \ \mathrm{H}_{n-1}(A)$$

as follows:

(1) Let $z \in \mathrm{H}_n(C)$.
(2) We pick $c \in C_n$ with $z = [c]$.
(3) By the surjectivity of p we have $c = p(b)$ for some $b \in B_n$.
(4) We have

$$\begin{array}{ccccccc}
p(\partial b) & = & \partial p(b) & = & \partial c & = & 0. \\
 & \uparrow & & & & \uparrow & \\
\text{since the diagram commutes} & & & & & \text{since } c \text{ is a cycle} &
\end{array}$$

(5) Since the second horizontal row in the above diagram is exact it follows immediately from (4) that $\partial b = i(a)$ for some uniquely determined $a \in A_{n-1}$.
(6) We put $\partial_n(z) := [a]$.

We refer to this map $\partial_n \colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)$ as the connecting homomorphism.

The following lemma summarizes two of the key properties of the connecting homomorphisms.

Lemma 74.8. (Connecting Homomorphism Lemma)

(1) Let $0 \to A_* \to B_* \to C_* \to 0$ be a short exact sequence of chain complexes. The connecting homomorphism $\partial_n \colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)$ is well-defined and it is indeed a homomorphism.
(2) The connecting homomorphism is natural, i.e. if

$$\begin{array}{ccccccccc}
0 & \longrightarrow & A_{*} & \xrightarrow{i} & B_{*} & \xrightarrow{p} & C_{*} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \\
0 & \longrightarrow & A'_{*} & \xrightarrow{i} & B'_{*} & \xrightarrow{p} & C'_{*} & \longrightarrow & 0
\end{array}$$

is a commutative diagram of chain maps where the horizontal sequences are exact, then the following diagram commutes for every $n \in \mathbb{N}$:

$$\begin{array}{ccc} \mathrm{H}_n(C) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(A) \\ {\scriptstyle c_*}\downarrow & & \downarrow{\scriptstyle a_*} \\ \mathrm{H}_n(C') & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(A') \end{array}$$

Remark. Let us explain why we say that the connecting homomorphism is "natural". Let $\mathcal{S}$ be the category of short exact sequences of chain complexes where the morphisms are chain maps. the Connecting Homomorphism Lemma 74.8 (2) says given any $n \in \mathbb{N}_0$ the connecting homomorphism $\partial_n \colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)$ is a natural transformation from the functor

$$\begin{array}{rcll} \mathcal{S} & \to & \mathit{AbGroup} & \text{to the} \\ (A_* \to B_* \to \mathrm{C}_*) & \mapsto & \mathrm{H}_n(C) & \text{functor} \end{array} \qquad \begin{array}{rcl} \mathcal{S} & \to & \mathit{AbGroup} \\ (A_* \to B_* \to \mathrm{C}_*) & \mapsto & \mathrm{H}_{n-1}(A). \end{array}$$

The proof of this lemma and the following proposition are done by a "diagram chase". This means that one needs to keep the commutative diagram on page 1620 in mind and one has to use on several occasions that the vertical maps are chain maps and that the horizontal sequences are exact. In both cases the proofs are quite elementary.

Proof.

The proof below is elementary but not very readable. It is much easier to prove the lemma on your own than to try to read the proof.

For the undeterred reader we now provide the fully gory details.

(1) We start out with the following claim.

Claim. The map
$$\partial_n \colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)$$
is well-defined.

Proof. Let $z \in \mathrm{H}_n(C)$. We denote by c, b and a the elements as in the definition of ∂_n. We need to show that the element a is indeed a cycle and that the definition of $\partial_n([c])$ does not depend on the choices of c and b.

The proofs of these two statements is not particularly difficult and it is done via "diagram chasing". First we note that

$$i(\partial a) \underset{\text{since the diagram commutes}}{\overset{\uparrow}{=}} \partial i(a) = \partial(\partial b) = 0.$$

Since i is injective we obtain that $\partial a = 0$, i.e. a is indeed a cycle. Now we show that the homology class $[a]$ depends only on the homology class $[c]$.

(a) If we chose a different element in B_n, then it follows from the fact that the horizontal sequences are exact that this element would be of the form $b + i(a')$ for some $a' \in A_n$. But then we obtain the following equality:

$$\partial(b + i(a')) = \partial b + \partial(i(a')) \overset{\text{since the diagram commutes}}{\overset{\downarrow}{=}} \underbrace{\partial b}_{=i(a)} + i(\partial a') = i(a + \partial a').$$

Since $[a] = [a + \partial a'] \in \mathrm{H}_{n-1}(A)$ this does not change the homology class.

(b) If we picked an other representative for $[c]$, then this representative would be of the form $c+\partial c'$ for some $c' \in \mathrm{C}_{n+1}$. Since the map $p\colon B_n \to C_n$ is an epimorphism there exists a $b' \in B_{n+1}$ with $p(b') = c'$. It follows that

$$p(b+\partial b') \;=\; p(b) + p(\partial b') \;\underset{\text{since the diagram commutes}}{\overset{\uparrow}{=}}\; c + \partial p(b') \;=\; c + \partial c'.$$

Since $\partial(b+\partial b') = \partial b$ we see that we have ended up with the same element in B_{n-1} as before. ⊞

Claim. The map

$$\partial_n\colon \mathrm{H}_n(C) \;\to\; \mathrm{H}_{n-1}(A)$$

is a homomorphism.

Proof. Thus let $[c_1]$ and $[c_2]$ be given. For $j = 1, 2$ we choose b_j as in this definition of ∂_n, and we denote by a_j the uniquely determined element with $i(a_j) = \partial b_j$. Then we also have $p(b_1+b_2) = c_1+c_2$ and $i(a_1+a_2) = i(a_1)+i(a_2) = \partial b_1+\partial b_2 = \partial(b_1+b_2)$. It follows that

$$\partial_n([c_1+c_2]) \;=\; [a_1+a_2] \;=\; [a_1]+[a_2] \;=\; \partial_n([c_1])+\partial_n([c_2]).$$ ⊞

(2) The second statement follows easily from the definitions. We leave the verification of the details to the reader. ■

Now we can formulate the following proposition which explains the name "connecting homomorphism".

Proposition 74.9. (LES Proposition)

(1) Let

$$0 \;\to\; A_* \;\xrightarrow{i}\; B_* \;\xrightarrow{p}\; C_* \;\to\; 0$$

be a short exact sequence of chain complexes. Then the sequence

$$\ldots \to \mathrm{H}_n(A) \xrightarrow{i_*} \mathrm{H}_n(B) \xrightarrow{p_*} \mathrm{H}_n(C) \xrightarrow{\partial} \mathrm{H}_{n-1}(A) \xrightarrow{i_*} \mathrm{H}_{n-1}(B) \xrightarrow{p_*} \ldots$$

is exact.

(2) The connecting homomorphism is natural. More precisely, let

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_* & \xrightarrow{i} & B_* & \xrightarrow{p} & C_* & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \\ 0 & \longrightarrow & A'_* & \xrightarrow{i} & B'_* & \xrightarrow{p} & C'_* & \longrightarrow & 0 \end{array}$$

be a commutative diagram of chain maps where the horizontal sequences are exact. Then the following diagram commutes:

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \mathrm{H}_n(A) & \xrightarrow{i_*} & \mathrm{H}_n(B) & \xrightarrow{p_*} & \mathrm{H}_n(C) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A) & \longrightarrow & \ldots \\ & & \downarrow{\scriptstyle a_*} & & \downarrow{\scriptstyle b_*} & & \downarrow{\scriptstyle c_*} & & \downarrow{\scriptstyle a_*} & & \\ \ldots & \longrightarrow & \mathrm{H}_n(A') & \xrightarrow{i_*} & \mathrm{H}_n(B') & \xrightarrow{p_*} & \mathrm{H}_n(C') & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A') & \longrightarrow & \ldots \end{array}$$

The fact that the square to the right commutes is just in plain words the statement that the connecting homomorphism is natural.

In the following we refer to the exact sequence of the LES Proposition 74.9 as the as *long exact sequence in homology* corresponding to the short exact sequence of chain complexes.

Proof of the LES Proposition 74.9. First note that Statement (2) is an immediate consequence of the Connecting Homomorphism Lemma 74.8. We included the statement for the convenience of the reader. Thus let us turn to the actual meat, namely Statement (1).

The proof below is elementary but not very readable. It is much easier to prove the proposition on your own than to try to read the proof.

Let
$$0 \to A_* \xrightarrow{i} B_* \xrightarrow{p} C_* \to 0$$
be a short exact sequence of chain complexes. Then the sequence
$$\ldots \to \mathrm{H}_n(A) \xrightarrow{i_*} \mathrm{H}_n(B) \xrightarrow{p_*} \mathrm{H}_n(C) \xrightarrow{\partial} \mathrm{H}_{n-1}(A) \xrightarrow{i_*} \mathrm{H}_{n-1}(B) \xrightarrow{p_*} \ldots$$
is exact. We examine the exactness at the three groups $\mathrm{H}_{n-1}(A), \mathrm{H}_n(B)$ and $\mathrm{H}_n(C)$. Put differently, at each of the three groups we want to show the following two statements:

(1) the image of the map to the left is contained in the image of the map to the right, or equivalently, the composition of the map to the left and the map to the right is zero,
(2) the kernel of the map to the right is contained in the image of the map to the left.

Now we perform these steps:

(A) First let $[c] \in \mathrm{H}_n(C)$. We want to show that $i(\partial[c]) = 0$. We choose b with $p(b) = c$ and denote by $a \in A_{n-1}$ the element with $i(a) = \partial b$. Then we have
$$i(\partial[c]) \underset{\substack{\uparrow \\ \text{definition of } \partial\colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A)}}{=} i([a]) = [\partial b] = 0 \in \mathrm{H}_{n-1}(B).$$
Now let $[a] \in \ker(i_*)$. Then $i(a) = \partial b$ for some $b \in B_n$. It follows immediately from the definitions that $\partial[p(b)] = [a]$.

(B) From $p \circ i = 0$ it follows that $p_* \circ i_* = 0$, i.e. $\mathrm{im}(i_*) \subset \ker(p_*)$.
Conversely let $b \in \ker(p_*)$. Then $p(b) = \partial c'$ for some $c' \in \mathrm{C}_{n+1}$. Since p is surjective, there exists a $b' \in B_{n+1}$ with $p(b') = c'$. From the commutativity it follows that $p(\partial b') = \partial p(b') = \partial c' = p(b)$. Thus it follows that $p(b - \partial b') = 0$, i.e. $b - \partial b' = i(a)$ for some $a \in A_n$. But then it follows that $[b] = [b - \partial b'] = [i(a)] \in \mathrm{im}(i_*)$.

(C) Let $[b] \in \mathrm{H}_n(B)$. We have to show that $\partial(p_*([b])) = 0$. In the definition of $\partial p_*([b])$ we choose some $b \in B$. Since $\partial b = 0$ it follows immediately that $\partial p_*([b]) = 0$.
Finally let $[c] \in \ker(\partial\colon \mathrm{H}_n(C) \to \mathrm{H}_{n-1}(A))$. We choose $b \in B_n$ with $p(b) = c$. Then there exists a uniquely determined $a \in A_{n-1}$ with $i(a) = \partial b$. Since we have $[a] = \partial[c] = 0 \in \mathrm{H}_{n-1}(A)$ there exists an $a' \in A_n$ with $\partial a' = a$. Then it follows that
$$\partial(b - i(a')) = \partial b - \partial i(a') = \partial b - i(\partial a') = \partial b - i(a) = 0,$$
i.e. $b - i(a')$ is a cycle. On the other hand we have $p(b - i(a')) = p(b) - (p \circ i)(a') = p(b)$. Thus we see that $p_*([b - i(a')]) = [c]$. We have thus shown that $\ker(\partial) \subset \mathrm{im}(p_*)$.

Thus we have proved the claim and therefore we have also completed the proof of the proposition. ∎

Lemma 74.10. (Five Lemma) Let

$$\begin{array}{ccccccccc} A & \xrightarrow{i} & B & \xrightarrow{j} & C & \xrightarrow{k} & D & \xrightarrow{l} & E \\ \downarrow{\scriptstyle a} & & \cong\downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \cong\downarrow{\scriptstyle d} & & \downarrow{\scriptstyle e} \\ A' & \xrightarrow{i'} & B' & \xrightarrow{j'} & C' & \xrightarrow{k'} & D' & \xrightarrow{l'} & E' \end{array}$$

be a diagram of groups (here for once we do not suppose that the groups are abelian) such that the horizontal sequences are exact and such that every squares commute (if all the groups are abelian, then it suffices it the squares commute up to a sign). If a is surjective, if b and d are isomorphisms, and if e is injective, then c is an isomorphism.[887]

Proof. One can prove the lemma via a "diagram chase". Filling in the details is precisely the task of Exercise 74.6. ∎

74.6. **Relative homology groups.** In this section we will introduce the relative homology groups which will play an important role in the proof of Theorem 74.3 and also in the remainder of this course.

Definition. Let (X, A) be a pair of topological spaces.[888] We view each chain group $\mathrm{C}_n(A)$ as a subgroup of $\mathrm{C}_n(X)$. Thus we can define

$$\mathrm{C}_n(X, A) \;:=\; \mathrm{C}_n(X)/\mathrm{C}_n(A)$$

and we consider the boundary map[889]

$$\begin{array}{rcl} \partial_n \colon \mathrm{C}_n(X, A) & \to & \mathrm{C}_{n-1}(X, A) \\ [c] & \mapsto & [\partial_n c]. \end{array}$$

We refer to

$$\ldots \xrightarrow{\partial_{n+2}} \mathrm{C}_{n+1}(X, A) \xrightarrow{\partial_{n+1}} \mathrm{C}_n(X, A) \xrightarrow{\partial_n} \mathrm{C}_{n-1}(X, A) \xrightarrow{\partial_{n-1}} \ldots$$

as the chain complex of the pair (X, A).[890] Given any $n \in \mathbb{N}_0$ we define the n-th relative homology group of (X, A) as follows:

$$\mathrm{H}_n(X, A) \;:=\; \mathrm{H}_n(\mathrm{C}_*(X, A)).$$

Remark. Let (X, A) be a pair of topological spaces and let $n \in \mathbb{N}_0$. We write

$$S \;:=\; \{\sigma \colon \Delta^n \to X \mid \mathrm{im}(\sigma) \cap (X \setminus A) \neq \varnothing\},$$

i.e. S denotes the set of all singular n-simplices of X that are not completely contained in A. Then it is straightforward to show that the map

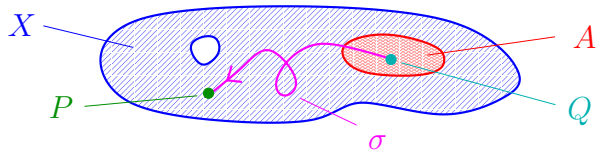
$$\begin{array}{rcl} \mathbb{Z}^{(S)} & \to & \mathrm{C}_n(X, A) \\ \sum\limits_{i=1}^{n} n_i \sigma_i & \mapsto & \left[\sum\limits_{i=1}^{n} n_i \sigma_i\right] \end{array}$$

---

[887] In many applications it suffices to remember the following slightly weaker statement: if the two vertical maps on the left and right are isomorphisms, then the middle map is also an isomorphism.

[888] Recall that according to the definition on page 439 this means that X is a topological space and $A \subset X$ is a subset.

[889] The map ∂_n is well-defined, since for any $c \in \mathrm{C}_n(A) \subset \mathrm{C}_n(X)$ the boundary ∂c lies obviously in $\mathrm{C}_{n-1}(A) \subset \mathrm{C}_{n-1}(X)$.



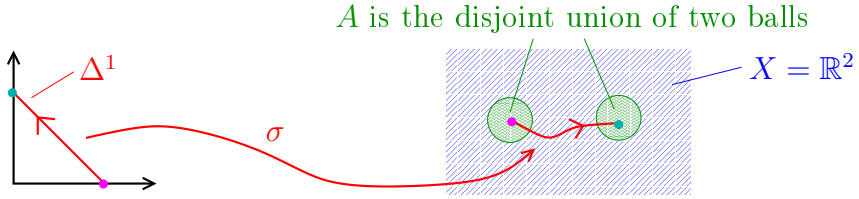
[890] Since $\partial_{n-1} \circ \partial_n \colon \mathrm{C}_n(X) \to \mathrm{C}_{n-2}(X)$ is the zero map it follows immediately that the composition $\partial_{n-1} \circ \partial_n \colon \mathrm{C}_n(X, A) \to \mathrm{C}_{n-2}(X, A)$ is also the zero map.

is an isomorphism. In particular we see that $\mathrm{C}_n(X, A)$ is a free abelian group.

Examples.

(1) If $A = \varnothing$, then for all $n \in \mathbb{N}_0$ we have $\mathrm{C}_n(\varnothing) = 0$ and $\mathrm{C}_n(X, \varnothing) = \mathrm{C}_n(X)$, i.e. we have $\mathrm{H}_n(X, \varnothing) = \mathrm{H}_n(X)$. In the following we will freely go back and forth between the notations $\mathrm{H}_n(X, \varnothing)$ and $\mathrm{H}_n(X)$.

(2) If X is a path-connected topological space and if A is non-empty, then $\mathrm{H}_0(X, A) = 0$. Indeed, let $P \in X$ be a point. We pick a point $Q \in A$. Since X is path-connected we can pick a map $\sigma\colon \Delta^1 \to X$ such that $\sigma(0, 1) = P$ and $\sigma(1, 0) = Q$. As discussed on page 1585, in $\mathrm{C}_*(X, A)$ we have $\partial\sigma = P - Q$, but since $Q = 0 \in \mathrm{C}_0(X, A)$ we have $\partial\sigma = P$, which shows that $P = 0 \in \mathrm{H}_0(X, A)$. But this clearly implies that $\mathrm{H}_0(X, A) = 0$. We refer to the figure below for an illustration.



(3) Whereas it is often difficult to write down singular cycles in absolute chain complexes $\mathrm{C}_*(X)$, it can be surprisingly easy to write down singular cycles in a relative chain complex $\mathrm{C}_*(X, A)$. Indeed, given any map $\sigma\colon \Delta^n \to X$ with $\sigma(\partial\Delta^n) \subset A$ we have

$$\partial_n(\sigma) \;=\; \sum_{j=0}^{n} (-1)^j \cdot \sigma \circ i_j^n \;\underset{\uparrow}{=}\; 0 \;\in\; \mathrm{C}_{n-1}(X, A) = \mathrm{C}_{n-1}(X)/\mathrm{C}_{n-1}(A).$$

since $\sigma \circ i_j^n\colon \Delta^{n-1}$ takes values in A we see that $\sigma \circ i_j^n \in \mathrm{C}_{n-1}(A)$

Thus σ defines a cycle in the chain complex $\mathrm{C}_n(X, A)$. As an example we consider $X = \mathbb{R}^2$ and $A = B_1(-2) \cup B_1(2)$. Let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex with $\sigma(0, 1) \in B_1(2)$ and $\sigma(1, 0) \in B_1(-2)$. (We refer to the figure below for an illustration.) It follows from the above discussion that σ is a cycle in $\mathrm{C}_*(X, A)$. Later, on page 1630, we will see whether or not $[\sigma] \in \mathrm{H}_1(X, A)$ is non-trivial.

Definition.

(1) Recall that we refer to the category that is given by

$$\begin{aligned} \mathrm{Ob}(\mathcal{PairTop}) &:= \text{all pairs of topological spaces,} \\ \mathrm{Mor}((X, A), (Y, B)) &:= \text{all continuous maps } f\colon X \to A \text{ with } f(A) \subset B \end{aligned}$$

with the usual composition of maps as the category of pairs of topological spaces.

(2) Let $f\colon (X,A)\to(Y,B)$ be a map of pairs of topological spaces, i.e. a map $f\colon X\to Y$ with $f(A)\subset B$. Then f induces maps

$$\begin{array}{rcl} f_*\colon \mathrm{H}_n(X,A) & \to & \mathrm{H}_n(Y,B) \\ \Big[\sum\limits_{j=1}^{n} a_j\sigma_j\Big] & \mapsto & \Big[\sum\limits_{j=1}^{n} a_j(f\circ\sigma_j)\Big]. \end{array}$$

It is straightforward to show that these maps are well-defined.

The following lemma follows almost immediately from the definitions.

Lemma 74.11. For each $n\in\mathbb{N}_0$ the maps

$$\begin{array}{rcl} (X,A) & \to & \mathrm{H}_n(X,A) \\ (f\colon (X,A)\to(Y,B)) & \mapsto & (f_*\colon \mathrm{H}_n(X,A)\to \mathrm{H}_n(Y,B)) \end{array}$$

define a covariant functor from the category *PairTop* of pairs of topological spaces to the category *AbGroup* of abelian groups.

Remark. If (Y,B) is a pair of topological spaces and if $X\subset Y$ and $A\subset B$, then we have the obvious inclusion map $(X,A)\to(Y,B)$ and we therefore obtain the induced maps $\mathrm{H}_n(X,A)\to\mathrm{H}_n(Y,B)$ in relative homology. If it is clear from the context that we are dealing with such an inclusion induced map, then on many occasions we will not explicitly point out that we are working with the inclusion induced maps.

Next we study the interaction between ordinary homology, relative homology and reduced homology. We introduce the following notation.

Notation. Let X be a topological space, let $A\subset X$ and let $n\in\mathbb{N}_0$. We introduce the following maps:

$$\mathrm{H}_n(X)\xrightarrow{=}\mathrm{H}_n(X,\varnothing)\longrightarrow\mathrm{H}_n(X,A)\qquad\text{and}\qquad \widetilde{\mathrm{H}}_n(X)\xrightarrow{\text{ж}}\mathrm{H}_n(X)\xrightarrow{\text{я}}\mathrm{H}_n(X,A).$$

$$\text{where } =:\text{я}=:\text{я}_{X,A} \qquad\qquad \text{where } =:\text{ж}_{X,A}$$

Lemma 74.12. Let X be a topological space and let $n\in\mathbb{N}_0$. The following statements hold:

(1) Let $A\subset X$. The maps $\text{я}_{X,A}$ and $\text{ж}_{X,A}$ are natural in the sense that if we are given a map $f\colon (X,A)\to(Y,B)$ of pairs of topological spaces then the following diagrams commute:

$$\begin{array}{ccc} \mathrm{H}_n(X) & \xrightarrow{f_*} & \mathrm{H}_n(Y) \\ {\scriptstyle \text{я}_{X,A}}\downarrow & & \downarrow{\scriptstyle \text{я}_{Y,B}} \\ \mathrm{H}_n(X,A) & \xrightarrow{f_*} & \mathrm{H}_n(Y,B) \end{array} \qquad\text{and}\qquad \begin{array}{ccc} \widetilde{\mathrm{H}}_n(X) & \xrightarrow{f_*} & \widetilde{\mathrm{H}}_n(Y) \\ {\scriptstyle \text{ж}_{X,A}}\downarrow & & \downarrow{\scriptstyle \text{ж}_{Y,B}} \\ \mathrm{H}_n(X,A) & \xrightarrow{f_*} & \mathrm{H}_n(Y,B). \end{array}$$

(2) For each $x_0\in X$ the map

$$\text{ж}_{X,\{x_0\}}\colon \widetilde{\mathrm{H}}_n(X)\ \to\ \mathrm{H}_n(X,\{x_0\})$$

is a natural isomorphism.

Proof.

(1) The first statement follows immediately from the definitions.

(2) We will provide the proof of this statement in Exercise 74.14. ■

Before we can state the next proposition we need to introduce the notion of a triple of topological spaces which is defined in almost the same fashion as a pair of topological spaces.

Definition.

(1) A triple of topological spaces is a triple (X, B, A) where X is a topological space and $A \subset B \subset X$ are subsets.
(2) A map $f\colon (X, B, A) \to (X', B', A')$ between triples of topological spaces is a continuous map $f\colon X \to X'$ such that $f(B) \subset B'$ and $f(A) \subset A'$.

Proposition 74.13. (Topological LES-Proposition) Let X be a topological space and let $A \subset B \subset X$ be two subsets. We denote by $i\colon (B, A) \to (X, A)$ and by $p\colon (X, A) \to (X, B)$ the obvious maps.

(1) For each $n \in \mathbb{N}_0$ the map[891][892]
$$\begin{array}{rcl} \partial_n\colon \mathrm{H}_n(X, B) & \to & \mathrm{H}_{n-1}(B, A) \\ \left[\sum_{j=1}^{k} a_j \cdot (\sigma_j\colon \Delta^n \to X)\right] & \mapsto & \left[\sum_{j=1}^{k} a_j \cdot \partial\sigma_j\right] \end{array}$$
is well-defined.
(2) We consider the category of triples of topological spaces.[893] The maps ∂_n from (1) define a natural transformation from the functor $(X, B, A) \to \mathrm{H}_n(X, B)$ to the functor $(X, B, A) \to \mathrm{H}_{n-1}(B, A)$. In down-to-earth language this means that for a map $f\colon (X, A, B) \to (\widetilde{X}, \widetilde{A}, \widetilde{B})$ of triples of topological spaces the following diagram commutes:
$$\begin{array}{ccc} \mathrm{H}_n(X, B) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(B, A) \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ \mathrm{H}_n(\widetilde{X}, \widetilde{B}) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(\widetilde{B}, \widetilde{A}). \end{array}$$
In particular the following diagram commutes:
$$\begin{array}{ccccccccc} \ldots & \longrightarrow & \mathrm{H}_n(B, A) & \longrightarrow & \mathrm{H}_n(X, A) & \longrightarrow & \mathrm{H}_n(X, B) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(B, A) & \longrightarrow & \ldots \\ & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \\ \ldots & \longrightarrow & \mathrm{H}_n(\widetilde{B}, \widetilde{A}) & \longrightarrow & \mathrm{H}_n(\widetilde{X}, \widetilde{A}) & \longrightarrow & \mathrm{H}_n(\widetilde{X}, \widetilde{B}) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\widetilde{B}, \widetilde{A}) & \longrightarrow & \ldots. \end{array}$$
(3) The maps
$$\ldots \to \mathrm{H}_n(B, A) \xrightarrow{i_*} \mathrm{H}_n(X, A) \xrightarrow{p_*} \mathrm{H}_n(X, B) \xrightarrow{\partial_n} \mathrm{H}_{n-1}(B, A) \to \ldots$$
form an exact sequence.

The long exact sequence of the Topological LES-Proposition 74.13 (2) is sometimes called the *long exact sequence of the triple* (X, B, A) and we refer to ∂_n as the *connecting homomorphism* of the triple (X, B, A).

[891] The fact that here the symbol "∂_n" denotes the boundary map of singular chains and the desired map $\mathrm{H}_n(X, B) \to \mathrm{H}_{n-1}(B, A)$ is an unfortunate problem in our choice of notation.
[892] Here we use that every homology class in $\mathrm{H}_n(X, B)$ admits by definition a representative in the quotient $\mathrm{C}_n(X, B) = \mathrm{C}_n(X)/\mathrm{C}_n(B)$, so it can be represented by a singular n-chain in X.
[893] It should be clear from the definitions preceding the definition what the objects and morphisms of this category are.

Proof. It follows immediately from the definitions and the third isomorphism theorem[894] that

$$0 \to \mathrm{C}_*(B,A) \xrightarrow{i_*} \mathrm{C}_*(X,A) \xrightarrow{p_*} \mathrm{C}_*(X,B) \to 0$$

is a short exact sequence of chain complexes.

Claim. The maps ∂_n introduced in Statement (1) of the propositions are precisely the connecting homomorphisms, as defined on page 1620, of the above short exact sequence of chain complexes. In particular the maps ∂_n are well-defined.

Proof. The claim follows basically immediately from the definitions. But for completeness' sake we give some details. We consider the following commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{C}_n(B,A) & \longrightarrow & \mathrm{C}_n(X,A) & \longrightarrow & \mathrm{C}_n(X,B) & \longrightarrow & 0 \\ & & \downarrow\partial & & \downarrow\partial & & \downarrow\partial & & \\ 0 & \longrightarrow & \mathrm{C}_{n-1}(B,A) & \longrightarrow & \mathrm{C}_{n-1}(X,A) & \longrightarrow & \mathrm{C}_{n-1}(X,B) & \longrightarrow & 0. \end{array}$$

Let $z \in \mathrm{H}_n(X,A)$. Now we will determine the image of z under the connecting homomorphism $\mathrm{H}_n(X,B) \to \mathrm{H}_{n-1}(B,A)$ which during the proof of the claim we denote by ∂^c.

We pick a representative $\sum_{j=1}^{k} a_j \cdot (\sigma_j \colon \Delta^n \to X)$ in $\mathrm{C}_n(X)$. Note that $\sum_{j=1}^{k} a_j \cdot (\sigma_j \colon \Delta^n \to X)$ also defines an element in $\mathrm{C}_n(X,A)$. We then take the boundary of the above singular n-chain under the boundary map $\partial_n \colon \mathrm{C}_n(X,A) \to \mathrm{C}_{n-1}(X,A)$ and we end up with the singular n-chain $\sum_{j=1}^{k} a_j \cdot \partial\sigma_j \in \mathrm{C}_{n-1}(X,A)$. As we have seen in the proof of the Connecting Homomorphism Lemma 74.8 this singular n-chain lies in fact in $\mathrm{C}_{n-1}(B,A) \subset \mathrm{C}_{n-1}(X,A)$. The homology class thereof is by definition precisely $\partial^c(z) \in \mathrm{H}_{n-1}(B,A)$. Summarizing we have shown that

$$\partial^c(z) \;=\; \Big[\sum_{j=1}^{k} a_j \cdot \partial\sigma_j\Big].$$

This shows that the map defined in (1) agrees with ∂^c. ⊞

Statement (2) of the lemma is an easy consequence of the Connecting Homomorphism Lemma 74.8. The fact that the stated sequence of homology groups is exact is now an immediate consequence of the LES Proposition 74.9. ■

For convenience we record two important special cases of the Topological LES-Proposition 74.13 in the following corollary.

Corollary 74.14. (Topological LES-Corollary)

(1) Let X be a topological space and let $B \subset X$ be a subset. The connecting homomorphism of the Topological LES-Proposition 74.13 applied to $A = \varnothing$ gives rise to along exact sequence

$$\ldots \longrightarrow \mathrm{H}_n(B) \xrightarrow{i_*} \mathrm{H}_n(X) \xrightarrow{p_*} \mathrm{H}_n(X,B) \xrightarrow{\partial} \mathrm{H}_{n-1}(B) \longrightarrow \ldots$$

[894] The third isomorphism theorem in group theory implies that we have a natural isomorphism $(\mathrm{C}_*(X)/\mathrm{C}_*(A))/(\mathrm{C}_*(B)/\mathrm{C}_*(A)) \cong \mathrm{C}_*(X)/\mathrm{C}_*(B)$.

Furthermore, for $n = 1$ the connecting homomorphism $\partial\colon \mathrm{H}_1(X, B) \to \mathrm{H}_0(B)$ takes values in $\widetilde{\mathrm{H}}_0(B)$ and we obtain a long exact sequence[895]

$$\ldots \longrightarrow \widetilde{\mathrm{H}}_n(B) \xrightarrow{i_*} \widetilde{\mathrm{H}}_n(X) \xrightarrow{\text{ж}_{X,B*}} \mathrm{H}_n(X, B) \xrightarrow{\partial} \widetilde{\mathrm{H}}_{n-1}(B) \longrightarrow \ldots$$

(2) The connecting homomorphisms in (1) are natural. In particular, given a map $f\colon (X, A) \to (Y, B)$ between pairs of topological spaces we obtain a commutative diagram

$$\begin{array}{ccccccccc}
\ldots & \longrightarrow & \mathrm{H}_n(A) & \xrightarrow{i_*} & \mathrm{H}_n(X) & \xrightarrow{\text{я}} & \mathrm{H}_n(X, A) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A) \longrightarrow \ldots \\
 & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\
\ldots & \longrightarrow & \mathrm{H}_n(B) & \xrightarrow{i_*} & \mathrm{H}_n(Y) & \xrightarrow{\text{я}} & \mathrm{H}_n(Y, B) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(B) \longrightarrow \ldots
\end{array}$$

The analogous statement also holds for reduced homology groups.

The long exact sequences of the Topological LES-Corollary 74.14 (1) are sometimes called the *long exact sequence* (*in reduced homology*) *of the pair* (X, B).

Proof. First note that the statement regarding unreduced homology follows from the Topological LES-Proposition 74.13 applied to $A = \varnothing$. Now we turn to the statement regarding reduced homology. This statement follows basically immediately from the unreduced case together with the Reduced Homology Lemma 74.1 (4) and Lemma 74.2. We leave it to the reader to fill in the dull details for the reduced case. ■

Remark. Let (X, B, A) be a triple of topological spaces. Then $(X, B, \varnothing) \to (X, B, A)$ is a map between triples of topological spaces and by the naturality of the long exact sequence we obtain the following commutative diagram

$$\begin{array}{ccccccccc}
\ldots & \longrightarrow & \mathrm{H}_n(B) & \longrightarrow & \mathrm{H}_n(X) & \longrightarrow & \mathrm{H}_n(X, B) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(B) \longrightarrow \ldots \\
 & & \downarrow & & \downarrow & & \downarrow{\scriptstyle =} & & \downarrow \\
\ldots & \longrightarrow & \mathrm{H}_n(B, A) & \longrightarrow & \mathrm{H}_n(X, A) & \longrightarrow & \mathrm{H}_n(X, B) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(B, A) \longrightarrow \ldots.
\end{array}$$

Example. Let X be a topological space. Furthermore let $x_0 \in X$ be a point. We denote by $i\colon \{x_0\} \to X$ the inclusion map. By the Topological LES-Corollary 74.14 we have a long exact sequence

$$\to \underbrace{\mathrm{H}_1(\{x_0\})}_{=0} \xrightarrow{i_*} \mathrm{H}_1(X) \to \mathrm{H}_1(X, \{x_0\}) \xrightarrow{i_*} \mathrm{H}_0(\{x_0\}) \to \mathrm{H}_0(X) \to \mathrm{H}_0(X, \{x_0\}) \to 0.$$

We obtain from this long exact sequence that the map $i_*\colon \mathrm{H}_0(\{x_0\}) \to \mathrm{H}_0(X)$ is a monomorphism. Together with the Single Point-Homology Lemma 72.6 we see that for each $n \in \mathbb{N}$ the map $\mathrm{H}_n(X) \to \mathrm{H}_n(X, \{x_0\})$ is an isomorphism.

We move on to a more elaborate example.

---

[895] Note that if B is non-empty, then it follows from the Reduced Homology Lemma 74.1 (0) that $\widetilde{\mathrm{H}}_{-1}(B) = 0$. Thus the last possibly non-zero term is $\mathrm{H}_0(X, B)$. On the other hand, if $B = \varnothing$, then we have $\widetilde{\mathrm{H}}_{-1}(B) = \widetilde{\mathrm{H}}_{-1}(\varnothing) = \mathbb{Z}$, and if $X = \varnothing$, then we have $\widetilde{\mathrm{H}}_{-1}(X) = \widetilde{\mathrm{H}}_{-1}(\varnothing) = \mathbb{Z}$. If $B = \varnothing$ the sequence is understood to continue with $\mathrm{H}_0(B, \varnothing) \xrightarrow{\epsilon} \mathrm{H}_{-1}(\varnothing) \to \mathrm{H}_{-1}(X)$.

Example. We let $X = \mathbb{R}^2$ and $A = B_1^2(-2) \cup B_1^2(2)$. We want to determine the relative homology groups of (X, A). We denote by $i\colon A \to X$ the inclusion map. By the Topological LES-Corollary 74.14 we have a long exact sequence

$$\mathrm{H}_2(X) \to \mathrm{H}_2(X, A) \to \mathrm{H}_1(A) \xrightarrow{i_*} \mathrm{H}_1(X) \to \mathrm{H}_1(X, A) \to \mathrm{H}_0(A) \to \mathrm{H}_0(X) \to \mathrm{H}_0(X, A) \to 0.$$

By the Homotopy Equivalence-H_*-Corollary 73.9 (3) together with Lemma 72.14 we have $\mathrm{H}_i(X) = \mathrm{H}_i(\mathbb{R}^2) = 0$ and also $\mathrm{H}_i(A) = \mathrm{H}_i(B_1(-2)) \oplus \mathrm{H}_i(B_1(2)) = 0$ for $i \geq 1$. Thus we see from the above long exact sequence that $\mathrm{H}_i(X, A) = 0$ for $i \geq 2$. We denote by $\epsilon\colon \mathrm{H}_0(\mathbb{R}^2) \to \mathbb{Z}$ the augmentation map that is an isomorphism by the H_0-Proposition 72.5. Similarly we denote by $\mu_1\colon \mathrm{H}_0(B_1(-2)) \to \mathbb{Z}$ and $\mu_2\colon \mathrm{H}_0(B_1(2)) \to \mathbb{Z}$ the isomorphisms that are given by the augmentation maps. We obtain the following commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{H}_1(X, A) & \xrightarrow{\partial} & \mathrm{H}_0(A) & \xrightarrow{i_*} & \mathrm{H}_0(X) & \longrightarrow & \mathrm{H}_0(X, A) \longrightarrow 0 \\
 & & \Big\downarrow{\scriptstyle =} & & \Big\downarrow{\scriptstyle \mu_1 \oplus \mu_2}^{\cong} & & \Big\downarrow{\scriptstyle \cong}^{\epsilon} & & \Big\downarrow{\scriptstyle =} \\
0 & \longrightarrow & \mathrm{H}_1(X, A) & \longrightarrow & \mathbb{Z}^2 & \longrightarrow & \mathbb{Z} & \longrightarrow & \mathrm{H}_0(X, A) \longrightarrow 0.
\end{array}$$

We want to determine the matrix representing the homomorphism $\mathbb{Z}^2 \to \mathbb{Z}$ at the bottom. We do so in the following claim.

Claim. The homomorphism $\epsilon \circ i_* \circ (\mu_1 \oplus \mu_2)^{-1}\colon \mathbb{Z}^2 \to \mathbb{Z}$ is given by the matrix $(1\ 1)$.

Proof. We pick a point $P \in B_1(-2)$ and we pick a point $Q \in B_1(2)$. It follows from the H_0-Proposition 72.5 and Lemma 72.14 that the map

$$\begin{array}{rcl}
\Psi\colon \mathbb{Z}^2 & \to & \mathrm{H}_0(A) = \mathrm{H}_0(B_1(-2)) \oplus \mathrm{H}_0(B_1(2)) \\
(m, n) & \mapsto & [m \cdot P + n \cdot Q]
\end{array}$$

is the inverse to $\mu_1 \oplus \mu_2$. Now it is easy to verify that $\epsilon \circ i_* \circ (\mu_1 \oplus \mu_2)^{-1} = \epsilon \circ i_* \circ \Psi$ applied to $(1, 0)$ and $(0, 1)$ gives in both cases the value 1. So the map is described by the matrix $(1\ 1)$. ⊞

Since the top sequence in the above commutative diagram is exact and since the vertical maps are isomorphisms we see that the bottom sequence is also exact. It is now straightforward to see that

$$\mathrm{H}_1(X, A) \ \cong\ \ker\left(\mathbb{Z}^2 \xrightarrow{(1\ 1)} \mathbb{Z}\right) \ \cong\ \mathbb{Z} \quad \text{and} \quad \mathrm{H}_0(X, A) \ \cong\ \operatorname{coker}\left(\mathbb{Z}^2 \xrightarrow{(1\ 1)} \mathbb{Z}\right) \ \cong\ 0.$$

Now we return to the situation of the example on page 1625. Let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex with $\sigma(0, 1) \in B_1(2)$ and $\sigma(1, 0) \in B_1(-2)$. We have

$$((\mu_1 \oplus \mu_2) \circ \partial)[\sigma] \underset{\substack{\uparrow \\ \text{description of } \partial \text{ in the Topological LES-Proposition 74.13}}}{=} ((\mu_1 \oplus \mu_2)([\partial\sigma]) = (\mu_1 \oplus \mu_2)([\underbrace{\sigma(0, 1)}_{\in B_1(2))}] - [\underbrace{\sigma(1, 0)}_{\in B_1(-2))}]) = (1, -1).$$

Since $(1, -1)$ is a generator of the kernel of $\mathbb{Z}^2 \xrightarrow{(1\ 1)} \mathbb{Z}$ we see that $[\sigma]$ is in fact a generator of $\mathrm{H}_1(X, A) \cong \mathbb{Z}$. In particular it is non-zero.

Recall that, as defined on page 439, we say that two maps $f, g\colon (X, A) \to (Y, B)$ between pairs of topological spaces are homotopic, if there exists a map $F\colon X \times [0, 1] \to Y$ such that $F(x, 0) = f(x)$ and $F(x, 1) = g(x)$ for all $x \in X$, and $F(a, t) \in B$ for all $a \in A$

and all $t \in [0,1]$. The following proposition extends the Homotopic Maps-and-Homology Proposition 73.6 to the relative case.

Proposition 74.15. Let $f, g\colon (X,A) \to (Y,B)$ be two maps between pairs of topological spaces. If f and g are homotopic, then the maps $f_*, g_*\colon \mathrm{C}_*(X,A) \to \mathrm{C}_*(Y,B)$ are chain homotopic, in particular for every $n \in \mathbb{N}_0$ we have

$$f_* = g_*\colon \mathrm{H}_n(X,A) \to \mathrm{H}_n(Y,B).$$

Proof. Let $f, g\colon (X,A) \to (Y,B)$ be two homotopic maps between pairs of topological spaces. To prove the proposition we have to look again at the proof of the Homotopic Maps-and-Homology Proposition 73.6. In that proof we explicitly constructed a chain $P_n\colon \mathrm{C}_n(X) \to \mathrm{C}_{n+1}(Y)$, $n \in \mathbb{N}_0$ between the maps f_* and g_* from $\mathrm{C}_*(X)$ to $\mathrm{C}_*(Y)$. It follows immediately from the definition of the chain homotopy that it has the property that $\mathrm{C}_n(A)$ gets sent to $\mathrm{C}_{n+1}(B)$. In particular the chain homotopy descends to maps $Q_n\colon \mathrm{C}_n(X,A) \to \mathrm{C}_{n+1}(Y,B)$ which then form a chain homotopy between the maps f_* and g_* from $\mathrm{C}_*(X,A)$ to $\mathrm{C}_*(Y,B)$. It now follows immediately from Lemma 73.2 that $f_* = g_*\colon \mathrm{H}_n(X,A) \to \mathrm{H}_n(Y,B)$. ∎

We conclude this section with the following result that can be viewed as a generalization of the Homotopy Equivalence-H_*-Corollary 73.9 to the relative setting.

Corollary 74.16.

(1) If $f\colon (X,A) \to (Y,B)$ is a homotopy equivalence of pairs of topological spaces,[896] then for every $n \in \mathbb{N}_0$ the induced map $f_*\colon \mathrm{H}_n(X,A) \to \mathrm{H}_n(Y,B)$ is an isomorphism.

(2) Let X be a topological space.
   (a) Let $A \subset B$ be subsets of X. If A is a deformation retract of B, then for every $n \in \mathbb{N}_0$ the inclusion induced map $\mathrm{H}_n(X,A) \to \mathrm{H}_n(X,B)$ is an isomorphism.
   (b) If A is a deformation retract of X, then $\mathrm{H}_n(X,A) = 0$ for all $n \in \mathbb{N}_0$.
   (c) Let $A \subset Y$ be subsets of X. If Y is a deformation retract of X, then for every $n \in \mathbb{N}_0$ the inclusion induced map $\mathrm{H}_n(Y,A) \to \mathrm{H}_n(X,A)$ is an isomorphism.

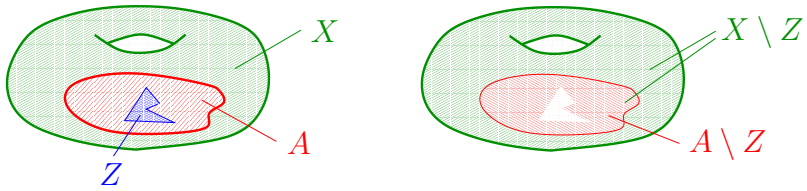
Proof. Let X be a topological space.

(1) We deduce this statement from Proposition 74.15 the same way we deduced the Homotopy Equivalence-H_*-Corollary 73.9 from the Homotopic Maps-and-Homology Proposition 73.6.

(2) (a) Let $A \subset B$ be a deformation retract of B. As we mentioned on page 440, the inclusion map $(X,A) \to (X,B)$ is a homotopy equivalence of pairs of topological spaces. Thus the desired statement follows from (1).
   (b) This statement follows from Statement (a) applied to $B = X$ and the trivial observation that $\mathrm{H}_n(X,X) = 0$ for all $n \in \mathbb{N}_0$.
   (c) Let $A \subset Y$ be subsets of X. If Y is a deformation retract of X, then we saw already on page 440 that the inclusion map $(Y,A) \to (X,A)$ is a homotopy equivalence of pairs of topological spaces. Thus the desired statement follows again from (1). ∎

The statement of the Topological LES-Corollary 74.14 looks already very similar to the statement of Theorem 74.3 that we actually want to prove. Now we "only" have to find

[896] We refer to page 440 for the definition.



the connection between the groups $\mathrm{H}_n(X, A)$ and $\mathrm{H}_n(X/A)$. The notations already look very similar, and they do so for good reasons, since in both cases "one ignores what lies in A". Nonetheless, proving the precise relationship will still require some substantial piece of work.

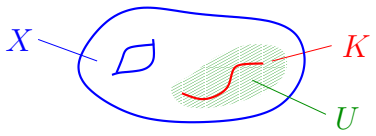
74.7. **The Excision Theorem.** The key step in finding the connection between the groups $\mathrm{H}_n(X, A)$ and $\mathrm{H}_n(X/A)$ is given by the following Excision Theorem 74.17.

Theorem 74.17. (Excision Theorem) Let X be a topological space and let $Z \subset A \subset X$ be subsets such that the closure of Z is contained in the interior of A. Then the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n(X \setminus Z, A \setminus Z) \xrightarrow{\cong} \mathrm{H}_n(X, A).$$

The theorem thus says in particular that if we are given a pair of topological spaces (X, A) and if we excise [897] a subset Z from the interior of A, then this does not affect the relative homology groups.

$$\mathrm{H}_n(X, A) \cong \mathrm{H}_n(X \setminus Z, A \setminus Z)$$



On many occasions we will need the following variation on the Excision Theorem 74.17.

Theorem 74.18. (Excision Theorem) Let X be a topological space.

(1) Let K be a subset of X and let U be a neighborhood of the closure of K. Then the inclusion $(U, U \setminus K) \to (X, X \setminus K)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n(U, U \setminus K) \xrightarrow{\cong} \mathrm{H}_n(X, X \setminus K).$$

(2) The hypotheses of (1) are satisfied if X is Hausdorff (e.g. if X is a topological manifold) and if K is a compact subset that is contained in an open set U.

here we have $\mathrm{H}_n(U, U \setminus K) \xrightarrow{\cong} \mathrm{H}_n(X, X \setminus K)$

Proof of Theorem 74.18 assuming Theorem 74.17.

(1) We have

$$\mathrm{H}_n(U, U \setminus K) \underset{\uparrow}{=} \mathrm{H}_n(X \setminus Z, A \setminus Z) \underset{\uparrow}{\xrightarrow{\cong}} \mathrm{H}_n(X, A) = \mathrm{H}_n(X, X \setminus K).$$

set $A := X \setminus K$ and $Z := X \setminus U$

since U is a neighborhood of the closure of K we see that the closure of Z is contained in the interior of A, thus we can apply the Excision Theorem 74.17

[897] The verb "to excise" means to cut out, or in German "ausschneiden".

(2) If X is Hausdorff and if K is a compact subset that is contained in an open set U, then it follows from the Compact-Closed Lemma 1.21 (2) that K is also a closed subset, hence we have $\overline{K} \subset U$. ■

Before we turn to the proof of the Excision Theorem 74.17 we first want to show that we can now relate the relative homology groups of a pair (X, A) to the homology groups of the quotient space X/A, assuming $A \subset X$ is good. To do so we need the following definition.

Definition. Let X be a topological space and let $A \subset X$ be a[898] subset. We denote by $p\colon (X, A) \to (X/A, A/A)$ the natural projection. For each $n \in \mathbb{N}_0$ we define

$$\mathrm{H}_n(X, A) \xrightarrow{p_*} \mathrm{H}_n(X/A, A/A) \xleftarrow[\cong]{\text{ж from Lemma 74.12}} \widetilde{\mathrm{H}}_n(X/A)\ .$$
$$\text{=: ю}$$

The following lemma summarizes two properties of the maps ю.

Lemma 74.19.

(1) Let X be a topological space and let $A \subset X$ be a subset. We denote by $p\colon X \to X/A$ the projection. The following diagram commutes:[899]

$$\begin{array}{ccc} & \mathrm{H}_k(X, A) & \\ {\scriptstyle \text{ж}}\nearrow & & \searrow{\scriptstyle \text{ю}} \\ \widetilde{\mathrm{H}}_k(X) & \xrightarrow{p_*} & \widetilde{\mathrm{H}}_k(X/A). \end{array}$$

(2) We denote by *PairTop* the category of pairs of topological spaces that we introduced on page 439. Furthermore as usual we denote by *AbGroup* the category of abelian groups. The above maps ю define a natural transformation from the functor

$$\begin{array}{ccc} \mathit{PairTop} & \to & \mathit{AbGroup} \\ (X, A) & \mapsto & \mathrm{H}_n(X, A) \end{array} \quad \text{to the functor} \quad \begin{array}{ccc} \mathit{PairTop} & \to & \mathit{AbGroup} \\ (X, A) & \mapsto & \widetilde{\mathrm{H}}_n(X/A). \end{array}$$

Proof.

(1) We consider the following diagram

$$\begin{array}{ccccc} & & \mathrm{H}_k(X, A) & & \\ & {\scriptstyle \text{ж}}\nearrow & \downarrow{\scriptstyle p_*} & \searrow{\scriptstyle \text{ю}} & \\ \widetilde{\mathrm{H}}_k(X) & & \mathrm{H}_k(X/A, A/A) & \xleftarrow[\cong]{\text{Lemma 74.12}} & \widetilde{\mathrm{H}}_k(X/A). \\ & {\scriptstyle [\sigma]\mapsto[\sigma]}\searrow & & \nearrow & \\ & & {\scriptstyle p_*} & & \end{array}$$

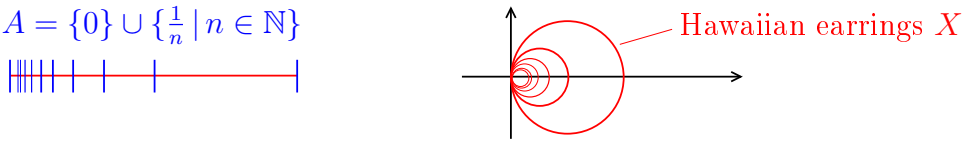
It follows immediately from the definitions that all three regions of the diagram commute. This observation gives us the desired statement.

(2) This statement follows basically immediately from the definitions. ■

The following proposition is much more interesting than the previous lemma.

[898] Note that the definition also makes sense if A is the empty set.

[899] The left diagonal map is the composition of the natural map $\widetilde{\mathrm{H}}_k(X) \to \mathrm{H}_k(X)$ from the Reduced Homology Lemma 74.1 with the natural map $\mathrm{H}_k(X) \to \mathrm{H}_k(X, A)$.



Proposition 74.20. (Homology-of-Quotients Proposition) Let X be a topological space, let $A \subset X$ be a subset and let $n \in \mathbb{N}_0$. If A is a good subset[900], then the natural homomorphism $\mathrm{H}_n(X,A) \xrightarrow{\text{IO}} \widetilde{\mathrm{H}}_n(X/A)$ is an isomorphism.

Remark. In Corollary 78.16 we will show the analogue of the Homology-of-Quotients Proposition 74.20 under the slightly different hypothesis that the inclusion map $i\colon A \to X$ is a closed cofibration.

Example. Let X be a topological space, let $A \subset X$ be a subset and let $n \in \mathbb{N}_0$. For better or worse the natural homomorphism $\mathrm{H}_n(X,A) \to \widetilde{\mathrm{H}}_n(X/A)$ is in general not an isomorphism. In fact in general the two groups $\mathrm{H}_n(X,A)$ and $\widetilde{\mathrm{H}}_n(X/A)$ are not even abstractly isomorphic.

For example consider $X = [0,1]$ and $A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$. In Exercise 56.1 we showed that the quotient space X/A is homeomorphic to the Hawaiian earrings. (See the figure below for an illustration.) In Exercise 74.18 we will prove the following two statements:

(1) The group $\mathrm{H}_1(X,A)$ is countable.
(2) The group $\mathrm{H}_1(X/A)$ is uncountable.

We will first provide a proof of the Homology-of-Quotients Proposition 74.20 assuming the Excision Theorem 74.17. This proof relies on the following elementary little lemma, which is precisely the content of Exercise 5.46.

Auxiliary Lemma 74.21. Let X be a topological space and let A be a closed subset of X.

(1) For every open subset $U \subset X \setminus A$ the obvious map $U \to X/A$ is an open embedding.
(2) For every open neighborhood W of A the obvious map $W \setminus A \to (W/A) \setminus (A/A)$ is a homeomorphism.

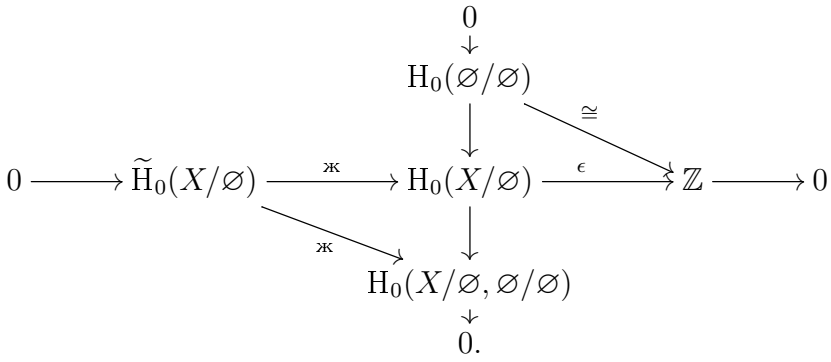
Proof of Lemma 74.21. Let X be a topological space and let A be a closed subset of X. We denote by $p\colon X \to X/A$ the natural projection.

(1) Let $U \subset X \setminus A$ be an open subset. Recall that we need to show that the map $q\colon U \to X \to X/A$ is an open embedding. It follows from $U \subset X \setminus A$ that q is an injection. Furthermore note that by the Topological-Quotient Proposition 5.15 (1a) we know that q is continuous. By the Open -Injective Map Lemma 2.16 (2) it remains to show that $q\colon U \to X/A$ is an open map. Now let $V \subset U$ be an open

[900] We refer to page 1614 for several examples of good subsets. For example we saw that if X is a CW-complex, then any subcomplex A is a good subset.

subset. We need to show that $q(V) \subset X/A$ is open. We break the argument into three easy steps:

(a) It follows from the Open -Closed Inclusion Lemma 2.10 (1) and the fact that A is by hypothesis closed, that V is also an open subset of X.



(b) Since $A \cap V = \varnothing$ we see that $p^{-1}(p(V)) = V$, which by (a) is in fact an open subset of X.

(c) It follows from (b) and the definition of the quotient topology that $p(V)$ is an open subset of X/A.

(2) Let W be an open neighborhood of A. We set $U := W \setminus A$. Since A is closed we see that U is an open subset of $W \setminus A$. Recall that we want to show that the obvious map $q\colon W \setminus A \to (W/A) \setminus (A/A)$ is a homeomorphism. It is clear that q is a bijection and it follows from the Twice Quotient Lemma 5.23 (2) that q is continuous. By the Open -Injective Map Lemma 2.16 (2) it remains to show that $q\colon W \setminus A \to (W/A) \setminus (A/A)$ is an open map. Thus let V be an open subset of $W \setminus A$. We have $q(V) = p(V) \cap (W/A \setminus A/A)$. It follows from (1c) and the definition of the subspace topology that $q(V)$ is an open subset of $(W/A) \setminus (A/A)$. ■

Proof of Proposition 74.20 assuming the Excision Theorem 74.17. Let X be a topological space, let $A \subset X$ be a good subset and let $n \in \mathbb{N}_0$.

First we need to get the annoying case that $A = \varnothing$ out of the way. Note that the map $(X, \varnothing) \to (X/\varnothing, \varnothing/\varnothing)$ is easily seen to be a homeomorphism of pairs of topological spaces. Thus it remains to show that the map $\text{ж}\colon \widetilde{\mathrm{H}}_n(X/\varnothing) \to \mathrm{H}_n(X, \varnothing)$ is an isomorphism. It follows immediately from the Reduced Homology Lemma 74.1 (4) and the Topological LES-Corollary 74.14 that the only dimension one needs to worry about for a second is $n = 0$. In this case we have the following diagram:

It follows from Lemma 74.2 and the Topological LES-Corollary 74.14 that the horizontal and the vertical sequences are both exact. The diagonal map on the top right is easily seen to be an isomorphism. Some mild diagram chasing, see Exercise 74.10, now shows that the diagonal map on bottom the is also an isomorphism.

Now we turn to the much more interesting case that $A \neq \varnothing$. We make the following simple preparations:

(1) Since A is good we can pick an open neighborhood U of A in X such that A is a deformation retract of U.

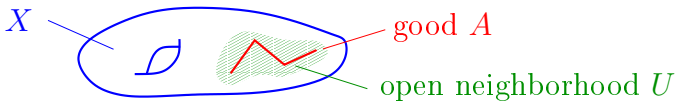
(2) We denote by $p\colon X \to X/A$ the projection .

(3) We denote by $q\colon X \setminus A \to (X/A) \setminus (A/A)$ the restriction of p to $X \setminus A$. For completeness' sake we point out that it follows from Lemma 2.1 that q is continuous.

Now we consider the following diagram

$$\begin{array}{ccccc} \mathrm{H}_n(X,A) & \longrightarrow & \mathrm{H}_n(X,U) & \longleftarrow & \mathrm{H}_n(X \setminus A, U \setminus A) \\ \downarrow{\scriptstyle p_*} & & \downarrow{\scriptstyle p_*} & & \downarrow{\scriptstyle q_*} \\ \mathrm{H}_n(X/A, A/A) & \longrightarrow & \mathrm{H}_n(X/A, U/A) & \longleftarrow & \mathrm{H}_n((X/A) \setminus (A/A), (U/A) \setminus (A/A)), \end{array}$$

here all the horizontal maps are induced by inclusions of pairs of topological spaces. It follows easily from the definitions that the diagram commutes. It follows from our hypothesis that A is closed, together with the above auxiliary Lemma 74.21 (2), that the map $q\colon (X \setminus A, U \setminus A) \to ((X/A) \setminus (A/A), (U/A) \setminus (A/A))$ is a homeomorphism of pairs of topological spaces. We obtain from this observation that the vertical map on the right is an isomorphism. Our actual goal is to show that the vertical map on the left is an isomorphism. This follows from the commutativity of the above diagram and from the following claim:



Claim. All horizontal maps are isomorphisms.

Proof. We distinguish three different situations:

(1) It follows from the Excision Theorem 74.17 that both the top horizontal and the bottom horizontal map on the right-hand side are isomorphisms.

(2) Since A is deformation retract of U we obtain from Corollary 74.16 that the top left horizontal map is an isomorphism.

(3) Recall that A is a deformation retract of U. It follows from the Quotient Deformation Retract Proposition 15.9 that A/A is a deformation retract of U/A.[901] As in (2) we now see that the bottom-left horizontal map is an isomorphism. ∎

Proof of Theorem 74.3 assuming the Excision Theorem 74.17. Let X be a topological space and let $A \subset X$ be a good subset. We denote by $i\colon A \to X$ the inclusion and we denote by $q\colon X \to X/A$ the projection . We consider the following diagram:

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \widetilde{\mathrm{H}}_n(A) & \xrightarrow{i_*} & \widetilde{\mathrm{H}}_n(X) & \xrightarrow{\text{ж}_{X,A*}} & \mathrm{H}_n(X,A) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{n-1}(A) & \longrightarrow & \widetilde{\mathrm{H}}_{n-1}(X) \xrightarrow{i_*} \ldots \\ & & & & & \searrow^{q_*} & \downarrow{\scriptstyle \text{ю}} & & & & \\ & & & & & & \widetilde{\mathrm{H}}_n(X/A). & & & & \end{array}$$

We make the following comments and observations:

(1) The horizontal sequence is the long exact sequence coming from the Topological LES-Corollary 74.14.

[901] The diligent reader who checks the statements we refer to will not fail to notice, that the Quotient Deformation Retract Proposition 15.9 rests eventually on the Whitehead Quotient Theorem 13.4. It is all too often overlooked (see see e.g. earlier version of these notes) that the Quotient Deformation Retract Proposition 15.9 is required and that it is non-trivial.

(2) The vertical map is the natural homomorphism that we defined on page 1633. By Lemma 74.19 (1) we know that the triangle commutes.
(3) Since A is good we obtain from the Homology-of-Quotients Proposition 74.20 that the vertical map ю is an isomorphism.

Now we consider the maps $\widetilde{\partial} := \text{ю}^{-1} \circ \partial \colon \widetilde{\mathrm{H}}_n(X/A) \to \widetilde{\mathrm{H}}_{n-1}(A)$. Since ю and ∂ are natural we see that the maps $\text{ю}^{-1} \circ \partial$ are also natural. By the above the sequence

$$\ldots \longrightarrow \widetilde{\mathrm{H}}_n(A) \xrightarrow{i_*} \widetilde{\mathrm{H}}_n(X) \xrightarrow{q_*} \widetilde{\mathrm{H}}_n(X/A) \xrightarrow{\widetilde{\partial}} \widetilde{\mathrm{H}}_{n-1}(A) \longrightarrow \widetilde{\mathrm{H}}_{n-1}(X) \xrightarrow{i_*} \ldots$$

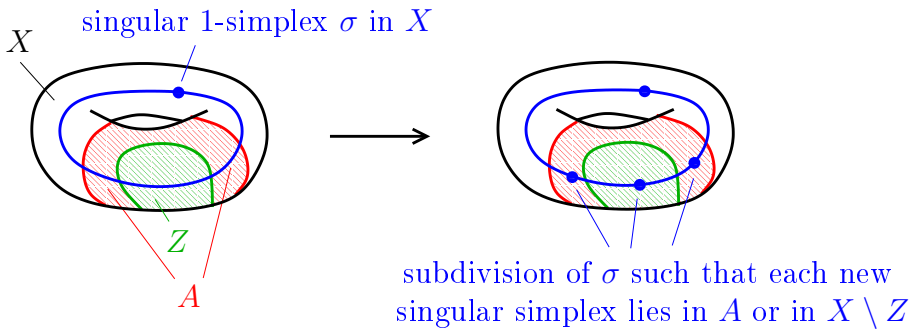
is exact. ■

74.8. **The proof of the Excision Theorem 74.17: the idea.** We are still not done with the proof of Theorem 74.3 since we still have to prove the Excision Theorem 74.17. In this section we want to come up with the idea for the proof of the Excision Theorem 74.17. The full details of the proof will then be given in the following section.
Thus let X be a topological space and let $Z \subset A \subset X$ be two subsets such that the closure of Z is contained in the interior of A. Our goal is to show that the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for every $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n(X \setminus Z, A \setminus Z) \;\to\; \mathrm{H}_n(X, A).$$

Let us attempt to prove that the map $\mathrm{H}_n(X \setminus Z, A \setminus Z) \to \mathrm{H}_n(X, A)$ is surjective. We take an element in $\mathrm{H}_n(X, A)$ and we choose a representative $a_1\sigma_1 + \cdots + a_r\sigma_r$ where $\sigma_i \colon \Delta^n \to X$, $i = 1, \ldots, r$ are singular n-simplices in X.
We make the following two basic observations:

(1) If the singular n-simplices $\sigma_1, \ldots, \sigma_r$ lie in $X \setminus Z$,[902] then $[a_1\sigma_1 + \cdots + a_r\sigma_r]$ evidently lies in the image of the inclusion induced map $\mathrm{H}_n(X \setminus Z, A \setminus Z) \to \mathrm{H}_n(X, A)$.
(2) If a singular n-simplex lies entirely in A, then it represents the zero element in the quotient group $\mathrm{C}_n(X, A) = \mathrm{C}_n(X)/\mathrm{C}_n(A)$.



The combination of these two observations proves the following lemma.

Lemma 74.22. Let X be a topological space and let $Z \subset A$ be two subsets of X. Let $c = a_1\sigma_1 + \cdots + a_r\sigma_r$ be a cycle in X such that each σ_i lies entirely in A or it lies entirely in $X \setminus Z$. Then $[c]$ lies in the image of $\mathrm{H}_n(X \setminus Z, A \setminus Z) \to \mathrm{H}_n(X, A)$.

Unfortunately not every cycle in $\mathrm{C}_n(X)$ satisfies the hypothesis of the lemma. But we will see in the next section that we can subdivide each singular simplex into smaller singular simplices that lie entirely in A or lie entirely in $X \setminus Z$.

74.9. **The proof of the Excision Theorem 74.17: the full details.** In this chapter we will now turn the vague idea of the last section into a rigorous proof of the Excision Theorem 74.17. This will take a surprisingly long time.
First we introduce a few definitions.

[902] Given a topological space X and a subset A we say that *a singular simplex* $\sigma \colon \Delta^n \to X$ *lies in* A if the image of σ lies in A.

Definition. Let again X be a topological space.

(1) On page 114 we defined a cover of X to be a family $\{U_i\}_{i\in I}$ of subsets of X such that $X = \bigcup_{i\in I} U_i$.

(2) We say a cover $\{U_i\}_{i\in I}$ is comfortable if $X = \bigcup_{i\in I} \overset{\circ}{U}_i$, i.e. if the interiors of the U_i also form a cover of X.

We move straight to the next definition.

Definition. Let again X be a topological space. Given a comfortable cover $\mathcal{U} = \{U_i\}_{i\in I}$ we consider the following subgroup of $\mathrm{C}_n(X)$:

$$\mathrm{C}_n^{\mathcal{U}}(X) := \left\{ \sum_{j=1}^{k} a_j \cdot \sigma_j \;\middle|\; \text{for each } j \text{ there exists a } U_i \in \mathcal{U} \text{ such that the image of } \sigma_j \text{ lies in } U_i \right\}.$$

It follows quite easily from the definitions that the restriction of the usual boundary map $\partial_n \colon \mathrm{C}_n(X) \xrightarrow{\partial} \mathrm{C}_{n-1}(X)$ to $\mathrm{C}_n^{\mathcal{U}}(X)$ restricts to a map $\partial_n \colon \mathrm{C}_n^{\mathcal{U}}(X) \xrightarrow{\partial} \mathrm{C}_{n-1}^{\mathcal{U}}(X)$. Since this map is the restriction of the usual boundary map it follows in particular that the composition $\partial_n \circ \partial_{n+1} \colon \mathrm{C}_{n+1}^{\mathcal{U}}(X) \xrightarrow{\partial} \mathrm{C}_{n-1}^{\mathcal{U}}(X)$ is the zero map. Thus we can define

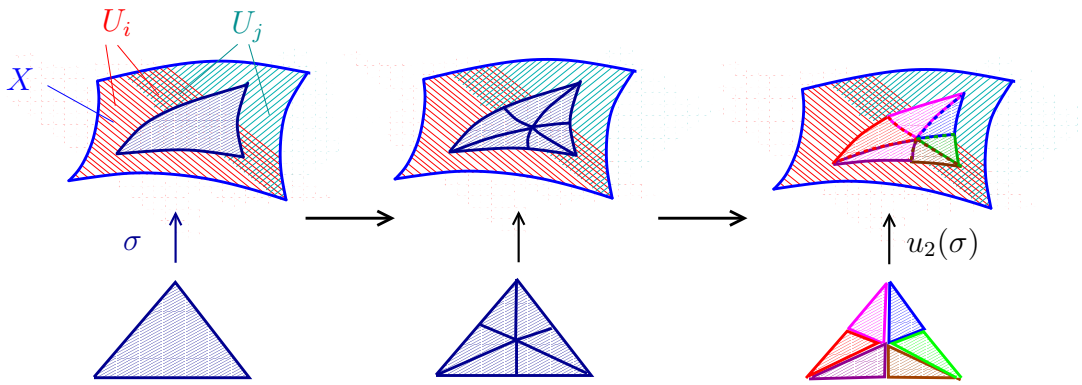
$$\begin{aligned} \mathrm{H}_n^{\mathcal{U}}(X) &:= \mathrm{H}_n\big(C_*^{\mathcal{U}}(X), \partial_*\big) \\ &= \ker\big(\partial_n \colon \mathrm{C}_n^{\mathcal{U}}(X) \to \mathrm{C}_{n-1}^{\mathcal{U}}(X)\big) \,/\, \mathrm{im}\,\big(\partial_{n+1} \colon \mathrm{C}_{n+1}^{\mathcal{U}}(X) \to \mathrm{C}_n^{\mathcal{U}}(X)\big). \end{aligned}$$

The homology groups $\mathrm{H}_n^{\mathcal{U}}(X)$ are thus defined by singular chains which are "small" in the sense that the image of each singular simplex lies in some U_i.

The following proposition says that we can determine the homology of a topological space through such "small" singular chains. As we will see later on many occasions, this proposition is at the heart of many methods for computing homology groups.

Proposition 74.23. (Comfortable Covering Proposition) Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i\in I}$ be a comfortable cover of X. Then the inclusion map

$$\mathrm{C}_*^{\mathcal{U}}(X) \;\to\; \mathrm{C}_*(X)$$



induces for every $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n^{\mathcal{U}}(X) \;\xrightarrow{\cong}\; \mathrm{H}_n(X).$$

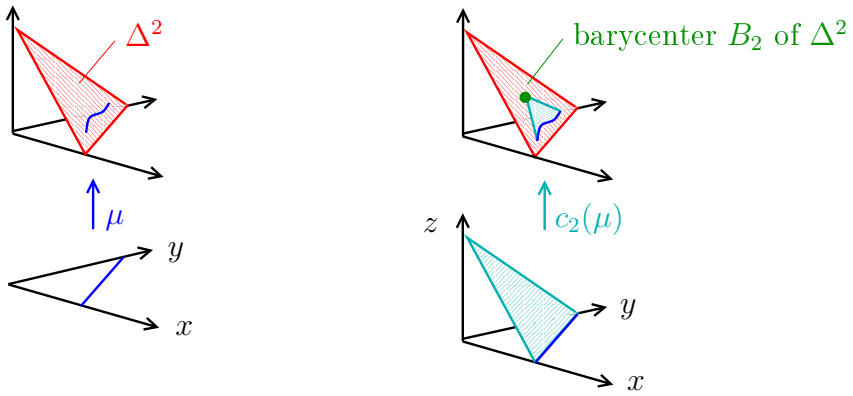
Remark. In fact a stronger statement holds: the inclusion map $\mathrm{C}_*^{\mathcal{U}}(X) \to \mathrm{C}_*(X)$ is in fact a chain homotopy equivalence. Later, in Section 81.2, we will show that this stronger statement follows in fact from the Comfortable Covering Proposition 74.23 and a purely

algebraic argument. Alternatively one can fight one's way through the proof of the Comfortable Covering Proposition 74.23 and upgrade the proof to this stronger statement. This approach is for example pursued in [**Hat2002**, Proposition 2.21]. The disadvantage is that it makes the proof even more complicated than it already is.

The idea of the proof of the Comfortable Covering Proposition 74.23 is the one we already described in the previous section. We want to replace systematically each singular n-simplex $\sigma\colon \Delta^n \to X$ by a singular n-chain of the form $\sum_{j=1}^{r} a_j \cdot \sigma_j$ such that the image of each singular simplex σ_j lies in some $U_i \in \mathcal{U}$. As we have seen before in Lemma 72.3 in the 1-dimensional case, an appropriate subdividing procedure does not change the homology class. The systematic approach we are going to use is given by "barycentric subdivision". The key idea is sketched in the figure below for the case $n = 2$.

Before we can execute this idea we have to introduce a few more definitions.

(1) Given $n \in \mathbb{N}_0$ we denote by $B_n := (\frac{1}{n+1}, \ldots, \frac{1}{n+1}) \in \Delta^n$ the *barycenter*[903] of the standard n-simplex Δ^n.



(2) Given a singular l-simplex $\mu\colon \Delta^l \to \Delta^n$ we consider the singular $(l+1)$-simplex $c_{l+1}(\mu)\colon \Delta^{l+1} \to \Delta^n$ which is defined as the composition of the (inverses) of the following two maps:

homeomorphism by the Compact-Hausdorff Proposition 2.17 (3) ; continuous by the Topological-Quotient Proposition 5.15 (1b)

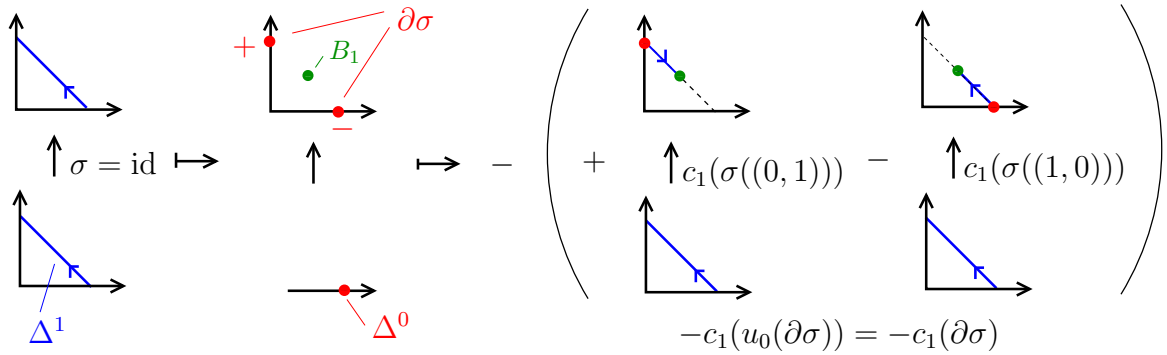
$$\begin{array}{rcccl} c_{l+1}(\mu)\colon \Delta^{l+1} & \overset{\cong}{\leftarrow} & (\Delta^l \times [0,1])/\Delta^l \times \{1\} & \to & \Delta^n \\ ((t_0,\ldots,t_l)\cdot(1-s),s) & \mapsto & [((t_0,\ldots,t_l),s)] & & \\ & & [((t_0,\ldots,t_l),s)] & \mapsto & \underbrace{\mu(t_0,\ldots,t_l)\cdot(1-s)+B\cdot s}_{\text{contained in } \Delta^n \text{ since } \Delta^n \text{ is convex}} \end{array}$$

Pictorially speaking the singular $(l+1)$-simplex $c_{l+1}(\mu)$ thus corresponds to the "cone" which is given by the singular l-simplex μ and the barycenter B_n. By Lemma 51.1 this map $\mu \to c_{l+1}(\mu)$ defines a linear map $\mathrm{C}_l(\Delta^n) \to \mathrm{C}_{l+1}(\Delta^n)$ that we also denote by c_{l+1} and which we call the $(l+1)$-*st cone map*.

[903] The word "barycenter" comes from the Greek word "barys" which means heavy. In physics the barycenter of an object is the center of mass, in our case the barycenter of the standard n-simplex is the center of mass if we view Δ^k as a physical object of uniform density.

(3) For $n = 0, 1, 2, 3, \ldots$ we now inductively do the following:
   (a) we define an element $\chi_n \in \mathrm{C}_n(\Delta^n)$, and
   (b) for each topological space X we define a homomorphism $u_n \colon \mathrm{C}_n(X) \to \mathrm{C}_n(X)$.

We do this inductive procedure as follows:
   (i) We set $\chi_0 = \mathrm{id} \colon \Delta^0 \to \Delta^0$ and for each topological space X we define u_0 to be the identity on $\mathrm{C}_0(X)$.
   (ii) Now suppose $\chi_{n-1} \in \mathrm{C}_{n-1}(\Delta^{n-1})$ and that furthermore all the homomorphisms $u_{n-1} \colon \mathrm{C}_{n-1}(X) \to \mathrm{C}_{n-1}(X)$ are already defined. Then we define



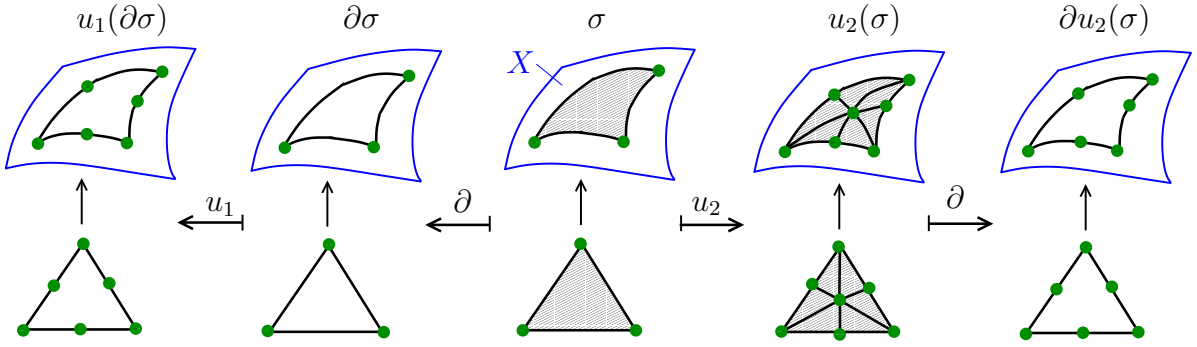
$$\chi_n \;:=\; (-1)^n \cdot c_n(u_{n-1}(\underbrace{\partial\, \mathrm{id}_{\Delta^n}}_{\in \mathrm{C}_{n-1}(\Delta^n)})) \;\in\; \mathrm{C}_n(\Delta^n).$$

Furthermore, for each topological space X we define

$$\begin{array}{rcl} u_n \colon \mathrm{C}_n(X) & \to & \mathrm{C}_n(X) \\ \sum_{l=1}^{r} a_l \cdot (\sigma_l \colon \Delta^n \to X) & \mapsto & \sum_{l=1}^{r} a_l \cdot (\sigma_l)_*(\underbrace{\chi_n}_{\in \mathrm{C}_n(\Delta^n)}). \end{array}$$

map $\sigma_l \colon \Delta^l \to X$ induces a map $(\sigma_l)_* \colon \mathrm{C}_n(\Delta^l) \to \mathrm{C}_n(X)$

Note that with this notation we have $u_n(\mathrm{id}_{\Delta^n}) = \chi_n$. The map u_n is illustrated for $n = 1$ in the figure below. For $n = 2$ we already gave a more schematic sketch in the figure below without considering signs and orientations.



Before we can continue we need to prove several technical lemmas about the subdivision maps.

Lemma 74.24. (Chain Subdivision Lemma) Let X be a topological space. The maps $u_n\colon \mathrm{C}_n(X) \to \mathrm{C}_n(X)$, $n \in \mathbb{N}_0$, form a chain map from the chain complex $(\mathrm{C}_*(X), \partial)$ to itself.

The statement of the Chain Subdivision Lemma 74.24 is equivalent to the statement that for any singular n-simplex σ in X we have

$$u_{n-1}(\partial\sigma) \;=\; \partial(u_n(\sigma)).$$

Put differently, the Chain Subdivision Lemma 74.24 says that it does not make a difference whether we first take the boundary and then subdivide, or whether we first subdivide and then take the boundary. This statement is sketched in the figure below. The picture is quite convincing.

Proof of the Chain Subdivision Lemma 74.24. [904] We adopt the following notation and we make the following remarks:

(1) We denote the barycenter of Δ^n by b.

(2) As on page 1584, given points $x_0, \ldots, x_k \in \Delta^n$ we denote by $[x_0, \ldots, x_k]$ the singular k-chain $\Delta^k \to \Delta^n$ that is given by[905]

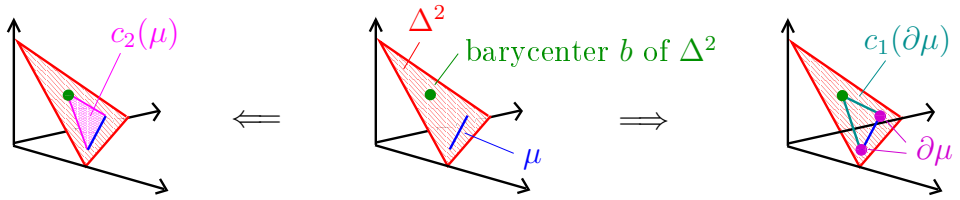
$$\begin{aligned} \Delta^k &\to \Delta^n \\ (t_0, \ldots, t_k) &\mapsto \sum_{i=0}^{k} t_i x_i, \end{aligned}$$

we refer to such a singular k-simplex as a *linear* singular simplex.

(3) We denote by $\mathrm{C}_k^{\mathrm{lin}}(\Delta^n)$ the subgroup of $\mathrm{C}_k(\Delta^n)$ generated by all the linear singular k-simplices. Note that the boundary map $\partial\colon \mathrm{C}_k(\Delta^n) \to \mathrm{C}_{k-1}(\Delta^n)$ restricts to a boundary map $\partial\colon \mathrm{C}_k^{\mathrm{lin}}(\Delta^n) \to \mathrm{C}_{k-1}^{\mathrm{lin}}(\Delta^n)$.

(4) For $x_0, \ldots, x_k \in \Delta^n$ we write

$$[x_0, \ldots, \widehat{x_i}, \ldots, x_k] \;:=\; [x_0, \ldots, x_{i-1}, x_{i+1}, \ldots, x_k].$$



The proof of the lemma will be broken into three claims.

Claim. For any $\mu \in \mathrm{C}_k^{\mathrm{lin}}(\Delta^n)$ we have

$$\partial(c_{k+1}(\mu)) \;=\; c_k(\partial\mu) + (-1)^{k+1} \cdot \mu \;\in\; \mathrm{C}_k(\Delta^n).$$

[904] We will not do this proof in the lectures. The proof is somewhat lengthy but straightforward. The cleverness hereby does not lie in the proof, but in the cleverly chosen definitions, which turn the verification into a simple calculation.

[905] It is straightforward to show that this map does indeed take values in Δ^n.

Proof. To prove the claim we first note that for any choice of points $x_0, \dots, x_{l-1} \in \Delta^n$ we have by definition of c_l that

$$c_l([x_0, \dots, x_{l-1}]) \;=\; [x_0, \dots, x_{l-1}, b].$$

It now follows that for any $w_0, \dots, w_k \in \Delta^n$ we have the following equality in $\mathrm{C}_k(\Delta^n)$:

$$\begin{aligned}
\partial(c_{k+1}([w_0, \dots, w_k])) &\overset{\text{by the above equality}}{\downarrow} \\
&= \partial([w_0, \dots, w_k, b]) \\
&\underset{\text{definition of } \partial \text{ and by the above equality}}{\uparrow} \\
&= \sum_{j=0}^{k} (-1)^j \cdot [w_0, \dots, \widehat{w_j}, \dots, w_k, b] + (-1)^{k+1} \cdot [w_0, \dots, w_k] \\
&\overset{\downarrow}{=} c_k(\partial([w_0, \dots, w_k])) + (-1)^{k+1} \cdot [w_0, \dots, w_k].
\end{aligned}$$

The claim immediately follows from this equality.

Claim. For any $n \in \mathbb{N}_0$ and any $\nu \in \mathrm{C}_n^{\mathrm{lin}}(\Delta^n)$ we have

$$\partial u_n(\nu) \;=\; u_{n-1}(\partial\nu).$$

Proof. We will prove this claim by induction on n. The case $n = 0$ is trivial. So now suppose we have already shown the case $n - 1$. It suffices to show the claim for all linear singular n-simplices. So let $\nu\colon \Delta^n \to \Delta^n$ be a linear singular n-simplex. We then have

$$\begin{aligned}
\partial u_n(\nu) &\overset{\text{def. of } u_n \text{ and } \chi_n, \text{ see page 1640}}{\downarrow} \partial(\nu_*(\chi_n)) \overset{\downarrow}{=} (-1)^n \cdot \partial(\nu_*(c_n(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})))) \overset{\text{since } \partial\circ\nu_* = \nu_*\circ\partial}{\downarrow} (-1)^n \cdot \nu_*\big(\partial(c_n(\underbrace{u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})}_{=:\mu}))\big) \\
&\underset{\text{we can apply the previous claim since } \mu := u_{n-1}(\partial\,\mathrm{id}_{\Delta^n}) \in \mathrm{C}_{n-1}^{\mathrm{lin}}(\Delta^n)}{\uparrow} (-1)^n \cdot \nu_*\big(c_{n-1}(\partial(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})) + (-1)^n \cdot u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})\big) \\
&\underset{\uparrow}{=} (-1)^n \cdot \nu_*\big(c_{n-1}(u_{n-2}(\underbrace{\partial\partial\,\mathrm{id}_{\Delta^n}}_{=0}))\big) \;+\; \nu_*(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})) \\
&\underset{\text{by induction hypothesis we have } \partial u_{n-1}(\rho) = u_{n-2}(\partial\rho) \text{ for } \rho \in \mathrm{C}_{n-1}^{\mathrm{lin}}(\Delta^n), \text{ applied here to } \rho = \partial\,\mathrm{id}_{\Delta^n}}{\uparrow} \\
&\underset{\text{Lemma 74.25 applied to } f=\nu}{\uparrow} u_{n-1}(\nu_*(\partial\,\mathrm{id}_{\Delta^n})) \;\underset{\text{by definition}}{\uparrow}{=}\; u_{n-1}(\partial\nu).
\end{aligned}$$

⊞

The following claim is just a reformulation of the statement of the lemma.

Claim. For any singular n-simplex σ in X we have $u_{n-1}(\partial\sigma) = \partial(u_n(\sigma))$.

Proof. So let $\sigma\colon \Delta^n \to X$ be a singular n-simplex in X. Then we have

$$\begin{array}{rcccccl} & & \text{Lemma 74.25 applied to } f=\sigma & & \text{since } \sigma_* \text{ is a chain map} & & \\ \partial(u_n(\sigma)) &=& \partial(u_n(\sigma_*(\mathrm{id}_{\Delta^n}))) &\overset{\downarrow}{=}& \partial(\sigma_*(u_n(\mathrm{id}_{\Delta^n}))) &\overset{\downarrow}{=}& \sigma_*(\partial(u_n(\mathrm{id}_{\Delta^n}))) \\ &=& \sigma_*(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})) &=& u_{n-1}(\sigma_*(\partial\,\mathrm{id}_{\Delta^n})) &=& u_{n-1}(\partial\sigma_*(\mathrm{id}_{\Delta^n})) \;=\; u_{n-1}(\partial\sigma). \\ & & \uparrow & & \uparrow & & \uparrow \\ & & \text{by the previous claim} & & \text{Lemma 74.25 applied to } f=\sigma & & \text{since } \sigma_* \text{ is a chain map} \end{array}$$

■

We continue with a refreshingly straightforward lemma.

Lemma 74.25. The maps $u_n\colon \mathrm{C}_n(X) \to \mathrm{C}_n(X)$ are natural,[906] in particular for any map $f\colon X \to Y$ between topological spaces and any $n \in \mathbb{N}_0$ we have

$$f_* \circ u_n \;=\; u_n \circ f_*\colon \mathrm{C}_n(X) \;\to\; \mathrm{C}_n(Y).$$

As we will see, Lemma 74.25 follows immediately from the definitions.

Proof. Let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. Then

$$\begin{array}{ccccc} f_*(u_n(\sigma)) & = & f_*(\sigma_*(\chi_n)) & = & (f\circ\sigma)_*(\chi_n) \quad = \quad u_n(f_*(\sigma)). \\ \uparrow & & \uparrow & & \uparrow \\ \text{by definition of } u_n(\sigma) & & \text{since } (f\circ\sigma)_* = f_*\circ\sigma_* & & \text{by definition of } u_n(f_*(\sigma)) \\ & & \text{as maps } \mathrm{C}_n(\Delta^n) \to \mathrm{C}_n(Y) & & \end{array}$$

Since the desired equality holds for all generators of $\mathrm{C}_n(X)$ it also holds for all of $\mathrm{C}_n(X)$. ■

The proof of the next lemma is again rather involved.

Lemma 74.26. Let X be a topological space. The chain maps

$$u_n\colon \mathrm{C}_n(X) \;\to\; \mathrm{C}_n(X)$$

are chain homotopic to the identity.

Proof. Showing that the chain maps $(u_n)_{n\in\mathbb{N}}$ are chain homotopic to the identity requires us to find maps $P_n\colon \mathrm{C}_n(X) \to \mathrm{C}_{n+1}(X), n \in \mathbb{N}_0$ such that for each $n \in \mathbb{N}_0$ the following equality holds:

$$\partial_{n+1} \circ P_n \;=\; -P_{n-1} \circ \partial_n + u_n - \mathrm{id}\,.$$

First we consider the case that X is a convex subset of some $\mathbb{R}^m$. Recall that we defined $\mathrm{C}_{-1}(X) = 0$, accordingly we define $P_{-1}\colon \mathrm{C}_{-1}(X) \to \mathrm{C}_0(X)$ to be the zero map. Let us suppose that we have already found maps $P_{-1}, \dots, P_{n-1}$ with the desired properties.

We want to define the next map $P_n\colon \mathrm{C}_n(X) \to \mathrm{C}_{n+1}(X)$. This map has to have the property that for each singular n-simplex σ we have

$$\partial_{n+1}(P_n(\sigma)) \;=\; -(P_{n-1}\circ\partial_n)(\sigma) \,+\, (u_n - \mathrm{id})(\sigma).$$

Put differently, to define $P_n(\sigma)$ we have to find a singular $(n+1)$-chain $E_\sigma \in \mathrm{C}_{n+1}(X)$ with

$$\partial E_\sigma \;=\; -(P_{n-1}\circ\partial)(\sigma) + (u_n - \mathrm{id})(\sigma),$$

---

[906] Let us explain in what sense these maps deserve to be called "natural". Given $n \in \mathbb{N}_0$ we consider the functor C_* from the category $\mathcal{T}op$ of topological spaces to the category $\mathcal{ChCplx}$ of chain complexes which is given by

$$\begin{array}{rcl} \text{topological space } X & \mapsto & \mathrm{C}_*(X) \\ \text{and} \qquad (f\colon X \to Y) & \mapsto & (f_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y)). \end{array}$$

Given a topological space X we denote by $\Phi_X\colon \mathrm{C}_*(X) \to \mathrm{C}_*(X)$ the map that is given by the n-th subdivision map that we defined on page 1640. Lemmas 74.24 an 74.25 say that these maps define a natural transformation from the functor C_* to itself.

so that we can then define $P_n(\sigma) := E_\sigma$. Thus let $\sigma\colon \Delta^n \to X$ be a singular n-simplex.

(1) For $n = 0$ we have

$$\big(\underbrace{P_{-1}}_{=0} \circ \partial_0 + \underbrace{u_0}_{=\mathrm{id}} - \mathrm{id}\big)(\sigma) \;=\; 0 \in \mathrm{C}_0(X),$$

and we put $E_\sigma := 0 \in \mathrm{C}_1(X)$.

(2) Now suppose that $n > 0$. Since X is convex we know from the discussion on page 1609 that $\mathrm{H}_n(X) = 0$. Therefore to show that an element $c \in \mathrm{C}_n(X)$ is the boundary of some element in $\mathrm{C}_{n+1}(X)$ it suffices to show that $\partial c = 0$. In our specific situation we calculate

by the Chain Subdivision Lemma 74.24 the subdivision maps form a chain map, i.e. $\partial \circ u_n = u_{n-1} \circ \partial$

$$\begin{aligned}\partial\big(\,(-P_{n-1}\partial_n + u_n - \mathrm{id})\,(\sigma)\big) &\overset{\downarrow}{=} -\partial P_{n-1}\partial\sigma + u_{n-1}\partial\sigma - \partial\sigma \\ &= \underbrace{(-\partial P_{n-1} + u_{n-1} - \mathrm{id})}_{=P_{n-2}\partial}(\partial\sigma) \;=\; P_{n-2}(\underbrace{\partial\partial\sigma}_{=0}) \;=\; 0.\end{aligned}$$

As we had just remarked, this implies that there exists an $E_\sigma \in \mathrm{C}_{n+1}(X)$ with $\partial(E_\sigma) = (P_{n-1}\partial_n - u_{n-1} - \mathrm{id})(\sigma)$.

Now we denote by $P_n\colon \mathrm{C}_n(X) \to \mathrm{C}_{n+1}(X)$ the map which assigns to each singular n-simplex σ the element $E_\sigma \in \mathrm{C}_{n+1}(X)$. Then it follows from the definition of E_σ that

$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; u_n - \mathrm{id}$$

as maps $\mathrm{C}_n(X) \to \mathrm{C}_n(X)$. This concludes the proof of Lemma 74.26 if X is a convex subset of some $\mathbb{R}^m$.

Now we deal with the general case. So let X be a topological space. We consider

$$\begin{aligned} P_n\colon \mathrm{C}_n(X) &\to \mathrm{C}_{n+1}(X) \\ \sum_{l=1}^r a_l \cdot (\sigma_l\colon \Delta^n \to X) &\mapsto \sum_{l=1}^r a_l \cdot (\sigma_l)_*(\underbrace{P_n(\mathrm{id}_{\Delta^n})}_{\uparrow}). \end{aligned}$$

defined since Δ^n is convex

It is straightforward to see that this is a chain homotopy from the subdivision map to the identity map. ∎

Remark. Later on, in Chapter 113.7, we will generalize the idea behind the proof of Lemma 74.26, to prove the Acyclic Model Theorems.

Definition. Given a topological space X and $m \in \mathbb{N}_0$ we denote by u_n^m the m-fold composition of $u_n\colon \mathrm{C}_n(X) \to \mathrm{C}_n(X)$.

Lemma 74.27. For each topological space X and every $m \in \mathbb{N}$ the maps $\{u_n^m\}_{n\geq 0}$ form a chain map $\mathrm{C}_*(X) \to \mathrm{C}_*(X)$ that is chain homotopic to the identity.

Proof. Recall that in the Chain Subdivision Lemma 74.24 we already saw that the maps $\{u_n\}_{n\geq 0}$ form a chain map $\mathrm{C}_*(X) \to \mathrm{C}_*(X)$. As we remarked on page 1592, the composition of chain maps is again a chain map. Thus for any $m \in \mathbb{N}_0$ the maps $\{u_n^m\}_{n\geq 0}$ are also chain maps.

By Lemma 74.26 we have $u_* \simeq \mathrm{id}$. By Lemma 73.1 (2) this implies $u_*^2 \simeq u_*$, and by Lemma 73.1 (1) this implies $u_*^2 \simeq \mathrm{id}$. An induction argument now shows that $u_*^m \simeq \mathrm{id}$ for all m. ∎

Definition. Given a singular chain c we can write it uniquely as $c = a_1\sigma_1 + \cdots + a_s\sigma_s$ with $a_1, \ldots, a_s \in \mathbb{Z} \setminus \{0\}$ and where the σ_i are pairwise different. We then say $\sigma_1, \ldots, \sigma_s$ are the pieces of c.

If $\sigma\colon \Delta^n \to X$ is a singular n-simplex, then the pieces of $u_n(\sigma)$ are evidently "smaller" than the pieces of σ, and by iteratively applying u_n one can hope to make the resulting pieces "arbitrary small". In the following two lemmas we will make it precise what we mean by "arbitrary small". Before we formulate the first lemma we need to recall and introduce several definitions.

Definition.

(1) Given a bounded subset A of $\mathbb{R}^{n+1}$ the diameter is defined as

$$\operatorname{diam}(A) \;:=\; \sup\big\{\|a-b\| \,\big|\, a,b \in A\big\} \in \mathbb{R}_{\geq 0}.$$

(2) Given a singular simple $\sigma\colon \Delta^n \to X$ we denote by $|\sigma|$ the image of σ.

Now we can formulate the following lemma.

Lemma 74.28. For any $x_0, \ldots, x_k \in \mathbb{R}^n$ and any piece τ of $u_k([x_0, \ldots, x_k])$ we have[907]

$$\operatorname{diam}(|\tau|) \;\leq\; \tfrac{n}{n+1} \cdot \operatorname{diam}(|[x_0, \ldots, x_k]|).$$

In the proof of Lemma 74.28 we will need the following elementary[908] geometric lemma.

Lemma 74.29. Let $y_0, \ldots, y_k \in \mathbb{R}^n$.

(1) We have the equality

$$\operatorname{diam}(|[y_0, \ldots, y_k]|) \;=\; \max\big\{\|y_i - y_j\| \,\big|\, i,j = 1, \ldots, k\big\}.$$

(2) We denote by $b = \frac{1}{k}\sum_{i=0}^{k} y_i$ the barycenter of $y_0, \ldots, y_k$. Then for any $i = 0, \ldots, k$ we have

$$\|y_i - b\| \;\leq\; \operatorname{diam}(|[y_0, \ldots, y_k]|).$$

Proof of Lemma 74.29.

(1) The inequality "$\geq$" follows immediately from the definitions and the observation that each y_i lies in

$$|[y_0, \ldots, y_k]| \;=\; \Big\{\sum_{i=0}^{k} t_i \cdot y_i \,\Big|\, t_i \in [0,1] \text{ and } \sum_{i=0}^{k} t_i = 1\Big\}.$$

We turn to the proof of the reverse inequality "$\leq$". So we pick $a, b \in |[y_0, \ldots, y_k]|$. By definition we can write $a = \sum_{i=0}^{k} s_i y_i$ and $b = \sum_{i=0}^{k} t_i y_i$ with $s_i, t_i \in [0,1]$ and such that

[907] Recall the definition on page 1584 of the map $[x_0, \ldots, x_k]\colon \Delta^k \to \mathbb{R}^n$.

[908] Here "elementary" means that the statement and the proof are basically high school level mathematics which does not mean that the proofs are entirely obvious.

$\sum_{i=0}^{k} s_i = \sum_{i=0}^{k} t_i = 1$. We then have

$$\begin{array}{rcl} \|a-b\| & \overset{\text{since } \sum_{i=0}^{k} t_i = 1}{=} & \left\|a - \sum_{i=0}^{k} t_i y_i\right\| = \left\|\sum_{i=0}^{k} t_i(a - t_i y_i)\right\| \leq \sum_{i=0}^{k} \|t_i(a-t_i y_i)\| \\ & \leq & \sum_{i=0}^{k} t_i \cdot \max_{i=0,\dots,k}\{\|a-y_i\|\} \overset{\text{since } \sum_{i=0}^{k} t_i = 1}{=} \max_{i=0,\dots,k}\{\|a-y_i\|\} \overset{\text{same argument applied to } a = \sum_{j=0}^{k} s_j y_j}{\leq} \max_{i,j=0,\dots,k}\{\|y_j - y_i\|\} \end{array}$$

(2) We denote by b_i the barycenter of $y_0, \dots, \widehat{y_i}, \dots, y_k$, i.e.

$$b_i = \tfrac{1}{k}\sum_{j\neq i} y_j.$$

We then have
$$b = \tfrac{1}{k+1} y_i + \tfrac{k}{k+1} b_i.$$

It follows that

$$\begin{array}{rcl} \|b-y_i\| = \left\|\frac{1}{k+1}y_i + \frac{k}{k+1}b_i - y_i\right\| & = & \left\|\frac{k}{k+1}b_i - \frac{k}{k+1}y_i\right\| \\ & = & \frac{k}{k+1}\|b_i - y_i\| \leq \frac{k}{k+1}\cdot \operatorname{diam}(|[y_0,\dots,y_k]|). \end{array}$$

Thus we have obtained the desired inequality. ■

Now we are ready to provide the proof of Lemma 74.28.

Proof of Lemma 74.28. We need to show that for any $x_0, \dots, x_k \in \mathbb{R}^n$ and any piece τ of $u_k([x_0,\dots,x_k])$ we have

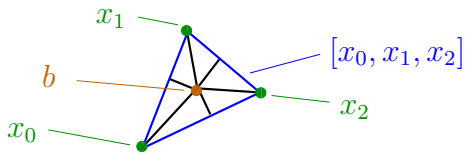
$$\operatorname{diam}(|\tau|) \leq \tfrac{n}{n+1}\cdot \operatorname{diam}(|[x_0,\dots,x_k]|).$$

We prove the claim by induction on k. For $k=0$ all the diameters are zero, so the inequality holds trivially. Now suppose that the claim holds for $k-1$. Let $x_0,\dots,x_k \in \Delta^n$ and denote by $b = \frac{1}{k}\sum_{i=0}^{k} x_i$ the barycenter of $x_0,\dots,x_k$. We denote by $\sigma_1,\dots,\sigma_r$ the pieces of $\partial[x_0,\dots,x_k]$.[909]

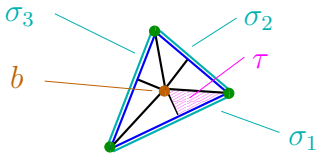
Now let τ be a piece of $u_k([x_0,\dots,x_k])$. By the definition of the subdivision map given on page 1640 we see that $|\tau| = |[w_0,\dots,w_{k-1},b]|$ where $[w_0,\dots,w_{k-1}]$ is a piece of $u_{k-1}(\sigma_s)$ for some $s \in \{1,\dots,r\}$. By Lemma 74.29 (1) it now suffices to prove the following claim.

Claim.
(1) For any $i,j = 0,\dots,k-1$ we have $\|w_i - w_j\| \leq \frac{k}{k+1}\cdot \operatorname{diam}(|[x_0,\dots,x_k]|)$.
(2) For any $i = 0,\dots,k-1$ we have $\|w_i - b\| \leq \frac{k}{k+1}\cdot \operatorname{diam}(|[x_0,\dots,x_k]|)$.

Proof. First let $i,j \in \{0,\dots,k-1\}$. Then



$$\|w_i - w_j\| \leq \operatorname{diam}([w_0,\dots,w_{k-1}]) \overset{\text{induction hypothesis applied to } \sigma_s}{\leq} \tfrac{k-1}{k}\cdot\operatorname{diam}(\sigma_s) \overset{\text{since } |\sigma_s| \subset |[x_0,\dots,x_k]| \text{ and } \frac{k-1}{k} \leq \frac{k}{k+1}}{\leq} \tfrac{k}{k+1}\cdot\operatorname{diam}([x_0,\dots,x_k]).$$



[909] Why does it not say that the number of pieces is $k+1$?

Now let $i \in \{0, \dots, k-1\}$. We then have

$$\|w_i - b\| \underset{\text{Lemma 74.29 (2)}}{\leq} \frac{k}{k+1} \cdot \operatorname{diam}(|[w_0, \dots, w_{k-1}]|) \underset{\text{since } |[w_0, \dots, w_{k-1}]| \subset |[x_0, \dots, x_k]|}{\leq} \frac{k}{k+1} \cdot \operatorname{diam}(|[x_0, \dots, x_k]|)$$

■

Lemma 74.30. Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i \in I}$ be an open cover of X. For every singular n-simplex $\sigma\colon \Delta^n \to X$ there exists an m such that $u_n^m(\sigma)$ lies in $\mathrm{C}_n^{\mathcal{U}}(X)$.

Proof. Let X be a topological space let $\mathcal{U} = \{U_i\}_{i \in I}$ be an open cover of X and let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. By the Lebesgue Lemma 6.5 there exists a $\delta > 0$ such that for any subset A of Δ^n with diameter $\operatorname{diam}(A) < \delta$ there exists an $i \in I$ such that $A \subset \sigma^{-1}(\mathring{U}_i)$.

We pick an $m \in \mathbb{N}$ such that $\left(\frac{n}{n+1}\right)^m < \delta$. We have

$$\begin{aligned} u_n^m(\sigma) &= u_n^m(\sigma_*(\mathrm{id}_{\Delta^n})) \underset{\text{Lemma 74.25}}{=} \sigma_*(u_n^m(\mathrm{id}_{\Delta^n})) \underset{\text{by Lemma 74.28 and } \left(\frac{n}{n+1}\right)^m < \delta}{=} \sigma_*\begin{pmatrix}\text{simplicial chain such that the image}\\ \text{has diameter less than } \delta\end{pmatrix} \\ &= \sigma_*\begin{pmatrix}\text{simplicial chain such that the image}\\ \text{of each piece lies in some } \sigma^{-1}(\mathring{U}_i)\end{pmatrix}. \\ &\qquad \underset{\text{by definition of } \delta}{\uparrow} \end{aligned}$$

But this means precisely that $u_n^m(\sigma) \in \mathrm{C}_n^{\mathcal{U}}(X)$. ■

Now we can prove the Comfortable Covering Proposition 74.23.

Proof of the Comfortable Covering Proposition 74.23. Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i \in I}$ be an open cover of X. We want to show that the inclusion map $\iota\colon \mathrm{C}_*^{\mathcal{U}}(X) \to \mathrm{C}_*(X)$ induces for each n an isomorphism

$$\iota_*\colon \mathrm{H}_n^{\mathcal{U}}(X) \xrightarrow{\cong} \mathrm{H}_n(X).$$

We first show that the map $\iota_*\colon \mathrm{H}_n^{\mathcal{U}}(X) \xrightarrow{\cong} \mathrm{H}_n(X)$ is surjective. Let $z \in \mathrm{H}_n(X)$ be given. We choose a cycle $c = \sum_{j=1}^{r} a_j \sigma_j \in \mathrm{C}_n(X)$ which represents $z \in \mathrm{H}_n(X)$. It follows from Lemma 74.30, applied to the singular n-simplices $\sigma_1, \dots, \sigma_r$, that there exists an $m \in \mathbb{N}$ such that $u_n^m(c) \in \mathrm{C}_n^{\mathcal{U}}(X)$. By Lemma 74.27 the maps $\{u_n^m\}_{n \in \mathbb{N}_0}$ form a chain map that is chain homotopic to the identity. By definition this means that there exists a chain homotopy $P_k\colon \mathrm{C}_k(X) \to \mathrm{C}_{k+1}(X)$, $k \in \mathbb{N}_0$. Thus we obtain that

$$z = [c] \underset{\text{since } \partial_{n+1}P_n + P_{n-1}\partial_n \,=\, u_n^m - \mathrm{id}}{=} \left[u_n^m(c) - P_{n-1}\overbrace{\partial_n(c)}^{=0} - \partial_{n+1}P_n(c)\right] = \left[u_n^m(c) - \partial_{n+1}P_n(c)\right] \underset{\text{equality in } \mathrm{H}_n(X)}{=} \overbrace{[u_n^m(c)]}^{\in \iota_*(\mathrm{H}_n^{\mathcal{U}}(X))}.$$

Thus we have shown that $\iota_*\colon \mathrm{H}_n^{\mathcal{U}}(X) \xrightarrow{\cong} \mathrm{H}_n(X)$ is surjective.

The argument that the map $\iota_*\colon \mathrm{H}_n^{\mathcal{U}}(X) \xrightarrow{\cong} \mathrm{H}_n(X)$ is injective is very similar. Indeed, let $[c] \in \mathrm{H}_n^{\mathcal{U}}(X)$ be an element such that $[c] = 0 \in \mathrm{H}_n(X)$. This means that there exists an $e \in \mathrm{C}_{n+1}(X)$ with $\partial e = c$. From Lemma 74.30 it follows, as above, that there exists an $m \in \mathbb{N}$ with $u_{n+1}^m(e) \in \mathrm{C}_{n+1}^{\mathcal{U}}(X)$. We again choose a chain homotopy $\{P_k\}_{k\in\mathbb{N}_0}$ between the chain maps $\{u_k^m\}_{k\in\mathbb{N}_0}$ and id. Then we have

$$c \;=\; \partial e \;\underset{\substack{\uparrow\\ \text{since } \partial P_{n+1} + P_n\partial = u_{n+1}^m - \mathrm{id}}}{=}\; \partial\big(u_{n+1}^m(e) - \partial P_{n+1}(e) - P_n\partial e\big) \;=\; \partial\underbrace{u_{n+1}^m(e)}_{\in \mathrm{C}_{n+1}^{\mathcal{U}}(X)} \;-\; \partial\underbrace{P_n(c)}_{\in \mathrm{C}_{n+1}^{\mathcal{U}}(X)}.$$

Thus have we have shown that c is indeed the boundary of an $(n+1)$-dimensional singular chain, in $C_{n+1}^{\mathcal{U}}(X)$ i.e. $[c] = 0 \in \mathrm{H}_n^{\mathcal{U}}(X)$. Put differently, we have now proved that $\iota_*\colon \mathrm{H}_n^{\mathcal{U}}(X) \xrightarrow{\cong} \mathrm{H}_n(X)$ is injective. ■

Using the Comfortable Covering Proposition 74.23 we can now prove the Excision Theorem 74.17.

Proof of the Excision Theorem 74.17. Let X be a topological space. Furthermore let $Z \subset A \subset X$ be subsets such that the closure of Z is contained in the interior of A. We have to show that the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n(X \setminus Z, A \setminus Z) \;\xrightarrow{\cong}\; \mathrm{H}_n(X, A).$$

We put $B := X \setminus Z$. Note that $A \cap B = A \setminus Z$. It follows from our hypothesis on Z and A that X is the union of the interiors of A and B, put differently, the two sets $\{A, B\}$ is a cover of X.

For each n we consider the following commutative diagram of abelian groups:[910]

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{C}_n(A) & \longrightarrow & \mathrm{C}_n^{\{A,B\}}(X) & \longrightarrow & \mathrm{C}_n^{\{A,B\}}(X)/\mathrm{C}_n(A) & \longrightarrow & 0 \\
 & & \downarrow{=} & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathrm{C}_n(A) & \longrightarrow & \mathrm{C}_n(X) & \longrightarrow & \mathrm{C}_n(X, A) & \longrightarrow & 0.
\end{array}$$

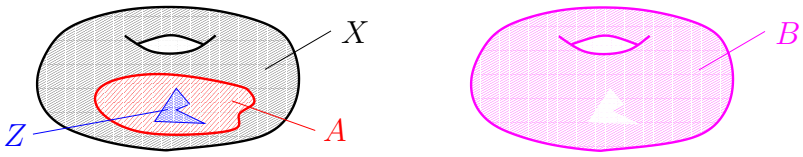
Note that by definition the horizontal sequences are in fact short exact sequences of chain complexes. We first make the observation that it follows immediately from the definition of $\mathrm{C}_n^{\{A,B\}}(X)$ that the inclusion

$$\begin{array}{rcl} \mathrm{C}_n(B) & \to & \mathrm{C}_n^{\{A,B\}}(X) \\ \mathrm{C}_n(B, A\cap B) & \to & \mathrm{C}_n^{\{A,B\}}(X)/\mathrm{C}_n(A) \end{array}$$

induces a chain map

that is in fact an isomorphism. Thus in the above diagram we can replace the chain complex $\mathrm{C}_n^{\{A,B\}}(X)/\mathrm{C}_n(A)$ by $\mathrm{C}_n(B, A\cap B) = \mathrm{C}_n(X \setminus Z, A \setminus Z)$.

Now we consider the long exact sequence of homology groups arising from the above short exact sequences of chain complexes. By the LES Proposition 74.9 we obtain the



[910] Here we use the definition from page 1638 which in this context says that

$$\mathrm{C}_n^{\{A,B\}}(X) \;:=\; \{\sigma + \tau \,|\, \sigma \in \mathrm{C}_n(A) \text{ and } \tau \in \mathrm{C}_n(B)\}.$$

following commutative diagram where the horizontal sequences are exact:

$$\begin{array}{ccccccccccc}
\ldots \longrightarrow & \mathrm{H}_n(A) & \longrightarrow & \mathrm{H}_n^{\{A,B\}}(X) & \longrightarrow & \overbrace{\mathrm{H}_n(B, A\cap B)}^{=\mathrm{H}_n(X\setminus Z, A\setminus Z)} & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A) & \longrightarrow & \mathrm{H}_{n-1}^{\{A,B\}}(X) & \longrightarrow \ldots \\
& \downarrow{=} & & \downarrow & & \downarrow & & \downarrow{=} & & \downarrow & \\
\ldots \longrightarrow & \mathrm{H}_n(A) & \longrightarrow & \mathrm{H}_n(X) & \longrightarrow & \mathrm{H}_n(X, A) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A) & \longrightarrow & \mathrm{H}_{n-1}(X) & \longrightarrow \ldots
\end{array}$$

From the Comfortable Covering Proposition 74.23 it follows that the second and fifth vertical map are isomorphisms. Since the first and fourth map are evidently isomorphisms it now follows from the Five Lemma 74.10 that the middle map is also an isomorphism. ■

74.10. **Excision for CW-complexes.** On some occasions the following variation on the Excision Theorem 74.17 is useful.

Theorem 74.31. (Excision Theorem for CW-complexes) Let X be a CW-complex and let A and B be two subcomplexes with $X = A \cup B$. For every $n \in \mathbb{N}_0$ the inclusion induced map

$$\mathrm{H}_n(B, A\cap B) \xrightarrow{\cong} \mathrm{H}_n(X, A)$$

is an isomorphism.

Proof. Let X be a CW-complex. Furthermore let A and B be two subcomplexes of X with $X = A\cup B$. We denote by $i\colon B \to X$ the inclusion. We consider the following diagram

$$\begin{array}{ccc}
\mathrm{H}_n(B, A\cap B) & \xrightarrow{\quad i_* \quad} & \mathrm{H}_n(X, A) \\
{\scriptstyle \text{ю}}\downarrow & & \downarrow{\scriptstyle \text{ю}} \\
\widetilde{\mathrm{H}}_n(B/(A\cap B)) & \xrightarrow{\quad i_* \quad} & \widetilde{\mathrm{H}}_n(X/A).
\end{array}$$

By Lemma 74.19 we know that the diagram commutes. Furthermore, since A and B are subcomplexes we obtain from the Homology-of-Quotients Proposition 74.20 that the vertical maps are isomorphisms. Finally note that by the CW-Complex Construction Lemma 68.32 (3) the quotients $B/(A\cap B)$ and X/A have natural CW-structures. It follows from the CW-Complex Homeomorphism Lemma 68.12 that the induced map $B/(A\cap B)$ and X/A is a homeomorphism. Thus we see that the bottom horizontal map is an isomorphism. It follows from this discussion that the top map is, as promised, an isomorphism. ■

Remark. In the Excision Theorem 75.10 for Topological Manifolds we will get to see another variation on the Excision Theorem 74.17.

Exercises for Chapter 74.

Exercise 74.1. Let X be a non-empty topological space. By the Reduced Homology Lemma 74.1 (4) we know that there exists an isomorphism $\mathrm{H}_0(X) \xrightarrow{\cong} \widetilde{\mathrm{H}}_0(X)\oplus\mathbb{Z}$. Show that

there is no *natural* isomorphism $\mathrm{H}_0(X) \xrightarrow{\cong} \widetilde{\mathrm{H}}_0(X) \oplus \mathbb{Z}$. More precisely, show that it is not possible to assign to each non-empty topological space X an isomorphism $\Phi_X \colon \mathrm{H}_0(X) \xrightarrow{\cong} \widetilde{\mathrm{H}}_0(X) \oplus \mathbb{Z}$ such that for any map $f \colon X \to Y$ between non-empty topological spaces the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_0(X) & \xrightarrow{\Phi_X} & \widetilde{\mathrm{H}}_0(X) \oplus \mathbb{Z} \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_* \oplus \mathrm{id}_{\mathbb{Z}}} \\ \mathrm{H}_0(Y) & \xrightarrow{\Phi_Y} & \widetilde{\mathrm{H}}_0(Y) \oplus \mathbb{Z}. \end{array}$$

Hint. Let X be the discrete space consisting of two points. If such a natural isomorphism Φ_X did exist, what should the map Φ_X do?

Exercise 74.2. Let

$$\mathbb{Z} \xrightarrow{f} B \xrightarrow{g} \mathbb{Z} \oplus \mathbb{Z}_6 \to 0$$

be an exact sequence, i.e. we know that $g \circ f = 0$, we know that $\mathrm{im}(f) = \ker(g)$ and we know that g is an epimorphism. What are the possible isomorphism types of the group B?

Exercise 74.3. We consider the following commutative diagram of homomorphisms between abelian groups:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A & \longrightarrow & B & \longrightarrow & C & \longrightarrow & 0 \\ \downarrow & & \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \downarrow \\ 0 & \longrightarrow & \widetilde{A} & \longrightarrow & \widetilde{B} & \longrightarrow & \widetilde{C} & \longrightarrow & 0. \end{array}$$

We suppose that the horizontal sequences are exact and that the maps a and c to the left and right are the zero map. Does it follow that the middle map b is also the zero map?

Exercise 74.4. Let X be a topological space with $\widetilde{\mathrm{H}}_0(X) \cong \mathbb{Z}$.

(a) Show that given any $\epsilon \in \{-1, 0, 1\}$ there exists a map $f \colon X \to X$ such that the induced map f_* on $\widetilde{\mathrm{H}}_0(X)$ is given by multiplication by ϵ.

(b) Show that given any map $f \colon X \to X$ the induced map f_* on $\widetilde{\mathrm{H}}_0(X)$ is given by multiplication by some $\epsilon \in \{-1, 0, 1\}$.

Exercise 74.5. Determine the homology groups of $S^2 \vee S^1$.

Exercise 74.6.

(a) Let

$$\begin{array}{ccccccccc} A & \xrightarrow{i} & B & \xrightarrow{j} & C & \xrightarrow{k} & D & \xrightarrow{l} & E \\ \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \downarrow{\scriptstyle d} & & \downarrow{\scriptstyle e} \\ A' & \xrightarrow{i'} & B' & \xrightarrow{j'} & C' & \xrightarrow{k'} & D' & \xrightarrow{l'} & E' \end{array}$$

be a commutative diagram such that the horizontal sequences are exact. Show that if a is surjective, if b and d are isomorphisms, and if e is injective, then c is an isomorphism.

(b) Does the statement in (a) also hold, if a injective and if e is surjective ?

Exercise 74.7. Let M be the Möbius band. Determine the relative homology groups of the pair $(M, \partial M)$.

Exercise 74.8. Give examples of two contractible subspaces A and B of $\mathbb{R}^2$ such that $\mathrm{H}_1(A \cup B)$ is infinitely generated.

Exercise 74.9. Let

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_* & \xrightarrow{\varphi} & B_* & \xrightarrow{\psi} & C_* & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \\ 0 & \longrightarrow & A'_* & \xrightarrow{\varphi'} & B'_* & \xrightarrow{\psi'} & C'_* & \longrightarrow & 0 \end{array}$$

be a commutative diagram of homomorphisms between abelian groups. Show that there exists an exact sequence

$$\begin{array}{l} 0 \longrightarrow \ker(a) \xrightarrow{\varphi} \ker(b) \xrightarrow{\psi} \ker(c) \\ \qquad\qquad \longrightarrow \operatorname{coker}(a) \xrightarrow{\varphi'} \operatorname{coker}(b) \xrightarrow{\psi'} \operatorname{coker}(c) \longrightarrow 0. \end{array}$$

This statement is sometimes referred to as the "Snake Lemma".
Hint. Try to prove the statement with as little effort as possible.

Exercise 74.10. We consider the following diagram of homomorphisms between abelian groups:

$$\begin{array}{ccccccccc} & & & & 0 & & & & \\ & & & & \downarrow & & & & \\ & & & & M & & & & \\ & & & & \downarrow{\scriptstyle \mu} & \searrow{\scriptstyle \beta\circ\mu} & & & \\ 0 & \longrightarrow & A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & C & \longrightarrow & 0 \\ & & & \searrow{\scriptstyle \nu\circ\alpha} & \downarrow{\scriptstyle \nu} & & & & \\ & & & & N & & & & \\ & & & & \downarrow & & & & \\ & & & & 0. & & & & \end{array}$$

We suppose that the horizontal and the vertical sequences are exact.

(a) Show that $\beta \circ \mu$ is a monomorphism if and only if $\nu \circ \alpha$ is a monomorphism.
(b) Show that $\beta \circ \mu$ is an epimorphism if and only if $\nu \circ \alpha$ is an epimorphism.

Exercise 74.11. Let

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_* & \longrightarrow & B_* & \longrightarrow & C_* & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & A'_* & \longrightarrow & B'_* & \longrightarrow & C'_* & \longrightarrow & 0 \end{array}$$

be a commutative diagram of short exact sequences of chain complexes. Show that if two of the vertical maps induce isomorphisms on homology, then so does the third.

Exercise 74.12. We consider the following commutative diagram:

$$\begin{array}{ccccccccc} & & & & \ker(\beta) & & & & \\ & & & \swarrow{\scriptstyle \varphi} & \downarrow & & & & \\ 0 & \longrightarrow & A & \longrightarrow & B & \longrightarrow & C & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \beta} & & \downarrow{\scriptstyle \gamma} & & \\ 0 & \longrightarrow & A' & \longrightarrow & B' & \longrightarrow & C' & \longrightarrow & 0. \end{array}$$

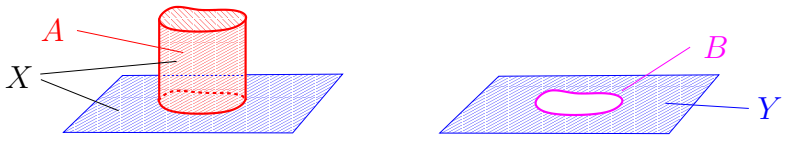
Evidently we assume that the horizontal sequences are exact. Furthermore we assume that $\alpha\colon A \to A'$ and $\beta\colon B \to B'$ are epimorphisms. Show that $\gamma\colon C \to C'$ is an isomorphism.

Exercise 74.13. For readers who really really enjoy diagram chases we have the following problem on offer. Suppose we are given the following commutative diagram of

$$\begin{array}{ccccccccc}
 & & 0 & & 0 & & 0 & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & A_* & \longrightarrow & B_* & \xrightarrow{h_B} & C_* & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow{\scriptstyle v_B} & & \downarrow & & \\
0 & \longrightarrow & D_* & \xrightarrow{h_D} & E_* & \longrightarrow & F_* & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle v_D} & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & G_* & \longrightarrow & \mathrm{H}_* & \longrightarrow & J_* & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & 0 & & 0 & & 0 & &
\end{array}$$

where the vertical and horizontal sequences are exact. We suppose that the chain complex H_* is acyclic, i.e. we suppose that homology groups of H_* vanish. Show that for any $k \in \mathbb{N}_0$ the following diagram commutes up to a minus sign:

$$\begin{array}{ccccc}
\mathrm{H}_k(D_*) & \xrightarrow{v_{D*}} & \mathrm{H}_k(G_*) & \xleftarrow[\cong]{\partial} & \mathrm{H}_{k+1}(K_*) \\
\downarrow & & & & \partial\downarrow\cong \\
\mathrm{H}_k(E) & \xrightarrow[\cong]{v_{B*}^{-1}} & \mathrm{H}_k(B) & \xrightarrow{h_{B*}} & \mathrm{H}_k(C).
\end{array}$$



Exercise 74.14. Let X be a topological space, let $x_0 \in X$ be a point and let $n \in \mathbb{N}_0$. Show that the map

$$\widetilde{\mathrm{H}}_n(X) \longrightarrow \mathrm{H}_n(X) \xrightarrow{=} \mathrm{H}_n(X, \varnothing) \longrightarrow \mathrm{H}_n(X, \{x_0\})$$
$$=: \Phi_{X,x_0}$$

is an isomorphism.

Exercise 74.15. We say that a map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ has *bounded displacement* if there exists a $C \in \mathbb{R}$ such that for any $x \in \mathbb{R}^n$ we have $\|x - f(x)\| \leq C$. Show that any map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ of bounded displacement is onto.
Hint. Use the Brouwer Fixed Point Theorem.

Exercise 74.16. Let (X, A) be a pair of topological spaces. Suppose there exists a deformation retraction $r\colon X \times [0,1] \to X$ from X to some subset $Y = r_1(X)$. We write $B = r_1(A)$. Show that the inclusion induced maps $\mathrm{H}_k(Y, B) \to \mathrm{H}_k(X, A)$ are isomorphisms.

Exercise 74.17. Let $X_0 \subset X_1 \subset X_2 \subset \cdots \subset X_m$ be a nested sequence of topological spaces.

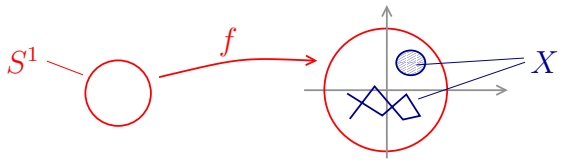
(a) Suppose that for each $k = 0, \dots, m-1$ we have $\mathrm{H}_n(X_{k+1}, X_k) = 0$ for all $n \in \mathbb{N}_0$. Show that $\mathrm{H}_n(X_m, X_0) = 0$ for all $n \in \mathbb{N}_0$.
(b) Let $n \in \mathbb{N}_0$. Suppose that for each $k = 0, \dots, m-1$ we have $\mathrm{H}_n(X_{k+1}, X_k) = 0$. Does it also follow that $\mathrm{H}_n(X_m, X_0) = 0$?

Exercise 74.18. We consider $X = [0,1]$ and $A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$. Prove the following two statements:

(a) The group $\mathrm{H}_1(X, A)$ is countable.
(b) The group $\mathrm{H}_1(X/A)$ is uncountable. For psychological reasons it might be convenient to recall that in Exercise 56.1 we showed that the quotient space X/A is homeomorphic to the Hawaiian earrings.

Remark. The homology groups of the Hawaiian earrings are computed in [**EKa2000**]. In particular it is shown that the higher homology groups $\mathrm{H}_i(X/A)$ are zero for $i \geq 2$, which is not clear at all, see e.g. [**BaM1962**].

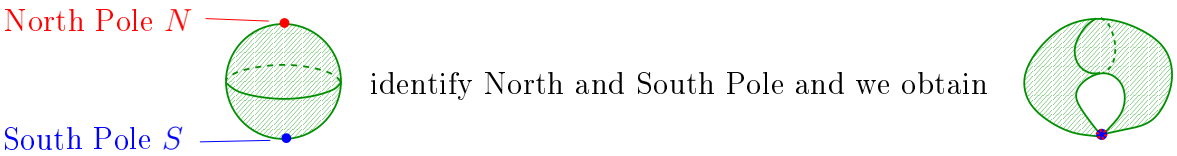
Exercise 74.19. Give an example of a topological space X and some non-empty subset A for which there is no exact sequence of the form



$$\dots \to \widetilde{\mathrm{H}}_{n+1}(X/A) \to \widetilde{\mathrm{H}}_n(A) \xrightarrow{i_*} \widetilde{\mathrm{H}}_n(X) \xrightarrow{p_*} \widetilde{\mathrm{H}}_n(X/A) \to \dots$$

where $i\colon A \to X$ is the inclusion and $p\colon X \to X/A$ is the projection.
Remark. You might want to consult your calculations from Exercise 74.18.

Exercise 74.20. Let X be a non-empty bounded subset of $\mathbb{R}^n$. We pick an $r \in \mathbb{R}_{>0}$ such that X is contained in the bounded n-ball $\overline{B}_r^n$ of radius r. We consider the map



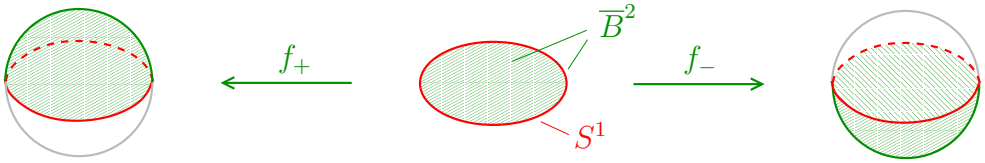
$$\begin{aligned} f\colon S^{n-1} &\to \mathbb{R}^n \setminus X \\ x &\mapsto 2r \cdot x. \end{aligned}$$

Show that the induced map $f_*\colon \mathrm{H}_{n-1}(S^{n-1}) \to \mathrm{H}_{n-1}(\mathbb{R}^n \setminus X)$ is a monomorphism.

Exercise 74.21. Show that for $k \geq 1$ the wedge $S^k \vee S^k$ is not a topological manifold.

Exercise 74.22. Compute the homology groups of the quotient of S^2 obtained by identifying the North Pole N and the South Pole S to a point. We refer to the figure below for an illustration.

Exercise 74.23. Let $T = S^1 \times S^1$ be the torus. We consider the subset $A := S^1 \times \{1\}$.



(a) Show that T/A is homeomorphic to the topological space $S^2/(S \cup N)$ considered in Exercise 74.22.
(b) Compute the homology groups of the torus.
(c) Bonus question: How far can you push the above approach if we start out with the Klein bottle instead of the torus?

Remark. We will soon see a more conceptual, less ad hoc, approach to calculating the homology groups of the torus.

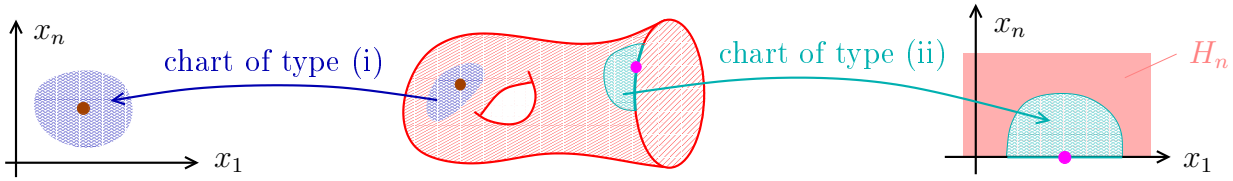
Exercise 74.24. We consider the two maps

$$\begin{array}{rcl} f_+\colon \overline{B}^2 & \to & S^2 \\ (x,y) & \mapsto & \left(x, y, \sqrt{1-x^2-y^2}\right) \end{array} \quad \text{and} \quad \begin{array}{rcl} f_-\colon \overline{B}^2 & \to & S^2 \\ (x,y) & \mapsto & \left(x, y, -\sqrt{1-x^2-y^2}\right) \end{array}$$

Show that these two maps $f_-, f_+\colon \overline{B}^2 \to S^2$ are not homotopic rel S^1.

75. Applications and variations of the Excision Theorem 74.17

As the title of this chapter suggests, in this chapter we will consider some applications of the Excision Theorem 74.17 and we will state and prove several variations thereof.



In particular we will prove several statements on the topology of topological manifolds which extend the results obtain in Section 19.8 from the setting of smooth manifolds to the more general context of topological manifolds. We will also use the opportunity to state a few other results on topological manifolds. At the end of the chapter we will introduce the double of a manifold. This construction makes sense, and is of interest, for smooth and for topological manifolds.

The chapter does not contain any real surprises. The overall message is that the statement of the Excision Theorem 74.17 holds in several convenient alternative settings and that many of the statements which we know and love about the topology of smooth manifolds also hold for topological manifolds. These variations and generalizations of earlier results are non-trivial, but most readers will have a hard time building up enthusiasm for these results. Thus it might be best to have a quick glimpse at the results and then move on to the next section.

75.1. **The local homology groups of a topological space.** We start out with the following definition which at first glance might look somewhat artificial.

Definition. Given a topological space X and a point $x_0 \in X$ the relative homology group $\mathrm{H}_n(X, X \setminus \{x_0\})$ is called the n-th local homology group of X at the point x_0.

The main goal of this section is to calculate the local homology groups of topological manifolds and to draw several consequences from this calculation. At this point it is helpful to recall the definition on page 511 of charts of type (i) and (ii) of a topological manifold. For the reader's convenience we illustrate the definitions in the figure below. We also recall that on page 511 we said that a point x on a topological manifold is a *boundary point* if x does not admit a chart of type (i).

The following lemma calculates the local homology groups of topological manifolds.

Lemma 75.1. (Manifold-Local Homology Lemma) Let M be a k-dimensional topological manifold.

(1) Every point on X admits either a chart of type (i) or it admits a chart of type (ii).
(2) Given any point $P \in M$, any $l \in \mathbb{N}_0$ and any neighborhood U of P we have

$$\mathrm{H}_l(U, U\setminus\{P\}) \xrightarrow[\uparrow]{\cong} \mathrm{H}_l(M, M\setminus\{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M \setminus \partial M \text{ and if } l = k, \\ 0, & \text{otherwise.} \end{cases}$$

induced by the inclusion $(U, U\setminus\{P\}) \to (M, M\setminus\{P\})$

Proof. Let P be a point on a k-dimensional topological manifold M. We start out with the following claim.

Claim. We have the following isomorphisms:

$$\mathrm{H}_l(U, U\backslash\{P\}) \xrightarrow{\cong} \mathrm{H}_l(M, M\backslash\{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } P \text{ admits a chart of type (i) and if } l = k, \\ 0, & \text{if } P \text{ admits a chart of type (ii) or if } l \neq k. \end{cases}$$

Proof. First we consider the case that P admits a chart of type (i). It follows easily from the definition of an open subset of $\mathbb{R}^k$ that we can pick a chart $\Phi\colon U \to B^k$ for P with $\Phi(P) = 0$. We then have the following isomorphisms:

$$\mathrm{H}_l(M, M\backslash\{P\}) \xleftarrow[\uparrow]{\cong} \mathrm{H}_l(U, U\backslash\{P\}) \xrightarrow[\downarrow]{\Phi_*} \mathrm{H}_l(B^k, B^k\backslash\{0\}) \xrightarrow[\uparrow]{\partial} \widetilde{\mathrm{H}}_{l-1}(B^k\backslash\{0\}) \xleftarrow[\uparrow]{\cong} \widetilde{\mathrm{H}}_{l-1}(S^{k-1}).$$

isomorphism by the Excision Theorem 74.18

isomorphism since Φ is a homeomorphism

isomorphism by the long exact sequence in reduced homology of the pair $(B^k, B^k \setminus \{0\})$ and the fact that $\widetilde{\mathrm{H}}_*(B^k) = 0$ by page 1612

isomorphism since S^{k-1} is homotopy equivalent to $B^k \setminus \{0\}$

The desired statement now follows from the calculation of the reduced homology groups of spheres given in Proposition 74.4.

Now we consider the case that P admits a chart of type (ii). Similar to the above we can pick a chart $\Phi\colon U \to B^k_{\geq 0} := B^k \cap \mathrm{H}_k$ for P with $\Phi(P) = 0$. By arguments that are very similar to the ones used above we see that we have the following isomorphisms:

$$\mathrm{H}_l(M, M\backslash\{P\}) \xleftarrow{\cong} \mathrm{H}_l(U, U\backslash\{P\}) \xrightarrow[\cong]{\Phi_*} \mathrm{H}_l(B^k_{\geq 0}, B^k_{\geq 0}\backslash\{0\}) \xrightarrow[\cong]{\partial} \widetilde{\mathrm{H}}_{l-1}(B^k_{\geq 0}\backslash\{0\}) \underset{\uparrow}{=} 0.$$

one can easily show that $B^k_{\geq 0}$ is contractible, hence its reduced homology vanishes by the Reduced Homology Lemma 74.1 ⊞

Now it is straightforward to prove the statements of the lemma.

(1) It follows from the above claim that $\mathrm{H}_k(M, M \setminus \{P\}) \cong \mathbb{Z}$ if and only if P admits a chart of type (i). This observation immediately implies the promised statement.
(2) The first map is an isomorphism by the Excision Theorem 74.18. The second isomorphism follows immediately from the above claim. ■

75.2. **The topology of topological manifolds.** With the results from Chapter 74 we can now generalize the Smooth Manifold Boundary Proposition 19.26 from the case of smooth manifolds to the more general setting of topological manifolds.

Proposition 75.2. (Topological Manifold Boundary Proposition) Let X be an n-dimensional topological manifold. The following statements hold:

(1) Every point on X admits either a chart of type (i) or it admits a chart of type (ii).
(2) If F is equipped with a smooth atlas, i.e. if we view F as a smooth manifold, then the boundary of F as a topological manifold agrees with the boundary of F viewed as a topological manifold.
(3) The boundary ∂X is an $(n-1)$-dimensional topological manifold with empty boundary, i.e. we have $\partial(\partial X) = \varnothing$.
(4) (a) Any union of components of ∂X is a closed subset of X. In particular ∂X itself is a closed subset of X.
    (b) If X is compact, then ∂X is also compact.
(5) If ∂X is non-empty, then $X \setminus \partial X$ is non-compact.

(6) Let N be a submanifold of X. The following two statements are equivalent:
   (a) N is a proper submanifold.
   (b) The following two conditions are satisfied:
      (i) N is a closed subset of X.
      (ii) We have the equality[911] $\partial N = N \cap \partial X$.
(7) If $N \subset X$ is a proper k-dimensional submanifold, then we have $N \cap \partial X = \partial N$, and $N \cap \partial X = \partial N$ is a proper $(k-1)$-dimensional submanifold of ∂X.
(8) If X is an m-dimensional topological manifold and if Y is an n-dimensional topological manifold, then $X \times Y$ is an $(m+n)$-dimensional topological manifold with $\partial(X \times Y) = (\partial X \times Y) \cup (X \times \partial Y)$.

Example. It follows from the Topological Manifold Boundary Proposition 75.2 and the examples of charts for $\overline{B}^n$ given on page 514 that the boundary of the n-dimensional topological manifold is indeed S^{n-1}. We had suspected this for a long time, but only recently did we acquire the tools for providing a proof.

Remark.

(1) For 2-dimensional topological manifolds we had proved some of the statements of the Topological Manifold Boundary Proposition 75.2 in Proposition 50.7.
(2) In Propositions 19.31 and 20.6 we showed the analogue of the Topological Manifold Boundary Proposition 75.2 (7) in the setting of smooth manifolds.
(3) Let M and N be two connected n-dimensional topological manifolds with empty boundary. If $M \times [0,1]$ is homeomorphic to $N \times [0,1]$, then evidently the corresponding boundaries are also homeomorphic. Note that it follows from the Topological Manifold Boundary Proposition 75.2 (7) that $\partial(M \times [0,1]) = M \times \{0,1\}$ and $\partial(N \times [0,1]) = N \times \{0,1\}$. Since M and N are connected we obtain easily from the above that M and N are homeomorphic. Even though this sounds quite reasonable, very similar sounding statements can easily be wrong. For example there exists a 3-dimensional topological manifold W (called the *Whitehead manifold*) which is non-compact and has no boundary, which is not homeomorphic to $\mathbb{R}^3$ but such that $W \times \mathbb{R}$ is homeomorphic to $\mathbb{R}^3 \times \mathbb{R} = \mathbb{R}^4$. We refer to [**Kir1989**, p. 87] and [**AnR1965**] for details.

Proof. Let X be an n-dimensional topological manifold.

(1) This statement is precisely the statement of the Manifold-Local Homology Lemma 75.1 (1). The only reason why we wrote down the statement again is to preserve the analogy with the Smooth Manifold Boundary Proposition 19.26.
(2) Verbatim the same argument as in the 2-dimensional setting, see the proof of Proposition 50.7 (2) on page 1132, shows how to deduce this statement from Statement (1).
(3) First note that it follows from Lemma 1.14 and from the Second Countability Lemma 9.1 (2) that ∂X is Hausdorff and second-countable. Now it remains to show that ∂X admits an $(n-1)$-dimensional atlas. Let $P \in \partial X$. By definition of ∂X there exists a chart $\Phi\colon U \to V$ of type (ii) for X with $P \in U$. Note that Φ is a chart of type (ii) precisely for the points in $\Phi^{-1}(\partial\,\mathbb{H}^n)$. Also note that it follows from (1) and

[911] Here ∂N denotes the boundary of N, viewed as a topological manifold in its own right.

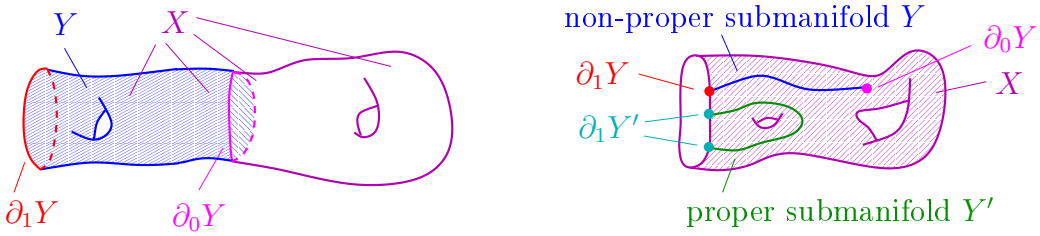
the definition of ∂X that $\Phi^{-1}(\partial \mathbb{H}^n) = \partial X \cap U$. In other words, under the obvious identification $\partial \mathbb{H}^n = \mathbb{R}^{n-1}$ we see that Φ restricts to an $(n-1)$-dimensional chart of type (i) for the topological space ∂X. This shows that ∂X is an $(n-1)$-dimensional topological manifold with empty boundary.

(4) This statement is precisely the content of the Manifold Boundary-Closed Subset Lemma 18.6 (1) and (2).

(5) This statement is the content of the Manifold Boundary-Closed Subset Lemma 18.6 (3).

(6) As we already saw in the proof of Statements (5) and (6) of the Smooth Manifold Boundary Proposition 19.26, this statement is straightforward consequence of (1) and (4).

(7) In the Topological Manifold Product Proposition 18.4 we already showed that $X \times Y$ is an $(m+n)$-dimensional topological manifold. Furthermore recall that in the Topological Manifold Product Proposition 18.4 we showed that each point in $(X \times Y) \setminus ((\partial X \times Y) \cup (X \times \partial Y))$ admits a chart of type (i) and we showed that each point in $(\partial X \times Y) \cup (X \times \partial Y)$ admits a chart of type (ii). By (1) and by definition of the boundary of a topological manifold this means that we have indeed $\partial(X \times Y) = (\partial X \times Y) \cup (X \times \partial Y)$. ■



Let X be a topological manifold and let Y be a submanifold. It follows almost immediately from the definitions that Y is a topological manifold in its own right. In particular it makes sense to consider its boundary ∂Y and in particular it makes sense to introduce the following definition which can be viewed as a generalization of the definition on page 568.

Definition. Let X be a topological manifold and let Y be a submanifold. We write

$$\partial_0 Y := \underset{\uparrow}{\partial Y} \setminus \partial X \quad \text{and} \quad \partial_1 Y := \underset{\uparrow}{\partial Y} \cap \partial X.$$

here ∂Y denotes the boundary of Y viewed as a topological manifold

The definition is illustrated in the figure below.

The next proposition gives us some results on the boundary of submanifolds. It can be viewed as an analogue of the Codimension-Zero Submanifold Proposition 19.38, which we had formulated in the smooth context.

Proposition 75.3. Let X be an m-dimensional topological manifold and let Y be an n-dimensional submanifold. We assume that Y is a closed subset of X. (In most applications Y will be compact).

(1) $\partial_0 Y$ and $\partial_1 Y$ are disjoint and each of them is a union of components of ∂Y.

(2) If Y is a proper submanifold, then $\partial Y = \partial_1 Y = Y \cap \partial X$.

(3) If Y is of codimension zero, then the interior $\overset{\circ}{Y}$ of Y as a subset of X agrees with $Y \setminus \partial_0 Y$. In particular $Y \setminus \partial_0 Y$ is an open subset of X.
(4) Suppose that Y is of codimension zero and that Y is compact.
   (a) The set $Z := X \setminus \overset{\circ}{Y}$ is also a codimension-zero submanifold of X and we have $Y \cap Z = \partial_0 Y = \partial_0 Z$.
   (b) If X and ∂Y are connected, then $Z = X \setminus \overset{\circ}{Y}$ is also connected.
   (c) If X is compact, then $Z = X \setminus \overset{\circ}{Y}$ is also compact.

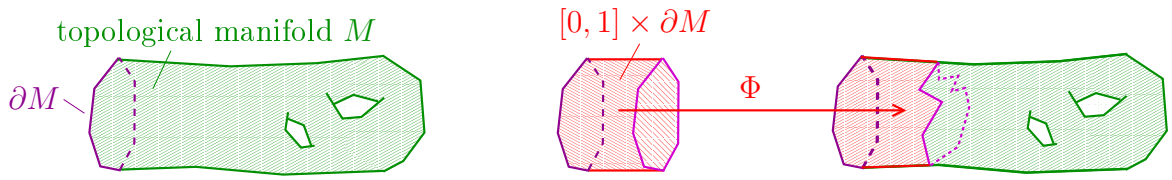
Proof. The proposition follows easily from making the obvious modifications to the proof of the Codimension-Zero Submanifold Proposition 19.38. The biggest change is that we need to replace the Smooth Manifold Boundary Proposition 19.26 by the Topological Manifold Boundary Proposition 75.2. We leave it to the reader to fill in the details. ■

We conclude this section with the following proposition which is the generalization of the Smooth Manifold-Dimension Proposition 19.28 from smooth manifolds to topological manifolds.

Proposition 75.4. (Topological Manifold-Dimension Proposition) Let M be an m-dimensional non-empty topological manifold and let N be an n-dimensional topological manifold. If M is homeomorphic to an open subset of N (e.g. if M is homeomorphic to N), then $m = n$.

It follows in particular from the Topological Manifold-Dimension Proposition 75.4 that the dimension of a non-empty topological manifold is well-defined.

Proof. By the remark on page 526 it suffices to consider the case that we are given a homeomorphism $f\colon M \to N$ between a non-empty m-dimensional topological manifold M and a topological manifold N. By the Topological Manifold Boundary Proposition 75.2 (5) we know that $M \setminus \partial M$ is non-empty. In particular we can find a point $P \in M \setminus \partial M$. Then



$$\begin{array}{ccccc} \mathbb{Z} & \underset{\uparrow}{\cong} & \mathrm{H}_m(M, M \setminus \{P\}) & \underset{\uparrow}{\overset{\cong}{\to}} & \mathrm{H}_m(N, N \setminus \{f(P)\}). \\ & \text{Manifold-Local Homology Lemma 75.1} & & \text{since } f \text{ is a homeomorphism} & \end{array}$$

It now follows from the Manifold-Local Homology Lemma 75.1 that N is also m-dimensional. ■

75.3. **The Topological Collar Neighborhood Theorem.** In the next section we will consider some useful variations on the Excision Theorem 74.17 for topological manifolds. To prove these results we will make use of the following following theorem which is an analogue of the Smooth Collar Neighborhood Theorem 28.3 for topological manifolds.

Theorem 75.5. (Topological Collar Neighborhood Theorem) Given any topological manifold M there exists a map $\Phi\colon [0,1) \times \partial M \to M$ with the following four properties:
(1) The map Φ is an embedding.
(2) The image of $[0,1) \times \partial M$ is an open subset of M.
(3) For every $P \in \partial M$ we have $\Phi(0, P) = P$.
(4) The image of $[0,1] \times \partial M$ is a closed subset of M.

Remark.

(1) In the compact case the Topological Collar Neighborhood Theorem 75.5 is also proved in [**Vic1994**, Theorem Appendix II.7] and [**Hat2002**, p. 253]. The general case, where M is also allowed to be non-compact, is also proved in [**BrownM1962**, Theorem 3] and [**Arm1970**, Theorem 1]. Note that [**Arm1970**, Theorem 1] has a few refinements which could be useful in some applications. The proof we provide is based on [**Conn1971**]

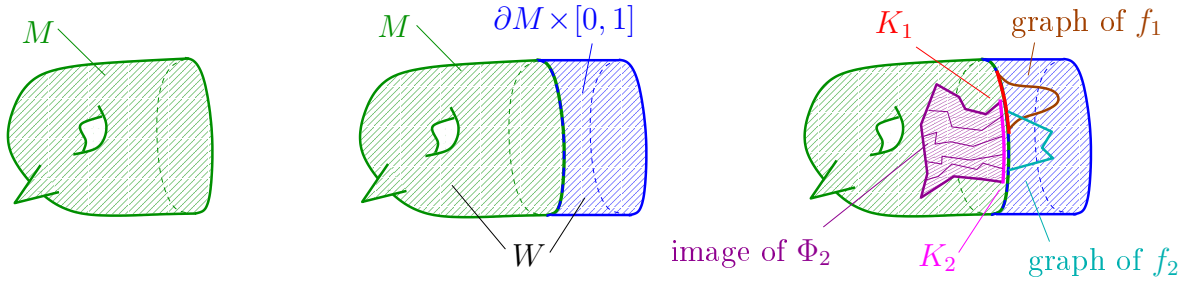
(2) In Exercise 120.1 we will prove a variation on the Topological Collar Neighborhood Theorem 75.5 for the case that M is a codimension-zero submanifold *with corner* of some other topological manifold.

(3) In Exercise 75.11 we will use the Topological Collar Neighborhood Theorem 75.5 to give a new proof of the Push Away From Boundary Lemma 18.13. In particular we will show again that a topological manifold X is path-connected if and only if $X \setminus \partial X$ is path-connected.

Proof of Theorem 75.5 for compact M. We consider M with an "external collar" attached, i.e. we consider $W := M \cup_{\partial M = \{0\} \times \partial M} ([0,1] \times \partial M)$. Let us assume for a second that we have found a homeomorphism $F\colon M \to W$ with $F(\partial M) = \{1\} \times \partial M$. In this fortunate setting one can verify easily, say using the Topological Pushout-Maps Lemma 5.34 (3) and (4), that the map

$$\begin{array}{rcl} \Phi\colon [0,1] \times \partial M & \to & M \\ (t,x) & \mapsto & F^{-1}([(1-t,x)]) \end{array}$$

has all the desired properties. Thus it remains to show that such an F actually exists.



We start out our search for such F with the following claim.

Claim. There exist compact subsets $K_1, \ldots, K_m \subset \partial M$, embeddings $\Phi_i\colon K_i \times [-1,0] \to M$ and maps $f_i\colon \partial M \to [0,1]$ such that the following are satisfied:

(1) For each $i \in \{1, \ldots, m\}$ we have $\Phi_i^{-1}(\partial M) = K_i \times \{0\}$.
(2) For each $i \in \{1, \ldots, m\}$ we have $\operatorname{supp}(f_i) \subset K_i$.
(3) We have $f_1 + \cdots + f_m = 1$ on all of ∂M.

Proof. It follows from the definition of ∂M, together with the Topological Manifold Boundary Proposition 75.2 (1), that for each $x \in \partial M$ there exists an open neighborhood U_x of x and an embedding $\Phi_x\colon [-1,0] \times U_x \to M$ with $\Phi_x^{-1}(\partial M) = \{0\} \times U_x$. For each x we can and will pick a compact neighborhood K_x with $K_x \subset U_x$. Since M is compact we know by the Topological Manifold Boundary Proposition 75.2 (4b) that ∂M is also compact. Evidently the interiors of the K_x cover all of ∂M. Since ∂M is compact we see that there exist $x_1, \ldots, x_m \in \partial M$ such that ∂M is covered by the interiors of the K_{x_i}. Finally note that it follows from the Manifold-Partitions of Unity Existence Theorem 21.1 that there exist maps $f_1, \ldots, f_m\colon \partial M \to [0,1]$ such that for each $i \in \{1, \ldots, m\}$ we have $\operatorname{supp}(f_i) \subset K_{x_i}$

and such that $f_1 + \cdots + f_m = 1$. Renaming K_{x_i} and Φ_{x_i} as K_i and Φ_i we obtain the desired result. ⊞

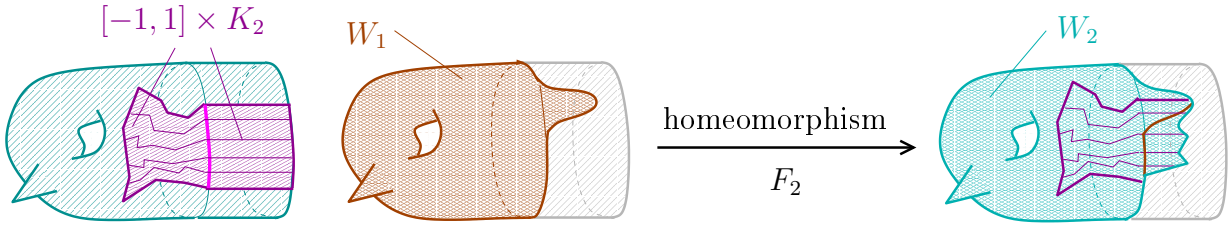
Next, for $i = 0, \ldots, m$ we set $g_i := f_1 + \cdots + f_i$ and we set

$$W_i := M \cup_{\partial M = \{0\} \times \partial M} \{(t, x) \,|\, x \in \partial M \text{ and } t \in [0, g_i(x)]\}.$$

By the Topological Pushout-Maps Lemma 5.34 (1) we know that W_0 is homeomorphic to M and evidently $W_m = W$.

Claim. For $i = 1, \ldots, m$ there exists a homeomorphism $F_i \colon W_{i-1} \to W_i$.

Proof. Let $i \in \{1, \ldots, m\}$. We consider the map



$$\begin{array}{rcl} \Theta \colon [-1,1] \times K_i & \to & W \\ (t, x) & \mapsto & \begin{cases} [\Phi_i((t,x))], & \text{if } t \in [-1, 0], \\ [(t, x)], & \text{if } t \in [0, 1]. \end{cases} \end{array}$$

It follows fairly easily from the Topological Pushout-Maps Lemma 5.34 (3) and (4), Lemma 5.36 and the Compact-Hausdorff Proposition 2.17 (2) that this map is a closed embedding. To simplify the notation we will identify $[-1, 1] \times K_i$ with its image in W. The desired homeomorphism $W_{i-1} \to W_i$ is now given by "stretching horizontally" along $[-1, 1] \times K_i$. More precisely, we consider the map

$$\begin{array}{rcl} F_i \colon W_{i-1} & \to & W_i \\ x & \mapsto & \begin{cases} x, & \text{if } x \notin [-1, 1] \times K_i \\ \big(-1 + \frac{1+g_i(y)}{1+g_{i-1}(y)} \cdot (t+1), y\big), & \text{if } x = (t, y) \in [-1, 1] \times K_i. \end{cases} \end{array}$$

It follows easily from the fact that $\operatorname{supp}(f_i) \subset K_i$, the Product Topology-Basics Lemma 5.4 (3) and Pasting Proposition 2.6 that this map is continuous and it follows from the Compact-Hausdorff Proposition 2.17 (2) that this map is in fact a homeomorphism. ⊞

It is now clear that $F := F_m \circ \cdots \circ F_1 \colon M \to W$ is a homeomorphism which has the feature that $F(\partial M) = \{1\} \times \partial M$. ■

Proof of the Topological Collar Neighborhood Theorem 75.5. Now let M be any topological manifold. The proof of the Topological Collar Neighborhood Theorem 75.5 in

this setting is not that different from the compact case. For space and time reasons we only sketch the argument.

It follows from the fact that ∂M is in particular second-countable together with the Manifold-Partitions of Unity Existence Theorem 21.1 that there exists an infinite sequence $K_1, K_2, \ldots$ of compact subsets, embeddings $\Phi_i \colon K_i \times [-1,0] \to M$ and maps $f_i \colon \partial M \to [0,1]$ such that beyond the aforementioned Statements (1), (2) and (3) the following extra condition is satisfied:

(4) For each $x \in \partial M$ there exists an open neighborhood V such that there exist only finitely many $i \in \mathbb{N}$ with $\operatorname{supp}(f_i) \cap U \neq \varnothing$.

As in the previous argument we now define functions $g_1, g_2, \ldots$, subsets $W_1, W_2, \ldots$ and homeomorphisms $F_i \colon W_{i-1} \to W_i$. It follows from (4) that the map

$$\begin{array}{rcll} F \colon M & \to & W & \\ x & \mapsto & (F_k \circ \cdots \circ F_1)(x) & \text{if } f_i(x) = 0 \text{ for } i \geq k \end{array}$$

is well-defined and continuous. In fact using the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19 it is straightforward to see that F is actually a homeomorphism. Furthermore, note that by construction we again have $F(\partial M) = \{1\} \times \partial M$. Thus, as in the proof of the compact case, we are done. ■

The following uniqueness statement for collar neighborhoods is almost verbatim the same as the statement of the Uniqueness of Collar-Proposition **??**.

Proposition 75.6. Let M be a topological manifold and let $f_0, f_1 \colon [0,1] \times \partial M \to M$ be two embeddings that are the identity map on $\{0\} \times \partial M = \partial M$. If ∂M is compact, then there exists an isotopy

$$H \colon M \times [0,1] \ \to \ M$$

rel ∂M from $H_0 = \mathrm{id}_M$ to a homeomorphism $\Phi = H_1 \colon M \to M$ with $\Phi \circ f_0 = f_1$. In particular Φ restricts to a homeomorphism

$$\Phi \colon f_0([0,1] \times \partial M) \ \to \ f_1([0,1] \times \partial M).$$

Remark. In the study of smooth manifold several constructions, in particular the gluing construction, depends on the choice of a smooth collar. The Uniqueness of Collar-Proposition **??** then shows that these constructions are well-defined up to diffeomorphism. In the context of topological manifolds constructions usually do *not* depend on the choice of a collar. Thus the uniqueness statement of Proposition 75.6 is nice to know, but we will never need to make use of it.

Proof. The proof is sketched in [**KSi1969**, Essay I, Theorem A.2]. The proof is also given in [**Arm1970**, Theorem 2].[912] ■

Convention. Suppose we are given a topological manifold M with compact boundary ∂M. We pick a map $\Phi \colon [0,1] \times \partial M \to M$ as in the conclusion of the Topological Collar

[912] The proof in [**Arm1970**] makes me slightly nervous, there is no hypothesis that ∂M is compact, and there is no statement that the image of $[0,1] \times \partial M$ needs to be closed. But that would imply that the "usual" collar neighborhood for $M = \{(x,y) \,|\, y \geq 0\}$ is equivalent to the one shown in the figure below, which is certainly *not* the case.

Neighborhood Theorem 75.5. Usually we identify $[0,1] \times \partial M$ with the image in M under the map Φ and we just refer to $[0,1] \times \partial M$ as a "collar neighborhood of ∂M". Sometimes we also find it convenient to use other intervals in our notation, e.g. we might write "let $[-3,0] \times \partial M$ be a collar neighborhood". It is then understood that $\{0\} \times \partial M = \partial M$.

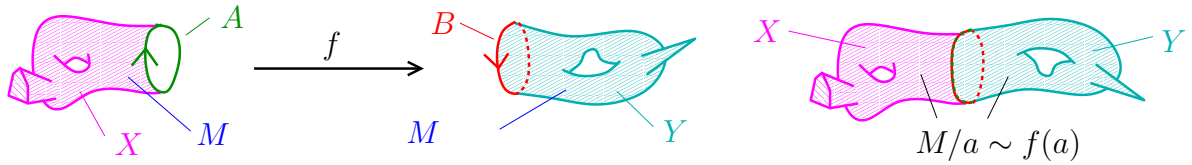
For later we record the following corollary to the Topological Collar Neighborhood Theorem 75.5 which is the analogue of the Basics-of-Collars Lemma 28.4 and the Push-Away-from-Boundary Corollary 28.5.

Corollary 75.7. Let M be an n-dimensional topological manifold. Let $[0,1] \times \partial M$ be a collar neighborhood.

(1) The subset $W := M \setminus ([0,1) \times \partial M)$ is an n-dimensional topological manifold with boundary given by $\{1\} \times \partial M$.
(2) The subset $W = M \setminus ([0,1) \times \partial M)$ is a deformation retract of M and it is a deformation retract of $M \setminus \partial M$.
(3) If M is non-empty, then M is homotopy equivalent to a non-compact n-dimensional topological manifold without boundary.

Proof. The proof of Corollary 75.7 is basically the same as the proof of the Basics-of-Collars Lemma 28.4 and the Push-Away-from-Boundary Corollary 28.5. We just need to replace the Smooth Collar Neighborhood Theorem 28.3 by the Topological Collar Neighborhood Theorem 75.5 and we need to replace the Smooth Manifold Boundary Proposition 19.26 by the Topological Manifold Boundary Proposition 75.2. ■

We conclude this discussion of the Topological Collar Neighborhood Theorem 75.5 with the following proposition that looks uncannily similar to the Gluing-Smooth Manifolds-Proposition **??**.



Proposition 75.8. (Gluing-Topological Manifolds-Proposition) Let M be an n-dimensional topological manifold (we do not assume that M is connected). Let A and B be disjoint unions of boundary components of M. Furthermore let $f\colon A \to B$ be a homeomorphism. Then the following two statements hold:

(1) The topological space
$$M/a \sim f(a) \quad \text{for } a \in A$$
is an n-dimensional topological manifold.
(2) If M consists of two components X and Y and if $A \subset X$ and $B \subset Y$, then the images of X and Y in $M/a \sim f(a)$ are codimension-zero submanifolds.
(3) If M is compact, then $M/a \sim f(a)$ is also compact.
(4) The boundary of $M/a \sim f(a)$ is given by $\partial M \setminus (A \cup B)$.
(5) If each component of M contains at least one component of A or B, then $M/a \sim f(a)$ is connected.

In Chapter 25 we will introduce the notion of an orientation of a topological manifold. To preserve the symmetry with the Gluing-Smooth Manifolds-Proposition **??** we add the

following statement, even though with the present knowledge it does not have any meaning yet.

(6) Assume that M is oriented. We equip A and B with the boundary orientations, as defined in the Topological Manifold-Boundary Orientation Proposition 105.19.
  (a) If f is orientation-reversing, then $M/a \sim f(a)$ admits an orientation such that the inclusion $M \setminus (A \cup B) \to M/a \sim f(a)$ is orientation-preserving.
  (b) If M is connected and if f is not orientation-reversing, then $M/a \sim f(a)$ is non-orientable.

Proof. For the most part the proof of the Gluing-Topological Manifolds-Proposition 75.8 is almost the same as the proof of the Gluing-Smooth Manifolds-Proposition **??**. For statements (1) to (5) we just need to make the following replacements:

(1) We need to replace the Smooth Manifold Boundary Proposition 19.26 (3a) by Lemma 18.6.
(2) We need to replace the Smooth Collar Neighborhood Theorem 28.3 by the Topological Collar Neighborhood Theorem 75.5.
(3) We need to replace the Smooth Manifold Boundary Proposition 19.26 (1) by the Topological Manifold Boundary Proposition 75.2 (1).

The alert reader will notice that in the proof of the Gluing-Topological Manifolds-Proposition 75.8 it is not really necessary to use the Topological Collar Neighborhood Theorem 75.5. For example, as we will see in Exercise 75.5, one can define an atlas for $M/a \sim f(a)$ "by hand". Nonetheless we leave the proof as it is, since the Topological Collar Neighborhood Theorem 75.5 greatly simplifies the discussion.

Finally we will prove Statement (6) in Exercise 105.4. ■

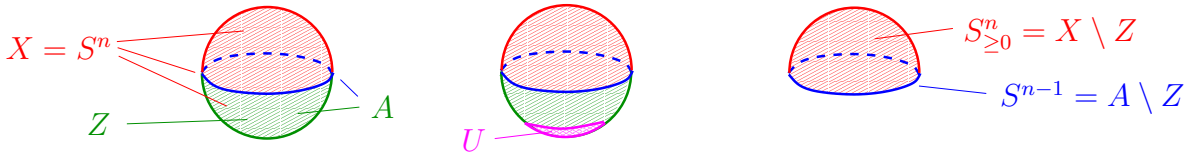
75.4. **Variations on the Excision Theorem 74.17.** In this section we will state and prove two variations on the Excision Theorem 74.17. First we have the following rather technical sounding theorem.

Theorem 75.9. Let X be a topological space and let $Z \subset A \subset X$ be two subsets. We suppose that there exists a subset $U \subset Z$ such that the closure of U is contained in the interior of A and such that the following statements hold:

(1) $X \setminus Z$ is a deformation retract of $X \setminus U$
(2) $A \setminus Z$ is a deformation retract of $A \setminus U$.

Then the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$\mathrm{H}_n(X \setminus Z, A \setminus Z) \xrightarrow{\cong} \mathrm{H}_n(X, A).$$



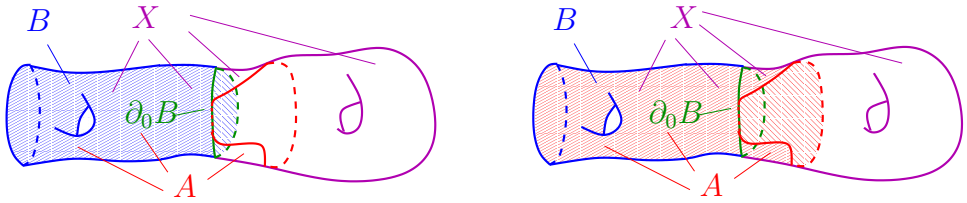
The hypotheses of Theorem 75.9 might sound complicated, but as we will see, in practice these conditions are often satisfied.

Example. Let $n \in \mathbb{N}$. As usual we denote by $S^n_{\geq 0}$ and $S^n_{\leq 0}$ the upper and lower hemisphere of S^n and we make the obvious identification $S^{n-1} = S^n_{\geq 0} \cap S^n_{\leq 0}$. It follows from

Theorem 75.9 and the choices of X, A, Z and U illustrated in the figure below that the inclusion induced map

$$\mathrm{H}_n(S^n_{\geq 0}, S^{n-1}) \;\to\; \mathrm{H}_n(S^n, S^n_{\leq 0})$$

is an isomorphism.



We can easily generalize the above example. More precisely, Theorem 75.9 also allows us to prove the following variation on the Excision Theorem 74.17. It says, under mild technical hypotheses, that in the relative homology of an m-dimensional topological manifold we can excise the interior of a codimension-zero submanifold.

Theorem 75.10. (Excision Theorem for Topological Manifolds) Let X be an m-dimensional topological manifold and let A be a subset of X. Furthermore let B be an m-dimensional submanifold of X that is a closed subset of X. We write $\mathring{B} := B \setminus \partial_0 B$.[913] If $\mathring{B} \subset A$, then for every $n \in \mathbb{N}_0$ the inclusion induced map

$$\mathrm{H}_n\big(X \setminus \mathring{B}, A \setminus \mathring{B}\big) \;\xrightarrow{\cong}\; \mathrm{H}_n(X, A)$$

is an isomorphism.

Example. If we take $X = S^n$, $A = S^n_{\leq 0}$ and $B = S^n_{\leq 0}$, then all the hypothesis of the Excision Theorem 75.10 for Topological Manifolds are satisfied and we obtain, as above, that the inclusion induced map

$$\mathrm{H}_n(S^n_{\geq 0}, S^{n-1}) \;\to\; \mathrm{H}_n(S^n, S^n_{\leq 0})$$

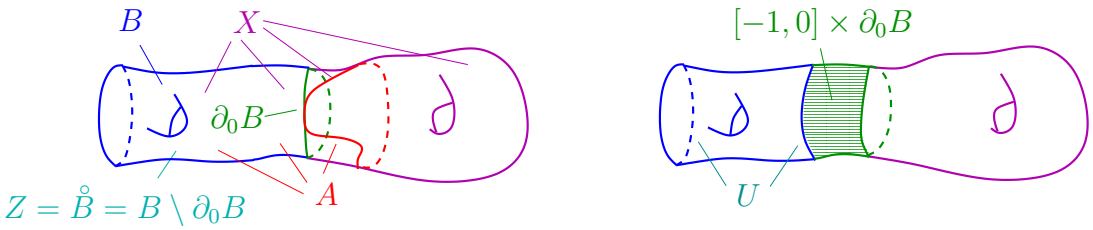
is an isomorphism.

Remark. In Theorem 120.2 we will generalize the statement of the Excision Theorem 75.10 for Topological Manifolds to the setting that B is a submanifold "with corner".

Proof of Theorem 75.10 assuming Theorem 75.9. Note that by Proposition 75.3 we know that $\partial_0 B$ is a union of boundary components of B and that $\mathring{B}$ is indeed the interior of B viewed as a subset of X. In particular we can apply the Topological Collar Neighborhood Theorem 75.5 to $\partial_0 B$. We obtain an embedding $\varphi\colon [-1,0] \times \partial_0 B \to B$ that is the identity map on $\{0\} \times \partial_0 B = \partial_0 B$. To simplify the notation we identify $[-1,0] \times \partial_0 B$ with its image in B. We set $Z = \mathring{B} = B \setminus (\{0\} \times \partial_0 B)$ and we set $U = B \setminus ((-1,0] \times \partial_0 B)$.

[913] We refer to page 1658 for the definition of $\partial_0 B$.

Claim. There exists a deformation retract from $X \setminus U$ to $X \setminus Z$.



Proof. First note that we can write $X \setminus U = (X \setminus Z) \cup ([-1,0] \times \partial_0 B)$. Furthermore note that $(X \setminus Z) \cap ([-1,0] \times \partial_0 B) = \{0\} \times \partial_0 B$. The idea is to use Lemma 52.11 to conclude that the obvious deformation retraction from $[-1,0] \times \partial_0 B$ to $\{0\} \times \partial_0 B$ gives rise to the desired deformation retraction.

We still have to perform the task of verifying the hypotheses of Lemma 52.11, i.e. we need to argue that $X \setminus Z$ and $[-1,0] \times \partial_0 B$ are closed subsets of $X \setminus U$. First note that by Proposition 75.3 we know that $Z = \mathring{B}$ is an open subset of X. It follows that $X \setminus Z$ is a closed subset of $X \setminus U$. Furthermore by Statement (4) of the Topological Collar Neighborhood Theorem 75.5 we know that $[-1,0] \times \partial_0 B$ is a closed subset of X, in particular it is a closed subset of $X \setminus U$. ⊞

Claim. There exists a deformation retract from $A \setminus U$ to $A \setminus Z$.

Proof. Since $\mathring{B} \subset A$ we have $A \setminus U = (A \setminus Z) \cup ([-1,0] \times \partial_0 B)$. Furthermore note that $(A \setminus Z) \cap ([-1,0] \times \partial_0 B) = \{0\} \times \partial_0 B$. Thus basically the same argument as in the proof of the previous claim shows that such a deformation retraction exists. ⊞

The statement of Excision Theorem 75.10 for Topological Manifolds now follows immediately from Theorem 75.9. ■

We conclude this section with the proof of Theorem 75.9.

Proof of Theorem 75.9. We consider the following commutative diagram of inclusion induced maps

$$\begin{array}{ccc} \mathrm{H}_n(X \setminus Z, A \setminus Z) & \longrightarrow & \mathrm{H}_n(X, A) \\ \downarrow & \nearrow_{\cong} & \\ \mathrm{H}_n(X \setminus U, A \setminus U). & & \end{array}$$

The diagonal map is an isomorphism by the Excision Theorem 74.17. Thus it suffices to show that the vertical map is an isomorphism.

We consider the following diagram:

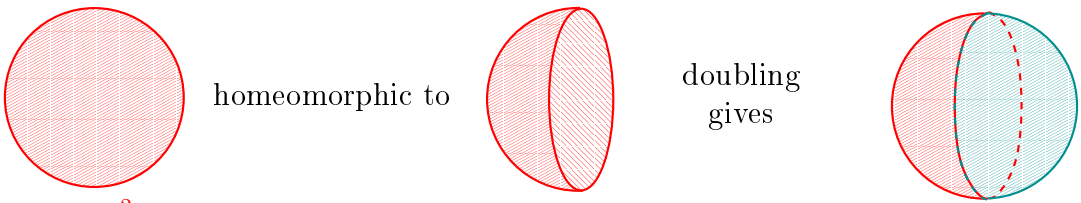
$$\begin{array}{ccccccccc} \mathrm{H}_n(A \setminus Z) & \longrightarrow & \mathrm{H}_n(X \setminus Z) & \longrightarrow & \mathrm{H}_n(X \setminus Z, A \setminus Z) & \longrightarrow & \mathrm{H}_{n-1}(A \setminus Z) & \longrightarrow & \mathrm{H}_{n-1}(X \setminus Z) \\ \downarrow{=} & & \downarrow & & \downarrow & & \downarrow{=} & & \downarrow \\ \mathrm{H}_n(A \setminus Z) & \longrightarrow & \mathrm{H}_n(X \setminus U) & \longrightarrow & \mathrm{H}_n(X \setminus U, A \setminus Z) & \longrightarrow & \mathrm{H}_{n-1}(A \setminus Z) & \longrightarrow & \mathrm{H}_{n-1}(X \setminus U) \\ \downarrow & & \downarrow{=} & & \downarrow & & \downarrow & & \downarrow{=} \\ \mathrm{H}_n(A \setminus U) & \longrightarrow & \mathrm{H}_n(X \setminus U) & \longrightarrow & \mathrm{H}_n(X \setminus U, A \setminus U) & \longrightarrow & \mathrm{H}_{n-1}(A \setminus U) & \longrightarrow & \mathrm{H}_{n-1}(X \setminus U). \end{array}$$

Here the horizontal maps are pieces of the long exact sequences of the various pairs of topological spaces provided by the Topological LES-Corollary 74.14 (1). Note that by the Topological LES-Corollary 74.14 (2) we know that the diagram commutes.

Furthermore the vertical maps are induced by the various inclusion maps. On the upper level the first and the fourth vertical maps are the identity. Furthermore it follows from the hypothesis that $X \setminus Z$ is a deformation retract of $X \setminus U$ and from Corollary 74.16 that the second and the fifth vertical map are also isomorphisms. It follows from the Five Lemma 74.10 that the upper middle vertical map is also an isomorphism.

Using the hypothesis that $A \setminus Z$ is a deformation retract of $A \setminus U$ one can show exactly the same way that the lower middle vertical map is also an isomorphism. Combining the two middle vertical maps we obtain the desired isomorphism. ■

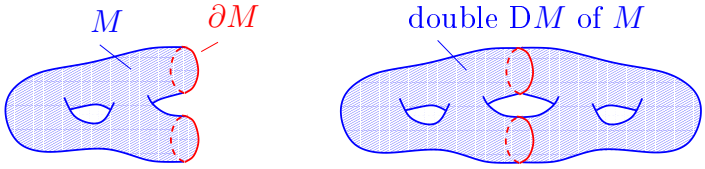
75.5. **The double of topological and smooth manifolds.** In this short section we introduce the double of a topological manifold. This construction associates to a compact manifold with non-empty boundary a closed manifold. This procedure comes in handy on several occasions. In particular sometimes this procedure allows us to reduce the proof of a certain statement for compact manifolds to the closed case. As the reader will notice, this section has only a moderately convincing justification for fitting into this particular chapter, but the material has to go somewhere, and some of the more technical statements in this section make use of the earlier results of this section.
After this apology, let us give the key definition of this section.



Definition. Let M be a topological manifold and let W be the union of some components of ∂M. We refer to

$$\mathrm{D}_W M \;:=\; (M \times \{1\}) \cup_{W \times \{1\} = W \times \{2\}} (M \times \{2\})$$

as the double of M along W. We refer to $\mathrm{D}M := D_{\partial M} M$ as the double of M.



Example. The double of M is given by taking two copies of M and identifying the boundary points "left and right" in the obvious way.

(1) On page 152 we gave an explicit homeomorphism $\overline{B}^n \xrightarrow{\cong} S^n_{\leq 0}$. Using this homeomorphism it is straightforward to see that the double of the n-ball $\overline{B}^n$ is homeomorphic to the n-dimensional sphere S^n. We refer to the figure below for an illustration.

disk $\overline{B}^2$ — lower hemisphere $S^2_{\leq 0}$ — double is homeomorphic to S^2

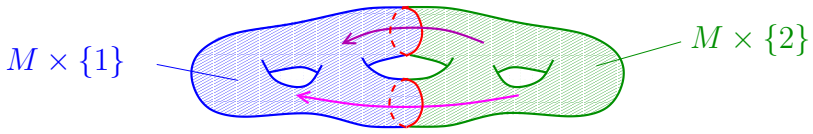
(2) the figure below makes a convincing case that the double of the torus minus two open disks is homeomorphic to the surface of genus 3. We refer to the figure below for an illustration.

(3) In Exercise 75.7 we will see that the double of the Möbius band and the Klein bottle minus an open disk are homeomorphic to well-known topological spaces.

The following definition allows us to relate a topological manifold to its double.

Definition. Let M be a topological manifold and let W be the union of some components of ∂M. We refer to the map

$$i\colon M \xrightarrow{P\mapsto(P,1)} M\times\{1\} \to (M\times\{1\})\sqcup(M\times\{2\}) \to \mathrm{D}_W M$$



as the natural inclusion. Furthermore we refer to the map

$$\begin{aligned} r\colon \mathrm{D}_W M = ((M\times\{1\})\cup(M\times\{2\}))/\!\sim &\to M \\ [(P,i)] &\mapsto P \end{aligned}$$

as the folding map. Finally we refer to the map

$$\begin{aligned} \rho\colon \mathrm{D}_W M &\to \mathrm{D}_W M \\ [(P,i] &\mapsto [(P,3-i)] \end{aligned}$$

as the natural involution on $\mathrm{D}_W M$.

Lemma 75.11. Let M be a topological manifold and let W be the union of some components of ∂M.

(1) The natural inclusion $i\colon M\to \mathrm{D}_W M$ is an embedding.
(2) The folding map $\mathrm{D}_W M\to M$ is continuous and it satisfies $r\circ i=\mathrm{id}_M$.
(3) The natural involution $\mathrm{D}_W M\to \mathrm{D}_W M$ is continuous and it is an involution, i.e. $\rho\circ\rho=\mathrm{id}$.

Proof. It follows from the Topological-Coproduct Proposition 5.11 and the Topological-Quotient Proposition 5.15 (1a) that the natural inclusion i is continuous and that the involution ρ are continuous. It is clear that $\rho\circ\rho=\mathrm{id}$. Furthermore it follows from the Topological-Coproduct Proposition 5.11 and the Topological-Quotient Proposition 5.15 (1b) that the folding map r is continuous. Clearly we have $r\circ i=\mathrm{id}_M$. This shows in particular that $i\colon M\to i(M)$ is a homeomorphism, i.e. i is an embedding.

Finally it follows from the Topological-Coproduct Proposition 5.11, the Topological-Quotient Proposition 5.15 (1a) and the Topological-Quotient Proposition 5.15 (1b) that the involution ρ is continuous. It is clear that $\rho\circ\rho=\mathrm{id}$. ■

Convention. Sometimes we will use the fact, established in Lemma 75.11, that the natural inclusion $M\to \mathrm{D}_W M$ is an embedding as an excuse to view M as a subspace of $\mathrm{D}_W M$ and to view $r\colon \mathrm{D}_W M\to M$ as a retraction.

The following lemma summarizes a few key properties of the doubling operation.

Lemma 75.12. (Doubling-Manifold Lemma) Let M be an n-dimensional topological (smooth) manifold and let W be the union of some components of ∂M. The following statements hold:

(1) (a) The double $\mathrm{D}_W M$ along W is an n-dimensional topological manifold such that $M \subset \mathrm{D}_W M$ is a submanifold and such that M is a closed subset of $\mathrm{D}_W M$.
   (b) If M is actually a smooth manifold, then the double $\mathrm{D}_W M$ is naturally an n-dimensional smooth manifold such that $M \subset \mathrm{D}_W M$ is a smooth submanifold and such that the natural inclusion $i\colon M \to \mathrm{D}_W M$ is a smooth embedding.[914]

(2) The boundary of the double $\mathrm{D}_W M$ is given by two copies of $\partial M \setminus W$. In particular the boundary of the double $\mathrm{D}M$ is empty.

(3) M is compact if and only if the double $\mathrm{D}_W M$ is compact.

(4) If M is connected and if $W \neq \varnothing$, then the double $\mathrm{D}_W M$ is also connected.

(5) If M is an oriented smooth manifold, then $\mathrm{D}_W M$ admits an orientation such that $M \to \mathrm{D}_W M$ is an orientation-preserving embedding. Conversely, if $\mathrm{D}_W M$ is oriented, then M admits an orientation such that the inclusion $M \to \mathrm{D}_W M$ is orientation-preserving.[915]

(6) For every $k \in \mathbb{N}_0$ the inclusion induced map

$$\mathrm{H}_k(M, W) \;\to\; \mathrm{H}_k(\mathrm{D}_W M, M)$$

is an isomorphism.

Proof. Let M be an n-dimensional topological (smooth) manifold. Statements (1), (2) and (4) follow immediately from applying the Gluing-Smooth Manifolds-Proposition **??** and the Gluing-Topological Manifolds-Proposition 75.8 iteratively to $(W \times \{1\}) \sqcup (W \times \{2\}) \subset (M \times \{1\}) \sqcup (M \times \{2\})$.

We turn to the proof of Statement (3). Note that it follows easily from Lemmas 75.11, 2.13 and 1.20 that M is compact if and only if the double $\mathrm{D}_W M$ is compact.

Next we provide the proof of Statement (5). Thus we suppose that M is an oriented smooth manifold. We equip $M \times \{1\}$ with the obvious orientation. Furthermore we equip $M \times \{2\}$ with the opposite orientation. With these orientations it is straightforward to see that the map $\partial(M \times \{1\}) \xrightarrow{(P,1) \mapsto (P,2)} \partial(M \times \{2\})$ is orientation-reversing. Thus it follows from the Gluing-Smooth Manifolds-Proposition **??** that the double $\mathrm{D}_W M$ admits an orientation such that $M \to \mathrm{D}_W M$ is an orientation-preserving embedding. Conversely, if $\mathrm{D}_W M$ is oriented, then it follows from the Basics-of-Orientations Lemma 25.13 (4) that M inherits an orientation such that the inclusion $M \to \mathrm{D}M$ is orientation-preserving.

Finally note that Statement (6) is an immediate consequence of the Excision Theorem 75.10 for Topological Manifolds, and the fact, established in (1), that M is a closed subset of $\mathrm{D}M$. ■

The following lemma relates some of the algebraic invariants of a manifold M to the invariants of its double $\mathrm{D}M$.

[914] Note though that the folding map $r\colon \mathrm{D}_W M \to M$ is *not* smooth.

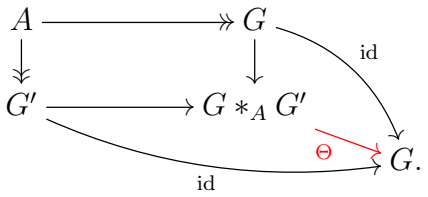
[915] In the Double-Orientability Lemma 105.18 we will prove an analogous statement for topological manifolds.

Lemma 75.13. Let M be a topological manifold and let W be the union of some components of ∂M.

(1) For every $j \in \mathbb{N}_0$ the inclusion induced map $\mathrm{H}_j(M) \to \mathrm{H}_j(\mathrm{D}_W M)$ is a monomorphism.
(2) If ∂M is non-empty and if x_0 is a point in ∂M, then for every $j \in \mathbb{N}_0$ the inclusion induced map $\pi_j(M, x_0) \to \pi_j(\mathrm{D}_W M, x_0)$ is a monomorphism.

Remark. In the Homology-of-Double Proposition 141.2 we will calculate the homology groups of $\mathrm{D}M$ in terms of the homology groups of M.

Proof. Let $i\colon M \to \mathrm{D}_W M$ be the natural inclusion map and let $r\colon \mathrm{D}_W M \to M$ be the folding map. In Lemma 75.11 we saw that both maps are continuous and that $r \circ i = \mathrm{id}_M$. The two statements now follow as usual from the functoriality of homology groups and homotopy groups. More precisely, in both cases we have $r_* \circ i_* = \mathrm{id}_*$, i.e. i_* needs to be a monomorphism. ■



In favorable circumstances we can fully control the fundamental group of the double.

Proposition 75.14. Let M be a compact connected n-dimensional topological manifold, let W be a component of ∂M and let $P \in W$. If the inclusion induced map $\pi_1(W, P) \to \pi_1(M, P)$ is an epimorphism, then the inclusion induced map $\pi_1(M, P) \to \pi_1(\mathrm{D}_W M, P)$ is an isomorphism.

The proof of Proposition 75.14 results on the following group-theoretic lemma, which is precisely the content of Exercise 53.13.

Lemma 75.15. Let A and G be groups and let $\varphi\colon A \to G$ be an epimorphism. Furthermore let G' be a copy of G. We consider the amalgamated product $G *_A G'$ given by using twice the epimorphism $\varphi\colon A \to G$ and $\varphi\colon A \to G' = G$. In this setting the natural homomorphism $G \to G *_A G'$ is an isomorphism.

Proof of Lemma 75.15. By Proposition 53.21 there exists a unique homomorphism $\Theta\colon G *_A G' \to G'$ that makes the following diagram commutes:

In particular we see that the right vertical map is a monomorphism. The left vertical map is by hypothesis an epimorphism. It follows from the Amalgamated Product Lemma 53.22 (3) that the right vertical map is also an epimorphism. Thus we shown that the right vertical map is indeed an isomorphism. ■

Proof of Proposition 75.14. Let $P \in W$. Since W is non-empty and connected we obtain from the Seifert-van Kampen Theorem 54.4 that the inclusions of the two copies of M into the double $\mathrm{D}_W M$ induce an isomorphism $\pi_1(\mathrm{D}M, P) \cong \pi_1(M, P) *_{\pi_1(W,P)} \pi_1(M, P)$. By our hypothesis the map $\pi_1(W, P) \to \pi_1(M, P)$ is an epimorphism. It follows from the above, together with Lemma 75.15, that the map $\pi_1(M, P) \to \pi_1(\mathrm{D}_W M, P)$ is indeed an epimorphism. ■

We conclude this introduction to the double of a topological manifold with the following harmless but at times useful lemma. The lemma follows almost immediately from the definitions, hence we leave it to the conscientious reader to fill in the details.

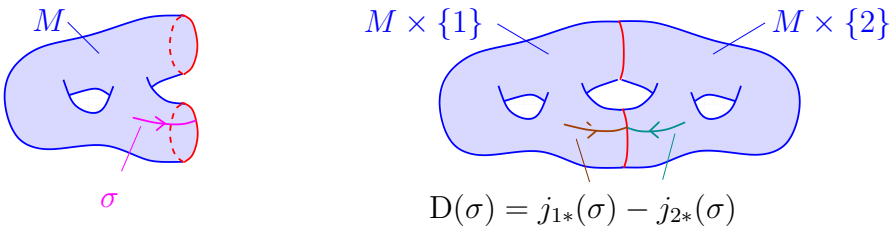
Lemma 75.16. (Doubling-Homology Lemma) Let M be a topological manifold and let W be the union of some components of ∂M. Given $i \in \{1,2\}$, we denote by $j_i \colon M \to M \times \{i\} \to \mathrm{D}_W M$ the obvious map.

(1) For every $k \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{D} \colon \mathrm{C}_k(M,W) & \to & \mathrm{C}_k(\mathrm{D}_W M) \\ \big[\underbrace{\sigma}_{\in \mathrm{C}_k(M)} \big] & \mapsto & j_{1*}(\sigma) - j_{2*}(\sigma) \end{array}$$

is well-defined.

(2) The maps from (1) define a natural chain map, in particular for every $k \in \mathbb{N}_0$ these maps induce a map



$$\mathrm{D} \colon \mathrm{H}_k(M,W) \to \mathrm{H}_k(\mathrm{D}_W M)$$

which is called the doubling homomorphism.

(3) We make the identification $M = j_1(M \times \{1\})$ and we write $M' = j_2(M \times \{2\})$. The doubling homomorphism has the property that the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}_k(M,W) & \xrightarrow{\quad \mathrm{D} \quad} & \mathrm{H}_k(\mathrm{D}_W M) \\ & \searrow \quad \swarrow & \\ & \mathrm{H}_k(\mathrm{D}_W M, M'), & \end{array}$$

where the diagonal maps are the obvious maps. (As an aside we mention that it follows from the Excision Theorem 75.10 that the left diagonal map is an isomorphism.)

Exercises for Chapter 75.

Exercise 75.1. Let M be a topological manifold. Furthermore let $x_1, \ldots, x_k$ be distinct points in M. Let $n \in \mathbb{N}_0$. For $i \in \{1, \ldots, k\}$ we denote by

$$\nu_i \colon \mathrm{H}_n(M, M \setminus \{x_1, \ldots, x_k\}) \to \mathrm{H}_n(M, M \setminus \{x_i\})$$

the map that is induced by the inclusion $M \setminus \{x_1, \ldots, x_k\} \to M \setminus \{x_i\}$. Show that the map

$$\bigoplus_{i=1}^{k} \nu_i \colon \mathrm{H}_n(M, M \setminus \{x_1, \ldots, x_k\}) \to \bigoplus_{i=1}^{k} \mathrm{H}_n(M, M \setminus \{x_i\})$$

is an isomorphism.

Hint. Use Excision Theorem 74.18.

Exercise 75.2. Let X be a finite topological graph, in other words, let X be a finite 1-dimensional CW-complex. Given any point $x \in X$ compute the local homology groups $\mathrm{H}_*(X, X \setminus \{x\})$.

Exercise 75.3. Let $n_1, \ldots, n_k \in \mathbb{N}$. We form the wedge $X := S^{n_1} \vee \cdots \vee S^{n_k}$. We denote by P the wedge point. Compute the local homology groups $\mathrm{H}_*(X, X \setminus \{P\})$.

Exercise 75.4. Let X be a topological space and let $n \in \mathbb{N}_0$. We consider the following two maps.

(1) Let $p\colon X \times S^1 \to X$ be the projection.
(2) We consider the homomorphism $\psi\colon \mathrm{H}_n(X \times S^1) \to \mathrm{H}_{n-1}(X)$ that is given by

$$\begin{aligned} \mathrm{H}_n(X \times S^1) \;&\to\; \mathrm{H}_n(X \times S^1, X \times S^1_{\leq 0}) \;\underset{\text{isomorphism by the Excision Theorem 75.9}}{\overset{\cong}{\leftarrow}}\; \mathrm{H}_n(X \times S^1_{\geq 0}, X \times \{\pm 1\}) \\ &\underset{\text{connecting homomorphism}}{\to} \mathrm{H}_{n-1}(X \times \{\pm 1\}) \underset{\text{projection induced homomorphism}}{\to} \mathrm{H}_{n-1}(X \times \{1\}) \;=\; \mathrm{H}_{n-1}(X). \end{aligned}$$

Show that the map

$$p_* \oplus \psi\colon \mathrm{H}_n(X \times S^1) \;\to\; \mathrm{H}_n(X) \oplus \mathrm{H}_{n-1}(X)$$

is an isomorphism.
Hint. Consider the long exact sequence of the pair $(X \times S^1, X \times S^1_{\leq 0})$.
Remark. In Lemma 78.21 we will give a different approach to calculating $\mathrm{H}_n(X \times S^1)$.

Exercise 75.5. Let M be an n-dimensional topological manifold and let A and B be disjoint unions of boundary components of M. Furthermore let $f\colon A \to B$ be a homeomorphism. Show, without using the Topological Collar Neighborhood Theorem 75.5, that the topological space

$$M/a \sim f(a) \quad \text{for } a \in A$$

is an n-dimensional topological manifold.

Exercise 75.6. We recall the following definitions:

(1) The suspension of a topological space X is defined to be the topological space

$$\Sigma(X) \;:=\; (X \times [-1, 1])/\!\sim$$

where we identify all points in $X \times \{-1\}$ and we identify all points in $X \times \{1\}$.
(2) A topological space X that has the property that for each $x \in X$ we have

$$\mathrm{H}_k(X, X \setminus \{x\}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise} \end{cases}$$

is called an *n-dimensional homology manifold*.
(3) We say that an n-dimensional topological manifold X is a *topological homology n-sphere* if for every $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(X) \cong \mathrm{H}_k(S^n)$.

Let Y be a homology n-sphere.

(a) Show that $Y \times \mathbb{R}$ is an $(n+1)$-dimensional homology manifold.
(b) Show that the suspension $\Sigma(Y)$ of Y is an $(n+1)$-dimensional homology manifold.
(c) Show that if $\pi_1(Y)$ is non-trivial, then the suspension $\Sigma(Y)$ is *not* a topological manifold.

Remark. In Proposition 98.11 we will see that there exists a closed orientable 3-dimensional smooth manifold Y that is a homology 3-sphere, but such that $\pi_1(Y)$ is a non-trivial group. Together with the above this shows that there exist homology manifolds that are not topological manifolds.

Exercise 75.7. What is a familiar topological space that is homeomorphic to the double of the Möbius band? Furthermore, which one is homeomorphic to the double of the Klein bottle minus an open disk?

Exercise 75.8. Let M be a compact connected n-dimensional topological manifold such that ∂M has $k \in \mathbb{N}$ components.

(a) Show that $\operatorname{rank}(\mathrm{H}_1(\mathrm{D}M)) \geq k-1$.
(b) Show that $\pi_1(M)$ admits an epimorphism onto a free group of rank $k-1$.

Exercise 75.9. Let X be a topological space and let $x \in X$. On page 319 we defined the *topological valence of* x as

$$\operatorname{topval}(x,X) := \min\left\{ n \in \mathbb{N} \cup \{\infty\} \;\middle|\; \begin{array}{c} \text{for every open neighborhood } U \text{ of } x \text{ there} \\ \text{exists an open neighborhood } V \text{ of } x \text{ with } V \subset U \\ \text{such that } V \setminus \{x\} \text{ has at least } n \text{ components} \end{array} \right\}.$$

(a) Show that if X is locally contractible and if x is not an isolated point, then

$$\operatorname{topval}(x,X) \;=\; \operatorname{rank}(\mathrm{H}_1(X, X \setminus \{x\})).$$

(b) Show that the conclusion of (a) does not necessarily hold if X is not locally contractible.

Exercise 75.10. Let M be a compact smooth manifold. Show that there exists a compact smooth manifold W with $\partial W = \mathrm{D}M$.

Exercise 75.11. Let M be a topological manifold, let X be a Rham co, let $A \subset X$ be closed and let $f\colon X \to M$ be a map with $f(A) \subset M \setminus \partial M$. Use the Topological Collar Neighborhood Theorem 75.5 to show that f is homotopic rel A to a map $g\colon X \to M \setminus \partial M$.
Remark. This exercise gives a new proof of the Push Away From Boundary Lemma 18.13. In particular one can use it to show again that if M is path-connected, then $M \setminus \partial M$ is also path-connected.
Remark. The exercise is the topological analogue of Exercise 28.2.

76. Homology and self-maps of spheres

By Proposition 74.4 we know that for any $n \in \mathbb{N}_0$ we have

$$\widetilde{\mathrm{H}}_k(S^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}$$

Thus we have determined the homology groups of all finite-dimensional spheres. In this chapter, given $n \in \mathbb{N}_0$, we will determine an explicit singular n-chain which is a generator of $\widetilde{\mathrm{H}}_n(S^n)$. Furthermore, given a map $f\colon S^n \to S^n$ we will get to know several techniques for determining the induced map $f_*\colon \widetilde{\mathrm{H}}_n(S^n) \to \widetilde{\mathrm{H}}_n(S^n)$. These results will allow us to prove various interesting results, e.g. the mysterious sounding Hair Ball Theorem. The results of this chapter will also be essential later on in Chapter 80 when we will introduce cellular homology.

76.1. **Explicit generators of relative homology groups.** We start out with the following elementary lemma that we will use explicitly and implicitly on many occasions.

Lemma 76.1. Let $n \in \mathbb{N}_0$. We have

$$\widetilde{\mathrm{H}}_k(\overline{B}^n, S^{n-1}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. We consider the long exact sequence in reduced homology of the pair $(\overline{B}^n, S^{n-1})$:

$$\ldots \to \underbrace{\widetilde{\mathrm{H}}_k(\overline{B}^n)}_{=0,\ \text{see page 1612}} \to \mathrm{H}_k(\overline{B}^n, S^{n-1}) \xrightarrow{\partial} \underbrace{\widetilde{\mathrm{H}}_{k-1}(S^{n-1})}_{\substack{\text{calculated in} \\ \text{Proposition 74.4}}} \to \underbrace{\widetilde{\mathrm{H}}_{k-1}(\overline{B}^n)}_{=0,\ \text{see page 1612}} \to \ldots$$

The statement of the lemma is now an immediate consequence of Proposition 74.4. ∎

We continue with the following lemma.

Lemma 76.2. Identity-is-Generator Lemma) For any $n \in \mathbb{N}_0$ the following two statements hold:

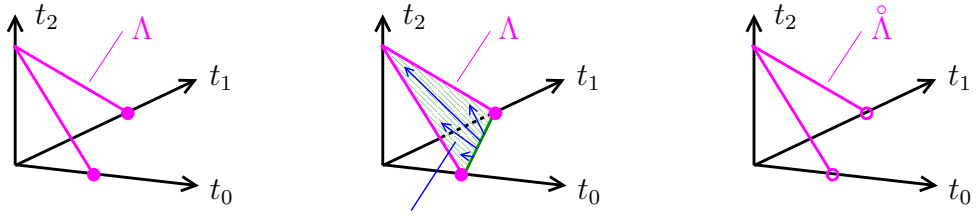
(1) $\mathrm{H}_n(\Delta^n, \partial\Delta^n) \cong \mathbb{Z}$.
(2) The identity map $\mathrm{id}\colon \Delta^n \to \Delta^n$ represents a generator of $\mathrm{H}_n(\Delta^n, \partial\Delta^n) \cong \mathbb{Z}$.

Proof. The first statement is an immediate consequence of Lemmas 76.1 and 72.1. Now we turn to the proof of the second statement. We prove the second statement by induction on n. It follows easily from the H_0-Proposition 72.5 that the statement holds for $n = 0$. Now we suppose that the desired statement holds for $n-1$ with $n \in \mathbb{N}$.

Our next goal is to find a connection between the two homology groups $\mathrm{H}_n(\Delta^n, \partial\Delta^n)$ and $\mathrm{H}_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1})$. We introduce the following notation.

(1) We consider

$$\Lambda \;:=\; \bigcup_{i=0}^{n-1} \{(t_0, \ldots, t_n) \in \Delta^n \,|\, t_i = 0\},$$



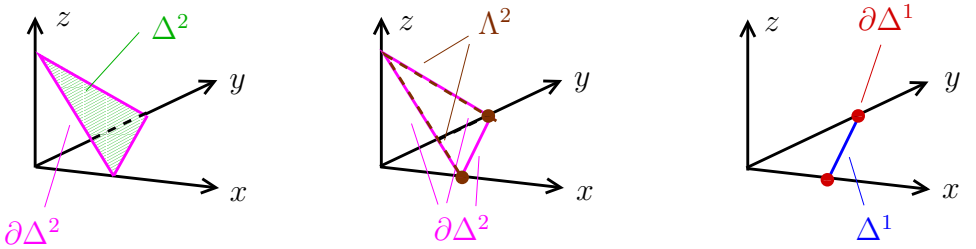
i.e. Λ is the union of all $(n-1)$-dimensional faces of Δ^n except for the face given by $t_n = 0$. A generalization of the argument of Exercise 15.13 (c) shows that Λ is a deformation retract of Δ^n. We refer to the figure below for an illustration.

(2) We write

$$\mathring{\Lambda} := \bigcup_{i=0}^{n-1} \{(t_0, \ldots, t_n) \in \Lambda \,|\, t_i = 0 \text{ and } t_n > 0\},$$

the set $\mathring{\Lambda}$ is thus the "interior" of Λ.

In the following we view $\mathbb{R}^n$ as the subset of $\mathbb{R}^{n+1}$ given by setting the last coordinate equal to zero. This point of view allows us to view Δ^{n-1} as a subset of Δ^n. Note that with this convention we have $\partial\Delta^{n-1} \subset \Lambda$.



deformation retraction from Δ^2 to Λ

Claim. We consider the maps

$$\mathrm{H}_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda) \xleftarrow{i_*} \mathrm{H}_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}).$$

Here the map on the left is the connecting homomorphism in the long exact sequence of the triple $(\Delta^n, \partial\Delta^n, \Lambda)$ and the right-hand map is induced by the inclusion. Then the following holds:

(1) Both maps are isomorphisms.
(2) $\partial([\mathrm{id}_{\Delta^n}]) = (-1)^n \cdot i_*([\mathrm{id}_{\Delta^{n-1}}])$.

It is clear that a proof of the claim together with the induction hypothesis implies that $[\mathrm{id}_{\Delta^n}]$ is a generator of $\mathrm{H}_n(\Delta^n, \partial\Delta^n)$. In particular a proof of the claim implies the Identity-is-Generator Lemma 76.2.

Proof. Of the two maps in the claim we first consider the map ∂ on the left. It follows from the exact sequence of the triple $(\Delta^n, \partial\Delta^n, \Lambda)$ that the following sequence is exact:

$$\underbrace{\mathrm{H}_n(\Delta^n, \Lambda)}_{\substack{= 0 \text{ by Corollary 74.16 since} \\ \Lambda \text{ is a deformation} \\ \text{retract of } \Delta^n}} \xrightarrow{p} \mathrm{H}_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda) \xrightarrow{i_*} \underbrace{\mathrm{H}_{n-1}(\Delta^n, \Lambda).}_{\substack{= 0 \text{ by Corollary 74.16 since} \\ \Lambda \text{ is a deformation} \\ \text{retract of } \Delta^n}}$$

This shows that $\mathrm{H}_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda)$ is an isomorphism. Furthermore we have

$$\underset{\text{Topological LES-Proposition 74.13}}{\partial([\mathrm{id}_{\Delta^n}])} \underset{\uparrow}{=} [\partial\,\mathrm{id}_{\Delta^n}] = \Big[\underbrace{\sum_{j=0}^{n-1}(-1)^j\,\mathrm{id}\circ i_j^n}_{\text{lies in } \mathrm{C}_{n-1}(\Lambda)} + (-1)^n\cdot\underbrace{\mathrm{id}\circ i_n^n}_{=\mathrm{id}_{\Delta^{n-1}}}\Big] \underset{\uparrow}{=} \underset{\text{since we work in } \mathrm{H}_{n-1}(\partial\Delta^n,\Lambda)}{(-1)^n\cdot[\mathrm{id}_{\Delta^{n-1}}]}.$$

Now we turn our attention to the right-hand map in the statement of the claim. It follows from Theorem 75.9, applied to $X = \partial\Delta^n$, $A = \Lambda$, $Z = \mathring{\Lambda}$ and $U = (0,\ldots,0,1)$[916] that the inclusion induced map

$$\mathrm{H}_{n-1}(\Delta^{n-1},\partial\Delta^{n-1}) = \mathrm{H}_{n-1}(\underbrace{\partial\Delta^n\setminus\mathring{\Lambda}}_{=\Delta^{n-1}},\underbrace{\Lambda\setminus\mathring{\Lambda}}_{=\partial\Delta^{n-1}}) \xrightarrow{i_*} \mathrm{H}_{n-1}(\partial\Delta^n,\Lambda)$$

is an isomorphism. Furthermore we evidently have $i_*([\mathrm{id}_{\Delta^{n-1}}]) = [\mathrm{id}_{\Delta^{n-1}}]$.

Thus we have proved that both maps in the claim are isomorphisms and that

$$\partial([\mathrm{id}_{\Delta^n}]) = (-1)^n\cdot[\mathrm{id}_{\Delta^{n-1}}] = (-1)^n\cdot i_*([\mathrm{id}_{\Delta^{n-1}}]).$$ ■

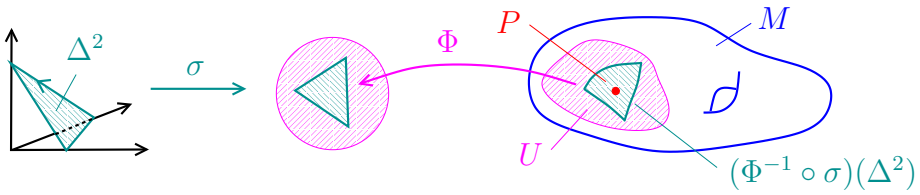
In the remainder of this section we explain how to find explicit generators of the local homology groups of a topological manifold. We recall the following lemma from the previous section.

Lemma 75.1. (Manifold-Local Homology Lemma) Let M be a k-dimensional topological manifold. Then for any $P \in M$, any $l \in \mathbb{N}_0$ and any open neighborhood U of P we have

$$\mathrm{H}_l(M, M\setminus\{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M\setminus\partial M \text{ and } l = k,\\ 0, & \text{otherwise.}\end{cases}$$

Examples. Our goal now is to give explicit generators for the relative homology groups $\mathrm{H}_k(M, M\setminus\{x\}) \cong \mathbb{Z}$. We first do so for open subsets of $\mathbb{R}^k$ and then we "transport" those generators to topological manifolds using charts.

(1) Let $U \subset \mathbb{R}^k$ be an open subset that contains 0. Let $\sigma\colon \Delta^k \to U$ be an injective affine linear map. We suppose that 0 lies in the image of the "interior" $\mathring{\Delta}^k := \Delta^k\setminus\partial\Delta^k$ of Δ^k. We claim that σ represents a generator of $\mathrm{H}_k(U, U\setminus\{0\})$. To prove this claim we consider the commutative diagram



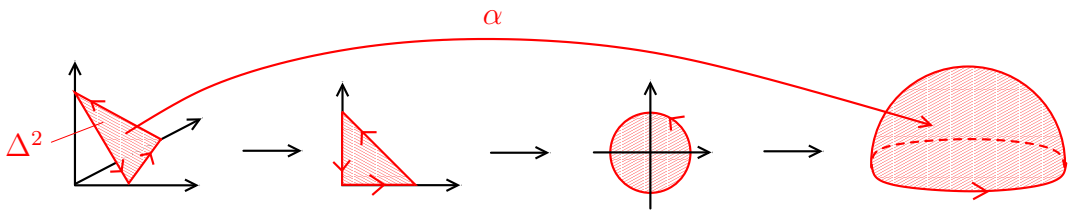
$$\begin{array}{ccccc} \mathrm{H}_k(\Delta^k,\partial\Delta^k) & & \xrightarrow{\quad\sigma_*\quad} & & \mathrm{H}_k(U, U\setminus\{0\}) \\ \downarrow{\scriptstyle\sigma_*} & & & & \downarrow{\scriptstyle\cong} \\ \mathrm{H}_k(\sigma(\Delta^k),\sigma(\partial\Delta^k)) & \longrightarrow & \mathrm{H}_k(\mathbb{R}^k,\sigma(\partial\Delta^k)) & \longrightarrow & \mathrm{H}_k(\mathbb{R}^k,\mathbb{R}^k\setminus\{0\}) \end{array}$$

where the maps that are not induced by σ are induced by the obvious inclusions. The left vertical map is an isomorphism since we know by the Compact-Hausdorff Proposition 2.17 (3) that $\sigma\colon \Delta^k \to \sigma(\Delta^k)$ is a homeomorphism. The bottom horizontal maps are isomorphisms by Corollary 74.16 since one can easily show that $\sigma(\Delta^k)$ is a deformation retract of $\mathbb{R}^k$ and similarly one can show that $\sigma(\partial\Delta^k)$ is deformation retract of $\mathbb{R}^k\setminus\{0\}$. By the Identity-is-Generator Lemma 76.2 we know that id_{Δ^n} represents a generator of $\mathrm{H}_n(\Delta^n,\partial\Delta^n)$. It follows from the above that $\sigma\circ\mathrm{id}_{\Delta^n} = \sigma$ represents a generator of $\mathrm{H}_k(\mathbb{R}^k,\mathbb{R}^k\setminus\{0\})$. But the right vertical map is

[916] One can easily show that U has the property required in Theorem 75.9.

an isomorphism by the Excision Theorem 74.18, hence σ also represents a generator of $\mathrm{H}_k(U, U \setminus \{0\})$.

(2) Let M be a k-dimensional topological manifold and let $P \in M \setminus \partial M$. In the following we want to give an example of an explicit singular k-simplex that represents a generator for $\mathrm{H}_k(M, M \setminus \{P\}) \cong \mathbb{Z}$. We pick a chart $\Phi\colon U \to B^k$ around P with $\Phi(P) = 0$ and we pick an affine linear map $\sigma\colon \Delta^k \to B^k$ as in (1). It follows from (1) together with the proof of the Manifold-Local Homology Lemma 75.1 that $\Phi^{-1} \circ \sigma\colon \Delta^k \to M$ represents a generator of $\mathrm{H}_k(M, M \setminus \{P\})$. We refer to the figure below for an illustration.



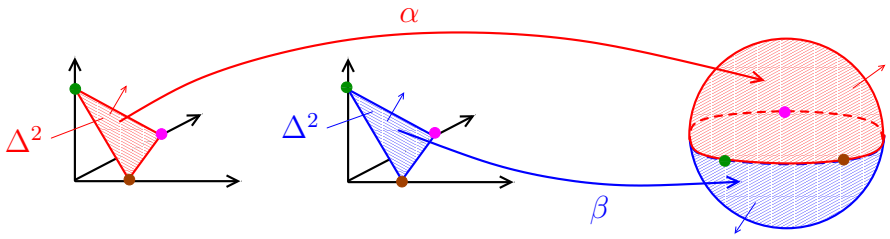
76.2. **The standard generator of $\mathrm{H}_n(S^n)$.** In this section we want to find explicit generators of $\mathrm{H}_n(S^n) \cong \mathbb{Z}$ for $n \geq 1$.

Notation. We consider the map $\alpha\colon \Delta^n \to S^n$ that is given by the concatenation of the following two maps

$$\Delta^n \xrightarrow[\text{by the Standard Simplex Homeomorphism Lemma 72.1}]{\text{homeomorphism given}} \overline{B}^n \subset S^n \subset \mathbb{R}^{n+1} = \mathbb{R}^n \times \mathbb{R}$$
$$x \mapsto \big(x, \sqrt{1 - \|x\|^2}\big).$$

We refer to the figure below for an illustration of the definition of the map α.

It follows easily from the definitions and the Compact-Hausdorff Proposition 2.17 (3) that this map α defines a homeomorphism $\Delta^n \to S^n_{\geq 0} = \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \geq 0\}$ and that it restricts to a homeomorphism $\partial\Delta^n$ to $S^{n-1} = \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} = 0\}$.



Notation. We denote by $\beta\colon \Delta^n \to S^n$ the map which is the composition of α with reflection in the hyperplane defined by $x_{n+1} = 0$. The maps $\alpha\colon \Delta^n \to S^n$ and $\beta\colon \Delta^n \to S^n$ both define singular n-chains in S^n. Note that α and β agree on $\partial\Delta^n$. Both maps are sketched in the figure below.

Lemma 76.3. Let $n \geq 1$. The above singular n-chain $\alpha - \beta \in \mathrm{C}_n(S^n)$ is a cycle and it represents a generator of $\widetilde{\mathrm{H}}_n(S^n) = \mathrm{H}_n(S^n)$.

Definition.

(1) Let $n \geq 1$. We refer to the generator from Lemma 76.3 as the standard generator of $\mathrm{H}_n(S^n)$.[917] With great foresight we denote it by $[S^n]$.

(2) We define $[c_1 - c_{-1}] \in \widetilde{\mathrm{H}}_0(S^0)$ to be the standard generator of $\widetilde{\mathrm{H}}_0(S^0)$.

Proof. We start out with the following claim.

Claim. The singular n-chain $\alpha - \beta$ is a cycle.

Proof. We denote by ρ the reflection in the hyperplane defined by $x_{n+1} = 0$. We have

$$\partial(\alpha - \beta) \;=\; \partial(\alpha - \rho_*(\alpha)) \;\underset{\text{since } \rho_* \text{ is a chain map}}{=}\; (\mathrm{id} - \rho_*)(\underset{\text{since } \alpha(\partial\Delta^n) \subset \mathbb{R}^n \times 0 \text{ we have } \partial\alpha \in \mathrm{C}_{n-1}(\mathbb{R}^n \times 0)}{\partial\alpha}) \;\underset{\text{since } \rho = \mathrm{id} \text{ on } \mathbb{R}^n \times 0 \subset \mathbb{R}^{n+1}}{=}\; 0.$$

⊞

As usual we denote by

$$\begin{aligned} S^n_{\geq 0} &:= \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \geq 0\} \\ S^n_{\leq 0} &:= \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \leq 0\} \end{aligned}$$

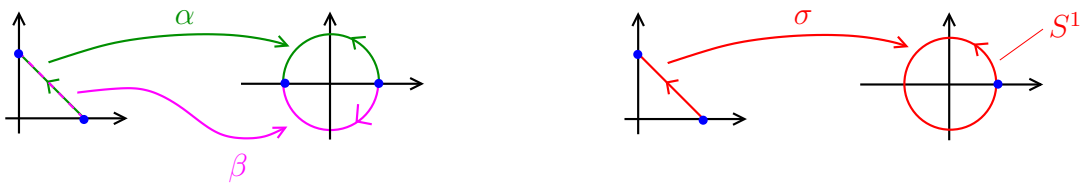
the two "hemispheres". By the discussion on page 152 both hemispheres are homeomorphic to the closed ball $\overline{B}^n$, in particular they are contractible which implies by the discussion on page 1612 that their reduced homology groups vanish. We also consider the "equator"

$$S^n_{=0} \;:=\; \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} = 0\}.$$

Next we consider the following sequence of maps

$$\begin{array}{ccccccc} \underset{\text{isomorphism by the long exact sequence in reduced homology of the pair } (S^n, S^n_{\leq 0})}{\downarrow} & & \underset{\text{isomorphism by example on on page 1665}}{\downarrow} & & \underset{\text{isomorphism since } \alpha \text{ is a homeomorphism}}{\downarrow} & & \\ \widetilde{\mathrm{H}}_n(S^n) & \to & \mathrm{H}_n(S^n, S^n_{\leq 0}) & \xleftarrow{i_*} & \mathrm{H}_n(S^n_{\geq 0}, S^n_{=0}) & \xleftarrow{\alpha_*} & \mathrm{H}_n(\Delta^n, \partial\Delta^n) \\ [\alpha - \beta] & \mapsto & [\alpha - \beta] = [\alpha] & \mapsto & [\alpha] & \mapsto & [\mathrm{id}_{\Delta^n}]. \\ & & \underset{\text{since } \beta = 0 \text{ in } \mathrm{C}_n(S^n, S^n_{\leq 0})}{\uparrow} & & & & \end{array}$$

So we have shown that all maps are isomorphisms. Furthermore, by the Identity-is-Generator Lemma 76.2 we know that $[\mathrm{id}_{\Delta^n}]$ is a generator of $\mathrm{H}_n(\Delta^n, \partial\Delta^n)$. But $[\mathrm{id}_{\Delta^n}]$ and $[\alpha - \beta]$ get sent to the same element in $\mathrm{H}_n(S^n, S^n_{\leq 0})$, therefore $[\alpha - \beta]$ must also be generator of $\widetilde{\mathrm{H}}_n(S^n)$. ■



In the following lemma we give an alternative description of the standard generator of the homology group $\mathrm{H}_1(S^1)$.

[917] It follows easily from Lemma 72.3 and the definitions that the two definitions of standard generator of $\mathrm{H}_1(S^1)$ agree.

Lemma 76.4. The singular 1-simplex

$$\begin{array}{rcl} \sigma\colon \Delta^1 & \to & S^1 \\ (1-t,t) & \mapsto & \exp(2\pi\,\mathrm{i}t) \end{array}$$

is a cycle that represents the standard generator $[S^1]$ of $\mathrm{H}_1(S^1) \cong \mathbb{Z}$.

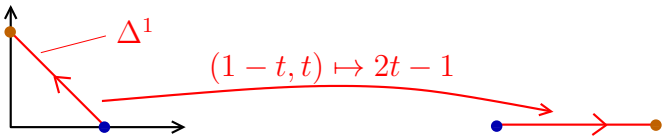
Proof. We denote by $\alpha, \beta\colon \Delta^1 \to S^1$ the singular 1-simplices in the definition of the standard generator of $\mathrm{H}_1(S^1)$. We have

$$[\alpha - \beta] \underset{\uparrow}{=} [\alpha + \overline{\beta}] \underset{\uparrow}{=} [\sigma] \in \mathrm{H}_1(S^1).$$

by Lemma 72.3 (2) and (3)

We refer to the figure below for an illustration. ∎

Remark. By Lemma 76.4 we know that there exists a singular 1-simplex σ that represents a generator of $\mathrm{H}_1(S^1)$. In Exercise 76.3 we will discuss the question, for which $n \in \mathbb{N}$ does there exist a singular n-simplex $\sigma\colon \Delta^n \to S^n$ that represents a generator of $\mathrm{H}_n(S^n)$.



We conclude this section with a short discussion of several related homology groups and their "standard generators".

Definition. Let $n \in \mathbb{N}$. The standard generator of $\mathrm{H}_n(\overline{B}^n, S^{n-1})$ is defined to be the unique element that gets sent to the standard generator of $\widetilde{\mathrm{H}}_{n-1}(S^{n-1})$ under the connecting homomorphism $\mathrm{H}_n(\overline{B}^n, S^{n-1}) \to \widetilde{\mathrm{H}}_{n-1}(S^{n-1})$ of the long exact sequence in reduced homology of the pair $(\overline{B}^n, S^{n-1})$. We denote the standard generator by $[\overline{B}^n]$.

Example. Recall that the standard generator of $\widetilde{\mathrm{H}}_0(S^0)$ is defined as $[c_1 - c_{-1}] \in \widetilde{\mathrm{H}}_0(S^0)$. It follows easily from the explicit description of the connecting homomorphism, see the Topological LES-Proposition 74.13, and the explicit description of the boundary of a singular 1-simplex, see page 1585, that the standard generator of $\mathrm{H}_1(\overline{B}^1, S^0)$ is represented by the cycle

$$\begin{array}{rcl} \Delta^1 & \to & \overline{B}^1 \\ (1-t,t) & \mapsto & 2t-1. \end{array}$$

We refer to the figure below for an illustration.

We have now introduced several standard generators of homology groups. The following proposition shows the relationship between these standard generators under various maps. The proposition, let alone the proof, are not much fun to read, but it is an absolutely essential proposition since it settles several rather subtle signs.

Proposition 76.5. (Standard Generator-Relationship Proposition) Let $n \in \mathbb{N}$. We denote by $f\colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ the homeomorphism from the Standard Simplex Homeomorphism Lemma 72.1 and we denote by $g\colon \overline{B}^n/S^{n-1} \to S^n$ the homeomorphism from the Ball-Quotient Sphere Lemma 5.20. We set $* := g([S^{n-1}])$.[918] We consider the following diagram:

$$\begin{array}{ccccccccc}
 & & & & \widetilde{\mathrm{H}}_n(\overline{B}^n/S^{n-1}) & \xrightarrow{g_*} & \widetilde{\mathrm{H}}_n(S^n) & & \\
 & & & \overset{\text{ю}}{\nearrow} & \text{ж}\downarrow\cong & & \cong\downarrow\text{ж} & & \\
\mathrm{H}_n(\Delta^n, \partial\Delta^n) & \xrightarrow{f_*} & \mathrm{H}_n(\overline{B}^n, S^{n-1}) & \longrightarrow & \mathrm{H}_n(\overline{B}^n/S^{n-1}, [S^{n-1}]) & \xrightarrow{g_*} & \mathrm{H}_n(S^n, *) & \longleftarrow & \mathrm{H}_n(S^n). \\
\partial\downarrow & & \downarrow\partial & & & & & & \\
\widetilde{\mathrm{H}}_{n-1}(\partial\Delta^{n-1}) & \xrightarrow{f_*} & \widetilde{\mathrm{H}}_{n-1}(S^{n-1}) & & & & & &
\end{array}$$

The following statements hold:

(1) The diagram commutes and the top vertical maps are isomorphisms.

(2) We have
$$f_*([\mathrm{id}_{\Delta^n}]) \;=\; (-1)^n \cdot \text{standard generator } [\overline{B}^n] \text{ of } \mathrm{H}_n(\overline{B}^n, S^{n-1}).$$

(3) The standard generator $[\overline{B}^n]$ of $\mathrm{H}_n(\overline{B}^n, S^{n-1})$ has the same image in $\mathrm{H}_n(S^n, *)$ as the standard generator $[S^n]$ of $\mathrm{H}_n(S^n)$.

(4) The image of the standard generator $[\overline{B}^n] \in \mathrm{H}_n(\overline{B}^n, S^{n-1})$ in $\mathrm{H}_{n-1}(S^{n-1})$ equals the standard generator $[S^{n-1}]$ of $\mathrm{H}_{n-1}(S^{n-1})$.

(5) We have
$$f_*(\partial[\mathrm{id}_{\Delta^n}]) \;=\; (-1)^n \cdot \text{standard generator } [S^{n-1}] \text{ of } \mathrm{H}_{n-1}(S^{n-1}).$$

Proof of the Standard Generator-Relationship Proposition 76.5.

(1) The triangle commutes by definition of ю, see page 1633. Furthermore it follows from Lemma 74.12 and the Topological LES-Corollary 74.14 that the two squares commute.

(3),(4) The calculation of these two signs is delicate and tricky. It becomes somewhat easier after we have developed a few more tools. Thus we postpone the proof of these two statements to Section 76.7.

(4) This statement is just a repetition of the definition of the standard generator $[\overline{B}^n]$.

(5) This statement is an immediate consequence of (1), (2) and (4). ■

We conclude this section with the following lemma which gives us another slightly subtle sign calculation.

Lemma 76.6. Let $n \in \mathbb{N}$. We consider the following sequence of maps

$$\mathrm{H}_n(S^n) \xrightarrow{\text{я}} \mathrm{H}_n(S^n, S^n_{\geq 0}) \xleftarrow[\uparrow]{\cong} \mathrm{H}_n(S^n_{\geq 0}, S^{n-1}) \xrightarrow{\partial} \widetilde{\mathrm{H}}_{n-1}(S^{n-1}).$$

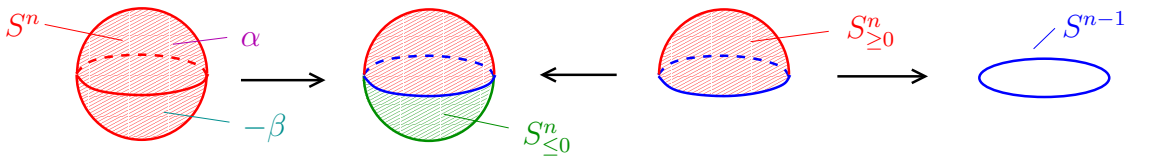
inclusion induced map is an isomorphism by the discussion on page 1665

The image of the standard generator $[S^n] \in \mathrm{H}_n(S^n)$ under this map is $(-1)^n \cdot [S^{n-1}]$.

[918] The fact that we use the expression $[S^{n-1}]$ for two very different objects, namely first for the point in $\overline{B}^n/S^{n-1}$ given by the equivalence class S^{n-1} and secondly for the standard generator of $\widetilde{\mathrm{H}}_{n-1}(S^{n-1})$ is unfortunate, but difficult to avoid if one wants to follow the standard conventions.

Proof. We recall and introduce the following notation:

(1) Let $f\colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ be the homeomorphism from the Standard Simplex Homeomorphism Lemma 72.1.
(2) Let $p_+\colon S^n_{\geq 0} \to \overline{B}^n$ be the natural projection and let $q_+\colon \overline{B}^n \to S^n_{\geq 0}$ be the map given by $x \mapsto (x, \sqrt{1 - \|x\|^2})$. Evidently p and q are inverses of one another. We define $p_-\colon S^n_{\leq 0} \to \overline{B}^n$ and $q_-\colon \overline{B}^n \to S^n_{\leq 0}$ in an analogous fashion.
(3) Note that $\alpha := q_+ \circ f\colon \Delta^n \to S^n$ and $\beta := q_- \circ f\colon \Delta^n$ are the singular n-simplices that we introduced on page 1677.



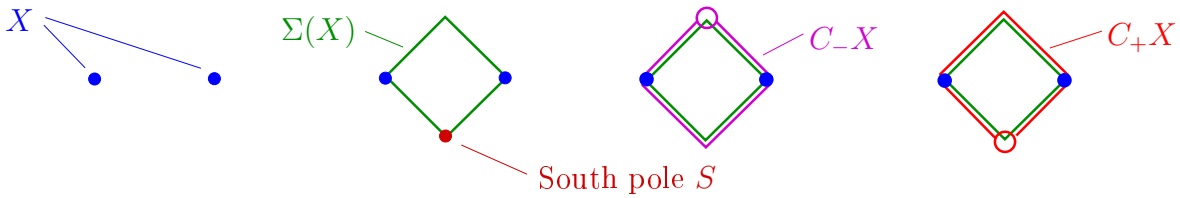
Next we consider the following diagram

$$\begin{array}{ccccccc} \mathrm{H}_n(S^n) & \xrightarrow{\text{я}} & \mathrm{H}_n(S^n, S^n_{\geq 0}) & \xleftarrow{i} & \mathrm{H}_n(S^n_{\geq 0}, S^{n-1}) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(S^{n-1}). \\ & & & & \uparrow{\scriptstyle q_+} \downarrow{\scriptstyle p_+} & \nearrow{\scriptstyle \partial} & \\ & & & & \mathrm{H}_n(\overline{B}^n, S^{n-1}) & & \end{array}$$

Note that the triangle to the right commutes by the naturality of the connecting homomorphism, see the Topological LES-Corollary 74.14. Now we see that

$$\begin{array}{ccccccc} & \text{definition of } [S^n] & & \text{definition of я} & & \text{since } \beta = 0 \in \mathrm{C}_n(S^n, S^n_{\leq 0}) & \\ \partial(i_*^{-1}(\text{я}([S^n]))) & \downarrow & & \downarrow & & \downarrow & \\ & = \partial(i_*^{-1}(\text{я}([\alpha - \beta]))) & = \partial(i_*^{-1}([\alpha - \beta])) & = \partial(i_*^{-1}([\alpha])) & = \partial([\alpha]) & & \\ & = \partial(q_{+*}([p_+ \circ \alpha])) & = \partial(q_{+*}([f])) & = \partial([f]) & = (-1)^n \cdot [S^{n-1}]. & & \\ & \uparrow & \uparrow & \uparrow & \uparrow & & \\ & \text{since } p_+ = q_+^{-1} & \text{since } \alpha = q_+ \circ f & \text{since the triangle commutes} & \text{Proposition 76.5 (5)} & & \end{array}$$

■



76.3. **Suspensions and homology groups.** In the next section we will study self-maps of spheres. In that section it will be useful to consider the effect of taking suspensions on homology. Since this is going to be interesting for larger classes of topological spaces we dedicate this short section to the study of homology groups of suspensions of topological spaces.

The following definition follows the definition on page 451 and the convention given by the Cone-Suspension Basics Lemma 16.8 (3).

Definition. Let X be a non-empty topological space.

(1) We define the suspension of X to be the topological space
$$\Sigma(X) \;:=\; (X \times [-1, 1])/\!\sim$$
where we identify all points in $X \times \{-1\}$ to a single point and we identify all points in $X \times \{1\}$ to a single point.
(2) We denote by $p\colon X \times [-1, 1] \to \Sigma(X)$ the natural projection. We write
$$C_-X \;:=\; p(X \times [-1, 1)) \quad \text{and} \quad C_+X \;:=\; p(X \times (-1, 1]).$$

By the Cone-Suspension Basics Lemma 16.8 (3) we know that the map $X \xrightarrow{x \mapsto p(x,0)} \Sigma(X)$ is a closed embedding. We use this embedding to view X as a subspace of $\mathrm{C}_{\pm}X$ and of $\Sigma(X)$.

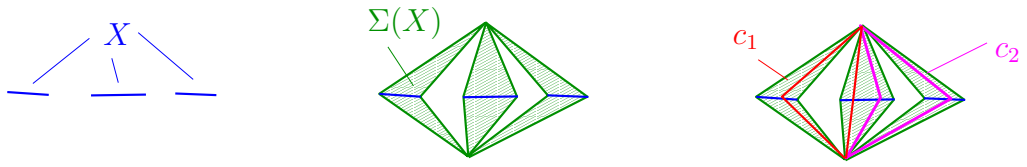
In the Suspension-π_1-Lemma 54.2 and Exercise 57.5 we calculated the fundamental group of the suspension of a non-empty topological space with finitely many path components. The following proposition, which is the main result of this section, determines the homology groups of a suspension.

Proposition 76.7. (Suspension-H_*-Proposition) Let X be a non-empty topological space and let $n \in \mathbb{Z}$.[919]

(1) The following maps are isomorphisms:

$$\widetilde{\mathrm{H}}_n(X) \xleftarrow{\partial} \mathrm{H}_{n+1}(C_+X, X) \xrightarrow{} \mathrm{H}_{n+1}(\Sigma(X), C_-X) \xleftarrow{\text{ж}} \widetilde{\mathrm{H}}_{n+1}(\Sigma(X)).$$

connecting homomorphism of the pair (C_+X, X) from the Topological LES-Corollary 74.14 — inclusion induced — natural map given by the Reduced Homology Lemma



(2) The resulting isomorphism

$$\Sigma_X \colon \widetilde{\mathrm{H}}_n(X) \xrightarrow{\cong} \widetilde{\mathrm{H}}_{n+1}(\Sigma(X))$$

is natural. In other words, given any map $f \colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_n(X) & \xrightarrow{\Sigma_X} & \widetilde{\mathrm{H}}_{n+1}(\Sigma(X)) \\ {\scriptstyle f_*}\downarrow & & \downarrow{\scriptstyle \Sigma(f)_*} \\ \widetilde{\mathrm{H}}_n(Y) & \xrightarrow{\Sigma_Y} & \widetilde{\mathrm{H}}_{n+1}(\Sigma(Y)). \end{array}$$

Example. Let $n \in \mathbb{N}$ and let X be the disjoint union of n intervals. It follows from the Suspension-H_*-Proposition 76.7 together with the Reduced Homology Lemma 74.1 that $\mathrm{H}_1(\Sigma(X)) \cong \mathbb{Z}^{n-1}$. In the figure below we show a generating set for $\mathrm{H}_1(\Sigma(X))$ for $n = 3$. We leave it to the reader to deduce from the proof of the Suspension-H_*-Proposition 76.7 that the given cycles do indeed form a generating set for $\mathrm{H}_1(\Sigma(X))$.

[919] Note that the proposition has non-trivial content for $n = -1$.

Proof. Let $n \in \mathbb{Z}$.

(1) (a) By the same argument as in the proof of the Cone Contractibility Lemma 16.7 we see that both C_-X and C_+X admit a deformation retraction to a point. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 that both are contractible, therefore by the Reduced Homology Lemma 74.1 (7) the reduced homologies of C_-X and C_+X vanish. Note that it follows in particular that the connecting homomorphism $\partial\colon \mathrm{H}_{n+1}(C_+X, X) \to \widetilde{\mathrm{H}}_n(X)$ is an isomorphism.

(b) We denote by $S := [X \times \{-1\}] \in \Sigma(X)$ the South Pole of the suspension. Note that $\Sigma(X) \setminus S = C_+X$ and $C_-X \setminus S = C_-X \cap C_+X$. Using this observation we obtain from the Excision Theorem 74.17[920] that the second horizontal map is an isomorphism.

(c) Similar to (a) we obtain from the Topological LES-Corollary 74.14 that the third horizontal map is an isomorphism.

(2) First note that the connecting homomorphism is natural by the Topological LES-Proposition 74.13 (2) and the fact that $\Sigma(f)|_X = f$. It is clear that the second horizontal map is natural. Finally it follows from the Reduced Homology Lemma 74.1 (3) that the map ж is natural. The combination of these observations shows that Σ_X itself is natural. ■

Example. Let $n \in \mathbb{N}$. Let $\Sigma(S^n) \to S^{n+1}$ be the homeomorphism from page 452. It follows quite easily from the definition of the suspension isomorphism $\Sigma_{S^n}\colon \mathrm{H}_n(S^n) \to \mathrm{H}_{n+1}(S^{n+1})$ and Lemma 76.6 that

$$\Sigma_{S^n}([S^n]) \;=\; (-1)^{n+1} \cdot [S^{n+1}] \qquad \in \mathrm{H}_{n+1}(S^{n+1}).$$

We conclude this section with the following corollary.

Corollary 76.8. Let X be a topological space that is compact and Hausdorff. Furthermore let $k \in \mathbb{N}_{\geq -1}$. For every $n \in \mathbb{Z}$ there exists a natural isomorphism

$$\widetilde{\mathrm{H}}_n(X) \;\xrightarrow{\cong}\; \widetilde{\mathrm{H}}_{n+k+1}(S^k * X).$$

($S^k * X$: join of S^k and X, see page 446 for the definition)

Here, recall that if X is the empty topological space, then by the Reduced Homology Lemma 74.1 (0) we have $\widetilde{\mathrm{H}}_{-1}(\varnothing) = \mathbb{Z}$.

Proof. First note that the case $X = \varnothing$ follows from the fact that, by definition, $S^k * \varnothing = S^k$, and the calculation of the reduced homology groups of S^k that we gave in Proposition 74.4.

Now assume that $X \neq \varnothing$. If $k = -1$, then we have, again by definition, the equality $S^{-1} * X = \varnothing * X = X$ which implies the desired statement. Thus it remains to deal with case that $k \geq 0$. To simplify the notation we only consider the case $k = 1$. In this case we have

$$\widetilde{\mathrm{H}}_{n+2}(S^1 * X) \overset{\text{Join of Spheres Lemma 16.4}}{\cong} \widetilde{\mathrm{H}}_{n+2}((S^0 * S^0) * X) \underset{\substack{\text{by the Join Associativity Proposition 16.6}\\ \text{see page 448 for the definition}\\ \text{of the homeomorphism}}}{\cong} \widetilde{\mathrm{H}}_{n+2}(S^0 * (S^0 * X)) \overset{\text{Exercise 16.5}}{\cong} \widetilde{\mathrm{H}}_{n+2}(\Sigma(\Sigma(X))) \underset{\substack{\text{Suspension-H}_*\text{-Proposition 76.7}\\ \text{applied twice}}}{\cong} \widetilde{\mathrm{H}}_n(X).$$

[920] One can easily verify that the hypotheses for the Excision Theorem 74.17 are satisfied.

It follows easily from the definitions of the maps that the isomorphism is in fact natural. ■

76.4. **The degree of a self-map of a sphere.** Now that we know the homology groups of spheres, we want to study the maps on homology induced by maps $f\colon S^n \to S^n$. This is interesting in its own right, but it will also play a major role later on in Chapter 80 when we will try to determine the homology groups of CW-complexes.
Throughout the remaining sections of this chapter we will work a lot with the following simple-minded definition.

Definition. Let $(G,+)$ be a group that is isomorphic to $\mathbb{Z}$. Furthermore let $\Phi\colon G \to G$ be a homomorphism. Note that Φ is given by multiplication by a unique integer which we refer to as the degree $\deg(\Phi)$.

For completeness' sake we record two basically obvious statements regarding the degree.

Lemma 76.9. Let $(G,+)$ be a group that is isomorphic to $\mathbb{Z}$.
(1) Let $g \in G$ be any non-trivial element. Furthermore let $\Phi\colon G \to G$ be a homomorphism. The degree $\deg(\Phi)$ is uniquely determined by the equality $\Phi(g) = \deg(\Phi)\cdot g$.
(2) Let $\varphi\colon G \to H$ be an isomorphism and let $f\colon H \to H$ be a homomorphism. Then $\deg(\varphi^{-1}\circ f\circ\varphi\colon G\to G) = \deg(f\colon H\to H)$.

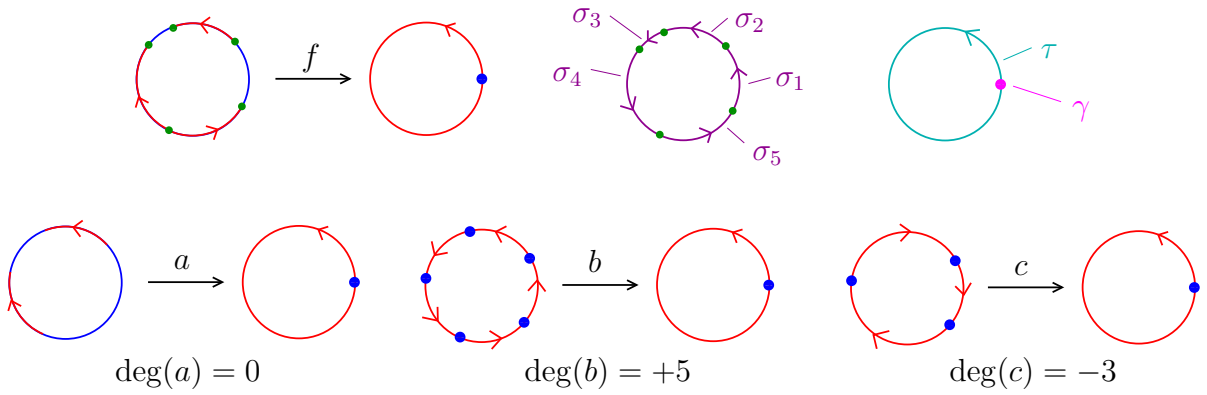
Next we relate the above definition to topology.

Definition. Let $n \in \mathbb{N}_0$ and let $f\colon S^n \to S^n$ be map. Since $\widetilde{\mathrm{H}}_n(S^n)$ is isomorphic to $\mathbb{Z}$ we can define the degree of f as

$$\deg(f) \;:=\; \deg\big(f_*\colon \widetilde{\mathrm{H}}_n(S^n) \to \widetilde{\mathrm{H}}_n(S^n)\big).$$

Remark. Let $n \in \mathbb{N}$. On page 899 we introduced in particular the degree of a *smooth* map $f\colon S^n \to S^n$. On page 1697 we will see that in the setting of a smooth map $f\colon S^n \to S^n$ the two definitions of the degree agree.

Example. We consider the map $f\colon S^1 \to S^1$ that is illustrated in the figure below on the left.[921] We denote by $\tau\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $\tau(1-t,t) = \exp(2\pi i t)$. By Lemma 76.4 we know that $[\tau] \in \mathrm{H}_1(S^1)$ is a generator.



We pick singular 1-simplices $\sigma_1,\dots,\sigma_5$ as in the middle of the figure below and we denote by $\gamma\colon \Delta^1 \to S^1$ the constant singular 1-simplex that sends all points to 1. Then

$$\begin{aligned} f_*([\tau]) \overset{\text{by Lemma 72.3 (3)}}{=} f_*([\sigma_1+\cdots+\sigma_5]) &= [\overbrace{\sigma_1\circ f}^{=\gamma} + \overbrace{\sigma_2\circ f}^{=\tau} + \overbrace{\sigma_3\circ f}^{=\gamma} + \overbrace{\sigma_4\circ f}^{=\overline{\tau}} + \overbrace{\sigma_5\circ f}^{=\tau}] \\ &= [2\cdot\tau + \overline{\tau} + 2\cdot\gamma] \overset{\text{Lemma 72.3 (2)}}{=} [\tau] = \underbrace{(+1)}_{=:\deg(f)}\cdot[\tau]. \end{aligned}$$

Summarizing we have shown that $\deg(f) = +1$. With almost the same approach we can calculate the degrees of the maps that are illustrated in the figure below.

Almost the same arguments that we used in the discussion of the above example gives us the following lemma.

[921] More precisely, given an "interval" on S^1 going from $\exp(i\alpha)$ to $\exp(i\beta)$ we mean the singular 1-simplex that is given by $(1-t,t) \mapsto \exp(i(\alpha\cdot(1-t)+\beta\cdot t))$.

Lemma 76.10. For any $k \in \mathbb{Z}$ the degree of the map

$$\begin{array}{ccc} S^1 & \to & S^1 \\ z & \mapsto & z^k \end{array}$$

equals k.

Proof. We denote by $\tau\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $\tau(1-t,t) = \exp(2\pi i t)$. By Lemma 76.4 we know that $[\tau] \in \mathrm{H}_1(S^1)$ is a generator.

Now we first consider the case $k \geq 1$. For $j = 0, \ldots, k-1$ we denote by $\sigma_j\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $(1-t,t) \mapsto \exp(2\pi \mathrm{i}(\frac{t+j}{k}))$. Then

$$f_*([\tau]) \underset{\substack{\uparrow \\ \text{by Lemma 72.3 (3)}}}{=} f_*([\sigma_0 + \cdots + \sigma_{k-1}]) = [\underbrace{f \circ \sigma_0}_{=\tau} + \cdots + \underbrace{f \circ \sigma_{k-1}}_{=\tau}] = k \cdot [\tau].$$

The case $k < 0$ is proved is proved in a similar fashion using Lemma 72.3 (2). Finally the case $k = 0$ follows from the fact that the map $S^1 \to S^1$, $z \mapsto 1$ is constant, hence, as discussed on page 1595, the induced map on first homology is the zero map. ■

Before we move on to the next lemma it is convenient to introduce the following notation.

Notation. As on page 419, given a matrix $A \in \mathrm{O}(n+1)$ we denote by $\rho(A)\colon S^n \to S^n$ the map given by $x \mapsto A \cdot x$.

The following lemma summarizes several important properties of the degree of the self-map of a sphere.

Lemma 76.11. (Sphere Degree Lemma) Let $f, g\colon S^n \to S^n$ be two maps. Then the following hold:

(1) $\deg(\mathrm{id}_{S^n}) = 1$.
(2) If f is not surjective, then $\deg(f) = 0$.
(3) If f is homotopic to g, then $\deg(f) = \deg(g)$. (In the Degree Isomorphism Proposition 86.8 we will see that the converse to this statement holds.)
(4) $\deg(f \circ g) = \deg(f) \cdot \deg(g)$.
(5) If f is a self-homeomorphism of S^n, then $\deg(f^{-1}) = \deg(f)$.
(6) Given any $A \in \mathrm{O}(n)$ we have $\deg(\rho(A)) = \det(A) \in \{-1, 1\}$.

Examples.

(1) If $f\colon S^n \to S^n$ is the reflection in a hyperplane, then it follows from the Sphere Degree Lemma 76.11 (6) that $\deg(f) = -1$,
(2) If $f\colon S^n \to S^n$ is the reflection in the origin i.e. if $f(x) = -x$ for all $x \in S^n$, then it follows from the Sphere Degree Lemma 76.11 (6) we have $\deg(f) = (-1)^{n+1}$.
(3) Let $A \in \mathrm{O}(n+1)$. Let $f\colon S^n \to S^n$ be the map that is given by $f(P) = A \cdot P$. If $\det(A) = 1$, then we saw on page 419 that f is actually homotopic to the identity. On the other hand, if $\det(A) = -1$, then it now follows from the Sphere Degree Lemma 76.11 (1), (3) together with the Sphere Degree Lemma 76.11 (6) that f is not homotopic to the identity.

Proof.

(1) Since $(\mathrm{id}_{S^n})_* = \mathrm{id}_{\mathrm{H}_n(S^n)}$ we know that $\deg(\mathrm{id}_{S^n}) = 1$.
(2) Suppose that the map $f\colon S^n \to S^n$ misses the point $P \in S^n$. We consider the commutative diagram

$$\begin{array}{ccc} & S^n\backslash\{P\} & \\ {\scriptstyle f}\nearrow & & \searrow{\scriptstyle i} \\ S^n & \xrightarrow[f]{} & S^n \end{array} \qquad \text{which gives rise to the commutative diagram} \qquad \begin{array}{ccc} & \mathrm{H}_n(S^n\backslash\{P\}) & \\ {\scriptstyle f_*}\nearrow & & \searrow{\scriptstyle i_*} \\ \mathrm{H}_n(S^n) & \xrightarrow[f_*]{} & \mathrm{H}_n(S^n). \end{array}$$

By the Orthogonal Action Lemma 5.26 (6) we know $S^n\backslash\{P\}$ is homeomorphic to $\mathbb{R}^n$. Thus we see that $S^n\backslash\{P\}$ is contractible which implies by the Homotopy Equivalence-H_*-Corollary 73.9 that $\mathrm{H}_n(S^n\backslash\{P\}) = 0$. But this means that $f_*\colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n)$ factors through the zero group, i.e. f_* is the zero map.
(3) If f is homotopic to g, then it follows from the Homotopic Maps-and-Homology Proposition 73.6 that $\deg(f) = \deg(g)$.
(4) We consider the following diagram

$$\mathrm{H}_n(S^n) \xrightarrow[\cdot\deg(f)]{f_*} \mathrm{H}_n(S^n) \xrightarrow[\cdot\deg(g)]{g_*} \mathrm{H}_n(S^n). \qquad \text{(curved arrow: } (f\circ g)_*\text{)}$$

This diagram commutes since $(f \circ g)_* = f_* \circ g_*$. It follows that the curved map is given by multiplication by $\deg(f) \cdot \deg(g)$, i.e. $\deg(f \circ g) = \deg(f) \cdot \deg(g)$.
(5) This statement follows immediately from (1) and (4).
(6) We start out with the following claim.

Claim. Let $\mu\colon S^n \to S^n$ be the reflection in the $(x_{n+1} = 0)$-hyperplane. Then we have $\deg(\mu) = -1$.

Proof. We consider again the singular chain

$$\begin{array}{rcccccc} \alpha\colon \Delta^n & \overset{\cong}{\to} & \left\{(x_1,\dots,x_n) \in [0,1]^n \;\middle|\; \sum_{i=1}^n x_i \in [0,1]\right\} & \overset{\cong}{\to} & \overline{B}^n & \to & S^n. \\ (t_0,\dots,t_n) & \mapsto & (t_0,\dots,t_{n-1}) & & x & \mapsto & \big(x, \sqrt{1-\|x\|^2}\big). \end{array}$$

that we had already considered on page 1677. We write $\beta = \mu \circ \alpha$. In Lemma 76.3 we saw that the singular n-chain $\alpha - \beta$ is a generator of $\mathrm{H}_n(S^n)$. Next we calculate

$$\mu_*([\alpha-\beta]) \;=\; [\mu\circ\alpha] - [\mu\circ\beta] \;=\; [\beta] - [\underbrace{\mu\circ\mu}_{=\mathrm{id}}\circ\alpha] \;=\; [\beta] - [\alpha] \;=\; -[\alpha-\beta].$$

The map μ_* is therefore given by multiplication with -1. ⊞

Now let $A \in \mathrm{O}(n+1)$. First we consider the case $\det(A) = 1$, i.e. we assume that $A \in \mathrm{SO}(n+1)$. By the Matrix Group Path-Component Proposition 2.37 we know that $\mathrm{SO}(n+1)$ is path-connected, so there exists a map $h\colon [0,1] \to \mathrm{SO}(n+1)$ with $h(0) = \mathrm{id}$ and $h(1) = A$. But then $F(x,t) = h(t) \cdot x$ defines a homotopy from id to $\rho(A)$. It follows from the Sphere Degree Lemma 76.11 (1) and (3) that $\deg(\rho(A)) = \deg(\mathrm{id}) = 1$.

Finally we consider the case that $\det(A) \neq 1$. Let $R \in \mathrm{O}(n+1)$ be the matrix such that $\rho(R) = \mu$. Now we see that

$$\deg(\rho(A)) \;=\; \deg(\rho(A \cdot R \cdot R^{-1})) \underset{\text{by (4)}}{\overset{\uparrow}{=}} \deg(\rho(A \cdot R)) \cdot \deg(\rho(R)) \underset{\text{since } \det(A\cdot R) = 1 \text{ and by the claim}}{\overset{\uparrow}{=}} 1 \cdot (-1) \;=\; -1.$$

■

We have now seen that the circle admits self-maps of arbitrary degrees and that every sphere admits self-maps of degree $-1, 0, 1$. It is natural to ask whether there are also maps on higher-dimensional spheres that have other degrees. The combination of Lemma 76.10 and the following lemma shows that in fact every $k \in \mathbb{Z}$ is realized as the degree of every high-dimensional sphere.

Lemma 76.12. (Degree-Suspension Lemma) Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a map. Let $\Sigma(f)\colon \Sigma(S^n) \to \Sigma(S^n)$ be the suspension of f that we defined on page 452. Furthermore let $\Theta\colon \Sigma(S^n) \to S^{n+1}$ be the homeomorphism from page 452. Then

$$\deg(\Theta \circ \Sigma(f) \circ \Theta^{-1}\colon S^{n+1} \to S^{n+1}) \;=\; \deg(f\colon S^n \to S^n).$$

Examples.

(1) Let $k \in \mathbb{Z}$. We view S^2 as a subset of $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R}$. We consider the map

$$\begin{array}{rcl} g\colon S^2 & \to & S^2 \\ (r \cdot \exp(\mathrm{i}\varphi), w) & \mapsto & (r \cdot \exp(\mathrm{i}\varphi k), w). \end{array}$$

One can easily verify that the map g equals $\Theta \circ \Sigma(z \mapsto z^k) \circ \Theta^{-1}$. Thus it follows from Lemma 76.10 and the Degree-Suspension Lemma 76.12 that $\deg(g) = \deg(\Sigma(z \mapsto z^k)) = k$.

(2) Let $n \in \mathbb{N}$ and let $k \in \mathbb{Z}$. It follows from Lemma 76.10 and the Degree-Suspension Lemma 76.12 that there exists a self-map $f\colon S^n \to S^n$ of degree k.

Proof. We consider the following diagram

$$\begin{array}{ccccc} \widetilde{\mathrm{H}}_n(S^n) & \xrightarrow{\Sigma_{S^{n+1}}} & \widetilde{\mathrm{H}}_n(\Sigma(S^n)) & \xrightarrow{\Theta_*} & \widetilde{\mathrm{H}}_{n+1}(S^{n+1}) \\ \downarrow{\scriptstyle \cdot \deg(f)} & & \downarrow{\scriptstyle \Sigma(f)_*} & & \downarrow{\scriptstyle (\Theta\circ\Sigma(f)\circ\Theta^{-1})_*} \\ \widetilde{\mathrm{H}}_n(S^n) & \xrightarrow{\Sigma_{S^{n+1}}} & \widetilde{\mathrm{H}}_{n+1}(\Sigma(S^n)) & \xrightarrow{\Theta_*} & \widetilde{\mathrm{H}}_{n+1}(S^{n+1}). \end{array}$$

First note that it follows from the Suspension-H_*-Proposition 76.7 that the square to the left commutes and that the horizontal maps to the left are isomorphisms. It is clear that the square to the right commutes. Furthermore, since Θ is a homeomorphism we see that the horizontal maps to right are isomorphism. Note that it follows immediately from the above discussion together with Lemma 76.9 (2) that $\deg(\Theta \circ \Sigma(f) \circ \Theta^{-1}) = \deg(f)$. ■

The following theorem is an interesting application of our discussion of degrees of self-maps of spheres.

Theorem 38.11. (Sphere-Degree Fixed Point Theorem) Let $f\colon S^n \to S^n$ be a map. If $\deg(f) \neq (-1)^{n+1}$, then f has a fixed point.

Example. The Sphere-Degree Fixed Point Theorem Theorem 38.11 says in particular that every map $f\colon S^2 \to S^2$ of degree one has a fixed point. Together with the Sphere Degree Lemma 76.11 this implies that every map $f\colon S^2 \to S^2$ that is homotopic to the identity has a fixed point. This means that we cannot "deform" the identity to a map that is fixed point free. This is in contrast to the case $n = 1$ where we can "deform" the identity into the map that is given by rotation by a small angle, which is of course a fixed point free map.

Proof. We had proved the Sphere-Degree Fixed Point Theorem Theorem 38.11 on page 908 using the notion of the degree of a smooth map $f\colon S^n \to S^n$. In a rather blatant case of self-plagiarism the proof we now provide is almost identical to the proof on page 908.

Let $f\colon S^n \to S^n$ be a map which admits no fixed point. This means that for all $x \in S^n$ we have $f(x) \neq x$. We need to show that $\deg(f) = (-1)^{n+1}$. We will do this by showing that f is homotopic to $-\operatorname{id}$.

Our hypothesis implies that $(1-t)f(x) \neq tx$ for all $t \in [0,1]$ and all $x \in S^n$.[922] Therefore we can consider the map

$$\begin{array}{rcl} F\colon S^n \times [0,1] & \to & S^n \\ (x,t) & \mapsto & \dfrac{(1-t)f(x) - tx}{\|(1-t)f(x) - tx\|}. \end{array}$$

This map is a homotopy between the maps $x \mapsto f(x)$ and $x \mapsto -x$. Thus it follows that

$$\deg(f) \underset{\uparrow}{=} \deg(-\operatorname{id}) \underset{\uparrow}{=} (-1)^{n+1}.$$

Sphere Degree Lemma 76.11 (3) Sphere Degree Lemma 76.11 (6) ■

In the following we recall the definition from page 638 of a vector field on a submanifold of $\mathbb{R}^n$.

Definition. Let $M \subset \mathbb{R}^n$ be a submanifold. Given $P \in M \setminus \partial M$ we denote by $\widetilde{\mathrm{T}}_P M \subset \mathbb{R}^n$ the physical tangent vector space as defined on page 620. A vector field on M is a continuous map $v\colon M \to \mathbb{R}^n$ such that for any $P \in M$ we have $v(P) \in \widetilde{\mathrm{T}}_P M$.

Examples.

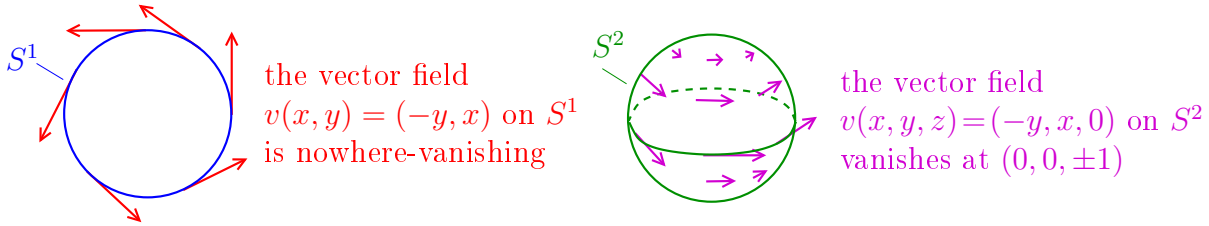
(1) Let P be a point on S^n. By Lemma 23.1 we have

$$\widetilde{\mathrm{T}}_P S^n = \{v \in \mathbb{R}^{n+1} \mid \langle P, v\rangle = 0\}.$$

(2) For an odd-dimensional sphere S^{2k-1} a vector field is given by[923]

$$\begin{array}{rcl} v\colon S^{2k-1} & \to & \mathbb{R}^{2k} \\ (x_1, x_2, \ldots, x_{2k-1}, x_{2k}) & \mapsto & (-x_2, x_1, \ldots, -x_{2k}, x_{2k-1}). \end{array}$$

[922] This case be seen as follows: if $t \neq \frac{1}{2}$ we have $\|(1-t)f(x)\| = 1 - t \neq t = \|tx\|$. On the other hand, for $t = \frac{1}{2}$ we have $(1-t)f(x) = \frac{1}{2}f(x) \neq \frac{1}{2}x = tx$.



[923] Indeed, for any $P \in S^{2k-1}$ we have $\langle P, v(P)\rangle = 0$, i.e. $v(P)$ does indeed lie in the tangent space $\mathrm{T}_P S^{2k-1}$.

This vector field has the property that it is nowhere-vanishing. In the case of the 1-sphere S^1 this is just the vector field of constant length 1 that points in the "counterclockwise direction".

(3) For an even-dimensional sphere S^{2k} a vector field is similarly given by

$$\begin{array}{rcl} v\colon S^{2k} & \to & \mathbb{R}^{2k+1} \\ (x_1, x_2, \ldots, x_{2k-1}, x_{2k}, x_{2k+1}) & \mapsto & (-x_2, x_1, \ldots, -x_{2k}, 0). \end{array}$$

This vector field vanishes at the "North Pole" $(0, \ldots, 0, 1)$ and it also vanishes at the "South Pole" $(0, \ldots, 0, -1)$. Both types of vector fields are sketched in the figure below.

In Question 23.17 we asked whether it is possible to find a nowhere-vanishing vector field on even-dimensional spheres. The following theorem says that this is not possible.

Theorem 38.12. (Hairy Ball Theorem) Every vector field on an even-dimensional sphere S^{2k} vanishes on at least one point.[924]

Remark.

(1) For $n = 2$ we get the following "real life application": on the surface of earth there always exists at least one point where the wind does not blow at all. This fact is illustrated at the following website

`https://earth.nullschool.net/`

(2) The "Hairy Ball Theorem" gets its observation that for $n = 2$ the theorem says that "you can't comb a hairy ball flat without creating a cowlick".

(3) Contrary to most other languages in German the Hairy Ball Theorem 38.12 is called the "Satz vom (gekämmten) Igel", i.e. it is referred to as the "Combed Hedgehog Theorem".

(4) Evidently the fun never stops. Now that we know that odd-dimensional spheres admit one nowhere-vanishing vector field the question arises, how many linearly independent vector fields can we find on a given odd-dimensional sphere. It turns out that there is complete and highly non-trivial answer, see [**Adam1962**], [**MillH1989**] and [**VogI**] for details.

Proof. We had proved the Hairy Ball Theorem 38.12 on page 909 using the notion of the degree of a smooth map $f\colon S^n \to S^n$. In an another shameless case of self-plagiarism the proof we now provide is again almost identical to our earlier proof.

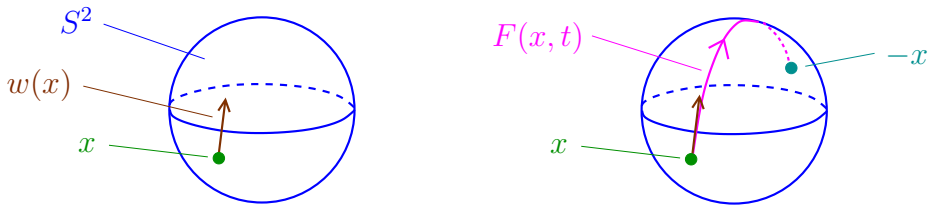
[924] On S^{2k} we had so far found vector fields which vanish at *two* points. Can we find a vector field on S^{2k} which vanishes on only *one* point? We will discuss this question in Exercise 76.6.

Let v be a vector field on the sphere S^n which is nowhere-vanishing. We have to show that n is odd. We consider the vector field w on S^n that is given by rescaling v to length one, i.e. that is given by

$$\begin{array}{rcl} S^n & \to & \mathbb{R}^{n+1} \\ x & \mapsto & w(x) := \frac{1}{\|v(x)\|} v(x). \end{array}$$

Furthermore we consider the map

$$\begin{array}{rcl} F\colon S^n \times [0,1] & \to & S^n \\ (x,t) & \mapsto & \cos(\pi t)\cdot x + \sin(\pi t)\cdot w(x). \end{array}$$



We refer to the figure below for an illustration. The map does indeed take values in S^n, since

$$\langle \cos(\pi t)x + \sin(\pi t)w(x), \cos(\pi t)x + \sin(\pi t)w(x)\rangle \underset{\substack{\uparrow \\ \text{since } \langle x, w(x)\rangle = 0}}{=} \cos(\pi t)^2\|x\|^2 + \sin(\pi t)^2\|w(x)\|^2 \underset{\substack{\uparrow \\ \text{since } \|x\| = \|w(x)\| = 1}}{=} 1.$$

The map $F_0 = F(-,0)$ is the identity and the map $F_1 = F(-,1)$ equals F is $-\mathrm{id}$. Put differently, the map F is a homotopy between the two maps id and $-\mathrm{id}$. It follows that

$$1 \underset{\substack{\uparrow \\ \text{Sphere Degree Lemma 76.11 (1)}}}{=} \deg(\mathrm{id}) \underset{\substack{\uparrow \\ \text{Lemma 76.11 (3)}}}{=} \deg(-\mathrm{id}) \underset{\substack{\uparrow \\ \text{Lemma 76.11 (6)}}}{=} (-1)^{n+1}.$$

But this means that n is odd. ∎

76.5. **The local degree I.** As the reader will have noticed, it is not entirely trivial to compute the isomorphism types of the homology groups of a given topological space. In the following two sections we will get to know a few tricks to address this problem.

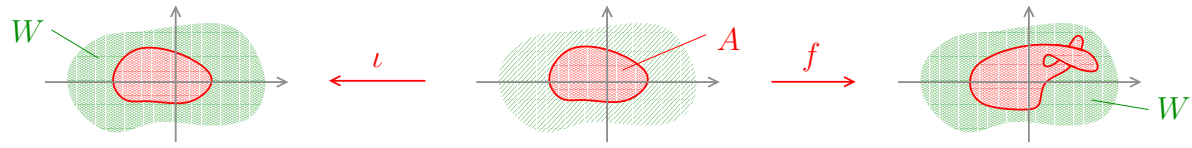
We start out with the following harmless lemma which is a variation on the Manifold-Local Homology Lemma 75.1.

Lemma 76.13. Let U be a subset of $\mathbb{R}^n$. For every point P in the interior of U we have

$$\mathrm{H}_k(U, U\setminus\{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. Since P lies in the interior of U there exists an $r > 0$ such that $B_r^n(P) \subset U$. Now we see that

$$\mathrm{H}_k(U, U\setminus\{P\}) \underset{\substack{\uparrow \\ \text{Excision Theorem 74.18}}}{\leftarrow} \mathrm{H}_l(B_r(P), B_r(P)\setminus\{P\}) \underset{\substack{\uparrow \\ \text{isomorphism by the long exact sequence in reduced homology of the pair } (B_r^n(P), B_r^n(P)\setminus\{P\})}}{\xrightarrow{\partial}} \widetilde{\mathrm{H}}_{k-1}(B_r^n(P)\setminus\{P\}) \underset{\substack{\uparrow \\ \text{isomorphism since } S^{n-1} \text{ is homotopy equivalent to } B_r^n(P)\setminus\{P\}}}{\leftarrow} \widetilde{\mathrm{H}}_{k-1}(S^{n-1}).$$



The lemma now follows from the calculation of $\widetilde{\mathrm{H}}_*(S^{n-1})$ in Proposition 74.4. ∎

We move on to the following much more interesting proposition.

Proposition 76.14. (Local Diffeomorphism-Degree Proposition) Let W be a subset of $\mathbb{R}^n$ and let A be a subset of W such the origin 0 is contained in the interior of U. Let $f\colon A \to W$ be an injective map with $f(0) = 0$. We suppose that f is a local diffeomorphism at 0. Then the degree of the map[925]

$$\mathrm{H}_n(W, W \setminus \{0\}) \xleftarrow[\cong]{\iota_*} \mathrm{H}_n(A, A \setminus \{0\}) \xrightarrow{f_*} \mathrm{H}_n(W, W \setminus \{0\})$$

equals $+1$ if f is orientation-preserving at 0 and -1 if f is orientation-reversing at 0.

In the proof of the Local Diffeomorphism-Degree Proposition 76.14 we will make use of the following two lemmas which we will also use on several other occasions later on.

Lemma 76.15. Let $f\colon U \to V$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$. Let $P \in U$. We denote by

$$\begin{array}{rcl} \lambda\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ x & \mapsto & (\mathrm{D}f_P)(x) + f(P) \end{array}$$

the linearization of f at P. There exists an open neighborhood $U' = B_r^n(P)$ of P such that the restrictions of f and λ to maps $(U', U' \setminus \{P\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{f(P)\})$ are homotopic.

Remark. Lemma 76.15 is the key to translating information from smooth methods into topology and later on homology groups.

Proof. Let $f\colon U \to V$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$. To simplify the notation we assume that $P = 0$ and that $f(P) = 0$. Furthermore, by restriction to an open ball we might as well assume that U is convex. We write $D := \mathrm{D}f_0$. Thus the linearization of f at $P = 0$ is given by the map $\lambda(x) = D \cdot x$. Since f is in particular a local diffeomorphism a $P = 0$ we know by the Chain Rule 19.10 together with the Smooth Invariance of Domain Proposition 19.11, that D is an invertible matrix.

Since $U \subset \mathbb{R}^n$ is convex we obtain from the Map-as-Matrix Multiplication Proposition 19.14 that there exists a smooth map $A\colon U \to \mathrm{M}(n \times n, \mathbb{R})$ such that $A(0) = \mathrm{D}f_0$ and such that $f(x) = A(x) \cdot x$ for all $x \in U$. Since $\det(A(0)) \neq 0$ we see that there exists an $r > 0$ such that $\det(A(x)) \neq 0$ for all $x \in B_r^n(0)$. This implies that the map

$$\begin{array}{rcl} B_r^n(0) \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & A(x \cdot (1-t)) \cdot x \end{array}$$

is a homotopy of the maps f and λ as maps $(B_r^n(0), B_r^n(0) \setminus \{0\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$ of pairs of topological spaces. ∎

We adopt the following notation:

Notation.

[925] By Lemma 76.13 we know that $\mathrm{H}_n(W, W \setminus \{0\}) \cong \mathbb{Z}$, thus it makes sense to talk of the degree of an automorphism of $\mathrm{H}_n(W, W \setminus \{0\})$.

(1) Given a matrix $P \in \mathrm{GL}(n,\mathbb{R})$ we denote by $\rho(P)\colon \mathbb{R}^n \to \mathbb{R}^n$ the map given by $x \mapsto P \cdot x$.
(2) Given a non-zero real number r we denote its sign by $\mathrm{sign}(r) \in \{-1,+1\}$.

Lemma 76.16. Let $n \in \mathbb{N}$. Given $A \in \mathrm{GL}(n,\mathbb{R})$ we have

$$\deg\big(\rho(A)_*\colon \mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) \to \mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\})\big) = \mathrm{sign}(\det(A))$$

and given $A \in \mathrm{O}(n)$ we have

$$\deg\big(\rho(A)_*\colon \mathrm{H}_n(\overline{B}^n,\overline{B}^n\setminus\{0\}) \to \mathrm{H}_n(\overline{B}^n,\overline{B}^n\setminus\{0\})\big) = \mathrm{sign}(\det(A)).$$

Proof of Lemma 76.16. For simplicity we only prove the first statement of the lemma. Thus let $A \in \mathrm{GL}(n,\mathbb{R})$. We start out by picking an orthogonal matrix $B \in \mathrm{O}(n)$ such that $\mathrm{sign}(\det(B)) = \mathrm{sign}(\det(A))$. Next we consider the following diagram

$$\begin{array}{ccccccc}
\mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) & \xrightarrow{\mathrm{id}} & \mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\mathbb{R}^n\setminus\{0\}) & \longleftarrow & \mathrm{H}_{n-1}(S^{n-1}) \\
\downarrow{\scriptstyle \rho(A)_*} & & \downarrow{\scriptstyle \rho(B)_*} & & \downarrow{\scriptstyle \rho(B)_*} & & \downarrow{\scriptstyle \rho(B)_*} \\
\mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) & \xrightarrow{\mathrm{id}} & \mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\mathbb{R}^n\setminus\{0\}) & \longleftarrow & \mathrm{H}_{n-1}(S^{n-1}).
\end{array}$$

We make the following observations:

(1) Since $\mathrm{sign}(\det(B)) = \mathrm{sign}(\det(A))$ we obtain from the Matrix Group Path-Component Proposition 2.37 (1) that there exists a path $[0,1] \to \mathrm{GL}(n,\mathbb{R})$ from A to B. Similar to the discussion on page 419 this path gives rise to a homotopy between $\rho(A)$ and $\rho(B)$. We obtain from Proposition 74.15 that $\rho(A)_* = \rho(B)_*$, in other words, the square to the left commutes.
(2) The square in the middle commutes by the naturality of the connecting homomorphism, see the Topological LES-Corollary 74.14.
(3) The horizontal maps to the right are induced by the inclusion $S^{n-1} \to \mathbb{R}^n \setminus \{0\}$. It is clear that the square to the right commutes.

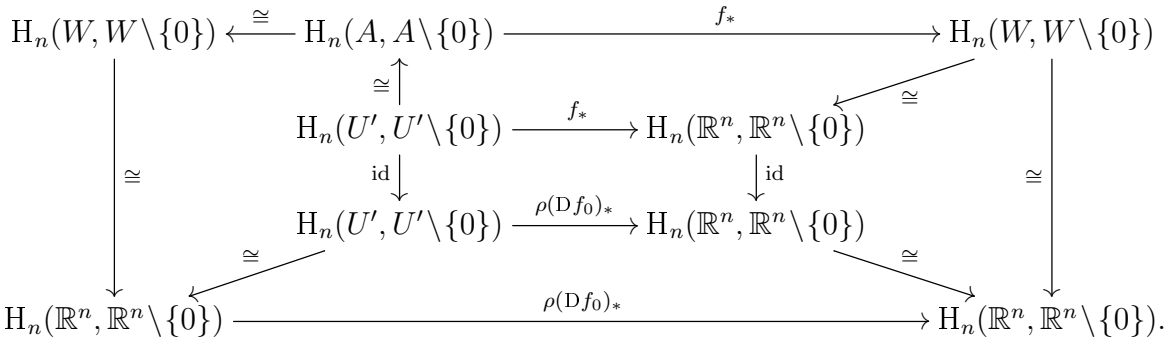
Now we see that

$$\begin{array}{ccccc}
 & & & & \text{by the above commutative diagram together with Lemma 76.9 (2)} \\
 & & & & \downarrow \\
\deg\big(\mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\}) & \xrightarrow{\rho(A)_*} & \mathrm{H}_n(\mathbb{R}^n,\mathbb{R}^n\setminus\{0\})\big) & = & \deg(\rho(B)\colon S^{n-1}\to S^{n-1}) \\
 & & = \det(B) & = \mathrm{sign}(\det(B)) & = \mathrm{sign}(\det(A)). \\
 & & \uparrow & \uparrow & \uparrow \\
 & & \text{Sphere Degree Lemma 76.11 (6)} & \text{since } B\in\mathrm{O}(n) \text{ we have } \det(B)\in\{\pm1\} & \text{choice of } B
\end{array}$$

■

Proof of the Local Diffeomorphism-Degree Proposition 76.14 . Let W be a subset of $\mathbb{R}^n$ and let A be a subset of W such that the origin 0 is contained in the interior. Let $f\colon A \to W$ be an injective map with $f(0) = 0$. We suppose that f is a local diffeomorphism at 0. Recall that this means that there exists an open neighborhood U of 0 that is contained in A and an open neighborhood V of 0 that is contained in B such that the map $f\colon U \to V$ is a diffeomorphism.

We start out with the following preparations.



(1) We set

$$\epsilon := \begin{cases} +1, & \text{if } f \text{ is orientation-preserving at } 0, \\ -1, & \text{if } f \text{ is orientation-reversing at } 0. \end{cases}$$

Note that it follows from the Orientation Checking-via-Differentials Lemma 25.12 that we have $\epsilon = \operatorname{sign}(\det(\mathrm{D}f_0))$.

(2) By Lemma 76.15 there exists an open neighborhood U' of 0 that is contained in U such that the restrictions of f and $\rho(\mathrm{D}f_0)$ to maps $(U', U' \setminus \{0\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$ are homotopic.

Now we consider the following diagram

We continue with the following clarifications and observations:

(3) The undecorated maps are induced by inclusions. All of them are isomorphisms by the Excision Theorem 74.18.

(4) It follows from (2) and Proposition 74.15 that the central square commutes. All other regions of the diagram commute by the functoriality of homology groups.

(5) By Lemma 76.16 the bottom horizontal map equals multiplication by $\operatorname{sign}(\det(\mathrm{D}f_0))$.

(6) It follows from all of the above that the top map is given by multiplication by ϵ. But that is precisely what we wanted to show. ■

76.6. **The local degree II.** As mentioned in the previous section, we want to develop some tools for addressing the following problem: given a map $f\colon X \to Y$ between topological spaces, how can we determine the induced map on homology? For example, let us consider the following question.

Question 76.17. Let f be a complex polynomial of degree ≥ 1. By Exercise 2.35 we know that the map

$$\begin{aligned} \Theta(f)\colon S^2 = \mathbb{C} \cup \{\infty\} &\to \mathbb{C} \cup \{\infty\} = S^2 \\ z &\mapsto \begin{cases} f(z), & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty \end{cases} \end{aligned}$$

is continuous. What is the induced map on homology, i.e. what is the degree of $\Theta(f)$?

In this section we will develop a method for determining the degree of a self-map of a sphere which can be applied in many "reasonable" cases. In particular we will be able to answer Question 76.17. The answer will give us an alternative proof of the Fundamental Theorem 26.3 of Algebra.

We start out with the following observation.

Observation. Let $n \geq 1$. Now let $x \in S^n$ be a point and let U be a neighborhood of x in S^n. We have isomorphisms

$$\begin{array}{ccccc} \mathrm{H}_n(S^n) & \xrightarrow{\text{я}} & \mathrm{H}_n(S^n, S^n \setminus \{x\}) & \xleftarrow{\cong} & \mathrm{H}_n(U, U \setminus \{x\}). \\ & \uparrow & & \uparrow & \\ & \text{isomorphism by the long exact of the pair } (S^n, S^n \setminus \{x\}) & & \text{isomorphism by the Excision Theorem 74.18} & \end{array}$$

Throughout this section will use frequently that these maps are isomorphisms.

Definition. We say a map $f\colon X \to Y$ between two topological spaces is nice at a point $x \in X$ if there exists a neighborhood U of x such that for all $x' \neq x$ in U we have $f(x') \neq f(x)$. We refer to such a neighborhood as a nice neighborhood of x.

Examples.

(1) Let $f\colon X \to Y$ be a map between two topological spaces and let $x \in X$. If U is a neighborhood such that $f|_U$ is injective, then U is evidently a nice neighborhood of x.

(2) We consider the functions

$$\begin{array}{rcl} f\colon \mathbb{R} & \to & \mathbb{R} \\ t & \mapsto & t^2 \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{R} & \to & \mathbb{R} \\ t & \mapsto & \begin{cases} 0, & \text{if } t = 0, \\ t\sin(\frac{1}{t}), & \text{if } t \neq 0. \end{cases} \end{array}$$

For the function f every point on $\mathbb{R}$ is nice, in fact for $x < 0$ we can take $U = (-\infty, 0)$, for $x > 0$ we can take $U = (0, \infty)$ and for $x = 0$ we can take $U = \mathbb{R}$. On the other hand it is straightforward to see that for the function g the point $x = 0$ is not nice.

The following is the key definition of this section.

Definition. Let $n \geq 1$, let $f\colon S^n \to S^n$ be a map and let $x \in S^n$ be a nice point. Let U be a nice neighborhood of x. The local degree of f at the point x is defined as the degree of the homomorphism[926]

$$\mathrm{H}_n(S^n) \xrightarrow{\text{я}} \mathrm{H}_n(S^n, S^n \setminus \{x\}) \xleftarrow{\cong} \mathrm{H}_n(U, U \setminus \{x\}) \xrightarrow{f_*} \mathrm{H}_n(S^n, S^n \setminus \{f(x)\}) \underset{\cong}{\xleftarrow{\text{я}}} \mathrm{H}_n(S^n).$$

We denote this local degree by $\deg(f, x)$.

Remark. We will generalize the notion of a local degree on page 2379 to maps between oriented topological manifolds.

Lemma 76.18. The local degree $\deg(f, x)$ of a map $f\colon S^n \to S^n$ at a nice point $x \in S^n$ is well-defined.

Proof. Let $n \geq 1$, let $f\colon S^n \to S^n$ be a map and let $x \in S^n$ be a nice point. Let U, U' be nice neighborhoods of x. After replacing U' by $U \cap U'$ we can without loss of generality

[926] Note that f induces a map of pairs $(U, U \setminus \{x\}) \to (S^n, S^n \setminus \{f(x)\})$ since U is nice.

assume that $U' \subset U$. We consider the following commutative diagram

$$\begin{array}{ccccccc} & & \mathrm{H}_n(U', U'\backslash\{x\}) & \xrightarrow{f_*} & \mathrm{H}_n(S^n, S^n\backslash\{f(x)\}) & & \\ & \overset{\cong}{\swarrow} & \downarrow \cong & & \downarrow \mathrm{id} & \overset{\cong}{\searrow} & \\ \mathrm{H}_n(S^n) \longrightarrow \mathrm{H}_n(S^n, S^n\backslash\{x\}) & & & & & & \mathrm{H}_n(S^n). \\ & \underset{\cong}{\nwarrow} & & & & \underset{\cong}{\nearrow} & \\ & & \mathrm{H}_n(U, U\backslash\{x\}) & \xrightarrow{f_*} & \mathrm{H}_n(S^n, S^n\backslash\{f(x)\}). & & \end{array}$$

All the non-decorated maps are induced by inclusions. It is clear that the diagram commutes. Also note that the left vertical map is an isomorphism by the Excision Theorem 74.18. It follows immediately from these observations that the local degree defined using U' agrees with the local degree defined using U. ■

Lemma 76.19. Let $n \geq 1$, let $f\colon S^n \to S^n$ be a map and let $x \in S^n$. If f is a homeomorphism, then for every nice point $x \in S^n$ we have

$$\deg(f, x) \;=\; \deg(f).$$

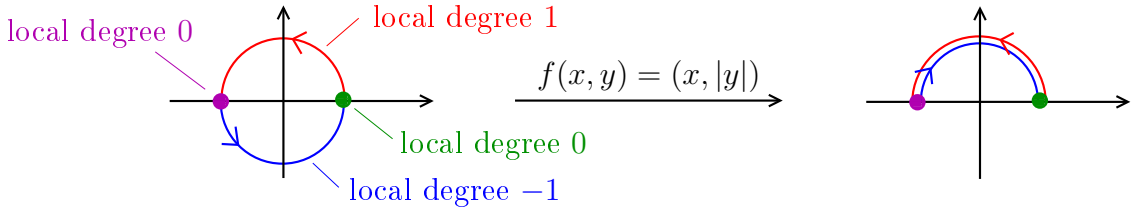
Proof. From the hypothesis that f is a homeomorphism we obtain that $U = S^n$ is a nice neighborhood for x. We take $V = S^n$ and we consider the following diagram

$$\begin{array}{ccc} \mathrm{H}_n(S^n) & \xrightarrow{\qquad f_* \qquad} & \mathrm{H}_n(S^n) \\ \cong \downarrow \text{я} & & \text{я} \downarrow \cong \\ \mathrm{H}_n(S^n, S^n \setminus \{x\}) & \xrightarrow{f_*} & \mathrm{H}_n(S^n, S^n \setminus \{f(x)\}) \end{array}$$

The statement now follows immediately from the definitions. ■

The following proposition can often be used to determine the local degree of a map.

Proposition 76.20. Let $f\colon S^n \to S^n$ be a map with $n \geq 1$ and let $x \in S^n$.



(1) If f is a local homeomorphism around x, then x is nice and

$$\deg(f, x) \;=\; \pm 1.$$

(2) If f is a local diffeomorphism around x, then x is nice and

$$\deg(f, x) \;=\; \begin{cases} 1, & \text{if } f \text{ is orientation-preserving at } x, \\ -1, & \text{if } f \text{ is orientation-reversing at } x. \end{cases}$$

Example. We consider the map $f\colon S^1 \to S^1$ given by $(x, y) \mapsto (x, |y|)$. It follows from Proposition 76.20 (2) that for every point on the open upper semicircle the local degree is $+1$ and that for every point on the open lower semicircle the local degree is -1. In Exercise 76.10 we will prove that the local degree at the points ± 1 is in both cases zero.

Remark. Proposition 76.20 shows that for a smooth map $f\colon S^n \to S^n$ and a point $x \in S^n$ at which f is a local diffeomorphism the definition of the local degree on page 898 agrees with the above definition.

Proof of Proposition 76.20. Let $f\colon S^n \to S^n$ be a map with $n \geq 1$ and let $x \in S^n$.

(1) Suppose that f is a local homeomorphism around the point x. Recall that this means that there exists an open neighborhood U of x and an open neighborhood V of $f(x)$ such that $f\colon U \to V$ is a homeomorphism. This implies in particular that U is nice. Now we consider the following rather simple diagram:

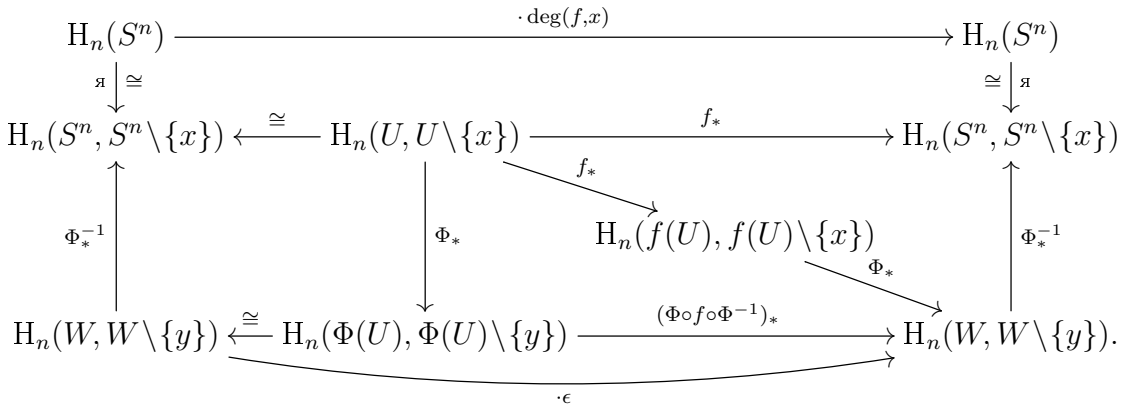
$$\begin{array}{ccccccccc} \mathrm{H}_n(S^n) & \xrightarrow{\cong} & \mathrm{H}_n(S^n, S^n\backslash\{x\}) & \xleftarrow{\cong} & \mathrm{H}_n(U, U\backslash\{x\}) & \longrightarrow & \mathrm{H}_n(S^n, S^n\backslash\{f(x)\}) & \xleftarrow{\cong} & \mathrm{H}_n(S^n). \\ & & & & \downarrow{\scriptstyle f_*} & \nearrow{\scriptstyle \cong} & & & \\ & & & & \mathrm{H}_n(V, V\backslash\{f(x)\}) & & & & \end{array}$$

It is clear that the diagram commutes. Since the map f restricts to a homeomorphism $(U, U\backslash\{x\}) \to (V, V\backslash\{f(x)\})$ of pairs we see that the vertical map is an isomorphism. Furthermore the diagonal map is an isomorphism by the Excision Theorem 74.18. Thus we see that all horizontal maps are isomorphism. This implies immediately that $\deg(f, x) = \pm 1$.

(2) Let $f\colon S^n \to S^n$ be a map with $n \geq 1$ and let $x \in S^n$. We assume that f is a local diffeomorphism around x. By the Orthogonal Action Lemma 5.26 we know that there exists an $A \in \mathrm{SO}(n-1)$ with $A \cdot f(x) = x$. By Exercise 25.5 we know that the map $z \mapsto A \cdot z$ is orientation-preserving and by the Sphere Degree Lemma 76.11 (6) we know that $\deg(z \mapsto A \cdot z) = 1$. Thus, after replacing f by the $z \mapsto A \cdot f(z)$, we might as well assume that $f(x) = x$.

We make a few further preparations.

(a) We pick a chart $\Phi\colon V \to W$ around x.



(b) Since f is a local diffeomorphism around x there exists an open neighborhood U of x such that $f\colon U \to f(U)$ is a diffeomorphism. Note that after possibly replacing U by $U \cap V \cap f^{-1}(V)$ we can assume that $U \subset V$ and $f(U) \subset V$.

(c) We set $y := \Phi(x)$.

(d) We set

$$\epsilon := \begin{cases} 1, & \text{if } f \text{ is orientation-preserving at } x, \\ -1, & \text{if } f \text{ is orientation-reversing at } x. \end{cases}$$

Next we consider the following diagram

We make the following observations and clarifications.

(a) As usual the undecorated maps are induced by inclusions.

(b) The top rectangle commutes by the definition of $\deg(f, x)$. The middle regions of the diagram commute by the functoriality of relative homology. Finally, note that $\Phi \circ f \circ \Phi^{-1}$ is orientation-preserving at y if and only if f is orientation-preserving at x. Thus we see that the bottom part of the diagram commutes by the Local Diffeomorphism-Degree Proposition 76.14.

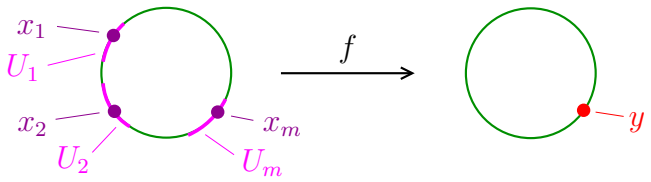
(c) It follows from the above together with Lemma 76.9 (2) that $\deg(f, x) = \epsilon$. ■

Using the following proposition we can determine the degree of a map from local degrees.

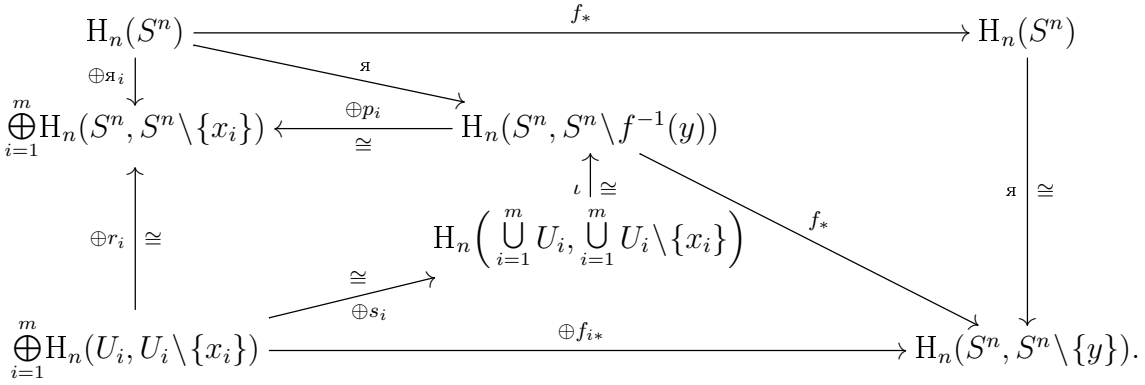
Proposition 76.21. (Local-Global Degree Proposition) Let $f\colon S^n \to S^n$ be a map where $n > 0$ and let $y \in S^n$ such that $f^{-1}(y)$ consists of finitely many points $x_1, \ldots, x_m$.[927] Then[928]

$$\deg(f) \;=\; \sum_{i=1}^{m} \deg(f, x_i).$$

Remark.



(1) In Proposition 106.32 we will generalize the Local-Global Degree Proposition 76.21 to a more general setting.



(2) Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a *smooth* map. In this setting we have two definitions of "degree", namely we have the definition from page 1684 and also from page 899. Mercifully it follows from the Local-Global Degree Proposition 76.21 together with Proposition 76.20 that the two definitions agree. We now see that we have some overlap of results, for example the Sphere Degree Lemma 76.11 overlaps with Theorems 38.3 and 38.4 and the Basics of Degree Lemma 38.8.

Proof. It follows easily from the fact that S^n is Hausdorff that we can choose disjoint open neighborhoods $U_1, \ldots, U_m$ for $x_1, \ldots, x_m$ and we choose an open neighborhood V of y such that $f(U_i) \subset V$ for $i = 1, \ldots, m$. We consider the following diagram:

[927] Does there always exist such a y?

[928] The hypothesis implies immediately that all the points $x_1, \ldots, x_m$ are nice, hence the local degrees are defined.

We make the following clarifications and observations:

(1) The maps r_i, s_i, p_i and ι are the maps induced by the obvious inclusions of pairs of topological spaces. Furthermore the maps $f_i \colon (U_i, U_i \setminus \{x_i\}) \to (S^n, S^n \setminus \{y\})$ are given by the restriction of f to U_i.

(2) It follows easily from the functoriality of relative homology groups that the diagram commutes.

(3) The argument on page 1597 shows that the diagonal map $\bigoplus_{i=1}^m s_i$ to the bottom left is an isomorphism.

(4) It follows from the Excision Theorem 74.17 that the vertical map ι and that the maps r_i are isomorphisms.

(5) It follows from the fact that the diagram commutes together with (3) and (4) that the horizontal map $\bigoplus_{i=1}^m p_i$ is also an isomorphism.

Since $я \colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n, S^n \setminus \{y\})$ is an isomorphism it suffices to prove the following claim.

Claim. We have

$$я(f_*([S^n])) \;=\; \sum_{i=1}^m \deg(f, x_i) \cdot я([S^n]) \;\in\; \mathrm{H}_n(S^n, S^n \setminus \{y\}).$$

Proof. We verify the claim by performing the following calculation:

$$я(f_*([S^n])) \overset{\text{since the diagram commutes and since the maps } \oplus p_i \text{ and } \oplus r_i \text{ are isomorphisms}}{=} \Big(\bigoplus_{i=1}^m f_{i*}\Big) \circ \Big(\bigoplus_{i=1}^m r_{i*}\Big)^{-1} \circ \Big(\bigoplus_{i=1}^m я_{i*}\Big)([S^n]) \overset{\text{by Lemma 72.12 (1) and (2) and since each } r_i \text{ is an isomorphism}}{=} \Big(\bigoplus_{i=1}^m f_{i*}\Big) \circ \Big(\bigoplus_{i=1}^m r_{i*}^{-1} \circ я_i\Big)([S^n])$$

$$= \Big(\bigoplus_{i=1}^m f_{i*}\Big)\Big(\sum_{i=1}^m \underbrace{(r_i^{-1} \circ я_i)([S^n])}_{\in \mathrm{H}_n(U_i, U_i \setminus \{x_i\})}\Big) = \sum_{i=1}^m (f_i \circ r_i^{-1} \circ я_i)([S^n]) = \sum_{i=1}^m \deg(f, x_i) \cdot я([S^n]).$$

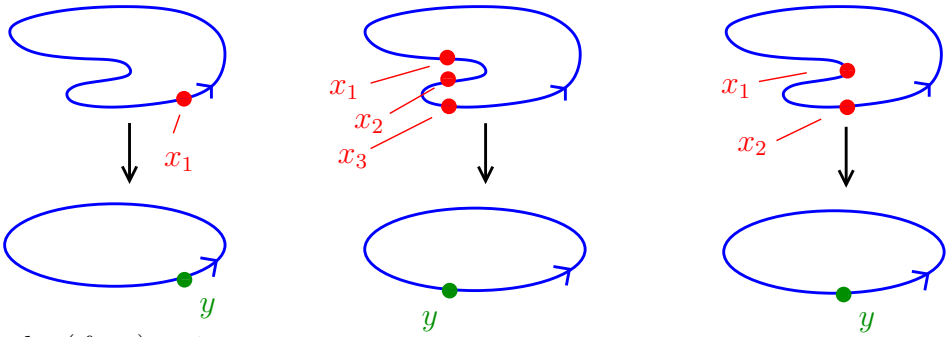
↑ definition of direct sum of type (I) of homomorphisms, see page 1596



↑ definition of local degree, see page 1694

■

Examples.

(1) The map $f\colon S^1 \to S^1$ given by $f(x,y) = (x, |y|)$ that is illustrated in the figure below has degree zero by the Sphere Degree Lemma 76.11. Taking preimages of points in S^1 one sees that in each case the sum of the local degrees of the preimages is zero.

(2) In the figure below we sketch a map $f\colon S^1 \to S^1$ and we choose several points $y \in S^1$.

$\deg(f, x_1) = 1$

$\deg(f, x_1) = 1$
$\deg(f, x_2) = -1$
$\deg(f, x_3) = 1$

$\deg(f, x_1) = 0$
$\deg(f, x_2) = 1$

We use Proposition 76.20 to determine the various degrees at the given points.[929] We see that the number of preimages and the degrees at the points in the preimages vary, but in all three cases the sum of the degrees at the points in the preimage is the same.

(3) We consider the map

$$\begin{array}{rccc} f\colon & S^1 & \to & S^1 \\ & z & \mapsto & z^m \end{array}$$

We had already determined in Lemma 76.10 that $\deg(f) = m$. Now we will show, just for fun, that the degree of f can also easily be determined using the Local-Global Degree Proposition 76.21.

First let $m \neq 0$. Then we choose $y = 1$. The preimages of y are given by $x_j = \exp(2\pi \mathrm{i} j/m)$ where $j = 1, \ldots, m$. It follows from Proposition 76.20 (2) that for each $j \in \{1, \ldots, m\}$ we have

$$\deg(f, x_j) \;=\; \begin{cases} 1, & \text{if } m > 0, \\ -1, & \text{if } m < 0. \end{cases}$$

Thus it follows from the Local-Global Degree Proposition 76.21 that $\deg(f) = |m| \cdot \operatorname{sign}(m) = m$. If $m = 0$, then $\deg(f) = 0$. The easiest way to see this is to take $y = -1$, since in this case the preimage is the empty set.

As promised, we can now provide an answer to Question 76.17:

[929] Why is in the third example the degree $\deg(f, x_1)$ equal to zero?

Proposition 76.22. Let f be a complex polynomial of degree ≥ 1. The degree of the map

$$\begin{array}{rcl} \Theta(f)\colon S^2 = \mathbb{C}\cup\{\infty\} & \to & \mathbb{C}\cup\{\infty\} = S^2 \\ z & \mapsto & \begin{cases} f(z), & \text{if } z\in\mathbb{C}, \\ \infty, & \text{if } z=\infty \end{cases} \end{array}$$

equals the degree of the polynomial f.

Sketch of proof. Let f be a complex polynomial of degree $n \geq 1$. We also consider the polynomial $g(z) = z^n$. We calculate that

$$\deg(\Theta(f)) \overset{\text{by the Sphere Degree Lemma 76.11 (3), since by Exercise 14.9 we know that } \Theta(f) \text{ and } \Theta(g) \text{ are homotopic}}{\downarrow =} \deg(\Theta(g(z)=z^n)) \overset{\uparrow}{=} n.$$

follows from the Local-Global Degree Proposition 76.21 and Proposition 76.20, see Exercise 76.7 ∎

More excitingly we can provide one more proof for the Fundamental Theorem of Algebra.

Theorem 26.3. (Fundamental Theorem of Algebra) ❀ Every nonconstant polynomial with coefficients in $\mathbb{C}$ has a zero in $\mathbb{C}$.

Remark. We already gave two other proofs on page 704 and page 704.

Proof. Let f be a nonconstant polynomial with complex coefficients. In other words, f is a complex polynomial of degree $n \geq 1$. By Proposition 76.22 we know that the degree of the self-map $\Theta(f)$ of $S^2 = \mathbb{C}\cup\{\infty\}$ equals $n \geq 1$. By the Sphere Degree Lemma 76.11 (2) this implies that $\Theta(f)\colon \mathbb{C}\cup\{\infty\} \to \mathbb{C}\cup\{\infty\}$ is surjective, in particular 0 lies in the image of $\Theta(f)$. Since $\Theta(f)(\infty) = \infty$ we see that 0 lies in the image of $f\colon \mathbb{C} \to \mathbb{C}\cup\{\infty\}$. In other words, there exists a $z \in \mathbb{C}$ with $\underbrace{\Theta(f)(z)}_{=f(z)} = 0$. ∎

76.7. Proof of the Standard Generator-Relationship Proposition 76.5.

For the tenacious reader we now provide the long-delayed proof of Statements (2) and (3) of the Standard Generator-Relationship Proposition 76.5. For the convenience of the reader we recall the relevant two statements.

Proposition 76.5. Let $n \in \mathbb{N}$. We denote by $f\colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ the homeomorphism from the Standard Simplex Homeomorphism Lemma 72.1 and we denote by $g\colon \overline{B}^n/S^{n-1} \to S^n$ the homeomorphism from Lemma 5.20. We set $* := g([S^{n-1}])$. We consider the following sequence of maps:

$$\mathrm{H}_n(\Delta^n, \partial\Delta^n) \xrightarrow{f_*} \mathrm{H}_n(\overline{B}^n, S^{n-1}) \longrightarrow \mathrm{H}_n(\overline{B}^n/S^{n-1}, [S^{n-1}]) \xrightarrow{g_*} \mathrm{H}_n(S^n, *) \xleftarrow{\text{я}} \mathrm{H}_n(S^n).$$

The following statements hold:

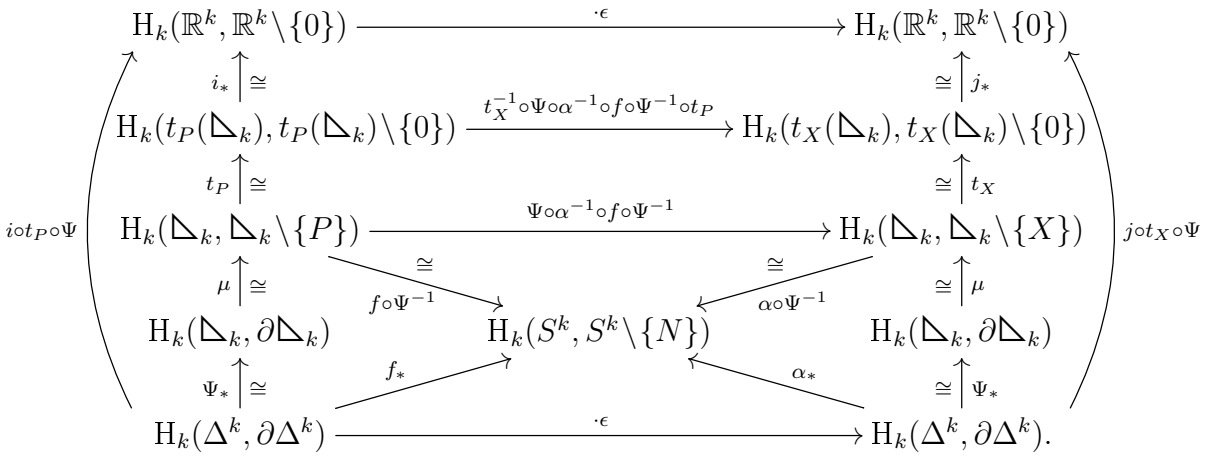
(2) We have

$$f_*([\mathrm{id}_{\Delta^n}]) \;=\; (-1)^n \cdot \underbrace{\text{standard generator } [\overline{B}^n] \text{ of } \mathrm{H}_n(\overline{B}^n, S^{n-1})}_{\text{defined by the condition } \partial([\overline{B}^n]) = [S^{n-1}], \text{ see page 1679}}.$$

(3) The standard generator $[\overline{B}^n]$ of $\mathrm{H}_n(\overline{B}^n, S^{n-1})$ has the same image in $\mathrm{H}_n(S^n, *)$ as the standard generator $[S^n]$ of $\mathrm{H}_n(S^n)$.

In the following we introduce and recall the following notation:

Notation. Let $n \in \mathbb{N}_0$.



(1) Given $P \in S^n$ we denote by $[S^n]_P$ the image of the standard generators $[S^n]$ under the map $\mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n, S^n \setminus \{P\})$.
(2) Let $\Psi\colon \Delta^n \to \mathbin{\triangle}_n$ be the obvious projection. In the Standard Simplex Homeomorphism Lemma 72.1 (1) we saw that Ψ is a homeomorphism. We write $\Phi := \Psi^{-1}\colon \mathbin{\triangle}_n \to \Delta^n$.
(3) Let $\alpha\colon \Delta^n \to S^n_{\geq 0} \subset S^n$ and $\beta\colon \Delta^n \to S^n_{\leq 0} \subset S^n$ be the two maps defined on page 1677.
(4) We denote by $N = (0, \ldots, 0, 1)$ the North Pole of S^n.

The proof of the Standard Generator-Relationship Proposition 76.5 requires the following lemma.

Lemma 76.23. Let $k \in \mathbb{N}_0$ and let $f\colon \Delta^k \to S^k$ be an injective map such that the map $f \circ \Phi\colon \mathring{\mathbin{\triangle}}_k \to S^k$ is a smooth embedding.[930] Then for every $Q \in f(\mathring{\Delta}^k)$ we have the following equality in $\mathrm{H}_k(S^k, S^k \setminus \{Q\})$:

$$[f_*(\mathrm{id}_{\Delta^k})] \;=\; \epsilon \cdot [S^k]_Q \qquad \text{where } \epsilon = \begin{cases} +1, & \text{if } f \circ \Phi\colon \mathring{\mathbin{\triangle}}^k \to S^k \text{ is orientation-preserving,} \\ -1, & \text{if } f \circ \Phi\colon \mathring{\mathbin{\triangle}}^k \to S^k \text{ is orientation-reversing.} \end{cases}$$

Proof of Lemma 76.23. First we deal with the special case that $Q = N$ and that $f(\Delta^k) \subset S^k_{\geq 0}$. We consider the following diagram:

We make the following clarifications and observations:

(1) We set $P := \Psi(f^{-1}(N)) \in \mathring{\mathbin{\triangle}}_k$ and $X := \Psi(\alpha^{-1}(N)) \in \mathring{\mathbin{\triangle}}_k$. Evidently we have the equality $(f \circ \Psi^{-1})(P) = N = (\alpha \circ \Psi^{-1})(X)$.
(2) Given $v \in \mathbb{R}^k$ we denote by $t_v\colon \mathbb{R}^k \to \mathbb{R}^k$ the map that is given by $x \mapsto x - v$.
(3) The maps $i\colon t_P(\mathbin{\triangle}_k) \to \mathbb{R}^k$ and $j\colon t_X(\mathbin{\triangle}_k) \to \mathbb{R}^k$ are the inclusion maps.
(4) The maps $\mu\colon (\mathbin{\triangle}_k, \partial\mathbin{\triangle}_k) \to (\mathbin{\triangle}_k, \mathbin{\triangle}_k \setminus \{P\})$ and $\mu\colon (\mathbin{\triangle}_k, \partial\mathbin{\triangle}_k) \to (\mathbin{\triangle}_k, \mathbin{\triangle}_k \setminus \{X\})$ are the inclusion maps of pairs of topological spaces.

[930] Note that $\mathring{\mathbin{\triangle}}_k$ is an open subset of $\mathbb{R}^k$, in particular, following the convention established on page 677, we will view it as an oriented k-dimensional smooth manifold.

(5) Since $f(\Delta^k) \subset S^k_{\geq 0}$ we have in particular that $f(\Delta^k) \subset \alpha(\Delta^k)$ which means that the map $\alpha^{-1} \circ f$ is actually defined.
(6) One can easily verify that $\alpha \circ \Psi^{-1}$ is orientation-preserving. As mentioned on page 683, the translation maps t_v are also orientation-preserving. Therefore we see that the map $t_X^{-1} \circ \Psi \circ \alpha^{-1} \circ f \circ \Psi^{-1} \circ t_P$ is orientation-preserving if and only if the map $f \circ \Psi^{-1} = f \circ \Phi$ is orientation-preserving. Thus we obtain from the Local Diffeomorphism-Degree Proposition 76.14 that the top square commutes.
(7) The second square from the top, the top triangle and the two triangles to the left and right commute basically by definition.
(8) It is straightforward to see that the maps $i \circ t_P \circ \Psi$ and $j \circ t_X \circ \Psi$ are homotopic as maps of pairs $(\Delta^k, \partial\Delta^k) \to (\mathbb{R}^k, \mathbb{R}^k \setminus \{0\})$. In particular we obtain from this observation together with Proposition 74.15 that the two sequences of vertical maps on the left and on the right are actually the same map.
(9) Using Corollary 74.16 (2a) and using the Excision Theorem 74.18 one can show fairly easily that all the vertical maps are isomorphisms and we see that the upper diagonal maps are isomorphisms. Since the triangles to the left and right commute we see that all diagonal maps are isomorphisms.
(10) It follows from (6), (7), (8) and (9) that the bottom triangle also commutes.

Now we are basically done with the proof for our special case. Indeed we see that

$$[f_*(\mathrm{id}_{\Delta^k})] \underset{\text{by (10)}}{\overset{\uparrow}{=}} \epsilon \cdot [\alpha_*(\mathrm{id}_{\Delta^k})] = \epsilon \cdot [\alpha] \underset{\text{since } \beta = 0 \in \mathrm{C}_k(S^n, S^n \setminus \{N\})}{\overset{\uparrow}{=}} \epsilon \cdot [\alpha - \beta]_Q \underset{\text{definition of } [S^k]}{\overset{\uparrow}{=}} \epsilon \cdot [S^k]_Q.$$

Now we still need to deal with the general case. In all likelihood few readers will have made it so far. So let us just sketch the ingredients for reducing the general case to the above special case:

(1) By the Orthogonal Action Lemma 5.26 (4) there exists an $A \in \mathrm{SO}(n+1)$ with $A \cdot Q = N$. By the discussion on page 419 the map $\varphi\colon S^n \to S^n$ that is given by $\varphi(x) = A \cdot x$ is homotopic to the identity.
(2) Every map $\varphi\colon \Delta^k \to S^k$ which contains N in its image is homotopic to some map $\psi\colon \Delta^k \to S^k_{\geq 0}$ into the upper hemispheres which has otherwise "the same properties".

We leave it to the reader to fill in the details. ■

Proof of the Standard Generator-Relationship Proposition 76.5 (2) and (3).

(2) We need to show that $f_*([\mathrm{id}_{\Delta^n}]) = (-1)^n \cdot [\overline{B}^n]$. To do so we recall the following maps:
  (a) As on page 1585 we denote by $i = i^n_n\colon \Delta^{n-1} \to \Delta^n$ the n-th face map that is given by $i(t_0, \ldots, t_{n-1}) = (t_0, \ldots, t_{n-1}, 0)$.
  (b) Below we will denote by ж the natural map from reduced homology to relative homology that we introduced in Lemma 74.12.

We consider the following diagram

$$\begin{array}{ccccccc}
\overset{[\mathrm{id}_{\Delta^n}]}{\mathrm{H}_n(\Delta^n,\partial\Delta^n)} & \xrightarrow{\partial} & \overset{\partial[\mathrm{id}_{\Delta^n}]}{\widetilde{\mathrm{H}}_{n-1}(\partial\Delta^n)} & \xrightarrow{\text{ж}} & \overset{\partial[\mathrm{id}_{\Delta^n}]=(-1)^n\cdot i_*([\mathrm{id}_{\Delta^{n-1}}])}{\mathrm{H}_{n-1}(\partial\Delta^n,\Lambda)} & \underset{\cong}{\overset{i_*}{\longleftarrow}} & \overset{(-1)^n\cdot[\mathrm{id}_{\Delta^{n-1}}]}{\mathrm{H}_{n-1}(\Delta^{n-1},\partial\Delta^{n-1})} \\
\downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & \swarrow{\scriptstyle (f\circ i)_*} & \\
\underset{[\overline{B}^n]}{\mathrm{H}_n(\overline{B}^n,S^{n-1})} & \xrightarrow{\partial} & \underset{[S^{n-1}]=[\alpha-\beta]}{\widetilde{\mathrm{H}}_{n-1}(S^{n-1})} & \xrightarrow{\text{ж}} & \underset{[\alpha-\beta]=[\alpha]}{\mathrm{H}_{n-1}(S^{n-1},S^{n-1}\setminus\{N\})} & \xleftarrow[\alpha_*]{} & \underset{[\mathrm{id}_{\Delta^{n-1}}]}{\mathrm{H}_i(\Delta^{n-1},\partial\Delta^{n-1})}.
\end{array}$$

(Here we put on top and above of the various groups the elements which will play a role in the subsequent argument.) Note that the diagram commutes by the Topological LES-Corollary 74.14 (2) and Lemma 74.12 (1). Now we see that we have the following equalities in $\mathrm{H}_{n-1}(S^{n-1},S^{n-1}\setminus\{N\})$:

$$\begin{array}{ccccccc}
 & & \text{since the diagram commutes} & & \text{we have } \text{ж}(\partial(\mathrm{id}_{\Delta^n}))=(-1)^n\cdot i_*(\mathrm{id}_{\Delta^{n-1}})\in \mathrm{C}_{n-1}(\partial\Delta^n,\Lambda) \text{ since all other summands of } \partial(\mathrm{id}_{\Delta^n}) \text{ are zero in } \mathrm{C}_{n-1}(\partial\Delta^n,\Lambda) & & \\
\text{ж}(\partial(f_*([\mathrm{id}_{\Delta^n}]))) & \overset{\downarrow}{=} & f_*(\text{ж}(\partial([\mathrm{id}_{\Delta^n}]))) & \overset{\downarrow}{=} & f_*((-1)^n\cdot i_*([\mathrm{id}_{\Delta^{n-1}}])) & = & (-1)^n\cdot[\alpha] \\
 & = & (-1)^n\cdot(f\circ i)_*([\mathrm{id}_{\Delta^{n-1}}]) & = & (-1)^n\cdot\alpha_*([\mathrm{id}_{\Delta^{n-1}}]) & & \\
 & & & & \uparrow & & \\
 & & \multicolumn{3}{c}{\text{we leave it to the reader to verify that } f\circ i\colon \Delta^{n-1}\to S^{n-1} \text{ and } \alpha\colon\Delta^{n-1}\to S^{n-1} \text{ are both orientation-preserving, thus the equality follows from Lemma 76.23}} & & \\
 & = & (-1)^n\cdot([\alpha-\beta]) & = & (-1)^n\cdot\text{ж}([S^{n-1}]) & = & (-1)^n\cdot\text{ж}(\partial([\overline{B}^n])). \\
 & & \uparrow & & \uparrow & & \uparrow \\
 & & \text{since } \beta=0\in \mathrm{C}_{n-1}(S^n,S^{n-1}\setminus\{N\}) & & \text{definition of } [S^{n-1}] & & \text{definition of } [\overline{B}^n]
\end{array}$$

As discussed earlier, by the various long exact sequences we know that the maps ∂ and ж are both isomorphisms. Thus we obtain from the above the desired equality $f_*([\mathrm{id}_{\Delta^n}])=(-1)^n\cdot[\overline{B}^n]$.

(3) We consider the following commutative diagram:

$$\begin{array}{ccccccc}
\mathrm{H}_n(\Delta^n,\partial\Delta^n) & \xrightarrow{f_*} & \mathrm{H}_n(\overline{B}^n,S^{n-1}) & \longrightarrow & \mathrm{H}_n(\overline{B}^n/S^{n-1},[S^{n-1}]) & \xrightarrow{g_*} & \mathrm{H}_n(S^n,*) \longleftarrow \mathrm{H}_n(S^n). \\
 & \searrow & & & & & \downarrow\cong \quad \swarrow \\
 & & & & & & \mathrm{H}_n(S^n,S^n\setminus\{-*\})
\end{array}$$

Let $\Phi\colon \triangle_n\to\Delta^n$ be the map that we introduced above. One can easily verify that the map $g\circ f\circ\Phi\colon \overset{\circ}{\triangle}_n\to S^n$ is orientation-preserving if and only if n is even. This observation, together with Lemma 76.23 implies that the image of $[\mathrm{id}_{\Delta^n}]$ in $\mathrm{H}_n(S^n,S^n\setminus\{-*\})$ under the diagonal map agrees with $[S^n]_{-*}$. Since the vertical map is an isomorphism we obtain the desired equality. ■

Exercises for Chapter 76.

Exercise 76.1. Let $n\in\mathbb{N}_0$ and let $P\in\overset{\circ}{\Delta}{}^n$. Show that $\mathrm{H}_n(\Delta^n,\Delta^n\setminus\{P\})=\mathbb{Z}\cdot[\mathrm{id}_{\Delta^n}]$.
Hint. Make use of the Identity-is-Generator Lemma 76.2.

Exercise 76.2. Let $n\in\mathbb{N}$. Let

$$\begin{array}{rcl}
\rho\colon\Delta^n & \to & \Delta^n \\
(t_0,t_1,t_2,\dots,t_n) & \mapsto & (t_1,t_0,t_2,\dots,t_n)
\end{array}$$

be the map that swaps the first two coordinates of Δ^n. Show that the induced map $\rho_*\colon \mathrm{H}_n(\Delta^n, \partial\Delta^n) \to \mathrm{H}_n(\Delta^n, \partial\Delta^n)$ is given by multiplication by -1.
Hint. First prove the statement for $n = 1$. Then use an induction argument similar to the proof of the Identity-is-Generator Lemma 76.2 (2). Hereby you need to use the naturality of the connecting homomorphism of the long exact sequence in homology of a pair of topological spaces.

Exercise 76.3. For which $n \in \mathbb{N}$ does there exist a singular simplex $\sigma\colon \Delta^n \to S^n$ that represents a generator of $\mathrm{H}_n(S^n)$?

Exercise 76.4. Let $f\colon \mathbb{R}^n \to \mathbb{R}^n$ be a map with $f(0) = 0$, with $f(\mathbb{R}^n \setminus \{0\}) \subset \mathbb{R}^n \setminus \{0\}$ and with $f(S^{n-1}) \subset S^{n-1}$. Show that

$$\deg(f_*\colon \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \to \mathrm{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})) \;=\; \deg(f_*\colon \mathrm{H}_{n-1}(S^{n-1}) \to \mathrm{H}_n(S^{n-1})).$$

Remark. The analogous statement also holds if we replace $\mathbb{R}^n$ by $\overline{B}^n$.

Exercise 76.5.

(a) Let $n \in \mathbb{N}_{\geq 2}$. Show that given any $k \in \mathbb{N}$ there exists a map $f\colon \overline{B}^n \to \overline{B}^n$ with $f(S^{n-1}) \subset S^{n-1}$ such that

$$\deg\big(f_*\colon \underbrace{\mathrm{H}_n(\overline{B}^n, S^{n-1})}_{\cong \mathbb{Z}} \to \mathrm{H}_n(\overline{B}^n, S^{n-1})\big) \;=\; k.$$

(b) Show that the conclusion of (a) does not hold for $n = 1$.

Exercise 76.6. On S^{2k} we had found a vector field which vanishes at *precisely two* points. Does there exist a vector field on S^2 which vanishes on only *one* point?

Exercise 76.7. Let $n \geq 1$. We consider the complex polynomial $g(z) = z^n$. Show that the degree of the map $\Theta(g)\colon S^2 \to S^2$ equals n.
Hint. Use the Local-Global Degree Proposition 76.21 and Proposition 76.20.

Exercise 76.8. Let X be a topological space. Suppose that the suspension $\Sigma(X)$ is a closed n-dimensional topological manifold. Show that X is a topological homology $(n-1)$-sphere, i.e. show that $\mathrm{H}_i(X) \cong \mathrm{H}_i(S^{n-1})$ for all $i \in \mathbb{N}_0$.
Remark. Also have a look at Exercise 76.9.

Exercise 76.9. Let $n \in \mathbb{N}_{\geq 3}$ and let M be a 0-connected space with non-trivial fundamental group.

(a) Show that the suspension $\Sigma(M)$ is *not* an n-dimensional topological manifold.
Hint. There are many different approaches one can take. One possibility is to study the fundamental group of $\Sigma(M)$ and to study the fundamental group of $\Sigma(M)$ with some points removed, and to use Exercise 52.3.

(b) Show that the suspension $\Sigma(M)$ is not a topological manifold of any dimension.

Remark. In Exercise 76.8 we just showed that if $\Sigma(M)$ is a closed n-dimensional topological manifold, then M is a topological homology $(n-1)$-sphere, i.e. $\mathrm{H}_i(M) \cong \mathrm{H}_i(S^{n-1})$ for all $i \in \mathbb{N}_0$. Together with (a) and the proof of the Poincaré Conjecture in all dimensions, see Chapter **??**, this shows that if $n \in \mathbb{N}_{\geq 2}$ and if M is a 0-connected n-dimensional topological manifold such that $\Sigma(M)$ is a topological manifold, then M is necessarily homeomorphic to S^n.

Exercise 76.10.

(a) We consider the map $f\colon S^1 \to S^1$ given by $(x, y) \mapsto (x, |y|)$. Show that the local degree at the point -1 is zero.

(b) Let $f\colon S^1 \to S^1$ be a map and let $z \in S^1$ be a nice point. Suppose that $\deg(f, z) = 1$. Does it follow that f is a local homeomorphism at z? It suffices to give a short justification for your answer.

Exercise 76.11. Let $f = f(z)$ be a polynomial with complex coefficients of degree ≥ 1. Let $\Theta(f)$ be the corresponding self-map of $S^2 = \mathbb{C} \cup \{\infty\}$ that we introduced on page 1693. Show that the local degree of $\Theta(f)$ at a root of $f(z)$ equals the multiplicity of the root.

Exercise 76.12. Let $n \in \mathbb{N}$ be even. Show that every map $f\colon \mathbb{R}\mathrm{P}^n \to \mathbb{R}\mathrm{P}^n$ has a fixed point.

Hint. Apply the Lift-to-Universal Coverings Proposition 61.13 to get a suitable map $\widetilde{f}\colon S^n \to S^n$. If $\deg(\widetilde{f}) \neq -1$, then we are basically done by the Sphere-Degree Fixed Point Theorem Theorem 38.11. What can we do if $\deg(\widetilde{f}) = -1$?

Exercise 76.13. Let $n \in \mathbb{N}_{\geq 2}$. In this exercise we identify S^{n-1} with the equatorial sphere $\{(x, 0) \in S^n \mid x \in S^{n-1}\}$.

(a) Let $f\colon S^n \to S^n$ be a map with $f(S^n_{\geq 0}) \subset S^n_{\geq 0}$ and with $f(S^n_{\leq 0}) \subset S^n_{\leq 0}$. Show that $\deg(f\colon S^n \to S^n) = \deg(f\colon S^{n-1} \to S^{n-1})$.

(b) Let $f\colon S^n \to S^n$ be a map with $f(S^n_{\geq 0}) \subset S^n_{\leq 0}$ and with $f(S^n_{\leq 0}) \subset S^n_{\geq 0}$. Show that $\deg(f\colon S^n \to S^n) = -\deg(f\colon S^{n-1} \to S^{n-1})$.

Exercise 76.14. Let X be a topological space. Given a homology class $\varphi \in \mathrm{H}_k(X)$ we define

$$\|\varphi\|_{\mathbb{Z}} \;:=\; \inf\Big\{ \sum_{i=1}^{n} |a_i| \;\Big|\; \sigma = \underbrace{\sum_{i=1}^{n} a_i \cdot \sigma_i}_{\text{with } \sigma_i \neq \sigma_j \text{ for } i \neq j} \text{ is a cycle with } [\sigma] = \varphi \in \mathrm{H}_k(X) \Big\}.$$

(a) Let X be a path-connected topological space. Show that for any $\varphi \in \mathrm{H}_1(X)$ we have $\|\varphi\|_{\mathbb{Z}} = 1$.

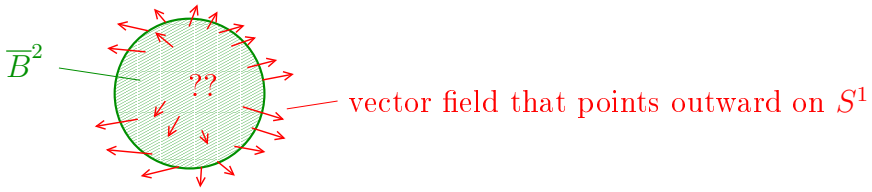
(b) Let $n \in \mathbb{N}$. Determine $\|[S^n]\|_{\mathbb{Z}}$.

Remark. The notation with the subscript "$\mathbb{Z}$" is used to distinguish this definition from the concept that we will introduce in Exercise 101.9.

Exercise 76.15. Let $f\colon S^n \to S^n$ be an orientation-preserving diffeomorphism. Show that f is homotopic to the identity.

Hint. You can easily arrange that f fixes say the North Pole $N = (0, \ldots, 0, 1)$. Now use Lemma 76.15 and push everything that is "awkward" into the South Pole.

Exercise 76.16. Given $z \in S^1$ we denote by $\Phi_z\colon S^2 \to S^2$ the map that is given by rotating S^2 along the z-axis by the angle z. The map



$$\begin{array}{rcl} G\colon S^1 \times S^2 & \to & S^1 \times S^2 \\ (z, v) & \mapsto & (z, \Phi_z(v)) \end{array}$$

is called the *Gluck twist*. Show that the Gluck twist is homotopic to the identity.

Hint. The exercise builds on Exercise 76.15.

Remark. The Gluck twist is in so far remarkable as it is not diffeotopic to the identity. This non-trivial fact is proved in [**Glue1962**, Chapter 5] and [**Wall1970**, p. 232].

Exercise 76.17. Let $n \in \mathbb{N}$. Show that every vector field on $\overline{B}^n$ that points outward on S^{n-1} admits at least one zero in $\overline{B}^n$.

Exercise 76.18. Let $k, l \in \mathbb{Z}$. We consider the sphere $S^3 = \{(z,w) \in \mathbb{C}^2 \,|\, |z|^2 + |w^2| = 1\}$ and the self-map

$$\begin{array}{rcl} f\colon S^3 & \to & S^3 \\ (z,w) & \mapsto & (z^k, w^l). \end{array}$$

Determine the degree of f.

Exercise 76.19. Let X be a topological space with subsets A, B, U, V and suppose that we have the following diagram of inclusion maps

$$\begin{array}{ccc} A & \xrightarrow{\ i\ } & U \\ \downarrow{\scriptstyle j} & & \uparrow{\scriptstyle k} \\ V & \xleftarrow{\ l\ } & B. \end{array}$$

Suppose that the inclusion induced maps i_*, j_*, k_*, l_* on the first homology groups are isomorphisms. Does it follow that $i_* \circ j_*^{-1} = k_* \circ l_*^{-1}\colon \mathrm{H}_1(V) \to \mathrm{H}_1(U)$?

Exercise 76.20. Let $n \in \mathbb{N}$ and let $f\colon S^n \times S^n \to S^n$ be a map. We pick $x_0, y_0 \in S^n$. We define the *bidegree* of f as

$$\mathrm{bideg}(f) := (p,q) \text{ where } p := \deg\begin{pmatrix} S^n & \xrightarrow{i} & S^n \\ x & \mapsto & f(x, y_0) \end{pmatrix} \text{ and } q := \deg\begin{pmatrix} S^n & \xrightarrow{j} & S^n \\ y & \mapsto & f(x_0, y) \end{pmatrix}.$$

(a) Show that the definition not depend on the choice of x_0 and y_0.

(b) Let $f\colon S^1 \times S^1 \to S^1$ be the map that is given by complex multiplication. Show that the bidegree of f equals $(1,1)$.
Remark. If you already know quaternions, perform the same exercise for the map $f\colon S^3 \times S^3 \to S^3$ that is given by quaternionic multiplication.

(c) Show that the map

$$\mathrm{H}_n(S^n) \oplus \mathrm{H}_n(S^n) \xrightarrow{i_* \oplus j_*} \mathrm{H}_n(S^n \times S^n) \xrightarrow{f_*} \mathrm{H}_n(S^n)$$

is of the form $\varphi \oplus \psi \mapsto p \cdot \varphi + q \cdot \psi$.

Exercise 76.21. Let $n \in \mathbb{N}$ and let G be a group that acts continuously on S^n. We suppose that the action of G is free. Recall that according to the definition on page 248 this means that for every $g \neq e$ and every $x \in S^n$ we have $g \cdot x \neq x$.

(a) Show that if n is even, then the map

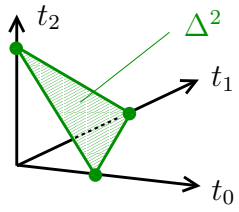
$$\begin{array}{ccc} G & \to & \{\pm 1\} \\ g & \mapsto & \deg\begin{pmatrix} S^n & \to & S^n \\ x & \mapsto & g\cdot x \end{pmatrix} \end{array}$$

is a monomorphism.

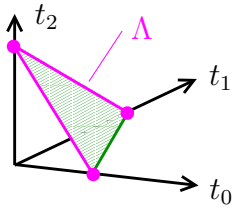
Remark. This exercise shows in particular that if a group admits a continuous free action on an even-dimensional sphere, then G has order at most 2. This gives in particular a complete answer to Question 48.8. We will give a different proof of this statement in Proposition 87.10.

(b) Show that the conclusion of (a) does not necessarily hold if n is odd.

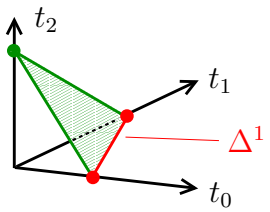
Exercise 76.22. Let $n \in \mathbb{N}_0$. We consider



$$\Lambda \;:=\; \bigcup_{i=0}^{n-1} \{(t_0,\ldots,t_n) \in \Delta^n \,|\, t_i = 0\},$$



i.e. Λ is the union of all $(n-1)$-dimensional faces of Δ^n except for the face given by $t_n = 0$. We make the identification



$$\Delta^{n-1} \;:=\; \{(t_0,\ldots,t_n) \in \Delta^n \,|\, t_n = 0\}.$$

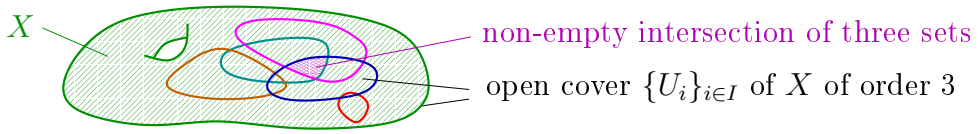
Let $f\colon \Delta^n \to \Delta^n$ be a map with $f(\Lambda) \subset \Lambda$, with $f(\Delta^{n-1}) \subset \Delta^{n-1}$ and which also satisfies $f(\partial\Delta^{n-1}) \subset \partial\Delta^{n-1}$. Show that

$$\deg\big(\mathrm{H}_n(\Delta^n,\partial\Delta^n) \xrightarrow{f_*} \mathrm{H}_n(\Delta^n,\partial\Delta^n)\big) \;=\; \deg\big(\mathrm{H}_{n-1}(\Delta^{n-1},\partial\Delta^{n-1}) \xrightarrow{f_*} \mathrm{H}_{n-1}(\Delta^{n-1},\partial\Delta^{n-1})\big).$$

77. The covering dimension of topological spaces II

Recall that in Chapter 11 we introduced the covering dimension of a topological space. Also recall that in Chapter 11 we managed to give upper bounds on the covering dimension for various topological spaces. For example in Proposition 11.11 we showed that for every subspace $X \subset \mathbb{R}^n$ we have $\operatorname{cdim}(X) \leq n$. But we failed to give any meaningful lower bounds on the covering dimension. Now, with the homology groups under our belt, we have the tools to rectify this issue. In particular we now have the tools to answer some questions that had occurred naturally, but that back then we could not answer.
First let us recall the following definition from page 369.

Definition. Let X be a topological space.



(1) A family $\{U_i\}_{i\in I}$ of subsets of X has order m if the following two statements hold:
   (a) There exists $J \subset I$ with $\#J = m$ such that $\bigcap_{j\in J} U_j \neq \varnothing$.
   (b) For every $J \subset I$ with $\#J > m$ we have $\bigcap_{j\in J} U_j = \varnothing$.

   If no such m exists, then we say that the family has infinite order.

(2) If X is non-empty, then we refer to

$$\operatorname{cdim}(X) \;:=\; \min\left\{ m \in \mathbb{N}_0 \cup \{\infty\} \;\middle|\; \begin{array}{c}\text{every open cover of } X \text{ admits an}\\ \text{open refinement of order} \leq m+1\end{array} \right\}$$

as the covering dimension of X. If X is empty, then we set $\operatorname{cdim}(X) := -1$.

The following is the main technical result of this section.

Theorem 77.1. Let $n \in \mathbb{N}_0$. The covering dimension of the standard n-simplex

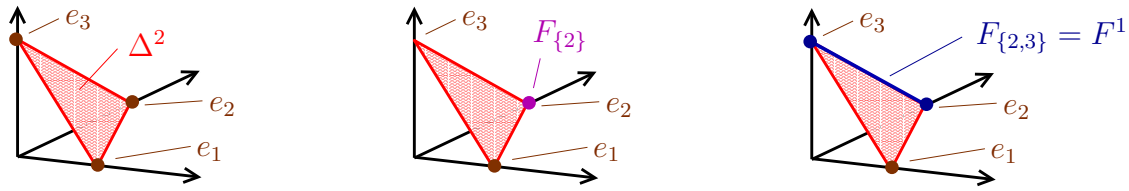
$$\Delta^n \;:=\; \{(x_0,\ldots,x_n) \in \mathbb{R}^{n+1} \,|\, x_0 + \cdots + x_n = 1 \text{ and } x_i \geq 0 \text{ for all } i = 0,\ldots,n\}$$

equals n.

Theorem 77.1 has many applications. For example, later in Theorem 77.4 we will use it to nail down the covering dimension of topological manifolds. But before we can revel in the applications, we first have to go through the hard slog of proving Theorem 77.1.
The proof of Theorem 77.1 requires some preparations. First let us recall the following definition from page 1582.

Definition. Let $n \in \mathbb{N}_0$. We denote by $e_1,\ldots,e_{n+1}$ the standard basis vectors of $\mathbb{R}^{n+1}$.

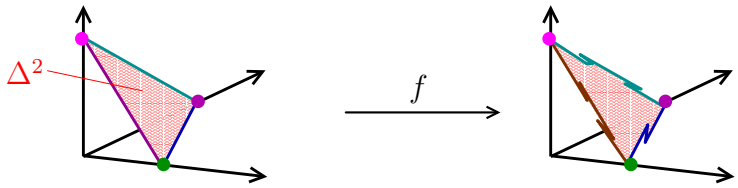
(1) Given a finite subset $K \subset \{1,\ldots,n+1\}$ with $r = \#K$ elements we refer to



$$\left\{ \sum_{k\in K} \lambda_k \cdot e_k \;\middle|\; \sum_{k\in K} \lambda_k = 1 \text{ and each } \lambda_k \in \mathbb{R}_{\geq 0} \right\} \;\subset\; \Delta^n$$

as an r-dimensional face of the standard n-simplex.

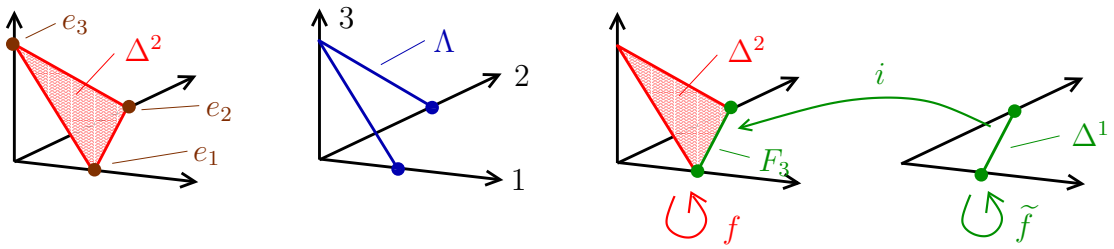
(2) Given $i \in \{1, \dots, n+1\}$ we denote by F^i the $(n-1)$-dimensional face that is given by the set $\{1, \dots, \widehat{i}, \dots, n+1\}$, i.e. we set



$$F^i := F_{\{1,\dots,\widehat{i},\dots,n+1\}} = \Big\{ \sum_{j=1}^{n+1} \lambda_j \cdot e_j \in \Delta_n \,|\, e_i = 0 \Big\}.$$

(3) As on page 1581 we write $\partial\Delta^n = \bigcup_{i=1}^{n+1} F_i$.

Auxiliary Lemma 77.2. Let $f\colon \Delta^n \to \Delta^n$ be a map. If f sends each face of Δ^n *into* itself, then[931] $f_*\colon \mathrm{H}_n(\Delta^n, \partial\Delta^n) \to \mathrm{H}_n(\Delta^n, \partial\Delta^n)$ is the identity, in particular it is an isomorphism.



Proof of Lemma 77.2. We prove the lemma by induction on n. The case $n = 0$ is basically trivial, it follows for example from the discussion on page 1594. So now suppose that the statement holds for some $n-1$. Let $f\colon \Delta^n \to \Delta^n$ be a map that sends each face of Δ^n into itself.

We introduce the following notation:

- As on page 1674 we denote by $\Lambda = F^1 \cup \dots \cup F^n$ the union of all $(n-1)$-dimensional faces of Δ^n except for the "last one", i.e. except for the $(n-1)$-dimensional face F^{n+1} that is given by $\{1, \dots, n\}$.
- We denote by $i\colon \Delta^{n-1} \to F^{n+1} \to \Delta^n$ the inclusion of Δ^{n-1} as the "last n-dimensional face", i.e. $i\colon \Delta^{n-1} \to F^{n+1} \to \Delta^n$ is the map given by $i(x) = (x, 0)$.
- The hypothesis that the map $f\colon \Delta^n \to \Delta^n$ sends each face of Δ^n into itself implies that $f(\Lambda) \subset \Lambda$, it implies that $f(\partial\Delta^n) \subset \partial\Delta^n$ and finally it implies that there exists a self-map $\widetilde{f}\colon \Delta^{n-1} \to \Delta^{n-1}$ such that $f \circ i = i \circ \widetilde{f}$. Note that $\widetilde{f}$ again has the property that it sends each face of Δ^{n-1} into itself.
- We denote by $\partial\colon \mathrm{H}_n(\Delta^n, \partial\Delta^n) \to \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda)$ the connecting homomorphism of the long exact sequence of the triple $(\Delta^n, \partial\Delta^n, \Lambda)$, see the Topological LES-Proposition 74.13 for details.

[931] Note that the hypothesis that f sends each face of Δ^n into itself implies that $f(\partial\Delta^n) \subset \partial\Delta^n$. Thus f does indeed induce a self-map of $\mathrm{H}_n(\Delta^n, \partial\Delta^n)$.

We obtain the following commutative diagram

$$\begin{array}{ccccc} \mathrm{H}_n(\Delta^n, \partial\Delta^n) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda) & \xleftarrow{i_*} & \mathrm{H}_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}) \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle \widetilde{f}_*} \\ \mathrm{H}_n(\Delta^n, \partial\Delta^n) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda) & \xleftarrow{i_*} & \mathrm{H}_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}). \end{array}$$

We make the following observations:

- The square to the left commutes by the naturality of the connecting homomorphism, see the Topological LES-Corollary 74.14. The square to the right commutes by the functoriality of homology groups and the fact that $f \circ i = ß \circ \widetilde{f}$.
- As on page 1675 we see that all of the horizontal maps are isomorphisms. For the reader's convenience we recall the argument. First note that the long exact sequence of the triple $(\Delta^n, \partial\Delta^n, \Lambda)$ looks as follows:

$$\underbrace{\mathrm{H}_n(\Delta^n, \Lambda)}_{\substack{=0 \text{ by Corollary 74.16 since} \\ \Lambda \text{ is a deformation} \\ \text{retract of } \Delta^n}} \xrightarrow{p} \mathrm{H}_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda) \xrightarrow{i_*} \underbrace{\mathrm{H}_{n-1}(\Delta^n, \Lambda).}_{\substack{=0 \text{ by Corollary 74.16 since} \\ \Lambda \text{ is a deformation} \\ \text{retract of } \Delta^n}}$$

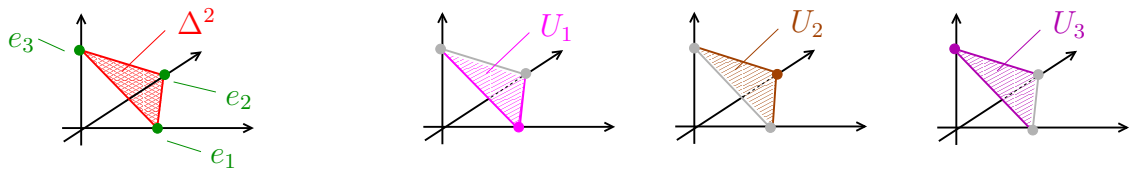
  Thus we see that the connecting homomorphism is an isomorphism. Now we turn our attention to the inclusion induced maps i_*. It follows from a variation on the Excision Theorem 74.17, namely Theorem 75.9, applied to $X = \partial\Delta^n$, $A = \Lambda$, $Z = \mathring{\Lambda}$ and $U = (0, \ldots, 0, 1)$[932] that the map

$$\mathrm{H}_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}) \;=\; \mathrm{H}_{n-1}(\underbrace{\partial\Delta^n \setminus \mathring{\Lambda}}_{=\Delta^{n-1}}, \underbrace{\Lambda \setminus \mathring{\Lambda}}_{=\partial\Delta^{n-1}}) \xrightarrow{i_*} \mathrm{H}_{n-1}(\partial\Delta^n, \Lambda)$$

  is an isomorphism.
- By induction hypothesis the right hand vertical map is the identity.
- It follows from the above that the left hand vertical map is also the identity. ■

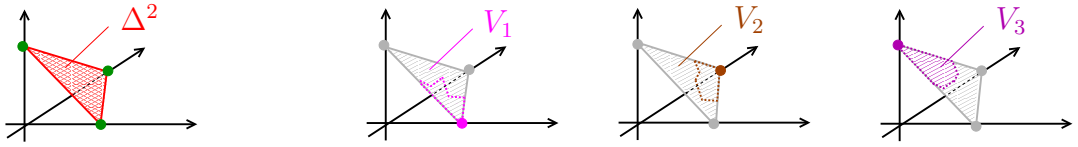
Before we head to the actual proof of Theorem 77.1 we recall, for the reader's convenience, the following lemma.

Lemma 11.2 Let X be a topological space with covering dimension $d := \mathrm{cdim}(X) \in \mathbb{N}_0$. Given any open cover $\{U_i\}_{i \in I}$ there exists an open cover $\{V_i\}_{i \in I}$ of order $\leq d+1$ such that for each $i \in I$ we have $V_i \subset U_i$.



[932] One can easily show that U has the property required in Theorem 75.9.

Proof of Theorem 77.1. Let $n \in \mathbb{N}_0$. We need to show that $\operatorname{cdim}(\Delta^n) = n$. By the Standard Simplex Homeomorphism Lemma 72.1 we know that Δ^n is homeomorphic to a compact subset of $\mathbb{R}^n$. Therefore it follows from Theorem 11.3 that $\operatorname{cdim}(\Delta^n) \leq n$. Thus it remains to show that $\operatorname{cdim}(\Delta^n) \geq n$. We assume by contradiction that $\operatorname{cdim}(\Delta^n) < n$.



We introduce some notation. Given $i \in \{1, \ldots, n+1\}$ we denote by F^i the $(n-1)$-dimensional face that is given by the set $\{1, \ldots, \widehat{i}, \ldots, n+1\}$, i.e.

$$F^i := F_{\{1,\ldots,\widehat{i},\ldots,n+1\}} = \left\{ \sum_{j=1}^{n+1} \lambda_j \cdot e_j \in \Delta_n \,|\, e_i = 0 \right\}.$$

Furthermore for $i = 1, \ldots, n+1$ we set $U_i := \Delta^n \setminus F^i$. Note that e_i is the only vertex of Δ^n that is contained in U_i. It is rather elementary to verify that each U_i is open in Δ^n. Furthermore, note that $U_1 \cup \cdots \cup U_{n+1} = \Delta^n$. In other words, $U_1, \ldots, U_{n+1}$ is an open cover of Δ^n. Since we assume that $\operatorname{cdim}(\Delta^n) < n$ we know, by Lemma 11.2, that there exists an

open refinement $\{V_1, \ldots, V_{n+1}\}$ of the open cover $\{U_1, \ldots, U_{n+1}\}$ of order $\leq n$ such that for each $i \in \{1, \ldots, n+1\}$ we have $V_i \subset U_i$.

Claim 1. There exists a partition of unity $\{\Phi_i \colon \Delta^n \to [0,1]\}_{i=1,\ldots,n+1}$ on Δ^n such that for each $i \in \{1, \ldots, n+1\}$ we have $\operatorname{supp}(\Phi_i) \subset V_i$.

Proof. In Lemma 10.1 we saw that it follows from the Paracompact-Criterion Lemma 10.2 that $\mathbb{R}^{n+1}$ is paracompact. We deduce from the Closed Subset-Paracompact Lemma 10.3 that the closed subset Δ^n is also paracompact. The statement now follows from the Paracompact-Partition of Unity Theorem 10.9 (1)⇒(3).[933] ⊞

Claim 2. The map

$$\begin{aligned} r \colon \Delta^n &\to \mathbb{R}^{n+1} \\ x &\mapsto \sum_{i \in \{1,\ldots,n+1\}} \Phi_i(x) \cdot e_i \end{aligned}$$

has the following properties:

(1) it sends each face of Δ^n into itself, in particular it sends Δ^n into itself,
(2) we have $r(\Delta^n) \subset \partial\Delta^n$.

Proof.

[933] Alternatively note that by the Standard Simplex Homeomorphism Lemma 72.1 we know that Δ^n is homeomorphic to $\overline{B}^n$, which implies easily that Δ^n is an n-dimensional topological manifold. Thus one can deduce Claim 1 from the Manifold-Partitions of Unity Existence Theorem 21.1

(1) Let $K \subset \{1, \ldots, n+1\}$ be a subset. As above we denote by

$$F_K \ := \ \Big\{ \sum_{k \in K} \lambda_k \cdot e_k \ \Big| \ \sum_{k \in K} \lambda_k = 1 \text{ and each } \lambda_k \in \mathbb{R}_{\geq 0} \Big\}$$

the corresponding face. We need to show that $f(F_K) \subset F_K$. We start out with the three observations:

(a) We have the following description of the face F_K:

$$F_K \ = \Big\{ \sum_{i=1}^{n+1} \lambda_i \cdot e_i \in \Delta^n \ \Big| \ \lambda_i = 0 \text{ if } i \notin K \Big\} = \bigcap_{i \notin K} F^i \ = \bigcap_{i \notin K} (\Delta^n \backslash U_i) \ = \ \Delta^n \backslash \Big(\bigcup_{i \notin K} U_i \Big).$$

(b) It follows from (a) that if $x \in F_K \cap U_i$, then $i \in K$.

(c) Let $x \in \Delta^n$. If $\Phi_i(x) \neq 0$, then $x \in \operatorname{supp}(\Phi_i) \subset V_i \subset U_i$.

Recall that we need to show that $r(F_K) \subset F_K$. Let $x \in F_K$. We calculate

$$r(x) \ \underset{\substack{\uparrow \\ \text{definition of } r}}{=} \ \sum_{i \in \{1,\ldots,n+1\}} \Phi_i(x) \cdot e_i \ \underset{\substack{\uparrow \\ \text{follows from (c)}}}{=} \ \sum_{i \ \in \ \{1,\ldots,n+1\} \text{ with } x \in U_i} \Phi_i(x) \cdot e_i \ \underset{\substack{\uparrow \\ \text{by (b) we know that } x \in F_K \cap U_i \\ \text{implies that } i \in K}}{=} \ \sum_{i \in K} \Phi_i(x) \cdot e_i \ \in \ F_K.$$

(2) Since the cover $\{V_i\}_{i \in \{1,\ldots,n+1\}}$ has order $\leq n$ we see that for each $x \in \Delta^n$ there exist at most n indices $i \in \{1, \ldots, n+1\}$ for which $\Phi_i(x) \neq 0$. But this means that $r(x)$ is the linear combination of at most n vertices, which means that $r(x) \in \bigcup_{i=1}^{n+1} F^i = \partial \Delta^n$. ⊞

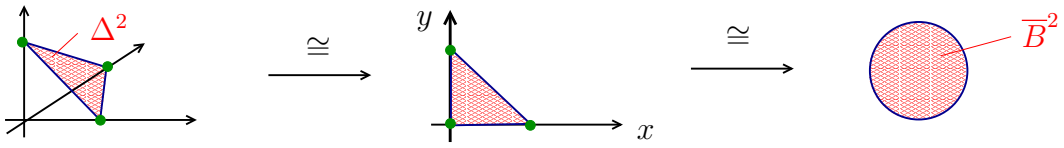
We consider the following diagram

$$\begin{array}{ccc} \mathrm{H}_n(\Delta^n, \partial\Delta^n) & \xrightarrow{\quad r_* \quad} & \mathrm{H}_n(\Delta^n, \partial\Delta^n). \\ & {\scriptstyle r_*} \searrow \quad \nearrow & \\ & \mathrm{H}_n(\partial\Delta^n, \partial\Delta^n) & \end{array}$$

We make the following observations:

- By Claim 2 (2) we know that $r(\partial\Delta^n) \subset \partial\Delta^n$. Thus we see that the top horizontal map is actually defined. Next with note that it follows from Claim 2 (2) together with Lemma 77.2 that the top horizontal map is an isomorphism.
- It follows from Claim 2 (3) that the top horizontal map factors through the bottom group.
- The bottom group is evidently zero.
- We know by the Identity-is-Generator Lemma 76.2 that the top groups are non-trivial.

The above four statements are incompatible. Thus we have found a contradiction to our hypothesis that $\operatorname{cdim}(\Delta^n) < n$. ■



Corollary 77.3. For each $n \in \mathbb{N}_0$ we have $\operatorname{cdim}(\overline{B}^n) = n$.

Proof. Note that

$$\operatorname{cdim}(\overline{B}^n) \ \underset{\substack{\uparrow \\ \text{by Lemmas 11.1 and 72.1}}}{=} \ \operatorname{cdim}(\Delta^n) \ \underset{\substack{\uparrow \\ \text{by Theorem 77.1}}}{=} \ n.$$

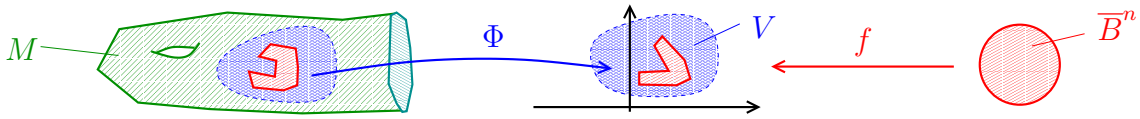
■

The name of the game is now to identify topological spaces that contained closed subsets that are homeomorphic to $\overline{B}^n$ or equivalently to Δ^n.

Theorem 77.4. Let $n \in \mathbb{N}_0$. Given any non-empty n-dimensional topological manifold M we have $\operatorname{cdim}(M) = n$.

Proof. Let M be a non-empty n-dimensional topological manifold. In the Covering Dimension-of-Manifolds Proposition 27.7 we already showed that $\operatorname{cdim}(M) \leq n$. Thus it remains to show that $\operatorname{cdim}(M) \geq n$.

Since M is non-empty there exists a chart $\Phi\colon U \to V$ where V is an open non-empty subset of $\mathbb{R}^n$ or $\mathbb{H}^n$. By pick an embedding $f\colon \overline{B}^n \to V$. Note that $\Phi^{-1} \circ f\colon \overline{B}^n \to M$ is an embedding. Now we see that



$$\operatorname{cdim}(M) \underset{\uparrow}{\geq} \operatorname{cdim}((\Phi^{-1} \circ f)(\overline{B}^n)) \overset{\downarrow}{=} \operatorname{cdim}(\overline{B}^n) \overset{\downarrow}{\geq} n.$$

this follows from the Closed Subspace Covering Dimension Lemma 11.5, since by the Compact Image Lemma 2.13 and the Compact-Closed Lemma 1.21 we know that $(\Phi^{-1} \circ f)(\overline{B}^n)$ is a closed subset

Lemma 11.1

Corollary 77.3

■

In Proposition 11.11 we showed that for every subset $X \subset \mathbb{R}^n$ we have $\operatorname{cdim}(X) \leq n$. We now have the following complementary result, which gives in particular an affirmative answer to Question 11.10.

Corollary 77.5. Let $X \subset \mathbb{R}^n$ be a subset. If the interior of X is non-empty, then $\operatorname{cdim}(U) = n$.

Proof. Let $X \subset \mathbb{R}^n$ be a subset with $\mathring{X} \neq \varnothing$. Note that by the Interior-Closure Lemma 1.9 we know that $\mathring{X}$ is an open subset of $\mathbb{R}^n$. It follows that there exists an embedding $f\colon \overline{B}^n \to \mathring{X}$. Now we see that

$$n \underset{\uparrow}{\geq} \operatorname{cdim}(X) \underset{\uparrow}{\geq} \operatorname{cdim}(f(\overline{B}^n)) \underset{\uparrow}{=} \operatorname{cdim}(\overline{B}^n) \underset{\uparrow}{\geq} n.$$

Proposition 11.11

by the Closed Subspace Covering Dimension Lemma 11.5 and since it follows from Lemmas 1.21 and 2.13 that $f(\Delta)^n)$ is a closed subset of M

Lemma 11.1

Corollary 77.3

■

Interestingly the converse to Corollary 77.5 holds:

Theorem 77.6. Given any subset $X \subset \mathbb{R}^n$ we have

$$\operatorname{cdim}(X) = n \iff \text{the interior of } X \text{ is non-empty.}$$

Proof. The "$\Leftarrow$"-direction is precisely the content of Corollary 77.5. The proof of the "$\Rightarrow$"-direction is given in [**Enge1978**, Theorem 1.8.10], except that the statement is formulated with the "inductive dimension" instead of the covering dimension. Also note that the

definition of "covering dimension" given in [**Enge1978**, Definition 1.6.7] differs slightly from our. But by [**Enge1978**, Theorem 1.7.7] and [**Enge1978**, Exercise 1.7.E] these three different notions of "dimension" agree for subsets of $\mathbb{R}^n$. ■

For completeness' sake we mention the following proposition which we will not make use of.

Proposition 77.7. Given any CW-complex X we have

$$\dim(X) \;=\; \operatorname{cdim}(X).$$

Proof. Let X be a CW-complex that contains an n-dimensional cell. Let $\Phi\colon \overline{B}^n \to X$ be the characteristic map of an n-cell. By the Characteristic Maps Lemma 68.7 we know that Φ is continuous. Furthermore, by definition, the restriction of Φ to $\overline{B}^n_{\frac{1}{2}} \to X$ is injective. Furthermore note that by the CW-Complex Properties Proposition 68.10 (1) we know that X is Hausdorff.

Since $\overline{B}^n_{\frac{1}{2}}$ is compact, since Φ is continuous and since X is Hausdorff we know by the Compact Image Lemma 2.13, the Compact-Closed Lemma 1.21 (2) and the Compact-Hausdorff Proposition 2.17 (2) that $\Phi\colon \overline{B}^n_{\frac{1}{2}} \to X$ is a closed embedding. Thus we see that

$$\begin{array}{ccccccc} \operatorname{cdim}(X) & \underset{\uparrow}{\geq} & \operatorname{cdim}(\Phi(\overline{B}^n_{\frac{1}{2}})) & \underset{\uparrow}{=} & \operatorname{cdim}(\overline{B}^n_{\frac{1}{2}}) & \underset{\uparrow}{=} & n. \\ & \text{Closed Subspace Covering Dimension Lemma 11.5} & & \text{Lemma 11.1} & & \text{Corollary 77.3} & \end{array}$$

This shows that $\operatorname{cdim}(X) \geq \dim(X)$. The reverse inequality is proved in [**FrPi1990b**, Theorem 4.4]. ■

Exercises for Chapter 77.

Exercise 77.1. We consider the cube $[-1,1]^n$. Given a subset $J = (j_1, \ldots, j_n) \in \{-1, 0, 1\}^n$ we define the corresponding J-face as the subset

$$F_J \;:=\; \{(x_1, \ldots, n_n) \in [-1,1]^n \,|\, \text{for every } i \in \{1, \ldots, n\} \text{ with } j_i \neq 0 \text{ we have } x_i = \epsilon_i\}.$$

Let $f\colon [-1,1]^n \to [-1,1]^n$ be a map that sends every J-face into itself. Show that f is surjective.

Exercise 77.2. Let $n \in \mathbb{N}$.

(a) Provide a finite set $\{M_j\}_{j \in J}$ of submanifolds of S^n such that the following statement holds: if $f\colon S^n \to S^n$ is a map such that for every $j \in J$ we have $f(M_j) \subset M_j$, then $f_*\colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n)$ is an isomorphism.

(b) What is the minimal cardinality for J that you can achieve?
Remark. The author does not know the answer, but evidently one should strive for minimal cardinality of J. If we allow all submanifolds, in particular open subsets, then the record is $n+2$. If we restrict ourselves to compact submanifolds, then the record is $2n+2$.

Exercise 77.3. Let X be an n-dimensional topological manifold. Show that for every subset $A \subset X$ the covering dimension A is $\leq n$.

78. The Mayer–Vietoris sequence and its applications

In this chapter we will state and prove the Mayer–Vietoris sequence for homology groups. It makes often allows us to compute the homology groups of a topological space from the homology groups of appropriate subspaces together with the knowledge of the nature of inclusion induced maps on homology.
The role of the Mayer–Vietoris sequence in homology theory is similar to the role of the Seifert–van Kampen Theorem 54.1 for fundamental groups. The Mayer–Vietoris sequence will give us the tool to compute the homology groups of many topological spaces that we are interested in. In particular we will determine the homology groups of $\mathbb{R}\mathrm{P}^2$, the torus and the Klein bottle.

78.1. **Split exact sequences.** We already saw in Theorem 74.3 that homology groups of different topological spaces are sometimes related by a long exact sequence of homology groups. The Mayer–Vietoris sequence that we will introduce later on in this chapter is another instance of such a long exact sequence. Very often one ends up in the situation that one knows the homology groups of two out of three topological spaces and hopefully one knows something about maps between these homology groups, and given this data one would like to determine the homology groups of the third topological space from the long exact sequence. Algebraically the question is as follows: suppose we are given an exact sequence

$$\ldots \to A_n \to B_n \to \mathrm{C}_n \to A_{n-1} \to \ldots$$

of abelian groups where we know the groups A_* and C_*, can we determine the groups B_* from this long exact sequence? The same question of course also arises when the roles of A, B and C are switched.
In this section we will study the simplest case, namely the case of a short exact sequence

$$0 \to A \to B \to C \to 0.$$

If we know A and C, can we read "read off" B from this short exact sequence? In general the answer is no. For example the short exact sequence

$$0 \to \mathbb{Z}_2 \longrightarrow B \longrightarrow \mathbb{Z}_2 \to 0$$

could be of the form

$$0 \to \mathbb{Z}_2 \xrightarrow{x\mapsto(x,0)} \mathbb{Z}_2 \oplus \mathbb{Z}_2 \xrightarrow{(x,y)\mapsto y} \mathbb{Z}_2 \to 0$$

but it could also be of the form[934]

$$0 \to \mathbb{Z}_2 \xrightarrow{x\mapsto 2x} \mathbb{Z}_4 \xrightarrow{x\mapsto x} \mathbb{Z}_2 \to 0.$$

In this short section we will give a criterion for when the naive guess $B \cong A \oplus C$ is actually the correct answer.

Definition. We say that a short exact sequence

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

of (not necessarily abelian) groups splits, if there exists a splitting $s\colon C \to B$, i.e. a homomorphism $s\colon C \to B$ such that $p \circ s = \mathrm{id}_C$.

[934] Are there any other possibilities for the isomorphism type of B?

For example the short exact sequence

$$0 \;\to\; \mathbb{Z} \;\xrightarrow{k\mapsto(k,0)}\; \mathbb{Z}\oplus\mathbb{Z}_n \;\xrightarrow{(k,l)\mapsto l}\; \mathbb{Z}_n \;\to\; 0$$

splits, in fact a splitting is given by the map $b \mapsto (0, b)$. On the other hand the short exact sequence

$$0 \;\to\; \mathbb{Z} \;\xrightarrow{k\mapsto nk}\; \mathbb{Z} \;\to\; \mathbb{Z}_n \;\to\; 0.$$

does not split.[935]

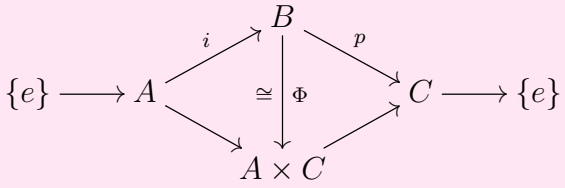
Lemma 78.1. Let

$$0 \;\to\; A \;\xrightarrow{i}\; B \;\xrightarrow{p}\; C \;\to\; 0$$

be a short exact sequence of abelian groups. If C is a free abelian group, then the short exact sequence splits.

Proof. Let $\{c_i\}_{i\in I}$ be a basis of the free abelian group C. For each $i \in I$ we choose a $b_i \in B$ with $p(b_i) = c_i$. By Lemma 51.1 there exists a unique homomorphism $s\colon C \to B$ with $s(c_i) = b_i$ for all i. We have $(p \circ s)(c_i) = c_i$ for each c_i. But then it follows from the uniqueness part of Lemma 51.1 that $p \circ s = \mathrm{id}_C$. The homomorphism s is thus indeed a splitting. ■

The following lemma gives two useful criteria for a short exact sequence to split.



Lemma 78.2. (Splitting Lemma) Let

$$\{e\} \;\to\; A \;\xrightarrow{i}\; B \;\xrightarrow{p}\; C \;\to\; \{e\}$$

be a short exact sequence of groups. The following two statements are equivalent:

(1) There exists a homomorphism $t\colon B \to A$ such that $t \circ i = \mathrm{id}_A$.

(2) There exists an isomorphism $\Phi\colon B \to A \times C$ such that the following diagram commutes:

where the lower left diagonal map is the obvious inclusion and the lower right diagonal map is the natural projection.

Furthermore, if B is abelian, then the above statements are also equivalent to the following statement:

(3) The short exact sequence splits.

Remark. If B is not abelian, then the implication (3) $\Rightarrow$ (1) of Splitting Lemma 78.2 does in general not hold. For example consider the sequence $0 \to \mathbb{Z}_3 \xrightarrow{\varphi} S_3 \xrightarrow{\sigma} \mathbb{Z}_2 \to 0$ where S_3 is as always the permutation group on the three elements, where $\varphi\colon \mathbb{Z}_3 \to S_3$ is the homomorphism given by $\varphi(1) = (1\,2\,3)$ and where $\sigma\colon S_3 \to \mathbb{Z}_2$ is the unique epimorphism from the permutation group S_3 onto $\mathbb{Z}_2$. A splitting of σ is given by $\varphi(1) = (1\,2)$. Since σ is also the only epimorphism from S_3 onto a non-trivial group we see that the sequence does not split, hence (1) is not satisfied.

[935] Why does it not split?

Proof.

(1)⇒(2) Let $t\colon B \to A$ be a homomorphism such that $t \circ i = \mathrm{id}_A$. We define

$$\begin{array}{rccc} \Phi\colon & B & \to & A \times C \\ & b & \mapsto & (t(b), p(b)). \end{array}$$

It follows easily from the exactness of the initial sequence that this map is in fact an isomorphism.[936] It is straightforward to verify that Φ has all the other desired properties.

(2)⇒(1),(3) Now suppose we are given an isomorphism $\Phi\colon B \to A \times C$ such that the given diagram commutes. It follows immediately from the definitions and given properties that the maps

$$B \xrightarrow{\Phi} A \times C \xrightarrow{(a,c)\mapsto a} A \quad \text{and} \quad C \xrightarrow{c\mapsto(0,c)} A \times C \xrightarrow{\Phi^{-1}} B$$

have the required properties.

Finally we assume that B is abelian.

(3)⇒(1) Let $s\colon C \to B$ be a splitting, i.e. let s be a homomorphism such that $p \circ s = \mathrm{id}_C$. We need to find an appropriate homomorphism $t\colon B \to A$. Since the sequence is exact, our task is basically the same as finding an appropriate homomorphism $B \to \ker(p)$. Let $b \in B$. We have

$$p(b - s(p(b))) \;=\; p(b) - \underbrace{(p \circ s)}_{=\mathrm{id}}(p(b)) \;=\; p(b) - p(b) \;= 0.$$

By the exactness of the short exact sequence there exists a unique $a \in A$ with $i(a) = b - s(p(b))$. We define $t(b) := a$. It follows easily from the fact that p and s are homomorphisms that the map $t\colon B \to A$ is a homomorphism. It remains to show that $t \circ i = \mathrm{id}_A$. Let $a \in A$. We have to show that $t(i(a)) - a = 0$. Since i is injective it suffices to show that $i(t(i(a))) - i(a) = 0$. We have

$$i(t(i(a))) - i(a) \underset{\substack{\uparrow \\ \text{since } t(y) \text{ is the unique element} \\ \text{with } i(t(y)) = y - s(p(y))}}{=} (i(a) - s(p(i(a)))) - i(a) \underset{\substack{\uparrow \\ \text{since } p \circ i = 0}}{=} i(a) - i(a) \;=\; 0.$$

■

In many applications we only need the following corollary that is an immediate consequence of Lemmas 78.1 and 78.2.

Corollary 78.3. (Direct Sum Corollary) Let

$$0 \;\to\; A \xrightarrow{i} B \xrightarrow{p} C \;\to\; 0$$

be a short exact sequence of abelian groups. Then the following hold:

(1) If C is a free abelian group, then $B \cong A \oplus C$.
(2) Suppose A and C are free abelian groups. If X is a basis for A and if $Y \subset B$ is a subset such that $p(Y)$ is a basis for C, then $X \sqcup Y$ is a basis for the free abelian group B.

Proof. The first statement is an immediate consequence of Lemmas 78.1 and 78.2. The second statement follows easily from Splitting Lemma 78.2 (1) ⇒ (3). We leave the details to the reader. ■

[936] In fact the argument is basically the same as in the proof of the Reduced Homology Lemma 74.1 (4a).

Example. Let B be an abelian group, let $b \in B$ and let $p\colon B \to \mathbb{Z}$ be a homomorphism with $p(b) = 1$. It follows immediately from the Direct Sum Corollary 78.3, applied to the short exact sequence $0 \to \ker(p) \to B \to \mathbb{Z} \to 0$, that we can write $B = K \oplus \mathbb{Z} \cdot b$ for some subgroup K that is isomorphic to $\ker(p)$.

The above discussion gives us tools for dealing with short exact sequence. The following lemma allows us to break a long exact sequence into shorter exact sequences.

Lemma 78.4. (Break-into-SES Lemma) Let

$$\ldots \to A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \to \ldots$$

be an exact sequence of abelian groups. Then for any n the sequences

$$0 \to \operatorname{coker}\left(A_{n+2} \xrightarrow{f_{n+2}} A_{n+1}\right) \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \to \ldots$$

and

$$\ldots \to A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} \ker\left(A_{n-1} \xrightarrow{f_{n-1}} A_{n-2}\right) \to 0$$

are also exact. In particular

$$0 \to \operatorname{coker}\left(A_{n+2} \xrightarrow{f_{n+2}} A_{n+1}\right) \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} \ker\left(A_{n-1} \xrightarrow{f_{n-1}} A_{n-2}\right) \to 0$$

is a short exact sequence.

Proof. The statements follow immediately from the definitions. We leave it to the reader to fill in the details. ■

Example. A typical application is that if we are given an exact sequence

$$\ldots A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n=0} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \xrightarrow{f_{n-2}} A_{n-3} \ldots$$

of abelian groups such that the map f_n is the zero map, then the exact sequence can be split "into the two halves" along that zero map, i.e.

$$0 \to A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \xrightarrow{f_{n-2}} A_{n-3} \ldots$$

and

$$\ldots A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \to 0$$

are also exact sequences. In the remainder of this course we will frequently use this fact without explicitly citing the Break-into-SES Lemma 78.4.

78.2. **The Mayer–Vietoris sequence.** In the following theorem and throughout the subsequent discussion we will use the following notation: given a topological space D and a subset $C \subset D$, we denote the corresponding inclusion map $C \to D$ by i_C. To avoid pandemonium with subscripts we often drop denote the inclusion induced maps on homology by i_C instead of the more accurate $(i_C)_*$.

Theorem 78.5. (Mayer–Vietoris Theorem) [937] Let X be a topological space and let $A, B \subset X$ be subsets such that $X = \mathring{A} \cup \mathring{B}$. Then the following two statements hold:

(1) For each $n \in \mathbb{N}$ there exists a unique homomorphism

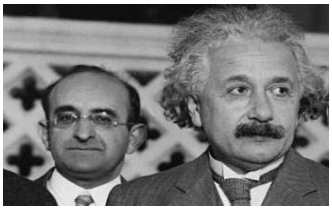
$$\partial_n\colon \mathrm{H}_n(X) \to \mathrm{H}_{n-1}(A \cap B)$$

which has the following property: for every $a \in \mathrm{C}_n(A)$ and $b \in \mathrm{C}_n(B)$ such that $a+b \in \mathrm{C}_n(X)$ is a cycle we have[938]

$$\partial_n([a+b]) \;=\; [\,\partial a\,] \;=\; -\,[\,\partial b\,] \;\in\; \mathrm{H}_{n-1}(A \cap B).$$

We refer to the maps $\partial_n \colon \mathrm{H}_n(X) \to \mathrm{H}_{n-1}(A \cap B)$ as the *connecting homomorphisms* corresponding to (X, A, B).

(2) The connecting homomorphism of (1) is natural in the following sense. Let X and Y be two topological spaces and let $A, B \subset X$ and $C, D \subset Y$ be subsets with $X = \mathring{A} \cup \mathring{B}$ and $Y = \mathring{C} \cup \mathring{D}$. If $f \colon X \to Y$ is a map with $f(A) \subset C$ and $f(B) \subset D$, then for every $n \in \mathbb{N}$ the following diagram commutes



$$\begin{array}{ccc} \mathrm{H}_n(X) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(A \cap B) \\ {\scriptstyle f_*}\downarrow & & \downarrow{\scriptstyle f_*} \\ \mathrm{H}_n(Y) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(C \cap D) \end{array}$$

where the horizontal maps are the connecting homomorphisms from (1).

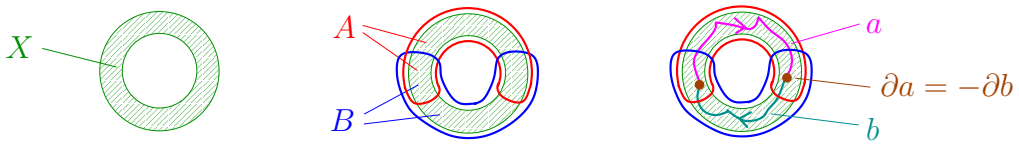
(3) The following sequence is exact:

$$\begin{array}{ccccccc} \ldots \to \mathrm{H}_n(A\cap B) & \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} & \mathrm{H}_n(A) \oplus \mathrm{H}_n(B) & \xrightarrow{i_A + i_B} & \mathrm{H}_n(X) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(A\cap B) \to \ldots \\ s & \longmapsto & (i_{A\cap B}(s), -i_{A\cap B}(s)) & & & & \\ & & & & s & \longmapsto & i_A(s) + i_B(s) \end{array}$$

Totally analogous statements also hold if we replace the homology groups of $A \cap B, A, B$ and X by the corresponding reduced homology groups.[939]

Walther Mayer (1887-1948) with some other person

Leopold Vietoris (1891-2002) at 110



The long exact sequence in Theorem 78.5 is usually called the *Mayer–Vietoris sequence* of the decomposition $X = A \cup B$.

Example. In the figure below we consider the annulus X together with two closed subsets A and B with $X = \mathring{A} \cup \mathring{B}$. Furthermore we show chains $a \in \mathrm{C}_1(A)$ and $b \in \mathrm{C}_1(B)$ such that $a+b$ form a cycle in $\mathrm{C}_1(X)$. The connecting homomorphism of the Mayer–Vietoris sequence sends $[a+b] \in \mathrm{H}_1(X)$ to $[\partial a] = -[\partial b] \in \mathrm{H}_0(A \cap B)$.

[937] Walther Mayer (1887-1948) and Leopold Vietoris (1891-2002) were two Austrian mathematicians. Vietoris was the longest living Austrian man ever.

[938] Here in the expression "∂a" we mean by ∂ the boundary map $\partial \colon \mathrm{C}_n(A) \to \mathrm{C}_{n-1}(A)$. In our case we will see that $\partial a \in \mathrm{C}_{n-1}(A \cap B) \subset \mathrm{C}_{n-1}(A)$. A similar statement holds for ∂b.

[939] Note though that for reduced homology groups we might need to use the fact, obtained in the Reduced Homology Lemma 74.1 (0), that $\widetilde{\mathrm{H}}_{-1}(\varnothing) = \mathbb{Z}$.

Remark.

(1) In many applications some of the inclusions appearing in Mayer–Vietoris Theorem 78.5 are homotopy equivalences, in particular, by the Homotopy Equivalence-H_*-Corollary 73.9 many of the inclusion induced maps on homology will be isomorphisms. If that is the case, then it is worth looking up Exercise 72.14 which might greatly simplify the calculations.

(2) Suppose that we are given a topological space X together with an open cover $\{U_i\}_{i\in I}$. If the cover consists of precisely two sets U_1 and U_2, then the Mayer–Vietoris Theorem 78.5 relates the homology groups of X, U_1, U_2 and the intersection $U_1 \cap U_2$. If the open cover consists of more than two sets, then the situation is much more tricky. In this more general setting the homology groups of X are related to the homology groups of the U_i and the homology groups of all finite intersections $U_{i_1} \cap \cdots \cap U_{i_m}$ via the "Mayer–Vietoris spectral sequence". We refer to [**LSVJ2011, Staf2015**], [**Dim2004**, Remark 2.3.9], [**TC2019**, Chapter 3] and [**BoT1982**, Chapter 15] for details. It is also worth having a look at Exercise 78.19.

Proof. Let X be a topological space and let $A, B \subset X$ be subsets such that $X = \mathring{A} \cup \mathring{B}$. There are two approaches to proving the Mayer–Vietoris Theorem 78.5.

The more elegant approach is as follows: In Exercise 78.1 we prove a purely algebraic statement, namely we construct the algebraic Mayer–Vietoris sequence. In Exercise 78.2 we use this exact sequence together with the Excision Theorem 74.17 and the long exact sequences of pairs of topological spaces to prove the desired statements. This approach allows us to prove Statements (2) and (3) of the Mayer–Vietoris Theorem 78.5 without working again on the "chain level".

In the following we will carry out the second approach. It works on the "chain level" and is thus arguably less conceptual. On the other hand it has the advantage that it is clearer "why it works". After this long preamble, let us remind the reader of the following notation from page 1638:

$$\mathrm{C}_n^{\{A,B\}}(X) \;:=\; \{a+b \,|\, a \in \mathrm{C}_n(A) \text{ and } b \in \mathrm{C}_n(B)\}.$$

The inclusion maps induce the following sequence of chain maps:

$$0 \to \mathrm{C}_*(A\cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{C}_*(A) \oplus \mathrm{C}_*(B) \xrightarrow{i_A + i_B} \mathrm{C}_*^{\{A,B\}}(X) \to 0.$$

Claim. The above sequence of chain maps is exact.

Proof. We prove the claim in the following four steps:

(a) It is clear that each of the maps $\mathrm{C}_*(A\cap B) \to \mathrm{C}_*(A)$ and $\mathrm{C}_*(A\cap B) \to \mathrm{C}_*(B)$ is already injective, in particular the map $i_{A\cap B} \oplus -i_{A\cap B}$ is injective.

(b) It is an immediate consequence of the definition of $\mathrm{C}_*^{\{A,B\}}(X)$ that the map $i_A + i_B$ is surjective.

(c) It follows immediately from the definitions that the composition of both maps is the zero map,[940] i.e. $\operatorname{im}(i_{A\cap B} \oplus -i_{A\cap B}) \subset \ker(i_A + i_B)$.

(d) It remains to show that $\ker(i_A + i_B) \subset \operatorname{im}(i_{A\cap B} \oplus -i_{A\cap B})$. Thus let $x \in \mathrm{C}_n(A)$ and $y \in \mathrm{C}_n(B)$ such that $(i_A + i_B)(x + y) = 0$. By definition this means that x and y, viewed as elements in $\mathrm{C}_n(X)$, satisfy $x = -y$. This means that x lies in $\mathrm{C}_n(A)$ and also in $\mathrm{C}_n(B)$. Put differently, $x \in \mathrm{C}_n(A) \cap \mathrm{C}_n(B) = \mathrm{C}_n(A \cap B)$. But then we have $(i_{A\cap B} \oplus -i_{A\cap B})(x) = x + y$. ⊞

Next we consider the following maps:

$$\begin{array}{ccccccccc} \ldots \longrightarrow \mathrm{H}_n(A\cap B) & \xrightarrow{i_{A\cap B}\oplus -i_{A\cap B}} & \mathrm{H}_n(A)\oplus\mathrm{H}_n(B) & \xrightarrow{i_A+i_B} & \mathrm{H}_n^{\{A,B\}}(X) & \xrightarrow{p_n} & \mathrm{H}_{n-1}(A\cap B) & \longrightarrow \ldots \\ & & & \searrow^{i_A+i_B} & \downarrow{\scriptstyle \Phi_n} & \nearrow_{:=\partial_n} & & \\ & & & & \mathrm{H}_n(X) & & & \end{array}$$

We make the following clarifications and observations:

(a) Given $n \in \mathbb{N}$ we denote by $p_n \colon \mathrm{H}_n^{\{A,B\}}(X) \to \mathrm{H}_{n-1}(A \cap B)$ the connecting homomorphism of the above short exact sequence of chain complexes, as defined on page 1620.

(b) By the LES Proposition 74.9 the top horizontal sequence is exact.

(c) It follows from the Comfortable Covering Proposition 74.23, together with our hypothesis that $X = \mathring{A} \cup \mathring{B}$, that for every $n \in \mathbb{N}_0$ the inclusion map

$$\mathrm{C}_*^{\{A,B\}}(X) \;\to\; \mathrm{C}_*(X)$$

induces an isomorphism

$$\Phi_n \colon \mathrm{H}_n^{\{A,B\}}(X) \;\xrightarrow{\cong}\; \mathrm{H}_n(X).$$

For each $n \in \mathbb{N}_0$ we now write $\partial_n := p_n \circ \Phi_n^{-1}$. It remains to show that these maps have the two desired properties stated in the theorem:

(3) It is clear from the above discussion that the sequence given in (3) is indeed exact.

(1) We leave it to the reader to verify that it follows from the definition of the connecting homomorphism p_n on page 1620 that for every $a \in \mathrm{C}_n(A)$ and $b \in \mathrm{C}_n(B)$ such that $a + b \in \mathrm{C}_n(X)$ is a cycle we have

$$\partial_n([a+b]) \;=\; p_n([a+b]) \;=\; [\partial a] \;=\; -\,[\partial b] \;\in\; \mathrm{H}_{n-1}(A \cap B).$$

Furthermore, the isomorphism $\Phi_n \colon \mathrm{H}_n^{\{A,B\}}(X) \xrightarrow{\cong} \mathrm{H}_n(X)$ shows that every element in $\mathrm{H}_n(X)$ is of the form $[a + b]$ for some $a \in \mathrm{C}_n(A)$ and $b \in \mathrm{C}_n(B)$, which implies that ∂_n is uniquely determined by the above rule.

(2) It follows basically immediately from the existence and uniqueness of the connecting homomorphisms ∂_n that these maps are also natural.

We leave it to the reader to verify, using the Reduced Homology Lemma 74.1, that the analogous statements also hold if we replace the homology groups of $A \cap B, A, B$ and X by the corresponding reduced homology groups. ■

The following lemma gives an alternative description of the connecting homomorphism of the Mayer–Vietoris sequence.

[940] Note that here we use the minus-sign that appears in the first map.

Lemma 78.6. Let X be a topological space and let A, B be two open subsets of X with $X = A \cup B$. The connecting homomorphism $\partial_n \colon \mathrm{H}_n(X) \to \mathrm{H}_{n-1}(A \cap B)$ equals the map

$$\mathrm{H}_n(X) \xrightarrow{\text{я}} \mathrm{H}_n(X, B) \xleftarrow[\uparrow]{\cong} \mathrm{H}_n(A, A \cap B) \xrightarrow[\uparrow]{\partial_n} \mathrm{H}_{n-1}(A \cap B).$$

inclusion induced map is an isomorphism by the Excision Theorem 74.17 — connecting homomorphism of pair $(B, A \cap B)$

Proof. This equality follows easily from the precise description of the connecting homomorphisms given in the Mayer–Vietoris Theorem 78.5 and in the Topological LES-Proposition 74.13. ■

We conclude this section with the following variation on the Mayer–Vietoris Theorem 78.5. This theorem might sound rather unnatural, but it will play an important role in the proof of the Non-Compact PD Theorem 119.18.

Theorem 78.7. (Inverted Mayer–Vietoris Theorem) Let X be a topological space and let U and V be open subsets. Then for all $n \in \mathbb{N}_0$ there exists a natural homomorphism $\partial_n \colon \mathrm{H}_n(X, U \cup V) \to \mathrm{H}_{n-1}(X, U \cap V)$ such that

$$\ldots \to \mathrm{H}_n(X, U \cap V) \xrightarrow{i \oplus -i} \mathrm{H}_n(X, U) \oplus \mathrm{H}_n(X, V) \xrightarrow{i+i} \mathrm{H}_n(X, U \cup V) \xrightarrow{\partial} \mathrm{H}_{n-1}(X, U \cap V) \to \ldots$$

is an exact sequence.

Proof. Note that as in the proof of Theorem 78.5 we have a short exact sequence

$$0 \;\to\; \mathrm{C}_n(X, U \cap V) \;\to\; \mathrm{C}_n(X, U) \oplus \mathrm{C}_n(X, V) \;\to\; \mathrm{C}_n(X) / \mathrm{C}_n^{\{U,V\}}(U \cup V) \;\to\; 0.$$

Thus we get a corresponding long exact sequence of homology groups. It suffices to show that the homology groups of the chain complex on the right are precisely the homology groups of the pair $(X, U \cup V)$. To do so we consider the following commutative pair of short exact sequences

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{C}_*^{\{U,V\}}(U \cup V) & \longrightarrow & \mathrm{C}_*(X) & \longrightarrow & \mathrm{C}_*(X) / \mathrm{C}_*^{\{U,V\}}(U \cup V) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{C}_*(U \cup V) & \longrightarrow & \mathrm{C}_*(X) & \longrightarrow & \mathrm{C}_*(X, U \cup V) & \longrightarrow & 0. \end{array}$$

We obtain the corresponding long exact sequence of homology groups:

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \mathrm{H}_n^{\{U,V\}}(U \cup V) & \longrightarrow & \mathrm{H}_n(X) & \longrightarrow & \mathrm{H}_n\big(\mathrm{C}_*(X) / \mathrm{C}_*^{\{U,V\}}(U \cup V)\big) & \longrightarrow & \mathrm{H}_{n-1}^{\{U,V\}}(U \cup V) & \longrightarrow & \ldots \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ \ldots & \longrightarrow & \mathrm{H}_n(U \cup V) & \longrightarrow & \mathrm{H}_n(X) & \longrightarrow & \mathrm{H}_n(X, U \cup V) & \longrightarrow & \mathrm{H}_{n-1}(U \cup V) & \longrightarrow & \ldots \end{array}$$

It follows from the Comfortable Covering Proposition 74.23 that the first and fourth vertical map are isomorphisms. The second map and the fifth map (which for space reasons is not shown) are the identity. Hence it follows from the Five Lemma 74.10 that the third vertical map is also an isomorphism. ■

78.3. **Applications of the Mayer–Vietoris sequence.** As a warm-up we first consider the homology groups of the suspension $\Sigma(X)$ of a topological space X. More precisely, we have the following lemma which basically gives a new proof for the Suspension-H_*-Proposition 76.7.

Proposition 76.7. (Suspension-H$_*$-Proposition) Let $k \in \mathbb{Z}$. Given any topological space X we have a natural isomorphism

$$\Sigma_X \colon \widetilde{\mathrm{H}}_k(X) \xrightarrow{\cong} \widetilde{\mathrm{H}}_{k+1}(\Sigma(X)).$$

Example. Let $n \in \mathbb{N}_0$. We perform the following calculation:

$$\begin{array}{ccccccc} \widetilde{\mathrm{H}}_k(S^n) & \cong & \widetilde{\mathrm{H}}_k(\Sigma(\ldots(\Sigma(S^0)))) & \cong & \widetilde{\mathrm{H}}_{k-n}(S^0) & \cong & \begin{cases} \mathbb{Z}, & \text{if } k=n, \\ 0, & \text{else.} \end{cases} \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{see page 452} & & \text{see the Suspension-H}_*\text{-Proposition 76.7} & & \text{see page 1597} & \end{array}$$

This recovers the calculation we made in Proposition 74.4.

Remark. Let X be a topological space. In Exercise 78.11 we will see that the two natural isomorphisms $\widetilde{\mathrm{H}}_k(\Sigma(X)) \xrightarrow{\cong} \widetilde{\mathrm{H}}_{k-1}(X)$ that we constructed in the Suspension-H$_*$-Proposition 76.7 and that we construct in the proof of the Suspension-H$_*$-Proposition 76.7 are actually the same on the nose.

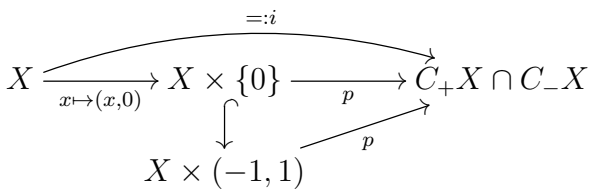
Proof. Let $k \in \mathbb{Z}$.

(1) Let X be a topological space. We denote by $p \colon X \times [-1,1] \to \Sigma(X)$ the natural projection. As on page 1681 we consider the subspaces $C_+ := C_+X = p(X \times (-1,1]))$ and $C_- := C_-X = p(X \times [-1,1))$. Note that C_+X and C_-X are both open subsets of $\Sigma(X)$ and that $\Sigma(X) = C_+X \cup C_-X$. We consider the corresponding long exact sequence in reduced homology from the Mayer–Vietoris Theorem 78.5:

$$\underbrace{\widetilde{\mathrm{H}}_{k+1}(C_+)}_{=0} \oplus \underbrace{\widetilde{\mathrm{H}}_{k+1}(C_-)}_{=0} \longrightarrow \widetilde{\mathrm{H}}_{k+1}(\Sigma(X)) \xrightarrow{\partial_k} \widetilde{\mathrm{H}}_k(C_+ \cap C_-) \longrightarrow \underbrace{\widetilde{\mathrm{H}}_{k+1}(C_+)}_{=0} \oplus \underbrace{\widetilde{\mathrm{H}}_{k+1}(C_-)}_{=0}$$

$$\widetilde{\mathrm{H}}_k(X) \xrightarrow{\Sigma_X} \widetilde{\mathrm{H}}_{k+1}(\Sigma(X)) \qquad \widetilde{\mathrm{H}}_k(X) \xrightarrow{i_*} \widetilde{\mathrm{H}}_k(C_+ \cap C_-)$$

We make the following clarifications and observations:



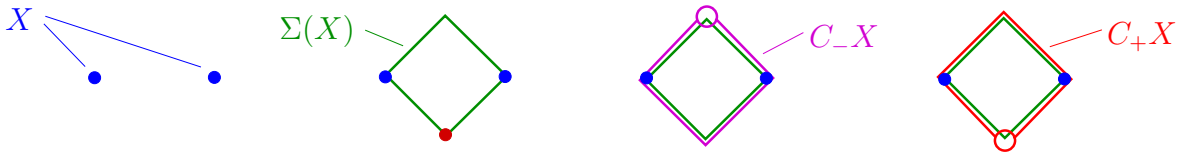
(a) Note that by the same argument as in the proof of the Cone Contractibility Lemma 16.7 we see that both $C_+ = C_+X$ and $C_- = C_-X$ admit a deformation retraction to a point. It follows from the Deformation Retract-Homotopy Equivalence Lemma 15.5 that both C_+ and C_- are contractible, therefore we know by the Reduced Homology Lemma 74.1 (7) the reduced homology groups of C_+X and C_-X vanish.

(b) It follows immediately from (1) that the connecting homomorphism

$$\partial \colon \widetilde{\mathrm{H}}_{k+1}(\Sigma(X)) \to \widetilde{\mathrm{H}}_k(C_+X \cap C_-X)$$

is in fact an isomorphism.

(c) We consider the following little diagram:



The vertical map is evidently a homotopy equivalence. Furthermore one can easily show, either by hand, or using Lemma 74.21 (1), that the diagonal map is a homeomorphism. We obtain that the map $i\colon X \to C_+X \cap C_-X$ is a homotopy equivalence. Thus we obtain from the Reduced Homology Lemma 74.1 (6) that the induced map $i_*\colon \widetilde{\mathrm{H}}_k(X \times \{0\}) \to \widetilde{\mathrm{H}}_k(C_+X \cap C_-X)$ is an isomorphism.

We define Σ_X to be the map

$$\widetilde{\mathrm{H}}_k(X) \;=\; \widetilde{\mathrm{H}}_k(X \times \{0\}) \xrightarrow{i_*} \widetilde{\mathrm{H}}_k(C_+X \cap C_-X) \xrightarrow{\partial_k^{-1}} \widetilde{\mathrm{H}}_{k+1}(\Sigma(X)).$$

(2) It follows easily from the definition of Σ_X and the naturality of the connecting homomorphisms of the Mayer–Vietoris sequence, see Theorem 78.5 (2), that the isomorphism Σ_X is natural. ∎

As our next example we want to determine the homology groups of the 2-dimensional projective space $\mathbb{R}\mathrm{P}^2$.

Lemma 78.8. Let $n \in \mathbb{N}_0$. We have

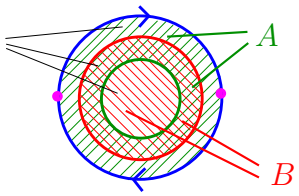
$$\mathrm{H}_n(\mathbb{R}\mathrm{P}^2) \;\cong\; \begin{cases} 0, & \text{if } n \geq 2, \\ \mathbb{Z}_2, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

Remark. In Exercise 78.10 we will determine an explicit cycle that represents the unique non-trivial element of $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2)$.

Proof. In the proof of Lemma 78.8 we use the description from page 258 of $\mathbb{R}\mathrm{P}^2$ as

$$\mathbb{R}\mathrm{P}^2 \;=\; \overline{B}^2/\!\sim \qquad \text{where } x \sim y \text{ if } x, y \in \partial\overline{B}^2 \text{ and } x = -y.$$

In the following we denote by p the projection $\overline{B}^2 \to \overline{B}^2/\!\sim$. We consider the open subsets



$$A \;:=\; p\big(\big\{z \in \overline{B}^2 \,\big|\, |z| > \tfrac{1}{4}\big\}\big) \qquad \text{and} \qquad B \;:=\; p\big(\big\{z \in \overline{B}^2 \,\big|\, |z| < \tfrac{3}{4}\big\}\big).$$

Evidently we have $\mathring{A} \cup \mathring{B} = A \cup B = \mathbb{R}\mathrm{P}^2$. From the Mayer–Vietoris Theorem 78.5 we obtain the following long exact sequence of reduced homology groups:

$$\cdots \to \widetilde{\mathrm{H}}_2(A) \oplus \widetilde{\mathrm{H}}_2(B) \to \widetilde{\mathrm{H}}_2(\mathbb{R}\mathrm{P}^2) \xrightarrow{\partial} \widetilde{\mathrm{H}}_1(A \cap B) \to \widetilde{\mathrm{H}}_1(A) \oplus \widetilde{\mathrm{H}}_1(B) \to \widetilde{\mathrm{H}}_1(\mathbb{R}\mathrm{P}^2) \to \ldots$$

Now we have to collect all the available information on the reduced homology groups of

$\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\!\sim$

A, B and $A \cap B$. We make the following observations:

(1) We remarked on page 1612 that the reduced homology of a disk vanishes, i.e. we have $\widetilde{\mathrm{H}}_n(B) = 0$ for all $n \in \mathbb{N}_0$.

(2) Note that $p(\frac{1}{2}S^1)$ is a deformation retract of $A \cap B = p(\{z \in \overline{B}^2 \,|\, |z| \in (\frac{1}{4}, \frac{3}{4})\})$. This implies that the map $j\colon S^1 \to A \cap B = p\big(\{z \in \overline{B}^2 \,|\, |z| \in (\frac{1}{4}, \frac{3}{4})\}\big)$ given by $z \mapsto \frac{1}{2}z$ is a homotopy equivalence. It follows from the Homotopy Equivalence-H_*-Corollary 73.9 (2) and Proposition 74.4 that $\widetilde{\mathrm{H}}_n(A \cap B) = 0$ for $n \neq 1$ and that $j_*\colon \widetilde{\mathrm{H}}_1(S^1) \to \widetilde{\mathrm{H}}_1(A \cap B)$ is an isomorphism.

(3) We consider the retraction

$$\begin{array}{rcl} r\colon A & \to & \{z \in \partial\overline{B}^2\}/z \sim -z \\ p(s\exp(\mathrm{i}\varphi)) & \mapsto & \exp(\mathrm{i}\varphi) \end{array}$$

which is easily seen to be a homotopy equivalence and we also consider the homeomorphism

$$\begin{array}{rcl} f\colon \{z \in \partial\overline{B}^2\}/z \sim -z & \to & S^1 \\ z & \mapsto & z^2. \end{array}$$

As in (2) it follows that $\widetilde{\mathrm{H}}_n(A) = 0$ for $n \neq 1$ and that $(f \circ r)_*\colon \widetilde{\mathrm{H}}_1(A) \to \widetilde{\mathrm{H}}_1(S^1)$ is an isomorphism.

The above Mayer–Vietoris sequence is thus in our case of the following form:

$$\begin{array}{l} \ldots \to 0 \to \widetilde{\mathrm{H}}_3(\mathbb{R}\mathrm{P}^2) \to 0 \to 0 \to \widetilde{\mathrm{H}}_2(\mathbb{R}\mathrm{P}^2) \xrightarrow{\partial} \widetilde{\mathrm{H}}_1(A \cap B) \xrightarrow{\quad i_* \quad} \widetilde{\mathrm{H}}_1(A) \xrightarrow{i_*} \widetilde{\mathrm{H}}_1(\mathbb{R}\mathrm{P}^2) \to 0 \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad {\scriptstyle j_*}\uparrow{\scriptstyle \cong} \qquad\qquad\qquad\qquad\quad {\scriptstyle \cong}\downarrow{\scriptstyle (f\circ r)_*} \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \mathrm{H}_1(S^1) \xrightarrow[\cdot \deg(f\circ r\circ i\circ j)]{(f\circ r\circ i\circ j)_*} \mathrm{H}_1(S^1). \end{array}$$

We obtain immediately that $\widetilde{\mathrm{H}}_n(\mathbb{R}\mathrm{P}^2) = 0$ for $n \geq 3$. Furthermore it follows immediately from the definitions that the map $f \circ r \circ i \circ j\colon S^1 \to S^1$ is given by $z \mapsto z^2$. By Lemma 76.10 this implies that $\deg(f \circ r \circ i \circ j) = 2$. Thus we obtain the following exact sequence

$$0 \;\to\; \widetilde{\mathrm{H}}_2(\mathbb{R}\mathrm{P}^2) \;\to\; \mathbb{Z} \;\xrightarrow{\cdot 2}\; \mathbb{Z} \;\to\; \widetilde{\mathrm{H}}_1(\mathbb{R}\mathrm{P}^2) \;\to\; 0.$$

It follows from the discussion on page 1614 that

$$\widetilde{\mathrm{H}}_2(\mathbb{R}\mathrm{P}^2) \cong \ker\big(\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}\big) = 0 \quad \text{and} \quad \widetilde{\mathrm{H}}_1(\mathbb{R}\mathrm{P}^2) \cong \operatorname{coker}\big(\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}\big) = \mathbb{Z}_2. \qquad \blacksquare$$

Remark. It is a non-trivial, but certainly very amusing exercise to generalize the calculation of Lemma 78.8 to compute the homology groups of any real projective space $\mathbb{R}\mathrm{P}^n$. We cordially invite the reader to try to make an educated guess of what the homology groups of $\mathbb{R}\mathrm{P}^n$ might be. We will compute the homology groups later on in Proposition 80.11 using a somewhat different approach.

78.4. **The Mayer–Vietoris Theorem for manifolds and CW-complexes.** Recall that when we studied fundamental groups we first proved the Seifert–van Kampen Theorem 54.1 for the decomposition of a topological space X into two *open* subsets. Afterwards we showed in Theorem 54.4 and Theorem 69.1 that an analogous statement holds if we decompose a smooth manifold into suitable submanifolds and if we decompose a CW-complex into subcomplexes.

In a similar fashion we now state and prove the "manifold version" and the "CW-complex version" of the Mayer–Vietoris Theorem 78.5.

Theorem 78.9. (Mayer–Vietoris Theorem for Topological Manifolds) Let X be an m-dimensional topological manifold and let $A, B \subset X$ be two m-dimensional submanifolds such that the following statements hold:

(a) $X = A \cup B$,
(b) $A \cap B$ is a union of components of ∂A and it is a union of components of ∂B,
(c) A and B are closed subsets of X. (Note that by the Compact-Closed Lemma 1.21 (2) this condition is satisfied if A and B are compact.)

The following three statements hold:

(1) For each $n \in \mathbb{N}_0$ there exists a unique homomorphism $\partial_n \colon \mathrm{H}_n(X) \to \mathrm{H}_{n-1}(A \cap B)$ which has the following property: If we are given $a \in \mathrm{C}_n(A)$ and $b \in \mathrm{C}_n(B)$ are such that $a + b \in \mathrm{C}_n(X)$ is a cycle, then

$$\partial_n([a+b]) \;=\; [\partial a] \;=\; -\,[\partial b] \;\in\; \mathrm{H}_{n-1}(A \cap B).$$

(2) The following sequence is exact:

$$\ldots \to \mathrm{H}_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n(A) \oplus \mathrm{H}_n(B) \xrightarrow{i_A + i_B} \mathrm{H}_n(X) \xrightarrow{\partial_n} \mathrm{H}_{n-1}(A \cap B) \to \ldots$$

(3) The connecting homomorphism $\partial_n \colon \mathrm{H}_n(X) \to \mathrm{H}_{n-1}(A \cap B)$ equals the map

$$\mathrm{H}_n(X) \xrightarrow{\text{я}} \mathrm{H}_n(X, B) \xleftarrow[\uparrow]{\cong} \mathrm{H}_n(A, A \cap B) \xrightarrow[\uparrow]{\partial_n} \mathrm{H}_{n-1}(A \cap B).$$

inclusion induced map is an isomorphism by the Excision Theorem 75.10

connecting homomorphism of pair $(B, A \cap B)$

A totally analogous statement also holds if we replace the homology groups of $A \cap B, A, B$ and X by the corresponding reduced homology groups.

Proof. Let X be an m-dimensional topological manifold and let $A, B \subset X$ be two m-dimensional submanifolds such that$A$ and B are closed subset of M, such that $X = A \cup B$ and such that $A \cap B$ is a union of components of ∂A and also a union of components of ∂B.

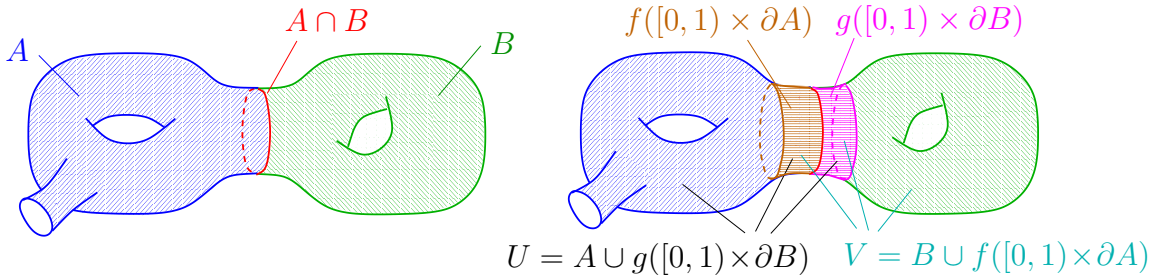
We pick maps $f \colon [0,1) \times \partial A \to A$ and $g \colon [0,1) \times \partial B \to B$ that are provided by the Topological Collar Neighborhood Theorem 75.5[941] We set

$$U \;:=\; A \cup \underbrace{(g([0,1) \times (A \cap B))}_{\subset [0,1) \times B} \quad \text{and} \quad V \;:=\; B \cup \underbrace{(f([0,1) \times (A \cap B))}_{\subset [0,1) \times A}.$$

As in the proof of Theorems 52.10 and 54.4 we note that the following statements hold:

(i) U and V are open subsets of X,[942]
(ii) A is a deformation retract of U,
(iii) B is a deformation retract of V, and
(iv) $A \cap B$ is a deformation retract of $U \cap V$.

[941] Of course, if X is a smooth manifold, then we could also use the Smooth Collar Neighborhood Theorem 28.3.
[942] At this point we secretly use our hypothesis that A and B are closed subsets of X.



Now we consider the following diagram

$$\begin{array}{ccccccccccc}
\dots & \dashrightarrow & \mathrm{H}_n(A\cap B) & \xrightarrow{i\oplus -i} & \mathrm{H}_n(A)\oplus \mathrm{H}_n(B) & \xrightarrow{i+i} & \mathrm{H}_n(X) & \overset{\partial_n}{\dashrightarrow} & \mathrm{H}_{n-1}(A\cap B) & \longrightarrow & \dots \\
 & & \downarrow & & \downarrow & & \downarrow \mathrm{id} & & \downarrow & & \\
\dots & \longrightarrow & \mathrm{H}_n(U\cap V) & \xrightarrow{i\oplus -i} & \mathrm{H}_n(U)\oplus \mathrm{H}_n(V) & \xrightarrow{i+i} & \mathrm{H}_n(X) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(U\cap V) & \longrightarrow & \dots
\end{array}$$

where the bottom sequence is given by the Mayer–Vietoris Theorem 78.5. We make the following observations:

(a) The two squares to the left commute since all the relevant maps are given by inclusions.
(b) The vertical maps are isomorphisms by the Homotopy Equivalence-H_*-Corollary 73.9.
(c) By (ii) we can now define the dotted map $\mathrm{H}_n(X) \overset{\partial_n}{\longrightarrow} \mathrm{H}_{n-1}(A\cap B)$ such that the third square also commutes.

It now follows from the Mayer–Vietoris Theorem 78.5 that the sequence in (2) is exact. We leave the somewhat technical task of verifying Statement (1) to the reader. Finally note that, as in the proof of Lemma 78.6, Statement (3) is a straightforward consequence of the descriptions of the various maps. ■

Now we turn to CW-complexes.

Theorem 78.10. (Mayer–Vietoris Theorem for CW-complexes) Let X be a CW-complex. If A and B are two subcomplexes of X such that $X = A \cup B$, then basically exactly the same conclusion as in the Mayer–Vietoris Theorem 78.9 for Manifolds holds.[943]

Proof. Let X be a CW-complex and let A and B be two subcomplexes of X with $X = A \cup B$. By the CW-Complex Properties Proposition 68.10 (8) there exist open neighborhoods U of A and V of B such that the following statements hold:

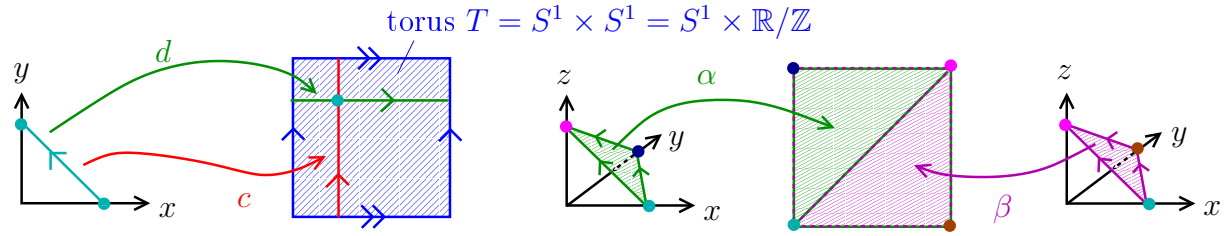
(1) A is a deformation retract of U,
(2) B is a deformation retract of V, and
(3) $A \cap B$ is a deformation retract of $U \cap V$.

The proof is now verbatim the same as the proof of the Mayer–Vietoris Theorem 78.9 for Topological Manifolds. ■

Later on in Theorem 109.14 we will generalize the above Mayer–Vietoris theorems to an even more general setting, namely to "excisive triads". But for the time being we will be able to handle most situations with the Mayer–Vietoris theorems that we stated above.

[943] In Statement (3) we just need to replace the Excision Theorem 75.10 for Topological Manifolds by the Excision Theorem 74.31 for CW-complexes.

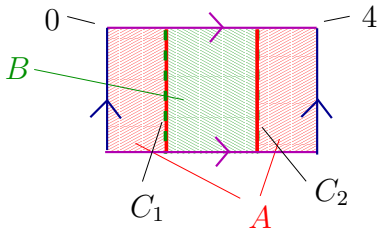
78.5. **The homology groups of the torus and the Klein bottle.** In this section we will determine the homology groups of the torus and the Klein bottle. We do so partly since the results are interesting, but partly also to get to some practice for applying the various Mayer–Vietoris Theorems.



Lemma 78.11. Let $T = S^1 \times S^1$ be the torus. The following two statements hold.

(1) We have the following isomorphisms

$$\mathrm{H}_n(T) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 2, \\ \mathbb{Z}^2, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$



(2) The homology groups are generated by the following cycles.[944]
   (a) The singular 1-simplices c and d shown in the figure below on the left are generators for $\mathrm{H}_1(T) \cong \mathbb{Z}^2$.
   (b) The singular 2-chain $\alpha - \beta$ that is given by the singular 2-simplices α and β shown in the figure below on the right is a generator for $\mathrm{H}_2(T) \cong \mathbb{Z}$. Note that this singular 2-chain is precisely the one that we had already considered in the figure below. In particular this answers our question from page 1589, the cycle $\alpha - \beta$ does indeed represent a non-trivial element in $\mathrm{H}_2(T)$.

Note that Lemma 78.11 (2) shows in particular that the cycles considered in the figure below represent non-trivial homology classes.

To increase readability we break the proof of Lemma 78.11 into two parts.

Proof of Lemma 78.11 (1). First we point out that throughout the proof we identify the torus T with $S^1 \times \mathbb{R}/4\mathbb{Z}$ in the obvious way. Next we introduce some notation. We denote by $p\colon S^1 \times \mathbb{R} \to T = S^1 \times \mathbb{R}/4\mathbb{Z}$ the projection . In the following we write $A := p(S^1 \times ([0,1] \cup [3,4]))$ and $B := p(S^1 \times [1,3])$. Evidently we have $T = A \cup B$. Furthermore we write $\mathrm{C}_1 := p(S^1 \times \{1\})$ and $\mathrm{C}_2 := p(S^1 \times \{3\})$. Evidently we have $A \cap B = \mathrm{C}_1 \cup \mathrm{C}_2$.

[944] Here the singular simplices in the figure below are understood to be given by the obvious affine maps $\Delta^n \to ([0,1] \times [0,1])/\sim$.

It is fairly easy[945] to verify that the hypotheses for the Mayer–Vietoris Theorem 78.9 for Manifolds are satisfied for $T = A \cup B$. Thus we obtain the following long exact sequence in homology[946]

$$\begin{array}{ccccccccc} & & & & \dots & \to & \mathrm{H}_2(T) & \xrightarrow{\partial} & \\ \to & \begin{matrix}\mathrm{H}_1(\mathrm{C}_1)\\ \mathrm{H}_1(\mathrm{C}_2)\end{matrix} & \xrightarrow{\begin{pmatrix} i_{\mathrm{C}_1} & i_{\mathrm{C}_2} \\ -i_{\mathrm{C}_1} & -i_{\mathrm{C}_2}\end{pmatrix}} & \begin{matrix}\mathrm{H}_1(A)\\ \mathrm{H}_1(B)\end{matrix} & \xrightarrow{i_A+i_B} & \mathrm{H}_1(T) & \xrightarrow{\partial} & \\ \to & \begin{matrix}\mathrm{H}_0(\mathrm{C}_1)\\ \mathrm{H}_0(\mathrm{C}_2)\end{matrix} & \xrightarrow{\begin{pmatrix} i_{\mathrm{C}_1} & i_{\mathrm{C}_2} \\ -i_{\mathrm{C}_1} & -i_{\mathrm{C}_2}\end{pmatrix}} & \begin{matrix}\mathrm{H}_0(A)\\ \mathrm{H}_0(B)\end{matrix} & \xrightarrow{i_A+i_B} & \mathrm{H}_0(T) & \longrightarrow & 0. \end{array}$$

Given $x \in [0,4]$ we consider the 0-cycle $Q_x := (1,x)$ and we consider the 1-cycle

$$\begin{array}{rcl} \sigma_x \colon \Delta^1 & \to & S^1 \times \mathbb{R}/4\mathbb{Z} \\ (1-t,t) & \mapsto & \exp(2\pi \mathrm{i} t). \end{array}$$

Let $I \subset \mathbb{R}$ be a compact interval of length less than four. We make the following four observations:

(a) Since the length of I is less than four one obtains almost immediately from the Compact-Hausdorff Proposition 2.17 (3) that $p \colon S^1 \times I \to p(S^1 \times I)$ is a homeomorphism.
(b) It is a straightforward consequence of the Homotopic Maps-and-Homology Proposition 73.6 that for any two points x, x' in I we have $[Q_x] = [Q_{x'}] \in \mathrm{H}_1(p(S^1 \times I))$ and $[\sigma_x] = [\sigma_{x'}] \in \mathrm{H}_1(p(S^1 \times I))$.
(c) It follows from (1) together with the H_0-Proposition 72.5 that for each $x \in I$ we have $\mathrm{H}_0(p(S^1 \times I)) = \mathbb{Z} \cdot [\sigma_x]$.
(d) It follows from (1) together with Lemma 76.4 and the Homotopic Maps-and-Homology Proposition 73.6 that for each $x \in I$ we have $\mathrm{H}_1(p(S^1 \times I)) = \mathbb{Z} \cdot [Q_x]$.

It follows from (c) and (d) that we can rewrite the above Mayer–Vietoris sequence as follows:

$$\begin{array}{ccccccccc} & & & & 0 & \to & \mathrm{H}_2(T) & \xrightarrow{\partial} & \\ \to & \begin{matrix}\mathbb{Z}\cdot[\sigma_1]\\ \mathbb{Z}\cdot[\sigma_3]\end{matrix} & \xrightarrow{\begin{pmatrix} i_{\mathrm{C}_1} & i_{\mathrm{C}_2} \\ -i_{\mathrm{C}_1} & -i_{\mathrm{C}_2}\end{pmatrix}} & \begin{matrix}\mathbb{Z}\cdot[\sigma_0]\\ \mathbb{Z}\cdot[\sigma_2]\end{matrix} & \xrightarrow{i_A+i_B} & \mathrm{H}_1(T) & \xrightarrow{\partial} & \\ \to & \begin{matrix}\mathbb{Z}\cdot[Q_{x_1}]\\ \mathbb{Z}\cdot[Q_{x_1}]\end{matrix} & \xrightarrow{\begin{pmatrix} i_{\mathrm{C}_1} & i_{\mathrm{C}_2} \\ -i_{\mathrm{C}_1} & -i_{\mathrm{C}_2}\end{pmatrix}} & \begin{matrix}\mathbb{Z}\cdot[Q_{x_0}]\\ \mathbb{Z}\cdot[Q_{x_2}]\end{matrix} & \xrightarrow{i_A+i_B} & \mathrm{H}_0(T) & \longrightarrow & 0. \end{array}$$

To determine the homology groups $\mathrm{H}_2(T)$ and $\mathrm{H}_1(T)$ we now need to understand the maps in the above long exact sequence. For example, it follows immediately from (b) that we have $i_{\mathrm{C}_1}([\sigma_1]) = [\sigma_1] = [\sigma_0]$. Basically identical considerations using (b) tell us that we

[945] To be completely fair, it might take a few lines to write down a complete argument why A and B are submanifolds of T.

[946] Here we write

$$\begin{matrix}\mathrm{H}_i(\mathrm{C}_1)\\ \mathrm{H}_i(\mathrm{C}_2)\end{matrix} \text{ instead of } \mathrm{H}_i(\mathrm{C}_1) \oplus \mathrm{H}_i(\mathrm{C}_2) \quad \text{and} \quad \begin{matrix}\mathrm{H}_i(A)\\ \mathrm{H}_i(B)\end{matrix} \text{ instead of } \mathrm{H}_i(A) \oplus \mathrm{H}_i(B).$$

The reason is that we think of direct sums as columns vectors so that we can use the usual matrix notation for describing the maps between the direct sums.

obtain the following long exact sequence:

$$\begin{array}{ccccccccc} & & & & 0 & \to & \mathrm{H}_2(T) & \xrightarrow{\partial} & \\ \to & \begin{matrix}\mathbb{Z}\cdot[\sigma_1]\\ \mathbb{Z}\cdot[\sigma_3]\end{matrix} & \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} & \begin{matrix}\mathbb{Z}\cdot[\sigma_0]\\ \mathbb{Z}\cdot[\sigma_2]\end{matrix} & \xrightarrow{(1\ 1)} & \mathrm{H}_1(T) & \xrightarrow{\partial} & \\ \to & \begin{matrix}\mathbb{Z}\cdot[Q_1]\\ \mathbb{Z}\cdot[Q_3]\end{matrix} & \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} & \begin{matrix}\mathbb{Z}\cdot[Q_0]\\ \mathbb{Z}\cdot[Q_2]\end{matrix} & \xrightarrow{(1\ 1)} & \mathrm{H}_0(T) & \longrightarrow & 0. \end{array}$$

We will now calculate the homology groups by hand. Alternatively one could now also use Exercise 72.14 to quickly calculate the homology groups. Note that it follows from the discussion on page 1614 that

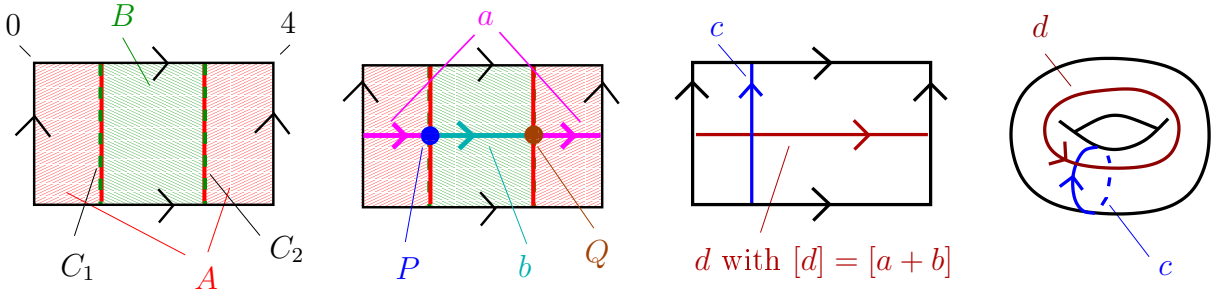
$$\mathrm{H}_2(T) \ \cong\ \ker\left(\begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix}\right) \ =\ \mathbb{Z}\cdot\begin{pmatrix}1\\ -1\end{pmatrix} \ \cong\ \mathbb{Z}.$$

To determine $\mathrm{H}_1(T)$ we consider the following diagram:

$$\begin{array}{ccccccccc} 0 & \to & \operatorname{coker}\left(\begin{matrix}\mathbb{Z}\cdot[\sigma_1]\\ \mathbb{Z}\cdot[\sigma_3]\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\cdot[\sigma_0]\\ \mathbb{Z}\cdot[\sigma_2]\end{matrix}\right) & \to & \mathrm{H}_1(T) & \xrightarrow{\partial_1} & \ker\left(\begin{matrix}\mathbb{Z}\cdot[\sigma_0]\\ \mathbb{Z}\cdot[\sigma_2]\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\cdot[Q_1]\\ \mathbb{Z}\cdot[Q_2]\end{matrix}\right) & \to & 0. \\ & & \cong\uparrow & & \mathrm{id}\uparrow & & \mathrm{id}\uparrow & & \\ 0 & \longrightarrow & \begin{matrix}\mathbb{Z}\cdot[\sigma_1]\\ 0\end{matrix} & \longrightarrow & \mathrm{H}_1(T) & \xrightarrow{\partial} & \mathbb{Z}\cdot\begin{pmatrix}[Q_1]\\ -[Q_2]\end{pmatrix} & \longrightarrow & 0. \end{array}$$

It follows from the above discussion and the Break-into-SES Lemma 78.4 that the top horizontal sequence is exact. Elementary linear algebra shows that the vertical maps are isomorphisms. Finally it is basically clear that the diagram commutes. Since in the bottom the groups to the left and right are both isomorphic to $\mathbb{Z}$ we obtain from the Direct Sum Corollary 78.3 that $\mathrm{H}_1(T) \cong \mathbb{Z}^2$. Finally it follows from the above long exact sequence and the discussion on page 1614 that[947]

$$\mathrm{H}_0(T) \ \cong\ \operatorname{coker}\left(\begin{matrix}\mathbb{Z}\cdot[Q_1]\\ \mathbb{Z}\cdot[Q_3]\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\cdot[Q_0]\\ \mathbb{Z}\cdot[Q_2]\end{matrix}\right) \ \cong\ \mathbb{Z}.$$



This concludes the proof of Statement (1) of the lemma. ■

Now we turn to the proof of the second statement of Lemma 78.11.

Proof of Lemma 78.11 (2). We continue with the notation that we introduced in the proof of Statement (1) of Lemma 78.11. Next we provide the proof of (2a). Note that $[c] = [\sigma_1] \in \mathrm{H}_1(C)$. Let a and b be the singular simplices in A and B that are indicated in the figure below. Recall that we have the following short exact sequence:

$$0 \longrightarrow \mathbb{Z}\cdot[\sigma_1] \longrightarrow \mathrm{H}_1(T) \xrightarrow{\partial} \mathbb{Z}\cdot\begin{pmatrix}[Q_1]\\ -[Q_2]\end{pmatrix} \longrightarrow 0.$$

[947] Of course we already knew by the H_0-Proposition 72.5 that $\mathrm{H}_0(T) \cong \mathbb{Z}$.

Evidently $[c] = [\sigma_1]$ represents a generator of the group on the left-hand side. Furthermore note that $a + b$ is a cycle in T with $a \in \mathrm{C}_1(A)$ and $b \in \mathrm{C}_1(B)$, thus we have

$$\partial_1([a+b]) \underset{\uparrow}{=} [\partial a] = [P - Q] = \begin{pmatrix} 1 \\ -1 \end{pmatrix} \in \begin{matrix} \mathrm{H}_1(\mathrm{C}_1) = \mathbb{Z} \\ \mathrm{H}_1(\mathrm{C}_2) = \mathbb{Z} \end{matrix}$$

see the definition of ∂_1 in Theorem 78.9 (1)

Thus we see that $\partial_1([a+b])$ is a generator of the group on the right-hand side of the above short exact sequence. It follows from the Direct Sum Corollary 78.3 (2) that $[c]$ and $[a+b]$ generate the free abelian group $\mathrm{H}_1(T) \cong \mathbb{Z}^2$. The desired statement now follows from the observation that Lemma 72.3 (3) implies that $[a + b] = [d]$. This concludes the proof of (2a).

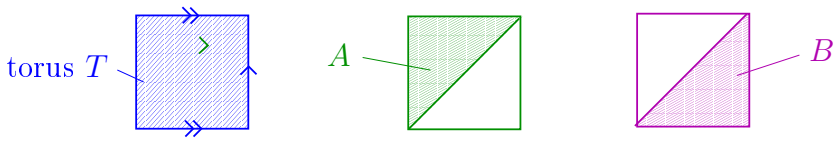
Now we turn to the proof of (2b). Let α and β be the two singular 2-simplices that are shown in the figure below on the right. It is straightforward to verify that the singular 2-chain $\alpha - \beta$ is indeed a cycle. Note that the proof that $\alpha - \beta$ represents a generator of $\mathrm{H}_2(T)$ is less immediate than the previous argument since the singular simplices α and β do not "fit" into any of the groups of our long exact sequence. In fact, as we will see, the proof that $\alpha - \beta$ represents a generator of $\mathrm{H}_2(T)$ is quite similar to the proof of Lemma 76.3.

We denote by A and B the images of $\alpha\colon \Delta^2 \to T$ and $\beta\colon \Delta^2 \to T$. (We refer to the figure below for an illustration.) We consider the following maps

$$\begin{array}{ccccccc} \mathrm{H}_2(T) & & \xrightarrow{[\alpha-\beta]\mapsto[\alpha-\beta]} & & \xleftarrow{[\mathrm{id}_{\Delta^2}]\mapsto[\alpha]} & & \mathrm{H}_2(\Delta^2, \partial\Delta^2) \\ \downarrow & & & & & & \downarrow \cong \\ \mathrm{H}_2(T/B) & \longrightarrow & \underbrace{\mathrm{H}_2(T/B, B/B)}_{\text{here } [\alpha-\beta]=[\alpha]} & \xleftarrow{\cong} & \mathrm{H}_2(A/\partial A, \partial A/\partial A) & \xleftarrow[\cong]{\alpha_*} & \mathrm{H}_2(\Delta^2/\partial\Delta^2, \partial\Delta^2/\partial\Delta^2). \end{array}$$

We make the following observations:

(i) By the Identity-is-Generator Lemma 76.2 we know that $[\mathrm{id}_{\Delta^2}] \in \mathrm{H}_2(\Delta^2, \partial\Delta^2) \cong \mathbb{Z}$ is a generator.



(ii) The two horizontal maps on the right are induced by homeomorphisms of pairs of topological spaces, hence they are isomorphisms.

(iii) The vertical homomorphism on the right is an isomorphism by the Homology-of-Quotients Proposition 74.20 and Lemma 74.12.

(iv) Note that statements (i), (ii) and (iii) imply that $[\alpha]$ represents a generator of the group $\mathrm{H}_2(T/B, B/B) \cong \mathbb{Z}$.

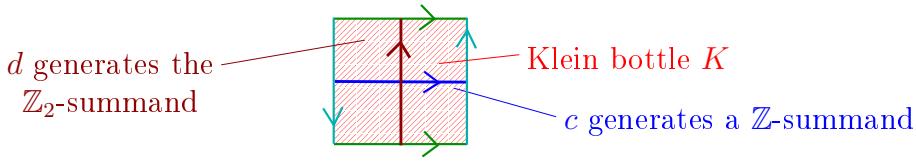
(v) The singular 2-simplex $\beta\colon \Delta^2 \to B$ is zero in $\mathrm{C}_2(T/B, B/B)$. Therefore we have $[\alpha - \beta] = [\alpha] \in \mathrm{H}_2(T/B, B/B)$.

(vi) Next note that statements (iv) and (v) imply that the image of $[\alpha - \beta] \in \mathrm{H}_2(T) \cong \mathbb{Z}$ under the map $\mathrm{H}_2(T) \to \mathrm{H}_2(T/B, B/B)$ is a generator of $\mathrm{H}_2(T/B, B/B) \cong \mathbb{Z}$. But this implies that $[\alpha - \beta]$ is a generator of $\mathrm{H}_2(T) \cong \mathbb{Z}$. ■

Lemma 78.12. Let

$$K \;=\; ([0,1]\times[0,1])/\sim \qquad \text{where } (x,0)\sim(x,1) \text{ and } (0,y)\sim(1,1-y)$$

be the Klein bottle as defined on page 265. We consider the two singular 1-cycles



$$\begin{array}{rcl} c\colon \Delta^1 & \to & K \\ (t,1-t) & \mapsto & [(\frac{1}{2},t)] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} d\colon \Delta^1 & \to & K \\ (t,1-t) & \mapsto & [(\frac{1}{2},t)] \end{array}$$

Then

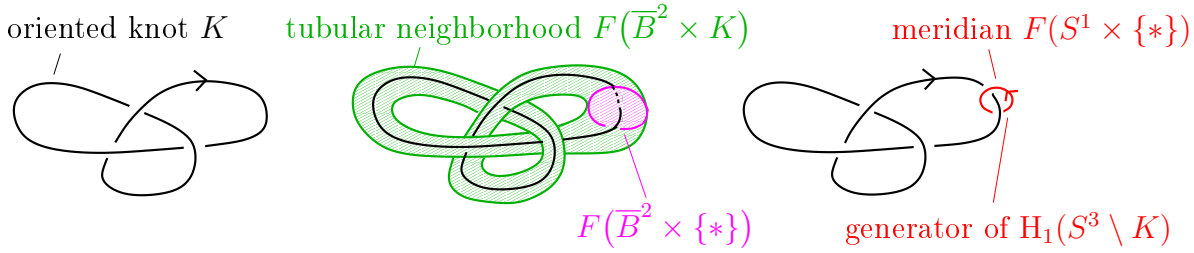
$$\mathrm{H}_n(K) \;=\; \begin{cases} \mathbb{Z}, & \text{if } n=0, \\ \mathbb{Z}\cdot[c]\oplus\mathbb{Z}_2\cdot[d], & \text{if } n=1, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. The lemma can be proved using the Mayer–Vietoris Theorem 78.9 for Manifolds. We will carry out the details in Exercise 78.3. ■

Furthermore we can determine explicitly two generators of $\mathrm{H}_1(K)$. More precisely, we consider the figure below. There the singular 1-simplex d generates the $\mathbb{Z}_2$-summand and the singular 1-simplex c generates a $\mathbb{Z}$-summand of $\mathrm{H}_1(K)$.[948] We leave the verification of this statement to the reader.

Remark. With some effort one could now use the Mayer–Vietoris Theorem 78.9 for Manifolds to compute the homology groups of the surfaces of genus ≥ 2. We will not carry out the argument in this chapter since in Proposition 80.10 we will perform the calculation using an alternative argument, namely using "cellular homology" which greatly simplifies the calculation. For the impatient reader we state the calculation of the homology groups of surfaces of genus ≥ 2 as Exercise 78.13.

78.6. **The first homology group of a knot complement.** Finally we want to determine the first homology group of the complement of a knot. We recall the relevant definitions from pages 1301 and 1305.



[948] It is straightforward to see that c generates an element of infinite order since the "vertical projection" $K \to [0,1]/\sim$ sends c to a generator of $\mathrm{H}_1([0,1]/\sim) = \mathrm{H}_1(S^1)$.

Definition. (1) A knot is a 1-dimensional submanifold of S^3 that is diffeomorphic to S^1.

(2) Let K be an oriented knot in S^3. By the Tubular Neighborhood Theorem **??** there exists an orientation-preserving smooth embedding $F\colon \overline{B}^2 \times K \to S^3$ such that $\Phi(0,P) = P$ for all $P \in K$. For any $* \in S^1$ we refer to the oriented submanifold $F(S^1 \times \{*\})$ as a meridian of the knot K.

We refer to the figure below for an illustration of an oriented knot and a meridian. We also introduce one new definition:

(3) Let M be a smooth manifold and let C be a closed oriented curve in M, see page 1123 for the definition. Sometimes, by a slight abuse of notation, we denote by C also the element in $\mathrm{H}_1(M)$ that is given by the image of the standard generator $[S^1]$ of $\mathrm{H}_1(S^1)$ under the map $\mathrm{H}_1(S^1) \xrightarrow{\Phi_*} \mathrm{H}_1(C) \to \mathrm{H}_1(M)$.[949]

Lemma 78.13. Let $K \subset S^3$ be a knot. Then[950]

$$\mathrm{H}_0(S^3 \setminus K) \cong \mathbb{Z} \quad \text{and} \quad \mathrm{H}_1(S^3 \setminus K) = \mathbb{Z} \cdot [\mu].$$

here μ is any meridian of K

Later, in Lemma 100.16, we will compute the remaining homology groups of $S^3 \setminus K$.

Remark. The result of Lemma 78.13 is easy to state but also slightly disappointing since it shows that the first homology groups cannot be used to distinguish different knots. In contrast to this fact we saw in Proposition 59.5 and Proposition 59.6 that the fundamental group can be used to distinguish the trivial knot from the trefoil.

Proof. Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem **??** there exists a smooth embedding $\Phi\colon \overline{B}^2 \times K \to S^3$ with $\Phi(0,P) = P$ for all $P \in K$. To simplify the notation we drop Φ from the notation, in particular we write $\overline{B}^2 \times K$ instead of $\Phi(\overline{B}^2 \times K)$. It is basically clear that the interiors of $S^3 \setminus K$ and $\overline{B}^2 \times K$ cover S^3. Therefore we can apply the Mayer–Vietoris Theorem 78.5 to the decomposition $S^3 = (S^3 \setminus K) \cup (\overline{B}^2 \times K)$

[949] It follows from the Diffeotopies-of-S^1-Classification Proposition 34.5 and the Homotopic Maps-and-Homology Proposition 73.6 that, up to a sign, the homology class does not depend on the choice of the orientation-preserving diffeomorphism Φ.

[950] By the H_0-Proposition 72.5 the first statement just says that $S^3 \setminus K$ is path-connected. This seems obvious from the pictures, but it is nonetheless somewhat non-trivial to prove. For example, as discussed in Corollary 42.6, this statement can be viewed as a consequence of the Transversality Theorem 42.4.

and we obtain the following exact sequence

$$\begin{aligned}\overbrace{\mathrm{H}_2(S^3)}^{=0} &\longrightarrow \mathrm{H}_1\big((\overline{B}^2\setminus\{0\})\times K\big) \longrightarrow \mathrm{H}_1(S^3\setminus K)\oplus\mathrm{H}_1(\overline{B}^2\times K) \longrightarrow \overbrace{\mathrm{H}_1(S^3)}^{=0}\longrightarrow\\ &\longrightarrow \widetilde{\mathrm{H}}_0((\overline{B}^2\setminus\{0\})\times K) \longrightarrow \widetilde{\mathrm{H}}_0(S^3\setminus K)\oplus\widetilde{\mathrm{H}}_0\big(\overline{B}^2\times K\big) \longrightarrow \underbrace{\widetilde{\mathrm{H}}_0(S^3)}_{=0}\longrightarrow 0.\end{aligned}$$

Now we have to study the homology groups of the various spaces in more detail.[951]

(1) We denote by $[\mu]=S^1\times\{*\}$ the meridian and we define $[\lambda]=\{*\}\times K$. It follows from Lemma 78.11 (2) that $[\mu]$ and $[\lambda]$ is a basis for $\mathrm{H}_1(S^1\times K)$. The inclusion $S^1\times K\to(\overline{B}^2\setminus\{0\})\times K$ is a homotopy equivalence. It follows from the above, the H_0-Proposition 72.5 and the Homotopy Equivalence-H_*-Corollary 73.9 that $\mathrm{H}_1\big((\overline{B}^2\setminus\{0\})\times K\big)\cong\mathbb{Z}\cdot[\mu]\oplus\mathbb{Z}\cdot[\lambda]$ and that $\widetilde{\mathrm{H}}_0((\overline{B}^2\setminus\{0\})\times K)=0$.

(2) We write $[\gamma]=\{0\}\times K$. The inclusion $\{0\}\times K\to\overline{B}^2\times K$ is a homotopy equivalence. Similar to (1) we see that $\mathrm{H}_1(\overline{B}^2\times K)\cong\mathbb{Z}\cdot[\gamma]$ and that $\widetilde{\mathrm{H}}_0(\overline{B}^2\times K)=0$.

(3) Under the inclusion induced map

$$\widetilde{\mathrm{H}}_1((\overline{B}^2\setminus\{0\})\times K) \;=\; \mathbb{Z}\cdot[\mu]\oplus\mathbb{Z}\cdot[\lambda] \;\to\; \widetilde{\mathrm{H}}_1(\overline{B}^2\times K) \;=\; \mathbb{Z}\cdot[\gamma]$$

we have $[\mu]\mapsto 0$[952] and we have $[\lambda]\mapsto[\gamma]$.[953].

Thus we obtain an exact sequence of the following form

$$\begin{aligned}0 &\longrightarrow \mathbb{Z}\cdot[\mu]\oplus\mathbb{Z}\cdot[\lambda] \xrightarrow[\cong]{\substack{[\mu]\mapsto([\mu],0)\\ [\lambda]\mapsto([\lambda],[\gamma])}} \mathrm{H}_1(S^3\setminus K)\oplus\mathbb{Z}\cdot[\gamma] \longrightarrow 0 \longrightarrow\\ &\longrightarrow 0 \longrightarrow \widetilde{\mathrm{H}}_0(S^3\setminus K)\oplus 0 \longrightarrow 0 \longrightarrow 0.\end{aligned}$$

Now it follows immediately from the Direct Sum Corollary 78.3 and Lemma 51.9 (1) that $\mathrm{H}_1(S^3\setminus K)\cong\mathbb{Z}$ and that $\widetilde{\mathrm{H}}_0(S^3\setminus K)\cong 0$. Furthermore note that it follows easily that $[\mu]\in\mathrm{H}_1(S^3\setminus K)=\mathrm{H}_1(S^3\setminus K)$ is a generator.[954] ■

Remark.

(1) In the proof of Lemma 78.13 we used the Mayer–Vietoris Theorem 78.5 in a different way than in the previous examples. More precisely, instead of decomposing $S^3\setminus K$ into smaller pieces, we used that for a decomposition $X=U\cup V$ the Mayer–Vietoris sequence not only relates the homology groups of U,V and $U\cap V$ to the homology groups of X, but also that it relates the homology groups of U to the homology groups of $V,U\cap V$ and X.

(2) The reader might wonder what the approach of Lemma 78.13 can say about the groups $\mathrm{H}_2(S^3\setminus K)$ and $\mathrm{H}_3(S^3\setminus K)$. In fact the approach shows that the exists an

[951] We will do the calculation by hand. Alternatively this calculation is also a good moment to use Exercise 72.14.

[952] This can be seen as follows: the map $\mathrm{H}_1(S^1\times\{*\})\to\mathrm{H}_1(\overline{B}^2\times K)$ factors through $\mathrm{H}_1(\overline{B}^2\times\{*\})=0$.

[953] Why is that?

[954] Why does this follow?

exact sequence

$$\mathrm{H}_3(S^3 \setminus K) \;\to\; \underbrace{\mathrm{H}_3(S^3)}_{\cong\mathbb{Z}} \xrightarrow[=??]{\partial} \underbrace{\mathrm{H}_2((\overline{B}^2 \setminus \{0\}) \times K)}_{\cong\mathbb{Z}} \;\to\; \mathrm{H}_2(S^3 \setminus K) \;\to\; 0.$$

Since do not know whether the connecting homomorphism is the zero map, injective or perhaps even an isomorphism we cannot determine $\mathrm{H}_2(S^3 \setminus K)$ and $\mathrm{H}_3(S^3 \setminus K)$. Later, in Chapter 100 will acquire the tools necessary to study this map. This will allow us in Lemma 100.16 to completely determine the isomorphism classes of the homology groups of $S^3 \setminus K$.

Lemma 78.14. Let $X \subset \mathbb{R}^n$ be a non-empty compact subset. As usual we denote by $S^n = \mathbb{R}^n \cup \{\infty\}$ the topological space $\mathbb{R}^n$ with a "point at infinity". Then for any $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(\mathbb{R}^n \setminus X) \;\cong\; \begin{cases} \mathrm{H}_k((\mathbb{R}^n \cup \{\infty\}) \setminus X) \oplus \mathbb{Z}, & \text{if } k = n-1, \\ \mathrm{H}_k((\mathbb{R}^n \cup \{\infty\}) \setminus X), & \text{otherwise.} \end{cases}$$

Proof. We outsource the proof of the lemma to Exercise 78.12. ∎

78.7. **The homology groups of a mapping cone (∗).** In this section we will discuss the homology groups of a mapping cone. Before we start the discussion we recall the relevant definitions.

Definition. (1) On page 450, given a non-empty topological space A we defined the cone on A as

$$\mathrm{Cone}(A) \;:=\; (A \times [0,1])/\!\sim \qquad \text{where } (a,0) \sim (a',0) \text{ for all } a, a' \in A.$$

If $A = \varnothing$, then we defined $\mathrm{Cone}(\varnothing) = \{*\}$ to be the topological space consisting of a single point $*$.

(2) Given a map $f\colon A \to X$ between topological spaces we defined on page 457 the corresponding mapping cone as

$$\mathrm{Cone}(f\colon A \to X) \;:=\; (\mathrm{Cone}(A) \sqcup X)/\!\sim \;\text{ where } (a,1) \sim f(a) \text{ for all } a \in A.$$

We refer to $[A \times 0]$ respectively $*$ as the cone point of $\mathrm{Cone}(A)$ and of $\mathrm{Cone}(i\colon A \to X)$.

The following lemma, which is an analogue of the Mapping Cone-π_1-Lemma reflem:mapping-cone, gives an elegant calculation of the homology groups of a mapping cone of an inclusion.

Lemma 78.15. (Mapping Cone-H_*-Lemma)

(1) Let X be a topological space and let $A \subset X$ be a subset. We denote by $i\colon A \to X$ the inclusion map. For any $n \in \mathbb{N}_0$ the two maps

$$\mathrm{H}_n(X,A) \underset{\uparrow}{\to} \mathrm{H}_n(\mathrm{Cone}(i\colon A \to X), \mathrm{Cone}(A)) \overset{\text{ex}}{\leftarrow} \widetilde{\mathrm{H}}_n(\mathrm{Cone}(i\colon A \to X))$$

induced by the embedding $X \to \mathrm{Cone}(i\colon A \to X)$

are isomorphisms.

(2) We denote by *PairTop* the category of pairs of topological spaces and we denote by *AbGroup* the category of abelian groups. The composition of the two isomorphisms

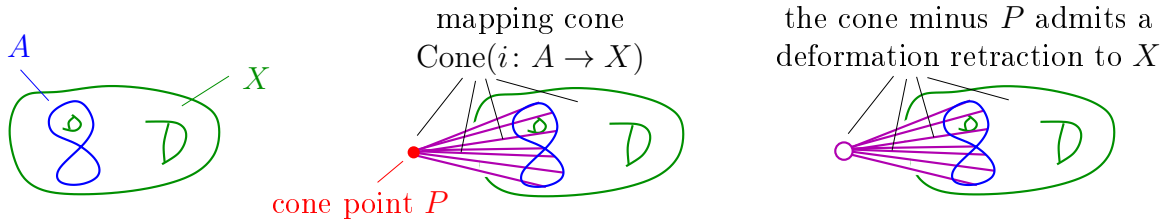
in (1) define a natural isomorphism from the functor[955]

$$\begin{array}{ccc} \mathcal{PairTop} & \to & \mathcal{AbGroup} \\ (X,A) & \mapsto & \widetilde{\mathrm{H}}_n(\mathrm{Cone}(i\colon A \to X)) \end{array} \quad \text{to the functor} \quad \begin{array}{ccc} \mathcal{PairTop} & \to & \mathcal{AbGroup} \\ (X,A) & \mapsto & \mathrm{H}_n(X,A). \end{array}$$

Proof.

(1) Just for kicks we throw in one more map:

$$\begin{array}{ccccc} & & \mathrm{H}_n\big(\mathrm{Cone}(A \xrightarrow{i} X)\setminus\{P\}, \mathrm{Cone}(A)\setminus\{P\}\big) & & \\ & \overset{\text{(a)}}{\nearrow} & & \overset{\text{(b)}}{\downarrow} & \\ \mathrm{H}_k(X,A) & \longrightarrow & \mathrm{H}_k(\mathrm{Cone}(i\colon A \to X), \mathrm{Cone}(A)) & \xleftarrow[\text{(c)}]{\text{ж}} & \widetilde{\mathrm{H}}_k(\mathrm{Cone}(i\colon A \to X)). \end{array}$$



Since the diagram commutes it suffices to show that the maps (a), (b) and (c) are isomorphisms.

(a) From a slight variation on the Mapping Cylinder Basics Lemma 16.12 (1) we obtain a deformation retraction from $\mathrm{Cone}(i\colon A \to X)\setminus\{P\}$ to X which restricts to a deformation retraction from $\mathrm{Cone}(A)$ to A. Thus it follows from Exercise 74.16 that the map (a) is an isomorphism.

(b) It follows from the Excision Theorem 74.17 that the vertical map (b) is an isomorphism.

(c) By the Cone Contractibility Lemma 16.7 we know that the cone $\mathrm{Cone}(A)$ is contractible. It follows from the Topological LES-Corollary 74.14 that the map (c) is an isomorphism.

(2) It is clear that the two maps in (1) are natural. Thus it follows that the two maps together define a natural isomorphism. ■

Remark.

(1) It is worth comparing the Mapping Cone-H_*-Lemma 78.15 to Lemma 74.12 which says that given a pointed topological space (X, x_0) the reduced homology groups $\widetilde{\mathrm{H}}_i(X)$ are naturally isomorphic to the relative homology groups $\mathrm{H}_i(X, \{x_0\})$.

(2) In the Homology-of-Quotients Proposition 74.20 we showed that, under favorable circumstances, we can replace the relative homology group $\mathrm{H}_n(X, A)$ by the homology group $\widetilde{\mathrm{H}}_n(X/A)$. the Mapping Cone-$\mathrm{H}_*$-Lemma 78.15 says that we can replace any relative homology group by the homology group of the mapping cone of the inclusion.

(3) Loosely speaking, the Mapping Cone-H_*-Lemma 78.15 says that for all intents and purposes we can usually replace the relative homology groups of a pair (X, A) of

[955] As in the Mapping Cone Functor Lemma 16.14 (3) we see that the left-hand side does indeed define a functor.

topological spaces by the reduced homology of the mapping cone of the inclusion $A \to X$.

Proof. We had just seen that the map is an isomorphism. It is straightforward to verify that the maps define a natural transformation. ■

We obtain the following convenient corollary which is a very close relative of the Homology-of-Quotients Proposition 74.20.

Corollary 78.16. Let X be a topological space and let $A \subset X$ be a subset. We denote by $i\colon A \to X$ the inclusion map. If i is a closed cofibration, then for any $n \in \mathbb{N}_0$ the natural map $\text{ю}\colon \mathrm{H}_n(X, A) \to \widetilde{\mathrm{H}}_n(X/A)$ from page 1633 is an isomorphism.

Proof. The case that $A = \varnothing$ is basically trivial and is left to the reader. In the following we assume that $A \subset X$ is a non-empty subset. Let $n \in \mathbb{N}_0$. We consider the following diagram

$$\begin{array}{ccc} \mathrm{H}_n(X, A) & \xrightarrow{\quad \text{ю} \quad} & \widetilde{\mathrm{H}}_n(X/A) \\ & {\scriptstyle\cong}\searrow \quad \nearrow{\scriptstyle\varphi} & \\ & \widetilde{\mathrm{H}}_n(\mathrm{Cone}(i\colon A \to X)). & \end{array}$$

We make the following clarifications and observations:

(1) The top horizontal map is the natural homomorphism that we introduced on page 1633.
(2) The left diagonal map is the natural *isomorphism* of the Mapping Cone-H_*-Lemma 78.15.
(3) The right diagonal map is the map

$$\begin{array}{rcl} \varphi\colon \mathrm{Cone}(i\colon A \to X) & \to & X/A \\ P & \mapsto & \begin{cases} [P], & \text{if } P \in X, \\ [A], & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1] \end{cases} \end{array}$$

that we introduced in the Cofibration-Quotient Lemma 17.7 (1).
(4) It follows easily from the definitions that the diagram commutes.
(5) Since $i\colon A \to X$ is by hypothesis a closed cofibration we obtain from the Cofibration-Quotient Lemma 17.7 (1) that φ is a homotopy equivalence. Therefore we obtain from the Homotopy Equivalence-H_*-Corollary 73.9 that the right diagonal map is also an isomorphism.
(6) Putting everything together we see that the top map is indeed an isomorphism. ■

Let A be a subset of a topological space X. We denote by $i\colon A \to X$ the corresponding inclusion map. It follows from the Topological LES-Corollary 74.14 together with the Mapping Cone-H_*-Lemma 78.15 that the inclusion induced maps $i_*\colon \mathrm{H}_k(A) \to \mathrm{H}_k(X)$ fit into the following natural long exact sequence

$$\ldots \to \mathrm{H}_k(A) \xrightarrow{i_*} \mathrm{H}_k(X) \to \underbrace{\mathrm{H}_k(X, A)}_{\cong \widetilde{\mathrm{H}}_k(\mathrm{Cone}(i\colon A \to X))} \xrightarrow{\partial} \mathrm{H}_{k-1}(A) \xrightarrow{i_*} \mathrm{H}_{k-1}(X) \to \ldots$$

The following lemma generalizes this neat fact to the setting of any map $f\colon A \to X$ between topological spaces.

Lemma 78.17. (Mapping Cone-H_*-Lemma)[956]

(1) Let $f\colon A \to X$ be a map between topological spaces.
   (a) We denote by $j(f)\colon X \to \mathrm{Cone}(f) = (\mathrm{Cone}(A) \sqcup X)/\sim$ the obvious inclusion map.
   (b) We denote by U the image of $A \times [0, \frac{3}{4})$ in $\mathrm{Cone}(f)$ and we denote by V the complement of the image of $A \times [0, \frac{1}{4}]$. (See also the figure below.) We consider the following diagram[957]

$$\begin{array}{ccccccccc} \ldots & \longrightarrow & \mathrm{H}_k(U) \oplus \mathrm{H}_k(V) & \longrightarrow & \mathrm{H}_k(\mathrm{Cone}(f)) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}(U \cap V) & \longrightarrow & \ldots \\ & & & & \uparrow \wr & & \uparrow \cong & & \\ & & & & \mathrm{H}_k(\mathrm{Cone}(f)) & \xrightarrow[=:\partial_k(f)]{\partial_k} & \mathrm{H}_{k-1}(A). & & \end{array}$$

   Here the top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 78.5[958] and the vertical map is induced by the inclusion $a \mapsto (a, \frac{1}{2})$ which is a homotopy equivalence. From the above diagram we obtain a map

$$\partial_k(f)\colon \widetilde{\mathrm{H}}_k(\mathrm{Cone}(f)) \;\to\; \mathrm{H}_{k-1}(A).$$

With these definitions the following sequence is exact

$$\ldots \longrightarrow \mathrm{H}_k(A) \xrightarrow{f_*} \mathrm{H}_k(X) \xrightarrow{j(f)_*} \widetilde{\mathrm{H}}_k(\mathrm{Cone}(f)) \xrightarrow{\partial_k(f)} \mathrm{H}_{k-1}(A) \longrightarrow \ldots$$

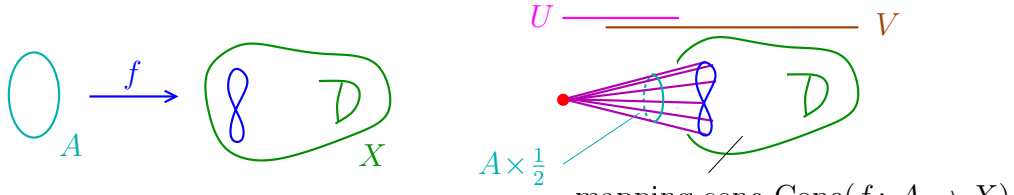
(2) The connecting homomorphism in (1) is natural. In particular given any commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{f} & X \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{A} & \xrightarrow{\widetilde{f}} & \widetilde{X} \end{array}$$

of maps between topological spaces the following diagram commutes:

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \mathrm{H}_k(A) & \xrightarrow{f_*} & \mathrm{H}_k(X) & \xrightarrow{j(f)_*} & \widetilde{\mathrm{H}}_k(\mathrm{Cone}(f)) & \xrightarrow{\partial_k(f)} & \mathrm{H}_{k-1}(A) & \longrightarrow & \ldots \\ & & \downarrow{\scriptstyle\varphi_*} & & \downarrow{\scriptstyle\psi_*} & & \downarrow & & \downarrow{\scriptstyle\varphi_*} & & \\ \ldots & \longrightarrow & \mathrm{H}_k(\widetilde{A}) & \xrightarrow{\widetilde{f}_*} & \mathrm{H}_k(\widetilde{X}) & \xrightarrow{j(\widetilde{f})_*} & \widetilde{\mathrm{H}}_k(\mathrm{Cone}(\widetilde{f})) & \xrightarrow{\partial_k(\widetilde{f})} & \mathrm{H}_{k-1}(\widetilde{A}) & \longrightarrow & \ldots. \end{array}$$

Here the vertical maps between the homology groups of the mapping cones are induced by the maps from the Mapping Cone Functor Lemma 16.14 (3).



(3) Let X be a topological space and let $A \subset X$ be a subset. We denote by $i\colon A \to X$ the inclusion map. The following diagram

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \mathrm{H}_k(A) & \xrightarrow{i} & \mathrm{H}_k(X) & \longrightarrow & \mathrm{H}_k(X, A) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{k-1}(A) & \longrightarrow & \widetilde{\mathrm{H}}_{k-1}(X) & \longrightarrow & \ldots \\ & & \downarrow{=} & & \downarrow{=} & & \downarrow{\cong} & & \downarrow{=} & & \downarrow{=} & & \\ \ldots & \longrightarrow & \mathrm{H}_k(A) & \xrightarrow{i} & \mathrm{H}_k(X) & \longrightarrow & \widetilde{\mathrm{H}}_k(\mathrm{Cone}(i)) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{k-1}(A) & \longrightarrow & \widetilde{\mathrm{H}}_{k-1}(X) & \longrightarrow & \ldots \end{array}$$

commutes. Here the middle vertical map is the natural isomorphism from the Mapping Cone-H_*-Lemma 78.15, the top sequence is the long exact sequence arising from

the Topological LES-Corollary 74.14 and the bottom sequence is the exact sequence from (1).

The obvious analogues of the above statements for reduced homology of A and X also hold.

mapping cone $\mathrm{Cone}(f\colon A \to X)$

Proof.

(1) We consider the following diagram:

$$\begin{array}{ccccccccc}
\ldots & \longrightarrow & \mathrm{H}_k(U\cap V) & \longrightarrow & \mathrm{H}_k(U)\oplus\mathrm{H}_k(V) & \longrightarrow & \mathrm{H}_k(\mathrm{Cone}(f)) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}(U\cap V) \longrightarrow \ldots \\
 & & \cong\uparrow & & \cong\uparrow \quad \uparrow\cong & & \mathrm{id}\uparrow & & \uparrow\cong \\
\ldots & \longrightarrow & \mathrm{H}_k(A) & \xrightarrow{c_*\oplus f_*} & \mathrm{H}_k(\{*\})\oplus\mathrm{H}_k(X) & \longrightarrow & \mathrm{H}_k(\mathrm{Cone}(f)) & \longrightarrow & \mathrm{H}_{k-1}(A) \longrightarrow \ldots \\
 & & \cong\uparrow & & \cong\uparrow \quad \uparrow\text{ж} & & \text{ж}\uparrow & & \uparrow\cong \\
\ldots & \longrightarrow & \mathrm{H}_k(A) & \xrightarrow{f_*} & \underbrace{\widetilde{\mathrm{H}}_k(\{*\})}_{=0}\oplus\mathrm{H}_k(X) & \xrightarrow{j(f)_*} & \widetilde{\mathrm{H}}_k(\mathrm{Cone}(f)) & \xrightarrow{\partial_k(f)} & \mathrm{H}_{k-1}(A) \longrightarrow \ldots
\end{array}$$

We make the following clarifications and observations:

(a) The top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 78.5 applied to the open cover $\mathrm{Cone}(f) = U \cup V$.

(b) We denote by $*$ the cone point of $\mathrm{Cone}(f)$.

(c) The vertical maps are the almost obvious inclusion maps. The map $c\colon A \to \{*\}$ is the constant map. It follows almost immediately from the definitions together with the Homotopic Maps-and-Homology Proposition 73.6 that the upper part of the diagram commutes.

(d) As in the Cone Contractibility Lemma 16.7 we see that the inclusion $\{*\} \to U$ is a homotopy equivalence. Furthermore, by the Reduced Homology Lemma 74.1 (7) we know that $\widetilde{\mathrm{H}}_k(\{*\}) = 0$.

(e) It follows now fairly easily from Lemma 74.2 that the lower part of the diagram also commutes and that the lower sequence is exact. But that is what we wanted to show.

(2) This statement follows from the naturality of the connecting homomorphisms of the Mayer–Vietoris sequence, see Theorem 78.5 (2).

(3) We will prove this statement in Exercise 78.18. ∎

[956] In the statement and the proof of the lemma we implicitly use Lemmas 16.8 and 16.13 (2) several times to show that various maps are open and closed embeddings. For example it follows from the Cone-Suspension Basics Lemma 16.8 that the map $j(f)$ given in (1a) is actually a closed embedding.

[957] We leave it to the reader to give a reasonable interpretation of what we say here in the special case that $A = \varnothing$.

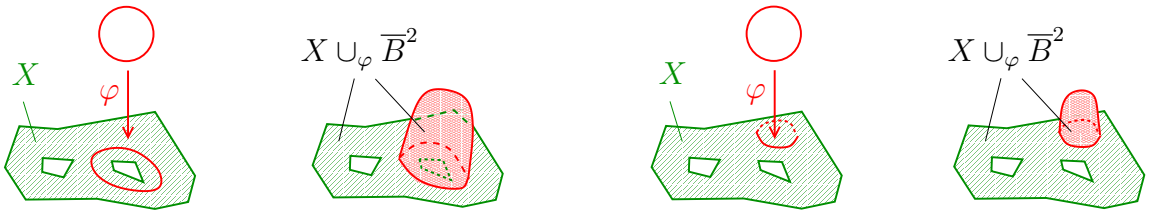
[958] Note that U and V are open subsets of $\mathrm{Cone}(f)$.

In the Cell Attachment-π_1-Proposition 69.11 we saw how attaching an n-cell to a topological space affects its fundamental group. Basically for free we now get a corresponding statement for homology groups.

Lemma 78.18. (Cell Attachment-H_*-Lemma) Let X be a topological space, let $n \geq 2$ and let $\varphi\colon S^{n-1} \to X$ be a map. We denote by $i\colon X \to X \cup_\varphi \overline{B}^n$ the obvious map. (Note that by the Topological Pushout-Maps Lemma 5.34 (3) and (4) we know that i is a closed embedding.) There exists a natural exact sequence of the form

$$0 \to \mathrm{H}_n(X) \xrightarrow{i_*} \mathrm{H}_n\big(X \cup_\varphi \overline{B}^n\big) \to \underbrace{\mathrm{H}_{n-1}(S^{n-1})}_{\cong \mathbb{Z}} \xrightarrow{\varphi_*} \mathrm{H}_{n-1}(X) \xrightarrow{i_*} \mathrm{H}_{n-1}\big(X \cup_\varphi \overline{B}^n\big) \to 0.$$

Furthermore, for any $k \neq n-1, n$ the inclusion induced map



$$i_*\colon \mathrm{H}_k(X) \xrightarrow{\cong} \mathrm{H}_k(X \cup_\varphi \overline{B}^n)$$

is an isomorphism.

Example. Let X be a topological space with finitely generated homology groups. Let $n \geq 2$ and let $\varphi\colon S^{n-1} \to X$ be a map. Loosely speaking the Cell Attachment-H_*-Lemma 78.18 says that gluing on a copy of $\overline{B}^n$ along φ has the following effect on homology:

	H_n	H_{n-1}
$\mathrm{H}_{n-1}(S^{n-1}) \xrightarrow{\varphi_*} \mathrm{H}_{n-1}(X)$ has infinite image	unchanged	rank goes down by 1
$\mathrm{H}_{n-1}(S^{n-1}) \xrightarrow{\varphi_*} \mathrm{H}_{n-1}(X)$ has finite image	rank goes up by 1	unchanged.

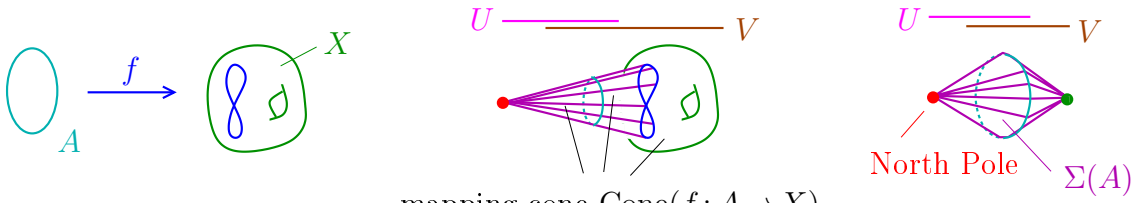
We illustrate these two different behaviors in the figure below.

$\varphi_*\colon \mathrm{H}_1(S^1) \to \mathrm{H}_1(X)$ has infinite image

$\varphi_*\colon \mathrm{H}_1(S^1) \to \mathrm{H}_1(X)$ has trivial image

Proof. On page 1527 we made the, almost trivial, observation that there exists a homeomorphism $\mathrm{Cone}(\varphi\colon S^{n-1} \to X) \xrightarrow{\cong} X \cup_\varphi \overline{B}^n$ which is the identity on X. The conclusion of the Cell Attachment-H_*-Lemma 78.18 follows immediately from this observation together with the Mapping Cone-H_*-Lemma 78.17, the calculation of the homology groups of S^{n-1}, see Proposition 74.4 and the observation that our hypothesis that $n \geq 2$ implies that we do not need to worry about reduced homology groups. ■

The last lemma of this section gives a neat reinterpretation of the connecting homomorphism in the long exact sequence of the Mapping Cone-H_*-Lemma 78.17.



Lemma 78.19. Let $f\colon A \to X$ be a map between topological spaces. For every $k \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \widetilde{\mathrm{H}}_k(\mathrm{Cone}(f\colon A \to X)) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{k-1}(A) \\ \downarrow & & \cong\downarrow \Sigma_A \\ \widetilde{\mathrm{H}}_k(\mathrm{Cone}(f\colon A \to X)/X) & \xrightarrow[\cong]{\varphi_*} & \widetilde{\mathrm{H}}_k(\Sigma(A)). \end{array}$$

Here we used the following notation:

(1) The top horizontal map is the connecting homomorphism of the long exact sequence given in the Mapping Cone-H_*-Lemma 78.17.
(2) The left vertical map is induced by the obvious projection.
(3) The map $\varphi\colon \mathrm{Cone}(f\colon A \to X)/X \to \Sigma(A)$ is the natural homeomorphism from the Mapping Cone Basics Lemma 16.13 (4).
(4) The map $\Sigma_A\colon \widetilde{\mathrm{H}}_{k-1}(A) \to \widetilde{\mathrm{H}}_k(\Sigma(A))$ is the natural isomorphism from the Suspension-H_*-Proposition 76.7.

Proof. The statement follows immediately from the explicit definition of the maps ∂ and Σ_A via Mayer–Vietoris sequences, from the explicit definition of the map φ, and from the naturality of the connecting homomorphism of the Mayer–Vietoris sequence, see Theorem 78.5 (2), that the isomorphism Σ_X is natural. We leave it to the reader to fill in the details. ■

mapping cone $\mathrm{Cone}(f\colon A \to X)$

78.8. **The homology groups of a mapping torus** (∗). On page 467 we defined the mapping torus of a self-homeomorphism and in the Mapping Torus-π_1-Proposition 50.6 we had determined the fundamental group of the mapping torus. In this section we will determine the isomorphism types of the homology groups of a mapping torus.
For convenience we recall from page 467 the definition of the mapping torus. Let X be a topological space and let $f\colon X \to X$ be a map. We refer to

$$\mathrm{Tor}(X, f) \;:=\; (X \times [0,1])/(x,0) \sim (f(x),1)$$

as the *mapping torus of* (X, f). In the following we will use on several occasions Lemma 16.22 which says that for any closed respectively open interval $I \subset \mathbb{R}$ of length less than one, the map

$$\varphi\colon X \times I \xrightarrow{(x,t)\mapsto[(x,t)]} (X \times \mathbb{R})/\!\sim \xrightarrow{[(x,t)]\mapsto[(x,t)]} \mathrm{Tor}(X, f)$$

is a closed respectively open embedding. Now we can state the main result of this section.

Proposition 78.20. (Mapping Torus-Homology Proposition) Let X be a topological space and let $f\colon X \to X$ be a map. For every $n \in \mathbb{N}_0$ we have a natural short exact

sequence[959]

$$0 \to \operatorname{coker}\big(\mathrm{H}_n(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_n(X)\big) \xrightarrow{i} \mathrm{H}_n(\mathrm{Tor}(X,f)) \to \ker\big(\mathrm{H}_{n-1}(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_{n-1}(X)\big) \to 0,$$

where the map i is induced by the embedding $X \xrightarrow{x \mapsto [(x,0)]} \mathrm{Tor}(X,f)$.

Example. First let $X = S^1$ and let $f\colon S^1 \to S^1$ be the self-homeomorphism that is given by $f(z) = \overline{z} = z^{-1}$. On page 469 we saw that the mapping torus $\mathrm{Tor}(S^1, f)$ is homeomorphic to the Klein bottle. It follows from the discussion on page 1594 the induced map $f_*\colon \mathrm{H}_0(S^1) \to \mathrm{H}_0(S^1)$ is the identity map. Furthermore we showed in Lemma 76.10 that the induced homomorphism $f_*\colon \mathrm{H}_1(S^1) \to \mathrm{H}_1(S^1)$ is given by multiplication by -1. Since $\mathrm{H}_0(S^1) \cong \mathbb{Z}$ and $\mathrm{H}_1(S^1) \cong \mathbb{Z}$ we now see that the short exact sequences of the Mapping Torus-Homology Proposition 78.20 are of the form

$$\begin{array}{lccccccccc}
n=2\colon & & & & 0 & \to & \mathrm{H}_2(\mathrm{Tor}(S^1,f)) & \to & \ker(\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}) & \to & 0 \\
n=1\colon & 0 & \to & \operatorname{coker}\big(\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}\big) & \to & \mathrm{H}_1(\mathrm{Tor}(S^1,f)) & \to & \ker(\mathbb{Z} \xrightarrow{\cdot 0} \mathbb{Z}) & \to & 0
\end{array}$$

and

$$n=0\colon \quad 0 \to \operatorname{coker}\big(\mathbb{Z} \xrightarrow{\cdot 0} \mathbb{Z}\big) \to \mathrm{H}_0(\mathrm{Tor}(S^1,f)) \to 0.$$

Using the Direct Sum Corollary 78.3 we now deduce that

$$\mathrm{H}_2(\mathrm{Tor}(S^1,f)) = 0, \quad \mathrm{H}_1(\mathrm{Tor}(S^1,f)) \cong \mathbb{Z}_2 \oplus \mathbb{Z} \quad \text{and} \quad \mathrm{H}_0(\mathrm{Tor}(S^1,f)) = \mathbb{Z}.$$

This confirms, as it should, the calculation that we had made in Lemma 78.12.

Proof. The proof of the proposition is quite similar to the calculation of the homology groups of the torus.[960] Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. We compute the homology of the following space that is clearly naturally homeomorphic to the mapping torus:

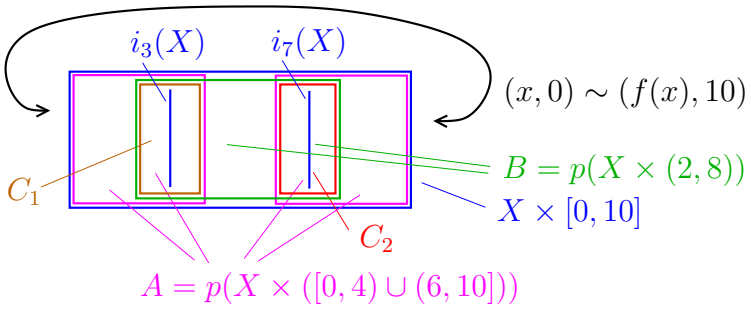
$$M := (X \times [0,10])/(x,0) \sim (f(x),10).$$

We denote by $p\colon X \times [0,10] \to M$ the natural projection. Furthermore we write $A := p(X \times ([0,4) \cup (6,10])) \subset M$ and $B := p(X \times (2,8)) \subset M$.[961] Finally, given $t \in [0,10]$ we denote by

$$\begin{array}{rccc} i_t\colon & X & \to & p(X \times \{t\}) \\ & x & \mapsto & p(x,t) \end{array}$$

the obvious inclusion map. We write $i_{3,A}$ for the composition of i_3 with the inclusion map $p(X \times \{3\}) \to A$. We denote analogous compositions by the obvious variations in the notation. The proof below crucially relies on the following claim.

[959] Recall that $\mathrm{H}_{-1}(X)$ is defined to be the trivial group.



[960] In fact if one reads the subsequent proof with $X = S^1$ and $f = \mathrm{id}$ in mind, then one obtains almost the same argument as for the torus.

[961] Throughout this proof we will freely use Lemma 16.22 which says that $p\colon X \times [0,1] \to M$, restricted to reasonable open subsets, is in fact an open embedding.

Claim. For any $n \in \mathbb{N}_0$ the following two diagrams commute

$$\begin{array}{ccc} \mathrm{H}_n(X) & \xrightarrow{\mathrm{id}} & \mathrm{H}_n(X) \\ & {\scriptstyle i_{3,B}} \searrow \quad \swarrow {\scriptstyle i_{7,B}} & \\ & \mathrm{H}_n(B) & \end{array} \qquad \text{and} \qquad \begin{array}{ccc} \mathrm{H}_n(X) & \xrightarrow{f_*^{-1}} & \mathrm{H}_n(X). \\ & {\scriptstyle i_{3,A}} \searrow \quad \swarrow {\scriptstyle i_{7,A}} & \\ & \mathrm{H}_n(B) & \end{array}$$

Proof. It follows almost immediately from the Homotopic Maps-and-Homology Proposition 73.6 that the two triangles commute. We leave the details to the reader. ⊞

Next we consider the following diagram:[962]

$$\begin{array}{ccccccccccc}
\to & \begin{matrix}\mathrm{H}_n(C_1)\\ \mathrm{H}_n(C_2)\end{matrix} & \xrightarrow{\left(\begin{smallmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2}\end{smallmatrix}\right)} & \begin{matrix}\mathrm{H}_n(A)\\ \mathrm{H}_n(B)\end{matrix} & \xrightarrow{(i_A\ i_B)} & \mathrm{H}_n(M) & \xrightarrow{\partial} & \begin{matrix}\mathrm{H}_{n-1}(C_1)\\ \mathrm{H}_{n-1}(C_2)\end{matrix} & \xrightarrow{\left(\begin{smallmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2}\end{smallmatrix}\right)} & \begin{matrix}\mathrm{H}_{n-1}(A)\\ \mathrm{H}_{n-1}(B)\end{matrix} & \to \\
 & \uparrow{\scriptstyle \left(\begin{smallmatrix} i_3 & 0 \\ 0 & i_7\end{smallmatrix}\right)} & & \uparrow{\scriptstyle \left(\begin{smallmatrix} i_3 & 0 \\ 0 & i_7\end{smallmatrix}\right)} & & \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle \left(\begin{smallmatrix} i_3 & 0 \\ 0 & i_7\end{smallmatrix}\right)} & & \uparrow{\scriptstyle \left(\begin{smallmatrix} i_3 & 0 \\ 0 & i_7\end{smallmatrix}\right)} & \\
\to & \begin{matrix}\mathrm{H}_n(X)\\ \mathrm{H}_n(X)\end{matrix} & \xrightarrow{\left(\begin{smallmatrix} \mathrm{id} & f_* \\ -\mathrm{id} & -\mathrm{id}\end{smallmatrix}\right)} & \begin{matrix}\mathrm{H}_n(X)\\ \mathrm{H}_n(X)\end{matrix} & \xrightarrow{(i_A\ i_B)} & \mathrm{H}_n(M) & \xrightarrow{\partial} & \begin{matrix}\mathrm{H}_{n-1}(X)\\ \mathrm{H}_{n-1}(X)\end{matrix} & \xrightarrow{\left(\begin{smallmatrix} \mathrm{id} & f_* \\ -\mathrm{id} & -\mathrm{id}\end{smallmatrix}\right)} & \begin{matrix}\mathrm{H}_{n-1}(X)\\ \mathrm{H}_{n-1}(X)\end{matrix} & \to \\
 & \uparrow{\scriptstyle \left(\begin{smallmatrix} \mathrm{id} \\ -\mathrm{id}\end{smallmatrix}\right)} & & \uparrow{\scriptstyle \left(\begin{smallmatrix} \mathrm{id} \\ 0\end{smallmatrix}\right)} & & \uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle \left(\begin{smallmatrix} \mathrm{id} \\ -\mathrm{id}\end{smallmatrix}\right)} & & \uparrow{\scriptstyle \left(\begin{smallmatrix} \mathrm{id} \\ 0\end{smallmatrix}\right)} & \\
\longrightarrow & \mathrm{H}_n(X) & \xrightarrow{\mathrm{id}-f_*} & \mathrm{H}_n(X) & \xrightarrow{i} & \mathrm{H}_n(M) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(X) & \xrightarrow{\mathrm{id}-f_*} & \mathrm{H}_{n-1}(X) & \longrightarrow
\end{array}$$

The above diagram arose as follows:

(1) Note that the interiors of $A = p(X \times ([0,4) \cup (6,10])) \subset M$ and $B = p(X \times (2,8)) \subset M$ cover all of M. Furthermore note that we have $A \cap B = C_1 \sqcup C_2$. On the top of the diagram we wrote down the corresponding exact Mayer–Vietoris sequence from Theorem 78.5.

(2) Note that the maps $i_3 \colon X \to A$, $i_3 \colon X \to C_1$, $i_7 \colon X \to C_2$ and $i_7 \colon X \to B$ are homotopy equivalences. It follows from the Homotopy Equivalence-H_*-Corollary 73.9 that the induced maps on homology are isomorphisms. In particular the vertical maps between the first and the second horizontal sequence are isomorphisms.

(3) Next we want to show that the top part of the diagram commutes. The squares involving $\mathrm{id} \colon \mathrm{H}_n(M) \to \mathrm{H}_n(M)$ commute by the functoriality of homology groups and by definition of the connecting homomorphism ∂ in the middle row. It remains to consider the squares which in our excerpt above are to the left and right. The

[962] Here we use the same notation as on page 1729.

discussion is perhaps less confusing if we explain how the maps on the middle row were found. The task was to find maps $a, b, c, d\colon \mathrm{H}_n(X) \to \mathrm{H}_n(X)$ such that the following equality holds:

$$\underbrace{\begin{pmatrix} i_{C_1,A} & i_{C_2,A} \\ -i_{C_1,B} & -i_{C_2,B} \end{pmatrix}\begin{pmatrix} i_{3,C_1} & 0 \\ 0 & i_{7,C_2} \end{pmatrix}}_{=\begin{pmatrix} i_{3,A} & i_{7,A} \\ -i_{3,B} & -i_{7,B} \end{pmatrix}} = \underbrace{\begin{pmatrix} i_{3,A} & 0 \\ 0 & i_{7,B} \end{pmatrix}\begin{pmatrix} a & b \\ c & d \end{pmatrix}}_{=\begin{pmatrix} i_{3,A}\circ a & i_{3,A}\circ b \\ i_{7,B}\circ c & i_{7,B}\circ d \end{pmatrix}}.$$

It follows from the above claim that a solution is given by $a = \mathrm{id}, b = f_*, c = -\mathrm{id}$ and $d = -\mathrm{id}$.

(4) It is straightforward to see that the bottom squares in the above diagram commute. We leave it to the reader to verify that the bottom sequence is also exact.

As we had just pointed out, the bottom horizontal sequence is exact. The proposition is thus an immediate consequence of the Break-into-SES Lemma 78.4. ∎

Now we can also easily prove the following lemma.

Lemma 78.21. Let X be a topological space. We denote by $p\colon X \times S^1 \to X$ the natural projection. For every $n \in \mathbb{N}_0$ there exists a natural map $\psi\colon \mathrm{H}_n(X \times S^1) \to \mathrm{H}_{n-1}(X)$ such that the map

$$\Xi_X := p_* \circ \psi\colon \mathrm{H}_n(X \times S^1) \xrightarrow{\cong} \mathrm{H}_n(X) \oplus \mathrm{H}_{n-1}(X)$$

is a natural isomorphism. Here natural means that for any map $f\colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_n(X \times S^1) & \xrightarrow[\cong]{\Xi_X} & \mathrm{H}_n(X) \oplus \mathrm{H}_{n-1}(X) \\ \downarrow{\scriptstyle (f\times \mathrm{id})_*} & & \downarrow{\scriptstyle f_* \quad f_*} \\ \mathrm{H}_n(Y \times S^1) & \xrightarrow[\cong]{\Xi_Y} & \mathrm{H}_n(X) \oplus \mathrm{H}_{n-1}(X). \end{array}$$

Example. Using an elementary and amusing induction argument one can show quite easily, using Lemma 78.21, that for $k = 0, \ldots, n$ we have

$$\mathrm{H}_k(n\text{-dimensional torus } (S^1)^n) \;=\; \text{free abelian group of rank } \binom{n}{k}$$

and that all other homology groups vanish.

Remark. We gave a different proof of Lemma 78.21 in Exercise 75.4.

Proof. Let $n \in \mathbb{N}_0$. Note that by the Mapping Torus-of-id Lemma 16.24 the map $\Theta\colon \mathrm{Tor}(X, f := \mathrm{id}) \to X \times S^1$ given by $[(x,t)] \mapsto (x, \exp(2\pi\,\mathrm{i}t))$ is a natural homeomorphism. We denote by $i\colon X \to \mathrm{Tor}(f)$ the natural embedding given by $x \mapsto [(x,0)]$ and we denote by $j\colon X \to X \times S^1$ the natural embedding given by $x \mapsto (x,1)$. Next we consider the following

diagram:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \operatorname{coker}\big(\mathrm{H}_n(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_n(X)\big) & \xrightarrow{i_*} & \mathrm{H}_n(\mathrm{Tor}(X,f)) & \xrightarrow{\partial} & \ker\big(\mathrm{H}_{n-1}(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_{n-1}(X)\big) & \longrightarrow & 0 \\
 & & \downarrow \mathrm{id} & & \downarrow \mathrm{id} & & \downarrow \mathrm{id} & & \\
0 & \longrightarrow & \mathrm{H}_n(X) & \xrightarrow{i} & \mathrm{H}_n(\mathrm{Tor}(X,f)) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(X) & \longrightarrow & 0 \\
 & & \downarrow \mathrm{id} & & \cong \downarrow \Theta_* & & \downarrow \mathrm{id} & & \\
0 & \longrightarrow & \mathrm{H}_n(X) & \underset{p_*}{\overset{j_*}{\rightleftarrows}} & \mathrm{H}_n(X \times S^1) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(X) & \longrightarrow & 0.
\end{array}$$

We make the following clarifications and observations:

(1) The top sequence is the short exact sequence obtained from the Mapping Torus-Homology Proposition 78.20.
(2) Since $f_* - \mathrm{id}_* = 0$ we obtain the two vertical identities on top.
(3) Since Θ is an isomorphism and since $\Theta \circ i = j$ we see that the bottom sequence also commutes.
(4) The map $p\colon X \times S^1 \to X$ is the natural map that is given by projection onto the first factor. Note that $p_* \circ i_* = (p \circ i)_* = \mathrm{id}$.

As in the proof of Splitting Lemma 78.2 we now see that the map

$$\begin{array}{rcl}
\Xi_X\colon \mathrm{H}_n(X \times S^1) & \to & \mathrm{H}_n(X) \oplus \mathrm{H}_{n-1}(X) \\
\sigma & \mapsto & p_*(\sigma) \oplus \partial(\sigma - (j_* \circ p_*)(\sigma))
\end{array}$$

is an isomorphism. Since all maps involved are natural we see that this isomorphism is in fact natural. ■

We conclude this long chapter with the following lemma which can be viewed as the analogue of the Mapping Torus-π_1-Proposition 50.6.

Lemma 78.22. (Mapping Torus-Homology Lemma) Let X be a path-connected topological space and let $f\colon X \to X$ be a map. We denote by $i\colon X \xrightarrow{x \mapsto [(x,0)]} \mathrm{Tor}(X,f)$ the natural embedding and we denote by $q\colon \mathrm{Tor}(X,f) \to S^1$ the natural projection that we introduced on page 467. With this notation the following sequence is natural and exact:

$$0 \;\to\; \operatorname{coker}\big(\mathrm{H}_1(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_1(X)\big) \;\xrightarrow{i}\; \mathrm{H}_1(\mathrm{Tor}(X,f)) \;\to\; \mathrm{H}_1(S^1) \;\to\; 0.$$

In particular we have an isomorphism

$$\mathrm{H}_1(\mathrm{Tor}(X,f)) \;\cong\; \mathbb{Z} \oplus \operatorname{coker}\big(\mathrm{H}_1(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_1(X)\big).$$

Remark. Later in the Hurewicz Theorem 85.5 we will show that the abelianization of the fundamental group $\pi_1(X,x_0)$ of a pointed path-connected topological space (X,x_0) is naturally isomorphic to the first homology group $\mathrm{H}_1(X)$. Thus we see that the Mapping Torus-Homology Lemma 78.22 is a modest generalization of Exercise 53.7.

Proof. Since X is path-connected we obtain immediately from the discussion on page 1594 that the map $f_* - \mathrm{id}\colon \mathrm{H}_0(X) \to \mathrm{H}_0(X)$ is the zero map. We consider the following maps:

$$\begin{array}{ccccccccccc} 0 & \longrightarrow & \operatorname{coker}\big(\mathrm{H}_1(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_1(X)\big) & \xrightarrow{i} & \mathrm{H}_1(\mathrm{Tor}(X,f)) & \longrightarrow & \mathbb{Z} & \longrightarrow & 0. \\ & & & & \downarrow{\scriptstyle p_*} & \swarrow{\scriptstyle \Psi} & & & \\ & & & & \underbrace{\mathrm{H}_1(S^1)}_{\cong \mathbb{Z}}. & & & & \end{array}$$

We make the following observations:

(1) The horizontal map is the short exact sequence from the Mapping Torus-Homology Proposition 78.20.
(2) Since $p \circ i$ is a constant map we see that $p_* \circ i_*$ is the trivial map.
(3) It follows from (1) and (2) that there exists a map $\Psi\colon \mathbb{Z} \to \mathrm{H}_1(S^1)$ that makes the diagram commute.
(4) Furthermore, since X is path-connected one can easily construct a left-inverse to $p\colon \mathrm{Tor}(X,f) \to S^1$. This implies that $p_*\colon \mathrm{H}_1(\mathrm{Tor}(X,f)) \to \mathrm{H}_1(S^1)$ is an epimorphism.
(5) Since $\mathrm{H}_1(S^1) \cong \mathbb{Z}$ and since any epimorphism from $\mathbb{Z} \to \mathbb{Z}$ is an isomorphism we obtain from the above that Ψ is an isomorphism.

This concludes the proof that the sequence in the statement of the lemma is indeed exact.

Finally note that since $\mathbb{Z}$ is free abelian it follows from the Direct Sum Corollary 78.3 that we have an isomorphism

$$\mathrm{H}_1(\mathrm{Tor}(X,f)) \;\cong\; \mathbb{Z} \oplus \operatorname{coker}\big(\mathrm{H}_1(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_1(X)\big). \qquad \blacksquare$$

Exercises for Chapter 78.

Exercise 78.1. We consider the following commutative diagram of homomorphisms between abelian groups:

$$\begin{array}{ccccccccccccc} \ldots & \longrightarrow & C''_{n+1} & \xrightarrow{\partial_{n+1}} & C'_n & \xrightarrow{i_n} & C_n & \xrightarrow{p_n} & C''_n & \xrightarrow{\partial_n} & C'_{n-1} & \longrightarrow & \ldots \\ & & \downarrow{\scriptstyle f''_{n+1}} & & \downarrow{\scriptstyle f'_n} & & \downarrow{\scriptstyle f_n} & & \downarrow{\scriptstyle f''_n} & & \downarrow{\scriptstyle f'_{n-1}} & & \\ \ldots & \longrightarrow & D''_{n+1} & \xrightarrow{\partial_{n+1}} & D'_n & \xrightarrow{j_n} & D_n & \xrightarrow{q_n} & D''_n & \xrightarrow{\partial_n} & D'_{n-1} & \longrightarrow & \ldots \end{array}$$

We suppose that the horizontal sequences are exact and we suppose that each f''_n is an isomorphism. For each $n \in \mathbb{N}_0$ we set $\Delta_n := \partial_n \circ (f''_n)^{-1} \circ q_n\colon D_n \to C'_{n-1}$. Show that the following sequence is exact

$$\ldots \longrightarrow C'_n \xrightarrow{i_n + f'_n} C_n \oplus D'_n \xrightarrow{f_n + j_n} D_n \xrightarrow{\Delta_n} C'_{n-1} \longrightarrow \ldots$$

Remark. The resulting exact sequence is sometimes called the *algebraic Mayer–Vietoris sequence*. The name will become clear in Exercise 78.2.

Exercise 78.2. Let X be a topological space and let $A, B \subset X$ be subsets such that $X = \mathring{A} \cup \mathring{B}$. Use the algebraic Mayer–Vietoris sequence from Exercise 78.1 together with the Excision Theorem 74.17 and the long exact sequence of the pair of topological spaces to give a new proof of of the Mayer–Vietoris Theorem 78.5 92) and (3). More precisely you need to show that there exists a long exact sequence of the form

$$\ldots \to \mathrm{H}_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{H}_n(A) \oplus \mathrm{H}_n(B) \xrightarrow{i_A + i_B} \mathrm{H}_n(X) \xrightarrow{\partial_n} \mathrm{H}_{n-1}(A \cap B) \to \ldots$$

where ∂_n is natural.
Hint. Consider the commutative diagram

$$\begin{array}{ccc} A \cap B & \xrightarrow{i_{A\cap B}} & A \\ {\scriptstyle i_{A\cap B}}\downarrow & & \downarrow{\scriptstyle i_A} \\ B & \xrightarrow{i_B} & X. \end{array}$$

Exercise 78.3.

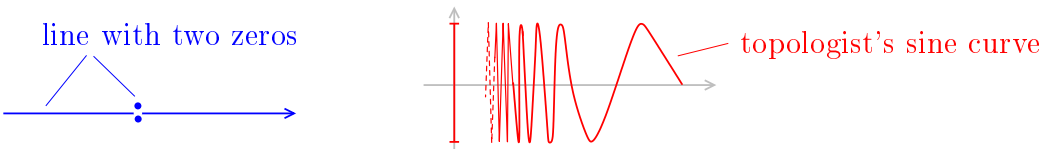
(a) We denote by

$$K \;=\; ([0,1] \times [0,1])/\!\sim \;\text{ with } (x,0) \sim (x,1) \text{ and } (0,y) \sim (1,1-y)$$

the Klein bottle as defined on page 265. We consider the two singular 1-cycles

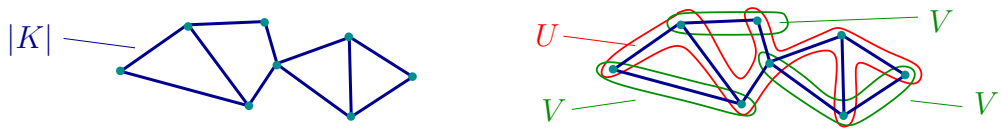
$$\begin{array}{rcl} c\colon \Delta^1 & \to & K \\ (t, 1-t) & \mapsto & [(\frac{1}{2}, t)] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} d\colon \Delta^1 & \to & K \\ (t, 1-t) & \mapsto & [(\frac{1}{2}, t)] \end{array}$$

Show that



$$\mathrm{H}_n(K) \;=\; \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z} \cdot [c] \oplus \mathbb{Z}_2 \cdot [d], & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$

(b) Give an example of an explicit map $f\colon S^1 \to K$ such that the inclusion induced map $f_*\colon \mathrm{H}_1(S^1) \to \mathrm{H}_1(K)$ is a monomorphism. Prove that the map f that you provide does indeed have this property.



Exercise 78.4. Let X be a topological space and let U and V be two open subset of X such that X and $U \cap V$ are path-connected and such that $U \cap V$ is non-empty. Show that U and V are path-connected.
Remark. This is of course just a special case of Exercise 6.11 (a). But it is great fun to prove this statement using the Mayer–Vietoris Theorem 78.5.

Exercise 78.5. Compute the isomorphism types of the homology groups of the real line with two zeros.

Exercise 78.6. Determine the isomorphism types of the homology groups of the Topologist's Sine Curve that we introduced on page 164.
Hint. Use Exercise 2.48.

Exercise 78.7. Let $K = (V, E, i, t)$ be a connected abstract graph. Determine the isomorphism types of the homology groups of the topological realization $|K|$.
Hint. The figure below shows an example of a convenient covering by open sets.

Exercise 78.8. In Lemma 78.11 we computed the homology groups of the torus $T = S^1 \times S^1$ the Mayer–Vietoris Theorem 78.9 for Manifolds. compute the *reduced* homology of the torus using the Mayer–Vietoris sequence with reduced homology groups.
Remark. Depending on how you go about this calculation you can easily end up with a contradictory calculation.

Exercise 78.9. Let $T = S^1 \times S^1$ be the torus. We denote by $p, q\colon S^1 \times S^1 \to S^1$ the two obvious projections. Show that the map

$$\begin{array}{rcl} p_* \oplus q_*\colon \mathrm{H}_1(S^1 \times S^1) & \to & \mathrm{H}_1(S^1) \oplus \mathrm{H}_1(S^1) \\ \varphi & \mapsto & p_*(\varphi) + q_*(\varphi) \end{array}$$

is an isomorphism.
Hint. You could make use of Lemma 78.11 (2).

Exercise 78.10. We consider the real projective plane

$$\mathbb{R}\mathrm{P}^2 \;=\; \overline{B}^2/\!\sim \qquad \text{where } x \sim y \text{ if } x, y \in \partial\overline{B}^2 \text{ and } x = -y.$$

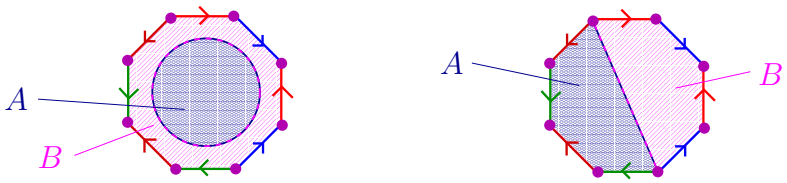
Determine an explicit cycle in $\mathrm{C}_1(\mathbb{R}\mathrm{P}^2)$ that represents the unique non-trivial element of $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2)$.

Exercise 78.11. Let X be a topological space and let $k \in \mathbb{Z}$. Show that the two natural isomorphisms $\widetilde{\mathrm{H}}_k(X) \xrightarrow{\cong} \widetilde{\mathrm{H}}_{k-1}(\Sigma(X))$ that we constructed in the Suspension-H_*-Proposition 76.7 and in the proof of the Suspension-H_*-Proposition 76.7 are actually the same.

Exercise 78.12. Let $X \subset \mathbb{R}^n$ be a non-empty compact subset. As in Lemma 2.18 we make the identification $S^n = \mathbb{R}^n \cup \{\infty\}$ of the sphere with the space $\mathbb{R}^n$ together with a "point at infinity".

(a) Show that for every $k \neq n-1$ the inclusion induced map

$$\mathrm{H}_k(\mathbb{R}^n \setminus X) \;\to\; \mathrm{H}_k(\underbrace{(\mathbb{R}^n \cup \{\infty\})}_{=S^n} \setminus X)$$



is an isomorphism.

(b) Show that there exists a short exact sequence

$$0 \;\to\; \mathbb{Z} \;\to\; \mathrm{H}_{n-1}(\mathbb{R}^n \setminus X) \;\to\; \mathrm{H}_{n-1}((\mathbb{R}^n \cup \{\infty\}) \setminus X) \;\to\; 0.$$

(c) Show that the short exact sequence in (b) splits.

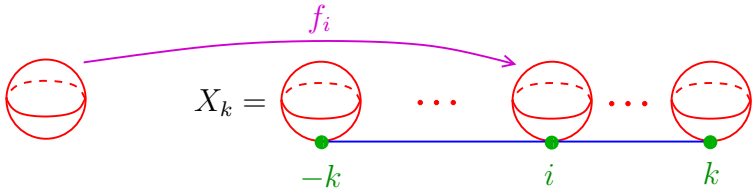
Exercise 78.13. Let $g \in \mathbb{N}_{\geq 2}$. Use the Mayer–Vietoris Theorem 78.9 for Manifolds, or some other flavor of the Mayer–Vietoris sequence, to determine the isomorphism types of the surface of genus g.
Hint. In the figure below we show two possible approaches to decomposing the surface of genus two.
Remark. We will give the calculation in Proposition 80.10 using "cellular homology".

Exercise 78.14. Let X be a topological space, let $k \in \mathbb{N}$ and let $n \in \mathbb{N}_0$. What is the isomorphism type of $\mathrm{H}_n(X \times S^k)$ in terms of the homology groups of X?

Exercise 78.15. Let $k \in \mathbb{N}$. We consider the topological space

$$X_k \;:=\; ([-k,k] \cup S^2 \times \{-k,\dots,k\})/\!\sim$$

where given $i \in \{-k,\dots,k\}$ we identify $i \in [-k,k]$ with $((0,0,-1),i) \in S^2 \times \{-k,\dots,k\}$. For $i = -k,\dots,k$ we denote by



$$\begin{array}{rcl} f_i\colon S^2 & \to & X_k \\ P & \mapsto & (P,i) \end{array}$$

the various "obvious" inclusion maps. (We refer to the figure below for an illustration.)

(a) Show that $\mathrm{H}_0(X_k) \cong \mathbb{Z}$.
(b) Show that $\mathrm{H}_i(X_k) = 0$ for $i \neq 0, 2$.
(c) Let $[S^2] \in \mathrm{H}_2(S^2)$ be the standard generator. Show that the map

$$\begin{array}{rcl} \mathbb{Z}^{2k+1} & \to & 2(X_k) \\ (a_{-k},\dots,a_k) & \to & \sum\limits_{i=-k}^{k} a_i \cdot f_{i*}([S^2]) \end{array}$$

is an isomorphism.

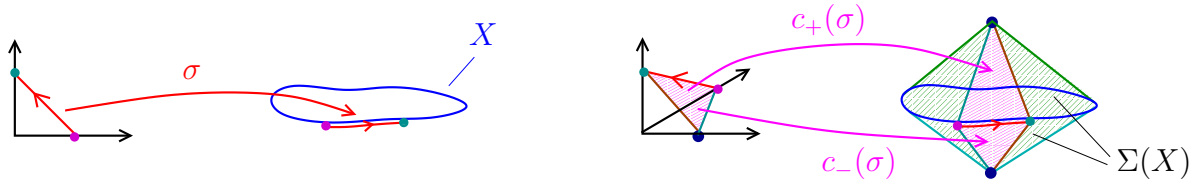
Exercise 78.16. Let X be a topological space. We consider the corresponding suspension $\Sigma(X) = (X \times [-1,1])/\!\sim$ which is given by identifying all points in $X \times \{-1\}$ and by identifying all points in $X \times \{1\}$.

(a) Given a singular k-simplex $\sigma\colon \Delta^k \to X$ we define the two maps

$$\begin{array}{rcl} c_\pm(\sigma)\colon \Delta^{k+1} & \to & \Sigma(X) \\ (t_0,t_1,\dots,t_{k+1}) & \mapsto & \begin{cases} \big([\big(\sigma\big(\frac{1}{1-t_0}(t_1,\dots,t_{k+1})\big),\pm t_0\big)\big], & \text{if } t_0 < 1, \\ [X \times \{\pm 1\}], & \text{if } t_0 = 1. \end{cases} \end{array}$$

Show that the maps $c_-(\sigma)$ and $c_+(\sigma)$ are continuous. (We refer to the figure below for an illustration of the definition of $c_\pm(\sigma)$.)
Hint. Consider $\Delta^k \times [0,1]$ and $(\Delta^k \times [0,1])/(\Delta^k \times \{1\})$.

(b) Note that the maps $\sigma \mapsto c_\pm(\sigma)$ define a homomorphisms $c_\pm \colon \mathrm{C}_k(X) \to \mathrm{C}_{k+1}(\Sigma(X))$. We set $s = (-1)^{k+1} \cdot (c_+ - c_-)$. Show that for any $\sigma \colon \Delta^k \to X$ we have



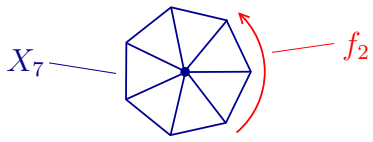
$$\partial s(\sigma) \;=\; \begin{cases} s(\partial\sigma), & \text{if } k > 0, \\ [X \times \{1\}] - [X \times \{-1\}], & \text{if } k = 0. \end{cases}$$

(c) Let $k \in \mathbb{N}_0$. Show that the map

$$\begin{array}{rcl} \widetilde{\mathrm{H}}_k(X) & \to & \mathrm{H}_{k+1}(\Sigma(X)) \\ \sigma & \mapsto & s(\sigma) \end{array}$$

is well-defined and that it is an isomorphism.

Remark. We refer to c_+, c_- as *cone operators* and we refer to s as the *suspension operator*.
.



Exercise 78.17. Let $k \in \mathbb{N}_{\geq 3}$ and let $m \in \mathbb{N}$. We consider the topological space

$$X_k \;:=\; S^1 \cup \{r \cdot \exp(2\pi \mathrm{i} j/k) \,|\, r \in [0,1] \text{ and } j \in \{0, \ldots, k-1\}\}$$

and we consider the homeomorphism

$$\begin{array}{rcl} f_m \colon X_k & \to & X_k \\ z & \mapsto & \exp(2\pi \mathrm{i} m/k) \cdot z. \end{array}$$

Determine the homology groups of the mapping torus $\mathrm{Tor}(X_k, f_m)$.

Exercise 78.18. Let X be a topological space and let $A \subset X$ be a non-empty subset. We denote by $i \colon A \to X$ the inclusion map. We consider the following diagram

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & \widetilde{\mathrm{H}}_n(A) & \xrightarrow{i} & \widetilde{\mathrm{H}}_n(X) & \longrightarrow & \mathrm{H}_n(X,A) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{n-1}(A) & \longrightarrow & \widetilde{\mathrm{H}}_{n-1}(X) \longrightarrow \ldots \\ & & \downarrow{=} & & \downarrow{=} & & \downarrow{\cong} & & \downarrow{=} & & \downarrow{=} \\ \ldots & \longrightarrow & \widetilde{\mathrm{H}}_n(A) & \xrightarrow{i} & \widetilde{\mathrm{H}}_n(X) & \longrightarrow & \widetilde{\mathrm{H}}_n(\mathrm{Cone}(i)) & \xrightarrow{\partial} & \widetilde{\mathrm{H}}_{n-1}(A) & \longrightarrow & \widetilde{\mathrm{H}}_{n-1}(X) \longrightarrow \ldots \end{array}$$

where the middle vertical map is the natural isomorphism from the Mapping Cone-H_*-Lemma 78.15, where the top sequence is the long exact sequence arising from the Topological LES-Corollary 74.14. and where the bottom sequence is the exact sequence from the Mapping Cone-H_*-Lemma 78.17. Show that the diagram commutes.

Exercise 78.19. Let X be a topological space and let U_1, U_2 and U_3 be open subsets of X with $X = U_1 \cup U_2 \cup U_3$.

(a) We suppose that $U_1 \cap U_2 \cap U_3 = \varnothing$. Show that there exists a long exact sequence of the form

$$\dots \to \begin{matrix} \mathrm{H}_n(U_1 \cap U_2) \\ \mathrm{H}_n(U_2 \cap U_3) \\ \mathrm{H}_n(U_1 \cap U_3) \end{matrix} \xrightarrow{\begin{pmatrix} i_{U_1\cap U_2} & 0 & i_{U_1\cap U_3} \\ -i_{U_1\cap U_2} & i_{U_2\cap U_3} & 0 \\ 0 & -i_{U_2\cap U_3} & -i_{U_1\cap U_3} \end{pmatrix}} \begin{matrix} \mathrm{H}_n(U_1) \\ \mathrm{H}_n(U_2) \\ \mathrm{H}_n(U_3) \end{matrix} \xrightarrow{i_{U_1}+i_{U_2}+i_{U_3}} \mathrm{H}_n(X) \xrightarrow{\partial_n} \dots$$

(b) Show that in general the conclusion of (a) does not hold if $U_1 \cap U_2 \cap U_3 \neq \varnothing$.

Remark. This exercise is related to the discussion on page 1720.

Exercise 78.20. Let X and Y be topological spaces. We consider the join $X * Y$ as defined on page 446. Show that for each $k \in \mathbb{N}_0$ there exists a short exact sequence of the following form:

$$0 \;\to\; \widetilde{\mathrm{H}}_k(X * Y) \;\to\; \widetilde{\mathrm{H}}_{k-1}(X) \oplus \widetilde{\mathrm{H}}_{k-1}(Y) \;\to\; \widetilde{\mathrm{H}}_{k-1}(X \times Y) \;\to\; 0.$$

Hint. In Exercise 16.15 we gave an explicit homeomorphism

$$X * Y \;\cong\; (\mathrm{Cone}(X) \times Y) \cup_{(X\times\{1\})\times Y = X\times(Y\times\{1\})} (X \times \mathrm{Cone}(Y)).$$

Note though that you need to argue why you can use this decomposition.
Remark. In the Künneth Theorem 90.8 we will learn how to calculate the homology groups of the product $X \times Y$.

Exercise 78.21. Let $X = \mathbb{Z}_n$ be the topological space whose underlying set is $\mathbb{Z}_n$ and whose topology is given by the discrete topology. Let $f\colon X = \mathbb{Z}_n \to X = \mathbb{Z}_n$ be the homeomorphism given by $f(x) = x + 1 \in \mathbb{Z}_n$. Compute the homology groups of the mapping torus $\mathrm{Tor}(X, f)$.

Exercise 78.22. Let $p, q \in \mathbb{N}$ be coprime. We consider the torus knot $T_{p,q}$ as defined on page 1312. Compute the homology groups of $S^3 \setminus T_{p,q}$.
Hint. Use the decomposition of $S^3 \setminus T_{p,q}$ given in the proof of Proposition 59.5.

Exercise 78.23. Let K be the Klein bottle minus one open disk. Show that ∂K is not a retract of K.

Exercise 78.24. Let $n \in \mathbb{N}$ and let M be S^2 minus n open disks. Show that the inclusion induced map $\mathrm{H}_1(\partial M) \to \mathrm{H}_1(M)$ is an epimorphism.

Exercise 78.25. We consider the two topological manifolds X and Y that are shown in the figure below. Use (relative?) homology groups to show that X and Y are not homeomorphic.
Remark. In Exercise 52.6 we attacked the same problem using fundamental groups. It should be much easier to deal with the problem at hand using (relative) homology groups.

Exercise 78.26. Given an n-dimensional smooth manifold M we define the

$$\text{embedding covering number } N(M) := \begin{array}{c}\text{minimal cardinality of an open cover } \{U_i\}_{i\in I} \\ \text{of } M \text{ such that each } U_i \text{ admits a} \\ \text{smooth embedding into } \mathbb{R}^n.\end{array}$$

In other words, the embedding covering number is precisely the minimal cardinality of a smooth atlas of M. Let M be a non-orientable smooth manifold. Show that if $N(M) = 2$, then $\mathrm{H}_1(M)$ is infinite.

Hint. Assume that there exists a smooth atlas for M consisting of two charts $\Phi_1 \colon U_1 \to V_1$ and $\Phi_2 \colon U_2 \to V_2$. Consider the Mayer–Vietoris sequence corresponding to the open cover $M = U_1 \cup U_2$ and use the Define Orientations-via Transition Maps Lemma 25.15. It helps to first consider the case that U_1 and U_2 are connected.

Remark. This exercise, together with the calculation of $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2)$ in Lemma 78.8, shows that the embedding covering number of the real projective plane $\mathbb{R}\mathrm{P}^2$ equals three.

79. Homology groups and direct limits

In this chapter we will discuss the relationship between homology groups and direct limits. This will allow us to determine the homology groups of suitable nested sequences of topological spaces. In a similar vein we will determine the homology groups of the wedge of arbitrarily many topological spaces. We concludes this chapter with the introduction of the Moore spaces. We will in particular see that all abelian group can appear as homology groups of topological spaces.
For the reader who is in a hurry only few of the results of this chapter are really important. In particular, very soon we will make use of the Wedge-H_*-Proposition 79.9. For this proposition we give two proofs, one building on the theme of this chapter. The other proof can be read independently of the rest of the chapter.

79.1. Direct limits and induced maps.

Notation. Given a directed set $(I, \leq)$ and a direct system $(\{K_i\}_{i\in I}, \{\chi_{ij}\}_{i\leq j})$ of abelian groups we write, as on page 1262

$$\varinjlim K_i \ := \ \Big(\bigsqcup_{i\in I} K_i\Big)/\sim \quad \text{where } k_i \sim \chi_{ij}(k_i) \text{ for all } i \leq j,\ k_i \in K_i$$

We adopt the following notation, given $k_i \in K_i$ we denote by $[k_i] \in \varinjlim K_i$ the element represented by k_i.

We make the following observation that follows immediately from the above definition of the direct limit.

Observation 79.1. Any element in $\varinjlim K_i$ is of the form $[k_i]$ for some $k_i \in K_i$.

Definition. Let $(I, \leq)$ be a directed set and let $(\{K_i\}_{i\in I}, \{\chi_{ij}\}_{i\leq j})$ and $(\{L_i\}_{i\in I}, \{\lambda_{ij}\}_{i\leq j})$ be direct systems of abelian groups.

(1) We define a homomorphism between the above two direct systems to be a family $\{f_i \colon K_i \to L_i\}_{i\in I}$ of homomorphisms that has the property that for any $i \leq j$ the following diagram commutes:

$$\begin{array}{ccc} K_i & \xrightarrow{f_i} & L_i \\ {\scriptstyle \chi_{ij}}\downarrow & & \downarrow{\scriptstyle \lambda_{ij}} \\ K_j & \xrightarrow{f_j} & L_j. \end{array}$$

(2) Given such a homomorphism we refer to

$$\begin{array}{ccc} \varinjlim K_i & \to & \varinjlim L_i \\ [k_i] & \mapsto & [f_i(k_i)] \end{array}$$

as the induced map. Sometimes we denote it by $\varinjlim f_i$.[963964] It is straightforward to verify that the induced maps are functorial.

Proposition 79.2. (Direct Limit-Exactness Proposition) Let $(I, \leq)$ be a directed set. Also let $(\{K_i\}_{i\in I}, \{k_{ij}\}_{i\leq j})$, $(\{L_i\}_{i\in I}, \{l_{ij}\}_{i\leq j})$ and $(\{M_i\}_{i\in I}, \{m_{ij}\}_{i\leq j})$ be direct systems of abelian groups. Furthermore suppose that we are given homomorphisms $f_i\colon K_i \to L_i$ and $g_i\colon L_i \to M_i$ of the direct systems. If for all $i \in I$ the sequence

$$K_i \xrightarrow{f_i} L_i \xrightarrow{g_i} M_i$$

is exact, then the induced sequence

$$\varinjlim K_i \xrightarrow{\varinjlim f_i} \varinjlim L_i \xrightarrow{\varinjlim g_i} \varinjlim M_i$$

is also exact.

Proof. We write $f = \varinjlim f_i$ and $g = \varinjlim g_i$. We have to prove that $g \circ f = 0$ and we need to show that $\ker(g) \subset \mathrm{im}(f)$. Both statements statements follow our hypothesis together with Observation 79.1 and the fact that in the definition of the induced map between direct limits we can take any representative. We leave the few remaining details to the reader. ■

The following corollary says that direct limits commute with kernels and cokernels.

Corollary 79.3. (Direct Limit-(Co-)-Kernel Corollary) Let $(I, \leq)$ be a directed set and let $(\{K_i\}_{i\in I}, \{k_{ij}\}_{i\leq j})$ and $(\{L_i\}_{i\in I}, \{l_{ij}\}_{i\leq j})$ be direct systems of abelian groups. Furthermore suppose that we are given a homomorphism $f_i\colon K_i \to L_i$ of the direct systems. There exist canonical isomorphisms

$$\varinjlim \ker(f_i\colon K_i \to L_i) \xrightarrow{\cong} \ker\left(\varinjlim K_i \to \varinjlim L_i\right)$$

and

$$\varinjlim \mathrm{coker}(f_i\colon K_i \to L_i) \xrightarrow{\cong} \mathrm{coker}\left(\varinjlim K_i \to \varinjlim L_i\right).$$

Proof. For each $i \in I$ the sequence

$$0 \to \ker(f_i) \to K_i \xrightarrow{f_i} L_i \to \mathrm{coker}(f_i) \to 0.$$

is exact. Evidently these homomorphisms form a homomorphism between the various direct systems. It follows from the Direct Limit-Exactness Proposition 79.2 (applied four times!) that the sequence

$$0 \to \varinjlim \ker(f_i) \to \varinjlim K_i \to \varinjlim L_i \to \varinjlim \mathrm{coker}(f_i) \to 0$$

is also exact. But this observation already implies the desired statements. ■

79.2. **The homology groups of a nested sequence of topological spaces.** In Propositions 56.7 and 71.11 we saw that in favorable situations the homotopy groups of a union of a nested sequence of topological spaces is the direct limit of the corresponding fundamental groups. Now we will see that a similar statement holds for homology groups.

[963] It follows immediately from the definitions that this map is well-defined, i.e. the map does not depend on the choice $[k_i]$ of a representative for an element in the direct limit.

[964] More formally one could say that the maps $K_i \to L_i \to \varinjlim L_i$ induce, by the universal property of a direct limit, a map $\varinjlim K_i \to \varinjlim L_i$. It is straightforward to see that this map is exactly the one we wrote down.

Proposition 79.4. (Exhaustions-H$_*$-Proposition) Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that $X = \bigcup_{i\in\mathbb{N}} X_i$ and such that one the following three conditions holds:

(1) every compact subset of X is already contained in one of the X_i, or
(2) each X_i is open in X, or
(3) X is a CW-complex and each X_i is a subcomplex.

Then for any $n \in \mathbb{N}_0$ the inclusion induced maps $\mathrm{H}_n(X_i) \to \mathrm{H}_n(X)$ induce an isomorphism

$$\varinjlim \mathrm{H}_n(X_i) \xrightarrow{\cong} \mathrm{H}_n(X).$$

We remark that it follows easily from the Finiteness the CW-Complex-Finiteness Theorem 68.14 that hypothesis (3) implies hypothesis (1). Furthermore we point out that it follows from Lemma 56.8 that hypothesis (2) implies hypothesis (1). Thus it suffices to prove the Exhaustions-H$_*$-Proposition 79.4 under the hypothesis (1). But in that case the proposition is an immediate consequence of the next two lemmas.

Lemma 79.5. (Exhaustion-Chain Complex Lemma) Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that every compact subset of X is already contained in one of the X_i. Then the chain complexes $\mathrm{C}_*(X_i), i \in \mathbb{N}$ together with the inclusion induced chain maps $\mathrm{C}_*(X_i) \to \mathrm{C}_*(X_j)$ for $i \leq j$ form a direct system of chain complexes.[965] Furthermore the inclusion induced maps $\mathrm{C}_*(X_i) \to \mathrm{C}_*(X)$ induce an isomorphism[966]

$$\varinjlim \mathrm{C}_*(X_i) \xrightarrow{\cong} \mathrm{C}_*(X)$$

of chain complexes.

Proof. Given a topological space Y and $n \in \mathbb{N}_0$ we denote by $\mathrm{S}_n(Y)$ the set of singular n-simplices in Y. It follows immediately from our hypothesis on the X_i, the fact that Δ^n is compact and the Compact Image Lemma 2.13 that

$$\mathrm{S}_n(X) = \bigcup_{i\in\mathbb{N}} \mathrm{S}_n(X_i).$$

As in the example on page 1258 we now see that

$$\varinjlim \mathrm{C}_n(X_i) = \varinjlim \mathbb{Z}^{(\mathrm{S}_n(X_i))} = \mathbb{Z}^{(\mathrm{S}_n(X))} = \mathrm{C}_n(X).$$

We leave it to the reader to verify that the inclusion maps also induce an isomorphism of chain complexes. ■

The second lemma required for the proof of the Exhaustions-H$_*$-Proposition 79.4 is purely algebraic.

Lemma 79.6. (Direct Limit-Homology Lemma) Let $(I, \leq)$ be a directed set and furthermore let $(\{\mathrm{C}_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ be a direct system of chain complexes. Then for each $n \in \mathbb{N}_0$ we obtain an induced direct system $(\{\mathrm{H}_n(\mathrm{C}_i)\}_{i\in I}, \{f_{ij*}\}_{i\leq j})$ of abelian groups.

[965] We refer to page 1257 for the definition of a direct system.

[966] The argument of the Direct Limit Existence Proposition 56.1 or respectively of page 1262 shows that the direct limit of a direct system of chain complexes always exists.

Furthermore, given any $n \in \mathbb{N}_0$ the maps $\mathrm{H}_n(\mathrm{C}_i) \to \mathrm{H}_n\big(\varinjlim \mathrm{C}_i\big)$ induce an isomorphism

$$\varinjlim \mathrm{H}_n(\mathrm{C}_i) \ \xrightarrow{\cong}\ \mathrm{H}_n\big(\varinjlim \mathrm{C}_i\big).$$

Proof. We have

$$\begin{aligned} \varinjlim \mathrm{H}_n(\mathrm{C}_i) &= \varinjlim \overbrace{\operatorname{coker}(\mathrm{C}_{i+1} \to \ker(\mathrm{C}_i \to \mathrm{C}_{i-1}))}^{=\mathrm{H}_n(\mathrm{C}_i)} \\ &= \operatorname{coker}\big(\varinjlim \mathrm{C}_{i+1} \to \ker\big(\varinjlim \mathrm{C}_i \to \varinjlim \mathrm{C}_{i-1}\big)\big) \ = \ \mathrm{H}_n\big(\varinjlim \mathrm{C}_i\big). \\ &\uparrow \\ &\text{Direct Limit-(Co-)-Kernel Corollary 79.3 applied twice} \end{aligned}$$

The fact that this isomorphism is induced by the maps $\mathrm{H}_n(\mathrm{C}_i) \to \mathrm{H}_n(\varinjlim \mathrm{C}_i)$ follows easily from the various definitions. ∎

We conclude this short section with a few examples:

Example. For any $n \in \mathbb{N}_0$ we have

$$\begin{aligned} \mathrm{H}_n(S^\infty) &= \varinjlim_{k\in\mathbb{N}} \mathrm{H}_n(S^k) &&= \varinjlim_{k\in\mathbb{N}} \begin{cases} \mathbb{Z}, & \text{if } n = k, 0, \\ 0, & \text{else} \end{cases} &&= \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ 0, & \text{else.} \end{cases} \\ &\uparrow &&\uparrow &&\uparrow \\ &\text{by the Homology-via-Exhaustions Proposition 79.4, where we view } S^\infty \text{ as a CW-complex as on page 1479} &&\text{Proposition 74.4} &&\text{Direct Limit Stabilization Lemma 56.2} \end{aligned}$$

The next lemma is basically also just an example. But since we will need it later on we formulate it as a lemma.

Lemma 79.7. We consider the real line with infinitely many 2-dimensional spheres attached, i.e. we consider

$$X \ := \ (\mathbb{R} \cup (S^2 \times \mathbb{Z}))/\!\sim \qquad \text{where } n \sim ((0,0,-1),n) \text{ for } n \in \mathbb{Z}.$$

Then[967]

$$\mathrm{H}_n(X) \ \cong \ \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^\infty, & \text{if } n = 2, \\ 0, & \text{else.} \end{cases}$$

In fact we can specify an isomorphism on $\mathrm{H}_2(X)$. Given $i \in \mathbb{Z}$ we denote by $f_i \colon S^2 \to X$ the "obvious" i-th inclusion map. Then an isomorphism is given by

$$\begin{aligned} \mathbb{Z}^\infty \cong \bigoplus_{i\in\mathbb{Z}} \mathbb{Z} \ &\to \ \mathrm{H}_2(X) \\ \bigoplus_{i\in\mathbb{Z}} a_i \ &\mapsto \ \sum_{i\in\mathbb{Z}} a_i \cdot f_i([S^2]). \end{aligned}$$

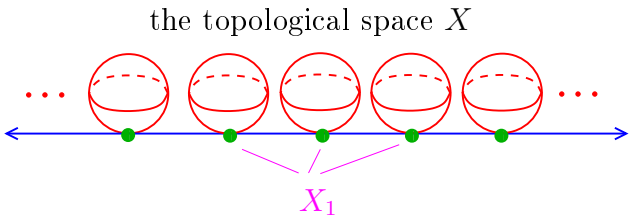
Proof. We view X as a CW-complex in the obvious way. Furthermore, given $k \in \mathbb{N}$ we consider the subcomplex

$$X_k \ := \ ([-k,k] \cup S^2 \times \{-k,\dots,k\})/\!\sim .$$

[967] Recall that

$$\mathbb{Z}^\infty \ := \ \mathbb{Z}^{(\mathbb{N})} \ = \ \{(x_1,x_2,\dots) \,|\, x_i \in \mathbb{Z} \text{ but only finitely many } x_i\text{'s are non-zero}\}.$$

Note that X_k is the interval $[-k, k]$ with $2k+1$ spheres attached. (We refer to the figure below for an illustration.) We see that



$$\mathrm{H}_n(X) \;=\; \varinjlim \mathrm{H}_n(X_k) \;=\; \varinjlim \begin{cases} \mathbb{Z}, & \text{if } n=0, \\ \mathbb{Z}^{2k+1}, & \text{if } n=2, \\ 0, & \text{else} \end{cases} \;=\; \begin{cases} \mathbb{Z}, & \text{if } n=0, \\ \mathbb{Z}^{\infty}, & \text{if } n=2, \\ 0, & \text{else.} \end{cases}$$

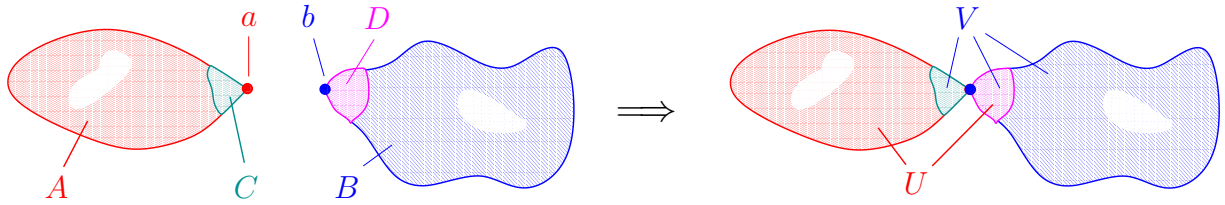
Homology-via-Exhaustions Proposition 79.4

see Exercise 78.15

see page 1258 and the Direct Limit Stabilization Lemma 56.2

The statement about the precise isomorphism of $\mathrm{H}_2(X)$ also follows from the explicit description of the isomorphism Exercise 78.15 and the discussion on page 1258. ■

79.3. **The homology groups of the wedge of topological spaces.** The following proposition says that under a mild hypothesis "homology groups are additive" under the operation of taking the wedge of two topological spaces. The proposition is very similar in vein to the Wedge-π_1-Proposition 52.3.



Proposition 79.8. (Wedge-H_*-Proposition) Let A and B be two topological spaces and let $a \in A$ and $b \in B$ be good points. We denote by $A \vee B$ the wedge defined using a and b. Then the natural inclusion maps $i\colon A \to A \vee B$ and $j\colon B \to A \vee B$ that we introduced on page 1134 induce for every $n \in \mathbb{N}_0$ an isomorphism

$$i_* \oplus j_*\colon \widetilde{\mathrm{H}}_n(A) \oplus \widetilde{\mathrm{H}}_n(B) \;\to\; \widetilde{\mathrm{H}}_n(A \vee B).$$

Furthermore, if we denote by $p\colon A \vee B \to A$ and $q\colon A \vee B \to A$ the natural projection s, then an inverse to the above isomorphism is given by

$$p_* + q_*\colon \widetilde{\mathrm{H}}_n(A \vee B) \;\to\; \widetilde{\mathrm{H}}_n(A) \oplus \widetilde{\mathrm{H}}_n(B).$$

Proof. We write $X = A \vee B$ and $x_0 = \{a, b\} \in A \vee B$. We pick an open neighborhood C in A of a such that $\{a\}$ is a deformation retract of C. Furthermore we pick an open neighborhood D of b in B such that b is a deformation retract of D. We consider $U := A \vee D$

and $V := B \vee C$. We consider the following diagram of maps

$$\begin{array}{ccccccccc} & & & & \widetilde{\mathrm{H}}_n(A) \oplus \widetilde{\mathrm{H}}_n(B) & & & & \\ & & & & \cong\downarrow \quad \downarrow\cong & & & & \\ \ldots & \longrightarrow & \widetilde{\mathrm{H}}_n(U \cap V) & \longrightarrow & \widetilde{\mathrm{H}}_n(U) \oplus \widetilde{\mathrm{H}}_n(V) & \longrightarrow & \widetilde{\mathrm{H}}_n(X) & \longrightarrow & \widetilde{\mathrm{H}}_{n-1}(U \cap V) \longrightarrow \ldots \end{array}$$

We make the following observations:

(1) The bottom sequence is exact by the Mayer–Vietoris Theorem 78.5.
(2) As in the proof of the Wedge-π_1-Proposition 52.3 we see that the intersection $U \cap V$ deformation retracts to x_0, in particular we obtain from the Homotopy Equivalence-H_*-Corollary 73.9 that we have the equality $\widetilde{\mathrm{H}}_n(U \cap V) = \widetilde{\mathrm{H}}_{n-1}(U \cap V) = 0$.
(3) By the proof of the Wedge-π_1-Proposition 52.3 we know that A is a deformation retract of U and that B is a deformation retract of V. Therefore the vertical maps are isomorphisms by the Homotopy Equivalence-H_*-Corollary 73.9.

The combination of these three observations shows that

$$i_* \oplus j_* \colon \widetilde{\mathrm{H}}_n(A) \oplus \widetilde{\mathrm{H}}_n(B) \;\to\; \widetilde{\mathrm{H}}_n(A \vee B)$$

is an isomorphism. It is clear that $(p_* + q_*) \circ (i_* + j_*)$ is the identity on $\widetilde{\mathrm{H}}_n(A) \oplus \widetilde{\mathrm{H}}_n(B)$, so we also get the second isomorphism. ■

The Wedge-H_*-Proposition 79.8 has nothing to do with the content of the present chapter, we could easily have proved it in Chapter 78. But odd as it may sound, soon we will be quite interested in the homology groups of the wedge $\bigvee\limits_{i \in I} X_i$ of an arbitrary family of topological spaces. If I is a finite set, i.e. if we take the wedge of finitely many topological spaces, then we can use the Wedge-H_*-Proposition 79.8 and an elementary induction argument to determine the homology groups.

It is a priori less clear how one can deal with the case that I is an infinite set. Fortunately the next proposition allows us to handle the general situation. This proposition is the generalization of the Wedge-H_*-Proposition 79.8 to the wedge of an arbitrary family of topological spaces.

Proposition 79.9. (Wedge-H_*-Proposition) Let $\{A_k\}_{k \in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$.[968] We use these points to form the wedge $\bigvee\limits_{k \in K} A_k$. Given $j \in K$ we denote by

$$i_j \colon A_j \;\to\; \bigvee_{k \in K} A_k \quad \text{respectively} \quad p_j \colon \bigvee_{k \in K} A_k \;\to\; A_j$$

the natural inclusion map respectively the natural projection that we introduced on page 1134. Then for every $n \in \mathbb{N}_0$ the map

$$\bigoplus_{k \in K} p_{k*} \colon \widetilde{\mathrm{H}}_n\Big(\bigvee_{k \in K} A_k\Big) \;\to\; \bigoplus_{k \in K} \widetilde{\mathrm{H}}_n(A_k)$$

is an isomorphism where the inverse is given by

$$\bigoplus_{k \in K} i_{k*} \colon \bigoplus_{k \in K} \widetilde{\mathrm{H}}_n(A_k) \;\to\; \widetilde{\mathrm{H}}_n\Big(\bigvee_{k \in K} A_k\Big).$$

We like the Wedge-H_*-Proposition 79.9 so much that we provide two different proofs. The first proof is quick and slick, but depending on your taste the first proof might have feel slightly unsatisfactory. The second proof is somewhat longer, but it fits in better with the discussion of this chapter. In fact, as an encore we will suggest one more proof of the Wedge-H_*-Proposition 79.9 in Exercise 79.2.

First proof of the Wedge-H_*-Proposition 79.9. We have the following isomorphisms:

$$\widetilde{\mathrm{H}}_n\Big(\bigvee_{k\in K} A_k\Big) \underset{\text{definition of the wedge operation}}{=} \widetilde{\mathrm{H}}_n\Big(\bigsqcup_{k\in K} A_k \Big/ \bigsqcup_{k\in K}\{a_k\}\Big) \underset{\text{since each } a_k \in A_k \text{ is good we see that } \bigsqcup_{k\in K}\{a_k\} \text{ is a good subset of } \bigsqcup_{k\in K} A_k, \text{ thus we can apply the Homology-of-Quotients Proposition 74.20}}{\overset{\cong}{\leftarrow}} \mathrm{H}_n\Big(\bigsqcup_{k\in K} A_k, \bigsqcup_{k\in K}\{a_k\}\Big) \underset{\text{by the obvious generalization of Lemma 72.14}}{\overset{\cong}{\leftarrow}} \bigsqcup_{k\in K} \mathrm{H}_k(A_k, \{a_k\})$$

$$\overset{\cong}{\leftarrow} \bigsqcup_{k\in K} \widetilde{\mathrm{H}}_k(A_k).$$

Lemma 74.12

We leave it to the reader to verify that the isomorphism is indeed given by $\bigoplus_{k\in K} p_{k*}$ and that the inverse is the map $\bigoplus_{k\in K} i_{k*}$. ■

The second proof of the Wedge-H_*-Proposition 79.9 is almost embarrassingly similar to the proof of Proposition 52.7.

Second proof of the Wedge-H_*-Proposition 79.9. Let $\{A_k\}_{k\in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. We use these points to form the wedge $\bigvee_{k\in K} A_k$. Recall that the fact that a_k is good means that

(1) $\{a_k\}$ is a closed subset of A_k and
(2) that there exists an open neighborhood U_k of a_k in A_k such that a_k is a deformation retract of U_k.

We will show that the map

$$\bigoplus_{k\in K} i_k \colon \bigoplus_{k\in K} \widetilde{\mathrm{H}}_n(A_k) \;\to\; \widetilde{\mathrm{H}}_n\Big(\bigvee_{k\in K} A_k\Big)$$

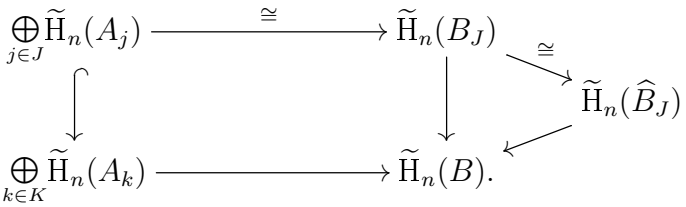
is an isomorphism. Once we will have established this fact it is straightforward to show that the inverse is given by $\bigoplus_{k\in K} p_{k*}$.

The idea of the proof is to show that the map is a monomorphism and an epimorphism, in a way which is reminiscent to the approach taken in the proofs of the Exhaustions-H_*-Proposition 79.4.

Claim. The map

$$\bigoplus_{k\in K} i_k \colon \bigoplus_{k\in K} \widetilde{\mathrm{H}}_n(A_k) \;\to\; \widetilde{\mathrm{H}}_n\Big(\bigvee_{k\in K} A_k\Big)$$

is an epimorphism.



Proof. We introduce the following notation:

(1) We write $B := \bigvee_{k\in K} A_k$ and we set $U := \bigcup_{k\in K} U_k \subset B$.

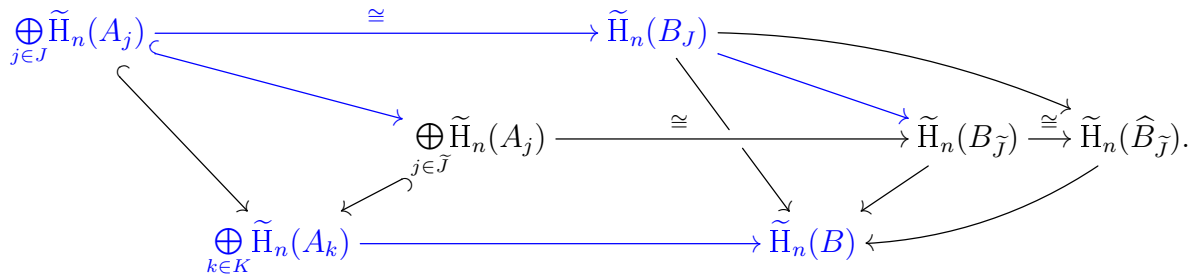
[968] Recall that by the discussion on page 1171 any point on a topological manifold is good and that by the CW-Complex Properties Proposition 68.10 (5) any point on a CW-complex is good.

(2) Given a subset $J \subset K$ we write $B_J := \bigvee_{j\in J} A_j$ and we write $\widehat{B}_J := U \cup B_J$.

Given a finite subset $J \subset K$ we have the following commutative diagram

We make the following observations and comments:

(1) The maps are either the obvious algebraic inclusion maps or they are the obvious maps induced by inclusions of topological spaces. It follows almost immediately from the definitions that the diagram commutes.
(2) Since J is finite we obtain, as pointed out above, from the Wedge-H_*-Proposition 79.8 that the top horizontal map is an isomorphism.
(3) By Exercise 50.8 we know that B_J is a deformation retract of $\widehat{B}_J$. It follows from the Homotopy Equivalence-H_*-Corollary 73.9 (4) that the top diagonal map is an isomorphism.
(4) By Exercise 50.9 we know that given any compact subset $L \subset B$ there exists a finite subset $J \subset K$ with $L \subset \widehat{B}_J$.



Now we show that the above map $\bigoplus_{k\in K} i_{k*}$ is an epimorphism. So suppose we are given a homology class $[\sigma] \in \widetilde{\mathrm{H}}_n(B)$. As in the proof of the Exhaustion-Chain Complex Lemma 79.5 we see that it follows from (4) there exists a finite subset $J \subset K$ such that $\sigma \in \mathrm{C}_n(\widehat{B}_J)$. But considering the above diagram, and using the fact that the top horizontal map is an isomorphism we see that $[\sigma]$ actually lies in the image of $\bigoplus_{k\in K} i_k$. ⊞

Claim. The map

$$\bigoplus_{k\in K} i_k \colon \bigoplus_{k\in K} \widetilde{\mathrm{H}}_n(A_k) \to \widetilde{\mathrm{H}}_n\Big(\bigvee_{k\in K} A_k\Big)$$

is a monomorphism.

Proof. We continue with the notation that we introduced in the proof of the previous claim. Given any two finite subsets $J \subset \widetilde{J} \subset K$ we have the following commutative diagram

The diagram together with the argument of Exercise 52.7 shows that the map $\bigoplus_{k\in K} i_{k*}$ is also a monomorphism. ■

79.4. **Moore spaces.** Now that we have played with homology groups the following question arises: which sequences of abelian groups can appear as the sequence of homology groups $\mathrm{H}_*(X)$ of a non-empty topological space? It turns out that anything goes, there are basically no restrictions, except that we know by Corollary 72.15 that $\mathrm{H}_0(X)$ is necessarily a non-trivial free abelian group.
In other words, we have the following proposition.

Proposition 79.10. If $\{A_n\}_{n\in\mathbb{N}_0}$ is a sequence of abelian groups. If A_0 is a non-trivial free abelian group, then there exists a CW-complex Z such that for any $n \in \mathbb{N}_0$ we have $\mathrm{H}_n(Z) \cong A_n$.

This proposition is hardly the most exciting result of these notes. But the following definition, which we will need in the proof of Proposition 79.10, will in fact turn out to be convenient.

Definition. Let $n \in \mathbb{N}$ and let π be an abelian group. We say that a non-empty topological space X is a Moore space of type $\mathrm{M}(\pi, n)$ if the following conditions are satisfied:

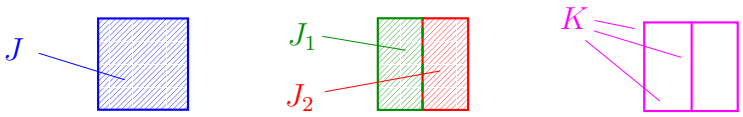
(1) X admits a CW-structure,
(2) for any $i \neq n$ we have $\widetilde{\mathrm{H}}_i(X) = 0$,
(3) $\mathrm{H}_n(X) \cong \pi$.
(4) If $n \geq 2$, then we also demand that X is simply connected.

Example. Let $n \in \mathbb{N}$. It follows from the Sphere-π_1-Proposition 47.13 and Proposition 74.4 that S^n is a Moore space of type $(\mathbb{Z}, n)$.

Proposition 79.11. (Moore Space Existence Proposition) Given any $n \in \mathbb{N}$ and given any abelian group π there exists an $(n+1)$-dimensional CW-complex that has no cells in dimensions $1, \ldots, n-1$ and that is a Moore space of type $\mathrm{M}(\pi, n)$.

Proof of Proposition 79.10 assuming the Moore Space Existence Proposition 79.11. Let $\{A_n\}_{n\in\mathbb{N}_0}$ be a sequence of abelian groups such that A_0 is a non-trivial free abelian group. In other words, we have $A_0 \cong \mathbb{Z}^{(S)}$ for some non-empty set S.

By the Moore Space Existence Proposition 79.11 we can find for each $n \in \mathbb{N}$ a CW-complex X_n that is a Moore space of type $\mathrm{M}(\pi, n)$. We consider the wedge $Y := \bigvee_{n\in\mathbb{N}} X_n$. By the CW-Complex Construction Lemma 68.32 (4) we can equip Y with a CW-structure. It follows from the Wedge-H_*-Proposition 79.9 that for every $n \in \mathbb{N}$ we have $\mathrm{H}_n(Y) \cong \mathrm{H}_n(X_n) \cong A_n$ and that $\mathrm{H}_0(Y) \cong \mathbb{Z}$. Since S is non-empty we can pick a point $* \in S$. We define $Z := Y \sqcup (S \setminus \{*\})$ where we equip $S \setminus \{*\}$ with the discrete topology. It follows from the CW-Complex Construction Lemma 68.32 that Z is a CW-complex. Finally it follows from the H_0-Proposition 72.5 and Lemma 72.13 that Z has the promised homology groups. ∎



In the proof of the Moore Space Existence Proposition 79.11 we will also need the following little calculation which will be of independent use.

Lemma 79.12. Let (X, x_0) be a pointed topological space, let $n \in \mathbb{N}$, let $\omega \in \mathrm{H}_n(I^n, \partial I^n)$ and let $f, g\colon (I^n, \partial I^n) \to (X, x_0)$ be two maps. Then

$$[f_*(\omega)] + [g_*(\omega)] \underset{\uparrow}{=} [(f * g)_*(\omega)] \in \mathrm{H}_n(X, x_0) = \mathrm{H}_n(X).$$

$\uparrow$ product of f and g as defined on page 1561

Proof. We write $J = I^n$, $J_1 = [0, \frac{1}{2}] \times I^{n-1}$ and $J_2 = [\frac{1}{2}, 1] \times I^{n-1}$. Furthermore we write $K = \partial J \cup (\{\frac{1}{2}\} \times I^{n-1})$. For $k = 1, 2$ we denote by $i_k\colon (J_k, \partial J_k) \to (J, K)$ the inclusion map. Finally we denote by $\varphi_k\colon (J_k, \partial J_k) \to (J, \partial J)$ the obvious homeomorphism given by stretching the last coordinate.

The map $f * g\colon (J, \partial J) \to (X, x_0)$ factors through a map $(J, K) \to (X, x_0)$ that we also denote by $f * g$. Thus we have the following commutative diagram

$$\begin{array}{ccccc} & & (J_1, \partial J_1) & & \\ & \overset{\varphi_1}{\nearrow} & \downarrow i_1 & \overset{f\circ\varphi_1^{-1}}{\searrow} & \\ (J, \partial J) & \xrightarrow{i} & (J, K) & \xrightarrow{f*g} & (X, x_0) \\ & \underset{\varphi_2}{\searrow} & \uparrow i_2 & \underset{g\circ\varphi_2^{-1}}{\nearrow} & \\ & & (J_2, \partial J_2). & & \end{array}$$

For $k = 1, 2$ we write $\omega_k = (\varphi_k)_*(\omega)$. Thus it suffices to show that $i_{1*}(\omega_1) + i_{2*}(\omega_2) = i_*(\omega)$. To prove this equality we consider the following commutative diagram[969]

$$\begin{array}{ccccc} & & \mathrm{H}_n(J_1, \partial J_1) & \xrightarrow{k_1} & \mathrm{H}_n(J, \partial J_1 \cup J_2) \\ & \overset{\varphi_1}{\nearrow} & \downarrow i_1 & \overset{j_1}{\nearrow} & \\ \mathrm{H}_n(J, \partial J) & \xrightarrow{i} & \mathrm{H}_n(J, K) & \overset{j_2}{\searrow} & \\ & \underset{\varphi_2}{\searrow} & \uparrow i_2 & & \\ & & \mathrm{H}_n(J_2, \partial J_2) & \xrightarrow[k_2]{} & \mathrm{H}_n(J, J_1 \cup \partial J_2), \end{array}$$

where all maps, except for φ_1 and φ_2, are induced by the obvious inclusion maps. We have

$$(j_1)(i(\omega)) = (k_1 \circ \varphi_1)(\omega) = j_1(i_1(\omega_1)) \underset{\uparrow}{=} j_1(i_1(\omega_1)) + j_1(i_2(\omega_2))$$

$\uparrow$ since $j_1 \circ i_2 = 0$

and similarly we show that $(j_2)(i(\omega)) = j_2(i_1(\omega_1)) + j_2(i_2(\omega_2))$.

[969] To simplify the notation we denote the induced map by the same symbol as the map between pairs of topological spaces, i.e. we drop the subscript $*$ from the notation.

It remains to show that $\ker(j_1) \cap \ker(j_2) = 0$. We consider the following diagram

$$\begin{array}{ccccc} & & & & \mathrm{H}_n(J, \partial J_1 \cup J_2) \\ & & & \overset{j_1}{\nearrow} & \\ & & \mathrm{H}_n(J, K) & & \\ & \nearrow & \uparrow{\scriptstyle i_2} & \searrow^{j_2} & \\ \mathrm{H}_n(J, \partial J_1 \cup J_2) & \xleftarrow[\cong]{} & \mathrm{H}_n(J_2, \partial J_2) & \xrightarrow[\cong]{k_2} & \mathrm{H}_n(J, J_1 \cup \partial J_2). \end{array}$$

We make the following clarifications and observations:

(1) The diagonal map to the bottom left of the diagram is induced by the inclusion $(J, \partial J_1 \cup J_2) \to (J, K)$.
(2) It follows easily from Corollary 74.16 (2a) and (2c) that the bottom two horizontal maps are isomorphisms.
(3) The diagonal sequence is exact by the Topological LES-Proposition 74.13.
(4) It now follows from some mild diagram chasing that $\ker(j_1) \cap \ker(j_2) = 0$. ■

Lemma 79.13.

(1) Let $f\colon S^n \to S^n_1 \vee S^n_2$ be the pinching map that we introduced on page 1565. Let $i \in \{1, 2\}$. If we denote by $S^n_1 \vee S^n_2 \to S^n_i = S^n$ the natural projection, then the induced map $(p_i \circ f)_*\colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n)$ is the identity.
(2) Given any $k \in \mathbb{Z}$ there exists a map $g_k\colon S^n \to S^n$ with $g_k(*) = *$ such that $g_{k*}\colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n)$ is given by multiplication by k.

Proof.

(1) The first statement follows easily from Lemma 79.12.
(2) The second statement follows almost immediately from Lemma 76.10 together with the Suspension-H_*-Proposition 76.7. ■

Now we turn to the proof of the Moore Space Existence Proposition 79.11.

Proof of the Moore Space Existence Proposition 79.11. Let $n \in \mathbb{N}$ and let π be an abelian group. Since π is abelian it follows immediately from Lemma 89.14 (1)[970] that there exist sets A and B, a homomorphism $\varphi\colon \mathbb{Z}^{(A)} \to \mathbb{Z}^{(B)}$ and a homomorphism $\rho\colon \mathbb{Z}^{(B)} \to \pi$ such that the following sequence is exact:

$$0 \to \mathbb{Z}^{(A)} \xrightarrow{\varphi} \mathbb{Z}^{(B)} \xrightarrow{\rho} \pi \to 0.$$

We let $X := \bigvee_{a \in A} S^n_a$ and we let $Y := \bigvee_{b \in B} S^n_b$. By the CW-Complex Construction Lemma 68.32 (4) we can equip X with the obvious CW-structure which has precisely one 0-cell and which has precisely one n-cell for each $a \in A$. Similarly we equip Y with the obvious CW-structure. Using the Wedge-H_*-Proposition 79.9 and using the standard generator of $\mathrm{H}_n(S^n)$ we can make the obvious identifications $\mathrm{H}_n(X) = \mathbb{Z}^{(A)}$ and $\mathrm{H}_n(Y) = \mathbb{Z}^{(B)}$.

[970] In this case the fact that we refer to a later lemma need not worry us. As the reader can see, the proof of Lemma 89.14 (1) relies only on information that we already know.

Claim. There exists a map $h\colon X \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_n(X) & \xrightarrow{h_*} & \mathrm{H}_n(Y) \\ {\scriptstyle =}\downarrow & & \downarrow{\scriptstyle =} \\ \mathbb{Z}^{(A)} & \xrightarrow{\varphi} & \mathbb{Z}^{(B)}. \end{array}$$

Proof. This map φ can be constructed explicitly using the following ingredients:

(1) the pinching map $f\colon S^n \to S^n_1 \vee S^n_2$,
(2) the maps $g_k\colon S^n \to S^n$ from Lemma 79.13,
(3) the natural inclusions and projections from page 1134,
(4) and the wedge of maps as introduced on page 1133.

The notation becomes somewhat cumbersome, thus in a short moment of lassitude we decide to leave it to the reader to fill in the details. A baby example is the content of Exercise 79.3. ⊞

Now let $Z := \mathrm{Cone}(h\colon X \to Y)$ be the mapping cone of the map $h\colon X \to Y$. It follows from the above claim and the Mapping Cone-H_*-Lemma 78.17 that we have the following commutative diagram of long exact sequences

$$\begin{array}{ccccccccccccc} \ldots & \longrightarrow & \overbrace{\mathrm{H}_{n+1}(Y)}^{=0} & \longrightarrow & \mathrm{H}_{n+1}(Z) & \longrightarrow & \mathrm{H}_n(X) & \xrightarrow{h_*} & \mathrm{H}_n(Y) & \longrightarrow & \mathrm{H}_n(Z) & \longrightarrow & \overbrace{\mathrm{H}_{n-1}(X)}^{=0} & \longrightarrow & \ldots \\ & & \downarrow & & \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle =} & & \downarrow{\scriptstyle =} & & & & \downarrow & & \\ \ldots & \longrightarrow & 0 & \longrightarrow & \mathrm{H}_{n+1}(Z) & \longrightarrow & \mathbb{Z}^{(A)} & \xrightarrow{\varphi} & \mathbb{Z}^{(B)} & \longrightarrow & \mathrm{H}_n(Z) & \longrightarrow & 0 & \longrightarrow & \ldots. \end{array}$$

It follows that $\mathrm{H}_n(Z) \cong \mathrm{coker}(\varphi) \cong \pi$. Furthermore, since φ is injective we see that $\mathrm{H}_{n+1}(Z) = 0$. Furthermore we see that all other reduced homology groups of Z are also zero.

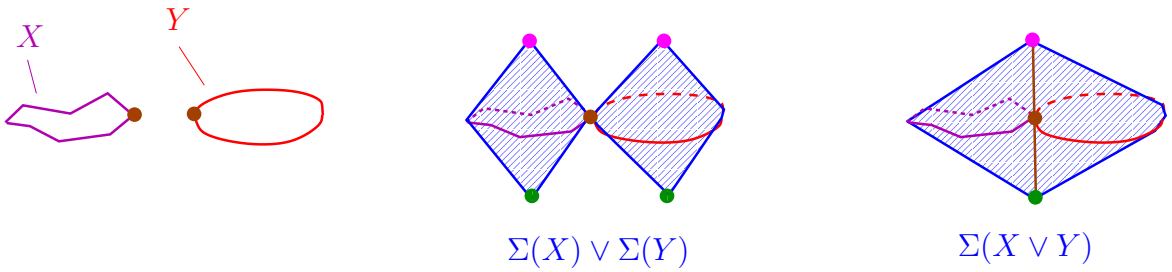
Next we equip Z with the natural CW-structure coming from the CW-Complex Cone Corollary 68.35. There is one small fly in the ointment. The CW-structure has two 0-cells (namely one corresponding to the tip of the cone and the 0-cell of Y), one 1-cell and otherwise indeed only cells in dimensions n and $n+1$. Let A be the subcomplex that consists of the 1-cell that connects the two 0-cells. By the CW-Complex Construction Lemma 68.32 we can view Z/A as a CW-complex which now has only one 0-cell and otherwise only cells in dimension n and $n+1$. By the discussion on page 1614 we know that A is a good subset of Z. It follows from Theorem 74.3 that the reduced homology groups of Z/A coincide with the reduced homology groups of Z. Thus we see that Z/A is the CW-complex of our dreams. ■

Given an abelian group π and $n \in \mathbb{N}$ there are in general infinitely many pairwise non-homeomorphic Moore spaces of type $\mathrm{M}(\pi, n)$. For example the topological spaces $\overline{B}^k$, $k \in \mathbb{N}_0$ are Moore spaces of type $\mathrm{M}(\{e\}, 1)$. It is slightly less absurd to wonder whether Moore spaces are well-defined up to say homotopy equivalence. We formulate this as a question, we will come back to it at a later point.

Question 79.14. Let π be an abelian group and let $n \in \mathbb{N}$. Are any two Moore spaces of type (π, n) homotopy equivalent?

Exercises for Chapter 79.

Exercise 79.1. Let X and Y be topological spaces and let $x_0 \in X$ and $y_0 \in Y$ be good points. We write $\widetilde{x}_0 = [(x_0, 0)] \in \Sigma(X)$ and $\widetilde{y}_0 = [(y_0, 0)] \in \Sigma(Y)$.



(a) Show that $\widetilde{x}_0 \in \Sigma(X)$ and $\widetilde{y}_0 \in \Sigma(Y)$ are good points. We use these points to define the wedge $\Sigma(X) \vee \Sigma(Y)$.

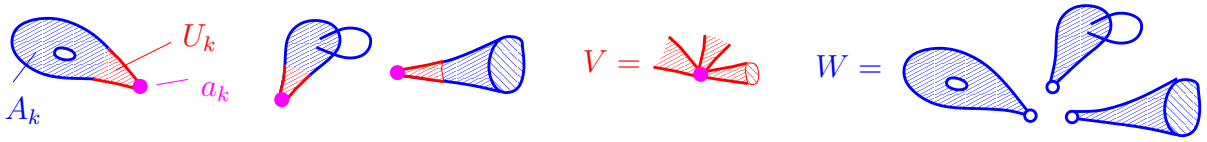
(b) Let $i\colon X \to X \vee Y$ and $j\colon Y \to X \vee Y$ be the obvious maps. Show that the map

$$(\Sigma(i) \vee \Sigma(j))_*\colon \mathrm{H}_k(\Sigma(X) \vee \Sigma(Y)) \;\to\; \mathrm{H}_k(\Sigma(X \vee Y))$$

is an isomorphism for each k.

Remark. You could make use of the *natural* isomorphism of the Suspension-H_*-Proposition 76.7.

Exercise 79.2. Let $\{A_k\}_{k\in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. By definition, see page 1171, this means that given any $k \in K$ the following statements hold:



(1) $\{a_k\}$ is a closed subset of A_k and

(2) there exists an open neighborhood U_k of a_k in A_k such that a_k is a deformation retract of U_k.

Provide a third proof of the Wedge-H_*-Proposition 79.9 using the following approach. First we write $W := \bigcup_{k\in K}(A_k \setminus \{a_k\})$. Now apply the (natural) reduced Mayer–Vietoris sequences from Theorem 78.5 to the decompositions

$$\bigvee_{k\in K} A_k \;=\; V \cup W \quad \text{and} \quad \bigsqcup_{k\in K} A_k \;=\; \Big(\bigsqcup_{k\in K}(U_k \setminus \{a_k\})\Big) \cup \Big(\bigsqcup_{k\in K}(A_k \setminus \{a_k\})\Big).$$

Remark. Do not forget to make use of the analogue of Exercise 52.7.

Exercise 79.3. Let $n \in \mathbb{N}$ and let $X = S^n \vee S^n$ and let $Y = S^n \vee S^n \vee S^n$. As in the proof of the Moore Space Existence Proposition 79.11 we can make the identification $\mathrm{H}_n(X) = \mathbb{Z}^2$ and $\mathrm{H}_n(Y) = \mathbb{Z}^3$. Show that there exists a map $\varphi\colon X \to Y$ such that the map

$\varphi_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(Y)$ is represented by the matrix

$$\begin{pmatrix} 2 & 1 \\ -5 & 1 \\ 0 & 7 \end{pmatrix}.$$

80. Cellular homology

We saw in the Fundamental Group-of-1-Complex Theorem 69.9 and the Cell Attachment-π_1-Proposition 69.11 that it is quite easy to compute the fundamental group of a finite CW-complex. In this section we will develop a relatively straightforward method for computing the homology groups of a finite CW-complex. We will use this method to finally determine the homology groups of the surfaces of genus ≥ 2 and all the projective spaces $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$.

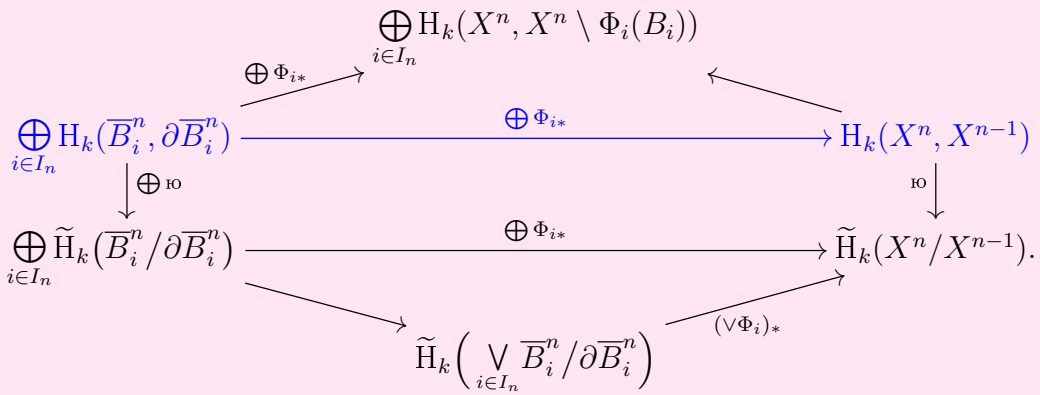
80.1. **The definition of cellular homology.** We turn to the systematic study of homology groups of CW-complexes. We need to recall two definitions:

(1) Recall that in the Standard Simplex Homeomorphism Lemma 72.1 we gave a homeomorphism $f\colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, \partial\overline{B}^n)$. This homeomorphism together with the Identity-is-Generator Lemma 76.2 gives us the following isomorphism:

$$\begin{array}{ccccc} \mathbb{Z} & \xrightarrow{\cong} & \mathrm{H}_n(\Delta^n, \partial\Delta^n) & \underset{\cong}{\xrightarrow{f_*}} & \mathrm{H}_n(\overline{B}^n, \partial\overline{B}^n) \\ 1 & \mapsto & [\mathrm{id}_{\Delta^n}] & & \end{array}$$

In the following we will usually identify $\mathrm{H}_n(\overline{B}^n, \partial\overline{B}^n)$ with $\mathbb{Z}$ using the above isomorphism.

(2) Let X be a topological space and let $A \subset X$ be a subset. As on page 1633 we consider the map



$$\mathrm{H}_n(X, A) \longrightarrow \mathrm{H}_n(X/A, A/A) \xleftarrow[\cong]{\text{Lemma 74.12}} \widetilde{\mathrm{H}}_n(X/A).$$
$$\text{ю}$$

By Lemma 74.19 we know that the map is a natural homomorphism.

Now we can formulate one of the key lemmas regarding homology groups of CW-complexes.

Lemma 80.1. (Skeleton-Homology Lemma) Let X be a CW-complex and let $n \in \mathbb{N}_0$.

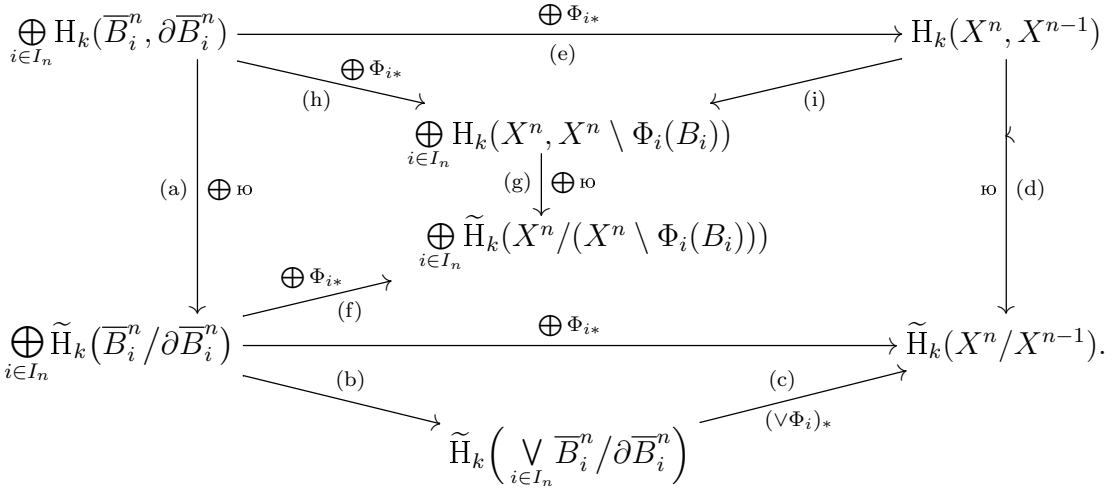
(1) Given $n \in \mathbb{N}_0$ we denote by I_n the set of n-cells and given $i \in I_n$ we denote by $\Phi_i\colon \overline{B}_i^n \to X^n$ the corresponding characteristic map. Then for every $k \in \mathbb{N}_0$ we have the following commutative diagram where all maps are isomorphisms:

In particular the following holds:

(a) For $k \neq n$ we have $\mathrm{H}_k(X^n, X^{n-1}) = 0$.

(b) The group $\mathrm{H}_n(X^n, X^{n-1})$ is a free abelian group where the rank equals the cardinality of the set I_n of n-cells in the CW-structure.

(2) For $k > n$ we have $\mathrm{H}_k(X^n) = 0$.



(3) For $k < n$ the inclusion $i\colon X^n \to X$ induces an isomorphism $i_*\colon \mathrm{H}_k(X^n) \xrightarrow{\cong} \mathrm{H}_k(X)$.

(4) The inclusion $i\colon X^n \to X$ induces an epimorphism $i_*\colon \mathrm{H}_n(X^n) \twoheadrightarrow \mathrm{H}_n(X)$.

Remark. The statements (3) and (4) of the Skeleton-Homology Lemma 80.1 can be viewed as "homology analogues" of the CW-Skeleton-π_n-Proposition 71.9.

Proof. Let X be a CW-complex.

(1) We consider the following diagram

We make the following observations:

(α) It follows from the definitions that the two triangles at the top and bottom commute.

(β) It follows almost immediately from the naturality of the maps ю that the big outer rectangle commutes and that the quadrilateral to the left commutes.

It remains to show that the maps numbered with (a) to (h) are isomorphisms.

(a) This map is an isomorphism by the Homology-of-Quotients Proposition 74.20.

(b) This map is an isomorphism by the Wedge-H_*-Proposition 79.9.

(c) This map is an isomorphism by the Skeleton-Quotient Lemma 68.33 (1).

(d) It follows from the Homology-of-Quotients Proposition 74.20 together with the CW-Complex Properties Proposition 68.10 (8) that this map is an isomorphism.

(e) It follows from the commutativity of the diagram and the fact that (a) to (d) are isomorphisms that this map is an isomorphism.

(f) This map is an isomorphism by the Skeleton-Quotient Lemma 68.33 (3).

(g) It follows immediately from the Homology-of-Quotients Proposition 74.20 together with the CW-Complex Properties Proposition 68.10 (8) and the Skeleton-Quotient Lemma 68.33 (3) that this map is an isomorphism.

(h) It follows from the fact that the quadrilateral to the left commutes and the fact that (a), (f) and (g) are isomorphisms that this map is an isomorphism.

(i) It follows from the fact that the top triangle commutes and the fact that (e) and (h) are isomorphisms that this map is an isomorphism.

The remaining statements of (1) are now an immediate consequence of Lemma 76.1.

(2) We fix $k \in \mathbb{N}$. We want to show that $\mathrm{H}_k(X^n) = 0$ for $n = 0, \dots, k-1$. For $r = 0, \dots, k-2$ we consider the long exact sequence of the pair (X^{r+1}, X^r):

$$\dots \to \mathrm{H}_{k+1}(X^{r+1}, X^r) \to \mathrm{H}_k(X^r) \to \mathrm{H}_k(X^{r+1}) \to \underbrace{\mathrm{H}_k(X^{r+1}, X^r)}_{\substack{= 0 \text{ by (1) since } r < k-1 \\ \text{i.e. since } k \neq r+1}} \to \dots$$

It follows that we have epimorphisms

$$\mathrm{H}_k(X^0) \to \mathrm{H}_k(X^1) \to \dots \to \mathrm{H}_k(X^{k-1}).$$

By the H_0-Proposition 72.5 and Lemma 72.14.[971] we know that $\mathrm{H}_k(X^0) = 0$. Thus all of the groups are zero.

(3) We fix $k \in \mathbb{N}_0$. Let $m > k$. This time we consider the following excerpt from the long exact sequence of the pair (X^{m+1}, X^m):

$$\dots \to \underbrace{\mathrm{H}_{k+1}(X^{m+1}, X^m)}_{= 0 \text{ by (1) since } k < m} \to \mathrm{H}_k(X^m) \to \mathrm{H}_k(X^{m+1}) \to \underbrace{\mathrm{H}_k(X^{m+1}, X^m)}_{= 0 \text{ by (1) since } k < m} \to \dots$$

This implies in particular that for each $k < n \leq l$ we have inclusion induced isomorphisms $\mathrm{H}_k(X^n) \xrightarrow{\cong} \mathrm{H}_k(X^{n+1}) \xrightarrow{\cong} \dots \xrightarrow{\cong} \mathrm{H}_k(X^l)$. In particular, if X is finite-dimensional, then claim (3) follows immediately from this observation. The infinite-dimensional case follows from the finite-dimensional case together with the Exhaustions-H_*-Proposition 79.4.

(4) We consider the following excerpt from long exact sequence of the pair (X^{n+1}, X^n):

$$\dots \longrightarrow \mathrm{H}_{n+1}(X^{n+1}, X^n) \longrightarrow \mathrm{H}_n(X^n) \longrightarrow \mathrm{H}_n(X^{n+1}) \longrightarrow \underbrace{\mathrm{H}_n(X^{n+1}, X^n)}_{= 0 \text{ by (1)}} \longrightarrow \dots$$

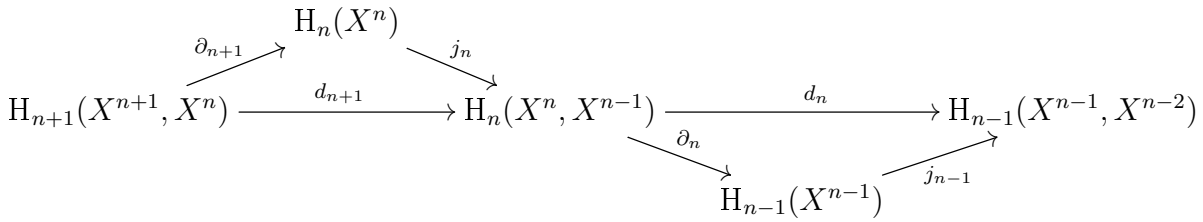
$$\mathrm{H}_n(X^n) \to \mathrm{H}_n(X) \quad \text{and} \quad \mathrm{H}_n(X^{n+1}) \xrightarrow{\cong \text{ by (3)}} \mathrm{H}_n(X)$$

We see that the inclusion induced map $\mathrm{H}_n(X^n) \to \mathrm{H}_n(X)$ is an epimorphism. ∎

Definition. Given a CW-complex X, we denote by $d = d_n$ the map

$$\mathrm{H}_n(X^n, X^{n-1}) \xrightarrow{\partial_n} \mathrm{H}_{n-1}(X^{n-1}) \xrightarrow{j_{n-1}} \mathrm{H}_{n-1}(X^{n-1}, X^{n-2}), \quad =: d = d_n$$

where ∂_n is the connecting map in the long exact sequence of the pair (X^n, X^{n-1}) and where j_{n-1} is the map induced by the projection $\mathrm{C}_{n-1}(X^{n-1}) \to \mathrm{C}_{n-1}(X^{n-1}, X^{n-2})$. We refer to d_n as the cellular boundary map.[972]



The name "cellular boundary map" already suggests that the maps d_n have the following important property:

[971] Here we use that X^0 has the discrete topology.

[972] It follows easily from the definitions that d_n is precisely the connecting homomorphism of the long exact sequence of the triple (X^n, X^{n-1}, X^{n-2}).

Lemma 80.2. For all $n \in \mathbb{N}_0$ we have $d_n \circ d_{n+1} = 0$.

Proof. We consider the following commutative diagram of maps

The map $\partial_n \circ j_n \colon \mathrm{H}_n(X^n) \to \mathrm{H}_{n-1}(X^{n-1})$ is the composition of two successive maps in the long exact sequence of the pair (X^n, X^{n-1}), i.e. the map $\partial_n \circ j_n$ is the zero map. Since the diagram commutes we obtain that $d_n \circ d_{n+1} = 0$. ■

Definition. Let X be a CW-complex.

(1) Given $n \in \mathbb{N}_0$ we write $\mathrm{C}_n^{\mathrm{CW}}(X) := \mathrm{H}_n(X^n, X^{n-1})$.
(2) We refer to $(\mathrm{C}_*^{\mathrm{CW}}(X), d_*)$ as the cellular chain complex of the CW-complex X.[973]
(3) We denote the homology groups of the cellular chain complex by $\mathrm{H}_n^{\mathrm{CW}}(X)$ and we refer to these groups as the cellular homology groups of the CW-complex X.

Remark. Let us summarize the content of the Skeleton-Homology Lemma 80.1 (1) in light of the above definition. Given a CW-complex X and given $n \in \mathbb{N}_0$ the n-th cellular chain group $\mathrm{C}_n^{\mathrm{CW}}(X)$ is a free abelian group and the characteristic maps of the n-cells give naturally rise to a basis of this free abelian group.

Example. We consider the n-sphere S^n for $n \geq 2$. On page 1472 we showed that we can view S^n as a CW-complex with one 0-cell and one n-cell. The cellular chain complex $\mathrm{C}_*^{\mathrm{CW}}(X)$ is thus of the form

$$0 \to \underbrace{\mathbb{Z}}_{=\mathrm{C}_n^{\mathrm{CW}}(X)} \to 0 \to \ldots \to 0 \to \underbrace{\mathbb{Z}}_{=\mathrm{C}_0^{\mathrm{CW}}(X)} \to 0.$$

Since $n \geq 2$ both the $\mathbb{Z}$'s are separated by at least one zero group. The cellular boundary maps are therefore necessarily the zero maps and we obtain that

$$\mathrm{H}_i^{\mathrm{CW}}(X) \cong \begin{cases} \mathbb{Z}, & \text{if } i = 0, n, \\ 0, & \text{otherwise.} \end{cases}$$

These are of course isomorphic to the "usual" homology groups of S^n. In the next section we will see that this is not a coincidence.

The "usual" homology groups define functors from the category of topological spaces to the category of abelian groups. We will now see that in a more restricted setting cellular homology groups also define a functor.

Definition.

(1) Recall that according to the definition on page 1492 a map $f \colon X \to Y$ between CW-complexes is called cellular if for each $n \in \mathbb{N}_0$ we have $f(X^n) \subset Y^n$.

[973] It follows from Lemma 80.2 that $(\mathrm{C}_*^{\mathrm{CW}}(X), d_*)$ is indeed a chain complex.

(2) As before we denote by $\mathcal{CW}$ the category of CW-complexes where the objects are CW-complexes and where the morphisms are cellular maps.

We conclude this section with the following lemma.

Lemma 80.3.

(1) Every cellular map $f\colon X \to Y$ between two CW-complexes induces a chain map

$$\begin{array}{rcl} f_*\colon \mathrm{C}_*^{\mathrm{CW}}(X) & \to & \mathrm{C}_*^{\mathrm{CW}}(Y) \\ f_*\colon \mathrm{H}_*^{\mathrm{CW}}(X) & \to & \mathrm{H}_*^{\mathrm{CW}}(Y) \end{array}$$

and hence also maps

on cellular homology.

(2) For each $n \in \mathbb{N}_0$ the maps

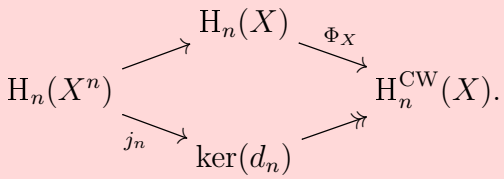
$$\begin{array}{rcl} X & \mapsto & \mathrm{H}_n^{\mathrm{CW}}(X) \\ (f\colon X \to Y) & \mapsto & (f_*\colon \mathrm{H}_n^{\mathrm{CW}}(X) \to \mathrm{H}_n^{\mathrm{CW}}(Y)) \end{array}$$

define a covariant functor from the category $\mathcal{CW}$ of CW-complexes to the category *AbGroup* of abelian groups.

Proof.

(1) Let $f\colon X \to Y$ be a cellular map. Since the map f is cellular we get for every $n \in \mathbb{N}_0$ an induced map $\mathrm{H}_n(X^n, X^{n-1}) \to \mathrm{H}_n(Y^n, Y^{n-1})$, i.e. we get an induced map $f_*\colon \mathrm{C}_n^{\mathrm{CW}}(X) \to \mathrm{C}_n^{\mathrm{CW}}(Y)$. It follows almost immediately from the naturality of the connecting homomorphism, see the Topological LES-Proposition 74.13 (2), that the above maps $f_*\colon \mathrm{C}_n^{\mathrm{CW}}(X) \to \mathrm{C}_n^{\mathrm{CW}}(Y)$, $n \in \mathbb{N}_0$ actually form a chain map.

(2) This statement follows easily from the fact that the usual chain complexes and homology groups are covariantly functorial. ■



80.2. **The relationship between cellular and singular homology.** Now we can formulate and prove the following proposition.

Proposition 80.4. (Singular-Cellular H_*-Isomorphism Proposition) Let $n \in \mathbb{N}_0$.

(1) For each CW-complex X there exists a uniquely determined isomorphism

$$\Phi_X\colon \mathrm{H}_n(X) \xrightarrow{\cong} \mathrm{H}_n^{\mathrm{CW}}(X)$$

with the property that the following diagram commutes:[974]

(2) Recall that we denote by $\mathcal{CW}$ the category of CW-complexes where the objects are CW-complexes and where the morphisms are cellular maps. The homomorphisms from (1) define a natural isomorphism between the functors $X \mapsto \mathrm{H}_n(X)$ and the functor $X \mapsto \mathrm{H}_n^{\mathrm{CW}}(X)$. In other words, for every cellular map $f\colon X \to Y$ and any

$n \in \mathbb{N}_0$ the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}_n(X) & \xrightarrow{f_*} & \mathrm{H}_n(Y) \\ {\scriptstyle \Phi_X}\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle \Phi_Y} \\ \mathrm{H}_n^{\mathrm{CW}}(X) & \xrightarrow{f_*} & \mathrm{H}_n^{\mathrm{CW}}(Y). \end{array}$$

Remark. Later on, in the Singular-Cellular Chain Complex Proposition 81.12, we will give an alternative proof that singular and cellular homology groups are naturally isomorphic. The latter proof has the advantage that it shows a stronger statement, namely it shows in fact that the singular and cellular chain complexes are chain homotopy equivalent.

Example. Even though the cellular boundary maps in the cellular chain complex are still somewhat mysterious, we can already use the proposition to do some calculations. As an example, we return to the *n-dimensional complex projective space* $\mathbb{C}\mathrm{P}^n$ which we defined on page 255 as

$$\mathbb{C}\mathrm{P}^n \;:=\; (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}).$$

In Lemma 68.1 we showed that we can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex which admits exactly one cell in dimensions $0, 2, \ldots, 2n$ and which admits no other cells. In particular the cellular chain complex is of the form

$$0 \to \underbrace{\mathrm{C}_{2n}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{\cong\mathbb{Z}} \to \underbrace{\mathrm{C}_{2n-1}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{=0} \to \cdots \to \underbrace{\mathrm{C}_{2}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{\cong\mathbb{Z}} \to \underbrace{\mathrm{C}_{1}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{=0} \to \underbrace{\mathrm{C}_{0}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{\cong\mathbb{Z}} \to 0.$$

Since every other group is trivial it follows that all boundary maps are also zero. In particular the homology groups equal the cellular chain groups. Thus we have shown that

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^n) \;\underset{\uparrow}{\cong}\; \mathrm{H}_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n) \;\cong\; \mathrm{C}_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

Singular-Cellular H_*-Isomorphism Proposition 80.4

It follows immediately from inspecting the cellular chain complex that for any $k \leq l$ and any $i \in \{0, \ldots, 2k\}$ the inclusion induced map

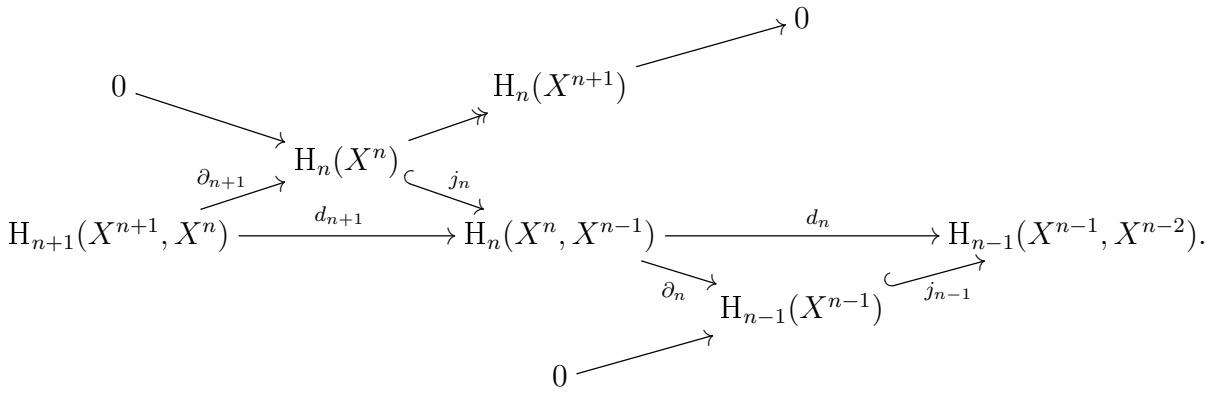
$$\mathrm{H}_i^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^k) \;\xrightarrow{\cong}\; \mathrm{H}_i^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^l)$$

is an isomorphism. By the naturality of the isomorphism of the Singular-Cellular H_*-Isomorphism Proposition 80.4 the same conclusion also holds for the inclusion induced map

$$\mathrm{H}_i(\mathbb{C}\mathrm{P}^k) \;\xrightarrow{\cong}\; \mathrm{H}_i(\mathbb{C}\mathrm{P}^l)$$

on singular homology. It follows from Lemma 68.6 (2) that we can view the infinite-dimensional complex projective space $\mathbb{C}\mathrm{P}^\infty$ as a CW-complex that has precisely one cell in each even dimension and no cells in odd dimensions. From the arguments above it follows that

$$\mathrm{H}_k(\mathbb{C}\mathrm{P}^\infty) \;\cong\; \mathrm{H}_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^\infty) \;\cong\; \mathrm{C}_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^\infty) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k \text{ is even,} \\ 0, & \text{if } k \text{ is odd.} \end{cases}$$



[974] Here we again denote by $j_n \colon \mathrm{H}_n(X^n) \to \mathrm{H}_n(X^n, X^{n-1})$ the obvious map. In the long exact sequence of the pair (X^n, X^{n-1}) we see that the image of $\mathrm{H}_n(X^n)$ in $\mathrm{H}_n(X^n, X^{n-1})$ lies in the kernel of the connecting homomorphism ∂_n. This implies that the map $j_n \colon \mathrm{H}_n(X^n) \to \mathrm{H}_n(X^n, X^{n-1})$ takes values in $\ker(d_n)$.

Furthermore, as above we see that the inclusion induced map

$$\mathrm{H}_i(\mathbb{C}\mathrm{P}^k) \xrightarrow{\cong} \mathrm{H}_i(\mathbb{C}\mathrm{P}^\infty)$$

is an isomorphism for $i \leq k+1$.

Proof of Proposition 80.4 (1). We add a couple of maps to the commutative diagram that we had already encountered in the proof of Lemma 80.2:

Claim. All the diagonal sequences in the above commutative diagram are exact.

Proof. From the Skeleton-Homology Lemma 80.1 (1) and (2) we know that

$$\mathrm{H}_n(X^{n+1}, X^n) = 0, \quad \mathrm{H}_n(X^{n-1}) = 0 \quad \text{and} \quad \mathrm{H}_{n-1}(X^{n-2}) = 0.$$

It thus follows that the diagonal sequences in the above commutative diagram are just the long exact sequences of the corresponding pairs of topological spaces. In particular all the diagonal sequences are exact. ⊞

Next we prove the following claim.

Claim. The map $j_n \colon \mathrm{H}_n(X^n) \to \mathrm{H}_n(X^n, X^{n-1})$ induces an isomorphism

$$\Phi \colon \mathrm{H}_n(X^n)/\operatorname{im}(\partial_{n+1}) \to \ker(d_n)/\operatorname{im}(d_{n+1}) = \mathrm{H}_n^{\mathrm{CW}}(X).$$

Proof. We will prove this claim once again by a "diagram chase".[975]

(1) Since $\partial_n \circ j_n = 0$ it follows that $j_n(\mathrm{H}_n(X^n)) \subset \ker(d_n)$.

(2) The map j_{n-1} is injective, i.e. $\ker(d_n) = \ker(\partial_n) = \operatorname{im}(j_n)$, i.e. the map j_n induces an epimorphism

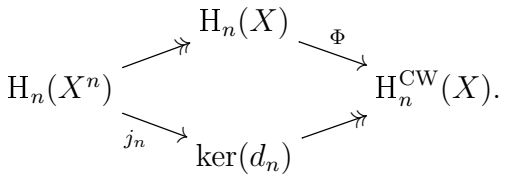
$$\mathrm{H}_n(X^n) \to \ker(d_n).$$

Since the left triangle commutes it also induces an epimorphism

$$\mathrm{H}_n(X^n)/\operatorname{im}(\partial_{n+1}) \to \ker(d_n)/\operatorname{im}(d_{n+1}).$$

(3) If an element $j_n(c) \in \mathrm{H}_n(X^n, X^{n-1})$ lies in the image of $d_{n+1} = j_n \circ \partial_{n+1}$, then $j_n(c) = j_n(\partial_{n+1}(d))$ for some $d \in \mathrm{H}_{n+1}(X^{n+1}, X^n)$. Since j_n is injective it follows that $c = \partial_{n+1}(d)$. Thus we have now shown that the map

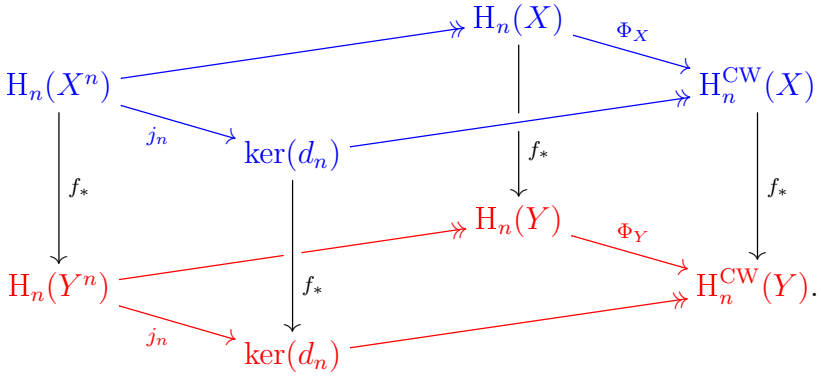
$$\mathrm{H}_n(X^n)/\operatorname{im}(\partial_{n+1}) \to \ker(d_n)/\operatorname{im}(d_{n+1})$$



is injective. ⊞

[975] It is arguably best not to read the remainder of the proof but to go on the chase on one's own.

Next we consider the diagram which gives us the definition of the isomorphism Φ:



$$\begin{array}{ccccc}
 & \text{isomorphism since in the above diagram left diagonal sequence is exact} & & \text{isomorphism by Skeleton-Homology Lemma 80.1 (3)} & \\
 & \downarrow & & \downarrow & \\
\mathrm{H}_n(X^n)/\operatorname{im}(\partial_{n+1}) & \to & \mathrm{H}_n(X^{n+1}) & \to & \mathrm{H}_n(X). \\
\text{by the claim we know that } j_n \text{ induces an isomorphism} \Big\downarrow & \cong & & & \Big\downarrow =: \Phi \\
\ker(d_n)/\operatorname{im}(d_{n+1}) & & \xrightarrow[\text{id}]{} & & \mathrm{H}_n^{\mathrm{CW}}(X)
\end{array}$$

By construction the isomorphism Φ has the property that the following diagram commutes:

Note that the top-left diagonal map is an epimorphism by the Skeleton-Homology Lemma 80.1 (4). This implies immediately that Φ is uniquely determined. ■

Proof of Proposition 80.4 (2). We need to show that the isomorphisms Φ_X that we just constructed is natural. Thus suppose we are given a cellular map $f\colon X \to Y$ and let $n \in \mathbb{N}_0$. We consider the following diagram:

Note that the sides of the hyperrectangle that do not involve Φ_X and Φ_Y, commute basically by definition. Furthermore the top and bottom parallelogram commute by definition of Φ_X and Φ_Y. But then it follows from the fact that the map $\mathrm{H}_n(X^n) \to \mathrm{H}_n(X)$ is an epimorphism that also the parallelogram involving Φ_X and Φ_Y commutes, and that is exactly, what we had to show. ■

In general the natural isomorphism from the Singular-Cellular H_*-Isomorphism Proposition 80.4 can be hard to pin down. The following lemma gives one instance where we can actually say exactly what is happening.

Lemma 80.5. Let X be a CW-complex and let $\Theta\colon \overline{B}^n \to X$ be the characteristic map of an n-cell such that $\Theta(\overline{B}^n)$ consists of a single point. Note that this means that Θ descends to a map $f\colon \overline{B}^n/S^{n-1} \to X$ and that it defines a cycle in $\mathrm{H}^n_{\mathrm{CW}}(X)$. We denote by $g\colon S^n \to \overline{B}^n/S^{n-1}$ the homeomorphism from the Ball-Quotient Sphere Lemma 5.20.

Under the natural isomorphism

$$\Phi_X \colon \mathrm{H}_n(X) \;\to\; \mathrm{H}_n^{\mathrm{CW}}(X)$$

of the Singular-Cellular H_*-Isomorphism Proposition 80.4 we have

$$\Phi_X((f \circ g)_*([S^n])) \;=\; [\Theta].$$

Proof. The lemma follows almost immediately from the definitions and the Standard Generator-Relationship Proposition 76.5. We leave it to the reader to fill in the details. ■

On page 1772 we already saw that the Singular-Cellular H_*-Isomorphism Proposition 80.4 can be useful, even if we cannot determine the boundary maps d_n. Another, more theoretical application is, that the cellular chain complex is "much smaller" than the singular chain complex. For example, if X is a CW-complex with finitely many cells, then the chain group $\mathrm{C}_*^{\mathrm{CW}}(X)$ in the cellular chain complex are *finitely generated* free abelian groups. This is in contract to the singular chain groups $\mathrm{C}_*(X)$ which are in almost all cases free abelian groups of uncountable rank.[976]

Using this observation we can now easily prove the following proposition. It can be viewed as an analogue to the CW-Skeleton-π_1-Proposition 69.13.

Proposition 80.6. (Homology-of-CW-Complex Proposition) Let X be a CW-complex. The following statements hold:

(1) If X contains precisely $d \in \mathbb{N}_0$ cells of dimension n, then $\mathrm{H}_n(X)$ is generated by at most d elements. In particular, if X has no cells of dimension n, then $\mathrm{H}_n(X) = 0$. Similarly, if X contains only countable many cells of dimension n, then $\mathrm{H}_n(X)$ is countable.

(2) If X consists only of finitely many cells, then all homology groups of X are finitely generated groups.

(3) If X is finite-dimensional, then

$$\mathrm{H}_k(X) \;=\; 0 \quad \text{for all } k > \dim(X).$$

(4) If X is an n-dimensional CW-complex, then $\mathrm{H}_n(X)$ is a free abelian group.

Example. It follows from the Homology-of-CW-Complex Proposition 80.6 that for any topological graph G we have $\mathrm{H}_i(G) = 0$ for every $i \geq 2$ and that $\mathrm{H}_1(G)$ is a free abelian group.

Remark.

(1) Later on, in the Singular-Cellular Chain Complex Proposition 81.12, we will give an alternative proof that singular and cellular homology groups are naturally isomorphic. The latter proof has the advantage that it shows a stronger statement, namely it shows in fact that the singular and cellular chain complexes are chain homotopy equivalent.

(2) In Chapter 140, in particular in Proposition 140.9, we will formulate and prove a pretty elementary algebraic statement that allows us in Proposition 140.11 (2) to prove that the "size" of homology groups give a lower bound on the number of cells

[976] For which topological spaces and which n is the singular chain complex $\mathrm{C}_n(X)$ finitely generated? Can you give a complete answer?

in a CW-structure. This result can be viewed as a refinement of the Homology-of-CW-Complex Proposition 80.6 (1).

Proof. Let X be a CW-complex.

(1) If X contains precisely $d \in \mathbb{N}_0$ cells of dimension n, then it follows from the Skeleton-Homology Lemma 80.1 that $\mathrm{C}_n^{\mathrm{CW}}(X) \cong \mathbb{Z}^d$. By Lemma 51.9 any subgroup U of $\mathbb{Z}^d$ is a free abelian group such that $\mathrm{rank}(U) \leq d$. Thus it follows that

$$\mathrm{H}_n(X) \cong \underbrace{\ker\big(d_n \colon \mathrm{C}_n^{\mathrm{CW}}(X) \to \mathrm{C}_{n-1}^{\mathrm{CW}}(X)\big)}_{\text{free abelian group of rank} \leq d} \big/ \operatorname{im}\big(d_{n+1} \colon \mathrm{C}_{n+1}^{\mathrm{CW}}(X) \to \mathrm{C}_n^{\mathrm{CW}}(X)\big)$$

is generated by at most d elements. The argument in the case that X has countably many cells of dimension n is very similar, we just need to use the Countability Lemma 0.8 several times.

(2) This statement follows immediately from (1).

(3) This statement is in fact already a consequence of the Skeleton-Homology Lemma 80.1 (2).

(4) Now suppose that X is an n-dimensional CW-complex X. We have

$$\mathrm{H}_n(X) \underset{\text{Proposition 80.4}}{\cong} \mathrm{H}_n^{\mathrm{CW}}(X) \underset{\text{we have } \mathrm{C}_{n+1}^{\mathrm{CW}}(X) = 0 \text{ since } X \text{ is } n\text{-dimensional}}{=} \ker\big(d_n \colon \mathrm{C}_n^{\mathrm{CW}}(X) \to \mathrm{C}_{n-1}^{\mathrm{CW}}(X)\big),$$

i.e. $\mathrm{H}_n(X)$ is a subgroup of the free abelian group $\mathrm{C}_n^{\mathrm{CW}}(X)$. It follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that the group $\mathrm{H}_n(X)$ itself is a free abelian group. ∎

By the Smooth Manifold-CW Structure Theorem 96.5 , which we already mentioned in a sneak preview on page 1474 we know that every compact n-dimensional smooth manifold admits a CW-structure with finitely many cells and such that the maximal dimension of a cell is n. If we combine this result with the Homology-of-CW-Complex Proposition 80.6 we obtain immediately the following useful result.

Proposition 96.6. Let M be a compact n-dimensional smooth manifold. Then the following holds:

(1) All homology groups are finitely generated abelian groups.

(2) For any $k > n$ we have $\mathrm{H}_k(M) = 0$.

Remark. We have now shown that for a CW-complex X the singular homology groups $\mathrm{H}_n(X)$ are isomorphic to the cellular homology groups $\mathrm{H}_n^{\mathrm{CW}}(X)$. One might now ask, whether one can generalize this statement, namely whether the singular chain complex $(\mathrm{C}_*(X), \partial_*)$ and the cellular chain complex $(\mathrm{C}_*^{\mathrm{CW}}, d_*)$ are in fact chain homotopic. This is indeed the case. But the proof requires more homological algebra than we have at the moment at our disposal. Therefore we postpone the proof to a later chapter.

80.3. **The cellular boundary maps.** If we want to use the Singular-Cellular H_*-Isomorphism Proposition 80.4 to calculate homology groups of CW-complexes we need to develop tools for computing the cellular boundary maps d_n in the cellular chain complex. Let X be a CW-complex and let $n \in \mathbb{N}_0$. Throughout this section we will use the following notation:

(1) We denote by I_n the set of n-cells of X.

(2) Given an n-cell α we denote by $\varphi_\alpha\colon S^{n-1}_\alpha \to X^{n-1}$ the corresponding attaching map and we denote by $\Phi_\alpha\colon \overline{B}^n_\alpha \to X^n$ the corresponding characteristic map.

(3) We denote by

$$\begin{aligned} \Psi_n\colon \bigvee_{\alpha\in I_n} \overline{B}^n_\alpha/\partial\overline{B}^n_\alpha &\to X^n/X^{n-1} \\ x &\mapsto \Phi_\alpha(x), \quad \text{if } x\in \overline{B}^n_\alpha. \end{aligned}$$

the map that is given by

It is straightforward to verify that Ψ_n is a homeomorphism.

(4) Given $\beta\in I_n$ we denote by

$$i_\beta\colon \overline{B}^n_\beta/\partial\overline{B}^n_\beta \to \bigvee_{\alpha\in I_n} \overline{B}^n_\alpha/\partial\overline{B}^n_\alpha \quad \text{and} \quad p_\beta\colon \bigvee_{\alpha\in I_n} \overline{B}^n_\alpha/\partial\overline{B}^n_\alpha \to \overline{B}^n_\beta/\partial\overline{B}^n_\beta,$$

the natural injection respectively the natural projection. By the Wedge-H_*-Proposition 79.9 the maps

$$\bigoplus_{\beta\in I_n} \mathrm{H}_n\big(\overline{B}^n_\beta/\partial\overline{B}^n_\beta\big) \underset{\oplus i_\beta}{\overset{\oplus p_\beta}{\rightleftarrows}} \mathrm{H}_n\Big(\bigvee_{\beta\in I_n} \overline{B}^n_\beta/\partial\overline{B}^n_\beta\Big).$$

are inverses of one another.

(5) Given $\alpha\in I_n$ we denote, by a slight abuse of notation, the standard generator of $\mathrm{H}_n(\overline{B}^n_\alpha,\partial\overline{B}^n_\alpha)\cong\mathbb{Z}$, as defined on page 1679, by α. Put differently, we have $\mathrm{H}_n(\overline{B}^n_\alpha,\partial\overline{B}^n_\alpha)=\mathbb{Z}\cdot\alpha$.

(6) By the Skeleton-Homology Lemma 80.1 we have the following commutative diagram where all maps are isomorphisms:

$$\begin{array}{ccccc} \bigoplus_{i\in I_n} \mathrm{H}_n(\overline{B}^n_i,\partial\overline{B}^n_i) & & \xrightarrow{\quad\Omega_n:=\oplus\Phi_{i*}\quad} & & \mathrm{H}_n(X^n,X^{n-1}) \\ \downarrow{\scriptstyle \oplus \mathrm{ю}} & & & & \downarrow{\scriptstyle \mathrm{ю}} \\ \bigoplus_{i\in I_n} \widetilde{\mathrm{H}}_n\big(\overline{B}^n_i/\partial\overline{B}^n_i\big) & \longrightarrow & \widetilde{\mathrm{H}}_n\Big(\bigvee_{i\in I_n} \overline{B}^n_i/\partial\overline{B}^n_i\Big) & \xrightarrow{(\vee\Phi_i)_*} & \widetilde{\mathrm{H}}_n(X^n/X^{n-1}). \end{array}$$

(7) By another abuse of notation we often denote $\Omega_n(\alpha)$ also by α. Put differently, we identify $\mathrm{C}^{\mathrm{CW}}_n(X)=\mathrm{H}_n(X^n,X^{n-1})$ with the free abelian group generated by the set I_n of all n-cells.

Our goal now is to determine the matrix of the cellular boundary map

$$d_n\colon \overbrace{\mathrm{H}_n(X^n,X^{n-1})}^{=\mathrm{C}^{\mathrm{CW}}_n(X)} \to \overbrace{\mathrm{H}_{n-1}(X^{n-1},X^{n-2})}^{=\mathrm{C}^{\mathrm{CW}}_{n-1}(X)}.$$

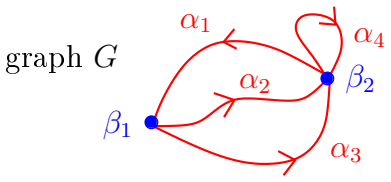
free abelian group generated by I_n — free abelian group generated by I_{n-1}

corresponding to the bases given by the cells. As a warm-up with start out with the case $n=1$.

Lemma 80.7. Let X be a CW-complex. We adopt all the notations introduced above.

(1) For a 1-cell α with attaching map $\varphi_\alpha\colon \overline{B}^1\to X^0$ we have

$$d_1(\alpha) \;=\; \varphi_\alpha(1)-\varphi_\alpha(-1).$$



(2) If X has precisely one 0-cell, then the cellular boundary map d_1 is the zero map.

Proof. The second statement of the lemma is evidently a consequence of the first statement. Therefore it suffices to prove the first statement. So let α be a 1-cell with characteristic map $\Phi_\alpha\colon \overline{B}^1 \to X^0$. We have to determine the map

$$\begin{array}{ccccc} \mathbb{Z}\cdot\alpha \;\to\; \bigoplus\limits_{j\in I_1} \mathrm{H}_1(\overline{B}^1_j, \partial\overline{B}^1_j) & \xrightarrow{\Omega_1} & \mathrm{H}_1(X^1, X^0) & & \\ & & \downarrow{\scriptstyle d_1} & & \\ & & \mathrm{H}_0(X^0, \underbrace{X^{-1}}_{=\varnothing}) & \xrightarrow{\Omega_0^{-1}} & \bigoplus\limits_{i\in I_0} \mathrm{H}_0(\overline{B}^0_i, \underbrace{\partial\overline{B}^0_i}_{=\varnothing}). \end{array}$$

Since $X^{-1} = \varnothing$ we see that in the present case we have $d_1 = \partial_1$, i.e. the cellular boundary map d_1 is the connecting homomorphism $\mathrm{H}_1(X^1, X^0) \to \mathrm{H}_0(X^0)$ of the long exact sequence of the pair (X^1, X^0). It follows immediately from the definitions of the connecting homomorphism, as defined in the Topological LES-Proposition 74.13 (1), that $d_1(\alpha) = \varphi_\alpha(1) - \varphi_\alpha(-1)$. ■

Example. We consider the topological graph G that is given in the figure below with two vertices β_1, β_2 and four edges $\alpha_1, \ldots, \alpha_4$. We view it as a CW-complex in the obvious way. According to Lemma 80.7 the cellular chain complex of X is of the following form

$$0 \;\to\; \mathrm{C}_1^{\mathrm{CW}}(G) = \mathbb{Z}^4 \xrightarrow{\begin{array}{c}\alpha_1\;\alpha_2\;\alpha_3\;\alpha_4\\ \beta_1\begin{pmatrix} 1 & -1 & -1 & 0\\ -1 & 1 & 1 & 0\end{pmatrix}\\ \beta_2\end{array}} \mathrm{C}_0^{\mathrm{CW}}(G) = \mathbb{Z}^2 \;\to\; 0.$$

Thus we obtain from the Singular-Cellular H_*-Isomorphism Proposition 80.4 that

$$\mathrm{H}_1(G) \cong \ker\left(\mathbb{Z}^4 \xrightarrow{\begin{pmatrix}1 & -1 & -1 & 0\\ 1 & 1 & 1 & 0\end{pmatrix}} \mathbb{Z}^4\right) \cong \mathbb{Z}^3 \quad \text{and} \quad \mathrm{H}_0(G) \cong \mathrm{coker}\left(\mathbb{Z}^4 \xrightarrow{\begin{pmatrix}1 & -1 & -1 & 0\\ 1 & 1 & 1 & 0\end{pmatrix}} \mathbb{Z}^4\right) \cong \mathbb{Z}.$$

After this example we return to the discussion of the cellular boundary maps. Let X be a CW-complex and let $n > 1$. We want to determine the cellular boundary map

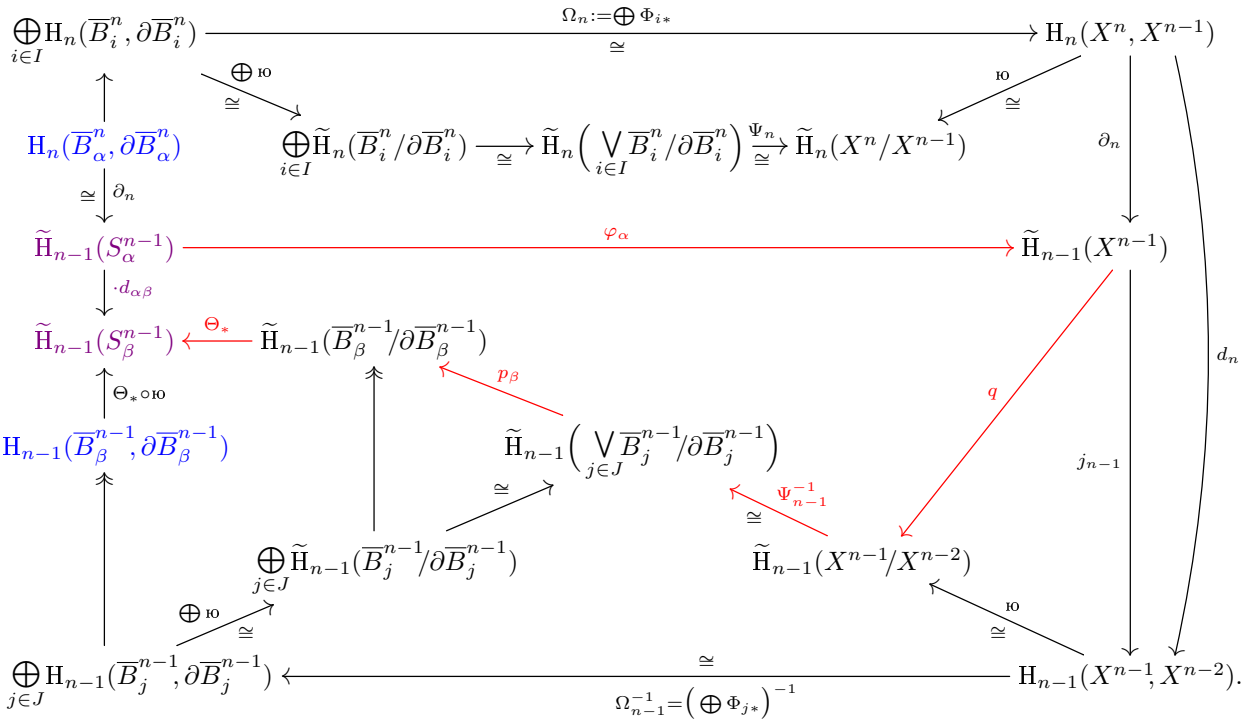
$$d_n\colon \mathrm{H}_n(X^n, X^{n-1}) \;\to\; \mathrm{H}_{n-1}(X^{n-1}, X^{n-2}).$$

Given an n-cell α and an $(n-1)$-cell β we consider the map

$$S^{n-1}_\alpha = \partial\overline{B}^n_\alpha \xrightarrow{\varphi_\alpha} X^{n-1} \xrightarrow{q} X^{n-1}/X^{n-2} \xrightarrow[\cong]{\Psi_{n-1}^{-1}} \bigvee_{j\in I_{n-1}} \overline{B}^{n-1}_j/\partial\overline{B}^{n-1}_j \xrightarrow{p_\beta} \overline{B}^{n-1}_\beta/\partial\overline{B}^{n-1}_\beta \xrightarrow[\cong]{\Theta} S^{n-1}_\beta$$

where $q\colon X^{n-1} \to X^{n-1}/X^{n-2}$ is the projection and where $\Theta\colon \overline{B}^{n-1}/\partial\overline{B}^{n-1} \xrightarrow{\cong} S^{n-1}$ denotes the homeomorphism from the Ball-Quotient Sphere Lemma 5.20. Since S^{n-1}_α and S^{n-1}_β are copies of S^{n-1} we can consider the degree of the map as defined on page 1684.

Now we will see that this degree is just the $\beta \times \alpha$–entry of the matrix that represents the cellular boundary map d_n with respect to the bases given by all n-cells and all $(n-1)$-cells. More precisely we have the following proposition:



Proposition 80.8. (Cellular Boundary Map-via-Degrees Proposition) Let X be a CW-complex. We use all the notation that we introduced above. Then for each n-cell α we have

$$d_n(\alpha) \;=\; \sum_{\beta \in I_{n-1}} d_{\alpha,\beta} \cdot \beta$$

where

$$d_{\alpha\beta} \;:=\; \text{degree of the map } S^{n-1}_\alpha \xrightarrow{\Theta \circ p_\beta \circ \Psi_{n-1}^{-1} \circ q \circ \varphi_\alpha} S^{n-1}_\beta.$$

Proof. We write $I := I_n$ and $J := I_{n-1}$. We consider the following diagram[977]:

We make the following claim.

Claim. The diagram commutes.

Proof. We consider the various parts of the diagram.

(1) It follows from the Skeleton-Homology Lemma 80.1 (1) that the pentagon at the top and the large triangle at the bottom commute.

[977] The strange shape of the diagram is due to space constraints.

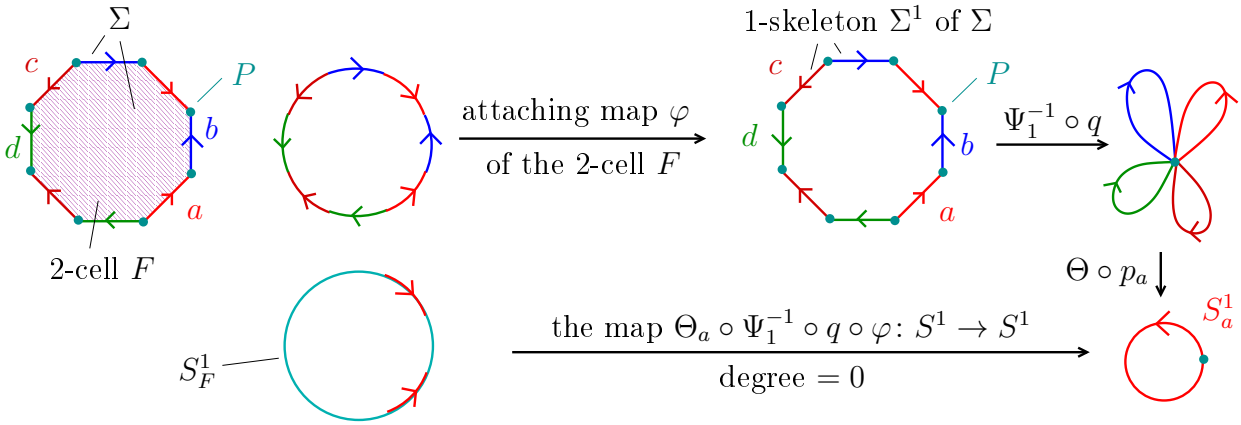
(2) It follows from the naturality of the connecting homomorphism, see the Topological LES-Corollary 74.14 (2), that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_n(\overline{B}^n_\alpha, \partial\overline{B}^n_\alpha) & \xrightarrow{\Phi_\alpha} & \mathrm{H}_n(X^n, X^{n-1}) \\ \downarrow{\scriptstyle \partial_n} & & \downarrow{\scriptstyle \partial_n} \\ \mathrm{H}_{n-1}(S^{n-1}_\alpha) & \xrightarrow{\varphi_\alpha} & \mathrm{H}_{n-1}(X^{n-1}). \end{array}$$

From this observation it follows that the upper rectangle in the diagram commutes.

(3) It follows immediately from the definitions that the pentagon to the bottom left commutes.

(4) It follows again immediately from the definitions that the triangle towards the bottom left, involving the map p_β commutes.

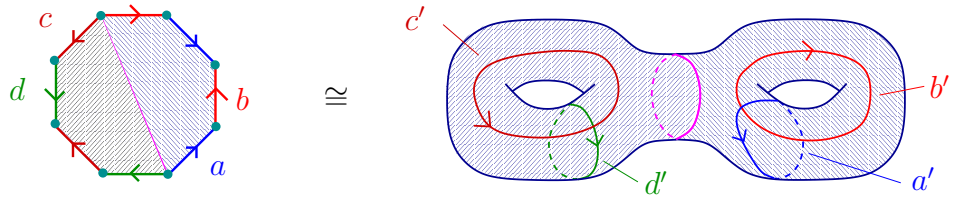


(5) It follows from Lemma 74.19 (1) that the triangle to the bottom right commutes. ⊞

Next note that it follows from the definition of the standard generator of $\mathrm{H}_n(\overline{B}^n, \partial\overline{B}^n)$ on page 1679 and from the Standard Generator-Relationship Proposition 76.5 that the two maps

$$\begin{array}{rcll} \partial_n \colon \mathrm{H}_n(\overline{B}^n_\alpha, \partial\overline{B}^n_\alpha) & \to & \widetilde{\mathrm{H}}_{n-1}(S^{n-1}_\alpha) & \text{and} \\ \Theta_* \circ \text{ю} \colon \mathrm{H}_{n-1}(\overline{B}^{n-1}_\beta, \partial\overline{B}^{n-1}_\beta) & \to & \widetilde{\mathrm{H}}_{n-1}(S^{n-1}_\beta) & \end{array}$$

send the standard generator to the standard generator. The reader who is still awake will notice that the proposition follows immediately from the claim and this observation. ■

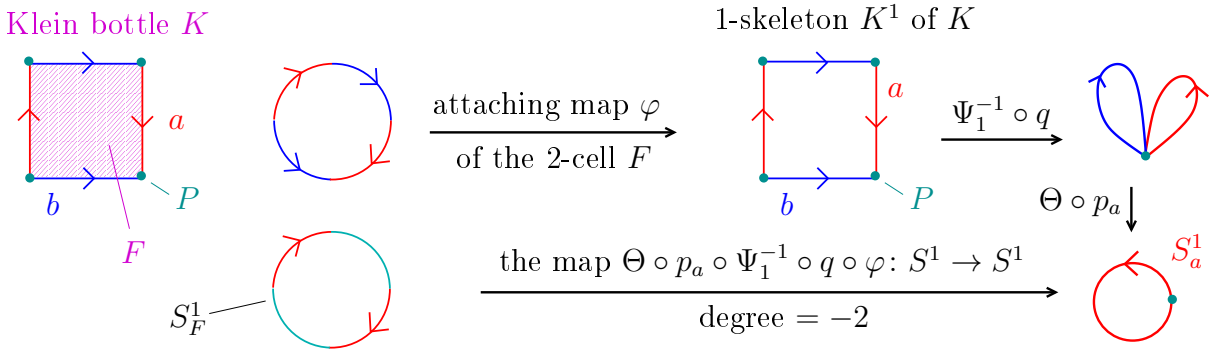


Example. We consider the surface Σ of genus 2. As usual we view Σ as a CW-complex with one 0-cell P, four 1-cells a, b, c, d and one 2-cell F. We denote by $\varphi\colon S^1 \to \Sigma^1$ the attaching map of the 2-cell F. (We refer to the figure below for an illustration.) It follows from the discussion on page 1684 that the degree of the map $p_a \circ \Psi_1^{-1} \circ q \circ \varphi\colon S^1_F \to S^1_a$ is zero. The same conclusion holds for all other 1-cells. It follows from the Cellular Boundary

Map-via-Degrees Proposition 80.8 that the cellular boundary map d_2 in the cellular chain complex of Σ is zero. Since Σ has only one 0-cell we know from Lemma 80.7 that the cellular boundary map d_1 is also zero. Thus we see that

$$\mathrm{H}_n(\Sigma) \underset{\text{Singular-Cellular Homology Isomorphism Proposition 80.4}}{\overset{\uparrow}{\cong}} \mathrm{H}_n^{\mathrm{CW}}(\Sigma) \underset{\text{since all the cellular boundary maps are zero}}{\overset{\uparrow}{=}} \mathrm{C}_n^{\mathrm{CW}}(\Sigma) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ \mathbb{Z}, & \text{if } n = 2, \\ \mathbb{Z}^4, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

In the figure below on the left-hand side we show closed curves a, b, c, d. It follows from the above calculation and Lemma 80.5 that these curves represent a basis for $\mathrm{H}_1(\Sigma) \cong \mathbb{Z}^4$. These curves in turn are isotopic to the curves a', b', c', d' on the right-hand side, which therefore, by the Homotopic Maps-and-Homology Proposition 73.6, also represent a basis for $\mathrm{H}_1(\Sigma) \cong \mathbb{Z}^4$.



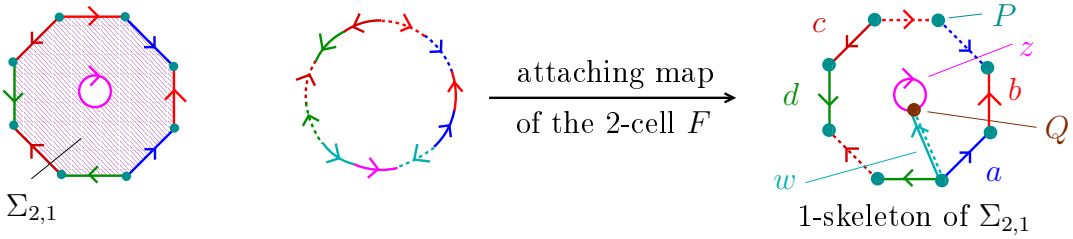
In the previous example we determined that $\mathrm{H}_1(\Sigma) \cong \mathbb{Z}^4$ and we gave an explicit basis for $\mathrm{H}_1(\Sigma)$. One might think that we now fully understand the homology groups of Σ. We will try to challenge this idea in Exercise 80.16.

Example. As a reality check we also consider once again the Klein bottle K. We view K as a CW-complex with one 0-cell P, two 1-cells a, b and one 2-cell F. (We refer to the figure below for an illustration.) It follows from the Cellular Boundary Map-via-Degrees Proposition 80.8, the discussion on page 1684 and Lemma 80.7 that the cellular chain complex is of the form

$$0 \to \mathbb{Z} \xrightarrow{\begin{pmatrix} -2 \\ 0 \end{pmatrix}} \mathbb{Z} \cdot a \oplus \mathbb{Z} \cdot b \xrightarrow{\begin{pmatrix} 0 & 0 \end{pmatrix}} \mathbb{Z} \to 0.$$

Therefore we see that $\mathrm{H}_2(K) = 0$, $\mathrm{H}_1(K) \cong \mathbb{Z}_2 \oplus \mathbb{Z}$ and $\mathrm{H}_0(K) \cong \mathbb{Z}$. This is of course the same result that we had already obtained in Lemma 78.12.

80.4. **The homology groups of 2-dimensional smooth manifolds.** Recall that given any $g, m \in \mathbb{N}_0$ we write[978]



$$\Sigma_{g,m} \quad := \quad \text{the surface of genus } g \text{ minus } m \text{ open disks}$$

and for $k \in \mathbb{N}$ and for $m \in \mathbb{N}_0$ we write

$$N_{k,m} \quad := \quad \text{the non-orientable surface of genus } g \text{ minus } m \text{ open disks.}$$

In the Surface Classification Theorem 55.4 we saw that every connected, compact 2-dimensional topological manifold is homeomorphic to either $\Sigma_{g,m}$ for unique $g, m \in \mathbb{N}_0$ or to $N_{k,m}$ for unique $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$.
Our goal in this section will be to determine the homology groups of $\Sigma_{g,n}$ and $N_{k,n}$. Before we consider the general case we will consider the special case $\Sigma_{2,1}$ in great detail.

Example. We consider $\Sigma_{2,1}$ and we equip it with the CW-structure that is illustrated in the figure below. This CW-structure has two 0-cells P, Q, six 1-cells a, b, c, d, w, z and it has one 2-cell F. Given $i = 1, 2$ we denote by A_i the matrix that represents the cellular

boundary map $d_i \colon \mathrm{C}_i^{\mathrm{CW}}(\Sigma_{2,1}) \to \mathrm{C}_{i-1}^{\mathrm{CW}}(\Sigma_{2,1})$ with respect to the given bases.

The argument on page 1780 shows that $A_2 = \begin{array}{c} \\ a \\ b \\ c \\ d \\ w \\ z \end{array} \begin{array}{c} F \\ \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{pmatrix} \end{array}$

It follows from Lemma 80.7 that we have $A_1 = \begin{array}{c} \\ P \\ Q \end{array} \begin{array}{c} \begin{array}{cccccc} a & b & c & d & w & z \end{array} \\ \begin{pmatrix} 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} \end{array}.$

Some elementary linear algebra shows that

$$\mathrm{H}_n(\Sigma_{2,1}) \underset{\uparrow}{\cong} \mathrm{H}_n^{\mathrm{CW}}(\Sigma_{2,1}) = \mathrm{H}_n\Big(0 \to \mathbb{Z} \xrightarrow{A_2} \mathbb{Z}^6 \xrightarrow{A_1} \mathbb{Z}^2 \to 0\Big) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}^4, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

Singular-Cellular H_*-Isomorphism Proposition 80.4

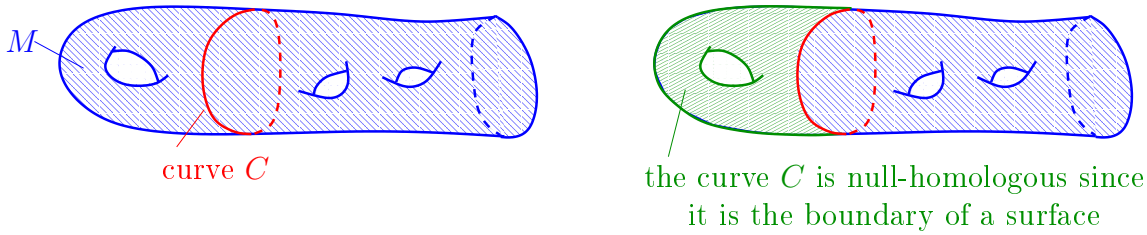
From this discussion we get in fact a more precise statement. Namely, by the choice of the CW-structure on $\Sigma_{2,1}$ we have that the map inclusion map $\partial\Sigma_{2,1} \to \Sigma_{2,1}$ is in fact a cellular map. Therefore it follows from the Singular-Cellular H_*-Isomorphism Proposition 80.4 (2)

[978] Also recall the definition on page 1233 what we mean by a "surface minus m open disks".

that the following diagram commutes

$$\begin{array}{ccc} \mathrm{H}_1(\partial\Sigma_{2,1}) & \xrightarrow{\quad f_* \quad} & \mathrm{H}_1(\Sigma_{2,1}) \\ \cong\downarrow & & \downarrow\cong \\ \mathbb{Z} = \mathrm{H}_1^{\mathrm{CW}}(\partial\Sigma_{2,1}) & \xrightarrow[[z]\mapsto[z]]{f_*} & \mathrm{H}_1^{\mathrm{CW}}(\Sigma_{2,1}) = \mathbb{Z}^4 \end{array}$$

where the vertical maps denote the isomorphisms from the Singular-Cellular H_*-Isomorphism Proposition 80.4. The 1-cell z is null-homologous in $\mathrm{C}_*^{\mathrm{CW}}(\Sigma_{2,1})$ since we have just seen that it is the boundary of the 2-cell F. Thus we see that the bottom horizontal map is the zero map, but that implies that the top horizontal map is also the zero map.



After the calculations that we just did we can now easily prove the following lemma.

Lemma 80.9.

(1) For any $g \in \mathbb{N}_0$ the inclusion induced map $\mathrm{H}_1(\partial\Sigma_{g,1}) \to \mathrm{H}_1(\Sigma_{g,1})$ is the zero map.
(2) Let M be a smooth manifold and let C be an oriented curve in M. If there exists a $g \in \mathbb{N}_0$ and a map $\psi\colon \Sigma_{g,1} \to M$ such that $\psi(\partial\Sigma_{g,1}) = C$, then $C = 0 \in \mathrm{H}_1(M)$.[979]

Remark. In Exercise 80.14 we will prove a generalization of Lemma 80.9 (1).

Example. Loosely speaking Lemma 80.9 (2) says that if a curve C is the boundary of a compact orientable surface in M, then the homology class $[C]$ represented by C is zero. For example in the figure below we see a curve C on a surface M. Since C is the boundary of a compact orientable subsurface contained in M we see that $[C] = 0 \in \mathrm{H}_1(M)$.

Proof.

(1) For $g = 1$ we proved the statement in the previous example. The general case is proved entirely the same way.
(2) Now let M be a smooth manifold and let C be an oriented curve in M. We denote by $i\colon C \to M$ the inclusion map. Suppose there exists a $g \in \mathbb{N}_0$ and a map $\psi\colon \Sigma_{g,1} \to M$ such that $\psi(\partial\Sigma_{g,1}) = C$. We pick a diffeomorphism $f\colon S^1 \to \partial\Sigma_{g,1}$. We get the commutative diagram

$$\begin{array}{ccccc} & & \mathrm{H}_1(C) & & \\ & \overset{(\psi\circ f)_*}{\nearrow} & & \overset{i_*}{\searrow} & \\ \mathrm{H}_1(S^1) & & & & \mathrm{H}_1(M). \\ & \underset{f_*}{\searrow} & & \overset{\psi_*}{\nearrow} & \\ & & \mathrm{H}_1(\partial\Sigma_{g,1}) & \longrightarrow & \mathrm{H}_1(\Sigma_{g,1}) \end{array}$$

[979] Following the convention of page 1733 the curve C defines a homology class in $\mathrm{H}_1(M)$ that we also denote by $[C]$.

By the first statement the bottom horizontal map is the zero map. But that shows that the homology class represented by C is also zero. ■

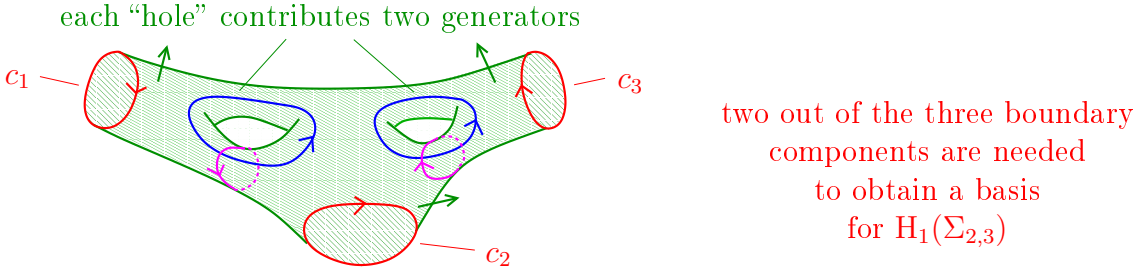
In the following proposition we give the calculation for the homology groups of all connected, compact 2-dimensional topological manifolds.

Proposition 80.10. For any $g \in \mathbb{N}_0$ we have

$$\mathrm{H}_n(\Sigma_g) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ \mathbb{Z}, & \text{if } n = 2, \\ \mathbb{Z}^{2g}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases} \quad \begin{array}{c} \text{Furthermore} \\ \text{for } m \geq 1 \\ \text{we have} \end{array} \quad \mathrm{H}_n(\Sigma_{g,m}) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}^{2g+m-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

For any $k \in \mathbb{N}$ we have

$$\mathrm{H}_n(N_k) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}_2 \oplus \mathbb{Z}^{k-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases} \quad \begin{array}{c} \text{Furthermore} \\ \text{for } m \geq 1 \\ \text{we have} \end{array} \quad \mathrm{H}_n(N_{k,m}) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}^{k+m-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$



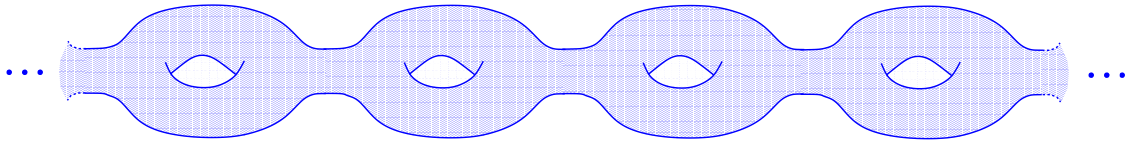
Proof. The calculation of the homology groups $\Sigma_{g,m}$ is a slight generalization of the arguments that we provided above and on page 1780. We leave the details to the reader.
We will deal with the homology of $N_{k,m}$ in Exercise 80.1. The calculation is evidently just a variation on the arguments we provided for Σ_2 and $\Sigma_{2,2}$. ■

Remark. A careful reading of the Proof of Proposition 80.10 gives us some extra information. First of all we endow $\Sigma_{g,m}$ with an orientation. The boundary components of $\Sigma_{g,m}$ then inherit an orientation. By the discussion on page 1733 the boundary components, viewed as oriented curves, then define elements $c_1, \ldots, c_m \in \mathrm{H}_1(\Sigma_{g,m})$. Then there exists an exact sequence

$$0 \to \mathbb{Z} \xrightarrow{1 \mapsto \sum c_i} \bigoplus_{i=1}^{m} \mathbb{Z} \cdot c_i \to \mathrm{H}_1(\Sigma_{g,m}) \to \mathrm{H}_1(\Sigma_g) \to 0.$$

(the map $\mathrm{H}_1(\Sigma_{g,m}) \to \mathrm{H}_1(\Sigma_g)$ is the inclusion induced map)

As we saw in the figure below, a basis for $\mathrm{H}_1(\Sigma_g)$ is given by a pair of curves for each "hole". The above exact sequence shows that a basis for the homology group $\mathrm{H}_1(\Sigma_{g,m}) \cong \mathbb{Z}^{2g+m-1}$ is obtained by a pair of curves for each "hole" together with boundary curves for all except one boundary component. This statement is illustrated in the figure below.



We conclude this section with the surface Σ_∞ of infinite genus that we had already encountered on page 1269. Using a variation on the proof of Lemma 56.11 one can show, using

the above calculations and the Exhaustions-H_*-Proposition 79.4, that

$$H_n(\Sigma_\infty) \cong \begin{cases} 0, & \text{if } n \geq 2, \\ \mathbb{Z}^\infty, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

We leave it to the reader to fill in the details.

surface of "infinite genus"

80.5. **The homology groups of real projective spaces.** In this section we will compute the homology groups of real projective spaces $\mathbb{R}P^n$. This calculation is significantly trickier than the previous ones, since the calculation of the cellular boundary maps is not as straightforward as in our previous examples. This time we will need the theory of local degrees that we developed in Section 76.6.

Proposition 80.11. For any $n \in \mathbb{N}_0$ we have[980]

$$H_k(\mathbb{R}P^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is odd and } k < n, \\ 0, & \text{if } k \text{ is even and } 0 < k \neq 0, \\ 0, & \text{if } k > n, \\ \mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd.} \end{cases}$$

Proof. As a reminder we defined

$$\mathbb{R}P^n = S^n/\!\sim \qquad \text{where } x \sim -x \text{ for all } x \in S^n.$$

In Lemma 68.1 we already saw that we can view $\mathbb{R}P^n$ as a CW-complex with the following two properties:

(1) the CW-structure has exactly one cell in the dimensions $0, 1, \ldots, n$ and no other cells,
(2) for each $k \leq n$ the k-skeleton of $\mathbb{R}P^n$ is given by $\mathbb{R}P^k$.

Now we recall the definition of this CW-structure. For each $k \in \mathbb{N}_0$ we define

$$\begin{array}{rcl} \varphi_k \colon S^{k-1} = \partial \overline{B}^k & \to & \mathbb{R}P^{k-1} \\ (x_1, \ldots, x_k) & \mapsto & [(x_1, \ldots, x_k)]. \end{array}$$

Then we obtain a homeomorphism

$$\begin{array}{rcl} \mathbb{R}P^{k-1} \cup_{\varphi_k} \overline{B}^k & \xrightarrow{\cong} & \mathbb{R}P^k \\ x & \mapsto & \begin{cases} (x, 0), & \text{if } x \in \mathbb{R}P^{k-1} \\ \big[\big(x, \sqrt{1 - \|x\|^2}\big)\big], & \text{if } x \in \overline{B}^k. \end{cases} \end{array}$$

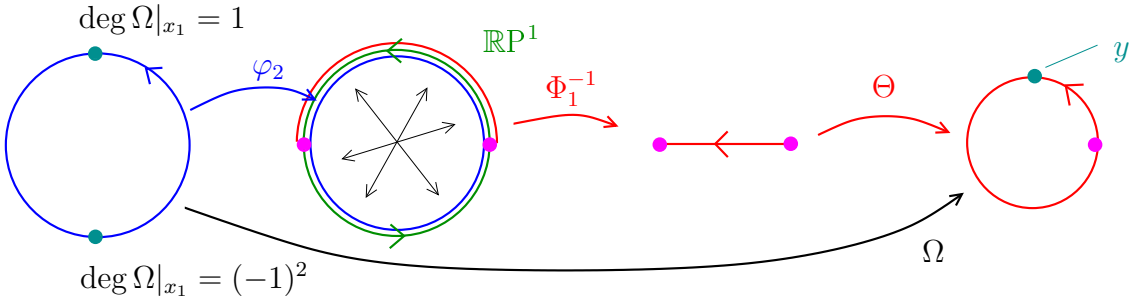
Thus we see inductively that we can view $\mathbb{R}P^n$ as a CW-complex with a single cell in the dimensions $0, \ldots, n$ where the attaching maps are given precisely by the maps $\varphi_1, \ldots, \varphi_n$.

[980] For $n = 2$ we thus obtain, as we should, the same result as in Section 78.3.

As usual we denote the characteristic map of the k-cell, which in this case is the obvious map $\overline{B}^k \to \mathbb{R}\mathrm{P}^k$, by Φ_k.

Claim. For each $k = 1, \dots, n$ the cellular boundary map

$$d_k \colon \mathbb{Z} = \mathrm{C}_k^{\mathrm{CW}}(X) \;\to\; \mathrm{C}_{k-1}^{\mathrm{CW}}(X) = \mathbb{Z}$$



is given by multiplication by $1 + (-1)^k$.

Proof. Let $k \in \{1, \dots, n\}$. We denote by $\Theta \colon \overline{B}^{k-1}/\partial\overline{B}^{k-1} \to S^{k-1}$ the homeomorphism from the Ball-Quotient Sphere Lemma 5.20 and we denote by $q \colon \mathbb{R}\mathrm{P}^{k-1} \to \mathbb{R}\mathrm{P}^{k-1}/\mathbb{R}\mathrm{P}^{k-2}$ the projection . By the Cellular Boundary Map-via-Degrees Proposition 80.8 it suffices to show that the degree of the map

$$S^{k-1} \xrightarrow{\varphi_k} \mathbb{R}\mathrm{P}^{k-1} \xrightarrow{q} \mathbb{R}\mathrm{P}^{k-1}/\mathbb{R}\mathrm{P}^{k-2} \xrightarrow{\Phi_{k-1}^{-1}} \overline{B}^{k-1}/\partial\overline{B}^{k-1} \xrightarrow{\Theta} S^{k-1}$$

$$=:\Omega$$

equals $1 + (-1)^k$. (We refer to the figure below for an illustration of the map.) We pick the point $y = (0, \dots, 0, 1) \in S^{k-1}$. The preimages of y under the map Ω are $x_1 = (0, \dots, 0, 1)$ and $x_2 = (0, \dots, 0, -1)$. We leave it to the reader to verify that[981] $\deg \Omega|_{x_1} = 1$ and that $\deg \Omega|_{x_2} = (-1)^n$. The desired statement now follows from the Local-Global Degree Proposition 76.21. ⊞

It follows from the claim that the cellular chain complex of X is of the form

$$0 \;\to\; \mathbb{Z} \xrightarrow{1+(-1)^n} \mathbb{Z} \;\dots\; \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \;\to\; 0.$$

It is now straightforward to determine the cellular homology groups which, by the Singular-Cellular H_*-Isomorphism Proposition 80.4, are isomorphic to the singular homology groups of $\mathbb{R}\mathrm{P}^n$. ■

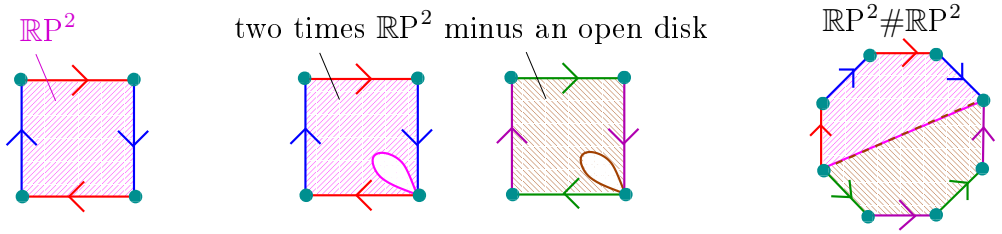
Remark. Using the approach of the proof of Proposition 80.11, applied to the infinite CW-complex $\mathbb{R}\mathrm{P}^\infty$, or alternatively using $\mathbb{R}\mathrm{P}^\infty = \bigcup_n \mathbb{R}\mathrm{P}^n$ and the Exhaustions-H_*-Proposition 79.4, we see that

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^\infty) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is odd}, \\ 0, & \text{if } k \text{ is even and } k > 0. \end{cases}$$

[981] It is not entirely easy to struggle through all the orientation conventions and all the maps, but it can indeed be done.

Remark. We have now seen that the homology groups of CW-complexes can be computed fairly easily using cellular chain complexes. One might ask, why did we introduce singular chain complexes, if it is so much easier to do calculations with cellular chain complexes. There are two related answers:

(1) we also want to study topological spaces that are not CW-complexes,
(2) it is much harder to prove some statements using cellular chain complexes, for example it is very difficult, if not impossible, to show that homeomorphic CW-complexes have isomorphic homology groups, just using the definition of cellular chain complexes.



A general slogan in topology is that for calculations it is usually best to work with "small objects", whereas for proving general properties, it is often best to work with "big objects".

Exercises for Chapter 80.

Exercise 80.1.

(a) Determine the homology groups of $\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2$.
(b) Determine the homology groups of $\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2$ minus an open disk.

Note: In both parts you can make use of the CW-structure for $\mathbb{R}\mathrm{P}^2\#\mathbb{R}\mathrm{P}^2$ illustrated in the figure below.
Remark. The homology groups are stated as Proposition 80.10. But it is a very good exercise to try to determine the homology groups without looking at the proposition.

Exercise 80.2. Show that given any finitely generated abelian group A there exists a topological space X with $\mathrm{H}_0(X) = \mathbb{Z}$ and $\mathrm{H}_1(X) \cong A$ and with $\mathrm{H}_i(X) = 0$ for $i \geq 2$.

Exercise 80.3. Let A be a finitely generated abelian group. Does there exist a topological space X with $\mathrm{H}_0(X) = \mathbb{Z}$, $\mathrm{H}_3(X) \cong A$ and $\mathrm{H}_i(X) = 0$ for $i \neq 0, 3$?

Exercise 80.4.

(a) Determine $\min\{\#\text{cells of } X \mid X \text{ is a CW-complex with } \mathrm{H}_2(X) \cong \mathbb{Z} \oplus \mathbb{Z}_2\}$.
(b) Determine $\min\{\#\text{cells of } X \mid X \text{ is a CW-complex with } \mathrm{H}_1(X) \cong \mathbb{Z} \oplus \mathbb{Z}_2\}$.
(c) Determine $\min\{\#\text{cells of } X \mid X \text{ is a connected CW-complex with } \pi_1(X) \cong \mathbb{Z} \times \mathbb{Z}_2\}$.

Exercise 80.5.

(a) Let X be the quotient space of S^2 under the identification $x \sim -x$ for all $x \in S^1$. Determine the homology groups of $X = S^2/\!\sim$.
(b) Let $m, n \in \mathbb{N}$ with $m < n$. As usual we view $\mathbb{R}\mathrm{P}^m$ as a subset of $\mathbb{R}\mathrm{P}^n$. Compute the homology groups of the quotient space $\mathbb{R}\mathrm{P}^n/\mathbb{R}\mathrm{P}^m$.

Exercise 80.6. Let C be a closed curve in a smooth manifold M. Suppose that C is the boundary of an embedded compact orientable surface in M. Show that the inclusion induced map $\mathrm{H}_1(C) \to \mathrm{H}_1(M)$ is the zero map.
More concisely, if a closed curve bounds a compact orientable surface, then the closed curve represents the trivial element in homology.

Exercise 80.7.

(a) Let Σ be a compact orientable connected 2-dimensional smooth manifold and let $F \subset \Sigma$ be a 2-dimensional submanifold. We denote by $i\colon F \to \Sigma$ the inclusion map. Show that $i_*(\mathrm{H}_1(F)) \subset \mathrm{H}_1(\Sigma)$ is a summand.
Hint. Consider the long exact sequence of the pair (Σ, F).

(b) Does the conclusion of (a) also hold if we do not assume that Σ is orientable?

Exercise 80.8. Let X be a topological space and let $n \in \mathbb{N}_0$. Suppose X is compact. Does it follow that $\mathrm{H}_n(X)$ is a finitely generated group?

Exercise 80.9. Let $n \in \mathbb{N}_0$. In Lemma 68.1 we showed that $\mathbb{R}\mathrm{P}^n$ admits a CW-structure which has exactly one cell in the dimensions $0, 1, \ldots, n$ and no other cells. Show that this is the "smallest" CW-structure on $\mathbb{R}\mathrm{P}^n$. More precisely, show that every CW-structure for $\mathbb{R}\mathrm{P}^n$ has at least one cell in the dimensions $0, 1, \ldots, n$.
Hint. Consider the (cellular) homology groups of $\mathbb{R}\mathrm{P}^n$.

Exercise 80.10. Let $m \leq n$. We denote by $i\colon \mathbb{R}\mathrm{P}^m \to \mathbb{R}\mathrm{P}^n$ the inclusion map. Determine for each $k \in \mathbb{N}_0$ the induced map $i_*\colon \mathrm{H}_k(\mathbb{R}\mathrm{P}^m) \to \mathrm{H}_k(\mathbb{R}\mathrm{P}^n)$.

Exercise 80.11. Let n be odd. By Proposition 80.11 we know that $\mathrm{H}_n(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}$. Show that there exists a singular simplex $\sigma\colon \Delta^n \to \mathbb{R}\mathrm{P}^n$ such that $[\sigma]$ is a generator of $\mathrm{H}_n(\mathbb{R}\mathrm{P}^n)$.
Hint.

(a) First you need to find an "interesting" cycle σ. You could use the identification $\mathbb{R}\mathrm{P}^n = \overline{B}^n/\sim$ from page 258. Or perhaps better, write $\mathbb{R}\mathrm{P}^n = \Delta^n/\sim$ for a suitable equivalence relation $\sim$.

(b) To show that the "interesting" cycle σ is actually a generator you could use the map $\overline{B}^n/\sim \to \overline{B}^n/S^{n-1}$ (which is continuous by the Twice Quotient Lemma 5.23 (2)) and results from Section 76.1.

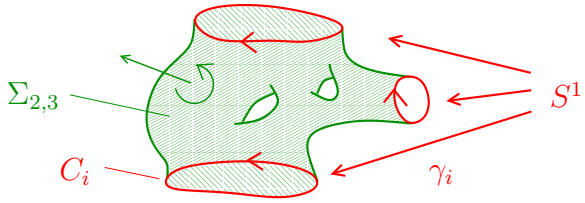
Exercise 80.12. Let $n \in \mathbb{N}$ be odd. By Proposition 80.11 we know that $\mathrm{H}_n(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}$. Let $p\colon S^n \to \mathbb{R}\mathrm{P}^n = S^n/\{\pm \mathrm{id}\}$ be the projection . Determine the induced map $p_*\colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(\mathbb{R}\mathrm{P}^n)$.
Hint. You could use the fact that the isomorphism between cellular and singular homology is natural.

Exercise 80.13. Let $n \in \mathbb{N}$ be odd. By Proposition 80.11 we know that $\mathrm{H}_n(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}$. Let $A \in \mathrm{GL}(n+1, \mathbb{R})$. We denote by $f\colon \mathbb{R}\mathrm{P}^n \to \mathbb{R}\mathrm{P}^n$ the map given by $f(x) := A \cdot x$. Determine the degree of the map $f_*\colon \mathrm{H}_n(\mathbb{R}\mathrm{P}^n) \to \mathrm{H}_n(\mathbb{R}\mathrm{P}^n)$.
Remark. You could make use of the homotopies considered on page 426.

Exercise 80.14. Let $g \in \mathbb{N}_0$ and let $k \in \mathbb{N}_0$. As on page 1234 we consider $\Sigma_{g,n}$, i.e. we consider the surface of genus g minus k open disks.

(a) Show that $\mathrm{H}_2(\Sigma_{g,n}, \partial\Sigma_{g,n}) \cong \mathbb{Z}$.

(b) Let $C_1, \dots, C_n$ be the boundary components. We equip $\Sigma_{g,n}$ with an orientation and we equip its boundary $\partial\Sigma_{g,n} = C_1 \sqcup \dots \sqcup C_n$ with the corresponding orientation given by the Boundary Orientation Lemma 25.17. For $i = 1, \dots, n$ we pick an orientation-preserving diffeomorphism $\gamma_i \colon S^1 \to C_i$. We write $[C_i] := \gamma_{i*}([S^1])$ and by a serious abuse of notation we denote by $[C_i]$ also the image of $[C_i]$ under the inclusion induced map $C_i \to \Sigma_{g,n}$. Show that there exists a generator φ of $\mathrm{H}_2(\Sigma_{g,n}, \partial\Sigma_{g,n}) \cong \mathbb{Z}$ such that



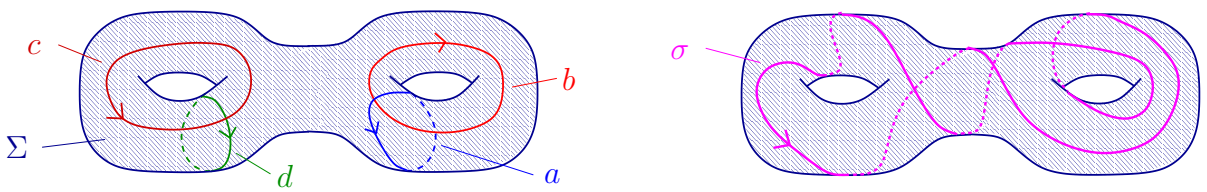
$$\underset{\substack{\uparrow \\ \text{connecting homomorphism of the pair } (\Sigma_{g,n}, \partial\Sigma_{g,n})}}{\partial_2(\varphi)} \;=\; [C_1] + \dots + [C_n] \;\in\; \mathrm{H}_1(\partial\Sigma_{g,n}).$$

(c) Show that $\mathrm{H}_1(\Sigma_{g,n}, \partial\Sigma_{g,n}) \cong \mathbb{Z}^{2g}$.

(d) We denote by $i \colon \partial\Sigma_{g,n} \to \Sigma_{g,n}$ and $j \colon \Sigma_{g,n} \to \Sigma_n$ the inclusion maps. Show that the following sequence is exact:

$$0 \;\to\; \mathrm{H}_2(\Sigma_{g,n}) \;\xrightarrow{\partial_2}\; \mathrm{H}_1(\partial\Sigma_{g,n}) \;\xrightarrow{i_*}\; \mathrm{H}_1(\Sigma_{g,n}) \xrightarrow{j_*} \mathrm{H}_1(\Sigma_g) \to 0.$$

Remark. In the Fundamental Class-of-Boundary Corollary 100.11 we will generalize Statement (a) to compact orientable manifolds in a suitable way.



Exercise 80.15. Let $k \in \mathbb{N}$ and let $m \in \mathbb{N}_0$. As on page 1234 we denote by $N_{k,m}$ the non-orientable surface of genus g minus m open disks.

(a) Determine the relative homology groups $\mathrm{H}_*(N_{k,m}, \partial N_{k,m})$.

(b) Use (a) together with Exercise 80.14 and Proposition 80.10 to show that the topological spaces $\Sigma_{g,n}$ and $N_{k,n}$ are pairwise non-homeomorphic.
Remark. This gives a new, perhaps more natural proof for the Surfaces-Non Homeomorphic Theorem 55.6.

Exercise 80.16. In the figure below we see to the left the surface Σ of genus two together with four oriented curves a, b, c, d and to the right we see an oriented curve σ. On page 1781 we showed that $\mathrm{H}_1(\Sigma) \cong \mathbb{Z}^4$ and we showed that the curves a, b, c and d represent a basis for $\mathrm{H}_1(\Sigma)$. In particular we can write $[\sigma] \in \mathrm{H}_1(\Sigma)$ uniquely as a linear combination of $[a]$, $[b]$, $[c]$ and $[d]$. Determine the coefficients of this linear combination.
Remark. In Exercise 126.13 we will get to know a charming approach to dealing with problems of this form.

Exercise 80.17. Let X be a CW-complex and let A be a subcomplex of X. We denote by $i\colon A \to X$ the inclusion map. We define the relative cellular chain complex

$$\mathrm{C}_*^{\mathrm{CW}}(X, A) \;:=\; \operatorname{coker}\big(i_*\colon \mathrm{C}_*^{\mathrm{CW}}(A) \to \mathrm{C}_*^{\mathrm{CW}}(X)\big),$$

and we refer to its homology groups as the relative cellular homology groups $\mathrm{H}_*^{\mathrm{CW}}(X, A)$. Show that there exists a natural isomorphisms

$$\Phi_{(X,A)}\colon \mathrm{H}_n(X, A) \;\to\; \mathrm{H}_n^{\mathrm{CW}}(X, A)$$

such that we obtain a commutative diagram as follows:

$$\begin{array}{ccccccccc}
\dots & \longrightarrow & \mathrm{H}_n(A) & \xrightarrow{i_*} & \mathrm{H}_n(X) & \longrightarrow & \mathrm{H}_n(X, A) & \xrightarrow{\partial} & \mathrm{H}_{n-1}^{\mathrm{CW}}(A) \longrightarrow \dots \\
 & & \downarrow{\scriptstyle \Phi_A} & & \downarrow{\scriptstyle \Phi_X} & & \downarrow{\scriptstyle \Phi_{(X,A)}} & & \downarrow{\scriptstyle \Phi_A} \\
\dots & \longrightarrow & \mathrm{H}_n^{\mathrm{CW}}(A) & \xrightarrow{i_*} & \mathrm{H}_n^{\mathrm{CW}}(X) & \longrightarrow & \mathrm{H}_n^{\mathrm{CW}}(X, A) & \xrightarrow{\partial} & \mathrm{H}_{n-1}^{\mathrm{CW}}(A) \longrightarrow \dots
\end{array}$$

Exercise 80.18. Let $k \leq n$ and let $i\colon \mathbb{R}\mathrm{P}^k \to \mathbb{R}\mathrm{P}^n$ be the embedding that is given by $i([x_0 : \cdots : x_k]) = [x_0 : \cdots : x_k : 0 : \cdots : 0]$. Use the relative cellular chain complex of Exercise 80.17 to compute the relative singular homology groups $\mathrm{H}_*(\mathbb{R}\mathrm{P}^n, i(\mathbb{R}\mathrm{P}^k))$.

81. The Fundamental Theorem of Homological Algebra

On several occasions we have now shown that certain homology groups are isomorphic, and it is reasonable to ask whether the underlying chain complexes are in fact chain homotopy equivalent. In this chapter we will see that, for purely algebraic reasons, the question can always be answered in the affirmative.

81.1. **The Fundamental Theorem of Homological Algebra.** We start out with the following definition which will arise time and again.

Definition.

(1) Let S be a non-empty set. We refer to

$$\mathbb{Z}^{(S)} := \text{all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s \in S$$

as the free abelian group generated by S.

(2) A group G is called free abelian if G is isomorphic to $\mathbb{Z}^{(S)}$ for some set S.

(3) A (free) resolution of an abelian group H is an exact sequence

$$\ldots \xrightarrow{f_3} F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

where the F_i are (free) abelian groups.

Example.

(1) The following is a free resolution for the abelian group $H = \mathbb{Z} \oplus \mathbb{Z}_2 \oplus \mathbb{Z}_5$:

$$0 \to \mathbb{Z}^2 \xrightarrow{\begin{pmatrix} 0 & 0 \\ 2 & 0 \\ 0 & 5 \end{pmatrix}} \mathbb{Z}^3 \xrightarrow{\text{obvious projection}} \mathbb{Z} \oplus \mathbb{Z}_2 \oplus \mathbb{Z}_5.$$

(2) Let $(\mathrm{C}_*, \partial_*)$ a chain complexes of *free* abelian groups. For each $n \in \mathbb{N}_0$ we write

$$Z_n := \ker(\partial_n \colon \mathrm{C}_n \to \mathrm{C}_{n-1}), \quad B_n := \operatorname{im}(\partial_{n+1} \colon \mathrm{C}_{n+1} \to \mathrm{C}_n) \quad \text{and} \quad H_n = Z_n / B_n.$$

Note that these groups form the following two types of short exact sequences

$$\text{(a)} \qquad 0 \to Z_n \hookrightarrow \mathrm{C}_n \xrightarrow{\partial_n} B_{n-1} \to 0,$$
$$\text{(b)} \qquad 0 \to B_n \hookrightarrow Z_n \to H_n \to 0.$$

Since all the chain groups are free abelian it follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that the subgroups Z_n and B_n are also free abelian. Thus the above two short exact sequences are free resolutions of B_{n-1} and H_n.

We will give many more examples of free resolutions in Section 89.4.

Definition. Let $\alpha \colon H \to H'$ be a homomorphism between abelian groups. Furthermore let F_* be a resolution of H and let F'_* be a free resolution of H'. An extension of α to the resolutions F_* and F'_* is a sequence of homomorphisms $\alpha_i \colon F_i \to F'_i$, $i \in \mathbb{N}_0$ such that the

following diagram commutes:

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \alpha_2} & & \downarrow{\scriptstyle \alpha_1} & & \downarrow{\scriptstyle \alpha_0} & & \downarrow{\scriptstyle \alpha} & & \\ \ldots & \longrightarrow & F_2' & \xrightarrow{f_2'} & F_1' & \xrightarrow{f_1'} & F_0' & \xrightarrow{f_0'} & H' & \longrightarrow & 0. \end{array}$$

Note that the horizontal exact sequences on top and bottom are in particular chain complexes and the maps α_* define a chain map from one complex to the other.
The following fundamental theorem underlies many arguments in homological algebra.

Theorem 81.1. (Fundamental Theorem of Homological Algebra) Let $\alpha\colon H \to H'$ be a homomorphism between abelian groups. Furthermore let F_* be a free resolution of H and let F_*' be a resolution[982] of H'.

(1) There exists an extension of α to the free resolutions F_* and F_*'.
(2) Any two extensions α_* and α_*', viewed as chain maps, are chain homotopic.

Proof. Let F_* be a free resolution of H and let F_*' be a resolution of H'. Statements (1) and (2) are both a straightforward consequence of some mild diagram chasing and the flexibility which Lemma 51.1 provides for defining homomorphisms starting from a free abelian group. In the following we fill in all the details.

(1) We have to show that there exists a sequence $\{\alpha_i\}_{i\in\mathbb{N}_0}$ of homomorphisms such that the following diagram commutes:

$$\begin{array}{ccccccccccc} \ldots & \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \alpha_2} & & \downarrow{\scriptstyle \alpha_1} & & \downarrow{\scriptstyle \alpha_0} & & \downarrow{\scriptstyle \alpha} & & \\ \ldots & \longrightarrow & F_2' & \xrightarrow{f_2'} & F_1' & \xrightarrow{f_1'} & F_0' & \xrightarrow{f_0'} & H' & \longrightarrow & 0. \end{array}$$

First we define the homomorphism α_0. We choose a basis $\mathcal{B}_0$ of the free abelian group F_0. For each $x_i \in \mathcal{B}_0$ we choose an $x_i' \in F_0'$ with $f_0'(x_i') = \alpha(f_0(x_i))$. This is possible, since f_0' is surjective. By Lemma 51.1 there exists a unique homomorphism $\alpha_0\colon F_0 \to F_0'$ with $\alpha_0(x_i) = x_i'$ for all $i \in I$. It is now evident that the right square commutes.

Now we turn to the definition of the map α_1. We choose a basis $\mathcal{B}_1$ of the free abelian group F_1. Let $x_i \in \mathcal{B}_1$. It follows from the commutativity of the square on the right that

$$f_0'((\alpha_0 \circ f_1)(x_i)) \;=\; \alpha(\underbrace{(f_0 \circ f_1)}_{=0}(x_i)) \;=\; 0.$$

Since the lower sequence is exact there exists an $x_i' \in F_1'$ with $f_1'(x_i') = (\alpha_0 \circ f_1)(x_i)$. Again by Lemma 51.1 there exists a unique homomorphism $\alpha_1\colon F_1 \to F_1'$ such that $\alpha_1(x_i) = x_i'$ for all $i \in I$. It is now evident that the "second square from the right" also commutes. It is now clear how inductively we can construct the homomorphisms $\alpha_2, \alpha_3, \ldots$.

(2) Now let $\alpha_i, \alpha_i'\colon F_i \to F_i', i \in \mathbb{N}_0$ be two extensions of α to the free resolutions F_* and F_*'. We have to find a chain homotopy from the chain map α_i to the chain map α_i'. The maps $\beta_i = \alpha_i - \alpha_i'$ are an extension of the zero map $\beta = 0\colon H \to H'$. Therefore

[982] Note that we do not demand that F_*' is a *free* resolution.

it suffices to find a chain homotopy λ from $\beta_i = \alpha_i - \alpha'_i$ to the zero chain map. The construction of the chain homotopy is very similar to the construction of the maps α_i in the first part of the proof.

Recall that we have to find a sequence of homomorphisms λ_i, $i \in \mathbb{N}_0$ such that for every $i \in \mathbb{N}_0$ we have

$$f'_{i+1} \circ \lambda_i + \lambda_{i-1} \circ f_i \;=\; \beta_i.$$

In the following discussion it is convenient to keep an eye on the following diagram that contains all the homomorphisms that we are given and that we need to construct:

$$\begin{array}{ccccccccccccc}
\ldots & \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \longrightarrow & 0 \\
 & \swarrow^{\lambda_2} & \downarrow{\scriptstyle \beta_2} & \swarrow^{\lambda_1} & \downarrow{\scriptstyle \beta_1} & \swarrow^{\lambda_0} & \downarrow{\scriptstyle \beta_0} & \swarrow^{\lambda_{-1}} & \downarrow{\scriptstyle \beta=0} & & \\
\ldots & \longrightarrow & F'_2 & \xrightarrow[f'_2]{} & F'_1 & \xrightarrow[f'_1]{} & F'_0 & \xrightarrow[f'_0]{} & H' & \longrightarrow & 0.
\end{array}$$

We put $\lambda_{-1} = 0$. Next we need to find a map $\lambda_0 \colon F_0 \to F'_1$ such that $\beta_0 = f'_1 \circ \lambda_0$. For each $x \in \mathcal{B}_0$ we choose an $x' \in F'_1$ with $f'_1(x') = \beta_0(x)$. The existence of such x' follows from the observation that $f'_0(\beta_0(x)) = \beta(f_0(x)) = 0$ and from the exactness of the lower sequence.

Now we suppose that we have already found maps $\lambda_0, \ldots, \lambda_{i-1}$ which have the desired property that

$$(*) \qquad f'_j \circ \lambda_{j-1} + \lambda_{j-2} \circ f_{j-1} \;=\; \beta_{j-1} \quad \text{for } j = 0, \ldots, i.$$

We choose again a basis $\mathcal{B}_i$ of the free abelian group F_i. We have to assign to x an element $x' \in F'_{i+1}$ which satisfies the equation

$$f'_{i+1}(x') \;=\; \beta_i(x) - \lambda_{i-1}(f_i(x)).$$

From the exactness of the lower sequence it follows that $\operatorname{im}(f'_{i+1}) = \ker(f'_i)$. Thus it suffices to show that $f'_i \circ (\beta_i - \lambda_{i-1} \circ f_i) = 0$. It turns out that indeed we have

$$\begin{aligned}
f'_i \circ (\beta_i - \lambda_{i-1} \circ f_i) \;&=\; f'_i \circ \beta_i - f'_i \circ \lambda_{i-1} \circ f_i \;\underset{\uparrow}{=}\; \beta_{i-1} \circ f_i - f'_i \circ \lambda_{i-1} \circ f_i \\
&\qquad \text{since the } \beta_i\text{'s are a chain map, i.e. } f'_i \circ \beta_i = \beta_{i-1} \circ f_i \\
&=\; (\beta_{i-1} - f'_i \circ \lambda_{i-1}) \circ f_i \;\underset{\uparrow}{=}\; \lambda_{i-2} \circ f_{i-1} \circ f_i \;\underset{\uparrow}{=}\; 0. \\
&\qquad\qquad \text{by } (*) \qquad\qquad \text{since } f_{i-1} \circ f_i = 0
\end{aligned}$$

■

.

We conclude this section with two applications to the Fundamental Theorem 81.1 of Homological Algebra.

Corollary 81.2. Let

$$\ldots \;\to\; F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \;\to\; 0$$

and

$$\ldots \;\to\; F'_2 \xrightarrow{f'_2} F'_1 \xrightarrow{f'_1} F'_0 \xrightarrow{f'_0} H \;\to\; 0$$

be two free resolutions of an abelian group H. Let $\alpha_i, i \in \mathbb{N}$ be an extension of the identity map $\mathrm{id} \colon H \to H$ to the free resolutions F_* and F'_*. The maps α_* form a chain homotopy equivalence between the two chain complexes F_* and F'_*.

Proof. We pick an extension $\alpha_i, i \in \mathbb{N}$ of the identity map $\mathrm{id}\colon H \to H$. We apply the Fundamental Theorem 81.1 of Homological Algebra to the free resolutions F'_* and F_* (i.e. we swap the roles of the free resolutions) and we obtain maps $\{\beta_i\}_{i\in\mathbb{N}_0}$ that give us the lower half of the following commutative diagram.

$$\begin{array}{ccccccccccc}
\ldots & \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \alpha_2} & & \downarrow{\scriptstyle \alpha_1} & & \downarrow{\scriptstyle \alpha_0} & & \downarrow{\scriptstyle \mathrm{id}} & & \\
\ldots & \longrightarrow & F'_2 & \xrightarrow{f'_2} & F'_1 & \xrightarrow{f'_1} & F'_0 & \xrightarrow{f'_0} & H & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \beta_2} & & \downarrow{\scriptstyle \beta_1} & & \downarrow{\scriptstyle \beta_0} & & \downarrow{\scriptstyle \mathrm{id}} & & \\
\ldots & \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \longrightarrow & 0.
\end{array}$$

The maps $\beta_i \circ \alpha_i$ now provide us with the following commutative diagram:

$$\begin{array}{ccccccccccc}
\ldots & \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \beta_2\circ\alpha_2} & & \downarrow{\scriptstyle \beta_1\circ\alpha_1} & & \downarrow{\scriptstyle \beta_0\circ\alpha_0} & & \downarrow{\scriptstyle \mathrm{id}} & & \\
\ldots & \longrightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \longrightarrow & 0.
\end{array}$$

This shows that the maps $\beta_i \circ \alpha_i$ define an extension of $\mathrm{id}\colon H \to H$ to the free resolutions F_i and F_i. But the identity maps also define an extension. By the Fundamental Theorem 81.1 of Homological Algebra the extensions $\{\beta_i \circ \alpha_i\}_{i\in\mathbb{N}_0}$ and $\{\mathrm{id}\}_{i\in\mathbb{N}_0}$ are chain homotopic. The same way one shows that the extensions $\{\alpha_i \circ \beta_i\}_{i\in\mathbb{N}_0}$ and $\{\mathrm{id}\}_{i\in\mathbb{N}_0}$ are chain homotopic. ■

Corollary 81.3. Let $(\mathrm{C}_*, \partial_*)$ be a chain complex of free abelian groups. If $(\mathrm{C}_*, \partial_*)$ is acyclic, i.e. if $\mathrm{H}_n(C_*) = 0$ for all $n \in \mathbb{N}_0$, then the identity map and the zero map of C_* to itself are chain homotopic.

Proof. We consider the following pretty dull diagram:

$$\begin{array}{ccccccccccc}
\ldots & \longrightarrow & C_2 & \xrightarrow{\partial_2} & C_1 & \xrightarrow{\partial_1} & C_0 & \xrightarrow{0} & 0 & \longrightarrow & 0 \\
 & & & & & & & & \downarrow{\scriptstyle 0} & & \\
\ldots & \longrightarrow & C_2 & \xrightarrow{\partial_2} & C_1 & \xrightarrow{\partial_1} & C_0 & \xrightarrow{0} & 0 & \longrightarrow & 0.
\end{array}$$

The hypothesis that $\mathrm{H}_n(C_*) = 0$ for all $n \in \mathbb{N}_0$ means that C_* is a free resolution of the trivial group, i.e. the top and bottom are free resolutions. The zero map on the right now has two extensions:

(1) The identity maps $\mathrm{id}\colon C_i \to C_i$ define an extension.
(2) The zero maps $\mathrm{id}\colon C_i \to C_i$ define an extension.

By Statement (2) of the Fundamental Theorem 81.1 of Homological Algebra these two extensions are chain homotopic. But that is precisely what we wanted to show. ■

81.2. **Quasi-isomorphisms are chain homotopy equivalences.** In this section we will state and discuss more consequences of the Fundamental Theorem 81.1 of Homological Algebra. We start out with the following definition.

Definition. Let $f\colon C_* \to D_*$ be a chain map between chain complexes. We say f is a quasi-isomorphism if for each $k \in \mathbb{N}_0$ the induced map $f_*\colon \mathrm{H}_k(C_*) \to \mathrm{H}_k(D_*)$ is an isomorphism.

In Lemma 73.2 we saw that chain homotopy equivalences are quasi-isomorphisms. If we are dealing with chain complexes of free abelian groups, the following proposition gives us now the converse statement.

Proposition 81.4. (Quasi Isomorphisms-are-Homotopy Equivalences Proposition) Let $f\colon C_* \to D_*$ be a chain map between chain complexes of *free abelian groups*. If f is a quasi-isomorphism, then f is in fact a chain homotopy equivalence.

Remark. The hypothesis that C and D_* are free abelian groups is essential. For example in Exercise 81.3 we will see that there exists a quasi-isomorphism between the chain complex

$$C_* = 0 \to \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \to \mathbb{Z}_2 \to 0$$

and the zero chain complex D_*, but we will see that the two chain complexes are not chain homotopy equivalent.

The following proposition is a convenient variation on the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4.

Proposition 81.5. Let C_* and D_* be two chain complexes of free abelian groups and let $\iota\colon C_* \to D_*$ be a chain map with the following two properties:

(a) The chain map $\iota\colon C_* \to D_*$ induces an isomorphism of homology groups.
(b) For each $k \in \mathbb{N}_0$ the map $\iota\colon \mathrm{C}_k \to D_k$ is a monomorphism and the image is a subsummand of D_k.

Then there exists a chain map $\pi\colon D_* \to \mathrm{C}_*$ with the following two properties:

(1) For each $k \in \mathbb{N}_0$ we have $\pi_k \circ \iota_k = \mathrm{id}_{\mathrm{C}_k}$.
(2) The maps ι and π are chain homotopy homotopy equivalences.

We provide the proofs of these two propositions in the next section. For the remainder of this section we want to discuss some consequences. For example we have have the following interesting corollary to the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4.

Corollary 81.6. (Two-Out-Of-Three-Homotopy Equivalence Corollary)[983] Let

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_* & \longrightarrow & B_* & \longrightarrow & C_* & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & A'_* & \longrightarrow & B'_* & \longrightarrow & C'_* & \longrightarrow & 0 \end{array}$$

be a commutative diagram of short exact sequences of chain complexes of free abelian groups. If two of the vertical maps are chain homotopy equivalences, then the third is also a chain homotopy equivalence.

Proof. By the LES Proposition 74.9 we get a commutative diagram of long exact sequences

$$\begin{array}{ccccccccccccc} \ldots & \longrightarrow & \mathrm{H}_{n+1}(C_*) & \xrightarrow{\partial} & \mathrm{H}_n(A_*) & \longrightarrow & \mathrm{H}_n(B_*) & \longrightarrow & \mathrm{H}_n(C_*) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A_*) & \longrightarrow & \ldots \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ \ldots & \longrightarrow & \mathrm{H}_{n+1}(C'_*) & \xrightarrow{\partial} & \mathrm{H}_n(A'_*) & \longrightarrow & \mathrm{H}_n(B'_*) & \longrightarrow & \mathrm{H}_n(C'_*) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(A'_*) & \longrightarrow & \ldots \end{array}$$

[983] This corollary is very close to the content of Exercise 74.11.

By our hypothesis, together with Corollary 73.4, we know that always two out of three vertical maps are isomorphisms. But then it follows from the Five Lemma 74.10 that the third vertical map is also an isomorphism. Now the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 implies that the corresponding map of chain complexes is also a chain homotopy equivalence. ■

As we pointed out above, the first time we had mentioned the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 was in the remark after the Comfortable Covering Proposition 74.23. In fact we can now prove the following strengthened version of the Comfortable Covering Proposition 74.23.

Proposition 81.7. Let X be a topological space. For every comfortable cover $\mathcal{U} = \{U_i\}_{i\in I}$ of X the inclusion map[984]
$$\mathrm{C}_*^{\mathcal{U}}(X) \;\to\; \mathrm{C}_*(X)$$
is a chain homotopy equivalence.

Proof. Let $k \in \mathbb{N}_0$. Note that $\mathrm{C}_k^{\mathcal{U}}(X)$ is the free abelian group generated by the set
$$\{\sigma\colon \Delta^k \to X \,|\, \text{there exists an } i \in I \text{ with } \sigma(\Delta^k) \subset U_i\}.$$
Therefore we can apply the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 and we obtain the desired result. ■

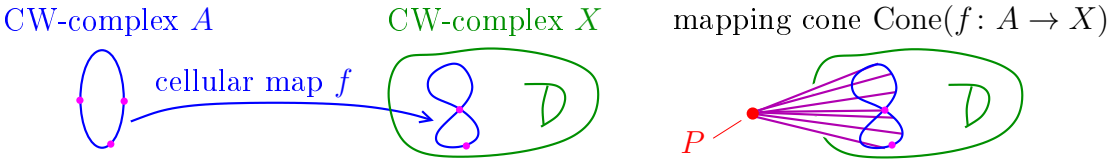
81.3. **Proof of Propositions 81.4 and 81.5.** This section will be occupied with the proofs of the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 and 81.5. We start out with the following definition.

Definition. Let (C_n, c_n) and (D_n, d_n) be two chain complexes and let $\varphi\colon C_* \to D_*$ be a chain map. The algebraic mapping cone of φ is the chain complex $(\mathrm{M}(\varphi), \partial_*)$ that is given by the chain groups
$$\mathrm{M}(\varphi)_n \;:=\; \begin{matrix}\mathrm{C}_{n-1}\\ D_n\end{matrix} \;:=\; \mathrm{C}_{n-1} \oplus D_n$$
and the boundary maps[985]
$$\partial\colon \begin{matrix}\overbrace{}^{\mathrm{M}(\varphi)_n}\\ \mathrm{C}_{n-1}\\ D_n\\ x\\ y\end{matrix} \;\begin{matrix}\to\\ \\ \\ \mapsto\\ \\ \end{matrix}\; \begin{matrix}\overbrace{}^{\mathrm{M}(\varphi)_{n-1}}\\ \mathrm{C}_{n-2}\\ D_{n-1}\\ -c_{n-1}(x)\\ \varphi_{n-1}(x) + d_n(y)\end{matrix} \qquad \text{which we write as block matrices} \qquad \begin{matrix}\mathrm{C}_{n-1} & D_n & \\ \end{matrix} \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} \begin{matrix}\mathrm{C}_{n-2}\\ D_{n-1}\end{matrix}$$

[984] Recall that a *comfortable cover of* X is a family $\mathcal{U} = \{U_i\}_{i\in I}$ of subsets of X such that the union of the interiors of the U_i equals X. On page 1638 we defined
$$\mathrm{C}_n^{\mathcal{U}}(X) \;=\; \Big\{ \sum_{j=1}^{k} a_j \sigma_j \,\Big|\, \text{for each } j \text{ there exists a } U_i \in \mathcal{U} \text{ such that the image of } \sigma_j \text{ lies in } U_i \Big\}$$
and we had observed that these groups form a subcomplex of $\mathrm{C}_*(X)$.

[985] Note that
$$\partial_{n-1} \circ \partial_n \;=\; \begin{pmatrix} -c_{n-2} & 0 \\ \varphi_{n-2} & d_{n-1} \end{pmatrix} \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} \;=\; \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$$
since φ is a chain map and $c_{n-2} \circ c_{n-1} = 0$ and $d_{n-1} \circ d_n = 0$

This shows that we have indeed defined a chain complex.



Remark. Let $f\colon A \to X$ be a map between topological spaces. Recall that on page 457 we defined the corresponding *mapping cone* as

$$\mathrm{Cone}(f\colon A \to X) \;:=\; (A \times [0,1] \sqcup X)/\!\sim$$

where $(a,1) \sim f(a)$ for all $a \in A$ and $(a,0) \sim (b,0)$ for all $a,b \in A$. As an application we showed on page 457 that for an inclusion map $i\colon A \to X$ there exists a natural isomorphism

$$\widetilde{\mathrm{H}}_n(\mathrm{Cone}(i\colon A \to X)) \;\xrightarrow{\cong}\; \mathrm{H}_n(X,A),$$

i.e. we can reinterpret relative homology groups as reduced homology groups of the corresponding mapping cone. Now suppose that A and X are finite CW-complexes and that f is a cellular map. By the CW-Complex Cone Corollary 68.35 (3) we can equip the mapping cone $\mathrm{Cone}(f\colon A \to X)$ with a natural CW-structure. In Exercise 81.2 we will show that the corresponding cellular chain complex is isomorphic to the algebraic mapping cone of the chain map $f_*\colon \mathrm{C}_*^{\mathrm{CW}}(A) \to \mathrm{C}_*^{\mathrm{CW}}(X)$.

Lemma 81.8. (Mapping Cone-LES Lemma) Let $\varphi\colon C_* \to D_*$ be a chain map between two chain complexes (C_n, c_n) and (D_n, d_n). We denote by $i\colon D_n \to \mathrm{M}(\varphi)_n = \mathrm{C}_{n-1} \oplus D_n$ the obvious natural inclusion map and we denote by $p\colon \mathrm{M}(\varphi)_n = \mathrm{C}_{n-1} \oplus D_n \to \mathrm{C}_{n-1}$ the obvious natural projection . Then the following sequence is exact

$$\ldots \;\to\; \mathrm{H}_n(C_*) \xrightarrow{\varphi_*} \mathrm{H}_n(D_*) \xrightarrow{i_*} \mathrm{H}_n(\mathrm{M}(\varphi)) \xrightarrow{p_*} \mathrm{H}_{n-1}(C_*) \xrightarrow{\varphi_*} \mathrm{H}_{n-1}(D_*) \;\to\; \ldots$$

Proof. For each $n \in \mathbb{N}_0$ we consider the following diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & D_n & \xrightarrow{i_n} & \begin{matrix}\mathrm{C}_{n-1}\\ D_n\end{matrix} & \xrightarrow{p_n} & \mathrm{C}_{n-1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle d_n} & & \downarrow{\scriptstyle \partial_n}\ \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} & & \downarrow{\scriptstyle c_{n-1}} & & \\
0 & \longrightarrow & D_{n-1} & \xrightarrow[i_{n-1}]{} & \begin{matrix}\mathrm{C}_{n-2}\\ D_{n-1}\end{matrix} & \xrightarrow[p_{n-1}]{} & \mathrm{C}_{n-2} & \longrightarrow & 0.
\end{array}$$

We make the following observations:

(1) the horizontal sequences are exact,
(2) the left-hand square commutes, i.e. the maps i_* define a chain map,
(3) the right-hand square commutes up to a minus sign, i.e. we have

$$c_{n-1} \circ p_n \;=\; -p_{n-1} \circ \partial_n.$$

Fortunately this minus sign in the above equality does not change the fact that the maps p_n induce a map between homology groups.

Despite the minus sign in (3) we can use verbatim the same construction as on page 1620 to obtain connecting homomorphisms $\partial_n\colon \mathrm{H}_n(D_*) \to \mathrm{H}_n(C_*)$, $n \in \mathbb{N}_0$, and verbatim the

same proof as in the LES Proposition 74.9 shows that these connecting homomorphisms give rise to a long exact sequence of the form

$$\ldots \to \mathrm{H}_n(C_*) \xrightarrow{\partial_n} \mathrm{H}_n(D_*) \xrightarrow{i_*} \mathrm{H}_n(\mathrm{M}(\varphi)) \xrightarrow{p_*} \mathrm{H}_{n-1}(C_*) \xrightarrow{\partial_{n-1}} \mathrm{H}_{n-1}(D_*) \to \ldots$$

It follows easily from the definition of the connecting homomorphism on page 1620 that for each $n \in \mathbb{N}_0$ we have the equality

$$\partial_n = \varphi_* \colon \mathrm{H}_n(C_*) \to \mathrm{H}_n(D_*).$$

We have thus now shown that the sequence in the statement of the lemma is exact. ■

Now we are finally fully prepared to provide the proof of the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4.

Proof of Proposition 81.4. Let $\varphi \colon C_* \to D_*$ be a chain map between chain complexes (C_*, c_*) and (D_*, d_*) of free abelian groups which induces an isomorphism on all homology groups. We need to show that φ is in fact a chain homotopy equivalence.

As above we denote by $(\mathrm{M}(\varphi)_*, \partial_*)$ the mapping cone of φ. We consider the long exact sequence from the Mapping Cone-LES Lemma 81.8:

$$\ldots \to \mathrm{H}_n(C_*) \xrightarrow{\varphi_*} \mathrm{H}_n(D_*) \xrightarrow{i_*} \mathrm{H}_n(\mathrm{M}(\varphi)) \xrightarrow{p_*} \mathrm{H}_{n-1}(C_*) \xrightarrow{\varphi_*} \mathrm{H}_{n-1}(D_*) \to \ldots$$

By our hypothesis the maps φ induce isomorphisms of homology groups, thus we see that $\mathrm{H}_n(\mathrm{M}(\varphi)) = 0$ for all $n \geq 0$. By Corollary 81.3 this means that we have a chain homotopy $\{P_n\}_{n\geq 0}$ from the identity map to the zero map. (Note that here we use that by our hypothesis on C_* and D_* each $\mathrm{M}(\varphi)_n = \mathrm{C}_{n-1} \oplus D_n$ is a free abelian group.)

Recall that this means that for each $n \in \mathbb{N}_0$ we have the equality

$$(*) \qquad P_{n-1} \circ \partial_n + \partial_{n+1} \circ P_n = \mathrm{id}_{\mathrm{C}_{n-1} \oplus D_n}.$$

Using the obvious matrix notation we write

$$P_n = \begin{pmatrix} P_n^{11} & P_n^{12} \\ P_n^{21} & P_n^{22} \end{pmatrix} \colon \underbrace{\begin{matrix} \mathrm{C}_{n-1} \\ D_n \end{matrix}}_{=\mathrm{M}(\varphi)_n} \to \underbrace{\begin{matrix} \mathrm{C}_n \\ D_{n+1}. \end{matrix}}_{=\mathrm{M}(\varphi)_{n+1}}$$

Now we can rewrite the above equality $(*)$ and we obtain that

$$\begin{pmatrix} P_{n-1}^{11} & P_{n-1}^{12} \\ P_{n-1}^{21} & P_{n-1}^{22} \end{pmatrix} \circ \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} + \begin{pmatrix} -c_n & 0 \\ \varphi_n & d_{n+1} \end{pmatrix} \circ \begin{pmatrix} P_n^{11} & P_n^{12} \\ P_n^{21} & P_n^{22} \end{pmatrix} = \begin{pmatrix} \mathrm{id}_{\mathrm{C}_{n-1}} & 0 \\ 0 & \mathrm{id}_{D_n} \end{pmatrix}.$$

Looking at the four entries separately we obtain the following four equalities:

$$\begin{aligned}
&\text{(a)} && -P_{n-1}^{11} \circ c_{n-1} + P_{n-1}^{12} \circ \varphi_{n-1} - c_n \circ P_n^{11} &&= \mathrm{id}_{\mathrm{C}_{n-1}}, \\
&\text{(b)} && P_{n-1}^{12} \circ d_n - c_n \circ P_n^{12} &&= 0, \\
&\text{(c)} && -P_{n-1}^{21} \circ c_{n-1} + P_{n-1}^{22} \circ \varphi_{n-1} + \varphi_n \circ P_n^{11} + d_{n+1} \circ P_n^{21} &&= 0, \\
&\text{(d)} && P_{n-1}^{22} \circ d_n + \varphi_n \circ P_n^{12} + d_{n+1} \circ P_n^{22} &&= \mathrm{id}_{D_n}.
\end{aligned}$$

We make the following observation:

(1) equation (b) implies that the homomorphisms $\{P_n^{12} \colon D_n \to \mathrm{C}_n\}_{n\in\mathbb{N}_0}$ define a chain map $D \to C$.

Now we claim that the chain map $\{P_n^{12}\}_{n\in\mathbb{N}_0}$ is a chain homotopy inverse to the chain map φ. We do so with the following two observations:

(2) equation (a) implies that $P^{12}\circ\varphi \simeq \mathrm{id}_{C_*}$ where the chain homotopy is given by the maps $P_n^{11}\colon \mathrm{C}_{n-1}\to C_n$,
(3) whereas equation (d) implies that $\varphi\circ P^{12}\simeq \mathrm{id}_{D_*}$, where the chain homotopy is given by the maps $P_n^{22}\colon D_n\to D_{n+1}$,

The last two statements together imply that φ is indeed a chain homotopy equivalence. ■

We conclude this section with the proof of Proposition 81.5.

Proof of Proposition 81.5. Let C_* and D_* be two chain complexes of free abelian groups and let $\iota\colon C_*\to D_*$ be a chain map with the following two properties:

(a) The chain map $\iota\colon C_*\to D_*$ induces an isomorphism of homology groups.
(b) For each $k\in\mathbb{N}_0$ the map $\iota\colon \mathrm{C}_k\to D_k$ is a monomorphism and the image is a subsummand of D_k.

We need to show that there exists a chain map $\pi\colon D_*\to \mathrm{C}_*$ with the following two properties:

(1) For each $k\in\mathbb{N}_0$ we have $\pi_k\circ\iota_k=\mathrm{id}_{\mathrm{C}_k}$.
(2) The maps ι and π are chain homotopy homotopy equivalences.

The key to proving the proposition is the following claim:

Claim. We set $\mathrm{C}_{-1}=D_{-1}=0$ and we define π_{-1} to be the zero homomorphism. Let $k\in\mathbb{Z}_{\geq -1}$. Suppose that for $j=-1,\ldots,k$ we are given maps $\pi_j\colon D_j\to\mathrm{C}_j$ such that for each $j\in\{0,\ldots,k\}$ we have the following equalities:

(1) $\pi_j\circ\iota_j=\mathrm{id}_{\mathrm{C}_j}$.
(2) $\partial\circ\pi_{j-1}=\pi_j\circ\partial$.

Then there exists a map $\pi_{k+1}\colon D_{k+1}\to\mathrm{C}_{k+1}$ such that the maps $\pi_0,\ldots,\pi_{k+1}$ have the above properties.

Proof. First note that by hypothesis we can pick for each $m\in\mathbb{N}$ a submodule $C_m^\dagger$ of D_m such that $D_m=\iota(\mathrm{C}_m)\oplus C_m^\dagger$. For orientation it is perhaps convenient to consider the following maps:

$$\begin{array}{ccc} D_{k+1}=\iota(\mathrm{C}_{k+1})\oplus C_{k+1}^\dagger & \xrightarrow{\partial_D} & \iota(\mathrm{C}_k)\oplus C_k^\dagger = D_k \\ {\scriptstyle\iota_{k+1}}\uparrow \quad \downarrow{\scriptstyle ?\pi_{k+1}?} & & {\scriptstyle\iota_k}\uparrow \quad \downarrow{\scriptstyle\pi_k} \\ \mathrm{C}_{k+1} & \xrightarrow[\partial_C]{} & \mathrm{C}_k \end{array}$$

Since $C_{k+1}^\dagger$ is a subgroup of the free abelian group D_{k+1} we know by the Subgroup-of-Free Abelian Group Lemma 51.2 that $C_{k+1}^\dagger$ is also a free abelian group. We pick a basis T for the free abelian group $C_{k+1}^\dagger$. Let $t\in T$. Since ι induces an isomorphism of homology groups we know that there exists a $c_{k+1}\in\mathrm{C}_{k+1}$ such that t and $\iota(c_{k+1})$ are homologous. We calculate that

$$\pi_k(\partial_D(t_{k+1})) \underset{\text{since } t_{k+1} \text{ and } \iota(c_{k+1}) \text{ are homologous we know that } \partial_D(t_{k+1})=\partial_D(\iota(c_{k+1}))}{=} \pi_k(\partial_D(\iota_{k+1}(c_{k+1}))) \underset{\text{since } \iota \text{ is a chain map}}{=} \pi_k(\iota_k(\partial_C(c_{k+1}))) \underset{\text{since } \pi_k\circ\iota_k=\mathrm{id}_{\mathrm{C}_k}}{=} \partial_C(c_{k+1}).$$

We set $\pi_{k+1}(t) := c_{k+1}$. Since T_{k+1} is a basis for the free abelian group $C_{k+1}^\dagger$ we obtain a homomorphism $\varphi\colon C_{k+1}^\dagger \to \mathrm{C}_{k+1}$. It is now straightforward to verify that the map

$$\begin{array}{rccc} \pi_{k+1}\colon D_{k+1} = \iota(\mathrm{C}_{k+1}) \oplus C_{k+1}^\dagger & \to & \mathrm{C}_{k+1} \\ \iota(c_{k+1}) + d_{k+1} & \mapsto & c_{k+1} + \varphi(d_{k+1}) \end{array}$$

has all the desired properties. ⊞

Since C_* and D_* are chain complexes of free abelian groups and since ι induces an isomorphism of homology groups we know by the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 that ι is a chain homotopy equivalence. By Property (2) of the claim the maps $\{\pi_n\colon D_n \to \mathrm{C}_n\}_{n\in\mathbb{N}_0}$ define a chain map. By Property (1) of the claim we have for each $k \in \mathbb{N}_0$ that $\pi_* \circ \iota_* = \mathrm{id}_{\mathrm{H}_k(C_*)}$. Thus we see that the chain map π_* also induces isomorphism of the homology groups. So once again we appeal to the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 to conclude that the maps π_* form a chain homotopy equivalence. ■

81.4. **Singular and cellular chain complexes.** In Chapter 80 we introduced the cellular chain complex and the cellular homology groups of a CW-complex. In the Singular-Cellular H_*-Isomorphism Proposition 80.4 we showed that cellular homology groups are naturally isomorphic to singular homology groups. At that point we did not say anything about the relationship between the cellular chain complex and the singular chain complex. We will rectify this in this section. The extra information that we gain in this section will stand us in good stead in Section 109.2 when we explore the relationship between cellular cohomology and singular cohomology.

First we recall some definitions and some notation, mostly from page 1770.

Definition. Let X be a CW-complex and let $n \in \mathbb{N}_0$.

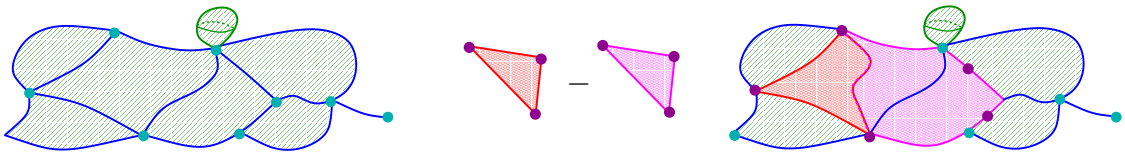
(1) We denote by X^n the n-skeleton of X, i.e. the union of all cells of dimension $\leq n$.

(2) We write $\mathrm{C}_n^{\mathrm{CW}}(X) := \mathrm{H}_n(X^n, X^{n-1})$ and we denote by $d_n\colon \mathrm{C}_n^{\mathrm{CW}}(X) \to \mathrm{C}_{n-1}^{\mathrm{CW}}(X)$ the cellular boundary map from page 1769, i.e. d_n is the map that is given by the composition of the following two maps:

$$\begin{array}{ccccc} \mathrm{H}_n(X^n, X^{n-1}) & \xrightarrow{\partial_n} & \mathrm{H}_{n-1}(X^{n-1}) & \to & \mathrm{H}_{n-1}(X^{n-1}, X^{n-2}). \\ & \uparrow & & & \\ & \text{connecting homomorphism of the long exact sequence of the pair } (X^n, X^{n-1}) & & & \end{array}$$

(3) We refer to

$$\ldots \xrightarrow{d_{n+2}} \mathrm{C}_{n+1}^{\mathrm{CW}}(X) \xrightarrow{d_{n+1}} \mathrm{C}_n^{\mathrm{CW}}(X) \xrightarrow{d_n} \mathrm{C}_{n-1}^{\mathrm{CW}}(X) \xrightarrow{d_{n-1}} \ldots$$



as the cellular chain complex. Its homology groups are denoted by $\mathrm{H}_n^{\mathrm{CW}}(X)$.

In the following we want to relate the cellular chain complex $\mathrm{C}_*^{\mathrm{CW}}(X)$ to the singular chain complex $\mathrm{C}_*(X)$. There is no obvious "interesting" chain map between these two chain complexes. But as we will see in a minute, it turns out that there is a nice "intermediate" chain complex which maps into both of the above chain complexes:

Definition. Given a CW-complex X and given $n \in \mathbb{N}_0$ we define the intermediate cellular chain complex[986]

$$\mathrm{C}_n^{\mathrm{int}}(X) := \ker\left(\mathrm{C}_n(X^n) \xrightarrow{\partial} \mathrm{C}_{n-1}(X^n) \xrightarrow{\pi} \mathrm{C}_{n-1}(X^n, X^{n-1})\right)$$

where $\pi\colon \mathrm{C}_{n-1}(X^n) \to \mathrm{C}_{n-1}(X^n, X^{n-1})$ is the natural projection.

CW-complex X element of $\mathrm{C}_2^{\mathrm{int}}(X)$

Lemma 81.9.

(1) Given any CW-complex X the intermediate cellular chain complex $\mathrm{C}_*^{\mathrm{int}}(X)$ is a subcomplex of the singular chain complex $\mathrm{C}_*(X)$.
(2) If $f\colon X \to Y$ is a cellular map between two CW-complexes, then the induced map $f_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y)$ restricts to a map $\mathrm{C}_*^{\mathrm{int}}(X) \to \mathrm{C}_*^{\mathrm{int}}(Y)$.

Proof.

(1) First note that by definition we have for any $k \in \mathbb{N}_0$ the equality

$$(*) \qquad \mathrm{C}_k^{\mathrm{int}}(X) = \{\sigma \in \mathrm{C}_k(X^k) \,|\, \partial_k(\sigma) \in \mathrm{C}_{k-1}(X^{k-1})\}.$$

Now let $\sigma \in \mathrm{C}_n^{\mathrm{int}}(X)$. We need to show that $\partial_n(\sigma) \in \mathrm{C}_{n-1}^{\mathrm{int}}(X)$.
(a) By $(*)$ we know $\partial_n(\sigma) \in \mathrm{C}_{n-1}(X^{n-1})$.
(b) Next note that $\partial_{n-1}(\partial_n(\sigma)) = (\partial_{n-1} \circ \partial_n)(\sigma) = 0$. In particular we obtain that $\partial_{n-1}(\partial_n(\sigma)) \in \mathrm{C}_{n-2}(X^{n-2})$.
(c) The combination of (a), (b) and $(*)$ shows that $\partial_n(\sigma) \in \mathrm{C}_{n-1}^{\mathrm{int}}(X)$.

(2) Let $f\colon X \to Y$ be a cellular map between two CW-complexes. We obtain the following diagram:

$$\begin{array}{ccccc}
\mathrm{C}_n(X^n) & \xrightarrow{\partial} & \mathrm{C}_{n-1}(X^n) & \xrightarrow{\pi} & \mathrm{C}_{n-1}(X^n, X^{n-1}) \\
\downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\
\mathrm{C}_n(Y^n) & \xrightarrow{\partial} & \mathrm{C}_{n-1}(Y^n) & \xrightarrow{\pi} & \mathrm{C}_{n-1}(Y^n, Y^{n-1}).
\end{array}$$

It follows from Lemma 72.9 that this diagram commutes. It follows immediately that $f_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y)$ restricts to a map $\mathrm{C}_*^{\mathrm{int}}(X) \to \mathrm{C}_*^{\mathrm{int}}(Y)$. ■

Lemma 81.10. Let X be a CW-complex. The maps

$$\begin{array}{rcl} p\colon \mathrm{C}_*^{\mathrm{int}}(X) & \to & \mathrm{C}_*^{\mathrm{CW}}(X) = \mathrm{H}_n(X^n, X^{n-1}) \\ \sigma & \mapsto & [\pi(\sigma)] \end{array}$$

are well-defined, in the sense that $\pi(\sigma)]$ is a cycle in $\mathrm{C}_*^{\mathrm{CW}}(X)$, and these maps form a chain map.

[986] Strictly speaking we only show in Lemma 81.9 that this is indeed a chain complex.

Proof. By definition of the boundary map of a relative chain complex we have the following commutative diagram:

$$\begin{array}{ccc} \mathrm{C}_n(X^n) & \xrightarrow{\quad\pi\quad} & \mathrm{C}_n(X^n, X^{n-1}) \\ {\scriptstyle\partial}\downarrow & & \downarrow{\scriptstyle\partial} \\ \mathrm{C}_{n-1}(X^n) & \xrightarrow{\quad\pi\quad} & \mathrm{C}_{n-1}(X^n, X^{n-1}). \end{array}$$

The statements of the lemma follow easily from this observation. ■

The following proposition gives us in particular a new proof of the main statements of the Singular-Cellular H_*-Isomorphism Proposition 80.4.

Proposition 81.11. (Intermediate Chain Complex Proposition) Let X be a CW-complex.

- We denote by $i\colon \mathrm{C}_*^{\mathrm{int}}(X) \to \mathrm{C}_*(X)$ the natural inclusion map.
- We denote by $p\colon \mathrm{C}_*^{\mathrm{int}}(X) \to \mathrm{C}_*^{\mathrm{CW}}(X)$ the natural chain map from Lemma 81.10.

For each $n \in \mathbb{N}_0$ the natural maps

$$(1)\ \ i_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(X)) \to \underbrace{\mathrm{H}_n(\mathrm{C}_*(X))}_{=\mathrm{H}_n(X)} \quad \text{and} \quad (2)\ \ p_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(X)) \to \underbrace{\mathrm{H}_n(\mathrm{C}_*^{\mathrm{CW}}(X))}_{=\mathrm{H}_n^{\mathrm{CW}}(X)}$$

are isomorphisms.

Remark. The proof of the proposition is modelled on the proofs provided in [**SchubH1968**, p. 303] or alternatively [**Lü1998**, Lemma 4.2] and [**Lü1989**, p. 263], see also [**Wall1966a**, Lemma 1].

Proof of Proposition 81.11 (1). Let X be a CW-complex and let $n \in \mathbb{N}_0$. We need to show that the map

$$i_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(X)) \to \underbrace{\mathrm{H}_n(\mathrm{C}_*(X))}_{=\mathrm{H}_n(X)}$$

is an isomorphism. Before we start, let us recall that in the Skeleton-Homology Lemma 80.1 we proved the following two convenient facts:

(a) The inclusion $k\colon X^{n+1} \to X$ induces an isomorphism $k_*\colon \mathrm{H}_n(X^{n+1}) \xrightarrow{\cong} \mathrm{H}_n(X)$.
(b) The inclusion $k\colon X^n \to X$ induces an epimorphism $k_*\colon \mathrm{H}_n(X^n) \twoheadrightarrow \mathrm{H}_n(X)$.

Claim. Let $n \in \mathbb{N}_0$.
(i) The map $i_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(X)) \to \mathrm{H}_n(\mathrm{C}_*(X)) = \mathrm{H}_n(X)$ is a monomorphism.
(ii) The map $i_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(X)) \to \mathrm{H}_n(\mathrm{C}_*(X)) = \mathrm{H}_n(X)$ is an epimorphism.

Proof. We consider the following two commutative diagrams

$$\begin{array}{ccccc} \mathrm{C}_{n+1}^{\mathrm{int}}(X) & \overset{j}{\hookrightarrow} & \mathrm{C}_{n+1}(X^{n+1}) & \overset{k}{\hookrightarrow} & \mathrm{C}_{n+1}(X) \\ {\scriptstyle\partial}\downarrow & & \downarrow{\scriptstyle\partial} & & \downarrow{\scriptstyle\partial} \\ \mathrm{C}_n^{\mathrm{int}}(X) & \overset{j}{\hookrightarrow} & \mathrm{C}_n(X^{n+1}) & \overset{k}{\hookrightarrow} & \mathrm{C}_n(X) \end{array} \qquad \text{and} \qquad \begin{array}{ccccc} & & \overset{i}{\frown} & & \\ \mathrm{C}_n^{\mathrm{int}}(X) & \overset{j}{\hookrightarrow} & \mathrm{C}_n(X^n) & \overset{k}{\hookrightarrow} & \mathrm{C}_n(X) \\ {\scriptstyle\partial}\downarrow & & \downarrow{\scriptstyle\partial} & & \downarrow{\scriptstyle\partial} \\ \mathrm{C}_{n-1}^{\mathrm{int}}(X) & \overset{j}{\hookrightarrow} & \mathrm{C}_{n-1}(X^n) & \overset{k}{\hookrightarrow} & \mathrm{C}_{n-1}(X). \end{array}$$

Here in each diagram the maps to the left are the obvious inclusion maps, for better or worse we refer to all of them as j. The maps to the right are induced by the inclusions $k\colon X^{n+1} \to X$ and $k\colon X^n \to X$. As we will now see, both statements of the claim follow easily from the diagrams together with (a) and (b) above:

(i) We consider the diagram to the left. Let $\sigma \in \mathrm{C}_n^{\mathrm{int}}(X)$ be a cycle with the property that $i(\sigma) \in \mathrm{C}_n(X)$ is null-homologous. It follows from (a) that $j(\sigma) \in \mathrm{C}_n(X^{n+1})$ is already null-homologous, i.e. there exists a $\tau \in \mathrm{C}_{n+1}(X^{n+1})$ with $\partial\tau = j(\sigma)$. By definition of $\mathrm{C}_n^{\mathrm{int}}(X)$ we know that $\sigma \in \mathrm{C}_n(X^n) \subset \mathrm{C}_n(X^{n+1})$. Thus we see that τ actually lies in

$$\mathrm{C}_{n+1}^{\mathrm{int}}(X) \;=\; \ker\big(\mathrm{C}_{n+1}(X^{n+1}) \xrightarrow{\partial} \mathrm{C}_n(X^{n+1}) \xrightarrow{\pi} \mathrm{C}_n(X^{n+1}, X^n)\big).$$

But this implies that σ is null-homologous in $\mathrm{C}_*^{\mathrm{int}}(X)$.

(ii) We consider the diagram to the right. Let $[\sigma] \in \mathrm{H}_n(X)$. By (b) we know that there exists a cycle $\tau \in \mathrm{C}_n(X^n)$ with $[k(\tau)] = [\sigma]$. Since $\partial\tau = 0$ we see that $\tau \in \mathrm{C}_n^{\mathrm{int}}(X)$. Since the bottom-left horizontal map is a monomorphism we see that $\tau \in \mathrm{C}_n^{\mathrm{int}}(X)$ is also a cycle. But this shows that $[\sigma] = [i(\tau)]$. ■

Proof of Proposition 81.11 (2). Let X be a CW-complex and let $n \in \mathbb{N}_0$. We need to show that the map

$$\begin{array}{rccc} p_*\colon \mathrm{H}_n(\mathrm{C}_*^{\mathrm{int}}(X)) & \to & \mathrm{H}_n(\mathrm{C}_*^{\mathrm{CW}}(X)) \\ [\sigma] & \mapsto & [\pi(\sigma)] \end{array}$$

is an isomorphism. For orientation purposes we show the following simple commutative diagram:

$$\begin{array}{ccc} \mathrm{C}_n(X^n) & \xrightarrow{\quad\pi\quad} & \mathrm{C}_n(X^n, X^{n-1}) \\ \downarrow{\scriptstyle\partial} & & \downarrow{\scriptstyle\partial} \\ \mathrm{C}_{n-1}(X^n) & \xrightarrow{\quad\pi\quad} & \mathrm{C}_{n-1}(X^n, X^{n-1}). \end{array}$$

Furthermore it is convenient to recall the following definitions:

$$\begin{array}{rcl} \mathrm{C}_n^{\mathrm{int}}(X) & = & \ker(\pi \circ \partial\colon \mathrm{C}_n(X^n) \to \mathrm{C}_{n-1}(X^n, X^{n-1})) \\ \mathrm{C}_n^{\mathrm{CW}}(X) & = & \mathrm{H}_n(X^n, X^{n-1}) = \mathrm{H}_n(C_*(X^n, X^{n-1})). \end{array}$$

Claim 1. For each $n \in \mathbb{N}_0$ the map $p\colon \mathrm{C}_n^{\mathrm{int}}(X) \to \mathrm{C}_n^{\mathrm{CW}}(X)$ is an epimorphism.

Proof. Let $[\sigma] \in \mathrm{C}_n^{\mathrm{CW}}(X)$, i.e. let $\sigma \in \mathrm{C}_n^{\mathrm{CW}}(X)$ such that $\partial\sigma = 0$. Since the projection $\pi\colon \mathrm{C}_n(X^n) \to \mathrm{C}_n(X^n, X^{n-1})$ is an epimorphism there exists $\nu \in \mathrm{C}_n(X^n)$ with $\partial\nu = \sigma$. Using the above commutative diagram one sees easily that $\nu \in \mathrm{C}_n^{\mathrm{int}}(X)$. ⊞

Given $n \in \mathbb{N}_0$ we set

$$D_n \;:=\; \ker\big\{p\colon \mathrm{C}_n^{\mathrm{int}}(X) \xrightarrow{p} \mathrm{C}_n^{\mathrm{CW}}(X)\big\}.$$

Note that $\nu \in \mathrm{C}_n(X^n)$ lies in D_n if and only if the following two conditions are satisfied:

(a) $(\pi \circ \partial)(\nu) = 0$,

(b) $\pi(\nu) \in \mathrm{C}_n(X^n, X^{n-1})$ represents the zero element of $\mathrm{C}_n^{\mathrm{CW}}(X) = \mathrm{H}_n(X^n, X^{n-1})$.

Furthermore note that the groups D_* form a subcomplex of $\mathrm{C}_*^{\mathrm{int}}(X)$.

Claim 2. For each $n \in \mathbb{N}_0$ we have $\mathrm{C}_{n+1}(X^n) \subset D_{n+1}$.

Proof. For orientation purposes we consider the following commutative diagram:

$$\begin{array}{ccccc}
\mathrm{C}_{n+1}(X^n) & \hookrightarrow & \mathrm{C}_{n+1}(X^{n+1}) & \twoheadrightarrow^{\pi} & \mathrm{C}_{n+1}(X^{n+1}, X^n) \\
\downarrow\partial & & \downarrow\partial & & \downarrow\partial \\
\mathrm{C}_n(X^n) & \hookrightarrow & \mathrm{C}_n(X^{n+1}) & \twoheadrightarrow^{\pi} & \mathrm{C}_n(X^{n+1}, X^n).
\end{array}$$

Let $\Theta \in \mathrm{C}_n(X^{n+1})$. Since the diagram commutes and since the horizontal sequences are exact we see that Θ satisfies (a) and we see that $\pi(\Theta) = 0 \in \mathrm{C}_{n+1}(X^{n+1}, X^n)$, the latter statement implies that (b) is also satisfied. ⊞

Note that by Claim 1 we have a short exact sequence

$$0 \;\to\; D_* \;\to\; \mathrm{C}_n^{\mathrm{int}}(X) \xrightarrow{p} \mathrm{C}_n^{\mathrm{CW}}(X) \;\to\; 0$$

of chain complexes. Considering the corresponding long exact sequence of homology groups, see the LES Proposition 74.9, it suffices to prove the following claim.

Claim 3. The chain complex D_* is acyclic, i.e. all homology groups of D_* are zero.

Proof. For orientation purposes we now consider the following commutative diagram:

$$\begin{array}{ccccc}
\mathrm{C}_{n+1}(X^{n-1}) & \overset{i}{\hookrightarrow} & \mathrm{C}_{n+1}(X^n) & \overset{\pi}{\twoheadrightarrow} & \mathrm{C}_{n+1}(X^n, X^{n-1}) \\
\downarrow\partial & & \downarrow\partial & & \downarrow\partial \\
\mathrm{C}_n(X^{n-1}) & \overset{i}{\hookrightarrow} & \mathrm{C}_n(X^n) & \overset{\pi}{\twoheadrightarrow} & \mathrm{C}_n(X^n, X^{n-1}) \\
\downarrow\partial & & \downarrow\partial & & \downarrow\partial \\
\mathrm{C}_{n-1}(X^{n-1}) & \overset{i}{\hookrightarrow} & \mathrm{C}_{n-1}(X^n) & \overset{\pi}{\twoheadrightarrow} & \mathrm{C}_{n-1}(X^n, X^{n-1}).
\end{array}$$

So let $\mu \in \ker(\partial\colon D_n \to D_{n-1}) \subset D_n \subset \mathrm{C}_n^{\mathrm{int}}(X) \subset \mathrm{C}_n(X)$. We need to show that there exists a $\Theta \in D_{n+1}$ with $\partial\Theta = \mu$. By (b) we know that $\pi(\mu) \in \mathrm{C}_n(X^n, X^{n-1})$ represents the zero element of $\mathrm{C}_n^{\mathrm{CW}}(X) = \mathrm{H}_n(X^n, X^{n-1})$. It follows that there exists a $\gamma \in \mathrm{C}_{n+1}(X^n, X^{n-1})$ with $\partial\gamma = \pi(\mu)$. Since the top horizontal sequence is exact we can pick $\widetilde{\gamma} \in \mathrm{C}_{n+1}(X^n)$ with $\pi(\widetilde{\gamma}) = \gamma$. Note that

$$\pi(\partial\widetilde{\gamma} - \mu) \underset{\substack{\uparrow \\ \text{since } \partial\circ\pi = \pi\circ\partial}}{=} (\pi\circ\partial)(\widetilde{\gamma}) - \pi(\mu) = \underbrace{\partial(\pi(\widetilde{\gamma}))}_{=\gamma} - \pi(\mu) \underset{\substack{\uparrow \\ \text{since } \partial\gamma = \pi(\mu)}}{=} 0.$$

Since the middle horizontal sequence is exact there exists an $\alpha \in \mathrm{C}_n(X^{n-1})$ such that $i(\alpha) = \partial\widetilde{\gamma} - \mu$. Note that $i(\partial\alpha) = \partial(i(\alpha)) = i(\partial(\partial\widetilde{\gamma} - \mu)) = (\partial\partial\widetilde{\gamma} - \partial\mu) = 0$. Since i is a monomorphism we see that $\partial\alpha = 0$. As mentioned above, by the Skeleton-Homology Lemma 80.1 we know that $\mathrm{H}_n(X^{n-1}) = 0$. This implies that there exists an $\widetilde{\alpha} \in \mathrm{C}_{n+1}(X^{n-1})$ with $\partial\widetilde{\alpha} = \alpha$. Then

$$\partial(\widetilde{\gamma} - i(\widetilde{\alpha})) \underset{\substack{\uparrow \\ \text{since } \partial\circ i = i\circ\partial}}{=} \partial\widetilde{\gamma} - (i\circ\partial)(\widetilde{\alpha}) = \partial\widetilde{\gamma} - \underbrace{i(\alpha)}_{=\partial\widetilde{\gamma}-\mu} = \partial\widetilde{\gamma} - \partial\widetilde{\gamma} + \mu = \mu.$$

We set $\Theta := \widetilde{\gamma} - i(\widetilde{\alpha}) \in \mathrm{C}^{n+1}(X^n)$. We just showed that $\partial\Theta = \mu$. Since $\Theta \in \mathrm{C}^{n+1}(X^n)$ we obtain from Claim 2 that Θ actually lies in D_{n+1}. ■

The following proposition gives us the promised relationship between the singular and cellular chain complex of a given CW-complex.

Proposition 81.12. (Singular-Cellular Chain Complex Proposition) Let X be a CW-complex.

(1) The two natural chain maps
$$i\colon \mathrm{C}_*^{\mathrm{int}}(X) \hookrightarrow \mathrm{C}_*(X) \quad \text{and} \quad p\colon \mathrm{C}_*^{\mathrm{int}}(X) \twoheadrightarrow \mathrm{C}_*^{\mathrm{CW}}(X),$$
which are given by the obvious inclusion and the natural projection, are chain homotopy equivalences.

(2) There exists a chain homotopy equivalence $\mathrm{C}_*(X) \to \mathrm{C}_*^{\mathrm{CW}}(X)$.

Remark. In the proof of the Singular-Cellular Chain Complex Proposition 81.12 we will make use of the Subgroup-of-Free Abelian Group Lemma 51.2 (which we did not prove) which says that the subgroup of a free abelian group is again a free abelian group. This purely algebraic fact lets us conclude that the intermediate chain groups $\mathrm{C}_k^{\mathrm{int}}(X)$ are free abelian groups. In Section 170.2 we will use a somewhat different approach to relate the chain complexes $\mathrm{C}_*(X)$ and $\mathrm{C}_*^{\mathrm{CW}}(X)$ that does not make use of this algebraic fact.

Proof. Let X be a CW-complex.

(1) By definition each $\mathrm{C}_k^{\mathrm{int}}(X)$ is a subgroup of the free abelian group $\mathrm{C}_k(X)$. It follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that each $\mathrm{C}_k^{\mathrm{int}}(X)$ itself is a free abelian group. In particular $\mathrm{C}_*^{\mathrm{int}}(X)$ is a chain complex of free abelian groups. By the Intermediate Chain Complex Proposition 81.11 we know that the chain maps $i\colon \mathrm{C}_*^{\mathrm{int}}(X) \hookrightarrow \mathrm{C}_*(X)$ and $p\colon \mathrm{C}_*^{\mathrm{int}}(X) \twoheadrightarrow \mathrm{C}_*^{\mathrm{CW}}(X)$ are quasi-isomorphisms. Since all chain complexes involved consist of free abelian groups we deduce from the Intermediate Chain Complex Proposition 81.11 that the chain maps are chain homotopy equivalences.

(2) This statement follows immediately from Statement (1) together with the fact, see Lemma 73.3, that being chain homotopy equivalent is indeed an equivalence relation. ■

81.5. **Abstractly isomorphic homology groups.** The following map shows that if we are given two chain complexes of free abelian groups, then any map on homology groups is induced by a chain map.

Proposition 81.13. (Lift-to-Chain Map-Proposition) Suppose $(\mathrm{C}_*, \partial_*)$ and (C'_*, ∂'_*) are two chain complexes of free abelian groups.

(1) If $\gamma_n\colon \mathrm{H}_n(C_*) \to \mathrm{H}_n(C'_*)$, $n \in \mathbb{N}_0$, is a family of homomorphisms, then there exists a chain map $f\colon C_* \to C'_*$ such that for every $n \in \mathbb{N}_0$ we have
$$f_* = \gamma_n\colon \mathrm{H}_n(C_*) \to \mathrm{H}_n(C'_*).$$

(2) If the maps γ_n in (1) are isomorphisms, then the chain maps f in (1) are chain homotopy equivalences.

Remark.

(1) We consider the following commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathbb{Z} & \xrightarrow{\cdot 2} & \mathbb{Z} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle n\mapsto(0,n)} & & \downarrow{\scriptstyle \mathrm{id}} & & \\ 0 & \longrightarrow & \mathbb{Z}\oplus\mathbb{Z} & \xrightarrow[(m,n)\mapsto m+2n]{} & \mathbb{Z} & \longrightarrow & 0. \end{array}$$

We view the top and bottom sequences as chain complexes C_* respectively D_* and we view the vertical maps as a chain map f. It is straightforward to see that f induces the zero map on homology but that it is not chain homotopic to the zero chain map. This shows that the chain map from the Lift-to-Chain Map-Proposition 81.13 is in general *not* unique up to chain homotopy.

(2) The combination of the Lift-to-Chain Map-Proposition 81.13 with the Singular-Cellular H_*-Isomorphism Proposition 80.4 gives us a new proof of the Singular-Cellular Chain Complex Proposition 81.12 (2).

Proof of the Lift-to-Chain Map-Proposition 81.13. Note that Statement (2) of the proposition is an immediate consequence of Statement (1), the fact that we are dealing with chain complexes of free abelian groups and the Intermediate Chain Complex Proposition 81.11. Thus it remains to prove Statement (1).

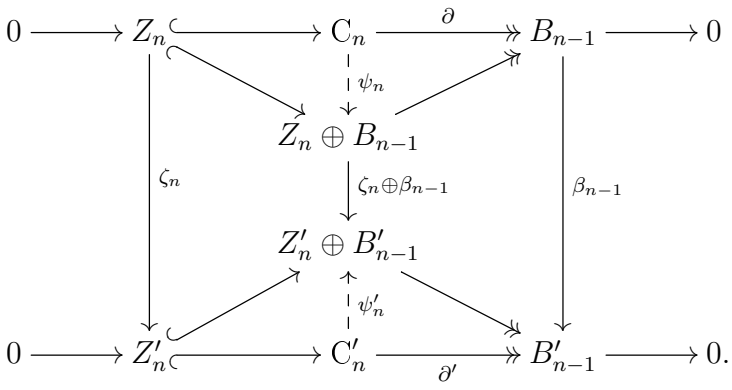
Let $(\mathrm{C}_*, \partial_*)$ and (C'_*, ∂'_*) be two chain complexes of free abelian groups. Furthermore let $\gamma_n\colon \mathrm{H}_n(C_*) \to \mathrm{H}_n(C'_*)$, $n \in \mathbb{N}_0$ be a family of homomorphisms. We have to show that there exists a chain map $f\colon C_* \to C'_*$ such that for every $n \in \mathbb{N}_0$ we have

$$f_* = \gamma_n\colon \mathrm{H}_n(C_*) \ \to \ \mathrm{H}_n(C'_*).$$

We start out by recalling some of the usual notation and basic observations regarding chain complexes. More precisely, for each $n \in \mathbb{N}_0$ we write

$$Z_n := \ker(\partial_n\colon \mathrm{C}_n \to \mathrm{C}_{n-1}), \quad B_n := \mathrm{im}(\partial_{n+1}\colon \mathrm{C}_{n+1} \to \mathrm{C}_n) \quad \text{and} \quad H_n = Z_n/B_n.$$

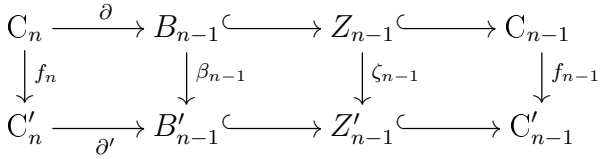
Recall that these groups form the following two types of short exact sequences



$$\begin{array}{lccccccccc} \text{(a)} & 0 & \to & Z_n & \hookrightarrow & \mathrm{C}_n & \xrightarrow{\partial_n} & B_{n-1} & \to & 0, \\ \text{(b)} & 0 & \to & B_n & \hookrightarrow & Z_n & \to & H_n & \to & 0. \end{array}$$

Similarly we define Z'_n, B'_n and H'_n for the chain complex C'_*. Evidently these groups also form short exact sequences that we denote by (a′) and (b′).

As we already mentioned on page 1791, since all the chain groups are free abelian it follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that the subgroups Z_n, B_n, Z'_n and B'_n are also free abelian. In particular the sequences (b) and (b′) are free resolutions of H_n respectively H'_n. It follows from the Fundamental Theorem 81.1 of Homological Algebra that for each $n \in \mathbb{N}_0$ there exist homomorphisms β_n and ζ_n such that the following diagram commutes:



$$\begin{array}{ccccccccc} 0 & \longrightarrow & B_n & \longrightarrow & Z_n & \longrightarrow & H_n & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \beta_n} & & \downarrow{\scriptstyle \zeta_n} & & \downarrow{\scriptstyle \gamma_n} & & \\ 0 & \longrightarrow & B'_n & \longrightarrow & Z'_n & \longrightarrow & H'_n & \longrightarrow & 0. \end{array}$$

Our goal is to extend the maps $\zeta_n\colon Z_n \to Z'_n$ to a chain map $f\colon \mathrm{C}_n \to \mathrm{C}'_n$. To do so we consider the following diagram

Here the top sequence is precisely the short exact sequence (a) and the bottom sequence is the short exact sequence (a′). Here the unlabeled maps are the obvious inclusion and projection s. It follows immediately from Lemmas 78.1 and 78.2 that there exist isomorphisms $\psi_n\colon \mathrm{C}_n \xrightarrow{\cong} Z_n \oplus B_{n-1}$ and $\psi'_n\colon \mathrm{C}'_n \xrightarrow{\cong} Z'_n \oplus B'_{n-1}$ which make the diagram commute. Now we define $f_n\colon \mathrm{C}_n \to \mathrm{C}'_n$ to be vertical homomorphism given by the diagram, i.e. $f_n = (\psi'_n)^{-1} \circ (\zeta_n \oplus \beta_{n-1}) \circ \psi_n$.

Now we need to show that the maps f_n form a chain map. We consider the diagram

where all unlabeled maps are the obvious inclusion maps. The middle square commutes by the choice of β_{n-1} and ζ_{n-1}. We had arranged the maps f_n, f_{n-1} in such a way that the squares to the left and right commute. This shows that the rectangle commutes. But that was exactly what we needed to do to show that the maps f_n, $n \in \mathbb{N}_0$ form a chain map.

Finally note that it follows easily from the choice of ζ_n that the chain map f_n induces the given maps γ_n on homology. ■

We conclude this chapter with the following lemma which we will use on several occasions.

Lemma 81.14. (Finite-Rank Chain Complex Lemma) Let (C_*, c_*) be a free chain complex such that for each $k \in \mathbb{N}_0$ the homology group $\mathrm{H}_k(C)$ is finitely generated. Then there exists a chain complex (D_*, ∂_*) with the following two properties:

(1) The chain complexes $(\mathrm{C}_*, \partial_*)$ and (D_*, ∂_*) are chain homotopy equivalent.
(2) Each chain group D_k is a free abelian group of *finite rank*.

Proof. Let $k \in \mathbb{N}_0$. Recall that we assume that $\mathrm{H}_k(C_*)$ is finitely generated. It follows immediately from the Finitely Generated Abelian Group Classification Theorem 51.4 that there exists a chain complex D^k_* and an isomorphism $\varphi_k\colon \mathrm{H}_k(D^k_*) \to \mathrm{H}_k(C_*)$ such that only the chain groups D^k_k and D^k_{k+1} are non-zero and such that both chain groups are finitely generated free abelian groups.

We define $D_* = \bigoplus_{k\in\mathbb{N}_0} D_*^k$. It follows immediately from the Lift-to-Chain Map-Proposition 81.13 and 81.4 that the chain complex D_* is chain homotopy equivalent to (C_*, c_*). ■

Exercises for Chapter 81.

Exercise 81.1.

(a) We consider the following commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathbb{Z} & \xrightarrow{\cdot 2} & \mathbb{Z} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle n\mapsto(0,n)} & & \downarrow{\scriptstyle \mathrm{id}} & & \\ 0 & \longrightarrow & \mathbb{Z}\oplus\mathbb{Z} & \xrightarrow[(m,n)\mapsto m+2n]{} & \mathbb{Z} & \longrightarrow & 0. \end{array}$$

We view the top and bottom sequences as chain complexes C_* respectively D_* and we view the vertical maps as a chain map f.

(i) Convince yourself that f induces the zero map on homology.

(ii) Show that the chain map f is not chain homotopic to the zero chain map.

(b) Give examples of chain complexes C_* and D_* of free abelian groups and quasi-isomorphisms $f_*, g_*\colon C_* \to D_*$ that induce the same isomorphism on homology groups, but that are not chain homotopic.

Exercise 81.2. Let $f\colon A \to X$ be a map between topological spaces. We define the corresponding *mapping cone* as

$$\mathrm{Cone}(f\colon A\to X) \;:=\; ((A\times[0,1])\sqcup X)/\!\sim$$

where $(a,1)\sim f(a)$ for all $a\in A$ and $(a,0)\sim(b,0)$ for all $a,b\in A$. Now suppose that A and X are finite CW-complexes and that f is a cellular map.

We equip the mapping cone $\mathrm{Cone}(f\colon A\to X)$ with the natural CW-structure of the CW-Complex Cone Corollary 68.35. Show that the corresponding cellular chain complex is isomorphic to the algebraic mapping cone of the chain map $f_*\colon \mathrm{C}_*^{\mathrm{CW}}(A) \to \mathrm{C}_*^{\mathrm{CW}}(X)$.

Exercise 81.3. We consider the chain complex.

$$C_* \;=\; 0 \to \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \to \mathbb{Z}_2 \to 0$$

and the zero chain complex D_*.

(a) Show that there exists a chain map $\varphi\colon C_* \to D_*$ which is a quasi-isomorphism.

(b) Show that the chain complexes C_* and D_* are not chain homotopy equivalent.

Exercise 81.4. Show that in the Lift-to-Chain Map-Proposition 81.13 we cannot drop the hypothesis that the chain complexes are free abelian groups. More precisely, give an example of chain complexes $(\mathrm{C}_*, \partial_*)$ and (C'_*, ∂'_*) and a sequence of homomorphisms $\gamma_n\colon \mathrm{H}_n(C_*) \to \mathrm{H}_n(C'_*)$, $n\in\mathbb{N}_0$, that is not realized by a chain map.

82. The Jordan-Brouwer Separation Theorem

We start out with the following proposition.

Theorem 82.1. (Sphere Complement-H_*-Theorem)

(1) For every injective map $h\colon \overline{B}^k \to S^n$ we have

$$\widetilde{\mathrm{H}}_i\big(S^n \setminus h(\overline{B}^k)\big) \;=\; 0 \quad \text{for all } i \in \mathbb{N}_0.$$

(2) For every injective map $h\colon S^k \to S^n$ we have

$$\widetilde{\mathrm{H}}_i\big(S^n \setminus h(S^k)\big) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = n-k-1, \\ 0, & \text{otherwise.} \end{cases}$$

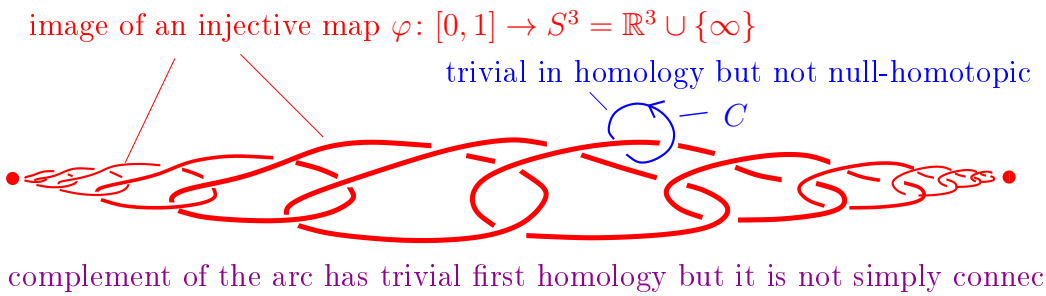
Example.

(1) Let $K \subset S^3$ be a knot, i.e. let K be a 1-dimensional submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to S^1. This means in particular that there exists a smooth embedding $h\colon S^1 \to S^3$ with $h(S^1) = K$. In Lemma 78.13 we had already determined that $\mathrm{H}_1(S^3 \setminus K) \cong \mathbb{Z}$. Now we can compute the higher homology groups as well. More precisely, the combination of the Sphere Complement-H_*-Theorem 82.1 (2) and the Reduced Homology Lemma 74.1 says that

$$\mathrm{H}_i(S^3 \setminus K) \;=\; \mathrm{H}_i(S^3 \setminus h(S^1)) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0, 1, \\ 0, & \text{otherwise.} \end{cases}$$

(2) In the Sphere Complement-H_*-Theorem 82.1 we do not assume that h is in any way smooth. For example there are injective maps $h\colon S^1 \to S^2$ of infinite length, see e.g.

`https://en.wikipedia.org/wiki/Koch_snowflake`,



to which the proposition nonetheless applies. Reduced homology is only defined for non-empty topological spaces. It is implicit in the statement of the Sphere Complement-H_*-Theorem 82.1 that $S^n \setminus h(\overline{B}^k)$ is not the empty set. Even this statement is not entirely obvious since, as we have pointed out on several occasions, there are non-injective maps $h\colon \overline{B}^1 \to S^n$ that are in fact surjective.

(3) In the figure below we see the image of an injective map $\varphi\colon [0,1] \to S^3 = \mathbb{R}^3 \cup \{\infty\}$ and we see a closed curve $C \subset S^3 \setminus \varphi([0,1])$. It follows from the Sphere Complement-H_*-Theorem 82.1 (1) that $\mathrm{H}_1(S^3 \setminus \varphi([0,1])) = 0$, in particular C is null-homologous in $\mathrm{H}_1(S^3 \setminus \varphi([0,1])) = 0$.[987] But on [**Sti1993**, p. 152] it is shown that the curve C represents in fact a non-trivial element in $\pi_1(S^3 \setminus \varphi([0,1]))$.

To make the exposition more readable we prove the two parts of the Sphere Complement-H_*-Theorem 82.1 separately.

Proof of the Sphere Complement-H_*-Theorem 82.1 (1)**.** We write $I = [-1,1]$. By the Convex-to-Ball Proposition 2.20 (2) there exists a homeomorphism $I^k \xrightarrow{\cong} \overline{B}^k$. Therefore

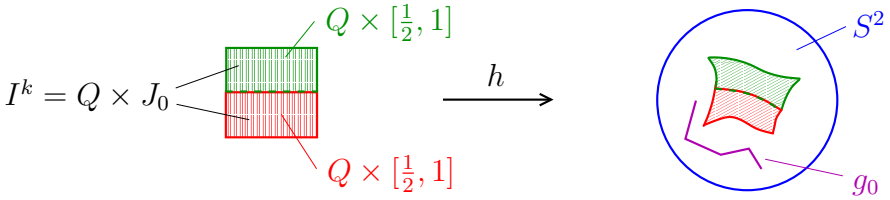
[987] In Lemma 80.9 we saw that the boundary curve of an orientable surface with one boundary component is null-homologous. In Exercise 82.1 we will see that the closed curve C is in fact the boundary of an orientable surface that is embedded in $S^3 \setminus \varphi([0,1])$.

in the statement of the Sphere Complement-H$_*$-Theorem 82.1 (1) we can replace $\overline{B}^k$ by I^k. So we now want to show that for any injective map $h\colon I^k \to S^n$ we have

$$\widetilde{\mathrm{H}}_i(S^n \setminus h(I^k)) \;=\; 0 \quad \text{for all } i \in \mathbb{N}_0.$$

We will prove this statement by induction on k. We start out with $k = 0$. So let $h\colon I^0 = \{0\} \to S^n$ be an injective map. It follows from the stereographic projection defined in Lemma 2.18 that $S^n \setminus h(\{0\})$ is homeomorphic to $\mathbb{R}^n$. Hence we obtain from the Homotopy Equivalence-H$_*$-Corollary 73.9 (3) that $\widetilde{\mathrm{H}}_*(S^n \setminus h(\{0\})) = 0$.

Now we do the induction step. We assume we know the desired statement for all injective maps $I^{k-1} \to S^n$. Now let $h\colon I^k \to S^n$ be an injective map. We suppose that the desired conclusion does not hold, i.e. we suppose that $\widetilde{\mathrm{H}}_j(S^n \setminus h(I^k)) \neq 0$ for some j. We pick a non-trivial element $g_0 \in \widetilde{\mathrm{H}}_j(S^n \setminus h(I^k))$.



We write $Q = I^{k-1}$, $J_0 = I$ and we write

$$A_1 \;=\; S^n \setminus h(Q \times [0, \tfrac{1}{2}]) \quad \text{and} \quad A_2 \;=\; S^n \setminus h(Q \times [\tfrac{1}{2}, 1]).$$

Since h is injective we have

$$A_1 \cap A_2 \;=\; S^n \setminus h(I^k) \quad \text{and} \quad A_1 \cup A_2 \;=\; S^n \setminus h(Q \times \{\tfrac{1}{2}\}).$$

From the Compact Image Lemma 2.13 (3) we know that A_1 and A_2 are open subsets of

$A_1 \cup A_2$. Therefore we can apply the Mayer–Vietoris Theorem 78.5 and we obtain the long exact sequence

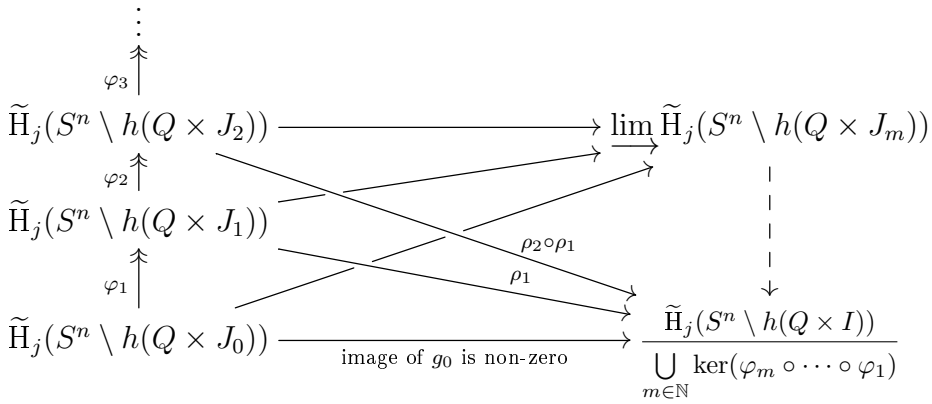
$$\ldots \to \underbrace{\widetilde{\mathrm{H}}_{j+1}(A_1 \cup A_2)}_{= 0 \text{ by induction}} \to \widetilde{\mathrm{H}}_j(A_1 \cap A_2) \;\to\; \widetilde{\mathrm{H}}_j(A_1) \oplus \widetilde{\mathrm{H}}_j(A_2) \to \underbrace{\widetilde{\mathrm{H}}_i(A_1 \cup A_2)}_{= 0 \text{ by induction}} \to \ldots$$

So we see that the middle map is an isomorphism. Thus there exists an $i \in \{1, 2\}$ such that the image of g_0 is non-trivial in $\widetilde{\mathrm{H}}_j(A_i)$. If $i = 1$, then we set $J_1 := [0, \frac{1}{2}]$, otherwise

we set $J_1 := [\frac{1}{2}, 1]$. We denote by

$$\varphi_1 \colon \widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times J_0)) \;\to\; \widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times J_1))$$

the inclusion induced map. By the above exact sequence φ_1 is an epimorphism. We denote by ρ_1 the inverse of the induced isomorphism



$$\widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times J_0))/\ker(\varphi_1) \;\to\; \widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times J_1)).$$

Now we iterate this process by running the same argument with J_0 replaced by J_1 and so on. For each $m \in \mathbb{N}$ we can find an interval J_m of length $\frac{1}{2^m}$ that is contained in J_{m-1} such that for the inclusion induced homomorphism

$$\varphi_m \colon \widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times J_{m-1})) \;\to\; \widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times J_m))$$

we have that $g_m := \varphi_m(g_{m-1})$ is non-zero. We define ρ_m the same way from φ_m as we had obtained ρ_1 from φ_1.

By the definition of the direct limit we have the following commutative diagram:[988]

Since each J_m has half the length of J_{m-1} we conclude that the intersection $\bigcap_{m \in \mathbb{N}} J_m$ contains a unique point $t \in [0, 1]$.[989] We have

$$\varinjlim \widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times J_m)) \;\underset{\uparrow}{\cong}\; \widetilde{\mathrm{H}}_j\Big(\bigcap_{m \in \mathbb{N}} S^n \setminus h(Q \times J_m)\Big) \;\underset{\uparrow}{=}\; \widetilde{\mathrm{H}}_j(S^n \setminus h(Q \times \{t\})) \;\underset{\uparrow}{=}\; 0.$$

by the Exhaustions-H$_*$-Proposition 79.4 since the subsets $S^n \setminus h(Q \times J_m)$ are open — since h is injective — by induction since $Q \times \{t\} \cong I^{k-1}$

But we have now obtained a contradiction, since the bottom horizontal map of the above commutative diagram has a non-trivial image but it factors through the trivial group. ■

Proof of the Sphere Complement-H$_*$-Theorem 82.1 (2). Recall that we have to show that for every injective map $h \colon S^k \to S^n$ we have isomorphisms

$$\widetilde{\mathrm{H}}_i\big(S^n \setminus h(S^k)\big) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = n - k - 1, \\ 0, & \text{otherwise.} \end{cases}$$

---

[988] Note that we have

$$\ker(\varphi_1) \subset \ker(\varphi_2 \circ \varphi_1) \subset \ker(\varphi_3 \circ \varphi_2 \circ \varphi_1) \subset \ldots$$

It follows that the union of these subgroups is again a subgroup.

[989] Why does this follow? What results from real analysis do we need to draw that conclusion?

We prove this statement by induction on k. For $k = 0$ we have

$$\widetilde{\mathrm{H}}_i(S^n \setminus h(S^0)) \underset{\text{since } S^n \setminus h(S^0) \text{ is homotopy equivalent to } S^{n-1}}{=} \widetilde{\mathrm{H}}_i(S^{n-1}) \underset{\text{by Proposition 74.4}}{\cong} \begin{cases} \mathbb{Z}, & \text{if } i = n-1, \\ 0, & \text{otherwise.} \end{cases}$$

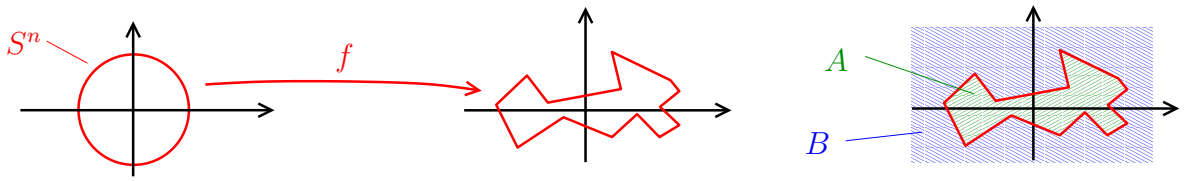
Now suppose we know the statement for some $k \in \mathbb{N}$. Suppose we are given an injective map $h\colon S^{k+1} \to S^n$. We denote by $S^{k+1}_{\leq 0}$ the lower hemisphere of S^{k+1} and we denote by $S^{k+1}_{\geq 0}$ the upper hemisphere of S^{k+1}. Note that $S^{k+1}_{\leq 0} \cap S^{k+1}_{\geq 0} = S^k$. We apply the Mayer–Vietoris Theorem 78.5 to the decomposition of $S^n \setminus h(S^{k+1})$ into the open sets $S^n \setminus h(S^{k+1}_{\leq 0})$ and $S^n \setminus h(S^{k+1}_{\geq 0})$. We obtain a long exact sequence[991]

$$\cdots \to \widetilde{\mathrm{H}}_i(S^n \setminus h(S^k)) \to \underbrace{\widetilde{\mathrm{H}}_i((S^n \setminus h(S^{k+1}_{\leq 0}))}_{\substack{= 0 \text{ by part (1) and} \\ \text{since } S^{k+1}_{\leq 0} \cong \overline{B}^{k+1}}} \oplus \underbrace{\widetilde{\mathrm{H}}_i(S^n \setminus h(S^{k+1}_{\geq 0}))}_{\substack{= 0 \text{ by part (1) and} \\ \text{since } S^{k+1}_{\geq 0} \cong \overline{B}^{k+1}}} \to \widetilde{\mathrm{H}}_i(S^n \setminus h(S^{k+1})) \to \ldots.$$

Thus we see that

$$\widetilde{\mathrm{H}}_i(S^n \setminus h(S^{k+1})) \cong \widetilde{\mathrm{H}}_{i-1}(S^n \setminus h(S^k)) \underset{\text{by induction}}{\cong} \begin{cases} \mathbb{Z}, & \text{if } i-1 = n-k-1, \\ 0, & \text{otherwise.} \end{cases}$$

■



We have the following immediate corollary to the Sphere Complement-H_*-Theorem 82.1.

Corollary 82.2. (Jordan–Brouwer Separation Theorem) Let $n \in \mathbb{N}$. Furthermore let $f\colon S^n \to \mathbb{R}^{n+1}$ be an injective map.

(1) The complement $\mathbb{R}^{n+1} \setminus f(S^n)$ has precisely two path-components, one of which is bounded and one which is unbounded.

(2) If A and B are the two path-components of $\mathbb{R}^{n+1} \setminus f(S^n)$, then

$$\partial A = \partial B = A \cap B = f(S^n).$$

Proof.

(1) Let $n \in \mathbb{N}$. Furthermore let $f\colon S^n \to \mathbb{R}^{n+1}$ be an injective map. We use the inclusion $\mathbb{R}^{n+1} \to \mathbb{R}^{n+1} \cup \{\infty\} = S^{n+1}$ to view $\mathbb{R}^{n+1}$ as a subspace of S^{n+1}. Now we see that

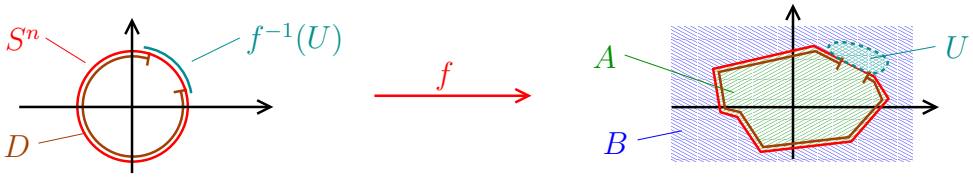
$$\widetilde{\mathrm{H}}_0(\mathbb{R}^{n+1} \setminus C) = \widetilde{\mathrm{H}}_0(\mathbb{R}^{n+1} \setminus f(S^n)) \underset{\text{see Exercise 78.12}}{\cong} \widetilde{\mathrm{H}}_0(S^{n+1} \setminus f(S^n)) \underset{\substack{\text{Homology-of-Sphere Complement} \\ \text{Theorem 82.1 (2)}}}{\cong} \mathbb{Z}$$

[990] Can you give a rigorous proof for the statement that the complement of two points in S^n is homotopy equivalent to S^{n-1}?

[991] Here we use, as in the proof of the Sphere Complement-H_*-Theorem 82.1 (1), implicitly the injectivity of h.

It follows from the Reduced Homology Lemma 74.1 (5) that $\mathbb{R}^{n+1} \setminus C$ has precisely two path-components. It remains to show that precisely one of them is unbounded.

Since S^n is compact there exists an $r \in \mathbb{R}$ such that $f(S^n) \subset B_r^{n+1}$. It is elementary to show that $\mathbb{R}^{n+1} \setminus B_r^{n+1}$ is path-connected. It follows that $\mathbb{R}^{n+1} \setminus B_r^{n+1}$ is contained in one of the two path-components. This shows that precisely one path-component is unbounded.



(2) First note that it follows from the Compact Image Lemma 2.13 and 1.21 that $\mathbb{R}^{n+1} \setminus f(S^n)$ is open. In particular, as we remarked on page 176, $\mathbb{R}^{n+} \setminus f(S^n)$ is locally path-connected. It follows easily that A and B are both open subsets of $\mathbb{R}^n$.

Claim. We have $\overline{A} = A \cup f(S^n)$.

Proof. Since B is open we know that $A \cup f(S^n) = \mathbb{R}^n \setminus B$ is closed. By definition of $\overline{A}$ this implies that $\overline{A} \subset A \cup f(S^n)$. Now let $P \in A \cup f(S^n)$. We need to show that $P \in \overline{A}$. Suppose that this is not the case. By the Interior-Closure Lemma 1.9 we know that $\overline{A}$ is closed. Thus our assumption that $P \notin \overline{A}$ implies that there exists an open subset $U \subset \mathbb{R}^{n+1}$ with $P \in U \subset \mathbb{R}^{n+1} \setminus \overline{A}$. By Exercise 82.5 there exists a subspace $D \subset S^n$, which is homeomorphic to $\overline{B}^n$ such that $S^n \setminus D \subset f^{-1}(U)$, i.e. such that $f(S^n \setminus D) \subset U$. We now obtain the following equalities:

$$\underbrace{\mathbb{R}^{n+1} \setminus f(D)}_{\substack{\text{path-connected by} \\ \text{the Homology-of-Sphere} \\ \text{Complement Theorem 82.1}}} = A \sqcup B \sqcup (f(S^n) \setminus f(D)) \overset{\substack{\text{since } f(S^n) \setminus f(D) = f(S^n \setminus D) \subset U \\ \downarrow}}{=} A \underset{\substack{\uparrow \\ \text{disjoint union since } U \cap A = \varnothing}}{\sqcup} (B \cup (U \cap \mathbb{R}^{n+1} \setminus f(D)).$$

We have thus written the path-connected space $\mathbb{R}^{n+1} \setminus f(D)$ as the disjoint union of the two open non-empty sets A and $B \cup (U \cap \mathbb{R}^{n+1} \setminus f(D))$. But by the Path-Connected Implies Connected Corollary 2.23 this is not possible. We have thus obtained a contradiction. ∎

For historic purposes we state the case $n = 1$ again with slightly different names. The following definition is a minute variation on the definition of a Jordan curve given on page 795.

Definition. A planar Jordan curve is the image of an injective map $S^1 \to \mathbb{R}^2$.

The following corollary is now just the case $n = 1$ of the Jordan–Brouwer Separation Theorem 82.2.

Corollary 82.3. (Jordan Curve Theorem) Let $C \subset \mathbb{R}^2$ be a planar Jordan curve.

(1) The complement $\mathbb{R}^2 \setminus C$ has precisely two path-components, one of which is bounded and one which is unbounded.

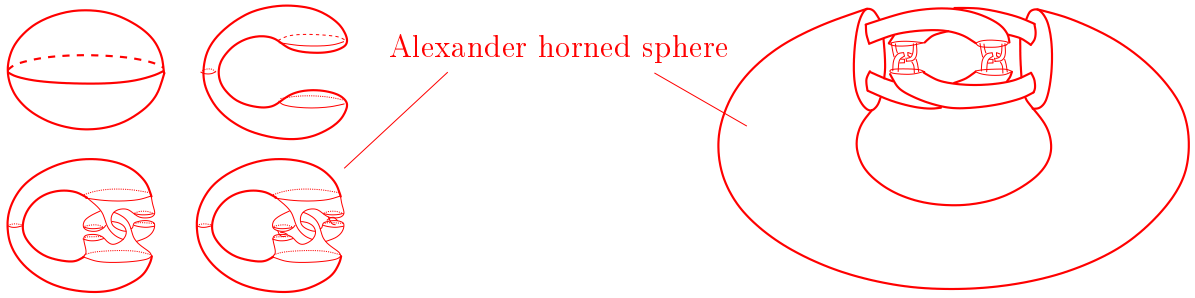
(2) If A and B are the two path-components of $\mathbb{R}^2 \setminus C$, then
$$\partial A \;=\; \partial B \;=\; A \cap B \;=\; C.$$

Remark.

(1) The Jordan Curve Theorem 82.3 might appear as "self-evident". To disabuse the reader of this idea recall that in Proposition 6.14 and Exercise 6.14 we saw that there exist planar Jordan curves with non-zero 2-dimensional Lebesgue measure.
(2) The Jordan Curve Theorem 82.3 takes its name from Camille Jordan [**Jor1887**][992] who formulated it in 1887. It seems like the first convincing proof was given by Oswald Veblen [**Veb1905**] in 1905.
(3) The general case of the Jordan–Brouwer Separation Theorem 82.2 was first proved by Luitzen Brouwer [**Brou1912b**] in 1912.

The Sphere Complement-H_*-Theorem 82.1, together with the Reduced Homology Lemma 74.1, says in particular, that if $h\colon S^{n-1} \to S^n$ is an injective map, then
$$\mathrm{H}_i(S^n \setminus h(S^{n-1})) \;\cong\; \begin{cases} \mathbb{Z}^2, & \text{if } i = 0, \\ 0, & \text{otherwise.} \end{cases}$$
Put differently, homologically the topological space $S^n \setminus h(S^{n-1})$ looks like the disjoint union of two open n-dimensional balls. One might now suspect that $S^n \setminus h(S^{n-1})$ is in fact homeomorphic to the union of two open n-dimensional balls.
This is in fact true in dimension $n = 2$. More precisely Arthur Schönflies[993] proved in 1908 the following theorem. We refer to [**Tn1992**, Section 3] for a perhaps more readable proof of the theorem.[994]

Theorem 82.4. (Schönflies Theorem) Let $h\colon S^1 \to S^2$ be an injective map. Then h extends to a homeomorphism of S^2, i.e. there exists a homeomorphism $H\colon S^2 \to S^2$ such that $H|_{S^1} = h$. In particular both components of $S^2 \setminus h(S^1)$ are homeomorphic to open disks.



Remark.

(1) The Schönflies Theorem is often also called the Jordan-Schönflies Theorem.
(2) If $h\colon S^1 \to S^2$ is a smooth embedding, then the conclusion of the Schönflies Theorem 82.4 also follows from the much easier Proposition 55.18.

It is natural to ask whether the conclusion of the Schönflies Theorem also holds in higher dimensions. But this hope breaks down already one dimension higher. More precisely, James Alexander[995] showed in 1924 that there exists an injective map $S^2 \to \mathbb{R}^3$ such that one of the two components of the complement of $h(S^2)$ is not simply connected. The image $h(S^2)$ is called the *Alexander horned sphere*. It is illustrated in the figure below. A more detailed description of the Alexander horned sphere and the proof that the complement is

[992] Camille Jordan (1838-1922) was a French mathematician who most readers will already have encountered in linear algebra.
[993] Arthur Schönflies (1853–1928) was a German mathematician.
[994] More precisely, in [**Tn1992**, Section 3] a proof for the following statement is given:
Let $g\colon S^1 \to \mathbb{R}^2$ be an injective map. Then g extends to a homeomorphism of $\mathbb{R}^2$.
We leave it to the reader to deduce Theorem 82.4 from that statement.
[995] James Alexander (1888-1971) was an American mathematician. He also introduced the Alexander polynomial of a knot.

not simply connected is given in [**Al1924a**] and also [**Hat2002**, p. 170] and in [**DV2009**, p. 46]. In Exercise 82.2 we invite the reader to modify the Example shown in the figure below to produce an injective map $S^2 \to \mathbb{R}^3$ such that neither of the two components of the complement of $h(S^2)$ is simply connected.

We have now seen that injective maps $S^2 \to S^3$ can be pretty "wild". The map that defines the Alexander horned sphere is continuous, but it is certainly not smooth. So what happens if we restrict ourselves to smooth maps? In fact in the smooth setting we have the following theorem.

Theorem 82.5. (Generalized smooth Schönflies Theorem) Let $h\colon S^{n-1} \to S^n$ be a smooth embedding. If $n \neq 4$, then there exists an orientation-preserving diffeomorphism $H\colon S^n \to S^n$ with $H|_{S^{n-1}} = h$.

For $n = 2$ the statement follows fairly easily from the classification of smooth 2-dimensional smooth manifolds that we gave in the Surface Classification Theorem 55.4, see e.g. [**Hirs1976**, p. 207]. For $n = 3$ this statement was proved by James Alexander [**Al1924b**]. See also [**Hat3**, Chapter 1] and [**Schul2014**, Theorem 3.2.5] and for an exposition of the proof. For $n \geq 5$ this statement was independently proved by Barry Mazur [**Maz1959**] in 1959 and by Morton Brown [**BrownM1960**] in 1960.
The case $n = 4$ is missing in the Generalized Schönflies Theorem. In fact it is still unknown whether the statement holds for $n = 4$.

Question 82.6. Is it true that given any smooth embedding $h\colon S^3 \to S^4$ there exists a diffeomorphism $H\colon S^4 \to S^4$ with $H|_{S^3} = h$?

This question is very much open and there is not even a consensus whether one expects the answer to be yes or no. If you can answer this question you would almost certainly obtain a Fields medal.[996]

We conclude this section with two more consequences of the Sphere Complement-H_*-Theorem 82.1. The following theorem was first proved by Luitzen Brouwer [**Brou1911**] in 1911. It can be viewed as a significant strengthening of the Smooth Invariant of Domain Theorem 19.13 (1).

Theorem 82.7. (Topological Invariance of Domain Theorem) Let U be an open subset of $\mathbb{R}^n$.

(1) If $h\colon U \to \mathbb{R}^n$ is an injective map, then $h(U)$ is also an open subset of $\mathbb{R}^n$.[997]
(2) If $h\colon U \to \mathbb{R}^m$ be an injective map, then $m \geq n$.

[996] But hurry up, you can only get a Fields medal if you are under 40.
[997] How can one prove the theorem for $n = 1$ using only the methods from real analysis?

Remark. The Open Mapping Theorem from complex analysis, see [**Lang1999**, Theorem II.6.2], says that if $G \subset \mathbb{C}$ is an open subset and if $f\colon G \to \mathbb{C}$ is a non-constant *holomorphic* function, then $f(G)$ is also open. In fact, one can deduce the "Open Mapping Theorem" from the Topological Invariance of Domain Theorem 82.7 since by [**Jä2011**, Satz 10] every non-constant holomorphic function on an open subset of $\mathbb{C}$ is locally the power of an injective function.

In the proof of Theorem 82.7 we need the following elementary lemma.

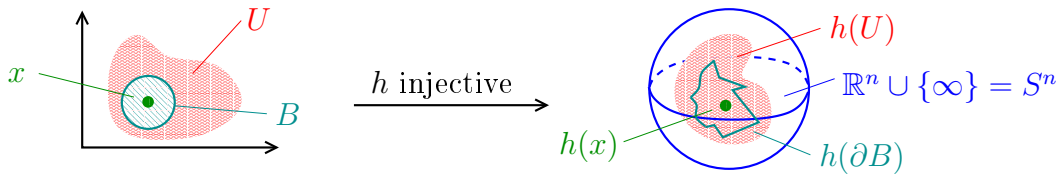
Lemma 82.8. Let $U \subset \mathbb{R}^n$ be a subset. If U is open in $\mathbb{R}^n$, then every path-component of U is also an open subset of $\mathbb{R}^n$.

Proof. Let C be a path-component of the subset subset $U \subset \mathbb{R}^n$. Let $P \in C$. Since U is open there exists an $r > 0$ such that $B_r(P) \subset U$. But all points in $B_r(P)$ are path-equivalent to P, hence $B_r(P) \subset C$. ■

Proof of the Topological Invariance of Domain Theorem 82.7.

(1) Recall that by the homeomorphism from Lemma 2.18 we can view $\mathbb{R}^n$ as an open subset of $\mathbb{R}^n \cup \{\infty\} = S^n$. So we can view h as a map from U to S^n and we need to show that $h(U)$ is an open subset of S^n.

Let $x \in U$. We pick a closed n-ball B in U that contains x in the interior. It suffices to show that $h(B \setminus \partial B) \subset h(U)$ is open in S^n. Note that $S^n \setminus h(\partial B)$ is open by the Compact Image Lemma 2.13 (3). By Lemma 82.8 it therefore suffices to show that $h(B \setminus \partial B)$ is a path-component of $S^n \setminus h(\partial B)$. We will do so in the following claim.



Claim. The topological space $S^n \setminus h(\partial B)$ has precisely two path-components namely the subsets $h(B \setminus \partial B)$ and $S^n \setminus h(B)$.

Proof. By the Sphere Complement-H$_*$-Theorem 82.1 (2) and the Reduced Homology Lemma 74.1 we know that

$$S^n \setminus h(\partial B) \;=\; h(B \setminus \partial B) \sqcup (S^n \setminus h(B))$$

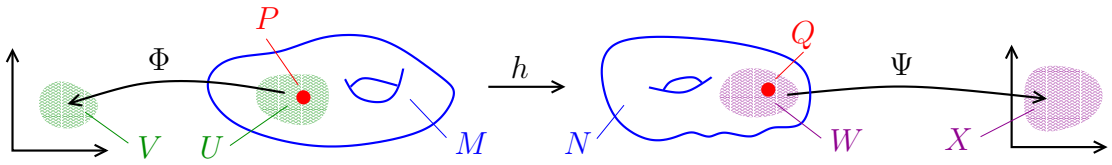
has two path-components. It suffices to show that the two sets on the right-hand side are path-connected. The first set $h(B \setminus \partial B)$ is path-connected since it is the image of the path-connected topological space $B \setminus \partial B$, while the second set $S^n \setminus h(B)$ is path-connected by the Sphere Complement-H$_*$-Theorem 82.1 (1) and the Reduced Homology Lemma 74.1. ⊞

(2) Let $h\colon U \to \mathbb{R}^m$ be an injective map with $m \leq n$. We consider the inclusion given by composing h with the inclusion $i\colon \mathbb{R}^m \xrightarrow{x \mapsto (x,0)} \mathbb{R}^n$. By (1) we know that $(i \circ h)(U)$ is an open subset. But a subset of $\mathbb{R}^m$ is open under the inclusion $i\colon \mathbb{R}^m \to \mathbb{R}^n$ only if $m = n$. Thus we have shown that $m \geq n$. ■

Corollary 82.9. Let M be a non-empty closed n-dimensional topological manifold and let N be a connected n-dimensional topological manifold without boundary. Let $h\colon M \to N$ be a map.

(1) If $h\colon M \to N$ is locally injective, then h is also surjective.
(2) If h is injective, then h is already a homeomorphism.

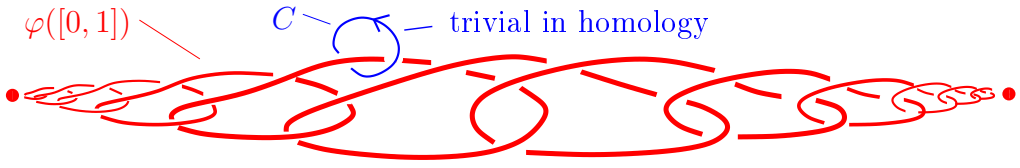
Example. Corollary 82.9 implies in particular that there exists no injective map from the closed smooth manifold S^n into the smooth manifold $\mathbb{R}^n$.[998]



Proof. The second statement of the corollary is an immediate consequence of the first statement and the Compact-Hausdorff Proposition 2.17 (3). So it suffices to prove the first statement.

Let $h\colon M \to N$ be a locally injective map from a non-empty closed n-dimensional topological manifold M to a connected n-dimensional topological manifold N without boundary.

The image $h(M)$ is closed in N since M is compact and since N is Hausdorff. Since N is connected and since M is non-empty it suffices to show that $h(M)$ is also open in N.



So let $Q \in h(M)$. We pick $P \in M$ with $h(P) = Q$. We pick a chart $\Phi\colon U \to V$ around P and we pick a chart $\Psi\colon W \to X$ around Q. After possibly replacing U by $U \cap h^{-1}(W)$ we can assume that $h(U) \subset W$. Since h is locally injective we can, after possibly shrinking U even more, assume that $h|_U$ is injective.

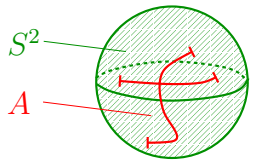
From Theorem 82.7 we know that $(\Psi \circ h \circ \Phi^{-1})(V)$ is an open subset of $\mathbb{R}^n$. Since Ψ is a homeomorphism we see that $h(\Phi^{-1}(V)) = h(U)$ is an open neighborhood of Q that is contained in $h(M)$. ■

Exercises for Chapter 82.

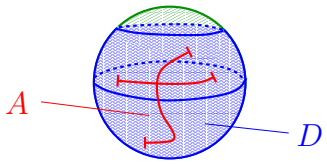
Exercise 82.1. In the figure below the exercise we see the image of an injective map $\varphi\colon [0,1] \to S^3 = \mathbb{R}^3 \cup \{\infty\}$ and we see a curve $C \subset S^3 \setminus \varphi([0,1])$. We know from the Sphere Complement-H_*-Theorem 82.1 (1) that x is null-homologous. Show that x is the boundary of an orientable surface Σ that is embedded in $S^3 \setminus \varphi([0,1])$. (In this context this can be seen as the converse to Exercise 80.6.)

[998] How can you show this for $n = 1$, just using methods from real analysis?

Exercise 82.2. Show that there exists an injective map $S^2 \to \mathbb{R}^3$ such that neither of the two components of the complement of $h(S^2)$ is simply connected.
Remark. You could try to modify the example shown in the figure on page 1815.



Exercise 82.3. Let M be a closed n-dimensional topological manifold, let X be a Hausdorff space, let $f\colon M \to X$ be a map and let $\Phi\colon B^n \to X$ be an embedding. Show that $f(M) \cap \Phi(B^n)$ is either empty or it equals $\Phi(B^n)$.
Remark. A typical example would be that X is a CW-complex and Φ is the characteristic map of an open n-cell.



Exercise 82.4. Let $\varphi\colon S^1 \to \mathbb{R}^2$ be an injective map. Show that there exist distinct three points $x, y, z \in S^1$ such that $\varphi(x), \varphi(y), \varphi(z)$ from an equilateral triangle.
Hint. Use the Jordan–Brouwer Separation Theorem 82.2 for $n = 1$. *Remark.* This is a generalization of Exercise 82.4.

Exercise 82.5. Let $n \in \mathbb{N}_0$ and let $A \subset S^n$ be a closed subset with $A \neq S^n$. Show that there exists a subspace D of S^n with the following two properties:

(1) D is homeomorphic to $\overline{B}^n$.
(2) $A \subset D$.

Hint. First deal with the case that $P = (0, \dots, 0, 1) \in S^n \setminus A$.

83. Topological robotics ❀

In this chapter we will first study the matrix groups SO(3) and SU(2), viewed as topological spaces. In particular we will determine $\pi_1(\mathrm{SO}(3))$ and we will use this result to give an application to topological robotics.

83.1. The matrix groups SO(3) and SU(2).

We recall that the Matrix Group-Smooth Manifold Proposition 26.7 implies in particular that we can view SO(3) and SU(2) as closed 3-dimensional smooth manifolds. In this section we will see that the smooth manifolds SO(3) and SU(2) are diffeomorphic to smooth manifolds we are already very familiar with. We start out our discussion of SO(3) and SU(2) with some definitions.

Definition. We consider the set of matrices[999]

$$T := \left\{B \in \mathrm{SL}(2,\mathbb{C}) \,\middle|\, \mathrm{tr}(B) = 0 \text{ and } B = \overline{B}^T\right\}.$$

Note that T is a 3-dimensional real vector space. We equip it with the basis given by the so-called "Pauli matrices"[1000]

$$E_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad E_3 = \begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix},$$

and we equip T with the inner product given by

$$\begin{array}{rcl} T \times T & \mapsto & \mathbb{R} \\ (A,B) & \mapsto & g(A,B) := \frac{1}{2}\,\mathrm{tr}\left(A\overline{B}^T\right). \end{array}$$

We consider the isomorphism

$$\begin{array}{rcl} \Phi\colon \mathbb{R}^3 & \to & T \\ e_i & \mapsto & E_i. \end{array}$$

It follows from a straightforward calculation that Φ defines an isometry from $(\mathbb{R}^3, \langle\,,\,\rangle)$ to (T,g).[1001] It follows immediately from this observation that Φ induces an isomorphism $\mathrm{SO}(3) \to \mathrm{SIsom}(T,g)$, where $\mathrm{SIsom}(T,g)$ denotes the group of isometries of (T,g) of determinant $+1$. We use this isomorphism to identify these two groups.

Lemma 83.1. The map

$$\begin{array}{rcl} q\colon \mathrm{SU}(2) & \to & \mathrm{SIsom}(T,g) = \mathrm{SO}(3) \\ A & \mapsto & (B \mapsto ABA^{-1}) \end{array}$$

is a smooth map between smooth manifolds and it is a well-defined group homomorphism. Furthermore for $A, A' \in \mathrm{SU}(2)$ we have

$$q(A) = q(A') \iff A = \pm A'.$$

Example. Given $t \in \mathbb{R}$ we consider the matrix

$$A = \begin{pmatrix} \exp(-\mathrm{i}t) & 0 \\ 0 & \exp(\mathrm{i}t) \end{pmatrix} \in \mathrm{SU}(2).$$

---

[999] Recall that the trace $\mathrm{tr}(A)$ of a matrix is defined as the sum of all the diagonal entries.

[1000] Wolfgang Pauli (1900–1958) was Swiss-American theoretical physicist and one of the pioneers of quantum physics. These matrices were also independently introduced by Paul Dirac. Wikipedia writes: "In 1928, building on 2×2-spin matrices which he [Paul Dirac] discovered independently of Wolfgang Pauli's work on non-relativistic spin systems, [...] he proposed the Dirac equation as a relativistic equation of motion for the wave function of the electron. This work led Dirac to predict the existence of the positron, the electron's antiparticle [...]."

[1001] In the calculation we only have to show that $g(E_i,E_j) = \frac{1}{2}\,\mathrm{tr}(E_i\overline{E}_j^T) = \delta_{ij} = \langle e_i, e_j\rangle$ for all choices of $i,j \in \{1,2,3\}$. But this can be verified easily.

We want to determine $q(A) \in \mathrm{SO}(3)$. This means that we have to express the linear map $T \to T$ that is given by $B \mapsto ABA^{-1}$ with respect to the ordered basis $\{E_1, E_2, E_3\}$. A straightforward calculation shows that

$$\begin{aligned} AE_1A^{-1} &= E_1, \\ AE_2A^{-1} &= \begin{pmatrix} 0 & \exp(-2\mathrm{i}t) \\ \exp(2\mathrm{i}t) & 0 \end{pmatrix} = \cos(2t)\cdot E_2 + \sin(2t)\cdot E_3, \\ & \qquad \uparrow \text{ since } \exp(\mathrm{i}s) = \cos(s) + \mathrm{i}\sin(s) \\ AE_3A^{-1} &= \begin{pmatrix} 0 & -\mathrm{i}\cdot\exp(-2\mathrm{i}t) \\ \mathrm{i}\cdot\exp(2\mathrm{i}t) & 0 \end{pmatrix} \downarrow = -\sin(2t)\cdot E_2 + \cos(2t)\cdot E_3. \end{aligned}$$

But this implies that the homomorphism $T \to T$ given by conjugation with A, with respect to the ordered basis $\{E_1, E_2, E_3\}$ is given by the matrix

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(2t) & -\sin(2t) \\ 0 & \sin(2t) & \cos(2t) \end{pmatrix} \quad \begin{matrix} \text{put differently,} \\ \text{we have} \end{matrix} \quad q\begin{pmatrix} \exp(-\mathrm{i}t) & 0 \\ 0 & \exp(\mathrm{i}t) \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(2t) & -\sin(2t) \\ 0 & \sin(2t) & \cos(2t) \end{pmatrix}.$$

Proof of Lemma 83.1. First we have to show that for $A \in \mathrm{SU}(2)$ and $B \in T$ we also have $ABA^{-1} \in T$. This is indeed the case since

$$\mathrm{tr}(ABA^{-1}) = \mathrm{tr}(B) = 0 \quad \text{and} \quad \big(\overline{ABA^{-1}}\big)^T = (\overline{A}^{-1})^T\overline{B}^T\overline{A}^T \underset{\substack{\uparrow \\ \text{since } B = \overline{B}^T \text{ and } A^{-1} = \overline{A}^T}}{=} A\overline{B}^TA^{-1}.$$

It follows easily from the definition that q is a group homomorphism. We also have to show that for $A \in \mathrm{SU}(2)$ we get indeed an isometry of (T, g). So let $B, C \in T$. Then we have indeed

$$\begin{aligned} g(q(A)(B), q(A)(C)) &= \tfrac{1}{2}\,\mathrm{tr}\left(ABA^{-1}\cdot\overline{ACA^{-1}}^T\right) = \tfrac{1}{2}\,\mathrm{tr}\left(AB\overbrace{A^{-1}\cdot(\overline{A}^{-1})^T}^{=\mathrm{id}}\overline{C}^T\overline{A}^T\right) \\ &= \tfrac{1}{2}\,\mathrm{tr}\left(AB\overline{C}^T\overline{A}^T\right) = \tfrac{1}{2}\,\mathrm{tr}\left(B\overline{C}^T\underbrace{\overline{A}^TA}_{=\mathrm{id}}\right) = \tfrac{1}{2}\,\mathrm{tr}\left(B\cdot\overline{C}^T\right). \end{aligned}$$

This shows that q defines group homomorphism $\mathrm{SU}(2) \to \mathrm{O}(3)$. By the Matrix Group Path-Component Proposition 2.37 we know that $\mathrm{SU}(2)$ is path-connected. The image $q(\mathrm{SU}(2))$ is a path-connected subset of $\mathrm{O}(3)$ that contains $q(\mathrm{id}) = \mathrm{id}$. It follows again the Matrix Group Path-Component Proposition 2.37 that $q(\mathrm{SU}(2))$ is contained in $\mathrm{SO}(3)$.

Finally let $A, A' \in \mathrm{SU}(2)$. If $A = -A'$ then we clearly have $q(A) = q(A')$. Now suppose that conversely we have $q(A) = q(A')$. We then have in particular $q(A)(E_i) = q(A')(E_i)$ for $i = 1, 2, 3$, i.e. we have $AE_iA^{-1} = A'E_i(A')^{-1}$ for $i = 1, 2, 3$. These equalities give us equations relating the four entries of the matrix A to the four entries of the matrix A'. An elementary calculation then shows that the only solutions are $A = \pm A'$. We leave the details to the reader.

This discussion shows that q is a well-defined map and that it is a group homomorphism. After one has unraveled the definitions it will also have become apparent that the map g is indeed a smooth map between smooth manifolds. ■

The following theorem is the main result of this section.

Theorem 83.2. (SU(2)-SO(3)-Covering Theorem) Let $q\colon \mathrm{SU}(2) \to \mathrm{SIsom}(T, g) = \mathrm{SO}(3)$ be the map from Lemma 83.1. Then the following two statements hold:

(1) The map q is a 2-fold covering map.
(2) There exist diffeomorphisms $f\colon S^3 \to \mathrm{SU}(2)$ and $g\colon \mathbb{R}\mathrm{P}^3 \to \mathrm{SO}(3)$ such that the following diagram commutes:

$$\begin{array}{ccc} S^3 & \xrightarrow[\cong]{f} & \mathrm{SU}(2) \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ \mathbb{R}\mathrm{P}^3 & \xrightarrow[\cong]{g} & \mathrm{SO}(3), \end{array}$$

where we denote by $p\colon S^3 \to \mathbb{R}\mathrm{P}^3 = S^3/\pm 1$ the usual projection .

Remark. In Exercise 5.47 we gave a somewhat different homeomorphism between $\mathbb{R}\mathrm{P}^3$ and SO(3). In future discussions we will prefer the homeomorphism from the SU(2)-SO(3)-Covering Theorem 83.2.

Convention. We will use the diffeomorphism from the SU(2)-SO(3)-Covering Theorem 83.2 to make the identifications $S^3 = \mathrm{SU}(2)$ and $\mathbb{R}\mathrm{P}^3 = \mathrm{SO}(3)$.

In the proof of the SU(2)-SO(3)-Covering Theorem 83.2 we will need the following technical lemma.

Lemma 83.3. Let $q\colon M \to N$ be a map between two n-dimensional topological manifolds. Suppose the following conditions are satisfied:

(1) the map q is surjective,
(2) the map q is locally injective, i.e. for each $P \in M$ there exists a neighborhood U such that $q|_U$ is injective,
(3) for each point $Q \in N$ the preimage $q^{-1}(Q)$ is a finite set.

Then q is a covering map.

Proof. Since q is surjective we only have to show that each $Q \in N$ admits an open neighborhood that is uniformly covered. So let $Q \in N$. We denote its preimages by $P_1, \ldots, P_r$. Let $i \in \{1, \ldots, m\}$. It follows easily from (2) and the hypothesis that M is a topological manifold that we can pick a closed ball B_i which is a neighborhood around P_i and such that $q\colon B_i \to N$ is injective. Since the topological manifold N is in particular Hausdorff it follows from the Compact-Hausdorff Proposition 2.17 (3) that $q\colon B_i \to q(B_i)$ is a homeomorphism. It follows from the proof of Corollary 82.9 that $q(\overset{\circ}{B}_i)$ is an open neighborhood of Q. It is now straightforward to see that $U := \bigcap_{i=1}^{m} q(\overset{\circ}{B}_i)$ is a uniformly covered open neighborhood of Q. ■

Proof of the SU(2)-SO(3)-Covering Theorem 83.2. Somewhat confusingly the proof of the SU(2)-SO(3)-Covering Theorem 83.2 is given in three steps (a), (b) and (c).

(a) One can easily show that the map[1002]

$$\begin{array}{rcl} f\colon S^3 & \to & \mathrm{SU}(2) \\ (z,w) & \mapsto & \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} \widetilde{f}\colon \mathrm{SU}(2) & \to & S^3 \\ \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} & \mapsto & (z,w) \end{array}$$

are inverses to one another and that both maps are smooth. This implies that both maps, in particular f, is a diffeomorphism.

(b) Now we want to show that $q\colon \mathrm{SU}(2) \to \mathrm{SO}(3)$ is a 2-fold covering map. By Lemma 83.1 we know that q is locally injective. But then it follows from Corollary 82.9 and the fact that SU(2) and SO(3) are closed 3-dimensional smooth manifolds and the fact that SO(3) is connected (which follows from the Matrix Group Path-Component Proposition 2.37 (3) together with Locally Path-Connected Lemma 2.40) that q is in fact also a surjection. Since the preimage of each $A \in \mathrm{SO}(3)$ consists of precisely two points in SU(2) we can apply Lemma 83.3 to deduce that q is indeed a 2-fold covering map.

(c) For any $(z,w) \in S^3$ we have $q(f(-z,-w)) = q(-f(z,w)) = q(f(z,w))$. Thus we see that the map

$$\begin{array}{rcl} g\colon \mathbb{R}\mathrm{P}^3 & \to & \mathrm{SO}(3) \\ [(z,w)] & \mapsto & q(f(z,w)) \end{array}$$

is well-defined. It follows immediately from the fact, obtained in (b), that q is surjective, that g is also surjective. Similarly it is straightforward to show, using (b), that the map g is injective. Since q, f and p are local diffeomorphisms and since locally g is given by a composition of q, f, p and their local inverses we see that g is a local diffeomorphism. But by the Smooth Pasting Proposition 19.23 (2) we know that a map between smooth manifolds that is a local diffeomorphism and a bijection is in fact a diffeomorphism.

Finally we note that it follows easily from the definitions that $g \circ p = q \circ f$, i.e. the diagram given in the theorem commutes. ■

From the SU(2)-SO(3)-Covering Theorem 83.2 and Corollary 48.18 we obtain immediately the following, perhaps initially somewhat surprising, corollary.

Corollary 83.4. We have

$$\pi_1(\mathrm{SU}(2)) \;=\; 0 \quad \text{and} \quad \pi_1(\mathrm{SO}(3)) \;\cong\; \mathbb{Z}_2.$$

In particular SU(2) is the universal covering of SO(3).[1003]

[1002] In Proposition 92.2 we will see that the map f arises naturally if we think of S^3 as the "unit quaternions".

[1003] The fact SU(2) is the universal covering of SO(3) plays an important role in theoretical physics and it is essential in understanding the notion of "spin" of an electron. At least that is a slogan that I remember from the days when I studied physics.

Remark. We can actually give an explicit description of the non-trivial element in the fundamental group $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$. More precisely, we consider the loop

$$\begin{array}{rcl} \gamma\colon [0,1] & \to & \mathrm{SO}(3) \\ t & \mapsto & \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(2\pi t) & \sin(2\pi t) \\ 0 & -\sin(2\pi t) & \cos(2\pi t) \end{pmatrix} \end{array}$$

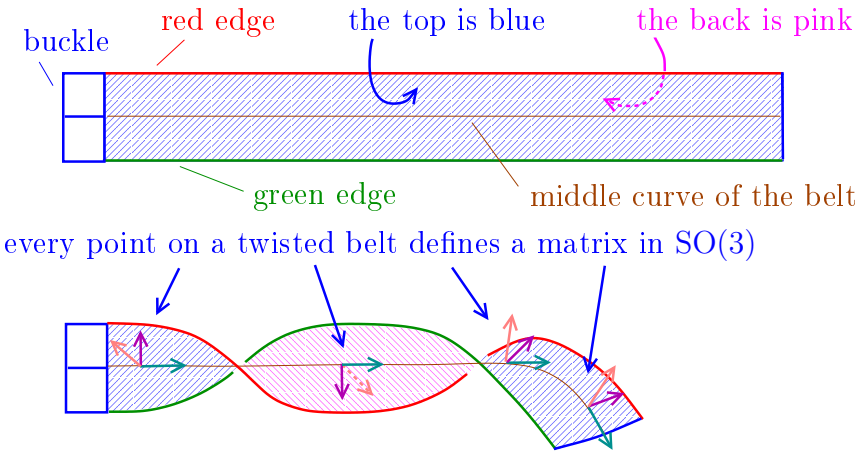
at the base point $\mathrm{id} \in \mathrm{SO}(3)$. The calculation on page 1819 shows that a lift of the path $\gamma\colon [0,1] \to \mathrm{SO}(3)$ to a path $[0,1] \to \mathrm{SU}(2)$ to the starting point $\mathrm{id} \in \mathrm{SU}(2)$ is given by

$$\begin{array}{rcl} \widetilde{\gamma}\colon [0,1] & \to & \mathrm{SO}(3) \\ t & \mapsto & \begin{pmatrix} \exp(-\mathrm{i}\pi t) & 0 \\ 0 & \exp(\mathrm{i}\pi t) \end{pmatrix}. \end{array}$$

Note that $\widetilde{\gamma}(1) = -\mathrm{id}$, i.e. $\widetilde{\gamma}$ is *not* a loop. Since $q\colon \mathrm{SU}(2) \to \mathrm{SO}(3)$ is a covering and since $\mathrm{SU}(2)$ is simply connected it follows from Lemma 48.15 that $[\gamma]$ is non-trivial in $\pi_1(\mathrm{SO}(3), \mathrm{id})$.

Corollary 83.4 also raises the following question.

Question 83.5. Let $n \geq 4$. What is $\pi_1(\mathrm{SO}(n))$?[1004][1005]



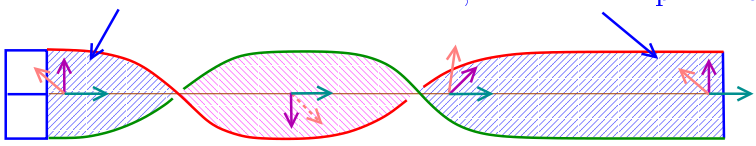
We will return to this question later on in Proposition 156.11.

83.2. **The belt trick ❀.** In this section we will see that one can visualize the non-trivial element in $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$ using a belt. We proceed as follows.

(1) First of all note that a matrix in $\mathrm{SO}(3)$ is precisely given by an ordered orthonormal basis, i.e. by a choice of an ordered set of three orthogonal vectors v_1, v_2, v_3 of length 1 in $\mathbb{R}^3$.
(2) We equip $\mathrm{SO}(3)$ with the base point given by the identity matrix, i.e. by the standard basis $\{e_1, e_2, e_3\}$.
(3) Now suppose we are given a belt with a buckle, a red edge and a green edge, with a blue top side and a pink lower side.
(4) Any point on a twisted belt defines a triple of orthogonal vectors:
   (a) the first vector lies in the plane defined by the belt and points away from the buckle,
   (b) the second vector also lies in the plane defined by the belt and points towards the red edge,
   (c) the third is orthogonal to the belt and it is attached to the top side of the belt.
(5) In the remainder of the discussion we fix the buckle in the xy-plane such that it points in the x-direction, so that to a point at the buckle we assign the identity matrix.
(6) We say that the end of the belt is in standard position if it lies in a plane parallel to the plane of the buckle and if it points into the x-direction. Put differently, the end of the belt is in standard position precisely if the matrix assigned to it is the identity matrix.
(7) When we walk on the middle curve of the belt from the buckle towards the other end of the belt, then we obtain a path $[0,1] \to \mathrm{SO}(3)$. In particular, if the end of

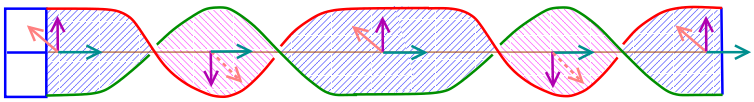
[1004] Recall that the Matrix Group Path-Component Proposition 2.37 (3) says that $\mathrm{SO}(n)$ is path-connected.
[1005] What is $\pi_1(\mathrm{SO}(2))$?

the belt is in standard position, then the path defined by the belt is in fact a loop in SO(3) at the base point id.



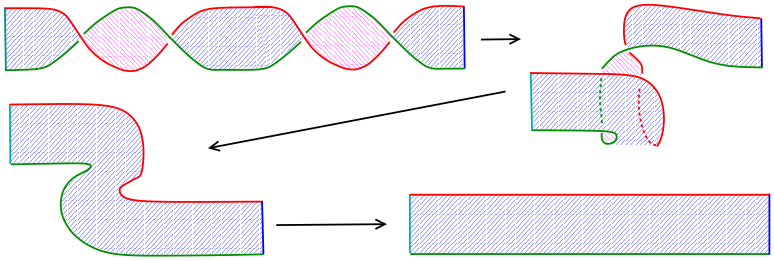
moving along the middle curve of the belt we get a path $[0,1] \to \mathrm{SO}(3)$

(8) When we hold the belt tightly without twisting it, then we assign the identity matrix to every point on the belt, i.e. the belt defines the constant loop $t \mapsto \mathrm{id} \in \mathrm{SO}(3)$.



(9) Now we give the belt, that is still fixed at the buckle, a full twist. As in (7) this defines a loop $\gamma\colon [0,1] \to \mathrm{SO}(3)$, in fact it is straightforward to see that this loop is precisely the loop that we had considered on page 1823. In particular we have visualized the non-trivial element $[\gamma] \in \pi_1(\mathrm{SO}(3), \mathrm{id}) \in \mathbb{Z}_2$.

both points define the standard basis of $\mathbb{R}^3$, i.e. the base point id $\in \mathrm{SO}(3)$



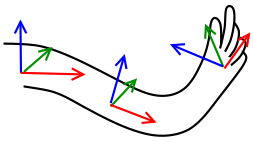
the path $\gamma\colon [0,1] \to \mathrm{SO}(3)$ defined by the matrices along the middle curve is a loop and thus defines an element $[\gamma] \in \pi_1(\mathrm{SO}(3), \mathrm{id})$

(10) The loop $\gamma * \gamma\colon [0,1] \to \mathrm{SO}(3)$ is given by performing another full twist along the belt. It follows from Corollary 83.4 that $[\gamma * \gamma] = [\gamma]^2$ is trivial in $\pi_1(\mathrm{SO}(3), \mathrm{id}) \cong \mathbb{Z}_2$, i.e. $\gamma * \gamma$ is null-homotopic.

the double full twist defines the loop $\gamma * \gamma$ which represents $[\gamma]^2 \in \pi_1(\mathrm{SO}(3), \mathrm{id})$

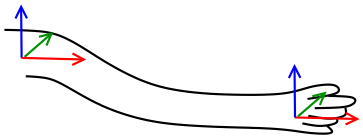
(10) One can see that the loop $\gamma * \gamma$ is null-homotopic as follows: one can untwist the belt while keeping the end in standard position, put differently, we can find a path-homotopy from the loop $\gamma * \gamma$ to the trivial loop. This homotopy is illustrated in the figure below.

The fact that $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$ lies at the heart of some other tricks, in particular the "plate trick" and "Dirac's string trick". More information and some videos can be found here:



https://en.wikipedia.org/wiki/Plate_trick
https://www.youtube.com/watch?v=JaIR-cWk_-o
https://www.youtube.com/watch?v=JDJKfs3HqRg
https://www.youtube.com/watch?v=ICEIgznuHmg

83.3. **The plate trick ❀.** The plate trick is a variation on the belt trick. It describes the same phenomenon as the belt trick. The plate trick has the great advantage that the only tool it requires is the body of a volunteer. The disadvantage is that it is perhaps mathematically slightly less compelling.

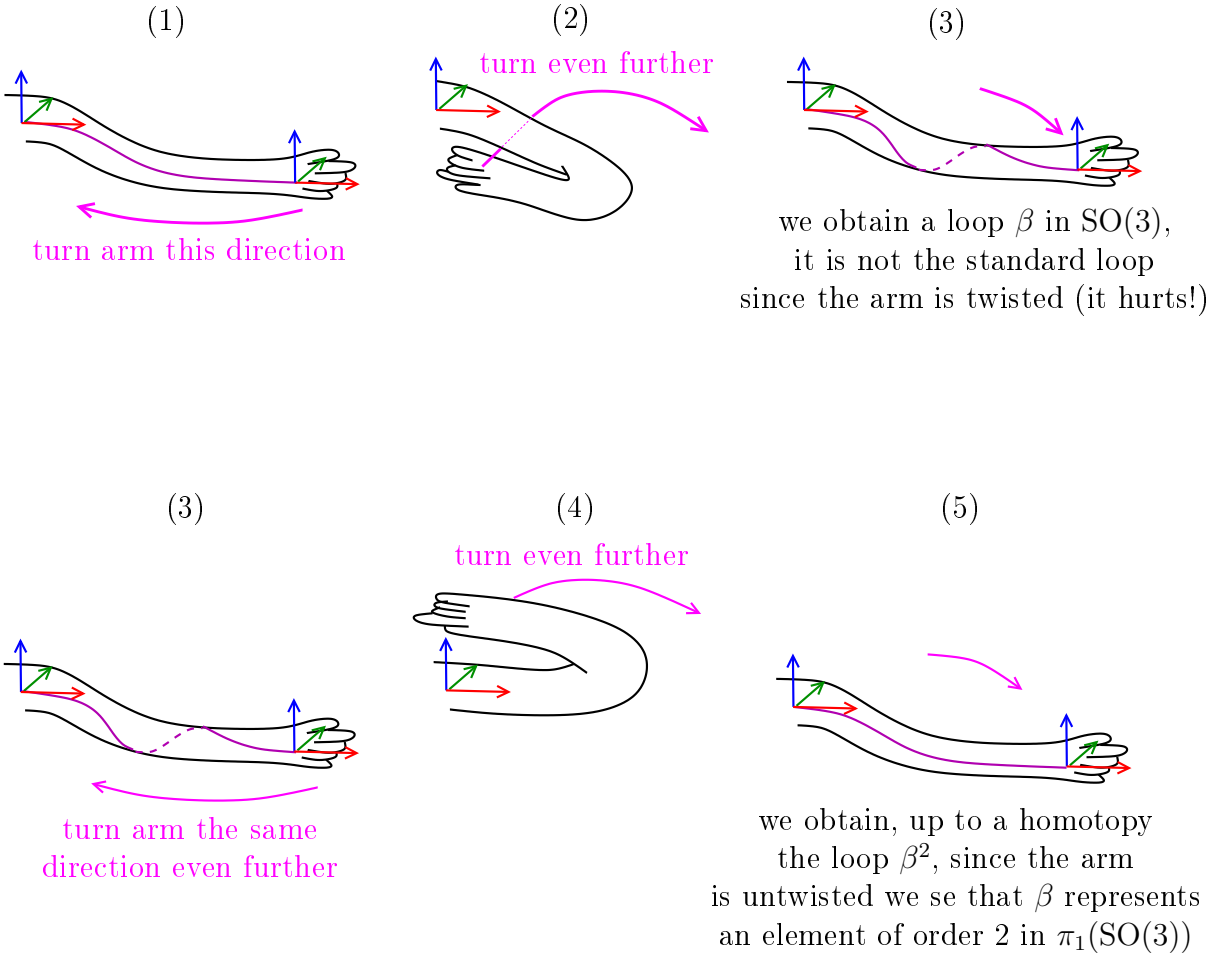


The basic idea is as in the belt trick. Namely we want to describe paths and loops in SO(3). This time we think of a path from the shoulder to ones left hand as a path in SO(3):

(a) the first vector lies on the arm and it points from the shoulder to the hand,
(b) the second vector also lies on the arm and it points from one side to the other,
(c) the third vector points away from the body.

If the fingers of the left hands are parallel to the shoulder, then we see a loop in SO(3).

the path from the shoulder
to the hand defines a path in SO(3)

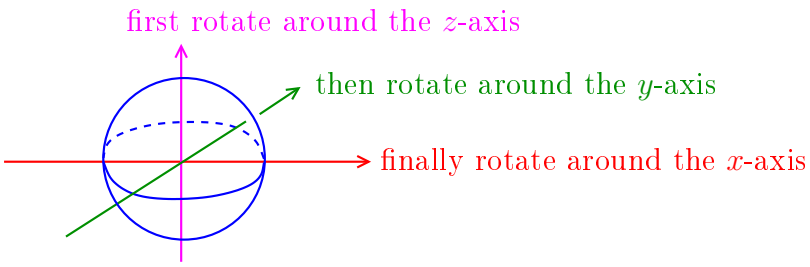


hand parallel to the shoulder
defines a loop in SO(3)

Now you, or your volunteer, does the following:

(1) You stretch your left arm and hands outwards such that the fingers are parallel to the shoulder.
(2) You rotate the left arm counterclockwise. The physiology of most arms will force the forearm to go under the arm.
(3) One continues till one does a 2π turn and the left arm is outstretched again. At this time we are describing a loop β in SO(3) which is non-constant since the arm is twisted. (If it doesn't hurt slightly, then the experiment is done incorrectly).

(4) Now one rotates the left arm still counterclockwise. The usual physiology will force the movement of the forearm to go over the arm.
(5) Again one continues till one has done another 2π turn. Up to a homotopy, keeping the end points fixed, the arm now describes $\beta * \beta$. But the arm turns out to be untwisted (which feels much better). This illustrates that β represents an element of order 2 in $\pi_1(\mathrm{SO}(3))$.



There are many more or less convincing illustrations and explanations of the plate trick. The most charming way of doing might be this one:

`http://ariwatch.com/VS/Algorithms/PlateTrick.htm`

83.4. **Topological robotics ❀.** In this section we want to discuss a "real-life" application of Corollary 83.4. Let us assume that we are given a solid ball and we are allowed to perform the following operations:

(1) first we can rotate the ball around the z-axis by an angle $\gamma \in S^1$,
(2) then we can rotate the ball around the y-axis by an angle $\beta \in S^1$, finally
(3) we can rotate the ball around the x-axis by an angle $\alpha \in S^1$.

Using these three operations, in that order, we can rotate the ball into any position. More precisely, we have the following lemma:

Lemma 83.6. The map

$$\begin{array}{rcl} \Phi\colon S^1\times S^1\times S^1 & \to & \mathrm{SO}(3) \\ (\alpha,\beta,\gamma) & \mapsto & \begin{array}{c}\text{rotation by } \alpha \\ \text{around the } x\text{-axis}\end{array} \circ \begin{array}{c}\text{rotation by } \beta \\ \text{around the } y\text{-axis}\end{array} \circ \begin{array}{c}\text{rotation by } \gamma \\ \text{around the } z\text{-axis}\end{array} \end{array}$$

is a surjection.[1006]

Remark. One can use Lemma 83.6 and a variation on the argument on page 1819 to give an alternative proof for the statement that $q\colon \mathrm{SU}(2)\to\mathrm{SO}(3)$ is surjective.

Sketch of proof. Let $A\in\mathrm{SO}(3)$ be matrix with columns v_1,v_2,v_3. After a rotation around the z-axis we can assume that v_1 lies in the xz-plane. After a rotation around the y-axis we can then arrange that v_1 lies in fact on the x-axis, i.e. we can arrange that $v_1=e_1$. Since $v_1=e_1,v_2,v_3$ is an orthonormal basis we see that v_2,v_3 lie in the yz-plane. After a rotation around the x-axis we can finally arrange that $v_2=e_2$ and $v_3=e_3$. ■

This lemma gives rise to the following practical problem: given a matrix $P\in\mathrm{SO}(3)$, can we continuously find parameters $\alpha(P),\beta(P),\gamma(P)\in S^1$ such that these parameters give back the matrix P? More precisely, we have the following question.

Question 83.7. Does there exist a continuous map $\Psi\colon \mathrm{SO}(3)\to S^1\times S^1\times S^1$ such that $\Phi\circ\Psi=\mathrm{id}_{\mathrm{SO}(3)}$?

It turns out that the answer is negative. More precisely, we have the following proposition.

Proposition 83.8. There is no continuous map $\Psi\colon \mathrm{SO}(3)\to S^1\times S^1\times S^1$ such that $\Phi\circ\Psi=\mathrm{id}_{\mathrm{SO}(3)}$.

This proposition falls into the area of "topological robotics", more information on this example and on topological robotics can be found in [**Gh2014**, p. 76]. Other aspects of topological robotics are discussed in the monograph [**Far2008**].

[1006] The map is also continuous. Why is that?

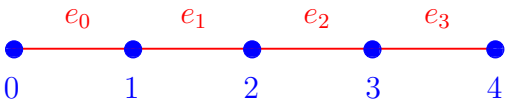
Proof. Let us suppose there exists a continuous map $\Psi\colon \mathrm{SO}(3) \to S^1 \times S^1 \times S^1$ such that $\Phi \circ \Psi = \mathrm{id}_{\mathrm{SO}(3)}$. Then we get the following commutative diagram

$$\begin{array}{ccc} & \overbrace{\pi_1(S^1 \times S^1 \times S^1)}^{\cong \mathbb{Z}^3} & \\ {\scriptstyle \Psi_*}\nearrow & & \searrow{\scriptstyle \Phi_*} \\ \underbrace{\pi_1(\mathrm{SO}(3))}_{\cong \mathbb{Z}_2} & \xrightarrow{\mathrm{id}_*} & \underbrace{\pi_1(\mathrm{SO}(3))}_{\cong \mathbb{Z}_2}. \end{array}$$

By Corollary 83.4 we have that $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$ and from Corollary 48.18 we know that $\pi_1(S^1 \times S^1 \times S^1) \cong \mathbb{Z}^3$. Since $\mathbb{Z}_2$ is a finite group and since $\mathbb{Z}^3$ is torsion-free we see that the homomorphism $\Psi_*\colon \pi_1(\mathrm{SO}(3)) \to \pi_1(S^1 \times S^1 \times S^1)$ is the trivial map. But that is not possible since the horizontal map is an isomorphism of a non-trivial group. ■

83.5. **Linkages ❀.** We conclude this chapter with a somewhat unrelated but fun topic that also appears in topological robotics. We recall a few definitions.

Definition.



(1) An undirected abstract graph G is a triple (V, E, λ) where V is a non-empty set, E is a set and λ is a map

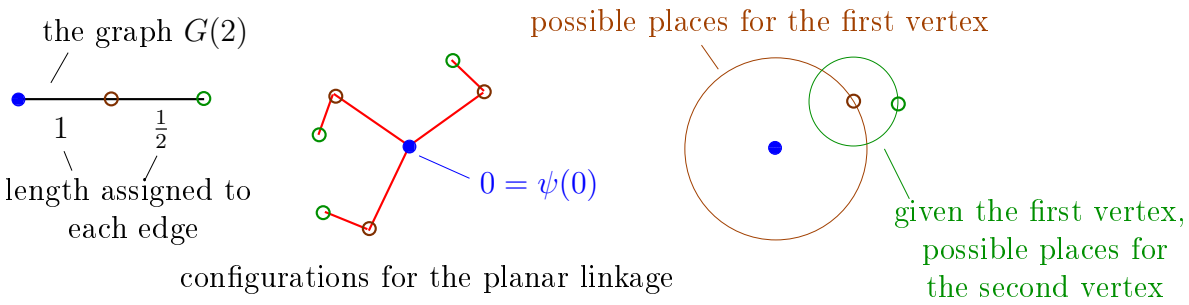
$$\lambda\colon E \ \to \ \{\text{subsets of } V \text{ with one or two elements}\}.$$

The elements of V are called vertices of G and the elements of E are called the edges of G. Furthermore, given $e \in E$ the points in $\lambda(e)$ are called the endpoints of e.

(2) Given $n \in \mathbb{N}$ we define the linear graph of length n to be the undirected abstract graph $G(n)$ which is given by the vertex set $V = \{0, \ldots, n\}$ and the edge set $\{e_0, \ldots, e_{n-1}\}$ with $\lambda(e_i) = \{i, i+1\}$ for $i = 0, \ldots, n-1$.

the linear graph $G(4)$

Definition.



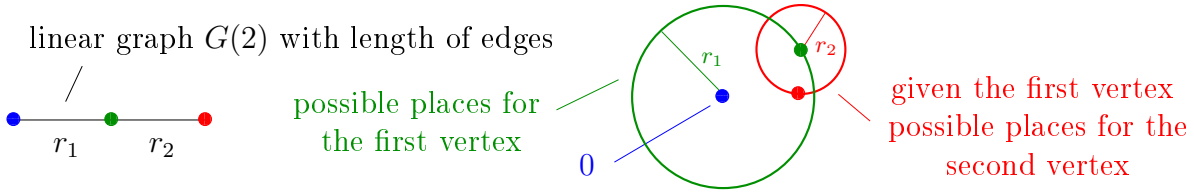
(1) A planar linkage is a triple $(G = (V, E), \lambda, \psi)$ consisting of a finite undirected abstract graph $G = (V, E)$, a function $\lambda\colon E \to \mathbb{R}_{>0}$ and a map $\psi\colon W \to \mathbb{C} = \mathbb{R}^2$ where W is a subset of V. Put differently, λ assigns a length to each edge and ψ represents a subset of the vertices by points in $\mathbb{C}$.

(2) A configuration of a planar linkage $(G = (V, E), \lambda, \psi)$ is a map $f\colon V \to \mathbb{R}^2 = \mathbb{C}$ such that $f|_W = \psi$ and such that for every edge e the distance between the endpoints of e is $\lambda(e)$.[1007]

(3) The set $C(G = (V, E), \lambda, \psi)$ of all configurations is called the configuration space of the linkage. We have an injective map

$$\begin{array}{rcl} C(G = (V, E), \lambda, \psi) & \to & \mathbb{C}^{|V|} := \mathrm{maps}(V \to \mathbb{C}) \\ f & \mapsto & (v \mapsto f(v)) \end{array}$$

thus we can view the configuration space $C(G = (V, E), \lambda, \psi)$ as a topological space.



configurations for the planar linkage

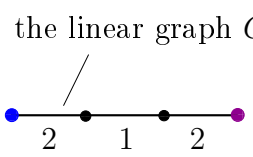
In some cases the topological shape of the configuration space of a planar linkage is easy to describe. More precisely, we have the following lemma which is a straightforward consequence of the definitions and the Compact-Hausdorff Proposition 2.17 (3). We leave it to the reader to provide the proof.

Lemma 83.9. Let $G(m)$ be the linear graph with m edges. We consider a planar linkage of the form $(G(m), \lambda, \psi(0) = 0)$. For $i = 1, \ldots, m$ we write $r_i = \lambda(e_i)$. Then the map

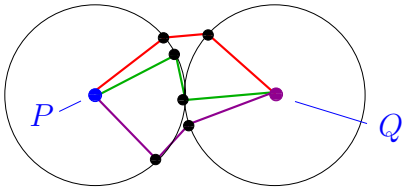
$$\begin{array}{rcl} (S^1)^m = S^1 \times \cdots \times S^1 & \to & C(G(m), \lambda, \psi) \\ (z_1, \ldots, z_m) & \mapsto & \left(\begin{array}{rcl} \{0, \ldots, m\} & \to & \mathbb{C} \\ k & \mapsto & \sum_{i=1}^{k} r_i z_i \end{array} \right) \end{array}$$

is a homeomorphism.

For general linkages the topology of the configuration spaces are much harder to describe than for free planar linkages.



(1) Given $r_1, \ldots, r_m > 0$ we denote by $C(r_1, \ldots, r_m, P, Q)$ the configuration space corresponding to the planar linkage defined by $G(m)$, $\lambda(e_i) = r_i$ and by the conditions that $\psi(0) = P$ and $\psi(m) = Q$.
   (a) Using elementary arguments one can easily show that



$$C(r_1, r_2, P, Q) \;=\; \begin{cases} \varnothing, & \text{if } r_1 + r_2 < d(P, Q), \\ \text{one point}, & \text{if } r_1 + r_2 = d(P, Q), \\ \text{two points}, & \text{if } r_1 + r_2 > d(P, Q). \end{cases}$$

   (b) Kevin Walker [**WalkK1985**, p. 35], see also [**Gh2014**, p. 12], showed in 1985 in his bachelor thesis that the surfaces of genus $0, 1, \ldots, 4$ are homeomorphic to configuration spaces of the type $(r_1, r_2, r_3, r_4, P, Q)$ for suitable values of $r_1, \ldots, r_4$ and points P and Q.

(2) Michael Kapovich and John Millson [**KaM2002**] showed that given any compact smooth manifold M there exists a planar linkage such that each component of the

[1007] In particular if e has only one endpoint, then we need $\lambda(e) = 0$.

configurations for the planar linkage

configuration space is homeomorphic to M. In particular this shows that any compact smooth manifold can be represented by a 2-dimensional physical object.

Exercises for Chapter 83.

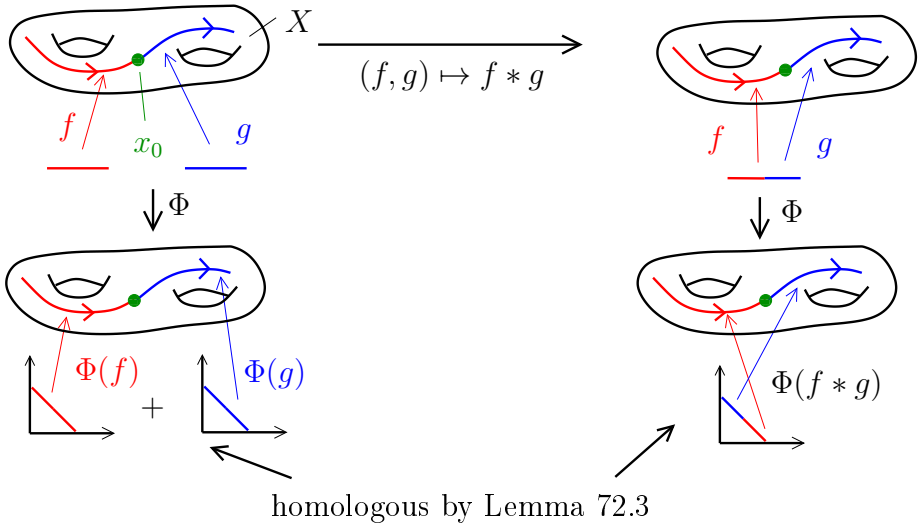
Exercise 83.1. Let $q\colon \mathrm{SU}(2) \to \mathrm{SO}(3)$ be the homomorphism that we defined in Lemma 83.1. Show that

$$q\begin{pmatrix} \mathrm{i} & 0 \\ 0 & -\mathrm{i} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix},\quad q\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix},\quad q\begin{pmatrix} 0 & -\mathrm{i} \\ -\mathrm{i} & 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

Remark. This calculation will actually turn out to be useful in Section 98.4.

84. The Hurewicz Theorem in dimension one

In this chapter we want to relate the first homology group to the fundamental group of a path-connected topological space X. Both are defined by mapping 1-dimensional smooth manifolds into X, hence it is reasonable to expect that there is a relationship. But in general these two groups associated to a topological space cannot be the same, since the first homology group is by definition abelian, whereas we saw on many occasions that fundamental groups can be non-abelian.
We start out with the following notation.



Notation. Let X be a topological space. Throughout this chapter we denote by Φ the following bijection:

$$\begin{array}{rcl} \Phi\colon \{\text{paths } [0,1] \to X\} & \to & \{\text{singular 1-simplices in } X\} \\ (\gamma\colon [0,1] \to X) & \mapsto & \begin{pmatrix} \Delta^1 & \to & X \\ (1-t,t) & \mapsto & \gamma(t) \end{pmatrix}. \end{array}$$

On many occasions we will use the trivial observation that for any path $\gamma\colon [0,1] \to X$ we have $\Phi(\overline{\gamma}) = \overline{\Phi(\gamma)}$.

Lemma 84.1. Let X be a topological space. If f and g are two paths in X such that the endpoint of f agrees with the starting point of g, then the singular 1-chains $\Phi(f) + \Phi(g)$ and $\Phi(f * g)$ are homologous.

Proof. The lemma follows quite easily from Lemma 72.3. We refer to the figure below for a sketch of the proof. We leave it to the reader to turn the sketch into a proper proof. ∎

Proposition 84.2. Let (X, x_0) be a pointed topological space.

(1) If γ is a loop in (X, x_0), then $\Phi(\gamma) \in \mathrm{C}_1(X)$ is a cycle.
(2) The map Φ induces a well-defined map

$$\begin{array}{rcl} \Phi_{(X,x_0)}\colon \pi_1(X,x_0) & \to & \mathrm{H}_1(X) \\ [\gamma\colon [0,1] \to X] & \mapsto & [\Phi(\gamma)]. \end{array}$$

(3) The map $\Phi_{(X,x_0)}\colon \pi_1(X,x_0) \to \mathrm{H}_1(X)$ is a group homomorphism.

(4) Let $x_1 \in X$ be some other point and let $\gamma\colon [0,1] \to X$ be a path from x_0 to x_1. We denote by

$$\begin{array}{rcl} \gamma_*\colon \pi_1(X,x_1) & \to & \pi_1(X,x_0) \\ [\varphi] & \mapsto & [\gamma * \varphi * \overline{\gamma}] \end{array}$$

the isomorphism that we introduced in the Change-of-Base Point Proposition 47.10. The following diagram commutes:

$$\begin{array}{ccc} \pi_1(X,x_1) & \xrightarrow{\Phi_{(X,x_1)}} & \\ \downarrow{\scriptstyle \gamma_*} & & \mathrm{H}_1(X). \\ \pi_1(X,x_0) & \xrightarrow{\Phi_{(X,x_0)}} & \end{array}$$

(5) Let *PTop* be the category of pointed topological spaces and let *Group* be the category of groups. The Hurewicz homomorphisms

$$\Phi_{(X,x_0)}\colon \pi_1(X,x_0) \to \mathrm{H}_1(X)$$

define a natural transformation from the functor

$$\begin{array}{rcl} \mathit{PTop} & \to & \mathit{Group} \\ (X,x_0) & \mapsto & \pi_1(X,x_0) \end{array} \quad \text{to the functor} \quad \begin{array}{rcl} \mathit{PTop} & \to & \mathit{Group} \\ (X,x_0) & \mapsto & \mathrm{H}_1(X). \end{array}$$

In plain English this means the following, given a map $f\colon X \to Y$ between topological spaces and given $x_0 \in X$ the following diagram commutes:

$$\begin{array}{ccc} \pi_1(X,x_0) & \xrightarrow{f_*} & \pi_1(Y,f(x_0)) \\ {\scriptstyle \Phi_{(X,x_0)}}\downarrow & & \downarrow{\scriptstyle \Phi_{(Y,f(x_0))}} \\ \mathrm{H}_1(X) & \xrightarrow{f_*} & \mathrm{H}_1(Y). \end{array}$$

Proof.

(1) The first statements follows immediately from the definitions and the description of $\partial_1\colon \mathrm{C}_1(X) \to \mathrm{C}_0(X)$ given on page 1585.

(2) We denote by $\sim$ the equivalence relation on $[0,1]$ that is generated by $0 \sim 1$. We denote by $\alpha\colon \Delta^1 \to [0,1]/\!\sim$ the map that is given by $\alpha(1-t,t) = [t]$. Note that α defines an element in $\mathrm{H}_1([0,1]/\!\sim)$. Now suppose that $f,g\colon [0,1] \to X$ are two path-homotopic loops in x_0. We denote by $\widetilde{f},\widetilde{g}\colon [0,1]/\!\sim \to X$ the induced maps. Then

$$[\Phi(f)] \underset{\substack{\uparrow \\ \text{since } \Phi(f) \text{ and } \widetilde{f}\circ\alpha \text{ are same map}}}{=} \left[\widetilde{f}\circ\alpha\right] = \widetilde{f}_*([\alpha]) \underset{\substack{\uparrow \\ \text{by the Homotopic Maps-and-Homology Proposition 73.6, since } \widetilde{f} \text{ and } \widetilde{g} \text{ are homotopic maps } [0,1]/\!\sim \to X}}{=} \widetilde{g}_*([\alpha]) = \left[\widetilde{g}\circ\alpha\right] = [\Phi(g)].$$

(3) The third statement is an immediate consequence of Lemma 84.1.

(4) This statement follows quite easily from Lemma 72.3.

(5) The last statement follows easily from the definitions. ∎

Definition. Given a pointed topological space (X,x_0) we refer to the homomorphism

$$\begin{array}{rcl} \Phi_{(X,x_0)}\colon \pi_1(X,x_0) & \to & \mathrm{H}_1(X) \\ [\gamma\colon [0,1] \to X] & \mapsto & [\Phi(\gamma)] \end{array}$$

as the Hurewicz homomorphism.[1008]

It is clear that the Hurewicz homomorphism is in general neither injective nor surjective:

(1) The Hurewicz homomorphism is in general not injective since $\pi_1(X, x_0)$ is in many cases a non-abelian group whereas $\mathrm{H}_1(X)$ is an abelian group, and it is not possible that a non-abelian group is a subgroup of an abelian group.
(2) The Hurewicz homomorphism is in general not surjective, since $\pi_1(X, x_0)$ depends only on the path-component of x_0, while $\mathrm{H}_1(X)$ "sees" all path-components of X. But as we will see in the next lemma, this turns out to be the only obstacle to Φ being surjective.

Proposition 84.3. Let X be a topological space and let $x_0 \in X$. If X is path-connected, then the Hurewicz homomorphism

$$\Phi_{(X,x_0)} \colon \pi_1(X, x_0) \ \to \ \mathrm{H}_1(X)$$

is surjective.

In the proof of Proposition 84.3 we will need the following lemma.

Lemma 84.4. Let X be a set and let $x_1, \ldots, x_k$ and $y_1, \ldots, y_l$ be elements in X. If

$$\sum_{i=1}^{k} x_i \ - \ \sum_{i=1}^{l} y_i \ = \ 0 \ \in \ \mathbb{Z}^{(X)},$$

then $k = l$ and there exists a permutation $s \in S_k$ such that $y_i = x_{s(i)}$ for $i = 1, \ldots, k$.

Proof. Let X be a set and let $x_1, \ldots, x_k$ and $y_1, \ldots, y_l$ be elements in X such that

$$\underbrace{\sum_{i=1}^{k} x_i}_{=:a} \ = \ \underbrace{\sum_{i=1}^{l} y_i}_{=:b} \quad \in \ \mathbb{Z}^{(X)}.$$

It follows from Lemma 51.1 that there exists a unique homomorphism $\psi \colon \mathbb{Z}^{(X)} \to \mathbb{Z}$ with the property that $\psi(x) = 1$ for all $x \in X$. By definition we have $\psi(a) = k$ and $\psi(b) = l$. So from $a = b$ we deduce that $k = l$.

Note that it follows from applying Lemma 51.1 once again that there exists a unique homomorphism $\psi \colon \mathbb{Z}^{(X)} \to \mathbb{Z}$ with the property that $\psi(x_k) = 1$ and $\psi(x) = 0$ for all $x \in X \setminus \{x_k\}$. By definition we have $\psi(a) > 0$. From $\psi(b) = \psi(a) > 0$ it follows that there exists an $n \in \{1, \ldots, k\}$ such that $y_n = x_k$. We define $s(k) = n$. We obtain an equality

$$\sum_{i=1}^{k-1} x_i \ = \ \sum_{i \in \{1,\ldots,k\} \setminus \{s(k)\}} y_i \ \in \ \mathbb{Z}^{(X)}$$

and we iterate this procedure to define $s(k-1), \ldots, s(1)$. By construction the map $s \colon \{1, \ldots, k\} \to \{1, \ldots, k\}$ is a bijection ∎

Proof of Proposition 84.3. We denote by Ψ the inverse of the above bijection

$$\Phi \colon \{\text{paths } [0,1] \to X\} \ \to \ \{\text{singular 1-simplices in } X\}$$

We pick a homology class $z \in \mathrm{H}_1(X)$. Let $c = \sum_{i=1}^{k} a_i \cdot \sigma_i$ be a cycle in $\mathrm{C}_1(X)$ that represents z. It follows from Lemma 72.3 that, after possibly replacing a singular chain σ_i by $\overline{\sigma}_i$, we can assume that all the coefficients a_i are positive. Furthermore, since we do not require that

[1008] Witold Hurewicz (1904-1956) was a Polish mathematician.

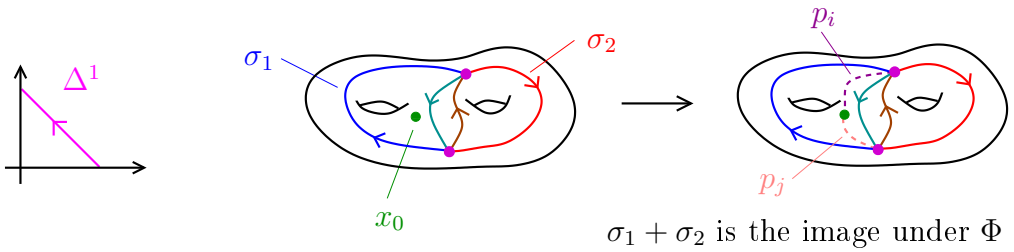
the σ_i's are different, we can in fact suppose that $a_1 = \cdots = a_k = 1$. Next note that we have

$$0 \underset{\uparrow}{=} \partial_1(c) = \partial_1\Big(\sum_{i=1}^{k}\sigma_i\Big) \underset{\uparrow}{=} \sum_{i=1}^{k}\sigma_i(0,1) - \sigma_i(1,0) = \sum_{i=1}^{k}\sigma_i(0,1) + \sum_{i=1}^{k} -\sigma_i(1,0).$$

since c is a cycle — see discussion on page 1585

On the right hand side each "positive summand" needs to cancel with a "negative summand". This means, see also Lemma 84.4, that there exists a permutation $\theta \in S_k$ such that for each i the "endpoint" $\sigma_i(0,1)$ of σ_i is just the "starting point" $\sigma_{s(i)}(1,0)$ of $\sigma_{s(i)}$.

Since X is path-connected we can choose for each $i \in \{1,\dots,k\}$ a path p_i from the base point x_0 to the starting point $\sigma_i(1,0)$ of σ_i.
We obtain the following equality in $\mathrm{H}_1(X)$:



$$\begin{aligned} c = \sum_{i=1}^{k}\sigma_i &\underset{\downarrow}{=} \sum_{i=1}^{k}\sigma_i + \sum_{i=1}^{k}\Phi(p_i) + \sum_{i=1}^{k}\Phi(\overline{p}_i) \underset{\downarrow}{=} \sum_{i=1}^{k}\big(\Phi(p_i) + \Phi(\Psi(\sigma_i)) + \Phi(\overline{p}_{s(i)})\big) \\ &= \sum_{i=1}^{k}\Phi\big(\underbrace{p_i * \Psi(\sigma_i) * \overline{p}_{s(i)}}_{\text{loop in } (X,x_0)}\big) = \Phi\Big(\underbrace{\prod_{i=1}^{k} p_i * \Psi(\sigma_i) * \overline{p}_{s(i)}}_{\text{loop in } (X,x_0)}\Big). \\ &\quad\uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\uparrow \end{aligned}$$

by Lemma 72.3 the singular chain $\Phi(p_i) + \Phi(\overline{p_i}) = \Phi(p_i) + \overline{\Phi(p_i)}$ is a null-homologous cycle

since $\Phi \circ \Psi = \mathrm{id}$ and since permutation of the summands does not change the sum

by Lemma 84.1 — by choice of s — by Lemma 84.1

Thus we have shown that $z = [c] \in \Phi(\pi_1(X,x_0))$. This concludes the proof that the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_1(X,x_0) \to \mathrm{H}_1(X)$ is surjective. ■

$\sigma_1 + \sigma_2$ is the image under Φ of the product of the blue and the red loop

In the following we want to study to what degree the Hurewicz homomorphism fails to be injective. Before we can do so we need to recall some definitions and results from Section 53.5.

Definition. Let π be a group.

(1) For $x, y \in \pi$ we denote by $[x,y] := xyx^{-1}y^{-1}$ the commutator of x and y.

(2) We refer to

$$[\pi,\pi] := \langle\langle \{[x,y] \mid x,y \in \pi\} \rangle\rangle = \Big\{ \prod_{i=1}^{n} [x_i,y_i] \,\Big|\, x_1,y_1,\dots,x_n,y_n \in \pi \Big\}$$

as the commutator subgroup of π.

(3) We refer to $\pi_{\mathrm{ab}} := \pi/[\pi,\pi]$ as the abelianization of π.

In Section 53.5 we saw that the abelianization is "the largest abelian quotient" of π. More precisely, if $\alpha\colon \pi \to H$ is a homomorphism from π to an abelian group H, then the

Abelianization Proposition 53.20 says that there exists a unique homomorphism $\beta\colon \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \to H$ such that the following diagram commutes:

$$\begin{array}{ccc} \pi & \longrightarrow & \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \\ & \searrow^{\alpha} & \downarrow{\scriptstyle \exists!\,\beta} \\ & & H. \end{array}$$

In particular, given a pointed topological space (X, x_0) the corresponding Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_1(X,x_0) \to \mathrm{H}_1(X)$ induces a homomorphism $\pi_1(X,x_0)_{\mathrm{ab}} \to \mathrm{H}_1(X)$ that we also denote by $\Phi_{(X,x_0)}$ and that we also refer to as the Hurewicz homomorphism. Now we can formulate the following proposition.

Theorem 84.5. (Hurewicz Theorem) Let (X, x_0) be a pointed topological space. If X is path-connected, then the Hurewicz homomorphism

$$\Phi_{(X,x_0)}\colon \pi_1(X,x_0)_{\mathrm{ab}} \;\to\; \mathrm{H}_1(X)$$

is a natural[1009] isomorphism.

Examples.

(1) If we compare our calculations of fundamental groups with our calculations of homology groups, then we see that we had encountered this isomorphism many times.
   (a) In Corollary 48.18 we showed that $\pi_1((S^1)^n) \cong \mathbb{Z}^n$, whereas on page 1744 we saw that $\mathrm{H}_1((S^1)^n) \cong \mathbb{Z}^n$.
   (b) For $n \geq 2$ we saw in Corollary 48.18 that $\pi_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$ and in Lemma 78.8 we had calculated that $\mathrm{H}_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$.
   (c) In the Fundamental Group-of-Surfaces Proposition 54.5 we showed that

$$\pi_1(\text{Klein bottle}) \;\cong\; \langle x, y \,|\, yxyx^{-1}\rangle.$$

   The abelianization of that group is isomorphic to $\mathbb{Z} \oplus \mathbb{Z}_2$ which is isomorphic to the first homology of the Klein bottle that we had determined in Lemma 78.12.
   (d) In the Fundamental Group-of-Surfaces Proposition 54.5 we showed that for any $g \in \mathbb{N}$ we have

$$\pi_1(\text{surface of genus } g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \,|\, [x_1,y_1]\cdot\cdots\cdot[x_g,y_g]\rangle.$$

   The abelianization of this group is isomorphic to $\mathbb{Z}^{2g}$ which is precisely the first homology group that we had determined in Proposition 80.10.
   (e) Let X be a path-connected topological space and let $f\colon X \to X$ be a homeomorphism. By the Mapping Torus-Homology Lemma 78.22 we know that there exists a short exact sequence

$$0 \;\to\; \operatorname{coker}\big(\mathrm{H}_1(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_1(X)\big) \;\xrightarrow{i}\; \mathrm{H}_1(\mathrm{Tor}(X,f)) \;\to\; \mathbb{Z} \;\to\; 0.$$

   On the other hand it follows from the Mapping Torus-π_1-Proposition 50.6 and the remark on page 1129 that there exists an isomorphism $\psi\colon \pi_1(\mathrm{Tor}(X,f)) \cong$

[1009] Whenever we write "natural" one needs to work out what the categories and functors are. In this case we consider the category of path-connected topological spaces, the category of groups and the functors $(X,x_0) \to \pi_1(X,x_0)_{\mathrm{ab}}$ and $(X,x_0) \mapsto \mathrm{H}_1(X)$.

$\pi_1(X) \rtimes \mathbb{Z}$ where the action of $1 \in \mathbb{Z}$ on $\pi_1(X)$ is induced by f. Therefore we can put $\pi_1(\mathrm{Tor}(X,f))$ into a short exact sequence

$$0 \;\to\; \pi_1(X) \;\to\; \pi_1(\mathrm{Tor}(X,f)) \;\to\; \mathbb{Z} \;\to\; 0$$

Now we apply the abelianization functor to these groups and homomorphisms. We obtain the exact sequence[1010]

$$\pi_1(X)_{\mathrm{ab}} \;\to\; \pi_1(\mathrm{Tor}(X,f))_{\mathrm{ab}} \;\to\; \mathbb{Z} \;\to\; 0$$

which, using the Hurewicz Theorem 84.5, we can rewrite as

$$\mathrm{H}_1(X) \;\to\; \mathrm{H}_1(\mathrm{Tor}(X,f)) \;\to\; \mathbb{Z} \;\to\; 0.$$

This is, fortunately, consistent with the above short exact sequence.

(2) Note that we now have a new, and depending on one's taste, more satisfying proof of the Knot Group-Abelianization Corollary 59.25: The Hurewicz Theorem 84.5 together with Lemma 78.13 implies that given any knot $K \subset S^3$ the abelianization of $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.

Proof of the Hurewicz Theorem 84.5. Let (X, x_0) be a pointed path-connected topological space. We write $\pi := \pi_1(X, x_0)$. By Proposition 84.2 we know that the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_{\mathrm{ab}} \to \mathrm{H}_1(X)$ is natural. Furthermore it follows from Proposition 84.3 that the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_{\mathrm{ab}} \to \mathrm{H}_1(X)$ is surjective. It remains to show that $\Phi_{(X,x_0)}$ is injective.

In the following we will make the identification $[0,1] = \Delta^1$ that is given by the homeomorphism $t \mapsto (1-t, t)$. In particular we will identify paths $[0,1] \to X$ with singular 1-simplices $\Delta^1 \to X$.

So let $f\colon [0,1] = \Delta^1 \to X$ be a loop in (X, x_0) such that $[f] = 0 \in \mathrm{H}_1(X)$. By definition this means that there exists a 2-chain $\sum_{j=1}^{s} n_j \sigma_j$ in X whose boundary is the singular 1-simplex f. Furthermore, since we do not demand that the σ_j are distinct, we can assume that all n_j are either -1 or 1. Given $j \in \{1, \dots, s\}$ and $k \in \{0,1,2\}$ we write[1011]

$$\mu_{(j,k)} := \sigma_j \circ i^2_k\colon [0,1] = \Delta^1 \to X \quad \text{ and } n_{(j,k)} := (-1)^k \cdot n_j.$$

We write $A = \{1, \dots, s\} \times \{0,1,2\}$. We have the following equality in $\mathrm{C}_1(X)$:

$$f \;=\; \partial_1\Big(\sum_{j=1}^{s} n_j \cdot \sigma_j\Big) \;\underset{\substack{\uparrow\\ \text{definition of } \partial_1}}{=}\; \sum_{j=1}^{s}\sum_{k=0}^{2} n_{(j,k)} \cdot \mu_{j,k} \;=\; \sum_{a \in A} n_a \cdot \mu_a.$$

By comparing the left and the right-hand side of this equality we see that there exists a $b \in A$ with $n_b \cdot \mu_b = 1 \cdot f$. We write $A_{\pm} = \{a \in A \setminus \{b\} \mid n_a = \pm 1\}$. Now we obtain from

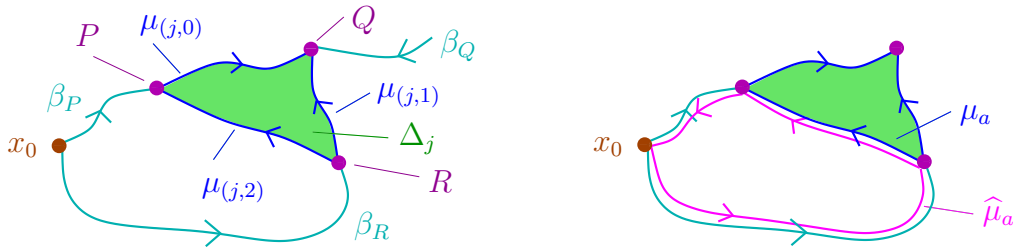
[1010] In Exercise 53.6 we saw that if $\varphi\colon A \to B$ is an epimorphism, then the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is also an epimorphism. We had also seen that there exist monomorphisms $\varphi\colon A \to B$ such that the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is not a monomorphism.

[1011] Recall that for $j \in \{0, \dots, n\}$ we denote by i^n_j the map

$$\begin{array}{rcl} i^n_j\colon \Delta^{n-1} & \to & \Delta^n \\ (t_0, \dots, t_{n-1}) & \mapsto & (t_0, \dots, t_{j-1}, 0, t_j, \dots, t_{n-1}). \end{array}$$

the above equality that

$$\sum_{a\in A_+}\mu_a \;+\; \sum_{a\in A_-}(-1)\cdot\mu_a \;=\; 0.$$



We make the following choices and introduce the following definitions:

(1) For each point P in X that is a starting or an endpoint of some μ_a we pick a path β_P from x_0 to P. For $P = x_0$ we just pick the constant path.

(2) Given $\mu_{(i,j)}\colon [0,1] = \Delta^1 \to X$ we write

$$\widehat{\mu}_{(i,j)} \;:=\; \beta_{\text{starting point of } \mu_{(i,j)}} * \mu_{(i,j)} * \overline{\beta}_{\text{endpoint of } \mu_{(i,j)}}.$$

Note that $\widehat{\mu}_{(i,j)}$ is a loop in (X, x_0), in particular it defines an element in the group $\pi = \pi_1(X, x_0)$ which, by a slight abuse of notation, we denote again by $\widehat{\mu}_{(i,j)}$.

We make the following elementary observation: for any $(i,j) \in \{1,\dots,s\}\times\{0,1,2\}$ we have the following equality in $\pi = \pi_1(X, x_0)$:

$$(*)\qquad \widehat{\mu}^{-1}_{(i,j)} \;:=\; \beta_{\text{starting point of } \overline{\mu}_{(i,j)}} * \overline{\mu}_{(i,j)} * \overline{\beta}_{\text{endpoint of } \overline{\mu}_{(i,j)}}.$$

In π_{ab} we have the following equalities:[1012]

$$e \;=\; \prod_{j=1}^{s} \beta_{\text{starting point of } \mu_{(j,0)}} * \Big(\overbrace{\mu_{(j,0)} * \overline{\mu}_{(j,1)} * \mu_{(j,2)}}^{\text{loop in the starting point of } \mu_{(j,0)}}\Big)^{n_j} * \overline{\beta}_{\text{starting point of } \mu_{(j,0)}}$$

$\uparrow$ since $\mu_{(j,0)} * \overline{\mu}_{(j,1)} * \mu_{(j,2)}$ is null-homotopic

$$= \prod_{j=1}^{s} \widehat{\mu}_{(j,0)}^{n_{(j,0)}} \cdot \widehat{\mu}_{(j,1)}^{n_{(j,1)}} \cdot \widehat{\mu}_{(j,2)}^{n_{(j,2)}} \qquad = \prod_{a\in\{1,\dots,k\}\times\{0,1,2\}} \widehat{\mu}_a^{n_a}$$

$\uparrow$ follows from inserting null-homotopic paths $\overline{\beta}_P * \beta_P$ together with the above equality $(*)$

$$= f \cdot \prod_{a\in A_-} \widehat{\mu}_a^{n_a} \cdot \widehat{\mu}_{\psi(a)}^{n_{\psi(a)}} \qquad = f \cdot \prod_{a\in A_-} \widehat{\mu}_a^{n_a} \cdot \widehat{\mu}_a^{-n_a} \;=\; f.$$

$\uparrow$ since $\{1,\dots,k\}\times\{0,1,2\} = (1,0) \sqcup A_- \sqcup \psi(A_-)$ since $\mu_{(1,0)} = f$ and since $\beta_{x_0} = c_{x_0}$

$\uparrow$ for $a \in A_-$ we have $\mu_{\psi(a)} = \mu_a$ and $n_a = -n_a$.

This completes the proof of the proposition.[1013] ■

For most topological spaces for which we had computed the fundamental group we had also determined the homology groups. But there is one rather interesting exception, namely the lens spaces. From Corollary 48.18 and the Hurewicz Theorem 84.5 we obtain immediately the following corollary.

[1012] In the notation we do not distinguish between loops and elements they represent in π_{ab}.

[1013] Where did we actually use that we work with π_{ab} instead of π?

Corollary 84.6. For any coprime $p, q \in \mathbb{N}$ we have

$$\mathrm{H}_1(\text{lens space } L(p,q)) \;\cong\; \mathbb{Z}_p.$$

Remark. The Hurewicz Theorem 84.5 is perhaps a mixed blessing. On the one hand it allows us to use the techniques that we had developed in earlier chapters to determine first homology groups. On the other hand it tells us that all the information that is contained in the first homology group is already contained in the fundamental group. So we do not get any new information. In particular, as we saw in Corollary 84.6, the first homology group cannot help us in our long-standing goal of distinguishing lens spaces with the same fundamental group.

Calculating (isomorphism types) of homology groups can get quite involved. But what is often even harder is to determine the maps on homology groups induced by maps between topological spaces. Using Proposition 84.2 (5) we can transfer calculations of induced maps on fundamental groups to obtain the corresponding induced maps on homology groups. For example we have the following lemma, which later on will be used on many occasions.

Lemma 84.7. (Action-on-Torus Homology Lemma) Let $n \in \mathbb{N}$. We denote by $T = \mathbb{R}^n/\mathbb{Z}^n = (S^1)^n$ the n-dimensional torus.

(1) We denote by $\sigma \in \mathrm{H}_1(S^1)$ the standard generator introduced on page 1677. Given $i \in \{1, \ldots, n\}$ we denote by

$$\begin{array}{rcl} p_i \colon S^1 & \to & (S^1)^n \\ z & \mapsto & (1, \ldots, 1, z, 1, \ldots, 1) \end{array}$$

the obvious i-th inclusion map. If we set $e_i := p_{i*}(\sigma)$, then $e_1, \ldots, e_n$ is a basis of $\mathrm{H}_1(T)$.

(2) Let $A \in \mathrm{GL}(n, \mathbb{Z})$ be a matrix. We denote by $T = \mathbb{R}^n/\mathbb{Z}^n$ the n-dimensional torus. By the Maps-on-Torus Lemma 19.37, the map

$$\begin{array}{rcl} f(A) \colon T = \mathbb{R}^n/\mathbb{Z}^n & \to & T = \mathbb{R}^n/\mathbb{Z}^n \\ [v] & \mapsto & [A \cdot v] \end{array}$$

is a homeomorphism. With respect to the above basis $e_1, \ldots, e_n$ of $\mathrm{H}_1(T)$ the induced map $f(A)_* \colon \mathrm{H}_1(T) \to \mathrm{H}_1(T)$ is given by multiplication by the matrix A.

Remark.

(1) In Exercise 117.6 we will study what self-maps of $H_2(S^2 \times S^2)$ can be realized by self-maps of $S^2 \times S^2$.

(2) Exercise 76.20 can be used to give an alternative proof of the Action-on-Torus Homology Lemma 84.7 (2).

Proof.

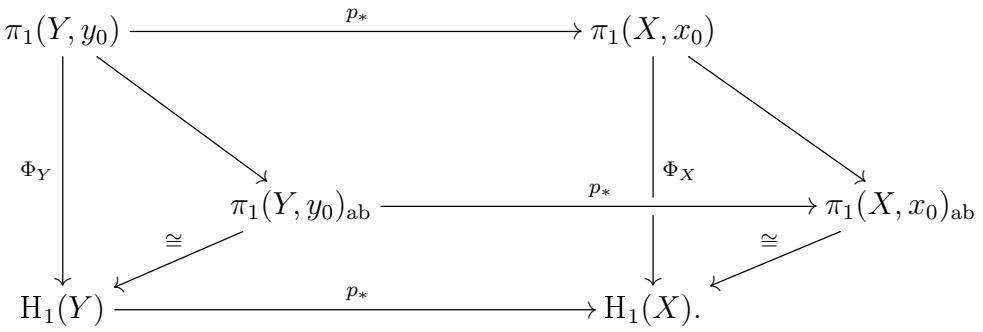
(1) This statement follows easily from the definitions, the Fundamental Group-via-Actions Theorem 48.16 and the Hurewicz Theorem 84.5.

(2) Let $\Theta\colon \pi_1(T,0) \to \mathbb{Z}^n$ be the isomorphism from the Fundamental Group-via-Actions Theorem 48.16. By Proposition 84.2 (5), the Fundamental Group-via-Actions Theorem 48.16 and Exercise 48.18 we obtain the following commutative diagram

$$\begin{array}{ccccc} \mathrm{H}_1(T) & \xleftarrow{\Phi_{(T,0)}} & \pi_1(T,0) & \xrightarrow[\cong]{\Theta} & \mathbb{Z}^n \\ {\scriptstyle f(A)}\downarrow & & \downarrow{\scriptstyle f(A)_*} & & \downarrow{\scriptstyle v\mapsto A\cdot v} \\ \mathrm{H}_1(T) & \xleftarrow{\Phi_{(T,0)}} & \pi_1(T,0) & \xrightarrow[\cong]{\Theta} & \mathbb{Z}^n. \end{array}$$

The desired statement follows from the observation that the horizontal isomorphism $\Theta \circ \Phi_{(T,0}\colon \mathrm{H}_1(T) \to \mathbb{Z}^n$ is precisely the one corresponding to the basis $e_1, \ldots, e_n$. ■

As another illustration of Proposition 84.2 (5) we also prove the following corollary.



Corollary 84.8. Let $p\colon Y \to X$ be a finite-index covering of path-connected topological spaces. Then the cokernel of the map

$$p_*\colon \mathrm{H}_1(Y) \;\to\; \mathrm{H}_1(X)$$

is finite.

Remark. Let $p\colon Y \to X$ be a finite-index covering of path-connected topological spaces. Let $y_0 \in Y$. By Corollary 48.14 the induced map $p_*\colon \pi_1(Y,y_0) \to \pi_1(X,p(y_0))$ is a monomorphism. On the other hand it is in general not true that the induced homomorphism $p_*\colon \mathrm{H}_1(Y) \to \mathrm{H}_1(X)$ is a monomorphism. For example on page 1070 we saw that there exists a 2-fold covering map $p\colon T \to K$ from the torus T to the Klein bottle K. By Lemmas 78.11 and 78.12 we know that $\mathrm{H}_1(T) \cong \mathbb{Z}^2$ and that $\mathrm{H}_1(K) \cong \mathbb{Z} \oplus \mathbb{Z}_2$. By Lemma 51.9 (2) there is no monomorphism from the group $\mathbb{Z}^2$ to $\mathbb{Z} \oplus \mathbb{Z}_2$.

Proof. We pick a base point y_0 of Y and we write $x_0 = p(y_0)$. We consider the following diagram of maps:

Here it follows from the Hurewicz Theorem 84.5 that the lower diagonal maps are isomorphisms. The "big rectangle in the back" commutes by Proposition 84.2 (5). The upper parallelogram commutes by the Abelianization Proposition 53.20 (7). Since the lower diagonal maps are isomorphisms it follows that the lower parallelogram also commutes.

By Lemma 48.15 and by our hypothesis that p is a finite covering we know that $p_*(\pi_1(Y,y_0))$ is a finite index subgroup of $\pi_1(X,x_0)$, i.e. $p_*\colon \pi_1(Y,y_0) \to \pi_1(X,x_0)$ has

a finite cokernel. It follows[1014] that $p_*\colon \pi_1(Y,y_0)_{\mathrm{ab}} \to \pi_1(X,x_0)_{\mathrm{ab}}$ also has a finite cokernel. From the commutativity of the lower parallelogram it follows immediately that the map $p_*\colon \mathrm{H}_1(Y) \to \mathrm{H}_1(X)$ has a finite cokernel as well. ■

Exercises for Chapter 84.

Exercise 84.1. Let $T = S^1 \times S^1$ be the torus. Let $\varphi, \psi\colon S^1 \to T$ be two smooth embeddings such that $\varphi_*([S^1]) = \psi_*([S^1]) \in \mathrm{H}_1(T)$. Show that φ and ψ are homotopic maps.

Exercise 84.2. Let $A \in \mathrm{SL}(2,\mathbb{Z})$. Prove the following statements:

(a) If $\mathrm{tr}(A) = 2$, then A is congruent over $\mathbb{Z}$ to a matrix of the form $\begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix}$.

(b) If $\mathrm{tr}(A) = 2$, then A is congruent over $\mathbb{Z}$ to a matrix of the form $\begin{pmatrix} -1 & * \\ 0 & -1 \end{pmatrix}$.

(c) If $\mathrm{tr}(A) \in (-2,2)$, then A is a matrix of finite order in the group $\mathrm{SL}(2,\mathbb{Z})$.

(d) If $\mathrm{tr}(A) \notin [-2,2]$, then A has two real eigenvalues λ, λ^{-1} with $|\lambda| > 1$.

Exercise 84.3. Let $A \in \mathrm{SL}(2,\mathbb{Z})$. We consider the map

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [A \cdot v] \end{array}$$

and following the definition on page 467 we consider the corresponding mapping torus

$$\mathrm{Tor}(\mathbb{R}^2/S^2, f(A)) \;=\; ((\mathbb{R}^2/S^2) \times [0,1])/(x,0) \sim (f(A)(v),1).$$

(a) Show that $\mathrm{Tor}(\mathbb{R}^2/S^2, f(A))$ is a closed oriented 3-dimensional smooth manifold.

(b) Determine $\mathrm{rank}(\mathrm{H}_1(\mathrm{Tor}(\mathbb{R}^2/S^2, f(A))$ and $\mathrm{H}_2(\mathrm{Tor}(\mathbb{R}^2/S^2, f(A))$ in terms of the classification of Exercise 84.2.
Remark. You might want to use the Mapping Torus-Homology Proposition 78.20 and the Action-on-Torus Homology Lemma 84.7.

Exercise 84.4. Let $p\colon S^1 \times S^1 \to S^1$ and $q\colon S^1 \times S^1 \to S^1$ be the projection onto the first respectively second factor and let $\mu\colon S^1 \times S^1 \to S^1$ be the multiplication map. Show that the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_1(S^1 \times S^1) & \xrightarrow{\quad\mu_*\quad} & \mathrm{H}_1(S^1). \\ & {\scriptstyle p_* \oplus q_*} \searrow \quad \nearrow {\scriptstyle (\varphi,\psi) \mapsto \varphi + \psi} & \\ & \mathrm{H}_1(S^1) \oplus \mathrm{H}_1(S^1) & \end{array}$$

Exercise 84.5. Let X and Y be path-connected topological spaces. Let $x \in X$ and let $y \in Y$. We denote by $i\colon X \to X \times Y$ the inclusion map that is given by $i(x) = (x,y)$ and similarly we denote by $j\colon Y \to X \times Y$ the inclusion map that is given by $j(y) = (x,y)$. Furthermore we denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the two natural projections Show that the map

$$i_* \oplus j_*\colon \mathrm{H}_1(X) \oplus \mathrm{H}_1(Y) \;\to\; \mathrm{H}_1(X \times Y)$$

[1014] This can be seen as follows: First we write $G = \pi_1(X,x_0)$ and $H = p_*(\pi_1(Y,y_0))$. Let $g_1, \ldots, g_k$ be coset representatives for G/H. One can easily verify that the images of $g_1, \ldots, g_k$ in G_{ab} have the property that $G_{\mathrm{ab}} = g_1 \mathrm{H}_{\mathrm{ab}} \cup \cdots \cup g_k \mathrm{H}_{\mathrm{ab}}$.

is an isomorphism and that the inverse is given by $p_* \oplus q_*$.
Hint. Use the Homotopy Groups-of-Product Proposition 71.8.

Exercise 84.6. Show that there exist maps $f, g\colon S^1 \times S^1 \to S^1 \times S^1$ such that $f \circ g$ and $g \circ f$ are not homotopic.
Remark. This exercise is the content of Exercise 38.5 (b). But with the methods of this chapter it is much easier to solve this exercise.

85. The Hurewicz Theorem in higher dimensions

The goal of this chapter is to formulate and prove the high-dimensional analogue of the Hurewicz Theorem 84.5 from Chapter 84. Furthermore in this chapter and in Chapter 86 we will discuss several applications of the higher-dimensional Hurewicz Theorem.

85.1. **The Hurewicz homomorphism in higher dimensions.** The Hurewicz Theorem 84.5 evidently raises the question whether there is a connection between higher homotopy groups and higher homology groups. As in the 1-dimensional case we first try to find a promising map from homotopy groups to homology groups.
Throughout the subsequent discussion the following notation is convenient.

Notation. We write $I = [0,1]$.

Next we introduce the following technical definition.

Definition. Let $n \in \mathbb{N}_0$. Let $\omega \in \mathrm{H}_n(\overline{B}^n, S^{n-1})$ be the standard generator as defined on page 1679. Let $\varphi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ be the homeomorphism from page 158. We refer to $\varphi_*(\omega) \in \mathrm{H}_n(I^n, \partial I^n)$ as the standard generator of $\mathrm{H}_n(I^n, \partial I^n)$.

Now comes the actual definition we are interested in.

Definition. Let X be a topological space, let $x_0 \in X$ and let $n \geq 1$. We denote by $\omega \in \mathrm{H}_n(I^n, \partial I^n)$ the standard generator as defined above. We refer to the map

$$\begin{array}{rcccc} & & & & \text{isomorphism since } n \geq 1\text{, see page 1629} \\ \Phi_{(X,x_0)}\colon \pi_n(X,x_0) & \to & \mathrm{H}_n(X,x_0) & \xleftarrow{\cong} & \mathrm{H}_n(X) \\ [f\colon (I^n,\partial I^n) \to (X,x_0)] & \mapsto & f_*(\omega) & & \end{array}$$

as the Hurewicz homomorphism.[1015]

Remark. It follows quite easily from the explicit description of the standard generator of $\mathrm{H}_1(\overline{B}^1, S^0)$ on page 1679 that for $n = 1$ the above definition of the Hurewicz homomorphism agrees with the definition given on page 1832.

In the next lemma we show in particular that the Hurewicz homomorphism is in fact a homomorphism.

Lemma 85.1.

(1) Let X be a topological space. Given any $x_0 \in X$ and given any $n \geq 1$ the Hurewicz homomorphism
$$\Phi_{(X,x_0)}\colon \pi_n(X,x_0) \to \mathrm{H}_n(X)$$
is a homomorphism.

[1015] It follows from the Homotopic Maps-and-Homology Proposition 73.6 that the Hurewicz homomorphism is indeed well-defined.

(2) Let X be a topological space and let $n \geq 1$. Furthermore let $\gamma\colon I \to X$ be a path from a point x_0 to some point x_1. The following diagram commutes:

$$\begin{array}{ccc} \pi_n(X, x_1) & \xrightarrow{\Phi_{(X,x_1)}} & \mathrm{H}_n(X) \\ {\scriptstyle \gamma_*}\downarrow & & \downarrow{\scriptstyle \mathrm{id}} \\ \pi_n(X, x_0) & \xrightarrow{\Phi_{(X,x_0)}} & \mathrm{H}_n(X). \end{array}$$

Here the vertical maps are defined in Propositions 47.10 and 71.5.

(3) As usual let *PTop* be the category of pointed topological spaces and let *Group* be the category of groups. The Hurewicz homomorphisms define a natural transformation from the functor

$$\begin{array}{ccc} \mathit{PTop} & \to & \mathit{Group} \\ (X, x_0) & \mapsto & \pi_n(X, x_0) \end{array} \quad \text{to the functor} \quad \begin{array}{ccc} \mathit{PTop} & \to & \mathit{Group} \\ (X, x_0) & \mapsto & \mathrm{H}_n(X). \end{array}$$

(4) Let X be a topological space, let $x_0 \in X$ and let $n \geq 1$. If we take the point of view from page 1565, i.e. if we view elements in $\pi_n(X, x_0)$ as homotopy classes of maps $(S^n, *) \to (X, x_0)$, then the Hurewicz homomorphism is given by the map

$$\begin{array}{ccc} \pi_n(X, x_0) & \to & \mathrm{H}_n(X) \\ [f\colon (S^n, *) \to (X, x_0)] & \mapsto & f_*(\omega) \end{array}$$

where $\omega \in \mathrm{H}_n(S^n)$ is the standard generator as defined on page 1677.

Proof.

(1) We denote by $\omega \in \mathrm{H}_n(I^n, \partial I^n)$ the standard generator. We need to show that for any two maps $f, g\colon (I^n, \partial I^n) \to (X, x_0)$ we have

$$[f_*(\omega)] + [g_*(\omega)] \;=\; [(f * g)_*(\omega)] \;\in\; \mathrm{H}_n(X, x_0).$$

But we showed precisely this equality in Lemma 79.12.

(2) Let $f\colon (S^n, *) \to (X, x_1)$ be a map. One easily sees that f and f^γ, viewed as maps $S^n \to X$ are homotopic. Thus it follows from the Homotopic Maps-and-Homology Proposition 73.6 that $f_*(\omega) = (f^\gamma)_*(\omega)$. But this means precisely that the given diagram commutes.

(3) This statement follows immediately from the functoriality of homology groups.

(4) This statement is a straightforward consequence of the Standard Generator-Relationship Proposition 76.5 (3). ∎

The following lemma gives in particular an affirmative answer to Question 71.17.

Lemma 85.2. For every $n \in \mathbb{N}$ the Hurewicz homomorphism

$$\Phi\colon \pi_n(S^n, *) \;\to\; \mathrm{H}_n(S^n) \cong \mathbb{Z}$$

sends $[\mathrm{id}_{S^n}\colon S^n \to S^n] \in \pi_n(S^n)$ to the standard generator of $\mathrm{H}_n(S^n)$, in particular the Hurewicz homomorphism is an epimorphism.

Proof. We denote by $\omega \in \mathrm{H}_n(S^n)$ the standard generator. By Lemma 85.1 (4) we have

$$\Phi(\underbrace{[\mathrm{id}_{S^n}\colon S^n \to S^n]}_{\in \pi_n(S^n, *)}) \;=\; (\mathrm{id}_{S^n})_*([\omega]) \;=\; [\omega].$$

Thus we see that the standard generator of $\mathrm{H}_n(S^n) \cong \mathbb{Z}$ lies in the image of the Hurewicz homomorphism. But this implies that the Hurewicz homomorphism $\Phi\colon \pi_n(S^n, *) \to \mathrm{H}_n(S^n)$ is an epimorphism. ■

The fairly simple-minded Lemma 85.2 actually already turns out to be quite useful. More precisely, we recall that for $\mathbb{A} = \mathbb{R}$ or $\mathbb{A} = \mathbb{C}$ and $k \leq l$ we can view $\mathbb{A}\mathrm{P}^k$ as a submanifold of $\mathbb{A}\mathrm{P}^l$. Now we can formulate the following application of Lemma 85.2.

Lemma 85.3. For $k < l$ the submanifold $\mathbb{R}\mathrm{P}^k$ is not a retract of $\mathbb{R}\mathrm{P}^l$.

Proof. We have

$$\pi_k(\mathbb{R}\mathrm{P}^k) \underset{\text{Coverings-}\pi_n\text{-Proposition 71.13}}{\cong} \pi_k(S^k) \overset{\text{Lemma 85.2}}{\neq} 0 \qquad \text{and} \qquad \pi_k(\mathbb{R}\mathrm{P}^l) \underset{\text{Coverings-}\pi_n\text{-Proposition 71.13}}{\cong} \pi_k(S^l) \overset{\text{Proposition 71.10}}{=} 0.$$

With this calculation, and the fact that π_n is functorial, the argument of Lemma 47.16 can be easily modified to show that $\mathbb{R}\mathrm{P}^k$ is not a retract of $\mathbb{R}\mathrm{P}^l$. ■

Lemma 85.3 raises the following question.

Question 85.4. Let $k < l$. Is the complex projective space $\mathbb{C}\mathrm{P}^k$ a retract of $\mathbb{C}\mathrm{P}^l$?

At this moment though, it is much more interesting to ask whether, given a path-connected topological space X and $n \geq 2$, the Hurewicz homomorphism

$$\Phi_{(X,x_0)}\colon \pi_n(X, x_0) \to \mathrm{H}_n(X)$$

is necessarily an isomorphism. But browsing through our examples shows that the Hurewicz homomorphism is in general neither a monomorphism nor an isomorphism:

(1) In Lemma 78.11 we showed that $\mathrm{H}_2(S^1 \times S^1) \cong \mathbb{Z}$ is non-zero, whereas on page 1573 we showed that $\pi_2(S^1 \times S^1) = 0$. This shows that the Hurewicz homomorphism $\pi_2(S^1 \times S^1) \to \mathrm{H}_2(S^1 \times S^1)$ is not an epimorphism.

(2) Here are two examples that show that in general the Hurewicz homomorphism is not a monomorphism:
   (a) We consider $X = \mathbb{R}\mathrm{P}^2$. By the Coverings-$\pi_n$-Proposition 71.13 and Lemma 85.2 we know that $\pi_2(\mathbb{R}\mathrm{P}^2) \cong \pi_2(S^2)$ is non-trivial. On the other hand we saw in Lemma 78.8 that $\mathrm{H}_2(\mathbb{R}\mathrm{P}^2) = 0$.
   (b) We consider $X = S^1 \vee S^2$. It follows immediately from Propositions 74.4 and 79.8 that $\mathrm{H}_2(S^1 \vee S^2) \cong \mathbb{Z}$. On the other hand we know by the Coverings-π_n-Proposition 71.13 and the discussion on page 1373 that $\pi_2(S^1 \vee S^2)$ is isomorphic to $\pi_2(\widetilde{X})$ where $\widetilde{X}$ is the real line "with infinitely many 2-spheres attached", see e.g. the figure on page 1573 for an illustration. Using the projections onto the various spheres and using Lemma 85.2 one can now show that $\pi_2(\widetilde{X})$ admits an epimorphism onto $\mathbb{Z}^\infty$.[1016] It follows from Lemma 51.9 (2) that there is no monomorphism from $\pi_2(X) = \pi_2(\widetilde{X})$ into $\mathrm{H}_2(X) \cong \mathbb{Z}$. In particular the Hurewicz homomorphism $\pi_2(X) \to \mathrm{H}_2(X)$, whatever it is precisely, cannot be a monomorphism.

The above examples show that we need to put some hypothesis on X for a higher Hurewicz homomorphism to be an isomorphism. This leads us to the following definition.

[1016] The proof of this statement is a slight variation on the proof of Exercise 71.3.

Definition. Let $k \in \mathbb{N}_0$. We say that a topological space X is k-connected, if $\pi_i(X) = 0$ for $i = 0, \dots, k$.[1017][1018]

The goal of this chapter is to prove the following theorem which can be viewed as the high-dimensional analogue of the original Hurewicz Theorem 84.5.

Theorem 85.5. (Hurewicz Theorem) Let (X, x_0) be a pointed topological space. Furthermore let $n \in \mathbb{N}_{\geq 2}$. If X is $(n-1)$-connected[1019], then the following two statements hold:

(1) we have $\widetilde{\mathrm{H}}_k(X; \mathbb{Z}) = 0$ for $k = 0, \dots, n-1$, and
(2) the Hurewicz homomorphism $\Phi_{(X,x_0)} \colon \pi_n(X, x_0) \to \mathrm{H}_n(X; \mathbb{Z})$ is an isomorphism.

Remark.

(1) On page 1844 we already saw that in general the hypothesis in the Hurewicz Theorem 85.5 that X is $(n-1)$-connected cannot be dropped.
(2) In Theorem 153.13 we will prove a relative version of the Hurewicz Theorem 85.5 that relates "relative homotopy groups" to relative homology groups.
(3) In Theorem 163.26 we will prove an addendum to the Hurewicz Theorem 85.5, which contains information on the map $\pi_{n+1}(X, x_0) \to \mathrm{H}_{n+1}(X; \mathbb{Z})$.

Using the Hurewicz Theorem 85.5 we can now determine some homotopy groups that had been eluding us for a long time.

Corollary 85.6.

(1) For any $n \in \mathbb{N}$ we have $\pi_n(S^n) \cong \mathbb{Z}$, in fact $\pi_n(S^n, *) = \mathbb{Z} \cdot [\mathrm{id}_{S^n}]$.
(2) For any $n \in \mathbb{N} \cup \{\infty\}$ we have $\pi_2(\mathbb{C}\mathrm{P}^n) \cong \mathbb{Z}$. In fact, if we make the identification $\mathbb{C}\mathrm{P}^1 = S^2$ from page 258 and if we use the convention from page 256 to consider $\mathbb{C}\mathrm{P}^1 = S^2$ as a subspace of $\mathbb{C}\mathrm{P}^n$, then $\pi_2(\mathbb{C}\mathrm{P}^n, *) = \mathbb{Z} \cdot [\mathrm{id}_{\mathbb{C}\mathrm{P}^1}]$.

Proof.

(1) Let $n \in \mathbb{N}$. By Proposition 71.10 we know that S^n is $(n-1)$-connected. Thus the statement follows immediately from the Hurewicz Theorems 84.5 and 85.5 and the fact that $\mathrm{H}_n(S^n; \mathbb{Z}) = \mathbb{Z} \cdot [S^n]$.
(2) Let $n \in \mathbb{N} \cup \{\infty\}$. We denote by $i \colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^n$ the obvious inclusion. From Lemma 85.1 (3) we obtain the following commutative diagram

$$\begin{array}{ccc} \pi_2(\mathbb{C}\mathrm{P}^1, *) & \xrightarrow{i_*} & \pi_2(\mathbb{C}\mathrm{P}^n, *) \\ {\scriptstyle \Phi_{(\mathbb{C}\mathrm{P}^1,*)}}\downarrow & & \downarrow{\scriptstyle \Phi_{(\mathbb{C}\mathrm{P}^n,*)}} \\ \mathrm{H}_2(\mathbb{C}\mathrm{P}^1; \mathbb{Z}) & \xrightarrow{i_*} & \mathrm{H}_2(\mathbb{C}\mathrm{P}^n; \mathbb{Z}). \end{array}$$

If $n \in \mathbb{N}$, then it follows immediately from Lemma 121.6 that the inclusion induced map $\mathrm{H}_2(\mathbb{C}\mathrm{P}^1; \mathbb{Z}) \to \mathrm{H}_2(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$ is an isomorphism. For $n = \infty$ we need to appeal to the discussion on page 1772 to draw the same conclusion. Finally, since $[\mathbb{C}\mathrm{P}^1] = [S^2]$

[1017] For example, X is 0-connected if and only if X is path-connected and *non-empty*. Furthermore, X is 1-connected if and only if it is simply connected.
[1018] Since a k-connected space is in particularly 0-connected and thus path-connected we see that we can ignore base points.
[1019] Recall that by the definition on page 1845 this means that $\pi_i(X) = 0$ for $i = 0, \dots, n-1$.

is a generator of $\mathrm{H}_2(\mathbb{C}\mathrm{P}^1;\mathbb{Z}) = \mathrm{H}_2(S^2;\mathbb{Z})$ we obtain that $\pi_2(\mathbb{C}\mathrm{P}^n,*) = \mathbb{Z}\cdot[\mathrm{id}_{\mathbb{C}\mathrm{P}^1}]$ from the above commutative diagram. ■

On several occasions we will also need the following straightforward corollary to the Hurewicz Theorem 85.5.

Corollary 85.7. (Hurewicz Corollary) Let (X,x_0) be a pointed topological space and let $n\in\mathbb{N}$. We suppose that X is simply connected. If given every $k\in\{2,\dots,n\}$ we have $\pi_k(X,x_0)=0$ or $\mathrm{H}_k(X;\mathbb{Z})=0$, then the following two statements hold:

(1) for $k=1,\dots,n$ we have $\pi_k(X,x_0)=\mathrm{H}_k(X;\mathbb{Z})=0$,

(2) the Hurewicz homomorphism $\pi_{n+1}(X,x_0)\to\mathrm{H}_{n+1}(X;\mathbb{Z})$ is an isomorphism.

Proof. We prove the corollary by induction on n. First consider the case $n=1$. Since X is simply connected we obtain from the Hurewicz Theorem 84.5 that $\mathrm{H}_1(X;\mathbb{Z})=0$. Furthermore it follows from the Hurewicz Theorem 85.5 that $\Phi_{(X,x_0)}\colon\pi_2(X,x_0)\to\mathrm{H}_2(X;\mathbb{Z})$ is an isomorphism.

Now suppose the statement holds for $n-1$ with $n\geq 2$. Suppose that for every $k\in\{2,\dots,n\}$ we have $\pi_k(X)=0$ or $\mathrm{H}_k(X;\mathbb{Z})=0$. By induction we know that the homotopy and homology groups vanish up to degree $n-1$. Thus we can apply the Hurewicz Theorem 85.5 which says that $\pi_n(X)$ and $\mathrm{H}_n(X;\mathbb{Z})$ are isomorphic. Since one is zero, both are zero. Hence we can apply the Hurewicz Theorem 85.5 once more to see that the Hurewicz homomorphism $\pi_{n+1}(X,x_0)\to\mathrm{H}_{n+1}(X;\mathbb{Z})$ is an isomorphism. ■

As a nice application to the Hurewicz Corollary 85.7 we can prove the following lemma.

Lemma 85.8. Let X be a 1-dimensional CW-complex and let $x_0\in X$ be base point. Then $\pi_n(X,x_0)=0$ for every $n\geq 2$.

The content of this lemma is the same as for Lemma 71.15, the only difference is that this time the proof is more satisfying than before.

Proof. Let X be a 1-dimensional CW-complex, let $n\geq 2$ and let $x_0\in X$ be a base point. If necessary we can replace X by the path-component of x_0. In other words, without loss of generality we can assume that X is path-connected. We denote by $\widetilde{X}$ the universal covering of X. By the CW-complex Covering Proposition 68.37 we know that $\widetilde{X}$ is again a 1-dimensional CW-complex. It follows from the Homology-of-CW-Complex Proposition 80.6 (1) that $\mathrm{H}_n(\widetilde{X})=0$ for all $n\in\mathbb{N}_{\geq 2}$. Furthermore, by definition of a universal covering we know that $\widetilde{X}$ is simply connected. It follows from the Hurewicz Corollary 85.7 that $\pi_n(X,x_0)=0$ for every $n\geq 2$. ■

We conclude this section with the following proposition.

Proposition 85.9. Let $n\in\mathbb{N}$ and let $f\colon S^n\to S^n$ be a homeomorphism with $f(*)=*$. Then the following equality holds in $\pi_n(S^n,*)$:

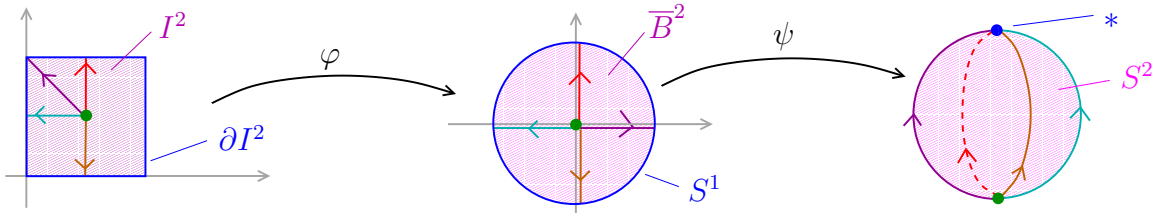
$$[f] \;=\; \begin{cases} [\mathrm{id}_{S^n}], & \text{if } f \text{ is orientation-preserving,} \\ -[\mathrm{id}_{S^n}], & \text{if } f \text{ is orientation-reversing.} \end{cases}$$

Remark. Let $n\in\mathbb{N}$. Proposition 85.9 says that every orientation-preserving self-homeomorphism f of S^n with $f(*)=*$ is *homotopic*, rel the base point $*$, to the identity. It is not clear to me whether f is *isotopic*, rel the base point $*$, to the identity. Put differently, can one find a homotopy F from f to id such that each $F_t\colon S^n\to S^n$ is also a homeomorphism?

Proof. Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a homeomorphism with $f(*) = *$. By the naturality of the Hurewicz homomorphism, see Lemma 85.1 (3), we have the following commutative diagram

$$\begin{array}{ccc} \pi_n(S^n,*) & \xrightarrow{f_*} & \pi_n(S^n,*) \\ {\scriptstyle \Phi_{(S^n,*)}}\downarrow & & \downarrow{\scriptstyle \Phi_{(S^n,*)}} \\ \mathrm{H}_n(S^n;\mathbb{Z}) & \xrightarrow{f_*} & \mathrm{H}_n(S^n;\mathbb{Z}). \end{array}$$

By Proposition 71.10 we know that S^n is $(n-1)$-connected. Therefore the vertical maps are isomorphisms by the Hurewicz Theorems 84.5 and 85.5. The corollary now follows from Proposition 107.2 and the simple observation that $[f] = f_*([\mathrm{id}_{S^n}]) \in \pi_n(S^n,*)$. ■



Now that we are fully convinced of the value of the Hurewicz Theorem 85.5 we turn to the proof thereof. We will discuss more applications in the Chapter 86.

85.2. **The group structure on $\pi_n(X,x_0)$.** Before we turn to the formulation of the high-dimensional Hurewicz Theorem we want to recall some conventions regarding higher homotopy groups and we want to introduce a useful approach to understanding the sum operation in the higher homotopy groups.
First we recall some conventions and notations that apply to any $n \in \mathbb{N}$.

(1) We write $* = (0,\dots,0,1) \in S^n$.
(2) We write $I = [0,1]$.
(3) We denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$.
(4) We denote by ∂I^n the boundary of I^n viewed as a subset of $\mathbb{R}^n$.
(5) Let $\varphi\colon (I^n,\partial I^n) \to (\overline{B}^n, S^{n-1})$ be the homeomorphism from page 158.
(6) Let $\psi\colon (\overline{B}^n, S^{n-1}) \to (S^n,*)$ be the map from Lemma 5.20 that induces the usual identification $\overline{B}^n/S^{n-1} \to S^n$.
(7) As on page 1565 we use φ and ψ to make the identifications

$$\pi_n(X,x_0) = \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (I^n,\partial I^n)\to(X,x_0)\\ \| \\ \text{set (of homotopy classes)}\\ \text{of maps } (\overline{B}^n, S^{n-1})\to(X,x_0).\end{array} = \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (S^n,*)\to(X,x_0)\end{array}$$

The maps φ and ψ are illustrated in the figure below.

Now let (X,x_0) be a pointed topological space and let $n \in \mathbb{N}$. Recall that on page 1561 we defined the group structure on $\pi_n(X,x_0)$ by considering elements in the homotopy groups as homotopy classes of maps $(I^n,\partial I^n) \to (X,x_0)$. Under the above identifications it is at times difficult to see what the group structure actually looks like. We start out with considering inverses of homotopy classes.

Lemma 85.10. Let $n \in \mathbb{N}$ and let (X, x_0) be a pointed topological space.

(1) Let $f\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$ be a map. If $\rho\colon \overline{B}^n \to \overline{B}^n$ is the reflection in some hyperplane of $\mathbb{R}^n$, then $-[f] = [f \circ \rho] \in \pi_n(X, x_0)$.

(2) Let $f\colon (S^n, *) \to (X, x_0)$ be some map. If $\rho\colon S^n \to S^n$ is the reflection in some hyperplane of $\mathbb{R}^{n+1}$ that contains the line[1020] $\mathbb{R} \cdot (0, \dots, 0, 1)$, then we have the equality $-[f] = [f \circ \rho] \in \pi_n(X, x_0)$.[1021]

Proof.

(1) Let $\varphi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ be the homeomorphism from page 158 that we use to identify the two different points of view regarding the homotopy group $\pi_n(X, x_0)$. It follows from Proposition 71.1 (2) and from considering the definition of ρ that if ρ is the reflection in the $(x_2 = 0)$-hyperplane V, then $-[f] = [f \circ \rho]$.

Claim. If ψ is the reflection in some other hyperplane W, then ψ and ρ are homotopic as maps $(\overline{B}^n, S^{n-1}) \to (\overline{B}^n, S^{n-1})$.

Proof. The claim follows from Lemma 33.9. For the reader's convenience we recall the argument. First note that by the Orthogonal Action Lemma 5.26 (5) there exists an orthogonal matrix $A \in \mathrm{SO}(n)$ with $A \cdot V = W$. By the Matrix Group Path-Component Proposition 2.37 (3) we know that there exists a path $\gamma\colon [0,1] \to \mathrm{SO}(n)$ with $\gamma(0) = \mathrm{id}$ and $\gamma(1) = A$. The map

$$\begin{array}{rcl} \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (P, t) & \mapsto & \rho_{\gamma(t)\cdot V}(P) \end{array}$$

is the desired homotopy. ⊞

But this claim implies $[f \circ \psi] = [f \circ \rho]$ and thus we see that $[f \circ \psi] = -[f]$.

(2) This statement follows easily from Statement (1) and from considering the map $\psi\colon (\overline{B}^n, S^{n-1}) \to (S^n, *)$ from Lemma 5.20 that we use to identify the two different points of view regarding the homotopy group $\pi_n(X, x_0)$. ■

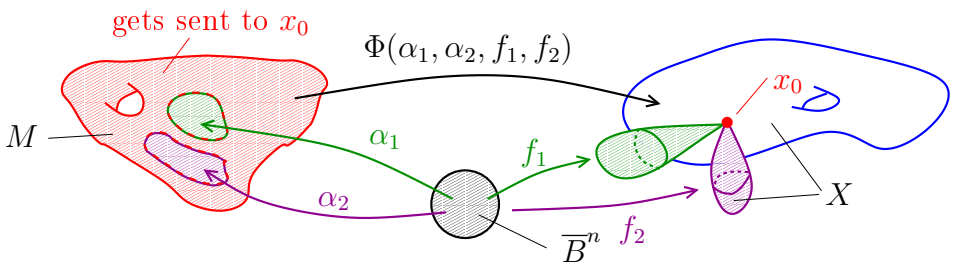
To consider the group structure on the higher homotopy groups we need the following new and fairly harmless definition.

Definition. Let $n \in \mathbb{N}$ and let M be an n-dimensional topological manifold.

(1) We say embeddings[1022] $\alpha_1, \dots, \alpha_m\colon \overline{B}^n \to M$ are (weakly) disjoint if the images (of the interiors) do not intersect.

(2) Let X be a topological space and let $x_0 \in X$. Given weakly disjoint embeddings $\alpha_1, \dots, \alpha_m\colon \overline{B}^n \to M$ and maps $f_1, \dots, f_m\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$ we define[1023]

$$\begin{array}{rcl} \Phi(\alpha_1, \dots, \alpha_m, f_1, \dots, f_m)\colon M & \to & X \\ y & \mapsto & \begin{cases} f_i(z), & \text{if } y = \alpha_i(z) \text{ with } z \in \overline{B}^n, \\ x_0, & \text{otherwise.} \end{cases} \end{array}$$



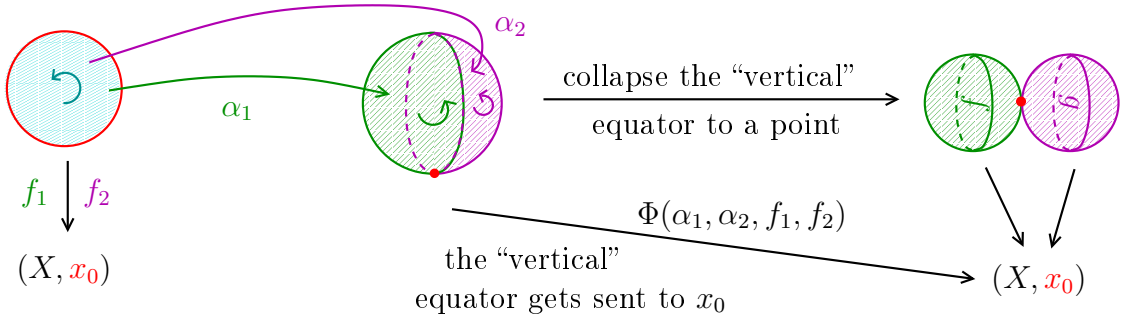
The following proposition gives a versatile tool for dealing with the group structure.

[1020] We can only consider such reflections since the point $* = (0, \dots, 0, 1)$ needs to be fixed.

[1021] Note that $\rho(*) = *$, hence $(f \circ \rho)(*) = x_0$.

[1022] We refer to page 718 for the definition of an embedding.

[1023] It follows from the Compact Image Lemma 2.13, the Closed-Compact Lemma 1.21, the Codimension-Zero Submanifold Proposition 19.38 and Pasting Proposition 2.6 (2) that this map is indeed continuous.



Proposition 85.11. (Addition-in-π_n-Proposition) Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. Suppose we are given weakly disjoint smooth embeddings[1024] $\alpha_1, \ldots, \alpha_m \colon \overline{B}^n \to S^n$ such that the images of the B^n lie in $S^n \setminus \{*\}$. Also suppose we are given maps $f_1, \ldots, f_m \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$. Given $i \in \{1, \ldots, m\}$ we write $\epsilon_i = 1$ if α_i is orientation-preserving otherwise we write $\epsilon_i = -1$. Then we have the following equality in $\pi_n(X, x_0)$:

$$\big[\underbrace{\Phi(\alpha_1, \ldots, \alpha_m, f_1, \ldots, f_m) \colon (S^n, *) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] = \sum_{i=1}^{m} \epsilon_i \cdot \big[\underbrace{f_i \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

Example. A slight modification of the map $\overline{B}^n \to S^n$ given in the Ball-Quotient Sphere Lemma 5.20 provides us with an orientation-preserving smooth embedding $\alpha_1 \colon \overline{B}^2 \to S^2$ that sends the disk to the "left hemisphere". Similarly we also obtain an orientation-preserving smooth embedding $\alpha_2 \colon \overline{B}^2 \to S^2$ that sends the disk to the "right hemisphere". It follows from the Addition-in-π_n-Proposition 85.11 that for any two maps $f_1, f_2 \colon (\overline{B}^2, S^1) \to (X, x_0)$ we have

$$[\Phi(\alpha_1, \alpha_2, f_1, f_2) \colon (S^2, *) \to (X, x_0)] = [f_1 \colon (\overline{B}^2, S^1) \to (X, x_0)] + [f_2 \colon (\overline{B}^2, S^1) \to (X, x_0)].$$

This situation is illustrated in the figure below. We obtain basically the same picture as we had already obtained on page 1566.

Remark. The statement of the Addition-in-π_n-Proposition 85.11 also holds for embeddings, i.e. we do not necessarily need that the embeddings are smooth. But in that case, in the proof below, one needs to replace the mainstream Smooth Ball Embedding Theorem 37.8 by the surprisingly difficult Theorem 132.10. In particular it is not clear to me

[1024] Note that here we work on purpose with "smooth embeddings" instead of "embeddings".

what goes into the proof of Theorem 132.10 (does it require the Hurewicz Theorem, are we in danger of using circular logic?). Therefore I prefer to stick to smooth embeddings.[1025]

In the proof of the Addition-in-π_n-Proposition 85.11 we need the following lemma which basically says the following: if we isotope the embeddings α_i, then the resulting Φ-maps are homotopic.

Lemma 85.12. Let $n \in \mathbb{N}$, let M be an n-dimensional smooth manifold and let Z be a subset of M. Furthermore suppose we are given a topological space X, a base point $x_0 \in X$ and maps $f_1, \ldots, f_m \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$. Finally suppose that for $i = 1, \ldots, m$ we are given homotopies

$$\Omega_i \colon \overline{B}^n \times [0,1] \ \to \ M \setminus Z$$

such that for each $t \in [0,1]$ the maps $\Omega_{1,t}, \ldots, \Omega_{m,t} \colon \overline{B}^n \to M$ are weakly disjoint embeddings, then the maps

$$\Phi(\underbrace{\Omega_{1,0}, \ldots, \Omega_{m,0}}_{\Omega \text{ at } t=0}, f_1, \ldots, f_m), \Phi(\underbrace{\Omega_{1,1}, \ldots, \Omega_{m,1}}_{\Omega \text{ at } t=1}, f_1, \ldots, f_m) \colon (M, Z) \ \to \ (X, x_0)$$

are homotopic as maps of pairs of topological spaces.

Proof. As before it follows from Lemmas 2.13 and 1.21, the Codimension-Zero Submanifold Proposition 19.38 and the Pasting Proposition 2.6 that the map

$$\begin{array}{rcl} H \colon M \times [0,1] & \to & X \\ (P,t) & \mapsto & \Phi(\Omega_{1,t}, \ldots, \Omega_{m,t}, f_1, \ldots, f_m)(P) \end{array}$$

is continuous. This map is then the desired homotopy. ∎

Sketch of a proof of the Addition-in-π_n-Proposition 85.11. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $f_1, \ldots, f_m \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$ be maps. Finally let $\alpha_1, \ldots, \alpha_m \colon \overline{B}^n \to S^n$ be weakly disjoint smooth embeddings such that the images of the B^n lie in $S^n \setminus \{*\}$. We start out with the following observations:

(1) Let $\rho \colon \overline{B}^n \to \overline{B}^n$ be the reflection in some hyperplane of $\mathbb{R}^n$. We replace every pair (α_i, f_i) for which α_i is orientation-reversing by the pair $(\alpha_i \circ \rho, f_i \circ \rho)$. It follows immediately from Lemma 85.10 that the desired equality holds for the new data if and only if it holds for the old data.

(2) If the α_i are not disjoint we make them disjoint by shrinking. More precisely, we consider the isotopies

$$\begin{array}{rcl} F_i \colon \overline{B}^n \times [0,1] & \to & M \\ (P,t) & \mapsto & \alpha_i(P \cdot (1 - \frac{t}{2})). \end{array}$$

Since the α_i were weakly disjoint we see that the resulting embeddings are now disjoint.

(3) In Lemma 5.20 we gave an explicit $(\overline{B}^n, S^{n-1}) \to (S^n, \{*\})$ and we showed that it restricts to a diffeomorphism $B^n \to S^n \setminus \{*\}$.

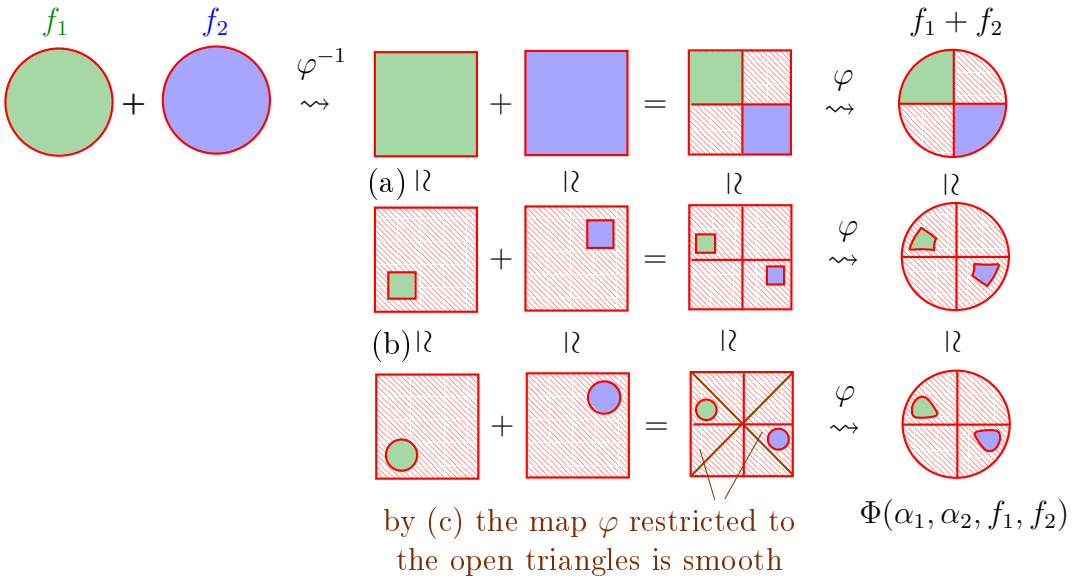
Keeping the above three observations in mind we obtain from Lemma 85.12 that it suffices to prove the following statement.

[1025] Recall that the absence of the word "topological" implies in our setup that smooth embeddings are smooth maps.

Statement. If $\alpha_1, \dots, \alpha_m \colon \overline{B}^n \to B^n$ are disjoint orientation-preserving smooth embeddings, then the following equality holds in $\pi_n(X, x_0)$:

$$\big[\underbrace{\Phi(\alpha_1, \dots, \alpha_m, f_1, \dots, f_m) \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] = \sum_{i=1}^{m} \big[\underbrace{f_i \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

Perhaps the key observation in the proof is that the Smooth Ball Embedding Theorem 37.8 (where we use our hypothesis that $n \geq 2$ and here we use that work with smooth embeddings not just embeddings of balls) together with Lemma 85.12 implies that we only need to prove the statement for a single choice of disjoint orientation-preserving smooth embeddings $\alpha_1, \dots, \alpha_m$. Put differently, it remains to prove the following claim.



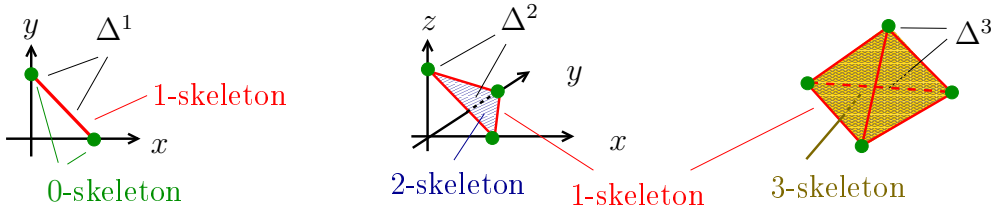
Claim. There are disjoint orientation-preserving smooth embeddings $\alpha_1, \dots, \alpha_m \colon \overline{B}^n \to B^n$ such that

$$\big[\underbrace{\Phi(\alpha_1, \dots, \alpha_m, f_1, \dots, f_m) \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] = \sum_{i=1}^{m} \big[\underbrace{f_i \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

Proof. By induction it suffices prove the claim for $m = 2$. Even your famously verbose author does not feel like spelling out all the details. We leave it to the reader to piece together the argument using the figure below and the following observations:

(a) by the Addition-in-π_n-Proposition 85.11 (or alternatively Lemma 71.2) we can "move cubes" in I^n,
(b) by Lemma 14.2 the map $\varphi^{-1} \colon \overline{B}^n \to I^n$ is isotopic to the identity,
(c) the restriction of the map $\varphi \colon I^n \to \overline{B}^n$ to each open cone on one of the sides of the cube I^n is smooth.

Using Lemma 85.12 these moves translate into homotopies of the corresponding maps. ■

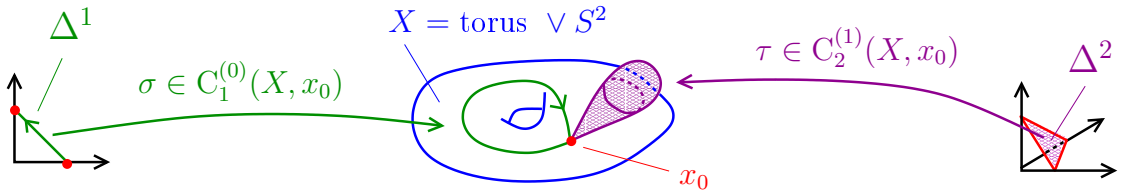


85.3. **The proof of the Hurewicz Theorem 85.5.** The proof of the Hurewicz Theorem 85.5 requires some preparations.

Convention. Let $k \in \mathbb{N}_0$. We view Δ^k as a CW-complex in the following way. Given $m \in \{0, \ldots, k\}$ the m-cells correspond precisely to all the maps

$$\begin{aligned} \overline{B}^m = \Delta^m &\to \Delta^k \\ (t_0, \ldots, t_m) &\mapsto \sum_{i=0}^{m} t_i e_{\varphi(i)} \end{aligned}$$

where φ is a strictly increasing map $\varphi\colon \{0, \ldots, m\} \to \{0, \ldots, k\}$. Note that the $(k-1)$-skeleton of Δ^k is given by $\partial\Delta^k$.



Definition. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_0$. Given $k \in \mathbb{N}_0$ we define[1026]

$$\mathrm{C}_k^{(n)}(X, x_0) := \begin{array}{l} \text{the subgroup of the relative chain group } \mathrm{C}_k(X, \{x_0\}) \text{ generated by} \\ \text{all singular simplices } \sigma\colon \Delta^k \to X \text{ with } \sigma(n\text{-skeleton of } \Delta^k) \subset \{x_0\}. \end{array}$$

These groups define a subcomplex of $\mathrm{C}_*(X, \{x_0\})$. In particular we obtain corresponding homology groups $\mathrm{H}_k^{(n)}(X, x_0)$ and the inclusion $\mathrm{C}_*^{(n)}(X, x_0) \to \mathrm{C}_*(X, \{x_0\})$ defines natural maps $\mathrm{H}_k^{(n)}(X, x_0) \to \mathrm{H}_k(X, \{x_0\})$.

Example. In the figure below we show a pointed topological space (X, x_0) and we consider an element $\sigma \in \mathrm{C}_1^{(0)}(X, x_0)$ and an element $\tau \in \mathrm{C}_2^{(1)}(X, x_0)$. From the pictures it becomes apparent that elements in $\mathrm{C}_n^{(n-1)}(X, x_0)$ are "close" to elements in $\pi_n(X, x_0)$. In particular it seems reasonable to expect that $\mathrm{H}_n^{(n-1)}(X, x_0)$ is a group that "sits between" $\mathrm{H}_n(X; \mathbb{Z})$ and $\pi_n(X, x_0)$.

In the following lemma we summarize a few basic facts about these new chain groups.

Lemma 85.13. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_0$. Furthermore let $k \in \{0, \ldots, n\}$. The following statements hold:

(1) We have $\mathrm{C}_k^{(n)}(X, x_0) = 0$,
(2) we have $\mathrm{H}_k^{(n)}(X, x_0) = 0$,
(3) any element in $\mathrm{C}_{k+1}^{(n)}(X, x_0)$ is a cycle.

[1026] Note that the notation $\mathrm{C}_k^{(n)}(X, x_0)$ instead of $\mathrm{C}_k^{(n)}(X, \{x_0\})$ is on purpose.

Proof. Let $k \in \{0, \dots, n\}$. Put differently, we have k with $n \geq k$. Note that this implies that Δ^k is the n-skeleton of Δ^k. In particular, by definition, $\mathrm{C}_k^{(n)}(X, x_0)$ is the subgroup of $\mathrm{C}_k(X, \{x_0\})$ generated by the constant maps $\Delta^k \to \{x_0\}$, but these are zero in the relative chain group $\mathrm{C}_k(X, \{x_0\})$. This concludes the proof of (1). The remaining two statements are immediate consequences of (1). ■

The following lemma is one of the key ingredients in the proof of the Hurewicz Theorem 85.5

Lemma 85.14. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}$. If X is n-connected, then the inclusion map

$$\mathrm{C}_*^{(n)}(X, x_0) \;\to\; \mathrm{C}_*(X, \{x_0\})$$

is a chain homotopy equivalence. In particular for any $k \in \mathbb{N}_0$ the induced map

$$\mathrm{H}_k^{(n)}(X, x_0) \;\to\; \mathrm{H}_k(X, \{x_0\})$$

is an isomorphism.

Proof. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}$. We suppose that X is n-connected. We recall the following notation from the Prism Boundary Lemma 73.7: given $t = 0$ and $t = 1$ and $k \in \mathbb{N}_0$ we denote by

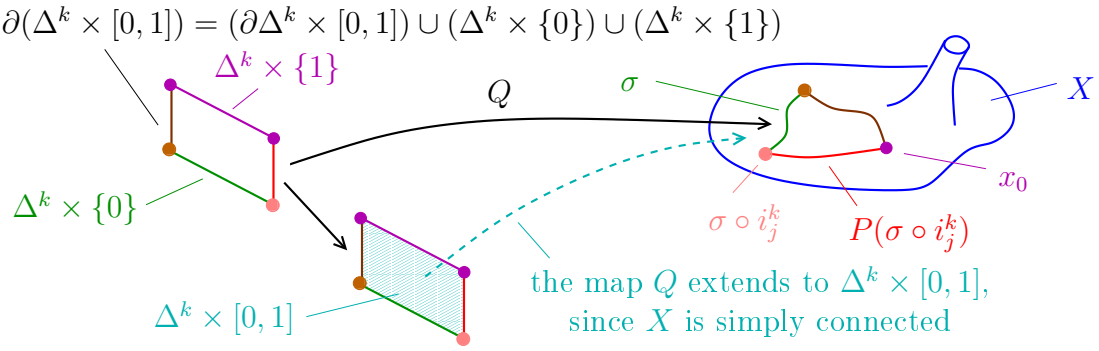
$$\begin{aligned} \eta_t \colon \Delta^k &\to \Delta^k \times [0,1] \\ x &\mapsto (x, t) \end{aligned}$$

the obvious inclusion map. We start out with the following claim which basically says that any singular simplices $\Delta^k \to X$ can be homotoped consistently to a singular simplices that lie in $\mathrm{C}_k^{(n)}(X, x_0)$.

Claim. Given any $k \in \mathbb{N}_0$ and given any singular simplex $\sigma \colon \Delta^k \to X$ we can choose a map $P(\sigma) \colon \Delta^k \times [0,1] \to X$ such that the following four statements are satisfied:

(a) we have $P(\sigma) \circ \eta_0 = \sigma \colon \Delta^k \to X$,
(b) the singular k-simplex $P(\sigma) \circ \eta_1 \colon \Delta^k \to X$ lies in $\mathrm{C}_k^{(n)}(X, x_0)$,
(c) if $\sigma \in \mathrm{C}_k^{(n)}(X, x_0)$, then $P(\sigma) = \sigma \circ \pi$ where $\pi \colon \Delta^k \times [0,1] \to \Delta^k$ is the projection , and
(d) for any $j \in \{0, \dots, k\}$ we have

$$P(\sigma) \circ \underbrace{(i_j^k \times \mathrm{id}_{[0,1]})}_{\Delta^{k-1}\times[0,1] \to \Delta^k \times [0,1]} \;=\; P(\underbrace{\sigma \circ i_j^k}_{\Delta^{k-1} \to X}) \colon \Delta^{k-1} \times [0,1] \to X.$$

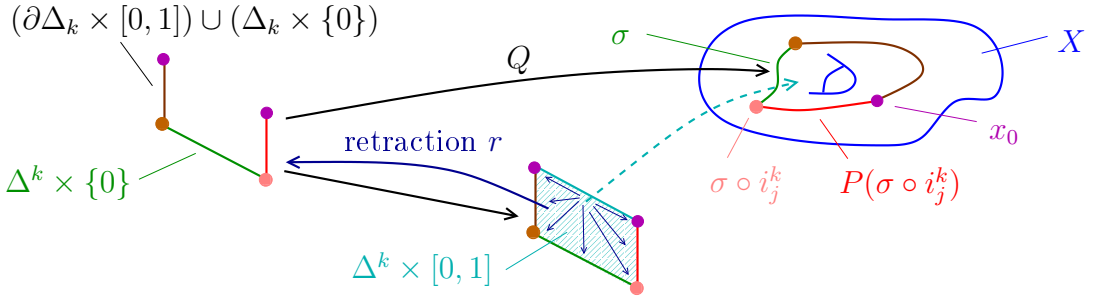


Proof. Property (d) already suggests that we should prove the claim by induction on k. It is convenient to view $k = -1$ as the (trivial) base case. Now let $k \in \mathbb{N}_0$ and suppose that we have proved the claim for all singular i-simplices with $i < k$. Now let $\sigma \colon \Delta^k \to X$ be a singular simplex. If $\sigma \in \mathrm{C}_k^{(n)}(X, x_0)$, then we set $P(\sigma) = \sigma \circ \pi$. In this case it is straightforward to verify that the conditions (a), (b) and (d) are satisfied.

Now consider the case that $\sigma \notin \mathrm{C}_k^{(n)}(X, x_0)$. We distinguish two cases.

(1) First we consider the case that $k \leq n$. By induction the maps $P(\sigma \circ i_j^k)$ have been defined for all j. We set $\partial(\Delta^k \times [0,1]) := (\partial\Delta^k \times [0,1]) \cup (\Delta^k \times \{0,1\})$ and we consider the map

$$Q \colon \partial(\Delta^k \times [0,1]) \;\to\; X$$



which is defined via σ on $\Delta^k \times \{0\}$, via the maps $P(\sigma \circ i^k_j)$ on $\partial\Delta^k \times [0,1]$[1027] and which sends all points in $\Delta^k \times \{1\}$ to x_0.[1028] (We refer to the figure below for an illustration of this map.) It follows almost immediately from the Convex-to-Ball Proposition 2.20 (2) that the pair $(\Delta^k \times [0,1], \partial(\Delta^k \times [0,1]))$ is homeomorphic to $(\overline{B}^{k+1}, S^k)$. Since $k \leq n$ and since X is n-connected we obtain from the Trivial-in-π_n-Lemma 71.4 that there exists an extension of Q to a map $\Delta^k \times [0,1] \to X$. We define $P(\sigma)$ to be any such extension. We obtain a map $P(\sigma)$ which is easily seen to have all the desired properties.

(2) Now we consider the case that $k > n$. Note that in this case condition (b) is satisfied "for free" by any map $\Delta^k \times [0,1] \to X$ that satisfies (d). Thus we only have to find a map $P(\sigma)$ that satisfies (a), (c) and (d). This is much easier than in (1). Indeed, similar to (1) we consider the map

$$G\colon (\Delta^k \times \{0\}) \cup (\partial\Delta^k \times [0,1]) \;\to\; X$$

that is defined via σ on $\Delta^k \times \{0\}$ and via the maps $P(\sigma \circ i^k_j)$ on $\partial\Delta^k \times [0,1]$. (We refer to the figure below for an illustration.) Note that by Lemma 70.6 (together with the homeomorphism $\overline{B}^k \cong \Delta^k$) there exists a retraction r from $\Delta^k \times [0,1]$ to the domain of G. Thus combining this retraction r with Q we obtain an extension of Q to map $\Delta^k \times [0,1] \to X$. We define $P(\sigma)$ to be this extension. It follows basically by construction that all the statements are satisfied. ⊞

[1027] Here we use that we assume that the maps $P(\mu)$ are defined for simplices of dimension $< k$.
[1028] It follows from Pasting Proposition 2.6 (2′) that this map is indeed continuous.

Now we turn to the actual proof of the statement that the inclusion map[1029]

$$\iota\colon \mathrm{C}_*^{(n)}(X,x_0) \;\to\; \mathrm{C}_*(X,\{x_0\})$$

is a chain homotopy equivalence. To do so we consider the map

$$\begin{aligned}\phi\colon \mathrm{C}_*(X,\{x_0\}) &\to \mathrm{C}_*^{(n)}(X,x_0)\\ (\sigma\colon \Delta^n\to X) &\mapsto \phi(\sigma) := \underbrace{P(\sigma)\circ\eta_1}_{\Delta^k\to\Delta^k\times[0,1]\to X}.\end{aligned}$$

that is determined by

It follows from (b) that ϕ does indeed take values in $\mathrm{C}_*^{(n)}(X,x_0)$ and it follows easily from (d) that ϕ is in fact a chain map. We want to show that ϕ is a chain homotopy inverse to ι. By (c) we have $\phi\circ\iota = \mathrm{id}$. Thus it remains to prove the following claim.

Claim. There exists a chain homotopy from $\iota\circ\phi$ to the identity of $\mathrm{C}_*(X,\{x_0\})$.

Proof. Let $k\in\mathbb{N}_0$. We recall that on page 1605 we introduced the singular $(k+1)$-chain

$$\Omega_k \;:=\; \sum_{j=0}^{k}(-1)^j\cdot\underbrace{[v_0,\dots,v_j,w_j,\dots,w_k]}_{\Delta^{k+1}\to\Delta^k\times[0,1]} \;\in\; \mathrm{C}_{k+1}(\Delta^k\times[0,1])$$

where $v_0,\dots,v_k,w_0,\dots,w_k$ denote the vertices of $\Delta^k\times[0,1]$, see page 1605 for details. The key property of these singular chains is that the Prism Boundary Lemma 73.7 says that for any $k\in\mathbb{N}_0$ we have

$$(*)\qquad \partial_{k+1}(\Omega_k)+\sum_{j=0}^{k}(-1)^j\cdot\underbrace{(i_j^k\times\mathrm{id}_{[0,1]})_*}_{\mathrm{C}_*(\Delta^{k-1}\times[0,1])\to\mathrm{C}_*(\Delta^k\times[0,1])}(\Omega_{k-1}) \;=\; \eta_1-\eta_0 \;\in\; \mathrm{C}_k(\Delta^k\times[0,1]).$$

For any $k\in\mathbb{N}_0$ we consider the map

$$\begin{aligned}D_k\colon \mathrm{C}_k(X,\{x_0\}) &\to \mathrm{C}_{k+1}(X,\{x_0\})\\ (\sigma\colon\Delta^k\to X) &\mapsto \underbrace{P(\sigma)_*}_{\mathrm{C}_*(\Delta^k\times[0,1])\to\mathrm{C}_*(X,\{x_0\})}(\underbrace{\Omega_k}_{\in\mathrm{C}_{k+1}(\Delta^k\times[0,1])}).\end{aligned}$$

that is determined by

We claim that these maps define a chain homotopy from $\iota\circ\phi$ to the identity of $\mathrm{C}_*(X,\{x_0\})$. Thus let $\sigma\colon\Delta^k\to X$ be a singular k-simplex. We need to show that $\partial D\sigma + D\partial\sigma = \phi(\sigma)-\sigma$. Indeed we have

$$\begin{aligned}\partial_{k+1}(D_k(\sigma))+D_{k-1}(\partial_k(\sigma)) &= \partial_{k+1}(D_k(\sigma))+D_{k-1}\Big(\sum_{j=0}^{k}(-1)^j\cdot\sigma\circ i_j^k\Big)\\ &= \partial_{k+1}(P(\sigma)_*(\Omega_k))+\sum_{j=0}^{k}(-1)^j\cdot P(\sigma\circ i_j^k)_*(\Omega_{k-1})\\ &\underset{\uparrow}{=} P(\sigma)_*\Big(\partial_{k+1}(\Omega_k)+\sum_{j=0}^{k}(-1)^j\cdot(i_j^k\times\mathrm{id}_{[0,1]})_*(\Omega_{k-1})\Big)\end{aligned}$$

in the first summand we used that $P(\sigma)_*$ is a chain map and
in the second summand we used that by (d) we have $P(i_j^k\circ\sigma) = P(\sigma)\circ(i_j^k\times\mathrm{id}_{[0,1]})$

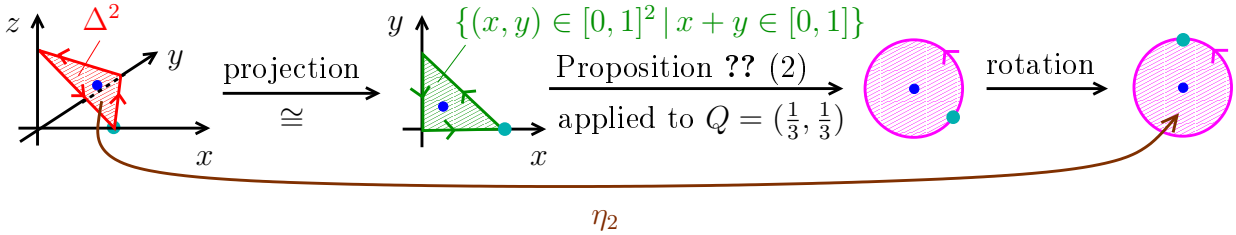
$$\begin{aligned}&\underset{\uparrow}{=} P(\sigma)_*(\eta_1-\eta_0) \;=\; P(\sigma)\circ\eta_1 - P(\sigma)\circ\eta_0 \underset{\uparrow}{=} \phi(\sigma)-\sigma.\end{aligned}$$

by the above equality $(*)$ by (a) and definition of ϕ ∎

[1029]Here and throughout the proof we do not distinguish in the notation between a singular chain in $\mathrm{C}_k(X)$ and the element it represents in $\mathrm{C}_k(X,\{x_0\})$.

Before we can continue with the proof of the Hurewicz Theorem 85.5 we need to introduce another, slightly different point of view, regarding higher homotopy groups.

Convention. So let $n \in \mathbb{N}$. We consider the homeomorphism $\eta_n \colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ that is given by the composition of the following three maps:[1030]



$$\eta_n \colon \Delta^n \xrightarrow{\cong} \left\{(x_1, \ldots, x_n) \in [0,1]^n \;\middle|\; \sum_{i=1}^{n} x_i \in [0,1]\right\} \xrightarrow[\text{with } Q = (\frac{1}{n+1}, \ldots, \frac{1}{n+1})]{\text{Proposition 2.20 (2)}} \overline{B}^n \xrightarrow[\text{by } A_n]{\text{multiplication}} \overline{B}^n.$$
$$(t_0, \ldots, t_n) \mapsto (t_0, \ldots, t_{n-1})$$

where $A_n \in \mathrm{O}(n)$ is a matrix which is chosen in such a way that we have the equality $\eta_n((1,0,\ldots,0)) = * := (0,\ldots,0,1)$.[10311032] We sketch the definition of η_n in the figure below.

We use the homeomorphism $\eta_n \colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ to identify these two pairs of topological spaces. In particular we use it to make the identification $\partial\Delta^n = S^{n-1}$. By a slight abuse of notation we write write $* := (1,0,\ldots,0) \in \Delta^n$. In particular for any $n \in \mathbb{N}_0$ we can extend the identifications from page 1847 to obtain the following identifications

$$\pi_n(X, x_0) \;=\; \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (I^n, \partial I^n) \to (X, x_0)\\ \|\\ \text{set (of homotopy classes)}\\ \text{of maps } (\overline{B}^n, S^{n-1}) \to (X, x_0)\\ \|\\ \text{set (of homotopy classes)}\\ \text{of maps } (\Delta^n, \partial\Delta^n) \to (X, x_0).\end{array} \;=\; \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (S^n, *) \to (X, x_0)\\ \|\\ \text{set (of homotopy classes)}\\ \text{of maps } (\partial\Delta^{n+1}, *) \to (X, x_0)\end{array}$$

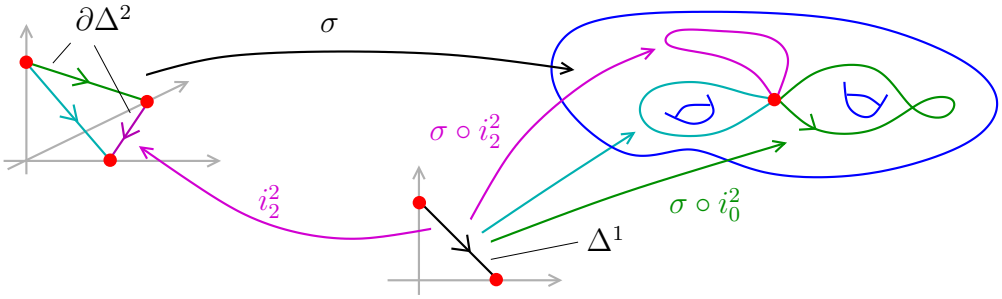
As above we will use these identifications to pick at each given moment our most convenient point of view.

As an illustration, under the above identifications the Trivial-in-π_n-Lemma 71.4 translates into the following lemma.

Lemma 85.15. Let (X, x_0) be a pointed topological space and let $n \geq 1$. Furthermore let $f \colon (\partial\Delta^{n+1}, *) \to (X, x_0)$ be a map. Then f represents the trivial element in $\pi_n(X, x_0)$ if and only if there exists a map $F \colon \Delta^{n+1} \to X$ so that $F|_{\partial\Delta^{n+1}} = f$.

The following lemma is the other key technical ingredient in the proof of the Hurewicz Theorem 85.5.

[1030] Note that the composition of the first two homeomorphisms is precisely the homeomorphism from the Standard Simplex Homeomorphism Lemma 72.1.



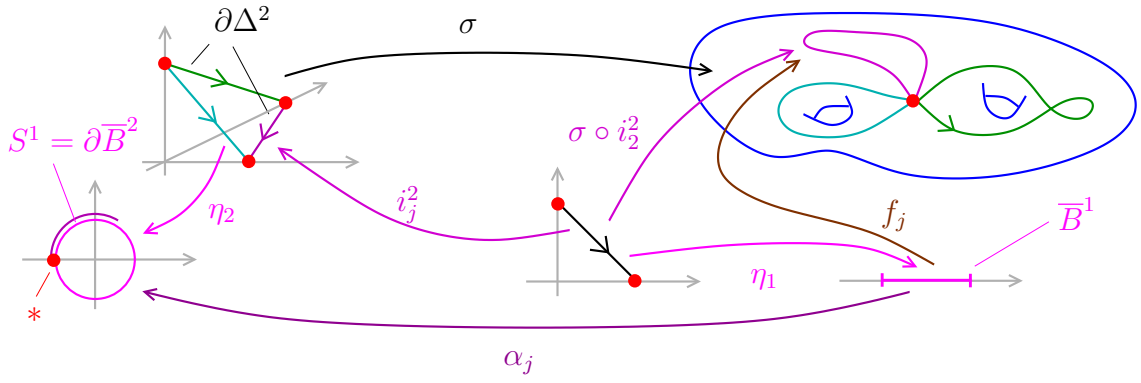
[1031] It follows from the Orthogonal Action Lemma 5.26 (3) that such a matrix exists.

[1032] The map η_n depends on the choice of the matrix A_n, this will not affect us at all.

Lemma 85.16. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $\sigma\colon \partial\Delta^{n+1} \to X$ be a map that sends the $(n-1)$-skeleton of $\partial\Delta^{n+1}$ to x_0. Then[10331034]

$$[\sigma\colon (\partial\Delta^{n+1}, *) \to (X, x_0)] \;=\; \sum_{j=0}^{n+1} (-1)^j \cdot [\sigma \circ i_j^{n+1}\colon (\Delta^n, \partial\Delta^n) \to (X, x_0)] \;\in\; \pi_n(X, x_0).$$

We refer to the figure below for an illustration for $n = 1$, even though this case is strictly speaking not allowed.



Proof. The reader might already have noticed that the statement of the lemma resembles the statement of the Addition-in-π_n-Proposition 85.11. Indeed, after some massaging we will be able to deduce the desired statement from the Addition-in-π_n-Proposition 85.11.

Given any $k \in \mathbb{N}_0$, let $\eta_k\colon (\Delta^k, \partial\Delta^k) \to (\overline{B}^k, S^{k-1})$ the homeomorphism from page 1856. Using our identifications the desired statement is now equivalent to the following statement.

Statement. Given $j \in \{0, \ldots, n+1\}$ we write $\alpha_i = \eta_{n+1} \circ i_j^{n+1} \circ \eta_n^{-1}\colon \overline{B}^n \to S^n = \partial\overline{B}^{n+1}$ and furthermore we write $f_j = \sigma \circ i_j^{n+1} \circ \eta_n^{-1}\colon \overline{B}^n \to X$. Then we have the following equality in $\pi_n(X, x_0)$:

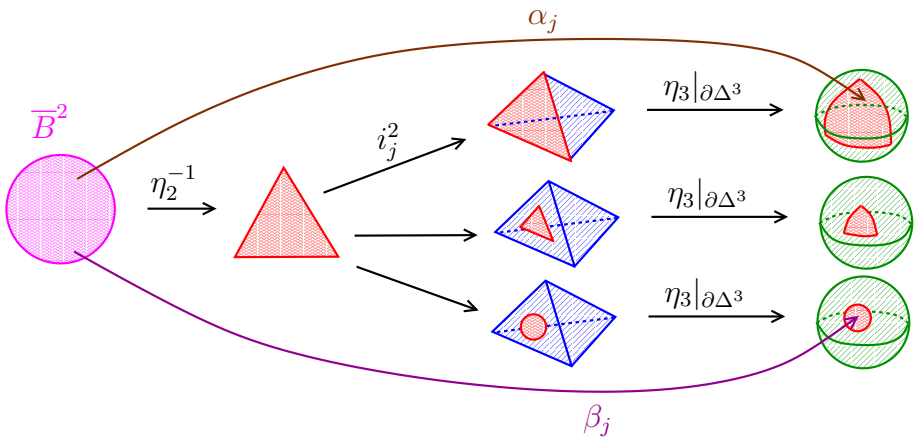
$$\big[\underbrace{\Phi(\alpha_0, \ldots, \alpha_n, f_0, \ldots, f_n)\colon (S^n, *) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] \;=\; -\sum_{j=0}^{n+1} (-1)^j \cdot \big[\underbrace{f_j\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

We refer to the figure below for an illustration.

[1033]Note that our hypothesis that σ sends the $(n-1)$-skeleton of $\partial\Delta^{n+1}$ to x_0 implies in particular that for all $j \in \{0, \ldots, n+1\}$ we have $(\sigma \circ i_j^{n+1})(\partial\Delta^n) = \{x_0\}$.

[1034]Also note that by our base point $*$ is chosen in such a way that it lies on the $(n-1)$-skeleton of $\partial\Delta^{n+1}$.

First note that it follows from the discussion on page 2325 that the maps η_k is orientation-preserving if and only if k is even. Furthermore it is fairly straightforward to see that the maps i_j^{n+1} are orientation-preserving if and only if j is even. In summary, the embedding α_j is orientation-preserving if and only if j is odd.[1035]



The only reason why we cannot apply the Addition-in-π_n-Proposition 85.11 immediately is that the maps α_j are embeddings but they are not smooth, so they are not smooth embeddings. Keeping Lemma in mind we see that it suffices to prove the following claim.

Claim. The maps $\alpha_0, \dots, \alpha_{n+1} \colon \overline{B}^n \to S^n$ are isotopic, through weakly disjoint embeddings, to smooth embeddings $\beta_0, \dots, \beta_{n+1}$.

Proof. For $j = 0, \dots, n+1$ we write $F_j = i_j^{n+1}(\mathring{\Delta}^n)$ and we write $\overline{F}_j = i_j^{n+1}(\Delta^n)$. Note that F_j is an n-dimensional submanifold of $\mathbb{R}^{n+1}$, we endow it with the usual orientation where the "normal vector sticks outward". Now this claim can be proved using the following observations:

(1) Similar to the discussion on page 1850 we can shrink the weakly disjoint embeddings $\alpha_j \colon \overline{B}^n \to \overline{F}_j$ to disjoint embeddings $\beta_j \colon \overline{B}^n \to F_j$.
(2) Using Lemma 14.2 we can isotope these embeddings $\beta_j \colon \overline{B}^n \to F_j$ to smooth embeddings[1036] $\gamma_i \colon \overline{B}^n \to F_j$.
(3) For each $j \in \{0, \dots, n+1\}$ the restriction of $\eta_{n+1} \colon \partial\Delta^{n+1} \to S^n$ to $\eta_{n+1} \colon F_j \to S^n$ is smooth and orientation-preserving.

Together with the figure below the reader should have no troubles assembling a full proof of the claim and the lemma using the above observations. ■

Now we can turn to the proof of the Hurewicz Theorem 85.5.

Proof of the Hurewicz Theorem 85.5. Let $n \in \mathbb{N}_{\geq 2}$ and let (X, x_0) be a pointed topological space. We suppose that X is $(n-1)$-connected.

Statement (1) of the theorem can be proved easily. Indeed, let $k \in \{0, \dots, n-1\}$. We have

[1035] Here we used the deep fact that precisely one out of the numbers n, $n+1$ is odd.
[1036] Recall that a smooth embedding is by definition smooth.

$$\widetilde{\mathrm{H}}_k(X;\mathbb{Z}) \underset{\text{Lemma 74.12}}{\cong} \mathrm{H}_k(X,\{x_0\};\mathbb{Z}) \underset{\substack{\text{by Lemma 85.14 since}\\ X \text{ is } (n-1)\text{-connected}}}{=} \mathrm{H}_k^{(n-1)}(X,x_0) \underset{\substack{\text{by Lemma 85.13 (2)}\\ \text{since } k \leq n-1}}{=} 0.$$

We turn to the much more interesting proof of Statement (2). As a reminder, we want to show that the map

$$\pi_n(X,x_0) \xrightarrow{\Phi_{(X,x_0)}} \mathrm{H}_n(X;\mathbb{Z})$$

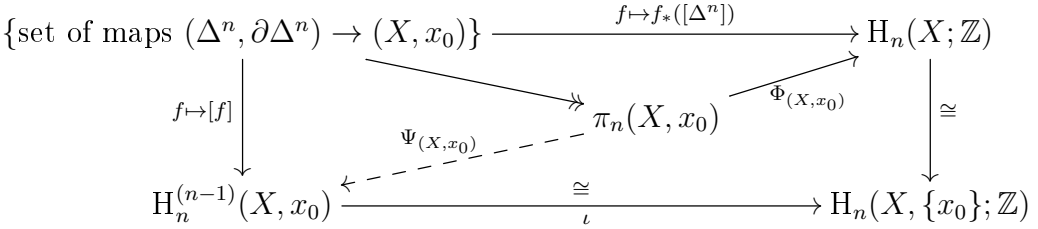
is an isomorphism. The goal again is to bring the homology groups $\mathrm{H}_n^{(n-1)}(X,x_0)$ into the game. This leads us to the following claim.

Claim.

(1) The map

$$\begin{array}{rcl} \Psi_{(X,x_0)}\colon \pi_n(X,x_0) & \to & \mathrm{H}_n^{(n-1)}(X,x_0) \\ [f\colon (\Delta^n,\partial\Delta^n) \to (X,x_0)] & \mapsto & \big[\underbrace{f\colon \Delta^n \to X}_{\in \mathrm{C}_n^{(n-1)}(X,x_0)}\big] \end{array}$$

is well-defined and it is a homomorphism.



(2) The following diagram commutes up to the sign $(-1)^n$:

$$\begin{array}{ccc} \pi_n(X,x_0) & \xrightarrow[[f]\mapsto f_*([S^n])]{\Phi_{(X,x_0)}} & \mathrm{H}_n(X;\mathbb{Z}) \\ \Big\downarrow{\scriptstyle \Psi_{(X,x_0)}} & & \Big\downarrow{\scriptstyle \cong} \\ \mathrm{H}_n^{(n-1)}(X,x_0) & \xrightarrow[\iota]{\cong} & \mathrm{H}_n(X,\{x_0\};\mathbb{Z}) \end{array}$$

where ι is induced by the inclusion $\mathrm{C}_*^{(n-1)}(X,x_0) \to \mathrm{C}_n(X,\{x_0\})$.

(3) The right-vertical and the bottom-horizontal maps of the diagram in (2) are isomorphisms.

Proof. We prove the claim using a somewhat convoluted logic.[1037] We consider the following diagram

We make the following observations:

(a) It follows from $n \geq 2$ and from the long exact sequence of homology groups of the pair $(X,\{x_0\})$, see the Topological LES-Corollary 74.14, that the right-hand vertical map of both diagrams is an isomorphism.

(b) It follows from Lemma 85.14 and our hypothesis that X is $(n-1)$-connected that the bottom horizontal map ι of both diagrams is an isomorphism.

(c) Let $f\colon (\Delta^n,\partial\Delta^n) \to (X,x_0)$ be a map. The $(n-1)$-skeleton of Δ^n equals $\partial\Delta^n$, thus the map $f\colon \Delta^n \to X$ does indeed define an element in $\mathrm{C}_n^{(n-1)}(X,x_0)$. Furthermore by Lemma 85.13 (3) we know that every element in $\mathrm{C}_n^{(n-1)}(X,x_0)$ is a cycle, thus f

[1037] The convoluted logic is forced upon us since proving (1) as a stand-alone statement is actually slightly tricky.

defines an element in $\mathrm{H}_n^{(n-1)}(X, x_0)$. This shows that in the above diagram the left vertical map is well-defined.

(d) It is clear that the "outer rectangle" of the above diagram commutes.

(e) It follows from the Standard Generator-Relationship Proposition 76.5 (2) that the top small triangle in the above diagram commutes up to the sign $(-1)^n$.

(f) We want to show that $\Psi_{(X,x_0)}$ is well-defined and that it is a homomorphism. By (b) we know that ι is an isomorphism. Thus it suffices to show these statements for $\iota \circ \Psi_{(X,x_0)}$. But these now follow from (d) and (e) and the fact, see Lemma 85.1 (1), that the Hurewicz homomorphism $\Phi_{(X,x_0)}$ is well-defined and a homomorphism. ⊞

By the claim it suffices to show that the homomorphism

$$\begin{array}{rcl} \Psi_{(X,x_0)} \colon \pi_n(X, x_0) & \to & \mathrm{H}_n^{(n-1)}(X, x_0) \\ [f \colon (\Delta^n, \partial\Delta^n) \to (X, x_0)] & \mapsto & [f \colon \Delta^n \to X] \end{array}$$

is in fact an isomorphism. We will do so by defining an explicit inverse.

Claim.

(1) The map

$$\begin{array}{rcl} \Xi_{(X,x_0)} \colon \mathrm{C}_n^{(n-1)}(X, x_0) & \to & \pi_n(X, x_0) \\ (\sigma \colon (\Delta^n, \partial\Delta^n) \to (X, x_0)) & \mapsto & [\sigma \colon (\Delta^n, \partial\Delta^n) \to (X, x_0)] \end{array}$$

that is induced by

is well-defined.

(2) The map $\Xi_{(X,x_0)}$ from (1) descends to a well-defined map

$$\mathrm{H}_n^{(n-1)}(X, x_0) \to \pi_n(X, x_0).$$

(3) The map $\Xi_{(X,x_0)}$ is an inverse to $\Psi_{(X,x_0)}$.

Proof. Since the end is near we set out with renewed vigor to prove the claim.

(1) Recall that we know from the Homotopy Group-Abelian Proposition 71.3 and our hypothesis $n \geq 2$ that the group on the right is abelian. Therefore it follows from Lemma 51.1 that the map is well-defined.[1038]

(2) Let $\sigma \colon \Delta^{n+1} \to X$ be a singular $(n+1)$-simplex that defines an element in the group $\mathrm{C}_{n+1}^{(n-1)}(X, x_0)$. We need to show that $\Xi_{(X,X_0)}(\partial\sigma) = 0$. We calculate that we have the following equality in $\pi_n(X, x_0)$:

$$\Xi_{(X,X_0)}(\partial\sigma) = \Xi_{(X,X_0)}\Big(\sum_{j=0}^{n+1}(-1)^j \cdot \sigma \circ i_j^n\Big) = \sum_{j=0}^{n+1}(-1)^j \cdot [\overbrace{\sigma \circ i_j^{n+1}}^{(\Delta^n,\partial\Delta^n)\to(X,x_0)}] = -[\overbrace{\sigma|_{\partial\Delta^{n+1}}}^{(\partial\Delta^{n+1},*)\to(X,x_0)}] = 0.$$

by definition of $\Xi_{(X,x_0)}$ (↑) Lemma 85.16 (↑) Lemma 85.15 (↑)

(3) It follows immediately from the definitions that $\Xi_{(X,x_0)} \circ \Psi_{(X,x_0)}$ is the identity on $\pi_n(X, x_0)$. Furthermore it follows easily from Lemma 85.13 and the definitions that $\Psi_{(X,x_0)} \circ \Xi_{(X,x_0)}$ is the identity on a generating set for $\mathrm{H}_n^{(n-1)}(X, x_0)$. But by the claim and Lemma 85.1 (1) we know that $\Psi_{(X,x_0)}$ and $\Xi_{(X,x_0)}$ are both homomorphisms. Thus we see that $\Psi_{(X,x_0)} \circ \Xi_{(X,x_0)}$ is actually the identity on all of $\mathrm{H}_n^{(n-1)}(X, x_0)$.

[1038] Put differently, it would be a serious dereliction of duty to use the additive notation for a group structure, if the group was not known to be additive.

This concludes the proof of the claim and thus we are done with the proof of the Hurewicz Theorem 85.5. ■

Remark. The most awkward aspect of the proof of the Hurewicz Theorem 85.5 is that one needs to go back and forth between the different points of view regarding elements in higher homotopy groups, in particular the fact that we need the Addition-in-π_n-Proposition 85.11 and Lemma 85.16 is arguably aesthetically somewhat unpleasant.

In fact there is, in principle, an elegant way around this problem: One could prove the Hurewicz Theorem 85.5 using "cubical singular homology" instead of the usual singular homology. As the name suggests, in this theory the "building blocks" are singular cubes, i.e. maps from $[0,1]^n$ to a topological space X. (This theory is developed in [**Mass1991**, Chapter VII.2].) Since cubes are also used in the definition of the product structure on higher homotopy groups I would expect that many of the technical issues we had to deal with vanish magically.

The downside is that one still needs to show that "cubical singular homology" is naturally isomorphic to the usual singular homology. This can be shown using the Acyclic Model Theorem 113.16.

Exercises for Chapter 85. In the following four exercises we need the following definition.

Definition. Let X be a topological space. We say X is aspherical if X is path-connected and if all higher homotopy groups $\pi_n(X)$, $n \geq 2$, vanish.

Exercise 85.1. Let X be a connected 2-dimensional CW-complex with $\pi_2(X) = 0$. Show that X is aspherical.

Exercise 85.2. Let X be a topological space and let U and V be open subsets of X. Let $n \in \mathbb{N}_{\geq 2}$. Suppose that U and V are $(n-1)$-connected and that $U \cap V$ is n-connected. We pick a base point $x_0 \in U \cap V$ and we denote by $i\colon U \to X$ and $j\colon V \to X$ the inclusion maps. Show that the map

$$i_* \oplus j_*\colon \pi_n(U, x_0) \oplus \pi_n(V, x_0) \ \to \ \pi_1(X, x_0)$$

is an isomorphism.

Exercise 85.3. Let X be a CW-complex and let U and V be path-connected subcomplexes of X. Suppose that $U \cap V$ is path-connected and furthermore suppose that the inclusion induced maps $\pi_1(U \cap V) \to \pi_1(U)$ and $\pi_1(U \cap V) \to \pi_1(V)$ are monomorphisms. Finally suppose that U, V and $U \cap V$ are aspherical. Show that X is also aspherical.
Hint. You might want to use Propositions 53.24, 63.5 and the Excisive Triad-Proposition 109.12 (6).

Exercise 85.4. We start out with the following easy-to-digest definition. Let X be a topological space and let $k \in \mathbb{N}_0$. We say X is *k-connected*, if $\pi_i(X) = 0$ for $i = 0, \ldots, k$. Now let M and N be two closed oriented n-dimensional smooth manifolds. Suppose there exists a $k \in \mathbb{N}$ such that M and N are k-connected. Show that the connected sum $M \# N$ is also k-connected.

Exercise 85.5. Let X be an n-dimensional CW-complex and let Y be a subcomplex of X that is homotopy equivalent to S^n. Show that the inclusion induced map $\pi_n(Y) \to \pi_n(X)$ is a monomorphism.

Exercise 85.6. We denote by $*$ suitable base points of the spheres. Now let $f\colon S^n \to S^n$ be a map with $f(*) = *$. We suppose that f is a map of degree $k \in \mathbb{Z}$, i.e. f is a map such that the induced map $f_*\colon \mathrm{H}_n(S^n;\mathbb{Z}) \to \mathrm{H}_n(S^n;\mathbb{Z})$ is given by multiplication by k.

(a) Let $g\colon S^n \to S^m$ be a map. Show that $[g \circ f] = k \cdot [g] \in \pi_n(S^m)$.

(b) Show that if $g\colon S^m \to S^n$ is a map, then it is not necessarily the case that the equality $[f \circ g] = k \cdot [g] \in \pi_m(S^n)$ holds.
Hint. We view S^3 as a subset of $\mathbb{C}^2$ and we make the usual identification $\mathbb{C}\mathrm{P}^1 = S^1$. Now consider the following commutative diagram:

$$\begin{array}{ccc} S^3 & \xrightarrow{(z,w)\to[(z,w)]} & S^2 \\ {\scriptstyle (z,w)\mapsto(\overline{z},\overline{w})}\downarrow & & \downarrow{\scriptstyle [(z,w)]\mapsto[(\overline{z},\overline{w})]} \\ S^3 & \xrightarrow{(z,w)\to[(z,w)]} & S^2. \end{array}$$

(c) Let $g\colon S^{m-1} \to S^{n-1}$ be map. As usual we denote by $\Sigma(g)\colon S^m \to S^n$ the suspension of g. Show that $[f \circ \Sigma(g)] = k \cdot [\Sigma(g)] \in \pi_m(S^n)$.

Exercise 85.7. Given $n \in \mathbb{N}$ we denote by $L(n,1) = S^3/\mathbb{Z}_n$ the lens space, as defined on page 1075. For which $n \in \mathbb{N}$ is the Hurewicz homomorphism $\pi_3(L(n,1)) \to \mathrm{H}_3(L(n,1);\mathbb{Z})$ an isomorphism?

Exercise 85.8. Let X be a topological homology n-sphere, i.e. X is an n-dimensional topological manifold such that for any $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(X) \cong \mathrm{H}_k(S^n)$. We denote by $\Sigma(X)$ the suspension of X as defined on page 451. Show that $\pi_i(\Sigma(X)) = 0$ for $i = 1, \ldots, n$.

Exercise 85.9. Let $n \in \mathbb{N}$. Let $\varphi\colon S^1 \to S^1$ be the map that is given by $z \mapsto z^n$. We consider the topological space $X := \overline{B}^2 \cup_\varphi S^1$. In other words, X is the CW-complex obtained by attaching a 2-cell to S^1 via the attaching map φ.

(a) Compute $\pi_1(X)$.

(b) Compute $\pi_2(X)$.

Exercise 85.10. Let $\varphi\colon S^1 \to S^5$ be a smooth embedding.

(a) Compute $\mathrm{H}_*(S^5 \setminus \varphi(S^1))$.

(b) Show that $\pi_3(S^5 \setminus \varphi(S^1)) \neq 0$.

Remark. For (b) you need to use that φ is a smooth embedding, the statement is in general not true, if we only assume that φ is an injective map. More precisely, in [**Haj2019**] it is shown that there exists an injective map $\varphi\colon S^1 \to S^5$ such that $\pi_3(S^5 \setminus \varphi(S^1)) = 0$.

Exercise 85.11. Show that there exists a closed 3-dimensional smooth manifold M such that $\pi_2(M)$ is infinitely generated.
Hint. You could try to imitate the topological space $S^1 \vee S^2$.

Exercise 85.12. Let X be a 0-connected countable CW-complex. Show that $\pi_2(X)$ is countable.
Remark. This answer Question 71.16 in the affirmative for $n = 2$.

86. Applications of the Hurewicz Theorem

In this chapter we want to spend some more time with the Hurewicz Theorems 84.5 and 85.5. In particular we want to discuss some applications thereof. This chapter is not entirely essential and can also be safely skipped at a first reading.

86.1. **The social choice problem ❀.** In this section we will consider the real-life problem that $n \in \mathbb{N}_{\geq 2}$ people have to agree in a democratic and reasonable way on one of the following:

(1) The temperature setting of a joint office.
(2) A vacation spot in Bavaria.
(3) A vacation spot on Earth.

More generally, the n people are supposed to agree on the following:

(4) A point in some topological space X.

One reasonable approach to solving this problem is the following. Each person gets to pick a point in X. We then need a map f which takes as input the n choices of points in X and which turns these choices into a common choice. In other words, we need a map

$$f\colon X^n = \underbrace{X \times \cdots \times X}_{n \text{ times}} \to X.$$

Our interpretation that the common choice should be chosen "democratically and reasonably" is that the map f should have the following three properties:

(a) A small change in choices of the people involved should correspond to a small change in the common choice.
(b) If everybody is of the same opinion, then evidently the common choice should be the point everybody picked.
(c) Everybody should be treated fairly, i.e. the social choice should not depend on the ordering of the n people.

In some cases it is easy to come up with a social choice. For example if X is a convex subset of some $\mathbb{R}^m$, e.g. if $X = \mathbb{R}^m$ itself, then given any $n \in \mathbb{N}$ the map[1039][1040]

$$\begin{array}{rcl} X^n & \to & X \\ (x_1, \ldots, x_n) & \mapsto & \frac{1}{n} \cdot \sum_{i=1}^{n} x_i \end{array}$$

evidently satisfies all of the above conditions. In particular this approach solves the problem for (1). If X is homeomorphic to a convex subset of some $\mathbb{R}^m$, then we can translate our problem into the previous situation and we can find a solution. In particular, Bavaria being to the best of my knowledge homeomorphic to a closed disk, we see that we have a solution to (2).[1041]

[1039] It follows easily from the convexity of X that the map does indeed take values in X.

[1040] For what choices of subsets X of $\mathbb{R}^m$ does the geometric mean $(x_1, \ldots, x_n) \mapsto (x_1 \cdot \cdots \cdot x_n)^{\frac{1}{n}}$ define a social choice?

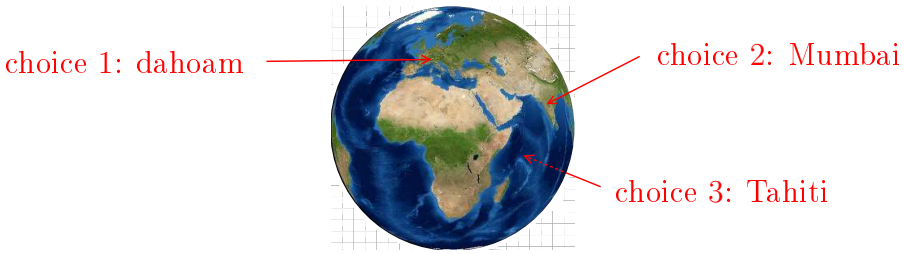
[1041] The fact that Bavaria lost the Pfalz in 1946 greatly simplifies finding a solution to (2).

In the following we will now study the third problem in greater detail. At this point it is convenient to introduce the following definition from [**Eckm2004**], which is just a formalization of our wish list above.

Definition. Let X be a topological space and let $n \in \mathbb{N}$. A social choice of type n is a map

$$f\colon X^n \;=\; \underbrace{X \times \cdots \times X}_{n \text{ times}} \;\to\; X$$

such that the following three axioms are satisfied:



(a) The map f is continuous.
(b) For every $x \in X$ we have $f(x, \ldots, x) = x$.
(c) For every permutation $\sigma \in S_n$ and any $(x_1, \ldots, x_n) \in X^n$ we have

$$f(x_{\sigma(1)}, \ldots, x_{\sigma(n)}) \;=\; f(x_1, \ldots, x_n).$$

We say that a topological space is social, if for every $n \in \mathbb{N}$ it admits a social choice of type n.

Thus the question of whether there exists a "democratic and reasonable" way for n people to settle on a vacation spot on earth can be interpreted as the following question.

Question 86.1. Does there exist a social choice of type n on S^2?

As we will see, this question will be short-lived. The key to answer this question is the following proposition which is the main result of this section.

Proposition 86.2.

(1) Let X be a 0-connected space. If X admits a social choice of type n for some $n \in \mathbb{N}_{\geq 2}$, then given any $k \in \mathbb{N}$ the group[1042] $\pi_k(X)$ is abelian, and it is either zero or infinitely generated.
(2) Let X be a connected non-empty CW-complex that has the property that for every $k \in \mathbb{N}$ the number of k-cells is finite. If for every $n \in \mathbb{N}_0$ the topological space X admits a social choice of type $n \geq 2$, then for every $k \in \mathbb{N}$ we have $\pi_k(X) = 0$.

Remark.

(1) It follows from the Whitehead Theorem 162.1 that in Proposition 86.2 (2) we can upgrade the conclusion to the statement that X is actually contractible.
(2) In the context of sociology, Proposition 86.2 was first formulated in 1980 by the mathematical economist Graciela Chichilnisky [**Chic1980**]. It turns out that the proposition was already proved earlier by Beno Eckmann [**Eckm1954**] in 1954. The

[1042] In this section we will only deal with path-connected topological spaces and we will only be interested in the isomorphism type of the higher homotopy groups, thus we will use the Change-of-Base Point Proposition 71.5 as an excuse to ignore base points.

discussion of this section follows mostly [**Eckm2004**]. For more information and some generalizations we refer to [**Eckm2004**] and [**Weinb2004**].

We are now already in a position to answer Question 86.1 in the negative.

Corollary 86.3. Let $k \in \mathbb{N}$. The sphere S^k does not admit a social choice for any $n \in \mathbb{N}_{\geq 2}$.

Proof. By Corollary 85.6 we know that $\pi_k(S^k) \cong \mathbb{Z}$. Since $\mathbb{Z}$ is neither zero nor infinitely generated we obtain from Proposition 86.2 (1) that S^k does not admit a social choice for any $n \in \mathbb{N}_{\geq 2}$. ■

The idea behind the proof of Proposition 86.2 is quite simple. We need to see what effect the existence of a social choice on X has on the higher homotopy groups. Perhaps not surprisingly, the properties of a social choice give rise to very similar properties of the homotopy groups. This leads us to the following definition.

Definition. Let G be a group and let $n \in \mathbb{N}_{\geq 2}$. We say a map $\varphi\colon G^n \to G$ is a social homomorphism of type n if the following conditions are satisfied:

(a) The map φ is a homomorphism.
(b) For every $g \in G$ we have $\varphi(g, \ldots, g) = g$.
(c) For every permutation $\sigma \in S_n$ and any $(g_1, \ldots, g_n) \in G^n$ we have

$$\varphi\big(g_{\sigma(1)}, \ldots, g_{\sigma(n)}\big) \;=\; \varphi(g_1, \ldots, g_n).$$

Example. Evidently, if we consider $G = (\mathbb{Q}, +)$ or $G = (\mathbb{R}, +)$, then taking the arithmetic mean defines a social homomorphism.

The following lemma relates social choices on topological spaces to social homomorphisms.

Lemma 86.4. Let X be a path-connected topological space. If X admits a social choice of some type $n \geq 2$, then for every $k \in \mathbb{N}$ the homotopy group $\pi_k(X)$ admits a social homomorphism of type n.

Proof. To simplify the notation a little bit we only consider the case $n = 2$. Thus let $f\colon X \times X \to X$ be a social choice of type 2. Let $k \in \mathbb{N}$. We fix a base point $x_0 \in X$. We consider the map

$$\begin{array}{rcl} \Theta\colon \pi_k(X, x_0) \times \pi_k(X, x_0) & \to & \pi_k(X \times X, (x_0, x_0)) \\ ([\alpha\colon (S^k, *) \to (X, x_0)], [\beta\colon (S^k, *) \to (X, x_0)]) & \mapsto & \left[\begin{array}{rcl} (S^k, *) & \to & (X \times X, (x_0, x_0)) \\ z & \mapsto & (\alpha(z), \beta(z)) \end{array}\right]. \end{array}$$

Next we consider the map

$$\varphi\colon \pi_k(X, x_0) \times \pi_k(X, x_0) \xrightarrow{\Theta} \pi_k(X \times X, (x_0, x_0)) \xrightarrow{f_*} \pi_k(X, x_0).$$

It remains to show that $\varphi = f_* \circ \Theta$ is a social homomorphism of type 2. We do so in the following three steps.

(a) By the Homotopy Groups-of-Product Proposition 71.8 (2) we know that the map Θ is actually a homomorphism. It follows that $\varphi = f_* \circ \Theta$ is a homomorphism.
(b) It follows immediately from the fact that for every $x \in X$ we have $f(x, x) = x$ that for every $g \in \pi_k(X)$ we have $\varphi(g, g) = g$.
(c) Similarly it follows immediately from the fact that for every $x, y \in X$ we have $f(x, y) = f(y, x)$ that for every $g, h \in \pi_k(X, x_0)$ we have $\varphi(g, h) = \varphi(h, g)$. ■

In light of Lemma 86.4 we now need to understand, given $n \in \mathbb{N}_{\geq 2}$, which groups admit social homomorphisms of type n.

Definition. Let G be an abelian group.

(1) Let $n \in \mathbb{N}$. We say G is strongly divisible by n, if the map $g \mapsto n \cdot g$ is an isomorphism of the group G.
(2) We say G is strongly divisible, if G is strongly divisible by any $n \in \mathbb{N}$.

Remark. Usually an abelian group G is called *divisible* if for every $g \in G$ and $n \in \mathbb{N}$ there exists an $h \in G$ with $n \cdot h = g$. This will also be our definition later on page 2441. Clearly a group which is strongly divisible is also divisible. But the converse does not hold, for example the abelian group $(\mathbb{Q}/\mathbb{Z}, +)$ is divisible but it is not strongly divisible.

The following lemma gives a satisfying characterization of groups that admit a social homomorphism of type n.

Lemma 86.5. Let G be a group and let $n \in \mathbb{N}_{\geq 2}$. The following two statements are equivalent:

(1) The group G admits a social homomorphism of type n.
(2) The group G is abelian and it is strongly divisible by n.

Proof. In the following let G be a group and let $n \in \mathbb{N}_{\geq 2}$. Since we will shortly see that the groups involved are abelian we will use additive notation throughout the argument.

First we deal with the implication "(2) $\Rightarrow$ (1)". If G is abelian and if it is strongly divisible by n, then evidently the usual "arithmetic mean formula"

$$(g_1, \ldots, g_n) \;\mapsto\; \tfrac{1}{n}(g_1 + \cdots + g_n) := \begin{array}{c}\text{inverse of the isomorphism}\\ G \to G \text{ given by } g \mapsto n \cdot g,\\ \text{applied to } g_1 + \cdots + g_n \in G\end{array}$$

defines a social homomorphism of type n.

Next we prove the much more interesting implication "(1) $\Rightarrow$ (2)". Let $\varphi\colon G^n \to G$ be a social homomorphism of type $n \geq 2$. Throughout the proof we mean by (a), (b) and (c) the three defining properties of a social homomorphism. First note that it follows immediately from (c) that for any $g \in G$ we have the equalities

$$\varphi(g, 0, \ldots, 0) \;=\; \varphi(0, g, 0, \ldots, 0) \;=\; \varphi(0, \ldots, 0, g) \;\in\; G.$$

We denote this common value by $\psi(g)$. We make the following observations:

(i) It follows immediately from (a) that $\psi\colon G \to G$ is also a homomorphism.
(ii) For any $g, h \in G$ we have

$$\begin{array}{rcccl} & & \overset{\text{since } n \geq 2}{\downarrow} & & \overset{\text{by (a)}}{\downarrow} \\ \psi(g) + \psi(h) & = & \varphi(g, 0, \ldots, 0) + \varphi(0, h, 0, \ldots, 0) & = & \varphi(g, h, 0, \ldots, 0) \\ & = & \varphi(0, h, \ldots, 0) + \varphi(g, 0, 0, \ldots, 0) & = & \psi(h) + \psi(g). \\ & & \underset{\text{by (a)}}{\uparrow} & & \underset{\text{since } n \geq 2}{\uparrow} \end{array}$$

(iii) For any $g \in G$ we have

$$\underbrace{\psi(g) + \ldots \psi(g)}_{= n \cdot \psi(g)} \underset{\text{by definition of } \psi}{=} \varphi(g, 0, \ldots, 0) + \cdots + \varphi(0, \ldots, 0, g) \underset{\text{by (a)}}{=} \varphi(g, \ldots, g) \underset{\text{by (c)}}{=} g.$$

(iv) Let $g, h \in G$. We have

$$\begin{array}{lll} & \overset{\text{by (iii)}}{\downarrow} & \overset{\text{by (i)}}{\downarrow} \\ g+h \overset{}{=} & \psi(g+h)+\cdots+\psi(g+h) & = \psi(g)+\psi(h)+\cdots+\psi(g)+\psi(h) \\ = & \psi(h)+\psi(g)+\cdots+\psi(h)+\psi(g) & = \psi(h+g)+\cdots+\psi(h+g) \overset{}{=} h+g. \\ & \underset{\text{by (ii)}}{\uparrow} & \underset{\text{by (i)}}{\uparrow} \qquad\qquad\qquad\qquad \underset{\text{by (iii)}}{\uparrow} \end{array}$$

This shows that G is abelian.

(v) Since G is abelian we know that multiplication by n is a homomorphism of G.

(vi) It follows almost immediately from (i) and (iii) that ψ is an inverse to the map $G \to G$ that is given by $g \mapsto n \cdot g$. Together with (v) this shows that $g \mapsto n \cdot g$ does indeed define an isomorphism of G. ■

The following lemma basically tells us which finitely generated abelian groups are strongly divisible by some $n \in \mathbb{N}_{\geq 2}$.

Lemma 86.6. Let $n \in \mathbb{N}_{\geq 2}$.

(1) The group $\mathbb{Z}$ is not strongly divisible by n.

(2) Let $m \in \mathbb{N}$. The cyclic group $\mathbb{Z}_m$ is strongly divisible by n if and only if m and n are coprime.

(3) If a finitely generated group is strongly divisible by n, then it is isomorphic to a direct sum $\bigoplus_{i=1}^{k} \mathbb{Z}_{m_i}$ where each m_i is coprime to n.

Proof. The first two statements are basically trivial. Finally the last statement follows from the previous two statements together with the Finitely Generated Abelian Group Classification Theorem 51.4. ■

Now we have assembled everything we need for the proof of Proposition 86.2.

Proof of Proposition 86.2.

(1) Let X be a 0-connected space that admits a social choice of type n for some $n \in \mathbb{N}_{\geq 2}$. Let $k \in \mathbb{N}$. By Lemma 86.4 we know that the group $\pi_k(X)$ is abelian and that it is strongly divisible by n. It follows almost immediately from Lemma 86.6 that $\pi_k(X)$ is either zero or infinitely generated.

(2) Let X be a connected non-empty CW-complex that has the property that for every $k \in \mathbb{N}$ the number of k-cells is finite. We assume that X is social, i.e. we assume that given any $n \geq 2$ there exists a social choice of type n on X. By Lemma 86.4 we know that every homotopy group $\pi_k(X)$ is abelian and that it is strongly divisible by n.

Next note that by the CW-Skeleton-π_1-Proposition 69.13 and our hypothesis that X has finitely many 1-cells we know that $\pi_1(X)$ is finitely generated. It follows from the above together with Lemma 86.6 that $\pi_1(X) = 0$.

Now suppose that we already know that $\pi_i(X) = 0$ for $i = 1, \ldots, k$. By the Hurewicz Theorem 85.5 we know that $\pi_{k+1}(X) \cong \mathrm{H}_{k+1}(X)$. Since X has finitely many $(k+1)$-cells we obtain from the Homology-of-CW-Complex Proposition 80.6 that $\pi_{k+1}(X) \cong \mathrm{H}_{k+1}(X)$ is finitely generated. Basically the same argument as above shows that $\pi_{k+1}(X) = 0$. Iterating this procedure shows that all homotopy groups of X vanish. ■

We conclude this section with the following question.

Question 86.7. Does there exist a non-empty CW-complex that is social but that is not contractible?

We will return to this question later on in Section 163.6.

86.2. **The degree of a self-map of a sphere II.** Let $n \in \mathbb{N}_0$ and let $f\colon S^n \to S^n$ be map. On page 1684 we defined the degree of f as follows:

$$\deg(f) \;:=\; \deg\big(f_*\colon \widetilde{\mathrm{H}}_n(S^n) \to \widetilde{\mathrm{H}}_n(S^n)\big).$$

In the Sphere Degree Lemma 76.11 (3) we showed that any two homotopic maps $S^n \to S^n$ have the same degree. Now we have the tools to prove the converse of this statement. In fact we have the following proposition.

Proposition 86.8. (Degree Isomorphism Proposition) For any $n \in \mathbb{N}$ the map

$$\begin{array}{rcl} \deg\colon \overbrace{[S^n, S^n]}^{\text{set of homotopy equivalence classes of maps } S^n \to S^n} & \to & \mathbb{Z} \\ [f\colon S^n \to S^n] & \to & \deg(f) \end{array}$$

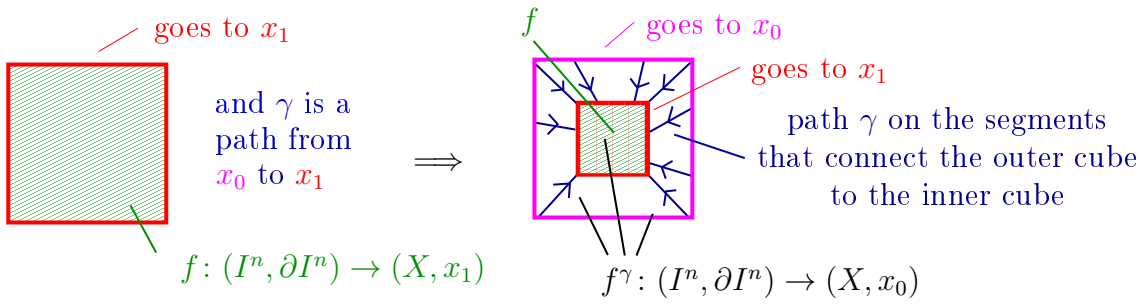
is an isomorphism. (The set $[S^n, S^n]$ is a monoid through composition of maps.)

Proof. First note that we know by the Sphere Degree Lemma 76.11 (3) and (4) that the degree map is well-defined and that it is a monoid morphism. It remains to show that the degree map is a bijection. Now let $* \in S^n$ be the standard base point. We consider the following diagram

$$\begin{array}{ccccc} \langle (S^n,*),(S^n,*)\rangle & \xrightarrow{\cong} & [S^n,S^n] & \xrightarrow{\deg(f)} & \mathbb{Z} \\ \big\downarrow{\scriptstyle =} & & \big\downarrow{\scriptstyle f\mapsto f_*([S^n])} & \nearrow{\scriptstyle \cong}_{k\cdot[S^n]\mapsto k} & \\ \pi_n(S^n,*) & \xrightarrow[[f]\mapsto f_*([S^n])]{\cong} & \mathrm{H}_n(S^n). & & \end{array}$$

We make the following observations and clarifications:

(1) By Corollary 70.10 we know that the map $\langle (S^n,*),(S^n,*)\rangle \to [S^n,S^n]$ is a bijection.
(2) By Theorem 85.5 we know that the bottom horizontal map is an isomorphism.
(3) The diagonal map is an isomorphism by Proposition 74.4.
(4) Finally note that it is clear that the diagram commutes. It follows from this observation and all of the above that the map $\deg\colon [S^n,S^n] \to \mathbb{Z}$ is indeed an isomorphism. ■



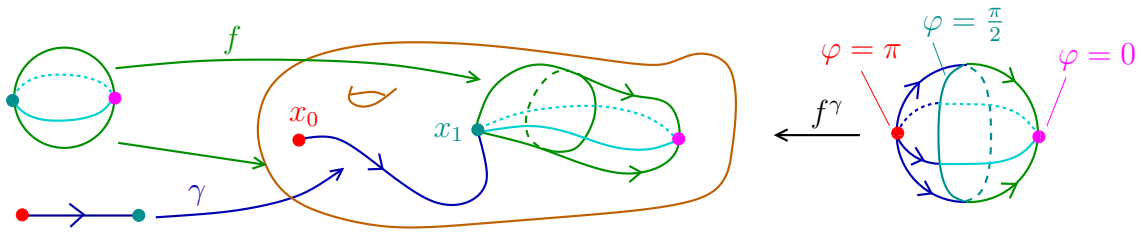
86.3. **Paths acting on homotopy groups.** In Propositions 47.10 and 71.5 we already saw that for path-connected topological spaces the *isomorphism types* of the homotopy groups do not depend on the choice of the base point.

In this section we want to discuss this statement in greater detail. We recall the following definition which appeared already in the proof of the Change-of-Base Point Proposition 71.5.

Definition. Let X be a topological space and let $n \in \mathbb{N}$. Let $\gamma\colon [0,1] \to X$ be a path from a point x_0 to a point x_1. Given a map $f\colon (I^n, \partial I^n) \to (X, x_1)$ we define the map

$$\begin{array}{rcl} f^\gamma\colon (I^n, \partial I^n) & \to & (X, x_0) \\ (t_1, \dots, t_n) & \mapsto & \begin{cases} f\big(2t_1 - \frac{1}{2}, \dots, 2t_n - \frac{1}{2}\big), & \text{if } (t_1, \dots, t_n) \in \big[\frac{1}{4}, \frac{3}{4}\big]^n, \\ \gamma(t), & \text{if } (t_1, \dots, t_n) \in \partial\big(\big[\frac{t}{4}, \frac{4-t}{4}\big]^n\big) \text{ for } t \in [0,1]. \end{cases} \end{array}$$

The definition of f^γ is illustrated in the figure below.



Example. We consider the case $n = 1$ in the above definition. In this situation the map $f\colon (I, \partial I) \to (X, x_1)$ is a loop. It follows almost immediately from the definitions that the new loop $f^\gamma\colon (I, \partial I) \to (X, x_0)$ equals, up to an orientation-preserving reparametrization, the loop $\gamma * f * \overline{\gamma}$ that is given by the product of the three paths γ, f and $\overline{\gamma}$. We refer to the figure below for an illustration.

Remark. We recall that on pages 1565 and 1847 we saw that we can interpret elements in a homotopy group $\pi_n(X, x_0)$ as homotopy classes of maps $(S^n, *) \to (X, x_0)$. Now let $\gamma\colon [0,1] \to X$ be a path from x_0 to x_1 and let $f\colon (S^n, *) \to (X, x_1)$ be a map. We define[1043]

$$\begin{array}{rcl} f^\gamma\colon S^n & \to & X \\ \underbrace{\cos(\varphi)\cdot(1,0,\dots,0) + \sin(\varphi)\cdot(0,v)}_{\varphi \in [0,\pi], v \in \mathbb{R}^{n-1}} & \mapsto & \begin{cases} f(\cos(2\varphi)\cdot(1,0,\dots,0) + \sin(2\varphi)\cdot(0,v)), & \text{if } \varphi \in [0, \frac{\pi}{2}] \\ \gamma(2 - \frac{2}{\pi}t), & \text{if } \varphi \in [\frac{\pi}{2}, \pi]. \end{cases} \end{array}$$

Of course one should only work with the formula if one is forced to at gun point. It is much more illuminating to look at the figure below where we try our best to visualize the map $f^\gamma\colon (S^n, *) \to (X, x_0)$. One can easily verify that, under the various identifications, the map f^γ corresponds to the construction on page 1869.

[1043] It follows easily from Pasting Proposition 2.6 (2′) that this map is continuous.

Before we continue we introduce the following basically self-explanatory definition.

Definition. Let G be a group and let A be a group (or module or vector space). An action of G on the group A (respectively module or vector space) is an action $G \times A \to A$ in the sense of the definition on page 248 such that for each $g \in G$ the map

$$\begin{array}{ccc} A & \to & A \\ a & \mapsto & g \cdot a \end{array}$$

is a group homomorphism (respectively module or vector space homomorphism).[1044]

The following proposition can be viewed as a more precise version of the Change-of-Base Point Proposition 71.5 and as a generalization of Proposition 47.20.

Proposition 86.9. Change-of-Base Point Proposition II) Let X be a topological space and let $n \in \mathbb{N}$.

(1) If $\gamma\colon [0,1] \to X$ is a path from x_0 to x_1, then the map

$$\begin{array}{rccc} \gamma_*\colon \pi_n(X,x_1) & \to & \pi_n(X,x_0) \\ [f] & \mapsto & [f^\gamma] \end{array}$$

is a well-defined isomorphism.

(2) If x_0 and x_1 are two points in X which lie in the same path-component of X, then $\pi_n(X,x_0)$ is isomorphic to $\pi_n(X,x_1)$.

(3) Let $\varphi\colon X \to Y$ be a map between topological spaces.

(a) If $\gamma\colon [0,1] \to X$ is a path from x_0 to x_1, then the following diagram commutes

$$\begin{array}{ccc} \pi_n(X,x_1) & \xrightarrow{\gamma_*} & \pi_n(X,x_0) \\ {\scriptstyle\varphi_*}\downarrow & & \downarrow{\scriptstyle\varphi_*} \\ \pi_n(Y,\varphi(x_1)) & \xrightarrow{(\varphi\circ\gamma)_*} & \pi_n(Y,\varphi(x_0)). \end{array}$$

(b) If $\varphi_*\colon \pi_n(X,x_0) \to \pi_n(Y,\varphi(x_0))$ is an isomorphism (epimorphism, monomorphism) for some base point $x_0 \in X$, then for any other base point x_1 in the same path component of X the map $\varphi_*\colon \pi_n(X,x_1) \to \pi_n(Y,\varphi(x_1))$ is also an isomorphism (epimorphism, monomorphism).[1045]

(4) Let γ and δ be two paths in X from x_0 to x_1. If γ and δ are path-homotopic in X, then the corresponding maps γ_* and δ_* from $\pi_n(X,x_1)$ to $\pi_n(X,x_0)$ agree.

(5) If γ is a path in X from x_0 to x_1 and if δ is a path in X from x_1 to x_2, then[1046]

$$(\underbrace{\gamma * \delta}_{\text{path from } x_0 \text{ to } x_2})_* = \gamma_* \circ \delta_*\colon \pi_n(X,x_2) \to \pi_n(X,x_0).$$

(6) The map

$$\begin{array}{rccc} \pi_1(X,x_0) \times \pi_n(X,x_0) & \to & \pi_n(X,x_0) \\ ([\gamma],[f]) & \mapsto & [\gamma]\cdot[f] := [f^\gamma] \end{array}$$

defines an action (in the sense of the definition on page 248) of the group $\pi_1(X,x_0)$ on the group $\pi_n(X,x_0)$.

[1044] In fact, since multiplication by g^{-1} is an inverse we see that these maps are actually isomorphisms.

(7) Let $f_0, f_1 \colon S^n \to X$ be two maps. We write $x_0 = f_0(*)$ and $x_1 = f_1(*)$. The following statement holds:

$$f_0 \text{ and } f_1 \text{ are homotopic} \iff \begin{array}{c}\text{there exists a path } \gamma \text{ from } x_0 \text{ to } x_1 \\ \text{such that } [f_1^\gamma] = [f_0] \in \pi_n(X, x_0).\end{array}$$

Remark. Let X be a topological space, let x_0, x_1 be two points in X and let γ and δ be two paths from x_0 to x_1. If X is simply connected, then Lemma 47.12 tells us that the two paths γ and δ are in fact homotopic. Therefore it follows from the Change-of-Base Point Proposition 86.9 (4) that $\gamma_* = \delta_* \colon \pi_n(X, x_0) \to \pi_n(X, x_1)$. In other words, if X is simply connected, then given any two base points x_0 and x_1 there exists in fact a natural[1047] isomorphism $\pi_n(X, x_0) \xrightarrow{\cong} \pi_n(X, x_1)$. In particular in this case it is almost always entirely safe to suppress the base point in the notation. By the Sphere-π_1-Proposition 47.13 this observation applies in particular to $X = S^k$ for $k \geq 2$.

Proof.

(0) Let $\gamma \colon [0,1] \to X$ be a path from x_0 to x_1. It is straightforward to see that the map

$$\begin{array}{rcl}\gamma_* \colon \pi_n(X, x_1) & \to & \pi_n(X, x_0) \\ [f] & \mapsto & [f^\gamma]\end{array}$$

is well-defined. It is also elementary, albeit potentially slightly painful, to see that γ_* is a group homomorphism. (See the corresponding discussion in the proof of the Change-of-Base Point Proposition 71.5.)

(4),(5) These two statements are basically elementary to verify. Nonetheless it is worth spending a second to convince oneself that in (5) we have the equality $(\gamma * \delta)_* = \gamma_* \circ \delta_*$ instead of $(\gamma * \delta)_* = \delta_* \circ \gamma_*$.

(1) Recall that in the Path-Homotopy Concatenation Proposition 47.5 (3) we saw that for any path δ the composition $\delta * \overline{\delta}$ is path-homotopic to the constant path. It follows easily from this observation together with (4) and (5) that γ_* is a bijection. Together with (0) we see that for any path $\gamma \colon [0,1] \to X$ from x_0 to x_1 the induced map $\gamma_* \colon \pi_n(X, x_1) \to \pi_n(X, x_0)$ is an isomorphism.

(2) This is an immediate consequence of (1)

(3) Statement (a) follows immediately from the definitions. Statement (b) is a consequence of the commutative diagram of (a) and the fact that the horizontal maps are isomorphisms by (1).

(6) It follows immediately from (4) and (5) that the map defines an action of $\pi_1(X, x_0)$ on the set $\pi_n(X, x_0)$. Furthermore (1) implies that this action is in fact an action on the group $\pi_n(X, x_0)$.

(7) The proof of this statement is a moderately complicated generalization of the proof of the Homotopies-of-Loops Proposition 50.16. We leave it to the reader to fill in the details. ∎

[1045] For $n = 1$ this is basically the content of Proposition 47.20.

[1046] Here it is worth remembering that by definition, see page 1052, the product path $\gamma * \delta$ is given by first traversing γ and then traversing δ.

[1047] As always, when the adjective "natural" gets used it is an amusing exercise to figure out what categories and functors are involved.

86.4. **Group rings.** Before we continue with our study of higher homotopy groups it is convenient to introduce the purely algebraic concept of a group ring.

Definition. Let G be a group and let R be a commutative ring. We denote the free R-module generated by the set G by $R[G]$. Put differently, with the notation from page 1147 we have

$$R[G] \;:=\; \Big\{ \sum_{i=1}^{m} r_i \cdot g_i \,\Big|\, r_1, \ldots, r_m \in R \text{ and } g_1, \ldots, g_m \in G \Big\}.$$

We equip $R[G]$ with the multiplication that is given by[1048]

$$\Big(\sum_{i=1}^{m} r_i \cdot g_i \Big) \cdot \Big(\sum_{j=1}^{n} s_j \cdot h_j \Big) \;:=\; \sum_{i=1}^{m} \sum_{j=1}^{n} \underbrace{r_i \cdot_R s_j}_{\in R} \cdot \underbrace{(g_i \cdot_G h_j)}_{\in G}.$$

We refer to $R[G]$ as the group ring of G with R-coefficients. (For $R = \mathbb{Z}$ we refer to $\mathbb{Z}[G]$ as the group ring of G.)

The following lemma summarizes a few basic facts about group rings.

Lemma 86.10. Let G be a group and let R be a commutative ring.

(1) The group ring $R[G]$ is an associative ring with a multiplicatively neutral element, namely $1 \cdot e$ where e denotes the trivial element in G.
(2) The group ring $R[G]$ is commutative if and only if G is an abelian group.
(3) If R is a field, then $R[G]$ is evidently an algebra over the field R.
(4) Given a unit $r \in R$ and an element $g \in G$ the product $r \cdot g$ is a unit in $R[G]$.
(5) If G has a torsion element, i.e. if there exists a non-trivial $g \in G$ such that $g^k = e$ for some $k \in \mathbb{N}$, then $R[G]$ has zero divisors.

Proof. All the statements are verified easily. Perhaps the most interesting statement is (5). We will not rob the reader of the pleasure of proving this in Exercise 86.3. ∎

Examples. Let R be a commutative ring.

(1) We consider the infinite cyclic group $\langle t \rangle$. In this case the group ring $R[\langle t \rangle]$ is isomorphic to the ring $R[t^{\pm 1}]$ of Laurent polynomials, more precisely the "obvious" map

$$\begin{array}{ccc} R[t^{\pm 1}] & \to & R[\langle t \rangle] \\ \sum_{i=r}^{i=s} a_i t^i & \mapsto & \sum_{i=r}^{i=s} a_i t^i \end{array}$$

is a ring isomorphism.
(2) More generally, if H is a free abelian group of rank m, then any choice of a basis $t_1, \ldots, t_m$ for H gives rise to a natural isomorphism from the multivariable Laurent polynomial ring $R[t_1^{\pm 1}, \ldots, t_m^{\pm 1}]$ to the group ring $R[H]$.

The group rings of free groups are particularly interesting. Therefore we dedicate a lemma to them.

Lemma 86.11. Let $\langle T \rangle$ be the free group on a generating set T. Given any ring S and given any map $g\colon T \to S$ there exists a unique ring homomorphism $\varphi\colon \mathbb{Z}[\langle T \rangle] \to S$ with $\psi(t) = g(t)$ for all $t \in T$.

[1048] The multiplication is basically given by naive "multiplying out".

Remark. Given a commutative ring R the group ring $R[\langle T\rangle]$ is sometimes called the *free ring on the set S over the ring R*.

Proof. It follows immediately from Lemma 51.15 that there exists a unique group homomorphism $\varphi\colon \langle T\rangle \to S^* := \{\text{units of } S\}$ that extends the given map g. It is now straightforward to verify that the map

$$\begin{array}{rcl} \mathbb{Z}[\langle T\rangle] & \to & S \\ \sum_{i=1}^{m} r_i \cdot g_i & \mapsto & r_i \cdot \varphi(g_i) \end{array}$$

is a ring homomorphism that extends g and that it is the unique ring homomorphism with this desirable property. ■

As a side remark we mention the following beautiful conjectures. These say in particular that in some sense the statements of Lemma 86.10 (4) and (5) are optimal.

Conjecture 86.12. (Kaplansky Conjectures) Let G be a torsion-free group and let $\mathbb{F}$ be a field.

(1) The elements 0 and 1 are the only idempotents of $\mathbb{F}[G]$, i.e. they are the only elements in $\mathbb{F}[G]$ with $x^2 = x$.
(2) The group ring $\mathbb{F}[G]$ is a domain, i.e. it has no non-trivial zero divisors.
(3) If $\mathbb{F}$ is of characteristic zero, then the only units in $\mathbb{F}[G]$ are the trivial units, i.e. the elements of the form $f \cdot g$ with $f \in \mathbb{F} \setminus \{0\}$ and $g \in G$.
(4) The group ring $\mathbb{C}[G]$ can be embedded in a skew field.

Remark.

(1) The conjectures are named after the Canadian mathematician Irving Kaplansky [**Kapy1957, Kapy1970**]. The first conjecture is often also referred to as the *zero divisor conjecture*. They are formulated in [**Lü2002**, Conjecture 10.14], [**Lam1991**, p. 95] and [**FrG2005**, p. 729]. As is pointed out in [**Lam1991**, p. 95], an proof of Conjecture (3) for a field $\mathbb{F}$ implies that Conjecture (2) holds for the same field $\mathbb{F}$. It is elementary to see that Conjecture (4) implies Conjecture (2) and that Conjecture (2) implies Conjecture (1).
(2) In (3) we need to add the hypothesis that $\mathbb{F}$ is of characteristic zero since Giles Gardam [**Garda2021**, Theorem A] showed that there exists a torsion-free group G such that $\mathbb{F}_2[G]$ has non-trivial units.
(3) The Kaplansky Conjectures are very attractive since they are easy to state. But it is usually very very hard to prove non-trivial group-theoretic statements that are valid for all (torsion-free) groups. In particular all of the Kaplansky Conjectures are still wide open. We refer to [**Lü2009**, Chapter 4.5] for a summary of what is known regarding these conjectures.

We continue with the following elementary lemma.

Lemma 86.13. Let G be a group and let A be an abelian group (with additive notation for the group structure). Suppose we are given a G-action on the group A. Then the map[1049]

$$\begin{array}{rcl} \mathbb{Z}[G] \times A & \to & A \\ \left(\sum_{i=1}^{m} r_i \cdot g_i, a\right) & \mapsto & \sum_{i=1}^{m} r_i \cdot (\underbrace{g_i \cdot a}_{\in A}) \end{array}$$

defines a natural left $\mathbb{Z}[G]$-module structure on A.[1050]

Proof. The lemma is indeed elementary and trivial. We leave it to the reader to ponder what "natural" might mean in this context. ■

Before we continue we introduce or recall the following convention:

Convention. If a homotopy group is abelian, then sometimes we use additive notation for the group multiplication instead of the multiplicative notation.

This convention, Lemma 86.13, Propositions 71.3 and the Change-of-Base Point Proposition 86.9 lead us to the following lemma.

Lemma 86.14. Let (X, x_0) be a pointed topological space. If $n \geq 2$, then the map

$$\begin{array}{rcl} \mathbb{Z}[\pi_1(X, x_0)] \times \pi_n(X, x_0) & \to & \pi_n(X, x_0) \\ ([\gamma], [f]) & \mapsto & [f^\gamma] \end{array}$$

induced by

defines a natural $\mathbb{Z}[\pi_1(X, x_0)]$-left module structure on $\pi_n(X, x_0)$.

86.5. **Homotopy groups of $S^1 \vee S^2$.** In this section we want to consider the homotopy groups of $S^1 \vee S^2$ since they are quite instructive. On page 1844 we already saw that $\pi_2(S^1 \vee S^2)$ is very big, more precisely, we saw that it admits an epimorphism onto $\mathbb{Z}^\infty$. We will now see that if we take the view of Lemma 86.14, i.e. if we view $\pi_2(S^1 \vee S^2)$ as a module over the group ring $\mathbb{Z}[\pi_1(S^1 \vee S^2)]$, then the apparently messy group $\pi_2(S^1 \vee S^2)$ suddenly gets a simple description.

We explicitly construct $X = S^1 \vee S^2$ by identifying the point $i \in S^1$ with the point $(0, 0, -1) \in S^2$. In the following we evidently use the wedge point as the base point of $X = S^1 \vee S^2$. We refer to it by x_0. Finally we denote by $\gamma\colon [0, 1] \to S^1 \subset X$ the obvious counterclockwise loop that starts at i. Furthermore we denote by $\mathrm{id}_{S^2}\colon S^2 \to S^2 \subset X$ the obvious inclusion map.

Now we can formulate the following proposition which delivers the promised concise description of $\pi_2(S^1 \vee S^2)$.

Proposition 86.15. To simplify the formulation and the proof of the proposition we use the base point $* = (0, 0, -1)$ for S^2 and we use this base point to define the second homotopy groups. This convention has the advantage that $\mathrm{id}\colon (S^n, *) \to (S^1 \vee S^2, x_0)$ is a

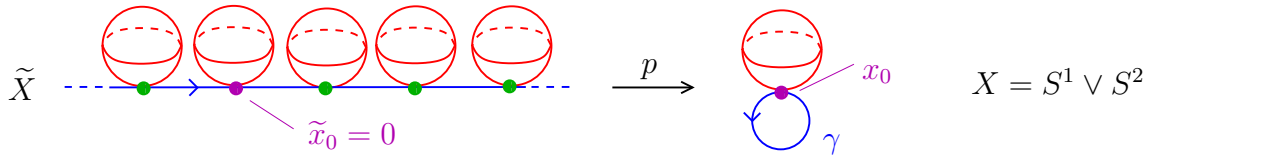
[1049] Here we use a somewhat perilous notation, namely we use the symbol "$\cdot$" with two different meanings. First of all, for $g \in G$ and $a \in A$ we denote by $g \cdot a \in A$ the element defined by the G-action on A. Secondly, for $r \in \mathbb{Z}$ and $b \in A$ we write, as usual, $r \cdot b = \underbrace{b + \cdots + b}_{r\text{-times}}$ for $r \geq 0$ and $r \cdot b = \underbrace{-b - \cdots - b}_{(-r)\text{-times}}$ for $r < 0$.

[1050] If R is a non-commutative ring, then one needs to be a little careful when one talks about "R-modules". More precisely, there are now two different concepts one can consider: Given an abelian group M one can demand that for any $r, s \in R$ and $m \in M$ one has $(rs) \cdot m = r \cdot (s \cdot m)$ in which case one says that M is an "R-left module". Alternatively one could demand that for any $r, s \in R$ and $m \in M$ one has $(rs) \cdot m = s \cdot (r \cdot m)$ in which case one says that M is an "R-right module". This discussion is the analogue of the discussion on page 249.

map of based topological spaces. Using this convention the homomorphism

$$\begin{array}{rcl}\Psi\colon \mathbb{Z}[t^{\pm 1}] & \to & \pi_2(S^1 \vee S^2, x_0) \\ \sum_{i=1}^{n} a_i \cdot t^i & \mapsto & \sum_{i=1}^{n} a_i \cdot \left[(\mathrm{id}_{S^2})^{\gamma^i}\right]\end{array}$$

that is determined by



is an isomorphism of $\mathbb{Z}[t^{\pm 1}] = \mathbb{Z}[\langle t \rangle] = \mathbb{Z}[\pi_1(S^1 \vee S^2, x_0)]$-modules. In particular, as an abelian group, $\pi_2(S^1 \vee S^2)$ is isomorphic to $\mathbb{Z}^\infty$.

Proof. It follows immediately from the definitions that the map Ψ is indeed a homomorphism of $\mathbb{Z}[t^{\pm 1}] = \mathbb{Z}[\langle t \rangle] = \mathbb{Z}[\pi_1(S^1 \vee S^2, x_0)]$-modules. Thus it remains to show that Ψ is an isomorphism of abelian groups.

As on page 1373 we see that the universal covering of $X = S^1 \vee S^2$ is given by the map

$$\begin{array}{rcl} p\colon \overbrace{\big(\mathbb{R} \cup (\mathbb{Z} \times S^2)\big) \,/\, n \sim (n,(0,0,-1))}^{=:\widetilde{X}} & \to & S^1 \vee S^2 \\ P & \mapsto & \begin{cases} \exp(2\pi \mathrm{i}(P + \frac{1}{4})), & \text{if } P \in \mathbb{R} \\ Q, & \text{if } P = (n,Q) \text{ with } n \in \mathbb{Z}, Q \in S^2. \end{cases}\end{array}$$

We pick the base points $x_0 = i \in S^1 \subset X$ and $\widetilde{x}_0 = 0 \in \mathbb{R} \subset \widetilde{X}$. Even though we have seen this covering map on numerous occasions we show it again in the figure below. We

consider the following sequence of maps

$$(*) \qquad \mathbb{Z}[t^{\pm 1}] \xrightarrow{\Psi} \pi_2(X, x_0) \xrightarrow{\Xi} \pi_2(\widetilde{X}, \widetilde{x}_0) \xrightarrow{\Phi_{(\widetilde{X},\widetilde{x}_0)}} \mathrm{H}_2(\widetilde{X}; \mathbb{Z}) \xleftarrow{\Omega} \mathbb{Z}[t^{\pm 1}].$$

Here $\Phi_{(X,x_0)}$ denotes the Hurewicz homomorphism. Since $\widetilde{X}$ is simply connected we obtain from the Hurewicz Theorem 85.5 that it is an isomorphism. The reader will not have failed to notice that we did not define the two maps Ξ and Ω yet. We will do so now.

(1) First we recall that given a map $g\colon (S^2, *) \to (X, x_0)$ there exists by the Map Lifting Criterion 61.2 a unique lift $\widetilde{g}\colon (S^2, *) \to (\widetilde{X}, \widetilde{x}_0)$. Now we consider the map

$$\begin{array}{rcl}\Xi\colon \pi_2(X, x_0) & \to & \pi_2(\widetilde{X}, \widetilde{x}_0) \\ [g\colon (S^2, *) \to (X, x_0)] & \mapsto & \left[\widetilde{g}\colon (S^2, *) \to (\widetilde{X}, \widetilde{x}_0)\right].\end{array}$$

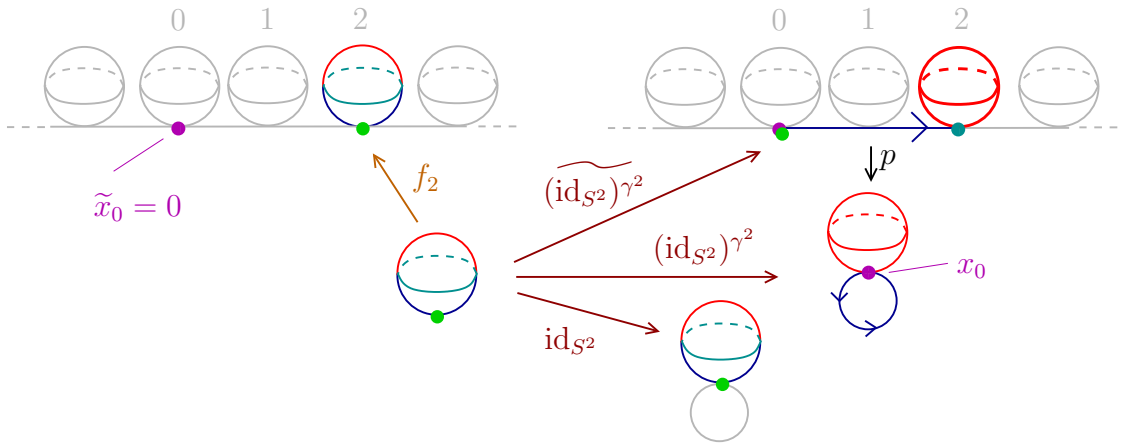
By the Coverings-π_n-Proposition 71.13 we know that Ξ is well-defined and that it is an isomorphism.

(2) Given $i \in \mathbb{Z}$ we denote by $f_i\colon S^2 \to X$ the "obvious" i-th inclusion map. In Lemma 79.7 we saw that the map

$$\begin{array}{rcl}\Omega\colon \mathbb{Z}[t^{\pm 1}] & \to & \mathrm{H}_2(\widetilde{X}; \mathbb{Z}) \\ \sum_{i=r}^{s} a_i \cdot t^i & \mapsto & \sum_{i=r}^{s} a_i \cdot f_i([S^2]).\end{array}$$

is an isomorphism.

We see in particular that in $(*)$ the three maps to the right are isomorphisms. Therefore it suffices to show that the maps $\Omega^{-1} \circ \Phi_{(X,x_0)} \circ \Xi \circ \Psi$ is the identity. In other words, it suffices to show the following claim.



Claim. For any $n \in \mathbb{Z}$ we have

$$(\Phi_{(X,x_0)} \circ \Xi \circ \Psi)(t^n) \;=\; \Omega(t^n) \;\in\; \mathrm{H}_2(\widetilde{X};\mathbb{Z}).$$

Proof. So let $n \in \mathbb{Z}$. It follows immediately from the definitions of the various maps that the desired statement is equivalent to the statement that

$$\underbrace{\left(\widetilde{(\mathrm{id}_{S^2})^{\gamma^n}}\right)_*}_{\text{map } S^2 \to \widetilde{X}}[S^2] \;=\; \underbrace{f_n}_{\text{map } S^2 \to \widetilde{X}}([S^2]) \;\in\; \mathrm{H}_2(\widetilde{X};\mathbb{Z}).$$

Thus by the Homotopic Maps-and-Homology Proposition 73.6 it suffices to show that the two maps $(\mathrm{id}_{S^2})^{\gamma^n}$ and f_n are homotopic maps from S^2 to $\widetilde{X}$. For those readers who are still awake this should be basically obvious.[1051] As a digestion aid we illustrate both maps in the figure below. ■

In the Homology-of-CW-Complex Proposition 80.6 we saw that the homology groups of a finite CW-complex are finitely generated abelian groups. Since the discussion on page 1844 we had known that the corresponding statement is not true for homotopy groups. But we now also know that one should really view the homotopy groups of a pointed topological space (X, x_0) as modules over the group ring $\mathbb{Z}[\pi_1(X, x_0)]$. Thus the following question arises.

Question 86.16. Let X be a finite CW-complex. Are the homotopy groups $\pi_n(X, x_0)$, $n \geq 2$, finitely generated $\mathbb{Z}[\pi_1(X, x_0)]$-modules?

It turns out that the answer is yes if X is simply connected. More precisely, Jean-Pierre Serre [**Ser1953**][1052] proved the following theorem.

[1051] In fact this follows from the "⇐"-direction of the Change-of-Base Point Proposition 86.9 (7).

[1052] Jean-Pierre Serre (*1926) is a French mathematician. He was, and remains, the youngest person ever to be awarded the Fields Medal.

Theorem 86.17. (Serre) If X is a *simply-connected* topological space such that all homology groups are finitely generated (for example X could be a compact topological manifold or a finite CW-complex), then all homotopy groups are also finitely generated abelian groups.[1053]

Example. It follows in particular from Serre's Theorem 86.17 that the homotopy groups of spheres are finitely generated. Even this statement is highly non-trivial. In particular it is much better than our only result in this direction, namely Corollary 94.10. which says that homotopy groups of spheres are countable.

Nonetheless, it turns out that the answer to Question 86.16 is negative. In fact, one does not need to wander off particularly far to find such an example:

Proposition 86.18. The group $\pi_3(S^1 \vee S^2)$ is not finitely generated over the group ring $\mathbb{Z}[\pi_1(S^1 \vee S^2)] = \mathbb{Z}[t^{\pm 1}]$.

Proof. A proof for the proposition is for example sketched in [**Hat2002**, Chapter 4.2, Exercise 38]. ■

Remark. The Hilton-Milnor theorem, see [**Hilt1955**, Theorem A],[**Miln1972**] or [**WhdG1978**, Chapter XI], gives a calculation of the homotopy groups of a finite wedge of spheres, more precisely, these homotopy groups are computed in terms of the homotopy groups of the spheres involved. Unfortunately, at least at a first glance, it is not so clear how the module structure over the group ring can be read off from the Hilton-Milnor theorem.

Exercises for Chapter 86.

Exercise 86.1. Let X be a topological space that admits a social choice of some type $n \geq 2$. Is X necessarily connected?

Exercise 86.2. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. We consider the Hurewicz homomorphism $\Phi\colon \pi_n(X, x_0) \to \mathrm{H}_n(X; \mathbb{Z})$. Show that for any $g \in \pi_1(X, x_0)$ and any $\sigma \in \pi_n(X, x_0)$ we have

$$\Phi(g \cdot \sigma) \;=\; \Phi(\sigma) \;\in \mathrm{H}_n(X; \mathbb{Z}).$$

Exercise 86.3. Let G be a group and let R be a commutative ring. Suppose there exists a non-trivial $g \in G$ such that $g^k = e$ for some $k \in \mathbb{N}$. Show that $R[G]$ has a zero divisor, i.e. show that there exist non-zero elements $p, q \in R[G]$ with $p \cdot q = 0$.
Hint. First consider the case that $G = \langle t \,|\, t^n \rangle$ is a finite cyclic group with $n \geq 2$ elements.

Exercise 86.4. Is the ring $\mathrm{M}(3 \times 3, \mathbb{R})$ of real (3×3)-matrices isomorphic, as a ring, to the real group ring $\mathbb{R}[G]$ of some group G?

Exercise 86.5. Let G be a finite group. We view $\mathbb{Q}[G]$ as a $\mathbb{Q}[G]$-left module via left multiplication. Show that $\mathbb{Q}[G]$ admits a submodule $V \neq 0$ with $V \neq \mathbb{Q}[G]$ that is isomorphic to the trivial $\mathbb{Q}[G]$-module $\mathbb{Q}$ where every $g \in G$ acts via the identity on $\mathbb{Q}$.

[1053] It follows immediately from the Hurewicz Theorem 85.5 that $\pi_2(X)$ is finitely generated. The fact that the higher homotopy groups are also finitely generated is much stronger.

Exercise 86.6. Let G be a finite group. Show that there exists a monomorphism from G to some unitary group $\mathrm{U}(n)$.

Exercise 86.7. We consider the ring $\mathrm{M}(2,\mathbb{R})$. Does there exist a finite set T and an epimorphism from the free ring $\mathbb{R}[\langle T\rangle]$ onto $\mathrm{M}(2,\mathbb{R})$?

Exercise 86.8. Let X be a simply connected space and let $f\colon X \to X$ be a self-homeomorphism. Recall that on page 467 we introduced the mapping torus

$$M \;:=\; (X \times [0,1])/(x,0) \sim (f(x),1).$$

Express the $\mathbb{Z}[\pi_1(M)]$-module $\pi_2(M)$ in terms of the homology groups of X and the action by f on the homology groups of X.

Exercise 86.9. Show that there exists a closed smooth manifold M such that $\pi_2(M)$ is infinitely generated as an abelian group.

87. The Euler characteristic

87.1. **The Euler characteristic and homology groups.** Let X be a finite CW-complex, i.e. let X be a CW-complex with finitely many cells. Recall that on page 1519 we defined the Euler characteristic $\chi(X)$ as follows:

$$\chi(X) \ = \ \sum_n (-1)^n \cdot \text{number of } n\text{-cells.}$$

A short glance on the examples in the figure below shows that the three different CW-structures for the torus provided in that figure have the same Euler characteristic. The following proposition explains why this is not a coincidence.

Proposition 87.1. (Euler Characteristic-H$_*$-Proposition) Let X be a finite CW-complex, then[1054]

$$\chi(X) \ = \ \sum_n (-1)^n \cdot \text{rank}(\text{H}_n(X)).$$

Examples.

(1) It follows either from the CW-structure of the n-dimensional sphere S^n with one 0-cell and one n-cell given on page 1472 or from the calculation of the homology groups in Proposition 74.4 that[1055]

$$\chi(S^n) \ = \ 1+(-1)^n \ = \ \begin{cases} 0, & \text{if } n \text{ is odd,} \\ 2, & \text{if } n \text{ is even.} \end{cases}$$

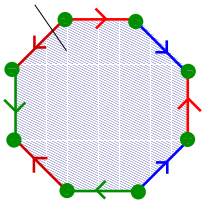
(2) Let $n \in \mathbb{N}_0$. We want to determine the Euler characteristic of $\overline{B}^n$. One could of course write down a CW-structure for $\overline{B}^n$.[1056] But with our knowledge it is quicker to point out that follows immediately from the Euler Characteristic-H$_*$-Proposition 87.1 and the Homotopy Equivalence-H$_*$-Corollary 73.9 (3) that $\chi(\overline{B}^n) = 1$.

(3) Given any $k, n \in \mathbb{N}_0$ we deduce from the Homotopy Equivalence-H$_*$-Corollary 73.9, Proposition 74.4 and the Euler Characteristic-H$_*$-Proposition 87.1 that $\chi(S^k \times \overline{B}^n) = \chi(S^k) = 1+(-1)^k$.

(4) It follows either from the obvious generalizations of CW-structure provided in the figure below or alternatively from Proposition 80.10 that for the surface Σ_g of genus g and that for the non-orientable surface N_k of genus k we have

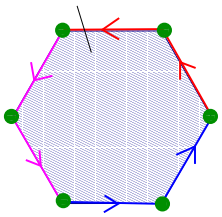
$$\chi(\Sigma_g) \ = \ 2-2g \qquad \text{and} \qquad \chi(N_k) \ = \ 2-k.$$

(5) It follows immediately from the CW-structures provided in Lemma 68.1 that for any $n \in \mathbb{N}_0$ we have



---

[1054] As a reminder, if G is a finitely generated abelian group, then it follows from the Finitely Generated Abelian Group Classification Theorem 51.4 that G is isomorphic to $\mathbb{Z}^r \oplus T$, where T is finite. We then call r the *rank* of G. Put differently, let $T \subset G$ be the torsion subgroup, then G/T is isomorphic to $\mathbb{Z}^r$ for an r, and this r is just the rank of G.



[1055] The statement that $\chi(S^2) = 2$ was proved, in a different language, by Leonhard Euler [**Eul1758**, p. 119]. This equality was already noted before by Francesco Maurolico [**Friedm2018**, p. 71] in 1537 and René Descartes [**Rabo2010**, p. 447] in 1628.

[1056] What is the "simplest" CW-structure you can find for $\overline{B}^n$?

surface Σ_g of genus $g=2$ | non-orientable surface N_k of genus $k=3$

1	number of 0-cells	1
$2 \cdot g$	number of 1-cells	k
1	number of 2-cells	1
$2-2\cdot g$	Euler characteristic	$2-k$

$$\chi(\mathbb{R}\mathrm{P}^n) \;=\; \begin{cases} 0, & \text{if } n \text{ is odd,} \\ 1, & \text{if } n \text{ is even} \end{cases} \qquad \text{and} \qquad \chi(\mathbb{C}\mathrm{P}^n) \;=\; n+1.$$

Before we turn to the proof of the Euler Characteristic-H_*-Proposition 87.1 we draw the following corollary.

Corollary 87.2. Let X and Y be finite CW-complexes. If X and Y are homotopy equivalent, then $\chi(X) = \chi(Y)$.

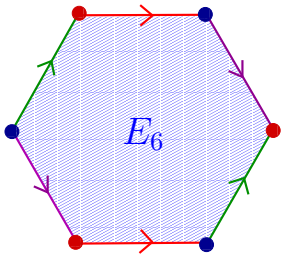
Proof. The corollary is an immediate consequence of the Euler Characteristic-H_*-Proposition 87.1 together with the Homotopy Equivalence-H_*-Corollary 73.9 (2). ■

Example. On page 1237 we introduced two examples of closed orientable 2-dimensional smooth manifolds for which we found it difficult to determine the genus. We show the same surfaces also in the figure below. Let us first consider the surface on the left: it is given identifying opposite sides of the hexagon E_6. The obvious CW-structures on the hexagon H_6 descends to a CW-structure on $E_6/\!\sim$. We make the following observations:

(1) the single 2-cell on E_6 defines a 2-cell for $E_6/\!\sim$,
(2) we identify every 1-cell of E_6 with the opposite 1-cell, thus $E_6/\!\sim$ has three 1-cells,
(3) we identify all 0-cells that differ by an even number of vertices, thus $E_6/\sim$ has precisely two 0-cells.

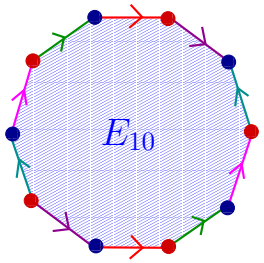
Summarizing we see that $E_6/\!\sim$ has Euler characteristic $2-3+1=0$. We had just seen on page 1879 that the surface of genus g has Euler characteristic $2-2g$. Thus we obtain from the Surface Classification Theorem 55.4 that $E_6/\!\sim$ is diffeomorphic to the surface of genus zero, i.e. the torus.

The same argument shows that $E_{10}/\!\sim$ has Euler characteristic $2-5+1=-2$ and that it is diffeomorphic to the surface of genus two. Evidently the same argument shows that if we take a regular $(4g+2)$-gon and if we identify opposite sides, then we obtain the surface of genus g.



It is a great mental exercise to visualize that the surface on the left is a torus and that the surface on the right is a surface of genus two.

The key step in the proof of the Euler Characteristic-H_*-Proposition 87.1 is the following purely algebraic lemma.



Lemma 87.3. Let

$$C_* \;:=\; 0 \;\to\; \mathrm{C}_k \xrightarrow{\partial_k} \mathrm{C}_{k-1} \xrightarrow{\partial_{k-1}} \;\dots\; \mathrm{C}_1 \xrightarrow{\partial_1} \mathrm{C}_0 \;\to\; 0$$

hexagon with opposite sides identified

dodecagon with opposite sides identified

in each case there are two equivalence classes of vertices: red and blue

be a chain complex of finitely generated abelian groups. Then the following equality holds:

$$\sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank}(\mathrm{C}_n) \;=\; \sum_{n=0}^{k}(-1)^n \operatorname{rank}(\mathrm{H}_n(C_*)).$$

The same statement holds if the C_i are vector spaces over a field and if we replace ranks by dimensions.

Proof. For the above chain complex (C_n, ∂_n) we write for each $n \in \mathbb{N}_0$[1057]

$$Z_n := \ker(\partial_n), \quad B_n := \operatorname{im}(\partial_{n+1}) \quad \text{and} \quad H_n = Z_n/B_n.$$

These groups form the following two types of short exact sequences

(a) $$0 \hookrightarrow Z_n \to \mathrm{C}_n \xrightarrow{\partial_n} B_{n-1} \to 0,$$

and

(b) $$0 \hookrightarrow B_n \to Z_n \to H_n \to 0.$$

Now we see that

$$\begin{aligned}
\sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank} \mathrm{C}_n
&\overset{\text{by (a) and the Rank Additivity Lemma 51.7 (2) we have } \operatorname{rank}\mathrm{C}_n = \operatorname{rank} Z_n + \operatorname{rank} B_{n-1}}{\downarrow} \\
&= \sum_{n=0}^{k}(-1)^n \cdot (\operatorname{rank} Z_n + \operatorname{rank} B_{n-1}) \\
&= \sum_{n=0}^{k}(-1)^n \cdot (\operatorname{rank} B_n + \operatorname{rank} H_n + \operatorname{rank} B_{n-1}) \\
&\overset{\text{by (b) and the Rank Additivity Lemma 51.7 (2) we have } \operatorname{rank} Z_n = \operatorname{rank} B_n + \operatorname{rank} H_n}{\uparrow} \\
&= \sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank} H_n \;+ \sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank} B_n + \sum_{n=0}^{k}(-1)^n \operatorname{rank} B_{n-1} \\
&\overset{\text{we do the substitution } m = n-1 \text{ and we use that } B_k = 0 \text{ and } B_{-1} = 0}{\uparrow} \\
&= \sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank} H_n \;+ \sum_{n=0}^{k-1}(-1)^n \cdot \operatorname{rank} B_n - \sum_{m=0}^{k-1}(-1)^m \cdot \operatorname{rank} B_m \\
&= \sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank} H_n.
\end{aligned}$$

Basically the same proof also applies if the C_i are vector spaces over a field and if we replace ranks by dimensions. ■

Now we can easily provide the proof of the Euler Characteristic-H_*-Proposition 87.1.

[1057] It is a common notation to call these groups Z_n and B_n, the names go back to the German words "Zykel" and "Bild".

Proof of the Euler Characteristic-H_*-Proposition 87.1. Let X be a finite k-dimensional CW-complex. We have

$$\begin{array}{rcccl} \chi(X) & = & \sum_{n=0}^{k}(-1)^n \cdot \text{number of } n\text{-cells} & \overset{\text{Skeleton-Homology Lemma 80.1}}{=} & \sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank}(\mathrm{C}_n^{\mathrm{CW}}(X)) \\ & \underset{\text{Lemma 87.3}}{=} & \sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank}(\mathrm{H}_n^{\mathrm{CW}}(X)) & \underset{\text{Singular-Cellular } \mathrm{H}_*\text{-Isomorphism Proposition 80.4}}{=} & \sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank}(\mathrm{H}_n(X)). \end{array}$$

■

Using Lemma 87.3 we can also easily prove the following lemma which be will useful on several occasions.

Lemma 87.4. Let

$$0 \to A_k \to A_{k-1} \to \ldots \to A_1 \to A_0 \to 0$$

be an exact sequence of finitely generated abelian groups. Then

$$\sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank} A_n = 0.$$

Proof. We can view this exact sequence of finitely generated abelian groups as a chain complex whose homology groups vanish. The lemma is therefore an immediate consequence of Lemma 87.3. ■

Definition.

(1) Given a topological space X and $n \in \mathbb{N}_0$ such that $\mathrm{H}_n(X)$ is a finitely generated abelian group we refer to

$$b_n(X) := \operatorname{rank}(\mathrm{H}_n(X))$$

as the n-th Betti number of X.[1058]

(2) Let X be a topological space. If all homology groups are finitely generated and if $\sum_n b_n(X)$ is finite, then we define the Euler characteristic of X to be

$$\chi(X) := \sum_n (-1)^n \cdot b_n(X).$$

Remark.

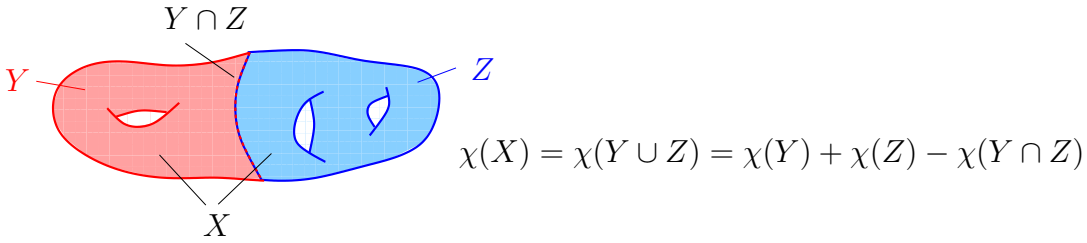
(1) It follows from the Euler Characteristic-H_*-Proposition 87.1 that this new definition of the Euler characteristic of a finite CW-complex agrees with the earlier definition.

(2) We will see in the Smooth Manifolds-Invariants Proposition 96.6 and alternatively on page 2997 that for every compact smooth manifold we can define the Euler characteristic. Furthermore we will see in the Topological Manifolds-Invariants Proposition 104.14 that we can also define the Euler characteristic for every compact topological manifold.

[1058] These numbers are named after the Italian mathematician Enrico Betti (1823-1892)

http://de.wikipedia.org/wiki/Enrico_Betti

who had studied an early version of homology groups.



Example. Using the Mapping Torus-Homology Proposition 78.20 and using Lemma 87.4 several times we will prove the following statement in Exercise 87.3: Let X be a topological space that is homotopy equivalent to a finite CW-complex, then for any self-homeomorphism f of X we have

$$\chi(\mathrm{Tor}(X,f)) \;=\; 0.$$

87.2. **Properties of the Euler characteristic.** The Euler characteristic is an invariant which "sees less" than the homology groups. On the other hand we will now see that it behaves better than the homology groups under several natural operations.
The following lemma makes it possible to determine the Euler characteristic of a CW-complex from suitable decompositions.

Lemma 87.5. (Euler Characteristic-Addition Lemma) Let $X = Y \cup Z$ be a decomposition of a finite CW-complex X into two subcomplexes Y and Z. Then the following equality holds

$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

Proof. We give two proofs for the lemma:

(1) Given $n \in \mathbb{N}_0$ and given a subset W we denote by $n(W)$ the number of open n-cells that are contained in W. In our case we have

$$n(X) \;\underset{\uparrow}{=}\; n(Y) + n(Z) - n(Y \cap Z).$$

since every open n-cell of X lies in Y or Z, the n-cells that lie in $Y \cap Z$ get counted twice in $n(Y) + n(Z)$, so we have to subtract $n(Y \cap Z)$

By performing the alternating sum over all n we obtain immediately that

$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

We have thus proved the desired equality.

(2) The lemma also follows from applying Lemma 87.4 and the Euler Characteristic-H_*-Proposition 87.1 to the long exact sequence of homology groups that we obtain by applying the Mayer–Vietoris Theorem for CW-complexes 78.10 to the decomposition $X = Y \cup Z$. ∎

In the following we provide two examples to which we already know the answer by other means. Nonetheless, the approach using the Euler Characteristic-Addition Lemma 87.5 gives particularly short and pleasing arguments.

Example. Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem **??** there exists a tubular map $\Phi\colon \overline{B}^2 \times K$. We set $X_K := S^3 \setminus \Phi(B^2 \times K)$. By the Smooth Manifold-CW Structure Theorem 96.5 there exists a CW-structure for S^3 such that X_K and $\Phi(\overline{B}^2 \times S^1)$

are subcomplexes. We see that

$$0 \underset{\uparrow}{=} \chi(S^3) = \chi\big(X_K \cup \Phi(\overline{B}^2 \times S^1)\big) \underset{\uparrow}{=} \chi(X_K) + \chi\big(\overline{B}^2 \times S^1\big) - \chi\big(\partial\overline{B}^2 \times S^1\big) \underset{\uparrow}{=} \chi(X_K).$$

see page 1879 — Euler Characteristic-Addition Lemma 87.5 — see page 1879

Of course this calculation also follows from Lemma 100.16.

Example. As usual, given $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$ we denote by $\Sigma_{g,n}$ the surface Σ_g of genus g minus n open disks. Now we want to determine the Euler characteristic $\chi(\Sigma_{g,n})$. We could do so by using Propositions 87.1 and 80.10. But here we use an alternative approach. By the Smooth Manifold-CW Structure Theorem 96.5 there exists a CW-structure on Σ_g such that $\Sigma_{g,n}$ and the closed disks that we remove are subcomplexes. It now follows that

$$2-2g \underset{\uparrow}{=} \chi(\Sigma_g) = \chi\Big(\Sigma_{g,n} \cup \bigcup_{i=1}^{n} \overline{B}^2\Big) \underset{\uparrow}{=} \chi(\Sigma_{g,n}) + \sum_{i=1}^{n}\chi(\overline{B}^2) - \sum_{i=1}^{n}\chi(\partial\overline{B}^2) \underset{\uparrow}{=} \chi(\Sigma_{g,n}) + n.$$

see page 1879 — Euler Characteristic-Addition Lemma 87.5 — see page 1879

Thus we see that $\chi(\Sigma_{g,n}) = 2 - 2g - n$.

We record the above example in a lemma.

Lemma 87.6.

(1) Let $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$. If we denote by $\Sigma_{g,n}$ the surface Σ_g of genus g minus n open disks, then $\chi(\Sigma_{g,n}) = 2 - 2g - n$.
(2) Let Σ and Σ' be two compact orientable connected 2-dimensional smooth manifolds. If Σ and Σ' have the same number of boundary components and if $\chi(\Sigma) = \chi(\Sigma')$, then Σ and Σ' are diffeomorphic.

Proof.

(1) We proved this statement in the example preceding the lemma.
(2) This statement follows immediately from (1) and the classification of compact orientable connected 2-dimensional smooth manifolds, see the Surface Classification Theorem 55.4. ■

We continue with a calculation of the Euler characteristic of a connected sum.

Lemma 87.7. (Connected Sum-χ-Lemma) If M and N are two compact connected n-dimensional smooth manifolds. We have the following equality:[1059]

$$\chi(M\#N) = \chi(M) + \chi(N) + \begin{cases} -2, & \text{if } n \text{ is even,} \\ 0, & \text{if } n \text{ is odd.} \end{cases}$$

Proof. We perform the following straightforward calculation:

$$\chi(M \setminus B^n) \underset{\uparrow}{=} \chi(M) - \chi(\overline{B}^n) + \chi(S^{n-1}) \underset{\uparrow}{=} \chi(M) + (-1)^{n-1}.$$

Euler Characteristic-Addition Lemma 87.5 — since $\chi(\overline{B}^n) = 1$ and $\chi(S^{n-1}) = 1 + (-1)^{n-1}$

[1059] Strictly speaking, if M and N are both orientable, then we need to assume that M and N are oriented to get a well-defined connected sum.

The same way we also see that $\chi(N \setminus B^n) = \chi(N) + (-1)^{n-1}$. It then follows, using the same type of arguments, that

$$\begin{aligned}\chi(M\#N) &= \chi(M \setminus B^n) + \chi(N \setminus B^n) - \chi(S^{n-1}) \\ &= \chi(M) + (-1)^{n-1} + \chi(N) + (-1)^{n-1} - (1 + (-1)^{n-1}) \\ &= \chi(M) + \chi(N) - 1 + (-1)^{n-1}.\end{aligned}$$

For completeness sake we point out that in the Connected Sum-H_*-Proposition 100.13 we will calculate the homology groups of the connected sum of two closed oriented smooth manifolds. Together the Euler Characteristic-H_*-Proposition 87.1 this gives an alternative proof of the above equality. ■

Examples.

(1) In the figure on page **??** we saw that the connected sum of two tori is the surface of genus two. By the Connected Sum-χ-Lemma 87.7 we obtain that[1060]

$$\chi(\text{surface of genus two}) = \underbrace{\chi(\text{torus})}_{=0} + \underbrace{\chi(\text{torus})}_{=0} - 2 = -2.$$

We had obtained the same result on page 1879 using a different method.

(2) Note that from the CW-structure for $\mathbb{R}P^2$ that we gave in the figure on page 1472 we read off that $\chi(\mathbb{R}P^2) = 1$. It follows from the Connected Sum-χ-Lemma 87.7 that for any $k \in \mathbb{N}$ we have

$$\chi(k \cdot \mathbb{R}P^2) = 1 - k.$$

Using the same argument as in Lemma 87.6 one can also show that

$$\chi(k \cdot \mathbb{R}P^2 \text{ minus } n \text{ open disks}) = 1 - k - n.$$

In the following we work our way through more constructions of CW-complexes and the effect on Euler characteristics. First we remind the reader of the following lemma.

Lemma 69.5. (Quotient-χ-Lemma) Let X be a finite CW-complex and let A be a subcomplex. We equip the quotient X/A with the CW-structure given by the CW-Complex Construction Lemma 68.32 (3). Then

$$\chi(X/A) = \chi(X) - \chi(A) + 1.$$

Next let X and Y be two finite CW-complexes. On page 1498 we introduced the product CW-structure which by Proposition 68.23 is indeed a CW-structure for the topological space $X \times Y$. The following lemma relates the Euler characteristics of X, Y and $X \times Y$ in an appealing way.[1061]

Lemma 87.8. (Product-χ-Lemma) Let X and Y be two finite CW-complexes, then

$$\chi(X \times Y) = \chi(X) \cdot \chi(Y).$$

Example. For any finite CW-complex X we have $\chi(S^1 \times X) = \chi(S^1) \cdot \chi(X) = 0$.

[1060] How many arguments can you find in the lecture notes that show that the Euler characteristic of the torus is zero?

[1061] Note that the lemma also gives an affirmative answer to the question posed in Exercise 69.2.

Proof. Let X and Y be two finite CW-complexes. Given $k \in \mathbb{N}_0$ we denote by c_k the number of k-cells of X and we denote by d_k the number of k-cells of Y.

We equip $X \times Y$ with the product CW-structure from page 1498. By construction we have

$$\#n\text{-cells of } X \times Y \;=\; \sum_{k+l=n} \#k\text{-cells of } X \cdot \#l\text{-cells of } Y \;=\; \sum_{k+l=n} c_k \cdot d_l.$$

It follows that

$$\chi(X) \cdot \chi(Y) \;=\; \Big(\sum_k (-1)^k \cdot c_k\Big) \cdot \Big(\sum_l (-1)^l \cdot d_l\Big) \;=\; \sum_n (-1)^n \sum_{k+l=n} c_k \cdot d_l \;=\; \chi(X \times Y). \;\blacksquare$$

Now let $p\colon \widetilde{X} \to X$ be a k-fold covering of path-connected topological spaces. We saw in Corollary 48.14 that the induced map $p_*\colon \pi_1(\widetilde{X}) \to \pi_1(X)$ is a monomorphism and we saw in Lemma 48.15 (3) that $p_*(\pi_1(\widetilde{X}))$ is a subgroup of index k of $\pi_1(X)$. There is no analogous statement for homology groups. For example the projection $p\colon S^2 \to S^2/\!\sim = \mathbb{R}\mathrm{P}^2$ is a 2-fold covering, but $\mathrm{H}_2(S^2) = \mathbb{Z}$ and $\mathrm{H}_2(\mathbb{R}\mathrm{P}^2) = 0$, which shows that the induced map on homology is in general not a monomorphism.

It is therefore perhaps surprising that we already saw in Proposition 69.4 that the Euler characteristic behaves well under finite coverings. For convenience we recall, a slightly simplified version, of the statement of Proposition 69.4.

Proposition 69.4. (Covering-χ-Proposition) Let $p\colon \widetilde{Y} \to Y$ be a finite covering of a finite connected CW-complex Y. Then $\widetilde{Y}$ is also a finite CW-complex with

$$\chi(\widetilde{Y}) \;=\; [\widetilde{Y} : Y] \cdot \chi(Y).$$

Example. We consider again the 2-fold covering $p\colon S^2 \to \mathbb{R}\mathrm{P}^2$. In this case we have by the calculation on page 1725 or alternatively in Proposition 80.11 that

$$\begin{array}{rcl} \mathrm{H}_0(S^2) &\cong& \mathbb{Z}, \\ \mathrm{H}_1(S^2) &\cong& 0, \\ \mathrm{H}_2(S^2) &\cong& \mathbb{Z}, \\ \mathrm{H}_i(S^2) &\cong& 0, \text{ for } i \geq 3, \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{H}_0(\mathbb{R}\mathrm{P}^2) &\cong& \mathbb{Z}, \\ \mathrm{H}_1(\mathbb{R}\mathrm{P}^2) &\cong& \mathbb{Z}_2, \\ \mathrm{H}_2(\mathbb{R}\mathrm{P}^2) &\cong& 0, \\ \mathrm{H}_i(\mathbb{R}\mathrm{P}^2) &\cong& 0, \text{ for } i \geq 3. \end{array}$$

Thus we see that the homology groups are quite different. Nonetheless we observe that $\chi(S^2) = 2$ is indeed twice $\chi(\mathbb{R}\mathrm{P}^2) = 1$, as we had determined on page 1879.

In Question 63.6 we asked how the genus of a surface changes if we take finite covers. We had answered this question already in the Subgroups-of-Surface Groups Proposition 64.6 (1). The proof of the following lemma is arguably more conceptual and easier to remember.

Lemma 87.9. Let Σ be the surface of genus g and let $p\colon \widetilde{\Sigma} \to \Sigma$ be a k-fold connected covering. Then[1062]

$$\mathrm{genus}(\widetilde{\Sigma}) \;=\; k \cdot (g-1) + 1.$$

Example. In the figure on page 1407 we illustrated a 3-fold covering of the surface of genus 4 over the surface of genus 2.

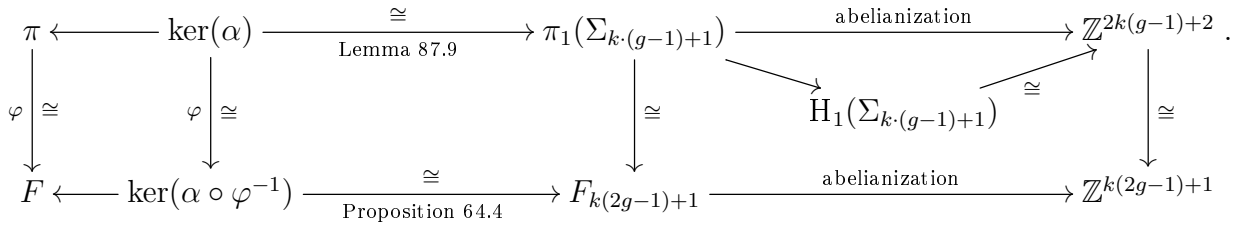
Remark. We had given an alternative proof of Lemma 87.9 in Exercise 64.6. The new proof using Euler characteristics is surely much more instructive than our previous proof.

[1062] Recall that by the Surface Classification Theorem 55.4 there exists precisely one $\widetilde{g}$ such that the closed, oriented 2-dimensional smooth manifold $\widetilde{\Sigma}$ is diffeomorphic to precisely the surface of genus $\widetilde{g}$.

Proof. We denote by $\widetilde{g}$ the genus of $\widetilde{\Sigma}$. The lemma follows immediately from the following two facts:

(1) By the remark on page 1879 we have $\chi(\Sigma) = 2 - 2g$ and $\chi(\widetilde{\Sigma}) = 2 - 2\widetilde{g}$.

(2) By Proposition 69.4 we have $\chi(\widetilde{\Sigma}) = k \cdot \chi(\Sigma)$. ∎



Now we can also give a new proof of the following proposition.

Proposition 64.17. If $g \geq 1$, then the group

$$\pi_1(\text{surface of genus } g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \,|\, [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \rangle$$

is not isomorphic to the free group F_{2g} on $2g$ generators.

Proof. Let Σ be a surface of genus $g \geq 1$. We write $\pi = \pi_1(\Sigma)$. Suppose that there exists an isomorphism $\varphi\colon \pi \to F$ where F is the free group on $2g$ generators. Let $\alpha\colon \pi \to \mathbb{Z}_k$ be an epimorphism for some $k \geq 2$.[1063] We denote by $p\colon \widetilde{\Sigma} \to \Sigma$ the covering which satisfies $p_*(\pi_1(\widetilde{\Sigma})) = \ker(\alpha)$ which is given by the Covering Existence Theorem 61.5. By Lemma 48.15 (3) this is a k-fold covering. We get the following commutative diagram:

It follows from $k \geq 2$ that $2k(g-1)+2 \neq k(2g-1)+1$, hence the two groups on the right cannot by isomorphic. We have thus obtained a contradiction. ∎

87.3. **Groups acting on spheres and surfaces.** We recall that on page 248 we said that a group G acts *freely* on a topological space X if for every $g \neq e$ and every $x \in X$ we have $g \cdot x \neq x$. For example for each $k \in \mathbb{N}$ the action

$$\begin{array}{rcl} \mathbb{Z}_k \times S^1 & \to & S^1 \\ (l, z) & \mapsto & \exp(2\pi \mathrm{i} l/k) \cdot z \end{array}$$

is free. We can easily generalize this example. More precisely, let S^{2n-1} be an odd-dimensional sphere. We view S^{2n-1} as subset of $\mathbb{R}^{2n} = \mathbb{C}^n$. Then it is straightforward to show that

$$\begin{array}{rcl} \mathbb{Z}_k \times S^{2n-1} & \to & S^{2n-1} \\ (l, (z_1, \ldots, z_n)) & \mapsto & (\exp(2\pi \mathrm{i} l/k) \cdot z_1, \ldots, \exp(2\pi \mathrm{i} l/k) \cdot z_n) \end{array}$$

is a free and continuous action of $\mathbb{Z}_k$ on S^{2n-1}.

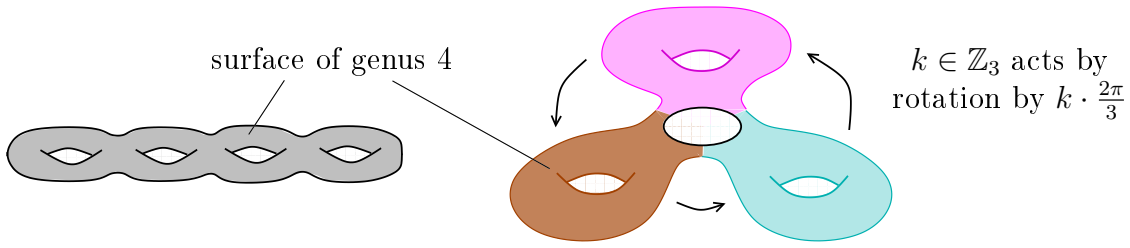
It is less clear what finite groups can act freely and continuously on even-dimensional spheres. The group $\mathbb{Z}_2 \cong \{\pm 1\}$ acts of course freely and continuously on any sphere. The following proposition says that $\mathbb{Z}_2$ is in fact the only finite non-trivial group that can act freely and continuously on an even-dimensional sphere. This proposition and the above example give a complete answer to Question 48.8.

Proposition 87.10. If a finite group G acts freely and continuously on an even-dimensional sphere, then G is either trivial or $G \cong \mathbb{Z}_2$.

[1063] Why does such an epimorphism exist?

Proof. Let G be a finite group that acts freely and continuously on S^{2n}. By Lemma 48.5 the action is also discrete. By the Actions-Covering Proposition 48.9 the projection $S^{2n} \to S^{2n}/G$ is a covering of degree $|G|$. We obtain the equalities

$$2 \underset{\substack{\uparrow \\ \text{see page 1616}}}{=} \chi(S^{2n}) \underset{\substack{\uparrow \\ \text{Proposition 69.4}}}{=} |G| \cdot \chi(S^{2n}/G).$$



Itt follows that $|G|$ divides two, i.e. $|G| = 1$ or $|G| = 2$. In first case the group G is the trivial group and in the second case we have $G \cong \mathbb{Z}_2$.[1064] ■

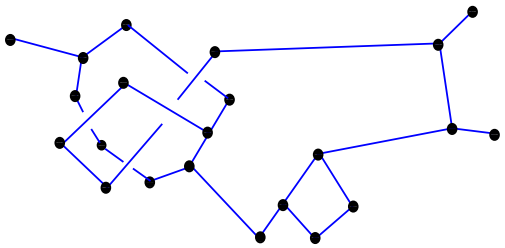
We already gave a different proof of Proposition 87.10 in Exercise 76.21. But whereas the approach of Exercise 76.21 made very much use of the topology of spheres, the approach taken in the above proof generalizes to many other settings:

Proposition 87.11. Let $g \in \mathbb{N}_0$. If a finite group G acts freely and continuously on the surface Σ of genus g, then the order of G divides $\chi(G) = 2 - 2g$.

Proof. The proof of Proposition 87.11 is verbatim the same as the proof of Proposition 87.10. The only change is that we need to use the fact, shown on page 1879, that $\chi(\Sigma) = 2 - 2g$. ■

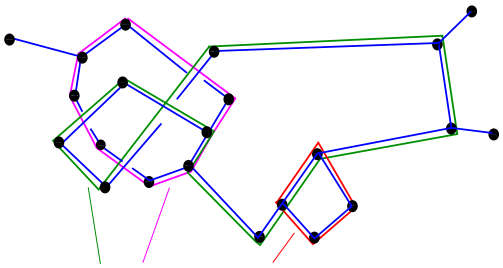
Example. Let Σ be the surface of genus four. By the remark on page 1879 we know that $\chi(\Sigma) = -6$. By Proposition 87.10 we know that the order of any finite group acting freely and continuously on Σ has to have an order that divides 6. In the figure below we sketch a free and continuous action of the group $\mathbb{Z}_3$ on Σ. In Exercise 87.10 we will see that given any n with $n|\chi(\Sigma)$ the cyclic group $\mathbb{Z}_n$ admits a free and continuous action on Σ.

87.4. **Topological graphs** (∗). Using the results of this chapter we can now easily prove the following lemma:



Lemma 87.12. Let G be a connected topological graph with v vertices and e edges. Then

$$\mathrm{H}_0(G) \cong \mathbb{Z}, \quad \mathrm{H}_1(G) \cong \mathbb{Z}^{e-v+1} \quad \text{and} \quad \mathrm{H}_i(G) = 0 \text{ for } i \geq 2.$$



Example. In the figure below we see a connected topological graph G with 22 vertices and 24 edges. It follows from Lemma 87.12 that its first homology group is isomorphic to $\mathbb{Z}^3$. In the figure below we sketched three cycles which represent a generating set for $\mathrm{H}_1(G) \cong \mathbb{Z}^3$.

Proof. Let G be a connected topological graph with v vertices and e edges. Recall that by the discussion on page 1470 we can view G as a 1-dimensional CW-complex with v 0-cells and e 1-cells.

[1064] Why is every group with two elements isomorphic to $\mathbb{Z}_2$?

topological graph G with 22 vertices and 24 edges

generating set for $\mathrm{H}_1(G) \cong \mathbb{Z}^3$

Now that we have developed so many techniques for computing homology groups it is perhaps not surprising that we can provide three different proofs for the lemma.

(1) First of all, from the H_0-Proposition 72.5 together with the CW-Complex Properties Proposition 68.10 (7) it follows immediately that $\mathrm{H}_0(G) \cong \mathbb{Z}$. Furthermore, from the Homology-of-CW-Complex Proposition 80.6 it follows that $\mathrm{H}_i(G) = 0$ for $i \geq 2$ and that $\mathrm{H}_1(G)$ is torsion-free. From the Euler Characteristic-H_*-Proposition 87.1 we obtain that

$$\chi(X) \;=\; \sum_i (-1)^i \cdot \mathrm{rank}(\mathrm{H}_i(X)).$$

Putting everything together we see that

$$1 - \mathrm{rank}(\mathrm{H}_1(G)) \;=\; \chi(X) \;=\; \#0\text{-cells} - \#1\text{-cells} \;=\; v - e.$$

Since $\mathrm{H}_1(G)$ is torsion-free we obtain that $\mathrm{H}_1(G) \cong \mathbb{Z}^{e-k+1}$.

(2) We can also modify the argument of (1) as follows: instead of calculating $\mathrm{H}_1(G)$ using the Euler characteristic, we could also have determined that $\mathrm{H}_1(G) \cong \mathbb{Z}^{e-k+1}$ by combining the calculation of the fundamental group in the Fundamental Group-of-Graph Proposition 52.5 with the isomorphism of the Hurewicz Theorem 84.5.

(3) An alternative proof for Lemma 87.12 is given as follows: we have

$$\widetilde{\mathrm{H}}_j(G) \;\underset{\text{Quotient-by-Tree Proposition 69.8 (1) and the Homotopy Equivalence-}\mathrm{H}_*\text{-Corollary 73.9}}{\cong}\; \widetilde{\mathrm{H}}_j(\text{wedge of } 1-\chi(G) \text{ circles}) \;\underset{\text{Wedge-Homology Proposition 79.8}}{\cong}\; \bigoplus_{i=1}^{1-\chi(G)} \widetilde{\mathrm{H}}_j(S^1) \;\underset{\text{Proposition 74.4}}{\cong}\; \begin{cases} \mathbb{Z}^{1-\chi(G)}, & \text{if } j=1, \\ 0, & \text{else.} \end{cases}$$

It is a matter of taste which of the three proofs is the nicest. ■

Exercises for Chapter 87.

Exercise 87.1. Show that every CW-structure for the torus with one 0-cell has precisely one 2-cell.

Exercise 87.2.

(a) Let $k \in \mathbb{N}$. By Proposition 49.4 we know that the non-orientable surface N_k admits an essentially unique 2-fold covering $\Sigma \to N_k$ that is orientable. What is the genus of Σ?

(b) Let $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$. By Proposition 49.4 we know that the non-orientable surface $N_{k,m}$ admits an essentially unique 2-fold covering $\Sigma \to N_{k,m}$ that is orientable. What is the genus of Σ and what is the number of boundary components of Σ?
Remark. You could use Exercise 49.12.

Remark. These are precisely the same questions as in Exercise 55.11. But this time you can give a different, shorter proof using Euler characteristics.

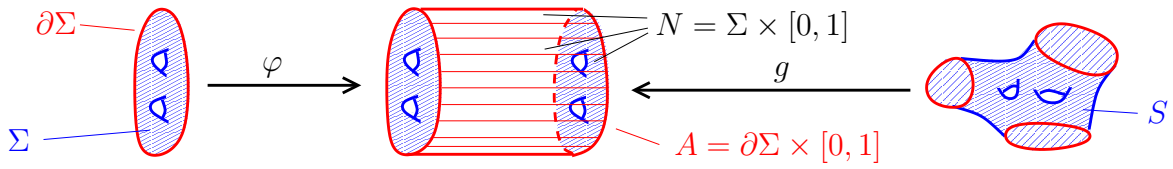
Exercise 87.3. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. In the Mapping Torus-Homology Proposition 78.20 we showed that for any $n \in \mathbb{N}_0$ there exists a short exact sequence

$$0 \to \operatorname{coker}\big(\mathrm{H}_n(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_n(X)\big) \to \mathrm{H}_n(\mathrm{Tor}(X,f)) \to \ker\big(\mathrm{H}_{n-1}(X) \xrightarrow{f_*-\mathrm{id}} \mathrm{H}_{n-1}(X)\big) \to 0.$$

(a) Let $T = \mathbb{R}^2/\mathbb{Z}^2$ be the torus. Given $A \in \mathrm{SL}(2,\mathbb{Z})$ we consider the homeomorphism

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [Av]. \end{array}$$

Determine the homology groups of $\mathrm{Tor}(T, f(-\mathrm{id}))$.
Remark. You can use the fact that under the usual identification $\mathrm{H}_1(T) = \mathbb{Z}^2$ the induced map $f(A)_*$ is given by multiplication by A.[1065]



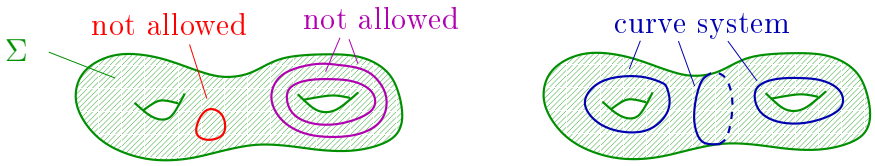
(b) Does there exist a matrix $A \in \mathrm{SL}(2,\mathbb{Z})$ such that $\mathrm{H}_1(\mathrm{Tor}(T, f(A))) \cong \mathbb{Z}$?

(c) Let X be a topological space that is homotopy equivalent to a finite CW-complex. Show that for any self-homeomorphism f of X we have

$$\chi(\mathrm{Tor}(X,f)) \;=\; 0.$$

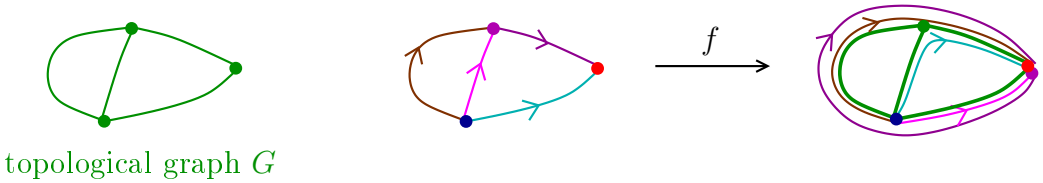
Exercise 87.4. For a topological space X and $n \in \mathbb{N}_0$ we denote by $b_n(X) \in \mathbb{N}_0 \cup \{\infty\}$ the rank of $\mathrm{H}_n(X)$. Does there exist a topological space X such that $b_1(X) < \infty$ but such that for a *finite* cover $\widetilde{X}$ of X we have $b_1(\widetilde{X}) = \infty$?

Exercise 87.5. Given $g, n, \in \mathbb{N}_0$ we denote by $\Sigma_{g,n}$ the surface of genus g minus n open disks. Let $g, k, m, n \in \mathbb{N}_0$. Suppose there exists a smooth embedding $\Sigma_{g,m} \to \Sigma_{k,n}$. Show that $g \le k$.
Hint. Use the Codimension-Zero Submanifold Proposition 19.38.



Exercise 87.6. Let Σ be a 2-dimensional smooth manifold. A *curve system* is a collection of disjoint curves (i.e. closed connected 1-dimensional smooth manifolds) $C_1, \dots, C_n$ on Σ with the following two properties:

(1) None of the C_i is the boundary of a disk on F.
(2) There is no annulus on F such that the boundary is the union of two curves.



In the figure below on the right we see a curve system on the surface of genus two consisting of three curves.

[1065] Why does this hold?

(a) Is there a curve system consisting of four curves on the surface of genus two?
(b) Given $g \in \mathbb{N}_0$, what is the maximal number of curves in a curve system on the surface of genus g?

Exercise 87.7. We consider the topological graph G together with the map $f\colon G \to G$ shown in Exercise 87.7. Determine the determinant and the trace of the induced map $f_*\colon \mathrm{H}_1(G) \to \mathrm{H}_1(G)$.
Remark. In the proof of Lemma 87.12 we gave three different, more or less explicit, isomorphisms $\varphi\colon \mathrm{H}_1(G) \xrightarrow{\cong} \mathbb{Z}^2$. The challenge now is to find an isomorphism φ that is explicit enough so that one can calculate the map $\varphi \circ f_* \circ \varphi^{-1}\colon \mathbb{Z}^2 \to \mathbb{Z}^2$.

topological graph G

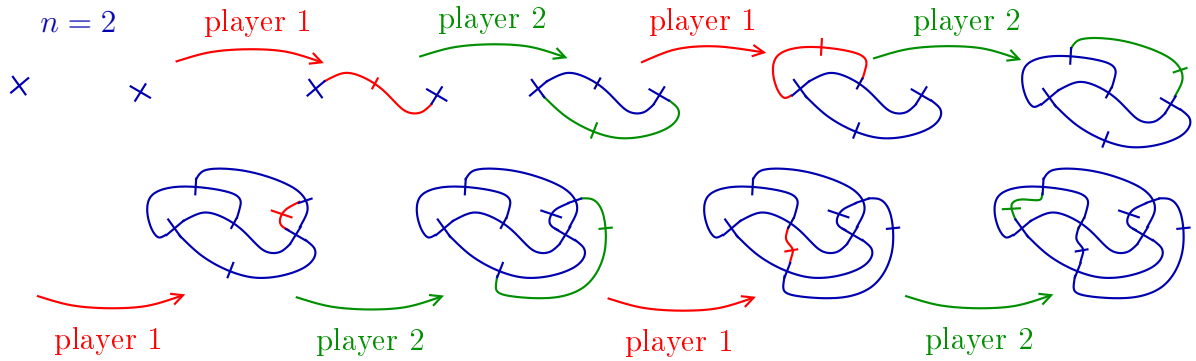
Exercise 87.8. Let M be a compact orientable connected 2-dimensional smooth manifold.
(a) Show that there exists a $g \in \mathbb{N}_0$ such that M admits g disjoint curves such that the complement is connected, but such that any $g+1$ disjoint curves disconnect M.
(b) Show that g equals the genus of M, as defined on page 1237.

Remark. This exercise gives an intrinsic definition of the genus of a compact orientable connected 2-dimensional smooth manifold.

Exercise 87.9. Let M be a closed non-orientable connected 2-dimensional smooth manifold. We define $k(M) \in \mathbb{N}_0$ to be the maximum $k \in \mathbb{N}_0 \cup \{\infty\}$ such that there exist k smooth embeddings of the Möbius band into M with the following two properties: the images are disjoint and the complement of images is connected.
(a) Let K be the Klein bottle. Show that $k(M) \geq 2$.
(b) Let M be a closed non-orientable connected 2-dimensional smooth manifold.
(i) Show that $k(M)$ is finite.
(ii) Show that $k(M)$ equals the genus of M, as defined on page 1237.
Remark. This exercise gives an intrinsic definition of the genus of a compact non-orientable connected 2-dimensional smooth manifold.

Exercise 87.10.
(a) Let $N_3 = \mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ be the non-orientable surface of genus three. Show that given any even $n \in \mathbb{N}$ there exists a connected orientable covering $p\colon \Sigma \to N_3$ of degree n.
(b) Let Σ be the surface of genus g. Show that given any $k \in \mathbb{N}$ that divides $\chi(\Sigma)$ there exists a continuous and free action by the cyclic group $\mathbb{Z}_n$ on Σ.

Remark. This exercise gives in particular a more systematic solution to Exercise 5.39.



Exercise 87.11. Let Σ be the torus minus one open disk. Furthermore let $\alpha, \beta\colon S^1 \to \Sigma$ be two disjoint embeddings with $\alpha_*([S^1]) = \beta_*([S^1]) \in \mathrm{H}_1(\Sigma)$. We denote this homology class by x.

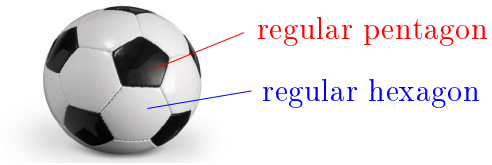
(a) Suppose that $x \neq 0$. Show that α is isotopic to β.
(b) Show that the conclusion of (a) does not necessarily hold, if we drop the hypothesis that $x \neq 0$.

Exercise 87.12. The two player game of "Brussels sprouts" works as follows:

(1) Initially one draws n disjoint crosses on a 2-dimensional smooth manifold.
(2) The two players take turns to do the following move: Join two free ends with a curve, without crossing any existing curve, and then put a short stroke across the new curve to create two new free ends.

Such a game with $n = 2$ is illustrated in the figure below.

(a) Suppose that the game takes place on the plane $\mathbb{R}^2$. Show that if n is odd, then the first player will always win and show that if n is even, then the second player invariably wins.
(b) Show that the conclusion of (a) also holds if the game takes place on a closed orientable 2-dimensional smooth manifold.



Remark. The game of "Brussels sprouts" is a variation on the more interesting game "sprouts" introduced by John Conway and Michal Paterson in the 1967. More information on "Sprouts" and "Brussels sprouts" can be found in [**FiG1991**, Chapter 6] and [**Gardn1989**, Chapter 1].

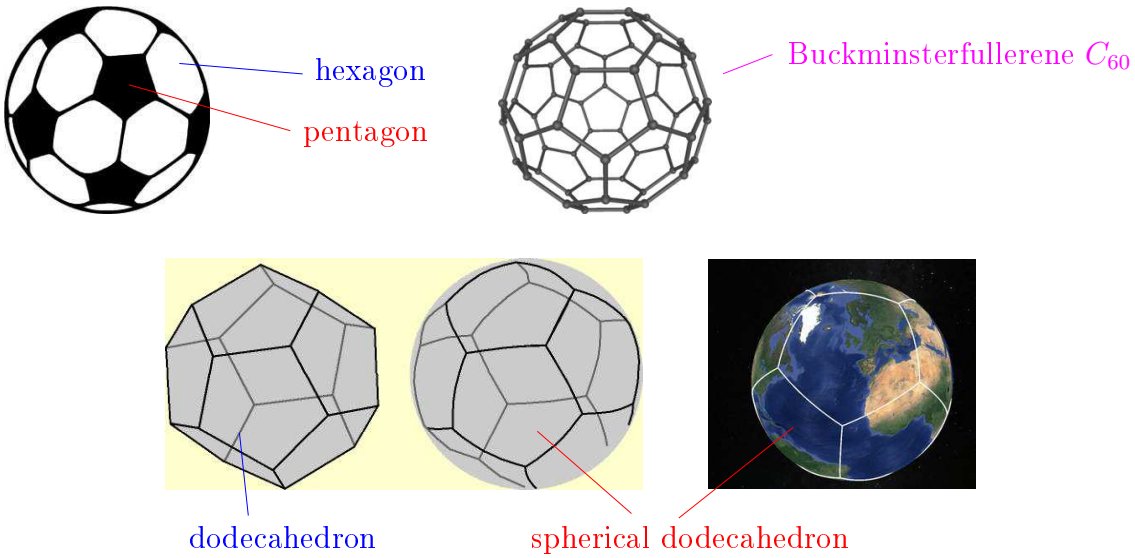
88. Applications of the Euler characteristic (∗)

In this chapter we show that the fairly simple concept of the Euler characteristic can be used to give answers to several questions about 3-dimensional objects. The reader is warned in that in this chapter at times we will sacrifice complete notational rigor for readability.

88.1. **Building a leather football ❀.** In this section we will discuss the shapes of footballs and the platonic solids. The results of this section will not be used later on and we will present some of the material in a slightly informal, somewhat less rigorous style.

Definition. An n-gon on the 2-dimensional sphere S^2 is called regular if the isometry group of the sphere acts transitively on the set of vertices and the set of faces of the n-gon. In particular all interior angles are the same. For example the classical leather football is made out of regular pentagons and hexagons.

Now we want to determine how many pentagons and hexagons are required to make a football. So suppose a football is made out of p spherical regular pentagons and h spherical regular hexagons where the vertices of the pentagons are precisely the vertices of hexagons. This endows S^2 with a CW-structure. We first note that each 1-cell bounds two 2-cells. Furthermore, elementary spherical geometry, see e.g. [**Bon2009**, p. 53] or [**Fen2001**, p. 260], says that the interior angle of a spherical pentagon and a spherical hexagon are larger than the corresponding Euclidean angles. Therefore we see that interior angles are larger than[1066] $\pi - \frac{2\pi}{5} = \frac{3}{5}\pi$. So at any vertex there are not more than three hexagons and pentagons that meet, which of course implies that there are precisely three hexagons and pentagons that meet. Therefore we see that



$$\begin{aligned} \#\text{2-cells} &= p + h \\ \#\text{1-cells} &= \tfrac{1}{2}(5p + 6h) \\ \#\text{0-cells} &= \tfrac{1}{3}(5p + 6h). \end{aligned}$$

By the Euler Characteristic-H_*-Proposition 87.1 and the above calculation of the Euler characteristic of S^2 we now have

$$2 \;=\; \chi(S^2) \;=\; \sum_{n=0}^{2}(-1)^n \cdot \#n\text{-cells} \;=\; \tfrac{1}{3}(5p+6h) - \tfrac{1}{2}(5p+6h) + (p+h) \;=\; \tfrac{1}{6}p.$$

Thus we see that a football has to have precisely 12 pentagons. On the other hand, the number of hexagons is not fixed. For example, the standard football has 20 hexagons, as pictured in the figure below on the left.
But in principle one could also build a football with zero hexagons, see the figure below one the right, and one obtains a spherical dodecahedron. One could also build with many hexagons, but they would be much less round since they would have bigger flat parts.

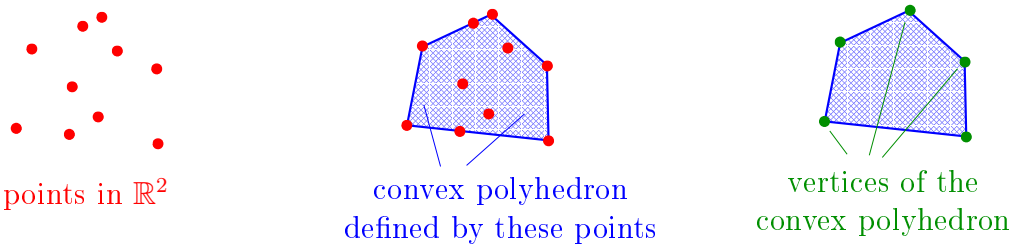
[1066] Where does that formula come from?

The 1-skeleton of this CW-structure were in fact already "invented by nature", more precisely, there exists a molecule, called the Buckminsterfullerene C_{60}, built out of 60 carbon atoms, which has exactly the same shape as a football. More information can be found at

`https://en.wikipedia.org/wiki/Buckminsterfullerene`

88.2. **Platonic solids ❀.** Recall that on page 157 we defined the *convex hull* of a subset $S \subset \mathbb{R}^n$ as the intersection of all convex subsets of $\mathbb{R}^k$ that contain S. Since the intersection of convex sets is again convex we see that the convex hull of S is a convex subset of $\mathbb{R}^k$.

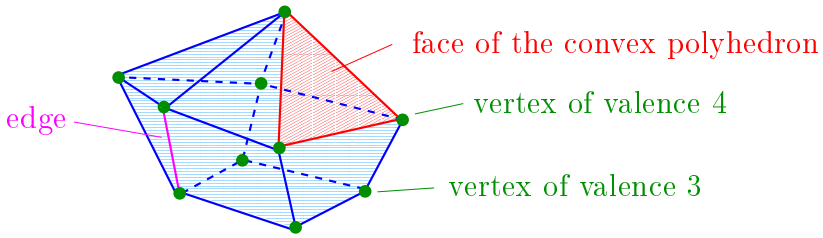
Definition.
(1) A convex polyhedron is the convex hull of finitely many points in $\mathbb{R}^k$.[1067] [1068][1069]
(2) The dimension of a convex polyhedron is defined as the minimal dimension of an affine subspace of $\mathbb{R}^k$ that contains the convex polyhedron.



We leave the task of providing a proof of the following lemma to the meticulous reader.

Lemma 88.1. If P is a convex polyhedron in $\mathbb{R}^k$, then there exists a unique finite set V such that P is the convex hull of V, but such that for any proper subset W of V, P is not the convex hull of W.

Definition. Let P be a convex polyhedron in $\mathbb{R}^k$.
(1) We refer to the finite set of Lemma 88.1 as the vertices of the convex polyhedron P.



[1067] It is an amusing little exercise to show that this notion of a convex polyhedron agrees with the notion that we had originally defined on page 1552.
[1068] In the literature a convex polyhedron is often also called a polytope.
[1069] Recall that we saw in Exercise 2.38 (a) that the convex hull of points $P_1, \ldots, P_n \in \mathbb{R}^k$ is given by the set

$$\Big\{ \sum_{i=1}^{n} t_i \cdot P_i \,\Big|\, t_1, \ldots, t_i \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^{n} t_n = 1 \Big\}.$$

(2) If P is a k-dimensional convex polyhedron, then an edge of the convex polyhedron is the convex hull of two vertices that has the property that it lies on ∂P.[1070]
(3) If P is a k-dimensional convex polyhedron, then an m-dimensional face of the convex polyhedron is the convex hull of m vertices that has the property that it lies on ∂P. (In particular, by definition a 1-dimensional face is exactly the same as an edge.)
(4) An edge is a 1-dimensional face and sometimes we refer to a 2-dimensional face just as a face, without specifying the dimension.
(5) The valence of a vertex is defined as the number of edges that contain the vertex.

Example. The notion of a vertex, an edge, a face and the valence of a vertex are illustrated in the figure below.

Proposition 88.2. (Euler's Formula) Let P be a k-dimensional convex polyhedron in $\mathbb{R}^k$.
(1) The interior $\mathring{P}$ of P is non-empty and all faces of P are of dimension $\leq k-1$.
(2) The boundary ∂P admits a CW-structure such that for each $j \in \mathbb{N}_0$ the j-cells are precisely the j-dimensional faces of P.
(3)
$$\sum_{j=0}^{k-1}(-1)^j \cdot \#j\text{-dimensional faces} \;=\; 1+(-1)^{k-1}.$$

Remark. The 3-dimensional version of Proposition 88.2 gives us that for the boundary of a 3-dimensional convex polyhedron in $\mathbb{R}^3$ we have

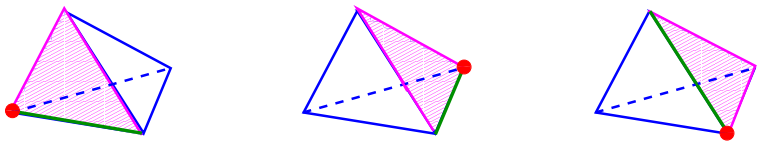
$$\text{number of vertices} - \text{number of edges} + \text{number of faces} \;=\; 2.$$

This equality is known as Euler's Formula and was first formulated Leonhard Euler in 1752. Arguably Euler's Formula is historically the first result in topology. A famous book by Imre Lakatos [**Lak1976**] is dedicated to the challenge of finding the correct statement of Euler's formula and of providing a rigorous proof of Euler's Formula without employing the technical machinery, namely singular homology, that we used.

[1070] Here ∂P is the boundary of P viewed as a subset of $\mathbb{R}^k$.

Proof. We leave the pleasure of proving the first two statements to the reader as Exercise 88.1. Now we calculate that

$$\sum_{j=0}^{k-1}(-1)^j \cdot \#j\text{-dimensional faces} \underset{\text{by (1) and (2)}}{=} \chi(\partial P) \overset{\text{Convex-to-Ball Proposition 2.20 (2) together with (1)}}{=} \chi(S^{k-1}) \underset{\text{see page 1879}}{=} 1+(-1)^{k-1}.$$



■

We move on to the next definitions.

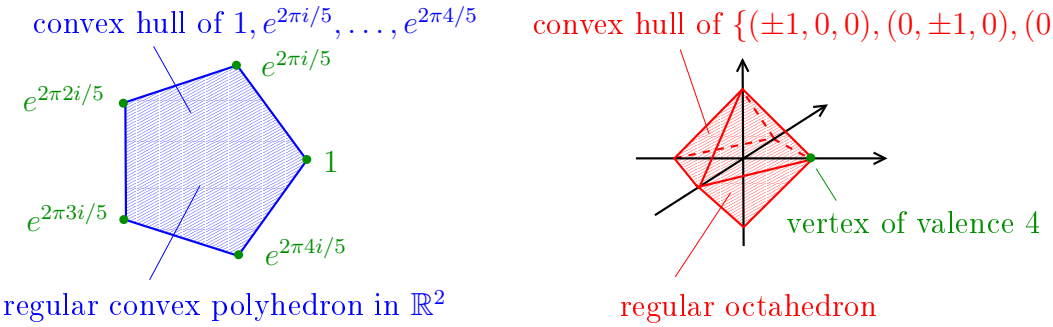
Definition.

(1) Let P be a convex m-dimensional polyhedron in $\mathbb{R}^k$.
   (a) A rotational symmetry of P in $\mathbb{R}^k$ is a matrix $A \in \mathrm{SO}(k)$ such that $A \cdot P = P$. The rotational symmetry group $\mathrm{Sym}(P) \subset \mathrm{SO}(k)$ is defined as the group of all rotational symmetries of P.
   (b) A flag of P is a sequence $F_0 \subset F_1 \subset \cdots \subset F_{m-1}$ of faces of P such that each F_i is i-dimensional.
   (c) A convex polyhedron P is called regular if the rotational symmetry group $\mathrm{Sym}(P)$ acts transitively on the set of flags of P.

(2) Two convex polyhedra P and Q in $\mathbb{R}^k$ are called equivalent if there exists an $r > 0$, a point $v \in \mathbb{R}^k$, and an orthogonal matrix $A \in \mathrm{SO}(k)$ with $P = A \cdot (r \cdot Q) + v$.

three flags in the regular tetrahedron T

Examples.

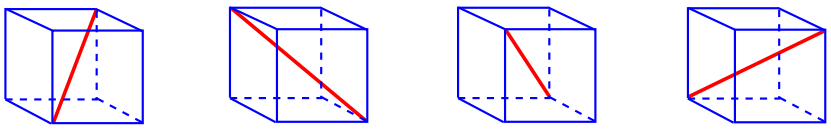


(1) Let T be the 3-dimensional polyhedron in $\mathbb{R}^3$ that has four 2-dimensional faces, each of which is an equilateral triangle. We show T together with three flags in the figure above. Some elementary geometry shows that T is, up to equivalence, uniquely defined and it is regular. We refer to T as the *regular tetrahedron*.

(2) The standard n-simplex Δ^n is an n-dimensional convex polyhedron in $\mathbb{R}^{n+1}$ with vertex set $\{(1,0,\ldots,0),(0,1,0,\ldots,0),\ldots,(0,\ldots,0,1)\}$. Each vertex has valence n. It is straightforward to see that Δ^n is regular.

(3) Let $n \in \mathbb{N}_{\geq 3}$ and $r > 0$. The convex hull of the points $r, r \cdot e^{\pi \mathrm{i}/n}, \ldots, r \cdot e^{2\pi \mathrm{i}(n-1)/n}$ in $\mathbb{C} = \mathbb{R}^2$ is a regular convex polyhedron with vertices $r, r \cdot e^{2\pi \mathrm{i}/n}, \ldots, r \cdot e^{2\pi \mathrm{i}(n-1)/n}$, where each vertex has valence 2. We leave it to the reader to show that, up to equivalence, these are all regular 2-dimensional convex polyhedra in $\mathbb{R}^2$. We refer to the figure below for an illustration.

(4) The convex polyhedron spanned by $\{(\pm 1,0,0),(0,\pm 1,0),(0,0,\pm 1)\}$ is a regular 3-dimensional convex polyhedron where each vertex has valence 4. This convex polyhedron is usually called the *regular octahedron*. We refer to the figure below for an illustration.



(5) We consider the cube $[-1,1]^3 \subset \mathbb{R}^3$. In [**Arm1988**, p. 38] it is shown that the group $\mathrm{Sym}([-1,1]^3)$ is isomorphic to S_4. More precisely, we denote by D the set of the

diagonals in the cube, i.e. the segments in $\mathbb{R}^3$ spanned by opposite vertices of the cube. Note that D has precisely four elements. We refer to the figure below for an illustration. Then the map

$$\begin{array}{rcl} \mathrm{Sym}([-1,1]^3) & \to & S_4 \cong \text{permutation group of } D \\ A & \mapsto & \begin{pmatrix} D & \to & D \\ d & \mapsto & A \cdot d \end{pmatrix} \end{array}$$

is shown in [**Arm1988**, p. 38] to be an isomorphism.[1071] It is clear that the cube is a regular convex polyhedron. Since it has six sides it is in our context also referred to as *regular hexahedron*.

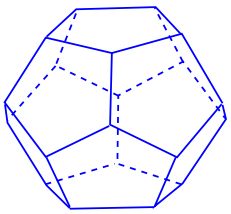
(6) Let $z := 1 + \frac{\sqrt{5}}{2}$ be the golden ratio. We denote by D the polyhedron that is spanned by the 20 vertices

$$(\pm 1, \pm 1, \pm 1), \quad (0, \pm z, \pm \tfrac{1}{z}), \quad (\pm \tfrac{1}{z}, 0, \pm z), \quad \text{and} \quad (\pm z, \pm \tfrac{1}{z}, 0).$$

It is illustrated in the figure below. By [**Cox1948**, p. 53] this is a regular polyhedron. We refer to is as the *regular dodecahedron*. Note that it has 12 faces and 20 vertices. We can inscribe five cubes $C_1, \ldots, C_5$ into the regular dodecahedron. In [**Arm1988**, p. 40] it is shown that the map

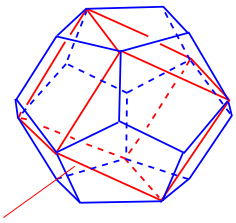
$$\begin{array}{rcl} \mathrm{Sym}(D) & \to & A_5 \cong \text{positive permutations of } \{C_1, \ldots, C_5\} \\ A & \mapsto & (C_i \mapsto A \cdot C_i) \end{array}$$

is an isomorphism.[1072]



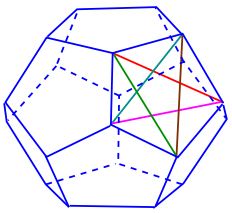
(7) Let $z := 1 + \frac{\sqrt{5}}{2}$ be the golden ratio. We denote by I the polyhedron that is spanned by the 12 vertices

$$(0, \pm 1, \pm z), \quad (\pm z, 0, \pm 1) \quad \text{and} \quad (\pm 1, \pm z, 0).$$



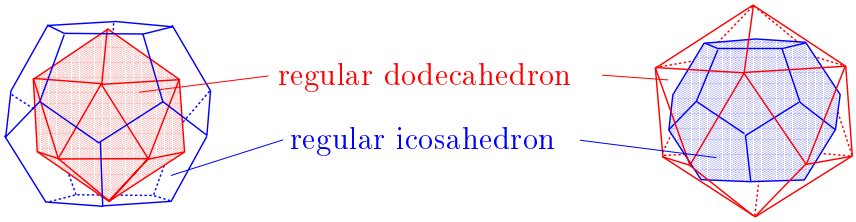
By [**Cox1948**, p. 52] this is a regular polyhedron. We refer to is as the *regular icosahedron*. Note that the regular dodecahedron has 20 vertices and 12 faces whereas

[1071] It is a good exercise to verify this statement.



[1072] The regular dodecahedron, and its symmetry group, will play a prominent role later on. More precisely in Section 98.4 we will use these to construct the Poincaré homology sphere which is a closed 3-dimensional smooth manifold M such that $\pi_1(M)$ is a group of order 120, but with trivial abelianization.

regular dodecahedron

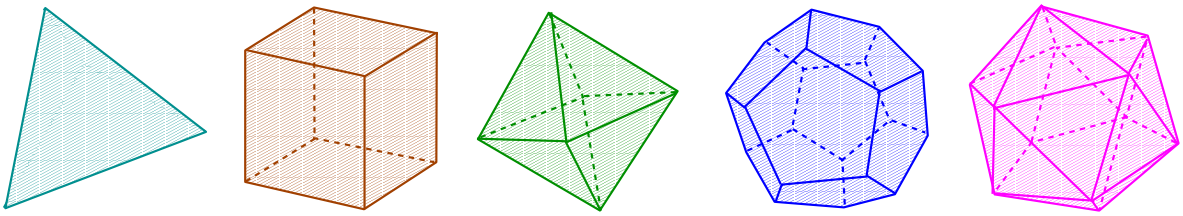


cube inscribed into the regular dodecahedron

the five diagonals of a face correspond precisely to one inscribed cube

the regular icosahedron has 12 vertices and 20 faces. In fact the regular icosahedron is dual to the regular dodecahedron in the following sense: up to a scaling factor and a rotation, the regular icosahedron is spanned by the centers of the faces of the regular dodecahedron and vice-versa. We refer to the figure below for an illustration of this fact. It follows that the symmetry group of the regular icosahedron I is in a suitable sense equal to the symmetry group of the regular dodecahedron D. In particular the group $\mathrm{Sym}(I)$ is isomorphic to A_5.

The following definition is one of the oldest in the history of mathematics.



Definition. A Platonic solid is a regular 3-dimensional convex polyhedron in $\mathbb{R}^3$.

Theorem 88.3. Up to rotation and stretching the only regular convex 3-dimensional polyhedra in $\mathbb{R}^3$ are the platonic solids illustrated in the figure below.[1073] They have the following types of faces and valences and they have the following rotational symmetry groups:

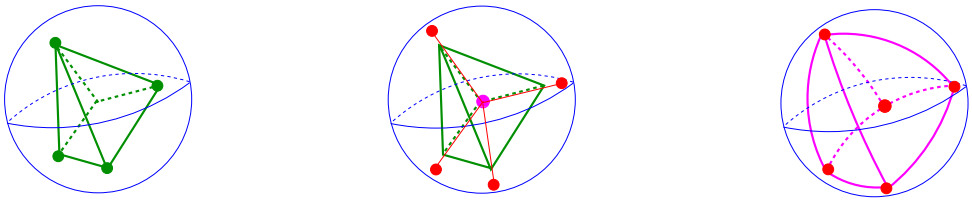
	tetrahedron	hexahedron	octahedron	dodecahedron	icosahedron
number of faces	4	6	8	12	20
shape of face	3-gon	4-gon	3-gon	5-gon	3-gon
valence of vertex	4	3	4	3	5
rotational symmetry group	A_4	S_4	S_4	A_5	A_5

Sketch of proof. We will not provide a full proof for the theorem. We refer to [**Cox1948**, Section 6.7] for a full proof that the list of five platonic solids is indeed complete. Furthermore we refer to [**Arm1988**, p. 40] or alternatively to [**Ae2008**, Chapter 5.5] for a proof of the statement regarding the rotational symmetry groups.[1074]

[1074] We had sketched the proofs for the regular hexahedron, the regular dodecahedron and the regular icosahedron.

In the following we will show that any platonic solid fits into the table of the theorem. Put differently, we will show that given any platonic solid the number of faces, the shape of faces and the valence of a vertex corresponds to one of the five columns in the above table.

Thus let P be a regular convex 3-dimensional polyhedron in $\mathbb{R}^3$. We make the following observations:



(1) It follows easily from the definition of a regular polyhedron that there exists an m such that each face of P is a regular m-gon.
(2) The number of faces that meet a vertex is the same for every vertex and it is at least three.

The following claim tells us the possible values for m and the number of faces that meet at a vertex.

Claim.

possible values for m	3	4	5
faces that meet at a vertex	3, 4, 5	4	3

Proof. First note that after a translation we can assume that the sum of all vertices is in the origin. Next we shrink the convex polyhedron so that it fits into the sphere S^2. Then we consider the projection of the vertices and edges of the convex polyhedron onto the sphere, see the figure below. Recall that the spherical interior angle of a regular m-gon is greater than the Euclidean angle of a regular m-gon. So it follows that in our case the interior angle is greater than the angle of a regular m-gon in $\mathbb{R}^3$, i.e. it is greater than $\pi - \frac{2\pi}{m}$. Since at any vertex at least three faces meet we obtain the restriction that $3(\pi - \frac{2\pi}{m}) < 2\pi$. It is now straightforward to see that we obtain the stated table. ⊞

Now we treat the cases $m = 3, 4, 5$ separately. We start out with the case $m = 3$, i.e. we assume that all the faces of the convex polyhedron are equilateral triangles. Let us first consider the case that three triangles meet at a vertex. Then we have

$$\#\text{faces} = k, \quad \#\text{edges} = \tfrac{1}{2} \cdot 3k \quad \text{and} \quad \#\text{vertices} = \tfrac{1}{3} \cdot 3k.$$

Now we see that

$$2 \underset{\text{Euler's Formula 88.2}}{=} \#\text{vertices} - \#\text{edges} + \#\text{faces} \underset{\text{by the above}}{=} k - \tfrac{3}{2}k + k = \tfrac{1}{2}k.$$

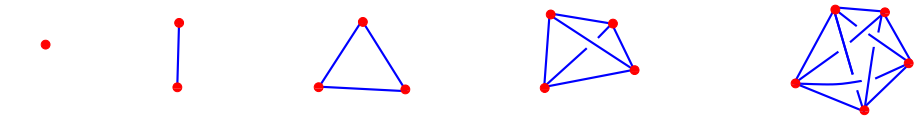
It follows that $k = 4$. Almost the same calculation shows that if four triangles meet at a vertex, then $k - \frac{3}{2}k + \frac{3}{4}k = 2$, i.e. $k = 8$. Finally by the above claim it remains to consider the case that five triangles meet at a vertex. In this case we see that $k - \frac{3}{2}k + \frac{3}{5}k = 2$, i.e. $k = 20$.

Next we consider the case $m = 4$, i.e. each face is a square. The same argument as above shows that the valence of a vertex can only be three and the same calculation shows that there have to be precisely six faces. Finally if $m = 5$, i.e. if each face is a regular pentagon, then as above we see that the valence of a vertex can only be three and that there have to be precisely twelve faces. ■

On page 1896 we had just seen that there exist infinitely many equivalence classes of regular convex polyhedra in $\mathbb{R}^2$. On the other hand we have just seen in Theorem 88.3 that in $\mathbb{R}^3$ there are only finitely many, namely precisely five equivalence classes of regular convex polyhedra in $\mathbb{R}^3$. This begs the question, what is the number in higher dimensions? It turns out that in $\mathbb{R}^4$ there are six equivalence classes of regular convex polyhedra, whereas in all higher dimensions there are only three equivalence classes of convex polyhedra. A nice exposition of these facts is given on the following website:

`http://math.ucr.edu/home/baez/platonic.html`

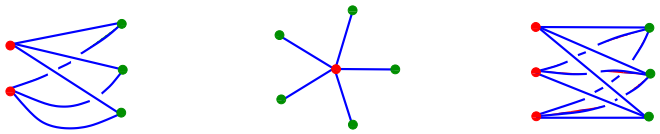
88.3. **Planar graphs ❀.** On pages 307 and 313 we defined the notions of an (ordered) abstract graph. By Lemma 7.5 and the discussion on page 313 we know that they have homeomorphic topological realizations. In this section we will mostly deal with undirected abstract graphs. Since this name is rather unwieldy we will refer to them just as graphs. For the convenience of the reader we recall the definition.



Definition. An (undirected abstract) graph G is a triple (V, E, φ) where V is a non-empty set, E is a set and φ is a map

$$\varphi\colon E \to \{\text{subsets of } V \text{ with one or two elements}\}.$$

The elements of V are called vertices of G and the elements of E are called the edges of G.



Examples.

(1) For $n \in \mathbb{N}$ we define the *complete graph* K_n as the abstract graph with vertex set $V = \{v_1, \dots, v_n\}$ and edge set $E = \{\{v_i, v_j\} \mid i, j \in \{1, \dots, n\} \text{ with } i \neq j\}$. Furthermore we define $\varphi\colon E \to V$ via $\varphi(e) = e$. Put differently, the complete graph K_n has n vertices and each vertex is connected to any other vertex by precisely one edge. In the figure below we show topological realizations of the complete graphs K_1, K_2, K_3, K_4 and K_5.

K_1 K_2 K_3 K_4 K_5

(2) For every choice of $m, n \in \mathbb{N}$ we define the *complete bipartite graph* $K_{m,n}$ as the abstract graph which is defined by the vertex set $V = \{x_1, \dots, x_m\} \cup \{y_1, \dots, y_n\}$, the edge set $E = \{\{x_i, y_j\} \mid i \in \{1, \dots, m\} \text{ and } j \in \{1, \dots, n\}\}$ and the map $\varphi\colon E \to V$ via $\varphi(e) = e$. Put differently, the complete bipartite graph $K_{m,n}$ consists of m "red-colored" vertices, n "green-colored" vertices and each "red-colored" vertex is connected to any "green-colored" vertex by precisely one edge. In the figure below we show topological realizations of the complete bipartite graphs $K_{2,3}$, $K_{1,5}$ and $K_{3,3}$.

$K_{2,3}$ $K_{1,5}$ $K_{3,3}$

Let $G = (V, E, \varphi)$ be a graph. On page 308 we introduced its topological realization $|G|$. It follows from Lemma 7.5 and the discussion on page 1470 that $|G|$ is naturally a 1-dimensional CW-complex where the 0-cells correspond to the vertices and the 1-cells correspond to the edges.
Let G be a finite graph. On page 312 we had already mentioned that there exists an embedding of its topological realization $|G|$ into $\mathbb{R}^3$. In Question 7.4 we asked, without really expecting a positive answer, whether one can always find an embedding of $|G|$ into $\mathbb{R}^2$. This leads us to the following dimension.

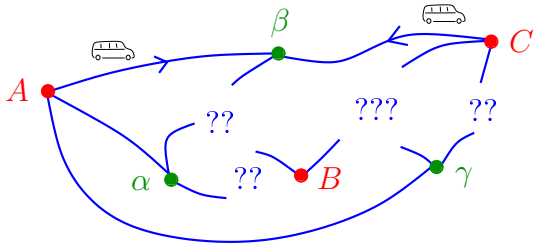
Definition. We say a finite graph G is planar if its topological realization $|G|$ admits an embedding $|G| \to \mathbb{R}^2$.

Examples.

(1) The above graphs K_1, K_2, K_3 and $K_{1,5}$ are planar. The above topological realizations of K_4 and $K_{2,3}$ are not planar. But as we see in the figure below both graphs admit planar realizations.

topological realizations of K_4 topological realizations of $K_{2,3}$

(2) One can easily verify that given an $m \in \mathbb{N}$ the bipartite graph $K_{2,m}$ is planar.



Now the following question arises.

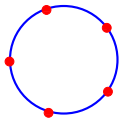
Question 88.4. Are the graphs K_5 and $K_{3,3}$ also planar?

If this question sounds to abstract and bipartite graphs sound too otherworldly let me reformulate the question regarding $K_{3,3}$.

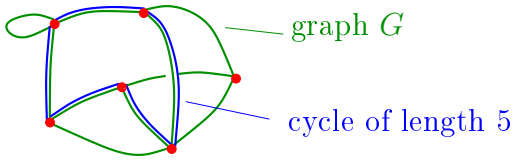
Question 88.5. Suppose we are in charge of finding efficient bus routes in a given city. Furthermore suppose the city has three main employers A, B and C. After work the employees, naturally, either want to go to the train station α, or the swimming pool β

or the shopping mall γ. Is it possible to find bus routes which connect each of the three employers with each of the three destinations such that the bus routes do not intersect?[1075]

To answer that question we need a few more definitions.



Definition. Let G be a graph.



(1) Given $n \in \mathbb{N}$ we denote by X_n the "circular graph with n vertices and n edges", more precisely, X_n is the graph with

$$V(X_n) = \{1, \dots, n\} \quad \text{and} \quad E(X_n) = \{\{1,2\}, \{2,3\}, \dots, \{n-1, n\}, \{n, 1\}\}.$$

(2) A cycle of length n in G is an injective map $\varphi\colon X_n \to G$ of graphs in the sense of the definition given in Exercise 7.10.

(3) The girth of G is the shortest length of a cycle in G. If G has no cycles, then we define its girth as ∞.

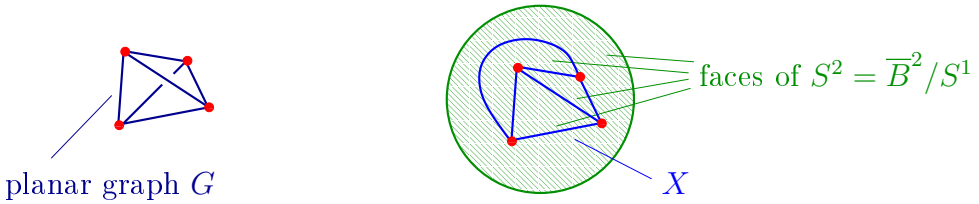
Examples.

(1) The girth of the graph shown in the figure above to the right is one, since it has an edge where the two endpoints agree.

(2) For any $n \geq 3$ the girth of the complete graphs K_n equals three.

(3) For any $n, m \geq 2$ the girth of the complete bipartite graphs $K_{n,m}$ equals four.

The following gives an obstruction to a graph being planar.



Proposition 88.6. Let G be a graph with v vertices and e edges. We denote by g the girth of G. If G is planar and if $g < \infty$, then

$$e \leq \frac{g}{g-2} \cdot (v-2).$$

Sketch of proof. Let G be a graph with v vertices and e edges. We suppose that the girth g of G is finite. Furthermore we suppose that G is planar, i.e. we suppose that there exists an embedding $\varphi\colon |G| \to \mathbb{R}^2$. We write $X = \varphi(|G|)$. Without loss of generality we can assume that X lies in $\overline{B}^2$.

Now we view X as a subset of the sphere $S^2 = \overline{B}^2/S^1$. We refer to the closures of the components of $S^2 \setminus X$ as *faces* and we denote by f the number of faces. We refer to the figure below for an illustration. We make the following observation:

[1075] It follows easily from Proposition 36.4 that the answer to this question does not depend on the precise location of A, B, C and α, β, γ, as long as they are distinct.

(1) The vertices, edges and faces define a CW-structure for $S^2 = \overline{B}^2/S^1$.[1076]
(2) We make the following two observations:
   (a) The boundary of each face is a cycle. By the definition of the girth each face is bounded by at least g edges.
   (b) Each edge lies in the boundary of at most two faces.

   Now we deduce that

$$\begin{aligned} g \cdot f &\leq \sum_{\text{faces } f} \text{number of edges in the boundary of } f \\ &= \text{number of pairs } (f,e) \text{ where } f \text{ is a face and } e \text{ an edge in the boundary of } f \\ &= \sum_{\text{edges } e} \text{number of faces that contain } e \text{ in the boundary } \leq 2e. \end{aligned}$$

   Here the first inequality follows from (a) and the last inequality follows from (b). Summarizing we see that $g \cdot f \leq 2e$.

Now we see that

$$2 \underset{\substack{\uparrow \\ \text{see page 1879}}}{=} \chi(S^2) = v - e + f \underset{\substack{\uparrow \\ \text{since } g \cdot f \leq 2e}}{\leq} v - e + \frac{2}{g}e = v - \frac{g-2}{g}e.$$

Solving for e we get the desired inequality $e \leq \frac{g}{g-2} \cdot (v-2)$. ■

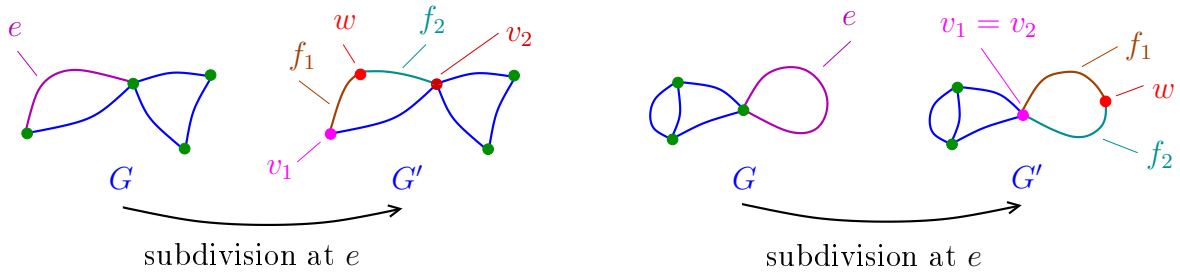
The following proposition gives in particular a negative answer to Question 88.4.

Proposition 88.7. If a graph G contains the complete graph K_5 or the complete bipartite graph $K_{3,3}$ as a subgraph, then G itself cannot be planar.

Proof.

(1) Let $m \in \mathbb{N}_{\geq 3}$. It is straightforward to see that the complete graph K_m has m vertices and $\frac{1}{2}m(m-1)$ edges. Furthermore the girth is three. It is straightforward to verify that the inequality of Proposition 88.6 is only satisfied for $m = 3$ and $m = 4$.
(2) Let $m, n \in \mathbb{N}_{\geq 2}$. Again it easy to verify that the complete bipartite graph $K_{m,n}$ has $m + n$ vertices and $m \cdot n$ edges. Furthermore,as we pointed out above, the girth is four. It is straightforward to verify that the inequality of Proposition 88.6 is only satisfied if $m = 2$ or $n = 2$.
(3) The Proposition now follows from (1) and (2) and the observation that if a graph is planar, then any subgraph is also planar. ■

[1076] Here is the reason why it is the sketch of a proof: we do not prove that each face is in fact homeomorphic to a closed disk. This statement is "clear from the picture" and it can be proved using the Schönflies Theorem 82.4. But we will not attempt to give a rigorous proof.



Remark. Let G be a graph that contains the complete graph K_7. By Proposition 88.7 the graph G cannot be planar. John Conway and Cameron Gordon proved in 1984 the following interesting variation: given any embedding $\varphi\colon |G| \to \mathbb{R}^3$ such that image is a polygon (i.e. it is the union of finitely many line segments) the image $\varphi(|G|)$ contains a non-trivial polygonal knot. More precisely, there exists a closed polygon C in $\varphi(|G|)$ such that $\pi_1(\mathbb{R}^3 \setminus C)$ is not isomorphic to $\mathbb{Z}$. We refer to **[CoG1983]** for the precise formulation of the theorem and the proof.

Now we will consider the question, to what degree the converse to Proposition 88.7 holds. First we need to introduce the notion of a subdivision of a graph. From the figure below it should become clear what is meant be a subdivision. As so often, the formal definition is a little cumbersome.

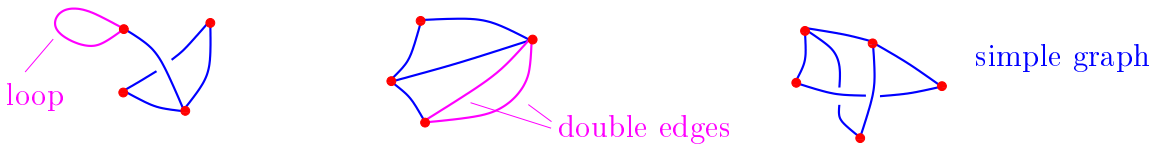
Definition. Let $G = (V, E, \varphi\colon E \to \mathcal{P}(V))$ be a graph.

(1) Let $e \in E$ be an edge. We say that a graph $G' = (V', E', \varphi'\colon E' \to \mathcal{P}(V'))$ is a subdivision of G at e if $V' = V \sqcup \{w\}$ and $E' = (E \setminus \{e\}) \sqcup \{f_1, f_2\}$ with $w \notin V$ and $f_1, f_2 \notin E$ such that $\varphi'(e') = e$ for $e' \in E \setminus \{e\}$, $\varphi'(f_1) = \{v_1, *\}$ and $\varphi'(f_2) = \{v_2, *\}$ where $\varphi(e) = \{v_1, v_2\}$.

(2) We say a graph G' is a subdivision of G if G' is obtained from G by a finite sequence of subdivisions along edges.

The following lemma says in particular that "planarity" is unaffected by subdivisions.

Lemma 88.8. Let G be a graph. If G' is a subdivision of G, then the topological realizations of G' and G are homeomorphic.



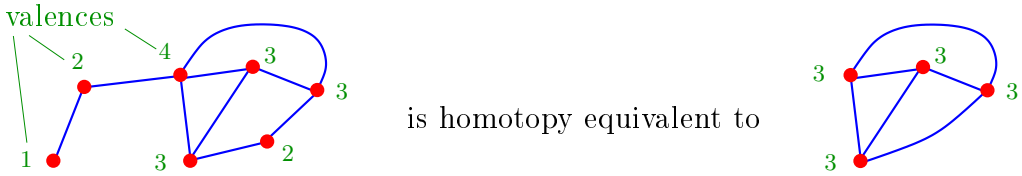
Proof. We leave it to the reader to provide the elementary proof of this lemma. ■

We move on to the final definition of this section.

Definition. We say a graph is simple if its girth is at least three.

Put differently, a graph G is simple if the following two conditions are satisfied:

(1) G has no loops, i.e. if there is no edge where the two endpoints agree,
(2) G does not have multiple edges, i.e. there are no two edges with the same endpoints.



In the remainder of this section we restrict ourselves to graphs that are simple. We start out with the following observations.

(1) If a simple graph G admits a vertex v of valence[1077] one, then v is the endpoint of a single edge e. If we delete v and e we obtain a new graph G'. An argument as in the proof of Proposition 50.15 shows that the topological realization of G' is homotopy equivalent to the topological realization of G. It is straightforward to see that G is planar if and only if G' is planar.

(2) If a simple graph admits a vertex v of valence two, then v is the endpoint of two edges e_1 and e_2. We can combine e_1 and e_2 into one edge and eliminate v. This way we obtain a new graph with a homeomorphic topological realization.

This shows that for the most part we can restrict ourselves to simple graphs where every vertex has valence at least three.

If we restrict ourselves to simple graphs such that every vertex has valence at least three, then the graphs K_5 and $K_{3,3}$ turn out to be the only obstruction to being planar. More precisely the following theorem was proved by Kuratowski[1078] in 1930. We refer to [**BoM2008**, Chapter 10.5] for a proof.

Theorem 88.9. (Kuratowski's Reduction Theorem) Let G be a finite simple graph such that every vertex has valence at least three. Then the following statements are equivalent:

(1) The graph G is planar.
(2) The G contains neither a subdivision of K_5 nor a subdivision of $K_{3,3}$ as a subgraph.

Exercises for Chapter 88.

Exercise 88.1.

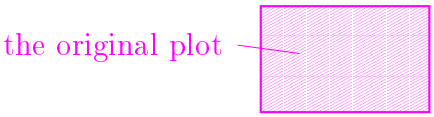
(a) Let P be a k-dimensional convex polyhedron in $\mathbb{R}^k$. Show that the interior $\overset{\circ}{P}$ of P is non-empty.

(b) Let Q be a k-dimensional convex polyhedron in some $\mathbb{R}^n$. Show that Q is homeomorphic to $\overline{B}^k$.
Hint. Use (a) and the Convex-to-Ball Proposition 2.20 (2).

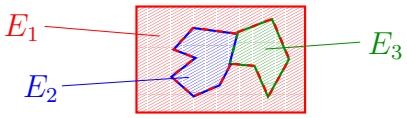
(c) Let P be a k-dimensional convex polyhedron in some $\mathbb{R}^n$. Show that P admits a CW-structure such that the boundary ∂P is a subcomplex and such that for each $j \in \mathbb{N}_0$ the j-cells in ∂P are precisely the j-dimensional faces of P.

Exercise 88.2.

(a) Show that there exist injective maps $K_5 \to S^1 \times S^1$ and $K_{3,3} \to S^1 \times S^1$.

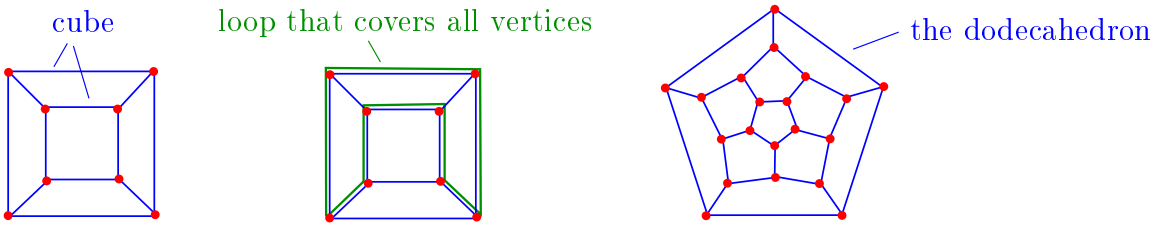


[1077] Recall that the *valence* of a vertex is defined as the number of edges that contain the vertex.
[1078] Kazimierz Kuratowski (1896-1980) was a Polish mathematician.



(b) Let $n \in \mathbb{N}_{\geq 6}$. What is the smallest g that you can find such that there exists an injective map from K_n to the surface of genus g?

Exercise 88.3. In his last will, a farmer, who owns a rectangular plot, wants to distribute his land among his sons as follows:



(1) every son gets a connected compact field with non-empty area,
(2) every son should be the neighbor of every other son.

What is maximal number of sons for which the farmer's last will can be fulfilled?
Remark. On the margin of the last will the farmer insists that the new distribution should give a CW-structure for the rectangular plot.

Exercise 88.4. Find an embedded loop on the edges of the dodecahedron that covers all vertices.
Remark. This is known as Hamilton's "icosian game". This puzzle was actually marketed in the 19th century as a board game.

89. Homology with coefficients

In this chapter we will introduce the homology groups of a topological space X with coefficients in a ring R. These homology groups will have many applications, for example they will be essential in relating the homology groups of a smooth manifold M to the de Rham cohomology groups of M. They will also be essential in proving theoretic statements, for example we will need to work with $\mathbb{F}_2$-coefficients to prove the higher-dimensional analogue of the Borsuk-Ulam Theorem 48.21. Before we can introduce the homology groups with coefficients we will need to introduce or recall some basic algebraic concepts.

89.1. The tensor product of abelian groups.

The key to defining homology groups with coefficients is the notion of the tensor product of two abelian groups.

Definition. Let A and B be abelian groups. We define the tensor product $A \otimes B$ to be the following abelian group:

$$A \otimes B := \left\{ \begin{array}{l} \text{free abelian group which is generated by all} \\ \text{symbols of the form } a \otimes b \text{ with } a \in A,\ b \in B \end{array} \right\} / N(A,B)$$

where $N(A,B)$ is the subgroup generated by the elements of the form

$$(a+a') \otimes b - (a \otimes b + a' \otimes b) \qquad \text{and} \qquad a \otimes (b+b') - (a \otimes b + a \otimes b')$$

with $a, a' \in A$ and $b, b' \in B$. For $a \in A$ and $b \in B$ we denote, by a slight abuse of notation, the image of $a \otimes b$ in $A \otimes B$ again by $a \otimes b$.

We summarize some elementary properties of the tensor product of two abelian groups in the following lemma.

Lemma 89.1. Let A and B be two abelian groups.

(1) For any $a, a' \in A$ and $b, b' \in B$ we have

$$\begin{array}{rcl} (a+a') \otimes b & = & a \otimes b + a' \otimes b \ \in \ A \otimes B \\ a \otimes (b+b') & = & a \otimes b + a \otimes b' \ \in \ A \otimes B. \end{array}$$

(2) For any $a \in A, b \in B$ and $m \in \mathbb{Z}$ we have

$$(m \cdot a) \otimes b \ = \ a \otimes (m \cdot b) \ = \ m \cdot (a \otimes b).$$

(3) Any element in $A \otimes B$ is of the form $\sum_{i=1}^{n} a_i \otimes b_i$.

(4) Let $n \in \mathbb{N}$. For any $c \in A \otimes \mathbb{Z}_n$ we have $n \cdot c = 0 \in A \otimes \mathbb{Z}_n$.

Proof. Let A and B be two abelian groups.

(1) This statement is an immediate consequence of the definition of the tensor product.

(2) Let $a \in A$ and $b \in B$. We first consider the case that $m > 0$. We have

$$(m \cdot a) \otimes b \ = \ \left(\sum_{i=1}^{m} a \right) \otimes b \ \underset{\text{by (1)}}{\uparrow} \ \sum_{i=1}^{m} a \otimes b \ = \ m \cdot (a \otimes b) \ \underset{\text{same argument backwards}}{\uparrow} \ \ldots \ = \ a \otimes (m \cdot b).$$

It follows easily from (1) that $0 \otimes b = a \otimes 0 = 0$ and that $(-a) \otimes b = a \otimes (-b) = -a \otimes b$. Using these observations we get Statement (2) for $m = 0$ and we can easily reduce the case $m < 0$ of (2) to the case $m > 0$ of (2).

(3) It follows immediately from the definition of the tensor product, together with the notational convention of "formal linear combinations" that we introduced on page 1147 that any element in $A \otimes B$ is of the form $\sum_{i=1}^{n} r_i \cdot (a_i \otimes b_i)$. But by (2) we know that $r_i \cdot (a_i \otimes b_i) = (r_i \cdot a_i) \otimes b_i$ thus we get the desired result.

(4) Let $n \in \mathbb{N}$ and let $c \in A \otimes \mathbb{Z}_n$. By (3) we can write $c = \sum_{i=1}^{m} a_i \otimes r_i$ with $a_1, \ldots, a_m \in A$ and $r_1, \ldots, r_m \in \mathbb{Z}_n$. Then

$$n \cdot c \;=\; n \cdot \Big(\sum_{i=1}^{m} a_i \otimes r_i \Big) \;\underset{\uparrow}{=}\; \sum_{i=1}^{m} a_i \otimes \underbrace{n \cdot r_i}_{=0} \;=\; 0.$$

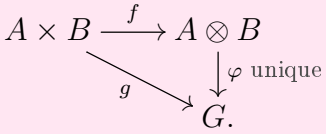
by Statement (2)

■

Definition. Let A, B and C be abelian groups. We say that a map $f\colon A \times B \to C$ is bilinear, if for all $a, a' \in A$, $b, b' \in B$ the following equalities hold:

$$f(a + a', b) \;=\; f(a, b) + f(a', b) \quad \text{and} \quad f(a, b + b') \;=\; f(a, b) + f(a, b').$$

We leave it to the reader to provide the elementary proof of the following lemma.



Lemma 89.2. Let A and B be abelian groups.

(1) The map

$$\begin{array}{rcl} f\colon A \times B & \to & A \otimes B \\ (a, b) & \mapsto & a \otimes b \end{array}$$

is bilinear.

(2) Given any abelian group G and any bilinear map $g\colon A \times B \to G$ there exists a unique homomorphism $\varphi\colon A \otimes B \to G$ such that the following diagram commutes:

(3) Given any abelian group G the map

$$\begin{array}{rcl} \mathrm{Hom}(A \otimes B, G) & \to & \text{set of bilinear maps } A \times B \to G \\ (\varphi\colon A \otimes B \to G) & \mapsto & (A \times B \xrightarrow{f} A \otimes B \xrightarrow{\varphi} G) \end{array}$$

is a bijection.

Remark. One can show quite easily that if a homomorphism $g\colon A \times B \to H$ is bilinear and if this homomorphism satisfies the universal property of Lemma 89.2 (2), then there exists an isomorphism $H \xrightarrow{\cong} A \otimes B$. We will not make use of this observation.

Before we state a few more properties of the tensor product it is convenient to introduce the following definition.

Definition. Let $f\colon A \to A'$ and $g\colon B \to B'$ be homomorphisms between abelian groups. We define $f \otimes g$ to be the homomorphism that is given by[1079]

$$\begin{array}{rcl} f \otimes g\colon A \otimes B & \to & A' \otimes B' \\ \sum_{i=1}^{n} a_i \otimes b_i & \mapsto & \sum_{i=1}^{n} f(a_i) \otimes g(b_i) \end{array}$$

[1079] It is straightforward to verify that the map $f \otimes g$ is indeed well-defined and that it is a homomorphism.

Now we can continue with the promised lemma on properties of the tensor product. On many occasions we will make use of it without explicitly referring to it.

Lemma 89.3. (Tensor Lemma) Let A, B, C and $A_i, i \in I$ be abelian groups.

(1) The maps
$$\begin{array}{rcl} A \otimes B & \to & B \otimes A \\ \sum_{i=1}^{n} a_i \otimes b_i & \mapsto & \sum_{i=1}^{n} b_i \otimes a_i \end{array} \quad \text{and} \quad \begin{array}{rcl} \left(\bigoplus_{i\in I} A_i\right) \otimes B & \to & \bigoplus_{i\in I} A_i \otimes B \\ \left(\sum_{i=1}^{n} a_i\right) \otimes b & \mapsto & \sum_{i=1}^{n} a_i \otimes b \end{array}$$
are well-defined and they are natural isomorphisms.

(2) The map
$$\begin{array}{rcl} (A \otimes B) \otimes C & \to & A \otimes (B \otimes C) \\ \sum_{j=1}^{n} (a_j \otimes b_j) \otimes c_j & \mapsto & \sum_{j=1}^{n} a_j \otimes (b_j \otimes c_j) \end{array}$$
is well-defined and it is a natural isomorphism.

(3) Let $k \in \mathbb{N}$. The maps[1080]
$$\begin{array}{rcl} \mathbb{Z}_k \otimes A & \to & A/kA \\ \sum_{i=1}^{m} n_i \otimes a_i & \mapsto & \sum_{i=1}^{m} n_i \cdot a_i \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathbb{Z} \otimes A & \to & A \\ \sum_{i=1}^{m} n_i \otimes a_i & \mapsto & \sum_{i=1}^{m} n_i \cdot a_i. \end{array}$$
are well-defined and they are natural isomorphisms.

(4) Suppose $(I, \leq)$ is an ordered set and $(\{A_i\}_{i\in I}, \{\varphi_{ij}\}_{i\leq j})$ is a direct system of abelian groups. Then the map
$$\varinjlim (A_i \otimes B) \xrightarrow{\cong} \left(\varinjlim A_i\right) \otimes B$$
that is induced by the maps $A_i \to \varinjlim A_i$ is a natural isomorphism.

Proof. We refer to [**Lang1993**, Corollary XVI.2.2] for a proof for the distributivity in (1). The other statements in (1) to (3) follow fairly easily from the definitions and Lemma 89.1. We refer to [**Mun1984**, Chapter 50] for details. A proof of the last statement is given in [**Bou2007**, Chapter II.6.3] or alternatively in [**Mats1989**, Theorem A1]. ■

Convention. Given several abelian groups $A_1, \ldots, A_k$ we use the Tensor Lemma 89.3 as an excuse to write $A_1 \otimes A_2 \otimes \cdots \otimes A_k$, even though strictly speaking as a set this object does depend on the parenthesis.

Remark.

(1) As we mentioned in the statement of the Tensor Lemma 89.3, all the isomorphisms are natural, in the sense that they define natural transformations between appropriate functors. For example if we denote by $\mathcal{AbGroup}$ the category of abelian groups, then the isomorphisms of the Tensor Lemma 89.3 (3) define a natural transformation between the two functors
$$\begin{array}{rcl} \mathcal{AbGroup} & \to & \mathcal{AbGroup} \\ A & \mapsto & A \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathcal{AbGroup} & \to & \mathcal{AbGroup} \\ A & \mapsto & \mathbb{Z} \otimes A. \end{array}$$
As an example, for every $k \in \mathbb{N}$ and any abelian group A we get a commutative diagram

[1080] Note that for an abelian group A and $k \in \mathbb{Z}$ the set $kA := \{k \cdot a \,|\, a \in A\}$ is a subgroup of A and we can thus form the quotient A/kA.

$$\begin{array}{ccc} \mathbb{Z}\otimes A & \xrightarrow[n\otimes a\mapsto n\cdot a]{\cong} & A \\ {\scriptstyle \cdot k\otimes \mathrm{id}}\downarrow & & \downarrow{\scriptstyle \cdot k} \\ \mathbb{Z}\otimes A & \xrightarrow[n\otimes a\mapsto n\cdot a]{\cong} & A. \end{array}$$

(2) We use these natural isomorphisms from the Tensor Lemma 89.3 to identify the various groups. Note that the Tensor Lemma 89.3 (2) allows us to write the tensor product $A\otimes B\otimes C$ unambiguously without having to worry about parentheses.

(3) In the Tensor Lemma 89.3 we saw that the tensor product commutes with forming direct sums. The analogous statement is not true if we replace direct sums by direct products. More precisely, in Exercise 89.11 we will see that

$$\Big(\prod_{n\in\mathbb{N}}\mathbb{Z}_n\Big)\otimes\mathbb{Q}\neq 0 \quad \text{but} \quad \prod_{n\in\mathbb{N}}\underbrace{(\mathbb{Z}_n\otimes\mathbb{Q})}_{=0,\text{ by the Tensor Lemma 89.3 (3)}} = 0.$$

Examples.

(1) Let $m,n\in\mathbb{N}$. We write $r=\gcd(m,n)$ and $s=m/r$. Then

$$\mathbb{Z}_m\otimes\mathbb{Z}_n \underset{\text{Tensor Lemma 89.3 (3)}}{\overset{\uparrow}{\cong}} \mathbb{Z}_n/m\mathbb{Z}_n = \mathbb{Z}_n/rs\mathbb{Z}_n = \mathbb{Z}_n/r\cdot(s\mathbb{Z}_n) \underset{\text{since } s \text{ is coprime to } n}{\overset{\uparrow}{=}} \mathbb{Z}_n/r\mathbb{Z}_n \xleftarrow[\cong]{\cdot n/r} Z_r = \mathbb{Z}_{\gcd(m,n)}.$$

(2) Let A be a finitely generated abelian group of rank r. By the Finitely Generated Abelian Group Classification Theorem 51.4 we have $A\cong\mathbb{Z}^r\oplus\bigoplus_{i=1}^n\mathbb{Z}_{a_i}$ where $a_1,\dots,a_n$ are non-zero natural numbers. For $S=\mathbb{Q}, S=\mathbb{R}$ or $S=\mathbb{C}$ we have

$$A\otimes S\cong\Big(\mathbb{Z}^r\oplus\bigoplus_{i=1}^n\mathbb{Z}_{a_i}\Big)\otimes S \underset{\text{Tensor Lemma 89.3 (1)}}{\overset{\uparrow}{=}} (\mathbb{Z}\otimes S)^r\oplus\Big(\bigoplus_{i=1}^n\mathbb{Z}_{a_i}\otimes S\Big) \underset{\text{Tensor Lemma 89.3 (3)}}{\overset{\uparrow}{\cong}} S^r\oplus\bigoplus_{i=1}^n S/a_iS \underset{\text{since } a_i\neq 0 \text{ in } S=\mathbb{Q},\mathbb{R},\mathbb{C}}{\overset{\uparrow}{=}} S^r.$$

(3) Let A be an abelian group, then

$$\ker\begin{pmatrix} A & \to & A\otimes\mathbb{Q} \\ a & \mapsto & a\otimes 1 \end{pmatrix} = \text{all torsion elements of } A.$$

If A is finitely generated, then this follows easily from the classification of finitely generated abelian groups together with the Tensor Lemma 89.3. If A is infinitely generated, then we can view it as the direct limit of finitely generated abelian groups and using the Tensor Lemma 89.3 the statement can be reduced to the finitely generated case. We leave the details to the reader.

(4) Recall that given a set W we denote by $\mathbb{Z}^{(W)}$ the free abelian group generated by W. Let A and B be two sets. We then have

$$\mathbb{Z}^{(A)}\otimes\mathbb{Z}^{(B)} = \Big(\bigoplus_{a\in A}\mathbb{Z}\cdot a\Big)\otimes\Big(\bigoplus_{b\in B}\mathbb{Z}\cdot b\Big) \underset{\text{Tensor Lemma 89.3 (1)}}{\overset{\downarrow}{=}} \bigoplus_{a\in A,b\in B}\mathbb{Z}\cdot a\otimes\mathbb{Z}\cdot b \underset{\text{Tensor Lemma 89.3 (3)}}{\overset{\downarrow}{=}} \bigoplus_{a\in A,b\in B}\mathbb{Z}\cdot(a,b) = \mathbb{Z}^{(A\times B)}.$$

(5) Let A and B be two finitely generated abelian groups. Using examples (1) and (2), the classification of finitely generated abelian groups and the Tensor Lemma 89.3 (1) and (4) one can now easily show that

$$\operatorname{rank}(A\otimes B) = \operatorname{rank}(A)\cdot\operatorname{rank}(B).$$

For future reference we record the following lemma:

Lemma 89.4. Let $f\colon A \to A'$ and $f'\colon A' \to A''$ be homomorphisms and let $g\colon B \to B'$ and $g'\colon B' \to B''$ be homomorphisms between abelian groups. Then we have

$$(f' \otimes g') \circ (f \otimes g) \;=\; (f' \circ f) \otimes (g' \circ g).$$

Proof. The statement follows immediately from the definitions. ■

The following elementary lemma will play a major role.

Lemma 89.5. (Tensor-with-Ring Lemma) Let R be a commutative ring.

(1) Given any abelian group A the map

$$\begin{aligned} (A \otimes R) \times R &\to A \otimes R \\ \left(\sum_{i=1}^{n} a_i \otimes b_i, r\right) &\mapsto \sum_{i=1}^{n} a_i \otimes b_i r \end{aligned}$$

defines an R-module structure on $A \otimes R$.

(2) If $f\colon A \to B$ is a homomorphism of abelian groups, then the map

$$\begin{aligned} f \otimes \mathrm{id}\colon A \otimes R &\to B \otimes R \\ \sum_i a_i \otimes r_i &\mapsto \sum_i f(a_i) \otimes r_i \end{aligned}$$

is a homomorphism of R-modules.

(3) The map

$$\begin{aligned} A &\mapsto A \otimes R \\ (f\colon A \to B) &\mapsto (f \otimes \mathrm{id}\colon A \otimes R \to B \otimes R) \end{aligned}$$

defines a functor from the category of abelian groups to the category of R-modules.

Proof. Once again the statements follow immediately from the definitions. ■

The Tensor-with-Ring Lemma 89.5 shows that tensoring with a commutative ring "turns" an abelian group into a module. In particular if we tensor with a field, we obtain a vector space. This is very convenient since sometimes it allows us to reduce problems about abelian groups into problems about vector spaces that we can handle with techniques from linear algebra.

For example we can now give a meaningful definition of the rank of any abelian group.

Definition. The rank of an abelian group A is defined as

$$\mathrm{rank}(A) \;:=\; \dim_{\mathbb{Q}}(A \otimes \mathbb{Q}).$$

Remark.

(1) Previously, on page 1152 we introduced the rank of finitely generated abelian groups. It follows from the discussion on page 1910 that for finitely generated abelian groups the two definitions of rank agree. Put differently, the above definition is an extension of the earlier notion of rank to all abelian groups.

(2) Let A be an abelian group. We can view A as a $\mathbb{Z}$-module and the above definition of the rank of the abelian group equals the rank of the corresponding $\mathbb{Z}$-module as introduced on page 99.

We conclude this section with the following lemma.

Lemma 89.6. (Tensor-Split-SES Lemma) Let

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence and let G be an abelian group. If the short exact sequence splits, then

$$0 \to A \otimes G \xrightarrow{i\otimes \mathrm{id}} B \otimes G \xrightarrow{p\otimes \mathrm{id}} C \otimes G \to 0$$

is also a short exact sequence and it also splits.

Remark. In most applications we will consider a short exact sequence

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

where C is a free abelian group. It then follows from Lemma 78.1 that the short exact sequence splits, which then implies by the Tensor-Split-SES Lemma 89.6 that for any abelian group G the sequence

$$0 \to A \otimes G \xrightarrow{i\otimes \mathrm{id}} B \otimes G \xrightarrow{p\otimes \mathrm{id}} C \otimes G \to 0$$

is also a short exact sequence which furthermore splits.

Proof. According to Splitting Lemma 78.2 we can without loss of generality suppose that the short exact sequence is of the form

$$0 \to A \xrightarrow{a\mapsto(a,0)} A \oplus C \xrightarrow{(a,c)\mapsto c} C \to 0.$$

If we tensor this short exact sequence with G, then using $(A \oplus C) \otimes G = A \otimes G \oplus C \otimes G$ we obtain the sequence

$$0 \to A \otimes G \xrightarrow{\sum_i a_i\otimes g_i \mapsto \left(\sum_i a_i\otimes g_i, 0\right)} A \otimes G \oplus C \otimes G \xrightarrow{\left(\sum_i a_i\otimes g_i, \sum_j c_j\otimes g_j\right)\mapsto \sum_j c_j\otimes g_j} C \otimes G \to 0,$$

which is evidently exact. It is also clear that the short exact sequence splits. ∎

89.2. The homology groups of a topological space with coefficients.

Definition. Let

$$\ldots \xrightarrow{\partial_{n+1}} \mathrm{C}_n \xrightarrow{\partial_n} \mathrm{C}_{n-1} \xrightarrow{\partial_{n-1}} \ldots \xrightarrow{\partial_2} \mathrm{C}_1 \xrightarrow{\partial_1} \mathrm{C}_0 \to 0$$

be an algebraic chain complex.

(1) Let G be an abelian group. We tensor the chain complex with G, i.e. we consider the following sequence of homomorphisms:[1081]

$$\ldots \to \mathrm{C}_n \otimes G \xrightarrow{\partial_n\otimes \mathrm{id}} \mathrm{C}_{n-1} \otimes G \xrightarrow{\partial_{n-1}\otimes \mathrm{id}} \ldots \xrightarrow{\partial_2\otimes \mathrm{id}} \mathrm{C}_1 \otimes G \xrightarrow{\partial_1\otimes \mathrm{id}} \mathrm{C}_0 \otimes G \to 0.$$

For all i we have

$$(\partial_{i-1} \otimes \mathrm{id}) \circ (\partial_i \otimes \mathrm{id}) \underset{\text{Lemma 89.4}}{=} (\partial_{i-1} \circ \partial_i) \otimes \mathrm{id} = 0 \otimes \mathrm{id} = 0,$$

i.e. the above sequence of maps is again a chain complex. We denote the corresponding homology groups by $\mathrm{H}_n(C;G) := \mathrm{H}_n(C_* \otimes G, \partial_* \otimes \mathrm{id})$.

(2) If we tensor the chain complex C_* with a commutative ring R, then it follows from the discussion in the previous section that we obtain a chain complex of R-modules, i.e. all chain groups are R-modules and all chain maps are R-homomorphisms. In particular also all homology groups are R-modules.

Remark. Most of the results which we have proved for chain complexes of abelian groups hold, with the obvious modifications, also for chain complexes of R-modules. In particular one can easily convince oneself that Lemma 72.7, Lemma 73.2, Corollary 73.4 and Propositions 74.9 and the Connecting Homomorphism Lemma 74.8 also hold in this more general context. In the remainder of the course we will use these generalizations without further comment.

Now we are ready to define the homology groups of a topological space with coefficients in an abelian group G.

Definition. Let X be a topological space. For an abelian group G we define

$$\mathrm{C}_*(X;G) \quad := \quad \mathrm{C}_*(X) \otimes G.$$

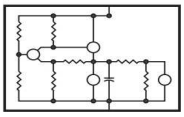
As discussed above, we obtain a chain complex and we denote by

$$\mathrm{H}_k(X;G) \quad := \quad \mathrm{H}_k(\mathrm{C}_*(X;G), \partial \otimes \mathrm{id})$$

the corresponding homology groups. We call $\mathrm{H}_k(X;G)$ the k-th homology group of X with G-coefficients. We define the notions of "cycle", "homologous" and "null-homologous" in exactly the same way as on page 1587.

Example. We consider an electric circuit as a finite undirected abstract graph X where at the vertices we have resistors or capacitors. Kirchhoff's current rule, see e.g.

`https://en.wikipedia.org/wiki/Kirchhoff's_circuit_laws`



states that

> *at any node (vertex) in an electrical circuit, the sum of currents flowing into that node is equal to the sum of currents flowing out of that node,*

or equivalently

> *the algebraic sum of currents in a network meeting at a point is zero.*

Put differently, a current defines a 1-cycle in $\mathrm{C}_1(X;\mathbb{R})$.[1082]

electric circuit 

We start out with the following three observations. Let X be a topological space.

(1) If the coefficients are given by a commutative ring R, e.g. if $R = \mathbb{Z}_n$ or $R = \mathbb{Q}, \mathbb{R}, \mathbb{C}$, then, as we pointed out above, each $\mathrm{C}_n(X;R) = \mathrm{C}_n(X) \otimes R$ is an R-module, each boundary map is an R-module homomorphism, and each homology group $\mathrm{H}_n(X;R)$ is also an R-module.

(2) From the Tensor Lemma 89.3 (3) it follows immediately that we have natural isomorphisms $\mathrm{C}_*(X;\mathbb{Z}) \xrightarrow{\cong} \mathrm{C}_*(X)$ and $\mathrm{H}_*(X;\mathbb{Z}) \xrightarrow{\cong} \mathrm{H}_*(X)$. In the following we will identify these groups and we will go back and forth between these two notations, depending on which one is more convenient.

[1081] Note that if G has also the structure of a commutative ring, then this becomes a chain complex of G-modules.

[1082] This observation and the figure are due to Ghrist's excellent book on applied topology [**Gh2014**].

(3) Let G be an abelian group. Given any singular k-simplex σ, given any $a \in \mathbb{Z}$ and any $g \in G$ we have by definition of the tensor product that $a\sigma \otimes g = \sigma \otimes ag$. From this observation it follows that any element in $\mathrm{C}_k(X;G)$ can be written as

$$\sum_{i=1}^{n} \sigma_i \otimes g_i \quad \text{where } \sigma_1, \ldots, \sigma_n \text{ are singular } k\text{-simplices and } g_1, \ldots, g_n \in G.$$

Most results for homology groups of topological spaces carry over, with the obvious modifications, to the theory of homology groups with G-coefficients. For example, given an abelian group G we have the following statements:

(1) A map $f\colon X \to Y$ between two topological spaces X and Y induces a chain map

$$f_* \otimes \mathrm{id}\colon \mathrm{C}_*(X;G) \to \mathrm{C}_*(Y;G)$$

which in turn, for each $k \in \mathbb{N}_0$, induces a homomorphism

$$(f_* \otimes \mathrm{id})_*\colon \mathrm{H}_k(X;G) \to \mathrm{H}_k(Y;G).$$

To simplify the notation we usually denote this induced map on homology groups also by f_*.

(2) The k-th homology group with G-coefficients defines a functor from the category of topological spaces to the category of abelian groups.

(3) If R is a commutative ring, then a map $f\colon X \to Y$ between topological spaces induces a chain map of R-homomorphisms $\mathrm{C}_*(X;R) \to \mathrm{C}_*(Y;R)$ and R-homomorphisms $f_*\colon \mathrm{H}_k(X;R) \to \mathrm{H}_k(Y;R)$. Furthermore the k-th homology group with R-coefficients defines a functor from the category $\mathcal{Top}$ of topological spaces to the category $R-\mathcal{Mod}$ of R-modules.

(4) The augmentation map $\epsilon\colon \mathrm{H}_0(X;G) \to G$ is defined almost the same way as in Lemma 72.4. More precisely, it is given by the map

$$\begin{array}{rcl} \epsilon_X\colon \mathrm{H}_0(X;G) & \to & G \\ \left[\sum_{i=1}^{k} \sigma_i \otimes g_i\right] & \mapsto & \sum_{i=1}^{k} g_i. \end{array}$$

If X is path-connected, then the argument of the H_0-Proposition 72.5 implies immediately that the augmentation map $\epsilon\colon \mathrm{H}_0(X;G) \to G$ is an isomorphism. At times we will use this natural isomorphism to make the identification $\mathrm{H}_0(X;G) = G$.

(5) Precisely as on page 1611 we can use the augmentation map $\epsilon\colon \mathrm{H}_0(X;G) \to G$ to define reduced homology groups $\widetilde{\mathrm{H}}_k(X;G)$ with G-coefficients.

(6) Recall that we saw in the Homotopic Maps-and-Homology Proposition 73.6 that if $f, g\colon X \to Y$ are two homotopic maps between topological spaces, then the induced maps $f_*, g_*\colon \mathrm{C}_*(X) \to \mathrm{C}_*(Y)$ are chain homotopic. By tensoring the chain homotopies we see that the corresponding induced maps $\mathrm{C}_*(X) \otimes G \to \mathrm{C}_*(Y) \otimes G$ are also chain homotopic, and we see that for any $n \in \mathbb{N}_0$ we have

$$f_* = g_*\colon \mathrm{H}_n(X;G) \ \to \ \mathrm{H}_n(Y;G).$$

In particular, if X and Y are homotopy equivalent topological spaces, then for any $n \in \mathbb{N}_0$ we have an isomorphism

$$\mathrm{H}_n(X;G) \ \xrightarrow{\cong} \ \mathrm{H}_n(Y;G).$$

(7) Given a pair (X, A) of topological spaces we can tensor the relative chain complex $\mathrm{C}_*(X, A)$ with G. We obtain the *relative chain complex* $\mathrm{C}_*(X, A; G) := \mathrm{C}_*(X, A) \otimes G$. The corresponding homology groups are the *relative homology groups* $\mathrm{H}_k(X, A; G)$.

(8) Let (X, B, A) be a triple of topological spaces. As pointed out on page 1625, the relative chain groups $\mathrm{C}_n(X, B; G)$ are free abelian groups. Thus it follows from the discussion on page 1912 that we obtain a short exact sequence of chain complexes $0 \to \mathrm{C}_*(B, A; G) \to \mathrm{C}_*(X, A; G) \to \mathrm{C}_*(X, B; G) \to 0$. By applying the obvious generalization of the LES Proposition 74.9 to this short exact sequence we obtain the following long exact sequence of homology groups with G-coefficients:

$$\ldots \to \mathrm{H}_n(B, A; G) \xrightarrow{i_*} \mathrm{H}_n(X, A; R) \xrightarrow{p_*} \mathrm{H}_n(X, B; G) \xrightarrow{\partial} \mathrm{H}_{n-1}(B, A; G) \to \ldots$$

(9) We have an obvious version of the Mayer–Vietoris Theorem 78.5 for homology groups with G-coefficients. The proof is basically identical to the proof of Theorem 78.5, we only have to note that when we consider the exact sequence

$$0 \to \mathrm{C}_*(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} \mathrm{C}_*(A) \oplus \mathrm{C}_*(B) \xrightarrow{i_A + i_B} \mathrm{C}_*^{\{A,B\}}(X) \to 0,$$

then it is a consequence of the discussion on page 1912 that the corresponding sequence with G-coefficients is also exact.

(10) We also have an obvious versions of the Excision Theorems 74.17 and 74.18, the proof for G-coefficients is almost verbatim the same as before.

(11) For a CW-complex X we can also consider the corresponding cellular chain complex $\mathrm{C}_*^{\mathrm{CW}}(X; G) := \mathrm{C}_*^{\mathrm{CW}}(X) \otimes G$ and the corresponding cellular homology groups $\mathrm{H}_*^{\mathrm{CW}}(X; G)$. Then, as in the Singular-Cellular H_*-Isomorphism Proposition 80.4, one can show that there exists a natural isomorphism $\mathrm{H}_*(X; G) \xrightarrow{\cong} \mathrm{H}_*^{\mathrm{CW}}(X; G)$. We can draw the following conclusions:
   (a) If X is an n-dimensional CW-complex, then $\mathrm{H}_i(X; G) = 0$ for $i \geq n + 1$.
   (b) If X has only finitely many n-cells, then given any field $\mathbb{F}$ the vector space $\mathrm{H}_n(X; \mathbb{F})$ is finite-dimensional.

(12) Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \ldots$ be a sequence of subsets such that $X = \bigcup_{i\in\mathbb{N}} X_i$ and such that one the following three conditions holds:
   (a) every compact subset of X is already contained in one of the X_i, or
   (b) each X_i is open in X, or
   (c) X is a CW-complex and each X_i is a subcomplex.

   Then a modest modification of the proof of the Exhaustions-H_*-Proposition 79.4 shows that for any $n \in \mathbb{N}_0$ the inclusion induced maps $\mathrm{H}_n(X_i; G) \to \mathrm{H}_n(X; G)$ induce an isomorphism

$$\varinjlim \mathrm{H}_n(X_i; G) \xrightarrow{\cong} \mathrm{H}_n(X; G).$$

(13) If X is a finite CW-complex and if $\mathbb{F}$ is a field, then the argument of the Euler Characteristic-H_*-Proposition 87.1 shows that

$$\chi(X) = \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(\mathrm{H}_i(X; \mathbb{F})).$$

Examples.

(1) Let $n \in \mathbb{N}$. As on page 1472 we equip S^n with the CW-structure with one 0-cell and one n-cell. For any abelian group G it follows from (10), and similar to the discussion on page 1770, that

$$\mathrm{H}_k(S^n;G) \;\cong\; \mathrm{H}_k^{\mathrm{CW}}(S^n;G) \;\cong\; \begin{cases} G, & \text{if } k = 0, n, \\ 0, & \text{otherwise.} \end{cases}$$

The same result holds for reduced homology with G-coefficients except that in this case we have $\widetilde{\mathrm{H}}_0(S^n;G) = 0$.

(2) We want to determine homology groups of the real projective plane $\mathbb{R}\mathrm{P}^2$ with $\mathbb{F}_2$-coefficients. As usual we equip $\mathbb{R}\mathrm{P}^2$ with the CW-structure with one 0-cell, one 1-cell and one 2-cell that we introduced on page 1785. In the proof of Proposition 80.11 we saw that the cellular chain complex is given by

$$0 \;\to\; \mathbb{Z} \;\xrightarrow{\cdot 2}\; \mathbb{Z} \;\xrightarrow{0}\; \mathbb{Z} \;\to\; 0,$$

i.e. $\mathrm{H}_2(\mathbb{R}\mathrm{P}^2) = 0$, $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2) = \mathbb{Z}_2$ and $\mathrm{H}_0(\mathbb{R}\mathrm{P}^2) = \mathbb{Z}$. On the other hand, if we tensor the above cellular chain complex with $\mathbb{F}_2$, then using the Tensor Lemma 89.3 (3) we obtain the chain complex

$$0 \;\to\; \mathbb{F}_2 \;\xrightarrow{\cdot 2 = 0}\; \mathbb{F}_2 \;\xrightarrow{0}\; \mathbb{F}_2 \;\to\; 0.$$

Using the isomorphism between cellular and singular homology with $\mathbb{F}_2$-coefficients we obtain that $\mathrm{H}_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$, $\mathrm{H}_1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$ and $\mathrm{H}_0(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$.

Note that even though the homology groups of $\mathbb{R}\mathrm{P}^2$ with $\mathbb{Z}$-coefficients and $\mathbb{F}_2$-coefficients are quite different, in both cases the alternating sums of the dimensions and ranks give, as promised in the Euler Characteristic-H_*-Proposition 87.1 and in (10) above, the Euler characteristic. Indeed, we have

$$\mathrm{rank}(\mathrm{H}_0(X)) - \mathrm{rank}(\mathrm{H}_1(X)) + \mathrm{rank}(\mathrm{H}_2(X)) \;=\; 1 - 0 + 0 \;=\; 1,$$

and

$$\dim_{\mathbb{F}_2}(\mathrm{H}_0(X;\mathbb{F}_2)) - \dim_{\mathbb{F}_2}(\mathrm{H}_1(X;\mathbb{F}_2)) + \dim_{\mathbb{F}_2}(\mathrm{H}_2(X;\mathbb{F}_2)) \;=\; 1 - 1 + 1 \;=\; 1.$$

(3) Basically the same argument as in (3) shows that for any $n \in \mathbb{N}$ we have

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \;\cong\; \begin{cases} \mathbb{F}_2, & \text{if } k = 0, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}$$

Furthermore, it is not difficult to see that for $m < n$ the inclusion induced maps $\mathrm{H}_k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2) \to \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ are isomorphisms for $k = 0, \ldots, m$. It follows that for any $k \in \mathbb{N}_0$ we have

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^\infty;\mathbb{F}_2) \;\underset{\substack{\uparrow \\ \text{see page 1915}}}{=}\; \varinjlim \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \;\underset{\substack{\uparrow \\ \text{by the above}}}{=}\; \mathbb{F}_2.$$

Remark. Why should we study the homology groups of a topological space with G-coefficients? There are several answers one can give:

(1) At times it is easier to work over a field instead of working over the ring $\mathbb{Z}$. For example, if we only want to determine the Euler characteristic of a CW-complex we can now use a field, even a very simple one like $\mathbb{F}_2$, instead of working with the integers.

(2) If we work over the field $\mathbb{F}_2$ then many calculations become particularly simple, since we do not need to worry about signs. Even in the previous example we already saw that working with $\mathbb{F}_2$-coefficients can simplify calculations.
(3) Recall that given a smooth manifold M and $k \in \mathbb{N}_0$ we denote its de Rham cohomology groups $\mathrm{H}^k_{\mathrm{dR}}(M)$, which is in fact a real vector space. For each k we can now also study the homology groups $\mathrm{H}_k(M;\mathbb{R})$ which are also real vector spaces. The notations $\mathrm{H}^k_{\mathrm{dR}}(M)$ and $\mathrm{H}_k(M;\mathbb{R})$ look similar and the names "de Rham cohomology" and "homology" also sound similar. We will study the relationship between these two objects later on in Chapters 110 and 118.

We conclude this section with the following elementary lemma.

Lemma 89.7.

(1) Let X be a topological space and let R be a commutative ring with neutral element 1_R. The maps
$$\begin{array}{rcl} \varphi_*\colon \mathrm{C}_*(X) & \to & \mathrm{C}_*(X;R) \\ \left[\sum_{i=1}^k a_i \cdot \sigma_i\right] & \mapsto & \left[\sum_{i=1}^k a_i \cdot \sigma_i \otimes 1_R\right] \end{array}$$
form a chain map, in particular for each $n \in \mathbb{N}_0$ we obtain an induced map
$$\varphi_*\colon \mathrm{H}_n(X) \to \mathrm{H}_n(X;R).$$
(2) Let X be a topological space and let $\varphi\colon A \to B$ be a homomorphism of abelian groups. Then the maps
$$\begin{array}{rcl} \varphi_*\colon \mathrm{C}_*(X;A) & \to & \mathrm{C}_*(X;B) \\ \left[\sum_{i=1}^k \sigma_i \otimes a_i\right] & \mapsto & \left[\sum_{i=1}^k \sigma_i \otimes \varphi(a_i)\right] \end{array}$$
form a chain map, in particular for each $n \in \mathbb{N}_0$ we obtain an induced map
$$\varphi_*\colon \mathrm{H}_n(X;A) \to \mathrm{H}_n(X;B).$$
(3) Given a topological space X and $n \in \mathbb{N}_0$ the maps $A \mapsto \mathrm{H}_n(X;A)$ from (1) define a covariant functor from the category of abelian groups *AbGroup* to itself.
(4) The maps from (1) define a natural transformation from "homology with A-coefficients" to "homology with B-coefficients", i.e. given a map $f\colon X \to Y$ of topological spaces we get a commutative diagram
$$\begin{array}{ccc} \mathrm{H}_n(X;A) & \xrightarrow{f_*} & \mathrm{H}_n(Y;A) \\ \downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\ \mathrm{H}_n(X;B) & \xrightarrow{f_*} & \mathrm{H}_n(Y;B). \end{array}$$

The above statements also generalize in an obvious way to pairs of topological spaces.

Proof. The lemma follows immediately from the definitions. ∎

89.3. **Exact functors.** The following question naturally arises from the discussion in the previous section:

Question 89.8. Given a topological space X and an abelian group G, what is the relationship between the usual homology groups of X and the homology groups with G-coefficients?

The example on page 1916 shows that for better or worse the naive guess that perhaps $\mathrm{H}_k(X;G) \cong \mathrm{H}_k(X) \otimes G$ is in general not correct. More precisely, we saw that

$$\mathbb{F}_2 = \mathrm{H}_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \;\neq\; \mathrm{H}_2(\mathbb{R}\mathrm{P}^2) \otimes \mathbb{F}_2 = 0.$$

In the following section we will see that, despite this sobering example, one can always deduce the homology groups $\mathrm{H}_*(X;G)$ of a topological space X from the usual homology groups $\mathrm{H}_*(X)$. But the connection between these homology groups will turn out to be less naive than one might have thought initially.
Before we can hope to answer Question 89.8 we have to introduce many more definitions and algebraic tools. We start out with the following definition from category theory.

Definition. Let $F\colon \mathcal{AbGroup} \to \mathcal{AbGroup}$ be a covariant functor from the category $\mathcal{AbGroup}$ of abelian groups to itself.

(1) We say F is left-exact, if for every exact sequence
$$0 \longrightarrow A \xrightarrow{i} B \xrightarrow{j} C$$
of abelian groups the sequence
$$0 \longrightarrow F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C)$$
is also exact.

(2) We say F is right-exact, if for every exact sequence
$$A \xrightarrow{i} B \xrightarrow{j} C \longrightarrow 0$$
of abelian groups the sequence
$$F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C) \longrightarrow 0$$
is also exact.

(3) We say F is exact if it is left-exact and right-exact, put differently, the functor F is exact, if for every exact sequence
$$0 \longrightarrow A \xrightarrow{i} B \xrightarrow{j} C \longrightarrow 0$$
of abelian groups the sequence
$$0 \longrightarrow F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C) \longrightarrow 0$$
is also exact.

Remark. Let $\varphi\colon A \to B$ be a homomorphism between two abelian groups. Furthermore let $F\colon \mathcal{AbGroup} \to \mathcal{AbGroup}$ be a covariant functor from the category $\mathcal{AbGroup}$ of abelian groups to itself.

(1) If F is a left-exact functor, then "taking F" commutes with "taking kernels", more precisely, if $\varphi\colon A \to B$ is a homomorphism, then by applying F to the exact sequence $0 \to \ker(\varphi) \to A \to B$ we see that $F(\ker(\varphi)) = \ker(\varphi_*\colon F(A) \to F(B))$.

(2) Similarly, if F is right-exact, then "taking F" commutes with "taking cokernels", i.e. if $\varphi\colon A \to B$ is a homomorphism, then by applying F to the exact sequence $A \to B \to \operatorname{coker}(\varphi) \to 0$ we see that $F(\operatorname{coker}(\varphi)) = \operatorname{coker}(\varphi_*\colon F(A) \to F(B))$.

Lemma 89.9. Let G be an abelian group. If G is free abelian, then tensoring with G is exact.

Proof. Let
$$0 \to A \xrightarrow{\varphi} B \xrightarrow{\psi} C \to 0$$
be a short exact sequence and let $G \cong \mathbb{Z}^{(S)}$ be a free abelian group. It follows from the Tensor Lemma 89.3 (1) and (3) that tensoring the above short exact sequence with $G \cong \mathbb{Z}^{(S)}$ results in an exact sequence that is isomorphic to the direct sum of S copies of the original sequence, hence it is again exact. ■

Example. In contrast to the previous lemma we will now see that tensoring with an abelian group G is in general not a *left-exact* functor. For example for any $k \in \mathbb{N}_{\geq 2}$ the sequence
$$0 \longrightarrow \mathbb{Z} \xrightarrow{\cdot k} \mathbb{Z} \longrightarrow \mathbb{Z}_k$$
is exact, but after tensoring with $\mathbb{Z}_k$ we obtain, using the Tensor Lemma 89.3 (3), the sequence
$$0 \longrightarrow \mathbb{Z}_k \xrightarrow[=0]{\cdot k} \mathbb{Z}_k \longrightarrow \mathbb{Z}_k$$
that is not exact.

In contrast to the previous example we will now see that tensoring with an abelian group G is a *right-exact* functor.

Lemma 89.10. As usual we denote by $\mathcal{AbGroup}$ the category of abelian groups. For every abelian group G the functor
$$\begin{array}{ccc} \mathcal{AbGroup} & \to & \mathcal{AbGroup} \\ A & \mapsto & A \otimes G \end{array}$$
is right-exact.

Proof. Let
$$A \xrightarrow{i} B \xrightarrow{j} C \to 0$$
be an exact sequence of abelian groups and let G be an abelian group. We have to show that the sequence
$$A \otimes G \xrightarrow{i\otimes \mathrm{id}} B \otimes G \xrightarrow{j\otimes \mathrm{id}} C \otimes G \to 0$$
is also exact.

(a) Since $j\colon B \to C$ is an epimorphism it follows immediately from Lemma 89.1 (3) that the homomorphism
$$\begin{array}{rcl} j \otimes \mathrm{id}\colon B \otimes G & \to & C \otimes G \\ \sum_{i=1}^{n} b_i \otimes g_i & \mapsto & \sum_{i=1}^{n} j(b_i) \otimes g_i \end{array}$$
is also an epimorphism.

(b) By Lemma 89.4 we have $(j \otimes \mathrm{id}) \circ (i \otimes \mathrm{id}) = (j \circ i) \otimes \mathrm{id} = 0$, i.e. we have
$$\mathrm{im}(i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G) \subset \ker(j \otimes \mathrm{id}\colon B \otimes G \to C \otimes G).$$

(c) By (b) it remains to show that
$$\ker(j \otimes \mathrm{id}\colon B \otimes G \to C \otimes G) \subset \mathrm{im}(i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G).$$
Put differently it remains to show that the homomorphism
$$\Psi\colon B \otimes G/\mathrm{im}(i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G) \to C \otimes G$$
that is induced by $j \otimes \mathrm{id}$, i.e. that is given by[1083]
$$[b \otimes g] \mapsto j(b) \otimes g,$$

is a monomorphism. We will do so by providing a left-inverse for Ψ, i.e. we will provide a map Φ with $\Phi \circ \Psi = \mathrm{id}$.

Claim. The map

$$\begin{array}{rcl} \varphi\colon C \times G & \to & B \otimes G / \operatorname{im}(i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G) \\ (c, g) & \mapsto & b \otimes g \quad \text{where } b \in B \text{ is an element with } j(b) = c. \end{array}$$

is well-defined.

Proof. Let $(c, g) \in C \times G$. Since j is by hypothesis surjective we know that there exists a $b \in B$ with $j(b) = c$. We have to show that $\varphi(c, g)$ is independent of the choice of b. So let $b, b' \in B$ with $j(b) = j(b') = c$, i.e. with $j(b - b') = 0$. From the exactness of the original short exact sequence at B it follows that $b - b' = i(a)$ for an $a \in A$. Then we obtain that

$$b \otimes g - b' \otimes g \;=\; (b - b') \otimes g \;=\; i(a) \otimes g \in \operatorname{im}(i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G).$$

Thus we have proved that φ is well-defined. ⊞

The map φ is easily seen to bilinear. It follows from Lemma 89.2 (2) that φ induces a well-defined map

$$\begin{array}{rcl} \Phi\colon C \otimes G & \to & B \otimes G / \operatorname{im}(i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G) \\ \sum_{i=1}^{k} c_i \otimes g_i & \mapsto & \sum_{i=1}^{k} \varphi(c_i, g_i). \end{array}$$

By construction we have $(\Phi \circ \Psi)([b \otimes g]) = [b \otimes g]$ for all $b \in B$ and $g \in G$. But the elements $b \otimes g$ generate $B \otimes G$, hence $\Phi \circ \Psi = \mathrm{id}$, i.e. the map Φ is indeed a right-inverse to the map Ψ. ■

89.4. **The G-torsion of an abelian group.** Our final goal is to relate the homology groups $\mathrm{H}_*(C)$ of a chain complex to the homology groups $\mathrm{H}_*(C; G)$ of the same chain complex with G-coefficients. To state the theorem relating these groups we need to introduce the G-torsion of an abelian group.

We start our discussion with recalling the definition of a free abelian group and a (free) resolution, which we had introduced on pages 1147 and 1921.

Definition.

(1) Let S be a non-empty set. We refer to

$$\mathbb{Z}^{(S)} := \text{all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s \in S$$

as the free abelian group generated by S.

(2) A group G is called free abelian if G is isomorphic to $\mathbb{Z}^{(S)}$ for some set S.

(3) It follows easily from the definitions that a group G is free abelian if and only if there exists a subset $\mathcal{B} = \{b_i\}_{i \in I} \subset G$ with the following property: For any abelian group A and each choice of elements $a_i \in A, i \in I$ there exists a unique homomorphism $\varphi\colon G \to A$ such that $\varphi(b_i) = a_i$ for all $i \in I$. As on page 1149 we call such a subset $\mathcal{B}$ a basis of G.

[1083] Note that it is a consequence of (b) that Ψ is well-defined.

(4) A (free) resolution of an abelian group H is an exact sequence

$$\ldots \xrightarrow{f_3} F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

where the F_i are (free) abelian groups. If there exists an $n \in \mathbb{N}_0$ with $F_n \neq 0$ but $F_m = 0$ for $m > n$, then we refer to n as the length of the resolution. If no such n exists, then we say that the length of the resolution is infinite.

Examples.

(1) Let $m \in \mathbb{N}$, then a free resolution of length 1 for $H = \mathbb{Z}_m$ is given by

$$0 \to \mathbb{Z} \xrightarrow{\cdot m} \mathbb{Z} \to \mathbb{Z}_m \to 0.$$

(2) Let G be a *finitely generated* abelian group. By the Finitely Generated Abelian Group Classification Theorem 51.4 there exists an $r \in \mathbb{N}_0$, non-zero natural numbers $a_1, \ldots, a_k$ and an isomorphism

$$\Phi\colon G \xrightarrow{\cong} \mathbb{Z}^r \oplus \bigoplus_{i=1}^{k} \mathbb{Z}_{a_i}.$$

Thus we obtain a free resolution[1084]

$$0 \to \mathbb{Z}^k \xrightarrow{0 \oplus \begin{pmatrix} a_1 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & a_k \end{pmatrix}} \mathbb{Z}^r \oplus \mathbb{Z}^k \to \underbrace{\mathbb{Z}^r \oplus \bigoplus_{i=1}^{k} \mathbb{Z}_{a_i}}_{\cong G} \to 0.$$

In most cases, when we want to work with explicit examples, this type of free resolution will turn out to be the most useful free resolution.

The final example is so important that it becomes a definition.

Definition. We recall the following basic fact: if M is an abelian group, then by Lemma 51.1 there exists a unique homomorphism $\alpha(M)\colon \mathbb{Z}^{(M)} \to M$ such that for each $m \in M$ we have $\alpha(M)(m) = m$. Evidently this map is an epimorphism. Now let H be an abelian group. We consider the sequence

$$\mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0.$$

The group $\mathbb{Z}^{(H)}$ is free abelian and $\alpha(H)$ is an epimorphism. In particular the sequence is exact. We set $H_1 := \ker\left(\mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H\right)$. Then

$$H_1 \hookrightarrow \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0$$

is exact. Now we consider

$$\mathbb{Z}^{(H_1)} \xrightarrow{\alpha(H_1)} \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0.$$

This sequence is exact and both the groups $\mathbb{Z}^{(H_1)}$ and $\mathbb{Z}^{(H)}$ are free abelian. Now we set $H_2 := \ker\left(\mathbb{Z}^{(H_1)} \xrightarrow{\alpha(H)} H\right)$ and we iterate this procedure. This way we obtain a free resolution of H.[1085] Note that this free resolution is unambiguously defined, we did not

[1084] Note that the homomorphism to the left is a monomorphism since $a_1, \ldots, a_k$ are non-zero.

make any choices along the way. Therefore we refer to this free resolution of H as the canonical free resolution of H.

The last example provides the proof for the following lemma.

Lemma 89.11. Every abelian group (not necessarily finitely generated) admits a canonical free resolution.

The following definition is one of the key definitions in homological algebra.

Definition. Let G and H be abelian groups. We denote by

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

the canonical free resolution from page 1922. We define the n-th G-torsion group of H as

$$\operatorname{Tor}_n(H,G) := \mathrm{H}_n(F_* \otimes G).$$

The following proposition is the key to calculating torsion-groups.

Proposition 89.12. (Tor-Free Resolution Proposition) Let G and H be abelian groups and let

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be a free resolution of H. Then there exists a natural isomorphism

$$\operatorname{Tor}_n(H,G) \xrightarrow{\cong} \mathrm{H}_n(F_* \otimes G).$$

Example. In many situations we are only interested in determining the isomorphism type of $\operatorname{Tor}_n(H,G)$ where H is a given finitely generated abelian group. In such situations it is usually much more convenient to work with the free resolution given on page 1921. For example, let $m,n \in \mathbb{N}$. We want to determine the isomorphism type of $\operatorname{Tor}_i(\mathbb{Z}_m,\mathbb{Z}_n)$ for $i \in \mathbb{N}_0$. We will do so by doing the following three step process:

(1) We pick the free resolution $0 \to \mathbb{Z} \xrightarrow{\cdot m} \mathbb{Z} \to \mathbb{Z}_m \to 0$,
(2) we tensor this free resolution of $\mathbb{Z}_m$ with $\mathbb{Z}_n$ and from the Tensor Lemma 89.3 (3) we obtain the sequence $0 \to \mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n \to \mathbb{Z}_m \otimes \mathbb{Z}_n \to 0$,
(3) we drop the term to the right and we compute the homology groups.

Now using an argument as in the calculation of the tensor product $\mathbb{Z}_m \otimes \mathbb{Z}_n$ on page 1910 we see that

$$\operatorname{Tor}_1(\mathbb{Z}_m,\mathbb{Z}_n) = \mathrm{H}_1\big(0 \to \mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n \to 0\big) = \ker(\mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n) \cong \mathbb{Z}_{\gcd(m,n)}$$

and

$$\operatorname{Tor}_0(\mathbb{Z}_m,\mathbb{Z}_n) = \mathrm{H}_0\big(0 \to \mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n \to 0\big) = \operatorname{coker}\big(\mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n\big) \cong \mathbb{Z}_{\gcd(m,n)}.$$

We will fill in the details in Exercise 89.10.

Proof. Let G and H be abelian groups and let

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be a free resolution of H. We want to show that there exists a natural isomorphism

$$\operatorname{Tor}_n(H,G) \xrightarrow{\cong} \mathrm{H}_n(F_* \otimes G).$$

[1085] Note that this procedure does not stop, i.e. it produces an infinite free resolution.

We denote by (F'_*, f'_*) the canonical free resolution of H. Since F'_* is a free resolution we obtain from the Fundamental Theorem 81.1 of Homological Algebra that there exists an extension $\alpha_i, i \in \mathbb{N}$ of the identity map $\mathrm{id}\colon H \to H$ from the free resolutions F'_* to the free resolution F_*.

Since both resolutions are free we obtain from Corollary 81.2 that the maps α_* form a chain homotopy equivalence between the two chain complexes F'_* and F_*. One easily verifies that $\alpha_* \otimes \mathrm{id}\colon F_* \otimes G \to F'_* \otimes G$ is also a chain homotopy equivalence. It follows from this observation together with Corollary 73.4 that the map

$$\begin{array}{rcl} \alpha_n \otimes \mathrm{id}\colon \overbrace{\mathrm{H}_n(F'_* \otimes G)}^{=\mathrm{Tor}_n(H,G)} & \to & \mathrm{H}_n(F_* \otimes G) \\ \left[\sum_{i=1}^{k} c_i \otimes g_i\right] & \mapsto & \left[\sum_{i=1}^{k} \alpha_n(c_i) \otimes g_i\right] \end{array}$$

is an isomorphism. Using Statement (2) of the Fundamental Theorem 81.1 of Homological Algebra one can easily show that this map does not depend on the choice of the extension α'_*. ■

Remark. Using the Fundamental Theorem 81.1 of Homological Algebra we can now show that the torsion groups $\mathrm{Tor}_n(G, H)$ are "covariantly functorial in both entries". More precisely the following two statements hold:

(1) We fix a group G. Let $\beta\colon H \to H'$ be a homomorphism between two abelian groups. It follows from the Fundamental Theorem 81.1 of Homological Algebra applied to the canonical free resolutions of H and H', together with Lemma 73.2, that β induces for each n a canonical homomorphism

$$\beta_*\colon \mathrm{Tor}_n(H, G) \to \mathrm{Tor}_n(H', G).$$

One can now easily show that the maps given by

$$\begin{array}{rcl} H & \mapsto & \mathrm{Tor}_n(H, G) \\ (\beta\colon H \to H') & \mapsto & (\beta_*\colon \mathrm{Tor}_n(H, G) \to \mathrm{Tor}_n(H', G)) \end{array}$$

define a covariant functor from the category of abelian groups to the category of abelian groups.

(2) We fix a group H. Let $\alpha\colon G \to G'$ be a homomorphism between two abelian groups. Let F_* be the canonical free resolution of H. Then $\mathrm{id} \otimes \alpha$ defines a chain map from $F_* \otimes G$ to $F_* \otimes G'$ and we get an induced map

$$\alpha_*\colon \mathrm{Tor}_n(H, G) \to \mathrm{Tor}_n(H, G').$$

One can now easily show that the maps given by

$$\begin{array}{rcl} G & \mapsto & \mathrm{Tor}_n(H, G) \\ (\alpha\colon G \to G') & \mapsto & (\alpha_*\colon \mathrm{Tor}_n(H, G) \to \mathrm{Tor}_n(H, G')) \end{array}$$

define a covariant functor from the category of abelian groups to the category of abelian groups.

The following lemma shows that the 0-th torsion groups are objects that we are already familiar with.

Lemma 89.13. (Tor_0–Lemma) Let G and H be abelian groups, then there exists a natural isomorphism [1086]

$$\mathrm{Tor}_0(H,G) \xrightarrow{\cong} H \otimes G.$$

In the remainder of this course we will use the isomorphism from the Tor_0–Lemma 89.13 to identify the groups $\mathrm{Tor}_0(H,G)$ and $H \otimes G$.

Proof. Let G and H be abelian groups. Let

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be the canonical free resolution of H. We know from Lemma 89.10 that the sequence

$$(*) \qquad F_1 \otimes G \xrightarrow{f_1 \otimes \mathrm{id}} F_0 \otimes G \xrightarrow{f_0 \otimes \mathrm{id}} H \otimes G \to 0$$

is exact. Now we obtain the following isomorphism

$$\begin{aligned} \mathrm{Tor}_0(H,G) &\overset{\text{by definition}}{=} \mathrm{H}_0\big(\cdots \to F_1 \otimes G \xrightarrow{f_1 \otimes \mathrm{id}} F_0 \otimes G \to 0\big) \\ &= \operatorname{coker}\big(F_1 \otimes G \xrightarrow{f_1 \otimes \mathrm{id}} F_0 \otimes G\big) \xrightarrow[\text{isomorphism since } (*) \text{ is exact}]{f_0 \otimes \mathrm{id}} H \otimes G. \end{aligned}$$

It is straightforward to verify that these isomorphisms define in fact a natural isomorphism from the functor $H \mapsto \mathrm{Tor}_0(H,G)$ to the functor $H \mapsto H \otimes G$ and also from the functor $G \mapsto \mathrm{Tor}_0(H,G)$ to the functor $G \mapsto H \otimes G$. ■

The following lemma shows that we do not need to worry about higher torsion groups for abelian groups.

Lemma 89.14.

(1) Every abelian group H admits a free resolution of length 1.
(2) For any two abelian groups H and G we have $\mathrm{Tor}_n(H,G) = 0$ for $n \geq 2$.

Proof.

(1) Let H be an abelian group. If H is finitely generated, then we already saw on page 1921 that H admits a free resolution of length 1. Now suppose that H is any abelian group. We have the exact sequence

$$0 \to \ker\big(\alpha(H)\colon \mathbb{Z}^{(H)} \to H\big) \to \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0$$

where $\alpha(H)$ is defined as in the proof of Lemma 89.11. It follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that the group $\ker\big(\alpha(H)\colon \mathbb{Z}^{(H)} \to H\big)$, as the subgroup of the free abelian group $\mathbb{Z}^{(H)}$, is itself free abelian. So in this general case we also found a free resolution of length 1.

(2) Let G and H be abelian groups. By (1) there exists a free resolution of length 1, i.e. of the form

$$0 \to F_1 \to F_0 \to H \to 0.$$

Finally note that it now follows immediately from the Tor-Free Resolution Proposition 89.12 that $\mathrm{Tor}_n(H,G) \cong \mathrm{H}_n(F_* \otimes G) = 0$ for $n \geq 2$. ■

[1086] Note that "natural isomorphism" means in this context that given an abelian group G we have natural isomorphisms from the functor $H \mapsto \mathrm{Tor}_0(H,G)$ to the functor $H \mapsto H \otimes G$ and also from the functor $G \mapsto \mathrm{Tor}_0(H,G)$ to the functor $G \mapsto H \otimes G$.

Definition. Given two abelian groups H and G we now write $\operatorname{Tor}(H,G) := \operatorname{Tor}_1(H,G)$ and we refer to this group as as the G-torsion of H.

Remark. For many purposes the long discussion of G-torsion groups can be summarized in the following statement: it follows from the Tor-Free Resolution Proposition 89.12 that for a free resolution $0 \to F_1 \xrightarrow{i} F_0 \xrightarrow{j} H \to 0$ of an abelian group H we have

$$\operatorname{Tor}(H,G) \;\cong\; \ker\big(F_1 \otimes G \xrightarrow{i\otimes \mathrm{id}} F_0 \otimes G\big).$$

Now we summarize several properties of the torsion groups $\operatorname{Tor}(H,G)$ in the following lemma.

Lemma 89.15. (Tor-Properties Lemma) Let G, H, $\{\mathrm{H}_i\}_{i\in I}$ and $\{G_j\}_{j\in J}$ be abelian groups. Then the following holds:

(1) There exists a natural isomorphism $\operatorname{Tor}\big(\bigoplus_i \mathrm{H}_i, G\big) \cong \bigoplus_i \operatorname{Tor}(\mathrm{H}_i, G)$.
(2) There exists a natural isomorphism $\operatorname{Tor}\big(H, \bigoplus_j G_j\big) \cong \bigoplus_j \operatorname{Tor}(H, G_j)$.
(3) If H is a torsion-free abelian group, then $\operatorname{Tor}(H,G) = 0$.
(4) If G is a torsion-free abelian group, then $\operatorname{Tor}(H,G) = 0$.
(5) If T denotes the torsion subgroup[1087] of H, then $\operatorname{Tor}(H,G) = \operatorname{Tor}(T,G)$.
(6) For all $n \in \mathbb{N}$ we have a natural isomorphism $\operatorname{Tor}(\mathbb{Z}_n, G) \cong \ker\big(G \xrightarrow{\cdot n} G\big)$.
(7) For all $n, m \in \mathbb{N}$ we have $\operatorname{Tor}(\mathbb{Z}_n, \mathbb{Z}_m) \cong \mathbb{Z}_{\gcd(n,m)}$.
(8) Given any two finitely generated abelian groups G and H the corresponding torsion group $\operatorname{Tor}(H,G)$ is finite.[1088]

Remark. Using this lemma one can usually determine the G-torsion of an abelian group H without any problems. For example the groups $(\mathbb{Q},+)$, $(\mathbb{R},+)$ and $(\mathbb{C},+)$ are torsion-free abelian groups[1089] Thus it follows immediately from the Tor-Properties Lemma 89.15 (4) that for every abelian group H we have

$$\operatorname{Tor}(H,\mathbb{Q}) \;=\; \operatorname{Tor}(H,\mathbb{R}) \;=\; \operatorname{Tor}(H,\mathbb{C}) \;=\; 0.$$

Proof.

(1) For each $i \in I$ we choose a free resolution F^i_* of H_i. Then $\bigoplus_i F^i_*$ is a free resolution of $\bigoplus_i \mathrm{H}_i$. The statement follows easily from the natural isomorphisms

$$\Big(\bigoplus_i F^i_j\Big) \otimes G \;\cong\; \bigoplus_i (F^i_j \otimes G)$$

of the Tensor Lemma 89.3 together with Lemma 72.13 and the Tor-Free Resolution Proposition 89.12.

(2) We pick a free resolution F_* for H. As in (1) the statement follows easily from the natural isomorphisms

$$F_i \otimes \bigoplus_j G_j \;\cong\; \bigoplus_j F_i \otimes G_j$$

[1087] The torsion subgroup of an abelian group is defined as the subgroup of all elements of finite order.
[1088] This fact explains the name "torsion group".
[1089] Note though that in Lemma 51.10 we saw that the abelian group $(\mathbb{Q},+)$ is not free abelian.

of the Tensor Lemma 89.3 together with Lemma 72.13 and the Tor-Free Resolution Proposition 89.12.

(3) If H is a free abelian group, then $0 \to F_0 := H \xrightarrow{\mathrm{id}} H \to 0$ is already a free resolution, and it follows immediately from the Tor-Free Resolution Proposition 89.12 that $\mathrm{Tor}(H, G) = 0$. Later on we will only use the special case that H is a free abelian group. Therefore we do not provide the proof of the general case of a torsion-free abelian group which is not free. We refer to [**Hat2002**, p. 265] for the proof.

(4) By Lemma 89.14 (1) we can pick a free resolution $0 \to F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H$ of length 1 for H. First we consider the case that G is a free abelian group. In this case we have $G \cong \bigoplus_I \mathbb{Z}$ for an index set I. It follows that

$$\mathrm{Tor}(H, G) = \mathrm{Tor}\left(H, \bigoplus_I \mathbb{Z}\right) \underset{\text{by (1)}}{=} \bigoplus_I \mathrm{Tor}(H, \mathbb{Z}) \underset{\text{Tor-Free Resolution Proposition 89.12}}{\cong} \bigoplus_I \mathrm{H}_1(0 \to \underbrace{F_1 \otimes \mathbb{Z}}_{=F_1} \to \underbrace{F_0 \otimes \mathbb{Z}}_{=F_0} \to 0) = 0.$$

Now we no longer suppose that G is free abelian, we just suppose that G is an abelian group that is torsion-free. We denote by $\{G_i\}_{i \in I}$ the set of finitely generated subgroups of G. It follows from the Finitely Generated Abelian Group Classification Theorem 51.4 that each G_i is a free abelian group. We write $i \leq j$ if and only if $G_i \subset G_j$. Together with the inclusion maps the groups $\{G_i\}_{i \in I}$ form a direct system. We leave it to the reader to verify that

$$G = \varinjlim G_i.$$

We have

$$\begin{aligned} \mathrm{Tor}(H, G) = \mathrm{Tor}(H, \varinjlim G_i) &= \mathrm{H}_1\big(0 \to F_1 \otimes \varinjlim G_i \to F_0 \otimes \varinjlim G_i\big) \\ &\underset{\text{by the Tensor Lemma 89.3 (4)}}{=} \mathrm{H}_1\big(\varinjlim (0 \to F_1 \otimes G_i \to F_0 \otimes G_i \to 0)\big) \\ &\underset{\text{Direct Limit-Homology Lemma 79.6}}{=} \varinjlim \underbrace{\mathrm{H}_1(0 \to F_1 \otimes G_i \to F_0 \otimes G_i \to 0)}_{\substack{=0, \text{ by the above, since } G_i \text{ is a} \\ \text{free abelian group}}} = 0. \end{aligned}$$

(5) If H is a finitely generated abelian group, then it follows from the Finitely Generated Abelian Group Classification Theorem 51.4 that we can write H as a direct sum $F \oplus T$, where is T the torsion subgroup and where F is a free abelian group. It follows from (1) and (2) that

$$\mathrm{Tor}(H, G) \cong \mathrm{Tor}(F \oplus T, G) \underset{\text{by (1)}}{\cong} \mathrm{Tor}(F, G) \oplus \mathrm{Tor}(T, G) \underset{\text{by (3)}}{=} \mathrm{Tor}(T, G).$$

For the proof in the case that H is not finitely generated we once again refer to [**Hat2002**, p. 265] for a proof.

(6) We consider the free resolution

$$0 \to \mathbb{Z} \xrightarrow{\cdot n} \mathbb{Z} \to \mathbb{Z}_n \to 0$$

for $H = \mathbb{Z}_n$. After tensoring with the abelian group G, and using the Tensor Lemma 89.3 we obtain the sequence

$$0 \to G \xrightarrow{\cdot n} G \to \mathbb{Z}_n \otimes G \to 0.$$

It follows from the Tor-Free Resolution Proposition 89.12 that $\mathrm{Tor}(\mathbb{Z}_n, G) = \ker\left(G \xrightarrow{\cdot n} G\right)$.[1090]

(7) We showed this isomorphism on page 1922. Alternatively one can deduce the statement using (6).

(8) Let G and H be two finitely generated abelian groups. It is a straightforward consequence of the Finitely Generated Abelian Group Classification Theorem 51.4, together with all of the above statements that the corresponding torsion group $\mathrm{Tor}(H, G)$ is finite. ■

89.5. **The Universal Coefficient Theorem.** Before we can state the Algebraic Universal Coefficient Theorem we need to introduce the following definition.

Definition. Let $(\mathrm{C}_*, \partial_*)$ be a chain complex and let G be an abelian group. Throughout this chapter, given $n \in \mathbb{N}_0$, we denote by μ the natural[1091] homomorphism[1092]

$$\begin{array}{rcl} \mu\colon \mathrm{H}_n(C_*) \otimes G & \to & \mathrm{H}_n(C_* \otimes G) \\ \sum_{i=1}^{m} [c_i] \otimes g_i & \mapsto & \left[\sum_{i=1}^{m} c_i \otimes g_i\right]. \end{array}$$

Now we can formulate and prove the following theorem which is the key result of the whole chapter.

Theorem 89.16. (Algebraic Universal Coefficient Theorem) Let (C_n, ∂_n) be a chain complex of free abelian groups and let G be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a natural homomorphism $p\colon \mathrm{H}_n(C; G) \to \mathrm{Tor}(\mathrm{H}_{n-1}(C), G)$ such that the following sequence is exact:

$$0 \to \mathrm{H}_n(C) \otimes G \xrightarrow{\mu} \mathrm{H}_n(C; G) \xrightarrow{p} \mathrm{Tor}(\mathrm{H}_{n-1}(C), G) \to 0.$$

Remark. The fact the homomorphisms μ and p are natural implies that given a chain map $f\colon C \to D$ and a homomorphism $\varphi\colon G \to G'$ between abelian groups the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{H}_n(C) \otimes G & \xrightarrow{\mu} & \mathrm{H}_n(C; G) & \xrightarrow{p} & \mathrm{Tor}(\mathrm{H}_{n-1}(C), G) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{H}_n(D) \otimes G' & \xrightarrow{\mu} & \mathrm{H}_n(D; G') & \xrightarrow{p} & \mathrm{Tor}(\mathrm{H}_{n-1}(D), G') & \longrightarrow & 0 \end{array}$$

[1090] The same argument, together with the Tor_0–Lemma 89.13 can be used to give a proof of the Tensor Lemma 89.3 (3), which back then was perhaps shoved under the carpet a little too quickly.

[1091] Here "natural" means that for a chain map $f_*\colon C_* \to D_*$ and a homomorphism $\varphi\colon G \to G'$ between abelian groups the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_n(C_*) \otimes G & \xrightarrow{\mu} & \mathrm{H}_n(C_* \otimes G) \\ \downarrow & & \downarrow \\ \mathrm{H}_n(D_*) \otimes G' & \xrightarrow{\mu} & \mathrm{H}_n(D_* \otimes G') \end{array}$$

where the vertical maps are induced by f and φ in the, hopefully, obvious way.

[1092] It is straightforward to show that the map is well-defined. We will discuss in Exercise 89.4 whether the "obvious converse" is also well-defined.

commutes. Here the vertical maps are all induced by the chain map $f\colon C \to D$ and the homomorphism $\varphi\colon G \to G'$.

Proof. Let (C_n, ∂_n) be a chain complex of free abelian groups. For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \operatorname{im}(\partial_{n+1})$. Note that it follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that B_n and Z_n are free abelian groups.

We consider the following diagram

$$\begin{array}{ccccccccc}
 & & \vdots & & \vdots & & \vdots & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & Z_n & \longrightarrow & \mathrm{C}_n & \xrightarrow{\partial_n} & B_{n-1} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle 0} & & \downarrow{\scriptstyle \partial_n} & & \downarrow{\scriptstyle 0} & & \\
0 & \longrightarrow & Z_{n-1} & \longrightarrow & \mathrm{C}_{n-1} & \xrightarrow{\partial_{n-1}} & B_{n-2} & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & \vdots & & \vdots & & \vdots & &
\end{array}$$

One sees easily that this diagram is commutative and that the horizontal sequences are exact. We can and will view the left and the right vertical columns as chain complexes. In other words, the above diagram is a short exact sequence of chain complexes. Recall that the groups B_n are free abelian groups, thus it follows from Lemmas 78.1 that each of the horizontal sequences splits.

Now let G be an abelian group. We tensor the above short exact sequence of chain complexes with G and we obtain the following diagram:

$$\begin{array}{ccccccccc}
 & & \vdots & & \vdots & & \vdots & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & Z_n \otimes G & \longrightarrow & \mathrm{C}_n \otimes G & \xrightarrow{\partial_n \otimes \mathrm{id}} & B_{n-1} \otimes G & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle 0} & & \downarrow{\scriptstyle \partial_n \otimes \mathrm{id}} & & \downarrow{\scriptstyle 0} & & \\
0 & \longrightarrow & Z_{n-1} \otimes G & \longrightarrow & \mathrm{C}_{n-1} \otimes G & \xrightarrow{\partial_{n-1} \otimes \mathrm{id}} & B_{n-2} \otimes G & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & \vdots & & \vdots & & \vdots & &
\end{array}$$

This is again a sequence of chain complexes.

Since the original short exact sequences split it follows from Lemmas 89.6 that the horizontal sequences obtained from tensoring with G are still exact. Therefore we can apply the LES Proposition 74.9 to obtain a long exact sequence of homology groups. Since the vertical boundary maps on the left and on the right are the zero maps, we obtain the following long exact sequence

$$\ldots \to B_n \otimes G \xrightarrow{d_n} Z_n \otimes G \to \mathrm{H}_n(C; G) \xrightarrow{\partial_n} B_{n-1} \otimes G \xrightarrow{d_{n-1}} Z_{n-1} \otimes G \to \ldots$$

where the maps d_n are the connecting homomorphisms of the long exact sequence. It follows easily from the definition that the connecting homomorphism $d_n\colon B_n \otimes G \to Z_n \otimes G$ is the map that is given by $i_n \otimes \mathrm{id}\colon B_n \otimes G \to Z_n \otimes G$ where $i_n\colon B_n \to Z_n$ denotes the obvious inclusion map.[1093]

[1093] Why is this the case?

Using the Break-into-SES Lemma 78.4 the above discussion implies that we obtain the following short exact sequence

$$0 \to \operatorname{coker}\left(B_n \otimes G \xrightarrow{i_n \otimes \mathrm{id}} Z_n \otimes G\right) \to \mathrm{H}_n(C; G) \to \ker\left(B_{n-1} \otimes G \xrightarrow{i_{n-1} \otimes \mathrm{id}} Z_{n-1} \otimes G\right) \to 0.$$

We still have to show that the expressions left and right coincide with the desired expressions. We have natural isomorphisms

$$\begin{array}{ccccc} \operatorname{coker}\left(B_n \otimes G \xrightarrow{i_n \otimes \mathrm{id}} Z_n \otimes G\right) & \xleftarrow{\cong} & \operatorname{Tor}_0(\mathrm{H}_n(C), G) & \xrightarrow{\cong} & \mathrm{H}_n(C) \otimes G \\ \uparrow & & & & \uparrow \\ \text{by the Tor-Free Resolution Proposition 89.12 since } B_n \xrightarrow{i_n} Z_n \to \mathrm{H}_n(C) & & & & \operatorname{Tor}_0\text{–Lemma 89.13} \\ \text{is a free resolution of } \mathrm{H}_n(C) & & & & \end{array}$$

Similarly we have a natural isomorphism

$$\ker\left(B_{n-1} \otimes G \xrightarrow{i_{n-1} \otimes \mathrm{id}} Z_{n-1} \otimes G\right) \xrightarrow{\cong} \operatorname{Tor}(\mathrm{H}_{n-1}(C), G).$$

We have thus shown the existence of the desired short exact sequences. The statement that the homomorphism p is natural follows easily from the definitions and Statement (2) of the Fundamental Theorem 81.1 of Homological Algebra. We leave the verification of the details to the reader. ■

The following theorem is for us the main application of the Universal Coefficient Theorem 89.16.

Theorem 89.17. (Universal Coefficient Theorem) Let (X, A) be a pair of topological spaces and let G be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a natural homomorphism $\mathrm{H}_n(X, A; G) \to \operatorname{Tor}(\mathrm{H}_{n-1}(X, A), G)$ such that the following sequence is exact:

$$0 \to \mathrm{H}_n(X, A) \otimes G \xrightarrow{\mu} \mathrm{H}_n(X, A; G) \to \operatorname{Tor}(\mathrm{H}_{n-1}(X, A), G) \to 0.$$

Remark. Note that the naturality of the maps implies for every map $f\colon (X, A) \to (Y, B)$ between pairs of topological spaces and any homomorphism $\varphi\colon G \to G'$ between abelian groups we obtain the following *commutative* diagram of short exact sequences:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{H}_n(X, A) \otimes G & \xrightarrow{\mu} & \mathrm{H}_n(X, A; G) & \longrightarrow & \operatorname{Tor}(\mathrm{H}_{n-1}(X, A), G) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{H}_n(Y, B) \otimes G' & \xrightarrow{\mu} & \mathrm{H}_n(Y, B; G') & \longrightarrow & \operatorname{Tor}(\mathrm{H}_{n-1}(Y, B), G') & \longrightarrow & 0, \end{array}$$

where the vertical maps are the obvious (?) ones induced by f and φ.

Proof. Let (X, A) be a pair of topological spaces and let G be an abelian group. As we pointed out on page 1625, the chain groups $\mathrm{C}_n(X, A)$, $n \in \mathbb{N}_0$, are free abelian groups. Thus we can apply the Universal Coefficient Theorem 89.16 and we immediately obtain the desired short exact sequence. ■

Before we consider a few examples let us jot down the following almost immediate corollary.

Corollary 89.18. Let $f\colon (X,A)\to(Y,B)$ be a map between pairs of topological spaces and let G be an abelian group. Then

$$\begin{array}{c}\text{the induced map}\\ f_*\colon \mathrm{H}_n(X,A)\to\mathrm{H}_n(Y,B)\text{ is}\\ \text{an isomorphism for all } n\in\mathbb{N}_0\end{array}\quad\Longrightarrow\quad\begin{array}{c}\text{the induced map}\\ f_*\colon \mathrm{H}_n(X,A;G)\to\mathrm{H}_n(Y,B;G)\text{ is}\\ \text{an isomorphism for all } n\in\mathbb{N}_0.\end{array}$$

Proof. The corollary follows immediately from the naturality of the short exact sequence of the Universal Coefficient 89.17 together with the Five-Lemma 74.10. ■

Examples.

(1) We consider again the real projective space $\mathbb{R}\mathrm{P}^n$. In Proposition 80.11 we saw that

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^n)\ \cong\ \begin{cases}\mathbb{Z}, & \text{if } k=0,\\ \mathbb{Z}_2, & \text{if } k \text{ is odd and } k<n,\\ 0, & \text{if } k \text{ is even and } 0<k\le n,\\ 0, & \text{if } k>n,\\ \mathbb{Z}, & \text{if } k=n \text{ and } n \text{ is odd.}\end{cases}$$

It follows from the Universal Coefficient Theorem 89.17, the discussion on page 1910 and the Tor-Properties Lemma 89.15 (7) that for any even number $2k\in\{0,\dots,n\}$ we have a short exact sequence

$$0\ \to\ \underbrace{\mathrm{H}_{2k}(\mathbb{R}\mathrm{P}^n)\otimes\mathbb{F}_2}_{\cong 0\otimes\mathbb{F}_2=0}\ \xrightarrow{\mu}\ \mathrm{H}_{2k}(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)\ \to\ \underbrace{\mathrm{Tor}(\mathrm{H}_{2k-1}(\mathbb{R}\mathrm{P}^n),\mathbb{F}_2)}_{\cong\mathrm{Tor}(\mathbb{F}_2,\mathbb{F}_2)\cong\mathbb{F}_2}\ \to\ 0$$

whereas for $2k+1\in\{0,\dots,n\}$ an odd number we have a short exact sequence

$$0\ \to\ \underbrace{\mathrm{H}_{2k+1}(\mathbb{R}\mathrm{P}^n)\otimes\mathbb{F}_2}_{\cong\mathbb{F}_2\otimes\mathbb{F}_2\cong\mathbb{F}_2\text{ or}\cong\mathbb{Z}\otimes\mathbb{F}_2\cong\mathbb{F}_2}\ \xrightarrow{\mu}\ \mathrm{H}_{2k+1}(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)\ \to\ \underbrace{\mathrm{Tor}(\mathrm{H}_{2k}(\mathbb{R}\mathrm{P}^n),\mathbb{F}_2)}_{\cong\mathrm{Tor}(0,\mathbb{F}_2)=0\ \text{ or }\cong\mathrm{Tor}(\mathbb{Z},\mathbb{F}_2)=0}\ \to\ 0.$$

Also it follows easily that $\mathrm{H}_k(\mathbb{R}\mathrm{P}^n)=0$ for $k>n$. Summarizing we obtain the following result:

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)\ \cong\ \begin{cases}\mathbb{F}_2, & \text{if } k=0,\dots,n,\\ 0, & \text{otherwise.}\end{cases}$$

Fortunately this calculation agrees with the calculation on page 1916.

(2) As in the Ball-Quotient Sphere Lemma 5.20 and as on page 258 we make the usual identifications $S^2=\overline{B}^2/S^1$ and $\mathbb{R}\mathrm{P}^2=\overline{B}^2/z\sim -z$ where $z\in S^1$. We denote by f the natural projection[1094]

$$f\colon \mathbb{R}\mathrm{P}^2=\overline{B}^2/z\sim -z\ \to\ S^2=\overline{B}^2/S^1.$$

As in the figure on page 1472 we equip $\mathbb{R}\mathrm{P}^2$ with the CW-structure with one 0-cell, one 1-cell and one 2-cell and as on page 1472 we equip S^2 with the CW-structure with one 0-cell and one 2-cell. With these CW-structures the above map f is given by collapsing the 1-cell to the unique 0-cell of S^2, in particular f is a cellular map. By the

[1094]Note that this is not a covering map and that this map has nothing to do with the more familiar projection $S^2\to\mathbb{R}\mathrm{P}^2$.

Singular-Cellular H_*-Isomorphism Proposition 80.4 and the discussion on page 1915 we obtain the following commutative diagram

$$\begin{array}{ccc} \mathrm{H}_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) & \xrightarrow{f_*} & \mathrm{H}_2(S^2;\mathbb{F}_2) \\ {\scriptstyle \Phi_{\mathbb{R}\mathrm{P}^2}}\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle \Phi_{S^2}} \\ \mathrm{H}_2^{\mathrm{CW}}(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) & \xrightarrow{f_*} & \mathrm{H}_2^{\mathrm{CW}}(S^2;\mathbb{F}_2). \end{array}$$

As we saw on page 1916, the 2-cell is a generator of $\mathrm{H}_2^{\mathrm{CW}}(S^2;\mathbb{F}_2)$ and it gets sent to the 2-cell in S^2 which is, as we saw on page 1770, a generator of $\mathrm{H}_2^{\mathrm{CW}}(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$. Thus we see that the bottom map is an isomorphism, it follows that the top map is also an isomorphism. Summarizing the short exact sequences of the Universal Coefficient Theorem 89.17 give us the following commutative diagram:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \overbrace{\mathrm{H}_2(\mathbb{R}\mathrm{P}^2)\otimes\mathbb{F}_2}^{=0} & \xrightarrow{\mu} & \overbrace{\mathrm{H}_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)}^{\cong\mathbb{F}_2} & \longrightarrow & \overbrace{\mathrm{Tor}(\mathrm{H}_1(\mathbb{R}\mathrm{P}^2),\mathbb{F}_2)}^{\cong\mathbb{F}_2} & \longrightarrow & 0 \\ & & {\scriptstyle =0}\downarrow{\scriptstyle f_*} & & {\scriptstyle \cong}\downarrow{\scriptstyle f_*} & & {\scriptstyle =0}\downarrow{\scriptstyle f_*} & & \\ 0 & \longrightarrow & \underbrace{\mathrm{H}_2(S^2)\otimes\mathbb{F}_2}_{\cong\mathbb{F}_2} & \xrightarrow{\mu} & \underbrace{\mathrm{H}_2(S^2;\mathbb{F}_2)}_{\cong\mathbb{F}_2} & \longrightarrow & \underbrace{\mathrm{Tor}(\mathrm{H}_1(S^2),\mathbb{F}_2)}_{=0} & \longrightarrow & 0. \end{array}$$

Note that the two vertical maps to the left and right are the zero map, whereas the middle map is actually an isomorphism. This slightly weird fact will play a role in the No-Natural Splitting Proposition 89.24.

In the following corollary we give two instances where the Tor-terms in the Universal Coefficient Theorem 89.17 are zero, i.e. two instances where we can "pull out" the coefficients.

Corollary 89.19.

(1) Let (X, A) be a pair of topological spaces and let G be a subgroup of $(\mathbb{C}, +)$. Then for each $n \in \mathbb{N}_0$ the map

$$\mu\colon \mathrm{H}_n(X, A; \mathbb{Z}) \otimes G \;\to\; \mathrm{H}_n(X, A; G)$$

is a natural isomorphism.

(2) Let (X, A) be a pair of topological spaces and let $\mathbb{F}$ be a subfield of $\mathbb{C}$. Then for each $n \in \mathbb{N}_0$ we have $\mathrm{rank}(\mathrm{H}_n(X, A)) = \dim_{\mathbb{F}}(\mathrm{H}_n(X, A; \mathbb{F}))$.

Example. It follows immediately from Proposition 80.11 together with Corollary 89.19 and the Tensor Lemma 89.3 (3) that

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^{2n+1};\mathbb{R}) \;\cong\; \begin{cases} \mathbb{R}, & \text{if } k = 0, 2n+1, \\ 0, & \text{otherwise.} \end{cases} \quad \text{and} \quad \mathrm{H}_k(\mathbb{R}\mathrm{P}^{2n};\mathbb{R}) \;\cong\; \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Proof.

(1) This statement is an immediate consequence of the Universal Coefficient Theorem 89.17 and the fact, obtained in the Tor-Properties Lemma 89.15 (4), that the torsion-groups are zero for any subgroup of $(\mathbb{C}, +)$.

(2) To shorten the notation we consider only the case $A = \varnothing$. We have

$$\mathrm{rank}(\mathrm{H}_n(X)) \underset{\text{by the definition on page 1911}}{\overset{\uparrow}{=}} \dim_{\mathbb{Q}}(\mathrm{H}_n(X)\otimes\mathbb{Q}) \underset{\text{by (1)}}{\overset{\uparrow}{=}} \dim_{\mathbb{Q}}(\mathrm{H}_n(X))\otimes\mathbb{Q} \underset{\text{follows fairly easily from } \mathbb{Q}\subset\mathbb{F}}{\overset{\uparrow}{=}} \dim_{\mathbb{F}}(\mathrm{H}_n(X))\otimes\mathbb{F}.$$

■

Remark.

(1) Let (X, A) be a pair of topological spaces and let R be a subring of $\mathbb{C}$. Since the map $\mu\colon \mathrm{H}_n(X, A; \mathbb{Z}) \otimes R \to \mathrm{H}_n(X, A; R)$ is natural we can and we will in the following identify the groups $\mathrm{H}_n(X, A; \mathbb{Z}) \otimes R$ and $\mathrm{H}_n(X, A; R)$ using the isomorphism from Corollary 89.19.

(2) Given a pair (X, A) of topological spaces and $n \in \mathbb{N}_0$ we refer to[1095]

$$b_n(X, A) \;:=\; \mathrm{rank}(\mathrm{H}_n(X, A))$$

as the *n-th Betti number of* (X, A). For $A = \varnothing$ we write of course $b_n(X) := b_n(X, \varnothing)$. Note that it follows from Corollary 89.19 that for any subfield $\mathbb{F}$ of $\mathbb{C}$ we have $b_n(X, A) = \dim_{\mathbb{F}}(\mathrm{H}_n(X, A; \mathbb{F}))$.

(3) Let R be a subring of $\mathbb{C}$. the Tor-Properties Lemma 89.15 (4) and the Universal Coefficient Theorem 89.16 show that taking the tensor product with R is an exact functor in the sense of the definition on page 1918.

We conclude this section with the following lemma which we will need later on in the generalization of the Borsuk-Ulam Theorem 48.21 to higher dimensions.

Lemma 89.20. (Degree-and-Coefficients Lemma) Let $f\colon S^n \to S^n$ be a map and let $k \in \mathbb{N}$. Then the induced map

$$f_*\colon \mathrm{H}_n(S^n; \mathbb{Z}_k) \;\to\; \mathrm{H}_n(S^n; \mathbb{Z}_k)$$

is given by multiplication by $\deg(f)$.

Proof. Let $f\colon S^n \to S^n$ be a map and let $k \in \mathbb{N}$. Since the short exact sequence of the Universal Coefficient Theorem 89.17 is natural we obtain the following commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{H}_n(S^n) \otimes \mathbb{Z}_k & \xrightarrow{\mu} & \mathrm{H}_n(S^n; \mathbb{Z}_k) & \longrightarrow & \mathrm{Tor}(\mathrm{H}_{n-1}(S^n), \mathbb{Z}_k) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle f_* \otimes \mathrm{id}} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \\
0 & \longrightarrow & \mathrm{H}_n(S^n) \otimes \mathbb{Z}_k & \xrightarrow{\mu} & \mathrm{H}_n(S^n; \mathbb{Z}_k) & \longrightarrow & \mathrm{Tor}(\mathrm{H}_{n-1}(S^n), \mathbb{Z}_k) & \longrightarrow & 0.
\end{array}$$

Note that $\mathrm{H}_{n-1}(S^n)$ is torsion-free, hence $\mathrm{Tor}(\mathrm{H}_{n-1}(S^n), \mathbb{Z}_k) = 0$ by the Tor-Properties Lemma 89.15. It follows from the exactness of the horizontal sequences that the horizontal maps μ on the left are isomorphisms. By definition the map $f_*\colon \mathrm{H}_n(S^n) \to \mathrm{H}_n(S^n)$ is given by multiplication by $\deg(f)$, hence $f_* \otimes \mathrm{id}$ is also given by multiplication by $\deg(f)$. It now follows that the middle vertical map is also given by multiplication by $\deg(f)$. ■

89.6. **Splittings of the Universal Coefficient Theorem.** Our goal had been to determine the homology groups $\mathrm{H}_n(C; G)$ only in terms of the original groups $\mathrm{H}_k(C)$ and the abelian group G. The Algebraic Universal Coefficient Theorem 89.16 gave us a short exact sequence

$$0 \;\to\; \mathrm{H}_n(C) \otimes G \;\xrightarrow{\mu}\; \mathrm{H}_n(C; G) \;\xrightarrow{p}\; \mathrm{Tor}(\mathrm{H}_{n-1}(C), G) \;\to\; 0.$$

But in general, as we already saw on page 1715, given a short exact sequence, it is not possible to determine the middle group of a short exact sequence from the groups to the

[1095] Recall that on page 1911 we defined the rank of an arbitrary abelian group.

left and the right. But we saw in Splitting Lemma 78.2 that if a short exact sequence of abelian groups

$$0 \;\to\; A \;\xrightarrow{i}\; B \;\xrightarrow{p}\; C \;\to\; 0$$

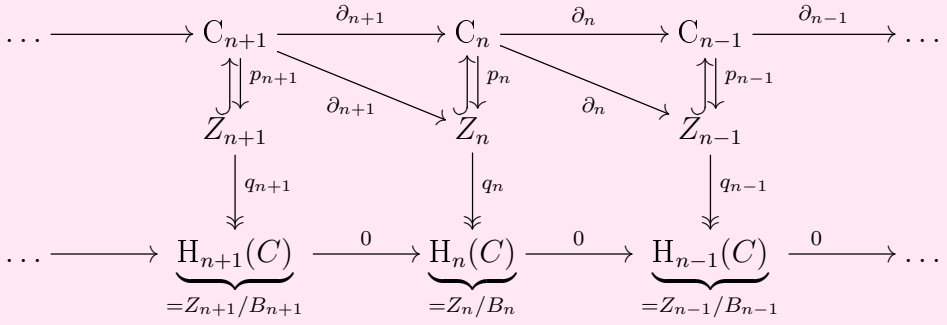
splits, then the middle group B is the direct sum of the "outer" groups A and C. The question arises, whether the short exact sequence in the Universal Coefficient Theorem 89.16 splits. This is fortunately the case:

Proposition 89.21. (UCT-Splitting Proposition) Let (C_n, ∂_n) be a free chain complex[1096] and let G be an abelian group. Then for any $n \in \mathbb{N}_0$ the short exact sequence

$$0 \;\to\; \mathrm{H}_n(C) \otimes G \;\xrightarrow{\mu}\; \mathrm{H}_n(C;G) \;\to\; \mathrm{Tor}(\mathrm{H}_{n-1}(C), G) \;\to\; 0$$

of the Algebraic Universal Coefficient Theorem 89.16 splits. In particular there exists an isomorphism

$$\mathrm{H}_n(C;G) \;\cong\; \mathrm{H}_n(C) \otimes G \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(C), G).$$



Proof. Let (C_n, ∂_n) be a chain complex of free abelian groups and furthermore let G be an abelian group. According to Splitting Lemma 78.2 it suffices to construct a homomorphism $\eta\colon \mathrm{H}_n(C;G) \to \mathrm{H}_n(C) \otimes G$ such that $\eta \circ \mu$ is the identity on $\mathrm{H}_n(C) \otimes G$.

For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \mathrm{im}(\partial_{n+1})$. We consider the short exact sequence

$$0 \;\to\; Z_n \;\hookrightarrow\; \mathrm{C}_n \;\xrightarrow{\partial_n}\; B_{n-1} \;\to\; 0.$$

The group $B_{n-1} \subset \mathrm{C}_{n-1}$ is a subgroup of a free abelian group, thus it is itself a free abelian group by the Subgroup-of-Free Abelian Group Lemma 51.2 . Therefore we can deduce from Lemma 78.1 that the above short exact sequence splits. In particular, according to Splitting Lemma 78.2, for each $n \in \mathbb{N}_0$ there exists a homomorphism $p_n\colon \mathrm{C}_n \to Z_n$ such that p_n is the identity on $Z_n \subset C_n$.

Claim. The following diagram commutes:

where the maps q_n are just the natural projections.

Proof. We start at C_{n+1}. If we go down and then right, then we end up with the zero map to $\mathrm{H}_n(C)$. On the other hand, if we first go right, then we end up in $B_n \subset Z_n$, but then the projection q_n to $\mathrm{H}_n(C) = Z_n/B_n$ is also the zero map. ⊞

The top and the bottom horizontal sequences of the claim are chain complexes. Since the diagram commutes we see that the vertical maps from top to bottom are chain maps.

[1096] A chain complex $(\mathrm{C}_*, \partial_*)$ is called *free*, if all the groups C_n are free abelian groups.

Now we tensor the top and the bottom horizontal sequences with G and we obtain the following diagram of chain complexes.

$$\begin{array}{ccccccccc}
\ldots & \longrightarrow & \mathrm{C}_{n+1} \otimes G & \xrightarrow{\partial_{n+1}\otimes \mathrm{id}} & \mathrm{C}_n \otimes G & \xrightarrow{\partial_n \otimes \mathrm{id}} & \mathrm{C}_{n-1} \otimes G & \xrightarrow{\partial_{n-1}\otimes \mathrm{id}} & \ldots \\
 & & \downarrow{\scriptstyle (q_{n+1}\circ p_{n+1})\otimes \mathrm{id}} & & \downarrow{\scriptstyle (q_n \circ p_n)\otimes \mathrm{id}} & & \downarrow{\scriptstyle (q_{n-1}\circ p_{n-1})\otimes \mathrm{id}} & & \\
\ldots & \longrightarrow & \mathrm{H}_{n+1}(C) \otimes G & \xrightarrow{0} & \mathrm{H}_n(C) \otimes G & \xrightarrow{0} & \mathrm{H}_{n-1}(C) \otimes G & \xrightarrow{0} & \ldots
\end{array}$$

The induced maps on the homology of these two chain complexes give us a homomorphism

$$\eta \colon \mathrm{H}_n(C; G) \;=\; \mathrm{H}_n(C_* \otimes G) \;\to\; \mathrm{H}_n(\text{lower sequence}) = \mathrm{H}_n(C) \otimes G.$$

It remains to prove the following claim.

Claim. The composition $\eta \circ \mu$ is the identity on $\mathrm{H}_n(C) \otimes G$.

Proof. Let $[\sigma] \otimes g \in \mathrm{H}_n(C) \otimes G$ where $\sigma \in Z_n$. Then

$$(\eta \circ \mu)([\sigma] \otimes g) \;=\; \eta([\sigma \otimes g]) \underset{\substack{\uparrow \\ \text{definition of } \eta}}{=} (q_n(p_n(\sigma))) \otimes g \underset{\substack{\uparrow \\ \text{since } p_n = \mathrm{id} \text{ on } Z_n}}{=} q_n(\sigma) \otimes g \;=\; [\sigma] \otimes g.$$

■

The following immediate corollary to the UCT-Splitting Proposition 89.21 shows in particular that the homology groups with G-coefficients of a topological space X are completely determined by the usual homology groups of X and the abelian group G.

Theorem 89.22. (UCT-Splitting Theorem) Let (X, A) be a pair of topological spaces and let G be an abelian group. Then for each $n \in \mathbb{N}_0$ the short exact sequence

$$0 \;\to\; \mathrm{H}_n(X, A) \otimes G \;\xrightarrow{\mu}\; \mathrm{H}_n(X, A; G) \;\to\; \mathrm{Tor}(\mathrm{H}_{n-1}(X, A), G) \;\to\; 0$$

from the Universal Coefficient Theorem 89.17 splits. In particular there exists an isomorphism

$$\mathrm{H}_n(X, A; G) \;\cong\; \mathrm{H}_n(X, A) \otimes G \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(X, A), G).$$

The following is an immediate corollary to the UCT-Splitting Theorem 89.22.

Corollary 89.23. Let (X, A) and (Y, B) be topological spaces and let G be an abelian group. Then

$$\begin{array}{c} \mathrm{H}_n(X, A) \text{ and } \mathrm{H}_n(Y, B) \text{ are} \\ \text{isomorphic for all } n \in \mathbb{N}_0 \end{array} \quad \Longrightarrow \quad \begin{array}{c} \mathrm{H}_n(Y, B; G) \text{ and } \mathrm{H}_n(X, A; G) \text{ and} \\ \text{isomorphic for all } n \in \mathbb{N}_0. \end{array}$$

Remark.

(1) Corollary 89.23 is in some sense a disappointment, it shows that homology groups with coefficients are not better at distinguishing topological spaces than ordinary homology groups.
(2) Corollary 89.23 is also an almost immediate consequence of Propositions 81.13 and 81.4.

The question now arises, whether given an abelian group G there exists in fact a *natural* isomorphism

$$\mathrm{H}_n(X; G) \;\cong\; \mathrm{H}_n(X) \otimes G \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(X), G).$$

The discussion on page 206 already shows that this sounds like a dubious idea. Indeed, the following proposition says that such a natural isomorphism does not exist for $G = \mathbb{F}_2$. More precisely, we have the following proposition.

Proposition 89.24. (No-Natural Splitting Proposition) It is not possible assign to each topology space X an isomorphism

$$\Phi_X \colon \mathrm{H}_n(X;\mathbb{F}_2) \ \to \ \mathrm{H}_n(X) \otimes \mathbb{F}_2 \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(X), \mathbb{F}_2)$$

such that for any map $f \colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_n(X;\mathbb{F}_2) & \xrightarrow[\cong]{\Phi_X} & \mathrm{H}_n(X) \otimes \mathbb{F}_2 \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(X), \mathbb{F}_2) \\ \downarrow f_* & & \downarrow f_* \quad \downarrow f_* \\ \mathrm{H}_n(Y;\mathbb{F}_2) & \xrightarrow[\cong]{\Phi_Y} & \mathrm{H}_n(Y) \otimes \mathbb{F}_2 \oplus \mathrm{Tor}(\mathrm{H}_{n-1}(Y), \mathbb{F}_2). \end{array}$$

Proof. So suppose instead that such a map Φ_X exists for every topological space X. We consider the map

$$f \colon \mathbb{R}\mathrm{P}^2 = \overline{B}^2/z \sim -z \ \to \ S^2 = \overline{B}^2/S^1$$

from page 1930. We obtain the following diagram:

$$\begin{array}{ccc} \overbrace{\mathrm{H}_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)}^{\cong \mathbb{F}_2} & \xrightarrow[\cong]{\Phi_{\mathbb{R}\mathrm{P}^2}} & \overbrace{\mathrm{H}_2(\mathbb{R}\mathrm{P}^2) \otimes \mathbb{F}_2}^{=0} \oplus \overbrace{\mathrm{Tor}(\mathrm{H}_1(\mathbb{R}\mathrm{P}^2), \mathbb{F}_2)}^{\cong \mathbb{F}_2} \\ {\scriptstyle f_*}\downarrow & & {\scriptstyle =0}\downarrow {\scriptstyle f_*} \quad {\scriptstyle =0}\downarrow {\scriptstyle f_*} \\ \underbrace{\mathrm{H}_2(S^2;\mathbb{F}_2)}_{\cong \mathbb{F}_2} & \xrightarrow[\cong]{\Phi_{\mathbb{R}\mathrm{P}^2}} & \underbrace{\mathrm{H}_2(S^2) \otimes \mathbb{F}_2}_{\cong \mathbb{F}_2} \oplus \underbrace{\mathrm{Tor}(\mathrm{H}_1(S^2), \mathbb{F}_2)}_{=0}. \end{array}$$

The horizontal maps are by hypothesis isomorphisms. We saw on page 1930 that the vertical map on the left is an isomorphism. On the other hand the two vertical maps on the right are zero since either the domain or the target is zero. Thus this diagram cannot possibly commute. We have thus found a contradiction to our assumption. ■

89.7. **The Eilenberg-Steenrod axioms for homology** $(*)$**.** In this section we give a very short introduction to the concept of (co-) homology theories which was introduced in the seminal book of Eilenberg–Steenrod [**ES1952**]. Before we can do so we introduce the following definition.

Definition. Let R be a commutative ring and let S be a set.

(1) An S-graded R-module is defined as an R-module M together with a direct sum decomposition $M = \bigoplus_{s \in S} M_s$ into R-modules M_s, $s \in S$. If $x \in M$ lies in some M_s, then we call x homogeneous and we refer to $\deg(x) := s$ as the degree of x.

(2) A morphism $f \colon M \to N$ between S-graded R-modules M and N is an R-module homomorphism such that for each $s \in S$ we have $f(M_s) \subset N_s$. Equivalently, it is a family of R-module homomorphisms $\{f_s \colon M_s \to N_s\}_{s \in S}$.

(3) The category $S\text{-}\mathcal{GradMod}_R$ of S-graded R-modules is the category where the objects are S-graded R-modules and the morphisms are the ones described in (2).

(4) Since abelian groups are for all intents and purposes the same as $\mathbb{Z}$-modules we define the category $S\text{-}\mathcal{GradAb}$ of S-graded abelian groups to be the category of $\mathbb{N}_0$-graded $\mathbb{Z}$-modules.

Example. Given a pair of topological spaces (X, Y) and an abelian group G we write

$$\mathrm{H}_*(X, Y; G) \;:=\; \bigoplus_{n\in\mathbb{N}_0} \mathrm{H}_n(X, Y; G)$$

and we view $\mathrm{H}_*(X, Y; G)$ as an $\mathbb{N}_0$-graded $\mathbb{Z}$-module.

The following definition goes back to [**ES1952**] and [**Miln1962b**].

Definition. A homology theory is a covariant functor

$$\mathcal{H}\colon \begin{array}{c}\text{category } \mathcal{PairTop} \text{ of}\\ \text{pairs of topological spaces}\end{array} \;\to\; \begin{array}{c}\text{category } \mathbb{N}_0\text{-}\mathcal{GradAb} \text{ of}\\ \mathbb{N}_0\text{-graded abelian groups}\end{array}$$

that satisfies the following axioms:[1097]

(1) (Homotopy invariant) If $f, g\colon (X, A) \to (Y, B)$ are homotopic maps between pairs of topological spaces, then $f_* = g_*$.

(2) (Connecting homomorphism) Given any pair (X, A) of topological spaces and any $n \in \mathbb{N}$ there exists a natural connecting homomorphism $\partial\colon \mathcal{H}_n(X, A) \to \mathcal{H}_{n-1}(A)$[1098] such that the sequence

$$\ldots \;\to\; \mathcal{H}_{n+1}(X, A) \;\xrightarrow{\partial}\; \mathcal{H}_n(A) \;\to\; \mathcal{H}_n(X) \;\to\; \mathcal{H}_n(X, A) \;\xrightarrow{\partial}\; \mathcal{H}_{n-1}(A) \;\to\; \ldots$$

is exact.

(3) (Excision) If U and A are subsets of a topological space X with $\overline{U} \subset \mathring{A}$, then for each $n \in \mathbb{N}_0$ the map $\mathcal{H}_n(X \setminus U, A \setminus U) \to \mathcal{H}_n(X, A)$ is an isomorphism.

(4) (Additivity) Let $\{(X_j, A_j)\}_{j\in J}$ be a family of pairs of topological spaces. We write $X = \bigsqcup_{j\in J} X_j$ and $A = \bigsqcup_{j\in J} A_j$. If given $j \in J$ we denote by $i_j\colon (X_j, A_j) \to (X, A)$ the obvious inclusion map, then for any $k \in \mathbb{N}_0$ the induced map

$$\bigoplus_{j\in J} i_{j*}\colon \bigoplus_{j\in J} \mathcal{H}_k(X_j, A_j) \;\to\; \mathcal{H}_k(X, A)$$

is an isomorphism.

(5) (Dimension axiom) We denote by $\star$ the topological space that consists of a single point. For $n \neq 0$ we have $\mathrm{H}_n(\star) = 0$.

Example. It follows from Proposition 74.15, the Topological LES-Corollary 74.14, the Excision Theorem 74.17, the obvious generalization of Lemma 72.14 and the Single Point-Homology Lemma 72.6 that singular homology is indeed a homology theory.

We conclude this chapter with a uniqueness theorem of homology theories. To formulate the theorem we need the following definition.

Definition. We call the category $\mathcal{FullPairCW}$

$$\begin{aligned}\mathrm{Ob}(\mathcal{FullPairCW}) &:= \text{all pairs of CW-complexes,}\\ \mathrm{Mor}((X, A), (Y, B)) &:= \text{all continuous maps } f\colon X \to Y \text{ with } f(A) \subset B,\end{aligned}$$

together with the usual composition of maps the full category of pairs of CW-complexes.[1099]

[1097] The axioms are usually called Eilenberg-Steenrod axioms.

[1098] Here we use the obvious notation that for a topological space Y we write $\mathcal{H}_n(Y) := \mathcal{H}_n(Y, \varnothing)$.

Now we can formulate the following uniqueness statement for homology theories.

Theorem 89.25. (Eilenberg-Steenrod Uniqueness Theorem) Let $\mathcal{H}$ and $\mathcal{H}'$ be two homology theories and let $\varphi\colon \mathcal{H}_0(\star) \to \mathcal{H}'_0(\star)$ be an isomorphism. Then there exists a natural isomorphism between $\mathcal{H}$ and $\mathcal{H}'$ viewed as functors

$$\begin{array}{c}\text{full category } \mathit{FullPairCW} \text{ of}\\ \text{pairs of CW-complexes}\end{array} \to \begin{array}{c}\text{category } \mathbb{N}_0\text{-}\mathit{GradAb} \text{ of}\\ \mathbb{N}_0\text{-graded abelian groups.}\end{array}$$

Sketch of a proof. Let G be an abelian group. We start our proof with the following observation: Given a pair (X, A) of CW-complexes we saw in the CW-Complex Cone Corollary 68.35 (3) that we can equip the mapping cone $\mathrm{Cone}(i\colon A \to X)$ of the inclusion map with a natural CW-structure. Given $n \in \mathbb{N}_0$ we define the n-th cellular homology $\mathrm{H}_n^{\mathrm{CW}}(X, A; G)$ as the reduced cellular homology with G-coefficients of the mapping cone.

the Singular-Cellular H_*-Isomorphism Proposition 80.4, together with the Mapping Cone-H_*-Lemma 78.15, the Singular-Cellular H_*-Isomorphism Proposition 80.4 and the discussion on page 1915 shows that for pairs of CW-complexes there exists a natural isomorphism between singular homology with G-coefficients and cellular homology with G-coefficients. Closer inspection of the proof shows that we can prove this statement only using the above Eilenberg-Steenrod axioms and the fact that $\mathrm{H}_0(\star; G) \cong G$.

Now let $\alpha\colon \mathcal{H}_0(\star) \to G$ be an isomorphism. By the above one can show that there exists a natural isomorphism from $\mathcal{H}$ to $\mathrm{H}_n^{\mathrm{CW}}(-; G)$. The same applies to $\mathcal{H}'$ and we obtain the theorem as long as φ is an isomorphism. This approach to the proof is developed in more detail in [**tD2008**, Chapter 12.2]. ■

Remark.

(1) Closely related results are also proved in [**ES1952**, p. 100] and [**Hu1966**, p. 52], see also [**GrH1981**, p. 138].
(2) The axioms of a cohomology theory are defined basically the same way with the obvious modifications and the analogue of the Eilenberg-Steenrod Uniqueness Theorem 89.25 also holds in this context, see [**DaK2001**, Theorem 1.31].
(3) If one drops the dimension axiom, then there are other (co-) homology theories, for example "topological K-theory". We refer to [**Karo2008**] for details.

Exercises for Chapter 89.

Exercise 89.1. Show that the abelianization functor from the category of groups to the category of abelian groups is right-exact and that it is not left-exact.

Exercise 89.2. Let $\mathcal{C}$ be the category of finitely generated abelian groups. Given an abelian group A we denote by $\mathrm{Tor}(A)$ as usual its torsion subgroup and furthermore we denote by $\mathrm{F}A := A/\mathrm{Tor}(A)$ the maximal torsion-free quotient. We consider the following two covariant functors:

$$\mathrm{F}\colon \begin{array}{ccc}\mathcal{C} & \mapsto & \mathcal{C}\\ A & \mapsto & \mathrm{F}A\end{array} \quad \text{and} \quad \mathrm{Tor}\colon \begin{array}{ccc}\mathcal{C} & \to & \mathcal{C}\\ A & \mapsto & \mathrm{Tor}(A).\end{array}$$

[1099] Note that we consider all continuous maps, we do not restrict ourselves to cellular maps. Thus *FullPairCW* is a full subcategory of the category *PairTop* of pairs of topological spaces.

(a) Show that the functor F is left-exact.
(b) Show that the functor F is not right-exact.
(c) Is the functor Tor left-exact?
(d) Is the functor Tor is right-exact?

Exercise 89.3. Let A be an $(m \times n)$-matrix over $\mathbb{Z}$ and let R be a commutative ring. Let $\varphi\colon \mathbb{Z} \to R$ be the ring homomorphism given by $\varphi(n) = n \cdot 1_R$. Finally let $\Theta_k\colon \mathbb{Z}^m \otimes R \to R^m$ and $\Theta_n\colon \mathbb{Z}^n \otimes R \to R^n$ be the natural isomorphisms provided by the Tensor Lemma 89.3. Show that the following diagram commutes:

$$\begin{array}{ccc} \mathbb{Z}^n \otimes R & \xrightarrow{(v \mapsto Av) \otimes \mathrm{id}_R} & \mathbb{Z}^m \otimes R \\ {\scriptstyle \Theta_n}\downarrow & & \downarrow{\scriptstyle \Theta_m} \\ R^n & \xrightarrow{w \mapsto \varphi(A)w} & R^m. \end{array}$$

Exercise 89.4. Let $(\mathrm{C}_*, \partial_*)$ be a chain complex and let G be an abelian group. We consider the following map:

$$\begin{array}{rcl} \mathrm{H}_n(C_* \otimes G) & \to & \mathrm{H}_n(C_*) \otimes G \\ \left[\sum\limits_{i=1}^{n} c_i \otimes g_i\right] & \mapsto & \sum\limits_{i=1}^{n} [c_i] \otimes g_i \end{array}$$

Is this map well-defined?

Exercise 89.5. What are the isomorphism types of the homology groups of $\mathbb{R}\mathrm{P}^5$ with $\mathbb{F}_3$-coefficients?

Exercise 89.6. Let $A \to B \to C$ be a short exact sequence of abelian groups and let G be an abelian group. Show that there exists an exact sequence of the form

$$0 \to \mathrm{Tor}(A, G) \to \mathrm{Tor}(B, G) \to \mathrm{Tor}(C, G) \to A \otimes G \to B \otimes G \to C \otimes G \to 0.$$

Hint. Use the Snake Lemma that we proved in Exercise 74.9.
Remark. This exact sequence is sometimes called the *six-term sequence* in homological algebra.

Exercise 89.7. Let $n \in \mathbb{N}$. Let G be an abelian group (which is not necessarily finitely generated). Suppose G admits an element of order g, i.e. $n \cdot g = 0$ and $m \cdot g \neq 0$ for $m = 1, \ldots, n-1$. Show that $\mathrm{Tor}(G, \mathbb{Z}_n) \neq 0$.
Remark. You could make use of Exercise 89.6.

Exercise 89.8.

(a) Let G_* be a chain complex. (We do not assume that the chain groups G_k are finitely generated.) Suppose that for every $k \in \mathbb{N}_0$ and every prime $p \in \mathbb{N}$ we have $\mathrm{H}_k(G_*; \mathbb{Q}) = 0$ and $\mathrm{H}_k(G_*; \mathbb{Z}_p) = 0$. Show that for every $k \in \mathbb{N}_0$ we have $\mathrm{H}_k(G_*) = 0$.
Remark. You might want to use Exercise 89.7.

(b) Let $f\colon C_* \to D_*$ be a chain map between two chain complexes. (We do not assume that the chain groups are finitely generated.) Suppose that for every $k \in \mathbb{N}_0$ and every prime $p \in \mathbb{N}$ the maps $\mathrm{H}_k(C_*; \mathbb{Q}) \to \mathrm{H}_k(D_*; \mathbb{Q})$ and $\mathrm{H}_k(C_*; \mathbb{Z}_p) \to \mathrm{H}_k(D_*; \mathbb{Z}_p)$ are isomorphisms. Show that for every $k \in \mathbb{N}_0$ the map $\mathrm{H}_k(C_*) \to \mathrm{H}_k(D_*)$ is an isomorphism.
Hint. Use the algebraic mapping cone that we introduced on page 1796.

Exercise 89.9. Determine $\operatorname{Tor}(\mathbb{Z}_n, \mathbb{Q}/\mathbb{Z})$.

Exercise 89.10. Let $m, n \in \mathbb{N}$. Show that

$$\operatorname{Tor}(\mathbb{Z}_m, \mathbb{Z}_n) \cong \mathbb{Z}_{\gcd(m,n)}.$$

Exercise 89.11. Show that

$$\Big(\prod_{n\in\mathbb{N}} \mathbb{Z}_n\Big) \otimes \mathbb{Q} \neq 0.$$

Exercise 89.12. Let $k \in \mathbb{Z} \setminus \{0\}$ and let $\varphi_k \colon \Delta^1 \to S^1$ be the map given by $(1-t, t) \mapsto \exp(k \cdot 2\pi t \mathrm{i})$. Furthermore let $i \colon \mathrm{H}_1(S^1) \to \mathrm{H}_1(S^1; \mathbb{R})$ be the homomorphism from Lemma 89.7 (1) that is induced by $\sigma \mapsto \sigma \otimes 1$. Show that

$$\big[\tfrac{1}{n} \otimes \varphi\big] \;=\; \tfrac{1}{n} \cdot i_*([S^1]) \;\in\; \mathrm{H}_1(S^1; \mathbb{R}).$$

We refer to the figure below for an illustration.

Exercise 89.13. Let $T = S^1 \times S^1$ and let K be the Klein bottle.

(a) Does there exist a map $f \colon K \to T$ such that $f_* \colon \mathrm{H}_2(K; \mathbb{F}_2) \to \mathrm{H}_2(T; \mathbb{F}_2)$ is an isomorphism?

(b) Does there exist a map $g \colon T \to K$ such that $g_* \colon \mathrm{H}_2(T; \mathbb{F}_2) \to \mathrm{H}_2(K; \mathbb{F}_2)$ is an isomorphism?

Exercise 89.14. Let $g \in \mathbb{N}$. We denote by N_g the non-orientable surface of genus g as defined on page 266. As a reminder, note that by Lemma **??** we know that N_g is diffeomorphic to the connected sum of g copies of $\mathbb{R}\mathrm{P}^2$. Show that

$$\mathrm{H}_i(N_g; \mathbb{F}_2) \;\cong\; \begin{cases} 0, & \text{if } i > 2, \\ \mathbb{F}_2, & \text{if } i = 0 \text{ or } i = 2, \\ \mathbb{F}_2^g, & \text{if } i = 1. \end{cases}$$

Remark. We calculated $\mathrm{H}_*(N_g)$ in Proposition 80.10.

90. The Künneth Theorem

In this chapter we want to study the following question:

Question 90.1. Let X and Y be two topological spaces. What is the connection between the homology groups of X and Y on the one hand and the homology groups of the product topological space $X \times Y$ on the other hand?

90.1. The tensor product of chain complexes.

First we want to find some connection between the chain complexes of X, Y and $X \times Y$. To do so we need the notion of the tensor product of chain complexes. Therefore we start out with a short excursion into homological algebra, i.e. into the study of chain complexes.

Lemma 90.2. Let $\mathcal{C} = (\mathrm{C}_*, \partial_*)$ and $\mathcal{C}' = (\mathrm{C}'_*, \partial'_*)$ be two chain complexes. Given $n \in \mathbb{N}_0$ we define

$$(\mathcal{C} \otimes \mathcal{C}')_n := \bigoplus_{p+q=n} \mathrm{C}_p \otimes \mathrm{C}'_q.$$

The consider the maps

$$d\colon (\mathcal{C} \otimes \mathcal{C}')_n \to (\mathcal{C} \otimes \mathcal{C}')_{n-1}$$

which are uniquely determined by

$$c_p \otimes c'_q \mapsto \partial c_p \otimes c'_q + (-1)^p \cdot c_p \otimes \partial' c'_q$$

for $c_p \in \mathrm{C}_p$ and $c'_q \in \mathrm{C}'_q$. The maps turn $\mathcal{C} \otimes \mathcal{C}'$ into a chain complex, called the tensor product $\mathcal{C} \otimes \mathcal{C}'$ of the chain complexes $\mathcal{C}$ and $\mathcal{C}'$.

We illustrate the definition of the tensor product of chain complexes in the following diagram:

$$\begin{array}{ccccc}
\mathrm{C}_0 \otimes \mathrm{C}'_2 & \xleftarrow{\partial_1 \otimes \mathrm{id}} & \mathrm{C}_1 \otimes \mathrm{C}'_2 & \xleftarrow{\partial_2 \otimes \mathrm{id}} & \mathrm{C}_2 \otimes \mathrm{C}'_2 \\
\downarrow{\scriptstyle \mathrm{id} \otimes \partial'_2} & & \downarrow{\scriptstyle -\mathrm{id} \otimes \partial'_2} & & \downarrow{\scriptstyle -\mathrm{id} \otimes \partial'_2} \\
\mathrm{C}_0 \otimes \mathrm{C}'_1 & \xleftarrow{\partial_1 \otimes \mathrm{id}} & \mathrm{C}_1 \otimes \mathrm{C}'_1 & \xleftarrow{\partial_2 \otimes \mathrm{id}} & \mathrm{C}_2 \otimes \mathrm{C}'_1 \\
\downarrow{\scriptstyle \mathrm{id} \otimes \partial'_1} & & \downarrow{\scriptstyle -\mathrm{id} \otimes \partial'_1} & & \downarrow{\scriptstyle -\mathrm{id} \otimes \partial'_1} \\
\mathrm{C}_0 \otimes \mathrm{C}'_0 & \xleftarrow{\partial_1 \otimes \mathrm{id}} & \mathrm{C}_1 \otimes \mathrm{C}'_0 & \xleftarrow{\partial_2 \otimes \mathrm{id}} & \mathrm{C}_2 \otimes \mathrm{C}'_0.
\end{array}$$

Proof. We still have to show that the maps d are indeed boundary maps of a chain complex, i.e. we have to verify that $d \circ d = 0$. This is the case since for any $c_p \in \mathrm{C}_p$ and $c'_q \in \mathrm{C}'_q$ we calculate that

$$\begin{aligned}
d(d(c_p \otimes c'_q)) &= d(\overbrace{\partial c_p}^{\in \mathrm{C}_{p-1}} \otimes c'_q) + d((-1)^p \cdot c_p \otimes \overbrace{\partial' c'_q}^{\in C'_{q-1}}) \\
&= \underbrace{\partial \partial c_p}_{=0} \otimes c'_q + (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q + (-1)^p \cdot \partial c_p \otimes \partial' c'_q + (-1)^p \cdot c_p \otimes \underbrace{\partial' \partial' c'_q}_{=0} \\
&= (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q - (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q = 0.
\end{aligned}$$

Thus we have shown that $(\mathcal{C} \otimes \mathcal{C}', d)$ is indeed a chain complex.[1100] ∎

[1100] Note that in the calculation we made use of the extra-term $(-1)^p$ in the definition of the boundary map. If we defined the boundary map "naively" as $d(c_p \otimes c'_q) = \partial c_p \otimes c'_q + c_p \otimes \partial' c'_q$, then the result would not have been a chain complex.

Example. Let

$$\mathcal{C} = \cdots \to \mathrm{C}_n \xrightarrow{\partial_n} \mathrm{C}_{n-1} \xrightarrow{\partial_{n-1}} \mathrm{C}_{n-2} \to \dots \quad \text{and} \quad \mathcal{C}' = 0 \to \underset{\substack{\uparrow \\ \text{in degree } k}}{G} \to 0$$

be two chain complexes where the second consists of a single abelian group. In this case we have the equality

$$(\mathcal{C}_* \otimes \mathcal{C}'_*)_n = \mathcal{C}_{n-k} \otimes G,$$

i.e. the tensor product is just given by tensoring the chain groups of $\mathcal{C}$ by G and shifting the degrees by $-k$.

We conclude this section with the following lemma.

Lemma 90.3. Let $\mathcal{C}$ and $\mathcal{D}$ be two chain complexes.

(1) Given two chain maps $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ the induced map

$$\begin{aligned} f \otimes f'\colon \mathcal{C} \otimes \mathcal{C}' &\to \mathcal{D} \otimes \mathcal{D}' \\ \sum_{i=1}^{n} c_i \otimes c'_i &\mapsto \sum_{i=1}^{n} f(c_i) \otimes f'(c'_i) \end{aligned}$$

is also a chain map.

(2) If $f, g\colon \mathcal{C} \to \mathcal{D}$ and $f', g'\colon \mathcal{C}' \to \mathcal{D}'$ are chain homotopic maps, then the induced maps

$$f \otimes f', g \otimes g'\colon \mathcal{C} \otimes \mathcal{C}' \to \mathcal{D} \otimes \mathcal{D}'$$

are also chain homotopic.

(3) If $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ are homotopy equivalences, then the induced map

$$f \otimes f'\colon \mathcal{C} \otimes \mathcal{C}' \to \mathcal{D} \otimes \mathcal{D}'$$

is also a homotopy equivalence.

Proof. The proof of the lemma is elementary. For completeness' sake and for a good conscience we provide the proof of the first statement. So let $\mathcal{C}$ and $\mathcal{D}$ be two chain complexes and let $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ be chain maps. Let $c \in C_n$ and $c' \in \mathrm{C}'_l$, then

$$\begin{aligned} \partial(f(c)\otimes f'(c')) &\underset{\substack{\uparrow \\ \text{since } \deg(f(c)) = \deg(c) = k}}{=} \partial f(c)\otimes f'(c') + (-1)^k \cdot f(c) \otimes \partial f'(c') \\ &= (f\otimes f')\big(\partial c \otimes c' + (-1)^k \cdot c \otimes \partial c'\big) \end{aligned} \qquad \begin{aligned} &\underset{\substack{\uparrow \\ \text{since } f \text{ and } f' \text{ are chain maps}}}{=} f(\partial c)\otimes f'(c') + (-1)^k \cdot f(c) \otimes f'(\partial c') \\ &= (f\otimes f')(\partial(c\otimes c')). \end{aligned}$$

■

90.2. **The Eilenberg-Zilber Theorem.** The following theorem, which was first proved in 1953, relates the singular chain complex $\mathrm{C}_*(X \times Y)$ of the product of two topological spaces X and Y to the tensor product $\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)$ of the two individual chain complexes.

Theorem 90.4. (Eilenberg-Zilber Theorem) Let X and Y be topological spaces. There exist natural[1101] chain maps

$$\begin{aligned} \Upsilon\colon \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) &\to \mathrm{C}_*(X \times Y) \\ \text{and} \qquad \Theta\colon \mathrm{C}_*(X \times Y) &\to \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y), \end{aligned}$$

with the following three properties:

(1) The maps are chain homotopy-inverses of one another. In particular, by Corollary 73.4, for each $n \in \mathbb{N}_0$ we have a natural isomorphism

$$\mathrm{H}_n(X \times Y) \xrightarrow[\cong]{\Theta_*} \mathrm{H}_n(\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)).$$

(2) For any $x \in X$ and any singular k-chain $\sigma\colon \Delta^k \to Y$ the singular chain $\Upsilon(\{x\} \otimes \sigma)$ equals the singular simplex $\Delta^k \to X \times Y$ that is given by $P \mapsto (x, \sigma(P))$.

(3) The same statement as in (2) also holds with the roles of X and Y swapped.

Proof. We postpone this technically intricate proof to Section 113.2. In that section the above statement follows from the EZ-Construction Theorem 113.2 together with the proof of the Eilenberg-Zilber Theorem provided on page 2496. ■

Since we just postponed the proof of the Eilenberg-Zilber 90.4 to significantly later let us prove a partial result that is much weaker, but that is good enough for many purposes. Namely we will prove an analogous statement for CW-complexes which will be sufficient for the calculations of homology groups that we want to do in this chapter. The proof of this special case is significantly easier to digest than the proof of the general case of the Eilenberg-Zilber Theorem.

Proposition 90.5. Let X and Y be two CW-complexes with finitely many cells in each dimension. Then there exists a natural[1102] isomorphism

$$C_*^{\mathrm{CW}}(X \times Y) \xrightarrow{\cong} C_*^{\mathrm{CW}}(X) \otimes C_*^{\mathrm{CW}}(Y)$$

of chain complexes.

Remark. Recall that, following the convention of page 1602, given two chain complexes C_* and D_* we write $C_* \simeq D_*$ if they are homotopy equivalent. Suppose that X and Y are CW-complexes which have only finitely many cells in each dimension. Then we have

$$\begin{array}{ccccccc} & & & & \text{Proposition 90.5} & & \\ & & & & \downarrow \cong & & \\ \mathrm{C}_*(X \times Y) & \underset{\uparrow}{\simeq} & \mathrm{C}_*^{\mathrm{CW}}(X \times Y) & \to & \mathrm{C}_*^{\mathrm{CW}}(X) \otimes \mathrm{C}_*^{\mathrm{CW}}(Y) & \underset{\uparrow}{\simeq} & \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y). \\ & & & & \text{Singular-Cellular Chain Complex Proposition 81.12 (2) and Lemma 90.3} & & \end{array}$$

For such X and Y this argument proves the existence of the chain homotopies in the statement of the Eilenberg-Zilber Theorem 90.4. But note that the chain homotopy equivalences of Lemma 90.3 are not natural, hence the above chain equivalences are not natural.

[1101] Here "natural" means that for maps $f\colon X \to X'$ and $g\colon Y \to Y'$ of topological spaces we obtain commutative diagrams

$$\begin{array}{ccc} \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) & \xrightarrow{\Upsilon} & \mathrm{C}_*(X \times Y) \\ \downarrow{\scriptstyle f_* \otimes f'_*} & & \downarrow{\scriptstyle (f \times g)_*} \\ \mathrm{C}_*(X') \otimes \mathrm{C}_*(Y') & \xrightarrow{\Upsilon} & \mathrm{C}_*(X' \times Y') \end{array} \quad \text{and} \quad \begin{array}{ccc} \mathrm{C}_*(X \times Y) & \xrightarrow{\Theta} & \mathrm{C}_*(X) \otimes \mathrm{C}_*(Y) \\ \downarrow{\scriptstyle (f \times g)_*} & & \downarrow{\scriptstyle f_* \otimes f'_*} \\ \mathrm{C}_*(X' \times Y') & \xrightarrow{\Theta} & \mathrm{C}_*(X') \otimes \mathrm{C}_*(Y'). \end{array}$$

[1102] Here the notion "natural" means "natural" in the category of CW-complexes, i.e. the isomorphisms Φ_{XY} are only natural with respect to cellular maps $X \to X'$ and $Y \to Y'$, i.e. the commutative diagram from Footnote 1101 only exists for such cellular maps.

Proof. Let X and Y be two CW-complexes with finitely many cells in each dimension. On page 1497 we introduced a CW-structure on $X \times Y$ where the n-cells of $X \times Y$ are precisely of the form $e \times f$ where e is a p-cell of X and f is an $(n-p)$-cell of Y. We quickly recall the definition of the product CW-structure on $X \times Y$:

(1) Using the homeomorphism from the Convex-to-Ball Proposition 2.20 (2) we identify the n-dimensional closed ball $\overline{B}^n$ with the n-dimensional cube $I^n = [0,1]^n$.
(2) We put $(X \times Y)^0 = X^0 \times Y^0$.
(3) Now we suppose that the $(n-1)$-skeleton $(X \times Y)^{(n-1)}$ has already been defined. We consider a p-cell e in X which is given by a characteristic map $\varphi\colon I^p \to X^p$ and an $(n-p)$-cell f in Y which is given by a characteristic map $\psi\colon I^{n-p} \to Y^{n-p}$. Then we denote by $e \times f$ the n-cell in $X \times Y$ which is given by the attaching map

$$\begin{array}{rcl} \partial(I^n) = (\partial I^p \times I^{n-p}) \cup (I^p \times \partial I^{n-p}) & \to & (X \times Y)^{n-1} \\ (x,y) & \mapsto & (\varphi(x), \psi(y)). \end{array}$$

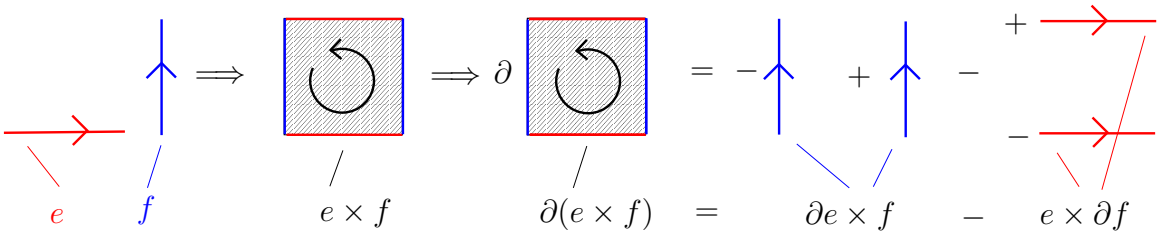
All these n-cells together define the n-skeleton of $X \times Y$.

Since X and Y have only finitely many cells in each dimension the above construction does indeed define a CW-structure on $X \times Y$.

Given $n \in \mathbb{N}_0$ we consider the map

$$C_n^{\mathrm{CW}}(X \times Y) \to C_p^{\mathrm{CW}}(X) \otimes C_{n-p}^{\mathrm{CW}}(Y)$$

which is induced by the property that for any p-cell e of X and any $(n-p)$-cell f of Y we have[1103]



$$[e \times f] \mapsto [e] \otimes [f].$$

As on page 1910 one can show that this map is an isomorphism. It remains to prove that the above maps form a chain map. This statement in turn is equivalent to the following claim.

Claim. For any p-cell e of X and any q-cell f of Y we have

$$\underbrace{\partial(e \times f)}_{\in C_{p+q-1}^{\mathrm{CW}}(X \times Y)} = \underbrace{\partial e \otimes f}_{\in C_{p-1}^{\mathrm{CW}}(X) \otimes C_q^{\mathrm{CW}}(Y)} + (-1)^p \cdot \underbrace{e \otimes \partial f}_{\in C_p^{\mathrm{CW}}(X) \otimes C_{q-1}^{\mathrm{CW}}(Y)}.$$

Proof. It is possible to prove this formula using the description of the cellular boundary map in the Cellular Boundary Map-via-Degrees Proposition 80.8 and by doing a very careful sign-analysis. We illustrate this argument in the figure below.

Following [**Bre1993**, Theorem 12.2] we will give an alternative proof instead. Given a k-cell σ and a $(k-1)$-cell μ we denote by $[\mu : \sigma]$ the coefficient of μ in $\partial\sigma$. It follows quite easily from the Cellular Boundary Map-via-Degrees Proposition 80.8 that for $p, q \in \mathbb{N}_0$

[1103] We follow the convention of page 1777 where saw that cells naturally give rise to a basis of the cellular chain complex.

there exists a unique sign $\epsilon_{p,q} \in \{-1, 1\}$ such that for any CW-complexes K and L, any p-cell e of K, any q-cell f of L and any $(q-1)$-cell g of L we have

$$[e \times g : e \times f] \;=\; \epsilon_{p,q} \cdot [g : f].$$

It follows immediately from the definitions that $\epsilon_{0,q} = 1$ for all q.

Now let e be a p-cell of a CW-complex K and let f be a q-cell of a CW-complex L. We denote by τ the set of $(p-1)$-cells of K and we denote by ϕ the set of $(q-1)$-cells of L. We compute that

$$\begin{aligned}\partial(e \times f) \;&=\; \sum_{\tau}[\tau \times f : e \times f]\cdot(\tau \times f) \;+\; \sum_{\phi}[e \times \phi : e \times f]\cdot(e \times \phi)\\ &=\; \sum_{\tau}[\tau : e]\cdot(\tau \times f) \;+\; \sum_{\phi}\epsilon_{p,q}\cdot[\phi : f]\cdot(e \times \phi) \;=\; (\partial e) \times f \;+\; \epsilon_{p,q}\cdot e \times (\partial f).\end{aligned}$$

It remains to show that $\epsilon_{p,q} = (-1)^p$. We will prove this indirectly. More precisely, since we know that $\partial^2 = 0$ in the cellular chain complex we obtain that

$$\begin{aligned}0 \;=\; \partial\partial(e \times f) \;&=\; \overbrace{(\partial\partial e) \times f}^{=0} + \epsilon_{p-1,q}\cdot(\partial e) \times (\partial f) + \epsilon_{p,q}\cdot(\partial e) \times (\partial f) + \epsilon_{p,q-1}\epsilon_{p,q}\cdot e \times \overbrace{(\partial\partial f)}^{=0}\\ &= \epsilon_{p-1,q}\cdot(\partial e) \times (\partial f) + \epsilon_{p,q}\cdot(\partial e) \times (\partial f) \;=\; (\epsilon_{p-1,q} + \epsilon_{p,q})\cdot(\partial e) \times (\partial f).\end{aligned}$$

But this equality can hold for all CW-complexes K and L only if $\epsilon_{p,q} = -\epsilon_{p-1,q}$. Since $\epsilon_{0,q} = 1$ we obtain iteratively that $\epsilon_{p,q} = (-1)^p$. ∎

90.3. **The Künneth Theorem for chain complexes.** Our goal is to determine the homology groups of the product $X \times Y$ of two topological spaces in terms of the homology groups of X and Y. In light of the Eilenberg-Zilber Theorem 90.4, or alternatively, considering Proposition 90.5, we have to find a connection between the homology groups of two chain complexes $\mathcal{C}$, $\mathcal{C}'$ and the corresponding tensor product $\mathcal{C} \otimes \mathcal{C}'$.
We start out with the following elementary lemma.

Lemma 90.6. Let $\mathcal{C}$ and $\mathcal{C}'$ be two chain complexes. The map

$$\begin{aligned}\Omega\colon \mathrm{H}_p(\mathcal{C}) \otimes \mathrm{H}_q(\mathcal{C}') \;&\to\; \mathrm{H}_{p+q}(\mathcal{C} \otimes \mathcal{C}')\\ \sum_{i=1}^{r}[c_i] \otimes [c_i'] \;&\mapsto\; \sum_{i=1}^{r}[c_i \otimes c_i']\end{aligned}$$

is well-defined and it is natural with respect to the chain complexes $\mathcal{C}$ and $\mathcal{C}'$.

Proof. Let $\mathcal{C} = (C_n, \partial_n)$ and $\mathcal{C}' = (\mathrm{C}_n', \partial_n')$ be two chain complexes. First note that if $c_i \in \mathrm{C}_p$ and $c_i' \in \mathrm{C}_q$ are cycles, then

$$d(c_i \otimes c_i') \;=\; \underbrace{\partial c_i}_{=0} \otimes c_i' + (-1)^p c_i \otimes \underbrace{\partial c_i'}_{=0} \;=\; 0$$

i.e. $c_i \otimes c_i' \in \mathcal{C} \otimes \mathcal{C}'$ is indeed a cycle. Second, if $c_i + \partial e_i$ is an other representative of $[c_i]$ then

$$[(c_i + \partial e_i) \otimes c_i'] \underset{\substack{\uparrow\\ \text{since } \partial' c' = 0}}{=} [c_i \otimes c_i' + d(e_i \otimes c_i')] \;=\; [c_i \otimes c_i'].$$

The same way one can show that the value of Ω does not depend on the choice of representative of the class in $\mathrm{H}_q(\mathcal{C}')$. It is straightforward to verify that Ω is in fact a natural map. ∎

Example. In some instances the homomorphism Ω from Lemma 90.6 is an isomorphism. For example let $\mathcal{C} = (C_n, \partial_n)$ be a chain complex of free abelian groups such that all boundary maps $\mathrm{C}_n \to \mathrm{C}_{n-1}$ in $\mathcal{C}$ are the zero map. In this case we have for any chain complex $\mathcal{C}'$ that

$$\bigoplus_{n\in\mathbb{N}_0} \mathrm{H}_p(\mathcal{C}) \otimes \mathrm{H}_{n-p}(\mathcal{C}'_*) \underset{\substack{\uparrow\\ \text{since all boundary maps}\\ \text{in } \mathcal{C} \text{ are zero}}}{=} \bigoplus_{n\in\mathbb{N}_0} \mathrm{C}_p \otimes \mathrm{H}_n(\mathcal{C}'_{*-p}) \underset{\substack{\uparrow\\ \text{by Theorem 89.16 and the}\\ \text{Tor-Properties Lemma 89.15 (3)}\\ \text{since all } \mathrm{C}_p \text{ are free abelian}}}{=} \bigoplus_{n\in\mathbb{N}_0} \mathrm{H}_n(\mathrm{C}_p \otimes \mathcal{C}'_{*-p}) \underset{\substack{\uparrow\\ \text{by the example on page 1941}\\ \text{since } \mathcal{C} \text{ is a direct sum}\\ \text{of trivial chain complexes}}}{=} \mathrm{H}_n(\mathcal{C}_* \otimes \mathcal{C}'_*).$$

Now we can formulate the following proposition which is the key algebraic result of this chapter.

Theorem 90.7. (Künneth Theorem for Chain Complexes)[1104] Let $\mathcal{C}$ and $\mathcal{C}'$ be two chain complexes. If $\mathcal{C}$ is free, i.e. if all chain groups of the chain complex $\mathcal{C}$ are free abelian groups, then there exists a natural short exact sequence

$$0 \to \bigoplus_{p+q=n} \mathrm{H}_p(\mathcal{C}) \otimes \mathrm{H}_q(\mathcal{C}') \xrightarrow{\Omega} \mathrm{H}_n(\mathcal{C} \otimes \mathcal{C}') \to \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p(\mathcal{C}), \mathrm{H}_q(\mathcal{C}')) \to 0.$$

If $\mathcal{C}'$ is also a free chain complex, then this short exact sequence splits.

Remark.

(1) The adjective "natural" means in this context that if $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ are chain maps, then we obtain a commutative diagram of short exact sequences:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \displaystyle\bigoplus_{p+q=n} \mathrm{H}_p(\mathcal{C}) \otimes \mathrm{H}_q(\mathcal{C}') & \xrightarrow{\Omega} & \mathrm{H}_n(\mathcal{C} \otimes \mathcal{C}') & \longrightarrow & \displaystyle\bigoplus_{p+q=n} \mathrm{Tor}(\mathrm{H}_p(\mathcal{C}), \mathrm{H}_q(\mathcal{C}')) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle f_*\otimes f'_*} & & \downarrow{\scriptstyle (f\otimes f')_*} & & \downarrow{\scriptstyle \mathrm{Tor}(f_*, f'_*)} & & \\
0 & \longrightarrow & \displaystyle\bigoplus_{p+q=n} \mathrm{H}_p(\mathcal{D}) \otimes \mathrm{H}_q(\mathcal{D}') & \xrightarrow{\Omega} & \mathrm{H}_n(\mathcal{D} \otimes \mathcal{D}') & \longrightarrow & \displaystyle\bigoplus_{p+q=n} \mathrm{Tor}(\mathrm{H}_p(\mathcal{D}), \mathrm{H}_q(\mathcal{D}')) & \longrightarrow & 0.
\end{array}$$

Here the middle map is given by Lemma 90.3 (1) and the map on the right is given by the functoriality of the torsion-groups that we had discussed on page 1923.

(2) If $\mathcal{C}'$ is a chain complex which consists of a single abelian group G, i.e. if it is of the form $0 \to G \to 0$ with G in degree 0, then $\mathrm{H}_0(\mathcal{C}') = G$ and all other homology groups are zero. The Künneth Theorem together with the example on page 1941 thus gives us the short exact sequence

$$0 \to \mathrm{H}_n(\mathcal{C}) \otimes G \to \mathrm{H}_n(\underbrace{\mathcal{C} \otimes G}_{=\mathcal{C}\otimes\mathcal{C}'}) \to \mathrm{Tor}(\mathrm{H}_{n-1}(\mathcal{C}), G) \to 0,$$

i.e. we recover the Universal Coefficient Theorem 89.16 as a special case of the Künneth Theorem. In fact, as we will see, the proof of the Künneth Theorem is quite similar to the proof of the Universal Coefficient Theorem 89.16.

(3) The fact that the short exact sequence of the Künneth Theorem splits implies that the middle group is isomorphic to the direct sum of the two groups to the left and right. But, as we saw in the discussion of the Universal Coefficient Theorem 89.16, see the No-Natural Splitting Proposition 89.24, this isomorphism is not natural.

[1104] Hermann Künneth (1892-1975) was a German mathematician.

Proof. Let $\mathcal{C} = (C_n, \partial_n)$ and $\mathcal{C}' = (\mathrm{C}'_n, \partial'_n)$ be two chain complexes such that all C_n are free abelian groups. As we will see, the proof of the theorem is quite similar to the proof of the Universal Coefficient Theorem 89.16.

For $p \in \mathbb{N}_0$ we consider again

$$Z_p \;:=\; \ker(\partial_p \colon \mathrm{C}_p \to \mathrm{C}_{p-1}) \quad \text{and} \quad B_p \;:=\; \mathrm{im}(\partial_{p+1} \colon \mathrm{C}_{p+1} \to \mathrm{C}_p).$$

We denote by $i \colon Z_p \to \mathrm{C}_p$ the inclusion map. Furthermore we denote by $\mathcal{Z}$ the chain complex which is given by the groups Z_p where all the boundary maps are the zero map. The same way we obtain from the groups B_p a chain complex $\mathcal{B}$.

Claim. The sequence

$$0 \;\to\; \mathcal{Z} \otimes \mathcal{C}' \;\xrightarrow{i\otimes \mathrm{id}}\; \mathcal{C} \otimes \mathcal{C}' \;\xrightarrow{\partial \otimes \mathrm{id}}\; \mathcal{B} \otimes \mathcal{C}' \;\to\; 0$$

is a sequence of chain maps and it is exact at each degree.

Proof. It follows easily from the definitions of the boundary maps in the various chain complexes, see also the diagram on page 1928, that the homomorphisms $i \otimes \mathrm{id} \colon \mathcal{Z} \otimes \mathcal{C}' \to \mathcal{C} \otimes \mathcal{C}'$ and $\partial \otimes \mathrm{id} \colon \mathcal{C} \otimes \mathcal{C}' \to \mathcal{B} \otimes \mathcal{C}$ are chain maps. It remains to show that the sequence is exact at each degree. The argument is exactly the same as on page 1928. For the reader's convenience we recall the argument. First note that by definition the sequences

$$0 \;\to\; Z_p \;\xrightarrow{i}\; \mathrm{C}_p \;\xrightarrow{\partial}\; B_{p-1} \;\to\; 0$$

are exact. Also recall that by hypothesis each C_n is a free abelian group. It follows from the Subgroup-of-Free Abelian Group Lemma 51.2 that each B_n is also free abelian. By Lemma 78.1 this means that the above short exact sequence splits. But then it follows from the Tensor-Split-SES Lemma 89.6 that the sequence stays exact even after tensoring it with any C'_q. The claim is an immediate consequence of these observations.

From the LES Proposition 74.9 and the claim we thus obtain the following long exact sequence[1105]

$$\cdots \to \mathrm{H}_n(\mathcal{B}\otimes\mathcal{C}') \xrightarrow{d_n} \mathrm{H}_n(\mathcal{Z}\otimes\mathcal{C}') \to \mathrm{H}_n(\mathcal{C}\otimes\mathcal{C}') \to \mathrm{H}_{n-1}(\mathcal{B}\otimes\mathcal{C}') \xrightarrow{d_{n-1}} \mathrm{H}_{n-1}(\mathcal{Z}\otimes\mathcal{C}') \to \dots$$

The connecting homomorphism $d_n \colon \mathrm{H}_n(\mathcal{B}\otimes\mathcal{C}') \to \mathrm{H}_n(\mathcal{Z}\otimes\mathcal{C}')$ from the LES Proposition 74.9 is hereby, as in the proof of the Universal Coefficient Theorem 89.16, induced by the map $i \otimes \mathrm{id}$ where i denotes the inclusion $\mathcal{B} \to \mathcal{Z}$.

Since the boundary maps in the chain complexes $\mathcal{B}$ and $\mathcal{Z}$ are the zero maps it follows from the example on page 1945 that we obtain the following long exact sequence:

$$\dots \xrightarrow{i\otimes\mathrm{id}} \bigoplus_{p+q=n} Z_p \otimes \mathrm{H}_q(\mathcal{C}') \to \mathrm{H}_n(\mathcal{C}\otimes\mathcal{C}') \to \bigoplus_{p+q=n-1} B_p \otimes \mathrm{H}_q(\mathcal{C}') \xrightarrow{i\otimes\mathrm{id}} \bigoplus_{p+q=n-1} Z_p \otimes \mathrm{H}_q(\mathcal{C}') \to \dots$$

[1105] The index goes down by one in the map $\mathrm{H}_n(\mathcal{C}\otimes\mathcal{C}') \to \mathrm{H}_{n-1}(\mathcal{B}\otimes\mathcal{C}')$, since the map is induced by the short exact sequence $0 \to Z_p \to \mathrm{C}_p \to B_{p-1} \to 0$.

From the Break-into-SES Lemma 78.4 we obtain a short exact sequence

$$0 \to \bigoplus_{p+q=n} \overbrace{\operatorname{coker}\left(B_p \otimes \mathrm{H}_q(\mathcal{C}') \xrightarrow{i\otimes \mathrm{id}} Z_p \otimes \mathrm{H}_q(\mathcal{C}')\right)}^{\substack{= \mathrm{H}_p(\mathcal{C}) \otimes \mathrm{H}_q(\mathcal{C}'), \text{ since} \\ 0 \to B_p \to Z_p \to \mathrm{H}_p(\mathcal{C}) \to 0 \text{ is a free resolution}}} \to \mathrm{H}_n(\mathcal{C} \otimes \mathcal{C}') \to$$
$$\to \bigoplus_{p+q=n-1} \underbrace{\ker\left(B_p \otimes \mathrm{H}_q(\mathcal{C}') \xrightarrow{i\otimes \mathrm{id}} Z_p \otimes \mathrm{H}_q(\mathcal{C}')\right)}_{\substack{= \operatorname{Tor}(\mathrm{H}_p(\mathcal{C}), \mathrm{H}_q(\mathcal{C}')), \text{ since} \\ 0 \to B_p \to Z_p \to \mathrm{H}_p(\mathcal{C}) \to 0 \text{ is a free resolution}}} \to 0.$$

This proves the existence of the short exact sequence. Using Statement (2) of the Fundamental Theorem 81.1 of Homological Algebra one can show that this short exact sequence is natural. We leave it to the reader to verify the details.

Finally we suppose that $\mathcal{C}'_*$ is also a free chain complex. We leave it again to the reader to adapt the argument of the proof of the UCT-Splitting Proposition 89.21 to show that the above short exact sequence splits. Alternatively we refer to [**Mun1984**, Chapter 58] for details. ■

90.4. **The Künneth Theorem for topological spaces.** Now we return to our initial Question 90.1 of the chapter, namely, what is the relationship between the homology groups of the topological spaces X, Y and $X \times Y$? The following theorem gives a comprehensive answer.

Theorem 90.8. (Künneth Theorem for Topological Spaces) Let X and Y be topological spaces. Then there exists a short exact sequence

$$0 \to \bigoplus_{p+q=n} \mathrm{H}_p(X) \otimes \mathrm{H}_q(Y) \xrightarrow{\Omega} \mathrm{H}_n(X \times Y) \to \bigoplus_{p+q=n-1} \operatorname{Tor}(\mathrm{H}_p(X), \mathrm{H}_q(Y)) \to 0$$

with the following four properties:

(1) Both maps are natural with respect to the topological spaces X and Y.
(2) For $p = 0$ the map $\Omega\colon \mathrm{H}_0(X) \otimes \mathrm{H}_q(Y) \to \mathrm{H}_q(X \times Y)$ is the "obvious" map, namely for a point $x \in X$ and a singular cycle σ the image of $[x] \otimes [\sigma] \in \mathrm{H}_0(X) \otimes \mathrm{H}_q(Y)$ under Ω equals the image of $[\sigma]$ under the map $\mathrm{H}_q(Y) \to \mathrm{H}_q(\{x\} \times Y) \to \mathrm{H}_q(X \times Y)$, where the first map is induced by the natural homeomorphism and the second map is induced by the inclusion.
(3) The analogue of (2) also holds for $q = 0$.
(4) The above short exact sequence splits.[1106]

Remark. Both maps in the short exact sequence of the Künneth Theorem 90.8 for Topological Spaces are difficult to describe explicitly. At least for the former map we will partly get a nice description in the Topological Product Orientation Proposition 113.10.

[1106] But as in the case of the Universal Coefficient Theorem 89.16, see the No-Natural Splitting Proposition 89.24, the splitting is not natural.

Proof. We consider the following maps:

$$0 \to \bigoplus_{p+q=n} \mathrm{H}_p(X) \otimes \mathrm{H}_q(Y) \xrightarrow{\Omega} \mathrm{H}_n(\mathrm{C}_*(X) \otimes \mathrm{C}_*(Y)) \to \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p(X), \mathrm{H}_q(Y)) \to 0$$

$$\cong \Big\downarrow \Upsilon$$

$$\underbrace{\mathrm{H}_n(\mathrm{C}_*(X \times Y))}_{=H_n(X \times Y)}.$$

Here the sequence on the top is exact and natural by the Künneth Theorem 90.7 for Chain Complexes. The vertical map is a natural isomorphism by the Eilenberg-Zilber Theorem 90.4 together with Corollary 73.4. We obtain the desired short exact sequence from replacing the upper middle term by the lower middle term $\mathrm{H}_n(\mathrm{C}_*(X \times Y)) = \mathrm{H}_n(X \times Y)$. One can easily verify that this short exact sequence has all the desired properties. ■

Examples.

(1) Let X be a topological space. We want to determine the homology groups of $S^1 \times X$. The homology groups of S^1 are of course $\mathbb{Z}$ in the dimensions 0 and 1. For any abelian group A we have by the Tensor Lemma 89.3 a natural isomorphism $\mathbb{Z} \otimes A = A$ and by the Tor-Properties Lemma 89.15 we have $\mathrm{Tor}(\mathbb{Z}, A) = 0$. It follows from the Künneth Theorem 90.8 for topological spaces that there exists a natural isomorphism

$$\mathrm{H}_n(S^1 \times X) \xrightarrow{\cong} \mathrm{H}_{n-1}(X) \oplus \mathrm{H}_n(X).$$

This is of course precisely the same result as in Lemma 78.21.

It follows fairly easily from Statement (2) that the map $\mathrm{H}_n(X) \to \mathrm{H}_n(S^1 \times X)$ is the map induced by the projection $S^1 \times X \to X$. It is less clear what the map $\mathrm{H}_n(S^1 \times X) \to \mathrm{H}_{n-1}(X)$ should be. Some more effort shows that this map is precisely the map that we had described in detail in Exercise 75.4.

(2) Let $n \in \mathbb{N}$ and let $m \in \mathbb{N}$. We want to determine the homology groups of the generalized torus $(S^m)^n$. In fact using the Künneth Theorem 90.8 for topological spaces one can easily show that for any $k \in \mathbb{N}_0$ there exists an isomorphism

$$\mathrm{H}_i((S^m)^n) \cong \begin{cases} \mathbb{Z}^{\binom{n}{k}} = \mathbb{Z}^{\frac{n!}{k! \cdot (n-k)!}} & \text{if } i = km \text{ with } k \in \{0, \ldots, n\}, \\ 0, & \text{otherwise.} \end{cases}$$

In particular we have an isomorphism

$$\mathrm{H}_i((S^m)^2) \cong \begin{cases} \mathbb{Z}, & \text{if } i = 0, 2m, \\ \mathbb{Z} \oplus \mathbb{Z}, & \text{if } i = m, \\ 0, & \text{otherwise.} \end{cases}$$

We will fill in the details in Exercise 90.1.

(3) Let X and Y be two path-connected topological spaces. Then we have isomorphisms

$$\mathrm{H}_1(X \times Y) \underset{\uparrow}{\cong} \mathrm{H}_1(X) \otimes \mathrm{H}_0(Y) \oplus \mathrm{H}_0(X) \otimes \mathrm{H}_1(Y) \underset{\uparrow}{=} \mathrm{H}_1(X) \oplus \mathrm{H}_1(Y).$$

Künneth Theorem 90.8 for topological spaces — H_0-Proposition 72.5 and the Tensor Lemma 89.3

This is consistent with the product formula for fundamental groups proved in the Fundamental Group-of-Product Proposition 48.20 and with the isomorphism of the Hurewicz Theorem 84.5.

Now we discuss the product $S^2 \times S^4$ in slightly more detail. It follows easily from the Künneth Theorem 90.8 for topological spaces, Proposition 74.4, the H_0-Proposition 72.5, the Tensor Lemma 89.3 and the Tor-Properties Lemma 89.15 that

$$\mathrm{H}_k(S^2 \times S^4) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, 6, \\ 0, & \text{otherwise.} \end{cases}$$

But by the calculation on page 1772 these are precisely the homology groups of the complex projective space $\mathbb{C}\mathrm{P}^3$. Furthermore it follows from Propositions 47.13 and 48.20 that $S^2 \times S^4$ is simply connected and it follows from the discussion on page 1533 that $\mathbb{C}\mathrm{P}^3$ is also simply connected. So all the invariants we are aware of, and that we know how to compute[1107], agree for $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$. This raises the following question which we will answer in Corollary 121.9.

Question 90.9. Are the topological spaces $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ homeomorphic?

Exercises for Chapter 90.

Exercise 90.1. Let $n \in \mathbb{N}$ and let $m \in \mathbb{N}$. Show that for every $k \in \mathbb{N}_0$ there exists an isomorphism

$$\mathrm{H}_i((S^m)^n) \;\cong\; \begin{cases} \mathbb{Z}^{\binom{n}{k}} = \mathbb{Z}^{\frac{n!}{k!\cdot(n-k)!}} & \text{if } i = km \text{ with } k \in \{0, \ldots, n\}, \\ 0, & \text{otherwise.} \end{cases}$$

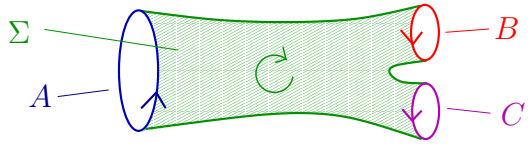
Exercise 90.2. Let $n \in \mathbb{N}_0$. Show that

$$\sum_{k=0}^{n} (-1)^k \cdot \binom{n}{k} \;=\; 0.$$

Remark. There are many ways to prove this equality, one fun way of doing this is by computing the Euler characteristic of the n-dimensional torus in two different ways.

Exercise 90.3. We consider the oriented 2-dimensional smooth manifold Σ that is shown in the figure below. It has three oriented boundary components A, B, C. We pick orientation-preserving diffeomorphisms $\beta\colon S^1 \to B$ and $\gamma\colon S^1 \to C$. We consider

$$M \;:=\; (\Sigma \times S^1)/\sim \qquad \text{where } (\varphi(z), w) \sim (\psi(z), \overline{w}) \text{ for } (z, w) \in S^1 \times S^1.$$

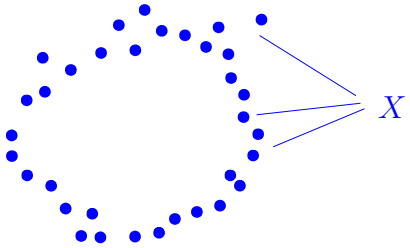


By the Gluing-Smooth Manifolds-Proposition **??** we know that M is a compact orientable 3-dimensional smooth manifold with boundary $\partial M = A \times S^1$. We denote by $i\colon \partial M \to M$

[1107] As of right now we do not know the higher homotopy groups of these two smooth manifolds, but these will not turn out to be very useful.

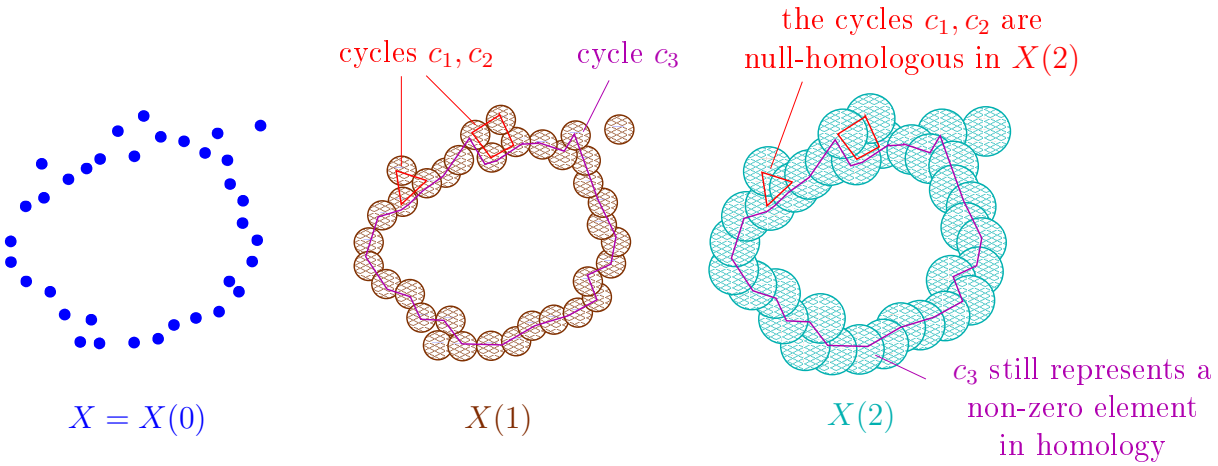
the inclusion. Show that there exist isomorphisms $\Phi\colon \mathbb{Z}\oplus\mathbb{Z}\to \mathrm{H}_1(\partial M)$ and $\Psi\colon \mathbb{Z}\oplus\mathbb{Z}_2\to \mathrm{H}_1(M)$ such that the following diagram commutes:

$$\begin{array}{ccc} \mathbb{Z}\oplus\mathbb{Z} & \xrightarrow{(a,b)\mapsto(2a,[b])} & \mathbb{Z}\oplus\mathbb{Z}_2 \\ {\scriptstyle\Phi}\downarrow{\scriptstyle\cong} & & {\scriptstyle\cong}\downarrow{\scriptstyle\Psi} \\ \mathrm{H}_1(\partial M) & \xrightarrow{i_*} & \mathrm{H}_1(M). \end{array}$$



Remark. The oriented boundary components A, B, C define elements $a, b, c \in \mathrm{H}_1(\Sigma)$. On page 1784 we saw that $\mathrm{H}_1(\Sigma) \cong (\mathbb{Z}\cdot a \oplus \mathbb{Z}\cdot b \oplus \mathbb{Z}\cdot c)/\mathbb{Z}\cdot(a+b+c)$.

91. Applications of homology groups



91.1. **Persistent homology ❀.** In this section we outline the idea behind "persistent homology". Persistent homology was introduced by Gunnar Carlsson [**Carl2009**] in 2009 More information and a much more careful treatment of persistent homology can for example be found in [**EdH2010**]. Some extra information can also be found in [**Gh2014**].

We consider the figure below. What do we see? If we forget about topology for a second, then we would say that we see a set X of dots that form a loop.

dots that appear to the eye to form a loop

If we view X as a topological space, then it is just a finite discrete subset of $\mathbb{R}^2$. In particular its homology groups are non-zero only in dimension 0. So how can we use the mathematical machine that we have developed over the last two semesters to "see the loop"?
Given $r \in [0, \infty)$ we denote by $X(r)$ the subset of $\mathbb{R}^2$ that is given by replacing each point $x \in X$ by the closed ball $\overline{B}_r(x)$ of radius r around x. The homeomorphism type of $X(r)$ changes with the radius r. For example in the figure below we see that at $r = 1$ all but one ball are joined up and we see that $\mathrm{H}_1(X(1)) \cong \mathbb{Z}^3$. We show three cycles c_1, c_2, c_3 in $X(1)$ which form a basis for $\mathrm{H}_1(X(1))$. Two of the generators, namely c_1, c_2 are formed "by accident", namely they arise from balls which are close by. This gets captured by the fact that they become null-homologous in $\mathrm{H}_1(X(2))$ whereas c_3 represents a non-trivial element for "much longer", i.e. for much larger values of r. Put differently, c_3 is a persistent element in homology, hence it captures global information.

Summarizing, given a subset X of $\mathbb{R}^2$ we can study the topological spaces $X(r)$ for any $r \in [0, \infty)$ and furthermore for any $r < s$ we can study the inclusion induced map $\mathrm{H}_n(X(r)) \to$

$\mathrm{H}_n(X(s))$. If there is a non-zero element in $\mathrm{H}_n(X(r))$ which stays non-zero for a "long time", then we say it is persistent and we hope that it captures something interesting.

The same approach can be applied to any finite subset of some $\mathbb{R}^n$. Pretty much any data one has in practice, e.g. blue pixels of a picture, measurements in an experiment, statistical data and so on, can be viewed as a finite subset of some $\mathbb{R}^n$, so in principle one can study its persistent homology. The real question is, whether one captures something significant or not. For example persistent homology was applied in **[SHP2016]**[1108] to study the "The topological shape of Brexit". It is perhaps debatable whether one can really obtain anything meaningful about the politics of Brexit using persistent homology.

91.2. **The transfer map.** Before we can give the next application of homology theory, namely the Borsuk-Ulam Theorem in higher dimensions, we need to introduce and study the transfer map in homology corresponding to a finite covering.

Let $p\colon \widetilde{X} \to X$ be a k-fold covering of a topological space X. Let $\sigma\colon \Delta^n \to X$ be a singular simplex. Since Δ^n is simply connected[1109] it follows from the Map Lifting Criterion 61.2 that there exist precisely k different lifts of σ to $\widetilde{X}$, i.e. there exist precisely k different singular simplices $\widetilde{\sigma}_1, \ldots, \widetilde{\sigma}_k\colon \Delta^n \to \widetilde{X}$ with $p \circ \widetilde{\sigma}_i = \sigma$ for $i = 1, \ldots, k$. We write

$$p^*(\sigma) \ := \ \sum_{i=1}^{k} \widetilde{\sigma}_i.$$

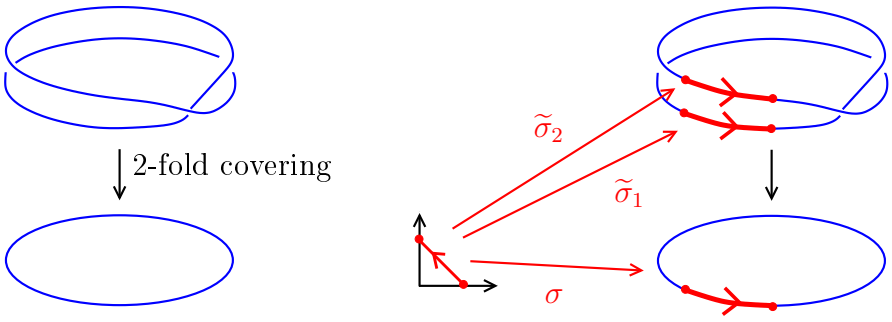
Given any commutative ring R we refer to the map

$$\begin{array}{rcl} p^*\colon \mathrm{C}_*(X;R) & \to & \mathrm{C}_*(\widetilde{X};R) \\ \sum_{i=1}^{n} \sigma_i \otimes r_i & \mapsto & \sum_{i=1}^{n} p^*(\sigma_i) \otimes r_i \end{array}$$

as the *transfer map* of the covering. It is straightforward to verify that the transfer map is in fact a chain map. In particular it induces a map

$$p^*\colon \mathrm{H}_*(X;R) \ \to \ \mathrm{H}_*(\widetilde{X};R).$$

Finally suppose we are given a subset $A \subset X$. We write $\widetilde{A} := p^{-1}(A)$. One easily verifies that the transfer map $p^*\colon \mathrm{C}_n(X;R) \to \mathrm{C}_*(\widetilde{X};R)$ induces a chain map



$$p^*\colon \mathrm{H}_*(X,A;R) \ \to \ \mathrm{H}_*(\widetilde{X},\widetilde{A};R).$$

Proposition 91.1. (Transfer Map Proposition) Let $p\colon \widetilde{X} \to X$ be a covering of degree $k \in \mathbb{N}$ of a topological space X and let $n \in \mathbb{N}_0$. Then the following hold:

(1) For any commutative ring R the transfer map $p^*\colon \mathrm{C}_n(X;R) \ \to \ \mathrm{C}_n(\widetilde{X};R)$ is a monomorphism.
(2) For any commutative ring R the map $p_* \circ p^*\colon \mathrm{H}_n(X;R) \to \mathrm{H}_n(X;R)$ is given by multiplication by k.
(3) The projection $p_*\colon \mathrm{H}_n(\widetilde{X};\mathbb{Q}) \to \mathrm{H}_n(X;\mathbb{Q})$ is an epimorphism.

[1108] Here is an easy way to tell that that paper was not written by mathematicians: In a mathematics paper the authors are invariably listed according to the alphabetic order of their last names. In most other sciences this is not the case.

[1109] To be precise, we also use that Δ^n is locally path-connected.

The analogous statements also hold in the relative setting.

Remark.

(1) If $p\colon \widetilde{X} \to X$ is a finite covering of path-connected topological spaces, then we saw in Corollary 84.8 that the map $p_*\colon \mathrm{H}_1(\widetilde{X}) \to \mathrm{H}_1(X)$ has finite cokernel. This implies in particular[1110] that $p_*\colon \mathrm{H}_1(\widetilde{X};\mathbb{Q}) \to \mathrm{H}_1(X;\mathbb{Q})$ is an epimorphism. Therefore we can view the Transfer Map Proposition 91.1 (3) as a generalization of Corollary 84.8.

(2) The conclusion of the Transfer Map Proposition 91.1 (3) does not hold if we drop the condition that the covering is finite. For example, we have an infinite covering $p\colon \mathbb{R} \to S^1$ but $0 = \mathrm{H}_1(\mathbb{R};\mathbb{Q}) \xrightarrow{p_*} \mathrm{H}_1(S^1;\mathbb{Q}) = \mathbb{Q}$ is not an epimorphism.

Proof. Let $p\colon \widetilde{X} \to X$ be a k-fold covering of a topological space X.

(1) Let $c \in \mathrm{C}_n(X;R)$ be non-trivial. We write $c = \sum_{i=1}^{n} \sigma_i \otimes r_i$ where $\sigma_1, \dots, \sigma_n$ are pairwise different singular simplices in X and where $r_1, \dots, r_n$ are all non-zero. Since each σ_i lifts to k different singular simplices and since for $i \neq j$ the lifts of σ_i and σ_j differ we see immediately from the definition that $p^*(\sigma)$ is also non-zero.

(2) Let R be a commutative ring. We denote by $p^*\colon \mathrm{C}_n(X;R) \to \mathrm{C}_n(\widetilde{X};R)$ the transfer map. Let $\sigma\colon \Delta^m \to X$ be a singular simplex. We denote the corresponding lifts by $\widetilde{\sigma}_1, \dots, \widetilde{\sigma}_k$. Then

$$(p_* \circ p^*)(\sigma) \;=\; p_*(\widetilde{\sigma}_1 + \cdots + \widetilde{\sigma}_k) \;=\; \underbrace{p\circ\widetilde{\sigma}_1 + \cdots + p\circ\widetilde{\sigma}_k}_{k \text{ summands}} \;=\; \underbrace{\sigma + \cdots + \sigma}_{k \text{ summands}} \;=\; k\cdot\sigma.$$

We thus see that $p_* \circ p^*\colon \mathrm{C}_m(X) \to \mathrm{C}_m(X)$ is multiplication by k for any m. It follows easily that the map

$$\mathrm{H}_n(X;R) \xrightarrow{p^*} \mathrm{H}_n(\widetilde{X};R) \xrightarrow{p_*} \mathrm{H}_n(X;R)$$

is also given by multiplication by k.

(3) Since multiplication by $k \neq 0$ is an isomorphism of any rational vector space we obtain from (1) that $p_* \circ p^*\colon \mathrm{H}_n(X;\mathbb{Q}) \to \mathrm{H}_n(X;\mathbb{Q})$ is an isomorphism. In particular the second map, namely p_*, is an epimorphism.

The proofs in the relative setting are basically identical to the above. ∎

[1110] Why does this follow?

Proposition 91.2. (Double Covering-LES-Proposition) Let $p\colon \widetilde{X} \to X$ be a 2-fold covering. Then there exists a natural long exact sequence of the form

$$\ldots \longrightarrow \mathrm{H}_n(X;\mathbb{F}_2) \xrightarrow{p^*} \mathrm{H}_n(\widetilde{X};\mathbb{F}_2) \xrightarrow{p_*} \mathrm{H}_n(X;\mathbb{F}_2) \xrightarrow{\partial} \mathrm{H}_{n-1}(X;\mathbb{F}_2) \longrightarrow \ldots.$$

Here "natural" means that if we are given a commutative diagram

$$\begin{array}{ccc} \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{Y} \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{f} & Y \end{array}$$

where $p\colon \widetilde{X} \to X$ and $q\colon \widetilde{Y} \to Y$ are 2-fold coverings, then the following diagram commutes:

$$\begin{array}{ccccccccc} \ldots \longrightarrow & \mathrm{H}_n(X;\mathbb{F}_2) & \xrightarrow{p^*} & \mathrm{H}_n(\widetilde{X};\mathbb{F}_2) & \xrightarrow{p_*} & \mathrm{H}_n(X;\mathbb{F}_2) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(X;\mathbb{F}_2) & \longrightarrow \ldots \\ & \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle \widetilde{f}} & & \downarrow{\scriptstyle \widetilde{f}} & & \downarrow{\scriptstyle f} & \\ \ldots \longrightarrow & \mathrm{H}_n(Y;\mathbb{F}_2) & \xrightarrow{q^*} & \mathrm{H}_n(\widetilde{Y};\mathbb{F}_2) & \xrightarrow{q_*} & \mathrm{H}_n(Y;\mathbb{F}_2) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(Y;\mathbb{F}_2) & \longrightarrow \ldots. \end{array}$$

Remark. Note that it follows from the Topological-Pullback Lemma 56.16 (3) a 2-fold covering $p\colon \widetilde{Y} \to Y$ together with a map $f\colon X \to Y$ of topological spaces naturally give rise to a commutative diagram as in the Double Covering-LES-Proposition 91.2.

Example. Now we will see that we can use the Double Covering-LES-Proposition 91.2 to calculate the homology groups $\mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ just using the following basic facts:

(1) By the discussion on page 1916 we know that

$$\mathrm{H}_k(S^n;\mathbb{F}_2) \;\cong\; \begin{cases} \mathbb{F}_2, & \text{if } k=0 \text{ or } k=n, \\ 0, & \text{otherwise} \end{cases}$$

(2) By the obvious generalization of the H_0-Proposition 72.5 we know that $\mathrm{H}_0(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) = \mathbb{F}_2$.

(3) Since $\mathbb{R}\mathrm{P}^n$ is an n-dimensional CW-complex we know from the discussion on page 1915 that $\mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) = 0$ for $k > n$.

In the following discussion we write $\mathbb{F} = \mathbb{F}_2$ for space reasons. Applying the Double Covering-LES-Proposition 91.2 to the 2-fold covering $p\colon S^n \to \mathbb{R}\mathrm{P}^n$ we obtain the following long exact sequence:

$$\underbrace{\mathrm{H}_{n+1}(\mathbb{R}\mathrm{P}^n;\mathbb{F})}_{=0} \xrightarrow{\partial} \mathrm{H}_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{\mathrm{H}_n(S^n;\mathbb{F})}_{=\mathbb{F}} \xrightarrow{p_*} \mathrm{H}_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{\partial} \mathrm{H}_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{\mathrm{H}_{n-1}(S^n;\mathbb{F})}_{=0} \to$$

which continues all the way to

$$\ldots \to \mathrm{H}_1(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{\mathrm{H}_1(S^n;\mathbb{F})}_{=0} \xrightarrow{p_*} \mathrm{H}_1(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{\partial} \mathrm{H}_0(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{\mathrm{H}_0(S^n;\mathbb{F})}_{=\mathbb{F}} \xrightarrow{p_*} \underbrace{\mathrm{H}_0(\mathbb{R}\mathrm{P}^n;\mathbb{F})}_{=\mathbb{F}} \to 0.$$

Now we can make the following observations:

(1) If we work our way upward through the long exact sequence we see that the connecting homomorphisms give us isomorphisms

$$\mathrm{H}_{n-1}(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \xrightarrow[\cong]{\partial} \mathrm{H}_{n-2}(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \xrightarrow[\cong]{\partial} \dots \xrightarrow[\cong]{\partial} \mathrm{H}_1(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \xrightarrow[\cong]{\partial} \mathrm{H}_0(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \;\cong\; \mathbb{F}.$$

(2) Now that we know that $\mathrm{H}_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \cong \mathbb{F}$ we obtain from the upper end of the long exact sequence that[1111]

$$\mathrm{H}_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \mathrm{H}_n(S^n;\mathbb{F}) \quad \text{and} \quad \mathrm{H}_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{\partial} \mathrm{H}_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{F})$$

are also isomorphisms.

Summarizing we have shown that

$$\mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \;\cong\; \begin{cases} \mathbb{F}, & \text{if } k = 0,\dots,n, \\ 0, & \text{otherwise.} \end{cases}$$

This agrees of course with the result that we had obtained on page 1916.

Proof of the Double Covering-LES-Proposition 91.2. Let $p\colon \widetilde{X} \to X$ be a 2-fold covering. First we want to show that the promised long exact sequence in homology exists. By the LES Proposition 74.9 it suffices to show that the following sequence of chain maps

$$0 \;\to\; \mathrm{C}_*(X;\mathbb{F}) \xrightarrow{p^*} \mathrm{C}_*(\widetilde{X};\mathbb{F}) \xrightarrow{p_*} \mathrm{C}_*(X;\mathbb{F}) \;\to\; 0$$

is in fact exact. As in Lemma 48.4 we consider the continuous map

$$\begin{aligned} f\colon \widetilde{X} &\to \widetilde{X} \\ x &\mapsto \text{the unique other element of } p^{-1}(p(x)). \end{aligned}$$

Using the Map Lifting Criterion 61.2 we pick for each singular cell σ of X a lift $\widetilde{\sigma}$ to $\widetilde{X}$. We make the following observations which follow easily from the definitions and the Map Lifting Criterion 61.2:

(a) given any singular n-simplex σ we have $p_*(\widetilde{\sigma}) = \sigma$,
(b) given any singular n-simplex σ we have $p^*(\sigma) = \widetilde{\sigma} + f_*(\widetilde{\sigma})$,
(c) given any singular simplex μ of $\widetilde{X}$ we have $p_*(f_*(\mu)) = p_*(\mu)$,
(d) any singular singular n-simplex μ of $\widetilde{X}$ is of the form $\mu = \widetilde{\sigma}$ or $\mu = f_*(\widetilde{\sigma})$ for some singular n-simplex σ of X.

Now we turn to the proof of the exactness of the above sequence.

(1) We first show that the map $p_*\colon \mathrm{C}_n(\widetilde{X};\mathbb{F}) \to \mathrm{C}_n(X;\mathbb{F}) = \mathrm{C}_n(X) \otimes \mathbb{F}$ is surjective. So let $c = \sigma_1 \otimes b_1 + \dots + \sigma_k \otimes b_k \in \mathrm{C}_n(X;\mathbb{F})$. It follows from (a) that

$$p_*\big(\widetilde{\sigma}_1 \otimes b_1 + \dots + \widetilde{\sigma}_k \otimes b_k\big) \;=\; \sigma_1 \otimes b_1 + \dots + \sigma_k \otimes b_k \;=\; c.$$

(2) By the Transfer Map Proposition 91.1 we know that the transfer map p^* is a monomorphism.

[1111] Why does this follow, why are there no other possibilities?

(3) Next we show that $\mathrm{im}(p^*) \subset \ker(p_*)$. For any singular n-simplex σ of $\widetilde{X}$ we have by (c) above that[1112] $(p_* \circ p^*)(\sigma) = p_*(\widetilde{\sigma} + f_*(\widetilde{\sigma})) = 2\sigma$, but it follows from Lemma 89.1 (4) that any multiple of two is zero in $\mathrm{C}_*(X;\mathbb{F}) = \mathrm{C}_*(X) \otimes \mathbb{F}$.

(4) Finally we have to show that $\ker(p_*) \subset \mathrm{im}(p^*)$. So let $c \in \ker(p_*)$. By (d) we can write
$$c = (\widetilde{\sigma}_1 \otimes a_1 + f_*(\widetilde{\sigma}_1) \otimes b_1) + \cdots + (\widetilde{\sigma}_k \otimes a_k + f_*(\widetilde{\sigma}_k) \otimes b_k)$$
where $\sigma_1, \ldots, \sigma_k$ are pairwise different and where $a_1, \ldots, a_k, b_1, \ldots, b_k \in \mathbb{F}$. By (c) we have
$$p(c) = \sigma_1 \otimes (a_1 + b_1) + \cdots + \sigma_k(a_k + b_k).$$
But this implies that $a_i = -b_i$ for $i = 1, \ldots, k$. But since we work over $\mathbb{F}$ we actually have $a_i = b_i$ for $i = 1, \ldots, k$. It follows from (b) that
$$c = p^*(\sigma_1 \otimes a_1 + \cdots + \sigma_k \otimes a_k),$$
as desired.

The fact the long exact sequence is indeed natural follows easily from the definitions and the naturality of the connecting homomorphism, see the Connecting Homomorphism Lemma 74.8 (2). ■

91.3. **The Borsuk-Ulam Theorem.** Our goal in this section is to give another proof of the following theorem:

Theorem 39.8. (Borsuk-Ulam Theorem) Let $n \in \mathbb{N}_0$. For every map $f\colon S^n \to \mathbb{R}^n$ there exists a pair of antipodal points x and $-x$ on S^n with $f(x) = f(-x)$.

Example. If our universe happens to be diffeomorphic to S^3, then there exists a pair of antipodal points where the temperature, distance to the Kneitinger and strength of the magnetic field agree.

Remark.

(1) We already gave a proof of the Borsuk-Ulam Theorem and in Sections 97.6 and 121.3 we will provide two other proofs of the Borsuk-Ulam Theorem 39.8. Also recall that in Theorem 48.21 we proved the Borsuk-Ulam Theorem in the special case that $n = 2$.

(2) l case $n = 2$.

(3) The Borsuk-Ulam Theorem 39.8 has many applications, in particular the Lusternik-Schnirelmann Theorem 40.1, the Ham-Sandwich Theorem 40.2, Pfister's Level Theorem 40.9 and the Necklace Theorem 40.11.

The key ingredient in the proof of the Borsuk-Ulam Theorem 39.8 is the following proposition.

Proposition 91.3. Let $f\colon S^n \to S^n$ be a map. If $f(-x) = -f(x)$ for all $x \in S^n$, then $\deg(f)$ is odd.

Remark. In the Smooth Odd Degree Proposition 39.9 we used a very different argument to provide a proof of the Odd Degree Proposition 39.9 under the stronger hypothesis that f is actually smooth.

Proof of the Odd Degree Proposition 91.3. Let $f\colon S^n \to S^n$ be a map such that $f(-x) = -f(x)$ for all $x \in S^n$. By the Degree-and-Coefficients Lemma 89.20 it suffices to show that $f_*\colon \mathrm{H}_n(S^n;\mathbb{Z}_2) \to \mathrm{H}_n(S^n;\mathbb{Z}_2)$ is an isomorphism.

[1112] That is of course basically the same argument as in the proof of the Transfer Map Proposition 91.1.

We start out with the observation that the map $f\colon S^n \to S^n$ evidently descends to a well-defined map

$$\begin{array}{rcl} \overline{f}\colon \mathbb{R}\mathrm{P}^n & \to & \mathbb{R}\mathrm{P}^n \\ [x] & \mapsto & [f(x)]. \end{array}$$

Claim. The diagram

$$\begin{array}{ccccccccccc} \longrightarrow \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & \mathrm{H}_k(S^n;\mathbb{Z}_2) & \xrightarrow{p_*} & \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \mathrm{H}_{k-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & \mathrm{H}_{k-1}(S^n;\mathbb{Z}_2) & \longrightarrow \\ \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle f_*} & \\ \longrightarrow \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & \mathrm{H}_k(S^n;\mathbb{Z}_2) & \xrightarrow{p_*} & \mathrm{H}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \mathrm{H}_{k-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & \mathrm{H}_{k-1}(S^n;\mathbb{Z}_2) & \longrightarrow \end{array}$$

where the horizontal sequences are the exact sequences given by the Double Covering-LES-Proposition 91.2, commutes.

Proof. By the LES Proposition 74.9 it suffices to show that the following diagram commutes for every $k \in \mathbb{N}_0$:

$$\begin{array}{ccccccccc} 0 & \rightarrowtail & \mathrm{C}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \overset{p^*}{\rightarrowtail} & \mathrm{C}_k(S^n;\mathbb{Z}_2) & \overset{p_*}{\twoheadrightarrow} & \mathrm{C}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \twoheadrightarrow & 0 \\ & & \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle \overline{f}_*} & & \\ 0 & \rightarrowtail & \mathrm{C}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \overset{p^*}{\rightarrowtail} & \mathrm{C}_k(S^n;\mathbb{Z}_2) & \overset{p_*}{\twoheadrightarrow} & \mathrm{C}_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \twoheadrightarrow & 0. \end{array}$$

Here the right-hand square commutes since by definition we have $p \circ f = \overline{f} \circ p$. Now we argue that the left-hand square commutes. So let $\sigma\colon \Delta^k \to \mathbb{R}\mathrm{P}^n$ be a singular k-simplex. We pick a point $P \in \Delta^k$. Furthermore we pick $Q \in S^n$ with $[Q] = \sigma(1,0,\ldots,0) \in \mathbb{R}\mathrm{P}^n$. We denote by $\widetilde{\sigma}_1$ and $\widetilde{\sigma}_2$ the two lifts of σ to S^n. Now we consider the singular simplex $\overline{f} \circ \sigma$. It remains to show that $p^*(\overline{f} \circ \sigma) = f \circ \widetilde{\sigma}_1 + f \circ \widetilde{\sigma}_2$. But this is indeed the case for the following reason:

(1) by construction we have $p \circ f = \overline{f} \circ p$ which implies that $f \circ \widetilde{\sigma}_1$ and $f \circ \widetilde{\sigma}_2$ are both lifts of $\overline{f} \circ \sigma$,
(2) it follows from $f(Q) = -f(Q)$ that $f \circ \widetilde{\sigma}_1$ and $f \circ \widetilde{\sigma}_2$ are two different lifts. ⊞

Now we consider the following diagram:

$$\begin{array}{ccccccccccc} \mathrm{H}_n(S^n;\mathbb{Z}_2) & \xleftarrow{p^*} & \mathrm{H}_n(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \ldots & \xrightarrow{\partial} & \mathrm{H}_1(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \mathrm{H}_0(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle \overline{f}_*} & & & & \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle \overline{f}_*} \\ \mathrm{H}_n(S^n;\mathbb{Z}_2) & \xleftarrow{p^*} & \mathrm{H}_n(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \mathrm{H}_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \ldots & \xrightarrow{\partial} & \mathrm{H}_1(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & \mathrm{H}_0(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2). \end{array}$$

We make the following observations:

(1) the diagram commutes by the previous claim,
(2) all the horizontal maps are isomorphisms by the discussion on page 1955,
(3) by the discussion on page 1594 the right vertical map is an isomorphism.

It follows that the left vertical map is an isomorphism. But that is exactly what we had wanted to prove. ■

Now we turn to the proof of the Borsuk-Ulam Theorem 39.8.

Proof of Theorem 39.8. Let $g\colon S^n \to \mathbb{R}^n$ be a map. Suppose there exists no pair of antipodal points x and $-x$ in S^n with $g(x) = g(-x)$. Put differently, suppose that for any

$x \in S^n$ we have $g(x) \neq g(-x)$. We consider the composition of the following two maps

$$\begin{array}{rcccl} \Phi\colon S^{n-1} \times [0,1] & \to & S^n_{\geq 0} & \to & S^{n-1}. \\ (y,t) & \mapsto & (y \cdot \sqrt{1-t^2}, t) & & \\ & & x & \mapsto & \underbrace{\frac{g(x)-g(-x)}{\|g(x)-g(-x)\|}} \\ & & & & \text{defined since } g(x) \neq g(-x) \end{array}$$

Now we see that

$$\text{odd number} \overset{\text{by definition we have } \Phi(-x,0) = -\Phi(x,0), \text{ thus it follows from the Odd Degree Proposition 91.3 that } \deg(\Phi_0) \text{ is odd}}{\downarrow =} \deg(\Phi_0) \underset{\text{since } \Phi_0 \text{ and } \Phi_1 \text{ are homotopic}}{\overset{\text{by the Sphere Degree Lemma 76.11 (3) since}}{\uparrow =}} \deg(\Phi_1) \underset{\text{by definition of } \Phi_1}{\overset{}{\uparrow =}} \deg(\text{constant map}) \overset{\text{Sphere Degree Lemma 76.11 (2)}}{\downarrow =} 0.$$

We have thus obtained a contradiction. ■

The Borsuk-Ulam Theorem 39.8 has many applications in quite different areas of mathematics. We present some of these applications in Chapter 40.

92. Division algebras and generalized projective spaces

92.1. **Division algebras.** We start out with the following purely algebraic definition.

Definition. An algebra over a field $\mathbb{F}$ is an $\mathbb{F}$-vector space A together with an $\mathbb{F}$-bilinear map

$$\begin{array}{ccc} A \times A & \to & A \\ (v, w) & \mapsto & v \cdot w. \end{array}$$

(1) We say that the algebra is commutative if for all $a, b \in A$ we have $a \cdot b = b \cdot a$.
(2) We say that the algebra is associative if for all $a, b, c \in A$ we have $a \cdot (b \cdot c) = (a \cdot b) \cdot c$.
(3) We say that the algebra has an identity if there exists an element $1 \in A$ with $1 \neq 0$ such that $1 \cdot a = a \cdot 1 = a$ for all $a \in A$.
(4) If A is an algebra with identity 1, then given $a \in A$ we say that $b \in A$ is an inverse of a if $a \cdot b = b \cdot a = 1$.
(5) A division algebra is an algebra such that for all $a \neq 0$ and $b \in A$ there exists an $x \in A$ with $a \cdot x = b$ and a $y \in A$ with $y \cdot a = b$.

Examples.

(1) The complex numbers $\mathbb{C} = \mathbb{R} \oplus \mathbb{R} \cdot \mathrm{i}$ with the usual multiplication are an algebra over $\mathbb{R}$ that is commutative and associative, it has an identity, and it is a division algebra.
(2) The set of $(n \times n)$-matrices $\mathrm{M}(n \times n, \mathbb{F})$ over a field $\mathbb{F}$, where the multiplication is given by the usual matrix multiplication, is an associative algebra over $\mathbb{F}$ with an identity. If $n \geq 2$ this algebra is clearly neither commutative nor is it a division algebra.
(3) The real vector space $\mathbb{R}^3$ together with the cross product

$$\begin{array}{ccc} \mathbb{R}^3 \times \mathbb{R}^3 & \to & \mathbb{R}^3 \\ \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix}, \begin{pmatrix} w_1 \\ w_2 \\ w_3 \end{pmatrix} & \mapsto & \begin{pmatrix} v_2 w_3 - w_2 v_3 \\ -(v_1 w_3 - w_1 v_3) \\ v_1 w_2 - w_1 v_2 \end{pmatrix} \end{array}$$

is an algebra over $\mathbb{R}$. We recall that the geometric interpretation of the cross product is given as follows: for $v, w \in \mathbb{R}^3$ the cross product $v \times w$ is the unique vector in $\mathbb{R}^3$ that satisfies the following three properties:
(a) the vector is orthogonal to v and w,
(b) the length equals the area of the parallelogram spanned by v and w,
(c) we have $\det(\underbrace{(v \;\; w \;\; v \times w)}_{3 \times 3\text{-matrix}}) \geq 0$.[1113]
We make the following observations:
(a) Clearly we have $v \times w = -w \times v$, hence the algebra is non-commutative.
(b) We have

$$(e_1 \times e_1) \times e_2 \;=\; 0 \times e_2 \;=\; 0 \;\neq\; -e_2 \;=\; e_1 \times e_3 \;=\; e_1 \times (e_1 \times e_2),$$

which shows that this algebra is non-associative.

[1113] If v and w are non-zero this just means that v, w and $v \times w$ form a positive basis for $\mathbb{R}^3$.

(c) It follows easily from the definition or the geometric interpretation that for $v \neq 0$ there is no vector w with $v \times w = v$, hence the algebra does not have an identity element.

(d) Finally it is straightforward to see that $(\mathbb{R}^3, \times)$ is not a division algebra. More precisely, one can easily show, using the geometric interpretation of the cross product, that given $a, b \in \mathbb{R}^3$ there exists a vector $x \in \mathbb{R}^3$ with $a \times x = b$ if and only if b is orthogonal to a.

We consider the next example in greater detail.

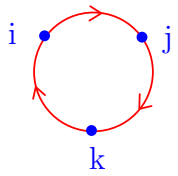
Definition. The quaternions $\mathbb{H}$ are defined as the 4-dimensional real vector space $\mathbb{R}^4$ spanned by $1, \mathrm{i}, \mathrm{j}, \mathrm{k}$ and the multiplication which is determined by

(1) $\mathrm{i}^2 = \mathrm{j}^2 = \mathrm{k}^2 = -1$,
(2) $1 \cdot \mathrm{i} = \mathrm{i} \cdot 1 = \mathrm{i}, \quad 1 \cdot \mathrm{j} = \mathrm{j} \cdot 1 = \mathrm{j}, \quad 1 \cdot \mathrm{k} = \mathrm{k} \cdot 1 = \mathrm{k}$, and
(3) $\mathrm{i} \cdot \mathrm{j} = k$, $\mathrm{j} \cdot \mathrm{k} = \mathrm{i}$, $\mathrm{k} \cdot \mathrm{i} = \mathrm{j}$ and $\mathrm{j} \cdot \mathrm{i} = -\mathrm{k}$, $\mathrm{k} \cdot \mathrm{j} = -\mathrm{i}$, $\mathrm{i} \cdot \mathrm{k} = -\mathrm{j}$.

For a quaternion

$$z := a \cdot 1 + b \cdot \mathrm{i} + c \cdot \mathrm{j} + d \cdot \mathrm{k} \in \mathbb{H}$$

we define the conjugate



$$\overline{z} := a \cdot 1 - b \cdot \mathrm{i} - c \cdot \mathrm{j} - d \cdot \mathrm{k}$$

and the norm

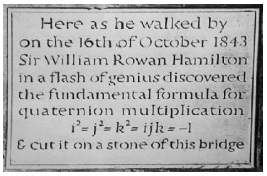
$$|z| := \sqrt{a^2 + b^2 + c^2 + d^2}$$

the same way as we did for complex numbers.

Remark. The multiplication table for $\mathbb{H}$ can be summarized in the diagram shown in the figure below. Namely we show the three generators i, j and k. We have $\mathrm{i} \cdot \mathrm{j} = \mathrm{k}$ and the analogous statement holds for any *cyclic* permutation of $\{\mathrm{i}, \mathrm{j}, \mathrm{k}\}$. On the other hand for an anti-cyclic permutation we pick up a minus sign, e.g. we have $\mathrm{j} \cdot \mathrm{i} = -\mathrm{k}$.

The following lemma summarizes a few key properties of the quaternions. In particular we see that the conjugate and the norm of the quaternions behave in a quite similar fashion as the conjugate and norm of complex numbers.

Lemma 92.1. (Quaternion Lemma)



(1) The quaternions are a non-commutative algebra over $\mathbb{R}$ with identity.
(2) For any $z \in \mathbb{H}$ we have $\overline{z} + z \in \mathbb{R}$.
(3) For all $z, w \in \mathbb{H}$ we have

$$\overline{\overline{z}} = z, \quad \overline{z + w} = \overline{z} + \overline{w} \quad \text{and} \quad \overline{z \cdot w} = \overline{w} \cdot \overline{z}.$$

(4) If we make the obvious identification $\mathbb{H} = \mathbb{R}^4$, then the norm $|-|$ on $\mathbb{H}$ agrees with the Euclidean norm $\|-\|$ on $\mathbb{R}^4$.
(5) For every $z \in \mathbb{H}$ we have $z \cdot \overline{z} = |z|^2 \in \mathbb{R} = \mathbb{R} \cdot 1$.
(6) For every $z \neq 0$ a multiplicative inverse is given by $z^{-1} = \frac{\overline{z}}{|z|^2}$.

(7) For all $z, w \in \mathbb{H}$ we have $|z \cdot w| = |z| \cdot |w|$.
(8) The quaternions are associative.
(9) The quaternions are a division algebra.

Proof. Statements (1) to (3) follow from elementary calculations. We provide the details for the remaining statements:

(4) This statement follows immediately from the definition of $|z|$.
(5) This statement follows from a straightforward calculation.
(6) This statement follows immediately from (5).
(7) Let $z_1 = a_1 \cdot 1 + b_1 \cdot \mathrm{i} + c_1 \cdot \mathrm{j} + d_1 \cdot \mathrm{k}$ and $z_2 = a_2 \cdot 1 + b_2 \cdot \mathrm{i} + c_2 \cdot \mathrm{j} + d_2 \cdot \mathrm{k}$ be two quaternions. We see that

$$\begin{aligned} |z_1 \cdot z_2|^2 &= |(a_1 \cdot 1 + b_1 \cdot \mathrm{i} + c_1 \cdot \mathrm{j} + d_1 \cdot \mathrm{k}) \cdot (a_2 \cdot 1 + b_2 \cdot \mathrm{i} + c_2 \cdot \mathrm{j} + d_2 \cdot \mathrm{k})|^2 \\ &= (a_1a_2 - b_1b_2 - c_1c_2 - d_1d_2)^2 + (a_1b_2 + b_1a_2 + c_1d_2 - d_1c_2)^2 + \\ &\quad + (a_1c_2 - b_1d_2 + c_1a_2 + d_1b_2)^2 + (a_1d_2 + b_1c_2 - c_1b_2 + d_1a_2)^2 \\ &= (a_1^2 + b_1^2 + c_1^2 + d_1^2) \cdot (a_2^2 + b_2^2 + c_2^2 + d_2^2) \;=\; |z_1|^2 \cdot |z_2|^2. \end{aligned}$$

(8) There are several approaches to proving associativity:
  (a) Since the quaternions are an algebra we only have to check associativity for products of three of the generators $\{1, \mathrm{i}, \mathrm{j}, \mathrm{k}\}$ and that can be done easily by hand.
  (b) A tedious little calculation shows that the map

$$\begin{aligned} \mathbb{H} &\to \mathrm{M}(2 \times 2, \mathbb{C}) \\ \underbrace{z + \mathrm{j} \cdot w}_{\text{with } z, w \in \mathbb{C}} &\mapsto \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} \end{aligned}$$

  is a ring homomorphism. Thus we see that $\mathbb{H}$ is isomorphic to a subring of the matrix ring $\mathrm{M}(2 \times 2, \mathbb{C})$, which is of course associative.
  (c) Finally one could use the more general result proved in Exercise 92.4.
(9) It remains to prove that $\mathbb{H}$ is in fact a division algebra. Thus let $a \neq 0$ and b be two elements in $\mathbb{H}$. We set $y := b \cdot a^{-1}$. Then

$$y \cdot a \;=\; (b \cdot a^{-1}) \cdot a \underset{\uparrow}{=} b \cdot (a^{-1} \cdot a) \;=\; b \cdot 1 \;=\; b.$$

since by (8) we know that $\mathbb{H}$ is associative

The same way we show that there exists an $x \in \mathbb{H}$ with $a \cdot x = b$. ∎

In the SU(2)-SO(3)-Covering Theorem 83.2 we saw that SU(2) is diffeomorphic to S^3. We give a refined version of this statement.

Proposition 92.2.
(1) The set $S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 \,|\, |z| = 1\}$ forms a group under multiplication of quaternions.

(2) (a) The map $\mathbb{H} \times \mathbb{C} \to \mathbb{H}$ given by $(z, w) \mapsto z \cdot w$[1114] defines a complex vector space structure on $\mathbb{H}$.
(b) A basis for $\mathbb{H}$ viewed as a complex vector space is given by $\{1, \mathrm{j}\}$.
(c) Let $z + \mathrm{j} \cdot w \in \mathbb{H}$ with $z, w \in \mathbb{C}$. Left-multiplication by $z + \mathrm{j} \cdot w$ defines a complex linear map $\mathbb{H} \to \mathbb{H}$. With respect to the basis $\{1, \mathrm{j}\}$ this linear map is represented by the matrix $\begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix}$.
(d) Left-multiplication by some $h \in \mathbb{H}$ defines a homomorphism of real vector spaces. If $h \neq 0$, then this homomorphism is represented, with respect to the standard basis of $\mathbb{H}$ as a real vector space, by a matrix in $\mathrm{GL}_+(4, \mathbb{R})$.

(3) The map

$$\begin{array}{rcl} f\colon S^3 & \to & \mathrm{SU}(2) \\ (z, w) = z + \mathrm{j} \cdot w & \mapsto & \underbrace{\begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix}}_{\substack{\text{matrix that represents} \\ \text{left-multiplication by } z + \mathrm{j} \cdot w \text{ with} \\ \text{respect to the complex basis } \{1, \mathrm{j}\} \text{ of } \mathbb{H}}} \end{array}$$

is a diffeomorphism and it defines an isomorphism of groups.

Remark. Note that the map $f\colon S^3 \to \mathrm{SU}(2)$ from Proposition 92.2 satisfies in particular

$$f(1) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad f(\mathrm{i}) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad f(\mathrm{j}) = \begin{pmatrix} \mathrm{i} & 0 \\ 0 & -\mathrm{i} \end{pmatrix}, \quad \text{and} \quad f(\mathrm{k}) = \begin{pmatrix} 0 & -\mathrm{i} \\ -\mathrm{i} & 0 \end{pmatrix}.$$

Recall that in Lemma 83.1 we defined a homomorphism $q\colon \mathrm{SU}(2) \to \mathrm{SO}(3)$. In Exercise 83.1 we calculated $q(f(\mathrm{i}))$, $q(f(\mathrm{j}))$ and $q(f(\mathrm{k}))$.

Proof.

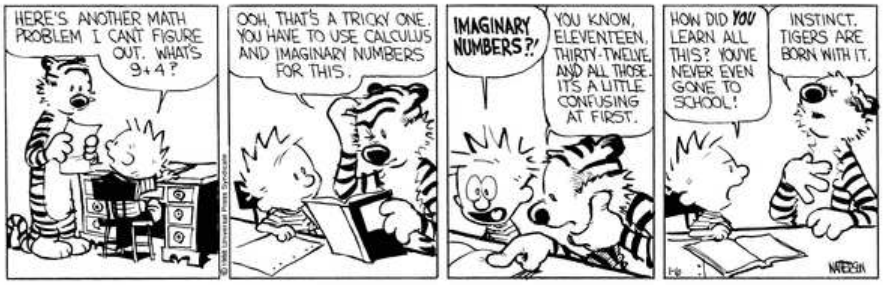
(1) This statement follows immediately from the Quaternion Lemma 92.1 (5), (6) and (7).
(2) (a) This statement follows immediately from the observation that the obvious map $\mathbb{C} \to \mathbb{H}$ is a ring homomorphism.
(b) It follows from $\mathrm{k} = -\mathrm{j} \cdot \mathrm{i}$ that any quaternion $a \cdot 1 + b \cdot \mathrm{i} + c \cdot \mathrm{j} + d \cdot \mathrm{k}$ can be uniquely written as $(a \cdot 1 + b \cdot \mathrm{i}) + \mathrm{j} \cdot (c \cdot 1 - d \cdot \mathrm{i})$ where $a \cdot 1 + b \cdot \mathrm{i}$ and $c \cdot 1 - d \cdot \mathrm{i}$ are complex numbers. This shows that $\{1, j\}$ is a basis for $\mathbb{H}$, viewed as a complex vector space.
(c) First note that it follows from the associativity of quaternions that left-multiplication by a quaternion commutes with right-multiplication by a quaternion, in particular with right-multiplication by a complex number. This shows that left-multiplication by a quaternion is indeed a complex linear map.
Now let us turn to the statement regarding the representative matrix. This statement is elementary, but we think it is nonetheless worth doing. So we consider the basis $\{1, j\}$. Evidently we have $(z + \mathrm{j} \cdot w) \cdot 1 = 1 \cdot z + \mathrm{j} \cdot w$. Thus

[1114] Here we view $\mathbb{C}$ as a subset of $\mathbb{H}$ in the obvious way. Note that the order in the definition is important since $\mathbb{H}$ is not commutative.

the first column of the matrix is given by $\begin{pmatrix} z \\ w \end{pmatrix}$. More interestingly, we have

$$(z + j \cdot w) \cdot \mathrm{j} \underset{\uparrow}{=} z \cdot \mathrm{j} + \mathrm{j} \cdot w \cdot \mathrm{j} = \mathrm{j} \cdot \overline{z} + \overline{w} \cdot \mathrm{j} \cdot \mathrm{j} \underset{\uparrow}{=} \mathrm{j} \cdot \overline{z} + 1 \cdot (-\overline{w}).$$

both equalities follow from the fact that $\mathrm{i} \cdot \mathrm{j} = -\mathrm{j} \cdot \mathrm{i}$



Thus the second column of the matrix is given by $\begin{pmatrix} \overline{z} \\ -\overline{w} \end{pmatrix}$.

(d) This statement follows easily from (c).

(3) We saw in the SU(2)-SO(3)-Covering Theorem 83.2 that the map $f\colon S^3 \to \mathrm{SU}(2)$ is a diffeomorphism. It follows from the associativity of quaternion multiplication and (2c), or alternatively from a tedious calculation, that the map

$$\begin{array}{rcl} f\colon \mathbb{H} & \to & \mathrm{M}(2 \times 2, \mathbb{C}) \\ (z, w) = z + \mathrm{j} \cdot w & \mapsto & \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} \end{array}$$

is a ring homomorphism, in particular it preserves the ring structure. This implies that the given map $f\colon S^3 \to \mathrm{SU}(2)$ is a group homomorphism. ■

Before we move on to the octonions it is helpful to give an alternative description of the quaternions. Namely we can view the Hamiltonians as elements in $\mathbb{C} \oplus \mathbb{C}$ with the multiplication given by

$$(z_1, z_2) \cdot (w_1, w_2) := (z_1 w_1 - \overline{w}_2 z_2, z_2 \overline{w}_1 + w_2 z_1)$$

the conjugate given by

$$\overline{(w, z)} := (\overline{w}, -z)$$

and the norm given by

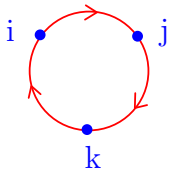
$$|(w, z)| := \sqrt{(w, z) \cdot \overline{(w, z)}}.$$

One easily verifies that this norm is multiplicative, i.e. given $a, b \in \mathbb{H} = \mathbb{C} \oplus \mathbb{C}$ one has $|a \cdot b| = |a| \cdot |b|$. An elementary calculation shows that the map $(w, z) \mapsto w + z \cdot \mathrm{j}$ defines an isomorphism between the two descriptions of $\mathbb{H}$, furthermore one can verify easily that this isomorphism preserves the conjugate and the norm.

Considering the above description of the quaternions one might hope to be lucky and just try to recycle the definitions:

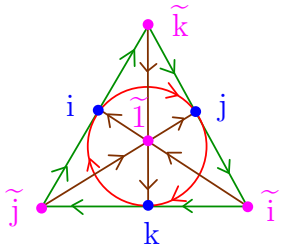
Definition. The Cayley octonions $\mathbb{O}$ (or usually just octonions) are defined as $\mathbb{O} = \mathbb{H} \oplus \mathbb{H}$ with the multiplication given by[1115]

$$(z_1, z_2) \cdot (w_1, w_2) := (z_1 w_1 - \overline{w}_2 z_2, z_2 \overline{w}_1 + w_2 z_1)$$



the conjugate given by $\overline{(w,z)} := (\overline{w}, -z)$

and the norm given by $|(w,z)| := \sqrt{(w,z)\cdot\overline{(w,z)}}.$



Remark. Octonionic multiplication can be summarized in the diagram shown in the figure below. More precisely, we write $\mathrm{i} = (\mathrm{i}, 0)$, $\mathrm{j} = (\mathrm{j}, 0)$, $\mathrm{k} = (\mathrm{k}, 0)$ and $\widetilde{1} = (0,1)$, $\widetilde{\mathrm{i}} = (0, \mathrm{i})$, $\widetilde{\mathrm{j}} = (0, \mathrm{j})$ and $\widetilde{\mathrm{k}} = (0, \mathrm{k})$. To the right of the figure below we show the *Fano plane*, which is a diagram with which has 7 points and 7 directed "lines". Similar to the discussion on page 1960 it encodes the multiplication where the product of two generators equals the third generator on the line with the positive sign if they are cyclic permutation of the given ordering and with a negative sign otherwise. For example we have

$$(\widetilde{\mathrm{j}} \cdot \mathrm{i}) \cdot \mathrm{j} = \widetilde{\mathrm{k}} \cdot \mathrm{j} = \widetilde{\mathrm{i}} \qquad \text{and} \qquad \widetilde{\mathrm{j}} \cdot (\mathrm{i} \cdot \mathrm{j}) = \widetilde{\mathrm{j}} \cdot \mathrm{k} = -\widetilde{\mathrm{i}}.$$

Note that this calculation also shows that the octonions are not associative. Finally we note that in [**Baez2001**, Chapter 2.1] the role of the Fano plane is explained in greater detail.

quaternionic multiplication

octonionic multiplication

The following lemma is the analogue of the Quaternion Lemma 92.1.

Lemma 92.3. (Octonion Lemma) The statements of the Quaternion Lemma 92.1 (1) to (7) also hold for octonions. For completeness' sake we spell out the precise statements:

(1) The octonions are a non-commutative algebra over $\mathbb{R}$ with identity.
(2) For any $z \in \mathbb{O}$ we have $\overline{z} + z \in \mathbb{R}$.
(3) For all $z, w \in \mathbb{O}$ we have

$$\overline{\overline{z}} = z, \quad \overline{z+w} = \overline{z} + \overline{w} \quad \text{and} \quad \overline{z \cdot w} = \overline{w} \cdot \overline{z}.$$

(4) If we make the obvious identification $\mathbb{O} = \mathbb{H} \oplus \mathbb{H} = \mathbb{R}^4 \oplus \mathbb{R}^4 = \mathbb{R}^8$, then the norm $|-|$ on $\mathbb{O}$ agrees with the Euclidean norm $\|-\|$ on $\mathbb{R}^8$.
(5) For every $z \in \mathbb{O}$ we have $z \cdot \overline{z} = |z|^2 \in \mathbb{R} = \mathbb{R} \cdot 1$.
(6) For every $z \neq 0$ a multiplicative inverse is given by $z^{-1} = \frac{\overline{z}}{|z|^2}$.
(7) For all $z, w \in \mathbb{O}$ we have $|z \cdot w| = |z| \cdot |w|$.

Furthermore, we have the following three statements:

(8) The octonions are *alternative*, this means that given any $x, y \in \mathbb{O}$ we have the equalities $(x \cdot y) \cdot y = x \cdot (y \cdot y)$ and $(x \cdot x) \cdot y = x \cdot (x \cdot y)$.
(9) Given any $x, y \in \mathbb{O}$ the algebra generated by 1, x and y is associative.

[1115] In fact these formulas also work for defining $\mathbb{C}$ as $\mathbb{R} \oplus \mathbb{R}$ where we equip $\mathbb{R}$ with the trivial involution.

(10) The octonions are a division algebra.

Remark.

(1) By the remark on page 98 we know that in an associative ring we can ignore parentheses when it comes to multiplication. Now that we are dealing with the octonions, which are not associative, we have to carefully keep track of parentheses.
(2) Our proof of the Octonion Lemma 92.3 (9) gets outsourced to a theorem of Artin. An alternative proof for the Octonion Lemma 92.3 (9), which does not rely on Artin's Theorem, is given in [**CSm2003**, p. 76].

Proof. As in the case of the Quaternion Lemma 92.1 the verification of (1) to (3) is totally elementary. The task of filling in the details is once again left to the reader. For later on it is helpful to consider the elementary prof of (4) in the notes:

(4) Given $(z, w) \in \mathbb{O}$ we calculate that

$$|(w,z)|^2 = (w,z)\cdot\overline{(w,z)} = (w,z)\cdot(\overline{w},-z) = (w\overline{w}+\overline{z}z, zw-zw) = \|w\|^2+\|z\|^2.$$

(5) This statement holds by definition of $|-|$.
(6) This statement follows immediately from (5).

Now we turn to the arguably more interesting proofs of the remaining four statements:

(7) It turns out that the proof of this statement is not totally straightforward. Thus let $z = (z_1, z_2)$ and $w = (w_1, w_2)$ in $\mathbb{O}$. We need the following super-technical claim.

Claim. $$\underbrace{z_2\overline{w}_1\overline{z}_1\overline{w}_2 + w_2z_1w_1\overline{z}_2 - z_1w_1\overline{z}_2w_2 - \overline{w}_2z_2\overline{w}_1\overline{z}_1}_{=:S(w_2)} = 0.$$

Proof. Evidently, if w_2 is a real number, then we have $S(w_2) = 0$. Now suppose that w_2 is a purely imaginary quaternion, i.e. $w_2 = a\cdot\mathrm{i} + b\cdot\mathrm{j} + c\cdot\mathrm{j}$ for some $a, b, c \in \mathbb{R}$. In this case we calculate that

$$S(w_2) \overset{\text{since } w_2 \text{ is purely imaginary we have } \overline{w}_2 = -w_2}{\downarrow} = w_2(\underbrace{z_2\overline{w}_1\overline{z}_1 + z_1w_1\overline{z}_2}_{=:c}) - (\underbrace{z_2\overline{w}_1\overline{z}_1 + z_1w_1\overline{z}_2}_{=:c})w_2 = w_2\cdot c - c\cdot w_2 \overset{\text{we have } \overline{c} = c, \text{ thus } c \text{ is a real number}}{=\!\!\uparrow} 0.$$

Finally note that for any $a, b \in \mathbb{H}$ we have $S(a+b) = S(a)+S(b)$. Since any quaternion is the sum of a real number and a purely imaginary we see that $S(w_2) = 0$ for any quaternion w_2. ⊞

Now we can provide the actual proof that the norm is multiplicative. Indeed, we calculate that

$$\begin{aligned}
|z \cdot w|^2 &= |(z_1, z_2) \cdot (w_1, w_2)|^2 = |(z_1 w_1 - \overline{w}_2 z_2, z_2 \overline{w}_1 + w_2 z_1)|^2 \\
&= (z_1 w_1 - \overline{w}_2 z_2) \cdot \overline{(z_1 w_1 - \overline{w}_2 z_2)} + (z_2 \overline{w}_1 + w_2 z_1) \cdot \overline{(z_2 \overline{w}_1 + w_2 z_1)} \\
&\quad \uparrow \text{see (4)} \\
&= (z_1 w_1 - \overline{w}_2 z_2) \cdot (\overline{w}_1 \overline{z}_1 - \overline{z}_2 w_2) + (z_2 \overline{w}_1 + w_2 z_1) \cdot (w_1 \overline{z}_2 + \overline{z}_1 \overline{w}_2) \\
&= (z_1 w_1) \cdot (\overline{w}_1 \overline{z}_1) - (z_1 w_1)(\overline{z}_2 w_2) - (\overline{w}_2 z_2) \cdot (\overline{w}_1 \overline{z}_1) + (\overline{w}_2 z_2) \cdot (\overline{z}_2 w_2) \\
&\quad + (z_2 \overline{w}_1)(w_1 \overline{z}_2) + (z_2 \overline{w}_1)(\overline{z}_1 \overline{w}_2) + (w_2 z_1) \cdot (w_1 \overline{z}_2) + (w_2 z_1) \cdot (\overline{z}_1 \overline{w}_2) \\
&= (z_1 w_1) \cdot (\overline{w}_1 \overline{z}_1) + (\overline{w}_2 z_2) \cdot (\overline{z}_2 w_2) + (z_2 \overline{w}_1)(w_1 \overline{z}_2) + (w_2 z_1) \cdot (\overline{z}_1 \overline{w}_2) \\
&\quad \uparrow \text{by the claim and the fact that the quaternions are associative} \\
&= (z_1 \overline{z}_1 + z_2 \overline{z}_2) \cdot (w_1 \overline{w}_1 + w_2 \overline{w}_2) = |(z_1, z_2)|^2 \cdot |(w_1, w_2)|^2 = |z|^2 \cdot |w|^2.
\end{aligned}$$

(8) Let $x, y \in \mathbb{O}$. We start out with the following claim.

Claim. We have the equalities $(x \cdot y) \cdot \overline{y} = x \cdot (y \cdot \overline{y})$ and $(x \cdot \overline{x}) \cdot y = x \cdot (\overline{x} \cdot y)$.

Proof. Let us first prove the first equality. We write $x = (x_1, x_2)$, $y = (y_1, y_2)$ with $x_1, x_2, y_1, y_2 \in \mathbb{H}$. Heroically we calculate that

$$\begin{aligned}
(xy) \cdot \overline{y} &= ((x_1, x_2)(y_1, y_2)) \cdot (\overline{y}_1, -y_2) = (x_1 y_1 - \overline{y}_2 x_2, y_2 x_1 + x_2 \overline{y}_1) \cdot (\overline{y}_1, -y_2) \\
&= ((x_1 y_1 - \overline{y}_2 x_2)\overline{y}_1 + \overline{y}_2 (y_2 x_1 + x_2 \overline{y}_1), (-y_2)(x_1 y_1 - \overline{y}_2 x_2) + (y_2 x_1 + x_2 \overline{y}_1) y_1) \\
&= ((|y_1|^2 + |y_2|^2) x_1, (|y_1|^2 + |y_2|^2) x_2) = (|y_1|^2 + |y_2|^2) \cdot (x_1, x_2) \\
&\quad \uparrow \text{since } \mathbb{H} \text{ is associative we have } (\overline{y}_2 x_2)\overline{y}_1 = \overline{y}_2 (y_2 x_1) \text{ and } y_2 (x_1 y_1) = (y_2 x_1) y_1 \\
&\quad \text{we also use that } \overline{y}_1 y_1 = |y_1|^2 \in \mathbb{R}, \text{ hence it commutes with any } z \in \mathbb{H} \\
&= |y|^2 \cdot x = x \cdot |y|^2 = x \cdot (y \overline{y}).
\end{aligned}$$

The proof of the second equality is basically the same. ⊞

Now, we use (2) to write $\overline{x} = -x + 2a$ and $\overline{y} = -y + 2b$ with $a, b \in \mathbb{R}$. We plug these equalities into the equalities of the claim and, since we are dealing with an algebra over the real numbers, we obtain the desired equalities $(x \cdot y) \cdot y = x \cdot (y \cdot y)$ and $(x \cdot x) \cdot y = x \cdot (x \cdot y)$.

(9) It is a non-trivial theorem of Emil Artin that any alternative algebra $\mathbb{A}$ has the property that given any two $x, y \in \mathbb{A}$ the algebra generated by 1, x and y is associative. A proof is for example provided in [**SchafR1966**, Theorem 3.1]. Alternatively see [**Baez2001**, p. 155].

(10) It remains to prove that $\mathbb{O}$ is in fact a division algebra. Since the octonions are not associative we cannot copy-paste the proof of the Quaternion Lemma 92.1 (9), since the latter proof used the associativity of the quaternions. Fortunately the spartan associativity result given in (8) is enough to give us the desired result.

Let $a, b \in \mathbb{O}$ with $a \neq 0$. We need to show that there exists an $x \in \mathbb{O}$ with $a \cdot x = b$ and a $y \in \mathbb{O}$ with $y \cdot a = b$. We set $x = a^{-1} \cdot b$. We calculate that

$$a \cdot x = a \cdot (a^{-1} \cdot b) = a \cdot \left(\tfrac{1}{|a|^2} \cdot \overline{a} \cdot b\right) = \tfrac{1}{|a|^2} \cdot a \cdot (\overline{a} \cdot b) \underset{\uparrow}{=} \tfrac{1}{|a|^2} \cdot (a \cdot \overline{a}) \cdot b = b.$$

by the claim in the proof of (8)

Basically the same calculation shows that we have $y \cdot a = b$. ■

Remark.

(1) The octonions were discovered[1116] by Arthur Cayley in 1845, shortly after Hamilton found the quaternions.
(2) The discussion in the previous pages shows that starting from $\mathbb{R}$ one can construct the complex numbers, which give rise to the quaternions and finally we obtain the octonions. When we move from the complex numbers to the quaternions we loose commutativity and when we go from the quaternions to the octonions we also loose associativity. Evidently the octonions are not commutative, but even worse, one can easily verify that the octonions are not even associative.[1117] The octonions are discussed in much greater detail in [**Baez2001**], [**CSm2003**, Chapter 6] and [**KaS1989**, Chapter 6].
(3) The definition of quaternions $\mathbb{H} = \mathbb{C} \oplus \mathbb{C}$ out of the complex numbers and the definition of the octonions $\mathbb{O} = \mathbb{H} \oplus \mathbb{H}$ out of the quaternions is a general procedure known as the *Cayley-Dickson construction* . This construction is discussed in greater detail in [**Baez2001**, Section 2.2]. In particular one can easily see that this process can be extended to define, basically by the same recipe, a 16-dimensional algebra $\mathbb{S} = \mathbb{O} \oplus \mathbb{O}$ with an identity, called the *sedenions*, this algebra is evidently neither commutative nor associative. On the other hand the properties stated in the Quaternion Lemma 92.1 (1)–(6) and the Octonion Lemma 92.3 (1)–(6) hold the same way, in particular $\mathbb{S}$ has multiplicative inverses, i.e. for each $a \in \mathbb{S} \setminus \{0\}$ there exists a $b \in \mathbb{S}$ with $a \cdot b = b \cdot a = 1$. But the proof of the Octonion Lemma 92.3 (7) and (8) do not carry over, since in the proof we made use of the fact that the quaternions are actually associative. In fact it turns out that the analogue of (7) does not hold for sedenions and that the sedenions are not a division algebra.[1118] [1119] We refer to [**More1997**] for more information on the failure of the sedenions to be a division algebra.

92.2. **Commutative division algebras.** After the discovery of quaternions and the octonions the question arose whether one can also find division algebras on $\mathbb{R}^n$ for some $n \neq 1, 2, 4, 8$. The following theorem, which was first proved by Heinz Hopf [**Hopf1940a, Hopf1940b, Hopf1964**] in 1940, is the best theorem that we can prove in this direction with our present knowledge.

Theorem 92.4. (Hopf Theorem on Commutative Division Algebras) Any finite-dimensional division algebra over $\mathbb{R}$ which is commutative and which has an identity is isomorphic either to $\mathbb{R}$ or to $\mathbb{C}$.

Remark.

[1116]Or were they invented by Arthur Cayley? This question whether mathematics is "discovered" or "invented" is a source for endless philosophical discussions.
[1117]To quote from [**Frie2012**, p. 5] the immortal words: "here, associativity is obviously a concern".
[1118]In fact this construction can be iterated and one obtains algebras which are creatively called pathions (32-dimensional), chingons (64-dimensional), routons (128-dimensional), voudons (256-dimensional). We challenge the reader to come up with the explanations for these names. Alternatively the reader can look at [**dMar2002**, p. 7].
[1119]Perhaps more fruitfully, the Cayley-Dickson construction can be applied to the real numbers to give the complex numbers and it can also be applied to the complex numbers to give the quaternions.

(1) Note that in Theorem 92.4 we do not assume that the division algebra is associative. It is a nice exercise in algebra and real analysis to show, using the Fundamental Theorem of Algebra, the weaker statement that if V is a finite-dimensional commutative and *associative* division algebra over $\mathbb{R}$, then V is isomorphic either to $\mathbb{R}$ or to $\mathbb{C}$.
(2) The statement of Theorem 92.4 does not hold if we drop the "finite dimension" condition. For example the field $\mathbb{R}(t)$ of rational functions over $\mathbb{R}$ is a commutative division algebra, but it is an infinite-dimensional real vector space.
(3) In Theorem 121.23 we will obtain further results on division algebras.

In the proof of Theorem 92.4 we will need the following basic lemma which might already be familiar from earlier algebra courses.

Lemma 92.5. Let A be a *finite-dimensional* algebra over a field $\mathbb{F}$. The following two statements are equivalent:

(1) A is a division algebra,
(2) A has no zero-divisors, i.e. for any $a, b \in A$ with $a \cdot b = 0$ we have $a = 0$ or $b = 0$.

Remark. Let A be a division algebra over a field $\mathbb{F}$. If A is associative, then it is clear that A has no zero-divisors. Indeed, if $a \cdot b = 0$ with $a \neq 0$, then we pick x with $x \cdot a = 1$ and we see that $0 = x \cdot 0 = x \cdot (a \cdot b) = (x \cdot a) \cdot b = 1 \cdot b = b$. The point about Lemma 92.5 is that it applies to non-associative algebras, as long as they are finite-dimensional.

Proof. Let A be a finite-dimensional algebra over a field $\mathbb{F}$. Let $a \in A$ be non-zero. Then the following holds:

$$\begin{aligned} \text{for any } y \in A \text{ there exists } x \in A \text{ with } ax = y &\Leftrightarrow \text{ the map } A \to A,\ x \mapsto ax \text{ is surjective} \\ &\Leftrightarrow \text{ the map } A \to A,\ x \mapsto ax \text{ is injective} \\ &\quad \uparrow \\ &\quad \text{since } x \mapsto ax \text{ is a homomorphism of finite-dimensional } \mathbb{F}\text{-vector spaces} \\ &\Leftrightarrow \text{ for any } b \neq 0 \text{ we have } ab \neq 0. \end{aligned}$$

The same statement holds for left-multiplication. The equivalence of (1) and (2) now follows easily from this observation and the definitions. ∎

Now we turn to the proof of Theorem 92.4.

Proof of Theorem 92.4. Let $(A, *)$ be a finite-dimensional division algebra over $\mathbb{R}$ which is commutative and which has an identity. Since A is a finite-dimensional vector space we can, after applying an isomorphism, assume that $A = \mathbb{R}^n$ for some $n \in \mathbb{N}$.

We first consider the case $n = 1$. We define $a := 1 * 1$. Since "$*$" is bilinear we have for all $x, y \in \mathbb{R}$ that $x * y = (x \cdot 1) * (y \cdot 1) = x \cdot (1 * 1) \cdot y = xay$. Since the algebra is a division algebra we obtain from Lemma 92.5 that $a \neq 0$. Then the map $\varphi(x) = ax$ defines an isomorphism from the algebra $(\mathbb{R}, *)$ to the algebra $(\mathbb{R}, \cdot)$.[1120]

Now suppose that $n \geq 2$. We first want to show that $n = 2$. To do this we consider the map

$$\begin{array}{rccl} f\colon S^{n-1} & \to & S^{n-1} & \\ x & \mapsto & f(x) & := \dfrac{x * x}{\|x * x\|}. \end{array}$$

[1120] Indeed, for $x, y \in \mathbb{R}$ we have $\varphi(x * y) = \varphi(x \cdot a \cdot y) = a \cdot x \cdot a \cdot y = (a \cdot x) \cdot (a \cdot y) = \varphi(x) \cdot \varphi(y)$.

This map is indeed well-defined, since for $x \neq 0$ it follows from our hypothesis on $(\mathbb{R}^n, *)$ and from Lemma 92.5 that $x * x \neq 0$. The map f is continuous since the multiplication map $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ is bilinear, hence continuous.[1121]

Since "$*$" is bilinear we have $f(-x) = f(x)$ for all $x \in \mathbb{R}^n$. It follows from the Topological-Quotient Proposition 5.15 (1b) that the map f descends to a continuous map

$$\begin{array}{rcl} \overline{f}\colon \mathbb{R}\mathrm{P}^{n-1} & \to & S^{n-1} \\ [x] & \mapsto & \overline{f}([x]) := f(x). \end{array}$$

Claim. The map $\overline{f}\colon \mathbb{R}\mathrm{P}^{n-1} \to S^{n-1}$ is injective.

Proof. So let $[x], [y] \in \mathbb{R}\mathrm{P}^{n-1} = S^{n-1}/\!\sim$. We have

$$\begin{array}{rcl} \underbrace{\overline{f}([x])}_{=f(x)} = \underbrace{\overline{f}([y])}_{=f(y)} \implies f(x) = f(y) & \implies & x * x = \alpha^2 \cdot (y * y) \text{ for } \alpha := \sqrt{\|x * x\| \cdot \|y * y\|^{-1}} \\ & \implies & 0 = x * x - \alpha^2 \cdot (y * y) \underset{\uparrow}{=} (x + \alpha y) * (x - \alpha y) \\ & & \qquad \text{since "}*\text{" is commutative and bilinear} \\ & \underset{\uparrow}{\implies} & x = \pm \alpha y \quad \underset{\uparrow}{\implies} \quad x = \pm y \quad \implies [x] = [y]. \\ & \text{Lemma 92.5} & \qquad \text{since } x, y \in S^{n-1} \end{array}$$

⊞

Since S^{n-1} is closed and connected (here we use that $n \geq 2$) and since $\mathbb{R}\mathrm{P}^{n-1}$ is a closed smooth manifold it follows from Corollary 82.9 that $\overline{f}\colon \mathbb{R}\mathrm{P}^{n-1} \to S^{n-1}$ is in fact a homeomorphism. In particular the fundamental groups of $\mathbb{R}\mathrm{P}^{n-1}$ and S^{n-1} are isomorphic. But it follows from the Sphere-π_1-Proposition 47.13 and Corollary 48.18 that this is only possible if $n = 2$.

It remains to show that the algebra $(A, *) = (\mathbb{R}^2, *)$ is isomorphic to the algebra $(\mathbb{C}, \cdot)$. We start out with the following claim.

Claim. There exists a $k \in A \setminus \mathbb{R} \cdot 1$ with $k * k = c \cdot 1$ for some $c \in \mathbb{R}_{<0}$.

Proof. We first pick a random element $j \in A \setminus \mathbb{R} \cdot 1$. Then 1 and j are a basis for $A = \mathbb{R}^2$ and therefore we can write $j * j = a \cdot 1 + b \cdot \mathrm{j}$ for some $a, b \in \mathbb{R}$. Then multiplying out and using this equality we see that

$$\underbrace{\left(j - \tfrac{b}{2} \cdot 1\right)}_{=:k} * \underbrace{\left(j - \tfrac{b}{2} \cdot 1\right)}_{=:k} = \underbrace{\left(a + \tfrac{1}{4} \cdot b^2\right)}_{=:c} \cdot 1.$$

We set $k := j - \frac{b}{2} \cdot 1$ and $c := a + \frac{1}{4} b^2$. We still need to show that $c < 0$. Suppose that $c \geq 0$. Then $k * k = c \cdot 1$ implies that $(k + \sqrt{c} \cdot 1) * (k - \sqrt{c} \cdot 1) = k * k - c \cdot 1 = 0$. From Lemma 92.5 we conclude that $k = \pm\sqrt{c} \cdot 1$. But this is not possible since $k = j - \frac{b}{2} \cdot 1$ is linearly independent from 1. ⊞

One can now easily verify that

$$\begin{array}{rcll} A & \to & \mathbb{C} & \\ x \cdot 1 + y \cdot \mathrm{k} & \mapsto & x + y \cdot \dfrac{\mathrm{i}}{\sqrt{-c}} & \text{with } x, y \in \mathbb{R} \end{array}$$

is an isomorphism from the algebra $(A, *)$ to the algebra $(\mathbb{C}, \cdot)$. ■

[1121] Indeed, the fact that the map is bilinear implies that there exists a real $n \times n$–matrix P such that for any $v, w \in \mathbb{R}^n$ we have $v \cdot w = v^T P w$, hence the map is continuous.

It is natural to ask what other division algebras exist. The following, purely algebraic, theorem classifies *associative* division algebras.

Theorem 92.6. (Frobenius Theorem) Any finite-dimensional division algebra over $\mathbb{R}$ which is associative and which has an identity is isomorphic to $\mathbb{R}, \mathbb{C}$ or to $\mathbb{H}$.

Remark. Note that in Exercise 92.6 we will see that there are many more *non-associative* division algebra structures on $\mathbb{R}^4$.

Proof. The statement was first proved by Frobenius in 1878. A short self-contained proof is for example given in [**Pal1968**]. ■

Finally let us record the following question.

Question 92.7. For which $n \in \mathbb{N}$, besides $n = 1, 2, 4, 8$ does $\mathbb{R}^n$ admit the structure of a division algebra?

We will answer this question in Theorem 121.25.

92.3. **Quaternionic and octonionic projective spaces.** In this section we introduce the quaternionic projective spaces $\mathbb{H}\mathrm{P}^n$ and we introduce the significantly more subtle octonionic projective space $\mathbb{O}\mathrm{P}^2$. These smooth manifolds get added to our ever expanding list of amusing topological spaces. At a later stage they will play an essential role.

On page 1472, given $n \in \mathbb{N}_0$, we introduced the real projective space $\mathbb{R}\mathrm{P}^n$ and the complex projective spaces $\mathbb{C}\mathrm{P}^n$. In the following we will introduce the quaternionic projective spaces $\mathbb{H}\mathrm{P}^n$. Since the quaternions $\mathbb{H}$ are non-commutative we do the constructions carefully.

Lemma 92.8. Given $v, w \in \mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\}$ we write $v \sim w$ if there exists a non-zero $h \in \mathbb{H}$ with $h \cdot v = w$. This defines an equivalence relation on $\mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\}$. The analogous statement also holds for $\mathbb{H}^\infty \setminus \{0\}$.

Proof.

(1) It is clear that $\sim$ is reflexive.
(2) Since $\mathbb{H}$ is a skew field we see that $\sim$ is symmetric.
(3) Finally suppose that $u \sim v$ and $v \sim w$. Thus there exist $g, h \in \mathbb{H} \setminus \{0\}$ with $gu = v$ and $hv = w$. Thus we see that

$$(hg)u \underset{\uparrow}{=} h(gu) = hv = w.$$

since the quaternions are associative!

■

Now we can define the quaternionic projective spaces.

Definition. Let $n \in \mathbb{N}_0$.

(1) For $(h_0, \ldots, h_n) \in \mathbb{H}^{n+1} \setminus \{0\}$ we denote by $[h_0 : \ldots : h_n]$ the corresponding equivalence class.
(2) Given $n \in \mathbb{N}$ we define the quaternionic projective space

$$\mathbb{H}\mathrm{P}^n := (\mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\})/\sim .$$

Similarly, we define the infinite-dimensional quaternionic projective space

$$\mathbb{H}\mathrm{P}^\infty := (\mathbb{H}^\infty \setminus \{0\})/\sim .$$

The following lemma summarizes some key properties of quaternionic projective spaces. $\mathbb{H}\mathrm{P}^n$. We will make use of some of them later on.

Lemma 92.9. (Quaternion-Projective Space Lemma) Let $n \in \mathbb{N}_0$.

(1) $\mathbb{H}\mathrm{P}^n$ is a closed orientable $4n$-dimensional smooth manifold.
(2) The map
$$\begin{array}{rcl} \mathbb{H}\mathrm{P}^1 & \to & \mathbb{H} \cup \{\infty\} = \mathbb{R}^4 \cup \{\infty\} \overset{\text{by Lemma 2.18}}{=} S^4 \\ [z_0 : z_1] & \mapsto & \begin{cases} z_0 \cdot z_1^{-1}, & \text{if } z_1 \neq 0, \\ \infty, & \text{if } [z_0 : z_1] = [1 : 0] \end{cases} \end{array}$$
is a homeomorphism.
(3) $\mathbb{H}\mathrm{P}^n$ admits a CW-structure that has exactly one cell in the dimensions $0, 4, 8, \ldots, 4n$.
(4) We have $\chi(\mathbb{H}\mathrm{P}^n) = n + 1$.
(5) $\mathbb{H}\mathrm{P}^n$ is 3-connected, i.e. we have $\pi_i(\mathbb{H}\mathrm{P}^3) = 0$ for $i = 1, 2, 3$.
(6) We have a homeomorphism $\varinjlim \mathbb{H}\mathrm{P}^n = \mathbb{H}\mathrm{P}^\infty$.
(7) We can equip $\mathbb{H}\mathrm{P}^\infty$ with a CW-structure that has exactly one cell in the dimensions $0, 4, 8, \ldots$.

Proof.

(1) This statement is proved in a very similar way as the Complex Projective Space-is-Complex Manifold Lemma 32.16.
(2) The proof of this statement is basically the same as the proof of Lemma 5.32 (2).
(3) The proof of this statement is an easy modification of the proof of Lemma 68.1.
(4) This statement follows immediately from (3).
(5) This follows from (3) and the CW-Skeleton-π_n-Proposition 71.9.
(6) This statement is proved the same way as Lemma 68.5 (1).
(7) This statement is proved basically the same way as Lemma 68.5 (3). ■

Since the octonions are not associative the definition on page 1472 cannot be applied to the octonions. But there is some hope in low dimensions. More precisely, as we will see shortly, one can use the octonions to construct smooth manifolds that have all the properties that one would naively expect $\mathbb{O}\mathrm{P}^1$ and $\mathbb{O}\mathrm{P}^2$ to have.

Definition.

(1) We equip[1122]
$$T_2 := \mathbb{O}^2 \setminus \{(0,0)\}$$
with the equivalence relation[11231124]
$$(x_1, y_1) \sim (x_2, y_2) \iff \begin{array}{l} \text{there exists a } \lambda \in \mathbb{R}_{>0} \text{ such that} \\ y_1\overline{y_1} = \lambda \cdot y_2\overline{y_2} \text{ and } x_1\overline{y_1} = \lambda \cdot x_2\overline{y_2}. \end{array}$$
We set
$$\mathbb{O}\mathrm{P}^1 := T_2/\sim$$
and we refer to $\mathbb{O}\mathrm{P}^1$ as the octonionic projective line.
(2) We equip
$$T_3 := \big\{(x, y, z) \in \mathbb{O}^3 \setminus \{(0,0,0)\} \,\big|\, 1, x, y, z \text{ generate an associative algebra}\big\}$$

with the equivalence relation[1125]

$$(x_1,y_1,z_1)\sim(x_2,y_2,z_2) \iff \begin{array}{l}\text{there exists a } \lambda\in\mathbb{R}_{>0} \text{ such that}\\ y_1\overline{y_1}=\lambda\cdot y_2\overline{y_2},\quad x_1\overline{y_1}=\lambda\cdot x_2\overline{y_2},\quad x_1\overline{z_1}=\lambda\cdot x_2\overline{z_2},\\ y_1\overline{y_1}=\lambda\cdot y_2\overline{y_2},\quad y_1\overline{z_1}=\lambda\cdot y_2\overline{z_2},\quad z_1\overline{z_1}=\lambda\cdot z_2\overline{z_2}.\end{array}$$

We set

$$\mathbb{O}\mathrm{P}^2 := T_3/\sim$$

and we refer to $\mathbb{O}\mathrm{P}^2$ as the octonionic projective plane. In the literature the octonionic projective plane is often also called the Cayley projective plane.

(3) We denote the equivalence class of a point $(x,y)\in T_2$ by $[x:y]$ and we denote the equivalence class of a point $(x,y,z)\in T_3$ by $[x:y:z]$.

The following proposition hopefully convinces the reader that the octonion line $\mathbb{O}\mathrm{P}^1$ and the octonion plane $\mathbb{O}\mathrm{P}^2$ deserve their names.

Proposition 92.10. (Octonion Plane Proposition)

(1) The octonionic projective line $\mathbb{O}\mathrm{P}^1$ and the octonionic projective plane $\mathbb{O}\mathrm{P}^2$ are both compact.

(2) The map

$$\begin{array}{rcl}\mathbb{O}\mathrm{P}^1 & \to & \mathbb{O}\cup\{\infty\}=\mathbb{R}^8\cup\{\infty\}\overset{\text{by Lemma 2.18}}{=}S^8\\ [x:y] & \mapsto & \begin{cases}x\cdot y^{-1}, & \text{if } y\neq 0,\\ \infty, & \text{if } [x:y]=[1:0]\end{cases}\end{array}$$

is well-defined and it is a homeomorphism.

(3) The octonionic projective plane $\mathbb{O}\mathrm{P}^2$ is a closed orientable 16-dimensional smooth manifold.

(4) The map[1126]

$$\begin{array}{rcl}\mathbb{O}\mathrm{P}^1 & \to & \mathbb{O}\mathrm{P}^2\\ [x:y] & \mapsto & [x:y:0]\end{array}$$

is an embedding. We use it to view $\mathbb{O}\mathrm{P}^1$ as a subspace of $\mathbb{O}\mathrm{P}^2$.

(5) The octonionic projective plane $\mathbb{O}\mathrm{P}^2$ admits a CW-structure with precisely one cell in dimensions 0, 8 and 16, and which has no other cells. Furthermore this CW-structure can be chosen such that the 8-skeleton is precisely $\mathbb{O}\mathrm{P}^1$.

(6) We have $\chi(\mathbb{O}\mathrm{P}^2)=3$.

(7) $\mathbb{O}\mathrm{P}^2$ is 7-connected, i.e. we have $\pi_i(\mathbb{O}\mathrm{P}^2)=0$ for $i=1,2,\dots,7$.

Proof.

(1) It is straightforward to define equivalence relations on S^{15} and on S^{23} such that the octonionic projective line $\mathbb{O}\mathrm{P}^1$ is homeomorphic to $S^{15}/\sim$ and such that the

[1122] What happens if we use these definitions of $\mathbb{O}\mathrm{P}^1$ and $\mathbb{O}\mathrm{P}^2$, but if we replace the octonions by our more familiar friends $\mathbb{R}$, $\mathbb{C}$ and $\mathbb{H}$?

[1123] Note that this is obviously an equivalence relation.

[1124] The definition of the equivalence relation is a priori asymmetric in the first and the second variable. Bu this asymmetry is an illusion, in fact if $y_1\overline{y_1}=\lambda\cdot y_2\overline{y_2}$ and $x_1\overline{y_1}=\lambda\cdot x_2\overline{y_2}$, then we also have

$$x_1\overline{x}_1 = x_1\overline{y}_1\overline{y}_1^{-1}y_1^{-1}y_1\overline{x}_1 = x_1\overline{y}_1(y_1\overline{y}_1)^{-1}\overline{x_1\overline{y}_1} = \lambda x_2\overline{y}_2(\lambda y_2\overline{y}_2)^{-1}\overline{\lambda x_2\overline{y}_2} = \lambda x_2\overline{y}_2\overline{y}_2^{-1}y_2^{-1}y_2\overline{x}_2 = \lambda x_2\overline{x}_2.$$

[1125] As for $\sim$ on T_2, this is basically by definition an equivalence relation.

[1126] It follows from the Octonion Lemma 92.3 (9) that this map is well-defined, i.e. given any point $(x_1,y_1)\in T_2$ we have indeed $(x_1,y_1,0)\in T_3$.

octonionic projective plane $\mathbb{O}\mathrm{P}^2$ is homeomorphic to $S^{23}/\sim$. It follows from the Compact Image Lemma 2.13 that $\mathbb{O}\mathrm{P}^1$ and $\mathbb{O}\mathrm{P}^2$ are both compact.

(2) First we need to show that the given map $\Theta\colon \mathbb{O}\mathrm{P}^1 \to \mathbb{O}\cup\{\infty\}$ is well-defined. Thus suppose that we are given two points (x_1, y_1) and (x_2, y_2) in $\mathbb{O}^2 \setminus \{(0,0)\}$ that are equivalent. One can verify easily that $y_1 \neq 0$ if and only if $y_2 \neq 0$. By definition of Θ we only need to worry about the case that $y_1, y_2 \neq 0$. In this case we do indeed have

$$x_1 y_1^{-1} \underset{\uparrow}{=} x_1 \cdot \frac{1}{|y_1|^2} \cdot \overline{y}_1 \underset{\uparrow}{=} \frac{1}{y_1 \cdot \overline{y}_1} \cdot (x_1 \cdot \overline{y}_1) \underset{\uparrow}{=} \frac{1}{y_2 \cdot \overline{y}_2} \cdot (x_2 \cdot \overline{y}_2) \underset{\uparrow}{=} \ldots = x_2 y_2^{-1}.$$

Octonion Lemma 92.3 (7) and (6); by definition of "$\sim$" we have $y_1\overline{y_1} = \lambda \cdot y_2\overline{y_2}$ and $x_1\overline{y_1} = \lambda \cdot x_2\overline{y_2}$; same steps backwards

We have thus shown that Θ is well-defined. It is clear that the map Θ is a surjection. In Exercise 92.8 we will verify that Θ is also an injection. Next note that the argument in the proof of Lemma 5.32 (2) shows that Θ is continuous. We just saw in (1) that $\mathbb{O}\mathrm{P}^1$ is compact. Evidently $\mathbb{O}\cup\{\infty\} = S^8$ is Hausdorff. In summary we obtain from the Compact-Hausdorff Proposition 2.17 (3) that $\Theta\colon \mathbb{O}\mathrm{P}^1 \to \mathbb{O}\cup\{\infty\}$ is a homeomorphism.

(3) We start out with the following claim:

Claim. The map

$$\begin{array}{rcl} \Phi_z\colon \{[x:y:z] \in \mathbb{O}\mathrm{P}^2 \mid z \neq 0\} & \to & \mathbb{O}^2 \\ [x:y:z] & \mapsto & (xz^{-1}, yz^{-1}) \end{array}$$

is a homeomorphism between an open subset of $\mathbb{O}\mathrm{P}^2$ and $\mathbb{O}^2 = \mathbb{R}^{16}$.

Proof. We prove the claim in three mostly elementary steps.

(a) Basically the same argument as in (2) shows that the map Φ_z is well-defined.

(b) It follows easily from the definition of the quotient topology that the domain of the map Φ_z is indeed an open subset of $\mathbb{O}\mathrm{P}^2$.

(c) Finally we consider the map

$$\begin{array}{rcl} \Psi_z\colon \mathbb{O}^2 & \to & \{[x:y:z] \in \mathbb{O}\mathrm{P}^2 \mid z \neq 0\} \\ (x,y) & \mapsto & [x:y:1]. \end{array}$$

Note that here we use the non-trivial the Octonion Lemma 92.3 (9) to conclude that Ψ_z is actually well-defined, i.e. to conclude that $(x, y, 1)$ is actually an element in T_3. Furthermore note that it follows from the Topological-Quotient Proposition 5.15 (1b) that Ψ_z is continuous. It is clear that $\Phi_z \circ \Psi_z = \mathrm{id}$. Finally note that given $[x:y:z] \in \mathbb{O}\mathrm{P}^2$ with $z \neq 0$ we have

$$\Psi_z(\Phi_z([x:y:z])) = [xz^{-1}:yz^{-1}:1] \underset{\uparrow}{=} [x:y:z]$$

follows with $\lambda = |z|^2$ and from the observation that the hypothesis $(x, y, z) \in T_3$ together with the Octonion Lemma 92.3 (2) implies that the elements $x, y, z, \overline{x}, \overline{y}, \overline{z}$ generate an associative algebra

We have thus shown that Ψ_z is an inverse to Φ_z. This implies that Φ_z is indeed a homeomorphism. ⊞

Similarly we define charts Φ_x and Φ_y. It is straightforward to verify that the transition maps between the three charts are smooth and orientation-preserving. In particular these three charts define a smooth atlas for $\mathbb{O}\mathrm{P}^2$. We obtain from Lemma 18.2 that $\mathbb{O}\mathrm{P}^2$ is second-countable. In (1) we showed that $\mathbb{O}\mathrm{P}^2$ is compact. Finally in

Exercise 92.9 we will show that $\mathbb{O}\mathrm{P}^2$ is Hausdorff.[1127] The combination of all of the above shows that $\mathbb{O}\mathrm{P}^2$ is indeed a closed 16-dimensional smooth manifold. Finally, since the transition maps between the three charts are orientation-preserving we obtain from the Define Orientations-via Transition Maps Lemma 25.15 that $\mathbb{O}\mathrm{P}^2$ is actually orientable.

(4) It follows basically immediately from the discussion in Footnote 1124 that the given map $\mathbb{O}\mathrm{P}^1 \to \mathbb{O}\mathrm{P}^2$ is an injection. By (1) we know that $\mathbb{O}\mathrm{P}^1$ is compact and by (3) we know that $\mathbb{O}\mathrm{P}^2$ is Hausdorff. Thus it follows from the Compact-Hausdorff Proposition 2.17 (2) that the given map $\mathbb{O}\mathrm{P}^1 \to \mathbb{O}\mathrm{P}^2$ is an embedding.

(5) We view $\mathbb{O}\mathrm{P}^1 = S^8$ as a CW-complex with one 0-cell and one 8-cell in the obvious way. Next, similar to the proof of Lemma 68.1 we consider the attaching map

$$\begin{array}{rcl} \varphi\colon S^{15} = \{(x_1, x_2) \in \mathbb{O}^2 \,|\, |x_1|^2 + |x_2|^2 = 1\} & \to & \mathbb{O}\mathrm{P}^1 \\ (x_1, x_2) & \mapsto & [x_1 : x_2]. \end{array}$$

Furthermore we consider the map

$$\begin{array}{rcl} \Theta\colon \mathbb{O}\mathrm{P}^1 \cup_\varphi \overline{B}^{16} & \to & \mathbb{O}\mathrm{P}^2 \\ [P] & \mapsto & \begin{cases} [x_1 : x_2 : 0], & \text{if } P = [x_1 : x_2] \in \mathbb{O}\mathrm{P}^1, \\ [P : 1 - \|P\|], & \text{if } P \in \overline{B}^{16}. \end{cases} \end{array}$$

It follows from the Octonion Lemma 92.3 (8) that the map actually does take values in $\mathbb{O}\mathrm{P}^2$. We leave the slightly tedious task of verifying that the map is well-defined and a bijection to the reader. The left-hand side is compact and the right-hand side is Hausdorff by (2). Thus it follows from the Compact-Hausdorff Proposition 2.17 (3) that the map is a homeomorphism. But this implies that $\mathbb{O}\mathrm{P}^2$ admits a CW-structure with precisely three cells, one in dimensions 0, 8 and 16.

(6) Statement (6) is an immediate consequence of (5).

(7) Finally Statement (7) follows from (5) and the CW-Skeleton-π_n-Proposition 71.9. ■

It is natural to ask whether there exists a smooth manifold that deserves the name $\mathbb{O}\mathrm{P}^n$ for $n \geq 3$. In the proof of the Octonion Plane Proposition 92.10 we used that $n = 2$ has the property, provided by the Octonion Lemma 92.3 (9), that for any $x_1, \ldots, x_n \in \mathbb{O}$ the elements $1, x_1, \ldots, x_n$ generate an associative algebra. It is straightforward to see that this statement is not true for $n \geq 3$. Nonetheless, one can wonder whether there exists an alternative way to define a meaningful higher dimensional octonionic projective space. This slightly vague question can be formulated in many different ways. Here is one possible interpretation of this question.

Question 92.11. Let $n \geq 3$. Does there exist a closed orientable $8n$-dimensional smooth manifold that admits a CW-structure with precisely one cell in dimensions $0, 8, 16, \ldots, 8n$?

We will answer this question in Exercise 152.2.

the Octonion Plane Proposition 92.10 says in particular that the octonion plane $\mathbb{O}\mathrm{P}^2$ is a closed orientable 16-dimensional smooth manifold that is 7-connected and that has odd Euler characteristic. The following question is, to the best of my knowledge, open:

[1127] An arguably more elegant proof that $\mathbb{O}\mathrm{P}^2$ is Hausdorff is given in [**Lackm2012**].

Question 92.12. Does there exist an 8-connected closed orientable smooth manifold with odd Euler characteristic?

In [**Hoe2017**, Theorem 1.2 together with Proposition 4.2] it is shown that the dimension of an 8-connected closed orientable smooth manifold with odd Euler characteristic, if it exists, has to be divisible by 16.

Exercises for Chapter 92.

Exercise 92.1. Let $n \in \mathbb{N}_0$. Show that the following are equivalent statements:

(a) For every map $f\colon S^n \to \mathbb{R}^n$ there exists an $x \in S^n$ with $f(x) = f(-x)$.
(b) For every odd map $f\colon S^n \to \mathbb{R}^n$ there exists an $x \in S^n$ with $f(x) = 0$.
(c) There is no odd map $f\colon S^n \to S^{n-1}$.
(d) There is no map $f\colon \overline{B}^n \to S^{n-1}$ such that the restriction of f to $S^{n-1} \to S^{n-1}$ is odd.

Exercise 92.2. Let $n \in \mathbb{N}_0$. Show that the Borsuk-Ulam Theorem 39.8 implies the Brouwer Fixed Point Theorem 31.4.

Remark. From Exercise 39.8 you can pick your favorite formulation of the Borsuk-Ulam Theorem 39.8.

Exercise 92.3. Let $q_1, q_2 \in S^3 = \{h \in \mathbb{H} \,|\, |h| = 1\}$. We consider the map

$$\begin{array}{rcl} \mathbb{R}^4 = \mathbb{H} & \to & \mathbb{R}^4 = \mathbb{H} \\ z & \mapsto & q_1 z q_2^{-1}. \end{array}$$

Show that the map is linear and that it is represented by a matrix in SO(4).

Exercise 92.4. Let R be a ring. An involution on R is a map $R \to R$, written $z \mapsto \overline{z}$ with the following properties:

(1) $\overline{z+w} = \overline{z} + \overline{w}$ for all $z, w \in R$,
(2) $\overline{z \cdot w} = \overline{w} \cdot \overline{z}$ for all $z, w \in R$,
(3) $\overline{\overline{z}} = z$ for all $z \in R$.

Now let R be a ring with involution. We consider $S := R \oplus R$ with the obvious multiplication and the multiplication given by

$$(z_1, z_2) \cdot (w_1, w_2) \;:=\; (z_1 w_1 - \overline{w}_2 z_2, z_2 \overline{w}_1 + w_2 z_1)$$

and the involution given by

$$\overline{(w, z)} \;:=\; (\overline{w}, -z).$$

We say S is obtained from R via the Cayley-Dickson construction.

(a) Show that S is a ring with involution.
(b) Show that if R is commutative, then S is associative.

Exercise 92.5. Let $n \in \mathbb{Z}$. Show that the degree of the map

$$\begin{array}{rcl} S^3 = \{v \in \mathbb{H} \,|\, \|v\| = 1\} & \to & S^3 \\ z & \mapsto & z^n \end{array}$$

equals n.

Hint. You could use the Local-Global Degree Proposition 76.21.

Exercise 92.6. Let $\mathbb{A} = \mathbb{R} \oplus \mathbb{R} \cdot \mathrm{i} \oplus \mathbb{R} \cdot \mathrm{j} \oplus \mathbb{R} \cdot \mathrm{k}$. We define the multiplication on $\mathbb{A}$ the same way as we did for the quaternions, see page 1960, except that we set $\mathrm{i}^2 = -1 + \epsilon \cdot \mathrm{j}$.

(a) Show that $\mathbb{A}$ is a division algebra.
(b) Show that i has a left-inverse and a right-inverse.
(c) Show that the left-inverse and the right-inverse of i differ for sufficiently small $\epsilon > 0$.

Exercise 92.7. Show that the octonions $\mathbb{O}$ are not associative.

Exercise 92.8. Show that the map

$$\begin{array}{rcl} \mathbb{O}\mathrm{P}^1 & \to & \mathbb{O} \cup \{\infty\} \\ [x:y] & \mapsto & \begin{cases} x \cdot y^{-1}, & \text{if } y \neq 0, \\ \infty, & \text{if } [x:y] = [1:0] \end{cases} \end{array}$$

is an injection.

Exercise 92.9. Show that $\mathbb{O}\mathrm{P}^2$ is Hausdorff.
Hint. First show that $\mathbb{O}\mathrm{P}^2$ is in fact homeomorphic to a suitable quotient of the sphere $S^{23} = \{(x,y,z) \in \mathbb{O}^3 \,|\, |x|^2 + |y|^2 + |z|^2 = 1\}$ and then apply the Quotient Hausdorff Lemma 5.21.

Exercise 92.10. Let $n \in \mathbb{Z}$. We consider S^3 as a subspace of the quaternions $\mathbb{H}$. What is the degree of the map

$$\begin{array}{rcl} S^3 & \to & S^3 \\ z & \mapsto & z^n \,? \end{array}$$

Part IX

Simplicial Complexes

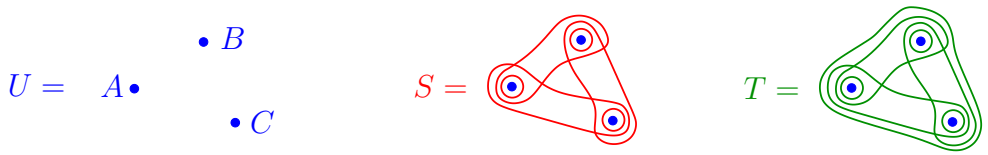
93. Simplicial complexes: Definition, examples and basic properties

In this section we introduce the notion of an abstract simplicial complex. Similar to the notion of an abstract graph these are purely combinatorial objects. The connection to topology comes from the fact that simplicial complexes admit topological realizations which can be used to combinatorially describe many interesting topological spaces. These topological realizations also lead to the notion of a simplicial complex which can be viewed as a special class of CW-complexes with particularly nice properties.

93.1. **Abstract simplicial complexes.** Before we do anything else we recall the following notation that we introduced on page 86.

Notation. Given a set X we denote by $\mathcal{P}(X)$ its power set, i.e. $\mathcal{P}(X)$ is the set of all subsets of X.

We continue with the following initially rather abstract definition.



Definition. An abstract simplicial complex is a pair (V, S) where V is a set and S is a subset of the power set $\mathcal{P}(V)$ of V such that the following conditions are satisfied:

(1) each $s \in S$ is finite and non-empty,
(2) if $s \in S$, then any non-empty subset of s also lies in S,
(3) given any $v \in V$ the set $\{v\}$ lies in S.

We refer to the elements of V as the vertices of the abstract simplicial complex and we refer to the elements of S as the simplices of the abstract simplicial complex.

Examples.

(0) The pair $(\varnothing, \varnothing)$ is an abstract simplicial complex, it is called the *empty abstract simplicial complex*. Every other abstract simplicial complex is called *non-empty*.
(1) We consider the set $U = \{A, B, C\}$. It is straightforward to verify that the pair $X := (U, S)$ with $S = \{\{A\}, \{B\}, \{C\}, \{A, B\}, \{A, C\}, \{B, C\}\}$ and that the pair $Y := (U, T)$ with $T = \mathcal{P}(U) \setminus \{\varnothing\}$ are abstract simplicial complexes. We illustrate these two abstract simplicial complexes in the figure below.[1128]

(2) Let $n \in \mathbb{N}$. The pairs
   (a) $D_n := (V, S)$ with $V = \{0, \ldots, n\}$ and $S = \mathcal{P}(V) \setminus \{\varnothing\}$, and
   (b) $S_{n-1} := (V, T)$ with $V = \{0, \ldots, n\}$ and $T = \mathcal{P}(V) \setminus \{\varnothing, V\}$,
   are abstract simplicial complexes.
(3) (a) Given $n \in \mathbb{N}_{\geq 3}$ the pair $R_n = (V, S)$ with

$$V := \mathbb{Z}_n \quad \text{and} \quad S := \{\{k\} \,|\, k \in \mathbb{Z}_n\} \cup \{\{k, k+1\} \,|\, k \in \mathbb{Z}_n\}$$

   is an abstract simplicial complex.
   (b) The pair $R_\infty := (V, S)$ with

$$V := \mathbb{Z} \quad \text{and} \quad S := \{\{n\} \,|\, n \in \mathbb{Z}\} \cup \{\{n, n+1\} \,|\, n \in \mathbb{Z}\}$$

[1128] To simplify the figures we will not draw the "trivial" simplices that are given by the vertices.

is an abstract simplicial complex.

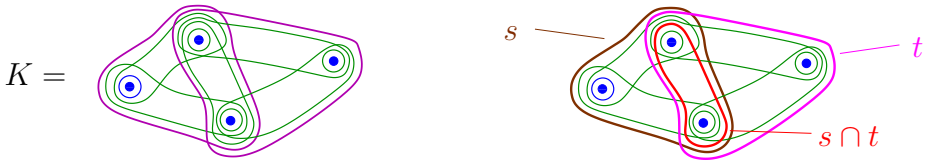
We illustrate these two abstract simplicial complexes in the figure below.

Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) We say $K = (V, S)$ is finite if V is finite.[1129] Similarly we say $K = (V, S)$ is countable if V is countable.
(2) If $s \in S$ has $k + 1$ elements, then s is called a k-dimensional simplex, or shorter, a k-simplex of (V, S).
(3) If $K = (V, S)$ is the empty abstract simplicial complex, then we define its dimension as -1. Now suppose that $K = (V, S)$ is non-empty. We define

$$\dim(K) \ := \ \max\{\#s - 1 \,|\, s \in S\} \ \in \ \mathbb{N}_0 \cup \{\infty\}.$$

In other words, the dimension of $K = (V, S)$ is the maximal dimension of a simplex of $K = (V, S)$.



Examples.

(1) The above abstract simplicial complex (U, S) is 1-dimensional and the above abstract simplicial complex (U, T) is 2-dimensional.
(2) Let $n \in \mathbb{N}$. The abstract simplicial complex D_n is n-dimensional and the abstract simplicial complex S_{n-1} is $(n-1)$-dimensional
(3) The abstract simplicial complexes R_n and R_∞ are one-dimensional.

We continue with a few more harmless definitions and statements.

Definition. Let $K = (V, S)$ be an abstract simplicial complex. Let t be a simplex. A face of t is a simplex s with $s \subset t$.

Lemma 93.1. Let $K = (V, S)$ be an abstract simplicial complex. Furthermore let s and t be two simplices. Then either the intersection $s \cap t$ is empty, or the intersection $s \cap t$ is again a simplex and it is a face of s and t.

Proof. Let s and t be two simplices of an abstract simplicial complex $K = (V, S)$. If $s \cap t = \varnothing$ then there is nothing to show. Now suppose that $s \cap t \neq \varnothing$. Evidently $s \cap t$ is a non-empty subset of s and t. By definition of an abstract simplicial complex this means that $s \cap t$ is also a simplex. Furthermore, since $s \cap t \subset s$ and $s \cap t \subset t$ the intersection is a face of s and t. ■

[1129] Note that this implies that S is also finite. In fact since every $v \in V$ defines a simplex we see that an abstract simplicial complex is finite if and only if S is finite.

Definition. Let $L = (W, T)$ be an abstract simplicial complex. An abstract subcomplex of $L = (W, T)$ is a pair $K = (V, S)$ with $V \subset W$, with $S \subset T$ and such that $K = (V, S)$ is an abstract simplicial complex in its own right. On most occasions we just say "subcomplex" instead of "abstract subcomplex".

Examples.

(1) Basically by definition $X = (U, S)$ is a subcomplex of $Y = (U, T)$.
(2) Let $n \in \mathbb{N}$. Again, basically by definition S_{n-1} is a subcomplex of D_n.
(3) Let $K = (V, S)$ be an abstract simplicial complex and let $n \in \mathbb{N}_0$. We refer to V together with all simplices of dimension $\leq n$ as the *n-skeleton of the abstract simplicial complex*. It is basically clear from the definitions that the n-skeleton is a subcomplex. For convenience we also write $K^\infty := K$.
(4) Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$.
   (a) The pair $(s, \mathcal{P}(s) \setminus \{\varnothing\})$ is a subcomplex of K. Often we abbreviate this subcomplex to s.
   (b) The pair $(s, \mathcal{P}(s) \setminus \{\varnothing, s\})$ is a subcomplex of K. Usually we refer to this subcomplex as ∂s.

The following lemma gives us elementary ways to construct subcomplexes.

Lemma 93.2. Let $\{L_i = (W_i, T_i)\}_{i \in I}$ be a family of abstract simplicial complexes. The following statements hold:

(1) $$\bigcap_{i \in I} L_i := \left(\bigcap_{i \in I} W_i, \bigcap_{i \in I} V_i \right) \quad \text{and} \quad \bigcup_{i \in I} L_i := \left(\bigcup_{i \in I} W_i, \bigcup_{i \in I} V_i \right)$$
are abstract simplicial complexes.
(2) $\bigcap_{i \in I} L_i$ is a subcomplex of each L_i and each L_i in turn is a subcomplex of $\bigcup_{i \in I} L_i$.
(3) If each L_i is a subcomplex of some abstract simplicial complex K, then $\bigcap_{i \in I} L_i$ and $\bigcup_{i \in I} L_i$ are also subcomplexes of K.

Proof. The lemma is close to being a tautology. ∎

As the reader will know by now, not only do we want to study objects, we also want to study maps or morphisms between them. The following gives us the type of maps we are now interested in.

Definition. Let $K = (V, S)$ and $L = (W, T)$ be abstract simplicial complexes.

(1) A simplicial map $f \colon K \to L$ is defined as a map $f \colon V \to W$ such that for every $s \in S$ we have $f(s) \in T$. In particular a simplicial map induces a map $S \to T$.
(2) A simplicial isomorphism between $K = (V, S)$ and $L = (W, T)$ is a simplicial map that is a bijection on the set of vertices and on the set of simplices.

Examples.

(1) The identity map of $U = \{A, B, C\}$ defines a simplicial map from $X = (U, S)$ to $Y = (U, T)$.
(2) The map $f \colon \{0, 1, 2\} \to \{A, B, C\}$ given by $f(0) = A$, $f(1) = B$ and $f(2) = C$ defines a simplicial isomorphism between D_2 and (U, T) and it defines a simplicial

isomorphism between S_1 and (U, S). Similarly one sees that the abstract simplicial complex R_3 is simplicially isomorphic to S_1 and (U, S).

(3) The inclusion of a subcomplex into an abstract simplicial complex is, basically by definition, a simplicial map.

It is clear that the composition of simplicial maps is again a simplicial map. Thus it makes sense to introduce the following definition.

Definition. We call the category $\mathcal{AbsSimpCplx}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{AbsSimpCplx}) &:= \text{all abstract simplicial complexes,} \\ \mathrm{Mor}(K, L) &:= \text{all simplicial maps from } K \text{ to } L, \end{aligned}$$

together with the usual composition of maps the category of abstract simplicial complexes.

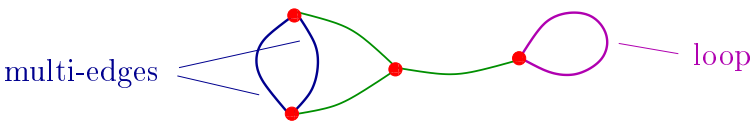
For future reference let us record the following lemma.

Lemma 93.3. Let K and L be two abstract simplicial complexes.

(1) If K and L are finite, then there exist only finitely many simplicial maps from K to L.

(2) If K is finite and if L is countable, then there exist only countably many simplicial maps from K to L.

Proof.



(1) This statement is obvious.

(2) Let $K = (V, S)$ and $L = (W, T)$ be two abstract simplicial complexes. We assume that K is finite and that L is countable. It follows from the Countability Lemma 0.8 (6) that there exist only countably many maps $V \to W$. Furthermore, since V is finite we see that given any map $V \to W$ there are only finitely many maps $S \to T$ such that the resulting map is a simplicial map. It follows from the Countability Lemma 0.8 (3) that there are indeed only countably many simplicial maps. ∎

Remark. The reader might have a certain sense of déjà vu: the definition of a 1-dimensional abstract simplicial complex sounds very similar to the definition of an undirected abstract graph which we gave on page 313. In fact some thought shows that the concepts are different since undirected graphs are more flexible. But once we rule out loops and multi-edges (see the figure below for a pictorial reminder of the definitions), then the concepts are basically the same. More precisely it follows easily from the definitions that the maps

$$\underbrace{(V, E, \varphi\colon E \to \mathcal{P}(V))}_{\substack{\text{undirected abstract graph} \\ \text{without loops \& multi-edges}}} \longmapsto \underbrace{(V, \varphi(E))}_{\substack{\text{1-dimensional abstract} \\ \text{simplicial complex}}} \quad \text{and} \quad \underbrace{(V, S \subset \mathcal{P}(V))}_{\substack{\text{1-dimensional abstract} \\ \text{simplicial complex}}} \longmapsto \underbrace{(V, S, \mathrm{id}\colon S \to \mathcal{P}(V))}_{\substack{\text{undirected abstract graph} \\ \text{without loops \& multi-edges}}}$$

define an isomorphism between the "category of undirected abstract graphs without loops and multi-edges" and the "category of 1-dimensional simplicial complexes".

93.2. **Ordered abstract simplicial complexes.** We recall the following definition from page 94.

Definition.

(1) A relation that is reflexive, transitive and antisymmetric is called a partial order.
(2) A partially ordered set is a set together with a partial order.
(3) A partial order that is connex is called a total order.
(4) A totally ordered set is a set together with a total order.
(5) In a totally ordered set $(P, \leq)$ we write $a < b$ if $a \leq b$ and $a \neq b$.

Examples.

(1) Let X be a set. We consider the power set $\mathcal{P}(X)$. The relation "$\subset$" is a partial order on $\mathcal{P}(X)$.
(2) The usual relation "$\leq$" on $\mathbb{Z}$ turns $\mathbb{Z}$ into a totally ordered set.
(3) Any subset of $\{A, B, \ldots, Z\}$ with the usual alphabetical ordering is a totally ordered set.

We continue with the following definition.

Definition.

(1) A total order on an abstract simplicial complex (V, S) is a total order on the vertex set S.
(2) An order on an abstract simplicial complex (V, S) is a partial order on V which has the property that the restriction to each simplex is actually a total order.
(3) An ordered abstract simplicial complex is an abstract simplicial complex together with an order.

Remark.

(1) Every totally ordered abstract simplicial complex is automatically also an ordered simplicial complex.
(2) By the Well-Ordering Theorem 0.7 we know that every set admits a total ordering. Thus every abstract simplicial complex can be turned into a totally ordered abstract simplicial complex.

The following definition is the obvious variation on the definition provided on page 1981.

Definition. We call the category $\mathit{OrdAbsSimpCplx}$ with

$$\begin{aligned} \mathrm{Ob}(\mathit{OrdAbsSimpCplx}) &:= \text{all ordered abstract simplicial complexes,} \\ \mathrm{Mor}(K, L) &:= \text{all order-preserving simplicial maps from } K \text{ to } L, \end{aligned}$$

together with the usual composition of maps the category of ordered abstract simplicial complexes.

93.3. **The topological realization of an abstract simplicial complex.** Since we are topologists we want to study abstract simplicial complexes with topological methods. The idea is to associate to an abstract simplicial complex a corresponding topological space. Before we can do so we need to introduce the following notation which is inspired by the definition of the free abelian group $\mathbb{Z}^{(S)}$ that we gave on page 1147.

Notation.

(1) Given any set V we write

$$\begin{array}{rcl} \mathbb{R}^V & := & \text{all maps from } V \text{ to } \mathbb{R} \\ \mathbb{R}^{(V)} & := & \text{all maps from } V \text{ to } \mathbb{R} \text{ which are non-zero for only finitely many } v \in V. \end{array}$$

We have the following conventions and observations:

(a) Given $v \in V$ we sometimes denote by v also the map $V \to \mathbb{R}$ which is given by $v \mapsto 1$ and $w \mapsto 0$ for $w \neq v$.

(b) One can easily verify that with this interpretation the set V forms a basis for the real vector space $\mathbb{R}^{(V)}$.

(c) If $V = \{v_1, \ldots, v_n\}$ is a finite set, then the map $v_i \mapsto e_i$ defines an isomorphism from $\mathbb{R}^V = \mathbb{R}^{(V)}$ to $\mathbb{R}^n$. In particular, if V is a finite set with a total order, then it follows from Exercise 0.4 that we have a natural isomorphism $\mathbb{R}^V \xrightarrow{\cong} \mathbb{R}^{|V|}$.

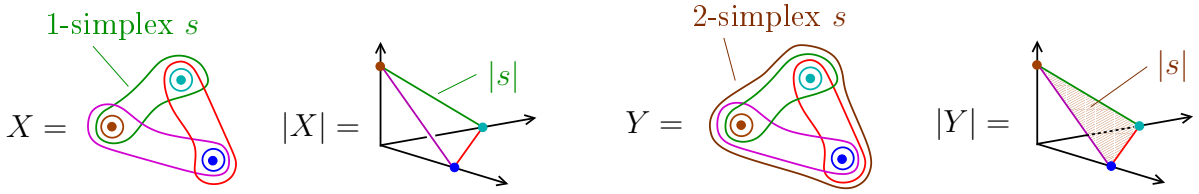
(2) If V is a subset of some set W, then we view $\mathbb{R}^{(V)}$ as a subset of $\mathbb{R}^{(W)}$ in the obvious way.

The following definition is the first step in our shift back to topology.

Definition. Let $K = (V, S)$ be some abstract simplicial complex. For a given n-simplex $s = \{v_0, \ldots, v_n\}$ we define

$$|s| := \left\{ \alpha \in \mathbb{R}^{(V)} \;\middle|\; \begin{array}{l} (1)\ \alpha(v) \geq 0 \text{ for all } v \in s \\ (2)\ \alpha(v) = 0 \text{ for all } v \notin s \\ (3)\ \text{we have } \sum_{v \in V} \alpha(v) = 1 \end{array} \right\} = \left\{ \underbrace{\sum_{i=0}^{n} t_i \cdot v_i}_{\in \mathbb{R}^{(V)}} \;\middle|\; \begin{array}{l} (1)\ \text{for each } i \text{ we have } t_i \geq 0 \\ (2)\ t_0 + \cdots + t_n = 1 \end{array} \right\}$$

Furthermore we set



$$|K| := \bigcup_{s \in S} |s| \subset \mathbb{R}^{(V)}.$$

Sometimes, by a serious abuse of language, we refer to $|s|$ as a n-simplex in $|K|$.

Examples.

(1) We consider the abstract simplicial complexes $X = (U, S)$ and $Y = (U, T)$ as above. The corresponding sets $|X|$ and $|Y|$ are the subsets of $\mathbb{R}^U = \mathbb{R}^{\{A,B,C\}} = \mathbb{R}^3$ that are shown in the figure below.

(2) Let $n \in \mathbb{N}$. Given the abstract simplicial complex R_n the corresponding set $|R_n|$ is a subset of $\mathbb{R}^{\mathbb{Z}_n} = \mathbb{R}^{n-1}$. This means that for $n \geq 5$ we have serious problems with visualizing the set $|R_n|$. The problem is even bigger for the infinite abstract simplicial complex R_∞.

Lemma 93.4. Given any abstract simplicial complex $K = (V, S)$ we have

$$|K| = \left\{ \alpha \in \mathbb{R}^{(V)} \;\middle|\; \begin{array}{ll} (1) & \text{the set } \{v \in V \,|\, \alpha(v) \neq 0\} \text{ is a simplex of } K \\ (2) & \text{for every } v \in V \text{ we have } \alpha(v) \geq 0 \\ (3) & \text{we have } \sum_{v \in V} \alpha(v) = 1 \end{array} \right\}.$$

Proof. We leave the elementary task of proving the equality to the reader. Note though that one actually needs to use that $K = (V, S)$ is an abstract simplicial complex. ■

Note that as of right now $|K|$ is just a set. But rest assured, we will equip $|K|$ with a suitable topology shortly.[1130] But first let us introduce a convention.

Convention. Let $K = (V, S)$ be an abstract simplicial complex. As discussed above, we can view V as a subset of $\mathbb{R}^{(V)}$. In fact it follows easily from the definitions that $V \subset |K|$. Throughout these notes we use this observation to view V as a subset of $|K|$.

We continue with the following definition.

Definition. Let $K = (V, S)$ be an abstract simplicial complex. Let $k \in \mathbb{N}_0$ and let s be a k-simplex.

(1) If $v_0 \leq \cdots \leq v_k$ is a total order on the set of vertices of s, then we refer to the map

$$\begin{aligned} \Phi_s \colon \Delta^k = \left\{ (t_0, \ldots, t_k) \in \mathbb{R}^{k+1}_{\geq 0} \;\middle|\; \sum_{i=0}^{k} t_i = 1 \right\} &\to |K| \\ (t_0, \ldots, t_k) &\mapsto \sum_{i=0}^{k} t_i \cdot v_i \end{aligned}$$

as a characteristic map of the simplex s.

(2) If K is actually an ordered abstract simplicial complex, then we use the corresponding order on s and we write $\Phi_s^{\leq} \colon \Delta^k \to |K|$. In this case we can refer to $\Phi_s^{\leq}$ unambiguously as the characteristic map of the simplex s.

Remark.

(1) Note that if in the above definition of a characteristic map we use two different orderings of the vertices of s, then we get two maps $\Phi, \Psi \colon \Delta^k \to |K|$ with the same image and such that $\Psi^{-1} \circ \Phi \colon \Delta^k \to \Delta^k$ is a homeomorphism. In other words, any two characteristic maps differ by precomposing by a homeomorphism. In practice this means that any two characteristic maps exhibit the same properties and we do not need to distinguish between different characteristic maps.

(2) Given a k-simplex s we have, by definition, $\Phi_s(\Delta^k) = |s|$.

Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) We say that a subset $U \subset |K|$ is open if for every simplex s of K the preimage $\Phi_s^{-1}(U)$ under a characteristic map[1131] Φ_s is open. An argument as in Exercise 2.37 shows that this defines a topology on $|K|$.

(2) We refer to the set $|K|$, together with this topology, as the topological realization of K.

[1130] A first idea might be to equip $\mathbb{R}^{(V)}$ with a suitable topology and then to endow $|K|$ with the subspace topology. But this is not really a good idea since this topology is artificial and does not reflect the structure of K. For example it would be rather unpleasant to have to show that a map out of K is continuous.

The following lemma summarizes a few basic properties of the topological realization of an abstract simplicial complex.

Lemma 93.5. (Simplex-Embedding Lemma) Let K be an abstract simplicial complex.

(1) A subset $A \subset |K|$ is closed if and only if for every simplex s of K the preimage $\Phi_s^{-1}(A)$ under a characteristic map Φ_s is closed.
(2) The topological realization $|K|$ is Hausdorff.
(3) For every k-simplex $s = \{v_0, \ldots, v_k\}$ of K any characteristic map $\Phi_s \colon \Delta^k \to |K|$ is a closed embedding. In particular the map $\Phi_s \colon \Delta^k \to |s|$ is a homeomorphism.

Proof. Let $K = (V, S)$ be an abstract simplicial complex.

(1) This statement follows almost immediately from the definition of the topology on $|K|$ together with the elementary the Image-Preimage Lemma 0.2 (8).
(2) Let P and Q be two disjoint points on $|K|$. Given $f, g \in \mathbb{R}^{(V)}$ we write

$$d(f,g) \;:=\; \sqrt{\sum_{v \in V} (f(v) - g(v))^2}.$$

One can easily verify that this is a metric on $\mathbb{R}^{(V)}$. By Proposition 1.13 we know that there exists an $\epsilon > 0$ such that the open ϵ-balls $B_\epsilon(P)$ and $B_\epsilon(Q)$ are disjoint in $\mathbb{R}^{(V)}$. It remains to show that $B_\epsilon(P) \cap |K|$ and $B_\epsilon(Q) \cap |K|$ are open in $|K|$. By definition of the topology on $|K|$ we need to prove the following claim.

Claim. Let $U := B_\epsilon(R)$ be an ϵ-ball in $\mathbb{R}^{(V)}$. For every simplex s the preimage $\Phi_s^{-1}(U \cap |K|)$ under a characteristic map Φ_s is open.

Proof. Let $s = \{v_0, \ldots, v_k\}$ be a k-simplex. We make the following observations:
(a) We have $\Phi_s^{-1}(U \cap |K|) = \Phi_s^{-1}(U)$.
(b) It follows from (a) and the observation that U is an open subset of the topological space $(\mathbb{R}^{(V)}, d)$ that it suffices to show that the map $\Phi_s \colon \Delta^k \to (\mathbb{R}^{(V)}, d)$ is continuous.
(c) We view $\Phi_s \colon \Delta^k \to \mathbb{R}^{(V)}$ as the composition of the maps

$$\Delta^k \;\xrightarrow{\Phi_s}\; \mathbb{R}^{k+1} = \mathbb{R}^{(s)} \;\hookrightarrow\; \mathbb{R}^{(V)}.$$

We consider the two maps separately.
(i) Note that $\mathbb{R}^{k+1} = \mathbb{R}^{(s)}$ is a finite-dimensional vector space and that the map $\Phi_s \colon \Delta^k \to \mathbb{R}^{(s)}$ is an affine linear map. It follows almost immediately from the Standard Simplex Homeomorphism Lemma 72.1 that this map is continuous.
(ii) It follows easily from the definition of topology on $\mathbb{R}^{k+1}$, via the usual Euclidean metric, and the definition of the metric d on $\mathbb{R}^{(V)}$, together with the simple-minded Exercise 2.13 (a), that the map $\mathbb{R}^{k+1} = \mathbb{R}^{(s)} \to \mathbb{R}^{(V)}$ is continuous.
Thus we see that the map $\Phi_s \colon \Delta^k \to (\mathbb{R}^{(S)}, d)$ itself is continuous. ⊞

[1131] It follows from the above remark that the statement that $\Phi_s^{-1}(U)$ is open does not depend on the choice of the characteristic map for the simplex s.

(3) Let s be a k-simplex of K. It follows almost immediately from the definitions that the map $\Phi_s\colon \Delta^k \to |K|$ defines a bijection $\Phi_s\colon \Delta^k \to |s|$. It follows immediately from the definition of the topology on $|K|$ that Φ_s is continuous. Evidently Δ^k is compact. By (1) we know that $|K|$ is Hausdorff. So once again the Compact-Hausdorff Proposition 2.17 (2) rides to our rescue and tells us that Φ_s is indeed an embedding and that the image is a closed subset. ■

The following is the simplicial analogue of the corresponding the Characteristic Maps Lemma 68.7 for CW-complexes.

Lemma 93.6. (Restrict-to-Simplex Lemma) Let $K = (V, S)$ be an abstract simplicial complex and let $f\colon |K| \to X$ be a map to some topological space X.

(1) If for each k-simplex $s \in S$ with characteristic map $\Phi_s\colon \Delta^k \to |K|$ the composition $f \circ \Phi_s\colon \Delta^k \to X$ is continuous, then the map f is continuous.

More generally we have the following continuity criterion:

(2) If for each simplex $s \in S$ there exists a k-simplex t with $s \subset t$ such that for some characteristic map $\Phi_t\colon \Delta^k \to |K|$ the composition $f \circ \Phi_t\colon \Delta^k \to X$ is continuous, then the map f is continuous.

Proof.

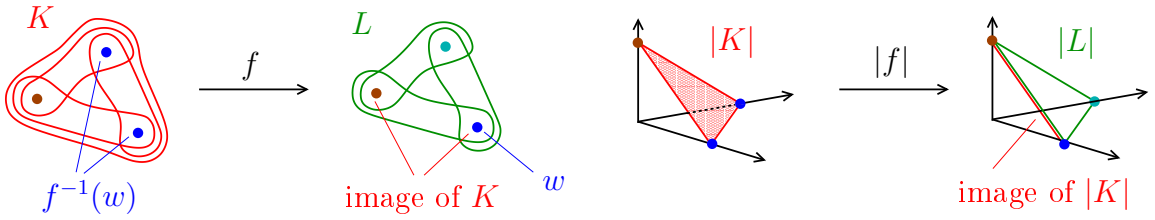
(1) This statement follows immediately from the definition of the topology on $|K|$.

(2) This statement follows immediately from (1) and the observation that characteristic maps are continuous. ■

The following proposition shows that not only do abstract simplicial complexes give rise to topological spaces, but simplicial maps also give rise to continuous maps between the topological realizations.

Proposition 93.7.

(1) If $f\colon K = (V, S) \to L = (W, T)$ is a simplicial map, then the map



$$\begin{array}{rcl} |f|\colon |K| & \to & |L| \\ (\alpha\colon V \to \mathbb{R}) & \mapsto & \left(\begin{array}{ccc} W & \to & \mathbb{R} \\ w & \mapsto & \sum\limits_{v \in f^{-1}(w)} \alpha(v) \end{array} \right) \end{array}$$

is well-defined and continuous. We refer to the figure below for an illustration.

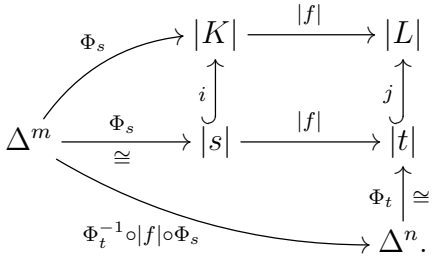
(2) Let $\mathcal{AbsSimpCplx}$ be the category of abstract simplicial complexes. The maps

$$\begin{array}{rcl} K & \mapsto & |K| \\ (f\colon K \to L) & \mapsto & (|f|\colon |K| \to |L|) \end{array}$$

define a covariant functor from the category $\mathcal{AbsSimpCplx}$ of abstract simplicial complexes to the category $\mathcal{Top}$ of topological spaces.

Remark.

(1) Let $f\colon K = (V, S) \to L = (W, T)$ be a simplicial map. It is elementary to see that, given a simplex $s = \{v_0, \ldots, v_k\}$ of K, the restriction of $|f|$ to $|s| \subset |K|$ is the map



$$\begin{array}{rcl} |f|\colon |s| & \to & |f(s)| \\ \sum\limits_{i=0}^{k} t_i \cdot v_i & \mapsto & \sum\limits_{i=0}^{k} t_i \cdot f(v_i). \end{array}$$

(2) As we will see, the proof of Proposition 93.7 (1) is slightly delicate since the topology of the topological realization of a simplicial complex is designed, see the Restrict-to-Simplex Lemma 93.6, in such a way that it is straightforward to verify that a map *out* of the topological realization is continuous. It is much less clear how one can show that a map *to* a topological realization is continuous. The same health-warning applies also to CW-complexes.

Proof.

(1) Let $f\colon K = (V, S) \to L = (W, T)$ be a simplicial map. A priori we have written down a map $|f|\colon |K| \to \mathbb{R}^{(W)}$. But it is straightforward to verify, e.g. using Lemma 93.4, that the map $|f|$ does indeed take values in the subset $|L|$. It remains to show that $|f|\colon |K| \to |L|$ is continuous. By the Restrict-to-Simplex Lemma 93.6 (1) it suffices to show that for each m-simplex $s \in S$ with some characteristic map $\Phi_s\colon \Delta^m \to |K|$ the composition $f \circ \Phi_s\colon \Delta^m \to |L|$ is continuous.

Thus suppose we are given such s and Φ_s. We write $t := f(s)$. By definition of a simplicial map we know that t is some n-simplex of T. For clarity we consider the following commutative diagram:

We make the following clarifications and observations:

(a) We define $|s| \subset |K|$ and $|t| \subset |L|$ as in the Simplex-Embedding Lemma 93.5 (3). We equip both with the subspace topology coming from $|K|$ and $|L|$. By the super elementary Lemma 2.1 (2) we know that the inclusion maps $i\colon |s| \to |K|$ and $j\colon |t| \to |L|$ are continuous.

(b) It follows immediately from the definition of $|f|$ that the restriction of $|f|$ to $|s|$ takes values in $|t|$.

(c) We picked a characteristic map $\Phi_t\colon \Delta^n \to |t|$ for t.

(d) By the Simplex-Embedding Lemma 93.5 (3) we know that the characteristic map $\Phi_t\colon \Delta^n \to |t|$ is a homeomorphism. In particular the inverse $\Phi_t^{-1}\colon |t| \to \Delta^n$ exists and it is continuous.

(e) It follows almost immediately from the definitions of the maps Φ_s, Φ_t and $|f|$ that the map $\Phi_t^{-1} \circ |f| \circ \Phi_s\colon \Delta^m \to \Delta^n$ is an affine linear map. Hence it follows,

say from the Standard Simplex Homeomorphism Lemma 72.1, that the map is continuous.

(f) It follows immediately from the above that the map

$$|f| \circ \Phi_s \;=\; j \circ \Phi_t \circ (\Phi_t^{-1} \circ |f| \circ \Phi_s) \colon \Delta^m \;\to\; Y$$

is indeed continuous.

(2) Let $f \colon K \to L$ and $g \colon L \to M$ be simplicial maps. For any vertex v of M we have $f^{-1}(g^{-1}(v)) = (g \circ f)^{-1}(v)$. It follows immediately from this observation that $|g| \circ |f| = |g \circ f|$. It is now straightforward to see that the given maps define a covariant functor. ■

The following lemma can be viewed as an analogue of the Subcomplex Lemma 68.18, which we formulated in the context of CW-complexes.

Lemma 93.8. (Subcomplex Lemma) Let $K = (V, S)$ be a subcomplex of some given abstract simplicial complex $L = (W, T)$.

(1) The inclusion $\mathbb{R}^{(V)} \to \mathbb{R}^{(W)}$ restricts to an inclusion $|K| \to |L|$.
(2) The inclusion $|K| \to |L|$ is a closed embedding.
(3) Let $\{K_i\}_{i \in I}$ be a family of subcomplexes of an abstract simplicial complex K. Then

$$\Big|\bigcap_{i\in I} K_i\Big| \;:=\; \bigcap_{i\in I} |K_i| \quad \text{and} \quad \Big|\bigcup_{i\in I} K_i\Big| \;:=\; \bigcup_{i\in I} |K_i|.$$

are subcomplexes of K.

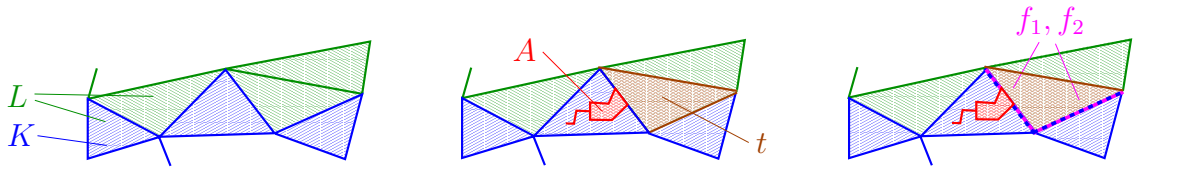
Remark. The statement and the proof of Lemma 93.8 is closely related to the content of the Subcomplex Lemma 68.18.

Convention. Let $K = (V, S)$ be a subcomplex of some given abstract simplicial complex $L = (W, T)$. We will use Lemma 93.8 to view $|K|$ as a subset of $|L|$. By Lemma 93.8 (2) we know that $|K|$ is in fact a closed subset of $|L|$.

Proof. Let $L = (W, T)$ be a simplicial complex and let $K = (V, S)$ be a subcomplex. We denote by $i \colon K \to L$ the inclusion map.

(1) It follows immediately from the definitions that the inclusion $\mathbb{R}^{(V)} \to \mathbb{R}^{(W)}$ restricts to an inclusion $|K| \to |L|$.
(3) This statement also follows immediately from the definitions. For readers who want to fill in the details, perhaps it is clearest to look at the description given in Lemma 93.4.
(2) Since $i \colon K \to L$ is a simplicial map we obtain from Proposition 93.7 (1) that the induced map $|i| \colon |K| \to |L|$ is continuous. Furthermore it follows easily from the definitions that the map $|i| \colon |K| \to |L|$ is in fact just the inclusion. In the remainder of the proof we will view $|K|$ as a subset of $|L|$.

By the Open -Injective Map Lemma 2.16 (1) it remains to show that the inclusion $|K| \to |L|$ is a closed map. Thus let $A \subset |K|$ be a closed subset. We need to show that A is also a closed subset of $|L|$. By the Simplex-Embedding Lemma 93.5 (1) and (3) it suffices to show that for each $t \in T$ the set $A \cap |t|$ is closed. Note that every simplex, in particular t itself, has only finitely many faces. Let $f_1, \ldots, f_m$ be



the faces of t that are contained in K. We consider the subsets $|f_1|, \ldots, |f_m|$ of $|K|$ and the subset $|t|$ of $|L|$ as defined on page 1983. We make the following observation:

(∗) It follows from the Simplex-Embedding Lemma 93.5 that the subspace topologies on $|f_i|$ coming from $|f_i| \subset |K|$ and $|f_i| \subset |t| \subset |L|$ agree and that $|f_i|$ is a closed subset of $|K|$ and a closed subset of $|t|$.

We have

$$\begin{aligned} A \cap |t| &= A \cap (|K| \cap |t|) && = A \cap \bigcup_{i=1}^{m} |f_i| = \bigcup_{i=1}^{m} (A \cap |f_i|) \\ &\uparrow \text{ since } A \subset |K| && \uparrow \text{ this follows from (3) since } K \text{ is a subcomplex} \\ &= \bigcup_{i=1}^{m} \text{closed subset of } |f_i| && = \bigcup_{i=1}^{m} \text{closed subset of } |t| = \text{closed subset of } |t|. \\ &\uparrow \text{ since } A \text{ is closed in } |K| \text{ and since} && \uparrow \text{ by the Open -Closed Inclusion Lemma 2.10 (2) since by the} \\ &\quad f_1, \ldots, f_m \in S \text{ are simplices of } K && \quad \text{Simplex-Embedding Lemma 93.5 (3) we know} \\ &&& \quad \text{that the } |f_i| \text{ are closed subsets of } |t| \end{aligned}$$

■

Example. Let $n \in \mathbb{N}$. We consider again the simplicial complex D_n and its subcomplex S_{n-1}. It follows almost immediately from the Simplex-Embedding Lemma 93.5 (3) that the map

$$\begin{aligned} \Psi \colon |D_n| &\to \Delta^n \\ \sum_{i=0}^{n} t_i \cdot \{i\} &\mapsto (t_0, \ldots, t_n) \end{aligned}$$

is a homeomorphism. By Proposition 93.7 (2) the map $|S_{n-1}| \to |D_n|$ is an embedding. Thus Ψ restricts to a homeomorphism $\Psi|_{|S_{n-1}|} \colon |S_{n-1}| \to \Psi(|S_{n-1}|)$ but basically by definition we have $\Psi(|S_{n-1}|) = \partial\Delta^n$. This shows that $|S_{n-1}|$ is homeomorphic to $\partial\Delta^n$.

Before we consider some examples we want to consider the topology for finite abstract simplicial complexes in greater detail. We recall that given any finite set X the vector space $\mathbb{R}^{(X)}$ is a finite-dimensional vector space. Furthermore recall that by the discussion on page 153 we know that any finite-dimensional real vector space has a natural topology.

Lemma 93.9. Let $K = (V, S)$ be an abstract simplicial complex. If K is finite, then the following two conclusions hold:

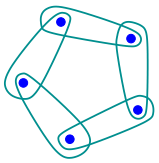
(1) The topological realization $|K|$ is compact.
(2) The topology of the topological realization $|K|$, defined on page 1984, agrees with the subspace topology which we obtain from viewing $|K|$ as a subset of the finite-dimensional real vector space $\mathbb{R}^V$.

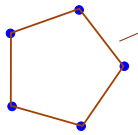
Proof. Let $K = (V, S)$ be a finite abstract simplicial complex.

(1) By the Simplex-Embedding Lemma 93.5 we know in particular that for each k-simplex s the characteristic map $\Phi_s \colon \Delta^k \to |K|$ is continuous. Since Δ^k is compact we obtain from the Compact Image Lemma 2.13 that $|s| = \Phi_s(\Delta^k)$ is compact. By definition $|K|$ is the union of all the subsets $|s|$. Thus, since K is finite we see that $|K|$

is the union of finitely many compact subsets. By the Compact-Union-Intersection Lemma 1.20 (1) this implies that $|K|$ itself is compact.

(2) We write $V = \{v_1, \ldots, v_n\}$ and we identify the vector spaces $\mathbb{R}^V$ and $\mathbb{R}^n$ in the obvious way. We denote by $\mathcal{T}$ the topology on $|K|$ defined above and we denote by $\mathcal{R}$ the subspace topology which comes from $\mathbb{R}^V$. We need to show that the identity map defines a homeomorphism $(|K|, \mathcal{T}) \to (|K|, \mathcal{R})$. We make the following observations:
   (a) For any k-simplex $s \in S$ and any characteristic map $\Phi_s \colon \Delta^k \to |s|$ the corresponding map $\Delta^k \xrightarrow{\Phi_s} |s| \to |K| \to \mathbb{R}^V = \mathbb{R}^n$ is an affine linear map. It follows from the Standard Simplex Homeomorphism Lemma 72.1 that this map is continuous. It follows from this observation together with the Restrict-to-Simplex Lemma 93.6 (1) that the map $(|K|, \mathcal{T}) \to (|K|, \mathcal{R})$ is continuous.
   (b) In (1) we just argued that $(|K|, \mathcal{T})$ is compact.
   (c) The topological space $(|K|, \mathcal{R})$ is evidently Hausdorff.
   It follows from the Compact-Hausdorff Proposition 2.17 (3) that the identity map is indeed a homeomorphism. ■





As we already noted above, the topological realizations of abstract simplicial complexes have a voracious appetite for dimensions. Fortunately, as well see shortly, in many cases we can reduce the dimensions drastically.

Lemma 93.10. Let $K = (V, S)$ be a finite abstract simplicial complex and let $\varphi \colon \mathbb{R}^V \to \mathbb{R}^n$ be a linear map such that the restriction of φ to $|K|$ is an injection. Then $\varphi \colon |K| \to \mathbb{R}^n$ is an embedding.

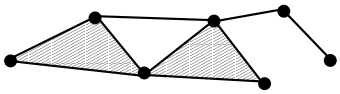
Proof. By Lemma 93.9 (1) we know that $|K|$ is compact. Furthermore, note that it follows from Lemma 93.9 (2) that the linear map $\varphi \colon \mathbb{R}^V \to \mathbb{R}^n$ restricts to a continuous map $\varphi \colon |K| \to \mathbb{R}^n$. Since $\mathbb{R}^n$ is Hausdorff it follows from the Compact-Hausdorff Proposition 2.17 (2) that $\varphi \colon |K| \to \mathbb{R}^n$ is indeed an embedding. ■

Example.

(1) Let $n \in \mathbb{N}_{\geq 3}$. As above we consider the abstract simplicial complex R_n. We consider the linear map $\varphi \colon \mathbb{R}^{\mathbb{Z}_n} \to \mathbb{R}^2$ that is given by $[k] \mapsto \exp(2\pi \mathrm{i} k/n)$. One can easily verify that the restriction of φ to $|R_n|$ is an injection. Thus we see that $|R_n|$ is homeomorphic to the regular n-gon that is shown in the figure below.

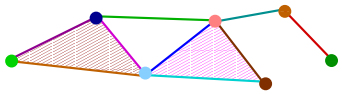
$R_5 =$  $|R_5|$ is homeomorphic to  regular 5-gon in $\mathbb{R}^2$

(2) Using the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19 one can formulate a suitable generalization of Lemma 93.10 to infinite abstract simplicial complexes. We will not work this out in detail, but using this approach one can fairly easily show that the topological realization of the abstract simplicial complex R_∞ is homeomorphic to $\mathbb{R}$. We refer to the figure below for a very convincing illustration of this fact.



$R_\infty =$  $|R_\infty|$ is homeomorphic to

Given an n-simplex s of an abstract simplicial complex $K = (V, S)$ we defined on page 1984 the corresponding subset $|s| \subset |K|$, which, somewhat dangerously, we referred to as an n-simplex of $|K|$. The following definition gives us a convenient variation on that definition.



Definition. Let $K = (V, S)$ be an abstract simplicial complex. If we are given an n-simplex $s = \{v_0, \dots, v_n\} \in S$, then we refer to[1132]

$$\langle s \rangle := \left\{ \alpha \in \mathbb{R}^{(V)} \;\middle|\; \begin{array}{l} (1)\ \alpha(v) > 0 \text{ for all } v \in s \\ (2)\ \alpha(v) = 0 \text{ for all } v \notin s \\ (3)\ \text{we have } \sum_{v \in V} \alpha(v) = 1 \end{array} \right\} = \left\{ \underbrace{\sum_{i=0}^{n} t_i \cdot v_i}_{\in \mathbb{R}^{(V)}} \;\middle|\; \begin{array}{l} (1)\ \text{for each } i \text{ we have } t_i > 0 \\ (2)\ t_0 + \cdots + t_n = 1 \end{array} \right\}$$

as the corresponding open n-simplex of $|K|$.

simplicial complex

the corresponding open simplices

The following lemma summarizes a few properties of open simplices.

Lemma 93.11. (Open Simplex Lemma) Let $K = (V, S)$ be an abstract simplicial complex.

(1) Let $s \in S$ be a k-simplex.
   (a) The closure of the open simplex $\langle s \rangle$ is given by $|s|$.
   (b) Every characteristic map $\Phi_s \colon \Delta^k \to |s|$ restricts to a homeomorphism $\mathring{\Delta}^k \to \langle s \rangle$.

(2) The topological realization $|K|$ is the disjoint union of the open simplices, i.e.

$$|K| \;=\; \bigsqcup_{s \in S} \langle s \rangle.$$

   Put differently, given any $\alpha \in |K|$ there exists a unique simplex s with $\alpha \in \langle s \rangle$.

(3) For two distinct simplices $s \neq t$ we have $\langle s \rangle \cap \langle t \rangle = \varnothing$.

(4) The union of the open simplices is precisely $|K|$.

(5) If $J = (U, R)$ is a subcomplex of K, then

$$|J| \;=\; \bigsqcup_{r \in R} \langle r \rangle \;=\; \bigcup_{r \in R} |r| \quad \text{and for any } s \in S \setminus R \text{ we have } |J| \cap \langle s \rangle = \varnothing.$$

   In particular, if s is a simplex of K with $\langle s \rangle \cap |J| \neq \varnothing$, then s is a simplex of J which implies that $|s| \subset |J|$.

(6) Let s and t be simplices. If $|s| \subset |t|$, then $s \subset t$. In particular, either $\dim(s) < \dim(t)$ or $s = t$.

(7) Let $s \in S$ be a simplex. If $U \subset |K|$ is an open subset with $U \cap |s| \neq \varnothing$, then $U \cap \langle s \rangle \neq \varnothing$.

Proof.

[1132] Here we use the convention of page 1984 which allows us to view V as a subset of $\mathbb{R}^{(V)}$.

(1) Let $s \in S$ be a k-simplex and let $\Phi_s\colon \Delta^k \to |s|$ be a characteristic map. By the Simplex-Embedding Lemma 93.5 (3) we know that the map $\Phi_s\colon \Delta^k \to |s|$ is a homeomorphism and that $|s|$ is a closed subset of $|K|$. By definition we have $\langle s\rangle \subset |s|$.
   (b) It is clear that Φ_s restricts to a bijection $\mathring{\Delta}^k \to \langle s\rangle$. Thus it follows immediately that Φ_s restricts to a homeomorphism $\mathring{\Delta}^k \to \langle s\rangle$.
   (a) Since $|s|$ is a closed subset of $|K|$ we see that the closure of $\langle s\rangle$ in $|K|$ is contained in $|s|$. It is elementary to see that Δ^k is the closure of $\mathring{\Delta}^k$. Since $\Phi_s\colon \Delta^k \to |s|$ is a homeomorphism it follows almost immediately that $|s| = \Phi_s(\Delta^k)$ is indeed the closure of $\langle s\rangle = \Phi_s(\mathring{\Delta}^k)$.
(2) Let $\alpha \in |K|$. We set $s := \{v \in V \,|\, \alpha(v) \neq 0\}$. By definition of $|K|$ we know that s is a simplex. Evidently $\alpha \in \langle s\rangle$ and evidently s is unique.
(3) This statement follows immediately from (1).
(4) Conveniently enough this statement also follows immediately from (1).
(5) Let J be a subcomplex of K. If $r \in R$, then evidently we have $\langle r\rangle \subset |r| \subset |J|$. Keeping (1) in mind we see that it remains to show that if we have $s \in S$ with $|J| \cap \langle s\rangle \neq \varnothing$, then $s \in R$. Thus let s be a simplex of K with $|J| \cap \langle s\rangle \neq \varnothing$. It follows from (1), applied to the abstract simplicial complex $J = (U, R)$, that there exists a simplex r of J with $\langle s\rangle \cap \langle r\rangle \neq \varnothing$. But since r is also a simplex of K we obtain from (1), applied to K, that $s = r \in R$.
(6) Let s and t be simplices with $|s| \subset |t|$. We apply (4) to the subcomplex that is defined by s. We immediately obtain that $s \subset t$. If $s \subsetneq t$, then by definition we have $\dim(s) = \#S - 1 < \#T - 1 = \dim(t)$.
(7) Let $s \in S$ be a k-simplex and let $U \subset |K|$ be an open subset with $U \cap |s| \neq \varnothing$. Let $\Phi_s\colon \Delta^k \to |s|$ be a characteristic map. By definition of the topology on $|K|$ and by our hypothesis we know that $\Phi_s^{-1}(U)$ is an open non-empty subset of Δ^k. It is elementary to see that $\Phi_s^{-1}(U) \cap \mathring{\Delta}^k \neq \varnothing$. It now follows from (1b) that $U \cap \langle s\rangle \neq \varnothing$. ■

The following proposition reminds us of the CW-Complex-Finiteness Theorem 68.14 which gives an analogous statement for CW-complexes. The proposition can also be viewed as a converse to Lemma 93.9 (1).

Proposition 93.12. (Simplicial Complex-Finiteness Proposition) Let L be an abstract simplicial complex.

(1) If $X \subset |L|$ is a compact subset, then there exists a finite subcomplex K of L such that $X \subset |K|$.
(2) If $|L|$ is compact, then L is a finite abstract simplicial complex.

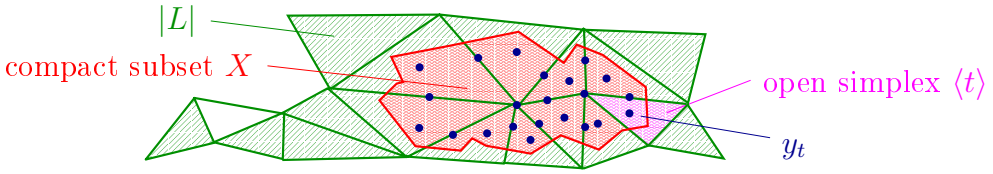
Remark. Let K be an abstract simplicial complex. Lemma 93.9 (1) together with the Simplicial Complex-Finiteness Proposition 93.12 shows that $|K|$ is compact if and only if K is finite. Later on in Proposition 94.6 we will prove the related result that $|K|$ is regionally compact if and only if K is "locally finite".

Proof. Let $L = (W, T)$ be an abstract simplicial complex. Clearly (2) is just a special case of (1). Thus it suffices to prove (1). Now let $X \subset |L|$ be a compact subset. For each simplex t of L with $\langle t\rangle \cap X \neq \varnothing$ we pick a point $y_t \in \langle t\rangle \cap X$. We denote by Y the set given by all the y_t. We equip Y with the subspace topology coming from $|L|$.

Claim.

(1) Every subset of Y, in particular Y itself, is a closed subset of $|L|$.
(2) Y is a discrete subset of $|L|$.

Proof.



(1) Let $A \subset Y$ be a subset. We need to show that A is a closed subset of $|L|$. By the Simplex-Embedding Lemma 93.5 (1) and (3) it suffices to show that for every simplex t of $|L|$ the intersection $A \cap |t|$ is closed. By the Open Simplex Lemma 93.11 (5) we know that $|t|$ intersects only the interiors of the simplices s with $s \subset t$. Since there are only finitely many simplices[1133] contained in t we see that $A \cap |t|$ is finite, in particular it is compact. By the Simplex-Embedding Lemma 93.5 (2) we know that $|t|$ is Hausdorff. Hence we obtain from the Compact-Closed Lemma 1.21 (2) that $A \cap |t|$ is indeed closed.
(2) We need to show that the subspace topology of Y is the discrete topology. It follows from (1) and the Neighborhood Openness Criterion 1.5 that every subset of Y is in fact a closed subset of Y. But this implies that every subset of Y is in fact an open subset of Y. In other words, the subspace topology is indeed the discrete topology. ⊞

It follows from (1) and the definition of the subspace topology that Y is a closed subset of the compact set X. Furthermore by (2) we know that Y is a discrete subset of $|L|$. Since $Y \subset X \subset |L|$ we see that Y is also a discrete subset of X. Since X is compact we obtain from the Compact-Discrete Lemma 1.22 that Y is finite.

We define $S := \{t \in T \,|\, X \cap \langle t \rangle \neq \varnothing\}$. Note that $\#S = \#Y$. Thus, by the above discussion we know that S is finite. Now we set K to be the subcomplex that is given the union of all the simplices $t \in S$.[1134] Since t is finite we see that K is a finite subcomplex. Now we have

$$X \overset{\text{Open Simplex Lemma 93.11 (4)}}{\downarrow =} X \cap \bigcup_{t \in S} \langle t \rangle = \bigcup_{t \in S} X \cap \langle t \rangle \overset{\text{by definition of } t}{\downarrow \subset} \bigcup_{t \in S} \langle t \rangle \subset \bigcup_{t \in S} |s| \overset{\text{Lemma 93.8 (3)}}{\downarrow =} |K|.$$

■

We conclude this section with the following lemma which gives a criterion for a subset of a simplicial complex to be a subcomplex.

Lemma 93.13. Let $L = (W, T)$ be an abstract simplicial complex and let $X \subset |L|$ be a closed subset. If for every simplex $t \in T$ we have either $\langle t \rangle \cap X = \varnothing$ or $\langle t \rangle \subset X$, then there exists a subcomplex K of L with $|K| = X$.

[1133] This finiteness statement makes the proof of this proposition significantly simpler than the technically slightly tricky proof of the CW-Complex-Finiteness Theorem 68.14.
[1134] Strictly speaking we view the simplices as subcomplexes, and then take the union as defined in Lemma 93.2.

Proof. We consider

$$V \;:=\; W \cap X \quad \text{and} \quad S \;:=\; \{t \in T \,|\, \langle t\rangle \subset X\}.$$

Claim. We claim that (V, S) is a subcomplex of $L = (W, T)$.

Proof. Let $s \in S$ be a simplex and let r be a face of s. We need to show that $r \in S$, i.e. we need to show that $\langle r\rangle \subset X$. Basically by definition we have $\langle r\rangle \subset |s|$. Thus it suffices to show that $|s| \subset X$.

Now note note that by the Open Simplex Lemma 93.11 we know that $|s|$ is the closure of the subset $\langle s\rangle$. Since X is by hypothesis a closed subset of $|L|$ we obtain from elementary point-set topology, see e.g. Exercise 2.24 (a), that $|s| \subset X$. ⊞

Now we see that

$$\begin{array}{ccccccccc} |K| & = & \bigcup\limits_{t\in S} \langle t\rangle & = & \bigcup\limits_{\substack{t\in T \text{ with} \\ \langle t\rangle \subset X}} \langle t\rangle & = & \bigcup\limits_{t\in T} (\langle t\rangle \cap X) & = & X. \\ & & \uparrow & & \uparrow & & \uparrow & & \uparrow \\ & & \text{Open Simplex} & & \text{definition} & & \text{by the hypothesis that} & & \text{Open Simplex} \\ & & & & \text{of } S & & \text{either } \langle t\rangle \cap X = \varnothing \text{ or } \langle t\rangle \subset X & & \\ & & \text{Lemma 93.11 (5)} & & & & & & \text{Lemma 93.11 (2)} \end{array}$$

■

93.4. **Simplicial complexes.** As on so many other occasions we start out this new section with a definition.

Definition.

(1) Let X be a topological space. A simplicial structure for X is a pair $(K, \Theta\colon |K| \to X)$ where the following holds:
   (a) K is an abstract simplicial complex,
   (b) Θ is a homeomorphism between the topological realization $|K|$ of K and the topological space X.

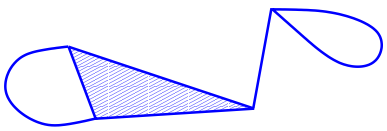
(2) A simplicial complex is a pair $(X, (K = (V, S), \Theta\colon |K| \to X))$ given by a topological space X together with a simplicial structure $(K = (V, S), \Theta\colon |K| \to X)$. We refer to X as the underlying topological space of the simplicial complex. To keep the notation at a manageable level we will often not distinguish in the notation between a simplicial complex and its underlying topological space.

(3) We say a simplicial complex is finite (respectively countable) if the corresponding abstract simplicial complex is *finite* (respectively *countable*).

(4) We say a simplicial complex is (totally) ordered if the corresponding abstract simplicial complex is (totally) ordered.

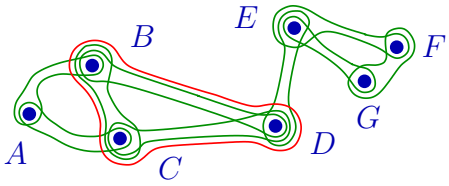
(5) Let $(X, (K = (V, S), \Theta\colon |K| \to X))$ be a simplicial complex. We introduce the following notions which are basically self-explanatory:
   (a) Given $v \in V$ we refer to $\Theta(v)$ as a vertex of the simplicial complex.
   (b) Let $s \in S$ be a k-simplex.
      (i) We refer to $\Theta(|s|) \subset X$ as a k-simplex of the simplicial complex. Furthermore we refer to $\Theta(\langle s\rangle) \subset X$ as an open k-simplex of the simplicial complex.
      (ii) If $\Phi_s\colon \Delta^k \to |s|$ is a characteristic map as defined on page 1984, then we refer to $\Theta \circ \Phi_s\colon \Delta^k \to X$ as a characteristic map of X.
      (iii) If t is a face of s, then we refer to $\Theta(|t|)$ as a face of the simplex $\Theta(|s|)$.

(c) We define the dimension of the simplicial complex to be the dimension of the corresponding abstract simplicial complex.
(d) Given $n \in \mathbb{N}_0$ we denote by $|K^n| \subset |K|$ the topological realization of the n-skeleton of K. We refer to $X^n := \Theta(|K^n|)$ as the n-skeleton of the simplicial complex X.



(6) Let $(Y, (L, \Theta\colon |L| \to Y))$ be a simplicial complex. A subcomplex is a simplicial complex $(X, (K, \Omega\colon |K| \to X))$ where X is a subspace of Y, K is a subcomplex of L and where the inclusion $X \to Y$ is precisely the map $\Theta \circ |i| \circ \Omega^{-1}$, where $i\colon K \to L$ is the inclusion map.

Remark.



(1) In many cases the choice of a simplicial structure gets suppressed from the notation.
(2) In the literature a *simplicial structure* is often called a *triangulation*.

Examples.

(1) Given any abstract simplicial complex K its topological realization $|K|$ is a simplicial complex in an obvious way.
(2) On page 1989 we wrote down an explicit homeomorphism $|D_n| \xrightarrow{\cong} \Delta^n$ which restricts to a homeomorphism $|S_{n-1}| \xrightarrow{\cong} \partial\Delta^n$. These two homeomorphisms endow Δ^n and $\partial\Delta^n$ with a simplicial structure, called the *standard simplicial structure*.
(3) We consider the topological space X to the left of the figure below. To the right we show an abstract simplicial complex K with seven vertices such that X is homeomorphic to $|K|$.[1135] We have thus found a simplicial structure for X.

topological space X

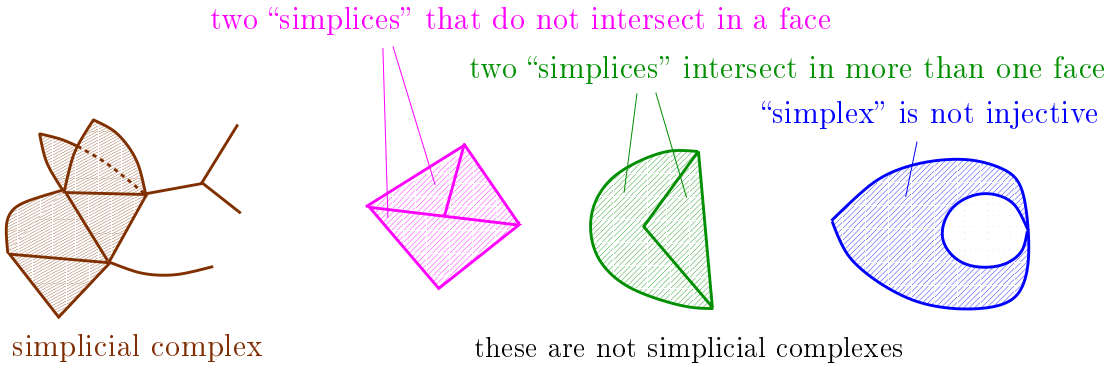
abstract simplicial complex K

Before we continue with more examples of simplicial complexes we want to formulate the following lemma which summarizes a few basic properties of simplices in a simplicial complex.

Lemma 93.14. Let Y be a simplicial complex.

(1) Any k-simplex of Y is homeomorphic to Δ^k.
(2) The intersection of two simplices of Y is either empty or it is given by a single face of the two simplices.
(3) Let X be a subcomplex of Y and let s be a simplex of Y. If the corresponding open simplex intersects X, then $s \subset X$.
(4) If $X \subset Y$ is the union of simplices of X, then Y admits a natural structure of a subcomplex.

Proof.

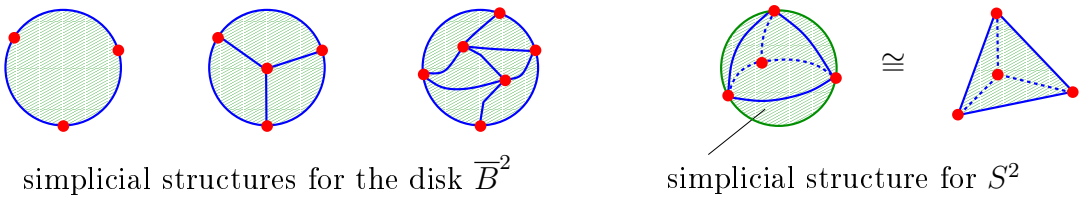


(1) This statement is a reformulation of the Simplex-Embedding Lemma 93.5.

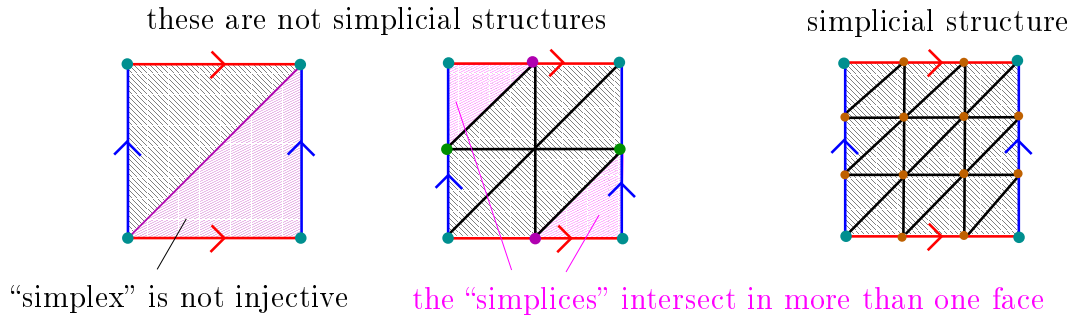
[1135] What is the role of the vertices A, F and G? Are they really needed?

(2) This statement is an immediate consequence of Lemma 93.1.
(3) This follows from the Open Simplex Lemma 93.11 (5).
(4) This statement follows almost immediately from the definitions. ■

Remark.



(1) In the following a simplicial structure for a topological space is often indicated by a suitable decomposition into simplices, i.e. into subsets which (look like they) are homeomorphic to some Δ^k. Some care though needs to be taken to make sure that one actually does define a simplicial structure. In particular one needs to ensure that the statements of Lemma 93.14 (1) and (2) are satisfied. We refer to the figure below for an illustration of examples and non-examples of simplicial complexes.
(2) In the following we often draw a simplicial complex and rely on the good will of the reader to read off the corresponding abstract simplicial complex.



We continue with more examples of simplicial complexes.

Examples.

(1) In the figure below to the left we show several simplicial structures for the disk $\overline{B}^2$. Furthermore, in the figure below to the right we show a simplicial structure for the sphere S^2.

(2) In the figure below we show the torus $T = ([0,1] \times [0,1])/\sim$ together with three attempts at endowing it with a simplicial structure. Using Lemma 93.14 we see that the two attempts to the left do not define a simplicial structure. Only the fairly complicated attempt to the right actually provides us with a simplicial structure for the torus.
(3) Let $n \in \mathbb{N}$. We will now equip the closed ball $\overline{B}^n$ and the sphere S^n with a canonical simplicial structure. To do so we consider the simplicial complex D_n and its subcomplex S_{n-1} that we introduced on page 1978. On page 1989 we saw that there exists a canonical homeomorphism $f\colon |D_n| \to \Delta^n$ which restricts to a homeomorphism $|S_{n-1}| \to \partial\Delta^n$. Furthermore, in the Standard Simplex Homeomorphism Lemma 72.1

we gave an explicit homeomorphism $\Phi\colon \overline{B}^n \to \Delta^n$ that restricts to a homeomorphism $S^{n-1} \to \partial\Delta^n$. We see that $(D_n, \Phi^{-1} \circ f\colon |D_n| \to \overline{B}^n)$ is a simplicial structure for $\overline{B}^n$ and that $(S_{n-1}, \Phi^{-1} \circ f|_{|S_{n-1}|}\colon |S_{n-1}| \to S^{n-1})$ is a simplicial structure for S^{n-1}. We refer to these as the *canonical simplicial structures* of $\overline{B}^n$ and S^{n-1}.

It is by now abundantly clear that most simplicial complexes admit many different simplicial structures. Finally we consider maps between simplicial complexes. What comes next is basically self-explanatory and only written down out of a sense of duty.

Definition. Let $(X, (K, \Theta\colon |K| \to X))$ and $(Y, (L, \Omega\colon |L| \to Y))$ be two simplicial complexes.

(1) A map $f\colon X \to Y$ is called simplicial if there exists a simplicial map $g\colon K \to L$ such that $f = \Omega \circ |g| \circ \Theta^{-1}$.
(2) We say the two simplicial complexes are simplicially isomorphic if there exist simplicial maps between the two simplicial complexes that are inverses of one another.

Example. If Y is a simplicial complex and X is a subcomplex, then it follows immediately from the definitions that the inclusion $X \to Y$ is a simplicial map.

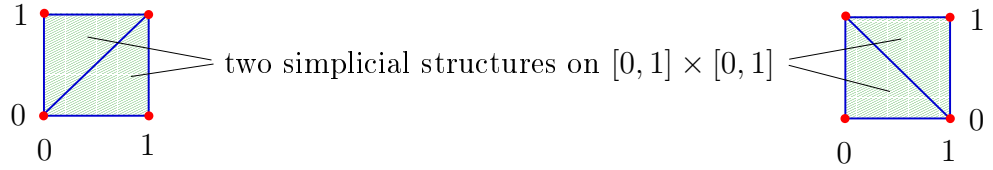
It follows immediately from the definitions that the composition of two simplicial maps is again simplicial. This leads us to the following definition.

Definition. We call the category $\mathcal{SimpCplx}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{SimpCplx}) &:= \text{all simplicial complexes,} \\ \mathrm{Mor}(K, L) &:= \text{all simplicial maps from } K \text{ to } L, \end{aligned}$$

together with the usual composition of maps the category of simplicial complexes. Similarly we define the category of (totally) ordered simplicial complexes.

We conclude this section with the following basic lemma.



Lemma 93.15. Let $(X, (K = (V, S), \Theta\colon |K| \to X))$ and $(Y, (L = (W, T), \Omega\colon |L| \to Y))$ be two simplicial complexes. Given a simplicial map $\varphi\colon K \to L$ there exists a unique

simplicial map $\Phi\colon X \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} V & \xrightarrow{\varphi} & W \\ {\scriptstyle\Theta}\downarrow & & \downarrow{\scriptstyle\Omega} \\ X & \xrightarrow{\Phi} & Y. \end{array}$$

Proof. The map Φ is given by $\Omega \circ |\varphi| \circ \Theta^{-1}$. Since Ω and Θ are homeomorphisms we see that Φ is also unique. ■

93.5. **The product of (abstract) simplicial complexes.** In this section we want to consider the product of (abstract) simplicial complexes. Let us first consider the simplicial complexes $X = Y = [0,1]$ with the "obvious" simplicial structure. As we see in the figure below, there are two very reasonable looking simplicial structures on the product $[0,1] \times [0,1]$.

It is not clear which of the two simplicial structures shown in the figure above is preferable or "more canonical". In fact to break the tie and to end up with a clear winner we need to work with ordered abstract simplicial complexes, as introduced on page 1978.
First we recall the following definition from page 92.

Definition. Let $(A, \leq)$ and $(B, \leq)$ be two partially ordered sets. Given (a, b) and (a', b') in $A \times B$ we define

$$(a,b) < (a',b') \quad :\Longleftrightarrow \quad \text{either } a < a' \text{ or } a = a' \text{ and } b < b'$$

and we define $(a,b) \leq (a',b')$ if either $(a,b) = (a',b')$ or $(a,b) < (a',b')$. We refer to "$\leq$" on $A \times B$ as the lexicographic order on $A \times B$.

Remark. Let $(A, \leq)$ and $(B, \leq)$ be two partially ordered sets. One can show easily that the lexicographic order is a partial order on $A \times B$ and similarly one can show easily that if $(A, \leq)$ and $(B, \leq)$ totally ordered sets, then the lexicographic order is also a total order.

Definition. Let $K = (V, S)$ and $L = (W, T)$ be two (totally) ordered abstract simplicial complexes. We define the product $K \times L$ of the abstract simplicial complexes to be the abstract simplicial complex[1136] that is given by the vertex set $V \times W$ and the simplex set[1137]

$$\left\{ \{(v_0,w_0),\dots,(v_k,w_k)\} \;\middle|\; \begin{array}{c} \{v_0,\dots,v_k\} \in S \text{ and } \{w_0,\dots,w_k\} \in T \text{ and} \\ \text{we have } v_0 \leq \cdots \leq v_k \text{ and } w_0 \leq \cdots \leq w_k \end{array} \right\}.$$

We equip $K \times L$ with the lexicographic order and we view $K \times L$ again as a (totally) ordered abstract simplicial complex.[1138]

Before we discuss examples we first state the following lemma which basically reassures us that we are doing something reasonable.

Lemma 93.16. (Simplicial Complex-Product Lemma) Suppose we are given by two ordered abstract simplicial complexes $K = (V, S)$ and $L = (W, T)$.

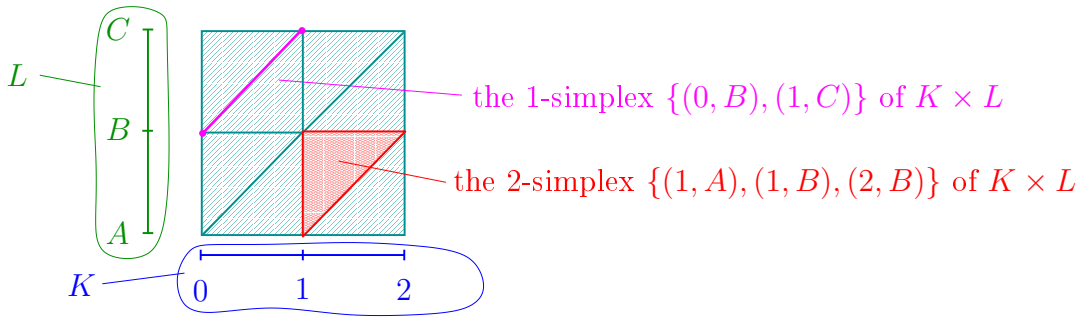
(1) The two natural projections $p\colon K \times L \to K$ and $q\colon K \times L \to L$ are simplicial maps.
(2) The ordered abstract simplicial complex $K \times L$ together with the natural projections from (1) is the product of K and L in the category $\mathcal{OrdAbsSimpCplx}$ of ordered abstract simplicial complexes, in the sense of the definition on page 211.
(3) The map
$$|p| \times |q|\colon |K \times L| \ \to \ |K| \times |L|$$
is a continuous bijection. If K and L are *finite*, then the map is in fact a homeomorphism.

Thus given two finite simplicial complexes K and L we can view the product also as a simplicial complex.

Remark.

(1) Lemma 68.24 teaches us that it is safer to stick to finite abstract simplicial complexes. In fact that is also all we ever need. For products of arbitrary abstract simplicial complexes we refer to [**FrPi1990a**, Proposition 4.3.5] and [**LW1969**, Corollary III.5.2]. Note though that one needs to tread carefully to make sure that the definitions and statements are indeed as desired.
(2) As mentioned earlier, the topology of the topological realization of an abstract simplicial complex is designed to make it easy to show that a map out of the topological realization is continuous. Furthermore, as we mentioned in Remark 5.2, the topology of a product of topological spaces makes it easy to find continuous maps to the product. This explains why in the Simplicial Complex-Product Lemma 93.16 we have a continuous map from left to right, but why we struggle to find a continuous map from right to left.

Proof.



(1) It follows immediately from the definitions that the projections are indeed simplicial.
(2) We will not make use of this statement, thus we will outsource it to Exercise 93.10.
(3) It follows from (1) together with Proposition 93.7 and the the Topological-Product Proposition 5.1 (1a) that the map $|p| \times |q|\colon |K \times L| \to |K| \times |L|$ is continuous. We leave it to the reader to verify that the map is a bijection.

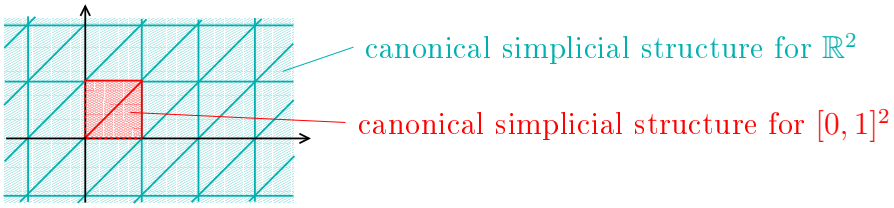
Finally suppose that K and L are finite. It follows from the Compact-Hausdorff Proposition 2.17 (3), together with Lemmas 93.5 (1) and 93.9 (1) and the Product Topology Properties Proposition 5.6 that the map is indeed a homeomorphism. ■

Examples.

[1136] One can indeed easily verify that this defines an abstract simplicial complex.
[1137] To rule out any potential confusion, the $v_0, \ldots, v_k$ and also the $w_0, \ldots, w_k$ do not need to be distinct vertices.
[1138] It follows almost immediately from the above remark that with this definition $K \times L$ is in fact a (totally) ordered abstract simplicial complex.

(1) We consider the two totally ordered abstract simplicial complexes K and L that are shown in the figure below. Here we use the obvious total orders given by $0 < 1 < 2$ and $A < B < C$. We also show the corresponding product $K \times L$.

(2) We equip S^1 with the canonical simplicial structure defined on page 1997. The product simplicial structure on the torus $S^1 \times S^1$ is simplicially isomorphic to the simplicial structure shown in the figure shown on page 1997 to the right.

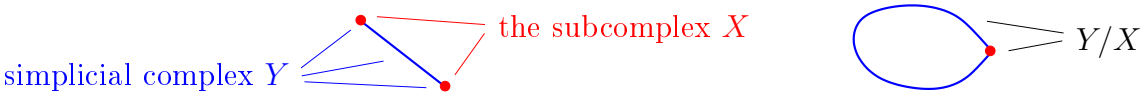


(3) Let I be the abstract simplicial complex given by $(V = \{(0, 1)\}, S = \{\{0\}, \{1\}, \{0, 1\}\})$. As in (1) we use the obvious total order given by $0 < 1$. We consider the product $I \times I$. Given any $n \in \mathbb{N}$ we can now view the cube $[0, 1]^n$ as a simplicial complex. For $n = 2$ we obtain the simplicial complex drawn in the figure shown on page 1998 on the left. We refer to this simplicial structure as the *canonical simplicial structure of* $[0, 1]^n$.

In plain English, the following lemma says that the $\mathbb{Z}^n$-translates of the canonical simplicial structure of $[0, 1]^n$ give a linear simplicial structure for $\mathbb{R}^n$.

Lemma 93.17. Let $n \in \mathbb{N}$. We denote by $(K = (V, S), \Theta\colon |K| \to [0, 1]^n)$ the canonical simplicial structure of $[0, 1]^n$. We define a new simplicial complex $\widetilde{K} = (\widetilde{V}, \widetilde{S})$ where

$$\widetilde{V} := \mathbb{Z}^n \quad \text{and} \quad \widetilde{S} := \{\{v_0 + w, \ldots, v_k + w\} \,|\, \{v_0, \ldots, v_k\} \in S \text{ and } w \in \mathbb{Z}^n\}.$$



The (hopefully) obvious map $\widetilde{\Theta}\colon |\widetilde{K}| \to \mathbb{R}^n$ is a homeomorphism, in particular it equips $\mathbb{R}^n$ with the structure of a linear simplicial complex.

Proof. It is elementary to see that the map $\widetilde{\Theta}\colon |\widetilde{K}| \to \mathbb{R}^n$, once it is written down properly, is continuous and a bijection. It follows from the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19 that the map is in fact a homeomorphism. ■

Arguably the most important ways to construct new topological spaces out of given ones are by taking products and by taking quotients. Within reasonable limits we saw in the CW-Complex Product Proposition 68.23 and the CW-Complex Construction Lemma 68.32 (3) that both operations can be done with CW-complexes. Furthermore, we just saw in the Simplicial Complex-Product Lemma 93.16 that we can take products of finite simplicial

complexes. Quotients on the other hand are a problem. In general, as is illustrated in the figure below, given a simplicial complex Y and a subcomplex X the simplicial structure of Y does not descend to a simplicial structure on the quotient Y/X.

Let us jot down the following question.

Question 93.18. Let Y be a simplicial complex and let X be a subcomplex. Does the quotient Y/X admit a simplicial structure?

In Corollary 93.26 we will give a partial answer to Question 93.18.

93.6. **The simplicial join of (abstract) simplicial complexes.** In this section we will continue with our task of finding useful constructions of (abstract) simplicial complexes that correspond to constructions that we already know from the world of topological spaces. More precisely, we want to consider the join construction from page 446 that so far we had not seriously used.

Definition. Let X and Y be two non-empty topological spaces. We define the join $X * Y$ to be the topological space obtained from $X \times [0,1] \times Y$, equipped with the product topology, by performing the following two types of identifications:

(1) for every $x \in X$ we identify all points in $\{x\} \times \{0\} \times Y$ to a single point and
(2) for every $y \in Y$ we identify all points in $X \times \{1\} \times \{y\}$ to a single point.

Furthermore, if one of X or Y is the empty topological space, then we define $X * Y$ to be the other topological space.

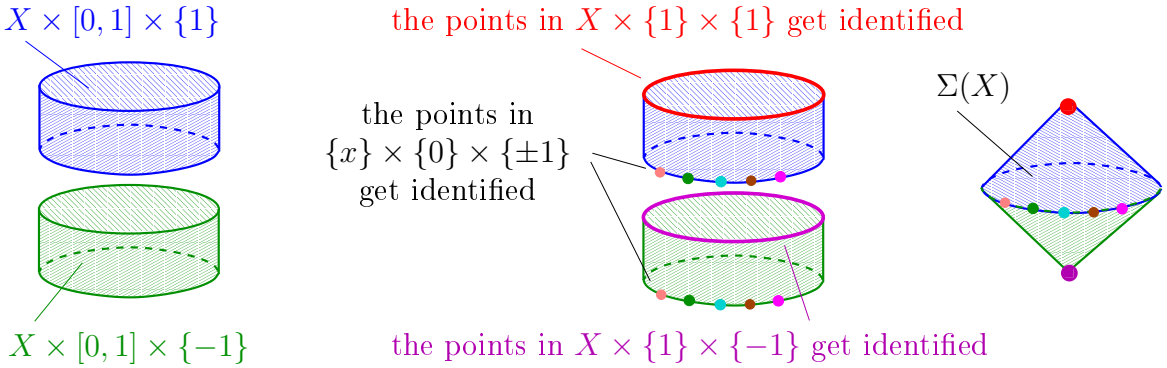
To get into the mood of thinking about joins let us first consider the following two examples.

Examples.

(1) Let X be a non-empty topological space and let $Y = \{1\}$ be the topological space given by a single point 1. We consider the maps

$$\begin{array}{rcl} X * \{1\} = (X \times [0,1] \times \{1\})/\sim & \to & \mathrm{Cone}(X) = (X \times [0,1])/(X \times \{1\}) \\ [(x,t,1)] & \mapsto & [(x,t)] \end{array}$$

One can easily verify that the map is a bijection. Furthermore, using the Topological-Quotient Proposition 5.15 (1b) and the Topological-Quotient Proposition 5.15 (1a) it is straightforward to see that this map and its inverse are continuous. Thus the map is a homeomorphism.



(2) Let X be a non-empty topological space and let $Y = \{-1, 1\}$ be the topological space given by the set with two elements ± 1 and the discrete topology. We also consider the suspension

$$\Sigma(X) \ := \ (X \times [-1,1])/\sim$$

which is defined by squashing all points in $X \times \{-1\}$ to a single point and by squashing all points in $X \times \{1\}$ to a single point. We consider the map

$$\begin{array}{rcl} X * \{-1,1\} = (X \times [0,1] \times \{-1,1\})/\sim & \to & \Sigma(X) = (X \times [-1,1])/\sim \\ [(x,t,\epsilon)] & \mapsto & [(x, \epsilon \cdot t)] \end{array}$$

With some minor effort one can show that this map is a bijection. Using the Topological-Quotient Proposition 5.15 (1b) and the Topological-Quotient Proposition 5.15 (1a) it is straightforward to see that this map is continuous. The fact that the inverse is also continuous needs slightly more effort, in fact this argument also requires Lemmas 5.23 and Lemma 5.36. We leave it to the reader to fill in the details. We refer to the figure below for $X = S^1$ for an illustration of the homeomorphism.

For completeness we note that for the empty topological space we have, basically by definition, that $\varnothing * \{1\} = \mathrm{Cone}(\varnothing)$ and $\varnothing * \{\pm 1\} = \Sigma(\varnothing)$

The following lemma gives us a few examples of joins which will play a role later on.

Lemma 93.19. (Join-Simplex Lemma)

(1) Given any $m, n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} S^m * S^n & \to & S^{m+n+1} \\ [(x,t,y)] & \mapsto & \underbrace{\left(x \cdot \cos\left(\frac{\pi t}{2}\right), y \cdot \sin\left(\frac{\pi t}{2}\right)\right)}_{\in \mathbb{R}^{m+1} \times \mathbb{R}^{n+1} = \mathbb{R}^{m+n+2}} \end{array}$$

is a homeomorphism.[1139]

(2) Given any $m, n \in \mathbb{N}_0$ the map

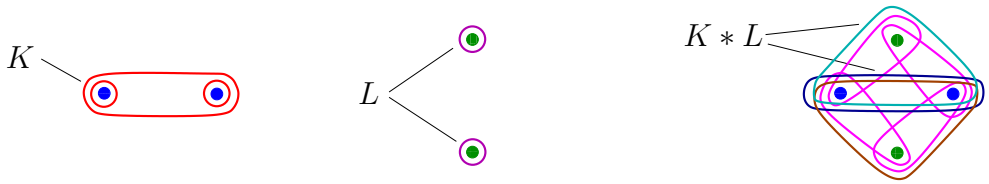
$$\begin{array}{rcl} \Delta^m * \Delta^n & \to & \Delta^{m+n+1} \\ [(x_0, \ldots, x_m, t, y_0, \ldots, y_n)] & \mapsto & (t \cdot x_0, \ldots, t \cdot x_m, (1-t) \cdot y_0, \ldots, (1-t) \cdot y_n) \end{array}$$

is a homeomorphism.

(3) Given any $n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \partial\Delta^n * \{\star\} & \to & \Delta^n \\ [(x,t,\star)] & \mapsto & x \cdot (1-t) + \left(\frac{1}{n+1}, \ldots, \frac{1}{n+1}\right) \cdot t \end{array}$$

Proof. The proof of (1), (2) and (3) is basically identical. In each case it is straightforward to verify that the map is well-defined and a bijection. It follows from the Topological-Quotient Proposition 5.15 (1b) that the given map is continuous. Finally it follows from Lemma 16.2 together with the Compact-Hausdorff Proposition 2.17 (3) that the given map is in fact a homeomorphism. ■



It turns out that in the simplicial setting we have an analogous construction.

[1139] In fact this statement is just the content of the Join of Spheres Lemma 16.4.

Definition. Let $K_i = (V_i, S_i)$, $i = 1, \ldots, m$ be abstract simplicial complexes. We define the simplicial join of $K_1, \ldots, K_m$ to be the abstract simplicial complex[1140][1141]

$$K_1 * \cdots * K_m := \left(V_1 \sqcup \cdots \sqcup V_m, \left\{ s_1 \sqcup \cdots \sqcup s_m \;\middle|\; \begin{array}{l} \text{for } i = 1, \ldots, m \text{ we have } s_i \in \overbrace{S_i \cup \{\varnothing\}}^{\subset \mathcal{P}(V_i)} \\ \text{and there exists at least one } s_i \neq \varnothing \end{array} \right\} \right).$$

This definition is illustrated, with limited success, in the figure below.

Remark. It follows immediately from the definitions that the join construction is associative, i.e. given abstract simplicial complexes K, L and M we have a natural isomorphism $(K * L) * M = K * (L * M)$ of abstract simplicial complexes.

The examples on page 2001 motivate the following definitions.

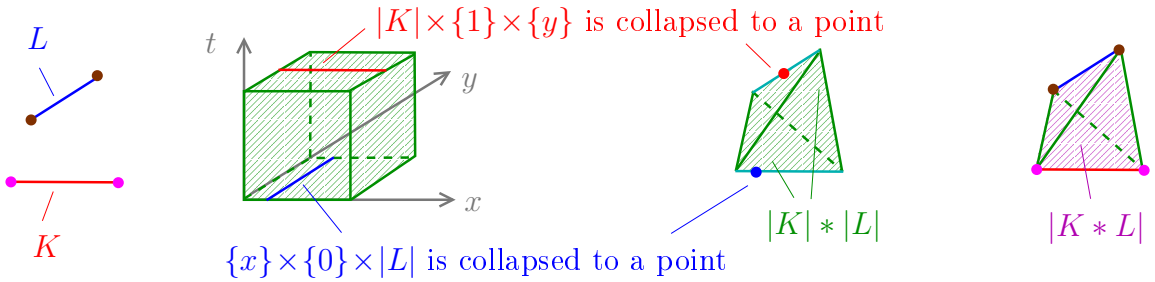
Definition. Let K be an abstract simplicial complex. Furthermore let $\{1\}$ be the abstract simplicial complex consisting of a single vertex 1 and finally let S_0 be the abstract simplicial complex $S_0 = (\{0, 1\}, \{\{0\}, \{1\}\})$ that we introduced on page 1978. We refer to

$$\mathrm{Cone}(K) := K * \{1\} \quad \text{respectively} \quad \Sigma(K) := K * S_0$$

as the simplicial cone on the abstract simplicial complex K respectively the simplicial suspension of the abstract simplicial complex K.

Example. Let $n \in \mathbb{N}_0$. We see that

$$\overbrace{\mathrm{Cone}\left(\{0, \ldots, n\}, \mathcal{P}(\{0, \ldots, n\}) \backslash \{\varnothing\}\right)}^{= \mathrm{Cone}(D_n), \text{ see definition of } D_n \text{ on page 1978}} \underset{\text{follows from the definition of the simplicial cone}}{=} \left(\{0, \ldots, n, *\}, \mathcal{P}(\{0, \ldots, n, *\} \backslash \{\varnothing\}\right) \underset{\text{induced by } * \mapsto n+1}{\overset{\cong}{\to}} D_{n+1}.$$



Lemma 93.20. (Join Lemma) Let K and L be two abstract simplicial complexes. If one of K or L is empty, then by definition we have a natural homeomorphism $|K| * |L| \cong |K * L|$. If K and L are non-empty, then the map

$$\begin{array}{rccl} \Theta\colon & \overbrace{(|K| \times [0,1] \times |L|)/\!\sim}^{= |K| * |L|} & \to & |K * L| \subset \mathbb{R}^{(V \sqcup W)} = \mathbb{R}^{(V)} \times \mathbb{R}^{(W)} \\ & [(x, r, y)] & \mapsto & (\underbrace{r \cdot x}_{\in \mathbb{R}^{(V)}}, \underbrace{(1-r) \cdot y}_{\in \mathbb{R}^{(W)}}) \end{array}$$

is a bijection and its inverse Θ^{-1} is continuous.[1142] Furthermore, if K and L are finite, then Θ is in fact a homeomorphism.

[1140] To avoid confusion it is perhaps worth recalling that the empty set is not a simplex.

[1141] One can easily verify that this is indeed an abstract simplicial complex.

Proof. Let $K=(V,S)$ and $L=(W,T)$ be two abstract simplicial complexes. If one of K or L is empty, then the statement is true basically by definition. Thus let us now assume that K and L are both non-empty. We consider the map

$$\begin{array}{rcl}\Theta\colon \overbrace{(|K|\times[0,1]\times|L|)/\!\sim}^{=|K|*|L|} & \to & |K*L|\subset\mathbb{R}^{(V\sqcup W)}=\mathbb{R}^{(V)}\times\mathbb{R}^{(W)}\\ [(x,r,y)] & \mapsto & (\underbrace{r\cdot x}_{\in\mathbb{R}^{(V)}},\underbrace{(1-r)\cdot y}_{\in\mathbb{R}^{(W)}}).\end{array}$$

We leave it to the reader to verify that the map does indeed take values in $|K*L|$ and that it is a bijection. Next we show that the inverse $\Theta^{-1}\colon |K*L|\to|K|*|L|$ is continuous.

Claim. The map $\Theta^{-1}\colon |K*L|\to|K|*|L|$ is continuous.

Proof. We use the continuity criterion from the Restrict-to-Simplex Lemma 93.6 (2) to show that Θ^{-1} is continuous. Since K and L are non-empty we see that every simplex of $K*L$ is contained in a simplex of the form $s\sqcup t$ where $s\in S$ and $t\in T$ are simplices. Thus let $s\in S$ be a k-simplex and let $t\in T$ be an l-simplex. Note that by the Join-Simplex Lemma 93.19 (2) we know that the map

$$\begin{array}{rcl}\Xi\colon \Delta^k*\Delta^l & \to & \Delta^{k+l+1}\\ [(x_0,\ldots,x_k,r,y_0,\ldots,y_l)] & \mapsto & (r\cdot x_0,\ldots,r\cdot x_k,(1-r)\cdot y_0,\ldots,(1-r)\cdot y_l)\end{array}$$

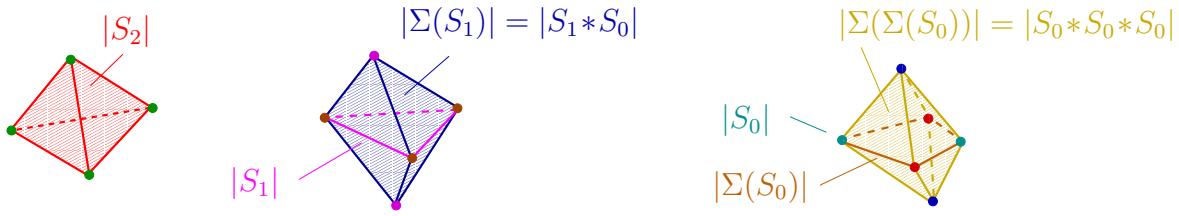
is a homeomorphism. Next we pick corresponding characteristic maps $\Phi_s\colon\Delta^k\to|K|$ and $\Phi_t\colon\Delta^l\to|L|$. It follows easily from the definitions that the map

$$\begin{array}{rcccl}\Phi_{s\sqcup t}\colon\Delta^{k+l+1} & \xrightarrow{\Xi^{-1}} & \overbrace{(\Delta^k\times[0,1]\times\Delta^l)/\!\sim}^{\Delta^k*\Delta^l} & \xrightarrow{\Omega} & |K*L|\subset\mathbb{R}^{(V\sqcup W)}=\mathbb{R}^{(V)}\times\mathbb{R}^{(W)}\\ & & [(x,r,y)] & \mapsto & (\underbrace{r\cdot\Phi_s(x)}_{\in\mathbb{R}^{(V)}},\underbrace{(1-r)\cdot\Phi_t(y)}_{\in\mathbb{R}^{(W)}})\end{array}$$

is a characteristic map for the simplex $s\sqcup t$. We obtain the following diagram

$$\begin{array}{ccccc}\Delta^{k+l+1} & \xrightarrow{\Phi_{s\sqcup t}} & |K*L| & \xrightarrow{\Theta^{-1}} & |K|*|L|\\ & \searrow^{\Xi^{-1}} & \uparrow{\scriptstyle\Omega} & \nearrow_{\Phi_s*\Phi_t} & \\ & & \Delta^k*\Delta^l & & \end{array}$$

[1142]This might be viewed as an odd formulation, but it is easier to write down the map Θ than to write down its inverse Θ^{-1}.



We make the following observations:

(1) It follows immediately from the definitions that the triangle to the left diagram commutes. Furthermore it is equally trivial to see that $\Theta \circ (\Phi_s * \Phi_t) = \Omega$, thus the triangle to the right also commutes.
(2) By the Join-Simplex Lemma 93.19 (2) we know that the left diagonal map is continuous.
(3) By Lemma 16.1 we know that the right diagonal map is continuous.
(4) It follows from the above that $\Theta^{-1} \circ \Phi_{s \sqcup t}$ is continuous.

It now follows from the Restrict-to-Simplex Lemma 93.6 (2) that $\Theta^{-1}\colon |K * L| \to |K| * |L|$ is continuous. ⊞

In the remainder of the proof we now assume that K and L are finite. We need to show that Θ is a homeomorphism. We already know that Θ is a bijection and that the inverse $\Theta^{-1}\colon |K * L| \to |K| * |L|$ is continuous. Furthermore, by the Simplex-Embedding Lemma 93.5 (2) together with Lemma 16.5 we know that $|K| * |L|$ is Hausdorff. Thus it follows, as so often, from the Compact-Hausdorff Proposition 2.17 (3) that Θ^{-1} is a homeomorphism. Thus Θ is also a homeomorphism. ■

Example. Let $n \in \mathbb{N}_0$. Recall that on page 1997 we gave an explicit simplicial structure $(S_n, \Theta\colon |S_n| \to S^n)$ for S^n. Now let $m, n \in \mathbb{N}$. By the Join-Simplex Lemma 93.19 (1) we know that S^{m+n+1} is homeomorphic to $S^m * S^n$. This observation, together with the Join Lemma 93.20, gives us lots of different simplicial structures on spheres. We sketch the resulting three simplicial structures for S^2 in the figure below.

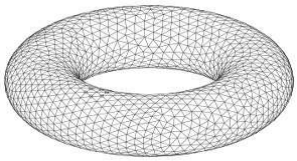
Corollary 93.21. (Simplicial Cone-Suspension Corollary) If $X = (K, \Theta\colon |K| \to X)$ is a finite simplicial complex, then the suspension $\Sigma(X)$ and the cone $\mathrm{Cone}(X)$ admit natural simplicial structures where the corresponding abstract simplicial complexes are given by $\Sigma(K)$ and $\mathrm{Cone}(K)$.

Proof. The corollary follows immediately from the Join Lemma 93.20 together with the two examples on page 2002. ■

Remark. In Section 94.4 we will introduce the simplicial analogue of the mapping cylinder and mapping cone.

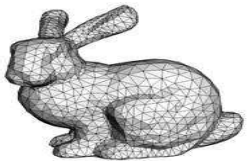
93.7. **Linear simplicial complexes.** In this short section we discuss an important special case of a simplicial complex.

Definition. A simplicial complex $(X, (K, \Theta\colon |K| \to X))$ is called linear if X is a subspace[1143] of some $\mathbb{R}^n$ and for each each simplex $s \in K$ the map $\Theta\colon |s| \to X$ is an affine linear map.



[1143] In particular we assume that X is endowed with the subspace topology coming from $\mathbb{R}^n$.

Example. Let $n \in \mathbb{N}$. The topological space $\mathbb{R}^n$ together with the canonical simplicial structure defined in Lemma 93.17 is clearly a linear simplicial complex.



Remark.

(1) Different books have different definitions for "simplicial complexes". Our approach mostly follows the approach taken in [**Spa1995**, Chapter 3]. In many books what we call a "linear simplicial complex" is basically used as the definition of a simplicial complex, see e.g. [**Matv2006**, p. 6] or [**Bre1993**, Chapter 21].

(2) Linear simplicial complexes play an important role in computer visualizations. More precisely, in computer visualizations surfaces in $\mathbb{R}^3$ are usually approximated by linear simplicial complexes. These have the nice feature that they can be described by a fairly small amount of data. We refer to the figure below for an illustration.

linear simplicial structure for the torus

linear simplicial structure for a bunny

Lemma 93.22. Every finite simplicial complex is simplicially isomorphic to a finite linear simplicial complex.

Remark. An (abstract) simplicial complex is called *locally finite* if each simplex is the face of only finitely many simplices. With this definition one can formulate a much stronger version of Lemma 93.22: By [**FrPi1990a**, Theorem 3.3.15] a simplicial complex is homeomorphic to a linear simplicial complex if and only if it is finite-dimensional, countable and locally finite. We will discuss this statement in Exercise 93.8.

Proof. By definition a finite simplicial complex is homeomorphic to the topological realization $|K|$ of a finite abstract simplicial complex $K = (V, S)$. In Lemma 93.9 we showed that we can view $|K|$ as a linear simplicial complex in $\mathbb{R}^V = \mathbb{R}^m$. ■

We adopt the following notation.

Notation. Given[1144] $v_0, \ldots, v_k \in \mathbb{R}^n$ we write

$$|\{v_0, \ldots, v_k\}| := \left\{ \underbrace{\sum_{i=0}^{k} t_i \cdot v_i}_{\in \mathbb{R}^n} \;\middle|\; \begin{array}{l} (1) \text{ for each } i \text{ we have } t_i \geq 0 \\ (2)\ t_0 + \cdots + t_k = 1 \end{array} \right\}.$$

Remark. Let $v_0, \ldots, v_k \in \mathbb{R}^n$. Furthermore let $w_0, \ldots, w_m \in |\{v_0, \ldots, v_k\}|$. An elementary calculation shows that $|\{w_0, \ldots, w_m\}| \subset |\{v_0, \ldots, v_k\}|$. This inclusion can also be obtained from Exercise 2.38 (a).

Lemma 93.23.

[1144] We do not assume that $v_0, \ldots, v_k$ are distinct.

(1) Let K be a linear simplicial complex in $\mathbb{R}^n$.
   (a) Every k-simplex s of K is of the form $s = |\{v_0, \ldots, v_k\}|$ for some distinct vertices $v_0, \ldots, v_k$.
   (b) Every simplex of K is a convex subset of $\mathbb{R}^n$.
   (c) Let $v_0, \ldots, v_k$ be distinct vertices of K. The following three statements are equivalent:
      (i) $|\{v_0, \ldots, v_k\}|$ is a simplex of K,
      (ii) $\{v_0, \ldots, v_k\}$ is the vertex set of a simplex of K,
      (iii) $|\{v_0, \ldots, v_k\}| \subset K$.

(2) Let $f\colon K \to L$ be a simplicial map between two linear simplicial complexes. The restriction of f to any k-simplex $|\{v_0, \ldots, v_k\}|$ of K is given by

$$\begin{array}{rcl} |\{v_0, \ldots, v_k\}| & \to & |\{\varphi(v_0), \ldots, \varphi(v_k)\}| \\ \sum_{i=0}^{k} t_i \cdot v_i & \mapsto & \sum_{i=0}^{k} t_i \cdot \varphi(v_i). \end{array}$$

Proof.

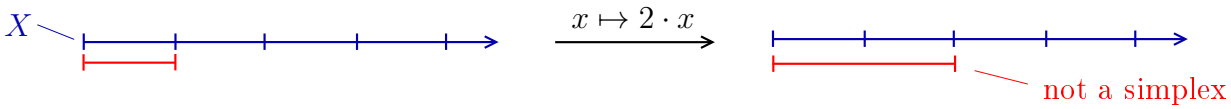
(1) Almost all of these statements follow easily from the definitions. The only statement which needs a little bit of thought is the fact that (iii) implies (i). Since we will not make use of this statement we feel comfortable with the thought of leaving the details to the reader.

(2) This statement follows immediately from the definition of a simplicial map, see page 1980 and the definition of the topological realization of a simplicial map between abstract simplicial complexes, see Proposition 93.7. ■

93.8. **Simplicial structures and CW-structures I.** It is pretty clear that simplicial complexes and CW-complexes have structural similarities. In particular few readers will be surprised by the following lemma.

Lemma 93.24. (Simplicial-Implies-CW Lemma) Every (ordered) simplicial complex admits a (natural) CW-complex structure where given any $n \in \mathbb{N}$ the n-simplices of the simplicial structure are precisely the n-cells[1145] of the CW-structure. In particular the following statements hold:

(1) The simplicial subcomplexes are precisely the cellular subcomplexes,
(2) For each $n \in \mathbb{N}_0$ the n-skeleton of the simplicial complex equals the n-skeleton of the CW-complex.
(3) Any simplicial map $f\colon X \to Y$ between simplicial complexes is a cellular map between the corresponding CW-complexes.

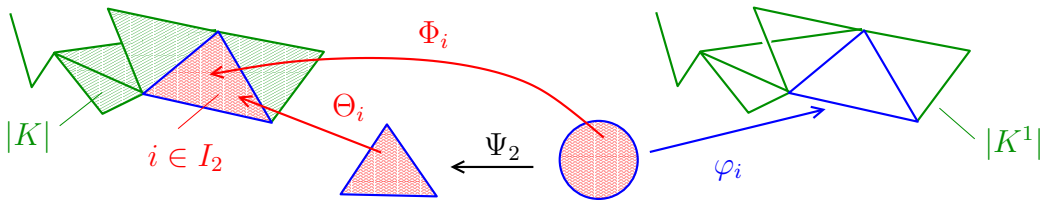


Remark. the Simplicial-Implies-CW Lemma 93.24 says in particular that there exists a functor

$$F\colon \begin{array}{c}\text{category } \mathcal{OrdAbsSimpCplx} \text{ of} \\ \text{ordered simplicial complexes}\end{array} \to \begin{array}{c}\text{category } \mathcal{CW} \text{ of} \\ \text{CW-complexes}\end{array}$$

which has the property that the functor keeps the underlying topological space fixed. The functor is faithful but not fully faithful. The latter is just a fancy way of saying that there exist cellular maps that are not simplicial. For example, consider the simplicial complex

[1145] Recall that cells and simplices are subsets, so it makes sense to talk of equality.



$X = [0, \infty)$ with the vertex set given by $\mathbb{N}_0$. We view X also as a CW-complex with the cellular structure that is induced from the simplicial structure. The map $f\colon X \to X$ given by $x \mapsto 2x$ is cellular but it is not simplicial. We refer to the figure below for an illustration.

Sketch of proof. Basically by definition of a simplicial complex it suffices to prove the statement for (ordered) abstract simplicial complexes and their topological realizations. The lemma now follows from fleshing out the following steps for a given (ordered) abstract simplicial complex $K = (V, S)$.

(a) Let $n \in \mathbb{N}_0$. Recall that in the Standard Simplex Homeomorphism Lemma 72.1 we had written down a specific homeomorphism $\Psi_n\colon (\overline{B}^n, S^{n-1}) \to (\Delta^n, \partial\Delta^n)$.
(b) Given $n \in \mathbb{N}_0$ we denote by K^n the n-skeleton of K. Recall that K^n is a subcomplex of K.
(c) Given $n \in \mathbb{N}_0$ let I_n be the set of n-simplices of K. For each $i \in I_n$ let $\Theta_i\colon \Delta^n \to |K|$ be a characteristic map as defined on page 1984. Recall that if K is ordered, then we saw on page 1984 that there is a natural choice of a characteristic map.
(d) Given $i \in I_n$ we write $\Phi_i := \Theta_i \circ \Psi_n\colon \overline{B}^n \to |K|$ and $\varphi_i := \Phi_i|_{S^{n-1}}\colon S^{n-1} \to |K^{n-1}|$. Note that φ_i takes values in $|K^{n-1}|$.
(e) Starting from $X^0 := V$ we can build up a CW-complex such that for each $n \in \mathbb{N}_0$ the attaching maps are precisely the maps $\varphi_i\colon S^{n-1} \to |K^{n-1}|$. The maps Ψ_i give rise to a map $\Xi_n\colon |X^n| \to |K^n|$ which is, basically by definition, a bijection.
(f) Eventually we get a CW-complex $X = \varinjlim X_n$ and the bijections Ξ_n can be combined to obtain a bijection $\Xi\colon |X| \to |K|$.
(g) It remains to show that Ξ is continuous. First note that it follows easily from the Restrict-to-Simplex Lemma 93.6 (1) together with the Characteristic Maps Lemma 68.7 (1) that Ξ is continuous. Furthermore, it follows from the Characteristic Maps Lemma 68.7 (4) together with the Simplex-Embedding Lemma 93.5 (3) that Ξ^{-1} is also continuous.
(h) In summary we have shown that $\Xi\colon |X| \to |K|$ is a homeomorphism.

It follows basically immediately from the construction of the CW-structure on $|K|$ that the properties (1), (2) and (3) are satisfied. ■

The Simplicial-Implies-CW Lemma 93.24 allows us to import many previous results about CW-complexes to the context of simplicial complexes. For example, the CW-Complex

Properties Proposition 68.10 (2) gives us a new proof that simplicial complexes are Hausdorff. More interesting of course are new results. The following corollary summarizes some of the nicest and most important ones.

Corollary 93.25.

(1) Simplicial complexes are normal.
(2) Simplicial complexes are locally contractible.[1146]
(3) A simplicial complex is connected if and only if it is path-connected.
(4) Let X be a simplicial complex and let A be a subcomplex. The following statements hold:
   (a) The inclusion $A \to X$ is a cofibration.
   (b) The map

$$\begin{array}{rcl} \varphi\colon \mathrm{Cone}(i\colon A \to X) & \to & X/A \\ P & \mapsto & \begin{cases} [P], & \text{if } P \in X, \\ [A], & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1] \end{cases} \end{array}$$

   is a homotopy equivalence.
   (c) If A is contractible, then the projection $X \to X/A$ is a homotopy equivalence.
(5) If X is a finite simplicial complex, then

$$\chi(X) \;=\; \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{number of } n\text{-simplices of } X.$$

Proof.

(1),(2) These two statements follow from the Simplicial-Implies-CW Lemma 93.24 together with the CW-Complex Properties Proposition 68.10 (2) and (6).
(3) This statement follows from (1) combined with Locally Path-Connected Lemma 2.40.
(4) (a) This statement follows from the Simplicial-Implies-CW Lemma 93.24 together with the Subcomplex Cofibration Theorem 17.9.
   (b) This follows from (a) together with the Cofibration-Quotient Lemma 17.7 (2).
   (c) This follows from (a) together with the Cofibration-Quotient Lemma 17.7 (3).
(5) This statement follows from the Simplicial-Implies-CW Lemma 93.24 together with the Euler Characteristic-H_*-Proposition 87.1. ■

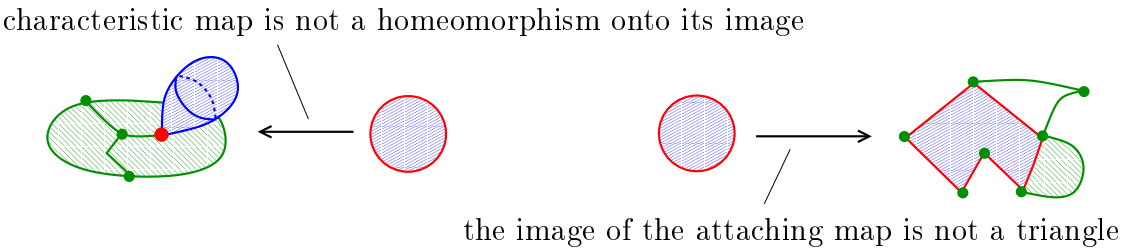
Now we can give a partial answer to Question 93.18.

Corollary 93.26. Let Y be a simplicial complex and let X be a subcomplex. If Y is finite, then there exists a finite simplicial complex, namely $Y \cup \mathrm{Cone}(X)$, that is homotopy equivalent to Y/X.

[1146] In the rather unlikely event that the reader forgot what these properties are good for, recall that by Corollary 61.11 this means in particular that any path-connected simplicial complex admits a universal covering. In Exercise 93.9 we will see that any covering of a simplicial complex is again a simplicial complex.

Remark. We leave it as an entertainment for long winter nights to figure out whether the Intervall CW-Product Lemma 68.8 can be used to generalize Corollary 93.26 to infinite simplicial complexes.

Proof. Basically by definition we only need to deal with abstract simplicial complexes and their topological realizations. Thus let $L = (W, T)$ be a finite abstract simplicial complex and let $K = (V, S)$ be a subcomplex. We denote by $i\colon K \to L$ the inclusion map. Recall that i is, basically by definition, simplicial. Since K and L are finite we can consider the abstract simplicial complex $\operatorname{Cone}(i\colon K \to L)$ that we will introduce on page 2027. Now we see that



$$|L|/|K| \xleftarrow[\text{Corollary 93.25}]{\simeq} \operatorname{Cone}(|i|\colon |K| \to |L|) = |L| \cup_{|K|} \operatorname{Cone}(|K|) \xleftarrow[\text{Simplicial Cone-Suspension Corollary 93.21}]{\cong} \overbrace{|L| \cup_{|K|} |\operatorname{Cone}(K)|}^{=|\operatorname{Cone}(i\colon K \to L)|}$$

■

It is pretty clear that there is no naive converse to the Simplicial-Implies-CW Lemma 93.24. For example, the CW-complex constructed in the proof of the Simplicial-Implies-CW Lemma 93.24 has some special properties:

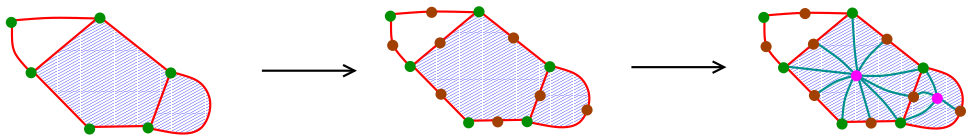
(1) It follows from the Simplex-Embedding Lemma 93.5 (2) that each characteristic map is an embedding.
(2) The CW-structure on the image of a characteristic map of an n-cell is equivalent to the one corresponding to the standard simplicial structure on $\partial\Delta^n$ that we defined on page 1995.

Both types of examples are illustrated in the figure below. Thus we see that many, arguably most, CW-structures do not come directly from simplicial structures.

It is perhaps more reasonable to ask, when does a CW-complex admit a simplicial structure? For example it is fairly obvious that the two cellular complexes shown in the figure above admit a simplicial structure. To formulate the relevant proposition we need the following definition.

Definition. A CW-complex is called regular if every characteristic map is an embedding.

Examples.



(1) The CW-complex shown in the figure above to the left is non-regular, whereas the CW-complex shown to the right is regular.
(2) Let X be a simplicial complex. We use the Simplicial-Implies-CW Lemma 93.24 to view X as CW-complex. It follows from the Simplex-Embedding Lemma 93.5 (3) that this CW-complex is regular.

Now we can formulate the promised proposition.

Proposition 93.27. Every (countable) regular CW-complex admits the structure of a (countable) simplicial complex.

Sketch of proof. We will not make use of this theorem, thus we refer to [**Geo2008**, Corollary 5.3.9] or alternatively to [**FrPi1990a**, Theorem 3.4.1] for a proof.

Here we only provide a sketch of a sketch of the proof. Thus let X be a regular CW-complex. We turn inductively the skeleta X^n into a simplicial complex. Suppose we already equipped X^{n-1} with a simplicial structure. For each n-cell of X^n we pick a point in the corresponding open cell and we use it to divide said n-cell into a suitable number of n-simplices. If the CW-complex X was countable, then it follows from the construction together with the Countability Lemma 0.8 that the simplicial complex is also countable. The reader should have no troubles with turning the above sketch of an argument into a formal proof. ■

regular CW-complex add point in each 1-cell add point in each 2-cell

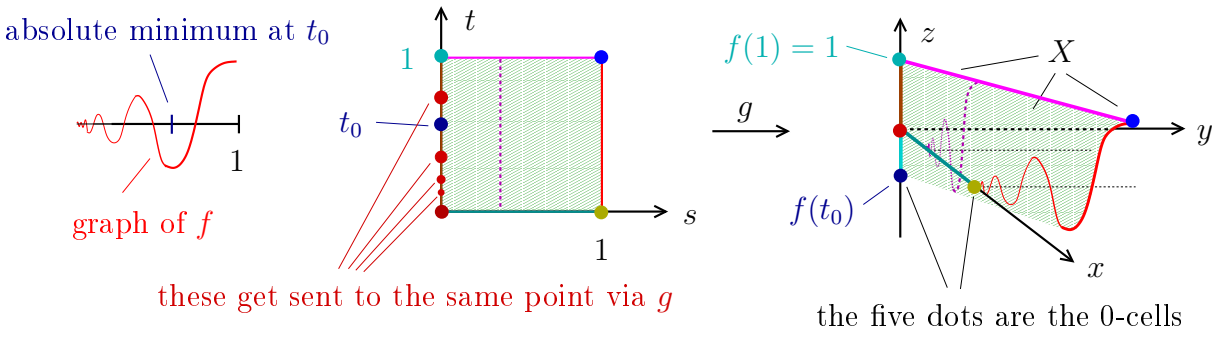
The relatively strong hypothesis of Proposition 93.27 indicates that it is perhaps too much to hope that every CW-complex admits a simplicial structure. Indeed, this fear turns out to be fully justified:

Proposition 93.28. There exists a finite CW-complex that does not admit a simplicial structure.

Remark. Proposition 93.28 is rather disappointing. Later on in Proposition 94.12 and Theorem 104.22 we will see that every (finite) CW-complexes is homotopy equivalent to a (finite) simplicial complexes.

Proof. We consider the function

$$f\colon [0,1] \to \mathbb{R}, \quad t \mapsto \begin{cases} 0, & \text{if } t = 0, \\ t\cdot\cos(\frac{2\pi}{t}) & \text{if } t \in (0,1] \end{cases}$$



and we consider the map

$$g\colon [0,1]^2 \to \mathbb{R}^3, \quad (s,t) \mapsto (s, s\cdot t, f(t)).$$

Note that f assumes its maximum at $t = 1$ and that it assumes its minimum at a unique $t_0 \in (0,1)$. We set $X := g([0,1]^2)$. It is not particularly difficult to see that X admits a CW-structure with five 0-cells, five 1-cells and one 2-cell.[1147] We refer to the figure below for an illustration.

In [**FrPi1990a**, p. 128-130] a careful argument is given why X does not admit a simplicial structure. Other examples of finite CW-complexes that do not admit a simplicial structure are given in [**LW1969**, p. 81] (with a very sketchy proof) and [**Met1967**]. ■

[1147] The five 0-cells and the five 1-cells are clearly indicated in the figure below.

Exercises for Chapter 93.

Exercise 93.1. For each $g \geq 2$ give an explicit simplicial structure for the surface of genus g.

Exercise 93.2. Give an explicit simplicial structure for $\mathbb{R}\mathrm{P}^2$.
Remark. In Exercise 94.5 we will construct an explicit simplicial structure for all $\mathbb{R}\mathrm{P}^n$.

Exercise 93.3. In the figure on page 1997 we gave a simplicial structure for the torus $S^1 \times S^1$ with 18 2-simplices. Does there exist a simplicial structure with less than 18 2-simplices?

Exercise 93.4.

(a) Show that the set of isomorphism classes of finite abstract simplicial complexes is countable.

(b) Show that the set of isomorphism classes of countable abstract simplicial complexes is uncountable.

Exercise 93.5. We consider the abstract simplicial complex $K = (V, S)$ which is given by $V = \mathbb{Z} \cup \{*\}$ and $S = \{\{v\} \,|\, v \in V\} \cup \{\{*, n\} \,|\, n \in \mathbb{Z}\}$. Show that $|K|$ is not homeomorphic to a linear simplicial complex.
Remark. (V, S) is just the simplicial cone on the abstract simplicial complex with vertex set $\mathbb{Z}$ and which has no simplices of dimension ≥ 1.

Exercise 93.6. Let $m, n \in \mathbb{N}_0$. Show that the simplicial join $D_m * D_n$ of the abstract simplicial complexes D_m and D_n is simplicially isomorphic to D_{m+n+1}.

Exercise 93.7. Let K be a finite n-dimensional simplicial complex. Show that K is homeomorphic to a finite linear simplicial complex that is contained in $\mathbb{R}^{2n+1}$.
Remark. In Proposition 88.7 we already showed that there exist finite 1-dimensional simplicial complexes that cannot be embedded into $\mathbb{R}^{2n}$. In fact the van Kampen-Flores Theorem, which can be proved using the Borsuk-Ulam Theorem 39.8, says that given any $n \in \mathbb{N}$ there exists a finite n-dimensional simplicial complex K that does not admit a map $K \to \mathbb{R}^{2n}$ which is a homeomorphism onto its image. We refer to [**Mato2008**, Theorem 5.1.1] for details.

Exercise 93.8. Let $K = (V, S)$ be an abstract simplicial complex that is finite-dimensional and countable. Furthermore we assume that it is locally finite, which means that each simplex is the face of only finitely many simplices. Show that $|K|$ is homeomorphic to a

linear simplicial complex.
Hint. Use the Closed Embedding-to-$\mathbb{R}^n$ Proposition 2.19.

Exercise 93.9. Let K be a simplicial complex and let $p\colon \widetilde{K} \to K$ be a covering in the sense of the definition on page 1067. Show that $\widetilde{K}$ admits a structure of a simplicial complex such that p is simplicial.

Exercise 93.10.

(a) Let $K = (V, S)$ and $L = (W, T)$ be two ordered abstract simplicial complexes. Show that the ordered abstract simplicial complex $K \times L$ that we defined on page 1998, together with the two natural projections $p\colon K \times L \to K$ and $q\colon K \times L \to L$, is the product of K and L in the category $\mathcal{OrdAbsSimpCplx}$ of ordered abstract simplicial complexes.
(b) Is the category $\mathcal{OrdAbsSimpCplx}$ of ordered abstract simplicial complexes closed under colimits?

Exercise 93.11. Let $K = (V, S)$ be an abstract simplicial complex and let $J = (U, R)$ be a subcomplex such that for any choice of simplices $r \in R$ and $s \in S \setminus R$ we have $r \cap s = \varnothing$. Show that $|J|$ is an open subset of $|K|$.
Remark. Note that by Lemma 93.8 (2) we know that $|J|$ is always a closed subset of $|K|$.

Exercise 93.12. Let $K = (V, S)$ be an abstract simplicial complex. We say $K = (V, S)$ is *connected* if given any $v, v' \in V$ there exist 1-simplices $s_0, \ldots, s_k \in S$ such that $v \in s_0$, such that for every $i \in \{0, \ldots, k-1\}$ we have $s_i \cap s_{i+1} \neq \varnothing$ and such that $v' \in s_k$.[1148] Show that the following statements are equivalent:

(a) The abstract simplicial graph K is connected.
(b) Given any two simplices $t, t' \in S$ there exist simplices $s_0, \ldots, s_k \in S$ such that $t \subset s_0$, such that for every $i \in \{0, \ldots, k-1\}$ we have $s_i \cap s_{i+1} \neq \varnothing$ and such that $t' \in s_k$.
(c) The topological realization $|K|$ is connected.

For completeness we mention that Corollary 93.25 (3) says that (c) is equivalent to the following statement:

(d) The topological realization $|K|$ is path-connected.

Remark. The equivalence of (a) and (b) is straightforward.
Remark. For the equivalence of (b) and (c) use the Union Connected Lemma 2.28, Lemma 93.8 (2) and Exercise 93.11.

Exercise 93.13. Let $K = (V, S)$ and $L = (W, T)$ be abstract simplicial complexes. We denote by X and Y the corresponding CW-complexes as defined in the Simplicial-Implies-CW Lemma 93.24. Let $X \otimes Y$ be the topological space that is given by the product CW-structure, see page 1500. Show that there exists a homeomorphism $|K \times L| \to X \otimes Y$.
Remark. Note that here we certainly do not assume that K and L are finite.

Exercise 93.14. Let X be a topological space that admits the structure of a 1-dimensional CW-complex. Show that X also admits the structure of a 1-dimensional simplicial complex.

[1148] This definition is modelled on the definition of the connectedness of an abstract graph, see page 307.

94. The Simplicial Approximation Theorem

In Chapter 93 we covered in great detail the basics of (abstract) simplicial complexes. In this chapter we will formulate and prove the first major result on simplicial complexes, namely the Simplicial Approximation Theorem.

94.1. **The barycentric subdivision.** In this section we introduce the barycentric subdivision of an abstract simplicial complex. This construction allows us to replace an abstract simplicial complex by a "finer" abstract simplicial complex. This will be a major tool in the proof of several theorems.

Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) For each k-simplex $s = \{v_0, \ldots, v_k\} \in S$ we define the barycenter of s to be the point
$$\underline{s} := \sum_{v \in s} \frac{1}{\dim(s)+1} \cdot v = \frac{1}{k+1} \cdot v_0 + \cdots + \frac{1}{k+1} \cdot v_k \in \langle s \rangle \subset \mathbb{R}^{(V)}.$$
Note that if $v \in V$ is a vertex, then the barycenter of the corresponding 0-simplex $\{v\}$ is v itself.

(2) Given $s, t \in S$ we write $\underline{s} \leq \underline{t}$ if $s \subset t$.

The following lemma summarizes a few properties of the barycenters.

Lemma 94.1. (Barycenter Lemma) Let $K = (V, S)$ be an abstract simplicial complex.

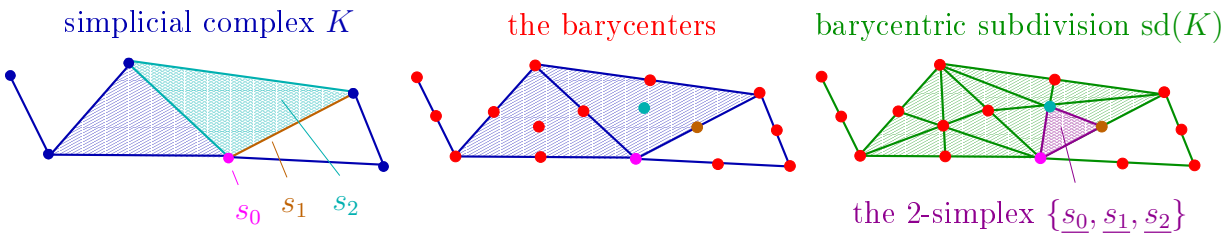
(1) The map $S \mapsto \mathbb{R}^{(V)}$ given by $s \mapsto \underline{s}$ is natural.
(2) For simplices $s, t \in S$ with $s \neq t$ we have $\underline{s} \neq \underline{t}$.
(3) For each 0-simplex s we have $s = \underline{s}$[1149] and for each simplex s of dimension ≥ 1 we have $\underline{s} \notin V$.

Proof.

(1) The most difficult part is to figure out what "natural" means in this context. We leave it to the reader to figure this out. Afterwards the statement is basically obvious.
(2) This statement follows from the Open Simplex Lemma 93.11 (2).
(3) This statement is trivial. (But it is nonetheless useful.) ■

The following lemma is much more interesting.

Lemma 94.2. Let $K = (V, S)$ be an abstract simplicial complex.



(1) The pair
$$\mathrm{sd}(K) = \left(\{\underline{s}\}_{s \in S}, \{\{\underline{s_0}, \ldots, \underline{s_k}\} \mid s_0 \subsetneq \cdots \subsetneq s_k\}\right)$$
is an abstract simplicial complex, called the barycentric subdivision of K.

(2) The relation "$\leq$" on the vertex set $\{\underline{s}\}_{s \in S}$ turns the barycentric subdivision $\mathrm{sd}(K)$ into an *ordered* abstract simplicial complex.

The definition of $\mathrm{sd}(K)$ is illustrated in the figure below.[1150]

[1149] Here we view, as usual, V as a subset of $\mathbb{R}^{(V)}$.

[1150] Here, as on many other occasions, we blur the difference between an abstract simplicial complex, its topological realization, and a linear simplicial complex that is simplicially isomorphic to the topological realization. In particular the illustrations shown in the figure below are dramatically dimensionally reduced.

Remark.

(1) Perhaps it is helpful to restate the definition of the barycentric subdivision $\mathrm{sd}(K)$ in other words: The vertices of $\mathrm{sd}(K)$ are precisely the barycenters of the original simplices and the simplices of the barycentric subdivision are given by the barycenters of an ascending sequence of simplices in K.

(2) The statement of Lemma 94.2 (2) is quite amazing: ex nihilo we created order where there was chaos.

(3) There is an alternative more formal, but basically equivalent definition of the barycentric subdivision. Namely, given an abstract simplicial complex $K = (V, S)$ one can consider the following abstract simplicial complex:

$$\widetilde{\mathrm{sd}}(K) \;=\; \{S, \{\{s_0, \ldots, s_k\} \,|\, s_0 \subsetneq \cdots \subsetneq\}\}.$$

The map $s \mapsto \underline{s}$ induces a natural isomorphism between the abstract simplicial complex $\widetilde{\mathrm{sd}}(K)$ and the abstract simplicial complex $\mathrm{sd}(K)$. Our first definition is arguably mnemonically superior, the second definition, which is for example used in [**dLon2013**, p. 179], is arguably purer.

Proof. The statements follow immediately from the definitions. ■

Notation. Let $K = (V, S)$ be an abstract simplicial complex. Given $i \in \mathbb{N}$ we refer to

$$\mathrm{sd}^i(K) \;:=\; \underbrace{\mathrm{sd}(\ldots \mathrm{sd}(\mathrm{sd}(K)) \ldots)}_{\text{sd applied } i \text{ times}}$$

as the i-th iterated barycentric subdivision of K.

The following lemma summarizes the most important properties of the barycentric subdivision of an abstract simplicial complex.

Lemma 94.3. (SD-Lemma) Let $K = (V, S)$ be an abstract simplicial complex.

(1) If K is finite, then $\mathrm{sd}(K)$ is also finite.

(2) The dimension of $\mathrm{sd}(K)$ equals the dimension of K.

(3) The map

$$\begin{array}{rcl} \mathfrak{V}\colon |\mathrm{sd}(K)| & \to & |K| \\ \alpha & \mapsto & \left(\begin{array}{ccc} V & \to & \mathbb{R}_{\geq 0} \\ v & \mapsto & \displaystyle\sum_{s \in S \text{ with } v \in s} \frac{1}{\dim(s)+1} \cdot \alpha(\underbrace{\underline{s}}_{\uparrow}) \end{array} \right) \end{array}$$

$\underline{s}$ is a vertex of $\mathrm{sd}(K)$, hence $\alpha(\underline{s})$ is defined

has the following properties:

(a) Let σ be a k-simplex of $\mathrm{sd}(K)$. By definition this means that $\sigma = \{\underline{s_0}, \ldots, \underline{s_k}\}$ where $s_0 \subsetneq \cdots \subsetneq s_k$ is an ascending sequence of simplices of K. The restriction of the map $\mathfrak{U}\colon |\mathrm{sd}(K)| \to |K|$ to $|\sigma|$ is given by[1151]

$$\begin{array}{ccc} |\sigma| & \to & |K| \\ \sum_{i=0}^{k} \lambda_i \cdot \underset{\uparrow}{\underline{s_i}} & \mapsto & \sum_{i=0}^{k} \lambda_i \cdot \underset{\uparrow}{\underline{s_i}} \\ \text{viewed as basis element of } \mathbb{R}^{(\mathrm{sd}(K))} & & \text{viewed as vector in } \mathbb{R}^{(V)} \end{array}$$

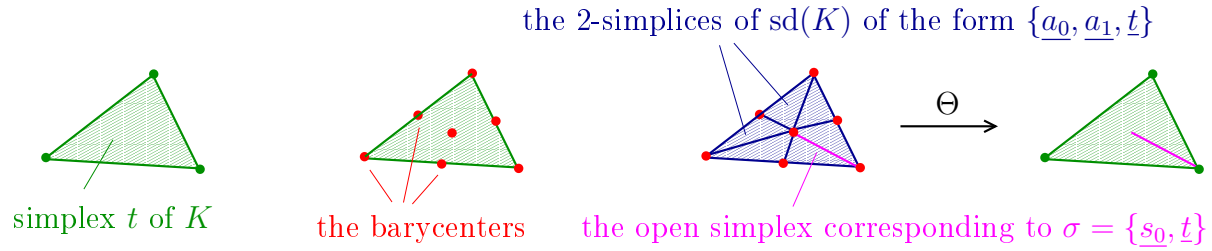
In particular we have $\mathfrak{U}(|\sigma|) \subset |s_k|$ and $\mathfrak{U}(\langle\sigma\rangle) \subset \langle s_k\rangle$.

(b) The map $\mathfrak{U}$ sends each vertex[1152] $\underline{s} \in \mathrm{sd}(K)$ to the corresponding point $\underline{s} \in |K|$.

(c) Given any k-simplex t of K the map $\mathfrak{U}$ restricts to a homeomorphism

$$\bigcup_{\substack{s = \{\underline{a_0}, \ldots, \underline{a_{k-1}}, \underline{t}\} \\ \text{a } k\text{-simplex of } \mathrm{sd}(K) \text{ where} \\ a_0 \subsetneq \cdots \subsetneq a_{k-1} \subsetneq t \\ \text{are simplices of } K}} |s| \xrightarrow{\cong} |t|.$$

(d) The map $\mathfrak{U}$ is a natural homeomorphism.



(4) If $f\colon K = (V, S) \to L = (W, T)$ is a simplicial map between two abstract simplicial complexes, then the map

$$\{\underline{s}\} \mapsto \{\underline{f(s)}\}$$

defines a simplicial map $f_*\colon \mathrm{sd}(K) \to \mathrm{sd}(L)$. This map has the property that the following diagram commutes:

$$\begin{array}{ccc} |\mathrm{sd}(K)| & \xrightarrow{\mathfrak{U}_K} & |K| \\ \downarrow{\scriptstyle |f_*|} & & \downarrow{\scriptstyle |f|} \\ |\mathrm{sd}(L)| & \xrightarrow{\mathfrak{U}_L} & |L|. \end{array}$$

(5) The maps from (4) turn $K \mapsto \mathrm{sd}(K)$ into a covariant functor from the category of abstract simplicial complexes to the category of (ordered) abstract simplicial complexes.

Given any abstract simplicial complex K and given any $i \in \mathbb{N}$ we will use the homeomorphism from the SD-Lemma 94.3 (3) to make the identification $|\mathrm{sd}^i(K)| = |K|$.

[1151] Note that this shows that $\mathfrak{U}$ does take values in $|K|$.

[1152] Here we use the convention from page 1984 that says that we view the vertex of an abstract simplicial complex as a subset of the topological realization.

Proof.

(1) This statement is basically clear.
(2) We will prove this statement in Exercise 94.3.
(3) Now we need to show that $\mho$ has all the promised properties:

(a) Let $\sigma = \{\underline{s_0}, \dots, \underline{s_k}\}$ be a k-simplex of $\mathrm{sd}(K)$. Given a point $P = \sum_{i=0}^{k} \lambda_i \cdot \underline{s_i}$ we calculate that

$$\mho(P) = \mho\Big(\sum_{i=0}^{k} \lambda_i \cdot \underline{s_i}\Big) = \sum_{i=0}^{k} \lambda_i \cdot \mho(\underline{s_i}) = \sum_{i=0}^{k} \lambda_i \cdot \mho\Big(\underbrace{\sum_{v \in s_i} \tfrac{1}{\dim(s_i)+1} \cdot v}_{=\underline{s_i}}\Big) = \sum_{i=0}^{k} \lambda_i \cdot \underline{s_i}.$$

Note that $\underline{s_0}, \dots, \underline{s_k}$ lie in $|s_k|$. Thus it follows from the calculation, together with the remark on page 2006, that $\mho(|\sigma|) \subset |s_k|$. Furthermore, if $P \in \langle\sigma\rangle$, then $\lambda_k > 0$, which in turn implies almost immediately that $\mho(P) \in \langle s_k\rangle$.[1153]

(b) This statement follows immediately from (a).

(c) Let t be a k-simplex t of K. We leave it to the reader to verify that $\mho$ restricts to a bijection

$$X := \bigcup_{s=\{\underline{a_0},\dots,\underline{a_{k-1}},\underline{t}\}} |s| \xrightarrow{\cong} |t|.$$

Note that the left-hand side X is actually a finite subcomplex of $|\mathrm{sd}(K)|$. Given a simplex $s = \{\underline{a_0}, \dots, \underline{a_{k-1}}, \underline{t}\}$ we pick a characteristic map $\Phi_s \colon \Delta^k \to |s|$. Furthermore we pick a characteristic map $\Phi_t \colon \Delta^k \to |t|$. It follows almost immediately from the definitions that the map $\Phi_t^{-1} \circ \mho \circ \Phi_s \colon \Delta^k \to \Delta^k$ is an affine linear map, in particular it is continuous. It follows from the Restrict-to-Simplex Lemma 93.6 (1) and the Simplex-Embedding Lemma 93.5 that the above map $\mho \colon X \to |t|$ is continuous. It now follows, as always, from the Compact-Hausdorff Proposition 2.17 (3) together with the Simplicial Complex-Finiteness Proposition 93.12 and the Simplex-Embedding Lemma 93.5 that the map $\mho \colon X \to |t|$ is a homeomorphism.

(d) Using (c) one can easily verify that $\mho$ is a bijection. Furthermore, it follows from the Restrict-to-Simplex Lemma 93.6 (1) together with (c) that $\mho$ is continuous. Finally, it follows from (c) that for each simplex t of K the map $\mho^{-1} \colon |t| \to |\mathrm{sd}(K)|$ is continuous. By the Restrict-to-Simplex Lemma 93.6 (1) this shows that $\mho^{-1} \colon |K| \to |\mathrm{sd}(K)|$ is continuous. We have thus shown that $\mho$ is indeed a homeomorphism. It follows easily from the definitions and the Barycenter Lemma 94.1 (1) that the homeomorphism is in fact natural.

(4) We leave the elementary task of verifying this statement to the reader.

(5) This statement follows almost immediately from the definitions. The only step which requires a short moment of reflection is to show that if $f \colon K \to L$ is a simplicial map, then the induced map $f_* \colon \mathrm{sd}(K) \to \mathrm{sd}(L)$ is actually order-preserving, i.e. it is a morphism in the category $\mathcal{OrdAbsSimpCplx}$ of ordered abstract simplicial complexes. ∎

The following definition is almost self-explanatory.

[1153] For the proof that $\mho(\langle\sigma\rangle) \subset \langle s_k\rangle$ it is arguably more efficient to work with the initial description of $\mho$.

Definition. Let $(X, (K, \Theta\colon |K| \to X))$ be a simplicial complex and let $i \in \mathbb{N}_0$. We define the i-th barycentric subdivision of (X, Θ) to be $(X, (\mathrm{sd}^i(K), \Theta\colon |\mathrm{sd}^i(K)| = |K| \to X))$

For completeness we state the following elementary lemma.

Lemma 94.4. For every $k \in \mathbb{N}_0$ the barycentric subdivision of a linear simplicial complex in $\mathbb{R}^n$ is again a linear simplicial complex in $\mathbb{R}^n$.

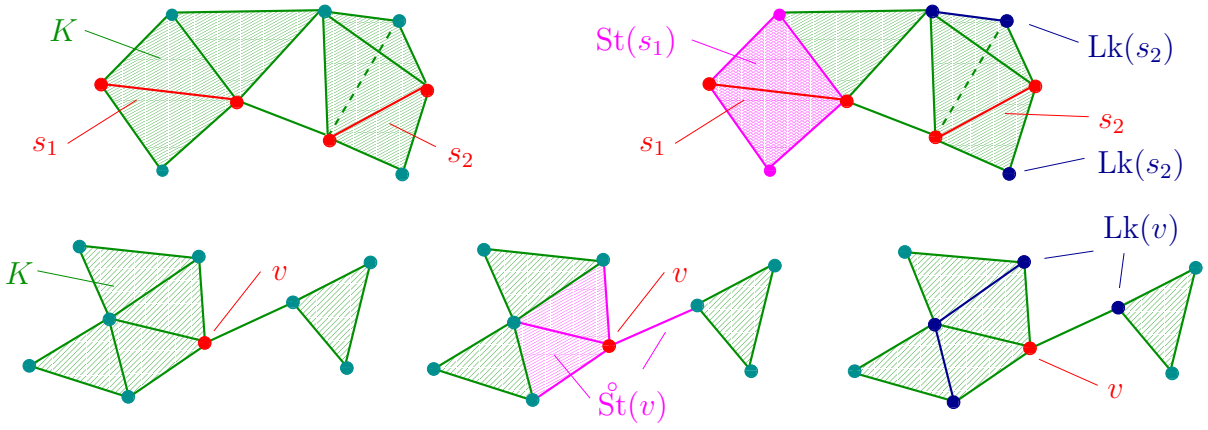
Proof. This statement follows almost immediately from the definition of the barycentric subdivision. ■

94.2. **Stars and links in simplicial complexes.** Given an (abstract) simplicial complex K and a simplex s we introduce and study the corresponding star $\mathrm{St}(K, s)$ and $\mathrm{Lk}(K, s)$. Both concepts are elementary, but both also play a major role in the study of (abstract) simplicial complexes.

Definition. Let $K = (V, S)$ be an abstract simplicial complex.

(1) Let $s \in S$ be a simplex. We introduce the following subsets of $|K|$:

$$\text{star } \mathrm{St}(K, s) := \bigcup_{t \in S \text{ with } s \subset t} |t| \quad \text{and the} \quad \text{open star } \mathring{\mathrm{St}}(K, s) := \bigcup_{t \in S \text{ with } s \subset t} \langle t \rangle.$$



Furthermore we define the link of s to be

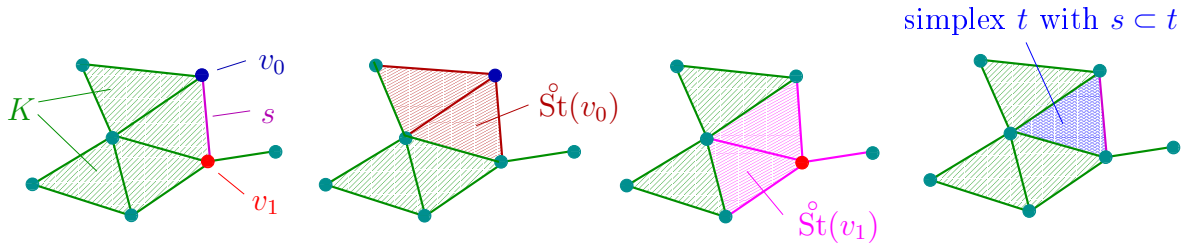
$$\mathrm{Lk}(K, s) := \bigcup_{\substack{t \in S \text{ with } s \cup t \in S \\ \text{but with } s \cap t = \varnothing}} |t|.$$

(2) Given a vertex v we use the obvious shorthand notations

$$\mathrm{St}(K, v) := \mathrm{St}(K, \{v\}), \quad \mathring{\mathrm{St}}(K, v) := \mathring{\mathrm{St}}(K, \{v\}) \text{ and } \mathrm{Lk}(K, v) := \mathrm{Lk}(K, \{v\}).$$

If K is understood, then we drop it from the notation. Furthermore we extend the definition in the obvious way to simplicial complexes.

Example. Let K be an abstract simplicial complex. We consider the simplicial cone $\mathrm{Cone}(K) = K * \{\star\}$ and the simplicial suspension $\Sigma(K) = K * \{\pm 1\}$ as defined on page 2003. Let $\epsilon \in \{-1, \}$. It follows easily from the definitions that $\mathrm{St}(\Sigma(K), \epsilon)$ is simplicially isomorphic to $\mathrm{Cone}(K)$ and that $\mathrm{Lk}(\Sigma(K), \epsilon) = K$.



Lemma 94.5. (the Link Star Lemma) Let $(X, (K = (V,S), \Theta\colon |K| \to X))$ be a simplicial complex.

(1) For every simplex $s \in S$ the following statements hold:
  (a) We have the equality
$$\mathrm{Lk}(s) \;=\; \mathrm{St}(s) \setminus \bigcup_{r \in S \text{ with } r \subset s} \mathring{\mathrm{St}}(r).$$
  (b) The star $\mathrm{St}(s)$ and the link $\mathrm{Lk}(s)$ are subcomplexes of X. The corresponding abstract simplicial complexes are given by
$$\Big(\bigcup_{\substack{t \in S \text{ with} \\ s \subset t}} t, \{t \in S \,|\, s \cup t \in S\} \Big) \text{ and } \Big(\bigcup_{\substack{t \in S \text{ with} \\ s \subset t}} t \setminus s, \{t \in S \,|\, s \cup t \in S \text{ and } s \cap t = \varnothing\} \Big).$$
  Furthermore $X \setminus \mathring{\mathrm{St}}(s)$ is a subcomplex, the corresponding abstract simplicial complex is given by
$$(V \setminus s, \{t \in S \,|\, t \cap s = \varnothing\}.$$
  (c) The star $\mathrm{St}(s)$ is naturally simplicially isomorphic to the simplicial join of the link $\mathrm{Lk}(s)$ with the simplex s.[11541155]
  (d) (α) The open star $\mathring{\mathrm{St}}(s)$ is an open neighborhood of every point $P \in \Theta(\langle s \rangle)$, in particular $\mathring{\mathrm{St}}(s)$ is an open subset of X.
  (β) The star $\mathrm{St}(K,s)$ is a closed neighborhood of every point $P \in \Theta(\langle s \rangle)$, in particular $\mathrm{St}(K,s)$ is a closed subset of X.
  (e) (α) The star $\mathrm{St}(s)$ admits a deformation retraction to the simplex $\Theta(|s|)$.
  (β) The open star $\mathring{\mathrm{St}}(s)$ admits a deformation retraction to the open simplex $\Theta(\langle s \rangle)$.
  (f) Both $\mathrm{St}(s)$ and $\mathring{\mathrm{St}}(s)$ are contractible.
  (g) (α) The link $\mathrm{Lk}(s)$ is a deformation retract of $\mathrm{St}(s) \setminus \Theta(|s|)$.
  (β) Given any $P \in \Theta(\langle s \rangle)$ the subcomplex $\partial s * \mathrm{Lk}(s)$ is a deformation retract of $\mathrm{St}(s) \setminus \{P\}$.
  (h) If t is a simplex with $s \subset t$, then $\mathrm{St}(t) \subset \mathrm{St}(s)$.

(2) (a) Let $s \in S$ be a simplex. For $P \in \Theta(\langle s \rangle)$ and $v \in V$ we have $P \in \mathring{\mathrm{St}}(v)$ if and only if $v \in S$.
  (b) The open stars $\{\mathring{\mathrm{St}}(v)\}_{v \in V}$ defined by the vertices are an open cover of X.

(3) Given simplices $s_0, \ldots, s_n \in S$ the following equality holds:[1156]
$$\mathring{\mathrm{St}}(s_0) \cap \cdots \cap \mathring{\mathrm{St}}(s_n) \;=\; \begin{cases} \mathring{\mathrm{St}}(s_0 \cup \cdots \cup s_n), & \text{if } s_0 \cup \cdots \cup s_n \text{ is a simplex,} \\ \varnothing, & \text{otherwise.} \end{cases}$$
  (Note that in Exercise 94.1 we will see that the analogous statement for the stars does *not* hold.)

(4) Given vertices $v_0, \ldots, v_n \in V$ the following statement holds:
$$\mathring{\mathrm{St}}(v_0) \cap \cdots \cap \mathring{\mathrm{St}}(v_n) \neq \varnothing \iff \{v_0, \ldots, v_n\} \text{ is a simplex of } K = (V,S).$$

Proof. Basically by definition we can assume that we are dealing with the topological realization $X = |K|$ of an abstract simplicial complex $K = (V, S)$.

(1) Let $s \in S$ be a k-simplex.

(a) We have the following equalities:

$$\mathrm{St}(s) \setminus \bigcup_{r \subset s} \mathring{\mathrm{St}}(r) = \bigcup_{s \subset t} |t| \setminus \bigcup_{r \subset s} \bigcup_{r \subset t} \langle t \rangle \overset{\text{follows from Open Simplex Lemma 93.11 (5) applied to the subcomplex defined by } t}{=} \bigcup_{s \subset t} \bigsqcup_{u \subset t} \langle u \rangle \setminus \bigcup_{r \subset s} \bigsqcup_{r \subset u} \langle u \rangle$$

$$= \bigcup_{\substack{u \in S \text{ with } s \cup u \in S \\ \text{but with } s \cap u = \varnothing}} \langle u \rangle = \bigcup_{\substack{t \in S \text{ with } s \cup t \in S \\ \text{but with } s \cap t = \varnothing}} \bigsqcup_{u \subset t} \langle u \rangle = \underbrace{\bigcup_{\substack{t \in S \text{ with } s \cup t \in S \\ \text{but with } s \cap t = \varnothing}} |t|}_{= \mathrm{Lk}(s)}.$$

(b) It follows easily from the definitions, (a) and Lemma 93.14 (4) that the star $\mathrm{St}(s)$, that the link $\mathrm{Lk}(s)$ and that $|K| \setminus \mathring{\mathrm{St}}(s)$ are subcomplexes of X and that the corresponding abstract simplicial complexes are the ones we wrote down.

(c) This statement follows immediately from the description of the abstract simplicial complexes given in (b) and the definition of the simplicial join that we gave on page 2003.

(d) First we show that $\mathring{\mathrm{St}}(s)$ is an open subset of $|K|$. By the definition of the topology on $|K|$, see page 1984, we need to show that for every k-simplex u, with some characteristic map $\Phi_u \colon \Delta^k \to |u|$, the preimage $\Phi_u^{-1}(\mathring{\mathrm{St}}(s))$ is an open subset of Δ^k. In fact

$$\Phi_u^{-1}\big(\mathring{\mathrm{St}}(s)\big) \underset{\text{by definition}}{=} \Phi_u^{-1}\Big(\bigcup_{s \subset t} \langle t \rangle\Big) \underset{\substack{\text{Image-Preimage} \\ \text{Lemma 0.2 (6)}}}{=} \bigcup_{s \subset t} \big(\Phi_u^{-1}(\langle u \rangle)\big) \underset{\text{Open Simplex Lemma 93.11 (2)}}{=} \begin{cases} \Phi_u^{-1}(\langle t \rangle) = \Delta^k \setminus \partial \Delta^k, & \text{if } s \subset u \\ \varnothing, & \text{else.} \end{cases}$$

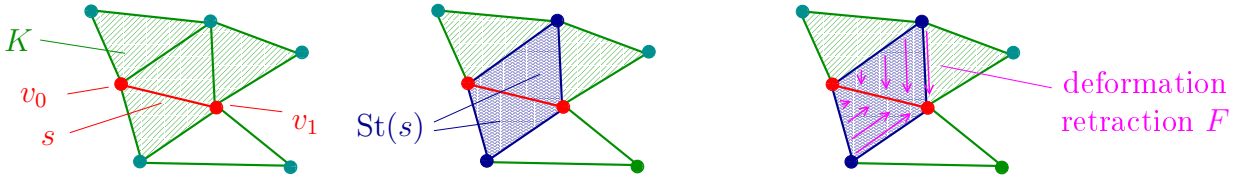
Since $\Delta^k \setminus \partial \Delta^k$ and $\varnothing$ are open subsets of Δ^k we are done. A very similar argument also shows that $\mathring{\mathrm{St}}(s)$ is a closed subset of $|K|$.

Now let $P \in \Theta(\langle s \rangle)$. By definition $P \in \mathring{\mathrm{St}}(s) \subset \mathrm{St}(s)$. Since $\mathring{\mathrm{St}}(s)$ is an open subset of $|K|$ we see that $\mathring{\mathrm{St}}(s)$ and $\mathrm{St}(s)$ are both neighborhoods of P.

[1154] Here we view $\mathrm{St}(s)$, $\mathrm{Lk}(s)$ and s as simplicial complexes.

[1155] In Exercise 94.2 we will prove the related statement that there exists a natural simplicial isomorphism $\mathrm{Lk}(K, s) * \partial s \cong \mathrm{Lk}(\mathrm{sd}(K), \underline{s})$.

[1156] To avoid confusion we point out that here, and in (4), we do not demand that the $s_0, \ldots, s_n$ are distinct.



(e) (α) We write $s = \{v_0, \dots, v_k\}$. Note that by (1) and Lemma 93.8 we can view $\mathrm{St}(s)$ as a simplicial complex in its own right. Now let t be a simplex t with $s \subset t$. We write $t = \{v_0, \dots, v_k, v_{k+1}, \dots, v_l\}$. We consider the map

$$\begin{array}{rcl} F_t \colon |t| \times [0,1] & \to & |t| \\ \left(\sum\limits_{i=0}^{l} \lambda_i \cdot v_i, r\right) & \mapsto & \sum\limits_{i=0}^{k} \lambda_i \cdot v_i + (1-r) \cdot \sum\limits_{i=k+1}^{l} \lambda_i \cdot v_i + r \cdot \left(\sum\limits_{i=k+1}^{l} \lambda_i\right) \cdot v_k. \end{array}$$

It follows immediately from the definitions that these maps F_t combine to give a well-defined map $F \colon \mathrm{St}(s) \times [0,1] \to \mathrm{St}(s)$. Furthermore it is fairly straightforward to deduce from the fact that $\mathrm{St}(s)$ is a simplicial complex, the Simplicial-Implies-CW Lemma 93.24 and the Intervall CW-Product Lemma 68.8 (3) that F is actually continuous. Now that continuity is out of the way it is clear that F is a deformation retraction from $\mathrm{St}(s)$ to $|s|$.

(β) In (α) we just gave an explicit deformation retraction from $\mathrm{St}(s)$ to $|s|$. It follows basically from the definitions that this map restricts to a deformation retraction from $\mathring{\mathrm{St}}(s)$ to the open simplex $\langle s \rangle$.

(f) This statement follows immediately from (e), together with the Simplex-Embedding Lemma 93.5 (3) and the observation that Δ^k and $\mathring{\Delta}^k$ are contractible.

(g) Let $P \in \Theta(\langle s \rangle)$. The proofs that the link $\mathrm{Lk}(s)$ is a deformation retract of $\mathrm{St}(s) \backslash |s|$ and that the subcomplex $\partial s * \mathrm{Lk}(s)$ is a deformation retract of $\mathrm{St}(s) \backslash \{P\}$ is quite similar to the proof of (e). We will fill in the details in Exercise 94.4.

(h) If t is a simplex with $s \subset t$, then it follows immediately from the definitions that $\mathrm{St}(t) \subset \mathrm{St}(s)$.

(2) (a) Let $s \in S$ be a simplex, let $P \in \langle s \rangle$ and let $v \in V$. We have

$$P \in \mathring{\mathrm{St}}(v) = \bigcup_{t \in S \text{ with } v \in t} \langle t \rangle \iff \langle s \rangle \subset \bigcup_{t \in S \text{ with } v \in t} \langle t \rangle \iff v \in s.$$

both statements follow from the Open Simplex Lemma 93.11 (2)

(b) Recall that the Open Simplex Lemma 93.11 (2) says that given any point $P \in K$ there exists an $s \in S$ with $P \in \langle s \rangle$. By (a) we know that for any vertex v of s we have $P \in \langle s \rangle \subset \mathring{\mathrm{St}}(v)$. This shows that the open stars corresponding to the vertices cover all of K. By (1d) we know that this cover is in fact an open cover.

(3) Let $s_0, \dots, s_n \in S$. We have the following equality:

$$\bigcap_{i=0}^{n} \mathring{\mathrm{St}}(s_i) \overset{\text{by definition}}{=} \bigcap_{i=0}^{n} \bigcup_{t \in S \text{ with } s_i \subset t} \langle t \rangle \overset{\text{Open Simplex Lemma 93.11 (5)}}{=} \bigcup_{t \in S \text{ with } s_0, \dots, s_n \subset t} \langle t \rangle \overset{\text{by definition of an open star}}{=} \begin{cases} \mathring{\mathrm{St}}(s_0 \cup \dots \cup s_n), & \text{if } s_0 \cup \dots \cup s_n \in S, \\ \varnothing, & \text{otherwise.} \end{cases}$$

(4) Given $v_0, \dots, v_n \in V$ the following holds:

$$\mathring{\mathrm{St}}(v_0) \cap \dots \cap \mathring{\mathrm{St}}(v_n) \neq \varnothing \quad \overset{\text{by (3)}}{\uparrow} \quad \Leftrightarrow \quad \begin{array}{c}\text{there exists a } t \in S \\ \text{with } v_0, \dots, v_n \in t\end{array} \quad \overset{\text{by definition of an abstract simplicial complex}}{\uparrow} \quad \Leftrightarrow \quad \{v_0, \dots, v_n\} \text{ is a simplex.}$$

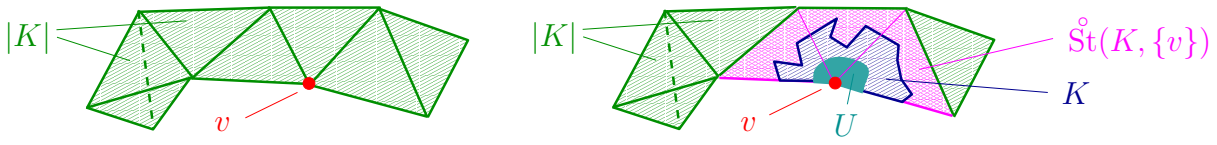
■

Definition. An abstract simplicial complex $K = (V, S)$ is called locally finite if given any vertex $v \in V$ there exist only finitely many simplices that contain v.

The following proposition can be viewed as an analogue of Proposition 68.11.

Proposition 94.6. Let $K = (V, S)$ be an abstract simplicial complex. The following three statements are equivalent:

(1) The abstract simplicial complex K is locally finite.
(2) For every vertex $v \in V$ the star $\mathrm{St}(K, \{v\})$ is a finite simplicial complex.
(3) For every vertex $v \in V$ the link $\mathrm{Lk}(K, \{v\})$ is a finite simplicial complex.
(4) The topological realization $|K|$ is regionally compact.



Proof. Let $K = (V, S)$ be an abstract simplicial complex.

We start out with (1) ⇔ (2) ⇔ (3). This equivalence of statements follows almost immediately from the definitions and the observation that an abstract simplicial complex is finite if and only if it has finitely many vertices.

We continue with (3) ⇒ (4). We need to show that $|K|$ is regionally compact. By Lemma 2.41 (2) together with the Simplex-Embedding Lemma 93.5 (2) it suffices to show that every point $P \in |K|$ admits a compact neighborhood. By the Open Simplex Lemma 93.11 there exists a simplex $s \in S$ such that P is contained in the open simplex $\langle s \rangle$. By the Link Star Lemma 94.5 (1d) we know that $\mathrm{St}(K, s)$ is a neighborhood of P. Since $\mathrm{St}(K, s)$ is a finite simplicial complex we obtain from Lemma 93.9 that $\mathrm{St}(K, s)$ is compact.

Finally we prove (4) ⇒ (3). Now we assume that $|K|$ is regionally compact. Let $v \in V$ be a vertex. By the Link Star Lemma 94.5 (1d) we know that the open star $\mathring{\mathrm{St}}(K, \{v\})$ is an open neighborhood of v. Since $|K|$ is regionally compact there exists a compact neighborhood X of v with $X \subset \mathring{\mathrm{St}}(K, \{v\})$. Since X is compact we know by the Simplicial Complex-Finiteness Proposition 93.12 that there exists a finite subcomplex L of K such that X is contained in $|L|$.

Since X is a neighborhood of v we know that there exists an open neighborhood U of v with $v \in U \subset X$. It follows from Open Simplex Lemma 93.11 (7) that for any simplex s with $v \in s$ we have $U \cap \langle s \rangle \neq \varnothing$. But by the Open Simplex Lemma 93.11 (5) that implies $|s| \subset |L|$. In other words, we see that $\mathrm{St}(K, \{v\}) \subset |L|$. Since L is finite we see that $\mathrm{St}(K, \{v\})$ is a finite simplicial complex. ■

We recall the following definition from page 285.

Definition. The diameter of a non-empty subset A of some $\mathbb{R}^n$ is defined as

$$\operatorname{diam}(A) \;:=\; \sup\{\|a-b\| \,|\, a,b \in A\} \;\in \mathbb{R}_{\geq 0} \cup \{\infty\}.$$

It is pretty clear that the barycentric subdivision of a linear simplicial complex results in more but smaller simplices. The following lemma is one way of formulating precisely that the simplices shrink.

Lemma 94.7. If X is a finite linear non-empty simplicial complex in $\mathbb{R}^n$, then

$$\lim_{k\to\infty} \max\{\operatorname{diam}(\underbrace{\operatorname{St}(\operatorname{sd}^k(X), v)}_{\uparrow}) \,|\, v \text{ is a vertex of } \operatorname{sd}^k(X)\} \;=\; 0.$$

underlying topological space of X and $\operatorname{sd}^k(X)$ is the same

the maximal diameter of a star shrinks

Proof. Let Y be a finite linear non-empty d-dimensional simplicial complex in $\mathbb{R}^n$. We define the *mesh of* Y as

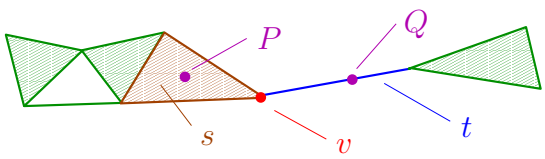
$$\operatorname{mesh}(Y) \;:=\; \max\{\operatorname{diam}(s) \,|\, s \text{ is a simplex of } Y\}.$$

The lemma follows from the SD-Lemma 94.3 (1) and (2), Lemma 94.4 and the following claim.

Claim.

(1) For every vertex v of Y we have $\operatorname{diam}(\operatorname{St}(v)) \leq 2 \cdot \operatorname{mesh}(Y)$.
(2) For every $k \in \mathbb{N}_0$ we have

$$\operatorname{mesh}(\operatorname{sd}^k(Y)) \;\leq\; \left(\tfrac{d}{d+1}\right)^k \cdot \operatorname{mesh}(Y).$$



Proof.

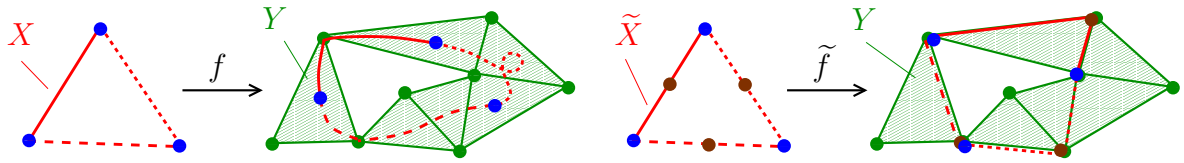
(1) Let v be a vertex of Y. We need to show that $\operatorname{diam}(\operatorname{St}(v)) \leq 2 \cdot \operatorname{mesh}(Y)$. Thus let $P, Q \in \operatorname{St}(v)$. By definition of the star $\operatorname{St}(v)$ there exist simplices s and t with $v, P \in s$ and with $v, Q \in t$. We see that

$$\|P-Q\| \underset{\uparrow}{\leq} \|P-v\| + \|Q-v\| \underset{\uparrow}{\leq} \operatorname{diam}(s) + \operatorname{diam}(t) \underset{\uparrow}{\leq} 2\operatorname{mesh}(Y).$$

triangle inequality; since $v, P \in s$ and $v, Q \in t$; definition of mesh

(2) Once the reader has untangled the definitions it will have become clear that this statement is nothing but a reformulation of Lemma 74.28. ∎

94.3. **The Simplicial Approximation Theorem.** In this section we will state and prove the Simplicial Approximation Theorem which is one of the main tools in the study of simplicial complexes. Before we can state the theorem we need to introduce one last basically self-explanatory notion.



Definition. Let X be an (abstract) simplicial complex and let A be a subcomplex. We refer to (X, A) as a pair of (abstract) simplicial complexes.

Now we are ready to formulate the main theorem of this section.

Theorem 94.8. (Simplicial Approximation Theorem) Let (X, A) and (Y, B) be pairs of simplicial complexes. Let $f\colon (X, A) \to (Y, B)$ be a map of pairs of topological spaces. If X is finite, then there exists an iterated barycentric subdivision $(\widetilde{X}, \widetilde{A})$ of (X, A) and a simplicial map $\widetilde{f}\colon (\widetilde{X}, \widetilde{A}) \to (Y, B)$ with the following properties:

(1) The map $\widetilde{f}$ is homotopic to f as a map $(X, A) \to (Y, B)$ of pairs of topological spaces.
(2) For every vertex v of $\widetilde{X}$ we have $f(\mathrm{St}(\widetilde{X}, v)) \subset \mathrm{St}(Y, \widetilde{f}(v))$.

Example. We consider the simplicial complexes X and Y and the map $f\colon X \to Y$ that are illustrated in the figure below. This map is actually *not* homotopic to a simplicial map.[1157] But after a single barycentric subdivision we see that f is homotopic to a simplicial map $\widetilde{f}\colon \mathrm{sd}(X) \to Y$.

Remark.

(1) The first statement of the Simplicial Approximation Theorem 94.8 is of course somewhat similar to the statement of the Cellular Approximation Theorem 70.15. But since simplicial complexes and simplicial maps are more rigid than their cellular siblings there are some important differences:
   (a) On the negative side the Simplicial Approximation Theorem 94.8 only applies to finite domains and we need to allow for several barycentric subdivisions.
   (b) On the plus side the output is much stronger since simplicial maps are much more restrictive than cellular maps. We will make use of this shortly.
(2) The second statement of the Simplicial Approximation Theorem 94.8 essentially says that the new map $\widetilde{f}$ does not stray too far away from the original map f.

Before we give a proof of the Simplicial Approximation Theorem 94.8, let us point out an important consequence. On page 1844 we saw that homotopy groups of fairly simple topological spaces, e.g. $S^1 \vee S^2$, can be uncomfortably large, for example we saw that $\pi_2(S^1 \vee S^2)$ is not necessarily finitely generated. In Question 71.16 we asked whether the homotopy groups of a countable CW-complex are actually countable. The following proposition gives us some evidence for a positive answer.

[1157] Why not?

Proposition 94.9. If X is a simplicial complex with countably many simplices, then for every $n \in \mathbb{N}$ and every $x_0 \in X$ the group $\pi_n(X, x_0)$ is countable.

Proof. Let X be a simplicial complex and let $n \in \mathbb{N}$. By the discussion on page 1997 we can pick a finite simplicial structure for S^n. Let $*$ be a vertex of S^n. By the Change-of-Base Point Proposition 71.5 it suffices to show that for a single vertex x_0 of X the group $\pi_n(X, x_0)$ is countable.

Next note that by the Simplicial Approximation Theorem 94.8, applied to the maps $(S^n, \{*\}) \to (X, x_0)$ we have a surjection

$$\bigcup_{i \in \mathbb{N}_0} \underbrace{\{\text{set of simplicial maps } (\mathrm{sd}^i(S^n), \{*\}) \to (X, x_0)\}}_{\text{countable set by Lemma 93.3 (2)}} \twoheadrightarrow \underbrace{[(S^n, *), (X, x_0)]}_{\substack{\text{set of homotopy classes} \\ \text{of maps } (S^n, *) \to (X, x_0)}} = \pi_n(X, x_0).$$

By Lemma 93.3 (2) together with the Countability Lemma 0.8 (3) the set on the left-hand side is countable. It follows from the Countability Lemma 0.8 (3) that the set on the right-hand side, i.e. $\pi_n(X, x_0)$, is also countable. ■

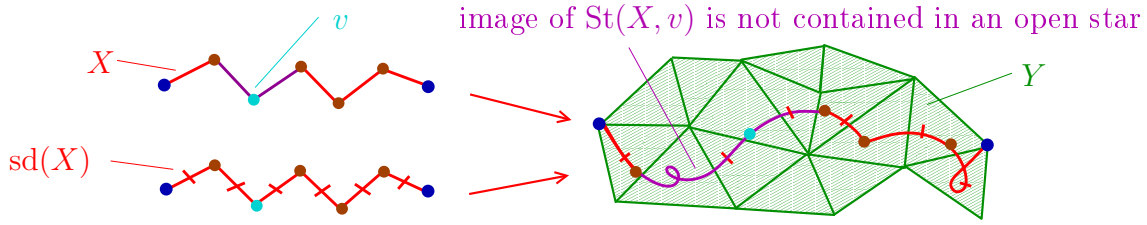
It is not immediately clear how one could possibly generalize the proof of Proposition 94.9 from simplicial complexes to CW-complexes. In particular at the moment we still lack the tools to tackle Question 71.16 completely. We will return to Question 71.16 with Proposition 104.21.

Before we turn to the proof of the Simplicial Approximation Theorem 94.8 let us record the following immediate corollary to Proposition 94.9.

Corollary 94.10. For every $n, k \in \mathbb{N}$ the group $\pi_n(S^k)$ is countable.

Now we turn to the proof of the Simplicial Approximation Theorem 94.8.

Proof of the Simplicial Approximation Theorem 94.8. In an attempt to keep the notation at a manageable level we will assume for simplicity that $A = B = \varnothing$. We leave it to the reader to modify the subsequent proof to provide a proof for the general case.



Thus let $(X, (K = (V, S), \Theta\colon |K| \to X))$ and $(Y, (L = (W, T), \Omega\colon |L| \to Y))$ be two simplicial complexes. For convenience we identify V with its image $\Theta(V) \subset X$ and we identify W with its image $\Omega(W) \subset Y$. Furthermore let $f\colon X \to Y$ be a continuous map. We make the following preparations.

(1) Recall that we assume that X is finite. Evidently we can assume that X is non-empty.
(2) It follows from the hypothesis that X is finite and the combination of Lemma 93.9, the Compact Image Lemma 2.13 and the Simplicial Complex-Finiteness Proposition 93.12 that $f(X)$ is contained in a finite subcomplex of Y. Thus we can assume that Y is also a finite simplicial complex.
(3) Since X and Y are finite it follows from Lemma 93.22 that we can and will assume that X and Y are linear simplicial complexes contained in some $\mathbb{R}^m$ respectively some $\mathbb{R}^n$. Recall that this means, by definition, that X and Y are equipped with the subspace topology coming from $\mathbb{R}^m$ and $\mathbb{R}^n$. In particular we can use the usual Euclidean metric on $\mathbb{R}^m$ to view X as a metric space.

We start out with the following claim.

Claim 1. There exists a $k \in \mathbb{N}_0$ such that for every vertex v of $\mathrm{sd}^k(X)$ there exists a $w \in W$ with $f(\mathrm{St}(\mathrm{sd}^k(X), v)) \subset \mathring{\mathrm{St}}(Y, w)$.

Proof. Recall that by the Link Star Lemma 94.5 (2) we know that the open stars $\{\mathring{\mathrm{St}}(w)\}_{w \in W}$, form an open cover of Y. It follows that the sets $U_w := f^{-1}(\mathring{\mathrm{St}}(w)) \subset X$ form an open cover of X. Since X is compact we obtain from the Lebesgue Lemma 6.5 that there exists an $\epsilon > 0$ such that for every subset A of X with $\mathrm{diam}(A) < \epsilon$ there exists a $w \in W$ with $A \subset U_w$. By Lemma 94.7 there exists a $k \in \mathbb{N}_0$ such that for every vertex v of $\mathrm{sd}^k(X)$ we have $\mathrm{diam}(\mathrm{St}(\mathrm{sd}^k(X), v)) < \epsilon$. In other words, this k has the desired property. ⊞

By the SD-Lemma 94.3 (1) and Lemma 94.4 we know that $\mathrm{sd}^k(X)$ is again a finite linear simplicial complex in $\mathbb{R}^m$. Thus we can safely replace X by $\mathrm{sd}^k(X)$. We are now in the following setting:

(∗) For every $v \in V$ there exists a $w \in W$ with $f(\mathrm{St}(X, v)) \subset \mathring{\mathrm{St}}(Y, w)$. In other words, there exists a map $\varphi\colon V \to W$ with the property that for every vertex $v \in V$ we have $f(\mathrm{St}(X, v)) \subset \mathring{\mathrm{St}}(Y, \varphi(v))$.

We continue the proof with the following claim.

Claim 2. For every simplex $s \in S$ the image $\varphi(s)$ is a simplex in T.

Proof. Let $s = \{v_0, \ldots, v_k\}$ be a simplex of $K = (V, S)$. Note that

$$
\begin{array}{ll}
 & \text{Link Star Lemma 94.5 (4)} \\
 & \downarrow \\
v_0, \ldots, v_k \text{ form a simplex in } X & \Rightarrow \mathring{\mathrm{St}}(v_0) \cap \ldots \cap \mathring{\mathrm{St}}(v_k) \neq \varnothing \quad \Rightarrow f\big(\mathring{\mathrm{St}}(v_0) \cap \ldots \cap \mathring{\mathrm{St}}(v_k)\big) \neq \varnothing \\
 & \Rightarrow f(\mathring{\mathrm{St}}(v_0)) \cap \ldots \cap f(\mathring{\mathrm{St}}(v_k)) \neq \varnothing \quad \Rightarrow \mathring{\mathrm{St}}(\varphi(v_0)) \cap \ldots \cap \mathring{\mathrm{St}}(\varphi(v_k)) \neq \varnothing \\
 & \uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\
 & \text{Image-Preimage Lemma 0.2 (4)} \qquad\qquad\qquad\qquad\qquad\qquad \text{by choice of } \varphi \text{ we have } f(\mathrm{St}(v_i)) \subset \mathring{\mathrm{St}}(\varphi(v_i)) \\
 & \Rightarrow \{\varphi(v_0), \ldots, \varphi(v_k)\} \text{ is a simplex in } T. \\
 & \uparrow \\
 & \text{Link Star Lemma 94.5 (4)}
\end{array}
$$

⊞

Claim 2 says that $\varphi\colon V \to W$ defines a simplicial map $K = (V, S) \to L = (W, T)$. It follows from Lemma 93.15 that there exists a simplicial map $g\colon X \to Y$ with $g|_V = \varphi$. We claim that g is the desired map.

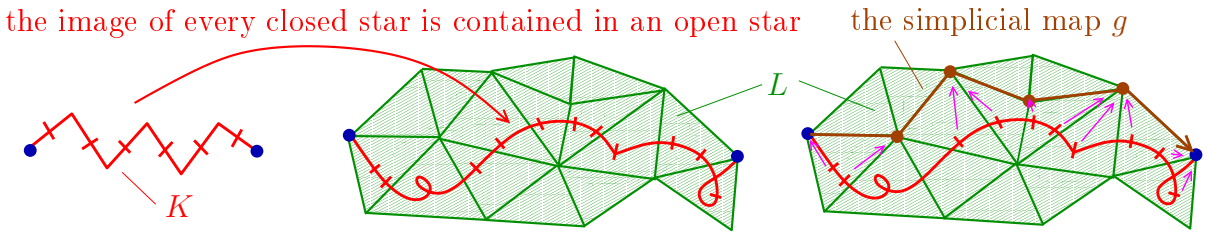
First note that it follows immediately from the construction of φ and g that for any vertex v of $\mathrm{sd}(X)$ we have $f(\mathrm{St}(X, v)) \subset \mathrm{St}(Y, g(v))$. Thus it remains to show that g is in fact homotopic to our original map f. To do so we consider the usual interpolation between the maps f and g:[1158]

$$
\begin{array}{rcl}
F\colon X \times [0,1] & \to & \mathbb{R}^n \\
(x, t) & \mapsto & f(x) \cdot (1 - t) + g(x) \cdot t.
\end{array}
$$

[1158] Note that we showed in the Convex Homotopy Lemma 14.1 that this map is actually continuous.

It remains to show the map F actually takes values in the subset $Y \subset \mathbb{R}^n$. For each $x \in X$ we know that $f(x) \in Y$ and $g(x) \in Y$. We need to show that for each $t \in [0,1]$ the point $f(x) \cdot (1-t) + g(x) \cdot t$ also lies in Y. In our setting this follows from the observation that simplices are convex, see Lemma 93.23 (1b), together with the following claim.

Claim 3. For every $x \in X$ there exists a $t \in T$ such that both $f(x)$ and $g(x)$ are contained in $\Omega(|t|)$.



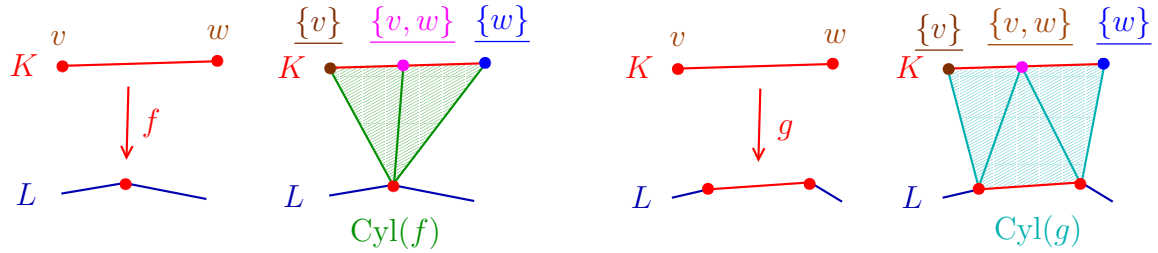
Proof. Now let $x \in X$. By the Open Simplex Lemma 93.11 (2) there exists a unique simplex $s = \{v_0, \ldots, v_k\}$ such that $x \in \Theta(\langle s \rangle)$. We see that

$$
\begin{array}{l}
\qquad\qquad\qquad\qquad \text{by the Link Star Lemma 94.5 (3), since } s = \{v_0, \ldots, v_k\} \\
x \in \Theta(\langle s \rangle) \;\overset{\downarrow}{\Rightarrow}\; x \in \mathring{\mathrm{St}}(v_0) \cap \ldots \cap \mathring{\mathrm{St}}(v_k) \;\Rightarrow\; f(x) \in f\big(\mathring{\mathrm{St}}(v_0) \cap \ldots \cap \mathring{\mathrm{St}}(v_k)\big) \\
\quad \underset{\uparrow}{\Rightarrow}\; f(x) \in f\big(\mathring{\mathrm{St}}(v_0)\big) \cap \ldots \cap f\big(\mathring{\mathrm{St}}(v_k)\big) \;\underset{\uparrow}{\Rightarrow}\; f(x) \in \mathring{\mathrm{St}}(\varphi(v_0)) \cap \ldots \cap \mathring{\mathrm{St}}(\varphi(v_k)) \\
\quad \text{Image-Preimage Lemma 0.2 (4)} \qquad\qquad \text{by choice of } \varphi \text{ we have } f(\mathrm{St}(v_i)) \subset \mathring{\mathrm{St}}(\varphi(v_i)) \\
\quad \underset{\uparrow}{\Rightarrow} \text{ there exists a } t \in T \text{ which contains } \varphi(s) = \{\varphi(v_0), \ldots, \varphi(v_k)\} \text{ and with } f(x) \in \Omega(\langle t \rangle). \\
\quad \text{Link Star Lemma 94.5 (3)}
\end{array}
$$

It remains to show that $g(x) \in \Omega(|t|)$. In fact we see that

$$
\begin{array}{ccccccc}
x \in \Theta(\langle s \rangle) & \underset{\uparrow}{\Rightarrow} & x \in \Theta(|s|) & \underset{\uparrow}{\Rightarrow} & g(x) \in \Omega(|\varphi(s)|) & \underset{\uparrow}{\Rightarrow} & g(x) \in \Omega(|t|). \\
\text{by definition of } \langle s \rangle \text{ and } |s| & & & \text{follows from the discussion on page 1987} & & \text{since } \varphi(s) \subset t &
\end{array}
$$

We have thus found the desired simplex t. ∎



94.4. **Mapping cylinders and mapping cones of simplicial maps.** In this section we will see that there exist simplicial analogues of the mapping cylinder and the mapping cone that we introduced on page 454 and 457. The definitions of these simplicial analogues that we give are taken from [**Kas2014**].

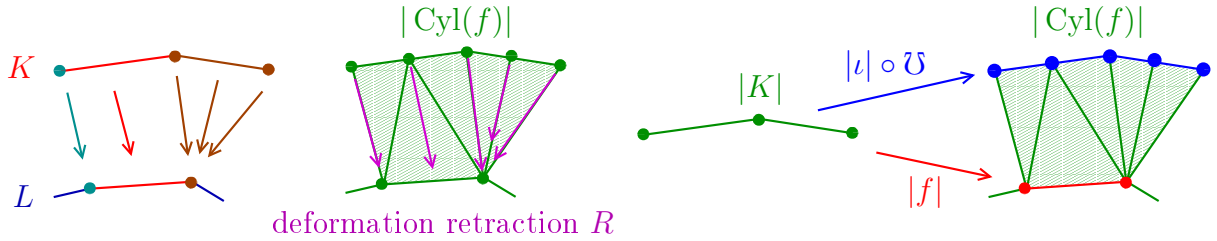
Definition. Let $f\colon K \to L$ be a simplicial map between two abstract simplicial complexes. The simplicial mapping cylinder $\mathrm{Cyl}(f\colon K \to L)$ is the abstract simplicial complex that is given by the following data:

(1) The vertex set is the disjoint union of the vertex set of the barycentric subdivision $\mathrm{sd}(K)$ of K and the vertex set of L.

(2) The set of simplices is given by

$$\left\{ \sigma \sqcup \tau \;\middle|\; \begin{array}{c} \sigma = \varnothing \text{ or } \sigma \text{ a simplex of } \mathrm{sd}(K) \;\&\; \tau = \varnothing \text{ or } \tau \text{ a simplex of } L \text{ or such that} \\ \text{for every vertex } v = \underset{\uparrow}{\underline{s}} \in \sigma \text{ and every vertex } w \in \tau \text{ we have } w \in f(s) \\ \text{where } s \text{ is a simplex of } K \end{array} \right\}.$$

Let $f\colon K \to L$ be a simplicial map between two finite abstract simplicial complexes. One might expect that the next lemma states, say under the hypothesis that K is finite, that the topological realization $|\operatorname{Cyl}(f\colon K \to L)|$ of the simplicial mapping cylinder is homeomorphic to the mapping cylinder $\operatorname{Cyl}(|f|\colon |K| \to |L|)$ of the map between the topological realizations. We will prove a weaker statement, but which nonetheless says that the simplicial mapping cylinder has all the essential properties we really need.



Lemma 94.11. (Simplicial Mapping Cylinder Lemma) Let $f\colon K \to L$ be a simplicial map between two abstract simplicial complexes.

(1) The simplicial mapping cylinder $\operatorname{Cyl}(f\colon K \to L)$ contains $\mathrm{sd}(K)$ and L as subcomplexes.

We now assume that K is actually a finite abstract simplicial complex. We denote by $\iota\colon \mathrm{sd}(K) \to \operatorname{Cyl}(f\colon K \to L)$ the natural inclusion and we denote by $\mho\colon |K| \to |\mathrm{sd}(K)|$ the natural homeomorphism from the SD-Lemma 94.3.

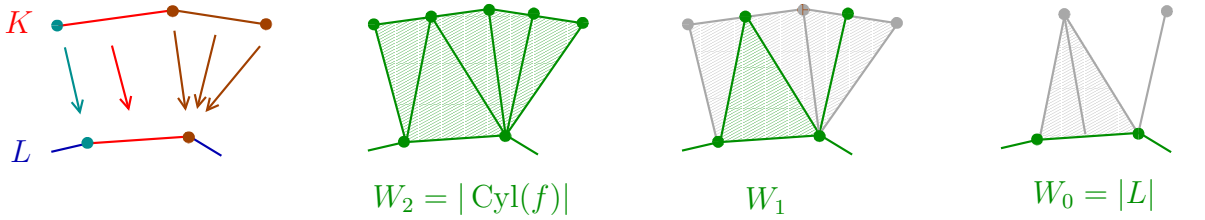
(2) There exists a deformation retraction $R\colon |\operatorname{Cyl}(f)| \times [0,1] \to |\operatorname{Cyl}(f)|$ from $|\operatorname{Cyl}(f)|$ to the subset $|L|$ such that $R_1 \circ \iota \circ \mho = f\colon |K| \to |\operatorname{Cyl}(f)|$.

(3) The map $|f|\colon |K| \to |\operatorname{Cyl}(f)|$ is homotopic to the map $|\iota| \circ \mho\colon |K| \to |\operatorname{Cyl}(f)|$.

Remark. It is not clear to me whether the statement of the Simplicial Mapping Cylinder Lemma 94.11 (2) also holds if K is infinite. For example one might be able to get stronger results using Lemma 70.13. But for our purposes it is good enough to know that the statement holds if K is finite.

Sketch of proof. Let $f\colon K \to L$ be a simplicial map between two abstract simplicial complexes.

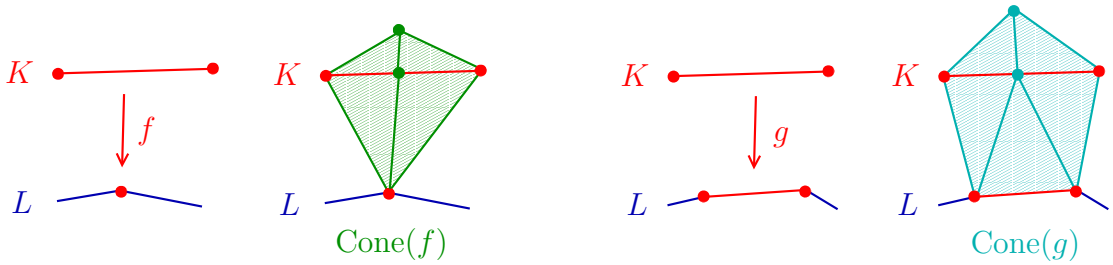
(1) By taking $\tau = \varnothing$ respectively $\sigma = \varnothing$ one sees immediately that $\mathrm{sd}(K)$ and L are subcomplexes of $\mathrm{Cyl}(f\colon K \to L)$.



We now assume that K is actually a finite abstract simplicial complex.

(2) Given $r \in \mathbb{N}_0$ we denote by W_r the topological realization of the maximal subcomplex of $\mathrm{Cyl}(f\colon K \to L)$ that contains all vertices of L and that contains all vertices $\mathrm{sd}(K)$ of the form $\underline{s}$ where s is a $\geq r$-simplex of K. We leave it to the reader to verify that for each $r \in \mathbb{N}_0$ there exists a unique homotopy

$$F_r\colon W_r \times [0,1] \;\to\; W_r$$



with the following properties:
(a) F_r is a homotopy rel W_{r-1}.
(b) Given any vertex $\underline{s}$ that lies in W_r but that does not lie in W_{r-1} the homotopy is given by $F_r(\underline{s},t) = \underline{s}\cdot(1-t) + \underline{f(s)}\cdot t$.
(c) The restriction of F_r to each simplex takes values in a simplex and it is linear.
Note that F_r is in particular a deformation retraction from W_r to W_{r-1}. The composition of the homotopies $F_{\dim(K)},\dots,F_1$ and F_0 has the desired properties.

(3) This statement follows immediately from (2). ∎

We conclude this section with the following definition.

Definition. Let $f\colon K \to L$ be a simplicial map between two abstract simplicial complexes. The simplicial mapping cone $\mathrm{Cone}(f\colon K \to L)$ is defined as the union of the simplicial mapping cylinder $\mathrm{Cyl}(f\colon K \to L)$ and the simplicial cone $\mathrm{Cone}(\mathrm{sd}(K))$ that we defined on page 2003.

In Section 94.5 we will see that the concept of a simplicial mapping cone is indeed useful.

94.5. **Simplicial structures and CW-structures II.** Recall that in the Simplicial-Implies-CW Lemma 93.24 we saw that every (ordered) simplicial complex admits a (natural) CW-complex structure where given any $n \in \mathbb{N}$ the n-simplices of the simplicial structure are precisely the n-cells of the CW-structure. The converse of this statement does not hold,

in fact in Proposition 93.28 we showed that there exists a CW-complex that does not admit a simplicial structure.
Nonetheless, in this section we will prove a partial converse to the Simplicial-Implies-CW Lemma 93.24, namely we will show that every CW-complex is *homotopy equivalent* to a simplicial complex. More precisely, we will prove the following proposition.

Proposition 94.12.

(1) Every finite CW-complex is homotopy equivalent to a finite simplicial complex of the same dimension.
(2) Every countable CW-complex is homotopy equivalent to a countable simplicial complex of the same dimension.
(3) Every CW-complex is homotopy equivalent to a simplicial complex of the same dimension.

Remark. Alternative proofs for Proposition 94.12 are given in [**Hat2002**, Theorem 2C.5], [**LW1969**, Theorem 6.1], [**WhdJ1949b**, Theorem 13] and [**Gra1975**, Corollary 16.44].

Most of the work in the proof of Proposition 94.12 is done in the following lemma.

Lemma 94.13. Let X be a CW-complex that is homotopy equivalent to the topological realization of an abstract simplicial complex K. Furthermore let $\varphi\colon S^{k-1} \to X$ be a map. There exists an $i \in \mathbb{N}_0$ a simplicial map $f\colon \mathrm{sd}^i(S_{k-1}) \to K$ such that $X \cup_\varphi \overline{B}^k$ is homotopy equivalent to the topological realization of the simplicial mapping cone $\mathrm{Cone}(f\colon \mathrm{sd}^i(S_{k-1}) \to K)|$.

The key ingredient in the proof of Lemma 94.13 is the Homotopy Pushout Theorem which we recall for the reader's convenience.

Theorem 17.19. (Homotopy Pushout Theorem) Suppose we are given the following commutative diagram of maps between topological spaces:

$$\begin{array}{ccccc} Y & \xleftarrow{f} & A & \xhookrightarrow{i} & X \\ {\scriptstyle\varphi_Y}\downarrow & & \downarrow{\scriptstyle\varphi_A} & & \downarrow{\scriptstyle\varphi_X} \\ Y' & \xleftarrow{f'} & A' & \xhookrightarrow{i'} & X'. \end{array}$$

If the vertical maps are homotopy equivalences and if the maps i and i' to the right are closed cofibrations, then the induced map

$$Y \cup_A X \;\to\; Y' \cup_{A'} X'$$

between the pushouts is a homotopy equivalence.

Proof of Lemma 94.13. We start out with the following preparations:

(1) By the discussion on page 1989 there exists a homeomorphism $g\colon |D_k| \to \overline{B}^k$ which restricts to a homeomorphism $g\colon |S_{k-1}| \to S^{k-1}$.
(2) Given any abstract simplicial complex L and given any $i \in \mathbb{N}_0$ we always denote by $\mho\colon |L| \to |\mathrm{sd}^i(L)|$ the homeomorphism from the SD-Lemma 94.3 (3).
(3) By the Simplicial Approximation Theorem 94.8 there exists an $i \in \mathbb{N}_0$, a simplicial map $f\colon \mathrm{sd}^i(S_{k-1}) \to K$ and a homotopy $F\colon |\mathrm{sd}^i(S_{k-1})| \times [0,1] \to |K|$ such that $F_0 = \theta \circ \varphi \circ g \circ \mho^{-1}$ and such that $F_1 = |f|$.

(4) We denote by $j\colon |K| \to |\operatorname{Cyl}(f\colon \operatorname{sd}^i(S_{k-1}) \to K)|$ the inclusion map. Note that by the Simplicial Mapping Cylinder Lemma 94.11 (2) we know that j is a homotopy equivalence.

(5) Finally note that it follows immediately from the Simplicial Mapping Cylinder Lemma 94.11 (3) that there exists a homotopy $G\colon |\operatorname{sd}^i(S_{k-1})| \times [0,1] \to |\operatorname{Cyl}(f\colon \operatorname{sd}^i(S_{k-1}) \to K))|$ with $G_0 = j \circ |f|$ and such that $G_1 = |\iota| \circ \mho$ where $\iota\colon \operatorname{sd}^{i+1}(S_{k-1}) \to \operatorname{Cyl}(f\colon \operatorname{sd}^i(S_{k-1}) \to K)$ is the natural inclusion.

We consider the following commutative diagram:

$$
\begin{array}{ccccc}
X & \xleftarrow{\varphi} & S^{k-1} & \hookrightarrow & \overline{B}^k \\
\downarrow{\scriptstyle \theta} & & \cong\downarrow{\scriptstyle g^{-1}} & & \cong\downarrow{\scriptstyle g^{-1}} \\
|K| & \xleftarrow{\theta\circ\varphi\circ g} & |S_{k-1}| & \hookrightarrow & |\operatorname{Cone}(S_{k-1})| \\
\downarrow{\scriptstyle \mathrm{id}} & & \cong\downarrow{\scriptstyle \mho} & & \cong\downarrow{\scriptstyle \mho} \\
|K| & \xleftarrow{\theta\circ\varphi\circ g\circ\mho^{-1}} & |\operatorname{sd}^i(S_{k-1})| & \hookrightarrow & |\operatorname{Cone}(\operatorname{sd}^i(S_{k-1}))| \\
\downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle x\mapsto(x,0)} & & \downarrow{\scriptstyle x\mapsto(x,0)} \\
|K| & \xleftarrow{F} & |\operatorname{sd}^i(S_{k-1})| \times [0,1] & \hookrightarrow & |\operatorname{Cone}(\operatorname{sd}^i(S_{k-1}))| \times [0,1] \\
\uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle x\mapsto(x,1)} & & \uparrow{\scriptstyle x\mapsto(x,1)} \\
|K| & \xleftarrow{|f|} & |\operatorname{sd}^i(S_{k-1})| & \hookrightarrow & |\operatorname{Cone}(\operatorname{sd}^i(S_{k-1}))| \\
\downarrow{\scriptstyle j} & & \downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle \mathrm{id}} \\
|\operatorname{Cyl}(f)| & \xleftarrow{j\circ|f|} & |\operatorname{sd}^i(S_{k-1})| & \hookrightarrow & |\operatorname{Cone}(\operatorname{sd}^i(S_{k-1}))| \\
\downarrow{\scriptstyle \mathrm{id}} & & \downarrow{\scriptstyle x\mapsto(x,0)} & & \downarrow{\scriptstyle x\mapsto(x,0)} \\
|\operatorname{Cyl}(f)| & \xleftarrow{G} & |\operatorname{sd}^i(S_{k-1})| & \hookrightarrow & |\operatorname{Cone}(\operatorname{sd}^i(S_{k-1}))| \times [0,1] \\
\uparrow{\scriptstyle \mathrm{id}} & & \uparrow{\scriptstyle x\mapsto(x,1)} & & \uparrow{\scriptstyle x\mapsto(x,1)} \\
|\operatorname{Cyl}(f)| & \xleftarrow{|\iota|\circ\mho} & |\operatorname{sd}^i(S_{k-1})| & \hookrightarrow & |\operatorname{Cone}(\operatorname{sd}^i(S_{k-1}))| \\
\mathrm{id}\downarrow & & \cong\downarrow{\scriptstyle \mho} & & \cong\downarrow{\scriptstyle \mho} \\
|\operatorname{Cyl}(f)| & \xleftarrow{|\iota|} & |\operatorname{sd}^{i+1}(S_{k-1})| & \hookrightarrow & |\operatorname{Cone}(\operatorname{sd}^{i+1}(S_{k-1}))|.
\end{array}
$$

It follows from (4) and elementary observations that all of the vertical maps are homotopy equivalences. Furthermore note that it follows immediately from the Manifold Boundary-Cofibration Proposition 17.8 and the Product-Cofibration Proposition 17.11 that all of the right horizontal maps are closed cofibrations. Thus it follows from the Homotopy Pushout Theorem 17.19, applied altogether eight times, that the induced maps between the various pushouts have homotopy inverses. Combining these eight homotopy equivalences, respectively their homotopy inverses, we obtain the promised homotopy equivalence

$$X \cup_{S^{k-1}} \overline{B}^k \;\to\; \underbrace{|\operatorname{Cyl}(f)| \cup_{|\operatorname{sd}^i(S_{k-1})|} |\operatorname{Cone}(\operatorname{sd}^{i+1}(S_{k-1}))|}_{=\operatorname{Cone}(f\colon \operatorname{sd}^i(S_{k-1}) \to K)}|. \qquad \blacksquare$$

Proof of Proposition 94.12 (1). Let X be a *finite* CW-complex. An induction argument over the number of cells, using Lemma 94.13, shows that X is homotopy equivalent to a finite simplicial complex of the same dimension. $\blacksquare$

Sketch of a proof of Proposition 94.12 (2) and (3). Now let X be any (countable) CW-complex. Without loss of generality we can and will assume that X is connected and non-empty.

Claim. There exists an ascending sequence $K_{-1} \subset K_0 \subset K_1 \subset K_2 \subset \dots$ of abstract simplicial complexes and a sequence of homotopy equivalences $\theta_n \colon X^n \to |K_n|$, $n \in \mathbb{Z}_{\geq -1}$ such that for each $n \in \mathbb{N}_0$ there exists a homotopy $F_n \colon X^n \times [0,1] \to |K_{n+1}|$ between the maps $X^n \xrightarrow{\theta_n} |K_n| \to |K_{n+1}|$ and $X^n \to X^{n+1} \xrightarrow{\theta_{n+1}} |K_{n+1}|$.

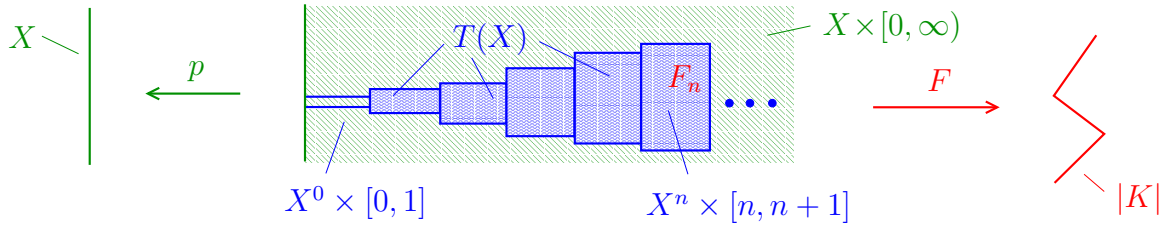
Proof. We take K_{-1} to be the empty simplicial complex. Assume that we have already constructed $K_{-1}, \dots, K_n$ and $\theta_{-1}, \dots, \theta_n$. We denote by $\{\varphi_i \colon S^n \to X^n\}_{i \in I}$ the attaching maps of the $(n+1)$-cells of X. By basically the same argument as in the proof of Lemma 94.13 we obtain $d_i \in \mathbb{N}_0$, simplicial maps $f_i \colon \operatorname{sd}^{d_i}(S_n) \to K_n$ and a homotopy equivalence

$$\theta_{n+1} \colon \underbrace{X^n \cup_{\bigsqcup \varphi_i} \bigsqcup_{i \in I} \overline{B}^{n+1}}_{=X^{n+1}} \to \underbrace{\left| \operatorname{Cyl}\left(\bigsqcup_{i \in I} f \colon \bigsqcup_{i \in I} \operatorname{sd}^{d_i}(S_n) \to K \right) \cup \bigsqcup_{i \in I} \operatorname{Cone}\left(\operatorname{sd}^{d_i+1}(S_n) \right) \right|}_{=:K_{n+1}}$$

such that the maps $X^n \xrightarrow{\theta_n} |K_n| \to |K_{n+1}|$ and $X^n \to X^{n+1} \xrightarrow{\theta_{n+1}} |K_{n+1}|$ are homotopic. ⊞

We set $K := \bigcup_{n \in \mathbb{N}_0} K_n$. If X is countable, then K is also countable. Thus it remains to show that X is homotopy equivalent to $|K|$.

(1) As on page1546 we equip $[0, \infty)$ with the CW-structure where the 0-skeleton is given by $\mathbb{N}_0$ and we refer to the CW-complex



$$T(X) \;:=\; \bigcup_{n \in \mathbb{N}_0} X^n \times [n, n+1] \quad \subset \; X \times [0, \infty)$$

as the *telescope of* X.

(2) The homotopies F_n define a map $F \colon T(X) \to |K|$ which is continuous by the Characteristic Maps Lemma 68.7.

(3) Furthermore the projections $X^n \times [0,1] \to X^n$ define a map $p \colon T(X) \to X$ which is also continuous by the Characteristic Maps Lemma 68.7.

We pick $P \in X^0$. It follows fairly easily from the Direct Limit-π_n-Proposition 71.11 and the claim that for every $n \in \mathbb{N}$ the maps $F_* \colon \pi_n(T(X), P) \to \pi_n(|K|, P)$ and $p_* \colon \pi_n(T(X), P) \to \pi_n(X, P)$ are isomorphisms. It follows from the Whitehead Theorem 162.1 that $F \colon T(X) \to |K|$ and $p \colon T(X) \to X$ are homotopy equivalences. We have thus shown that X is homotopy equivalent to $|K|$.[1159] ■

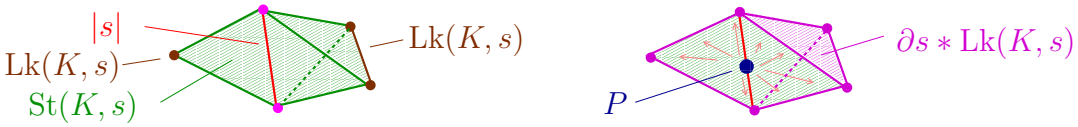
[1159] We leave it to the industrious reader to figure out whether one can avoid the cheap exit via the Whitehead Theorem 162.1 by using say the Telescope Lemma 70.14 in a clever fashion.

Exercises for Chapter 94.

Exercise 94.1. Let $K = (V, S)$ be an abstract simplicial complex. By the Link Star Lemma 94.5 (3) we know that for any choice of simplices $s_0, \ldots, s_n \in S$ the following equality regarding *open* stars holds:

$$\mathring{\mathrm{St}}(s_0) \cap \cdots \cap \mathring{\mathrm{St}}(s_n) \;=\; \begin{cases} \mathring{\mathrm{St}}(s_0 \cup \cdots \cup s_n), & \text{if } s_0 \cup \cdots \cup s_n \text{ is a simplex,} \\ \varnothing, & \text{otherwise.} \end{cases}$$

Show that in general the analogous statement for stars does *not* hold.



Exercise 94.2. Let K be an abstract simplicial complex and let s be a k-simplex. Show that there exists a natural simplicial isomorphism $\mathrm{Lk}(K, s) * \partial s \cong \mathrm{Lk}(\mathrm{sd}(K), \underline{s})$.

Exercise 94.3. Let $K = (V, S)$ be an abstract simplicial complex. Show that the dimension of the barycentric subdivision $\mathrm{sd}(K)$ equals the dimension of K.

Exercise 94.4. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$.

(a) Show that the link $\mathrm{Lk}(s)$ is a deformation retract of $\mathrm{St}(s) \setminus |s|$.
Hint. Consider the proof of the Link Star Lemma 94.5 (e).

(b) Let $P \in \langle s \rangle$. Show that $\partial s * \mathrm{Lk}(s)$ is a deformation retract of $\mathrm{St}(s) \setminus \{P\}$.
Hint. Turn the idea of "pushing away from P" into a rigorous argument.

Exercise 94.5. Let $n \in \mathbb{N}$. As on page 1978 we consider the abstract simplicial complex $S_n := (V, T)$ with $V = \{0, \ldots, n+1\}$ and $T = \mathcal{P}(V) \setminus \{\varnothing, V\}$. Note that given a k-simplex s of S_n the set $V \setminus s$ is an $(n-k)$-simplex. Next we consider the barycentric subdivision $\mathrm{sd}(S_n)$ together with the map

$$\begin{array}{rccc} f\colon & \mathrm{sd}(S_n) & \to & \mathrm{sd}(S_n) \\ & \underline{s} & \mapsto & \underline{V \setminus s}. \end{array}$$

(a) Show that f is a simplicial map.

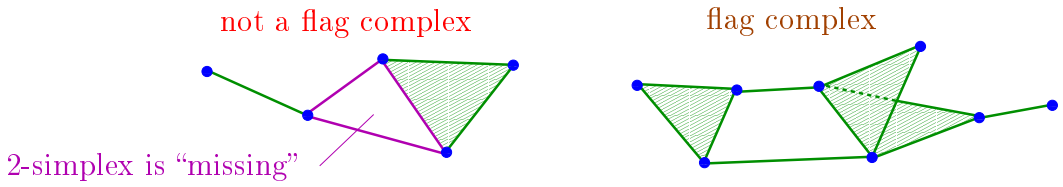
(b) Show that $S_n/s \sim f(s)$, interpreted in the obvious way, is an abstract simplicial complex with $2^{n+1} - 1$ vertices.

(c) Sketch the abstract simplicial complex $S_n/s \sim f(s)$ for $n = 1$ and $n = 2$.

(d) Show that the topological realization of $S_n/s \sim f(s)$ is homeomorphic to the real projective space $\mathbb{R}\mathrm{P}^n = S^n/x \sim -x$.

Remark. It is not known what is the "smallest" simplicial structure for the real projective spaces $\mathbb{R}\mathrm{P}^n$. It is shown in **[ArM1991]** that any simplicial structure for $\mathbb{R}\mathrm{P}^n$ needs to have at least $\frac{1}{2}(n+1)(n+2)$ vertices. But all known simplicial structures seem to have about 2^n vertices.

Exercise 94.6. Let $n \in \mathbb{N}$ and let $k \in \{1, \ldots, n-1\}$. Use the Simplicial Approximation Theorem 94.8 to show that $\pi_k(S^n) = 0$.
Remark. This statement is of course the content of Proposition 71.10 which we proved using the Cellular Approximation Theorem 70.15.



Exercise 94.7. We say an abstract simplicial complex $K = (V, S)$ is a *flag complex* if the following condition is satisfied:

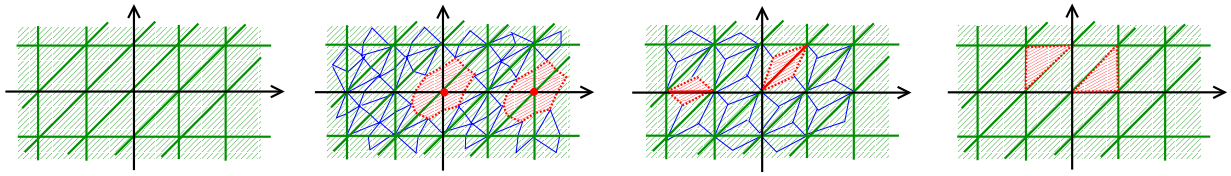
(∗) If $v_0, \ldots, v_n \in V$ have the property that $\{v_i, v_j\} \in S$ for all $i, j \in \{0, \ldots, n\}$, then $\{v_0, \ldots, v_n\} \in S$.

More loosely speaking, K is a flag complex, if a simplex exists whenever its 1-skeleton exists. We refer to the figure below for an illustration of the definition.

(a) Show that every flag complex is determined by its 1-skeleton. More precisely, let $K = (V, S)$ and $L = (W, T)$ be two abstract simplicial complexes. Suppose that $\varphi\colon K^1 \xrightarrow{\cong} L^1$ is a simplicial isomorphism between the 1-skeleta. We suppose that K and L are flag complexes. Show that φ can be extended to a simplicial isomorphism $K \xrightarrow{\cong} L$.

(b) Let K be an abstract simplicial complex. Show that the barycentric subdivision $\mathrm{sd}(K)$ is a flag complex.

Exercise 94.8. We recall the following definition from page 369. We say a family $\{U_i\}_{i \in I}$ of subsets of a set X has *order* $\leq n$ if for any $J \subset I$ with $\#J > n$ we have $\bigcap_{j \in J} U_j = \varnothing$.



(a) Let $K = (V, S)$ be an n-dimensional abstract simplicial complex. Given $i \in \{0, \ldots, n\}$ we denote by K_i the abstract simplicial complex one obtains from barycentric subdivision of all simplices of degree $> i$.[1160] As usual we use (a slight generalize of) the SD-Lemma 94.3 to identify the various topological realizations, i.e. we write $|K| = |K_0| = \cdots = |K_n|$. We denote by $\mathcal{V}_i$ the collection of open stars of the i-simplices of K in $|K_i|$. Show that the sets in $\mathcal{V}_0 \cup \cdots \cup \mathcal{V}_n$ form an open cover of $|K| = |K_0| = \cdots = |K_n|$ of order $n + 1$.

Next we recall another definition from page 369. Let X be a non-empty topological space. We say $\mathrm{cdim}(X) \leq n$ if every open cover of X admits an open refinement of order $n + 1$.

(b) Show that every finite simplicial complex X of dimension n has $\mathrm{cdim}(X) \leq n$.

(c) Show that every compact subspace X of $\mathbb{R}^n$ has $\mathrm{cdim}(X) \leq n$.

Remark. This approach gives a new proof for Theorem 11.3.

[1160] We did not define this construction, but the reader should have no troubles making sense of it.

95. Simplicial homology

In this chapter we introduce the simplicial homology groups of an (ordered) abstract simplicial complex. As we will see, the definition is refreshingly straightforward. Later in the chapter we discuss the relationship between simplicial and singular homology.

Before we get into details it is convenient to recall the following definition from basic group theory which we will need on numerous occasions throughout this chapter.

Definition. Let $n \in \mathbb{N}$. Given a permutation $\sigma \in S_n$ we refer to[1161]

$$\operatorname{sign}(\sigma) \;:=\; \begin{array}{c}\text{determinant of the } (n \times n)\text{-matrix for which the} \\ (i,\sigma(i))\text{-entries are one and all the other entries are zero}\end{array}$$

as the sign of the permutation.

The following lemma summarizes the two key properties of the sign of a permutation.

Lemma 95.1. Let $n \in \mathbb{N}$.

(1) The map $\operatorname{sign}\colon S_n \to \{-1, 1\}$ is a homomorphism.
(2) If σ is a transposition, then $\operatorname{sign}(\sigma) = -1$.

Proof. The proof follows immediately from standard properties of the determinant. ■

Definition. Let X be a finite set and let $\sigma \in \operatorname{Bij}(X)$. We set $n := \#X$. We pick a bijection $\varphi\colon \{1, \dots, n\} \to X$. We define $\operatorname{sign}(\sigma) = \operatorname{sign}(\varphi^{-1} \circ \sigma \circ \varphi)$. It follows easily from Lemma 95.1 that this definition is independent of the choice of the bijection φ.

Throughout this chapter we adopt the following convention.

Convention. Given $n \in \mathbb{N}$ we identify the permutation group $S_n = \operatorname{Bij}\{1, \dots, n\}$ with the group $\operatorname{Bij}\{0, \dots, n-1\}$ in the obvious way.

95.1. Simplicial homology of an ordered abstract simplicial complex.

In this section we will define the simplicial chain complex and the simplicial homology groups of an *ordered* abstract simplicial complex. This is going to be surprisingly easy. In the subsequent section we will then deal with abstract simplicial complex that are not equipped with an order.

We start out with the following elementary observation which we will use frequently throughout this chapter.

Observation. Let $(T, \leq)$ be a totally ordered set and let $v_0, \dots, v_n \in T$. By Exercise 0.4 there exists a unique permutation $\sigma \in S_{n+1}$ such that $v_{\sigma(0)} < \dots < v_{\sigma(n)}$.

After this preliminary remark we can now turn to an interesting definition.

Definition. Let $K = (V, S)$ be an ordered abstract simplicial complex.[1162] Given $n \in \mathbb{N}_0$ we define

$$\mathrm{C}_n^{\mathrm{simp},\leq}(K) \;:=\; \text{free abelian group generated by the set of } n\text{-simplices of } K.$$

[1161] Surely the reader will have seen the definition of the sign of a permutation. We leave it to the reader to show that the previous definition agrees with our definition.

Furthermore we consider the boundary map

$$\begin{array}{rcl} \partial_n \colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_{n-1}^{\mathrm{simp},\leq}(K) \\ \underbrace{\{v_0 < \cdots < v_n\}}_{\substack{\text{any } n\text{-simplex } s \text{ is uniquely} \\ \text{of the form } s = \{v_0, \ldots, v_n\} \\ \text{with } v_0 < \cdots < v_n}} & \mapsto & \sum_{i=0}^{n} (-1)^i \cdot \{v_0, \ldots, v_{i-1}, \widehat{v_i}, v_{i+1}, \ldots, v_n\}. \end{array}$$

Lemma 95.2. Let $K = (V, S)$ be an ordered abstract simplicial complex. Given any $n \in \mathbb{N}_0$ we have $\partial_{n-1} \circ \partial_n = 0$. In other words, $(C_*^{\mathrm{simp},\leq}(K), \partial_*)$ is a chain complex.

Proof. The proof of the lemma is almost verbatim the same as the proof of Proposition 72.2. We leave it to the reader to make the necessary minute modifications. ■

The reader is by now well aware of the fact that such a lemma leads straight to the following definition.

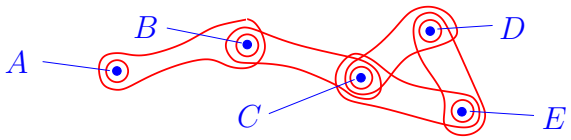
Definition. Let K be an ordered abstract simplicial complex. We refer to the chain complex $(\mathrm{C}_*^{\mathrm{simp},\leq}(K), \partial_*)$ as the simplicial chain complex. Given $n \in \mathbb{N}_0$ we define the n-th simplicial homology group of K as the n-th homology group of the simplicial chain complex, i.e. we define

$$\mathrm{H}_n^{\mathrm{simp},\leq}(K) \;:=\; \frac{\ker\left(\partial_n \colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp},\leq}(K)\right)}{\mathrm{im}\left(\partial_{n+1} \colon \mathrm{C}_{n+1}^{\mathrm{simp},\leq}(K) \to \mathrm{C}_n^{\mathrm{simp},\leq}(K)\right)}.$$

Example. We consider the 1-dimensional abstract simplicial complex $K = (V, S)$ shown in the figure below. It has five vertices $\{A, B, C, D, E\}$, it has the corresponding five 0-simplices and it has five 1-simplices. We view $K = (V, S)$ as an ordered abstract simplicial complex in the obvious way, i.e. we have $A < B < C < D < E$. The corresponding simplicial chain complex is given as follows:

$$0 \;\to\; \begin{array}{l} \mathbb{Z} \cdot \{A, B\} \\ \mathbb{Z} \cdot \{B, C\} \\ \mathbb{Z} \cdot \{C, D\} \\ \mathbb{Z} \cdot \{D, E\} \\ \mathbb{Z} \cdot \{C, E\} \end{array} \xrightarrow{\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & 1 \\ 0 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & -1 & -1 \end{pmatrix}} \begin{array}{l} \mathbb{Z} \cdot \{A\} \\ \mathbb{Z} \cdot \{B\} \\ \mathbb{Z} \cdot \{C\} \\ \mathbb{Z} \cdot \{D\} \\ \mathbb{Z} \cdot \{E\} \end{array} \;\to\; 0.$$

We leave it as an elementary exercise in linear algebra to show that



$$\mathrm{H}_n^{\mathrm{simp},\leq}(K) \;\cong\; \begin{cases} 0, & \text{if } n > 1, \\ \mathbb{Z}, & \text{if } n = 0, 1. \end{cases}$$

Furthermore one can easily show that

$$\mathrm{H}_1^{\mathrm{simp},\leq}(K) \;=\; \ker\left(\partial_1 \colon \mathrm{C}_1^{\mathrm{simp},\leq}(K) \to \mathrm{C}_0^{\mathrm{simp},\leq}(K)\right) \;=\; \mathbb{Z} \cdot [\{C, D\} + \{D, E\} - \{C, E\}].$$

As always, not only do we want to associate groups to our given objects, but we really want to construct a functor. This is done in the following lemma.

[1162] Recall that according to the definition on page 1982 "ordered" means that the vertex set V is equipped with a partial order such that the restriction to each simplex is a total order.

Lemma 95.3.

(1) Given an order-preserving simplicial map $f\colon K = (V,S) \to L = (W,T)$ between ordered abstract simplicial complexes we define

$$\begin{array}{rcl} f_*\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n^{\mathrm{simp},\leq}(L) \\ \{v_0,\dots,v_n\} & \mapsto & \begin{cases} \{f(v_0),\dots,f(v_n)\}, & \text{if } f(v_0),\dots,f(v_n) \text{ are pairwise different,} \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

These maps form a chain map, thus they induce maps $f_*\colon \mathrm{H}_n^{\mathrm{simp},\leq}(K) \to \mathrm{H}_n^{\mathrm{simp},\leq}(L)$.

(2) The maps

$$\begin{array}{rcl} (K,\leq) & \mapsto & \mathrm{C}_*^{\mathrm{simp},\leq}(K) \\ (f\colon (K,\leq) \to (L,\leq)) & \mapsto & (f_*\colon \mathrm{C}_*^{\mathrm{simp},\leq}(K) \to \mathrm{C}_*^{\mathrm{simp},\leq}(L)) \end{array}$$

define a covariant functor from the category *OrdAbsSimpCplx* of ordered abstract simplicial complexes to the category *ChCplx* of chain complexes. In particular, for each $n \in \mathbb{N}_0$ the maps

$$\begin{array}{rcl} (K,\leq) & \mapsto & \mathrm{H}_n^{\mathrm{simp},\leq}(K) \\ (f\colon (K,\leq) \to (L,\leq)) & \mapsto & (f_*\colon \mathrm{H}_n^{\mathrm{simp},\leq}(K) \to \mathrm{H}_n^{\mathrm{simp},\leq}(L)) \end{array}$$

define a covariant functor from the category *OrdAbsSimpCplx* of ordered abstract simplicial complexes to the category *AbGroup* of abelian groups.

Proof. The statements follow easily from the definitions. We leave it to the reader to fill in the details. ■

Naturally the question arises, to what degree do the simplicial homology groups of an ordered abstract simplicial complex depend on the choice of the order. As the following lemma shows, the answer is, not very much.

Lemma 95.4. Let $K = (V,S)$ be an abstract simplicial complex and let "$\leq$" and "$\widetilde{\leq}$" be two orders on K. The maps

$$\begin{array}{rcl} \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n^{\mathrm{simp},\widetilde{\leq}}(K) \\ \{v_0 < \dots < v_n\} & \mapsto & \underbrace{\operatorname{sign}(\sigma) \cdot \{v_{\sigma(0)} \widetilde{<} \dots \widetilde{<} v_{\sigma(n)}\}}_{\substack{\sigma \in S_n \text{ is the unique permutation} \\ \text{such that } v_{\sigma(0)} \widetilde{\leq} \dots \widetilde{\leq} v_{\sigma(n)}}} \end{array}$$

define an isomorphism of chain complexes.

Proof. The proof of the lemma is an appealing little calculation that will be done in Exercise 95.1. ■

95.2. **Simplicial homology.** In the last section we introduced simplicial homology for *ordered* abstract simplicial complexes. In this section we will introduce simplicial homology for "unordered" abstract simplicial complexes. Evidently the definition is going to be very similar, but as we will see, the definition is ever so more subtle.

Definition. Let $K = (V, S)$ be an abstract simplicial complex and let $n \in \mathbb{N}_0$.

(1) An ordered n-simplex of K is an $(n+1)$-tuple $(v_0, \ldots, v_n) \in V^{n+1}$ such that $\{v_0, \ldots, v_n\}$ is an n-simplex of $K = (V, S)$.

(2) Given an ordered n-simplex $(v_0, \ldots, v_n)$ we denote by $\lfloor (v_0, \ldots, v_n) \rfloor := \{v_0, \ldots, v_n\}$ the corresponding n-simplex of K.

(3) Let $n \in \mathbb{N}_0$. We define

$$\widehat{\mathrm{C}}_n^{\mathrm{simp}}(K) := \text{free abelian group generated by the set of ordered } n\text{-simplices of } K.$$

Furthermore we define the n-th simplicial chain group to be

$$\mathrm{C}_n^{\mathrm{simp}}(K) := \widehat{\mathrm{C}}_n^{\mathrm{simp}}(K)/I_n$$

where I_n is the subgroup of $\widehat{\mathrm{C}}_n^{\mathrm{simp}}(K)$ generated by all elements of the form

$$(v_0, \ldots, v_n) - \mathrm{sign}(\sigma) \cdot (v_{\sigma(0)}, \ldots, v_{\sigma(n)}) \qquad \text{where } \sigma \in S_{n+1} = \mathrm{Bij}\{0, \ldots, n\}$$

Given an ordered simplex $(v_0, \ldots, v_n)$ we denote its image in $\mathrm{C}_n^{\mathrm{simp}}(K)$ by $[v_0, \ldots, v_n]$.

Remark. Let $K = (V, S)$ be an abstract simplicial complex. Since the set of vertices is in a natural bijection with the set of 0-simplices and since the permutation group S_1 is trivial we see that we have a natural identification $\mathrm{C}_0^{\mathrm{simp}}(K) = \mathbb{Z}^{(V)}$.

Lemma 95.5. Let $K = (V, S)$ be an abstract simplicial complex. If "$\leq$" is an order on $K = (V, S)$, then for each $n \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n^{\mathrm{simp}}(K) \\ \{v_0 < \cdots < v_n\} & \mapsto & [v_0, \ldots, v_n] \end{array}$$

is a natural isomorphism.

Proof. Let $n \in \mathbb{N}_0$. First note that it follows immediately from the definitions that the map is natural.

It remains to show that the given map is an isomorphism. We denote by P_n the set of ordered n-simplices, as defined above. Note that by definition we have $\widehat{\mathrm{C}}_n^{\mathrm{simp}}(K) = \mathbb{Z}^{(P_n)}$. In the following we denote by Q_n the set of all ordered n-simplices $(v_0, \ldots, v_n)$ such that $v_0 < \cdots < v_n$. By Lemma 51.1 there exist unique homomorphisms as follows:

$$\begin{array}{rcl} \Phi\colon \mathbb{Z}^{(P_n)} & \to & \mathbb{Z}^{(Q_n)} \\ (v_0, \ldots, v_n) & \mapsto & \mathrm{sign}(\sigma) \cdot (v_{\sigma(0)}, \ldots, v_{\sigma(n)}) \end{array}$$

here $\sigma \in S_{n+1}$ is the unique permutation with $v_{\sigma(0)} < \cdots < v_{\sigma(n)}$

and

$$\begin{array}{rcl} \Psi\colon \mathbb{Z}^{(Q_n)} & \to & \mathbb{Z}^{(P_n)} \\ (v_0, \ldots, v_n) & \mapsto & (v_0, \ldots, v_n). \end{array}$$

Furthermore we denote by $\pi\colon \mathbb{Z}^{(P_n)} \to \mathbb{Z}^{(P_n)}/I_n = \mathrm{C}_n^{\mathrm{simp}}(K)$ the obvious projection. It follows easily from Lemma 95.1 that $\Phi\colon \mathbb{Z}^{(P_n)} \to \mathbb{Z}^{(Q_n)}$ descends to a homomorphism $\overline{\Phi}\colon \mathbb{Z}^{(P_n)}/I_n \to \mathbb{Z}^{(Q_n)}$. Note that it is an immediate consequence of the definitions that $\overline{\Phi} \circ \pi irc \Psi$ is the identity on the basis Q_n of $\mathbb{Z}^{(Q_n)}$ and that $\pi \circ \Psi \circ \overline{\Phi}$ is the identity on the generating set $\pi(P_n)$ of $\mathbb{Z}^{(P_n)}/I_n$. This shows that $\pi \circ \Psi$ and $\overline{\Phi}$ are isomorphisms. The promised statements follow readily from this observation. ∎

Lemma 95.6. Let K be an abstract simplicial complex.

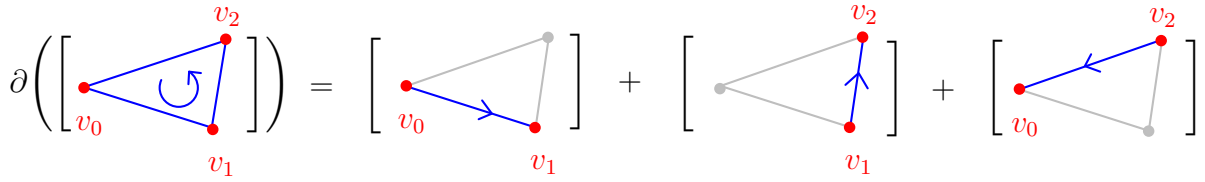
(1) Given any $n \in \mathbb{N}_0$ the group $\mathrm{C}_n^{\mathrm{simp}}(K)$ is a free abelian group where the rank is given by the cardinality of the set S_n of n-simplices of K. In fact, if we choose for each n-simplex $s \in S_n$ an ordered n-simplex $\widetilde{s}$ with $\lfloor \widetilde{s} \rfloor = s$, then $\{[\widetilde{s}]\}_{s \in S_n}$ is a basis for $\mathrm{C}_n^{\mathrm{simp}}(K)$.

(2) Let $n \in \mathbb{N}$. There exists a unique homomorphism

$$\partial_n \colon \mathrm{C}_n^{\mathrm{simp}}(K) \quad \to \quad \mathrm{C}_{n-1}^{\mathrm{simp}}(K)$$

with the property that given any ordered n-simplex $(v_0, \ldots, v_n)$ of K we have

$$\partial_n([v_0, \ldots, v_n]) \quad = \quad \sum_{i=0}^{n} (-1)^i \cdot [v_0, \ldots, v_{i-1}, \widehat{v_i}, v_{i+1}, \ldots, v_n].$$



(3) For every $n \in \mathbb{N}_0$ we have $\partial_{n-1} \circ \partial_n = 0$.

Remark. Let $K = (V, S)$ be an abstract simplicial complex and let $n \in \mathbb{N}_0$. Lemma 95.5 and Lemma 95.6 (1) say in particular that $\mathrm{C}_n^{\mathrm{simp}}(K)$ is a free abelian group. If $K = (V, S)$ is an ordered abstract simplicial complex, then this free abelian group has a natural basis. In the absence of an order there is only a natural basis where each element of the basis is well-defined "up to sign".

Example. For an ordered simplex (v_0, v_1, v_2) in an abstract simplicial complex K we see that

$$\partial([v_0, v_1, v_2]) \quad = \quad [v_1, v_2] - [v_0, v_2] + [v_0, v_1] \quad = \quad [v_0, v_1] + [v_1, v_2] + [v_2, v_0].$$

In other words, if we consider the figure below, then we see that the boundary is exactly what we would naively had thought.

Proof.

(1) It follows from the Well-Ordering Theorem 0.7 that we can equip $K = (V, S)$ with an order. Thus the desired statement is now an almost immediate consequence of Lemma 95.5

(2) Let $n \in \mathbb{N}$. By Lemma 51.1 there exists a unique homomorphism

$$\partial_n \colon \widehat{\mathrm{C}}_n^{\mathrm{simp}}(K) \quad \to \quad \mathrm{C}_{n-1}^{\mathrm{simp}}(K)$$

with the property that given any ordered n-simplex $(v_0, \ldots, v_n)$ of K we have

$$\partial_n((v_0, \ldots, v_n)) \quad = \quad \sum_{i=0}^{n} (-1)^i \cdot [v_0, \ldots, v_{i-1}, \widehat{v_i}, v_{i+1}, \ldots, v_n].$$

It remains to show that ∂_n factors through $\mathrm{C}_n^{\mathrm{simp}}(K) = \widehat{\mathrm{C}}_n^{\mathrm{simp}}(K)/I_n$. In other words, we need to show that ∂_n vanishes on I_n. Since the permutation group S_n is generated by transpositions and since transpositions have the sign -1 it remains to prove the following claim.

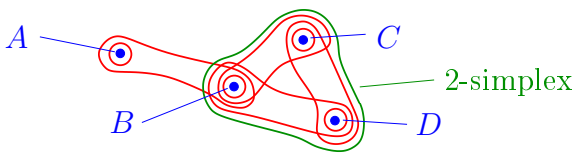
Claim. For any $0 \leq k < l \leq n$ and any ordered n-simplex $(v_0, \ldots, v_n)$ of K we have
$$\partial_n(v_0, \ldots, v_l, \ldots, v_k, \ldots, v_n) \;=\; -\partial_n(v_0, \ldots, v_k, \ldots, v_l, \ldots, v_n).$$

Proof. Let $(v_0, \ldots, v_n)$ be an ordered n-simplex and let $0 \leq k < l \leq n$. We calculate that

$$\begin{aligned}
&\partial_n(.., v_l, .., v_k, ..) \;= \\
&= \sum_{i \neq k,l} (-1)^i \cdot \underbrace{[.., v_l, .., \widehat{v_i}, .., v_k, ..]}_{=-[..,v_k,..,\widehat{v_i},..,v_l,..]} + (-1)^k \cdot \underbrace{[.., \widehat{v_l}, .., v_k, ..]}_{\substack{= (-1)^{l-k-1} \cdot [., v_k, \ldots, \widehat{v_l}, .] \\ \text{since } l\text{-}k\text{-}1 \text{ transpositions} \\ \text{are used}}} + (-1)^l \cdot \underbrace{[.., v_l, .., \widehat{v_k}, ..]}_{\substack{= (-1)^{l-k-1} \cdot [., \widehat{v_k}, \ldots, v_l, .] \\ \text{since } l\text{-}k\text{-}1 \text{ transpositions} \\ \text{are used}}} \\
&= -\sum_{i \neq k,l} (-1)^i \cdot [.., v_k, .., \widehat{v_i}, .., v_l, ..] - (-1)^l \cdot [.., v_k, .., \widehat{v_l}, ..] - (-1)^k \cdot [.., \widehat{v_k}, .., v_l, ..] \\
&= -\partial_n(.., v_k, .., v_l, ..).
\end{aligned}$$

(3) The proof of this lemma is almost verbatim the same as the proof of Proposition 72.2. We leave the pleasant task of copy-pasting the proof to the reader. ■

Lemma 95.6 leads us right away to the following definition.



Definition. Let K be an abstract simplicial complex. We refer to the chain complex $(\mathrm{C}_*^{\mathrm{simp}}(K), \partial_*)$ as the simplicial chain complex. Given $n \in \mathbb{N}_0$ we define the n-th simplicial homology group of K as the n-th homology group of the simplicial chain complex, i.e. we define
$$\mathrm{H}_n^{\mathrm{simp}}(K) \;:=\; \frac{\ker\left(\partial_n \colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_{n-1}^{\mathrm{simp}}(K)\right)}{\mathrm{im}\left(\partial_{n+1} \colon \mathrm{C}_{n+1}^{\mathrm{simp}}(K) \to \mathrm{C}_n^{\mathrm{simp}}(K)\right)}.$$

Examples.

(1) We consider the 2-dimensional abstract simplicial complex $K = (V, S)$ shown in the figure below. It has four vertices $\{A, B, C, D\}$, it has the corresponding four 0-simplices, it has four 1-simplices and it has one 2-simplex. The corresponding simplicial chain complex is given as follows:

$$0 \;\to\; \mathbb{Z} \cdot [B, C, D] \xrightarrow{\begin{pmatrix} 0 \\ 1 \\ -1 \\ 1 \end{pmatrix}} \begin{matrix} \mathbb{Z} \cdot [A, B] \\ \mathbb{Z} \cdot [B, C] \\ \mathbb{Z} \cdot [B, D] \\ \mathbb{Z} \cdot [C, D] \end{matrix} \xrightarrow{\begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 1 & 0 \\ 0 & -1 & 0 & 1 \\ 0 & 0 & -1 & -1 \end{pmatrix}} \begin{matrix} \mathbb{Z} \cdot [A] \\ \mathbb{Z} \cdot [B] \\ \mathbb{Z} \cdot [C] \\ \mathbb{Z} \cdot [D] \end{matrix} \;\to\; 0.$$

Elementary linear algebra shows that
$$\mathrm{H}_n^{\mathrm{simp}}(K) \;\cong\; \begin{cases} 0, & \text{if } n > 0, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

(2) If $K = (V, S)$ is an abstract simplicial complex with no simplices of dimension ≥ 1, then it follows immediately from the definitions that for $n \in \mathbb{N}_0$ we have

$$\mathrm{H}_n^{\mathrm{simp}}(K) \;\cong\; \begin{cases} \mathrm{C}_0^{\mathrm{simp}}(K) = \mathbb{Z}^{(V)}, & \text{if } n = 0, \\ 0, & \text{otherwise.} \end{cases}$$

The following is the obvious analogue of Lemma 95.3.

Lemma 95.7.

(1) Given a simplicial map $f\colon K = (V, S) \to L = (W, T)$ we define

$$\begin{array}{rcl} f_*\colon \mathrm{C}_n^{\mathrm{simp}}(K) & \to & \mathrm{C}_n^{\mathrm{simp}}(L) \\ [v_0, \ldots, v_n)] & \mapsto & \begin{cases} [f(v_0), \ldots, f(v_n)], & \text{if } f(v_0), \ldots, f(v_n) \text{ are pairwise different,} \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

These maps form a chain map, thus they induce maps $f_*\colon \mathrm{H}_n^{\mathrm{simp}}(K) \to \mathrm{H}_n^{\mathrm{simp}}(L)$.

(2) The maps

$$\begin{array}{rcl} K & \mapsto & \mathrm{C}_*^{\mathrm{simp}}(K) \\ (f\colon K \to L) & \mapsto & (f_*\colon \mathrm{C}_*^{\mathrm{simp}}(K) \to \mathrm{C}_*^{\mathrm{simp}}(L)) \end{array}$$

define a covariant functor from the category $\mathcal{AbsSimpCplx}$ of abstract simplicial complexes to the category $\mathcal{ChCplx}$ of chain complexes. For each $n \in \mathbb{N}_0$ the maps

$$\begin{array}{rcl} K & \mapsto & \mathrm{H}_n^{\mathrm{simp}}(K) \\ (f\colon K \to L) & \mapsto & (f_*\colon \mathrm{H}_n^{\mathrm{simp}}(K) \to \mathrm{H}_n^{\mathrm{simp}}(L)) \end{array}$$

define a covariant functor from the category $\mathcal{AbsSimpCplx}$ of abstract simplicial complexes to the category $\mathcal{AbGroup}$ of abelian groups.

Proof. As in the case of the proof of Lemma 95.3 we leave it to the reader to provide the proof. ■

For completeness we state the following elementary lemma.

Lemma 95.8. Let $K = (V, S)$ be an ordered abstract simplicial complex. The maps

$$\begin{array}{rcl} \Omega_n\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n^{\mathrm{simp}}(K) \\ \{v_0 < \cdots < v_n\} & \mapsto & [v_0, \ldots, v_n] \end{array}$$

define a natural isomorphism of chain complexes. In particular they induce natural isomorphisms

$$\Omega_*\colon \mathrm{H}_n^{\mathrm{simp},\leq}(K) \;\to\; \mathrm{H}_n^{\mathrm{simp}}(K).$$

Remark. In the following we will discuss the simplicial homology groups $\mathrm{H}_n^{\mathrm{simp}}(K)$ in greater detail. By Lemma 95.8 the subsequent statements have obvious analogues for the simplicial homology groups $\mathrm{H}_n^{\mathrm{simp},\leq}(K)$.

Proof. A very short moment of reflection shows that the given map is a natural chain map. We deduce from Lemma 95.6 (1) that the chain map is in fact an isomorphism of chain complexes. ■

The next lemma can be viewed as an analogue of the Skeleton-Homology Lemma 80.1 (2) and (3).

Lemma 95.9. Let K be an abstract simplicial complex and let $m \in \mathbb{N}_0 \cup \{\infty\}$. As usual we denote by K^m the m-skeleton of K. Furthermore let $n \in \mathbb{N}_0$.

(1) If K has only finitely many n-simplices, then $\mathrm{H}_n^{\mathrm{simp}}(K)$ is finitely generated.
(2) If $n > m$, then $\mathrm{H}_n^{\mathrm{simp}}(K^m) = 0$.
(3) If $n < m$, then the inclusion induced map $\mathrm{H}_n^{\mathrm{simp}}(K^m) \to \mathrm{H}_n^{\mathrm{simp}}(K)$ is an isomorphism.

Analogous statements also hold for ordered abstract simplicial complexes and the homology groups $\mathrm{H}_n^{\mathrm{simp},\leq}(K^m)$ and $\mathrm{H}_n^{\mathrm{simp},\leq}(K)$.

Proof.

(1) This statement follows easily from the definitions together with Lemma 51.9 (2b).
(2) This statement follows from the observation that $\mathrm{C}_n^{\mathrm{simp}}(K^m) = 0$ for $n > m$.
(3) This statement follows almost immediately from the observation that by definition we have $\mathrm{C}_i^{\mathrm{simp}}(K^m) = \mathrm{C}_i^{\mathrm{simp}}(K)$ for $i = 0, \ldots, m$. ■

It is clear that given any finite abstract simplicial complex one can compute the corresponding homology groups by a brute force calculation. But for large examples this can be very inefficient. Furthermore, it is rather unsatisfactory to outsource calculations to a computer. It is much more entertaining to try to do calculations cleverly on one's own. In the following we will get to know a few approaches to calculating simplicial homology groups. We will develop more techniques in Exercises 95.3 and 95.7.

As for singular homology, some calculations, statements and proofs become easier if we consider *reduced* simplicial homology.

Definition. Let K be an abstract simplicial complex.

(1) We refer to the map[1163]
$$\begin{array}{rcl} \epsilon\colon \mathrm{C}_0^{\mathrm{simp}}(K) & \to & \mathbb{Z} \\ \left[\sum_{i=1}^m a_i \cdot [v_i]\right] & \mapsto & \sum_{i=1}^m a_i \end{array}$$
as the augmentation.
(2) We consider the following generalized[1164] chain complex
$$\ldots \xrightarrow{\partial_3} \mathrm{C}_2^{\mathrm{simp}}(K) \xrightarrow{\partial_2} \mathrm{C}_1^{\mathrm{simp}}(K) \xrightarrow{\partial_1} \underset{\text{degree } 0}{\mathrm{C}_0^{\mathrm{simp}}(K)} \xrightarrow{\epsilon} \underset{\text{degree } -1}{\mathbb{Z}} \to 0.$$
We introduce the following two definitions.
(a) We refer to this chain complex as the augmented simplicial chain complex $\widetilde{\mathrm{C}}_*^{\mathrm{simp}}(K)$ of K.
(b) Let $k \in \mathbb{N}_0$. We define the k-th reduced simplicial homology group $\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(K)$ of K to be the k-th homology group of the augmented chain complex.

Remark. The above definition also makes sense for the empty abstract simplicial complex $\varnothing$. Furthermore, similar to the Reduced Homology Lemma 74.1 (0) we see that $\mathrm{H}_{-1}^{\mathrm{simp}}(\varnothing) = \mathbb{Z}$ and $\mathrm{H}_i^{\mathrm{simp}}(\varnothing) = 0$ for $i \neq -1$.

[1163] Morally the group $\mathbb{Z}$ is the free abelian group on the "empty" simplex.
[1164] It requires about one second to verify that this is indeed a generalized chain complex.

The following lemma is the analogue of the Reduced Homology Lemma 74.1 (4). It basically says that in the following it suffices to calculate reduced simplicial homology groups.

Lemma 95.10. (Reduced Homology Lemma) Let $K = (V, S)$ be an abstract simplicial complex.

(1) Given any vertex $v \in V$ the map

$$\begin{array}{rcl} \widetilde{\mathrm{H}}_0^{\mathrm{simp}}(K) \oplus \mathbb{Z} & \to & \mathrm{H}_0^{\mathrm{simp}}(K) \\ [\sigma] \oplus n & \mapsto & [\sigma] + [n \cdot v] \end{array}$$

is an isomorphism. In particular, if K is non-empty, then we have an isomorphism $\widetilde{\mathrm{H}}_0^{\mathrm{simp}}(K) \oplus \mathbb{Z} \cong \mathrm{H}_0^{\mathrm{simp}}(K)$.

(2) For every $n \geq 1$ we have the equality $\mathrm{H}_n^{\mathrm{simp}}(K) = \widetilde{\mathrm{H}}_n^{\mathrm{simp}}(K)$.

Proof. The proof is basically identical to the already rather straightforward proof of the Reduced Homology Lemma 74.1 (4). ∎

By the Cone Contractibility Lemma 16.7 we know that the cone on a topological space is contractible, in particular we know by the Homotopy Equivalence-H_*-Corollary 73.9 (3) that its reduced homology groups vanish. The following lemma can be viewed as a simplicial analogue of this observation.

Lemma 95.11. (Cone Homology Lemma) Let K be an abstract simplicial complex. Let $\mathrm{Cone}(K)$ be the simplicial cone as defined on page 2003. Given any $k \in \mathbb{N}_0$ we have

$$\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(\mathrm{Cone}(K)) \;=\; 0.$$

Proof. Let $K = (V, S)$ be an abstract simplicial complex. We set $L := \mathrm{Cone}(K)$. Note that it follows from Lemma 73.5 that it remains to prove that the identity map $\mathrm{id}\colon \mathrm{C}_*^{\mathrm{simp}}(L) \to \mathrm{C}_*^{\mathrm{simp}}(L)$ is homotopic to the zero map. In other words, it suffices to prove the following claim.

Claim. We can find "diagonal" maps P_n, $n \in \mathbb{Z}_{\geq -1}$, to obtain a diagram

$$\begin{array}{ccccccccccccccc}
\ldots & \longrightarrow & C_3^{\mathrm{simp}}(L) & \xrightarrow{\partial_3} & C_2^{\mathrm{simp}}(L) & \xrightarrow{\partial_2} & C_1^{\mathrm{simp}}(L) & \xrightarrow{\partial_1} & C_0^{\mathrm{simp}}(L) & \xrightarrow{\partial_0 := \epsilon} & \mathbb{Z} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle P_3} & \downarrow{\scriptstyle \mathrm{id}} & \downarrow{\scriptstyle P_2} & \downarrow{\scriptstyle \mathrm{id}} & \downarrow{\scriptstyle P_1} & \downarrow{\scriptstyle \mathrm{id}} & \downarrow{\scriptstyle P_0} & \downarrow{\scriptstyle \mathrm{id}} & \downarrow{\scriptstyle P_{-1}} & \downarrow{\scriptstyle \mathrm{id}} & \\
\ldots & \longrightarrow & C_3^{\mathrm{simp}}(L) & \xrightarrow[\partial_3]{} & C_2^{\mathrm{simp}}(L) & \xrightarrow[\partial_2]{} & C_1^{\mathrm{simp}}(L) & \xrightarrow[\partial_1]{} & C_0^{\mathrm{simp}}(L) & \xrightarrow[\partial_0 := \epsilon]{} & \mathbb{Z} & \longrightarrow & 0
\end{array}$$

such that for every $n \in \mathbb{Z}_{\geq -1}$ we have the equality

$$(*) \qquad \partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; \mathrm{id}\,.$$

Proof. In the following we denote the cone point of $\mathrm{Cone}(L)$ by "$\star$". To prove the claim we consider the map

$$\begin{array}{rcl} P_{-1}\colon \mathbb{Z} & \to & \mathrm{C}_0^{\mathrm{simp}}(L) \\ n & \mapsto & n \cdot [\star] \end{array}$$

and for $n \geq 0$ we consider the map[1165]

$$\begin{array}{rcl} P_n\colon \mathrm{C}_n^{\mathrm{simp}}(L) & \to & \mathrm{C}_{n+1}^{\mathrm{simp}}(L) \\ ][v_0, \ldots, v_n] & \mapsto & \begin{cases} [\star, v_0, \ldots, v_n], & \text{if all } v_i \neq \star, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

We claim that $(*)$ holds for all $n \in \mathbb{Z}_{\geq -1}$. The case $n = -1$ can be verified easily. Thus it remains to show that $(*)$ holds if $n \in \mathbb{N}_0$. In fact, given $[v_0, \ldots, v_n] \in \mathrm{C}_n^{\mathrm{simp}}(L)$ with $v_0, \ldots, v_n \in V$ we immediately see that

$$\underbrace{[v_0, \ldots, v_n] + \sum_{i=1}^{n+1} (-1)^i \cdot [\star, v_0, \ldots, \widehat{v_{i-1}}, \ldots, v_n]}_{=(\partial_{n+1} \circ P_n)([v_0, \ldots, v_n])} + \underbrace{\sum_{i=0}^{n} (-1)^i \cdot [\star, v_0, \ldots, \widehat{v_i}, \ldots, v_n]}_{=(P_{n-1} \circ \partial_n)([v_0, \ldots, v_n])} = [v_0, \ldots, v_n].$$

Furthermore, given $[\star, v_0, \ldots, v_{n-1}] \in \mathrm{C}_n^{\mathrm{simp}}(L)$ with $v_0, \ldots, v_{n-1} \in V$ it is equally straightforward to verify that the equality holds. ■

Next we want to calculate the simplicial homology groups of the abstract simplicial complexes D_n and S_n that we introduced on page 1978. By the Reduced Homology Lemma 95.10 it suffices to compute the reduced simplicial homology groups.

Lemma 95.12. Given any $n \in \mathbb{N}$ and given any $k \in \mathbb{N}_0$ we have

$$\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(D_n) \;=\; 0 \quad \text{and} \quad \widetilde{\mathrm{H}}_k^{\mathrm{simp}}(S_n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Proof.

(1) Given any $n \in \mathbb{N}$ and given any $k \in \mathbb{N}_0$ we calculate that

$$\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(D_n) \;\underset{\text{see page 2003}}{\cong}\; \widetilde{\mathrm{H}}_k^{\mathrm{simp}}(\mathrm{Cone}(D_{n-1})) \;\underset{\text{by the Cone Homology Lemma 95.11}}{=}\; 0.$$

(2) Let $n \in \mathbb{N}_0$. We consider the following diagram:

$$\begin{array}{ccccccccccccc}
0 & \longrightarrow & 0 & \longrightarrow & \mathrm{C}_n^{\mathrm{simp}}(S_n) & \xrightarrow{\partial} & \mathrm{C}_{n-1}^{\mathrm{simp}}(S_n) & \xrightarrow{\partial} & \ldots & \xrightarrow{\partial} & \mathrm{C}_0^{\mathrm{simp}}(S_n) & \xrightarrow{\epsilon} & \mathbb{Z} \longrightarrow 0 \\
 & & \downarrow & & \downarrow{=} & & \downarrow{=} & & & & \downarrow{=} & & \downarrow{=} \\
0 & \longrightarrow & \mathrm{C}_{n+1}^{\mathrm{simp}}(D_{n+1}) & \longrightarrow & \mathrm{C}_n^{\mathrm{simp}}(D_{n+1}) & \xrightarrow{\partial} & \mathrm{C}_{n-1}^{\mathrm{simp}}(D_{n+1}) & \xrightarrow{\partial} & \ldots & \xrightarrow{\partial} & \mathrm{C}_0^{\mathrm{simp}}(D_{n+1}) & \xrightarrow{\epsilon} & \mathbb{Z} \longrightarrow 0 \\
 & & \downarrow{\cong} & & \downarrow & & \downarrow & & & & \downarrow & & \downarrow \\
0 & \longrightarrow & \mathbb{Z} & \xrightarrow{\partial} & 0 & \xrightarrow{\partial} & 0 & \xrightarrow{\partial} & \ldots & \xrightarrow{\partial} & 0 & \xrightarrow{\partial} & 0 \longrightarrow 0.
\end{array}$$

We make the following clarifications and comments:

(a) The top two horizontal sequences are the reduced chain complexes of the abstract simplicial complexes S_n and D_{n+1}.

(b) Recall that by definition the simplices of S_n and D_{n+1} are the same except that D_{n+1} has a single $(n+1)$-simplex whereas S_n has no $(n+1)$-simplices. This observation explains the vertical maps.

(c) The diagram clearly commutes and it is clear that the vertical sequences are exact.

(d) It follows from the above that we can apply the LES Proposition 74.9 and we obtain a long exact sequence of homology groups. Together with (1) we obtain the reduced simplicial homology groups of S_n. ■

[1165] One can easily verify that the map P_n is actually well-defined.

In the Suspension-H_*-Proposition 76.7 we studied the singular homology groups of a suspension. Statement (2) of the following lemma is the simplicial analogue of the Suspension-H_*-Proposition 76.7.

Lemma 95.13. (Join-Homology Lemma) Let K be a non-empty abstract simplicial complex.

(1) Let $n \in \mathbb{N}_0$ and let S_n be the abstract simplicial complex that we introduced on page 1978. For every $k \in \mathbb{N}_0$ there exists a natural isomorphism
$$\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(K * S_n) \;\cong\; \widetilde{\mathrm{H}}_{k-(n+1)}^{\mathrm{simp}}(K).$$

(2) We denote by $\Sigma(K)$ the simplicial suspension of K as defined on page 2003. For every $k \in \mathbb{N}_0$ there exists an isomorphism
$$\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(\Sigma(K)) \;\cong\; \widetilde{\mathrm{H}}_{k-1}^{\mathrm{simp}}(K).$$

Example. Let $n \in \mathbb{N}$. Given any $k \in \mathbb{N}_0$ we see that
$$\widetilde{\mathrm{H}}_k\big(\overbrace{\Sigma(\Sigma(\ldots\Sigma(S_0)))}^{n\text{-fold simplicial suspension}}\big) \;\underset{\uparrow}{\cong}\; \widetilde{\mathrm{H}}_{k-n}(S_0) \;\underset{\uparrow}{\cong}\; \begin{cases} \mathbb{Z}, & \text{if } k-n=0, \\ 0, & \text{otherwise.} \end{cases}$$
Join-Homology Lemma 95.13 applied n times see the discussion on page 2041

Proof. Since the author has no intention of monopolizing all the fun we will leave the proof of Statement (1) as Exercise 95.2 to the reader. Note that Statement (2) is an immediate consequence of Statement (1) since $\Sigma(K)$ is naturally isomorphic to $K * S_0$. ∎

Next we extend the definition of simplicial homology groups in the obvious way to simplicial complexes:

Definition. Let $(X, (K = (V, S), \Theta\colon |K| \to X))$ be a simplicial complex. Given $n \in \mathbb{N}_0$ we define
$$\mathrm{H}_n^{\mathrm{simp}}(X) \;:=\; \mathrm{H}_n^{\mathrm{simp}}(K).$$
Similarly, given a simplicial map $f\colon X = (X, \Theta) \to Y = (L, \Omega)$ between two simplicial complexes we define the induced map $f_*\colon \mathrm{H}_n^{\mathrm{simp}}(X) \to \mathrm{H}_n^{\mathrm{simp}}(Y)$ as the induced map $f_*\colon \mathrm{H}_n^{\mathrm{simp}}(K) \to \mathrm{H}_n^{\mathrm{simp}}(L)$.

Finally we introduce simplicial homology with coefficients in the obvious way. More precisely, we have the following definition which is the obvious variation on the definition given in Section 89.2.

Definition. Let G be an abelian group and let $n \in \mathbb{N}_0$. Given an abstract simplicial complex K we set
$$\mathrm{H}_n^{\mathrm{simp}}(K; G) \;:=\; \mathrm{H}_n(\mathrm{C}_*^{\mathrm{simp}}(K) \otimes G).$$
If K is actually ordered we set $\mathrm{H}_n^{\mathrm{simp},\leq}(K; G) := \mathrm{H}_n(\mathrm{C}_*^{\mathrm{simp},\leq}(K) \otimes G)$. Finally given a simplicial complex $(X, (K = (V, S), \Theta\colon |K| \to X))$ we define, following the above convention, $\mathrm{H}_n^{\mathrm{simp}}(X; G) := \mathrm{H}_n^{\mathrm{simp}}(K; G)$.

Surely there is no need to state all the self-evident properties of simplicial homology with coefficients. Let us just mention that it follows from the Tensor Lemma 89.3 (3) that given any abstract simplicial complex K and given any $n \in \mathbb{N}_0$ the map
$$\begin{array}{ccc} \mathrm{H}_n^{\mathrm{simp}}(K; \mathbb{Z}) & \to & \mathrm{H}_n^{\mathrm{simp}}(K) \\ \Big[\sum\limits_{i=0}^{k} s_i \otimes m_i\Big] & \mapsto & \Big[\sum\limits_{i=0}^{k} s_i \cdot m_i\Big] \end{array}$$

is a natural isomorphism. Throughout these notes we will use this isomorphism to make the identification $\mathrm{H}_n^{\mathrm{simp}}(K;\mathbb{Z}) = \mathrm{H}_n^{\mathrm{simp}}(K)$.

95.3. **The Simplicial Künneth Theorem.** Let $(K,\leq)$ and $(L,\leq)$ be two ordered abstract simplicial complexes. Recall that on page 1998 we introduced the corresponding product $K \times L$. The following theorem, which can be viewed as the simplicial analogue of the Künneth Theorem 90.8 for Topological Spaces, computes the simplicial homology groups of $K \times L$ in terms of the simplicial homology groups of K and L.

Theorem 95.14. (Simplicial Künneth Theorem) Let $(K,\leq)$ and $(L,\leq)$ be two ordered abstract simplicial complexes. There exists a short exact sequence

$$0 \to \bigoplus_{p+q=n} \mathrm{H}_p^{\mathrm{simp},\leq}(K) \otimes \mathrm{H}_q^{\mathrm{simp},\leq}(L) \xrightarrow{\Omega} \mathrm{H}_n^{\mathrm{simp},\leq}(K \times L) \to \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p^{\mathrm{simp},\leq}(K), \mathrm{H}_q^{\mathrm{simp},\leq}(L)) \to 0$$

with the following four properties:

(1) Both maps are natural with respect to the ordered abstract simplicial complexes K and L.
(2) For $p = 0$ the map $\Omega\colon \mathrm{H}_0^{\mathrm{simp},\leq}(K) \otimes \mathrm{H}_q^{\mathrm{simp},\leq}(L) \to \mathrm{H}_q^{\mathrm{simp},\leq}(K \times L)$ is the "obvious" map, namely for any vertex v of K and any simplicial cycle $\sigma \in \mathrm{C}_q^{\mathrm{simp},\leq}(L)$ the image of the class $[v] \otimes [\sigma] \in \mathrm{H}_0^{\mathrm{simp},\leq}(K) \otimes \mathrm{H}_q^{\mathrm{simp},\leq}(L)$ under Ω equals the image of $[\sigma]$ under the map $\mathrm{H}_q^{\mathrm{simp},\leq}(L) \to \mathrm{H}_q^{\mathrm{simp},\leq}(\{v\} \times L) \to \mathrm{H}_q^{\mathrm{simp},\leq}(K \times L)$, where the first map is induced by the natural isomorphism and the second map is induced by the inclusion.
(3) The analogue of (2) also holds for $q = 0$.
(4) The above short exact sequence splits.

We will not really make use of the Simplicial Künneth Theorem 95.14, thus we will only provide a sketch of the proof. A full proof is given in [**FePi2011**, Theorem III.6.4].

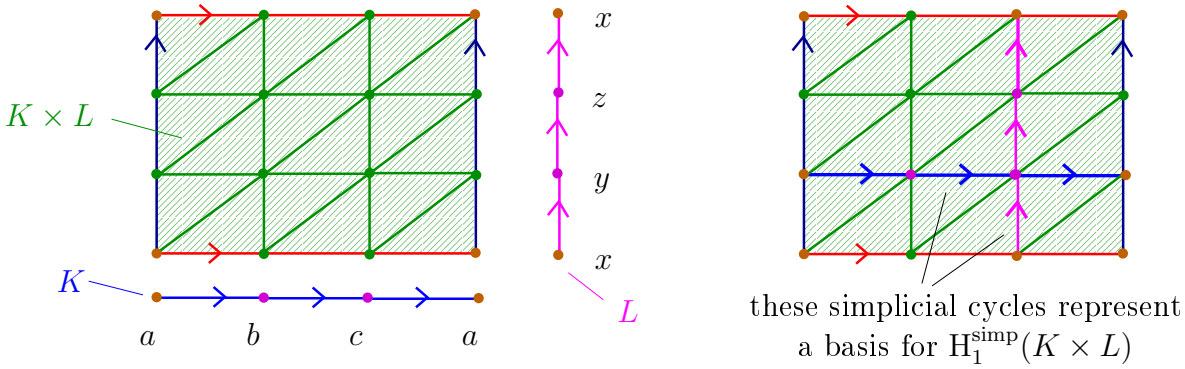
Sketch of proof. Using the Acyclic Model Theorem 113.16, together with Exercise 95.5, one can prove a simplicial analogue of the Eilenberg-Zilber Theorem 90.4, i.e. one can prove that there exists a natural chain map

$$\Upsilon\colon C_*^{\mathrm{simp},\leq}(K) \otimes C_*^{\mathrm{simp},\leq}(L) \ \to \ C_*^{\mathrm{simp},\leq}(K \times L)$$

with the following three properties:

(1) The chain map is a chain homotopy equivalence.
(2) Given any vertex v of K and given any ordered simplex $(w_0,\ldots,w_k)$ of L we have $\Upsilon([v] \otimes [w_0,\ldots,w_k]) = [(v,w_0),\ldots,(v,w_k)]$.
(3) The analogue of (2) with the roles of K and L swapped also holds.

The precise construction of such a map is given in [**FePi2011**, Chapter III.6]. Next we consider the following maps:



$$\begin{array}{ccccccccc} & & & & \mathrm{H}_n^{\mathrm{simp},\leq}(\mathrm{C}_*^{\mathrm{simp},\leq}(K)\otimes \mathrm{C}_*^{\mathrm{simp},\leq}(L)) & & & & \\ & & & \overset{\Omega}{\nearrow} & \downarrow \cong \Upsilon & \searrow & & & \\ 0 & \to & \bigoplus_{p+q=n} \mathrm{H}_p^{\mathrm{simp},\leq}(K)\otimes \mathrm{H}_q^{\mathrm{simp},\leq}(L) & & & & \bigoplus_{p+q=n-1} \mathrm{Tor}(\mathrm{H}_p^{\mathrm{simp},\leq}(K), \mathrm{H}_q^{\mathrm{simp},\leq}(L)) & \to & 0. \\ & & & \searrow & \underbrace{\mathrm{H}_n^{\mathrm{simp},\leq}(\mathrm{C}_*^{\mathrm{simp},\leq}(K\times L))}_{=\mathrm{H}_n(K\times L)} & \nearrow & & & \end{array}$$

Here the sequence on the top is the natural short exact sequence provided by the Künneth Theorem 90.7 for Chain Complexes. It follows from the above together with Corollary 73.4 that the vertical map is a natural isomorphism. It is now fairly straightforward to see that we obtain the desired short exact sequence from replacing the upper middle term by the lower middle term $\mathrm{H}_n^{\mathrm{simp},\leq}(\mathrm{C}_*^{\mathrm{simp},\leq}(K\times L)) = \mathrm{H}_n^{\mathrm{simp},\leq}(K\times L)$. ■

Example. We consider the ordered abstract simplicial spaces K and L that are shown in the figure below. Both are simplicially isomorphic to the simplicial circle S_1. Furthermore we consider the "simplicial torus" $K \times L$. It follows from the Simplicial Künneth Theorem 95.14 that

$$\mathrm{H}_i^{\mathrm{simp}}(K\times L) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0, 2, \\ \mathbb{Z}^2, & \text{if } i = 1, \\ 0, & \text{if } i > 2. \end{cases}$$

Furthermore it follows easily from Statement (2) of the Simplicial Künneth Theorem 95.14 that the two singular cycles shown in the figure below form a basis for $H_1^{\mathrm{simp},\leq}(K\times L)$.

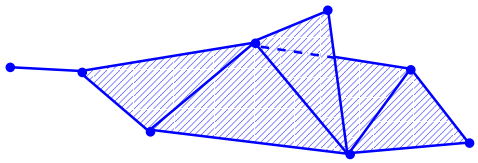
95.4. **The topological invariance of simplicial homology I.** The following question arises naturally.

Question 95.15. Let $(X, (K, \Theta\colon |K| \to X))$ be a simplicial complex and let $n \in \mathbb{N}_0$. Does the isomorphism type of the simplicial homology group $\mathrm{H}_n^{\mathrm{simp}}(X)$ only depend on the homeomorphism type of X?

For example, we know by the discussion on page 1997 and on page 2005 that the topological realizations of S_n and of the n-fold simplicial suspension of S_0 are both homeomorphic to

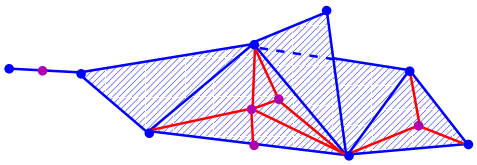
S^n and conveniently enough we know by Lemma 95.12 and the last example of the previous section that the homology groups are indeed isomorphic.

The following "research program" summarizes the traditional approach to tackling Question 95.15.



Program 95.16.

(1) Show that any two (let us say finite) abstract simplicial complexes with homeomorphic topological realizations are related by a finite sequence of "moves".
(2) Show that the isomorphism type of simplicial homology groups is unchanged under these "moves".



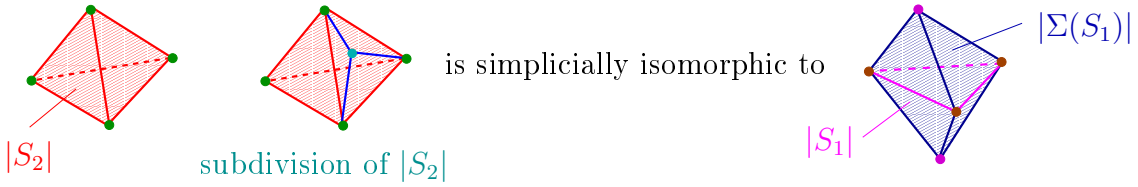
This idea leads straight to the definition of a subdivision of a simplicial complex.

Definition. We say that a simplicial complex $(X, (K = (V, S), \Omega\colon |K| \to X))$ is a subdivision of some simplicial complex $(X, (L = (W, T), \Theta\colon |L| \to X)$ if the following two conditions are satisfied:

(1) Every simplex of $|K|$ is contained in some simplex of $|L|$. More precisely, given any simplex $s \in S$ of K there exists a simplex $t \in T$ of L such that $\Omega(|s|) \subset \Theta(|t|)$.
(2) For every k-simplex s of K and every l-simplex t of L with $\Omega(|s|) \subset \Theta(|t|)$ the map $\Phi_t^{-1} \circ \Theta \circ \Omega \circ \Phi_s\colon \Delta^k \to |s| \subset |t| \to \Delta^l$ is affine linear.

simplicial complex

subdivision of the simplicial complex



Remark.

(1) Note that for linear simplicial complexes condition (3) is automatically satisfied.
(2) The definition of a subdivision we give agrees with the definition in most sources, see e.g. [**Hud1969**, p. 5], [**Pon1952**, p. 36], [**RS1972**, p. 15], [**Gla1970**, p. 7], [**Spa1995**, p. 121] and [**Zee1963b**, p. I.4].
(3) In [**Mun1984**, p. 83] the definition of a subcomplex has the extra condition that every simplex of X equals the union of finitely many simplices of Y. It follows from [**Hud1969**, Lemma 1.2] together with the Simplicial Complex-Finiteness Proposition 93.12 (2) that the above definition agrees with the definition provided in [**Mun1984**, p. 83].
(4) The definition of a subdivision is somewhat unsatisfactory. In the spirit that abstract simplicial complexes should be purely combinatorial objects there should be a "topology free" definition of the subdivision of an abstract simplicial complexes, which then mirrors the topological definition given above. We will return to the question of how to work completely combinatorially in Section 96.6.

Examples.

(1) It follows from the SD-Lemma 94.3 (3a) and (3c) that the barycentric subdivision $\mathrm{sd}(X)$ of a simplicial complex X is indeed a subdivision in the sense of the above definition.

(2) In the figure below we see that a subdivision of the simplicial complex $|S_2|$ is simplicially isomorphic to $\Sigma(S_1)$.

(3) Let $n \in \mathbb{N}_0$. By the Join-Simplex Lemma 93.19 (3) we know that the map

$$\begin{array}{rcl} f\colon \partial\Delta^n * \{\star\} & \to & \Delta^n \\ [(x,t,\star)] & \mapsto & x\cdot(1-t) + \left(\frac{1}{n+1},\dots,\frac{1}{n+1}\right)\cdot t \end{array}$$

is a homeomorphism. It follows easily from this observation that the simplicial complex $(S_{n-1} * \{\star\}, |S_{n-1} * \{\star\}| = \partial\Delta^n * \{\star\} \xrightarrow{f} \Delta^n)$ is a subdivision of the simplicial complex $(D_n, \Omega\colon |D_n| \to \Delta^n)$. We refer to the figure below for an illustration.

For completeness' sake we mention the following result.

Proposition 95.17.

(1) Let X and Y be two finite linear simplicial complexes. If $|X| = |Y|$, then there exist subdivisions X' of X and Y' of Y which are simplicially isomorphic.
(2) If we are given two subdivisions X' and X'' of some finite linear simplicial complex X, then there exists a subdivision Y of X which is a subdivision of X' and X''.

Proof.

(1) This statement is proved in [**Gla1970**, Corollary I.4] and [**Zee1963b**, Corollary I.1].
(2) This statement follows immediately from (1) together with Lemma 93.22. ■

The following theorem gives us part (2) of Program 95.16. We will not provide a proof, instead we refer to [**Mun1966a**, Theorem 17.2] for a detailed proof.

Theorem 95.18. Let X be a simplicial complex and let X' be a subdivision of X. If $\varphi\colon X' \to X$ is a simplicial approximation of the identity map $X' \to X$, then the induced map $\varphi_*\colon \mathrm{H}_n^{\mathrm{simp}}(X') \to \mathrm{H}_n^{\mathrm{simp}}(X)$ is an isomorphism for every $n \in \mathbb{N}_0$.

So an obvious candidate for the "moves" of Program 95.16 is a combination of subdivisions and simplicial isomorphisms. Now that we have dealt with part (2) of Program 95.16, let us try to tackle part (1). In fact this part is the following conjecture, which came to be known as the "Hauptvermutung". It was originally formulated by Heinrich Tietze [**Tie1908**, p. 13f] in 1908. The conjecture was also raised as a question by Ernst Steinitz [**Steini1908**, p. 32] in 1908.

Conjecture 95.19. (Hauptvermutung) Let X and Y be two finite simplicial complexes. If the underlying topological spaces are homeomorphic, then there exist subdivisions of X and Y which are simplicially isomorphic.

For better or worse it turned out that the Hauptvermutung was too optimistic. More precisely, the Hauptvermutung was eventually disproved by John Milnor [**Miln1961**, Theorems 1 and 2] in 1961.

Theorem 95.20. There exist two finite linear simplicial complex X and Y for which the underlying topological spaces are homeomorphic, but such that there are no subdivisions of X and Y which are simplicially isomorphic.

Remark. In fact a few years later Rob Kirby and Larry Siebenmann [**KSi1977**] (see also [**Ran1996**, Chapter 4]) showed that given any $n \geq 5$ there exist such finite abstract simplicial complexes such that the underlying topological space is a compact n-dimensional topological manifold.

Proof. The theorem is proved in [**Miln1961**, Theorems 1 and 2]. Alternative proofs are given in [**CoheM1973**, p. 84], [**Stal1965b**, p. 252] and [**Ran1996**, Chapter 2]. ■

Even though Part (1) of Program 95.16 did not work out, it turns out that Question 95.15 nonetheless has a positive answer. More precisely we have the following theorem.

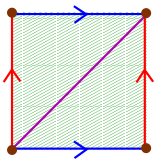
Theorem 95.21. Let X and Y be two simplicial complexes. If the underlying topological spaces X and Y are homeomorphic, then for every $n \in \mathbb{N}_0$ the simplicial homology groups $\mathrm{H}_n^{\mathrm{simp}}(X)$ and $\mathrm{H}_n^{\mathrm{simp}}(Y)$ are isomorphic.

Using the Simplicial Approximation Theorem 94.8 and several other tools from the theory of simplicial complexes one can give a direct proof of Theorem 95.21. This approach is for example pursued in [**Mun1966a**, Corollary 18.2], [**Pra2007**, Chapter 2.2] and [**Gib2010**, p. 136].

We will instead take an indirect approach to proving Theorem 95.21, namely we will show that given a simplicial complex the *simplicial* and *singular* homology groups are isomorphic. By the functoriality of *singular* homology the isomorphism type of *singular* homology groups only depends on the homeomorphism type of the topological space. With this observation in mind we see that Theorem 95.21 is a consequence of the following theorem.

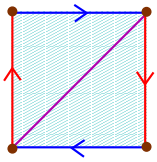
Theorem 95.22. Let X be a simplicial complex. For every $n \in \mathbb{N}_0$ there exists a natural[1166] isomorphism $\Phi_X \colon \mathrm{H}_n^{\mathrm{simp}}(X) \xrightarrow{\cong} \mathrm{H}_n(X)$.

We postpone the proof of Theorem 95.22 to the next section. In fact, in the next section we will formulate and prove a more precise version of Theorem 95.22. But before we delve into the detailed arguments let us first discuss the respective advantages and disadvantages of simplicial homology.



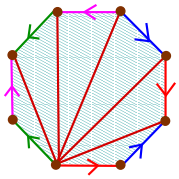
[1166] Here "natural" means that if $f \colon X \to Y$ is a simplicial map, then the following diagram commutes:

$$\begin{array}{ccc} \mathrm{H}_n^{\mathrm{simp}}(X) & \xrightarrow{f_*} & \mathrm{H}_n^{\mathrm{simp}}(Y) \\ \downarrow{\scriptstyle \Phi_X} & & \downarrow{\scriptstyle \Phi_L} \\ \mathrm{H}_n(X) & \xrightarrow{f_*} & \mathrm{H}_n(Y). \end{array}$$



In some textbooks, see e.g. [**Matv2006, Mun1984, SZ1994, HY1988**], homology groups are initially introduced via simplicial homology. This approach has several advantages:

(1) The definition of simplicial homology is much more elementary and intuitive than the definition of singular homology.
(2) One can immediately compute the simplicial homology groups of interesting simplicial complexes, e.g. as we will see in Exercise 95.10, with enough patience and a little bit of cleverness one can compute the simplicial homology groups of abstract simplicial complexes that correspond to the surface of genus g.



Nonetheless there are serious disadvantages to this approach. A first problem, which is already apparent in the case of the torus, is that even for relatively simple examples the simplicial structures tend to have a large number of simplices, thus the corresponding chain complexes tend to be fairly large and brute force computations by hand become unpleasant. It turns out that there are some ways around this, for example one can extend the theory of simplicial homology from simplicial complexes to "Δ-complexes", which tend to have a significantly smaller number of simplices. Loosely speaking a Δ-complex is a topological space that is decomposed into simplices but now we only demand that the interiors of the simplices are embedded. To give a flavor of the theory we show three Δ-complexes in the figure below. The theory of Δ-complexes is developed in detail in [**Hat2002**, Chapter 2.1].

Δ-complex structure for the torus

Δ-complex structure for $\mathbb{R}\mathrm{P}^2$

Δ-complex structure for the surface of genus 2

Here are more serious reasons why we, and most modern authors, decided against starting out with simplicial homology and why we do not develop the theory of simplicial homology in greater detail:

(1) For slightly more complicated topological spaces it is rather laborious to compute simplicial homology groups. For example we challenge the reader to compute the simplicial homology groups of the projective spaces $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$ without reverting to cellular homology.
(2) Most topological spaces one wants to study (e.g. the complement of a knot in S^3), do not come with an obvious simplicial structure, it can be quite cumbersome to show that a simplicial structure exists, let alone to give an explicit simplicial structure.
(3) For a given topological space X which admits a simplicial structure we know by Theorem 95.21 that we have a well-defined *isomorphism type* of simplicial homology groups, but there is no single group that we can associate to X.
(4) Simplicial homology is functorial with respect to simplicial maps. Most maps are not simplicial. We do have the Simplicial Approximation Theorem 94.8 as a tool. But to use it in a sensible fashion one needs to show that the simplicial approximations of a given continuous map induce the same map on simplicial homology.

It should have become clear by now that simplicial homology comes with a Pandora's box of issues and problems. Overall, the initial extra effort in developing the theory of singular homology groups eventually pays of handily. The theory of singular homology groups is much more natural and much more flexible than the rather pedestrian theory of simplicial homology groups.
We conclude this section with the following piece of wisdom which was handed down to the author from his advisor:

> *For actual calculations it is best to work with very small objects, for proving general statements it is best to work with very large objects.*

95.5. **The topological invariance of simplicial homology II.** In this section we will first show that given an abstract simplicial complex the simplicial homology groups are naturally isomorphic to singular homology groups. Afterwards we will try to find a natural chain homotopy equivalence.
We start out with the first key result of this section.

Theorem 95.23. (Simplicial-Singular Homology Isomorphism Theorem) Let $(K, \Theta\colon |K| \to X)$ be a simplicial complex. For each $n_0 \in \mathbb{N}$ there exists a natural isomorphism $\mathrm{H}_n^{\mathrm{simp}}(K) \to \mathrm{H}_n(X)$.

The proof of the Simplicial-Singular Homology Isomorphism Theorem 95.23 builds on a proposition which relates the simplicial chain complex to the cellular chain complex. Before we state the proposition we recall that given a CW-complex we consider $\mathrm{C}_n^{\mathrm{CW}}(X) := \mathrm{H}_n(X^n, X^{n-1})$ together with the boundary map d_n which is given by the composition

$$\mathrm{H}_n(X^n, X^{n-1}) \xrightarrow{\partial_n} \mathrm{H}_{n-1}(X^{n-1}) \xrightarrow{j_{n-1}} \mathrm{H}_{n-1}(X^{n-1}, X^{n-2})$$
$$\underbrace{\qquad\qquad\qquad\qquad\qquad\qquad}_{=:d_n}$$

where ∂_n is the connecting map in the long exact sequence of the pair (X^n, X^{n-1}) and where j_{n-1} is the natural map from absolute to relative homology.
Now we can formulate the promised proposition.

Proposition 95.24. Let K be an abstract simplicial complex. Given an ordered n-simplex $s = (v_0, \ldots, v_n)$ of K we denote by

$$\begin{aligned} \Phi_s^{\leq}\colon \Delta^n = \left\{(t_0, \ldots, t_n) \in \mathbb{R}_{\geq 0}^{n+1} \,\middle|\, \sum_{i=0}^n t_i = 1\right\} &\to |s| \subset |K| = X \\ (t_0, \ldots, t_n) &\mapsto \sum_{i=0}^n t_i \cdot v_i \end{aligned}$$

the corresponding characteristic map. The maps[1167]

$$\begin{aligned} \Upsilon_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) &\to \mathrm{C}_n^{\mathrm{CW}}(|K|) \\ [s] &\mapsto (\Phi_s^{\leq}\colon \Delta^n \to |K|) \end{aligned}$$

form a natural isomorphism of chain complexes.

Proof of Proposition 95.24. Let $K = (V, S)$ be an abstract simplicial complex. We write $X := |K|$. Given $n \in \mathbb{N}_0$ we denote by S_n the set of ordered n-simplices of K. Next

[1167]Recall that in the Simplicial-Implies-CW Lemma 93.24 we showed that the simplicial complex $|K|$ admits a natural CW-structure.

we consider the following diagram

$$\begin{array}{ccc}
\mathrm{C}_n^{\mathrm{simp}}(K) := \Big(\bigoplus_{s\in S_n} \mathbb{Z}\cdot s\Big)/I_n & \xrightarrow{[s]\mapsto[\Phi_s^{\leq}]} & \mathrm{H}_n(X^n, X^{n-1}) = \mathrm{C}_n^{\mathrm{CW}}(X) \\
\Big\downarrow{\scriptstyle \partial_n} & \swarrow{\scriptstyle \partial} & \Big\downarrow{\scriptstyle d_n} \\
\mathrm{C}_{n-1}^{\mathrm{simp}}(K) := \Big(\bigoplus_{s\in S_{n-1}} \mathbb{Z}\cdot s\Big)/I_{n-1} & \xrightarrow{[s]\mapsto[\Phi_s^{\leq}]} & \mathrm{H}_{n-1}(X^{n-1}, X^{n-2}) = \mathrm{C}_{n-1}^{\mathrm{CW}}(X).
\end{array}$$

$$\mathrm{H}_{n-1}(X^{n-1}) \xrightarrow{j_{n-1}} \mathrm{H}_{n-1}(X^{n-1}, X^{n-2})$$

We make the following clarifications and observations:

(1) If s is an ordered k-simplex, then it follows immediately from the definition of the CW-structure on X that $\Phi_s^{\leq}(\Delta^k) \subset X^k$ and that $\Phi_s^{\leq}(\partial\Delta^k) \subset X^{k-1}$. In particular this shows that $\Phi_s^{\leq}$ represents an element in $\mathrm{H}_k(X^k, X^{k-1})$.
(2) It follows fairly easily from (1) together with Lemma 51.1 and Proposition 76.20 that the horizontal maps are well-defined.
(3) Basically the same argument as in the Skeleton-Homology Lemma 80.1 (1) shows that the horizontal maps are isomorphisms.
(4) As explained above, the top diagonal map $\partial\colon \mathrm{H}_n(X^n, X^{n-1}) \to \mathrm{H}_{n-1}(X^{n-1})$ is the connecting homomorphism of the pair (X^n, X^{n-1}) and the bottom diagonal map $j_{n-1}\colon \mathrm{H}_{n-1}(X^{n-1}) \to \mathrm{H}_{n-1}(X^{n-1}, X^{n-2})$ is the natural map from absolute homology to relative homology. The map d_n is by definition the composition of these two maps. In other words, the triangle commutes by definition.
(5) It follows fairly immediately from the definition of the connecting homomorphism, see the Topological LES-Proposition 74.13, and the definition of the maps $\Phi_s^{\leq}$ that the pentagon to the left commutes.
(6) It follows from (4) and (5) that the outer square of the diagram also commutes.
(7) The horizontal maps are basically by definition natural.

The above discussion shows that the horizontal maps define a natural isomorphism of chain complexes. ∎

For the reader's convenience we recall the following proposition.

Proposition 80.4. (Singular-Cellular H_*-Isomorphism Proposition) Given any CW-complex X and given any $n \in \mathbb{N}_0$ there exists a uniquely determined isomorphism

$$\Phi_X\colon \mathrm{H}_n(X) \xrightarrow{\cong} \mathrm{H}_n^{\mathrm{CW}}(X)$$

with the property that the following diagram commutes:[1168]

$$\begin{array}{ccccc}
 & & \mathrm{H}_n(X) & & \\
 & \nearrow & & \searrow{\scriptstyle \Phi_X} & \\
\mathrm{H}_n(X^n) & & & & \mathrm{H}_n^{\mathrm{CW}}(X). \\
 & \searrow{\scriptstyle j_n} & & \nearrow & \\
 & & \ker(d_n) & &
\end{array}$$

Furthermore this map Φ_X is natural.

Now we can put everything together to obtain a proof of the Simplicial-Singular Homology Isomorphism Theorem 95.23.

Proof of Theorem 95.23. It follows immediately from the definitions that we only need to consider the case of the topological realization of an abstract simplicial complex K. We equip $|K|$ with the CW-structure provided by the Simplicial-Implies-CW Lemma 93.24. Now given any $n \in \mathbb{N}_0$ we have the following two natural isomorphisms:

$$\underset{\text{natural isomorphism } \Upsilon_K \text{ given by Proposition 95.24}}{\mathrm{H}_n^{\mathrm{simp}}(K)} \xrightarrow[\uparrow]{\cong} \mathrm{H}_n^{\mathrm{CW}}(|K|) \xleftarrow[\uparrow]{\cong} \underset{\text{natural isomorphism } \Phi_{|K|} \text{ given by the Singular-Cellular } \mathrm{H}_*\text{-Isomorphism Proposition 80.4}}{\mathrm{H}_n(|K|).}$$

The natural isomorphism $\Phi_X^{-1} \circ \Upsilon_K$ is the natural isomorphism of our desires. ■

One problem with the Simplicial-Singular Homology Isomorphism Theorem 95.23 is that it does not give us an explicit isomorphism between the homology groups. This issue gets mostly resolved by the following more sophisticated theorem.

Theorem 95.25. (Simplicial-Singular Chain Complex Theorem) Let K be an *ordered* abstract simplicial complex. The maps

$$\begin{array}{rcl} \Theta_n \colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n(|K|) \\ s & \mapsto & (\Phi_s^{\leq} \colon \Delta^n \to |K|) \end{array}$$

are a natural[1169] chain homotopy equivalence. In particular for each $n \in \mathbb{N}_0$ the induced map

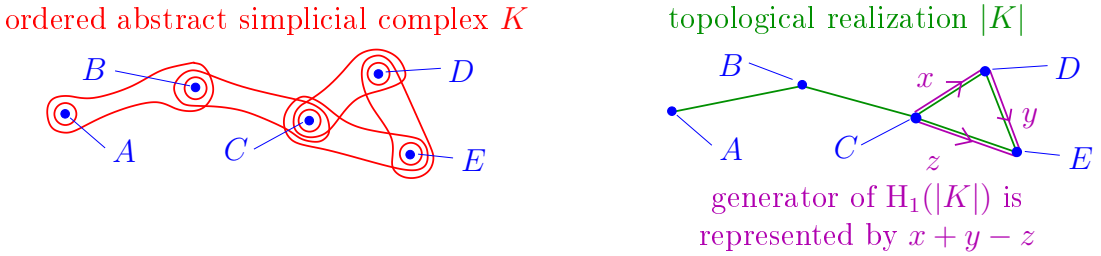
$$\Theta_* \colon \mathrm{H}_n^{\mathrm{simp},\leq}(K) \to \mathrm{H}_n(|K|)$$

is a natural isomorphism.

Remark. The Simplicial-Singular Chain Complex Theorem 95.25 can actually be quite useful in practice. Let us elaborate. In practice, given a topological space X one would like to perform the following three types of tasks:

(1) Determine the isomorphism type of the homology groups $\mathrm{H}_k(X)$.
(2) Determine explicit cycles in $\mathrm{C}_k(X)$ that represent a basis or a generating set for the homology groups $\mathrm{H}_k(X)$.
(3) Calculate induced maps $\mathrm{H}_k(X) \to \mathrm{H}_k(Y)$ with respect to, say, given bases or generating sets for the homology groups $\mathrm{H}_k(X)$ and $\mathrm{H}_k(Y)$.

In fact in many situations, e.g. in applications of the Mayer–Vietoris Theorem 78.5, these problems feed on one another. Even though by now we have a long list of tools, the fact that the singular chain groups $\mathrm{C}_*(X)$ are basically always of infinite, in fact mostly of uncountable, rank makes it hard to attack the above problems directly.



Fortunately, in many situations the Simplicial-Singular Chain Complex Theorem 95.25 allows us to translate the above problems into tasks in a simplicial chain complex. For reasonable abstract simplicial complexes, these problems in turn boil down to elementary problems in linear algebra that usually can be solved easily.

[1168] Here we again denote by $j_n \colon \mathrm{H}_n(X^n) \to \mathrm{H}_n(X^n, X^{n-1})$ the obvious map. In the long exact sequence of the pair (X^n, X^{n-1}) we see that the image of $\mathrm{H}_n(X^n)$ in $\mathrm{H}_n(X^n, X^{n-1})$ lies in the kernel of the connecting homomorphism ∂_n. This implies that the map $j_n \colon \mathrm{H}_n(X^n) \to \mathrm{H}_n(X^n, X^{n-1})$ takes values in $\ker(d_n)$.
[1169] Here "natural" means with respect to the category of *ordered* abstract simplicial complexes.

Example. We consider the 1-dimensional ordered abstract simplicial complex K shown in the figure below which we had already considered on page 2036. By the discussion on page 2036 we know that

$$\mathrm{H}_1^{\mathrm{simp},\leq}(K) = \ker\left(\partial_1 \colon \mathrm{C}_1^{\mathrm{simp},\leq}(K) \to \mathrm{C}_0^{\mathrm{simp},\leq}(K)\right) = \mathbb{Z} \cdot [\{C,D\} + \{D,E\} - \{C,E\}].$$

We write $x = \Theta_1(\{C,D\})$, $y = \Theta_1(\{D,E\})$ and $z = \Theta_1(\{C,E\})$. It follows from the Simplicial-Singular Chain Complex Theorem 95.25 and the above discussion that $x+y-z$ represents a generator of $\mathrm{H}_1(|K|)$.[1170]

Proof of the Simplicial-Singular Chain Complex Theorem 95.25. Let K be an ordered abstract simplicial complex. It follows almost immediately from the definitions that the maps

$$\begin{array}{rcl} \Theta_n \colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n(|K|) \\ s & \mapsto & (\Phi_s^{\leq} \colon \Delta^n \to |K|) \end{array}$$

define a natural chain map. We leave it to the skeptical reader to verify that this statement is indeed true and basically trivial. It remains to show that the maps Θ_n define a chain homotopy equivalence. By the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 it now suffices to prove the following claim.

Claim. Let K be an ordered abstract simplicial complex. For every $n \in \mathbb{N}_0$ the induced map

$$\Theta_* \colon \mathrm{H}_n^{\mathrm{simp},\leq}(K) \to \mathrm{H}_n(|K|)$$

is an isomorphism.

Proof. We start out with two observations. Let K be an ordered abstract simplicial complex, let $m \in \mathbb{N}_0 \cup \{\infty\}$ and let $n \in \mathbb{N}_0$. We write $X = |K|$. It follows from Lemma 95.9 and the Skeleton-Homology Lemma 80.1 that the following statements hold:

(i) The two inclusion induced maps

$$\begin{array}{rcl} \mathrm{H}_n^{\mathrm{simp},\leq}(K^m) & \to & \mathrm{H}_n^{\mathrm{simp},\leq}(K) \\ \mathrm{H}_n(|K^m|) & \to & \mathrm{H}_n(|K|) \end{array}$$ are both isomorphisms whenever $n < m$.

(ii) If $n > m$, then $\begin{array}{rcl} \mathrm{H}_n^{\mathrm{simp},\leq}(K^m) & = & 0 \\ \mathrm{H}_n(|K^m|) & = & 0. \end{array}$

It follows immediately from (i) that it suffices to prove the claim for finite-dimensional ordered abstract simplicial complexes. As usual, for finite-dimensional ordered abstract simplicial complexes we proceed by induction on the dimension. The case of an empty and of a 0-dimensional ordered abstract simplicial complex is trivial. So suppose we have

[1170] What other methods do you know for proving this statement?

shown the statement for all ordered abstract simplicial complexes of dimension $\leq m-1$. Now let K be an m-dimensional ordered abstract simplicial complex. We write $X := |K|$ and we denote by $i\colon K^{m-1} \to K$ and $i\colon X^{m-1} \to X$ the inclusion maps. It follows from (i) and (ii), the naturality of Θ and our induction hypothesis that we only need to worry about the two maps

$$\Theta_*\colon \mathrm{H}_m^{\mathrm{simp},\leq}(K) \ \to \ \mathrm{H}_m(X) \quad \text{and} \quad \Theta_*\colon \mathrm{H}_{m-1}^{\mathrm{simp},\leq}(K) \ \to \ \mathrm{H}_{m-1}(X).$$

To take care of this map we consider the following diagram:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathrm{H}_m^{\mathrm{simp},\leq}(K) & \hookrightarrow & \mathrm{C}_m^{\mathrm{simp},\leq}(K) & \xrightarrow{\partial} & \mathrm{H}_{m-1}^{\mathrm{simp},\leq}(K^{m-1}) & \xrightarrow{i_*} & \mathrm{H}_{m-1}^{\mathrm{simp},\leq}(K) \longrightarrow 0 \\
 & & \downarrow{\scriptstyle \Theta_*} & & \cong\downarrow{\scriptstyle \Psi_*} & & \downarrow{\scriptstyle \cong\ \Theta_*} & & \downarrow{\scriptstyle \Theta_*} \\
 & & & & \mathrm{C}_m^{\mathrm{CW}}(X) & & & & \\
 & & & & \downarrow{\scriptstyle \mathrm{id}} & & & & \\
0 & \longrightarrow & \mathrm{H}_m(X) & \longrightarrow & \mathrm{H}_m(X, X^{m-1}) & \xrightarrow{\partial} & \mathrm{H}_{m-1}(X^{m-1}) & \xrightarrow{i_*} & \mathrm{H}_{m-1}(X) \longrightarrow 0.
\end{array}$$

We make the following observations and clarifications:

(1) First we show that the horizontal maps on the top actually make sense. Since $K = K^m$ we see that $\mathrm{H}_m^{\mathrm{simp},\leq}(K)$ is a subgroup of $\mathrm{C}_m^{\mathrm{simp},\leq}(K)$. In fact by definition it equals $\ker(\partial\colon \mathrm{C}_m^{\mathrm{simp},\leq}(K) \to \mathrm{C}_{m-1}^{\mathrm{simp},\leq}(K))$. Furthermore note, that basically by definition, given $s \in \mathrm{C}_m^{\mathrm{simp},\leq}(K)$ we have $\partial s \in \mathrm{C}_{m-1}^{\mathrm{simp},\leq}(K^{m-1})$. Since $\partial \circ \partial = 0$ we see that ∂s defines an element in $\mathrm{H}_{m-1}^{\mathrm{simp},\leq}(K^{m-1})$.

(2) Using (1) and using the explicit definitions of simplicial homology groups it is not hard to see that the top horizontal sequence is exact.

(3) It follows from $X = X^m$ and the Skeleton-Homology Lemma 80.1 that $\mathrm{H}_i(X, X^{m-1}) = 0$ for $i \neq m$. Thus we see that the bottom horizontal sequence is a segment of the long exact sequence of the pair (X, X^{m-1}).

(4) It follows easily from the definition of the maps Θ and Ψ and the explicit description of the connecting homomorphism $\partial\colon \mathrm{H}_m(X, X^{m-1}) \to \mathrm{H}_{m-1}(X^{m-1})$ that we gave in the Topological LES-Proposition 74.13 that the two squares to the left commute. It follows from the naturality of Θ_* that the square to the right commutes.

(5) It follows from induction that the vertical map $\Theta_*\colon \mathrm{H}_{m-1}^{\mathrm{simp},\leq}(K^{m-1}) \to \mathrm{H}_{m-1}(X^{m-1})$ to the right is an isomorphism.

(6) By Proposition 95.24 we know that Ψ_* is an isomorphism.

(7) It follows from all of the above together with the Five-Lemma 74.10 that the vertical maps $\Theta_*\colon \mathrm{H}_m^{\mathrm{simp},\leq}(K) \to \mathrm{H}_m(X)$ and $\Theta_*\colon \mathrm{H}_{m-1}^{\mathrm{simp},\leq}(K) \to \mathrm{H}_{m-1}(X)$ to the left and right are isomorphisms. ■

Given an abstract simplicial complex K together with an order "$\leq$" on K we denote by $\Omega_{\leq,k}\colon \mathrm{C}_k^{\mathrm{simp},\leq}(K) \to \mathrm{C}_k^{\mathrm{simp}}(K)$ the natural chain isomorphism given by Lemma 95.8. Together with the Simplicial-Singular Chain Complex Theorem 95.25 we obtain an isomorphism

$$\mathrm{H}_k^{\mathrm{simp}}(K) \ \xleftarrow{\Omega_{\leq,k}^{-1}} \ \mathrm{H}_k^{\mathrm{simp},\leq}(K) \ \xrightarrow{\Theta_{\leq,k}} \ \mathrm{H}_k(|K|).$$

A priori this isomorphism depends on the choice of the order "$\leq$". The next lemma shows that fortunately this is not the case.

Lemma 95.26. Let K be an abstract simplicial complex and let "$\leq$" and "$\subseteq$" be two orders on K. The two chain maps

$$\begin{aligned} & \mathrm{C}_k^{\mathrm{simp}}(K) \xrightarrow{\Omega_{\leq,k}^{-1}} \mathrm{C}_k^{\mathrm{simp},\leq}(K) \xrightarrow{\Theta_{\leq,k}} \mathrm{C}_k(|K|) \\ \text{and} \quad & \mathrm{C}_k^{\mathrm{simp}}(K) \xrightarrow{\Omega_{\subseteq,k}^{-1}} \mathrm{C}_k^{\mathrm{simp},\subseteq}(K) \xrightarrow{\Theta_{\subseteq,k}} \mathrm{C}_k(|K|) \end{aligned}$$

are chain homotopic. In particular they induce the same maps on homology.

Proof. Let $K = (V, S)$ be an abstract simplicial complex. We start with the following preparations:

(1) For each $i \in \mathbb{N}_0$ we pick once and for all for each i-simplex $s \in S$ an ordered i-simplex $\widetilde{s}$ with $\lfloor \widetilde{s} \rfloor = s$. We denote by $\widetilde{S}_i$ the set given by all these ordered i-simplices.

(2) We introduce the following convention. If for some $i \in \mathbb{N}_0$ we are given for every $\widetilde{s} \in \widetilde{S}_i$ a singular chain $P_i(\widetilde{s}) \in \mathrm{C}_{i+1}(|\widetilde{s}|)$ then we denote by P_i the map

$$\begin{aligned} \mathrm{C}_i^{\mathrm{simp}}(K) &\to \mathrm{C}_{i+1}(|K|) \\ \widetilde{s} &\mapsto P_i(\widetilde{s}) \quad \text{viewed as an element in } \mathrm{C}_{i+1}(|K|) \text{ via the inclusion } |\widetilde{s}| \subset |K| \end{aligned}$$

Now let "$\leq$" and "$\subseteq$" be two orders on $\Delta = (V, S)$.

Claim. Let $l \in \mathbb{N}$. Suppose that for every $i \in \{0, \ldots, l-1\}$ and for every $\widetilde{s} \in \widetilde{S}_i$ we are given a singular chain $P_i(\widetilde{s}) \in \mathrm{C}_{i+1}(|\widetilde{s}|)$ such that for every $i \in \{0, \ldots, l-1\}$ we have the equality

$$(*) \qquad \partial_{i+1} \circ P_i + P_{i-1} \circ \partial_i \;=\; \Theta_{\leq,i} \circ \Omega_{\leq,i}^{-1} - \Theta_{\subseteq,i} \circ \Omega_{\subseteq,i}^{-1} \colon \mathrm{C}_i^{\mathrm{simp}}(K) \to \mathrm{C}_i(|K|).$$

Then for every $\widetilde{s} \in \widetilde{S}_l$ we can also find $P_l(s) \in \mathrm{C}_{l+1}(|\widetilde{s}|)$ such that the above equality holds for $i = 0, \ldots, l$.

Proof. Let $\widetilde{s} \in \widetilde{S}_l$. Note that we have

$$\begin{aligned} \partial_l((-P_{l-1} \circ \partial_l + \Theta_{\leq,l} \circ \Omega_{\leq,l}^{-1} - \Theta_{\subseteq,l} \circ \Omega_{\subseteq,l}^{-1})(\widetilde{s})) &\overset{\text{since } \Theta_{\leq,i} \circ \Omega_{\leq,i}^{-1} \text{ and } \Theta_{\subseteq,i} \circ \Omega_{\subseteq,i}^{-1} \text{ are chain maps}}{=} (-\partial_l \circ P_{l-1} + \Theta_{\leq,l-1} \circ \Omega_{\leq,l-1}^{-1} - \Theta_{\subseteq,l-1} \circ \Omega_{\subseteq,l-1}^{-1})(\partial_l(\widetilde{s})) \\ &= (P_{l-2} \circ \partial_{l-1})(\partial_l(\widetilde{s})) = P_{l-2}(\partial_{l-1} \circ \partial_l)(\widetilde{s}) = 0. \end{aligned}$$

(the last equality: by equality $(*)$ for $i = l-1$)

Note that by construction all terms are contained in $\mathrm{C}_l(|\widetilde{s}|) \subset \mathrm{C}_l(|K|)$. For orientation it is helpful to consider the following diagram

$$\begin{array}{ccccccc} & & \mathrm{C}_l^{\mathrm{simp}}(\widetilde{s}) & \xrightarrow{\partial_l} & \mathrm{C}_{l-1}^{\mathrm{simp}}(\widetilde{s}) & \xrightarrow{\partial_{l-1}} & \mathrm{C}_{l-1}^{\mathrm{simp}}(\widetilde{s}) \\ & \overset{P_l}{\swarrow} & \downarrow & \overset{P_{l-1}}{\swarrow} & \downarrow & \overset{P_{l-1}}{\swarrow} & \downarrow \\ \mathrm{C}_{l+1}(|\widetilde{s}|) & \xrightarrow[\partial_{l+1}]{} & \mathrm{C}_l(|\widetilde{s}|) & \xrightarrow[\partial_l]{} & \mathrm{C}_{l-1}(|\widetilde{s}|) & \xrightarrow[\partial_{l-1}]{} & \mathrm{C}_{l-2}(|\widetilde{s}|) \end{array}$$

Note that we are dealing with $l \in \mathbb{N}_0$. This implies that $\mathrm{H}_l(|\widetilde{s}|) = 0$. But this means that every cycle is in fact a boundary. In particular the above cycle is the boundary of some $P_{l+1}(\widetilde{s}) \in \mathrm{C}_{l+1}(|\widetilde{s}|)$, i.e. we have

$$(\partial_{l+1}(P_{l+1}(\widetilde{s})) \;=\; (-P_{l-1} \circ \partial_l + \Theta_{\leq,l} \circ \Omega_{\leq,l}^{-1} - \Theta_{\subseteq,l} \circ \Omega_{\subseteq,l}^{-1})(\widetilde{s}).$$

By construction all these $P_{l+1}(\widetilde{s})$ have the desired property. ⊞

Now we can easily find the desired chain homotopy. Indeed, for every 0-simplex s we set $P_0(s) = 0 \in \mathrm{C}_1(|s|)$. Since $\Omega_{\subseteq,0} = \Omega_{\subseteq,0} \colon \mathrm{C}_0^{\mathrm{simp}}(K) \to \mathrm{C}_0(|K|)$ we see that can start the machine provided by the claim and iteratively we construct maps P_i which are precisely the promised chain homotopy. ■

The following is now an almost immediate corollary to Lemma 95.8, the Simplicial-Singular Chain Complex Theorem 95.25 and Lemma 95.26.

Corollary 95.27. Let K be an abstract simplicial complex. We pick an order "$\leq$" on K. The maps

$$\Xi_k := \Theta_{\leq,k} \circ \Omega_{\leq,k}^{-1} \colon \mathrm{H}_k^{\mathrm{simp}}(K) \ \to \ \mathrm{H}_k(|K|),$$

which by Lemma 95.26 do not depend on the choice of the order "$\leq$", define a natural isomorphism between functors from the category *AbsSimpCplx* of abstract simplicial complexes (the key here is that the word "ordered" is missing) to the category *AbGroup* of abelian groups.

It is worth repeating the following:

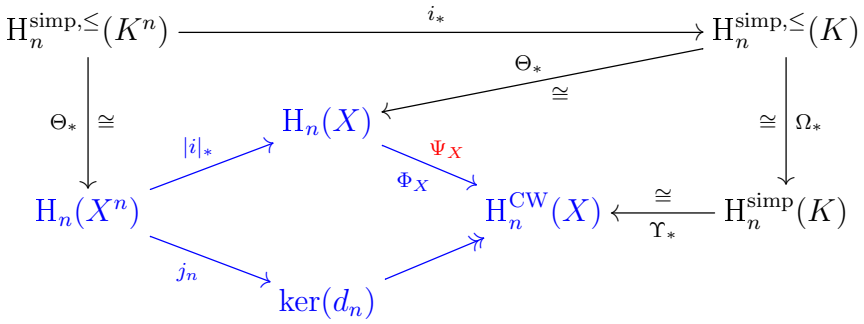
(1) Given any abstract simplicial complex K and given any $k \in \mathbb{N}_0$ there exists a natural isomorphism $\mathrm{H}_k^{\mathrm{simp}}(K) \to \mathrm{H}_k(|K|)$ of homology groups.
(2) If K is an ordered abstract simplicial, then there is in fact a natural chain homotopy equivalence $\mathrm{C}_*^{\mathrm{simp},\leq}(K) \to \mathrm{C}_*(|K|)$.

The alert reader will have noticed that given an abstract simplicial complex we gave two natural isomorphisms $\mathrm{H}_n^{\mathrm{simp}}(K) \to \mathrm{H}_n(|K|)$. The following proposition shows that the two isomorphisms agree.

Proposition 95.28. Let K be an abstract simplicial complex and let $n_0 \in \mathbb{N}$. We write $X = |K|$. We denote by

$$\Upsilon_* \colon \mathrm{C}_*^{\mathrm{simp}}(K) \ \to \ \mathrm{C}_*^{\mathrm{CW}}(X) \quad \text{and} \quad \Phi_X \colon \mathrm{H}_n(X) \ \to \ \mathrm{H}_n^{\mathrm{CW}}(X)$$

the isomorphisms given by Propositions 95.24 and 80.4. Next we pick an order "$\leq$" on K. We consider the chain homotopy equivalences



$$\Omega \colon \mathrm{C}_*^{\mathrm{simp},\leq}(K) \ \to \ \mathrm{C}_*^{\mathrm{simp}}(K) \quad \text{and} \quad \Theta \colon \mathrm{C}_*^{\mathrm{simp},\leq}(K) \ \to \ \mathrm{C}_*(|K|)$$

from Lemma 95.8 and the Simplicial-Singular Chain Complex Theorem 95.25. With this notation the following equality holds:

$$\Phi_X^{-1} \circ \Upsilon_* \ = \ \Theta_* \circ \Omega_*^{-1} \colon \mathrm{H}_n^{\mathrm{simp}}(K) \ \to \ \mathrm{H}_n(X).$$

Notation. Let K be an abstract simplicial complex and let $n_0 \in \mathbb{N}$. By a slight abuse of notation we denote by $\Theta_K \colon \mathrm{H}_n^{\mathrm{simp}}(K) \to \mathrm{H}_n(|K|)$ the natural isomorphism given by the Simplicial-Singular Homology Isomorphism Theorem 95.23 and Proposition 95.28.

Proof. We write $\Psi_X := \Upsilon_* \circ \Omega_* \circ \Theta_*^{-1}$. We need to show that $\Psi_X = \Phi_X$. To do so we consider the following diagram:

We make the following clarifications and observations:

(1) The map $i\colon K^n \to K$ is the inclusion map.
(2) The triangle shaped quadrangle to the upper left commutes by the naturality of Θ_*.
(3) By the definition of Ψ_X the quadrangle to the right commutes.
(4) It follows easily from the definitions of the various maps that the "outer diagram" commutes, i.e. the two maps from $\mathrm{H}_n^{\mathrm{simp},\leq}(K^n)$ to $\mathrm{H}_n^{\mathrm{CW}}(X)$ agree.
(5) Since Υ_*, Ω_* and Θ_* are isomorphisms we see that Ψ_X is an isomorphism and we see, in combination with (2), (3) and (4), that Ψ_X makes the parallelogram commute. But by the characterization of Φ_X in the Singular-Cellular H_*-Isomorphism Proposition 80.4 this means that $\Psi_X = \Phi_X$. ■

95.6. **Relative simplicial homology.** In this section, given an (ordered) abstract simplicial complex K together with a subcomplex L we introduce the relative simplicial homology groups $\mathrm{H}_k^{\mathrm{simp}}(K,L)$ and $\mathrm{H}_k^{\mathrm{simp},\leq}(K,L)$. This section contains no surprises and can be skipped easily. We will make little use of relative simplicial homology groups, except that they will come in handy in the proof of the Simplicial Poincaré Duality Theorem 103.4.

Definition. Let K be an abstract simplicial complex and let L be a (possibly empty) subcomplex of K.

(1) Given $k \in \mathbb{N}_0$ we define

$$\mathrm{C}_k^{\mathrm{simp}}(K,L) \;:=\; \mathrm{C}_k^{\mathrm{simp}}(K)/\mathrm{C}_k^{\mathrm{simp}}(L).$$

The usual boundary map $\partial_k\colon \mathrm{C}_k^{\mathrm{simp}}(K) \to \mathrm{C}_{k-1}^{\mathrm{simp}}(K)$ descends to a boundary map $\partial_k\colon \mathrm{C}_k^{\mathrm{simp}}(K,L) \to \mathrm{C}_{k-1}^{\mathrm{simp}}(K,L)$ and we can thus define the corresponding relative simplicial homology groups $\mathrm{H}_k^{\mathrm{simp}}(K,L)$.
(2) If "$\leq$" is an order on K, then we endow L with the corresponding order and we introduce $\mathrm{C}_k^{\mathrm{simp},\leq}(K,L)$ and $\mathrm{H}_k^{\mathrm{simp},\leq}(K,L)$ in the obvious way.

Lemma 95.29. Let K be an abstract simplicial complex and let L be a subcomplex of K. The sequence

$$\begin{array}{ccccccccccc} \ldots & \to & \mathrm{H}_k^{\mathrm{simp}}(L) & \to & \mathrm{H}_k^{\mathrm{simp}}(K) & \to & \mathrm{H}_k^{\mathrm{simp}}(K,L) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}^{\mathrm{simp}}(L) & \to & \ldots \\ & & & & & & [\sigma] & \mapsto & [\partial_k(\sigma)] & & \end{array}$$

is exact and the connecting homomorphism is natural. The analogous statement also holds if K is equipped with an order.

Proof. The lemma is an immediate consequence of the LES Proposition 74.9. ■

We conclude this short section with the following lemma.

Lemma 95.30. (Simplicial-Singular Homology Isomorphism Lemma) Let K be an abstract simplicial complex and let L be a subcomplex of K.

(1) Let "$\leq$" be an order on K. The natural maps

$$\begin{array}{rcl} \mathrm{C}_k^{\mathrm{simp},\leq}(K,L) & \to & \mathrm{C}_k^{\mathrm{simp}}(K,L) \\ [\sigma] & \mapsto & [\Omega(\sigma)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{C}_k^{\mathrm{simp},\leq}(K,L) & \to & \mathrm{C}_k(|K|,|L|) \\ [\sigma] & \mapsto & [\Theta(\sigma)] \end{array}$$

are chain homotopy equivalences. Furthermore the natural maps

$$\begin{array}{rcl} \mathrm{H}_k^{\mathrm{simp},\leq}(K,L) & \to & \mathrm{H}_k^{\mathrm{simp}}(K,L) \\ [\sigma] & \mapsto & \Omega(\sigma)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{H}_k^{\mathrm{simp},\leq}(K,L) & \to & \mathrm{H}_k(|K|,|L|) \\ [\sigma] & \mapsto & [\Theta(\sigma)] \end{array}$$

are isomorphisms.

(2) The map $\Xi := \Omega \circ \Theta^{-1} \colon \mathrm{H}_k^{\mathrm{simp}}(K,L) \to \mathrm{H}_k(|K|,|L|)$ does not depend on the choice of the order "$\leq$" on K, and it defines a natural isomorphism.

(3) The following diagram commutes:

$$\begin{array}{ccccccccc} \ldots & \longrightarrow & \mathrm{H}_k^{\mathrm{simp},\leq}(K) & \longrightarrow & \mathrm{H}_k^{\mathrm{simp},\leq}(K,L) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}^{\mathrm{simp},\leq}(L) & \longrightarrow & \mathrm{H}_{k-1}^{\mathrm{simp},\leq}(K) \longrightarrow \ldots \\ & & \Xi\downarrow & & \Xi\downarrow & & \Xi\downarrow & & \Xi\downarrow \\ \ldots & \longrightarrow & \mathrm{H}_k(|K|) & \longrightarrow & \mathrm{H}_k(|K|,|L|) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}(|L|) & \longrightarrow & \mathrm{H}_{k-1}(|K|) \longrightarrow \ldots \end{array}$$

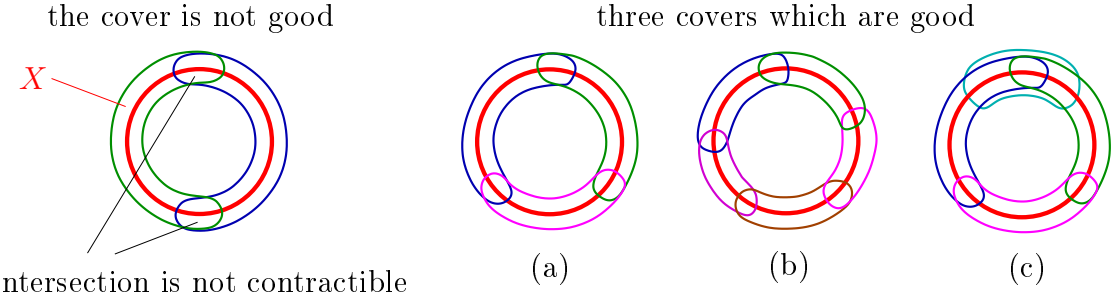
Proof. We consider the following diagram:

$$\begin{array}{ccccccccc} \ldots & \longrightarrow & \mathrm{H}_k^{\mathrm{simp}}(L) & \longrightarrow & \mathrm{H}_k^{\mathrm{simp}}(K) & \longrightarrow & \mathrm{H}_k^{\mathrm{simp}}(K,L) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}^{\mathrm{simp}}(L) \longrightarrow \mathrm{H}_{k-1}^{\mathrm{simp}}(K) \longrightarrow \ldots \\ & & \Omega\uparrow & & \Omega\uparrow & & \Omega\uparrow & & \Omega\uparrow \\ \ldots & \longrightarrow & \mathrm{H}_k^{\mathrm{simp},\leq}(L) & \longrightarrow & \mathrm{H}_k^{\mathrm{simp},\leq}(K) & \longrightarrow & \mathrm{H}_k^{\mathrm{simp},\leq}(K,L) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}^{\mathrm{simp},\leq}(L) \longrightarrow \mathrm{H}_{k-1}^{\mathrm{simp},\leq}(K) \longrightarrow \ldots \\ & & \Theta\downarrow & & \Theta\downarrow & & \Theta\downarrow & & \Theta\downarrow \\ \ldots & \longrightarrow & \mathrm{H}_k(|L|) & \longrightarrow & \mathrm{H}_k(|K|) & \longrightarrow & \mathrm{H}_k(|K|,|L|) & \xrightarrow{\partial_k} & \mathrm{H}_{k-1}(|L|) \longrightarrow \mathrm{H}_{k-1}(|K|) \longrightarrow \ldots \end{array}$$

It follows easily from the definitions and the naturality of the connecting homomorphisms, see the LES Proposition 74.9, that the diagram commutes. By Lemma 95.29 and by the Topological LES-Corollary 74.14 we know that the horizontal sequences are exact. Furthermore by Lemma 95.8 and the Simplicial-Singular Chain Complex Theorem 95.25 we know that the outer two vertical maps are isomorphisms. Now it follows from the Five-Lemma 74.10 that the middle vertical maps are also isomorphisms. It follows from the Quasi Isomorphisms-are-Homotopy Equivalences Proposition 81.4 that the corresponding chain maps are chain homotopy equivalences. This concludes the proof Statement (1).

The same argument as in the proof of Corollary 95.27 shows that the composition of the middle vertical maps does not depend on the choice of the order "$\leq$".[1171]

Finally Statement (3) follows from the fact that the above diagram commutes. ■



95.7. **The Nerve Theorem.** In this section we will state the "Nerve Theorem". In many situations it gives an effective way for showing that a given topological space is homotopy equivalent to a simplicial complex.

Definition. Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i\in I}$ be a cover of X.

(1) We say the cover $\mathcal{U} = \{U_i\}_{i\in I}$ of X is good if for every choice of $i_1, \ldots, i_m \in I$ the intersection $U_{i_1} \cap \cdots \cap U_{i_m}$ is either empty or contractible.

(2) We say the cover $\mathcal{U}$ of X is point-finite if each point $x \in X$ is contained in only finitely many U_i.[1172]

Example. In the figure below we show the topological space $X = S^1$ with one cover which is not good and three covers which are actually good.

As we will see, the following lemma is a straightforward consequence of the Link Star Lemma 94.5.

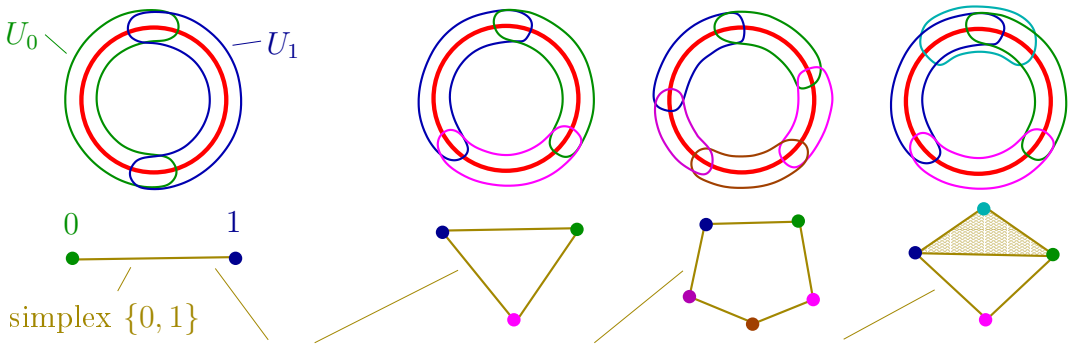
Lemma 95.31. (Open Stars-Good Cover Lemma) Let $K = (V, S)$ be an abstract simplicial complex. The open stars $\{\mathring{\mathrm{St}}(v)\}_{v\in V}$ are an open good point-finite cover.

Proof. Let $K = (V, S)$ be an abstract simplicial complex. Let $P \in |K|$. By the Open Simplex Lemma 93.11 (2) we know that there exists a unique $s \in S$ with $P \in \langle s \rangle$. Furthermore, by the Link Star Lemma 94.5 (2) we know that $P \in \mathring{\mathrm{St}}(v)$ if and only if v is a vertex of s. This discussion, together with the Link Star Lemma 94.5 (2), shows that the open stars $\mathring{\mathrm{St}}(v)$ form an open point-finite cover of $|K|$. It remains to show that the cover

[1171]Note that Exercise 74.3 shows that one cannot reduce this statement "Five Lemma"-style to the fact that we already know that the composition of the outer two vertical maps is independent of the choice of the order "$\leq$".

[1172]Note that this notion is weaker than the notion of a locally finite cover that we introduced on page 114.

is good. Thus let $v_0, \dots, v_n \in V$. We have



$$\mathring{\mathrm{St}}(v_0) \cap \dots \cap \mathring{\mathrm{St}}(v_n) \underset{\text{Link Star Lemma 94.5 (3)}}{=} \begin{cases} \overbrace{\mathring{\mathrm{St}}(\{v_0, \dots, v_n\})}^{\text{contractible by the Link Star Lemma 94.5 (1f)}}, & \text{if } \{v_0, \dots, v_n\} \text{ is a simplex,} \\ \varnothing, & \text{otherwise.} \end{cases}$$

We have thus shown that the open stars $\{\mathring{\mathrm{St}}(v)\}_{v \in V}$ are a good point-finite cover. ■

As we will see shortly, the Open Stars-Good Cover Lemma 95.31 has a partial converse, namely the mysteriously named Nerve Theorem. To state this converse we need the following definition.

Definition. Let X be a set and let $\mathcal{U} = \{U_i\}_{i \in I}$ be a family of subsets of X. We refer to the abstract simplicial complex that is given by the vertex set I and the simplex set[1173] $\{\{i_1, \dots, i_r\} \,|\, i_1, \dots, i_r \in I \text{ with } U_{i_1} \cap \dots \cap U_{i_m} \neq \varnothing\}$ as the nerve complex $N(\mathcal{U})$ of the covering.

Example. In the figure below we revisit the four covers of S^1 that we showed in the figure on page 2061. This time we also show the topological realizations of the corresponding nerve complexes. As is clear from the figure, for the cover to the left, which is not good, the topological realization of the nerve complex does not look at all like S^1. On the other hand, for the three covers to the right, which are good, the topological realization of the nerve complex is homeomorphic or at least homotopy equivalent to S^1. As we will see in a minute, that is not a coincidence.

To formulate the Nerve Theorem of this section it is convenient to introduce the following definition.

Definition. We say that a map $f\colon X \to Y$ between path-connected topological spaces is a weak homotopy equivalence if there exists $x_0 \in X$ such that for every $k \in \mathbb{N}_0$ the induced map $f_*\colon \pi_k(X, x_0) \to \pi_k(Y, f(x_0))$ is an isomorphism.

By the Homotopy-π_n-Proposition 71.7 (2) a homotopy equivalence between path-connected topological spaces is a weak homotopy equivalence. The following theorem says, rather amazingly, that for CW-complexes the converse holds.

[1173] It follows easily from the definitions that this is indeed an abstract simplicial complex.

Theorem 162.1. (Whitehead Theorem) Let $f\colon X \to Y$ be a map between two connected CW-complexes.[1174] If $f\colon X \to Y$ is a weak homotopy equivalence, then f is a homotopy equivalence.

As is clear from the numbering, we will prove the Whitehead Theorem 162.1 much later in these notes. But, as we will see, this theorem greatly facilitates the discussion of the Nerve Theorem.

Recall that in the Open Stars-Good Cover Lemma 95.31 we showed that every simplicial complex admits a good cover. We can now formulate and prove the Nerve Theorem which can in particular be viewed as a partial converse to the Open Stars-Good Cover Lemma 95.31.

Theorem 95.32. (Nerve Theorem) Let X be a path-connected topological space and let $\mathcal{U} = \{U_i\}_{i\in I}$ be an open good point-finite cover of X. The following two statements hold:

(1) There exists a weak homotopy equivalence $|N(\mathcal{U})| \to X$ from the topological realization of the nerve complex $N(\mathcal{U})$ to X. In fact there exists a weak homotopy equivalence $f\colon |N(\mathcal{U})| \to X$ such that for any simplex $\{i_0, \ldots, i_k\}$ of $N(\mathcal{U})$ we have $f(|\{i_0, \ldots, i_k\}|) \subset U_{i_0} \cap \cdots \cap U_{i_k}$.
(2) If X is furthermore a CW-complex, then any map $f\colon |N(\mathcal{U})| \to X$ as in (1) is in fact a homotopy equivalence.

Remark.

(1) The Nerve Theorem has its origins in the work of Karol Borsuk [**Bor1948**] from 1948 and Jean Leray [**Ler1950**] from 1950. As stated the theorem was basically proved by André Weil [**Weil1952**, p. 141] in 1952.
(2) Let X be a CW-complex. It follows from the CW-Complex Properties Proposition 68.10 (8) that the conclusion of the Nerve Theorem 95.32 also holds if $\mathcal{U} = \{U_i\}_{i\in I}$ is a family of *subcomplexes* which form a good point-finite cover of X.
(3) There are many variations on the statement and on the proof of the Nerve Theorem 95.32.
   (a) In [**Bj1995**, Theorem 10.6] and [**Bj2003003**, Theorem 6] a Nerve Theorem is formulated for the case that X is a regular CW-complex[1175] and the U_i are subcomplexes. In this case the cover does not need to be point-finite.
   (b) Other versions are formulated in [**Nago2007**, Theorem 3.3] and [**BoS1973**, Theorem 8.2.1].
   (c) An elegant proof of the Nerve Theorem 95.32 for the case of a finite cover is given in [**Koz2008**, Theorem 15.21].

Proof. Statement (2) of the Nerve Theorem is an immediate consequence of Statement (1) together with the Whitehead Theorem 162.1. Thus it remains to prove Statement (1). In the discussion below we will only sketch an argument. A full proof of Statement (1) is given in [**McCor1967**, Theorem 1].

[1174] Note that we do not assume that the map f is cellular.

[1175] We refer to page 2010 for the definition of a regular CW-complex, note that simplicial complexes are regular CW-complexes.

Thus let X be a topological space and let $\mathcal{U} = \{U_v\}_{v\in V}$ be an open good point-finite cover of X. We adopt the following notation:

(1) We set
$$S \;:=\; \{\{v_0,\dots,v_n\}\,|\,v_0,\dots,v_n\in V \text{ with } U_{v_0}\cap\dots\cap U_{v_n}\neq\varnothing\}.$$
Recall that by definition the nerve complex is given by $N(\mathcal{U}) := (V,S)$. For convenience we write $N = N(\mathcal{U})$.

(2) Given $s=\{v_0,\dots,v_n\}\in S$ we set $U_s := U_{v_0}\cap\dots\cap U_{v_n}$.

(3) We consider the barycentric subdivision
$$\mathrm{sd}(N) \;=\; \big(\{\underline{s}\}_{s\in S}, \{\{\underline{s_0},\dots,\underline{s_k}\}\,|\,s_0\subsetneq\dots\subsetneq s_k\}\big).$$
By the SD-Lemma 94.3 we have a natural homeomorphism $|\mathrm{sd}(N)|\to|N|$ which we use to identify these two topological spaces.

Next we define inductively a map $F\colon|\mathrm{sd}(N)|\to X$ which satisfies the following condition:

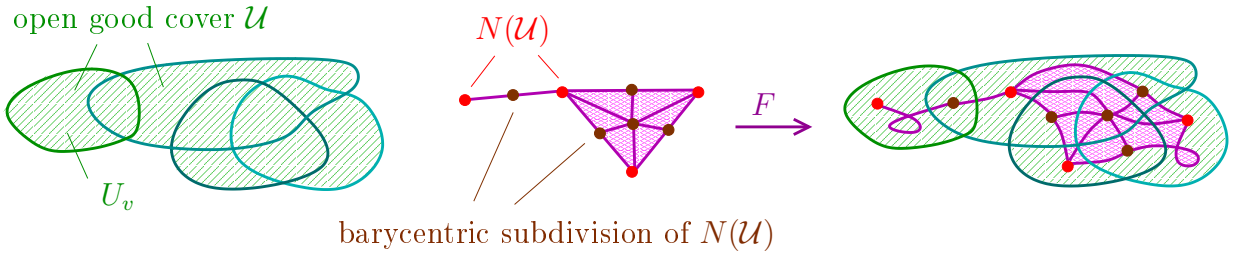
($\star$) For every simplex $\{\underline{s_0},\underline{s_1},\dots,\underline{s_k}\}$ of $\mathrm{sd}(N)$ we have
$$F\big(\big|\{\underline{s_0},\underline{s_1},\dots,\underline{s_k}\}\big|\big) \;\subset\; U_{s_0}.$$

We construct F inductively as follows:

(1) For each $\underline{s}$ we pick a point $F(\underline{s})\in U_s$.

(2) Suppose that F is defined on the $(n-1)$-skeleton of $|\mathrm{sd}(N)|$. We want to extend F to the n-skeleton of $|\mathrm{sd}(N)|$. Let $t=\{\underline{s_0},\dots,\underline{s_n}\}$ be an n-simplex of $\mathrm{sd}(N)$ and let $\Phi_t^{\leq}\colon\Delta^n\to|\mathrm{sd}(N)|$ be the corresponding characteristic map. Note that
$$(F\circ\Phi_t^{\leq})(\partial\Delta^n) \;=\; \bigcup_{i=0}^{n} \underbrace{F\big(\big|\{\underline{s_0},\dots,\widehat{\underline{s_i}},\dots,\underline{s_n}\}\big|\big)}_{\subset U_{s_0}\text{ or }\subset U_{s_1}\text{ by }(\star)} \;\subset\; U_{s_0}.$$
by definition we have for $s\subset t$ that $U_t\subset U_s$, in particular we have $U_{s_1}\subset U_{s_0}$

By hypothesis we know that U_{s_0} is contractible. It follows from the Homotopy-π_n-Proposition 71.7 and the Trivial-in-π_n-Lemma 71.4 together with the fact, shown in the Standard Simplex Homeomorphism Lemma 72.1 (3), that the pair $(\Delta^n,\partial\Delta^n)$ is homeomorphic to $(\overline{B}^n,S^{n-1})$, that $F\circ\Phi_t^{\leq}\colon\partial\Delta^n\to U_{s_0}$ extends to a map $G\colon\Delta^n\to U_{s_0}$. Now we define F on $|t|=|\{\underline{s_0},\dots,\underline{s_n}\}|$ to be the map $G\circ\Phi_t^{-1}$. Note that this map still satisfies ($\star$).



It follows almost immediately from the SD-Lemma 94.3 and ($\star$) that $F\colon|N|=|\mathrm{sd}(N)|\to X$ has the desired property that for every simplex $\{v_0,\dots,v_k\}$ of $N=N(\mathcal{U})$ we have the inclusion $F(|\{v_0,\dots,v_k\}|)\subset U_{v_0}\cap\dots\cap U_{v_k}$.

It remains to show that F is a weak homotopy equivalence. Unfortunately this is where our discussion of the proof peters out. We suggest to use the Weak Homotopy-vs-Homology Isomorphisms Proposition 161.6 below to show that F is a weak homotopy equivalence. One should be able to employ this proposition using the following two approaches:

(1) One uses the Mayer–Vietoris 54.1 and the HNN-Seifert–van Kampen Theorem 57.3, and suitable analogues for simplicial complexes, to show that F induces an isomorphism of homotopy groups.

(2) One uses cleverly the naturality of the long exact sequence coming from the Mayer–Vietoris Theorem 78.5 (or more elegantly, the naturality of the Mayer–Vietoris spectral sequence which we alluded to on page 1720) to show that the lift $\widetilde{F}$ of F to the universal covers of $|\operatorname{sd}(N)|$ and X induces an isomorphism of all homology groups.

We leave it as a rather challenging exercise to the reader to make the above approach work. Even the case of a finite cover is already rather delicate. ■

For completeness we also state the following variation on the Nerve Theorem 95.33.

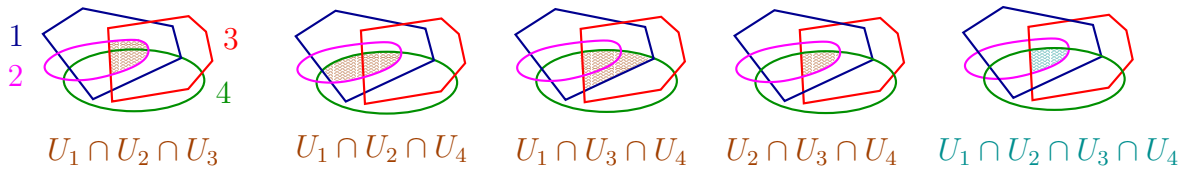
Theorem 95.33. (Nerve Theorem) Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i\in I}$ be an good open cover of X. If X is paracompact, then there exists a homotopy equivalence $|N(\mathcal{U})| \to X$.

Proof. Since X is paracompact it follows from the Paracompact-Partition of Unity Theorem 10.9 that there exists a partition of unity $\{\varphi_i\}_{i\in I}$ such that for each $i \in I$ we have $\operatorname{supp}(\varphi_i) \subset U_i$. We define

$$\begin{array}{rcl} G\colon X & \to & |N(\mathcal{U})| \\ x & \mapsto & \begin{pmatrix} I & \to & \mathbb{R} \\ i & \mapsto & \varphi_i(x) \end{pmatrix}. \end{array}$$

In [**Hat2002**, Proposition 4G.2] it is shown that the map G is a homotopy inverse to the map $F\colon |N(\mathcal{U})| \to X$ that we constructed in the proof of the Nerve Theorem 95.32. ■

One of the many fun applications of the Nerve Theorem 95.32 is the following theorem which was first proved by Eduard Helly [**Hel1923**] in 1923 using much more elementary techniques. Our proof is arguably technological overkill, but it has the advantage that from our point of view it is very conceptual.



Theorem 95.34. (Helly's Theorem) Let $n \in \mathbb{N}_0$ and let $U_1, \ldots, U_m$ be convex open subsets of $\mathbb{R}^n$. If any choice of $n+1$ of those sets has non-empty intersection, then the intersection of all those sets is non-empty, i.e. we also have

$$U_1 \cap \cdots \cap U_m \neq \varnothing.$$

Examples.

(1) For $n = 1$ and $m = 3$ Helly's Theorem 95.34 says that if we are given three open intervals such that any two of them have a non-empty intersection, then the intersection of the three open intervals is non-empty.

(2) For $n = 2$ and $m = 4$ Helly's Theorem 95.34 says if we are given four convex open subsets of $\mathbb{R}^2$, such that any three of them have non-empty intersection, then the intersection of all four subsets is also non-empty. This situation is illustrated in the figure below.

Remark.

(1) In our formulation of Helly's Theorem 95.34 we require that the sets U_i are open. This is in fact just an artifact of our proof. In fact the statement holds without this assumption. We refer to [**Mato2002**, Theorem 1.3.2] for an elementary proof of this more general statement.
(2) As we mentioned above, our topological proof of Helly's Theorem 95.34 is strictly speaking more difficult than necessary. But the advantage of the topological approach taken in these notes is that it is easier to generalize this approach to non-convex subsets.
(3) We refer to [**Eckh1993**] for a long list of references for proofs of Helly's Theorem and for a discussion of the relevance of Helly's Theorem.

In our proof of Helly's Theorem we will need the following proposition which is interesting in its own right.

Proposition 95.35. If M is an open subset of $\mathbb{R}^n$, then $\mathrm{H}_k(M) = 0$ for $k \geq n$.

Proof. The proposition follows from a fun argument using the Mayer–Vietoris Theorem 78.5. We invite the reader to fill in the details in Exercise 95.15. ■

Proof of Helly's Theorem 95.34. Let $n \in \mathbb{N}_0$. We prove the theorem by induction on m. For $m \leq n+1$ there is nothing to show. Now suppose that the theorem holds for some $m \geq n+1$. Let $\mathcal{U} := \{U_1, \ldots, U_{m+1}\}$ be a family of convex open subsets of $\mathbb{R}^n$ such that the intersection of any $n+1$ of those subsets has non-empty intersection. By induction hypothesis we know that the following holds:

(i) The intersection of any m of the sets in $\mathcal{U}$ is non-empty.

We need to show that $U_1 \cap \cdots \cap U_{m+1} \neq \varnothing$. We do a proof by contradiction. So we assume that the following holds:

(ii) $U_1 \cap \cdots \cap U_{m+1} = \varnothing$.

Next we consider the corresponding nerve complex $N(\mathcal{U})$.

(1) It follows immediately from (i) and (ii) that the nerve complex $N(\mathcal{U})$ is simplicially isomorphic to the simplicial complex S_{m-1} that we introduced on page 1978.
(2) As we mentioned before, one of the key properties of convex subsets is that any intersection of convex subsets is again convex, in particular any intersection is contractible. Thus $\mathcal{U}$ is an open good finite cover of $U_1 \cup \cdots \cup U_{m+1}$.

Now we see that

$$\begin{array}{ccccccccc} \mathbb{Z} & \cong & \mathrm{H}_{m-1}^{\mathrm{simp}}(S_{m-1}) & \cong & \mathrm{H}_{m-1}^{\mathrm{simp}}(N(\mathcal{U})) & \cong & \mathrm{H}_{m-1}(|N(\mathcal{U})|) & \overset{\downarrow}{\cong} & \mathrm{H}_{m-1}\big(\underbrace{U_1 \cup \cdots \cup U_{m+1}}_{\text{open subset of } \mathbb{R}^n}\big) & = & 0. \\ \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \\ \text{Lemma 95.12} & & \text{by (1)} & & \text{Simplicial-Singular Homology Isomorphism Theorem 95.23} & & & & \text{by Proposition 95.35, since } m-1 \geq n & & \end{array}$$

by the Nerve Theorem 95.32 which we can apply by (2), together with the Homotopy Equivalence-H_*-Corollary 73.9

We have thus obtained a contradiction to (ii). ■

The Nerve Theorem 95.32 gives a practical tool for showing that a given topological space is homotopy equivalent to a simplicial complex. It is natural to go through familiar classes of topological spaces and to see whether it applies. Fortunately the next theorem shows that it applies to everybody's favorite topological spaces, namely smooth manifolds.

Theorem 95.36. (Smooth Manifold-Good Cover Theorem)

(1) Every compact smooth manifold admits an open good finite cover.
(2) Every smooth manifold admits an open good point-finite cover.

Remark. To the best of my knowledge it is not known whether every topological manifold admits an open cover that is good, let alone good and point-finite.

Sketch of proof. Let M be an n-dimensional smooth manifold. There are many approaches to proving the desired statements.[1176]

(1) If M is a smooth manifold without boundary, then in the Smoothly Good Cover Theorem **??** we proved a stronger statement, namely we showed that one can find a finite (respectively locally finite) smoothly good cover. Here, according to the definition on page **??**, "smoothly good" means that in the definition of a good cover we replace "contractible" by "diffeomorphic to $\mathbb{R}^n$".
(2) In the Smooth Manifold-Simplicial Structure Theorem 96.2 we will see that M admits a smooth simplicial structure, which by the Open Stars-Good Cover Lemma 95.31 gives us the desired result.
(3) A detailed proof of the theorem (at least for closed smooth manifolds) is given in [**Weil1952**, p. 120], [**vGl1985**] and [**GuH2019**, Theorem 5.3.2].
(4) Proofs with less detail are given in [**BoT1982**, Theorem 5.1], [**KaL1987**, Chapter VI.3] and [**Lee2009**, Theorem 10.17].

In all approaches, except for the second one, the cases of smooth manifolds with non-empty boundary are not really treated. It is left as a challenge to the reader to extend the results from smooth manifolds without boundary to smooth manifolds with boundary. ■

We obtain the following corollary from the combination of the Smooth Manifold-Good Cover Theorem 95.36, the Nerve Theorem 95.32 and the Simplicial-Implies-CW Lemma 93.24.

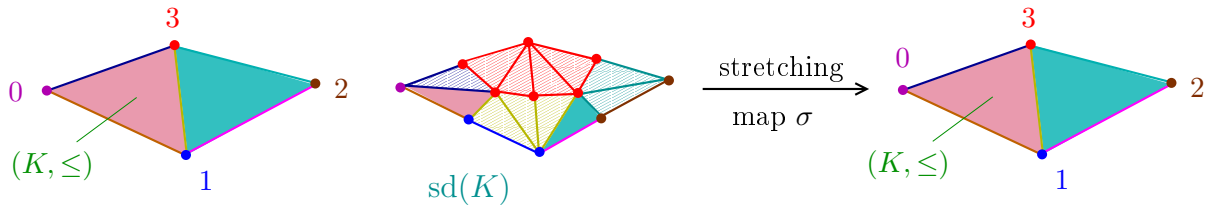
Corollary 95.37. Every (compact) smooth manifold is weakly homotopy equivalent to a (finite) simplicial complex, in particular it is weakly homotopy equivalent to a (finite) CW-complex.

[1176] It is not clear to me whether (2) and (3) give smoothly good covers, that is why we did not mention them in the discussion of the Smoothly Good Cover Theorem **??**.

Later, in the Smooth Manifold-CW Structure Theorem 96.5 , we will see that a much stronger version of Corollary 95.37 holds.

95.8. **The simplicial subdivision map.** Let $(K, \leq)$ be an ordered abstract simplicial complex. By the Simplicial-Singular Homology Isomorphism Theorem 95.23 and the SD-Lemma 94.3 we know that the simplicial homology groups of K and of its barycentric subdivision $\mathrm{sd}(K)$ are isomorphic.
In this section we will strengthen this result. More precisely, we will give a natural map $\sigma\colon \mathrm{sd}(K) \to K$ and we will give a natural chain map

$$u_*\colon \mathrm{C}_*^{\mathrm{simp},\leq}(K) \ \to \ \mathrm{C}_*^{\mathrm{simp},\leq}(\mathrm{sd}(K))$$



such that the chain maps σ_* and u_* are chain homotopy inverses of one another. These two constructions will prove their worth later on when we study continuous self-maps $f\colon |K| \to |K|$. More precisely, by the Simplicial Approximation Theorem 94.8 we know that a given continuous map $f\colon |K| \to |K|$ is homotopic to a simplicial map $g\colon |\mathrm{sd}^i(K)| \to |K|$, thus we get an induced chain map $g_*\colon \mathrm{C}_*^{\mathrm{simp},\leq}(\mathrm{sd}^i(K)) \to \mathrm{C}_*^{\mathrm{simp},\leq}(K)$. Unfortunately this is a chain map between *different* chain complexes. But if we combine g_* with an i-fold iteration of u_*, then we obtain an *endomorphism* $\mathrm{C}_*^{\mathrm{simp},\leq}(\mathrm{sd}^i(K)) \to \mathrm{C}_*^{\mathrm{simp},\leq}(\mathrm{sd}^i(K))$ of a chain complex.
We start out with the following lemma.

Lemma 95.38. (Stretching Map Lemma) Let $(K, \leq)$ be an ordered abstract simplicial complex.

(1) There exists a unique simplicial map $\sigma\colon \mathrm{sd}(K) \to K$ with the following property: given an n-simplex $s = \{v_0 < \cdots < v_n\}$ of K the map σ sends the corresponding vertex $\underline{s}$ of $\mathrm{sd}(K)$ to the vertex v_n of K.
(2) The stretching map $\sigma\colon \mathrm{sd}(K) \to K$ is order-preserving. (Here we equip $\mathrm{sd}(K)$ with the natural order introduced in Lemma 94.2 (2).)
(3) The stretch map σ is natural. Here "natural" means that given any order-preserving simplicial map $f\colon (K, \leq) \to (L, \leq)$ between two ordered abstract simplicial complexes and given any $n \in \mathbb{N}_0$ the following diagram commutes:[1177]

$$\begin{array}{ccc} \mathrm{sd}(K) & \xrightarrow{f_*} & \mathrm{sd}(L) \\ {\scriptstyle\sigma}\downarrow & & \downarrow{\scriptstyle\sigma} \\ K & \xrightarrow{f_*} & L. \end{array}$$

We refer to this map σ as the stretching map.

[1177] Recall that by the SD-Lemma 94.3 (5) we know that the maps $K \mapsto \mathrm{sd}(K)$ define a covariant functor from the category $\mathcal{OrdAbsSimpCplx}$ of ordered abstract simplicial complexes to itself.

Proof. It follows easily from the definitions that the given map on the set of vertices induces a simplicial map, that this map is order-preserving and that this map is natural. We leave it to the reader to fill in the details. ■

In basically all cases the stretching map $\sigma\colon \mathrm{sd}(K) \to K$ is not a simplicial isomorphism, in particular the induced map on the simplicial chain complexes is not an isomorphism. Our goal now is to show the "best possible result", namely that the induced chain map $\sigma_*\colon \mathrm{C}_*^{\mathrm{simp},\leq}(\mathrm{sd}(K)) \to \mathrm{C}_*^{\mathrm{simp},\leq}(K)$ is a chain homotopy equivalence. We will do so by giving an explicit chain map in the other direction.

Definition. Let $(K,\leq)$ be an ordered abstract simplicial complex.

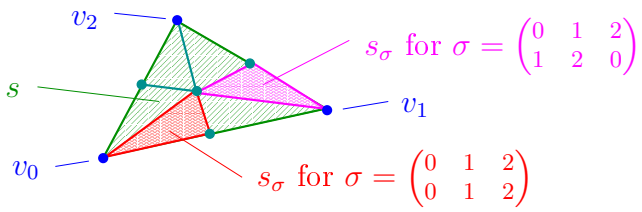
(1) Given an n-simplex $s = \{v_0 < \cdots < v_n\}$ of K, given[1178] $\sigma \in \mathrm{Bij}\{0,\ldots,n\}$ and given $m \in \{0,\ldots,n\}$ we write

$$s_{\sigma,m} \;:=\; \{v_{\sigma(0)},\ldots,v_{\sigma(m)}\}.$$

Note that $s_{\sigma,n} = s$. Furthermore, we set

$$s_\sigma \;:=\; \{\overbrace{\underline{s_{\sigma,n}}}^{=\underline{s}}, \underline{s_{\sigma,n-1}},\ldots,\underline{s_{\sigma,0}}\}.$$

Note that s_σ is an n-simplex of $\mathrm{sd}(K)$.



(2) Given an n-simplex s of K we define

$$u_n(s) \;:=\; \sum_{\sigma\in\mathrm{Bij}\{0,\ldots,n\}} \mathrm{sign}(\sigma)\cdot s_\sigma \;\in\; \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)).$$

We refer to the resulting map[1179]

$$\begin{array}{rccc} u_n\colon & \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)) \\ & s & \mapsto & u_n(s) \end{array}$$

as the simplicial subdivision map.

The following lemma can be viewed as an analogue of the Chain Subdivision Lemma 74.24 and Lemma 74.25.

Lemma 95.39. (Chain Subdivision Lemma) Let $(K,\leq)$ be an ordered abstract simplicial complex. The simplicial subdivision maps

$$u_n\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) \;\to\; \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)), \quad n \in \mathbb{N}_0$$

[1178] Given $n \in \mathbb{N}_0$ we denote by $\mathrm{Bij}\{0,\ldots,n\}$ the group of bijections of the set $\{0,\ldots,n\}$. Note that we have an obvious isomorphism $\mathrm{Bij}\{0,\ldots,n\} \cong S_{n+1}$. Given $\sigma \in \mathrm{Bij}\{0,\ldots,n\}$ we define $\mathrm{sign}(\sigma)$ basically the same way as we did on page 2035.

[1179] Recall that $\mathrm{C}_n^{\mathrm{simp},\leq}(K)$ is by definition the free abelian group generated by the set of simplices. Thus to specify a homomorphism $\varphi\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) \to A$ to some abelian group we only need to specify $\varphi(s)$ for each n-simplex s of K.

are a natural chain map. Here "natural" means that given any order-preserving simplicial map $f\colon (K,\leq) \to (L,\leq)$ between two ordered abstract simplicial complexes and given any $n \in \mathbb{N}_0$ the following diagram commutes:

$$\begin{array}{ccc} \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \xrightarrow{\quad f_* \quad} & \mathrm{C}_n^{\mathrm{simp},\leq}(L) \\ {\scriptstyle u_n}\downarrow & & \downarrow{\scriptstyle u_n} \\ \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)) & \xrightarrow{\quad f_* \quad} & \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(L)). \end{array}$$

Proof. Let $(K,\leq)$ be an ordered abstract simplicial complex. We need to show that the maps

$$u_n\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) \;\to\; \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)), \quad n \in \mathbb{N}_0$$

are a natural chain map. In fact it follows immediately from the definitions and the Barycenter Lemma 94.1 (1) that the maps u_n are natural. Thus it remains to prove that the maps u_n are a chain map. We will do so in the following claim.

Claim. For any $n \in \mathbb{N}_0$ and any n-simplex s of K we have the following equality:

$$\partial u_n(s) \;=\; u_{n-1}(\partial s).$$

Proof. We introduce the following notation. Given an n-simplex $t = \{w_0 < \cdots < w_n\}$ and given $i \in \{0,\ldots,n\}$ we write $t(i) := \{w_0 < \cdots < \widehat{w}_i < \cdots < w_n\}$, i.e. $t(i)$ is the $(n-1)$-simplex given by striking out the vertex w_i. Now let $s = \{v_0 < \cdots < v_n\}$ be an n-simplex of K. We perform the following slightly messy calculation:

$$\partial u_n(s) \overset{\text{by definition of } u_n}{=} \partial\Big(\sum_{\sigma\in\mathrm{Bij}\{0,\ldots,n\}} \mathrm{sign}(\sigma)\cdot s_\sigma\Big) \overset{\text{definition of } \partial}{=} \sum_{i=0}^{n}(-1)^i \cdot \sum_{\sigma\in\mathrm{Bij}\{0,\ldots,n\}} \mathrm{sign}(\sigma)\cdot(s_\sigma)(i) \overset{\text{split the sum into } i=0 \text{ and } i=1,\ldots,n}{=}$$

$$= \sum_{\sigma\in\mathrm{Bij}\{0,\ldots,n\}} \mathrm{sign}(\sigma)\cdot(s_\sigma)(0) + \sum_{i=1}^{n}(-1)^i \cdot \sum_{\sigma\in\mathrm{Bij}\{0,\ldots,n\}} \mathrm{sign}(\sigma)\cdot(s_\sigma)(i)$$

second summand vanishes since for a fixed $i \in \{1,\ldots,n\}$ and for $\mu,\nu \in \mathrm{Bij}\{0,\ldots,n\}$ we have $(s_\mu)(i) = (s_\nu)(i)$ if $\mu(i-1) = \nu(i)$, if $\mu(i) = \nu(i-1)$ and if all other values of μ and ν are the same, thus given the fixed $i \in \{1,\ldots,n\}$ we can pair up the elements in $\mathrm{Bij}\{0,\ldots,n\}$ to give the same contribution $(s_\sigma)(i)$ to the sum, but with opposite sign

$$= \sum_{\sigma\in\mathrm{Bij}\{0,\ldots,n\}} \mathrm{sign}(\sigma)\cdot(s_\sigma)(0) \overset{\text{follows from considering the bijection}}{=} \sum_{\tau\in\mathrm{Bij}\{0,\ldots,n-1\}} \sum_{i=0}^{n}(-1)^i\cdot\mathrm{sign}(\tau)\cdot(s(i))_\tau \overset{\text{by definition of } \partial \text{ and } u_{n-1}}{=} u_{n-1}(\partial s).$$

$$\{0,\ldots,n\}\times\mathrm{Bij}\{0,\ldots,n-1\} \to \mathrm{Bij}\{0,\ldots,n\}$$

$$(i,\tau) \mapsto \left(\begin{array}{ccc} \{0,\ldots,n\} & \to & \{0,\ldots,n\} \\ j & \mapsto & \begin{cases} i, & \text{if } j=0, \\ j-1, & \text{if } j\in\{1,\ldots,i\}, \\ j, & \text{if } j>i. \end{cases} \end{array}\right)$$

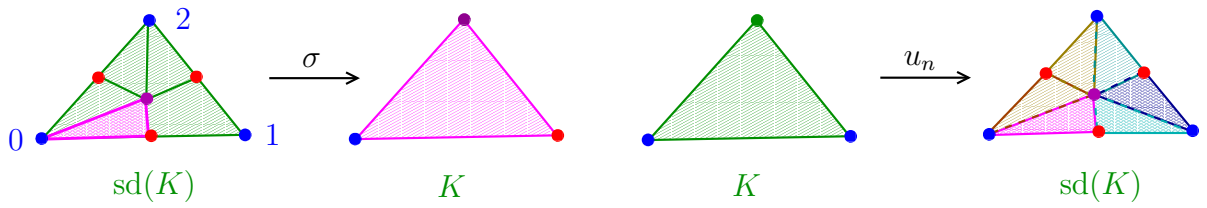
■

The following lemma finally relates the stretching maps to the simplicial subdivision maps.

Lemma 95.40. (Stretching-Subdivision Lemma) Let $(K, \leq)$ be an ordered abstract simplicial complex. As before we denote by $\sigma\colon \operatorname{sd}(K) \to K$ the stretching map introduced in the Stretching Map Lemma 95.38.

(1) The induced chain map

$$\sigma_*\colon \mathrm{C}_*^{\mathrm{simp},\leq}(\operatorname{sd}(K)) \to \mathrm{C}_*^{\mathrm{simp},\leq}(K)$$



and the simplicial subdivision maps

$$u_n\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) \to \mathrm{C}_n^{\mathrm{simp},\leq}(\operatorname{sd}(K)), \quad n \in \mathbb{N}_0$$

are chain homotopy inverses of one another.

(2) The maps σ_* and the maps u_* are chain homotopy equivalences.

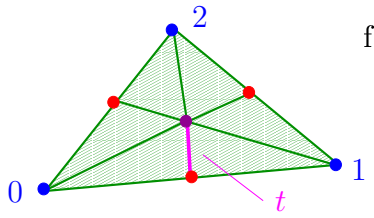
(3) The maps $\sigma_*\colon \mathrm{H}_*^{\mathrm{simp},\leq}(\operatorname{sd}(K)) \to \mathrm{H}_*^{\mathrm{simp},\leq}(K)$ and $u_*\colon \mathrm{H}_*^{\mathrm{simp},\leq}(K) \to \mathrm{H}_*^{\mathrm{simp},\leq}(\operatorname{sd}(K))$ are natural isomorphisms and they are inverses of one another.

Remark. The Stretching-Subdivision Lemma 95.40 (2) can be viewed as an analogue of Lemma 74.26 where we proved a similar statement for the singular subdivision map.

Proof. Statement (2) of the lemma is an immediate consequence of Statement (1). Furthermore Statement (3) follows from Statements (1) and (2) together with Corollary 73.4 and the naturality statements of the Stretching Map Lemma 95.38 and the Chain Subdivision Lemma 95.39. Thus it remains to prove Statement (1).

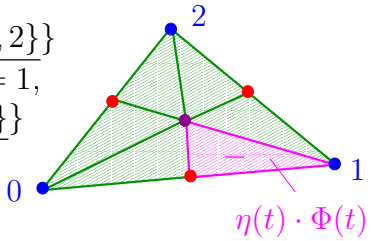
Let $(K, \leq)$ be an ordered abstract simplicial complex. It follows easily from the definitions that for each $n \in \mathbb{N}_0$ the map $\sigma_* \circ u_n\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) \to \mathrm{C}_n^{\mathrm{simp},\leq}(K)$ is the identity. Thus it remains to prove that $u_* \circ \sigma_*$ is chain homotopic to the identity.

The definition of the chain homotopy requires some preparations and extra definitions. Let $n \in \mathbb{N}_0$ and let $t = \{\underline{s_0}, \ldots, \underline{s_n}\}$ be an n-simplex of $\operatorname{sd}(K)$ with $\#s_n = n+2$. For convenience we set $s_{-1} := \varnothing$. Since $\#s_n = n+2$ and since for each $i \in \{0, \ldots, n\}$ we have $s_{i-1} \subsetneq s_i$ we see that there exists a unique $i \in \{0, \ldots, n\}$ with $\#s_i = \#s_{i-1} + 2$. Thus there exist two vertices $v < w$ of K such that $s_i = s_{i-1} \sqcup \{v, w\}$. We say that t can be *expanded upward* if w is larger than every element in s_{i-1}. In this case we set

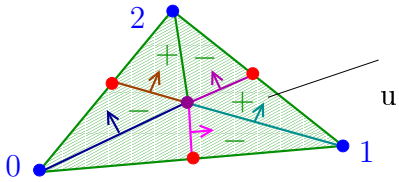


$$\Phi(t) := \overbrace{\{\underline{s_0}, \ldots, \underline{s_{i-1}}, \underline{s_{i-1} \cup \{w\}}, \underline{s_i}, \ldots \underline{s_n}\}}^{(n+1)\text{-simplex of } \operatorname{sd}(K)}$$

and

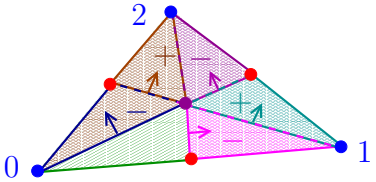


$$\eta(t) := \operatorname{sign}(\sigma) \text{ where } \sigma \in \operatorname{Bij}\{0, \ldots, n\} \text{ with } \Phi(t) = (s_n)_\sigma.$$



notation from page 2069

These definitions are illustrated in the figures below.



for the 1-simplex $t = \{\underline{\{0,1\}}, \underline{\{0,1,2\}}\}$
we have $i = 0$ and $v = 0$ and $w = 1$,
thus $\Phi(t) = \{\underline{\{1\}}, \underline{\{0,1\}}, \underline{\{0,1,2\}}\}$
and we see that $\eta(t) = -1$

arrow indicates
upward expansion

For each $n \in \mathbb{N}_0$ we consider the following map

$$\begin{array}{rcl} P_n \colon \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)) & \to & \mathrm{C}_{n+1}^{\mathrm{simp},\leq}(\mathrm{sd}(K)) \\ t = \{\underline{s_0}, \ldots, \underline{s_n}\} & \mapsto & \begin{cases} \eta(t) \cdot \Phi(t), & \text{if } \#s_n = n+2 \text{ and if } t \text{ can be expanded upward,} \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

We leave it to the reader's unrelenting zest for verifying technical details to show that these maps P_n form a chain homotopy between the identity and the chain map $\sigma_* \circ u_*$. ■

We defined the simplicial subdivision map for *ordered* abstract simplicial complexes. As we will see shortly, the choice of an ordering is irrelevant.

Definition. Let $(K, \leq)$ be an abstract simplicial complex.

(1) Let $s = (v_0, \ldots, v_n)$ be an ordered n-simplex of K. Given $m \in \{0, \ldots, n\}$ we set

$$F_m(s) \ := \ \{v_0, \ldots, v_m\}.$$

Furthermore we set

$$F(s) \ := \ \big(\underline{F_0(s)}, \underline{F_1(s)}, \ldots, \underline{F_n(s)}\big).$$

Note that $F(s)$ is an ordered n-simplex of $\mathrm{sd}(K)$.

(2) Note that any two ordered n-simplices $s = (v_0, \ldots, v_n)$ and $t = (w_0, \ldots, w_n)$ of K with $\{v_0, \ldots, v_n\} = \{w_0, \ldots, w_n\}$ there exist a unique $\sigma \in \mathrm{Bij}\{0, \ldots, n\}$ such that $v_i = w_{\sigma(i)}$ for all $i = 0, \ldots, n$. We set $\mathrm{sign}(s,t) := \mathrm{sign}(\sigma)$.

(3) Given an ordered n-simplex $s = (v_0, \ldots, v_n)$ we set

$$u_n(s) \ := \ \sum_{\substack{t = (w_0, \ldots, w_n) \text{ an ordered} \\ n\text{-simplex of } K \text{ with} \\ \{v_0, \ldots, v_n\} = \{w_0, \ldots, w_n\}}} (-1)^{\mathrm{sign}(s,t)} \cdot F(t)$$

More precisely, we have the following lemma.

Lemma 95.41. (Chain Subdivision Lemma) Let K be an abstract simplicial complex.

(1) For every $n \in \mathbb{N}_0$ the map
$$\begin{array}{ccc} \mathrm{C}_n^{\mathrm{simp}}(K) & \to & \mathrm{C}_n^{\mathrm{simp}}(\mathrm{sd}(K)) \\ [s] & \mapsto & [u_n(s)] \end{array}$$
is well-defined. We refer to this map again as the *simplicial subdivision map*.

(2) The maps u_n are natural in the sense that given a simplicial map $f\colon K \to L$ the following diagram commutes
$$\begin{array}{ccc} \mathrm{C}_n^{\mathrm{simp}}(K) & \xrightarrow{f_*} & \mathrm{C}_n^{\mathrm{simp}}(L) \\ \downarrow{\scriptstyle u_n} & & \downarrow{\scriptstyle u_n} \\ \mathrm{C}_n^{\mathrm{simp}}(\mathrm{sd}(K)) & \xrightarrow{f_*} & \mathrm{C}_n^{\mathrm{simp}}(\mathrm{sd}(L)). \end{array}$$

(3) If K is equipped with an order "$\leq$", then for every $n \in \mathbb{N}_0$ the following diagram commutes:
$$\begin{array}{ccc} \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \xrightarrow{u_n} & \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)) \\ \cong\downarrow & & \downarrow\cong \\ \mathrm{C}_n^{\mathrm{simp}}(K) & \xrightarrow{u_n} & \mathrm{C}_n^{\mathrm{simp}}(\mathrm{sd}(K)). \end{array}$$
Here the vertical maps are the natural isomorphisms given by Lemma 95.5.

(4) The maps $u_n\colon \mathrm{C}_n^{\mathrm{simp}}(K) \to \mathrm{C}_n^{\mathrm{simp}}(\mathrm{sd}(K))$ form a chain homotopy equivalence. In fact, if we pick an order on K and we consider the corresponding stretching map $\sigma\colon \mathrm{sd}(K) \to K$, then the maps u_n and the maps $\sigma_*\colon \mathrm{C}_*^{\mathrm{simp}}(\mathrm{sd}(K)) \to \mathrm{C}_*^{\mathrm{simp}}(K)$ are chain homotopy inverses.

(5) The induced maps $u_*\colon \mathrm{H}_n^{\mathrm{simp}}(K) \to \mathrm{H}_n(\mathrm{sd}^{\mathrm{simp}}(K))$ are natural isomorphisms.

Remark. Note in contrast the stretching maps certainly do depend on the choice of an order.

Proof. The first three statements follow easily from the definitions. The only statement which perhaps needs a little bit of thought is the first statement. We leave it to the reader to fill in the details. Let us turn to the proof of Statement (4). As mentioned before, by the Well-Ordering Theorem 0.7 we can pick an order "$\leq$" on K. Let $n \in \mathbb{N}_0$. By (2) we have the following commutative diagram:
$$\begin{array}{ccc} \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \xrightarrow{u_n} & \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)) \\ \cong\downarrow & & \downarrow\cong \\ \mathrm{C}_n^{\mathrm{simp}}(K) & \xrightarrow{u_n} & \mathrm{C}_n^{\mathrm{simp}}(\mathrm{sd}(K)). \end{array}$$
By the Stretching-Subdivision Lemma 95.40 we know that the top horizontal maps form a chain homotopy equivalence and that a chain homotopy inverse is given by the stretching maps. It follows that the analogous statements hold for the bottom horizontal maps. Finally Statement (5) follows from (2) and (4) together with Corollary 73.4. ■

In the remainder of this section we want to discuss the relationship of the stretching map and the simplicial division map with various maps on the topological realizations. First we recall that given an abstract simplicial complex K we gave in the SD-Lemma 94.3 (3)

an explicit natural homeomorphism $\mho\colon |\operatorname{sd}(K)| \to |K|$. This allows us to formulate the following lemma.

Lemma 95.42. Let $(K, \leq)$ be an abstract simplicial complex. We denote by $\sigma\colon \operatorname{sd}(K) \to K$ the stretching map from the Stretching Map Lemma 95.38. The map $|\sigma| \circ \mho^{-1}\colon |K| \to |K|$ is homotopic to the identity.

Proof. Since we will not make use of Lemma 95.42, therefore we outsource the proof thereof to Exercise 95.17. ■

We recall some more maps and statements from earlier on.

(1) Let K be an ordered abstract simplicial complex. By the Simplicial-Singular Chain Complex Theorem 95.25 we know that the maps

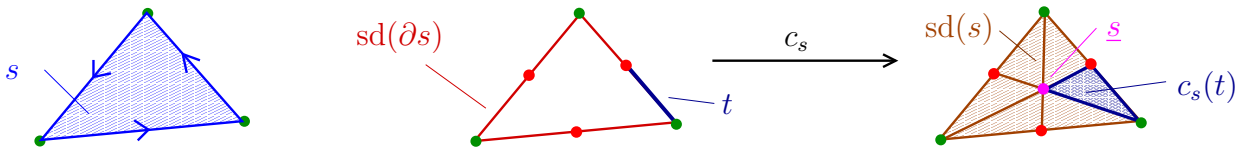
$$\begin{aligned} \Theta_K\colon \mathrm{C}_n^{\mathrm{simp},\leq}(K) &\to \mathrm{C}_n(|K|) \\ s &\mapsto (\Phi_s^{\leq}\colon \Delta^n \to |K|) \end{aligned}$$

are a natural chain homotopy equivalence.

(2) Given a topological space X and $n \in \mathbb{N}_0$ we denote by $u_n\colon \mathrm{C}_n(X) \to \mathrm{C}_n(X)$ the singular subdivision map as defined in page 1640.

Now we can formulate the following proposition.

Proposition 95.43. For every ordered abstract simplicial complex $(K, \leq)$ and every $n \in \mathbb{N}_0$ the following diagram commutes:

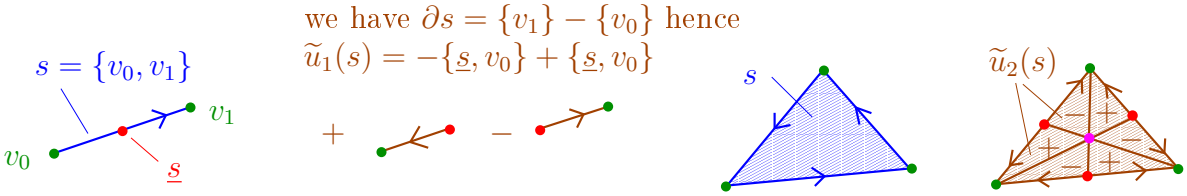


$$\begin{array}{ccc} \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \xrightarrow{u_n} & \mathrm{C}_n^{\mathrm{simp},\leq}(\operatorname{sd}(K)) \\ \Big\downarrow{\scriptstyle \Theta_K} & & \Big\downarrow{\scriptstyle \Theta_{\operatorname{sd}(K)}} \\ & & \mathrm{C}_n(|\operatorname{sd}(K)|) \\ & & \Big\downarrow{\scriptstyle \mho_*} \\ \mathrm{C}_n(|K|) & \xrightarrow{u_n} & \mathrm{C}_n(|K|). \end{array}$$

Furthermore all maps form natural chain homotopy equivalences.

The key step in proving Proposition 95.43 is to give an alternative description of the simplicial subdivision map that resembles the definition of the singular subdivision map which we gave on page 1640. We start out with the following definition.

Definition. Let $(K, \leq)$ be an ordered abstract simplicial complex. Given a k-simplex s of K we define the "coning map"



$$\begin{aligned} c_s\colon \mathrm{C}_i^{\mathrm{simp},\leq}(\operatorname{sd}(\partial s)) &\to \mathrm{C}_{i+1}^{\mathrm{simp},\leq}(\operatorname{sd}(s)) \\ &\mapsto \{\underline{s}\} \cup t. \end{aligned}$$

Definition. Let $(K, \leq)$ be an ordered abstract simplicial complex. We define the map [1180] $u_0\colon \mathrm{C}_0^{\mathrm{simp},\leq}(K) \to \mathrm{C}_0^{\mathrm{simp},\leq}(\operatorname{sd}(K))$ to be the obvious inclusion. Furthermore, for $n \geq 1$ we

define inductively the following maps:

$$\begin{array}{rccl} \widetilde{u}_n\colon & \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n^{\mathrm{simp},\leq}(\mathrm{sd}(K)) \\ & s & \mapsto & (-1)^n \cdot c_s\big(\underbrace{u_{n-1}(\partial s)}_{\in \mathrm{C}_{n-1}^{\mathrm{simp},\leq}(\mathrm{sd}(\partial s))}\big). \end{array}$$

The following lemma gives the promised alternative description of the simplicial subdivision maps.

Lemma 95.44. Let $(K, \leq)$ be an ordered abstract simplicial complex. Given any n-simplex s of K we have $\widetilde{u}_n(s) = u_n(s)$.

Proof of Lemma 95.44. Let $(K, \leq)$ be an ordered abstract simplicial complex. We prove the lemma by induction on n. For $n = 0$ the statement is basically obvious. Now suppose that the statement holds for some $n \in \mathbb{N}_0$. Let $s = \{v_0 < \cdots < v_{n+1}\}$ be some $(n+1)$-simplex. Given $i \in \{0, \ldots, n+1\}$ we write $s(i) := \{v_0, \ldots, \widehat{v_i}, \ldots, v_{n+1}\}$. We calculate that

$$\begin{array}{rcl} u_{n+1}(s) & \overset{\text{definition of } \widetilde{u}_{n+1}}{=} & (-1)^{n+1} \cdot c_s(\widetilde{u}_n(\partial s)) \\ & \overset{\text{by definition of } \partial s}{=} & (-1)^{n+1} \cdot c_s\Big(u_n\Big(\sum_{i=0}^{n+1}(-1)^i \cdot s(i)\Big)\Big) \\ & \overset{\text{by induction and definition of } c_s}{=} & (-1)^{n+1} \cdot \sum_{i=0}^{n+1}(-1)^i \cdot \sum_{\sigma \in \mathrm{Bij}\{0,\ldots,n\}} \mathrm{sign}(\sigma) \cdot \{\underline{s}, s(i)_\sigma\} \\ & = & \sum_{\tau \in \mathrm{Bij}\{0,\ldots,n+1\}} \mathrm{sign}(\tau) \cdot s_\tau \;=\; u_n(s). \end{array}$$

see definition on page 2069

here we use the following bijection:

$$\Psi\colon \{0, \ldots, n+1\} \times \mathrm{Bij}\{0, \ldots, n\} \to \mathrm{Bij}\{0, \ldots, n+1\}$$

$$(i, \sigma) \mapsto \left(\begin{array}{rcl} \{0, \ldots, n+1\} & \to & \{0, \ldots, n+1\} \\ j & \mapsto & \begin{cases} j, & \text{if } j \in \{0, \ldots, i-1\}, \\ i, & \text{if } j = n+1, \\ j+1, & \text{if } j \in \{i, \ldots, n\} \end{cases} \end{array} \right)$$

and we use that $\mathrm{sign}(\Psi(i, \sigma)) = (-1)^{i+1} \cdot (-1)^{n+2} \cdot \mathrm{sign}(\sigma)$

We have thus proved the induction step. ∎

Now we can easily prove Proposition 95.43.

Proof of Proposition 95.43. It follows immediately from Lemma 95.44 together with the definitions of the various maps that the diagram commutes.

By Lemmas 95.40 and 74.26 we know that the horizontal maps form chain homotopy equivalences. Furthermore by the Simplicial-Singular Chain Complex Theorem 95.25 the top vertical maps also form chain homotopy equivalences. Finally the map $\mho$ is a homeomorphism. Thus the bottom vertical maps $\mho_*$ also form a chain homotopy equivalence. ∎

We conclude with the following "unordered" version of Proposition 95.43.

[1180] Recall that in Lemma 94.2 (2) we saw that $\mathrm{sd}(K)$ is naturally an ordered abstract simplicial complex.

Proposition 95.45. For every abstract simplicial complex K and every $n \in \mathbb{N}_0$ the following diagram commutes:[1181]

$$\begin{array}{ccc} \mathrm{H}_n^{\mathrm{simp}}(K) & \xrightarrow{u_n} & \mathrm{H}_n^{\mathrm{simp}}(\mathrm{sd}(K)) \\ & & \downarrow \Theta_{\mathrm{sd}(K)} \\ \Theta_K \downarrow & & \mathrm{H}_n(|\,\mathrm{sd}(K)|) \\ & & \downarrow \mathfrak{o}_* \\ \mathrm{H}_n(|K|) & \xrightarrow{u_n} & \mathrm{H}_n(|K|). \end{array}$$

Furthermore all maps are natural.

Proof. The proposition follows easily from the fact that every abstract simplicial complex admits an order together with Lemma 95.8 and Proposition 95.45 and together with Proposition 95.28. ■

Remark. For the record we point out that some of the definitions and results in this section are at least implicit in [**Deo2018**, Theorem 4.9.1] and [**Mun1966a**, p. 99].

Exercises for Chapter 95.

Exercise 95.1. Let $K = (V, S)$ be an abstract simplicial complex and let "$\leq$" and "$\widetilde{\leq}$" be two orders on K. Show that the maps

$$\begin{array}{rcl} \mathrm{C}_n^{\mathrm{simp},\leq}(K) & \to & \mathrm{C}_n^{\mathrm{simp},\widetilde{\leq}}(K) \\ \{v_0 < \cdots < v_n\} & \mapsto & \underbrace{\mathrm{sign}(\sigma) \cdot \{v_{\sigma(0)} \widetilde{<} \ldots \widetilde{<} v_{\sigma(n)}\}}_{\substack{\sigma \in S_n \text{ is the unique permutation} \\ \text{such that } v_{\sigma(0)} \widetilde{<} \ldots \widetilde{<} v_{\sigma(n)}}} \end{array}$$

define an isomorphism of chain complexes.

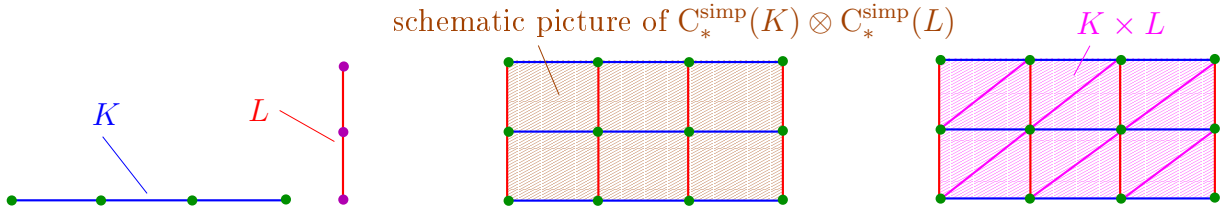
Exercise 95.2. Let K be a non-empty abstract simplicial complex, let $n \in \mathbb{N}_0$ and let S_n be the abstract simplicial complex that we introduced on page 1978. Show that for every $k \in \mathbb{N}_0$ there exists a natural isomorphism

$$\widetilde{\mathrm{H}}_k^{\mathrm{simp}}(K * S_n) \;\cong\; \widetilde{\mathrm{H}}_{k-(n+1)}^{\mathrm{simp}}(K).$$

Exercise 95.3. Let $K = (V, S)$ be an abstract simplicial complex. Recall that on page 2013 we said that $K = (V, S)$ is *connected* if given any $v, v' \in V$ there exist 1-simplices $s_0, \ldots, s_k \in S$ such that $v \in s_0$, such that for every $i \in \{0, \ldots, k-1\}$ we have $s_i \cap s_{i+1} \neq \varnothing$ and such that $v' \in s_k$. Show that if K is a connected non-empty abstract simplicial complex, then given any abelian group G the map

$$\begin{array}{rcl} \mathrm{H}_0^{\mathrm{simp}}(K; G) & \to & G \\ \left[\sum_{i=0}^{k} \{v_i\} \otimes g_i\right] & \mapsto & \sum_{i=0}^{k} g_i \end{array}$$

is a natural isomorphism



Remark. This is the simplicial analogue of the H_0-Proposition 72.5.

[1181] Here the vertical maps Θ are the natural isomorphisms introduced on page 2058.

Exercise 95.4. In this exercise we give a down-to-earth proof of the Simplicial Künneth Theorem 95.14 in the special case that we are dealing with 1-dimensional abstract simplicial complexes.

(a) Let K and L be two ordered 1-dimensional abstract simplicial complexes. Show that the tensor product of the chain complexes $\mathrm{C}_*^{\mathrm{simp}}(K)$ and $\mathrm{C}_*^{\mathrm{simp}}(L)$, as defined on page 1940, is chain homotopy equivalent to the chain complex $\mathrm{C}_*^{\mathrm{simp}}(K \times L)$.
(b) Prove (a) for arbitrary finite-dimensional abstract simplicial complexes.
(c) Prove (a) for arbitrary abstract simplicial complexes.

Remark. Together with the Künneth Theorem 90.7 for chain complexes this exercise makes it possible to calculate the simplicial homology groups of $K \times L$ directly in terms of the simplicial homology groups of K and L.

Exercise 95.5. Let $p, q \in \mathbb{N}_0$. We consider the product $D_p \times D_q$ of the ordered abstract simplicial complexes defined on page 1978. Show that

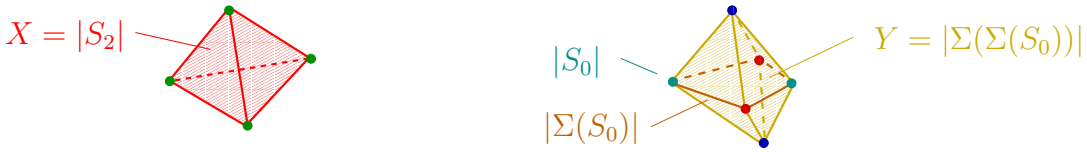
$$\mathrm{H}_i^{\mathrm{simp}}(D_p \times D_q) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Remark. This exercise goes into the proof of the Simplicial Künneth Theorem 95.14. In particular you are not allowed to use this theorem.

Exercise 95.6. Show that for any abstract simplicial complex K and any simplex s of K we have for every $i \in \mathbb{N}$ that $\mathrm{H}_i^{\mathrm{simp}}(\mathrm{St}(K, s)) = 0$.

Exercise 95.7.

(a) Formulate and prove a Mayer–Vietoris style theorem for simplicial homology, along the lines of the Mayer–Vietoris Theorem 78.5.
(b) Use the exact sequence from (a) to provide a new solution to Exercise 95.2.



Exercise 95.8. Let K be a simplicial complex and let A and B be two subcomplexes with $A \cup B = K$. Show that for each $k \in \mathbb{N}_0$ the natural map $\mathrm{H}_k^{\mathrm{simp}}(A, A \cap B) \to \mathrm{H}_k^{\mathrm{simp}}(X, B)$ is an isomorphism.
Remark. This statement can be viewed as the Simplicial Excision Theorem. The biggest difference to the singular setting is that in the simplicial setting the proof is almost embarrassingly easy.

Exercise 95.9. Let K be an abstract simplicial complex and let L be a subcomplex of K. Show that for each $k \in \mathbb{N}_0$ there exists a natural isomorphism

$$\mathrm{H}_k^{\mathrm{simp}}(K, L) \;\cong\; \widetilde{\mathrm{H}}_k^{\mathrm{simp}}\big(\underbrace{K \cup_L \mathrm{Cone}(L)}_{\text{mapping cone of } L \to K}\big).$$

Exercise 95.10. Compute the simplicial homology groups of an abstract simplicial complex K such that $|K|$ is homeomorphic to the surface Σ of genus two.
Hint. As we saw in the figure on page **??**, we can view Σ as the connected sum of two tori and you could use Exercise 95.7.

Exercise 95.11. Show that the two simplicial complexes $X = |S_2|$ and $Y = |\Sigma(\Sigma(S_0))|$ which are shown in the figure below admit subdivisions X' and Y' which are simplicially isomorphic.

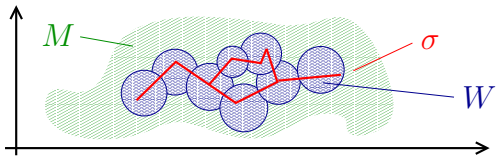
Exercise 95.12. Let $K = (V, S)$ be an abstract simplicial complex. Let $\mathcal{U} = \{\mathring{\mathrm{St}}(v)\}_{v \in V}$ be the open cover of the topological realization $|K|$ that is given by the open stars. What is the relationship between the original abstract simplicial complex K and the nerve complex $N(\mathcal{U})$?

Exercise 95.13. Formulate and prove a simplicial analogue of the Mayer–Vietoris Theorem 78.5.
Remark. The proof is significantly easier than the original proof of the Mayer–Vietoris Theorem 78.5.

Exercise 95.14. Let K and L be two ordered abstract simplicial complexes. Show that for each $k \in \mathbb{N}_0$ there exists a short exact sequence of the following form:

$$0 \;\to\; \widetilde{\mathrm{H}}_k^{\mathrm{simp}}(K * L) \;\to\; \widetilde{\mathrm{H}}_{k-1}^{\mathrm{simp}}(K) \oplus \widetilde{\mathrm{H}}_{k-1}^{\mathrm{simp}}(L) \;\to\; \widetilde{\mathrm{H}}_{k-1}^{\mathrm{simp}}(K \times L) \;\to\; 0.$$

Remark. This statement is the simplicial analogue of Exercise 78.20. In fact at least if K and L are finite, then we can reduce the simplicial statement to the singular statement. The challenge is to give a purely combinatorial argument.



Exercise 95.15. Let $n \in \mathbb{N}_0$.

(a) Let W be an open subset of $\mathbb{R}^n$ that is the union of finitely many convex open subsets. Show that $\mathrm{H}_k(W) = 0$ for $k \geq n$.
Hint. Use the Mayer–Vietoris Theorem 78.5 and do an induction argument on the number of convex open subsets. As on many other occasions we point out the convenient fact that the intersection of convex subsets of $\mathbb{R}^n$ is again convex.

(b) Let M be an open subset of $\mathbb{R}^n$ and let $\sigma \in \mathrm{C}_n(M)$ be a cycle. Show that there exists an open subset W of $\mathbb{R}^n$ that is the union of finitely many convex open subsets such that $\sigma \in \mathrm{C}_n(W)$ and such that $W \subset M$.

(c) Let M be an open subset of $\mathbb{R}^n$. Show that $\mathrm{H}_k(M) = 0$ for $k \geq n$.

Exercise 95.16. Let $P_1, \ldots, P_s$ be points in $\mathbb{R}^2$ with $s \geq 3$. We assume that any three of those points are contained in an open disk of radius r. Show that all the given points are contained in an open disk of radius r.

Exercise 95.17. Let $(K, \leq)$ be an abstract simplicial complex. Let $\sigma\colon \mathrm{sd}(K) \to K$ be the stretching map from the Stretching Map Lemma 95.38. Show that the map $|\sigma| \circ \mathfrak{V}^{-1}\colon |K| \to |K|$ is homotopic to the identity.
Remark. Use the Interval CW-Product Corollary 68.9 to overcome any continuity anxieties that might arise.

Exercise 95.18. Let K be an abstract simplicial complex. Show that the maps

$$\begin{array}{rcl} \mathrm{C}_k^{\mathrm{simp}}(K) \otimes \mathbb{Q} & \to & \mathrm{C}_k(|K|) \otimes \mathbb{Q} \\ [v_0, \ldots, v_k] \otimes r & \mapsto & \frac{1}{(k+1)!} \cdot \sum_{\sigma \in S_{k+1}} \cdot \left(\begin{array}{rcl} \Delta^k & \mapsto & |K| \\ (t_0, \ldots, t_k) & \mapsto & \sum_{i=0}^{k} t_i \cdot v_{\sigma(i)} \end{array} \right) \otimes r \end{array}$$

are a natural chain homotopy equivalence.

Exercise 95.19. Let $n \in \mathbb{N}_0$. Let $K = ((V, S), \Theta\colon |K| \to \Delta^n)$ be a subdivision of the standard simplex Δ^n. We denote by $e_0, \ldots, e_n \in V$ the vertices that get sent to the standard vertices of Δ^n. Let Z be a finite set and let $\varphi\colon V \to Z$ be a map. We refer to φ as a *coloring of* K.

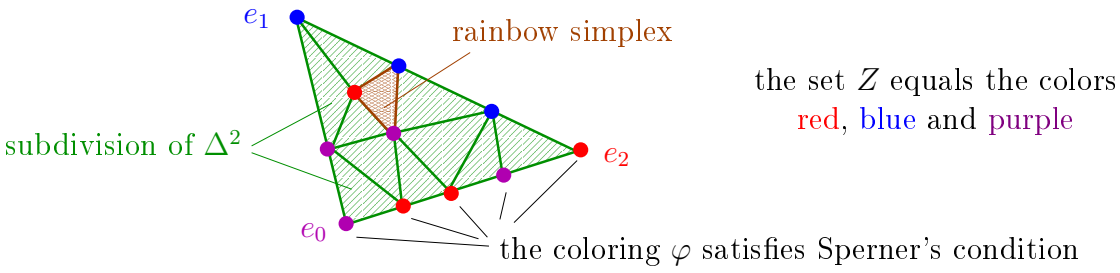
(1) We say φ satisfies *Sperner's condition* if $\varphi\colon V \to Z$ is injective on $\{e_0, \ldots, e_n\} \subset V$ and if for each $v \in V$ with $\Theta(v) \in |\Theta(\{e_{r_1}, \ldots, e_{r_s}\})|$ we have $\varphi(v) \in \{\varphi(e_{r_1}), \ldots, \varphi(e_{r_s})\}$. In other words, the vertices $e_0, \ldots, e_n$ have distinct colors, and if a vertex lies on a face spanned by some of the e_i, then the vertex has the color of one of the e_i.
(2) We say an n-simplex s of K is a *rainbow simplex* if $\varphi\colon s \to Z$ is injective, put differently, if the colors of vertices of s are all different.

We want to prove the following statement:
Sperner's Lemma. *If φ satisfies Sperner's condition, then the number of rainbow simplices is odd.*
To prove this statement we introduce some notation:

(3) We set $\Delta^Z := \left\{ \sum_{z \in Z} t_z \cdot z \mid \sum_{z \in Z} t_z = 1 \text{ and each } t_z \geq 0 \right\} \subset \mathbb{R}^Z$.
(4) We denote by $f^\varphi\colon |K| \to \Delta^Z$ the unique map which agrees with φ on V and which is affine linear on each $|s| \subset |K|$.
(5) We define $\partial|K| := \Theta^{-1}(\partial\Delta^n)$ and we define $\partial\Delta^Z$ the same way as we defined $\partial\Delta^n$.
(6) We write

$$\deg(\varphi) \;:=\; \deg\Big(\underbrace{\mathrm{H}_n(|K|, \partial|K|; \mathbb{F}_2)}_{\cong \mathbb{F}_2} \to \underbrace{\mathrm{H}_n(\Delta^Z, \partial\Delta^Z; \mathbb{F}_2)}_{\cong \mathbb{F}_2}\Big) \;\in\; \mathbb{F}_2.$$

Sperner's Lemma follows from solving the following two exercises:



(a) Show that if φ satisfies Sperner's condition, then $\deg(\varphi) \neq 0$.
Hint. Use Exercise 76.22 to prove this statement by induction on n.

(b) Show that

$$\deg(\varphi) \;=\; \text{number of rainbox simplices } \in \mathbb{F}_2.$$

Hint. The n-simplices of K give rise to a generator of $\mathrm{H}_n(|K|, \partial|K|; \mathbb{F}_2)$.

Remark. The conclusion of this slightly challenging exercise is known as Sperner's Lemma. It was first formulated and proved by Emanuel Sperner [**Spe1928**, p. 267] in 1928. Sperner's Lemma can be proved in a purely combinatorial fashion, see [**AZ2014**, Chapter 27.6], [**Pra2006**, Theorem 2.26] or [**Harz1978**, Satz 12.2]. Sperner's Lemma can be used to give a purely combinatorial proof of the Brouwer Fixed Point Theorem 31.4, we refer to [**Harz1978**, Chapter 12] or [**Pra2006**, p. 81] for details. Sperner's Lemma also has fun applications, for example it can be applied to achieve "rental harmony" [**Su1999**]. Finally we refer to [**DGMM2019**] for a survey on Sperner's Lemma, its cousin Tucker's Lemma, and its many applications and ramifications.

96. Simplicial and PL-structures on manifolds

In this chapter we will see that smooth manifolds admit a simplicial structure. In fact we will see that they admit particularly nice simplicial structures. There will be many benefits. For example we can almost immediately draw conclusions on the homology groups and homotopy groups of smooth manifolds.

96.1. **Simplicial structures on smooth manifolds.** We recall the following definition from page 1994.

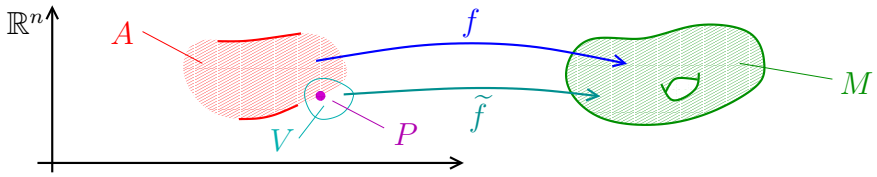
Definition. A simplicial structure for a given topological space X is defined as a pair $(K = (V, S), \Theta\colon |K| \to X)$ where the following holds:

(1) K is an abstract simplicial complex,
(2) Θ is a homeomorphism between the topological realization $|K|$ of K and the topological space X.

Given a simplex $s \in S$ we refer to $\Theta(|s|)$ as a simplex of X and we refer to $\Theta(\langle s\rangle)$ as an open simplex of X.

In this section we want to consider simplicial structures on smooth manifolds. Since the smooth structure on smooth manifolds is important for many arguments and constructions it is reasonable to consider simplicial structures that reflect the smooth structure. In the following the idea is to consider simplicial structures (K, Θ) such that for each k-simplex the characteristic map $\Theta \circ \Phi_s\colon \Delta^k \to M$ is a smooth embedding. Since Δ^k is not a smooth manifold it takes a little bit of an effort to explain what a "smooth embedding" is supposed to be in this case.

We start out with the following definition. The first part just recalls the definitions introduced on pages 549 and 532.



Definition. Let $n \in \mathbb{N}_0$ and let A be a subset of $\mathbb{R}^n$ for which there exists an open subset U of $\mathbb{R}^n$ with $U \subset A \subset \overline{U}$. Furthermore let M be a smooth manifold.

(1) We say a map $f\colon A \to M$ is smooth at a point $P \in A$, if there exists an open neighborhood V of P in $\mathbb{R}^n$ and a smooth map $\widetilde{f}\colon V \to \mathbb{R}^m$ which coincides with f on $A \cap V$. We define $\mathrm{D}f_P := D\widetilde{f}_P\colon \mathbb{R}^n \to \mathrm{T}_{f(P)}M$.[1182] We refer to the figure below for an illustration.
(2) We say a map $f\colon A \to M$ is an immersion if f is smooth at every $P \in A$ and if given any $P \in A$ the differential $\mathrm{D}f_P$ has rank n.[1183]
(3) We say a map $f\colon A \to M$ is a smooth embedding if it is an immersion and an embedding.

Example. Given $k \in \mathbb{N}_0$ we consider the map

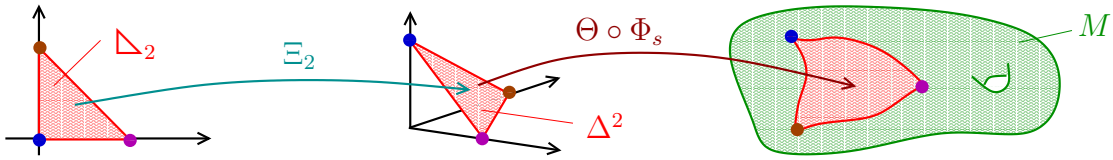
$$\begin{aligned}\Xi_k\colon \triangle_k := \Big\{(t_1,\dots,t_k) \in [0,1]^k \;\Big|\; \sum_{j=1}^{k} t_j \in [0,1]\Big\} &\to \mathbb{R}^{k+1}\\ (t_1,\dots,t_k) &\mapsto \Big(t_1,\dots,t_k,1-\sum_{j=1}^{k} t_j\Big).\end{aligned}$$

[1182] We leave it to the reader to verify, using our restrictive choice of domain A and using Exercise 2.33 (1), that the definition of $\mathrm{D}f_P$ does not depend on the choice of the smooth extension $\widetilde{f}$.
[1183] If A is in fact an open subset of $\mathbb{R}^n$, then this definition of an immersion agrees of course with the definition given on page 651.

This map has two interesting properties:

(1) By picking the obvious extension of Ξ_k to a map $\mathbb{R}^k \to \mathbb{R}^{k+1}$ we see that Ξ_k is an immersion.

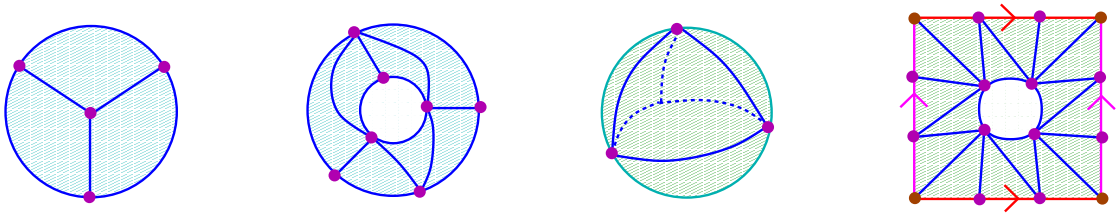
(2) It follows easily from the Compact-Hausdorff Proposition 2.17 (3) that the map Ξ_k defines a homeomorphism $\Xi_k \colon \triangle_k \to \Delta^k$.



The combination of (1) and (2) shows that Ξ_k is an embedding.

This leads us to the following definition.

Definition. Let M be a smooth manifold.



(1) Let $k \in \mathbb{N}_0$. We say that a map $\Phi \colon \Delta^k \to M$ is a smooth embedding if the composition $\Phi \circ \Xi_k \colon \triangle_k \to M$ is a smooth embedding.
